Somatosensory Function and Gait Biomechanics In Individuals With Anterior Cruciate Ligament Reconstruction

Derek Dewig, Christopher Johnston, Brian Pietrosimone, FACSM, Troy Blackburn. *The University of North Carolina at Chapel Hill, Chapel Hill, NC.* Email: ddewig@live.unc.edu (No relevant relationships reported)

Somatosensory function of the knee is reportedly altered following anterior cruciate ligament reconstruction (ACLR), potentially influencing the risk of osteoarthritis (OA). Poorer somatosensory function is associated with aberrant gait biomechanics in individuals diagnosed with knee OA, but this relationship has not been evaluated following ACLR. **PURPOSE:** To compare somatosensory function between limbs in individuals with ACLR and evaluate associations between somatosensory function of the ACLR limb and gait biomechanics. **METHODS:** Sixty-eight individuals with unilateral ACLR (72% females; age 21 ± 3 yr; time since ACLR 27 ± 15 mo) volunteered. Somatosensory function was assessed bilaterally as the ability to replicate a specified knee flexion angle during a joint position sense task (i.e. joint position sense error - JPSE). Gait outcomes were assessed during the first 50% of stance including vertical ground reaction force (vGRF), instantaneous loading rate, internal extension moment, and internal valgus moment. **RESULTS:** There was no difference in JPSE between the ACLR limb and the contralateral limb (2.9 ± 1.2° vs 2.8 ± 1.7°, p = 0.71). Additionally, there was no correlation between the ACLR limb JPSE and vGRF (r = -0.095, p = 0.44), instantaneous loading rate (r = -0.121, p = 0.33), internal extension moment (r = -0.018, p = 0.88), or internal valgus moment (r = -0.073, p = 0.55). **CONCLUSIONS:** JPSE did not differ between the ACLR and contralateral limbs, and JPSE in the ACLR limb was not associated with gait biomechanics. The mean time since ACLR in our sample was approximately 2 years, thus somatosensory adaptations may have occurred bilaterally at time of testing. Moreover, neuromuscular function of the contralateral limb is also influenced by ACLR, potentially confounding a comparison of JPSE between limbs that may have both undergone changes post-

WEDNESDAY, MAY 29, 2019

operatively. These findings suggest the need to compare somatosensory function to a healthy cohort. Furthermore, the small magnitude and limited variability of JPSE likely minimized its ability to predict gait outcomes. Future research is necessary to determine whether somatosensory deficits emerge at later time points post-ACLR compared to a healthy cohort and if they influence knee OA risk.

The Relationship Between Body Composition and Quadriceps Function Following Anterior Cruciate Ligament Reconstruction

Christopher D. Johnston, Hope Davis, Brian Pietrosimone, FACSM, Troy Blackburn. *University of North Carolina at Chapel Hill, Chapel Hill, NC.*
 Email: cdjohnst@email.unc.edu
 (No relevant relationships reported)

Anterior cruciate ligament reconstruction (ACLR) and obesity are primary risk factors for posttraumatic knee osteoarthritis (PTOA). ACLR leads to quadriceps dysfunction, and greater fat mass may exacerbate this dysfunction as adipose tissue negatively influences strength and muscle activation. Deficiencies in quadriceps function may result in reduced capacity to attenuate energy at the knee, potentially contributing to aberrant joint loading that contributes to PTOA.

Purpose: To determine the relationship between body composition and quadriceps function in individuals with ACLR.

Methods: Thirty-five (20 F, 15 M; 71±12 kg; 23.7±2.8 BMI; 48±35 months since ACLR) individuals at least 6 months removed from unilateral ACLR volunteered for the study. Total body fat percentage (BF%), limb fat mass (LFM), and limb lean mass (LLM) were obtained bilaterally using dual x-ray absorptiometry (DXA). LLM and LFM were normalized to total body mass. Quadriceps function was assessed bilaterally from maximal voluntary isometric contractions (MVIC) and a single limb hop (SLH) task. Peak torque (PT) was averaged from 2 MVIC trials and normalized to body mass. Maximum hop distance was averaged from 3 hop trials. Associations between measures of body composition and quadriceps function were analyzed via Pearson Product Moment correlations.

Results: In the ACLR limb, PT was associated with BF% ($r=-0.620$, $p<0.001$), LFM ($r=-0.525$, $p<0.001$), and LLM ($r=0.552$, $p<0.001$). Hop distance in the ACLR limb was also associated with BF% ($r=-0.656$, $p<0.001$), LFM ($r=-0.698$, $p<0.001$), and LLM ($r=0.441$, $p=0.008$). PT and SLH distances for the contralateral limb were also significantly related to BF%, LFM, and LLM. Body mass index (BMI) was not significantly related to PT or SLH distance in either limb.

Conclusion: BF%, LLM, and LFM are related to measures of quadriceps function following ACLR. The negative associations between functional outcomes (PT and SLH distance) and measure of adipose composition (BF% and FT) indicate that greater fat tissue may contribute to exacerbated quadriceps dysfunction after ACLR. Continued research is needed to evaluate body compositional changes following ACLR and how it influences other factors related to the development of PTOA.

Landing Biomechanics Following Patellar And Hamstring Tendon Anterior Cruciate Ligament Reconstruction

Ahmad Alanazi¹, Alexis Ortiz, FACSM². ¹Majmaah University, Majmaah, Saudi Arabia. ²UT Health San Antonio, San Antonio, TX.
 Email: aalanazi@mu.edu.sa
 (No relevant relationships reported)

Individuals with an ACL reconstruction (ACLR) have different landing adaptations depending if they received patellar (PG) or hamstring tendon (HG) graft reconstruction. No study has evaluated landing biomechanics following these procedures in soccer players.

Purpose: To compare landing biomechanics between soccer players following PG or HG ACLR during planned and unplanned landing tasks.

Methods: Six soccer players with a PG ACLR (age, 25.83 ± 4.44 years; height, 1.73 ± 0.04 m; weight, 70.91 ± 8.00 kg, BMI, 23.64 ± 3.29 kg/m², time since surgery, 4 ± 3.38 years) and 6 soccer players with a HG ACLR (age, 26.83 ± 3.25 years; height, 1.69 ± 0.08 m; weight, 67 ± 6.16 kg, BMI, 23.40 ± 2.08 kg/m² time since surgery, 5 ± 2.89 years) participated in the study. Planned landing (PL) included jumping forward and landing on two force plates, whereas unplanned landing (UL) included jumping forward to head a soccer ball and landing on the force plates. Participants performed 4 trials of each landing task. Outcome measures included peak flexion angles and extension moments of the hip, knee, and ankle joints, and electromyography of gluteus maximus, quadriceps, hamstrings, and gastrocnemius muscles. A 2×2 ANOVA (group × landing) was performed for each measure.

Results: There were no significant group × landing interactions for any of the outcomes. Significant main effects of landing were found. The UL showed smaller hip flexion ($F_{1,10} = 48.77$, $p < 0.001$), smaller knee flexion ($F_{1,10} = 28.02$, $p < 0.001$), and

lower ankle plantarflexion moments ($F_{1,10} = 26.48$, $p < 0.001$). Significant main effects for group for quadriceps muscle and hip extension moments were found showing that the PG group landed with reduced quadriceps activity ($F_{1,10} = 11.72$, $p = 0.007$), and greater hip extension moments ($F_{1,10} = 14.69$, $p = 0.003$).

CONCLUSION: The UL showed greater injury predisposing factors compared with the PL. Although the PG group showed nearly similar landing biomechanics to the HG group during both maneuvers, they (PG) demonstrated a protective landing pattern by reducing quadriceps activity and increasing the demand on the hip extensors. These findings reinforce the clinical emphasis on improving the use of hip and knee joints during landing to reduce the risk of consequent injuries in soccer players following PG ACLR.

1009 Board #243 May 29 3:30 PM - 5:00 PM
Improvements in Somatosensory Function with Vibration do not Influence Gait Biomechanics in Individuals with Anterior Cruciate Ligament Reconstruction

Troy Blackburn, Brian Pietrosimone, FACSM, Derek Dewig, Chris Johnston. *University of North Carolina at Chapel Hill, Chapel Hill, NC.* (Sponsor: Brian Pietrosimone, FACSM)
 Email: troyb@email.unc.edu
 (No relevant relationships reported)

Anterior cruciate ligament reconstruction (ACLR) incurs somatosensory deficits that potentially alter gait biomechanics and contribute to knee osteoarthritis (OA) risk. Individuals diagnosed with knee OA also display somatosensory deficits, and improving somatosensory function in this population improves gait biomechanics linked to OA progression. Vibratory stimuli potentially improve somatosensory function and may be an effective approach for reducing knee OA risk following ACLR. **Purpose:** To evaluate the effects of vibration on somatosensory function and determine if improving somatosensory function influences gait biomechanics in individuals with ACLR. **Methods:** Gait biomechanics and somatosensory function were assessed in 68 individuals with unilateral ACLR (72% females; age 21 ± 3 yr; time since ACLR 27 ± 15 mo) prior to and following one session of a whole body vibration (WBV), local muscle vibration (LMV), or control (CON) intervention. Gait outcomes included the peak vertical ground reaction force (vGRF) and its instantaneous loading rate, peak internal knee extension and valgus moments, and knee flexion displacement during the first 50% of stance. Somatosensory function was assessed as the ability to reproduce a specified knee angle (active joint position sense error - JPSE) by calculating the difference between the target and reproduced angles. **Results:** WBV ($3.0 \pm 0.3^\circ$ vs. $2.0 \pm 0.2^\circ$, $p = 0.010$) and LMV ($3.1 \pm 0.3^\circ$ vs. $2.2 \pm 0.2^\circ$, $p = 0.045$) decreased JPSE, but no effect was noted with CON ($2.8 \pm 0.3^\circ$ vs. $2.8 \pm 0.2^\circ$, $p = 0.927$). However, the change in JPSE was not correlated with changes in knee flexion displacement ($r = -0.169$, $p = 0.175$), vGRF ($r = -0.047$, $p = 0.706$), loading rate ($r = -0.058$, $p = 0.643$), or internal knee extension ($r = -0.194$, $p = 0.120$) or valgus ($r = -0.034$, $p = 0.789$) moments. **Conclusions:** Vibration improved somatosensory function, but this enhancement did not influence gait biomechanics. A ceiling effect potentially limited the influence on gait biomechanics as evidenced by the small magnitude and limited variability of JPSE. Additionally, a single exposure to vibration may be insufficient to permit somatosensory enhancement that manifests as improvements in gait biomechanics. Future work is necessary to evaluate the relevance of somatosensory deficits to knee OA risk following ACLR.

1010 Board #244 May 29 3:30 PM - 5:00 PM
Walking Biomechanics Six and Twelve Months Following Anterior Cruciate Ligament Reconstruction Compared to Healthy Controls

Hope C. Davis¹, Steven J. Pfeiffer¹, Christopher D. Johnston¹, Matthew K. Seeley², Matthew S. Harkey³, J Troy Blackburn¹, Ryan P. Fockler¹, Jeffrey T. Spang¹, Brian Pietrosimone, FACSM¹. ¹UNC Chapel Hill, Chapel Hill, NC. ²Brigham Young University, Provo, UT. ³Tufts Medical School, Boston, MA.
 Email: davishc@live.unc.edu
 (No relevant relationships reported)

Vertical ground reaction force (vGRF) during walking is associated with cartilage metabolism, cartilage composition, and patient symptoms in individuals with anterior cruciate ligament reconstruction (ACLR). However, it is unclear how vGRF changes throughout stance between 6- and 12-months following ACLR compared to an uninjured control group.

Purpose: Compare vGRF between the uninjured and involved limbs 6- and 12-months following ACLR, as well as to a healthy control limb. **Methods:** vGRF normalized to body weight (BW) was collected at 6- and 12-months following surgery in individuals with ACLR and at one time point in healthy controls. 2 × 2 functional analyses of variance were used to evaluate the effects of limb (involved and uninjured) and time (6- and 12-months) on time-normalized vGRF waveforms in

individuals with ACLR. Pairwise comparison functions were used to compare time-normalized vGRF waveforms in controls and the involved and uninvolved limbs at 6- and 12-months.

RESULTS: Thirty individuals with ACLR (50% female, 21.6±3.4 years, body mass index (BMI)=24.2±3.2 kg/m²) and 48 controls (67% female, 20.3±1.6 years, BMI=23.1±3.3 kg/m²) completed the current study. At 12-months, both the involved and uninvolved limbs demonstrated lesser vGRF (-3% BW) during the first peak (13-28% of stance) and greater vGRF (+2% BW) during mid-stance (46-66% of stance) compared to 6-months. Over time, the involved limb demonstrated lesser vGRF (-2 to -4% BW) at the first (13-28% of stance) and second (77-87% of stance) peaks compared to the uninvolved limb. Healthy controls demonstrated greater vGRF at the first (6-months: +8% BW, 1-32% of stance; 12-months: +10% BW, 1-33% of stance) and second peaks (6-months: +5% BW, 69-91% of stance; 12-months: +4% BW, 72-92% of stance) and lesser vGRF in mid-stance (6-months: -2% BW, 39-54% of stance; 12-months: -3% BW, 38-64% of stance) compared to the involved limb at both 6- and 12-months. **CONCLUSIONS:** Individuals may achieve more symmetrical loading over time by lowering vGRF of the uninvolved limb between 6- and 12-months following ACLR. Future gait retraining programs may seek to achieve optimal loading in both the involved and uninvolved limbs, as well as symmetrical loading between limbs in individuals with an ACLR.

(No relevant relationships reported)

The structural alignment of the medial longitudinal arch has an influential role in generating the locomotive mechanisms in bipedalism. Evidence suggests healthy arch types exhibit foot function advantageous in forward propulsion. Further, studies indicate that any compositional alterations may result in accessory motion and dysfunction of the foot. However, recent anecdotal assumptions propose that such compromised foot architecture may develop biomechanical characteristics beneficial for propulsive patterns in the medial and lateral directions. The purpose of this study was to examine the influence normal arch (NA) and low (LA) arch types have on propulsive mechanics during directional-specific locomotive tasks. **METHODS:** Twenty-two male collegiate athletes, eleven NA and LA, participated in the study. The Arch Height Index Measurement System was utilized to obtain foot anthropometric measurement for arch height classification. Participants performed three complete trials of lateral hopping (one-leg ski jumping; LJ), unilateral forward hopping (FH), and unilateral stationary hopping (SH), at a self-selected speed. Normalized peak mediolateral ground reaction forces (mGRFs) were collected during the propulsion phase of each task. **RESULTS:** A 2 (arch type) x 3 (jumping/hopping tasks) mixed-factorial ANOVA were performed to determine the effects of arch height on the propulsion phase of each condition. A significant main effect across conditions was observed ($F(1.258, 25.154) = 11.526, p < 0.001, \eta^2 = 0.366$). Follow-up pairwise comparisons indicated that LJ yielded significantly greater lateral force, when compared to FH ($p = 0.011$) and SH ($p = 0.001$). Additionally, a significant difference was observed between arch height ($F(1, 20) = 4.502, p = 0.047, \eta^2 = 0.184$), indicating LA produced larger lateral forces when compared to the NA individuals. However, there was no significant interaction between arch height and the conditions ($F(1.258, 25.154) = 1.756, p = 0.198$). **CONCLUSION:** While the differences amongst conditions were expected, the results revealed that LA displayed larger mGRFs when compared to NA. These findings of this study may suggest that the altered foot positioning of the LA, specifically the everted posture, may act as a beneficial source for directionally specific tasks.

Effect of Sex on Linear and Nonlinear Kinematic Variability during a Stop Jump

Alex Peebles, Shane Ross, Robin Queen, FACSM. *Virginia Tech, Blacksburg, VA.*
Email: apeebles@vt.edu
(No relevant relationships reported)

Women are 4 to 6 times more likely to sustain a non-contact ACL injury compared to men. Sex differences in lower extremity landing mechanics are believed to be associated with this increased risk. However, no previous studies have examined sex-specific differences in the variability of lower extremity mechanics during a landing. Variability may provide unique information regarding movement control which pertains to injury risk. **Purpose:** To compare variability in hip and knee kinematics during a stop jump between men and women. **Methods:** 22 male and 20 female healthy uninjured individuals completed seven bilateral stop jumps while lower extremity kinematics and kinetics were collected. Hip and knee joint 3D kinematics were calculated from initial contact to toe off of the first landing and time normalized using Visual 3D. Linear variability was quantified as the standard deviation of peak knee flexion and peak knee ab/adduction across the seven trials, then as the average standard deviation during ground contact. Joint couples were created between knee flexion and knee abduction, hip flexion and knee abduction, hip rotation and knee abduction, knee flexion and knee flexion velocity, and knee abduction and knee abduction velocity, all isolated to the landing phase. Vector coding variability and divergence of nearest neighboring trajectories was quantified for each couple and divergence was quantified for knee flexion and knee abduction angle time series. All variability outcome measures were compared between sex for the dominant limb only using independent t-tests. **Results:** There were no sex-based differences when looking at any linear variability measures. Women had increased vector coding variability for the knee abduction/knee abduction velocity coupling ($F: 36^\circ \pm 12^\circ, M: 29^\circ \pm 7^\circ, p = 0.025$). Women had increased trajectory divergence of knee abduction angles ($F: 1.3^\circ/s \pm 4^\circ/s, M: 1.0^\circ/s \pm 3^\circ/s, p = 0.009$) and of the knee abduction/knee abduction velocity coupling ($F: 1.4^\circ/s \pm 4^\circ/s, M: 1.1^\circ/s \pm 3^\circ/s, p = 0.013$). No other sex-specific differences were observed. **Conclusion:** Women have increased knee kinematic variability during landing then men, particularly when looking at knee abduction. Linear methods of quantifying variability may be insensitive for identifying sex differences in landing variability.

1013 Board #247 May 29 3:30 PM - 5:00 PM

The Effect Of Video And Verbal Biofeedback In Landing Mechanics Parameters During Drop Vertical Jump.

Gabriel A. Paz¹, Haroldo G. Santana¹, Marianna F. Maia¹, Antônio CB Brandão², Victor Dos Santos Júnior², Humberto Miranda¹. ¹*Federal University of Rio de Janeiro, Rio de Janeiro, Brazil.* ²*Physical Assessment and Training Center – CAFT, Rio de Janeiro, Brazil.*
Email: gabriel.andrade.paz@gmail.com
(No relevant relationships reported)

The video and verbal feedback, could offer a quick, simple and effective alternative to training programs for altering high-risk movement patterns during landing tasks such drop vertical jump. **PURPOSE:** To investigate the effect of verbal and video biofeedback on height, power, flight time and contact time during drop vertical jump. **METHODS:** Twenty-two recreationally trained women (22 ± 4 yrs; 72; 72 ± 3.9 kg; 172 ± 2.9) performed the drop vertical jump (DVJ) using a 40 cm box on three different protocols: control set (CS) – three DVJ were performed without any feedback; video feedback (VF) – the participant watched the video of the CS and were instructed to improve the stability or power in the next trials; verbal feedback (VBF) – the researcher provide instructions regarding landing, lower limb alignment and knee stabilization after CS. Three-minute rest were adopted between trials. A randomized order was adopted between protocols. The DVJ was assessed using a OPTOGAIT System. The jump height, relative power, flight time and contact time were measured during DVJ. **RESULTS:** Regarding the DVJ height (CS = 18.6 ± 7.5cm; VF = 20 ± 6.3cm; VBF = 20.1 ± 5.3cm), no main effects for protocols was noted ($F_{2,26} = 1.647; p = 0.212$). Similar results were observed for relative power (CS = 14.9 ± 4.1 w/kg; VF = 15.2 ± 3.2 w/kg; VBF = 15.1 ± 2.7 w/kg; $F_{2,26} = 0.195; p = 0.824$) and flight time (CS = 0.37 ± 0.08 sec; VF = 0.39 ± 0.06 sec; VBF = 0.39 ± 0.05 sec; $F_{2,26} = 2.776; p = 0.081$). However, a significant main effect for protocols was noted for contact time (CS = 0.64 ± 0.11 sec; VF = 0.69 ± 0.08 sec; VBF = 0.72 ± 0.09 sec; $F_{2,26} = 3.996; p = 0.031$). Longer contact time was observed under VF ($p = 0.033$) and VBF ($p = 0.031$) than CS. **CONCLUSION:** Therefore, the increase in contact time noted under VF and VBF protocols would lead to a decrease in the rate of loading experienced by the hip, knee and ankle joints during the initial landing of DVJ, therefore decreasing injury risk.

Table 1 – Drop vertical jump parameters between biofeedback protocols.
* Significant difference for control set ($p < 0.05$).

| | Control Set | Video | Verbal |
|--------------------|-------------|--------------|--------------|
| Height (cm) | 18.6 (7.5) | 20 (6.3) | 20.1 (5.3) |
| Power (Watts/kg) | 14.9 (4.1) | 15.2 (3.2) | 15.1 (2.7) |
| Flight time (sec) | 0.37 (0.08) | 0.39 (0.06) | 0.39 (0.05) |
| Contact Time (sec) | 0.64 (0.11) | 0.69 (0.08)* | 0.72 (0.09)* |

(No relevant relationships reported)

The interactions between neuromuscular and metabolic processes can produce muscular contraction; Thus, the sympathetic nervous system takes special relevance because of its contribution in the autonomic control, which participates in the energetic supply of the muscular fibers and in the neuromuscular performance. This performance can be evaluated by using the vertical jump test, and its relationship with autonomic regulation is determined by the analysis of heart rate variability (HRV).

PURPOSE: The aim of this study is to describe correlations between HRV and jump performance variables in young female professional soccer players.

METHODS: Thirteen professional female soccer players (Aged: 20.7 +/- 2.6 years; Weight: 60.9 +/- 4.4 Kg) were analyzed, we evaluated HRV to determine autonomic regulation, we also evaluated neuromuscular performance during countermovement (CMJ) and squat jump (SJ) using tri-axial force platform. A statistical analyses was calculated to determine associations between variables of autonomic regulation and jump performance.

RESULTS: Positive associations were found between CMJ contraction time and maximal heart rate (HR) during standing position ($p=0.01$, $r_2=0.4$), SJ peak concentric velocity and LF/HF index in immediate postural change ($P=0$, 0453, $r_2=0$, 2739). Additionally, negative correlations were observed in CMJ concentric force and Stress Index ($p=0.001$, $r_2=0.42$), sympathetic index ($p=0.001$, $r_2=0.41$), average HR ($P=0.002$ $r_2=0.58$) and minimum HR in supine position ($p=0.005$, $r_2=0.52$) and SJ peak concentric velocity and LF/HF index in orthostatic postural change ($P=0$, 0453, $r_2=0$, 2739).

CONCLUSIONS: There is an inverse correlation between concentric contraction force and sympathetic modulation. Likewise, a positive association was found between some parameters related to neuromuscular power and variables of sympathetic activity, evidencing the existence of an influence of sympathetic system in explosive sports. According to this correlation, we suggest the use of HRV parameters that reflect sympathetic activity in the monitoring of training loads.

Screening for Injury Risk in Gymnasts: Examining the Sport Specificity of the Drop Vertical Jump

Valerie Cohen¹, Shannon Linderman¹, Donna M. Scarborough¹, Deborah King², Dave Diggin², Luke S. Oh¹. ¹Massachusetts General Hospital, Boston, MA. ²Ithaca College, Ithaca, NY.
Email: vcohen1@ithaca.edu

(No relevant relationships reported)

Gymnastics has one of the highest rates of lower extremity (LE) ligamentous injury even among contact sports. Excessive frontal plane motion of the LE during landing from a DVJ is linked to injury at the hip, knee and ankle. In addition, sagittal plane motion plays a key role in absorption of forces upon landing. Frontal and sagittal plane motion of the LE during DVJ tasks are often used to screen injury risk in field sport athletes. However, no gymnastics-specific screening tool exists.

PURPOSE: To evaluate the differences in landing biomechanics during the DVJ and a sport specific landing during the roundoff back handspring (ROBHS) among gymnasts.
METHODS:

15 gymnasts (mean age: 17.0 ± 3.1 y, height: 1.58 ± 0.81 m, mass: 55.6 ± 9.3 kg) underwent 3D motion capture during ROBHS and DVJ tasks using a 20-camera motion capture system (240 Hz, Vicon™). A 15-segment model was created for joint calculations in Visual 3D™. Ankle, knee, and hip angles were analyzed at initial contact (IC) and peak knee flexion (PKF) of one trial of the ROBHS and DVJ. Paired samples T-test assessed differences in joint kinematics between the two skills ($\alpha=0.05$). **RESULTS:** At IC, sagittal plane ankle (DVJ -19.33 ± 6.61°, ROBHS 5.04 ± 7.9°, $p < .001$), hip (DVJ 23.43 ± 12.17°, ROBHS 62.91 ± 12.36°, $p < .001$), and frontal plane hip angles (DVJ 4.30 ± 3.74°, ROBHS -2.48 ± 3.23°, $p < .001$) are significantly different between skills. At PKF, sagittal plane knee motion is significantly different between skills (DVJ 75.70 ± 14.43°, ROBHS 93.02 ± 7.61°, $p < .001$). Hip motion between IC and PKF in two planes (sagittal: DVJ 35.08 ± 17.96°, ROBHS -25 ± 5.24°, $p < .001$ and transverse: DVJ -5.16 ± 5.90°, ROBHS .40 ± 4.60°, $p = .001$) are significantly different between skills. **CONCLUSIONS:** The difference in hip frontal plane results at IC and PKF between skills could be due to the difference in stance width. Additionally, the DVJ jump task encourages an upright posture at IC, rather than the flexed trunk position at IC of the ROBHS. Furthermore, the sagittal plane results at IC suggest that force absorption across joints differs during the two skills. Our results show that the DVJ may not be a sport specific screening tool for gymnastics. Therefore, further investigation is needed with comparison to other tumbling passes to clarify its usefulness in gymnastics.

Sport-related concussion (SRC) is now classified as a major public health concern affecting millions of athletes each year. Recent evidence suggests that previously concussed athletes are at greater risk for lower extremity (LE) injury beyond the resolution of traditional SRC assessment batteries. The current literature has yet to elucidate the biomechanical movement patterns of sport-specific activities that may provide rationale for LE injury risk following SRC.

PURPOSE: To examine landing biomechanics in adolescent athletes who report a SRC history.

METHODS: Three athletes with a SRC history (age: 11.3 ± 3.5 yrs; previous SRCs: 1.3 ± 0.6) and two athletes without a SRC history (age: 13.0 ± 4.2 yrs) completed drop-landings from 30 cm and 60 cm. Three dimensional kinematic data were measured via a 10-camera motion analysis system at 100 Hz, while kinetic data were collected at 1000 Hz with two adjacent force platforms. The preferred limb to initiate the drop-landing was used for data analysis in comparing landing mechanics between groups. Five landing trials were collected to ensure landing performance stability. The independent variables were group (concussion, control) and landing height (30, 60 cm), while the dependent variables included maximum vertical ground reaction force (vGRF), loading rate, and knee joint kinematic parameters during the landing tasks. **RESULTS:** Athletes with a previous SRC demonstrated a 7.9% increase (4.22 BWs vs 3.89 BWs) in maximum vGRF and 14.7% increase in loading rate (109.2 BWs / sec vs 93.2 BWs / sec) from the 60 cm height compared to control athletes. Additionally, previously concussed athletes demonstrated an 8.8 degrees (-4.9° vs 3.9°) and 11.2 degrees (-8.1° vs 3.1°) increase in knee abduction angle from the 30 cm and 60 cm heights compared to control athletes. Knee sagittal plane range of motion was decreased by 56.2% (52.0° vs 81.2°) from the 30 cm height and 30.3% (62.3° vs 81.1°) from the 60 cm height in athletes with a previous SRC. **CONCLUSIONS:** Preliminary analysis highlights that previously concussed adolescent athletes demonstrate landing mechanics that may increase LE injury risk. Specifically, athletes with a SRC history demonstrate sagittal and frontal plane knee motion during landings that are associated with greater risk of an anterior cruciate ligament injury.

Post-Trial Feedback May Alter Single and Dual Task Landing Performance in Female Collegiate Athletes

Maria Lee¹, Jess Onsager¹, Jeremie Schiedermaier¹, Becky Heinert², Drew Rutherford¹, Thomas W. Kernozek, FACSM¹. ¹University of Wisconsin-La Crosse, La Crosse, WI. ²Gundersen Health System, La Crosse, WI.

(No relevant relationships reported)

Anterior cruciate ligament (ACL) injuries are common during athletic landing activities especially in females. The use of performance-based feedback may be used to alter landing mechanics. **PURPOSE:** Provide vertical ground reaction force (vGRF), loading asymmetry (LA), and qualitative frontal-plane video (FPV) as post-trial feedback of each landing task using a low-cost custom portable system to evaluate

and train female collegiate athletes during single- and dual-task landing performances. **METHODS:** 65 female collegiate athletes participated. Trials were either single-task (ST) drop landings or dual-task (DT with/without jumping for a suspended ball). These were performed from a 50 cm drop height in blocks of 3 ST and 6 DT pre-tests, 6 ST and 6 DT with post-trial visual feedback (peak vGRF in bodyweight (BW), LA, and FPV), and 3 ST and 6 DT post-tests. Peak vGRF and frontal plane knee-to-ankle ratio between landing task (ST or DT) and over time (pre-test, feedback, post-test) were compared using a two-way repeated measures ANOVA. **RESULTS:** There was a decrease in the peak vGRF (4.29 ± 0.93 vs. 3.55 ± 0.57 vs. 3.44 ± 0.66 BW, $p < 0.001$) as well as an improvement in knee-to-ankle ratio (0.97 ± 0.15 vs. 1.01 ± 0.12 vs. 1.04 ± 0.13 , $p < 0.001$) over the time course of the blocked trials. A main effect showed ST to have lower peak vGRF than DT (3.71 ± 0.82 vs. 3.81 ± 0.83 BW, $p = 0.002$), with the greatest difference in the post-test (3.35 ± 0.57 vs. 3.53 ± 0.73 BW, $p = 0.001$). **CONCLUSION:** Peak vGRF was different between ST and DT landing but improved with immediate post-trial feedback. Knee-to-ankle ratio was not different between ST and DT landing but improved with post-trial feedback. Post-trial feedback appears to produce immediate short term changes in landing performance in female collegiate athletes within a single training session.

Cognition Matters: Brain Function May Explain Deficiencies In Unanticipated Single-leg Landing Quality

Florian Giesche, Jan Wilke, Tobias Engeroff, Daniel Niederer, Lutz Vogt, Winfried Banzer, FACSM. *Goethe University, Frankfurt, Germany.* (Sponsor: Winfried Banzer, FACSM)
 Email: giesche@sport.uni-frankfurt.de
 (No relevant relationships reported)

It has been speculated that cognitive performance may play a role in injury risk during sports-related movements such as jump landings. However, there is a paucity of research concerning this hypothesis. **PURPOSE:** The present study aimed to elucidate the potential association between brain function and biomechanical stability as well as decision-making success in an unanticipated jump-landing task. **METHODS:** Twenty healthy male participants (27 ± 4 years) performed 70 counter-movement jumps with single-leg landings ($n = 35$ anticipated/ unanticipated each) on a pressure plate. In the anticipated condition, the required landing leg was indicated already before take-off. For the unanticipated jumps, this information was presented only during the flight phase. Biomechanical landing quality was estimated from vertical peak ground reaction force (pGRF), time to stabilization (TTS), center of pressure path way (COP), and standing errors (i.e. falls, touching the ground with the free leg). Decision-making accuracy was assessed as the amount of landing errors (wrong/both feet). Differences between conditions as well as their associations with several measures of cognitive function were analyzed controlling for relevant covariates. **RESULTS:** Unanticipated landings resulted in higher COP values (588 vs. 516 mm, $p < .001$, $d = .65$) and more standing errors ($n = 2.1$ vs. 0.3 , $p < .001$; $d = 1.1$) than anticipated trials. While the biomechanical deficit was not related to cognitive function ($p > .05$), there was an unexpected correlation between the increase in standing errors and higher cognitive flexibility ($r = -.481$, $p = .037$) as well as better working memory capacity ($r = .502$, $p = .028$). An opposite pattern was found for the landing errors occurring in the unanticipated condition: poor decision-making was associated with deficits in cognitive flexibility ($r = .609$; $p < .001$) and working memory ($r = -.500$; $p < .05$). **CONCLUSIONS:** Cognitive function may be an important but understudied moderator of unanticipated jump landing safety. Further research should be dedicated to the development of specific training methods aiming to improve movement-related decision-making under time constraints.

Risk Factors Associated With Medial Tibial Stress Syndrome In Military Cadets During Basic Training

Jonathan R. Malaver¹, Jenner R. Cubides², Rodrigo Argothy³, Daniel D. Cohen⁴. ¹Universidad del Rosario, Bogotá, Colombia. ²Escuela Militar de Cadetes General José María Córdova, Bogotá, Colombia. ³Coldeportes, Bogotá, Colombia. ⁴Universidad de Santander (UDES), Bucaramanga, Colombia.
 Email: jony10_milan@hotmail.com
 (No relevant relationships reported)

Medial Tibial Stress Syndrome (MTSS) is one of the most frequent pathologies in military personnel. As the muscles of the lower extremity contribute to the attenuation of impact forces in activities such as running and jumping, neuromuscular performance deficiencies and asymmetries may be associated with an increased risk for musculoskeletal injuries. **PURPOSE:** To determine the kinetic risk factors associated with MTSS through the bilateral countermovement jump (CMJ) in army cadets. **METHODS:** Ethical approval was granted by the General José María Córdova Military School of Cadets where the study was conducted. This observational study

was executed in a cohort of 123 cadets (followed for 24 weeks) who entered to the military school in 2017. Anthropometric, demographic data and MTSS history were recorded. Jump height (cm), peak landing force (N*kg), peak landing force asymmetry (%), concentric mean force (N*kg), concentric mean force asymmetry (%), eccentric deceleration rate of force development (EDRFD [N/s*Kg]) and EDRFD asymmetry (%) were evaluated through the bilateral CMJ on a pair of uniaxial force platforms. After the follow-up, the cadets with MTSS were determined through the clinical history. **RESULTS:** The incidence of MTSS was 13% ($n = 16$). In the bivariate analysis, height, EDRFD asymmetry, sex (female; $RR = 2.84$; 95% $CI = 1.16-6.94$), provenance (rural; $RR = 2.65$; 95% $CI = 1.04-6.72$), and MTSS history (yes; $RR = 5.71$; 95% $CI = 2.23-14.62$), were significantly associated with MTSS ($p \leq 0.05$). In the logistic regression, EDRFD asymmetry ($OR = 1.03$; 95% $CI = 1.00-1.07$), sex ($OR = 4.91$; 95% $CI = 1.38-13.37$), and provenance ($OR = 4.82$; 95% $CI = 1.04-6.72$), were significantly associated with MTSS ($p \leq 0.05$). MTSS history was significant for $p \leq 0.1$ ($OR = 8.95$; 95% $CI = 0.68-118.73$). The predictive model was significantly associated with MTSS ($p \leq 0.01$), had a sensitivity of 31.3% and a specificity of 99.1% (overall prognosis of 90.2%). **CONCLUSIONS:** While we identified important non-modifiable risk factors for MTSS in cadets during basic training, we also found that higher CMJ EDRFD asymmetry was a significant risk factor. This suggests that the bilateral CMJ may be a useful tool for pre-entry screening in and that high EDRFD asymmetry could be a potential target of pre-basic training risk reduction conditioning.

A Comparison Of On- And Off-Duty Physical Activity In Career Firefighters

Allison M. Barry¹, Katie J. Lyman², Nathan D. Dicks², Kassiani D. Landin², Christi R. McGeorge², Tanis J. Walch³. ¹Pittsburg State University, Pittsburg, KS. ²North Dakota State University, Fargo, ND. ³University of North Dakota, Grand Forks, ND.
 (Sponsor: Donna J. Terbizan, FACSM)
 Email: abarry@pittstate.edu
 (No relevant relationships reported)

Physical inactivity coupled with increasing obesity levels in firefighters plays a critical role in accumulating cardiovascular events. **PURPOSE:** To examine differences in career firefighters' objectively measured physical activity (PA) levels while on- and off-duty. **METHODS:** Twenty-nine career firefighters (age: 34.45 ± 7.15 yr; BMI: 28.97 ± 2.52 kg \cdot m⁻²) participated in a non-experimental, within-subjects study. Firefighters wore an accelerometer during waking hours of their nine-day tour, which included three, 24-hour on-duty days and six, off-duty days. Accelerometers assessed PA intensity using Freedson (1998) cut-points and step count. Height and weight were also measured to calculate BMI. Dependent t-tests, independent t-tests, and Pearson product-moment correlations were used to analyze the data in SPSS (v24). **RESULTS:** Firefighters (overweight=20; obese=9; normal weight=0) met the ACSM PA guidelines more often while on-duty ($n = 17$) compared to when they were off-duty ($n = 9$). While on-duty, firefighters attained an average of 35.51 ± 19.22 minutes of moderate-to-vigorous physical activity (MVPA) compared to 27.82 ± 18.91 minutes ($p = 0.055$, $d = 0.40$) when off-duty. Firefighters engaged in significantly more light PA during on-duty days (351.11 ± 59.90 minutes) compared to off-duty days (315.83 ± 86.90 minutes) ($p = 0.026$; $d = 0.47$). There were significant correlations between on- and off-duty days for sedentary behavior ($r = -0.53$, $p < 0.001$), moderate PA ($r = 0.37$, $p < 0.05$), and MVPA ($r = 0.41$, $p < 0.05$). **CONCLUSION:** As a group, firefighters in this study did not meet ACSM PA guidelines, especially when off-duty, which may place them at greater risk for a cardiac event. Firefighters must rely on their cardiovascular health to perform the physiologically demanding tasks that their job requires. In the future, researchers need to collaborate with fire departments across the country to assess and develop ways to enhance PA levels in firefighters with the goal of improving their overall health and well-being, which ultimately may decrease the risk of cardiac events.

1021 Board #255 May 29 2:00 PM - 3:30 PM
Comparing Physical Fitness in Career vs. Voluntary Firefighters

Cody E. Morris¹, Scott W. Arnett², Andrew J. Jackson², Lee J. Winchester³. ¹University of Alabama at Birmingham, Birmingham, AL. ²Western Kentucky University, Bowling Green, KY. ³University of Alabama, Tuscaloosa, AL. (Sponsor: Scott Lyons, FACSM)
 Email: cemorris@uab.edu
 (No relevant relationships reported)

PURPOSE: Some firefighting departments are composed of professional firefighters (career firefighters) while some smaller towns cannot fully fund a professional firefighting department and rely on their citizens to volunteer their time and put their lives at risk to perform fire suppression and other related firefighting tasks when those events arise. The purpose of this study was to assess the potential similarities and differences in health and physical fitness profile between career firefighters and volunteer firefighters.

METHODS: The research protocol consisted of a health and physical fitness assessment testing the 5 components of health-related fitness (body composition, cardiovascular fitness, muscular strength, muscular endurance, and flexibility) using previously published and accepted protocols. The participant population consisted of career firefighters (CFF) who were all members of the Bowling Green Fire Department in Bowling Green, KY and voluntary firefighters (VFF) were all members of the Warren County Fire Department (Warren County, KY). The total sample size consisted of 139 firefighters comprised of 120 CFF and 19 VF.

RESULTS: An independent *t*-test showed evidence of CFF having a significantly higher value/score for the following variables: height ($p = 0.034$), $\dot{V}O_2$ max ($p = 0.006$), push-ups completed ($p = 0.023$), and plank time ($p < 0.0005$). VFF had a significantly higher value for the following variables: fat mass ($p = 0.002$), body fat percentage ($p < 0.0005$), and absolute grip strength ($p = 0.029$). There were not shown to be any significant differences between groups for the following variables: age ($p = 0.299$), body mass ($p = 0.161$), fat-free mass ($p = 0.292$), body mass index ($p = 0.056$), flexibility ($p = 0.097$), or relative grip strength ($p = 0.934$).

CONCLUSIONS: In regards to the physical fitness testing of the current sample, the VFF had a significantly worse health and fitness profile across a number of variables compared to the CFF. Despite the financial and commitment status of volunteer firefighting departments, they perform an equally dangerous and important job as firefighters of professional/career firefighting departments and more attention should be directed at developing the fitness and performance of these firefighters as well.

Handgrip Strength Levels in Male and Female Brazilian Military Firefighters

Kevin A. Barreto¹, Daniel Saint Martin¹, Richard X. Fonseca¹, Edgard M. K. Von Koenig Soares², Mayda Castro³, Rosenkranz Maciel Nogueira⁴, Guilherme E. Molina¹, Denise L. Smith, FACSM⁵, Luiz Guilherme Grossi Porto⁶. ¹University of Brasilia Faculty of Physical Education, Brasilia, Brazil. ²University of Brasilia Faculty of Physical Education; Health and Human Physiological Sciences, Skidmore College, Saratoga Springs, Brasilia, Brazil. ³University of Brasilia Faculty of Physical Education; Civil Police of the Federal District, Brasilia, Brazil. ⁴University of Brasilia Faculty of Physical Education; Brasilia Fire Department Firefighters, Brasilia, Brazil. ⁵Health and Human Physiological Sciences, Skidmore College, Saratoga Springs, Brasilia, Brazil. ⁶University of Brasilia Faculty of Physical Education; Harvard T.H. Chan School of Public Health, Brasilia, Brazil.
 Email: thekevinvalves@gmail.com
 (No relevant relationships reported)

Low handgrip muscular strength (HMS) is associated with increased morbi-mortality. HMS has been shown to predict some firefighters' job-related task performance. However, little is known about firefighters HMS descriptive values and there is no specific fitness categories for grip strength for firefighters. **PURPOSE:** To describe HMS in Brazilian military firefighters in association with gender and job experience. **METHODS:** We evaluated 290 firefighters (70% men) with mean age of 28.9±6.4 yrs. HMS was measured using a calibrated handgrip dynamometer (SaehanCorp, Korea). Volunteers performed to maximally maximal contractions with each hand, holding the dynamometer in line with the forearm in the upright position (ACSM 10th ed guideline). Final score was the sum of the highest values on each hand and categorized by ACSM guideline. Fair or poor HMS were classified as suboptimal, all other categories (excellent, very good and good) were classified as good strength. Data are presented as median (min-max) values due to nonparametric distribution (Kolmogorov-Smirnov test). Chi-square (of Fisher) test was used to compare

classification. Job experience was classified as rookie (those who have just finished training academy) and as veteran. Mann-Whitney test was used for comparisons. **RESULTS:** Absolute HMS was higher in men as compared to women: 100 (61-156) vs 64 (45-97) kg/f ($p=0.05$). However, the proportion of volunteers in each category was similar among genders ($p=0.26$). Proportions of HMS categories are shown on Table 1. **CONCLUSION:** This cross-sectional study showed that about 25% of volunteers showed suboptimal HMS and that male veterans had higher strength than rookies. Data support the recommendation for upper limbs strength training among firefighters, mainly among those joining the corporation.

| Sex | Strength Classification | Rookie | Veteran | p value* |
|--------|-------------------------|-------------|------------|----------|
| Male | Good | 101 (63.1%) | 35 (83.3%) | 0.01 |
| | Suboptimal | 59 (36.9%) | 7 (16.7%) | |
| Female | Good | 58 (73.4%) | 7 (77.8%) | 1.00 |
| | Suboptimal | 21 (26.6%) | 2 (22.2%) | |

Total Energy Intake and Self-selected Macronutrient Distribution During Wildland Fire Suppression

Alexander Marks¹, Joe Sol², Joe Domitrovich², Molly West³, Brent C. Ruby, FACSM¹. ¹University of Montana, Missoula, MT. ²United States Forest Service, Missoula, MT. ³University of California, Berkeley, Berkeley, CA. (Sponsor: Brent Ruby, FACSM)
 (No relevant relationships reported)

Wildland firefighters (WLFF) are required to work long hours in extreme environments resulting in high daily rates of total energy expenditure (TEE) (Ruby, 2002; Cuddy, 2015). Increasing the number of eating episodes throughout the workshift and/or providing rations that better promote convenient nutrient delivery (Cuddy, 2007; Montain, 2008) has been shown to augment self-selected work output on the fireline. Regular consumption of supplemental carbohydrate (CHO) has also demonstrated enhanced work output, particularly during the shifts' latter hours (Cuddy, 2007). However, it remains unclear how current feeding strategies of WLFF compare to more frequent nutrient delivery. **PURPOSE:** The aim of the current study was to determine the self-selected field total energy intake (TEI), composition and patterns of WLFF feeding during wildland fire suppression shifts. **METHODS:** 86 WLFF (16 female, 70 male; 27.5±6.4 yrs) were deployed to 12 different wildland fire assignments across six regions of the US during the 2018 fire season. Pre- and post-shift food inventories were collected at WLFF basecamp and provided item-specific nutrient content (calories [kcal], CHO, fat, protein). Workshift nutrient consumption (TEI, feeding frequency [total number of and interval between feeding episodes], feeding episodic composition) was monitored in real-time by field researchers on the fireline via observational data capture in mobile tablets. **RESULTS:** Workshift length averaged 14.0±1.2 hr, with a TEI of 1523±639 kcal (51±10, 37±9, 14±5 % for CHO, fat, and protein, respectively). The total number of eating episodes was 4.3±1.7 with an average interval of 117±76 min. Eating episodes averaged 346±311 kcal and included 44±38 g CHO. Using similar intake metrics, TEI was 893±353 and 1356±560 kcal for breakfast and dinner, respectively. **CONCLUSION:** The present workshift TEI approximates 34% of the TEE compared to our prior doubly labeled water studies (Ruby, 2002; Cuddy 2015). These data also demonstrate that WLFF consumption patterns using current rations may not deliver adequate nutrients for the occupational demands of WLFF. Future work should elucidate the impact of workshift provisions on overall patterns of self-selected work output.

Longitudinal Changes in Single-Leg Dynamic Balance Asymmetries Among Firefighter Recruits: An Observational Cohort Study

David J. Cornell¹, Stacy L. Gnacinski², Kyle T. Ebersole³. ¹University of Massachusetts Lowell, Lowell, MA. ²Drake University, Des Moines, IA. ³University of Wisconsin-Milwaukee, Milwaukee, WI. (Sponsor: Terry J. Housh, FACSM)
 Email: david_cornell@uml.edu
 (No relevant relationships reported)

Previous research has demonstrated a link between asymmetries in single-leg dynamic balance ability and musculoskeletal injury (MSKI) risk. Specifically, previous research has indicated that a right vs. left asymmetry of ≥ 4 cm on the anterior reach direction of the star excursion balance test (SEBT_{ANT}) is associated with a greater risk of MSKI.

Previous research also suggests that the overall dynamic balance ability of firefighter recruits increases as they progress through their firefighter recruit training academy, but then decreases during the transition into active-duty service. However, longitudinal changes in single-leg dynamic balance asymmetries during and after firefighter recruit training academies have yet to be examined. **PURPOSE:** To describe longitudinal changes in single-leg dynamic balance asymmetries among firefighter recruits. **METHODS:** 27 male firefighter recruits (mean \pm SD, age = 29.9 \pm 4.1 yrs; height = 179.8 \pm 4.6 cm; body mass = 87.2 \pm 9.7 kg) enrolled in the same training academy volunteered to participate in the current study. The SEBT_{ANT} was conducted bilaterally at the beginning (W1) and end (W14) of their firefighter training academy, as well as at the end of the probationary period of their active-duty service (W38). All SEBT_{ANT} data were recorded in cm and right vs. left SEBT_{ANT} asymmetries were defined as: < 4 cm and \geq 4 cm. A Cochran's Q Test was utilized to examine for changes in the frequency of SEBT_{ANT} right vs. left asymmetries across time. An alpha of 0.05 determined statistical significance. **RESULTS:** Although the number of firefighter recruits who demonstrated a right vs. left SEBT_{ANT} asymmetry of \geq 4 cm increased from W1 to W14 (7/27 to 9/27), and from W14 to W38 (9/27 to 11/27), there was not a significant ($Q = 1.333$, $df = 2$, $P = 0.513$) change in asymmetry frequency over time (25.9% vs. 33.3% vs. 40.7%). **CONCLUSION:** Despite previous research suggesting that there are significant changes in dynamic balance ability among firefighter recruits as they progress through their firefighter recruit training academy and begin active-duty service, similar significant changes in single-leg dynamic balance asymmetries were not identified. Future research should prospectively examine which factors of dynamic balance ability are most predictive in MSKI risk among this cohort population.

1025 Board #259 May 29 2:00 PM - 3:30 PM
Contributors to Perceived Occupational Fatigue in Career Firefighters

Gena R. Gerstner, Jacob A. Mota, Hayden K. Giuliani, Eric D. Ryan. *University of North Carolina at Chapel Hill, Chapel Hill, NC.* (Sponsor: Abbie Smith-Ryan, FACSM)
 (No relevant relationships reported)

Firefighters are susceptible to work-related fatigue due to long and strenuous shiftwork. Work-related fatigue can be linked to the majority of the fatal and non-fatal injuries in the fire service. **PURPOSE:** The purpose of this study was to examine the influence of isometric strength, body mass index, and age on perceived work-related fatigue in career firefighters. **METHODS:** Thirty-two firefighters [29 males, 3 females; age: 33.7 \pm 9.2 years (20-50); stature: 177.2 \pm 7.6 cm (153.0-190.5); mass: 94.5 \pm 20.8 kg (64.0-152.0)] volunteered for this investigation. Participants completed an occupational fatigue questionnaire that measured three dimensions of work-related fatigue: acute fatigue (AF), chronic fatigue (CF), and inter-shift recovery (IR). Participants performed 3-4 leg extension isometric maximal voluntary contractions (MVCs) on a custom-built calibrated load-cell dynamometer with a two minute recovery period in between each contraction. Maximal strength, or isometric peak force, was calculated as the highest 100ms value during the MVC plateau. Local firefighters work three 24-hr shifts on-off over one rotation followed by four days of rest. Maximal strength testing was completed pre-rotation and post-rotation (five days apart). Percent change in maximal strength [% Δ PF = (Post-Pre)/Pre \times 100] was calculated. Stepwise regression analyses were conducted for each dimension of fatigue. Predictor variables were Δ PF, body mass index, and age. An alpha level was set *a priori* at 0.05 for all analyses. **RESULTS:** The stepwise analyses suggest that age alone significantly contributed to AF ($R^2=0.274$, $P=0.001$) and CF ($R^2=0.280$, $P=0.001$). Age and Δ PF combined significantly contributed to IR ($R^2=0.269$, $P=0.004$). BMI failed to significantly contribute to any of the stepwise regression models. **CONCLUSION:** These findings suggest that older firefighters experience greater levels of perceived acute and chronic work-related fatigue. Furthermore, older firefighters with greater maximal strength losses experience poorer perceived IR. While age is non-modifiable, interventions aiming to mitigate strength loss across shiftwork may be helpful at enhancing IR. Supported by the National Institute of Occupational Safety and Health (T42OH008673)

Sedentary Behavior and Daily Steps Count In Brazilian Wildland Military Firefighters - Brasília Firefighters Study

Daniel R F Saint-Martin, Leonardo Segedi, Edgard M K Von Koenig Soares, Rosenkranz Maciel Nogueira, Guilherme Eckhardt Molina, Luiz Guilherme Grossi Porto. *University of Brasília and GEAFS, Brasília, Brazil.*
 (No relevant relationships reported)

Wildland firefighters' (WF) routine involves long displacements and intense physical demands, interspersed with sedentary behavior (SB). Little is known about SB and daily steps pattern of WF during routine work. **PURPOSE:** We analyzed the SB and total daily steps of Brazilian WF during a 24-hour shift-work. **METHODS:** We evaluated 22 WF, aged 35.9 \pm 6.4 yrs, BMI of 25.3 \pm 2.9 kg/m², during the dry season.

Volunteers wore an accelerometer (ActiGraph-GT3X+) during a 24h shift work and reported main duties performed on a log. SB was evaluated by the vector magnitude using <200 counts/min as cut-off point. We compared SB and daily steps according to 3 periods of the day: morning (08:00-11:59 plus 06:00-07:59 of the following day); afternoon (12:00-17:59) and evening (18:00-23:59). Night period (00:00 to 05:59) was excluded due to insufficient data. We compared SB and daily steps during the day and between those who participated or not in at least one episode of wildland fire suppression (Mann-Whitney text). Friedman text with a Wilcoxon post-hoc test (p -value \leq 0,02) were used to compare the 3 moments. Data are shown as median (min-max). **RESULTS:** WF spent 73 (15-142) min in the morning, 131 (17-192) min in the afternoon and 109 (13-193) min in the evening on SB. They accumulated 3,508 (1,322-12,237) steps in the morning, 4,105 (963-18,450) in the afternoon and 5,499 (571-13,883) in the evening. Those who participated or not in at least one episode of wildland fire suppression showed similar SB and daily steps ($p>0,05$). SB pattern throughout the day are show on Figure 1. **CONCLUSION:** WF achieved similar daily steps in the 3 periods of the day. Time spent in SB was higher in the evening as compared to the morning. Our results suggest that WF remain little time in SB as compared to other professions and achieved a high daily steps count (>10,000) during a 24-h routine work.

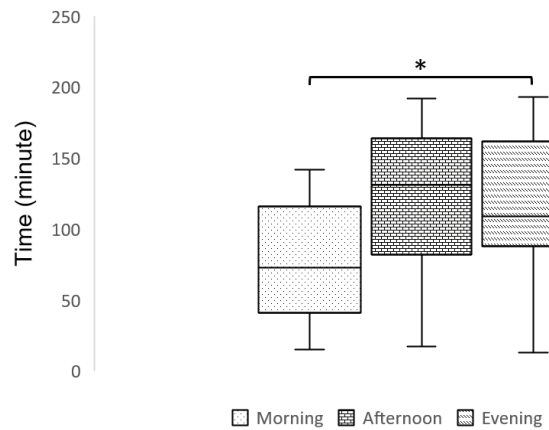

Figure 1. Sedentary behavior by different moment on day among on-duty firefighters Friedman text ($p = 0.03$); *Wilcoxon text ($p = 0.01$)

(No relevant relationships reported)

Firefighting is a hazardous profession. Occupational hazard may negatively impact quality of life (QoL). Firefighters' job-related activities result in vigorous physical effort that requires considerable cardiorespiratory fitness (CRF). The National Fire Protection Association (NFPA) recommends a CRF \geq 42 ml·kg⁻¹·min⁻¹ (12METs) for safety purposes. **PURPOSE:** We evaluated QoL of male and female firefighters in association with CRF. **METHODS:** We evaluated 104 female (35.0±6.2 yrs, BMI: 23.2±2.5 kg/m²) and 686 male (37.9±6.8 yrs, BMI: 26.3±3.0 kg/m²) Brazilian firefighters. CRF was estimated by the 12-min Cooper test and QoL was evaluated by the World Health Organization QoL questionnaire in four domains: physical (PHYD), psychological (PSYD), social relationship (SRD) and environment (ENVD). QoL was compared within each gender among those who met or did not meet the minimum CRF recommendation for firefighters. Among men we used the NFPA CRF cut-off point (12 METs) and for women we used its corresponding value from the Cooper test gender-specific classification (9.5 METs). Comparison were made by Mann-Whitney test; GLM was applied for age-adjustment and Spearman test for correlations. **RESULTS:** Absolute CRF among men was higher than among women: 12.2±1.7 vs 10.1±1.7 METs ($p<0.001$), but the proportion of volunteers who met the recommended CRF was similar between genders. QoL was similar between genders in all domains ($p\geq 0.21$). QoL comparisons by gender are shown on Table 1. QoL showed low significant correlation with CRF among women ($0.2 < r_s < 0.26$) and men ($0.16 < r_s < 0.28$) ($p<0.04$). **CONCLUSION:** Among both men and women firefighters, better QoL was significantly associated with higher CRF. Firefighters with CRF above the minimum recommended gender-specific threshold showed higher values of QoL. Our results support the recommendation for regular physical training among firefighters both for safety and QoL reasons.

Comparing the Subjective and Objective Responses to Submaximal and Maximal Tasks in Firefighter Recruits

Edward K. Smith¹, Kyle T. Ebersole¹, Rudi A. Zander¹, Michael H. Haischer¹, Vanessa J. Kleiss¹, Cody S. Tesch². ¹University of Wisconsin-Milwaukee, Milwaukee, WI. ²City of Milwaukee Fire Department, Milwaukee, WI.
(No relevant relationships reported)

Previous literature has established that numeric ratings of perceived exertion (RPE_{NUM}) are associated with heart rate (HR) during a task. Recently, the use of a 100mm visual analog scale (RPE_{VAS}) has been used as an alternative to RPE_{NUM}. Prior FF research has not concurrently examined RPE_{NUM}, RPE_{VAS}, and HR during tests of varying intensity. If RPE_{NUM} and RPE_{VAS} are not different from an objective measure such as HR during tasks of varying intensity, then RPE may represent a low cost method to determine the level of exertion following a FF task. **PURPOSE:** To determine the influence of test (submaximal and maximal) on RPE_{NUM}, RPE_{VAS}, and HR. **METHODS:** Seventeen FF recruit volunteers (20.63 ± 0.5 yrs, 178.0 ± 8.2 cm, 84.89 ± 14.82 kg) from an urban fire department completed a submaximal Step-Test (SUB) and maximal Tower Climb Test (MAX). RPE_{NUM} and RPE_{VAS} were collected following each test and expressed as a percent of maximal possible response. HR was the average HR from each test and expressed as a percent of estimated maximum. A 2x3 repeated measures ANOVA was performed to determine the effect of test (SUB, MAX) on response (RPE_{NUM}, RPE_{VAS}, HR). An alpha of $p<0.05$ determined statistical significance with an adjusted alpha of $p<0.017$ for follow-up tests. **RESULTS:** The 2x3 ANOVA indicated a significant interaction between test type and response ($F(1.463, 64)=41.626, p<0.001$). Follow-up paired *t*-tests revealed that for each response, SUB was significantly ($p<0.001$) lower than MAX. There were non-significant differences between RPE type for the SUB (RPE_{NUM} [28.2 ± 6.3%] vs. RPE_{VAS} [26.9 ± 11.1%]; $p=0.489$) and MAX (RPE_{NUM} [76.8 ± 17.6%] vs. RPE_{VAS} [76.7 ± 15.2%]; $p=0.949$) tests. For the SUB test, HR (69.9 ± 5.3%), was significantly ($p<0.001$) higher than both RPE types, whereas for the MAX test HR (86.0 ± 4.7%) was not different from RPE_{NUM} ($p=0.059$) or RPE_{VAS} ($p=0.036$). **CONCLUSIONS:** The absence of a difference between RPE and HR during MAX suggests that RPE may be a suitable alternative to heart rate monitors to monitor intensity in FF recruits during maximal tasks. The significant differences between RPE_{NUM} and RPE_{VAS} and HR during SUB suggests that FF recruits may underestimate the intensity of a SUB task. Practitioners should use caution when relying solely on subjective feedback from SUB tasks as RPE may underestimate actual intensity.

1029 Board #263 May 29 2:00 PM - 3:30 PM

Effect Of Uncompensable Heat From The Wlff Helmet

Charles L. Dumke, FACSM, Tyler Stenersen. University of Montana, Missoula, MT.
Email: charles.dumke@umontana.edu
(No relevant relationships reported)

Despite upwards of 40-50% of heat lost through the head during exercise, little regard has been given to the role of the wildland firefighter (WLFF) helmet in uncompensable heat stress. **PURPOSE:** To investigate factors of heat stress with and without a standard issue WLFF helmet. **METHODS:** Eleven male subjects (age = 25.2±4.9 yrs) were recruited with a $VO_{2max} > 40$ ml·kg⁻¹·min⁻¹ and ≤ 65 ml·kg⁻¹·min⁻¹ ($VO_{2max} = 54.2 \pm 5.5$ ml·kg⁻¹·min⁻¹). Subjects were required to finish a 90-minute exercise protocol in a heat chamber (35°C and 30% RH), with a standard WLFF para-aramid shirt and pants, cotton t-shirt, and either with or without a WLFF helmet. A randomized crossover design was implemented, with a minimum two week washout period. Skin blood flow to the head and neck (SBFh; SBFn), head heat (HH), T_{sk}, skin temperature on chest and neck (T_{skc}; T_{skn}), HR, PSI, RPE, perceived head heat (PHH) and sweat rate were recorded during trials. A 2x3 ANOVA was used to analyze SBF, and 2x4 ANOVA was used to analyze HH, CT, ST, HR, PSI, RPE, and PHH. One-way ANOVA was used to analyze sweat rate. **RESULTS:** Nine of the 11 subjects were able to finish the 90 minute exercise trial. The HH, SBFh, and PHH (36.41±0.76°C w/helmet v. 35.22±0.98°C w/out helmet; 211.9±86.8 AU w/helmet v. 185.5±73.3 w/out helmet; 10.1±3.2 AU w/helmet v. 8.5±2.6 w/out helmet; respectively) were all significant ($p<0.05$) with a main effect between trials. HR, PSI, T_{sk}, and T_{skc} demonstrated main effects of time ($p<0.05$), but were not different between trials. Sweat rate was not significant among trials (2.09±0.44 L·h⁻¹ w/helmet vs. 1.85±0.44 L·h⁻¹ w/out helmet). **CONCLUSION:** These data (HH, SBFh, and PHH) suggest that the current WLFF helmet causes heat accumulation and resultant redirection of blood flow to the head. While some physiological factors (T_{skc}, HR, T_{skn}, PSI, and sweat rate) did not reach significance between trials; trends existed for PSI ($p=0.09$) and RPE ($p=0.09$). The design of the WLFF helmet lacks ventilation, which from these data, may result in metabolic alterations, and perceived discomfort.

Th Effects Exercise Within Personal Protective Equipment Microclimate On Mental Processing On Different Age Populations
 Morgan D'Ganigian, Cory Coehoorn, Lynneth Stuart-Hill.
University of Victoria, Victoria, BC, Canada.
 (No relevant relationships reported)

PURPOSE: The purpose of this study was to determine the effects of exercise within personal protective equipment microclimate leading to rapid head acquisition on mental processing and decision making in different age populations. **METHODS:** The study was factorial in design and included 15 male participants with an age range from 19-54 who were divided into 2 groups: 30 years old and above group (+30) (n=8), and 29 years old and below group (-29) (n=7). Each group preformed a Go/No-Go test while wearing a Muse headband to obtain P300 ERPs, prior to and post exercise in firefighting turnout gear (PPE) and t-shirts and shorts while wearing a backpack matched in mass to the gear worn in PPE (CON). Subjects completed a graded exercise test until core temperature had rose 39.5 °C, or voluntary max had been achieved. The muse data was collected/analyzed by Peer-Analytics and later tested within Excel by a 2 tailed T-test between: 30+ and -29, and CON and PPE conditions. **RESULTS:** There was no significant differences between the 30+ and -29 P300 ERPs or within each groups CON/PPE conditions. However, both groups made significantly more errors (p<0.05) post-PPE than pre-PPE (+30: $\mu_{post} = 18.375$, $\mu_{pre} = 5.625$ -29: $\mu_{post} = 25.143$, $\mu_{pre} = 10.714$) while only the 30+ showed significant difference between post CON/PPE trails ($\mu_{PPE} = 18.375$, $\mu_{CON} = 12.5$). There was no difference between -23 and +30 when comparing post-PPE errors. **CONCLUSION:** Exercising within a personal protective equipment microclimate will negatively affect executive function of decision making regardless of age.

Commercial Footwear with Lateral Torsional Stiffness that May Reduce Injury Risk in Army Basic Trainees
 Jesse Hall¹, Erin M. Miller², Donald L. Goss². ¹University of New England, Biddeford, ME. ²Baylor University-Keller Army Community Hospital Division I Sports Physical Therapy Fellowship, West Point, NY.
 (No relevant relationships reported)

Musculoskeletal injuries place a burden on the U.S. Military with estimates that 25% of men and 50% of women experience an injury in Army Basic Training. In 2016, 18% of Cadet basic trainees at the U.S. Military Academy (USMA) sustained a lower-extremity (LE) injury. In that sample, Cadets wearing shoes with mild to moderate lateral torsional stiffness (1.30 - 2.29 Newton [N] meters[m]) were 49% less likely to incur any type of LE injury and 52% less likely to incur an overuse LE injury than Cadets wearing shoes with minimal (<.0130 Nm) or extreme (>.0230 Nm) lateral torsional stiffness. **PURPOSE:** To identify athletic footwear, commercially available at West Point, NY, with mild to moderate lateral torsional stiffness characteristics. **METHODS:** Twenty (10 shoes men's size 10, 10 shoes women's size 8) new shoes of varying brands were included in this analysis. The Shoe Stiffness in Torsion Measurements device and methods of data collection described by Zifchock, were used to quantify lateral torsional stiffness. Each shoe was measured twice by a single rater and averaged for the overall analysis. Rater reliability analyses suggest the SySTM device is useful for repeatable measurements of lateral torsional stiffness. **RESULTS:** Six out of 20 shoes (2 men's, 4 women's) demonstrated mild to moderate lateral torsional stiffness to include; Men's New Balance Minimus MT10GG, and Nike Flex 2017 RN; Women's Sketchers Go Run 3, Asics Gel-Fit Sana 3, Nike Free TR 7 Selfie, and Nike Flex Trainer 7. Fourteen out of 20 shoes (8 men's, 6 women's) did not demonstrate mild to moderate lateral torsional stiffness. Of those 14 shoes, 13 demonstrated extreme lateral torsional stiffness; Men's Nike Lunar Fingertap TR, Nike Retaliation TR, Nike Air Zoom Pegasus 34, Asics FuseX Rush, Asics Gel-Contend 4, Brooks Adrenaline GTS 18, and New Balance Trufuse 860v7; Women's Under Armour Micro G Assert 7; Asics RoadHawk FF, Asics GT 1000-6, Brooks Ghost 10, Adidas Cosmic 2, and New Balance W940GP3. One demonstrated minimal lateral torsional stiffness; Women's Asics Metrolyte Gem. **CONCLUSION:** We identified 6 shoes commercially available at West Point, NY, with mild to moderate lateral torsional stiffness. These shoe recommendations can inform Cadet basic trainees on footwear that may be protective of LE injury during USMA Army Basic Combat Training.

 (No relevant relationships reported)

The last major investigations of body composition in Basic Combat Training (BCT) were in 1989 and 1993, before training was integrated for men and women. The data demonstrated that, with BCT, most individuals gained lean mass and the fattest individuals lost the greatest amount of fat mass. Current Army accession standards are derived from the changes observed during BCT for this earlier generation of recruits. **PURPOSE:** To assess changes in body composition in current-day Army recruits. **METHODS:** Trainees (n=109 women, W, and 254 men, M), aged 17-38, body mass index 24.0±2.7 kg·m⁻² (W, mean±SD) and 25.0±3.5 kg·m⁻² (M), were assessed for body composition (DXA, Prodigy, GE Lunar) in the first week of BCT and during the final week (wk 8). Repeated measures ANOVA were used to assess changes in body mass (BM), body fat (%BF), and lean mass (LM). **RESULTS:** Average BM at entry was 62.9±8.5 kg (W), 77.7±12.2 kg (M), with changes by wk 8 of 0.3±3.1 kg (W) (p=0.29) and 1.2±4.5 kg (M)(p<0.01). Women started with 31.8%±5.3% BF and lost 3.8%±2.2%; men began with 22.4%±6.2% BF and lost 3.3%±2.9% (p<0.01 for both). Women began BCT with 41.5±5.7 kg LM and gained 2.5±1.7 kg; men began with 58.2±7.0 kg LM and gained 1.7±2.1 kg (p<0.01 for both). **CONCLUSIONS:** Compared to a national sample (NHANES), Army recruits are leaner than the US population, especially female recruits. During BCT, further gain in LM and loss of fat, especially in women, were masked in small or nonsignificant changes in BM. These pilot data provide up-to-date descriptions of the entry body composition of Army recruits and the magnitude of change that occurs with BCT; further analyses of the larger cohort including musculoskeletal injury, fitness testing, and long term service outcomes will help validate and redefine Army entry standards. *The views expressed in this abstract are those of the authors and do not reflect the official policy of the Department of Army.*

Relationship Of Sex And Physical Activity On Vertical Jump Power Changes In U.s. Army Trainees
 Peter N. Frykman, Kathryn M. Taylor, Barry A. Spiering, Marilyn A. Sharp, Brittany R. Hotaling, Julie M. Hughes, Stephen A. Foulis. *USARIEM, Natick, MA.*
 Email: peter.n.frykman.civ@mail.mil
 (No relevant relationships reported)

One goal of Basic Combat Training (BCT) is to improve the general fitness of recruits to successfully meet the demands of military activities. Previous studies have focused on the aerobic fitness responses to BCT. In contrast few investigations have examined the changes in whole body power production following BCT and if these changes may be modified by various pre-BCT factors. More specifically, do all recruits show similar training responses in terms of muscular power production as measured by vertical jump (VJ) testing? **PURPOSE:** To determine the relationship of sex and physical activity history on changes in VJ power output following BCT. **METHODS:** Four hundred fourteen recruits (298 men; 116 women; (mean ± SD) age: 21 ± 3 y; height: 172 ± 9 cm; body mass: 73.0 ± 13.4 kg) performed maximal VJ testing before and after 8 weeks of U.S. Army BCT. Body mass and VJ height were used to estimate VJ peak power using the Harman equation. Recruits filled out a survey on their prior physical activity during the 2 months prior to entering BCT. Logistic regression was used to calculate odds ratios showing whether sex or physical activity prior to BCT is predictive of changes in a recruit's VJ power output. **RESULTS:** Females were 2.1 times more likely to show an increase in VJ power than males (p=0.01). Recruits that performed running training 3-4 times per week were 1.8 times more likely to improve their VJ power than recruits that only ran 0-2 times per week (p=0.01). Recruits that had an average running mile time from 7:00-7:59 (min:sec) were 1.6 times more likely to generate more VJ power than those running at a sub 7:00 mile time (p=0.03). **CONCLUSION:** Recruits showed differential changes in VJ performance following BCT, depending on sex, prior running training experience, and average 1-mile running time. **DISCLAIMER:** The views expressed in this abstract are those of the authors and do not reflect the official policy of the Department of Army, Department of Defense, or the U.S. Government. Effects of U.S. Army Basic Combat Training on Vertical Jump Ability in Men and WomenBarry A. Spiering, Peter N. Frykman, Marilyn A. Sharp, Brittany R. Hotaling, Kathryn M. Taylor, Julie M. Hughes, Stephen A. Foulis. *U.S. Army Research Institute of Environmental Medicine, Natick, MA.*

Email: barry.a.spiering.ctr@mail.mil

(No relevant relationships reported)

U.S. Army basic combat training (BCT) is designed to improve the general fitness of recruits. However, little scientific data exists to describe the effects of BCT on muscular power capabilities. Existing data indicates BCT has little or even a net negative effect on vertical jump (VJ) performance. This finding is concerning given the positive relationship between muscular power capabilities and military occupational task performance. **PURPOSE:** To describe the effects of BCT on VJ performance in men and women. **METHODS:** Four hundred fourteen recruits (298 men; 116 women; mean \pm SD age: 21 \pm 3 y; height: 172 \pm 9 cm; mass: 73.0 \pm 13.4 kg) performed maximal VJ testing before and after 10 weeks of BCT. Body mass and VJ height were used to estimate VJ peak power using the Harman equation. Comparisons were made using a sex by time repeated-measures ANOVA and Fisher LSD post hoc tests. **RESULTS:** A significant ($p < 0.05$) sex by time interaction existed for body mass, VJ height, and VJ peak power (Table 1). Men decreased body mass and VJ ability, while women maintained body mass and slightly improved VJ ability.

Table 1. Effects of basic combat training (BCT) on body mass, vertical jump (VJ) height, and VJ peak power in men and women

| | | Pre-BCT | Post-BCT |
|--------------------------------|-------|-----------------|-----------------|
| Body Mass (kg) [^] | Men | 77.3 \pm 12.7 | 75.9 \pm 9.9* |
| | Women | 62.2 \pm 8.0 | 62.7 \pm 7.2 |
| VJ Height (cm) [^] | Men | 51 \pm 9 | 50 \pm 9* |
| | Women | 35 \pm 7 | 36 \pm 6* |
| VJ Peak Power (W) [^] | Men | 7761 \pm 652 | 7643 \pm 618* |
| | Women | 6221 \pm 491 | 6299 \pm 472* |

Values = mean \pm SD; [^] = significant sex by time interaction; * = significantly different than corresponding pre-BCT value.

CONCLUSIONS: Men and women demonstrated differential responses to BCT; however, the changes were extremely small, indicating that BCT is not an effective stimulus to improve VJ performance.

(No relevant relationships reported)

The military continues to evaluate body composition as a consideration for service. However, limited data are available comparing active duty (AD) and civilian (CIV) individuals. **PURPOSE:** To evaluate body composition of fat mass (FM), fat-free mass (FFM) and percent body fat (%fat) in AD and CIV men and women. **METHODS:** AD men (n = 213, 32.1 \pm 7.5 yrs, 177.6 \pm 6.9 cm, 87.6 \pm 12.7 kg) and women (n = 115, 32.2 \pm 9.3 yrs, 163.1 \pm 8.0 cm, 70.4 \pm 11.3 kg) and CIV men (n = 64, 46.1 \pm 7.5 yrs, 177.7 \pm 7.6 cm, 89.6 \pm 15.0 kg) and women (n = 46, 40.0 \pm 9.6 yrs, 163.4 \pm 6.4 cm, 75.9 \pm 15.9 kg) were stratified by exercise level as sedentary (SED), low active (LACT), active (ACT), and Very active (VACT) based on standard parameters. Each participant volunteered to be measured by whole body plethysmography. **RESULTS:** A sex \times duty \times activity (2 \times 2 \times 4) MANOVA produced nonsignificant interaction effects ($p > 0.32$) for %fat, FM, and FFM. Men were significantly lower in %fat (23.5 \pm 8.3%) and higher in FFM (66.6 \pm 8.3 kg) than women (33.6 \pm 8.5% and 47.3 \pm 6.0 kg, respectively), with no significant difference in FM (21.6 \pm 10.2 vs 25.1 \pm 10.2 kg). AD was significantly lower in %fat (26.5 \pm 9.3%) and FM (21.8 \pm 9.3 kg) and higher in FFM (59.7 \pm 11.9 kg) than CIV (31.2 \pm 10.4%, 26.0 \pm 11.5 kg, and 55.6 \pm 12.0 kg, respectively). More active individuals had significantly lower %fat (24.1 \pm 9.0%) and FM (19.8 \pm 8.9 kg) with no significant difference in FFM (61.2 \pm 12.1 kg) than sedentary individuals (33.0 \pm 8.2%, 27.7 \pm 9.9 kg, and 54.9 \pm 10.9 kg, respectively). Age was significantly correlated with %fat ($r = 0.20$) and FM ($r = 0.18$) but accounted

for no more than 4% of the common variable between them. Age was also negatively correlated with activity level in AD ($r = -0.23$, $p < 0.001$) but not in CIV ($r = -0.03$, $p = 0.78$). A greater portion of AD were ACT (51%) or VACT (16%) compared to CIV (30% and 11%, respectively). When sex was partitioned out, body mass index (BMI) had a slightly stronger correlation with %fat and FM in CIV ($r = 0.78$ and 0.91, respectively) than in AD ($r = 0.70$ and 0.82, respectively). **CONCLUSION:** Air Force AD personnel have better body composition profiles than CIV personnel but both appear to gain FM and %fat over time based on cross-section analysis. Further research should investigate the ability of other indices to longitudinally track body composition changes in military personnel.

Backpack Hip Strap Use on Oxygen Consumption, Blood Pressure and Muscle Oxygen Saturation While WalkingPeter A. Hosick¹, Ryan S. Delgado², Angelica Del Vecchio¹, William Sullivan¹, Evan L. Matthews¹. ¹*Montclair State University, Montclair, NJ.* ²*Iowa State University, Ames, IA.*

Email: hosickp@mail.montclair.edu

(No relevant relationships reported)

Previous work has shown that energy expenditure increases while carrying a loaded backpack. However, few investigations have focused on the impact of utilizing a hip strap. **PURPOSE:** To determine if using a backpack hip strap (HS) has any physiological effects while walking. **METHODS:** Thirteen subjects (23 \pm 4.8 yrs; 5 females, 8 males) walked for 30 mins on a treadmill with a backpack containing 30% of the subject's bodyweight at a 3% grade and speed eliciting 40-50% of their heart rate reserve. Two trials were performed: without a HS (UnST) and with HS (ST). Heart rate (HR), oxygen consumption ($\dot{V}O_2$), systolic blood pressure (SBP), and oxygen saturation of the quadriceps ($Q\ SmO_2$) and calf ($C\ SmO_2$) were measured throughout each trial. Five minute averages were calculated for HR, $\dot{V}O_2$, $Q\ SmO_2$ and $C\ SmO_2$ at baseline (BL), mins 0-5, 6-10, 11-15, 16-20, 21-25, and 26-30. SBP was analyzed as a change score from baseline. A repeated measures ANOVA was used to evaluate the differences between trials at each time point. **RESULTS:** HR at mins 0-5 (UnST: 121 \pm 4 bpm; ST: 120 \pm 3 bpm) was elevated ($p < 0.001$) compared to BL (UnST: 81 \pm 4 bpm; ST: 80 \pm 4 bpm) and remained elevated from BL for the remainder of the trial. All other HR measures were similar with no difference between trials ($p = 0.912$). $\dot{V}O_2$ at mins 0-5 (UnST: 1.6 \pm 0.1 L/min; ST: 1.5 \pm 0.1 L/min) was elevated ($p < 0.001$) compared to BL (UnST: 0.38 \pm 0.02 L/min; ST: 0.38 \pm 0.03 L/min), but was similar to all other time points with no difference between trials ($p = 0.317$). The change in SBP at mins 0-5 (UnST: 26 \pm 8 mmHg; ST: 31 \pm 6 mmHg) was similar to all other time points ($p = 0.115$) and did not differ between trials ($p = 0.224$). $Q\ SmO_2$ at mins 11-15 (UnST: 87 \pm 3 %; ST: 84 \pm 4 %) was higher compared to BL (UnST: 78 \pm 3 %; ST: 79 \pm 4 %; $p = 0.040$) and remained elevated for the remainder of the trial with no difference between trials ($p = 0.515$). $C\ SmO_2$ at mins 0-5 (UnST: 55 \pm 6 %; ST: 47 \pm 7 %; $p < 0.001$) was lower compared to BL (UnST: 72 \pm 4 %; ST: 74 \pm 4 %; $p < 0.001$) and remained lower until mins 11-15 (UnST: 69 \pm 6 %; ST: 66 \pm 6 %; $p = 0.776$). No further changes occurred throughout the rest of the trial ($p < 0.040$). $C\ SmO_2$ did not differ at any time between the trials ($p = 0.263$). **CONCLUSIONS:** This preliminary data suggests a backpack HS has little physiological effect during 30 minutes of walking with a load of 30% the wearers body weight.

(No relevant relationships reported)

A negative energy balance has implications for the health and performance of military personnel, with women possibly more susceptible to metabolic perturbations associated with reduced energy availability than men. Women are increasingly employed in more physically arduous military roles, and therefore, there is a requirement to better understand the energy status of women operating in environments of high energy expenditures. **PURPOSE:** To investigate the sex differences in energy balance during 44 weeks (three terms of 14 weeks) of arduous military training. **METHODS:** Twenty Officer Cadets (men: n = 8; mean \pm SD, age 26 \pm 3 y, height 1.84 \pm 0.07 m, body mass 85.0 \pm 7.7 kg; women: n = 12; age 25 \pm 3 y, height 1.70 \pm 0.04 m, body mass 65.3 \pm 5.6 kg) participated. Dietary intake was measured during each term by researcher-lead weighed food during scheduled mealtimes, and food diaries and wrapper collection during non-scheduled mealtimes, over three 10 d periods (one per term). Total energy

expenditure (TEE) was measured over each 10 d sampling period using doubly labelled water. Body composition was measured by DXA at the start of training and at the end of each term. **RESULTS:** Average daily energy intake (3160 ± 568 vs 2609 ± 568 kcal·d⁻¹) and TEE (4552 ± 534 vs 3365 ± 416 kcal·d⁻¹) were higher for men than women, respectively (both $P \leq 0.005$). Both sexes demonstrated negative average daily energy balance, with a greater deficit in men compared to women (-1333 ± 965 vs -756 ± 826 kcal·d⁻¹, respectively, $P = 0.016$). There was no difference in average daily carbohydrate (4.3 ± 1.1 vs 4.7 ± 1.5 g·kg⁻¹·d⁻¹), protein (1.7 ± 0.4 vs 1.6 ± 0.4 g·kg⁻¹·d⁻¹) or fat intake (1.5 ± 0.4 vs 1.7 ± 0.5 g·kg⁻¹·d⁻¹) between men and women, respectively ($P \geq 0.167$). Lean and fat mass did not differ in either sex over time (all $P \geq 0.336$). **CONCLUSION:** The observed greater energy deficit in men is predominantly due to the higher TEE, and should be considered when designing feeding strategies. Despite the acute demonstration of negative energy balance in both men and women, there were no differences in lean or fat mass in either sex at our measured timepoints. This finding may reflect an underestimation of energy intake, or the limited frequency of DXA measurements. Future work should explore how dietary intake may be optimised to achieve energy balance in arduous military training environments.

1038 Board #272 May 29 2:00 PM - 3:30 PM
Physical Fitness Decrements In The Postpartum Us Army Servicewoman

David DeGroot, FACSM¹, Kelly Langan¹, Collin Sittler¹, Sean Penberthy¹, Keith Huret², Alan Gehrich¹. ¹*Tripler Army Medical Center, Honolulu, HI.* ²*Army Public Health Center, Aberdeen Proving Ground, MD.*

Email: dr.david.degroot@gmail.com

(No relevant relationships reported)

United States military service members are required to maintain a requisite level of physical fitness. Women in the US Army are exempt from fitness standards for the first 6 months postpartum. While many women successfully meet the minimum standards 6 months postpartum, the time course necessary to re-attain pre-pregnancy fitness levels is unknown. **Purpose:** To determine the time course necessary to re-attain pre-pregnancy physical fitness, as determined via the Army Physical Fitness Test (APFT), in a cohort of postpartum US Army women. **Methods:** 236 primigravid active duty Army women who delivered at Tripler Army Medical Center between 1 Jan 2011 and 31 March 2017 were eligible for inclusion. APFT data (push-up and sit-up repetitions, 2 mile run time) were obtained from the Digital Training Management System; the last test prior to and all available tests postpartum were used for analysis. Data were analyzed with repeated measures ANOVA and Fisher's exact test. **Results:** The number of postpartum APFTs available for analysis ranged from 1 to 6 per individual. Follow-up time ranged from 4.5 to 72 months postpartum. During the last pre-pregnancy APFT push-up, sit-up and 2 mile run scores were 39.2 ± 11.6 reps, 68.2 ± 11.5 reps and 17.1 ± 1.8 min, respectively. 6 months post-partum, push-up and sit-up scores were lower and run time was significantly longer (34.1 ± 11.1 , 61.5 ± 12.5 and 18.0 ± 1.8 , respectively; $p < 0.01$ for all). While scores gradually progressed towards pre-pregnancy levels, pre-pregnancy fitness was not re-attained during the study period. By 30 months postpartum push-up reps, sit-up reps and run times were 36.7 ± 12.4 , 66.6 ± 12.8 and 17.7 ± 1.7 , respectively, $p < 0.01$ vs pre-pregnancy for all. The failure rate for the APFT was 3.8% pre-pregnancy, 14.2% at the first postpartum APFT and ranged from 7.7-9.9% for all time points thereafter. **Conclusions:** These data indicate that the postpartum US Army servicewoman fails to return to pre-pregnancy fitness levels, when followed for up to 72 months. While a majority of the women meet minimum fitness standards, ~8-10% did not. The causal factors underlying these results are unknown. However, as ~25% of women had higher scores at the first postpartum APFT vs pre-pregnancy, it is possible to re-attain pre-pregnancy fitness levels.

Equation to Estimate Total Energy Expenditure in Military Populations Using a Wrist-Worn Physical Activity Monitor

Sam D. Blacker¹, Andrew G. Siddall¹, Sarah Needham-Beck¹, Steven D. Powell¹, Victoria C. Edwards¹, Sarah S. Kefyalew², Priya A. Singh², Elise R. Orford², Michelle C. Venables², Sarah Jackson³, Julie P. Greeves³, Stephen D. Myers¹. ¹*University of Chichester, Chichester, United Kingdom.* ²*Medical Research Council, Cambridge, United Kingdom.* ³*British Army, Andover, United Kingdom.*

Email: s.blacker@chi.ac.uk

(No relevant relationships reported)

PURPOSE: The gold-standard method for measuring free-living Total Energy Expenditure (TEE) is the Doubly Labelled Water (DLW) technique, but it is expensive and can only quantify TEE over 7-10 days. Wrist-worn physical activity monitors (PAM) are cheaper and can be used to estimate TEE over any time periods. Equations have been developed to estimate TEE from wrist-worn PAM in civilian but not in

military populations, where TEE and activity type differ markedly. The aim of this study was to develop an equation to estimate TEE from a wrist-worn PAM in a military population.

METHODS: Twenty-six (14 male, 12 female) Officer Cadets (OC, mean \pm SD: age 23 ± 2 years, height 1.73 ± 0.09 m, body mass 77.2 ± 9.4 kg) wore a PAM (GENEActiv, Cambridge, UK) continuously on the dominant wrist over three 10-day blocks of military training on base and field exercises. Immediately prior to each 10-day block, OCs consumed a bolus of DLW and provided daily urine samples, which were analysed by mass spectrometry to determine TEE_{DLW}. The PAM recorded continuously at 50 Hz throughout each 10-day block and the manufacturer's software was used to estimate TEE for each OC using an equation developed in a civilian population (TEE_{CIV}). Each OC in each 10-day block was treated as a separate 'observation' (n=53). A random sample of 30 observations were entered into a linear regression to produce a model to estimate TEE for military populations (TEE_{MIL}). The TEE_{MIL} equation was applied to the remaining 23 observations to quantify the mean bias \pm 95% Limits of Agreement (LoA) between TEE_{DLW} and TEE_{CIV} or TEE_{MIL}. **RESULTS:** The TEE_{MIL} equation [TEE_{MIL} = $563.116 + (0.886 \times \text{TEE}_{\text{CIV}})$] exhibited a strong correlation ($r=0.826$) and a Standard Error of the Estimate of 475 kcal·day⁻¹. Applying the equation reduced mean bias \pm 95% LoA against TEE_{DLW} from -194 ± 1055 kcal·day⁻¹ for TEE_{CIV} to 0.79 ± 996 kcal·day⁻¹ for TEE_{MIL}. **CONCLUSIONS:** The TEEMIL equation developed in this study improves the estimation of TEEDLW from a PAM in military populations compared to an existing TEECIV equation. Future research should explore data processing techniques to identify different physical activity types from wrist-worn PAM in military settings to further improve TEE estimation and validate these equations in different military cohorts.

Differences Between Responders and Non-responders for Endurance Performance During Combined Training in Military Operation

Kai Pihlainen¹, Matti Santtila², Keijo Häkkinen³, Heikki Kyröläinen, FACSM¹. ¹*The Finnish Defence Forces, Helsinki, Finland.* ²*National Defence University, Helsinki, Finland.* ³*University of Jyväskylä, Jyväskylä, Finland.* (Sponsor: Heikki Kyröläinen, FACSM)

Email: kai.pihlainen@mil.fi

(No relevant relationships reported)

Military operations lasting several months may cause negative changes in aerobic fitness of deployed soldiers. Despite the well-known benefits of physical training on soldier readiness, intervention studies focusing on endurance performance during military operations are lacking.

PURPOSE: To investigate inter-individual variation in training adaptations of endurance performance during deployment.

METHODS: 91 male soldiers (30 \pm 8 yr) volunteered for the baseline tests including assessments of body composition, physical performance (3000-m run, max. isometric leg and arm extension, 1-min push-ups and sit-ups, and standing long jump), as well as a military simulation test (MST). Training was monitored using diaries. After the 19-week follow-up, the available data was divided into two groups based on the change in endurance performance: Responders (n=25) decreased their 3000-m run time while non-responders (n=24) maintained or increased their 3000-m run time.

RESULTS: The responders initially had higher fat mass (12.8 ± 3.6 vs. 9.6 ± 5.7 kg, $p < 0.001$), lower muscle mass (38.0 ± 3.9 vs. 40.3 ± 4.1 kg, $p = 0.046$), poorer standing long jump (227 ± 16 vs. 242 ± 27 cm, $p = 0.016$) and MST performance (156 ± 23 vs. 143 ± 24 s, $p = 0.028$) compared to non-responders. Both groups performed a similar volume of endurance training during the follow-up (1.7 ± 0.8 vs. 1.9 ± 2.8 times/week, $p = 0.22$). During the operation, the responders maintained their training frequency at the level of pre-deployment ($\Delta 0.1 \pm 1.1$ vs. -1.2 ± 1.9 times/week, $p = 0.012$). In addition, they performed lower body strength training with lower average volume load (14354 ± 6076 vs. 19489 ± 6202 kg/week, $p = 0.010$). However, their fat mass decreased (-7.6 ± 11.7 vs. 14.2 ± 20.4 %, $p < 0.001$) and MST time improved (-13.6 ± 6.8 vs. -7.5 ± 6.5 %, $p = 0.006$) more when compared to the non-responders.

CONCLUSIONS: Soldiers who initially demonstrated lower physical fitness and higher fat mass improved their physical performance more than their non-responder counterparts. Positive training responses in non-responders might have been achieved using higher volume and / or intensity of endurance training. In addition, it is obvious that more individualized strength and endurance training should be emphasized during prolonged military operations.

The Effect of Body Mass on Physical Performance in Naval Special Warfare Operators
 Dallas Wood¹, David Swain, FACSM². ¹Naval Special Warfare, Virginia Beach, VA. ²Old Dominion University, Norfolk, VA.
 (No relevant relationships reported)

The Effect of Body Mass on Physical Performance in Naval Special Warfare Operators

Dallas E. Wood, David P. Swain, FACSM.
 Naval Special Warfare, Virginia Beach, VA, Old Dominion University, Norfolk, VA
 US Naval Special Operations Forces have performed some of the US Military's most rigorous missions. The Human Performance Program (HPP) developed a physical performance testing battery to assess and monitor physical performance. Testing bias relative to body mass has been noted in past literature, including military physical fitness tests. **PURPOSE:** This retrospective study looked to determine if there is body mass bias in the HPP performance assessment and if an optimum body mass for each performance test could be determined. **METHODS:** Data from 333 subjects (age: 28.4 ± 5.0 yr; height: 178.4 ± 6.2 cm; mass: 86.0 ± 9.2 kg) were analyzed to compare body mass to performance on the eight performance tests: standing long jump, Pro-Agility test, weighted pull-up, body weight bench press, 1-RM deadlift, 274-m shuttle run, 4.83-km run, and 800-m swim. Linear regression analysis was used to analyze the relationship of body mass to performance; a 2nd degree polynomial was utilized to determine best-fit curves for each of the physical performance tests; ANOVA was utilized to examine differences in performance between body mass quartiles. **RESULTS:** Significantly better performance for lighter subjects was found in the Pro-Agility test, weighted pull-up, body weight bench press, 274-m shuttle run, and 4.83-km run. Heavier subjects performed better in the 1-RM deadlift. Second-degree polynomial regression revealed optimum body mass for the Pro-Agility test, 274-m shuttle run, and 4.83-km run to be somewhat heavier than the lowest body mass. **CONCLUSION:** These findings could help professionals better assess and train operators of varying body size.

The views and opinions expressed are the authors' and do not reflect those of Naval Special Warfare Command, the US Navy or the Department of Defense.

Minimalist Style Military Boot Improves Running Economy Under Load In Trained Males
 Eric K. O'Neal¹, Montia T. Pace¹, Jonathan C. Swain¹, Ryan T. Albino¹, James M. Green, FACSM¹, Lauren G. Killen¹, Jeffrey D. Simpson², Harish Chander³. ¹University of North Alabama, Florence, AL. ²University of West Florida, Pensacola, FL. ³Mississippi State University, Starkville, MS.
 Email: eoneal1@una.edu
 (No relevant relationships reported)

PURPOSE: Minimalist style boots (MIN) may improve running economy for soldiers under load versus the traditional boot type (TRD). However, running economy (RE) under load with MIN has not been examined. **METHODS:** In this study, male participants (n = 14) completed a VO₂ peak test (46.6 ± 7.3 ml/kg/min) under load (16 kg) while wearing their normal athletic shoes. Treadmill speed for RE tests was determined by the slowest pace in which participants completed a full stage with a running gait pattern during the VO₂ peak test. Load was applied using a ~7.5 kg weighted compression garment to simulate body armor and a ruck sack of ~8.5 kg. During the second trial participants completed two, 5-min running treadmill exercise bouts with the same load arrangement while wearing MIN (~500 g) and TRD (~800 g). RE was evaluated using indirect calorimetry (TrueOne2400, Parvo Medics Inc. Provo, Utah) and calculated by averaging the 60-s average values of minutes 3-4 and 4-5 with confirmation of steady state (difference in VO₂ < 0.1 L/min between minutes). There was a 10-min rest period between running bouts (counter-balanced crossover design). **RESULTS:** Paired sample t-tests indicated a significant difference (p = 0.003) in RE between MIN (2.95 ± 0.28 L/min) and TRD (3.04 ± 0.30). Thirteen participants had lower RE during MIN producing a small-moderate effect size (Cohen's d = 0.32). RER also increased (p < .001) during TRD (0.99 ± 0.07) versus MIN (0.94 ± 0.06). Overall, leg, and breathing RPE (p < 0.05) were all improved during MIN. **CONCLUSIONS:** When moving at minimal running speed under load, MIN provides notable improvement in RE.

- 1043** Board #277 May 29 2:00 PM - 3:30 PM
Effects Of Core Stability Exercise On Subjective Rating Of Low Back Pain In ROTC Cadets
 Tunde Szivak, Kevin Richard, Jamilia Almonte. Merrimack College, North Andover, MA.
 (No relevant relationships reported)

PURPOSE: While previous research has investigated lower extremity injuries and low back pain in Soldiers during basic training, little research has investigated load carriage and low back pain in Reserve Officer Training Corps (ROTC) program participants. Thus the purpose of this study was to investigate the effects of a core stability program on subjective rating of low back pain and overall physical function during load carriage exercise.

METHODS: Subjects (age: 19.75 +/- 1.55 years) included cadets enrolled in the ROTC program at the University of Massachusetts (Amherst) (n=10) who were randomly assigned into a core stability or a non-core stability group. All subjects completed a 1.5 hour ruck march with 35lb load at volitional pace once per week over a 3-week period. At baseline and upon completion of the 3-week intervention period, subjects completed a 3-mile timed ruck march. Immediately prior to each 1.5 hour ruck march session, the core stability group performed a series of core stability exercises. Subjective low back pain score (Visual Analog Scale) was obtained immediately after completion of each ruck march session.

RESULTS: The core stability group showed a significantly lower average low back pain score (mean score = 1.90) over the course of the intervention period compared to the control group (mean score = 3.00). No significant difference (p = 0.49) was found between pre- and post-intervention 3-mile ruck march completion times between groups.

CONCLUSIONS: The core stability program resulted in significant decreases in subjective rating of low back pain associated with load carriage in ROTC participants. Study results suggest that implementing a core stability program in military personnel during basic training or tactical operations involving load carriage may thus provide benefit in preventing low back pain.

- 1044** Board #278 May 29 2:00 PM - 3:30 PM
Factors Impacting Soldier-Athletic Performance of U.S. Service Academy Cadets
 Todd A. Crowder, Dan A. Jaffe, Jennifer K. Hewitt. US Military Academy, West Point, NY.
 Email: Todd.Crowder@Westpoint.edu
 (No relevant relationships reported)

Early identification of factors impacting soldier-athletic performance can assist in designing training programs & selection of key personnel. **PURPOSE:** Investigate factors via selected physical assessment tests {(PAT's); Soldier Performance Index (SPI); Cadet Combine (CC)} which identify overall soldier-athletic performance of U.S. Service Academy cadets (USSAC's). **METHODS:** 66 fit subjects (42 men; 24 women) participated in a 19-hour lecture/lab course over a 2-month period which included 2 embedded PAT's examining combat readiness components of strength, endurance, mobility, power/speed. Specific data analysis & criterion determination was used on the 0-368+ point SPI & 0-137.5 point CC. **RESULTS:** Multiple regression analysis indicated push-ups (PU) & 400 meter run; adjusted R² = 0.83 for CC, while PU, 500 meter row & reps to failure of 220-lb trap bar dead lift (TBDL); adjusted R² = 0.84 for SPI. Correlation between the two PAT's; r = 0.91, adjusted R² = 0.83. Criterion cut points (70% of USSAC's best scores; or top 10 performers) for both SPI & CC revealed a stable metric in identifying higher end physical performance cadets. Descriptive data:

| Group (n) (±SD) | HT in | BM Lbs | 45lb GSq Rep | 65lb BP Reps | 5- Sec Pull-ups Reps | 2MR Secs | 300 MF/RSB Secs | 155lb BP Reps | APFT Pts | SPI Pts | CC Pts | TBDL/BM Ratio |
|------------------------|-----------------|--------------|--------------|--------------|----------------------|-------------|-----------------|-----------------|--------------|--------------|--------------|---------------|
| ALL (66) | 68 (3.8) | 163 (26.5) | 63.7 (27) | 51.6 (34.3) | 7.4 (4.4) | 862.2 (103) | 66.9 (7.7) | 5.6 (7.1) | 276.8 (31.6) | 180.2 (57.8) | 92.9 (24.2) | 1.75 (31) |
| 70% Best >240 SPI (10) | 71.3 (3.1) | 186.9 (19.8) | 82.8 (23) | 104.8 (37.9) | 11.3 (1.6) | 811 (64.6) | 62.3 (3.6) | 17.6 (6.4) | 294.8 (39.8) | 261.5 (15.2) | 116.9 (5.5) | 1.99 (30) |
| Group (n) | HT/BM in/lb | 5-10-5 Secs | SLJ cm | MB Put cm | 5- Sec Pull-ups Reps | Beep levls | 500 M Row Secs | 220lb TBDL Reps | APFT Pts | SPI Pts | CC Pts | TBDL/BM Ratio |
| ALL (66) | Same | 5.1 (41) | 217 (36) | 621.4 (118) | 7.4 (4.4) | 8.4 (1.6) | 110 (13.4) | 9.1 (10.2) | 276.8 (31.6) | 180.2 (57.8) | 92.9 (24.2) | 1.75 (31) |
| 70% Best >87 CC (41) | 70.6/175 2.6/21 | 4.89 (27) | 232 (24) | 691 (90.5) | 10.1 (2.3) | 9.3 (1.3) | 102.4 (7.2) | 14.2 (9.9) | 279.9 (31.2) | 216.5 (33.4) | 109.7 (8.9) | 1.84 (32) |
| >240 SPI (10) | Same | 4.83 (20) | 251 (21) | 771 (92) | 11.3 (1.6) | 9.3 (1.5) | 97.2 (9.7) | 20.8 (9.7) | 294.8 (39.8) | 261.5 (15.2) | 116.9 (5.5) | 1.99 (30) |
| >116 CC (10) | 70.8/174.4 | 4.81 (16) | 246 (22) | 747 (55.5) | 11.6 (1.4) | 9.9 (85) | 97.0 (3.9) | 19.4 (8.7) | 302.9 (31.5) | 253.4 (22.9) | 119.2 (2.96) | 2.08 (36) |

DISCUSSION: Our data indicate that both SPI & CC provide a stable metric in PAT's & the top tier (n=10) are able to provide robust physical ability in the strength, endurance, mobility, power/speed realm. Lower body strength as indicated via reps of 220-lb TBDL & 1-RM TBDL/BM ratio suggests a simple test which is predictive of higher SPI & CC scores respectively. While soldier-athletic performance is key, our robust PAT's were not influenced via BM when separated via gender. **CONCLUSIONS:** For soldier-athletes desiring success on the five combat readiness components, reps of 220-lb TBDL, 400 meter run, 500 meter row, PU and either the SPI or CC are simple, reliable field tests which can assist classify and select personnel for more arduous military applications. An enhanced physical profile should be the goal of any soldier-athlete.

1045 Board #279 May 29 2:00 PM - 3:30 PM Sleep Patterns During Arduous Military Training in Men and Women

Fiona N. Manderson Koivula¹, Sophie L. Wardle¹, Rebecca L. Double¹, Robert M. Gifford², David R. Woods³, Rebecca M. Reynolds³, Sally Handford¹, Jennifer Wright¹, Thomas J. O'Leary¹, Julie P. Greeves¹. ¹Army HQ, Andover, United Kingdom. ²University of Edinburgh, Edinburgh, United Kingdom. ³Leeds Beckett University, Leeds, United Kingdom. Email: Fiona.Koivula928@mod.gov.uk (No relevant relationships reported)

Sleep is a critically important component of health, but is often restricted in a military environment as a stressor in training and in preparation for operations. Following the recent opening of combat roles to women serving in the UK military, quantifying sleep parameters during arduous training, and understanding how men and women respond to disturbed sleep, is necessary for management of health and performance. Sex differences in sleep quantity and efficiency may manifest in responses to training-related stressors, and it is therefore important to quantify these sleep parameters in a basic military setting. **Purpose:** To quantify sleep duration and efficiency in male and female Officer Cadets over 7 days of arduous basic military training. **Methods:** Twenty-six Officer Cadets (mean ± SD; 9 men; age: 25.3 ± 3.2 y, height: 1.83 ± 0.07 m, weight: 84.7 ± 7.2 kg; and 17 women; age: 24.8 ± 2.5 y, height: 1.71 ± 0.04 m, weight: 66.5 ± 5.9 kg) wore wrist-based tri-axial accelerometers (GeneActiv, UK) continuously for 7 days, during the first term of British Army Officer Training at the Royal Military Academy, Sandhurst, UK. Data were processed using commercially-available software (GeneActiv, UK) to derive: time in bed (min); time asleep (min) and sleep efficiency (%). **Results:** Officer Cadets spent an average of 412 ± 140 min (6h 52 min) in bed, and 329 ± 80 min (5h 29 min) asleep, giving a mean sleep efficiency of 83% ± 14%, over 7 days. Compared with men, women spent longer in bed (433 ± 149 (7h 13 min) vs 370 ± 108 min (6h 10 min), respectively, P≤0.01) and longer asleep (341 ± 83 (5h 41 min) vs 304 ± 67 min (5h 4 min), respectively, P≤0.01). There was no difference in sleep efficiency between the sexes (84 ± 13% vs 82 ± 14%, respectively, P=0.30). **Conclusion:** Officer Cadets slept less than the 7-9 hours per night recommended by The National Sleep Foundation. This may have implications for musculoskeletal and immune health during arduous training. Women slept more than men, however it is unclear whether this is due to physiological or behavioural differences between the sexes. The implications of inadequate sleep, and the mechanisms for the reported sex difference, warrant further examination to optimise performance and reduce injury risk in arduous military basic training.

1046 Board #280 May 29 2:00 PM - 3:30 PM Sympathetic Nervous System Response During Close Quarters Combat in Elite Military Men

Andrew E. Jensen, Jason T. Jameson, Karen R. Kelly. Naval Health Research Center, San Diego, CA. (No relevant relationships reported)

Combat is physiologically stressful and associated with alterations and declines in several performance domains vital to the success of ground combat element (GCE) operations. Acutely, the body responds to stress via the "fight-or-flight" system, which alters activity of the autonomic nervous system (ANS) and can be monitored via heart rate variability (HRV). Currently, it is not well understood if ANS plays a role in the shooting performance of GCE operators. **PURPOSE:** To determine if HRV is correlated to shooting performance. **METHODS:** Active duty, elite GCE operators (n = 40) were recruited to participate in a 21-day close quarters combat (CQC) training program. Measures of HRV, marksmanship, and tactical/safety violations (errors) were recorded prior to (anticipation), during (execution), and immediately after (recovery) a similar shooting task on Day 1 and Day 21 of training. **RESULTS:** Heart rate was significantly less at every time point on Day 21 when compared to Day 1 (anticipation: -8.9%, execution: -11.5%, recovery: -8.6%; p < .05). The mean normalized low frequency power (LFnu)—a measure of sympathetic drive—was not different between days (p > .05), but it was significantly lower during the execution phase in comparison to the anticipation (-11.2%) and recovery phases (-12.0%, p < .05). The mean normalized high frequency power (HFnu)—a measure of parasympathetic modulation—was 14.9% higher in Day 21 compared to Day 1 (p < .05). In addition, the HFnu was 17.7% lower in the recovery compared to the execution phase (p < .05). The mean ratio of LF to HF (LF/HF) power was not different between days (p > .05), but it was significantly higher during recovery (35.4%) when compared to the execution phase (p < .05). Pearson product-moment correlation analysis revealed there was also a positive correlation between the LF/HF power ratio during the anticipation phase and the number of errors committed during execution on Day 1 (r = .635, p < .05). **CONCLUSION:** There is a positive correlation between sympathetic drive, during the anticipation phase of CQC training, and error rate at the onset of CQC training. These data suggest that those with a lower sympathetic tone perform better than those with a higher sympathetic tone.

1047 Board #281 May 29 2:00 PM - 3:30 PM Leveraging Machine Learning Techniques to Reveal Relationships between Neuromuscular Traits in Previously Concussed Warfighters

Shawn Eagle¹, Qi Mi¹, Anthony P. Kontos², Shawn D. Flanagan¹, Bradley C. Nindl, FACSM¹, Kim Beals¹, Chris Connaboy¹. ¹University of Pittsburgh, Pittsburgh, PA. ²UPMC Sports Medicine Concussion Program, Pittsburgh, PA. (Sponsor: Bradley C. Nindl, FACSM) Email: seagle@pitt.edu (No relevant relationships reported)

Concussions are common in military personnel and may result in an increased risk of musculoskeletal injury. The underlying mechanisms for this increase risk are unknown and warrant additional research. One plausible explanation may be that neuromotor deficiencies may enhance injury risk following concussion through altered muscular activation or contraction timing. **Purpose:** To compare military personnel with at least one concussion during the past 1 month to 2 years (CONCUSSED) to military branch-, age- and Special Forces group- matched controls (CONTROL) on physiological, musculoskeletal and biomechanical performance. **Methods:** A total of 48 (24 CONCUSSED, 24 CONTROL) male Air Force Special Operators and Naval Special Warfare Operators aged 19 to 34 years participated in the study. Participants provided self-reported demographics and injury history and the following assessments: 1) physiological- body composition, anaerobic power and capacity, aerobic capacity and lactate threshold; 2) musculoskeletal- isokinetic strength testing of the lower extremity, including time to peak torque for each muscle group, and balance using the Neurocom system; and 3) biomechanical- single-leg jump and landing task, including landing kinematics of the hip, knee and ankle. A C5.0 decision tree algorithm and one-way ANOVA were used to compare the two groups on the physiological, musculoskeletal, and biomechanical outcomes. **Results:** No differences were demonstrated using one-way ANOVA. The C5.0 algorithm revealed CONCUSSED demonstrated quicker time to peak knee flexion angle during the single-leg landing task (<=0.170 secs; CONCUSSED: n=22 vs. CONTROL: n=14), longer time to peak torque in knee extension isokinetic strength testing (>500 msec; CONCUSSED: n=18 vs. CONTROL: n=4) and larger knee flexion angle at initial contact (>7.7°; CONCUSSED: n=18 vs. CONTROL: n=2). **Conclusion:** The findings supported the hypothesis that CONCUSSED military personnel would demonstrate altered neuromuscular control in landing strategies and muscular activation. Future research should assess prospectively potential neuromuscular changes following concussion and determine if these changes increase the risk of subsequent musculoskeletal injuries and concussion.

1048 Board #282 May 29 2:00 PM - 3:30 PM Effects Of Exercise And Sanqi Ginseng Interventions On Mtss Of Swat Trainees

Yuxin Liu¹, Weimo Zhu, FACSM². ¹Nanjing Forest Police College, Nanjing, China. ²University of Illinois at Urbana-Champaign, Urbana, IL. (Sponsor: Weimo Zhu, FACSM)
Email: 467885289@qq.com
(No relevant relationships reported)

PURPOSE: To investigate the therapy effects of exercise and Sanqi Ginseng, a Chinese herbs, and their combination on medial tibial stress syndrome (MTSS) of the *special weapons and tactics* (SWAT) trainees.

METHODS: 162 SWAT trainees with MTSS were divided randomly into 3 groups: exercise (E), Sanqi ginseng tablets group (S), and their combination (ES). Participants in E-group maintained the original training, including jumping and all of other training movements, for four months while S-group used oral Sanqi ginseng tablets, (1.2 g for each time, 3 times per day to control the pain at a mid-level for 4 months) without training, and finally, ES-group took both exercise and Sanqi tablets at the same time. The MTSS healing rates measured (numerical ratings scale (NRS) = 0 was seemed as healing) were compared 4 months later. The tibia bone mineral density and average lumbar T score, left and right leg muscle mass, subjective pain NRS were tested also before and after the intervention.

RESULTS: The healing rates of E, S and ES groups were 63.0, 88.9, 96.3%, respectively; the average NRS in ES (mean =1.04 & SD =0.3) group after the intervention was lower than E (mean =3.5 & SD =0.46, $p < 0.05$, $\eta_p^2=0.899$) and S (mean =1.4 & SD =0.51, $p < 0.05$, $\eta_p^2=0.023$), and the lower limb muscle mass was significantly higher than that in the other two groups ($p < 0.05$, for SE vs E, $\eta_p^2= 0.595$; for SE vs S, $\eta_p^2= 0.266$).

CONCLUSIONS: A combination of exercise and Sanqi ginseng could effectively reduce the NRS during training process, resulting in a better healing effect of MTSS.

1049 Board #283 May 29 2:00 PM - 3:30 PM Cardiovascular Risk Factors of Working Primary School Teachers

Martina Uvacek, Mate Petrekanits, Lilla Török, Judit Boda-Ujlaky. *University of Physical Education, Budapest, Hungary.* (Sponsor: Pat Vehrs, FACSM)
Email: uvacek.martina@tf.hu
(No relevant relationships reported)

In Hungary about 77000 people work as teachers in primary school. Generally, stressful work negatively affects health and can increase risk of noncommunicable diseases. Previous research revealed that teachers have better physical health status compared to the general population (Seibt 2011). Health status is often assessed using questionnaires, and as a result, there is a lack of research using objective measures of health in primary school teachers. **PURPOSE:** To collect data about health status, body composition, blood pressure and arterial stiffness in primary school teachers and compare some results to the EHIS study results reported in 2014. The participants involved were over 35 years of age and had more than ten years' experience as school teachers.

METHODS: 24 subjects (mean age: 46.8±7.4y.) were recruited from different primary schools using the snowball research method (Kaltun2001). Data collected included body mass index (BMI) and body composition (BF%), information from a health behaviour questionnaire (eating habits, physical activity, smoking) (WHO 2010) and resting arterial stiffness measured via TensioMed arteriography (Illyés 2005). Descriptive statistical analysis and Chi square tests were used with SPSS Statistics program version 22.

RESULTS: The mean BMI was 26.9±5.5 and BF% was 26.9±6.5 in teachers, 50% were overweight or obese. According to the questionnaire 62% of the teachers ate breakfast regularly and only 20% were physically active ≥ 2.5h/week, 20% smoked, 22% had elevated blood pressure and 20% had elevated pulse wave velocity or augmentation index (Willum-Hansen et al. 2006). Compared to data from the European Health Interview Survey (EHIS) (www.ksh.hu/docs/hun/xftp/stattukor/elef14.pdf) teachers in this study were the same active (4.1%vs.4.5%) and were the same overweight and obese (50%vs.54%) as Hungarians in the general population. The prevalence of smoking among teachers was significantly ($p < 0.05$) less (20%) than the general population (29%).

CONCLUSIONS: Half of the investigated middle-aged teachers already had some health problems. The health-related concepts and mental health programs for teachers are essential to prevent chronic diseases and psychosomatic disorders.

1050 Board #284 May 29 2:00 PM - 3:30 PM**Effects of Environmental Condition and Body Fat Percentage on Substrate Utilization during and following Exercise**

Brittany N. Followay¹, Jeremiah A. Vaughan², Eliott Arroyo³, Brandon M. Gibson³, Joseph A. Laudato³, Ellen L. Glickman, FACSM³, Adam R. Jajtner³. ¹Ripon College, Ripon, WI. ²Bemidji State University, Bemidji, MN. ³Kent State University, Kent, OH. (Sponsor: Ellen Glickman, FACSM)
(No relevant relationships reported)

PURPOSE: To examine the effects of environmental condition and body fat percentage on substrate utilization during and following exercise.

METHODS: Recreationally active men consisting of 4 low-fat (LF; 10.9% ± 2.5; 23.8 ± 3.1yrs; 182.6 ± 7.1cm; 80.7 ± 4.5kg; 4.03 ± 0.34L·min⁻¹) and 4 high-fat (HF; 15.9% ± 2.2; 23.3 ± 1.9yrs; 180.9 ± 4.3cm; 79.6 ± 5.9kg; 3.63 ± 0.13L·min⁻¹) completed six experimental trials: a VO₂max test and 5 cycling trials in 5°C/20%RH (LT), 22°C/45% RH (MTMH), 22°C/70% RH (MTHH), 35°C/45% RH (HTMH), and 35°C/20% RH (HTLH) in a counterbalanced fashion. During cycling trials, participants completed 60-min of cycling at 60% VO₂max, a 15-min rest period, cycling at 90% VO₂max until exhaustion (TTE), and a 60-min recovery (REC). AUCi for absolute carbohydrate (CHO) utilization was calculated during cycling at 60% VO₂max, TTE, and REC for each condition. Data were analyzed using a mixed-design ANOVA.

RESULTS: A condition x BF interaction was observed during cycling at 60% VO₂max ($F=2.907$; $p=0.048$). Specifically, CHO utilization was greater during LT (496.9 ± 83.43kcal; $p=0.015$) compared to MTHH (416.12 ± 73.91kcal) in LF individuals, with no significant differences between conditions in HF individuals ($p > 0.05$). During the TTE, no condition x BF interaction was observed ($F=0.410$; $p=0.799$) however; a main effect of condition was observed ($F=3.412$; $p=0.028$). Specifically, CHO utilization was greater during MTMH (73.53 ± 11.96kcal; $p=0.020$) and MTHH (75.66 ± 16.69kcal; $p=0.019$) compared to HTMH (29.87 ± 5.55kcal). During REC a condition x BF interaction was observed ($F=5.982$; $p=0.004$). Post-hoc analysis indicated a main effect of condition in LF individuals ($F=12.371$; $p=0.016$). Specifically, absolute CHO utilization was significantly higher in LT (96.259 ± 4.929kcal) compared to HTLH (5.783 ± 1.583kcal). No main effect of condition was observed in the HF individuals ($F=1.402$; $p=0.292$).

CONCLUSIONS: Data suggests that individuals with a lower BF% may utilize greater absolute CHO during exposure to cold environments compared to those with higher BF%, during both moderate intensity exercise and resting conditions. Additionally, exposure to moderate compared to hot temperatures may result in prolonged TTE, likely due to a longer TTE.

Study partially funded by the Kent State University Research Council.

1051 Board #285 May 29 2:00 PM - 3:30 PM**An Examination of Physiological Responses in EMT Students During Occupational and Heat Stress**

Hayden Gerhart¹, Amy Fiorentini¹, Kristi Storti¹, Robert Alman¹, Yongsuk Seo², Louis Pesci¹, Madeline Bayles, FACSM¹. ¹Indiana University of Pennsylvania, Indiana, PA. ²Center for Disease Control and Prevention, Pittsburgh, PA. (Sponsor: Madeline P. Bayles, FACSM)
Email: hdgerhart@gmail.com
(No relevant relationships reported)

PURPOSE: The purpose of the present study is to observe the impact of a hyperthermic environment on physiological responses in EMT students performing a simulated occupational task. **METHODS:** Ten EMT students completed a simulated occupational task in two conditions; thermoneutral environment, or hyperthermic condition (100°F, 60-70% RH). The following primary dependent variables were analyzed; heart rate (HR), mean arterial pressure (MAP), rating of perceived exertion (RPE), oxygen consumption (VO₂), thermal sensation (TS), mood (TMD), core temperature (T_c), and mean skin temperature (MST). Following 30 minutes of acclimation participants completed an aerobic bout of exercise followed immediately by an anaerobic bout of exercise. The aerobic exercise consisted of a 10-minute treadmill walk at 70%-80% of their previously determined maximal heart rate. The anaerobic exercise consisted of lifting a 50 lb. sandbag to a metronome over the course of 5 minutes. This process was repeated once, resulting in a total exercise time of 30 minutes. **RESULTS:** A main effect of condition was found for T_c ($p=0.033$), further explained by elevated T_c post-exercise in the hyperthermic condition (38.08±0.38°C) compared to the thermoneutral condition (37.71±0.33°C) ($p=0.002$). A significant time by condition interaction was seen for TS ($p=0.043$), further explained by elevated TS scores at every time point with the exception of post-exercise. During exercise, average TS score was 8.35±0.87 in the hyperthermic condition, compared to 6.85±0.78 in the thermoneutral condition ($p < 0.05$). MST also elicited a significant time by condition interaction ($p=0.033$). MST was elevated at all time points in the hyperthermic condition when compared to the thermoneutral condition. Average MST during exercise was 36.75±0.70°C in the hyperthermic condition, compared to 33.44±0.73°C

in the thermoneutral condition ($p < 0.001$). No difference was observed for TMD between conditions ($p = 0.354$), although a worsening mood following acclimation (19.96 ± 42.00) compared to baseline (-77.08 ± 74.41) was observed. **CONCLUSION:** Future research should emphasize a focus on maintaining a lower core and skin temperature while focusing on enhanced mood under occupational and heat stress in order to improve physiological and motor performance.

1052 Board #286 May 29 2:00 PM - 3:30 PM
Effects Of Nsaid Use On Biomarkers Of Kidney Stress Following A Marathon

Whitley C. Atkins¹, Aaron R. Caldwell¹, Cory L. Butts², Lisa Jansen¹, Melani R. Kelly³, Margaret Gibson⁴, Dawn M. Emerson³, Brendon P. McDermott, FACSM¹. ¹University of Arkansas, Fayetteville, AR. ²Weber State University, Ogden, UT. ³University of Kansas, Lawrence, KS. ⁴Truman Medical Center, Kansas City, MO.

(No relevant relationships reported)

The use of nonsteroidal anti-inflammatory drugs (NSAID) is common practice by participants in marathons and other endurance events. Previous research suggests that renal stress is apparent immediately following marathon completion. However, the potential exacerbating effect of NSAID use during a marathon is not well-understood. **PURPOSE:** Investigate the effect of NSAID use on biomarkers of renal stress following a marathon. **METHODS:** Twenty-two volunteer participants (14 males, 8 females; 38 ± 10.2 y, 70.7 ± 10.1 kg, 171.0 ± 7.7 cm) at the Kansas City Marathon were recruited and assigned to either a control ($n = 15$) or NSAID ($n = 7$) group based on planned or habitual use. Pre-race NSAID ingestion was self-reported as 9.15 ± 4.62 mg/kg of ibuprofen ($n=4$) or 3.75 ± 1.73 mg/kg naproxen sodium ($n=3$). Urine samples were collected pre-marathon, post-marathon, and 24-h post-marathon. Samples were stored at -80°C and later analyzed for urinary neutrophil gelatinase lipocalin (uNGAL) and urinary cystatin C (uCyC). A robust two-way mixed ANOVA with trimmed means was utilized to account for potential outliers. When significant interaction or main effects were observed, pairwise comparisons were calculated using robust bootstrapped effect sizes with 95% confidence intervals. **RESULTS:** Immediately post-marathon, there was a significant increase in uNGAL (Cohen's $d_r = 0.47$ 95% C.I. [0.23, 0.85]) but there was no longer a significant elevation by 24-h post-marathon (Cohen's $d_r = 0.16$ 95% C.I. [-0.61, 3.36]). There were no significant effects detected for Cystatin C. Further, NSAID ingestion did not affect uCyC or uNGAL values. **CONCLUSION:** Renal stress biomarkers suggest potential kidney tubular injury immediately post-marathon, but potential renal stress was negated by 24-h of recovery. Moderate NSAID ingestion before the marathon did not affect kidney stress biomarkers.

1053 Board #287 May 29 2:00 PM - 3:30 PM
A Novel Assessment of Law Enforcement Officer Response to a Dynamic Shooting Protocol

JohnEric W. Smith¹, Brandon D. Shepherd¹, Teena M. Garrison¹, Benjamin M. Krings², Matthew J. McAllister³. ¹Mississippi State University, Mississippi State, MS. ²University of Wisconsin-Platteville, Platteville, WI. ³Texas State University, San Marcos, TX.

Email: johneric.smith@msstate.edu

(No relevant relationships reported)

Police officers' responses to violent situations are frequently scrutinized. **PURPOSE:** This study was created to establish a Target Assessment, Action, and Accuracy Protocol (TAAAP), assessing law enforcement personnel's decision making and firearm proficiency in a dynamic environment. We hypothesized the TAAAP would result in a greater performance differentiation than a traditional shooting test. **METHODS:** Healthy, non-colorblind, law enforcement officers ($n=7$) participated in four trials; traditional fatigued, TAAAP fatigued, traditional fresh, and TAAAP fresh. The traditional protocol required officers to fire eight shots in 15 s at a target 3 m away, then fire four rounds in 6 s at a target 6.1 m away. Following a magazine change, the protocol was repeated. The TAAAP consisted of multiple targets, both hostile and friendly, at varying distances across five separate shooting bays. Fatigued protocols required participants to run until volitional fatigue and shoot, whereas subjects had no physical exertion prior to beginning the fresh trials. Shooting accuracy and response time were collected and analyzed. **RESULTS:** The traditional shooting test demonstrated an accuracy rate of $88 \pm 9\%$ while the TAAAP demonstrated an accuracy rate of $49 \pm 17\%$. The findings of the current study demonstrated TAAAP is a more challenging assessment tool as compared to traditional shooting tasks. **CONCLUSIONS:** While the traditional task demonstrated a potential ceiling effect, the TAAAP may provide a better example of shooting accuracy in naturalistic settings when compared to the results from officer involved shootings at less than 6.1 m.

1054 Board #288 May 29 2:00 PM - 3:30 PM
Correlation Between $\dot{V}O_{2\max}$ and Anaerobic Power in Law Enforcement SWAT Team Members

Shea B. Caddel, Matthew C. Jackson, Nicole C. Dabbs, Jason Ng. California State University, San Bernardino, San Bernardino, CA.

(No relevant relationships reported)

PURPOSE: The purpose of this investigation was to examine the relationship between maximal oxygen uptake ($\dot{V}O_{2\max}$) and anaerobic power in Special Weapons and Tactics (SWAT) team members of law enforcement. **METHODS:** Fourteen healthy men and one healthy woman (age: 33 ± 6 y, height: 179.6 ± 6.7 cm, body mass: 89.6 ± 10.4 kg) performed a graded exercise test to measure $\dot{V}O_{2\max}$ and a Wingate Anaerobic Test to measure anaerobic power on two separate occasions. $\dot{V}O_{2\max}$ was determined with a graded exercise test on a motorized treadmill using the Costill-Fox protocol. Anaerobic power was determined using the Wingate Anaerobic Test where participants cycled against a resistance of 9% of body mass (8 ± 1 kg) on a Wingate cycle ergometer. Pearson's r correlations were conducted to analyze the relationship between absolute $\dot{V}O_{2\max}$ and absolute power as well as relative $\dot{V}O_{2\max}$ and relative power. **RESULTS:** Absolute $\dot{V}O_{2\max}$ was significantly positively correlated to absolute peak power ($r = 0.60$; $p = 0.02$) and absolute average power ($r = 0.75$; $p < 0.01$). Moreover, relative $\dot{V}O_{2\max}$ was significantly positively correlated to relative peak power ($r = 0.56$; $p = 0.03$) and relative average power ($r = 0.64$; $p = 0.01$). **CONCLUSIONS:** There are moderate-to-strong positive correlations between $\dot{V}O_{2\max}$ and anaerobic power. It is possible that adaptations that occur with high intensity anaerobic exertions might be related to changes in aerobic metabolism. Future research might consider examining the effectiveness of anaerobic power training on aerobic fitness among the tactical athlete populations.

Influence Of Working Hours On Pregnancy Outcomes: A Systematic Review And Meta-analysis

Margie H. Davenport, Robin Featherstone, Ben Vandermeer, Meghan Sebastianski, Chenxi Cai. University of Alberta, Edmonton, AB, Canada.

Email: mdavenpo@ualberta.ca

(No relevant relationships reported)

Approximately 90% of women remain employed during pregnancy. Long working hours have been hypothesized to be associated with an increased risk of adverse pregnancy outcomes including miscarriage and preterm delivery. **PURPOSE:** The purpose of this review was to evaluate the effect of long working hours (>40 hour work week) on maternal and fetal health outcomes. **METHODS:** Five electronic databases and two grey literature sources were searched up to March 12, 2018 and the results underwent duplicate independent screening. Studies of all designs were included (except case studies), and contained information on the Population [women who engaged in paid work during pregnancy], Exposure [>40 h work week], Comparator [working ≤ 40 h/week], and Outcomes [preterm birth, low birthweight (birthweight $< 2,500$ g), small for gestational age, miscarriage, gestational hypertension, pre-eclampsia and intrauterine growth restriction]. Pooled odds ratio (OR) and 95% confidence interval (CI) were calculated using a random-effect, inverse variance method. Grading of Recommendations Assessment, Development and Evaluation (GRADE) framework was used to assess the quality of evidence. **RESULTS:** A total of 41 observational studies ($N=126,632$) were included. "Low" to "Very low" quality evidence from observational studies revealed that compared with normal working hours (working ≤ 40 h/week), long working hours were associated with an increased odds of having a preterm delivery (OR: 1.16, 95% CI: 1.04, 1.3, $I^2=53\%$), a small-for-gestational age baby (OR: 1.13, 95% CI: 1.00, 1.27, $I^2=47\%$) and miscarriage (OR: 1.36, 95% CI: 1.17, 1.59, $I^2=47\%$). When meta-analysis was restricted only to adjusted ORs, long working hours were associated with an increase in risk of preterm delivery (OR: 1.18, 95% CI: 1.01, 1.37, $I^2=60\%$) and miscarriage (OR: 1.39, 95% CI: 1.09, 1.78, $I^2=54\%$). We found no significant association between long work hours and low birth weight, pre-eclampsia, gestational hypertension or intrauterine growth restriction. **CONCLUSIONS:** Engaging in a work week over 40 hours is associated with an increased risk of adverse pregnancy outcomes. Supported by an Occupational Health and Safety Futures Research Grant, Alberta SPOR SUPPORT Unit KT Platform and Heart & Stroke Foundation of Canada National New Investigator Award (MD).

1056 Board #290 May 29 2:00 PM - 3:30 PM

Influence Of Shift Work On Pregnancy Outcomes: A Systematic Review And Meta-analysisChenxi Cai, Robin Featherstone, Meghan Sebastianski, Margie H. Davenport. *University of Alberta, Edmonton, AB, Canada.*
Email: ccai1@ualberta.ca*(No relevant relationships reported)*

Shift work including rotating shift and night shift has been suggested to be associated with risk of adverse pregnancy outcomes due to disrupted circadian rhythms and neuroendocrine adaptations which may affect fetal growth and timing of parturition. **PURPOSE:** To evaluate the association between shift work and pregnancy outcomes. **METHODS:** Five electronic databases and two grey literature sources were searched up to March 12, 2018 and the results underwent duplicate independent screening. Studies of all designs were included (except case studies), and contained information on the Population [women who engaged in paid work during pregnancy], Exposure [rotating shift work (working a pattern of days and nights) or fixed night shift (typical working day between 22:00 to 08:00)], Comparator [fixed day shift (typical working day between 8:00-18:00)], and Outcomes [preterm birth, low birthweight, small for gestational age, miscarriage, gestational hypertension and pre-eclampsia]. Pooled odds ratio (OR) and 95% confidence interval (CI) were calculated using a random-effect, inverse variance method. Grading of Recommendations Assessment, Development and Evaluation (GRADE) framework was used to assess the quality of evidence. **RESULTS:** A total of 41 observational studies (N=145,671) were included. "Low" to "Very low" quality evidence from observational studies revealed that compared with fixed day shift, rotating shift was associated with an increased odds of preterm delivery (OR: 1.16, 95% CI: 1.03, 1.3, I²=34%) and having a small-for-gestational age baby (OR: 1.23, 95% CI: 1.08, 1.39, I²=11%). Fixed night shift was associated with an increase odds of preterm delivery (OR: 1.25, 95% CI: 1.05, 1.48, I²=36%), miscarriage (OR: 1.31, 95% CI: 1.09, 1.57, I²=34%) and gestational hypertension (OR: 1.22, 95% CI: 1.01, 1.48, I²=0%). When meta-analysis was restricted only to adjusted ORs, fixed night shift was associated with an increase in risk of miscarriage (OR: 1.34, 95% CI: 1.10, 1.63, I²=38%). Rotating shift or fixed night shift were not significantly associated with low birth weight or pre-eclampsia. **CONCLUSIONS:** Pregnant women who work with rotating shift or fixed night shift have an increased risk of adverse pregnancy outcomes.

Supported by Alberta OHS Futures Research Grant and the Alberta SPOR SUPPORT Unit.

Effects of Powered Air-Purifying Respirators on Tear Osmolarity after ExerciseEdward J. Sinkule, FACSM¹, Jeffrey B. Powell¹, Amanda L. Strauch¹, Tyler D. Quinn². ¹Centers for Disease Control and Prevention/NIOSH, Pittsburgh, PA. ²University of Pittsburgh, Pittsburgh, PA.

Email: esinkule@cdc.gov

(No relevant relationships reported)

Powered air-purifying respirators (PAPRs) are used frequently in healthcare because they provide superior respiratory protection and improved comfort when compared to N95 filtering facepiece respirators. However, dry eyes from airflow on the face with PAPRs have been reported by users. Tear osmolarity is among several factors for diagnosing dry eye syndrome. **PURPOSE:** This study compared tear osmolarity measurements among participants performing the same energy expenditures while wearing two different NIOSH-approved PAPRs. **METHODS:** After protocol approval by the NIOSH IRB, men (n=12) and women (n=12) provided written informed consent. Participants wore randomly-assigned PAPRs at the same absolute energy expenditures. The treadmill exercise trials included four minutes each of standing rest, VO₂=1.0 L/min, VO₂=2.0 L/min, and VO₂=3.0 L/min or maximum (all STPD); separated by 20 minutes of sitting rest and rehydration. All PAPRs were equipped with HEPA filters. Tear osmolarity (mOsm/L) was measured with an instrument which uses a 50 nanoliter tear sample. The largest measurement from both eyes was used for the results. The BASELINE tear osmolarity measurements were the average of osmolarity measurements obtained when participants arrived and the pre-exercise period before donning the PAPR. The tear osmolarity measurements from both PAPRs (PAPR1 and PAPR2) were measured immediately after each exercise trial. **RESULTS:** Tear osmolarity between the men and women across all trial periods were not statistically different (BASELINE p=0.17; PAPR1 p=0.53, PAPR2 p=0.11). Mean (±SD) tear osmolarity for BASELINE, PAPR1, and PAPR2 from men were 315±19, 304±12, and 314±23, respectively. Mean (±SD) tear osmolarity for BASELINE, PAPR1, and PAPR 2 from women were 307±9, 307±11, and 300±14, respectively. Tear osmolarity of each PAPR was not statistically different from BASELINE for men (PAPR1 p=0.07; PAPR2 p=0.81) and women (PAPR1 p=0.90; PAPR2 p=0.18). **CONCLUSION:** After wearing PAPRs for more than 20 minutes, tear osmolarity for each PAPR was not different than baseline. Areas of future research include the evaluation of tear osmolarity with longer

periods of PAPR use and the comparison of tear osmolarity with blood osmolarity for research when instantaneous, non-invasive osmolarity measurements would be beneficial.

1058 Board #292 May 29 2:00 PM - 3:30 PM

Validity and Reproducibility of Commercial Cycling Power Meters in Hot and Cold Environmental TemperaturesCamille Larson. *University of Nebraska at Omaha, Omaha, NE.*
(Sponsor: Dustin Slivka, FACSM)*(No relevant relationships reported)*

PURPOSE: Power meters provide objective monitoring of exercise intensity, unaffected by day-to-day physiological variations. The validity and reliability of most power meters have been assessed in laboratory settings with controlled, stable environmental conditions. Since a factor of importance for athletes exercising in a wide range of different environmental temperatures is the accurate recording of the training values regardless of environmental fluctuations. The purpose of this study was to examine potential differences in power output of the CompuTrainer, PowerTap, Stages, and Vector power meters in hot and cold compared to a room temperature environment. **METHODS:** Recreationally trained participants (7 males, 3 females, n = 10, age: 24 ± 1 years, height: 176 ± 6.1 cm, weight: 75.4 ± 10 kg, VO_{2peak}: 56.6 ± 8.3 ml · kg⁻¹ · min⁻¹) completed three incremental VO_{2peak} cycling trials in hot (33°C), cold (7°C), and room temperature (RT, 20°C) conditions. The power meters were placed on a standard road bicycle and power output was logged and recorded. **RESULTS:** The CompuTrainer's power output was higher in the RT trial compared to the cold (p = 0.006) and hot (p = 0.047), but not between the hot and cold trial (p = 0.734). The PowerTap's power output was not different in RT and cold (p = 0.875), but was lower in the hot compared to RT (p < 0.001) and compared to cold (p < 0.001). The Stages' power output was not different between RT and cold (p = 0.234), but was lower in the hot compared to RT (p < 0.001) and cold (p < 0.001). The Vector's power output was not different between RT and cold (p = 0.067) but was lower in the hot compared to RT (p < 0.001) and cold (p < 0.001). **CONCLUSION:** Environmental temperature may affect the reproducibility of power meters, thus revealing the significance of recognizing potential differences between temperatures when choosing a power meter.

Effect of Recreational Soccer Play in the Air of Fine Particulate Matter on Pulmonary Function and Blood Pressure in Collegiate MenMin Gi Jung, Jaemyung Kim, Yunbin Lee, Somi Yun, Eunjin Hwang, Dahye Lim, Dae Taek Lee. *Kookmin University, Seoul, Korea, Republic of.*

Email: cjswo3956@hanmail.net

(No relevant relationships reported)

PURPOSE: Although exercise in polluted air was not recommended, no concrete information regarding health effects of air pollution has been established in real situations. This study aimed to examine the effects of polluted air on pulmonary responses and blood pressure following vigorous outdoor exercises. **METHODS:** A total of 9 healthy young men (21.5±1.5 yrs, 172.2±5.2 cm, 68.4±9.9 kg), who formed an intramural collegiate team and regularly played recreational soccer, participated in two of four-week experiments. Each was conducted in the fall (October, FS) and the Spring (April, SS). Before (Wk0) and after (Wk4) the experiments, their maximal oxygen uptake (VO_{2max}), forced vital capacity (FVC), forced expiratory volume in first second (FEV₁), FEV₁/FVC, and systolic and diastolic blood pressure (SBP, DBP) were measured. During each of the experimental period, they played on the average of six sessions while recording their heart rate. In each session, they were trained for 54±1 min (at an intensity of 60.4±2.5 and 57.8±4.8% of VO_{2max} in FS and SS, respectively) followed by 55±4 min of friendly game (at 84.8±3.0 and 82.6±1.1% of VO_{2max} in FS and SS, respectively). After each play session, FVC, FEV₁, FEV₁/FVC, SBP, and DBP were measured. Air quality was measured by light-scattering method. PM₁₀ and PM_{2.5} in FS was 44.0±34.1 and 24.1±23.7 µg/m³, while those in SS was 92.0±23.7 and 49.3±25.7 µg/m³, respectively. **RESULTS:** When the change of measured variables between Wk0 and Wk4 was compared, no differences were found. Repeated measures of FVC, FEV₁, FEV₁/FVC, SBP, and DBP during sessions of FS did not revealed any significances, but FVC, FEV₁, FEV₁/FVC and SBP in SS were significantly increased (p<0.05). When the lowest and the highest particulate concentrations were compared in each season (20 vs. 107 of PM₁₀ and 8 vs. 69 µg/m³ of PM_{2.5} in FS; 28 vs. 159 of PM₁₀ and 17 vs. 90 µg/m³ of PM_{2.5} in SS), no differences were noticed during FS. But FVC and FEV₁ were increased higher after play sessions in highly polluted air than clean air. **CONCLUSIONS:** In general, the concentration of fine particulate matter in the air did not affect pulmonary and blood pressure responses for the healthy recreational exercisers. But the higher concentration of particulate matter in the air may influence on pulmonary responses after vigorous outdoor activities.

Blood Pressure Responses to Air Pollution in Chinese Children: Effect Modification by Obesity
 Zhaohuan Gui¹, Mao Wang¹, Li Cai¹, Jun Ma², Yinghua Ma², Jin Jing¹, Yajun Chen¹. ¹*School of Public Health, Sun Yat-sen University, Guangzhou, China.* ²*School of Public Health, Peking University, Guangzhou, China.*
 (No relevant relationships reported)

PURPOSE: To assess effect modification by obesity on the association between pollutants and blood pressure (BP) in Chinese children.

METHODS: We investigated 26,039 Chinese children, aged 6-18 years old, from 50 elementary schools and 44 middle schools from seven provinces in China in 2014. The weight, height, waist circumferences, and BP were measured. Total seven and half months concentrations of particulates with an aerodynamic diameter < 2.5 and ≤10 μm (PM_{2.5} and PM₁₀), ozone (O₃), sulfur dioxide (SO₂), nitrogen dioxides (NO₂), and carbon monoxide (CO) were assessed based on the measurement from national monitoring stations and the personal short-term inhalation rate. Two-level regression analysis was used to examine the effects, controlling for sex, age, early life factors, physical activity, screen time, socioeconomic status, passive smoking exposure, and family history of hypertension.

RESULTS: The results showed that associations existed between elevated BP and pollutants. The increase in systolic BP ranged from 0.21 mmHg per 62.2 mg/m³ increase for CO (95%CI: 0.03-0.40 mmHg) to 1.49 mmHg per 1320.4 μg/m³ increase for PM₁₀ (95%CI: 1.21-1.86 mmHg). The increases in mean diastolic BP ranged from 0.42 mmHg per 368.6 μg/m³ increase for NO₂ (95%CI: 0.22-0.62 mmHg) to 0.82 mmHg per 1320.4 μg/m³ increase for PM₁₀ (95%CI: 0.54-1.10 mmHg). Compared to children with normal weight or non-abdominal obesity, underweight, overweight, obese, or abnormally obese children exhibited consistently stronger effects.

CONCLUSIONS: Study findings indicate that high levels of PM_{2.5}, PM₁₀, SO₂, NO₂, O₃, and CO are associated with increased BP among Chinese children. Underweight, overweight, obesity, and abdominal obesity may increase the risk.

Jeffrey Janot, Chantal Bougie, Anna Kohler, Sierra Freid, Jessica Nagel, Maddy Downing, Lindsey Opelt, Marquell Johnson, Nick Beltz, Andrew Floren, Saori Braun
ABSTRACT

Effect of two equipment load bearing strategies on low back discomfort in on-duty police officers

KEY WORDS: back pain, load bearing vest, occupational health

PURPOSE: Low back pain is a common condition affecting active-duty police officers. Carrying equipment at the waist using a standard duty belt has been linked to discomfort while on duty. The purpose of this study was to determine if a load bearing vest worn on the trunk is more effective at decreasing low back discomfort compared to the standard duty belt. **METHODS:** 15 police officers (13 m, 2 f), aged 25-45 y/o, were recruited for this study. Screening criteria were active duty for 1 year and a rating of "minimal disability" on the Oswestry LBP Disability scale. Officers were randomized into either a duty belt or load bearing vest group pre-study. A crossover design was used for the 6-mo study requiring each officer to wear the duty belt or vest each for a 3-mo period. Each work shift the officers rated their level of low back discomfort using a visual-analog scale (VAS) numbered 0-10 (0 = no pain; 10 = worst pain imaginable). Other physical measures included in the analysis were body composition, spine mobility, and core and aerobic endurance. **RESULTS:** There were significant ($p < .05$) differences between vest and belt conditions for each month (1: 2.97±0.73 belt vs 0.95±1.24 vest; 2: 4.08±1.03 belt vs 0.55±1.12 vest; 3: 4.17±1.21 belt vs 0.24±0.41 vest; 4: 4.97±2.43 belt vs 2.03±1.63 vest; 5: 3.33±1.18 belt vs 1.29±1.05 vest; 6: 4.90±2.57 belt vs 1.03±1.10 vest). Pearson's r values indicated weak ($r = -.26$ to $.39$) and nonsignificant ($p > .05$) correlations between belt VAS scores and physical measures and some moderate ($r = -.51$ to $.46$) but nonsignificant ($p > .05$) correlations between vest VAS scores and physical measures. **CONCLUSIONS:** Results demonstrated that a load bearing vest produced lower VAS scores compared to the duty belt. There were no significant relationships between physical measures and VAS scores indicating that the load bearing devices were most responsible for eliciting the VAS results reported. Thus, to decrease discomfort, we recommended that officers use a load bearing vest system while on duty.

 Email: sscholten@augie.edu
 (No relevant relationships reported)

Vitamin D is known to affect bone health and muscle function. Insufficient vitamin D (25(OH)D) status may negatively affect adolescent physical performance levels.

Purpose: To examine the cross-sectional association between 25(OH)D status and several markers of physical performance in youth club soccer athletes.

Methods: 42 adolescent, male and female club soccer players age 14-18 were recruited during the winter season. 25(OH)D status, measured in January, was assessed from a capillary blood sample analyzed using liquid chromatography-tandem mass spectrometry. Physical performance was evaluated using a variety of agility, muscular strength, and cardiorespiratory fitness tests. Participants were classified as 25(OH)D Deficient (< 50 nmol/L), Insufficient (50-75 nmol/L), or Sufficient (> 75 nmol/L) and a relationship between physical performance and 25(OH)D classification was determined using a one-way ANOVA.

Results: Mean 25(OH)D status was 67.0 ± 16.7 nmol/L. 19% (8/42) of the participants were vitamin D deficient, 55% (23/42) were vitamin D insufficient, and 26% (11/42) were vitamin D sufficient. There were no associations found between 25(OH)D status and the variety of agility, muscular strength, and cardiorespiratory fitness tests ($p > 0.05$).

Conclusions: This investigation demonstrates there are no associations between 25(OH)D status and physical performance in adolescent soccer players. Our participants were competitive adolescent athletes with none being severely deficient which may mask associations in this population group.

Acute and Chronic Changes of Hematological Variables in College Football Athletes with Sickle Cell Trait
 Haoyan Wang¹, Nathan P. Lemoine, Jr.¹, Matt Martone¹, Brian A. Irving, FACSM¹, Guillaume Spielmann¹, Jack Marucci¹, Shelly Mullenix¹, Derek D. Calvert¹, Timothy S. Church², Jennifer Rood², Brian Harrell³, Neil M. Johansen¹. ¹*Louisiana State University, Baton Rouge, LA.* ²*Pennington Biomedical, Baton Rouge, LA.* ³*Baton Rouge General Sports Medicine, Baton Rouge, LA.*
 Email: hwang56@lsu.edu
 (No relevant relationships reported)

PURPOSE: To determine the acute and chronic changes of hematological in NCAA Division I football players with sickle cell trait (SCT) and healthy control (CON) before and after a single practice (acute) and pre-and post-training camp in pre-season (chronic). **METHODS:** Eight athletes (n=4 SCT; n=4 CON) had blood drawn pre-and post-training camp in pre-season. Six of them (n=3 SCT; n=3 CON) had blood drawn before and after a single pre-season scrimmage. Hemoglobin electrophoresis (Hb-A, Hb-A2, Hb-S and Hb-F), complete blood count, and chemistry panel 26 were analyzed using 2-way RM ANOVA. **RESULTS:** Baseline total hemoglobin content was similar between SCT and CON (mean±SD; 14.1±0.6 g/dL vs. 14.5±0.6g/dL; $P=0.41$). However, Hb-A was lower (58.4±3.8% vs. 86.6±17.5%; $P=0.02$) and Hb-S was higher in SCT than CON (36.8±3.6% vs. 0.2±0.4; $P<0.0001$), and results were consistent at all time points. After a single practice, uric acid was significantly higher in SCT compared to CON (7.5±0.8mg/dL vs. 6.4±0.4mg/dL; $P_{all}=0.04$). However, blood urea nitrogen (BUN) was lower in SCT (16.1±3.5mg/dL) than CON (23.4±1.6mg/dL; $P_{all}=0.006$). The chronic changes between pre-and-post camp showed that SCT had lower in BUN (16.1±3.9mg/dL vs. 20.5±3.3 mg/dL; $P_{all}=0.015$) and total bilirubin (0.73±0.14mg/dL vs. 1.13±0.27mg/dL; $P_{all}=0.027$) compared to CON. In complete blood count profile, white blood count, neutrophils, lymphocytes, and monocytes significantly decreased in both groups ($P_{all}<0.05$). **CONCLUSION:** Both acute and chronic changes showed SCT had lower BUN than CON suggesting exercise might have different effects on kidney function between two groups. Subclinical changes in resting immune cell counts between pre- and post-training camp suggest that athletes' immune function may be dampened by repeated bouts of exhaustive exercise.

Blood Flow Response and Changes in Fluid Distributions after Percussive Massage Therapy

Timothy R. Macaulay, Joel E. Ramirez, Jaehyung Choi, Malcolm Jones, E. Todd Schroeder, FACSM. *University of Southern California, Los Angeles, CA.*
Email: tmacaula@usc.edu

(No relevant relationships reported)

PURPOSE: Percussive massage therapy is a widely used modality for sports rehabilitation and recovery after intense exercise. Recent advancements in handheld vibration technology have further increased its popularity. While athletes, trainers, and therapists collectively tout its practical benefits for sports performance, the underlying mechanisms are largely unknown. To provide such insight, we assessed blood flow response and changes in fluid distributions after applying percussive massage therapy to the quadriceps muscles of each leg.

METHODS: Forty-one participants (23 female, 25.1 ± 3.0 years of age) with a range of body fat percentage (23.8 ± 7.9%) were tested. Percussive massage therapy was applied for 2 minutes by a study investigator. Two devices were used simultaneously, TheraGun G2PRO and HyperIce Hypervolt, with similar speed setting (40 percussions per second) and randomly assigned to one of each participants' legs. A thermal camera (FLIR C2) was used as a proxy for blood flow. All images were taken with participants seated and an ice-water slurry between their abducted legs as a control for temperature. Fluid distributions, including extracellular water (ECW) and the ratio of ECW to total water (ECW/TW), were assessed through bioelectrical impedance analysis (Biospace Inbody 770).

RESULTS: Immediately after the treatment, there was no difference in surface temperature compared to baseline in either thigh. However, the temperature in both thighs was greater than baseline in the 3rd to 8th minutes (~3°F, P<0.006), indicating a delayed blood flow response. Temperatures returned to baseline by the 12th minute post-massage. Differences between devices were observed. The percent change from baseline was significantly greater in the G2PRO thigh than the Hypervolt thigh at minutes 5 (3.7% vs 3.2%), 6 (3.7% vs 3.2%), 7 (3.6% vs 3.1%), and 12 (1.9% vs 1.4%, respectively) post-massage (all P<0.006). For ECW and ECW/TW, a significant decrease was observed only in the G2PRO leg between 2 and 9 minutes post-massage (P<0.0167). However, there was no difference between legs.

CONCLUSIONS: Overall, the G2PRO and Hypervolt induce a delayed blood flow response; however, the G2PRO has a larger, longer-lasting effect. In addition, the G2PRO appears to influence fluid distributions, while the Hypervolt does not.

Low Energy Availability May Cause REE Suppression and Bone Loss in Japanese Male Athletes

Motoko Taguchi¹, Kuniko Moto¹, Sihyung Lee¹, Suguru Torii¹, Nobuko Hongu, FACSM². ¹Waseda University, Saitama, Japan. ²University of Arizona, Tucson, AZ. (Sponsor: Nobuko Hongu, FACSM)

(No relevant relationships reported)

PURPOSE: Recently, it has been reported that low energy availability (EA) affects physical conditions (i.e. impairments of metabolic rate, bone health, immune functions, protein synthesis etc.) in male athletes as well as female. However, few EA data of male athletes have been reported. The aim of this study was to estimate EA of Japanese male athletes, and to examine the relationship between their EA and resting energy expenditure (REE), and the status of bone health.

METHODS: Five male collegiate long-distance runners (age: 19.6±0.8 yrs., average running time: 133±20 min/day) during a training season participated in this study. Total energy intake (TEI) was assessed using 7-day dietary records with food pictures that were taken by the athletes. Further, they were interviewed on their food picture by a sports dietitian. Exercise energy expenditure (EEE) was determined by HR-VO₂ method. EA was calculated by subtraction of EEE from TEI and normalized by fat free mass (FFM). REE was measured in the morning fasting by indirect calorimetry using Douglas bag technique, and blood sampling were conducted to assess Triiodothyronine, sex hormones and bone resorption maker (serum NTx). Body composition was measured by DXA (Hologic Horizon A). REE was predicted using organ-tissue mass derived from DXA, and REE suppression was estimated by the ratio of measured REE to predicted REE.

RESULTS: Mean EA of the subjects was 16.4±3.3 kcal/kg FFM/day, which was below the cut off value (30kcal/kg FFM/day). Measured REE was also below the average of Japanese athletes presented in our previous study. Based on the mean ratio of measured REE to predicted REE (0.91), energy metabolism of these athletes seemed to be suppressed. In addition, the value of NTx showed a high value exceeding the reference range, subjects were considered to be in a state where bone resorption was promoted.

CONCLUSIONS: These data suggested that low EA could impair energy metabolism and bone health in Japanese male collegiate long-distance runners.

1066 Board #300 May 29 3:30 PM - 5:00 PM

Nocturnal Hypoglycemia Incidents Following Moderate and Vigorous Physical Activity in Athletes With Type 1 Diabetes

Jason R. Jagers, Kristi King, Kupper Wintergerst. *University of Louisville, Louisville, KY.* (Sponsor: Ann Swank, FACSM)

Email: jason.jagers@louisville.edu

(No relevant relationships reported)

PURPOSE: For adolescent athletes with type 1 diabetes mellitus (T1DM), proper glucose management during and after prolonged activity could prove difficult because of the body's response throughout the process of gluconeogenesis. Understanding their body's glucose response to physical activity could aid in effectively addressing nocturnal hypoglycemia. Therefore, the purpose of this investigation was to examine the acute temporal associations between blood glucose and measures of moderate and vigorous intensity physical activity via an accelerometer in a sample of athletes with T1DM. **METHODS:** 10 adolescent athletes with diagnosed T1DM between the ages of 13 - 17 and who were involved in competitive sports in the previous 12 months were recruited for this study. All participants wore an accelerometer and continuous glucose monitor (CGM) consecutively for a minimum of 2-weeks with a total of 168 patient-days of collected data. Nocturnal hypoglycemia was defined as a blood glucose reading <70 mg/dl during sleeping hours that lasted ≥ 10 minutes as indicated by the CGM.

RESULTS: Incidents of nocturnal hypoglycemia occurred 29% of the nights measured with an average duration of 52.33 ± 41.04 minutes. A multiple linear regression showed vigorous intensity to be a significant predictor of nocturnal hypoglycemia after controlling for all variables (β=0.169, p=0.02) with an average time of 26 minutes of vigorous intensity. **CONCLUSIONS:** Engaging in vigorous intensity physical activity increased the risk of prolonged nocturnal hypoglycemia in adolescent athletes with T1DM. Incorporating accelerometers into patient care could prove beneficial when making further recommendations for athletes by improving glucose management. Funded by Children's Hospital Foundation, Christensen Family, Norton Children's Hospital, and University of Louisville.

1067 Board #301 May 29 3:30 PM - 5:00 PM

The Implications of New Blood Pressure Guidelines on Hypertension Prevalence in Former NFL Players

Garrett H. Williams, Genevieve E. Smith, Mark M. Cassidy, Gregory W. Stewart, FACSM. *Tulane University School of Medicine, New Orleans, LA.* (Sponsor: Gregory Stewart, MD, FACSM)

(No relevant relationships reported)

Purpose: Examine potential implications of the new 2017 ACC/AHA hypertension (HTN) guidelines on the prevalence of HTN in a population of former professional football players.

Methods: Blood pressure (BP), height, weight, and waist circumference were collected from former professional football players (n = 1240) between April 2015 and August 2018 during cardiovascular screening events held throughout the U.S. Demographic information was collected, including age, race, career playing position, and previous HTN diagnosis. HTN status was assessed via 2010 JNC (2010) and 2017 ACC/AHA (2017) guidelines. Means were analyzed using one-way ANOVA, Pearson's correlation, and Chi square, where appropriate.

Results: The overall prevalence of hypertensive BP observed in this cohort was 38.5% (2010) and 70.5% (2017; p < 0.0001). While all subjects previously identified as having stage 1 HTN by 2010 guidelines were re-categorized as stage 2 under new 2017 guidelines, 72.8% of subjects previously identified as prehypertensive were re-categorized as having stage 1 HTN. There was an overall increase (p < 0.0001) in HTN prevalence by 2017 versus 2010 criteria in all groups when data were stratified by age, race, and playing position. There was an 83.4% increase in the prevalence of previously undiagnosed HTN under the new 2017 guidelines (48.6%) versus 2010 guidelines (26.5%; p < 0.0001). Correlation of body mass index and waist circumference with HTN revealed a significant association (p < 0.0001) of body mass index and HTN under both 2010 guidelines (r = 0.2036) and 2017 guidelines (r = 0.1547). Conversely, the association between waist circumference and HTN under 2010 guidelines (r = 0.1825; p < 0.0001) was better than that of 2017 guidelines (r = 0.0422; p = 0.1379), but only the correlation with HTN under 2010 guidelines was found to be significant.

Conclusions: Changes to the guidelines for the categorization of BP are expected to substantially increase HTN diagnosis in this population of former professional football players, as previously undiagnosed HTN under the new 2017 guidelines almost doubled in the current study. Given the significant increase in former players found to have stage 2 HTN, it is also likely that the number of men in this population prescribed antihypertensive medications will increase substantially.

Comparison between Dual X-ray Absorptiometry and Magnetic Resonance Imaging for Visceral Fat Assessment in Athletes

Hiroko Murata¹, Tomoyoshi Yagi¹, Eri Takai¹, Suguru Torii¹, Taishi Midorikawa², Nobuko Hongu, FACSM³, Motoko Taguchi¹. ¹Waseda University, Tokyo, Japan. ²Obirin University, Tokyo, Japan. ³Arizona University, Tuscon, AZ. (Sponsor: Nobuko Kay Hongu, FACSM)
(No relevant relationships reported)

PURPOSE: Visceral fat is related to cardiometabolic risk in athletes as well as non-athletes. Magnetic resonance imaging (MRI) estimates visceral adipose tissue (VAT) from a direct differentiation of VAT from subcutaneous adipose tissue. Recently, some validation studies of VAT assessment using dual X-ray absorptiometry (DXA) have been reported. This study aimed to compare DXA measurements of VAT with the gold standard MRI in athletes with wide ranges of body size.

METHODS: This study included 77 male collegiate athletes (age, 20 ± 2 yr; height, 175.1 ± 7.4 cm; body weight, 79.6 ± 17.4 kg; body mass index, 25.9 ± 5.3 kg/m²) from different sports (e.g. sumo, judo, lifters, wrestlers, basketball, volleyball, swimming, etc.) Paired measurement of VAT was performed using MRI (Signa 1.5T; General Electric Co., Ltd., WI, USA) and DXA (Horizon A configured with software APEX 5.6, Hologic Inc.). MRI-VAT volume was calculated by integrating six 65-mm single MRI slices corresponding to the level of DXA-VAT volume measurement. Data were compared using Wilcoxon signed rank test and a Bland-Altman plot was used to assess systematic error. Data were shown mean ± SD for parametric data and median (Inter quartile range) for nonparametric data.

RESULTS: The VAT volumes of DXA (248 (212 - 298) cm³) and MRI (211 (180 - 269) cm³) differed significantly (p<0.01). Regression analysis showed a linear relationship between DXA and MRI VAT volumes (r=0.89). The fit line for the relationship between MRI and DXA VAT volume was calculated as follows: DXA-VAT volume = 0.87×MRI-VAT volume + 68 (cm³). Bland-Altman analysis showed DXA-VAT volume overestimated by 37 ± 50 cm³ compared with MRI-VAT volume, with no systematic error (p=0.75).

CONCLUSIONS: DXA-VAT volume was overestimated compared to MRI-VAT volume among male collegiate athletes with wide ranges of body size. The overestimation of DXA-VAT volume needs further investigation.

Rapid Diagnostic Testing as a Tool for Guiding Treatment of Infectious Disease in Elite Athletes

Andrew Hedges, Dustin Nabhan, FACSM, William Moreau, FACSM. *United States Olympic Committee, Colorado Springs, CO.* (Sponsor: 7960, FACSM)
Email: andrew.hedges13@gmail.com
(No relevant relationships reported)

PURPOSE:

To describe the most common etiologies of upper respiratory tract infections (URI) in elite athletes presenting to an ambulatory sports medicine clinic as diagnosed with polymerase chain reaction rapid diagnostic testing (PCR).

METHODS:

Retrospective analysis of medical records from 42 patient-athletes who presented to a sports medicine clinic for evaluation of URI. Clinic care pathways identify a criterion for the implementing PCR testing of patient's presenting with symptoms and objective signs of an URI. Descriptive statistics were used to describe the etiology of URI in this cohort.

RESULTS:

42 URI cases met clinical criteria for PCR testing. 22 of these cases yielded positive identification of at least one pathogen. 21 of the 22 positive cases represented viral agents (95%). Influenza was the responsible agent in 50% of positive cases. *Chlamydia pneumoniae* was the sole bacterial pathogen identified. There were 3 cases of co-infection composed of multiple viral pathogens.

CONCLUSION:

Viral pathogens are the most common cause of URI in the elite athlete population. The identification of viral URI with PCR testing in athlete populations provides for the opportunity to implement evidence-based management. The significant number of negative PCR findings in patients with upper respiratory symptoms suggests there are additional unidentified etiologies for respiratory symptoms in athletes. The impact of PCR on the treatment strategies and outcomes of URI requires further investigation.

Effects of Two Cooling Strategies on Performance and Perceptual Measures Among Athletes with an SCI

Kathleen R. Connor¹, Robert C. Pritchett¹, Kelly L. Pritchett¹, Charles P. Katica², Gary E. McCall, FACSM³, Stacey T. Yee³, Ruyuan H. Cheng³, Bryce Ulrich³, Nathan Adams², Sarah Johnston². ¹Central Washington University, Ellensburg, WA. ²Pacific Lutheran University, Parkland, WA. ³University of Puget Sound, Tacoma, WA.
(No relevant relationships reported)

Individuals with spinal cord injury (SCI) have thermoregulatory inhibition, increasing the risk for heat related complication during exercise. Studies have examined cooling methods within this population, however many strategies are impractical.

PURPOSE: To compare the effects of ad libitum use of two practical cooling methods: ice slurry (IS) and artificial sweat (SB), on performance and perceptual measures in recreationally trained athletes with SCI.

METHODS: Recreational wheelchair basketball (WB) and rugby (WR) athletes with SCI (n=5; age 32.8±12.0 y; playing 3.2±1.9 y; BMI 25.0±8.1 kg/m²; peak oxygen consumption [VO_{2peak}]) 19.6±3.5 ml/kg/min) completed three lab visits; a familiarization, and two cooling trials in a climate controlled chamber (30.1±0.2°C, 51.7±2.0% relative humidity). Following familiarization, participants were assigned to IS or SB with an isocaloric, isovolumetric control beverage (CON). Participants completed an arm ergometry game simulation consisting of four quarters (four minutes of active recovery (A₁, A₂, A₃, A₄) and a 15-s sprint (S₁, S₂, S₃, S₄)). The assigned ad lib cooling method was available during programmed rest after each sprint. IS and CON were split into two 3.4g/kg boluses provided 10-min prior to exercise and during passive rest. Peak power output (W), perceived exertion (RPE), and thermal sensation (TS) were collected every four and five min.

RESULTS: W (mean±SD) was greater during sprints with SB than IS, respectively (S₁: 93.6±57.8W, 85.9±53.5W; S₂: 97.1±53.2W, 86.5±40.8W; S₃: 99.1±57.0W, 90.9±48.9W; S₄: 96.5±51.2W, 90.6±47.7W). TS (mean±SD) was similar across all exercise for both SB and IS, respectively: S1: 5.2±1.1, 5.4±0.5; S2: 6.0±1.0, 6.2±0.8; S3: 6.4±0.9, 6.4±0.6; S4: 6.8±1.1, 6.8±0.5; A1: 5.0±0.7, 5.4±0.5; A2: 5.4±1.1, 6.0±1.0; A3: 6.2±0.8, 6.6±0.9; A4: 6.6±0.9, 6.6±0.6. RPE (mean±SD) was similar for SB and IS, respectively, with SB trending higher at the end of exercise: S1: 12.4±1.6, 12.4±2.0; S2: 14.2±1.6, 13.8±1.6; S3: 15.6±0.9, 13.8±1.3; S4: 15.4±1.5, 14.6±1.1; A1: 10.2±1.8, 11.0±2.5; A2: 11.8±0.8, 12.4±1.8; A3: 13.4±2.5, 12.8±1.3; A4: 14.0±1.4, 13.2±1.5. **CONCLUSIONS:** Implementation of SB yielded a greater power output and RPE than IS, but similar TS outcomes. Athletes may use either cooling method based on comfort and availability.

Hydration Status and Drinking Behavior of Adolescent Athletes

Dalya Navot-Mintzer, Einav Grosman, Idit Shub, Eyal Shargal, Inbar Vinarski, Ben-El Berkovich. *Wingate, Netanya, Israel.* (Sponsor: Naama Constantini, FACSM)

(No relevant relationships reported)

Professional young athletes should adopt an appropriate nutritional behavior including fluid consumption and hydration program. Previous studies showed high prevalence of inappropriate pre-training hydration status and poor drinking habits among athletes.

Purpose: To estimate pre and post-training hydration status and to assess water consumption patterns of young elite athletes during a training session at the Academy for Sport Excellence at Wingate Institute.

Methods: Seventy seven academy athletes (38 females, ages 13-21) training in basketball, waterpolo, volleyball, handball, rugby, triathlon and swimming were included. Body weight, urine specific gravity (USG) and volume of fluid intake before and after afternoon training session were measured.

Results: The average USG prior training was 1.021±0.007 (no difference between different sports), indicating dehydration status equal to the loss of 3%-5% body weight (according to Casa DJ et al, 2000). A further decrease of an average of 1.5±0.7% Body weight was measured during practice, which sums up to a deficit of approximately 4.5-6.5% in body weight by the end of practice. Athletes lost an average of 0.4 (± 0.57) kilograms and consumed 0.7 (± 0.44) liters of water during training, both with a significant difference between teams at different sport professions (P<0.001, P=0.001 respectively). Volleyball players lost less weight than other athlete during training (difference was significant when compared to swimmers and basketball players (difference between groups=0.7 and 0.8 kilograms; P=0.018, P=0.002 respectively). Swimmers, waterpolo players and triathletes drank less compared to other athletes and most significantly less than handball players (difference between groups=0.9, 0.9 and 1.1 liters; P=0.007, P<0.001 and P=0.003 respectively).

Conclusions: Young athletes in our center do not consume sufficient amount of fluids. Both pre-training hydration status and water consumption during training were not

adequate, and varied between different sport disciplines. Water-sports athletes drank less than other athletes. Education and intervention should be conducted to improve athletes drinking behavior and hydration status.

 (Sponsor: Martin Schweltnus, FACSM)
 (No relevant relationships reported)

PURPOSE: Limited data are available on medical encounters, including serious life-threatening encounters and deaths during cycling events. The purpose was to determine the incidence and nature of medical encounters during a community-based mass participation cycling event.

METHODS: This retrospective, descriptive study was conducted during the Cape Town Cycle Tour (109km) in South Africa over 3 years, and involved 102251 race starters. Medical encounters were recorded on race day each year and are reported as an incidence rate (IR per 1000 starters; 95% CI). Overall illness-related (by organ system) or injury-related (by anatomical region) encounters, and severity (moderate, serious life-threatening, sudden cardiac arrest / death) were recorded.

RESULTS: In 3 years, 539 medical encounters were recorded (IR 5.27 (4.84-5.74), with a significantly higher injury- (3.23; 2.90-3.60) compared to illness-related (2.10; 1.84-2.40) ($p < 0.0001$) incidence. Incidence of serious life-threatening medical encounters was 0.49 (95%CI; 0.37-0.65) and 2 cardiac arrests and 1 death occurred (1/51126 and 1/102251 respectively). Injury incidence was highest in upper limb (1.85; 1.60-2.13), lower limb (0.96; 0.79-1.0) and head/ neck (0.77; 0.62-0.96) while illnesses incidence was highest for fluid/electrolyte abnormalities (0.59; 0.46-0.76) and the cardiovascular system (0.48; 0.36-0.63).

CONCLUSIONS: In a 109km community-based mass participation cycling event, 1 in 190 cyclists starting the race required medical assistance or evaluation by the medical team on race day. Injury-related (1 in 310 cyclists) encounters were higher than illness-related medical encounters (1 in 476) among race starters. Serious life-threatening medical encounters occurred in 1 in 2045 race starters. Risk factors associated with medical encounters need to be determined to enable implementation of safer cycling strategies.

Impact of Silver Ion Laundry Treatment on Athletic Gear and Environmental Pathogens and Athlete Health
 Priya Balachandran¹, John J. Openshaw². ¹*Applied Silver, Inc., Hayward, CA.* ²*Stanford University, Palo Alto, CA.*
 Email: priya@appliedsilver.com
 (No relevant relationships reported)

Community-acquired infections caused by *Staphylococcus* and MRSA can spread easily through sharing towels, gear and contaminated surfaces. The resulting skin infections can lead to athlete disqualifications, cancellations of competitions and potential impact on team performance. In this study, we evaluate a residual antimicrobial textile treatment as an environmental hygiene and infection control strategy through improved textile cleanliness and reduced athlete risk for infection. **PURPOSE:** To determine the impact of silver-based residual antimicrobial textile treatment on *Staphylococcus* and MRSA levels on athletic gear, environmental surfaces, athlete infection rates and number of missed play days. **METHODS:** The study, conducted at a professional sports facility over a six-month period, included pre-season and regular season use. Residual antimicrobial silver ion laundry additive was injected onto textiles during the final rinse stage of the facility's standard laundry process. Bioburden data for *Staphylococcus* and MRSA was collected approximately every 4 weeks using contact plates. Athletes' shirts, shorts, jerseys, girdles and towels, and locker room surfaces including carpets, upholstery and other hard surfaces were sampled. Infection rates and number of days missed pre- and post-laundry treatment are also being recorded. Samples collected before initiating the silver ion textile treatment served as the control data set. **RESULTS:** Prior to silver-ion treatment implementation, significant levels of *Staphylococcus* were measured on athlete textiles (average 75 CFU/100 sq. cm.) and on environmental surfaces (average 16 CFU/100 sq. cm.). Silver ion treatment of the textiles resulted in dramatic decreases in *Staphylococcus* by 77% on textiles and by 37.5% on environmental surfaces. Similar trends were also observed with MRSA. The overall bioburden levels continue to trend downward during the period of treatment. **CONCLUSIONS:** The current results demonstrate that a normal laundry process augmented with an active antimicrobial

treatment provide athletic gear and a locker room environment that are and stay cleaner. Final data related to cleanliness, infection rates and player days will be tallied at the close of 2018.

Effects of Mistletoe Extract Supplementation on Inflammation Markers after Strenuous Exercise in Rowers
 Soo-Min Ha¹, Jung-Sook Kim¹, Bo-Sung Kim¹, Jeong-Ah Lee², Yoon-Jung Choi¹, Do-Yeon Kim¹. ¹*Pusan National University, Busan, Korea, Republic of.* ²*Kyungsung University, Busan, Korea, Republic of.*
 Email: fantasista@pusan.ac.kr
 (No relevant relationships reported)

Excessive long-term training and extensive exertion during exercise can inflammatory cytokine expression. Various measures have been explored to minimize this, and dietary supplements having anti-inflammatory and antioxidant functions can help athletes recover from repetitive intensive exercises, thereby preventing reduced vitality.

Purpose: This study aimed to identify the effect of mistletoe extract consumption on inflammatory markers of university male rowing athletes for 8 weeks during the winter training period. **Methods:** This study included 20 male rowing athletes divided into the Korean Mistletoe extract supplement group (KME, $n = 10$) and the control group (CON, $n = 10$). The KME group took 110 mL of mistletoe extract every morning and evening after meals (total of 220 mL) for eight weeks. Before and after taking mistletoe for eight weeks, 2,000 m rowing performance capabilities were measured, and KME group took 110 mL of mistletoe extract after recovery from the rowing exercise. Blood samples were collected during the rest, immediately after exercise, and after 30 min of recovery. Among inflammatory markers, IL-6 and TNF- α were analyzed. **Results:** Both groups showed a significantly reduced 2,000-m rowing time (KME; $p < 0.001$, CON; $p < 0.01$), and the total number of strokes were significantly fewer in the KME group than in the CON group ($p < 0.05$). After supplementation the levels of IL-6 and TNF- α were lower in the KME group than in the CON group in all periods of the rest ($p < 0.001$), immediately after exercise (IL-6; $p < 0.01$, TNF- α ; $p < 0.001$), and after 30 min of recovery ($p < 0.01$). **Conclusion:** Therefore, mistletoe extract intake can reduce the serum inflammatory cytokine levels (which are otherwise increased due to high-strength exercise) among active individuals, indicating improved anti-inflammatory activity.

A Retrospective Analysis Of VPBs In Trained Bicuspid Aortic Valve Athletes.
 Matteo Donadei¹, Lorenzo Casatori¹, Giorgio Galanti², Pietro Amedeo Modesti³, Laura Stefani². ¹*Sports Medicine, Florence, Italy.* ²*Sports Medicine-FIMS(Italian Federation of Sport Medicine), Florence, Italy.* ³*Sports Medicine Center-University of Florence, Florence, Italy.*
 (No relevant relationships reported)

Purpose: Bicuspid aortic valve (BAV) represents a common congenital cardiac disease (1-2%) normally compatible with sports activity. In case of competitive sports, the eligibility can be otherwise limited by the presence of symptoms, aortic valve dysfunction or arrhythmias. The investigation aims to verify, in a large cohort of BAV athletes, the prevalence of ventricular arrhythmic events (VPBs) found at the maximal exercise test (ET) at the first sports medicine clinical evaluation. **Methods:** A sample of 356 BAV athletes, regularly followed at Sports Medicine Center of the University of Florence, since 10 years, was retrospectively evaluated for arrhythmic events found at the first check-up. The athletes (321 M and 35 F) were in the range of 8-50 years old (medium 24.00 ± 14.14) and practiced sports at high cardiovascular impact (predominantly soccer, basketball and track and field). Inclusion criteria were to undergo a 2D echocardiography and ET conducted at 85% of their maximal effort. VPBs were reported if they were ≥ 3 at rest and/or during the test. Exclusion criteria were age > 50 years and the presence of any other cardiac or systemic structural disease. They were matched with a control group of 400 athletes (age 19.70 ± 9.7) without BAV and similarly trained. **Results:** Only 25 (7.02%) showed VPBs at the ET. The total amount was 403 single VPBs and 4 monomorphic couples; a polymorphic pattern was present in only 3 athletes and only 5 had induced-exercise VPBs at peak. None of them showed acute events or had major arrhythmias. The difference of the VPBs prevalence in BAV athletes versus control (VPBs in 6.25%) was not significant ($p > 0.05$). **Conclusions:** Prevalence of VPBs is low in BAV athletes and it seems to be not different from athletes without BAV. In case of sports eligibility, BAV should not be considered as a cause of risk of major arrhythmic events. More data in this field could optimize the cost/effective ratio for the eventual ECG holter indications.

Knowledge, Attitude, and Behavior Related to Exertional Heat Illnesses in Japanese College Athletes

Yuki Murata¹, Kazuaki Kato¹, Yuri Hosokawa², Samantha E. Scarneo³, Ryo Uchida¹. ¹Nagoya University, Nagoya, Japan. ²Ritsumeikan University, Kusatsu, Japan. ³Korey Stringer Institute at University of Connecticut, Storrs, CT.
 (No relevant relationships reported)

Previous studies reported sport was number one cause of heat illness for young people visiting the emergency department in Japan. However, information of athletes' perception for exertional heat illnesses (EHI) is limited.

Purpose: To examine the current level of knowledge, attitude, and behavior of EHI in Japanese college athletes.

Methods: We distributed a questionnaire to 1386 students among 5 universities in Japan, and 556 athletes responded, resulting in a response rate of 57%. Knowledge was measured with 18 true/false questions, attitude was measured with 1 scenario toward playing through symptoms of EHI on 4-point Likert scale, behavior was measured with 3 questions on 4-categories modified based on the Transtheoretical Stages of Change (unaware, undecided to implement, decided to implement, implemented) about EHI. Descriptive statistics and Chi-Squared tests of association were conducted.

Results: Only 4 subjects correctly answered all of the knowledge questions. More than half of the subjects answered incorrectly to questions about the relationship between survival rate and duration of hyperthermia (60%, n=326), the best cooling method for EHI (91%, n=493), and heat acclimatization (56%, n=302). Thirty percent of subjects (n=160) reported they would play through symptoms of EHI. Thirty nine percent (n=205) of subjects were unaware that physical activities should be canceled if temperature exceeds 35°C, while 39% (n=206) undecided to implement, 11% (n=59) decided to implement, and 11% (n=58) had already implemented the recommendation. Twenty percent (n=104) of subjects were unaware ice should be prepared for workouts in the heat, while 13% (n=67) undecided to implement, 15% (n=80) decided to implement, and 52% (n=278) had already implemented the recommendation. Subjects who were undecided to implement the recommendation to cancel workouts when temperature exceeds 35°C were associated with continuing exercise despite having EHI symptoms ($X^2=27.64$ (df=3), $p<.01$).

Conclusion: Most of the respondents had not implemented the recommendation to cancel physical activities in extreme heat condition and the behavior was associated with an attitude toward the need to stop exercise when having EHI symptoms. The overall findings of this study show the need for improved education for Japanese athletes.

1077 Board #311 May 29 3:30 PM - 5:00 PM
Comparison of Various Body Condition Measurements to Air Displacement Plethysmography in Female Collegiate Athletes

Ryan Z. Lawless, Emily L. Langford, Michelle L. Eisenman, Ronald L. Snarr, Greg A. Ryan. *Georgia Southern University, Statesboro, GA.*
 (No relevant relationships reported)

Body composition is an important consideration for athletes and coaches. Air displacement plethysmography (ADP) is often preferred in this population due to relative ease of administration and accuracy of measurement. However, other methods may provide a quicker or more cost-effective way of determining body fat percentage (BF%) in athletes. **Purpose:** To compare BF% from various body fat estimators to the criterion of ADP in female Division-I collegiate athletes. **Methods:** Forty-eight female athletes (age: 18.0 ± 0.7 years, height: 146.3 ± 56.9 cm, weight: 55.9 ± 23.8 kg) underwent a body composition test battery consisting of: 1) hand-to-foot bioelectrical impedance spectroscopy (HF-BIS); 2) hand-to-foot bioelectrical impedance analysis (HF-BIA); 3) foot-to-foot BIA (FF-BIA); and 4) 3-site Jackson-Pollack skinfold (SF). All SF testing was performed by the same test administrator, and BF% was estimated using the Brozek body density formula. Mean comparisons were assessed using a one-way ANOVA against the criterion of ADP and all correlations were run using Pearson's product moment correlations. **Results:** Significant, positive relationships were found between all variables when compared to ADP (HF-BIS: $r = 0.68$, $p < .01$; HF-BIA: $r = 0.79$, $p < .01$; FF-BIA: $r = 0.76$, $p < .01$; and SF $r = 0.84$, $p < .01$). When compared to the criterion of ADP ($22.2 \pm 7.1\%$), only the HF-BIA ($26.1 \pm 5.4\%$) was found to significantly overestimate BF% ($p = 0.03$). No significance was noted with HF-BIS ($25.5 \pm 5.6\%$, $p = 0.38$), FF-BIA ($22.1 \pm 5.7\%$, $p = 0.16$), or SF ($24.6 \pm 6.1\%$, $p = 0.21$). **Conclusion:** The results of this study suggest that a moderate-to-strong relationship exists between BF% estimated via ADP and other laboratory and field-based methods. Given the strength of its relationship to ADP, it appears 3-site SF analysis may provide a cheap, time-saving estimate of BF% in Division-I female athletes.

1078 Board #312 May 29 3:30 PM - 5:00 PM
The Association Between Sleep Quality On Quality Of Life Among Healthy High School Athletes

Morgan N. Potter, David R. Howell, Katherine S. Dahab, Emily A. Sweeney, Jay C. Albright, Aaron J. Provance. *Children's Hospital Colorado, Aurora, CO.*
 Email: morgan.potter@childrenscolorado.org
 (No relevant relationships reported)

Purpose: The objective of our study was to investigate the association between self-reported sleep quality (SQ) and quality of life (QOL) measures in healthy high school athletes.

Methods: We assessed the SQ and QOL of high school athletes (age range = 13-18 years) during their pre-participation physical examination (PPE). Participants completed the Pittsburgh Sleep Quality Index (PSQI), and the PROMIS Pediatric Profile 37 QOL questionnaire. Standard PPE forms which included demographics, sports participation, and injury history were also completed by the participants. Based upon the self-reported sleep habits assessed during the PSQI, we grouped participants into poor (PSQI score ≥ 5) or good (PSQI score < 5) SQ. We compared QOL between groups using independent sample t-tests and Fisher's exact tests. A series of multivariable linear regression models were then constructed to evaluate the independent association between PSQI and QOL ratings after adjusting for age and sex.

Results: A total of 99 participants completed both the PSQI and PROMIS 37 questionnaires; 33 were classified as having poor SQ [mean PSQI: 6.8 ± 2.0 ; mean age: 15.1 ± 1.0 ; 56% female] and 66 were classified as having good SQ [mean PSQI: 2.2 ± 1.3 ; mean age: 15.2 ± 1 ; 59% female]. There were no significant demographic differences (age, sex, level of play, hours per week in sports, injury history) between the groups. While the two groups reported similar bed times, the poor SQ group reported taking significantly longer to fall asleep than the good SQ group (mean= 25.7 ± 18.6 vs. 11.2 ± 5.5 minutes; $p < .001$), and woke up one hour earlier than the good SQ group (mean= $6:10$ AM vs. $6:28$ AM; $p < .001$). Multivariable regression analysis indicated that worse SQ was significantly associated with higher pain interference ($\beta = 0.42$; 95% CI= $0.14-0.70$; $p = 0.004$), anxiety ($\beta = 0.48$; 95% CI= $0.16-0.80$; $p = 0.004$), depressive symptoms ($\beta = 0.49$; 95% CI= $0.19-0.80$; $p = 0.002$), and fatigue ($\beta = 0.60$; 95% CI= $0.14-0.70$; $p = 0.004$) ratings.

Conclusion: Poor self-reported SQ among healthy adolescent athletes is associated with more anxiety and depressive symptoms, fatigue, and pain interference ratings. When treating youth athletes, clinicians should consider assessing sleep hygiene and patterns in order to provide guidance on issues pertaining to reduced QOL.

Examination of Athletic Identity and Quality of Life Related to Sport Participation

Heather E. Key, Toni M. Torres-McGehee, Samantha R. Weber, Rachel Sharpe, Eva Monsma, Mike McCall. *University of South Carolina, Columbia, SC.*
 (No relevant relationships reported)

Athletes often develop athletic identities over time, which helps an athlete's performance and self-esteem during sport participation but can have negative repercussions once an athlete retires. Preparation for this loss is important in preventing negative mental health consequences and decreases in the quality of life.

Purpose: To examine overall quality of life and athletic identity (e.g., immediately after retirement and "now" in retirement) and determine differences across gender, sport type (team vs. individual), and number of years of participating in sport and number of years retired (e.g., 0-5, 6-10, 10-15 year, etc.). **Methods:** Retired athletes (n=125; ages: 29.1 ± 11.1 years; males: n=51; females: n=74) were recruited via convenience sample to participate in an online survey. Each participant completed at minimum of 4 years of high school sports, or ≥ 2 years of collegiate athletics, or ≥ 2 years of professional sports. The survey included demographic questions, the Athletic Identity Measurement Scale (AIMS) to measure athletic identity (immediately following sport and "now") and the Quality of Life Index (QLI). Basic descriptive, independent samples t-tests and ANOVAs were used. **Results:** A significant difference between gender and AIMS "now" in retirement was found (males: 31.2 ± 10.1 ; females: 26.4 ± 7.5 ; $P = .003$); but no differences were found between gender and QLI total, QLI subscales and AIMS "now" in retirement. No significant differences were found between team vs. individual sport and total QLI and both AIMS. A significant difference was revealed between number of years participating in sport and AIMS immediately following retirement ($P = 0.02$) and QLI-family subscale ($P = 0.014$). There was a significant difference between number of years retired and the QLI-family subscale ($P = .014$); with Tukey post hoc revealing significant differences between years 0-5 and 21-25 (6.08 ± 4.5 vs. 12.8 ± 2.2 ; $P = .018$). **Conclusion:** Those who played sports longer, had the strongest athletic identities upon retirement. Men are more

likely to maintain a strong athletic identity, even after retirement. Men and women are equally likely to exhibit a decrease in quality of life, in regards to family 25 years post retirement.

1080 Board #314 May 29 3:30 PM - 5:00 PM
Effect of Low Ph Magnesium-sulfate Foam on Night Leg Cramps: A Double-blind Randomized Trial

Toni Marie Torres-McGehee¹, Scott M. Strayer², Erin M. Moore³, Amber Williams¹, James Hardin¹, Samantha R. Weber¹, Allison B. Smith¹, Justin M. Goins¹. ¹University of South Carolina, Columbia, SC. ²University of South Carolina School of Medicine, Columbia, SC. ³University of South Florida, Tampa, FL.
 Email: torresmc@mailbox.sc.edu
 (No relevant relationships reported)

A large portion of the adult population suffers from night leg cramps (NLC); but there are few safe and effective treatment options. Magnesium oxide supplementation has been found ineffective; however, low pH topical foam with magnesium sulfate has not been examined. **Purpose:** Examine the effectiveness of a topical low pH foam with and without magnesium sulfate on NLC spasm frequency, severity/pain and the effects on activities of daily life. **Methods:** A double-blind randomized trial of 36 (females = 27, males = 9) adult participants (age: 52.0 ± 11.9 yrs.; weight: 94.8 ± 24.3 kg; height: 167.9 ± 9.0 cm; body fat%: 39.8%±12.3%) who experienced a minimum of 3-NLCs per week were recruited from local medical facilities in southeast region. Participants were randomized into 2 groups (Control [C] or Intervention [INT]) and completed a 14 consecutive day home-based treatment (Theraworx Relief®). Participants were given 5 bottles of foam (C or INT) to rub on their lower limbs twice a day and in the event of a cramp for the 14 days and completed surveys to assess frequency of NLC, pain levels, restless leg syndrome quality of life questionnaire (RLSQL) and the multi-dimensional fatigue inventory to assess social and daily function, sleep quality, and emotional well-being which were turned in at the end of each week. **Results:** The INT group had significant improvements in post-intervention: total social function ($P=0.02$), total daily function ($P=0.003$), total emotional well-being ($P=0.03$), and total RLSQL ($P=0.01$). Regression models also demonstrated significant improvement within the INT group in emotional well-being (-13.3; $P=.03$), total number of NLCs (-1.9; $P=.02$), and severity x frequency (-12.8; $P=.02$). The C group had significant improvements in daily (-11.5; $P=.03$) and social function (-10.9; $P=.04$). **Conclusion:** Theraworx Relief® with magnesium significantly improved quality of life as measured by domains on the total RLSQL. Although there was no difference in frequency and severity of NLCs between groups, we did see a significant reduction in NLCs within the intervention group. Few evidence-based treatments options are available for NLCs. Given the high prevalence of this condition and potential impact on health and well-being this treatment has the potential to improve health outcomes in patients who suffer with NLCs.

1081 Board #315 May 29 3:30 PM - 5:00 PM
Difference Between USI Humeroulnar Medial Joint Space Measurements Using Gravity-induced Vs. 3kg External Load Valgus Forces

Arie J. van Duijn¹, Shawn D. Felton², Jacqueline van Duijn¹. ¹Florida Gulf Coast University, Fort Myers, FL. ²Florida International University, Miami, FL. (Sponsor: Mitchell L Cordova, FACSM)
 Email: avanduij@fgcu.edu
 (No relevant relationships reported)

PURPOSE: Injuries of the ulnar collateral ligament (UCL) are a common pathology in overhead athletes. Ultrasound imaging is becoming a more common diagnostic tool to diagnose UCL pathology. Ultrasound imaging protocols have been described using external mechanical valgus forces to evaluate medial joint space (MJS) opening as an indicator of joint instability and UCL insufficiency. However, this external mechanical force is often poorly tolerated by athletes with acute injuries. A gravity induced valgus force is often better tolerated, however this method may potentially result in lesser joint space opening. The purpose of this pilot study was to examine differences in joint space opening measurements between these two methods of applying valgus force while performing ultrasound imaging. **METHODS:** Nine asymptomatic NCAA Division I collegiate baseball pitchers (age 20.1 ± 1.3 yrs) participated in this study. Ultrasound images were obtained of the MJS on the participant's throwing arm using a GE LOGIQ e ultrasound unit. Participants were placed supine with elbow position at 30 degrees, with a wedge placed underneath the humerus creating a gravity induced valgus force on the MJS. Ultrasound imaging measurements to evaluate MJS opening were performed from the apex of the trochlea to the apex of the ulna. A 3-kg valgus force, as measured by a hand-held dynamometer, was applied 20 cm distal to the medial epicondyle, and the imaging measurement was repeated. A paired t-test was performed to evaluate differences in joint space measurements between the two test protocols. **RESULTS:** There was no significant difference between the MJS

measurements (mean difference .005cm, $t = -.743$, $p = .479$) using the gravity-induced valgus method (mean opening .441cm, SD .074cm) and the 3kg external force method (mean opening .446cm, SD .071cm).

CONCLUSIONS: The results of this pilot study indicate that a gravity induced valgus force during ultrasound imaging of the UCL and MJS may yield similar joint opening compared to a mechanically induced 3kg external force. As external valgus force is often poorly tolerated in the presence of acute injury, gravity induced force may provide for an alternate method of evaluating medial joint space opening. Further research is recommended using larger sample size and symptomatic populations.

Comparison of Two Diabetic Education Programs Designed to Tread Adult-Onset Diabetes Mellitus

Judy R. Wilson, FACSM, Katelyn Wilson, Cynthia Trowbridge, Mark Ricard. University of Texas @ Arlington, Arlington, TX.
 Email: jrwilson@uta.edu
 (No relevant relationships reported)

INTRODUCTION: Diabetes mellitus or adult onset diabetes or type 2 diabetes, is the most common form of diabetes. Millions of Americans are diagnosed with type 2 diabetes every year, and many more are unaware they are at high risk.

PURPOSE: The purpose of this study was to compare the diabetic education programs of two certified diabetic dietitians, one with a focus on diet and the other with a focus on exercise, over 6 months, to determine which program was more successful in the treatment of type 2 diabetes.

METHODS: Forty participants were randomly selected and separated into two groups. The subject pool was limited to those using oral diabetic medications. All participants had an initial evaluation of body mass index (BMI), hemoglobin A1c, fasting blood sugar, waist circumference, and weight. These measurements were repeated again after three and six months of treatment for analysis. The exercise group and the diet group each included 10 males and 10 females. The exercise (E) group met with their trainer five times per week and the diet (D) group received information about choosing foods to limit impact on blood glucose. A 2 x 3 repeated measures ANOVA was used to determine the effects of an exercise vs diet program.

RESULTS: All participants completed their respective programs. The exercise group (10 males, 10 females) were 62.4 ± 8.6 yrs and the diet group (10 males, 10 females) was of 65.1 ± 9.8 yrs. The exercise group (31.9 ± 4.5) had a significant decrease ($p < 0.05$) in BMI at 6 months when compared to the diet group (29.5 ± 4.32). Measurements of A1c (E=6.94±0.7%; D=7.77±1.1%), fasting blood glucose (E=132.2±13.4 mg/dl; D=132.2±16.0 mg/dl), waist circumference (E=40.4±4.5 in; D=45.2±6.5 in), and weight (E=207.9±43.1 lbs; D=222±43.8 lbs) decreased in both groups over the six month study, however, the changes were accelerated in the exercise group resulting in significantly lower values.

CONCLUSION: After six months of either an intensive exercise regimen or diet regimen, there were significant decreases seen for all variables. However, the results for the exercise group were associated with accelerated decreases as compared to the diet group by a significant margin. Individualized exercise programs appear to be the most effective at controlling type 2 diabetes with the potential for decreasing the risk of other comorbidities.

Post-Meal Walking Improves Postprandial Glycaemia in Women with Gestational Diabetes Mellitus

Hannah Christie, Robin Pezzutto, Julie Kinsey, Monique Francois. University of Wollongong, Wollongong, Australia.
 Email: francois@uow.edu.au
 (No relevant relationships reported)

PURPOSE: To investigate the effects of post-meal walking (PMW) on glycaemic control in women with Gestational Diabetes Mellitus (GDM).

METHODS: Eighty women with physician-diagnosed GDM will be randomised to i) Control standard-care alone (CON), or ii) PMW in addition to standard-care, from weeks 28 to 36 of gestation. Participants in the PMW group were advised to perform 10 min of PMW after main meals, whilst the CON group were advised to perform 30 min of daily physical activity. Blood glucose was assessed using continuous Glucose Monitoring (iPro CGM) and physical activity, sedentary time and adherence was assessed using ActivPal accelerometers for 7-days at weeks 28 and 35 of gestation. Fasting glucose was measured from capillary glucometer measures each morning.

RESULTS: Preliminary data from nine women with GDM are presented (PMW n=5 and CON n=4). Postprandial, fasting glucose and physical activity did not

differ between the CON and PMW groups during the first 7-day monitoring period. Compared to baseline, the PMW improved the 3-h average glucose after breakfast (-0.35 mmol.L-1, p = 0.03) and lunch (-0.34 mmol.L-1, p = 0.01), enough to remain in target ranges for blood glucose (5.0 - 7.4 mmol.L-1). No difference was seen after dinner in the PMW group (-0.11 mmol.L-1, p = 0.22), due to reduced adherence (40%) to PMW after dinner. **CONCLUSIONS:** Preliminary data supports the notion that PMW can improve blood glucose levels after breakfast and lunch in women with GDM when adhered to, however the impact of dinner requires further research. PMW may be an effective adjunct to standard-care for the management of GDM in pregnancy.

Accuracy Of A Handheld Blood Glucose Monitor During Exercise And An Oral Glucose Tolerance Test

James R. Peterson, Davoncie M. Granderson, Clayton L. Camic, Peter J. Chomentowski, Steven M. Howell, Emerson Sebastiao, Northern Illinois University, DeKalb, IL. (Sponsor: Carl Foster, FACSM)

Email: jpeterson19@niu.edu

(No relevant relationships reported)

PURPOSE: The purpose of the present study was to examine the validity and reliability of a handheld blood glucose monitor during an oral glucose tolerance test (OGTT) and 60-minute bout of exercise.

METHODS: A total of 30 subjects (mean age ± SD = 22.3 ± 1.9 yrs; body mass = 77.6 ± 14.2 kg; height = 171.3 ± 9.6 cm; physical activity = 6.2 ± 4.3 hr·wk⁻¹) volunteered to participate in a single visit to the laboratory for an OGTT (n=15) or 60-minute treadmill exercise test (n=15). For the OGTT, the subjects were required to visit the laboratory in the morning following an 8-hour overnight fast and ingest a 75-gram load of glucose. For the treadmill test, the subjects were required to walk at 5.6 km·hr⁻¹ for 60 minutes. Blood glucose concentrations were measured from the fingertip at six different time points during the OGTT (0, 10, 20, 30, 60, and 90 min) and treadmill test (0, 5, 10, 15, 30, and 60 min). Each blood sample was analyzed four times at each time point, two by the reference method and two by the handheld monitor.

RESULTS: Our findings indicated that the blood glucose values provided by the handheld monitor were significantly (P < 0.05) greater than the reference method at all time points of the OGTT and treadmill test. In addition, the handheld device exhibited an overall mean absolute relative deviation (±SD) of 9.0 (±7.0) and did not meet the 95% accuracy requirements of ISO 15197:2013 (only 87.2% of all values met the criteria). The Bland-Altman plot for constant error (reference method - handheld monitor) versus the reference method indicated an average negative bias (CE = -8.2 mg·dL⁻¹) that increased (r = -0.23) at higher blood glucose values. Intra-device reliability analyses for the handheld monitor on two consecutive measurements taken at the same time points demonstrated the intra-class correlation (ICC) was R = 0.99 and coefficient of variation (CV) = 3.0%, with no mean differences between measurements.

CONCLUSIONS: The present findings indicated that the handheld monitor provided highly reliable, yet inaccurately high blood glucose values compared to the reference method during the dynamic conditions associated with an OGTT and exercise.

Effects of IT-based Interactive Exercise Education Program on Exercise Duration in Gestational Diabetes Mellitus Patients

Ah Reum Jung¹, Yoon Hee Choi², Dae Taek Lee¹. ¹Kookmin university, Seoul, Korea, Republic of. ²The Catholic University of Korea Seoul St. Mary's Hospital, Seoul, Korea, Republic of. Email: jal003@naver.com

(No relevant relationships reported)

Purpose : Adoption of Information Technology (IT) to promote and manage health behaviors in clinical settings is an emerging modality. This study investigates the effects of IT-based interactive exercise education program on exercise duration in Gestational Diabetes Mellitus (GDM) patients.

Methods : For 3 months long study, 49 pregnant women (33.6±3.3 yrs, 161±5 cm, 60.6±13.8 kg, and 23.4±5.1 kg/m², before pregnancy), who were diagnosed GDM at 24-28 weeks of gestation (100 g oral glucose tolerance test; 89±10, 186±26, 179±20, and 148±23 mg/dL, at 0, 60, 120, and 180 min, respectively), agreed to participate. Only those who met study criteria were included in the study. Prior to the study, they were educated how to use and record their on-line life log including exercise duration, intensity and types. They were recommended to participate in exercise program; aerobic activities for 20-30 min/d, a minimum of 150 min/week, at perceived exertion (RPE) of 11-13, and/or 40-60% of heart rate reserve, and strength training 2-3 d/week, 10-15 rep/set, and 2-3 sets. Based on the on-line communication frequencies, they were grouped as less frequent (LF, n=27, as <1 times/week) and highly frequent (HF, n=22, as ≥1 times/week). Statistical software SAS version 9.4 were used and statistical significance was set at p <0.05.

Results : A total of 5,947 life log from 49 participants were acquired. Approximately 88.5% of participants preferred walking as an aerobic exercise mode, and they walked at RPE of 11-13. The communication frequency was 4.5±4.3 times for LF and 24.3±19.4 times for HF (p<0.001). The daily exercise duration was 25.1±28.6 and 51.9±41.9 min/day (p<0.05), and weekly exercise duration was 164±177 and 356±271 min/week in LF and HF, respectively (p<0.05).

Conclusion : They met exercise recommendations in terms of exercise duration, intensity, and type. The frequent interactive communications between GDM patients and exercise professionals thru on-line using IT-based exercise behavior data may be effective for the GDM patients to exercise longer.

Exercise Stress Echocardiography and Myocardial Perfusion Testing in Pediatric Patients with Coronary Artery Anomalies

Malloree Rice, Wayne Mays, Sandy Knecht, Justine Shertzer, Andrea Grzeszczak, Devin Tinker, Adam Powell, Samuel Wittekind, Clifford Chin, Tom Kimball. Cincinnati Childrens Hospital Medical Center, Cincinnati, OH.

Email: Malloree.Rice@gmail.com

(No relevant relationships reported)

Introduction: Exercise stress echocardiography (echo) detects ischemic wall motion abnormalities. Exercise stress nuclear imaging (Mibi) detects perfusion abnormalities. We present results of Cardiopulmonary Exercise testing (CPET) with simultaneous echo and Mibi in pediatric patients with coronary artery anomalies, including those with other congenital heart disease. **Purpose:** To determine the yield of CPET electrocardiography with two simultaneous imaging techniques (echo and Mibi) in the detection of exercise-induced myocardial ischemia. **Methods:** Retrospective review of CPET with echo and Mibi results in patients with coronary abnormalities (CAA). CAA group was age, gender, and size matched to normals (Control) undergoing CPET only. CPET performed with a ramped cycle protocol with echo and Mibi images obtained at rest and peak exercise. Oxygen consumption (VO₂), carbon dioxide production (VCO₂) and respiratory minute volume (VE) were measured throughout exercise. Respiratory exchange ratio (RER), oxygen uptake efficiency slope (OUES), VE/VO₂ and VE/VCO₂ equivalents and VE/VCO₂ slope were calculated at anaerobic threshold (AT) and peak exercise. **Results:** No significant difference in Peak RER. Significant difference was seen in VE/VCO₂ slope and OUES at AT and VE/VO₂, VE/VCO₂ equivalents and VE/CO₂ slope at peak exercise. At peak, CAA group had 1 patient with significant ST segment depression, another had significant wall motion abnormalities and a third had a perfusion defect. No significant ST depression in the control group.

| CPET Results | | | | | | | |
|---|---------|--------------------|---------------------|---------------------------|----------|-------------|------------|
| | AT | Peak | | | | | |
| VE/VCO ₂ Slope | OUES | VE/VO ₂ | VE/VCO ₂ | VE/VCO ₂ Slope | OUES | RER | |
| Normal (n=9) | 20 ± 6 | 2672 ± 1164 | 32 ± 5 | 28 ± 5 | 25 ± 5 | 2501 ± 1110 | 1.21 ± 0.1 |
| CAA (n=9) | *27 ± 7 | *1617 ± 580 | **41 ± 8 | **34 ± 5 | **32 ± 5 | 1891 ± 681 | 1.16 ± 0.1 |
| Inter-group comparisons were made using an unpaired student t-test. *P<0.05, **P<0.01 | | | | | | | |

Conclusion: Both groups had similar exercise intensity. There were significant differences in VE/VO₂, VE/VCO₂ equivalents and VE/VCO₂ slope at peak exercise suggesting aerobic and ventilatory inefficiency in CAA patients. There was a significant frequency of ischemic response to exercise uncovered equally by each testing modalities. Combined use of Mibi and echo improves diagnostic yield in CAA patients with ischemia.

Cardiopulmonary Exercise Testing in Pediatric Idiopathic Bronchiectasis
 Ronen Bar-Yoseph¹, Michal Gur¹, Merav Zucker-Toledano¹, Gur Mainzer², Vered Nir¹, Lea Bentur¹. ¹Ruth Children's Hospital, Rambam Health Care Campus, Haifa, Israel. ²The Baruch Padeh Medical Center, Poriya, Israel, Poriya, Israel.
 Email: r_bar-yoseph@rambam.health.gov.il
 (No relevant relationships reported)

Abstract:

Introduction: Pediatric bronchiectasis etiologies consist mainly of cystic fibrosis (CF), primary ciliary dyskinesia (PCD) and idiopathic. Cardiopulmonary exercise testing (CPET) is gaining importance in clinical medicine and provides clinical insight into overall fitness, exercise limitations, disease prognosis, and therapeutic interventions. While there is growing data on exercise capacity using CPET in pediatric CF and PCD patients, studies on idiopathic bronchiectasis (IB) are scarce. **Purpose:** To compare exercise capacity using CPET in IB vs CF and PCD in pediatric population. **Methods:** Cross-sectional retrospective/prospective controlled study assessing CPET using cycle ergometer. Exercise parameters were compared. **Results:** Forty-two patients with bronchiectasis and 50 controls were evaluated; 12 IB (age 13.4 ± 3.4 y/o, FEV₁%predicted 84.3 ± 15.3), 9 PCD (11.7 ± 3.6 y/o, FEV₁%predicted 72.8 ± 23.5) and 21 CF (12.2 ± 3.2 y/o, FEV₁%predicted 80.7 ± 11.5). Peak oxygen uptake (peak $\dot{V}O_2$) was preserved in IB and CF groups vs. control (2104.0 ± 712.4; 1695.6 ± 537.3; 1937.8.0 ± 718.2 mL/min respectively) while PCD patients had decreased values (1315.0 ± 330.7) vs. IB and control (p < 0.005). Breathing limitation was found in all study groups vs. control; low breathing reserve (25% in IB; 52% CF; 33% PCD; 4% control, p < 0.02) and increased $\dot{V}E/\dot{V}CO_2$ (IB 29.1 ± 2.6; CF 32.1 ± 4.0; PCD 32.0 ± 4.4; control 27.2 ± 2.1, p < 0.015). Moreover, IB patients had lower $\dot{V}E/\dot{V}CO_2$ compared to CF patients (p < 0.03). **Conclusions:** CPET parameters may differ between IB and other bronchiectasis etiologies. IB pediatric patients demonstrated preserved exercise capacity and lower $\dot{V}E/\dot{V}CO_2$ compared to PCD and CF respectively. Larger longitudinal studies are needed to better study exercise capacity in different etiologies pediatric bronchiectasis.

Estimation of Ventilatory Thresholds in Physically Active Subjects During an Incremental Treadmill Test
 Romeu C. Silva, Jr, Robson Spolao, Domingos R. Pandelo, Jr, Alexandre Correia Rocha. FEFIS / CAP, Santos, Brazil.
 Email: romeuj7@gmail.com
 (No relevant relationships reported)

Purpose: The aim of the present study is to develop equations to estimate ventilatory thresholds (VT) 1 and 2 in physically active subjects. Such equations can be very useful for training prescription, since most physical education professionals and athletes do not have access to ergospirometric tests.

Methods: Fifteen physically active men, age 32.53 ± 11.83 years, with VO₂peak of 54.17 ± 11.74 ml / kg / min participated in the study. All volunteers underwent a progressive ergospirometric treadmill test, which was maintained at a one percent slope (to simulate the friction of a run on the street) and speed was increased by 1 km/h each stage (2 minutes). This incremental procedure was adopted until the subject reached fatigue. A gas analyzer and a heart rate monitor were used to measure VO₂peak. The gas analyzer has been calibrated as per manufacturer's specifications. Based on the results, a linear regression was used to estimate the speed in km/h of VT 1 and 2 as a function of the maximum speed (MS) reached, in km/h of the final heart rate (FHR), in beats per minute.

Summary of Results: The ventilatory threshold 1 was given by equation 1:

$$VT1 \text{ (km/h)} = 0.160 + 0.745 \text{ (MS)} - 0.004 \text{ (FHR)}$$

In the regression a R² of 0.86 (and an R of 0.94) was found, which can be considered a model with a good fit, as a function of the explained variance.

The ventilatory threshold 2 was given by equation 2:

$$VT2 \text{ (km/h)} = -1.043 + 1.054 \text{ (MS)} - 0.007 \text{ (FHR)}$$

In the regression, a R² of 0.94 (and an R of 0.97) was found, which can be considered a model with an excellent fit, as a function of the explained variance.

Conclusion: According to the results obtained, the proposed equations can be a very useful alternative for estimating ventilatory thresholds 1 and 2, constituting an important instrument, mainly for professionals who do not have access to laboratory measures, according to their applicability and assistance in planning and application of physical activity.

1089 Board #323 May 29 3:30 PM - 5:00 PM
Methodological Considerations for Calculating Ventilatory Efficiency from a Maximal Exercise Test in Apparently Healthy Adults
 James E. Peterman, Adam Grim, Leonard A. Kaminsky, FACS, Mitchell H. Whaley, Bradley S. Fleenor, Matthew P. Harber, FACS, Ball State University, Muncie, IN. (Sponsor: Matthew P Harber, FACS)
 (No relevant relationships reported)

The slope of the relationship between ventilation rate (V_E) and rate of carbon dioxide production (VCO_2) known as ventilatory efficiency (V_E/VCO_2 slope), is associated with mortality in clinical populations and may have prognostic utility in apparently healthy adults. Despite its prognostic potential, there is currently no standardized method for calculating the V_E/VCO_2 slope in apparently healthy adults. **PURPOSE:** To compare how different methods of data averaging influence the calculation of the V_E/VCO_2 slope from a maximal cardiopulmonary exercise test (CPX). **METHODS:** Two hundred seventy-two apparently healthy adults (49% female, age 44 ± 20 y, body mass index 27.1 ± 5.6 kg/m², VO_{2max} 33.3 ± 12.5 ml/kg/min) performed a maximal CPX to determine cardiorespiratory fitness. For each test, the V_E/VCO_2 slope was determined by commercially available metabolic software (ParvoMedics TrueOne 2400) calculating CPX data using time averages of 60, 30, 20, 15, and 10s, and also by averaging every 4 breaths. Pearson correlations and one-way analysis of variance with Dunnett's multiple comparison tests were used to examine differences between averaging methods. The criterion method was the 20s average. **RESULTS:** The different data averaging methods were all significantly correlated to the criterion (all P < 0.001; r = 0.99). However, in comparison to the criterion mean (29.6 ± 4.6), all other methods were significantly different (60s: 29.2 ± 4.6; 15s: 29.7 ± 4.7; 10s: 29.7 ± 4.7; 4-breath: 30.4 ± 4.9; all P < 0.001), with the exception of 30s averaging (29.5 ± 4.6; P = 0.22). The greatest difference from the criterion occurred with the 4-breath averaging method (mean difference -0.9; CI: -1.0, -0.8). **CONCLUSIONS:** The calculation of ventilatory efficiency is impacted by varying methods of data averaging. However, the differences between data averaging methods is small and future research is needed to determine if these differences influence the prognostic utility of ventilatory efficiency in this population.

1090 Board #324 May 29 3:30 PM - 5:00 PM
Comparison of Peak Cardiopulmonary Exercise Parameters in Recumbent Bicycle Versus Treadmill Exercise Testing
 Julie C. Fernie, Sonali S. Patel, Roni M. Jacobsen, Christopher M. Rausch. Children's Hospital Colorado, Aurora, CO.
 (No relevant relationships reported)

The recumbent bicycle (RB) is a novel exercise testing modality that has a patient exercise in a semi-supine position, allowing for increased echocardiographic imaging during exercise compared to a treadmill (TM) test. Previous studies have shown higher peak heart rate (HR) and higher VO₂peak measured on the TM versus an upright bicycle ergometer (UBE). More recent studies between RB and UBE demonstrate lower peak HR on a RB but no significant difference in VO₂peak on RB versus UBE. There are no studies that directly compare exercise parameters on the TM to those on a RB. **PURPOSE:** To determine if RB testing yields comparable maximal cardiopulmonary exercise results to the TM. **METHODS:** Patients with a history of non-progressive Kawasaki disease who performed a maximal Bruce TM test and RB test within two years per standard of care were evaluated. All tests were performed on the same metabolic system (MedGraphics). Group differences were evaluated with t-testing. **RESULTS:** Nine children completed maximal tests on both the TM and RB. There were no significant differences in age (TM 13.2 years ± 3.9, RB 14.7 ± 3.7, p = 0.4324), height (TM 154.2 cm ± 18.56, RB 161.6 ± 12.88, p = 0.3454) weight (50.3 kg ± 18.38, RB 55.2 ± 13.70, p = 0.5332) or BMI (TM 20.31 ± 4.22, RB 20.89 ± 3.47, p = 0.7550) between groups. There was no significant difference in peak HR (TM 194 ± 5.5, RB 186 ± 13.5, p = 0.1343) or VO₂peak (mL/kg/min; TM 47.68 ± 13.15, RB 45.21 ± 13.53, p = 0.7001) between modalities. There was no significant difference in anaerobic threshold (AT; TM 32.24 ± 13.11, RB 27.88 ± 10.26, p = 0.4602) or percentage of VO₂peak at which AT occurred (TM 67% ± 15, RB 62% ± 10, p = 0.4618). Peak respiratory exchange ratio (RER) was significantly higher on the RB (TM 1.02 ± 0.07, RB 1.11 ± 0.0175, p = 0.0175) and VE/VCO₂ was significantly higher on the TM (TM 27.63 ± 1.73, RB 22.18 ± 3.62, p = 0.0009). **CONCLUSION:** Exercise testing by RB yields comparable peak exercise parameters (HR, VO₂peak, AT, and AT percent of VO₂peak) compared to the TM despite a different body position. The significant difference seen in peak RER and VE/VCO₂ between modalities may be due to different positional body mechanics or small sample size.

Twelve-lead ECG and Echocardiography Evaluation in Division II College Athletes

Ludmila Cosio-Lima, Emily Grammer, Cameron Addie, Marisa Straughn, Lauren Adlof, Jeffrey Simpson, Youngil Lee, Amy Crawley
 University of West Florida, Pensacola, FL 32514
 The presence of cardiac abnormalities due to ventricular mass and volume has been documented in elite and Division I College athletes. Due to limited resources, cardiovascular screening among Division II College athletes is scarce or non-existent. **PURPOSE:** To examine ventricular remodeling through electrocardiographic (ECG) characteristics and focused echocardiography (FECH) in Division II college athletes. **METHODS:** Thirty six athletes (males = 18; females = 18) of different ethnicities (Caucasian = 60%, African American = 40%) from basketball (48%), soccer (27%), volleyball (9%) and football (16%) completed cardiovascular screening with a resting 12-lead ECG and focused echocardiography analysis. ECG abnormalities were compared with race, gender, and sports using a mixed model ANOVA. **RESULTS:** Although sports teams were not predictors for an abnormal ECG, 20% of the athletes presented with abnormal ECGs. The highest independent predictor of abnormal ECGs was found in African American males, when compared to Caucasians (65% vs. 32%; $p = 0.035$). African American male athletes had, on average, higher left ventricular mass indexes (72 ± 8 vs 66 ± 8 g/m²; $p = 0.008$), higher mass/volume ratio (1.01 ± 0.11 vs 0.98 ± 0.07 g/ml; $p = 0.002$), and higher QRS vector magnitudes (2.9 ± 0.5 vs 2.4 ± 0.4 mV; $p = 0.002$) than Caucasian male athletes. In addition African American athletes demonstrated a significantly greater prevalence of left ventricular hypertrophy compared to Caucasians male athletes (68% vs. 32%; $p = 0.04$) and all female athletes (72% vs. 21%; $p = 0.001$). **CONCLUSIONS:** African American male athletes at the Division II level present with increased concentric ventricular remodeling and ventricular voltage in comparison to Caucasian athletes of both genders. This highlights the need for a greater emphasis to be placed on cardiovascular screenings, specifically for African American males in Division II athletics, as a diagnostic tool to detect early warning signs of cardiovascular irregularities.

Hemodynamic Responses to an Exercise Stress Test in Parkinson's Disease Patients without Orthostatic Hypotension

Kirk B. Roberson¹, Joseph Signorile², Carlos Singer³, Kevin Jacobs, FACSM², Moataz Eltoukhy², Nicolette Ruta², Nicole Mazzei², Andrew Buskard². ¹Stetson University, DeLand, FL. ²University of Miami, Coral Gables, FL. ³University of Miami, Miami, FL. (Sponsor: Dr. Kevin Jacobs, FACSM)
 Email: kroberson1@stetson.edu
 (No relevant relationships reported)

The presence of postganglionic sympathetic denervation is well established in Parkinson's disease (PD). Denervation at cardiac and peripheral blood vessel sites may lead to abnormal cardiovascular and hemodynamic responses to exercise. **PURPOSE:** The aim of the present investigation was to examine how heart rate (HR) and hemodynamics are affected by an exercise test in PD patients without orthostatic hypotension. **METHODS:** Fourteen individuals with PD and sixteen age-matched healthy controls performed an exercise test on a cycle ergometer. HR, blood pressure, and other hemodynamic variables were measured in a fasted state during supine rest, active standing, exercise, and supine recovery. **RESULTS:** Peak HR and percent of age-predicted maximum HR (HRmax) achieved were significantly blunted in PD (MD=9, $p < .05$; MD=5, $p < .01$). HRmax remained significantly elevated in PD at minutes five (MD=7, $p = .03$) and ten (MD=6, SE=2, $p < .05$) of recovery, compared to controls. Systolic, diastolic, and mean arterial pressures were significantly lower at multiple time-points during active standing in PD compared to controls, but not a peak exercise. Systemic vascular resistance (SVRi) decreased significantly at the onset of exercise in PD compared to control (Stage 1: MD=-335.9, $p = .03$), and remained significantly lower during exercise (Stage 2: MD=-338.6, $p = .01$) and the first minute of supine recovery (MD=-328.6, $p = .02$). End diastolic volume (EDVi) was significantly lower in PD during supine rest (MD=-10.2, $p = .04$) and at minutes one (MD=-9.7, $p = .01$) and five (MD=-7.1, $p = .04$) of recovery. **CONCLUSIONS:** Our results indicate for the first time that normal hemodynamics are disrupted during orthostatic stress and exercise in PD. Despite significant differences in EDVi at rest and during recovery, and SVRi during exercise, cardiac index was not affected. Our finding of significantly blunted HRmax and HR recovery in PD patients has substantial implications for exercise prescription and recovery guidelines.

Influences Of Race And Body Composition On Vo2 Peak: Findings From The Activity Counseling Trial

Karrie Curry, Kershaw Patel, Colby Ayers, Ambarish Pandey, Jarett Berry. *UT Southwestern Medical Center, Dallas, TX.*
 (No relevant relationships reported)

Previous studies suggested blacks have lower estimated cardiorespiratory fitness (CRF) levels compared to whites, reflecting a higher burden of obesity among blacks. Lesser known are the joint effects of race and measures of obesity on directly measured CRF. **PURPOSE:** To characterize the impact of obesity [body mass index (BMI) and body fat percent (% fat)] on directly measured CRF in blacks and whites. **METHODS:** We included 874 Activity Counseling Trial participants (24.8% self-reported blacks) who completed maximal oxygen uptake (VO₂ peak) treadmill exercise test, BMI, and percent body fat, determined by skinfold measurement, at baseline. Linear regression models were constructed with VO₂ peak as the outcome and adjusted for age, sex, race, socioeconomic status, BMI, % body fat, and cardiovascular risk factors. **RESULTS:** VO₂ peak indexed to body mass was substantially lower in blacks (20.40 vs 26.70 ml/kg/min, $p < .0001$), reflecting higher indices of obesity in blacks (BMI: 32.73 vs 28.32, $p < .0001$; % body fat 36.58 vs 31.44, $p < .0001$). Similar findings were observed comparing absolute VO₂ peak (1919.18 vs. 2229.72 ml/min, $p < .0001$). In multivariable adjusted models, black race was strongly associated with both lower absolute and indexed VO₂ peak [Std. Beta (blacks vs. whites = -0.12 & -0.14 respectively $p < 0.0001$ for both)]. There was a significant interaction between race and both BMI ($p < .0001$) and % body fat ($p < .0001$) on indexed VO₂ peak. In race-stratified analyses, we observed a modestly weaker association between BMI and VO₂ peak in blacks (see Table). Similar findings were observed for % body fat. **CONCLUSIONS:** Directly measured VO₂ peak is lower in blacks reflecting a higher burden of obesity. Nevertheless, the impact of obesity on VO₂ peak is modestly greater among whites, suggesting excessive adipose tissue has a slightly more negative impact on VO₂ peak among whites.

Table: Association between measures of BMI, % body fat and indexed VO₂ peak in blacks and whites.

| | Blacks | Whites | Intercept p-value |
|------------|-----------|-----------|-------------------|
| | Std. Beta | Std. Beta | |
| BMI | -0.32 | -0.40 | <.0001 |
| % Body fat | -0.37 | -0.50 | <.0001 |

Influence of an Exercise Program on Cardiopulmonary Exercise Testing Derived Variables

Spencer M. Romanowski, Dylan S. Whetstone, Bradley S. Fleenor, Matthew P. Harber, FACSM. *Ball State University, Muncie, IN.* (Sponsor: Matthew P. Harber, FACSM)
 (No relevant relationships reported)

Cardiopulmonary exercise testing (CPX) has emerged as a useful tool in assessing disease severity and prognosis in clinical populations. Yet, little is known about the trainability of specific variables, aside from cardiorespiratory fitness (CRF), particularly in apparently healthy individuals. **PURPOSE:** The purpose of this study was to evaluate the changes in oxygen consumption at ventilatory threshold (VO₂ at VT), oxygen uptake efficiency slope (OUES), ventilatory power (VP; systolic blood pressure/VE/VCO₂ slope) and circulatory power (CP; peak SBP x VO_{2max}) which is a surrogate for cardiac power in apparently healthy adults following an exercise program. **METHODS:** Participants (n=79, 34 males/45 females, age 51.3±1.5 years, body mass index 29.0±0.7 kg/m²) performed a maximal VO_{2max} test before and after ~6 months of exercise training to determine VO₂ at VT, OUES, CP, and VP. Statistical analysis used were matched paired t-tests. **RESULTS:** VO₂ at VT (ml/kg/min) increased in the total sample (Pre: 19.8±0.4 vs. Post: 20.7±0.4, $p = 0.001$), males (Pre: 20.7±0.7 vs. Post: 22.3±0.8, $p = 0.0024$), and females (Pre: 16.9±0.6 vs. Post: 18.5±0.8, $p = 0.0003$). CP (ml/kg/min-mmHg) increased in the total sample (Pre: 5428.9±136.0 vs. Post: 5655.6±123.4, $p = 0.001$), males (Pre: 5790.1±294.7 vs. Post: 6254.0±243.3, $p = 0.0142$), and females (Pre: 4130.0±175.5 vs. Post: 4808.6±197.5, $p = 0.001$). OUES increased in males only (Pre: 2.3±0.1 vs. Post: 2.5±0.1, $p = 0.0013$). VP (mmHg) did not increase in any group. **CONCLUSION:** VO₂ at VT and CP can be altered with exercise training, independent of sex, while the adaptability of OUES appears to be sex-specific. Additionally, VP is not influenced by exercise training. Future research should explore the sex-specific response of CPX-variables to exercise training.

Dichotomy In The Mechanism Of Ramp-incremental Exercise Intolerance In Chronic Heart Failure

Carrie Ferguson¹, Matthew J. Davies¹, Jack O. Garnham¹, John Gierula¹, Maria F. Paton¹, Harry B. Rossiter, FACSM², Klaus K. Witte¹. ¹University of Leeds, Leeds, United Kingdom. ²Los Angeles Biomedical Research Institute at Harbor-UCLA Medical Center, Torrance, CA. (Sponsor: Dr Harry Rossiter, FACSM)
Email: C.Ferguson@leeds.ac.uk

(No relevant relationships reported)

Chronic heart failure (CHF) is a complex multifaceted disease that has wide ranging detrimental effects on each step in the delivery and utilization of O₂, irrespective of CHF etiology. Aerobic capacity (VO_{2peak}) is reduced and exercise tolerance is limited by fatigue and/or dyspnea. Exercise intolerance is the strongest predictor of mortality in CHF. Whether fatigue or symptoms is the primary mechanism of exercise intolerance in CHF is unknown.

PURPOSE: To use an innovative ramp-incremental cardiopulmonary exercise test (RI-CPET) to investigate whether fatigue or symptoms predominate as the mechanism of exercise limitation in CHF.

METHODS: Sixteen CHF patients (left ventricular ejection fraction (LVEF) = 28 ± 8 %) completed RI-CPET to intolerance that ended with measurement of maximal voluntary isokinetic power (MVIP) at VO_{2peak}. MVIP was measured during 4-5 s of maximal effort. At VO_{2peak} comparison of MVIP with peak RI-work rate (RI-WR_{peak}) identified fatigue (inability to increase MVIP above RI-WR_{peak}) or symptoms (MVIP > RI-WR_{peak}) as the primary mechanism of exercise intolerance. Breath-by-breath VO₂ was measured throughout.

RESULTS: At VO_{2peak} (n = 16; VO_{2peak} = 17.2 ± 5.2 ml·kg⁻¹·min⁻¹), MVIP was greater than RI-WR_{peak} (213 ± 132 vs. 109 ± 44 W; p = 0.002). However, two patterns of response emerged: (1) MVIP not different to RI-WR_{peak} (n = 6; 144 ± 66 vs. 115 ± 47 W; p = 0.547); (2) MVIP > RI-WR_{peak} (n = 10; 256 ± 145 vs. 105 ± 44 W; p = 0.002). There was no difference in VO_{2peak} (19.1 ± 4.9 vs. 16.1 ± 5.3 ml·kg⁻¹·min⁻¹; p = 0.268) or LVEF (28 ± 8 vs. 29 ± 7 %; p = 0.827) between these two sub-groups.

CONCLUSION: These data suggest that a maximum voluntary isokinetic measurement, at the end of a standard RI-CPET, may identify CHF patients in whom exercise intolerance is limited by the capacity of the neuromuscular system to generate power (the 'fatigue' group: MVIP ≤ RI-WR_{peak}) compared with those in whom exercise was limited with a substantial reserve in the power producing capacity of the neuromuscular system (the 'symptoms' group: MVIP > RI-WR_{peak}). This dichotomy in mechanism of RI-CPET exercise limitation was independent of VO_{2peak} or LVEF. This variability in the mechanism of exercise limitation, objectively identified using an innovative RI-CPET, may have implications for targeting treatment to optimize outcomes in CHF.

1096 Board #330 May 29 3:30 PM - 5:00 PM

6-minute Walk Work (6-mww) Better Correlates With Vo₂ Peak Than 6-minute Walk Distance (6-mwd)

G. Stephen Morris, FACSM¹, Alexandra Schumacher², Kevin Brueilly³, Reid Hayward⁴. ¹Wingate University, Wingate, NC. ²University of Northern Colorado, Greeley, CO. ³Augusta University, Augusta, GA. ⁴University of Northern Colorado, Greeley, GA.

Email: s.morris@wingate.edu

(No relevant relationships reported)

PURPOSE: Results from the 6-Minute Walk Test (6-MWT) are often used clinically as a surrogate measure of physiologic function (aerobic capacity) despite the fact that distance alone is not a determinant of work performed and hence not a measure of energy expenditure (Chung et al. Respir Med. 2001; 95: 618). Therefore, we hypothesized that expressing the distance covered during a 6-MWT relative to body weight (6-minute walk work, 6-MWW) would be more closely associated with VO_{2peak} than 6-MWT distance (6-MWD) alone

METHODS: 187 adult survivors of a variety of cancer types (115 females) underwent the validated University of Northern Colorado Cancer Rehabilitation Institute (UNCCRI) maximal exercise test, exercising to volitional fatigue. VO_{2peak} was estimated using ACSM walking equations. One week later subjects completed the 6-MWT as described by the American Thoracic Society (Am J Respir Crit Care Med. 2002;166:111). 6-MWW (m·kg) was calculated (6-MWD (m) X body weight (kg)). Means and standard deviations were generated for the variables of interest. Correlational analysis was performed to explore the relationship between 6-minute walk outcomes and estimated VO_{2peak}.

RESULTS: Subjects weighed 81.2 ± 23.7 kg, were 61.5 ± 13 years old, and covered 485 ± 107 m during the 6-MWT. 6-MWW averaged 38816 ± 12190 kg·m and cost 1.89 ± 0.68 L of O₂/min of activity. The correlation coefficient (r) between estimated VO_{2peak} and 6-MWD and 6-MWW were 0.479 and 0.758 respectively. Correlation

coefficients between gender and 6-MWD and 6-MWW were similar and moderate in males (0.517 and 0.537 respectively) and disparate in females (0.482 and 0.871 respectively).

CONCLUSIONS: The strong correlation between VO_{2peak} and 6-MWW suggests that this derived outcome measure provides a more clinically useful biomarker of physiologic status in a population of cancer survivors than 6-MWD. Because 6-MWD is a well-recognized biomarker of physical functional status, clinicians might report both 6-MWD and 6-MWW to create a more complete assessment of their patients with a history of cancer. The strength of these associations supports developing a predictive equation for VO_{2peak} based on 6-MWW. However, the gender disparity in r values supports the direct assessment of aerobic capacity rather than relying on a surrogate measure such as the 6-MWW.

Cancer Exercise Rehabilitation Training - A Case Study

Suzanne L. McDonough, Mississippi College, Clinton, MS.
Email: smcdonou@mc.edu

(No relevant relationships reported)

Cancer exercise therapy has been shown to increase physical function, reduce fatigue and build self-confidence. There is a gap in the research pertaining to the implementation of a cancer therapy program in a setting that would be effective and easily replicated. **PURPOSE:** The purpose of this study was to show the effectiveness of the implementation of cancer exercise therapy with a breast cancer survivor in a local fitness facility. **METHODS:** The Rocky Mountain Cancer Rehabilitation Institute (RMCRI) (Colorado, USA) has developed a protocol for the assessment and implementation of a cancer exercise rehabilitation program. RMCRI's protocol utilizes a "phase" system to guide the exercise prescription for each participant very similar to cardiac rehabilitation treatment plans. The guidelines were implemented by the exercise physiologist who conducted this research. Additionally, the researcher also sat for and passed the ACSM's Certified Cancer Exercise Trainer certification exam prior to conducting the training. The exercise session consisted of 60 minutes of resistance and flexibility exercises specifically prescribed for the patient. The patient's heart rate and oxygen saturation were monitored during each session. The study was for 16 weeks three times per week. **RESULTS:** A pre and post fitness assessment was administered to the patient. The largest improvements were found in balance, muscular strength, core stability, and cardiorespiratory fitness. Balance improved by 75%, core stability improved by 100%, and cardiorespiratory endurance (VO_{2peak}) improved by 16.7%. There were also large percent increases in 1RM for leg extension (70%), leg press (68%), shoulder press (64%), and chest press (29%). QOL index measures also increased 33% during the intervention. **CONCLUSIONS:** The results of this case study suggest that successful implementation of an exercise therapy program can be effective in a health and fitness center. With the growing number of cancer survivors there will be an increased need for the development of cancer exercise training that is easy to implement in a local fitness facility. This study shows the relative ease of implementation in a community based fitness facility.

C-06 Thematic Poster - Athlete Nutrition I

Thursday, May 30, 2019, 9:30 AM - 11:30 AM

Examination of Low Energy Availability and Macronutrient Intake among Male and Female Recreational Athletes

Stephanie A. McKeen¹, Toni M. Torres-McGehee¹, Erin M. Moore², Dawn M. Emerson³, Kelly Pritchett⁴, Allison B. Smith¹.
¹University of South Carolina, Columbia, SC. ²University of South Florida, Tampa, FL. ³University of Kansas, Lawrence, KS. ⁴Central Washington University, Ellensburg, WA.
(No relevant relationships reported)

Low energy availability (LEA) may be prevalent in both male and female recreational athletes and can be a catalyst for negative health consequences. **Purpose:** Examine the prevalence of LEA and macronutrient intakes (protein [PRO], carbohydrate [CHO], and fats) and differences between gender in recreational athletes. **Methods:** Data from a larger cross-sectional study was used to examine recreational athletes (n=103, age: 27.9±7.1 years; males: n=59, height: 175.3±9.5 cm, weight: 77.5±13.2 kg; female: n=44, height: 167.9±8.0 cm; weight: 71.4±15.2 kg). Athletes were moderately trained (exercised a minimum of 3-4 days/week. Data collection consisted of anthropometric data, surveys (eg, demographics, age, gender, etc.), resting metabolic rate, a 7-day online dietary log to measure energy intake (EI), and exercise logs to measure exercise energy expenditure (EEE). Basic descriptive stats, Chi-squares, and cross-tabulations were used to examine the proportion of participants classified as "at risk" for LEA (males: <20 kcal/kg/FFM; females: <30 kcal/kg/FFM) and met the micronutrient recommendation across gender. **Results:** Overall, 48.1% (n=50) of athletes demonstrated the following for males and females, respectively: LEA (26.0±10.4 vs. 28.4±14.9 kcal/kg/FFM; EI: 2287.9±943.4 vs. 1881.9±591.7 kcals, EEE: 589.8±399.1 vs. 423.1±199.8 kcals). Differences were found between LEA and gender (P<0.04), with females (28.8%) displaying higher risks than males (19.2%). No differences were found between LEA and PRO, CHO, or fat intake recommendations across gender. However, males overall consumed more than the recommendation for protein than females (15.5% vs. 11.7%; > 2 g/kg/day). Most recreational athletes (90.3%, n=93) reported low CHO intake (< 5 g/kg/day). Fat intake was adequately met by 64.1% (n=66) of athletes, however, 35.9% (n=37) of athletes with LEA consumed fats above the recommendation. **Conclusions:** Recreational athletes are moderately at risk for LEA. Most of these athletes demonstrated compromised low CHO intake compared to the recommendation, and despite LEA, over 1/3 of the athletes over consumed fat. Recreational athletes would benefit from proper nutritional education, specifically EI and macronutrient intake, which is necessary for proper nutritional fueling in recreational athletes.

1135 Board #2 May 30 9:30 AM - 11:30 AM

Examination of Low Energy Availability and Macronutrient Intake among Female Collegiate Athletes

Morgan M. Larson¹, Toni M. Torres-McGehee¹, Erin M. Moore², Kelly Pritchett³, Allison B. Smith¹. ¹University of South Carolina, Columbia, SC. ²University of South Florida, Tampa, FL. ³Central Washington University, Ellensburg, WA.
(No relevant relationships reported)

Low energy availability (LEA: ≤ 30kcal/kg/FFM) is one component of the Female Athlete Triad and is a catalyst for negative health consequence. Female athletes may be at increased risk for LEA due to a multitude of risks: individual judgments, body size expectations, uniforms, lack of nutrition knowledge or pathogenic behaviors. **Purpose:** Examine the prevalence of LEA and macronutrient intakes (protein [PRO], carbohydrate [CHO], and fats) and differences between sport type and academic status (e.g., freshman, sophomore, junior, senior) in female collegiate athletes. **Methods:** Data from a larger cross-sectional study was used to examine 75 Female collegiate athletes (age: 19.5 ± 1.3 years; height: 170.4 ± 6.8 cm; weight: 65.6 ± 8.8 kg) across various sports [beach volleyball (n=18), softball (n=17), equestrian (n=28), and indoor volleyball (n=12)]. Data collection consisted of anthropometric data, surveys (e.g., demographics, health history, etc.), resting metabolic rate, a 7 day online dietary to measure energy intake (EI) and exercise logs to measure exercise energy expenditure (EEE). Basic descriptive stats and Chi-squares and cross-tabulations were used to

examine the proportion of participants classified as "at risk" for LEA and across sport and academic status. **Results:** Overall, 92% (n=69) of athletes demonstrated LEA (13.3±11.9 kcal/kg/FFM, EI: 1490.2±437.3 kcals, EEE: 874.4±490.8 kcals). Differences were found between LEA and PRO intake for both sport type (p<0.04) and academic status (p=0.04), with most equestrian athletes and freshman not meeting protein recommendations (<1.2 g/kg/day). Most athletes (98.7%, n=74) reported low CHO intake (< 5 g/kg/day) with 90.7% (n=68) of athletes with LEA had inadequate CHO intake. Fat intake was adequately met by 64% (n=48) of athletes, however, 26.7% (n=20) of athletes with LEA consumed fats above the recommendation. **Conclusions:** Majority of female athletes demonstrated compromised LEA and macronutrient intake (CHO and PRO). Proper nutritional education, specifically EI and macronutrient intake, is essential for adequate health status and performance in athletes. Healthcare professionals should be aware of recommendations for proper dietary intake, be a resource for education, and implementation of proper nutritional fueling for female athletes.

1136 Board #3 May 30 9:30 AM - 11:30 AM

Athlete Iron Consumption: Timing Is Everything, But When Is Best?

Rachel McCormick¹, Diego Moretti², Alannah McKay¹, Dorine W. Swinkels³, Rachel vanSwelm³, Debbie Trinder⁴, Gregory Cox⁵, Michael Zimmerman⁶, Marc Sim⁷, Carmel Goodman⁸, Brian Dawson¹, Peter Peeling¹. ¹The University of Western Australia, Crawley, Western Australia, Australia. ²Laboratory of Human Nutrition, Institute of Food Nutrition and Health, ETH, Zürich, Switzerland, Switzerland. ³Radboud University, Nijmegen, Netherlands. ⁴University of Western Australia, Fiona Stanley Hospital, Murdoch, Western Australia, Australia. ⁵Bond University, Gold Coast, Queensland, Australia. ⁶Laboratory of Human Nutrition, Institute of Food Nutrition and Health, ETH, Zürich, Switzerland. ⁷Edith Cowan University, Joondalup, Western Australia, Australia. ⁸The Western Australian Institute of Sport, Mt Claremont, Western Australia, Australia.
Email: rmcormick@wais.org.au
(No relevant relationships reported)

PURPOSE: The influence of exercise timing on the subsequent inflammatory, hepcidin and iron absorption responses in endurance athletes was examined. **METHODS:** Sixteen endurance-trained runners (10 male, 6 female) with serum ferritin (sFer) < 50 µg/L completed a 90 min running protocol (65% vVO_{2max}) in the morning (AM), and the afternoon (PM), in a crossover design. An iron-fortified fluid labelled with stable iron isotopes (⁵⁷Fe or ⁵⁸Fe) was administered with a standardized meal 30 min following the exercise and control conditions during each trial, serving as a breakfast and dinner meal. Venous blood samples were collected pre-, immediately post-, and 3 h post- the exercise and control conditions for measures of sFer, Interleukin-6 (IL-6), and hepcidin-25. A final venous blood sample was collected 14 d after each trial to determine the erythrocyte iron incorporation. **RESULTS:** The immediate post-run levels of IL-6 were significantly increased from pre-run in both the AM and PM condition (both p=0.004). Hepcidin-25 levels increased 3 h following the AM run (p=0.012), returning to baseline by 12.5 h post-run. During the PM trial, hepcidin levels exhibited diurnal tendency, increasing from baseline to pre-run (p=0.002), before further increasing from pre- to 3 h post-run (p<0.001). Fractional iron absorption was greater at breakfast following the AM run, compared with both the rested condition (p=0.016) and dinner in the AM run trial (p=0.037). **CONCLUSION:** While exercise resulted in increased levels of inflammation and hepcidin, iron was best absorbed in the morning following exercise, indicating there may be a transient mechanism during the acute post-exercise window to promote iron absorption before the homeostatic regulation of hepcidin elevations become more influential.

1137 Board #4 May 30 9:30 AM - 11:30 AM

Evaluation of a Method to Rapidly Assess Beverage Intake in Collegiate Athletes

Samantha Kostelnik¹, Brittany Thorpe¹, Catherine Cockrill¹, Michelle Rockwell¹, Valisa Hedrick¹, Travis Thomas², Kevin Davy, FACSM¹, Brenda Davy, FACSM¹. ¹Virginia Tech, Blacksburg, VA. ²University of Kentucky, Lexington, KY.
(Sponsor: Brenda Davy, FACSM)
(No relevant relationships reported)

Fuel intake recommendations have been established for both general and athletic populations in order to promote adequate hydration. The Beverage Intake Questionnaire (BEVQ-15) is a food frequency questionnaire that rapidly measures habitual beverage intake and has been validated in children and adults. However, there is no beverage consumption questionnaire that has been validated in athletic populations.

PURPOSE: The purpose of this investigation is to evaluate the validity and reproducibility of the BEVQ-15 for determining habitual beverage intake in collegiate athletes.

METHODS: National Collegiate Athletic Association (NCAA) Division 1 collegiate athletes from a variety of sports from two universities in Virginia were recruited to participate. The study consisted of three sessions on nonconsecutive days within 2 weeks. At each session, the participants completed a 24-hr dietary recall, which was analyzed via NDSR. At the first and third sessions, participants completed the BEVQ-15. Validity was assessed using by comparing reported beverage intake determined by the BEVQ-15 to the average of three 24-hour recalls, using a Spearman's correlational analysis; reproducibility was assessed by comparing BEVQ-15 results from the two administrations, using a Pearson's correlational analysis.

RESULTS: Eighty-five collegiate athletes (60% female) participated in the study. Mean water and total beverage intake were 80.9±89.5 fl oz and 112.9±95.4 fl oz, respectively. Total beverage intake (fl oz, kcal) between the average BEVQ-15 administration and the recalls was associated (fl oz: $r=0.51$; kcal: $r=0.36$, both $p<0.01$). Correlations between the two BEVQ-15 administrations were significantly associated for water (fl oz: $r=0.80$; $p<0.01$) and total beverage intake (fl oz, kcal: $r=0.74$ and 0.77 , respectively; $p<0.01$).

CONCLUSIONS: These results suggest that the BEVQ-15 is a valid and reproducible method to assess water and total beverage intake in collegiate athletes. The BEVQ-15 is a practical tool (<5 minute completion time) which may be used to measure collegiate athletes' beverage intake. Additional research is needed to determine if the BEVQ-15 is sensitive to detect changes in athlete's beverage intake over time.

Dietary Intake Of Calcium, Magnesium, And Zinc In Female And Male Athletes

Maria S. Terry, Joseph R. Stanzione, Stella L. Volpe, FACSM.
Drexel University, Philadelphia, PA. (Sponsor: Stella L. Volpe, FACSM)

Email: mst83@drexel.edu

(No relevant relationships reported)

There are limited data on the micronutrient intake of athletes from various sports. Of particular interest are calcium (Ca), magnesium (Mg), and zinc (Zn) intakes among athletes due to their role in metabolic and physiological processes. **PURPOSE:** To determine differences in dietary Ca, Mg, and Zn intake among female and male runners (RN), triathletes (TA), CrossFit athletes (CF), rowers (CW), and general athletes (GA), 18 years of age and older. **METHODS:** This was a cross-sectional study, where 246 athletes (119 women, 127 men; 35±11 years of age) completed a food frequency questionnaire (FFQ) to determine average daily dietary micronutrient intake. We utilized one-sample t-test to compare dietary intake of Ca, Mg, and Zn in athletes with the Recommended Dietary Allowance (RDA) for each micronutrient. **RESULTS:** The results are shown in Table 1 below.

| Sex | Sport | n | Ca (mg) | Mg (mg) | Zn (mg) |
|-----|-------|-----|--------------------------------|-----------------------------|-----------------------------|
| F | All | 119 | 815.5±401.4 ($p<0.00001$) | 349.3±123.2 ($p<0.05$) | 10.1±4.1 ($p<0.00001$) |
| F | RN | 50 | 920±578.3 | 384.3±137.6 ($p<0.01$) | 11.3±5.3 ($p<0.001$) |
| F | TA | 19 | 845.7±317.7 | 345.6±156.0 | 10.8±4.5 ($p<0.05$) |
| F | CF | 10 | 809.2±151.4 ($p<0.05$) | 372.6±107.2 | 9.6±1.4 ($p<0.05$) |
| F | CW | 16 | 699.2±209.1 ($p<0.001$) | 320.1±97.9 | 7.9±2.2 |
| F | GA | 37 | 764.2±264.4 ($p<0.0001$) | 338.4±97.8 | 10.0±3.0 ($p<0.001$) |
| M | All | 127 | 971.9±429.3 | 405.8±173.3 | 13.4±6.0 ($p<0.0001$) |
| M | RN | 38 | 917.5±344.0 | 383.8±151.0 | 12.2±5.0 |
| M | TA | 27 | 1055±505.0 | 441.3±216.6 | 14.2±5.8 ($p<0.01$) |
| M | CF | 6 | 1015.5±691.6 | 336.7±124.3 | 13.2±5.9 |
| M | CW | 16 | 1154.0±474.2 | 477.9±179.7 | 16.6±7.0 ($p=0.01$) |
| M | GA | 23 | 802.8±297.1 ($p<0.05$) | 379.6±129.5 | 10.8±4.1 |

CONCLUSIONS: All female athletes combined reported Ca intakes significantly below the RDA, while Mg and Zn intakes were significantly higher than the RDA. Significantly low dietary Ca was revealed in female CF, CW, and GA. All male athletes combined reported Zn intakes significantly higher than the RDA. Male GA reported Ca intakes significantly lower than the RDA. Further research is needed to explore the effect of low Ca intake on athletic performance in female and male athletes. This study was not funded.

The Effect of Different Post-Exercise Beverages with Food on Voluntary Dietary Intake and Subsequent Performance

Danielle McCartney¹, Christopher Irwin¹, Gregory R. Cox², Ben Desbrow¹. ¹Griffith University, Gold Coast, Australia. ²Bond University, Gold Coast, Australia. (Sponsor: Louise Burke, FACSM)

Email: danielle.mccartney@griffithuni.edu.au

(No relevant relationships reported)

PURPOSE: Recent evidence suggests that different beverages promote similar fluid recovery but alter nutrient provision when consumed voluntarily with food post-exercise (Campagnolo et al., 2017; McCartney et al., In Press). However, when preparing to undertake another bout of exercise, individuals may exhibit different dietary behavior (e.g. to reduce gastrointestinal distress, optimize performance). This study investigated the effect of consuming water or a carbohydrate (CHO)-electrolyte sports beverage ('Sports Drink') *ad libitum* with food during a 4h post-exercise recovery period on fluid restoration, nutrient provision, and subsequent endurance cycling performance.

METHODS: On two occasions, 16 trained cyclists, 8 male (M) (age: 31±9y; VO_{2max} : 54±6mL·kg⁻¹·min⁻¹) and 8 female (F) (age: 33±8y; VO_{2max} : 50±7mL·kg⁻¹·min⁻¹), lost 2.3±0.3% and 1.6±0.3% of their body mass (BM) (respectively) during 1h of fixed-intensity cycling. Participants then had *ad libitum* access to either Water or Sports Drink (103kJ·dL⁻¹; 5.8g CHO·dL⁻¹) and food for the first 195 min of a 4h recovery period. At the end of the recovery period, participants completed a cycling performance test (45 min fixed-intensity pre-load and an incremental test to exhaustion [peak power output, PPO]). Beverage intake; water/nutrient intake; and indicators of fluid recovery (BM, urine output, plasma osmolality [P_{osm}]) were assessed throughout trials. **RESULTS:** Participants returned to a similar state of positive fluid balance prior to recommencing exercise, regardless of the beverage provided (Water: +0.4±0.5 L; Sports Drink: +0.3±0.3 L, $p=0.529$). While Sports Drink increased post-exercise energy (M: +1.8±1.0MJ; F: +1.3±0.5MJ) and CHO (M: +114±31g; F: +84±25g) intake (p 's<0.001), this did not affect subsequent endurance cycling performance (Water: 337±40W [M] and 252±50W [F]; Sports Drink: 340±40W [M] and 258±47W [F], $p=0.242$).

CONCLUSIONS: Recovery beverage recommendations should consider the post-exercise environment (i.e. availability of food), an individual's tolerance for food/fluid, the immediate requirements for refueling (e.g. CHO demands of subsequent activity) and the athlete's overall dietary goals.

A Pilot Nutrition Education Intervention with Division I Women's Basketball Players

Emily N. Werner, Alyssa Guadagni, James M. Pivarnik, FACSM.
Michigan State University, East Lansing, MI. (Sponsor: James M. Pivarnik, FACSM)

Email: enwerner34@gmail.com

(No relevant relationships reported)

Appropriate nutrition is important for both health and optimization of sport performance; however, many athletes do not have sufficient nutrition knowledge to engage in ideal nutrition practices. Few studies have been conducted to investigate the efficacy of a nutrition education intervention on athletes' nutrition knowledge, and even fewer have done so using a validated assessment tool. **PURPOSE:** To evaluate changes in nutrition knowledge of NCAA Division I women's basketball players after a sport-focused nutrition education intervention using a validated nutrition knowledge survey. **METHODS:** NCAA Division I women basketball players (N=8) completed a validated nutrition knowledge survey (Caella et al., 2017) that evaluated both general and sport nutrition. Athletes then participated in six, once weekly, 20-minute nutrition education sessions led by a Registered Dietitian. Topics included: hydration, carbohydrates, protein, fats, meal planning, and micronutrients/supplements. At the end of six weeks, the survey was re-administered. Scores were summed as +1 for a correct answer and +0 for no answer, an incorrect answer, a double-answer, or the "I don't know" option. Maximum possible score was 97. A paired-samples t-test was conducted to evaluate baseline versus follow-up scores. **RESULTS:** At baseline, athletes scored 40.5±18.0 out of 97 possible, 27.0±12.7 out of 64 possible, and 13.9±6.2 out of 33 possible for the total survey, general nutrition and sport nutrition sections, respectively. Significant average score increases were found for the total survey overall (62.2±11.7, $p=0.004$), within the general nutrition section (40.4±7.7, $p=0.015$), and within the sport nutrition section (21.9±5.9, $p<0.001$). **CONCLUSION:** The education intervention used in this pilot study succeeded in increasing nutrition knowledge of Division I women's basketball players. Future research should include intake assessments to determine whether eating habits improve after nutrition education.

This research was funded by the MSU College of Education via a Summer Research Fellowship.

The Importance of Iron Testing for D3 Cross Country Runners

Preston Kauder, Nathan Goslin-Klemme, Jake Till, Elaina Biechler. *Loras College, Dubuque, IA.* (Sponsor: Vincent Paolone, FACSM)
 Email: pkaud24@gmail.com

(No relevant relationships reported)

PURPOSE: Iron is an important mineral carried throughout the body, which helps carry oxygen rich molecules via hemoglobin. For endurance athletes, blood iron levels may be an important predictor of performance. Previous research has shown that iron absorption rates are lower in athletes in comparison to sedentary individuals. The purpose of the current investigation was twofold: first, to measure pre-season blood iron levels in division III collegiate cross country runners to determine if iron deficiency existed, and secondly, improve blood iron levels with a five week nutrition intervention for subjects classified as low.

METHODS: Capillary puncture was utilized to measure blood iron levels during the week of pre-season practice in division III male (N=26) & female (N=20) cross country runners. Athletes were classified as low iron if the males were below 13.0mg/dL, and 12.0mg/dL for the females. If subjects were classified as low, they received a nutritional pamphlet as an intervention, and were retested five weeks later.

RESULTS: The researchers classified 26.92% of males as iron deficient, and 5.00% of females as deficient. After retesting the deficient subjects, a paired t-test was utilized to determine if significant improvements in blood iron occurred following the five week intervention. A p-value of 0.002 (2-tail) was yielded showing a significant improvement in hemoglobin levels from pre-season in comparison to 5 weeks following the intervention (12.28 +/- 1.09, 13.94 +/- 0.25 respectively).

CONCLUSIONS: After a five week intervention, iron levels in those previously deficient, were significantly improved. Iron is a significant mineral for athletes, especially runners who are greatly dependent on oxygen for their performance. Thus, making sure cross country runners are educated on good nutritional habits, allowing them to maintain the said desirable blood iron levels is key to optimize their performance. Lastly, meeting the recommended guidelines for iron is vastly important, and educating athletes can result in a substantial improvement in blood iron levels.

C-07 Thematic Poster - Clinical Exercise Physiology: Exercise and Type 2 Diabetes

Thursday, May 30, 2019, 9:30 AM - 11:30 AM

Impact Of A Clinical Exercise Program On Trajectories Of Hba1c And Weight In Older Veterans

Jamie Giffuni, Rebecca Melvin, Bethany Lyons, Odessa Addison, Alyssa Stookey, Leslie Katzel. *Baltimore Veterans Affairs Medical Center, Baltimore, MD.*
 Email: jamie.giffuni@va.gov

(No relevant relationships reported)

Purpose Gerofit is a clinical exercise program for Veterans ≥65 years, originally developed at the Durham VA Medical Center and offered at the Baltimore VA Medical Center (BVAMC) since 2013. Veterans receive individualized exercise programs and participation in the program is voluntary. We assessed hemoglobin A1C (A1C) and weight changes in Veterans with a diagnosis of diabetes who completed one year of exercise training in Gerofit. **Methods** Older Veterans with primary care at the BVAMC were referred to Gerofit. Functional assessments included measures of weight and were used in conjunction with patients' personally identified exercise goals to develop comprehensive exercise programs including cardiorespiratory, strength, and flexibility training. Clinical chart reviews were conducted to determine A1C and weight one year prior to starting Gerofit, time of enrollment, and one year into participation. Initial program enrollment eligibility did not exclude for elevated A1C, but was later modified to include pre-program A1C ≤10%. Veterans could attend Gerofit exercise sessions up to 3 days per week. **Results** Forty-four Veterans with diabetes (43 male, 73.5 ± 5.6 years, 89% African American, BMI 32.9 ± 5.0 kg/m²) completed 1 year

of Gerofit. On average, both weight and A1C increased in the year prior to initiating Gerofit (A1C 7.2 ± 1.2 to 7.4 ± 1.5%, weight +1.2 lbs.). Overall A1C declined to 7 ± 1.1% (p <0.05) and weight by -.04 ± 41.5 (p= 0.73) 1 year into the program. Half the group (22/44) experienced a decrease in A1C, 2/44 had no change, and 17/44 increased A1C. The group that decreased A1C at 1 year started with a significantly higher A1C at time of enrollment compared to those that increased A1C at 1 year (7.8 ± 1.6% vs. 6.8 ± 1.2%). **Conclusion** Diabetic Veterans who participated in one year of Gerofit overall demonstrated a reversed trajectory of rising A1C and weight. Overall, the decline in A1C approached the clinically significant reduction of 0.5%. Those Veterans with a higher A1C at time of enrollment demonstrated a statistically and clinically significant reduction; reducing potential diabetes complications. Results demonstrate the importance of advocating for participation in a low level, multi-component exercise program for weight and diabetes management.

Long-term Changes On Bdnf And Igf-1 In Patients With T2dm - Training At Different Intensities

João P. Magalhães, Pedro B. Júdice, Megan Hetherington-Rauth, Duarte neto, Catarina Matias, Luís B. Sardinha. *Faculdade de Motricidade Humana, Universidade de Lisboa, Lisbon, Portugal.*

(No relevant relationships reported)

A growing body of evidence suggests that exercise can influence the central nervous system through circulating growth factors that can cross the blood-brain barrier. Among these factors are the brain-derived neurotrophic factor (BDNF) and insulin-like growth factor-1 (IGF-1), which work simultaneously to improve brain plasticity and functioning. However, the long-term effects of different exercise intensities on BDNF and IGF-1 in patients with type 2 diabetes mellitus (T2DM) have never been examined. **PURPOSE:** Examine the impact of a 12-month randomized controlled trial of combined high-intensity interval training (HIIT) with resistance training (RT) vs. a combined moderate continuous training (MCT) with RT, on circulating levels of BDNF and IGF-1, in patients with T2DM. **METHODS:** Patients with T2DM (n=80) were randomized into three groups (Control, HIIT with RT, and MCT with RT). Exercise training was performed 3 days per week for 12 months, while supervised by exercise physiologists. Resting serum BDNF and IGF-1 levels were measured at baseline and 12-months. Within- and between-group changes in BDNF and IGF-1 were assessed using generalized estimating equations were used.

RESULTS: After adjustment for sex and baseline moderate-to-vigorous physical activity, there was no significant between-group changes for both HIIT and MCT on BDNF (MCT: β=-0.05, p=0.474; HIIT β=-0.01, p=0.950) and IGF-1 (MCT: β=1.73, p=0.358; HIIT β=2.75, p=0.173) in the intention-to-treat analyses. With similar results, the per protocol analysis (>70% adherence to prescribed sessions) showed no significant changes for both MCT and HIIT on BDNF (MCT: β=-0.03, p=0.723; HIIT β=0.03, p=0.602) and IGF-1 (MCT: β=0.52, p=0.829; HIIT β=1.84, p=0.455).

CONCLUSIONS: These findings indicate that a 12-month intervention using a combination of HIIT with RT or MCT with RT had no significant impact on serum levels of both BDNF and IGF-1 in patients with T2DM. There is a heterogeneous and wide response to exercise on BDNF and IGF-1, especially when considering long-term interventions. Thus, future studies on the long-term effects of exercise are warranted to better understand the influence of these specific growth factors on brain health.

1145 Board #3 May 30 9:30 AM - 11:30 AM
Vascular Changes In Patients With T2DM Following 1-year Of Exercise, Irrespective Of Cardiorespiratory Fitness Improvement

Megan Hetherington-Rauth¹, João P. Magalhães¹, Pedro B. Júdice¹, Xavier Melo², Luís B. Sardinha¹. ¹Faculty of Human Kinetics, University of Lisbon, Lisbon, Portugal. ²Ginásio Clube Português, Lisbon, Portugal.

(No relevant relationships reported)

Micro- and macro-vascular changes occurring in patients with type 2 diabetes mellitus (T2DM) are major contributors to the development of cardiovascular disease, a leading cause of morbidity and mortality for these individuals. Increased cardiorespiratory fitness (CRF) from exercise training has been associated with improvements in metabolic and vascular health outcomes. Despite mean improvements in CRF from exercise training there remains a portion of participants having little or no improvement. **PURPOSE:** Given the importance of vascular function in people with T2DM, we assessed whether non-responders to CRF also failed to improve structural and functional arterial indices following a 1-year exercise intervention. **METHODS:** We assessed patients with T2DM (n=63) who participated in a three arm 1-year randomized controlled exercise intervention involving a control group, moderate continuous training or high intensity interval training combined with resistance training. Exercise responders were classified based on changes in CRF (ΔVO_{2max} ≥ 5%). Vascular structural and functional indices were measured using ultrasound imaging and applanation tonometry. Changes in vascular measures were compared

across control (n=22), exercise responders (n=15), and exercise non-responders (n=26) using generalized estimating equations. **RESULTS:** Compared to controls, both responders and non-responders had significant improvements in carotid intima-media thickness (responders: $\beta=-3.54$ [CI -6.40, -0.68], non-responders: $\beta=-5.59$ [CI -9.18, -2.01]) and peripheral arterial stiffness indices, such as carotid to distal posterior tibial artery pulse wave velocity (responders: $\beta=-0.16$ [CI -0.28, -0.04], non-responders: $\beta=-0.13$ [CI -0.24, -0.03]) and on the distensibility coefficient (responders: $\beta=0.00$ [CI 3.01e-5, 0.00], non-responders: $\beta=0.00$ [CI 1.41e-6, 0.00]), while only responders improved central arterial stiffness (carotid pulse wave velocity, $\beta=-0.06$ [CI -0.11, -0.01]). No improvements in the remaining vascular indices and hemodynamic variables were observed. **CONCLUSIONS:** Regardless of increasing CRF, a 1-year exercise intervention entails significant benefits for vascular function in patients with T2DM.

Influence of High Intensity Body-Weight Circuit Training in Adults with Type II Diabetes.

Brian Kliszczewicz, FACSM, Robert Buresh, FACSM, Emily Bechke. *Kennesaw State University, Kennesaw, GA.*
 Email: bkliszcz@kennesaw.edu

(No relevant relationships reported)

PURPOSE: To determine the effectiveness of a 15-week intervention of a minimal dose high-intensity bodyweight circuit (HIBC) program in persons with type 2 diabetes (T2D) on markers of metabolic function, autonomic balance, and body composition. **METHODS:** Three females (55±4yrs) and two males (64±1yrs) with T2D underwent assessments of glycosylated hemoglobin (HbA1c) and fasting plasma glucose (FG), insulin (INS), and lipids. Body composition was determined using dual-energy x-ray absorptiometry, aerobic fitness (submaximal treadmill test), blood pressure (SBP/DBP), and resting heart rate (RHR) were assessed. Participants completed 15-weeks of bodyweight circuit training (10 banded bodyweight squats, 5 modified pull-ups, 5 modified push-ups, 10 abdominal crunches). Participants completed as many cycles as possible in each session. Session duration progressed from 5-10 minutes, as tolerated, and session frequency progressed from 3-4 sessions per week. All assessments were repeated after 15 weeks of training. **RESULTS:** Body composition: Pre and Post changes in mean weight ($p = 0.395$), body fat % ($p = 0.632$), lean mass ($p = 0.372$). Aerobic fitness: estimated VO_{2max} ($p = 0.232$), SBP ($p = 0.062$), DBP ($p = 0.90$), RHR ($p = 0.727$). Metabolic biomarkers: FG ($p = 0.942$), HDL ($p = 0.271$), LDL ($p = 0.671$), HbA1c ($p = 0.810$), INS ($p = 0.762$). **CONCLUSIONS:** The HIBC did not appear to be effective in improving markers of metabolic function or health-related physical fitness in the five participants. However, when removing a singular outlying participant, several factors demonstrate substantial improvements in several outcome measures. HIBC may be an appropriate and appealing intervention for those with T2D.

1147 Board #5 May 30 9:30 AM - 11:30 AM
Effects of Novel Compression Exercise Technology on Glycohemoglobin Levels and Weight in Type II Diabetics

Chloe Wernecke¹, Richard Henderson², Cristian Torres¹. ¹Vaspar Systems, Moffett Field, CA. ²Covenant Medical, Lubbock, TX.
 Reported Relationships: C. Wernecke: Salary; Vaspar Systems.

The most potent lifestyle intervention for treatment of Type II Diabetes (T2D) is consistent exercise. However, for many patients with the condition, other comorbidities such as osteoarthritis, hypertension, and high body mass indexes prevent them from being able to exercise intensively and consistently enough to experience optimal metabolic benefits. Recent research has supported the use of compression exercise in physically limited populations and demonstrated physiologic responses at lower intensities (10-20% one repetition maximum vs. 70% for hypertrophic response in conventional resistance exercise). The combination of compression technology with core cooling further lowers the exertional requirements and has been used in cardiopulmonary rehabilitation populations to provide a safe and reliable exercise intervention. Compression exercise has also been shown to significantly increase muscle hypertrophy, with a greater growth in type II fibers (higher expressors of GLUT4). Therefore, this technology could directly address basal metabolism through increasing muscle protein turnover, increasing glucose storage in skeletal muscle mass, and improving glycemic control. This capacity to attenuate the insulin response combined with the accessibility of the platform suggests a clinical implication for diabetes management.

PURPOSE: To establish safe use of cooled compressive exercise in Type II Diabetics and to examine the effect of 6 months of training on biometabolic markers, especially Glycohemoglobin levels and weight.

METHODS: Thirty Type II Diabetics agreed to 3 training sessions a week for 6 months. Biometabolic markers via blood draw were analyzed at 0, 3, and 6 months.

RESULTS: Midpoint data from 16 participants at 0 and 3 months were analyzed with a two-tailed T-test, revealing significant differences in Glycohemoglobin and weight. There was an 8% average decrease in Glycohemoglobin levels (8.5±2.2 vs. 7.8±1.8 mg/dl, $p = 0.002$) and an average weight loss of 3.6 lbs (211±50 vs. 208±48 lbs, $p = 0.032$). **CONCLUSION:** The preliminary results of this study suggest exercise with compression and cooling contributes to a reduction in biometabolic markers of diabetes. This intervention has promise in contributing to effective management of T2D with a low physical burden.

1148 Board #6 May 30 9:30 AM - 11:30 AM
Impact Of Short-term Exercise Training And Diet On Glucose Effectiveness Between Prediabetes Phenotypes

Kara C. Anderson, Natalie Z.M. Eichner, Nicole M. Gilbertson, Emily M. Heiston, Steven K. Malin, FACSM. *University of Virginia, Charlottesville, VA.* (Sponsor: Steven K. Malin, FACSM)

(No relevant relationships reported)

PURPOSE: Although exercise improves glucose effectiveness (GE) in adults with type 2 diabetes, the influence of exercise on GE across the prediabetes phenotypes is unknown. Additionally, the impact of dietary intake on GE after an exercise intervention is limited. The purpose of this study was to examine the effect of short-term exercise training and habitual dietary intake on GE in adults with impaired fasting glucose (IFG) compared with IFG plus impaired glucose tolerance (IFG+IGT). **METHODS:** Female subjects (Age 59.4±7.2 yrs.; BMI 34.4±1.4 kg/m²) were screened for IFG (n=7, FPG: 103.9±2.3 mg/dl; 2-hr glc: 116.7±7.2 mg/dl) and IFG+IGT (n=10 FPG: 99.1±3.5 mg/dl; 2-hr glc: 152.9±11.0 mg/dl) using ADA criteria (120 min 75g OGTT). Subjects underwent 12 bouts of exercise at ~70% of HR_{peak} for 60 min/d over 2-weeks. A 180 min, 75g OGTT was used to collect glucose and insulin to determine GE via a validated minimal model before and after training. VO_{2peak} and body composition (BIA) were also tested. Energy expenditure during training was calculated using a linear regression equation based on VO_{2} and heart rate. Subjects were also asked to record their diet before and after the intervention using 3-d food logs.

RESULTS: Exercise training reduced BMI ($P < 0.05$), but had no effect on lean body mass (LBM) or VO_{2peak} ; and there was no difference in exercise energy expenditure in either group (all, $P > 0.72$). However, adults with IFG+IGT increased GE post-training (within effect; $P = 0.02$), and this rise in GE tended to be greater in IFG+IGT than IFG (0.23±0.08 vs. 0.00±0.08 mg/dl per min; $P = 0.059$). Increased GE correlated with elevated LBM ($r = 0.42$, $P = 0.09$), but not reduced BMI ($r = -0.08$, $P = 0.75$) or increased fitness ($r = 0.02$, $P = 0.95$). While dietary protein reduction was linked with increased GE ($r = -0.49$, $P = 0.05$), no association was seen between GE and carbohydrates ($r = -0.24$, $P = 0.37$), fat ($r = -0.17$, $P = 0.53$) or total kcal ($r = -0.23$, $P = 0.40$). **CONCLUSION:** Independent of weight loss and fitness, short-term exercise training increased GE in adult women with IFG+IGT but not those with IFG. The results also suggest dietary protein may modulate the exercise effect on GE. Future work is needed to examine how nutrition can optimize exercise induced glucose regulation in individuals with prediabetes.

1149 Board #7 May 30 9:30 AM - 11:30 AM
Effect of Weight Loss on Physical Function in Overweight and Obese Individuals

Jason M. Brown¹, Gary D. Miller². ¹Wake Forest Baptist Health, WINSTON SALEM, NC. ²Wake Forest University, Winston Salem, NC.

(No relevant relationships reported)

Impaired physical function is a major health concern in obesity across the adult lifespan. Reducing weight and improving body composition may be critical for improving physical function in overweight and obese adults. **Purpose:** Investigate physical function before and during weight loss and study the relationships of body composition with changes in physical function. **Methods:** Data were obtained from women (n=127, age 49.3±12.8 years; weight 101.8±17.9 kg; BMI 37.8±6.6 kg/m²) and men (n=17, age 54.4±10.1 years; weight 131.9±31.9 kg; BMI 40.5±9.9 kg/m²) enrolled in a medical supervised comprehensive weight loss program at Wake Forest Baptist Health Weight Management Center. Mean follow up was 6.7 months. Body composition, grip strength, gait speed, chair rise time, and submaximal VO_{2max} were determined before and at the end of follow-up. Paired samples t-tests analyzed changes between baseline and follow-up. Pearson correlations examined relationships between pre-and-post functional performance tests and fat free mass (FFM), and fat mass (FM). **Results:** Mean weight loss was 11.8±9.8 kg. Approximately 74.9% of weight loss was from fat mass: [FM (48.3±18.5 kg at baseline and 38.9±12.7 kg at follow-up, $p < .001$) and FFM (57.9±10.6 kg at baseline and 55.7±10.9 kg at follow-up, $p < .001$)]. Grip strength (29.3±8.1 to 32.9±11.2 kg, $p < .001$), chair rise time (9.1±2.9 to 7.8±2.7 s, $p = .018$), gait speed (1.2±0.2 to 1.3±0.2 m/s, $p = .001$), and submaximal VO_{2max} (32.7±3.9 to 34.7±4.5 ml/kg/min, $p < .001$) all improved from baseline to follow-up, respectively. Gait speed

($r = -.292, p = .005$) grip strength ($r = -.215, p = .041$) and chair rise ($r = -.273, p = .009$) changes were correlated with FM changes but not FFM changes. **Conclusions:** A comprehensive weight loss generally improves physical function. This improvement is possibly mediated by FM losses rather than FFM changes.

1150 Board #8 May 30 9:30 AM - 11:30 AM
Sex-Specific HbA1c Responses to Structured Exercise Among Patients with Type 2 Diabetes

Diana Devitskaya¹, Cynthia Villalobos¹, J. Mark VanNess¹, Paul D. Vosti², Alexis C. King³, Courtney D. Jensen¹. ¹University of the Pacific, Stockton, CA. ²St. Joseph's Medical Center, Stockton, CA. ³University of Illinois at Urbana-Champaign, Champaign, IL.

(No relevant relationships reported)

In the United States, 1 in every 9 adult women and 1 in every 8 adult men have diabetes; 95% of these cases are Type 2 diabetes. The efficacy of exercise training as an intervention for treatment is likely attributed to a combination of biological and environmental factors, including age, physical fitness, and sex. Despite the large number of exercise trials observing the effects of physical activity on Type 2 diabetics, few studies compare the benefits of the intervention exclusive to the participants' sex. **PURPOSE:** To evaluate sex-specific glycated hemoglobin (HbA1c) changes to structured exercise among males and females with Type 2 diabetes. **METHODS:** 24 males and 40 females with Type 2 diabetes were enrolled in an exercise program involving aerobic activity, resistance exercise, and flexibility training. At the initial evaluation, subjects underwent a health history exam, multiple assessments of physical fitness, cardiometabolic testing, and an assessment of HbA1c. Following 10 weeks of bi-weekly exercise sessions, participants that remained active in the program were reassessed. A repeated measures ANOVA with Greenhouse-Geisser correction compared HbA1c levels at baseline and follow-up between sexes. **RESULTS:** Subjects were assigned to "completers" (N=39) or "non-completers" (N=28) based on adherence to the exercise program. At baseline, HbA1c levels did not differ between completers and non-completers ($p = 0.234$). Sex was not related to completion of the trial ($p = 0.660$) or baseline HbA1c ($p = 0.117$). The repeated measures ANOVA found HbA1c to improve with exercise ($F = 7.878, p = 0.008$) and an interaction effect with sex ($F = 6.734, p = 0.014$) whereby males decreased more than females (0.61 compared to 0.02). **CONCLUSION:** In our sample, a structured exercise program induced greater reductions in HbA1c among male participants versus female participants. These findings help illustrate clinical importance for personalizing sex-specific exercise programs for persons at risk for or diagnosed with Type 2 diabetes.

C-08 Thematic Poster - Oxygen Uptake Kinetics

Relationship Between Muscle Deoxygenation And Workload At Peak Exercise In Healthy Adults Using Near-infrared Spectroscopy

Ashley M. Goodwin¹, Jacqueline Montes¹, Ipek Ensari², Feliz Marie Hernandez¹, Kayla Coutts¹, Ashwini K. Rao¹, Carol Ewing Garber, FACSM³. ¹Columbia University Irving Medical Center, New York, NY. ²Columbia University Data Science Institute, New York, NY. ³Teachers College, Columbia University, New York, NY. (Sponsor: Dr. Carol Ewing Garber, FACSM)
 Email: amg2310@cumc.columbia.edu

(No relevant relationships reported)

Near-infrared spectroscopy (NIRS) is used to investigate muscle oxygenation, but the association of muscle deoxygenation (deoxygenated hemoglobin, deoxy[Hb+Mb]; ΔHHb) to workload during exercise needs further study. **PURPOSE:** To characterize the relationship between the change in muscle deoxygenation (ΔHHb) and maximal workload (MW) achieved during maximal cardiopulmonary exercise test (CPET). **METHODS:** 6 men and 5 women (mean ± SD: 39.09 ± 17.2 years [age]) underwent CPET on a recumbent cycle ergometer. ΔHHb in the vastus lateralis muscle was measured using NIRS, and MW as recorded in Watts. A polynomial model ($\Delta HHb \sim MW + MW^2 + \text{peak oxygen uptake; } VO_{2,peak}$) was compared to a semi-linear regression model (with an added interaction term between $VO_{2,peak}$ and MW) to

characterize the relationship. **RESULTS:** ΔHHb during CPET was strongly correlated with peak workload (0.881, $p = 0.0003$) and $VO_{2,peak}$ (0.934, $p = 0.0001$). The polynomial model explaining the relationship was significant (Adj.R²: 0.821, $F(4,7) = 7.853, p = 0.009$); however, the point estimates were not. The semi-linear regression model was better able to characterize the overall trend (Adj.R²: 0.90, $p = 0.0002$) and the drop in ΔHHb at the higher ends of MW, and indicated that $VO_{2,peak}$ had a significant effect ($B = 54.9, p = 0.019$), and interacted with MW ($B = -0.157, p = 0.04$). **CONCLUSION:** These preliminary results show that the linear increase in ΔHHb with incremental workload appears to attenuate and slightly decrease at greater MW, especially for those with higher exercise capacity. Supported by NIH Grant K01HD084690-01A1.

1153 Board #2 May 30 9:30 AM - 11:30 AM
The Oxygen Mean Response Time At Different Ramp-Incremental Cycling Slopes.

Rafael de Almeida Azevedo¹, Danilo Iannetta¹, Daniel Keir², Juan Murias¹. ¹University of Calgary, Calgary, AB, Canada. ²University of Health Network, Toronto, ON, Canada.

(No relevant relationships reported)

During a ramp-incremental (RI) cycling exercise, the measurement of oxygen uptake ($\dot{V}O_2$) at the level of the mouth has a time delay from the onset of exercise, which is defined as the mean response time (MRT). It has been shown that the MRT is best calculated using the steady-state $\dot{V}O_2$ from a bout of moderate-intensity exercise prior to the RI test, and then matching this $\dot{V}O_2$ to the time at which this metabolic rate occurs during the RI test. Previous research has used RI slopes of 25 and 30 $W \cdot \text{min}^{-1}$ to measure the MRT. In this context, it is known that the $\dot{V}O_2$ to work rate relationship is affected by the slopes of the ramp, which might affect the duration of the MRT. However, there is no empirical data to support this assumption. **PURPOSE:** To determine the influence of different RI slopes on the MRT. **METHODS:** Six healthy young men (age: 28 ± 10 years; height: 179 ± 6 cm; weight: 72 ± 5 kg; $\dot{V}O_{2,max}$: 4.0 ± 0.3 $L \cdot \text{min}^{-1}$) performed six RI cycling tests with slopes of 5, 10, 15, 25, 30 and 100 ($W \cdot \text{min}^{-1}$). The ramp-incremental test was preceded by a moderate-intensity step-transition (i.e., 6 min at 20 followed by 6 min at 100 W), from which the steady-state $\dot{V}O_2$ could be determined before the ramp $\dot{V}O_2$ vs power output relationship was established. The difference between the power output at the steady-state $\dot{V}O_2$ and the ramp-specific power output at a similar $\dot{V}O_2$ was transformed into time to calculate the MRT. **RESULTS:** The MRT for 5 (11 ± 6 s), 10 (16 ± 11 s), 15 (22 ± 12 s), 25 (26 ± 11 s), 30 (32 ± 13 s) and 100 (25 ± 10 s) $W \cdot \text{min}^{-1}$ showed a significant main effect ($P = 0.001$). Post-hoc comparisons showed shorter MRT for 5 compared to 25 ($P = 0.025$) and 30 ($P = 0.001$) $W \cdot \text{min}^{-1}$, and for 10 compared to 30 ($P = 0.015$) $W \cdot \text{min}^{-1}$. **CONCLUSION:** Different ramp-incremental slopes directly influences the MRT, where it appears that MRT progressively becomes greater with steeper ramp slopes, until a certain level is reached (i.e., ~ 25 $W \cdot \text{min}^{-1}$) where there was no further lengthening of the MRT. From a practical perspective, less steep RI slopes will result in smaller adjustments in power output due to the shorter MRT. Thus, in RI slopes of 5 and 100 $W \cdot \text{min}^{-1}$ the power output adjustment would be ~ 1 and ~ 40 W, respectively.

Skeletal Muscle Oxygen Kinetics During Exercise In Adults With Obstructive Sleep Apnea.
 Jeffrey E. Herrick¹, Shirpa Puri², Monira Aldhahi², Vivek Jain³, Lisa MK Chin⁴. ¹University of Lynchburg, Lynchburg, VA. ²George Mason University, Fairfax, VA. ³George Washington University, Washington DC, DC. ⁴National Institutes of Health Clinical Research Center, Bethesda, MD.
 Email: herrick_je@lynchburg.edu
 (No relevant relationships reported)

Obstructive sleep apnea (OSA) is associated with persistent and progressive nighttime sympathetic nervous system (SNS) arousal strain in response to both hypopnea and apnea events. This repetitive strain of nighttime activation of the SNS may promote daytime hyperactivity, possibly limiting microvascular reactivity.

PURPOSE: The purpose of this study was to examine the on-kinetic profile of muscle deoxygenation during sub-maximal walking in adults with OSA.

METHODS: Twelve adults with OSA (age=48±10years, BMI=29±5kg/m², Apnea-hypopnea index (AHI)=50±24) and 12 healthy non-OA (NO) adults (42±8years, BMI=24±3kg/m²) completed two 6-minute bouts of submaximal exercise on a motorized treadmill, corresponding to 85% of anaerobic threshold. Using near-infrared spectroscopy (NIRS), concentration changes in deoxygenated hemoglobin-myoglobin (Δ [HHb]), was measured continuously from the left lateral gastrocnemius muscle. The two bouts were averaged to form a single Δ [HHb] response profile per subject. Indices of Δ [HHb] on-kinetics include the time constant (τ), Δ [HHb] amplitude (Δ [HHb]amp), and mean response time (MRT=time delay+ τ). In addition, the transition constant ($K_t = \Delta$ [HHb]amp/MRT) reflects the overall normalized rate of Δ [HHb] on-kinetics. Data were compared using age, BMI, gender, race, total physical activity and sleep duration as covariates for ANCOVA.

RESULTS: Both τ and MRT did not differ between the groups (OSA:19.8±8.2s, NO:19.4±4.4s, $p=0.835$; and OSA:28.9±7.2s, NO:24.4±5.9s, $p=0.515$ respectively). However, Δ [HHb]amp and K_t were lower in OSA compared to NO (OSA:2.8 ±2a.u., NO:8.7±5.3a.u., $p=0.011$; and OSA:0.101±0.07a.u./s, NO:0.354±0.17a.u./s, $p=0.002$, respectively). Further, the multivariate regression analysis showed that AHI was a strong predictor of and was negatively associated with Δ [HHb]amp as well as K_t ($p=0.015$ and $p=0.019$ respectively).

CONCLUSION: The lower normalized response rate of muscle deoxygenation may be reflective of impaired capability of the muscle to extract/utilize oxygen, which may contribute towards a decreased ability to sustain physical activity. Disease severity was also directly related to the normalized Δ [HHb] response rate, which has implications for physical activity participation in persons with OSA.

Gemfibrozil And Oxygen-hemoglobin Binding Affinity In Humans
 Chad C. Wiggins, Paolo B. Dominelli, Sarah E. Baker, John-Rodger A. Shepherd, Koji Uchida, Michael J. Joyner, FACSM. Mayo Clinic, Rochester, MN. (Sponsor: Michael J. Joyner, M.D., FACSM)
 Email: wiggins.chad@mayo.edu
 (No relevant relationships reported)

Exercise tolerance, in humans, is determined primarily by the diffusive and convective components of oxygen transport. Each of these can be acutely altered by changing the oxygen binding affinity for hemoglobin (right-shifting the oxygen-hemoglobin dissociation curve (ODC)). The tradeoffs associated with any acute shift in the ODC and the associated effects on O₂ transport are very context-dependent. Lipid-lowering drugs such as fibrates directly permeate the erythrocyte membrane and alter the hemoglobin molecule effectively lowering (right-shifting) the oxygen binding affinity to hemoglobin, in vitro. **PURPOSE:** To determine if fibrates (gemfibrozil) are effective in therapeutic doses, in vivo, at altering O₂ binding affinity for hemoglobin, and oxygen uptake kinetics during moderate intensity exercise. **METHODS:** Five volunteers (3M/2W, age= 32.3 ± 2.3 years, BMI = 23.5 ± 1.6 kg/m², $\dot{V}O_{2max}$ = 42.5 ± 4.2 ml/kg/min) completed a single study visit in which we measured oxygen binding affinity (P_{50} and Hill's n), and oxygen uptake kinetics during moderate intensity exercise (power output that elicited 40% $\dot{V}O_{2max}$) at rest and following two separate 1,200mg doses of gemfibrozil (administered approximately 2h apart). **RESULTS:** Gemfibrozil did not alter oxygen-hemoglobin binding affinity with either dose (Baseline P_{50} = 26.8 ± 1.4, Hill's n = 2.5 ± 0.1; Dose #1 P_{50} = 27.0 ± 0.7, Hill's n = 2.5 ± 0.0; Dose #2 P_{50} = 27.5 ± 1.1 Hill's n = 2.5 ± 0.0). Oxygen uptake kinetics during exercise at a power output eliciting 40% $\dot{V}O_{2max}$ were not different following the administration of either dose of gemfibrozil (Baseline $\Delta\dot{V}O_2$ = 0.88 ± 0.32 L/min, τ = 22.1 ± 9.7s; Dose #1 $\Delta\dot{V}O_2$ = 0.88 ± 0.31 L/min, τ = 21.5 ± 9.7s; Dose #2 $\Delta\dot{V}O_2$ = 0.90 ± 0.31 L/min, τ = 19.7 ± 8.2s). **CONCLUSION:** Therapeutic doses of gemfibrozil administered acutely are not an effective allosteric modifier of oxygen binding affinity for hemoglobin, in vivo, therefore, there were no changes in the O₂ kinetics during moderate intensity exercise.

1156 Board #5 May 30 9:30 AM - 11:30 AM
Comparison of Oxygen Uptake Kinetics Between Kidney Transplant Recipients and Healthy Subjects
 Alessandro Patti, Daniel Neunhaeuserer, Sara Ortolan, Fausto Roman, Lucrezia Furian, Veronica Baiocco, Sara Rovai, Andrea Gasperetti, Andrea Ermolao. Padua University-Hospital, Italy, Padua, Italy.
 Email: alessandro.patti@studenti.unipd.it
 (No relevant relationships reported)

Aerobic exercise capacity is reduced in kidney transplant recipients (KTRs), with a progressive improvement after transplantation. KTRs show central exercise limiting factors such as chronotropic incompetence, anemia, heart or vascular diseases. Moreover, peripheral alterations at a muscular level are present in this population. It has been reported that slower oxygen uptake ($\dot{V}O_2$)-kinetics during a moderate constant load exercise, expressed as an increased time constant (τ), may reflect an impaired muscular oxidative metabolism.

PURPOSE: To analyze the $\dot{V}O_2$ -kinetics in a population of KTRs.

METHODS: two groups of KTRs enrolled 3 and 12 months (n=21 and 14, respectively) after transplantation and a control group of healthy young adults (n=16) underwent cardiopulmonary exercise testing at cycle-ergometer. The protocol consisted in two subsequent constant, moderate-load exercise phases with a final incremental test until exhaustion.

RESULTS: The τ was increased in KTRs compared to controls (50.4±13.11 s at 3 and 43.84±11.57 s at 12 months vs 28.91±8.37 s in controls; both $P<0.01$) while $\dot{V}O_{2peak}$ was reduced, but significantly higher in the group evaluated at 12 months (21.30±4.34 vs 26.36±7.96 ml/kg/min ($P=0.04$), vs 41.7±7.82 ml/kg/min in controls (both $P<0.01$). Consistently with this result, an increased hemoglobin (Hb) concentration was found 12 months after transplantation (12.77±1.67 vs 14.55±1.74 g/dL ($P<0.01$)). Also, lower peak heart rate (HR) might affect KTRs' exercise capacity (79.67±12.16% of predicted at 3 and 84.29±11.49% at 12 months vs 93.38±5.21% in controls; both $P<0.01$). Among KTRs, the τ showed a moderate negative correlation with $\dot{V}O_{2peak}$ and oxygen uptake efficiency slope ($R=-0.51$ and $R=-0.57$, respectively), less depending on Hb and particularly on peak HR ($R=-0.33$ and $R=-0.13$, respectively). **CONCLUSION:** KTRs show slower $\dot{V}O_2$ -kinetics, reduced peak $\dot{V}O_2$ and HR when compared to a population of healthy young adults. $\dot{V}O_{2peak}$ and Hb seem to improve during the first year after transplantation. The reduced aerobic capacity of KTRs was associated with slower $\dot{V}O_2$ -kinetics, which seem to be less affected by the oxygen transport. These findings suggest that an impaired oxidative muscle metabolism could be a peripheral limiting factor contributing to decreased exercise capacity in KTRs.

1157 Board #6 May 30 9:30 AM - 11:30 AM
The Effect of Passive Stretch on Vascular Control during Exercise
 Lillie M. Huckaby, Andrew M. Alexander, Kaylin D. Didier, Shane M. Hammer, Camryn N. Webster, Thomas J. Barstow, FACSM. Kansas State University, Manhattan, KS.
 (No relevant relationships reported)

It has been demonstrated that daily stretching leads to an increase in blood flow to the skeletal muscle during exercise in rats; however, little is known about the effects of daily muscle stretching on adaptations of muscle blood flow in humans. **Purpose:** Therefore, the purpose of this study was to investigate the effect of passive stretch on vascular control (VC) during exercise. We tested the hypothesis that acute static stretch would not elicit changes in deoxygenated or total heme (deoxy-[heme], total-[heme] respectively) during exercise. Furthermore, we hypothesized that chronic stretch would elicit a decrease in oxygen extraction (deoxy-[heme]) through an increase in blood volume (total-[heme]). **Methods:** 4 healthy males (24.8 ± 3.6 yr, 179 ± 2.2 cm, 92.1 ± 7.8 kg) completed a controlled passive stretch of the plantar flexors. 2 subjects completed 2 days of a 30 min stretching protocol, while the other 2 subjects completed 2 days of a 10 min stretching protocol. Following the first two days of stretching, all subjects completed a moderate intensity (40% P_{peak}) plantar flexion constant load test to determine acute effects of stretching on VC. All subjects then continued with the 10 min stretching protocol for the remaining 5 days, resulting in 7 consecutive days of stretch. Following the 7th day of stretch, subjects completed another moderate intensity (40% P_{peak}) constant load test to determine the chronic effects of stretching on VC. Near-infrared spectroscopy was used to continuously measure deoxy-[heme] and total-[heme] during exercise. **Results:** Although no statistical differences were found, the 2 subjects who had completed the 30 min acute stretching protocol showed a marked decrease in deoxy-[heme] following acute stretching (5.13 ± 2.98 μ M to 1.40 ± 1.83 μ M), however no differences were observed in the 2 subjects who completed the 10 min acute stretching protocol. Following exercise in both the acute and chronic stretch protocols, no differences were observed in total-[heme]. **Conclusions:** The observed decrease in deoxy-[heme] lead us to believe that an acute static stretch of 30 minutes improves VC through better matching in the oxygen perfusion to extraction ratio during exercise. This VC enhancement was lost with chronic stretch, which could have been due to an insufficient stimulus on the microvasculature.

Oxygen Utilization During The Contraction-relaxation Of Isometric Knee Extension Exercise

Camryn N. Webster, Shane M. Hammer, Andrew M. Alexander, Kaylin D. Didier, Lillie M. Huckaby, Thomas J. Barstow, FACSM. *Kansas State University, Manhattan, KS.*
(No relevant relationships reported)

PURPOSE: Sufficiently high intramuscular pressures during contraction can lead to increased resistance to perfusive oxygen delivery and therefore increased fractional oxygen extraction in order to maintain muscle VO₂. Near-infrared spectroscopy (NIRS) has been used to estimate fractional oxygen extraction via deoxygenated heme concentrations (deoxy-[heme]) and changes in microvascular hematocrit via changes in total heme concentrations (total-[heme]). We tested the hypotheses that during severe and extreme intensities 1) deoxy-[heme] would decrease during contraction compared to relaxation and 2) total-[heme] would be unchanged during the contraction-relaxation cycle.

METHODS: Four subjects (2 men, 24.0 ± 3.7 yrs, 81.9 ± 27.4 kg, 168.9 ± 10.2 cm) completed two isometric knee extension tests to failure at 40% (severe) and 70% (extreme) MVC. NIRS was placed on the right vastus lateralis to continuously measure deoxy-[heme] and total-[heme] during relaxation and contraction. Deoxy-[heme] and total-[heme] were averaged during the final 5 contraction-relaxation cycles and compared using paired t-tests.

RESULTS: Average deoxy-[heme] during contraction and relaxation at 40% was 44.8 ± 31.8 μM and 44.4 ± 31.6 μM, respectively. Average deoxy-[heme] during contraction and relaxation at 70% was 41.9 ± 24.5 μM and 40.1 ± 23.6 μM, respectively. Average total-[heme] during contraction and relaxation at 40% was 127.0 ± 106.4 μM and 124.2 ± 105.2 μM, respectively. Average total-[heme] during contraction and relaxation at 70% was 116.0 ± 89.4 μM and 115.0 ± 90.5 μM, respectively. Although statistical significance was not detected (p=0.06), all four subjects demonstrated an increase in deoxy-[heme] at 70% MVC, but not at 40%.

CONCLUSIONS: These data suggest that the contraction-relaxation cycle may result in fluctuations in fractional oxygen extraction during extreme but not severe isometric exercise. Furthermore, the contraction-relaxation cycle does not appear to alter microvascular hematocrit.

C-09 Thematic Poster - Taking Steps to Improve Walking and Walkability

Thursday, May 30, 2019, 9:30 AM - 11:30 AM
Room: CC-102B

Step It Up! Prioritizing Community Supports for Walking in the United States

Eric T. Hyde, John D. Omura, Kathleen B. Watson, Janet E. Fulton, FACSM, Susan A. Carlson. *Centers for Disease Control and Prevention, Atlanta, GA.* (Sponsor: Janet E. Fulton, FACSM)
Email: mme7@cdc.gov
(No relevant relationships reported)

PURPOSE: *Step It Up! The Surgeon General's Call to Action to Promote Walking and Walkable Communities* (Call to Action) calls on Americans to be physically active and for the nation to better support walking and walkability. The Call to Action presents five goals, along with related strategies and actions, to support walkability in the U.S. Our study assessed U.S. adults' perceived presence and prioritization of four community supports for walking related to the goals of the Call to Action.

METHODS: Data from a nationwide sample of U.S. adults who completed the 2016 *SummerStyles* survey were analyzed (N = 4,043). Participants were asked to identify which of the following four supports that encourage residents to walk were present in their community: walking groups, safe streets, access to walkable locations, and promotional campaigns. Participants were also asked which of these supports should be of highest priority for their community to encourage walking. We calculated prevalence of the presence and prioritization of supports overall and by demographic factors. Adjusted logistic regression analyses were conducted to examine the association between presence and prioritization of each support.

RESULTS: Overall, 46.5% of adults reported access to walkable locations, 29.2% reported safe streets, 12.9% reported walking groups, and 9.6% reported promotional

campaigns. The prevalence of these supports varied by sex, age, education, income level, and physical activity level. Access to walkable locations and safe streets were the two supports most often reported together (13.6%). Access to walkable locations (60.0%) and safe streets (50.6%) were most often selected as highest priority for communities, followed by promotional campaigns (23.6%) and walking groups (18.8%). For all supports, positive associations were observed between having the support and rating it as highest priority (range of adjusted prevalence ratios: 1.57-2.53).

CONCLUSIONS: The most commonly reported community supports for walking in the U.S. are access to walkable locations and safe streets. In addition, these two supports are most often selected as the highest priorities to encourage walking in communities. Establishing community supports for walking and improving resident awareness of them may help promote walking among U.S. adults.

1161 Board #2 May 30 9:30 AM - 11:30 AM

Do Older Adults Achieve Moderate Intensity When Walking At Their Self-selected Pace?

Scott W. Ducharme¹, Elroy J. Aguiar¹, Aston K. McCullough¹, Christopher C. Moore¹, Colleen J. Sands¹, Marcos A. Amalbert-Birriel¹, Zachary R. Gould¹, John M. Schuna, Jr², Tiago V. Barreira³, Stuart R. Chipkin¹, Catrine Tudor-Locke, FACSM¹.
¹University of Massachusetts, Amherst, Amherst, MA. ²Oregon State University, Corvallis, OR. ³Syracuse University, Syracuse, NY (Sponsor: Catrine Tudor-Locke, FACSM)

(No relevant relationships reported)

Walking at a cadence of ≥100 steps/min consistently corresponds to minimally moderate intensity physical activity (PA). While current PA guidelines emphasize the importance of PA intensity for positive health outcomes, most young adults already naturally walk at cadences ≥100 steps/min. It is unknown whether older adults select these same cadences and intensities when they freely select their walking pace.

PURPOSE: To determine cadence and intensity of self-paced walking in older adults, and to evaluate the accuracy of using ≥100 steps/min to indicate moderate intensity in this population. **METHODS:** Twenty-six healthy, ambulatory older adults (10M,16W; mean±SD; age=68.3±4.8 years; height=1.67±0.08 m; mass=73.4±12.3 kg) walked continuously for 5min at their self-selected pace back and forth along a 13m pathway that included a 7m gait mat. Oxygen uptake (VO₂; mL/kg/min) was determined using indirect calorimetry and converted to absolutely-defined metabolic equivalents (METs; VO₂/3.5). Average cadence was quantified using the gait mat. Prevalence of cadences ≥100 and METs ≥3 was calculated as the number of participants above the respective thresholds divided by total participants (n=26). Classification Accuracy (ACC; true positive + true negative / total participants) determined the accuracy of ≥100 steps/min indicating ≥3 METs. **RESULTS:** The majority of participants (23/26, 83.3%) walked at a cadence ≥100 steps/min (cadence=113±9 steps/min), and many (20/26, 76.9%) achieved moderate intensity (METs=3.43±0.59). A cadence of ≥100 steps/min was a strong indicator of moderate intensity during self-paced walking (i.e., ≥3 to <6 METs, ACC = 80.8%). **CONCLUSION:** Most healthy older adults attain at least moderate metabolic intensity during self-paced walking. These findings further suggest that "going for a walk" can be recommended, even in the absence of specific PA intensity guidelines. However, these results are preliminary and include only healthy, ambulatory, and relatively young (i.e., only one participant >75 years old) older adults. Future studies should continue to explore self-paced walking in a more representative sample of older adults, and include more of the oldest adults (i.e., >75 years), or those with disease or ambulatory limitations. **FUNDING:**NIH-NIA-5R01AG049024

Association between the National Walkability Index and Walking Among U.S. Adults

Kathleen B. Watson¹, Geoffrey P. Whitfield¹, John V. Thomas², David Berrigan³, Janet E. Fulton, FACSM¹, Susan A. Carlson¹.
¹Centers for Disease Control and Prevention, Atlanta, GA.
²Environmental Protection Agency, Washington D.C., DC.
³National Cancer Institute, Washington D.C., DC. (Sponsor: Janet E. Fulton, FACSM)
Email: iyr4@cdc.gov

(No relevant relationships reported)

Step It Up! The Surgeon General's Call to Action to Promote Walking and Walkable Communities calls on Americans to work together to increase walking and improve walkability. No universal tool exists to measure community walkability; therefore, the Environmental Protection Agency created the National Walkability Index (NWI), a measure based on environmental features that affect the likelihood of whether people will walk as a mode of transportation. It is unknown, however, how strongly NWI is associated with transportation and leisure walking.

PURPOSE: To describe the association between the NWI and transportation and leisure walking among U.S. adults.

METHODS

We used data from the 2015 Cancer Control Supplement of the National Health Interview Survey (NHIS) to assess adults' past week participation in transportation and leisure walking for ≥10 minutes (n=33,672). NWI scores were linked to HIS data based on the block group of the respondent's residence. NWI scores were categorized into national level quartiles. Logistic regression analyses were used to describe the association between NWI quartiles and transportation and leisure walking.

RESULTS

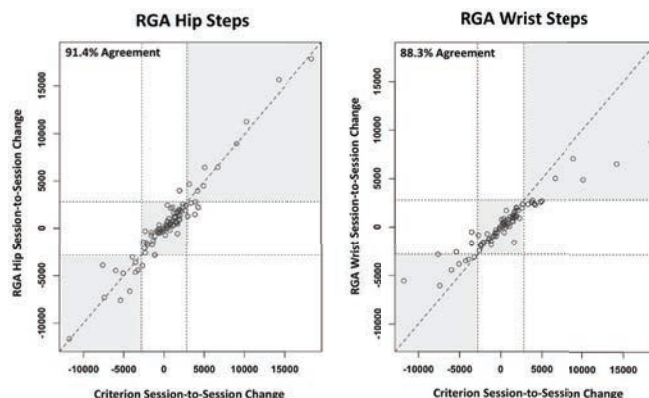

NWI quartiles exhibited significant linear and quadratic trends (p<0.05) with transportation walking and a significant linear trend (p<0.05) with leisure walking. Prevalence of transportation walking increased 23 percentage points and leisure walking increased 5 percentage points from least to most walkable communities (see Table).

| | National Walkability Index (NWI) | | | |
|-------------------------------------|----------------------------------|------------------------|------------------------|-------------------|
| | Least walkable | Below average walkable | Above average walkable | Most walkable |
| NWI range | (1.00-5.75) | (>5.75-10.50) | (>10.50-15.25) | (>15.25-20.00) |
| Transportation walking (% , 95% CI) | 24.5 (22.7, 26.5) | 27.7 (26.4, 29.0) | 38.0 (36.2, 39.9) | 47.7 (44.6, 50.7) |
| Leisure walking (% , 95% CI) | 49.5 (47.2, 51.9) | 52.5 (51.1, 53.9) | 52.3 (50.6, 54.0) | 54.9 (52.3, 57.4) |

¹Prevalence adjusted for sex, age, race/ethnicity, education, region, and rural/urban status
²NWI encompasses density, land use mix, and proximity to transit

CONCLUSIONS

NWI is a free and publicly available standardized tool to measure community walkability. Our findings suggest NWI is positively associated with transportation and leisure walking, although, the association was stronger for transportation walking. These findings may be useful to researchers and to public health, transportation, and planning professionals and other relevant stakeholders, as they promote transportation-related walking and walkability in communities.

CONCLUSIONS: These data show that RGA's worn on the wrist and hip are sensitive in detecting change in steps in free living settings and both detect changes in steps in free-living settings. This device can be employed for interventions designed to increase walking behavior.

Funded by: NIH: F31HL129802

A Research-grade Accelerometer Is Sensitive In Detecting Step Changes In Free-living Settings

Albert R. Mendoza¹, John Staudenmayer², Patty S. Freedson, FACSM². ¹California State University, East Bay, Hayward, CA. ²University of Massachusetts-Amherst, Amherst, MA. (Sponsor: Patty S. Freedson, FACSM)
 (No relevant relationships reported)

Research-grade wearable accelerometers (RGA) are valuable tools to monitor steps. Despite the broad appeal of such devices, there is limited evidence as to how well RGA detect change in steps in free-living settings. **PURPOSE:** To determine the sensitivity of RGA in detecting change in steps compared to changes in directly observed steps (criterion) in free-living settings.

METHODS: Thirty-two participants were directly observed and video-recorded on three separate days for 2-hours each day in free-living settings. Participants wore commonly used hip- and wrist-worn RGA's. Criterion steps were assessed using a validated direct observation (DO) method applied to the video recordings. Session-to-session step differences (session 1 - session 2, session 2 - session 3, session 1 - session 3) were calculated. Linear-mixed models were used to determine within-subject standard deviation of criterion measured session-to-session changes in steps and to identify significant changes in steps (greater than ±1 SD of within-subject SD). DO classified pairs of sessions for each participant based on whether steps changed (i.e., greater than ±1 SD of within-subject SD). The same classification method was applied to the RGA's and percent agreement between the two methods was then calculated.

RESULTS:

1164 Board #5 May 30 9:30 AM - 11:30 AM

Assessing Walkability By Questionnaires: Construct, Validity, And Reliability

Jingyuan Zhu, Zezhao Chen, Weimo Zhu, FACSM. *University of Illinois at Urbana-Champaign, Urbana, IL.*
 Email: jz5@illinois.edu
 (No relevant relationships reported)

PURPOSE: To determine the psychometrics of the walkability questionnaires, including their construct, validity, and reliability. **METHODS:** Using keywords "walkability," "measurements," "scales," "NEWS," etc., a comprehensive literature search was conducted, and identified questionnaires were reviewed and analyzed. **RESULTS:** Over 200 research publications were found and 27 questionnaires, including 14 different versions of Neighborhood Environment Walkability Scales (NEWS), focusing mostly on urban settings, were used for the final analysis. Ten key components were found in forming the construct of walkability, including residential density, land use mix-density, land use mix-access, street connectivity, walking/cycling facilities, aesthetics. Furthermore, 209 subcomponents were nested within the key components; e.g., "Residential Density" is consist of subcomponents of detached single-family residences, townhouses, apartments with different floors and so on. For validity, about 80% of questionnaires have reported it. The most used validation method (about 70%) was the "contracted groups", in which various levels of walkability and conditions neighborhoods were compared, with an effect size ranging from -0.65 to 3.81, followed by the correlational (with objective environmental attributes) approach (20%), with the validity coefficients ranging from 0.45 to 0.87. Finally, intra-rater/test-retest reliability was often (about 75%) computed for the reliability of the questionnaire, with a range from 0.25 to 0.99. **CONCLUSION:** A set of questionnaires with sound psychometric quality has been developed to assess the walkability in urban settings and more tools to evaluate walkability in a small community, rural settings are urgently needed.

1165 Board #6 May 30 9:30 AM - 11:30 AM

The Effect of Environmental Changes on Hospital Employee Walking Duration

Ryan Doyel, Joseph Dadabo, Prakash Jayabalan. *Northwestern University Feinberg School of Medicine / Shirley Ryan AbilityLab, Chicago, IL.*
 (No relevant relationships reported)

Purpose

Employee health is known to be associated with work-related physical exertion. The objectives of this study were to assess the effect on employee daily steps taken by transitioning a free-standing rehabilitation hospital to a larger facility and to compare step count differences across age, sex, and occupations.

Methods

Data from personal fitness devices linked to an employer-sponsored wellness program assessed the number of steps taken in two specific months (July and November) in the year prior to and in the year following the move to a rehabilitation facility three-times

THURSDAY, MAY 30, 2019

the size of the original. Participant data were only included for those enrolled in the program in these specific months pre- and post-move. Daily step counts accounted for activity both during and outside of work.

Results

Participants (n=70) had significantly less average daily steps for both July (9708 steps vs. 8008 p=0.02) and November (8839 vs. 7779 p=0.006) following the move to the new rehabilitation facility. Groups with significant step reduction included women compared to men (p=0.03), those aged 21-35 years (p=0.03), and the occupations of health care assistants (HCAs) and nursing (p=0.01), for both months. However, medical providers (physicians and nurse practitioners) had a trend towards increased step counts, regardless of age group or sex.

Conclusion

Transitioning a rehabilitation facility to a larger building does not necessarily lead to increased employee work-related physical activity. In our study, the transition to a larger facility was associated with a reduction in employee daily steps taken with relation to age, gender, and occupation. These findings may reflect strategic planning within the new workspace, which optimizes efficiency specifically for nurses and HCAs, allowing occupational duties to be confined to a smaller area. This could lead to employees having less daily work-related physical exertion, although this will be investigated further in future studies.

Perceived Neighbourhood Walkability and Different Types of Physical Activity in Canadian Men and Women**

Vikram Nichani¹, Chelsea Christie¹, Jennifer Vena², Christine Friedenreich¹, Gavin McCormack¹. ¹University of Calgary, Calgary, AB, Canada. ²Alberta Health Services, Calgary, AB, Canada.
Email: Gavin.McCormack@ucalgary.ca
(No relevant relationships reported)

Purpose:

Few Canadian studies have examined whether associations between neighbourhood walkability and physical activity differ by gender. We estimated associations between perceived neighbourhood walkability and physical activity among urban Canadian men and women.

Methods:

This study included cross-sectional survey data from the 'Alberta's Tomorrow Project' (2008; n=9101), in which the International Physical Activity Questionnaire captured weekly physical activity and the Neighbourhood Environment Walkability Scale abbreviated version (NEWS-A) captured self-reported neighbourhood characteristics. NEWS-A subscale scores were standardized and overall walkability scores computed. Sociodemographic characteristics were also captured. Covariate-adjusted generalized linear models estimated the associations between physical activity participation and minutes (transportation walking: TW, recreational walking: RW, moderate-intensity: MPA, and vigorous-intensity: VPA) and walkability scores. Odds ratios (ORs) were estimated for participation and beta coefficients (Bs) were estimated for minutes of physical activity, with 95% confidence intervals (95CIs).

Results:

Overall walkability was positively associated with participation in TW (OR 1.05; 95CI 1.04, 1.06), RW (OR 1.02; 95CI 1.01, 1.03), MVPA (OR 1.02; 95CI 1.01, 1.03) and VPA (OR 1.02; 95CI 1.01, 1.03) and minutes of TW (B 1.14; 95CI 0.59, 1.69). In men, positive associations were found between lack of parking and MPA participation (OR 1.14; 95CI 1.06, 1.23) and residential density and TW minutes (B 8.31; 95CI 2.85, 13.78). In women, RW participation was associated with land use mix diversity (OR 1.11; 95CI 1.04, 1.17) and infrastructure and safety for walking (OR 1.15; 95CI 1.09, 1.21) and MPA participation associated with traffic safety (OR 0.91; 95CI 0.86, 0.96). Notably, residential density was negatively associated with RW minutes among women only (B -3.69; 95CI -6.62, -0.76).

Conclusions:

Neighbourhood walkability is associated with participation and time spent in different physical activities for men and women. Modifying perceptions, possibly via improving neighbourhood urban design, has the potential to increase physical activity in Canadian adults.

US Vision Zero Plans: Opportunity to Support Safer Walking and Bicycling**

Kelly R. Evenson, FACSM¹, Carmen C. Cuthbertson¹, Rebecca B. Naumann¹, Samantha Schilsky¹, Camden Spade¹, Seth LaJeunesse². ¹UNC-Chapel Hill, Chapel Hill, NC. ²Highway Safety Research Center, Chapel Hill, NC.
(No relevant relationships reported)

Vision Zero is defined by a systems perspective to equitably reduce fatalities and serious injuries from road traffic crashes to zero. Recently, United States' (US) cities

began developing Vision Zero plans to address safety for all road users, including pedestrians/bicyclists. **PURPOSE:** We described the content of these plans to identify areas for improvement and facilitate creation of new plans. **METHODS:** We identified, collected, and analyzed 14 US Vision Zero plans published from 2014-2017. An extensive quantitative and qualitative coding tool was developed to identify elements of high quality plans. **RESULTS:** In total, 13 municipal and 1 county plan were abstracted. Nine of 14 plans described public participation in plan development, with 6 holding public meetings, 5 using surveys, 5 using map mark-ups, and 1 using social media. Most (n=13) plans had a vision statement and included goals/objectives to achieve the vision (n=12), but few included timelines to accomplish the goals (n=3). The goals to reach zero fatalities/serious injuries targeted the year 2020 (n=1), 2025 (n=3), 2028 (n=1), and 2030 (n=6), while 3 plans did not set a target date. All plans described the number of local-area crashes, but only half (n=7) reported the crash type, including involvement of a pedestrian/bicyclist. Plans included policy (11 traffic calming, 10 walking/bicycling to school, 9 Complete Streets, 5 no right turn on red), engineering (9 slow zones, 3 shared space for all road users), and educational (12 school education on pedestrian/bicyclist safety, 11 mass media/educational campaign on safety/speeding, 2 crosswalk ambassadors) strategies to address safety of pedestrians/bicyclists. Three of 14 plans proposed funding strategies for their implementation activities. Nine plans mentioned an evaluation plan for measuring progress, but most evaluation descriptions were brief. **CONCLUSION:** The assessment of US Vision Zero plans indicates that improvements could be made by involving the public more deliberately in plan development, including a clearer vision statement with connection to a target goal date and evaluation plan, and identifying funding sources for implementation activities. A number of target strategies could improve safety for pedestrians/bicyclists and should eventually be evaluated for their impacts.

C-10 Thematic Poster - The Spine and Spinal Cord Injury

(No relevant relationships reported)

Muscle atrophy and neuromuscular impairment are consequences of spinal cord injury (SCI) that impede quality of life and functional recovery.

PURPOSE: To examine time course changes in muscle fiber type distribution, fiber cross-sectional area (fCSA), and other histologic characteristics of muscle pathology occurring in rats in response to moderate-severe contusion SCI.

METHODS: Twenty-four 4-month old male Sprague-Dawley rats received SHAM surgery or T9 laminectomy plus moderate-severe (250 kilodyne) contusion SCI by a computer-guided impactor. Body weight and Basso-Beattie-Bresnahan (BBB) hindlimb locomotor rating scores were measured weekly. Animals were euthanized and soleus were harvested at 2-weeks, 1-month, 2-months, or 3-months post-surgery. Soleus fiber-type distribution, fCSA, and muscle-nerve bundle morphology were assessed by immunofluorescent staining, imaged using an epifluorescent microscope, and quantified with semi-automatic muscle analysis using segmentation of histology (SMASH).

RESULTS: At 1-week post-surgery, SCI animals exhibited near-complete hindlimb paralysis (indicated by BBB scores <3), with minimal improvement in voluntary hindlimb locomotor function thereafter. Body weight, soleus mass, and median fCSA were significantly lower in SCI vs SHAM animals (p<0.01 at all timepoints). A slow-to-fast fiber-type shift was observed in SCI animals, with a progressive ~20% decrease in the number of type I fibers, ~8% increase in type IIa fibers, and ~5% increase in hybrid type I/IIa fibers at each consecutive timepoint, along with the emergence of unstained type IIx/b muscle fibers (~30% of total) at 3-months. In addition, muscle fiber splitting was present in SCI animals at 2-months, as well as reduced

neurofilament staining in SCI muscle-nerve bundles. Furthermore, evidence of growth related remodeling occurred in SHAM muscles from increased centrally nucleated fibers across timepoints but not in SCI.

CONCLUSION: Deterioration in motor ability accompanying SCI produced muscle atrophy and progressive impairments in muscle oxidative capacity that may have resulted from repetitive denervation-reinnervation cycles. These factors may have contributed to muscle pathology resulting in limited capacity for muscle growth and remodeling.

Does Reduced Blood Flow Affect the Rate of Muscle Loss in Rats Post Spinal Cord Injury

Michael C. Reynolds, Christine F. Conover, Dana M. Otzel, Russell D. Wnek, Kinley H. Buckley, Micah Flores, Ean G. Phillips, Darren T. Beck, Danielle McCullough, Joshua F. Yarrow. *North Florida/South Georgia Veterans Healthcare System, Gainesville, FL.*

(No relevant relationships reported)

Muscle atrophy is a major sequela occurring after spinal cord injury (SCI) that results from disuse. Additionally, other secondary complications of SCI (e.g., alterations in muscle blood flow) may contribute to muscle loss. **PURPOSE:** To determine the time course of muscle blood flow changes in relation to muscle atrophy in a rodent severe contusion SCI model. **METHODS:** Sixty-three 4-months-old (skeletal-mature) male Sprague-Dawley rats received SHAM surgery (T9 laminectomy) or severe (250 kdynes) contusion SCI using a computer-guided impactor. At 1-, 2-, and 4-weeks (wk) post-surgery, an intravenous catheter was implanted into the tail vein of SHAM and SCI animals. Colored microspheres (15µm diameter) were then infused into the circulation, allowing for the measurement of regional blood flow (ml/min/g tissue mass). Subsequently, the animals were euthanized and the mass of the dissected right and left soleus, gastrocnemius, and plantaris were taken. Concentrations of the colored microspheres within each muscle were determined via spectrophotometry, following chemical digestion of the muscle. Muscle blood flow calculations were then averaged across the contralateral hindlimbs for the aforementioned muscles. SCI vs SHAM comparisons were made at each time point using independent samples t-tests and Pearson's correlation coefficients. **RESULTS:** SCI animals exhibited 23-41% lower soleus mass, 17-27% lower gastrocnemius mass, and 16-29% lower plantaris mass vs SHAM, at all time points ($p < 0.001$). Soleus and gastrocnemius blood flow (corrected for tissue mass, ml/min/g) was 51% lower ($p < 0.001$) and 25% lower ($p < 0.05$) after SCI, respectively, at 1-wk only. Additionally, a positive relationship between soleus mass and blood flow (corrected for mass) was identified at 1-wk ($r = 0.687$, $p < 0.01$). No significant alterations in plantaris blood flow were identified at any time point. **CONCLUSION:** Hindlimb muscle atrophy and reduced muscle blood flow occurred within 1-wk of severe contusion SCI. Thereafter, muscle blood renormalized in comparison with SHAM animals. Further research is needed to determine whether the reductions in muscle blood flow occurring after SCI contribute to muscle loss and/or whether prevention of blood flow deficits preserves muscle mass.

Effects of Activity-Based Rehabilitation on Cancellous Bone Loss Following Contusion Spinal Cord Injury in Rats

Russell D. Wnek, Christine F. Conover, Dana M. Otzel, Michael C. Reynolds, Kinley H. Buckley, Micah Flores, Ean G. Phillips, Joshua F. Yarrow. *North Florida/South Georgia Veterans Health System, Gainesville, FL.*

Email: rw_nek@yahoo.com

(No relevant relationships reported)

Severe cancellous bone loss occurs after spinal cord injury (SCI), which increases fracture risk. Bodyweight-supported treadmill training (TM) and passive Cycle training are activity-based rehabilitation therapies that improve neuromuscular plasticity after SCI. However, the skeletal adaptations to these therapies remain unknown.

PURPOSE: Determine whether TM or Cycle training alter the rate of cancellous bone loss in a rodent severe contusion SCI model. **METHODS:** 16-wk old male Sprague-Dawley rats received: 1) SHAM surgery (T9 laminectomy) (n=9), 2) T9 laminectomy plus severe contusion SCI (n=8), 3) SCI+TM (n=14), or 4) SCI+Cycle (n=7). TM and Cycle were initiated 1-wk post-SCI and consisted of two 20 min bouts/day for 3 wks. For TM, 40% bodyweight support was provided and the paralyzed hindlimbs were manually positioned into plantar stepping (3.5 m/min, increasing 0.1 m/min/day). For Cycle, the paralyzed hindlimbs were secured to pedals on a motor-driven bike and moved passively through a cycling motion that mimicked normal gait patterning (12 rotations/min). Distal femur cancellous bone was quantified before surgery (baseline), and at 2- and 4-wk post-surgery via *in vivo* microCT. Outcomes are reported as percent change from baseline. **RESULTS:** Across all groups, cancellous bone volume (cBV/TV) was reduced 52-75% at 2-wk and 54-84% at 4-wk, compared with baseline ($p < 0.01$). cBV/TV loss was 22% greater in SCI at 2-wk and 29% greater at 4-wk vs

SHAM ($p < 0.01$), characterized by 28% lower trabecular number (Tb.N) and 90% higher trabecular separation (Tb.Sp) ($p < 0.01$) and a higher trabecular pattern factor (Tb.Pf) ($p < 0.05$) that indicates a less connected trabecular network. At 2-wk, neither TM nor Cycle prevented SCI-induced bone deficits. However, at 4-wk SCI+Cycle displayed 25-30% higher cBV/TV, 23-24% higher trabecular thickness (Tb.Th), 17-22% higher Tb.N, and lower Tb.Pf vs SCI and SCI+TM ($p < 0.01$). Ultimately, no differences in cancellous bone outcomes were present between SCI+Cycle and SHAM at 4-wk, except for 16% higher Tb.Th in SCI+Cycle ($p < 0.01$). **CONCLUSION:** Our data indicate Cycle better attenuated cancellous bone loss in rodents after severe SCI. The higher cBV/TV and Tb.Th in SCI+Cycle at 4-wk also suggests that this modality stimulated bone formation; although, further investigation is needed.

1172 Board #4 May 30 9:30 AM - 11:30 AM
Trabecular Bone Integrity at the Proximal Tibia Following a Contusion Spinal Cord Injury in Rats

Aaron S. Gomez, Christine F. Conover, Ean G. Phillips, Taylor E. Bassett, Micah Flores, Russell D. Wnek, Joshua F. Yarrow. *Malcom Randall VA Medical Center, Gainesville, FL.*

(No relevant relationships reported)

Bone loss following spinal cord injury (SCI) is a major contributor to bone fracture risk, particularly at the proximal tibia. **PURPOSE:** To determine longitudinal changes in trabecular bone integrity at the proximal tibia in a rodent contusion SCI model. **METHODS:** 16-week old male Sprague-Dawley rats (n = 28) were randomized to receive no surgery (Non-Surgical Controls), T9 laminectomy (SHAM), or T9 laminectomy plus severe (250 kdynes) contusion SCI using a computer-guided impactor and were euthanized 2- or 4-weeks (w) post-surgery. Hindlimb locomotion was assessed weekly using the BBB locomotor scale and trabecular bone integrity at the proximal tibia was assessed weekly using *in vivo* microCT. Comparisons were made using one-way ANOVAs and post-hoc analyses were done when appropriate. **RESULTS:** SCI animals exhibited significant losses in hindlimb locomotor function [BBB score < 6 (0-21 scale); $p < 0.01$ vs SHAM at all time points]. Percent cancellous bone volume (cBV/TV) was 32% lower at 2-w and 42% lower at 4-w in SCI vs SHAM animals ($p < 0.01$). This bone loss was exemplified by progressively lower trabecular thickness (Tb.Th) and trabecular number (Tb.N) at 2- and 4-w ($p < 0.01$) and higher trabecular separation (Tb.Sp) ($p < 0.01$ at 4-w only). No differences in trabecular pattern factor (Tb.Pf), an inverse indicator of trabecular network connectedness, were present at 1-w. However, Tb.Pf was higher at 2- and 4-w in SCI vs SHAM ($p < 0.01$). Structure model index (SMI) was higher at 2- and 4-w in SCI vs SHAM ($p < 0.01$), indicating transition from rod- to plate-shaped trabecular spicules. Similarly, in SCI animals, cBV/TV was 48-75% lower, Tb.Th was 15-27% lower, Tb.N was 36-62% lower across the 4-w period in comparison with Non-Surgical Controls ($p < 0.01$ for all), while Tb.Sp was progressively higher in SCI animals ($p < 0.05$ for 2- and 4-w). Higher Tb.Pf and SMI were also found in SCI vs Non-Surgical Controls at all timepoints ($p < 0.05$). Only cBV/TV was lower in SHAM vs Non-Surgical Controls across the 4-w period ($p < 0.01$). **CONCLUSION:** Our findings indicate that trabecular bone integrity at the proximal tibia was significantly impaired in rats following a severe contusion SCI due to both bone loss and diminished bone quality. As such, our rodent model may be useful to examine effectiveness of strategies intended to prevent SCI-induced bone loss.

Testosterone and Resistance Training Improves Muscle Quality Following Spinal Cord Injury

Matthew E. Holman, Ashraf S. Gorgey, FACSM. *Hunter Holmes McGuire VA Medical Center, Richmond, VA.* (Sponsor: Ashraf S. Gorgey, FACSM)

Email: holmanme@vcu.edu

(No relevant relationships reported)

Spinal cord injury (SCI) adversely effects muscle quality and testosterone levels. Following SCI, resistance training (RT) has been shown to increase muscle cross-sectional area (CSA). Testosterone replacement therapy (TRT) in other populations has also been shown to improve muscle quality. **PURPOSE:** To examine if the combination of RT and TRT (TRT+RT) can maximize the beneficial effects to muscle quality following SCI. **METHODS:** Twenty-two SCI subjects were randomized into two intervention groups for 16-weeks: TRT+RT (n = 11), or TRT (n = 11). Muscle quality was assessed by measuring peak torque at speeds of 0, 60, 90, and 180°/sec (PT-0°, PT-60°, PT-90°, PT-180°), knee extensor CSA (KE-CSA), specific tension (ST), and contractile speeds (rise time [RTi], and half-time to relaxation [$\frac{1}{2}$ TiR]) for each limb prior to testing and following the intervention. 2x2 mixed models with subject identifiers added as random effects and post-hoc Tukey-Kramer HSD tests identified pairwise differences within interactions ($P < 0.05$). **RESULTS:** Following the intervention period, participants in the TRT+RT group increased PT-0° (48.4%, $P = 0.017$), KE-CSA (30.8%, $P < 0.001$), ST (8%, NS), and RTi (17.7%, $P = 0.012$). PT-0° decreased (17%, NS), KE-CSA slightly increased (10%, NS), ST decreased (20%, NS), and RTi also slightly decreased (9%, NS) in the TRT group. Changes to

PT-60°, PT-90°, PT-180°, and ½TIR for each group were similar following the 16-week intervention. **CONCLUSION:** Mechanical stress induced via RT combined with TRT maximizes enhancements of muscle quality when compared to TRT interventions alone in men with complete SCI. Our study shows that TRT+RT increases both muscle size, strength, and also improves muscle contractile properties.

1174 Board #6 May 30 9:30 AM - 11:30 AM
Intervertebral Disc And Vertebral Health In Long-term Runners

Ulrike H. Mitchell, Robert E. Larson, Jennifer A. Bowden, Bruce Bailey. *Brigham Young University, Provo, UT.* (Sponsor: Allen Parcell, FACSM)
Email: rike_mitchell@byu.edu
(No relevant relationships reported)

Intervertebral disc (IVD) and bone health is strongly associated with nutrient flow and loading. Running places repeated substantial axial forces on the lower back, which likely influence its tissue health. Two theories exist: 1) cyclic loading is correlated to improved IVD and vertebral health parameters, because it brings about hypertrophic changes that make the tissue stronger, and 2) mechanical overload produces localized trauma and tissue damage, which outpaces the tissue's ability to repair itself and leads to accelerated degradation. Both theories are based on sound research, but the implications contradict. **PURPOSE:** To determine if long-term runners exhibit different IVD and bone health parameters compared to matched sedentary controls. **METHODS:** 10 male runners with an average of 25 year history of running (average 84km/week) and 5 age and sex-matched sedentary controls received Magnetic Resonance Imaging (MRI) and DXA scans. MRI T1 and T2 imaging techniques were used to obtain morphological characteristics, including the level of disc degeneration (Pfirrmann grading system). Diffusion-weighted imaging was used to calculate the apparent diffusion coefficient (ADC), which represents a mean estimate of water diffusion. The DXA scan was used to obtain bone mineral density (BMD) of the lumbar spine and femoral neck. **RESULTS:** The groups were not different in age, height or weight, but in BMI ($p=0.03$) and total fat mass ($p=0.005$). On average the sedentary controls demonstrated significantly greater L5 vertebral heights ($p=0.009$). The runners exhibited greater L5/S1 mid-IVD height ($p=0.03$) and less disc degeneration, but this difference was not significant. There was no difference in ADC. There was no difference in BMD. There was no difference in Z-scores, but on average the runners' Z-score was below 0 in the lower spine and above 0 in the femoral neck, while this was reversed in the sedentary subjects. **CONCLUSIONS:** This small sample seems to indicate that long term running is correlated with better IVD morphology, but smaller lumbar vertebral height. Running is not correlated with significantly higher BMD. The latter might change with an increased subject number, as all the runners' BMD numbers are consistently higher in respect to femoral neck and shaft and consistently lower in respect to L1-L4 vertebrae.

Thorax and Spine Abnormalities in Health Sciences Students

Sergio Márquez-Gamiño, Karla S. Vera-Delgado, Cipriana Caudillo-Cisneros, Fernando Sotelo-Barroso, Montserrat G. Vera-Delgado. *Universidad de Guanajuato, León, Mexico.*
Email: smgamino@fisica.ugto.mx
(No relevant relationships reported)

PURPOSE: To evaluate trunk and thorax alterations prevalence in health sciences students.

METHODS: 293 recently admitted students to the Health Sciences Division of the University of Guanajuato, in Central Mexico, were clinically assessed for scapular girdle, spine alignment and thorax deformities.

RESULTS: In 208 women, and 85 men no previous diagnostic, symptomatology nor orthosis use were detected. Two of the participants had thorax asymmetry, corresponding to 0.7%. By contrast, 14.0% (41) presented dorsal hump. Also, the scapular girdle exhibited higher alterations indexes. For example, the shoulder blades were asymmetric in 19.5 (57) and 3.1% (9) for the right and left sides, respectively. Shoulders descended occurred in 23.5 (69), 4.4 (13), and 0.7% (2) (right, left, and both, in such order). Lumbar hump was observed in 45 (15.4%) students. No scoliosis was detected.

CONCLUSIONS: The structural problems detected involved the upper body and are quite important due to its implications for low back pain development. In fact, they can progressively evolve to cause nerve compression and its derived musculoskeletal conditions (MEC). In their practice, health professionals are exposed to risk behaviors for MEC, between others long standing periods, abnormal postures, patient's mobilization, etc. The information obtained can support new ways to train and physically fit the health sciences students as preventive measures for MEC development.

The Effectiveness of Acute Resistance Exercise Training among Young Adults with Analogue Generalized Anxiety Disorder

Brett R. Gordon, Mark Lyons, Matthew P. Herring. *University of Limerick, Limerick, Ireland.*
Email: brett.gordon@ul.ie
(No relevant relationships reported)

Evidence has supported positive effects of acute aerobic exercise and exercise training among adults with analogue and clinical Generalized Anxiety Disorder (GAD). However, the effects of acute resistance exercise (RE) are untested. **Purpose:** This study investigated the effects of acute RE, compared to quiet rest (QR), on worry among young adults with analogue GAD (AGAD) and otherwise healthy young adults (OH). **Methods:** Twenty-three young adults (25.3 ± 4.5 years; 15 female, 8 male) were block randomized by AGAD status (Psychiatric Diagnostic Screening Questionnaire GAD subscale score ≥ 6 , and Penn State Worry Questionnaire (PSWQ) ≥ 45) to acute RE or 30-min QR. RE consisted of two sets of 8-12 repetitions of eight exercises performed at moderate intensity in a laboratory, supervised by a researcher. Appropriate resistance for each exercise was determined following three weekly familiarization sessions prior to the acute RE. Worry was assessed at baseline and pre-post condition with the PSWQ. Two AGAD status X two Condition X two Time RM-ANOVA examined differences between RE and QR. Significant interactions were decomposed with simple effects analysis. Hedges' *d* effect sizes quantified magnitude of change. Potential moderation by sex, depression status, and sleep quality was also explored. **Results:** As expected, baseline worry was significantly greater among AGAD participants ($p \leq 0.001$). There were no baseline differences between conditions. The three-way interaction for worry was statistically significant ($F_{(1,19)}=18.50$, $p \leq 0.001$). Decomposition of the interaction showed a significant reduction in worry from pre- to post-RE for AGAD (mean difference = -2.86, $p \leq 0.04$), and a significant increase in worry from pre- to post-QR for AGAD (mean difference = 4.17, $p \leq 0.01$). Compared to QR, RE resulted in a large magnitude improvement ($d=0.98$) among AGAD participants. Among OH participants, there were no significant changes in worry in either condition. Worry response to RE was not significantly moderated by sex, depression status, or sleep quality (all $p > 0.05$). **Conclusion:** Preliminary findings support both positive effects of acute RE on worry, the hallmark symptom of GAD, and the need for future investigations of the acute and chronic effects of RE among participants with analogue GAD.

1178 May 30 9:45 AM - 10:00 AM
State Anxiety and Worry Responses to a Single Sprint Before and After Sprint Interval Training

Matthew P. Herring, Courtney Fregopoulos, Chloe Forte, Tom P. Aird, Brian P. Carson. *University of Limerick, Limerick, Ireland.*
Email: matthew.herring@ul.ie
(No relevant relationships reported)

There has been continued interest in the anxiolytic effects of diverse and non-traditional exercise modes. However, the acute and chronic effects of sprint interval training (SIT) on anxiety and worry are not well known, and the degree to which chronic SIT changes the acute response to a single sprint is untested.

PURPOSE: This study quantified state anxiety and worry responses to a single sprint (Wingate), state anxiety and worry responses to three weeks of SIT, and, the extent to which chronic SIT changed acute responses to a single sprint.

METHODS: Eighteen healthy young adult males (25.2 ± 3.6 y) completed a single 30s Wingate at 7.5% body mass before and after a 3-wk SIT intervention comprised of nine sessions of 4-6 sprints. Acute and chronic effects of SIT on state anxiety, worry, and worry engagement were assessed with the State subscale of the State-Trait Anxiety Inventory and the Penn State Worry Questionnaire, respectively. Paired *t*-tests quantified pre-training acute responses and training responses (i.e., baseline to post-SIT); magnitude of change was quantified with standardized mean difference (*d*). RM-ANOVA examined differences between pre-training and post-training acute responses. The magnitude of change in acute responses was quantified with Hedges' *d* effect sizes.

RESULTS: At pre-training, state anxiety was significantly increased ($t_{17}=-2.34$, $p\leq 0.032$) and worry engagement was significantly decreased ($t_{17}=3.14$, $p\leq 0.006$) following a single sprint. Small-to-moderate magnitude reductions were found for worry engagement ($d=0.37$) and worry ($d=0.18$), and a small-to-moderate magnitude increase was found for state anxiety ($d=0.36$). No statistically significant changes were found for state anxiety, worry, or worry engagement following SIT (all $p>0.23$); however, small magnitude reductions were found for state anxiety ($d=0.11$), worry ($d=0.26$), and worry engagement ($d=0.21$). Following SIT, a statistically non-significant small magnitude attenuation ($d=0.14$) of state anxiety response to a single sprint was found.

CONCLUSION: Findings provide proof of principle that even a single high-intensity sprint can acutely perturb state anxiety and improve worry. Short-term SIT may elicit improved resting levels of anxiety and worry and response to a single high-intensity sprint in healthy young men.

1179 May 30 10:00 AM - 10:15 AM

The Effects of a Physical Activity Program on Mood States in College Students

Lisa D. Powell¹, Erin J. Reifsteck², Pam K. Brown², Diane L. Gill, FACSM². ¹University of North Carolina, Greensboro, NC. ²University of North Carolina at Greensboro, Greensboro, NC.
Email: lisa.powell@cnu.edu

(No relevant relationships reported)

College students are at risk for adverse mental and physical health. Physical activity (PA) can reduce risks and promote positive mental health; however, less than half (49.9%) of college students meet the ACSM recommendations for PA (American College Health Association, 2017), reporting barriers such as lack of motivation, energy and time. Evidence-based, person-centered PA programs can overcome such barriers to enhance mood states and overall health. **PURPOSE:** To implement and evaluate a PA program (#cnubwell) designed to enhance mood states and promote continued PA in college students. **METHODS:** College students ($n=10$) participated in #cnubwell for 5 wks. Students completed pre and post measures of perceived health, PA (Godin), intrinsic motivation (IMI), and mood states (POMS2), and a post program evaluation. Additionally, participants recorded Feeling Scale (FS) and Felt Arousal Scale (FAS) ratings before, during and after each weekly PA session. **RESULTS:** Participants experienced significant ($p<0.05$) increases in positive feelings (FS) and energy levels (FAS) during each of the #cnubwell PA sessions. Intrinsic motivation increased from pre ($M=34.8$) to post ($M=37.4$), but the difference was not significant ($p>0.05$). Ratings of perceived health and mood states remained unchanged from pre to post. On the evaluations, participants reported feeling more autonomous, confident and connected; and that they enjoyed learning new workouts, exercising at their own pace/abilities (i.e., modifications provided), engaging in structured activities, and connecting with new people. **CONCLUSION:** While notable positive feelings and energy levels were experienced by the participants during the PA sessions, pre and post measures of perceived health and mood states did not differ. Confounding factors such as participant illness and campus mourning (i.e., deaths of two students the week before) may influence results. Also, the study was conducted from beginning to mid-semester, which is likely a more stressful time for students. Possibly, PA provided a coping strategy during those stressful times. Additional research with larger samples may provide greater insight into benefits of the program on mental health and wellness.

The Relationship Between Self-reported Lifestyle Habits and Depressive Symptoms in Older Adults 'At Risk' for Dementia

Bonnie A. Tran, Loren Mowszowski, Haley M. LaMonica, Sharon L. Naismith, Shantel L. Duffy. *The University of Sydney, Sydney, Australia.*

Email: bonnie.tran@sydney.edu.au

(No relevant relationships reported)

PURPOSE: Depressive symptoms are now well-established as an independent risk factor for dementia, however the association between health-related lifestyle habits and depressive symptom severity remains unclear. As such, this study aimed to investigate the relationship between self-reported physical activity levels, sleep behaviour and diet quality, and self-reported depressive symptoms in older adults 'at risk' for dementia. **METHODS:** Participants aged ≥ 50 years were recruited from the Healthy Brain Ageing Clinic at the Brain and Mind Centre, The University of Sydney, and underwent comprehensive psychiatric, medical and neuropsychological assessments. Self-reported symptoms of depression were assessed via the 15-item Geriatric Depression Scale. Participants completed questionnaires to quantify volume of physical activity, and to characterise sleep behaviour and diet quality. **RESULTS:** A total of 90 participants (mean age=66yrs) with subjective and/or objective cognitive impairment were recruited. Depressive symptoms were correlated with somnolence ($r=0.342$, $p=0.001$), greater symptoms of insomnia ($r=0.270$, $p=0.010$), larger meal portion size ($r=0.232$, $p=0.029$), and a lower intake of protective foods ($r=-0.355$, $p=0.001$).

Of note, a trend between a higher number of bouts of moderate intensity physical activity and lower depressive symptoms was observed but did not reach significance ($r=-0.208$, $p=0.052$). Based on significant univariate correlations and age, a stepwise multiple regression analysis was performed. The regression model was statistically significant [$R^2=0.286$, $F(3,86)=11.483$, $p<0.001$], and showed that age, somnolence and frequency of protective foods consumed each contributed 4%, 12% and 8% to the variance in depressive symptom severity, respectively. **CONCLUSIONS:** Outcomes of this study demonstrate that age, somnolence and the intake of protective foods account for a considerable proportion (28.6%) of depressive symptom severity in older adults 'at risk' for dementia. These results support recent research highlighting the benefit of non-pharmacological interventions for depressive symptom management. Further research looking at the longitudinal relationship, underlying mechanisms and the possibility of a bidirectional relationship is now warranted.

1181 May 30 10:30 AM - 10:45 AM

Active Older Women Differentiated RPE while Affective Responses Remained Stable During Spontaneous or Prescribed Walking

Maressa P. Krause¹, Sergio G. da Silva², André L. Peres¹, Liézer L. Cardoso¹, Fredric L. Goss, FACSM³, Robert J. Robertson, FACSM³. ¹Universidade Tecnológica Federal do Paraná, Curitiba-PR, Brazil. ²Universidade Federal do Paraná, Curitiba-PR, Brazil. ³University of Pittsburgh, Pittsburgh, PA.
Email: maressakrause@hotmail.com

(No relevant relationships reported)

Purpose: To compare psychophysiological responses and walking speeds between spontaneous, self-selected and prescribed conditions in elderly active women.

Methods: Seventeen older active women participated in this investigation (66.9 \pm 5.0 yrs). The study consisted of six experimental sessions of 20-min walking: 1. spontaneous (S) where subjects performed their usual walking speed unaware that research data were being collected; 2. self-selected (SS) where subjects were instructed to walk at their "preferred intensity"; 3. self-selected reproduction (SR) where subjects used the same instructions as SS; 4. Prescribed Exertion (PE) where subjects walked at easy (PEE), moderate (PEM) and hard (PEH) exertion. The last three sessions were counterbalanced. Psychophysiological (RPE - OMNI scale, and affective valence (AV) - Feeling Scale) and heart rate (HR) were measured immediately after exercise, and distance was recorded to calculate average walking speed. One way ANOVA examined differences in dependent variables between conditions and post-hoc Tukey tests were used to decompose significant main effects ($p<0.05$). **RESULTS:**

| Psychophysiological and WS across the different walking conditions (mean; SD) | | | | | | |
|---|---------------------|--------------------|--------------------|-----------------------|---------------------|-------------------------|
| | S | SS | SR | PEE | PEM | PEH |
| HR (bpm) | 130.5 \pm 14.6 | 136.2 \pm 7.7 | 138.9 \pm 6.0 | 114.8 \pm 7.3abc | 138.6 \pm 4.4d | 147.7 \pm 4.9abcde |
| AV (FS -5 - +5) | 4.6 \pm 0.6 | 4.8 \pm 0.3 | 4.6 \pm 0.5 | 4.6 \pm 0.5 | 4.5 \pm 0.5 | 4.8 \pm 0.4 |
| RPE (0 - 10) | 6.2 \pm 1.7 | 6.2 \pm 0.8 | 6.5 \pm 0.8 | 4.3 \pm 0.7abc | 6.1 \pm 0.8d | 8.4 \pm 0.6abcde |
| WS (m/s) | 1.42 \pm 0.15 | 1.43 \pm 0.12 | 1.43 \pm 0.10 | 1.14 \pm 0.09abc | 1.40 \pm 0.07d | 1.61 \pm 0.07abcde |

S: spontaneous; SS: self-selected; SR: self-selected reproduction; PEE: prescribed exertion-easy; PEM: prescribed exertion-moderate; PEH: prescribed exertion-hard. ^aDiffer from S; ^bDiffer from SS; ^cDiffer from SR; ^dDiffer from PEE; ^eDiffer from PEM (all $p<0.05$).

Conclusion: Active older women were able to discriminate between different prescription instructions designed to produce low, moderate and hard exertion. Interestingly, the spontaneous and self-selected intensities elicited similar walking speeds as the prescribed moderate exertion session. Public health strategies may use simple exertional cues to help guide individuals in producing moderate intensity exercise, which may lead to health-fitness benefits. The pleasurable feeling associated with this intensity may in turn improve exercise adherence.

Bodily Pain in U.S. Navy Explosive Ordnance Disposal Technicians: Exploring Biobehavioral Relationships

Trevor B. Viboch, D. Christine Laver, Lisa M. Hernández, Marcus K. Taylor, FACSM. *Naval Health Research Center, San Diego, CA.* (Sponsor: Marcus K Taylor, FACSM)

Email: trevor.b.viboch.ctr@mail.mil

(No relevant relationships reported)

Pain is a complex experience which may interact with biological, psychological, and social factors. Evidence supports a relationship between bodily pain and depression in which one may augment the other. This connection was shown in U.S. Marines

but not yet studied in U.S. Navy Explosive Ordnance Disposal (EOD) Technicians. Characterizing EOD and understanding these interactions is a key aspect of managing warfighter health and performance.

PURPOSE: The primary purpose is to assess bodily pain and medication (med) use in EOD Technicians. The secondary purpose is to evaluate associations between bodily pain and biobehavioral correlates, such as depression, anxiety, and posttraumatic stress disorder (PTSD). **METHODS:** Eighty-four EOD Technicians self-reported bodily pain (0–10 scale), pain med use, and symptoms of depression, anxiety, and PTSD. One-way analysis of variance evaluated the relationship between med type and bodily pain. Pearson product-moment correlations examined associations between pain and biobehavioral measures. **RESULTS:** Self-reported bodily pain: none = 6.9%, mild = 69.4%, moderate = 22.2%, severe = 1.4%; \bar{x} = 2.4/10 for bodily pain. Of those reporting pain, 67.4% were taking meds, which represents 36.9% of all participants. Higher pain was reported in those taking prescription meds compared to over-the-counter meds or no meds [$F(4, 67) = 8.72, p < .001$]. Positive relationships were found between pain and depression ($r = .34$), anxiety ($r = .33$), and PTSD ($r = .53$) symptoms (all $p < .01$). **CONCLUSION:** Most EOD Technicians reported some level of pain contrasted with roughly half the general population (55.7%). Compared to U.S. Marines, pain ratings were similar; however, EOD Technicians reported over twice the prevalence of pain med use. Additionally, findings indicate that EOD Technicians using prescription meds reported higher pain. With respect to biobehavioral correlates, the relationship between pain and depression in EOD Technicians was similar to reports in Marines. Combined with the associations observed between pain, anxiety, and PTSD, this reinforces the premise that pain and behavioral health are interrelated. These findings may be useful for clinicians when evaluating military members for potential comorbidities, particularly following trauma when symptoms may be most severe.

1183 May 30 11:00 AM - 11:15 AM

Pain Sensitivity And Psychological Variables Affect Delayed Onset Muscle Soreness (DOMS)

Einat Kodesh, Anat Sirkis-Gork, Simone Shamay-Tsoory, Tzipora Mankovsky-Arnold, Irit Weissman-Fogel. *University of Haifa, Haifa, Israel.* (Sponsor: Bareket Falk, FACSMM) Email: ekodesh@univ.haifa.ac.il

(No relevant relationships reported)

Delayed onset muscle soreness (DOMS) is an acute muscle pain condition occurring after eccentric muscular activity in some but not all people. Physiological and psychological factors may affect DOMS. **PURPOSE:** To investigate whether individual pain sensitivity and psychological variables predict DOMS. **METHODS:** Thirty two participants completed pain-related psychological questionnaires and quantitative sensory testing (QST) and thereafter the DOMS protocol was carried out for the upper extremity. The second session was held 24 h later, participants completed the DOMS-related interference questionnaire and QST was then reapplied. To compare QST parameters and psychological variables between those developing DOMS and those who did not, independent sample t-tests were conducted. Multiple regression analyses were used to determine the predictive role of QST and psychological variables on DOMS intensity. **RESULTS:** Out of the 32 participants, 17 showed a DOMS response. Participants who developed DOMS had higher trait anxiety ($p=0.010$), depression ($p=0.025$), and stress ($p=0.034$) scores, compared to those who did not develop DOMS. Trait anxiety predicted the intensity of DOMS ($r=0.63, P<0.000$). Additionally, those who developed DOMS demonstrated a higher systemic pain sensitivity at baseline, expressed by a lower pressure pain threshold in the muscle that was exercised and in a remote muscle, and by a lower pain inhibition efficiency ($P<0.02$). No correlation was found between the level of pain sensitivity at baseline and the intensity of DOMS. **CONCLUSIONS:** The endogenous ability to regulate pain has a significant impact on pain development in DOMS. Development of DOMS is affected by baseline systemic pain sensitivity as well as psychological and personality traits. Our findings highlight the contribution of physiological and psychological factors to the development of DOMS.

1184 May 30 11:15 AM - 11:30 AM

Acute Pain And Fatigue Responses To Resistance Exercise Among Gulf War Veterans With Chronic Pain

Jacob Lindheimer¹, Aaron J. Stegner¹, Ryan J. Dougherty², Stephanie M. VanRiper², Neda E. Almassi², Jacob V. Ninneman², Laura D. Ellingson-Sayen, FACSMM³, Patrick J. O'Connor, FACSMM⁴, Dane B. Cook, FACSMM¹. ¹US Department of Veterans Affairs, Madison, WI. ²University of Wisconsin-Madison, Madison, WI. ³Iowa State University, Ames, IA. ⁴University of Georgia, Athens, GA. (Sponsor: Dane B. Cook, FACSMM) (No relevant relationships reported)

The chronic effects of exercise training have previously been explored in Persian Gulf War Veterans (GV) with chronic musculoskeletal pain (CMP). However, the

effect of a single bout of resistance exercise on pain and fatigue has not been reported. The magnitude and direction of those effects over several months of a progressive resistance exercise training (RET) program is also unknown.

PURPOSE: To examine changes in pain and fatigue in response to acute bouts of resistance exercise across 16 wks of RET among GV with CMP. It was hypothesized that perceived pain and fatigue would decrease after each training session and the magnitude of this change would increase over the course of the intervention.

METHODS: GV who met criteria for widespread CMP ($n=22; 50\pm 7$ years) completed 16 wks of RET. Training intensity started at 25% and 35% of estimated one-repetition maximum (1RM) and systematically progressed over the course of the intervention. Pre and post exercise pain and fatigue scores on a 0-100 visual analog scale were examined for the first RET session of each training wk. Data gathered during 1RM testing (baseline, mid-program, and end-program) were excluded, resulting in analysis of 13 training wks. Hypotheses were tested with separate 2 (time: pre, post) x 13 (program length: wk 1-13) repeated measures ANOVA models.

RESULTS: Average pre-exercise pain and fatigue were 27.8 ± 2 and 21.8 ± 3 , respectively. Pre-exercise trend line slopes were 0.04 and 0.02 for pain and fatigue, respectively. Significant interaction effects for pain, $F = 2.80, p = .006$, partial eta squared = 0.12, and fatigue, $F = 2.23, p = .03$, partial eta squared = 0.10, models were found. Relative to pre-exercise, post-exercise scores were lower following earlier training sessions (e.g., wks 1-5) and higher following later training sessions (e.g., wks 10-13).

CONCLUSION: Contrary to our hypothesis, post-exercise pain and fatigue appeared to increase across wks 1-13, which could be related to the progression of exercise intensity over the course of the program. However, the stability of the pre-exercise scores across wks 1-13 suggests that weekly pre-exercise pain and fatigue were not exacerbated by acute responses to RET.

Breaking3: Performance Characteristics Of A Sub-three-hour Septuagenarian Marathoner

Austin T. Robinson¹, Joseph C. Watson¹, Matthew C. Babcock¹, Michael J. Joyner, FACSMM², William B. Farquhar, FACSMM¹. ¹University of Delaware, Newark, DE. ²Mayo Clinic, Rochester, MN. (Sponsor: William B. Farquhar, PhD, FACSMM) Email: ausrobin@udel.edu

(No relevant relationships reported)

Purpose: In this case study we characterize the physiological profile of an elite 70-year old endurance runner who ran 2:55:18 at the Scotiabank Toronto Marathon on Oct 21, 2018, breaking his own American record for a 70-year old male by over two-minutes. **Methods:** The athlete underwent a familiarization visit, health screening, and performance-testing. During the screening visit, a resting electrocardiogram and a fasted venous blood sample for biochemical analysis were obtained, and dual energy X-ray absorptiometry was performed to assess body composition. Performance testing consisted of graded treadmill running and indirect calorimetry for determination of maximum oxygen uptake ($\dot{V}O_{2max}$), running economy testing (RE; 12-16 km/hr, 0% grade, 5 minutes each), and lactate threshold (LT; blood draws during running via venous catheter). **Results:** Height was 176.5 cm, weight was 64.2 kg, and he exhibited exceptional cardiometabolic health for his age (body fat: 19.1%, blood pressure: 122/75 mmHg, blood glucose: 86 mg/dL, total cholesterol: 173 mg/dL, LDL: 84 mg/dL, HDL: 66 mg/dL, and triglycerides: 135 mg/dL). The only medication he reported taking was daily low-dose aspirin. His $\dot{V}O_{2max}$ was 46.9 mL/kg/min (max heart rate: 156, 104% age-predicted HR_{max} , RPE 19 out of 20). This $\dot{V}O_{2max}$ is exceptional for a 70-year old, but lower than what is expected for a performance-matched younger runner. He reached his LT at ~14 km/hr, which corresponded, to a $\dot{V}O_2$ of 44.0 mL/kg/min or 93.8% of his $\dot{V}O_{2max}$, and a heart rate of 147, or 94% of HR_{max} . Near $\dot{V}O_{2max}$ levels of oxygen consumption were reached during the final stage of RE testing (16 km/hr, 46.0 mL/kg/min) and blood lactate also plateaued at 14.4 mmol/L. Running economy at the submaximal speeds was comparable to elite younger runners.

Conclusion: Running a marathon in 2:55:18 requires a running speed of ~14.5 km/hr, a speed which is faster than this elite masters athlete's laboratory-measured LT speed

(14km/hr). Our data indicate that his ability to maintain a remarkably high percentage of his measured $\dot{V}O_{2\max}$ (>90%) enable him to compete with performance-matched younger runners who have much higher $\dot{V}O_{2\max}$ values.

1187 May 30 9:45 AM - 10:00 AM

Body Fat Is More Strongly Associated Than Lean Mass With Physical Function In Middle-aged Women

Christie L. Ward-Ritacco, Ashley L. Meyer, Walker Grace, Natalie J. Sabik, Deb Riebe, FACSM. *University of Rhode Island, Kingston, RI.* (Sponsor: Deb Riebe, FACSM)
Email: CHRISTIEWARD@URI.EDU
(No relevant relationships reported)

PURPOSE: Research in older adults suggests that percent body fat is more strongly associated with physical function compared to lean mass when examining relationships between body composition and functional performance. Poor physical function has been associated with increased risk for disability and loss of independence in older women; however, the component of body composition most strongly associated with physical function in middle-aged females is incompletely characterized. Poorer physical function earlier in the lifespan may predispose people to decreased quality of life in older age. The purpose of this study was to examine the strength of the associations between lean mass and percent fat on objectively measured physical function performance in middle-aged females.

METHODS: Eighty females (ages 52.58 ± 6.10 yrs) were assessed for body composition (lean mass, percent fat) via dual-energy x-ray absorptiometry, physical activity and sedentary time via accelerometer (steps per day, minutes per day), and physical function via Timed Up-And-Go, 30-Second Chair Stand, Transfer Task, Six-Minute Walk, and Lift and Carry.

RESULTS: Measures of lean mass (total lean mass, lean mass index) were not related to any measures of physical function (all $p > 0.05$), while percent fat was related to Timed Up-And-Go ($r = .32$), 30-Second Chair Stand ($r = -.35$), Transfer Task ($r = .53$), and Six-Minute Walk ($r = -.48$) performance (all $p \leq 0.05$) but not Lift and Carry performance ($r = .22$, $p = .06$). Hierarchical linear regression analyses revealed: (1) age, steps per day, and percent fat were related to Transfer Task, 30-Second Chair Stand, and Six-Minute Walk performance, explaining 40%, 25%, 25% of the variance, respectively (all $p \leq 0.05$); (2) age, sedentary minutes per day, and percent fat were related to Timed Up-And-Go, explaining 18% of the variance, $p \leq 0.01$; (3) age, and average steps per day, but not percent fat, were associated with Lift and Carry performance, explaining 11% of the variance.

CONCLUSIONS: In middle-aged women, percent fat was more strongly associated with physical function performance compared to total mass, lean mass, or lean mass index. This suggests that reducing percent fat via intervention may be an effective method for improving functional performance among women in this age group.

1188 May 30 10:00 AM - 10:15 AM

Age-related Differences in Rectus Femoris Muscle Size and Hip Flexion Maximal and Rapid Torque Characteristics

Ty B. Palmer, Bailey M. Palmer. *Texas Tech University, Lubbock, TX.* (Sponsor: C. Roger James, FACSM)
(No relevant relationships reported)

Previous studies have reported that decreases in muscle size of the rectus femoris (RF) may contribute to age-related deficits in leg extension strength. However, we are aware of no studies that have examined the contribution of RF muscle size to age-related differences in hip flexion strength, and more specifically, the age-related differences in maximal and rapid torque characteristics. **PURPOSE:** To determine the effects of age on RF muscle size (cross-sectional area [CSA]) and hip flexion maximal and rapid torque characteristics in young and old men. **METHODS:** Fifteen young (age = 25 ± 3 yr; body mass = 86 ± 17 kg; height = 176 ± 5 cm) and 15 old (73 ± 4 yr; 83 ± 10 kg; 173 ± 6 cm) men underwent two diagnostic ultrasound assessments followed by two isometric maximal voluntary contractions (MVCs) of the hip flexors on an isokinetic dynamometer. RF CSA (cm^2) was measured on the right leg using a portable B-mode ultrasound imaging device and linear-array probe. For each MVC, participants laid supine with the knee- and ankle-joints immobilized using custom-built stabilizing apparatuses. All MVCs were performed on the right leg at a hip joint angle of 20° above the horizontal plane. Participants were instructed during each MVC to flex the thigh at the hip "as hard and fast as possible" for 3-4 s. Isometric MVC peak torque (PT; Nm) was calculated as the highest mean 500 ms epoch during the entire 3-4 s MVC plateau. Rate of torque development (RTD; $\text{Nm}\cdot\text{s}^{-1}$) was calculated as the peak of the first derivative of the torque signal. **RESULTS:** There were no differences between the young and old men for body mass ($P = 0.624$) and height ($P = 0.156$). The old men exhibited lower CSA (old = 10.05 ± 1.82 cm^2 ; young = 12.16 ± 2.59 cm^2 ; $P = 0.015$), PT (old = 117.22 ± 17.42 Nm; young = 144.16 ± 29.72 Nm; $P = 0.005$), and RTD (old = 1129.62 ± 374.77 $\text{Nm}\cdot\text{s}^{-1}$; young = 1718.26 ± 633.04 $\text{Nm}\cdot\text{s}^{-1}$; $P = 0.005$) than the young men. Significant relationships were observed between CSA and PT ($r = 0.520$; $P = 0.003$) and RTD ($r = 0.534$; $P = 0.002$). **CONCLUSION:** These findings

demonstrated that RF muscle size and hip flexion PT and RTD decrease in old age. The significant relationships observed between CSA and PT and RTD in the young and old men perhaps suggest that these age-related declines in RF muscle size may play an important role in the lower hip flexion maximal and rapid torque values observed in older adults.

1189 May 30 10:15 AM - 10:30 AM

The Effects Of 5-week Cup-tap Or Lower-limb-strength Exercise On Proprioception And Mobility In Community-dwelling Elderly

Xiaochun Tian¹, Yujie Tong¹, Yejun Wang¹, Jia Han¹, Gordon Waddington², Roger Adams², Jeremy Witchalls², Doa El-Ansary³. ¹Shanghai University of Sport, Shanghai, China. ²University of Canberra, Canberra, Australia. ³Swinburne University of Technology, Melbourne, Australia.
(No relevant relationships reported)

There is strong evidence to support strength or balance training for a duration of 6 to 12 weeks as an exercise intervention to improve proprioception and mobility in community-dwelling elderly. However, it is unknown if a shorter duration of exercise can be effective in improving proprioception and mobility in this population. **PURPOSE:** To determine whether a 5-week program of cup-tap balance control or lower limb strength exercise can improve proprioception and mobility in healthy community-dwelling older people. **METHODS:** Sixty-eight healthy community-dwelling elderly (19M, 49F, 70.91 ± 6.61 yrs old, range 55-90 yrs old) were randomly allocated into 3 groups: cup-tap balance control exercise group (CTE), lower limb strength exercise group (LSE) or education group (EC). A 60 minutes per session, twice weekly cup-tap or strength exercise program was delivered for 5 weeks duration. Key outcome measures included ankle proprioception measured by using the active movement extent discrimination apparatus (AMEDA), and mobility assessed by using the Timed Up and Go test (TUG) and the 30-second Sit to Stand test (30STS). **RESULTS:** ANOVA analysis showed that there was no significant difference in baseline measures: ankle proprioception ($F = 1.605$, $p = 0.209$), TUG ($F = 0.473$, $p = 0.625$), and 30STS ($F = 1.201$, $p = 0.307$) among the 3 groups. Paired t-tests used for examining pre- and post-intervention differences indicated that 1) for the CTE group, the performance of 30STS and the ankle proprioception were significantly improved ($p = 0.005$, $p = 0.016$ respectively); 2) for the LSE group, both TUG and 30STS were significantly improved ($p = 0.023$, $p = 0.03$ respectively); and 3) no significant changes were observed for the EC group. In addition, Pearson's correlation analysis showed that 30STS and TUG performances were moderately correlated ($r = -0.598$, $p < 0.001$) and TUG was significantly correlated with age ($r = 0.416$, $p < 0.001$). **CONCLUSION:** The current findings suggest that the proprioception and mobility of older people can be improved by a short duration of balance control or strength training exercise. However, we suggest that the exercise program must be target-specific with respect to different impairments associated with the aging process for optimal results.

Lower-Extremity Torque Capacity and Physical Function in Mobility-Limited Older Adults

Gregory J. Grosicki¹, Davis A. Englund², Lori Lyn Price³, Megumi Iwai⁴, Makoto Kashiwa⁴, Kieran F. Reid², Roger A. Fielding². ¹Georgia Southern University, Savannah, GA. ²Tufts University, Boston, MA. ³Tufts Medical Center, Boston, MA. ⁴Astellas Pharma Inc, Osaka, Japan.
Email: ggrosicki@georgiasouthern.edu
(No relevant relationships reported)

Skeletal muscle weakness and an increase in fatigability independently contribute to age-related functional decline. **PURPOSE:** The objective of this study was to examine the combined contribution of these deficiencies (i.e., torque capacity) to physical function, and then to assess the functional implications of progressive resistance training (PRT) mediated-torque capacity improvements in mobility-limited older adults. **METHODS:** Seventy mobility-limited (Short Physical Performance Battery (SPPB) ≤ 9) older adults (~79 yrs) were recruited and randomized to either PRT or home-based flexibility 3 days/week for 12 weeks. Torque capacity was defined as the sum of peak torques from an isokinetic knee extension fatigue test. Relationships between torque capacity and performance-based and patient-reported functional measures were examined using partial correlations adjusted for age, sex, and body mass index. **RESULTS:** Skeletal muscle torque capacity explained ($P < 0.05$) 10 and 28% of the variance in six-minute walk distance and stair climb time, respectively. PRT-mediated torque capacity improvements were paralleled by increases ($P < 0.05$) in self-reported activity participation (+20%) and advanced lower extremity function (+7%), and associated ($P < 0.05$) with a reduction in activity limitations ($r = 0.44$) and an improved SPPB score ($r = 0.32$). **CONCLUSION:** Skeletal muscle torque capacity, a composite of strength and fatigue, may be a proximal determinant of physical function in mobility-limited older individuals. To more closely replicate the musculoskeletal

demands of real-life tasks, future studies are encouraged to consider the combined interaction of distinct skeletal muscle faculties to overall functional ability in older adults.

Purpose: To describe and analyze the muscular trend, related to circumferences of non-sedentary women over three different decades **Methods:** The present study is part of the Mixed Longitudinal Project of Physical Fitness and Aging. Sample composed only women's, 50 years-old and older and participated in at least one evaluation between 1998 and 2017, totalizing a sample of 6367 individuals. The circumferences (cm) analyzed were: contracted and relaxed leg and arm. To analyze the trend, the sample was divided into age groups: 50 to 59 years, 60 to 69 years and 70 years old and over. Polynomial regression models were estimated. In the modeling process, the mean of each one of the anthropometric variables was considered as dependent variable and the years of evaluation as independent variable. For each variable, the model with the highest statistical significance and the best accuracy measure (r²) was selected. **Results:** Leg circum. (cm) presented a positive trend in the age group of 50 to 59 years, and a negative trend in the age groups of 60 to 69 years, and in the 70 years and over group. The contracted arm circum. (cm) presented a positive tendency in the age groups of 50 to 59 years and 60 to 69 years. On the other hand, the circum. of the relaxed arm (cm) presented a positive tendency only in the 50 to 59 years-old group. In the age group of 50 to 59 years, the mean leg circum. was 35.77 cm, the mean arm circum. contracted was 30.68 cm and the mean arm circum. relaxed was 30.43 cm. In both cases, there was an increase of 0.01 cm every year. In the age group of 60 to 69 years, mean leg circum. was 35.11 cm, and there was a decrease of 0.01 cm in every year; the mean of the contracted arm circum. was 29.97 cm, with an increase of 0.01 cm every year. In the age group of 70 years and over, mean leg circum. was 34.81 cm, with a decrease of 0.01 cm every year. **Conclusion:** Over the three decades analyzed, the younger elderly showed a positive tendency for the muscularity indices; while older groups presented mixed results.

Table. Trend analysis of circumference among non-sedentary elderly according to age group.

| | 50 to 59 years | | 60 to 69 years | | 70 years and over | |
|-----------------------------------|-------------------------------|----------------|-------------------------------|----------------|-------------------------------|----------------|
| | Model | r ² | Model | r ² | Model | r ² |
| Leg Circumference (cm) | y = 35.77 + 0.01 ^a | 0.50 | y = 35.11 - 0.01 ^b | 0.53 | y = 34.81 - 0.01 ^c | 0.53 |

Health and Lifestyle Behaviors of U.S. Master's World Cup Field Hockey Players

Karen A. Croteau, FACSM¹, Nina Eduljee¹, Laurie Murphy¹, Lisa Ahearn². ¹Saint Joseph's College of Maine, Standish, ME. ²Plymouth State University, Plymouth, NH.
Email: kcroteau@sjcme.edu
(No relevant relationships reported)

PURPOSE: The purpose of this study was to examine health status and lifestyle behaviors of U.S. master's field hockey athletes. **METHODS:** Participants were 122 athletes (72 females, 50 males) who competed for the U.S. in the Master's Field Hockey World Cup in 2018. Mean age was 50.12±8.28 (range = 35-71). Participants completed the 42-item Health and Wellbeing of Master's Field Hockey Athletes Survey. **RESULTS:** Mean BMI was 24.9±3.1 (range = 15.6-35.5). Participants rated their health as very good/excellent (86.9%), had no major health conditions (61.5%) or medication use (70.5%), and had at least one injury (53.3%). Perceived stress was rated as rare or not at all by 56.6% of participants. Participants consumed ≥2 fruits (68.9%) and ≥2 vegetables per day (83.6%), daily breakfast (68%), ≤1 sugar-sweetened beverages (86.9%) and ≥7 cups of water (54.0%) per day, and ≤2 alcoholic beverages per week (59.8%). Participants reported ≥7 hours of sleep per night (65.5%) and no/little restless sleep (52.4%). Just under half of participants reported sitting ≥5

hours per day (46.7%). Exercise frequency at ≥3 days per week and ≥30 minutes was cited by 95.9% and 98.4% of the sample. **CONCLUSION:** Master's field hockey athletes practice lifestyle behaviors conducive to positive health.

1193 May 30 11:15 AM - 11:30 AM
Effects of Tai Chi Exercise Versus BINGO on Fine Motor Functions in Older Adults

Saira Talwar¹, Chih-Chia Chen², John Lamberth², Yonjoong Ryuh², Poram Choi², Morgan Hommel², Zhujun Pan². ¹University of Wisconsin - Milwaukee, Milwaukee, WI. ²Mississippi State University, Mississippi State, MS. (Sponsor: Scott Strath, FACSM)
Email: talwar@uwm.edu
(No relevant relationships reported)

Tai Chi exercise (TC) improves gross motor skills in older adults; however, fine motor skills, which enhance performance of daily living activities (ADLs), have not been thoroughly examined. **PURPOSE:** The purpose of this study was to investigate the effects of TC versus BINGO on fine motor skills in older adults. **METHODS:** Twenty-seven self-ambulatory older adults (age: 76 ±9.00; female: N = 26) with no restrictive health conditions and MMSE score ≥ 21, completed this study. Participants engaged in 1-hour, twice-per-week TC or BINGO sessions for 8 weeks (wk). Fine motor skills were assessed using the unilateral Jebsen Taylor Hand Function Test (JTHFT), including 7 ADL-like tasks; less time (s) to complete a task reflected better performance. Repeated measures 2x4 [2(TC x BINGO) x 4(Baseline x Intra-intervention x Post x Retention)] ANOVA was used with alpha of 0.05; data was analyzed separately for each hand. **RESULTS:** There were no significant group differences (p > 0.05). Significant time main effects were found for 6 tasks using the dominant hand (DH) and 7 tasks using the nondominant hand (NH) (Table 1). Significant time x group interaction was found for simulated feeding using the DH (p = 0.001). TC improved by 1.69 s across the 8-wk intervention, with a 1.23 s improvement after 4 wk. BINGO improved by 0.07 s across the 8 wk. Significant time x group interaction was also found for lifting large, heavy objects using the NH (p = 0.039). TC improved by 0.65 s across the 8 wk intervention, with a 0.50 s improvement after 4 wk. BINGO improved by 0.09 s across 8 wk. **CONCLUSION:** This study was one of the first to explore the effects of TC on fine motor functions. TC does not demand precise finger movements such as those required for BINGO; however, improvements specific to tasks requiring eye-hand coordination, manual dexterity, wrist range of motion, and hand grip strength were noted 4 wk into the TC intervention. TC may improve fine motor functions in older adults. Supported by MSU College of Education.

Leg Pain in a 23 Year Old Football Player

Kyle H. Yost, Valerie Cothran, Ralph F. Henn. *University of Maryland Medical System, Baltimore, MD.*

Email: kyleost08@gmail.com

(No relevant relationships reported)

HISTORY

A 23 year old male reported getting kicked in the leg during a collegiate football game. He noted immediate pain in his lateral calf after attempting a tackle. He did not feel or hear a pop. He had a noticeable limp walking off the field. There was no pain in the ankle or foot, but he noted pain with ankle movement. He had pain with weight-bearing but denied any numbness or tingling.

The next day, he developed worsening pain that was unbearable with any change of position or movement. The pain was greatest along the mid-lateral leg but extended along the entire leg anterior and laterally. He had limited ability to move his toes and foot which was a new symptom.

PHYSICAL EXAMINATION

General: Alert and oriented in mild distress at rest.

Left leg

Edema: Anterior and lateral leg without pitting.

Compartments: Diffusely tender but not tense.

Tenderness: Diffuse, anterior and lateral compartments more than fibula and posterolateral.

Range of motion: DF 0 degrees, PF 30 degrees. Pain was worse with initiation. He tolerated gradual passive stretch of the anterior, more than the lateral.

Pain with inversion and eversion .

Strength: 1/5 anterior tibialis, EHL, EDL, Peroneals with pain, 2/5 GS/PT with pain.

Neurovascular: Intact, 2+ PT/DP pulses, cap refill < 2 sec.

DIFFERENTIAL DIAGNOSIS

1. Gastrocnemius Strain
2. Compartment Syndrome
3. Popliteus Strain
4. Fibular Fracture
5. High Ankle Sprain

TESTS AND RESULTS

XRays

1. Fluoroscopic imaging of the tib-fib and ankle were negative.

2. Tib-fib and Ankle xrays were negative for fracture and stress view demonstrated stable joint.

Compartment Testing

Diastolic pressure: 74

Left lower leg anterior compartment: 20

Left lower leg lateral compartment: 28

Left lower leg posterior superficial compartment: 27

Left lower leg posterior deep compartment: 26

MRI

1. Nondisplaced fracture of the middle third of the fibula.

2. Acute grade 1 muscular injury of the peroneal muscles of the lateral compartment.

FINAL WORKING DIAGNOSIS

Midshaft fibular stress fracture

TREATMENT AND OUTCOMES

1. Patient was admitted to the hospital for observation for one night.

2. Patient was discharged and allowed to weight bear as tolerated in the tall CAM boot for two weeks.

3. At two weeks, he was weaned out of the boot and allowed to progress into activities.

4. At six weeks, he was participating in football without any limitations.

1198 May 30 9:50 AM - 10:10 AM

Lower Extremity Pain - Field Hockey

Jessica Traver, Lyle Micheli, FACSM. *Boston Children's Hospital, Boston, MA.* (Sponsor: Lyle Micheli, MD, FACSM)

Email: jessica.traver@childrens.harvard.edu

(No relevant relationships reported)

Lower Leg Pain – Field Hockey

HISTORY: A 20-year-old collegiate field hockey player 1 year, 2 months out from bilateral anterior/lateral/deep posterior compartment fasciotomies for chronic exertional compartment syndrome, recurrence of pain along her bilateral medial legs and medial/plantar foot numbness. Worsening over previous 6 months. Pain is daily, constant. Had MRI/MRA arterial duplex performed at onset of symptoms and was told it was negative. No improvement with neuropathic pain medication, physical therapy, hydrodissection.

PHYSICAL EXAMINATION: Examination revealed healed surgical incisions. Mild scar hypertrophy along medial incisions with moderate tenderness to palpation. Full knee/ankle ROM. Pain reproduced with resisted ankle plantar flexion after 30 seconds, numbness along medial/plantar aspect of foot in tibial nerve distribution. Easily palpable dorsalis pedis/posterior tibialis pulses.

DIFFERENTIAL DIAGNOSIS:

1. Recurrent chronic exertional compartment syndrome
2. Saphenous nerve compression neuropathy
3. Popliteal Artery Entrapment Syndrome

TEST AND RESULTS:

1. Repeating compartment pressure testing: normal compartment pressures
2. EMG/NCS: normal without evidence of compression neuropathy
3. MRA (PRISMA 3T) study: forced plantarflexion demonstrates bilateral compression of the popliteal arteries at the popliteal fossa between the medial and lateral heads of the gastrocnemius muscle.

FINAL/WORKING DIAGNOSIS:

Popliteal Artery Entrapment Syndrome

TREATMENT AND OUTCOMES:

1. Referred to plastic surgery colleagues.
2. Underwent bilateral popliteal artery releases 1 year, 8 months after index surgery.
3. Improvement of both pain and numbness along medial aspect of foot.
4. Last seen at 3 months post-operatively. Full, painless ROM. No pain with resisted plantarflexion. Normal sensation. Anticipate return to sport over the next 6 weeks.

1199 May 30 10:10 AM - 10:30 AM

Pain And Function: A Ten(din)uous Link In The Runner

Peter Francis, Isobel Thornley, Ashley Jones. *Leeds Beckett University, Leeds, United Kingdom.*

Email: peter.francis@leedsbeckett.ac.uk

(No relevant relationships reported)

HISTORY: A male runner (30-years, 10-km time: 33-min 46-sec) had been running with suspected insertional achilles tendinopathy (AT) for 2.5 years when the pain reached a threshold that prevented running.

PHYSICAL EXAMINATION: Diagnostic ultrasound (US), prior to a high volume stripping injection, confirmed right sided medial insertional AT.

DIFFERENTIAL DIAGNOSIS: Right sided medial insertional AT.

TEST AND RESULTS: The athlete failed to respond to the injection and ceased running for a period of 5-weeks. At the beginning of this period, the runner completed the Victoria institute of sports assessment-achilles questionnaire (VISA-A) and the foot and ankle disability index (FADI), prior to undergoing an assessment of bilateral gastrocnemius medialis (GM) muscle architecture (muscle thickness (MT) and pennation angle (PA); US), muscle contractile properties (maximal muscle displacement (Dm) and contraction time (Tc); Tensiomyography (TMG)) and calf endurance (40 raises/min). VISA-A and FADI scores were 59%/100% and 102/136 respectively. Compared to the left leg, the right GM had a lower MT (1.60 cm vs. 1.74 cm), a similar PA (22.0° vs. 21.0°), a lower Dm (1.2 mm vs. 2.0 mm) and Tc (16.5 ms vs. 17.7 ms). Calf endurance was higher in the right leg compared to the left (48 vs. 43 raises).

FINAL/WORKING DIAGNOSIS: Right sided medial insertional AT.

TREATMENT AND OUTCOMES: The athlete began a metronome guided (15-BPM), 12-week progressive eccentric training protocol using a weighted-vest (1.5kg increments per week), whilst receiving 6-sessions of shockwave therapy concurrently (within 5-weeks). On returning to running, the athlete kept daily pain (VAS) and running scores (miles*RPE). Foot and ankle function improved according to scores recorded on the VISA-A (59% vs. 97%) and FADI (102 vs. 127/136). Improvements in MT (1.60 cm vs. 1.76 cm) and PA (22.0° vs. 24.8°) were recorded via US. Improvements in Dm (1.15 mm vs. 1.69 mm) and Tc (16.5 ms vs. 15.4 ms) were recorded via TMG. Calf endurance was lower in both legs and the asymmetry between legs remained (L: 31, R: 34). Pain intensity (mean weekly VAS scores) decreased

between week-1 and week-12 (6.6 vs. 2.9), while running scores increased (20 vs. 38) during the same period. The program was maintained up to week-16 at which point weekly mean VAS was 2.2 and running score was 47.

1200 May 30 10:30 AM - 10:50 AM

Medial Lower Leg Pain in a Middle-Aged Triathlete

Allison N. Schroeder, Stephen Schaaf, Kentaro Onishi.
University of Pittsburgh Medical Center, Pittsburgh, PA.

(Sponsor: Tom Best, FACSM)

Email: aschroe1@alumni.nd.edu

(No relevant relationships reported)

HISTORY: A 43-year-old triathlete presented with left distal medial lower leg pain that started gradually about 2-3 weeks prior to presentation. He denied inciting trauma and described the pain as a 5/10 sharp pain provoked by walking, running, and ankle dorsiflexion and plantarflexion movements. He endorsed mild left distal medial leg swelling but denied leg weakness or numbness and previous injury to this area. He was taking ibuprofen and had seen a chiropractor who performed several treatments including grastin, massage, taping, and a compression sleeve with minimal relief. He was training for his first full Ironman triathlon, scheduled for 12 days from presentation.

PHYSICAL EXAMINATION: Gait was non-antalgic. No visible swelling or ecchymoses of the left lower leg. Only tender to palpation in the left distal medial leg near the myotendinous junction of the medial gastrocnemius. Full ROM at the knee and ankle, but left end-range ankle dorsiflexion was painful. Strength was 5/5 about the knee and ankle, but he had pain with toe raises and toe walking on the left.

DIFFERENTIAL DIAGNOSIS:

1. Gastrocnemius strain or tear
2. Soleus strain or tear
3. Plantaris strain or tear
4. Achilles tendon injury
5. Posterior tibialis strain or tear
6. Fascial defect/muscle herniation
7. Deep posterior compartment syndrome
8. DVT

TEST AND RESULTS: Limited diagnostic ultrasound of the left distal medial leg revealed a near tear of the plantaris tendon near the myotendinous junction with evidence of disruption of tendon fibers and surrounding anechoic fluid. There was neovascularization on color doppler and tenderness to sonopalpation.

FINAL/WORKING DIAGNOSIS: Plantaris Tendinopathy

TREATMENT AND OUTCOMES: He was encouraged to continue symptomatic treatments with his chiropractor and could also consider kinesiotaping. His goal was to complete the full Ironman, even if he was slower than anticipated and called about one week later to ask if there were additional treatment options. He wished to proceed with experimental sonographically-guided injection of dextrose hyperosmolar solution to the site of pathology of his plantaris tendon, which was performed 4 days prior to the Ironman triathlon. By race day, his pain had improved, and he was able to complete the full Ironman within his original goal time.

C-14 Clinical Case Slide - Neurologic Injuries

Post-concussion Syndrome With Retrograde Amnesia in a Pediatric Patient

Andrew Alexander, Weston Northam, Kevin Carneiro, Jason Mihalik. *University of North Carolina at Chapel Hill, Chapel Hill, NC.* (Sponsor: Kevin Guskiewicz, FACSM)

Email: andrew_alexander@med.unc.edu

(No relevant relationships reported)

HISTORY: A 14-year-old female with a history of pervasive developmental disorder (PDD), mild speech abnormalities, dyslexia, hearing loss and migraines sustained a concussion after falling on a slip and slide. The patient hit her head but did not lose consciousness. At clinic 3.5 weeks post injury, she complained of a headache with varied intensity. Reading provoked headaches and blurred vision. The patient experienced photophobia, phonophobia and dizziness. She took more naps during the day and had mood lability. The patient was amnesic to the event and had severe memory lapses. She forgot how to do simple math problems, the names of her family, friends, boyfriend, and that she was a cheerleader.

PHYSICAL EXAMINATION: Neurologic: 1) Slow eye movements that provoked headache, 2) Accommodation (blurred vision) and convergence (diplopia) insufficiencies, and 3) Undershooting and eye strain with vertical and horizontal saccades. Tenderness to palpation on right side of the neck and suboccipital region. Patient named current president when asked, but unable to name previous or first president. Otherwise, normal neurologic and musculoskeletal exam.

DIFFERENTIAL DIAGNOSIS:

- 1) Post-concussion syndrome with retrograde amnesia
- 2) Anxiety disorder exacerbated by trauma
- 3) Malingering

TESTS AND RESULTS:

CT head and neck:

— Normal

Neuropsychology Evaluation:

— Test of Memory Malingering - adequate effort

— ImPACT: deficits in Verbal Memory, Visual Memory, Visual Motor Speed, and Reaction Time

— Behavior Rating Inventory of Executive Functioning: Normal

Revised Children's Anxiety and Depression Scale:

— Clinically insignificant

Sensory Organization Test:

— No significant balance problems

FINAL/WORKING DIAGNOSIS:

Post-concussion syndrome with retrograde amnesia. Underlying PDD, and comorbidities at baseline described earlier likely contributing to headache and cognitive difficulties.

TREATMENT AND OUTCOMES:

1. Physical therapy for cervicogenic headaches
2. Vestibular therapy for dizziness and vestibulo-oculomotor dysfunction
3. Neuro-optometry evaluation and rehabilitation
4. All deficits and symptoms greatly improved 2 months post-injury. Vision rehabilitation will be continued prior to return-to-sport.

1205 May 30 9:50 AM - 10:10 AM

Headache, Vision Loss And Loss Of Consciousness-WrestlingJaron Santelli. *University of Maryland School of Medicine, Baltimore, MD.**(No relevant relationships reported)***HISTORY**

JJ is a 20 y/o male with 2 episodes of acute posterior neck pain with radiation into his occiput followed by acute loss of vision bilaterally and brief loss of consciousness vs. presyncopal like episode. The first event occurred while wrestling and the second while bench pressing. There was no preceding chest pain, shortness of breath, or other symptoms. All symptoms resolved approximately 15 minutes after each event.

At the time of the visit he was asymptomatic and unable to reproduce symptoms with head movement. No recent illness. No cardiac or pulmonary past medical history.

PHYSICAL EXAMINATION

The examination is overall unremarkable with normal pupillary and extra ocular muscle exam, no visual deficits, normal visual acuity, no midline cervical tenderness, and negative Spurling's test. JJ had a normal extensive neurologic exam including cranial nerves, coordination, sensation and strength. Cardiovascular and pulmonary exams are also normal.

DIFFERENTIAL DIAGNOSIS

Vertebral Artery Dissection

TIA/CVA

Vasovagal Syncope

Dehydration

TESTS AND RESULTS

CBC, CMP, TSH, EKG all unremarkable

CTA head and neck: bilateral hypoplastic vertebrobasilar system

MRI: negative for ischemia

Transcranial Doppler: nonspecific changes

FINAL WORKING DIAGNOSIS

Hypoplastic Vertebrobasilar system

TREATMENT AND OUTCOMES

At time of the diagnosis, there was no evidence of ischemia as a result of the occurrences. Possible treatment options for hypoplastic vertebrobasilar systems without ischemia include aspirin and lifestyle modifications. Activity modifications have been made to include proper hydration, training to the start of symptoms but no further and reducing the activities that induce valsalva unnecessarily. Since these modifications have been put in place, there have been no new events. Follow up plans include repeat MRI at 6 months.

1206 May 30 10:10 AM - 10:30 AM

After Lightning Strikes: A Case Of Anoxic Encephalopathy In A 30 Year Old Soccer PlayerMichael Harbus, Miguel X. Escalon. *Mount Sinai School of Medicine, New York, NY.**(No relevant relationships reported)*

History: A 30 year old male with a past medical history of hypothyroidism was out playing soccer when he was struck by lightning. After the lightning strike, the patient experienced cardiac arrest, and CPR was performed. Spontaneous circulation was achieved after a 17 minutes of CPR, and the patient was admitted to a burn unit for partial thickness burns of his left anterior chest, abdomen, and right medial lower calf. During the patient's stay on the burn unit, he was noted to have severe cognitive deficits secondary to an anoxic brain injury sustained during his cardiac arrest, and also had a PEG tube placed after developing aspiration pneumonia. Following the burn unit, the patient was transferred to an acute rehab facility to address the severe cognitive deficits he had developed. Upon arrival at the acute rehabilitation facility, the patient was a Rancho Los Amigos level three.

Physical Exam: The patient was lying comfortably in bed. He was able to mimic behavior, but was unable to follow commands consistently. On ocular exam, the patient had a left pupil that was fixed and dilated, and sub-conjunctival hemorrhages. Abdominal exam was significant for an in-place PEG tube. Integumentary was significant for partial thickness wounds on his anterior chest and right lower extremity. The patient demonstrated full active range of motion of his upper and lower extremities.

Differential Diagnosis:

Anoxic encephalopathy

Encephalopathy secondary to electrocution

Toxic metabolic encephalopathy

Tests and Results: -Labs on admission were significant for the following: White blood cell count of 5.0; hemoglobin of 10.3; blood urea nitrogen of 55; AST of 42 and ALT of 70. -CT head on admission showed no evidence of intracranial hemorrhage, lobar infarct, hydrocephalus, or midline shift.

Final Diagnosis: Anoxic encephalopathy secondary to lightning strike

Treatment and Outcomes: The patient was started on amantadine to stimulate increased attention and wakefulness, and seroquel and trazadone to help address the patient's nocturnal agitation and promote sleep. At the end of his 5 week stay on the acute rehabilitation unit, the patient had advanced to a Rancho Los Amigos level eight. He was fully oriented to his environment, tolerating an oral diet, engaging in appropriate conversation, and ambulating with a walker.

1207 May 30 10:30 AM - 10:50 AM

She's Only Weak Because She Doesn't Play SportsBrian Vernau. *Children's Hospital of Philadelphia, Philadelphia, PA.**(No relevant relationships reported)*

HISTORY: 8 year-old female presents to pediatric sports medicine for evaluation of clumsiness and muscle weakness. She had been following with the school physical therapist for about one year for concerns about balance, coordination, and core strength. School initially had a concern about her confidence and speed on stairs and not keeping up in gym class. She was referred due to continued coordination issues. Per mother, her difficulty with stairs started when she was pushed down the stairs by a peer. She typically places both feet on the step when she climbs stairs. Her core weakness had been attributed to deconditioning and disinterest in sports. Mom feels the school PT is cutting into education time and would like it to stop. She has always been clumsy, which is present in the rest of the family as well.

The patient endorses mild hip and gluteal muscle soreness that has been attributed to growing pains. She falls a lot but no significant injuries. She has always been a toe walker. No handwriting difficulties. Normal developmental milestones per mother.

PHYSICAL EXAMINATION: Genu valgum. Holds thighs together during gait with poor hip swing. Intermittent toe walking with pes cavus. Full pain free ROM about the hips and knees. Mild heel cord tightness. Ligamentous laxity throughout. No tenderness to palpation about the lower extremities. Muscle tone diffusely decreased other than mild increased tone at ankles and feet without atrophy. Strength testing reveals 3/5 straight leg testing, using hands under thighs to move legs. Otherwise, she is 4/5 strength throughout other than 5/5 strength with ankle plantarflexion, great toe extension. DTRs 1+ throughout. Gower's sign negative, but she does walk hands up to feet before standing with difficulty.

DIFFERENTIAL DIAGNOSIS: Muscular dystrophy - Beckers, limb-girdle, spinal muscular atrophy, facioscapulohumeral muscular dystrophy, Myositis. Other myopathy

TEST AND RESULTS: CMP, lipids, TSH unremarkable CK 235, Genetic testing:

Spinal Muscular Atrophy Type 3 **FINAL WORKING DIAGNOSIS:** Spinal Muscular Atrophy Type 3

TREATMENT AND OUTCOMES: She has started nusinersen (Spinraza) therapy and continues with physical therapy. She remains ambulatory 3 months into treatment. Starting to use AFOs for toe walking.

C-15 Rapid Fire Platform - Muscle Fatigue and Force DevelopmentThursday, May 30, 2019, 9:30 AM - 10:50 AM

Tropomyosin-based Effects Of Acidosis On Thin-filament Regulation During Muscle FatigueBrent Scott¹, Mike Woodward¹, Thavanareth Prum², Jeffrey R. Moore², Edward P. Debold¹. ¹*University of Massachusetts Amherst, Amherst, MA.* ²*University of Massachusetts Lowell, Lowell, MA.*

Email: bdsco@umass.edu

(No relevant relationships reported)

Skeletal muscle fatigue is defined by a loss in the force and velocity generating capacity of a muscle. A portion of the loss in function is attributable to effects of acidosis (i.e. low pH) on the regulatory proteins, troponin and tropomyosin (Tm), which regulate the binding of myosin and actin in a calcium (Ca⁺⁺) dependent manner. However, the relative role of the regulatory proteins is not clear, nor are the mechanisms underlying the effect acidosis has on them. **PURPOSE:** To determine the role of Tm in the acidosis-induced depression of muscle function using isolated muscle proteins in an in vitro motility assay.

METHODS: To test this idea we expressed 3 mutant constructs of Tm with the 2 amino acid residues affected by low pH (histidine residues) replaced with alanine residues (H153A, H276A, H153A/H276A). These constructs were compared to a wild-type Tm, to test the hypothesis that acidosis-induced charge changes of the histidine amino acid governs tropomyosin's pH-dependent decrease in maximal velocity and Ca⁺⁺-sensitivity. The effect on RTF function was determined by assessing the impact of acidosis on myosin's ability to move regulated actin filaments (RTF) in the motility assay as a function of increasing level of Ca⁺⁺. This was done separately for the wt-Tm and each structural variant.

RESULTS: A two-way ANOVA (pH x Tm construct) revealed that acidosis significantly (p<0.05) depressed the maximal sliding velocity of the RTFs across all versions of Tm, but that the magnitude of the depression was similar among the wt and all of the Tm mutants. Acidosis did not significantly depress the sensitivity to Ca⁺⁺ under the unloaded conditions of this assay (p>0.05).

CONCLUSIONS: These data suggest that the histidine residues in tropomyosin do not mediate the acidosis-induced depression in contraction velocity observed during muscle fatigue. However, it is possible that these residues are more important in mediating the depression in force, therefore we are currently testing the impact of these mutations in Tm on the acidosis-induced depression in the Ca⁺⁺-sensitivity using a loaded in vitro motility assay. Is Fatigue-induced Loss Of Power Associated With a Change In The Curvature Of The Force-velocity Relation?

Anders Meldgaard Kristensen, Ole Bækgaard Nielsen, Thomas Holm Pedersen, Kristian Overgaard. Aarhus University, Aarhus, Denmark.

Email: amk@ph.au.dk

(No relevant relationships reported)

In skeletal muscles, the ability to generate power is reduced during fatigue. Maximal power (P_{max}) is determined by the force-velocity relationship, which can be closely approximated by the Hill equation, containing three key parameters: 1) Maximal isometric force (F_{max}) 2) Maximum contraction velocity (V_{max}) and 3) Force-velocity curvature. **PURPOSE:** To investigate the possible association between the fatigue-induced loss of power and changes in curvature of the force-velocity relation in muscles with different fiber type composition. **METHODS:** The force-velocity relationship was measured before and during development of fatigue in isolated rat soleus (slow-twitch) and EDL (fast-twitch). Muscles were incubated in Krebs-Ringer solution at 30 C° and stimulated electrically at 60 Hz for 0.75 s (soleus) or at 150 Hz for 0.2 s (EDL) to obtain serial concentric contractions leading to fatigue. The Force-velocity relationship was measured at different stages of fatigue and after 1 hour of recovery. Force-velocity data were fitted to the Hill equation, and curvature was determined as the ratio of the curve parameters a/F₀ (inversely related to curvature). **RESULTS:** At the end of the fatiguing protocol, maximal power had decreased by 58 ± 5% (soleus) and 69 ± 4% (EDL) compared to initial values in non-fatigued muscles. Curvature increased in both muscle types as judged from the decrease in a/F₀ of 81 ± 20% (soleus) and by 31 ± 12% (EDL). At the end of the fatiguing protocol, the calculated contributions to the total loss of P_{max} was 25 ± 10% from F_{max}, 17 ± 3% from V_{max} and 58 ± 14% from a/F₀ (soleus) and 64 ± 6% from F_{max}, 16 ± 3% from V_{max} and 20 ± 9% from a/F₀ (EDL). Complete recovery of a/F₀ was observed following one hour of rest in both muscle types. **CONCLUSIONS:** Increased curvature of the force-velocity relationship occurs during fatigue in both slow and fast twitch muscles. Particularly in slow-twitch muscles, this increase in curvature is strongly associated with fatigue-induced loss of power.

The Effect Of Low Frequency Fatigue On Dynamic Muscle Function

Jon H. Herskind, Anders M. Kristensen, Kristian Vissing, Frank V. de Paoli, Kristian Overgaard. Aarhus University, Aarhus C, Denmark.

Email: jherskind@ph.au.dk

(No relevant relationships reported)

Following fatiguing contractions, muscle contractile function is decreased more at low frequency stimulation compared to high frequency stimulation. This low frequency fatigue (LFF) is well investigated in isometric contraction models, but the effects on dynamic muscle function are less clear. Furthermore, the degree of LFF induced in dynamic contractions by different contraction modes (concentric, isometric, eccentric) has not been compared.

Purpose: To investigate the effect of LFF induced by different types of fatiguing contractions on dynamic muscle function.

Methods: Soleus muscles from Wistar rats were dissected out and incubated in Krebs-Ringer solution. The force-velocity relationship was assessed by a series of brief concentric contractions elicited at 20 and 80 Hz before and 1 h after fatiguing

contractions. Fatigue was induced using 3x 5s of either concentric, eccentric or isometric contractions at 60 Hz. Force-velocity data were fitted to the Hill equation. In some experiments, muscles were exposed to supraphysiological concentration of caffeine to assess the influence of calcium release.

Results: After fatigue induction, both maximal force, velocity and power parameters were more severely decreased at 20 Hz of stimulation compared to 80 Hz of stimulation for all 3 types of fatiguing protocols. Isometric contractions caused a smaller decrease in maximal power compared to concentric contractions and tended to cause a smaller decrease compared to eccentric contractions. Caffeine alleviated the effects of LFF on both maximal force, velocity and power.

Conclusion: LFF can be induced by different types of muscle contraction and affects both maximal isometric force, maximal velocity and maximal power during concentric contractions. These effects can be mitigated by caffeine, indicating an impaired calcium release during LFF.

Figure 1: 20/80 Hz power ratio. *significant difference between baseline and fatigued state.

Comparison of Agonist and Antagonist Muscle Fatigue on Coactivation and Force Production

Cameron S. Mackey, Jesus A. Hernandez-Sarabia, Micheal J. Luera, Alejandra Barrera-Curiel, Jason M. DeFreitas. Oklahoma State University, Stillwater, OK.

(No relevant relationships reported)

Little research has been done on whether the fatigue status of a muscle influences its magnitude of coactivation during antagonistic contractions. We hypothesized that a fatigued antagonist would coactivate less, thereby increasing agonist force production. **PURPOSE:** To compare the effects of antagonist fatigue on muscle activation and force producing capabilities of the biceps brachii (BB) and triceps brachii (TB). **METHODS:** Fifteen healthy, college-aged men and women volunteered for this study (n = 15; mean ± SD: age = 25 ± 3 yrs). Surface electromyography (sEMG) was recorded from the BB and TB during elbow extension (EXT) and flexion (FLX) maximal voluntary contractions (MVC) prior to and immediately following EXT or FLX fatigue protocols. Fatigue was induced with intermittent, submaximal contractions, each held at 70% MVC for 10-s with 5-s rest periods. The protocol continued until 70% of the pre-MVC could not be achieved. The amplitude of each EMG signal was assessed as the root-mean-square (RMS; V) and normalized to the value obtained during that muscle group's pre MVC. Separate 2-way (time [pre and post] × condition [FLX-fatigue and EXT-fatigue]; "within-within") repeated measures ANOVAs were performed for each dependent variable: FLX force (N), EXT force (N), agonist activation, and antagonist coactivation (%). **RESULTS:** There was a significant time × condition interaction observed for FLX force (p = 0.005) and EXT Force (p ≤ 0.001), but not for BB activation (p = 0.648), TB activation (p = 0.084), nor coactivation during the FLX (p = 0.076) or EXT (p = 0.681). Post-hoc tests revealed that FLX fatigue had no effect on EXT force (p = 0.307). However, EXT fatigue did significantly affect FLX force (MD = -35.96 N; p ≤ 0.001). Surprisingly, FLX fatigue affected the magnitude of TB coactivation during FLX MVCs (MD = +8.3%; p = 0.015), but EXT fatigue did not (MD = +1%; p = 0.696). Neither the FLX fatigue condition (p = 0.30), nor the EXT fatigue condition (p = 0.21) influenced the magnitude of BB coactivation during EXT MVCs. **CONCLUSION:** Contrary to our hypothesis, EXT fatigue had a negative effect on FLX force, not a positive effect. Also unexpected was that EXT fatigue had no effect on TB coactivation during FLX, but FLX fatigue did. More research is needed to determine the factors that influence the magnitude of antagonist coactivation.

Effects Of Intermittent Fasting And High Intensity Training On Regulators Of Muscle Mass And Metabolism

Matthew B. Cooke¹, Robin Wilson², Alan Hayes², Christos G. Stathis². ¹Swinburne University of Technology, Melbourne, Australia. ²Victoria University, Melbourne, Australia.
Email: mbcooke@swin.edu.au

(No relevant relationships reported)

Diet-induced obesity can lead to higher intramuscular fat deposition and inflammatory cell accumulation, ultimately having a negative impact on skeletal muscle morphology and function leading to mitochondrial dysfunction and insulin resistance. Intermittent fasting (IF) and high intensity interval training (HIIT) are both effective strategies for losing weight, specifically fat mass. However, the effects on skeletal muscle, specifically genes that regulate mitochondrial function, energy homeostasis, and muscle atrophy are unknown. **PURPOSE:** To investigate the effects of IF and/or HIIT on molecular markers of skeletal muscle mass and metabolic function in diet-induced obesity. **METHODS:** Eight week old mice (C57BL/6, n=39) had ad libitum access to an obesogenic diet (60% fat, 30% sugar) for 12 weeks. They were then randomly allocated to three intervention groups: IF (fasting for 2 alternate days/week), HIIT (3 days/week), combined IF+HIIT (2 alternate fasting days and 3 days HIIT) or control (CON) for a further 12 weeks. Extensor digitorum longus (EDL) muscle weight and expression of PGC1 α , AMPK, citrate synthase (CS), muscle atrophy F-box (MAFbx), and muscle RING Finger-1 (MuRF1) genes were measured at the end of the intervention period. Data was analysed using ANOVA. **RESULTS:** Muscle weights were similar between groups at the end of the intervention period (CON: 9.5 \pm 1.3mg, HIIT: 9.2 \pm 0.8mg, IF: 9.2 \pm 0.4mg, IF+HIIT: 9.7 \pm 0.8mg, p>0.05). PGC1 α and CS gene expression was significantly lower in the IF group compared to the CON (PGC1 α : 0.8 \pm 0.1 vs 1.0 \pm 0.2, CS: 0.8 \pm 0.2 vs 1.0 \pm 0.4, p<0.05). AMPK gene expression was also significantly lower in the IF group, but only compared to the IF+HIIT group (0.9 \pm 0.1 vs 1.0 \pm 0.1, p<0.05). MAFbx and MuRF1 gene expression was significantly higher in the HIIT group (1.7 \pm 0.8 & 2.2 \pm 0.9) group compared to CON (1.0 \pm 0.4 & 1.0 \pm 0.2), IF (0.9 \pm 0.2 & 0.8 \pm 0.2), and IF+HIIT (1.4 \pm 0.3 & 0.9 \pm 0.2, p<0.01) groups. **CONCLUSIONS:** Intermittent fasting reduced gene expression markers of mitochondrial biogenesis and energy homeostasis, while HIIT appeared to increase markers of atrophy at the end of the intervention period. The combination of IF and HIIT did not show any synergistic effects within the muscle.

Muscle Fibertype Composition Affects Contractile Rate of Force Development (RFD) in vivo

Per Aagaard, Søren Smedegaard, Thomas Madsen, Niels Ørtenblad. University of Southern Denmark, Odense, Denmark.
Email: paagaard@health.sdu.dk

(No relevant relationships reported)

Differences in muscle fiber type composition across human skeletal muscles are paralleled by comparable differences in electrically evoked contractile Rate of Force Development (RFD), with muscles dominated by type II fibers expressing higher RFD (more steep Force-Time curves) than type I dominated muscles (Harridge et al. 1996). However, little is known about the relationship between muscle fiber type composition and RFD when examined in single heterogeneous muscles in vivo (Maffiulletti et al. 2016, Rodriguez-Rosell et al. 2018). **PURPOSE:** To examine the association between fiber type composition and isolated single-joint RFD for the human quadriceps muscle. **METHODS:** Nine untrained male subjects (physical education students) without prior experience in systematic resistance training were recruited for the study (24.2 \pm 7.3 (SD) yr). Maximal isometric gravity-corrected knee extensor torque (MVC) was obtained at 1000 Hz sampling rate at 70° knee joint angle (0° = full knee extension) (KinCom 500H, Chattecx Corp). RFD was analyzed in the early (0-30 and 50 ms) and late (0-100 and 200 ms) phases of rising muscle force (Aagaard et al. 2002). Muscle biopsy samples (VL) were analyzed for fiber type composition and cross-sectional area (CSA) (Andersen & Aagaard 2000). Linear regression analysis was performed using Pearson product-moment method. **RESULTS:** Fiber CSA was 4535 \pm 1271, 5084 \pm 1865 and 4502 \pm 1970 μ m² for type I, IIA and IIX fibers (\pm SD), respectively, while fiber type area percentage was 48.5 \pm 3.1, 35.5 \pm 2.5 and 15.9 \pm 1.7 %. RFD correlated positively (p \leq 0.01) with type II fiber area percentage (0-30 ms: r=0.79; 0-50 ms: r=0.83; 0-100 ms: r=0.81 and 0-200 ms: r=0.78) (0 ms = onset of force). No relationship was observed between MVC and fibertype composition. **CONCLUSIONS:** Rapid force capacity (RFD) of the human knee extensors was strongly and positively associated with the area weighted proportion of type II myofibers, which explained 63-69% and 61-66% of the variance (r²) in RFD during the early (0-30/50 ms) and later (0-100/200 ms) phases of rising muscle force, respectively. In consequence, resistance training aiming to preferentially increase type II myofiber CSA is expected to result in amplified gains in RFD.

Effects Of Doublet Stimulation On Dynamic Muscle Contractility In Muscles With K⁺-suppressed Excitability

Katja K. Pedersen, Ole B. Nielsen, Kristian Overgaard. Aarhus University, Aarhus, Denmark.

Email: katja@ph.au.dk

(No relevant relationships reported)

PURPOSE: Obtaining optimal dynamic muscle contractility demands activation frequencies higher than those needed to produce maximal isometric force. However, such high activation frequencies increase cellular efflux of K⁺ potentially leading to impaired muscle excitability. *In vivo* stimulation frequencies are often low (*sub-tetanic*), and only contain brief bursts of high frequencies (*supra-tetanic*) in the form of doublets. In the present study, we examined how dynamic muscle contractile performance in fast twitch fibers responds to high constant stimulation frequency or doublets and how this response was modulated by a suppression of excitability through increased extracellular [K⁺]. **METHODS:** Dynamic contractions were elicited in isolated rat EDL muscles stimulated either by constant frequency trains of *tetanic* (150 Hz), by *supra-tetanic* (300 Hz) frequencies, or by a *sub-tetanic* frequency (50 Hz) with or without an initiating doublet (300 Hz). Muscles were incubated at 30°C in Krebs Ringer buffer at 4 or 11 mM K⁺. **RESULTS:** Increasing frequency from 150 Hz to 300 Hz increased maximal power (P_{max}) by 15 \pm 3 %, maximal velocity (V_{max}) by 8 \pm 3 %, and rate of force development (RFD) by 23 \pm 3 % at 4 mM K⁺, but at 11 mM K⁺ these increases were attenuated (V_{max} increased by 5 \pm 2 %) or abolished. When using *sub-tetanic* frequency trains, addition of a high frequency doublet induced increases at both 4 and 11 mM K⁺ in maximal force (F_{max}) (15 \pm 3% and 6 \pm 2 %), P_{max} (62 \pm 13 % and 23 \pm 3 %), V_{max} (35 \pm 3 % and 22 \pm 2) and RFD (59 \pm 7 % and 31 \pm 4 %). These relative doublet-induced increases were significantly higher at 4 mM K⁺ than at 11 mM K⁺. However, the absolute level of dynamic contractile function (with or without doublets) was equal or better at 11 mM K⁺ than at 4 mM K⁺ because an increase in [K⁺] *per se* potentiated the dynamic contractile parameters at the *sub-tetanic* stimulation frequency. **CONCLUSION:** These results show that the improved contractility achieved with high constant stimulation frequency is strongly attenuated when excitability is suppressed by high extracellular [K⁺]. However, when using doublets to initiate a train of *sub-tetanic* frequency, thus, mimicking an *in-vivo* like activation pattern, contractile improvements may be achieved both at normal and at high extracellular [K⁺].

Relationship Between Rate of Force Development and Correlates of Muscle Contraction for A Normative Data Set.

Alexander Olczak. State University of New York at Brockport, Brockport, NY. (Sponsor: Dr. Daniel Too, FACSM)

(No relevant relationships reported)

PURPOSE: As a performance measure, rate of force development (RFD) is largely underinvestigated, yet has a profound influence on explosiveness, joint stabilization, and rehabilitation. As a result, little is known about the meaningfulness of RFD and its relationship to neuromuscular function in general. The purpose of this study was to present a normative database for RFD, and to investigate relationships between RFD and factors of muscle contraction. **METHODS:** Two hundred participants completed a series of squat exercises at a speed of 10 degrees per second using a multi-joint, isokinetic dynamometer. Normative data was generated for RFD (M = 2070.2 N*s⁻¹, SD = 1076.0) and presented in the form of percentile ranks. Correlations were examined between RFD and factors of muscle contraction, including force, power, time to peak force, time to peak power, position of peak force, and position of peak power. **RESULTS:** Significant positive correlations were observed between RFD and force (r = .441, p = .000) and power (r = .649, p = .000); significant negative correlations were observed between RFD and time to peak force (r = -.653, p = .000), time to peak power (r = -.655, p = .000), peak force position (r = -.181, p = .010), and peak power position (r = -.552, p = .000). **CONCLUSIONS:** The result is a novel, normative database providing a relative scale of RFD, and relating RFD to correlates of muscle contraction. 4.4482216152605 = 9.80665 * 0.45359237

C-29 Free Communication/Poster - Energetics

Thursday, May 30, 2019, 7:30 AM - 12:30 PM

Characteristics Of The Fecal Microbiota In Professional Martial Arts athletes: Comparison Between Different Competitive Levels

Ru Liang¹, Xiangji Peng¹, Jiyuan Zhou². ¹Beijing Sport University, Beijing, China. ²Peking University Shenzhen Hospital, Shenzhen Peking University-The Hong Kong University of Science and Technology Medical Center, Shenzhen, China.
Email: liangru126@126.com
(No relevant relationships reported)

PURPOSE: Recent evidences suggest that the athletes have distinct microbial features compared to the sedentary subjects. However, few data have been assessed for the gut microbiota characteristics of athletes at different levels of competition. The aim of this study is to investigate whether gut microbiome is significant difference between higher and lower-level athletes. **METHODS:** Fecal microbiota communities were analyzed by using hypervariable tag sequencing of the V3-V4 region of the 16S rRNA gene among 28 professional hard martial arts athletes, including 12 higher-level and 16 lower-level athletes. **RESULTS:** The gut microbial richness and diversity (Shannon diversity index ($p = 0.019$) and Simpson diversity index ($p = 0.001$)) were significantly higher in higher-level athletes than in lower-level ones. Genera *Phascolarctobacterium*, *Parabacteroides*, *Anaerostipes*, *Anaerotruncus*, *Bifidophila*, *Cloacibacillus*, *Desulfovibrio*, *Flavonifractor* and *Oscillibacter* were enriched in the higher-level group. Interestingly, the genera *Parabacteroides* abundance was significantly correlated with time reported exercising during an average week. Further analysis of the functional prediction revealed that three energy metabolism and methane metabolism were markedly over-represented in the gut microbiota of the higher-level athletes. **CONCLUSIONS:** This study provides the first insight into the gut microbiota characteristics of professional hard martial arts athletes. The higher-level athletes have increased diversity and high metabolic capacity of the gut microbiome, which may be positively influential to their performances. This study was supported by China Postdoctoral Science Foundation (grant number 194837) and SZSM201612071.

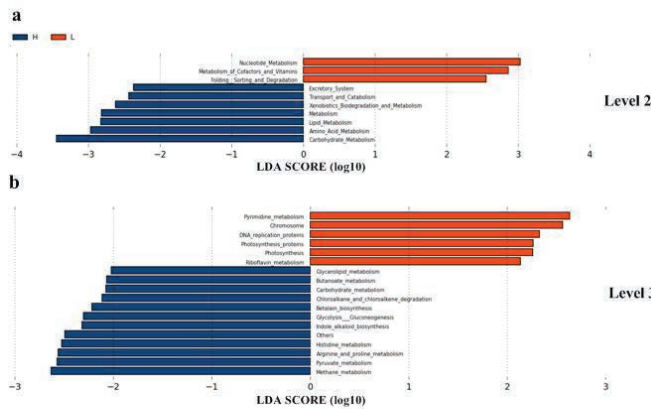

Figure 1. Functional predictions for the fecal microbiome of the higher-level (H) and the lower-level (L) groups. Relative Exercise Intensity And Energy Expenditure Of Exercising On The Freebouncer™

Jared Hartung, Paul Mutch, John P. Porcari, FACSM, Kimberly Radtke, Abigail Ryskey, Carl Foster, FACSM. *University of Wisconsin-La Crosse, La Crosse, WI.* (Sponsor: John Porcari, FACSM)
(No relevant relationships reported)

The Freebouncer™ Fitness and Rehab machine incorporates a spring-loaded platform attached to a metal frame and is designed to provide a low-impact total body aerobic workout. The Freebouncer™ has characteristics similar to mini-trampolines, which have been shown to improve aerobic fitness and positively affect body composition. To date, no research has evaluated the intensity of exercising on the Freebouncer™. **PURPOSE:** To examine the relative intensity of exercising on the Freebouncer™ and determine if it meets ACSM guidelines for improving cardiorespiratory fitness and body composition. **METHODS:** Fourteen apparently- healthy volunteers (9 M, 5 F; mean age = 22.6 yrs) completed an incremental maximal exercise test on a treadmill to determine maximal HR (HRmax) and maximal oxygen consumption (VO₂max). After practice, they then completed a 12-minute interval workout on the Freebouncer™, alternating 30 seconds of squats and bursts with 15 seconds of less vigorous exercises. **RESULTS:** It was found subjects exercised at an average of $75 \pm 12.74\%$ of HRmax and $48.0 \pm 4.54\%$ of VO₂max. Average RPE was 12.3 ± 1.35 . Males burned an average of 10.9 ± 1.57 kcal/min and females burned an average of $6.6 \pm .90$ kcal/min. **CONCLUSION:** Collectively these data suggest that exercising on the Freebouncer™ provides a “moderate-intensity” workout that would result in significant improvements in aerobic capacity and body composition if the product is used regularly.

Rica¹, Nelson Cavas Jr⁴, Gustavo Allegritti João¹, Danilo Sales Bocalini⁵. ¹Universidade São Judas Tadeu, Sao Paulo, Brazil. ²Faculdades Metropolitanas Unidas - FMU, Sao Paulo, Brazil. ³Universidad Mayor, Santiago, Chile. ⁴Universidade Ibirapuera, Sao Paulo, Brazil. ⁵Universidade Federal do Espírito Santo, Espírito Santo, Brazil.
Email: fernandalopes.fisio@gmail.com
(No relevant relationships reported)

Strength training (ST) is considered an important strategy for maintaining body weight, as it promotes an increase in total energy expenditure (EE). However, the combination and manipulation of variables (intensity and volume) allows different training methods. **PURPOSE:** This review aimed to investigate the effect of ST on EE in adults by a systematic literature review and subsequent meta-analysis. **METHODS:** A search was performed on the electronic databases Virtual Library for Health Studies (BVS), PubMed and Science Direct using the following keywords: strength training (resistance training; strength training; strength training method) and energy expenditure (energy metabolisms; energy expenditure; caloric expenditure, caloric cost) with “AND” and “OR” combination. Manual searches of references were also conducted for additional relevant studies. After evaluating the inclusion and exclusion criteria, the selected studies were analyzed according to strength training methods and the training variables used to measure EE. **RESULTS:** The study identified two ST methods from literature review: circuit training (CT) and traditional training (TT). The training density was significantly higher in the CT method when compared with the TT method (TT = 330.61 ± 147.32 vs. CT 749.24 ± 583.70 , $\Delta = -442.32$; IC 95% [-833,17, -51,46] t (-2,52), $p < 0.05$). Meta-analysis showed a significant effect in increases in EE in favor of the TT when compared with CT (-0.99 [95% CI: -1.96, -0.02], $p < 0.01$) with I² of 89% ($p < 0.01$). After adjusting for bias risk, no significant differences were found in EE associated with intensity (-0.40, 95% CI [0.98, 0.18], $p = 0.18$). **CONCLUSIONS:** Therefore, the present review and meta-analysis allowed to conclude that the intensity does not seem to be associated to the increase of EE in ST.

1242 Board #4 May 30 9:30 AM - 11:00 AM Net Energy Efficiency during Synchronous and Asynchronous Arm Cranking at Three different Body Postures

Haejung Jang¹, Somi Yun¹, Jaemyung Kim¹, Eunjin Hwang¹, Ah Reum Jung¹, Hee Jin Lee¹, Dae Taek Lee¹, Ikjin Kwon².
¹Kookmin University, Seoul, Korea, Republic of. ²Chung-Ang University, Seoul, Korea, Republic of.
(No relevant relationships reported)

PURPOSE: This study examined the net energy efficiency (Ee) during synchronous (Syn) and Asynchronous (Asyn) submaximal arm cycling at three different body postures.

METHODS: Nine healthy young men (25.1±3.1 yrs, 177±5 cm, 79.5±12.1 kg, 25.5±3.4 kg/m²), who were not familiar with arm ergometer prior to study, were tested for estimating maximal aerobic capacity (VO_{2max}) during asynchronous arm cranking on an arm ergometer in 3 body postures; upright (UP; 20.8±2.2, 179±14), recline (RC; 21.1±3.4, 168±17), and forward-bent (BF; 21.4±2.8 ml-O₂/kg/min, 167±17 beat/min of maximal heart rate). Based on VO_{2max}, 70% of work intensity was determined for each posture. All participants underwent 6 submaximal arm cranking tests (3 postures by 2 arm cranking modes; Syn or Asyn). They cranked at 50 rpm for 10 min at each test. During tests, their oxygen uptake (VO₂) and mechanical work rate was measured. Ee was calculated from work rate divided by energy expenditure, and compared between 2 modes and 3 postures.

RESULTS: The average VO₂ was 15.3±2.3, 14.3±2.9, 17.0±2.9, 15.5±1.6, 15.7±3.2, and 16.2±2.1 ml-O₂/kg/min at UP-Syn, RC-Syn, BF-Syn, UP-Asyn, RC-Asyn, and BF-Asyn, respectively (p>0.05). Their work rate was ranged from 58.3±6.6 to 61.7±7.9 kilojoule. No differences in Ee were found between Syn (20.4±2.5) and Asyn (19.8±1.7%) in UP. Ee was higher during Syn (21.7±2.7) than Asyn (19.0±2.6%) in RC (p<0.05). Ee was not different between Syn (16.9±2.3) and Asyn (17.8±2.2%) in BF. When comparing Ee during Asyn between postures, no differences were found. Ee during Syn in both UP (p<0.05) and RC (p<0.005) was higher than BF.

CONCLUSIONS: Ee during Syn arm cranking at RC showed the highest, while that during Syn cranking at BF did the lowest. In UP, the arm cranking mode did not affect Ee. In RC, Syn cranking was highly efficient than Asyn. Ee was less than 18% in BF at two cranking modes. It is certain that Ee was dependent on the body posture and the arm cranking mode.

1243 Board #5 May 30 9:30 AM - 11:00 AM Urine Lactate after Continuous and Interval Cycling Exercise Bouts Eliciting Different Blood Lactate Concentrations

Gregory C. Bogdanis¹, Spiros Tsirigkakis², George Mastorakos³, Vassilis Mougios⁴. ¹National and Kapodistrian University of Athens, Dafne, Greece. ²University of Thessaly, Trikala, Greece. ³National and Kapodistrian University of Athens, Athens, Greece. ⁴Aristotle University of Thessaloniki, Thessaloniki, Greece.
Email: gbogdanis@phed.uoa.gr
(No relevant relationships reported)

Post-exercise urine lactate (UL) has been suggested as a novel exercise biomarker of lactate production. The few studies examining the association between post-exercise peak blood lactate (BL) and UL have reported moderate to high linear correlations. However, these studies have not considered BL concentration during exercise.

Also, the range of BL values was narrow (about 10 mmol/L), thus limiting the predictive value of UL. **PURPOSE:** To examine the association between UL and BL concentrations during continuous and interval exercise of equal mean power.

METHODS: Eleven healthy young males performed four trials in random, counterbalanced order, one week apart. All trials included 20 min of cycling with equal mean power output, performed either continuously (CON) or in the form of interval training including 48 x 10 s (HIIT10), 16 x 30 s (HIIT30), or 8 x 60 s (HIIT60) bouts at a power output corresponding to 100% of VO_{2max}. Recovery intervals during the HIIT trials included cycling at 15% of VO_{2max} for 150% of the exercise bout time. Capillary BL concentration was measured at rest and every 5 min during exercise, and UL concentration was measured in urine samples obtained pre- and 1 hour post-exercise, with controlled hydration. BL and UL results were analyzed using 2-way ANOVA with repeated measures (trial x time). The association between incremental area under the blood lactate curve (BL-AUC) and UL concentration was determined using linear and exponential functions.

RESULTS: BL increased compared with baseline in all trials from the first 5 min of exercise (p < 0.01). BL-AUC increased from CON to HIIT10, HIIT30 and HIIT60 (61.7 ± 21.2, 83.4 ± 29.0, 97.8 ± 34.0, 147.4 ± 44.2 mmol/L x min, respectively, p < 0.01). However, post-exercise UL increased from baseline only in HIIT60 (from 1.2 ± 1.0 to 22.5 ± 23.3 mmol/L, p < 0.001). Exercise BL ranged from 3.0 to 17.7 mmol/L, while post-exercise UL ranged from 0.2 to 76.4 mmol/L. The best function describing the BL-AUC and UL relationship was exponential (r = 0.68, p < 0.05).

CONCLUSIONS: The lack of increase in UL despite an increase in BL and their exponential association suggest that there may be a threshold above which BL cannot be disposed within the body and is excreted by the kidneys.

1244 Board #6 May 30 9:30 AM - 11:00 AM The Autonomic Balance Of Master Athlete During Stress Is Associated To Antioxidant Profile

Lysleine Alves Deus, Thiago Santos Rosa, Larissa Alves Maciel, José Morais Souto Filho, Samuel Silva Aguiar, Caio Victor Sousa, Rodrigo Vanerson Passos Neves, Herbert Gustavo Simões. Universidade Católica de Brasília, Brasília, Brazil.
Email: lys.deus@gmail.com
(No relevant relationships reported)

There is a lack in the literature regarding the relationship between autonomic function, as measured by markers of heart rate variability, and the redox balance of master athletes. **PURPOSE:** The redox profile and autonomic responses to stress were measured in master athletes and untrained controls, and the relationships between markers of HRV and redox balance were determined. **METHODS:** Participants (n=55) were 16 master athletes (52.75±9.7yrs, minimal of 20 yr. of lifelong athletic training), 19 age-matched (49.5±10.5yrs) and 20 young controls (22.42±3.8yrs). The volunteers remained seated for 15-min in early morning, with the final 10-min being considered for baseline HRV recordings (Polar RS800X Heart Rate Monitor®), and then were submitted to a cold pressure test (CPT) by immersing the right hand in cold water (3-4 °C) for two minutes in which HRV was measured. The pro- and anti-oxidant status were determined in blood after 8-hour fasting by using commercial kits. A two-way ANOVA with repeated measures and Pearson's moment correlation enabled for comparisons and correlations.

RESULTS: The autonomic profile of master athletes was better than age-matched controls and similar to young control group. No significant correlations were observed between redox profile and HRV parameters in resting [SOD, CAT, AU e TBARS (p>0.05)]. However, during stress (CPT) the participants who presented a higher HRV index (indicating an increased parasympathetic tone during CPT) had a better antioxidant defense, with significant correlations between SOD vs. SDNN (r=0.389; p=0.02), RMSSD (r=0.362; p=0.03), and nn50 (r=0.416; p=0.01); between CAT vs. Mean R-R (r=0.346; p=0.03), SDNN (r=0.375; p=0.02), and RMSSD (r=0.348; p=0.03); as well as between AU vs. nn50 (r=0.383; p=0.02). Similar relationships were observed during post-stress recovery: SOD vs RMSSD (r=0.386; p=0.02) and nn50 (r=0.395; p=0.02); CAT vs. RMSSD (r=0.436; p=0.008) and nn54 (r=0.413; p=0.01); and AU vs. RMSSD (r=0.386; p=0.02) and nn50 (r=0.350; p=0.03). **CONCLUSION:** Besides having a better autonomic and redox balance in comparison to aged-matched controls, the responses of master athletes were similar to young group. Moreover, an improved autonomic balance during stress was associated to a better antioxidant status of the participants.

2.

Research Fellow of the Japan Society for the Promotion of Science

3. DESCENTE Ltd. Osaka, Japan

PURPOSE: To determine effect of wearing compression tights on muscle oxygenation and exogenous glucose utilization during prolonged cycling in endurance athletes.

METHODS: Ten triathletes (19.9 ± 1.2 years, 172.2 ± 4.4 cm, 62.0 ± 3.8 kg, BMI; 20.9 ± 0.7 kg·m⁻²; VO₂max; 59.3 ± 4.4 ml·kg⁻¹·min⁻¹) completed 3 trials under respective conditions: 1) wearing a compression tight with approximately 15 mmHg [MED trial], 2) wearing a compression tight with approximately 30 mmHg [HIGH trial], and 3) wearing a tight with below 5 mmHg [CON trial]. The exercise consisted of 90 min of cycling at 65% of VO₂max. Changes in exogenous glucose utilization (¹³C excretion in expired gas after consuming ¹³C labeled glucose), muscle oxygenation (oxy-hemoglobin, deoxy-hemoglobin, total hemoglobin and tissue saturation index), blood parameters (blood glucose and lactate, and serum glycerol, insulin and total ketone body concentrations), blood gas parameters (pH, pO₂, pCO₂, HCO₃⁻, Na⁺ and K⁺), respiratory variables (VO₂, VCO₂, VE, RER), heart rate and rating of perceived exertion were evaluated throughout the exercise. Time to exhaustion test (at 85% of VO₂max) was performed after completing 90 min of cycling to evaluate endurance performance.

RESULTS: Exercise rapidly increased ¹³C excretion, but highest value of ¹³C excretion was significantly shown earlier in the MED trial (47.1 ± 9.9 min) compared with in the other trials (HIGH trial: 67.3 ± 23.7 min, CON trial: 54.0 ± 9.5 min, *P* = 0.033).

Although MED trial showed significant lower oxy-hemoglobin throughout the exercise (*P* = 0.003), the changes in deoxy-hemoglobin, total hemoglobin and tissue oxygenation index did not differ among the trials. No significant difference was observed for changes in other variables among the trials.

CONCLUSION: Wearing a compression tights exerting approximately 15 mmHg on thigh facilitated exogenous glucose utilization during 90 min of cycling.

Seasonal Changes in Salivary Biomarkers and Psychomotor Function Among Elite Fencers
 Valeriu Tomescu¹, David Bellar². ¹National Olympic Committee, Bucarest, Romania. ²University of Louisiana at Lafayette, Lafayette, LA.
 Email: olimpicus@yahoo.com
 (No relevant relationships reported)

PURPOSE: The present investigation sought to follow a group of elite fencers (n=10) through the competitive season monitoring salivary biomarkers and psychomotor function in order to develop a better understanding of the effects of training and peak competition in this sport.

METHODS: The methods for the present investigation are consistent with the declaration of Helsinki. Athletes provided saliva samples during the morning hours on 22 separate occasions during the main competitive phase of their annual training plan. Additionally, these same athletes completed a standard finger tapping psychomotor test on a tablet before and after training during this same phase of the annual plan. The saliva samples were analyzed via a point of care salivary analysis system for salivary IgA and Cortisol hormone. Finally, the primary coaches for the fencers provided a rank order for the athletes to determine highest and lowest performers. Data was analyzed for trends over time, by athlete rank and by pre-post training sessions using JMP 13.0 Pro software. Statistical significance was set a priori at *p*<0.05.

RESULTS: A significant main effect for time was noted when analyzing pre to post practice change in finger tapping speed over the course of the season (*F*=5.23, *p*=0.024). Further analysis revealed that rank order of athletes (*F*=2.08, *p*=0.043) produced a significant main effect within the data for change in finger tapping speed pre to post practice. (Top half of athletes: 0.259 sec pre, 0.246 sec post; Bottom half of athletes: 0.282 sec pre, 0.251 sec post). Additionally, a significant main effect for time was noted for morning salivary cortisol (*F*=2.35, *p*<0.001). Average values for the group were less than 12 nm during the initial part of the training season, peaked during the middle of the monitoring period at 20.6 nm then fell towards the conclusion of the

season during the main competitions back below 12 nm. A main effect for time was not noted for salivary IgA (*F*=0.969, *p*=0.504). Average values for the season for salivary IgA were 402.5 ± 203 ug/ml.

CONCLUSIONS: Based upon the results of this observational study it appears that stress hormones in elite fencers peak mid-season then decline during the taper at the end of the season. Additionally, it appears that the best of the elite athletes have better baseline psychomotor function.

Perceived Energy and Well Being in Collegiate Football Players with and without Sick Cell Trait
 Matt Martone¹, Shelly Mullenix¹, Nathan Lemoine, Jr¹, Jack Marucci¹, Derek Calvert¹, Timothy S. Church², Brian Harrell², Guillaume Spielmann¹, Brian Irving, FACSM¹, Jennifer Rood², LaKietha Poole², Neil Johannsen¹. ¹Louisiana State University, Baton Rouge, LA. ²Pennington Biomedical Research Center, Baton Rouge, LA. (Sponsor: Brian Irving, FACSM)
 (No relevant relationships reported)

Sickle cell Trait (SCT) has measurable physiological effects. Whether SCT has marked psychological effects in elite collegiate football players (ie perceived their energy levels, mood state, and overall well-being) compared to position-matched controls is unknown. **Purpose:** To examine self-perceptions of sleep quality, mood state, and general well-being in Division 1 football players with and without SCT. **Methods:** Participants with SCT were identified by a team physician and confirmed by electrophoresis and paired with position-matched controls (n=12). Assessments included the Pittsburgh Sleep Quality Inventory (PSQI), Daily Analysis of Life Demands for Athletes Questionnaire (DALDA), Activation-Deactivation Adjective Check List (AD-ACL), and General Well-Being Questionnaire (GWB). Data was collected at three time points; before pre-season camp, after pre-season camp, post-season. **Results:** SCT reported higher levels of energy on the AD-ACL assessment than the control group at baseline (13.65 ± 0.68 vs. 11.56 ± 0.66, *p*<0.05). No group*time interaction existed (*p*=0.20). On the GWB, no differences between groups were found; however, a significant decrease in perceived well-being between pre-camp and post-camp (38.86 ± 1.80 vs. 32.08 ± 1.72, *p*<.05) and pre-camp and post-season (38.86 ± 1.80 vs. 32.69 ± 1.86, *p*<.05) was noted across all participants. Perceived sleep quality was similar across all participants at all time points. **Conclusion:** Participants with SCT reported a greater energy level coming into training camp and had similar perceived energy at the beginning and end of the competitive season compared to position-matched controls. GWB did not differ between groups but decreased in all athletes throughout the season. Interestingly, the post-season survey may be skewed by the win or loss from the final game. The decrease at the start of the season could be due to increased stress due to academic responsibilities or the expectation to perform well and win competitions. Future research will correlate these psychological findings to biological markers of stress and fatigue.

Effect of Gas Exchange Measurements on Critical Power and Determination of Peak Oxygen Uptake during 3 min Critical Power Tests
 Alan D. Moore, FACSM¹, Joshua M. Kern², Shannon L. Jordan¹, Daniel R. Chiles¹. ¹Lamar University, Beaumont, TX. ²Louisiana State University, Baton Rouge, LA.
 Email: alan.moore@lamar.edu
 (No relevant relationships reported)

No data have been reported regarding the effect of performing gas exchange measurements during 3 min "all-out" tests of cycling Critical Power (CP) on the CP value itself. Conflicting data exists regarding the validity of determining peak oxygen uptake (VO_{2peak}) during 3 min CP tests. **PURPOSE:** To determine if differences exist between CP measurements performed with metabolic gas exchange data (WMD) and without (Control) during 3 min leg cycling tests. A second aim of this study was to determine if VO_{2peak} can be determined using data from the 3 min CP test. **METHODS:** Nineteen physically active (VO_{2peak} = 34.7 ± 7.7 ml/kg/min) subjects completed a ramp test to determine VO_{2peak} and two 3 min CP tests (WMD and control). VO_{2peak} was determined from an average of the last 30 sec of the ramp test and compared to VO₂ measured during the final 30 sec of the WMD CP test. Critical power (watts) was the mean power attained during the last 30 sec of the CP tests. The curvature constant (W') was computed as the power-time integral above CP. **RESULTS:** No differences (*p* = 0.11) were observed for CP in the WMD trial compared to the control condition (172 ± 46 W, 169 ± 49 W, respectively). Similarly, no differences occurred for W' (11.3 ± 5.4 kJ WMD, 11.7 ± 4.4 kJ control, *p* = 0.61) and peak watts (673 ± 326 W WMD, 636 ± 335 W control, *p* = 0.84). In regard to VO_{2peak} measured during the CP test (2517 ± 576 ml/min) and that of the ramp test (2564 ± 550 ml/min), there were no differences (*p* = 0.23). **CONCLUSIONS:** These data indicate that CP, peak W, and W' values do not differ between a 3 min all-out test performed with or without gas exchange measurements. Thus, one can be confident

that performing metabolic gas measures during the 3 min CP test does not bias the CP and W' data. As no significant differences were found for VO_{2peak} between the ramp and CP test, the data supports the contention that it is possible to obtain VO_{2peak} in a 3 min all-out CP test.

Potential Benefit of Repeated Resting Metabolic Rate Measurements

Gregory Davis¹, Mary Lavergne¹, Derek Scott¹, Benjamin Kern¹, David Bellar¹, Arnold Nelson, FACSM². ¹University of Louisiana at Lafayette, Lafayette, LA. ²Louisiana State University, Baton Rouge, LA. (Sponsor: Arnold Nelson, FACSM)
 Email: grd4805@louisiana.edu
 (No relevant relationships reported)

Obtaining valid and reliable measurements for resting metabolic rate (RMR) via indirect calorimetry is critical for clinical and research purposes. **PURPOSE:** The primary aim of the study was to determine the reliability of RMR measurements under standard (best practice conditions). The secondary aim was to determine if normal fluctuations in skin temperature, core temperature, heart rate, or environmental factors affect repeated RMR measurements. **METHODS:** Twenty college-aged men entered the lab following an overnight fast. Following twenty minutes of sitting quietly, continuous measurements of environmental temperature, relative humidity, skin temperature, core temperature, and heart rate were recorded along with RMR. Following the initial RMR measurement, participants sat quietly for an additional forty minutes. A second RMR measurement was then completed following the same protocol. Differences between the initial measurement and second measurement for RMR, inter-beat interval, core temperature, skin temperature, and environment were determined using a paired samples t-test for normally distributed data. A Wilcoxon signed-rank test was used for non-normally distributed data. Multiple linear regression was used to determine the relationship between inter-beat interval, core temperature, skin temperature, and environment on RMR measurements. All data are presented as mean \pm SEM. **RESULTS:** The higher of the two RMR measurements was 2067.58 ± 66.03 kcal/day while the lower of the two RMR measurements was 1975.31 ± 64.85 kcal/day ($t = 4.32$, $p < 0.01$). Similarly, the higher of the two core temperature measurements was $37.05 \pm 0.09^\circ\text{C}$ while the lower of the two core temperature measurements was $36.74 \pm 0.09^\circ\text{C}$ ($t = 7.17$, $p < 0.01$). The change in R-R interval for heart rate was significantly correlated with the higher and lower RMR measurements ($r = 0.47$, $p = 0.04$ and $r = 0.53$, $p = 0.02$, respectively). No other factors were significantly related to changes in RMR. **CONCLUSION:** Even when best practice guidelines are followed, significant variability in RMR measurements separated by forty minutes suggest that two measurements of RMR may be necessary to obtain accurate data.

Effects Of Eccentric Versus Concentric Exercise Of The Trunk Extensor On Muscle Function, Blood Lipid Profile And Glycemic Response

Ah-Ram Kim¹, Ho-Seong Lee². ¹Namseoul University, Cheonan-si, Korea, Republic of. ²Dankook University, Cheonan-si, Korea, Republic of.
 Email: ptark@nsu.ac.kr
 (No relevant relationships reported)

The variability in the insulin-stimulated glucose uptake of different skeletal muscles may be partly attributable to the differences in the muscle fiber type composition and the level of expression of the insulin-responsive glucose transporter known as Glucose transporter type 4. **PURPOSE:** To compare and evaluate the functional and metabolic changes from EIMD of the trunk extensor as compared with those induced by concentric contractions. **METHODS:** In a double-blinded, randomized, crossover trial, and ten men performed a single bout of 50 maximal voluntary concentric (CON) and eccentric (ECC) contractions of the trunk extensor at 2 weeks interval. The indirect markers of muscle damage (muscle soreness; SOR, creatine kinase; CK), the muscle function (muscle strength and muscle endurance), the lipid profile (triaclylglycerols; TGs, total cholesterol; TC, high-density lipoprotein cholesterol; HDLC, low-density lipoprotein cholesterol; LDLC) and the glycemic response (glucose, insulin, homeostasis model assessment; HOMA, and glycosylated hemoglobin) were measured before, immediately after, and 24, 48, 72, and 96 hours after each bout of exercise. Moreover, the muscle activity of paraspinal muscles were also recorded during CON and ECC.

RESULTS: The SOR at 24, 48, 72, and 96 hours after ECC had significant increased as compared with that after CON ($p < 0.05$). The TG, TC, LDLC, and TC/HDLC levels were significant lower at 48, 72, and 96 hours after ECC, as compared with those after CON ($p < 0.05$, respectively). The levels of glucose and HOMA were significantly higher at 48 and 72 hours after ECC as compared with those after CON ($p < 0.05$, respectively). However, no significant changes in the muscle strength and endurance,

HDLC, insulin, and glycosylated hemoglobin were observed between the two groups. Meanwhile, the LM and ILL activities were significantly higher during ECC than during CON ($p < 0.05$, respectively).

CONCLUSIONS: Thus, the study confirmed that EIMD of the trunk extensor had positive effects on the blood lipid profile and the glycemic response, and the LM and ILL showed a high level of muscle activity during ECC.

Lactate Threshold Velocity At 4 mMol/l Does Not Maintain Blood Lactate Levels During Steady State Intensity

Juan C. Mazza¹, Raúl L. Festa¹, Sandra L. Prieto², Patricia Cosolito¹, Alvaro N. Gurovich, FACSM³. ¹Biosystem Institute Sports Sciences, Rosario, Argentina. ²Colombia State University, Bogotá D.C., Colombia. ³The University of Texas at El Paso, El Paso, TX.
 Email: juancmazza@wninternet.com
 (No relevant relationships reported)

Evidence shows that lactate threshold (LT) is a valid tool to evaluate endurance capacity and is used to prescribe training intensities. However, there are discrepancies between LT test methodologies and the way to use LT to prescribe training velocities, maintaining metabolic stress in steady-state intensity bouts. Few studies have investigated the relationship of LT Velocity at 4 mMol/l (V4) with intensity prescription on Interval Training (IT) workouts. **PURPOSE:** To determine if V4, obtained via an incremental test, can maintain Blood Lactate (BL) predicted, during a steady-state IT workout in swimmers. **METHODS:** Ten well trained swimmers (19.42 ± 6.77 yrs) performed two freestyle tests: an incremental 6x200-m test with 1-min passive rest, measuring Heart Rate (HR) and BL after each repetition to determine V4; and, 4 days after, a steady-state IT 10x200-m test with 1-min passive rest at V4, measuring BL and HR after reps. 2-4-6-8-10. Paired t-tests were used to compare V4 vs. IT speeds and times and BL@V4 vs. BL after reps. 2-4-6-8-10. In addition, repeated measures ANOVA was used to compare BL after reps. 2-4-6-8-10. Finally, Pearson's correlations (r) were obtained between BL vs HR in both incremental and steady state tests. **RESULTS:** Same speeds and times for V4 and IT were observed (1.38 ± 0.07 m/s and 145.4 ± 7.6 s vs 1.38 ± 0.07 m/s and 145.5 ± 7.5 s, respectively, $p > 0.05$). BL levels were maintained at BL@V4 levels only during reps 2 and 4 (4.10 ± 0.52 ; 3.72 ± 0.63 mMol/l, respectively, $p > 0.05$ vs. BL@V4); however, BL levels decreased over time during reps 6, 8, and 10 (3.59 ± 0.29 ; 3.40 ± 0.33 ; 3.13 ± 0.30 mMol/l, respectively, $p < 0.01$ vs. BL@V4 and vs. reps 2 and 4). Additionally, there was a moderate correlation ($r = 0.69$) between BL and HR during the incremental test. However, a low correlation ($r = 0.26$) between BL and HR during the steady state IT test was observed. **CONCLUSION:** V4 from an incremental test underestimates BL level showing, a progressive decrease during the steady-state IT test. These results suggest that IT at V4 might not be enough to maintain metabolic stress during an IT bout, especially during the second half of it. Additionally, the moderate and low correlations observed between BL vs. HR suggest that HR might not be a good marker of exercise intensity in swimmers.

Validation Of Gas Analysis Over Incremental Work Intensities - A Comparison Of Two Metabolic Measurement Systems

Leila A. Walker¹, David P. Looney¹, Heather M. Hansen¹, Maxwell N. Rome², William J. Tharion¹, Alexander P. Welles¹, Adam W. Potter¹, Christopher R. Chalmers², Reed W. Hoyt¹, Holly L. McClung¹. ¹US Army Research Institute of Environmental Medicine, Natick, MA. ²Oak Ridge Institute for Science and Education, Oak Ridge, TN.
 (No relevant relationships reported)

Indirect calorimetry is a practical and accurate method of measuring metabolic gas exchange rate, specifically volume of oxygen and carbon dioxide ($\dot{V}O_2$ and $\dot{V}CO_2$). Commercial stationary and mobile systems typically include automated metabolic gas analyses. Metabolic cart systems are considered the standard; however, they pose limitations due to cost and portability. **PURPOSE:** To compare the accuracy of a commercially available mobile system (CareFusion Oxycon Mobile®, OXYCON) to a criterion stationary cart system (ParvoMedics TrueOne 2400®, PARVO). **METHODS:** Fifteen volunteers (13 Male, 2 Female; 24 ± 6 y (mean \pm SD), 77 ± 13 kg BW, VO_{2peak} 3.9 ± 0.7 L \cdot min⁻¹) completed four trials over two non-consecutive study days. Trials consisted of a rest period, followed by three incremental treadmill work rates: walk ($23\text{-}36\%$ VO_{2peak}), jog ($49\text{-}67\%$ VO_{2peak}), and run ($60\text{-}76\%$ VO_{2peak}) in controlled laboratory conditions ($20 \pm 0.5^\circ\text{C}$; $45 \pm 22\%$ RH). Metabolic system order was randomized and data collected was averaged over 3-4 minute steady-state periods from each work intensity. Correlation coefficients and systematic bias were used to evaluate the agreement between the systems. **RESULTS:** Measurements of $\dot{V}O_2$ from

the OXYCON and PARVO were highly correlated ($R^2=0.99$). The OXYCON showed some positive bias ($0.18 \pm 0.16 \text{ L}\cdot\text{min}^{-1}$) that increased with work intensity: rest ($\dot{V}O_2 0.05 \pm 0.06 \text{ L}\cdot\text{min}^{-1}$), walk ($\dot{V}O_2 0.15 \pm 0.09 \text{ L}\cdot\text{min}^{-1}$), jog ($\dot{V}O_2 0.26 \pm 0.16 \text{ L}\cdot\text{min}^{-1}$), and run ($\dot{V}O_2 0.31 \pm 0.16 \text{ L}\cdot\text{min}^{-1}$).

CONCLUSION: The mobile OXYCON is an acceptable alternative to stationary metabolic cart systems for measuring metabolic gas exchange rate during rest and low intensity exercise. Clinicians may consider alternative devices for assessments at higher work intensities.

Tissue Oxygen Index Response During Maximal On-ice And Cycling Performances With Short Track Speed Skaters

Fanie St-Jean Miron¹, Emily Walsh², Bianca Marois¹, Gilles Gouspillou¹, Alain Steve Comtois¹. ¹University of Quebec in Montreal, Montreal, QC, Canada. ²Loyola University Chicago Stritch School of Medicine, Chicago, IL.

(No relevant relationships reported)

Cycling tests are usually performed to assess short track speed skater's performances. However, the cycling movement patterns and body position are quite different from the skating movement patterns and the low position that skaters adopt during speed skating on the short track. Thus, a comparison of muscle oxygenation between cycling and skating was conducted, as the low skating position may restrict blood flow to the lower limbs.

PURPOSE: The aim of this project was to create an on-ice test to compare skaters' $\dot{V}O_{2\text{max}}$ and tissue oxygen index (TOI%), while performing maximal progressive tests during on-ice skating and on a cycle ergometer.

METHODS: Twenty-four Canadian short track speed skaters of the provincial level or higher participated in the study. Skaters took part in two separate progressive maximal tests on ice and on a cycle ergometer. Oxygen consumption ($\dot{V}O_2$) was continuously monitored during both tests with a portable metabolic analyzer. Tissue oxygen index (TOI%) was also continuously measured on the vastus lateralis of both legs during both tests and during the post exercise recovery phase. A modified Borg scale was used to assess the rate of perceived cardiovascular effort (RPE), as well as leg pain.

RESULTS: $\dot{V}O_{2\text{max}}$ reached on-ice was significantly lower than $\dot{V}O_{2\text{max}}$ reached on a cycle ergometer (3.56 ± 0.65 vs $4.28 \pm 0.79 \text{ L}\cdot\text{min}^{-1}$, $p=0.001$). When expressed as a function of $\dot{V}O_2$, the TOI% was significantly lower during skating vs cycling for any tested $\dot{V}O_2$. The TOI% of the right leg (RL) was significantly lower than the left leg (LL) at any $\dot{V}O_2$ for both skating and cycling. At maximal capacity ($\dot{V}O_{2\text{max}}$), TOI% was similar for both skating and cycling (~10%). During the recovery phase, TOI% peaked at 80% after 180s of recovery after skating, while it took 120s after cycling. The RPE of cardiovascular effort was significantly lower at the end of the on-ice test vs ergometer cycling test (15.9 ± 2.1 vs 17.0 ± 2.1 , $p=0.005$). However, no differences were detected for leg pain (18.5 ± 1.1 vs 18.4 ± 1.5 , $p=0.671$, respectively).

CONCLUSIONS: The low position adopted by speed skaters appears to restrict blood flow to the lower limbs and thereby negatively impacts muscle oxygenation. These findings reveal the importance of testing short track speed skaters directly on the ice.

1254 Board #16 May 30 9:30 AM - 11:00 AM
Minimal Effects of Hypoxia on Energy System Contribution during Supramaximal Upper-Body Exercise in Women

Tristan Starling-Smith¹, David Boffey¹, Michael La Monica², Jeffrey Stout¹, David Fukuda¹. ¹University of Central Florida, Orlando, FL. ²Missouri State University, Springfield, MO.

(No relevant relationships reported)

High-intensity exercise performed under hypoxic conditions may yield beneficial physiological adaptations due to altered reliance on the anaerobic energy system. This type of intervention is commonly evaluated during lower body cycling; however, considerable differences exist in the upper body musculature, particularly in women.

PURPOSE: To determine the effects of normobaric hypoxia on energy system contribution in females during high-intensity upper-body time to exhaustion trials. **METHODS:** Thirteen recreationally active women (age: 22.7 ± 2.6 y; height: 167 ± 8.6 cm; weight: 66.4 ± 9.7 kg; body fat: $27.6 \pm 5\%$ body fat) completed a graded exercise test in both normobaric hypoxia (H; $F_{iO_2} \sim 14\%$) and normoxia (N; $F_{iO_2} \sim 20\%$) to exhaustion on an arm ergometer to determine the relationship between O_2 uptake and peak power output (PPO). Each participant completed two constant work-rate arm-cranking tests at 110 and 120% PPO in both N and H. Utilizing oxygen consumed during the constant work-rate tests, energy system contribution was determined using the accumulated oxygen deficit method. Two-way (condition \times intensity) repeated measures ANOVA was used to compare absolute AOD ($\text{L}\cdot\text{min}^{-1}$) and AOD relative to lean arm mass ($\text{L}\cdot\text{min}^{-1}\cdot\text{kg}^{-1}$). Three-way (condition \times intensity \times energy system) repeated measures ANOVA was used to compare the percent contributions of the aerobic and anaerobic energy systems. Results are reported as

95% confidence intervals (CI). **RESULTS:** No significant condition \times intensity interactions were noted for relative or absolute AOD ($p>0.05$). A main effect was observed for energy system ($p<0.05$) with aerobic values (95% confidence interval: 59.8% to 71.3%) being greater than anaerobic values (95% CI: 28.7% to 40.2%), while an intensity \times energy system interaction was shown ($p<0.05$) with greater anaerobic contribution at 120% PPO (95% CI: 32.6% to 44.3%) compared to 110% PPO (95% CI: 22.9% to 27.9%). **CONCLUSIONS:** Moderate normobaric hypoxia had little effect, if any, on energy system contribution during high-intensity, constant work-rate arm-cranking in women. These findings suggest that limitations may exist for women when considering hypoxia as a means of altering metabolic stress during supramaximal upper body exercise.

Dual Stress Warm-Up Protocol Does Not Significantly Alter Blood Glucose Concentration

Margaret M. Glick¹, Matthew P. Sacco¹, Eric C. Bredahl¹, Michael T. Lane², Jacob A. Siedlik¹. ¹Creighton University, Omaha, NE. ²Eastern Kentucky University, Richmond, KY.

(Sponsor: Joan Eckerson, FACSM)

(No relevant relationships reported)

Dual stress challenges (e.g. paired physical and psychological challenges) have been shown to increase catecholamine and cortisol responses above that of exercise alone; however, the underlying mechanisms to explain this effect are not well defined. The increased hormonal response is thought to be the result of a greater glucose demand due to the challenges imposed on both the brain and skeletal muscle. **PURPOSE:** To determine whether a dual stress warm-up protocol significantly alters circulating glucose concentrations before and after a Wingate Anaerobic Test (WAnT).

METHODS: Thirteen college-aged subjects (Mean \pm SD; age = 21 ± 3 yr; Height = 177 ± 9 cm; Weight = 81.8 ± 11.8 kg) volunteered to participate and completed a familiarization WAnT on a Monark cycle ergometer using a resistance of 7.5% bodyweight prior to testing. On two separate visits, separated by at least 3 d but no more than 1 wk, subjects randomly completed a WAnT preceded by either a 5 min warm-up at a resistance of 1.5% BW at a pedal rate of 70-80 rpm (CTRL) or the same warm-up while also completing the Paced Auditory Serial Test, which is a mental arithmetic challenge (EXPT). Blood glucose was measured at 5 time points (pre, post warm up, post WAnT, and at 5 min and 10 min post WAnT) using a Contour NEXT Blood Glucose Monitor. Subjects abstained from caffeine, alcohol, and exercise for the 24 hr prior to testing. Diet was standardized across subjects for the 12 hr prior to each visit. Data were analyzed using a 2x5 repeated measures ANOVA ($\alpha < 0.05$).

RESULTS: There were no significant interactions between the two conditions. However, there was a main effect for time ($p = .001$) with glucose concentrations significantly increased at 5 min post WAnT. **CONCLUSION:** These findings suggest that incorporating a psychological challenge during a warm-up session had no effect on glucose concentrations following a WAnT when compared to warm-up session alone. The lack of a significant finding may be due to the relatively small sample size or by the lack of difficulty of the mental challenge. Future studies are warranted using higher-stress cognitive tests to gain a better understanding of the effect of dual stress challenges on glucose concentrations prior to and following exercise.

Exercise Intensity, Energy Expenditure And Enjoyment During Variable High Intensity Exercise In Healthy Adults.

Jenna Thompson, Matthew Wolfe, Meral Culver, Kelly E. Johnson, Justin P. Guilkey. Coastal Carolina University, Conway, SC.

Email: jthomp4@coastal.edu

(No relevant relationships reported)

Variable high-intensity exercise bouts may generate similar energy expenditures and possibly be favored over moderate-intensity exercise as an alternative to obtain optimal health benefits. **PURPOSE:** To examine exercise intensity, energy expenditure and perceptual responses to work-matched moderate-intensity steady-state exercise (MIE) and variable-intensity exercise (VIE) conditions in healthy adults ($n = 6$, age = 24.3 ± 5.4 yrs). **METHODS:** A graded exercise test on the cycle ergometer to maximal exertion was utilized to determine maximal oxygen uptake ($\dot{V}O_2$), maximal heart rate (HR) and work rate max (WRmax) for subsequent conditions. The two experimental conditions (MIE and VIE) were randomized and performed on separate days. MIE consisted of continuous moderate-intensity exercise at 40% of WRmax. VIE consisted of sixteen 10-sec supramaximal sprints (120% WRmax), sixteen 20-sec high intensity bouts (60% WRmax) and low-intensity recovery (20% WRmax) interspersed throughout the exercise. Total duration and total work were matched between conditions. $\dot{V}O_2$, heart rate (HR) were averaged over the entire bout for both conditions. OMNI ratings of perceived exertion (RPE) and affect, via Feelings Scale, were measured during exercise and enjoyment was measured post-exercise using the physical activity enjoyment scale. Responses between conditions were analyzed

using paired t-tests. Significance was established if $p < 0.05$. **RESULTS:** During VIE and MIE, HR (156 ± 10 bpm vs. 141 ± 12 bpm) and percent of maximal HR ($81.6 \pm 3.2\%$ vs. $73.3 \pm 4.1\%$) were significantly different. Absolute $\dot{V}O_2$ during VIE and MIE were 1.42 ± 0.22 L \cdot min $^{-1}$ and 1.27 ± 0.24 L \cdot min $^{-1}$ ($p = 0.13$). The intensities relative to $\dot{V}O_{2max}$ were similar between bouts (VIE = $50.9 \pm 10.3\%$; MIE = $44.9 \pm 8.0\%$). Total energy expenditure of VIE and MIE were 212.5 ± 32.3 kcal and 189.4 ± 36.3 kcal, respectively ($p = 0.12$). While perceived exertion (VIE = 4.6 ± 0.9 ; MIE = 3.6 ± 1.3) was similar between trials, in-exercise affect and post-exercise enjoyment were greater in VIE (2.0 ± 0.9 and 92.2 ± 3.3) compared to MIE (1.7 ± 1.0 and 77.2 ± 5.8). **CONCLUSION:** In healthy adults, VIE was perceived as more positive and enjoyable, while eliciting a greater HR response and similar energy expenditure compared to MIE. VIE may be an alternative exercise to MIE to obtain health benefits.

Muscle Energy and Salivary Cytokine Response During a 100 Mile Trail Run: A Case Study

Taran Bailey¹, Ellis Jensen², Steven Namanny², Andrew Creer².
¹allen parcell, Provo, UT. ²Utah Valley University, Orem, UT.
(Sponsor: allen parcell, FACSM)
(No relevant relationships reported)

Purpose: The purpose of this study was to determine the impact of competing in a 100-mile ultramarathon on muscle fuel stores and cytokine production. **Methods:** One experienced male runner (40 yrs, 76.3 kg, 177.8 cm) completed the 100.5-mile distance in 32.9 hrs. Measurements were collected pre-race, at each support crew accessible aid station (28.5, 41, 52, 66, and 80 miles), and post-race. Measures included saliva cytokine markers (IL-6 and TNF- α), muscle energy status, and body mass. Saliva was collected using a passive drool technique and samples were stored on dry ice until they could be sent out for analysis. Muscle energy status (MES) was determined by scanning the right rectus femoris with a portable ultrasound transducer. Scanned muscle images were uploaded to a cloud-based application where they were analyzed for MES, which is an arbitrary number assigned to the muscle based on predicted glycogen concentration. Caloric expenditure was predicted based off average pace and terrain. Caloric intake was monitored by a combination of self-reporting, product wrapper collection, and unconsumed fluid measurement. **Results:** Caloric expenditure was estimated at 13,184 kcal (401 kcal/hr), while caloric intake was recorded at 5888.3 kcal (180 kcal/hr). Body mass declined 2.4% from pre to post-race, although it fluctuated throughout the race (76.3, 74.7, 74.1, 75.1, 75.9, 75.4, 74.5 kg; respectively). MES was reduced 57% from pre to post-race, but also fluctuated throughout the race (88.0, 34.4, 71.9, 25.1, 69.1, 70.9, 38.2). IL-6 levels correlated with MES values ($R^2 = 0.6987$). TNF- α values followed a similar pattern to IL-6; however, no correlation was found between TNF- α and MES. **Conclusion:** These data provide some interesting insights into potential MES plasticity and cytokine regulation during prolonged exercise. More specifically, fluctuating MES values observed during the current activity suggest that glycogenolysis and glycogenesis may occur throughout an ultra-event depending on terrain and intensity, even with a discrepancy between caloric intake and expenditure. Additionally, salivary IL-6 activity may be related to MES, suggesting that periods of low glycogen may increase physiological stress.

Tissue Oxygen Recovery Time in Back and Front Squats

Patrick R. Davis, John P. Yakel, Matthew C. Wagner, Allison P. Glave. Sam Houston State University, Huntsville, TX.
Email: davis@shsu.edu
(No relevant relationships reported)

Near infrared spectroscopy (NIRS) can be used to measure skeletal muscle tissue oxygen (SmO_2) levels, which may be a useful indicator of recovery and fatigue during resistance training.

Purpose: The purpose of this study was to determine the SmO_2 recovery rate in both the Vastus Lateralis (VL) and Biceps Femoris (BF) muscles in traditional back squats and front squats.

Methods: Eleven recreationally resistance trained participants completed the study. The 1-repetition maximum (1-RM) was determined for the front and back squats on two different occasions. In subsequent visits a wireless NIRS device was applied over the VL and BF on each leg. Participants completed 3 sets of 15 repetitions with 2-3 minutes of recovery using 70% of their 1-RM weight. During recovery, participants sat on a bench next to the squat rack. To complete the study, participants would repeat the above procedures for the other squat form (front or back) with at least 48 hours in-between visits. Repeated measures ANOVA was used to determine differences in the recovery rate.

Results: The recovery rate of SmO_2 (% $SmO_2/0.5$ sec) was calculated as the slope of SmO_2 over time between 10-50 seconds of during each recovery period. The mean recovery rate during the third set recovery for VL in back squats was 0.885 ± 0.194 % $SmO_2/0.5$ sec and 0.785 ± 0.129 % $SmO_2/0.5$ sec in front squats. Mean recovery rate for third set recovery for BF in back squats was 0.449 ± 0.083 % $SmO_2/0.5$ sec

and 0.290 ± 0.059 % $SmO_2/0.5$ sec in front squats. There were significant differences in the SmO_2 recovery rates between the BF and VL in both legs ($p < 0.05$). There were no significant differences between the recovery rates in back vs front squats. Similar differences were found in the first and second set recovery periods.

Conclusion: During front and back squats the initial rate of recovery of SmO_2 is more rapid in the VL than in the BF. Additionally, there are no differences in SmO_2 recovery rate between front and back squats.

Myocardial Strain Imaging in Asian Competitive Athletes - A Single Centre

Yann Shan Keh. Singhealth Cardiology, Singapore, Singapore.
Email: yannshan.keh@mohh.com.sg
(No relevant relationships reported)

ABSTRACT INTRODUCTION

To date there has been limited literature pertaining to Athlete's Heart Syndrome in Asian athletes, especially for those in South East Asia.

METHODS

We performed a single center cross-sectional case-control study of elite athletes and controls, using current speckle-tracking echocardiography (STE) and tissue Doppler imaging (TDI)-based techniques. We reanalyzed previous data to further characterize the biomechanical changes in exercise induced cardiac remodeling elite athletes and controls at a tertiary hospital in Singapore.

RESULTS

The Left Ventricular (LV) strain of the athletes' group was significantly lower as compared to the control group (-19.0 ± 2.0 vs -20.3 ± 1.8 , $p = 0.011$). Furthermore, both LV torsion (14.3 ± 17.8 %/s vs 14.4 ± 6.7 %/s, $p = 0.031$) and Lateral S' (7.21 ± 1.4 vs 8.7 ± 1.6 , $p = 0.001$) showed small but statistically significant decreases in the athletes' group versus the controls. The athletes group demonstrated a significantly lower Basal Right Ventricular (RV) free wall strain as compared to the controls (-19.8 ± 5.5 vs -26.5 ± 6.4 P < 0.001). The mid RV strain was marginally higher in the athletes' group versus the controls (-25.0 ± 4.3 vs -24.7 ± 15.3 P = 0.023).

CONCLUSIONS

Our findings of impaired LV strain and torsion as well as basal RV free walls strain in the South East Asian athletes group mirror studies done in Western cohorts. The higher mid RV free wall strain could represent compensatory response to the impaired basal RV function in athletes.

Factors Affecting Aortic Root Diameter in a Population of Former Professional Football Players

Genevieve E. Smith, Mark M. Cassidy, Gregory W. Stewart, FACSM. Tulane University, New Orleans, LA. (Sponsor: Gregory Stewart, MD, FACSM)
Email: glum@tulane.edu
(No relevant relationships reported)

Purpose: Examine potential factors affecting aortic root size and dilation prevalence in former professional football players. Additionally, two methods of aortic root dilation (ARD) assessment were compared. **Methods:** For this cross-sectional study, former professional football players ($n = 1325$) were sampled for demographics, anthropometry, blood pressure, and 2D echocardiographic measurement of aortic root diameter (AoD) at the Sinus of Valsalva. Body surface area (BSA) was used to obtain indexed aortic root diameter (IAR). ARD was assessed by two methods: using previously described nomograms for IAR prediction (pIAR) and by $IAR > 1.9$ cm/ m^2 (ASi), according to normal IAR range. Subjects were stratified by age and position groups for comparison. Statistical analysis included ANOVA, T-test, and Chi-square where appropriate. **Results:** The prevalence of ARD was $15.2\% \pm 2.4$ and $2.4\% \pm 1.0$ according to pIAR and ASi methods, respectively ($p < 0.0001$). Both age and position group (PG) had a significant effect on AoD ($p < 0.0001$ and $p = 0.0018$, respectively) and IAR ($p < 0.0001$ and $p = 0.0005$, respectively). However, when age was considered a covariate for PG, only IAR tended to remain significant ($p = 0.0560$). Both AoD and IAR increased with age; While ARD prevalence increased with each 20-year increase in age according to both prediction methods (pIAR: $p < 0.0001$; ASi: $p = 0.0025$), there was no effect of PG (pIAR: $p = 0.2879$; ASi: $p = 0.4856$). While IAR was greater in hypertensive versus normotensive subjects ($p = 0.0076$), AoD did not differ between the two ($p = 0.6616$), and ARD prevalence was higher in hypertensive subjects only via the ASi method ($p = 0.0202$). Finally, the presence of left ventricle

hypertrophy (LVH) contributed to ARD prevalence when pIAR was used ($p < 0.0001$), but not when the ASi method was considered ($p = 0.1047$), with larger AoD in subjects with LVH versus those with normal geometry ($p = 0.0090$), while IAR did not differ between the two ($p = 0.1106$). **Conclusions:** Body size, age, playing position, and LVH were all found to impact both aortic root size and ARD. Thus, methods of ARD assessment in these men should ideally account for both body size and age. Therefore, pIAR may be best for assessment of ARD in this population.

Effects of Aerobic and Resistance Training on Diabetic Heart Function: Roles of Titin and Collagen

Shunchang Li¹, Min Liang¹, Derun Gao¹, Quansheng Su¹, Ismail Laher². ¹Chengdu Sport Institute, Chengdu, China. ²University of British Columbia, Vancouver, BC, Canada. (Sponsor: Tongjian You, FACSM)

Email: lishunchang_1983@163.com

(No relevant relationships reported)

PURPOSE: To examine the effects of aerobic and resistance exercise training on cardiac function, and investigate the roles of cardiomyocyte passive tension regulators (titin and collagen) in the mechanism of exercise-induced changes in cardiac function in diabetic rats.

METHODS: Sixty male SD rats were randomly divided into six groups: control (C), aerobic exercise (A), resistance exercise (R), diabetic (D), diabetic plus aerobic exercise (DA), and diabetic plus resistance exercise (DR). Type II diabetes was induced by high-fat diet feeding and low-dose streptozocin injection. Rats in the A and DA groups ran on a treadmill at 21m/min for 60 min, and rats in R and DR groups climbed a ladder bearing incremental loads daily, 5 days per week for 8 weeks. Fasting blood glucose (FBG) and insulin (FINS) concentrations were determined by a standard procedure. Cardiac function (such as the specific indicators of cardiac diastolic dysfunction-- Min dp/dt, Tau) was measured using a catheter insertion through the right carotid artery and a Labchart data acquisition and analysis system. Expression levels of collagen I, collagen III and TGFβ1 were determined using Western blot, and titin expression levels were analyzed using Immunofluorescence. Two-way ANOVA and post-hoc tests were used to assess differences between groups.

RESULTS: Compared to non-diabetic groups, diabetic groups had higher FBG ($P < 0.01$), lower Min dp/dt ($P < 0.05$), and longer Tau ($P < 0.05$); in addition, the diabetic groups had significantly lower expression levels of titin ($P < 0.05$), and higher expression levels of collagen I and TGFβ1 ($P < 0.05$). Compared to non-exercise diabetic rats, diabetic plus exercise groups had lower FBG ($P < 0.01$), -54.3% in DA and -66.0% in DR) and HOMA-IR ($P < 0.01$, -46.6% in DA and -53.8% in DR); the DA rats had higher expression levels of titin ($P < 0.05$) and Min dp/dt ($P < 0.05$), lower expression levels of collagen I ($P < 0.05$) and TGF-β1 ($P < 0.05$), and shorter Tau ($P < 0.05$), but the DR rats had higher expression levels of collagen I ($P < 0.05$) and TGFβ1 ($P < 0.01$).

CONCLUSION: Greater improvements in diabetic cardiac function occurred with aerobic exercise training, possibly through decreasing titin-dependent myocardial stiffness and collagen-dependent interstitial fibrosis.

Cardiovascular Drift Response Over Two Different Constant-load Exercises In Healthy Non-athletes. Case Study.

Camilo Germán Alberto Pérez Chaparro, Frank Mayer, Claudia Beckendorf. *University of Potsdam, Potsdam, Germany.*

Email: perezcha@uni-potsdam.de

(No relevant relationships reported)

Cardiovascular drift (CV-d) is a steady increase in heart rate (HR) over time while performing constant load moderate intensity exercise (CME) > 20 min. CV-d presents problems for the prescription of exercise intensity by means of HR, because the work rate (WR) during exercise must be adjusted to maintain target HR, thus disturbing the intended effect of the exercise intervention. It has been shown that the increase in HR during CME is due to changes in WR and not to CV-d.

Purpose

We aimed to investigate whether, indeed, the CV-d in healthy young people exercising at the WR corresponding to the lactate individual anaerobic threshold (IAT) determined in two different cardiorespiratory exercise test (CPT), was related to the WR difference.

Methods

Seven participants (30 ± 3 years old, 1.75 ± 0.1 m., 74.6 ± 12.8 Kg.) performed on different days two CPT with a WR increase of 20 Watts (W) every one or three minutes until exhaustion. The WR corresponding to the IAT was determined during these tests. The participants then performed two CME with a WR corresponding to the IAT. HR and blood lactate (La) were continuously measured during all tests. A comparison between CPTs and CMEs were made using a paired *t*-test. A one-way ANOVA repeated measurements was used to compare La values during the CME.

Results

VO_{2max} (36.9 ± 5.9 vs. 35.6 ± 5.7 ml·Kg⁻¹·min⁻¹; $p > 0.05$), maximal HR (181 ± 9 vs. 178 ± 11 bpm; $p = 0.3$), and peak La (8.7 ± 1.6 vs. 7.8 ± 1.6 ; $p = 0.1$) did not differ between CPTs. Maximal power output (271 ± 80 vs. 223 ± 75 W; $p < 0.001$) and WR at the IAT (164 ± 63 vs. 137 ± 45 W; $p > 0.01$) were different between CPTs. La between CMEs and minutes 10 and 30 were not different (3 ± 0.4 vs. 3.3 ± 0.5 ; $p = 0.1$). One-CME mean HR was 157 ± 12 bpm with an increase of 8 ± 4 bpm between minutes 10-30. Three-MCE HR was 147 ± 14 bpm and the HR increased by 9 ± 7 bpm between minute 10-30. Only a difference in HR between the two CME was found ($p = 0.009$) whereas there was no difference in the HR change between minute 10-30 ($p = 0.7$).

Conclusion

In this case study, the CV-d was not significantly different between the two CMEs (One-IAT and Three-IAT) despite a significant difference in the amount of WR between CMEs (26 ± 19). Other factors aside from the WR like an increase in peripheral blood flow, hyperthermia, plasma volume reduction, catecholamine levels, and training status play a role in the CV-d phenomenon.

Evaluations Of Nonstationary And Stationary Autonomic Nervous Function Using Heart Rate Variability For Syncope Patientswith Non-cardiogenic Causes

Noritaka Hata¹, Kazukuni Hirabuki¹, Tomoya Suda¹, Yuki Sano¹, Marina Fukuie², Takahiro Uechi¹, Ai Hirasawa¹, Takeaki Matsuda¹, Shigeki Shibata¹. ¹Kyorin University, Tokyo, Japan. ²University of Tsukuba, Ibaraki, Japan.

Email: hatanori1019@gmail.com

(No relevant relationships reported)

Background:One of the main causes of syncope is neuroregulatory syncope. Thus, it is very important to assess autonomic nervous function for syncope patients. Heart rate variability (HRV) was widely used for indirect evaluation of cardiac autonomic function. HRV was usually assessed with RR intervals changes of resting condition. Recently, however, HRV analysis using 24 hours Holter electrocardiogram became available to evaluate cardiac autonomic function during activity. **Purpose:**The aim of this study was to evaluate cardiac autonomic function of non-cardiogenic syncope patients using HRV analysis. **Method:**Seventy-six patients with non-cardiogenic causes of syncope were enrolled. They were divided into initial group ($n=31$, 68 ± 15 years old, 19 males, 12 females) and recurrence group ($n=45$, 57 ± 24 years old, 24 males, 21 females). RR intervals were measured with electrocardiogram at rest (stationary) and with 24 hours Holter electrocardiogram during activity (nonstationary). The three HRV frequency-domains (low frequency power: LF, high frequency power: HF, LF/HF ratio) were calculated. **Results:** At the nonstationary state, HF was significantly higher in the recurrence group than in the initial group. (HF: 160 ± 19 ms² vs. 410 ± 69 ms², $P=0.01$, ANCOVA; age and sex). There were no significant differences in LF and LF/HF ratio between the two groups at the nonstationary state. At the stationary state, there were no differences in LF, HF and LF/HF ratio between the two groups. There were significant relationships in LF and HF between the stationary and nonstationary states (LF: $r=0.78$, HF: $r=0.83$, $P < 0.01$), while LF/HF ratio did not show significant relationship. **Conclusion:** Our results indicated that the recurrent non-cardiogenic syncope patients had increased parasympathetic nerve activity at the nonstationary state. The evaluation of HRV at the nonstationary state may be more important for syncope patients than that at the stationary state, although HRV showed significant relationships between the stationary and nonstationary states.

The Effects of Low Intensity Resistance Exercise Training on Cardiac Autonomic Function in Obese Postmenopausal Women

Alexei Wong¹, Arturo Figueroa, FACSM². ¹Marymount University, Falls Church, VA. ²Texas Tech University, Lubbock, TX. (Sponsor: Arturo Figueroa, FACSM)

Email: awong@marymount.edu

(No relevant relationships reported)

Menopause and obesity are associated with a deterioration of cardiac autonomic dysfunction (CAF) and are independent risk factors for cardiovascular disease (CVD). Heart rate variability (HRV) is a non-invasive tool for the evaluation of CAF. HRV is adversely influenced by menopause and obesity in women. Resistance exercise has emerged as an important strategy for the prevention and treatment of CVD. Low intensity resistance exercise training (LIRET) appears to be a useful modality for promoting improvements in muscular mass and strength, while being relatively safe for populations with increased cardiovascular risk. However, the possibility of improving CAF in obese postmenopausal women is currently unknown. **PURPOSE:** The purpose of this study was to examine the effects of LIRET on HRV and strength

in obese postmenopausal women. **METHODS:** Twenty obese postmenopausal women [age (54 ± 1 years) and body mass index (34.4 ± 0.8 kg/m²)] were randomized to either (n= 10) or no-exercise control group (n= 10) for 12 weeks. LIRET consisted on 4 different exercises for the leg musculature per session 3 x week. Participants performed 2-3 sets involving 18-22 repetitions for each exercise per session. Total power (TP), low-frequency power (LF), high-frequency power (HF) (vagal tone), the LF to HF ratio (LF/HF) (sympathovagal balance), heart rate (HR) and leg strength were measured before and after 12 weeks. LF and HF were normalized to TP resulting in nLF (sympathetic activity) and nHF. Logarithmic transformation (Ln) was performed to normalize the HRV variables in absolute units. **RESULTS:** There were significant group-by-time interactions ($P < 0.05$) for nLF, nHF, LnLF/LnHF, and ($P < 0.01$) for leg strength. There were significant decreases ($P < 0.01$) in nLF ($-6 \pm 1\%$) and LnLF/LnHF (-0.7 ± 0.1) as well as significant increases ($P < 0.01$) in nHF ($5 \pm 1\%$) and leg strength (27 ± 2 kg) following LIRET compared with no changes after control. No significant changes were observed in LnTP or HR after 8 weeks for both groups. **CONCLUSIONS:** Our findings indicate that LIRET improves CAF by improving sympathovagal balance in obese postmenopausal women.

Atg7 Involves In Cardioprotection Induced By Exercise Preconditioning Against Exhaustive Exercise-induced Myocardial Injury

Dongfeng Wan, Shanshan Pan. *Shanghai University of Sport, Shanghai, China.*

Email: derfulwon@126.com

(No relevant relationships reported)

The cardioprotective effects induced by exercise preconditioning (EP) in early phase has been proved, while the mechanism involved in cardioprotection is a multifactorial process. Several studies have identified that autophagy is one of the mechanisms of cardioprotection induced by EP. As a rate-limiting enzyme, Atg7 plays a pivotal role in autophagy.

Purpose: The aim of this research was to investigate the alteration of Atg7 during the early cardioprotective effects of EP against exhaustive exercise-induced myocardial injury.

Methods: Male 8-week-old Sprague-Dawley rats were divided into four experimental groups randomly: Group C (control), Group EE(exhaustive exercise), Group EEP (early exercise preconditioning) was subjected to an intervallic exercise of four periods of 10 min running at 30 m/min with 10 min intervallic rest. Group EEP+EE (early exercise preconditioning plus exhaustive exercise) was used to explore cardioprotection of EEP against exhaustive exercise-induced myocardial injury. Atg7 was detected by immunofluorescence and western-blot.

Results: In group C, Atg7 positive expression stained red and scattered in myocardial cytoplasm, and the nucleus was bright blue. Compared with group C, the positive reaction of Atg7 increased strongly in group EE and group LEP. The high Atg7 levels observed after exhaustive exercise were significantly (0.46 ± 0.14 vs. 0.73 ± 0.40 , $p < 0.05$). The levels of Atg7 were increased significantly after early phase of EP (0.46 ± 0.14 vs. 0.74 ± 0.30 , $p < 0.05$). Although there were no significant differences of Atg7 levels between group EE and group EEP+EE ($p > 0.05$), they had a downward trend in group EEP+EE.

CONCLUSION: The increased levels of Atg7 induced by autophagy might involve in the early cardioprotection of EP against exhaustive exercise-induced myocardial injury. Supported by the National Natural Science Foundation of China (Grant No. 31471136)

(No relevant relationships reported)

Previous studies conducted with athletes have suggested a minimum of 3 days are required for identifying training induced adaptations in supine, morning, resting heart rate variability (HRV). However, there are no studies evaluating the minimum days required for appropriate reliability of HRV measures in non-athletes, and during different conditions of evaluation. **PURPOSE:** 1) To evaluate the reliability of a prominent HRV measure, the root mean square of the successive differences of R-R intervals (RMSSD), during different conditions in non-athletes; 2) to identify the minimum number of days required for weekly (5-day) evaluations of RMSSD. **METHODS:** Thirty-four young, physically active individuals (22.2 ± 3.6 years) completed daily 4-min R-R recordings during supine, seated, standing and walking (5 km/h) conditions over 5 days. Relative (intraclass correlation coefficients, ICC) and absolute (technical error of measurement, TEM; coefficient of variation, %CV)

reliability, and bias were calculated for 1, 2, 3, and 4 days, and compared with weekly (5 days) assessments. **RESULTS:** Excellent reliability was identified for all conditions over 4 days ($ICC \geq 0.986$, $CV \leq 2.8\%$) that was diminished when examined over 3 ($ICC \geq 0.970$, $CV \leq 3.4\%$), 2 ($ICC \geq 0.932$, $CV \leq 5.7\%$) and 1 ($ICC \geq 0.804$, $CV \leq 10.2\%$) day. When compared with weekly recordings, 2 day recordings demonstrated excellent and similar reliability values for all conditions examined, with better values observed for supine vs. seated vs. standing vs. walking conditions. **CONCLUSIONS:** From the current results, daily assessment of RMSSD is highly reliable with a minimum of 2 days of recordings recommended for determination of weekly HRV in non-athletes, regardless of the condition.

Effects of Wheel Running on Health-Related Outcomes in Growth Restricted Mice.

Eric C. Leszczynski, Logan A. Pendergrast, David P. Ferguson. *Michigan State University, East Lansing, MI.*

(No relevant relationships reported)

Growth restriction caused by early life undernutrition leads to an increased risk of cardiovascular disease, hypertension, type II diabetes and sarcopenia. However, limited information exists on the beneficial effects of physical activity engagement in growth restricted individuals. **PURPOSE:** To determine the effects of wheel running access on health-related outcomes in growth restricted mice. **METHODS:** Mice were undernourished in gestation (GUN, N=15) or lactation (PUN, N=17) by feeding FVB mothers a low protein diet (8% protein). The control group (CON, N=14) was fed a normal protein diet (20% protein) throughout gestation and lactation. At postnatal day 21 (PN21), all pups were weaned and re-fed with the control diet. At PN45, mice were singly housed and either given access to a free moving running wheel (VOL-wheel access) or used as a non-active control (SED-sedentary). At PN70 a maximal treadmill test was performed to determine exercise capacity, and at PN72 echocardiography was performed to evaluate cardiovascular function. **RESULTS:** Final body weight showed SED PUN (M: 21.22 ± 2.07 g, F: 17.42 ± 1.7 g) weighed significantly ($P = 0.0002$) less than SED CON (M: 26.83 ± 2.2 g, F: 20.65 ± 1.65 g) and SED GUN (M: 26.9 ± 1.5 g, F: 19.98 ± 1.6 g) mice, while the VOL CON mice (M: 24.9 ± 1.62 g, F: 23.0 ± 1.42 g) were significantly larger ($P = 0.0441$) than VOL PUN mice (M: 22.6 ± 2.7 g, F: 20.0 ± 2.26 g). Wheel access improved treadmill running time to exhaustion in CON ($P = 0.045$, VOL: $1078 \pm 47s$, SED: $936 \pm 40s$), and GUN mice ($P = 0.042$; VOL $1021 \pm 39s$ SED $890 \pm 44s$), but not PUN mice ($P = 0.59$; VOL $933 \pm 31s$ and SED $908 \pm 32s$). Echoes showed heart rate was significantly lowered ($P = 0.002$) in GUN mice (VOL: 366 ± 11 bpm; SED: 421 ± 10 bpm) with running wheel access. Stroke volume was also significantly higher ($P = 0.02$) in GUN mice (VOL: 27 ± 1.2 uL; SED: 23 ± 1.1 uL). VOL CON ($1.64 \pm 0.08mm$) mice had a significantly greater ($P = 0.05$) left ventricular anterior wall thickness at systole than SED CON ($1.38 \pm 0.08mm$). **CONCLUSION:** Voluntary wheel access does not attenuate growth-restriction in PUN mice nor does it improve maximal treadmill tests. This is due to a lack of improvements in cardiac function for PUN mice, despite access to voluntary wheel running, while GUN mice did improve.

Carnosine Essential For Cardiac Function. A Study With Knockout Rats For The Carnosine Synthase Gene

Livia S. Goncalves, Lucas Sales, Alan Lins Fernandes, Tiemi Raquel Saito, José Natali, Leonardo Jensen, Alexandre Arnold, Isis Correa, Diogo Sant'Anna, Juliane Campos, Lislely Ramalho, Maria Cláudia Irigoyen, Júlio Ferreira, Guilherme Giannini Artioli. *University of Sao Paulo, São Paulo, Brazil.*

Email: liviasouzaigoncalves@gmail.com

(No relevant relationships reported)

Carnosine is present in high concentrations in heart, where it appears to increase the sensitivity of the contractile apparatus to Ca²⁺. However, it is currently unknown whether this role is relevant to the cardiac physiology. **Purpose:** To evaluate the impact of the lack of carnosine on myocardial contractile function in rats knockout (KO) for the CARN1 gene (carnosine synthase1). **Methods:** We developed the first KO animal model for the CARN1 gene through CRISPR-Cas9 technology. Male wild-type (WT) and KO rats (4 months-old) were used. *In vivo* cardiac function was assessed by echocardiography (ECO) and cardiac electrical activity by electrocardiography (ELECTRO). Cardiomyocyte contractile function was assessed in isolated cardiomyocytes by measuring cardiomyocyte and sarcomere contractility analysis, along with the determination of Ca²⁺ transient. Unpaired t-tests were used to compare variables between WT and KO. The study was approved by the Ethics Committee on the Use of Animals of USP. **Results:** ECO (WT:n=4; KO:n=6) showed that KO rats presented a higher systolic diameter (WT: 0.008 ± 0.001 mm/g; KO: 0.011 ± 0.001 mm/g; $p = 0.002$), lower Fraction of Left Ventricular Ejection (WT: $80.26 \pm 6.86\%$; KO: $69.86 \pm 4.67\%$; $p = 0.01$) and lower Fraction of Left Ventricular Shortening (WT: $51.12 \pm 7.39\%$; KO: $40.88 \pm 3.92\%$; $p = 0.01$), characterizing systolic dysfunction. ELECTRO (WT: n=8; KO: n=8) showed higher T wave amplitude in the KO group (WT: 0.06 ± 0.02 mV; KO: 0.13 ± 0.03 mV; $p = 0.005$), indicating a disturbance

in the Ca²⁺ channels. *In vitro* contractility data (WT: n=3; KO:n=3) showed that sarcomere shortening is reduced in the KO (WT:11.75±4.20%; KO:9.28±3.71%) (WT:6.81±3.15s; KO:4.33±1.87s ; p<0.0001), and the time to reach 50% of maximal shortening is longer in the KO (WT:0.04±0.01s; KO:0.05±0.01s; p<0.0001). Ca²⁺ transient analysis showed lower amplitude of Ca²⁺ in the KO group (WT:0.20±0.10; KO:0.16±0.06 F340/380 ratio; p=0.001) and longer time for to reach 50% of the Ca²⁺ decay rate (WT:0.21±0.04s; KO:0.24±0.03s; p=0.001). **Conclusion:** Absence of carnosine resulted in systolic dysfunction associated with Ca²⁺ transient changes in cardiac muscle. This is the first evidence to demonstrate *in vivo, ex vivo* and *in vitro* that carnosine is essential for normal cardiac function. Supported by FAPESP 2014/11948-8 and CAPES

Left Ventricular Morphology and Function of Recurrent Syncope Patients

Kazukuni Hirabuki. *Kyorin University, tokyo, Japan.*
Email: hirabuki0303@gmail.com
(No relevant relationships reported)

[Purpose]

It has been known that number of syncope episodes during life is the strongest predictor for future syncope recurrence. It has been reported that impaired left ventricular diastolic function (LVDF) and low cardiac output due to left ventricular (LV) atrophy are related with orthostatic intolerance. The aim of this study was to clarify whether the number of syncope episodes would be related to LV morphology and function.

[Methods]

We enrolled clinically non-cardiogenic syncope patients who presented at the emergency department of Kyorin University Hospital between 2015 and 2018. We divided them into 2 groups: F (1 episodes of syncope during life) and R (2 or more). Early diastolic filling velocity (E), atrial filling velocity (A), deceleration time (DT), peak early diastolic velocity of the mitral annulus (e'), E/A, and E/e' were assessed by echocardiography. LV mass (LVM) was calculated by Devereux Formula, which was normalized by BSA (LVM index, LVMI). Stroke volume (SV) and ejection fraction (EF) were estimated by modified Simpson's method. ANCOVA statistics, adjusting for sex and age, was used to compare those parameters between the 2 groups.

[Results]

Of 80 patients enrolled, F group were 35 (68±17 years old, 19 men) and R group were 45 (56±23 years old, 23 men). E/e' was significantly lower in the F group than that in the R group (E/e': 8.72±0.44 vs. 10.00±0.39, p=0.037). There were no significant difference between the two groups in E (67±3 vs 70±2 m/s, p=0.45), A (73±3 vs 74±2 m/s, p=0.85), E/A (1.05±0.05 vs 1.11±0.05, p=0.44), DT (222±11 vs 227±9 ms, p=0.72), e' septal (7.3±0.2 vs 6.8±0.2 m/s, p=0.18), e' lateral (9.0±0.4 vs 9.1±0.3 m/s, p=0.87), SV (48±2 vs. 46±2 ml, p=0.36), EF (65±1 vs. 63±1 %, p=0.66), LVM (138±7 vs. 148±6 g, p=0.28) and LVMI (86±4 vs. 91±3 g/m², p=0.36).

[Conclusions]

These results suggest that impaired LVDF is one possible pathophysiology for repeated non-cardiogenic causes of syncope, but LV morphology and systolic function are not.

The Impact Of Acute Hyperglycemia On Heart Rate Variability In Men And Women.

Jennifer S. Williams, Taylor Stimpson, Jacob T. Bonafiglia, Joshua C. Tremblay, Alyssa M. Fenuta, Brendon J. Gurd, Kyra E. Pyke. *Queen's University, Kingston, ON, Canada.*
Email: willij3@mcmaster.ca
(No relevant relationships reported)

BACKGROUND: Heart rate variability (HRV) is used to non-invasively assess autonomic nervous system (ANS) regulation of the heart. Chronic hyperglycemia has been known to reduce HRV; however, no research has examined the impact of acute hyperglycemia on HRV, considering the potential for sex- and menstrual cycle phase-based differences. **PURPOSE:** To examine the impact of acute hyperglycemia on HRV, in men and women during the early and late follicular phases of the menstrual cycle. **METHODS:** 41 healthy men and naturally menstruating women (17F, age: 21±1 years) were recruited. Women were assessed during the early and late follicular phases of the menstrual cycle. 'Ultra short-term' assessments of HRV (1-minute recordings) were completed using an electrocardiogram before, and 60- and 90-min after consuming a 75g oral glucose challenge. Analysis of HRV time-domain variables was performed. **RESULTS:** Acute hyperglycemia resulted in elevated HR (shorter R-R intervals) at 60- and 90-min post-glucose ingestion (Pre: 61±1, Post60: 65±1, Post90: 66±1 bpm; p=0.005, p<0.001 respectively), with no differences between men and women, or across phases of the menstrual cycle. The root mean square of successive differences between R-R intervals (RMSSD) and standard deviation in normal R-R intervals (SDNN) were significantly lower Post90 vs Pre (p=0.022, p=0.048 respectively), with no sex differences. Additionally, women, regardless of phase, had higher average HR compared to men (p<0.001). **CONCLUSION:** Acute

hyperglycemia appears to decrease HRV, indicative of an acute change in ANS regulation. Furthermore, this study confirmed previously observed sex differences in HR, but not in HRV. Research supported by: NSERC Discovery Grant & Canadian Graduate Scholarship - Master's

Post exercise Heart Rate And Vagal Reactivation Correlates With Vagal Withdrawn After Orthostatic Maneuver In Men

Guilherme Eckhardt Molina, Edgard Soares, Davi A. de Lima, Daniel Saint Martin, Giliardi Lago Garcia, Carlos Janssen da Cruz, Luiz Guilherme Grossi Porto. *University of Brasilia, Brasilia, Brazil.*
Email: gmolina@unb.br
(No relevant relationships reported)

PURPOSE: The relationship between post-exercise parasympathetic reactivation, chronotropic reserve recovery (CRR) and the cardiac autonomic modulation responsiveness to active postural change at rest is still an open field to be explored. Therefore, our objective was correlate parasympathetic reactivation, CRR with cardiac autonomic status after an orthostatic maneuver (active stand from supine position) at rest.

METHODS: Cardiac Parasympathetic reactivation (rMSSD) at 1st min and CRR from the 1st, to 5th min following sub-maximal graded exercise were correlated with absolute and relative change of time-domain index (rMSSD) after active postural change from supine to standing position using heart rate variability (HRV) in 20 physically active, non-athlete men. Statistical analysis employed non-parametric tests with two-tailed p-value set at 5%.

RESULTS: Parasympathetic reactivation in the 1st min of post-exercise recovery correlated positively with absolute and relative vagal withdrawal (rMSSD) after orthostatic maneuver ($r_s = 0.41$ p= 0.02 and $r_r = 0.58$ p= 0.01). CRR at 1st min post-exercise time did not correlated with absolute or relative cardiac autonomic modulation responsiveness after active postural change at rest. However, CRR from the 2nd to the 5th min positively correlated with absolute and relative vagal withdrawal (rMSSD) after orthostatic maneuver (Absolute: $r_s = 0.64$ -0.73; p = 0.01 - < 0.01) and (Relative: $r_s = 0.37$ -0.53; p = 0.04 - < 0.01).

CONCLUSIONS: Parasympathetic reactivation and CRR during the initial 1st to 5th minutes of the recovery period after sub-maximal graded exercise is exercise is positively correlated with the parasympathetic decrease (reserve) after active postural change at rest in physically active, non-athlete men. In others words, we observed that highest parasympathetic decrease after postural change at rest, highest was CRR during post-exercise recovery.

(No relevant relationships reported)

Age-related metabolic dysfunctions occur in a wide variety of clinical manifestations, including hyperglycemia, dyslipidemia and increased body fat. These conditions increase the risk of cardiovascular diseases (CVD), which can develop low heart rate variability (HRV) and higher resting heart rate (HR). The pathological metabolic conditions in older adults are associated with a hyperactive sympathetic nervous system (SNS). **PURPOSE:** To compare the SNS activity and metabolic markers associated to CVD in type 2 diabetic (T2D) and non-diabetic (ND) Mexican older adults. **METHODS:** Volunteers were 11 T2D (Age = 60.8 ± 5.2 yr., body mass index [BMI]= 29.9 ± 4.6 kg/m²) and 17 ND (Age = 64 ± 4.8 yr., BMI = 28.4 ± 4.1 kg/m²) older adults residing in Baja California, Mexico. Morning blood serum samples were collected after 8-h fasting following body composition analysis (InBody 770, Cerritos, CA). A 5-min resting ECG recording (BioRadio, Cleveland, OH) was used to analyze HRV. Time and frequency domain analysis were assessed with Kubios HRV 3.1 software (Kubios Oy, Finland). **RESULTS:** Between-group differences were found on blood glucose (T2D = 171.9±91.6 vs. ND = 80.17±12.0mg/dL, p < 0.001), and triglycerides (T2D = 266.9±126.17 vs. ND = 60.54 ± 47.8mg/dL, p < 0.02). Non-significant between-group differences were found on cholesterol (T2D = 183.0±45.1 vs. ND = 180.9±29.7mg/dL, p = 0.88), HDLc (T2D = 60.54±55.8 vs. ND = 47.88±20.73mg/dL, p = 0.92) and LDLc levels (T2D = 84.4±44.6 vs. ND = 107.84±26.74mg/dL, p = 0.22). The HR (T2D = 72.6±11.5 vs. ND = 71.7±7.8bpm, p = 1.0), beat-to-beat intervals (RR) (T2D = 845.7±128.7 vs. ND = 843.7±93ms, p =

0.94), Root Mean Square of the Successive Differences (RMSSD) (T2D = 68.7±58.0 vs. ND = 45.6±31.2ms, $p = 0.45$) and relative successive beats with > 50ms of difference (pNN50) (T2D = 23.4±25.5 vs. ND = 9.7±13.7%, $p = 0.32$) were similar in both groups. High- (T2D = 48.14±24.64 vs. ND = 45.5±22.9n.u., $p = 0.67$) and Low-frequency (T2D = 51.7±24.5 vs. ND = 54.0±23.3n.u., $p = 0.70$) time domains and LF/HF ratio (T2D = 2.0±2.4 vs. ND = 2.4±3.0, $p = 0.68$) were similar in both groups. **CONCLUSIONS:** Diabetic conditions did not affect substantially SNS activity compared with non-diabetic condition in a sample of Mexican older adults.

Effects of Maturational Development on Central Hemodynamics in Pre and Post Adolescent Children

Austin T. Lassiter, Kaitlin T. McShea, Hwan Kim, Nicholas D. Tocci, Marco Meucci. *Appalachian State University, Boone, NC.* (Sponsor: Scott R. Collier, FACSM)
Email: lassiterat@appstate.edu
(No relevant relationships reported)

There has been a clear trend of increased cardiovascular disease risk development in adulthood as children have begun to develop large artery stiffness at an earlier age due to possible increased adiposity and poor diet. In recent years, there has been a pressing need to observe the implications of maturation on central hemodynamic parameters among children before and after pubertal development. **PURPOSE:** This study sought to observe the differences in central hemodynamic parameters between children pre and post-adolescence. **METHODS:** Children pre and post-adolescence (ages 7-12 and 13-17 years, N= 33, N= 20, respectively) were included in this study. Central hemodynamics including ejection duration percentage (ED%), forward pulse height (PH_f), reflected pulse height (PH_r), reflection magnitude (RM%), augmentation index (AIx75), heart rate period (HRP), and time to reflected wave (T2) were assessed through brachial blood pressure measurement using the Sphygmocor XCEL device. Pulse wave velocity (PWV) was obtained through carotid applanation tonometry. **RESULTS:** From pre-adolescence to post-adolescence, values indicate a significant decrease in ED% (42.2 ± 5.7% to 37.4 ± 4.3%, $p = 0.002$), AIx75 (13.6 ± 13.6% to 3.2 ± 9.7%, $p = 0.004$), and RM% (49.2 ± 6.1% to 44.0 ± 5.9%, $p = 0.003$). However, significant increases were observed in PWV (4.3 ± 0.7 m/s to 5.1 ± 0.8 m/s, $p = 0.0003$), HRP (791.2 ± 133.5 ms to 929.8 ± 134.3 ms, $p = 0.001$), and PH_f (25.5 ± 4.0 mmHg to 29.5 ± 4.5 mmHg, $p = 0.002$). **CONCLUSION:** Major findings indicate that increases in PWV may be due to pubertal development and ED%, and HRP may be associated with an increase in heart mass. decreases in AIx75 and RM% and an increased PH_f may be associated with increased height or vessel length. Future studies are necessary to determine possible factors responsible for seen changes.

The Influence of Cardiovascular and Metabolic Variables on Autonomic Nervous System Activity

Michael Jarrett, Travis Anderson, Laurie Wideman, FACSM, Paul Davis, FACSM. *University of North Carolina, Greensboro, Greensboro, NC.* (Sponsor: Paul G. Davis, FACSM)
Email: msjarret@uncg.edu
(No relevant relationships reported)

Multiple factors influence the balance of parasympathetic (PS) and sympathetic (SY) drive in the autonomic nervous system (ANS). Root mean square of successive differences of R-R intervals (RMSSD), is a linear metric obtained during the assessment of heart rate variability (HRV) and represents PS input to the heart. Systolic time intervals (STI) assessed via pre-ejection period (PEP, the time from the start of the QRS complex to the opening of the aortic valve), are a non-invasive measure that reflects SY activity at rest. **PURPOSE:** To investigate the effects of biological variables typically associated with metabolic syndrome on ANS activity as measured by RMSSD and PEP. **METHODS:** Utilizing the Atherosclerosis Risk in Communities (ARIC) dataset, 1,216 subjects (62.8% female, 74±4.8yrs) free from known cardiovascular disease, hypertension, myocardial infarction, and diabetes, not currently taking beta-blockers, and non-smokers were evaluated for fasting glucose (FBG) and insulin (FI) concentrations, waist circumference (WC), blood pressure (BP), RMSSD and PEP. Simultaneous 5-minute recordings of resting ECG, carotid arterial pulse, and phonocardiogram were used to assess PEP and RMSSD. FBG, FI, and WC inferred a latent variable termed glucose management (GM), where pulse and diastolic BP inferred a latent variable termed cardiac control (CC). Path analysis assessed the relationship between latent variables and RMSSD and PEP, after controlling for age, race, and sex. **RESULTS:** The model fit was acceptable (root mean square error of approximation = 0.108 [90% CI = .098, .118], comparative fit index = .649, and standardized root mean square residual = .07), with CC positively associated with PEP ($\beta = .27, p < .01$), but negatively associated with RMSSD ($\beta = -.41, p < .01$). Contrary to CC, GM was negatively associated with PEP ($\beta = -.18, p < .01$), but positively associated with RMSSD ($\beta = .20, p < .01$). **CONCLUSIONS:** Latent variables (CC and GM) in this model show opposing associations with RMSSD and PEP, suggesting that the metabolic syndrome risk factors included influence HRV and STI. This

Abstract was prepared using ARIC Research Materials obtained from the NHLBI Biologic Specimen and Data Repository Information Coordinating Center and does not necessarily reflect the opinions or views of the ARIC or the NHLBI.

Early Ovarian Hormone Deprivation Increases Cardiac Contractility In Old Female Rats - Role Of Physical Training

HUGO C.D. SOUZA, Ana Carolina S. Felix, Sabrina G.V. Dutra, Stella V. Philbois, Tábata P. Faccioli. *UNIVERSITY OF SAO PAULO, Ribeirão Preto, Brazil.*
Email: hugocds@fmrp.usp.br
(No relevant relationships reported)

Physiological menopause occurs around 51 years of age. However, in some cases, menopause can happen early, that is, before the age of 40. Of the main consequences of early ovarian hormones deprivation or early menopause, one of the most alarming is the increased risk of cardiovascular diseases, contributing to an increase in the morbidity and mortality rate in these women. Our hypothesis is that early deprivation of ovarian hormones, when associated with the aging process, promotes more adverse cardiac remodeling and greater damage to cardiac function related to physiological ovarian failure. Thus, aerobic physical training is fundamental to attenuate these deleterious effects. **PURPOSE:** The objective of the present study was to investigate the effects of early deprivation of ovarian hormones on cardiac morphological and functional parameters in 82 week-old female rats subjected to ovariectomy at 10 weeks of age, as well as to evaluate the application of aerobic training as a non-pharmacological therapeutic tool. **METHODS:** Female Wistar rats (N = 48) were divided into two groups, at 10 weeks of life: early ovarian hormones deprivation by ovariectomy (OVX; N=24) and sham (SHAM; N=24). Between weeks 62 and 82, 12 animals of each group underwent aerobic training (OVX-T and SHAM-T, N=12). At the end of week 82, all were evaluated by echocardiography, cardiac function (Langendorff technique) and cardiac β -adrenergic receptor expression quantification. **RESULTS:** Echocardiography showed slight changes in morphology between OVX and SHAM. OVX ($\Delta = 101 \pm 4.7$ mmHg) showed higher values for maximal left intraventricular pressure in response to dobutamine, when compared to SHAM ($\Delta = 55 \pm 11.8$ mmHg). Both OVX-T ($\Delta = 70 \pm 4.0$ mmHg) and SHAM-T ($\Delta = 22 \pm 6.6$ mmHg) showed a reduction in this response. While, β -adrenergic receptor expression was not different between the sedentary groups, SHAM-T (0.23 ± 0.02AU) and OVX-T (0.29 ± 0.01AU) showed decreased expression of these receptors when compared to their respectively sedentary groups. **CONCLUSIONS:** Early ovarian hormones deprivation associated with aging, promotes discrete changes in cardiac morphology, increasing cardiac contractility. Aerobic training decreases β -adrenergic receptors expression, influencing the cardiac contractility. Supported by FAPESP Grant 01937-9

Strength Training Attenuates Hypertension And Preserves The Diastolic Function Of Spontaneously Hypertensive Rats: Role Of Linear Periodization

Danilo S. Bocalini¹, Roberta L. Rica², Ariana A. Silva², Adriano F. Maia¹, Mauro S. Perilhão³. ¹Federal University of Espírito Santo, Vitoria, Brazil. ²São Judas Tadeu University, São Paulo, Brazil. ³Federal University of São Paulo, São Paulo, Brazil.
(No relevant relationships reported)

PURPOSE: Among non-pharmacological strategies to hypertension control, aerobic physical training as well as strength training has been indicated as an important time point to general treatment. However, little is known when the training program is periodized in a linear progression. In this way the aim of this study was evaluated the effects of a linear strength training program on parameters of cardiac remodeling in spontaneously hypertensive rats. **METHODS:** Thirty rats were distributed in three groups: untrained normotensive (N, n: 10), untrained hypertensive (H, n: 10) and trained hypertensive (TH, n: 10). The training protocol (12 climbs with 90 second intervals) was organized in three mesocycles of four weeks, with an increase in the training load organized in a linear progression (60%, 65%, 70% and 75%) for each block, considering the weight established in the maximum load test. The following parameters were evaluated: ventricular function evaluated by echocardiogram, systemic blood pressure, ventricular hemodynamics, cardiac morphometric and myocardium contractility. **RESULTS:** No significant changes ($p > 0.05$) were found in FEAT between groups, however, animals from group H had a longer isovolumetric relaxation time compared to other groups, which did not differ between them. There was a significant reduction of caudal BP in the TH group after eight training weeks, additionally, negative correlations were found between systolic blood pressure and increased muscle strength as well as total work, indicating the influence of these parameters on SBP control. The HR, PSVE, and PDFVE values of the H and TH groups did not differ, but both were higher than N group. The values of +dP/dt of H group were lower than the N and HT groups, which did not differ from each other. The RV, LV and cardiac mass values did not differ ($p > 0.05$) between the H and HT

groups, however, they were superior to the N group. The nuclear volume was not different between groups; however, the total collagen content of H group was higher than N and HT group. **CONCLUSIONS:** Briefly, the findings in this study suggest that the training program performed promoted pressure attenuation and preserved the ventricular function of spontaneously hypertensive rats with no change in heart mass.

(No relevant relationships reported)

Purpose:

To determine if there is a relationship between turnout, self-reported hip symptoms, and femoral head anterior translational motion under dynamic ultrasound in a population of adolescent ballet dancers.

Methods:

Cross-sectional cohort study. Population: 25 ballet academy students, 17 females and 8 males, ages 14-18 yrs. Dynamic ultrasound of the bilateral hips was performed on each study participant in supine position. With the low frequency linear ultrasound probe in sagittal oblique plane, the distance between the femoral head and acetabular rim was measured in 3 positions: both hips in neutral position, ipsilateral hip in neutral and contralateral hip hyperflexed, and with the ipsilateral hip in extension and external rotation and the contralateral hip hyperflexed. Compensated turnout was defined as difference between functional turnout angle in first position and total bilateral hip passive external rotation in prone. Each participant completed the Hip Osteoarthritis and Outcome Score (HOOS) questionnaire.

Results:

Spearman's rho correlation coefficient (r) was used to test strength of association between variables, defined as <0.3 = poor, $0.3-0.5$ = fair/moderate, $0.5-0.7$ = good, >0.7 = strong. $P=0.05$ was used as threshold for statistical significance. IBM SPSS software (version 23, SPSS, Chi, IL) was used for all analyses. Mean maximal femoral translation distance for the right hip: 0.66mm ($\pm 1.74\text{mm}$), and the left hip: 1.56mm ($\pm 1.93\text{mm}$). Mean compensated turnout: 62.8° ($\pm 14.8^\circ$). There was no significant correlation between femoral translation and HOOS scores, nor between femoral translation and compensated turnout (right: $p=.56$, $r=0.123$, left: $p=.203$, $r=-0.64$). There was a significant correlation between greater compensated turnout and higher mean bilateral HOOS scores, with strongest association in the domains: symptoms ($p=.02$, $r=.463$), quality of life ($p=.003$, $r=.561$) and activities of daily living ($p=.034$, $r=.426$).

Conclusions:

In this population of adolescent ballet dancers, there was no significant correlation between femoral head translational motion on ultrasound and compensated turnout or self-reported symptoms. There was significant correlation between degree of compensated turnout and more favorable self-reports on hip symptoms and function.

1278 Board #40 May 30 9:30 AM - 11:00 AM Effects Of Downhill Running On Muscle MRI T2 In Young mdx Mice

Zahra Moslemi, Christopher Lopez, Abhinandan Batra, Andrew Rennick, Sean C. Forbes. *University of Florida, Gainesville, FL.*
Email: zmoslemi@ufl.edu
(No relevant relationships reported)

Previous studies have demonstrated that downhill treadmill running causes skeletal muscle damage that can be detected with magnetic resonance transverse relaxation time (T_2) in adult dystrophic mice (*mdx*). However, young *mdx* mice (under 12 weeks of age) are characterized by a peak inflammatory phase with greater heterogeneity among muscles, potentially making it more difficult to detect T_2 changes. **PURPOSE:** To determine whether muscle damage following downhill running can be detected in young *mdx* mice using proton magnetic resonance imaging (MRI) and spectroscopy (MRS). **METHODS:** C57BL/10ScSn-DMDmdx (*mdx*, $n=5$) and wild-type C57BL/10ScSn (controls, $n=5$) male mice of 6-9 weeks of age performed downhill

running on a treadmill (14% grade at 8-12m/min for 45-60 min). MRI/MRS was conducted prior to and 24 hours following running in the mice hindlimbs. T_2 -weighted, multiple-slice, single spin-echo MR axial images were acquired (TR 2s, TE 14/40 ms, 12 slices) from the hindlimbs. MRI T_2 values were calculated on a pixel-by-pixel basis for the anterior compartment (AC), posterior compartment (PC), and the deep medial region between the tibia and fibula (MC). In addition, single voxel ^1H -MRS data were acquired from the soleus and gastrocnemius using stimulated echo acquisition mode (STEAM; TR 9 s, 32 TE's exponentially spaced: 5-288 ms, 4 phase cycles) with a 4.7 T Varian/Agilent MR system. **RESULTS:** At baseline, T_2 was elevated ($p<0.05$) in *mdx* mice ($26.8\pm 1.2\text{ms}$) compared to controls ($24.8\pm 0.9\text{ms}$). Following downhill running, the *mdx* mice had elevated ($p<0.05$) T_2 values compared to baseline when a composite of the compartments were compared (Pre: $26.8\pm 1.2\text{ms}$; Post: $28.8\pm 1.4\text{ms}$). The MC was typically (80%) the most affected hindlimb region in the *mdx* mice. Similarly, ^1H -MRS derived T_2 values were increased ($p=0.05$) in a composite measure of the soleus and gastrocnemius after downhill running ($29.8\pm 4.2\text{ms}$) in *mdx* compared to before downhill running ($26.4\pm 2.8\text{ms}$). There were no significant changes in T_2 in control mice after performing the downhill running protocol. **CONCLUSIONS:** Overall, our findings support the use of downhill running combined with MR T_2 measures as a valuable approach for testing potential therapeutic interventions in young dystrophic mice. **Funding Source:** NIH (NIAMS) R01 AR070101.

1279 Board #41 May 30 9:30 AM - 11:00 AM Interactions Among Age, Sex, and Scanning Location in the Assessment of Rectus Femoris Echo Intensity

Adam Burton, Matthew Stock. *University of Central Florida, Orlando, FL.*
Email: aburton426@gmail.com
(No relevant relationships reported)

Echo intensity is an ultrasound-derived measurement of skeletal muscle quality believed to reflect both fibrous tissue content and adipocyte infiltration. Moderate correlations between echo intensity and measures of muscle function have been reported in older adults. But, it is less clear if the aging process results in comparable declines in muscle quality in men and women. Also, it has yet to be determined if age and sex discrepancies are uniform throughout a muscle. **PURPOSE:** The purpose of this investigation was to examine differences in echo intensity among younger and older men and women along the length of the rectus femoris. **METHODS:** Fifteen younger men (mean \pm SD age = 23 ± 3 years), fifteen younger women (21 ± 2 years), eight older men (75 ± 6 years), and sixteen older women (70 ± 5 years) participated in this study. Participants were untrained, healthy, and had a body mass index $\leq 30\text{ kg/m}^2$. B-mode ultrasonography was used to acquire panoramic images of the dominant rectus femoris in the transverse plane at the one-third, one-half, and two-thirds distances along the length of the rectus femoris. ImageJ software was used to analyze the images. Echo intensity was corrected for subcutaneous tissue thickness using sex-specific equations. Analyses of variance and effect size statistics were used to analyze the data. **RESULTS:** When collapsed across scanning location, differences between men and women (marginal mean difference = 28.1 AU , $p < .001$) were greater in magnitude than those for younger versus older adults (marginal mean difference = 7.0 AU , $p = .237$). However, age had a strong influence on differences among scanning locations, with proximal echo intensity ($107.8 \pm 14.5\text{ AU}$) being significantly lower than the middle ($127.6 \pm 13.7\text{ AU}$) and distal ($130 \pm 19.6\text{ AU}$) values for older men ($F = 7.4$, $p = .018$, partial $\eta^2 = .514$), with a similar trend for older women ($F = 2.9$, $p = .073$, partial $\eta^2 = .164$). Within each sex, younger adults had very similar echo intensity values at the proximal, middle, and distal sites (greatest mean difference $< 5.0\text{ AU}$). **CONCLUSION:** The difference in corrected echo intensity is greater for men versus women compared to younger versus older adults. Furthermore, aging results in nonuniform changes in muscle quality throughout the belly of the rectus femoris, with greater deterioration at the middle and distal portions.

1280 Board #42 May 30 9:30 AM - 11:00 AM Can Changes In Echo-intensity Be Used To Detect The Presence Of Muscle Swelling?

Noam Yitzchaki, Tayla E. Kuehne, Samuel L. Buckner. *University of South Florida, Tampa, FL.* (Sponsor: Marcus Kilpatrick, FACSM)
Email: noamy@mail.usf.edu
(No relevant relationships reported)

When examining skeletal muscle, it has been suggested that changes in echo-intensity (EI) measured with B-mode ultrasound can detect the presence of edema-induced muscle swelling. Specifically, if an increase in muscle size is accompanied by an increase in EI it is thought that true growth has not occurred. Interestingly, our research group has shown that small upward and downward tilting of the ultrasound probe can have a large influence on EI, while having minimal impact on muscle thickness (MT). This suggests that proposed changes in EI following resistance exercise may be artifact from probe tilt as opposed to swelling. **PURPOSE:** To examine the acute changes in biceps MT and EI, while accounting for probe tilt, following 4 sets of biceps curls.

METHODS: 49 resistance-trained men and women were recruited. Individuals in the experimental group (n = 23) visited the laboratory twice. During the first visit, paperwork and one repetition maximum (1RM) strength were measured. During the second visit, individuals performed 4 sets of biceps curls to volitional failure using 70% of their 1RM. B-mode ultrasound images of the biceps were taken to examine changes in both MT and EI. The ultrasound probe was equipped with a standard spirit level to ensure that probe tilt would play a minimal role in all EI measurements. Ultrasound measurements were taken immediately before and following exercise. Individuals in the control group (n = 26) visited the lab on one occasion and served as a time-matched control for changes in both MT and EI. Results are presented as means (95% CI). **RESULTS:** For MT there was a group by time interaction ($p < 0.001$). MT increased in the experimental group [mean change = 0.44 (0.33-0.54) cm], but not in the control group [mean change = -0.015 (-0.03-0.01) cm]. For EI, there was no group x time interaction ($p = 0.074$). In addition, there were no main effects for group ($p = 0.254$) or time ($p = 0.314$). The mean difference in the change in EI between groups was -2.99 (-6.25-3.03) arbitrary units. **CONCLUSIONS:** Our results suggest that EI does not appreciably change in response to acute swelling when accounting for probe tilt. In addition, changes in EI were not different compared to a time matched non-exercise control. It seems unlikely that EI can provide meaningful information regarding the presence of muscle swelling following exercise.

1281 Board #43 May 30 9:30 AM - 11:00 AM
The Validity And Reproducibility Of A 5-minute
Endurance Test Of The Diaphragm Muscle

Hallie R. Wachsmuth, Elizabeth K. Pryor, Kevin K. McCully, FACSM. *University of Georgia, Athens, GA.* (Sponsor: Dr. Kevin McCully, FACSM)
 Email: hrw89340@uga.edu
 (No relevant relationships reported)

Diaphragmatic function could be important in treating respiratory failure. Electrical stimulation and accelerometer-based mechanomyography have been used to identify the endurance index of various muscles, but not of the diaphragm.

PURPOSE: Measure the validity and reproducibility of an endurance test of the diaphragm muscle using electrical stimulation of the phrenic nerve.

METHODS: Ten healthy subjects (21.3±1.1 yrs) were tested in the supine position on two separate occasions within one week. Custom-made stimulation electrodes were placed on the left (n=12) or right (n=2) phrenic nerve, which lies underneath the sternocleidomastoid muscle. The stimulation intensity to induce a vigorous contraction was determined. An accelerometer was placed on the abdomen. The endurance test consisted of 5 minutes of electrical stimulation on 5 Hz, with a sampling rate of 400 Hz. The average acceleration per minute was recorded. The endurance index, which equals the ending value/peak value*100, was then calculated. A series of practice tests were performed before data collection.

RESULTS: The test was successfully completed 27/30 times. The time to find the phrenic nerve was 43.9±50.4 s for trial 1 and 25.9±26.3 s for trial 2. The average endurance index for trial 1 and 2 were 70.5±11.2% and 70.4±12.4%, respectively (between days, $p=0.54$, $CV=7.71\%$).

CONCLUSIONS: The time to find the phrenic nerve decreased with practice. The endurance test was reproducible and did not have an order effect. With additional training and testing, the diaphragm endurance test may be practical in clinical populations.

1282 Board #44 May 30 9:30 AM - 11:00 AM
Effects Of Downhill Running On Skeletal Muscle Of
Dystrophic Mice Evaluated By ³¹P-MRS
resonance spectroscopy

Christopher Lopez, Abhinandan Batra, Zahra Moslemi, Andrew Rennick, Sean C. Forbes. *University of Florida, Gainesville, FL.*
 Email: christopherlopez@phhp.ufl.edu
 (No relevant relationships reported)

In this study we examined the effects of downhill treadmill running on dystrophin-deficient skeletal muscle of *mdx* mice, an animal model of Duchenne muscular dystrophy (DMD). **Purpose:** We hypothesized that *mdx* mice would be susceptible to muscle damage following downhill running and this would be associated with altered muscle energetic status and magnesium (Mg^{2+}). **Methods:** Mice (wild-type 5, *mdx* 5) underwent downhill running (14° decline) on a motorized treadmill at a speed of 8-10 m/min, for 45-60 min. Unlocalized ³¹P-MRS data was collected using an 11.1T MR system from the posterior hindlimb compartment to measure adenosine triphosphate (ATP), phosphocreatine (PCr), inorganic phosphates (Pi), intracellular pH, and magnesium (Mg^{2+}) before and 24 hours after exercise. In addition, we acquired MRI-T₂ weighted images to identify regions of muscle damage in the hindlimbs and performed localized ³¹P-MRS measures to co-register with damaged regions. **Results:** Downhill running resulted in a significant ($p<0.01$) decrease in relative intracellular Mg^{2+} concentration in *mdx* compared to pre-exercise (Pre: 0.398 ± 0.072 mM; Post: 0.241 ± 0.050 mM), but no differences

were observed in controls. Also, there was a trend ($p=0.18$) towards an elevated Pi/PCr in the gastrocnemius and soleus muscles in *mdx* after exercise compared to before exercise (Pre: 0.046 ± 0.028; post: 0.061 ± 0.018). The energetic alterations in *mdx* were enhanced in the regions of muscle damage identified with T₂-weighted MRI. **Conclusions:** Downhill running resulted in intracellular changes in *mdx* mice evident with ³¹P-MRS, including lower intracellular Mg^{2+} concentrations, likely due to compromised sarcolemma integrity. Overall, ³¹P-MRS measures are sensitive to acute muscle damage induced by downhill running and may be a valuable technique for testing potential therapeutic interventions in dystrophic muscle. **Funding Source:** NIH (NIAMS) R01 AR070101.

1283 Board #45 May 30 9:30 AM - 11:00 AM

Evaluation of Resistane Exercise-Induced Muscle Swelling Using Bioelectrical Impedance Analysis

Maki Atsuta, Yuri Misonoo, Shun Kondo, Hiroaki Ito, Yuto Yamada, Natsuko Okamoto, Atsushi Iwashita, Yusuke Mizutani, Haruna Nagatsuka, Kurumi Watanabe, Mikihiro Wata, Seishiro Kayanuma, Ayame Iwata, Kazushige Goto. *Ritsumeikan University, Kusatsu, Japan.* (Sponsor: Robert Kraemer, FACSM)
 Email: sh0141sh@ed.ritsumei.ac.jp
 (No relevant relationships reported)

PURPOSE: The purpose of the present study was to examine time course changes of muscle swelling evaluated by bioelectrical impedance analysis (BIA) following resistance exercise.

METHODS: Nine subjects (20.8 ± 0.4 yrs, 174.4 ± 6.8 cm, 67.4 ± 8.1 kg) conducted exercise condition (EX) and rest condition (REST) on different days (a week between conditions). In the EX, subjects conducted unilateral arm curl exercise (12 repetitions × 5 sets, 90 s rest period between sets) for biceps brachii muscle at 60% of maximal voluntary contraction. In the REST, the subjects maintained rest for identical period from exercise duration in the EX. Time course changes in BIA (locally evaluated BIA for biceps brachii muscle), muscle thickness (evaluated by ultrasound) for biceps brachii muscle, circumference of upper arm and blood lactate concentrations were determined before exercise (or rest), immediately after, 30 min and 60 min after exercise (or rest).

RESULTS: The EX caused significant increases in muscle thickness and circumference during post-exercise ($p < 0.05$). Moreover, blood lactate concentration was significantly increased in the EX after exercise ($p < 0.05$). In contrast, no significant change was observed for these variables in the REST. The EX showed rapid reduction of BIA immediately after exercise (from 28.7 ± 10.4 kΩ to 18.5 ± 4.6 kΩ, $p < 0.05$). Furthermore, BIA revealed significantly lower values in the EX than those in the REST immediately after exercise (EX: 18.5 ± 4.6 kΩ vs. REST: 27.7 ± 6.7 kΩ, $p < 0.05$) and 15 min after exercise (EX: 22.0 ± 7.0 kΩ vs. REST: 29.5 ± 9.5 kΩ, $p < 0.05$).

CONCLUSION: Resistance exercise reduced local BIA during post-exercise, with concomitant increases in muscle thickness and circumference. Therefore, acute reduction of BIA following resistance exercise may reflect exercise-induced muscle swelling and increased water volume in the muscle.

1284 Board #46 May 30 9:30 AM - 11:00 AM

The Assessment Of Muscular Characteristics Using Tensiomyography In Hemiplegic Stroke Patients

Shin Who Park, M.D., Won Kim, M.D., Kyoung Hyo Choi, M.D., Ph.D. *Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of.*
 (No relevant relationships reported)

PURPOSE:

Tensiomyography (TMG) has been used to assess muscular characteristics of the lower extremity. However, in stroke patients, the TMG characteristics have not been reported to date. The aim of this study was to investigate the functional behavior and stiffness of muscles in hemiplegic stroke patients

METHODS: Fifteen patients with hemiplegic stroke (mean age: 64±12.51 years; 13 males, 2 females) were recruited. In hemiplegic side, the presence of hypertonus was proved by the H/M ratio and we excluded the subjects with abnormal muscle tone in sound side. The evaluation included: muscular function by TMG with a digital transducer Dc-Dc Trans-Tek® and muscle stiffness by sonoelastography. Functional elements of the lower extremity muscle groups (Rectus femoris, RF, Biceps femoris, BF, Gastrocnemius, GCM and Tibialis anterior, TA) were evaluated and the following parameters were assessed from muscular point of view: contraction time (Tc), sustain time (Ts), delay time (Td), relax time (Tr) and displacement maximal amplitude (Dm) after electrical stimulation. We performed comparative analysis of between the sonoelastographic data of sound side and affected side. Then, we checked the correlation between TMG parameters and the sonoelastographic parameters.

RESULTS: 1) There were no significant differences in the vast majority of the TMG parameters between affected and sound side of lower extremities. The RF-Tr ($p=0.008$), the RF-Dm ($p=0.041$) and the TA-Tr ($p=0.05$) were decreased, compared to the sound side. 2) At the affected side of BF, GCM and TA, the quantitative analysis of

the color histogram revealed a significantly greater intensity of red ($p=0.030$, $p=0.001$, $p=0.004$) and a lower intensity of blue ($p=0.004$, $p=0.001$, $p=0.026$) than sound side. 3) In affected side, the red intensity of TA is correlated with the RF-Tc ($r=-0.566$, $p=0.044$) and TA-Ts ($r=0.618$, $p=0.043$). The red intensity of GCM is correlated with the GCM-Tc ($r=0.714$, $p=0.047$) and the GCM-Tr ($r=-0.786$, $p=0.021$). The red intensity of BF is correlated with GCM-Tr ($r=-0.857$, $p=0.014$).

CONCLUSIONS:

The results of our study help understanding muscle physiologic change associated with CNS lesion. These are useful to detect muscle dysfunction and assess the effect of neuromuscular rehabilitation in stroke patients

1285 Board #47 May 30 9:30 AM - 11:00 AM Exercise-induced Changes In Muscle Thickness As Measured By Both A-mode And B-mode Ultrasound

Tayla E. Kuehne¹, Noam Yitzchaki¹, B. Sue Graves, FACSM², Samuel L. Buckner¹. ¹University of South Florida, Tampa, FL. ²Florida Atlantic University, Boca Raton, FL.
Email: tkuehne@mail.usf.edu
(No relevant relationships reported)

Acute changes in muscle thickness (MT) following resistance exercise are often examined to determine the anabolic potential of an exercise stimulus. This acute change is often attributed to swelling and has been postulated to act as a proliferative signal resulting in a shift towards muscle growth. B-mode ultrasound is commonly used to track acute changes in MT. However, A-mode ultrasound presents a more affordable alternative to measure these same changes. Although A-mode ultrasound may be used to image skeletal muscle, this method does not allow live imaging across a large area of tissue like B-mode ultrasound. In addition, interface detection may be more difficult due to the quality of the image. **PURPOSE:** To compare MT values between A-mode and B-mode ultrasound before and following four sets of biceps curls. **METHODS:** Participants visited the laboratory twice. During the first visit, paperwork and one repetition maximum (1RM) strength assessment were completed. During the second visit, participants performed 4 sets of biceps curls to volitional failure using an exercise load equal to 70% of 1RM. MT measurements were taken before and immediately following exercise. MT measures were taken with both A-mode and B-mode ultrasound. Results are displayed as means (95% CI). **RESULTS:** A total of 23 resistance trained men ($n=12$) and women ($n=11$) completed the study. For MT, there was no interaction, the mean difference in the exercise-induced change in ultrasound-measured MT between A-mode and B-mode was 0.02 (-0.11 - 0.05) ($p = .51$) cm. There were, however, main effects for time ($p < 0.001$) and measurement type ($p = 0.001$). MT increased from pre [3.62 (3.25-3.99) cm] to post [4.07(3.66-4.47) cm] exercise. In addition, MT values as measured by A-mode ultrasound were smaller than those measured by B-mode ultrasound [mean difference 0.174 (0.08- 0.26) cm]. **CONCLUSIONS:** Our results suggest MT measurements taken using A-mode ultrasound are smaller than those using B-mode ultrasound. Despite this difference, it appears A-mode can detect similar acute changes in MT following resistance exercise when compared to B-mode. These results suggest that A-mode ultrasound can serve as a useful tool to examine acute changes in MT, which may also help to better understand the effectiveness of a resistance exercise stimulus.

1286 Board #48 May 30 9:30 AM - 11:00 AM Age-related Change In Cross Sectional Area Of The Psoas Major Muscle In Japanese

Mitsuharu KAYA¹, Masanori Takemura², Junzo Tsujita³, Ken-ichi Ichihashi². ¹Hyogo University of Health Sciences, Kobe, Japan. ²Ichihashi Clinic, Kobe, Japan. ³Institute of Health & Sports Medical Science, Hyogo, Japan.

(No relevant relationships reported)

Although skeletal muscle mass decreases in sarcopenia, it is not clear whether it occurs systemically or partially. It is important to clarify the age-related change of each skeletal muscle as a basic component of sarcopenia research. **PURPOSE:** The purpose of this study was to investigate characteristics of age related changes in the cross sectional area of psoas major muscle as part of elucidation of sarcopenia. **MRTHODS:** Subjects consisted of 2014 persons (938 males and 1076 females) aged 10 to 91 (classified every 5years) examined at our clinic. Using MRI, muscle cross-sectional area was measured on psoas major muscle at height of the iliac crest (L4 - L5). Data was divided into gender and age, and analysis of variance and multiple comparisons were performed. We also examined the relationship with BMI for 614 subjects who were able to confirm their height and weight. **RESULTS:** The cross-sectional area of psoas major muscle peaked the ages of 15 to 19, and declined with age. The decline was noticeable after the aging 50s in both sexes. A remarkable decrease was also observed in the late 30s and 70s in men. Interaction between sex and age was observed, and differences in patterns were observed between men and women. As a result of analysis of variance, no correlation was found between BMI and age, but a correlation was found between gender and BMI and between sex and age. In all age

groups, it was confirmed that the group having a larger BMI exhibited a larger muscle cross sectional area. **CONCLUSIONS:** These results showed the characteristics of age-related change of cross sectional area of the psoas major muscle. Further investigation is needed for sarcopenia research.

1287 Board #49 May 30 9:30 AM - 11:00 AM Skeletal Muscle VO₂ Kinetics By Nirs "Repeated Occlusions Method" During Recovery From Cycle Ergometer Exercise

Lucrezia Zuccarelli. *Università degli Studi Udine, Udine, Italy.*
(Sponsor: Bruno Grassi, FACSM)
(No relevant relationships reported)

Near-infrared spectroscopy (NIRS) has been utilized as a non-invasive method to evaluate skeletal muscle mitochondrial function in humans, by calculating muscle VO₂ ($\dot{V}O_{2m}$) recovery kinetics (repeated occlusions method) following brief (~15 s) light-intensity (unknown work rate) plantar flexion exercise. **PURPOSE:** The aim was to determine $\dot{V}O_{2m}$ recovery kinetics, by the same approach, following standard cycle ergometer exercise of different intensities, and to compare them with pulmonary VO₂ ($\dot{V}O_{2p}$) recovery kinetics. **Methods:** Fifteen young physically active healthy males performed on a cycle ergometer an incremental exercise (INCR) up to exhaustion (to determine peak $\dot{V}O_{2p}$ and the gas exchange threshold [GET]) and two repetitions of constant work-rate (CWR) exercises at 80% of GET (MOD) and at 40% of the difference between GET and peak $\dot{V}O_{2p}$ (HEAVY). $\dot{V}O_{2p}$ and vastus lateralis muscle fractional O₂ extraction by NIRS ($\Delta[\text{deoxy}(\text{Hb}+\text{Mb})]$) were recorded continuously. Transient arterial occlusions (5-10 s each; rapid cuff inflation at ~300 mmHg) were carried out at rest and during the recovery for $\dot{V}O_{2m}$ calculation by standard methods. The time constants (τ) of the monoexponential $\dot{V}O_{2m}$ and $\dot{V}O_{2p}$ kinetics during the first 7 6 minutes of recovery were determined. **Results:** Peak $\dot{V}O_{2p}$ was 47.5 ± 6.7 mlkg⁻¹min⁻¹. $\dot{V}O_{2m}$ values at the onset of recovery were ~27, ~38 and ~35 times higher (in MOD, HEAVY and INCR, respectively) than at rest. τ of $\dot{V}O_{2m}$ recovery (coefficient of determination, r^2 , ranging from 0.93 to 0.99) was lower (faster kinetics) following MOD (29.1 ± 6.8 s) vs. HEAVY ($P < 0.001$) or INCR ($P < 0.001$) (40.8 ± 10.9 and 42.9 ± 10.9 , respectively). Also τ of $\dot{V}O_{2p}$ recovery was lower following MOD (37.5 ± 6.2 s) vs. HEAVY ($P < 0.01$) or INCR ($P < 0.001$) (41.9 ± 5.9 and 44.7 ± 5.1 , respectively). A significant difference between τ of $\dot{V}O_{2m}$ and $\dot{V}O_{2p}$ kinetics was observed only in MOD ($P < 0.0001$). τ of $\dot{V}O_{2p}$ recovery kinetics were significantly ($P = 0.0002$, $r = 0.53$) correlated with τ of $\dot{V}O_{2m}$. **Conclusion:** Both $\dot{V}O_{2m}$ and $\dot{V}O_{2p}$ kinetics were faster in the recovery from moderate- vs. heavy- or maximal-intensity cycle ergometer exercise. $\dot{V}O_{2m}$ recovery kinetics, determined non-invasively by the NIRS "repeated occlusions" technique can be utilized as a functional evaluation tool also following conventional cycle ergometer exercise.

1288 Board #50 May 30 9:30 AM - 11:00 AM Pelvic Limbs Length And Knee Alterations In Health Sciences College Students.

Karla S. Vera-Delgado, Cipriana Caudillo-Cisneros, Fernando Sotelo-Barroso, Sergio Marquez-Gamiño, Montserrat Vera-Delgado. *Universidad de Guanajuato, León, Mexico.*
Email: ksvera@ugto.mx
(No relevant relationships reported)

PURPOSE: To assess muscle-skeletal conditions (MEC) of pelvic limbs and knees in the University of Guanajuato Health Sciences Division freshmen. **METHODS:** Transversal, descriptive study designed to clinically evaluate musculoskeletal alterations of the pelvic limbs and knees in first-year students enrolled in health sciences college programs of a Central Mexico University. The evaluation was performed by a team integrated by a certified orthopedist and traumatologist, two physiologists, a medical sciences doctor, and a graduate student. Methods were based on Viladot (2004). **RESULTS:** 293 students mean age 18.9 ± 1.7 (\pm s.d.) were evaluated. 208 of them women and 85 men; 291 singles and two married; 39 employed, 247 do not have a different occupation than being students; 7 did not responded the question. Four participants were classified as obese, 15 as robust, 205 as having medium complexion and 68 as being slim. The sample showed various limbs and knees musculoskeletal alterations: four participants had a center of gravity anteriorized; eighty had shortening in the right pelvic member, and five in the left side. 52 persons shown *genu valgum* and five, *genu varum*. One participant presented tibial *varum*. **CONCLUSIONS:** Prevalence of limb and knee musculoskeletal alterations in freshman health sciences students is similar to the one for other sectors of the Mexican population. Considering that health providers are prone to develop bone, muscle and joints alterations derived from their professional activities, it is important to know predisposing conditions, to support exercise preventing programs.

1289 Board #51 May 30 9:30 AM - 11:00 AM

Effect Of Limb Position On Vastus Lateralis Muscle Morphology Measured By B Mode Ultrasonography

Isobel Thornley, Mark I. Johnson, Peter Francis. *Leeds Beckett University, Leeds, United Kingdom.*
Email: i.thornley@leedsbeckett.ac.uk
(No relevant relationships reported)

PURPOSE: A narrative review of studies which measured vastus lateralis (VL) muscle thickness (MT) using Ultrasonography (US) revealed inconsistencies in the procedures and techniques used for measurement. One consideration for measurement is the position of the limb and participant. Knee extension was the most commonly reported position, however some studies used knee flexion. The extent to which this alters muscle morphology is unknown and therefore, there is uncertainty as to whether data from studies using different positions can be compared. The aim of this study was to analyse whether limb position, knee extension or knee flexion, had a significant effect on VL-MT, pennation angle and fascicle length.

METHODS: In order to have a homogenous sample, thirty two full time male professional soccer players took part in the study [age = 18.3 ± 0.5 years (mean ± SD), height = 179 ± 1.7cm, mass = 77.3 ± 3.5kg]. In vivo MT and architecture was measured using B mode US (LOGIQ e, GE Healthcare). Two images were taken of the VL in the dominant leg while the participant was supine with their knee extended or flexed at 90 degrees (leg off the bed). Images were downloaded to an imaging software (Image J, v1.51k; NIH; Bethesda; USA). Analysis of the data was conducted in SPSS v24. Descriptive statistics were calculated for each of the dependant variables (MT, pennation angle and fascicle length). A Paired T test was performed for each of the data sets. P < 0.05 was classed as significant. **RESULTS:** MT was significantly greater in the supine/knee extended position compared to the supine/knee flexed position (2.43 ± 0.18cm vs. 2.36 ± 0.17cm; t(31) = 2.76, p = < .010). Pennation angle was also significantly larger in knee extension compared to knee flexion (18.47 ± 1.18° vs. 16.87 ± 1.14°; t(31) = 7.59, p = < .000). Whereas fascicle length was significantly greater in knee flexion compared to knee extension (9.87 ± 0.53cm vs. 9.04 ± 0.92cm; t(31) = -7.652, p < .000). **CONCLUSIONS:** This study is the first to demonstrate differences in muscle morphology, dependent on limb position, as measured by US. The differences in MT were less than the smallest real difference calculated for US in our laboratory. A standard operating procedure for the measurement of MT using US is required. This study only addresses one aspect of a standard operating procedure.

Profiles of Quadriceps Muscles after Downhill Running using Ultrasonography

Min-Ghyu SUN, Maengkyu KIM, Choun-Sub KIM, Hye-Young JUNG, Yong-Woo KIM. *Kyungpook National University, Daegu, Korea, Republic of.*
Email: sunminghyu@naver.com
(No relevant relationships reported)

PURPOSE: The aim of study was to examine the changes of muscle properties after downhill running at different intensities, and further to investigate the optimal biomarkers for muscle damage. **METHODS:** Eleven sedentary men were randomly assigned to repeated measured running sessions set up either at High (HS, 70% HR_{max}) or Low (LS, 50% HR_{max}) with -9° (-16% gradient). Each session consisted of 30 min downhill running on separate occasions 2-wk apart. Range of motion (ROM) was calculated from voluntary maximal extension and flexion. Muscle soreness was recorded on visual analog scale (VAS) with algometry on rectus femoris (RF), vastus lateralis (VL), and vastus medialis (VM). Echo intensity (EI) was scanned with B-mode ultrasonography and analyzed with gray scale analysis. In addition, serum creatine kinase (CK) activity had evaluated as a blood biomarker. All parameters were taken at PRE, POST, 24, 48, and 72hr, respectively. **RESULTS:** Significant differences were found in EI and CK activity (p < .05, respectively) between sessions including baseline. Interestingly, significant increases of EI were found on RF (at POST, 24hr, & 48hr) and VL (at POST & 24hr) after HS (p < .05, respectively). Also, significant interactions were found on RF and VL after HS (p < .05, respectively) whilst no significant differences and interactions were indicated on VM at both sessions. In particular, significantly greater EI was found after HS than LS (p < .05). In addition, CK activity was significantly different at both sessions (at 24 & 48hr), but HS had significantly greater CK activity at 24hr, compared to LS (p < .05). Moreover, significantly greater VAS on RF (p < .05 at 24 & 48hr, respectively) and VL (p < .05 at 24hr) after HS yet there were no significant differences after LS. Furthermore, ROM had significant differences at both sessions, compared to baseline (p < .05, respectively) while significantly greater changes were found after HS (p < .05 at 48hr). **CONCLUSIONS:** Downhill running at different intensities does have effect on serum protein and muscle quality. In particular, echo intensity reflected the muscle damage differences depending on exercise intensities, similar to CK changes. Thus, this study has suggested the non-invasive ultrasonography is an effective method for muscle damage evaluation. Supported by NRF-2017R1C1B1006196

Feasibility of Using Shear Wave Elastography to Quantify Achilles Tendinopathy Stiffness Before and After Rehabilitation

Robert A. Whitehurst¹, Shane L. Koppenhaver², Stephanie R. Albin³, Matt T. Hartshorne⁴, Darren W. Hearn⁵, Mita T. Lovalekar¹, Bradley C. Nindl, FACSM¹. ¹University of Pittsburgh, Pittsburgh, PA. ²Baylor University, Waco, TX. ³Regis University, Denver, CO. ⁴Geneva Foundation, Tacoma, WA. ⁵University of North Carolina, Chapel Hill, NC. (Sponsor: Bradley C. Nindl, FACSM)
(No relevant relationships reported)

BACKGROUND: Chronic Achilles tendinopathy is characterized by a softening of the elastic property of the tendon which can be quantified with Shear Wave Elastography (SWE). Blood flow restriction training (BFR) may increase tenocyte proliferation and repair when combined with a loading protocol, thereby restoring stiffness to softened tendons. **PURPOSE:** The primary purpose of this study was to evaluate the feasibility of using SWE to measure changes in Achilles tendon elasticity before and after rehabilitation. A secondary purpose was to evaluate feasibility and effectiveness of incorporating BFR or sham BFR in addition to an eccentric exercise protocol. **METHODS:** Participants presenting with unilateral Achilles tendinopathy to outpatient physical therapy clinics performed eccentric exercises as a home exercise program (HEP) 2x/day. Participants came into the clinic 2x/week for 12 weeks and were randomized to perform either BFR (limb occlusion pressure = 80%, n = 6) or sham BFR (limb occlusion pressure < 10%, n = 5). Tendon stiffness was quantified with SWE as Young's modulus in symptomatic (SYM) and asymptomatic (ASY) tendons at baseline and after 12 weeks. **RESULTS:** At baseline participants' (n = 11, age = 33.9 ± 10, weight = 80.6 ± 16.3 kg, male = 63.6%, weeks of symptoms = 34.1 ± 24.1) Young's modulus was lower in SYM tendons than in ASY tendons (mean ± SD = 432.2 ± 124.8 kPa vs 496.6 ± 66.5 kPa). At the end of 12 weeks the SYM tendon had normalized to the ASY side (530.0 ± 93.1 kPa vs 527.0 ± 75.4 kPa). The change in Young's modulus in the BFR group was approximately twice that of the sham BFR group (123.2 ± 71.4 kPa vs 67.4 ± 185.8 kPa) in the SYM tendons. Both groups compliance with the HEP was > 80% (BFR 83.3% vs sham BFR 91.6%), and there was no difference between in-clinic compliance (BFR 74.4% vs sham BFR 74.7%). Blinding in the sham BFR group resulted in 80% of subjects unable to determine correct group assignment. **CONCLUSIONS:** It is feasible to use SWE to measure changes in Achilles tendon stiffness. The addition of BFR to eccentric exercises may result in larger improvements in tendon stiffness. High compliance in both groups support the feasibility of BFR training in addition to a HEP of eccentric exercise, and sham BFR can be used as a control. This work was funded by the AMEDD Advanced Technology Initiative #6042, TATRC, US Army MRMC.

Examination of Tendon and Muscle Architecture and Their Influence on Postural Stability

Lauren E. Pacinelli, Jeffery A. Williams, John P. Vardiman, Ryan M. Thiele. *Kansas State University, Manhattan, KS.*
(No relevant relationships reported)

Total length of the Achilles tendon (AT_{Length}) and strength characteristics of the triceps surae have been utilized to investigate musculotendinous stiffness and tendon compliance. However, very few studies have examined the relationship between tendon characteristics and fascicle-specific muscle architecture (pennation angle; PA), or their influence on subsequent functional performance. **PURPOSE:** Evaluate the relationship between AT_{Length} and medial gastrocnemius (MG) PA, as well as their influence on balance performance (overall stability index; OSI). **METHODS:** Eighteen female (mean ± SD: age = 19 ± 1 years) participants laid in a prone position on a cushioned table, with their hip and knee in extension, and ankle maintained in a neutral position (90°). Ultrasonography (US) PA images were scanned in a longitudinal position at the medial 1/3 of the low leg with a linear-array probe at the level of the tibial tuberosity, and were identified as the angle formed between the muscle fascicles and the deep fascia of the MG muscle. AT_{Length} was captured in the extended-field of view setting starting at the calcaneal insertion of the AT and ending at the MG musculotendinous junction (MTJ). AT_{Length} was identified as the distance (cm) between the calcaneal notch and MG MTJ. All US image measurements were analyzed using a third-party image analysis software. Balance assessments were performed on a commercially designed balance unit with an adjustable dynamic platform and involved three, 20-s single leg balance trials. Pearson product-moment correlation coefficients (r) were used to examine the relationships between AT_{Length}, MG PA, and OSI. **RESULTS:** A significant negative correlation (r = -0.499; R² = 0.247; p = 0.035) was observed between MG PA and AT_{Length}. No significant correlations were observed between OSI and MG PA (r = -0.109, R² = 0.012; p = 0.666) or OSI (r = 0.071; R² = 0.005; p = 0.778) and AT_{Length}. **CONCLUSION:** The present investigation revealed a longer Achilles tendon length was associated with a diminished pennation angle of the

medial gastrocnemius in young females. Additionally, balance assessments may not be a sensitive measure for determining the influence of musculotendinous architecture on functional performance.

Assessing Agreement of Lateral Leg Composition Using Dual X-ray Absorptiometry

Christiana J. Raymond-Pope, Tyler A. Bosch, Donald R. Dengel, FACSM. *University of Minnesota, Minneapolis, MN.* (Sponsor: Donald R. Dengel, FACSM)
 Email: raymo191@umn.edu
 (No relevant relationships reported)

PURPOSE: Recently, we reported the accuracy of a novel lateral segmentation dual X-ray absorptiometry (DXA) scanning method for measuring lower extremity total, lean, and fat masses in the lateral view on the GE Lunar iDXA compared to the standard whole-body frontal DXA scanning view. Therefore, the current study was undertaken to examine the agreement of this lateral segmentation DXA scanning method using a Hologic Horizon A DXA scanner. **METHODS:** Thirty healthy college-age participants (16 female; $\bar{X}_{age} = 21.5 \pm 1.7$ yrs.) received three DXA scans (1 whole-body and 2 lateral leg scans) to quantify and compare leg composition in the frontal and lateral plane. To mark regions of interest (ROIs) that would be visible on the DXA scan, metallic markers were placed at 60% of the length above and below each leg's lateral epicondyle. Using lateral subject positioning, leg composition was measured with participants lying on their right and left sides, with the scanned leg elevated using two foam pads at the ankle and the widest portion of the upper-leg. Paired t-tests examined the lateral DXA scanning method's agreement when quantifying total, lean, and fat masses, and bone mineral content (BMC) compared to measurements of equal area obtained in the standard whole-body frontal DXA scanning view. **RESULTS:** Comparisons of frontal and lateral view DXA scan measurements for right leg total mass (7.12±0.91 kg vs. 6.40±0.85 kg), lean mass (5.14±1.05 kg vs. 4.78±0.93g), fat mass (1.70±0.44 kg vs. 1.36±0.33 kg), and BMC (0.28±0.06 kg vs. 0.23±0.05 kg), respectively, were significantly different (all $p < 0.001$). Similarly, comparisons of frontal and lateral left leg total mass (7.12±0.97 kg vs. 6.44±0.93 kg), lean mass (5.15±1.12 kg vs. 4.82±1.01 kg), fat mass (1.70±0.44 kg vs. 1.35±0.41 kg), and BMC (0.28±0.06 kg vs. 0.23±0.06 kg), respectively, were all significantly different (all $p < 0.001$). **CONCLUSIONS:** Unlike our previous study in which we reported agreement of lateral leg composition measurements in comparison to frontal composition measurements of equal area utilizing the GE iDXA scanner, we did not observe agreement between the two views using the Hologic Horizon A DXA scanner. Therefore, caution should be used when examining leg composition in the lateral view using a Hologic Horizon A DXA scanner.

Neuromuscular Responses in Lower Limb Bilateral Deficit: A Pilot Study

M. Travis Byrd, Taylor K. Dinyer, Pasquale J. Succi, Haley C. Bergstrom
 University of Kentucky, Lexington, KY
 The bilateral deficit is the phenomenon in which the sum of the forces produced unilaterally is greater than the force produced bilaterally during maximal contractions of the limbs. **PURPOSE:** This study examined the neuromuscular responses during the measurement of lower limb bilateral and unilateral muscular strength. **METHODS:** Twelve (male: n = 6; female: n = 6) subjects (mean ± SD age: 24.5 ± 4.8 yrs, body mass: 74.2 ± 14.6 kg) completed randomized, isometric, seated leg extension bilateral and unilateral maximum voluntary isometric contractions (MVIC). On a separate day, the subjects completed a randomized, bilateral and unilateral dynamic, seated leg extension for the determination of the 1 repetition maximum (1RM) strength. The electromyographic (EMG) and mechanomyographic (MMG) amplitude (AMP) and mean power frequency (MPF) were measured from the vastus lateralis of the right and left lower limbs during the MVIC and 1RM trials, and were normalized to the corresponding signal from the MVIC trials. Statistical analyses included paired samples t-test ($p \leq 0.05$). **RESULTS:** Six of the 12 subjects demonstrated a 1RM bilateral deficit (BLD; -9% ± 2.9%). Within the BLD subjects, the EMG MPF was significantly greater ($p = 0.03$) during the unilateral 1RM than the bilateral 1RM, but

EMG AMP, MMG AMP, and MMG MPF were not different (Figure 1). There were no differences between unilateral and bilateral neuromuscular responses for the non-BLD (n = 6) subjects. **CONCLUSION:** These findings indicated the BLD could be due to different motor control strategies, such as changes in muscle fiber conduction velocity, in a bilateral versus a unilateral movement of the lower limbs.

Figure 1. Mean ± SD of the bilateral and unilateral (normalized) electromyographic mean power frequency (EMG MPF) normalized values during the dynamic, seated leg extension 1RM for the subjects (n = 6) with a 1RM bilateral deficit (BLD) and the subjects (n = 6) with no bilateral deficit (non-BLD). *Significantly ($p < 0.05$) greater than the bilateral dynamic, seated leg extension 1RM.

Recommendations For The Evaluation Of The Foot Tapping Test (ftt) In A Healthy Population

Morgan K. Delp, Brian A. Pribble, Daniel J. Larson, Christopher D. Black, FACSM, Rebecca D. Larson. *University of Oklahoma, Norman, OK.*
 Email: Morgan.K.Delp-1@ou.edu
 (No relevant relationships reported)

The foot tapping test (FTT) is a neurological exam used to assess upper-motor neuron (UMN) function in clinical populations. However, little research has been done to determine the best method of conducting the FTT. Furthermore, it is unknown how participant characteristics such as lower limb lean mass may impact the FTT. **PURPOSE:** This study sought to evaluate the reliability of the FTT in a healthy population when using different counting methods and testing conditions, as well as to assess the impact of lower limb muscle mass on tapping rates. This information could be used to establish testing recommendations for the FTT in clinical populations. **METHODS:** Thirty-eight healthy individuals (age 18-63) completed a series of FTT trials over 4 visits. Participants had their foot positioned so that the ball of the foot was over a small force plate and the heel off. They were then instructed to tap as many times as possible over a 10 second period. A total of 32 trials under different conditions (shoes ON, shoes OFF, dom. foot, and non-dom. foot) were performed. A DXA scan was used to measure lower limb mass. Means were compared between trial #, visit #, shoe condition (ON or OFF), dom. vs. non-dom. foot (footedness), and counting method. Correlations between subject characteristics (such as age, activity level, shoe size, weight, height, and lower limb lean mass) and tapping rates were also calculated. **RESULTS:** Significant differences were found between footedness, shoes ON/OFF and in foot taps counted using each counting method ($p < 0.001$). In addition, significant interactions were found between force plate count and shoes ON/OFF ($p = 0.011$), as well as live count and shoes ON/OFF ($p < 0.001$). Live and video counts showed no significant differences; however, force plate counts were significantly lower ($p < 0.001$). Foot tapping rate was not correlated with any of the participant characteristics ($p > 0.05$, $R < 0.282$ for all). **CONCLUSION:** These results suggest that the FTT should be performed whilst wearing shoes, and measured using the force plate counting method. These conditions were found to be the most accurate for this population, and thus should be used if a force plate is available. Future research should attempt to determine normative FTT rates in clinical and aging populations in order to evaluate the extent that UMN function is affected.

Sleep Restriction Negatively Influences Visually and Memory-Guided Force Control

Sarah A. Brinkerhoff¹, Stephen M. Strayer², Jaimie A. Roper¹, Anne-Marie Chang², Kristina A. Neely¹. ¹Auburn University, Auburn, AL. ²The Pennsylvania State University, State College, PA. (Sponsor: Mark Tillman, FACSM)
 Email: sab0042@auburn.edu
 (No relevant relationships reported)

Cognitive performance is negatively influenced by sleep restriction, and athletic performance is improved through sleep extension. However, little work has quantified motor output under rigorous and controlled conditions of sleep restriction. **PURPOSE:** This study examined the effects of sleep restriction on visually and memory-guided grip force control. **METHODS:** Participants (N=9) were inpatients in a sleep restriction study, during which behavioral, physiological, and neuroimaging experiments occurred. Here, we report the results of a grip force task conducted on three days: (D1) after two nights of adequate sleep, (D2) after four consecutive nights of sleep restriction, and (D3) after one night of recovery sleep. Participants completed four

20-s trials of isometric force with their index finger and thumb, to 25% of their maximal voluntary contraction. In the full-vision (FV) condition, visual feedback was provided for the duration of the trial. In the no-vision (NV) condition, visual feedback was provided for the first 8 s of the trial, and then visual feedback was removed. Participants were to maintain force output for the remaining 12 s. **RESULTS:** In FV, participants produced less mean force on D2 (24.0%) relative to D1 (24.9%) and D3 (25.0%). Mean force did not differ as a function of day in NV. The coefficient of variation was higher on D2 relative to D1 and D3, in both FV (D1: 1.7%, D2: 5.6%, D3: 1.5%) and NV (D1: 5.2%, D2: 5.6%, D3: 5.0%). **CONCLUSIONS:** These findings are the first demonstrations that restricted sleep negatively impacts force control.

The Effect of Muscle Contraction Type on Neuromuscular Complexity in Trained Individuals

Luis Hernandez, Peter Chomentowski, Clayton L. Camic.
Northern Illinois University, DeKalb, IL.
Email: LHernandez6@niu.edu
(No relevant relationships reported)

Physiological systems exhibit high levels of complexity characterized by non-linearity and persistent fractal correlations (low levels corresponding to states such as disease, injury, and fatigue) and has become recognized as a defining feature of healthy physiological functioning. Neuromuscular complexity is affected by fatigue and intensity of contractions, although no study has investigated the effect of contraction type on complexity.

Purpose: The purpose of this study was to investigate the effect of contraction type on neuromuscular complexity.

Methods: Twelve collegiate-aged resistance-trained females (21 ± 1 years, 63.3 ± 7.4 kg) were recruited to visit the laboratory on two occasions, the first for familiarization purposes. In session two, participants performed three maximal knee extensor contractions on an isokinetic dynamometer for each contraction type [concentric (CON), eccentric (ECC), and isometric (ISO)] in random order. Relative knee angle was standardized to 120° during ISO contractions. Angular speed was standardized to $30^\circ \cdot s^{-1}$ and range of motion to 90° ($90^\circ - 180^\circ$ at full extension) during CON and ECC contractions. Each contraction lasted three seconds with three seconds rest between contractions. Electromyographic (EMG) signals were recorded from the vastus lateralis using a bipolar electrode configuration. Sample entropy (SE), a unitless measure of statistical irregularity was used as an index of physiological complexity. A one-way repeated measures ANOVA was performed to investigate differences in EMG SE among contraction types. Alpha level was set to 0.05.

Results: Contraction type was observed to have a significant effect on EMG SE ($F(2,22) = 7.212, p = 0.004$). Specifically, CON contractions (1.671 ± 0.193) displayed significantly greater EMG SE than ECC ($1.497 \pm 0.321, p = 0.017$) and ISO ($1.569 \pm 0.223, p = 0.028$) contractions.

Conclusion: These findings indicated that neuromuscular complexity is contraction-type dependent, being significantly higher during CON than ECC and ISO contractions. In addition, there exists no generally accepted framework to explain the underlying factors regulating complexity and thus, further investigation may provide valuable insight into these potential mechanisms.

Reliability of Motor Unit Behavior during a Maximal Voluntary Isometric Contraction of the Knee Extensors

Ryan J. Colquhoun, Patrick M. Tomko, Mitchel A. Magrini, Sydney R. Fleming, Matthew C. Ferrell, Nile F. Banks, Trey Gradnigo, Nathaniel D.M. Jenkins. Oklahoma State University, Stillwater, OK.

(No relevant relationships reported)

PURPOSE: To establish the intra- and inter-day reliability of the mean firing rate (MFR) versus recruitment threshold (RT) of the vastus lateralis (VL) during a maximal voluntary isometric contraction (MVIC) of the knee extensor muscle. **METHODS:** Thirty-two young, healthy males (Mean \pm SD; Age: 23 ± 3 years; Height: 176.4 ± 5.9 cm; Weight: 87.3 ± 13.4 kg) reported to the laboratory on three separate occasions, each separated by 6 ± 1 days. Each visit occurred at the same time of day (± 1 hour) and consisted of MVIC testing and ramp contractions, during which MU behavior was recorded. Specifically, subjects completed 2 MVIC attempts each separated by approximately 2 min., in the subject's maximal force (F_{MAX}) was obtained. Following an additional 2 minutes of rest, subjects completed 2 maximal ramp contraction, each separated by 2 minutes of rest, during which MU behavior was recorded through surface electromyography (sEMG). The ramp contraction trajectory consisted of a 3 second quiescent period, followed by a 10 second linear increase to F_{MAX} , a 6 second hold at F_{MAX} , a 5 second linear decrease back to baseline and another 3 second quiescent period. Both relative intra- and inter-day reliability of the MFR versus RT relationship were examined using the intra-class correlation coefficients ($ICC_{2,1}$). The standard error of measurement (SEM) was calculated as the square root of the mean square error term from the ANOVA table and expressed in

the units of measurement. The coefficient of variation (CV) was also calculated by expressing the SEM relative to the grand mean (%). **RESULTS:** For intra- and inter-day analyses, 16 and 20 subjects met the inclusion criteria and were included in final analyses, respectively. Both intra- and inter-day reliability statistics are presented in Table 1. **CONCLUSIONS:** The MFR versus RT relationship of the VL demonstrates strong intra- and inter-day reliability during a maximal voluntary contraction in young, healthy men.

A Comparison of Motor Unit Control Strategies Between Two Different Isometric Muscle Actions

Sunggun Jeon, Xin Ye, William Miller. University of Mississippi, University, MS.

Email: sjeon3@go.olemiss.edu

(No relevant relationships reported)

The isometric muscle action is primarily responsible for performing two different tasks: attempting to shorten the muscle against an immovable object, and maintaining a fixed posture/joint position while resisting the lengthening inertial imposed by an external load. **PURPOSE:** To compare the motor unit control strategies between the two different tasks with similar mechanical requirements. **METHOD:** Twelve healthy men (Age: 23.7 ± 3.9 years; Weight: 84.8 ± 12.1 kg; Height: 172.8 ± 5.7 cm) and seven women (Age: 21.1 ± 1.6 years; Weight: 73.4 ± 15.6 kg; Height: 164.3 ± 3.9 cm) participated in this study. After the first visit as the familiarization, Visits 2 and 3 were randomly sequenced for force task and position task experimental testing. During both visits, maximal voluntary isometric contraction (MVIC) was measured, followed by the designated submaximal isometric trapezoid contraction task. Specifically, the force task required the participants to gradually increase the force from 0 to 40% MVIC in 4 seconds, held it for 10 seconds, and then gradually decreased the force to 0% in 4 seconds. For the position task, the participants were required to maintain a constant position, and to resist against the pulling force, created by the investigator with the same rate and intensity as those during the force task. Surface EMG signals from the biceps brachii muscle were collected and decomposed into constituent motor unit action potential trains. The relationship between the motor unit recruitment threshold and average firing rate, and between the recruitment and derecruitment thresholds were examined using linear regression analyses. **RESULTS:** Paired samples t-tests showed no significant differences between two tasks for the mean slope coefficient (-0.51 ± 0.34 vs. $-0.58 \pm 0.29, p = 0.515$) and y-intercept (24.80 ± 12.37 vs. $26.59 \pm 9.43, p = 0.589$) for the recruitment threshold vs. average firing rate relationship. In addition, the mean slope coefficient (1.23 ± 0.76 vs. $1.62 \pm 0.78, p = 0.125$) and y-intercept (-12.98 ± 23.54 vs. $-18.98 \pm 13.45, p = 0.391$) were also not different between two tasks for the relationship between recruitment and derecruitment thresholds. **CONCLUSION:** The motor unit control strategies did not seem to differ between the two submaximal isometric muscle actions.

Badminton Players Show A Lower Coactivation And Higher Beta Band Emg-emg Coupling Between Antagonist Muscles

Lejun Wang¹, Wenxin Niu¹, Jingyuan Chen¹, Shengnian Zhang², Li Li, FACSM³, Tianfeng Lu¹. ¹Tongji University, Shanghai, China. ²Shanghai University of Sport, Shanghai, China. ³Georgia Southern University, Statesboro, GA.

(No relevant relationships reported)

PURPOSE: Previous studies have suggested that skilled athletes may show a specific muscle activation pattern with a lower antagonist coactivation level. Based on the point, we hypothesize that the coupling of antagonistic muscles may be different between elite badminton players and non-skilled individuals during exercises. The current work was designed to verify the hypothesis.

METHODS: Ten male college students and eight male badminton players performed three maximal voluntary isometric contractions (MVIC) and a set of three maximal concentric ankle dorsiflexion and plantar flexion at angular velocity of $30^\circ, 60^\circ, 120^\circ$

and 180°. Surface EMG were recorded from the tibialis anterior (TA) and lateral gastrocnemius (LG) muscles during the test. Normalized average amplitude of the integrated EMG and phase synchronization index (PSI) between the EMG of TA and LG were calculated.

RESULTS: Antagonist muscle coactivation were significantly lower (22.1% ± 9.4%, 24.7% ± 12.8%, 22.4%±9.4%, 22.4% ± 9.7% for non-players and 10.7% ± 3.7%, 10.1% ± 4.9%, 11.2% ± 2.5%, 10.6% ± 2.5% for badminton players in four angular velocity speed, P<0.05 for four group comparison) and PSI in beta frequency band were significantly higher (0.42 ± 0.06, 0.36 ± 0.13, 0.36 ± 0.10, 0.35 ± 0.12 for non-players and 0.47 ± 0.15, 0.47 ± 0.15, 0.48 ± 0.11, 0.49 ± 0.14 for badminton players in four angular velocity speed, P<0.05 for four group comparison) in badminton players group compared to non-players group during isokinetic ankle dorsiflexion contraction, while no significant difference was found in antagonist muscle coactivation and PSI between two group subjects during ankle plantar flexion.

CONCLUSIONS: The decrease of antagonist coactivation may indicate an optimal motor control style to increase the contraction efficiency, while the increase coupling of antagonistic muscles may be related to the compensation of joint stability as a result of the decrease of antagonist coactivation.

Does Strict Validation Criteria for Individual Motor Units Alter Extrapolation Analyses of the Motor Unit Pool?

Jesus A. Hernandez-Sarabia, Alejandra Barrera-Curiel, Ryan J. Colquhoun, Jason M. DeFreitas. *Oklahoma State University, STILLWATER, OK.*
 Email: jesusah@okstate.edu
 (No relevant relationships reported)

Recent technology allows for motor units (MU) action potentials (AP) to be acquired from multi-electrode surface EMG decomposition. Due to the high yield of MUs, this technology can be used to extrapolate findings for the entire MU pool (e.g. the relationship between mean firing rate (MFR) and recruitment threshold (RT)). However, it is unknown if characteristics of individual MUs affect extrapolation to the pool. **PURPOSE:** To have decomposed MU trains undergo strict validation based on interspike interval (ISI) variability, and to determine if analyses are affected if limited to only the validated MUs. **METHODS:** Five subjects performed 1 maximal ramp contraction of 15 sec. MU APs were obtained using a 5-pin array placed over the vastus lateralis. Two samples of MUs were used for analyses: an original (ORG) and a validated yield (VAL). ORG consisted of MUs that demonstrated >90% accuracy using the Decompose-Synthesize-Decompose-Compare test. VAL consisted of MUs from ORG that met further, strict criteria of ISI variability and histogram shape. All VAL MUs had a coefficient of variation (COV) < 30%, with an ISI histogram demonstrating a unimodal, kurtotic shape, absent of excess (> 2) counts in regions that represent missed or additional firings. Slope and intercept values were calculated for the MFR/RT relationship from ORG and VAL for each subject. Pedhazur's test for comparing regression equations was used to determine if the regression coefficients changed for each subject. **RESULTS:** 54% of the ORG MUs passed the validation. The COVs of the validated MUs (M±SD; 22.5 ± 2.3%) were significantly (p < .001) lower than the discarded MUs (26.2 ± 3.4%). There were no significant differences in the regression coefficients between the two outputs for any of the subjects (Table 1). **CONCLUSION:** When using the outputs from a high-yield of MUs to extrapolate to the entire MU pool, strict validation criteria of individual MU firings does not alter the outcome of the analyses.

Table 1.
 Simple regression coefficients of original (O) vs. validated (V) motor units

| | Recruitment Threshold vs. Mean Firing Rate | | | | | |
|-----|--|-------|------|------------|-------|------|
| | Slopes | | | Intercepts | | |
| | O | V | p | O | V | p |
| S01 | -0.54 | -0.73 | 0.36 | 40.93 | 51.22 | 0.38 |
| S02 | -0.21 | -0.24 | 0.33 | 22.11 | 23.21 | 0.91 |
| S03 | -0.74 | -0.82 | 0.68 | 53.35 | 57.38 | 0.67 |

Differences In Biomechanical And Electromyographic Strategies Between Young And Old Persons During The Timed Up-and-go

Lawrence Villanueva, Keri Strand, Jeonghoon Oh, Moataz Eltoukhy, Jordan Strnad, Kevin Posner, Nathaniel Strand, Lauren Catena, Joseph F. Signorile. *University of Miami, Miami, FL.*
 (Sponsor: Dr. Kevin Jacobs, FACSM)
 (No relevant relationships reported)

PURPOSE: The timed-up-and-go (TUG) is one of the most common tests used to assess functional mobility. Although researchers have examined strategies used by specific groups in completing the turning component of the test, none have analysed electromyographical (EMG) activity. This study compared ground reaction force (GRF) vectors and EMG of the medial (MGas) and lateral (LGas) heads of the gastrocnemius, the vastus medialis (VM) and vastus lateralis (VL) during the turning component of the TUG. **METHODS:** Eight old (OG: 69.8±7.3 y) and 10 young (YG: 21.5±2.6 y) subjects performed three trials of the TUG. Force plates were positioned behind the cone to allow GRF collection, while EMG was simultaneously collected on the MGas, LGas, VM and VL using telemetry. EMG values during the turn were normalized using values during the approach. Subjects were instructed to perform the task as rapidly as possible. **RESULTS:** An ANCOVA covarying for subjects' weight revealed a significant difference in medio-lateral force vectors in the direction of the cone by age for the left (p=.033; η²=.348) and right (p=.001; η²=.348) leg stance phase. Pairwise comparisons showed the values were higher for the YG versus OG (right: Mdiff=250.2±106.5 N; left: Mdiff=97.5±23.2 N). These differences were also reflected in the analysis of vertical force to mediolateral force ratios on each side (right: p=.023, η²=.298; left: p=.005, η²=.419) and pairwise comparisons (right: Mdiff=1.62±.64; left: Mdiff=2.07±.63). Multivariate analysis of the nEMG data for the right and left LGas, MGas, VL, and VM showed a single significant difference with YG having lower utilization than their OG counterparts (Mdiff=.397±.149, p=.018). **CONCLUSION:** Although the YG showed larger lateral GRF vectors toward the cone than OG, the lack of difference between groups for all but one muscle during the turn indicates that factors other than greater muscle activation appear to have allowed this strategy.

Knee Proprioception Measurement Reliability and its Relationship to Single Leg Reach Distance

Megan M. Walters, Cody M. Ballay, Cruz A. Finnicum, Chelsea L. Jentsch, Orion J. Swanson, Daniel R. Richie, Ajit MW Chaudhari, FACSM. *The Ohio State University, Columbus, OH.*
 (No relevant relationships reported)

Improving knee proprioception is often recommended in rehabilitation after knee injuries. The best technique or tool for measuring knee proprioception is not yet identified. Additionally, evidence suggesting the role of proprioception in mechanics and injury risk is mixed, requiring further investigation. **PURPOSE:** To evaluate the validity and reliability of an inertial measurement unit (IMU) based clinical tool to assess knee proprioception, and to determine the association between proprioception and dynamic function. **METHODS:** Active joint position sense (JPS) was measured using an IMU-based tool (CoreX Therapy Pro, CX) and Biodex System III in 29 healthy participants (18F, aged 22-27y) with no current knee pain or prior knee surgery. For JPS on the Biodex, seated participants extended their knee and then flexed to 30° and held for 5s to learn the position. They extended the knee, and then matched the position as best they could. One practice and 5 trials were recorded. A similar procedure was completed for CX but testing was completed standing on the non-test leg. The anterior component of the Y-balance test was performed with heel down and hands on hips while standing on the test leg. Five recorded trials after 1 practice were averaged and normalized to leg-length. Intra-class correlation coefficients were calculated to establish within-session reliability of each proprioception measurement and Pearson correlation coefficients were used to assess the associations between proprioception and reach distance. **RESULTS:** The middle 3 values of each JPS measurement were averaged. Intra-session reliability of CX (ICC(2,k) = 0.800) and Biodex (ICC(2,k) = 0.813) were both good. However, agreement between CX and Biodex measurements was poor (ICC(2,1) = 0.083). Neither the Biodex (r = 0.174) nor CX (r = -0.198) correlated with single-leg reach distance. **CONCLUSIONS:** After analyzing the differences between CX and Biodex measurements, we conclude the tools are assessing different aspects of proprioception. Additionally, knee proprioception does not appear to be the primary limiting factor in single-leg reaching. More research should be done to determine test-retest reliability of CX and Biodex and better understand the relationships between knee proprioception and knee function.

The Motor Unit Mean Firing Rate versus Recruitment Threshold Relationship is Unaffected by Short-Term Disuse

Rob J. MacLennan, David Ogilvie, John McDorman, Ernest Vargas, Nathan Becker, Ethan Davis, Michael Sahebi, Matt S. Stock. *University of Central Florida, Orlando, FL.*
 Email: robjmaclellan@gmail.com

(No relevant relationships reported)

The loss of muscle strength during periods of disuse is rapid. Some investigators have postulated that these changes are due to neural, rather than muscular, adaptations. It is unclear, however, if short-term immobilization of the knee joint affects the voluntary control of motor units. **PURPOSE:** To determine whether the slope and y-intercept of the motor unit mean firing rate versus recruitment threshold relationship is altered by 72 hours of disuse. **METHODS:** Fifteen healthy females (mean \pm SD age = 21 \pm 2 years, body mass index [BMI] = 23.1 \pm 2.3 kg/m²) voluntarily underwent left knee joint unloading via ambulating on crutches and use of a brace. The brace was worn at all times except during sleep, and compliance was confirmed via accelerometers secured around both ankles. Following two extensive familiarization sessions at the laboratory, testing was performed immediately prior to immobilization (PRE) and 72 hours later (POST). During both testing sessions, participants performed trapezoidal isometric contractions at a torque level corresponding to 50% of their maximal voluntary contraction (MVC). Participants were instructed to increase torque from 0 to 50% in five seconds, maintain 50% MVC for 15 seconds, and decrease torque from 50% to 0 in five seconds. Bipolar surface electromyographic (EMG) signals were recorded from the vastus lateralis. A surface EMG signal decomposition algorithm was used to calculate the mean firing rate (pulses per second [pps]) and recruitment threshold (% MVC) of each detected motor unit. Motor units with decomposition accuracy levels < 90% were discarded. Linear regression was then used to quantify the slope (pps/% MVC) and y-intercept (pps) of each relationship. **RESULTS:** Immobilization had no influence on the linear slope coefficient for the mean firing rate versus recruitment threshold relationship (PRE = -0.362 \pm 0.127, POST = -0.399 \pm 0.108 pps/%MVC; p = 0.413, d = 0.218). Similarly, no change in the y-intercept was observed (PRE = 23.2 \pm 2.8, POST = 23.3 \pm 4.0 pps; p = 0.972, d = 0.009) **CONCLUSION:** Our findings demonstrated that 72 hours of knee joint immobilization in healthy females had little influence on vastus lateralis motor unit control during submaximal contractions.

Aging and Altered Brain Activation during Isometric Contractions with the Lower Limb

Tejin Yoon¹, Marnie L. Vanden Noven², Sandra K. Hunter, FACSM³. ¹Kangwon National University, Chuncheon, Korea, Republic of. ²Belmont University, Nashville, TN. ³Marquette University, Milwaukee, WI. (Sponsor: Sandra Hunter, FACSM)
 Email: tyoon@kangwon.ac.kr

(No relevant relationships reported)

Many daily tasks require maintenance of steady contractions of limb muscles which are more challenging for older adults possibly due to the age-related changes of the brain. **PURPOSE:** The purpose of this study was to determine intensity and patterns of brain activation in healthy old and young adults during isometric target-matching contractions of the ankle dorsiflexors using functional magnetic resonance imaging (fMRI). **METHODS:** Twenty-one young adults (11 males, 24.7 \pm 7.9 years) and 24 older adults (12 males, 69.6 \pm 6.4 years) performed three sets of 16-s isometric contractions at 10, 30, 50 and 70% of maximal voluntary contraction of the right ankle dorsiflexor muscles while lying supine in a 3.0 T MRI scanner. Each 16-s contraction was followed by 60 s of rest. Force steadiness was quantified as the coefficient of variation (CV=standard deviation/mean \times 100%) of force. Percent signal changes (PSCs, %) of the blood oxygenation level-dependent response for each contraction was extracted using region of interest analysis. Pearson product-moment correlations were used to determine the relationships between the force steadiness and the PSCs. **RESULTS:** Older adults were weaker (p <0.05) and less steady (p <0.01) than young adults. A total of 21 cortical and subcortical areas were identified as task-related regions. PSCs in some regions including paracentral lobule (primary motor area of dorsiflexors) and cerebellum increased linearly with contraction intensity and were greater for older adults (p <0.05). PSCs in precentral gyrus and cerebellum were associated with the force steadiness in older adults (r =-2.7 and -0.39 respectively, p <0.05). **CONCLUSION:** Older adults exhibited greater brain activation than young adults while maintaining the same intensity of contraction with the ankle dorsiflexor muscles. In addition, the age-related changes in brain activation were related to the impaired steadiness suggesting that aging alters brain activation when performing target matching submaximal contractions of the distal lower limb muscles.

Acute Effects of Transcranial Direct Current Stimulation on Knee Extensor Torque-Producing Capabilities

Carlos A. Estrada, Tyler W.D. Muddle, Cameron S. Mackey, Masoud Moghaddam, Jason M. DeFreitas, Bert H. Jacobson, FACSM. *Oklahoma State University, Stillwater, OK.* (Sponsor: Bert H. Jacobson, FACSM)

(No relevant relationships reported)

Transcranial direct current stimulation (tDCS) is a method of neuromodulation aimed to increase cortical excitability. Recently, tDCS has been utilized as a modality treatment in various medical conditions (e.g. stroke rehabilitation); however, few investigations have examined its effect on motor function.

PURPOSE: To examine the acute effects of tDCS on torque producing capabilities of the knee extensors.

METHODS: Thirty-two recreationally active females (Age = 21.8 \pm 2.6; Height = 165.3 \pm 6.3cm; Weight = 68.1 \pm 11.6kg) participated in this single-blind investigation. Participants were required to report to the laboratory on two separate occasions to receive two randomized conditions, tDCS or sham stimulation. During the initial visit, participants were familiarized with maximal voluntary isometric knee extension (MVIC; 120° knee extension) testing procedures via an isokinetic dynamometer, which was utilized to assess peak torque (PT) and peak rate of torque development (pRTD). Subsequently, participants underwent a 5-minute low-intensity warm-up via a cycle ergometer prior to data acquisition. Participants performed two MVICs with a 2-minute rest period between contractions. Following initial isometric testing procedures, participants were outfitted with a set of commercially available headphones designed to deliver tDCS to the primary motor cortex for a duration of 21 minutes, during which, they performed various low-intensity dynamic movements. Participants then completed an additional series of MVICs identical to pre-testing following "stimulation".

RESULTS: Two separate 2x2 (time x condition) repeated-measures ANOVAs were conducted to assess differences in pre- to post-stimulation PT and pRTD within conditions. No differences were observed in PT for either condition (p > 0.05). pRTD revealed no interaction effect (p > 0.05); however, a main effect of time was observed ($F_{1,31} = 9.97$, $p = .004$). Follow-up paired-samples t-tests revealed decreases in pRTD from pre- to post-stimulation within the tDCS condition ($t_{31} = 2.643$, $p = 0.013$).

CONCLUSIONS: Although tDCS does not appear to alter PT production, our findings suggest that tDCS may negatively affect an individual's ability to rapidly produce force.

Effects of Brief and Prolonged Vibration on Longitudinally Tracked Motor Units

Alejandra Barrera Curriel, Ryan J. Colquhoun, Jesus A. Hernandez-Sarabia, Jason M. DeFreitas. *Oklahoma State University, Stillwater, OK.*
 Email: ale.barrera_curriel@okstate.edu

(No relevant relationships reported)

Vibration applied to the muscle has been shown to manipulate the sensitivity of muscle spindles by either facilitation (brief vibration less than 25 seconds) or depression (prolonged vibration 20 minutes). These effects have been reported on averaged motor unit (MU) behavior properties, which could result in incorrect interpretations.

PURPOSE: To analyze the effects of altered stretch reflex sensitivity on individual motor units that have been longitudinally tracked. **METHODS:** Twenty-four young participants (25 \pm 6 years) performed 1 maximal knee extension under 3 conditions: control, brief vibration, and prolonged vibration. Multi-channel EMG was recorded from the vastus lateralis and decomposed in to MU action potential trains. Cross-correlation of action potential shapes were used to longitudinally track the same MUs across the 3 conditions. **RESULTS:** Surprisingly, a significant decrease in recruitment thresholds was seen after both acute (-5.63%; $p = 0.03$) and prolonged (-8.99%; $p = 0.001$) vibration. **CONCLUSION:** It is possible that altering muscle spindle activity results in an altered motor unit recruitment pattern.

VL muscles of both legs were recorded simultaneously during each repetition of the fatiguing bout. The EMG RMS, EMG MPF, MMG RMS, and MMG MPF were normalized to their corresponding maximal isometric voluntary contraction values and torque values were normalized to maximal bilateral isokinetic concentric peak torque values at 180°·s⁻¹. The repetitions were normalized to each 10% of the total number of repetitions completed. Four, 2 (right and left VL) x 10 (10-100% of the total repetitions) repeated measures ANOVAs were used to determine mean differences for each neuromuscular parameter. A 1 x 10 repeated measures ANOVA was used to examine torque production. Post-hoc Student Newman-Keuls was used to identify when the neuromuscular and torque values changed from the values at 10% of the total repetitions. **Results:** The results demonstrated no significant interactions involving the right and left VL muscles or main effects for repetitions for any of the neuromuscular parameters. The maximal bilateral peak torque (311.4 ± 51.2 N·m) decreased significantly ($p < 0.01$; $\eta^2 = 0.688$) at 90% of the total repetitions. **Conclusion:** The results of the present study demonstrated no differences between the right and left VL muscles for their patterns of neuromuscular responses during the fatiguing bilateral leg extensions. While peak torque decreased, no changes occurred for any of the neuromuscular parameters across the repetitions. Therefore, the current findings suggested that the decrease in torque production was due to peripheral mechanisms of fatigue and not a decrease in central neural drive to the muscles.

Vastus Lateralis Motor Unit Recruitment Thresholds in Younger Versus Older Men

Ryan Girts¹, Jacob A. Mota², Kylie K. Harmon¹, Rob J. MacLennan¹, Matt S. Stock¹. ¹University of Central Florida, Orlando, FL. ²University of North Carolina at Chapel Hill, Chapel Hill, NC.
 Email: ryangirts@knights.ucf.edu
 (No relevant relationships reported)

Aging results in a variety of muscular adaptations which may affect the recruitment of motor units. **Purpose:** We sought to determine if younger and older men recruit motor units at similar isometric force levels. **Methods:** Twelve younger (age = 25 ± 3 years, mass = 65.2 ± 8.9 kg, height = 1.72 ± 0.1 m) and twelve older (mean ± SD age = 75 ± 8 years, mass = 78.9 ± 10.2 kg, height = 1.74 ± 0.1 m) men performed trapezoidal isometric contractions of the dominant knee extensors at a force level corresponding to 50% maximal voluntary contraction (MVC). Bipolar surface electromyographic (EMG) signals were detected from the vastus lateralis during each contraction. A surface EMG signal decomposition algorithm was then used to quantify the recruitment threshold of each detected motor unit, which was defined as the isometric force level corresponding to the first firing. Recruitment thresholds were calculated in both relative (% MVC) and absolute (N) terms. Motor units with accuracy levels < 93.0% were not considered for analysis. **Results:** The mean ± SD number of motor units detected was 17 ± 5 for younger and 13 ± 4 for older men. MVC force was significantly greater in younger vs. older men (709.6 ± 197.8 vs. 520.8 ± 121.6 N [$p = 0.010$; Cohen's $d = 1.15$]). The relative median recruitment threshold values were significantly greater for younger (26.6 ± 9.1% MVC) compared to older (15.6 ± 7.9% MVC [$p = 0.005$; $d = 1.29$]) men. Younger men also demonstrated greater median recruitment threshold values when expressed in absolute terms (198.0 ± 99.2 vs. 81.2 ± 43.0 N [$p = 0.001$; $d = 1.53$]). Similarly, large differences in the mean recruitment thresholds were found when expressed in both relative (25.9 ± 7.7 vs. 16.2 ± 7.8% MVC [$p = 0.005$; $d = 1.27$]) and absolute (191.4 ± 87.5 vs. 85.1 ± 44.9 N [$p = 0.001$; $d = 1.53$]) terms. The relative recruitment threshold range was not significantly different between younger (22.6 ± 9.5% MVC) and older (18.5 ± 6.4% MVC [$p = 0.235$; $d = 0.50$]) men. However, the absolute range was considerably larger for younger (167.6 ± 92.4 N) compared to older (95.7 ± 36.5 N [$p = 0.020$; $d = 1.02$]) men. **Conclusion:** Older men tend to recruit motor units at lower force levels. We speculate that motor unit recruitment threshold compression may be a neural adaptation that serves to compensate for denervation and subsequent re-innervation in aged muscle.

Is the Mean Firing Rate versus Recruitment Threshold Relationship Linear?

Kylie K. Harmon, Ryan M. Girts, Robert J. MacLennan, Matt S. Stock. University of Central Florida, Orlando, FL.
 (No relevant relationships reported)

Advances in surface electromyographic (EMG) signal decomposition now allow investigators to analyze firing rate data for 20-50 motor units per contraction. To simplify data interpretation, some investigators have relied on group mean analysis of the mean firing rate versus recruitment threshold relationship. It is unclear, however, whether this association is consistently linear.

Purpose: To determine whether the motor unit mean firing rate versus recruitment threshold relationship is strongest when analyzed via linear, quadratic, or cubic regression.

Methods: Twenty-one men (mean ± SD age = 24 ± 4 years) participated in this study. After determining maximal voluntary contraction (MVC) force of the dominant knee extensors, participants performed trapezoidal isometric contractions at 50% MVC by tracing a visual template displayed on a monitor directly in front of them. Participants were instructed to increase force from 0 to 50% in five seconds, maintain 50% MVC for 15 seconds, and decrease force from 50% to 0 in five seconds. Bipolar surface EMG signals were recorded from the vastus lateralis during each contraction. A surface EMG signal decomposition algorithm was used to calculate mean firing rate and recruitment threshold of each detected motor unit. Motor units with decomposition accuracy levels < 90% were discarded. Polynomial regression was used to determine if each mean firing rate versus recruitment threshold relationship was best fit with a linear, quadratic, or cubic model. Data were interpreted on an individual participant basis.

Results: Statistically significant ($p < .05$) moderate to strong ($r^2 = .599-.964$) linear relationships existed for all 21 participants. Fourteen of the 21 participants demonstrated relationships that were best fit with a linear model ($r^2 = .599-.964$). Of the remaining seven participants, five were best fit with a quadratic model ($r^2 = .864-.953$) and two were best fit with a cubic model ($r^2 = .977-.989$).

Conclusion: While moderate to strong linear relationships were found between the firing rate of motor units and their recruitment thresholds for all participants, in certain cases the strength of the association was enhanced when analyzed via a non-linear model. Our findings provide further support for the need to examine motor unit data on a participant-by-participant basis.

Electromyographic Analysis of the Intensity Progression of Mat Pilates Exercises

Paula Finatto. Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil. (Sponsor: Rafael Escamilla, FACSM)
 Email: paula.finatto@hotmail.com
 (No relevant relationships reported)

Studies evaluating the electromyographic activation (EMG) of spine flexor muscles during Pilates exercises (PE) concluded that EMG is different among abdominal exercises, even when classified in the same intensity category. **PURPOSE:** To compare EMG of spine extensors, flexors and rectus femoris in seven mat PE among basic (B), intermediate (I) and advanced (A) variations. **METHODS:** The EMG of upper rectus abdominis (URA), lower rectus abdominis (LRA), external oblique (EO), internal oblique (IO), rectus femoris (RF) and multifidus were assessed for the Roll Up (RU), Single Leg Stretch (SLs), Double Leg Stretch (DLS), Hundred (HD), and Rolling Like a Ball (RLB) exercises in B, I, and A. Also evaluated in I and A were Double

Straight Leg Stretch (DLSL) and Single Straight Leg Stretch (SSLS). EMG results were expressed as a percentage of maximum voluntary isometric contraction. One-way ANOVA with repeated-measures was used ($\alpha < 0.05$) to compare the three variations. **RESULTS:** In HD exercise, LRA and IO EMG was significantly less ($p < 0.01$) in B variation (48.5% and 41.1%, respectively) than I (68.7% and 68.5%, respectively) and A (75.1% and 80.7%, respectively), and EO EMG was significantly greater ($p < 0.01$) in A (63.4%) compared to B (39.8%), while I (54.2%) was equal to A and B. In RU exercise, URA EMG was significantly greater ($p = 0.04$) in A (43.8%) than B (34.9%). In DLS exercise, LRA EMG was significantly less ($p < 0.01$) in B variation (43.7%) than I (53.2%) and A (66.8%), EO EMG was significantly greater ($p < 0.01$) in A (57.7%) than B (36.1%), and IO EMG was significantly greater ($p < 0.01$) in A (73.5%) than B (39.7%) and I (55.5%). In SLS exercise, LRA, IO and OE EMG were significantly less ($p < 0.01$) in B (35.5%, 37.4% and 41.5%, respectively) than A (55%, 52.4% and 61.1%, respectively). In DLSL exercise, EO and RF EMG were significantly greater ($p = 0.04$) in A (81.6% and 29.3%, respectively) than I (71.7% and 23.29%, respectively). In SSLS and RLB exercises, no significant differences were found among B, I, and A. **CONCLUSION:** The higher URA EMG may be more related to upper limb positions while higher LRA, EO and IO EMG may be more related to lower limb positions and changes greater than 45° of raising or lowering lower or upper limbs seems to be necessary. Supported by Capes and CNPq.

Neural And Contractile Determinants Of Rate Of Force Development: A Preliminary Analysis
 Mitchel A. Magrini, Ryan Colquhoun, Nathaniel Jenkins, Jason DeFreitas. *Oklahoma State University, Stillwater, OK.*
 (No relevant relationships reported)

Neural and contractile factors have been suggested as important determinants for different phases of the rate of force development (RFD). **PURPOSE:** To examine the influence of rate of muscle activation, motor nerve conduction velocity (CV) and motor unit number estimation (MUNE) of the vastus lateralis on early and late phase RFD. **METHODS:** Fifteen males (age = 23 ± 3 y) completed 2 maximal (MVIC) and rapid (rMVIC) voluntary isometric contractions. Participants were instructed to kick out as hard as possible, and as fast as possible for the MVICs and rMVICs, respectively. The RFD values were calculated during the first 50 ms (nRFD50) and 100 to 150 ms (nRFD100-150) and normalized to maximal force (%MVIC/s). The rate of electromyographic signal rise (RER) was calculated during the first 50 ms of muscle excitation (nRER50) and normalized to the peak-to-peak M-wave amplitude (%MPP/s). MUNE was calculated as a ratio of the ensemble average of the single motor unit potential area to the compound muscle action potential area, and was corrected for alternation. Motor CV (m/s) was assessed as the time (m/s) from maximal stimulation of the femoral nerve to onset of muscle activity. Pearson's correlation coefficients were used to analyze the relationships between the dependent variables. Additionally, stepwise multiple regression was used to examine the degree to which the predictor variables (nRER50, MUNE, Motor CV) explained a significant proportion of the total variance in each RFD phase (nRFD50 and nRFD100-150). **RESULTS:** nRER50 (41.47 ± 25.16 %MPP/s) was significantly related to nRFD50 (249.4 ± 94.4 N) ($r = .640$, $p = .01$). nRFD100-150 was not related to any of the predictor variables. nRER50 was the only significant predictor ($\beta = .640$, $p = .015$), explaining 41% of the variance in nRFD50. **CONCLUSION:** These preliminary data are in agreement with previous research suggesting that the early phase RFD is primarily determined by neural factors. Continued sampling will determine if additional variables significantly contribute to predicting early and late RFD performance. **ACKNOWLEDGEMENTS:** The funding for this study was provided, in part, by the Central States American College of Sports Medicine Student Research Grant.

Examining Quadriceps Muscle Excitability Throughout A Progressive Exercise Test: A Pilot Study
 Emily M. Adamic, Joel T. Greenshields, Jessica A. Freemas, Koichi Kitano, David M. Kocaja, Timothy Mickleborough. *Indiana University, Bloomington, IN.*
 Email: emadamic@indiana.edu
 (No relevant relationships reported)

PURPOSE: A metabolic threshold occurs during progressive exercise with a non-linear increase in blood lactate. The power output at which this occurs closely corresponds to the ventilatory threshold, a non-linear increase in minute ventilation (\dot{V}_E). These factors may affect muscle excitability and thus force generating capacity. Muscle excitability has been shown to decrease after high-intensity whole-body exercise, however it has not been identified when this decrease occurs during progressive exercise. Therefore, the purpose of this study was to examine quadriceps muscle excitability throughout a progressive exercise test. **METHODS:** Five men (age 23 ± 3.5 years) performed a step-wise cycling test, beginning at 100W and increasing 25W/min until volitional exhaustion. Minute averages of oxygen consumption ($\dot{V}O_2$) and \dot{V}_E were collected, and heart rate (HR)

and rating of perceived exertion (RPE) were recorded at the end of every minute. M-waves were induced using a stimulating electrode positioned over the femoral nerve and given at a fixed crank angle of 90° while the subject was cycling. During the exercise test, supramaximal stimulations were given every 10 seconds and averaged over the minute. Using a mixed linear model to control for within-subject variance, both absolute and relative (percent decrease) M-wave amplitudes for each minute were compared to the first minute of exercise.

RESULTS: Subjects exercised for an average of 10 (± 0.7) minutes. \dot{V}_{O_2} , HR, and RPE increased significantly each minute in a linear fashion. Ventilatory threshold occurred at minute 7 (± 1 minute). Compared to the first minute of exercise, absolute M-wave amplitude decreased significantly at minute 7 (2.14 ± 2.45mV versus 3.78 ± 2.58mV), whereas relative M-wave amplitude decreased significantly at minute 6 (-20.44% ± 28.53%). After this point, both remained reduced until exhaustion.

CONCLUSIONS: These data show that the M-wave may exhibit an excitability threshold corresponding to that of the ventilatory threshold. This could reflect the metabolic state of the muscle, indicating the division between sustainable and unsustainable exercise intensities. Further research should examine the neural response to progressive exercise in relation to peripheral losses of excitability.

Optimizing Dance Interventions To Improve Motor Function In People With Parkinson'S Disease And Older Adults
 Angela L. Ridgel, FACSM, Jin Hyun Kim, Peter Gates, Robert Melczak, Fred Discenzo, Margaret Busch, Joan Meggitt. *Kent State University, Kent, OH.*
 Email: aridgel@kent.edu
 (No relevant relationships reported)

Dance comprises a broad range of techniques and styles, which have been utilized in classes specifically designed for individuals with Parkinson's disease (PD) and healthy older adults. Previous studies have shown that a series of dance sessions can improve balance, posture, and mobility for people diagnosed with PD and healthy older adults. However, these studies have not analyzed the linkage between repetitive movement types and persistent changes in motor skills. In order to begin understanding the causative factors of repetitive movement types that result in improved motor skill performance, the functional relationship between movement features and observed performance improvements needs to be examined. **PURPOSE:** To identify dance movement patterns resulting in the greatest improvement in tests of gait, balance and upper extremity function using partnered and non-partnered dance to music in PD and healthy older adults. We hypothesize that scripted variation in movement will promote improvements in motor performance. **METHODS:** Participants in structured group dance classes were recruited for this study. Performance measures of upper and lower extremity were collected before and after each dance class. Motion capture, video and live observations were used to examine movement patterns. **RESULTS:** Individuals with PD had slower baseline performance in the 9 hole peg test (9HPT) than healthy older adults in both left ($p = 0.026$, 33.5 s vs 24.9 s) and right hand ($p = 0.008$, 31.2 s vs 26.5 s). There was also a significant improvement in the 9HPT for the left hand after the dance classes in the individuals with PD ($p = 0.035$, 3.44 s). Factors that led to observed improvements in mobility and movement execution included: repetition of foundational weight shifts in a separate preparatory exercise, engagement of the spine and arms in counterbalancing movement in the legs, incorporating flexion at the knee into the dance stride, and partnering with a moderately-skilled dancer. Increased amplitude and ease of stride and greater lift in the feet in locomotion were also documented. **CONCLUSIONS:** These preliminary results suggest that repetitive shifts in balance and movement during dance with music can lead to upper extremity motor performance and increased amplitude of movement in the lower extremity in individuals with PD.

1315 Board #77 May 30 10:30 AM - 12:00 PM
Effects Of A Cooling Vest On Dual-task Performance And Fatigability In Persons With Multiple Sclerosis

Samantha Everett, Chelsea Comeau, Virginia Thomas, Srikant Vallabhajosula. *Elon University, Elon, NC.* (Sponsor: Stephen Bailey, FACSM)

(No relevant relationships reported)

Fatigue and heat sensitivity are commonly reported symptoms in persons with multiple sclerosis (PwMS). PwMS also often have difficulty performing concurrent cognitive and motor tasks that presents as a dual-task decrement. Heat sensitivity along with a dual-task decrement may hinder activities of daily living and quality of life for PwMS. Though using a cooling vest could help decrease heat sensitivity, it is currently unknown if it improves dual-tasking performance in PwMS. **PURPOSE:** To examine the effects of a cooling vest on cognitive-motor dual-task cost (DTC) and fatigability in PwMS. **METHODS:** 5 PwMS participated in two sessions that were at least 1 week apart. During one session participants wore a sham cooling vest and the other session an actual cooling vest. During each session participants completed a Timed 25-Foot Walk Test (T25FWT), 6 Minute Walk Test (6MWT), T25FWT while performing Serial 3's, and a 6MWT while narrating a story. The type of vest and order of tests was randomized for each participant. Total times for T25FWT and total distances for 6MWT were recorded. DTC, defined as the percent change between single- and dual-task performance, was calculated. Fatigability, defined as the difference between the averages of the first two and the last two lap times of the 6MWT, was calculated. Paired samples t-tests were used to compare DTC during cooling and non-cooling sessions and fatigability during single- and dual-task conditions within each session. **RESULTS:** The mean DTC during the 6MWT for cooling and non-cooling was -4.1% and -6.5%, respectively. The DTC during the T25FWT for cooling was 7.3% and 11.5% for non-cooling. The mean distance walked during 6MWT dual-task increased from 275.5m without cooling to 285.6m with cooling. There was a trend towards significant difference between single- and dual-task fatigability during 6MWT for non-cooling session (Single: 1.6±7.6m; Dual: 6.2±5.3m; p=.051), but not for cooling session (Single: 0.7±3.8m; Dual: 12±16.4m; p=.082). **CONCLUSION:** Preliminary results with lower DTC and no significant difference between single- and dual-task fatigability when using a cooling vest suggests that a cooling vest may have a benefit PwMS while dual-tasking during endurance activities. Further research with a larger sample size is needed to confirm these findings.

Comparing Turn Performance In Parkinsonism

Sidney Baudendistel, Abigail Schmitt, Ashley Rodriguez, Chris Hass, FACSM. *University of Florida, Gainesville, FL.* (Sponsor: Chris J Hass, FACSM)

Email: sbaudendistel@ufl.edu

(No relevant relationships reported)

Turning while walking is one of the main tasks of daily living known to elicit falls in healthy older adults and persons with movement disorders, such as Parkinson's disease. Essential tremor is the most common adult movement disorder; recent work has identified meaningful gait impairments in this population. However, turning performance has not been evaluated in this population. **PURPOSE:** To determine differences in gait patterns between patients with Parkinson's disease and those with Essential Tremor during a turning task and their relationship to reported falls. **METHODS:** 15 persons with Essential Tremor (ET) and 15 persons with Parkinson's disease (PD) age matched within 3 years, performed two 180 degree turns, as part of the Primary Gait Screen, on an instrumented pressure mat. Average time to complete the turn, amount of steps required to turn, and cadence (number of steps/time) of the turn we calculated. Reported falls in the last six months on a categorical scale, (0: No falls, 1: Rarely, 2: Monthly, 3: Weekly, 4: Daily), age at diagnosis, and age at first symptom were collected. Paired t-tests were used to compare measures between groups while a simultaneous multiple regression was performed to analyze potential predictors of falls. **RESULTS:** No significant differences were found between the ET and PD groups ($p>.05$) with the exception of cadence. Those with PD had a significantly higher cadence during the turn than those with ET ($2.17 \pm .301$ steps/sec vs. $1.91 \pm .369$ steps/sec, $p=.042$). Using regression to analyze possible predictors, the overall model failed to obtain significance in predicting falls ($F(6)= 1.855$, $p=.134$, $R^2=.336$). Only age at evaluation ($p=.011$) and age at diagnosis ($p=.032$) were statistically significant predictors in this model, as age at evaluation increased ($B=.084 \pm .030$, $Beta=.813$) so did falls and as age at diagnosis decreased ($B=-.058$, $Beta=-.700$), falls increased. Average time, number of steps, age at first symptom, and diagnosis (ET or PD) were not significant predictors ($p>.05$). **CONCLUSION:** Surprisingly, turning performance was similar between those with ET and PD, suggesting that gait impairment in ET is more prevalent than clinically recognized. However, turning performance was not predictive of fall frequency.

Neuromuscular Impairment of the Plantar Flexors In Adults With and Without Prader-Willi Syndrome

Eric J. Shumski¹, Skylar C. Holmes¹, Brett K. Post¹, Steven A. Garcia², Derrick Escano¹, Daniela A. Rubin, FACSM¹, Derek N. Pamukoff¹. ¹California State University, Fullerton, Fullerton, CA. ²University of Michigan, Ann Arbor, MI.

Email: ericshumski@csu.fullerton.edu

(No relevant relationships reported)

Muscle weakness is common in individuals with Prader-Willi Syndrome (PWS), but the source of weakness is unclear. **PURPOSE:** The purpose of this study was to compare neuromuscular function, and muscle size and quality of the plantar flexor muscles between individuals with and without PWS. **METHODS:** Ten participants with PWS were matched on sex to 10 obese control and 10 lean control participants. Hoffman (H) reflex and muscle response (M-wave) were obtained from the soleus by stimulating the tibial nerve to determine the H:M ratio. Isometric plantar flexor strength was assessed using an isokinetic dynamometer to find peak torque (PT), early (RTD100) and late (RTD200) rate of torque development. Surface electromyography (EMG) was recorded from the soleus and gastrocnemii during strength assessments to determine early (RER100) and late (RER200) rise in EMG, and early (I100) and late (I200) integrated EMG. EMG data were normalized to peak EMG amplitude collected during the MVIC trial. Strength variables were normalized to lean mass. Ultrasound imaging was used to quantify gastrocnemii cross sectional area (CSA) and echointensity (EI). One-way ANOVA was used to compare dependent variables between groups. **RESULTS:** There were group differences in H:M ratio ($p=0.03$), RTD100 ($p<0.01$), RTD200 ($p=0.01$), RER100 ($p=0.02$), and CSA ($p<0.01$). Post hoc tests indicated that the PWS group had lower H:M ratio (0.29 ± 0.18 vs. 0.52 ± 0.13 , $p=0.03$), RTD100 (1.49 ± 0.64 vs. 5.19 ± 3.26 Nm/kg, $p<0.01$), and RTD200 (2.20 ± 1.05 vs. 4.95 ± 2.48 Nm/kg $p<0.01$) compared to lean controls. The PWS group had lower RER100 (1.07 ± 1.14 vs. 2.84 ± 1.49 %MVIC/sec, $p=0.02$) in the soleus compared to obese controls. Obese controls had larger CSA compared to lean controls (2527.99 ± 579.02 vs. 1638.55 ± 354.52 mm², $p<0.01$) and compared to the PWS group (1797.29 ± 764.77 mm², $p=0.026$). There were no differences between groups in RER200, I100, I200, or EI. **CONCLUSIONS:** A lower H:M ratio in adults with PWS compared to controls may indicate lower α -motoneuron excitability. Similarly, lower RTD100 in adults with PWS compared to controls may indicate lower motor unit recruitment and firing rate, which is supported by lower RER100. Conversely, lower RTD200 may be attributed to smaller CSA. Muscle weakness in adults with PWS may originate from neural and morphologic factors.

(No relevant relationships reported)

Scientific literature has shown motor impairment in adolescent boys with Attention-Deficit/Hyperactivity Disorder (ADHD), but little is known about girls with ADHD. **PURPOSE:** The purpose of this study was to evaluate the impact of ADHD on Gross Motor Skills (GMS) of adolescent girls. **METHODS:** GMS of 7 girls with ADHD (mean=15.3 ± 1.8 years old) was compared to 7 control girls (mean=15.1 ± 1.6 years old) using the «Myg & Gym» GMS test battery for Reaction Time, Limb Speed, Agility, Coordination, and Balance. Scores were compared between groups controlling for the following covariates: Age, BMI percentile and presence of Pharmacological Treatment. **RESULTS:** Girls with ADHD showed significantly slower arm and leg limb speed when compared to girls without ADHD (Arm: 63.43 ± 9.43 vs 88.43 ± 11.25 single touch, $p=0.001$; Leg: 21.14 ± 3.02 vs 25.71 ± 3.68 double touches, $p=0.03$). Girls with ADHD showed significantly less hand-eye coordination when compared to girls without ADHD (2.8 ± 1.5 vs 7.8 ± 1.2 throws, $p<0.001$). Correcting for Age, BMI and Pharmacological Treatment did not affect the differences in GMS outcomes. **CONCLUSION:** It appears that significant differences are present between girls with ADHD when compared to girls without ADHD for GMS functions. Future motor development research should include female participants with ADHD and include an assessment of executive functions. This would help better understand the possible causes of the motor impairment identified in individuals with ADHD.

Aquatic-based Exercise For Individuals With Parkinson's Disease: A Systematic Review And Meta-analysis Of Randomized Controlled Trials
 Lucia Cugusi¹, Andrea Manca², Marco Bergamin³, Andrea Di Blasio⁴, Franca Deriu², Marco Monticone¹, Giuseppe Mercurio¹.
¹University of Cagliari, Monserrato, Italy. ²University of Sassari, Sassari, Italy. ³University of Padova, Padova, Italy. ⁴G. d'Annunzio University of Chieti-Pescara, Chieti, Italy.
 (No relevant relationships reported)

PURPOSE: What are the effects of aquatic-based exercise (AqEx) on motor and non-motor symptoms, functional performance and quality of life (QOL) in individuals with Parkinson's disease (IwPD)? Does AqEx have greater effects on these outcomes than other forms of exercise in IwPD? **METHODS:** A systematic review and meta-analysis of randomized controlled trials (RCTs), which enrolled IwPD in supervised AqEx programs > 2 weeks, was conducted. The primary outcomes were motor symptoms and functional performance; the secondary outcomes were non-motor symptoms and QOL outcomes. **RESULTS:** Of the 129 records identified, seven trials met the inclusion criteria and six entered the meta-analysis (159 subjects). One trial assessed the effect of AqEx compared to usual care and found a significant improvement at the Unified Parkinson's Disease Rating Scale Part-III (UPDRS-III, mean difference, MD -4.6, 95% CI -7.5 to -1.7) in favour of AqEx. Six studies compared AqEx with Land-based exercise (LEx) Post-intervention (after an average of 7.2 ± 2.2 weeks of training; 159 subjects). The effect of AqEx was superior to LEx on the Berg Balance Scale (MD 2.7, 95% CI 1.6 to 3.9), the Falls Efficacy Scale (MD -2.1, 95% CI -3.1 to -1.0) and the 39-item Parkinson's Disease Questionnaire (MD -6.0, 95% CI -11.3 to -0.6), with no significant between-groups differences in the other outcomes considered. The significant between-group difference for the Berg Balance Scale was maintained at the follow-up assessment (54 subjects, MD 6.3, 95% CI 2.1 to 10.5). **CONCLUSIONS:** AqEx significantly improves motor symptoms in IwPD. It also has slightly to moderately greater benefits than LEx on balance capacity, postural stability and perceived well-being in IwPD, especially in those presenting with specific functional and mobility impairments. On other outcomes, the benefits of AqEx were similar to those of LEx. **REVIEW REGISTRATION:** PROSPERO CRD42017077370

Single-Arm Torque Perceptual Deficits in Individuals with Chronic Hemiparetic Stroke
 Angelica C. Alberto¹, Justin Drogos², Ninghe Cai², Neha Reddy², Julius Dewald², Netta Gurari². ¹California State University, Northridge, Northridge, CA. ²Northwestern University, Chicago, IL.
 Email: Angelica.Alberto.736@my.csun.edu
 (No relevant relationships reported)

Background: To perform activities of daily living safely and efficiently, an individual with hemiparetic stroke needs to accurately perceive how much force is generated about their joints, i.e., torque perception. We know that individuals with moderate to severe motor impairments post hemiparetic stroke have between-arms torque perceptual impairments. However, a question that has yet to be addressed is whether these individuals have a torque perceptual impairment within their paretic arm and/or non-paretic arm.

Objective: To compare single-arm torque perception between individuals with chronic hemiparetic stroke and individuals without neurological impairments (i.e., controls).

Methods: Nine individuals with chronic hemiparetic stroke and five similarly-aged individuals without neurological impairments (i.e., controls) partook in the study. By following automated audiovisual cues, each participant generated 25% of their maximum voluntary elbow extension torque for three seconds, relaxed for two seconds, and then matched the remembered torque for one second without receiving feedback on their torque-matching ability. This torque-matching task was performed in each arm.

Results: The mean \pm standard deviation of the normalized absolute torque matching error was $26.5 \pm 18.3\%$ and $28.2 \pm 23.3\%$ for the participants with chronic hemiparetic stroke in their paretic and non-paretic arm, respectively, and $19.8 \pm 7.1\%$ and $20.1 \pm 11.3\%$ for the controls in their dominant and non-dominant arm, respectively. Absolute error was not found to significantly differ depending on the arm tested ($p=0.53$).

Conclusions: Our participants with chronic hemiparetic stroke and controls matched torques similarly in each arm. This result supports the notion that unilateral torque perceptual deficits may not occur in individuals with chronic hemiparetic stroke who exhibit motor impairments during unimanual activities.

Functional Motor Control Deficits In Fragile X Mental Retardation 1 Gene Premutation Carriers
 Seoung Hoon Park¹, Zheng Wang¹, Walker McKinney², Evangelos A. Christou¹, Matthew W. Mosconi². ¹University of Florida, Gainesville, FL. ²University of Kansas, Lawrence, KS.
 Email: shpark@ufl.edu
 (No relevant relationships reported)

Individuals with the fragile X mental retardation 1 (FMR1) gene premutation are at increased risk for fragile X associated tremor/ataxia syndrome (FXTAS). However, it is unknown whether FMR1 gene premutation carriers, with or without FXTAS, exhibit functional motor control deficits compared with healthy individuals. **PURPOSE:** To determine whether FMR1 premutation carriers exhibit impaired ability to perform functional motor tasks. **METHODS:** Eight FMR1 gene premutation carriers (4 with FXTAS and 4 without FXTAS; 58.88 ± 9.25 yrs) and eight age- and sex-matched healthy individuals (60.13 ± 9.25 yrs) performed 1) a constant isometric force control task with the index finger at 20% MVC; 2) a dynamic stance task where a participant continuously swayed anteriorly-posteriorly; and 3) a single step initiation task. We recorded the force from the index finger during a constant contraction task, the center of pressure (COP) during a dynamic stance task, and the time and velocity during a single step initiation task. **RESULTS:** Compared with healthy controls, FMR1 gene premutation carriers exhibited 1) greater force variability (coefficient of variation of force) during a constant force task (1.48 ± 1.02 vs. $0.63 \pm 0.37\%$; $p < 0.04$); 2) less anterior-posterior trajectory distance (4.24 ± 0.71 vs. 5.30 ± 0.42 cm; $p < 0.01$) during a dynamic stance task; and 3) greater step duration (0.39 ± 0.14 vs. 0.27 ± 0.04 s; $p < 0.05$) and less step velocity (111.07 ± 24.62 vs. 136.42 ± 16.47 cm/s; $p < 0.05$) during a single step initiation task. **CONCLUSION:** Irrespective of existence of FMR1-related tremor/ataxia syndrome, FMR1 premutation carriers exhibit functional motor control deficits compared with healthy individuals.

Supported by NIMH R01 Research Project Grant Program (MH 112734), Once Upon a Time Foundation Award, the Kansas Center for Autism Research and Training (K-CART) Research Investment Council Strategic Initiative Grant to Dr. Mosconi, and the NICHD U54 Kansas Intellectual and Developmental Disabilities Research Center Award (U54HD090216).

The Relationship Between Y Balance Performance & Hip Strength & Recreationally Trained Women.
 HAROLDO SANTANA¹, Gabriel A. Paz¹, Antonio Brandão², Victor Dos SANTOS JÚNIOR², Kim HÉBERT-LOSIER³, Humberto Miranda¹. ¹UF RJ - Federal University of Rio de Janeiro, RIO DE JANEIRO, Brazil. ²Physical Assessment and Training Center - CAFT, RIO DE JANEIRO, Brazil. ³University of Waikato, Tauranga, New Zealand.
 (No relevant relationships reported)

PURPOSE: This study aimed to identify the relationship between the Y Balance Test - Lower Quarter (YBT-LQ) and hip isometric strength and to compare outcomes between preferred and non-preferred limbs in recreationally resistance-trained women.

METHODS: Twenty young college females (22.3 ± 2.1 years) with background in regular strength or plyometric training volunteered to participate in this study. Maximal reach distance in each of the three YBT-LQ reach directions (anterior, posteromedial, and posterolateral) and a composite reach score (sum of the three directions) were recorded for the preferred and non-preferred leg and normalized to leg length. A handheld dynamometer was used to measure the maximum voluntary isometric strength of each participant for the hip extensors, flexors, adductors, abductors, and internal and external rotators (N).

RESULTS: Significantly lower normalized scores were noted for the preferred ($81.2 \pm 11.7\%$) compared to the non-preferred leg ($83.6 \pm 12.4\%$) for anterior distance. For the composite score of the YBT-LQ and hip strength measures, associations were weak for hip extension and external rotation; moderate for hip flexion, adduction, and abduction; and strong for hip external rotation ($r = 0.516$, $p = 0.059$).

CONCLUSIONS: The strong association between hip external rotator strength and composite score of the YBT-LQ suggest that strengthening this muscle group might be important for dynamic postural control and the reduction of injury risk factors in recreationally active females.

Effect of Treadmill vs. Recumbent Cross Trainer on Gait and Leg Electromyography after Chronic Stroke

Nicholas Siekirk¹, Qin Lai², Victoria Pardo², Sujay Galen³, Brad Kendall⁴, Tamara Hew-Butler, FACSM². ¹Georgia Southern University, Statesboro, GA. ²Wayne State University, Detroit, MI. ³Georgia State University, Atlanta, GA. ⁴Taylor University, Upland, IN. (Sponsor: Tamara Hew-Butler, FACSM)
 Email: nsiekirk@georgiasouthern.edu
 (No relevant relationships reported)

A recumbent cross trainer (RCT) relies on similar neural networks as gait. Therefore, neurologically impaired individuals may improve walking ability after exercise on the RCT. **PURPOSE:** The purpose of this investigation was to compare the effects of the RCT and Treadmill (TM) on intra-exercise electromyography and post-exercise spatial-temporal gait parameters. **METHODS:** 34 participants were divided into two groups; stroke (CVA) (10 ± 5 years post-CVA) and age and sex-matched control. Participants completed two 5-minute exercise bouts on both the RCT and TM at an RPE based self-selected cadence. Intra-exercise Mean electromyography (mEMG) values were normalized to maximum voluntary contraction and were recorded bilaterally at the rectus femoris, vastus medialis oblique, semitendinosus, tibialis anterior, medial gastrocnemius, and soleus. Change in joint range of motion was calculated (maximum-minimum degree; ΔROM) from wireless goniometer measures at the hip, knee, and ankle. Gait parameters were evaluated by the Wireless Gait Assessment Tool (WiGAT) immediately following each exercise bout (3 x 10m walk). HR and BP were monitored to ensure the return to pre-exercise levels. **RESULTS:** Stroke (n = 15) and healthy (n = 19) did not differ in age (*Mdn*: 66 years vs. 57 years, respectively) or BMI (Stroke: *M* = 27.02, *SD* = 4.57 vs. Healthy: *M* = 26.46, *SD* = 4.63), *p* > .05. Healthy participants were stronger at all joints, *p* < .025. Preferred TM speed was faster in the healthy condition despite no statistical difference in RPE, *p* < .05. RCT average steps per minute did not differ between the conditions, *p* > .05. RPE did not differ between groups or across exercise modes. The TM elicited a higher mEMG on a majority of the studied muscles in both populations, *p* < .025. TM demonstrated an increased ΔROM in the R knee and both ankles in the healthy population, *p* < .025. There were no statistical differences between the TM and RCT in the CVA's ΔROM. WiGAT determined the RCT decreased the stance percentage (%) and increased swing % on the non-affected leg, *p* < .05. Neither exercise mode modulated the affected-side stance %, affected-side swing %, double support time or bilateral (affected vs. non-affected) stride length, *p* > .05. **CONCLUSION:** Five minute RCT intervention improved non-affected side gait parameters in a chronic CVA population.

Acute Effects of Yoked Prism Lenses on Gait in Individuals with Acquired Brain Injuries

Nathan Bedel¹, Melissa McDonald¹, Susan Durham², Alma Privette², Srikant Vallabhajosula¹. ¹Elon University, Elon, NC. ²Brier Creek Vision Care, Raleigh, NC. (Sponsor: Stephen Bailey, FACSM)
 Email: nbedel@elon.edu
 (No relevant relationships reported)

Acquired brain injuries (ABI) have been known to lead to a host of neurological impairments including visual imbalances that can greatly impact everyday life. Along with headaches, dizziness, and photophobia individuals with ABI report difficulty with postural alignment, balance, and gait. It has been suggested that common symptoms associated with ABIs are due in part to poor integration of the sensory motor system. Recent research has shown that yoked prisms can alter spatial perception and if used correctly draw the visual midline to its corrected position. **PURPOSE:** To examine the effects of yoked prism lenses on individuals with acquired brain injuries to determine if there is a change in gait. **METHODS:** 13 individuals with ABI (mean age: 43.1±18.1 years) walked 2-4 times at their self-selected speed across a 14' GAITrite walkway under two conditions with current vision correcting prescription: without additional yoked prisms (WOP) and with a yoked prism lens (WP). Spatiotemporal gait parameters consisting of gait speed, stride length, stride width, and single support percent were extracted and averaged across the trials within each condition. Paired samples t-test was used to compare the gait parameters across both the conditions. **RESULTS:** Wearing yoked prism lenses resulted in increased gait speed (WOP: 92.3±25.9 cm/s; WP: 99.1±28.9 cm/s; *p*=0.007) and stride length (WOP: 102.1±17.7 cm; WP: 108.3±20.0 cm; *p*=0.035). Stride width (WOP: 10.8±3.8 cm; WP: 10.8±3.0 cm; *p*=0.855) and single support percent (WOP: 37.0±2.8; WP: 37.3±2.9; *p*=0.335) did not show significant changes. **CONCLUSION:** When participants with reported ABIs wore yoked prism lenses they may be experiencing better integration of their sensory motor systems including a corrective shift in visual midline which allows for an increase in gait speed and stride length, indicating an overall improvement in gait. Our findings suggest that yoked prism lenses have acute benefits to improve gait in individuals with ABIs. Long-term benefits need to be evaluated.

Effects of Activity-Based Physical Rehabilitation on Locomotor Recovery in Rats after Severe Spinal Cord Injury

Kinley H. Buckley, Christine F. Conover, Russell D. Wnek, Michael C. Reynolds, Micah Flores, Ean G. Phillips, Dana M. Otzel, Joshua F. Yarrow. Malcom Randall VA Medical Center, Gainesville, FL.
 (No relevant relationships reported)

Activity-based physical rehabilitation (e.g., bodyweight supported treadmill training (TM) or passive Cycle training) promotes recovery of voluntary locomotor function after moderate-severity spinal cord injury (SCI). However, little evidence supports efficacy of these treatments following severe SCI. **Purpose:** To determine the effects of TM and passive Cycle training on the recovery of voluntary locomotor function in rodents after severe SCI. **Methods:** 16-week old male Sprague-Dawley rats (n=44) received either a T9 laminectomy (SHAM) surgery or T9 laminectomy plus severe (250 kilodyne) contusion SCI using a computer-guided impactor. SCI animals were then stratified into groups that received 1) no training (SCI), 2) TM training (SCI+TM), or 3) Cycle training (SCI+Cycle). TM and Cycle training were initiated 1-week post-surgery and consisted of two 20 min bouts/day, performed 5 days/week for 3 weeks. Hindlimb locomotion was assessed weekly using the BBB Locomotor Rating Scale. **Results:** One-week post-surgery, all SCI animals exhibited locomotor deficits (BBB score <3 on a 0-21 scale, *p*<0.01 vs baseline), indicating near-complete hindlimb paralysis. Thereafter, the SCI group spontaneously regained some voluntary hindlimb function (BBB = 6.1 ± 0.993 at week 4, *p*<0.01 vs week 1). However, SCI animals did not recover the ability to hindlimb weight support in stance or to perform stepping patterns. Similarly, BBB scores improved in the SCI+TM group from week 1 to week 4 (*p*<0.01), although, hindlimb locomotor recovery was not greater than SCI alone. In contrast, BBB scores did not improve significantly from weeks 1-4 in the SCI+Cycle group. SCI+TM exhibited higher BBB scores than SCI+Cycle at weeks 3-4 (week 4 average: SCI+TM = 8.1 ± 1.025; SCI+Cycle = 4.4 ± 0.561, *p*<0.05) **Conclusion:** Our findings suggest that neither TM nor Cycle training promoted locomotor recovery after a 3-week time span in male rodents after severe SCI. Additionally, Cycle training may have limited locomotor recovery in our model, given that BBB scores did not improve in SCI+Cycle animals. Future research is needed to determine an alternative treatment that can be used in conjunction with locomotor training to improve ambulatory status after severe SCI.

C-34 Free Communication/Poster - Posture and Balance

Thursday, May 30, 2019, 7:30 AM - 12:30 PM

Dry Needling Improves Static and Dynamic Balance in Individuals with Chronic Ankle Instability

Jennifer Mullins, Matthew C. Hoch, Kyle B. Kosik, Nicholas R. Heebner, Philip A. Gribble, Philip M. Westgate, Author J. Nitz. University of Kentucky, Lexington, KY.
 Email: jennifer.mullins@uky.edu
 (No relevant relationships reported)

Individuals with chronic ankle instability (CAI) commonly exhibit balance deficits that are associated with dysfunction of the fibularis longus (FL) muscle. Dry needling (DN) is a treatment that targets muscular trigger points and is hypothesized to improve neurophysiological function of treated muscles. The ability of FL DN to improve dynamic and static balance in patients with CAI is unknown. **Purpose:** Examine the effect of FL DN on dynamic and static balance in individuals with CAI. **Methods:** Twenty-five adults with CAI (9 males, 16 females; 26±9.42 years; 173.12±9.85cm; 79.27±18kg) volunteered to participate. Participants completed the Star Excursion Balance Test (SEBT) and postural control measures before and immediately after a single DN treatment to the FL. The anterior, posterolateral, and posteromedial directions of the SEBT were tested in a random order and reach distances were normalized to a percent of leg length. A composite SEBT score was calculated by dividing the normalized, average scores in each direction by three. Postural control was assessed in single-limb stance on a forceplate through time to boundary (TTB) measurements and calculated in the mediolateral and anteroposterior directions under eyes open and eyes closed conditions. A single DN treatment was performed on the FL using a "pistonning" technique. Descriptive statistics (mean change ± SD), paired t-tests, and standardized response mean effect sizes were calculated to compare balance measures before and immediately after the FL DN intervention (*p*<0.05). **Results:** Following DN, significant improvements were identified in the composite (3.98 ± 4.45%, *p*<0.001, ES=0.89), posteromedial (4.85±5.75%, *p*<0.001, ES=0.84)

and posterolateral reach directions ($4.96 \pm 5.49\%$, $p < 0.001$, $ES = 0.90$) but not in the anterior reach direction ($2.11 \pm 5.77\%$, $p = 0.08$, $ES = 0.37$). Under eyes-open conditions, TTB improved in the mediolateral (0.27 ± 0.43 , $p = 0.004$, $ES = 0.63$) and anteroposterior (0.84 ± 1.43 , $p = 0.007$, $ES = 0.59$) directions. However, no significant changes were identified in any TTB measures with eyes closed ($p \leq 0.20$). **Conclusions:** FL DN created immediate improvements in dynamic and static balance in individuals with CAI. Future studies should examine the effects of multiple DN treatments and the mechanism behind this therapeutic effect.

(No relevant relationships reported)

Several alterations of sensorimotor and motor performance processing occur during the process of normal aging. In women, aging is associated with the onset of menopause, which influences body composition with increased central adiposity, leading to changes in the gynoid to android fat distribution pattern. These changes may alter the center of gravity, compromising body stability and causing risk of falls. **PURPOSE:** The study aimed to analyze the influence of body mass on postural stability in postmenopausal women. **METHODS:** Forty women (age: 71.2 ± 5.4 years, height: 154.6 ± 5.8 cm, weight: 72.0 ± 21.2 kg and BMI: 28.9 ± 4.5 kg/m²) were evaluated. According to the body mass, participants were divided into two groups: overweight group (OWG, $n = 23$) and normal weight group (NWG, $n = 17$). Body mass assessment was performed using multiple frequency bioimpedance analysis (MF-BIA) and postural stability was evaluated on the Biodex Balance System (BBS), using Postural Stability Test (PST) at levels of oscillation 8 and 4 at the anterior-posterior (AP) and mid-lateral (ML) directions. Statistical analysis was performed by Shapiro-Wilk normality-test; comparisons between groups by Mann Withney test and correlations by Spearman correlation coefficient. Statistical significance was set at $p < 0.05$. **RESULTS:** OWG presented significantly ($p < 0.05$) lower postural stability (AP-PST-8: 1.32 ± 0.49 ; ML-PST-8: 1.05 ± 0.50 ; AP-PST-4: 2.20 ± 0.89 ; ML-PST-4: 1.78 ± 0.91) to the NWG for all the variables determined in the BBS (AP-PST 8: 0.71 ± 0.34 ; ML-PST-8: 0.70 ± 1.06 ; AP-PST-4: 1.35 ± 0.81 ; ML-PST-4: 1.24 ± 0.84). Also, there was a positive and moderate correlation between BMI with AP-PST 8 ($r = 0.58$), BMI with ML-PST 8 ($r = 0.45$), BMI with AP-PST 4 ($r = 0.51$) and BMI with ML-PST 4 ($r = 0.46$). **CONCLUSION:** These data suggest that overweight predisposes postmenopausal women to greater postural instability.

Diurnal Influence On The Modified Test Of Sensory Integration And Balance (mCTSIB)

Brandon Doan, Kade Carrigan, Sarah Camp, Jeff Pasley. Georgia Gwinnett College, Lawrenceville, GA. (Sponsor: Patrick O'Connor, FACSM)
Email: bdoan@ggc.edu

(No relevant relationships reported)

PURPOSE: The mCTSIB evaluates sensory integration and balance, which have been shown to degrade due to brain injury and neurological disease. Time-of-day affects sensory integration and balance. The purpose of this research was to investigate diurnal effects on the mCTSIB diagnostic protocol. **METHODS:** The Georgia Gwinnett College Institutional Review Board approved this research protocol. The research participants were 21 healthy women (12) and men (9) with an average age of $22.4 (\pm 3.5)$ years, height of $165.9 (\pm 15)$ cm, and weight of $69.3 (\pm 8.2)$ kg. Participants completed morning mCTSIB trials between 7:00 AM and 10:00 AM and evening trials between 4:00 PM and 7:00 PM. Treatment order was randomized and balanced. Participants were instructed to get a normal night's sleep prior to testing and refrain from caffeine use on the day of testing. Participant sleep, physical activity, and concussion history were recorded by survey. **RESULTS:** No statistically significant mCTSIB differences were detected between time-of-day conditions. See chart below for a summary of average postural sway velocities by balance condition and time of day.

CONCLUSION: Based on this investigation, there appears to be no difference in morning compared to afternoon tests of sensory integration and balance among healthy young adults. This is an important finding; possibly informing clinicians that time-of-day is not an important factor to consider when conducting mCTSIB repeated measures or normative comparisons.

1329 Board #91 May 30 10:30 AM - 12:00 PM

The Effects of Cognitive Load and Postural Demand on Static Balance

Nathan Ward¹, Kell Grandjean da Costa¹, John Ramsay², Lee Hancock², Kari L. Loverro², Erika K. Hussey², Alekya Menta¹, Francesca Railneau¹, Eduardo B. Fontes¹, Elizabeth Marfeo¹. ¹Tufts University, Medford, MA. ²Natick Soldier Research, Development and Engineering Center, Natick, MA.
Email: nathan.ward@tufts.edu

(No relevant relationships reported)

A growing body of research indicates that measures of static balance (e.g., postural sway) are influenced under cognitive demands. Similar measures are also impacted under different balance demands (e.g., stable vs unstable stances). However, to date, there is little known about how the difficulty of postural demands impact the relationship between balance and cognition. **PURPOSE:** Within the same individuals, we parametrically compared balance demands and cognitive demands on static balance ability using state-of-the-art inertial sensors. **METHODS:** 34 healthy young adults completed tasks of static balance with and without a cognitive demand (CD). Six wireless inertial sensors (APDM Opals) were attached to the wrists, feet, chest and lower back. The static balance task involved the participants standing for 30 seconds on a firm surface with their eyes closed in three different postural demand (PD) positions: feet apart (Low PD), feet together (Moderate PD), and feet in tandem (High PD). After completing these tasks alone (Low CD), participants were asked to complete these tasks while doing serial seven subtractions from a randomly presented three-digit number (High CD). **RESULTS:** We conducted repeated measures ANOVAs with Cognitive Demand (High vs Low) and Postural Demand (High vs. Moderate vs. Low) on measures of Path Length and Jerk. For Path Length, there was a main effect of CD [$F(1,32) = 13.19$, $p < .001$, $High = 32.39$, $Low = 18.42$] and a main effect of PD [$F(2,64) = 99.69$, $p < .001$, $High = 62.32$, $Moderate = 8.19$, $Low = 5.71$]; however, there was no interaction between these factors. Path Length was longer under High CD relative to Low CD, and for Tandem PD relative to Likewise, for Jerk, there was a main effect of CD [$F(1,32) = 4.28$, $p < .05$, $High = 22.92$, $Low = 17.36$] and a main effect of PD [$F(2,64) = 28.65$, $p < .001$, $High = 37.08$, $Moderate = 14.07$, $Low = 9.27$], but there was no interaction between these factors. **CONCLUSION:** Using two precise measurements of static balance, we observed that performance was impacted by separate cognitive and postural demands. Since these factors did not interact, our results suggest that adding a cognitive task to a balance assessment may have an impact independent of the balance demands.

Relationship Between Physical Function, Diet, And Body Composition With Postural Limits Of Stability
 Sarah E. Heaven, Dean L. Smith, Gabrielle A. Volk, Denise Y. Chan, Hannah N. Moland, Victoria E. Warren, Kyle L. Timmerman, FACSM. *Miami University, Oxford, OH.*
(No relevant relationships reported)

Approximately one out of four older adults will fall each year. Falls are the leading cause of fatal and non-fatal injuries among older adults and represent a significant public health problem. Body composition, diet and physical function are modifiable through lifestyle and may represent potential targets to improve postural stability. However, little is known about the relationships between these variables and limits of stability (LOS) in overweight, older adults. LOS is a reliable test that incorporates maximum center-of-gravity excursion, which is associated with fall risk. **PURPOSE:** To investigate the associations between body composition, physical activity/performance and diet to components of LOS. LOS includes measures of reaction time (RT), movement velocity (MVL), maximum excursion (MXE), endpoint excursion (EXE), and directional control (DCL). **METHODS:** In twenty overweight (body mass index $\geq 27 \text{ kg/m}^2$), older adults ($\geq 58 \text{ y}$), we obtained measures of stability (force plate), habitual physical activity (7-day accelerometry), habitual dietary macronutrient intake (3-day dietary recall), cardiorespiratory fitness (graded exercise test to volitional exhaustion with indirect calorimetry), gait speed from a 4-meter walk test, and body composition (bioelectrical impedance, InBody720). Associations among variables were determined using partial correlations (controlling for age and sex). Statistical significance was set at $\alpha \leq 0.05$. **RESULTS:** Subjects (16 female, 4 male) were 64.2 ± 4.77 years old and had a body mass of $95.34 \pm 15.55 \text{ kg}$, a body mass index of $34.7 \pm 4.68 \text{ kg/m}^2$, and a maximal cycle ergometer VO_2 of $15.64 \pm 2.26 \text{ ml/kg/min}$. Average LOS component values were RT: $0.784 \pm 0.155 \text{ sec}$; MVL: $4.56 \pm 1.46 \text{ deg/sec}$; EPE: $69.41 \pm 10.6\%$; MXE: $87.24 \pm 9.24\%$; and DCL: $70 \pm 8.85\%$. Significant partial correlations were noted for DCL and gait speed, $r = -0.49$, $p = .039$ as well as MVL and height, $r = -0.60$, $p = 0.008$. **CONCLUSION:** Height and gait speed from a standard 4-meter walk test were both significantly correlated to postural limits of stability. Prospective studies are needed to examine the influence of gait speed, DCL and lifestyle interventions on fall risk.
 Supported by a grant from the National Institute on Aging: 1R15AG055923-01.

1331 Board #93 May 30 10:30 AM - 12:00 PM
Aerobic Rumba Training Effects on Static Balance and Lower Limb Power in Older Female Adults
 Cristian Andres Yanez, Jaime Granados, Carlos Castillo, Catalina Gutierrez, Manuel Riveros, Jhonatan Peña. *Area Andina Foundation University, Bogota, Colombia.*
(No relevant relationships reported)

PURPOSE: The objective of this study was to identify the effects of aerobic rumba training of static balance and power in the lower limbs in elderly women. **METHODS:** Twelve healthy older adult women were randomly assigned to one intervention group (INT, $n = 6$, 67.16 ± 5.34 years), body weight ($64.88 \pm 9.79 \text{ kg}$), average weight lean muscle ($24.1 \pm 2.38\%$), body fat ($38.15 \pm 6.56\%$) and a control group (CON, $n = 6$, 67.66 ± 5.98 years), body weight ($65.3 \pm 12.90 \text{ kg}$, average weight lean muscle ($23.56 \pm 2.40\%$) and body fat (42.76 ± 6.48). A progressive dance program was carried out over a period of 8 weeks (twice a week, with a total of 16 sessions) (50 minutes per session and 10 minutes of warm-up) The intensity was measured by means of the effort perception scale. The program was taught by a professional aerobic rumba instructor, who dictated the basic steps, with forward, backward, transversal and rotational direction along with the simplest movements of different musical genres. The variables of stabilometry in the orthostatic position were determined, applying the Romberg test in a bipodal and unipodal way with eyes opened and closed for 30 seconds, using a plantar pressure platforms (BTS P Walk). To determine the power variables through the execution of 3 countermovement jump (CMJ), a force platform (BTS 6000) was used. **RESULTS:** Significant correlations (r) were found next to the p value and the effect size (ES) of the intervention group, on the stabilometric variables in the orthostatic position and those of countermovement jump respectively. Distance COP (DCOP, $p = 0.006$, $r = 0.93$, $ES = 0.5$), mean velocity (MV, $p = 0.007$, $r = 0.93$, $ES = 0.5$), lateral side flexion (LSF, $p = 0.1$, $r = 0.61$, $ES = 0.6$), left foot radius (LFR, $p = 0.02$, $r = 0.87$, $ES = 0.4$), right foot radius (RRF, $p = 0.14$, $r = 0.66$, $ES = 0.0$). CMJ performance variables: jump height (JH, $p = 0.0009$, $r = 0.97$, $ES = 2.3$), Peak Power (PP, $p = 0.02$, $r = 0.86$, $ES = 0.3$), peak concentric force (PCF, $p = 0.01$, $r = 0.90$, $ES = 0.7$) and rate of force development (RFD, $p = 0.009$, $r = 0.92$, $ES = 0.2$). **CONCLUSIONS:** the neuromuscular effect in the lower limbs through the stimulation of the aerobic rumba leads to an improvement in the muscle activation, associated to a better control of the center of pressure of the body (COP), together with the static balance and the power like a preventive factor on the risk of falls in older adults.

1332 Board #94 May 30 10:30 AM - 12:00 PM
The Effect of Music on Virtual Reality Induced Postural Sway
 Shaquitta Dent, Jefferson W. Streepey. *IUPUI, Indianapolis, IN.*
 Email: srdent@iupui.edu
(No relevant relationships reported)

The use of a moving virtual reality (VR) environment to induce postural sway is well established. The extent to which music presented along with VR motion can enhance sway is unknown. **PURPOSE:** To determine if music, presented in modified and unmodified forms, will affect postural sway while standing in a moving VR environment. **METHODS:** Twenty-eight subjects (15 females; 13 males) aged 18-35 stood barefoot on a balance plate while wearing a VR headset. AP and ML center of pressure (COP) data was collected as the subjects experienced 3 visual conditions (VR scene translating in the AP direction at 0.1 Hz, no translation, and eyes closed) and 4 music conditions (music modified to scale loudness at 0.1 Hz and 0.25 Hz, unmodified music, and no music). AP and ML COP excursions, COP RMS, and COP velocities were calculated. **RESULTS:** A significant interaction effect ($p = 0.0439$) showed that combining scene translation with 0.1 Hz modified music increased AP COP excursion ($p < 0.05$) compared to all conditions except 0.25 Hz modified and unmodified music with scene translation. Main effects ($p = 0.009$ and $p < 0.001$) showed the 0.1 Hz modified music increased excursion compared to the 0.25 Hz modified and unmodified music conditions and that scene translation increased excursion compared to the other visual conditions. Similar effects were observed for RMS and velocities. **CONCLUSION:** VR induced sway may be enhanced by music presented in a manner to reinforce visual input. These findings could be used to optimize VR-based training protocols to improve postural control.

Comparison of Postural Changes in Esports Athletes in Gaming and Non-Gaming Chairs. A Case Series.
 Mark Gugliotti, Pamela Karp, William Werner, Dost Khalique. *NYIT, Old Westbury, NY.* (Sponsor: Gordon Schmidt, FACSM)
 Email: mgugliot@nyit.edu
(No relevant relationships reported)

Seventy to eighty percent of the population will experience one episode of neck and low back pain in their lifetime, respectively. Deviations in posture can contribute to this onset of spinal pain. One subgroup of the population that is known to experience similar pain is eSports athletes. It has been shown that 34% of forty recently polled eSports athletes experience neck and back pain when competitively gaming. Concerns have been raised over their sustained aberrant postural positioning during play and its contribution to their pain. **PURPOSE:** To examine postural changes in collegiate eSports athletes while playing in eSports gaming chairs compared to non-gaming chairs. **METHODS:** Four collegiate eSports athletes (21.75 ± 2.06 years old) were recruited to participate in this observational study. Measurements of three joint angles were performed over four days with sessions lasting one hour. Each day the athletes were randomly assigned to a different chair before the gaming session. The chairs included two commercial gaming brands from different vendors (chairs 1 and 2), an office chair (chair 3), and a standard chair (chair 4). Reflective markers were placed at specific bony prominences to capture both sagittal and coronal postures during play. Motion capture was recorded using two GoPros™ and later analyzed with Kinovea™ software. **RESULTS:** There was a significant difference within group ($t = -3.38$, $p = 0.03$) between the pre and posttest neck angle measure for chair 1 of the commercial brands. Using an ANOVA, significant differences were found between chairs 1 and 2 ($F(3,28) = 2.6$, $p = 0.028$) and chairs 2 and 3 ($F(3,28) = 2.6$, $p = 0.023$).

CONCLUSION: The differences found in posture within gaming chairs and non-gaming chairs may impact upon injuries in eSports players. These preliminary results warrant further testing to possibly help reduce injury in eSports athletes.

Effects of Ankle Bracing on Postural Sway

Mohammed S. Zaman, Adam E. Jagodinsky. *Illinois State University, Normal, IL.* (Sponsor: David Thomas, FACSM)
Email: mszaman@ilstu.edu
(No relevant relationships reported)

Ankle bracing can alter postural control strategies during static and dynamic tasks, theoretically through mechanical constraint of the ankle joint and/or sensorimotor reorganization. While a majority of studies have focused on center of pressure (COP) characteristics or clinical tests of balance to explore this theory, fewer studies have investigated sway characteristics of the center of mass (COM). Additionally, the effects of various styles of ankle braces on postural sway remains inconclusive. Assessing the effects of ankle bracing on postural sway could provide additional insight into potential systemic motor adaptations that occur in response to ankle constraint.

PURPOSE: Examine effects of lace-up and semi-rigid bracing on postural sway characteristics during a quiet-standing task. **METHODS:** Thirty-five adults between the ages of 18-30yrs (height: $1.72 \pm 0.1\text{m}$; mass: $75.49 \pm 18\text{kg}$) participated in the study. Participants performed a single one-minute trial of quiet-standing during each of the following conditions: No brace (NB), lace-up brace (LB), and semi-rigid brace (SRB). A ten-camera motion capture system was utilized to capture lower extremity position. To assess postural sway, mediolateral (ML) and anteroposterior (AP) lower extremity COM trajectories were extracted, and root-mean-square deviation (RMSx, RMSy) and velocity (RMSvx, RMSvy) of the COM were calculated. Repeated-measures ANOVAs were employed to assess differences in postural sway measures across all conditions. **RESULTS:** Analysis revealed a significant main effect for RMSy ($F = 7.061$; $p < .01$). Pairwise comparisons indicated that RMSy was significantly lower in the SRB condition ($1.770 \pm 1.698\text{mm}$) compared to C ($2.182 \pm 1.515\text{mm}$) ($p < .01$). **CONCLUSION:** Results from study indicate that subjects exhibited an altered AP postural sway pattern when a semi-rigid brace is applied. These findings align with previous research reporting reduced AP COP excursions with ankle bracing during quiet-standing. Altered sway patterns with ankle bracing appears to support the presence of sensorimotor reorganization, possibly due to altered proprioceptive and/or haptic feedback stemming from greater mechanical constraint of the ankle joint.

1335 Board #97 May 30 10:30 AM - 12:00 PM
Minimal Detectable Change Scores For Measures of Functional Balance in Adolescents With Chronic Ankle Instability

Mary Spencer Cain¹, Benjamin M. Goerger¹, Rebecca J. Ban², Shelley W. Linens³. ¹*University of North Carolina at Chapel Hill, Chapel Hill, NC.* ²*Georgia State University, Atlanta, GA.* ³*University of Oregon, Eugene, OR.* (Sponsor: Erik Wikstrom, FACSM)
Email: msccain@email.unc.edu
(No relevant relationships reported)

Chronic Ankle Instability (CAI) is an issue that can affect individuals with a history of ankle sprains. Improving functional balance is one of the key goals in ankle rehabilitation programs. However, the threshold for defining a meaningful level of improvement for certain assessments has not been determined.

PURPOSE: To establish the minimal detectable change (MDC) values for 2 different functional balance assessments in an active adolescent population with CAI. **METHODS:** Forty-three active adolescents with CAI (20 males and 23 females, 16 ± 1 years, $171.75 \pm 12.05\text{cm}$, $69.38 \pm 18.36\text{kg}$). CAI inclusion criteria consisted of ankle sprain history, current symptoms of pain, weakness and instability and repeated episodes of giving-way. Participants completed 4-weeks of either strength training, balance board training, combination training (completion of both strength and balance board exercises) or no intervention. Dependent variables were pre and post-intervention scores for two measures of functional balance: side-hop test required participants to hop 30-centimeters medially/laterally for 10 repetitions and figure-of-8 hop test required participants to hop in a figure-of-8 pattern over a 5-meter distance for 2 repetitions. Both tests were completed twice on the involved leg. Hopping ability was measured in time to complete (seconds). A positive change score indicated improvement by a decrease in time needed to perform each test. The MDC with 95% confidence intervals was calculated for each variable [$\text{MDC} = 1.96\text{SD} \times (1 - \text{ICC})^{1/2} \times (2)^{1/2}$]. **RESULTS:** Average pre and post-intervention scores were $12.55 \pm 4.51\text{sec}$ and $10.06 \pm 2.45\text{sec}$ for side-hop and $14.60 \pm 2.70\text{sec}$ and $13.00 \pm 1.80\text{sec}$ for figure-of-8 hop respectively. MDC was 2.60sec for both side-hop and figure-of-8 hop. These values reflect the minimal score necessary to be 95% confident that any measured change surpasses the statistical error associated with the test. Approximately 34.38% of the intervention participants had a clinically meaningful change of >2.60 seconds for side-hop test and 31.25% for figure-of-8 hop test. **CONCLUSIONS:** When these functional

balance tests are used to detect beneficial changes from rehabilitation interventions, these MDC scores should be used as a minimum threshold to detect a true and clinically meaningful change.

1336 Board #98 May 30 10:30 AM - 12:00 PM
Relationship Between Balance And Anterior Talofibular Ligament And Superior Extensor Ankle Retinaculum Thickness

Brooke Malloy, Adrian Aron, David Farrow, Haily Cook, Elizabeth Smoot, Lindsey Cash, Kristen Jagger, Brent Harper. *Radford University, Radford, VA.* (Sponsor: Lynn Millar, FACSM)
(No relevant relationships reported)

Ankle sprains are a common injury, with affected individuals often experiencing recurrent symptoms that can progress to chronic ankle instability (CAI). Balance impairments are routinely present in subjects with CAI. Changes in tissue structure of the anterior talofibular ligament (ATFL) and superior extensor ankle retinaculum (SEAR) may occur after an ankle sprain, and may contribute to impaired balance through altered proprioception. **PURPOSE:** To determine if ATFL/SEAR thicknesses were related to dynamic balance in individuals with CAI. **METHODS:** Subjects were 14 males and 15 females (Age = 24.52 ± 3.46 years). Ankle instability was assessed using the Cumberland Ankle Instability Tool (CAIT), with a cut-off score of 25 to define two groups: those with and without CAI. Real-time ultrasound was used to assess ATFL and SEAR thicknesses. Dynamic balance was measured with the Y Balance Test (YBT) and the NeuroCom® motor control and adaptation tests. For subjects with CAI, we analyzed stable versus unstable ankles; for those without CAI, we analyzed right versus left ankles.

RESULTS: There was no difference in mean ATFL thickness (0.24 ± 0.03 vs. 0.22 ± 0.04 cm, respectively, $p=0.21$) or in SEAR thickness (0.09 ± 0.01 vs. 0.10 ± 0.02 cm, respectively, $p=0.19$) between the stable and unstable ankles in those with CAI. For those without CAI, there was also no difference between the right and left ATFL thickness (0.22 ± 0.06 vs. 0.20 ± 0.04 cm, $p=0.14$) or SEAR thickness (0.09 ± 0.01 vs. 0.09 ± 0.01 cm, $p=0.95$). There was no difference in YBT scores in those with or without CAI ($p=0.21$, $p=0.89$ respectively). Additionally, sway energy for upward or downward forces was comparable between those with and without CAI, ($p=0.15$, $p=0.36$). Similarly, composite latencies were also no different ($p=0.68$).

CONCLUSIONS: There was no relationship between ligament thickness and balance, supporting a multifactorial CAI rather than dependency upon tissue changes alone. Central nervous system sensory integration, neuromuscular control compensations, or psychosomatic reactions may be the ones affecting the balance more. Likewise, subject perception of ankle instability may not coincide with impaired dynamic balance. Finally, tests used to assess dynamic balance may not be sensitive enough to identify differences caused by CAI.

Lower Limb Impairments In Patients With Knee Osteoarthritis

Hechmi Toumi¹, Thomas M. Best, FACSM², Eric Lespessailles¹. ¹*Orleans University, Service de Rhumatologie, Centre Hospitalier Régional d'Orléans, Orléans, France.* ²*UHealth Sports Medicine Institute, Department of Orthopedics, Division of Sports Medicine, U of Miami, Coral Gables, FL 33146, USA, Miami, FL.* (Sponsor: Thomas Best, FACSM)

(No relevant relationships reported)

PURPOSE:

Self-reported knee pain is a frequent reason of consulting medical doctors. In the setting of knee osteoarthritis (KOA) care, although it has been shown that muscle function is more closely associated with joint pain than the grade of joint space narrowing, its assessment is generally neglected. In addition, knee malalignment and foot imbalance which are recognized potential risk factor for KOA are not systematically considered. The aim of our study was to determine the frequency of foot imbalance and quadriceps strength and activations disorders and their relationship with knee pain.

METHODS:

150 patients suffering from knee pain (64 men and 88 women) aged 45-74 years (mean age 58.9 , $\text{SD} = 8.1$) underwent quantitative tests of 3D foot scan, quadriceps strength, surface electromyography foot balance during maximal isometric, squat and walking exercises. Inclusion criteria included; radiographic K-L (Kellgren and Lawrence) grades less than 2. Exclusion criteria included: (1) a history of lower limb surgery; and (2) a history of arthrocentesis and acorticosteroid or hyaluronic acid injection within 3 months of study commencement.

RESULTS:

3D foot scan showed that 28% of patients had asymmetrical foot print shape during static position (normal stance) in both feet, 32% in the painful leg and 21% in the

non-painful leg. 44% of the subjects had quadriceps weakness (during isometric test, painful limb was significantly weaker). 28% and 17% unequal vastus medialis versus vastus lateralis ratio activation and 18% and 11% delay in Vastus medialis activation during squatting and walking respectively. When analysed by multiple logistic regression, quadriceps strength, vastus medialis /vastus lateralis ratio activation and foot pronation were independently associated with knee pain. Quadriceps strength and vastus medialis/vastus lateralis ratio activation were not associated with foot misbalance.

CONCLUSIONS:

The findings indicate that, knee pain is a multifactorial process in which several mechanical factors could be associated— but both weakness of the quadriceps muscles and misbalance in the foot are often altered. We may recommend lower limb biomechanics analysis, muscle activation and 3D foot print to optimise both diagnosis and treatment in patients with knee pain.

1338 Board #100 May 30 10:30 AM - 12:00 PM Obesity and Falls in Older Women: Mediating Effects of Muscle Quality, Foot Loads and Balance

Silvia G. R. Neri¹, Lara A. Harvey², Anne Tiedemann³, André B. Gadelha¹, Ricardo M. Lima¹. ¹Faculty of Physical Education, University of Brasilia, Brasilia, Brazil. ²Neuroscience Research Australia, University of New South Wales, Sydney, Australia. ³Institute for Musculoskeletal Health, The University of Sydney, Sydney, Australia.

(No relevant relationships reported)

PURPOSE: Obesity is associated with risk of falls in older women. However, it is not certain whether factors commonly associated with obesity and/or falls mediate this risk. This study examined whether muscle quality, foot loads and postural balance mediate the relationship between obesity and falls. **METHODS:** At baseline, 246 female participants underwent obesity screening (BMI≥30kg/m²), and had muscle quality (isokinetic dynamometer and DXA), foot loads (pressure platform) and postural balance (force platform) evaluated. Incident falls were recorded at the end of the 18-month follow-up period. To identify mediating factors of obesity and falls, a series of modified Poisson regression analyses were conducted as per Baron and Kenny's 3 step criteria. Each potential mediator was individually assessed for its association with obesity (step 1), and if this association was significant, then each potential mediator was assessed for its association with falls (step 2). If the potential mediator was significantly and independently associated with both obesity and falls, the potential mediator and obesity were both included as independent variables in a model to assess their association with falls (step 3). If the 3 mediating conditions were all met, the intervening variable effect was examined using Freedman and Schatzkin test. Significance level was set at p<.05. **RESULTS:** 204 volunteers (83%) completed the follow-up. Obese participants had an increased risk of falls during the 18-month period (RR= 2.13, 95% CI= 1.39-3.27). The table below presents the mediation analysis of the relationship between obesity and falls. Of the variables analysed, only muscle quality (specific torque) was a significant mediator (t= 4.026, p<.001). **CONCLUSION:** Low muscle quality was identified as a mediator for the relationship between obesity and falls in older women. Thus, the inclusion of muscle strengthening as a part of a falls prevention program may benefit this population.

| Assessment of potential mediating factors of obesity and falls. Data are RR (95% CI) | | | |
|--|-------------------|------------------|------------------|
| Potential mediators | Step 1 | Step 2 | Step 3 |
| Muscle quality | | | |

1339 Board #101 May 30 10:30 AM - 12:00 PM Does Movement Strategy Change Directional Balance Reach Test Performance Variability?

Yo-Rong Chen, Larry R. Munger, Troy Hooper, C. Roger James, FACSM. Texas Tech University Health Sciences Center, Lubbock, TX.
Email: yo-rong.chen@ttuhsc.edu
(No relevant relationships reported)

The Directional Balance Reach Test (DBRT) outcome measurement is a composite score (CS) based on the maximum reach distances of three trials in each of three testing directions: anterior (ANT), posterior-medial (PM), and posterior-lateral (PL). Movement strategy, with and without specific movement cues, may alter within trial reach distance performance variability. It may provide different clinical information about individual movement control during DBRT. **PURPOSE:** The purpose of this study was to determine whether movement strategy impacted CS and performance variability in DBRT. **METHODS:** Sixteen subjects (eight males and eight females) were randomly assigned to two groups. Each group performed DBRT on the dominate support (DS) and dominate kick (DK) legs by using personal (P) and specific (S) strategies in different orders (P-S, S-P). The ANT, PM, and PL reach directions were randomized during nine reaching trials. Reach distance was normalized to the subject's leg length. Performance variability of reach distance in each direction was defined by measuring absolute error (AE=[∑_{i=1-3}|xi- \bar{x} |]/3). Two-way mixed ANOVAs, strategy(2) x order(2), were used in a preliminary analysis to rule out an order effect in CS. Two-way repeated ANOVAs, strategy (2) x reach direction (3), were used to determine whether these independent variables affected performance variability. **RESULTS:** For CS, there was no main order effect (p>.05). However, there was a significant strategy effect for both legs (p<.001; DS: P=90.01±6.98%, S=82.92±5.97%; DK: P=89.53±7.93%, S=82.82±7.80%). For AE in DS, there was no significant strategy effect, but there was a main direction effect (p =.001, η^2 =.376, Power=.953; ANT=3.48±2.02%, PM=5.18±4.15%, PL=6.05±4.12%). For AE in DK, there was a significant strategy by direction interaction (p =.044, η^2 =.189, Power=.606). Post-Hoc tests revealed a significant strategy effect (p<.05) for PL only (P=4.78±3.10, S=7.33±5.15). **CONCLUSION:** The movement strategy used impacted CS. However, AE was only altered in the PL direction in DK. The DBRT, a closed chain dynamic balance test, may be a novel task for assessing DK leg performance variability.

Automated Identification of Postural Control for Individuals with Parkinson's Disease using a Machine Learning Approach

Yumeng Li¹, Shuqi Zhang², Christina Odeh², Li Guan³. ¹Texas State University, San Marcos, TX. ²Northern Illinois University, DeKalb, IL. ³University of Georgia, Athens, GA.
 Email: yumeng.li@txstate.edu

(No relevant relationships reported)

Machine learning is a branch of artificial intelligence that enables computer systems to learn from data and analyze data without being explicitly programmed. Interest in machine learning has grown rapidly in clinical settings because the diagnosis of diseases or disorders can be automated by computer systems with high accuracy and minimum human intervention. However, the use of machine learning to identify postural control patterns for people with Parkinson's disease (PD) is not well established.

PURPOSE: The purpose of the study was to develop and validate an automated identification of PD postural control patterns using a machine learning approach.

METHODS: 12 participants with PD (age = 75.3 ± 6.6 yr, height = 1.71 ± 0.12 m, mass = 83.1 ± 12.4 kg) and 18 healthy controls (age = 83.3 ± 5.5 yr, height = 1.62 ± 0.08 m, mass = 73.1 ± 16.2 kg) were recruited. Participants were instructed to stand on a force plate and maintain still for 2 minutes during eyes-open and eyes-closed conditions. The center of pressure (COP) data were collected at 50 Hz; sway area, linear displacements, total distances, standard deviations of COP positions and average velocities were calculated. 3 supervised machine learning algorithms (i.e., logistic regression (LR), k-nearest neighbors (KNN) and naïve Bayes (NB)) were used to identify PD postural control patterns. All participants were divided into two datasets: 70% for training and 30% for testing.

RESULTS: KNN achieved the highest overall accuracy rate (0.90) to identify PD postural control. LR and NB also exhibited satisfactory performance. The overall accuracy of LR ranged was 0.86; and the overall accuracy of NB was 0.81. Though all three models are capable of analyzing small-sample data, model performance to identify PD postural control could be potentially improved by recruiting a larger sample size and exploring other machine learning models in future research.

CONCLUSIONS: Computer-aided machine learning models successfully identified postural control patterns of PD patients with high accuracy. The use of machine learning may provide a valid and efficient approach to better understand PD postural control features and thus, could be beneficial for the early diagnosis and early intervention in individuals with PD.

 Email: takeshima@alice.asahi-u.ac.jp

(No relevant relationships reported)

PURPOSE: With increasing interest in addressing quality of life of older individuals, tests such as the Functional Independence Measure (FIM) are widely used measures of infirmity and burden of care. However, these scales are largely qualitative and especially problematic when assessing movement-based tasks. While effective, reliable analysis of human movement is technically complicated and expensive; an infrared depth sensor is potentially a low-cost, portable device which may provide a quantitative aspect to clinical testing. Our purpose was to assess the utility of the Kinect™ sensor in providing an objective evaluation of human movement using an oft measured ADL (march-in-place test; MIP). **METHODS:** Community-dwelling older adults living in 6 districts and were users of daycare 3 facilities within 4 prefectures in JAPAN. Men (n= 31) and women (n= 74) between the age of 62 and 93 years, consisting of independent (IG; n = 58) and dependent (DG; n = 47) older adults performing the March test. FIM was administered to all subjects (scored by a physical therapist). On a separate day, subjects completed a 20-s MIP test and joint point coordinate data was recorded with a Kinect™ v2 during the final 10-s of the test. Initial head position is the origin (H (0)) and head position at any time t is H (t). The Euclidean distance |H (t) - H (0)| between these two points (0) was calculated and summed as the maximum moving distance (MMD) max {|H (t) - H (0)|}. **RESULTS:** Age, height, body mass and BMI were similar between groups. MMD was greater (p<0.05) in DG (0.293 ± 0.187m) than IG (0.153 ± 0.102m), and was related to age (r=-0.605, p=0.051). An optimal threshold for MMD identifying frailty was determined by a receiver-operator characteristic curve with a MMD of 0.207m providing the

combination of sensitivity (62%) and specificity (79%). **CONCLUSIONS:** During the 20-s MIP test, the increased MMD observed in DG appears to indicate that staggering during stepping is large. The result seems to represent instability during marching and poor balancing ability in frail adults. The 20-s MIP and associated MMD identifies frailty in the present population with good sensitivity and specificity.

Time-of-day Influence On The Stability Evaluation Test (set)

Jeff Pasley, Sara Camp, Kade Carrigan, Brandon Doan. Georgia Gwinnett College, Lawrenceville, GA. (Sponsor: Patrick O'Connor, FACSM)

Email: jpasley@ggc.edu

(No relevant relationships reported)

PURPOSE: Postural control is impaired following a concussion and is one diagnostic method used by medical professionals for return-to-play decisions in concussed athletes. Circadian rhythm affects human function, including postural control. The purpose of this research was to investigate time of day variation related to the SET postural control diagnostic protocol on a Neurocom Balance Master.

METHODS: The Georgia Gwinnett College Institutional Review Board approved this research protocol. The research participants were 19 healthy women (11) and men (8) with an average age of 21.7 (± 2) years, height of 165.9 (± 15) cm, and weight of 69.3 (± 8.3) kg. The participants completed the SET in the morning (between 7:00 AM and 10:00 AM) for one treatment and in the evening (between 3:00 PM and 7:00 PM) for the other treatment condition. A SET familiarization session was completed and treatment order was randomized and balanced to attempt to account for order effects. Participants were instructed to get a normal night's sleep prior to testing and refrain from caffeine use on the day of testing. Participant sleep, physical activity, and concussion history were recorded by survey.

RESULTS: There was less average postural sway during the morning testing for all conditions except for the least challenging balance condition (double-leg firm surface), trending towards larger differences in the more challenging balance conditions (see chart below). The only statistically significant difference (p < 0.05) was for the overall SET composite score, 2.07 (± .19) Deg/s in the AM versus 2.39 (± .30) Deg/s in the PM condition.

CONCLUSIONS: While greater sample size, age, athletic specificity and gender range are needed, these results may begin to inform practitioners as to the importance of controlling time-of-day between SET conditions. This may improve accuracy of comparison between baseline and post-injury diagnostic testing which would enable more confident return-to-activity decisions.

1343 Board #105 May 30 10:30 AM - 12:00 PM
Vestibular And Proprioceptive Alteration Influence Postural Instability During Dual Tasks In Adults Diagnosed With HIV

Leah Hammer¹, Gabriel Gines², Jonathan Marshall¹, Martin Rosario¹. ¹Texas Woman's University, Dallas, TX. ²Puerto Rico University, Ponce, PR.

Email: lhammer@twu.edu

(No relevant relationships reported)

PURPOSE: People diagnosed with HIV can exhibit impaired postural control as a consequence of infection or from secondary effects of medication. Characterize the role of the vestibular and proprioceptive systems during dual postural control tasks in Individuals with HIV. We hypothesize that postural stability will decrease with the increase of task complexity.

METHODS: The study was conducted in San Juan, Puerto Rico at a community-based program, La Perla de Gran Precio. 24 subjects (13 male and 11 female, age average 59.2± 1.7 years) participated in the study. Participants had to be diagnosed with HIV

with a CD4 count of >200 cells/uL to enroll in the study. After signing the informed consent and collecting demographic data, a member of the research team placed a lumbar accelerometer on each subject. Each participant was instructed to quiet stand in a static bi-pedal posture on a firm surface or a thick foam pad. Each task took 15 seconds to be performed. The first task was to stand on a firm surface (baseline), the eight remaining balance tasks were performed with a thick balance foam mat (four single and four dual cognitive tasks). For the cognitive dual tasks participants were instructed to count backward 3 numbers at a time.

RESULTS: Postural control was measured with Body-worn accelerometers (ACC). The two variables of interest in this study were jerk sway acceleration in an anterior-posterior (A-P) and mediolateral direction (M-L), m^2/s^5 . A MANOVA analysis was used to compare the variables of interest, between baseline (BL) (firm surface eyes open) and single/double tasks. AP sway increased significantly during single (BL $0.020 \pm .01 m^2/s^5$ versus single task $0.20 \pm 0.02 m^2/s^5$ $P < 0.005$) and dual tasks (BL $0.020 \pm .01 m^2/s^5$ versus dual task $0.23 \pm 0.03 m^2/s^5$ $P < 0.005$) when visual input was canceled.

CONCLUSIONS: Single and dual tasks showed a similar challenge and results regarding increased acceleration and instability. It appears that the vestibular and proprioceptive systems could be impaired in HIV diagnosed people. Because there is no fall history among the participants of this study and these findings, it seems that patients with HIV rely on the visual system to a higher degree to attain postural control.

1344 Board #106 May 30 10:30 AM - 12:00 PM
Age-associated Decline In Directional Dynamic Balance In Community-dwelling Older Women

Hidehiro Yamamoto¹, Nobuo Takeshima¹, Nicole L. Rogers², Michael E. Rogers, FACSM². ¹Asahi University, Mizuho, Japan. ²Wichita State University, Wichita, KS. (Sponsor: Michael E. Rogers, FACSM)
 (No relevant relationships reported)

PURPOSE: To determine whether there is an age-associated decline in leaning directions of DB in community-dwelling older women. **METHODS:** DB was determined in 558 older women. DB was characterized by limits of stability (LOS) that measured end-point excursion (EXE) and maximum excursion (MXE) of the body's center of pressure, reaction time (RT), mean velocity (MVL), and directional control (DLC). LOS consisted of 8 leaning tests around a center square at 0, 45, 90, 135, 180, 225, 270, and 315 degrees. Average (composite) values for each variable in all directions, as well as for each variable in the forward (0 degrees), backward (180 degrees), right (45 degrees), and left (270 degrees) directions, were analyzed. **RESULTS:** For overall composite scores and the 4 directions, relationships existed between age and RT ($r = 0.18$ to 0.34 , $p < 0.001$), between age and MVL ($r = -0.13$ to -0.30 , $p < 0.001$), age and EPE ($r = -0.27$ to -0.49 , $p < 0.001$), age and MXE ($r = -0.27$ to -0.43 , $p < 0.001$), and age and DLC ($r = -0.11$ to -0.38 , $p < 0.001$). Although age had a significant effect on all balance parameters, there was a higher correlation coefficient with age and composite values compared to the directional results. The influence of age on forward, backward, right, and left directions was not clear. **CONCLUSIONS:** Age had a significant main effect on all balance measures. Balance ability declined in all directions but it is not clear if certain directions are affected differently. Not only was the distance that one can lean without losing balance (EPE and MXE) negatively affected by age, the rate of decline in RT and MVL were also large in all directions. Balance exercise should be designed to address each of these parameters when leaning in the forward, backward, and lateral directions in order to prevent falls.

1345 Board #107 May 30 10:30 AM - 12:00 PM
Is Wobble Board Balance Performance Influenced by Sex and Anthropometric Characteristics?

Cristina Cortis¹, Giuseppe F. Giancotti¹, Philip X. Fuchs², Herbert Wagner², Rubens A. da Silva³, Andrea Fusco¹. ¹University of Cassino e Lazio Meridionale, Cassino, Italy. ²University of Salzburg, Salzburg, Austria. ³Université du Québec à Chicoutimi, Saguenay, QC, Canada. (Sponsor: Carl Foster, FACSM)
 Email: c.cortis@unicas.it
 (No relevant relationships reported)

It has been demonstrated that balance can be influenced by anthropometric characteristics and sex. However, controversial findings are reported, mainly due to the large variability in subjects tested and methodologies adopted. Therefore, new hi-tech approaches, able to limit this variability, are needed to accurately evaluate balance control. **PURPOSE:** To assess the influence of anthropometric characteristics and sex on computerized wobble board (WB) balance measures. **METHODS:** Forty-eight (women=24; men=24) young (age=24.0±3.0years) adults were selected to cover a wide range of anthropometrics (mass=64.6±11.5kg; height=167.3±8.5cm; body mass index [BMI]=23.0±3.2kg·m⁻²). Subjects performed three 30-second trials per limb on a WB equipped with a triaxial accelerometer. Time (s) spent on the platform keeping it flat

at 0° was collected for subsequent analysis. Pearson's correlation was used to evaluate the relationships between WB values and the anthropometrics (height, mass, BMI). ANOVA was used to examine WB performance differences between sex for dominant and non-dominant limbs ($p < 0.05$). **RESULTS:** The measured anthropometrics did not significantly correlate with the WB performance. Although women (dominant limb=19.2±4.6s; non-dominant limb=19.8±4.9s) presented better balance than men (dominant limb=18.8±3.5s; non-dominant limb=19.1±4.1s), no significant sex differences were observed for both dominant ($p = 0.73$) and non-dominant ($p = 0.60$) limb. **CONCLUSIONS:** Interestingly, anthropometrics and sex did not affect the WB performance. Due to the close relationship previously reported between WB training and ankle muscles activity, it could be hypothesized that the WB performance is affected by their strength, stiffness or activity. WB improvements after training protocol using WB exercises, can be understood as consistent change in performance not affected by other source of variability such as variation in body mass. Therefore, trainable neuromuscular factors should be targeted during training protocols to gain postural control improvements, without controlling the anthropometrics, independently from the sex. From a clinical point of view, during preventive and rehabilitative programs a special attention should be given to the ankle muscles.

1346 Board #108 May 30 10:30 AM - 12:00 PM
Adults Diagnosed with HIV Report Decreased Balance Confidence Compared to Non-Faller Older Adults

Gabriel Gines¹, Leah Hammer², Lauryn Deschamps², Jonathan Marshall², Flavia Bayron³, Martin G. Rosario². ¹Ponce Health Science University, Ponce, PR. ²Texas Woman's University, Dallas, TX. ³University of Puerto Rico, San Juan, PR.
 Email: gabriel.gines7@gmail.com
 (No relevant relationships reported)

Individuals diagnosed with HIV often experience balance impairments caused by the virus or medication. These deficiencies due to compensation of the postural control systems might be unperceived for years until the impairments are to advance. **PURPOSE:** Assess perceived balance confidence in people with HIV compared to a group of older adults without an HIV diagnosis. **METHODS:** The study was conducted in San Juan, Puerto Rico at an HIV Rehabilitation Clinic (La Perla de Gran Precio) for the HIV group (HIVG). 24 subjects (13 male and 11 female) participated in the study (age 59.2± 1.7 years). To enroll in the study, participants needed an HIV diagnosis with a CD4 count of > 200 cells/uL. The control group (CG) was recruited from the Community Center Complejo Deportivo Carcaño Alicea, Bayamon, Puerto Rico. A total of 25 subjects in the control group (5 males and 20 females) with an age average of 71.5 ± 3.6 years old participated in the study. A member of the research team verbally asked the subjects 16 questions that involved a variety of daily functional activities from the Activities-specific Balance Confidence (ABC) Scale. Each participant was instructed to give a percentage (0-100%) on how confident their balance is while attempting to do these specific functional activities. **RESULTS:** A MANOVA analysis was used to compare ABC scale data between groups. HIVG exhibited significantly reduced balance confidence in six out of sixteen subsets of the ABC scale. Chair and Reach (CG 81.20 +/- 22.651, HIV group 55.67 +/- 19.680, $P \leq 0.05$), Sweep (CG 93.60 +/- 9.631, HIV group 76.67 +/- 12.660, $P \leq 0.05$), Crowded Mall (CG 87.40 +/- 21.704, HIV group 66.67 +/- 12.873, $P \leq 0.05$), Mall (CG 84.40 +/- 12.189, HIV group 68.00 +/- 17.264, $P \leq 0.05$), Escalator (CG 77.40 +/- 23.722, HIV group 52.40 +/- 11.995, $P \leq 0.05$), and Icy Sidewalks (CG 74.40 +/- 26.900, HIV group 43.67 +/- 15.880, $P \leq 0.05$).

CONCLUSIONS: These results indicate that adults with HIV are likely to have less confidence in their balance with those tasks, which may result from decreased proprioception and also may result in increased fall risk. Clinicians should make an effort to identify perceived balance confidence in early stages of the condition to reduce the risk of fall in these population.

1347 Board #109 May 30 10:30 AM - 12:00 PM
Effect Of The Modified Broström-Gould Surgery On Balance In Chronic Ankle Instability

Andrew S. Bartlett¹, Brittney Mazzone². ¹Nazareth College, Penfield, NY. ²IDoD-VA Extremity Trauma and Amputation Center of Excellence, San Diego, CA; ²Naval Medical Center San Diego, San Diego, CA, San Diego, CA.

 (No relevant relationships reported)

Purpose: Chronic ankle instability (CAI) has a high incidence and impacts individuals ranging from young athletes to sedentary adults. CAI can result from a single ankle sprain or from repeated ankle sprains at the lateral ankle. The main deficits associated with CAI are balance impairments, poor postural control, and recurrent sprains. The modified Broström-Gould surgery is considered when conservative treatment has been ineffective at addressing CAI. This procedure involves the reattachment of the ruptured anterior talofibular and calcaneofibular ligaments, with reinforcement through the

inferior extensor retinaculum. There is a lack of research regarding objective outcome measures for balance following this procedure. The purpose of this report was to assess changes in static and dynamic balance for an individual who underwent the modified Broström-Gould surgery.

Methods: A 28 year-old female with right CAI completed pre-testing (two weeks prior to surgery) and post-testing (two months following surgery). Outcome measures included the modified STAR Excursion Balance Test (mSEBT), the Balance Error Scoring System (BESS), and Single Leg Hop Down Test for time to stabilization (TTS) using force plate testing.

Summary of Results: Postoperatively, the patient showed improvements in all directions on the mSEBT for the affected and unaffected lower extremities (LE), with greater improvement seen on the affected LE by 22-30%. The patient improved her overall score for the BESS, demonstrating a reduced number of errors on the affected LE from 20 to 15. The Single Leg Hop Down Test revealed a decrease in the average TTS on the affected LE from 1.88 seconds to 1.01 seconds.

Conclusion: After completion of the modified Broström-Gould surgery and in conjunction with rehabilitation, the patient showed an improvement in dynamic balance measures, possibly due to increased strength and reduced pain levels following rehabilitation after surgery. Future studies should examine the role of exercise interventions and fitness level in determining patient outcomes following the modified Broström-Gould surgery.

Validation Of The Tekscan Strideway Plantar Pressure Mat Compared To A Force Platform

Rachael A. Ard, Jake A. Melaro, Alex M. Carnall, Alexis K. Nelson, Sarah E. Blackmore, Victoria A. White, Max R. Paquette, Douglas W. Powell, FACSM. *University of Memphis, Memphis, TN.*

Email: rachael.a.ard@gmail.com

(No relevant relationships reported)

Force platforms represent the criterion method of assessing external force applied to an athlete during a given task. However, force platforms have several characteristics that may limit their use in sport and clinical environments including limited portability. Therefore, a need exists for portable equipment with high validity to measure load-related variables such as vertical force. **PURPOSE:** To validate vertical force measured using the Tekscan Strideway Plantar Pressure system compared to a force platform. **METHODS:** Five participants performed three 10-second quiet standing trials in each of eight weighting conditions. Increased weighting was achieved by increasing load during a deadlift. Vertical ground reaction force was measured independently using a plantar pressure mat (PPM, 500 Hz, Tekscan Strideway Plantar Pressure Mat, Boston, MA) and a force platform (FP, 1000 Hz, AMTI, Watertown, MA). Custom software (MATLAB, MathWorks, Natick, MA) was used to analyze vertical force data from the PPM and FP. FP data were downsampled to 500 Hz and the average force across the final 5 seconds of each trial was calculated. A correlation analysis was conducted to determine the strength of agreement between the PPM and FP. A paired samples t-test was conducted to compare mean force values measured using the PPM and FP. Cohen's d effect sizes were calculated to determine the meaningfulness of differences between the FP and PPM. **RESULTS:** No differences in vertical force were observed between the PPM and FP were observed ($p = 0.483$; PPM: 227.9 ± 64.7 N/kg; FP: 237.5 ± 57.9). A small effect size ($d = 0.15$) suggests the small differences were likely not meaningful. A high level of agreement ($r = 0.959$) was observed between the PPM and FP. **CONCLUSIONS:** These data demonstrate that vertical force measured using the Tekscan Strideway plantar pressure system are comparable to the more expensive criterion method of a strain gauge-based force platform measures. Moreover, the Strideway platform is mobile providing a solution for non-laboratory based assessments of vertical forces. Further research should evaluate the validity of the Strideway plantar pressure system during more dynamic activities such as jumping and landing and for different force-related variables.

Should We Stick with Step Counts after Incomplete Spinal Cord Injury? A Case-Control Investigation

Whitley J. Stone, Amanda J. Wakeman, Braden A. Younklin, Dustin W. Davis, Matthew J. Garver, H Scott Strohmeier. *University of Central Missouri, Warrensburg, MO.* (Sponsor: Thomas Scott Lyons, FACSM)

(No relevant relationships reported)

Step count is a common metric or criterion to prescribe physical activity. Step activity benchmarks were designed to reflect an overall daily energy expenditure, but this objective measure is exposed to error when gait is impaired. Individuals with functional limitations are known to expend more energy during locomotion when compared to non-impaired controls (CON).

PURPOSE: The primary goal was to evaluate metabolic cost per step for someone with an incomplete spinal cord injury (iSCI) when compared to a CON. A secondary goal was to evaluate estimated daily energy expended between the individuals to determine if step count is an appropriate metric for activity recommendations for those with functional limitations. **METHODS:** This case-control study included a participant with an iSCI and an age-, sex-, height-matched CON. Participants completed a 6-minute walk (6MWT) and timed walks at slow, moderate, and fast paces (matching the step monitor's intensity benchmarks) while wearing a portable metabolic cart. Relative oxygen consumption (VO_2) was determined using a 15-breath moving average. Daily step activity was recorded during the 7-day period between sessions. Stride length was determined using 3D motion analysis. **RESULTS:** Differences were observed between participants for average 6MWT VO_2 (iSCI=21.5 ml/kg/min; CON=28.18 ml/kg/min), step length (iSCI: 0.36m; CON: 0.73m), energy expenditure during the 6MWT (iSCI: 0.34kcal/m; CON: 0.09kcal/m), and daily step activity (iSCI: 2616, CON: 9890). Estimated energy expended from walking for iSCI and CON was 336 kcal/day and 735 kcal/day, respectively, when extrapolating VO_2 from paced walks to data retrieved from the step monitor. **CONCLUSION:** Supporting previous literature, it is likely inappropriate to standardize activity recommendations based on step metrics for those with functional limitations. Unrealistic expectations may heighten perceived barriers, undermine mobility related self-efficacy, and discourage adoption or adherence. Exercise prescription based on energy expenditure goals may serve as an alternative means to individualize recommended daily activity. Future research should attempt to establish new recommendations based on functional status for those outside of the typical gate norm.

The Effects of 8-weeks Structural Exercise-Based Intervention on Autism Spectrum Disorders

Qiang Ye, Haolei Xue, Yuqin Ji. *Nanjing Sport Institute, Nanjing, China.*

Email: yeqiang@nsi.edu.cn

(No relevant relationships reported)

Lack of physical activity reduces the effects of interventions and brings more health risks for individuals with ASDs (Autism Spectrum Disorders). Accumulating evidences indicate exercise program integrated varied types of exercises in a structured framework would achieves maximum gains in fitness for them. However, most of existed studies focused on one special exercise type to reduce the autism-specific impairments.

PURPOSE: to observe fitness changes with a 8-weeks structured exercise-based intervention for ASDs.

METHODS: The subjects were 6 adolescents with ASDs between the ages of 11-14 yrs (male = 5, female = 1) were recruited. They were mild-moderate and severe ASD patients according scores from the Social Responsiveness Scale. The intervention program was seen in Tab1. The Physical fitness was measured by body composition analysis with indicators, including fat mass (FM), body mass index (BMI) etc. The mental fitness was evaluated by Autism Treatment Evaluation Checklist (ATEC). Data comparisons were made using paired t-test.

RESULTS: The overall weight of the subjects decreased about 2.4%, and significant decrease happened in FM at 11.7% (27.35 ± 14.36 vs. 24.16 ± 13.78 Kg, $p < 0.05$). Among 4 subclasses of ATEC, significant decrease happened in Communication (18.50 ± 3.42 vs. 12.00 ± 3.46 , $p < 0.01$) and Sociability (25.00 ± 6.38 vs. 15.75 ± 6.40 , $p < 0.01$). Average total score of subjects was in moderate category, while was in severe category before the intervention.

CONCLUSION: Structured exercise-based intervention efficiently manage weights, prompts speech and communication skills, enhances sensory ability, and improves health behaviors through whole environmental construction. It is a feasibly alternative intervention for ASDs.

Does The Severity Of Autistic Symptoms Influence The Effects Of An Exercise Intervention Program?

Sharon Kinsella¹, Craig Coffey¹, Damien Sheehan¹, Avery Faigenbaum, FACSM². ¹Institute of Technology Carlow, Carlow, Ireland. ²The College of New Jersey, Ewing, NJ. (Sponsor: Professor Avery Faigenbaum, FACSM)
 Email: sharon.kinsella@itcarlow.ie

(No relevant relationships reported)

PURPOSE: The purpose of this study was to examine if improvements in training-induced fitness levels are related to the severity of autistic symptoms in children with autism.

METHODS: A total of 26 children (7.88 years ± 2.27) with a diagnosis of autism, were recruited for this study. Prior to and on completion of the exercise intervention, the children's fitness levels were assessed using the Modified Eurofit Physical Fitness Battery, which included a 20m Sprint, Stork Balance test, Standing Broad Jump, Sit & Reach and a Hand Grip Strength Test. The exercise intervention was 8 weeks duration with three 1-hour sessions per week. The exercises included push and pull upper and lower body exercises, incorporating fundamental movement skills, through games aimed at the interests of the children. The severity of autism symptoms was assessed using the Gilliam Autism Rating Scale (GARS), completed by their teacher. Based on this rating, the children were divided into low, moderate or high groups, in terms of their autism symptoms. A spearman's correlation was undertaken between the GARS score and the overall percentage change in fitness levels for each child within the 3 categories.

RESULTS: The results of the study demonstrated that children who had the greatest symptoms of autism (high group) demonstrated the greater correlation to change in fitness levels (r=1.0, p < 0.01) with a mean percentage change in fitness levels of 285.93% ± 322.16. In comparison the moderate and low groups only had a correlation of r= 0.35 (p > 0.05) and r= 0.592 (p < 0.05) and their overall mean percentage changes in fitness levels were 26.87% ± 33.79 and 65.93% ± 114.79.

CONCLUSIONS: The results of this study suggest that exercise programs for children with autism appear to be most effective for participants with more severe autistic symptoms.

Wrist-worn Actigraph Cut-points For Classifying Activity Intensity In Spinal Cord Injury

Akhila Veerubhotla, Dan Ding. University of Pittsburgh, Pittsburgh, PA.
 Email: ALV47@pitt.edu

(No relevant relationships reported)

Physical activity (PA) recommendations are often made in terms of intensity, frequency, and duration. Accelerometer-based devices are increasingly used by users to track their own PA behaviors and by researchers to examine the association of habitual PA and health indicators. There are well-recognized accelerometer cut-points to estimate time spent in sedentary, lightweight, and moderate-to-vigorous (MVPA) intensities of PA, but such estimation is often dependent on the population, sensor placement, and activities that were used to derive the cut-points. Limited work has been done to derive accelerometer cut-points for people with spinal cord injury (SCI). Many of these individuals use wheelchairs for mobility and rely on their upper extremities for almost all PA.

PURPOSE: To derive wrist-worn accelerometer cut-points for classifying activity intensity in people with SCI using a range of daily activities and exercise.

METHODS: Thirty-one subjects with SCI who use a manual wheelchair for primary mobility wore an accelerometer-based ActiGraph device on their wrist and performed 18 activities of daily living and exercise at different intensities for 10 minutes each. The criterion intensity was obtained from a portable metabolic cart. Activity counts from the Actigraph was correlated with the criterion to derive cut-points using linear regression. Data from 80% of the subjects was used to derive cut-points using an iterative process with 1000 iterations while the derived cut-points were tested for accuracy on the remaining 20% of the subjects. Cut-points were also tested on data from 14 subjects in a separate study following a similar protocol.

RESULTS: Accelerometer cut-points derived for people with SCI yielded an overall accuracy of 84.3% with 98%, 82.3% and 65.8% accuracy for classifying sedentary, light and MVPA activities, respectively, when tested on the 20% subjects, and an overall accuracy of 86.9% with 94.7%, 86.6% and 74.7% for the three intensities, respectively, when tested on the 14 subjects in the other study.

CONCLUSION: The high accuracy of the cut-points particularly for classifying sedentary behavior may be very useful tool for interventions aiming at reducing sedentary behavior in this population.

Acute Effects of Upper Limb Vibration Exercise on Physiological Measures for Wheelchair Users

Sarah Bass¹, Theresa Crytzer, PT, DPT, ATP², Alicia Konntz, Ph.D.². ¹University of Pittsburgh, Pittsburgh, PA. ²Human Engineering Research Laboratory, Pittsburgh, PA.
 Email: srb94@pitt.edu

(No relevant relationships reported)

Strong upper limb(UL) musculature is essential for people with spinal cord injury (SCI) to perform vital activities of daily living(ADL's). The benefits of UL resistance training for manual wheelchair users (MWU) include gains in muscle strength, endurance, decreased pain and improved performance of ADL's. Studies in non-SCI populations have shown the potential for vibration to enhance training benefits.

PURPOSE: The purpose of this study was to determine the acute physiological effects of heart rate (HR), blood lactate (BL), power output and ratings of perceived exertion (RPE) during upper limb vibration training compared to standard dumbbell training.

METHODS: Thirteen MWU with SCI below T2 were recruited. Participants completed two training protocols: using a Galileo vibrating dumbbell (VT) at 30hz and a standard dumbbell (DT). For VT, the participant held the dumbbell in a static position for 45-60 seconds. For the DT, participants completed 10 repetitions of each exercise. Training protocols were completed in separate study visits. Heart rate was collected throughout both trainings. Ratings of perceived exertion for each exercise were measured after completion of the exercise. Power output from a Wingate test and blood lactate were collected before and after each protocol and were examined using a two-way repeated measures ANOVA. A dependent t-test was used to examine RPE and heart rate for each exercise between training sessions.

RESULTS: Participants average (STD) age, height and weight were 48 (10) years, 175(6) cm and 83 (17) kg respectively. There were no significant differences in the physiological measures (BL: p = .868, Power: p =.815, HR p =.116-.949) except for RPE shown in Table 1.

Table 1. RPE Results

| Exercise | Mean (std) | | p-value |
|--------------------|------------|-------------|---------|
| | VT | DT | |
| Side Flies | 13.9 (1.7) | 11.62 (1.4) | .002 |
| Straight Arm Row | 13.1 (2.8) | 10.8 (2.0) | .032 |
| Bicep Curls | 12.7 (2.8) | 11.9 (1.4) | .387 |
| Triceps Extensions | 13.2 (1.7) | 10.9 (1.6) | .005 |
| Front Raise | 15.1 (2.5) | 11.8 (1.1) | .001 |
| Bent Over Rows | 13.1 (2.3) | 12.0 (1.8) | .058 |

CONCLUSION: All but two of the exercises were perceived by participants to be more difficult with vibration compared to a standard dumbbell. A long-term study with additional participants is needed to examine the training benefits of vibration in SCI.

Differences in Exercise Effects from Static versus Dynamic Standing in Non-Ambulatory Children with Cerebral Palsy

Åsa B. Tornberg¹, Victor Hansson², Andreas Jakobsson², Katarina Lauruschkus¹. ¹Department of Health Sciences, Lund University, Lund, Sweden. ²Centre for Mathematical Sciences, Lund University, Lund, Sweden.
 Email: asa.tornberg@med.lu.se
 (No relevant relationships reported)

PURPOSE: To compare the metabolic adaptive effects to four months of two types of structured training regimes, static standing (StS) versus dynamic standing (DyS), on cardiopulmonary and metabolic parameters among non-ambulatory children with cerebral palsy (Na-CP).

METHODS: Eighteen Na-CP participated in an exercise intervention study with a crossover design, comparing four months of StS to four months of DyS. During StS, the Na-CP were encouraged to exercise according to standard care recommendations in Sweden including daily supported StS for 30-90 minutes. During DyS, daily exercise for at least 30 minutes at a speed between 30 to 50 rpm in an Innowalk (Made for movement, Norway) was recommended. We assessed adaptive effects from the exercise programs through indirect calorimetry during 30 minutes of StS and DyS. Exercise test to evaluate StS was performed in a standing frame and to evaluate DyS using an Innowalk (Made for movement, Norway). An airtight mask covering the mouth and nose was worn in order to measure breath-by-breath VO_2 , VCO_2 and VE (Oxycon Mobile, Jaeger, Germany). Heart rate was recorded continuously throughout the test (Polar T1, Polar, Finland). As many of the variables were linearly correlated, we used robust Principal Component Analysis (rPCA) to determine the components carrying most information. A multidimensional Shapiro-Wilk test indicates that the data can be well described as being multivariate normal distributed, allowing the use of a Hotelling T^2 test.

RESULTS: In a multidimensional statistical analysis of metabolic exercise effects, oxygen consumption, carbon dioxide production, and ventilation were concluded to carry most information and additionally, seen to be statistical different between StS and DyS revealing a p-value for the two groups having different means of $4.6 \cdot 10^{-5}$.

CONCLUSIONS: A highly statically significant difference was found in the metabolic adaptation, described as VO_2 , VCO_2 and VE, to StS versus DyS.

Figure. Shows the two most relevant components (rpc1 and rpc2), computed using Robust PCA (RPCA). The dark points are the differences of the second and first measurement for StS, the lighter points are the same difference for DyS. A multidimensional Shapiro-Wilk test was used to define the 95 % confidence level ellipses to be drawn.

Effects of Inpatient Multicomponent Occupational Rehabilitation on Physical Activity Levels

Marius S. Fimland, Martin Skagseth, Tom IL Nilsen, Lene Aasdahl. Norwegian University of Science and Technology, Trondheim, Norway.
 Email: marius.fimland@ntnu.no
 (No relevant relationships reported)

PURPOSE: To assess whether inpatient multicomponent occupational rehabilitation, including physical activity (PA), increases the PA level of participants more than an outpatient program without PA, and whether changes in PA are associated with future work outcomes. **METHODS:** 265 participants were included in one of two randomized clinical trials. Participants had been sick listed 2 to 12 months with a musculoskeletal, psychological or general/unspecified diagnosis. We measured PA by questionnaires at the start of the programs, and at 3, 6 and 12 months of follow-up. Between-group differences in PA were assessed using linear mixed models. Associations between change in PA and future work outcomes were assessed by logistic and linear regression. **RESULTS:** There was no difference in change in PA between the inpatient and outpatient programs during 12 months of follow-up. We did not find any associations between the amount of PA and future work outcomes. However, intensity of PA was positively associated with return to work (RTW); participants reporting

increased vigorous PA had an odds ratio (OR) for RTW of 4.1 (95% confidence interval [CI] 1.1 to 15.7) whereas participants reporting consistently high intensity of PA had an OR of 3.1 (95% CI 1.0 to 9.7), compared to participants reporting low intensity PA. **CONCLUSION:** Inpatient occupational rehabilitation, including PA, did not increase PA-level in the follow up period more than a less comprehensive program without PA. The amount of PA was not associated with future work outcomes. However, vigorous PA showed a positive association with RTW.

Sedentary And Physical Activity Patterns In Adults With Intellectual Disability

Guillermo R. Oviedo¹, Nauris Tamulevicius², Casimiro Javierre³, Núria Massó-Ortigosa⁴, Myriam Guerra-Balic¹. ¹FPCEE-Blanquerna (URL), Barcelona, Spain. ²FPCEE-Blanquerna (University of TampaURL), Tampa, FL. ³Universitat de Barcelona, Barcelona, Spain. ⁴Facultat de Ciències de la Salut-Blanquerna (URL), Barcelona, Spain.
 Email: guillermorubeno@blanquerna.url.edu
 (No relevant relationships reported)

Introduction: Adults with intellectual disabilities (ID) present higher health risks due to their extremely low physical activity (PA) levels. It is important to enhance our knowledge about PA levels and sedentary time (ST) among this specific population.

Purpose: This study describes and compares PA levels and ST of active (AG) and a non-active (NAG) groups of adults with ID versus a group of adults without ID (AWID).

Method: Thirty-seven participants from an AG with ID, 29 participants from a NAG with ID and 31 adults AWID participated in this study. An informed consent and a health screening questionnaire were completed by each participant and each legal guardian. Height and weight were obtained to calculate BMI. PA and ST levels were assessed with ActiGraph accelerometers for 7 consecutive days. A chi-square test of independence was performed to examine the relation between groups and ID levels. Variables of age and anthropometry were analyzed by using a one-way analysis of variance (ANOVA). Total PA and PA levels of each group were compared by using a one-way analysis of covariance (ANCOVA).

Results: The AG performed higher values of moderate to vigorous PA compared to the NAG ($p = 0.018$), but, similar to the group of AWID. The group of AWID spent less time in ST and more time in light PA than both groups of adults with ID (all $p < 0.001$). The participants of the AG did not demonstrate less ST than the NAG.

Conclusion: When assessing PA levels in ID participants, it was observed that participants presented large amounts of sedentary behaviors in both groups. The participants of the AG, despite participating in PA programmes did not demonstrate less ST. We believe that, by including well designed and structured PA programmes into their workdays, as well as incorporating breaks to reduce bouts in ST and total ST, could be of great help to increase daily PA levels in adults with ID. **Partially supported by:** MEC (DEP2017-86862-C2-1-R)

The Fitness Effects Of A School-based Exercise Program On Children With Autism.

Craig Coffey, Sharon Kinsella, Damien Sheehan. *Institute of Technology Carlow, Carlow, Ireland.* (Sponsor: Avery Faigenbaum, FACSM)
Email: Craig.Coffey@itcarlow.ie
(No relevant relationships reported)

PURPOSE: To examine the effects of a school-based exercise program on the fitness level of elementary school children who attend an autism class.
METHODS: A total of 35 (7.66 years ± 2.1) children with a diagnosis of autism were recruited for this study. Prior to and on completion of the exercise intervention the fitness levels of the children was assessed using the Modified Eurofit Physical Fitness Battery, including a 20m Sprint, Stork Balance test, Standing Broad Jump, Sit & Reach and a Hand Grip Strength Test. The exercise program was 8 weeks duration, with

the children partaking in 3, 1-hour supervised sessions per week. The intervention was comprised of push and pull upper and lower body exercises and incorporated fundamental movement skills. These movements were achieved through games aimed at the interests of the children and were adapted to each child's specific needs through the use of visual aids using an iPad. The data were analysed using paired t-tested.

RESULTS: All variables except Hand Grip strength significantly improved (p < 0.05) over the eight-week period. 20m sprint times improved (p < 0.05) by 0.46s ± 1.36. The Stork balance test significantly improved (p < 0.05) by 17.82s ± 38.86. The standing broad jump significantly increased (p < 0.05) by 14.54cm ± 20.29. The Sit and Reach score significantly increased (p < 0.05) by 3.05cm ± 4.51. No significant (p > 0.05) change was noted in the Hand Grip strength which increased by 0.38psi ± 1.38.

CONCLUSIONS: These preliminary findings indicate that an 8-week school-based exercise intervention can significantly improve selected fitness variables in children with autism.

The Examination of Judo on Physical Activity and Sleep in Children with Autism Spectrum Disorder

Paola M. Rivera¹, Justine Renziehausen¹, Kayla Baker¹, Nicholas Leahy¹, Jeanette Garcia¹, Lei Xu². ¹University of Central Florida, Orlando, FL. ²East Carolina University, Greenville, SC.
(No relevant relationships reported)

PURPOSE: The aim of this study was to examine the effects of an 8-week judo program on moderate-to-vigorous physical activity (MVPA), sedentary behavior (SB), and sleep quality in children with Autism Spectrum Disorder (ASD).

METHODS: Participants included 15 children (ages 8-17, with a formal diagnosis of ASD). The sample participated in an 8-week judo program (45 minutes, 1X week), with measures taken at baseline and at the end of the 8-weeks. In order to assess activity levels and sleep quality, participants were instructed to wear Actigraph GT9X Accelerometers for 7 days and nights, only removing the device during water-based activities. Non-parametric paired t-tests were conducted to compare differences in MVPA, SB, and sleep quality (i.e. sleep efficiency, total sleep time, number of awakenings, and wake after sleep onset) pre and post judo. Chi-square tests compared the number of participants who met sleep and MVPA recommendations.

RESULTS: Results indicate participants spent a significantly greater percentage of time in daily MVPA (8% vs 4%, p=0.05) following the program, however, actual MVPA minutes per day did not reach statistical significance (74.46 vs 48.58 minutes per day, p=0.1) There was a significant increase in total sleep duration (572.56 vs 333.8, p=0.008) following the program, and although not statistically significant, a trend existed for improved sleep efficiency (92% vs 88%, p=0.1). There was an increase in the number of participants meeting MVPA (53% vs 27%) and sleep recommendations (40% vs 7%), although results were not statistically significant.

CONCLUSIONS: Improvements in MVPA and sleep quality were observed following the 8-week judo program, although statistically significant findings were limited due to the small sample size. Future studies should include larger samples of youth with ASD, over a longer intervention period.

1359 Board #121 May 30 9:30 AM - 11:00 AM

A Community-based Running Program Enhances Gait Parameters in Children and Young Adults with Developmental Disabilities

Jilda Vargus-Adams, Jennifer Angeli, Micah Garcia, Ana Livecchi, Jason Long, Madison Peck, Sarah Schwab. *Cincinnati Children's Hospital Medical Center, Cincinnati, OH.* (Sponsor: Kevin Ford, FACSM)
(No relevant relationships reported)

PURPOSE: This study aimed to substantiate the efficacy of a voluntary 10-week running program for children and young adults with developmental disabilities. We hypothesized that the running intervention would positively influence temporal-spatial parameters (TSPs) of gait. **METHODS:** Sixteen children and young adults with developmental disabilities, ages 7-24 years (M=15.3 ± 4.4 years) enrolled in a "Sit to Fit" training program. Participants engaged in group running practices in an outdoor community setting, twice weekly for 10 weeks. Training sessions followed a time-based progression of walk-run intervals with a gradual increase (~15%) in total run time each week. At the conclusion of the training, all participants completed a 5K race. TSPs of gait were measured one month prior to program start and repeated within one month of program conclusion, using the GAITRite Portable Walkway System (CIR Systems Inc. Clifton, NJ). Participants completed the Six Minute Walk Test at a self-selected speed on a walking loop that included the GAITRite mat. Each participant walked across the mat 6-10 times. TSPs were averaged across all trials for each visit. Analysis included cadence (steps/minute), normalized walking velocity (leg length/second), stride length (cm), and step width (cm). Descriptive statistics, effect size (mean change score/mean standard deviation), and a two-tailed paired t-test for each TSP were computed. **RESULTS:** Cadence (mean difference 7.25 steps/min, p<0.05), walking velocity (mean difference 0.14 leg length/sec, p<0.05), and stride

length (mean difference 8.16 cm, $p < 0.05$) increased significantly following the 10-week training period. We calculated a moderate effect size for stride length ($d = 0.50$), small to moderate effect sizes for cadence ($d = 0.38$) and walking velocity ($d = 0.26$), and negligible effect size for step width ($d = 0.06$). **CONCLUSION:** A community-based running program contributed to improved gait mechanics in a cohort of children with mobility impairments. Others have shown that walking ability gains are associated with improved bipedal gross motor skills like running. The results of this study indicate that the reverse may also be true: running was associated with gains in walking ability in children and young adults with developmental disabilities.

Flourishing and Physical Activity in Adolescents With and Without Autism Spectrum Disorder
 Stephanie M. McCoy, Kristen Morgan. *University of Southern Mississippi, Hattiesburg, MS.*
(No relevant relationships reported)

Autism spectrum disorder (ASD) is characterized by behaviors that can negatively affect daily life. However, little is known about the effects of physical activity (PA) participation on measures of flourishing (i.e. resilience in functioning) as well as excessive arguing and behavioral conduct problems in those with ASD vs. typically developing (TD) youth. **PURPOSE:** To compare measures of flourishing, excessive arguing, and behavioral conduct problems in youth with ASD compared to TD peers and determine if physical activity participation mediates these differences. **METHODS:** Analyses included 22,873 youth (51% male) aged 10 to 17 years (mean 13.8 ± 2.3 yrs) from the 2016 National Survey of Children's Health. Youth were grouped into those with ASD ($n = 656$), and TD ($n = 22,217$). Outcome variables included measures of flourishing (finishing tasks, staying calm, showing interest in new things), excessive arguing, and behavioral conduct problems. Logistic regression models, adjusted for age, race, gender, SES, ASD severity, and medication assessed the odds of each outcome comparing ASD to TD. Further analyses examined whether participation in PA (≥ 4 d/wk) mediated the relationships between ASD and outcome variables. **RESULTS:** Within youth with ASD, only 31% engaged in regular PA (≥ 4 d/wk) vs. 51% of TD youth. In adjusted models, those with ASD were 58% less likely to finish tasks ($OR = 0.42$; $p < 0.001$), and 65% less likely to stay calm when faced with a challenge ($OR = 0.35$; $p = 0.009$) compared to TD youth. Additionally, those with ASD were 3.48 times more likely to argue excessively ($OR = 2.98$; $p < 0.001$), and 5.54 times more likely to experience behavioral conduct problems ($OR = 5.54$; $p < 0.001$) compared to TD youth. After adjustment for PA, relationships were slightly attenuated for flourishing ($OR = 0.46$, $p = 0.001$; $OR = 0.38$, $p = 0.014$), excessive arguing ($OR = 2.80$; $p < 0.001$), and behavioral conduct problems ($OR = 5.10$; $p < 0.001$). ASD was not associated with showing interest in learning new things. **CONCLUSIONS:** Those with ASD were significantly less likely to flourish, and more likely to experience behavioral conduct problems and argue excessively compared to TD youth. However, PA attenuated these relationships. These findings suggest that regular PA may increase positive flourishing behaviors and decrease negative behaviors.

Age-related Changes In Para-athletics And Racing Wheelchair Performance
 Julien Schipman, Pasquale Gallo, Andy Marc, Juliana Antero, Jean-françois Toussaint, Adrien Sedeaud, Adrien Marck. *INSEP, France, France.*
(No relevant relationships reported)

PURPOSE: How aging affects para-athletics performance? During the last decades, following the motto "Citius, Altius, Fortius", all the para-athletic categories have significantly increased their performance levels. Such an improvement is not only reached by highly optimized prosthetics, but also by a gradual improvement on training, of nutrition, and recovery methods. Few studies have investigated the performance determinants in para-athletics. We studied the effect of age on maximal performances for racing wheelchair- and para-athletes. **METHODS:** We collected data on the 53,554 results from previous international competitions between 2009 and 2017 for women and men para-athletics and racing wheelchair disciplines for a total of 472 sport disciplines (considering impairment types for each discipline). We fitted maximal performance by age through the validated Moore equation for each para-athletics and racing wheelchair disciplines. **RESULTS:** We found a similar age-related pattern in maximal performance between able-bodied, para-athletes and wheelchair athletes. However, the age of peak performance varies according to sex, impairment type and discipline. The top 100 best performances include a large age range (from 15 years to 55 years) in each discipline suggesting that performance haven't probably been optimized yet for most elite racing wheelchair and para-athletes. Maximal performance differences appear for running disciplines between the two categories: in sprinting disciplines para-athletes are faster than wheelchair athletes. To the contrary, para-athletes are slower than wheelchair athletes in endurance discipline, and the difference increases with distance **CONCLUSIONS:** Data reveal that only a few

disabilities classes contributed to the maximal performance both in para-athletes and racing wheelchair discipline. Further studies will contribute to increase knowledge about age-related changes in para-athletes and racing wheelchair athletes.

1362 Board #124 May 30 9:30 AM - 11:00 AM
Comparison Of Physical Activity Levels During Therapeutic Camp Activities In Youth With Disabilities
 Vincenzo G. Nocera, Tyler J. Kybartas, Angela J. Wozencroft, Dawn P. Coe, FACSM. *The University of Tennessee, Knoxville, Knoxville, TN.*
 Email: vnocera@vols.utk.edu
(No relevant relationships reported)

Youth with disabilities have limited opportunities to engage in leisure time physical activity (PA). Outdoor therapeutic recreation (TR) camps provide diverse PA opportunities that include structured (dramatic, functional, game, constructive) and unstructured (free time) activities that have the potential to benefit these individuals cognitively and physically. However, little is known about the PA levels during these activities. **Purpose:** To compare the PA levels of youth attending an outdoor TR camp, across various activity contexts. **Methods:** Youth ($n = 25$; 14.6 ± 3.9 y) with disabilities attending an overnight TR camp, participated in the study. PA was assessed using ActiGraph GT3X or GT3X+ accelerometers worn on the wrist during camp activities. Participants engaged in 14 activities of varying contexts based on the primary skill addressed, creating five distinct areas. Gross/Functional activity involves simple motor activities (e.g., yoga, ropes course). Game play is activity that involves set rules (e.g., sports, games). Dramatic play includes pretend play (e.g., theatre, team building activities). Fine/constructive play involves manipulation of objects for creative purposes (e.g., science experiments, cooking). During free time, the youth choose their activities (e.g., playground activity, hang out in cabin). The mean vector magnitude [VM; counts per minute (counts·min⁻¹)] of individual activities was used to calculate the PA level of each area. One-way ANOVAs were used to determine differences in VM for each area as well among individual activities within an area. **Results:** There were no differences ($p = .999$) in the mean VM for any area: Gross/Functional (2601.4 ± 1648.9 counts·min⁻¹), Game (2599.3 ± 1551.9 counts·min⁻¹), Drama (2569.3 ± 1420.9 counts·min⁻¹), Fine/Constructive (2601.3 ± 1552.29 counts·min⁻¹), and Free Time (2557.9 ± 1398.8 counts·min⁻¹). Additionally, there were no differences ($p = .999$) among activities within each domain. **Conclusion:** The results revealed a consistent level of PA across all areas of activity. These findings suggest the activities offered in this outdoor TR program provide an opportunity for youth with disabilities to accumulate PA that may also benefit them cognitively and physically.

Recreational Ballroom Dance and Multiple Sclerosis
 Linda B. Piacentine¹, Alice F. Yan², Alexander V. Ng, FACSM¹.
¹Marquette University, Milwaukee, WI. ²University of Wisconsin-Milwaukee, Milwaukee, WI.
 Email: linda.piacentine@marquette.edu
(No relevant relationships reported)

Multiple Sclerosis (MS) symptoms include fatigue, pain, spasticity, sensory changes, motor dysfunctions, postural instability, sexual and bladder dysfunctions, as well as cognitive impairments and depression. Despite the known benefits of exercise in mitigating symptoms in persons with MS, adherence to physical activity recommendations is low and often MS patients are sedentary. Recreational ballroom dancing is a fun form of exercise, or physical activity, in which partners can support each other while learning basic to more complex dance steps. **PURPOSE:** This study investigated the physical and psychological changes perceived by persons with MS who participated in a novel structured ballroom dance intervention. A secondary purpose was to gather suggested improvements for the intervention with the aim of promoting physical activity among persons with MS. **METHODS:** Community-dwelling persons with MS ($n = 13$) participated in a ballroom dance pilot intervention which met twice/week for 8 weeks. Dances included rumba, foxtrot, waltz, salsa, swing, and tango. One week after program completion, participants were invited to one-hour focus group sessions. The focus groups were audiotaped and transcribed verbatim. Thematic analysis was completed using NVivo qualitative analysis software. **RESULTS:** Four major themes emerged, which identified several benefits of ballroom dance among participants: (1) Physical and Psychological Benefits: Ballroom dance improved their perceived symptoms including improved strength, endurance, coordination, and balance, along with less fatigue and depression; (2) Positive Social Support: Ballroom dance provided positive social support and was a fun date night activity with their partners; (3) Improved Confidence: The dance intervention built confidence in future exercise and lifestyle change; and (4) Barriers to Exercise Removed: Ballroom dancing removed barriers for exercise specific to MS patients. Participants noted difficulty with classes late in day and at inconvenient locations. **CONCLUSIONS:** Recreational ballroom dancing was well-tolerated and

was perceived to be beneficial for promoting positive physical and psychological changes in people with MS. Future interventions could be improved regarding times and locations.

C-36 Free Communication/Poster - Physical Activity Assessment and Measurement Methods

Thursday, May 30, 2019, 7:30 AM - 12:30 PM
Room: CC-Hall WA2

1364 Board #126 May 30 9:30 AM - 11:00 AM Accelerometer-Based Activity Classification Algorithm for Toddlers: Machine Learning Approach

Soyang Kwon¹, Pinky Sindu², Katherine Nickle¹, Patricia Zavos¹, Albert Sugianto², Mark V. Albert². ¹Ann & Robert H. Lurie Children's Hospital of Chicago, Chicago, IL. ²Loyola University Chicago, Chicago, IL.
Email: skwon@luriechildrens.org
(No relevant relationships reported)

PURPOSE: To develop activity classifiers based on accelerometer data to recognize toddler's eight distinct activities: walking/running, climbing up/down, standing, crawling, sitting, lying down, being carried, and riding a stroller/wagon.
METHODS: Twenty-four toddlers aged 13 to 35 months (50% girls) performed various prescribed activities during free play in a commercial indoor playroom, while wearing Actigraph wGT3X-BT accelerometers on the hip and wrist. Their activities were video recorded. The video data were annotated and synchronized with accelerometer data. Five machine learning classifiers, including random forest, support vector machine, decision tree, K-nearest neighbors, and logistic regression, were trained and tested. Classifier performance was evaluated using subject-wise cross-validation.
RESULTS: Activity classifiers were developed based on 1,011 two-second window accelerometer signal clips from the 24 participants. Of the five classifiers tested, the random forest classifier presented the highest overall accuracy (69% for hip and 55% for wrist). Overall, hip data showed higher accuracy than wrist data. Based on the hip random forest classifier, 91% of "walking/running" activities and 84% of "sitting" activities were correctly identified. However, 35% of "being carried" activities and 30% of "standing still" activities were misclassified as "walking/running". Only 8% of "stroller/wagon ride" activities were misclassified as "walking/running".
CONCLUSIONS: This pilot study demonstrates that the machine learning approach can be used to detect toddler's "walking/running" activities at a high level of sensitivity. However, the algorithm developed in this pilot study often misclassified "standing still" or "being carried" as "walking/running". "Stroller/wagon ride" was less frequently misclassified as "walking/running". Overall, hip data demonstrated higher accuracy than wrist data in detecting key activities for toddlers. Future research should follow to refine the algorithms and test external validity.

1365 Board #127 May 30 9:30 AM - 11:00 AM Thresholds of Sedentary Behavior in Children Based on Various Measures

Ying Gao, Eero A. Haapala, Anssi Vanhala, Martti Melin, Arja Sääkslahti, Merja Rantakokko, Arto Laukkanen, Arto J. Pesola, Timo Rantalainen, Taija Finni. *University of Jyväskylä, Jyväskylä, Finland.*
Email: ying.y.gao@jyu.fi
(No relevant relationships reported)

PURPOSE: To investigate the classification accuracy of estimates of energy expenditure (EE), accelerometry (ACC), muscle EMG, and heart rate (HR) for sedentary and non-sedentary activities in children. The agreement of directly measured value of metabolic equivalent of task (MET) with commonly used adult MET value was assessed.
METHODS: $\dot{V}O_2$, HR, triaxial ACC and thigh muscle EMG were simultaneously recorded from 35 healthy 7-12 year-old children, who performed 3 pre-determined sedentary and 5 non-sedentary tasks in a random order. Mean values of the concurrent 2 minutes epochs from the measures for each activity were analyzed. Resting EE (REE) was determined during 30 minutes rest in supine position. Adult-estimated MET (METa, $\dot{V}O_{2 \text{ tasks}} / \dot{V}O_{2 \text{ estimated for adult}}$ in 3.5ml/kg/min) and REE-based measured MET (METr, $\dot{V}O_{2 \text{ tasks}} / \dot{V}O_{2 \text{ REE}}$) were calculated. Mean amplitude deviation (MAD) was computed for ACC and EMG was normalized to mean muscle activity during self-paced walking. The classification accuracy of METr, METa, HR, ACC and EMG for SB was investigated by receiver operating characteristic (ROC) curves, the area under

the ROC curve (AUC) with (95% confidence interval (CI) and optimal cut-points with sensitivity (Se) and specificity (Sp) for METr, METa, HR, ACC, and EMG were computed.
RESULTS: METa was 28.5% lower than METr in any activity ($p < 0.001$). Measured REE in children was 5.0 ± 0.8 ml/kg/min. Figure 1 shows the ROC curves with AUC and its 95%CI for METr, METa, HR, MAD and EMG. The optimal cut-points for SB was 1.3 for METr (Se=80% Sp=80%), 1.9 for METa (Se=80% Sp=82%), 104 beats/min for HR (Se=78% Sp=82%), 0.003g for MAD (Se=83% Sp=89%) and 13% for EMG (Se=81% Sp=94%).
CONCLUSIONS: The SB threshold based on adult METs (≤ 1.5 METs) did not appear to be appropriate for children. All of the used indicators had reasonable classification accuracy with appropriate sensitivity and specificity for sedentary and non-sedentary activities in children.

Figure 1. Receiver operator characteristic curves for classifying of "sedentary" and "non-sedentary" activities among METr, METa, HR, MAD and EMG. The tasks included lying down, sitting quietly, sitting while playing mobile game, standing quietly, standing while playing mobile game, walking on a treadmill at 4km/h and 6km/h, and walking over ground.

Funding OKM/59/626/2016.

1366 Board #128 May 30 9:30 AM - 11:00 AM Associations Among School Day Sedentary Behavior, Physical Activity, and Motor Skills: A Compositional Data Analysis

Ryan D. Burns, Youngwon Kim, Wonwoo Byun, Timothy A. Brusseau, Jr. *University of Utah, Salt Lake City, UT.*
Email: ryan.d.burns@utah.edu
(No relevant relationships reported)

PURPOSE: A novel analytic approach, Compositional Data Analysis (CoDa), has recently been used to analyze physical activity data. CoDa assumes co-dependence among physical activity compositional parts within a time-constrained data analytic framework, which makes it appropriate for assessing and analyzing physical activity behavior during school hours. The purpose of this study was to examine the relationships among school day sedentary times (SED), light physical activity (LPA), and moderate-to-vigorous physical activity (MVPA) with gross motor skills in children using Compositional Data Analysis (CoDa).
METHODS: Participants were 409 children (Mean age = 8.4±1.8 years) recruited across five low-income schools. Gross Motor Skills were assessed using the Test of Gross Motor Development - 3rd Edition (TGMD-3) and physical activity was assessed using accelerometers. Isometric Log Ratio coordinates (ILRs) were calculated quantifying the relative proportion of percent of the school day (%) spent in SED, LPA, and MVPA. The associations of the ILRs with the TGMD-3 scores were estimated using general linear mixed effects models adjusted for age, BMI, and estimated $VO_{2 \text{ Peak}}$.
RESULTS: A higher proportion of the school day spent in %MVPA relative to %SED and %LPA significantly associated with higher TGMD-3 total scores (γ MVPA = 14.44, $P = 0.012$). This relationship was also observed for the ball skills subtest scores (γ MVPA = 16.12, $P = 0.003$). A 5% reallocation in % of time spent in SED and LPA to MVPA was independently associated with a 0.48 and 1.74-point increase in ball skills scores, respectively, after controlling for the potential confounders of age, BMI, and estimated $VO_{2 \text{ Peak}}$.
CONCLUSIONS: Replacing %SED and %LPA with %MVPA during school hours may an effective strategy for improving gross motor skills, specifically ball skills, in low-income elementary school-aged children.

1367 Board #129 May 30 9:30 AM - 11:00 AM
Validity Of Objectively-measured And Self-reported Sedentary Behavior Across Three Trimesters Of Pregnancy

Bethany Barone Gibbs¹, Melissa A. Jones¹, Joshua L. Paley¹, Kara M. Whitaker², Christopher P. Connolly³, Janet M. Catov¹.
¹University of Pittsburgh, Pittsburgh, PA. ²University of Iowa, Iowa City, IA. ³Washington State University, Pullman, WA.
 Email: bbarone@pitt.edu
 (No relevant relationships reported)

PURPOSE: Sedentary behavior (SED), low intensity behavior in a seated, reclining, or lying posture, is a potential risk factor for poor pregnancy outcomes. We evaluated the validity of commonly used methods to assess SED across three trimesters of pregnancy. **METHODS:** This cohort study of pregnant women measured objective and self-reported SED during each trimester including: 7 days (valid if ≥4 days with ≥ 10 hr) of thigh-worn activPAL micro3 (criterion) and waist-worn Actigraph GT3X and self-report from the Global Physical Activity Questionnaire (GPAQ; modified SED question in hr/day and relative Likert scale) and the Pregnancy Physical Activity Questionnaire (PPAQ; SED subscale, hr/day only). SED hr/day and percent time in SED (SED%) from activPAL were compared to GT3X, GPAQ, and PPAQ using paired t-tests and Pearson's *r*. Correlations were rated as: <0.5 poor; 0.5-0.69 moderate, 0.7-0.89 good, and ≥0.9 excellent. **RESULTS:** Fifty-eight women (mean age 32 ± 5 yr; pre-pregnancy BMI 25 ± 6 kg/m²; 76% white) provided three trimesters of valid activPAL data. Compared to activPAL, GT3X SED was similar in the 1st and 2nd trimester, slightly lower in the 3rd (p=0.03), and moderately correlated (Table). Self-reported SED was systematically lower by GPAQ and higher by PPAQ (all p<0.001); correlations with activPAL were poor-to-moderate (GPAQ) or poor (PPAQ). SED% was slightly higher by GT3X vs. activPAL in the 1st trimester (p=0.04), but otherwise similar, with moderate correlations throughout pregnancy. GPAQ (Likert) underestimated %SED (p<0.01) from activPAL in the 1st and 2nd trimesters, but not the 3rd, and had poor-to-moderate correlations. **CONCLUSIONS:** Compared to activPAL, waist-worn GT3X resulted in only moderate correlations with SED and SED% across pregnancy, though differences in mean estimates were minimal. Self-report questionnaires had large absolute error and were poorly correlated to SED hr/day during pregnancy; GPAQ SED% was the best self-report method.

Table. Sedentary behavior (SED) in hr/day, percent time in SED (SED%), and correlations (r) between activPAL and GT3X, the Global Physical Activity Questionnaire (GPAQ), and the Pregnancy Physical Activity Questionnaire (PPAQ)

Dog Walking Intensity And Its Contribution To Owners' Total Moderate-to-vigorous Physical Activity

Caitlin Rajala, Robert T. Marcotte., Greg J. Petrucci, Jr., Connor Saleeba, Katie Becofsky Potter. *University of Massachusetts, Amherst, MA.*
 Email: crajala@umass.edu
 (No relevant relationships reported)

Approximately half of American households own a dog, and dog ownership is associated with higher levels of physical activity (PA). These increased PA levels are assumed to be dog-related, but there is limited scientific evidence to support this assumption. Though dog walking is classified as moderate intensity PA (3 METS) in the PA compendium, few studies have used objective PA measures to track intensity during dog walking bouts. **PURPOSE:** To 1) determine the % of daily accelerometer-estimated moderate-to-vigorous PA (MVPA) minutes that are accumulated during self-reported dog walking bouts, and 2) quantify the % of dog walking minutes that qualify as MVPA. **METHODS:** Thirty-three healthy dog owners (30 female; BMI 27.2±5.3; age 45.2±15.3) wore an ActiGraph GT3X+ accelerometer on their right hip for 7 days. Dogs were a mean age of 5.85±3.7 (size: 11 small, 12 medium, 9 large). Participants were asked to maintain their normal routine, log leisure-time activity with and without their dog, and ActiGraph on/off periods. T-tests were used to compare differences in MVPA for dog age (<7 vs. >7) and size (med/large vs. small). **RESULTS:** Thirty-three

participants averaged 56.62 ±31.1 min/day in MVPA. An average 42.12 ±25.25% of this time was spent dog walking. Of time spent dog walking, 65.19 ±26% was MVPA. There was no significant difference in % of MVPA min/day attributable to dog walking or % of dog walking in MVPA based on dog age or size (p≥0.4). Combined ActiGraph and self-report data provides context for participants' PA, and further insight for investigation (Figure 1). **CONCLUSION:** The sample demonstrated large variability, with some participants accumulating almost all MVPA from dog walking, and others accumulating little or none. Two-thirds of dog walking minutes were MVPA, but also varied by individual. Variations were not explained by dog size or age. Given the prevalence of dog ownership in America, further investigation into how dog ownership affects PA is warranted.

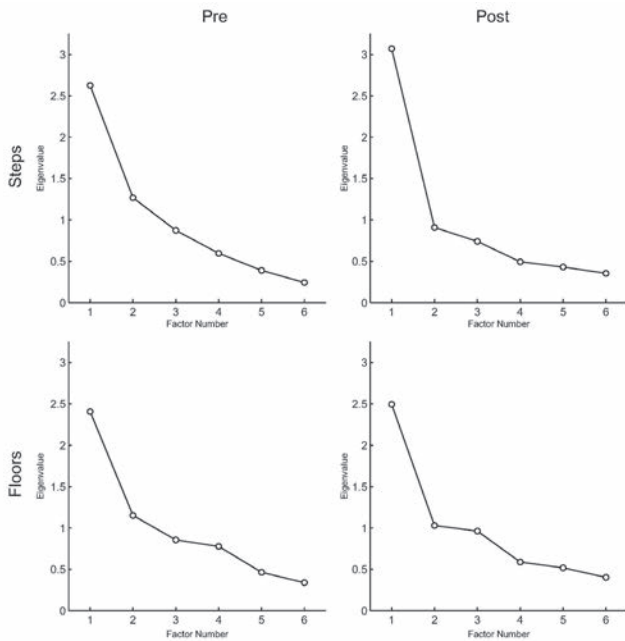

Figure 1. Combined ActiGraph and self-reported data of sample participant.

Unidimensionality and Internal Consistency Reliability of Step Counts and Floors Climbed in 4th-5thGrade Students

Amelia A. Miramonti, James A. Bovaird, Lisa Franzen-Castle, Michelle Krehbiel. *University of Nebraska - Lincoln, Lincoln, NE.*
 Email: amelia.miramonti@unl.edu
 (No relevant relationships reported)

PURPOSE: To determine if weekday and weekend days step counts and floors climbed are unidimensional and internally consistent indicators of physical activity 4th- and 5th-grade students. **METHODS:** Students in 4th and 5th grade (n = 83, age [mean ± SD]: 10.1 ± 0.6 years) at two Title I schools participated in a 12-week after-school program focused on nutrition, cooking skills, and physical activity. At the beginning (T1) and end (T2) of the program the students wore commercial activity trackers for six days, including two weekend days. Unidimensionality and internal consistency reliability (Cronbach's coefficient α) of the six daily step counts (ST) and floors climbed (FL) values were analyzed at T1 and T2. Days with ST < 500 were excluded. Complete ST data was available for 67 (T1) and 68 (T2) students and complete FL data was available for 41 students at both T1 and T2. Principal axis factoring (initial, unrotated solution) was used to confirm unidimensionality. **RESULTS:** Both ST and FL at T1 and T2 were unidimensional based on visual inspection of the scree plots (Figure 1) and interpretability of the factors. Variance explained by the first factor was 32.9% (T1) and 42.0% (T2) for ST and 30.2% (T1) and 31.5% (T2) for FL, respectively. Coefficient α was 0.74 (T1) and 0.80 (T2) for ST and 0.69 (T1) and 0.68 (T2) for FL. **CONCLUSIONS:** In this sample of 4th-5th grade students step counts and floors climbed are unidimensional indicators of physical activity. Step counts across six days are a reliable indicator of physical activity in 4th and 5th grade students, but the lower reliability of floors climbed suggests these data should be interpreted with caution.

(No relevant relationships reported)

PURPOSE: To determine sleep patterns of a newborn and his parents during the first months following birth.
METHODS: A family expecting a child in May 2018 agreed to be in the study. Both parents wore a wrist-worn sleep tracking device (GA) on their non-dominant wrist while sleeping at night. The newborn was fitted with a calf-worn sleep tracking device (SP), which was fitted just before the final feeding prior to bed time. The GA recorded sleep (total, light, deep) and wake (time, number) data, and the SP recorded sleep (total, stirring) and wake (time, number) data during the night. Number of feedings during the night were also documented by parents. Sleep tracking started on the second night following the baby's birth and continued for four months. Month-by-month comparisons of sleep variables were compared using repeated-measures ANOVA. Additionally, comparisons of parents' sleep patterns to a control condition (four months of GA data) a year previously was conducted using paired-samples t-tests. **RESULTS:** Newborn's total sleep time increased progressively by month (month 1: 338.4 vs. month 4: 445.4 minutes/night) and number of feedings decreased significantly from month 1 (1.9 feedings/night) to months 2-4 (0.3-0.7 feedings/night). Time stirring (5.3-14.1 minutes/night) and time awake (15.2-18.0 minutes/night) were not significantly different among months. For both parents, the first month post-birth resulted in significant differences in wake variables compared to control (mother: +71.8 minutes awake/night, +2.6 awakenings/night; father: +25.7 minutes awake/night, +1.8 awakenings/night). Differences from control persisted for all four months for the mother and non-significantly trended for the father. Sleep variables were not significantly different among months 2-4 for the mother or father. Total sleep time was not different for either parent following birth compared to control, although the mother had significantly more deep sleep (+38.7 to +51.8 minutes/night) and significantly less light sleep (-50.6 to -84.9 minutes/night) during all four months, while the father's were not different from control. **CONCLUSIONS:** The first month following childbirth resulted in substantial changes to newborn and parental sleep patterns, which largely seemed to reach a "new normal" in month 2.

Assessment of Machine Learning Performance for the Detection of Activity Type in Military Training

Elliott Fullerton, Katherine Brooke-Wavell, Paul Sanderson, Dale Eslinger, Massimiliano Zecca. *Loughborough University, Leicester, United Kingdom.*
Email: e.fullerton@lboro.ac.uk
(No relevant relationships reported)

Recognition of activities performed during military training may benefit the identification and quantification of factors that may predispose to the high prevalence of injury. There is evidence to suggest that the use of machine learning classifiers along with features from accelerometry data can achieve accurate activity recognition; however, there is no evidence to this application within military activities. **PURPOSE:** To develop and determine the accuracy of decision tree (DT), support vector machine (SVM), k-nearest neighbour (KNN) and ensemble bagged tree (EBT) models to classify military training type activities. **METHODS:** 15 male participants (mean ± SD: age: 25.9 ± 3.0 height: 177.9 ± 6.8cm body mass: 80.9 ± 8.7 kg) completed three sessions that consisted of performing military activities (walking, running, marching, weighted marching, halt to attention, countermovement jump and sedentary) with a low cost accelerometer (Axivity AX3, UK) mounted on the distal third of the medial tibia. Accelerometer data were segmented into two-second windows with a 50% overlap to introduce activity variance. Raw data along with filtered (butterworth, chebyshev and elliptic) were processed through a variety of features and classifiers (DT, SVM, KNN, EBT). Models were trained (80%) and hold-out validated (20%) using the classification learner within MATLAB (MathWorks Ltd, UK). Accuracy was determined by the percentage of true values during validation. **RESULTS:** 40,207 two second episodes of activities were recognized (1340 minutes). Hold-out validation accuracy for the EBT model and raw data (no improvement through filtering) was 0.96 (95% confidence interval (CI), 0.96- 0.96). Other models demonstrated good validation accuracies [DT - 0.90 (95% CI, 0.88- 0.91), SVM - 0.94 (95% CI, 0.93-0.95) and KNN - 0.91 (95% CI, 0.90-0.92)]. Validation accuracy was moderate to excellent (>80%) for walking and excellent (>90%) for all other activities. **CONCLUSIONS:** All machine learning models (especially EBT) provided excellent classification accuracy with the use of a tibial mounted accelerometer. These low-cost sensors and models thus offer potential for characterising military activity and examining relationships of activity parameters with injury. Supported by EPSRC and Loughborough University Studentship 1814563

Cross-cultural Adaptation and Validation of the Arabic Version of the Rapid Assessment Of Physical Activity

Bader A. Alqahtani, Aqeel M. Alenazi. *Prince Sattam Bin Abdulaziz University, Alharaj, Saudi Arabia.*
(No relevant relationships reported)

Measuring physical activity (PA) is a challenge especially with lack of validated questionnaires for specific populations such as Arabic population. Rapid Assessment Physical Activity (RAPA) is an easy to administer, valid and reliable measure. However, this questionnaire is in English and has not been translated or culturally adapted for Arabic speakers. **PURPOSE:** The aim of the study was to cross-culturally adapt the Rapid Assessment of Physical Activity (RAPA) for Arabic speaking people and examine the test-retest reliability and the construct validity in Saudi older adults. **METHODS:** A total of 46 older adults (67% male, mean age 71 ± 5 years) were included in this study. The original RAPA was translated into Arabic following standardized guidelines including the following steps: forward translation, synthesis of the translation, backward translation, expert committee and testing the pre-final version. Test-retest reliability was assessed over two testing visits occurring one week apart, and analyzed using weighted Kappa (K). The construct validity between RAPA and Short Physical Performance Battery (SPPB) and Timed Up and Go (TUG) was examined by Spearman's rank correlation coefficient. A weighted K value of > 0.7 for the reliability and a value of greater than or equal to 0.3 for the construct validity were considered acceptable for physical activity measurements. **RESULTS:** Data from the RAPA shows, about 9 (19.6%) of participants were categorized as sedentary, 12 (26%) as underactive, 7 (15%) as regular underactive, 13 (28%) as regular underactive, 5 (11%) as regular active. About half of the subjects (52%) reported that they did not participate in flexibility or strength activities. For the test-retest reliability, the weighted K was 0.87 (95% CI=0.76-0.98), which indicates very good reliability. There was a significant correlation between the Arabic version of RAPA and the SPPB (Spearman $\rho = 0.536, P < 0.001$), and the TUG test (Spearman $\rho = -0.435, P < 0.01$). **CONCLUSIONS:** The Arabic version of the Rapid Assessment of Physical Activity questionnaire adapted for Saudi older adults provides an easy, valid and reliable way to measure physical activity. Researchers in Saudi Arabia can use this questionnaire to quickly assess PA levels because of short time required to complete and its suitability to the Saudi culture.

A Comparison of Two Algorithms for Generating ActiLife Equivalent Activity Counts
 John M. Schuna, Jr., *Oregon State University, Corvallis, OR.*
 Email: John.Schuna@oregonstate.edu
 (No relevant relationships reported)

Previous algorithms have been developed to approximately replicate ActiLife software's activity counts when used with raw acceleration data from physical activity accelerometers.

PURPOSE: To compare a new algorithm based upon two cascaded infinite impulse response filters (ALG1) to an existing algorithm (ALG2; Brond, Andersen, & Arvidsson [2017]) for generating activity counts from raw acceleration data.
METHODS: Sixteen adult participants (19-81 yrs; 56-85 kg) completed a series of simulated free-living activities (e.g., walking, climbing stairs, eating, sitting down, brushing teeth, etc.) while wearing an accelerometer on their right wrist initialized at a sampling frequency of 32 Hz. These activity data are publicly available (<https://archive.ics.uci.edu/ml/machine-learning-databases/00283/>) within the UCI Machine Learning Repository. Activities varied in duration but averaged 155 seconds each. Vector magnitude activity counts/second (cps) were calculated using ALG1, ALG2, and ActiLife for each participant. Equivalence testing (equivalence margin: $\pm 5\%$ error from ActiLife cps) was used to compare mean cps values from ALG1 and ALG2 with those from ActiLife (criterion). Correlations and mean absolute errors for ALG1 and ALG2 with ActiLife cps were also quantified. Correlation magnitudes were compared between algorithms using Meng's z-test.
RESULTS: Mean error (% error from ActiLife [$M = 65.4$ cps]) for ALG1 (1.7%; 99%CI: 0.8 to 2.7%) and ALG2 (-1.0%; 99%CI: -2.2 to -0.2%) was small and indicates both algorithms provided equivalent estimates to those obtained from ActiLife. Correlations for ALG1 ($r = 0.992$) and ALG2 ($r = 0.987$) with ActiLife cps were strong; however, the ALG1 correlation was of a significantly greater magnitude than the ALG2 correlation ($p = 0.025$). Moreover, mean absolute error was smaller for ALG1 (4.9 cps) than for ALG2 (6.4 cps).
CONCLUSION: Mean vector magnitude cps values from ALG1 and ALG2 were comparable to those generated by ActiLife. Estimates from ALG1 appear to be more strongly correlated with ActiLife cps and have smaller absolute errors than ALG2. Additional research is needed to evaluate the performance of each algorithm for generating estimated ActiLife activity counts with acceleration data collected at other body locations (e.g., waist, chest, ankle, etc.).

1374 Board #136 May 30 9:30 AM - 11:00 AM
Validity Of Self-report Methods For Measuring Physical Activity And Sitting Time In Chilean Workers
 Pia Martino, Nicolas Aguilar. *Universidad de La Frontera, Temuco, Chile.* (Sponsor: Wendy J Brown, FACSM)
 Email: pia.martino@ufrontera.cl
 (No relevant relationships reported)

PURPOSE: to test the validity of a single question (SQ) for measuring sitting time (ST) and the GPAQ for measuring physical activity (PA) and ST in workers using the ActivPAL μ (AP) as reference.

METHODS: Workers wore an AP for 7 days to measure ST, standing and walking time (WT). The volunteers answered the SQ: How many hours each day do you typically spend sitting down while doing things like visiting friends, driving, reading, watching television, or working at a desk or computer on (a) an usual weekday, (b) usual weekend day?. They also answered the GPAQ that measures PA (at work, leisure and travel) and ST. Reliability of the SQ was tested with intraclass correlation (ICC). Validity was tested using correlation, mean bias and limits of agreement (LoA), and kappa to assess agreement between AP and both the SQ and GPAQ.
RESULTS: 91 workers (50.6% male) provided valid data. For AP, mean wear time was 16.2 ± 1.17 h/day; on average, participants spent 9.0 ± 1.87 h/day in ST, with no difference by sex ($p = 0.052$) or week and weekend days ($p = 0.066$). Mean standing time was 5.1 ± 1.47 h/day, with women standing more than men (5.4 ± 1.33 vs 4.8 ± 1.55 , $p = 0.044$). WT was 2.1 ± 0.71 h/day on average, with no differences by sex ($p = 0.96$), but more WT on week than weekend days (2.2 ± 0.82 vs 1.9 ± 0.88 h/day, $p > 0.001$). For the SQ, the ICC for ST was 0.53 for a usual day, 0.36 for weekdays and 0.45 for weekend days. The SQ showed fair correlation with AP on a usual day ($r = 0.24$) and week days ($r = 0.23$), but poor for weekend days ($p = 0.17$), with mean biases of about -2 h/day when compared with AP. When ST was categorized into tertiles, agreement was significant but poor between the SQ and AP (46.1%, $k = 0.19$, $p = 0.019$). The GPAQ showed fair correlation with AP for measuring PA ($r = 0.39$) with mean bias of -5.7 h/day (LoA: -14.5, 3.0 h/day). Moderate correlation was observed between the GPAQ and AP for PA at work ($r = 0.41$, mean bias: -4.3 h/day; LoA: -11.1, 2.6 h/day). The GPAQ question for ST showed fair correlation with AP ($r = 0.37$, mean bias: -2.7 h/day, LoA: -10.2, 4.8 h/day). When categorized into tertiles, agreement between GPAQ and AP was fair for both ST ($k = 0.22$) and PA ($k = 0.22$).

CONCLUSION: Both instruments showed fair to moderate validity and poor ability for correctly classifying individuals into tertiles of ST and PA when compared with the AP.

Rapid Assessment Of Physical Activity And Yale Physical Activity Survey Convergent Validity For Cancer Survivors.
 Amerigo Rossi¹, Alyssa Graham¹, Carol Ewing Garber, FACSM², Dennis YS Kuo³, Nicole Nevadunsky³. ¹Long Island University Brooklyn, Brooklyn, NY. ²Teachers College, Columbia University, New York, NY. ³Montefiore Medical Center, Bronx, NY.
 Email: amerigo.rossi@liu.edu
 (No relevant relationships reported)

PURPOSE: The Rapid Assessment of Physical Activity (RAPA), a simple physical activity survey containing nine questions with accompanying images, may be a valid method for assessing underserved populations. The purpose of this study was to evaluate the convergent validity of the RAPA and Yale Physical Activity Survey (YPAS) for socioculturally diverse endometrial cancer survivors.

METHODS: Fifty-nine endometrial cancer survivors were approached during their gynecologic oncology follow-up appointments. The 52 survivors who agreed to participate were administered the nine-item RAPA, which requires approximately 3 minutes to complete, and 35-item YPAS, which requires approximately 15 minutes to complete. The RAPA is scored by stratifying respondents into one of five groups; group 1 was sedentary, groups 2 - 4 engaged in insufficient activity of progressively higher volumes, and group 5 achieved the recommended targets for aerobic physical activity. The YPAS provided Energy Expenditure (EE) and Summary Indices. Kendall Rank Correlation Coefficients (τ) were analyzed to evaluate the convergent validity between the RAPA and YPAS. Data are presented as mean \pm standard deviation. Statistical significance was set *a priori* at $p < 0.05$.

RESULTS: Mean age (64 ± 10 yrs) and Body Mass Index (34 ± 8 kg·m⁻²) indicated an older, mostly overweight and obese sample. Mean time since diagnosis was 2.6 ± 1.7 years. The sample was socioculturally diverse, with 31% non-Hispanic black, 31% non-Hispanic white, 29% Latina, and 8% other race/ethnicity. Forty-two percent reported having earned a college degree, and 11% reported not having graduated high school. According to the RAPA results, 4% of the participants were sedentary, 44% were insufficiently active, and 52% were active (27 out of 52). The five RAPA categories were significantly correlated to the YPAS Summary Index ($\tau = 0.34$, $p = 0.001$) and the YPAS Energy Expenditure Index ($\tau = 0.23$, $p = 0.016$). Although there were significant correlations between measures, the strength of the associations was not large. **CONCLUSIONS:** There was convergent validity between the RAPA and YPAS questionnaires, but with relatively weak strength of association. Further research should be conducted to validate each measure with an instrumented criterion, such as accelerometry, among cancer survivors.

Validation of Apple Watch for Estimating Moderate-to-Vigorous Physical Activity in Children
 Sunku Kwon, Youngwon Kim, Wonwoo Byun. *The University of Utah, Salt Lake City, UT.*
 Email: sunkukwon@gmail.com
 (No relevant relationships reported)

Identifying accurate instruments for assessing physical activity (PA) is crucial for surveillance and promotions of PA in children. Apple Watch has been appeared as one of the most popular wearable devices that are designed to monitor individual's PA. However, little knowledge is available whether it provides an accurate estimate of time spent in moderate-to-vigorous PA (MVPA) in children. **PURPOSE:** To examine the validity of Apple Watch 3 in measuring MVPA in children using a portable indirect calorimetry system (Cosmed K5) as a criterion measure. We hypothesized the estimate of MVPA from Apple Watch would be comparable with that from Cosmed K5 for simulated free-living activities. **METHODS:** 20 school-age children (girls: 45%; age: 9.7 ± 2.0 yrs, BMI: 16.3 ± 3.2 kg/m²) were fitted with an Apple Watch 3 on their dominant wrist and Cosmed K5 portable indirect calorimetry. All participants performed sedentary (i.e., sitting, watching TV), light PA (i.e., slow walking, playing with toys), and MVPA (i.e., brisk walking) over a 45-minute period. We calculated MET_{RMR} by dividing obtained VO₂ values from Cosmed K5 by child's predicted resting metabolic rates using the age- and sex-specific Schofield equations. We used ≥ 3 MET_{RMR} as a cut-off value to define a criterion measure of MVPA time (i.e. Cosmed K5) against which Exercise Time from Apple Watch was compared. Pearson's correlation coefficient and mean absolute percent error (MAPE) were calculated, and equivalence test using SAS Proc Mixed procedure was performed to examine whether the Apple Watch's Exercise Time is comparable to MVPA time from Cosmed K5. **RESULTS:** The Exercise Time from Apple Watch showed a moderate correlation (r

= 0.35, $p = 0.13$) and relatively high MAPE ($30.2 \pm 4.9\%$) in relation to MVPA time from Cosmed K5. The 90% confidence interval of the Apple Watch's Exercise Time was from 16.7 to 22.9 min, which was not completely included within the zone of equivalence defined as $\pm 10\%$ of the values of Cosmed K5 (22.8 to 27.9 min); this indicates non-equivalence between Apple Watch and Cosmed K5. **CONCLUSION:** Apple Watch showed poor agreement with Cosmed K5 for estimating MVPA time in this convenient sample of children. Subsequent research is needed to further examine the validity of Apple Watch monitor for quantifying various intensities of PA under free-living conditions.

1377 Board #139 May 30 9:30 AM - 11:00 AM
Multi-phased Step Detection Algorithm For A Wrist-worn Triaxial Accelerometer
 Aston K. McCullough, Catrine Tudor-Locke, FACSM.
University of Massachusetts Amherst, Amherst, MA. (Sponsor: Catrine Tudor-Locke, PhD, FACSM)
 Email: mccullough@umass.edu
(No relevant relationships reported)

Purpose: To test a multi-phased, signal pattern-specific step detection (SD) algorithm for a wrist-worn triaxial accelerometer
Methods: Adults [N=30; age: 37(11); female: 65%; BMI: 25.4(3.8)] wore accelerometers while engaged in 5-minute activity bouts (see Table 1), and hand-tallied steps were simultaneously recorded as the ground truth. Phase 1—Raw signals sampled at 60Hz were downloaded and processed by: 1) low-pass filtering, 2) calculating the bandpass filtered vertical accelerations (VA) in gravity seconds (gs), and 3) calculating the integrated area under the curve for the VA time series. For all activities, the VA peak heights (VAPH) that minimized SD error relative to the ground truth were determined by brute force. Phase 2—Signal features for each activity (triaxial vector magnitude, signal variability, and device angle) were passed to a k-means clustering algorithm, which grouped all activities into 3 clusters. Phase 3—A Random Forest (RF) algorithm was used to estimate VAPH for each cluster using activity signal features as inputs, and the cross-validated root-mean-square (RMS) for the RF-determined VAPH were calculated. Phase 4—RF-determined VAPH were applied to the original VA time series for SD. Bias (mean difference) and accuracy (median absolute percentage error) were calculated to evaluate SD performance. Sign tests were used to check for significant bias ($p < 0.05$).
Results: SD performance is shown in Table 1. RMS for the VAPH ranged from 0.011 to 0.019gs across clusters. Bias and accuracy were acceptable for most ambulatory activities and seated non-ambulatory activities, but not for non-ambulatory upper body activities and slow walking.
Conclusions: A signal pattern-specific algorithm provides reasonable step estimates for a wrist-worn accelerometer across ambulatory and non-ambulatory activities. Further research is needed to optimize SD during non-ambulatory upper body activities and slow walking.
Funding: NIH-NIA-5R01AG049024

Using Heart Rate to Predict Energy Expenditure: A Validity Generalization Study
 Zezhao Chen¹, Xiaofei Wang², Hai Yan¹, Xiong Qin¹, Jingyuan Zhu¹, Weimo Zhu, FACSM¹. ¹University of Illinois at Urbana Champaign, Champaign, IL. ²Tsinghua University, Beijing, China.
 Email: zchen106@illinois.edu
(No relevant relationships reported)

Physical activity (PA) plays a critical role in preventing chronic diseases. Heart rate has been frequently used to predict PA energy expenditure (PAEE). While a number of prediction equations has been developed, their generalizability has not been confirmed. **PURPOSE:** To examine the validity generalization of heart rate prediction equations for PAEE. **METHODS:** Key words such as “energy metabolism,” “energy expenditure,” “heart rate,” “heart rate determination,” “prediction,” and “equation,” were searched in the scientific databases including PubMed, Web of Science, Google Scholar etc. Eligibility criteria was restricted to studies that predict PAEE using heart rate. The validity generalization model (Pearlman, Schmidt, & Hunter, 1980) was utilized for the analysis. Four components including sample size, observed validity coefficients, test reliability coefficients, and criterion reliability coefficients were summarized and examined from each study. When test and criterion reliability coefficients were not reported, the information was derived from the literature. The percentages of variance accounted for “by artifacts” were computed. **RESULT:** 98 validity studies were screened and 27 studies (M±SD: Sample size = 45±13; Validity coefficients = .70±.13; Test reliability coefficients = .83±.03; & Criterion reliability coefficients = .95±.02) were analyzed to determine the degree of validity generalization using heart rate to predict PAEE. The percentage of variance accounted

for “by the artifacts” was only at 65%. Thus, the needed “75% decision rule” was not met. The estimated “90% credibility value” for the true validities was at .55, and the estimated average true validity was at .69. **CONCLUSION:** The validity to use heart rate predicting PAEE did not appear to be generalizable and these heart rate prediction equations should be used with caution, especially when it is used for another population.

1379 Board #141 May 30 9:30 AM - 11:00 AM
Aerobic Exercise Training and Blood Lipids-Lipoproteins Among Healthy Adults: A Methodological Umbrella Review

Lucas P. Santos¹, Angélica T. De Nardi¹, Lucinéia O. Pfeifer¹, Nórton L. Oliveira², Yin Wu³, Daniel Umpierre¹, Linda S. Pescatello, FACSM³. ¹Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil. ²Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil. ³University of Connecticut, Storrs, CT. (Sponsor: Linda Pescatello, FACSM)
 (No relevant relationships reported)

PURPOSE: Meta-analyses (MA) that have examined whether aerobic exercise training (AET) affects blood lipids-lipoproteins have yielded conflicting findings. Since methodological characteristics and completeness of reporting may influence interpretation and generalizability of MA results, we sought to assess the quality of these parameters in published MA that examined the blood lipids-lipoproteins response to AET. **METHODS:** We used search terms related to AET and blood lipids-lipoproteins in six databases to find MA published in English, Portuguese, or Spanish. The MA included trials that: (1) enrolled adults with no established disease; (2) compared AET to a non-exercising, non-dieting arm (CONTROL); and (3) measured lipids-lipoproteins pre- and post-intervention. Study selection and data coding were conducted in duplicate. Methodological quality was assessed using a modified exercise-specific version of Assessing the Methodological Quality of Systematic Reviews 2 (AMSTAR2). **RESULTS:** Seven MA qualified for our umbrella review, with a total of 8,721 subjects (mean 1,245.8±602.2, range 393 to 2,024). Of these, five reported the number of AET groups for lipids-lipoproteins analysis (mean 10.3±8.3, range 2 to 35). Effect sizes (ES) for AET versus CONTROL ranged from +0.9mg/dL to -8.5mg/dL for total cholesterol, 0 to +4.6mg/dL for high-density lipoprotein, 0 to -10.1mg/dL for low-density lipoprotein, and 0 to -13.7mg/dL for triglycerides. Only one of 20 items on the modified AMSTAR2 was fully satisfied by all MA which was the reporting of the Population, Intervention, Comparator, and Timing (PICOT). Meanwhile, most MA lacked a *priori* study design (n=6, 85.6%), failed to explore the relationship between features of the exercise interventions and ES (n=4, 57.1%), and interpreted results without discussing risk of bias (n=5, 71.4%). **CONCLUSION:** Overall, included MA showed low adherence to current methodological standards, which may partially explain the disparate findings of the effects of AET on blood lipids-lipoproteins. Future MA following current methodological standards that explore possible effect modifiers are needed to more precisely estimate the influence of AET on lipids-lipoproteins.

Regression Equation To Predict Body Fat In Elderly Women Using Body Circumference Measures

ELIANE C. GONCALVES. *Multivix and Unip, VITORIA, Brazil.*
 Email: elianecgc@hotmail.com
 (No relevant relationships reported)

Purpose: The purpose of this study was to develop and validate an equation to estimate body composition in elderly women above 60 years of age using body circumference measures. **Methods:** The sample consisted of 60 women individuals with an average age of 68.23 ±5.84 years, 63.97±10.65kg, 1.542±0.52m from the Vitoria metropolitan area. The group was split into two subgroups: a regression group (n=50) used to develop the equations and a validation group (n=10) used for cross reference. A multiple linear regression was used to develop the equation. Both equations were compared using the Student's *t* test for paired samples. The reliability of the equations was analyzed by the *Blant and Altman* method. **Results:** The regression group had the following descriptive metrics: age 67.62±5.87 years, body weight 64.27±11.11kg, height 1.53±0.11m; and percent body fat 41.73±5.69%. The validation group had the following descriptive metrics: 71.3±4.8years, body weight 62.49±8.34kg, 1.55±0.53m; and percent body fat 41.75±4.04%. Body circumferences variables were used to develop equations to predict body fat. Using the stepwise selection criteria, the following equation was developed: % body fat = 0.343 (hip) + 0.289 (waist) - 0.0714 (handle)². Several parameters validated the strength of the equation: R² = 0.997; EPE = 3.29; EPE ≤ 3.5%; and validation of the model based on the partial significance (F) of the subset of variables that showed the strongest effect. **Conclusion:** It is possible to develop an accurate and specific equation to estimate of body fat percent in elderly women using circumference measurements. The more important is that is easy to use by health professionals.

Is Cadence A Better Predictor Of The Walk-to-run Transition Than Speed And/or The Froude Number?

Colleen J. Sands, Scott W. Ducharme, Elroy J. Aguiar, Christopher C. Moore, Zachary R. Gould, Catrine Tudor-Locke, FACSM. *University of Massachusetts Amherst, Amherst, MA.* (Sponsor: Catrine Tudor-Locke, FACSM)
 (No relevant relationships reported)

Preliminary evidence suggests that a cadence of 140 steps/min is associated with the walk to run transition (W2R). However, this cadence threshold does not take into consideration leg length. Alternatively, the Froude number is used to compare the similarities of locomotion across individuals by incorporating leg length, and provides a theoretical prediction of the W2R at a value of 0.5. Additionally, the W2R has been shown to occur at an estimated speed of 2.09 m/s. If supported, a W2R cadence value could be used to identify running in free-living accelerometer-based data sets. **PURPOSE:** To examine whether 140 steps/min is a more accurate predictor of the W2R than a Froude number of 0.5 or a speed of 2.09m/sec. **METHODS:** Twenty-eight healthy adults (20 men, 8 women; age=22.6±1.9 years, height=172.5±11.8 cm, weight=79.3±18.8 kg) completed a treadmill protocol consisting of 5-minute bouts during which speed increased by 0.5 mph per trial from 0.5-6.0 mph. Participants could choose to run or walk each bout, and the protocol was terminated following the first bout at which the participant chose to run. The analytic sample consisted of two bouts for each participant (the running bout, and the bout immediately preceding walking) to identify the W2R transition. Cadence was derived by dividing directly-observed step counts (hand-tally) by 5 minutes. Froude numbers were calculated as $Froude = v^2 / (gd)$, where v =walking velocity, g =gravity, and d =leg length. W2R sensitivity, specificity and overall accuracy were calculated. **RESULTS:** 140 steps/min predicted the W2R with a sensitivity of 85.7%, a specificity of 100%, and an overall accuracy of 92.9%. A Froude number of 0.5 predicted the W2R with a sensitivity of 35.7%, a specificity of 96.4%, and an overall accuracy of 66.0%. A speed of 2.09 m/s predicted the W2R with a sensitivity of 14.3%, a specificity of 96.4%, and an overall accuracy of 55.4%. **CONCLUSION:** A cadence of 140 steps/min was a more accurate predictor of the W2R than the traditionally supported Froude or speed values. Given the high sensitivity, specificity and overall accuracy values, 140 steps/min may be used to identify running behaviors in free-living accelerometer-based data.

Validation Study of Inbody Band2 and Agreement Between Inbody Band2 and Omron 306 in Adults

Phoebe Monnier Manalang¹, Mr. Guy Danhoff¹, Dr. Robert T. Davidson², Dr. Andrew Elvington¹. ¹Missouri Baptist University, St. Louis, MO. ²Logan University, St. Louis, MO.
 Email: phoebe@daywaneti.com
 (No relevant relationships reported)

Activity trackers (AT) continue to be one of the top fitness trends as the wearable market continues to diversify. As new features of AT's emerge, the need for evidence-based research is needed for reporting the reliability and validity of existing devices. **Purpose:** The purpose of this study was to assess the validity and reliability of the single frequency bio-impedance analysis (SF-BIA) device, InBody Band2 (IB2) compared to the Omron HBF-306c (O306c). **Methods:** A total of 54 individuals participated in the reliability and validation study (23 males and 31 females; average age 45.27 years). Each instrument provided percent body fat (%BF). The Pearson correlation, Bland-Altman analysis, t-test and one-way ANOVA were used to determine significance of relationship between the two SF-BIA devices and reliability of the IB2. **Results:** A Pearson's product-moment correlation was run to assess the relationship between measurements of %BF in adults using the IB2 and O306c. Analysis showed a statistically significant and a strong positive correlation between the instruments, $r(49) = 0.91$, $p < 0.01$. The mean difference (i.e., IB2 - O306c) was -0.11 with a 5.85 upper confidence line and a lower confidence line of -2.92. No proportional bias or statistical difference between the IB2 and O306c was found. Examination of the residuals obtained from multiple linear regression indicated there was not a statistical difference between the measurements of the IB2 and O306c ($t = -1.5$). The one-way repeated measures ANOVA determined that the IB2 measurements of %BF did not result in statistically significant changes, $F(1.683, 84.141) = 1.690$, $p = 0.195$, partial $w^2 = 0.01$. The IB2 showed excellent reliability with repeat measurements differing by 0.125 (95% CI, 0.14 to 0.39). **Conclusions:** Findings indicate that the estimates of %BF obtained from the IB2 did not exceed estimates from O306c. Overall the measurements were equivalent. IB2 showed excellent reliability.

Comparing ActiGraph Data Processing Methods For Measuring Sedentary Behavior In Older Adults With COPD

Katelyn Webster, Ronald Dechert, Janet Larson. *University of Michigan, Ann Arbor, MI.*
 Email: katewebs@umich.edu
 (No relevant relationships reported)

Accelerometers, such as the ActiGraph (AG), are commonly used for measuring sedentary behavior, but the ActivPAL (AP) has been validated as the gold standard. The use of various AG processing methods, including filters and non-wear time algorithms, influences sedentary time estimates. The optimal combination of AG filter and non-wear algorithm may depend on the population being studied. **PURPOSE:** To perform a secondary data analysis to identify which AG filter and non-wear algorithm produce estimates of sedentary time that have the strongest agreement with AP-measured sedentary time in a sample of 34 older adults with chronic obstructive pulmonary disease (COPD). **METHODS:** Participants wore AG and AP monitors concurrently for 7 consecutive days. Each participant's AG data was processed using six different methods, using all possible combinations of two filters (normal and low frequency extension) and non-wear algorithms with three different minimum lengths (60 minutes, 90 minutes, and 120 minutes). The Bland-Altman method was used to assess concordance in sedentary behavior time (minutes per day) between AP and each of the six AG estimates. **RESULTS:** Concordance correlation coefficients between AP-measured sedentary time and AG-measured sedentary times range from 0.388 to 0.511 (see table). The AG low frequency extension filter with the 60-minute non-wear algorithm resulted in the highest concordance correlation, along with a low mean difference between sedentary minutes per day measured by the two devices. **CONCLUSIONS:** Although concordance correlations showed moderate agreement, the AG measures of sedentary time are reasonably accurate if the appropriate filter and non-wear algorithm are used. This analysis provides evidence supporting the combination of the AG low frequency extension filter with the 60-minute non-wear algorithm as the optimal method of processing AG data to measure sedentary time in older adults with COPD.

| Processing Method (Filter & Non-Wear Algorithm Length) | Concordance Correlation (SE) | Mean Difference AP-AG (SD) |
|--|------------------------------|----------------------------|
| Normal & 60 min. | 0.409 (0.149) | -12.9 (114.7) |
| Normal & 90 min. | 0.388 (0.146) | -20.8 (119.7) |
| Normal & 120 min. | 0.409 (0.139) | -36.5 (117.0) |
| Low Frequency Extension & 60 min. | 0.511 (0.132) | 4.4 (106.3) |
| Low Frequency Extension & 90 min. | 0.490 (0.134) | -2.2 (112.4) |
| Low Frequency Extension & 120 min. | 0.510 (0.129) | -12.9 (109.3) |

 Email: merrillfunk@hotmail.com
 (No relevant relationships reported)

Establishing the accuracy of devices that measure daily activity is important in controlled lab settings and in real-life settings. **PURPOSE:** To assess the accuracy of a pedometer and 6 popular activity trackers at measuring steps while walking on a treadmill and walking outside. **METHODS:** Twenty-three college students (Mean±SD; 22.2±3.9yrs; 24.9±4.1kg/m², 11 male) walked 500 steps at 3mph on a treadmill while wearing 7 different activity trackers (Pedometer (PED), Blaze (BLA), Charge HR (CHR), Alta (ALT), Flex (FLE), Zip (ZIP), One (ONE)). During a second visit, participants wore the devices while walking 400 meters at 3mph outside. Steps were counted by a trained researcher using a hand tally counter. Mean Absolute Percent Error (MAPE) values were calculated for each device relative to the tally counter and were correlated between each of the devices and the tally counter using Pearson correlations. Significance was set at p<0.05. Mean bias scores were calculated between the step counts for each device and the tally counter. **RESULTS:** MAPE values were significantly correlated between the treadmill and outdoor protocol for the PED (r=0.634, p<0.001). The remaining devices were not correlated between protocols (p>0.05). The treadmill protocol produced underestimations in step counts for 5 devices (mean bias±SD: PED = -1.4±41.5steps; BLA = -35.3±70.8; CHR = -3.9±51.9; ALT = -86.5±74.4; FLE = -16.9±71.6) and slight overestimations for 2 devices (mean bias±SD: ZIP = 2.1±3.5; ONE = 0.3±2.2). The outdoor protocol produced step count overestimations for all devices. MAPE values were approximately twice as large

or greater for all devices in the outdoor protocol compared to the treadmill protocol except for the PED (MAPE±SD: 4.0±7.2 treadmill vs. 3.5±5.2 outdoor). Besides the PED, the ONE was the most accurate during the treadmill protocol (MAPE±SD: 0.3±0.3) and the ZIP was the most accurate during the outdoor protocol (MAPE±SD: 14.7±6.6). **CONCLUSION:** The step counting devices in this study performed better in the controlled laboratory setting compared to the outdoor setting with a device worn on the waist producing the best results in each trial. These findings indicate that step counts in real-life settings from commercial activity devices may produce significant error.

The Accuracy Of A Smartphone To Measure Laboratory And Free-living Physical Activity

Nicola K. Thomson¹, Lauren McMichan², Eilidh Macrae¹, Julien Baker¹, David Muggeridge³, Chris Easton¹. ¹*University of the West of Scotland, South Lanarkshire, United Kingdom.* ²*University of Strathclyde, Glasgow, United Kingdom.* ³*University of the Highlands and Islands, Inverness, United Kingdom.* (Sponsor: Professor Jason Allen, FACSM)
 Email: nikki.thomson@uws.ac.uk
 (No relevant relationships reported)

Accelerometers worn on the wrist or hip can be used to measure physical activity (PA) levels in free-living populations. Most modern smartphones also contain an inbuilt accelerometer but the capacity of this technology to accurately measure parameters of PA needs to be further established. **PURPOSE:** The primary objective of this study was to assess the validity of a popular smartphone to count steps and estimate energy expenditure (EE) during laboratory-based PA. A second objective was to compare free-living daily step counts measurements from the smartphone with a waist-worn accelerometer commonly used in research studies. **METHODS:** Healthy adults (n=20, 28 ± 5 yrs) took part in a single laboratory trial and a free-living trial (n=16, 42 ± 17 yrs). Participants wore the smartphone and accelerometer in a waist-mounted pouch continuously during both trials. Laboratory trials comprised 5 min bouts of treadmill walking and jogging. Step counts were manually counted (MC) and EE was measured using indirect calorimetry (IC). The estimates of PA parameters from the smartphone and accelerometer were compared to each other and to the gold standard measures (MC and IC) using the concordance correlation coefficient (CCC) with the thresholds: almost perfect >0.90; substantial >0.8 - 0.9; moderate 0.65 - 0.8; poor <0.65. Levels of agreement are expressed as mean bias with 95% limits of agreement (LOA). **RESULTS:** Compared to MC (700 ± 98 steps), the smartphone (703 ± 97 steps; CCC 0.992; mean bias 3 steps, LOA -19 to 25 steps) and accelerometer (675 ± 133 steps; CCC 0.76; mean bias -25 steps, LOA -179 to 129 steps) provided accurate measurements of step count. Compared to IC (8 ± 3 kcal·min⁻¹), the smartphone (6 ± 1 kcal·min⁻¹) underestimated EE with poor agreement between methods (CCC = 0.48; mean bias -1.9 kcal·min⁻¹, LOA -5.6 to 1.8 kcal·min⁻¹). During free-living, the smartphone (7990 ± 4673 steps·day⁻¹) substantially underestimated step count compared to the accelerometer (9085 ± 4647 steps·day⁻¹; mean bias -1095 steps·day⁻¹, LOA -4780 to 2591 steps·day⁻¹). **CONCLUSION:** The smartphone provided accurate measurements of step count during a controlled laboratory walking trial but substantially underestimated PA in comparison to an accelerometer during a period of free living. Supported by a grant from the Digital Health and Care Institute.

Temporal Relationships Between The Act24 And A Monitor-based Method For Estimating Energy Expenditure Over A 24 Hour Period

Nicholas R. Lamoureux¹, Paul R. Hibbing², Charles E. Matthews³, Gregory J. Welk, FACSM¹. ¹*Iowa State University, AMES, IA.* ²*University of Tennessee, Knoxville, TN.* ³*National Cancer Institute, Bethesda, MD.* (Sponsor: Greg Welk, FACSM)
 Email: nr11@iastate.edu
 (No relevant relationships reported)

The ability to quantify physical activity (PA) behavior and energy expenditure (EE) remains an important metric in public health and fitness research. While monitor-based methods remain popular, they cannot provide the context needed to understand relationships between PA, sedentary behavior, and sleep. The ACT24 is a promising online, self-guided recall survey that enables activities to be summarized and processed by day, activity or time. **PURPOSE:** To compare EE estimates from the ACT24 with estimates from the established Sensewear armband (SWA) across full days as well as at the minute-by-minute level. **METHODS:** 91 adults (36% male, mean±SD age 26.0±10.2 years) wore a SWA for 24 hours and completed the ACT24 the following morning. The compendium of physical activities was used to quantify self-reported activity levels based on ACT24 responses. To compare overall relationships, estimates of total daily EE from the

SWA and ACT24 were correlated, and the mean absolute percent error (MAPE) of the ACT24 estimate was calculated relative to the SWA values. To assess the potential for contextualizing monitor data, data from Act24 were temporally matched with the SWA files and similar correlation and descriptive analyses were performed and averaged across individuals.

RESULTS: The daily estimates were highly correlated $r = 0.88$, $p < 0.0001$ and similar in magnitude for total daily EE (SWA: 2929 +/- 1106kcal; ACT24: 2902 +/- 950kcal) with a group level MAPE of 13.6%. The associations of temporally matched estimates revealed individual correlations ranging from $r = 0.08$ to $r = 0.93$ (mean of $r = 0.54$ +/- 0.15). The individual MAPE values for the temporally matched data ranged from 0.02% to 56.1% (mean MAPE = 14% +/- 11.6%).

CONCLUSION: Previous-day recalls such as ACT24 may be useful alternatives to questionnaires or wearable devices for assessment of daily activities over 24-h periods. The robust export options also enable data to be temporally matched with other data sources to provide contextual information to be merged with monitor data. The results reveal good overall agreement between the two methods at both the group and individual level and provides a promising way to investigate PA context; however, additional research is needed to understand the factors influencing error between report-based and monitor-based methods.

The Comparison of Using the Preferred or Non-Preferred Wrist When Measuring Physical Activity

Bryce T. Daniels, Kaitlyn M. Gallagher, Michelle Gray, Erin K. Howie. *University of Arkansas, Fayetteville, AR.*
Email: bxd013@uark.edu

(No relevant relationships reported)

People who participate in regular physical activity (PA) have a decreased risk of chronic diseases and premature death. A dramatic decrease of PA occurs from adolescence to young adulthood. With serious implications on health, PA is a critical behavior to measure. However, inconsistencies exist on how to measure PA. When using accelerometers, differences between the preferred (arm most commonly used to perform daily tasks of living, P) or non-preferred (NP) wrist may result in different estimates of PA. **PURPOSE:** The purpose of this study was to compare the P and NP wrist measured PA using commonly used research accelerometers during structured daily college activities and free-living (FL) conditions of college students. **METHODS:** 30 college students (15 females and 15 males) completed 7 lab tasks including shooting a basketball (BB), relaxing on a couch (Relax), hitting a racquetball (RB), walking up and down stairs (WUS), walking on an inclined surface (WUI), walking while using a smart phone (WSP), and using a laptop (COM). An accelerometer was placed on each wrist and the right hip. After the tasks, the students completed one week of FL conditions wearing an accelerometer on each wrist. Accelerometer counts from the P and NP wrists were compared using *Wilcoxon signed-rank tests* for the lab activities and a paired *t tests* for the FL conditions with α at 0.05. **RESULTS:** P and NP total counts per minute (tCPM) from the respective accelerometer were significantly different for BB, COM, RB, Relax, WSP, and WUS. The FL conditions showed no significant differences between the P and NP wrist. All means, standard deviations, and p-values are displayed in Table 1. **CONCLUSION:** Researchers should be aware of differences between the P and NP wrist in PA measurements during structured activities. Though for FL conditions, less concern should be placed on the P or NP wrist. Findings suggest that future studies should further investigate wrist placement and tightness of the device on the wrist.

Table 1

| Condition | P tCPM | NP tCPM | p-value |
|-----------|--------------------|--------------------|------------------|
| BB | 37,624.1 (5,194.6) | 35,0789 (5,420) | 0.010 |
| COM | 1,183.4 (1,077.2) | 1,522.0 (884.7) | 0.004 |
| RB | 25,719.0 (4,318.3) | 20,715.8 (5,405.3) | <0.001 |
| Relax | 1,276.0 (1,065.6) | 1,783.1 (1,385.6) | 0.037 |
| WSP | 7,895.4 (2,457.4) | 10,450.9 (2,736.5) | <.001 |
| WUI | 10,290.8 (6,522.5) | 10,304.4 (7,472.6) | 0.894 |
| WUS | 12,477.6 (2,820.7) | 13,225.2 (3,050.1) | 0.009 |
| FL | 3,015.2 (665.5) | 2,897.2 (671.2) | 0.092 |

Device-specific Cadence (steps/min) Thresholds For Metabolic Intensities of Walking

Marcos A. Amalbert-Birriel¹, Christopher C. Moore¹, Aston K. McCullough¹, Scott W. Ducharme¹, Zachary R. Gould¹, Colleen J. Sands¹, Elroy J. Aguiar¹, John M. Schuna, Jr.², Tiago V. Barreira³, Stuart R. Chipkin¹, Catrine A. Tudor-Locke, FACSM¹.

¹University of Massachusetts Amherst, Amherst, MA. ²Oregon State University, Corvallis, OR. ³Syracuse University, Syracuse, NY. (Sponsor: Catrine Tudor-Locke, FACSM)

Email: mamalbertbir@umass.edu

(No relevant relationships reported)

In studies where steps are directly observed, walking cadences of 100 steps/min and 130 steps/min have emerged as thresholds for absolutely-defined moderate (MOD; 3 metabolic equivalents [METs]) and vigorous (VIG; 6 METs) intensities, respectively. However, there is limited information regarding device-specific cadence thresholds provided for guidance.

PURPOSE: To estimate device-specific cadence thresholds for MOD and VIG in 61-85 year old adults.

METHODS: Thirty-seven healthy older adults (62.3% women; age=68.5±4.6 years; BMI=26.3±3.8 kg/m²) walked on a treadmill for 5-min bouts. The first bout was conducted at 0.5 mph. Speed increased in 0.5 mph increments until participants reached 75% of their age-predicted maximum heart rate, started to run, or reported a Borg Rating of Perceived Exertion > 13. Cadence (steps/min) was measured across all speeds with multiple devices: ActiGraph GT9x (hip and wrist), activPAL (thigh), StepWatch (ankle), Fitbit Zip (waist), and Garmin vivoactive® 3 (wrist). Oxygen uptake was measured with indirect calorimetry and converted to METs. Receiver Operator Characteristic (ROC) analysis was used to determine optimal cadence thresholds associated with MOD and VIG intensity using Youden's index.

RESULTS: Device-specific cadence thresholds for MOD and VIG intensity are presented in Table 1. The optimal device-specific cadence thresholds were associated with very good to excellent classification accuracy for both intensities (AUC > 0.8). Except for the wrist-worn ActiGraph, which had relatively lower specificity for identifying thresholds, optimal cadence thresholds for all devices ranged from 86-104 steps/min for MOD and 125-140 steps/min for VIG intensity.

CONCLUSION: Device-specific cadence thresholds appear to be acceptable indicators of MOD and VIG walking intensities.

FUNDING: NIH-NIA-5R01AG049024

Table 1: Device-specific cadence thresholds by intensity

| Device | Absolutely-defined Intensity | Cadence (steps/min) | Specificity (%) | Sensitivity (%) | AUC | AUC 95% CI |

The Accuracy of Activity Trackers Measuring Energy Expenditure while Walking
 Melissa Renee Cook, Alyne L. Williams, Douglas Bernardes Oliveira, Christi Wolgemuth, Whitney Yoder. *Indiana Wesleyan University, Marion, IN.*
 Email: melissa.cook@indwes.edu
 (No relevant relationships reported)

PURPOSE: Activity trackers are becoming increasingly popular worldwide. As a result, the market has expanded with different brands that produce a variety of activity trackers varying in function and ability. Consumers who purchase these devices rely on the functions that are advertised, especially when cost, exercise, and lifestyle choices are considered. The purpose of this study was to assess the accuracy of the energy expenditure function of three popular activity trackers (1, 2, and 3).

METHODS: A sample was drawn from students attending Indiana Wesleyan University. Of those eligible, a total of 35 participants completed the study. Each participant wore the three devices and walked on a treadmill for 10 minutes at 3.0 mph with no incline. To assess accuracy, a t-test was used to compare the total energy expenditure measurement obtained from each device to the indirect calorimetry measurement obtained, which is considered the gold standard of energy expenditure. Correlations were calculated to analyze the relationships between the activity trackers. **RESULTS:** All three activity trackers overestimated energy expenditure ($p < .05$) when compared to the indirect calorimetry measurement. Activity tracker 1, 2, and 3 overestimated by 37, 22, and 4 kcalories, respectively. Activity tracker 1 ($r = 0.667$), 2 ($r = 0.570$), and 3 ($r = 0.568$) had a moderate correlation to the indirect calorimetry measurement.

CONCLUSIONS: Based on the findings of this study, consumers who purchase one of these devices will read an overestimated energy expenditure. Purchasing activity trackers can be expensive so doing research on which one is the most accurate is essential for consumers.

C-37 Free Communication/Poster - Carbohydrate Metabolism

Muscle Glycogen Depletion And Body Water Status Assessed With Segmental Bioimpedance Spectroscopy
 Keisuke Shiose¹, Yosuke Yamada², Keiko Motonaga³, Hideyuki Takahashi³. ¹Fukuoka University, Fukuoka, Japan. ²National Institutes of Biomedical Innovation, Health and Nutrition, Tokyo, Japan. ³Japan Institute of Sports Sciences, Tokyo, Japan.
 (No relevant relationships reported)

Glycogen is stored in combination with 3-5 g/g of water in muscle tissue, and carbohydrate (CHO) loading is accompanied by an increase in body water content, especially intracellular water. Therefore, body water status may be useful as an indicator of muscle glycogen level. However, body water status under conditions of glycogen depletion has not been investigated.

PURPOSE: To determine the effect of muscle glycogen depletion on body water distribution using segmental bioimpedance spectroscopy (S-BIS).

METHODS: Twelve healthy men performed cycling exercise aimed at muscle glycogen depletion, and 24 hours later consumed a high- (HIGH group; CHO, 7 g/kg/day) or low- (LOW group; CHO, <1 g/kg/day) CHO diet. Thigh muscle glycogen content was measured at baseline, immediately after, and 24 hours after exercise using ¹³C-magnetic resonance spectroscopy. Intra- and extracellular water content (ICW and ECW) in the leg was assessed using S-BIS; measurement was performed at baseline and 24 hours after exercise to avoid the effect of exercise-induced acute changes in blood flow and metabolite concentration, but not glycogen, on body electrical properties.

RESULTS: Muscle glycogen content decreased after exercise in both groups (HIGH, 76.2 ± 16.4 to 28.1 ± 16.8 mmol/kg w.w.; LOW, 71.6 ± 12.1 to 25.5 ± 10.1 mmol/kg w.w.; both $p < 0.05$ vs. baseline). At 24 hours after exercise, muscle glycogen content recovered in the HIGH group, but not in the LOW group (HIGH, 72.7 ± 21.2 mmol/kg w.w.; LOW, 33.2 ± 12.6 mmol/kg w.w.; $p < 0.05$ between groups). ICW and ECW in the leg were unchanged from baseline in both groups (ICW; HIGH, 7.70 ± 1.43 to 7.59 ± 1.37; LOW, 7.53 ± 1.24 to 7.58 ± 1.35; ECW; HIGH, 4.73 ± 0.50 to 4.69 ± 0.54; LOW, 4.66 ± 0.67 to 4.49 ± 0.53).

CONCLUSION: Muscle glycogen was obviously decreased in thigh muscles, but ICW and ECW in the leg were unchanged. We conclude that muscle glycogen depletion per se does not alter body water status assessed with S-BIS.

PURPOSE: Examine the effects of low-volume high-intensity interval exercise (HIIE) and moderate-intensity continuous exercise (MICE) on postprandial glucose, insulin, and triglyceride (TG) concentration following a mixed meal (MM). **METHODS:** Recreationally active men ($n = 7$; age = 22.2 ± 2.1 yrs; body mass = 93.7 ± 18.0 kg; BMI = 28.3 ± 4.6; body fat% = 29.2 ± 8.1; WC = 91.3 ± 16.5) completed a 1) rest bout, 2) MICE bout, and 3) HIIE bout in a randomized order. Rest consisted of sitting quietly for 20 minutes. MICE required 20 minutes of continuous cycling at 60% maximal work rate (WR_{max}). HIIE consisted of performing 20 (15-second) cycling sprints (@ 130% WR_{max}) followed with 45 seconds of passive cycling. Thirty minutes following the completion of each trial, participants consumed a MM in the form of a milkshake providing 5.3 ± 0.7 kcal/kg BM (body mass) with a macronutrient composition of 50% carbohydrate (CHO), 15% protein, and 35% fat. Blood samples were acquired prior to each trial and at 0, 0.5, 1, and 2 hours post-MM. Blood samples were analyzed for glucose, insulin, and TG concentration. Postprandial responses were quantified via the incremental area under the curve (AUC_i) using the trapezoidal method. Significant differences ($p < .05$) between trials were determined using a one-way, repeated measures ANOVA and Bonferroni post-hoc test. **RESULTS:** The average work performed over 20 minutes was similar between MICE (120.8 ± 30.8 W) and HIIE (115.6 ± 15.7 W) ($p = .63$, ES = .17). Glucose AUC_i was reduced following HIIE (26.4 ± 38.2 mg·dl⁻¹·2hr⁻¹) when compared to MICE (44.8 ± 35.9 mg·dl⁻¹·2hr⁻¹) ($p = .018$, ES = .51). HIIE was not different from rest (42.6 ± 66.4 mg·dl⁻¹·2hr⁻¹) ($p = .13$, ES = .30). Insulin AUC_i was unchanged between trials, however HIIE did elicit the lowest AUC_i (32.8 ± 31.8 μIU·ml⁻¹·2hr⁻¹) compared to rest (51.6 ± 31.7 μIU·ml⁻¹·2hr⁻¹) ($p = .17$, ES = .59) and MICE (52.4 ± 30.2 μIU·ml⁻¹·2hr⁻¹) ($p = .15$, ES = .63). TG AUC_i was unchanged between trials. **CONCLUSION:** Low-volume HIIE may reduce the postprandial glucose and insulin concentration. While there was no statistical significance with insulin AUC_i , there was a moderate effect size with HIIE. The lack of change in TG AUC_i was anticipated as previous studies have reported that exercise completed immediately prior to a mixed meal does not influence postprandial TG concentration.

Circulating Lactate Is Elevated in Prediabetes Phenotypes Compared with Normal Glucose Tolerant Counterparts
 Brielle L. Dotson, Emily M. Heiston, Stephanie L. Miller, Natalie Z.M. Eichner, Nicole M. Gilbertson, Steven K. Malin, FACSM. *University of Virginia, Charlottesville, VA.* (Sponsor: Steven K. Malin, FACSM)
 Email: bld2cm@virginia.edu
 (No relevant relationships reported)

Purpose: Prediabetes can be characterized as impaired fasting glucose (IFG) with or without impaired glucose tolerance (IGT; 2-hr blood glucose). IFG is depicted by impaired liver insulin sensitivity, while IFG+IGT is related to reduced liver and muscle insulin sensitivity. Lactate is a byproduct of non-oxidative glycolysis that may mediate altered glucose regulation. However, whether people with IFG and/or IFG+IGT have elevated lactate concentrations compared to normal glucose tolerant (NGT) controls is unclear. We hypothesized that individuals with IFG and IFG+IGT would have higher lactate levels than NGT controls in relation to glucose metabolism. **Methods:** Forty-one obese adults (Age: 54.8 ± 2.0 yrs; BMI: 36.0 ± 1.0 kg/m²; 34F/7M) were screened for NGT, IFG, or IFG+IGT (75g OGTT, ADA criteria) following an overnight fast. Plasma lactate, glucose, and insulin were measured during a 120min 75g OGTT. The oral minimal model was used as an estimate for insulin sensitivity. Aerobic fitness (VO_{2peak}), fasting substrate oxidation (respiratory exchange ratio (RER), indirect calorimetry) and body composition (bioelectrical impedance) were also tested. **Results:** There were no differences in VO_{2peak} , body fat or fasting RER across groups. Individuals with IFG+IGT had lower insulin sensitivity compared with IFG and NGT ($P < 0.01$). However, both IFG and IFG+IGT had increased lactate tAUC compared to NGT ($P < 0.01$ and $P = 0.01$, respectively). Increased lactate tAUC correlated with fasting glucose ($r = 0.33$, $P = 0.03$) and reduced VO_{2peak} ($r = -0.34$, $P = 0.03$). Fasting lactate also related to fasting RER ($r = 0.31$, $P = 0.04$). **Conclusion:** Despite no differences between prediabetes phenotypes, adults with IFG and IFG+IGT have elevated lactates compared to NGT controls. Lactate tAUC directly associates with fasting glucose and fitness, but not insulin sensitivity. These data suggest that fitness may mediate lactate metabolism via the liver. Future work is warranted to determine the mechanism by which lactate influences type 2 diabetes risk.

Effects of Breaking-up Prolonged Sitting with Three Different Walking Break Conditions on Glucose Metabolism
 Zhen-Bo Cao, Sheng-Xia Ma, Yan-yu Lin, Xiao-mei Liu, Sheng Zhao, Li-qiong Ma, Zheng Zhu. *Shanghai University of Sport, Shanghai, China.*
 Email: caozb_edu@yahoo.co.jp
 (No relevant relationships reported)

PURPOSE: To compare the metabolic effects of interrupting prolonged sitting with three different walking break conditions in healthy adults.
METHODS: In a randomized crossover trial, 16 inactive healthy adults (male: $n = 7$) aged 21-30 years (body mass index: 22.2 ± 2.3 kg/m²) completed four 26-h (from 8:00 AM on day 1 to 10:00 AM on day 2) laboratory conditions that included a 9-h intervention phase as follows: 9-h continuous sitting (SIT), 3-min brisk walking (60%VO_{2max}) every 35 min during 9-h sitting (WALK3), 5-min brisk walking every 50 min during 9-h sitting (WALK5), and 8-min brisk walking every 70 min during 9-h sitting (WALK8). Continuous interstitial glucose monitoring (CGM) was performed during the 26-h intervention period. Four 2-h postprandial periods were also analyzed. Four meals and meal times were standardized across the conditions for all the participants.
RESULTS: Compared with that in SIT (mean \pm SD: 5.66 ± 0.44 mmol/L), the 26-h mean glucose level during WALK3 (5.42 ± 0.42 mmol/L), WALK5 (5.44 ± 0.46 mmol/L), and WALK8 (5.44 ± 0.50 mmol/L) were significantly lower (all $P < 0.01$), with similar results for glucose total areas under the curve (AUC; attenuated by 3%-4%; all $P < 0.01$), but no significant differences were found among the three intervention conditions. The 2-h breakfast postprandial glucose incremental area under the curve (iAUC) was significantly lower for WALK3 (33%) and WALK8 (25%) than for SIT (all $P < 0.05$) on day 1, whereas 2-h dinner postprandial glucose iAUC was significantly higher for WALK8 (25%) than for SIT ($P = 0.038$). No significant treatment effects on both lunch (day 1) and breakfast (day 2) postprandial glucose iAUC were found.
CONCLUSIONS: Three kinds of regular walking break conditions attenuated 26-h glucose responses. WALK8 most likely influenced the 2-h postprandial glucose metabolism of the healthy young adults in this study.

Does Pattern of Drink Intake Affect Exogenous Carbohydrate Oxidation During Prolonged Submaximal Running?
 Stephen A. Mears, Benjamin Boxer, David Sheldon, Hannah Wardley, Caroline Tarnowski, Lewis J. James, Carl J. Hulston. *Loughborough University, Loughborough, United Kingdom.*
 Email: s.a.mears@lboro.ac.uk
 (No relevant relationships reported)

Marathons and half-marathons usually position drink stations every 5 km, providing opportunity for fast runners to consume fluid and carbohydrate approximately every 15-20 min. In recent attempts to break the marathon world record, drinks have been provided at more frequent intervals, often in smaller volumes. **PURPOSE:** To determine how the pattern of carbohydrate ingestion during running affects exogenous carbohydrate oxidation rates and measures of gastrointestinal (GI) comfort.
METHODS: Twelve well-trained male runners (27 ± 7 y, 67.9 ± 6.7 kg, $\dot{V}O_{2peak}$: 68 ± 7 mL/kg/min) completed three exercise trials of 100 min steady state running at 70% $\dot{V}O_{2peak}$. During the first trial, 200 mL water was consumed every 20 min and results were used for background correction of ¹³CO₂ breath enrichment. In the final two trials a 1 L volume of a 10% dextrose solution, enriched with [U-¹³C] glucose, was consumed at a rate of either 200 mL every 20 min (CHO-20) or 50 mL every 5 min (CHO-5). Expired breath and venous blood samples were collected at rest and every 20 min during exercise. Subjective scales of GI comfort were recorded at regular intervals.
RESULTS: Exogenous carbohydrate oxidation rates were higher after 80 (0.58 ± 0.16 v 0.48 ± 0.16 g/min; $P = 0.020$) and 100 min (0.67 ± 0.14 v 0.58 ± 0.15 g/min; $P = 0.016$) of running in CHO-20 compared to CHO-5. During exercise, total carbohydrate oxidation rates were similar between trials and remained within a range of 2.0 to 2.5 g/min ($P > 0.168$). Oxidation of endogenous carbohydrate was lower in CHO-20 (1.87 ± 0.37 v 2.08 ± 0.44 g/min; $P < 0.05$). Serum glucose concentration increased above 5 mmol/L after drink ingestion, remaining elevated throughout exercise with no difference between trials ($P = 0.095$). There were no differences in reported symptoms of GI comfort ($P > 0.05$), with no subject reporting severe symptoms (all ≤ 6) in either trial.
CONCLUSIONS: Ingestion of a larger volume of carbohydrate solution at less frequent intervals increased exogenous carbohydrate oxidation rates, resulting in similar rates of total carbohydrate oxidation but with reduced contribution from endogenous carbohydrate stores.

Acute Effects of Rotating Shift Work Paradigm on Activity and Metabolism
 Vasavi Shabrish. *University of Texas at Austin, Austin, TX.*
 (No relevant relationships reported)

Shift work, which involves working during normal sleeping periods, results in asynchrony between central and peripheral molecular circadian clocks and is associated with increased risk for metabolic disease. Catecholamines released during physical activity act as entrainers of the circadian clock, and disruption of physical activity patterns may contribute to the negative effects of shift work.
PURPOSE: The purpose of this study was to investigate the acute effects of rotating shift work on physical activity patterns, glucose tolerance, and body composition.
METHODS: Eleven-week-old male mice on a FVB/N background were individually housed and randomly assigned to either a control group or a rotating shift work group. Control group mice were exposed to a normal 12:12 light/dark cycle, while the shift work mice were exposed to alternating 12:12 light/dark and dark/light inversions to simulate a rotating shift work pattern of 3 days "on shift"/4 days "off shift" for one week, followed by 4 days "on shift"/3 days "off shift" during the following week. Shift work conditions were maintained for two-weeks, followed by a 4-week period on normal light cycles and then another 3 weeks of alternating light cycles. Both groups received *ad-libitum* access to wireless running wheels, normal chow, and water. Glucose tolerance tests and body composition were measured at baseline, after two weeks, and the study end.
RESULTS: Acute exposure to rotating shift work resulted in the shift work group being significantly more active between zt0-zt12 (5 vs 28 km, $p < 0.001$; 11.8 vs 61 km, $p < 0.001$) and during lights on (15.9 vs 24.5 km, $p < 0.01$; 11.8 vs 51 km, $p < 0.01$) and significantly less active between zt12-zt24 (23.7 vs 49.9 km, $p < 0.01$) compared to the control group. Activity in the shift work group was more distributed throughout the 24-hour period compared to the control group. Acute exposure demonstrated significant differences between groups for fasting glucose ($p < 0.05$) indicating dysregulation in carbohydrate metabolism. No significant differences were observed in body weight and body composition between groups at any time point.
CONCLUSIONS: Acute exposure to a rotating shift work paradigm disrupts normal activity patterns and dysregulates carbohydrate metabolism.

Acute Resistance Exercise Fails to Alter Post-Exercise Glycemic Control
 William A. Braun, FACSM, Zach Rollar, Dan Hauck. *Shippensburg University, Shippensburg, PA.*
 Email: wabrau@ship.edu
 (No relevant relationships reported)

Acute exercise has commonly been found to transiently enhance glycemic control during recovery from the exercise. This effect has more commonly been observed following aerobic exercise. **PURPOSE:** This study combined results from two recent smaller investigations to gauge the effects of resistance exercise on post-exercise blood glucose (BG) response to an oral glucose tolerance test (OGTT). **METHODS:** Data from seventeen resistance-trained volunteers were used. All subjects completed a resting control trial consisting of a 75-min OGTT following consumption of a 25% glucose solution dosed at 1 g/kg body mass. On a separate day, subjects completed either 30 repetitions of squat only exercise (at 10-RM); 30 repetitions each of squat, bench press and biceps curl (at 10-RM); or ~30 repetitions each of biceps curl and knee extension (at 10-RM). BG was assessed via fingertip sampling prior to exercise, post-exercise and during the OGTT (every 15 min). Blood lactate was collected at rest and upon completion of exercise. **RESULTS:** Resistance exercise resulted in significantly increased blood lactate vs. resting state (8.58 ± 0.87 vs. 1.39 ± 0.22 mmol/L). OGTT response following acute resistance exercise was not significantly different ($p > 0.05$) from the resting OGTT condition. BG area under the curve was 2% smaller ($p > 0.05$) following resistance exercise compared to resting control (11330.6 ± 320 vs. 11551.3 ± 405 arbitrary units). **CONCLUSIONS:** Based on the results of this investigation, acute resistance exercise was not found to elicit enhanced glycemic control. The volume of working muscle, the overall energy deficit induced by exercise and the magnitude of the body's glycogen depletion may be important factors to consider when examining post-exercise blood glucose response to an OGTT challenge.

The Effects of High-Versus Low-Intensity Resistance Exercise on Acute Hyperglycemia in Young Healthy Males

Brandon Beimborn, Luis Segura, Joshua Cotter, PhD, Evan Schick PhD. *California State University, Long Beach, Long Beach, CA.*

(No relevant relationships reported)

ACSM 2019

THE EFFECTS OF HIGH- VERSUS LOW- INTENSITY RESISTANCE EXERCISE ON ACUTE HYPERGLYCEMIA IN YOUNG HEALTHY MALES
Luis E. Segura, Brandon Beimborn, Shayan Emamjomeh, Josh A. Cotter, PhD, Evan E. Schick, PhD

Nearly one-third of Americans older than 18 years of age are pre-diabetic, yet much remains to be understood about this condition. Regular exercise can help control prolonged hyperglycemia, a flagship symptom of type 2 diabetes, however, the nature in which exercise can alleviate periods of acute hyperglycemia, a common symptom of pre-diabetes, is unclear. **Purpose:** The purpose of this study was to examine the effect of high-intensity (HI) versus low-intensity (LO) resistance exercise (RE) on acute hyperglycemia in resistance-trained males. **Methods:** Thirteen recreationally trained males (age, 23.43 ± 2.18 yrs.; height, 175.16 ± 10.44 cm; mass, 77.02 ± 8.91 kg) completed three randomized testing sessions separated by 96 hours: 1) no exercise control (CON), 2) HI (5x4, 90% 1-RM), and 3) LO (3x14, 65% 1-RM). Following overnight fast, all three-testing session commenced with oral ingestion of a high glucose drink (2 g glucose/kg body weight). HI and LO RE protocols began 30 mins post-glucose ingestion. Capillary blood samples obtained via finger stick occurred immediately pre- and 30, 60, 90 and 120-mins post-glucose ingestion. **Results:** A two-way ANOVA revealed a significant (p<0.015) time main effect for plasma glucose and insulin concentrations throughout the 120 min testing duration, however neither glucose or insulin differed between conditions at any of the individual time points. One-way ANOVA showed that total glucose response in the HI condition, as assessed by AUC, was significantly greater (p<0.012) than in both CON and LO. Strong negative correlations existed between total body mass and lean body mass (r = -0.78) as well as lean body mass and LO glucose AUC (r = -0.78). **Conclusions:** High intensity resistance exercise may exacerbate acute episodes of hyperglycemia, thus combining high intensity with lower intensity resistance exercise may optimally manage skeletal muscle health and glycemic control.

Impact of Reduced Carbohydrate Intake after Exercise on Breath Acetone Levels

naoki ota, hiroto ito, kazushige goto. *ritumeikaniversity, kyoto, Japan.* (Sponsor: Robert Kraemer, FACSM)

Email: n.ota0820@gmail.com

(No relevant relationships reported)

PURPOSE: The purpose of the present study was to determine the impact of reduced carbohydrate (CHO) intake after sprint exercise on breath acetone levels during post-exercise.

METHODS: Nine subjects (20.8 ± 0.2 yrs, 170.1 ± 1.6 cm, 65.1 ± 1.8 kg) conducted two trials, consisting lower CHO trial (LOW) or normal CHO trial (NOR). In each trial, the subjects came to the laboratory at 7:30 to evaluate breath acetone level, blood variables and resting metabolic rate. From 17:00, they started repeated sprint exercise (4 × 30 s maximal cycle sprint exercise). After exercise, isoenergetic meals (during 2-3 h after exercise) were provided with containing normal CHO (60% for CHO, 20% for protein, 20% for fat) for NOR or reduced CHO (20% for CHO, 20% for protein, 60% for fat) for LOW. Time course changes in breath acetone levels were monitored immediately before exercise, immediately after exercise, 1 h, 3h, 4h and on the following morning.

RESULTS: In the LOW, exercise markedly increased breath acetone levels during post-exercise (trial × time interaction: p<0.05). At 4 h after exercise, breath acetone level was significantly higher in LOW (0.9 ± 0.02 ppm) than in NOR (0.66 ± 0.07 ppm, p < 0.05). However, a significant difference between the trials was not observed on the following morning. Respiratory exchange ratio (RER) on the following morning was significantly lower in the LOW (0.81 ± 0.02) than in the NOR (0.87 ± 0.02, p < 0.05). Moreover, LOW showed significantly lower contribution of CHO oxidation (34 ± 4.8 %) than that in NOR (50 ± 6.2 %, p < 0.05), whereas fat oxidation was significantly higher in LOW (66 ± 4.8 %) than in NOR (50 ± 6.2 %, p < 0.05).

CONCLUSIONS: Reduced CHO intake after exercise increased breath acetone level during early phase of post-exercise (4 h after exercise), suggesting augmented fat metabolism in the liver under impaired CHO availability. However, the increased breath acetone level by reduced CHO intake was not evident on the following morning. The results may suggest that breath acetone levels can be available to evaluate CHO availability following intensive exercise.

1399 Board #161 May 30 10:30 AM - 12:00 PM
Effects of Acute Swimming Exercise on Pancreatic Enzyme Activity and Intestinal Glucose Transporters in Rats

Saki Kondo, Ayumi Fukazawa, Shin Terada. *The University of Tokyo, Tokyo, Japan.* (Sponsor: Mitsuru Higuchi, FACSM)

(No relevant relationships reported)

PURPOSE: It has been reported that long-term endurance exercise training increases pancreatic amylase activity in rats, suggesting that chronic exercise training enhances the carbohydrate digestive capacity. To clarify whether an acute bout of endurance exercise can also induce the pancreatic adaptation and affect glucose transport capacity in small intestine as well, we evaluate the effects of acute swimming exercise with different duration on pancreatic amylase activity and intestinal glucose transporter contents in rats. **METHODS:** Male Sprague-Dawley rats performed acute bout of swimming exercise for 1 h (Ex-1h group) or 6 h (Ex-6h group, two 3-h bouts separated by 1h of rest). Sedentary rats were used as a control (Con group). Immediately and 24 h after the exercise, pancreas and small intestine (jejunum) were dissected out and amylase activity and glucose transporters (GLUT2 and SGLT1) content were measured, respectively. **RESULTS:** While no significant difference in total pancreatic amylase activity was observed between the Con and Ex-1h groups, the Ex-6h group had significantly lower total amylase activity compared with the Con group in both immediately (1233 ± 229 vs. 2088 ± 205 U, p < 0.05) and 24 h after the exercise (1295 ± 112 vs. 1954 ± 227 U, p < 0.05). There were no significant differences in GLUT2 and SGLT1 protein contents among the three groups. **CONCLUSIONS:** These results suggest that acute bout of prolonged exercise for longer time (~6 h) may decrease the carbohydrate digestive capacity in the rat pancreas through the diminished amylase activity, although it has little effect on intestinal glucose transporters content.

cfDNA As A Metabolic Marker

David Ochmann, Charlotte Kreuz, Silvia Wenzel, Perikles Simon. *Institution of Sports Science, Mainz, Germany.*

Email: ochmann@uni-mainz.de

(No relevant relationships reported)

PURPOSE: We observed in previous studies that incremental running tests to exhaustion and continuous aerobic running leads to significant increases of cell-free DNA (cfDNA) in capillary blood, which showed a high positive correlation with total energy expenditure. Here we investigated the increases of cfDNA during different interval loads with a focus on metabolic rates, heart rate (HR), and TRIMP. We hypothesized that cfDNA shows a high association with carbohydrate energy expenditure.

METHODS: 14 male subjects were subjected to a stepwise incremental exercise test until exhaustion to determine the individual anaerobic threshold (IAT; as LT + 1.5 mmol/l) and subsequently participated in three different interval training sessions. cfDNA and lactate were taken after every step and metabolic data were monitored continuously after a 10min warmup phase on the treadmill (+1.5%) during 6 x 400m intervals at 18km/h with 2min pauses, 6 x 400m intervals at 18km/h with 5min pauses, and 6 x 1000m intervals at IAT with 2min pauses. The order of the first two tests that only differed in duration of pause was randomized. Heart rate and subsequent calculation of TRIMP was done based on ECG Monitoring.

RESULTS: cfDNA analysis showed a significantly higher increase in the 400m interval setting with short pause time (8.2-fold; 95% CI: 6.3-10.6; p<0.0001) compared to 400m interval setting with long pause time (3.4-fold; 95% CI: 2.6-4.4; p<0.0001). In contrast to cfDNA TRIMP showed a significantly higher increase in the 400m interval setting with a long pause time (long: 4.8-fold; 95% CI: 4.4-5.2; p<0.0001) compared to 400m interval setting with short pause time (4.3-fold; 95% CI: 4.0-4.7; p<0.0001). In a global analysis across all interval tests and points in time cfDNA increased 7.0-fold (95% CI: 5.4-9.1; p<0.0001) and the highest correlation of this increase with all other physiological parameters was with carbohydrate energy expenditure (r = 0.87; p<0.0001).

CONCLUSIONS: cfDNA appeared to reflect training load of the 400m interval settings more properly than TRIMP. Here we report for the first time a high correlation between cfDNA and carbohydrate energy expenditure. Further studies will have to investigate the validity of cfDNA releases during exercise as a marker for carbohydrate energy expenditure.

Metabolic Responses of Pre-Exercise Carbohydrate Ingestion in Cycling and Running

Michaela Alexandrou¹, Chrysoula Kontrafour¹, Damianos Papafili¹, Argyro Pountoukidou¹, Efraimia Tsolaki¹, Maria Evangelia Koloutsou¹, Evangelia Tzeravini¹, Elias Zacharogiannis¹, Ioannis Lambropoulos², Costas Chryssanthopoulos¹, Alexander Kokkinos¹, Maria Maridaki¹, Michael Koutsilieris¹, Anastassios Philippou¹. ¹National and Kapodistrian University of Athens, Athens, Greece. ²Biomedicine, Diagnostic and Research Laboratories, Marousi, Greece.
Email: alexmichaela@yahoo.gr

(No relevant relationships reported)

Several studies have examined the metabolic responses of pre-exercise carbohydrate (CHO) ingestion in cycling and running, however, none of the existing studies compared directly cycling and running on the same individuals. **PURPOSE:** To examine the metabolic responses of pre-exercise CHO ingestion in cycling and running on the same individuals. **METHODS:** Eleven males (25.5 ± 3.2 years old, 175.7 ± 2.0 cm, body fat percentage 12.4 ± 4.2%, mean ± SE), following an overnight fast, cycled or ran for 30 min at 77-83% maximal heart rate (HR_{max}) after ingestion of either 1g/kg body weight maltodextrin (CHO-Cycle and CHO-Run respectively) or placebo (PL-Cycle and PL-Run) solutions. Fluids were ingested 30min before exercise in a double-blind and random way. Data were analyzed using three-way ANOVA, whereas pre-post exercise changes were compared by two-way ANOVA. **RESULTS:** Blood glucose and serum insulin responses were higher before exercise in CHO (mean CHO-Cycle+CHO-Run) (Glucose: 7.3 ± 0.4 mmol⁻¹; Insulin: 59 ± 10 mU⁻¹) compared to placebo trials (mean PL-Cycle+PL-Run) (Glucose: 4.7 ± 0.1 mmol⁻¹; Insulin: 8 ± 1 mU⁻¹) (p<0.01). No differences were observed during exercise among the 4 conditions, while blood glucose did not drop below 4.1 mmol⁻¹ in any trial. Blood lactate increased with exercise (post - pre difference) more in cycling (CHO-Cycle+PL-Cycle: 3.4 ± 0.4 mmol⁻¹) compared to running (CHO-Run+PL-Run: 0.7 ± 0.2 mmol⁻¹) (p<0.01). At the end of exercise plasma free fatty acids (FFA) were higher in placebo compared to CHO irrespective of exercise mode (PL-Cycle+PL-Run: 0.36 ± 0.03 vs. CHO-Cycle+CHO-Run: 0.14 ± 0.03 mmol⁻¹), while at the same time plasma glycerol was higher in PL-Run (137 ± 8 mmol⁻¹) compared to PL-Cycle (87 ± 8 mmol⁻¹) (p<0.01). **CONCLUSIONS:** During 30min exercise at 77-83% HR_{max}, lactate was higher in cycling compared to running irrespective of fluid ingestion, whereas glycerol was increased more in running when no CHO was provided. The ingestion of CHO reduced FFA concentrations independently of the mode of exercise, while glucose and insulin responses were not affected by the exercise mode

Electrolyte-based Carbohydrate Drink: Effect On Steady State Exercise Done Against Progressively Higher Workloads

William D. Gray, Ian T. O'Brien, Amy E. Kozerski, Alexandria C. Vanhoover, Charles B. McEnroe, John F. Caruso. *University of Louisville, Louisville, KY.*

Email: john.caruso@louisville.edu

(No relevant relationships reported)

Aerobic exercise with progressively higher workload stages done in succession challenges a person's cardiorespiratory system as their VO₂max is estimated. Higher heart rates (HR) at the end of stages lowers a person's estimated VO₂max. Adding electrolytes to a carbohydrate-based drink may raise VO₂max values if ingested before exercise. **Purpose:** Compare the merits of added electrolytes, in two otherwise similar beverages, when consumed before VO₂max tests that entail progressively higher workload stages. **Methods:** In a randomized double-blind study subjects (13 men, 21 women) first gave written informed consent, followed by two stationary cycle ergometer workouts to estimate their VO₂max. Workouts were preceded by intake of a 2% sucrose solution, one of which was an electrolyte-rich (500 mg of vitamin C, 1 mg of B-12, 100 mg of Mg²⁺, 400 mg of K⁺, 200 mg of Na⁺, 1 μg of Cr) beverage, while the other was devoid of added electrolytes and served as a placebo. HR were recorded before, four times during, and after workouts. Ratings of perceived exertion (RPE) were provided at the end of workouts. HR were compared with a three-way (gender, treatment, time) ANOVA, with repeated measures for treatment and time. Estimated VO₂max and RPE were assessed with two-way (gender, treatment) ANCOVAs, with repeated measures for treatment. Body mass and body fat percentage were examined as covariates. Scheffe's served as our post-hoc and a α= 0.05 denoted significance. **Results:** There were significant inter-time differences for HR. RPE and VO₂max each had inter-gender differences. Yet there were no inter-treatment differences. **Conclusions:** Little research exists on the ergogenic effects on electrolyte formulations added to carbohydrate beverages, yet our results concur with studies that also saw a lack of inter-treatment differences.

The Effects of a Carbohydrate Mouth Rinse on Central and Peripheral Fatigue Following High and Low Intensity Fatiguing Exercise

Angelina Curiel, Kody Haskins, Michael G. Bemben, FACSM, Rebecca D. Larson, Christopher D. Black, FACSM. *University of Oklahoma, Norman, OK.*

(No relevant relationships reported)

Carbohydrate (CHO) mouth rinsing has been shown to improve performance during long duration, aerobic exercise. However, the ability of a CHO mouth rinse to attenuate fatigue during shorter term exercise is not well characterized. **PURPOSE:** This study sought to determine the effects of a CHO mouth rinse on torque production and voluntary activation following high and low intensity isometric exercise. **METHODS:** Twelve, active male participants completed 6 sessions—2 familiarization and 4 testing visits. Knee extension MVC was determined (PRE), followed by performance a high (80% of MVC) or a low (20% of MVC)-intensity isometric exercise held to task failure. An 8% CHO solution or placebo was then rinsed for 20-secs. MVC was then reassessed immediately following (iPOST) the rinse and following 5-min of rest (SPOST). Voluntary activation (VA%) was determined during each MVC via twitch-interpolation and rate of torque development (RTD) and relaxation (RTR) were calculated from twitch torque (TT). **RESULTS:** There were no significant interactions (p≥0.31) between exercise intensity, time, and rinse condition on all variables. MVC was reduced compared to PRE following 20% and 80% exercise (p<0.01), but greater reductions were found at iPOST following exercise at 20% of MVC (-24.1% vs. -14.2%; p<0.001). VA% decreased following both exercise protocols (p≤0.02), but was reduced to a greater extent following exercise at 20% of MVC (-18.7% vs. -6.7%; p<0.004). A significant main effect for time (p = 0.01) was found on TT with reductions observed iPOST (p≤0.047), but not at SPOST (p>0.05). RTD was reduced following exercise at 80% (281±65 vs. 251±70 Nm·s⁻¹; p<0.05), but not following exercise at 20% of MVC (p≥0.06). RTR was reduced following exercise at both 20% and 80% of MVC (p≤0.01) at iPOST. Greater reductions were observed following exercise at 80% of MVC (216±55 to 144±37 vs. 222±54 to 184±54; p<0.04). **CONCLUSIONS:** We were successful in eliciting differing levels of central and peripheral fatigue by exercising at a low and high intensity. Despite significantly larger declines in VA% following exercise at 20% of MVC, CHO mouth rinsing had no effects compared to placebo on any measured variable.

1404 Board #166 May 30 10:30 AM - 12:00 PM

Influence of Chronic Carbohydrate Ingestion During High Intensity Exercise on Incidences of Gastrointestinal Distress

Ben M. Krings¹, Hunter S. Waldman², Brandon D. Shepherd², Matthew J. McAllister³, JohnEric W. Smith². ¹University of Wisconsin- Platteville, Platteville, WI. ²Mississippi State University, Mississippi State, MS. ³Texas State University, San Marcos, TX.

(No relevant relationships reported)

The effects of carbohydrate (CHO) ingestion during endurance exercise on gastrointestinal distress (GID) has been well researched, but there is limited research with high intensity exercise. **PURPOSE:** The purpose of this study was to examine the effects of chronic CHO ingestion on GID responses during a 4 week concurrent resistance training (RT) and high intensity interval training (HIIT) program. **METHODS:** 18 resistance trained males, aged 18-24 years old, were stratified into one of two groups: ingesting a 500 mL beverage containing a 6% CHO solution during exercise or ingesting a 500 mL artificially flavored placebo. Each group completed 4 weeks of RT and HIIT, three days per week of RT, and two days per week of HIIT, repeated all-out 30 second cycling sprints. GID was measured immediately before and after one RT session and one HIIT session per week for a total of 8 sessions. GID was measured using a 10-point Likert scale assessing feelings of nausea, regurgitation/reflux, stomach fullness, abdominal cramps, gas/flatulence, and urge to defecate. GID was analyzed using a four-way repeated measures ANOVA (exercise × group × time × week). **RESULTS:** There was a main effect for time for nausea (pre-exercise 0.29 ± 0.68, post-exercise 1.31 ± 2.24), regurgitation/reflux (pre-exercise 0.24 ± 0.75, post-exercise 1.53 ± 2.00), and abdominal cramps (pre-exercise 0.09 ± 0.54, post-exercise 0.83 ± 1.56) (p < 0.05), suggesting these symptoms of GID increased pre- to post-exercise independent of exercise type, group, or week. There were no interaction effects or main effects for gas/flatulence or urge to defecate (p < 0.05). **CONCLUSION:** Ingesting beverages containing CHO or artificial sweeteners both increase GID during high intensity exercise. Chronic CHO ingestion during endurance training has been suggested to train the gut to better absorb nutrients, but based on the results from this investigation, signs and symptoms of GID are not reduced following 4 weeks of chronic ingestion during high intensity exercise.

Carbohydrate Effects on Post-Exercise Performance in Prepubescent Girls

C. Eric Heidorn, Brandon J. Dykstra, Cori A. Conner, Anthony D. Mahon. *Ball State University, Muncie, IN.*
(No relevant relationships reported)

Carbohydrate (CHO) consumption is a common practice during variable-intensity exercise (VIE) such as team sports. The effects of CHO on performance during VIE have been studied in adults; however, the effects are less defined in children and apparently not at all in prepubescent girls. **PURPOSE:** To investigate the effects of a 6% CHO drink on a one-minute performance test following 30-minutes of VIE in prepubescent girls. **METHODS:** Ten girls (10.4±0.7 yrs.) participated in this study. During the initial visit, maximal aerobic power was determined followed by a familiarization of the protocol used during the next two visits in which the child consumed either a CHO drink or an electrolyte-matched placebo (PL). The experimental protocol involved two 15-minute bouts of VIE (20, 55, 95% maximal aerobic power and 6-second maximal sprint); beverages were consumed prior to exercise and after each 15-minute segment. A one-minute performance trial was then completed at maximal effort. Measurements during VIE included heart rate (HR), rating of perceived exertion (RPE), sprint mean power (MP) and sprint peak power (PP). During the one-minute performance bout, HR, RPE, PP, total work (TW), and fatigue index (FI) were assessed. Data were analyzed using a 2-way ANOVA and paired t-tests. **RESULTS:** $\dot{V}O_{2max}$ was 39.7 ± 5.5 mL·kg⁻¹·min⁻¹ and HR_{max} was 196 ± 11 bpm. During VIE, there were no interaction effects, no trial effects ($p > 0.05$) for HR, %HR_{max}, RPE, sprint MP, sprint PP and no time effects ($p > 0.05$) for HR, %HR_{max}, or MP. However, there were time effects ($p < 0.05$) for RPE (VIE1 < VIE2) and PP (VIE1 > VIE2). No differences were found between trials (CHO vs. PL) for one-minute performance for HR (190 ± 9 vs. 189 ± 9 bpm), %HR_{max} (97.0 ± 3.2 vs. 96.6 ± 3.0 %), RPE (7.8 ± 2.3 vs. 8.1 ± 1.9), PP (238 ± 70 vs. 235 ± 60 W), FI (54.7 ± 10.0 vs. 55.9 ± 12.8 %), and TW (9.37 ± 2.6 vs. 9.37 ± 2.1 kJ). **CONCLUSION:** A 6% CHO drink is ineffective at improving one-minute performance following 30-minutes of VIE in pre-pubertal girls. Based upon the current findings, CHO supplementation does not appear to be beneficial with respect to improving performance for prepubescent children completing VIE activity lasting 30-minutes.

Influence Of Sports And Energy Intake On BMD In Female Athletes Compared To Sedentary Controls

Adriana De la Parra Sólomon, Hugues Plourde, Sebastien Beauregard, Ross E. Andersen, FACSM. *McGill University, Montreal, QC, Canada.*
 Email: adriana.delaparrasolomon@mail.mcgill.ca
(No relevant relationships reported)

Physical activity, particularly percussive activities with adequate energy intake may influence bone mineral density (BMD) in young female adults. Unfortunately, it is common to see energy deficiencies in this population that can put them at risk of health issues including lower BMD. **PURPOSE:** To determine the influence of the type of sport and energy intake on BMD in female athletes compared to sedentary students. **METHOD:** Seventy-three female students (age 20.8 ± 1.9 y, height 167.4 ± 8.8 cm, weight 62.3 ± 9.2) from McGill University were evaluated (44 from McGill Varsity Teams: basketball (BB n=13), volleyball (VB n=11), figure skating (FS n=13), and synchronized swimming (SS n=7); and 29 sedentary healthy women (controls). Dietary intake (kcal/day) was assessed using a 3-day Food Log and analysed with the Food Processor™ Software. Lumbar spine (LS) (L1-L4) and femoral neck (FN) BMD were assessed by DXA scanning. A one-way ANOVA explored between-group differences and an ANCOVA examined the influence of energy intake on BMD. **RESULTS:** A significant difference in BMD at the LS and FN sites was observed between the type of sports ($F(4,68) = 8.6, p < .001, \eta^2 = .335; F(4,68) = 6.3, p < .001, \eta^2 = .272$, respectively). Also, BB (LS = $1.7 \pm 1.53, p < .001$; FN = $1.7 \pm 1.13, p = .001$) and VB (LS = $1.5 \pm 1.55, p = .001$; FN = $1.7 \pm 1.66, p = .002$) players had a significantly higher BMD in both sites compared to their non-athletic counterparts (LS = -0.3 ± 1.19 ; FN = 0.1 ± 1.04). The FS and SS athlete's bone densities were not different from the control group ($p = .719; p = .246$). No significant association was observed between BMD at both sites and total energy intake/day across all groups ($F(1,67) = .496, p = .484, \eta^2 = .007; F(1,67) = .035, p = .852, \eta^2 = .001$). There was a significant difference between the delta energy intake (recommended intake minus actual intake) in both BB and SS groups compared to the control group ($p = .003$ and

$p = 0.02$, respectively). **CONCLUSION:** The type of sport revealed an influence on BMD. However, no significant relationship was observed between energy intake and BMD. A significant discrepancy was found between the required versus actual energy intake in some athletes. These data suggest that female varsity athletes should work closely with sports dietitians to promote healthy eating and optimize bone health.

1407 Board #169 May 30 10:30 AM - 12:00 PM
The Role of Acute Fasting on Substrate Utilization During Submaximal Exercise

Melhaney Reichelt, Lauren Yanni, John Wygand, FACSM, John Petrizzo, Robert M. Otto, FACSM. *Adelphi University, Garden City, NY.* (Sponsor: John Wygand, FACSM)
 Email: melaneyreichelt@mail.adelphi.edu
(No relevant relationships reported)

Purportedly, performing 20 minutes of aerobic exercise following an overnight fast has a greater effect on fat loss than in the postprandial state. Theoretically, a fast may attenuate glycogen stores, thus shifting to the utilization of increased free fatty acids, and resulting in greater fat burn throughout exercise. **Purpose:** To determine if exercising at a titrated intensity, as determined by equal fat and carbohydrate fuel utilization, will elicit more fat utilization in a fasted state when compared to a fed state. **Methods:** 13 (12♂) asymptomatic (ht. 176.6 ± 2.9 cm; wt. 79.1 ± 17.2 kg), healthy college students (age range 19-24) who regularly engage in aerobic exercise a minimum of twice per week volunteered for the study. During familiarization, individual treadmill workloads were titrated by using a ramp protocol (speed increase of 13.4 m/min) at 1% grade to achieve a RER of .85. All trials were preceded by a 12 hr fast w 24 hr abstinence from alcohol & caffeine, and 30 minutes of rest immediately prior to the trial. The fasted trial (Fa) required 25 minutes of rest and 5 min of measured resting metabolism (RMR) prior to the treadmill exercise, while the fed trial (Fe) required ingestion of 450 kcal (74% CHO, 14% pro, & 12% fat) in 10 minutes with 15 minutes of rest immediately prior to 5 min of RMR. Single blind randomization determined trial cross over order. Blood glucose (BG) was obtained by finger stick. Statistical analysis by paired samples T-test were applied to these data ($p < .05$). **Results:** The RER at RMR of 0.88 Fe & 0.83 Fa, was significantly different, however, exercise $\dot{V}O_2$ of 2.46 ± 0.8 & 2.36 ± 0.8 and RER of 0.89 & 0.87 for Fe & Fa, respectively, was NSD ($p > .05$). BG pre and post exercise of 81.3 ± 9.2 & 61.8 ± 9.1 for Fe and 80.9 ± 5.5 & 85.5 ± 10.1 mg/dL for Fa was NSD for Fa. **Conclusion:** A 12 hr fast can alter resting fuel substrate, but exercise fuel sources are unaffected. Reductions in BG from exercise during the fed state may be attributed to fuel use, however the maintenance of BG in the fasted state may be related to glucagon release. Relative to fat expenditure, there is no advantage to exercising in an acute fasted state (12 hr) or in a fed state, however an extended fast may provide a different outcome.

Effects of Concussion on Whole-Body Energy Metabolism and Caloric Intake: A Preliminary Investigation

Samuel R. Walton, Steven K. Malin, FACSM, Sibylle Kranz, Donna K. Broshek, Jay Hertel, FACSM, Jacob E. Resch. *University of Virginia, Charlottesville, VA.*
 Email: swaltonatc@gmail.com
(No relevant relationships reported)

PURPOSE: Prior studies suggest changes in resting metabolic rate (RMR) and brain substrate use in severe traumatic brain injuries (TBI). However, no data exist in humans with concussion. The purpose of this study was to examine the effect of concussion on RMR, estimated substrate use, and diet throughout recovery in male and female athletes.

METHODS: Concussed participants ($N = 25$ [13 males, 12 females]) were recruited from a university and local high schools. RMR was determined by indirect calorimetry < 72 hours following a diagnosed concussion (T1), 7 days after T1 (T2), and 14 days after T1 (T3). Percent carbohydrate (CO) and lipid (LO) oxidation were calculated from $\dot{V}O_2$ and $\dot{V}CO_2$. Dietary intake was self-reported for the day of and two days following each time point. Total caloric intake (kcal) and percentage from carbohydrates (CI), proteins (PI) and lipids (LI) were calculated. Separate repeated measures ANOVAs were used to assess sex by time changes in RMR and CI. Descriptive statistics were used to assess macronutrient intake and use. **RESULTS:** Participant demographics, metabolic, and nutrient data are in Table 1. RMR did not change over time ($p = .49, \eta^2 = .03$) and sex did not significantly influence RMR over time ($p = .08, \eta^2 = .11$). Total kcal decreased over time ($p = .002, \eta^2 = .32$) such that intake at T1 was greater than T2 and T3, and there were no effects of sex over time ($p = .20, \eta^2 = .10$). CO appeared to increase over time.

CONCLUSION: Our preliminary data suggest that concussions may influence whole-body and carbohydrate metabolism in a sex specific manner. While not significant, there was a moderate effect of sex on RMR where males increased from T1 to T3 and females did not, and there may have been an acute decrease in CO which elevated

throughout recovery. CI was elevated acutely and decreased throughout recovery, but macronutrient intake ratios did not drastically change. Further investigations of these measures with a larger sample size is warranted given our preliminary data.

Table 1. Demographic, Substrate Utilization, and Food Preference Descriptive Statistics*

Effects of Time Restricted Feeding on Peak VO₂ and Substrate Utilization in Healthy Adults

Corbyn R. Bendtsen, Megan M. Coyle, Megan M. Lind, Nicole L. Schweitzer, Eric A. Norman, Lauren M. Kaminski, Cassandra A. Fileccia, Marquel A. Fleischacker, Andrew L. Kezar, Emma P. Masiulewicz, Justin R. Geijer. *Winona State University, Winona, MN.*

(No relevant relationships reported)

Time Restricted Feeding (TRF) is a type of Intermittent Fasting, which refers to the finite time to intake calories during the day. TRF has become a dietary approach that is used for weight loss and overall health. Individuals that partake in TRF may experience a decrease in peak volume of oxygen uptake (VO_{2peak}) due to minimization of glycolytic stores. To date, few studies have compared the impact of TRF on VO_{2peak}. **PURPOSE:** The current study aimed to further investigate the metabolic impact of TRF. **METHODS:** Twenty one participants, ages 18-60, completed an eleven week longitudinal study to examine differences in VO_{2peak}, substrate utilization crossover, and resting substrate utilization. Participants self-reported diet, exercise, sleep, and medications over two separate four week periods. The first four weeks were without TRF and the following four were with TRF. A maximal exercise test and a resting metabolic test were performed three times, four weeks apart from each other. A repeated measures ANOVA was performed to determine within subject differences. A post-hoc analysis was performed to determine the time effect. **RESULTS:** VO_{2peak} was significantly lower after implementing TRF ($p < 0.001$). The mean pre-test VO_{2peak} was 2.95 ± 0.59 L/min and the non-TRF testing was 3.14 ± 0.68 L/min. During TRF, the mean was 2.76 ± 0.54 L/min. There was a significant difference between the pre-test and TRF ($p = 0.012$). Also, there was a significant difference between non-TRF and TRF ($p = 0.002$). Resting RQ showed a significant increase ($p < 0.004$). The pre-test mean for resting RQ was 0.716 ± 0.071 . Non-TRF resting RQ had a mean of 0.736 ± 0.082 and the TRF resting RQ was 0.802 ± 0.097 . There was a significant difference between the pre-test and TRF ($p = 0.010$). Substrate utilization crossover showed a significant decrease ($p < 0.03$) in fat usage after TRF implementation. There was a significant difference between the pre-test (123.9 ± 30.1 watts) and TRF (98.8 ± 30.1 watts; $p = 0.05$). **CONCLUSION:** An earlier crossover of substrate utilization implies a decrease in fat usage and an increase in carbohydrate usage, therefore significantly lowering fat oxidation and VO_{2peak}. Future studies are needed to examine the physiological mechanisms that may lead to shifts in substrate utilization during TRF.

The Impact of Energy Balance on Sleep Time and Recovery

Andrew Jagim, Hannah Zabriskie, Brad Currier, Patrick Harty, Richard Stecker, Chad M. Kerkick, FACSM. *Lindenwood University, St. Charles, MO.* (Sponsor: Chad Kerkick, FACSM)
 Email: andrew.jagim@gmail.com

(No relevant relationships reported)

In female athletes, prolonged energy deficits have been demonstrated to negatively influence performance, recovery, and impair sleep. **PURPOSE:** The purpose of this study was to evaluate the relationship between energy status, sleep quality, recovery and training satisfaction in Division II female lacrosse players. **METHODS:** Twenty-two female lacrosse players (20.4 ± 1.79 years, 69.1 ± 8.7 kg, 168 ± 6.3 cm, $28.1 \pm 2.99\%$ fat) wore a physical activity monitor to assess total daily energy expenditure (TDEE) and recorded dietary intake using MyFitnessPal over a four-day period during NCAA season play. Energy balance over the four-day period was then calculated based on the sum of total energy in - TDEE. Upon returning the physical activity

monitor, players also completed a questionnaire that assessed total sleep, sleep quality, ratings of recovery, soreness and satisfaction with training using visual analog scales. **RESULTS:** Players presented with an average energy deficit of $-1,186.85$ kcal/d (SD = 813.09) and an average of 6.77 (SD = 1.02) hrs. of sleep per night. Those in a state of higher energy balance reported more hours of sleep ($r = 0.641$, $p = 0.001$), felt more rested ($r = 0.535$, $p = 0.01$) and were more satisfied with training ($r = 0.484$, $p = 0.023$). **CONCLUSION:** Our results imply that an improved energy state helps to facilitate an increase in total hours slept. An improved energy state also appears to result in athletes feeling more rested and satisfied with training during the competitive season. Female lacrosse players demonstrated that a more favorable state of energy balance appears to be associated with more total hours of sleep, feeling better rested and being more satisfied with training. Therefore maintaining a positive energy balance should be a primary focus for coaches and athletes to help promote optimal training, performance, and recovery.

1411 Board #173 May 30 10:30 AM - 12:00 PM
"Train-high Sleep-low" Dietary Periodization Does Not Alter Ventilatory Strategies During Cycling Exercise

Hunter L. Paris¹, Timothy J. Fulton², Daniel P. Wilhite³, Marissa N. Baranaukas², Robert F. Chapman, FACSM², Timothy D. Mickleborough². ¹Pepperdine University, Malibu, CA. ²Indiana University, Bloomington, IN. ³Southwestern Medical Center, Dallas, TX.

(No relevant relationships reported)

"Train-high sleep-low" (THSL) dietary periodization elicits favorable adaptations within skeletal muscle, and improves endurance exercise performance. The effect of THSL on ventilatory patterns during exercise, however, has received little attention. If THSL alters ventilatory strategies during exercise, then exercise intensities and adaptations may unknowingly be influenced. **PURPOSE:** To investigate the effects of short-term exposure to THSL dietary periodization on ventilatory strategies during cycling exercise at submaximal and maximal intensities. **METHODS:** Eight trained men [age (mean \pm SEM) = 28 ± 1 y; $\dot{V}O_{2peak}$ = 56.8 ± 2.4 ml·kg⁻¹·min⁻¹] completed a glycogen-depleting protocol on a cycle ergometer. Afterwards, participants were given a low carbohydrate (CHO) meal and beverages containing either no additional CHO (THSL) or beverages containing 1.2 g·kg⁻¹ CHO [traditional CHO replacement (TRAD)]. The following morning, participants completed 4 min of cycling below (Stage 1), at (Stage 2), and above (Stage 3) gas exchange threshold, followed by a 5 km time-trial. Metabolic data were collected continuously throughout exercise. Inspiratory capacity maneuvers were performed in the last minute of each stage as well as during the time-trial, for calculation of expiratory reserve volume (ERV) and inspiratory reserve volume (IRV). **RESULTS:** Respiratory exchange ratio (RER) was significantly lower ($P < 0.01$) in THSL compared to TRAD at every exercise stage. During Stage 1, $\dot{V}O_2$ was 37.9 ± 1.5 mL·kg⁻¹·min⁻¹ in the TRAD condition and 39.6 ± 1.8 mL·kg⁻¹·min⁻¹ in THSL ($P = 0.05$). During Stage 2, $\dot{V}O_2$ was 44.6 ± 1.7 mL·kg⁻¹·min⁻¹ in the TRAD condition and 47.0 ± 1.9 mL·kg⁻¹·min⁻¹ in THSL ($P = 0.07$). No differences in \dot{V}_E , V_T , or $\dot{V}CO_2$ occurred between conditions at any exercise intensity ($P > 0.05$). No change in ERV or IRV was detected between dietary conditions at any exercise intensity ($P > 0.05$). 5 km time-trial performance was significantly faster in TRAD compared to THSL (8.7 ± 0.3 min and 9.0 ± 0.3 min, respectively; $P = 0.02$). **CONCLUSIONS:** THSL dietary periodization does not alter $\dot{V}E$, $\dot{V}CO_2$, V_T , ERV, or IRV when cycling at submaximal or maximal intensities. THSL impairs performance immediately following the dietary intervention, and may influence $\dot{V}O_2$ at submaximal intensities.

Low Carbohydrate Intake Is Related To Energy Deficiency And Hypometabolism In Physically Active Population

Amanda Santos, Gisele Vaz, Cintia Oliveira, Daniel Lima. *Itaúna University, Itaúna, Brazil.*
 Email: dcarvalholima@gmail.com

(No relevant relationships reported)

PURPOSE: The aim of this study was to analyse metabolic factors associated to energy availability deficiency (EAD) in physically active people. **METHODS:** We evaluated 147 physically active people. The free fat mass (FFM), caloric intake (CI) and energy expenditure (EE) were analysed by Petroski (1995) protocol, 3-day self-reported food journal and metabolic equivalent calculation, respectively. Energy deficiency was assumed at ≤ 30 Kcal/Kg FFM/day by the EA equation: (CI - EE) x FFM (kg)⁻¹. The hypometabolism was diagnosed when the ratio between resting metabolic rate (measured by indirect calorimetry) and Cunningham equation values was < 0.90 . The associations were analysed by Pearson correlation, Chi-squared, Odds Ratio (IC 95%) and Fisher's tests, considering $p < 0.05$. **RESULTS:** We observed 80% of EAD. The hypometabolism was presented in 37% of ED people. Also, they had carbohydrate (2.8 ± 1.1 g/kg bw) and fat (0.76 ± 0.3 g/kg bw) consumption below the recommendations. As expected, the lower macronutrients caloric intake

were related to reduced energy availability in EAD sportspeople (carb., $r=0.60$; prot., $r=0.35$; e; fat, $r=0.66$; $p<0.05$). Interestingly, the magnitude of its reductions was greater in carbohydrate, analysed by slope curves (carb., 25 ± 3 ; prot., 9 ± 2 ; fat, 16 ± 2 ; $p<0.001$). In addition, only carbohydrate intake was independently associated to hypometabolism in EAD population (OR, 2.91; IC 95%, 1.08 - 7.82; $p<0.05$). **CONCLUSION:** Low carbohydrate intake is the major diet contributors to energy deficiency and hypometabolism development in physically active people. It may impair the weight loss protocols.

Acute Carbohydrate Restriction During Recovery From Prolonged Exercise Enhances Intramuscular Triglyceride Resynthesis

Sam Shepherd¹, Emily FP Jevons¹, Juliette A. Strauss¹, Kasper D. Gejl², Kurt Jensen², Lars G. Hvid², Ulrik Frandsen², Kent Sahlin³, Niels Ørtenblad². ¹Liverpool John Moores University, Liverpool, United Kingdom. ²University of Southern Denmark, Odense, Denmark. ³Stockholm University, Stockholm, Sweden. Email: s.shepherd@ljmu.ac.uk
 (No relevant relationships reported)

Intramuscular triglyceride (IMTG) is an important substrate during moderate-intensity exercise, but providing a high carbohydrate (CHO) diet following exercise impairs IMTG resynthesis. Restricting CHO intake in the post-exercise period may augment the adaptive response to exercise, but whether this strategy enhances IMTG resynthesis is not known. Furthermore, because the lipid droplet (LD)-associated perilipin (PLIN) proteins promote IMTG storage, their distribution and interaction with LD may determine their role in post-exercise IMTG resynthesis. **Purpose:** To determine the effect of acutely restricting CHO during recovery from prolonged exercise on IMTG resynthesis and PLIN protein dynamics. **Methods:** 14 male triathletes (27 ± 1 y, 66.5 ± 1.3 ml.kg⁻¹.min⁻¹) completed 4 h of cycling at $\sim 56\%$ VO_{2max} . In the initial 4 h period following exercise 7 participants consumed a high CHO diet whereas 7 participants consumed only water. For the remaining recovery period (20 h) all participants received the same CHO-rich diet. Muscle samples collected pre and post-exercise, and 4 and 24 h post-exercise were analysed using confocal immunofluorescence microscopy to determine muscle fibre type-specific IMTG content and PLIN localisation to LDs. **Results:** Exercise reduced IMTG content in type I fibres (-53% , $P<0.05$), with LD both associated and not associated with PLIN2, PLIN3, and PLIN5 being used. During recovery, IMTG content tended to increase in type I fibres after 4 h in the water condition only ($+63\%$, $P=0.076$), and at 24 h IMTG content was similar to pre-exercise levels ($P=0.987$). Despite no change in PLIN protein content, the number of LD with PLIN2 or PLIN3 associated tended to increase during recovery in type I fibres only ($P=0.08$), and to a similar extent between conditions, whereas the number of LD with PLIN5 associated only increased in the CHO condition ($P=0.002$). **Conclusion:** Acute restriction of CHO during recovery from prolonged exercise has a tendency to initially enhance IMTG resynthesis, although a CHO-rich diet does not impair overall IMTG resynthesis 24 h later. A redistribution of PLIN proteins appears to support post-exercise IMTG resynthesis, but the predominant PLIN isoform supporting post-exercise IMTG storage may be dependent on post-exercise CHO availability.

ACSM SCIENTIFIC ABSTRACT

INTRODUCTION: Tactical training personnel are exposed to frequent intense physical activity and sleep deprivation, the combination of which may compromise health. Insufficient energy availability (EA) can exacerbate these issues. **PURPOSE:** The aims of this study were to investigate in tactical training personnel, i) energy intake (EI), exercise energy expenditure (EEE) and EA, ii) reported injury and illness incidence and iii) dietary intake vs. estimated nutritional recommendations. **METHODS:** On four consecutive days during two weeks of tactical training, nine weeks apart, participants recorded all food eaten in a smartphone application (Nutritics Education v4.315, 2011). Injury and illness incidence were recorded weekly using the Oslo Sports Trauma Research Centre Questionnaire on health problems and the females completed the Low Energy Availability in Females Questionnaire (LEAF-Q) to assess risk of low energy availability (LEA). **RESULTS:** Mean daily EI was 2523 (± 469) kcal for males and 2182 (± 380) kcal for females. EEE increased significantly from W1 (Mean= 656 kcal, ± 76) to W2 (Mean=842 kcal, ± 93) $P<0.001$. Insufficient carbohydrate (3.3g/kg BW/day vs. recommended 6g/kg BW/day, $P<0.001$) and excess fat consumption was observed (37% dietary energy (DE) vs. the recommended 20-35% DE). There were 274 reported health problems; 160 injuries and 114 illnesses. Of females, 59% were classified as at risk of LEA. **CONCLUSIONS:** These findings demonstrate the need to improve awareness of EA during training for health and performance. Implementation of adequate fueling strategies is necessary for tactical training personnel to optimise health and performance.

The Effects of Endurance Training Under Low Energy Availability on Muscle Glycogen Contents

Chihiro Kojima¹, Aya Ishibashi², Yoko Tanabe², Kaito Iwayama³, Akiko Kamei², Hideyuki Takahashi², Kazushige Goto¹. ¹Ritsumeikan University, Shiga, Japan. ²Japan Institute of Sports Sciences, Tokyo, Japan. ³Tenri University, Nara, Japan. (Sponsor: Robert Kraemer, FACSJM) Email: chii.2727@gmail.com
 (No relevant relationships reported)

PURPOSE: Some previous studies demonstrated that acute bout of exercise suppressed appetite and reduced energy intake among athletes. However, the accumulative effects of reduced energy intake during consecutive days of training period remains unclear. The purpose of the present study was to investigate the influences of 3 days of endurance training under low energy availability on muscle glycogen content, endocrine responses and endurance capacity. **METHODS:** Seven male long distance runners (19.9 ± 0.4 years, 175.6 ± 1.8 cm, 61.4 ± 2.0 kg, 67.5 ± 1.6 ml/kg/min) completed 3 consecutive days of endurance training under low energy availability trial (LEA, 18.9 ± 0.7 kcal/kg FFM/day) and normal energy availability trial (NEA, 52.9 ± 1.9 kcal/kg FFM/day). The order of two trials was randomized with two weeks interval between trials. The experiment consisted of 3 consecutive days of endurance training (days 1-3) and exercise performance test on the following morning (day 4). The endurance training consisted of 75 min of treadmill running at 70% of maximal oxygen uptake (VO_{2max}) in both trials. Muscle glycogen contents, respiratory gas variables, subjective parameters, blood and urinal variables were evaluated in the morning during 3 days of training periods (day 1-day 3) and on the following morning after the training (day 4). As an indication of endurance capacity, time to exhaustion during submaximal running test was determined on day 4. **RESULTS:** LEA trial showed that body weight, free fat mass and skeletal muscle volume were significantly reduced during training period ($P<0.05$). Also, muscle glycogen contents were significantly decreased in LEA ($P<0.001$) with significant lower values than those in NEA trial ($P<0.001$). Blood glucose, serum free testosterone and insulin like growth factor-1 concentrations were significantly lowered with training under LEA ($P<0.05$). On the other hand, serum leptin concentration did not change significantly in LEA trial during training period ($P>0.05$). Time to exhaustion during submaximal running test evaluated on day 4 was not significantly different between LEA trial (1170 ± 127 s) and NEA trial (1361 ± 196 s, $P>0.05$). **CONCLUSION:** Three consecutive days of endurance training under Low EA reduced muscle glycogen content. However, endurance capacity was not attenuated.

Acute Effects of Exercise With and Without Energy Replacement on Energy Expenditure and Substrate Utilization

Jie Kang, FACSM, Saif B. Hassan, Nicole L. Ellis, Ira T. Vought, Nicholas A. Ratamess, Jill A. Bush, FACSM, Avery D. Faigenbaum, FACSM. *The College of New Jersey, Ewing, NJ.*
 Email: kang_08055@yahoo.com
 (No relevant relationships reported)

It has been well documented that exercise of sufficient energy expenditure can elicit an increase in fat oxidation that persists following exercise. However, whether and how this exercise-induced metabolic benefit would be affected by replacing the energy expended during exercise remains unclear. **Purpose:** To compare energy expenditure and substrate utilization between exercise with and without energy replacement at rest and during exercise. **Methods:** Fourteen healthy and recreationally trained subjects including 7 men and 7 women volunteered to participate in this study. Each subject underwent three 2-day experimental protocols in a random order. Each protocol consisted of no exercise (NE), exercise only (EO), or exercise with energy replacement (ER) on day 1 that was followed by metabolic assessment that took place in a fasted condition on day 2. The exercise in EO and ER was a treadmill running at 60% $\dot{V}O_{2max}$ that induced an energy expenditure of 500 kilocalories. The replacement meal used in ER contained 500 kilocalories made up by 45% carbohydrate, 30% fat, and 25% protein. During the metabolic assessment, oxygen uptake ($\dot{V}O_2$), heart rate (HR), respiratory exchange ratio (RER), and rates of carbohydrate (COX) and fat oxidation (FOX) were determined in three successive 10-min periods that included rest, exercise at 50% $\dot{V}O_{2max}$ and exercise at 70% $\dot{V}O_{2max}$. **Results:** No differences in $\dot{V}O_2$ and HR were found at rest between NE, EO, and ER. However, RER was lower in EO than NE (0.840 ± 0.014 vs. 0.889 ± 0.012 , $p < 0.05$), COX ($\text{g} \cdot \text{min}^{-1}$) was lower in ER than NE (0.144 ± 0.016 vs. 0.197 ± 0.019 , $p < 0.05$), and FOX ($\text{g} \cdot \text{min}^{-1}$) was higher in either EO or ER than NE (0.054 ± 0.010 or 0.057 ± 0.009 vs. 0.034 ± 0.007 , $p < 0.05$). When these variables were compared under the exercise conditions, no treatment effects were noted for all variables at either intensity. **Conclusion:** Our results demonstrate that an acute bout of aerobic exercise can elicit an increase in fat oxidation even when the exercise-induced energy deficit is replaced by energy intake. These findings suggest that factors other than caloric deficit mediate the exercise-induced lipolytic effect.

Comparing Liver And Skeletal Muscle Sensitivity In Response To Acute And Chronic Calorie Restriction

Erik Kirk, FACSM¹, Dominic Reeds², Sam Klein². ¹*Southern Illinois University Edwardsville, Edwardsville, IL.* ²*Washington University School of Medicine, Saint Louis, MO.*
 Email: ekirk@siue.edu
 (No relevant relationships reported)

PURPOSE: We determined the effects of acute and chronic calorie restriction on hepatic and skeletal muscle insulin sensitivity. **METHODS:** Twenty-three obese subjects (body-mass index, $36.3 \pm 0.7 \text{ kg/m}^2$) followed an energy-deficit diet (1,200kcal/day). Magnetic resonance spectroscopy, muscle biopsies, and a euglycemic-hyperinsulinemic clamp were used to determine insulin action, cellular insulin signaling and intrahepatic triglyceride content before, after 48-h, and after ~12 wks (7% weight loss) of diet therapy. **RESULTS:** Intrahepatic triglyceride content significantly decreased at both 48-h ($-16.6 \pm 2.3\%$, $p < 0.001$) and 7% weight loss ($-40.7 \pm 6.2\%$; $p < 0.001$) compared to baseline. Basal glucose production rate significantly decreased at 48-h ($-21.8 \pm 3.2\%$, $p < 0.001$) and after 7% weight loss ($-20.8 \pm 3.4\%$, $p < 0.001$). Insulin-mediated glucose uptake did not significantly change at 48-h ($-5.2 \pm 12.8\%$, $p > 0.05$) but did significantly increase at 7% weight loss ($26.1 \pm 4.3\%$, $p < 0.05$). Insulin-stimulated phosphorylation of Jun N-terminal kinase did not change at 48-h ($-0.2 \pm 16.2\%$, $p > 0.05$) but did significantly decrease at 7% weight loss (-29.9 ± 12.6 , $p < 0.05$) and phosphorylation of Akt increased by $15.2 \pm 14.6\%$ ($p > 0.05$) and $36.2 \pm 8.8\%$ ($p < 0.05$), after 48-h and 7% weight loss, respectively. **CONCLUSION:** A low calorie diet acutely reduced intrahepatic triglyceride content and improved hepatic insulin sensitivity whereas moderate weight loss is necessary to improve insulin sensitivity in the skeletal muscle.

Neither Autophagy Inhibition Nor High Intensity Interval Training Alter Exercise Adaptations During High Fat Feeding

Megan E. Rosa-Caldwell, Lisa T. Jansen, Seongkyun Lim, Kirsten R. Dunlap, Wesley A. Haynie, Katarina A. Bejarano, Tyrone A. Washington, Nicholas P. Greene. *University of Arkansas, Fayetteville, AR.* (Sponsor: Dr. Matthew Gano, FACSM)
 Email: mrosa@uark.edu
 (No relevant relationships reported)

Obesity and associated comorbidities remain a significant health crisis. Exercise mitigates many of these pathologies, however, controversy remains on optimal exercise types for favorable adaptations. More so, mechanisms underlying these adaptations are not fully understood. Evidence suggests autophagy (cellular degradation and recycling of proteins) may be an important mediator for adaptations, however, the necessity of autophagy, specifically autophagosome formation, on exercise adaptations during obesity has yet to be investigated. **PURPOSE:** To investigate the individual and combined effects of different exercise interventions and autophagy inhibition on glucose handling and exercise capacity after high fat feeding. **METHODS:** C57BL/6J male mice initiated 45% high fat diet at 8 wks of age. After 6 wks of high fat diet, animals were divided into moderate intensity (MOD) or high intensity interval training interventions (HIIT), animals were further subdivided into autophagy inhibition (AI) or control (CON) conditions. Animals exercised their respective protocols 3X/wk; work and average intensity were matched between exercise groups. Autophagy was inhibited by 3X/wk injections of NSC185058 at 100mg/kg of bodyweight, to block autophagosome formation, CON animals received vehicle injections. Animals continued interventions for 4 wks. Glucose tolerance tests (GTTs) and graded exercise tests (GXTs) were completed pre-high fat diet, pre-interventions, and post-interventions. **RESULTS:** High fat diet resulted in impaired glucose handling (~20% increase in glucose area under the curve (AUC)), while exercise interventions normalized glucose handling to pre-exercise levels, without any differences between groups. Additionally, high fat diet induced a ~20% lower aerobic capacity, which were normalized to baseline values after exercise interventions. AI animals had ~2.5g of weight loss from pre- to post- exercise interventions with no differences noted in CON animals. **CONCLUSIONS:** When exercise intensities and total work are matched, HIIT and MOD confer similar adaptations on exercise capacity and glucose tolerance in high fat fed mice. Also, late stage autophagy inhibition does not influence exercise adaptations, but does appear to influence body weight, which warrants further investigation.

Effects of Time Restricted Feeding on Resting Energy Expenditure and Respiratory Quotient

Lauren M. Kaminski¹, Cassandra A. Fileccia², Corbyn R. Bendtsen², Megan M. Coyle², Marquel A. Fleischacher², Megan M. Lind², Emma P. Masiulewicz², Nicole L. Schweitzer², Eric A. Norman², Andrew L. Kezar², Justin R. Geijer². ¹*Winona State, Buffalo, MN.* ²*Winona State, Winona, MN.*
 (No relevant relationships reported)

Time restricted feeding (TRF) is a form of dietary intake which limits the feeding time in a day. Researchers have observed weight loss and improved body composition as the original motivators for investigation of TRF. With a variation in energy intake during TRF, resting energy expenditure (REE) has been shown to increase with high caloric consumption. An increase in REE is also associated with an increase in fat free mass and physical activity. Respiratory quotient (RQ) demonstrates the ratio between CO_2 production and O_2 uptake, determining substrate utilization at rest. RQ has been shown to change through altered macronutrient intake. Studies indicate, a diet high in carbohydrate intake increases RQ whereas diets high in fat intake have been shown to lower RQ. RQ has also been found to decrease when subjects partake in endurance training. **Purpose:** The intent of this study was to determine the impact TRF may have on REE and RQ. **Methods:** Thirty-four apparently healthy adults ages 19-51 participated in 4 weeks non-TRF and 4 weeks of TRF. The feeding window for the TRF was a nine-hour period. Participants were provided journals over the course of the study to self-record caloric intake, exercise type, and duration. REE and RQ were measured using a metabolic cart initially, after 4 weeks of non-TRF, and 4 weeks after TRF. Data was analyzed using IBM SPSS statistics. **Results:** RQ increased significantly between pretest (0.721 ± 0.015) and TRF testing (0.808 ± 0.02) ($p = 0.01$). No significance was found between non-TRF and TRF. REE had no significant difference between any of the three testing periods ($p = 0.233$). There was no significant change in caloric intake throughout the testing ($p = 0.94$). A significant decrease was found in total exercise days between non-TRF and TRF periods ($p = 0.023$). **Conclusion:** This study did not find a significant change in REE during TRF. The increase in RQ may be attributed to increases in carbohydrate intake. Caloric intake was hypothesized to increase the first couple of days due to the time-restricted nature, but overall was not

hypothesized to have a significant impact on energy intake or REE. Future studies should investigate the impact of TRF on macronutrient intake and carbohydrate utilization at rest.

Resistance Exercise-mediated Improvements In Post-prandial Metabolic Responses Are Related To Exercise Volume And Muscle Mass

Patrick M. Tomko, Ryan J. Colquhoun, Nile F. Banks, Christina M. Sciarrillo, Nicholas A. Koemel, Sam R. Emerson, Nathaniel D.M Jenkins. *Oklahoma State University, Stillwater, OK.*
 (No relevant relationships reported)

PURPOSE: To examine the effects of full-body resistance exercise on the post-prandial metabolic response to a high-fat meal (HFM) in healthy men. **METHODS:** Ten males (mean \pm SD, age = 24 ± 3 y, BMI = 26.8 ± 2.9 kg/m²) participated in this randomized, repeated measures, crossover study. Participants visited the laboratory for familiarization, and baseline strength and body composition testing. They then returned to the laboratory and completed either a session of resistance exercise (RE), consisting of three sets of 8 exercises using a 12 repetition maximum load, or no exercise (NE) and consumed a protein shake (300 - 400 kcal; protein = 0.3/kg) as their last meal. After a 12-h overnight fast, participants consumed a HFM (12 kcal/kg, 63% fat, 34% carbohydrate). Blood draws were performed prior to, and 1-, 3-, and 5-h post-meal to determine triglyceride (TG), glucose (GLU), and total metabolic load index (MLI; sum of TG and GLU) responses. Three separate, 2 (Condition) \times 2 (Time) repeated measures ANOVAs were used to examine the TG, GLU, and MLI responses. Zero-order correlations and stepwise multiple regression analyses were used to examine the relationships and relative contributions of RE volume (VOL) and skeletal muscle mass (SMM) to the change in MLI from NE to RE (Δ MLI). **RESULTS:** There were significant condition \times time interactions for TG ($F_{3,27} = 3.5$; $p = 0.03$) and MLI ($F_{3,27} = 3.0$; $p < 0.05$). Both TG and MLI were lower at 3- (TG, 152.6 ± 74.8 vs. 182.4 ± 103.9 mg/dL; MLI, 224.2 ± 72.9 vs. 257.4 ± 106.8 au) and 5-h (TG, 132.2 ± 85.3 vs. 175.6 ± 118.0 mg/dL; MLI = 210.5 ± 86.3 vs. 260.2 ± 119.0 au) post HFM in the RE versus NE condition, respectively. There were condition ($F_{1,9} = 8.9$; $p = 0.02$) and time main effects ($F_{3,27} = 8.4$; $p < 0.01$) for GLU. GLU was lower in the RE (76.4 ± 7.1 mg/dL) than NE (82.4 ± 6.8 mg/dL) condition and decreased from baseline (88 ± 3.6 mg/dL) to 1- (74.6 ± 6.4 mg/dL), 3- (73.3 ± 2.4 mg/dL), and 5-h (81.5 ± 4.5 mg/dL). Both VOL ($r = 0.66$) and SMM ($r = 0.80$) were independently related to, and significantly contributed to the prediction ($R^2 = 0.76$; beta coefficients = VOL [-1.03] and SMM [1.79]) of Δ MLI. **CONCLUSIONS:** A session of full-body resistance exercise improves the postprandial metabolic response to a HFM in healthy men. Further, VOL and SMM explained 76% of the variance in the metabolic response improvement caused by resistance exercise.

Energy Expenditure and Load Carriage Exceeded Military Recommendations in Special Operations Forces Deployed to Afghanistan

William R. Conkright¹, Nicholas D. Barringer². ¹University of Pittsburgh, Pittsburgh, PA. ²U.S. Army Research Institute of Environmental Medicine, Natick, MA.
 Email: wrc16@pitt.edu
 (No relevant relationships reported)

U.S. Army Special Operations Forces (SOF) undergo difficult missions in extreme environments, oftentimes while carrying heavy loads, the combination of which results in a high energy output. Energy expenditure in excess of intake may result in weight loss and impaired performance. In a scenario where energy demands consistently exceed intake, Soldiers are at increased risk of injury and mission compromise. **PURPOSE:** To determine the energy expenditure of SOF Soldiers based on present-day missions in the Central Command (CENTCOM) region. **METHODS:** Demographics of the participants were as follows: age (yrs) 30.3 ± 3.5 , height (in) 70.65 ± 2.8 , weight (lbs) 195.2 ± 24 , enlisted (86%), officer (7%), warrant officer (7%), years in the Army 8.3 ± 3.9 , and total time deployed during career (yrs) 1.26 ± 1.2 . Surveys were collected from 46 SOF Soldiers operating in eight locations in the CENTCOM theater of operations. Information from the surveys revealed the mission energy requirements and difficulty of exertion pre-, during-, and post-mission. A physical activity factor was determined based on multiple aspects surrounding mission intensity and used to calculate estimated energy expenditure based on a SOF-specific equation. **RESULTS:** During a six-month deployment, participants underwent a multitude of missions (17.25 ± 8.66). Ninety percent of respondents reported carrying a load 40% heavier than the recommended fighting load (32.9 ± 8.62 vs. 21.8 kg, respectively) based on military doctrine. Average estimated energy expenditure (4848 ± 525 kcal-day⁻¹) far exceeded the military dietary reference intake of 3400 kcal-day⁻¹. All but three respondents reported a rate of energy expenditure exceeding the benchmark of 300 kcal-day⁻¹ necessary to maintain adequate energy reserves upon enemy contact. **CONCLUSION:** Excessive load carriage is a major contributor to

high energy expenditure. The reported loads carried by SOF Soldiers exceeded the recommendations in Army doctrine. Additionally, their high energy expenditure, if not matched by an equally high energy intake, has been shown to result in performance decrements and may compromise mission success. Special attention must be given to pack weights during pre-mission planning and nutrition strategies aimed at meeting mission demands and recovery from strenuous activity.

Effects Of Menstrual Cycle On Energy Utilization And Endurance Performance In Eumenorrheic Women

Tomoka Matsuda¹, Mizuki Yamada², Hazuki Ogata¹, Kayoko Kamemoto¹, Mikako Sakamaki-Sunaga². ¹Graduate School, Nippon Sport Science University, Tokyo, Japan. ²Nippon Sport Science University, Tokyo, Japan.
 (No relevant relationships reported)

The blood concentrations of estrogen and progesterone change during various phases of the menstrual cycle. The levels of estrogen and progesterone are lower during the menstrual period (MP) and higher during the luteal phase (LP) in eumenorrheic women. Previous studies have indicated that the menstrual cycle influences energy utilization during endurance exercises. Alterations in energy utilization that may occur during the different phases of the menstrual cycle in eumenorrheic women may also influence endurance performance.

PURPOSE: The purpose of this study was to compare energy utilization and endurance performance between the MP and LP of the menstrual cycle during exercise.

METHODS: The subjects were fifteen women (age, 22.1 ± 1.0 years) with regular menstrual cycle. Subjects exercised on a cycle ergometer at 60% $\dot{V}O_{2peak}$ for 45 min, and then exercise intensity was increased to 80% $\dot{V}O_{2peak}$ until exhaustion during the two phases of the menstrual cycle (MP and LP). Blood samples were collected at rest, 45 min during exercise, immediately after exercise, and 30 min after completion of exercise. Blood levels of estradiol, progesterone, glucose, and free fatty acid (FFA) were assessed. The duration of each menstrual cycle phase was estimated by assessing the levels of the estradiol and progesterone.

RESULTS: The menstrual cycle of the subjects was 30.9 ± 1.9 days. MP was 4.1 ± 1.4 days, and LP was 24.8 ± 2.2 days. Blood concentrations of estradiol (MP, rest, 35 ± 14.6 pg/mL; LP, rest, 164 ± 58.3 pg/mL, $p < 0.001$) and progesterone (MP, rest, 0.3 ± 0.2 ng/mL; LP, rest, 13.1 ± 5.0 ng/mL, $p < 0.001$) were significantly higher in LP than in MP. No significant differences were observed in the levels of glucose ($p = 0.36$), FFA ($p = 0.80$), and respiratory exchange ratio ($p = 0.34$) at all time points. Carbohydrate oxidation (MP, 38.5 ± 7.7 g; LP, 39.2 ± 6.4 g, $p = 0.66$), fat oxidation (MP, 11.6 ± 2.9 g; LP, 11.2 ± 3.4 g, $p = 0.64$), and exercise time to exhaustion were not different between MP and LP (MP, 7.4 ± 7.9 min; LP, 6.8 ± 6.0 min, $p = 0.55$).

CONCLUSION: Our results reveal no effect of the menstrual cycle phase on substrate oxidation and prolonged endurance exercise performance during cycle ergometer exercise in eumenorrheic women.

A Short-term Calorie Restricted Diet with High-fat on Inflammatory Biomarkers and Plasma Lipids

Yunsuk Koh. Baylor University, Waco, TX.
 Email: yunsuk_koh@baylor.edu
 (No relevant relationships reported)

A high-fat (HF) diet may play a positive role in weight management and body composition, yet its role in inflammation and blood lipids is not clearly understood.

PURPOSE: To examine the effects of a short-term calorie restricted diet with HF or high-carbohydrate (HC) and an acute bout of exercise on plasma lipids and inflammatory biomarkers. **METHODS:** In a randomized, cross-over design, 9 physically inactive college-aged individuals were assigned to a calorie restricted diet (20% reduction of total calorie intake from their typical diet) with either HF or HC for 2 weeks. The HF diet consisted of 70% fat (mostly mono- and poly-unsaturated fatty acids) and 30% carbohydrate and protein, whereas the HC diet consisted of 70% carbohydrate and 30% fat and protein. There was a one-week wash-out period between the two diet interventions. At the end of each diet intervention, a single bout of aerobic exercise was performed at 70% heart rate reserve for 40 minutes. Overnight fasting blood samples were collected at pre- and 24-hours post-exercise at the end of each diet intervention (pre-intervention, HF, and HC) to analyze changes in the key biomarkers of inflammation and plasma lipids, including glucose and triglycerides.

RESULTS: Either HF or HC diet did not change any inflammatory biomarkers or plasma lipids. However, a single bout of exercise significantly decreased B-cell activating factor (BAFF, 1619.37 ± 446.57 to 1520.94 ± 476.05 pg/mL, $p = 0.019$), matrix metalloproteinase-3 (MMP-3, 1700.82 ± 1090.16 to 1227.33 ± 976.38 pg/mL, $p = 0.021$), thymic stromal lymphopoietin (TSLP, 2.38 ± 1.4 to 1.88 ± 1.0 pg/mL, $p = 0.048$), and TNF-related weak inducer of apoptosis (TWEAK, 26.26 ± 10.36 to 22.53 ± 3.0 pg/mL, $p = 0.048$). **CONCLUSION:** A short-term calorie restricted diet with either HF or HC may not significantly influence soluble inflammatory markers or plasma lipids. However, a single bout of aerobic exercise, independent of dietary modification, can

improve inflammatory responses in healthy, sedentary young adults. Future studies need to further examine the effects of a long-term diet intervention on the responses of inflammatory markers in a variety of subject populations, including obese and patients with metabolic diseases in order to better understand the role of high-fat diet in inflammation.

Impact of Time Restricted Feeding on Muscular Strength Within a Healthy Adult Population.

Eric A. Norman, Nicole L. Schweitzer, Corbyn R. Bendtsen, Megan M. Coyle, Cassie A. Fileccia, Marquel A. Fleischacker, Lauren M. Kaminski, Andrew L. Kezar, Megan M. Lind, Emma P. Masiulewicz, Justin R. Geijer. *Winona State University, Winona, MN.*
 (No relevant relationships reported)

Time restricted feeding (TRF) is a feeding habit that restricts the amount of time during the day in which individuals consume calories. TRF has been shown to produce several health benefits, one of which may be an increase in force production. Muscular strength and nutritional intake have been strongly researched prior to this study. Though little research exists investigating the impacts of TRF on muscular strength in human subjects. **PURPOSE:** The purpose of this study was to identify the potential impacts of TRF on muscular strength. **METHODS:** Participants participated in two, four-week periods during which caloric intake, sleep duration, sleep quality, exercise, and medications were all documented. The first period, participants partook in non-TRF eating behavior. The second period participants were exposed to a nine-hour window of TRF. To measure muscular strength, participants were tested using an isokinetic dynamometer. Resting metabolism was also measured. Statistical analyses quantifying within subject effects were performed with a repeated measures ANOVA. Post-hoc analyses were performed to elicit differences between testing periods. **RESULTS:** Both mean torque flexion at 60 degrees/second (MTF 60) (83.92 Nm \pm 29.53 Nm vs. 95.63 Nm \pm 28.95 Nm) and mean torque flexion at 180 degrees/second (MTF 180) (66.75 Nm \pm 25.9 Nm vs. 69.01 Nm \pm 21.29 Nm vs. 75.55 Nm \pm 23.9 Nm; $F = 7.920$ Nm) had a significant increase from pre-test to TRF, as well as non-TRF to TRF. Post-hoc testing revealed significant differences between pre-test and TRF MTF 60 increased (p-value=0.001). Similar results were found for MTF 180 as well (p-value=0.037). When observing respiratory quotient (RQ) at rest (0.716 \pm 0.077 vs. 0.73 \pm 0.077 vs. 0.08 \pm 0.79; $F = 8.352$) there was a significant increase from pre-test to TRF (p-value=0.008), as well as non-TRF to TRF (p-value=0.034). Lastly, after analyzing total strength training days from non-TRF to TRF (8.11 days \pm 1.18 vs. 5.22 days \pm 1.48), a significant decrease was found (p-value=0.003). **CONCLUSION:** Post TRF, participants showed an increase in muscular strength and resting RQ despite a decrease in strength training. Increased glucose utilization may be linked to short bouts of increased muscular strength activity. Future studies are needed to identify physiological mechanisms behind these findings.

 VClínica de Nutrição Research Institute

Purpose: To evaluate whether the Whole 30 dietary program alters resting energy expenditure, oxygen consumption, and heart rate in CrossFit trained individuals. **Methods:** Sixty four subjects (age range: 21-54 years) attended to nutrition education class to learn food items and recommended volumes comprising the Whole 30 program for 30 days (allowed foods: meats, seafood/ fish, eggs, fruit, vegetables and mono and polyunsaturated fats; forbidden foods: sugar, sweeteners, alcohol, flour, oat, quinoa, corn, rice, starch, beans, soy, milk and dairy products) and underwent a training protocol (4d/week) during the program period. Resting energy expenditure and oxygen consumption were evaluated before the beginning and one day after the end of protocol by indirect calorimetry (CardioCoach, Korr™), and the resting heart rate by oximeter finger. Samples were tested for normal distribution and groups were compared by Student's t-test. The type I error was set at p<0.05. **Results:** Of the 64 initial participants, 38 participants who had no follow-up information were excluded and final analysis was performed in 26 (40.63%) participants. There was a significant reduction in resting energy expenditure (1402 \pm 255.7 vs 1087 \pm 303.3, pre

and post, respectively, p=0.00001), resting oxygen consumption (203.6 \pm 36.91 vs 154.3 \pm 35.58, pre and post, respectively, p=0.0001) and resting heart rate (59.58 \pm 15.32 vs 51.46 \pm 13.73, pre and post, respectively, p=0.0001). **Conclusion:** The Whole 30 dietary program promoted resting energy expenditure, oxygen consumption and heart rate reduction in trained Crossfit individuals, which may be related to the lower carbohydrate consumption proposed by the program.

1426 Board #188 May 30 10:30 AM - 12:00 PM
A Short Term Paleolithic Dietary Intervention Does Not Alter Adipokines Implicated In Obesity

Rachel M. Graff¹, Kristopher Jennings², Natalie A. Davies³, Andres E. Carrillo³, Emily C. LaVoy¹, Edward J. Ryan³, Melissa M. Markofski¹. ¹*University of Houston, Houston, TX.* ²*University of Texas Medical Branch, Galveston, TX.* ³*Chatham University, Pittsburgh, PA.*
 (No relevant relationships reported)

Adipokines, including adiponectin, omentin, nesfatin, and vaspin, are dysregulated with obesity and may respond favorably to diet-induced fat loss. The Paleolithic (Paleo) diet, characterized by an emphasis on hunter-gatherer type foods accompanied by an exclusion of grains, dairy products, and highly processed food items, is often promoted for weight loss and a reduction in cardiometabolic disease risk factors. The **PURPOSE** of this study was to evaluate the effects of an 8-week Paleo dietary intervention on serum adiponectin, omentin, nesfatin, and vaspin levels in a cohort of physically inactive but otherwise healthy adults. **METHODS:** Seven physically inactive adults participated in 8 weeks of a Paleo diet intervention. Anthropometric measures, body composition data, and fasting blood samples were collected from each participant pre- and post-intervention. Serum adiponectin, omentin, nesfatin, and vaspin were measured with commercially available ELISA kits. **RESULTS:** The Paleo dietary intervention elicited reductions (p<0.05) in mean relative body fat (-4.4%), waist circumference (-5.9 cm), and sum of seven-site skinfolds (-36.8 mm). No changes were observed in waist to hip ratio (WHR) or any of the measured adipokines (p>0.05). **CONCLUSIONS:** It is possible that short-term modest fat loss will not induce changes in adiponectin, omentin, nesfatin, or vaspin in apparently healthy but physically inactive adults. Longer-term studies that examine Paleo diet-induced changes across sex, body composition, and in populations with metabolic dysregulation are warranted in order to determine whether the Paleo diet is effective in improving biomarkers related to obesity, metabolism and overall health.

Narrow Cuffs Decrease The Perceptual Of Discomfort With Blood Flow Restricted Exercise

Robert W. Spitz, Raksha N. Chatakondi, Zachary W. Bell, Vickie Wong, Scott J. Dankel, Takashi Abe, Jeremy P. Loenneke. *The University of Mississippi, University, MS.*
 (No relevant relationships reported)

Wide cuffs cause arterial occlusion at lower pressures but may produce greater discomfort during blood flow restricted exercise compared to more narrow cuffs when applied to the same absolute pressure. Whether this is true at the same relative pressure or if this differs by sex is currently unknown. **PURPOSE:** To examine how cuff size and sex affect perceptual discomfort following blood flow restricted exercise. **METHODS:** Forty-nine participants (25 males and 24 females) completed two conditions in a random order with 10 minutes of rest prior to each condition (one on each arm). Participants performed 4 sets of unilateral elbow flexion to failure. Pressure was applied with either a narrow (5 cm) or a wide cuff (12 cm) with each cuff set to the same relative arterial occlusion pressure (40%). Discomfort was rated following the 4th set (0: no discomfort, 100: maximal discomfort). Following exercise the participants were asked to choose which condition they would prefer to use regularly. A repeated measures analysis with a between subject factor of sex was used to assess differences in discomfort. Default priors were used for fixed effects (r=0.5) and random effects (r=1). A contingency table with a default prior concentration of 1 was used to determine if cuff preference differed by sex. Bayes Factors (BF₁₀) were used to quantify evidence for the null and alternative hypothesis. Data are presented as mean (SD) unless otherwise stated. **RESULTS:** There was evidence for an effect of cuff size (BF₁₀: 6.752) but no evidence for an interaction or an effect of sex (BF₁₀: .699). The narrow [42 (17) AU] cuff had less discomfort than the wide [47 (18) AU] cuff [median δ (95% credible interval) -53 (-928, -145)]. When participants rated which cuff they would prefer to exercise with, participants preferred the narrow cuff

and this did not differ by sex (BF_{10} joint multinomial: .262). The lower discomfort and greater preference for the narrow cuff was found despite completing more repetitions with the narrow cuff [Narrow: 70 (25) vs. Wide: 59 (16) repetitions; BF_{10} of 67.2]. **CONCLUSIONS:** A narrow cuff appear to cause less discomfort than a wider cuff when inflated to the same relative pressure with no difference between sexes. The use of a narrow cuff was preferred and may help increase the palatability of blood flow restricted exercise.

Session RPE Following a Six-minute Bout of Cardiopulmonary Resuscitation Training
 Alex B. Shafer, Wyatt I. Witty, Dana A. Lubieniecki, Kasie D. Cooper. *Montana State University Billings, Billings, MT.* (Sponsor: Elizabeth Nagle, FACSM)
 Email: alex.shafer@msbillings.edu
 (No relevant relationships reported)

Ratings of perceived exertion (RPE) are used to monitor intensity during exercise. A session RPE (S-RPE) provides an estimate of exercise intensity of a completed exercise session. S-RPE has demonstrated adequate validity and reliability for quantifying exercise intensity in traditional aerobic and anaerobic modalities. However, the efficacy of S-RPE during the physically demanding task of cardiopulmonary resuscitation (CPR) has yet to be explored. **PURPOSE:** The purpose of this investigation is to explore the relationship between RPE and S-RPE assessed during and after a 6-minute bout of CPR training. **METHODS:** Thirty healthy young adults (age 24.3±6.0 y; BMI 26.1±3.5 kg/m²) completed a 6-minute bout of CPR on a CPR manikin. RPE values were recorded during the last 15 seconds of each minute of exercise, and S-RPE was recorded 2 min post exercise using the Adult OMNI-RPE scale. Heart rate (HR) was recorded during each minute of activity. A repeated measures ANOVA was used to compare RPE values from minute 1-6 and S-RPE recorded during the CPR bout. A paired samples t-test compared the average RPE for the 6-minute bout to S-RPE. Statistical significance was accepted at $p < 0.05$. **RESULTS:** RPE values recorded during the CPR bout are reported in table 1. Participants obtained a peak HR of 132.3±25.7 bpm during the 6-minute bout of CPR. A paired samples t-test shows S-RPE was significantly higher than the average RPE for the 6-minute bout (4.7±1.9 vs. 4.1±1.7, $p < 0.0001$). However, S-RPE did not differ from the RPE obtained from minutes 3-6 of the CPR bout. **CONCLUSION:** Current findings suggest that S-RPE for a bout of CPR may not represent the average RPE, but reflects the RPE reported during the later stages of exercise. In this case, S-RPE represented exertion levels reported during the final two-thirds of the exercise session. Similar findings have been reported during aerobic and resistance training studies, where S-RPE represents exertion of the later stages of activity.

Table 1. S-RPE and RPE values for each minute of CPR

| Min 1 | Min 2 | Min 3 | Min 4 | Min 5 | Min 6 | Session |
|----------|----------|---------|---------|---------|---------|---------|
| 2.8±1.4* | 3.4±1.7* | 4.1±1.7 | 4.6±1.9 | 4.8±2.0 | 5.0±2.1 | 4.7±1.9 |

*significantly less than S-RPE, $p < 0.05$

Enjoyment In Low Intensity Continuous Training Versus High Intensity Interval Training In An Iso-caloric Design
 Sigurd Pedersen, Tord Markussen Hammer, Tommy Hamsund, Mathilde Nordhus Kristiansen, Edvard Hamnvik Sagelv. *UiT the Norwegian Arctic University, Tromsø, Norway.*
 Email: sigurd.pedersen@uit.no
 (No relevant relationships reported)

Purpose: To examine the enjoyment during and after one exercise session of continuous aerobic exercise (CE) versus one session of high intensity aerobic interval training (HIIT) in an iso-caloric design. **Methods:** Seven young healthy participants (3 males, 4 females, age: 23.4±2 years, maximal oxygen uptake: 52±8.7 ml·kg⁻¹·min⁻¹) were recruited to undergo two different exercise sessions of similar total caloric expenditure in randomized order: 1) one CE session at 70% of heart rate maximum (HRmax) and 2) one HIIT session of 4x4 minutes intervals at > 90% of HRmax with 3 minutes rest between interval sets. Maximal oxygen uptake (VO₂max) and HRmax were tested prior to the experiment. During and after both exercise session, the participants reported perceived exercise enjoyment using an 8-item short form of the Physical Activity Enjoyment Scale (PACES) (Raedeke, 2007, *J Appl Sport Psychol*). This is a reduced scale of the original 18-item scale from Kendzierski & DeCarlo (1991, *J. Sport Exerc Psychol*). Additionally, the participants also reported rating of perceived exertion (RPE) (Borg, 1981, *Med Sci Sport Exerc*), during and after both exercise sessions. **Results:** There were no difference in PACES score between HIIT and CE during (HIIT:

94.4±12.9, CE: 91.1±16.3, $p = 0.61$) and after the two exercise sessions (HIIT: 96.6±13.2, CE: 94.4±15.4, $P = 0.75$). The participants reported higher RPE both during and after the HIIT session compared with the CE session (During HIIT: 15.4±1.3, CE: 9.8±1.2, $p < 0.01$, after HIIT: 17.0±1.3, CE: 10.0±1.3, $p < 0.001$). When pooling the reported PACES scores, there were no difference in perceived enjoyment between the HIIT and CE session (95.5±12.4 vs 92.4±15.4, respectively, $p = 0.68$). The participants reported higher RPE for the HIIT session compared with the CE session in the pooled analysis (16.2±1.0 vs 9.9±1.3, $p < 0.001$). **Conclusion:** Although a higher perceived exertion was reported following high intensity exercise, participants reported similar enjoyment following exercise independent of exercise intensity in this iso-caloric design. Thus, if enjoyment is the depending factor for engaging in exercise, one should expect similar exercise adherence probability following HIIT and CE when prescribing aerobic exercise as preventive medicine.

Comparison Of Two Cold Water Immersions Protocols On Psychological Variables Of Recovery
 Braulio Sánchez-Ureña¹, Kristy Barrantes-Brais¹, Pedro Ureña-Bonilla¹, Felipe Araya-Ramírez¹, Juan José Romero-Zúñiga¹, Daniel Rojas-Valverde¹, Julio Calleja-González², Jeffrey M. Mjaanes, FACSM³. ¹National University of Costa Rica, Heredia, Costa Rica. ²University of the Basque Country, Araba, Spain. ³Northwestern University, Evanston, IL. (Sponsor: Jeffrey M. Mjaanes3, FACSM)
 Email: brau09@hotmail.com
 (No relevant relationships reported)

In sport, recovery is a multifactorial process and one modality commonly recommended for athletes is cold water immersion (CWI). Few studies, have analyzed the psychological effects of CWI protocols, specifically with regards to pain and perceived recovery. **Purpose:** Compare the effects of two CWI protocols on psychological variables of recovery. **Methods:** Forty healthy male participants (age 21.8 ± 2.76 years, weight 73.15 ± 8.15 kg, height 176.6 ± 5.3 cm, and 13.5 ± 3.4% body fat). Participants performed a fatigue protocol (8 sets of 30-second countermovement jumps with 90-second of rest between sets). Were randomized to one of three recovery conditions: control group (CG) (12-min sitting in a 23 °C room), continuous cold water immersion (CnCW) (12-min in water at 12 ± 0.4 °C), and intermittent cold water immersion (InCW) (12-min in water at 12 ± 0.4 °C as follows: 2-min in cold water, 1-min in a controlled environment at 23 °C, until the 12-min of immersions were completed). Delayed onset muscle soreness (DOMS) was assessed through a Visual Analog Scale (VAS-Pain) and perceived recovery were used. Both were evaluated at pre, post-CWI, 24 and 48 hours post. A mixed ANOVA was used. Significance was accepted at $p < 0.05$. **Results:** Statistically significant differences were found in DOMS ($F_{(8,148)} = 5.15$, $p < .001$, $\omega^2 = .174$) in post immersion CnCW vs. CG (2.7 ± 2.28 vs. 6.42 ± 1.9, $p < 0.001$) and InCW vs. CG (2.7 ± 2.1 vs. 6.42 ± 1.9, $p < 0.001$), in the post 24h CnCW vs. CG (3.07 ± 2.3 vs. 5.1 ± 1.7, $p < 0.01$) and InCW vs. CG (3.2 ± 1.8 vs. 5.1 ± 1.7, $p < 0.01$). In the post 48h testing, results showed CnCW vs. CG (3.3 ± 2.3 vs. 6.1 ± 2.2, $p < 0.002$) and InCW vs. CG (3 ± 1.9 vs. 6.1 ± 2.2, $p < 0.001$). In terms of perceived recovery ($F_{(6,111)} = 2.49$, $p = .027$, $\omega^2 = .070$), results included post immersion CnCW vs. CG (15.92 ± 1.7 vs. 14 ± 1.2, $p < 0.001$) and InCW vs. CG (16.3 ± 1.6 vs. 14 ± 1.2, $p < 0.001$), in the post 24h CnCW vs. CG (16.3 ± 2.4 vs. 12.8 ± 1.12, $p < 0.001$) and InCW vs. CG (14.9 ± 2 vs. 12.8 ± 1.12, $p < 0.001$). In the case of post 48h, results were CnCW vs. CG (15.9 ± 2.6 vs. 12 ± 3.3, $p < 0.001$) and InCW vs. CG (15.3 ± 2.6 vs. 12 ± 3.3, $p < 0.001$). **Conclusion:** CWI protocols are effective in reducing DOMS and improving perceived recovery all post fatigue measurements. Either the CnCW or InCW protocol could be used as both had similar effects on psychological variables of recovery.

1431 Board #193 May 30 9:30 AM - 11:00 AM
Time Courses of Changes In Perceptual, Respiratory, and Neuromuscular Responses in the Severe Intensity Domain
 Haley C. Bergstrom¹, Terry J. Housh, FACSM², Taylor K. Dinyer¹, M. Travis Byrd¹, Pasquale J. Succ¹, Nathaniel D.M. Jenkins³, Kristen C. Cochrane-Snyman⁴, Richard J. Schmidt², Glen O. Johnson, FACSM². ¹University of Kentucky, Lexington, KY. ²University of Nebraska-Lincoln, Lincoln, NE. ³Oklahoma State University, Stillwater, OK. ⁴California State University, Fresno, CA.
 Email: hbergstrom@uky.edu
 (No relevant relationships reported)

The severe intensity domain zone 1 (SIZ₁) includes intensities between critical velocity (CV) and 50%Δ (Δ = difference between CV and VO_{2peak}), where exhaustion may occur below VO_{2peak}. The severe intensity domain zone 2 (SIZ₂) includes intensities

> 50%Δ but < 175% CV, where $\dot{V}O_{2peak}$ is reached at exhaustion. **PURPOSE:** This study examined the time course of changes in ratings of perceived exertion (RPE), breathing frequency (f_b), electromyographic amplitude (EMG AMP) and EMG mean power frequency (MPF) during exhaustive treadmill runs within the SIZ_1 and SIZ_2 . **METHODS:** Ten runners (Age: 23 ± 3 yrs) performed an incremental treadmill test to determine the velocity at $\dot{V}O_{2peak}$ (vVO_{2p}). The CV was determined from 4 constant velocity runs. The RPE, f_b , EMG AMP, EMG MPF (from the vastus lateralis) and times to exhaustion (T_{lim}) were examined during SIZ_1 and SIZ_2 runs. Polynomial regression was used to examine the normalized (% change from the initial values) RPE, f_b , EMG AMP, and EMG MPF versus % T_{lim} (10-100%) relationships for the SIZ_1 and SIZ_2 runs. Repeated measures ANOVAs and Student Newman-Keuls tests were used to determine the time course of changes from the initial 10% of T_{lim} . **RESULTS:** During the SIZ_1 ($86 \pm 5\%$ vVO_{2p} , $\sim 33\%$ Δ, $T_{lim} = 17.7 \pm 2.6$ min) run, there was a quadratic increase for RPE ($R^2 = 0.99$, $p < 0.001$), significant from 30 to 100% of T_{lim} , a cubic increase for f_b ($R^2 = 0.99$, $p < 0.001$), significant from 30 to 100% of T_{lim} , a linear increase for EMG AMP ($r^2 = 0.85$, $p < 0.001$), significant at 100% of T_{lim} , and a linear decrease for EMG MPF ($r^2 = 0.66$, $p = 0.004$), but no differences among time points. During the SIZ_2 ($98 \pm 4\%$ vVO_{2p} , 93% Δ, $T_{lim} = 6.6 \pm 0.8$ min) run, there was a linear increase for RPE ($r^2 = 0.99$, $p < 0.001$), significant from 30 to 100% of T_{lim} , a quadratic increase for f_b ($R^2 = 0.99$, $p = 0.03$), significant from 20 to 100% of T_{lim} , a quadratic increase for EMG AMP ($R^2 = 0.68$, $p = 0.02$), but no differences among time points, and a cubic decrease for EMG MPF ($R^2 = 0.84$, $p = 0.01$), significant at 100% of T_{lim} . **CONCLUSIONS:** These findings indicated RPE was more closely related to increases in f_b , than to neuromuscular fatigue in both the SIZ_1 and SIZ_2 . It is possible feedback from group III and IV afferents in the respiratory muscles contributed to increased perceptions of effort to a greater degree than those in the leg muscles during severe exercise intensities.

1432 Board #194 May 30 9:30 AM - 11:00 AM
Mood Changes In Runners During An Ultra-marathon
 Caleb B. Bockoras, Tracie Wilkins Zimmer, Steven B. Hammer, James W. Agnew. *Indian River State College, Fort Pierce, FL.*
 Email: Caleb.bockoras@gmail.com
 (No relevant relationships reported)

PURPOSE: There is currently very little data available in literature on the effects of ultra-marathon training and competition regarding mood. Ultra-marathons are races with distances greater than the standard marathon distance of 26.2 miles. The purpose of this experiment was to examine differences in mood during an ultramarathon competition. We speculated that perceived exertion (RPE) and pain would be the predominant determinates of mood during the race. **METHODS:** Pain, RPE, and mood were assessed using Visual Analog Scales (VAS) prior to the race, at predetermined ten-mile marker points, and immediately at the completion of the race. The support teams that would accompany each runner throughout the race were given instructions prior to the start on how to collect the data. They were instructed not to "coach" responses from the runners and not to assume their runner's responses or answer for them. The mood scale started at 10 representing best mood and decreased to 0 as mood declined. Pain and RPE scales started at 0 for no pain and no exertion respectively, increasing to a maximum of 10 for maximum pain or maximum exertion. Data were analyzed using regression analyses with $p < 0.05$ as our accepted level of significance. **RESULTS:** The regression analysis revealed a ($R^2 = 0.89$). Mood steadily decreased from 9.6 one hour before the race to 9.4 ten miles into the race. At 90 miles, mood was 5.2, then 6.2 at the completion of the race. RPE and pain steadily increased throughout the race. Pain was 0 before the start, 0.6 at ten miles and 7 at 100 miles. RPE was 1.4 one hour before the race and 2.6 at ten miles increasing to 6.8 at the end of the race. Subjective pain assessment was significantly correlated to mood throughout the race ($p < .05$), and RPE had no significant associations ($P > .05$). **CONCLUSION:** These data suggest that the increase in subjective pain assessment with runners completing a 100-mile ultra-marathon is directly related to a decrease in mood throughout the race. RPE was also correlated and is surely an important factor impacting mood throughout the race, but it did not reach statistical significance. This suggests that pain has greater association with mood compared to RPE during an ultra-marathon. Further analysis is needed to fully identify the primary factors impacting mood in ultra-endurance activities.

1433 Board #195 May 30 9:30 AM - 11:00 AM
Physical Aspects of Fatigue Throughout a Season
 Jordan F. Norris¹, Nicholas F. Boér¹, Richard Henderson².
¹University of Tennessee at Chattanooga, Chattanooga, TN.
²McCallie School, Chattanooga, TN.
 (No relevant relationships reported)

High school athletes experience changes in performance throughout sport seasons. It's important to discover if an athlete is fatigued in order to make modifications to their practice and training regimen.

PURPOSE: The purpose of this investigation is to use the jump squat measurement to determine athlete fatigue throughout a season. **METHODS:** 58 male varsity students that attend a private college preparatory school volunteered to participate in the

study (N=21 football; N=11 lacrosse; N=6 track; N=12 basketball; N=9 wrestling). The average grade level for the participants was 10.91 (0.89). Students completed a modified Borg scale of rate of perceived exertion (RPE) to determine physical RPE. Students self-reported practice time and sleep. A jump squat using "Just Jump" with a flight time calculator was used to measure the level of fatigue. Data was recorded by the strength and conditioning coaches. Each athlete recorded a jump squat each week throughout the season; however, due to missing data, data was analyzed through a repeated measures analysis at times corresponding to the beginning of the season, the one-third mark, the two-third mark, and at the end of the season.

RESULTS:

| | | | | |
|-----------------------|---------------|---------------|---------------|---------------|
| Average Physical RPE | 5.19; 1.75 | 5.19; 1.44 | 5.00; 1.87 | 4.93; 1.69 |
| Average Sleep | 7.61; 0.90 | 7.55; 0.81 | 7.80; 1.15 | 7.69; 0.82 |
| Average Practice Time | 130.45; 16.08 | 129.30; 18.55 | 125.96; 19.00 | 122.02; 24.07 |
| Average jump Squat | 18.99; 3.07 | 19.22; 3.10 | 19.29; 2.91 | 19.85; 3.04 |

CONCLUSION: It was assumed that students who recorded lower jump squat scores experienced fatigue at that point in the season. While there were individual differences, there were no significant differences among the teams. There was a gradual increase in performance, rather than a fatigue effect, which indicates that training modalities addressed individual fatigue levels. A limitation of this study is the data collection methods; academia and strength coaches will need to work together to develop data collection methods that meet the needs of both the coaching staffs and researchers.

The Interactive Effect of DOMS and Topical Analgesic on Corticospinal Excitability of the Biceps Brachii
 Evan J. Lockyer¹, Lucas Stefanelli¹, Brandon W. Collins¹, Nicholas J. Snow¹, Julie Crocker¹, Christopher Kent¹, Michael Holmes², Kevin E. Power¹, Duane C. Button¹. ¹Memorial University of Newfoundland, St. John's, NL, Canada. ²Brock University, St. Catharines, ON, Canada.
 Email: elockyer@mun.ca
 (No relevant relationships reported)

Delayed onset muscle soreness (DOMS) is a normal response to strenuous, unfamiliar exercise characterized by muscle swelling, tenderness and pain. Typically arising 24-72 hours following exercise, DOMS results in neuromuscular impairment such as decreased muscular strength and activation. Recently, the application of topical analgesics has been proposed as a possible means to mitigate the symptoms and negative outcomes of DOMS, though the mechanisms of action are not well-understood. It is currently unknown how the presence of DOMS with and without the application of topical analgesia influences central nervous system excitability. **PURPOSE:** The purpose of this study was to investigate the interactive effects of DOMS and the application of a menthol-based topical analgesic on corticospinal excitability (CSE) to the biceps brachii. **METHODS:** A total of 32 participants completed two separate experiments; *Experiment A* (No DOMS; $n = 16$) and *Experiment B* (DOMS; $n = 16$). For each experiment, participants were randomly assigned to two groups: 1) topical analgesic gel (Topical Analgesic, $n = 8$), or 2) placebo gel (Placebo, $n = 8$). Prior to the application of gel (pre-gel), as well as 5, 15, 30, and 45 min post-gel, motor evoked potential (MEP) area, latency, and silent period, as well as cervicomedullary MEP (CMEP) and maximal compound motor unit action potential (M_{max}) areas and latencies were measured. In addition, pressure-pain threshold (PPT) was measured pre-DOMS and at the same time points in *Experiment B*. **RESULTS:** In *Experiment A*, neither group showed a significant change for any outcome measure. In *Experiment B*, both groups exhibited a significant decrease in PPT from pre-DOMS to pre-gel ($p < .05$). Following the application of topical analgesic, but not placebo, there was a significant increase in PPT at 15, 30, and 45 min post-gel ($p < .05$), respectively compared to pre-gel and an increase in silent period at post-30 and 45 min ($p < .05$) compared to pre-gel. Participants with DOMS had reduced MEP ($p < .02$) and CMEP areas ($p < .05$), and increased MEP silent periods ($p < .05$) compared to those who did not have DOMS. **CONCLUSIONS:** These findings suggest that DOMS reduced CSE to the biceps brachii, and that the application of a menthol-based topical analgesic reduced pain, which was accompanied by an increase in corticospinal inhibition.

The Influence of Temperature on Prefrontal Cortex Activation and Performance During a Fatiguing Task
 Kevin C. Phillips¹, Derek Verbrugghe¹, Alex Gabe¹, Brittany Jauquet¹, Claire Eischer¹, Steven Elmer¹, Tejin Yoon². ¹Michigan Technological University, Houghton, MI. ²Kangwon National University, Chuncheon, Korea, Republic of.
 Email: kcphilli@mtu.edu
 (No relevant relationships reported)

Evidence suggests the prefrontal cortex (PFC) may play a role in interpreting afferent feedback during fatiguing tasks. Temperature changes are known to influence fatigability. It is unknown how changing the temperature of a limb influences PFC activation during a fatiguing task. **PURPOSE:** To examine changes in PFC oxygenation, psychological ratings, and muscular function in response to a fatiguing task, following thermal alterations of the exercising arm. **METHODS:** Nineteen healthy adults completed three experimental sessions. At baseline, participants performed maximum voluntary isometric contractions (MVIC) of the elbow flexors. Next, participants submerged their right arm in a water bath for 15 min. Cold (C), neutral (N), and hot (H) water temperatures were maintained at 8°, 33° and 44°C, respectively. Following water immersion, participants performed an isometric elbow flexion contraction, at 20% of MVIC, for 5 minutes. Ratings of perceived exertion (RPE) and muscular discomfort were assessed. Functional near-infrared spectroscopy was used to measure oxygenation of the right PFC during the fatiguing task. Repeated measures ANOVAs were used to analyze changes in dependent variables. **RESULTS:** There was an increase in PFC oxygenation throughout the fatiguing task, however, the increase in oxygenation was greater for the H (14.1±4.9 µM) and N (12.7±5.6 µM) conditions, compared to the C condition (11.1±4.4 µM, time x temperature, p<0.01). There was an increase in RPE throughout the fatiguing task, however, the increase in RPE was greater for the H (8.7±0.9) and N (8.0±0.9) conditions, compared to the C condition (7.2±1.1, time x temperature, p<0.01). Muscular discomfort at the end of the fatiguing task was lower in the C condition compared to the H condition (2.7±0.1 vs. 3.7±0.1, p<0.001). There was a reduction in MVIC torque at the end of the fatiguing task, however, the reduction in MVIC torque was greater for the H (25.7±8.4 %) and N (22.2±9.6 %) conditions, compared to the C condition (17.5±8.9 %, temperature x fatigue, p<0.05). **CONCLUSION:** Precooling before a fatiguing task attenuated the rise in PFC oxygenation, RPE, muscular discomfort, and muscular fatigue. These results have implications for reducing mental workload and improving performance in workers, athletes, and patients.

Factors Affecting the Outcome of an Ultramarathon Before the Race Starts
 Steven B. Hammer. Indian River State College, Fort Pierce, FL.
 Email: shammer@irsc.edu
 (No relevant relationships reported)

Purpose: Very little data is available concerning the influence of pre-race mood and pain on ultra-marathon completion. This research was designed to answer questions such as how pain, mood and exertion affect ultramarathon race performance (defined as any race greater than 26.2 miles). **Methods:** Data was collected at the 2018 Keys 100 and 2017 Saint Sebastian 100 (n=23). Each research participant was presented with visual analog scales, one each for Pain (0=low pain to 10=maximum pain), Mood (10=great mood to 0=bad mood) and exertion (RPE) (0=no exertion to 10=maximum exertion). Scores were collected pre-race. Those participants who did not finish (DNF) were recorded as such. Independent sample t-test (SPSS version 21) was used with independent variable coded post-race, Finished or DNF, dependent variables were Mood, Pain and Exertion collected Pre-Race (p<0.05). **Results:** Pain pre-race for finishers (0.23±0.44) and DNF's (0.86±0.38), paired differences were t(19)=3.18, p=0.005. Mood pre-race for finishers (9.5±0.85) and DNF's (7.3±2.56) paired difference were t(19)=-2.98, p=0.008. Exertion pre-race for finishers (1.07±0.99) and DNF's (0.86±0.38), paired differences were t(19)=-0.54, p=0.59. **Conclusion:** Pre-race numerical scores that rank higher in mood and lower in pain have a positive impact on race outcome. Current research shows a greater link between psychological state and performance than previously postulated. Our research supports the hypothesis that the athlete's physical performance affects their mental state. Furthermore their mental state, in turn, effects their performance. We believe this to be the first collected data of this type to show these results on ultra-marathon performance.

Effects of Transspinal Direct Current Stimulation on Cycling Perception of Effort and Time to Exhaustion
 Christopher A. De la Vega¹, Anthony B. Ciccone¹, Trent J. Herda², Andrew C. Fry², Dawn M. Emerson², Joseph P. Weir, FACSMT. ¹Utah Valley University, Orem, UT. ²University of Kansas, Lawrence, KS. (Sponsor: Dr. Joseph Weir, FACSMT)
 (No relevant relationships reported)

PURPOSE: In the past decade, researchers have investigated the efficacy of transspinal direct current stimulation (tsDCS) on central nervous system and afferent neuron function in humans. In the past year, data has suggested it may be possible for such tsDCS-induced changes in neuromuscular function to enhance performance. This study utilized non-invasive thoracic spine tsDCS to determine if cycling performance and perception of effort (RPE) could be modulated by tsDCS. **METHODS:** In three different stimulation conditions, anodal, cathodal, and sham, participants cycled at 80% of their maximal aerobic capacity until exhaustion and reported their RPE every minute. From this period, researchers compared the RPE responses over the first three minutes and time to exhaustion. **RESULTS:** There was no significant difference in time to exhaustion between anodal (408 ± 121 s), cathodal (413 ± 168 s), and sham (440 ± 189 s) conditions (p=0.58). There was no significant difference in RPE from minutes 1-3 (collapsed across time) between anodal (12.9 ± 2.4 AUs), cathodal (13.3 ± 2.2 AUs), and sham (12.9 ± 2.1 AUs) conditions (p=0.51). **CONCLUSIONS:** These data suggest tsDCS condition did not influence cycling performance or perception of effort during high-intensity cycling. Therefore, thoracic spine and lower abdominal montage delivering a current density of 0.071 mA/cm² for 20 minutes likely does not affect high-intensity cycling work capacity. Therefore, more research is needed to investigate the efficacy of tsDCS and which stimulation methods may and may not enhance human performance.

Relationship Among Site Specific Fat, Lean Mass, And Pressure Pain Sensitivity
 Ashley Dioguardi, Jessica Peterson, Cameron Lohman, Michael G. Bembem, FACSMT, Rebecca Larson, Christopher D. Black, FACSMT. University of Oklahoma, Norman, OK. (Sponsor: Christopher Black, FACSMT)
 Email: ashley.j.dioguardi-1@ou.edu
 (No relevant relationships reported)

Chronic pain and obesity are significant public health issues. Although the association between a higher BMI and chronic pain has been established, little data exist on the relationship among more direct measures of body composition and pain sensitivity. **PURPOSE:** The purpose of the study was to examine the relationship between pressure pain thresholds (PPT), total body fat and lean tissue, and fat and muscle mass at the PPT assessment site. **METHODS:** PPT of 73 participants (38 female) were assessed in the vastus lateralis (VL) and brachioradialis (BR) using a pressure algometer on the left (L) and right (R) sides of the body. Whole body and limb specific fat and lean tissue were assessed via DEXA scan, and muscle and fat thickness were assessed in the VL and BR using ultrasound and skinfold measures. **RESULTS:** PPT in both arms correlated with whole body lean mass (LBR: r=0.284; p=0.015; RBR: r=0.249; p=0.034), and site specific lean mass (LBR: r=0.263; p=0.025; RBR: r=0.238; p=0.043). LBR was also correlated to muscle thickness (r=0.235; p=0.045). No relationships were found between PPT and measures of fat mass in the LBR (p>0.05). PPT in the RBR were inversely correlated with BF% (r=-0.231; p=0.049). PPT in both legs were correlated with whole body lean mass (LVL: r=0.422; p<0.0001; RVL: r=0.444; p<0.0001), site specific lean mass (LVL: r=0.425; p<0.0001; RVL: r=0.397; p=0.001) and muscle thickness (LVL: r=0.262; p=0.025; RVL: r=0.312; p=0.007). No relationships found with any measure of fat mass in the LVL (p>0.05). PPT RVL inversely correlated with BF% (r=-0.239; p=0.042) and RL fat% (r=-0.331; p=0.004) but no relationship was found with region specific fat mass measures (p>0.05). **CONCLUSION:** PPT and assessments of fat tissue were not related. However, lean mass tended to have a positive relationship with PPT. These findings suggest a loss of lean tissue mass, which typically occurs with aging and inactivity, may play a role in increased sensitivity to pain.

1439 Board #201 May 30 9:30 AM - 11:00 AM
Self-Efficacy for Changing Sedentary Behavior or Physical Activity: Comparisons in Healthy and Chronic Pain Populations

Jeni E. Lansing, Jacob D. Meyer, Maria Perez, Gabriel Cruz-Maldonado, Laura D. Ellingson, FACSM. *Iowa State University, Ames, IA.* (Sponsor: Laura Ellingson, FACSM)
 (No relevant relationships reported)

Physical activity (PA) has well known health benefits, especially for clinical populations like individuals with chronic pain (CP). However, interventions aimed at increasing PA often report low adherence, possibly due to low self-efficacy (SE). Reducing sedentary time (SED) also has health benefits and may be perceived as more achievable than increasing PA. **PURPOSE:** To compare levels of SE for reducing SED to those for increasing PA in healthy adults (HA) and individuals with CP and to explore SE for overcoming barriers for each behavior. **METHODS:** Participants completed a survey assessing SE for changing PA and SED and common barriers. Questions were rated on a Likert scale from 1 (Not at all Confident) to 10 (100% Confident). T-tests and effect sizes (Cohen's *d*) compared differences between behaviors. **RESULTS:** Participants were 1,240 HA (age = 26 ± 12; 61% female) and 273 individuals with CP (age = 34 ± 16; 70% female). Both HA and individuals with CP reported greater SE for reducing daily SED by 1 hour compared to increasing daily MVPA by 30 minutes, with moderate effects observed in both groups ($p < 0.001$, CP: $d = 0.60$; HA: $d = 0.58$). Additionally, SE was greater ($p < 0.001$) for overcoming barriers related to changing SED than PA, except social norms. In CP, the effect sizes between SE for overcoming barriers related to SED to barriers related to PA were small to moderate for fatigue ($d = 0.46$), time ($d = 0.42$), environment ($d = 0.44$), motivation ($d = 0.37$), pain ($d = 0.27$), and mood ($d = 0.24$). In HA, moderate effects for environment ($d = 0.66$) and fatigue ($d = 0.50$) and small effects for time ($d = 0.44$), motivation ($d = 0.44$), pain ($d = 0.37$) and mood ($d = 0.24$) were observed. However, SE for resisting social norms to sit was lower than SE for social norms surrounding exercise ($p < 0.001$, CP: $d = -0.32$, HA: $d = -0.59$). **CONCLUSION:** While the health effects of each behavior are not equivalent, both patients and HA may be more likely to change behavior when encouraged to sit less rather than exercise more, which may still result in substantial benefits. Individuals with CP had the lowest average SE for interrupting SED when feeling unwell or in pain, feeling sad or unhappy, or in social situations where others are sitting. Interventions targeting SED may benefit from discussing mental and physical benefits of reducing SED and strategies for overcoming social norms.

Evaluation Of Perception And Tolerance To Acute Pain Thru Typological Groups Of Gender Schemas

Claudia Dias Leite¹, Isabela Almeida Ramos², Gislane Ferreira de Melo³. ¹*UniProjeção, Brasília, Brazil.* ²*Catholic University of Brasilia, UniProjeção, Brasília, Brazil.* ³*Catholic University of Brasilia, Brasília, Brazil.*
 (No relevant relationships reported)

Pain is defined as a physiological and psychological experience, composed of an interaction between emotional, cognitive and sensorial components. The cultural aspects associated with the individual experiences of pain, tend to influence the way that individual reaction to a painful stimulus. **PURPOSE:** to evaluate if typological groups of gender schemas, generate by the Interactive Model, differs on acute pain perception and tolerance. **METHODS:** 137 athletes and 175 non-athletes, male and female (22.95 ± 4.29 yrs) were allocated into Masculine Heteroschematic (MH - Inventory of the Self-Concept's Gender Schemas - IMEGA), Isoschematic (ISO) and Feminine Heteroschematic (FH - Feminine Inventory of Self-Concept's Gender Schemas - IFEGA), groups. A scale called Factor of Acute Pain (FSAP) was developed to evaluate the sensations of acute pain. Pain threshold, pain tolerance, and pain super tolerance were evaluated during some test where the pain was induced by immersing hand on ice (0.1°C to 0.3°C). To FSAP validation and reliability were used Factorial Analysis and Cronbach's Alpha, and for acute pain perception and tolerance analysis was used inferential analysis Three-Way MANOVA and *post hoc* Least Significant Differences (LSD). **RESULTS:** Significant differences in acute pain perception and tolerance between typological groups were found ($p=0.03$). At graphic 1 is possible to observe that MH and ISO showed higher pain super tolerance than FH (00:18,16min and 00:06;32min respectively; $p=0.01$). For acute pain sensations, athlete woman FH reported more unpleasant sensation of pain ($\Delta=00:55,05min$) than MH. **CONCLUSIONS:** gender schemas at typological groups support different high levels of acute pain, as well as different sensations of unpleasant caused by the cold thermal sensations. Groups with developed masculine schema tend to have a higher tolerance to maximum pain than the other groups.

Graphic 1. Pain threshold, pain tolerance and pain super tolerance between gender schemas typological groups. * $p < 0.05$ different compared with FH.

Grit, Fitness, And Goal Setting

Ethan E. Hull, Jason Vultaggio. *Slippery Rock University, Pittsburgh, PA.*
 Email: ethanhull@gmail.com
 (No relevant relationships reported)

Grit is a measure of passion and perseverance and has been associated with academic and career success. Whether grit is associated with success in other areas such as health, fitness, or goal setting is unknown. **PURPOSE:** This research attempted to examine whether grit and additional variables such as self-control and growth mindset would predict success in physical fitness goal setting and tolerance to discomfort during endurance fitness testing. **METHODS:** Eligible participants ($n = 51$, 60% male, 21.45 ± 1.7 years old) were drawn from wellness classes at Slippery Rock University. Participants completed questionnaires on grit, self-control, and growth mindset at baseline and six weeks later at follow-up. Pre and post measures also included a FitnessGRAM push-up test to failure, the level of discomfort in the upper body during the push-up test, and various other upper body fitness tests. Participants set a strength goal and trained for six weeks performing a variety of upper body exercises twice per week, consisting of strength training and plyometric exercises. **RESULTS:** Significant improvements were seen in push-up endurance scores (24.9 ± 10.2 vs 28.6 ± 9.0, $p < 0.01$) and discomfort tolerance during the push-up test (7.3 ± 1.7 vs. 8.0 ± 1.4, $p < 0.01$). No significant changes were noticed in grit (3.6 ± 0.4 vs. 3.7 ± 0.6, $p = 0.86$), self-control, or growth mindset scores. A weak correlation ($r = 0.30$, $p = 0.03$) was noticed between baseline grit levels and baseline push-up scores. No other associations were found between grit and improvements in fitness. **CONCLUSIONS:** Results appeared to show that improvements in endurance, strength, and tolerance to discomfort were not associated with levels of grit, growth mindset, or self-control. Although these variables have been highlighted as predictive of success, future research should continue to examine their relation to goal setting in health and fitness.

1442 Board #204 May 30 9:30 AM - 11:00 AM
Firefighter Turnout Suit Weight Influences Simulated Exercise Performance

Stephanie Gipson, Meredith McQuerry, Margaret Morrissey, Jacob Kisiolek, Michael Ormsbee, FACSM. *Florida State University, Tallahassee, FL.*
 Email: sgd13b@my.fsu.edu
 (No relevant relationships reported)

PURPOSE: To investigate how structural firefighter protective ensemble weight influences rate of perceived exertion (RPE) during firefighter simulated exercise (FFSE). **METHODS:** 10 active firefighters (age: 33 ± 6 years, Ht: 178.2 ± 3.1 cm, Wt: 78.6 ± 16.7 kg) were asked to wear, in random order, two ensembles: 1) a single layer (SL) outer shell (2.45 kg) and 2) a traditional turnout suit (4.57 kg). On each laboratory visit, the firefighters performed the FFSE that consisted of two rounds of a 15.24m hose advance, a 15.24m weighted (40.83 kg) carry, sledge hammer exercise, a 15.24m tire flip, a 15.24m dummy drag, rope pull, and unweighted stair climb, with a 1-minute rest period between rounds. The FFSE included a 5-minute acclimation period in the ensemble, a warm up (10 pushups, 10 squats, 20 jumping jacks). Subjects were asked to complete the FFSE as fast as possible. The traditional turnout suit consisted of an outer shell, moisture barrier, and thermal barrier typically found in most turnout suits. The Borg rating of perceived exertion scale was asked immediately at the end of each round of FFSE and ensemble weights were measured pre-FFSE.

RESULTS: The SL resulted in lower average RPE for round 1 (SL: 12.8 ± 1.7 vs. Traditional: 13.8 ± 1.7 ; $p=0.05$) and round 2 (SL: 14.2 ± 1.6 vs. Traditional: 16.2 ± 2.3 , $p=0.01$) than the traditional turnout. In addition, round 2 of the FFSE was completed significantly faster than the traditional turnout suit (SL: 262.8 ± 55.7 vs. Traditional: 293.4 ± 64.9 sec; $p=0.02$). **CONCLUSIONS:** The weight of the turnout suit increases RPE, which appears to influence performance for FFSE. Supported by Fire-Dex, LLC.

Pre-Exercise Perceptions of Energy and Fatigue are Significantly Related to Performance during Sprint Interval Cycling

Carly L. A. Wender, Sun Joo Ahn, Patrick J. O'Connor, FACSM.
University of Georgia, Athens, GA.
Email: carly.wender10@uga.edu
(No relevant relationships reported)

Administration of ergogenic aids before exercise can increase feelings of energy and improve performance while completion of a demanding cognitive task before exercise can increase physical fatigue and decrease performance. Studies on this topic have been small (7-10 participants) and have failed to adequately measure perceptions of mental energy and fatigue. Thus, relationships between pre-exercise feelings of energy, fatigue and physical performance are not well understood.

PURPOSE: Describe relationships between anaerobic power during brief all-out cycling sprints and pre-exercise feelings of physical energy, physical fatigue, mental energy and mental fatigue.

METHODS: Ninety-four healthy men and women (18 to 29 years) completed 3 x 30-sec sprints at a high resistance. Participants were randomly assigned to cycle in an interactive or non-interactive virtual environment presented through a virtual reality setup (data presented elsewhere). Perceived feelings of energy and fatigue were measured pre-exercise using the Mental and Physical State Energy and Fatigue Scales. Compared to their capacity to perform typical mental or physical activities, participants rated their "right now" feelings of energy, vigor, pep, fatigue, exhaustion, and being worn out, on 10-cm visual analog scales. Scores were summed to yield criterion scores for physical energy, physical fatigue, mental energy and mental fatigue. Correlations between perceptions of energy, fatigue, mean power (MP) and objective performance fatigue (MP during the 1st sprint minus MP during the 3rd sprint) were used to evaluate relationships.

RESULTS: All variables were normally distributed. MP during the 1st 30-sec sprint was significantly related to pre-exercise perceptions of physical fatigue ($r = -0.300$, $p = .003$), mental fatigue ($r = -0.270$, $p = .008$) and mental energy ($r = 0.246$, $p = .017$). Performance fatigue was significantly related to pre-exercise perceptions of physical fatigue ($r = -0.237$, $p = .021$) and mental energy ($r = 0.224$, $p = .030$). Partial correlations controlling for the experimental condition and removal of outliers did not influence these relationships.

CONCLUSIONS: There are significant, small relationships between pre-exercise feelings of physical and mental fatigue, anaerobic power and performance fatigue.

Assessment of Performance Fatiguability During Resistance Exercise Anchored to Ratings of Perceived Exertion

Joshua L. Keller, Terry J. Housh, FACSM, Ethan C. Hill, Cory M. Smith, Richard J. Schmidt, Glen O. Johnson, FACSM.
University of Nebraska - Lincoln, Lincoln, NE. (Sponsor: Terry Housh, FACSM)
(No relevant relationships reported)

PURPOSE: According to the critical threshold hypothesis, fatiguing single-leg exercise at intensities above the critical force should result in performance fatiguability that is unvarying. The purpose of the present study was to examine the fatigue-related decreases in maximal voluntary isometric contractions (MVIC) as an indirect measure of performance fatiguability at intensities anchored by ratings of perceived exertion (RPE).

METHODS: Ten recreationally-active men (22.9 ± 2.0 yr) performed 3 randomly ordered, sustained submaximal isometric leg extension muscle actions anchored to RPE values of 2, 5, and 8 (OMNI-RES 10-point scale) until the RPE value could no longer be maintained or a maximal time-limit of 5-min was reached. The percent decline in MVIC was defined as the difference between pretest and posttest values. A 1x3 repeated measures ANOVA was used to examine mean differences in MVIC percent decline values at RPE=2, 5, and 8.

RESULTS: The mean (\pm SD) actual time-limits for the sustained muscle actions anchored to RPE=2, RPE=5, and RPE=8 were 300.0 ± 0.0 s, 202.0 ± 95.5 s, and $RPE 8 = 72.7 \pm 27.6$ s, respectively. The pretest to posttest decreases in MVIC values for RPE=2, 5, and 8 were 61.9 ± 14.3 to 42.8 ± 11.4 , 62.4 ± 14.3 to 47.9 ± 12.8 and 63.0 ± 12.6 to 54.0 ± 14.7 kg, respectively. There was a significant ($p=0.023$) difference in MVIC percent decline, and the pairwise comparisons indicated that the percent decline

in MVIC was significantly ($p<0.001$) greater for RPE=2 ($30.4 \pm 11.6\%$) than RPE=8 ($15.1 \pm 13.6\%$), but there were no differences ($p>0.05$) for RPE=5 ($22.0 \pm 14.0\%$) versus RPE=2 or 8.

CONCLUSIONS: In general, the similar MVIC percent decline values at RPE=5 and 8, as well as the greater percent decline at RPE=2, supported the critical threshold hypothesis. Furthermore, performance fatiguability as assessed from MVIC measurements followed the expected pattern of responses as those previously described for involuntary potentiated twitch amplitude. These findings also suggested that RPE=2 was below critical intensity, but RPE=5 and RPE=8 were not.

Association between Dietary Quality and Fatigability among the Elderly in the Geisinger Rural Aging Study

Brett Davis¹, James E. Stampley¹, G. Craig Wood², Diane C. Mitchell³, Gordon L. Jensen⁴, Yi-Hsuan Liu³, Xiang Gao³, Bethann Whilden², Marianne Yohn², Krystal Cunningham², Megan Lamotte², Christopher D. Still⁵, Brian A. Irving, FACSM¹. ¹Louisiana State University, Baton Rouge, LA. ²Geisinger Medical Center, Danville, PA. ³Penn State University, University Park, PA. ⁴University of Vermont, Burlington, VT. ⁵Penn State University, Danville, PA. (Sponsor: Brian A Irving, PhD, FACSM)
Email: bdavis159@lsu.edu
(No relevant relationships reported)

Poor dietary quality contributes to impaired physical function and frailty in the elderly. Elevations in perceived fatigue, fatigability, likely exacerbate impairments in physical function and frailty. However, the association between dietary quality and fatigability is unknown. **PURPOSE:** We examined the cross-sectional association between overall diet quality and fatigability among the elderly in the Geisinger Rural Aging Study (GRAS). **METHODS:** In the present study, we included 122 (66F, 56M) elderly (≥ 80 years) participants from the GRAS who completed the Pittsburgh Fatigability Scale (PFS) and Diet Screening Tool (DST). We used multiple linear regression to measure the association between the PFS - Physical Fatigability Score (0-50, no fatigue to extreme fatigue) and the DST Score (0-100, <60 at risk, >75 low risk) adjusted for age group, sex, BMI, and number of medications used over the past two years. **RESULTS:** The mean (SD) Physical Fatigability Score, DST Score, BMI, and number of medications were 23 (10), 60 (12), 28 (5) kg/m² and 18 (8), respectively. The females reported higher Physical Fatigability Scores compared to males (26 ± 1 vs. 21 ± 1 , $p<0.01$), while those in the 90+ years old group reported higher Physical Fatigability Scores (28 ± 2 , $n=20$) compared to those in the 80-84 (20 ± 1 , $n=51$) and 85-89 (23 ± 1 , $n=51$) groups (both $p<0.05$). Low diet quality, as assessed by the DST, was associated with high Physical Fatigability Score in the crude model ($r = -0.25$, $p=0.007$). Further adjustment for age, sex, BMI and number of medications did not change the significant inverse correlation between diet quality and physical fatigability ($r = -0.31$, $p = 0.0006$). **CONCLUSION:** Our results suggest that elderly individuals with lower dietary quality may also have higher physical fatigability independent of age, sex, BMI, and number of medications. In addition, both females and the oldest-of-old reported the highest levels of physical fatigability. Further studies should examine the impact that individual macronutrients as well as micronutrients have on physical fatigability in the elderly. This study is funded by the USDA, Agricultural Research Service agreement 8050-51530-012-01A

The Effects of Music Tempo on an Exerciser's Experiences During Isometric Strength Task

Jason R. Kostrna¹, Robyn Feiss², Gershon Tenenbaum³. ¹Florida International University, North Miami, FL. ²Auburn University, Auburn, FL. ³Florida State University, Tallahassee, FL.
Email: jkostrna@fiu.edu
(No relevant relationships reported)

PURPOSE: This study examined the effects of different music tempos on effort-related thoughts, rating of perceived exertion (RPE), affect, heart rate, and performance during isometric strength exercises. Recent research on musical stimuli during exercise supports that music has multiple physiological and psychological responses during exercise including: attention, RPE, affect, and performance (e.g., Atler et al., 2015; Connon, 2011; Crust, 2004; Dyrland & Winger, 2008; Karageorghis, Terry, Lane, Bishop, & Priest, 2011).

METHODS: Participants were assigned randomly to one of three conditions: silent control, fast tempo music first followed by slow tempo music, and slow tempo music first followed by fast tempo music, and performed a two different isometric strength exercises in a counter-balanced order. **RESULTS:** RM ANOVAs revealed non-significant differences among conditions during any of the trials, indicating that the presence of music of either slow or fast tempo failed to influence HR, $F(2, 55) = 2.48$,

$p = .09$, $\eta^2 = .07$, RPE, $F(2, 60) = 0.75$, $p = .48$, $\eta^2 = .02$, attention, $F(2, 60) = 0.15$, $p = .86$, $\eta^2 < .01$, time to voluntary exhaustion, $F(2, 60) = .81$, $p = .45$, $\eta^2 = .02$, and affect, $F(2,60) = 1.98$, $p = .15$, $\eta^2 = 0.07$.

CONCLUSIONS: Music of either tempo did not have an effect on exerciser's experience of an isometric strength test. However, these results are in line with Tenenbaum's (2001) social-cognitive model which postulates that as exercise intensity increases attentional flexibility decreases and attention narrows to associative, somatic cues.

Association between Fatigability and Physical Function among the Elderly in the Geisinger Rural Aging Study

James E. Stampley¹, Brett Davis¹, G. Craig Wood², Diane C. Mitchell³, Gordon L. Jensen⁴, Yi-Hsuan Liu³, Xiang Gao³, Bethann Whilden², Marianne Yohn², Krystal Cunningham², Megan Lemotte², Christopher D. Still², Brian A. Irving, FACSM¹. ¹Louisiana State University, Baton Rouge, LA. ²Geisinger Medical Center, Danville, PA. ³Penn State University, University Park, PA. ⁴University of Vermont, Burlington, VT. (Sponsor: Brian A Irving, PhD, FACSM)

(No relevant relationships reported)

Elevations in perceived fatigue, fatigability, likely contribute to impairments in physical function in the elderly. However, the independent and combined effects of physical and mental fatigability on physical function in the elderly is unknown. **PURPOSE:** We examined the cross-sectional associations between physical fatigability, mental fatigability, and physical function among the elderly in the Geisinger Rural Aging Study (GRAS). **METHODS:** Here, we included 122 (66F, 56M) elderly (≥ 80 years) participants from the GRAS who completed the Pittsburgh Fatigability Scale (PFS) and PROMIS Physical Function, Short-Form 20a [question pfa11 was excluded due to missing values]. We used multiple linear regression to measure the association between the PROMIS Physical Function Score (19-95) and PFS - Physical Fatigability Score (0-50, no to extreme physical fatigue) and PFS - Mental Fatigability Score (0-50, no to extreme mental fatigue) adjusted for age, sex, BMI, and number of medications used over the past two years. **RESULTS:** The mean (SD) Physical Function Score, Physical Fatigability Score, Mental Fatigability Score, BMI, and number of medications were 80 (11), 23 (10), 12 (11), 28 (5) kg/m² and 18 (8), respectively. Low Physical Function Scores were associated with higher Physical and Mental Fatigability Scores in crude models ($r = -0.65$, $p < 0.0001$ and $r = -0.38$, $p < 0.0001$, respectively). When Physical and Mental Fatigability Scores were included in the same model, the association between the Physical Function and Physical Fatigability Scores remained significant ($r = -0.57$, $p < 0.0001$), while the association between the Physical Function and the Mental Fatigability Scores was no longer significant ($r = 0.07$, $p = 0.43$). Adjustment for age, sex, BMI and number of medications did not change the significant inverse association between the Physical Function and Physical Fatigability Scores ($r = -0.65$, $p < 0.0001$). **CONCLUSION:** Our results suggest that elderly individuals with lower physical function may also have higher physical fatigability independent of age, sex, BMI, and number of medications. Future studies should examine the impact of improving physical fatigability on physical function in the elderly. This study is funded by the USDA, Agricultural Research Service agreement 8050-51530-012-01A

Longitudinal Association Between Fatigability and Executive Function: Results from the Baltimore Longitudinal Study of Aging

Elizabeth Salerno¹, Amal Wanigatunga², Jacek Urbanek², Eleanor Simonsick³, Susan Resnick³, Jennifer Schrack². ¹National Cancer Institute, Bethesda, MD. ²Johns Hopkins Bloomberg School of Public Health, Baltimore, MD. ³National Institute on Aging, Baltimore, MD. (Sponsor: Charles Matthews, FACSM)
(No relevant relationships reported)

Cognitive decline, specifically within the domains of executive function, has been consistently associated with diminished life satisfaction and the ability to carry out activities of daily living in older adults. As the population continues to age, identifying methods of attenuating cognitive decline is important for promoting long-term survival and quality of life. Previous research has suggested that fatigability, one's perceived exertion after a standardized walking task, is associated with declines in physical function; however, it remains unclear as to whether these effects may also extend to cognitive function. **PURPOSE:** To examine whether fatigability is associated with executive function among individuals participating in the Baltimore Longitudinal Study of Aging (BLSA). **METHODS:** The BLSA is an ongoing study of normative human aging. Participants included 1,068 older adults ($M_{age} = 67.3 \pm 12.7$ years)

seen between 2007 and 2015. At baseline and after $M = 4.5 \pm 1.8$ years of follow-up, individuals completed a physical examination, health history assessment, standardized walking task to assess fatigability, and cognitive battery assessing several domains of executive function. **RESULTS:** Multiple linear regression analyses revealed significant effects of baseline fatigability on several domains of executive function at follow-up: Digit Symbol Substitution Test ($\beta = -0.47$, $p = 0.011$), Trails Part B ($\beta = 1.85$, $p = 0.031$), and Trail Making Delta (Part B-Part A; $\beta = 1.56$, $p = 0.038$). Specifically, higher baseline fatigability was significantly associated with poorer cognitive performance at follow-up after controlling for age, sex, race, body mass index (kg/m²), years of education, years of follow-up, and number of comorbid conditions. **CONCLUSIONS:** Our findings suggest that the perception of fatigue in response to a standardized walking task may act as an indicator of future cognitive decline, at least in the short-term (e.g., 5 years). More research is warranted to examine the underlying biological mechanisms contributing to this relationship as well as how future interventions may target fatigability in mid-life to potentially attenuate age-related cognitive decline. The Perceptual Responses to Continuous vs Intermittent Blood Flow Restriction Resistance Exercise

Eduardo D. S. Freitas¹, Ryan M. Miller¹, Aaron D. Heishman¹, Japneet Kaur¹, Brady S. Brown¹, Julio C. G. Silva², Rodrigo R. Aniceto³, Joao B. Ferreira-Junior⁴, Michael G. Bembem, FACSM¹. ¹University of Oklahoma, Norman, OK. ²Federal University of Paraíba, João Pessoa, Brazil. ³Federal Institute of Rio Grande do Norte, Currais Novos, Brazil. ⁴Federal Institute of Southwest Minas Gerais, Rio Pomba, Brazil. (Sponsor: Michael G. Bembem, FACSM)
(No relevant relationships reported)

PURPOSE: To investigate the perceptual responses (ratings of perceived exertion [RPE] and discomfort [RD]) to continuous and intermittent resistance exercise (RE) with blood flow restriction (BFR; 50% of total occlusion pressure), as well as to compare these responses to high- and low-load RE without BFR. **METHODS:** Fifteen untrained participants were randomly assigned to 4 RE conditions: 1) low-load with continuous BFR (cBFR: cuffs remain inflated between sets); 2) low-load with intermittent BFR (iBFR: cuffs are deflated between sets); 3) low-load without BFR (LI); and 4) high-load without BFR (HI). For all low-load conditions, participants performed 4 sets (30-15-15-15 reps) of bilateral leg press and knee extension at 20% of 1RM, whereas the HI condition involved 4 sets (10-10-10-10 reps) at 70% of 1RM for the same exercises. RPE was assessed after each set using the OMNI-RES scale with scores ranging from 0 to 10. RD was assessed before exercises and after each set using a visual analog pain scale with scores ranging from 0 to 10. Data were analyzed using the Friedman's and the Wilcoxon tests with Bonferroni correction and p set at 0.05. **RESULTS:** There were no significant ($p > 0.05$) differences in RPE after each set of leg press for the cBFR and iBFR conditions. HI was significantly ($p < 0.05$) greater than all low-load conditions after each set except for cBFR at sets 1 and 2. There were no significant differences ($p > 0.05$) in RD after each set of the cBFR, iBFR, and HI conditions, except after set 4, when HI was significantly ($p < 0.05$) greater than iBFR. For knee extension, similar responses were observed for RPE after each set, with no significant differences ($p > 0.05$) observed for cBFR, iBFR, and LI conditions; however, HI was significantly ($p < 0.05$) greater than the other 3 conditions. For the HI condition, RD was significantly ($p < 0.05$) greater than the iBFR condition at baseline. Similar RD values were observed for the cBFR, iBFR, and HI conditions after each set, which was significantly ($p < 0.05$) greater than the LI condition. **CONCLUSION:** Continuous and intermittent RE with BFR seem to elicit similar perceptual responses. For RPE, these responses were similar to those from low-load RE and lower than those from high-load. For RD, both BFR conditions were similar to high-load levels and greater than the low-load condition.

Emotional Influence Of Music In Relation To The Effect Of Music On Exercise Performance

Kayla M. Baker, Jeanette Garcia, Tal Belity. University of Central Florida, Orlando, FL.
(No relevant relationships reported)

PURPOSE: The purpose of this study is to examine the relationship between individuals' emotional influence of music (EIM) and the effect of listening to music during treadmill running. **METHODS:** Twenty-two recreationally-active adults (21.7 ± 1.78 yrs) completed six visits, including an initial visit to complete a questionnaire to assess EIM. During this visit, participants also created a personal playlist from a song database which utilized cadences of 180 beats per minute. Participants completed treadmill familiarization trials, running at a self-selected pace for 20 minutes, during the second and third visits. Participants then completed a VO2max test on the treadmill during the fourth visit, where running speeds and ratings

of perceived exertion (RPE) were measured. During the final two visits, participants completed time-to-exhaustion (TTE) trials while running at a speed corresponding to 80% of their VO₂max on a treadmill. For these trials, two separate conditions were utilized: 1) no music (NM); and 2) self-selected music (SSM). Bivariate correlations were used to determine the relationship between EIM and physiological variables, while paired samples t-tests were used to examine differences between TTE trials. **RESULTS:** A significant difference was found between TTE with NM (M=12.18±5.77) and TTE with SSM (M=14.36±5.22) (t=4.124, p<0.001). EIM was positively correlated to RPE during the TTE without music (r=0.457, p<0.05), while VO₂max was negatively correlated to the difference between TTE trials (r=-0.481, p<0.05). **CONCLUSION:** Individuals with a higher EIM perceived greater exertion during running without music compared to running while listening to music, indicating that these individuals may experience a heightened level of motivation or inspiration while using music as an external stimulus during exercise and a diminished level of motivation when music is not utilized. Additionally, individuals with a greater VO₂max experienced less of a difference between TTE trials, suggesting that individuals with greater aerobic fitness may not rely on external stimuli for motivation, regardless of EIM. Utilizing music as an external stimulus to increase motivation may be a beneficial tool for certain individuals, whether it be in a personal training environment or a physical rehabilitation setting.

Declines In Mental Energy Led To Decreases In Functional Balance: A Pilot Study Using Machine Learning To Detect Changes In Functional Balance
 Ali Boolani, Jenna Ryan, Trang Vo, Brandon Wong, Natasha Kholgade Banerjee, George Fulk. *Clarkson University, Potsdam, NY.* (Sponsor: Dr. Bert Jacobson, FACSM)
 Email: aboolani@clarkson.edu
 (No relevant relationships reported)

Purpose: The purpose of this study was to determine the impact of mental task performance on fall risks and to use machine learning to predict changes in fall risk assessments.
Methods: Using a crossover-design, older adults (N=11) were recruited from the community and assigned to random allocation of days where they performed fall risk assessments (30 second chair stand test (CST), Timed-up-and-go (TUG), and Berg Balance Scale (BBS) prior to and after the completion of mental tasks or days where they were told to perform non-mentally and physically taxing tasks (i.e. talk, listen to music) in between the completion of fall risk assessments. A Wilcoxon Sign Rank Test was used to assess differences in fall risks and a Friedman's rank test was used to assess changes in mood (energy, fatigue, physical and mental energy and fatigue). Using the X-box Kinect we measured variances in 25 joints. A random forest classifier was used to predict changes in functional balance. **Results:** Analysis yielded statistically significant declines in feelings of energy (p=.003), specifically mental energy (p=.015), and a decline in the BBS (p<.001) for participants on days when they completed mental tasks compared to days they did not. There were no significant differences (p>.05) between other moods and fall risk assessments. We observed a significant increase (p=.006) in joint variance during the "standing with eyes closed" part of the BBS after the subjects had performed mental tasks. In the post-hoc analysis our random-forest algorithms allowed us to predict with 79.0% accuracy whether the "standing with eyes closed" part of the BBS was performed after a decline a mental energy or not. The false positive rate was 40.0% and the false negative rate was 21.0%. **Conclusions:** The results of our study suggest that declines in mental energy negatively impacts postural control. Our work was able to predict with a fair degree of accuracy when someone had a decline in mental energy based on changes in functional balance however, it was unable to predict when there was no mental work performed. This suggests that when there is no decline in feelings of energy there is no change in functional balance, and mental work leads to declines in postural control.

Exercise Intensity: Do Individuals Perceive It as We Physiologically Define It?
 Kristofer Wisniewski. *Saint Francis University, Loretto, PA.*
 Email: kwisniewski@francis.edu
 (No relevant relationships reported)

The ACSM defines exercise intensities using physiological measures (%VO₂max, %VO₂R, %HRmax, %HRR). Currently, there are no studies examining if individuals perceive the exercise intensity as it is defined by the physiological ranges for each measure. **PURPOSE:** To determine if individuals perceive aerobic exercise intensities as defined by ACSM physiological criteria. **METHODS:** Sixty-three subjects (31 females, 32 males) aged 28.3 ± 11.3 years, BMI 25.0 ± 3.5 kg·m⁻², and VO₂max 43.0 ± 9.0 mL·kg⁻¹·min⁻¹ participated in this study. Subjects completed a Bruce treadmill protocol to maximal exertion while rating the intensity at the end of each stage using a Perceived Intensity (PI) scale. The scale reads: Very Light, Light, Moderate, Vigorous, Near Maximal, and Maximal. Subjects were given standard instructions on how to

use the scale prior to the test. Actual Intensity (AI) was determined using %VO₂max, %VO₂R, %HRmax, and %HRR attained at the end of each stage. PI rated at the end of each stage was compared against the AI for each variable. **RESULTS:** Correlation analyses showed strong relationships between PI responses and %VO₂max (r = 0.886, p < 0.05), %VO₂R (r = 0.891, p < 0.05), %HRmax (r = 0.858, p < 0.05), and %HRR (r = 0.862, p < 0.05). Cohen's Kappa (K) for the total sample showed fair to moderate agreements between PI and AI for %VO₂max (K = 0.405, p < 0.05), %VO₂R (K = 0.394, p < 0.05), %HRmax (K = 0.386, p < 0.05), and %HRR (K = 0.392, p < 0.05). The Contingency table for %VO₂max showed only 37.0% of PI ratings at a Moderate intensity were accurate with 61.1% of PI rated as less than Moderate. Vigorous intensity ratings were similar with 33.9% accuracy, and 61.3% of ratings as less than Vigorous. **CONCLUSION:** Current physical activity recommendations state that adults should participate in moderate and vigorous intensity activities for health-related benefits. Despite having strong relationships with physiological criteria, the majority of subjects under-rated moderate and vigorous intensities. The results suggest that further subjective definitions of intensity may be needed to match perceptions with physiological measures. Therefore, individuals may need additional familiarization with intensity definitions if they are going to use perceptual measures to regulate intensity.

Effect of Prescribing Exercise through Verbal Commands on Psychophysiological Responses in Walkers or Runners
 Sergio G. da Silva¹, Armando L. Bonfim Neto¹, Lucio Follador¹, Sandro S. Ferreira¹, Murilo Bastos¹, Ragami C. Chaves¹, Antoby G. Lopes¹, Maressa P. Krause², Carlo Baldari, FACSM³. ¹Universidade Federal do Parana, Curitiba, Brazil. ²Universidade Tecnologica Federal do Parana, Curitiba, Brazil. ³Link Campus University, Rome, Italy.
 Email: sergiogregorio1@gmail.com
 (No relevant relationships reported)

Purpose: To compare the effect of prescribing exercise intensity through verbal commands on physiological, perceptual and affective responses in habitual walkers or runners. **Methods:** Fifteen walkers or runners (11 men, 4 women; age: 39.9 ± 9.9 years; height: 172.0 ± 6.1 cm; body mass: 72.6 ± 9.5 kg; BMI: 24.5 ± 2.5 kg·m⁻²; VO₂max: 46.3 ± 7.4 mL·kg⁻¹·min⁻¹; HR_{max}: 177.2 ± 11.5 bpm) were submitted to four trials of walking or running at self-selected intensities corresponding to the following verbal commands: Preferred, Low, Moderate and High. All trials were performed in a randomized order. Heart rate (%HR_{max}), ratings of perceived exertion (RPE 0-10, OMNI-Walk/run scale) and feelings of pleasure/displeasure (-5 to +5, Feeling Scale) were recorded at the end of each trial. **Results:** Walking or running based on the Preferred-intensity verbal command elicited similar speed, %HR_{max} and RPE values, and pleasant feelings compared to the Moderate trial. The High trial was the most effortful and the least pleasant one. All trials elicited %HR_{max} values that are within the range proposed by the ACSM to promote health-related outcomes.

| | Preferred | Low | Moderate | High |
|---------------------------------|------------|-------------------------|-------------------------|---------------------------|
| Speed (m.s⁻¹) | 3.3 ± 0.6 | 2.7 ± 0.6 ^a | 3.1 ± 0.6 ^b | 3.7 ± 0.6 ^{abc} |
| %HR_{max} | 91.3 ± 6.3 | 81.4 ± 9.7 ^a | 89.9 ± 8.4 ^b | 96.2 ± 3.9 ^{abc} |
| RPE | 4.5 ± 0.6 | 2.3 ± 0.4 ^a | 4.5 ± 0.4 ^b | 7.8 ± 0.4 ^{abc} |
| Feeling Scale | 3.6 ± 1.0 | 2.4 ± 2.1 | 3.7 ± 1.3 | 0.5 ± 2.5 ^{ac} |

^adifferent from Preferred; ^bdifferent from Low; ^cdifferent from Moderate. p < .01.

Conclusion: Prescribing walking or running through verbal commands seems highly attractive due to its effectiveness and simplicity. Walking or running at the Preferred-intensity verbal command may promote health-related outcomes and elicit a positive affective experience, which might influence exercise adherence.

Relationship Among Site Specific Fat, Lean Mass, And Endogenous Pain Inhibitory Function
 Jessica A. Peterson, Cameron Lohman, Michael Bembem, FACSM, Rebecca Larson, Christopher D. Black, FACSM. *University Of Oklahoma, Norman, OK.* (Sponsor: Christopher Black, FACSM)
 Email: jessica.a.peterson-1@ou.edu
 (No relevant relationships reported)

Overweight individuals experience greater functional and psychological complications of chronic pain. Dysfunction of endogenous pain-modulatory mechanisms such as conditioned pain modulation (CPM) and exercise-induced hypoalgesia (EIH) have

been found across a host of chronic pain conditions. **PURPOSE:** The purpose of the study was to assess endogenous pain inhibitory function and its relationship with whole body and site specific lean and fat mass. **METHODS:** PPT of 73 participants (38F; 35M) were assessed in the vastus lateralis (VL) and brachioradialis (BR) using a pressure algometer on both sides of the body before and after submersion of their feet in an ice bath (2°C) for 1min and an isometric knee extension, time to failure task based off of 25% of their maximal voluntary contraction. The difference between post and pre measures was defined CPM response (ice bath) and EIH response (exercise condition). Whole body and site specific fat and lean tissue were assessed via DXA scan, and muscle and fat thickness were assessed in the right (R) and left (L) VL and BR using ultrasound and skinfolds. **RESULTS:** Both CPM and EIH responses significantly increased PPTs for all of the four measured sites ($p \leq 0.001$). BF% ($r=0.256$; $p=0.029$) and fat mass ($r=.277$; $p=0.018$) correlated with LBR CPM but not with site specific measures ($p>0.05$). RBR, RVL, and LVL CPM did not correlate with any measures of body composition ($p>0.05$). An inverse relationship was found between dominant VL EIH and whole body lean mass ($r=-0.259$; $p=0.028$), as well as limb specific lean mass ($r=-0.262$; $p=0.026$). No relationships were found between any of the body composition measures and non-dominant VL ($p>0.05$). **CONCLUSION:** It appears that in young, healthy adults, whole body and site specific fat mass does not influence endogenous pain-inhibitory function. However, having more lean tissue may have a negative effect on the EIH response. This may be due to larger muscle mass leading to a faster rate of fatigue, reducing exercise time which may have influenced the EIH response rather than muscle mass per se.

Effects Of Carbonated Sports Drink Intake After High-intensity Exercise On Fatigue Recovery In Athletic Sprinters

Natsuki Hasegawa¹, Shumpei Fujie², Naoki Horii¹, Takafumi Hamaoka, FACSM³, Motoyuki Iemitsu¹. ¹*Ritsumeikan University, Kusatsu, Japan.* ²*University of Tsukuba, Ibaraki, Japan.* ³*Tokyo Medical University, Shinjuku-ku, Japan.* (Sponsor: Takafumi Hamaoka, FACSM)
 Email: hase0528@fc.ritsumeik.ac.jp
 (No relevant relationships reported)

Carbonic acid bathing elevates vasodilation and blood flow due to transcutaneous absorption of carbonic acid, resulting in acceleration of fatigue recovery. On the other hand, carbonated drink intake has no effect on aerobic exercise performance in endurance athletes. However, the effect of carbonated drink intake on anaerobic exercise performance remains unclear. **PURPOSE:** This study aimed to clarify whether carbonated sports drink intake after high-intensity exercise promotes fatigue recovery, leading to attenuation of performance decrement in athletes. **METHODS:** Seven male and four female athletic sprinters were enrolled in this study (20.4±0.4 years). All subjects performed wingate exercise session, as an index of anaerobic exercise capacity, (3 sets of 20-sec all-out pedaling on a cycle ergometer against a resistance equivalent to 7.5 % of body weight, with a 30-sec rest), and the same exercise session is performed once again after a 25-min break. They orally took carbonated sports drink (CSD) containing 2g of carbonic acid or non-carbonated sports drink (NCSD) (500mL) during the 25-min break in a crossover randomized trial with 3-4days between each trial. Blood lactate concentration was measured at rest and 1, 3, 5 and 10 mins after the first exercise session. **RESULTS:** In all athletic sprinters, mean power output of the first set at the second exercise session was significantly higher in the CSD intake than the NCSD intake ($P<0.05$). Additionally, in males, mean power output of the first set at the second exercise session in the CSD intake tended to be higher compared with the NCSD intake ($P=0.07$), whereas, no significant difference was observed in females. Moreover, in males, lactic acid integrated value after 10 mins of first exercise session in males was significantly lower in the CSD intake than NCSD intake ($P<0.05$), but there was no significant difference in females. **CONCLUSIONS:** These results suggest that the carbonated sports drink intake after high-intensity exercise may promote fatigue recovery, and this effect may differ by gender. Circulating Mcp-1 During And Following Prolonged Cycling In Cold Temperature

Ellen L. Glickman, FACSM, Cody Dulaney, Emily Tagesen, Eliot Arroyo, Brittany N. Followay, Jeremiah A. Vaughan, Adam R. Jajtner. *Kent State University, Kent, OH.*
 Email: eglickma@kent.edu
 (No relevant relationships reported)

PURPOSE: The purpose of this investigation was to examine the impact of aerobic exercise in a cold condition on the recruitment of classical monocytes (CD14++CD16-). **METHODS:** Six recreationally active men (24.7±3.9 yrs; 182.3±6.9 cm; 85.7±12.8 kg; 3.7±0.3L·min⁻¹) completed three experimental conditions; a VO₂max test, and a cycling protocol in 9°C/55% Relative Humidity (RH)(LTLH), and 24°C/38%RH (MTMH). The exercise session consisted of 60-min cycling at 60% VO₂max, 15-min rest, and a time to exhaustion at 90% VO₂max (TTE). Blood samples were obtained before (PRE), after 60-min of cycling (60), after TTE (90) and after 1-hour of recovery (REC). Blood was analyzed for plasma concentration of Monocyte Chemoattractant Protein 1 (MCP-1) via ELISA, and the expression of MCP-1 receptor (CCR2) on classical monocytes and assessed by flow cytometry. Expression was determined based on fold changes over fluorescence minus one (FMO). Data were analyzed using within-subjects repeated measures ANOVA. **RESULTS:** No interaction ($F = 2.3$; $p = 0.128$; $\eta^2_p = 0.251$), main effect for time ($F = 1.9$; $p = 0.202$; $\eta^2_p = 0.209$) nor main effect of condition was observed ($F = 0.13$; $p = 0.727$; $\eta^2_p = 0.018$) for circulating MCP-1. No interaction ($F = 1.7$; $p = 0.251$; $\eta^2_p = 0.249$) was observed for CCR2 expression on classical monocytes, however, a main effect for time ($F = 31.2$; $p = 0.002$; $\eta^2_p = 0.862$) was observed. CCR2 expression was maintained from PRE (137.6 ± 37.4) to 60 (124.4 ± 91.2, $p = 0.068$), before decreasing at 90 (124.4 ± 36.8, $p = 0.001$) and REC (86.4 ± 25.2, $p < 0.001$). **CONCLUSION:** This data indicates that prolonged cycling in cold temperature may reduce the recruitment of classical monocytes, evident by reduced CCR2 expression. This may indicate a suppression of classical monocyte recruitment during exercise in moderate and cold temperatures. Further research is warranted to assess these responses at greater intensities or duration.

Effects Of Cooled Compression Exercise Technology On Health, Sleep, And Quality Of Life In Veterans.

Pat Marques¹, Grove Higgins¹, Chloe Wernecke², Sara Webb¹, Lindsay Haughton¹, Liz Grimm¹, Mary Wilson¹, Aaron Black¹, Cristian Torres². ¹*Colorado Springs Center for Human Performance and Rehabilitation, Colorado Springs, CO.* ²*Vaspar Systems, Moffett Field, CA.*
 (No relevant relationships reported)

Veterans are disproportionately affected by physical and emotional functional disorders compared to their civilian counterparts, a discrepancy that is deepened by delay to care within the Veterans Health Administration. Research has supported use of compression exercise in physically limited populations and demonstrated physiological responses at lower intensities (10-20% one repetition maximum vs 70% for hypertrophy in resistance exercise). Combination of low-pressure compression exercise and cooling has shown elevated growth hormone and testosterone and depressed nighttime cortisol, indicating this may be beneficial for addressing emotional and sleep dysfunctions. **PURPOSE:** To determine the safety and efficacy of an accessible cooled compression exercise system on markers of physical and emotional function in veterans. **METHODS:** 14 veterans completed 24 sessions in 12 weeks. Baseline and endpoint questionnaires validated for clinical significance were administered to determine sleep quality (Pittsburg Sleep Quality Index), quality of life (RAND Short Form 36), and respiratory dysfunction related to stress and anxiety (Nijmegen Questionnaire). **RESULTS:** Two-tailed T-tests were performed on the data. Sleep quality improved in 71% of subjects (9.15±6.87 vs 5.57±3.74, $p = 0.0232$), 57% improved quality of life (73.45±17.17 vs 84.46±9.27, $p = 0.0316$), and 71% decreased adverse respiratory symptoms (11.29±8.38 vs 7.86±6.26, $p = 0.0594$) compared to baseline. Increases were seen in all 8 sub-scores of quality of life, with statistically significant improvements in social functioning (75±28.17 vs 94.64 ±11.62, $p = 0.0058$), energy and fatigue (48.93±25.21 vs 65.63±19.26, $p = 0.0426$), emotional wellbeing (66±24.29 vs 85.14±14.16, $p = 0.0054$, and general health (72.14±15.78 vs 79.64±12.78, $p = 0.0497$). For sleep quality, those subjects with baseline scores defined as clinically disturbed sleep (n=8, 58%) all (100%) experienced sleep improvements (9.14±6.87 vs 5.57±3.74, $p = 0.00301$), with 25% resolving below clinical delineation.

CONCLUSION: These findings suggest that the combination of cooling and compression exercise may be an effective intervention method to address symptoms in veterans and other individuals living with insomnia, post-traumatic stress, chronic fatigue, and depression.

Whole-body Cryotherapy: Case Series Of Sleep, Pain And Anxiety In Healthy Individuals

Jennifer L. Scheid¹, James W. Kenney², Daniel H. Lang², Nicole Chimera³. ¹Daemen College, Amherst, NY. ²Cryo Wellness of America, Depew, NY. ³Brock University, St. Catharines, ON, Canada.
 Email: jscheid@daemen.edu
 (No relevant relationships reported)

BACKGROUND: Whole-body cryotherapy (WBCT) takes place in an enclosed chamber at -184 degrees Fahrenheit. WBCT is currently used to alleviate inflammation and pain in arthritis and osteoarthritis and for pain relief in fibromyalgia. However, to date, only anecdotal evidence exists on the benefits of cryotherapy to provide deep, restful sleep. **PURPOSE:** The purpose of this case series was to test the hypothesis that WBCT would have a positive impact on sleep, pain levels and anxiety of healthy individuals. **METHODS:** Surveys regarding sleep, pain levels and anxiety were administered before and after 10 WBCT sessions (max 3 minutes) to five participants (Age > 50). Sleep was assessed using the Pittsburg Sleep Quality Assessment Index (PSQI), pain was assessed using the Borg Rate of Perceived Pain Scale, and anxiety was assessed using the Hamilton Anxiety Scale. **RESULTS:** One male (Age 74, BMI = 30.7 kg/m², Caucasian) and one female (Age 73, BMI = 24.9kg/m², Caucasian) presented with pain from arthritis and while the WBCT had no impact on sleep or anxiety, their pain was reduced from moderate/strong pain (Borg = 4) to extremely weak pain (Borg = 0.5) and from moderate/strong pain (Borg = 4) to weak/moderate pain (Borg = 2.5), respectively. One female (Age 52, BMI = 24.0 kg/m², Caucasian) presented with stress/anxiety and sleep problems. Her pain improved from moderate (Borg = 3) to very weak (Borg = 1), her sleep quality improved by 12 points on the PSQI and her anxiety score improved by 18 points on the Hamilton anxiety scale. Finally, two females (Age 65 and 72) both had no specific reason for trying the WBCT. Both demonstrated no changes in pain, sleep, or anxiety. **CONCLUSION:** These five cases demonstrate that WBCT can improve pain if the subjects present with moderate (or greater pain) and that WBCT may be able to improve sleep and anxiety in subjects that present with problems with sleep or anxiety. Future research is needed in larger samples of people with a history pain, anxiety and/or sleep issues to continue to test the hypothesis that WBCT may have a positive impact on sleep, pain levels and anxiety.

Human Physiologic Thermogenic Response to Resting Cold-Water Immersion: A Thorough Calorimetric Inquiry

James E. Campbell, Elizabeth R. Bergeron, Christopher D. Gallagher, John P. Florian. Navy Experimental Dive Unit, Panama City, FL.
 (No relevant relationships reported)

PURPOSE: Navy Diver thermal protection, a primary concern in attempting or completing cold-water tasks, remains inadequate. Optimal heat distribution with minimal energy input is sought. Therefore, heating requirements that support thermal balance (TB) in various cold-water scenarios were quantified. **METHODS:** Nine active duty Navy personnel underwent four resting immersion scenarios in a temperature-controlled 4900-gallon water tank after donning the same full-body tubsuit calorimeter (for diver heat delivery and measurement), undergarments, and a dry suit (total 1.2 Clo). Each subject achieved TB (\leq 2hrs immersion). TB was defined as temperature equilibrium where core and mean skin temperatures varied \leq 0.2°F over 20 minutes time. The four scenarios were combinations of the independent variables: 1) inlet tubsuit water temperature (89 and 102°F), and 2) immersion tank temperature (35 or 50°F). **RESULTS:** Metabolic compensation continuously increased over time (Fig 1a) in the 89°F tubsuit/35°F immersion temperature water group. At the fourth quartile time point (during achievement of thermal balance, Fig 1a - Fourth), subjects in the groups of greater tubsuit heat delivery (102°F) required significantly less metabolic activity than did the coldest scenario (89°F/35°F). Distal anatomical sites showed much lower temperatures than proximal sites (data not shown). Tubsuit heat delivery (Wattage) increased significantly (Fig 1b) with both greater tubsuit temperature (102°F vs 89°F) and in colder water immersion (35°F vs 50°F). Thermal balance was achieved in all scenarios thereby allowing steady-state assessment of heat input/extraction parameters. All * indicate p<0.05. **CONCLUSIONS:** Given that thermal balance was achieved over the course of each \leq 2-hr exposure, results suggest that using a lower tubsuit perfusion temperature (89°F vs 102°F) requires less Wattage provided a sufficient metabolic response is activated during the immersion.

Consecutive, Long-Duration Hyperoxic Immersions Effect on Skeletal Muscle Performance in Well Trained, Male Divers

Christopher M. Myers¹, Jeong-Su Kim, FACSM¹, John Florian, FACSM². ¹Florida State University, Tallahassee, FL. ²Navy Experimental Dive Unit, Panama City Beach, FL. (Sponsor: John Florian, FACSM)
 Email: cmm13c@my.fsu.edu
 (No relevant relationships reported)

PURPOSE: The primary objective of this study was to investigate how resting, long-duration hyperoxic water immersions (WIs) at 1.35 atmospheres absolute (ATA) effected neuromuscular strength performance. We hypothesized that following five consecutive days of hyperoxic WIs, neuromuscular strength performance would be diminished post-WI and remain reduced longer than 72-hrs post-WI. **METHODS:** Thirteen (n=13), active male divers [31.3 ± 1.7 (24-43) yrs., mean ± SEM] completed five consecutive 6-hour resting WIs with 18-hour surface intervals while breathing 100% O₂ (n=13) at 1.35 ATA. Skeletal muscle performance assessments occurred immediately before and after each WI, and 24 and 72 hours after the final WI. Performance assessments included maximum voluntary isometric contraction (MVIC) and maximal isokinetic (IK) knee extensions and elbow flexions, and maximum handgrip strength (MHG). We measured neuromuscular activation of the quadriceps, biceps brachii, and brachioradialis via surface electromyography (sEMG). **RESULTS:** MHG declined by 7.8% (p<0.001) by WI 5 with performance returning to baseline by 24-hr post-WI. Brachioradialis neuromuscular activation increased by 42% (p<0.001) on WI 5. MVIC knee extension performance dropped by 4% (p=0.001) on WI 3 with an 11% overall decrease in quadriceps neuromuscular activation. Maximal IK knee extension dropped by 3.3% (p=0.008) on WI 5 with 9.3% (p=0.014) drop in overall quadriceps activation dropped by 7% (p=0.013) during the same period. MVIC elbow flexion performance declined by 5.1% (p<0.001) with an 18% decline in neuromuscular activation by WI 5 but returned to baseline by 72-hr post-WI. Maximal IK elbow flexion performance dropped by 8.6% (p<0.001) on WI 5 with a continual decline in biceps brachii neuromuscular activation by 24% (p<0.001) on WI 5. **CONCLUSION:** The decreases in neuromuscular activation and strength performance coinciding with the non-load bearing muscles affected more than the load-bearing muscles. Yet, the brachioradialis had increases in neuromuscular activation with decreases in performance. These types of hyperoxic WIs caused significant changes to neuromuscular performance after three days of WI with recovery varying with each measured variable with some decrements lasting until the 72-hr post-WI recovery period.

Carotid Body Chemosensitivity is Not Attenuated During Hyperbaric Hypoxia

Hayden W. Hess, Corey R. Carden, Brett A. Siders, Lindsey N. Russo, Brian M. Clemency, David Hostler, FACSM, Blair D. Johnson. University at Buffalo, BUFFALO, NY. (Sponsor: Dave Hostler, FACSM)
 Email: haydenhe@buffalo.edu
 (No relevant relationships reported)

Water immersion causes CO₂ retention, thus increasing the risk of CO₂ toxicity. Hyperoxia reduces carotid body (CB) tonic activity, which reduces the ventilatory response to hypercapnia. However, it is not known if CB chemosensitivity is altered during the high partial pressure of oxygen associated with hyperbaria. **PURPOSE:** We tested the hypothesis that oxygen breathing would lower CB chemosensitivity more than breathing air at 6.1 msw depth. **METHODS:** Five subjects (age: 23±2 y; BMI: 28±5 kg/m²) completed two, four-hour dry dives at 6.1 msw (1.6 ATA) breathing either 100% O₂ or air. CB chemosensitivity was assessed using hypoxic ventilatory response (CB_{o2}) and brief hypercapnic ventilatory response (CB_{CO2}) tests pre-dive, 75 and 155 min into the dives, immediately post-dive, and 60 min post-dive. CB_{o2} consisted of

inhaling 100% N₂ for 2-6 breaths, repeated four times, with 2 min between hypoxic exposures. CB_{CO₂} consisted of inhaling 13% CO₂, 66% N₂, 21% O₂ for one breath, repeated four times, with 2 min between hypercapnic exposures. CB chemosensitivity was calculated as the slope of the linear regression line of the peak minute ventilation (MV) in three consecutive breaths vs. the nadir oxygen saturation (pulse oximetry; SpO₂) or peak end tidal CO₂ tension (capnography; PETCO₂) for CB_{O₂} and CB_{CO₂}, respectively. Data are reported as a change from pre-dive (mean±SD). **RESULTS:** SpO₂ was higher than pre-dive at all time points (all p<0.01), but was not different between conditions (p=0.24). The change in MV was not different over time (p=0.11) or between conditions (p=0.42). PETCO₂ increased during the dive at 75 (Air: 10±5 vs. O₂: 7±4 mmHg) and 155 min (Air: 8±5 vs. O₂: 5±3 mmHg; p<0.01), but did not differ between conditions (p=0.14). CB_{O₂} and CB_{CO₂} were not different at any time point (p=0.29 and p=0.48, respectively) and were not different between 100% O₂ or air conditions (p=0.64 and p=0.32, respectively). **CONCLUSIONS:** These data indicate that CB chemosensitivity to hypoxia and hypercapnia is not attenuated during hyperbaric hyperoxia. Therefore, the carotid body chemoreceptors do not appear to contribute to CO₂ retention in hyperbaria.

Prolonged Hyperbaric Exposure Alters Gut Mucus, Microbiota Composition And Intestinal Antimicrobial Defense In Mice

Dao Xiang¹, Beibei Luo², Yiqun Fang¹, Ji Xu¹, Jia He¹, Peijie Chen². ¹Second Military Medical University, Shanghai, China. ²Shanghai University of Sport, Shanghai, China.
 Email: x-a1@163.com

(No relevant relationships reported)

PURPOSE: Divers with prolonged hyperbaric exposure may suffer from digestive dysfunctions, which relate to impairment of intestinal mucosal immune system and gut microbiota homeostasis. We studied the effects of a 4-day hyperbaric exposure on gut microbiota and intestinal antimicrobial peptides (AMPs) in mice.

METHODS: 20 male C57 Mice, 8-week old, were randomly divided into hyperbaric exposure group (HE, n=10) and control group (CON, n=10). The Hyperbaric environment was established by compressed N₂/O₂ mixed gas, and sustained the ambient pressure at 500kPa for 4 days in the pressure chamber. Intestines were excised and stained with Hematoxylin and Eosin (H&E) and alcian blue-periodic acid-schiff staining (AB-PAS). Feces and intestines were collected and extract gDNA and RNA respectively. We used qPCR to assay bacterial population (*Bacteroides*, *Clostridia*, *Lactobacilli*, *Enterobacteria*, and *Akkermansia muciniphila*) of the feces, and the AMPs (*Defa5*, *Defb1*, *Retnlb*, *Reg3b* and *Reg3g*) of small intestine and colon.

RESULTS: During the hyperbaric exposure, the mice did not exhibit any behavioral abnormality, including nitrogen narcosis. According to the AB-PAS staining, the mucus was reduced in colons post hyperbaric exposure. And there was no significant morphological difference between intestines and colons from the mice of HE group and CON by H&E staining. By comparing with the 16S rRNA genes, results revealed a significant increase in the relative abundances of *A. muciniphila* (9.28±5.67) and *Clostridia* (3.45±0.63) in HE. The relative abundance of *Lactobacilli* was lower (0.40±0.24) in HE. Moreover, a distinct increase of *Enterobacteria* (23.34±8.88) was observed in HE compared with CON. Gene expressions for *Defa5* and *Defb1* in HE were decreased in small intestine, while *Defb1* and *Reg3g* in HE were significantly decreased, and *Defa5* and *Reg3b* increased in colon.

CONCLUSIONS:

In sum, the data showed that a four-day hyperbaric exposure induced changes in the mucus of colon, the mRNA level of AMPs, and the gut microbiota composition in mice.

Individual Differences in Effects of Muscular Endurance Training under Hyperoxic Condition

Yuta Kojima¹, Chiho Fukusaki¹, Naokata Ishii². ¹The University of Tokyo, Chiba, Japan. ²The University of Tokyo, Tokyo, Japan.
 Email: 9302916162@edu.k.u-tokyo.ac.jp

(No relevant relationships reported)

Hyperoxic condition causes an acute enhancement of dynamic muscular endurance. We hypothesized that muscular endurance training under hyperoxic condition increases training volume, thereby results in larger improvement in muscular endurance as compared to training under normoxic condition. We also hypothesized that there would be considerable individual differences in the effects of the training under hyperoxia, because our previous studies have shown individual differences in the acute effects of hyperoxia.

PURPOSE: To investigate the effects of muscular endurance training under hyperoxic condition and individual differences in the effects.

METHODS: Fifteen healthy young men were assigned to two groups: one group conducted muscular endurance training under hyperoxic condition (30.0% O₂; HOX group, n=7) and the other group conducted the same training under normoxic condition

(20.9% O₂; NOX group, n=8). They performed one set of one-hand preacher curl at an intensity of 30% 1RM until exhaustion, three times per week for six weeks. The number of repetition until exhaustion was recorded every training and summed up every six sessions (1st and 2nd weeks, 3rd and 4th weeks, and 5th and 6th weeks) to estimate training volume. Before and after the training period, maximal number of repetition (R_{max}) was measured under both HOX and NOX conditions.

RESULTS: R_{max} under NOX condition (R_{max-NOX}) significantly increased after 6-week training in both HOX and NOX groups (P < 0.01). Increasing ratio of R_{max-NOX} (R_{max-NOX} after training / R_{max-NOX} before training) was 683.3 ± 683.9% in HOX group and 171.2 ± 123.0% in NOX group. There was a significant correlation between the increase in R_{max-NOX} after the training and the difference between R_{max} under HOX and R_{max} under NOX measured before the training (acute effect of hyperoxia; r = 0.872, P = 0.010). Four subjects in the HOX group who showed large (more than 150%) increases in R_{max-NOX} after the training performed larger training volume than NOX group during 5th and 6th weeks of training period (P = 0.009).

CONCLUSIONS: These results indicated a large individual difference in the effects of muscular endurance training under hyperoxic condition. The difference may be related to the acute effect of hyperoxia on the training volume at the late stage of training period.

(No relevant relationships reported)

Exercise in acute normobaric hypoxia has been shown to delay parasympathetic reactivation after submaximal but not supramaximal exercise; however, the behavior of parasympathetic withdrawal at the onset of exercise has yet to be fully explored.

PURPOSE: The purpose of this study was to evaluate trends for time-domain kinematics of parasympathetic withdrawal at the onset of high-intensity upper-body ergometry exercise during normobaric hypoxia and normoxia. **METHODS:** Nine recreationally-active men (21.6±1.3 y) performed a graded exercise test to determine peak power output under normobaric hypoxia (FiO₂ = 14.0±0.1%) and normoxia (FiO₂ = 20.1±0.2%) on different days, and four time to exhaustion trials randomized over two days at 90% and 110%, and 100% and 120% of peak power output, respectively, under similar conditions. A heart rate monitor recorded R-R intervals at 1000 Hz that were later analyzed using commercially-available software. Root mean square of the standard deviation of R-R intervals (RMSSD) values were calculated using a time-varying method with 64-s moving windows and a 3-s shift. A piecewise bilinear fitting function was utilized to determine the vagal response to high-intensity steady-state arm cranking. Two-way (condition × intensity) repeated measures ANOVA was used to compare estimates of the initial RMSSD (y-intercept of the first linear function), rate of RMSSD decline (slope of the first linear function), time to parasympathetic withdrawal (x-value at the intersection of the first and second linear functions), RMSSD at the time of parasympathetic withdrawal (y-value at the intersection of the first and second linear functions). **RESULTS:** No significant interactions or main effects were noted for initial RMSSD (p>0.05; 23.42 ± 3.2 ms), rate of RMSSD decline (p>0.05; -0.45 ± -0.08 ms/s), time to vagal withdrawal (p>0.05; 46.1 ± 2 s), and RMSSD at the time of vagal withdrawal (p>0.05; 3.79 ± 0.67 ms). **CONCLUSION:** Parasympathetic withdrawal does not seem to be affected during upper-body exercise under normobaric hypoxic or normoxic conditions at exercise intensities between 90% and 120% of peak power output in male participants. Funding disclosure: This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

The Effects Of Body Composition, Physical Fitness On Time Of Useful Consciousness In Hypobaric Hypoxia
 Jungwoon Kim, Junsik Kim, Jungjun Lim, Gunhee Kim, Yeonsoo Kim. *Seoul National University, Seoul, Korea, Republic of.*
 (No relevant relationships reported)

Abstract

PURPOSE: The purpose of this study was to investigate the effect of body composition and physical fitness of Air Force pilots on hypoxic tolerance (Time of Useful Consciousness, TUC) under hypoxic hypoxic conditions.

METHODS: At the sea level, we measured the body composition and physical fitness of 99 adults who were not exposed to hypoxic environment. In the hypoxia chamber, which can simulate high altitudes, we set the altitude to 25,000 feet and measured the TUC and the maximum heart rate (HRmax(H)). Pearson's Correlation was used to determine the relationship between TUC and other variables, and multiple regression was performed to determine the independent variables that best explain the TUC.

RESULTS: TUC is positively correlated with maximum oxygen uptake (VO₂max), Stroke Volume (SV), arteriovenous oxygen difference (a-vO₂ diff) and endurance (Sit-up, Push-up). The maximum heart rate on the ground (HRmax(S)), HRmax(H), body fat mass, and percent body fat were negatively correlated with TUC. A regression analysis showed that 84.5% of the TUC can be explained by body composition and physical fitness.

CONCLUSION: Our results revealed that increased cardiorespiratory fitness and decreased fat could significantly impact TUC. Therefore, for Air Force pilots who are always at high altitudes and at risk for exposure to hypoxia, aerobic exercise is essential.

Influence Of Acetazolamide On Manual Dexterity During 30-hour Exposure To Hypobaric Hypoxia (3,500 M)
 Adam C. Nixon, Beau R. Yurkevicius, Karleigh E. Bradbury, Katherine M. Mitchell, Billie K. Alba, Kirsten E. Coffman, Robert W. Kenefick, FACSM, Nisha Charkoudian, FACSM. *USARIEM, Natick, MA.* (Sponsor: Nisha Charkoudian, FACSM)
 (No relevant relationships reported)

High altitude missions pose challenges not seen during sea level expeditions. In order for missions to be successful, it is imperative for Soldiers to maintain physical and cognitive performance. Acetazolamide (AZ) is known to decrease the effects of Acute Mountain Sickness (AMS), but reported side effects (e.g., drowsiness, peripheral paresthesias) could potentially impair manual dexterity. **PURPOSE:** The purpose of the study is to evaluate whether AZ treatment (250 mg bid) alters manual dexterity during 30 hours exposure to 3,500 m simulated altitude. **METHODS:** Six volunteers (6 males, 22.2 ± 3.2 y, 77.5 ± 11.5 kg, 176.2 ± 7.1 cm) took part in two separate 30 hour exposures to 3,500 m simulated altitude in the USARIEM hypobaric chamber. Volunteers received AZ (250 mg twice daily) or a placebo, in a single-blind crossover design. Prior to exposure, volunteers were trained at sea level in all procedures. Dexterity testing included the Purdue Pegboard (sum of rows completed in 30 seconds with right hand only, left hand only and both hands), and magazine/ cartridge loading (number of cartridges loaded in 2 minutes). **RESULTS:** Both Purdue Pegboard and magazine cartridge loading performance were not different between placebo and AZ trials (Purdue Pegboard: placebo: 38 ± 6 vs. AZ: 36 ± 7 rows, P > 0.05; cartridge loading: placebo: 57 ± 12 vs. AZ: 59 ± 13 cartridges, P > 0.05). **CONCLUSION:** Our results suggest that AZ treatment and potential side effects do not impair manual dexterity during a 30 hour exposure to 3500 m altitude. Future studies could evaluate whether higher (500 mg bid) doses of AZ would demonstrate different results. *Funded by USAMRMC; author views not official US Army or DOD policy.*

Oxygen Consumption, Heart Rate and Work Rate During Maximal Exercise in Moderate Altitude Natives: Real versus Predicted Values
 Manuel Augusto Cárdenas-Romero, Juan Camilo Cardenas-Arciniegas, Manuela Zanoletti-Mannello, Julián Andrés Serrano-Giraldo, Julio César Bermúdez-Muñoz. *Pontificia Universidad Javeriana, Bogota DC, Colombia.*
 Email: manuel.cardenas@javeriana.edu.co
 (No relevant relationships reported)

Roughly 23% of Colombian population live at moderate altitude (>2500 m above sea level) and is exposed to 28% lower inspired oxygen pressure that affects oxygen delivery and utilization systems. Maximal heart rate (HRmax), maximal oxygen

consumption (VO₂max), and maximal work rate (Wmax) during cardiopulmonary exercise testing (CPET) are key parameters for diagnostic and exercise prescription purposes, the last two of them have been reported to be about 10% lower in moderate hypobaric hypoxia. Predictive equations for VO₂max, HRmax and Wmax have been developed mainly from sea-level populations.

PURPOSE: To evaluate the published predictive equations for VO₂max, HRmax and Wmax in healthy young residents in moderate altitude.

METHODS: VO₂max, HRmax and Wmax were measured during maximal ramp cycle ergometer CPET in 136 healthy subjects (62 females) 18-25 years old, born and raised at >2,500 m and living at 2600 m. From a systematic search on Medline and Embase databases 22 studies (71 predictive equations) with similar population (healthy, age group), CPET protocols (incremental/ramp maximal cycle ergometer test) and measured parameters (VO₂max, HRmax, Wmax) were selected; all studies were conducted at low altitude. Normal distribution was tested by Shapiro-Wilk test and mean differences between direct measurements and estimated values were compared by paired T-Student test (alpha error = 0.05). Estimated values with no significant mean difference from direct measurements were further assessed by Pearson product-moment correlations.

RESULTS: Most real and estimated mean values were significantly different for VO₂ (male 19/21, female 16/19) and Wmax (male 7/8, female 6/9); for HRmax, significant differences were found in approximately half of them (male 3/8, female 6/9); of the remaining equations only one exhibited a strong correlation with direct values for VO₂max in females (r=0.89, p<0.005).

CONCLUSIONS: In general, available predictive equations do not accurately estimate VO₂max, Wmax or HRmax in a young, healthy Colombian population born and raised at moderate altitude. Differences in population characteristics (adaptation to hypobaric hypoxia, anthropometric differences, training level) can partially explain these results. Supported by COLCIENCIAS grant number 120356934972, 713-2013.

Accumulated Oxygen Deficit During Arm Cranking: Effects Of Hypoxia And Methodological Considerations
 David Boffey¹, Michael B. La Monica², Tristan M. Starling-Smith¹, Jeffrey R. Stout¹, David H. Fukuda¹. ¹University of Central Florida, Orlando, FL. ²Missouri State University, Springfield, MO.
 Email: dboffey@knights.ucf.edu
 (No relevant relationships reported)

Under normobaric hypoxia, aerobic capacity is inherently limited, possibly leading to changes in energy system contribution. While most of the research has focused on lower body cycling or full-body exercise, upper body differences in muscle fiber type distribution and diffusion distance may require greater anaerobic energy provisions as reflected by accumulated oxygen deficit (AOD). **PURPOSE:** To observe the effects of normobaric hypoxia on AOD and energy system contribution during different intensities of upper-body arm cranking exercise. **METHODS:** Twenty-one recreationally active men (21.4 ± 1.4 yr.; 175.5 ± 5.7 cm; 84.8 ± 11.7 kg) performed a graded exercise test (GXT) in normobaric normoxia (N; FiO₂ ~20%) and normobaric hypoxia (H; FiO₂ ~14%) to determine peak power output (PPO). Time to exhaustion (TTE) trials were later conducted at 110% and 120% PPO under both N and H. AOD (in L·min⁻¹) was calculated as the difference between predicted O₂ consumption (extrapolated from a regression equation calculated from GXT) and measured O₂ consumption during the TTEs, standardized to time. Anaerobic energy system contribution (%AN) was calculated as [1-(actual O₂ consumed/predicted O₂)] × 100. AOD and %AN were calculated in three conditions: N, H, and H using the N regression equation (H_N). Two-way (condition × intensity) repeated measures ANOVAs were conducted for AOD and %AN. **RESULTS:** There was a significant condition × intensity interaction for %AN (p=.009) and AOD (p=.007). At 110% PPO, %AN was significantly greater (p=.013) in H_N compared to N (14% vs. 6.8%, respectively), but not H compared to N. At 120% PPO there were no differences in %AN between conditions. At 110% PPO, AOD was significantly greater (p=.029) in H_N compared to N (0.33 vs. 0.19 L·min⁻¹, respectively) but not H compared to N. At 120% PPO there were no differences in AOD between conditions. **CONCLUSION:** Calculating AOD for hypoxic exercise using a regression equation derived from normoxic conditions reveals a greater anaerobic contribution relative to normoxic exercise. The greater AOD and %AN in hypoxia compared to normoxia that was present at 110% PPO was not reproduced at 120% PPO. This may suggest a possible threshold at which hypoxia has no further effect on energy system contribution in this exercise modality.

The Effects of Altitude Training Masks Worn During Low-Intensity Bouts on Performance

Haley N. Yohn, Eric M. Hultquist, Megan A. Morris, Kaitlin L. Barnett, Jacqueline Denning, Joshua G. Woolstenhulme. *The George Washington University, Washington, DC.*
(No relevant relationships reported)

Altitude training masks (ATMs) are frequently used during exercise to enhance physiologic adaptations, yet few studies have examined the effects of ATMS when used during recovery periods.

PURPOSE: To examine the effects of ATMs used only during low-intensity recovery intervals in a high-intensity interval training (HIIT) program in healthy young adults. **METHODS:** Participants engaged in 18 HIIT over a 6-week period using a treadmill. HIIT sessions were comprised of 6-8, 60-second high-intensity bouts at a relative work rate corresponding to 95% of participants' maximal heart rates, alternating with 90-second low-intensity recovery bouts at a relative work rate corresponding to 20% VO₂max. Participants were randomly assigned to an experimental group (EXP) which wore an ATM only during the low-intensity bouts or to a control group (CON) which did not use an ATM. Cardiopulmonary exercise tests (CPET) were performed before and after the HIIT.

RESULTS: 10 participants completed the study in the EXP group (6 females; 26±4.1 years; BMI: 24.2±1.6 kg/m²) and 10 in the CON group (7 females; 24.3±3.5 years; BMI: 22.8±2.1 kg/m²). Both groups experienced improvements in VO₂max (EXP: 39.9±4.6 vs. 42.8±6.0 ml/kg/min, p=0.02; CON: 39.7±6.1 vs. 43.9±8.3 ml/kg/min, p=0.01; baseline vs. follow-up, mean±SD). The EXP group alone saw improvements after training in time to anaerobic threshold (169±31.2 vs. 213±56.2 sec, p=0.04), increased peak work rate during CPET (44±26.9 vs. 88±54.3 Watts, p=0.03), and increased minute ventilation during peak exercise (108±15.5 to 113.64±19.6 L/min, p=0.04). No other changes were observed in the CON group.

CONCLUSIONS: Using ATMs only during the low-intensity bouts of HIIT appears to have afforded participants with unique training adaptations not observed in standard HIIT. Conventional use of ATMs employs the masks during exertional portions of exercise training, not solely during recovery periods. These findings suggest that ATMS may serve as a valuable training adjunct even if used only during recovery periods in HIIT. Supported by: GWU SMHS Emerging Scholars Award 2016-2018

Effect Of Intermittent Hypoxic Exercise Training On Improving Altitude Acclimatization

Xinxin Hao, Dalei Wang, Xiaofei Wang, Yubo Shen. *National University of Defense Technology, Changsha, China.*
Email: haoxin010@126.com
(No relevant relationships reported)

PURPOSE: The purpose of this study was to evaluate the effect of hypoxic exercise training towards altitude acclimatization through systematic literature synthesis, and establish a potential strategy to improve altitude acclimatization.

METHODS: A selective PubMed, CNKI and Google Scholar search on intermittent hypoxic exercise training and altitude acclimatization was conducted. By search and screening, 11 articles of PubMed/Google Scholar and 4 articles of CNKI were included for final analysis and assessment.

RESULTS: Moderate-intensity intermittent hypoxic exercise training could blunt oxidative stress and decrease Acute Mountain Sickness (AMS) at elevations of ~3200m, but it has little effect on physical performance compared to intermittent hypoxic exposure. Vigorous-intensity intermittent hypoxic exercise training can improve human endurance performance. None moderate exercise is performed to increase AMS or worsen AMS severity, while exceed health bearing can worsen symptoms of AMS.

CONCLUSIONS: 1) intermittent hypoxic exercise training can improve altitude acclimatization to AMS and physical health status. 2) A proper hypoxic exercise training intensity may be a crucial factor to maintain and raise human physical performance at high altitude.

Lipolysis Mechanism By Down-regulating Mir-92a Activating Wnt/β-catenin Signaling Pathway In Hypoxic training Rats

xuewen tian¹, qipeng song¹, yingli lu², cui zhang¹. ¹Shandong institute of sport science, jinan, shandong, China. ²China Institute of Sport Science, Beijing, China.

Lipolysis mechanism by down-regulating miR-92a activating Wnt/β-catenin signaling pathway in hypoxic training rats

Studies showed that the loss of body weight in high altitude or hypoxic training conditions was more significant than that in normoxic training conditions. Wnt/β-catenin signaling is a molecular switch that governs adipogenesis. Some studies showed that hypoxia can induce lipolysis and inhibit fat synthesis and influence Wnt/β-catenin signaling.

PURPOSE: This study investigates the role of miR-92a via Wnt/β-catenin signaling in lipid metabolism of hypoxic training rats.

METHODS: Microarray and real-time polymerase chain reaction (RT-PCR) were used to detect the mRNA change of miR-92a in the perirenal fat and epididymis fat of hypoxic training and normoxic training rats. The downstream target mRNA of miR-92a was predicted using bioinformatics and further identified with dual luciferase assay. The Fzd10 and c-myc expression change was detected in the perirenal fat and epididymis fat by using RT-PCR and Western blot.

RESULTS: The microarray and RT-PCR results showed a significantly decreased expression of miR-92a in the fat tissues of hypoxic training rats more than that of normoxic training rats. Result of dual luciferase assay showed that the target gene of miR-92a is Fzd10, which is an acceptor in the Wnt pathway. Fzd10 expression was upregulated in hypoxic training rats. The mRNA expression of the c-myc located at downstream of Wnt pathway increased significantly.

The significantly increased mRNA and protein levels of Fzd10 and c-myc may be related to miR-92a downregulation, leading to lipolysis through Wnt/β-catenin signaling pathway regulation and subsequently causing rat's body weight loss of hypoxic training rats.

Effects Of Acute Intermittent Hypoxia (AIH) On Metabolism, Substrate Partitioning, And Dysglycemia In Obese Individuals With Spinal Cord Injury: A Case Series

Jennifer L. Maher¹, James L. Bilzon², Mark S. Nash, FACSM¹.
¹University of Miami, Miami, FL. ²University of Bath, Bath, United Kingdom.

(No relevant relationships reported)

Innovative approaches are essential for achieving clinically meaningful improvements in cardiometabolic health in individuals with spinal cord injury (SCI).

PURPOSE: Examine changes in glycemic control and metabolism while at rest and during exercise after 4 days of resting exposure to AIH compared with a time-matched normoxic (SHAM) treatment.

METHODS: Participants were 4 males aged 34-57 with chronic (3-18 yrs) SCI at C6-T8. Participants reported to the laboratory after an 8-10 hour fast. After 30 minutes

of rest, participants performed a graded arm exercise test (GXT) to establish peak O_2 consumption. Substrate oxidation rates were derived from cardiorespiratory data averaged over the last minute of each 3-minute stage where RER was < 1.0 . On a non-consecutive day, participants underwent a baseline (BL) 75-gram oral glucose tolerance test (OGTT). Participants were exposed to AIH for 4 consecutive days involving hour long intervals of alternating 6-minute hypoxia ($\text{F}_{\text{I}\text{O}_2} = 0.09\text{-}0.12$) and 3-minute normoxia ($\text{F}_{\text{I}\text{O}_2} = 0.21$). The SHAM protocol was the same except with continuous normoxia. Following the final exposure of each intervention, participants performed a follow-up OGTT, and a GXT 24 hours later.

RESULTS: All participants were obese by population-specific criteria (BMI = 23.0-44.7 kg/m^2) and two were insulin resistance per the Homeostatic Model-2 (HOMA2-IR) Assessment (HOMA-IR = 3.8-4.2). No changes were seen in HOMA-IR after intervention, however, post-AIH OGTT showed fasted insulin concentrations 31% lower than observed at BL, while glucose remained similar across both trials (2% Δ). Insulin area under the curve was 26% lower after AIH compared to BL with little change (11%) in glucose. There were no differences in metabolism and substrate utilization at rest or exercise across trials.

CONCLUSION: Lower pre-load insulin concentration and lower peak insulin values observed following AIH suggests an insulin-sensitizing effect of treatment. However, the duration of this benefit requires testing. No differences were reported in metabolism and substrate partitioning in four participants, however this needs to be investigated in a larger population. This case series demonstrates that in these individuals with SCL, AIH exposure was well tolerated and can be administered without adverse events.

Short-term Altitude Training Effects on Aerobic Performance Parameters in Collegiate Cross-country Runners

Nauris Tamulevicius¹, Tanuj Wadhi¹, Guillermo R. Oviedo², Ashmeet S. Anand¹, Fraser Houston¹, Eric Vlahov¹. ¹The University of Tampa, Tampa, FL. ²University Ramon Llull, Barcelona, Spain.

Email: ntamulevicius@ut.edu

(No relevant relationships reported)

Endurance athletes have been using altitude training for over half a century to improve sea-level performance. Live High-Train Low (LHTL), a contemporary form of altitude training, was proven best for long-distance (5000m) athletes. However, while athletes continue to use this training technique in an acute fashion (< 2 weeks), no study has shown the effects of such a short-term use on aerobic performance. **PURPOSE:** To evaluate aerobic performance parameters, i.e., aerobic capacity ($\text{VO}_{2\text{peak}}$) and ventilatory threshold (VT), after 6 days of LHTL altitude training in collegiate cross-country runners. **METHODS:** Fourteen male NCAA cross-country runners (age: 19.07 \pm 0.92 y.o.) with initial $\text{VO}_{2\text{peak}}$ of 73.13 \pm 5.65 ml/kg/min participated in the study. $\text{VO}_{2\text{peak}}$ and VT were evaluated using a metabolic cart at sea-level, pre- and post-training. Runners from sea level traveled to high altitude where they lived at 1322m above sea-level for 6 days. Six training sessions were performed at altitudes ranging from 881.25 \pm 148.87m to 1047.70 \pm 237.29m above sea-level with training sessions averaging a duration of 75.25 \pm 7.04 mins, speed of 13.02 \pm 1.60 kmph and distance of 16.42 \pm 2.95 km. **RESULTS:** There was no significant effect on either absolute ($p=0.325$) or relative $\text{VO}_{2\text{peak}}$ ($p=0.643$). A significant main effect of time was found for absolute VT ($p<0.001$), which changed from 3.35 \pm 0.52 L/min to 3.89 \pm 0.55 L/min, and VT relative to $\text{VO}_{2\text{peak}}$ ($p<0.001$), which changed from 74.29 \pm 8.54% of $\text{VO}_{2\text{peak}}$ to 87.57 \pm 3.48% of $\text{VO}_{2\text{peak}}$. Consequently, there was a significant main-effect of time for heart rate at VT ($p=0.025$), which changed from 168.50 \pm 14.87 bpm to 176.07 \pm 11.02 bpm. **CONCLUSION:** Although there was no significant change in $\text{VO}_{2\text{peak}}$, short-term LHTL training had a positive effect on VT in trained cross-country runners. This is possibly due to the hemodilution resulting from return to sea level combined with the preserved ventilatory adaptations from altitude training.

Exogenous Glucose Oxidation During Endurance Exercise in Hypoxia

Daichi Sumi, Nanako Hayashi, Haruka Yatsutani, Kazushige Goto. *Ritsumeikan University, Kusatsu, Japan.*

Email: sh0034vr@ed.ritsumei.ac.jp

(No relevant relationships reported)

The exercise under hypoxic condition augmented carbohydrate (CHO) metabolism during exercise (Sumi et al. 2018). However, detailed CHO oxidation pattern during exercise under hypoxic condition remain unclear.

PURPOSE: The purpose of the present study was to evaluate the effect of endurance exercise under moderate hypoxic condition at the same energy expenditure or exercise intensity on exogenous glucose oxidation.

METHODS: Nine active healthy males completed three trials on different days, consisting of 30-min running at each exercise intensity of the following: 1) 65% of normoxic $\text{VO}_{2\text{max}}$ under the normoxic condition ($\text{FiO}_2 = 20.9\%$; NOR), 2) 65% of

hypoxic $\text{VO}_{2\text{max}}$ under the hypoxic condition ($\text{FiO}_2 = 14.5\%$; HYPOR), 3) 65% of normoxic $\text{VO}_{2\text{max}}$ under the hypoxic condition ($\text{FiO}_2 = 14.5\%$; HYPOA). Venous blood samples were collected before and after exercise. The subjects consumed ^{13}C -labeled glucose immediately before exercise, and we collected expired gas during exercise to determine ^{13}C -excretion (calculated by $^{13}\text{CO}_2/^{12}\text{CO}_2$).

RESULTS: Running velocity were significantly lower in the HYPOR (9.4 \pm 0.3 km) than in the NOR (10.6 \pm 0.3 km) and HYPOA (10.6 \pm 0.3 km). Exercise-induced blood lactate elevation was significantly augmented in the HYPOA than in the NOR and HYPOR ($P = 0.001$). The HYPOA showed significantly higher CHO oxidation (evaluated by VO_2 and VCO_2) during exercise compared with other two trials ($P = 0.01$). In contrast, exogenous glucose oxidation (^{13}C -excretion) during exercise was significantly lower in the HYPOA than in the NOR ($P = 0.01$).

CONCLUSIONS: Endurance exercise under moderate hypoxic conditions promoted whole body CHO metabolism during exercise. However, exogenous glucose oxidation during exercise was attenuated compared with the same exercise under normoxic condition.

Effect of Sprint Exercise in Hypoxia on Muscle Glycogen Utilization

Nobukazu Kasai¹, Fumiya Tanji², Aya Ishibashi², Hayato Ohnuma², Hideyuki Takahashi², Kazushige Goto¹, Yasuhiro Suzuki². ¹Ritsumeikan University, Kusatsu, Japan. ²Japan Institute of Sports Sciences, Kitaku, Japan. (Sponsor: Robert Kraemer, FACSM)

Email: nobunbun100@gmail.com

(No relevant relationships reported)

The influence of maximal sprint exercise in hypoxia on muscle glycogen content muscle has not been directly evaluated.

PURPOSE: The purpose of the present study was to determine the effect of a single bout of maximal sprint exercise in hypoxia on muscle glycogen content among competitive athletes.

METHODS: Ten sprinters (height; 176.9 \pm 1.9 cm, body weight; 66.9 \pm 2.0 kg, BMI; 21.4 \pm 0.5 kg/m^2 , athletic career, 10.3 \pm 2.9 years) performed two exercise trials under either hypoxic [HYP, fraction of inspired oxygen ($\text{F}_{\text{I}\text{O}_2}$): 14.5%, a simulated altitude of 3,000m] or normoxic (NOR, $\text{F}_{\text{I}\text{O}_2}$: 20.9%) conditions with a randomized, a single-blind and crossover design. The exercise in each trial consisted of three sets of 30-s maximal sprint. Muscle glycogen content was measured using carbon magnetic resonance spectroscopy (^{13}C -MRS) in the vastus lateralis and vastus intermedius muscles before and after the exercise. Moreover, time-course changes in power output, percutaneous oxygen saturation (SpO_2), blood lactate, metabolic responses and muscle oxygenation were evaluated.

RESULTS: The average SpO_2 value was significantly lower in the HYP trial (91.0 \pm 0.3%) than in the NOR trial [95.9 \pm 0.3%, $P < 0.01$, effect size (ES) = 5.08]. Mean power output did not differ significantly between the two trials ($P = 0.80$, ES = 0.01). There was a significant main effect for time ($P < 0.01$, ES = 0.97) for blood lactate concentration, but no significant difference between the two trials was observed ($P = 0.31$, ES = 0.12). Change in muscle glycogen content showed significant interaction ($P = 0.03$, ES = 0.40) and main effect for time ($P < 0.01$, ES = 0.89). Relative change in muscle glycogen content between before and after the exercise was significantly greater in the HYP trial (-43.5 \pm 0.4%) than in the NOR trial (-34.0 \pm 0.3%, $P < 0.01$, ES = 0.83).

CONCLUSION: Maximal sprint exercise in hypoxia caused further decrement of muscle glycogen content compared with the same exercise under normoxia.

1476 Board #238 May 30 9:30 AM - 11:00 AM

Effects Of Systemic Hypoxia-hyperoxia Preconditioning On Acute Heavy Resistance Exercise-induced Muscle Damage In Athletes

Szu-Hsien Yu¹, Peng-Wen Chen². ¹National Ilan University, Yilan City, Taiwan. ²University of Taipei, Taipei City, Taiwan. (Sponsor: Chia-Hua Kuo, FACSM)

Email: meek168@hotmail.com

(No relevant relationships reported)

PURPOSE: Local ischemic preconditioning was shown to improve exercise performance in previous studies, but it also causes pain. The aim of the present study is to investigate the effects of systemic hypoxia-hyperoxia preconditioning on muscle damage caused by a bout of acute heavy resistance exercise (RE).

METHODS: In this double-blind, randomized-controlled crossover study design, 11 voluntary male athletes (20-24 years old) were recruited as participants. Subjects were randomly divided into normoxia and hypoxia-hyperoxia groups. For a duration of 50 min, the hypoxia-hyperoxia group was alternately supplied with 10% or 100% oxygen in 5 min intervals. The normoxia group was supplied with 20.9% oxygen for 50 min during the same period. 30 min after preconditioning, all subjects performed a bout of acute heavy RE. After a 14-day washout time, subjects swapped groups.

RESULTS: The results showed that the high intensity RE decreased peak torque and increased muscle pain in both groups. Circulating creatine kinase (CK), myoglobin and interleukin 6 (IL-6) also increased immediately after RE in normoxia subjects. CK, myoglobin and testosterone/cortisol ratio (T/C ratio) of hypoxia-hyperoxia group were lower than those of normoxia group 24 and 48 h after RE. However, IL-6 of hypoxia-hyperoxia group was higher than that of normoxia group 24 and 48 h after RE. No differences were found in thiobarbituric acid reacting substance (TBARS) levels or peak torque levels between normoxia and hypoxia-hyperoxia groups.

CONCLUSIONS: Systemic hypoxia-hyperoxia preconditioning could reduce muscle damage induced by high intensity RE. These effects may be due to increased anti-inflammatory cytokine secretion.

The Integrative Physiological and Neuromuscular Effects of High Altitude Cycling in World Class Endurance Athletes

Craig E. Broeder, FACSM¹, Dan Turner², Per Lundstam³, Holden Macrae⁴. ¹Exercising Nutritionally, LLC, Naperville, IL. ²Red-Bull Corporation, Santa Monica, CA. ³RedBull Corporation, Santa Monica, CA. ⁴Pepperdine University, Malibu, CA. Email: en.llc@me.com

(No relevant relationships reported)

PURPOSE: Six pro endurance athletes (3 men, 3 female) participated in a study investigating the effects of cycling at high altitude on physiological & neuro-muscular systems.

METHODS: Athletes were tested in three locations using identical procedures and equipment. Baseline testing took place in Santa Monica, CA. Then, the entire lab's equipment was transported to two additional study locations (Death Valley and Mammoth Mountain, CA). Each athlete completed a 5-stage, 3-min/stage ramp exercise trial. Athletes performed the ramp test in duplicate at each test site (morning and afternoon). Respiratory-metabolic measurements, regional oxygen saturation (SMO2), substrate oxidation rates, and EMG activity were recorded continuously. Blood samples were taken the last 15-secs of each stage. Data were analyzed using repeated-measures ANOVA models and Turkey Post-Hoc test to identify specific areas of significance when appropriate.

RESULTS: The mean workload across all 5 stages was 227 ± 60 watts (Stage 1 = 117 watts; Stage 5 = 287 watts). Compared to sea level, the over-all mean SMO2 saturation at the 227 watts mean was 24.5% lower at altitude ($p = 0.04$) while deoxy hemoglobin was 18.5% higher ($p = 0.04$). Correspondingly, lactate concentrations were 27.2% greater, but this difference did not reach significance. However, lactate concentrations during stage 5 were 34% greater at altitude compared to sea level ($p = 0.035$). At sea level, quadricep (Quad) muscle activation accounted for 58% of the total force produced while cycling at altitude quad work was reduced to 51%. Lactate concentrations had an inverse relationship with EMG Quad activity ($p = 0.03$) and direct relationship with hamstring force activation ($p = 0.03$). RER values indicated greater CHO oxidation rates at altitude across all stages combined (Sea level: 2.127 gm/min; Altitude: 2.954 gm/min, $p = 0.01$). For stages 4 & 5, despite greater respiration rates, over-all ventilation volumes declined cycling at altitude lowering oxygen uptake by 10.2% and 19.4% respectively despite being at the same workload compared to sea level.

CONCLUSIONS: These results indicate cycling at altitude requires greater physiological-metabolic response to maintain neuro-muscular function cycling at work rates up to 80% of max effort.

1478 Board #240 May 30 9:30 AM - 11:00 AM
Effect of Acetazolamide on Hand and Finger Strength During 30 Hours Exposure to 3500m Altitude

Beau R. Yurkevicius, Adam C. Nixon, Karleigh E. Bradbury, Katherine M. Mitchell, Billie K. Alba, Kirsten E. Coffman, Robert W. Kenefick, FACSM, Nisha Charkoudian, FACSM. USARIEM, Natick, MA. (Sponsor: Nisha Charkoudian, FACSM) (No relevant relationships reported)

Activities that require rapid ascent to altitude, such as those that commonly occur in military, mountain rescue, and recreational settings, often require substantial hand and finger strength in order to complete tasks. Many who deploy quickly to altitude experience symptoms of acute mountain sickness (AMS), which have been shown to be decreased by acetazolamide (AZ). Although AZ may cause peripheral paresthesia, potential influences on hand and finger strength are currently unclear. **PURPOSE:** The purpose of this study was to test the hypothesis that AZ treatment during an acute, 30-hour exposure to 3500 m simulated altitude would decrease hand and finger strength relative to placebo treatment.

METHODS: Six male volunteers (22.2 ± 3.2 yrs, 77.5 ± 11.5 kg, 176.2 ± 7.1 cm) participated in two separate 30 hour altitude exposures (3500 m, 20°C, 20% RH) in the USARIEM hypobaric chamber. Participants were given either a placebo or 250 mg AZ twice a day for 3.5 days (2 sea-level days + the 30 hour altitude exposure) in

a randomized, single-blind crossover design. During each altitude exposure, strength tests were performed which comprised of maximal hand grip and finger pinch (palmar, key, tip) strength tests.

RESULTS: No volunteers reported sensations of peripheral paresthesia. There was no difference between altitude exposures in any of the measures of hand and finger strength (placebo vs. AZ; hand grip: 43 ± 7 vs. 43 ± 8 kg; palmar pinch: 11 ± 2 vs. 12 ± 2 kg; key pinch: 11 ± 1 vs. 11 ± 1 kg; tip pinch: 8 ± 1 vs. 8 ± 1 kg; $p > 0.05$ for all).

CONCLUSIONS: Our results suggest that 500 mg/day AZ treatment does not influence hand and finger strength during a 30 hour exposure to 3500 m altitude. Future studies could evaluate if higher doses of AZ, that may induce more paresthesia, would influence hand and finger strength differently.

The Effect Of Moderate Hypoxia On Skeletal Muscle Cell Growth And Related Protein Expression

Koki SAKUSHIMA¹, Maki YOSHIKAWA¹, Takeshi HASHIMOTO, FACSM². ¹Ritsumeikan University, Kyoto, Japan. ²Ritsumeikan University, Siga, Japan. (Sponsor: Takeshi Hashimoto, FACSM) Email: saku00812@gmail.com

(No relevant relationships reported)

PURPOSE: Skeletal muscle atrophy is one of the adaptations of hypoxic environment. However, previous study showed resistance training under hypoxic environment (16% oxygen concentration) causes greater muscle hypertrophy than normoxic environment (Nishimura et al., 2010). Because direct effect of hypoxia on skeletal muscle cell growth remains unknown, in Vitro studies to investigate cell responses to hypoxia are needed. Although some studies reported that severe hypoxia (i.e., 1% to 5% oxygen concentration) attenuated cell growth (Marie Csete et al., 2001; Gustafsson et al., 2005), we hypothesized that moderate hypoxia (e.g., 10% oxygen concentration) might ameliorate muscle cell growth. The purpose of this study was to examine the effect of 10% oxygen environment on skeletal muscle cell growth and related protein expressions.

METHODS: C2C12 skeletal muscle cells were divided into two groups: control group cultured in 20.9% oxygen environment (CON) while hypoxia group cultured in 10% oxygen environment (HYP) during differentiation. We analyzed expressions of myogenesis-related proteins Myogenin, using Western blotting. As well, we analyzed mTOR signaling. We also conducted immunocytochemical analyses to assess myotube diameter and Differentiation Index (DI), an indicator of muscle differentiation (Oishi et al., 2015). The lactate concentration in the medium was measured every day.

RESULTS: The myotube diameter in the HYP was significantly greater than that in the CON ($p < 0.05$). The DI was significantly higher in the HYP than in the CON ($p < 0.05$). The protein expression of myogenin was significantly higher in the HYP than in the CON ($p < 0.05$). The expression level of phosphorylated mTOR was significantly higher in the HYP than in the CON ($p < 0.05$). The lactate concentration was higher in the HYP than in the CON ($p < 0.05$). Myotube atrophy was observed 8 days after the differentiation in the CON, while moderate hypoxia maintained myotube thickness.

CONCLUSIONS: The findings suggest that 10% hypoxic environment may promote skeletal muscle cell growth and hypertrophy. Supported by Grant-in-Aid for Scientific Research from the Japanese Ministry of Education, Culture, Sports, Science, and Technology (Grants 26702029, 18K19762).

Effects of Chronic Continuous Exposure to Low Dose Carbon Monoxide on Hemoglobin Mass and Performance

Walter FJ Schmidt¹, Torben Hoffmeister¹, Sandra Haupt¹, Nadine Wachsmuth¹, Dirk Schwenke², William C. Byrnes, FACSM³. ¹University of Bayreuth, Bayreuth, Germany. ²University of Dresden, Dresden, Germany. ³University of Colorado at Boulder, Boulder, CO. (Sponsor: William C Byrnes, FACSM) Email: walter.schmidt@uni-bayreuth.de

Reported Relationships: **W.F. Schmidt:** Receipt of Intellectual Property Rights/Patent Holder; **Walter Schmidt** is a managing partner of the company 'Blood tec GmbH', but he is unaware of any direct or indirect conflict of interest with the contents of this abstract..

Inhalation of carbon monoxide (CO) blocks the oxygen binding sites of the hemoglobin molecule and may produce similar effects as exposure to altitude. While single CO-doses and short-term application which are used in medicine and science do not exert measurable effects on erythropoiesis and performance, no data exists about chronic administration.

PURPOSE: To determine the effect of chronic low dose CO-application on hemoglobin mass and performance. **METHODS:** For three weeks, eleven male healthy and moderately trained subjects inhaled a CO-bolus five times the day to increase their HbCO concentration in blood by approx. 5%. Eleven matched subjects

received a placebo. Hemoglobin mass (Hbmass), serum erythropoietin concentration [EPO], ferritin, and basic hematological parameters were determined before and weekly during and until three weeks after the CO-inhalation period. An incremental step test until exhaustion on a cycle ergometer was performed before, at the end and one week after the CO administration period. **RESULTS:** During and after the intervention period, there were significant interactions between time and groups for Hbmass ($p < 0.001$), ferritin ($p < 0.05$), [EPO] ($p < 0.001$), percentage (%) and immature reticulocytes (IRF) (both $p < 0.05$). A tendency for an interaction was found for max. power and VO_{2max} ($p = 0.1$). In the CO-group, Hbmass continuously increased from 919 ± 69 g to 962 ± 78 g in week 3, ($p < 0.001$) and persisted for the following three weeks. Whole blood and plasma volume did not change. Reticulocytes (%) and IRF increased after one week (ret% from $1.21 \pm 0.31\%$ to $1.40 \pm 0.29\%$, $p < 0.01$; IRF from $5.1 \pm 1.7\%$ to $7.0 \pm 2.7\%$, $p < 0.05$). [EPO] tended to increase after one week ($p = 0.07$) and was suppressed in the post period ($p < 0.01$). Ferritin markedly decreased during the inhalation period (from 106 ± 37 ng/ml to 72 ± 37 ng/ml, $p < 0.001$). VO_{2max} tended to increase from 4230 ± 280 ml/min to 4350 ± 350 ml/min ($p < 0.1$) immediately after the inhalation period and showed a significant relationship to the change in Hbmass ($y = 2.9x + 29$, $r = 0.55$, $p < 0.05$). In the placebo group no effect was observed. **CONCLUSIONS:** Chronic continuous exposure to low dose carbon monoxide increasing HbCO by $\sim 5\%$ significantly increased erythropoietic activity and showed a positive effect on performance.

High Intensity Interval Training And Acute Altitude Exposure In A Masters Athlete: A Case Study

Katherine Woolley, Thomas Martin. *Quinnipiac University, Hamden, CT.*

(No relevant relationships reported)

This study involved an experienced, 64 year-old male mountaineer who trained at sea-level and climbed Mount Kilimanjaro (5,895 m). High Intensity Interval Training (HIIT) is a time-saving mode of exercise consisting of bursts of all-out effort and active recovery which has shown to improve cardiovascular fitness and strength. Hypoxia induces Acute Mountain Sickness (AMS) which poses many health risks to individuals of all age. **PURPOSE:** To assess the effects of a HIIT protocol on a Masters climber and investigate physiologic changes due to altitude exposure and incidence of AMS. **METHODS:** The six-week training program consisted of six alternating rounds of 85-90% max HR progressing from 90-120 seconds followed by 3 minutes active recovery. Subject was tested at: baseline, post-training/pre-climb, and post-climb. For baseline and post-training body composition, pulmonary function, hematology, cognitive function, reaction time, VO_2 max, and muscle strength were measured. Post-climb all measures were repeated except VO_2 max and strength. While climbing, physiologic and GPS data were collected. At each basecamp, resting SpO_2 , HR, Lake Louise Score (LLS), reaction time, cognitive function (Stroop test), and coordination tests were performed. The LLS is the standard for diagnosing AMS. **RESULTS:** Subject summited and returned healthy. HIIT increased VO_2 max (36.4 to 47.1 ml/kg/min), muscle symmetry, and FEV1/FVC increased 0.86% , body fat increased from 7.2 to 8% . Subject experienced mild AMS on days two and three of the ascent. Reaction time increased by 1 second, and the incongruent Stroop test time increased 57 seconds at high camp compared to baseline. On average, SpO_2 and HR dropped 3.2% and 5.8 bpm respectively overnight at camps. HR, and RR increased with altitude. Upon return, serum Potassium and Creatine Kinase were elevated (5.4 , 268), and FEV1/FVC decreased 4.1% , body fat decreased to 3.6% . **CONCLUSIONS:** HIIT is a safe and effective way to train a Masters athlete for the rigor of high altitude. These findings are of clinical importance for athletes preparing for high altitude mountaineering. Masters athletes are capable of training for, experiencing, and surmounting AMS. With proper training a Masters athlete can complete a high-altitude climb.

Acute Effects Of Electrical Stimulation In Hypoxia On Arterial Stiffness

Masato Nishiwaki¹, Mami Fujibayashi², Naoyuki Matsumoto³.
¹Osaka Institute of Technology, Osaka, Japan. ²Setsunan University, Osaka, Japan. ³Prefectural University of Kumamoto, Kumamoto, Japan.
 Email: masato.nishiwaki@oit.ac.jp
 (No relevant relationships reported)

PURPOSE: This study aimed to examine acute effects of electrical stimulation in hypoxia on arterial stiffness.

METHODS: Seven healthy male adults (21 ± 1) participated in experiments of four different protocols (*i.e.*, rest in normoxia (NR), rest in hypoxia (HR), electrical stimulation in normoxia (NES), and electrical stimulation in hypoxia (HES)) in random order on separate days. Throughout a 40-min trial, the subjects breathed normoxic ($20.9\% O_2$) or hypoxic ($15.3 - 15.5\% O_2$) gas via a facemask connected to the oxygen generator. Also, in NES and HES, a 20-minute electrical stimulation of 4 Hz was conducted

in a lower limb in the latter 20-min of the trial. Before (baseline) and after (Post) each trial, arterial stiffness was assessed by cardio-ankle vascular index (CAVI), which is theoretically adjusted by blood pressure.

RESULTS: During electrical stimulation, heart rate and oxygen uptake in NES and HES increased, compared with each baseline. However, no significant difference was observed in the mean heart rate between NES and HES. Conversely, oxygen uptake during electrical stimulation was significantly lower in HES than in NES. There was no significant change in CAVI of NR and HR. However, CAVI of HES and NES significantly reduced (HES, Baseline: 5.9 ± 0.1 , Post: 4.9 ± 0.2 vs. NES, Baseline: 5.6 ± 0.2 , Post: 5.1 ± 0.2 , both $P < 0.05$), and the reduction in CAVI was significantly greater in HES than that in NES (% change, HES vs. NES: $-16.4 \pm 8.9\%$ vs. $-9.9 \pm 5.4\%$; $P < 0.05$). In addition, lactate concentrations and respiratory exchange ratio were significantly higher in HES than the other three trials.

CONCLUSIONS: These findings suggest that electrical stimulation in hypoxia can induce greater reduction in arterial stiffness than those in normoxia.

1483 Board #245 May 30 9:30 AM - 11:00 AM
Functional Inspiratory Muscle Training Improves The Strength of Inspiratory Muscles During Load Carriage In Cold-hypoxia

Katrina Hinde¹, Chris Low², Ray Lloyd³, Carlton Cooke³.
¹University of Chichester, Chichester, United Kingdom. ²Leeds Beckett University, Leeds, United Kingdom. ³Leeds Trinity University, Leeds, United Kingdom.
 Email: k.hinde@chi.ac.uk

(No relevant relationships reported)

PURPOSE: Load carriage (LC) exceeding 20kg elicits respiratory muscle fatigue (RMF) in sea level thermo-neutral conditions. Sub-maximal physical activity in cold-hypoxia has shown to elicit RMF. Inspiratory muscle training (IMT) combined with LC has failed to reduce RMF. Functional IMT (FIMT) may activate non-respiratory roles of the diaphragm and respiratory muscles resulting in adaptations beyond that of static IMT. **METHODS:** Loaded (18.2kg) walking trials were completed pre, mid and post training (trial 1, 2 and 3, respectively). Participants ($n = 15$) performed a 6km loaded walk at $50\% VO_{2max}$ over 4 stages 0 - 6km in 0.5 increments at 0, 5, and 10% gradient in cold-hypoxia ($4300m$ in $-10^\circ C$). Following trial 1, participants were randomly assigned to control (Con=7) or experimental (Exp=8) to undertake 4 weeks of IMT using a pressure threshold training device. The Exp performed 2 x 30 breaths daily at 50% maximal inspiratory pressure (P_{imax}) and Con performed 60 daily breaths at $15\% P_{imax}$. FIMT (5 exercises designed to engage core muscles, 3 involved LC) was then performed 3 times weekly at the same intensities as IMT. **RESULTS:** Inspiratory muscle fatigue was prevalent following trial 1 ($p < .001$). Relative to baseline (126.9 ± 15.7 cmH₂O) trends were identified for greater P_{imax} in Exp post-IMT (145.5 ± 20.5 cmH₂O, $p = .066$) with no changes in Con. FIMT showed no further significant increase in P_{imax} ($p = .104$). P_{imax} values post-6km in Exp were significantly greater than Con and higher than pre-6km pre-intervention values ($p = .007$). However, ΔP_{imax} was unchanged in Exp ($p \geq .214$). No significant relationships were observed between ΔP_{imax} vs baseline P_{imax} and VO_{2max} vs ΔP_{imax} . **CONCLUSION:** Four weeks of IMT and FIMT strengthened inspiratory muscles by 23%. Despite no reduction in RMF, P_{imax} values were significantly greater post-6km in Exp and higher than pre-6km pre-intervention values. Protocols employing more progressive training loads may reduce RMF. Due to the low intensity and prolonged nature of LC in cold-hypoxia, respiratory muscle endurance may be more dominant than strength. Thus, requiring further investigation.

Comparing Physiological Responses to Single and Double Leg Submaximal Cycling in Normoxia and Hypoxia

Shane N. Draper¹, Tyler Singer², Cody Dulaney², Sarah Kearney², John McDaniel². ¹Utah Valley University, Orem, UT. ²Kent State University, Kent, OH.
 Email: ShaneD@uvu.edu
 (No relevant relationships reported)

INTRODUCTION: It has been well established that exercise intensity as well as exercise performance declines at altitude. However, it has yet to be determined how femoral blood flow and muscle oxygenation kinetics (total tissue saturation, oxy- and deoxygenated hemoglobin, as well as total hemoglobin) are influenced by altitude during submaximal and maximal performances. Furthermore, it has yet to be determined if the utilization of small muscle mass exercise, which allows for greater blood flow to the active muscle, will allow an individual to generate the same muscle oxygenation kinetics in hypoxic conditions that is achieved during larger muscle mass activities in normoxia. **PURPOSE:** Thus, the purpose of this study was to determine if tissue oxygenation was compromised at altitude during submaximal bouts of exercise and whether reducing the active muscle mass exercise could be used to offset any observed decrement due to increases in blood flow.

METHODS: 10 individuals performed double leg cycling for four minutes at 50%, 60%, 70% and 80% of their maximal oxygen consumption, rested for 15 minutes and then performed single leg cycling utilizing the same protocol but at half the double leg work rate in both normoxic and hypoxic conditions (oxygen concentration of 15% which simulated an altitude of 2,740 meters).

RESULTS: The amount of blood flow during the single leg trial in hypoxia was significantly higher compared to blood flow during double leg cycling in hypoxia ($p = 0.02$). There was no significant difference between the single leg trial in hypoxia and the double leg trial in normoxia ($p = 0.36$) nor between the two double leg trials in normoxia and hypoxia ($p = 0.87$). No difference was found in the amount of oxygenated hemoglobin when comparing the single leg trial in hypoxia to the double leg trials in normoxia ($p = 0.36$) and hypoxia ($p = 0.13$).

CONCLUSIONS: The results suggest that elevated hemoglobin saturation and femoral blood flow during the single leg condition in hypoxia are similar to that observed during double leg cycling in normoxia and may prove to be a viable training modality that would offset the main disadvantage of living at altitude by enabling an individual to exercise at the same level of intensity achieved at normoxia.

1485 Board #247 May 30 9:30 AM - 11:00 AM Impact Of Long-acting Reversible Contraceptives On Bone Density During Simulated Microgravity

Heather C.M. Allaway, Sarah E. Little, Harry A. Hogan, Susan A. Bloomfield, FACSM. *Texas A&M University, College Station, TX.*

(No relevant relationships reported)

Hormonal contraception is routinely used by premenopausal women, including female astronauts, to suppress ovarian function and menstrual cycling. Combined oral contraceptive pill (COC, ethinyl estradiol and progestin) use leads to a suppression of bone turnover and reduced bone mineral density (BMD) gain with long-term exercise. Long-acting, reversible contraceptives (LARC, progestin-only) provide many practical advantages over COC. With increasing numbers of women in the US astronaut corps, we risk sending female crew members into microgravity without a clear understanding of the impact of LARC use on bone health.

Purpose: We hypothesize that LARC use will blunt decreases in BMD associated with hindlimb unloading (HU).

Methods: Virgin female Sprague-Dawley rats ($n=26$; 4-mo-old) were singly housed and randomly assigned to placebo and LARC groups, via a slow-release etonogestrel pellet (0.00ug/d vs. 0.30ug/d) implanted under the skin. Animals were further randomized into ambulatory and HU subgroups ($n=6-7$ /subgroup), with HU initiated a week following pellet insertion and lasting for 6 weeks. Pre/post HU, proximal tibia metaphysis (PTM) were scanned in vivo with peripheral quantitative computed tomography (pQCT). Univariate and repeated measures 2-way ANOVA were used.

Results: There was a time*loading group interaction ($p<0.01$) for body weight and food consumption. HU animals weighed less over the last 4 weeks of the study but consumed more food over 6 weeks of HU vs. ambulatory animals. Soleus wet weights were significantly lower in HU compared to ambulatory animals ($p<0.001$). There was a main effect of time for ($p<0.001$) PTM total, cancellous, and cortical volumetric BMD and total and cortical areas. For marrow area at the PTM there was a time*loading group interaction ($p=0.044$), such that over time the HU animals had a decrease in marrow area compared to the ambulatory animals. No impact of LARC on these outcomes was detected.

Conclusions: Early results indicate that LARC use does not alter the PTM bone response to mechanical unloading of simulated microgravity assessed by in vivo pQCT.

Can Acute Galactic Cosmic Radiation-induced Bone Loss Be Mitigated By Dietary Modulation Of Inflammatory Cytokines?

Sarah E. Little¹, Heather CM Allaway¹, Rihana S. Bokhari¹, Derek V. Seidel¹, Kimberly L. Wahl¹, Nancy D. Turner², John R. Ford¹, Larry Suva¹, Susan A. Bloomfield, FACSM¹. ¹Texas A&M University, College Station, TX. ²Michigan State University, College Station, TX.

(No relevant relationships reported)

The space environment includes weightlessness and galactic cosmic radiation (GCR), both of which can have a negative impact on bone parameters. In particular, acute exposures to space-relevant doses (2 Gy or less) of simulated GCR lead to a rapid acceleration of bone resorption activity and suppression of bone forming osteoblasts, resulting in diminished bone mineral density (BMD), strength and altered microarchitecture. A key mechanism driving these changes may be a radiation-induced increase in pro-inflammatory cytokines, such as TNF- α . Consuming a diet rich in omega-3 fatty acids has been associated with attenuated reductions in bone parameters in astronauts, mice and elderly humans with corresponding reductions in circulating inflammatory cytokines. **PURPOSE:** To test the hypothesis that a diet high in omega-3 fatty acids will mitigate radiation-induced bone loss and reduce inflammatory cytokines in bone osteocytes and serum.

METHODS: Adult (30- to 50-week-old) female Lgr5-EGFP C57BL/6 mice ($n=4-6$ per group) were acclimated to a corn oil/cellulose (COC) or fish oil/pectin (FOP) diet for 3 weeks. Animals were subsequently randomized to total body low dose high-energy radiation (0.1, 0.25, 0.5 Gy of 1000 MeV/n ⁶⁰Fe at 25 cGy/min at Brookhaven National Lab) or non-irradiated control (sham) and euthanized 8 weeks later. MicroCT (ScanCo, Switzerland) analyses were performed to assess bone geometry and microarchitecture at the mid-shaft and distal end of the femur. Significance was assessed using an α of 0.10.

RESULTS: There was a significant main effect of diet on mid-shaft femur periosteal diameter (Peri.Dm) ($p=0.001$) and endocortical diameter (Endo. Dm.) ($p<0.001$). The FOP diet led to larger Peri.Dm. ($p<0.051$ for all) and Endo.Dm. ($p<0.041$ for all) than did the COC diet at all doses. We could not detect an impact of ⁶⁰Fe on cortical area or cancellous bone volume at the distal femur. Irradiation with 0.25 and 0.5 Gy in the FOP mice showed significant increases in distal femur volumetric BMD ($p=0.014$, $p=0.063$) and trabecular thickness ($p=0.058$, $p=0.028$), as compared with sham FOP mice.

CONCLUSIONS: Though we did not detect a significant impact of radiation on bone parameters, these early data analyses suggest some modest benefits from a diet high in omega-3 fatty acids on cortical and cancellous bone parameters.

Circulating MicroRNA Expression and Serum Biomarker Changes After 30 Days of Head-Down Bed Rest

Samuel R. Buchanan¹, Carl Ade², Breanne Baker¹, Debra Bembem, FACSM¹. ¹The University of Oklahoma, Norman, OK. ²Kansas State University, Manhattan, KS. (Sponsor: Debra Bembem, FACSM)

Email: samuel.r.buchanan-1@ou.edu

(No relevant relationships reported)

Microgravity is known to have negative effects on bone health. Circulating microRNAs (c-miRNA) are non-coding RNA molecules assessed in blood that have potential as biomarkers of osteoporosis and may be beneficial for tracking changes in bone status. **PURPOSE:** To examine selected c-miRNAs and serum markers of inflammation and bone turnover responses to a 30 day six-degree head-down bed rest protocol at an ambient 0.5% CO₂. **METHODS:** 11 adults (6 males, 5 females), 25-50 years, participated in the study at the Institute for Aerospace Medicine in Germany. Participants had fasted blood draws collected 3 days before, and on the final day of bed rest. Serum samples were assayed for relative expression of miR-21-5p, -100-5p, -125b-5p, and -126-3p using qPCR. Bone markers (Bone ALP, P1NP, TRAP 5b, sclerostin), inflammation markers (TNF α , IL-6), and Vitamin D were measured using ELISA. **RESULTS:** Only miR-21-5p increased relative expression pre to post ($p=0.02$). TNF α and calcium increased, and all bone marker concentrations increased pre to post, except Bone ALP. Baseline relative expression of miR-21-5p was correlated with pre calcium ($r_s=0.745$, $p<0.01$), miR-100-5p with sclerostin ($r_s=0.627$, $p=0.04$), pre IL-6 ($r_s=0.661$, $p=0.03$), and vitamin D ($r_s=0.645$, $p=0.03$), and miR-125b-5p with osteocalcin ($r_s=0.864$, $p<0.01$). Log₂ fold changes in miR-125-5p and absolute change in TRAP 5b were negatively correlated ($r_s=-0.782$, $p<0.01$), and Log₂ fold changes in miR-21 and absolute change in vitamin D were positively correlated ($r_s=0.609$, $p=0.047$). **CONCLUSION:** 30 days of 6-degree head-down bed rest significantly increased bone turnover as evidenced by increases in both P1NP and TRAP5b. Baseline c-miRNAs significantly correlated with multiple measures of bone

metabolism. MiRNA fold changes were correlated with absolute changes in Vitamin D (miR-21-5p) and TRAP5b (miR-125-5p), warranting further investigation into the use of miRNAs as biomarkers of space flight.

Table 1. Serum Biomarkers Pre and Post Bed Rest (mean ± SD).

| Variable | Pre | | | Post | | | mean change | | |
|--------------------------------------|---------------|---|--|----------------|---|--|------------------|------|--------|
| | | | | | | | Log2 Fold Change | | |
| miR-21-5p | -0.54 ± 0.49 | ± | | -0.07* ± 0.36 | ± | | 0.29 | ± | 0.60 |
| miR-100-5p | -8.93 ± 1.04 | ± | | -8.49 ± 1.03 | ± | | 0.32 | ± | 0.61 |
| miR-125b-5p -5.67 ± 0.77 -5.34 | | | | | | | | | |
| | | | | | | | 0.62 | 0.43 | ± 1.36 |
| miR-126-3p | -0.90 ± 0.41 | ± | | -0.61 ± 0.52 | ± | | 0.47 | ± | 0.55 |
| | | | | | | | Absolute Change | | |
| Sclerostin | 0.47 ± 0.14 | ± | | 0.53* ± 0.17 | ± | | 0.06 | ± | 0.08 |

Relationships Between Circulating MicroRNA and Muscular Performance Responses to a 30 Day Bed Rest Protocol
 Cameron Combs¹, Carl Ade², Samuel Buchanan¹, Debra Bembem, FACSM¹. ¹University of Oklahoma, Norman, OK. ²Kansas State University, Manhattan, KS. (Sponsor: Dr. Debra Bembem, FACSM)
 Email: cameron.s.combs-1@ou.edu
 (No relevant relationships reported)

Microgravity is known to have detrimental effects on muscle tissue, leading to atrophy and a decline in performance. Although underlying mechanisms are not clear, microRNAs (miRNA) may play a role as they have regulatory effects on skeletal muscle gene expression. **PURPOSE:** To determine the effects of a 30 day six-degree head-down bed rest protocol at an ambient 0.5% CO₂ on lower body muscular performance. Relationships between circulating miRNAs and changes in muscle variables were also examined. **METHODS:** 11 healthy subjects, 5 males and 6 females, were recruited for this study. The intervention involved a 30 day, six-degree head-down bed rest platform to simulate International Space Station flight. Maximal muscular performance was assessed for isokinetic knee extension (IsokKE), isokinetic knee flexion (IsokKF), isometric knee extension (IsomKE), isometric knee flexion (IsomKF), jump velocity (JV), absolute jump power (AbJP), and relative jump power (RelJP) 5 days before and 2 days after bed rest. Serum miRNAs (miR-21-5p, -100-5p, -125b-5p, -126-3p) were assessed by qPCR and fold changes (FC) were correlated with muscle performance variables. **RESULTS:** All muscular performance measures decreased (p<0.05) after bed rest (absolute changes: IsokKE -36±27N, IsokKF -16±17N, IsomKE -28±22N, IsomKF -12±14N, JV -0.21±0.08m/s, AbsJP -0.45±0.19kW, RelJP Power -5.23±1.88W/kg). Pre bed rest miR-100-5p relative expression was positively correlated with Pre strength measures and jump power (r=0.603 to 0.727, p<0.05). MiR-126-3p FC was negatively related to absolute change in relative power (r=-0.705, p<0.05), and miR-125b-5p FC was positively correlated (p<0.05) with absolute changes in IsomKE (r=0.627), IsomKF (r=0.817), and JV (r=0.700). MiR-100-5p FC was positively correlated (p<0.05) with absolute changes in IsomKE (r=0.652) and IsomKF (r=0.759). **CONCLUSION:** As expected, muscle performance significantly declined after 30 days of bed rest. Significant relationships were found between miRNAs and muscle variables at baseline (miR-100-5p), and miRNA fold changes (miR-100-5p, -125b-5p, -126-3p) were correlated with absolute changes in muscle strength and power. These miRNAs require further investigation to explore their possible mechanistic roles in muscle performance declines after bed rest.

1489 Board #251 May 30 9:30 AM - 11:00 AM
Cerebral Blood Flow Responses To Long Term Head-down Bed Rest

 Email: ogoh@toyo.jp
 (No relevant relationships reported)

PURPOSE: The present study was designed to investigate the effect of a 60-days, -6° head-down bed rest (HDBR) on both arterial and venous cerebral blood flows. **METHODS:** Twenty male healthy volunteers were evaluated. Blood flow in right side of the neck arteries (internal carotid artery; ICA and vertebral artery; VA) and veins (internal jugular vein; IJV and vertebral vein; VV) was measured by using ultrasonography on the day before HDBR (baseline); 30th day and 57th day of HDBR. **RESULTS:** ICA blood flow decreased at 30th day of the HDBR compared with baseline (P = 0.002), and returned to baseline at 57th day of the HDBR. On the other hand, VA blood flow was unchanged throughout the HDBR (P=0.402). At the venous side, IJV blood flow decreased at both 30th and 57th day of the HDBR (P = 0.002 and P = 0.005, respectively), in contrast, VV blood flow increased at 30th day (P=0.004) and was unchanged at 57th day compared with baseline. **CONCLUSIONS:** These findings suggest that the long-term HDBR decreased anterior cerebral arterial and venous blood flows, while posterior cerebral arterial and venous blood flows were well maintained. The heterogeneous blood flow response of the cerebral arteries may be associated with cerebral venous outflow but its physiological mechanism remains unclear.

Laughlin¹. ¹University of Houston, Houston, TX. ²IMBP, Moscow, Russian Federation. ³University of Applied Sciences, Aachen, Germany. ⁴German Aerospace Center (DLR), Cologne, Germany. (Sponsor: Richard Simpson, FACSM)
 Email: jtreed@uh.edu
 (No relevant relationships reported)

Purpose
 To examine the effects of space flight on knee extensors and flexors over six month flight missions.
Methods
 Four crewmembers were tested on board the International Space Station (ISS) after 8.9 (SD 3.0), 49.1 (SD 10.1) and 131.5 (SD 27.7) days in-flight, as well as pre- and post-flight, using the Muscle Atrophy Research and Exercise System (MARES). Voluntary isometric torque during maximal knee extension and flexion was obtained at starting positions of 90, 60 and 45 degrees of flexion. Surface EMG was simultaneously measured for the biceps femoris, semitendinosus, vastus lateralis and rectus femoris. Root mean squared (RMS) EMG within a 500 ms window centered on the time of peak torque was identified, and ratios of EMG to peak torque (EMG/T) were calculated for each isometric contraction.
Results
 Peak knee extension and flexion force declined immediately in-flight from pre-flight values. Knee extension decreased by 35.25%, 23.52% and 35.71% while flexion decreased by 25.55%, 27.59%, and 30.76% at 90, 60 and 45 degrees, respectively. Peak torque during knee extension progressively increased during flight such that the differences between pre-flight values and those of the third in-flight testing session were reduced to deficits of 25.65%, 11.37% and 0% for 90, 60 and 45 degrees, respectively. Knee flexion declined slightly at both 90 and 60 degrees (30.84% and 28.18%) however improved slightly at 45 degrees (25.39%) for in-flight 2 with a reciprocal change at in-flight 3 to 23.68%, 22.97% and 34.2% at 90, 60 and 45 degrees, respectively. By the second in-flight test, EMG/T ratios reflected a changing relationship between neuromuscular activation and torque production, with greater relative activation required to produce similar levels of torque when compared to pre-flight values.
Conclusions
 Results suggest that space flight results in an immediate decline of peak torque production for both knee extension and flexion. Current in-flight countermeasures appear to trend towards functional restoration of knee extension while knee flexion remained relatively unchanged.

The Hypercapnic Ventilatory Response and Cerebrovascular Reactivity to CO₂ during Waist Water Immersion with Acute Hypercapnia and Head Out Water ImmersionJames R. Sackett¹, Zachary J. Schlader, FACSM², David Hostler, FACSM², Blair D. Johnson². ¹Cornerstone University, Grand Rapids, MI. ²University at Buffalo, Buffalo, NY.
Email: james.sackett@cornerstone.edu

(No relevant relationships reported)

During head out water immersion (HOWI), the hypercapnic ventilatory response (HCVR) is augmented and cerebrovascular reactivity to CO₂ (CVR) is attenuated; possibly due to water pressure exerted on the chest wall, central hypervolemia, and/or hypercapnia. Waist water immersion with acute hypercapnia (WWI+CO₂) causes central hypervolemia and hypercapnia without exerting water pressure on the chest wall. However, it is unknown if HCVR and CVR are different during WWI+CO₂ vs. HOWI. **PURPOSE:** We tested the hypotheses that the HCVR is augmented and CVR is attenuated during WWI+CO₂ and HOWI. **METHODS:** Twelve subjects (age: 24±3 y, BMI: 25±3 kg/m², 6 women) completed one hour of thermoneutral (35±0°C) WWI+CO₂ and HOWI. The partial pressure of end tidal CO₂ (PETCO₂; capnograph), minute ventilation (MV; pneumotachometer), and middle cerebral artery blood velocity (MCAv; transcranial doppler) were recorded. CO₂ was added to the inspire during WWI+CO₂ to match the increase in PETCO₂ during HOWI. Subjects rebreathed 7% CO₂ and 93% O₂ from a 10 L bag for 3.5 min at baseline, 10 min, 30 min, and 60 min of water immersion. The HCVR and CVR were calculated as the slope of the linear regression line of MV vs. PETCO₂ and MCAv vs. PETCO₂ every 30 s throughout the test. Data are reported as a change from baseline (mean±SD). **RESULTS:** PETCO₂ increased from baseline during WWI+CO₂ and HOWI at every time point (p<0.01) and was matched between conditions (p≥0.26). MV increased from baseline during WWI+CO₂ at 60 min (p=0.03) but did not change during HOWI at any time point (p≥0.38). MCAv increased from baseline during WWI+CO₂ at every time point and during HOWI at 10 min and 30 min (all p<0.01). The HCVR did not change from baseline during WWI+CO₂ at any time point (all p≥0.35) but increased from baseline during HOWI at every time point (10 min: 0.59±0.34, 30 min: 0.58±0.46, 60 min: 0.63±0.45 L/min/mmHg; p<0.01). The CVR was lower during WWI+CO₂ vs. HOWI at 10 min, 30 min, and 60 min (p<0.01). CVR decreased from baseline during WWI+CO₂ and HOWI at every time point (p<0.01) but was not different between conditions at any time point (p≥0.16). **CONCLUSIONS:** The elevated HCVR during HOWI is likely caused by water pressure exerted on the chest wall. However, reductions in CVR during HOWI are likely caused by central hypervolemia and/or hypercapnia.

Inflamm-aging Is Associated With Impairing The Process Of Maintaining Telomere Length In LPS Stimulated PBMCsCharles S. Schwartz¹, Aaron Slusher², Tiffany Zúñiga³, Keshu Shah¹, Edmund Acevedo, FACSM¹. ¹Virginia Commonwealth University, Richmond, VA. ²University Of Michigan, Ann Arbor, MI. ³University of Arizona, Tucson, AZ. (Sponsor: Edmund Acevedo, FACSM)
Email: schwartzcs@vcu.edu

(No relevant relationships reported)

PURPOSE: This study examined the impact of the inflamm-aging phenotype on the capacity of isolated PBMCs to express a key mechanistic component involved in maintaining longer telomere lengths, human telomerase reverse transcriptase (hTERT), following *ex vivo* cellular stimulation with lipopolysaccharide (LPS). **METHODS:** Plasma inflammatory cytokines (i.e., IL-6, IL-10, TGF-β, and TNF-α), PBMC telomere lengths, and LPS-stimulated hTERT mRNA expression following *ex vivo* stimulation of PBMCs with LPS in 15 middle-aged (40-64 years) and 15 young adults (20-31 years) were quantified. **RESULTS:** Aging was accompanied by the accumulation of centrally located visceral adipose tissue (p ≤ 0.005), in the absence of weight gain (p = 0.932) or changes in BMI (p = 0.081), and alterations in the systemic inflammatory milieu (decreased plasma concentrations of the anti-inflammatory cytokine TGF-β; increased plasma concentrations of the pro-inflammatory cytokine TNF-α [p ≤ 0.050]). Likewise, shorter telomere lengths in middle-aged compared to young adults (p = 0.011) were associated with increased age, body fat percentages, and plasma TNF-α concentrations (r =

-0.404, p = 0.027; r = -0.427, p = 0.019; r = -0.323, p = 0.041, respectively). Finally, the capacity of PBMCs to express hTERT mRNA following cellular stimulation was impaired in middle-aged compared to young adults (p = 0.018), and negatively associated with telomere lengths (r = 0.353, p = 0.028).

CONCLUSIONS: Inflamm-aging is associated with the impaired the capacity of PBMCs to express hTERT mRNA and provides a mechanistic target to counter age-related telomere attrition and disease.

Effect Of Self control Exercise On Lymphocyte Subsets Of Lung Cancer Patients During RehabilitationJIBING WANG¹, Weimo Zhu, FACSM², Renwei Wang³, Jiaying Lang¹. ¹Tongji University, Shanghai, China. ²University of Illinois at Urbana-Champaign, urbana, IL. ³Shanghai University of Sport, Shanghai, China.

(No relevant relationships reported)

PURPOSE: Self-Control Exercise (SCE), known also as Guolin Qigong, is a mind-body exercise being used in China for cancer survival for more than 40 years. This study was to examine the effect of SCE on lymphocyte subsets of lung cancer patients and the possible mechanisms.

METHODS: 26 lung cancer patients (8 males & 18 females; Age in yr: 60.08±5.41; Cancer survival yr: 1.69±0.72) were recruited from the Shanghai Cancer Club. All the patients were diagnosed pathologically. The patients began to learn SCE for 3 weeks and then performed 6 months SCE at their will. Cancer history was surveyed, physical activity including SCE was recorded during the intervention. The lymphocyte surface antigen CD3/CD4/CD8/CD28/CD(16+56)/CD19/CD4CD25Foxp3 were examined by direct immunofluorescence staining and flow cytometry. Paired-samples t test was performed to compare the change of lymphocyte surface antigen before and after the intervention.

RESULTS: It was found that CD3⁺ increased significantly (50.52±13.09, 56.77±11.56 p < 0.05), CD4⁺ (22.54±6.70, 33.21±7.55) and CD4⁺/CD8⁺ (1.05±0.46, 1.80±0.69) increased significantly (p < 0.01), CD4⁺/CD25⁺Foxp3 declined significantly (18.99±8.55, 13.04±5.86, p < 0.05), CD16⁺CD56⁺ increased significantly (17.58±8.35, 21.48±8.81, p < 0.05) after the intervention. CD8⁺, CD8⁺/CD28⁺ and CD19⁺ showed no statistical difference (p > 0.05) before and after intervention.

CONCLUSIONS: SCE intervention improved the cellular immune function which mediated by T cell and NK cell, and it may be related to the suppression and down-regulation of the T regulatory cells to the cell immunity.

Effects Of Endurance Exercise Under Heat And Hypoxia On Hecpidin ResponsesNanako Hayashi, Haruka Yatsutani, Hisashi Mori, Hiroto Ito, Kazushige Goto. *Ritsumeikan University, Kusatsu, Japan.*
Email: sh0108hx@ed.ritsumei.ac.jp

(No relevant relationships reported)

Interleukin-6 (IL-6) promotes exercise-induced hepcidin elevation which is an iron regulating hormone, leading to increased risk of iron deficiency in athletes.

PURPOSE: The purpose of the present study was to compare exercise-induced hepcidin elevation between "heat and hypoxic condition" or "hypoxic condition". **METHODS:** Twelve males (21.5 ± 0.3 years, 168.1 ± 1.2 cm, 63.6 ± 2.0 kg) participated in the present study. They conducted a 60 min of cycling at 60 % of VO_{2max} under either "heat and hypoxia" (HHYP; FiO₂ 14.5%, 32°C), "hypoxia" (HYP; FiO₂ 14.5%, 23°C) or "normoxia" (NOR; FiO₂ 20.9%, 23°C). Exercise intensity was relatively matched for VO_{2max} under each environment, and the respective values of VO_{2max} were 42.7 ± 1.4 (HHYP), 41.2 ± 1.3 (HYP) and 50.8 ± 2.1 (NOR) ml/kg/min. After completing exercise, subjects stayed under the prescribed conditions during 3 h of post-exercise. Blood samples were collected before exercise, immediately after and 3 h after exercise. **RESULTS:** Blood lactate levels were significantly elevated with progress of exercise (P < 0.05), however, there was no significant difference among the three trials (P > 0.05). Serum ferritin level did not differ significantly among the trials (P > 0.05). Serum iron level did not change after exercise and no significant difference was observed among the trials (P > 0.05). In NOR, plasma IL-6 levels were significantly increased immediately after exercise and 3 h after exercise (P < 0.05), with no significant difference among the trials (P > 0.05). Serum hepcidin level was increased 3 h after exercise in all trials (P < 0.05). However, there was no significant difference among the trials during post-exercise (P > 0.05).

CONCLUSIONS: Endurance exercise under heat and hypoxia did not facilitate exercise-induced hepcidin elevation compared with the same exercise under hypoxia.

Time-course Of Physiological Changes Following An Extreme Conditioning Competition

Ramires A. Tibana¹, Nuno Manuel Frade de Sousa², Matheus Baffi³, Gabriel Veloso Cunha⁴, Fabricio Azevedo Voltarelli¹.
¹Federal University of Mato Grosso, Cuiabá, Brazil. ²Faculdade Estacio de Vitoria, Vitoria, Brazil. ³Laboratório de Correas, Rio de Janeiro, Brazil. ⁴Catholic University of Brasilia, Brasilia, Brazil.

(No relevant relationships reported)

Purpose: Extreme conditioning programs (ECPs) are characterized by utilizing a high volume of training and using a variety of high intensity exercises. The purpose of the present study was to monitor the time-course response of cytokines (IL-10 and IL-1 β), immune variables (C-reactive protein -CRP and immunoglobulin A-IgA), hormonal milieu (cortisol-C, total testosterone-TT, free testosterone-FT and testosterone/cortisol-T/C ratios), creatine kinase-CK, muscle performance (jump height) and perceived well-being (WB) following an ECP competition. The initial hypothesis is that an extreme conditioning competition increases inflammatory response as well as metabolic stress, impairing the hormonal milieu, and decreasing muscle performance. **Methods:** Nine amateur male athletes (age 27.1 \pm 4.1 years; training experience 2.2 \pm 1.3 years) completed five workouts over three consecutive days of EC-competition. All variables were measured before, 24 h, 48 h and 72 h following the last day of competition. **Results:** The EC-competition induced a decrease in IL10/IL1 β ratio approximately 5% after 24h, 21% after 48h and 31% after 72h. Delta T/C ratio remained unchanged during the post-competition period. IgA displayed a significant increase 24h and 72h post-EC-competition. The WB status score was higher 72h after the ECP as compared with pre-competition. **Conclusion:** The present findings suggest that ECP induces transient changes in some inflammatory and hormonal biomarkers, and perceived well-being seems to be efficient to detect changes in muscle performance. These data may be useful to coaches for monitoring fatigue and prescribing training (lower intensity sessions and/or resting days) in days following an EC competition. Furthermore, psychometric measurement tools seem to be an effective and easy method for assessing fatigue in participants after the competition.

Impact Of Exercise Intensity And Resting Intervals During Resistance Exercise On Acute Sparc Secretion In Healthy Young Males: A Pilot Study

Shohei Dobashi, Masato Hashimoto, Toshiki Kaneuchi, Katsuhiko Koyama, Daisuke Ando. *University of Yamanashi, Kofu, Japan.*

(No relevant relationships reported)

PURPOSE: Recently, it is going noteworthy that an exercise-induced novel myokine, secreted protein acidic and rich in cysteine (SPARC) has the potential to prevent colon cancer. Moreover, regular resistance exercise (RE) has been known to reduce the mortality risk of cancer. From these points of view, RE might prevent colon tumorigenesis via increasing SPARC, while it is unclear whether resistance exercise can promote SPARC secretion in human. Thus, the purpose of this study was to investigate the both effects of exercise intensity and duration of rest interval between exercise sets on acute response of RE-induced SPARC secretion.

METHODS: We designed two experiments in this study. In study 1, 7 subjects completed three experiments in a random order. They performed two RE at both 70% (High) and 35% (Low) of the individual's one repetition maximum (1-RM), and stayed rest condition without RE (Rest). The RE consisted of 8 kinds of exercise (double arm curl, shoulder press, double knee extension, chest press, lat-pull down, triceps press down, parallel squat, and seated rowing), for 3 sets of 7 repetitions. We recruited different 7 subjects in study 2, and let them conduct three experiments in a random order: RE (the same 8 kinds of exercise as described in study 1, 16 repetitions \times 3 sets at 50% 1-RM) with long inter-set rest interval (LIE, 150 s), RE with short inter-set rest interval (SIE, 50 s), and rest with no-exercise (NE). Blood samples were obtained before, immediate after, and 1h after RE in both study.

RESULTS: In study 1, serum SPARC concentration immediately after RE was significantly increased from baseline in High trial ($P < 0.05$), and that level was significantly higher than those in Rest and Low trials ($P < 0.05$, in both). In study 2, serum SPARC level immediately after RE in SIE trial significantly elevated compared with baseline ($P < 0.05$), and the increase was also significantly higher than NE trial ($P < 0.05$). However, the elevated SPARC concentrations in both High and SIE trials were swiftly returned to baseline within 1 h after RE.

CONCLUSIONS: Our findings indicate that RE can induce temporally SPARC secretion. It is also conceivable that increasing exercise load and/or shortening rest intervals between exercise sets during RE might enhance SPARC production.

Serum Uric Acid Levels and Cardiometabolic Risk Among Adolescents

Josi R. Gabaldon¹, Nate T. Berry¹, Jessica Dollar¹, Lilly Shanahan², Susan Keane¹, Lenka Shriver¹, Susan Calkins¹, Laurie Wideman¹. ¹University of North Carolina at Greensboro, Greensboro, NC. ²University of Zurich, Zurich, Switzerland.
 Email: jrgabald@uncg.edu

(No relevant relationships reported)

Uric acid (UA) is a biomarker of inflammation that has been linked to obesity, hypertension, metabolic syndrome (MetS) and other factors associated with cardiometabolic risk (CMR). UA levels are often elevated in minority populations and tend to increase in response to poor lifestyle behaviors (i.e diet, inactivity, sleep). Multiple definitions exist for MetS—some of which include UA—but it is really the clustering of CMR factors in adolescence that is crucial for identification of disease risk and prevention. However, little is known about the relation between UA across the CMR spectrum in adolescents. **PURPOSE:** To investigate the relations between CMR classification, sex, physical activity, and sleep on UA among adolescents. **METHODS:** At age 16, subjects [Caucasian=45.9%; Male: N=47, BMI=24.6 \pm 6.7; Female: N=67, BMI=23.9 \pm 9.3] came to the lab for a fasted blood draw, anthropometric measures and assessment of physical activity (PA) and sleep [Godin and Pittsburgh Sleep Quality Index (PSQI), respectively]. CMR biomarkers were assessed using multiplex assays and ELISAs. Serum UA was assessed using a commercial EIA. A linear mixed model was used to investigate UA by CMR profile (low, dyslipidemia, high) and sex, controlling for BMI, PA and sleep. **RESULTS:** Similar to previous studies in adolescents, the mean UA level was higher for males (7.11 \pm 1.19) compared to females (5.59 \pm 0.85). While men had a higher mean UA concentration, females had a higher UA after adjusting for BMI, PA, and sleep ($p=0.056$). More specifically, females in the low ($p<0.001$) and dyslipidemia risk ($p<0.001$) groups had higher UA compared to their male counterparts. Also, BMI was significantly associated with UA regardless of group or sex ($p=0.047$). **CONCLUSIONS:** These findings suggest that 1) subjects in the dyslipidemia profile had higher UA after controlling for BMI, PA and sleep compared to subjects in either the low or high CMR profiles and 2) while males may have higher mean UA concentrations on average, females have higher UA concentrations after adjusting for BMI, PA, and sleep. Future studies should track UA levels across adolescence and investigate whether or not the relation between CMR profiles and UA levels changes from adolescence in to adulthood. Exercise-mediated Apoptotic And Autophagic Responses Are Differentially Modulated In Pbmcs Of Obese Individuals

Chun-Jung Huang, FACSM¹, Alexandra L. Rodriguez¹, Nishant P. Visavadiya¹, Brandon G. Fico², Aaron L. Slusher³, Peter J. Ferrandi⁴, Michael Whitehurst, FACSM¹. ¹Florida Atlantic University, Boca Raton, FL. ²University of Texas, Austin, TX. ³University of Michigan, Ann Arbor, MI. ⁴Purdue University, West Lafayette, IN.
 Email: chuang5@fau.edu

(No relevant relationships reported)

PURPOSE: Obesity is associated with over activation of the pro-apoptotic pathway, implicating in the development of various comorbidities, such as insulin resistance and cardiovascular disease. While autophagy has been recently discovered as a critical molecular process in promoting cell survival against apoptosis, increased autophagic activation in obese individuals may serve as a pro-survival regulator to eliminate damaged proteins, organelles, or aggregates, and/or to enhance the cellular metabolic responses associated with physical stressors. Therefore, the purpose of this study was to examine whether or not maximal aerobic exercise-mediated apoptosis in obesity might be underlying the involvement of autophagy in the peripheral blood mononuclear cells (PBMCs).

METHODS: Twelve healthy male subjects (6 obese and 6 normal-weight) were recruited to participate in a maximal graded exercise test on a treadmill. Western blot analysis was used to determine the level of apoptotic and autophagic markers (Bax/Bcl-2 and LC3-II/LC3-I; respectively) in PBMCs prior to, immediately following exercise, and one and two hours into recovery from exercise.

RESULTS: Obese subjects exhibited a significantly lower Bax ($p = 0.028$), but a higher Bcl-2 protein level ($p = 0.006$) in conjunction with a reduced Bax/Bcl-2 area-under-the-curve "with respect to increase" (AUCi) ($p = 0.024$) compared to normal-weight subjects following maximal aerobic exercise. Furthermore, a greater LC3-II/LC3-I ratio and LC3-II/LC3-I AUCi was observed in obese subjects compared to normal-weight subjects in response to exercise ($p = 0.003$ and $p = 0.005$; respectively). LC3-II/LC3-I AUCi was also positively associated with obesity-associated parameters (BMI, waist/hip circumference, and fasting insulin level), but was negatively correlated with Bax/Bcl-2 AUCi ($r = -0.835$, $p = 0.001$).

CONCLUSIONS: These findings demonstrate that maximal aerobic exercise differentially mediates the intrinsic apoptotic pathway and autophagic activity in human PBMCs isolated from obese compared to normal-weight individuals, suggesting the importance of autophagy as a critical molecular process in promoting cell survival against exercise-induced apoptosis.

Exercise Training Modulates Metabolic Inflammation In Kidney Of Diabetic Db/db Mice

HUNG-WEN LIU. *National Taiwan Normal University, Taipei, Taiwan.*
 Email: hwliu@ntnu.edu.tw
 (No relevant relationships reported)

PURPOSE: Chronic inflammation and metabolic dysregulation may eventually cause tissue damage in type 2 diabetes. We examined the protective effects of moderate intensity aerobic exercise on kidney function in diabetic db/db mice.

METHODS: Functional and morphological alterations and metabolic and inflammatory signaling were examined in type 2 diabetic db/db mice with or without exercise training (5.2m/min, 1h/day, and 5days/week for a total of 8weeks).

RESULTS: Exercise training prevented weight gain (-7.0%) in db/db+Ex mice, but it did not reduce glucose and insulin levels. Exercise lowered serum creatinine, urea, and triglyceride levels in db/db+Ex mice. Reduced kidney size (0.37 vs 0.4g, $P=0.036$) and morphological alterations including decreased glomerular cross-sectional area (0.0235 vs 0.0367mm², $P<0.001$) were observed in db/db+Ex mice compared with untrained db/db mice. Mechanistically, preventing loss of SIRT1 (+62%, $P=0.048$) through exercise was linked to reduced acetylation of NF- κ B (-48%, $P=0.002$) in kidney of db/db+Ex mice. Exercise increased citrate synthase (+132%, $P=0.038$) and mitochondrial complex I activity (+80%, $P=0.004$), subunits of mitochondrial complexes (I, II, and V) and PGC1 α (+24%, $P=0.039$) at protein level in kidney of db/db+Ex mice compared with non-exercise db/db mice.

CONCLUSIONS: Moderate exercise training modulates metabolic dysfunction and inflammatory process, thereby attenuating the progression of diabetic nephropathy in type 2 diabetes mellitus.

Static Cerebral Autoregulation is Not Altered in Symptomatic Concussed Athletes During Acute Central Hypervolemia

Morgan L. Worley, Morgan C. O'Leary, James R. Sackett, Zachary J. Schlader, FACSM, John J. Leddy, Blair D. Johnson. *University at Buffalo, Buffalo, NY.*
 Email: mworley@buffalo.edu
 (No relevant relationships reported)

Dynamic cerebral autoregulation is impaired in concussed individuals. However, less is known regarding static cerebral autoregulation in symptomatic concussed athletes during a central hypervolemic challenge that increases blood pressure. **PURPOSE:** We tested the hypothesis that static cerebral autoregulation during a central hypervolemic challenge is impaired in symptomatic concussed college athletes (CA) vs healthy controls (HC). **METHODS:** Seven CA (age: 19 \pm 2 y, 5 females) and ten HC (age: 21 \pm 2 y, 6 females) completed one study visit. After 5 min of resting baseline, 20 mmHg of lower body positive pressure (LBPP) was applied for 5 min using an airtight chamber. Beat to beat blood pressure (photoplethysmography) and middle cerebral artery blood velocity (MCAv; transcranial Doppler) were recorded continuously. Static cerebral autoregulation was calculated using Fourier transfer function analysis with 3 min segments at baseline and after mean arterial pressure (MAP) stabilized during LBPP. Cerebral vascular resistance (CVR) was calculated as MAP/MCAv. Pulsatility index (PI) was calculated as the difference of peak systolic MCAv and end diastolic MCAv, divided by mean MCAv. Values are reported as a change from baseline. **RESULTS:** MAP (CA: 90 \pm 6 vs HC: 92 \pm 11 mmHg; $P=0.32$), MCAv (CA: 58.7 \pm 19.4 vs HC: 62.6 \pm 11.1 cm/s; $P=0.30$), gain (CA: 0.7 \pm 0.2 vs HC: 0.8 \pm 0.2 cm/s/mmHg; $P=0.17$), coherence (CA: 0.5 \pm 0.1 vs HC: 0.5 \pm 0.1; $P=0.21$), CVR (CA: 1.7 \pm 0.6 vs HC: 1.5 \pm 0.3 mmHg/cm/s; $P=0.21$), and PI (CA: 0.9 \pm 0.1 vs HC: 0.9 \pm 0.2; $P=0.31$) were not different at baseline. The change in MAP was not different between CA (12 \pm 6 mmHg) and HC (8 \pm 6 mmHg; $P=0.12$). The change in MCAv was greater in CA (CA: 4.8 \pm 4.6 vs HC: -4.3 \pm 8.7 cm/s; $P=0.01$). There were no differences in the change from baseline for gain (CA: 0.1 \pm 0.2 vs HC: 0.1 \pm 0.5 cm/s/mmHg; $P=0.49$) or coherence (CA: -0.0 \pm 0.1 vs HC: -0.0 \pm 0.1; $P=0.40$). The increase in CVR was attenuated in CA (CA: 0.0 \pm 0.2 vs HC: 0.3 \pm 0.3 mmHg/cm/s; $P=0.04$). The decrease in PI was greater in

CA (CA: -0.1 \pm 0.0 vs HC: 0.0 \pm 0.1; $P=0.02$). **CONCLUSION:** These data indicate that indices of static cerebral autoregulation are not different between CA and HC during an acute increase in MAP. The blunted increase in CVR and greater decrease in PI appears to allow for a rise in MCAv during an acute increase in MAP in CA.

Whole-Body Reactive Agility Asymmetries among Athletes with Concussion History Are Modifiable

Gary B. Wilkerson¹, Dustin C. Nabhan, FACSM², William J. Moreau². ¹University of Tennessee at Chattanooga, Chattanooga, TN. ²United States Olympic Committee, Colorado Springs, CO. (Sponsor: Gregory Heath, FACSM)
 Email: Gary-Wilkerson@utc.edu
 (No relevant relationships reported)

PURPOSE: This study assessed associations between self-reported concussion history and measures of perception-action coupling, as well as changes in reactive responses after upper extremity training that imposed both cognitive and visuomotor demands.

METHODS: A cohort of 22 elite athletes representing 6 Olympic sports (14 males & 8 females; 26.1 \pm 5.1 years) performed pre- and post-training tests of upper extremity choice reaction time (RT) and whole-body reactive agility. The choice RT test used 10 congruent and 10 incongruent Eriksen flanker 5-arrow displays to designate correct left versus right manual responses for deactivation of illuminated buttons. Whole-body tests required lateral movement responses to 20 left or right visual targets and diagonal movement responses to 12 visual targets presented in right/left and forward/backward combinations. One-minute cognitive-visuomotor training sessions were completed 2-3 times per week over 4 weeks, which involved simultaneous manual responses (button deactivations) and verbal responses (center arrow direction for 20 5-arrow displays).

RESULTS: At least 6 training sessions were completed by each athlete (7.7 \pm 0.6). Concussion history was reported by 55% (12/22; 5.0 \pm 4.9 years; range: 0.3 - 16.5 years), which was strongly associated with asymmetries in both lateral and diagonal/backward reactive agility measures of RT, speed, acceleration, and deceleration (AUC=.808). The average of the 8 asymmetry values \geq .18 discriminated with 89% PPV, 69% NPV, and OR=18.0 (90% CI Lower Limit: 2.4; χ^2 Exact 1-Sided $P=0.01$). Upper extremity choice RT incongruent-congruent difference \geq 80 ms classified concussion history status with PPV=69%, NPV=67%, and OR=4.5 (90% CI Lower Limit: 1.0; χ^2 Exact 1-Sided $P=.11$). Among the athletes with concussion history, 7 of 8 reactive agility asymmetries were reduced after training. Standardized response means for reactive agility asymmetry reduction ranged from .17 to .48, and average choice RT incongruent-congruent difference improved from 103 \pm 51 ms to 54 \pm 79 ms (SRM=.53).

CONCLUSIONS: Asymmetry in reactive responses may be a manifestation of dysfunctional interhemispheric brain connectivity. Our findings suggest that cognitive-visuomotor training with the upper extremities can reduce whole-body movement asymmetries.

 (No relevant relationships reported)

The King-Devick (KD) test of rapid eye movement is a common instrument used to assess concussion in able-bodied (AB) sport but data are limited for disability sport athletes. **PURPOSE:** The purpose of this study was to report updated normative KD values for wheelchair basketball sport participants. **METHODS:** One-hundred twenty wheelchair basketball players (101 males, 18 females, 1 non-report) completed baseline KD assessments via an iPad application approximately 10 minutes before a scheduled practice or competition. Because some athletes had limited or impaired grip, iPads were placed on music stands or in iPad clips on a tripod at a standardized height and distance from each participant. Per KD protocol, two baseline assessments were administered with the lowest score reflecting true baseline. **RESULTS:** Mean KD baseline score was 62 \pm 24 sec. No significant difference on mean KD baseline score existed between genders or prior concussion experience. However, significant differences on baseline KD existed between age groups (adults = 55 \pm 17 sec; youth = 71 \pm 27 sec; $F=14.92$, $p=0.00$) and among impairment types (spinal cord injury = 52 \pm 13 sec, spina bifida = 71 \pm 25 sec, amputee = 53 \pm 11 sec, cerebral palsy = 88 \pm 31 sec; $F=14.92$, $p=0.00$). **CONCLUSIONS:** KD normative scores were meaningfully higher than previously reported norms in AB sport for both adults and youth. Baseline KD scores varied by impairment type which is an important consideration for normative development in wheelchair basketball athletes.

 (No relevant relationships reported)

Prior concussion history is posited to influence many outcomes. Understanding how concussion history affects quality of life may identify student-athletes needing intervention and those predisposed to other conditions. **PURPOSE:** To examine how prior concussion history influences college athletes' pre-season baseline health-related quality life (HRQOL). **METHODS:** Student-athletes (n = 1599) from six Canadian and US college institutions and 24 college sports, completed a comprehensive concussion baseline assessment including an HRQOL evaluation (PROMIS-29, Neuro-QOL Fatigue, and Neuro-QOL Cognition Scales). The primary predictor was concussion history and covariates included age, sex, BMI, and contact sport participation. Primary outcomes were Anxiety, Physical Function, Depression, Sleep Disturbance, Social Role/Activities, Pain Interference, Pain Intensity, Cognition, and Neuro-related Fatigue raw scores. Linear regression models clustered on study site using generalized estimating equations examined the association between concussion history and HRQOL outcomes. **RESULTS:** Analysis was limited to 1509 (94%) participants with complete outcome and covariate data [538 females (35.6%); median age = 19 years (range: 18-27); 553 (36.7%) with 1+ prior concussions]; 1154 (76.5%) played a contact sport]. Concussion history, adjusted for age, sex, BMI, and contact sport participation, were associated with greater anxiety, sleep disturbance, depressive feelings, fatigue, and worse cognition function. However, these differences were mostly minor. Clinically meaningful mean differences (MD) suggest those with multiple concussions report worse cognitive function (MD=-1.2; 95%CI: -2.4, -0.1 for 3+ vs 0 concussions; MD=-1.1, 95% CI:-2.3, 0.1 for 2 vs. 0 concussions) and greater neuro-related fatigue (MD=1.3, 95% CI: -0.1, 2.7 for 3+ vs 0 concussions; MD=0.9, 95% CI: 0.1, 1.7 for 2 vs 0 concussions). **CONCLUSIONS:** After controlling for covariates, these data suggest that following primary recovery, those with prior concussions may exhibit increased cognitive and fatigue related complaints. These residual effects may confound incident concussion assessments, particularly when pre-season baseline measures are not available.

Supported in part by a grant from the National Football League

Long Term Effects of Concussion on Eye Tracking Patterns

Lauren A. Dougherty, Kathryn L. Van Pelt, Andrew P. Lapointe, Griffin J. Feinberg, Allyssa K. Memmini, Katherine M. Breedlove, Steven P. Broglio, FACSM. University of Michigan, Ann Arbor, MI. (Sponsor: Steven Broglio, FACSM)
 (No relevant relationships reported)

Purpose: The purpose of this study is to investigate long-term changes in eye-tracking patterns in previously concussed individuals (>1-year post-injury) compared to non-concussed controls. **Methods:** This case control study will include 40 total participants, but currently includes 12 participants with (n=5 concussed, 3.00±1.79 concussions, 4.92±2.43 years post-injury, 22.80±2.23 years, 170.18±6.62 cm, 71.49±9.19 kg) and without (n=7; 27.00±4.96 years, 177.8±9.40 cm, 77.69±12.83 kg) a concussion history were evaluated. Participants were excluded if they only had a previously undiagnosed concussion, were currently playing contact sports, did not have normal or corrected to normal vision without glasses. Participants completed two eye-tracking tasks: an anti-saccade task consisting of 5 test blocks, 40 trials each and a circle tracking task consisting of 3 trials. The anti-saccade task measured saccadic and anti-saccadic movements, while the circle tracking task measured smooth pursuit eye movements. In both groups, results were analyzed using independent T-tests. **Results:** The mean reaction and processing times in the saccade task in formerly concussed subjects was significantly different from controls (p=0.02 and p<0.01). The control group had a 7.41% slower reaction time and 12.64% slower processing time than the concussed group. Other anti-saccade task variables (i.e. movement time, number of correct saccades, number of trials where saccade ended outside of the target zone, percent of accurate saccades, distance from target block, distance from target block for correct trials) and circle tracking (i.e. horizontal root mean squared error (RMSE), vertical RMSE, horizontal delay, mean vertical delay) were not significant (p>0.05). **Conclusions:** Counter to work on the acute effects of concussion, the preliminary findings of this study indicate that concussion may not have a long-term effect on eye-tracking reaction and processing time. Additional work in this area with larger samples is warranted.

Examining Differences Between Patient and Clinician Measurements of Post-Concussion Near-Point of Convergence Distance

Nathan D'Amico¹, Melissa Womble², Katie Stephenson-Brown¹, Anthony Kontos³, RJ Elbin¹. ¹University of Arkansas, Fayetteville, AR. ²Inova Sports Medicine, Fairfax, VA. ³University of Pittsburgh Medical Center, Pittsburgh, PA.
 (Sponsor: Dr. Brendon McDermott, FACSM)
 Email: nrdamico@uark.edu
 (No relevant relationships reported)

Near-point of convergence (NPC) is the distance an individual can view a target without diplopia. The assessment of NPC distance is an important component of the Vestibular Ocular Motor Screening (VOMS) for sport-related concussion (SRC). The VOMS requires that the NPC distance is obtained by the patient and recorded by the clinician. However, some clinicians anecdotally report obtaining a more accurate and consistent measurement than patients due to more training and experience. Measurement differences between these two administration methods are important to investigate, as a NPC distance less than 5cm is predictive of SRC. No study to date has compared patient and clinician measurements of NPC distance following concussion.

PURPOSE: To examine differences between patient and clinician measurements of post-concussion NPC distance.

METHODS: One hundred and two patients (17.80±7.43 years) seeking care for a medically diagnosed SRC participated in this study. For the patient measurement, the patient focused his/her eyes on a 14-point font target (i.e., fixation stick) and slowly moved the target toward the center of the patient's eyes until the patient reported double vision. For the clinician measurement, the clinician slowly moved the target toward the patient until the patient reported double vision and recorded the NPC distance. The NPC distance was recorded as the average of three trials. Paired-samples t-tests were performed to examine differences in NPC distance between patient and clinician administration. Chi-square analyses were performed to compare the number of cases exceeding clinical cutoffs (>5cm) between the two administration methods. Statistical significance was set at p<.05.

RESULTS: There were no significant differences between patient and clinician administered NPC distance measurements (t[102]=-1.66, p=.10). The number of NPC distance measures that exceeded clinical cutoffs (>5cm) were not significantly different between patient (n=28) and clinician administrations (n=31) (χ²[1,204]=.22, p=.64).

CONCLUSIONS: Patients can accurately administer NPC distance despite not having the training and experience of clinicians. All 28 patients that exceeded clinical cutoffs during patient administration also exceeded clinical cutoffs during clinician administration.

1506 Board #268 May 30 10:30 AM - 12:00 PM
The Effect of School Socioeconomic Status and Sport on Adolescent Athletes' Baseline Concussion Assessment

Paul J. Gubanich, FACSM¹, Matthew S. Propst², Christy Reed¹, Tim S. Foster³, Kelsey Logan¹, Adam W. Kiefer¹. ¹Cincinnati Children's Hospital Medical Center, Cincinnati, OH. ²CHI St. Joseph Health, College Station, TX. ³University of Cincinnati, Cincinnati, OH.
 Email: paul.gubanich@cchmc.org
 (No relevant relationships reported)

PURPOSE: The purpose is to examine the effect of school socioeconomic status (SES) and sport on the baseline performance of adolescent athletes on the King-Devick test (KD), modified Balance Error Scoring System (mBESS), and Post Concussive Symptom Inventory (PCSI).

METHODS: A retrospective cohort study was conducted on athletes' baseline concussion assessments completed as part of a concussion surveillance program. Testing included a history and risk factor questionnaire, KD, mBESS, and PCSI. Schools and sports clubs were classified as high SES (private or <50% free/reduced lunches) vs. low SES (public, > 75% free/reduced lunches). Sports were categorized as collision, contact, and non-contact. An ANCOVA was performed for each outcome while controlling for age

RESULTS: Analysis was conducted on 377 athletes (63% M), average age 15.9±1.5 years (range 12.1-19.2). Two schools and 1 club were classified as high SES (n=162); 5 schools (n=215) were classified as low SES. For KD score, only a significant school × sport interaction was observed (p=0.01), with age as a significant co-variate (p=0.01). Only a significant main effect of school was observed for the mBESS (p=0.02), while a significant main effect of school (p=0.001) and school × sport interaction (p=0.02) was observed for PCSI. Age was not significant for either mBESS or PCSI (p>0.47).

CONCLUSIONS: This study examines the influence of school SES and sport on baseline KD, mBESS, and PCSI. KD scores were slower in contact and non-contact athletes of high SES schools compared to low SES school athletes. Additionally, low SES school contact and non-contact athletes reported higher baseline PCSI scores

compared to their high SES school counterparts. These findings have implications for how baseline scores are considered as comparisons for concussion surveillance; however, more studies are necessary to examine other confounding factors and the utility of these measures in managing injury recovery.

| Baseline Concussion Outcome by School SES and Sport Type | | | | | |
|--|-------------|-----|--------------|-----------------|----------------|
| School | Sport type | n | Mean KD (SD) | Mean mBESS (SD) | Mean PCSI (SD) |
| High SES | Collision | 29 | 45.76(8.15) | 26.76(2.25) | 4.66(6.77) |
| | Contact | 59 | 50.41(10.29) | 26.54(2.84) | 4.73(5.93) |
| | Non-contact | 73 | 48.93(9.49) | 26.22(3.15) | 4.15(6.94) |
| Low SES | Collision | 125 | 48.30(10.40) | 24.93(3.26) | 4.29(7.68) |
| | Contact | 64 | 44.14(8.02) | 25.84(3.25) | 7.83(10.52) |
| | Non-contact | 26 | 44.47(7.79) | 26.23(2.52) | 10.65(10.87) |

 (No relevant relationships reported)

Computerized neurocognitive testing (CNT) is an important component for the management of sport-related concussion (SRC). The cognitive demands required to complete CNT may exacerbate SRC symptoms.

PURPOSE: To prospectively examine changes in post-concussion symptom reporting after completing CNT. **METHODS:** One hundred forty-five athletes (15.72 ± 1.78 years) with a medically diagnosed SRC completed the Post-Concussion Symptom Scale (PCSS) before and after completing a CNT (e.g., The Immediate Post-Concussion Assessment and Cognitive Testing: ImPACT). Changes in total PCSS symptoms and symptom clusters (somatic, affective, and cognitive-migraine-fatigue) were examined with a series of paired samples *t*-tests. Participants were also assigned to groups based on the time elapsed from injury until their first clinical visit: 0-7, 8-14, and 15-21 days. A series of 3 (time since injury group) X 2 time (pre, post) analysis of variance were performed on symptom totals and clusters. Statistical significance was set at a Bonferroni-corrected *p* < .01.

RESULTS: There were no significant differences in total (*t* (145) = -.69, *p* = .49), somatic, (*t* (145) = -1.02, *p* = .31), or cognitive-migraine-fatigue symptoms (*t* (145) = -1.75, *p* = .08) before and after CNT. There was a significant difference for affective symptoms (*t* (145) = 2.51, *p* = .01). Affective symptoms were significantly higher before CNT (*M* = 2.19, *SD* = 3.15) compared to after CNT (*M* = 1.80, *SD* = 2.89). There were no between-subjects or within-subjects main effects for total, somatic, affective, or cognitive-migraine-fatigue symptom clusters (*p* > .05). There were also no significant group x time interactions for total symptoms (*Wilks* λ = .99, *F* [1, 142] = 0.20, *p* = .40, η^2 = .01), somatic, (*Wilks* λ = 1.00, *F* [2, 142] = .30, *p* = .74, η^2 = .004), affective (*Wilks* λ = .99, *F* [2, 142] = 0.89, *p* = .43, η^2 = .01), or cognitive-migraine-fatigue symptom clusters (*Wilks* λ = .99, *F* [2, 141] = 0.41, *p* = .67, η^2 = .01). **CONCLUSIONS:** The administration of CNT during recovery from SRC does not increase concussion symptoms. Sports medicine professionals should administer CNT to concussed athletes even when symptomatic, to more accurately identify neurocognitive impairment, which will help determine targeted treatment options.

No Differences in Tandem Gait Performance between Males and Females Acutely Post-Concussion

Jessie R. Oldham¹, David R. Howell², Kelsey N. Bryk³, William P. Meehan III¹, Thomas A. Buckley³. ¹Boston Children's Hospital, The Micheli Center, Waltham, MA. ²Children's Hospital Colorado, University of Colorado School of Medicine, Aurora, CO. ³University of Delaware, Newark, DE.
 Email: Jessie.Oldham@childrens.harvard.edu
 (No relevant relationships reported)

Postural control impairments are common following concussion and traditionally assessed using the Balance Error Scoring System (BESS). Tandem gait (TG) has

successfully identified impairments in postural control acutely post-concussion that were undetected by the BESS; thus, TG may be a more robust postural control assessment following concussion. While sex differences in BESS performance after concussion have been explored, there is no literature regarding sex differences in post-concussion TG. **PURPOSE:** To examine sex differences in TG performance among collegiate student-athletes acutely post-concussion relative to pre-injury performance. **METHODS:** Forty-eight concussed collegiate student-athletes (30 females) and twenty-five healthy controls (13 females) completed TG tests during pre-season and again acutely post-concussion. Participants walked heel-to-toe down a 3-meter line, turned, and returned as quickly as possible, completing four single-task (ST) and dual-task (DT) TG trials. During DT trials, they simultaneously answered mini-mental style questions. The best ST and DT times were recorded. A 2x2 (group*sex) ANOVA was used to examine TG change between pre-injury and post-injury tests (positive value=slower/worsening; negative value=faster/improving).

RESULTS: The change in TG time from pre-injury to post-injury was significantly higher for the concussion group relative to the control group during both ST (Concussion: 1.6±2.6 seconds, Controls: -1.1±0.8 seconds, *p*<0.001) and DT (Concussion: 2.0±3.8 seconds, Controls: -0.9±1.7 seconds, *p*<0.001) TG. There were no significant interactions (ST: *p*=0.17, DT: *p*=0.23) or main effects for sex (ST: *p*=0.63, DT: *p*=0.91).

CONCLUSIONS: There were no sex-specific differences in TG performance acutely post-concussion. However, all concussed participants, regardless of sex, performed significantly worse on TG than male and female controls after injury relative to baseline, while controls did not demonstrate such a change. These results suggest that TG can appropriately identify postural control impairments following concussion; however, there do not appear to be differences in performance between males and females.

1509 Board #271 May 30 10:30 AM - 12:00 PM
Post-Concussion Symptom Factors in Male and Female High School and Collegiate Athletes

Morgan Anderson, Abigail C. Bretzin, Kyle M. Petit, Jennifer L. Savage, Tracey Covassin. Michigan State University, East Lansing, MI.
 Email: ande1997@msu.edu
 (No relevant relationships reported)

Previous research suggests concussed female athletes report higher severity of total symptoms; however, sex differences for symptom factors across recovery are understudied. **PURPOSE:** To examine sex differences in post-concussion symptom factors across concussion recovery (i.e., ≤72 hours, return-to-play, >one-month). **METHODS:** Symptoms were rated from 0 (none) to 6 (severe) on the Post-Concussion Symptom Scale (PCSS), which consists of 22 total symptoms and a total symptom severity score ranging from 0-132. The PCSS was broken into two symptom factors: cognitive-migraine-fatigue (headache, dizziness, fatigue, drowsiness, sensitivity to light/noise, feeling slowed down, foggy, difficulty concentrating/remembering) and affective (sadness, nervousness, feeling more emotional). A 2 sex (male, female)*2 group (concussed, healthy)*3 time (≤72 hours, return-to-play, >one-month) repeated measures ANOVA was used to analyze sex differences in symptom factors throughout recovery between concussed and healthy athletes. **RESULTS:** There were 167 (*M*=17.46 years, *SD*=2.2; male=97, female=70; concussed=78, healthy=89) total athletes. There were no significant sex differences between testing sessions at ≤72 hours (*M*=2.03 days, *SD*=0.8, *p*=.42), return-to-play (*M*=16.09 days, *SD*=11.7, *p*=.95), and >one-month (*M*=59.72 days, *SD*=21.4, *p*=.65). There was no significant within-subject interaction for sex*group*time for the cognitive-migraine-fatigue or affective symptom factors. There was a significant between-subjects sex*group interaction for the cognitive-migraine-fatigue symptom factor (*F*_(1,163) = 5.52, *p* = .02, η^2 = .03). Simple main effects analysis revealed concussed females (*M* = 7.39, *SE* = 0.57) reported significantly higher severity for the cognitive-migraine-fatigue symptom factor than concussed males (*M* = 4.83, *SE* = 0.48; *p* ≤ .001), yet no sex differences were observed between healthy athletes (*p* = .82). There was no significant between-subjects sex*group interaction for the affective post-concussion symptom factor. **CONCLUSIONS:** Concussed females reported greater symptom severity for the cognitive-migraine-fatigue symptom factor compared to concussed males, which may direct targeted concussion management approaches between female and male athletes.

Patient-parent Agreement On The Health And Behavior Inventory After Pediatric Concussion

Tatiana Patsimas, David R. Howell, Morgan N. Potter, Aaron J. Provance, Michael W. Kirkwood, Julie C. Wilson. *University of Colorado, Denver, CO.*

Email: tatiana.patsimas@gmail.com

(No relevant relationships reported)

PURPOSE: The purpose of our study was to examine patient-parent agreement on measures of concussion symptom frequency after pediatric sport-related concussion, and identify differences in patient-parent agreement between child and adolescent age groups.

METHODS: We conducted an analysis of data collected from a prospective registry of patients with concussion in a sports medicine clinic. Patients and their parents completed the Health and Behavior Inventory (HBI) at each clinic visit. Wilcoxon signed rank tests were used to assess for potential differences in symptom frequency ratings. Spearman rho correlations and Fisher's r to z transformation were used to assess linear agreement for total HBI score between parents and children (ages 6-12 yrs), compared to parents and adolescents (ages 13-18 yrs). Multiple regression analyses were used to evaluate the association between parent-reported and patient-reported HBI ratings with return to play (RTP) time and symptom duration.

RESULTS: A total of 267 patients (24% children, 28% females, evaluated 8.9±5.2 days post-concussion) were included in the analysis. For total HBI score, the agreement between children and their parents was high ($r_s=0.88$; 95% CI=0.80-0.95). Adolescents also highly agreed with their parents ($r_s=0.78$; 95% CI=0.71-0.85). However, child-parent agreement was significantly higher than adolescent-parent agreement ($z=2.21$; $p=0.03$). Additionally, combined child and adolescent patient HBI ratings were significantly associated with symptom resolution time ($\beta=0.296$; 95% CI=0.091-0.501; $p=0.005$) and RTP time ($\beta=0.487$; 95% CI = 0.009-0.965; $p=0.046$), whereas parent HBI ratings were not.

CONCLUSIONS: Overall, there was strong agreement between patients and their parents on the HBI, though children demonstrated significantly higher agreement with their parents compared to adolescents. Additionally, patient-reported HBI scores were more predictive of symptom duration and RTP time than parent-reported HBI scores. Clinicians may find this useful when setting expectations regarding concussion symptom duration and RTP timing for patients and their families. Significant reporting discrepancies between patients and their parents may also be a relevant factor for clinicians to consider during acute post-concussion evaluations.

1511 Board #273 May 30 10:30 AM - 12:00 PM
Three-dimensional Multiple Object Tracking's Role In Injury Incidence Reduction In Collegiate Athletics

Emma Foss, Christina Renodin, Daniel Antonoff, Erin Hartigan, Jasmine Honey, Taylor Langevin, Wallace Marsh, John Rosene. *University of New England, Biddeford, ME.*

Email: efoss1@une.edu

(No relevant relationships reported)

Three-dimensional multiple object tracking (3D-MOT) has been proposed as a training tool for processing dynamic events such as sports activities, and has been hypothesized to reduce athletic injuries through increased awareness of player movement.

PURPOSE: The purpose of this study was to determine if 3D-MOT is an effective intervention to minimize the risk of injury in collegiate ice hockey and lacrosse.

METHODS: 78 NCAA Division III ice hockey and lacrosse players volunteered for a season-long investigation. Players were assigned to a 3D-MOT training intervention (3D-MOT; $n=38$) or a control group (C; $n=40$). 3D-MOT training gains were measured by mean speed threshold (m/s) obtained from Core training sessions and were analyzed using paired t-tests. Athletic trainers (ATs) attended school-sanctioned team conditioning sessions, practices, and competitions from which injury data was collected. Repeated measures analysis of variance (RM-ANOVA) were performed to compare total number of injuries over time and between groups (3D MOT and C). Two additional RM-ANOVA were performed to explore if 3D-MOT training decreased the number of injuries over time based on injury mechanism (i.e., contact vs. non-contact).

RESULTS: The mean speed threshold significantly increased from the first Core session to the last Core session ($p=0.000$). The total number of injuries significantly decreased over the course of the season ($p=0.002$). When comparing the 3D-MOT to C, there was no significant difference in the total number of injuries ($p=0.293$). For those injured at baseline, the total number of injuries also significantly decreased over time ($p=.002$) though the 3D-MOT intervention had no effect on the number of injuries in athletes injured at baseline ($p=.204$). The 3D-MOT intervention did not have an effect on mechanism of injury, however both contact ($p=.016$) and non-contact injuries ($p=.013$) significantly decreased over time (length of season). **CONCLUSIONS:** Motion perception training with 3D-MOT did not decrease injury incidence in NCAA Division III men's and women's ice hockey and lacrosse athletes compared to controls. NCAA Division III men's and women's ice hockey and lacrosse athletes experience fewer injuries, both contact and non-contact, as their seasons' progress.

Head Motion Predicts Transient Loss of Consciousness in Human Head Trauma: Insights From Mixed Martial Arts

Alexandra E. Fogarty¹, Christian S. Guay¹, Gabrielle Simoneau², Berdale Colorado¹, G Ross Segal³, Kent Werner⁴, Jeffery M. Ellenbogen⁵. ¹Washington University in St Louis, St Louis, MO.

²McGill University, Montreal, QC, Canada. ³Segal and Iyer Orthodontics, Marlton, NJ. ⁴Johns Hopkins University School of Medicine, Baltimore, MD. ⁵Baltimore County Fire Department, Baltimore, MD.

Email: afogarty@wustl.edu

(No relevant relationships reported)

Transient loss of consciousness (tLOC) is commonly observed in athletes with concussion. Despite evidence that tLOC has long-term clinical implications, the mechanism by which it occurs is not well characterized in human models. **Purpose:** To investigate the strike patterns that produce concussion with tLOC using professional mixed martial arts (MMA) competitors. **Methods:** An online database was screened for Ultimate Fighting Championship (UFC) fights ending with knockouts (KO). Inclusion criteria for analysis were classification as KO, dated from January 2013 to December 2015. Videos were excluded if a strike leading to tLOC could not be definitively identified and characterized. Demographic information of athletes was compiled into fight profiles. Two blinded, independent reviewers generated impact profiles, which included timing of strike, striking implement, strike location, and head motion. This was performed for all KO strikes (cases) and for a group of non-KO (NKO) strikes (controls). Winner and loser characteristics were compared using 2-tailed t-tests. Multivariate logistic regression analyses were used to compute odds ratios for the strike characteristics associated with tLOC. The Kaplan-Meier estimate was used to describe the temporal distribution of KOs. **Results:** A total of 130 fights were identified for review and 106 fights met criteria for analysis. Analysis of impact profiles revealed that the strongest independent predictor for LOC was axial head rotation (OR, 45.3; 95% CI, 20.8 - 98.6). Other independent risk factors included non-fist striking implements (OR, 11; 95% CI, 4.58 - 26.4), strike location affecting the mandible (OR, 2.84; 95% CI, 1.26 - 6.41) or maxilla (OR, 3.74; 95% CI, 1.32 - 10.6), and strikes resulting in flexion, extension or lateral head flexion (OR, 4.94; 95% CI, 2.09 - 11.7). The Kaplan-Meier survival curve demonstrates a decreasing risk of KO through time. **Conclusion:** Our study is among the first investigations of directly observed human head trauma and the first to directly link axial head rotation as a major contributing variable for whether trauma causes LOC in humans, in line with an extensive literature in animals.

Agreement Between Segmental Bioimpedance Devices, Air Displacement Plethysmography, and Dual Energy X-Ray Absorptiometry in Obese Adults

Brett S. Nickerson¹, Cherilyn N. McLester², John R. McLester, FACSM², Brian M. Kliszczewicz, FACSM². ¹Texas A&M International University, Laredo, TX. ²Kennesaw State University, Kennesaw, GA.

Email: brett.nickerson@tamiu.edu

(No relevant relationships reported)

Segmental bioimpedance analysis (BIA) has emerged as a desirable technique for assessing body composition in obese populations when more sophisticated laboratory equipment is not readily available. Nonetheless, research has yet to examine the agreement of various segmental BIA devices, air displacement plethysmography (ADP) and dual energy X-ray absorptiometry (DXA). **PURPOSE:** This study examined the agreement of segmental BIA devices, ADP and DXA for estimating body composition in obese adults. **METHODS:** Fifty obese adults (25 men and 25 women; age = 34.2 ± 11.2 years; BMI = 36.1 ± 5.3 kg/m²) had their total body fat percentage (BF%) and fat-free mass (FFM) evaluated with two segmental BIA devices, ADP, and DXA. **RESULTS:** The effect size of the mean differences for all BF% and FFM comparisons (segmental BIA vs. ADP, segmental BIA vs. DXA; ADP vs. DXA) were trivial (Cohen's $d < 0.20$). The standard error of estimate (SEE), total error (TE), and 95% limits of agreement (LOAs) were similar for the segmental BIA devices (SEE < 2.26% and 2.35 kg; TE < 2.58% and 2.66 kg; 95% LOAs < ±4.94% and 4.86 kg) and ADP (SEE = 2.39% and 2.57 kg; TE = 2.34% and 2.56 kg; 95% LOAs = 4.63%

and 5.06 kg) when compared to DXA. Validity statistics were slightly higher, but considered acceptable, when comparing the segmental BIA devices against ADP (SEE < 3.37% and 3.63 kg; TE < 3.44% and 3.79 kg; 95% LOAs < ±5.82% and 7.19 kg). **CONCLUSION:** The main findings from the present study revealed the segmental BIA devices are interchangeable with ADP and DXA when utilized on obese adults. ADP and DXA also had good agreement with each other. These results suggest that clinicians and practitioners can employ segmental BIA devices in obese adults when the ADP or DXA are not available.

The Effects of Swimming Training on Arterial Stiffness, Muscular Strength and Cardiorespiratory Endurance in Postmenopausal Women with Stage 2 Hypertension
 Steven Scott¹, Alexei Wong², Yi-Sub Kwak³, Won-Mok Son⁴, Jung-jun Park⁴, Elizabeth Pekas¹, Song-Young Park¹. ¹University of Nebraska at Omaha, Omaha, NE. ²Marymount University, Arlington, VA. ³Dong-eui University, Busan, Korea, Republic of. ⁴Pusan National University, Busan, Korea, Republic of.

Purpose: Aging is associated with progressive decreases in arterial health and function as well as overall fitness. It is crucial to prevent or reduce the negative effects of aging on vasculature and fitness components by implementing appropriate lifestyle interventions, such as exercise training. We examined the effects of a swimming (SWM) regimen on arterial stiffness (pulse wave velocity, PWV), blood pressure (BP), wave reflection (AIx), muscle strength and aerobic capacity in postmenopausal women with stage 2 hypertension. **Methods:** Using a parallel experimental design, participants were randomly assigned to either a SWM (n=52) or non-exercising control group (n=48) for 20 weeks. Participants in the SWM group trained 3-4 days/week, progressing in duration from 25 to 45 min. Participants' carotid to radial PWV (crPWV), BP, AIx, muscular strength and cardiorespiratory capacity were measured at baseline and after 20 weeks of their assigned intervention. **Results:** There was a significant group x time interaction (P<0.05) for crPWV, AIx, and systolic and diastolic BP, which significantly decreased (P<0.05); and strength and cardiorespiratory capacity, which significantly increased (P<0.05) following SWM compared to no changes in control. **Conclusion:** SWM led to reductions in arterial stiffness, wave reflection and BP while increasing strength and aerobic capacity in postmenopausal women with stage 2 hypertension. SWM may be an effective intervention in the prevention and treatment of age-related vascular complications as well as declines in muscle strength and cardiorespiratory capacity. <!--EndFragment-->

Hypertension is one of the cardiovascular diseases responsible for more deaths worldwide. Although isometric exercise (IE) has been showing promising results to treat hypertension, the physiological mechanisms underneath blood pressure (BP) responses are still warranted, being oxidative stress (OS) and nitric oxide (NO), major factors involved in acute and chronic pathophysiology of this disease. **PURPOSE:** The aim of this study was to investigate the OS, NO responses to IE in normotensive (NTG) and hypertensive (HTG) individuals. **METHODS:** After body composition and muscular strength assessment, twenty-four adult men (14 hypertensive and 10 normotensive). Individuals were submitted to 3 sessions of IE in Bench and Leg press exercises. The sessions in each exercise consisted in: i) assessment of maximal voluntary isometric contraction (MVIC); ii) 8 sets x 1' contraction at 30% MVIC with 2' rest pause; iii) control session (CS). Blood samples were collected at rest, immediately after the session and 60-min post-exercise. NO- were obtained through the Griess reaction method. OS parameters (uric acid, TBARS, TEAC, GSH, catalase and SOD) were analyzed using commercial kits. For the statistical analysis, a repeated-measures ANOVA with Bonferroni post-hoc was used. **RESULTS:** A significant increase in plasmatic NO-bioavailability immediately after the IE session was observed only in HTG ($\Delta = 23.9 \pm 8.45 \mu\text{L}$). Regarding OS parameters, TBARS presented a significant reduction after the IE session in both groups in comparison to CS ($\Delta = -0.94 \pm 0.9$ and $-0.63 \pm 0.53 \text{ nmol/L}$) for HTG and NTG respectively. Catalase increased in both groups against CS ($\Delta = 48.66 \pm 13.7$ and $36.92 \pm 19.18 \text{ U} \cdot \text{mL}^{-1}$ for HTG and NTG respectively). Whereas no statistical differences were identified for uric

acid, TEAC, GSH and SOD analysis within- or between-group. **CONCLUSIONS:** In conclusion, 8 minutes of isometric exercise with large muscle mass elicits an elevated pro-oxidant activity, increased antioxidant reaction, leading to a greater NO bioavailability in hypertensive individuals.

 (No relevant relationships reported)

PURPOSE: To examine body composition (BC) changes by dual energy x-ray absorptiometry (DXA) after cardiac rehabilitation (CR) participation. We hypothesized that CR would improve multiple components of body composition. **METHODS:** The Mayo Clinic CR database was reviewed; 296 had DXA at baseline and after CR completion from January 2014 to August 2018. DXA and relevant clinical metrics (e.g. age, sex, height, weight, hip and waist circumference (WC), and clinical diagnosis) were extracted from the medical record. Referral diagnoses included myocardial infarction (29%), coronary artery disease (4%), percutaneous coronary intervention (23%), coronary artery bypass grafting (14%), heart valve surgery (14%), heart transplant (4%), heart failure (6%), and other (6%). Data are presented as mean±SD and analyzed with ANOVA, chi-square and fisher's exact test when appropriate.

RESULTS: There was no difference in age between groups at enrollment. As expected, men weighed more, had more lean mass, were taller, had larger WC, and higher waist to hip ratio (WHR; p<0.05) at baseline. Women had higher body fat % and gynoid fat mass % (p<0.05). After CR, weight did not change significantly in men or women; however, BC changed significantly as presented in the table. Specifically, in men compared to women, CR resulted in greater reductions in fat mass and body fat %, with greater increases in lean mass (p<0.05). Men also demonstrated greater reductions in android fat mass % and WHR (p<0.05). Conversely, women had a significant reduction in gynoid fat mass % but no change in android fat mass % or WHR (p<0.05). Fat mass index was reduced in both groups and significantly between the sexes (p<0.05).

CONCLUSIONS: CR participation significantly reduced BC in men and women; however, men demonstrate greater reductions compared to women. Additionally, the distribution of BC improvements appears to differ between sexes suggesting sex specific CR programming may be appropriate.

A Novel 4 Pillar® Model Of Exercise Delivery Reduces Cardiovascular Risk Factors In Cardiac Patients

Yvonne Rumble, Matthew Thompson, Sam Olden, Gavinder Kandola, Ivor Cradock. *CP+R, London, United Kingdom.*
 Email: yvonne.rumble@cpandr.co.uk
 (No relevant relationships reported)

PURPOSE: Cardiovascular disease (CVD) accounts for an estimated 31% of deaths worldwide (WHO, 2017). Current strategies to manage CVD include medical therapy and invasive procedures, with cardiac rehabilitation (CR) offered as a secondary treatment. According to the UK National Audit of CR (2017) only 51% of referred patients commence a programme, which lasts a median of 9 weeks. In addition, the current outcomes from CR are underwhelming and research has found it is not yet effective at reducing the risk of MI or revascularization and all-cause mortality (Cochrane review, 2016). The current study investigates the effectiveness of an alternative approach to CR using a novel 4 Pillar model of exercise delivery and nutritional guidance, on reducing key modifiable risk factors in a cardiac population. **METHODS:** 120 patients (4 MI, 24 MI + PCI, 7 MI + CABG, 15 CABG, 48 PCI, 27 Valve Surgery) (109M, 11F), aged 56.5 ± 10.8 years, completed a 12-week cardiac rehabilitation programme at CP+R. This involved twice-weekly supervised resistance sessions reaching overload, twice-weekly aerobic training within a prescribed heart rate zone, on-going step-count monitoring and nutritional guidance. The programme was led by a clinical exercise specialist and overseen by a clinical nurse. All patients underwent pre and post physiological and psychological measures including systolic (SBP) and diastolic (DBP) blood pressure, body mass (BM) body fat percentage (BF%), cardio-respiratory fitness (predicted VO_{2peak}), hospital anxiety and depression (HAD) and exercise confidence (Ex Con). **RESULTS:** 95% of patients completed the full 12 weeks CR programme. There were significant reductions in SBP 8.6 ± 12.6 mmHg, DBP 6.3 ± 9.0 mmHg, BM 2.3 ± 3.2 kg and BF% 1.2 ± 2.3 %. A significant increase in predicted VO_{2peak} 5.5 ± 7.4 ml/kg/min and significant improvements in HAD 16.6 ± 56.1 % and Ex Con 17.0 ± 16.4 % (all P < 0.01). **CONCLUSIONS:** This novel exercise and nutrition programme incorporating a 4 Pillar model significantly reduced SBP, DBP, BM, BF and increased predicted VO_{2peak} in cardiac patients. This could provide a blueprint for an achievable and effective application of lifestyle intervention following primary care that should be routinely offered to individuals to reduce further risk and improve quality of life.

The Inorganic Nitrate For eXercise In Heart Failure (INIX-HF) Trial: Rationale, Design, And Preliminary Data

Andrew R. Coggan, FACSM¹, Derrick Gray¹, Susan B. Racette², W. Todd Cade², Dakkota Thies², Kenneth B. Schechtman², Linda R. Peterson². ¹Indiana University Purdue University Indianapolis, Indianapolis, IN. ²Washington University in St. Louis, St. Louis, MO.

 (No relevant relationships reported)

Peak oxygen uptake (VO_{2peak}) and muscle contractile function are both impaired in patients with heart failure with reduced ejection fraction (HFrEF), with these deficits significantly contributing to the diminished quality of life and possibly even early mortality of such individuals. In previous pilot studies, however, we have reported that these deleterious changes can be ameliorated by acute ingestion of nitrate (NO₃⁻), which *in vivo* can be converted to nitric oxide (NO) via the enterosalivary NO₃⁻ → nitrite (NO₂⁻) → NO pathway.

PURPOSE Based on these studies, the INIX-HF trial is a proposed multi-center (i.e., 8 site), randomized control trial of the effects of acute (i.e., single dose) and chronic (i.e., 2 wk) dietary NO₃⁻ supplementation (in the form of KNO₃) on VO_{2peak} and muscle contractility in patients with HFrEF. We are presently performing the work that is necessary and sufficient to set up this trial, including determining the optimal dose of KNO₃ to utilize.

METHODS Using a double-blind, crossover design, six patients with HFrEF (5 men, 1 woman; age = 49 ± 4 y; EF = 32 ± 3%) were studied 2-3 h after acute ingestion of either 10 or 20 mmol KNO₃. On each occasion, VO_{2peak} was measured during an incremental treadmill exercise test (modified Naughton protocol) and muscle function was determined using isokinetic dynamometry.

RESULTS The increase in plasma NO₃⁻ was greater following ingestion of 20 vs. 10 mmol KNO₃ (Δ = 430 ± 51 vs. 218 ± 19 μmol/L; P = 0.002). However, plasma NO₃⁻ increased to a similar degree in both trials (Δ = 0.219 ± 0.078 vs. 0.169 ± 0.044 μmol/L; P = 0.67). Presumably as a result, VO_{2peak} did not differ between treatments (i.e., 18.0 ± 1.5 vs. 17.7 ± 1.3 mL min⁻¹ kg⁻¹; P = 0.74). There was also no difference in maximal knee extensor power (4.52 ± 0.56 vs. 4.25 ± 0.59 W/kg; P = 0.69) across trials. 27% of subjects experienced moderate-to-severe nausea and/or vomited after ingesting the higher dose KNO₃, vs. only 9% after the lower dose.

CONCLUSION There was no difference in the efficacy of 10 vs. 20 mmol KNO₃ in influencing VO_{2peak} or muscle power in patients with HFrEF. The higher dose, however, was associated with a greater frequency of gastrointestinal distress. Based on these preliminary data, it appears that 10 mmol KNO₃ is the preferred dose for a larger, multicenter trial.

Body Mass Index and Exercise Performance in Patients with Single Ventricle Fontan Circulation

Sydney Bouressa, Michael Danduran. *Marquette University, Milwaukee, WI.*
 Email: sydney.bouressa@marquette.edu
 (No relevant relationships reported)

Single ventricle physiology is the most devastating of the congenital heart diseases affecting nearly 5000 children annually. Staged surgical palliation that concludes with the Fontan surgery results in elimination of the pulmonary pump, increased venous pressures, and a decreased exercise tolerance. Body mass index (BMI) is associated with exercise performance in the healthy populations but its utility as a correlate to exercise performance in the Fontan population has not been explored. **PURPOSE:** Assess the utility of BMI as a predictor of exercise performance in Fontan patients. **METHODS:** A review of Fontan patients below 20 years of age who performed exercise testing at the Children's Hospital of Wisconsin was performed (n=397). Age, gender, BMI, as well as exercise time (EXTM), VO₂ and HR were assessed. Maximal efforts were verified by a respiratory quotient (RQ) greater than 1.05. Mean and standard deviation were obtained for BMI at each age category. Correlations between BMI and EXTM were determined. **RESULTS:** Fontan patient's BMIs fall on average near the 50th percentile, consistent with normal growth across early lifespan. BMI did not predict EXTM in this patient population. Sub-analysis of patients that fell below the 5th or above the 85th percentile resulted in no prediction of EXTM. **CONCLUSION:** The determinants of exercise limitations of patients having undergone Fontan palliation are multi-factorial and complex. Our findings suggest that BMI may not be a sensitive marker in patients with complex congenital heart disease. The inability of BMI as a singular measure may not account for the diminished muscle size or function that may result from chronic states of hypoxia or altered cardiovascular physiology resulting in decreased EXTM. These results warrant further investigation into potential peripheral factors of exercise limitations not yet identified in this population of patients.

 Email: pkoutakis@fsu.edu

(No relevant relationships reported)

Patients with peripheral artery disease (PAD) develop a myopathy in their ischemic limbs which is characterized by myofiber degeneration, mitochondrial dysfunction and impaired leg function. Degenerated myofibers have cytoskeletal abnormalities the best described of which is a disorganized accumulation of desmin filaments.

Purpose: We hypothesized that the levels and organization of desmin in the myofibers of the gastrocnemius of PAD patients improve after revascularization and correlate with increases in mitochondrial respiration and calf muscle strength. **Methods:** Gastrocnemius biopsies were collected from 32 PAD patients (61.6 ± 5.2 yrs, 31.0 ± 9.0 kg/m²) before and six months after revascularization. Accumulation and organization of desmin protein in myofibers were determined by quantitative fluorescence microscopy and desmin gene transcripts were quantified by rtPCR of RNA in biopsy homogenates. The effects of revascularization on these parameters and their association with ischemic window, mitochondrial function determined by respirometry, and calf muscle strength determined by isokinetic testing with the Biodex system were evaluated. Data were analyzed in SPSS 21 using paired-t test and Pearson correlation with a level of significance at p<0.05. **Results:** Revascularization reduced the abnormal accumulation of disorganized desmin protein and gene transcripts in the PAD gastrocnemius. The ischemic window (Δ =529 mm Hg x min; p<0.05), myofiber morphology (Δ =657 μ m²; p<0.05), mitochondrial respiration (Δ ETC I=12.3 ± 22 and ETC II=21.6 ± 33 O₂ · min⁻¹ · unit⁻¹ · CS activity⁻¹; p<0.05) and calf muscle strength (Δ =8.33 ± 19 N*min) were significantly improved after revascularization. After revascularization, the decreased desmin expression was associated with a more structured appearance of the protein, suggesting a return to the normally filamentous structure. These changes in desmin correlated with improved mitochondrial function (r=-0.406; p<0.05) and increased calf muscle strength (r=-0.313; p<0.05). **Conclusions:** Revascularization operations improve the levels and organization of the desmin filaments in the gastrocnemius of patients with PAD and these changes correlate with improved mitochondrial function and calf muscle strength.

Metabolomic Profiling of Amino Acid Metabolism in Peripheral Artery Disease Patients

Ahmed Ismael¹, Marco E. Franco², Ramon Lavado², Panagiotis Koutakis¹. ¹Florida State University, Tallahassee, FL. ²Baylor University, Waco, TX. (Sponsor: Lynn Pantan, FACSM)
 Email: ai18@my.fsu.edu

(No relevant relationships reported)

The spectrum of symptoms of peripheral artery disease (PAD) is classified according to the Fontaine classification. Patients presenting with intermittent claudication are classified in Stage II, and in the latest stages of PAD referred to as critical limb ischemia (CLI), patients exhibit rest pain with or without ulcers and gangrene. Although systemic risk factors for PAD have been established, an omics approach may represent an innovative method to comprehensively investigate the molecular basis of PAD pathogenesis. **Purpose:** To determine the metabolomics profile of amino

acid metabolism of patients with PAD and identify changes as the disease progresses.

METHODS: Blood samples were acquired from 24 Stage II PAD patients (PAD-II: 62.1±6.9yrs), 24 CLI patients (CLI: 68.2±9.9yrs), and 26 healthy controls (HC: 63.2±7.4yrs). For targeted metabolomic analysis to identify and quantify amino acid metabolite concentrations, serum was extracted, and samples were measured using the AbsoluteIDQ p400 kit, and an Orbitrap mass spectrometer coupled to an UltiMate 3000 Rapid Separation Quaternary high performance liquid chromatography (HPLC) system. To examine differences between groups, one-way ANOVA was carried out, followed by Tukey's test for post-hoc analysis. **RESULTS:** Relative to PAD-II and HC, CLI showed significantly lower content of alanine (HC: 296.5 ± 109.2 μ M, PAD-II: 361.2 ± 143.0 μ M, CLI: 247.4 ± 84.4 μ M; p=0.004) arginine (HC: 106.8 ± 32.5 μ M, PAD-II: 114.7 ± 20.3 μ M, CLI: 94.2 ± 25.5 μ M; p=0.033), glutamine (HC: 569.7 ± 82.8 μ M, PAD-II: 568.3 ± 93.2 μ M, CLI: 505.3 ± 118.9 μ M; p=0.043), histidine (HC: 75.7 ± 10.8 μ M, PAD-II: 77.2 ± 12.6 μ M, CLI: 54.6 ± 16.4 μ M; p<0.001), ornithine (HC: 68.5 ± 15.7 μ M, PAD-II: 61.3 ± 17.0 μ M, CLI: 54.6 ± 26.1 μ M; p=0.065), proline (HC: 202.3 ± 54.2 μ M, PAD-II: 220.3 ± 63.7 μ M, CLI: 169.3 ± 54.5 μ M; p=0.011), tryptophan (HC: 50.9 ± 13.9 μ M, PAD-II: 53.8 ± 17.9 μ M, CLI: 32.7 ± 10.9 μ M; p<0.001), and tyrosine (HC: 62.7 ± 15.6 μ M, PAD-II: 58.3 ± 18.2 μ M, CLI: 47.2 ± 14.8 μ M; p=0.004). **CONCLUSION:** The metabolic fingerprint of amino acid metabolites of CLI is considerably different from PAD-II and HC. Perturbations in amino acid metabolism may contribute to CLI pathology and may serve as a diagnostic/prognostic tool to alter the management of CLI.

(No relevant relationships reported)

INTRODUCTION: Bariatric surgery effectively reduces weight and some comorbidities in obese patients; however, surgery incurs in severe muscle waste and functionality impairments, warranting the investigation of therapeutic strategies to mitigate these outcomes. **PURPOSE:** To examine the effects of exercise training on vastus lateralis fiber cross-sectional area (fCSA), strength and functionality in women undergoing bariatric surgery. **METHODS:** Sixty-two obese women were randomly allocated to receive either bariatric surgery (RYGB: BMI=47±8) or bariatric surgery plus exercise training (RYGB+ET: BMI=49±7). Patients were assessed at baseline (PRE), three (POST3), and nine months (POST9) after surgery for fCSA, lower- and upper-limb 1RM, and timed-up-and-go (TUG) and timed-stands (TST) test. The 6-month exercise intervention started at POST3 for RYGB+ET, while RYGB followed standard care. **RESULTS:** Type I and II fCSA was decreased in both RYGB (-21 and -27%) and RYGB+ET (-22 and -27%) at POST3 (all p<0.0001). RYGB+ET increased types I and II fCSA from POST3 to POST9 (23%, p=0.0053 and 32%, p=0.0055), whereas no changes were observed in RYGB (4% and 1%, respectively; both p>0.05). Importantly, type I and II fCSA were significantly greater in RYGB+ET than in RYGB at POST9 (both p=0.0001). Lower- (RYGB=-32% and RYGB+ET=-24%, both p<0.0001) and upper-limb 1RM (RYGB=-26% and RYGB+ET=-29%, both p<0.0001) were reduced at POST3. Exercise increased lower- and upper-limb strength (49%, p<0.0001 and 11%, p=0.0024, respectively). In contrast, no differences were observed in RYGB (1% and 4%, respectively; both p>0.05). Additionally, lower-limb 1RM was significantly greater in RYGB+ET than in RYGB at POST9 (p<0.0001). No effects of surgery were observed in either TUG or TST (all p>0.05). RYGB+ET increased TUG and TST scores from POST3 to POST9 (11%, p<0.0001 and 26%, p<0.0001, respectively), while no significant differences were observed in RYGB (2% and 3%, respectively, both p>0.05). TST were significantly greater in RYGB+ET than in RYGB at POST9 (p<0.0001). **CONCLUSIONS:** Our data suggest that a 6-month exercise training program is effective in counteracting the loss of muscle mass, strength and functionality that occur after bariatric surgery. Clinicaltrials.gov: NCT02441361

The Role of Physical Activity on Abdominal Fat Patterning in Pre and Post-Menopausal Women
 Emily W. Flanagan, Arlette C. Perry, FACSM, Wesley N. Smith.
University of Miami, Coral Gables, FL.
 Email: e.white6@umiami.edu
(No relevant relationships reported)

Changes in the hormonal milieu with menopause are associated with increases in both total body fat and abdominal fat storage (AFS), both of which are related to an adverse metabolic profile and increased cardiovascular disease risk. Physical activity (PA) is a common intervention to ameliorate adipose fat accumulation during all life-stages.

PURPOSE: To examine differences in the protective effect of physical activity on total adiposity and fat patterning in pre and post-menopausal women.

METHODS: A total of 1018 women (pre-menopausal 425; post-menopausal 593) participated in the study. Each patient completed anthropometric measurements and a physical activity survey using the HealthSnap platform, which encompasses a streamlined health evaluation with lifestyle recommendations. Patients were stratified by age to predict menopausal status (pre-menopausal <35 yrs; post-menopausal >45 yrs). BMI was computed as kg/m² and AFS was determined using a waist-to-hip ratio above 0.85. PA was defined as MET-minutes equivalent to >75 minutes of vigorous activity, or >150 minutes of moderate activity, per week.

RESULTS: As expected, in both groups of pre and post-menopausal women, a significant association was observed between PA and BMI (RR=1.8, CI: 1.24-2.70 and RR = 2.18, CI: 1.67-2.80; p<0.001, respectively). In contrast, PA was only associated with AFS patterning in post-menopausal (RR=1.45, CI: 1.24-1.70; p<0.001) but not pre-menopausal women (RR= 1.034, CI: 0.83-1.30; p=0.74).

CONCLUSIONS: PA is protective against BMI in both pre and post-menopausal women. However, PA appears to be protective against the development of AFS in post-menopausal women, but not pre-menopausal women. To our knowledge, this is the first study to show a dichotomous relationship between PA and an AFS patterns between two life stages in women. These findings suggest that exercise is an effective therapeutic intervention to prevent or reduce abdominal fat deposition and its associated health consequences. These adverse health risks associated with endocrine changes in post-menopausal women may be ameliorated by meeting weekly PA recommendations.

Obesity Further Impairs Neuromuscular and Functional Performance in Older Women
 Ryan M. Miller, Eduardo D.S. Freitas, Aaron D. Heishman, Japneet Kaur, Brady S. Brown, Michael G. Bembem, FACSM.
University of Oklahoma, Norman, OK. (Sponsor: Michael G Bembem, FACSM)
(No relevant relationships reported)

INTRODUCTION: Age-related changes in body composition consists of reductions in total body lean body mass as well as a concomitant increase in total body fat through the 8th decade of life. Accompanied with these alterations in body composition is the gradual reduction in muscular strength. Obesity has been suggested to further impair neuromuscular performance; however, previous data often employs the body mass index (BMI) approach to classify obesity, whereas waist circumference (WC) may be a better indicator considering the redistribution of adiposity and spinal compression associated with natural aging. **PURPOSE:** The purpose of this study was to examine the differences in grip strength (HGS), jump power (JPOW), bench press one-repetition maximum (BP1RM), timed up and to (TUG) speed, and Berg Balance testing (BBT), in women between the ages of 50 to 70 years classified as having normal WC (≤89cm) or elevated WC (>90cm). Women with normal WC were considered non-obese and those with elevated WC were classified as obese. **METHODS:** Forty-one older women (non-obese: n = 21, obese: n = 19) completed two visits which consisted of visit 1 including consenting, questionnaires, and familiarization trials and visit 2 including body composition analysis via dual-energy X-ray absorptiometry (DXA) and performed BP1RM, VJ, JPOW, HGS, TUG, and BBT. Independent samples t-tests were used to determine mean differences between non-obese and obese women and Pearson's correlation coefficients examined the relationships between WC and performance measures. **RESULTS:** According to the physical activity scale for the elderly questionnaire, 38/41 women met the recommended amount of physical activity when stratified by age and sex. With the exception of the BBT (p=0.35), women classified as non-obese performed significantly better for the BP1RM (p=0.04, ES: 0.25), VJ (p<0.01, ES: 0.71), JPOW (p=0.02, ES: 0.54), HGS (p<0.001, ES: 1.3), and TUG (p<0.001, ES: 0.94). Additionally, WC was inversely, but significantly correlated with HGS (r = -0.51, p=0.01) and TUG (r = -0.48, p=0.01) values. **CONCLUSION:** These data suggest that neuromuscular and functional measures may be further reduced when accompanied with obesity in older women. Remarkably, these differences were still observed with no differences in physical activity.

Limiting Factors In Cycling And Knee Extension Exercise In Obese Subjects
 Filippo Vaccari¹, Mirco Floreani¹, Alessandro Sartorio², Stefano Lazzar¹. ¹Udine University, Udine, Italy. ²Istituto Auxologico Italiano, Verbania, Italy.
 Email: filippo.vaccari@live.com
(No relevant relationships reported)

In whole body exercise like cycling, maximal oxygen uptake is mainly limited by cardiac output rather than the oxygen extraction and utilization capacity of the muscle¹. When the exercise is performed with small muscle mass (like in single leg knee extension exercise), the muscle oxygen uptake should be not limited by central circulation, but from peripheral factors like peak muscle perfusion, oxygen diffusion or mitochondrial respiratory capacity². Obese patients (OB) compared with normal weight people (CTRL) have similar peak oxygen consumption (V'O₂ Peak), lower V'O₂ Peak for 1 Kg of fat free mass and lower peak work rate in Cycling Exercise³. On the other hands Obese show greater isometric force and hypertrophy³. **PURPOSE:** In the present study, we investigated if maximal oxygen uptake is mainly limited by cardiac output rather than the capacity to oxygen extraction and utilization of the muscle in OB and CTRL subjects, during maximal incremental test on Cycle Ergometer (CE) and on single leg Knee Extension (KE) ergometer. **METHODS:** 15 OB (age 25±7 y; BMI 43±7 kg/m²) and 13 CTRL subjects (age 27±7 y; BMI 22±3 kg/m²) participated in this study. V'O₂ and Cardiac Output (CO) were measured during CE and KE. Maximal voluntary contraction (MVCs) of knee extensor muscle were performed before and immediately after the two incremental tests. **RESULTS:** Peak V'O₂ (mL min⁻¹) and CO (mL min⁻¹) were significantly higher (p<0.05) in CE than KE with no differences between OB and CTRL (V'O₂ CE: OB 2.68±0.68, CTRL 3.04±0.65; V'O₂ KE: OB 1.36±0.51, CTRL 1.15±0.26) (CO CE: OB 20.81±5.42, CTRL 20.61±4.04; CO KE: OB 15.97±5.89, CTRL 12.00±2.45). Maximal work rate (W) was lower in OB than CTRL (191±38 vs 226±39, p<0.05) in CE but similar between two groups in KE (62±13 vs 61±14, p>0.05) The MVC reduction after CE was lower in OB compared with CTRL (14±13 vs 26%±16%, p<0.05), while in KE was the same (32±11 vs 32%±18%). **CONCLUSIONS:** The limiting factor during KE should reside in the muscle for both groups, instead the performance during CE might be limited due to central mechanisms. This is particularly true for OB where cardio respiratory system might have played a role in determining the cessation of CE as it can be evinced by a lower MVC reduction at exhaustion compared to the one produced after KE. 12-week of Tai Chi Training Reduces Visceral Fat in Centrally Obese Older Adults
 Angus, P. Yu¹, Doris S. Yu², Stanley S. Hui, FACSM², Jean Woo², Parco M. Siu, FACSM¹. ¹The University of Hong Kong, Hong Kong, Hong Kong. ²The Chinese University of Hong Kong, Hong Kong, Hong Kong. (Sponsor: Dr. Parco M. Siu, FACSM)
 Email: aphyu@connect.hku.hk
(No relevant relationships reported)

Excess visceral fat is associated with metabolic abnormality and increased susceptibility to diabetes and cardiovascular diseases. It is known that visceral fat is reduced with strenuous physical exercise. However, older adults (age ≥ 50) may prefer to manage their visceral fat with alternate exercise modalities. **PURPOSE:** To examine the effectiveness of Tai Chi, a popular mind-body exercise among older adults, in the reduction of visceral fat in centrally obese older adults. **METHODS:** This randomized controlled trial was conducted from March to August, 2018. In this three-arm, single-blinded randomized controlled trial, 102 Chinese adults aged ≥50 years with central obesity (male with waist circumference (WC) ≥ 90 cm / female ≥ 80 cm) were randomly assigned to Control (n= 33; received no intervention), Fitness (n= 35; received 12-week conventional exercise intervention) or Tai Chi groups (n= 34; received 12-week Tai Chi intervention). The primary outcome was the determination of visceral fat mass by dual-energy x-ray absorptiometry at 12-week post-randomization, while the secondary endpoints were the risk factors of metabolic syndrome (i.e. WC, blood pressure, fasting blood glucose, high-density lipoprotein-cholesterol and triglyceride). Data were analyzed by Generalized linear model with baseline as covariate. Pairwise comparison was done by closed test procedure. **RESULTS:** Visceral fat was reduced by 1.6% and 4.1% in the Tai Chi and Fitness groups respectively whereas the control group manifested a 3.8% increase. A main effect of intervention was observed in visceral fat (P<0.001). The pairwise comparison shown that both the Tai Chi (P=0.001) and Fitness (P=0.022) groups exhibited lower visceral fat content compared with their control counterpart. A main effect of intervention was observed in waist circumference (P<0.013) and triglyceride (P<0.046). Pairwise comparisons showed that the waist circumference (P=0.011) and triglyceride level (P=0.043) were reduced significantly in response to Tai Chi intervention.

CONCLUSIONS: These data suggest that Tai Chi training reduces visceral fat, waist circumference and blood triglyceride.

Functional Evaluation and VO₂-kinetics in Obese Patients Before and After Sleeve Gastrectomy

Daniel Neunhaeuserer¹, Sara Ortolan¹, Alessandro Patti¹, Andrea Gasperetti¹, Francesco Savalla¹, Francesca Battista¹, Stefano Gobbo¹, Silvia Bettini², Anna Belligoli², Andrea Ermolao¹.

¹Sport and Exercise Medicine Division, Padova, Italy. ²Internal Medicine 3, Padova, Italy.

Email: daniel.neunhaeuserer@unipd.it

(No relevant relationships reported)

Sleeve gastrectomy (SG) has become an important therapeutic option for patients with severe obesity, showing a positive impact on patients' comorbidities. Even though poor cardiorespiratory function is a powerful predictor of mortality, functional evaluation has been given little attention after SG.

PURPOSE

To investigate the effects of SG on functional capacity six months after surgery, with specific analysis of peripheral oxidative muscle metabolism by determination of VO₂-kinetics.

METHODS

In this longitudinal observational study 36 patients (age 44±11 years, 78% females) with severe obesity (BMI 43.95±5.67 kg/m²) were evaluated one month before (pre-SG) and six months after SG (post-SG). A maximal cardiopulmonary exercise test was performed on treadmill with an initial 5 min constant, moderate load exercise and a subsequent incremental Bruce protocol. VO₂-kinetics during constant load exercise were analyzed by mono-exponential function. Furthermore, muscle strength was evaluated by isometric handgrip strength test. Patients' physical activity level was assessed by the Global Physical Activity Questionnaire (GPAQ).

RESULTS

As expected, a significant weight loss (-31.14±9.45 kg, p<0.001) and a reduction of waist circumference (-15.35 cm, p<0.001) were observed post-SG, associated with improved exercise time (14.48±2.5 vs 16.90±2.15 min; p<0.001) and capacity (8.38±2.5 vs 10.66±2.08 METs; p<0.001). While the VO₂peak/kg was significantly increased, a reduction of the absolute VO₂peak and Oxygen Uptake Efficiency Slope (OUES) were shown after surgery (all p<0.001). Furthermore, the time-constant Tau (τ) of the fundamental phase of VO₂-kinetics significantly worsened post-SG (37.71±12.20, vs 43.75±11.35 s; p<0.02). However, muscle strength remained unchanged in these patients (handgrip: 29.87±11.73 vs 28.91±10.83 kg; p=0.1), showing also an increased level of weekly physical activity post-SG (GPAQ, p<0.01).

CONCLUSIONS

Even though patients after SG improved functional capacity due to a significant weight loss, absolute aerobic capacity and VO₂-kinetics significantly worsened despite increased physical activity. The study findings thus suggest an impaired peripheral oxidative muscle metabolism post-SG without affecting patients' muscle strength.

Athletic Obesity and Long-Term Health

Justin B. Ethington, Utah Valley University, Orem, UT.

Email: justin.ethington@hotmail.com

(No relevant relationships reported)

PURPOSE: Obesity in athletes is closely correlated with many comorbidities such as hypertension, dyslipidemia, osteoporosis, diabetes mellitus, left ventricular hypertrophy, and lower self-esteem; all of which can lead to decreased quality of life both during an athlete's career and after. It is the objective of this systematic review to compare the long and short-term health risks associated with athletes who are clinically overweight or obese.

METHODS: Studies were obtained using online databases such as PubMed, Google Scholar, and Scopus. Search terms included obese, obesity, athletes, body composition, health risk, anthropometry, adult, American Football, rugby, professional, athletes, BMI, female, women, overweight, BF%, body image, sumo wrestling, unhealthy, left ventricular hypertrophy, health, retired, and NFL. To be included in this review, articles needed to meet a list quality assessment.

RESULTS: Active collegiate and professional level athletes, regardless of their BMI, are shown to have healthier BF% than those of comparable BMI. These findings are consistent with linemen, rugby players, and lightweight sumo wrestlers. However, when comparing football players and non-athletes of comparable BMI it was concluded that linemen had an even greater risk for developing CVD and metabolic syndrome (metsyn) than non-athletes. Little information could be found on the effects of obesity among female athletes. Retired Athletes who were obese due to the nature of their professional sport and maintained obesity status were more likely to have

sustained cognitive impairment during their career and cardiovascular diseases (CVD). Furthermore, a significant increase in mortality due to CVD has been directly linked to athletes who retire from a career in professional football.

CONCLUSIONS: In conclusion, athletes that compete at a high level generally have a healthier body fat percentage (BF%) and cholesterol vitals than comparable non-athletic populations. However, due to their excessive amount of muscle mass, these athletes are susceptible to high BP and other cardiovascular risks putting them at greater risk for LVH. This is consistent with observations that athletes who maintain high BMI after their career will develop and sustain cardiovascular-related diseases and other severe health risks.

Mechanical Assistance During Unloaded Pedaling Improves the Dynamic Range of the Metabolic Response in Obesity

Tolulope Popoola¹, William Stringer¹, Tomohiko Kisaka², Kathy Sietsema¹.

¹Los Angeles Biomedical Institute (LABIOMED) at Harbor-UCLA Medical Center, Torrance, CA. ²Hiroshima University, Hiroshima, Japan. (Sponsor: Harry Rossiter, PhD, FACSM)

Email: teepopoola@yahoo.com

Reported Relationships: T. Popoola: Industry contracted research; MITSUBISHI ELECTRIC ENGINEERING Co.,LTD..

PURPOSE: Obese individuals have a greater oxygen uptake (VO₂) than lean individuals for a given work rate during cycling exercise due to higher resting metabolic rate and metabolic cost from lifting heavier legs against gravity. This can result in the majority of the total increase in VO₂ occurring early in the exercise test, resulting in short test duration and obscuring the gas exchange details. We hypothesized that mechanical assistance of pedaling early in exercise could reduce the initial increase in VO₂ of obese subjects, and increase the VO₂ range.

METHODS: 20 obese (O, BMI 40.2 ± 6.1 kg/m²) and 10 lean otherwise normal subjects (L, BMI 24.9 ± 2.2) were tested. Subjects performed 2 symptom-limited ramp incremental tests on a cycle ergometer capable of providing variable degrees of mechanical assistance to pedaling (Ergo-strength, Mitsubishi Electrical Engineering, Osaka, Japan). Ventilation and pulmonary gas exchange were measured breath by breath (Vyair, Yorba Linda, California). During warm up, in random order, the subjects performed either unmodified cycling (UM) or mechanical assistance (MC) to pedaling. After warm up, each subject performed a progressively increasing test to exhaustion.

RESULTS: The MC protocol resulted in a lower initial VO₂ compared to UM in 19 of 20 O subjects and 8 of 10 L subjects, with average differences of 165 +/- 125 ml/min (p < 0.00001) and 101 ml/min +/- 94 (p < 0.008) for O and L, respectively, by paired T-tests. Peak VO₂ did not differ systematically within subjects by protocols (p=NS).

| All Values L/min except DVO2/DWR: ml/min/W | VO ₂ atRest | Warm Up UM | Warm Up MC | DVO2/DWR UM | DVO2/DWR MC | Peak VO ₂ UM | Peak VO ₂ MC |
|--|------------------------|------------|------------|-------------|-------------|-------------------------|-------------------------|
| Obese | 0.352±0.07 | 0.706±0.20 | 0.541±0.17 | 10.3±1.4 | 11.2±1.1 | 2.006±0.56 | 1.974±0.56 |
| Lean | 0.290±0.05 | 0.501±0.01 | 0.400±0.08 | 9.3±1.7 | 9.64±1.5 | 2.897±0.92 | 2.267±0.66 |

CONCLUSIONS: Mechanical assisted cycling during the initial phase of an incremental exercise test was effective in modulating the initial increase in VO₂ with unloaded cycling, and increases the VO₂ testing range in obese and normal weight subjects. This may be a significant proportion of the entire response in a patient with exercise limitation, and therefore useful in exercise testing and training. Funding: MITSUBISHI ELECTRIC ENGINEERING Co.,LTD.

Using Rhythmic Auditory Stimulation to Increase Cadence in Individuals with Chronic Obstructive Pulmonary Disease**

Alison Hernandez¹, Eileen Collins², David X. Marquez, FACSM², Alana Steffen², Cynthia Fritsch², Laurretta T. Quinn², Ulf Bronas², ¹Northwestern University, Chicago, IL. ²University of Illinois at Chicago, Chicago, IL.
Email: alison.hernandez@northwestern.edu
(No relevant relationships reported)

Rhythmic Auditory Stimulation (RAS) uses the physiologic effects of auditory rhythm to facilitate movements that are inherently rhythmic, such as walking. There is a strong sensorimotor connection between the brain and the motor system while walking to rhythmic cues that occurs without cognitive learning efforts.

PURPOSE: To determine if cadence and Six-Minute Walk Distance (6MWD) are increased while walking to RAS-tempo enhanced music as compared to walking to music-without tempo enhancement (MC) or no-music (NM) in individuals with Chronic Obstructive Pulmonary Disease (COPD). **METHODS:** Three 6-Minute Walk Tests (6MWT) were completed in random order under three conditions (RAS, MC, NM). Tempo for the MC walk was matched to the patient's usual cadence, which was determined by a one-minute manual step count. Cadence was measured manually for 60-seconds between minutes 1-2, 3-4, and 5-6 for all 6MWT conditions. The tempo of the music for the RAS walk was increased 5-10 beats per minute higher than usual cadence. **RESULTS:** Twenty-five older adults (age=71±5yr) with moderate to severe COPD (47±15.0% FEV₁ % predicted), with 56±27 years of smoking were enrolled. The mean usual cadence was 103±8 steps/min in one minute. When comparing RAS to NM, cadence was consistently significant at all minute intervals 1-2 (110vs105), 3-4 (110vs107), and 5-6 (110vs107) respectively. When comparing cadence of NM to MC, and RAS to MC no consistent significant increases were found. Participants matched their cadence to the elevated tempo of the RAS music during the entire 6MWT (110 ± 12 steps). Individuals walked 12m further during the 6MWT with RAS (463 ± 72 m) when compared to NM (451 ± 81 m); t (24) =-2.63, p=.015) or MC (451 ± 80 m); t (24) =-2.26, p=.033). **CONCLUSIONS:** Best method for prescribing cadence through music tempo in individuals with COPD has not been established. Individuals walked further and were able to match and sustain elevated cadence during the RAS walking condition. This observation may support the premise that beat perception mechanisms can be neurologically entrained. RAS music may be a useful tool in pulmonary rehabilitation to increase walking distance in individuals with COPD. Supported by RR&D, Veterans Administration

**1531 Board #293 May 30 10:30 AM - 12:00 PM
Ventilatory Efficiency Among Patients With Pulmonary Hypertension With Varying Levels Of Adaptation To Exercise Training**

Zoe Morris¹, Lisa Chin², Leighton Chan², Randall Keyser, FACSM¹. ¹George Mason University, Fairfax, VA. ²National Institutes of Health, Bethesda, MD.
(No relevant relationships reported)

The 6-minute walk test (6MWT) is universally accepted as a measure of functional capacity in patients with pulmonary hypertension (PH). While aerobic exercise training (AET) has generally been shown to improve exercise tolerance and 6MWT distance in patients with PH, some patients have been observed to adapt differently to AET, with minimal or even negative changes in 6MWT distance being reported. Differences in patient characteristics and peak ventilatory efficiency to AET have not been characterized and compared in these subset of patients. **Purpose:** To determine differences in ventilatory efficiency, defined as peak ventilatory equivalents for O₂ uptake (VE/VO₂), peak ventilatory equivalents for CO₂ output (VE/VCO₂), end-tidal CO₂ (PETCO₂) and tidal volume (TV), in patients with high (HI, >42 meters), low (LI, 0-42 meters) and negative (NEG, <0 meters) change in 6MWT distance after AET. **Methods:** Subjects were 25 females (age 54±11 years; BMI 31±7 kg/m²) enrolled in the NIH Exercise Therapy for Advanced Lung Disease Trial. Participants completed 24-30 supervised treadmill walking exercise sessions, over 10 consecutive weeks, at a training intensity of 70% to 80% of heart rate reserve. The thrice-weekly sessions were 30-45 minutes in duration. A cardiopulmonary exercise test and 6MWT was completed before and after the 10-weeks of training. Ten of the 25 subjects were classified as HI (range = 47-143 meters), 11 were classified as LI (range = 4 - 37 meters) and 4 were classified as NEG (range = -17-53 meters). **Results:** After AET, peak values in VE/VO₂

(p=0.02), VE/VCO₂ (p=0.002), PETCO₂ (p=0.016) and TV (p=0.016) were improved for the HI versus NEG group. Peak values for VE/VO₂ (p=0.003) and TV (p=0.041) were improved for the LI versus NEG group. **Conclusion:** Previous studies suggest that reduced ventilatory efficiency (VE/VCO₂) is associated with a poor prognostic outcome in patients with PH. To our knowledge this is the first study to look at changes in ventilatory efficiency after AET, specifically in HI, LI and NEG subsets. Findings from this study suggest that reduced ventilatory efficiency may also contribute to reduced functional capacity in patients with PH, contributing to the etiological basis for the association between 6MWD and mortality in these patients. Funding NIH IRP [1 Z01 CL060068-05 CC].

Is The EVH Test Best For Diagnosing Exercise Induced Bronchoconstriction In Swimmers?**

Michael G. Leahy, Caitlin M. Geary, Michael S. Koehle, Donald C. McKenzie, James Brotherhood, Carli M. Peters, Andrew W. Sheel, FACSM. University of British Columbia, Vancouver, BC, Canada. (Sponsor: Dr. Andrew William Sheel, FACSM)
Email: mick.leahy@ubc.ca
(No relevant relationships reported)

Competitive swimmers have high rates of exercise induced bronchoconstriction (EIB), which may be associated with repeated exposure to chlorinated pool water. The eucapnic voluntary hyperpnea (EVH) test is often used in a laboratory setting to provoke a reduction in lung function associated with EIB. However, swimmers experience EIB symptoms in warm, humid and chlorinated environments. The relationship between EVH testing environment and the development of EIB from swim exercise is unclear.

PURPOSE: To compare the provoking effects of inspired air and high-intensity exercise in inducing EIB in swimmers to laboratory-based EVH methods. **METHODS:** 15 collegiate swimmers (n=5 male, n=10 female; 21±2 years) completed three days of testing in random order. On day one, subjects performed an EVH test in a laboratory (EVH-L). On a separate day, swimmers performed a modified EVH test, while breathing chlorinated pool air (EVH-Cl). On a third day subjects completed a swimming challenge, performing consecutive 200 and 400 m freestyle efforts at 85 % of their season's best time (Average achieved 200 and 400 m time; 2:18.52±7.79 and 4:55.22±20.38, respectively) and age predicted heart rate maximum. Lung function was measured at baseline, as well as 3, 5, 10, 15, and 20 minutes following EVH testing and swim exercise. **RESULTS:** Greatest achieved fall index of forced expired volume in one second (FEV₁) was significantly different between all three methods (p<0.05). EVH-L elicited a -9.7±6.4 % fall compared to the EVH-Cl test, -6.6±9.2 % (p>0.05) and swim effort, -3.0±7.5 % (p<0.05). A greater Pearson's correlation in FEV₁ fall index between EVH-L vs. EVH-Cl (r=0.78, p<0.05) was seen compared to EVH-L vs. Swimming (r=0.20, p>0.05) and EVH-Cl vs. Swimming (r=0.50, p>0.05). A greater reduction in forced expired flow between 25 and 75 % lung volume (FEF₂₅₋₇₅) was induced by the EVH-L (-16.6±8.7 %) compared to the EVH-Cl (-8.2±14.9 %) (p>0.05) and swimming test (-1.3±15.6 %) (p<0.05). **CONCLUSION:** The EVH-L elicits a greater bronchoconstrictive response, compared to EVH-Cl and swimming. There is little relationship in reduction of lung function between the EVH-L test and swimming.

Red Blood Cell Deformability is an Independent Predictor of Exertional Dyspnea in Deployed Veterans**

Duncan S. Ndirangu, Michael R. Condon, Jacquelyn C. Klein-Adams, Thomas Alexander, Steven D. Greer, Michael J. Falvo. Department of Veterans Affairs New Jersey Health Care System, East Orange, NJ.
Email: Duncan.ndirangu@va.gov
(No relevant relationships reported)

PURPOSE: Respiratory symptoms on exertion that are disproportionate to cardiopulmonary function represent a challenging clinical scenario that has been increasing in frequency among Iraq and Afghanistan veterans following their deployment. Among their exposures were burning trash, dust, sand, and air pollution. We hypothesized that impairment in oxygen delivery, due to impaired red blood cell (RBC) deformability, may contribute to reports of dyspnea in this population.

METHODS: We recruited 18 symptomatic Iraq and Afghanistan veterans (34.1±7.0 yrs; 2 female) and 13 asymptomatic controls (n = 13; 34.1±8.9 yrs; 3 female) to participate in this study. All participants completed spirometry and maximal cardiopulmonary exercise testing. Blood samples were obtained before and immediately post-exercise for the determination of RBC deformability, calculated as cell deformation at infinite stress (EI_{MAX}), by laser diffraction analysis using an ektacytometer. Dyspnea was assessed at

peak exercise via the Borg breathlessness scale. We examined the association between EI_{MAX} (rest and peak exercise) and peak dyspnea, adjusting for age, body mass index, smoking and airway obstruction (FEV_1/FVC).

RESULTS:

Demographics were similar between groups, but spirometry was reduced in veterans (veterans vs. controls; FEV_1 : 95.2 ± 18.3 vs. $114.3 \pm 14.7\%$ predicted; FVC : 101.0 ± 13.6 vs. $116.0 \pm 13.3\%$ predicted; $p < 0.01$, Hedges' $g = 1.11 - 1.17$). Peak exercise capacity was similar (VO_2/kg : 34.9 ± 8.9 vs. 36.1 ± 10.5 ml·kg⁻¹·min⁻¹), but veterans endorsed greater dyspnea (5.6 ± 1.8 vs. 3.6 ± 1.0 Borg units; $p = 0.001$, $g = 1.32$). EI_{MAX} was similar at rest (0.59 ± 0.04 vs. 0.57 ± 0.02 ; $p = 0.08$, $g = 0.67$), but not at peak exercise (0.59 ± 0.04 vs. 0.56 ± 0.03 , $p = 0.01$, $g = 0.83$). In our adjusted model, larger EI_{MAX} at rest ($\beta = 22.8$, 95% CI 4.7, 40.9, $p = 0.016$) and immediately post-exercise ($\beta = 19.2$, 95% CI 3.1, 35.3, $p = 0.016$) were associated with greater dyspnea at peak exercise.

CONCLUSION:

In our sample, increased RBC deformability measured at rest and immediately post-exercise was independently associated with exertional dyspnea. Future studies are necessary to confirm these findings and investigate mechanisms of altered RBC rheology in the contexts of dyspnea.

1534 Board #296 May 30 10:30 AM - 12:00 PM Respiratory Resistance And Reactance (FOT) Classifications In Chronic Obstructive Pulmonary Disease And Healthy Control Patients.

Jesse Schwartz, Courtney Wheatley, Bruce Johnson. *Mayo Clinic, Scottsdale, AZ.*

(No relevant relationships reported)

Forced oscillation technique (FOT) is a method of measuring lung obstruction of central airways (resistance, Rrs) and elastic properties/distal airway ventilation (reactance, Xrs), which is different from spirometry since it is performed during tidal breathing, utilizing various sound frequencies (5, 11, and 19 Hz) to separate out regions of the lungs and isolates breathing cycles (inspiration and expiration). **PURPOSE:** To evaluate FOT metrics of lung mechanics and obstruction within a chronic obstructive pulmonary disease (COPD) population based upon severity (mild [MLD], moderate [MOD], and severe [SEV]). **METHODS:** Seventeen COPD, and fourteen healthy (H) patients (age: 69.5 ± 5.8 vs. 49.3 ± 17.6 yr.*; height: 169.9 ± 11.3 vs. 163.7 ± 18.1 cm; weight: 77.8 ± 18.8 vs. 83.3 ± 32.4 kg, COPD vs. H respectively, * $p < 0.05$) completed spirometry and FOT measurements. COPD participants completed the St. George Respiratory Questionnaire (SGRQ) and severity was classified based on GOLD spirometry (MLD, MOD, and SEV). **RESULTS:** In those with MOD&SEV COPD, total Rrs and Xrs at all frequencies, except expiratory R_{11} , were significantly different ($p < 0.05$) from H, but only R_{19} was different for MLD participants. R_5 : 3.9 ± 1.1 v 3.1 ± 1.3 , 5.9 ± 2.5 *cmH₂O/L/s; X_5 : -1.1 ± 0.9 , -1.4 ± 0.6 , -4.8 ± 3.2 *cmH₂O/L/s; R_{19} : 0.3 ± 0.07 , 2.4 ± 0.9 *, 3.3 ± 1.0 *cmH₂O/L/s; X_{19} : 0.4 ± 0.03 , -0.2 ± 0.7 , -1.1 ± 1.0 *cmH₂O/L/s, for H, MLD, and MOD&SEV groups respectively, * $p < 0.05$ vs. H. No significant difference ($p > 0.05$) between COPD severities were shown for Rrs or Xrs at 5, 11, or 19Hz. SGRQ scores were not different based on spirometric severity (M: 44.6 ± 18.6 ; MOD: 42.9 ± 15.2 ; S: 43.8 ± 11.8). **CONCLUSION:** FOT metrics made distinctions between COPD MOD&SEV and H, as well as MLD and H for mixed respiratory tract obstruction. However, no distinctions between COPD severities could be made. Obstruction increased with severity highlighting that more heterogeneous total airway obstruction (frequency dependent) is observed with mild severity patients, followed by more homogeneous obstruction as severity increased. Elastic properties and efficiency of ventilation decreased (became more negative) with increased COPD severity as airflow to and from distal airways become more limited due to hyperinflation from loss of alveolar support and elastic recoil.

1535 Board #297 May 30 10:30 AM - 12:00 PM Asthma and EIB Testing Among Collegiate Athletes in Indoor Winter Sports

Matthew J. Garver¹, Dustin W. Davis¹, Molly A. Jennings¹, Taylor K. Dinyer², Alex Rickard¹, Steve Burns¹, Brian J. Hughes¹, Dave M. Burnett³. ¹University of Central Missouri, Warrensburg, MO. ²University of Kentucky, Lexington, KY. ³University of Kansas Medical Center, Kansas City, KS. (Sponsor: Dr. Michael Godard, FACSM)

Email: garver@ucmo.edu

(No relevant relationships reported)

Pulmonary conditions, such as asthma and exercise-induced bronchoconstriction (EIB), influence airway diameter, and these conditions may be impacted by seasonal patterns. Systematic, team-wide screening among collegiate athletes is infrequent, and evidence shows a range of prevalence rates. **PURPOSE:** The goal of the current study was to investigate prevalence of asthma, undiagnosed asthma, and EIB in collegiate athletes practicing and performing in indoor arenas for winter sports. **METHODS:** Data collection occurred between mid- and late-fall. The testing protocol began with

baseline spirometry; athletes expired maximally and were encouraged to achieve a 6-second plateau. Values were taken in duplicate. Subjects failing to achieve a forced expiratory volume in one second (FEV_1) at or over 70% of a predicted value were noted and removed. Athletes followed with performance of a bout of exercise intensifying to 80-90% of predicted maximal heart rate. Confirmation of appropriate exercise intensity was verified with maximal ventilation values ($35 * FEV_1 * 0.5$ and $35 * FEV_1 * 0.6$). Athletes continued at target heart rate for 4 minutes. Athletes repeated maximal spirometry efforts post-exercise at 2, 5, 10, 15, and 20 minutes. Values were reviewed by a registered respiratory therapist, and a drop in $FEV_1 > 10\%$ from baseline was considered positive for EIB. **RESULTS:** Sixty athletes (wrestling or basketball, males=48, females=12) volunteered for testing. Four athletes confirmed previous diagnosis of asthma. Among the 56 tested, 54 obtained a minimum of 70% of predicted FEV_1 at pre-test (2 wrestlers were noted and removed). Among the 54 undergoing the exercise protocol, 11 (of 54=20.4%) tested positive for EIB as they failed to maintain 90% of their pre-exercise FEV_1 (mean drop $14.2 \pm 2.3\%$) at one of the post-exercise time points. In 3 subjects, one from each sport, results were not conclusive. **CONCLUSIONS:** Evidence of reduced pulmonary function was present in athletes across the sports spectrum. Over 20% of the athletes exemplified undiagnosed asthma or underlying EIB, which may have been exacerbated by seasonal patterns. Awareness and systematic testing of these pulmonary conditions in collegiate athletes would support health and potentially effect performance outcomes.

1536 Board #298 May 30 10:30 AM - 12:00 PM Echogenicity Is Related to Skeletal Muscle Strength in Patients with Acute Respiratory Failure

Michael J. Berry, FACSM¹, Daniel C. Files¹, Claudia L. Campos¹, Rita N. Bakhru¹, Brittany M. Skaggs¹, Peter E. Morris². ¹Wake Forest University, Winston-Salem, NC. ²University of Kentucky, Lexington, KY.

Email: berry@wfu.edu

Reported Relationships: **M.J. Berry:** Industry contracted research; Isagenix, LLC.

Patients with acute respiratory failure (ARF) show changes in skeletal muscle structure and strength. **PURPOSE:** The purpose of this study was to examine the relationship between muscle thickness (MT), echogenicity, and strength in patients with ARF. **METHODS:** Thirteen (6 females/7 males) patients with ARF participated in the study. Knee extensor (KE) strength was measured via a handheld dynamometer and quadriceps images were obtained via ultrasonography at hospital discharge. The ultrasound images were used to obtain MT and both mean and standard deviation echogenicity of the rectus femoris, vastus lateralis (VL), and vastus medialis. Partial correlations, controlling for age BMI and fluid intake, were used to describe the relationships among KE strength and echogenicity and MT. **RESULTS:** KE strength and vastus lateralis standard deviation echogenicity were significantly correlated when controlling for age, BMI and fluid intake ($r = .69$, $P = .029$). Mean \pm standard deviation knee extensor strength and vastus lateralis standard deviation echogenicity were 19.1 ± 8.0 kg and 19.8 ± 5.4 units. No other correlations between strength and ultrasound measures were found to be significant. **CONCLUSION:** These results show skeletal muscle echogenicity to be significantly correlated with skeletal muscle strength in patients with ARF. As such, it may be useful in identifying muscle weakness in these patients when they are unable or unwilling to perform voluntary strength testing.

1537 Board #299 May 30 10:30 AM - 12:00 PM Participation In Norseman Extreme Triathlon; The Effect On Lung Function And Oxygen Saturation

Trine Stensrud¹, Maria Mathiassen², Jørgen Melau³, Hege N. Østgård¹, Jonny Hisdal⁴, Julie Stang¹. ¹Norwegian School of Sport Sciences, Oslo, Norway. ²Telemark Hospital Trust, Skien, Norway. ³Vestfold Hospital Trust., Tønsberg, Norway. ⁴Oslo University Hospital, HF, Oslo, Norway.

Email: trine.stensrud@nih.no

(No relevant relationships reported)

PURPOSE: Primary: To examine changes in lung function, forced expiratory volume in one second (FEV_1) and forced vital capacity (FVC), and oxygen saturation (SpO_2) from before to after participation in Norseman extreme triathlon, consisting of 3.8 km open water swim, 180 km cycling and 42 km running. Secondary: To assess possible relationships between the physiological variables and respiratory symptoms and training volume. **METHODS:** In a quasi-experimental non-controlled study, 57 recreational triathletes (45 males and 12 females) aged 40.3 (9.0) years (mean (SD)) measured lung function by maximal expiratory flow volume loops (FEV_1 and FVC) and SpO_2 by pulse oximetry the day before the race, 8-10 minutes after finishing the race and the day after the race. Weekly training volume and respiratory symptoms were recorded with a modified AQUA-questionnaire at baseline. Anova for repeated measures was used to test for differences in lung function and SpO_2 and statistical significance was accepted at 0.05 level. The study was approved by the Regional Ethical Committee.

RESULTS: Twenty-six participants (46%) developed exercise-induced bronchoconstriction (EIB) defined as $\geq 10\%$ reduction in FEV₁ from baseline immediately after the race and 16 participants (28%) had still EIB the day after the race. FVC and FEV₁ were significantly reduced immediately after the race (mean: 8.9% and 11.8% respectively) and the day after the race (mean: 6.2% and 7.5% respectively). Thirty-five participants (61%) developed mild to moderate exercise induced arterial hypoxemia (EIAH) defined as $\geq 4\%$ reduction in SpO₂ from baseline. Further, oxygen saturation was significantly reduced immediately after the race (mean: 4.6%) and the day after the race (mean: 2.4%), respectively. There were no significant correlation between changes in lung function and SpO₂, respiratory symptoms or training volume ($p > 0.05$). **CONCLUSIONS:** Our results demonstrated that 46% of the participants developed EIB and 61% developed EIAH after Norseman extreme triathlon. The reduction in lung function may be due to fatigue in the respiratory muscles. Further investigation is needed to confirm our results as well as examine the mechanisms in age group triathletes.

Title: Resistance-training induced regional body composition changes in females with obesity vs. normal weight obesity

Selvaraj, BS, Mahan, C., Kloiber, S., Givan, A., Clements, M., Sanguinette, D., Larumbe-Zabala, E., Fernandez-del-Valle M.

Purpose: The aim of this study was to compare the effects of resistance training on regional body composition and fat loss, including upper and lower limbs and trunk, in females with obesity and normal weight obesity (NWO).

Methods: A total of 12 young females with obesity (BMI: 34.1±3.3; percentage body fat [%BF]: 49.2±2.9) and 15 with NWO (BMI: 22.2±1.8; %BF: 35.1±4.5) were randomized into control (obesity n=6, NWO n=8) and resistance training (obesity n=6, NWO n=7). Dual-energy X-ray absorptiometry (DXA) and a maximal strength test were performed before and after a 3-week intervention. Percent change (%Δ) of left and right trunk, arms, legs (LTfat, RTfat, LAfat, RAfat, LLfat and RLfat, respectively) and body fat were recorded. Training consisted of 3 sessions/week for 3 weeks, and 3 sets of 10 repetitions including 7 exercises that targeted major muscle groups. Participants were trained at 80% of their 1-repetition maximum.

Results: Non-parametric tests showed a statistically significant difference in %ΔLTfat (-1.05±3.99%, $p=0.032$) and a trend in %ΔBF (-1.73±1.93%, $P=0.056$) in the resistance training obesity group when compared to control. No statistically significant changes were found in NWO group.

Conclusion: Resistance training has shown to induce significant changes in the obesity group by reducing LTfat content. However, no changes were detected in the NWO group. Future research should include larger sample size to facilitate the detection of regional body composition changes and to help understand the differential impact of resistance training in women with obesity and NWO.

Selective Effectiveness Of 10wk-exercise Protocols On Mets Reduction

Roberto C. Burini, FACSM¹, Mariana S. Nakagaki², Hugo T. Kano¹. ¹São Paulo State University (UNESP), Botucatu, Brazil. ²Londrina State University, Londrina, Brazil.
Email: burini@fmb.unesp.br

(No relevant relationships reported)

MetS is recognized as a pervasive condition whose abnormalities result from a mismatch between contemporary environment and our ancient tailored genome. Hence, diet and physical exercise are considered the pillars in the implementation of effective strategies against MetS.

PURPOSE: The responses of MetS subjects to different types of physical exercises was investigated in a dynamic cohort study ("Move for Health" program) based on spontaneous demand for healthy lifestyle with supervised exercises and dietary counseling.

METHODS: Demographic, socio-economic and physical activity was recorded from IPAQ (version 8) and, dietary quality (HEI) and food intake, from a 24h questionnaire recall. Anthropometry and fast-blood analysis were used for MetS diagnosis (NCEP-ATP III). After clinical selection and baseline assessments they were spontaneously assigned to structured protocols involving supervised exercises of strength (Pac, n=43) isolated or combined with endurance (walking) exercises (PMi, n=146), hydro-gymnastics (PHy, n=50) and treadmill high-intensity exercises (PHit, n=63), applied during 10 weeks. Nutritional counseling was conducted weekly. Protocols were compared statistically using SAS vs 9.3 for $p=0.05$.

RESULTS: Sample of 55.5 ± 108 yrs old (n=302), predominantly female (88%), presented adequate physical activity (91%), cardio-respiratory fitness (63%) and strength (78%), referring themselves as in good health (67.8%). At baseline, groups were similar in anthropometry, fitness and MetS (averaging 48.7%). Altered components of MetS ranked from waist circumference (72.9%) to triglycerides (37.9%). After 10-wk of exercises, increased aerobic capacity was found in all groups and, strength only in Pac and PMi. MetS reduction averaged 16.9%, mainly and significantly in PHy (25.4%) and PMi (12.7%). Among the MetS components, a major decreasing to exercise protocols was found in hyperglycemia (20.6%) and hypertension (15.9%).

CONCLUSIONS: The reduction of MetS occurred in different types of physical exercises with higher responsiveness in PHy and PMi having hyperglycemia and hypertension as its most responsive components. Support CNPq and CAPES.

Reason To Exercise In Diabetic Populations: Use Of Rapid-acting Insulin Predicts Falls In At-risk Patients

Saejel G. Mohan¹, Tina Bhateja¹, Kathy L. Leslie¹, J. Mark VanNess¹, Jonathan M. Saxe², Lewis E. Jacobson², Courtney D. Jensen¹. ¹University of the Pacific, Stockton, CA. ²St. Vincent Hospital, Indianapolis, IN.

(No relevant relationships reported)

Diabetes is present in 9.4% of American adults. Insulin is used in Type 1 and Type 2 cases, but without lifestyle change, it can hasten the progression of the disease. Limited data supports an association between diabetes and fall risk in older adults, with greater risk found among insulin-treated patients. Little is known about different insulin classes.

PURPOSE: To evaluate the effect of insulin classes on incidence of falls in older adults.

METHODS: We conducted retrospective and prospective analyses of 615 hospital patients age ≥ 65 years who sustained a fall in 2015. Data was extracted from their first fall-related admission that year, including demographic reports, health history, injury characteristics, relevant diagnoses, and home medications. We exported the number of previous falls since 2010 and used logistic and Poisson regressions to test the effect of insulin on the odds of experiencing falls and the total number experienced. We then tracked patients forward until August 2016 and tested the effect of insulin on return visits for new fall-related admissions.

RESULTS: Patients were 80.0±9.1 years old, 6.2% used long-acting insulin, 0.5% used intermediate insulin, and 4.2% used rapid-acting insulin. They were admitted 1.9±1.3 times previously and had 0.5±0.9 return visits. There was no relationship with intermediate insulin and the number of previous ($P=0.223$) or future ($P=0.383$) falls. Long-acting insulin associated with modest increases in the number of previous ($P=0.053$) and return ($P=0.050$) falls. Rapid-acting insulin significantly predicted both. Controlling for weather, age, balance, and cognitive condition, patients using rapid-acting insulin had a 4.2-fold increase in the odds of sustaining multiple previous falls ($P=0.002$; 95% CI of odds ratio=1.68-10.54), a 37.2% increase in the number of previous visits ($P=0.012$; 95% CI of IRR: 1.07-1.76), a 2.4-fold increase in the odds of readmission ($P=0.033$; 95% CI of odds ratio: 1.07-5.50), and a 64.3% increase in the number of return visits ($P=0.026$; 95% CI of IRR: 1.06-2.54).

CONCLUSIONS: Diabetics taking rapid-acting insulin express an elevated risk of falls. Exercise may serve two functions in this population: it can mitigate the acute and chronic effects of diabetes via non-insulin dependent glucose uptake, and it can protect against fall risk.

 Email: cathie0501084@163.com
 (No relevant relationships reported)

Purpose: Exercise therapy of traditional Chinese medicine (TCM) has a long history in treating diabetes. Few evidence to date have shown its effects on the glucose metabolism and muscle fitness. We evaluated the effects of TCM exercise therapy and sedentary lifestyle on sugar metabolism and physical fitness in both female individuals with prediabetes and type II diabetes mellitus (T2DM).

Methods: Thirty-three diabetic subjects and 33 prediabetic subjects were randomly divided into the exercise therapy group (diabetic: ED, prediabetic: EP) or sedentary group (diabetic: CD, prediabetic: CP) as a 2:1 ratio. ED and EP groups were given the same traditional exercise for moderate intensity, 50min, 3 times a week. Hemoglobin a1c (HbA1c), fasting insulin, oral glucose tolerance test (OGTT), peak oxygen uptake (VO_{2peak}), grip strength, back strength, and sit-ups (muscle endurance) were taken at the pro and post of 12-week-exercise. Responses were compared between prediabetes and diabetes.

Results: Compared with CP and CD group, HbA1c decreased by 0.156 mmol/L ($P < 0.05$) and 0.45 mmol/L ($P < 0.01$) with EP and ED, respectively. Fasting insulin decreased by 4.61 cycles U/mL in EP group, and 13 of them returned to normal blood glucose, both fasting and postprandial ones, according to the OGTT test. The VO_{2peak} , muscle strength and endurance of the diabetic groups were significantly lower than those of the prediabetic groups ($P < 0.001$). VO_{2peak} of the exercise groups increased significantly (EP: +6.55%, ED: +33.43%, $P < 0.001$). Muscle fitness improvements were significant ($P < 0.05$) on the grip strength (ED: +1.75kg, CD: -0.44kg), back strength (ED: +8.47kg, CD: -0.27kg), and sit-ups (ED: 3.50 more, CD: 0.18 less) in diabetic groups but not obvious in prediabetic groups.

Conclusions: The VO_{2peak} and muscle fitness of diabetic patients were significantly lower than that of prediabetes. TCM exercise therapy can improve sugar metabolism and physical fitness, which is safe and effective. The same traditional exercise is better for diabetes than prediabetes.

Combined Metformin and Exercise Treatment Improves Glucose Control and Insulin Sensitivity in Type-2 Diabetes Patients.

Juan F. Ortega, Miguel Ramirez-Jimenez, Felix Morales-Palomo, Ricardo Mora-Rodriguez. *University of Castilla-La Mancha, Toledo, Spain.*
 Email: juanfernando.ortega@uclm.es
 (No relevant relationships reported)

BACKGROUND: The antidiabetic medicine, Metformin, and exercise are cornerstones in the treatment of type-2 diabetes. However, there is conflicting evidence about the benefits of combining both interventions. **PURPOSE:** To compare free-living ambulatory glycemic control and insulin sensitivity among the separated and combined effects of metformin and exercise.

METHODS: Twelve middle-aged (55.5 ± 1.4 years) adults, diagnosed with type-2 diabetes and obesity ($BMI 32.0 \pm 1.2$ kg/m²) undergoing pharmacological treatment with metformin (>3 yrs.) participated in the study. All participants underwent 4 trials in a randomized order: i) taking their habitual doses of metformin (MET), ii) after 48-hours of metformin withdrawal, which was replaced by two (43 min) daily bouts of high-intensity interval training (EX), iii) combining medicine and exercise (MET+EX), and iv) a Control trial withdrawing from metformin (48-hours) and exercise (CONT). Ambulatory glycemic control was inferred from interstitial fluid glucose concentration (IFG), which was frequently monitored during 72 h (FreeStyle Libre, Abbott, USA) in each experimental condition. In addition, after an overnight fasting, a blood sample was collected 24 h after each experimental condition for the assessment of glucose and insulin concentration and subsequent calculation of insulin sensitivity (i.e., HOMA-IR). **RESULTS:** During the 72 hours of IFG monitoring an average of 109 + 11 readings per trial were obtained (i.e., 1.5 readings per hour). IFG in EX (7.3 ± 1.9 mmol/L) was similar than CON (7.3 ± 1.9 mmol/L; $P=0.604$). However, in MET (6.9 ± 1.6 mmol/L) and MET+EX (6.6 ± 1.3 mmol/L) IFG was significantly lower than CONT ($P < 0.001$ and $P=0.05$, respectively). IFG peaks (i.e., IFG > 11.1 mmol/L) were more frequent in CONT than in the rest of the trials. However, IFG peaks frequency was lower in MET+EX than in MET ($P=0.025$) and EX ($P=0.030$). Finally, insulin resistance (i.e., HOMA-IR) was lower than CONT in MET+EX ($P=0.031$) and in MET ($P=0.001$) but not in EX alone. **CONCLUSIONS:** The combination of metformin and exercise reduces the occurrence of IFG peaks thus improving glucose control in

a sample of type-2 diabetic individuals in a free-living situation. Monitoring of IFG seems adequate to track the effects of both, exercise and pharmacological treatment (metformin).

A Review Of Intervention Of Baduanjin For Diabetes And Complications

Shuxin Wu, Xiaohui Yang, Lu Sun, Hongfeng Sun, Shuli Cheng.
Dongfang Hospital Affiliated to Beijing University of Chinese Medicine, Beijing, China.
 Email: 15120039753@163.com
 (No relevant relationships reported)

PURPOSE: The traditional Chinese guidance technique—fitness qigong · Baduanjin exercise, which means the eight-section brocade exercise in English, has the functions of body building. It is widely used in diabetic patients as exercise therapy, we systematically reviewed the history and role of Baduanjin exercise applied to diabetes and its complications.

METHODS: The source and historical evolution of Baduanjin exercise were systematically analyzed based on ancient Chinese literature. Health benefits of Baduanjin exercise intervention in diabetes and its complications were summarized based on clinical research literature.

RESULTS: (1) The development of Baduanjin exercise went through five periods:

①The guidance technique in ancient times about 2000 BC was its origin; ②The Northern Song Dynasty from 960 to 1127 AD was the formation period of movements; ③It became popular in the Southern Song Dynasty from 1127 to 1279 AD and was first recorded in the book “Yijianzhi”. And it became mature from the Southern Song Dynasty to Yuan Dynasty of 1280; ④It was widely spread and promoted in the Ming and Qing Dynasties from 1368 to 1912; ⑤After the foundation of the People’s Republic of China in modern times, a lot of books in regard to Baduanjin exercise were published. The fitness qigong management center of General Administration of Sport of China organized the compilation and creation of the exercise, which was named “fitness qigong · Baduanjin exercise”. The nationwide fitness program was carried out actively and the exercise was promoted around the world. (2) After practicing Baduanjin exercise for 3-6 months, FBG and HbA1C can be significantly reduced. BP, TG and blood lipid levels such as LDL-C, HDL-C can be adjusted. The SNCV and MNCV can be enhanced. Psychological index scores such as HAMD, SDS, SAS, DSQ and so on of diabetes patients with depression or anxiety can be improved. **CONCLUSIONS:** The development of Baduanjin exercise went through five stages. As an exercise therapy, it can improve glucose and lipid metabolism and diabetic neuropathy. The level of mental health can be enhanced. Therefore, it deserves to be widely promoted and co-developed internationally to gain more benefits. Fund support: The Technology Research Project of the fitness qigong center of General Administration of Sport of China (QG2017038)

Relationships Between Exercise Level, Beliefs About Exercise, And Exercise Promotion Among Cardiologists And Oncologists

Heather Leach¹, Kelli LeBreton¹, Barry Braun, FACSM¹, Steven Schuster², Patrick Green². ¹Colorado State University, Fort Collins, CO. ²University of Colorado Health, Aurora, CO.
 (Sponsor: Barry Braun, FACSM)
 Email: heather.leach@colostate.edu
 (No relevant relationships reported)

PURPOSE: This study examined the relationships between cardiologists’ and oncologists’ exercise levels, beliefs about exercise for their patients, and frequency of discussing or recommending exercise.

METHODS: A survey was distributed to oncologists and cardiologists via Qualtrics. Questions and responses were: (1) “I believe exercise is safe for most of my patients, most of patients are capable of exercise, exercise is effective for improving my patients’ well-being, and exercise can reduce likelihood of disease recurrence, or increase chances of survival in my patients (strongly disagree to strongly agree), (2) “How often do you discuss exercise with your patients?” (none/few, some, most/all visits), (3) “What percent of patients have you recommended should exercise in the past month?” (none/few, some, most/all), and (4) “How do you provide information about exercise?” (referral as a yes/no option). Self-reported exercise was categorized at meeting exercise guidelines or not. Fisher’s Exact (FE) tests with Cramer’s V were used to compare the proportion of responses in each category between questions. **RESULTS:** Out of 154 surveys distributed, 58 (n=25 cardiologists, n=33 oncologists) were returned (37.7% response rate). Respondents were $M=45.7 \pm 11.3$ years old and 63.6% male. Those who agreed (vs. neutral/disagreed) with “...exercise can reduce likelihood of disease recurrence or increase survival...” were more likely to refer patients to an exercise program ($FE=5.588$, $p=.040$, $V=.324$). Cardiologists who agreed with the same statement were more likely to discuss exercise at most/all patient

visits ($FE=9.351$, $p=.027$, $V=.514$). More than half (58.6%) reported meeting exercise guidelines, and there were no differences in beliefs about exercise for patients between those meeting vs. not meeting guidelines.

CONCLUSION: Cardiologists and oncologists who believe exercise can reduce the likelihood of disease recurrence or improve survival for their patients, may be more likely to discuss exercise or refer patients to an exercise program. Beliefs about exercise did not differ by exercise level. These findings suggest that cardiologists' and oncologists' beliefs about the benefits of exercise for improving disease outcomes may be a viable path to increase exercise promotion.

Outcome measures of sexual health and function (International Index of Erectile Function (IIEF), the Expanded Prostate Cancer Index Composite (EPIC) and the EORTC-PR25 were assessed at baseline and 12-weeks. **RESULTS:** After adjusting for baseline values, there were no differences between groups for any of the measures of sexual function and activity, $p>0.05$. Additionally, there were no differences between groups for urinary and bowel function as assessed by the EORTC-PR25 ($p>0.05$). **CONCLUSIONS:** A M3EP program does not improve indices of sexual health and function in men with advanced prostate cancer. <!--EndFragment-->

Baduanjin's Impact on Quality of Life and Sleep Quality in Breast Cancer Survivors Receiving: An Intervention Study

XIAOHUI HOU. GUANGZHOU SPORT UNIVERSITY, GUANGZHOU, China.
Email: lilyhxx@163.com

(No relevant relationships reported)

Purpose

To investigate the impact of Baduanjin, a traditional Chinese exercise intervention, on quality of life and sleep quality in breast cancer survivors receiving aromatase inhibitors.

Patients and Methods

A 3-month intervention study was conducted in 68 breast cancer survivors who were receiving treatment with aromatase inhibitors (AIs). All patients were instructed to participate in 12 weeks of Baduanjin exercise training, which involved three 90-minute sessions per week. Group 1 attended ≥2 sessions per week (n=33), while group 2 attended <2 sessions per week (n=35). Questionnaires measuring quality of life (QOL) and sleep quality were completed at baseline and 3 months after the intervention. Quality of life was assessed using the European Organization for Research and Treatment of Cancer Quality-of-Life Questionnaire Core 30 (EORTC QLQ- C30). Sleep quality was measured using the Pittsburgh Sleep Quality Index (PSQI).

Results

The indexes of quality of life, which included functional scores, general health and symptom relief, significantly improved in group 1 ($P<0.05$) and had a larger effect size compared to group 2 (P value for group difference < 0.05). Compared with group 2, group 1 had a higher score on the functional scales ($P<0.05$), while the functional scale scores for group 2 worsened. The overall PSQI score in group 1 decreased by 4.85 points (47.92%) ($P<0.01$) and was lower than that of group 2 (P for group difference < 0.05).

Conclusion

A 12-week Baduanjin exercise training program led to improvements in the quality of life and sleep quality of breast cancer patients receiving AIs.

Evaluating The Translation Of Dutch Exercise Oncology Trials Into Clinical Practice Using The RE-AIM Framework

Laurien M. Buffart¹, Anne M. May², Rosalie Huijsmans¹, Neil K. Aaronson³, Martijn M. Stuiver⁴. ¹Amsterdam UMC, Amsterdam, Netherlands. ²UMC Utrecht, Utrecht, Netherlands. ³Netherlands Cancer Institute, Amsterdam, Netherlands. ⁴Netherlands Cancer Institute and Amsterdam University of Allied Sciences, Amsterdam, Netherlands.
Email: l.buffart@vumc.nl

(No relevant relationships reported)

PURPOSE: Implementation of exercise programs for cancer patients is challenging. This study evaluated the potential for implementation of exercise programs from Dutch exercise oncology trials.

METHODS: Three randomized controlled trials (PACES, REACT, PACT), examining effects of exercise during or following chemotherapy treatment with curative intent, were evaluated using the 5 dimensions of the RE-AIM framework: Reach, Effectiveness, Adoption, Implementation, and Maintenance.

RESULTS: *Reach:* Participation rates were 37-45%. Compared to non-participants, participants were higher educated, less fatigued or distressed, and had higher scores on behavioral variables. *Effectiveness:* No serious exercise-related adverse events occurred. Significant benefits of exercise were found for physical fitness, fatigue, and quality of life. A significant benefit on chemotherapy completion was found in one study but not in another. *Adoption:* To enable twice weekly exercise session attendance close to patients' homes, local physiotherapists (PTs) were educated about exercise supervision for cancer patients. Generally, the PTs felt sufficiently capable to deliver exercise programs, but less capable to support behavioral change. *Implementation:* 61-89% of participants had high attendance at the supervised sessions. Education, additional radiotherapy, BMI, fatigue and self-efficacy predicted adherence in some studies. Basic insurance does not cover the program, but some additional coverage policies do. Some evidence for cost-effectiveness of the programs was found.

Maintenance: Exercise-induced gains in physical fitness and quality of life post cancer treatment, and benefits from exercise during chemotherapy on physical activity and function maintained, whereas maintenance of fatigue benefits were inconsistent across studies. Sustainability of program delivery is ensured by incorporation of the exercise protocols in post-graduate oncology education for PTs. A quality control system has been implemented via Onconet.

CONCLUSIONS: The exercise programs have high potential for successful implementation in clinical oncology practice, but reach and adherence should be monitored, and lack of reimbursement is currently a barrier. Future studies should focus on improving maintenance of benefits.

1548 Board #310 May 30 10:30 AM - 12:00 PM

Effects of Different Volumes of Combined Training in Breast Cancer Survivors: A Pilot Study

Stephanie Pinto¹, Elisa Portella¹, Cristine Alberton¹, Rochele Pinheiro¹, Gabriela David¹, Pedro Lopez², Maria Laura Brizio¹, Gustavo Schaan¹, Daniel Umpierre². ¹Federal University of Pelotas, Pelotas, Brazil. ²Federal University of Rio Grande do Sul, Porto Alegre, Brazil.
Email: tetisantana@yahoo.com.br

(No relevant relationships reported)

PURPOSE: We aimed to assess the effects of different volumes of eight-week combined training on neuromuscular, cardiorespiratory, fatigue and quality of life parameters in breast cancer patients in stages I-III who have finished treatment, such as surgery, chemotherapy and radiotherapy. **METHODS:** Ten women (57.1 ± 9.6 years) were placed into either a group based on a single set (SS) protocol or a group following multiple sets (MS) protocol for prescribed resistance exercises. The eight-week combined training included resistance and aerobic exercise within the same training sessions, which were performed twice a week. Resistance exercises were performed with sets of maximal repetitions and along the training the number of repetitions decreased. The intensity of aerobic exercise was based on the anaerobic threshold, monitored by relative heart rate (first weeks) or velocity of the anaerobic and aerobic thresholds (last weeks). Before and after the intervention, the following variables were evaluated: maximal dynamic and isometric strength of knee extensors, maximal isometric electromyography (EMG) activity of vastus lateralis, muscle thickness of quadriceps, peak oxygen uptake, fatigue and quality of life. The training-related effects were assessed using a Generalized Estimating Equations and Bonferroni post-hoc test ($\alpha=0.05$). **RESULTS:** The maximal dynamic strength of knee extensors (SS: 32.10 ± 45.70 vs. MS: 23.33 ± 13.59%, $p<0.001$), muscle thickness of quadriceps (SS: 14.60 ± 4.64 vs. MS: 25.50 ± 19.30%, $p=0.001$), peak oxygen uptake (SS: 8.67

± 8.76 vs. MS: $12.07 \pm 12.04\%$, $p < 0.001$) and quality of life (SS: 2.71 ± 6.91 vs. MS: $5.75 \pm 7.97\%$, $p = 0.039$) increased after training, with comparable changes for both groups. For maximal isometric strength of knee extensors and EMG activity of vastus lateralis there were no significant changes in both groups after training. For cancer-related fatigue, only the MS group showed decreases ($16.24 \pm 135.32\%$). We highlight these results are preliminary. **CONCLUSIONS:** In this pilot study, a short period of combined training, independent of the volume of resistance training, promoted key benefits for functional variables and quality of life in sedentary breast cancer survivors.

1549 Board #311 May 30 10:30 AM - 12:00 PM
Feasibility Of Exercise Prehabilitation During Neo-adjuvant Chemotherapy In Oesophago-gastric Cancer Surgery

Janine Zylstra¹, Andrew R. Davies¹, Jim Pate², Gemma Tham¹, Nick Maisey¹, Cara R. Baker¹, Mark Kelly¹, James Gossage¹, Mike Browning³, Greg Whyte⁴. ¹Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom. ²Centre for Health and Human Performance, London, United Kingdom. ³Maidstone and Tunbridge Wells NHS Trust, London, United Kingdom. ⁴Liverpool John Moore's University, London, United Kingdom. Email: janine.zylstra@gstt.nhs.uk
 (No relevant relationships reported)

PURPOSE:

To determine the feasibility and potential benefits of patients diagnosed with operable gastro-oesophageal cancer undertaking a structured-exercise cancer prehabilitation program (prehab) during neo-adjuvant chemotherapy (NAC) versus patients on a standard care pathway.

METHODS:

Patients were enrolled in a prospective, cohort-controlled trial. Prehab was based on World Health Organisation (WHO) 'recommended levels of physical activity for adults over the age of 18'.

Cardiopulmonary exercise tests (CPEX) were performed at 4 time-points: 1. Baseline/pre-NAC. 2. Post-NAC. 3. Before surgery. 4. After surgery. Participants wore wearable tracker devices.

CPEX variables analysed included anaerobic threshold (AT) and peak oxygen uptake (VO₂peak).

Clinical and pathological data variables were recorded.

RESULTS:

At time of writing, 25 male and female patients, aged 25 - 78years, had participated in the study; 22 had undergone surgery. Mean baseline AT in the prehab group was 17.57 ± 3.35 SD (range 10.77 - 20.94; n=10) ml/kg/minute, compared to 15.19 ± 3.57 SD (range 11.10 - 22.90; n=12) ml/kg/minute in the control group.

Mean baseline VO₂peak achieved was 27.55 ± 5.63 SD (range 15.18 - 36.83) ml/kg/minute and 23.39 ± 4.06 SD (range 18.75 - 29.94)ml/kg/minute, respectively.

Mean values of AT and VO₂peak between the groups pre-surgery were of little scientific value. However, Δ VO₂peak in individual patients showed a trend towards improvement in the prehab cohort. Post-surgery values decreased markedly in both groups:

Mean AT prehab decreased to 13.46 ± 2.29 SD (range 10.54 - 15.91)ml/kg/minute versus 13.10 ± 2.60 SD (range 10 - 18.4)ml/kg/minute in control group.

Mean VO₂peak reduced to 20.33 ± 4.94 (range 14.01 - 26.81)ml/kg/minute compared to 19.56 ± 2.74 SD (range 18.00 - 24.76)ml/kg/minute respectively.

CONCLUSIONS: Cancer prehabilitation during NAC is feasible. Recovery of peak oxygen uptake shows an improvement trend in patients undergoing prehab during and after NAC. Post-surgery mean AT and VO₂ values confirm physiological stress in patients undergoing high-risk, intra-thoracic and intra-abdominal oesophagectomy.

Moving Cancer Care Ontario's Exercise Guidelines Into Oncology Practice: Using The Theoretical Domains Framework To Validate A Questionnaire

Sarah Neil-Sztramko¹, Michelle Nadler². ¹McMaster University, Hamilton, ON, Canada. ²University of Toronto, Toronto, ON, Canada. Email: neilszts@mcmaster.ca
 (No relevant relationships reported)

PURPOSE: The purpose of this study was to validate a questionnaire used to identify barriers and facilitators to use of exercise guidelines in oncology care.

METHODS: A questionnaire was designed to explore knowledge, beliefs, practices, barriers and facilitators to discussion of exercise guidelines in oncology patients. It was optimized for face and content validity through pilot testing, and administered to oncology care providers at a regional tertiary cancer. To offer more strategic and precise data collection, and to inform the development of interventions with a higher likelihood of applicability and success, we validated the questionnaire based on the

updated 14-item Theoretical Domains Framework (TDF). The TDF is a knowledge translation (KT) framework used to identify potential targets for health professional behavior change related to evidence-based practice. Cronbach's alpha was calculated to assess internal consistency between items within each domain of the TDF. **RESULTS:** Existing items were mapped successfully within the eight TDF domains deemed to be relevant to exercise discussion in oncology care. Internal consistency was generally high across domains, with all domains > 0.7 , with the exception of intentions, and beliefs about consequences. Four questions were removed, which increased the internal consistency within domains.

CONCLUSIONS: Many KT frameworks emphasize context in developing and assessing the effectiveness of implementation strategies. Our questionnaire, based on a commonly used KT framework, has the potential to assist other researchers to collect valuable contextual data prior to the design phase of an intervention to promote exercise discussion in cancer practice. The consideration of these formative data in the development of KT interventions that have a greater likelihood of success in closing the gap between the known benefits of exercise in people with cancer and coverage in care planning.

Exercise in Patients Newly Diagnosed with Multiple Myeloma - a Randomized Controlled Feasibility Study

Rikke F. Larsen¹, Mary Jarden², Lisbeth R. Minet³, Ulf C. Frølund¹, Niels Abildgaard³. ¹Zealand University Hospital, Roskilde, Denmark. ²University Hospital of Copenhagen, Copenhagen, Denmark. ³Odense University Hospital, Odense, Denmark.

Email: rfl@regionsjaelland.dk

(No relevant relationships reported)

Exercise is considered a feasible, safe and beneficial complementary treatment for patients with hematological cancer. However, there is a lack of knowledge regarding exercise interventions (EI) in patients with newly diagnosed multiple myeloma (MM). Our ongoing randomized controlled trial (RCT) examines the effect of an EI in newly diagnosed patients with MM, irrespective of age and treatment regimen, on muscle strength, physical function and physical activity. **PURPOSE:** To report an interim analysis of feasibility and safety of the early initiated exercise intervention. **METHODS:** A two-center RCT with blinded outcome assessors. Baseline tests are carried out three days after starting anti-myeloma treatment, followed by randomization to control group (CG) or intervention group (IG). The EI is a 10-week supervised and home-based exercise program comprising aerobic and strengthening exercises and physical activity. Feasibility outcome measures are study eligibility, acceptance and drop-out rates. Further, intervention adherence, tolerability and safety by registration of adverse events (AE) are assessed. IG is compared to CG by k-sample test for medians and by Fisher's exact test for categorical variables. **RESULTS:** Of 49 patients screened, 80% were eligible for inclusion, 77% accepted participation. Median age 69 years, range (38-90), 77% were men. No difference between CG and IG in age ($p = 0.713$) and gender ($p = 0.666$). From IG, five patients dropped out (29%); prior to start of intervention due to no surplus energy ($n = 3$), treatment near by home town ($n = 1$) or because of sudden impairment ($n = 1$). Adherence was high; 99% of the supervised ES were completed and 89% of the home-based ES were completed. Tolerability was high; only two patients had to discontinue one supervised ES, each due to non-serious AE (pain and dyspnea/dizziness). No serious AE (e.g. pathological fractures) were reported. **CONCLUSION:** Early initiated exercise in patients with MM, regardless of age and treatment regimen, is feasible, tolerable and safe and may be important in preventing physical decline during treatment for MM. **SUPPORTED BY:** Zealand University Hospital; Region Zealand; Region of Southern Denmark; REHPA, The Danish Knowledge Centre for Rehabilitation and Palliative Care; Amgen; The Association of Danish Physiotherapists.

Effects Of Exercise And Yoga On Sleep Problems In Women With Breast Cancer: A Meta-analysis

Charlotte Kreutz, Martina E. Schmidt, Karen Steindorf. DKFZ, Heidelberg, Germany. (Sponsor: Jürgen Scheerhag, FACSM)

Email: charlotte.kreutz@nct-heidelberg.de

(No relevant relationships reported)

Sleep problems are one of the top five long-term health issues in breast cancer patients. However, the optimal treatment still needs to be defined. Exercise and yoga are promising approaches. **Purpose:** To conduct a meta-analysis evaluating the effects of physical exercise and yoga interventions on self-reported and objective sleep problems in breast cancer patients during or post-cancer treatment. **Methods:** PubMed, Web of Science and Cochrane library databases were systematically searched for randomized controlled trials with any type of exercise or yoga intervention in women with breast cancer. Outcomes were self-reported or objective measurements of sleep. Standardized mean differences (SMDs) using random-effects models were calculated. **Results:** The meta-analysis included 22 trials with 2091 participants. Sleep was assessed in

17 studies with the Pittsburgh Sleep Quality Index (PSQI). Only 6 studies included objective sleep assessments (ActiGraph). Physical exercise interventions included aerobic exercise, resistance exercise or a combination of both. Most interventions were supervised. Yoga interventions comprised various yoga protocols. Also 3 studies with Tai-Chi or Qigong were included in the yoga group for the meta-analysis. Both, physical exercise interventions (SMD -0.32; 95% CI -0.54 to -0.10) and yoga interventions (SMD -0.27; 95% CI -0.44 to -0.09), resulted in improvements of sleep problems. There was no significant difference between the effects of physical exercise and yoga. Subgroup analyses revealed no clear difference between interventions conducted during cancer therapy versus post therapy. Considering the PSQI subscores, exercise resulted in improvements of sleep quality (SMD -0.28; 95% CI -0.44 to -0.11) and of sleep disturbances (SMD -0.26; 95% CI -0.45 to -0.06). Regarding the objective sleep measurements, no significant effects were found, however, the number of studies was very limited. **Conclusions:** Physical exercise as well as yoga, Tai-Chi or Qigong might reduce sleep problems and improve subjective sleep quality in breast cancer patients, both during and after cancer treatment. Effect sizes were small to moderate. Future studies should clarify which type of intervention might be most effective depending on individual patients' and treatment characteristics.

Preventive Action Of Cardiorespiratory Fitness On Health Outcomes In Childhood Acute Lymphoblastic Leukemia Survivors

Maxime Caru¹, Valérie Lemay¹, Mariia Samoilenko¹, Simon Drouin¹, Nathalie Alos¹, Geneviève Lefebvre², Emile Levy¹, Sarah Lippé¹, Valérie Marcil¹, Serge Sultan¹, Laurence Bertout¹, Maja Krajinovic¹, Caroline Laverdière¹, Marie-Josée Raboisson¹, Daniel Sinnett¹, Gregor Andelfinger¹, Daniel Sinnett¹, Daniel Curnier¹. ¹Sainte-Justine University Hospital, Montreal, QC, Canada. ²University of Quebec in Montreal, Montreal, QC, Canada.

Email: maxime.caru@umontreal.ca

(No relevant relationships reported)

PURPOSE: Most childhood acute lymphoblastic leukemia (ALL) survivors develop chronic treatment-related adverse effects several years after the end of therapy. A regular practice of physical activity and a good cardiorespiratory fitness have the potential to reduce the risk of chronic diseases and to improve quality of life. It is currently unknown whether a good cardiorespiratory fitness or the regular practice of physical activity is enough to induce a preventive action on late adverse effects. The first aim of this study was to evaluate the association between a good cardiorespiratory fitness and major long-term health outcomes. The second aim of this study was to assess the association between the respect of physical activity guidelines and major long-term health outcomes.

METHODS: 247 ALL survivors underwent a cardiopulmonary exercise test. They also completed a physical activity questionnaire and a battery of clinical exams. We calculated the odds ratio to obtain the preventive fraction in order to evaluate the effects of cardiorespiratory fitness and physical activity levels on health outcomes (i.e. obesity, metabolic health, cardiac health, cognitive health and mood, bone health)

RESULTS: Despite their young age, 88% of the survivors presented at least one adverse health outcome, and 46% presented 3 or more adverse health outcomes. Their cardiorespiratory fitness had a median VO2 peak reaching 84% of predicted value, which was lower than expected. In the analyses regarding cardiorespiratory fitness, statistically significant preventive fractions were observed for obesity (30%), low HDL-cholesterol (21%) and depression (26%). In the physical activity level analyses, statistically significant preventive fractions were observed for obesity (55%), depression (81%) and low bone mineral density (60%).

CONCLUSIONS: Our results indicated that a good cardiorespiratory fitness and physical activity level induced a preventive action for most health outcomes studied and was associated with a lower late adverse effects prevalence in ALL survivors. Clinicians and researchers have an important role to play in the reduction of late adverse effects in ALL survivors. This study provides additional evidence regarding the benefits of physical activity for cancer survivors

C-49 Basic Science World Congress/Poster - Circadian and Sleep Behavior in Adolescents

Thursday, May 30, 2019, 7:30 AM - 12:30 PM
Room: CC-Hall WA2

Descriptive Analysis of Objectively Measured Physical Activity and Sleep Activity in Adolescents: a Preliminary Analysis.

Sarah N. Brown, Sarah E. Domoff, Aubrey L. Borgen, Ryan Foley, Rachael K. Nelson. *Central Michigan University, Mount Pleasant, MI.*

(No relevant relationships reported)

Although growing evidence suggests a link between physical activity (PA) behavior and sleep quality in adolescents, a causal relationship between these two variables has yet to be elucidated. Methodological differences in data collection (subjective vs. objective) has been highlighted as a limiting factor in data interpretation. In fact, the majority of the literature includes subjective or subjective combined with objective data, with only two studies comparing objective measures of both PA and sleep in adolescents within the same analysis. **PURPOSE:** To objectively examine PA behavior and sleep activity in adolescents using accelerometers. **METHODS:** 7 males and 3 females, age: 10±1 yrs., BMI: 20±5 were recruited for this study. PA and sleep were monitored by Actigraph wGT3x accelerometers worn on participants' non-dominant wrist to assess sedentary (SED), light-intensity (LPA), and moderate-to-vigorous activity (MVPA), as well as sleep activity including: total sleep time (TST), wake after sleep onset (WO), and average wake length (WL). Time spent awake and sedentary (aSED) was calculated as $aSED = SED - TST$. Participants were instructed to wear the accelerometer for 7 consecutive days only removing it while swimming, bathing, or playing contact sports. Our analysis only included data from participants who wore the accelerometer continuously for ≥4 days. **RESULTS:** On average participants accumulated 435±15 min/day of sleep equal to 7.3±0.3 hours per night. Participants also accumulated 473±24 min/day of MVPA, 371±29 min/day aSED, and 141±8 min/day LPA. There was not a significant difference between TST and MVPA per day (p=0.22). Participants spent the majority of their day sleeping (33% time/day) or engaged in MVPA (31%) followed by aSED (26%), and the fewest proportion of their day engaged in LPA (10%; p<0.01). We observed a negative association between LPA and TST (p=0.01). However, we observed a positive association between LPA and WO (p=0.03) and WL (p=0.03). No other significant associations were observed between PA and sleep variables. **CONCLUSION:** Outcomes of this analysis suggest that adolescents accumulate less than the recommended 8-10 hours of sleep per night and parameters of sleep disturbance may be linked to engaging in higher amounts of light-intensity physical activity.

24-hour Movement Behaviors, Body Composition And Cognitive Performance In Adolescents

Erin K. Howie, Marilou D. Shreve, Connie Lamm, Matthew S. Ganio, FACSM. *University of Arkansas, Fayetteville, AR.*
Email: ekhowie@uark.edu

(No relevant relationships reported)

PURPOSE: The purpose of this pilot study was to examine associations between 24-hour movement behaviors (sleep, physical activity, and sedentary time), body composition, and executive functions in adolescents with and without obesity. **METHODS:** Adolescents between the ages of 12 and 18 years (n=30, n=14 girls, mean age=14.9 years) wore accelerometers on the hip for 24-hours to measure total night sleep time, minutes of moderate-to-vigorous physical activity (MVPA), and percentage of waking wear in sedentary activity. Body composition including lean mass, fat mass and bone mineral density was measured using dual-energy x-ray absorptiometry. Cognitive performance, particularly attention and inhibitory control, was tested using the Go/NoGo task. **RESULTS:** Mean sleep time was 487.2 (SD 80.0) minutes per night, median minutes of moderate-to-vigorous physical activity were 16 (10.2, 25.3 25th to 75th percentiles) minutes per day, and 68.5% (SD 6.95) of waking time was spent in sedentary activity. There were no differences in sleep or sedentary time in adolescents with and without obesity, however, adolescents with obesity participated in less MVPA compared to those without obesity (median 13.4 vs 23.3 minutes per day respectively, p=.024). In linear regression models with all three behaviours as independent variables adjusted for total body mass, sex, and age, total sleep time (minutes/day), but not sleep efficiency, was positively associated with total body percent fat (0.05, 95%CI: 0.002, 0.11, p=.043) and negatively associated with total lean mass (-37.8 grams, 95%CI: -71.7, -4.0, p=.030). Using negative binomial regression adjusted for age and sex, there were no associations of any of the movement

behaviors with accuracy (errors of omission or commission) or reaction times. Body fat percentage (IRR 1.06, 95%CI: 1.01, 1.12), $p=.026$ and total lean mass (kg) (IRR 0.89, 95%CI, 0.80, 0.97, $p=.013$) were associated with omission errors of inattention. **CONCLUSION:** In this sample of adolescents, total sleep time was associated with body fat and lean mass. Body composition was associated with inattention. Novel interventions that integrate sleep strategies to improve health and cognitive performance in adolescents should be explored.

What Affects the Sleep of Youth? Results from the 2017 Youth Risk Behavior Surveillance Survey

Hai Yan, *University of Illinois at Urbana Champaign, Champaign, IL.* (Sponsor: Weimo Zhu, FACSM)
 Email: haiyan2@illinois.edu
 (No relevant relationships reported)

Background/Purpose: Sleep plays a critical role in metabolism, memory, learning, and other vital functions. Sleep deprivation is associated with an increased risk of developing diabetes, cardiovascular disease, and many other complications. However, evidence has shown that youth are sleeping less than before. Understanding what influences sleep time is extremely important in designing interventions to help to improve the sleep time and sleep quality of youth. The aim of this study was to examine the influencing factors of sleep for youth age from 12 to 18 yr.

Methods: The data were derived from the 2017 Youth Risk Behavior Surveillance System (YRBSS) and a total of 14,765 youth responded to the survey. Descriptive analysis was used to explore the sleep patterns and Pearson's Chi-squared test was applied to examine the gender and race/ethnicity difference. Logistic regression was implemented to explore the impact of health-related behaviors such as physical activity (PA), playing video games (GAME), smoking (SMOKE), and drinking alcohol (DRINK) on sleep time.

Result: Only 23.88% female and 25.78% male reported having 8 or more hours of sleep on an average school night. Significant disparities exist among demographic subgroups of youth defined by gender ($\chi^2 = 5.70$, $p = 0.02$) and race ($\chi^2 = 30.13$, $p = 0.00$). Results of logistic regression were displayed in the table below:

| Factor | | Odds Ratio | SE | <i>p</i> |
|---------|------------------|------------|------|----------|
| Age | | 0.79 | 0.02 | 0.00 |
| Gender | Male | 1.08 | 0.06 | 0.14 |
| Race | Black | 0.94 | 0.08 | 0.72 |
| | White | 1.14 | 0.07 | 0.03 |
| | Asian | 0.62 | 0.08 | 0.00 |
| | Pacific Islander | 0.58 | 0.20 | 0.11 |
| | Native American | 0.69 | 0.22 | 0.24 |
| Obesity | Non-obese | 1.22 | 0.10 | 0.01 |
| PA | | 1.04 | 0.01 | 0.00 |
| GAME | | 0.91 | 0.01 | 0.00 |
| SMOKE | | 1.07 | 0.03 | 0.02 |
| DRINK | | 0.83 | 0.03 | 0.00 |

Comparing with Hispanic youth, White youth tended to have longer sleep time ($p = 0.03$) while Asian youth had significantly less sleep time ($p = 0.00$). Youth who were non-obese and physically active were more likely to have 8-hour sleep, while those who played video games and consumed alcohol tended to sleep less.

Conclusion: About 75% of the youth did not meet the 8-hour sleep needs and promote physical activity and reduce alcohol consumption may help to increase the sleep time of youth.

Role Of Gender In Anti-oxidant Response To A Bout Of Aerobic Exercise In Healthy Adults

Anam Ahmad¹, Zoe Morris¹, Lisa M.K. Chin¹, Rebekah Feng¹, Leo Saligan¹, Leighton Chan¹, Randall Keyser, FACSM².
¹National Institutes of Health, Bethesda, MD. ²George Mason University, Fairfax, VA.
Email: anam.ahmad@nih.gov
(No relevant relationships reported)

Aerobic exercise acutely increases the production of reactive oxygen species (ROS), which creates an imbalance between free radicals and the body's antioxidant defenses, resulting in increased oxidative stress. Oxidative stress levels are reportedly higher in males compared to females, however there is limited knowledge regarding the role of gender in the antioxidant response following an acute bout of aerobic exercise.

Purpose: To determine whether changes in serum antioxidant levels after an acute aerobic exercise bout differed between genders. **Methods:** The study comprised of 15 healthy adults (9 females, 6 males; age 27±8 years; BMI 24±3 kg/m²) enrolled in the NIH Fatigue in Healthy Individuals Protocol (NCT00888563). During the first visit, subjects completed a treadmill cardiopulmonary exercise test (CPET) to volitional exhaustion. On a separate visit, subjects performed a vigorous-intensity continuous work rate (WR) test, to volitional exhaustion on the treadmill. Serum samples were collected before and immediately after the vigorous exercise bout. A Human Oxidative Stress Multiplex panel was used to determine serum peroxidase (PRX2) and catalase levels. Student's t-tests were performed between genders for WR and antioxidant levels. **Results:** Males performed vigorous-intensity exercise at a higher WR than females (p<0.0001). No difference was found in baseline PRX2 and catalase levels between males and females. Relative change in PRX2 (+32% in males; -17% in females) and catalase (+18% in males; -11% in females) was different between genders after a vigorous bout of aerobic exercise (p=0.0136, p=0.0344, respectively). This difference became insignificant when WR was accounted for. **Conclusion:** This study suggests that higher levels of oxidative stress in males may be explained by higher work rates. However, response to exercise-induced oxidative stress demonstrated that males (6 of 6) increased anti-oxidant levels, while females (8 out of 9) showed decreased levels. Previous studies have suggested that gender differences in oxidative stress may be related to an increased production of ROS by NADPH-oxidase in males, or antioxidant properties of estrogen which may assist in minimizing oxidative stress in females.

Email: ltjansen@uark.edu
(No relevant relationships reported)

Muscle atrophy is a comorbidity in many disease conditions, contributing to accelerated disease progression/terminal outcomes. Muscle wasting results alterations in the ratio of protein synthesis to degradation, with wasting conditions favoring degradation. Atrophic conditions differentially affect discrete muscle types. For many diseases, onset and progression of muscle atrophy presents differently between muscle fiber types and sex; **PURPOSE:** To assess gene content outcomes of three established anabolic regulators Pgc-1α4, IGF-1, and Deptor, in female and male mice during initiation and progression of disuse atrophy across multiple fiber types. **METHODS:** 100 female and male C57BL/6J mice were hindlimb unloaded for 0h, 24h, 48, 72 and 168h, to induce muscle atrophy. At assigned endpoints, soleus and gastrocnemius muscles were excised and processed for mRNA analysis of Pgc-1α4, IGF-1, and Deptor using RT-PCR. Data were analyzed by one-way ANOVA within

each sex, α=0.05. Pre-planned contrast comparisons determined sex differences at each time point, α=0.01. **RESULTS:** Soleus and gastrocnemius masses presented lower at 24h in female (-11.8%, -9%; p<0.05) and 48h in male (-16%, -13%; p<0.05) compared to control. In predominantly type I soleus, Pgc-1α4 mRNA content showed a decline from control across time in females, while spiking >9, >6-fold in males at 72h and 168h (p<0.05). In contrast, IGF-1 showed higher content in females at 72h and 168h (+77%, +27%; p<0.05) than males. In gastrocnemius, a more mixed fiber type, Pgc-1α4 content was 3-fold higher in females at 24h (p<0.05). Female IGF-1 content was significantly elevated compared to male at 72h (p<0.05). Deptor content in gastrocnemius was >3-fold from baseline at 24h in females and >2-fold from baseline at 48h in males (p<0.05) depicting the only mRNA content change aligning with the observed time course for appearance of loss in muscle mass. **CONCLUSION:** Anabolic regulator responses to atrophic stimuli differ across sex, muscle tissue and time course of muscle atrophy. These early findings could suggest Deptor as a novel therapeutic target to ameliorate muscle wasting conditions.

Similar Central and Peripheral Fatigue in Men and Women after Running

Beth W. Glace, Ian J. Kremenec, Malachy P. McHugh, FACSM. *Nicholas Inst. of Sports Med. and Athletic Trauma, Lenox Hill Hosp., New York, NY.* (Sponsor: Malachy P. McHugh, FACSM)
Email: lb@nismat.org
(No relevant relationships reported)

PURPOSE: Women may be less fatiguable than men during prolonged endurance exercise. There are a paucity of studies which have compared fatigue in both sexes after moderately long duration running typical of marathon-type training. **METHODS:** We compared sex differences in peripheral and central fatigue in 8 men and 6 premenopausal women runners. Volunteers [38±2 and 32±2 yrs, p=0.017; VO_{2peak} 59±3 and 54±3, ml/kg/min, p=0.202, men vs women respectively] ate a standardized breakfast [6 Kcal/kg] 90 minutes prior to commencing testing. Water was provided at 1% of body mass/hr, during a 2-hr run at their ventilatory threshold [-65% VO_{2peak}], followed by a self-paced 2-km time trial. RPE and respiratory measures were determined every 20 minutes. Strength was tested in a semi-reclined position [75° hip flexion, to facilitate femoral nerve stimulation] pre-exercise, after the 2-hr run and post-time trial as follows: voluntary isometric quad strength was measured on the Biodex with the knee flexed 60°, and with superimposed peripheral magnetic stimulation [PMS] of the femoral nerve to determine central activation [CAR]. PMS was also applied in a 3-second pulse train on a relaxed muscle to measure peripheral fatigue. Changes in strength and in metabolic measures were analyzed with repeated measures ANOVA.

RESULTS: Following running, voluntary strength declined by ~16% in both sexes [effect of time p<0.001; sex X time p=0.206]. CAR also decreased in both men and women [effect of time p=0.020, time X sex p=0.762]. PMS-stimulated forces, our measure of peripheral fatigue, were unchanged after running: there was no effect of time [p=0.10] in men or women [time X sex, p=0.322]. Substrate use and RPEs did not differ between sexes.

CONCLUSIONS: We found that both sexes fatigued similarly after a 2-hr run plus a 2-km time trial, and that all of the fatigue was central in nature. While women may be more fatigue-resistant than men, those differences might not be apparent until a greater duration of running is engaged in, e.g. ultramarathon distances.

1590 Board #4 May 30 1:30 PM - 3:30 PM
The Effects Of Swimming On Bone Density In Female Collegiate Swimmers.

Margaret Miller, Sarah Kojetin, Lesley M. Scibora. *University of St. Thomas, St. Paul, MN.*
(No relevant relationships reported)

Swimming provides numerous health benefits, but as a non-weight bearing activity research suggests it provides no constructive benefits on bone strength at dual energy x-ray absorptiometry (DXA)-measured hip and lumbar spine sites. However, little research has focused on skeletal sites stressed during swimming such as the upper arm. **Purpose:** To determine potential site-specific bone strength adaptations at the humerus among collegiate swimmers compared to sedentary controls. **Methods:**

Bone geometry and strength were assessed by peripheral quantitative computed tomography (pQCT) in ten collegiate female swimmers (BMI 23 kg/m²; mean 13.9±1.5 pool hours/week) and ten sedentary controls (BMI 24 kg/m²; <150 minutes/week of physical activity) ages 18-23 years. Total volumetric bone mineral density (vBMD, mg/mm³) and total bone area (ToA, mm²) were assessed at the distal (4%) tibia. Cortical bone area (CoA, mm²), cortical density (vBMD), cortical thickness

(CoTh, mm), bone bending strength (polar strength-strain index (SSIp, mm³) were measured at the midshaft (66%) tibia, humerus (50%), and radius 33% sites. Using DXA areal BMD (g/cm²) was assessed at the hip, humerus and radius sites.

Results:

There were no significant between-group differences in DXA outcomes at any site. PQCT-derived outcomes are presented in Table 1. At the 66% tibia site the control group had a 14.8% greater CoA and 6.1% greater CoD compared to swimmers (both $p < 0.05$). However, no significant bone strength differences were found at the humerus, radius, or distal tibia sites.

Table 1: pQCT-derived Outcomes.

| | Swim | Control | Significance (p<0.05) |
|--|--------------|--------------|-----------------------|
| Radius 33% | | | |
| Cortical Area (CoA, mm ²) | 78.4±3.4 | 85.0±3.6 | 0.215 |
| Cortical Density (vBMD, mg/cm ³) | 1191.3±8.6 | 1163.6±9.1 | 0.051 |
| Cortical Thickness (CoTh, mm) | 3.1±0.1 | 3.5±0.1 | 0.097 |
| SSIp (mg/mm ⁴) | 215.4±13.2 | 227.0±14.0 | 0.574 |
| Humerus 50% | | | |
| Cortical Area (CoA, mm ²) | 178.0±6.8 | 172.5±7.2 | 0.596 |
| Cortical Density (vBMD, mg/cm ³) | 1170.5±12.3 | 1173.0±13.0 | 0.890 |
| Cortical Thickness (CoTh, mm) | 4.1±0.1 | 4.0±0.2 | 0.856 |
| SSIp (mg/mm ⁴) | 886.0±55.2 | 868.5±58.4 | 0.835 |
| Tibia 66% | | | |
| Cortical Area (CoA, mm ²) | 270.1±13.5 | 313.2±14.2 | 0.045 |
| Cortical Density (vBMD, mg/cm ³) | 1074.4±8.0 | 1143.1±8.4 | 0.000 |
| Cortical Thickness (CoTh, mm) | 4.6±0.2 | 5.0±0.2 | 0.179 |
| SSIp (mg/mm ⁴) | 2121.5±134.2 | 2178.6±134.3 | 0.764 |
| Tibia 4% | | | |
| Total Area (ToA, mm ²) | 139.4±25.4 | 141.6±26.9 | 0.953 |
| Total Density (vBMD, mg/cm ³) | 507.0±35.5 | 538.1±38.5 | 0.571 |

Conclusion:

Our results showed that swimming does not appear to improve bone microarchitecture or strength, even at loaded sites such as the humerus. This data suggests that swimming should be supplemented with weight-bearing and resistance exercises to preserve bone strength. Future research should investigate whether site-specific bone adaptations occur at skeletal sites not yet measured.

Sex Differences in Recovery from Extreme and Severe Intensity Exercise

Andrew M. Alexander, Shane M. Hammer, Kaylin D. Didier, Lillie M. Huckaby, Camryn N. Webster, Thomas J. Barstow, FACSM. *Kansas State University, Manhattan, KS.*
 Email: andrewa06@ksu.edu

(No relevant relationships reported)

Previous protocols investigating neuromuscular fatigue have typically discarded the first 2 of 6 electrical stimulation sets in recovery and have reported the average of the remaining force values. However, our lab has recently shown that central (as measured by maximal voluntary contraction force, MVC; and voluntary activation, VA) and peripheral fatigue (as measured by potentiated twitch force, Q_{tw}) had significantly recovered within 90 s following extreme intensity exercise and would otherwise be missed using contemporary protocols. **PURPOSE:** The purpose of this study was to test the hypothesis that MVC, VA, and Q_{tw} immediately following task failure of extreme intensity exercise would be significantly lower than those measured 2 min into recovery in both men and women, while remaining suppressed following severe exercise.

METHODS: Two men (26 ± 5 yrs; 109 ± 9 kg; 179 ± 1 cm) and two women (23 ± 2 yrs; 55 ± 3 kg; 159 ± 1 cm) performed 2 intermittent isometric knee extension tests to exhaustion at 40% (severe intensity) and 70% (extreme intensity) MVC in random order. Neuromuscular measurements were made every 30 s beginning immediately

after task failure for a total of 6 sets. The last two MVC, VA, and Q_{tw} were averaged and compared to the first measurement immediately following task failure using paired t-tests.

RESULTS: Q_{tw} and MVC significantly decreased following severe and extreme exercise ($p < 0.01$). However, VA was not different across severe or extreme exercise. VA was not different across recovery following severe or extreme exercise. MVC was not different following severe, however, had increased following extreme ($p = 0.02$) exercise. Q_{tw} was significantly recovered after severe ($p < 0.01$) and extreme ($p < 0.02$) exercise. Further, qualitative analysis suggests women may be able to recover MVC and Q_{tw} faster than men following extreme exercise, while these differences may not be evident following severe exercise.

CONCLUSIONS: These current data suggest central fatigue (as measured by VA) does not significantly impact exercise tolerance during severe or extreme exercise. Importantly, these data suggest that the measurements typically used to represent the condition of the muscle are taken too far post-exercise such that much of the recovery of the muscle has already occurred, especially following extreme exercise.

(No relevant relationships reported)

Arduous training can result in an energy deficit, the consequences of which include impaired bone health and increased stress fracture risk, as determined by acute interventional or cross-sectional studies. Women are more prone to stress fractures than men, and possibly more susceptible to metabolic perturbations associated with reduced energy availability. No study has longitudinally examined the effect of a prolonged severe energy deficit on bone in women. **Purpose:** To investigate the skeletal effects of the first all-female trans-Antarctic expedition. **Methods:** Six women (mean ± SD, age 32 ± 3 years, height 1.72 ± 0.07 m, body mass 72.1 ± 3.8 kg) each hauled an 80 kg sledge over 1700 km in 61 days from coast-to-coast across the Antarctic. Whole-body areal bone mineral density (aBMD) (dual energy x-ray absorptiometry) and tibial volumetric BMD (vBMD), geometry, microarchitecture and mechanical properties (high-resolution peripheral quantitative computed tomography) were assessed 39 days before (pre-expedition) and 15 days after (post-expedition) the expedition. Serum and plasma markers of bone turnover were assessed pre-expedition, and 4 and 15 days after the expedition. **Results:** There were reductions in trunk (-2.6%), ribs (-5.0%) and spine (-3.4%) aBMD from pre- to post-expedition (all $P \leq 0.046$); arms, legs, pelvis and total body aBMD were not different (all $P \geq 0.075$). Tibial vBMD, geometry, microarchitecture and mechanical properties at the distal metaphysis (4% site) and diaphysis (30% site) were not different between pre- and post-expedition (all $P \geq 0.082$). Bone-specific alkaline phosphatase was higher 15 days post- than 4 days post-expedition (18.0 vs 16.3 μg·l⁻¹, respectively, $P = 0.028$). Total 25(OH)D decreased markedly from pre- to 4 days post-expedition (112 vs 76 nmol·l⁻¹, respectively, $P = 0.008$). Sclerostin, procollagen 1 N-terminal propeptide, C-telopeptide cross-links of type 1 collagen and adjusted calcium were unchanged (all $P \geq 0.154$). **Conclusion:** The deleterious effect of the expedition on aBMD may be due to indirect and direct effects of prolonged energy deficit on bone turnover. We propose that weight-bearing exercise was protective against the effects of low energy availability on tibial vBMD, geometry, microarchitecture and strength.

BMI as a Predictor of Bone Mineral Density Among Premenopausal Women

Stephanie M. Otto. *Gustavus Adolphus College, St. Peter, MN.*
 Email: sotto@gustavus.edu

(No relevant relationships reported)

Bone mineral density is an important women's health topic. Osteoporosis is one of the most common bone diseases and is expected to affect more than 61 million people in the U.S. by the year 2020. According to the International Osteoporosis Foundation, low body weight is associated with greater bone loss and increased fracture risk. Body Mass Index is a commonly assessed physical characteristic which has also been linked with bone health and could be a useful tool in osteoporosis prevention (Asomaning, Bertone-Johnson, Philip, Hooven, Pekow, 2006). Much of the existing research has historically focused on postmenopausal groups. **PURPOSE:** The purpose of this study was to assess whether BMI was a significant predictor of bone mineral density (BMD) among a group of premenopausal women. **METHODS:** A total of 42 premenopausal women (38.69 ± 7.95 years) participated in this study. Anthropometric

data were collected and BMD (g/cm²) was measured at the hips and lumbar spine with a Hologic dual energy x-ray absorptiometry (DEXA) machine. **RESULTS:** Significant correlations ($p < .05$) were found between lumbar spine and hip BMD, and BMI ($r = .33, p = .031$), ($r = .35, p = .022$) respectively. Regression analysis confirmed that BMI was a statistically significant predictor of BMD for both the hips $F(1,41) = 5.71, MSE = .02, p = .022, Adj. R^2 = .10$ and lumbar spine $F(1,41) = 5.02, MSE = .03, p = .031, Adj. R^2 = .09$. **CONCLUSIONS:** Among this group of premenopausal women, BMI was positively correlated with, as well as being a significant predictor of BMD at the hips and lumbar spine. Medical and fitness professionals may find it useful to advise clients about the importance of having a healthy BMI value not only for the management and prevention of obesity but also for healthy bone mineral density and osteoporosis prevention. Future research might establish more clear guidelines for the use of BMI as it relates to osteoporosis risk among men and women. IRB# 1213-0223

Dynapenic Abdominal Obesity And The Incidence Of Falls In Older Women: An 18-month Follow-up Study
 André B. Gadelha¹, Juscelia C. Pereira², Aparecido P. Ferreira¹, Martim Bottaro³, Silvia G. R. Neri³, Ricardo M. Lima³.
¹Faculdade ICESP, Brasília, Brazil. ²Federal Institute of Education of Triângulo Mineiro, Paracatu, Brazil. ³University of Brasília, Brasília, Brazil.
 Email: andrebonadias@gmail.com
 (No relevant relationships reported)

PURPOSE: To assess the association between dynapenic abdominal obesity (DAO) and the incidence of falls over 18 months in older community-dwelling women.
METHODS: A total of 188 older women (67.97±6.02 years; 27.70kg/m²) underwent waist circumference (WC) measurement and had handgrip strength assessed at the dominant arm using a hydraulic dynamometer. Dynapenia was classified using the lower tertile of handgrip strength as cut-off value (20.7kgf), while obesity was considered as a WC > 88cm. DAO was the combination of both aforementioned criteria. Therefore, volunteers were divided into 4 groups: Eutrophic, Dynapenic, Obese, and DAO. Participants were tracked by phone calls for ascertainment of falls during a follow-up period of 18 months. Chi-square and modified Poisson regressions were conducted.
RESULTS: Proportions of each classification were 17.6%, 46.8%, 13.3%, and 22.3% for eutrophic, obese, dynapenic, and DAO, respectively. The incidence of falls over 18-month follow-up period was 24.5%. Thus, the proportion of fallers regarding each classification were 12.1%, 12%, 25%, and 40.5% for eutrophic, dynapenic, obese, and DAO, respectively ($X^2=10.662; p=0.014$). Noteworthy, only DAO was consistently associated with a higher risk of falls (relative risk: 3.339; 95% CI: 1.242-8.979), even after adjustments for age, body mass index, physical activity level, regular use of four or more medications, reduced peripheral sensation, presence of two or more chronic diseases, and history of lower-limbs pain.
CONCLUSIONS: These results provide support for the concept that the combination of abdominal obesity and dynapenia has clinical implications and might be an useful supplement to other routine falls risk assessment tools. These relationships were stronger than obesity or dynapenia alone.

D-09 Thematic Poster - Physical Activity & Behavioral Science during Pregnancy and Motherhood
 Thursday, May 30, 2019, 1:30 PM - 3:30 PM

Baseline Correlates Of Sedentary Behavior In The Health In Pregnancy And Postpartum (HIPP) Study
 Sara Wilcox, FACSM¹, Jihong Liu¹, Brent Hutto¹, Ellen Wingard¹, Gabrielle Turner-McGrievy¹, Judith Burgis², Alycia Boutte¹, Lara Schneider¹. ¹University of South Carolina, Columbia, SC. ²University of South Carolina School of Medicine, Columbia, SC.
 Email: wilcox@mailbox.sc.edu
 (No relevant relationships reported)

Despite the benefits of physical activity and the potential risks of sedentary behavior (SB), few studies have examined sensor-measured SB in pregnant women.
PURPOSE: To report SB in a sample of women in early pregnancy and examine associations with sociodemographic and psychological variables.
METHODS: We analyzed baseline data from the HIPP trial, a RCT enrolling SC women who are <16 wks gestation, overweight or obese, white or African American, 18 to 44 yrs old, and without exercise contraindications. Participants wore a SenseWear armband ≥ 20 hrs/d for ≥ 5 days (including ≥ 1 weekend day). SB was defined as MET values < 1.5. Total time in non-sleep SB, # of SB bouts ≥ 30 min, and total time in SB bouts ≥ 30 min were calculated. Differences in SB by parity, race, education, marital status, and employment (t-tests), as well as BMI, age, depressive symptoms, perceived stress, and satisfaction with body function and appearance (Pearson rs) were tested.
RESULTS: To date, participants (n=202) randomized with usable armband data are 12±2 wks gestation, 42% nulliparous, 30±5 yrs old, 45% African American, 53% obese, 59% college educated, 67% married, and 61% employed full-time. On average, participants spent 12.0±1.7 hrs/d in non-sleep SB, representing 51% of total wear time and 75% of wake time. They averaged 6.2±1.9 SB bouts/d that were ≥ 30 min and spent 5.7±2.3 hrs/d in these bouts. Total SB time, SB time in ≥ 30 min bouts, and # of SB bouts ≥ 30 min were greater in African American (p<.0001), obese (p<.0001), and unmarried (p<.01) women, and in those without a college degree (total time & # bouts, p<.05). All three SB variables were strongly and positively associated with BMI (rs = .48 to .53, p<.0001). SB time in ≥ 30 min bouts and # of SB bouts ≥ 30 min were positively associated with depressive symptoms (rs = .15, p<.05) and negatively associated with satisfaction with body function (rs = -.17 p<.05). SB variables did not differ by parity, employment, age, perceived stress, or satisfaction with body appearance.
CONCLUSIONS: Total SB time, SB time in ≥ 30 min bouts, and # of SB bouts ≥ 30 min appear to be high in early pregnancy, with these behaviors of particular concern in several demographic subgroups. SB was also related to more negative psychological experiences. Interventions to target SB could benefit pregnant women. Funded by NIH/NICHD.

Overweight and obese pregnant women may benefit from physical activity (PA) in pregnancy, yet few studies have examined sensor-measured PA in pregnancy.
PURPOSE: To evaluate sensor-measured PA in overweight and obese pregnant women and its sociodemographic and psychological correlates.
METHODS: We analyzed baseline data from an ongoing behavioral lifestyle intervention trial in Columbia, SC (n=202). PA was measured with the SenseWear Armband; compliance was set at wearing for 20+ hrs/d, 5+ days (including 1+ weekend day). PA measures were daily duration of light PA (LPA), moderate to

THURSDAY, MAY 30, 2019

vigorous PA (MVPA), daily steps, and meeting MVPA guidelines (≥ 150 min/wk of MVPA in ≥ 10 min bouts). PA was presented as median (interquartile range). Subgroup differences in medians were examined with quantile regression models. Correlations of PA measures with perceived stress, depressive symptoms, PA social support, PA self-efficacy, and PA self-regulation were studied. A logistic regression model was used to examine correlates of meeting MVPA guidelines.

RESULTS: Participants (mean of 12.4 weeks gestation) had a median of 203 (154, 258) min/d LPA, 34 (20, 49) min/d MVPA, and 4,870 (3768, 6590) steps/d. LPA, MVPA, and steps were lower in African American and obese women ($p < .05$). LPA was lower in nulliparous women ($p < .05$). Participants with less than college education had lower MVPA and steps ($p < 0.05$). Further, LPA, MVPA, and steps were positively associated with PA self-efficacy (r 's ranging from 0.13 to 0.16, $p \leq .05$) and PA goal setting (r 's ranging from 0.16 to 0.21, $p < .05$). MVPA was positively associated with PA planning ($r = 0.16$, $p < .05$). Only 10.4% of participants met MVPA guidelines, which was more prevalent in white (17.1%) vs African American (2.2%) women and in overweight (17.9%) vs obese women (3.7%) ($p < 0.05$). After adjusting for age, parity, and marital status, white women and overweight women had higher odds of meeting MVPA recommendation than their counterparts: white: 5.8 (1.2-28.6); overweight: 5.2 (1.6, 16.9).

CONCLUSION: Sensor-measured PA was low in overweight and obese pregnant women in early pregnancy with significant differences by race, education, parity, and pre-pregnancy weight status. Programs targeting PA are needed for this population. Funded by NIH/NICHD.

The Association Between Type and Intensity of Physical Activity on Cortisol Levels Among Low-Income, Ethnic-Minority Mothers

Wendy Miranda, Guido Urizar. *California State University, Long Beach, Long Beach, CA.*

Email: wnymiranda@gmail.com

(No relevant relationships reported)

Physical activity has been linked to many health benefits such as reduced cardiovascular disease risk. Furthermore, the health benefits of intensity and type of activity varies (e.g., vigorous aerobic activity reducing cardiovascular risk more than moderate). During parenthood, mothers can experience increased levels of stress, such as the stress hormone cortisol, and are also less likely to engage in physical activity compared to other populations. However, few studies have focused on mothers and on the impact of type and intensity of physical activity on their cortisol levels. **PURPOSE:** The current pilot study examined whether different types and intensities of physical activity (walking, housework, fitness, recreational, occupational, and miscellaneous activity; moderate and vigorous activity) were associated with cortisol patterns among 30 low-income, ethnic-minority mothers (57% average annual income $< \$20,000$; 53% Latina) and whether this association varied by the number of children the mothers had. **METHODS:** The majority of our sample were sedentary with only 3% meeting the national recommendations of daily aerobic activity (> 30 minutes or more of moderate to vigorous aerobic activity). Mothers completed an activity log of their physical activity over three days. During this three-day period, mothers also collected their saliva at four times on one collection day (upon waking time, 30 minutes after waking, 4pm, and 8pm) to assess for cortisol levels. **RESULTS:** Multiple regression analyses found that mothers who engaged in greater minutes of vigorous recreational activity had higher cortisol levels, but only among mothers with more children ($\beta = 1.65$, $t(21) = 2.40$, $p = 0.03$). Additionally, mothers who engaged in greater minutes of moderate or vigorous miscellaneous (e.g., heavy lifting) activity had higher cortisol levels, but only among mothers with more children ($\beta = 6.93$, $t(21) = 3.12$, $p = 0.01$). No significant association was found with other types of activity. **CONCLUSION:** Despite the benefits of physical activity, results suggest that low-income, ethnic minority mothers with more children are not receiving these benefits and that number of children may be a stressor. Future research should consider family size when designing and implementing physical activity interventions in this population.

1599 Board #4 May 30 1:30 PM - 3:30 PM

Self-regulation Capacity Of Low-income Mothers In Community-based Nutrition Program

Alyssa Abreu¹, Eric J. Jones¹, Dustin Joubert¹, Mark D. Farries².

¹Stephen F. Austin State University, Nacogdoches, TX. ²Texas A&M AgriLife Extension, College Station, TX. (Sponsor: Thomas J. Pujol, FACSM)

(No relevant relationships reported)

Diet is strongly associated with many risk factors for chronic disease. Educational programs such as the Expanded Food and Nutrition Education Program (EFNEP) are designed to improve dietary behaviors among low-income populations. Although EFNEP has seen improvements, they do not yet meet recommendations. Self-

regulation is the process of guiding thoughts, feelings, and behaviors to stay in line with perceived goals. Previous studies have been successful in eliciting behavior change when improving self-regulation in conjunction with dietary education.

PURPOSE: The purpose of this study was to examine self-regulation in EFNEP participants and its relationship to participants change in dietary behavior.

METHODS: All participants were currently enrolled in EFNEP and were asked to complete an additional self-regulation survey. This survey included five questions on a Likert scale from 1-5, with 5 indicating high self-regulation. These were averaged to assess overall self-regulation capacity pre- and post-program. Fruit and vegetable intake were measured using EFNEP's current diet-recall survey.

RESULTS: On average, the participants had low levels of self-regulation both pre- and post-intervention (2.74 ± 0.71 and 2.59 ± 0.78 , respectively). Regarding vegetable intake, there was no statistically significant change from pre- to post-program (1.51 ± 1.36 and 1.42 ± 1.32 cups, respectively). However, there was a statistically significant difference regarding fruit intake, increasing from 0.86 ± 0.94 to 1.39 ± 1.39 cups per day. Neither fruit nor vegetables increased to MyPlate recommendations.

CONCLUSIONS: Participants self-regulation capacity was on average low, and did not increase from pre- to post-program. Results also indicate that fruit and vegetable intake did not reach MyPlate recommendations. From these results, we can conclude that self-regulation training may be a necessary supplement to the program to see improvements in the participants dietary behavior.

1600 Board #5 May 30 1:30 PM - 3:30 PM

Physical Activity Does Not Moderate the Relationship Between Postpartum Body Satisfaction and Depressive Symptoms

Faith C. LaFramboise, Rebecca A. Schlaff, Samantha J. Deere, Meghan Baruth. *Saginaw Valley State University, University Center, MI.*

(No relevant relationships reported)

Postpartum depressive symptoms (PDS) are common among U.S. women and may be related to postpartum body image satisfaction (BIS). The effect of postpartum moderate to vigorous intensity physical activity (MVPA) on this relationship is less studied. **PURPOSE:** To examine the relationship between postpartum BIS and PDS, and to examine whether MVPA moderates this relationship. **METHODS:** Non-pregnant women who were ≤ 12 months postpartum and ≥ 18 years of age completed an online survey. Participants ($n = 256$) self-reported 1) demographics, 2) pre-pregnancy height and weight, 3) current BIS via Body Attitudes Questionnaire (BAQ; six subscales: attractiveness, feeling fat, disparagement, strength and fitness, salience of weight/shape, and lower body fat), 4) PDS via the 10-item Center for Epidemiologic Depression Scale (CES-D), and 5) postpartum MVPA. Relationships between BAQ subscales and PDS were examined using linear regression, controlling for months postpartum. MVPA and the BAQ x MVPA interaction were added to the model to examine the moderating effects of MVPA on the relationship between postpartum BIS and PDS. An alpha level of 0.05 was used to determine statistical significance. **RESULTS:** On average, participants were 30.3 ± 3.9 years of age and 5.6 ± 3.8 months postpartum. A majority of the sample were Caucasian (96.1%), married (89.9%), and college graduates (75.2%). Four BAQ subscales were positively related to PDS (disparagement: $p < 0.0001$, feeling fat: $p < 0.0001$, salience: $p < 0.0001$ and lower body fatness: $p = 0.005$); two were inversely related (attractiveness: $p = 0.0007$ and strength and fitness: $p = 0.003$). MVPA did not moderate the relationship between BIS and PDS (BAQ subscale x MVPA interactions: attractiveness: $p = 0.7998$, disparagement: $p = 0.8842$, feeling fat: $p = 0.4515$, salience: $p = 0.1311$, lower body fatness: $p = 0.9376$, and strength and fitness: $p = 0.7429$). **CONCLUSION:** Postpartum BIS may be a significant factor that predicts PDS; however, our findings indicate that MVPA may not moderate this relationship. Future intervention research should include strategies that promote positive body image during the postpartum period. Although not a moderator, efforts aimed at promoting PA should continue, as it has numerous other benefits to pregnant and postpartum women.

1601 Board #6 May 30 1:30 PM - 3:30 PM

Impact of Weight Related Variables on Postpartum Depressive Symptoms

Samantha J. Deere, Meghan Baruth, Rebecca A. Schlaff. *Saginaw Valley State University, University Center, MI.*

(No relevant relationships reported)

Postpartum mental health issues are common, yet predictors are less understood. Pre-pregnancy weight and weight change during pregnancy through the postpartum period may be associated with postpartum mental health issues. **PURPOSE:** To investigate the associations between postpartum depressive symptoms and 1) pre-pregnancy body mass index (BMI), 2) weight gain during pregnancy, 3) weight loss at 6 months postpartum, and 4) postpartum weight retention (PPWR). **METHODS:** Women ($n = 323$) who gave birth within the past 12 months completed an online survey assessing demographics, self-reported pre-pregnancy weight and height (to calculate pre-pregnancy BMI), weight gain during pregnancy, weight loss at 6 months

postpartum (to calculate weight retention at 6 months), and current weight (to calculate PPWR). The 10-item Centers for Epidemiological Studies Depression Scale (CES-D 10) measured postpartum depressive symptoms. Regression models examined the relationship between postpartum depressive symptoms and 1) pre-pregnancy BMI, 2) weight gain during pregnancy (controlling for pre-pregnancy BMI), 3) weight loss at 6 months postpartum (controlling for weight gain), and 4) PPWR (controlling for months postpartum). **RESULTS:** On average, women were 30.1±3.9 years of age and 5.5±3.7 months postpartum. Mean pre-pregnancy BMI was 27.5±6.8 kg/m², and weight gain was 29.8±14.1 pounds. A majority were Caucasian (97%), married (88%), and college graduates (77%). Results showed a significant, positive relationship between postpartum depressive symptoms and 1) pre-pregnancy BMI (p=0.04) and 2) PPWR (p=0.04). A significant negative relationship was identified between postpartum depressive symptoms and weight loss at 6 months (p=0.01). There was no significant relationship between postpartum depressive symptoms and weight gain during pregnancy (p=0.93). **CONCLUSION:** Women with a higher pre-pregnancy BMI, higher PPWR, and lower weight lost at 6 months postpartum, may be at a greater risk for postpartum depressive symptoms; weight gain during pregnancy was not associated with postpartum depressive symptoms. Understanding factors associated with postpartum depressive symptoms can help develop and implement appropriate screenings/follow-ups and interventions among those at greatest risk.

1602 Board #7 May 30 1:30 PM - 3:30 PM
Joint Influence Of Physical Activity And Quality Of Sleep On Pregnancy - Related Anxiety

Emma K. Wilsie¹, Christopher P. Connolly¹, Zoe Wright Osborn¹, Maria Gartstein¹, Sara Waters². ¹Washington State University, Pullman, WA. ²Washington State University, Vancouver, WA.

(No relevant relationships reported)

Pregnancy-related anxiety (PRA) is experienced by many women, given the physical and psychosocial challenges common during pregnancy and the prospect of childbirth. Some health behaviors, such as physical activity and quality of sleep (QS), are related to decreased PRA, but their joint influence is unclear. **PURPOSE:** We examined the individual and joint influences of physical activity behaviors and QS on PRA among pregnant women at two locations. **METHODS:** Third-trimester pregnant women (N=33) participated in a series of measurements between 28-36 weeks gestational age. Participants answered questions recalling their moderate and vigorous physical activity (min/wk) for pre-pregnancy, in the first and second trimesters, and concurrently. Moderate to vigorous physical activity (MVPA) was calculated for pre-pregnancy and for each trimester. Participants also wore a validated physical activity monitor (Modus StepWatch) for one week, and average steps/day were calculated. QS was evaluated with the Pittsburgh Sleep Quality Index (PSQI), calculating a global score. The Pregnancy Related Anxiety Questionnaire (PRAQ-R) was used to assess women's anxiety regarding childbirth and the health of the baby. Median split was used to categorize PRA as "high" [≥15.0 PRA scale] or "low" [<15.0]. Mann-Whitney U-tests were used to compare the distribution of MVPA for all timepoints, steps/day, and also QS between high and low PRA participants. Hierarchical logistic regression determined the joint influence of MVPA and quality of sleep on PRA. **RESULTS:** Mann-Whitney U-tests showed lower PRA participants had significantly superior third trimester global QS scores [p=0.048]. Likewise, global QS scores were related to increased odds of high PRA [β=1.34, 95% CI: 0.99-1.80]. Average steps/day and self-reported MVPA prior to pregnancy and at all pregnancy timepoints were not related to PRA. Hierarchical analyses did not reveal an interactive effect of steps/day and QS or MVPA and QS on PRA as hypothesized. **CONCLUSIONS:** Lower QS is related to higher PRA during the third trimester of pregnancy. Physical activity was not related to PRA and interactive effects with QS on PRA were not found. Larger samples are needed to confirm these findings.

D-10 Thematic Poster - Physical Activity Interventions in the Modern Age

Thursday, May 30, 2019, 1:30 PM - 3:30 PM

Effects of Four Types of Physical Activity Courses on College Students' Perceived Stress, Well-Being, and Social Support

Zhonghui He¹, SenLin Chen², Weiyun Chen³, Linchen Kong⁴.
¹Peking University, Beijing, China. ²Louisiana State University, Baton Rouge, LA. ³University of Michigan, Ann Arbor, MI.
⁴University of Virginia, Charlottesville, VA.
 Email: hezh@pku.edu.cn

(No relevant relationships reported)

PURPOSE: Physical activity participation is associated with mental health benefits. The primary purpose of this study was to examine the effects of four types of physical activity classes on college students' perceived stress, well-being, and social support. The secondary purpose was to compare effects by gender and year of study. **METHODS:** The sample consisted of 548 college students (Males: n=294; Age: M=20.72 years old) who were voluntarily enrolled in the four types of courses in an academically prestigious university: fitness, team sports, net and individual sports, and Tai-Chi. They responded to validated scales to assess perceived stress (Sheldon Cohen, 1983), well-being (Diener & Biswas-Diener, 2009), and social support (Zimet, Dahlem et al., 1988) at three weeks prior to the start and then in the 15th week of the semester. **RESULTS:** Significant decreases were observed for perceived stress in all groups: fitness group (ΔM=-0.79, p<0.01), team sports group (ΔM = -0.76, p<0.01), net and individual sports group (ΔM= -0.77, p<0.01) and Tai-Chi group (ΔM = -0.57, p<0.01). Females experienced a greater drop in perceived stress than males (ΔM=0.08, p<0.01). Significant increase in well-being was observed in three types of courses led by team sports group (ΔM=1.55, p<0.01) followed by fitness group (ΔM=1.54, p<0.01), and net and individual sports group (ΔM=1.34, p<0.01). Senior students showed greater increase in well-being (ΔM=2.05, p<0.01) than younger students (ΔM=1.16, 1.07 and 0.85, respectively). The net and individual sports groups showed decreased perceived social support by 0.22 (p<0.01), while no changes were observed in other groups. **CONCLUSIONS:** All four types of physical activity courses showed significant effects on perceived stress reduction (especially in female students), while three types of courses showed increase in well-being (especially in seniors). Instructors of net and individual sports courses should increase social processing to increase perceived social support.

1605 Board #2 May 30 1:30 PM - 3:30 PM
The Effects of Peer Health Coaching for Lifestyle Behavior Change Among College Students

Kathryn J. DeShaw, Gregory J. Welk, FACSM. Iowa State University, Ames, IA. (Sponsor: Gregory J. Welk, FACSM)

(No relevant relationships reported)

PURPOSE: The transition from high school to college often leads to poor health decisions such as insufficient physical activity (PA) and poor eating habits. Health coaching (HC) may be an effective strategy to promote adoption and adherence to healthy lifestyle behaviors as well as aiding in accountability for behavior change among new college students. **METHODS:** A sample of 69 Freshmen and Sophomore undergraduate students were recruited from a college campus to receive peer HC sessions (79% female; age 18.6 ± .9; BMI 25.1 ± 5.7). Participants received 4 HC sessions in an 8-week period and were encouraged through motivational interviewing (MI) techniques to work toward self-selected goals focused on either PA, healthy dietary habits (Diet), or stress management (Stress). Changes in each lifestyle outcome were assessed pre and post using established tools (PA with the International Physical Activity Questionnaire Short-Form, diet with the Eating Habits Confidence Survey, and stress levels via the Perceived Stress Scale). **RESULTS:** Three group x time repeated measures ANOVAs were conducted to investigate differences in lifestyle behavior changes based on the selected goal. It was hypothesized that changes would be greatest in students based on the targeted goal (PA: n=37, Diet: n=15, Stress: n=17). Significant main effects of time were observed for all three behaviors with participants having a 21.1% gain in PA (p=0.02), 15.3%

THURSDAY, MAY 30, 2019

decline in dietary habit ($p=0.01$), and 20.4% decline in stress levels ($p=0.01$). There were no significant group by time interactions, indicating that students had similar outcomes regardless of what behavior they were targeting.

CONCLUSIONS: HC seems to be an effective strategy for promoting healthy lifestyles in college students. Students had similar gains in PA and similar declines in stress, regardless of the behavior they reported focusing on. It is not clear why confidence in sticking with dietary changes decreased over time, but this may be due to participants possibly becoming more sensitized to their dietary habits through the HC sessions. Additional research is needed to understand student reactions to peer-led HC in college settings.

1606 Board #3 May 30 1:30 PM - 3:30 PM
Per-protocol Analysis Of BAILAMOS™ Dance Program On Self-reported And Device-assessed Physical Activity In Older Latinos

Guilherme M. Balbim¹, Susan Aguiñaga², Priscilla Vazquez³, Isabela G. Marques⁴, Jaqueline Guzman², Deborah Salvo⁵, David X. Marquez, FACSM¹. ¹University of Illinois at Chicago, Chicago, IL. ²University of Illinois at Urbana-Champaign, Champaign, IL. ³University of California San Diego, San Diego, CA. ⁴University of Victoria, Victoria, BC, Canada. ⁵Washington University in St. Louis, St. Louis, MO. (Sponsor: David X. Marquez, FACSM)
 Email: gbalbi2@uic.edu
 (No relevant relationships reported)

PURPOSE: Test the impact of the BAILAMOS™ dance program on PA levels in older Latinos.

METHODS: Older Latino adults ($n=333$; $M_{age}=64.89\pm7.08$) were randomized into a dance ($n=167$) or health education (HE) ($n=166$) group. For purposes of per-protocol analysis, participants with attendance $\geq 75\%$ in dance and HE classes, respectively, were included. The final analytic sample was 145 participants (dance = 63, HE = 82). The dance group participated in four months of Latin dancing, two times per week for one hour per session. The HE group participated in classes once per week for two hours per session for four months. Participants completed the CHAMPS PA Questionnaire and wore an ActiGraph™ GT3X+ accelerometer for seven consecutive days on their non-dominant wrist. Data was used if the participant wore for it at least 10 hours/day over three days. Wrist cut-points utilized were proposed by Kamada (2016) (moderate-to-vigorous PA (MVPA) ≥ 7500 counts per minute). We performed a fixed-intercept mixed model ($p < .05$), adjusting for baseline covariates of age, sex, education, income, and health status. Cohen's d effect sizes were computed.

RESULTS: Self-reported MVPA (minutes) increased significantly ($t(1, 120)=3.2$, $p=0.002$) from baseline (Dance: $M=140.81\pm211.35$; HE: $M=115.48\pm182.65$) to month-4 (Dance: $M=29.11\pm20.45$; HE: $M=23.21\pm18.27$), but no group*time interaction was demonstrated ($t(1, 121)=1.33$, $p=0.19$, $d=0.22$). Total leisure-time PA (LTPA) (minutes) increased significantly from baseline (Dance: $M=280.50\pm285.35$; HE: $M=360.71\pm361.05$) to month-4 (Dance: $M=579.72\pm346.10$; HE: $M=500.34\pm483.04$), with significant group*time interaction ($t(1, 121)=2.16$, $p=0.03$, $d=0.33$). Accelerometer-assessed MVPA did not increase significantly from baseline (Dance: $M=24.43\pm22.67$; HE: $M=22.51\pm17.91$) to month-4 (Dance: $M=29.11\pm20.45$; HE: $M=23.21\pm18.27$) and there was no group*time interaction ($t(1, 112)=1.53$, $p=0.13$, $d=0.43$).

CONCLUSIONS: The BAILAMOS® dance program showed a positive impact on self-reported LTPA. This impact was not observed in device-assessed PA, however, there was a moderate effect. Supported by NIH Grant R01NR013151-01.

1607 Board #4 May 30 1:30 PM - 3:30 PM
Reducing the Uncertain Geographic Context Problem in Physical Activity Research: The Houston TRAIN Study

Deborah Salvo¹, Casey P. Durand², Erin E. Dooley³, Ashleigh M. Johnson³, Abiodun Oluyomi⁴, Kelley P. Gabriel, FACSM³, Alexandra E. van den Berg³, Adriana Perez³, Harold W. Kohl III, FACSM³. ¹Washington University in St. Louis, Saint Louis, MO. ²The University of Texas Health Science Center at Houston, Houston, TX. ³The University of Texas Health Science Center at Houston, Austin, TX. ⁴Baylor College of Medicine, Houston, TX.
 Email: dsalvo@wustl.edu
 (No relevant relationships reported)

PURPOSE: The Uncertain Geographic Context Problem (UGCP) arises when studying the effect of static area-level factors (e.g. parks within walking distance from home) on individual-level outcomes, like physical activity. The UGCP is largely due to temporal uncertainty, as people may spend significant portions of the day outside of

the geographic area captured by static spatial measures. The aim of this study was to determine if spatial exposure indicators for physical activity research are improved by including measures of both the home and work neighborhood environments.

METHODS: Baseline data from the Houston TRAIN Study were used ($n=153$). Participant home and work addresses were geocoded, and two spatial exposure indicators were built per location: transit stops within 1.25 Km, and parks within 2.25 Km (counts). A categorical variable was built for each feature, with four levels based on median splits: high access at home & work, high access at home & low access at work, low access at home & high access at work, and low access at both locations. Weekly minutes of moderate to vigorous physical activity (MVPA) were measured with wGT3X-BT Actigraph monitors using Freedson cut-points. Linear regressions estimated the association between the combined 'home plus work' access variables and MVPA. Models were adjusted for sex, age, education, and race/ethnicity.

RESULTS: Relative to the 'low-low' group, having high access to transit in both the home and work neighborhood was associated with 3.7 ± 1.2 additional weekly minutes of MVPA ($p=0.039$). Similarly, those having high access to parks both in their home and work neighborhood had 2.5 ± 1.9 ($p=0.044$) more weekly minutes of MVPA than those with low access in both locations. Having high transit or park access only in one of the two studied neighborhood locations was not significantly associated with MVPA ($p>0.05$).

CONCLUSIONS: When examining the effect of both transport and leisure related urban infrastructure on MVPA, the UGCP is improved by incorporating measures of both the home and work environment. Pending confirmatory studies, our results suggest that approaches exclusively focused on improving the built environment of residential neighborhoods may have limited impact on physical activity. A citywide, systems level approach may be warranted. Supported by NIH R01DK101593

1608 Board #5 May 30 1:30 PM - 3:30 PM
Developing a National Network of Physical Activity Promotion: The Case of Germany

Stefan Peters¹, Hagen Wäsche², Alexander Woll², Gerhard Huber³. ¹DVGS e.V., Hürth-Effern, Germany. ²Karlsruhe Institute of Technology, Karlsruhe, Germany. ³Heidelberg University, Heidelberg, Germany.
 Email: stefan.peters@dvgs.de

Reported Relationships: S. Peters: Salary; Stefan Peters works for the DVGS, which is one of the actors in physical activity promotion that have been a central part of the presented research.

PURPOSE: Physical activity supports the health of human beings of every age group in various ways. However, the worldwide prevalence of physical inactivity is high and many people do not reach the amount of physical activity that is recommended by physical activity guidelines. National Action Plans (NAPS) and Initiatives try to counteract this situation but have not always been successful. To support targeted measures in such NAPs, it is necessary to gain knowledge of relevant actors, professionals groups and multipliers as well as their structural connection. In Germany, an explorative study addressed 2 goals accordingly: (1) the identification of relevant actors, professional groups and multipliers of physical activity promotion, and (2) the analysis of structural relations among these actors as well as the formulation of recommendations for the sustainable development of a national network of physical activity promotion.

METHODS: Qualitative expert interviews, a subsequent network visualization and an analysis for network development were carried out.

RESULTS: It became apparent that the field of actors in the area of physical activity promotion is very heterogeneous and extensive with regard to different forms of actors, sectors of society and administrative levels. Overall, 128 actors were identified, of which 22 actors are considered to hold key positions. Concerning the multipliers, 19 current and 17 potential ones were identified. Structural relations among actors are sparse.

CONCLUSIONS: For carrying out a network development of physical activity promotion, various prerequisites, benefits, and barriers were revealed. Subsequently, recommendations that contribute to the development and effective governance are presented. The study provides a first detailed consideration of the structure of physical activity promotion in Germany and thereby offers a perspective, which can also inform NAPS around the globe.

1609 Board #6 May 30 1:30 PM - 3:30 PM
Exercise Interventions Improve Drug Abstinence at an In-Patient Rehabilitation Center

Emily L. Roessel¹, J. Mark VanNess¹, Mercedes K. Steidley¹, Ryan C. Bain², Courtney D. Jensen¹. ¹University of the Pacific, Stockton, CA. ²Tree House Rehabilitation, Orange County, CA.
 (No relevant relationships reported)

Exercise training likely enhances coping skills and sobriety among patients with substance use disorder. Better examination of the mechanisms producing these changes may help identify more effective interventions. **PURPOSE:** To test the effect

of a vigorous exercise prescription on drug abstinence in voluntary rehabilitation patients. **METHODS:** 25 male subjects in a drug treatment program underwent a 12-week intervention, which included cardiovascular exercise, resistance training, and supportive psychotherapy. Five days a week, subjects were asked to participate in either yoga with mindfulness practices or action-based induction therapy lasting two hours; there was also a 90-minute exercise boot camp. Data collected were exercise adherence, exercise performance, sobriety and relapse rates, and an assessment of emotional coping skills. Chi-squared tests and t-tests compared exercisers to non-exercisers; logistic and linear regressions tested the effect of exercise behavior on measurements of coping and sobriety. **RESULTS:** Subjects had experienced frequent relapse (5±8 episodes) prior to the current admission. Across the sample, 84% were sober on completion of the program, 8% relapsed during treatment, and 36% relapsed after treatment. During the program, 84% exercised regularly, 68% practiced yoga, and 60% followed a disciplined diet. Bench press max improved over the program (39%; $p<0.001$), as did squat max (55%; $p<0.001$) and deadlift max (70%; $p<0.001$). Among patients who exercised regularly, 91% were sober on completion compared to 50% of patients who did not engage in regular exercise ($p=0.043$). Owing to a small sample of patients who relapsed during treatment ($N=2$), the difference in exercisers who relapsed during treatment (5%) and non-exercisers who relapsed (25%) was not significant ($p=0.171$). Following treatment, 29% of exercisers and 75% of non-exercisers relapsed ($p=0.076$). The odds of successfully managing adverse emotional states when they arose increased 20-fold in subjects who exercised regularly ($p=0.036$). Each additional session of yoga per week predicted a 20-day increase in the longest duration of sobriety ($p=0.016$). **CONCLUSION:** Exercise appears to exert a positive effect on drug and alcohol sobriety and coping skills in a population that struggles with frequent relapse.

1610 Board #7 May 30 1:30 PM - 3:30 PM
Effectiveness Of Aerobic Exercise Programs For Health Promotion In Metabolic Syndrome

Felix Morales Palomo, Miguel Ramirez-Jimenez, Juan Fernando Ortega, Ricardo Mora-Rodriguez. *UCLM, Toledo, Spain.*
(No relevant relationships reported)

The effects of different modalities of aerobic training on cardiorespiratory fitness (CRF) and metabolic syndrome (MetS Z-Score) have been previously studied in patients with different cardiometabolic diseases. Continuous (Jonhson et al., 2007) and interval (Mora-Rodriguez et al., 2014) training have been shown to be effective to improve MetS Z-Score. On the other hand, a recent metanalysis suggest that high-intensity interval training (HIIT) may be superior to traditional moderate intensity continuous training (MICT) to improve CRF (Milanovic et al., 2015) even when programs were matched by total work performed. However, to our knowledge no study has compared the capacity of three training modalities on improving MetS Z-Score and CRF in middle-aged MetS patients with low initial levels of CRF.

PURPOSE: To compare the improvement in CRF and MetS- Z-score of 3 modalities of aerobic exercise. **METHODS:** One hundred and twenty-one MetS patients (age, 57±8 yr; weight, 92±15 kg and MetS factors, 4±1 components) with low initial CRF (VO_{2PEAK} , 24.0±5.5 mL·kg⁻¹·min⁻¹) were randomized to undergo one of the following 16 week exercise program: a) 4x4-min high-intensity interval training at 90% of HR_{MAX} (4HIIT group; n = 32), b) 50-min moderate-intensity continuous training at 70% of HR_{MAX} (MICT group; n = 35), c) 10x1-min HIIT at 100% of HR_{MAX} (1HIIT group; n = 32) or d) no exercise control group (CONT; n = 22). We measured the evolution of all five MetS components (i.e., MetS Z-Score) and CRF (assessed by VO_{2PEAK}) before and after intervention. **RESULTS:** MetS Z-score decreased -41% after 4HIIT and -52% in MICT (both $P<0.01$) whereas it did not change in 1HIIT and CONT group (-24%; $P=0.21$ and 20%; $P=0.22$, respectively). However, the three exercise groups improved similarly their VO_{2PEAK} (4HIIT 11%; MICT 12% and 1HIIT 14%; all $P<0.001$). **CONCLUSION:** Our findings suggest that in sedentary individuals with MetS and low initial CRF level any of the three aerobic training modalities which were compared, provide sufficient stimulus to raise CRF. However, the more intense but shorter 1HIIT training program is not effective on improving MetS Z-Score and thus, its recommendation for health promotion purposes in this population should be done with caution.

Use Of A Smartphone App To Improve Physical Activity In Insufficiently Active Adults: A Feasibility Sequential Multiple Assignment Randomized Trial (SMART)

Victor Z. Dourado¹, Bárbara Gonze¹, Maria do Socorro Simões¹, Neli Proença¹, Evandro Sperandio¹, Wesley Vieira¹, Vinicius Lauria¹, Marcello Romiti², Antônio Gagliardi², Rodolfo Arantes², Ricardo Padovani¹. ¹Federal University of Sao Paulo (UNIFESP), Santos, Brazil. ²Angiocorpore Institute of Cardiovascular Medicine, Santos, Brazil.
 Email: vzdourado@yahoo.com.br
(No relevant relationships reported)

The SMART design allows changes in the intervention during the research period. Despite its potential and feasibility for defining the best sequence of interventions, so far it has been utilized in a smartphone/gamified intervention for physical activity. **PURPOSE:** To investigate the effects of a SMART design on the behavior of the average number of steps/day in a smartphone app intervention for physical activity in insufficiently active adults. **METHODS:** We conducted a feasibility 24-week/2-stage SMART in which 18 insufficiently active participants (< 10000 steps/day) were first randomized to Group 1 (smartphone app only), Group 2 (smartphone app + tailored messages) and a control group. Participants were asked to increase at least 2000 steps/day on average each week. Based on the 12-week intermediate outcome, responders kept their interventions and non-responders were rerandomized to a subsequent treatment. In group 3 (Smartphone app + gamification), participants were instructed to form groups to use several game elements available in the chosen application (Pacer®). We fit linear regressions for each participant with the relationship between weeks and steps/day. We considered responders those with any positive slope at the end of the 1st stage intervention. We compared the accelerometer-based steps/day before and after the intervention as well as the slopes of the app-based steps/day between the 1st and second stages of treatment **RESULTS:** Twelve participants, five controls, finished the intervention. We identified two responders in group 1. We did not observe significant changes in the steps/day neither throughout the intervention nor compared to the control group. However, the rerandomization of the five non-responders was able to change the slope of the steps/day of a median, -198 steps/day (interquartile range, -279 to -103) to 20 steps/day (-204 to 145), $p = 0.079$. Finally, we observed in three participants in the group 2 an increase in the number of steps/day up to the sixth week and then an inflection to the baseline values or even lower (i.e., a quadratic relationship). **CONCLUSIONS:** The SMART design was feasible and changed the behavior of the steps/day after rerandomization. Our results suggest that the rerandomization should be implemented earlier to take advantage of the tailored messages.

D-11 Thematic Poster - Running Injuries

Increased Ground Reaction Force Load Rates In Runners With Active Patellofemoral Pain

Caleb D. Johnson, Jereme Outerleys, Julia M. Reilly, Adam S. Tenforde, Irene S. Davis, FACSM. *Harvard University, Cambridge, MA.* (Sponsor: Dr. Irene Davis, FACSM)
 Email: cdj9825@gmail.com
(No relevant relationships reported)

Increased vertical ground reaction force load rates have been associated with running injuries, and specifically with tibial stress fractures and plantar fasciitis. Inconsistent findings have been reported regarding the role of load rates in runners with patellofemoral pain (PFP), one of the most common injuries in runners. Limited studies in this patient population have been performed and prior investigators did not examine components of load rates beyond the vertical component. **PURPOSE:** To compare vertical, resultant, posterior, medial and lateral load rates, and peak vertical forces in runners with active PFP to healthy controls. **METHODS:** 30 runners with active PFP (16F, 14M, 40.2±12.8 yrs, 67.5±10.0 kg) and 30 healthy controls (CON) (18F, 12M, 34.8±10.9 yrs, 70.4±14.0 kg), all habitual rearfoot strikers, completed an instrumented treadmill assessment at a self-selected speed. Controls were matched for speed (PFP=2.50 m/s, CON=2.51 m/s). Load rates (vertical average and instantaneous

(VALR, VILR), resultant instantaneous (RILR), posterior instantaneous (PILR), medial instantaneous (MILR) and lateral instantaneous (LILR)) over the first 25% of stance and normalized to bodyweights. Peak vertical ground reaction forces (vGRF) were calculated over all of stance. Values were averaged across 10 consecutive strides. The injured leg was analyzed for the PFP group, and the right/left leg was randomly selected and counterbalanced for CON. **RESULTS:** Runners in the PFP group showed significantly higher mean VALR ($p=0.036$, $d=0.56$), VILR ($p=0.040$, $d=0.54$) and RILR ($p=0.036$, $d=0.55$) than CON. No differences were found in PILR ($p=0.668$), MILR ($p=0.193$), and LILR ($p=0.367$) (Figure 1), or in peak vGRF (Mean difference= 0.03 BW, $p=0.458$). **CONCLUSION:** Runners with active PFP exhibit higher vertical and resultant load rates.

Figure 1. Mean load rates between patellofemoral pain and control groups

-VALR, VILR, RILR plotted on left axis; PILR, MILR, and LILR plotted on right

Effects Of Running Biomechanics On The Occurrence Of Iliotibial Band Syndrome- A Prospective Study
 Qipeng Song, Peixin Shen. *Shandong Sport University, Jinan, China.*
 (No relevant relationships reported)

Iliotibial band syndrome (ITBS) is the second most common running injury, accounts for 1.6%-12% of all running-related injuries. The exact etiology of ITBS is unclear, but gait and posture are considered one of the factors. Most of studies on ITBS were retrospective cross-sectional in design and could not elaborate on the pathogenesis of ITBS.

PURPOSE: This prospective study aimed to determine the gait characteristics that easily induce ITBS and explore the posture changes after the occurrence of ITBS. **METHODS:** 15 ITBS-stricken runners (I group) and matched 15 healthy runners (C group). All participants underwent two gait trials, namely, before the first day of running (trial1) and after 8-week running (trial2). An eight-camera motion capture system was used to collect kinematic data. Sub-group comparisons were assessed via respective 95% confidence intervals of mean difference.

RESULTS: In trial2, the ITBS group exhibited greater peak anterior pelvic tilt and hip flexion angle than the control group (Fig1a). The ITBS group showed increased peak trunk inclination angle, whereas the control group demonstrated lower peak hip flexion (Fig1b) and peak hip adduction than those at trial1 (Fig1c).

Fig1. Comparison of joint activity between the two groups
 ■■ Represent significant differences between the two groups in trial 2.
 ▲▲ Significant differences in the control group compared with trial 1.

Abbreviation: t1: trial1; t2: trial2; LTD=left foot touch down; LTO=left foot take off; RTD=right foot touch down; RTO= right foot take off;

CONCLUSION: Decreasing the peak hip flexion and peak hip adduction angle may be a reasonable strategy to avoid the occurrence of ITBS. Occurrence of ITBS may be due to the lack of timely gait adjustment. The posture of excessive trunk inclination and anterior pelvic tilt may be a risk factor in the development of ITBS during running. This work was supported by the Project of Shandong Science & Technology Department (2017G006044).

1615 Board #3 May 30 1:30 PM - 3:30 PM
Achilles Tendon Loading Patterns During A 30-minute Steady-state Run In Patients With Achilles Tendinopathy
 Patrick Corrigan, Karin Gräware Silbernagel. *University of Delaware, Newark, DE.*
 Email: dpwc@udel.edu
 (No relevant relationships reported)

Achilles tendinopathy is an overuse injury that commonly sidelines runners. During rehabilitation, return-to-sport (RTS) decisions are made with minimal guiding evidence. With reinjury rates as high as 44%, evidence is needed to improve clinical decisions. Aberrant loading patterns while running may partially explain reinjury rates. **PURPOSE:** To determine if Achilles tendon loading patterns change during a 30-minute steady-state run in patients with Achilles tendinopathy and explore relationships between loading patterns and kinesiophobia.

METHODS: 12 runners (7M) with Achilles tendinopathy were included (age:44±11y; height:171±10cm; mass:70±12kg; VISA-A score:71±10; current mileage:40±29km/wk). Participants ran for 30 minutes at their endurance pace (2.9±0.3m/s) on an instrumented treadmill with retroreflective markers affixed to their lower limbs and feet. After a 6-minute familiarization period, marker trajectories and ground reaction forces were sampled during the 7th and 29th minute. Data was reduced to 10 gait cycles bilaterally. Sagittal plane ankle joint angles, moments and powers were calculated and a previously described musculoskeletal model was used to estimate Achilles tendon loads. Tampa Scale for Kinesiophobia (TSK) quantified the degree of kinesiophobia.

RESULTS: On the injured side, there was a significant decrease in peak concentric ankle power (7thmin=4.9±1.0W/kg·m; 29thmin=4.7±1.1W/kg·m; $p=0.02$) and peak dorsiflexion (7thmin=23.4±3.9°; 29thmin=22.7±3.7°; $p=0.02$), but no changes in peak plantarflexion moment, peak eccentric power, Achilles tendon peak load, loading rate or, impulse ($p=0.12-0.65$). No changes occurred on the uninjured side ($p=0.17-0.90$). There were significant relationships between the TSK scores (32±7) and changes in Achilles tendon impulse, peak concentric ankle power, and peak plantarflexion moment ($r=-0.66-0.60$; $p=0.02-0.04$), indicating increased unloading of the injured side during the run in patients with higher degree of kinesiophobia.

CONCLUSIONS: Ankle joint power and motion change during a 30-minute steady-state run in patients with Achilles tendinopathy. Additionally, changes in loading patterns are associated with kinesiophobia.

Flexor Hallucis Brevis Morphology is Associated with Visual Reliance While Balancing in Previously Injured Runners
 Erik A. Wikstrom, FACSM, Aliza K. Nedimyer, Brittney A. Luc-Harkey, Brian G. Pietrosimone, FACSM. *UNC - Chapel Hill, Chapel Hill, NC.*
 Email: wikstrom@unc.edu
 (No relevant relationships reported)

Running related injuries to the foot and lower leg are pervasive and thought to be due to poor plantar intrinsic muscle (foot core) function. Previously injured runners have decreased cross sectional area (CSA) and thickness of the flexor hallucis brevis (FHB) and increased reliance on visual information while balancing relative to uninjured runners. However, it remains unknown if FHB morphology is associated with an increased reliance on visual information. **PURPOSE:** To determine if visual reliance while balancing is associated with FHB morphology in those with a history of running related injuries. **METHODS:** Twenty-four runners with foot and/or leg running injuries within the past three years but were currently asymptomatic (age: 21.66±2.44 years, mass: 66.84±10.03kg, height: 169.21±19.34cm, runs per week: 4.37±1.30, miles per week: 14.16±8.88) volunteered. Three, 10-second eyes open and eyes closed single leg stance trials on the injured limb were recorded. Center of pressure velocity (cm/s) for each condition was used to calculate %-modulation (%-modulation=[(eyes open-eyes closed)/eyes open]). Larger negative scores indicates greater reliance on visual information. While standing in a weight-bearing, subtalar neutral position, diagnostic ultrasound was used to image the FHB in a relaxed state and contracted state (while holding a short foot contraction). Images were processed to calculate CSA and FHB thickness. CSA was defined as the area (cm²) within the fascial borders of the muscle. Thickness was the distance (cm) between superior to inferior fascia perpendicular to the muscle fibers. Pearson product moment correlations determined the strength of associations and an a priori alpha level of 0.05 was used for all analyses. **RESULTS:** Larger negative %-modulation was associated with the less contracted FHB thickness ($r=0.451$, $p=0.027$) and trended towards being associated with less relaxed FHB thickness ($r=0.368$, $p=0.077$). No association was noted with the FHB CSA ($r=0.273$, $p=0.198$). **CONCLUSIONS:** In previously injured runners decreased FHB thickness is associated with an increased reliance on visual information while balancing. Short foot exercises, aimed at increased FHB strength may decrease reliance on visual information but future research is needed to confirm this hypothesis.

Joint Moment Contributions During Flat, Incline and Decline Running in Individuals with ACLR
 Hillary H. Holmes, Katie Corona, Randall Fawcett, Jaimie A. Roper. *Auburn University, Auburn, AL.* (Sponsor: Mark Tillman, FACSM)
(No relevant relationships reported)

PURPOSE: To compare ankle, knee and hip joint moment contributions during flat, incline and decline running between limbs in ACLR individuals.
METHODS: 9 participants (4 males, 5 females, mean age 22 ± 2 yrs) provided consent to participate. Participants ran during flat (0°), incline (10°) and decline (-10°) treadmill conditions, with predetermined speeds of 2.5m/s (0°) and 1.8m/s (10° and -10°). Kinematic and kinetic data were collected during the final 30s of each condition using 17 cameras (Vicon) and an instrumented split-belt treadmill (Bertec). Joint moment contribution percentages at the hip, knee and ankle were determined by dividing the peak, sagittal, external joint moments (N.mm/kg) by the sum of all three joint moments during stance. A 2x3 (limb x condition) ANOVA was used to evaluate interlimb differences across conditions with post-hoc Bonferroni adjustments.
RESULTS: There was no significant limb x condition interaction or main effect of limb, but there was a significant main effect of condition. Knee joint moment contributions were 35% greater in decline running when compared to incline running (50-15%), and 31% greater when compared to flat running (50-19%). Ankle contributions were 39% less in decline running when compared to incline running (24-63%) and 26% less in decline running when compared to flat running (24-50%).
CONCLUSIONS: Knee and ankle joint moment contributions are altered with flat, incline, and decline running in persons with ACLR. Individuals with ACLR did not display asymmetries in joint moment contributions between the involved and uninvolved limb.

A Novel Approach to Investigate Running Kinematics in Achilles Tendinopathy Patients Using Inertial Sensors
 Jasper Reenalda¹, Michel Klaassen¹, Marit Zandbergen¹, Jelle Harbers¹, Roland Haalman², Gijs Lentjes², Jaap Buurke¹, Frank Backx². ¹*Roessingh Research and Development, University of Twente, Enschede, Netherlands.* ²*Utrecht University, Utrecht, Netherlands.* (Sponsor: Jos J. De Koning, FACSM)
 Email: j.reenalda@rrd.nl
(No relevant relationships reported)

Mid-portion Achilles tendinopathy (AT) is a common injury in runners. Overloading the tendon results in pain, swelling and impaired running performance. Recovery involves rest and a gradual build up. Determining whether patients can resume training is difficult and currently rather qualitative. To provide quantitative data to the physician to assist clinical decision-making, we studied the between leg differences in running kinematics for AT patients using inertial sensors in the clinical setting.

PURPOSE: To investigate lower limb kinematics in AT patients during 5 minute treadmill running in the clinic, using inertial magnetic measurement units (IMUs).
METHODS: 4 runners diagnosed with mild unilateral AT (4M, 48.8 \pm 7.5 yrs, 188.8 \pm 11.2 cm, 82.5 \pm 11.1 kg) performed a 5 min. treadmill run in the sports medicine clinic, as part of a larger study, with 8 IMU's at the feet, tibia, upper legs, sacrum and sternum. Ankle and knee angles were determined at initial contact (IC) and mid stance (MS). Additional parameters that were calculated were the vertical lower leg angle at IC (VLL), peak tibial impact (PTA), peak sacral impact (PSA), push-off power (POP) (lin. velocity at toe off, TO) and internal rotation (IR) of the tibia (at TO). Parameters were determined for the injured and non-injured leg at 1-min. intervals. An independent Mann-Whitney U-test was used to test for differences within patients between the injured and non-injured leg.
RESULTS:

Table 1
CONCLUSIONS: The injured leg of these AT patients showed significantly different running kinematics. AT strongly affected ankle mechanics, possibly as a compensatory strategy, indicating non-full recovery of the patients. The use of IMUs to determine the recovery of AT patients quantitatively is promising. Using IMUs there is no need for 3d optical motion capture systems or an instrumented treadmill to quantify running kinematics. Future research should follow up on these measurements to identify fully recovered patients.

Table 1 Mean values \pm standard deviation of the selected outcome parameters. Statistical differences was tested for using an independent Mann-Whitney U-test.

| | Ankle (IC) [°] | Ankle (MS) [°] | Knee (IC) [°] | Knee (MS) [°] | VLL [°] | PTA [m/s ²] | PSA [m/s ²] | POP [m/s] | IR [°/s] |
|------------------------|------------------|------------------|------------------|------------------|------------------|-------------------------|-------------------------|------------------|-----------------|

Ankle Joint Kinetics in Runners with Medial Tibial Stress Syndrome
 James Becker¹, Louis Osternig, FACSM², Stanley James³, Li-Shan Chou². ¹*Montana State University, Bozeman, MT.* ²*University of Oregon, Eugene, OR.* ³*Slocum Center for Orthopedics and Sports Medicine, Eugene, OR.* (Sponsor: Louis Osternig, FACSM)
(No relevant relationships reported)

Medial tibial stress syndrome (MTSS) is a common overuse running injury. While numerous studies have reported abnormal ankle kinematics in runners with MTSS, to date, no studies have evaluated ankle kinetics in this population. **PURPOSE:** To compare ankle kinetics in runners with and without MTSS. **METHODS:** Participants included eight runners with MTSS (sex: 7M/1F; age: 35 ± 11.3 years) and eight matched controls (CON; sex: 7M/1F; age: 35 ± 8.7 years). Kinematics and ground reaction forces were recorded while participants ran overground. Sagittal plane kinetics were calculated about an axis connecting the malleoli while frontal plane kinetics were calculated about an axis approximating the 23° medially deviated and 42° inclined orientation of the subtalar joint. Joint work was calculated by integrating the joint power curves. Paired *t*-tests were used to compare peak moments, powers, and work between MTSS and CON groups. **RESULTS:** Neither peak plantar flexor (MTSS: 2.14 ± 0.53 , CON: 2.24 ± 0.57 Nm/kg) nor peak invertor (MTSS: 1.04 ± 0.34 , CON: 1.16 ± 0.32 Nm/kg) moments were different between groups ($p = .720$, $p = .472$, respectively). There were no differences in sagittal plane powers or work between groups. In the frontal plane, the MTSS group demonstrated lower peak positive power (MTSS: 1.97 ± 0.38 , CON: 3.05 ± 1.12 W/kg, $p = .021$), and performed less negative (MTSS: -0.09 ± 0.02 , CON: -0.16 ± 0.07 J/kg, $p = .032$), positive (MTSS: 0.14 ± 0.03 , CON: 0.22 ± 0.07 J/kg, $p = .039$), and total (MTSS: 0.23 ± 0.06 , CON: 0.37 ± 0.15 J/kg, $p = .032$) work. **CONCLUSIONS:** Compared to healthy individuals, runners with MTSS are not able to generate as much energy to invert their foot during late stance. This may explain why previous studies have observed runners with MTSS have prolonged rearfoot eversion during stance.

Figure 1. Frontal plane joint moments (A) and powers (B). The solid line represents the CON group and the dotted line represents the MTSS group. Error bars show one standard deviation above and below the mean curve for the CON group.

1620 Board #8 May 30 1:30 PM - 3:30 PM
Does Y-Balance Test Performance Predict Injury-Related Running Mechanics?
 Scott Wilson, James Becker. *Montana State University, Bozeman, MT.*
(No relevant relationships reported)

The Y-balance test is commonly used to screen for injury risk in athletic settings. However, much of the research evaluating the predictive ability of this test focuses on multidirectional sports such as football or basketball. To date there is little evidence regarding the utility of the Y balance test for unidirectional sports such as running. **PURPOSE:** Determine whether performance on the Y-balance test predicts running variables previously linked to running injury. **METHODS:** 23 Division-I collegiate distance runners (9M/14F; age: 19.6 ± 1.0 years; weekly mileage: 59.4 ± 14.6 miles) participated in this study. Whole body kinematics during the Y-balance and while running were recorded using 10 and 6 camera motion capture systems, respectively. Ground reaction forces for running were measured using an instrumented treadmill. Maximum reach in the anterior (A), posterior lateral (PL), and posterior medial (PM) directions were used to calculate Y-balance composite scores (CS). Eleven specific kinematic and kinetic running gait variables which have been previously linked to running injuries were calculated (Table 1). Linear regressions were used to determine whether Y-balance CS predicted each running gait variable. **RESULTS:** Mean Y balance CS was $0.87 (\pm 0.09)$ with maximum reach distances of 0.84 ± 0.06 , 0.93 ± 0.11 and 0.84 ± 0.06 % of leg length in the A, PL, and PM directions, respectively. Of all 11 variables, Y balance CS only significantly predicted peak knee flexion during stance phase of running, and even then only accounted for 12% of the variance (Table 1). **CONCLUSION:** Performance on the Y-balance test may not be useful for

predicting injury risk in runners as the test does not predict variables previously linked to running injuries. However, further prospective studies tracking occurrence of actual injuries as well as internal loading at common running injury sites are required to fully clarify whether the Y balance test is suitable for screening runners.

Table 1. Linear regression results comparing Y-balance CS to gait variables previously linked to running injuries, BW = bodyweight (kg), $p < 0.05^*$

The Effect Of Acute Chronic Training Load Ratio On Daily Stress, Fatigue, And Soreness Level In A Ncaa Division 1 Soccer Players

Yasuki Sekiguchi¹, Ryan M. Curtis¹, Robert A. Huggins¹, Courtney L. Benjamin¹, William M. Adams², Shawn M. Arent, FACSM³, Rajat K. Jain⁴, John S. Miller⁵, Chris A. West¹, James R. Hale⁵, Douglas J. Casa, FACSM¹. ¹University of Connecticut, Storrs, CT. ²University of North Carolina at Greensboro, Greensboro, NC. ³Rutgers University, New Brunswick, NJ. ⁴Northwestern University, Evanston, IL. ⁵Penn state University, University Park, PA. (Sponsor: Douglas Casa, FACSM)
Email: yasuki.sekiguchi@uconn.edu

(No relevant relationships reported)

PURPOSE: To investigate the effect of acute chronic work load ratio (ACWL) on daily stress, fatigue, and soreness throughout a collegiate men's soccer season. **METHODS:** Sixty-four male collegiate soccer players (mean±SD; age, 20±2y; body mass, 77.3±6.7kg; height, 179.9±6.4cm; VO_{2max}, 53.0±5.0ml·kg⁻¹·min⁻¹) participated in this study, which took place during the 2016 and 2017 NCAA soccer season. During each training session and match, players donned a heart rate and GPS enabled chest strap to measure training impulse (TRIMP). Daily stress, fatigue, and soreness levels were collected using 1 to 10 Likert-scales before each training session and match. ACWL was calculated for TRIMP using the ratio of the previous 7-day average to the previous 28-day average. ACWL values were categorized into three groups: low, ACWL<0.8; medium, 0.8≤ACWL<1.5; high, ACWL≥1.5. Stress, fatigue, soreness levels were transformed to corresponding z-scores to account for individual differences. One-way ANOVA with Tukey pairwise comparison was used to assess stress, fatigue, soreness levels in different ACWL groups. Mean difference (MD), 95% confidence interval (95%CI) and effect size (ES), suggested by Cohen were calculated. **RESULTS:** Stress levels were significantly higher when ACWL was high compared to low (MD=0.47, 95%CI=0.34-0.60, ES=0.44) and medium (MD=0.37, 95%CI=0.25-0.48, ES=0.28) (p=0.001). Fatigue levels were significantly higher when ACWL was high (0.36±1.15) compared to low (MD=0.56, 95%CI=0.42-0.69, ES=0.55) and medium (MD=0.38, 95%CI=0.26-0.49, ES=0.36) (p=0.001). Fatigue levels were also significantly higher when ACWL was medium compared to low (MD=0.18, 95%CI=0.07-0.29, ES=0.20, p=0.001). Soreness level was significantly higher when ACWL was high compared to low (MD=0.51, 95%CI=0.37-0.64, ES=0.49) and medium (MD=0.38, 95%CI=0.26-0.50, ES=0.31) (p=0.001). **CONCLUSIONS:** ACWL could impact daily stress, fatigue, and soreness levels. A large change in ACWL (≥1.5) was associated with moderate to large changes in stress, fatigue, and soreness levels compared to low ACWL. Thus, ACWL may be used to manage athlete's daily stress, fatigue, and soreness levels and optimize periodization. However, other factors should be also considered, such as sleep.

1623 Board #2 May 30 1:30 PM - 3:30 PM Sleep Quality Effects Mood, Anxiety And Disablement In Division I National Collegiate Athletic Association Men's Soccer Players

Courtney L. Benjamin¹, Ryan M. Curtis¹, Robert A. Huggins¹, Yasuki Sekiguchi¹, William M. Adams², Shawn M. Arent, FACSM³, Rajat K. Jain⁴, John S. Miller⁵, Bruin C. Armwold⁵, Jason M. Pullara⁴, Douglas J. Casa, FACSM¹. ¹Korey Stringer Institute at the University of Connecticut, Storrs, CT. ²University of North Carolina at Greensboro, Greensboro, NC. ³Rutgers University, New Brunswick, NJ. ⁴Northwestern University, Evanston, IL. ⁵Penn State University, University Park, PA.

(No relevant relationships reported)

PURPOSE: To examine differences in mood, anxiety and physical health measurements between individuals who reported good sleep quality and individuals who reported poor sleep quality. **METHODS:** 110 male collegiate soccer players (mean±SD; age, 20±2y; body mass, 77.1±6.7kg; height, 179.9±6.3cm; VO_{2max}, 54.0±4.7ml·kg⁻¹·min⁻¹) participated in this study. During the 2016 and 2017 NCAA soccer seasons, the Pittsburgh Sleep Quality Index (PSQI), Profile of Mood States (POMS), Sports Anxiety Scale (SAS), and Disablement in the Physically Active Scale (DPA) questionnaires were administered at various timepoints throughout the season. Groups were classified as those who reported good sleep quality (PSQI ≤ 4) and those who reported poor sleep quality (PSQI ≥ 5). Multi-level linear mixed models were used to assess differences between a fixed sleep quality factor. Individual and time point were added as random intercepts to account for variance associated with these factors. Statistical significance was set a priori p<0.05. Results are reported as mean difference (MD) and effect size (ES). **RESULTS:** 47.4% of PSQI results yielded scores ≥ 5. Individuals with good sleep quality had significantly lower levels of depression (MD=-2.68, ES=-0.39; p<0.001), tension (MD=-1.36, ES=-0.33; p<0.001), anger (MD=-2.09, ES=-0.33; p<0.001), fatigue (MD=-1.95, ES=-0.56; p<0.001), confusion (MD=-1.26, ES=-0.38; p<0.001) and total mood disturbance (MD=-9.11, ES=-0.39; p<0.001) than those who reported poor sleep quality. Individuals who reported good sleep quality had significantly less concentration disruption (MD=-0.45, ES=-0.25; p=0.01) than those who reported poor sleep quality. Individuals who reported good sleep quality scored significantly lower on the DPA (MD=-2.73, ES=-0.26; p=0.01), indicating improved physical function and well-being, compared to those who reported poor sleep quality. **CONCLUSION:** Poor sleep quality is prevalent (almost 50%) in this sample of collegiate soccer players. Athletes with poor sleep quality appear to have increased negative mental health outcomes and higher ratings on a disablement scale. Establishing student-athlete wellness monitoring programs may provide a tailored approach to improve the collegiate athlete experience.

1624 Board #3 May 30 1:30 PM - 3:30 PM The Influence of Match Congestion, Load and Wellness on Injury Risk in Collegiate Men's Soccer

Robert A. Huggins¹, Ryan M. Curtis¹, Courtney L. Benjamin¹, Yasuki Sekiguchi¹, Erin B. Wasserman², David A. Klossner³, William M. Adams⁴, Shawn M. Arent, FACSM⁵, Rajat K. Jain⁶, S. (No relevant relationships reported)

The impact of match congestion, training load (TL), perceived stress, fatigue and soreness on the odds of injury remains unclear. **PURPOSE:** To examine the influence of: 1) days rest between matches on injury rate (IR) and odds of injury and; 2) TL on injury, perceived stress, fatigue and soreness. **METHODS:** A prospective multi-site study tracked daily exposures, TL (distance and duration), injury and perceptual data from six Division I NCAA men's soccer teams in one season. Overall and non-contact (NC) IRs expressed per 1000 athlete exposures (AEs), and odds ratios (OR) were determined by days before and after matches. Associations between injury and changes in both TL and perception were analyzed using a multilevel logistic regression. **RESULTS:** 132 players experienced 116 injuries in 125 matches and 75 injuries in 301 practices. Overall match and practice IRs (per 1000AEs [95%CI]) were 47.9 [39.1,

56.6] and 12.7 [9.8, 15.5], respectively. Match IRs [range = 0.0 to 57.9] were highest 1 to 5 days [range = 1 to 12] from the last match. While insignificant ($p > 0.21$), match IRs were highest 3 days between matches (IR= 57.9 [39.0, 76.8]). Players were at increased odds of being injured in a match with 1 to 5 days since the last match vs. 6+ days (OR [95% CI] = 1.85 [1.10, 3.12]). Practice IRs were highest in the preseason (IR = 26.8 [13.2, 40.3]). Players were at increased odds of being injured in practice 3 and 4 days before vs. 1 day before (OR= 6.19 [3.03, 12.66] and 3.89 [1.92, 7.88]). Players were at increased odds ($p < 0.001$) of feeling fatigue (> 5) (OR= 7.04 [3.75, 13.21]) and soreness (> 5) (OR= 4.00 [2.17, 7.37]) in practice with 1 vs. 6 days since the last game. For each additional 3500m covered on a day, odds of NC injury, stress, soreness and fatigue increased (OR = 1.70 [1.38, 2.10], 1.16 [1.02, 1.31], 1.55 [1.40, 1.72], 1.69 [1.52, 1.89]), respectively. For each additional hour of activity on a day, odds of NC injury, stress, soreness and fatigue increased (1.83 [1.59, 2.12], 1.08 [0.97, 1.20], 1.28 [1.17, 1.39], 1.34 [1.22, 1.47]), respectively. **CONCLUSION:** Days between matches and acute TL increases on a given day had a negative impact on odds of injury and perception. The odds of getting injured in a match were greater with 1 to 5 days vs. 6+ days between matches. These data may be used to inform and guide the NCAA in determining optimal scheduling and recovery.

1625 Board #4 May 30 1:30 PM - 3:30 PM
Effect of Two Regimes of Sled Sprinting on 40m Sprint Performance in Collegiate Soccer Players

Patrick J. Mara, Erik Blekeberg, Dr. Todd Astorino. *California State University San Marcos, San Marcos, CA.*
 Email: mara001@cougars.csusm.edu
 (No relevant relationships reported)

Speed is one of the most important factors dictating athletic performance especially in field based team sports including soccer. Sports performance coaches continue to design training programs to enhance this ability. In addition to lower body resistance training and plyometrics, one method that is frequently employed is resisted sprinting (RS). However, data concerning the efficacy of RS is equivocal and there is much debate over the proper resistance to prescribe. Previous research has been conducted at loads near 10% of body weight (BW), but recent studies suggest the optimal load for power output in RS is 70 - 80% BW. **Purpose:** The purpose of this study was to compare the effects of two 5wk RS programs varying in load on sprint performance and jumping ability in male collegiate soccer players. **Methods:** At baseline, 20 collegiate male soccer players performed testing of 40m-sprint performance with split times at 10m and 20m and broad jump. They were matched and separated into a heavy RS group ($n=10$) or light RS group ($n=10$). Over a 5 wk period, they performed 10 sessions of progressive RS at 70-80% or 10-20% BW. Athletes simultaneously participated in 3 d/wk of full body resistance training and 2 d/wk of soccer specific conditioning. Sprint and jump testing performance tests were repeated 72 h after the final training session. **Results:** Results showed a significant effect of time for the 20m ($p=0.005$) and 40m distances ($p=0.008$) as well as for the broad jump ($p=0.002$). 10m sprint times remain unchanged ($p > 0.05$) and there was no group \times time interaction for any variable. Very large effects were seen for 20m (2.82 ± 0.1 s to 2.77 ± 0.11 s) and 40m performance (5.02 ± 0.2 s to 4.95 ± 0.2 s) in response to heavy RS training, with a huge effect seen for broad jump. Large effects were seen at the 20m (2.85 ± 0.07 s to 2.81 ± 0.1 s) and 40m (5.02 ± 0.15 s to 4.97 ± 0.2 s) distances after light RS training, with medium effects seen in 10m sprint times and broad jump. **Conclusion:** A 5-week RS intervention significantly improves sprinting performance and broad jump in collegiate soccer players irrespective of magnitude of resistance, which suggests that both light and heavy RS is efficacious to enhance these outcomes.

1626 Board #5 May 30 1:30 PM - 3:30 PM
The Dose-Response Relationship of Neuromuscular Training to Prevent Lower Extremity Injuries in Young Soccer Players. A Cluster Randomised Controlled Trial

Anna Lina Rahlf¹, Astrid Zech². ¹Friedrich-Schiller-University Jena, Jena, Germany. ²Friedrich Schiller University Jena, Jena, Germany.
 Email: anna.lina.rahlf@uni-jena.de
 (No relevant relationships reported)

The regular execution of neuromuscular training has been shown to reduce injuries of the lower extremities in youth athletes. However, to date there are inconsistent results on the dose-response relationship of neuromuscular training. **Purpose:** The aim of this study was to evaluate the optimal duration of neuromuscular training to prevent injuries of the lower extremities in young soccer players. **Methods:** 342 (15.4 ± 1.7 years) male soccer players were included in the study, and cluster-randomized into two intervention groups. Both groups completed the same soccer specific warm-up program (FIFA 11+) twice a week, but for a different duration: one intervention group (INT10, $n=175$) twice a week for 10 minutes, the other (INT20, $n=167$) twice a week for 20 minutes. The player exposure hours (hrs) were collected monthly over six months during one soccer season. Primary outcome was the incidence of lower extremity (LE) injuries. Secondary outcomes were injury type, severity, mechanism and compliance to

the intervention. **Results:** During the entire season 123 young soccer players sustained a total of 145 lower extremity injuries (INT 10: 55; INT 20: 90). (INT 10: 55; INT 20: 90). No significant group difference was found between INT10 (6.37 per 1000 hrs) and INT20 (7.20 per 1000 hrs) for the relative risk of injuries of the lower extremities (RR= 1.03, 95 % confidence interval 0.59, 1.79), nor for the distribution of injury location, type, severity, mechanism or conditions. **Conclusion:** The results suggest that performing preventive exercises for 10 minutes is just as effective as a performance of 20 minutes. Consequently, the implementation of a neuromuscular training for 10 minutes twice a week seems to be sufficient to reduce injuries of the lower extremities in young male football players.

1627 Board #6 May 30 1:30 PM - 3:30 PM
Importance of Position in Highly Talented Soccer Players: Peripheral Perception, Selective Attention and Reaction Abilities

Nils Schumacher, Ruediger Reer, Klaus-Michael Braumann.
University of Hamburg, Hamburg, Germany.
 Email: nils.schumacher@uni-hamburg.de
 (No relevant relationships reported)

The importance of sports-specific cognitive and perceptual skills in soccer has already been examined in various studies (Ward & Williams, 2003). However, the role of general perceptual-cognitive abilities and the relation of position is not clarified in detail (Schumacher et al., 2018).

PURPOSE: To analyze the relation of position to peripheral perception, selective attention and reaction abilities in highly talented soccer players.

METHODS: 147 highly talented male soccer players (14.8 ± 2.6 yrs, age range 11 to 23 years) were involved. The subjects performed computer-based selective attention, peripheral perception and reaction tests (using Vienna Test System). In the peripheral perception test stimuli were presented left and right sided. The soccer players were subdivided into offensive player group (OPG: striker, midfielder) and defensive player group (DPG: goalkeeper, defender). They were recruited from a youth academy of a professional soccer club and played at the highest and 2nd highest national soccer competition for their age. Group differences were tested using the student t-test.

RESULTS: Significant differences for position groups were observed, with regard to correct answers (OPG: 216.1 ± 32.0 ; DPG: 231.3 ± 26.0) in selective attention test ($t(140) = 3.05, p < 0.01$) and peripheral reaction time left (OPG: 0.71 ± 0.09 sec; DPG: $.67 \pm 0.10$ sec) in peripheral perception test ($t(141) = 2.32, p < 0.01$). No differences were found for variables in the reaction test.

CONCLUSIONS: Our results indicate that defender and goalkeeper outperform striker and midfielder in general selective attention tasks and in peripheral reaction tasks left sided. Additional research is needed to further clarify position-specific differences between left and right peripheral reaction time of highly talented soccer players.

1628 Board #7 May 30 1:30 PM - 3:30 PM
NCAA Preseason Demonstrates Greatest Impact on Heart Rate Variability, Training Load and Sleep In Men's Soccer

Cody R. Butler, Ryan M. Curtis, Robert A. Huggins, Courtney L. Benjamin, Yasuki Sekiguchi, Chris West, Lindsey K. Lepley, Douglas J. Casa, FACSM. *University of Connecticut, Storrs, CT.*
 (Sponsor: Douglas J. Casa, FACSM)
 Email: cody.butler@uconn.edu
 (No relevant relationships reported)

PURPOSE: The purpose of this study was to compare training load (TL), sleep, heart rate variability (HRV) and resting (RHR) by season phase over a full NCAA collegiate men's soccer season. **METHODS:** Daily TLs (duration [min], distance covered [m], time spent in heart rate $>80\%$ of the individual's max [min], number of sprints [n]), and distance covered while running >14.4 km \cdot h $^{-1}$ [m]) were monitored in 31 male NCAA Division 1 male soccer athletes (mean \pm SD; age, 20 ± 2 y; body mass, 79.92 ± 6.69 kg; height, 181.48 ± 6.35 cm; VO_{2max} , 50.87 ± 4.38 ml \cdot kg $^{-1}$ \cdot min $^{-1}$) using GPS-enabled player tracking devices during the Fall 2016 soccer preseason (PRE), regular season (REG), and post-season (POST). Sleep duration (min), sleep efficiency (%), and RHR and HRV z-scores (SD) were tracked using a multi-sensor wrist-worn device and a validated self-reported sleep questionnaire (Karolinka Sleep Diary). Linear mixed effects models with a fixed factor of season phase and a random factor of participant was used. Mean differences (MD) were assessed post-hoc with a Tukey HSD, with alpha set at 0.05 for all analysis. **RESULTS:** During PRE, participants experienced an increased distance (1527 ± 177 m), time (31 ± 3 min) and sprints (8 ± 1) (all $p < 0.001$) per session vs. REG, and increased distance (1793 ± 312 m), time (39 ± 6 min) and sprints (9 ± 1) per session vs. POST (all $p < 0.001$). A decrease in sleep efficiency was observed during PRE vs. REG (MD = $-2.00 \pm 0.05\%$; $p = 0.004$). Self-reported sleep duration during REG was longer vs. PRE (MD = 45 ± 8 min; $p < 0.001$) and POST (MD = 32 ± 12 min; $p = 0.01$). No differences were observed for objective sleep duration or RHR at any point throughout the season ($p > 0.05$). RHR was found to be lower during PRE vs. REG (MD = -0.16 ± 0.06 SD; $p = 0.02$). Finally, HRV during

REG was reduced vs. PRE (MD = -0.14 ± 0.06 SD; $p = 0.05$). **CONCLUSION:** This study indicates higher HRV, greater physical and physiological loading, decreased self-reported sleep and decreased sleep efficiency during PRE compared to REG. In this men's soccer team, PRE training was associated with significantly increased physical stress, adverse sleep characteristics and increased HRV. These responses should be considered when designing and implementing optimal training and recovery strategies.

1629 Board #8 May 30 1:30 PM - 3:30 PM
Relationship between the Different Energy Substrates and Skin Temperature Response in Professional Soccer Players

Jonathan Galan¹, Andrea Suarez², Guillermo Oviedo¹, Miriam Guerra-Balic¹. ¹Blanquerna - University of Ramon Llull, Barcelona, Spain. ²Blanquerna- University of Ramon Llull, Barcelona, Spain.
 Email: jonathangc@blanquerna.url.edu
 (No relevant relationships reported)

Elite professional soccer players have high aerobic requirements throughout a game and extensive anaerobic demands during periods of a match leading to major metabolic and thermodynamic changes. Assessing skin temperature (Tsk); blood lactate concentration [La^-], fat and carbohydrate oxidation (FATox; CHOox) might provide an indirect method to assess metabolic flexibility and oxidative capacity during exercise. **Purpose:** To study the relationship between Tsk; [La^-] and substrate oxidation patterns. **Methods:** We used indirect calorimetry and [La^-] measurements, and monitored the Tsk to study the metabolic and thermodynamic response to exercise in twenty professional male soccer players (age 24.5 ± 3.4 yrs.; VO_2peak 53.2 ± 4 ml/kg/min) during a maximal incremental treadmill test. **Results:** The maximal FATox rate was 0.47 ± 0.16 g min^{-1} , reached at $62.5 \pm 6.5\%$ of the VO_2peak . A significant inverse correlation was found between average FATox rates and average blood [La^-] ($p < 0.005$). A significant correlation was found between the average values of Tsk and FATox rates ($p < 0.006$). Maximal values reached of FATox and CHOox rates were 0.80 and 6.82 g min^{-1} respectively. **Conclusion:** These results indicate that FATox rates are inversely associated with blood lactate production; which may be due to a higher adrenergic activation that limits the increase of Tsk and the FATox capacity. Our data also show relationships between the Tsk and FATox rates, which may be associated to an increase of tissue blood flow. More research is required to determine how the thermodynamic and metabolic responses to affect performance in soccer.

| Variables | Age (years) | Height (cm) | Weight (kg) | BMI (%) | Body fat (%) | Fat free mass (%) | Max speed (km/h) |
|-----------|----------------|-----------------|----------------|------------------|------------------|-------------------|------------------|
| n=20 | 24.5 ± 3.4 | 180.6 ± 5.5 | 76.7 ± 6.2 | 23.54 ± 1.54 | 10.29 ± 1.85 | 46.58 ± 2.14 | 16 ± 1 |

Composition of Movement Behaviors and Risk of Weight Gain

Erika Rees-Punia, Ying Wang, Mark A. Guinter, Elizabeth A. Fallon, Susan M. Gapstur, Alpa V. Patel, FACSM. *American Cancer Society, Atlanta, GA.* (Sponsor: Alpa Patel, FACSM)
 (No relevant relationships reported)

Physical activity, sedentary behavior, and sleep are three movement behaviors that are mutually exclusive parts of a whole (i.e., a 24-hour day) and therefore may be related to weight in a co-dependent manner. Compositional data analyses (CoDA) provide the opportunity to analyze associations between constrained behaviors and health outcomes without violating statistical assumptions involving collinearity.

PURPOSE: To use CoDA to investigate the relationships between the composition of four movement behaviors (objectively-measured sedentary time [SED], light intensity physical activity [LPA], moderate-vigorous intensity physical activity [MVPA] and self-reported sleep duration) and one-year changes in body mass index (BMI) and waist circumference (WC).

METHODS: Participants were 716 adults from the Cancer Prevention Study-3 (mean age 52.2 [SD 9.9] years, 59% female, 66% white, 40% normal BMI). Self-reported weight, height, and self-measured WC were captured one year apart. Participants wore an accelerometer (Actigraph GT3x) for a minimum of 14 hours/day for three days and self-reported sleep duration via 24-hour diaries. CoDA was used to examine associations between all movement behaviors and change in BMI or change in WC. CoDA isotemporal substitution models estimated associations for the replacement of 30 minutes of SED for other behaviors in the composition. Models were stratified by sex and adjusted for age, race/ethnicity, smoking status, and average daily caloric intake.

RESULTS: Participants spent most of their time SED (mean proportion of time SED = 0.414), followed by sleeping (0.344), in LPA (0.195), and in MVPA (0.047). The overall composition of movement behaviors was associated with a one-year change in BMI ($p = 0.003$) and WC ($p = 0.048$) among men, but not among women ($p = 0.19$ and $p = 0.43$). Among men, compositional isotemporal substitution models suggested that replacing 30 minutes of SED with 30 minutes of MVPA while holding LPA and

sleep constant was associated with a one-year BMI decrease of 0.26 kg/m², while the replacement of SED with LPA and sleep were associated with smaller decreases in BMI (0.06 kg/m² and 0.12 kg/m², respectively).

CONCLUSION: Findings suggest that targeting all movement behaviors throughout the day may be an effective approach for weight loss, especially among men.

1632 May 30 1:45 PM - 2:00 PM

Cardiorespiratory Fitness and Years Lived Free of Cardiovascular Disease: Cardiovascular Lifetime Risk Pooling Project

Amanda E. Paluch¹, Hongyan Ning¹, Mercedes R. Carnethon¹, Kelley Pettee Gabriel, FACS², Norrina B. Allen¹, Donald M. Lloyd-Jones¹, John T. Wilkins¹. ¹Northwestern University, Chicago, IL. ²University of Texas Health Science Center at Houston and School of Public Health – Austin Campus, Austin, TX. (Sponsor: Kelley Pettee Gabriel, FACS) Email: amanda.paluch@northwestern.edu (No relevant relationships reported)

PURPOSE: Quantifying cardiorespiratory fitness (CRF) with years lived free of cardiovascular disease (CVD) allows for contextualization of the population burden of CVD and provides a metric for clinician-patient communication.

METHODS: CRF was measured with graded exercise treadmill tests in 8,129 adults in the Coronary Artery Risk Development in Young Adults and Framingham Offspring studies. Individual-level data were pooled. Cohort-specific z-scores for CRF were categorized into sex- and age- specific quintiles. We defined low fit as quintile 1, moderate (mod) fit as quintiles 2-3, and high fit as quintiles 4-5. Rates (person-years) of incident CVD and death were summed for participants up to age 85 years, or the oldest age of observation. Irwin's restricted mean was used to calculate years lived free from CVD and overall survival stratified by sex.

RESULTS: At baseline the mean age was 32.5±11.6 years, 43.6% women, and 30.8% black. Over 219,812 person-years of follow-up, 762 CVD events were observed. For total survival time, high fit men lived 2.1 years longer and mod fit men lived 1.4 years longer vs low fit men. Additionally, high fit men lived 3.3 more healthy years and mod fit men lived 2.3 more healthy years free of CVD vs the low fit group. Among men, relative follow up time spent with CVD was 5.0% for high fit, 5.7% for mod fit, and 8.0% for low fit groups. While high and mod fit women were similar, both had greater longevity and health span than low fit women. Mod fit women lived 1.9 total years longer and lived 1.7 more healthy years CVD-free vs the low fit women. Time spent with CVD was similar across fitness groups in women, ranging from 2.8-3.2% of follow-up time.

CONCLUSIONS: The benefits of higher fitness appear to extend multiple decades into older ages. Higher fitness in early adulthood is associated with longer overall and CVD-free survival. Men with higher fitness levels as young adults live less of their life with CVD, suggesting a compression of morbidity at older ages.

Low fit defined as quintile 1 (bottom 20%); Mod Fit defined as quintile 2-3 (middle 40%); High Fit defined as quintile 4-5 (upper 40%)
 CARDIA measured fitness at baseline/Year 0 exam (1985-86) using a maximal treadmill test using a modified Balke protocol.
 FOS measured fitness at exam cycle 2 (1979-83) using a submaximal treadmill test (85% of age- and sex- predicted max heart rate) using a modified Bruce protocol

Leisure-time Physical Activity And TV Viewing Associations With Life Expectancy With And Without Cardiovascular Disease

Carmen C. Cuthbertson, Xianming Tan, Gerardo Heiss, Anna Kucharska-Newton, Hazel B. Nichols, Chirayath M. Suchindran, Kelly R. Evenson, FACS^M. University of North Carolina at Chapel Hill, Chapel Hill, NC. Email: carmenc@email.unc.edu (No relevant relationships reported)

PURPOSE: Although high levels of physical activity are associated with longer overall and cardiovascular disease (CVD) free life expectancy (years lived without

CVD) research has been limited and sedentary behavior has not been considered. Therefore, we examined associations between leisure-time moderate-to-vigorous physical activity (LTPA) and television (TV) viewing with life expectancy overall and with and without three types of CVD.

METHODS: We included 13,534 participants from the Atherosclerosis Risk in Communities Study prospective cohort. LTPA in the past year (no LTPA, ≤ median (13.2 MET hours/week), > median) and TV viewing (often/very often, sometimes, seldom/rarely) were self-reported. Outcomes included all-cause mortality, and incident nonfatal coronary heart disease (CHD), stroke, and heart failure (HF). We used a multistate survival model to estimate associations of LTPA and TV viewing with life expectancy (95% confidence interval (CI)) with and without nonfatal CHD, stroke, and HF at age 50 separately for men and women. Models were adjusted for time-varying covariates (age, gender, race by study center, education, smoking, ethanol intake). Missing data were imputed with multiple imputation.

RESULTS: Over a median of 27 years of follow-up, the average life expectancy at age 50 was 26 years. Compared to participants who engaged in no LTPA, participants who engaged in LTPA above the median had greater overall life expectancy (1.8 years each for men and women), greater nonfatal CHD-free life expectancy (men 1.5 years (95% CI 1.0, 2.0), women 1.6 years (95% CI 1.1, 2.2)), greater nonfatal stroke-free life expectancy (men 1.8 years (95% CI 1.2, 2.3), women 1.8 years (95% CI 1.3, 2.3)), and greater nonfatal HF-free life expectancy (men 1.6 years (95% CI 1.1, 2.1), women 1.7 years (95% CI 1.2, 2.2)). For each type of CVD, life expectancy with disease was similar across three levels of LTPA. Watching less TV compared to more viewing was associated with longer overall and disease-free life expectancy of 0.8 years each. These findings were similar for CHD, stroke, and HF.

CONCLUSIONS: Engaging in more LTPA and less TV viewing were associated with longer overall and nonfatal CVD-free life expectancy. Increasing LTPA levels and limiting TV viewing could potentially increase longevity and years lived CVD-free.

Cardiorespiratory Fitness Incidence and Mortality from Lung Cancer in Male Smokers

Baruch Vainshelboim¹, Ricardo M. Lima², Peter Kokkinos, FACS^M, Jonathan Myers, FACS^M. ¹Saint Francis University, Loretto, PA. ²University of Brasilia, Brasilia, Brazil. ³Washington DC Veterans Affairs Medical Center, Washington, DC. ⁴Veterans Affairs Palo Alto Health Care System/ Stanford University, Palo Alto, CA. Email: baruch.v1981@gmail.com (No relevant relationships reported)

Cardiorespiratory fitness (CRF) is an established prognostic marker for many chronic diseases including lung cancer but, this association has not been assessed among smokers. **PURPOSE:** To evaluate the association between CRF, lung cancer incidence and cancer mortality in former and current male smokers. **METHODS:** Maximal treadmill exercise testing was performed in 2,979 men [former smokers (n=1,602), 39.6±25 pack/years and current smokers (n=1,377), 43±27 pack/years] aged 59.2±17.3 years, who were free from malignancy at baseline. Cox hazard models adjusted for cancer risk factors were analyzed. Population attributable risks (PAR%) of low CRF (<5 METs) for lung cancer outcomes were also determined. **RESULTS:** During 11.6±7 years follow-up, 99 lung cancers were diagnosed [46 (2.9%) among former smokers and 53 (3.8%) among current smokers]. Seventy-nine of those died from cancer (40 in former and 39 in current smokers) after 3.6±4.6 years from diagnosis. Among former smokers each 1-MET increase and categories of moderate and high CRF were associated with 16% (p=0.002), 60% and 83% (p trend=0.001) reductions in lung cancer incidence, respectively. Among current smokers who were later diagnosed with lung cancer, 1-MET increase and categories of moderate and high CRF were associated with 18% (p=0.008), 81% and 82% (p trend <0.001) reductions in cancer mortality, respectively. The PAR% for lung cancer incidence was 12.5% among former smokers and 21.5% for cancer mortality among current smokers. **CONCLUSIONS:** Higher CRF is associated with lower lung cancer incidence in former smokers. Current smokers who were diagnosed with lung cancer and were more fit exhibited reduced cancer mortality. These results suggest potential protective benefits of higher CRF for prevention of lung cancer outcomes among both former and current smokers. Eliminating low CRF as a risk factor could potentially reduce considerable lung cancer morbidity and mortality.

Is Leisure-time Physical Activity Before Pregnancy Associated With Risk Of Hyperemesis Gravidarum During Pregnancy?

Katrine M. Owe¹, Nathalie Støer¹, Borgny H. Wold², Maria C. Magnus³, Wenche Nystad³, Åse V. Vikanes¹. ¹*Oslo University Hospital, Oslo, Norway.* ²*Norwegian University of Science and Technology, Trondheim, Norway.* ³*Norwegian Institute of Public Health, Oslo, Norway.*
Email: owekam@outlook.com

(No relevant relationships reported)

Hyperemesis gravidarum (HG) is characterised by excessive nausea and vomiting often leading to maternal weight loss, dehydration, electrolyte imbalance, and vitamin deficiencies. HG is the most common reason for hospitalisation in the first half of pregnancy and its prevalence varies depending on maternal country of birth. Women who experience excessive nausea and vomiting in early pregnancy are less likely to participate in leisure-time physical activity (LTPA) during pregnancy. Whether LTPA before pregnancy is associated with hyperemesis gravidarum has not yet been studied. Prepregnancy LTPA may lessen the risk of gestational diabetes, pelvic girdle pain, and hypertensive disorders including preeclampsia, all of which are associated with HG.

PURPOSE: To estimate associations between prepregnancy LTPA and HG in pregnancy.

METHODS: We present data from 37 442 primiparous women with singleton pregnancies enrolled in The Norwegian Mother and Child Cohort Study. Prepregnancy LTPA was self-reported by questionnaire in pregnancy week 17. HG was defined as prolonged nausea and vomiting in pregnancy requiring hospitalisation before the 25th gestational week. We estimated the crude and adjusted associations between LTPA and HG using multiple logistic regression. We assessed effect modification by prepregnancy BMI or smoking by stratified analysis and interaction terms.

RESULTS: A total of 398 (1.1%) women developed HG. Before pregnancy 76.4% conducted LTPA at least 3 times weekly, while only 7.3% of women conducted LTPA less than once a week. Compared to women reporting LTPA 3 to 5 times weekly, no LTPA or a frequency of 1 to 3 times a month had an increased risk of HG (adjusted odds ratio [aOR] 2.58; 95% confidence interval [CI], 1.29 to 5.18, and aOR 1.35; 95% CI, 0.95 to 1.92, respectively). LTPA-HG associations differed by prepregnancy BMI but not by prepregnancy smoking. The increase in risk of HG was more than 4-fold for women with BMI_≥25 kg/m² reporting no LTPA prepregnancy (aOR 4.89; 2.13 to 11.22, test for trend, *P*=0.45).

CONCLUSIONS: Lack of LTPA before pregnancy was associated with an increased risk of HG. Inactive women with overweight or obesity before pregnancy may have the highest risk of HG during pregnancy.

1636 May 30 2:45 PM - 3:00 PM

Is Midlife Quadriceps Muscular Strength Protective Against Later Life Osteoarthritis and Subsequent Total Joint Replacement?

Andjelka Pavlovic, Benjamin L. Willis, David S. Leonard, Stephen W. Farrell, FACSM, Carolyn E. Barlow, Laura F. DeFina. *The Cooper Institute, Dallas, TX.* (Sponsor: Stephen W. Farrell, FACSM)

Email: apavlovic@cooperinst.org

*(No relevant relationships reported)***Abstract:**

We have previously shown a relationship between cardiorespiratory fitness/physical activity and the likelihood of developing hip/knee osteoarthritis (OA) later in life. Another possible predictor of hip/knee OA is weakness of the quadriceps musculature. Because it is unknown whether or not midlife quadriceps strength predisposes to OA and hip/knee total joint replacement (HKR) later in life, the current study was undertaken.

Purpose: The purpose of this study was to examine the relationship between midlife quadriceps muscle strength and the likelihood of developing OA and undergoing a HKR later in life

Methods: We linked strength and clinical data from 3944 (3431 men and 513 women) participants in the Cooper Center Longitudinal Study from 1981-1989 to Medicare claims from 1999-2009 (13% women, mean age 49 years). Quadriceps muscular strength was measured via 1-repetition maximum (1-RM) leg press assessment and expressed individually relative to body weight. Outcome measures for OA and HKR were obtained using Medicare administrative data. Proportional hazards regression was used to estimate the risk of incident OA and subsequent risk of HKR after developing OA.

Results: During 20,672 person years of Medicare follow up, 1100 OA events (913 events in men, 187 events in women) were observed. After controlling for age, sex and year of muscle strength assessment, a significant relationship was observed between 1-RM leg press and the likelihood of developing OA later in life (HR 0.76, 95% CI 0.59 - 0.98). Among those who developed OA, we observed 293 hip/knee total joint

replacements (244 joint replacements in men, 49 joint replacements in women) during 4947 subsequent person years of observation. When adjusted for the same covariates, higher 1-RM leg press suggested a protective role against HKR, but the findings were not statistically significant (HR 0.80, 95% CI 0.49 - 1.29).

Conclusion: Midlife quadriceps muscular strength may play a protective role against onset of OA later in life. More research is needed to determine if increasing quadriceps muscle strength leads to a reduction in risk of undergoing HKR.

Measures Of Adiposity And Its Association To Physical Activity In Adults: The Tromsø Study

Edvard H. Sagelv¹, Ulf Ekelund, FACSM², Jonas Johansson¹, Boye Welde¹, Sameline Grimsgaard¹, Nina Emaus¹, Anna Nordström³, Søren Brage⁴, Alexander Horsch¹, Laila A. Hopstock¹, Bente Morseth¹. ¹*UiT the Arctic University of Norway, Tromsø, Norway.* ²*Norwegian School of Sport Sciences, Oslo, Norway.* ³*Umeå University, Umeå, Sweden.* ⁴*University of Cambridge, Cambridge, United Kingdom.*
Email: edvard.h.sagelv@uit.no

(No relevant relationships reported)

PURPOSE: The purpose of this study was to examine the pattern and magnitude of associations between moderate-to-vigorous physical activity (MVPA) and three different methods for assessing adiposity: body mass index (BMI), waist circumference (WC) and dual-energy x-ray absorptiometry (DXA). **METHODS:** In the seventh wave of the Tromsø Study 2015-2016, 6289 women and men aged 40-84 years wore an accelerometer (ActiGraph wGT3X-BT) on the hip for eight consecutive days. Of these, 6125 participants provided valid accelerometer data, of which 5925 participants also provided data on BMI (kg·m⁻²) and WC (cm), and 2741 participants attended DXA measurement, providing data on total body fat (%). MVPA (min·d⁻¹) was estimated from the vector magnitude (the square root of the sum of squared activity counts) of triaxial acceleration counts and defined as >2690 counts per minute. In order to compare the magnitude of the association between MVPA and the three adiposity measures, the associations were considered significantly different if the 95% CI of the standardized β's overlapped by <50%. **RESULTS:** After adjustment for age, sex, body height, smoking and educational level, for every 10-minute increase in MVPA, BMI decreased with -0.29 kg·m⁻² (95% CI: -0.25-0.33 kg·m⁻²), WC decreased with -0.94 cm (95% CI: -0.83-1.04 cm) and percentage total body fat decreased with -0.81% (95% CI: -0.72-0.90%). The association between MVPA and percentage body fat (standardized β=-0.270, 95%CI: -0.236-0.296) were considered significantly larger than for WC (standardized β=-0.220, 95%CI: -0.189-0.235) and BMI (standardized β=-0.200, 95%CI: -0.163-0.214) (*p*<0.05). MVPA explained 6%, 20%, and 44% of the variance in BMI, WC and percentage total body fat, respectively, after adjustment for potential confounders.

CONCLUSIONS: Adiposity measured with DXA, explained more of the variation in the association with MVPA than WC and BMI, indicating that the association between adiposity and physical activity depends on the accuracy of the measurement. As DXA distinguishes between fat and fat-free mass, whereas BMI and WC acts as proxy measures of adiposity, DXA may be the best choice for expressing adiposity. Due to the cross-sectional design of our analyses, we cannot establish causality in the association between MVPA and adiposity.

Associations Between Steps Per Day And Mortality In A Representative Sample Of US Adults

Pedro F. Saint-Maurice, Richard P. Troiano, Barry I. Graubard, Erik Willis, Charles E. Matthews, FACSM. *National Cancer Institute, Rockville, MD.* (Sponsor: Charles E. Matthews, FACSM)

Email: pedro.saintmaurice@nih.gov

(No relevant relationships reported)

PURPOSE: Walking is the most popular form of physical activity among adults, but it's still unknown how many steps per day are necessary to reduce mortality risk. This study examined the relation between objectively measured steps/day and mortality using NHANES data. **METHODS:** Participants were a representative sample of US adults (n=4,840 adults; ≥40 years) assessed for physical activity in 2003-06 using an accelerometer device and followed through 2015 for mortality status and cause of death using ICD-10 codes. Accelerometer-derived steps/day were modelled against all-cause, cardiovascular disease (CVD), and cancer mortality using cox proportional hazard models [(Hazard Ratios (HR) and 95% CI)]. Hazard ratios were adjusted for: age, sex, race-ethnicity, education, alcohol consumption, diet quality, smoking, BMI, health status, reduced mobility, and self-reported diagnosis of diabetes, coronary heart disease, stroke, and cancer. The 10th percentile for steps/day (~4000 steps/day) was defined as the referent group. We conducted sensitivity analyses excluding participants

with reduced mobility, poor/very poor health condition, and excluding the first two years of follow-up. NHANES population sample weights and adjustments for the complex survey design were employed.

RESULTS: A total of 1,165 deaths occurred during follow-up (406 from CVD, and 283 from cancer). The relation between steps/day and mortality was non-linear ($p < .01$). When compared to our reference ~4000 steps/day, an increase of 2,000 steps/day was associated with 36% lower risk for all-cause mortality (HR=0.64, 95% CI: 0.59, 0.70), 46% lower CVD mortality (HR=0.54, 95% CI: 0.20, 1.43), and 21% lower cancer mortality (HR=0.79, 95% CI: 0.69, 0.91). There were negligible reductions in risk beyond 10,000-12,000 steps/day. Results from sensitivity analyses did not alter the activity-mortality associations. **CONCLUSIONS:** Modest increases in steps/day (2000 steps/day) are associated with reduced risk for mortality with no extended benefits beyond 10,000-12,000 steps/day. The steps/day-mortality associations described here can help setting public health/clinical goals.

D-14 Free Communication/Slide - Physical Activity/ Exercise in Clinical Populations

Thursday, May 30, 2019, 1:30 PM - 3:15 PM

1640 May 30 1:30 PM - 1:45 PM Examining the Impact of Obesity on Ventilatory Responses During Acute Exercise in Patients with HFpEF

Brittany L. Christensen¹, Peter H. Brubaker, FACSM¹, Georgina Tiarks¹, J Thomas Becton², Dalane Kitzman². ¹Wake Forest University, Winston-Salem, NC. ²Wake Forest Baptist Medical Center, Winston-Salem, NC. (Sponsor: Peter Brubaker, FACSM)
Email: chrib117@wfu.edu

(No relevant relationships reported)

PURPOSE: Heart Failure (HF) is a major cause of morbidity and mortality worldwide. Ventilatory responses to acute exercise have important prognostic value in HF patients. This study examined baseline ventilatory measures to determine if obesity further impacts ventilatory responses in normal subjects and heart failure patients with preserved ejection fraction (HFpEF). **Methods:** All participants performed a cardiopulmonary exercise test to maximal effort to quantify ventilatory responses (tidal volume (TV), breathing frequency (Bf), and minute ventilation (VE)) at submaximal (25 watts) and peak exercise. Ventilation efficiency was determined by assessing VE/VCO₂ at submax and the VE/VCO₂ slope. Obese vs. non-obese HFpEF participants were categorized based on BMI ≥30 kg/m². One-way ANOVA was performed to determine if there were significant ($p < 0.05$) differences between groups. **Results:** The obese HFpEF group had higher VE during peak exercise than the non-obese group ($p < 0.05$), which was mainly due to greater Bf ($p = 0.08$) versus TV ($p = 0.24$). The VE/VCO₂ at the submaximal workload and VE/VCO₂ slope were significantly higher in the non-obese HFpEF group. **Conclusion:** As hypothesized, obese HFpEF participants exhibited worse ventilatory function than the non-obese HFpEF patient at similar levels of exercise. However, obese HFpEF participants demonstrate a similar degree of ventilatory inefficiency compared to normal weight HFpEF participants. Since ventilatory efficiency was not abnormal in obese HFpEF it appears that their prognosis is no worse than normal weight HFpEF participants.

1641 May 30 1:45 PM - 2:00 PM Comparison of Two High-Intensity Interval Training Modalities on Cardiometabolic Health in Overweight/ Obese Women

Ozgur Alan, Emily W. Flanagan, Lafayette T. Watson, Andrew N.L. Buskard, Demet Tekin, Arlette Perry, FACSM. *University of Miami, Coral Gables, FL.* (Sponsor: Arlette Perry, FACSM)
Email: o.alan@umiami.edu

(No relevant relationships reported)

High-intensity interval training (HIIT) has been used to reduce risk factors for diabetes, obesity, cardiovascular diseases and metabolic syndrome (MetS). Few studies have compared resistance-HIIT (R-HIIT) to aerobic-HIIT (A-HIIT) in a worksite wellness program designed to reduce risk factors for the MetS. **PURPOSE:** To compare the effects of A-HIIT and R-HIIT to that of a control group (CON) on

physical characteristics, cardiometabolic health, and self-reported well-being in women employees attending a worksite wellness program. **METHODS:** A total of 48 overweight/obese women possessing one or more MetS risk factors were randomly assigned to one of three groups with 31 women completing all testing and training procedures: A-HIIT (n=10), R-HIIT (n=10), and CON (n=11). A-HIIT and R-HIIT groups trained 3x/wk for 25 minutes in an 8-week program at an average training intensity of $81.0 \pm 1\%$ HR_{max} and $81.9 \pm 1\%$ HR_{max}, respectively. ANCOVA was used to determine differences among groups on all dependent variables at post-testing after adjusting for baseline values. Post-hoc analyses were performed using Bonferroni adjustments. **RESULTS:** Both A-HIIT ($M_{diff} = 23.9$ m, $p = 0.029$) and R-HIIT ($M_{diff} = 23.8$ m, $p = 0.029$) had higher aerobic fitness than CON ($M_{diff} = 190.9$ m SEM= 6.3) using the 2-minute walk test following training. Only R-HIIT ($M_{diff} = 45.3$ W, $p = 0.002$) showed increases in upper body power over CON ($M_{diff} = 94.9$ W SEM= 8.2) while displaying lower fasting insulin ($M_{diff} = -5.6$ μU/ml, $p = 0.036$) compared to CON ($M_{diff} = 17.4$ μU/ml, SEM= 1.4). R-HIIT also showed greater reductions in HOMA2-IR ($M_{diff} = -0.7$, $p = 0.046$) than CON ($M_{diff} = 2.2$, SEM= 0.2). Furthermore, HOMA2-%B was lower in R-HIIT compared to both CON ($M_{diff} = 159.3\%$, SEM= 8.8, $M_{diff} = -38.5\%$, $p = 0.017$), and A-HIIT ($M_{diff} = 172.2\%$, SEM= 9.4, $M_{diff} = -51.4\%$, $p = 0.002$). Finally, R-HIIT had significantly higher scores on the physical function domain of Patient Reported Outcome Measurement System (PROMIS[®])-57 well-being questionnaire compared to the CON group ($M_{diff} = 51.8$ SEM= 1.4, $M_{diff} = 5.7$, $p = 0.035$). **CONCLUSIONS:** Our study showed that R-HIIT can be considered as part of a risk reducing worksite-wellness strategy for improving physical characteristics, cardiometabolic health, and well-being in women possessing one or more components of the MetS. Supported by UM Citizens Board Grant

1642 May 30 2:00 PM - 2:15 PM Short and Long term Effects of Exercise Intensity on Conduit Artery Function in Cardiac Rehabilitation Patients

Jenna Taylor¹, Jeff S. Coombes, FACSM¹, David J. Holland¹, Shelley E. Keating¹, Daniel J. Green², Tom G. Bailey¹. ¹The University of Queensland, Brisbane, Australia. ²The University of Western Australia, Perth, Australia. (Sponsor: Professor Jeff Coombes, FACSM)

Email: j.kirchner@uq.edu.au

(No relevant relationships reported)

PURPOSE: Patients with coronary artery disease (CAD) commonly present with conduit artery dysfunction characterized by decreased brachial artery flow-mediated dilation (FMD). Reduced FMD of 1% is associated with an 8-13% increased risk of future cardiovascular events¹, and thus interventions designed to improve FMD in patients with CAD are warranted. Short-term supervised exercise training may improve FMD, however whether improvements are maintained longer term following cessation of supervised cardiac rehabilitation (CR), is unclear. We compared the short- and long-term effect of High Intensity Interval Training (HIIT) and Moderate Intensity Continuous Training (MICT) on FMD in patients with CAD commencing a 4-week CR program in a real world hospital-based setting.

METHODS: Patients with angiographically-proven CAD (Age: 64 ± 7 ; 35 males, 3 females) completed 3 sessions per week (2 supervised, 1 home-based) for 4-weeks, randomized to either 1) HIIT (n=21): 4 x 4 minute high intensity intervals at a rating of perceived exertion (RPE) 15-18 interspersed with 3 minute active recovery periods or 2) MICT usual care (n=17): 40 minutes moderate intensity continuous exercise at an RPE 11-13. Patients then continued 3 unsupervised home-based sessions per week of their randomized training for a further 11 months. FMD was measured at baseline, 4 weeks, 3 months, 6 months, and 12 months. Data was analyzed using a linear mixed model with baseline diameter and shear rate as covariates. Data is presented as mean (95% CI).

RESULTS: Baseline FMD was not different between groups [HIIT: 3.1%(2.2 to 4.0); MICT: 2.9%(1.9 to 3.9), $p = 0.657$]. FMD increased from baseline at 4 weeks, 6 months and 12 months in the HIIT group [4 weeks: +1.8%(0.8 to 2.7), $p < 0.001$; 6-months: +1.6%(0.7 to 2.6), $p = 0.01$; 12-months: +1.4%(0.4 to 2.3), $p = 0.007$], with negligible changes in the MICT group [4 weeks: +0.4%(-1.1 to 1.0), $p = 0.94$; 6 months: +1.0%(-0.1 to 2.1), $p = 0.063$; 12 months: +0.3%(-0.7 to 1.3), $p = 0.52$].

CONCLUSIONS: A 4-week CR program of HIIT, but not MICT (usual care), improved conduit artery function in patients with CAD. Improved FMD with HIIT was maintained long-term at 6- and 12 months with home-based training.

Optimizing Utilization Of A Cardiac Rehabilitation Facility For Chronic Disease Prevention.

Jaini Patel, Aashish Contractor. *Sir H.N. Reliance Foundation Hospital, Mumbai, India.*
 Email: drjainipatel@gmail.com
 (No relevant relationships reported)

PURPOSE: Cardiac rehabilitation (CR) involves delivery of structured exercise, education and risk reduction, in a cost-effective manner. Despite its benefits, and clinical practice guideline recommendations, CR programs are grossly underused due to multiple barriers. A large study of 2,67,427 patients showed that CR was used in 13.9% of patients hospitalized for AMI and in 31.0% of those who underwent CABG surgery. To help optimize utilization of resources, at our hospital, we utilised our cardiac rehabilitation facility to include other disease groups such as cancer, respiratory and stable cerebrovascular diseases, since the principles of exercise prescription for these disease groups are similar to CR and require similar infrastructure. The purpose was to utilise a cardiac rehabilitation centre as a chronic disease prevention centre for oncology, and pulmonary patients. To also assess the effects of the comprehensive program on physical fitness levels of these patients using the 6-minute walk test. **METHODS:** 319 patients, which included those with cardiac disease (185), pulmonary disease (36) and cancer (98) were assessed as part of this study over a period of 3 years. The program comprised aerobic exercises, resistance training, yoga, and disease specific rehabilitation. The aerobic capacity was assessed before and after one month of rehabilitation by means of the 6 Minute Walk Test (6MWT). **RESULTS:** The 6-minute walk test distance (6MWT) in the cardiovascular group improved from 331.56 (\pm 99.68) to 413.99 (\pm 104.43) meters, 24.86% increase from baseline ($p < 0.0001$); pulmonary group improved from 313.17 (\pm 100.90) to 339.31 (\pm 116.92) meters, 8.35% increase from baseline ($p = 0.0002$) and oncology group improved from 380.29 (\pm 97.24) to 431.20 (\pm 96.44) meters, 13.39% increase from baseline ($p < 0.0001$). **CONCLUSIONS:** A comprehensive CR facility can be successfully used to include other chronic disease group patients. It helps to improve overall aerobic capacity as indicated by significant increase in 6-minute walk test distance in cardiac, pulmonary and oncology patients. This can help hospitals deploy their rehabilitation services in an efficient and cost-effective manner.

Bidirectional Relationships of Daily Physical Activity and Sleep Among Patients with Heart Failure and Insomnia

Garrett I. Ash, Sangchoon Jeon, Nancy S. Redeker. *Yale University, New Haven, CT.* (Sponsor: Yanniss P. Pitsiladis, FACSM)
 Email: garrett.ash@yale.edu
 (No relevant relationships reported)

Physical activity is associated with better sleep quality across a wide range of populations, but the causal direction of this relationship is unclear due to lack of longitudinal and experimental studies. Patients with heart failure (HF) bear particular risk of poor sleep and low physical activity. **PURPOSE:** Examine the relationships between within-person day-to-day fluctuations in physical activity and sleep quality among patients with stable NYHA Class I-IV HF and insomnia (insomnia severity index > 7). **METHODS:** Patients wore a uniaxial wrist accelerometer (Actiwatch) for 14 consecutive days and nights to measure total daytime activity counts, total sleep time, sleep onset latency and sleep continuity (sleep efficiency and wake time after sleep onset (WASO)). Two-level multilevel models with daily and individual variation predicted daytime activity outcomes and sleep outcomes, separately. We adjusted for covariates within (day of the week) and between subjects (age, Charlson Comorbidity Index (CCI), NYHA HF Class, and body mass index (BMI)). Significance $p < 0.05$. **RESULTS:** Participants ($n = 114$, $M = 62.4 \pm 12.1$ years, female 43%, black 22%, white 75%, NYHA Class 1.9 ± 0.8) on average obese (BMI 31.4 ± 7.6 kg/m²) with multiple comorbidities (CCI 3.2 ± 2.0). Daytime activity ($177 \pm 82 \times 10^3$ counts/day) was associated with younger age ($\beta = -1.32 \pm 0.50$), fewer comorbidities ($\beta = -10.57 \pm 3.26$), lower NYHA class ($\beta = -17.99 \pm 7.80$), and a tendency for lower BMI ($\beta = -1.58 \pm 0.83$, $p = 0.06$). Comorbidity was associated with poorer sleep efficiency ($\beta = -0.98 \pm 0.48$) and more WASO ($\beta = 5.94 \pm 2.05$). After adjustment for all significant covariates, daytime activity was not associated with sleep characteristics the next night, but every minute less total sleep time ($\beta = -0.075 \pm 0.015$) or WASO ($\beta = -0.114 \pm 0.042$) was associated with $\sim 70 - 100$ more activity counts the next day. **CONCLUSIONS:** Similar to studies in other populations, less WASO and less total sleep time both were associated with more activity the next day, but these were not bidirectional relationships since activity the previous day was not associated with sleep characteristics. Future research should confirm these results by polysomnography and hip accelerometry and evaluate mechanisms.

Support: NIH- R01NR016191; Yale Center for Sleep Disturbance in Acute and Chronic Conditions.

1645 May 30 2:45 PM - 3:00 PM

Measuring Physical Activity in People with Heart Failure - An Accelerometer Calibration Study

Grace O. Dibben¹, Rod S. Taylor¹, Hasnain M. Dalal¹, Brad Metcalf¹, Manish M. Gandhi², Lars H. Tang³, Patrick Doherty⁴, Melvyn Hillsdon¹. ¹University of Exeter, Exeter, United Kingdom. ²Royal Devon and Exeter NHS Hospital Foundation Trust, Exeter, United Kingdom. ³University of Southern Denmark and Odense University Hospital, Odense, Denmark. ⁴University of York, York, United Kingdom.
 Email: gd318@exeter.ac.uk
 (No relevant relationships reported)

PURPOSE: To estimate acceleration values corresponding to light and moderate to vigorous intensity physical activity (PA) in people with heart failure via calibration with oxygen consumption (VO₂). **METHODS:** 21 adults with heart failure undertook a range of typical lifestyle activities (including laying down, and walking at different speeds) whilst wearing three accelerometers (each wrist and the left hip) and a portable gas analyser. Resting metabolic rate (RMR) was established and participants also undertook an incremental shuttle walk test (ISWT) to estimate fitness. Location specific activity intensity thresholds were established via Receiver Operator Characteristic (ROC) curve analysis. **RESULTS:** Participants had an average age of 71.1 ± 14.3 years, the majority were male (24% female) and average BMI was 28.2 ± 4.4 kg/m². Average distance walked during the ISWT was 279 ± 192 m, and average RMR was 0.76 ± 0.19 METS. The measured metabolic cost of slow paced walking (average pace 2.6 kph) was 4.09 ± 1.08 METS - higher than estimates based on standard methods i.e. VO₂/3.5 ml/kg/min (3.03 ± 0.63 METS) or the Compendium of PA (2.0 METS). Similarly, moderate paced walking (average pace 3.5 kph) averaged 4.65 ± 1.08 METS using measured RMR compared to 3.46 ± 0.78 METS via the standard methods and 2.8 METS via the Compendium. ROC curve analysis will be used to estimate acceleration values corresponding to light and moderate to vigorous intensity PA. **CONCLUSIONS:** Using single accelerometer values for estimating PA intensity assumes energy expenditure is the same for specific activities irrespective of fitness level, which risks underestimating the PA levels of low fit populations such as people with heart failure. It may also risk prescribing PA intensities that are too high for this population. Results of this study indicate that the measured metabolic cost of activities such as walking at a light pace are much higher than estimated METs reported in the PA compendium. Population specific accelerometer thresholds for estimating light and moderate to vigorous intensity PA will permit more precise measures of the prevalence of PA in people with heart failure.

1646 May 30 3:00 PM - 3:15 PM

The Effect Of A Personalized Multi-component Lifestyle Intervention Program In Stage 3 & 4 CKD Patients.

Samuel A. Headley, FACS¹, Jasmin Hutchinson¹, Brian Thompson¹, Marissa Ostroff², Courtney Doyle-Campbell², Allen Cornelius³, Kristen Dempsey¹, Jennifer Siddall¹, Emily Miele¹, Elizabeth Evans¹, Brianna Wood¹, Cherilyn Sirois¹, Brett Winston¹, Michael Germain⁴. ¹Springfield College, Springfield, MA. ²Western New England University, Springfield, MA. ³University of the Rockies, Denver, CO. ⁴Renal and Transplant Associates of New England, Springfield, MA.
 Email: sheadley@springfieldcollege.edu
 (No relevant relationships reported)

PURPOSE: We studied the effect of a comprehensive lifestyle intervention (nutrition, physical activity, pharmacy, and behavioral counseling) on health related outcomes in 42 stage 3 & 4 (eGFRs 15-59 ml/min/1.73m²) CKD patients (age 60.2 ± 9.2 , BMI 34.5 ± 7.8). **METHODS:** Patients were assigned randomly to a treatment (T, $n = 27$) or usual care (UC, $n = 15$) group, and asked to attend four test sessions: baseline (BL), month 1 (M1), month 3 (M3) and month 6 (M6). Anthropometrics, medication use, three-day nutritional intake, central (cSBP/cDBP) & brachial blood pressures (bSBP/bDBP), augmentation index (AIx@75), Short Physical Performance Battery (SPPB) test, the six-minute walk test (6MWT), leg strength & power, self-efficacy to adhere to diet and physical activity (PA) recommendations, and the KDQOL were assessed at each visit. PA levels and inflammatory markers (IL6 & hsCRP) were assessed at BL and M6. Patients in T received individual counseling at BL, M1, & M3 with biweekly follow-up phone contact. Patients in UC were asked to follow the instructions of their nephrologist. **RESULTS:** All data are presented as means \pm SD. Primary outcome variables were analyzed by 2 x 2 mixed factor ANOVAs. See table for some of the findings:

| Variable | BL | M3 | M6 | | | | |
|--------------------------------|------------|------------|--------------|--------------|---------------|--------------|--------|
| | T | UC | T | UC | T | UC | |
| bSBP mm Hg T, n=22, UC n=13 | 137.4±14.3 | 128.2±23.4 | *127.6±13.7 | 131.7±17.2 | 132.6±15.0 | 124.7±19.7 | p=.01* |
| cSBP mm Hg T, n=22, UC n=13 | 124.2±12.6 | 116.1±20.1 | *115.6±12.4 | 119.6±14.4 | 120.7±14.1 | 112.9±17.3 | p=.01* |
| cDBP mm Hg T, n=22, UC n=13 | 78.9±10.1 | 76.7±12.3 | *73.7±9.7 | 77.7±9.7 | 76.9±12.9 | 75.3±11.4 | p=.02* |
| Alx@75 T, n=22, UC n=13 | 27.7±8.0 | 26.9±11.1 | 27.6±11.4 | 26.9±12.7 | 29.3±12.2 | *21.9±9.98 | p=.02* |
| SPPB T, n=23, UC n=14 | 10.±2.1 | 10.±1.4 | 9.9±2.3 | 10.3±1.2 | 9.9±1.8 | 10.2±1.1 | p=.53 |
| Effect of CKD T, n=23, UC n=14 | 85.3±20.9 | 88.2±13.9 | *88.9±14.1 | 84.2±17.3 | *91.5±14.6 | 85.3±15.1 | p=.02* |
| Kcals T, n=23, UC n=14 | 1809.7±571 | 1630±653 | 1422.8±628.5 | 1418.4±460.8 | 1463.8*±594.0 | 1768.4±515.8 | p=.03* |

CONCLUSION: In conclusion, this program led to reductions in bSBP, cSBP and cDBP at M3 which were attenuated at M6. Patients in T felt less restricted by their disease than the UC group. This home- based program resulted in no improvements in functional outcomes (SPPB or 6MWT). Supervised, in-center programs are preferred when working with CKD patients.

D-15 Clinical Case Slide - Chest Pain

Thursday, May 30, 2019, 1:30 PM - 3:10 PM

Chest Pain in a Football Strength Coach
Michael Anacker, Keri Denay, FACSM. *University of Michigan, Ann Arbor, MI.* (Sponsor: Keri Denay, FACSM)
(No relevant relationships reported)

HISTORY: A 29-year-old adopted, African American male football coach traveled with the football team to Colorado to hike Pikes Peak. At 14,000 feet, he developed mid-sternal chest pain that radiated to his left upper abdomen and left shoulder. The pain worsened with deep breathing and exertion. He presented to a local ED, where a CT abdomen/pelvis revealed splenomegaly. Routine labs revealed a mild anemia and thrombocytopenia. Upon returning home, the pain continued for 2 days so he presented to clinic. There, he denied calf pain, extremity swelling, fever, nausea, palpitations, vomiting, hematuria, and syncope. He denied taking medications, supplements, and alcohol/drugs. He reported developing similar symptoms in 2015, also when hiking. At that time, he was diagnosed with pericarditis with symptom resolution in a few days.
PHYSICAL EXAMINATION:
Temp 36.9F, BP 132/61, HR 67, RR 16, O2 sat 97%
At rest, he was alert and comfortable. Breathing comfortably with symmetric aeration; no wheezing or crackles. Heart had regular rate and rhythm, without murmur.

Abdomen was soft and non-distended, though he was tender to palpation in the left upper quadrant. No lower extremity edema; calves were symmetric and non-tender to palpation.

DIFFERENTIAL DIAGNOSIS:

Pulmonary Embolus
Pericarditis
Mononucleosis

Sickle cell crisis in a patient with sickle cell trait

TEST AND RESULTS: A CT angiography chest, chest radiograph, and abdominal ultrasound were obtained and were notable for splenomegaly (14.3cm); otherwise unremarkable. An EKG revealed sinus bradycardia with sinus arrhythmia. Labs were obtained including CBCPD, CMP, CK, haptoglobin, LDH, and hemoglobin electrophoresis, and notable for a mild anemia (hemoglobin 12.2), thrombocytopenia (platelets 52), mild transaminitis (AST 42, ALT 37), and evidence of hemolysis (haptoglobin < 10, LDH 486, CK 348). Hemoglobin electrophoresis was consistent with sickle cell trait.

FINAL WORKING DIAGNOSIS: Sickle cell crisis in a patient with sickle cell trait

TREATMENT AND OUTCOMES:

1. Trended labs for 2 weeks.
2. Avoid strenuous activity until pain resolved.
3. Provide counseling regarding hydration, heat illness, and training especially at altitude.
4. Follow up with hematology.
5. Consider screening NCAA coaches/athletic trainers given NCAA athletes are screened for sickle cell.

1651 May 30 1:50 PM - 2:10 PM

Rib Pain - Football

Christopher Hicks. *University of Virginia, CHARLOTTESVILLE, VA.* (Sponsor: John M. MacKnight, M.D., FACSM)
Email: c.hickstwo@gmail.com
(No relevant relationships reported)

HISTORY: 21-year-old collegiate football defensive lineman complained of rib pain after a road game in Tennessee. Aside from a mild ankle sprain, he denied any specific injury to his torso/ribs. Pain began on the left side and then migrated to the right side with radiation to flank and sternum areas bilaterally. Had pain with deep breathing and sensation of tightness in the rib area. Took naproxen with some relief of his symptoms. Denied chest pressure, shortness of breath, palpitations, fevers or chills.

PMH: HTN, ADD
Meds: Amlodipine, Adderall
SH: No tobacco, social ETOH, no illicit drugs
FH: Non contributory

PHYSICAL EXAMINATION:

Well gentlemen in mild distress due to pain
Blood pressure 140/90, pulse 72, RR 14.
Neck- No JVD
CV: RRR, normal heart sounds. No gallop or rub. No murmur.
Pulmonary: No respiratory distress. Breath sounds normal. Good air movement. No wheezes or rales.
Chest: Tenderness to palpation along the flank areas greatest over ribs 5-7 bilaterally. No true focal pain noted.
Ext: DP and PT +2. No edema.

DIFFERENTIAL DIAGNOSIS:

1. Costochondritis
2. Rib fracture
3. Chest wall strain
4. Pneumothorax
5. Pulmonary Embolism

Interim History: Treated for chest wall injury with varying response over the next 4 days. Re-presented 2 hours before the next home game with shortness of breath, tachypnea, and worsening chest discomfort. Transferred to ER.

TEST AND RESULTS:

Chest x-ray- focal right lower lobe opacification
D-Dimer 774
CT PA- acute bilateral segmental and sub-segmental pulmonary emboli, without evidence of right heart strain
Factor V Leiden, Anti-Cardiolipin, and Prothrombin negative
Lupus anticoagulant, Protein S, Protein C and Antithrombin III pending

FINAL/WORKING DIAGNOSIS: Acute bilateral segmental and sub-segmental pulmonary emboli, unclear etiology.

TREATMENT AND OUTCOMES:

1. Anticoagulation therapy with Apixaban for minimum of 3 months with considerations for lifetime treatment.
2. No contact sports or activities while on anticoagulation.
3. Continued hematology follow-up of coagulation workup.
4. Ongoing discussion of importance of inclusion of PE on the differential for chest pain even in healthy athletes with no discernible risks.

1652 May 30 2:10 PM - 2:30 PM

10 Months of Dyspnea Following Long Runs in Marathon Athlete

Jay Shah, Jose Velasquez, James Pearson, Hamed Shalika.
Citrus Valley Health Partners, West Covina, CA. (Sponsor: Dr. Aaron Rubin, FACSM)
 Email: jashah80@gmail.com

(No relevant relationships reported)

HISTORY:

A 51-year-old male marathon runner presented with pleuritic chest pain and increasingly progressive shortness of breath at the end of his runs. At baseline, he was running a marathon in 3 hours, but his runs were reduced to less than 15 miles. He completed a 15k in 1 hour and 30 minutes but with severe dyspnea on exertion. Patient was referred to the Sports medicine clinic for further evaluation.

PHYSICAL EXAMINATION:

Vitals within normal limits
 NAD, speaking in full sentences, no chest wall tenderness. CV: regular rate and rhythm. no edema. Pulmonary: normal respiratory effort without distress, absent of wheezes or rales.

DIFFERENTIAL DIAGNOSIS:

- 1) Overtraining syndrome
- 2) Asthma/Exercise induced bronchospasm
- 3) Viral syndrome
- 4) Pulmonary embolism

TESTS AND RESULTS:

8/2017: EKG nonspecific/chest X-ray reported small bilateral pleural effusion
 8/2017: Non contrast chest CT - no pleural effusion
 8/2017: TTEcho: EF 60-65%, unremarkable valves & chambers
 8/2017: Treadmill test unspecific, high exercise tolerance
 9/2017: CXR - persistence of bilateral pleural effusion.
 1/2018: Myocardial perfusion scan - no evidence of stress induced ischemia
 3/2018: Spirometry - normal, no response to Bronchodilators.
 3/2018: Non Contrast chest CT - Diminished right lung pleural opacity, probably represented inflammatory change
 9/2018: D-dimer 564
 9/2018: CT-A - small embolus in a subsegmental branch of the pulmonary artery to the left lower lobe. Second pulmonary embolus in a segmental branch of the pulmonary artery to the right lower lobe.

FINAL/WORKING DIAGNOSIS

Bilateral unprovoked pulmonary embolism

TREATMENT AND OUTCOMES

- 1) Discussed indications, risks, benefits, and dietary & activity precautions of anticoagulation with Warfarin vs. Direct Oral Anticoagulant such as Pradaxa with patient in extensive detail. Patient opted for Pradaxa.
- 2) Hypercoagulable work-up sent and hematology referral

1653 May 30 2:30 PM - 2:50 PM

Chest Injury-football

Kendrick I. Watkins, Rehal A. Bhojani. *University of Texas Health Science Center, Houston, TX.* (Sponsor: Charles Chassay, FACSM)

(No relevant relationships reported)

HISTORY: 17 year old high school football wide receiver presented with left back and rib pain. He sustained a hit in that region during a football game the night before. He was taken out of the game due to pain and difficulty breathing which ultimately kept him from finishing the game. After the game he continued to have pain for which he took a muscle relaxant that he had from a previous injury and over the counter pain medication with minimal pain relief. The pain persisted through the night and into the following morning. His pain was worse with deep breathing and any pressure on his chest. He denied any shortness of breath, dyspnea with exertion, cough, wheezing or hemoptysis.

PHYSICAL EXAMINATION: Appeared in no acute distress, Ecchymosis over the posterior lateral aspect of left lower ribs with tenderness to palpation. No crepitus, No palpable deformity, Symmetric chest expansion, posterior rib/back pain reproduced with deep inspiration, Equal bilateral breath sounds, No hyper-resonance to percussion, Normal respiratory rate, Negative anterior posterior compression test, Positive lateral compression test, Full AROM of the back

DIFFERENTIAL DIAGNOSIS: Rib fracture, Pneumothorax, Pulmonary contusion, Pulmonary embolism

TEST AND RESULTS: X-ray Rib series: Small left apical pneumothorax involving approximately 20% of the hemi thorax. Suspected nondisplaced fractures involving the posterolateral left eighth and ninth ribs with small linear lucencies within these regions. Chest CT scan: Small left-sided pneumothorax approximately 20%. No acute osseous injury.

FINAL WORKING DIAGNOSIS: Pneumothorax

TREATMENT AND OUTCOMES:

The patient was sent to ER after being seen in clinic to expedite getting a CT scan done after the X-rays. After the CT scan was obtained it was decided by the ED to admit the patient for observation. He obtained a subsequent x-ray that evening 12 hours after is initial which showed a slightly smaller left apical pneumothorax. He was discharged the next day. Repeat chest x-ray done three days after discharge showed improving pneumothorax. Patient was seen in clinic 2 weeks after his discharge from the hospital and was started on a graded exercise program with repeat x-ray at 1 week after clinic visit showed resolution of pneumothorax. He returned to full game play at 4 weeks after his initial injury.

1654 May 30 2:50 PM - 3:10 PM

Focal Chest Pain- Rugby

Joshua Martin, Prakash Jayabalan, Joseph Ihm, FACSM. *Shirley Ryan AbilityLab/ Northwestern, Chicago, IL.*

(No relevant relationships reported)

HISTORY: A 21-year old rugby-playing male presented with a one year history of worsening anterior chest wall pain. Pain was associated with a popping sensation in the anterior chest. Additionally, symptoms were aggravated by overhead movements and chest exercises. Pain was focal, without discomfort in the ribs or thoracic back. He denied shortness of breath, pain while coughing, and all other systemic symptoms.

PHYSICAL EXAMINATION: Local examination revealed a tender swelling at the manubriosternal joint (MSJ). Chest expansion was full and deep breaths did not elicit pain. Full painless range of motion at the shoulder, with strength intact to manual muscle testing throughout

DIFFERENTIAL DIAGNOSIS:

1. Strain of pectoralis major
2. Costochondritis
3. Inflammatory arthritis
4. Osteoarthritis of the MSJ
5. Pulmonary embolism
6. Pneumothorax
7. Pericarditis

TEST AND RESULTS:

Prior cardiology work-up did not reveal an eliciting cause
 Lateral x-ray of the chest (sternal view)
 - Bone resorption on both sides of the MSJ, and soft tissue swelling anterior to the joint.

Chest MRI

- Irregularity at the sternal and manubrial articular surfaces, along with a small effusion, compatible with osteoarthritis.

Further rheumatological workup for inflammatory markers

- Unremarkable CBC, ESR and CRP

FINAL WORKING DIAGNOSIS: Manubriosternal osteoarthritis

TREATMENT AND OUTCOMES:

1. Refrained from rugby for several months
2. Started on regular daily meloxicam 7.5mg for 1 month
3. Significant improvement in symptoms

D-16 Clinical Case Slide - Foot and Ankle

Thursday, May 30, 2019, 1:30 PM - 3:10 PM

Recurrent Foot Pain - A Case Series of Two Division 1 College Football Athletes
Elizabeth L. Albright. *Penn State Health, State College, PA.*
(Sponsor: Peter Seidenberg, MD, FACSM)
(No relevant relationships reported)

HISTORY: Patient 1 (P1) is a 21 y/o white male who presented for pain over lateral aspect of his right foot after twisting on it during scrimmage. He had immediate pain with ambulation. He denied hearing/feeling a pop or paresthesias. Patient 2 (P2) is a 21 y/o African-American male who presented after feeling a pop in his lateral left foot during cutting maneuver at practice. He had significant pain with ambulation and denied paresthesias. Both were 5 months status post percutaneous screw fixation of Jones fracture of the ipsilateral foot. After initial injury, Vitamin D levels were 24 and 27 ng/ml respectively. They were started on Vitamin D supplementation and provided a bone stimulator. They remained non-weightbearing in CAM boot for 4 weeks followed by weightbearing in CAM boot for 2 weeks. At 6 weeks, they progressed back into regular shoes. They completed rehab with athletic trainer and had returned to full activity at time of reinjury. **PHYSICAL EXAMINATION:** Both: Skin intact. Full ankle ROM. TTP of Base of 5th metatarsal. Neurovascularly intact. No TTP of navicular, bilateral malleoli, ankle ligaments, Lisfranc joint, peroneal tendons, bifurcate ligament, calcaneus, or cuboid. Both had flexible, forefoot induced, inverted varus positioning of calcaneus with positive Coleman block test. P1 had equivocal fulcrum test and pes cavus. P2 had mild edema of lateral foot and pes planus. **DIFFERENTIAL DIAGNOSIS:** Repeat Jones Fracture, 5th Metatarsal shaft or Avulsion fracture, Peroneal Tendon Rupture, Bifurcate Ligament Sprain, Cuboid Subluxation, Avascular Necrosis **TESTS AND RESULTS:** P1: New lucency at previously healed fracture site on XR, No hardware issues P2: Initially improved compared to previous XR but bone reabsorption evident at 2 weeks. No hardware issues **FINAL WORKING DIAGNOSIS:** Recurrent Jones Fracture **TREATMENT AND OUTCOMES:** Non-weight bearing in CAM boot. Restart bone stimulator. Continue Vitamin D. At 1 week, transitioned to weightbearing in CAM boot. At 4 weeks, P1 transitioned into regular shoe with custom clamshell orthotic to correct hindfoot deformity and started return to play progression. At 6 weeks, he returned to full activity with orthotic in cleats. P2 required an additional 2 weeks in boot for slow fracture remodeling but then started RTP with full return by 8 weeks

1659 May 30 1:50 PM - 2:10 PM
Heel Injury-Figure Skate
Naoko Onizuka, Suzanne Hecht, FACSM. *University of Minnesota, Minneapolis, MN.* (Sponsor: Suzanne Hecht, FACSM)
(No relevant relationships reported)

HISTORY: A nine year old female figure skater presented with 6 weeks of atraumatic right foot pain. She recently started training double jumps prior to the onset of pain. Pain was located on the plantar side of the right midfoot and she initially noticed it following practices. Weight bearing increased her pain and eventually it hurt during practice as well as after practice. No changes in training time or frequency. She has been figure skating for two years. No history of previous foot injuries or bone stress injuries. No family history of osteoporosis. Her past medical history is significant for chronic Lyme's disease.

PHYSICAL EXAM: Ht 4' 6" (1.372 m) | Wt 69 lb (31.3 kg) | BMI 16.64 kg/m2 (56 percentile), Healthy and NAD. Accompanied by her mother.
Examination:
Inspection: Neutral foot type. Normal alignment of lower extremities. There was no redness, swelling, or skin changes.
Palpation: moderate tenderness on the right plantar mid foot.
Range of motion: there was full active range of motion of the ankle, without significant pain.
Strength: Muscle strength (ankle plantarflexion, dorsiflexion, inversion, eversion) full.
Special tests: Fracture test (tap, percussion, bump) negative, squeeze test negative, anterior drawer test negative, Talar tilt test negative, Stress test negative, Thompson test negative.
DIFFERENTIAL DIAGNOSIS:
1.Navicular bone stress injury
2.Tarsal coalition
3.Anterior tibialis tendinopathy
4.Posterior tibialis tendinopathy
5.Bone tumor
6.Nerve entrapment
7.Heel pad syndrome
8.Sever disease
TEST AND RESULTS:
1.Ankle X-ray- No obvious fracture or callus
2.MRI Ankle- bone marrow edema in the neck of the calcaneus
3.DXA- Normal bone density
FINAL DIAGNOSIS: Calcaneus bone stress injury
TREATMENT AND OUTCOMES:
1.Decreased activity level
2.Non-weight bearing on crutches for 2 weeks
3.Walking boot for 3 weeks with partial weight bearing on crutches
4.PT 1-2x/ week for 2-3 weeks
5.Vitamin D 2000 IU everyday
6.Partial weight bearing to full weight bearing as tolerated
7.Gradual return to sports after 12 weeks of injury, when she did not have pain with ambulation, and repeat MRI showed no evidence of residual bone marrow edema.

1660 May 30 2:10 PM - 2:30 PM
Ankle Pain - Basketball
Mary Lynch, David Soma. *Mayo Clinic, Rochester, MN.*
(Sponsor: Karen Newcomer, FACSM)
(No relevant relationships reported)

HISTORY: Our patient is a healthy 17 year old female basketball and softball player who had been treated for bilateral Achilles tendonitis. Two weeks prior to presentation, she jumped and created a moment of extreme plantar flexion of her left foot. She had immediate posterior ankle pain without edema or erythema. A physical therapist recommended heel cups. She did not consistently rest. Her basketball performance was poor over the next two weeks.
• **PHYSICAL EXAMINATION:** Normal gait and inspection. Tender deep to the Achilles tendon near the junction of the talus and calcaneus with mild tenderness along the Achilles tendon and musculotendinous junction. No tenderness of the calcaneus, medial or lateral malleolus, or midfoot. Active ROM preserved. Passive ROM limited a few degrees in both dorsiflexion and plantar flexion compared to the contralateral foot. 5/5 plantar flexion and dorsiflexion strength. Resisted plantar flexion and hopping on left foot caused significant discomfort. Normal Achilles squeeze test.
• **DIFFERENTIAL DIAGNOSIS:**
• 1. Achilles tendonitis
• 2. Retrocalcaneal bursitis
• 3. Fracture of os trigonum
• 4. Tendonitis of flexor hallucis or flexor digitorum tendon
• 5. Posterior facet arthritis of the subtalar joint
• **TEST AND RESULTS:**
• **X-ray:** Originally radiologist read as normal, but sports medicine interpretation was that there appeared to be a lucency extending through the lateral tubercle of the posterior process of the talus consistent with acute fracture.
• **MRI:** Nondisplaced fracture of the Stieda process of the talus with associated bone marrow edema. Additional findings include small effusions in the posterior facet of the subtalar and tibiotalar joints, minimal tendinopathy of distal Achilles tendon, and a tiny amount of fluid in the retrocalcaneal bursa.
• **FINAL WORKING DIAGNOSIS:** Fracture of Stieda process
• **TREATMENT AND OUTCOMES:**
• 1. After two weeks of rest in a boot, she began isometric exercises without the boot and stationary cycling in the boot.
• 2. After four weeks in the boot, she progressed to one week of light activity before returning to play at the end of her senior year of high school basketball and playoffs. She was counseled about the risk of non-union or re-injury given that she did not rest for a more prolonged period.
• 3. One year later, she remains pain free playing college basketball.

THURSDAY, MAY 30, 2019

1661 May 30 2:30 PM - 2:50 PM

Atypical Ankle Pain In A 10-year-oldRobyn C. Knutson Bueling. *TRIA Orthopedics, Woodbury, MN.*
Email: robyn.knutsonbueling@parknicollet.com*(No relevant relationships reported)*

HISTORY: Active 10-year-old non-athlete with acute onset of severe ankle pain and swelling for two days. Occurred while at school but can't recall injury during PE or recess. Taken to Children's hospital ER and treated with ice. Presented to Acute Injury Clinic for further evaluation.

PHYSICAL EXAMINATION: Significant TTP diffusely about R ankle. Moderate-to-severe R ankle joint effusion. Unable to weight-bear. Limited ROM secondary to pain. No rash. No fever. L ankle exam normal.

DIFFERENTIAL DIAGNOSIS: Occult injury. Lyme disease. Joint infection. Post-infectious septic joint. Tumor.

TEST AND RESULTS: -Aspirate normal CBC, elevated uric acid, normal CRP, negative culture, negative crystals, substantial RBC and some WBC, Lyme negative. -MRI with large tibiotalar joint effusion with multiple large intra-articular masses consistent with polyvillous nodular sclerosis or other synovial metaplasia.

FINAL WORKING DIAGNOSIS: PVNS R ankle

TREATMENT AND OUTCOMES: -Very uncommon presentation of PVNS in atypical joint and atypical age-group. -Splinted for comfort. Narcotic pain medicines prn. -Evaluated by orthopedic oncology. Take for surgical intervention. -Patient has now had full return to full activity with ongoing surveillance.

1662 May 30 2:50 PM - 3:10 PM

A Poorly Timed Slapshot To The Foot in a Hockey PlayerJohn Gunel, Christopher Lutrzykowski. *Maine Dartmouth Sports Medicine Fellowship, Augusta, ME.* (Sponsor: James Dunlap, MD, FACSM)*(No relevant relationships reported)*

History: This is a 16 year old female ice hockey player who is a senior at a boarding school. She presents with right medial foot pain. This occurred after blocking a slap shot with her instep three weeks prior. Being recruiting season, she continued to play on her painful foot, lift weights daily, and run 3 miles two times per week. She has changed her gait to reduce pain with these activities. NSAIDs and working with her AT on strengthening and range of motion have not improved her symptoms. Due to worsening pain with weight bearing, she received right foot xrays at an urgent care center and she would like to follow up on the results. She anxiously states that in two weeks, she will be returning to her boarding school where she seeks to participate in a showcase tournament where multiple scouts will be present. **PE:** Gen: NAD.

MSK: BL foot and ankles: Inspection: Soft tissue swelling in anteriolateral right ankle. Palpation: TTP over navicular. No TTP over 5th metatarsal or medial/lateral malleolus. Squeeze test positive. ROM: normal in all planes but painful at right at end ranges of motion. Strength: 5/5 in all planes. Special tests: negative drawer and false tilt. Sensation: intact Vascular: DP 2+, cap refill Proprioception: Single leg stance, heel raise: normal **Differential Diagnosis:** Stress fracture Bipartite navicular Osteochondritis dissecans Avascular necrosis Avulsion fracture Morton's Neuroma Tarsal coalition **Imaging:** 1) X-RAY, RIGHT FOOT - possible navicular fracture. No other bony abnormalities, malalignment, soft tissue abnormality.

2) MRI FOOT, RIGHT: Edema throughout the navicular, proximal diaphysis of the third metatarsal, and the base of the fourth metatarsal. **Final Diagnosis:** Stress fracture of the Navicular, third metatarsal, and fourth metatarsal. **Treatment:** Non weight bearing with boot for 5 weeks, then gradual return to weight bearing.

Outcome: Ongoing pain with weight bearing but no TTP at follow up. Her treatment was complicated by her boarding school not having a team physician for our office to release her to.

After a risk/benefit discussion, the patient elected to participate in a showcase tournament with pain in her navicular while playing. She otherwise complied with the treatment plan. Her pain resolved at 6 weeks and she signed a letter of intent with a DI school for ice hockey.

D-17 Clinical Case Slide - RunningThursday, May 30, 2019, 1:30 PM - 3:10 PM
Room: CC-3061663 **Chair:** Adam S. Davis, FACSM. *Harvard Medical School Spaulding-Cambridge, Cambridge, MA.**(No relevant relationships reported)*

1666 May 30 1:30 PM - 1:50 PM

A Rare Cause Of Pain In A Runner: The "Nail-Patella Syndrome"Kenneth Vitale, Evelyne Fliszar. *University of California San Diego, School of Medicine, La Jolla, CA.**(No relevant relationships reported)*

HISTORY: 26-yo female presented with 1 year of anterior knee pain with running, worse on hills and squatting. Had seen multiple providers and diagnosed with patellofemoral pain but didn't improve with treatment. ROS was significant for elbow stiffness, unable to fully extend elbows since childhood. No known medical/family history but reports that multiple relatives have same problem. She also reported "unusual appearance" of thumbnails since childhood, covers with fake nails and polish. Had seen Orthopedics and Dermatology without clear answer. **PHYSICAL EXAMINATION:** 5' 5", 99lb, BMI 16.5. Bilateral knees no effusion, ROM 0-150° with patellar maltracking and palpably small patellae. Increased femoral anteversion and femoral adduction, but normal composite hip ROM. Hypoplastic thumbnails noted with ridging and splitting. Bilateral elbow flexion contractures ~45°. Normal neurovascular exam. **DIFFERENTIAL DIAGNOSIS:** Patellofemoral pain syndrome, Patellar subluxation/dislocation, Painful bipartite patella, Congenital deformity/dysplasia. **TEST AND RESULTS:** Knee x-rays showed severely hypoplastic patellae, trochlear dysplasia with prominent lateral femoral trochlea. Elbow x-rays revealed hypoplastic convex radial heads and capitellum with chronic posterior radial head dislocations. Due to these findings a pelvic x-ray was recommended which displayed iliac bone exostoses, confirming the diagnosis. **FINAL WORKING DIAGNOSIS:** Hereditary Osteo-Onychodysplasia, the "Nail-Patella Syndrome." **TREATMENT AND OUTCOMES:** Patient had been treated for individual manifestations of disease without recognition of the syndrome. Education was provided on diagnosis; as Nail-Patella is a syndrome of multiple abnormalities, including renal anomalies, a Nephrology referral was given to screen for renal dysplasia. Understanding of these congenital abnormalities is key to management of associated sequelae, and genetic counseling was further recommended as this is an autosomal dominant disorder. Elbow treatment option would be radial head resection, which may not improve elbow extension; patient declined. Focused leg strengthening and activity modification to accommodate knee abnormalities resulted in pain reduction, and in 2 months was able to return to light jogging (without hills) and modified yoga.

1667 May 30 1:50 PM - 2:10 PM

Barefoot Rehabilitation Of Arch Pain In A Veteran Foot Injury--RunningMatt Heindel¹, Kirsten Buchanan¹, Irene Davis, FACSM².¹University of New England, Portland, ME. ²Harvard Medical School, Cambridge, MA.*(No relevant relationships reported)*

HISTORY: The patient was a 39-year-old male veteran who complained of dull pain along the plantar portion of the left, medial longitudinal arch. This pain persisted for 3 months and was most noticeable during weight bearing activities. Most notably, the patient was unable to participate in recreational running of any duration secondary to pain. The patient was evaluated by his primary care physician who referred him to outpatient physical therapy after ruling out a fracture through x-ray examination. **PHYSICAL EXAMINATION:** The patient presented with increased pain along the left medial longitudinal arch during heel elevation, mild swelling along the medial

malleolus, decreased left dorsiflexion range of motion, decreased left plantarflexion and inversion strength, a flexible flatfoot deformity, and pain with any attempt to run recreationally.

DIFFERENTIAL DIAGNOSIS:

1. Posterior Tibialis Tendon Dysfunction
2. Eversion Ankle Sprain
3. Foot/ankle fracture

TEST AND RESULTS:

Strength: Manual muscle testing 3+/5 with pain on left foot plantarflexion and inversion

Range of motion: Left talocrural dorsiflexion 2° with knee extended and 5° with knee flexed to 90°

Ligamentous testing: Negative external rotation test, anterior drawer, and talar tilt

Neural testing: Negative sciatic nerve tension test with tibial nerve sensitization

Foot fracture: Negative Ottawa ankle rules

Functional Outcomes:

- LEFS 49/80
- Single leg Heel Rise Test: 0 reps

FINAL/WORKING DIAGNOSIS: Stage II posterior tibialis tendon dysfunction

TREATMENT AND OUTCOMES:

1. Strengthening
 - a. Barefoot short-foot exercise - 3 sets of 10 reps 1x/day
 - b. Inversion strengthening with red resistance band - 150-600 reps for 3 sets per day
 - c. Double heel rise with unilateral descent - 3 sets of 10 reps 1x/day
 - d. Gluteal Strengthening
2. Stretching
 - a. Barefoot gastroc and soleus stretches. 3 sets of 30 seconds 1x/day
3. Joint Mobilization
 - a. Modified Mulligan technique into dorsiflexion for 3 sets of 30 seconds
4. Outcomes
 - a. LEFS score improved from 49/80 to 71/80
 - b. Single leg heel rise test increased from 0 to 16 reps
 - c. Range of motion with left dorsiflexion improved from 2° to 10° with full knee extension and from 5° to 15° with 90° of knee flexion
 - d. Strength improved from 3+/5 to 5/5 with PF and inversion
 - e. Patient reported 3 consecutive days of running 2 miles without pain

1668 May 30 2:10 PM - 2:30 PM

Ankle Injury -- Running

Jaire N. Saunders MPH, MD, Kevin Mullins MD, Brandee Waite MD. *UC Davis, Sacramento, CA.* (Sponsor: Brian Davis MD, FACSM)

(No relevant relationships reported)

HISTORY

57yr old female with pmhx HTN, T2DM, HLD, previously seen in clinic for right knee OA secondary to remote injury. Presenting with 3-week history of acute onset right ankle pain. Occurred while running on treadmill after prolonged decrease in activity level due to BUE injuries. Receiving viscosupplementation in right knee with good relief. With the positive relief, three months prior to injury, patient started to increase frequency and intensity of exercise to help lose gained weight. Reports no obvious injuries to RLE.

PHYSICAL EXAMINATION

Heavy body habitus (BMI 34 kg/m²). Unable to walk on right ankle without significant pain. Antalgic gait.

INSPECTION- Significant soft-tissue swelling RLE. Right foot edema. No major bruising. No erythema in

PALPATION- Severe tenderness in all areas of the ankle limiting physical exam.

Increased warmth around foot and ankle. Unable to palpate pulses in foot or ankle, but RLE warm.

RANGE OF MOTION- Limited active and passive ROM and in all planes due to swelling and pain

DIFFERENTIAL DIAGNOSIS

1. Ankle sprain or other ligamentous injury at ankle or foot
2. Ankle or foot fracture
3. Achilles injury
4. Gout
5. Other inflammatory arthropathy
6. Stress fracture
7. Avascular necrosis

TEST AND RESULTS

Ankle xray: negative
 ESR: 6 (nl 0 - 30mm/Hr)
 CRP: 0.7 (nl 0.1 - 0.8mg/dL)
 Uric acid: 7.9 (2.2 - 7.7mg/dL)

CT Gout Study lower extremity: No evidence of monosodium urate deposition in ankle or foot.

MRI lower extremity joint: transverse fracture through distal tibial metaphysis

CT Scan Addendum (after MRI completed): Findings of a distal right tibial fracture

DEXA: pending

FINAL DIAGNOSIS

Tibia fracture (from stress fracture)

TREATMENT AND OUTCOMES

1. Non-weight bearing
2. Knee scooter
3. Activity modification/maintain cardiovascular exercise
4. Advance activities in 6-8 weeks
5. Awaiting DEXA for possible treatment

1669 May 30 2:30 PM - 2:50 PM

A Case For Running Without Toes!

Lindsay Wasserman, Irene S. Davis, FACSM. *Spaulding National Running Center, Cambridge, MA.* (Sponsor: Irene Davis, FACSM)

Email: lwasserman@partners.org

(No relevant relationships reported)

TEXT:

HISTORY: 43 yr. old F runner training for her 1st half marathon had an amputation of all 10 toes distal to MTP on October 2014 due to a systemic infection. By October 2016, she started a run/walk program and began to develop L lateral ankle pain, due to increased inversion during gait. After undergoing surgery to remove scar tissue from her lateral foot and re-align the EHL tendon to resist inversion, the lateral ankle pain decreased. However, when she attempted to run or walk long distances, she experienced medial lower leg pain, L>R, that progressed to a 7/10 on the L. Despite being told she wouldn't be able run anymore, her goal was train for another half-marathon.

PHYSICAL EXAM:

1. Callus formation L 5th metatarsal, suggesting increased lateral loading
2. Pain/ tenderness noted on the medial lower leg BIL, L>R
3. Limited calcaneal eversion on the L and ankle DF on the R
4. Weakness of the inverters, everters, and plantarflexors BIL
5. Weakness of the Hip ABD, EXT and ER L>R. Lower abdominals were also very weak
6. Running Gait (w/custom orthotics and a cushioned running shoe)

Rearfoot striker BIL

Increased hip ADD, IR and pelvic drop BIL

L inverted and toed-in at foot strike

Increased L arch drop during mid support

Pain was 3/10 on the L. When cued to toe out on the L, symptoms reduced and shifted to the calf.

WORKING DIAGNOSIS

Posterior tibialis tendinosis L>R due to weakness and reduced mobility in foot/ankle, along with medialization of the leg due to Hip ADD and IR.

TREATMENT:

1. Weaned pt. slowly out of orthotics to reduce lateral loading
2. Transition to minimal shoes for walking to promote foot/ankle strength
2. Increase mobility of foot/ankle
3. Promote foot/ankle function and control with balance and plyometrics
4. Incr. hip/core strength to improve dynamic alignment
5. Gait retraining to reduce toe in, inv. at foot strike and improve alignment proximally

OUTCOME: Pt was discharged March 2018 running 30 min 3x/wk pain-free in a low profile partial minimal cushion shoe w/o orthotics. She exhibited improved foot alignment and reduced hip add, IR and CPD. Pt continued to wear full minimal shoes during her cross-training. She was able to wear high heels for the first time since her amputations without pain. In Sept 2018, she completed her half marathon pain-free

1670 May 30 2:50 PM - 3:10 PM

Knee Pain - Running

Adam K. Willson, Joshua Berkowitz. *UNC Chapel Hill, Chapel Hill, NC.*

(No relevant relationships reported)

HISTORY: 19 year old female who developed right knee pain over two years ago during mile 23 of a marathon without specific, focal injury. She then consistently developed severe right posterior lateral knee pain after running around 2 miles, significant enough that she cannot continue running. Pain is improved with rest. She was a college athlete (running) but had to quit due to this pain. She had completed 3 courses of physical therapy without improvement. She did not report any other symptoms. She has no pain with activities other than running, or with running distances up to 1.5-2 miles. Prior MRI is normal with the exception of some slight signal in the distal biceps femoris tendon.

PHYSICAL EXAMINATION: Right knee – no erythema, swelling or ecchymosis. Mild to moderate tenderness to palpation at the posterior lateral fibular head and just proximally. No other abnormalities.

DIFFERENTIAL DIAGNOSIS:

1. Biceps femoris tendinopathy

2. Popliteus tendinitis
3. Popliteal artery entrapment syndrome
4. Common peroneal nerve entrapment

TEST AND RESULTS:

- PVL arterial duplex: No change in PT and AT artery waveforms with plantar and dorsiflexion. Not suspicious for popliteal artery entrapment
- MRI right knee: Suggestive of mild trochlear dysplasia. Visualized posterolateral corner right knee structures were normal. Intact right knee ligaments and meniscus
- US-guided diagnostic (anesthetic) injection to the biceps femoris tendon sheath yielded no improvement in symptoms
- US-guided corticosteroid injection to the posterolateral corner (deep to the biceps femoris tendon) provided 3 weeks of complete symptomatic relief and she was able to run 5 miles without symptoms

FINAL/WORKING DIAGNOSIS:

- Low-grade posterolateral corner injury only symptomatic with prolonged exertion

TREATMENT AND OUTCOMES:

- Clinically has characteristics localizing to the posterolateral corner, deep to the biceps femoris tendon, possibly related to scar tissue formation or dynamic entrapment
- Ultrasound-guided corticosteroid injection deep to the distal biceps femoris tendon provided relief but only for 3 weeks
- Plan for PRP injection to the posterior lateral corner for further treatment and evaluation
- Possible consideration of exploratory arthroscopy if even transient response to posterior lateral corner treatment can be redemonstrated

D-18 Rapid Fire Platform - Acute Hypoxia and Aerobic Performance

Thursday, May 30, 2019, 1:30 PM - 2:40 PM

The Role of Ventilatory Responsiveness During Exercise in Performance Impairment in Acute Hypoxia
Keren Constantini, Anna C. Bouillet, Bruce J. Martin, Robert F. Chapman, FACSM. *Indiana University, Bloomington, IN.*
Email: keconsta@indiana.edu
(No relevant relationships reported)

The ability to increase exercise ventilation to defend arterial oxyhemoglobin saturation during hypoxic exercise is commonly viewed as an important factor contributing to large individual variations in the degree of performance impairment in hypoxia. While the hypoxic ventilatory response (HVR) could provide insight into the underpinnings of such impairments, it is almost exclusively measured at rest, under isocapnic conditions.

Purpose: 1) to determine in a cohort of highly trained athletes whether the integrated ventilatory response to progressive hypoxia at rest (HVR_{REST}) and during exercise (HVR_{EX}) are comparable, and 2) to determine whether HVR_{EX} is related to the degree of performance impairment in acute hypoxia.

Methods: Sixteen endurance-trained men ($\dot{V}O_{2peak}$: 62.6 ± 6.2 ml·kg⁻¹·min⁻¹) performed two poikilocapnic HVR tests: 1) during seated rest (HVR_{REST}) where inspired O₂ fraction (FiO₂) was progressively reduced; and 2) while cycling at 40% of power at normoxic $\dot{V}O_{2peak}$ (HVR_{EX}) where FiO₂ was reduced in a square-wave fashion every 5 min (FiO₂ = 0.21, 0.18, 0.15 and 0.12). On two separate visits, subjects (n = 12) performed a 10km cycling time trial (TT) while breathing either room air or a hypoxic gas mixture (FiO₂ = 0.16), in a randomized order. Performance impairment was calculated as the percentage change in time to complete the TT between normoxia and hypoxia (ΔTT).

Results: HVR_{EX} was significantly ($p < 0.05$) greater than HVR_{REST} (1.51 ± 0.45 and 0.22 ± 0.14 l·min⁻¹·%⁻¹, respectively), and the two measures were not correlated ($r = -0.05$, $p = 0.84$). ΔTT was not correlated with HVR_{REST} ($r = -0.06$, $p = 0.86$) or HVR_{EX} ($r = 0.36$, $p = 0.28$). The percentage change in VCO₂ and ventilation between TTs was significantly ($p < 0.05$) correlated with ΔTT ($r = -0.72$ and $r = -0.58$, respectively), and these variables together explained 71% of the variance in performance impairment in acute hypoxia ($p < 0.01$).

Conclusions: 1) HVR_{REST} may not be an appropriate or applicable measure to utilize when studying ventilatory and other physiological responses to exercise and/or exercise performance; and 2) Although HVR_{EX} may explain little to the degree of performance impairment in acute hypoxia, (adequate) ventilation is likely essential for mitigating these expected hypoxia-induced impairments in performance, at least to some degree.

- 1673** May 30 1:40 PM - 1:50 PM

Sex Differences In Respiratory And Circulatory Cost And Arterial Oxygen Saturation During Hypoxic Walking

Masahiro Horiuchi¹, Yoko Handa Kirihara¹, Yoshiyuki Fukuoka², Herman Pontzer³. ¹Mt. Fuji Research Institute, Fuji-yoshida, Japan. ²Doshisya University, Kyoutanabe, Japan. ³Duke University, Durham, NC.

(No relevant relationships reported)

PURPOSE: Since women have smaller lungs and a decreased capacity for lung diffusion compared to men, these differences may increase the work required for women to maintain a given rate of pulmonary ventilation (\dot{V}_E), resulting in greater exercise-induced arterial hypoxemia (EIAH). Previous studies have ignored the energy expenditure (EE) on circulation (i.e., heart rate; HR) and ventilation during exercise. **METHODS:** We sought to investigate sex differences in EE, \dot{V}_E and HR in response to changes in SpO₂. We hypothesized that women would experience greater EIAH, and that the contribution rate of EE, \dot{V}_E and HR in response to changes in SpO₂ would be different between the sexes. We measured EE during walking on a level gradient under normoxia (room air, 21% O₂), and moderate hypoxia (13% O₂). Ten healthy young men and ten healthy young women walked on a treadmill at seven speeds (0.67-1.67 m s⁻¹). Each walking speed lasted for four minutes. EE was calculated using pulmonary oxygen uptake and carbon dioxide output. **RESULTS:** During walking, reductions in SpO₂ trended slightly greater in women under hypoxia (71.5 ± 4.5 % for men and 67.7 ± 6.1 % for women at the fastest gait speed, $P > 0.05$). Hypoxia-induced elevation in EE, HR, and \dot{V}_E were calculated by the difference between values in hypoxia and normoxia. Using a multivariate model that combined EE, \dot{V}_E and HR to predict ΔSpO₂ (hypoxia-induced reduction), we obtained a very strong fit model both for men ($r^2 = 0.900$, $P < 0.001$) and for women ($r^2 = 0.957$, $P < 0.001$). We also tried to estimate the relative contributions of ΔEE, Δ \dot{V}_E and ΔHR to predict ΔSpO₂ by using standard partial regression coefficients. The contribution rate to predict ΔSpO₂ was markedly different between men and women. In women, the effect of ΔEE and Δ \dot{V}_E were greater (EE: 28.1% in women vs. 15.8% in men; \dot{V}_E : 4.1% in women vs. 1.7% in men). Conversely, in men the contribution of ΔHR was greater (82.5 % in men and 67.9 % in women). Moreover, significant sex differences in breathing frequency and tidal volume were observed ($P < 0.05$, respectively).

CONCLUSIONS: These findings suggested that high-altitude adaptation in response to hypoxemia has different underlying mechanisms between men and women. Our results can help to explain how men and women adapt high-altitude environments.

Hypoxia Reduces Steady State Cycling Workload

Charli D. Aguilar. *University of Nevada Las Vegas, Las Vegas, NV.* (Sponsor: James Navalta PhD., FACSM)
Email: audrey.coffee@unlv.edu

(No relevant relationships reported)

Training in hypoxia is growing in popularity among athletes. Exercise in hypoxic conditions produces decrements in steady state and maximal workload capacity.

PURPOSE: The purpose of this pilot study was to characterize the differences in steady-state exercise power between hypoxic and normoxic conditions. **METHODS:** 10 healthy adults (5 males, 5 females) mean age of 23.8 ± 4.5 years volunteered to participate in the study. Pretesting included a graded exercise test to determine cycle resistance at 75% of age predicted heart rate max for each condition. The two conditions are defined as, normoxia (FiO₂ = 20.5%) and normobaric hypoxia (FiO₂ = 14.4%). A Hypoxic 5570 Everest Summit II Altitude training system was used to create conditions. Intervention days were at least 72 hours apart but no more than one week. A single blinded and counterbalanced model was used. Steady state exercise was performed on a cycle ergometer (Watt bike Pro, Waukesha, WI, USA) at a rate of 60 RPM for 30 min. Heart rate (HR), blood oxygen saturation (SPO₂), cycling watts and mean power was recorded every minute. **RESULTS:** SPO₂ were significantly lower during hypoxic exercise than during normoxic exercise (average SPO₂ = 80.58 ± 4.3 in hypoxia and 95.23 ± 0.97 in normoxia) $p < 0.001$. Average cycle wattage was also significantly decreased during hypoxic exercise (110.7 ± 34.5 , compared to 125.9 ± 49.6) $p = 0.044$. Mean HR was not significantly different between the two conditions. Mean power output in normoxia to wattage in hypoxia, $r^2 = 0.7556$. Pearson's correlation = 0.869 $p < 0.001$. **CONCLUSION:** Hypoxia reduced steady state power without changes in relative intensity. Mean cycling power in normoxic conditions and hypoxic positively correlate. These preliminary findings suggest that a predictive equation could be possible with further data collection.

1675 May 30 2:00 PM - 2:10 PM

Higher Muscle Tissue Oxygenation When Exposed To Hypobaric Hypoxia Than Normobaric Hypoxia

Ben Meister, Christina Angeli, Robert Shute, Dustin Slivka, FACSM. *University of Nebraska at Omaha, Omaha, NE.*
(Sponsor: Dustin Slivka, FACSM)
(No relevant relationships reported)

PURPOSE: There has been recent debate on the potential difference in physiological response between exposure to simulated altitude (normobaric hypoxia) and terrestrial altitude (hypobaric hypoxia). Therefore, the purpose of this research was to determine the difference in the physiological response to normobaric and hypobaric hypoxia during exercise. **METHODS:** Eight recreationally active subjects (age: 27 ± 5 y, body weight: 73.1 ± 7.4 kg, height: 170.6 ± 6.7 cm, body fat: 19.3 ± 9.2 %) completed incremental cycling exercise to volitional fatigue in three separate environments, normobaric normoxia (NN; 350 m), normobaric hypoxia (NH; simulated 3094 m) and hypobaric hypoxia (HH; 3094 m). Heart rate, blood oxygen saturation, and muscle tissue oxygenation were measured at rest and continuously throughout the exercise trials. **RESULTS:** Blood oxygen saturation (SpO_2) was ~10% higher in NN compared to the two hypoxic conditions ($p < 0.001$) at rest and all exercise stages, with no difference between NH and HH ($p > 0.05$). Heart rate was higher at rest in HH (98 ± 13 bpm) compared to NN (83 ± 15 bpm, $p = 0.011$) and NH (84 ± 14 bpm, $p = 0.001$) which persisted until 165 watts at which point no difference was observed ($p > 0.05$). Muscle tissue oxygenation was 17% higher in HH compared to NN and 19% higher than NH throughout exposure ($p < 0.05$). **CONCLUSIONS:** This data indicates that the hypoxic stress resulting from normobaric and hypobaric hypoxia are not the same and that hypobaric hypoxia may not result in hypoxia at the level of the tissue.

1676 May 30 2:10 PM - 2:20 PM

Hypoxic Exercise Performance with an Antihistamine: Influence of Aerobic Fitness

Marissa N. Baranaukas¹, Cameron A. Nowrouzi¹, Chad C. Wiggins², Robert F. Chapman, FACSM¹. ¹*Indiana University, Bloomington, IN.* ²*Mayo Clinic, Rochester, MN.* (Sponsor: Dr. Robert Chapman, FACSM)
Email: marbaran@indiana.edu
(No relevant relationships reported)

At altitude, impairments in pulmonary oxygen diffusion and oxygen delivery have a detrimental effect on endurance exercise tolerance. Analogues of over-the-counter antihistamines have been shown to improve oxyhemoglobin saturation (S_pO_2) and oxygen delivery during heavy exercise, but hypoxic performance outcomes have not been studied. **Purpose:** To determine the effect of the antihistamine, cetirizine (Zyrtec®) on hypoxic exercise performance in recreationally active subjects. **Methods:** Eight subjects [6 men, 2 women; age = 22 ± 1 y; $\dot{V}O_{2max} = 44.3 \pm 8.3$ ml·kg⁻¹·min⁻¹ (range: 32.0-55.2 ml·kg⁻¹·min⁻¹)] completed constant load exercise at 45% and 65% of normoxic $\dot{V}O_{2max}$ and an 8km time trial in conditions of normoxia (NORM), hypoxia with placebo (HYP+P), and hypoxia with cetirizine (HYP+C). Subjects inspired 15% oxygen to simulate an altitude of 2,500m for HYP+P and HYP+C and were given a 10mg fixed-dose of cetirizine one hour prior to exercise for HYP+C. Measures of S_pO_2 via pulse oximetry and muscle tissue oxyhemoglobin concentration ($[OxyHb+Mb]_p$) of the vastus lateralis via near infrared spectroscopy were continuously measured throughout exercise. **Results:** There was no significant difference ($P \geq 0.232$) in S_pO_2 between HYP+P and HYP+C during the 45% ($89 \pm 6\%$ vs. $89 \pm 4\%$) and 65% ($87 \pm 6\%$ vs. $85 \pm 5\%$) constant loads. The cetirizine intervention had a significant effect ($P = 0.005$) on $\Delta [OxyHb+Mb]$ (%) during the 65% constant load with a difference between HYP+P and HYP+C ($-28 \pm 45\%$ vs. $+14 \pm 16\%$). There was no difference in 8km performance times between HYP+P and HYP+C (18.08 ± 2.87 min vs. 17.03 ± 1.92 min, $P = 0.112$, $d_s = 0.63$). However, when co-varied by $\dot{V}O_{2max}$, cetirizine had a significant effect ($P = 0.047$) on 8km time trial performance with a difference of 1.06 min (95% CI [0.01, 2.11]) between HYP+P and HYP+C. $\dot{V}O_{2max}$ accounted for 53% of the variance in time trial performance changes between interventions. **Conclusion:** Cetirizine improves endurance exercise performance in hypoxia with a larger effect on individuals with lower $\dot{V}O_{2max}$. The cetirizine intervention resulted in greater skeletal muscle oxygenation at 65% $\dot{V}O_{2max}$ with hypoxia. These results would suggest that cetirizine does not improve S_pO_2 , but improves hypoxic exercise performance perhaps through enhanced oxygen delivery to the skeletal muscles.

1677 May 30 2:20 PM - 2:30 PM

The Influence of Acetazolamide on Endurance Exercise Performance at 3500 m

Karleigh E. Bradbury, Beau R. Yurkevicius, Katherine M. Mitchell, Kirsten E. Coffman, Charles S. Fulco, Roy R. Salgado, Robert W. Kenefick, FACSM, Nisha Charkoudian. *USARIEM, Natick, MA.* (Sponsor: Nisha Charkoudian, FACSM)
(No relevant relationships reported)

Members of the military and recreational athletes often rapidly ascend to altitude with the intention of completing physically demanding tasks. Rapid ascent can result in acute mountain sickness (AMS) which is commonly treated with acetazolamide (AZ). However, the side effects of AZ may impair exercise capability and previous literature regarding the impact of AZ on exercise performance is unclear. **PURPOSE:** To determine the impact of AZ on endurance exercise performance during a 30-hour exposure to hypobaric hypoxia equivalent to 3500 m altitude. **METHODS:** After completing three familiarization time trials (TT) at sea level (SL), six men (Age: 22.2 ± 3.2 yrs; Weight: 77.5 ± 11.5 kg; Height: 176.2 ± 7.1 cm; SL $\dot{V}O_{2peak}$: 50.8 ± 6.5 ml·kg⁻¹·min⁻¹) completed two, 30 hr altitude exposures at ~3500 m. In a single blind, randomly assigned study design, subjects were given 250 mg of AZ twice a day during one exposure and a placebo during the other. Administration of the doses started 48 hr prior to entering the hypobaric chamber, and continued through the 30 hr exposure. Exercise testing was completed ~24 hr after ascent to altitude and consisted of 15 min steady state walking on a treadmill at 40-45% SL $\dot{V}O_{2peak}$, followed by a 2 mile self-paced, treadmill TT. During the TT, subjects were blinded to treadmill speed and were only notified of distance completed at half mile increments. Heart rate (HR) and oxygen saturation (SaO_2) were recorded at baseline and every half mile. Rate of perceived exertion (RPE) was recorded at baseline and at the end of the TT. **RESULTS:** There was no difference in time to complete 2 miles between the AZ and placebo TT after ~24 hr of hypobaric hypoxia (22.3 ± 3.7 vs 22.0 ± 2.6 min, respectively; $P > 0.05$). Furthermore there were no differences in final TT HR (186 ± 13 vs 182 ± 16 , $P > 0.05$) or RPE (17 ± 3 vs 17 ± 2 , $P > 0.05$) between trials. SaO_2 was significantly higher at the end of the AZ TT vs the placebo TT (83 ± 4 vs 80 ± 4 , $P < 0.05$). **CONCLUSION:** Our results suggest that AZ (500 mg/day) does not negatively impact endurance exercise performance at 3500 m and that its stimulatory effect on ventilation helped maintain higher levels of oxygen saturation. *Funded by USAMRMC; author views not official US Army or DOD policy.*

Influence Of Acetazolamide On The Physiological And Perceptual Responses To Steady-state Exercise At Altitude

Katherine Mitchell, Karleigh Bradbury, Beau Yurkevicius, Kirsten Coffman, Charles Fulco, Roy Salgado, Robert Kenefick, FACSM, Nisha Charkoudian, FACSM. *US Army Research Institute of Environmental Medicine, Natick, MA.* (Sponsor: Nisha Charkoudian, FACSM)
(No relevant relationships reported)

Acetazolamide (AZ) is a common prophylactic for acute mountain sickness (AMS), particularly during rapid ascent to moderate or high altitudes. However, its diuretic effect could have a negative impact on physiological responses during steady-state exercise; these potential influences are poorly understood. **PURPOSE:** To evaluate the impact of AZ on heart rate (HR), rate of perceived exertion (RPE), and oxygen saturation (SaO_2) during steady-state treadmill walking after ~24 hours exposure to hypobaric hypoxia equivalent to 3500 m altitude.

METHODS: After completing three sea level familiarization trials, six men (Age: 22.2 ± 3.2 yr; Weight: 77.5 ± 11.5 kg; Height: 176.2 ± 7.1 cm; SL $\dot{V}O_{2peak}$: 50.8 ± 6.5 ml·kg⁻¹·min⁻¹) completed two 30 hr altitude exposures (AZ and placebo, single-blind randomized crossover design) in a hypobaric chamber equivalent to ~3500 m. After ~24 hr of exposure, volunteers completed exercise testing consisting of 15 min of steady-state treadmill exercise at 40-45% sea level $\dot{V}O_{2peak}$. HR & SaO_2 were recorded at baseline and at minutes 5, 10, and 15 of exercise. RPE was recorded at baseline and at minute 15 of exercise.

RESULTS: There were no significant differences between AZ and placebo for post-exercise HR (AZ: 141 ± 11 bpm [mean \pm SD] vs. Placebo: 145 ± 12 bpm; $p > 0.05$) or RPE (AZ: 9.5 (6-13) [median (range)] vs. Placebo: 9.0 (7-14); $p > 0.05$). SaO_2 was significantly higher in the AZ trial (AZ: $86 \pm 3\%$ vs. Placebo: $81 \pm 4\%$, $p < 0.01$). Furthermore, the extent (delta) of desaturation from pre- to post- steady-state exercise was less in the AZ trial compared to the placebo trial (AZ: $-5 \pm 3\%$ vs. Placebo: $-7 \pm 1\%$; $p < 0.05$). **CONCLUSIONS:** Our results suggest that AZ does not negatively impact physiological and perceptual responses during steady-state exercise. Indeed, AZ may be beneficial by helping to maintain oxygen saturation during steady-state exercise in hypobaric hypoxia. *Funded by USAMRMC; author views not official US Army or DOD policy.*

D-38 Thematic Poster - Biomechanics after ACL Reconstruction

Effect of Lower Extremity Static Alignment on Dynamic Valgus in Adolescents Following ACL Reconstruction

Tishya Wren¹, Daniel Feifer¹, Natalya Sarkisova¹, Mia Katzel¹, Curtis VandenBerg¹, James L. Pace², Nicole Mueske¹.
¹Children's Hospital Los Angeles, Los Angeles, CA. ²Connecticut Children's Medical Center, Hartford, CT.
Email: twren@chla.usc.edu
(No relevant relationships reported)

PURPOSE: Knee abduction moments may lead to valgus collapse, potentially causing ACL rupture. The contribution of static lower extremity alignment to knee abduction moments is unknown. This study assessed relationships among lower extremity static alignment and dynamic kinematics and kinetics during side-step cutting in uninjured adolescent athletes.

METHODS: This retrospective study included 8 adolescents with recent unilateral ACL reconstruction (mean age 14.8 yr, SD 1.2; 3/8 female). Frontal plane hip to ankle imaging (EOS) was used to measure mechanical axis deviation (perpendicular distance from the center of the femoral condyles to the mechanical axis line connecting the center of the femoral head to the center of the talar dome) and tibial-femoral angle. 3D motion capture provided lower extremity kinematics and kinetics during quiet standing and loading (initial contact to peak knee flexion) of an anticipated 45° side-step cut; 2-3 trials per limb were averaged for analysis. Relationships among imaging, static motion capture and dynamic motion capture measures were investigated using correlation, and backward stepwise linear regression was used to evaluate potential predictors of average dynamic knee abduction moment.

RESULTS: Regardless of surgical status, standing knee abduction angle was correlated with standing hip adduction (r=0.60, p=0.02) and ankle eversion (r=0.85, p<0.0001) along with larger mechanical axis deviations (r=0.83, p=0.0001) and higher knee abduction on EOS (r=0.44, p=0.09). Dynamic knee abduction moment was best predicted by a combination of EOS knee abduction angle, standing ankle eversion, standing knee abduction, standing knee rotation, ankle eversion during cutting, along with ground reaction force and age (R²=0.94; p<0.004). There was no significant relationship between knee abduction moment and side (surgical vs. contralateral) (p=0.63).

CONCLUSIONS: In this small group of adolescent athletes with recent ACLR, knee abduction moment during side-step cutting was related to age and anatomic lower limb alignment in addition to dynamic factors such as ankle positioning and ground reaction force. Anatomic alignment or standing posture with greater hip adduction, knee abduction, and ankle eversion may indicate a higher risk for injury during dynamic activities.

Wearable Sensor-based Classification Of ACL Reconstructed Limbs During Exercise In Male And Female Patients

Joseph M. Hart, FACSM¹, Varun Mandalapu², Stephan Bodkin¹, John Lach¹, Nutta Homdee¹, Jiaqi Gong². ¹University of Virginia, Charlottesville, VA. ²University of Maryland, Baltimore County, Baltimore, MD.
Email: jmh3zf@virginia.edu
(No relevant relationships reported)

Purpose: Early identification of subtle, sub-clinical, aberrant motion characteristics in patients with ACL reconstructed knees can inform rehabilitation and return to sports decision making. Wearable sensors enable characterization of movement in native sport and activity environment. The purpose of the study was the ability of a machine learning algorithm to accurately classify male and female participants' reconstructed limb from the contralateral healthy limb using inter-limb movement variability from sensor data during walking and jogging. **Methods:** We evaluated 109 patients (23.5±10.2Yr, 172.6±9.6cm, 73.4±16.7kg) with primary, unilateral and uncomplicated ACLR at approximately 6 months from index surgery. All participants walked for 5 minutes at 3 mph and jogged for 3 minutes at 6mph on a treadmill. Subjects were fitted with 5 wireless sensors (Shimmer3 IMU Unit, Dublin, Ireland)

secured bilaterally on the wrists and ankles and around the waist at the sacrum. Accelerations from the sensors were continuously monitored during the walking and jogging trials. The multi-dimensional time-varying biomechanical data captured by the sensors were processed to generate a graphical model and matrixes to represent the cause-and-effect relationship in inter-limb movement. The matrixes extracted from the sensor data were used to train machine learning algorithms and then these trained algorithms were evaluated to classify participants' ACLR limb from their contralateral healthy limb. The performance of these trained algorithms was calculated to generate the individual classification accuracy. **Results:** While walking, the trained algorithms were able to classify the ACLR limb in males with 81.5% accuracy and females with 73.7% accuracy. While jogging, ACLR limbs were classified with 76.7% accuracy in males and 83.0% accuracy in females. **Conclusion:** Cause-and-effect analysis of inter-limb movement variability demonstrated a high level of accuracy in classifying an injured ACLR limb from a healthy contralateral limb during exercise. The accuracy of classification may be influenced by gait speed and sex.

The Impact of a Functional Knee Brace on Sports Performance Following ACL Reconstruction.

William E. Garrett, Jr, FACSM¹, Abigail C. Schmitt¹, Robin M. Queen, FACSM². ¹Duke University Medical Center, Durham, NC. ²Virginia Tech, Blacksburg, VA.
Email: william.garrett@duke.edu

Reported Relationships: W.E. Garrett: Industry contracted research; Don Joy Orthopaedics.

Up to 250,000 anterior cruciate ligament (ACL) injuries occur in the United States annually with most athletes undergo an ACL reconstruction. No literature has examined physical performance during return to sport (RTS) and the impact of a functional knee brace. Braces have been shown to improve mechanics, but compliance remains an issue due to performance concerns.

PURPOSE: To determine differences in performance between braced (B) and non-braced (NB) tasks across time (RTS and six weeks following RTS (RTS+6)). We hypothesize that performance will improve across time with no differences between brace conditions.

METHODS: ACL patients (n=40; 20 male, 20 female) were enrolled after being RTS. Participants were provided a custom fit knee brace and instructed to wear the brace for all activities more dynamic than walking. A series of tasks (40 yard dash, 5-10-5 shuttle run, vertical jump, broad jump, and a triple hop) were completed at RTS and RTS+6. Each participant completed three practice trials and two recorded trials. Task and brace condition order was randomized. The ACL-RSI, IKDC and a VAS pain scale were completed. A 2X2 (time: RTS, RTS+6 by brace: B, NB) repeated measure ANOVA for performance measures and a paired t-test for patient reported outcomes were performed (p<0.05).

RESULTS: Participants (height: 1.7±0.1 m, weight: 75±15 kg, age: 18.6±3 yr) demonstrated improvements in ACL-RSI (p=.003) and IKDC (p<.001) with no difference in VAS pain (p=.297). Performance declined during the 40yd Dash, vertical jump, and broad jump in the B condition. Performance improved across time for the broad jump and triple hop (Table 1).

CONCLUSIONS: Brace condition differences were small (40yd Dash: 0.1 sec, Vertical Jump: 0.5 in, Broad Jump: 0.9 in) or nonexistent and would not likely lead to noticeable sport deficits. Performance concerns should be minimal in ACL patients looking to RTS when wearing a knee brace.

ACKNOWLEDGEMENTS: This work was supported by a DonJoy Orthopaedics grant.

Lower Extremity Kinetic and Kinematic Asymmetries 4, 6, and 9 Months Post-ACL Reconstruction In Elite Collegiate Athletes

Daniel G. Cobian, Mikel R. Stiffler-Joachim, Matthew D. Bjork, Jennifer L. Sanfilippo, Bryan C. Heiderscheid. *University of Wisconsin-Madison, Madison, WI.*
 Email: cobian@pt.wisc.edu

(No relevant relationships reported)

Abnormal lower extremity (LE) biomechanics post-anterior ligament reconstruction (ACL) may increase re-injury risk and reduce sports performance. Although most athletes return to sport (RTS) within 1 year from ACLR, the timeline for recovery of LE kinetics and kinematics during athletic tasks is not well defined. Identifying specific movement deficiencies will guide rehabilitation efforts to promote successful RTS and reduce re-injury risk. **PURPOSE:** To evaluate vertical ground reaction forces (vGRF) and hip, knee, and ankle kinematics during running and jumping in elite collegiate athletes 4, 6, and 9 months post-ACLR.

METHODS: Twelve Division I athletes (age 20.5 ± 1.2 , BMI 25.9 ± 3.6 , 6 female) performed maximal countermovement jumps (CMJ) and treadmill running at a maximally comfortable speed 4.0 ± 0.3 , 6.1 ± 0.5 and 8.9 ± 1.5 months post-surgery while whole body kinematics were recorded. VGRF impulses, knee flexion excursion, and peak sagittal plane hip, knee, and ankle joint angles were obtained during the stance phase of running (RUN) and the eccentric, concentric (CON), and landing (LAND) phases of the CMJ. Limb symmetry indices (LSI) were computed for all variables and effect sizes (ES) were calculated. LSIs at each interval were evaluated using the Wilcoxon Signed-Ranks test.

RESULTS: At 4 months post-surgery, all CMJ and RUN asymmetries were significant (LSI: 69.5-95.9%, $p < .023$, ES: .46-.62). Involved limb CMJ CON phase and RUN vGRF impulses were significantly less than uninvolved limb values at all intervals (LSI: 85.7-94.2%, $p < .005$, ES: .58-.63). RUN peak joint angle and knee flexion excursion asymmetries were significant at all intervals (LSI: 69.5-94.7%, $p < .013$, ES: .51-.62). Involved limb CMJ CON phase knee (LSI: 90.6-98.6%, $p < .041$, ES: .42-.62) and ankle (LSI: 80.2-86.1%, $p < .010$, ES: .53-.62) angles were reduced throughout, while no CMJ LAND phase asymmetries were detected 9 months post-op. **CONCLUSIONS:** Despite excellent surgical care and high volumes of rehabilitation, elite collegiate athletes present with LE kinetic and kinematic asymmetries 9 months post-surgery, after or close to typical RTS. In particular, knee joint kinematics during the stance phase of running and the CON phase of the CMJ are categorically asymmetric and should be addressed with targeted interventions.

Physical Factors Differentiate Pain-free Return To Play And Return With Knee Symptoms 9 Months After ACL Reconstruction

Andy Franklyn Miller¹, Enda King¹, Chris Richter¹, Ray Moran¹, Mark Jackson¹, Siobhan Strike². ¹Sports Surgery Clinic, Dublin 9, Ireland. ²University of Roehampton, London, United Kingdom.
 Email: afranklynmiller@me.com

(No relevant relationships reported)

Purpose

The aim of this study was to identify strength, power and biomechanical differences between male athletes who made a pain free return to play (RTP) and those that did not at 9 month post ACL reconstruction.

Methods

Nine months after ACLR 158 males athletes who had returned to pre-injury sport participation (64 reporting knee symptoms/94 reporting none) carried out strength testing using isokinetic dynamometry on quadriceps and hamstrings and 3D biomechanical analysis of single countermovement jump, single leg drop jump and planned and unplanned 90° change of direction (CoD) as well as an IKDC questionnaire. Differences in IKDC, strength and jump height measures on the ACLR side and in limb symmetry index (LSI) between groups were analysed with statistical parametric mapping (SPM, 0D unpaired t-test). The odds ratio for making a pain free RTP if LSI >90% was also calculated for the strength and jump variables independently and collectively. Biomechanical differences in the jump and CoD tests on the ACLR side and in symmetry between groups was analysed with SPM (1d, unpaired t-test). Effect size was calculated using Cohen's D for all analyses.

Results

There was a large effect size (ES) difference in IKDC score between groups (89 +/- 6 with no pain; 80 +/- 8 with pain; ES 1.1). There were medium effect size differences in quadriceps strength on ACLR side (ES 0.42) and LSI (0.45) with an odds ratio of 2.7. There were similar differences in SLDJ height on ACLR side (ES 0.3) and LSI (0.37) with an odds ratio of 3.5. The odds of making a pain free RTP when LSI >90% on all tests was 6.8. There were no biomechanical differences between groups on the jump tests. There were biomechanical differences on the more demanding CoD tests with differences on the ACLR side and symmetry in foot rotation angle, knee

extension moment and hip rotation angle (ES 0.51 to 0.61) in the unplanned CoD and in symmetry of posterior and vertical ground reaction force and COM velocity at initial contact (ES 0.5 to 0.58) in the unplanned CoD with greater asymmetry in the painful group.

Conclusion

This study demonstrates strength, power and biomechanical differences in those that RTP with knee symptoms after ACLR with those achieving >90% LSI in all 4 strength and jump tests almost 7 times more likely to make a pain free RTP.

A Long-term Follow-up Of Patients With Physseal-Sparing Iliotibial Band ACL Reconstruction: Kinetic Analyses

Dai Sugimoto¹, Amy Whited², Jeff Brodeur², Kathryn Williams³, Koche Mininder³, Lyle Micheli, FACSM³, Benton Heyworth³. ¹Boston Children's Hospital, Waltham, MA. ²Boston Children's Hospital / The Micheli Center for Sports Injury Prevention, Waltham, MA. ³Boston Children's Hospital, Boston, MA.

(Sponsor: Lyle J. Micheli, MD, FACSM)

Email: Dai.Sugimoto@childrens.harvard.edu

(No relevant relationships reported)

Longer-term biomechanical implications of anterior cruciate ligament reconstruction with Iliotibial band autograph (ACLR-ITB) remain under-investigated. **PURPOSE:** To determine biomechanical parameters of knee function at various time intervals following the ACLR-ITB: 1-2 years, 2-5 years, 5-10 years, and >10 years post-surgically. **METHODS:** Patients who had undergone ACLR-ITB as skeletally immature children were recruited for testing, which included drop vertical jumps and vertical single-limb hops. A three dimensional (3D) motion analysis system with force plates was used to assess various parameters. The landing phase was defined as the moment of initial contact with the force plates, where the vertical ground reaction force (VGRF) exceeded 10 N, to 500 ms after initial contact. Major outcome variables included external knee moments (sagittal, frontal, and horizontal planes), VGRF, and vertical jump height. The knee moments and VGRF were normalized by mass (kg), and vertical jump height was calculated through following equation: $\frac{1}{2}g(t/2)^2$, where $g=9.81$ m/s² and t =time in seconds in the air. Peak values of each outcome variable were analyzed. Paired t-tests were employed to compare VGRF and vertical jump height between the two limbs by four groups (1-2 years, 2-5 years, 5-10 years, and >10 years) separately. **RESULTS:** Based on available data (N=38, 30 males, 8 females; 1-2 years: N=8; 2-5 years: N=10; 5-10 years: N=10; >10 years: N=8), paired t-tests showed no statistically significant differences in peak knee moment (sagittal plane: $p=.613$, frontal plane: $p=.340$ horizontal plane: $p=.248$) and peak VGRF ($p=.106$) in drop vertical jump test. Also, no statistical significant difference was detected in peak knee moment (sagittal plane: $p=.101$, frontal plane: $p=.955$ horizontal plane: $p=.341$), peak VGRF ($p=.384$) and peak vertical jump height ($p=.876$) in single-limb hops. The findings were consistent when the data was analyzed based on the 4 follow-up time groups. **CONCLUSIONS:** The biomechanical function of knees undergoing this procedure appears to be no different compared to the uninjured side at 1-2 years, 2-5 years, 5-10 years, and >10 years following ACLR-ITB procedure. The current data support a long-term safety of the ACLR-ITB procedure for skeletally immature athletes with complete ACL tears.

Competing After ACL Injury: Profiles of Division 1 Athletes who Successfully Return to Sport

Darren Hearn¹, Darin Padua¹, Courtney Chabaan¹, Linghao Kong¹, Ben Goerger¹, Abbie Smith-Ryan, FACSM¹, Abby Verchick². ¹UNC-Chapel Hill, Chapel Hill, NC. ²NC State, Raleigh, NC.

(No relevant relationships reported)

Female athletes face significant risk of musculoskeletal injury when playing collegiate level sports. Sustaining injury, particularly to the ACL, can end an athlete's career. Prior research has evaluated individuals' movement profiles and patient reported outcomes (PROs) following ACL injury; however, there is a dearth of evidence evaluating the movement profile and PROs of those who successfully return to sport at an elite level following ACL injury. **PURPOSE:** To compare the movement profile and PROs of Division 1 women's college athletes who successfully return to sport following ACL injury to healthy athletes. **METHODS:** We conducted a cross-sectional analysis of baseline data on 66 participants collected as part of standard injury screening for Division 1 women's soccer, lacrosse, and field hockey teams (mean \pm SD; Age = 19.9 ± 1.3 yrs, Ht = 166.6 ± 5.8 cm, Wt = 64.1 ± 8.1 lbs). We used health history and survey data to identify those who had previously sustained an ACL injury as well as single assessment numeric evaluation (SANE) scores for the knee. The Landing Error Scoring System (LESS) was used to evaluate each athlete's movement pattern while completing a jump landing task. The LESS and SANE scores for the injured and non-injured groups were compared using T-Tests with pooled variance

($\alpha=0.05$). **RESULTS:** T-Test results showed that those athletes who went on to play Division 1 sports following ACL injury ($n=18$) had significantly better ($p<0.02$) LESS scores than did their previously uninjured counterparts (Successful Return: 3.9 ± 1.4 faults, Previously Uninjured: 5.2 ± 2.0). SANE scores were significantly different ($p<0.03$) in the opposing direction (Successful Return: 89.8 points ± 7.6 , Previously Uninjured: 95.3 ± 9.1). **CONCLUSION:** Female athletes who successfully returned to compete in Division 1 sports following an ACL injury demonstrated a better movement profile than those without history of ACL injury; notably scoring below previously established cut points (5.0 faults) for increased risk of injury. This was in the setting of the lower PRO scores than their uninjured counterparts. This may indicate that athletes who sustain injury and wish to play at elite levels may need to improve their movement profile to a point better than their peers and care must be taken to balance PROs with an objective measure of movement.

1749 Board #8 May 30 3:45 PM - 5:45 PM
Altered Center of Pressure Dispersion and Regularity during Dual-Task Balance following Anterior Cruciate Ligament Reconstruction

Scott M. Monfort¹, Sarah C. Miko², Janet E. Simon², Dustin R. Grooms². ¹Montana State University, Bozeman, MT. ²Ohio University, Athens, OH.
 Email: scott.monfort@montana.edu
 (No relevant relationships reported)

Athletes demonstrate neuroplastic changes and altered neuromuscular control after anterior cruciate ligament reconstruction (ACLR). Conflicting reports of impaired balance and cognitive performance exist for dual-task balance following ACLR. Thus, significant gaps remain in understanding altered postural control strategies in this population. **PURPOSE:** To understand altered postural control strategies in ACLR individuals in the presence of sensory, motor, and cognitive challenges. **METHODS:** Fourteen ACLR (20.7 ± 2.0 yr, 76.9 ± 19.1 kg, 1.7 ± 1.4 m, 6.7 ± 1.9 Tegner) and 14 matched healthy control participants (CON) (21.2 ± 1.4 yr, 75.4 ± 15.3 kg, 1.7 ± 1.5 m, 7.4 ± 1.4 Tegner) were analyzed. Three 20-second trials of single-leg balance (ACLR limb, matched side for CON) were performed under the following conditions: eyes open (EO), eyes closed (EC), dual cognitive (DC), and dual motor (DM). DC involved mental addition every two seconds and DM required participants to catch a ball from a ball machine every 2 seconds. Traditional center of pressure (CoP) measures of 95% confidence ellipse area (EA) and medial-lateral root-mean-squared excursion (RMS_ml) were calculated after a 5 Hz 4th-order Butterworth low-pass filter. These measures were log transformed to satisfy model assumptions. Sample entropy (SEn, unitless) was also calculated for increment resultant CoP data after downsampling to 50Hz, without filtering. Linear mixed models included subject pair as a random effect and ACLR status, trial type, and ACLR * trial type as fixed effects. **RESULTS:** The ACLR group had increased CoP dispersion (e.g., ln(EA): ACLR: 7.74 ± 0.78 mm², CON: 7.47 ± 0.91 mm², $P = 0.003$) and increased CoP signal regularity (SEn: ACLR: 0.78 ± 0.20 , CON: 0.86 ± 0.23 , $P = 0.001$). Significant interactions were also observed for SEn, EA, and RMS_ml that suggest the ACLR group impairments are most pronounced during the DC condition (e.g., 95% confidence interval for CON - ACLR for DC SEn: (0.03, 0.35), $P = 0.01$). **CONCLUSION:** Altered postural control is present following ACLR compared to healthy controls. A cognitively-challenging task resulted in greater ACLR-specific balance alterations compared to closing eyes or a motor dual-task. These findings are consistent with ACLR individuals adopting a more attentionally-focused approach to postural control.

D-39 Thematic Poster - Blood Flow

Resistance Training with and Without Blood Flow Restriction to Repetition Failure: More Pain, Same Gain

Christopher Pignanelli, Jamie F. Burr, FACSM. University of Guelph, Guelph, ON, Canada.
 Email: cpignane@uoguelph.ca
 (No relevant relationships reported)

Evidence suggests blood flow restricted (BFR) resistance training performed with low-loads (20-40% 1-repetition maximum; 1-RM) is superior to low-load training

when volume (load x repetitions) is matched. Since it has been shown using traditional resistance training that similar gains in muscle strength and hypertrophy occur between high- and low-load training when performed to repetition failure, it is of interest if this also occurs with low-load training with/without BFR. Moreover, the perception of pain at repetition failure between protocols and over time has not been examined in a training setting.

PURPOSE: To determine if low-load resistance training to repetition failure with/without BFR elicits similar muscular strength, hypertrophy and perceived pain. **METHODS:** Seven young (25 ± 1 yr) males were recruited to perform single-leg Smith-machine squats 3 d/wk for 6 wk. Each leg was randomly assigned to perform 30% 1-RM with (BFR) or without BFR (RT) for 3 sets to repetition failure with 100s of rest after each set. Tourniquet pressure was set at 60-70% of the lowest occlusive pressure and remained inflated throughout the 3 sets. Leg strength (1-RM), muscle hypertrophy (leg lean mass; LLM) by dual-energy X-ray absorptiometry, and ultrasound derived vastus lateralis (VL) muscle thickness (MT), were measured before and after the 6-weeks. A visual analog scale (1000 point) was used to assess pain after each set and rest period for the 1st, 4th, 8th, 11th and 15th training session. **RESULTS:** 1-RM increased similarly in both groups after training (BFR 79 ± 13 to 95 ± 13 kg vs. RT 82 ± 13 to 100 ± 13 kg, $p<0.002$) and VL MT (BFR: 2.69 ± 0.08 to 2.98 ± 0.1 vs. RT: 2.75 ± 0.16 to 2.96 ± 0.1 cm, $p<0.016$) with non-significant changes in LLM (BFR 7.29 ± 0.38 to 7.40 ± 0.39 vs. RT 7.28 ± 0.37 to 7.34 ± 0.36 kg, $p<0.243$). There was an increase in perceived pain with BFR training compared to the RT group across all sessions following the first rest period (BFR: 288 ± 25 vs. RT: 155 ± 9 a.u., $p<0.05$) and second rest period (BFR: 433 ± 31 vs. RT: 160 ± 9 a.u., $p<0.05$). While there was a trend for a decrease in pain over time with repeated training, this effect was non-significant. **CONCLUSIONS:** When performed to failure, low-load training with and without BFR have similar muscle strength and hypertrophy despite differences in perceived pain. Supported by NSERC, CFI and ERA

1752 Board #2 May 30 3:45 PM - 5:45 PM
Investigating The Use Of Vibration Platform And Blood Flow Restriction As A Warm-up Procedure

Ricardo Parra, Jovanna Bonilla, Elda Padilla, Laura Rodriguez, Murat Karabulut, FACSM. University of Texas - Rio Grande Valley, Brownsville, TX.
 (No relevant relationships reported)

PURPOSE: The purpose of this study was to observe the combined effect of a whole body vibration (WBV) warm up and Blood Flow Restriction (BFR) on muscle temperature, flexibility, vertical jump height, and estimated $\dot{V}O_{2max}$. **METHODS:** Nineteen subjects (8 males and 11 females; Mean \pm STDEV age = 24.21 ± 3.47 years; height = 166.94 ± 8.82 cm) completed the study, which involved performing a warm-up protocol under 5 conditions. The conditions were: 5-min treadmill walking (C1), 5-min WBV at a low amplitude (C2), 5-min WBV at a low amplitude with BFR (C3), 5-min WBV at a high amplitude (C4), 5-min WBV at a high amplitude with BFR (C5). For the BFR sessions, cuffs were placed on the uppermost portion of the thighs. Cuffs were then inflated to 120 mmHg, and then increased in increments of 20 mmHg until the final pressure was achieved. Final pressure was found via thigh circumference and capillary refill time. The vibration plate was set at a frequency of 30 Hz. During the four interventions, the subjects performed 3 lower-body exercises (squat, sumo squat, calf raises) for 60 seconds each, with 30 seconds of rest between exercises. Thigh temperature was measured between exercises. Total training time with rest was 12 minutes. Following the warm-ups, vertical jumping height, flexibility, and aerobic fitness (via Queen's College Step Test) were assessed. **RESULTS:** Significant time and gender main effects for thigh temperature were seen ($p < .01$). Males had a higher mean thigh temperature than females. A significant condition main effect for average flexibility values was detected ($p < .01$). The C4 (compared to C1, C2, and C3) and C5 (compared to C1 and C2) protocols resulted in higher values in flexibility ($p < 0.03$). There was also a significant condition*gender interaction for estimated $\dot{V}O_{2max}$ ($p < 0.04$). Females had the highest values for estimated $\dot{V}O_{2max}$ following the C1 protocol and the lowest for the C5 protocol, but males had the highest values for estimated $\dot{V}O_{2max}$ following the C5 protocol. **CONCLUSION:** Based on our findings, the high amplitude WBV condition with or without BFR improved flexibility, but the effects of conditions on estimated $\dot{V}O_{2max}$ values were different for each gender. The findings indicate that gender of individuals performing tests may be important and should be considered for testing different health/fitness variables.

Effects Of Hyperoxic-Supplemented High Intensity Interval Training On Endurance Performance, Maximal Oxygen Consumption And Mitochondrial Function In Trained Cyclists

Daniele A. Cardinale¹, Filip J. Larsen¹, Peter Lindholm², Björn Ekblom¹, Robert Boushel³. ¹The Swedish School of Sport and Health Sciences (GIH), Stockholm, Sweden. ²Karolinska Institutet, Stockholm, Sweden. ³University of British Columbia, Vancouver, BC, Canada.
 Email: daniele.cardinale@gih.se
 (No relevant relationships reported)

PURPOSE: Hyperoxia (HYPER) increases O₂ delivery to the working muscles together with an improved lactate metabolism, power output and endurance compared to normoxia (NORM) (Cardinale & Ekblom, 2017). Considering the O₂ delivery limitation and the exercise induced hypoxemia at exercise intensities near to maximum it was hypothesized that muscle mitochondrial oxidative phosphorylation (OXPHOS) capacity would be upregulated along with a higher endurance performance following endurance interval training with HYPER compared to NORM. **METHODS:** 23 trained cyclists, age 35.3±6.4 years (mean ± standard deviation (SD)) body mass 75.2±9.6 kg, height 179.8±7.9 m, and VO₂max 4.5±0.7 L·min⁻¹ performed 6 weeks endurance training on a cycle ergometer consisting of supervised HIIT sessions 3 days/week (3-8 min) and additional long slow distance training 2 days/week. Cyclists were randomly assigned to either HYPER (FiO₂ 0.30; n=12) or NORM (FiO₂ 0.21; n=11) breathing condition during training in a single blinded study design. VO₂max, OXPHOS capacity in permeabilized fibers and in isolated mitochondria, and 20 min cycle performance were tested pre and post intervention. **RESULTS:** Over the intervention change in VO₂max (HYPER 1.1±3.8%, NORM 0.0±3.7%; p = 0.55, ES= 0.08), mass-specific mitochondrial respiration (HYPER 27.3±46.0%, NORM 16.5±49.1%; p = 0.21, ES= -0.06); intrinsic mitochondrial respiration (HYPER 26.1±80.1%, NORM 15.9±73.3%; p = 0.66, ES= 0.69) and mean power output during 20 min trial (HYPER 6.0±3.7%, NORM 2.4±5.0%; p = 0.073, ES= 0.32) did not statistically significantly differ between the groups. **CONCLUSIONS:** These data showed that 6 weeks hyperoxic-supplemented high-intensity interval-training on a cycle ergometer was not superior to conventional training at sea level in improving VO₂max, intrinsic and mass-specific mitochondrial respiration and cycle performance in already trained cyclists. Therefore, despite the small meaningful positive effect in cycling performance that might be relevant in sport, considering the cost/benefit of performing hyperoxic-supplemented HIIT, it is questionable whether this strategy is worthwhile in maximizing endurance performance in already trained cyclists.

 (No relevant relationships reported)

PURPOSE: This investigation measured local microcirculation, neuromuscular activation and systematic metabolite in underweight women during bilateral knee extension exercise in five conditions: high load [80% of one-repetition maximum (1RM)] without blood flow restriction [BFR, (HL)], low load (30%1RM) without BFR (LL) and low load (30% 1RM) with 40% (BFR₄₀), 60% (BFR₆₀), 80% (BFR₈₀) of arterial occlusion pressure. **METHODS:** 18 moderately active underweight women (17.63±0.68kg/m²) performed four sets of knee extension to failure with 60 s rest in five conditions. Variables of microcirculatory function [Oxygen saturation (SO₂), relative hemoglobin (rHb), blood flow (flow) and blood velocity (velo)] and neuromuscular activation of the vastus lateralis (VL) and the whole blood lactate (WBL) were measured across different time points. Finally, calculating the repetitions of five conditions. **RESULTS:** SO₂ in HL and LL were similar during whole process (HL: 79.2±19.1%, LL: 72.4±18.20%) which were significantly higher than the other three conditions (P<0.05). Flow was highest in BFR₆₀ with the other conditions were similar (e.g., set3: 213.1 AU for BFR₆₀ vs-196.3 AU for other conditions). After exercise, velo in BFR₆₀ (56.8±1.2AU) was higher than the other conditions [-51.8±1.5AU, (P<0.05)]. rHb did not change in all conditions. LL resulted in greatest activation during the first two sets when exercise is taken to failure (e.g., set1: 69.3%MVIC in LL vs-47.9%MVIC in other conditions). After exercise, WBL was highest in BFR₆₀ and lowest in HL (BFR₆₀>LL>BFR₄₀>BFR₈₀>HL). Changes in SO₂ and muscular activation were similar between pressures, while higher pressure led to fewer repetitions during exercise. **CONCLUSIONS:** Low-load exercise to failure results in a greater neuromuscular response to that of high-load exercise in

underweight women. When different pressures are applied to low-load exercise, there are considerable changes in microcirculation and metabolite, among which BFR₆₀ has the characteristics of greater perfusion and higher metabolic stress. **Funding:** This study was supported by Major Natural Science Research Projects in Colleges and Universities of Jiangsu Province, China (18KJA320002) and Postgraduate Research and Practice Innovation Plan of Jiangsu Province, China (KYCX17_1367).

The Effect Of Blood Flow Restriction And Whole-body Vibration As A Warm-up Strategy

Jonathan Salinas, Natalie Castillo, Aaron Garcia, Jessica Martinez, Ricardo Parra, Murat Karabulut, FACSM. University of Texas Rio Grande Valley, Brownsville, TX.
 (No relevant relationships reported)

PURPOSE: The purpose of this study was to examine the effects of blood flow restriction (BFR) and whole-body vibration (WBV) on hemodynamics, muscle temperature, flexibility, and explosive power. **METHODS:** Twenty-five subjects (14 females (age = 24 ±2.7 years) and 11 males (age = 24.5 ±3.5 years) completed the study, which involved following 6 sessions: a 5-min (5-WBV) and a 10-min (10-WBV) lower-body warm up on a vibration platform, a 5-min (5-BFR) and a 10-min (10-BFR) lower-body warm up using blood flow restriction cuffs, and a 5-min (5-CYC) and a 10-min (10-CYC) warm up on a cycle ergometer. For the BFR session, cuffs were placed on the uppermost portion of the thigh. Inflation began at 120 mmHg and progressively increased to a target pressure, which was based on the subject's thigh circumference and capillary perfusion. Squat exercises were performed between the knee angle of 90-180 degrees for 5 or 10 sets (each set lasted 60 s with a 60 s rest in between sets) on a vibration platform at 30 Hz with low amplitude or a flat surface while wearing BFR cuffs. Pre and post-exercise data for hemodynamics, quad and hamstring temperature, flexibility, and explosive power index were recorded. Explosive power was measured using a jump mat, where 60 maximal exertion jumps were performed, with mean ground contact time (GCT), mean vertical jump height (MVJ), and explosive power index (EPI) for the first 15 and last 15 jumps. Hemodynamics, muscle temperature, and flexibility were again recorded following the explosive power index test. **RESULTS:** There was no condition*time interaction or condition main effect for GCT, MVJ, and EPI, but there was a time main effects for all three variables (p<0.01). There were significant condition and time main effects and condition*time interaction for heart rate (p<0.01), time main effect for systolic blood pressure (p<0.01) and flexibility (p<0.01). Significant time main effect and condition*time interaction were detected for quadricep (p<0.01) and hamstring muscle temperatures (p<0.01). **CONCLUSIONS:** Our findings indicate that all the conditions and durations investigated resulted in similar responses in flexibility and jump performance. Future studies should examine different pressure settings of BFR and/or frequency/amplitude setting of WBV on the variables tested in the study.

Physiological Responses to Intermittent Endurance Exercise with Blood Flow Restriction in the Moderate Intensity Domain

Austin Moran¹, Meral Culver¹, Justin Guilkey¹, Timothy R. Rotarius², Jakob D. Lauver¹. ¹Coastal Carolina University, Conway, SC. ²Adrian College, Adrian, MI.
 (No relevant relationships reported)

Blood flow restriction (BFR) endurance training may induce both endurance and strength improvements. However, there is no consensus on the ideal BFR endurance exercise prescription in order to balance the physiological and perceptual responses. **Purpose:** The purpose of this investigation was to examine the physiological responses, as well as the perceived exertion in responses to a range of BFR endurance protocols. **Methods:** Participants randomly performed 7 exercise protocols: 50% of the difference between peak oxygen uptake (VO₂) and ventilatory threshold (VT) (Δ50%), 90%, 80%, and 70% of VT with and without BFR. Each protocol consisted of two sets of five work intervals (2 minutes work, 1 minute rest) separated by 5 minutes of recovery. Pulmonary VO₂ was recorded breath-by-breath, muscle activation (vastus medialis (VM), vastus lateralis (VL)) was assessed by surface electromyography (sEMG), microvascular oxygenation (tissue oxygenation index (TOI)) was assessed by near-infrared spectroscopy (NIRS), and level of perceived exertion (RPE) was assessed using the Borg scale. The last 30 seconds of intervals 5 and 10 were used for analysis. sEMG data were normalized to baseline cycling (20 watts). TOI during each condition was analyzed compared to baseline cycling and then expressed as change from baseline (arbitrary units) to compare between conditions. **Results:** The Δ50% protocol resulted in a higher end exercise (interval 10) VO₂ compared to all other conditions, no other differences in VO₂ were observed. No sEMG differences were observed between conditions (VL- p = 0.24, VM- p = 0.33) or between interval 5 and 10. All BFR conditions resulted in a decrease in TOI from baseline. TOI was greater for all BFR conditions (70%BFR = -36.4 ± 21.9, 80%BFR = -40.4 ± 6.5, 90%BFR = -44.7±7.25)

compared to the non-BFR conditions (70% = $+4.3 \pm 20.2$, 80% = $+11.8 \pm 5.5$, 90% = $+7.25$). No differences in TOI between $\Delta 50$ (-36.93 ± 10.8) and any BFR conditions were observed. RPE was greater during 90%BFR (18.0 ± 0) and 80%BFR (17.1 ± 1.1) compared to 70% (11.3 ± 0.6) and 90% (13.0 ± 0). No differences were observed between 70%BFR (14.6 ± 0.6) and non-BFR conditions. **Conclusion:** This study demonstrated that cycling with the addition of BFR at an intensity equivalent to 70% of VT may provide a balance between physiological strain and perceived exertion.

University of Wisconsin-La Crosse, La Crosse, WI. (Sponsor: Carl Foster, FACSM)
 Email: sjaime@uwlax.edu
 (No relevant relationships reported)

PURPOSE: Pacing strategies are necessary during endurance events in which the goal is to finish in as little time as possible. Both anaerobic and aerobic attributable sources of ATP are used during such efforts. Rating of Perceived Exertion (RPE) increases linearly as heart rate (HR) and power output (PO) increases, however these markers of intensity are not instantaneous. Near infrared spectroscopy (NIRS) allows for the measurement of local muscle oxygen saturation (SmO_2) which may respond to short-term fluctuations in PO. Previously, SmO_2 has shown a moderate correlation with oxygen consumption (VO_2) and HR during an incremental exercise. The purpose of this study was to determine how SmO_2 changes with increases in PO during a non-incremental cycling time trial (20-km) with various interspersed sprints and if decrements in PO due to shorter rest times were associated with lower SmO_2 .

METHODS: Well-trained cyclists ($n=9$) ($VO_{2max}=55.4 \pm 10.4$ ml \cdot kg $^{-1}\cdot$ min $^{-1}$; $PO_{max}=305 \pm 45$ W), habituated to 20-km trial, performed a self-paced 20-km time trial and two time trials with 1-km sprints imposed, separated by 2- or 4-km of self-paced cycling. SmO_2 saturation, PO, and HR were measured. RPE was recorded each kilometer. Pearson's partial correlations were used to analyze relationship between SmO_2 and PO. A one-way analysis of variance was used to determine if there were differences in finishing times between trials.

RESULTS: There was a significant inverse relationship between SmO_2 and PO during all time trials ($r = -0.263$, $P < 0.0001$). There was no significant difference ($p = .572$) between the finishing times amongst 20-km protocols.

CONCLUSIONS: This study revealed that the imposed sprints caused reciprocal changes in the extent of SmO_2 and PO that are larger than the changes in a self-paced time trial. In other words, as the subjects were instructed to significantly increase their PO to simulate a break-away, the SmO_2 decreased in a reciprocal manner.

1758 Board #8 May 30 3:45 PM - 5:45 PM
Living In Confinement Conditions: Physical Training Can Improve Muscular Oxygen Uptake and Heart Rate Kinetics

Uwe Hoffmann, Uwe Drescher, Lutz Thieschäfer, Jessica Koschate. *German Sport University, Koeln, Germany.*
 Email: u.hoffmann@dshs-koeln.de
 (No relevant relationships reported)

PURPOSE: Inside the NASA Human Exploration Research Analog (HERA) facility the effects of 45 d of confinement in combination with restrictions for sleep and a defined physical training on muscular oxygen uptake ($V'O_{2musc}$) kinetics and cardiovascular regulation during exercise was investigated.

METHODS: To date, fourteen healthy individuals (5 females, 9 males, 37 ± 7 y, 23 ± 3 kg \cdot m $^{-2}$) were analyzed 8 d before (MD-8), during and 4 d after (MD+4) a simulated Space mission. A cycle exercise test with pseudo-random binary work rate changes (WR) of 30 W and 80 W and an incrementally increasing step protocol (25 W min $^{-1}$) to assess peak oxygen uptake ($V'O_{2peak}$) was applied. Heart rate (HR) and mean arterial blood pressure (MAP) were measured beat-to-beat and pulmonary oxygen uptake ($V'O_{2pulm}$) breath-by-breath. $V'O_{2musc}$ was estimated from HR and $V'O_{2pulm}$. Kinetics responses were assessed by maxima of the cross correlation function (CCFmax) between WR and the respective parameter indicate faster kinetics (Hoffmann et al., Eur J Appl Physiol 113:1745-1754, 2013). During the mission, exercise training sessions were scheduled every second day with a maximal HR restricted to below 85% of the age-related maximum. Sleep was restricted to 5 h per weekday and 8 h at the weekends. Differences in $V'O_{2peak}$ and kinetics from MD-8 to MD+4 were calculated and correlated with the values measured at MD-8 using the Pearson test. Level of significance was set to $\alpha = 5\%$.

RESULTS: $V'O_{2peak}$ differed not significantly ($P=0.221$) between MD-8 (37.8 ± 5.8 ml min $^{-1}$ kg $^{-1}$) and MD+4 (38.9 ± 4.6 ml min $^{-1}$ kg $^{-1}$). Changes in CCFmax(HR) correlated significantly with CCFmax(HR) at MD-8 ($r = -0.839$, $P < 0.001$), changes in

CCFmax($V'O_{2musc}$) correlated significantly with CCFmax($V'O_{2musc}$) at MD-8 ($r = -0.641$; $P = 0.014$) and the difference in $V'O_{2peak}$ correlated with $V'O_{2peak}$ at MD-8 ($r = -0.614$; $P = 0.019$).

CONCLUSIONS: Exercise training during forty-five days of confinement in combination with sleep restrictions, may prevent from losses in cardio-muscular kinetics. Those individuals who started with slow kinetics or a low $V'O_{2peak}$ benefited from the exercise training during the mission. The volume and/or intensity of the exercise training intervention might have been higher during the HERA C4 missions compared to most of the crew members' everyday life activities.

D-40 Thematic Poster - Combined Environmental Stressors

Erythropoietin Response to Endurance Exercise under Heat and Hypoxic Conditions

Haruka Yatsutani¹, Hisashi Mori¹, Hiroto Ito¹, Nanako Hayashi¹, Kazunobu Okazaki², Kazushige Goto¹. ¹Ritsumeikan university, Kusatsu, Japan. ²Osaka City university, Osaka, Japan. (Sponsor: Robert Kraemer, FACSM)
 Email: sh0114re@ed.ritsumei.ac.jp
 (No relevant relationships reported)

Hypoxic training has been shown to improve aerobic capacity because hypoxia stimulates erythropoiesis due to increased erythropoietin (EPO) production. However, it takes several weeks to increase hemoglobin mass during endurance training in hypoxia. In the present study, we have focused on the combined effects of "hypoxia" and "heat stress" for EPO production. Considering that endurance exercise under heat condition augments plasma volume, hypoxic and heat conditions may promote additively erythropoiesis.

PURPOSE: The purpose of the present study was to determine EPO response to endurance exercise under heat and hypoxic conditions.

METHODS: Twelve healthy males (21.5 \pm 0.3 yrs, 168.1 \pm 1.2 cm, 63.6 \pm 2.0 kg) participated. They conducted a 60 min pedaling exercise at 60% of VO_{2max} under either "heat and hypoxic condition (H+H)" [fraction of inspiratory oxygen (FiO_2): 14.5%, 32°C], "hypoxic condition (HYPO)" (FiO_2 : 14.5%, 23°C) or "normoxic condition (NOR)" (FiO_2 : 20.9%, 23°C). After completing the exercise, subjects remained in the chamber for 3 h to evaluate metabolic and endocrine responses during post-exercise. We evaluated changes in muscle oxygenation (using NIRS) during exercise, blood variables, percutaneous oxygen saturation (SpO_2), muscle temperature during exercise and 3 h of post-exercise.

RESULTS: The SpO_2 was significantly decreased both under H+H and HYPO ($P < 0.01$). Blood lactate level increased during exercise ($P < 0.05$), but with no difference between the three conditions. Serum growth hormone level significantly increased ($P < 0.01$), and H+H showed significantly higher level compared with HYPO ($P < 0.05$). Serum EPO level was significantly increased in both H+H and HYPO 3 h after exercise, but no difference was observed between the two conditions.

CONCLUSIONS: Serum EPO level was significantly increased with endurance exercise under hypoxic condition. However, heat stress during endurance exercise in hypoxia (heat and hypoxic condition) did not augment the EPO response.

Neuromuscular Responses to Combined Heat Stress and Hypoxia During 20-km Cycling Time Trials

Geoffrey L. Hartley, Cory Tremblay, Stephanie Munten, Shelby Dickey, Caleb Mady. *Nipissing University, North Bay, ON, Canada.*
 Email: geoffh@nipissingu.ca
 (No relevant relationships reported)

The effect of combined heat stress and hypoxia on exercise performance may be dependent on the modality of exercise. In response to constant-work exercise, combined environmental stressors demonstrate an interaction effect on time to exhaustion; however, similar combined stressors have an independent influence on cycling time-trial (TT) performance. Investigation of the neuromuscular responses to combined environmental stressors may clarify the underlying mechanism(s) that

contribute to apparent task-specific responses. **PURPOSE:** To examine the isolated and combined effects of ambient temperature [cool (18°C, 20% rh) vs hot (35°C, 20% rh)] and inspired oxygen content [normoxia (F_iO₂ 0.21) vs hypoxia (F_iO₂ 0.16)] on neuromuscular function in response to a cycling TT. **METHODS:** Five physically active male participants (23 ± 6 y) performed four 20-km cycling TTs in different environmental conditions [cool/normoxia (COOL); hot/normoxia (HOT); cool/hypoxia (HYPO); hot/hypoxia (H-H)]. Neuromuscular responses of the soleus, as indicated by changes in isometric MVC (iMVC), M-wave, twitch force (Q_{tw}), and voluntary activation (VA), were assessed prior to and following each time-trial. Linear mixed model analyses were used to examine the neuromuscular responses, with fixed effects for each condition and a random intercept for participants. **RESULTS:** Time-trial performance was impaired during HOT (2211±85s; 192±18W), HYPO (2213±122s; 192±27W), and H-H (2214±117s; 192±27W) compared to COOL (2090±54s; 221±14W, p<0.02). Similar reductions in iMVC (-9.0±12.0%) and VA (-14.0±9.6%) were observed across all conditions (p<0.05); however, no significant differences were observed in M-wave (p=0.09) or Q_{tw} (p=0.43). **CONCLUSION:** Neuromuscular impairments following 20-km cycling TT are attributed to central mechanism(s) (i.e., VA); however, neuromuscular adaptations were similar in conditions where heat stress and hypoxia were combined, to conditions where each environmental stressor was examined in isolation.

Physiological Responses to Repeated Sprint Exercise under Combined Heat and Hypoxic Conditions

Keiichi Yamaguchi, Nobukazu Kasai, Nanako Hayashi, Haruka Yatsutani, Kazushige Goto. *Ritsumeikan university, Kusatsu, Japan.* (Sponsor: Robert Kraemer, FACSM)
 Email: sh0114ef@ed.ritsumei.ac.jp
 (No relevant relationships reported)

During sprint exercise in hypoxia, anaerobic energy supply is increased with augmented blood volume in muscle. Exposure to heat stress also increases anaerobic energy supply and blood volume in the muscle. Therefore, the combined treatments of “hypoxic exposure” and “heat stress” may cause further increases in above responses. **PURPOSE:** To determine the effect of combined heat and hypoxic conditions on physiological responses to repeated sprint exercise. **METHODS:** Ten male athletes (19.6 ± 0.3 yrs, 173.3 ± 2.2 cm, 71.6 ± 1.8 kg) completed repeated sprint exercise (three sets of 3 × 10 s maximal pedaling exercise) under four different conditions: [1] control condition (CON, 20 °C, F_iO₂: 20.9 %), [2] hypoxic condition (HYP, 20 °C, F_iO₂: 14.5 %), [3] hot condition (HOT, 35 °C, F_iO₂: 20.9 %), [4] combined hot and hypoxic conditions (HH, 35°C, F_iO₂: 14.5 %). Power output, muscle oxygenation in vastus lateralis [evaluated by near infrared spectroscopy (NIRS)], respiratory variables and arterial oxygen saturation (S_pO₂) were continuously monitored throughout the exercise. We also measured skin and muscle temperature, heart rate, and blood variables (blood lactate, glucose, pH, PO₂, PCO₂ levels). **RESULTS:** HYP and HH showed significantly lower average oxygen uptake (CON: 2.3 ± 0.1 L/min, HYP: 1.9 ± 0.1 L/min, HOT: 2.4 ± 0.1 L/min, HH: 2.0 ± 0.1 L/min) and average S_pO₂ (CON: 94.8 ± 0.6 %, HYP: 89.5 ± 0.5 %, HOT: 94.8 ± 0.5 %, HH: 89.5 ± 0.4 %) compared with CON and HOT (p<0.05). Muscle temperature was significantly higher in HOT and HH compared with CON and HYP throughout the exercise (p<0.05). Furthermore, HOT and HH presented significantly greater peak power output in the first set of the exercise compared with CON and HYP (p<0.05). No significant difference among trials was observed for changes in blood variables, and muscle oxygenation in vastus lateralis. **CONCLUSIONS:** Peak power output was higher in HOT and HH, although HH showed lower oxygen uptake and S_pO₂. These results suggest that combined heat and hypoxic conditions (HH) would cause greater power output than control condition in spite of decreased aerobic energy supply.

Downhill Running: An Effective Countermeasure To Limitations Of Exercise In Acute Hypoxia?

Trevor Gillum, Felipe Gorini Pereira. *California Baptist University, Riverside, CA.*
 Email: tgillum@calbaptist.edu
 (No relevant relationships reported)

Exercise stress that results in increased expression of heat shock protein 72 (Hsp72) is linked to physiologic adaptations. Adaptations to one environmental stressor, such as heat, increase Hsp72 and induce cross adaptations to other stressors (i.e. hypoxia). Previously, two bouts of downhill running (DHR) conferred classic markers of heat acclimation (lower T_c, earlier onset of sweating). We sought to increase Hsp72 through repeated DHR to potentially expedite the acclimation process. **PURPOSE:** To analyze the effect of DHR on exercise performance in normobaric hypoxia. **METHODS:** 8 males (23.8 ± 5.8 years, VO_{2max} 54.1 ± 5.1 ml kg⁻¹ min⁻¹, 13.6 ± 5.2% body fat) performed two 45-minute DHR bouts (-12.5% grade) separated by 5-7 days in the speed that elicited V_T while running downhill. Pre and post blood samples were collected to quantify monocyte Hsp72. Muscle soreness (DOMS) was assessed 24

and 48 hours after each downhill bout using a Likert scale. Two normobaric hypoxic (16% FiO₂) 5 km time trials (TT) were performed: one before any DHR and one 5-7 days after the last bout. Hydration was assessed before the TT while blood lactate was measured pre and post TT. During the TT, heart rate, RPE and O₂ saturation (SaO₂) were recorded every 1 km. **RESULTS:** Monocyte Hsp72 showed no change across time (p=0.53). Specifically, basal concentration from DHR I to DHR II were not different (3.5 ± 2.3 to 2.9 ± 1.5 AU). TT performance was similar between conditions (1377 ± 192; 1364 ± 174 sec). Hydration (1.018 ± 0.007; 1.013 ± 0.009 urine specific gravity), RPE (14.9 ± 1.1; 14.6 ± 1.3), HR (178 ± 8; 178 ± 8), and blood lactate (post TT1 11.6 ± 1.8; post TT2 12.0 ± 3.1 mM) were similar in both TTs. However, SaO₂ significantly increased from TT1 to TT2 (84.5 ± 4.0; 87.2 ± 2.3%, p<0.05). DOMS was significantly lowered 24 (5.1 ± 0.8 to 3.5 ± 1.4, p = 0.00) and 48 (4.6 ± 1.0 to 2.6 ± 1.5, p = 0.00) hours following the second DHR trial when compared to the first trial. **CONCLUSIONS:** While no change in Hsp72 or TT time were observed, this could be due to large variations found in the data with these variables. The increase in SaO₂ after DHR may improve exercise capacity at elevation during moderate exercise intensities.

Heat Acclimation Mediated Crosstolerance In C2C12 Myotubes

Garrett W. Hill¹, Ben J. Lee², Trevor L. Gillum³, Roger A. Vaughan¹, Matthew R. Kuennen¹. ¹High Point University, High Point, NC. ²University of Chichester, Chichester, United Kingdom. ³California Baptist University, Riverside, CA.
 (No relevant relationships reported)

Background. Heat acclimation enhances animal and human tolerance during subsequent novel hypoxic stress exposure. This heat-acclimation-mediated crosstolerance (HACT) is attributed to shared cellular stress response pathways. Although skeletal muscle is the largest organ (by mass) in the mammalian body, to our knowledge no research has been conducted examining HACT in skeletal muscle cells. **Purpose.** The timecourse of HACT and the mechanisms behind this response were examined in differentiated C2C12 myotubes. **Methods.** Heat acclimation (HA) was established by heating (40°C) C2C12 myotubes for 6 consecutive days (2h/d). Control myotubes were maintained for the same duration under control conditions (37°C). Control and HA myotubes were subsequently challenged with Hypoxia (1% F_iO₂) or Hypoxia + LPS (1% F_iO₂ + 500 ng/ml LPS) for 2h. Cell lysates were collected immediately post (+0h) and 12h post (+12h) challenge. Western blot was used to assess protein markers of the heat shock response (HSR), inflammation, and apoptosis. Data were analyzed with two-way ANOVA with Newman-Keuls post-hocs. **Results.** HA myotubes exhibited increased phosphorylation of HSF-1 [+59%, p=0.03] and reduced phosphorylation of IKBα [-56%, p=0.01] at +0h. Control myotubes exhibited reduced SIRT1 at +0h following challenge with Hypoxia [-36%, p=0.04] and Hypoxia + LPS [-47%, p=0.02]. By +12h Control myotubes that had been challenged with Hypoxia or Hypoxia + LPS exhibited increased phosphorylation of HSF-1 [+86% (p<0.01) and +77% (p<0.01); respectively] and HSP70 content [+158% (p<0.01) and +153% (p=0.04); respectively]. However, these changes occurred too late to afford cytoprotection, as Control myotubes that were challenged with Hypoxia + LPS also exhibited increased TLR4 (+77%, p=0.01) and NFκB (+117%, p=0.03), in conjunction with elevated phosphorylation of JNK [+55%, p=0.03] and Caspase 3 content (+25%, p=0.02). **Conclusion.** We present evidence of HACT in C2C12 myotubes. We speculate that through elevations in SIRT1 and activation of the HSR, HA confers lower inflammatory and apoptotic drive in skeletal muscle cells. We note that HACT is not evident until +12h following challenge, suggesting studies that do not follow an extended timecourse for cell lysate collection could potentially miss benefits associated with this response.

Pre-intervention Endothelial Function and Hyperglycemia Modifies Flow-mediated Dilation Following Short-term Exercise Training in Adults with Prediabetes

Stephanie L. Miller, Natalie Z.M. Eichner, Nicole M. Gilbertson, Emily M. Heiston, Arthur Weltman, FACSM, Steven K. Malin, FACSM. *University of Virginia, Charlottesville, VA.* (Sponsor: Steven K Malin, FACSM)

(No relevant relationships reported)

Purpose: Impaired glucose tolerance (IGT) elevates type 2 diabetes and cardiovascular disease (CVD) risk above and beyond impaired fasting glucose (IFG) alone. Hyperglycemia can impair endothelial function through increased inflammatory responses. However, it is unknown whether exercise training vascular function differently among prediabetes phenotypes. We examined whether improvements in endothelial function following 2-wks of aerobic training is affected different in adults with IFG+IGT compared to those with IFG alone. **Methods:** Middle-aged, obese adults with IFG (n=11, 58.3±9yrs; 34.2±7.9 kg/m²; FPG: 106.5±6.1mg/dl, 2-hr glc: 127.0±31.7mg/dl) and IFG+IGT (n=13, 61.6±8.1yrs; 32.8±3.1 kg/m²; FPG: 104.2±10mg/dl, 2-hr glc: 162.2±29.6mg/dl) were randomized to 12-work matched cycling aerobic exercise bouts (~70% HR_{peak}, 60 min/d) over 2-wks. A 2-hr 75g OGTT was performed pre and post-intervention to determine glucose tolerance. Endothelial function was determined by brachial artery flow mediated dilation (FMD) prior to the OGTT. Aerobic fitness (VO_{2peak}), body composition (BIA), and vascular inflammation (VCAM, ICAM) were also assessed before and after training. **Results:** Training significantly increased VO_{2peak} (P=0.03), fat-free mass (P=0.001) and VCAM (P=0.01) in both phenotypes. There was no effect of training on FMD in either IFG+IGT or IFG (0.33±3.9 vs. 1.13±4.7%, P=0.66 respectively). However, pre-intervention FMD (r=-0.45, P=0.04) and glucose total area under the curve (r=-0.56, P=0.007) were associated with increased FMD in response to training. Moreover, increased FMD adaptation was linked to decreased circulating VCAM after training (r=-0.52, P=0.02). **Conclusion:** These data highlight that impaired endothelial function and hyperglycemia prior to exercise treatment may affect improvements in endothelial function following short-term training in people with different prediabetes phenotypes. The mechanism by which people with prediabetes respond to exercise-induced vascular adaptation may relate to reduced vascular inflammation and warrants further investigation.

Low-Calorie Diet With or Without Interval Exercise Reduces Post-Prandial Aortic Waveform in Obese Women

Emily M. Heiston, Nicole M. Gilbertson, Natalie Z.M. Eichner, Steven K. Malin, FACSM. *University of Virginia, Charlottesville, VA.* (Sponsor: Steven Malin, FACSM)
Email: emh5bh@virginia.edu

(No relevant relationships reported)

Purpose: Arterial stiffness is considered a strong predictor of cardiovascular disease (CVD). Women have higher values of arterial stiffness than men, suggesting that females are at a greater risk of heart-related complications. While a low calorie diet (LCD) reduces arterial stiffness, in part through lowering metabolic syndrome (MetS) risk factors and/or increasing insulin sensitivity, no study has tested if interval exercise (INT) adds to the benefit of LCD on arterial stiffness in obese women. **Methods:** Twenty-four obese women (49.2 ± 2.4yrs; 37.9 ± 1.3kg/m²) were randomized to LCD (n=12; mixed meals of ~1200 kcal/d) or LCD+INT (n=12; 60 min/d of supervised INT at 90% HR_{peak} for 3 min and 50% HR_{peak} for 3 min). An additional 350kcal was provided to LCD+INT post-exercise to equate energy availability between groups. Augmentation index (AIx, systemic aortic waveform adjusted for heart rate of 75 bpm) and carotid-femoral pulse-wave velocity (cfPWV, central index) were measured during a 75g OGTT before and after the intervention to assess arterial stiffness. MetS risk

severity (z-scores) and insulin sensitivity (Si; simple index of insulin sensitivity) were also measured. **Results:** LCD+INT increased VO_{2peak} (L/min) and HDL compared to LCD (P=0.03 and P=0.04, respectively). However, both interventions decreased body fat, fasting SBP, TG, total cholesterol, MetS severity and LDL (all P<0.01) as well as improved Si (P=0.03). Despite no effect on fasting AIx (LCD: -3.2 ± 3.2 vs. LCD+INT: -2.7 ± 3.8%, P=0.32) or cfPWV (LCD: -0.22 ± 0.54 vs. LCD+INT: 0.73 ± 0.83 m/s, P=0.76), LCD and LCD+INT decreased AIx tAUC_{120min} (-662.5 ± 263.3 vs. -801.0 ± 286.5, P=0.04, respectively). Pre AIx_{0min} correlated with pre fasting DBP (r=0.40, P=0.04) and decreased AIx_{0min} (r=-0.45, P=0.03). Further, this decreased AIx_{0min} correlated with increased Si after treatment (r=-0.44, P=0.03). **Conclusion:** Independent of exercise, LCD reduces post-prandial aortic waveform and MetS severity in obese women. Decreased systemic arterial stiffness appears to be related to insulin sensitivity following reduced energy availability, given no effect on cfPWV. Further work is warranted to determine how dietary manipulation, with and without exercise, impacts fasted vs. post-prandial arterial stiffness to optimize CVD risk reduction.

Effects of Exercise Modality on Glycemic Control After 6 Weeks of Training in Middle Aged Men

Evelyn B. Parr, Marcus J. Callahan, John D. Waters, Brooke L. Devlin, Bridget E. Radford, John A. Hawley, Donny M. Camera. *Australian Catholic University, Melbourne, Australia.*
Email: evelyn.parr@acu.edu.au

(No relevant relationships reported)

BACKGROUND: Glycemic control is impaired with age and is accompanied by an age-related decline in muscle mass. Regular exercise maintains muscle mass and improves glycemic control. Whether the mode of exercise training differentially affects glycemic control during middle-age is unknown.

PURPOSE: To investigate changes to glycemic control after a 6 week exercise training program in inactive, middle-aged men with overweight/obesity.

METHODS: Thirty-five men (39.6 ± 2.4 y, BMI: 28.8 ± 3.7 kg/m²; mean ± SD) enrolled in a 6-week training study and were randomly stratified (by lean body mass) to one of three training groups (endurance cycling (END, n=12); high intensity interval cycling training (HIIT, n=12); resistance training (REX, n=11)) in a parallel groups design. Two-hour OGTTs were conducted as secondary analyses on two occasions (pre and post intervention) and total AUC (trapezoid method) was calculated. Statistical analyses were performed using linear mixed models (group × time), with significance set at P<0.05.

RESULTS: For glucose variables, there were no differences between groups at baseline (fasting glucose: 5.2 ± 0.6 mmol/L; AUC: 13.7 ± 3.2 mmol/L/h). A main effect of time for lower post-intervention total AUC glucose was observed (-0.7 ± 2.0 mmol/L/h, P=0.043). Fasting glucose concentrations showed a group × time interaction (P=0.008) where REX training increased fasting glucose levels post-training (+0.4 ± 0.5 mmol/L, P=0.005). Training modality had a similar effect on fasting insulin or total insulin AUC. However, a main effect of time was observed for the reduction in total AUC insulin from pre to post intervention (-15 ± 42 mIU/mL/h, P=0.046).

CONCLUSIONS: Regardless of modality, exercise training for 6 weeks induced improvements in total glucose and insulin AUC measures in response to an OGTT in middle-aged men with overweight/obesity. The small improvements in glycemic control are likely related to the normal glycemic tolerance at baseline. Future investigations of exercise modality should be performed in individuals with abnormal glucose tolerance to determine if exercise modality is an important factor in improving glycemic control.

ACKNOWLEDGEMENTS: This study was funded by ACURF grants to Dr Camera and Dr Parr.

(No relevant relationships reported)

INTRODUCTION: Older adults have the highest rates of prediabetes and diabetes in the US. Exercise is a well-established method to improve glycemic control, however, the optimal dose (duration and intensity) of exercise required to improve glycemic control among older adults is unclear. **PURPOSE:** To compare the effect of 12 weeks of moderate vs. high intensity exercise training on daily glycemic control in older adults with prediabetes. **METHODS:** 15 older adults (66.4 ± 5.1 yrs) with prediabetes (HbA1c 5.7-6.4% or fasting glucose 100-125 mg/dl) participated in a 12-week supervised aerobic exercise training intervention. Participants were screened prior

to being randomized to the moderate (MOD: 60-65% HR_{max}) or vigorous (VIG: 80-85% HR_{max}) intensity training group. During the intervention, participants exercised 4 days per week (45 minutes/session) in their target heart rate range. Continuous glucose monitors (CGM) were worn for 1 week at baseline and during the 12th week of supervised exercise training. Daily glycemic control was quantified over 24 hour periods (00:00 to 23:29) for each day the CGMs were worn during the week at baseline and after exercise training. We calculated mean, total area under the curve (trapezoidal method), and duration of hyperglycemia (percent time glucose \geq 140mg/dL). Using linear mixed models with repeated measures, we determined the effect of exercise training and whether the effect of training varied by exercise intensity group. Significance was set at $p < 0.05$. Data are reported as mean \pm SD. **SUMMARY OF RESULTS:** There were no significant differences in any baseline participant characteristics (e.g. sex, age, BMI) between exercise training groups. At baseline, VIG had significantly lower mean (MOD: 136.0 \pm 18.4; VIG: 122.6 \pm 7.4 mg/dL), total area under the curve (AUC) (MOD: 3243.0 \pm 505.1; VIG: 2873.4 \pm 226.2 mg²hr/dL), and duration of hyperglycemia (MOD: 38.5 \pm 28.6%; VIG: 19.9 \pm 9.6%). After the intervention, there were no significant changes in mean glucose, AUC, or duration of hyperglycemia in either group. **CONCLUSION:** Regardless of exercise intensity, 12 weeks of aerobic exercise training did not significantly change daily glycemic control in older adults with prediabetes, suggesting that changing other lifestyle factors may be needed to improve glycemic control in this population.

 Email: mallinsonrj@psu.edu
 (No relevant relationships reported)

Exercising women in whom energy intake is inadequate for energy expenditure develop low energy availability (EA) and are at risk for menstrual disturbances and poor bone health. The first line of treatment is an increase in energy intake to reverse low EA. REFUEL is the first randomized controlled trial (RCT) to assess the effectiveness of 12 months of increased energy intake on menstrual function and bone health in women with exercise-associated menstrual disturbances (EAMD).

Purpose: To determine if an intervention of increased energy intake improves menstrual regularity among women with EAMD.
Methods: Young, exercising women with EAMD were randomized into two groups. The treatment group (EAMD+Cal, n=32) increased energy intake 20-40% above baseline energy needs; whereas, the EAMD Control group (n=30) maintained exercise and eating habits. Menstrual function was tracked throughout the intervention with menstrual calendars and daily urine samples for reproductive hormones. A conditional recurrent events Cox Proportional Hazards model tested the effects of the intervention.
Results: The EAMD+Cal women (21.6 yrs, BMI: 20.2 kg/m²) increased energy intake by 353 kcal/day ($p < 0.001$ vs. Control) and gained 1.9 kg of body weight ($p = 0.035$ vs. Control), which corresponded with a 1.2 kg increase in fat mass ($p = 0.080$ vs. Control) and 64% increase in leptin ($p = 0.074$ vs. Control); whereas, the EAMD Controls (20.9 yrs, BMI: 21.3 kg/m²) had no change in energy intake (-32 kcal/day) and minimal change in body weight (0.8 kg), fat mass (0.4 kg), and leptin (21% increase). After controlling for BMI and menstrual status at baseline, the intervention had a positive effect on the likelihood of experiencing menses vs. the Control group ($p < 0.001$). Women in the EAMD+Cal group were twice as likely (104% increase) to experience menses during the intervention than those in the EAMD Control group.
Conclusions: Exercising women with EAMD who moderately increased energy intake were twice as likely to experience menses vs. EAMD women who maintained their usual exercise and eating habits. The intervention was associated with a modest increase in body weight. This study is the first RCT to demonstrate the effectiveness of a nutritional intervention for the improvement of menstrual function in women with EAMD.

 (No relevant relationships reported)

Energy deficiency in exercising women can lead to menstrual disturbances (MD). There is no gold standard to accurately estimate energy deficiency. Ratios of measured

to predicted resting metabolic rate (RMR) have been used as a proxy to categorize women as energy deficient. **PURPOSE:** To evaluate whether measured to predicted RMR ratios are predictive of amenorrhea or other MD. **METHODS:** We performed a cross-sectional comparison of 223 exercising women (\geq 2 hrs/wk, age 18-35 years, BMI 16-30 kg/m²) who were ovulatory (OV), amenorrheic (AMEN), or subclinical MD (sMD) (including oligomenorrhea, anovulation, and luteal phase defects). Menstrual status was determined using urinary measures of reproductive hormones and menstrual calendars. Body composition was measured with DXA and RMR with the SensorMedics Vmax. Harris-Benedict, Cunningham, and DXA equations were used to calculate predicted _{HB}RMR, _cRMR, and _{DXA}RMR and to calculate the measured to predicted RMR ratio. ANOVA and Kruskal-Wallis tests determined group differences and logistic regression determined predictors of AMEN or any MD. Calculations of sensitivity, specificity and positive predictive value (PPV) assessed accuracy of predictions. **RESULTS:** Groups did not differ in lean or fat free mass. AMEN had lower body mass ($p < 0.01$) than sMD, and lower BMI, percent body fat, fat mass ($p < 0.001$) and measured RMR (1172 \pm 21 kcal/d) ($p < 0.05$) than OV (1227 \pm 20 kcal/d) and sMD (1233.68 \pm 17 kcal/d). _{HB}RMR was lower in AMEN (1402 \pm 8 kcal/d) vs sMD (1434 \pm 9 kcal/d) ($p < 0.05$). _cRMR ratio (0.84 \pm 0.01) was lower in AMEN vs OV (0.88 \pm 0.01) ($p < 0.05$), but _{DXA}RMR ratio (0.90 \pm 0.01) was lower in AMEN vs both OV (0.96 \pm 0.01) and sMD (0.95 \pm 0.01) ($p < 0.01$). Each ratio predicted AMEN (_{HB}RMR: $\chi^2 = 4.822$, $p < 0.05$; _cRMR: $\chi^2 = 8.708$, $p < 0.01$; _{DXA}RMR: $\chi^2 = 14.068$, $p < 0.001$), but only _{DXA}RMR ratio predicted any MD ($\chi^2 = 6.795$, $p < 0.01$). _{DXA}RMR ratio correctly identified the most women with AMEN (ppv=0.5; sensitivity= 0.49, specificity= 0.74) and with any MD (AMEN+sMD: ppv=0.75; sensitivity= 0.39, specificity= 0.75). **CONCLUSIONS:** Each ratio may be used to predict AMEN, but only _{DXA}RMR significantly predicts MD, regardless of severity. Similarly, _{DXA}RMR ratio correctly identified the most subjects. _{DXA}RMR ratio can be utilized to correctly identify women with AMEN or MD secondary to energy deficiency.

Effect of Interval Exercise Plus a Low-Calorie Diet on Endothelial Function in Obese Women

Nicole M. Gilbertson, Stephanie L. Miller, Natalie ZM Eichner, Steven K. Malin, FACSM. University of Virginia, Charlottesville, VA. (Sponsor: Steven K. Malin, FACSM)
 Email: nmg4xk@virginia.edu
 (No relevant relationships reported)

PURPOSE: Low caloriédiet (LCD) and interval exercise (INT) both improve endothelial dysfunction, in part, by reducing hyperglycemia. Whether adding INT to LCD raises endothelial function compared with LCD under energy available matched conditions though is unknown. **METHODS:** Obese women (47.2 \pm 2.6y, 37.5 \pm 1.3kg/m²) were randomized to 2-wks of a LCD (n=12; mixed meals of 1000-1200kcal/d) or LCD+INT (n=13; 60min/d of supervised INT at 90% and 50% HR_{peak} for 3 min each). LCD+INT subjects received 350kcal post-exercise to equate energy availability with LCD. A 75g OGTT was performed pre- and post-test to examine fasting, 1 and 2h large conduit artery endothelial function (FMD; flow mediated dilation) and substrate use (respiratory exchange ratio (RER) via indirect calorimetry) as well as glucose and insulin incremental area under the curve (iAUC) and insulin sensitivity (IS; Matsuda Index). Fitness (VO_{2peak}), body composition (BodPod), and vascular inflammation (VCAM, ICAM) were also determined. **RESULTS:** LCD+INT increased VO_{2peak} ($P = 0.02$) compared to LCD, and both treatments improved fat mass ($P < 0.001$), IS ($P = 0.02$), and ICAM ($P = 0.002$). LCD+INT and LCD had no effect on fasting or iAUC FMD, but there was notable variation. In fact, low baseline fasting and iAUC FMD was linked to enhanced fasting and iAUC FMD post-treatment ($r = -0.71$, $P < 0.001$; $r = -0.89$, $P < 0.001$, respectively). When comparing subjects who increased fasting endothelial function after each treatment ($>50\%$; LCD n=5, LCD+INT n=7), LCD+INT increased fasted FMD more than LCD (6.3 vs. 2.8%, $P = 0.04$), and LCD+INT attenuated FMD iAUC compared to LCD (-499.3 vs. 64.6%, $P = 0.02$). Enhanced fitness related to increased fasting FMD ($r = 0.43$, $P = 0.03$) and attenuated FMD iAUC ($r = -0.44$, $P = 0.03$). Attenuated FMD iAUC correlated with reduced glucose iAUC ($r = 0.55$, $P = 0.004$), as well as increased fasting and 1h RER ($r = -0.55$, $P = 0.004$ and $r = -0.42$, $P = 0.04$, respectively). **CONCLUSIONS:** There was large FMD variation post-treatment. However, INT enhanced the effect of LCD on fasting FMD in those with low endothelial function, and this was mirrored by low post-prandial FMD stimulation. Low post-prandial FMD was linked to improved glucose tolerance and carbohydrate metabolism, suggesting INT enhanced nutrient delivery and utilization to lower type 2 diabetes and CVD risk.

 (No relevant relationships reported)

PURPOSE: Postprandial exercise has been shown to reduce postprandial glucose (PPG) response to a greater degree than preprandial exercise, suggesting an important yet under-acknowledged role for exercise timing on glycemic control. Whether diurnal timing of exercise imparts additional benefits on PPG responses remains unclear. This study aimed to determine the diurnal effect of exercise timing on PPG response in individuals enrolled into a 12-week supervised multi-modal exercise training program. **METHODS:** Forty sedentary overweight individuals (17 males, 23 female; age: 51 ± 13 years; BMI: 30.9 ± 4.2 kg/m²) with (n = 20) or without T2DM diagnosis were randomly allocated to either a morning (amEX) or evening (pmEX) exercise training group. All participants completed the 12-week supervised multi-modal exercise training program (3 days per week), which consisted of 30 minutes of aerobic exercise (walking protocol) and 4 resistance-based exercises (3 sets of 12-18 repetitions). The amEX and pmEX training sessions occurred in the postprandial state between 0700-0900h and 1700-1900h, respectively. Changes in postprandial glucose (PPG) and insulin (PPI) responses, during a mixed meal tolerance test (MMTT) were the primary outcome measures of the study assessed at baseline and post-intervention at 12 weeks. All data is displayed as mean differences ± SD.

RESULTS: Exercise training reduced (main effect of time, $p < 0.01$) PPG and PPI concentrations during the MMTT, with no group differences observed ($p = 0.69$). A significantly greater reduction in PPG-iAUC was observed for the pmEX group (-78.56 mmol/L) when compared to the amEX group (-33.22 mmol/L) at post-intervention ($p = 0.03$). Reductions in PPI iAUC (main effect of time, $p < 0.01$) were observed at post-intervention, with no group differences reported ($p = 0.18$)

CONCLUSIONS: Irrespective of the diurnal timing of exercise performance, 12-weeks of multi-modal exercise training significantly improved PPG and PPI responses in both overweight non-T2DM and T2DM individuals.

D-42 Thematic Poster - Head Impacts and Concussion

A Comparison of Head Impacts in Boys and Girls High School Lacrosse
 Amanda Esquivel, Mirel Ajdaroski, Breana Cappuccilli.
 University of Michigan - Dearborn, Dearborn, MI.
 Email: aoe@umich.edu
 (No relevant relationships reported)

Purpose: The purpose of this study was to compare the number and severity of head impacts between high school varsity girls and boys lacrosse players. **Methods:** Twenty-four subjects (13 girls, 9 boys) were individually assigned a wearable sensor (gForceTracker) for one season to measure the number of head impacts and the corresponding linear and angular acceleration. The sensor was fixed via headband (girls) or attached via dual lock strip onto the inside of a helmet (boys). A total of 21 (10 practices, 11 games) events for girls and 16 (11 practices, 5 games) events for boys were monitored. A 10g threshold was used and false impacts were removed by observing the events. Previously established correction equations were applied to raw data. Data were analyzed by t-test ($p < 0.05$). Institutional review board approval was received. **Results:** Boys experienced 33% more impacts per AE compared with girls, while girls had a higher average PLA than the boys ($p = 0.007$). There was a wide range of impacts per AE when examining individual athletes. The female athletes ranged from 0-12 impacts per AE, while the range for males was 3-20 impacts per AE. The majority of the impacts recorded were below 20 g for both boys and girls across either event. Surprisingly, a higher percentage of impacts were below 20 g for games when compared with practices for both girls (75% vs 56%) and boys (73% vs 69%). Girls experienced more impacts above 90 g than boys across either event. **Conclusion:**

Female athletes in similar or same sports sustain more concussions than males. The reason for this is unclear. Few studies have directly compared the number of impacts and head acceleration in boys and girls sports at the high school level. One previous study compared boys and girls hockey and also found that boys had a higher number of impacts but girls had a slightly higher average PLA, which is similar to our findings.

| | Boys | Girls | P-val |
|--|--------|--------|--------|
| Number Of Impacts Per Athletic Event | | | |
| Total | 9.7 | 3.5 | |
| For Games | 9.1 | 4.4 | |
| For Practices | 9.9 | 2.5 | |
| Peak Linear Acceleration (g) | | | |
| Total | 19.6 | 21.1 | 0.007 |
| For Game | 19.4 | 20.1 | 0.327 |
| For Practice | 19.7 | 23.6 | <0.001 |
| Peak Angular Acceleration (rad/s²) | | | |
| Total | 1208.3 | 1166.2 | 0.217 |

Evaluation of Concussion Prediction with Head Impact Density by Receiver Operating Characteristic
 Katherine M. Breedlove, Allyssa K. Memmini, Steven P. Broglio, FACSM. University of Michigan, Ann Arbor, MI.
 (Sponsor: Steven Broglio, FACSM)
 (No relevant relationships reported)

PURPOSE: Head impact density has previously been introduced as a novel metric to evaluate the concussive risk of a series of head impacts. The originally proposed head impact density was calculated by summing the magnitude of a given impact divided by the time from the previous impacts for each of the 20 previous impacts. However, because the 20 previous impacts may occur over multiple days, this study computes density as the sum of head impact magnitudes divided by time since the previous impact for all impacts on a single day. The purpose of this study is to evaluate the predictiveness of a daily impact density and other head impact metrics using a receiver operating characteristic curve.

METHODS: 185 high school football players (n=185, age 16.3 ± 0.8 years, 180.8 ± 8.1 cm, 85.0 ± 18.3 kg) were outfitted with a head impact telemetry system that measured the magnitude, number, and location of head impacts sustained during all games and practices over a course of a football season. From the telemetry system, peak linear acceleration (PLA), peak rotational acceleration (PRA), kinematic impulse, daily PLA impact density, and daily PRA impact density were computed. A support-vector binary classifier (SVC) was fit to the data to predict whether or not a player had sustained a concussion on the given day. Receiver operating characteristic (ROC) and corresponding area under ROC (auROC) was computed using k-fold cross-validation with 5 folds.

RESULTS: Best auROC of 0.75 ± 0.11 was obtained using sum peak linear accelerations (PLA) for the day of impact, sum of peak rotational accelerations (PRA) for the day of impact, PLA impact density for the day, PRA impact density for the day, and the kinematic impulse density for the day as predictors. Despite a moderate auROC, the model's positive predictive value (PPV) was only 0.01 (f1-score = 0.02). **CONCLUSIONS:** Prior work has shown that density based head impact metrics are correlated with the concussion risk. Nevertheless, a binary classifier based only on head impact metrics was not able to provide a high level of PPV (i.e., precision). While head impact metrics are likely important to predicting concussion risk, this work adds to a growing body of evidence that neither individual hit characteristics nor the characteristics of a series of hits are reliable predictors of concussion.

Head Impact Biomechanics in Youth Flag Football: An Exploratory Analysis
 Landon B. Lempke, Rachel S. Johnson, Melissa N. Anderson, Rachel K. Le, Julianne D. Schmidt, Robert C. Lynall. *University of Georgia, Athens, GA.*
 Email: lblempke@uga.edu
 (No relevant relationships reported)

Youth flag football has been proposed as a safe alternative to tackle football due to rising concerns of neurodegeneration from repetitive blows, but the true head impact (HI) burden in youth flag football is unknown.

PURPOSE: To examine overall and age-specific HI exposure and magnitude in youth flag football.

METHODS: Five youth flag football teams ($n = 35$, age = 8.5 ± 1.1 yrs, height = 138.5 ± 10.5 cm, mass = 35.3 ± 8.8 kg) comprised of two age groups (7-8Us and 9-10Us) wore HI sensors (Triax Sim-G) during practice and game sessions over one season. Sensors recorded HI frequency, linear (\bar{g}), and rotational acceleration (rad/s^2). Athlete exposure was calculated as one player participating in one practice or game session. Impact rates (IR) were calculated as impacts per 10 athlete exposures. Impact rate ratios (IRR) compared session type and age groups. Acceleration values were placed into low- and high-magnitude categories via median splits. Magnitude category frequencies were compared between age groups using χ^2 tests ($p < 0.05$).

RESULTS: We observed 203 overall flag football HIs (127 game, 76 practice; 5.8 impacts/player; 0.56 impacts/exposure). Overall median linear acceleration was $32.7\bar{g}$ ($16.0\bar{g} - 100.9\bar{g}$) and angular acceleration was $4,300 \text{ rad/s}^2$ ($1,000 \text{ rad/s}^2 - 12,500 \text{ rad/s}^2$). 90th percentile accelerations were $63.0\bar{g}$ and $8,400 \text{ rad/s}^2$ during games and $49.5\bar{g}$ and $8,200 \text{ rad/s}^2$ during practices. Players experienced significantly higher IRs during practices than games (IRR = 1.54, 95% CI: 1.16-2.05). There were no age group HI differences overall (IRR = 1.12, 95% CI: 0.83-1.51) or for games (IRR = 1.15, 95% CI: 0.80-1.64). Practices resulted in 1.80 times the IR (95% CI: 1.02 - 3.17) in the 9-10Us compared to the 7-8Us. No significant associations between age groups were observed for low- and high-magnitude HIs for linear ($p = 0.73$) or angular acceleration ($p = 0.32$).

CONCLUSIONS: Flag football players experienced a low-frequency of HIs and relatively high-impact magnitudes, but whether high-frequency or magnitude HIs contribute to neurodegeneration is unknown. Practices had greater odds for HI frequencies than games, suggesting practice modifications can further decrease total HI. The 9-10Us experienced greater HI frequencies, potentially indicating more aggressive or risky game play with age.

Effect Of A Dynamic Dual-Task Paradigm And Concussion History On Motor And Cognitive Performance
 Maria Talarico, Christopher Ballance, Laura Boucher, James Onate. *The Ohio State University, Columbus, OH.*
 (No relevant relationships reported)

Prior to and following a concussion, athletes exhibit deficits in gait and cognitive performance between single-task (ST) and dual-task (DT) paradigms. Current motor tasks used in these divided attention paradigms may not be challenging enough to detect long-term changes following injury. **PURPOSE:** To determine if differences exist between ST and DT paradigms while performing a multi-directional gait task and Stroop test. **METHODS:** Fifteen male Big Ten Universities Rugby Conference athletes (20.53 ± 1.60 yrs; 1.76 ± 0.10 m; 86.11 ± 9.47 kg) and 17 male American Collegiate Hockey Association athletes (20.06 ± 1.75 yrs; 1.79 ± 0.07 m; 85.96 ± 10.25 kg) volunteered to participate. Two tasks were performed: 1) recite the color of the Stroop stimulus and 2) walk around a 3.05×3.05 m (10×10 ft.) box while maintaining forward gaze. Tasks were completed independently (ST) and concurrently (DT). Attempted responses were calculated as a percentage of attempted out of total possible responses (56 stimuli). The number of incorrect responses were calculated as $([\text{incorrect responses} / \text{attempted responses}] * 100)$. Dual-task effect (DTE) was calculated as $([\text{DT performance} - \text{ST performance}] / \text{DT performance} * 100)$ for box distance and attempted responses. A paired samples t-test was performed to determine if differences in DTE existed between motor and cognitive performance. For all remaining outcome variables, 2 (paradigm) \times 2 (concussion history) mixed-model ANOVAs were performed. Alpha level was set *a priori* at $p < 0.05$. **RESULTS:** Participants walked a shorter distance under DT (10.49 m) compared to ST (11.66 m) ($p < 0.01$). Athletes with a concussion history had a higher percentage of incorrect responses (2.73%) compared to those without a history of concussion (0.58%) ($p = 0.01$). There were no differences in attempted responses between paradigms ($p = 0.38$) or concussion history ($p = 0.66$). DTE for box distance (-12.45%) and attempted responses (-3.80%) DTE were different ($p = 0.02$). **CONCLUSIONS:** Motor and cognitive differences existed under a DT paradigm whereby DT elicited a

greater degree of change from ST for motor performance than cognitive performance. Establishing a normative healthy DT baseline performance is warranted to better inform clinicians on appropriate return-to-play decisions following injury.

The Relationship of Nonlinear Metrics of Postural Control Following Sport Related Concussion
 Brian Szekely¹, Barry Munkasy², Nicholas Murray¹. ¹University of Nevada, Reno, Reno, NV. ²Georgia Southern University, Statesboro, GA.
 (No relevant relationships reported)

Postural control is a cardinal sign of sport-related concussion (SRC) and can be quantified via center of pressure (CoP) data using linear and nonlinear metrics. Recently, nonlinear metrics such as approximate (ApEn), sample (SampEn) and complexity index (CI) have been proposed as methods of analyzing the neurological organization or health of the postural control system. This is partially due to the properties of the signals being analyzed. Currently, research is divided about which of these nonlinear metrics are appropriate to use to quantify postural control deficits in neurological disorders, such as (SRC). However, these metrics have not been compared within the same sample of SRC. **PURPOSE:** The purpose of this study was to examine the relationship between ApEn, SampEn, and CI in a group of healthy match controls (CON) and sport-related concussion (SRC). **METHODS:** Sixteen Division 1 athletes with SRC and 16 CON performed 3 trials of feet together quiet upright stance in the eyes open (EO) and eyes closed (EC) conditions for 30 seconds on a force platform (100Hz) at 24-48 hours post-injury. SRC was diagnosed by the head team physician and verified by the presence of 2 or more vestibular/ocular symptom scores on Vestibular Ocular Motor Screening (VOMS) test. CON data were collected at pre-participation physicals. Raw CoP data were analyzed using ApEn and SampEn ($m=2$, $r=0.2$, $N=300$), and MSE ($m=2$, $r=0.15$, $S=1-10$, $N=300-3,000$). The data were analyzed using independent samples t-tests and Pearson's Product Correlations. **RESULTS:** A significant decrease in ApEn ($p=0.024$; $\text{SRC}=0.59 \pm 0.11$, $\text{CON}=0.68 \pm 0.10$ Cohen's $d=0.86$) SampEn ($p=0.022$; $\text{SRC}=0.65 \pm 0.14$, $\text{CON}=0.76 \pm 0.13$, Cohen's $d=0.81$), and MSE ($p=0.025$; $\text{SRC}=41.86 \pm 8.79$, $\text{CON}=48.69 \pm 7.55$, Cohen's $d=0.83$) was noted in the EC AP direction for SRC. No other significant differences were noted. A significant relationship was noted between ApEn and SampEn ($p < 0.001$, $r=0.99$), ApEn and MSE ($p < 0.001$, $r=0.99$), and SampEn and MSE ($p < 0.001$, $r=0.99$) in the EC AP direction for both SRC and CON. **CONCLUSION:** These results may indicate that ApEn, SampEn, and MSE are highly related to one another and may be viable in determining deficits postural control following SRC.

Baseline Postural Control Measures: An Indicator For Increased Injury Frequency Following Sport-related Concussion
 Nicholas G. Murray¹, Brian Szekely¹, Emily Belson², Arthur Islas¹, Jay Henke¹, Jessica Gaubatz¹, Daniel Cipriani³, Barry Munkasy², Douglas Powell, FACSM⁴. ¹University of Nevada, Reno, Reno, NV. ²Georgia Southern University, Statesboro, GA. ³West Coast University, Los Angeles, CA. ⁴University of Memphis, Memphis, TN. (Sponsor: Douglas Powell, FACSM)
 Email: nicholasmurray@unr.edu
 (No relevant relationships reported)

Recent research indicates that within 1 year following sport-related concussion (SRC), those who have experienced a SRC are 1.97 to 3.5 times more likely to sustain an acute lower extremity (LE) injury with a risk rate that ranges from 2.88 to 6.22 per 1000 athlete exposures. These studies suggest that an association between SRC and LE injury exists, however, no known research has examined the potential cause. It has been suggested that lingering postural control deficits as a result of SRC, may play a role in the increased prevalence of injury. **PURPOSE:** The purpose of this study was to investigate the potential relationship between baseline postural control metrics and acute LE injury frequency in NCAA Division I athletes with a prior history of SRC. **METHODS:** Eighty-four NCAA Division I athletes (42 with a history of SRC [CONC]; 42 without a history of SRC [CTRL]) performed three trials of 30 seconds eyes open (EO) and eyes closed (EC) quiet upright stance during pre-participation baseline screening on a force platform (1000Hz). Acute LE injuries were prospectively tracked for a single athletic season following baseline. Raw center of pressure (CoP) data were further analyzed using a custom MATLAB code to obtain Root Mean Square (RMS), Mean Velocity (MEV), and Multiscale Entropy's Complexity Index (CI) for both anteroposterior (AP) and mediolateral (ML) directions. **RESULTS:** The results indicated that over the course of the season, 27.4% of the athletes reported an injury ($\text{CONC} = 15$, $\text{CTRL} = 8$ injuries) with a significant association between prior SRC history and incidence of injuries ($p=0.043$, relative risk=1.88 [$\text{CI}_{95} = 1.09, 3.95$]). In EO condition, RMS ($p=0.049$; $\text{CONC}=5 \pm 0.28$ mm, $\text{CTRL}=4.1 \pm 0.22$ mm; Cohen's $d=3.6$) and CI ($p=0.021$; $\text{CONC}=10.25 \pm 0.52$, $\text{CTRL}=11.80 \pm 0.57$; Cohen's $d=2.9$) in

the ML direction were significantly different between groups. Furthermore, in the EC condition, CI ($p=0.026$; $CONC=14.08\pm 0.63$, $NORM=15.93\pm 0.52$; Cohen's $d=3.2$) in the ML directions was significantly different between groups. No other significant differences were observed. **CONCLUSION:** These results indicate that a prior history of SRC is associated with a greater incidence of LE injury and postural control differences can be detected prior to injury occurrence using postural control variability.

Laboratory Validation Of A Head Impact Sensor For Use In Water Polo And Non-helmeted Land Sports

Nicholas J. Cecchi, Derek C. Monroe, Theophil J. Oros, Steven L. Small, James W. Hicks. *University of California, Irvine, Irvine, CA.*
 Email: ncechi@uci.edu
 (No relevant relationships reported)

Repetitive head impact exposure can result in brain injury, and impact sensors are increasingly being used to quantify head impact kinematics and patterns of risk in sports. Water polo is a contact sport that carries a risk of head impact from the ball and contact between players. However, monitoring head impacts presents a challenge since the sensors must be waterproof and small enough to be worn in a water polo cap. The SIM-G (Triax Technologies) sensor meets these criteria, but a validation of the SIM-G in a water polo cap has not yet been published.

PURPOSE

To evaluate the accuracy and reliability of a head impact sensor, previously validated for use in non-helmeted land sports, mounted in a standard water polo cap.

METHODS

A SIM-G sensor was placed in i) a water polo cap and ii) a headband. Each headgear was fitted to a 50th Percentile Male Hybrid III head and neck (headform; HF). A linear impactor impacted the HF at seven sites and four velocities (1.7, 2.7, 4.7, and 6.4 m/s). 1.7 m/s did not consistently produce impacts large enough for the SIM-G to detect, thus 155 impacts (77 headband, 78 water polo cap) were analyzed. Peak linear acceleration (PLA), rotational velocity (PRV), rotational acceleration (PRA) were recorded for all impacts. SIM-G reliability was tested using a series of regression analyses to compare PLA, PRA, and PRV to HF values. Differences in the regression coefficients were tested by the interaction term (i.e., magnitude x headgear). Accuracy was tested using a mixed model ANOVA with sensor (HF, SIM-G) as a repeated measure and headgear (cap, headband) as a between-trial factor. Interactions were decomposed with *post hoc* Bonferroni-corrected t tests.

RESULTS

The SIM-G sensor reliably quantified PLA, PRA, and PRV relative to the HF [$\beta>.559$, $t(151)>6.682$, $p<.001$] independent of headgear ($p>.191$). Regarding accuracy, there were sensor x headgear interactions [$F(1,153)>29.383$, $p<.001$, $\eta^2>.161$]. Relative to the HF, the SIM-G overestimated PLA, PRA, and PRV when mounted in the water polo cap and underestimated PRV when mounted in the headband ($p<.001$).

CONCLUSION

The SIM-G sensor demonstrated sufficient reliability for quantifying in the water polo cap and headband. However, due to sensor inaccuracy, relative metrics, rather than absolute impact magnitudes, are advised when calculating head impact exposure.

Biomechanical Analysis of Head Impacts during Real Time Soccer Play: a Preliminary Study

Caroline Lecours¹, Yvan Petit², Éric Wagnac². ¹École de technologie supérieure, Montreal, QC, Canada. ²École de technologie supérieure and Hôpital du Sacré-Cœur Research Center, Montreal, QC, Canada.
 Email: caroline.lecours.1@ens.etsmtl.ca
 (No relevant relationships reported)

Linear and angular head accelerations are recognized as the foremost mechanisms of head injuries in sports. However, in non-contact sports such as soccer, little is known about onfield head accelerations during soccer play, which limits the understanding of the risk and mechanism of head injury. **PURPOSE:** To assess the biomechanics underlying the risk of head injury during soccer play. **METHODS:** An instrumented headband was worn by 8 elite male (M) players (18 ± 0 yrs, 73.7 ± 9.5 kg, 1.73 ± 0.1 m) and 16 amateur female (F) players (24.1 ± 1.4 yrs, 63.5 ± 7.8 kg, 1.63 ± 0.1 m) during 7 (M) and 9 (F) games of a summer season. Head kinematics of each impact (peak linear and angular accelerations of the head) were grouped as heading techniques or involuntary impacts. Heading techniques were sub-categorized as jump, stable, head rotation or unstable. Involuntary impacts were sub-categorized as player-to-player contact, ball control (feet or chest), running (acceleration or deceleration), change-of-direction, ground impact, unstable or involuntary head-to-ball impact. Head kinematics were subjected to standard descriptive statistics. Wilcoxon signed-rank test was used to compare heading techniques and involuntary impacts kinematic. **RESULTS:** In total 239 head impacts were registered for M and 139 for F. Heading techniques accounted for 92 impacts for M ($36g\pm 15g$; 4175 ± 2517 rad/s²) and 97 for F ($33g\pm 13g$; 3334

± 1747 rad/s²). Involuntary impacts accounted for 147 impacts for M ($20g\pm 9g$; 1934 ± 1511 rad/s²) and 42 for F ($21g\pm 11g$; 2095 ± 1603 rad/s²). For M and F, the average peak linear and angular accelerations of the head caused by heading techniques were associated with higher values than involuntary impacts ($p<0.05$). For both M and F, the most frequent heading technique was the jump and player-to-player contact was the most frequent for involuntary impact. **CONCLUSION:** Preliminary results show that heading techniques can cause higher values of head accelerations than involuntary impacts and therefore, could cause a higher risk of head injury in two different populations of players.

Executive Function Performance And Cortical Activation When Cycling On An Active Workstation In Young Adults

Qian Gu, Tao Huang, Zhangyan Deng, Yue Xue, Jilun Cai, Jimeng Zhang, Kun Wang. *Shanghai Jiao Tong University, Shanghai, China.*
 Email: sjtuguqian@sjtu.edu.cn
 (No relevant relationships reported)

BACKGROUND: Previous studies suggested that exercise on an active workstation while working may be a promising intervention strategy for reducing sedentary time at workplace. The influence of active workstation on cognitive function are not well studied and the existing studies yielded mixed findings.

OBJECTIVE: To investigate the effects of cycling on an active workstation on executive function and cortical activation in young adults.

METHODS: In a cross-over study design, 35 young adults (mean age = 21.4 ± 2.6 years, 45.7% females) were randomly assigned the following two task conditions separated by 48 hours: performing cognitive tests while sitting (SIT) and performing cognitive tests while self-paced cycling on an active workstation (ACTIVE). Executive function was assessed by a task-switching paradigm and Stroop Color and Word Test (SCWT) programed using E-Prime 2 professional (Psychology Software Tools, Inc., Sharpsburg, PA, USA), respectively. Global switch costs, local switch costs and Stroop effects were derived and used as the behavioral outcomes of the two tasks. Cortical activation during the two conditions was monitored using a 38-channel fNIRS (NIRx Medical Technologies LLC, USA).

RESULTS: There were no significant differences on Stroop effects (136.25 ± 125.67 vs. 101.61 ± 137.10 , $p=0.19$) between SIT and ACTIVE conditions. The global switch costs (463.19 ± 206.86 vs. 452.77 ± 167.05 , $p=0.73$) and local switch costs (-6.14 ± 147.22 vs. 9.97 ± 156.08 , $p=0.70$) also did not differ. For the fNIRS results, ACTIVE condition led to greater cortical activity in left-dorsolateral prefrontal cortex (left-DLPFC) related to Stroop effects (0.88 ± 17.75 vs. 13.85 ± 19.44 a.u., $p=0.02$). For the task switch test, there were no significant differences in cortical activation between SIT and ACTIVE conditions.

CONCLUSION: The results suggests that the performances on Stroop task and task-switching were not impaired by self-paced cycling on a workstation. Importantly, cycling led to greater recruitment of sub-region of prefrontal cortex indicated by a greater cortical activation related to Stroop effects in the left-DLPFC.

PURPOSE: To investigate whether physical exercise (PE) is differentially associated with global and domain-specific cognitive trajectories (memory, language, visuospatial skills, attention) among Apolipoprotein E (APOE) $\epsilon 4$ carriers and non-carriers.

METHODS: We included 2,060 community-dwelling individuals aged 70 years and older (50.5% males, 26.6% APOE $\epsilon 4$ carriers). Participants were cognitively unimpaired at baseline, and underwent serial cognitive testing and self-reported assessment of PE engagement in midlife (between 50-65 years of age) and late-life (within one year prior to assessment). We calculated linear mixed-effect models comparing three PE groups (light intensity such as leisurely walking or slowly dancing; at least moderate intensity such as hiking or swimming; at least vigorous intensity such as jogging or tennis singles) versus a none PE reference group (defined as each level of PE carried out less than once per week). Models were adjusted for age, sex, education and medical comorbidities, and run separately for mid- and late-life PE.

RESULTS: Among APOE $\epsilon 4$ non-carriers, midlife light PE was associated with less decline in memory (time x PE interaction coefficient 0.044, $p = 0.01$); midlife vigorous PE was associated with less decline in memory (0.033, $p = 0.05$); and late-life vigorous PE was associated with less decline in visuospatial skills (0.025, $p = 0.03$) and global cognition (0.034, $p = 0.03$). Among APOE $\epsilon 4$ carriers, late-life vigorous PE was associated with less decline in memory (0.067, $p = 0.03$), attention (0.083, $p = 0.01$) and global cognition (0.073, $p = 0.02$); and late-life moderate PE was associated with less decline in global cognition (0.048, $p = 0.05$).

CONCLUSIONS: Engaging in PE (light, moderate and vigorous) is associated with less decline in memory, attention, visuospatial skills and global cognition among community-dwelling older individuals, including those that are APOE $\epsilon 4$ genotype carriers who are at an increased risk of Alzheimer's disease.

Effects of Acute High Intensity Interval Training on Information Processing Speed: An Electromyography Study

Bradley Kendall¹, Qin Lai², Nicholas Siekirk³. ¹Taylor University, Upland, IN. ²Wayne State University, Detroit, MI. ³Georgia Southern University, Statesboro, GA.

Email: brad_kendall@taylor.edu

(No relevant relationships reported)

Steady-state aerobic exercise has been shown to improve information processing speed. However, the effects of high intensity interval training (HIIT) on information processing speed using surface electromyography (sEMG) is limited. **PURPOSE:** The purpose of this study was to compare the effects of a single session of either aerobic HIIT (HIIT-A) or aerobic/resistance HIIT (HIIT-AR) to a resting control group on information processing speed. **METHODS:** Participants (N=57, mAge = 23.1) provided consent and were randomly assigned into the HIIT-A (n=20), HIIT-AR (n=18), or the control group (n=19). Information processing was assessed via a reaction time (RT) task using a serial response box, integrated with a Biopac MP100 system allowing for measurement of sEMG. The sEMG signals of the agonist synced with RT were temporally partitioned to assess central (premotor time (PMT)) and peripheral processing (motor time (MT)). A 3 (HIIT-A, HIIT-AR, & controlled) x 2 (pre-test & post-test) ANCOVA was performed for RT, PMT, and MT. **RESULTS:** For regular foreperiods (consistent time), the interaction between group and time for RT and MT was not significant ($p > .05$). There was a significant interaction between group and time for PMT, $F(2, 51) = 4.194$, $p = .021$, partial $\eta^2 = .141$. This interaction was likely due to a simple main effect of time (pre to post) and not group allocation. For irregular foreperiods (variable time), the interaction between group and time for RT ($F(2, 51) = 4.543$, $p = .015$, partial $\eta^2 = .151$) and PMT ($F(2, 51) = 3.219$, $p = .048$, partial $\eta^2 = .112$) was significant while the interaction for MT was not ($p > .05$). For RT, there was a significant simple main effect of group, $F(2, 53) = 7.271$, $p = .002$, partial $\eta^2 = .215$. Post hoc analyses revealed that both exercise groups had significantly faster RTs than the control group ($p < .01$). Additionally, for PMT, there was a significant simple main effect of group ($F(2, 53) = 4.275$, $p = .019$, partial $\eta^2 = .139$).

Post hoc analyses revealed that both exercise groups had significantly faster PMTs than the control group ($p < .01$). **CONCLUSION:** Improved RT appeared to be a result of reduced central processing rather than a significant change in peripheral processing. This study demonstrated that acute HIIT-A and HIIT-AR can significantly improve information processing speed in young adults.

Abstract: Age-related cognitive decline affects several aspects of cognitive performance, including processing speed, inhibition, executive function, and visual scanning. Aerobic exercise is a potential solution to mitigate age-related cognitive decline. Furthermore, older adults are more susceptible to benefits from the effects of both chronic and acute aerobic exercise compared to younger adults. **PURPOSE:** To determine the associations of life-long aerobic exercise as well as the effects of acute aerobic exercise on cognitive function among healthy older adults (65 - 84 years old). **METHODS:** Model-based cluster analyses were conducted based on parameters of the participant's cardiovascular health: (1) age; (2) VO_{2max} ; (3) Carotid Augmentation Index; (4) Carotid-femoral pulse wave velocity (cfPWV); (5) Aortic systolic blood pressure (SBP); (6) Carotid intima-media thickness (IMT). A cross-sectional design was utilized to compare 27 active (A) with 31 inactive (I) older adults (70±5yrs). Cognitive function was measured at rest and after 15 minutes of moderate intensity exercise (55-65% HRR) via the trail-making test (TMT Form A and Form B). A series of one-way ANOVAs were performed on dependent variables. A repeated measures MANOVA was used to test differences on the TMT-A and TMT-B at rest compared to after an acute bout of exercise. Pearson's correlation analysis tested the associations among VO_{2max} , age, carotid IMT, cfPWV, and cognitive performance. **RESULTS:** VO_{2max} was not related to carotid IMT ($r = .15$, $p = .27$) or cfPWV ($r = -.12$, $p = .38$). Time to complete TMT-A (26±1 vs 23±1 seconds, $F(1,57) = 15.12$, $p < .001$) and TMT-B (57±2 vs 53±2, $F(1,57) = 7.20$, $p < .01$) increased after an acute bout of exercise compared to at rest. VO_{2max} ($r = -.16$, $p = .23$), carotid IMT ($r = .17$, $p = .21$), and cfPWV ($r = .15$, $p = .26$) were not significantly correlated with cognitive performance on the TMT-A and TMT-B. Age was correlated with cognitive performance on the TMT-A and TMT-B ($r = .60$, $p < .01$). **CONCLUSION:** An acute bout of aerobic exercise may diminish cognitive performance among healthy older adults.

Effects of Duration and Intensity of Aerobic Exercise on Cognitive Performance in Trained Individuals

Christopher Irwin, Ben Desbrow, Danielle McCartney. Griffith University, Gold Coast, Australia. (Sponsor: Prof. Louise Burke, FACSM)

Email: c.irwin@griffith.edu.au

(No relevant relationships reported)

PURPOSE: This study explored the effect of acute aerobic exercise on cognitive performance in trained cyclists/triathletes. Specifically, it investigated the impact of different exercise durations (completed at a fixed moderate-intensity) and high/maximal intensity exercise (H/MIE) to volitional exhaustion (following a sustained bout of dehydrating activity) on simple and complex cognitive skills.

METHODS: On two separate occasions, 21 trained cyclists/triathletes; 11 male (M) (age: 31±8 y; VO_{2max} : 57±9 mL·kg⁻¹·min⁻¹) and 10 female (F) (34±7 y; VO_{2max} : 51±9 mL·kg⁻¹·min⁻¹), completed 45 min of fixed-intensity cycling (M: 80±8%; F: 74±5% HR_{max}) followed immediately by an incremental test to volitional exhaustion. Cognitive function was assessed at Baseline, after 15 and 45 min of exercise (15EX; 45EX), and at Exhaustion using a 4-choice reaction time (CRT) and Stroop Word-Color Association test (Incongruent/Congruent Reaction Time [RT]). A placebo treatment ("to improve cognition") was administered after 15EX on one trial to determine if positive expectancy influenced cognitive responses.

RESULTS: *Exercise Duration:* CRT, Congruent RT and Incongruent RT decreased (improved) at 15EX and 45EX compared to Baseline (p 's<.005). While CRT and Congruent RT were faster at 45EX than 15EX (p 's<.020), Incongruent RT was not ($p=1.000$). *Exercise Intensity:* The incremental test lasted ~11.4±2.8 min, with participants achieving a maximum heart rate (HR) equal to ~93±7% HR_{max} . CRT, Congruent RT and Incongruent RT decreased at Exhaustion compared to Baseline, (p 's<.005), despite large fluid losses (M: -2.3±0.3% BM; F: -1.7±0.3% BM). The placebo treatment did not affect cognitive responses to H/MIE (p 's>.05).

CONCLUSIONS: Acute aerobic exercise improves cognitive performance in trained athletes. These effects are more pronounced when exercising for longer durations (~1hr), employing higher exercise intensities and/or more complex cognitive tasks.

Accelerometer-Measured Sustained MVPA Is Related To Higher Decision-Making Competence Among Young Adults

Dominika M. Pindus¹, Christopher Zwilling¹, Jennifer Jarret¹, Hillary Schwarb¹, Charles H. Hillman², Neal J. Cohen¹, Arthur F. Kramer², Aron K. Barbey¹. ¹University of Illinois at Urbana-Champaign, Urbana, IL. ²Northeastern University, Boston, MA. (Sponsor: Steve Petruzzello, FACSM)
Email: pindus@illinois.edu

(No relevant relationships reported)

More competent decision makers report greater success in avoiding negative decision outcomes irrespective of general cognitive ability. While physically active young adults show more optimal executive functions, the relationship between daily moderate-to-vigorous physical activity (MVPA) patterns and decision-making competence (DMC) remains under-examined. **PURPOSE:** In this study, we assessed the relationship between accelerometer-measured sporadic and sustained MVPA to DMC in young adults. **METHODS:** We analyzed pre-intervention data from 220 participants (115 (52%) females, $M_{age}=24.3 \pm 5.4$ yrs, $BMI=24.4 \pm 4.0$ kg/m²) from the INSIGHT randomized controlled trial. MVPA was measured over 7 days with a hip-worn wGT3X-BT accelerometer. Valid wear time was defined as ≥ 4 days, ≥ 10 hrs/d. Daily (min/d), bouts of sporadic (<10 consecutive min) and sustained MVPA (≥ 10 consecutive min; frequency and min/d) were estimated using NHANES cut points. DMC was measured with the Adult-Decision Making Competence (A-DMC) battery and expressed as individual subtest scores and an A-DMC index (z-score). The relationships between MVPA and A-DMC variables were assessed with Spearman's rho controlling for wear time, age, sex, education, intelligence, fat free VO_{2max} , BMI and sedentary time (ST; <100 counts/min). **RESULTS:** After controlling for daily MVPA, frequency and time spent in sustained MVPA bouts were positively related to the ability to recognize social norms ($\rho_s=[0.15; 0.16]$, $P_s \leq 0.04$) and ignore unrecoverable costs when considering future decision outcomes ($\rho_s=[0.14; 0.15]$, $P_s \leq 0.04$). In contrast, neither sporadic nor daily MVPA were related to A-DMC subtests ($P_s \leq 0.08$). **CONCLUSION:** The quality of decision making varied primarily as a function of sustained MVPA. Young adults who engaged in more sustained MVPA were able to use their experience more effectively and make more rational choices to optimize decision outcomes. Our data reveal a novel relationship between MVPA patterns and a distinct set of higher order cognitive skills which are relevant to real-world decisions. Alterations in Exercise-Affect between Those With Higher and Lower Intensity Preference and Tolerance

Allyson G. Box, Shelby E. Dietz, Annmarie Chizewski, Steven J. Petruzzello, FACSM. University of Illinois Urbana-Champaign, Urbana, IL. (Sponsor: Steven J. Petruzzello, FACSM)
(No relevant relationships reported)

High-intensity exercise results in a more negative affective response when compared to moderate- or low-intensity exercise. However, a large number of individuals continue participating in high-intensity exercise, in spite of these declines in affective state. **PURPOSE:** Determine whether differences exist in exercise-affect for those with higher versus lower exercise intensity preference and/or tolerance. **METHODS:** Undergraduates ($n=245$, 20.3 ± 1.7 yrs, 23.7 ± 3.8 BMI, 60.8% female, 82% regular exercisers) completed the Preference for and Tolerance of Exercise Intensity Questionnaire [Higher-intensity exercise preference, tolerance (HIP, HIT) ≥ 24 ; $n=155$, $n=154$; lower-intensity preference, tolerance (LIP, LIT) <24; $n=45$, $n=51$] along with completing 15-minutes of a high-intensity circuit (HIC), a walk, and a reading condition. Affective valence (via Feeling Scale) was taken prior to, every 3-minutes during, and 20-minutes post (P20) condition, while activity enjoyment was assessed immediately post. **RESULTS:** Multivariate ANOVAs revealed significant differences ($P < 0.05$) for preference-intensity groups in valence during HIC at minutes 3 (HIP=2.4, LIP=1.4; $d=0.615$), 6 (HIP=2.5, LIP=1.1; $d=0.772$), 9 (HIP=2.5, LIP=1.2; $d=0.659$), 12 (HIP=2.3, LIP=0.9; $d=0.625$), 15 (HIP=2.4, LIP=0.9; $d=0.632$), and at P20 (HIP=3.1, LIP=2.0; $d=0.554$), and for enjoyment following HIC (HIP=95.6, LIP=85.3; $d=0.545$), but not for walking or reading conditions. For those with differing intensity-tolerance levels, differences ($P < 0.05$) in exercise-affect were only observed during minutes 3 (HIT=2.4, LIT=1.5; $d=0.535$) and 6 (HIT=2.3, LIT=1.7; $d=0.366$), and enjoyment differed following HIC (HIT=95.8, LIT=86.5; $d=0.492$). **CONCLUSIONS:** These findings suggest the intensity-preference trait influences how an individual feels

during exercise at high-intensity intensity, but is less important during moderate/lower intensities. These differences may be predictive of whether an individual will continue high-intensity exercise programming.

Training Modulation Using Heart Rate Variability Improves Daily Training Cognitions for High Intensity Functional Training

Katie M. Heinrich¹, Nicholas B. Drake², Brady K. Kurtz¹, Justin A. DeBlauw¹, Derek A. Crawford³. ¹Kansas State University, Manhattan, KS. ²University of Nevada, Las Vegas, Las Vegas, NV. ³Pittsburg State University, Pittsburg, KS. (Sponsor: Yuri Feito, FACSM)
Email: kmhphd@ksu.edu

(No relevant relationships reported)

Participants in group-based high intensity functional training (HIFT) maintain exercise enjoyment and intentions; those training ≥ 5 days/week report highest intrinsic and extrinsic motives. Yet, overtraining and overreaching concerns exist. A promising monitoring method is heart rate variability (HRV), which tracks cardiac autonomic nervous system activity. **PURPOSE:** To examine differences in daily training cognitions for HIFT participants. Participants with workouts modulated based on HRV status were expected to report significantly better daily training cognitions. **METHODS:** Participants included 55 healthy adults randomized to HIFT-HRV (intervention) or HIFT (comparison). HIFT-HRV participants ($n=26$) were 23.7 ± 4.5 years, 46% female, body fat percentage (BF%) = $27.3 \pm 9.8\%$, and $VO_{2max} = 44.4 \pm 6.4$ mL/kg/min. HIFT participants ($n=29$) were 34.1 ± 4.1 years, 58.6% female, BF% = $32.4 \pm 10.7\%$, and $VO_{2max} = 42.1 \pm 6.8$ mL/kg/min. The 11-week study included 2 weeks baseline waking HRV, baseline testing week, 3 HIFT weeks (5 sessions/week), mid-point testing week, 3 HIFT weeks (5 sessions/week), and post-intervention testing week. HRV was recorded daily via photoplethysmography using a smartphone app. Self-reported motivation to train and fatigue, during HIFT weeks, were collected prior to training with performance satisfaction (PS) and perceived effort (RPE) collected immediately following. The training-related cognitions were assessed using the Visual Analog Scale and RPE using Borg's (6-20) scale. **RESULTS:** No significant differences were found between groups at baseline. HIFT-HRV participants reported cognitions for 674 daily training sessions and HIFT participants reported cognitions for 763. Average motivation was significantly higher for the HIFT-HRV than the HIFT group, $t(1435) = 2.41$, $p = .016$. Average fatigue [$t(1361) = 3.22$, $p = .001$] and RPE [$t(1271) = 5.68$, $p < .001$] were significantly lower for the HIFT-HRV than the HIFT group. No significant differences were found for PS. **CONCLUSIONS:** HRV modulation during HIFT training resulted in greater daily motivation and lower daily fatigue and perceived exertion. HRV status is a promising method to monitor and modulate HIFT training and may facilitate adherence; future work could focus on applied interventions for existing HIFT populations.

D-44 Free Communication/Slide - Understanding the Health Effects of Sitting, Fitness, and Physical Activity

Sedentary Behavior Across Pregnancy, Gestational Age at Delivery, and Birthweight

Melissa A. Jones¹, Janet Catov¹, Arun Jeyevallan¹, John Jakicic, FACSM¹, Kara Whitaker², Bethany Barone Gibbs¹. ¹University of Pittsburgh, Pittsburgh, PA. ²University of Iowa, Iowa City, IA.
Email: maj133@pitt.edu

(No relevant relationships reported)

PURPOSE: Lower gestational age at delivery (GAD) and large for gestational age birthweight (LGA) are indicators of poorer maternal-fetal health. While physical activity during pregnancy has been associated with greater GAD and lower risk of LGA, the effects of sedentary behavior (SB) on these outcomes are unknown. We aimed to describe patterns of SB across pregnancy and associations with GAD and risk for LGA. **METHODS:** In this cohort study, SB (activPAL micro3) and physical

activity (waist-worn ActiGraph GT3X-BT) were assessed in women for ≥ 4 days with ≥ 10 hours, in each trimester of pregnancy. This preliminary analysis (59% recruited) includes women with available birth records and valid activity data for ≥ 1 trimester ($n=56$). Birthweight (BW) and GAD were abstracted from medical records. BW was categorized as LGA if $\geq 90^{\text{th}}$ percentile ($n=18$, 31%). Mean (SD) percent time spent sedentary was calculated in each trimester and differences across trimesters were tested using linear mixed models. The association of SB with continuous GAD and odds of LGA were estimated in separate regression models for each trimester. All beta coefficients were standardized (std β) per SD and adjusted for pre-pregnancy body mass index. If SB was associated with outcomes, further models estimated the effect of replacing SB with light physical activity (LPA) or moderate to vigorous physical activity (MVPA). **RESULTS:** Women spent a high percentage of time sedentary across trimesters: 1st ($n=53$) 64.0% (10.9); 2nd ($n=50$) 63.5% (9.5); and 3rd ($n=47$) 63.8% (10.4). SB did not differ across trimesters ($p=0.792$). Higher percent time spent sedentary in the first trimester was associated with lower GAD (std $\beta=-0.45$, $p=0.038$). Replacing first trimester SB with LPA (std $\beta=0.48$, $p=0.037$), but not MVPA (std $\beta=-0.12$, $p=0.581$), was associated with greater GAD. SB was not significantly associated with GAD in the 2nd (std $\beta=-0.24$, $p=0.241$) or 3rd (std $\beta=-0.22$, $p=0.264$) trimester. Odds of LGA was not significantly associated with SB in the 1st (OR=0.75, $p=0.389$), 2nd (OR=0.80, $p=0.503$), or 3rd (OR=1.03, $p=0.932$) trimester. **CONCLUSIONS:** Women in this study were highly and consistently sedentary across pregnancy. Higher LPA and lower SB during the first trimester may be advantageous for greater GAD, though risk for LGA offspring did not appear to be associated with SB.

1794 May 30 4:00 PM - 4:15 PM

Structured Exercise as a Potential Treatment Option for Prenatal Depression

Taniya S. Nagpal¹, Marina Vargas-Terrones², Maria Perales³, Harry Prapavessis¹, Ruben Barakat², Michelle F. Mottola, FACSM¹. ¹University of Western Ontario, London, ON, Canada. ²Technical University of Madrid, Madrid, Spain. ³Camilo Jose Cela University, Madrid, Spain. (Sponsor: Michelle F. Mottola, FACSM)
Email: tnagpal@uwo.ca

(No relevant relationships reported)

PURPOSE: Up to 20% of pregnant women experience prenatal depression and up to 19% will continue to have depressive symptoms in the postpartum. Previous research supports exercise during pregnancy as an effective way to prevent prenatal depression, however evidence is lacking regarding exercise as a potential treatment for women who enter pregnancy already at risk for depression. Therefore the purpose was to determine if exercise during pregnancy is an effective option to treat depression during pregnancy. **METHODS:** This is a secondary analysis of two randomized controlled trials that followed the same exercise protocol and study methodology in Madrid, Spain. Women <16 weeks pregnant were randomized to an exercise group (EG) or standard care control group (CG). The EG participated in group fitness classes three times per week. The classes included moderate intensity aerobics and resistance training in accordance to the American College of Obstetrics and Gynecology guidelines. All participants completed the Centre for Epidemiologic Studies Depression scale (CES-D) at baseline and at the end of the intervention (36-38 weeks gestation). Women who scored ≥ 16 on the CES-D at baseline (at risk for depression) were included in the current study. A One-Way ANOVA was performed to determine if there was a difference in post CES-D scores between the EG and CG. A Chi-Square Analysis was performed to determine if there was a difference between the two groups for the number of women who had a decrease in their score at the end of the intervention and also scored below 16 post-intervention. **Results:** Thirty-six women in the EG and 25 women in the CG scored ≥ 16 on the CES-D at baseline. Post-intervention, the EG had a significantly lower mean CES-D score (14.4 \pm 8.6) than the CG (19.4 \pm 11.1; $p<0.05$). Additionally, more women decreased their score in the EG ($n=30$, 83.3%) than the CG ($n=14$, 56%; $p<0.05$) however there was no difference in the number of women who went below the 16 point cut-off between the two groups. **CONCLUSION:** A structured exercise program offered during pregnancy may reduce depressive symptoms among women who begin pregnancy already at risk for prenatal depression. Therefore exercise may be a viable treatment option for prenatal depression.

Effects Of Breaking-up Prolonged Sitting With Stair-climbing On Vascular-metabolic Function After A High-fat Meal

Min Jeong Cho, Hyun Jeong Kim, Eun sun Yoon, Sae Young Jae. University of Seoul, Seoul, Korea, Republic of.
Email: lovelyjmj0816@naver.com

(No relevant relationships reported)

Frequent high-fat meal intake and prolonged sedentary time are prevalent in our modern society and associated with increased risk of cardiovascular disease. Alternatively, breaking up prolonged sitting is introduces health benefits, although not always practical.

PURPOSE: To test whether stair-climbing could be an effective way of breaking up prolonged sitting. **METHODS:** Twelve healthy adults (male=7) participated in two trials after a high-fat meal: 1) 4-h uninterrupted sitting, 2) 4-h sitting interrupted with 5-min of stair-climbing every hour (interrupted sitting). We measured triglycerides, glucose, brachial artery flow-mediated dilation, popliteal artery blood flow and shear rate. All variables were measured five times (before and every hours after high-fat meal), except for brachial artery flow-mediated dilation, which was measured before and after 4-h sitting. **RESULTS:** The intensity of 5-min stair-climbing was 66% of heart rate reserve. High fat meal increased glucose and triglycerides concentrations, without any significant differences between trials. Brachial artery flow-mediated dilation decreased in sitting trial, but increased in the interrupted sitting trial (uninterrupted sitting: 9.2 \pm 2.16 to 9.0 \pm 3.23, interrupted sitting with stair-climbing: 7.9 \pm 2.55 to 10.3 \pm 2.89, $p=0.009$). Popliteal blood flow and shear rate were increased in the interrupted sitting trial with a significant interaction effect (blood flow: $p<0.001$, shear rate: $p=0.006$). Also, interrupted sitting attenuated the prolonged sitting-induced increase of systolic blood pressure and pulse pressure. **CONCLUSION:** Stair-climbing appears to be an effective way of breaking up prolonged sitting to improve vascular function with easy accessibility in various settings.

Associations of Fast Walking with Sleep Quality and Duration in Older Adults

Angelique Brellenthin, Duck-chul Lee, FACSM. Iowa State University, Ames, IA. (Sponsor: Duck-chul Lee, FACSM)

(No relevant relationships reported)

Purpose: Poor sleep has been associated with negative health outcomes in older adults. Since walking is the most popular form of physical activity in older adults, we examined the effects of daily steps and fast walking on sleep quality and duration. **Methods:** This cross sectional study included 402 older adults (56% women; 72 years old). Participants wore an accelerometer-based pedometer (Omron) during waking hours for 7 days. We used total average daily steps and average daily fast walking steps defined as ≥ 100 steps/min. Sleep duration and quality were measured using the Pittsburgh Sleep Quality Index (PSQI). Poor sleep quality (PSQ) was defined as a PSQI global score of >5 , and inadequate sleep duration (ISD) was defined as <7 hours/night. Odds ratios (ORs) and 95% confidence intervals (CIs) for PSQ and ISD were calculated among 4 groups: no daily fast steps and tertiles (thirds) of fast steps. Covariates were sex, age, body mass index, smoking, heavy alcohol intake, depression, anxiety, diabetes, hypertension, hyperlipidemia, and sleep apnea. **Results:** On average, participants took 5,764 steps, 1,598 fast steps (70% had at least 1 daily fast step), had a PSQI score of 4.6, and a sleep duration of 7.1 hours. Total steps were not associated with quality or quantity (both $p>0.05$). However, fast walking was associated with sleep quality with ORs (95% CIs) of 0.47 (0.24-0.90), 0.53 (0.27-1.04), and 0.82 (0.35-1.92) for <940 (lower third), 941-2600 (middle third), and >2600 (upper third) of fast steps, respectively, compared with no fast steps, adjusting for the confounders including total daily steps. Obtaining any fast steps was associated with 0.52 (0.30-0.90) reduced odds of PSQ compared with no fast steps. However, no associations were observed between fast steps and ISD. In a joint analysis, compared with those who took $<5,000$ daily steps and 0 fast steps, there were reduced odds of PSQ among those with $<5,000$ steps and >1 fast steps (0.43 [0.23-0.83]) as well as those with $\geq 5,000$ steps and >1 fast steps (0.42 [0.24-0.74]), suggesting the benefits of fast walking on sleep quality regardless of total daily steps. **Conclusion:** These results indicate that even small amounts of fast walking, rather than total daily steps, are associated with better sleep quality in older adults. Supported by unrestricted research grant by Biospace.

Differences of Plasma Metabolites in Prediabetes with Different Cardiorespiratory Fitness and the Effects of Exercise

Bowen Li¹, Mian Jia², Yan Wang², Juan Wang², Zhengzhen Wang, FACSM², Biao Sun². ¹Beijing Sport University and Nanjing Sport Institute, Beijing, China. ²Beijing Sport University, Beijing, China. ³Nanjing Sport Institute, Nanjing, China. (Sponsor: Zhengzhen Wang, FACSM)
Email: libowen_sy@sina.com

(No relevant relationships reported)

PURPOSE: To identify the most significant plasma metabolites for higher and lower cardiorespiratory fitness (CRF) in pre-diabetes mellitus (PDM), and the effect of aerobic exercise training on these metabolites. **METHODS:** All 80 PDM subjects were selected [age: (51.62±10.03) yrs; body mass index: (26.17±3.60) kg/cm²; 24 males]. CRF was measured directly with a graded exercise test. Exercise intervention program: 3 times/week, 50 min per session at 46%-64% VO_{2max}, 3 month. Body composition was measured by dual-energy x-ray absorptiometry. Plasma metabolites were detected by ultra high performance liquid mass spectrometry (UPLC-MS), and analyzed by PCA and OPLS-DA. **RESULTS:** 1) Compared with lower CRF group, HOMA-IR, HOMA-β, LDL-C, BMI and Fat% of higher CRF group were lower, and the amount of low intensity activity was more. 2) There were different expressions of 7 metabolites in different CRF groups, including PC (20:1/14:1), PC(18:3/16:0), LysoPC(16:0), Valine, isocitric acid, Octyl carnitine and Linoleyl carnitine. 3) After 3-month exercise training, the fasting and OGTT-2h blood glucose of 61.11% of PDM subjects turned to normal; PDM subjects' VO_{2max} increased significantly (6.84%); but there was no significant correlation between the increase of VO_{2max} and 7 metabolites. **CONCLUSION:** PC, LysoPC, valine, isocitrate and acylcarnitine were different in different CRF groups, they may be potential biological markers of CRF. Exercise intervention improved the glucose metabolism and CRF of prediabetes mellitus, but we hadn't found the correlation between VO_{2max} increase and 7 metabolites expression change after exercise, which needs more study. Supported by Key Projects of State General Sports Administration of China (2014B007), the National Key Technology Research and Development Program of Prevention and Control of Major Chronic Non-communicable Diseases (2016YFC1300202)

Longitudinal Associations of Physical Activity and Blood Lipid Levels in Midlife Women in SWAN

Sylvia E. Badon¹, Kelley Pettee Gabriel, FACSM², Barbara Sternfeld, FACSM¹, Ellen B. Gold³, L. Elaine Waetjen³, Monique M. Hedderson¹. ¹Kaiser Permanente Northern California, Oakland, CA. ²University of Texas Health Science Center, Austin, TX. ³University of California Davis, Davis, CA.
Email: sylvia.e.badon@kp.org

(No relevant relationships reported)

Decreasing levels of estrogen production, combined with the detrimental effects of aging, lead to large increases in cardiovascular disease (CVD) risk among midlife women. Physical activity has the potential to attenuate this increase in CVD risk; however, longitudinal associations of physical activity and blood lipid levels, important contributors to CVD, have not been studied in midlife women.

PURPOSE: To estimate the longitudinal associations of physical activity with blood lipid levels in midlife women.

METHODS: We used data from 3,230 participants in the Study of Women's Health Across the Nation (SWAN), a longitudinal cohort study spanning 14-17 years of nearly annual follow up. Women reported physical activity using the Kaiser Physical Activity

Survey at 7 study visits. We used the sports and exercise physical activity index score to estimate leisure-time moderate to vigorous intensity physical activity. SWAN measured total cholesterol, triglycerides, HDL, and LDL in blood collected at 8 study visits. We used generalized estimating equations to estimate longitudinal associations of moderate to vigorous intensity physical activity with each blood lipid biomarker, adjusted for age, race/ethnicity, education, and body mass index category. **RESULTS:** Women were 46 years old, on average, at study entry. Forty-seven percent were non-Hispanic white; 28% were black; 9% were Japanese; 8% were Chinese, and 8% were Hispanic. Each additional one-unit increase in the sports and exercise physical activity index score was associated with an average 1.9 mg/dl lower triglyceride level (95% CI: -3.5, -0.2) and 0.6 mg/dl greater HDL level (95% CI: 0.4, 0.9). The sports and exercise physical activity index score was not associated with total cholesterol (mean difference=0.3; 95% CI: -0.4, 1.0) or LDL (mean difference=-0.2; 95% CI: -0.8, 0.4).

CONCLUSIONS: Moderate to vigorous physical activity is longitudinally associated with lower triglyceride levels and higher HDL levels in midlife women. Who Is The Reference Group? An Examination Of The Involuntarily Inactive And Mortality

Eric J. Shiroma¹, I-Min Lee, FACSM², Lenore J. Launer¹, Tamara B. Harris¹. ¹National Institute on Aging, Baltimore, MD. ²Brigham and Women's Hospital / Harvard Medical School, Boston, MA. (Sponsor: I-Min Lee, FACSM)
Email: eric.shiroma@nih.gov

(No relevant relationships reported)

PURPOSE: Physical activity studies often use inactive participants as a reference comparison group implying that all inactive participants can become more active. However, it remains unclear how much of this group is involuntarily inactive due to physical function limitations. This study aims to examine the involuntarily inactive and the association with mortality among older adults. **METHODS:** Study participants were from the National Health and Nutrition Examination Survey (NHANES), a population-based study with mortality follow-up through 2011. Participants were 60+ years old and wore the accelerometer for 4+ days (N = 2415). Moderate-to-vigorous physical activity (MVPA) was derived using standard accelerometer cutpoints and categorized based on the US Federal Physical Activity Guidelines: 1) <15 minutes (inactive); 2) 15—37.5 minutes; 3) 37.5-150 minutes; 4) ≥150 minutes per week (recommended). Participants self-reported limitations in walking, activities of daily living, and carrying objects and were classified as 1) no impairment, 2) some impairment, or 3) most impaired. To compare mortality rates, we calculated hazard ratios (95% confidence intervals), adjusting for relevant covariates. **RESULTS:** Over an average of 74.1 (SD = 23.8) months of follow-up, there were 572 deaths. Of the inactive participants (n = 719), 24.8% reported no impairment, 34.6% some impairment, and 40.6% were most impaired. There was no significant mortality rate difference between the inactive group and those participating in 15 to 37.5 minutes per week of MVPA in any of the function groups. Among those with no or some impairment, there was a significant decrease (39 to 62%) in premature mortality among those with at least 37.5 minutes per week of MVPA. Among those with the most impairment, a mortality rate reduction of 85% (HR = 0.15 (95% CI: 0.06, 0.35)) was observed among those with 37.5 – 150 minutes of MVPA, but no significant difference among those meeting the guidelines (HR = 0.72 (95% CI: 0.31, 1.67)), compared to the inactive group. **CONCLUSIONS:** Inactive referent groups may contain a disproportionate number of participants with physical limitations, however even among those with some or most impairment, greater levels of physical activity are associated with similar or greater mortality benefits.

1800 May 30 5:30 PM - 5:45 PM

The Use Of Resistance Exercises To Interrupt Sitting: Acceptability And Impact On Sleepiness, Discomfort, And Fatigue

Robert J. Kowalsky¹, John M. Jakicic, FACSM², Andrea L. Hergenroeder², Renee J. Rogers², Bethany Barone Gibbs². ¹Texas A&M University Kingsville, Kingsville, TX. ²University of Pittsburgh, Pittsburgh, PA.
Email: robert.kowalskyjr@tamuk.edu

(No relevant relationships reported)

Emerging research suggests cardiometabolic benefit from using simple resistance exercises to interrupt prolonged sitting, yet it is unclear if such programming is acceptable and can affect discomfort, fatigue, and sleepiness. **Purpose:** To examine the acceptability of hourly, brief resistance exercise bouts and the effects on subjective

ratings of discomfort, sleepiness, and fatigue. **Methods:** Fourteen adults (age 53.4±9.5 years, BMI 30.9±4.8 kg/m²) completed two 4-hour randomized simulated laboratory-based work conditions on separate days: prolonged sitting (SIT) and sitting with hourly resistance exercise breaks (REX). Acceptability was assessed after REX in 5 domains: 1) willingness to use REX, 2) confidence to use REX unsupervised, 3) co-worker acceptance of REX, 4) employer acceptance of REX, and 5) Feasibility of frequency and Amount of REX. During each 4-hr protocol, ratings of sleepiness (Karolinska Sleepiness Scale), discomfort, and fatigue (Physical Discomfort and Fatigue Questionnaire) were assessed at baseline and then hourly. Linear mixed models evaluated overall condition effects and differences at each hour following Bonferroni adjustment. Cohen's d estimated magnitude of effects. **Results:** A majority of participants reported high to very high acceptability on the 5 domains of REX (Table). Overall physical discomfort ($\beta=-0.15$ log-points, $p=0.074$, $d=0.34$), mental fatigue ($\beta=-0.23$ log-points, $p=0.116$, $d=0.18$), physical fatigue ($\beta=-0.30$ $p=0.056$, $d=0.20$), and sleepiness ($\beta=-0.33$ log-points, $p=0.106$, $d=0.14$) did not differ by condition. Mental fatigue was significantly lower (better) at 4 hours in favor of REX ($\beta=-0.48$ log-points, $p=0.020$, $d=0.37$). **Conclusion:** Hourly simple resistance breaks were rated as an acceptable method to interrupt prolonged sitting during work; however, REX did not improve discomfort, fatigue, or sleepiness compared to SIT. Investigating adaptations and acceptability with chronic usage are warranted.

Table. Acceptability of Simple Resistance Exercise Breaks to Interrupt Sedentary Behavior

| Acceptability Questionnaire | Frequency | Percentage |
|---|-----------|------------|
| Question 1: Willingness to Use REX | | |
| Very low or Low | 0 | 0% |
| Neither low or high | 2 | 14.2% |
| High or Very high | 12 | 85.8% |
| Question 2: Confidence to Use REX Unsupervised | | |
| Very low or Low | 0 | 0% |
| Neither low or high | 0 | 0% |
| High or Very high | 14 | 100% |
| Question 3: Coworker's Acceptance of REX | | |
| Very low or Low | 1 | 7.2% |
| Neither low or high | 3 | 21.4% |
| High or Very high | 10 | 71.4% |
| Question 4: Supervisor's Acceptance of REX | | |
| Very low or Low | 1 | 7.2% |
| Neither low or high | 5 | 35.7% |
| High or Very high | 8 | 57.1% |
| Question 5: Feasibility of Frequency and Amount of REX | | |
| Very low or Low | 3 | 21.4% |
| Neither low or high | 2 | 14.3% |
| High or Very high | 9 | 64.3% |

D-45 Clinical Case Slide - Chest Pain and Medical Issues

Thursday, May 30, 2019, 3:45 PM - 5:25 PM

Chest Injury - Horseback Riding
Philipp J. Underwood, Bryan M. McCarty, Hillary Moss, North Shore University Hospital, Manhasset, NY
HISTORY: A 56 year old female fell off of her horse, causing her to land on her right shoulder. She experience immediate severe pain in her right shoulder and chest. She denied any head, neck or spine injury or pain, and denied numbness, weakness, paresthesia or headache. She reported no shortness of breath, abdominal pain or extremity injury or pain.
PHYSICAL EXAMINATION: The patient reported pain of 10/10 on arrival and had an elevated blood pressure. Other vital signs were normal. Primary survey was

unremarkable. On secondary survey, head, neck and spine were normal. Ribs and abdomen were also normal. Examination of upper extremity revealed deformity of the right shoulder girdle with tenderness and swelling over the proximal right clavicle. The neuro-vascular exam of the upper extremities were normal and symmetrical. She was not able to move the right shoulder due to severe pain. The lower extremities were normal. Neurological examination was normal as was examination of the skin.

DIFFERENTIAL DIAGNOSIS:

1. Clavicle fracture
2. Sterno-clavicular (SC) dislocation
3. Rib fracture
4. Pectoralis muscle tear

TESTS AND RESULTS:

Chest Xray, Clavicle Xray, Shoulder Xray - fracture medial right clavicle and possible dislocation of SC joint
CT of Head and Cervical spine - unremarkable and without acute injury
CT of Abdomen and Pelvis - unremarkable and without acute injury
CT of Chest - fracture and posterior dislocation of the right SC joint with compression of the brachiocephalic artery and vein

FINAL/WORKING DIAGNOSIS:

Fracture and posterior dislocation of the right SC joint with compression of the brachiocephalic artery and vein

TREATMENT AND OUTCOMES:

1. Evaluation by Trauma Surgery, Cardio-Thoracic Surgery with admission to Orthopedics for operative repair
2. Taken to OR and under general anesthesia and fluoroscopic visualization, reduction of SC dislocation
3. Reduction was unstable and ORIF performed with trans-osseous sutures and reconstruction of capsule
4. Discharged next day on Xarelto for 8 weeks and no weight bearing of right upper extremity
5. Physical therapy for 8 weeks begun 2 weeks post op.
6. Patient has returned to riding and experiences only minimal stiffness at right SC joint

1805 May 30 4:05 PM - 4:25 PM

Extremity Paralysis After Boot Camp Workout

Kulraj S. Dhah¹, Roger Mortimer², Robert Sallis, FACSM¹.
¹Kaiser Permanente Fontana, Fontana, CA. ²University of California San Francisco, Fresno Medical Education Program, Fresno, CA.

(No relevant relationships reported)

HISTORY: 37 y/o African American female with history of anemia presented to ED with severe abdominal pain, tachycardia and rapidly progressive bilateral upper and lower extremity paralysis. She reported recently starting Boot Camp style workouts with the last session two days prior to first admission. Patient admitted to using diet pills and intermittent fasting. She was admitted for 3 weeks initially and readmitted four days after being discharged with recurrence of symptoms.

PHYSICAL EXAMINATION: Vitals were within normal range. Normal respiratory effort but only able to speak 3-4 words per breath. Diffuse abdominal tenderness. Paralysis of upper and lower extremities bilaterally with minimal motor function of fingers and toes, full sensation intact, CN 2-12 intact, DTRs +2.

DIFFERENTIAL DIAGNOSIS: 1. Guillain-Barre Syndrome 2. Rhabdomyolysis 3. Amyotrophic Lateral Sclerosis (ALS) 4. Porphyria 5. Progressive Peripheral Neuropathy

TEST AND RESULTS: MRI Head and Spine negative for lesions, nerve root compression or myelopathy. Creatine Kinase levels were mildly elevated. CT Abdomen/Pelvis was negative. CSF analysis and EMG testing suggested variant of Guillain-Barre Syndrome. Negative Inspiratory Force (NIF) testing remained within normal limits. No improvement with IVIG. Labs that were sent out during first admission came back during her second admission (4 weeks later) with dramatically elevated Urine porphobilinogens at 1529 mg/L (ref: <2mg/L). Stool porphobilinogens were also elevated.

FINAL WORKING DIAGNOSIS: Variegate Porphyria

TREATMENT AND OUTCOMES: The patient was started on high volume D10 IV (125ml/hr) for 2 days until IV Hemin was obtained from the only lab in the US that manufactures it. The patient showed mild improvement in motor function within one hour of starting IV Hemin drip. She required a full 7 day course of IV Hemin with gradual increase in motor function but not back to baseline. She underwent a second course of IV Hemin with further improvement in motor function. NGT was replaced by PEG tube for adequate nutrition. Four weeks later, she was discharged from Medicine Service to Acute Inpatient Rehab floor. She continued to improve and was able to return to oral diet and perform ADLs with assistance from family. She was discharged home after two months and moved out of town to live with family.

1806 May 30 4:25 PM - 4:45 PM

Muscle Weakness: Boxing

Belmarie Rodriguez-Santiago, David Atkins, Brenda Deliz-Roldan, William Micheo, FACSM. *University of Puerto Rico, San Juan, Puerto Rico.*

(No relevant relationships reported)

HISTORY: A 50-year-old right-handed retired male boxer with no past medical history presented progressive weakness and muscle wasting of bilateral upper extremities. He denied any numbness, tingling or paresthesia, bowel or bladder incontinence, lower extremity weakness or dysphagia. Three weeks before symptoms started, he suffered a fall with impact in the forehead. The patient has a 17-year history of boxing career with a total of 250 combats.

Physical Examination: Generalized muscle atrophy and fasciculations observed in bilateral upper extremities. Full passive range of motion in bilateral upper extremities but limited active shoulder flexion and abduction and incomplete handgrip bilaterally. Strength was 2/5 in shoulder abduction, 3/5 in elbow flexion and extension, and in right wrist flexion and 0/5 in wrist extension. Sensation was intact to pinprick, soft touch and vibration. Deep tendon reflexes 1+ throughout upper and lower extremities.

Differential Diagnosis:

1. Cervical Polyradiculopathy
2. Central Cord Syndrome
3. Motor Neuron Disease: Brachial Amyotrophic Diplegia
4. Chronic Traumatic Encephalopathy

Tests and Results:

Cervical Spine MRI: Multilevel degenerative disc disease. Anterior cervical cord compression at C3-C4 and less prominent at C5-C6 without myelomalacia. No neural foraminal stenosis.

Electrodiagnostic Study: Normal sensory nerve conduction study (NCS). Motor NCS showed low amplitude in the right Median and Ulnar nerves. Electromyographic study revealed active denervation and reinnervation potentials in bilateral upper extremities. Fibrillation and positive sharp waves were observed in cervical and thoracic paraspinal muscles.

Brain MRI: Mild cerebral cortical atrophy. No other intracranial abnormality.

Final Working Diagnosis:

-Motor Neuron Disease: Brachial Amyotrophic Diplegia.

Treatment and Outcomes:

1. Physical therapy for light strengthening and aerobic training.
2. Occupational therapy for assistive device and activities of daily living evaluation and training.
3. Referred to Neuromuscular Clinics for multidisciplinary management.
4. Started in Riluzole.
5. Referred to Speech and Swallow evaluation.
6. Followed up every 3 months to monitor neurological symptoms and remained stable with no signs of neurological deterioration.

1807 May 30 4:45 PM - 5:05 PM

Syncope On The Green - Golf

Noor Alzarka, Mark Chassay, FACSM. *University of Texas Health Science Center at Houston, Houston, TX.*

(No relevant relationships reported)

HISTORY: 22-year-old female collegiate Division I golfer presents with intermittent dizziness, palpitations, and pre-syncope symptoms. She reports a history of syncope as well. She also describes episodes of palpitations or subjective tachycardia at rest and in association with exertion. Symptoms worsen during strenuous weight training exercises. She does not use any prescription medications, supplements, or recreational drugs. Her father has a history of a cardiac arrhythmia and cardiac arrest. She seeks a cardiology referral for diagnostic evaluation.

PHYSICAL EXAMINATION: BP 122/80, HR 91, RR 16, SpO2 99%, BMI 30.5.

Well-appearing female. Unlabored respirations, lungs clear to auscultation bilaterally. Regular heart rate and rhythm, non-displaced PMI, without murmurs. Normal pulses in all extremities. Steady station and gait.

DIFFERENTIAL DIAGNOSIS: Reflex syncope. Arrhythmia. Structural cardiopulmonary disease. Dehydration. Orthostatic hypotension. Drug reaction. Dysautonomia. Seizure.

TEST AND RESULTS: EKG: normal sinus rhythm.

7-day Holter monitor: Average HR 93 BPM. No ventricular or supraventricular ectopics noted.

Tilt Table Test: Passive phase is non-diagnostic. Drug provocation phase with nitroglycerin challenge is positive for syncope, a HR decrease from 136 to 40, and then sinus arrest with a 6.1 second pause while blood pressure remains stable.

FINAL WORKING DIAGNOSIS: Vasovagal syncope with sinus arrest consistent with cardio-inhibitory component.

TREATMENT AND OUTCOMES: 1. The cardiac electrophysiologist cleared her for participation in golf and to work out with activity modifications in order to moderate her physical workload and avoid excessive strain that might trigger vasovagal syncope.

2. She was advised to self-monitor for pre-syncope symptoms; to modify activities as needed, including using lighter weights, taking more breaks, and lying down to recover when needed; and to avoid pushing through symptomatic episodes.
3. The cardiac electrophysiologist also recommended optimizing hydration, including increased salt and electrolyte intake.
4. She was counseled about the possibility of serious injury resulting from syncope.

1808 May 30 5:05 PM - 5:25 PM

Assisted Breathing Manual Therapy for Soccer Chest-Trap Anterior Chest Wall Injury

John C. Hannon. *private practice, San Luis Obispo, CA.*

Email: feldenkrais.slo@gmail.com

(No relevant relationships reported)

Chest wall injury—Soccer

John C. Hannon, private practice, San Luis Obispo, CA

HISTORY: A 17-year-old high school senior soccer left back, during the last quarter of a late-season game, chest-trapped a long and hard soccer ball experiencing instant breathlessness and incapacitating anterior chest pain aggravated by deep breathing, head, spine and arm movement. At the ED, she experienced less intense symptoms. Later, she, and her parents, worried her continued chest pain (which increased with exertion, coughing, and difficulty breathing when running) would ruin her chances to be seen favorably by college soccer scouts. The next day she presented for manual therapy.

PHYSICAL EXAMINATION: Examination revealed a mild pectus excavatum with bilaterally painful 2nd and 3rd sterno-chondral joints and diminished respiratory excursion, accessory breathing muscle activity and elevated shoulders. Muscle splinting interfered with overhead reaching and spinal twisting. Interestingly, marked pain relief occurred with manual skin stretch tangentially applied in the left midaxillary line along the path of the 5th rib with the stretch directed posterior-to-anterior. Similar relief was obtained by firm pressure over the left costal diaphragm muscle attachments. Pain-free palpation of spinal, costo-chondral and costo-vertebral joints. SC, AC and GH joint-play intact.

DIFFERENTIAL DIAGNOSIS: 1. Fracture 2. Sprain/strain 3. Infection 4. Primary tumor 5. Tietze's syndrome 6. Costochondritis 7. Myofascial trigger points 8. Panic disorder 9. Exercise-induced asthma 10. Cardiovascular, gastrointestinal disease 11. Fibromyalgia 12. Seronegative spondyloarthropathies

TEST AND RESULTS: Normal AP and Lateral chest-xray

FINAL WORKING DIAGNOSIS: Sternocostal sprain-Diaphragm strain

TREATMENT AND OUTCOMES: 1. Tangential skin stretch resolved the breathing distress and relieved most of the chest pain. 2. Manually patterned breathing allowed pain-free but apprehensive ROM spinal twisting and arm overhead reaching. 3. Reassurance, explanation of the mechanics of injury, breathing exercises.

4. Symptom-free return to play 5 day post-injury. 1 month later, accepted 4-year athletic scholarship.

D-46 Clinical Case Slide - Knee II

Thursday, May 30, 2019, 3:45 PM - 5:25 PM

Knee Pain and Effusion in a Medically Complex Patient

Aubrey Armento. *University of Colorado Denver, Denver, CO.*
(Sponsor: John Hill, FACSM)
Email: aubrey.armento@childrenscolorado.org

(No relevant relationships reported)

HISTORY: An 8-year old female presents with a chief complaint of left knee pain and swelling. The pain started one month ago with no acute inciting injury. The pain is located over the anterior knee and is exacerbated with running and bike riding and alleviated with rest and ice. The knee swelling worsens after activity. She has no warmth or erythema of the joint. She denies fever, rash, or other joint complaints. The patient has a history of isolated Langerhans cell histiocytosis of the pituitary stalk and diabetes insipidus, which was diagnosed a year ago. She takes an oral steroid burst and receives vinblastine for chemotherapy every three weeks.

PHYSICAL EXAMINATION: There is a palpable joint effusion of the knee without erythema or warmth. There is diffuse peripatellar tenderness to palpation. She has limited knee flexion to 110 degrees but full extension. Patellar grind test is negative. There is no patellar apprehension. The Lachman test, anterior and posterior drawer tests, varus and valgus stress testing, and McMurray's test are all negative.

DIFFERENTIAL DIAGNOSIS:

1. Musculoskeletal lesion of Langerhans cell histiocytosis
2. Osteochondritis dissecans of the knee
3. Septic arthritis of the knee in an immunocompromised patient
4. New-onset juvenile idiopathic arthritis (JIA)

TESTS AND RESULTS:

-X-rays of the knee showed no acute bony abnormality.
-MRI of the left knee with and without contrast revealed a large joint effusion with enhancing synovitis but otherwise no abnormality.
-Labs including a complete blood count (CBC), erythrocyte sedimentation rate (ESR), and C-reactive protein (CRP) were within normal limits other than the a slightly elevated CRP.

-The patient had an ophthalmologic evaluation and was diagnosed with right anterior uveitis, so she was referred to Rheumatology.

-Knee joint aspiration was performed, with synovial fluid analysis consistent with an inflammatory arthritis. Cultures had no growth.

FINAL/WORKING DIAGNOSIS: Juvenile idiopathic arthritis

TREATMENT AND OUTCOMES: The patient underwent a steroid injection of the left knee. Hopefully, her arthritis can be managed with naproxen and intermittent steroid injections. If not, further discussion must be had between Rheumatology and the Oncology teams about the risk and benefits of disease modifying anti-rheumatic drugs (DMARDs).

1813 May 30 4:05 PM - 4:25 PM

Knee Pain - Swimming in Dangerous Waters

Lauren Nadkarni¹, Kate Quinn². ¹*Maine Medical Center, Portland, ME.* ²*Maine Medical Partners, Portland, ME.*
(Sponsor: Heather Gillespie, FACSM)

(No relevant relationships reported)

Title: Knee Pain - Swimming in Dangerous Waters

Authors: Lauren Nadkarni, MD and Kate Quinn, DO (sponsored by Heather Gillespie, MD, MPH, FACSM)

History:

A 17-year-old male with a non-contributory past medical history developed acute pain in his left knee while swimming 3 days prior to presentation. He experienced a popping sensation with hyperextension of his knee while treading water and throwing a rope swing to his friends on the bank of a river. He had immediate swelling and felt pressure on the lateral and posterior parts of his knee, associated with sharp and stabbing pain when straightening his knee. His pain was worse with flexion beyond 90 degrees, straightening his leg, or walking, but was improved with rest and ice. He did not have any give-way or locking episodes.

Physical Exam:

Office examination of his left knee was limited by guarding but demonstrated a very subtle posterior sag sign and a positive effusion. There were no overlying skin changes. His range of motion was 5 degrees of hyperextension to 110 degrees flexion actively his flexion increased to 120 degrees passively. He also had mild posterior lateral joint line tenderness, negative patellar testing, and positive posterior drawer and lateral flexion pinch testing. His anterior drawer testing was negative, although he did exhibit guarding. His contralateral knee, ipsilateral hip/ankle, and neurovascular exams were unremarkable.

Differential diagnosis:

- PCL injury
- ACL injury
- Lateral meniscus injury
- Posterior lateral corner injury
- Patellar subluxation
- Lateral tibial plateau contusion or fracture
- Lateral femur contusion or fracture

Tests and results:

Left knee x-ray:

- Normal anatomy with small effusion
- No acute fracture

Left knee MRI:

- Isolated PCL rupture

Final/working diagnosis:

- Isolated PCL rupture

Treatment and Outcomes:

- Knee immobilizer for 3-4 weeks
- Physical therapy with initial avoidance of hamstring activation for the first 4 weeks
- Over the counter analgesics as needed
- Return to sport progression

1814 May 30 4:25 PM - 4:45 PM

Osteochondritis Dissecans With Loose Body In A Golfer

Krishna Israni, Daniel Montero. *Mayo Clinic, Jacksonville, FL.*
(Sponsor: George Pujalte, FACSM)

Email: israni.krishna@mayo.edu

(No relevant relationships reported)

History:

A 63-year-old gentleman with no significant past medical history presented in sports medicine clinic due to left knee pain that began 3 months prior. He states that he stays physically active. Four months prior, he was on the golf range and noticed mild discomfort. He then noticed worsening discomfort with running. His symptoms improved with rest but then would return with activity. Mild pain relief with ibuprofen. Soon after, he started to have painful clicking and catching of the left knee. He returned to Montana where he saw an orthopedist who prescribed meloxicam and ordered x-rays that had essentially normal findings. He then underwent magnetic resonance imaging (MRI) which revealed cartilage defects. His pain improved but he still described occasional, sharp, left lateral knee pain, and less commonly, medial knee pain. He described the pain as aching, sometimes sharp, and measuring 4/10 on the pain scale. Running and walking exacerbated his symptoms; straightening his leg worsened the pain. He had occasional night pain also.

Physical Exam:

Healthy-appearing gentleman, had muscular legs, able to rise from a seated position without difficulty, with nonalgic gait. Normal range of motion without restriction, minimally tender over the left lateral joint line, no ligament instability, no obvious effusion, positive McMurray, negative Lachman.

Differential Diagnosis:

- Meniscal tear
- Osteoarthritis
- Plica syndrome
- Osteochondritis dissecans

Tests and Results:

X-rays grossly unrevealing.

MRI: Large osteochondral defect in the left lateral femoral condyle, measuring approximately 1 cm across, with apparent loose body in the posterior fossa. Smaller osteochondral defect seen in the medial femoral condyle which appeared stable. Associated bony edema on the lateral femoral lesion.

Final Working Diagnosis:

Osteochondritis dissecans with loose body

Treatment and Outcomes:

- Patient was very active and wanted to return to playing golf. His daily activities were much improved but still limited compared to prior level of activity.

- Recommended modified activities and possible steroid injection if pain continued to limit activities.

- Repeat MRI to reassess bony edema and loose body with further consideration of knee scope and other procedures, based on clinical response and imaging.

1815 May 30 4:45 PM - 5:05 PM

**Biologically Repaired, Neurologically Prepared?
Rethinking Knee Injury and a Novel Rehabilitation
Model - Soccer**

Corey Petersen, Kersten Schwanz, Sarah Wambheim. *University of Minnesota, Minneapolis, MN.* (Sponsor: Suzanne Hecht, FACSM)

(No relevant relationships reported)

HISTORY: A 21-year-old female NCAA Division I soccer defender sustained a non-contact right knee injury while chasing a ball in the 70th minute of an international spring season game. Her right foot caught on the turf and she felt a “pop” before falling. No previous history of knee injuries.

PHYSICAL EXAMINATION: Examination on the field by an ATC revealed no effusion or deformity, non-tender to palpation, full pain free ROM, a positive Lachman’s and anterior drawer test, and no laxity of the MCL or LCL.

DIFFERENTIAL DIAGNOSIS: 1. Isolated ACL tear. 2. ACL with collateral ligament and/or meniscal injury. 3. Transient knee dislocation

TEST AND RESULTS: Right Knee MRI- Full thickness ACL tear with intact collateral ligaments and menisci- Subchondral edema present in lateral femoral condyle and lateral tibial plateau

FINAL WORKING DIAGNOSIS: Isolated complete ACL tear

TREATMENT AND OUTCOMES: 1. ACL reconstruction with BTB Patellar Tendon graft. 2. Full ROM was achieved by week 3 post-op. Rehabilitation progression included traditional rehabilitation models. Additional focus on neurological rehabilitation was initiated week 3 and maintained throughout. 3. Triphasic training and movement progressions with concurrent sensory inputs and cognitive interference were employed, resulting in a multidisciplinary 3-fold rehabilitation model designed to target 3 injury-associated areas (motor, sensory, neuroplastic). Triphasic training utilizes block periodization of multi-joint movements to target each action of the stretch shortening cycle. Isometric movements increase motor unit recruitment and rate coding while eccentrics increase corticospinal signal. The resulting program combats the motor inhibition while simultaneous sensory overload and cognitive interference oppose neuroplastic changes through neural resource competition and may accelerate return to play. 4. Cleared to play 5.5 months following ACL reconstruction by orthopaedic surgeon.

1816 May 30 5:05 PM - 5:25 PM

Bilateral Knee Pain in Pregnancy

Michelle Sriwongtong, *UCLA, Santa Monica, CA.* (Sponsor: Aurelia Nattiv, FACSM)

Email: msriwongtong@mednet.ucla.edu

(No relevant relationships reported)

HISTORY: 37F G3P2 @32w4d pregnant presents with nontraumatic right knee pain for 1 week. Right knee outside MRI showed extensive marrow edema in the medial femoral condyle, consistent with avascular necrosis. She was made non-weight bearing. Her pain progressed and she became wheelchair bound. She delivered a baby girl @39w5d via C-section. She came to our clinic 3 weeks postpartum for persistent right knee pain and 3 weeks of new left knee pain.

PHYSICAL EXAM: BMI 30. Unable to bear weight due to pain. Bilateral knee exam with tenderness to palpation on her proximal tibia, medial and lateral joint lines, ROM 0-135 degrees, no effusion. Quadriceps and hip abductor strength 3/5 bilaterally.

DIFFERENTIAL DIAGNOSIS:

- Transient osteoporosis of pregnancy
- Avascular necrosis of the femoral condyle
- Stress fractures bilateral distal femur and/or proximal tibia
- Osteoporosis with insufficiency fractures

TEST AND RESULTS:

1. MRI R knee (initial) 5/2018: Extensive marrow edema present in the medial femoral condyle extending over 2.5 cm possibly related to stress reaction or early avascular necrosis. No subchondral or cortical fracture.
2. XR knee bilateral 7/2018: patchy demineralization around the right knee. When correlating clinical history with outside MRI, findings suggest transient osteoporosis.
3. MRI L knee 7/31/18: Small subchondral insufficiency fracture of medial femoral condyle with very mild surrounding bone marrow edema. Faint bone marrow edema in the lateral femoral condyle without fracture.
4. MRI R knee (f/u) 7/31/18: New subchondral insufficiency fracture of the lateral femoral condyle with moderate surrounding bone marrow edema. Resolution of medial femoral condyle bone marrow edema.
5. Labs, 8/18: PTH 44, Free T4 1.3, TSH 5.7, BMP 143/4.7/103/21/0.83/23<88, Ca 9.7, Vit D-25 OH 35

FINAL WORKING DIAGNOSIS:

- Transient osteoporosis of pregnancy
- Left subchondral insufficiency fracture of the medial femoral condyle
- Right subchondral insufficiency fracture of the lateral femoral condyle

TREATMENT AND OUTCOMES

- Tylenol/Norco PRN
- Started weight bearing with crutches 5 months after initial injury
- PT
- Ca 500mg QD, plus 1000mg dietary for breastfeeding
- Vit D3 2000IU QD
- After discussion with her pediatrician, bisphosphonates were held because she was breastfeeding and improving on current therapy

Elbow Pain - Recreational Athlete

Shawn D. Felton¹, Arie J. van Duijn². ¹*Florida International University, Miami, FL.* ²*Florida Gulf Coast University, Ft. Myers, FL.* (Sponsor: Mitchell L. Cordova, FACSM)

Email: sfelton@fiu.edu

(No relevant relationships reported)

HISTORY: 21-year-old recreational athlete (185.4cm, 93.44 kg) with no prior history of injury was participating at an extreme sports center performing acrobatic type activities when he completed a back flip on the trampoline and landed on his left outstretched arm. Athlete noted an audible “pop” and the inability to fully extend or flex his arm. He self referred to ED for immediate evaluation and stabilization.

PHYSICAL EXAMINATION: Athlete was examined in sports medicine research lab by licensed physical therapist and athletic trainer. Gross swelling was present on exam. Athlete unable to perform active ROM and complained of intense pain 6/10 on VAS. Athlete pt. tender along medial joint line and specifically distal attachment of the medial collateral ligament. Valgus Stress test performed revealing extreme laxity compared bilateral with minimal stress. Neurological examination and circulatory exam = WNL. Physical examination discontinued due to pain and point of care ultrasound imaging continued of the medial elbow.

DIFFERENTIAL DIAGNOSIS: 1. Medical Collateral ligament sprain 2. Medical Collateral Ligament Disruption 3. Common Flexor Tendon Pathology 4. Pronator Teres Strain 5. Medial Epicondyle Avulsion

TEST AND RESULTS: Elbow AP/Lateral/Oblique Radiographs: WNL; MRI w/o contrast: Complete tear of the proximal ulnar collateral ligament, Avulsion flexor tendon with bone marrow edema, Nondisplaced fracture of the radial head associated joint

effusion. MSK Diagnostic Ultrasound Imaging: 1.07 cm widening of the medial joint space (MJS), 1.49 cm hypoechoic disruption of the UCL, Discontinuity of the flexor pronator group

FINAL WORKING DIAGNOSIS : Grade 3 UCL Strain with pronator muscle group avulsion. **TREATMENT AND OUTCOME:** Athlete underwent surgery to repair the Grade 3 UCL Strain medial collateral ligament and reattachment of the flexor pronator group avulsion at the medial epicondyle. The diagnosis of such injuries are evident in clinical examinations and the management of the case is common among athletes suffering from traumatic UCL strains, this case clearly illustrated the use of point of care ultrasound imaging in identifying these types of lesions. It further allowed for a more detailed examination when the physical examination was limited as a result of pain. The athlete has made a full recovery.

Right Elbow Pain in a Teenage Softball Player

Shelby E. Johnson, Edward R. Laskowski, FACSM. *Mayo Clinic, Rochester, MN.*

Email: johnson.shelby@mayo.edu

(No relevant relationships reported)

HISTORY:

A 16 year-old right-hand dominant softball player presented with right elbow pain after an overhead throw two months prior. During the initial throw she felt a pop and acute pain, swelling, and ecchymosis at her posteromedial elbow. Her pain improved with rest and range of motion exercises. However, two days prior to presentation, she performed an overhead throw and again felt a pop with immediate pain and recurrent ecchymosis. She had tingling in her fourth and fifth fingers immediately after the throw but denied ongoing sensory symptoms.

PHYSICAL EXAMINATION:

Inspection revealed ecchymosis at the medial elbow. She was tender to palpation over the ulnar nerve along the cubital tunnel and over the medial triceps with mild tenderness of the ulnar collateral ligament. Range of motion, strength, and sensation were normal. Resisted elbow extension reproduced her pain. Valgus stress testing was painful with slight asymmetric opening compared to the left. Dynamic elbow flexion and extension produced dislocation of the ulnar nerve and medial triceps. Tinel's sign at the cubital tunnel was positive.

DIFFERENTIAL DIAGNOSIS:

1. Ulnar neuritis secondary to dislocating ulnar nerve
2. Snapping medial triceps
3. Ulnar collateral ligament injury
4. Medial epicondylitis
5. Triceps tendinopathy

TEST AND RESULTS:

Elbow X-ray: Negative for effusion, fracture, or osseous abnormality.

Elbow MRI: Nonspecific increased T2 signal of the ulnar nerve within and just distal to the cubital tunnel. Collateral ligaments intact.

FINAL WORKING DIAGNOSIS:

Right ulnar neuritis with a dislocating ulnar nerve and snapping medial triceps

TREATMENT AND OUTCOMES:

The patient initially tried rest and physical therapy. Due to progressive pain the patient decided to pursue more definitive treatment and underwent a right ulnar nerve transposition with partial resection of the medial triceps. One month post-operatively her symptoms had largely resolved and she gradually returned to softball.

Arm Injury - Crossfit

Jeremy Hreha, Mohamad K. Shaath, Joseph C. Tauro, Irfan H. Ahmed, Michael M. Vosbikian. *Rutgers New Jersey Medical School, Newark, NJ.*

Email: hrehaja@njms.rutgers.edu

(No relevant relationships reported)

HISTORY:

A healthy, thirty-year-old male without antecedent pain presented with anterior elbow pain and elbow flexion weakness in his dominant upper extremity. At the time of injury, the patient was performing the CrossFit "butterfly pull-ups" in which the forearm is pronated while the elbows are actively flexed to bring the body up to the bar with the body swinging to build momentum. During this movement, he felt immediate pain at his distal anterior brachium but did not hear a pop. Following the injury he noted swelling and pain exacerbated by motion of the elbow. Once the swelling had resolved, the patient noticed a cosmetic defect at the proximal lateral elbow. On presentation, two weeks after the initial injury, his chief complaint was weakness during elbow flexion without any weakness during supination.

PHYSICAL EXAMINATION:

On presentation, no edema or ecchymosis were present. There was a notable defect in the lateral aspect of the arm just proximal to the elbow joint. With flexion of his elbow, the biceps tendon was clearly visualized. No "reverse popeye deformity" was present. A Ruland biceps squeeze test demonstrated intact supination of the forearm, and a hook test demonstrated an intact biceps tendon. There was no appreciable weakness with elbow flexion or supination compared to the contralateral arm. He did not demonstrate fatigability in supination. His range of motion was symmetric to the contralateral side. Neurologic examination showed that there was intact motor function throughout the arm and no sensory deficits were noted.

DIFFERENTIAL DIAGNOSIS:

1. Brachialis muscle rupture
2. Distal Biceps Brachii muscle rupture
3. Proximal Biceps Brachii muscle rupture

TESTS AND RESULTS:

1. Elbow radiographs were negative for osseous pathology
2. MR imaging demonstrated edema at the brachialis consistent with intrasubstance muscle tear. The biceps tendon was intact.

FINAL/WORKING DIAGNOSIS:

Isolated acute brachialis muscle rupture

TREATMENT AND OUTCOMES:

1. No immobilization given subacute presentation
2. Physical therapy: Initially maintenance of range of motion, then strengthening starting at 8 weeks post injury
3. At 1 year follow up, patient was pain free with full range of motion and no appreciable weakness with elbow flexion

1823 May 30 4:45 PM - 5:05 PM

Shoulder Pain-- Range of MotionNicole Messenger, Kelly Estes. *Washington University in Saint Louis, Saint Louis, MO.*

Email: messengern@wustl.edu

(No relevant relationships reported)

HISTORY: 49-year-old female with rheumatoid arthritis on methotrexate and oral prednisone presents to the walk-in orthopedic injury clinic for acute severe sharp pain in left shoulder radiating into left elbow and hand. No injury or trauma. Symptoms are constant, worse with overhead movements. She reports associated muscle spasms. She has tried acetaminophen and ice with limited relief. She notes her prednisone was increased to 10mg daily for worsening hand arthralgias recently.

Physical Exam: Patient is well appearing in no distress. Range of motion at the bilateral shoulders is 120 on the right, 110 on the left. She has 5/5 strength with supraspinatus and external rotators, as well as negative belly press and bear hug. 5/5 strength to bilateral upper extremities distally. Full range of motion of her cervical spine with pain only with left side bending. The left posterior cervical paraspinal area has a well-defined erythematous area with overlying vesicular lesions. There are few scattered lesions overlying the left shoulder extending down into the left arm.

Differential Diagnosis:

1. Cervical radiculopathy
2. Shoulder impingement syndrome
3. Varicella zoster virus
4. Herpes simplex Virus
5. Rotator cuff tendinopathy

Tests/Results:

Shoulder Xray

Final/working Diagnosis:

Varicella zoster virus in C6 Dermatome

Treatment and Outcomes:

1. Valacyclovir prescription: 1g tablet by mouth TID for 7 days
2. Pain control with Hydrocodone-acetaminophen 5-325mg per tablet QID PRN for pain
3. Rheumatology follow-up for discussion of modification of her immunosuppression regimen
4. Primary Care follow-up

1824 May 30 5:05 PM - 5:25 PM

Neck Pain and Arm Swelling in a Professional DancerShannon Powers¹, Leda Ghannad². ¹*Rush University Medical Center, Chicago, IL.* ²*Midwest Orthopaedics at Rush, Chicago, IL.**(No relevant relationships reported)*

HISTORY: A 33-year-old female professional dancer presents to training room with three weeks of right-sided neck pain. The pain is located at base of the right neck and worsens with flexion. She denies an inciting trauma, but recently began performing new choreography involving repetitive overhead lifting. Associated symptoms include swelling in her right upper extremity and a prominence of her chest wall veins. She denies weakness or paresthesias. **PHYSICAL EXAMINATION:** Inspection reveals mild prominence of veins along the right side of the neck and chest wall, with mild swelling in the right forearm. There is tenderness to palpation at C7 spinous process, right-sided cervical paraspinal muscles, right upper trapezius muscle, and right pectoralis muscle insertion. There is full pain-free range of motion in the cervical spine, right shoulder, and right elbow. Spurling test is negative. Roos test is positive with venous engorgement in the right upper extremity after 30 seconds. Strength is 5/5, reflexes 2/4, and sensation is intact to light touch in the bilateral upper extremities.

DIFFERENTIAL DIAGNOSIS: 1. Deep venous thrombosis 2. Vascular thoracic outlet syndrome 3. Cervical muscle strain

TEST AND RESULTS: —VAS Duplex Upper Extremity Veins: No DVT —Cervical Spine anterior-posterior and lateral radiographs: unremarkable, no cervical ribs.

—VAS Functional Maneuvers Upper Extremity: Absent digital pulsatility with the right arm at 180 degrees. —VAS Duplex Upper Extremity Artery/Bypass Graft: Patent upper extremity arteries without stenosis **FINAL WORKING DIAGNOSIS:** Vascular Thoracic Outlet Syndrome/Paget-Schroetter Syndrome. **TREATMENT AND OUTCOME:** 1. Prescribed Medrol Dosepak and NSAIDs. 2. Started physical therapy and restricted arm motions in practice. 3. Consultation with cardiothoracic surgeon; recommended right first rib resection. 4. Prior to surgery, developed new occlusive DVT in right subclavian and axillary veins. Apixaban initiated. 5. Underwent transaxillary first rib resection, subclavian tenolysis and arteriolytic, and right brachial plexus neurolysis. 6. Returned to sport 6 weeks post-operatively and completed physical therapy. 7. Underwent right upper extremity venogram with angioplasty for chronic occluded central right subclavian vein 3 months post-operatively.

Arm Injury - CarpentryDylan Homen, Mimi Zumwalt, E.L. Domingo-Johnson, Matthew Helm, Melinda Schalow. *Texas Tech University Health Science Center, Lubbock, TX.* (Sponsor: Jacalyn McComb, FACSM)*(No relevant relationships reported)*

HISTORY 70y/o M RHD presented to consultant hand clinic for R elbow evaluation 8 weeks post injury. He was building a deer hunting blind when the platform fell and landed on the posterior aspect of his right elbow. He noted immediate pain, swelling, and ecchymosis about the elbow at the initial traumatic episode. He also complained of a painful popping sensation whenever he ranged the elbow. He had difficulty straightening his arm, with pain and weakness upon attempted elbow extension. Past medical history included hand osteoarthritis and former 30-year smoker, quit in 2010. Denies history of pain, prior trauma at the site or exogenous corticosteroid use. **PHYSICAL EXAMINATION** R upper extremity-tenderness to palpation over olecranon tip, pain with elbow range of motion (ROM); unable to maintain active elbow extension against gravity or resistance. Unrestricted, passive ROM arc 0-140 with no blocks & full pronation/supination. Distally no neurological or vascular deficits. **DIFFERENTIAL DIAGNOSIS** Olecranon fracture Triceps bony avulsion Triceps tendon rupture **TESTS and RESULTS** Radiographs - elbow lateral view revealed a small osseous fragment ~5 cm proximal to the olecranon tip. MRI - showed complete tear of the triceps with hematoma at its insertion site and ~3 cm tendon retraction. **FINAL WORKING DIAGNOSIS** R triceps tendon rupture **TREATMENT and OUTCOMES** Underwent delayed primary repair 2 months post injury. Posterior splint x 2 weeks with elbow 60-70 degrees of flexion. Hinged elbow brace x 2 months with weight restriction of 5 lbs. Gradual increase in ROM progressing to strengthening exercises for another couple of months. Latest follow-up 4 months post-op after OT patient with near full elbow ROM, pain free and functional

No Relationship Between Muscle Flexibility and Blood Flow in the Lower Legs of Competitive RunnersMegan Battles¹, Rachel Bowden¹, Cameron Greene¹, Justin Staneck², Arbin Thapaliya¹, Jeffrey Williams¹. ¹*Franklin College, Franklin, IN.* ²*Illinois State University, Normal, IL.* (Sponsor: Kristen Lagally, FACSM)*(No relevant relationships reported)*Megan Battles¹, Rachel Bowden¹, Cameron Greene¹, Justin Staneck², Arbin Thapaliya¹, Jeffrey Williams¹

¹Franklin College, Franklin, IN

²Illinois State University, Normal, IL

Muscular adaptations in the upper limb from training are associated with hypertrophy, inflexibility, and diminished vascular perfusion. Despite these findings in upper extremity athletes, no studies have examined the relationship between peripheral vascular adaptations and muscle flexibility in the lower legs of runners. Through a better understanding of blood flow and muscle flexibility adaptations, clinicians can more accurately assess and treat running injuries.

Purpose: To examine the relationship between blood flow in the posterior tibial artery and sagittal plane ankle range of motion (ROM) among a sample of collegiate runners.

Methods: Blood flow in the posterior tibial artery and sagittal plane ankle ROM were measured bilaterally on 25, asymptomatic collegiate track athletes (16 males, 9 females, age = 20.0 ± 1.2 years, height = 171.5 ± 10.2 cm, mass = 66.7 ± 13.7 kg). Pearson correlation analysis was used to analyze the relationship between blood flow in the posterior tibial artery and ROM of the talocrural joint.

Results: Findings revealed no significant relationship between blood flow in the dominant leg's posterior tibial artery and dorsiflexion ($r = .14, P = .52$) or plantarflexion ($r = -.32, P = .12$) and no significant relationship between blood flow in the non-dominant leg's posterior tibial artery and dorsiflexion ($r = -.02, P = .93$) or plantarflexion ($r = -.02, P = .92$).

Conclusion: Although muscle inflexibility contributes to compromised blood flow in other body regions, findings of this study demonstrated no relationship between flexibility of the plantarflexor muscles and blood flow in the posterior tibial arteries of competitive runners. Future research should continue examining blood flow in the lower limb as one, among many, physical adaptations runners may experience from training.

Effect of Increased Respiratory Muscle Activation on Blood Flow to Inactive and Active Limb Muscles

Kana Shiozawa¹, Kanako Goto¹, Kaori Shimizu¹, Mitsuuro Saito², Koji Ishida¹, Luyu Zhang¹, William Sheel, FACSM³, Keisho Katayama¹. ¹Nagoya University, Nagoya-shi Chikusa-ku, Japan. ²Toyota Technological Institute, Nagoya-shi Tenpaku-ku, Japan. ³University of British Columbia, Vancouver, BC, Canada.

(Sponsor: A. William Sheel, FACSM)

Email: shiozawa.kana@k.mbox.nagoya-u.ac.jp

(No relevant relationships reported)

It is unclear whether blood flow to inactive and active limb muscles are altered when the respiratory muscle activation is increased during submaximal exercise. **PURPOSE:** The purpose of this study was to clarify the effect of increasing inspiratory muscle work on blood flow to inactive and active limbs. **METHODS:** Healthy young men (n=7, 20±2 yrs) performed two mild bilateral dynamic knee-extension and -flexion exercises for 10 min. The trials consisted of spontaneous breathing for 5 min followed by voluntary hyperventilation either with or without inspiratory resistance for 5 min (40% of maximal inspiratory mouth pressure, inspiratory duty cycle of 50% and a breathing frequency of 40 breaths/min). Mean arterial blood pressure (MAP) was monitored using finger photoplethysmography. Blood flow to the brachial artery (inactive limb) and in femoral artery (active limb) were recorded using Doppler ultrasound. **RESULTS:** MAP during exercise was higher (P<0.05) with inspiratory resistance (121±6 mmHg) than without resistance (98±6 mmHg). Brachial artery blood flow increased during exercise without inspiratory resistance (127±38 ml/min) as compared with resting level, while it decreased with inspiratory resistance (69±31 ml/min). Femoral artery blood flow increased at the onset of exercise and was maintained throughout exercise without inspiratory resistance (2426±573 ml/min) and was unchanged when inspiratory resistance was added (2517±663 ml/min) (P>0.05). **CONCLUSIONS:** These results suggest that sympathetic control of blood redistribution to active limbs is promoted, partly, by respiratory muscle-induced metaboreflex.

The Effects of Recumbent Angle on Cardiac Responses and Hemodynamics during Bicycle Ergometer Exercise in Patients with Atrial Fibrillation

Ilguy Jeong¹, Hee-Hyeok Lee¹, Myunghwa Kim², Jae-Hyun Lee¹, Seongdae Kim¹. ¹Hannam University, Daejeon, Korea, Republic of. ²Woosong University, Daejeon, Korea, Republic of.

Email: Jig1229@hanmail.net

(No relevant relationships reported)

Recumbent cycling is well-established mode of exercise that is used in patients with cardiovascular disease to rehabilitate. However, through more hemodynamic researches for patients with atrial fibrillation, the necessity to establish the safety and availability of recumbent bicycle exercise has been required. **PURPOSE:** To determine the effects of recumbent bicycle ergometer exercise on hemodynamics in patients with atrial fibrillation. **METHODS:** In randomized, double-blind, crossover study,

three female and eight male patients with atrial fibrillation (63.3±6.1yrs) were asked to perform the incremental bicycle ergometer exercise three times in the upright, 60° recumbent (R), and 30°R postures with a week interval, respectively. Exercise intensity was set initially at 10W and increased by 15W every 2 minutes to 70W. Cardiac output (CO) and systemic vascular resistance (SVR) measured at rest, 5 minutes during exercise and 10 minutes during exercise using electrical cardiometry. Rate pressure product (RPP) was calculated by systolic blood pressure (SBP) and heart rate (HR). All data were analyzed using two-way ANOVA (3 postures x 3 times) with repeated measures. **RESULTS:** HR in 30°R and 60°R was significantly lower than in upright postures at 5 minutes during exercise (88±6 and 84±12 vs. 98±16 bpm, p<.05) and 10 minutes during exercise (95±11 and 94±13 vs. 113±18 bpm, p<.05). RPP in 30°R and 60°R was significantly lower than in upright postures at 5 minutes during exercise (10414±1480 and 10620±2754 vs. 15115±5174 bpm × mmHg, p<.05) and 10 minutes during exercise (11757±1680 and 12195±2367 vs. 16186±3228 bpm × mmHg, p<.05). However, CO, SVR and stroke volume were not significant different between three postures. **CONCLUSIONS:** These results suggest that recumbent bicycle exercise have the advantage of reducing myocardial workload by regulating HR and SBP in patients with atrial fibrillation.

The Influence of EMG-based MVC Intensity on Middle Cerebral Artery Velocity, Cardiac Output and Respiratory Variables

Hee-Hyeok Lee¹, Seongdae Kim¹, Myungjin Oh², Jae-Hyun Lee¹, Ilgyu Jeong¹. ¹Hannam University, Daejeon, Korea, Republic of. ²Baekseok University, Cheonan, Korea, Republic of. (No relevant relationships reported)

It has been reported that cerebral blood flow velocity (CBFV) might be reduced according to the increase of exercise intensity determined by %EMG-based maximal voluntary contraction (MVC_{EMG}) during a static exercise test. But, how %MVC_{EMG} induced-changes of CBFV might be associated with cardiac output (CO) and respiratory response remains unclear. **PURPOSE:** To evaluate the influence of %MVC_{EMG} on middle cerebral artery velocity (MCA V_{mean}), CO and respiratory variables during isometric strength type exercise. **METHODS:** Eight healthy male (21.3±0.9yrs) were asked to perform the 45° knee extension isometric contraction during 60 seconds. All participants performed four times in random order at the isometric intensity of 100%, 90%, 80% and 70% MVC with a week interval. The intensity of %MVC was determined by root mean square (RMS) of EMG at right rectus femoris muscle. Each participant was asked to conduct and maintain the predetermined intensity of % MVC_{EMG} confirming the figures on a monitor. MCA V_{mean} was measured at rest, 30 and 60 seconds during exercise, 30 seconds recovery, 150 seconds recovery using transcranial-Doppler sonography. CO and respiratory variables were measured by electrical cardiometry monitor and gas analyzer. All data were analyzed using two-way ANOVA (4 intensities x 5 times) with repeated measures. **RESULTS:** MCA V_{mean} in 70% MVC_{EMG} was significantly higher than MCA V_{mean} in 100% and 80% MVC_{EMG} at 60 seconds during exercise (92±9 vs. 68±15 and 78±11 cm/s, p<.05). On the other hand, CO were not significant different between 100%, 90%, 80% and 70% MVC_{EMG}. V_{co2} in 70% MVC_{EMG} was significantly lower than in 100% MVC_{EMG} at 60 seconds during exercise (0.49±0.22 vs. 1.23±0.86 L/min, p<.05) and had significantly negative correlation with the changes of MCA V_{mean} (r=-.524, p<.01). **CONCLUSIONS:** These results suggest that MCA V_{mean} might have the tendency of decrement over the intensity of 70% isometric MVC_{EMG} and negatively relate to V_{co2}.

Blood Flow Patterns during Flow-Mediated Dilation

Francisco Morales-Acuna, Carolina Valencia, Alvaro N. Gurovich, FACSM. The University of Texas at El Paso, El Paso, TX.

Email: fmoralesac@miners.utep.edu

(No relevant relationships reported)

PURPOSE: Flow mediated dilation (FMD) has been the most common assessment of endothelial function in research but it has failed in obtaining a widespread use in clinical setting due to a lack of standardization and a large inter-subject variability. Normalization of FMD to endothelial shear stress (ESS) has been proposed to solve its technical limitations. However, studies have not considered the characteristic of the blood flow during FMD under pulsatile conditions in their ESS estimations. Therefore, the aims of this study were to quantify the magnitude of FMD-induced ESS and to characterize the blood flow under pulsatile conditions during FMD testing. **METHODS:** A total of 26 young healthy subjects (15 females and 11 males) underwent FMD testing. Microhematocrit measurement was used to determine blood density (ρ) and viscosity (μ). ESS was calculated by Womersley's approximation, ESS = μ * 2K * Velocity/Diameter, where K is a function of Womersley's parameter (α). The presence of turbulent flow was determined by comparing Reynolds number (Re

THURSDAY, MAY 30, 2019

$= (V * D * \rho) / \mu$), to critical Reynolds ($Re_{peak(crit)} = 169 * \alpha^{0.83} * St^{0.27}$, $St = freq * D * V$). Statistical analysis included repeated measures ANOVA to detect ESS differences during FMD until peak dilation. Significance was established at $p < 0.05$.

RESULTS: The mean (SD) FMD% and time to peak dilation were 7.4 (3.1) % and 35 (9.3) seconds, respectively. ESS was significantly reduced from ischemia release until peak dilation, ($F(3.83, 80.43) = 6.51$, $p < 0.001$, two-tailed). Turbulent blood flow was the only type of flow observed until peak dilation in 96.15% of the sample (Figure).

CONCLUSIONS: Peak dilation of the brachial artery during FMD testing in a young healthy population is triggered mostly by antegrade, high-ESS under turbulent flow conditions. Due to the pulsatile nature of blood flow and the appearance of a turbulent pattern during FMD, ESS should be estimated by Womersley's approximation rather than Poiseuille's law.

Relationship Between Increased Resting Muscle Blood Flow And Muscle Force Loss After Repeated Eccentric Contractions

Hisashi MAEDA¹, Mitsuru SAITO², Koji ISHIDA¹, Hiroshi AKIMA¹. ¹Nagoya University, Nagoya, Japan. ²Toyota Technological Institute, Nagoya, Japan. (Sponsor: Dr. Katsumi ASANO, FACSM)

Email: hisashi.gogo.tf@gmail.com

(No relevant relationships reported)

Unaccustomed eccentric contractions (ECs) induce muscle force reduction and increased resting muscle blood flow. Whereas muscle force reduction has been well accepted as an index of exercise-induced muscle damage (EIMD), physiological meaning of increased resting muscle blood flow is not fully understood. **PURPOSE:** The purpose of the present study was to assess the relationship between the increased resting muscle blood flow and muscle force reduction after repeated ECs in healthy individuals. **METHODS:** Eight young healthy men (age, 20.9 ± 1.7 years; height, 172.1 ± 3.9 cm; weight, 64.5 ± 5.2 kg; body mass index, 21.8 ± 1.7 kg/m²) participated in this study. Maximal voluntary contraction (MVC) force of isometric elbow flexion at elbow joint angle of 90°, heart rate, and blood pressure were measured before and after 24 h of repeated ECs task. Resting forearm blood flow as an index of muscle blood flow was also measured by plethysmography. Subjects performed five sets of 20 repetitions of eccentric contractions of elbow flexors (no contractions at concentric phase) with a load equal to 60% of MVC force with the use of dumbbells. Each action was performed through the same range of motion at a rate of 4-s. **RESULTS:** MVC force significantly decreased by 44% (17.4 ± 2.2 kg to 9.7 ± 3.2 kg, $p < 0.01$) after 24 h of repeated ECs. Resting forearm blood flow increased by 22% (5.8 ± 1.2 ml/min/100 g to 7.4 ± 1.9 ml/min/100 g, $p < 0.05$) after 24 h of repeated ECs. Resting heart rate and blood pressure were not significantly different between before and after 24 h of ECs. The change of resting forearm blood flow was negatively correlated with the change of MVC force ($r = -0.88$, $p < 0.01$). **CONCLUSION:** Increased resting muscle blood flow was associated with muscle force reduction after repeated ECs. Our results suggested that increased resting muscle blood flow could result from EIMD-induced inflammatory vasodilation after repeated ECs.

1851 Board #7 May 30 2:00 PM - 3:30 PM
Effects of Capsaicin on Leg Blood Flow in Response to Passive Limb Movement

Robert M. Restaino¹, Gaia Giuriato², Alexs A. Matias¹, Edgard Soares³, Stephen J. Ives¹. ¹Skidmore College, Saratoga Springs, NY. ²University of Verona, Verona, Italy. ³University of Brasilia, Brasilia, Brazil. (Sponsor: Paul Arciero, FACSM)

(No relevant relationships reported)

Given the high rates of cardiovascular disease morbidity and mortality in the United States, and worldwide, finding strategies that might mitigate CVD is paramount. Vascular dysfunction is a critical component and likely precursor measure to CVD. Recently, the passive leg movement (PLM) method has been developed to assess nitric oxide (NO)-dependent vascular function. The nutraceutical Capsaicin has been shown to have cardioprotective effects, enhancing vasorelaxation and attenuating sympathetic vasoconstriction in an endothelium dependent manner via activation of transient receptor potential vanilloid type 1 (TRPV1) channels; this however has only been demonstrated using *in vitro* or animal models. **PURPOSE:** In this study, a single-blind, crossover design was used to examine the potential effects of capsaicin-induced improvement of leg blood flow in response to PLM. **METHODS:** Femoral artery blood flow and microvascular perfusion of the vastus lateralis were examined in 12 young, healthy men, using Doppler ultrasound and multi-distance frequency domain based near-infrared spectroscopy. Central hemodynamics (stroke volume, SV; heart rate, HR; cardiac output, CO; and mean arterial pressure, MAP) were measured using finger photoplethysmography. Hemodynamic measurements were continuously taken at rest and during a single bout of PLM (sPLM), a variant of PLM which minimizes the central hemodynamic response. **RESULTS:** A significant hyperemic response was recorded in response to PLM under both conditions (Capsaicin and Placebo); however the microvascular perfusion response to PLM was not significantly altered ($p > 0.05$) following ingestion of Capsaicin compared to Placebo (Capsaicin: 10.4 ± 3.1%, Placebo: 14.1 ± 3.9%). Femoral artery blood flow was also not significantly augmented ($p > 0.05$) under Capsaicin (Capsaicin: 362 ± 119% Placebo: 295 ± 61% in response to PLM). Expectedly, there were no significant differences in basal microvascular perfusion, basal femoral blood flow, and central hemodynamic responses (HR, SV, CO, MAP) between conditions ($p > 0.05$). **CONCLUSION:** These results indicate Capsaicin does not further augment hyperemia in response to sPLM in young healthy males. Further study of this nutraceutical is warranted in populations at high risk, or prevalence, of cardiovascular disease.

1852 Board #8 May 30 2:00 PM - 3:30 PM
Does Capsaicin Ingestion Affect Functional Sympatholysis And Vascular Functions?

Gaia Giuriato¹, Meaghan Lynch², Brian Lora², Massimo Venturelli¹, Stephen J. Ives². ¹University of Verona, Verona, Italy. ²Skidmore College, Saratoga Springs, NY.

(No relevant relationships reported)

During exercise, heat and metabolites (e.g. H⁺, etc.) attenuate sympathetically-mediated vasoconstriction in contracting muscle, known as functional sympatholysis, remains poorly understood. Previous work has shown that activation of transient receptor potential vanilloid type 1 channels (TRPV1) with Capsaicin (CAP, spicy ingredient in peppers), elicits a sympatholytic effect *in vitro* in humans. **PURPOSE:** To determine if acute ingestion of CAP elicits or enhances sympatholysis at rest and during exercise *in vivo* in humans. **METHODS:** In a single blind crossover design, in 10 young healthy males we measured forearm microvascular responses (oxyhemoglobin and myoglobin HbO₂+MbO₂) using near infrared spectroscopy (NIRS) and central/peripheral hemodynamic (cardiac output, CO, and mean arterial pressure, MAP, via Finometer) responses at rest, lower body negative pressure at rest (rLBNP), rhythmic handgrip (HG) exercise at 30% MVC and during HG with LBNP (HG+LBNP) under placebo (PL, 800 mg fiber) and Capsaicin (780 mg pepper extract). **RESULTS:** No differences ($P > 0.05$) were found between PL and CAP in microvascular and central hemodynamics at rest. At rest the LBNP-induced change in HbO₂+MbO₂ (-1.5 ± 2.3 vs 0.3 ± 2.3 %Δ) or conductance index (HbO₂+MbO₂/MAP: 5.5 ± 2 vs 6.0 ± 3 %Δ) were not different ($P > 0.05$). During exercise, HbO₂+MbO₂ were not different (105 ± 28 vs 105 ± 21 uM), though tissue oxygen saturation tended to be higher (64 ± 16 vs 70 ± 13 %, $P = 0.07$), and deoxyhemoglobin lower in CAP (44 ± 5 vs 37 ± 4 uM, $P = 0.05$). The LBNP-induced change during exercise in HbO₂+MbO₂ (-0.1 ± 7.1 vs 1.3 ± 7.2 %Δ) or conductance (5.6 ± 3 vs 2.8 ± 4 %Δ) were not significant ($P > 0.05$), but tended to be better in CAP. Systemic vascular conductance was not significant different at rest between conditions (5.3 ± 0.2 vs. 4.8 ± 0.4 L/min/mmHg). The LBNP-induced change in SVC at rest (5.6 ± 5.5 vs 6.1 ± 5.7 %Δ) and during exercise (5.2 ± 2.4 vs 1.7 ± 5.2 %Δ), were not different, despite a tendency to be attenuated during exercise with CAP. **CONCLUSION:** Acute CAP does not affect resting hemodynamics or the response to sympathoexcitatory LBNP. During exercise, CAP seems to improve microvascular responses, but does not impact the response to LBNP, despite trends for CAP to mitigate the LBNP-induced reductions in both systemic and local conductance.

The Effect Of The Speed And Range Of Motion Of Movement On The Hyperemic Response To Passive Leg Movement
 Brady Hanson, Travis Bloomfield, Trevor Davis, Amy Addington, Erin McMullin, Taysom Wallace, Meagan Proffit, Jayson Gifford. *Brigham Young University, Provo, UT.*
(No relevant relationships reported)

PURPOSE: Passive leg movement (PLM)-induced hyperemia is used to assess the function of the vascular endothelium. This study sought to determine the impact of movement speed and ROM on the hyperemic response to PLM and determine if the currently recommended protocol of moving the leg through a 90° ROM at 180°/s provides an optimal peak hyperemic response to PLM.

METHODS: 11 healthy adults underwent multiple bouts of PLM, in which either movement speed (60-240°/s) or ROM (30-120° knee flexion) were varied. Femoral artery blood flow (Doppler Ultrasound) and mean arterial pressure (MAP; photoplethysmography) were measured throughout.

RESULTS: Movement speed generally exhibited positive linear relationships with the hyperemic response to PLM, eliciting ~20-30% increase in hyperemia and conductance for each 60°/s increase in speed ($P<0.05$). However, increasing the movement speed above 180°/s, which was physically difficult, did not elicit significant increases in hyperemia in many cases. ROM exhibited curvilinear relationships ($P<0.05$) with hyperemia and conductance, which peaked at 90°, such that a 30° increase or decrease in ROM from 90° resulted in a 10-40% attenuation ($P<0.05$) in the hyperemic response. Alterations in the balance of antegrade and retrograde flow appear to play a role in this attenuation.

CONCLUSIONS: Movement speed and ROM have a profound impact on PLM-induced hyperemia, as well as the feasibility of the test. When using PLM to assess vascular endothelial function, it is recommended to perform the test at the traditional 180°/s with 90° ROM, which offers a large hyperemic response, while maintaining test feasibility.

The Relationship Between Left Ventricular Systolic Function And Cerebral Blood Flow
 Ai Hirasawa¹, Tomoya Suda¹, Kazukuni Hirabuki¹, Noritaka Hata¹, Yuki Sano¹, Marina Fukuie², Takahiro Uechi¹, Takeaki Matsuda¹, Shigeki Shibata¹. ¹*Kyorin University, Tokyo, Japan.*
²*University of Tsukuba, Ibaraki, Japan.*
(No relevant relationships reported)

PURPOSE: The positive relationship between cardiac output and cerebral blood flow (CBF) has been indicated in healthy individuals and patients with cardiovascular diseases. Previous studies reported that the reduced cardiac output was related with a low brain volume and an increased risk for Alzheimer's disease. Also, compromised left ventricular (LV) diastolic function was reported to be associated with a cerebral white matter lesions. Therefore, cardiac function may play an important role for the maintenance of CBF. However, the relationship between LV systolic function and CBF is still unclear. The purpose of this study was to test our hypothesis that the LV systolic function would be associated with CBF.

METHODS: Sixty-three outpatients who presented to our hospital due to transient loss of consciousness were enrolled (59 ± 22 years old, range 17 to 93 years old, 31 females). LV function was assessed by stroke volume (SV), LV ejection fraction (LVEF) and mass (LVmass) by echocardiography, and pre-ejection period (PEP), ejection time (ET) and ET/PEP by phonocardiogram. ET was corrected by heart rate (ETc). On the other hand, CBF was estimated from systolic, diastolic and mean blood flow velocity in middle cerebral artery (MCA), measured by transcranial Doppler ultrasound. The multiple linear regression analysis was performed using MCA blood flow velocities (MCAv) as independent variables, and age, sex and each LV function as dependent variables.

RESULTS: SV, LVEF, LVmass and PEP were not correlated with MCAv. In contrast, ETc was significantly correlated with both systolic ($\beta = 0.32$, $P = 0.01$) and mean ($\beta = 0.25$, $P = 0.02$) MCAv. ET/PEP was significantly correlated with systolic MCAv ($\beta = 0.22$, $P = 0.04$) only.

CONCLUSIONS: These results indicated that LV systolic function evaluated by phonocardiogram may play more significant role for regulating CBF as compared with that by echocardiography such as LVEF.

Differential Cardiovascular Responses to Acute Exercise in Children with Autism Spectrum Disorder
 Jacob A. Manriquez, Kauionalani P. Kekuawela, Romina Shafikhani, Areum K. Jensen. *San Jose State University, San Jose, CA.*
(No relevant relationships reported)

Autism Spectrum Disorder (ASD) is a complex neurological disorder identified in early childhood and is characterized by impaired social interaction and atypical behaviors. A very few studies reported that children with ASD tend to have higher heart rate (HR) and blood pressure (BP) at rest compared to typically developing children (TDC). Although structural abnormalities have been identified in the brain stem where cardiovascular control center is located, the physiological basis for ASD has not been established. Furthermore, whether there are alterations in cardiovascular responses to exercise in ASD is unidentified. **PURPOSE:** To determine differential cardiovascular responses to acute handgrip exercise in children with ASD. **METHODS:** Total of 23 adults, TDC and children with ASD participated in the study. HR from ECG, beat to beat arterial BP from Finapres and brachial BP, and respiration from pneumobelt were continuously measured before, during and after 2 minutes of dynamic handgrip exercise at 50% of maximal voluntary contraction. In addition, diameter, blood flow velocity, and flow of the brachial artery were measured using Doppler Ultrasound on the contracting arm throughout the experiment. **RESULTS:** Mean BP was significantly increased to exercise from resting baseline in all groups with no group differences ($\Delta 10.0 \pm 1.5$ adults, $\Delta 8.2 \pm 1.4$ TDC, and $\Delta 6.9 \pm 1.8$ ASD mmHg; $P>0.05$). HR was significantly increased to exercise from rest in adult and TDC groups (58 ± 2 adult vs. 78 ± 2 TDC at rest, 65 ± 2 adult vs. 85 ± 2 TDC exercise bpm; $P<0.05$); however, there was no change in HR to exercise from rest in children with ASD (77 ± 4 at rest, 78 ± 5 exercise bpm). Both adult and TDC groups had similar increase in blood flow velocity during exercise compared to rest ($\Delta 17.6 \pm 3.2$ adult vs. $\Delta 13.5 \pm 2.2$ TDC cm/s; $P<0.05$). However, blood flow velocity in ASD did not change from rest to exercise ($\Delta 0.6 \pm 2.2$ ASD cm/s). **CONCLUSION:** While HR increased to exercise in both adult and TDC groups in similar fashion, HR did not change in children with ASD. It suggests that higher total peripheral resistance may contribute to increase BP during exercise in ASD. Such increase in BP can be attributed to attenuated vasodilation in contracting skeletal muscles during exercise in children with ASD. Supported by CASA RSCA Infusion and Undergraduate Research Grant, SJSU

1856 Board #12 May 30 2:00 PM - 3:30 PM
Altered Blood Flow in Lower Legs of Runners Over the Course of a Competitive Season
 Rachel L. Bowden, Cameron Greene, Megan Battles, Arbin Thapaliya, Jennifer Austin, Jeffrey Williams. *Franklin College, Franklin, IN.*
(No relevant relationships reported)

Forceful and repetitive motions in sport lead to adaptations in various tissues. Hypertrophy and inflexibility of muscle tissue are common adaptations associated with decreased vascular perfusion and injury. Such findings have been validated in the upper limbs of throwers over the course of competitive seasons. To date, no studies have examined the influence of a competitive season of running on blood flow in the lower legs of runners. A more comprehensive understanding of blood flow adaptations may advance clinicians' abilities to predict and prevent running related injuries.

Purpose: To examine blood flow in lower legs of collegiate runners over the course of a competitive season.

Methods: Blood flow in the posterior tibial artery was measured bilaterally on 25 asymptomatic collegiate track athletes (15 males, 10 females, age = 20.0 ± 1.2 years, height = 171.5 ± 10.2 cm, mass = 66.7 ± 13.7 kg). Measurements were performed in one session at pre-season and immediately following the season. An independent t-test was used to compare blood flow in dominant versus non-dominant limbs at the start of season. Repeated measures t-tests were used to compare changes in blood flow from pre- to post-season in the dominant and non-dominant limbs.

Results: At pre-season, blood flow in the dominant (123.34 ± 43.73) and non-dominant (112.64 ± 40.31) posterior tibial arteries was not significantly different ($t_{48} = .90$, $P = .373$). Blood flow in the dominant legs, however, significantly decreased from pre- (118.26 ± 46.52) to post-season (102.99 ± 30.76) ($t_{19} = 2.089$, $P = 0.05$). No significant difference was seen in blood flow in the non-dominant leg between pre- (109.53 ± 42.03) and post-season (102.55 ± 33.21) ($t_{19} = 1.1017$, $P = 0.322$).

Conclusion: This study reveals blood flow significantly decreased in the dominant posterior tibial arteries among runners over the course of a competitive season. Such findings support the idea of limb lateralization and asymmetrical adaptations among this population. Changes in blood flow may predispose runners to injury. These changes may be due to factors in running gait and potentially disproportionate use of one limb during the stabilization and propulsive phases of gait. Further research should examine mechanisms underlying changes in blood flow and its influence on injury incidence among runners.

1857 Board #13 May 30 2:00 PM - 3:30 PM
The Temperature Surface Radiation Pattern - A non-invasive Insight into Skin Blood Flow Response to Exercise
 Barlo Hillen, Perikles Simon. *Johannes Gutenberg University Mainz, Mainz, Germany.*
 Email: b.hillen@uni-mainz.de
 (No relevant relationships reported)

Infrared thermography (IR-T) is a non-invasive and mobile tool to measure and portray changes of the body surface radiation (T_{sr}) or the surface radiation pattern (T_{spp}) in real-time. **PURPOSE:** The comparison and examination of the T_{spp} of the back of the legs during an exercise test, between endurance athletes and patients with cystic fibrosis (CF). **METHODS:** 7 CF patients (G1) and 14 male endurance athletes (G2) performed a step-wise incremental exercise test on a treadmill. T_{sr} was measured via IR-T with a high-resolution detector. T_{spp} was calculated as the difference in temperature ($^{\circ}\text{C}$) between the 10% of the darkest and 10% of the lightest pixels in the region of interest. T_{spp} data were analyzed at "resting condition" (rest), "individual anaerobic threshold" (IAT) and "maximum load" (max), by repeated measures ANOVA. **RESULTS:** By looking at the complete optical information of temperature patterns over time in high-resolution, we were able to recognize the anatomy of subcutaneous arterioles and their sensitive adjustments due to exercise over time. For G1 global testing for T_{spp} was significant across all measuring points (rest: 2.1°C ; IAT: 2.7°C ; max: 3.0°C SD: 0.2°C ; $p < 0.05$), with a significant group difference between rest and max, only ($p = 0.022$). For G2 global testing was highly significant (rest: 2.3°C ; IAT: 3.4°C ; max: 3.8°C SD: 0.1°C ; $p < 0.01$), and all between-group comparisons were highly significant ($p < 0.01$). The course of the T_{spp} during the load does not differ significantly between G1 and G2 ($p = 0.124$). **CONCLUSION:** The T_{spp} increases across groups during an exercise test. The T_{spp} can be distinguished between rest, IAT and max for endurance athletes. In the chronically ill patients, the increase in the difference in T_{spp} appeared to be less pronounced, which could be due to the limited capacity of the patients. The adjustment of arterioles during exercise was therefore dependent on the intensity of exercise and on individual prerequisites. High-resolution IR-T measurement has the potential to become a performance diagnostic tool, to generate sensitive insights into individual exercise physiology. Technological innovations like improved algorithms, automated data processing as well as deep learning should be applied in further research studies to improve IR-T diagnostics and the detection of the T_{spp} .

Effects of External Calf Compression on Microvascular Oxygenation in the Lower Limb of Young Men
 Patricia Pagan Lassalle¹, Adam J. Palamar¹, Jacob P. DeBlois¹, Wesley K. Lefferts², Kevin S. Heffernan¹. ¹Syracuse University, Syracuse, NY. ²University of Illinois, Chicago, IL. (Sponsor: Bo Fernhall, FACSM)
 (No relevant relationships reported)

Compression garments are used in clinical and sports settings to improve blood flow. Pressure applied by the compression garments varies widely with some garments applying as little as 5 mmHg and as much as 60 mmHg of pressure. Although compression can increase blood flow, compression to a pressure of 60 mmHg for short periods of time (~30 min) has been shown to cause endothelial damage. This is important because endothelial dysfunction is a precursor of atherosclerosis and may impair microvascular oxygenation. **PURPOSE:** Examine the effect of lower versus higher external compression pressures on microvascular oxygenation in healthy, young men. **METHODS:** Near-infrared spectroscopy (NIRS) was used to measure vastus medialis muscle oxygen saturation (SMO_2) and total hemoglobin (THB) in 29 healthy, young men (22 ± 5 years of age, body mass index $23 \pm 2 \text{ kg}\cdot\text{m}^{-2}$). Oxygenation was measured continuously for 10 min at rest and during external compression, which consisted of inflation of a cuff applied to the calf to 5 mmHg and 60 mmHg in a randomized order. There was a 5 min recovery period between conditions. Each compression condition was maintained for 30 minutes. Data were binned into 5 min epochs and analysed using a 2 (condition) \times 9 (time points) ANOVA with repeated measures. **RESULTS:** A significant time effect was detected for SMO_2 . When comparing the final epoch (min 25-30) to baseline, SMO_2 increased 5.75% and 5.86% with compression to 5 mmHg and 60 mmHg, respectively ($p < 0.001$). No condition by time interaction was detected ($p = 0.89$). A significant time effect was detected for THB. When comparing the final epoch (min 25-30) to baseline, THB increased 1.08% and 1.15% with compression to 5 mmHg and 60 mmHg, respectively ($p < 0.001$). No condition by time interaction was detected ($p = 0.76$). **CONCLUSION:** Although previous studies suggest that higher compression pressures of 60 mmHg lead to endothelial dysfunction, our findings suggest that there were no subsequent detrimental effects on microvascular oxygenation. Compression increased microvascular oxygenation and increases were similar between the 5 mmHg and 60 mmHg conditions. These findings suggest that both lower and higher compression pressures may have similar modest beneficial effects on microvascular oxygenation.

Blood Pressure, Body Composition, and Plasma Lipids Are Not Related to Indices of Vascular Health
 Jason R. Lytle, Karina L. Wilson, Sean T. Stanelle, Steven E. Martin, Stephen F. Crouse, FACSM. *Texas A&M, College Station, TX.* (Sponsor: Stephen Crouse, FACSM)
 (No relevant relationships reported)

Blood pressure, body composition and plasma lipoprotein concentrations are important markers for cardiovascular disease (CVD) risk.

PURPOSE: To examine potential relationships between blood pressure, body composition, plasma lipoprotein concentrations and indices of vascular health as assessed with carotid-femoral pulse wave velocity (PWV) and flow mediated dilation (FMD).

METHODS: Fourteen male subjects (age 32 ± 13 yrs, height 177.6 ± 6.6 cm, weight 83.3 ± 9.0 kg, lean mass 61.7 ± 6.3 kg, fat mass 18.4 ± 6.8 kg) volunteered for lab testing as part of a health assessment program, which included resting blood pressure, dual energy x-ray absorptiometry (DXA), FMD, PWV, and blood analysis. All testing was completed on the same day after an overnight fast. The vascular measures were taken via ultrasound, in a temperature controlled room with dim lighting. Each subject would lay supine for 10 minutes prior to the vascular measures. FMD was assessed in the brachial artery in response to a 5-minute distal occlusion. FMD results are given as a percent change from baseline. The PWV measure was assessed on the carotid and femoral arteries using 80% of the total distance between measure sites. PWV results are given in meter per second. All PWV and FMD measures were completed according to previously published procedures (Bortel, 2011; Corretti, 2002.). Body composition was assessed via DXA. Relationships among the data were analyzed with Pearson's r ($\alpha = 0.05$).

RESULTS: No significant relationships were found with PWV or FMD and any of the CVD risk factors measured. The strongest correlations for PWV and FMD are listed in Table 1.

Table 1.

| | Lean Mass | % Body Fat | % Android Fat | LDL Particle Size |
|-----|-----------|---------------|---------------|-------------------|
| PWV | R = -0.32 | R = -0.26 | R = -0.28 | R = -0.27 |
| | Lean Mass | Triglycerides | LDL | HDL |
| FMD | R = -0.23 | R = -0.37 | R = -0.31 | R = -0.34 |

CONCLUSION: Based on our results, accepted risk factors for CVD, including blood pressure, plasma lipoproteins, and body composition, are not related to indices of vascular health as assessed with PWV and FMD.

Greater Forearm Blood Flow is Associated with Better Walking Economy and Gait Speed in Older Adults
 Kevin N. Hamidi¹, Devon A. Dobrosielski¹, Jennifer A. Schrack², Nicolas D. Knuth¹. ¹Towson University, Towson, MD. ²Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.
 Email: khamidi1@students.towson.edu
 (No relevant relationships reported)

Gait speed decline is a well-established predictor of disability and mortality in older adults. Compromised energetic efficiency (i.e. walking economy) is a strong contributor to gait speed decline, but the underlying mechanisms influencing walking economy are undefined. Impaired vascular function is common with aging and thus may be an important contributor to the development of compromised walking economy and slow gait speed, yet the relationships among blood flow within skeletal muscle, walking economy, and gait speed in older adults are unknown. **PURPOSE:** To examine the relationship between measured forearm blood flow and (i) walking economy and (ii) gait speed in older men and women. **METHODS:** Resting arterial inflow and reactive hyperemic blood flow (RHBF) of the left forearm was measured in 55 participants of the Longitudinal Aging Study at Towson (LAST; 53% male, mean age 70, range 51-91 years) using venous occlusion plethysmography. Walking economy was measured as the average rate of oxygen consumption during the final 2 minutes of a 5 minute standardized treadmill-based walking test at 1.5 mile per hour. Gait speed was assessed during 2.5 minutes of normal-paced walking over a 20-meter course. The association between RHBF and walking economy and RHBF and gait speed was modeled using linear regression, adjusting for age, height, and fat-free mass. Sobel tests were used to assess possible mediating effects. **RESULTS:** In fully adjusted models, RHBF (mean RHBF: $18.0 \pm 5.9 \text{ mL}\cdot 100\text{mL tissue}^{-1}\cdot\text{min}^{-1}$) was negatively associated with oxygen consumption ($\beta = -7.5$, $p < 0.01$), indicating that walking economy was 7.5 mL/min lower for each one-unit increase in blood flow. Gait speed (mean $1.3 \pm 0.2 \text{ m/s}$) was positively associated with blood flow ($\beta = 0.01$, $p = 0.05$), indicating that gait speed was 0.01 m/s faster for each one-unit increase in blood flow. Mediation analyses further suggested that blood flow may mediate the association between walking economy and gait speed ($p = 0.06$). **CONCLUSION:** RHBF is

a significant predictor of both walking economy and gait speed in older adults, suggesting that better overall vascular health is related to enhanced walking economy and gait speed. Therefore, interventions aimed at improving vascular health in the aging population may be beneficial in maintaining gait speed and mobility with age.

Racial Differences In Vascular Function And Blood Flow Responses During Upper And Lower Limb Exercise

Austin Hogwood. *Virginia Commonwealth University, Richmond, VA.*
 Email: hogwoodac@vcu.edu
 (No relevant relationships reported)

PURPOSE: Recently, it has been shown that young African American males display lower hyperemic responses, but preserved shear-induced dilation, in response to dynamic handgrip exercise when compared to Caucasian American counterparts; however, it is unknown whether this blunted exercise hyperemia is also present in the lower limbs.

METHODS: Young African American (AA) (n = 4) and Caucasian American (CA) (n = 3) males performed two separate incremental exercise bouts of rhythmic handgrip and plantar flexion exercise while blood flow and diameter were evaluated in the brachial and superficial femoral arteries, respectively. Mean arterial pressure (MAP) and blood flow/vascular function variables (blood flow, shear rate, flow-mediated dilation) were measured in the last minute of each 3-minute workload.

RESULTS: The data revealed no significant group differences during handgrip exercise when examining blood flow (e.g. 24 kg: AA: 666 ± 52; CA: 711 ± 60 mL.min⁻¹; p = 0.5), MAP (e.g. 24 kg: AA: 109 ± 5; CA: 99 ± 6 mmHg; p = 0.3), or vascular conductance (e.g. 24 kg: AA: 6.2 ± 0.7; CA: 7.4 ± 0.8 mL.min⁻¹.mmHg⁻¹; p = 0.3) across all workloads. During plantar flexion exercise, no group differences were reported when evaluating blood flow (e.g. 32 kg: AA: 993 ± 83; CA: 713 ± 97 mL.min⁻¹; p = 0.2), MAP (e.g. 32 kg: AA: 104 ± 4.9; CA: 106 ± 4.8 mmHg; p = 0.3), or vascular conductance (e.g. 32 kg: AA: 9.6 ± 0.8; CA: 7.1 ± 0.8 mL.min⁻¹.mmHg⁻¹; p = 0.6) across all workloads. Slopes derived from the relationship between shear rate and arterial dilation across all exercise workloads were not different between groups when examined in the brachial (AA: 0.00136 ± 0.00034; CA: 0.00004 ± 0.00003; p = 0.7) or superficial femoral artery (AA: 0.0013 ± 0.0003; CA: 0.0002 ± 0.0007; p = 0.6).

CONCLUSIONS: Preliminary data revealed no differences in exercise-induced blood flow or vascular responses in the upper or lower limbs when comparing young African American and Caucasian American males.

Improved Maximal Oxygen Uptake Following High-intensity Interval Training Relates To An Increase In Blood Volume

Mirko Mandic, Björn H. Hansson, Thomas Gustafsson, Eric Rullman. *Karolinska Institutet, Stockholm, Sweden.*
 Email: mirko.mandic@ki.se
 (No relevant relationships reported)

Improved maximal oxygen uptake following high-intensity interval training relates to an increase in blood volume

High-intensity interval training (HIT) is an effective training mode for improving maximal oxygen uptake (VO₂max). As past research has focused on peripheral adaptations to HIT, little is known about central factors governing cardiac output and thus VO₂max. **PURPOSE:** The aim of this study was to test the hypothesis that HIT-induced improvements in VO₂max are accompanied by increases in blood volume (BV) and cardiac stroke volume. Further, we investigated if inter-individual differences in the increase in in VO₂max could be attributed to changes in BV. **METHODS:** Twenty subjects (10 females, 10 males) participated in a 6-week long training intervention consisting of 3 HIT sessions per week. Each session comprised of three 30 s all-out sprints against a breaking force equivalent to 7.5% of body weight. The sprints were separated by 2 min rest. VO₂max, peak exercise cardiac output and BV (measured with carbon monoxide rebreathing) was assessed before (PRE) and after (POST) the intervention. **RESULTS:** VO₂max increased by 9% (44.9±7.9 to 48.7±7.8 mL/min/kg) from PRE to POST (P < 0.05) and the increase in BV was 5% (5.4±0.8 to 5.7±0.9 L, P < 0.05) with a corresponding increase in peak exercise stroke volume. Accounting for inter-individual variance, approximately 60% of the change in VO₂max could be attributed to changes in BV. **CONCLUSION:** This is the first study to show that improvements in VO₂max with HIT are associated with increased blood volume. This suggest that a large part of HIT-induced improvements in VO₂max are mediated by increased oxygen delivery, which at least in part is due to increased blood volume.

1863 Board #19 May 30 2:00 PM - 3:30 PM
Visceral Adiposity is Associated with Lower Cerebral Blood Velocity in Older Adults

Natalia S. Lima¹, Alexander J. . Rosenberg², Georgios Grigoriadis¹, Elizabeth C. Schroeder¹, Wesley K. Lefferts¹, Tracy Baynard, FACSM¹. ¹University of Illinois at Chicago, Chicago, IL. ²University of North Texas Health Science Center, Fort Worth, TX. (Sponsor: Tracy Baynard, FACSM)
 Email: nlima3@uic.edu
 (No relevant relationships reported)

Aging is associated with an increased prevalence of obesity and preferential increase in visceral adiposity. Visceral adiposity has detrimental effects on vascular function, which may contribute to reductions in brain blood flow with aging, thereby contributing to stroke risk and cognitive decline. The impact of visceral fat and other components of body composition (total body fat, lean mass) on cerebral blood velocity in older adults has yet to be elucidated. **Purpose:** To evaluate the effects of lean mass (LM), fat mass (FM), and visceral fat (VF), on middle cerebral artery (MCA) mean velocity and conductance in older adults. **Methods:** Twenty-five older adults (60 ± 6 years; 30 ± 5 kg/m²) completed body composition assessments via dual x-ray absorptiometry (Lunar iDXA, GE, Waukesha, WI). Absolute LM, FM, and VF values were obtained and also made relative to total body weight, i.e. LM (kg)/total body weight (kg). Mean MCA velocity (MCAv) was assessed using a 2-MHz transcranial Doppler ultrasound probe on the right temporal window. Mean MCA conductance (MCAc) was calculated as MCAv /mean arterial pressure (MAP), with MAP obtained from finger photoplethysmography. **Results:** The range of values for this sample were: MCAv (30 - 105 cm/s), MCAc (0.30 - 1.05 cm/s/mmHg), MAP (79 - 116 mmHg), LM (30.73 - 68.80 kg), FM (15.55 - 63.25 kg), VF (0.20 - 3. kg), and body weight (51 - 123 kg). Absolute LM and VF were negatively associated with MCAv and MCAc, however, only VF remained after controlling for body weight (p < 0.05; Table). No relationship was observed for relative LM or FM (either absolute or relative). **Conclusion:** These results indicate that increased visceral adiposity is negatively related to cerebral blood flow in older adults, whereas whole body fat mass was not as sensitive. This suggests the importance of visceral adipose interacting with cerebrovascular physiology in contrast to whole body fat mass among older adults.

An Exaggerated Muscle Metaboreflex In Diabetic Rats Is Mediated By Potentiated Skeletal Muscle Afferent Responsiveness

Rie Ishizawa¹, Han Kyul Kim¹, Norio Hotta², Gary A. Iwamoto¹, Wanpen Vongpatanasin¹, Jere H. Mitchell, FACSM¹, Scott A. Smith¹, Masaki Mizuno¹. ¹University of Texas Southwestern Medical Center, Dallas, TX. ²Chubu University, Kasugai, Japan.
 (No relevant relationships reported)

Patients with type 2 diabetes (T2D) exhibit an excessive increase in blood pressure during exercise. Evidence suggests that the skeletal muscle metaboreflex is exaggerated in T2D. However, the underlying mechanisms remain poorly understood. Metaboreflex sensory signals from exercising muscle are generated by activation of chemically-sensitive group IV afferent neurons. It is logical to suggest, therefore, that heightened metaboreflex function in T2D may be caused by enhanced muscle afferent responsiveness to chemical stimulation. **PURPOSE:** The purpose of this study was to

1) examine whether the heightened cardiovascular response to exercise in T2D results from muscle metaboreflex overactivity *in vivo*, and 2) investigate the impact of T2D on neuronal responses to chemical stimulation in skeletal muscle afferents *in vitro*. **METHODS:** For 14-16 weeks, rats were given either a normal diet (control group) or a high fat diet in combination with a low dose (35 mg/kg) of streptozotocin (T2D group). *In vivo*, we measured changes in renal sympathetic nerve activity (RSNA) and mean arterial pressure (MAP) in response to capsaicin administration (0.3 and 1.0 $\mu\text{g}/100\ \mu\text{l}$) in the hindlimb arterial supply. *In vitro*, the function of chemically (1 μM capsaicin) activated group IV neurons were assessed by obtaining single-fiber recordings using a muscle-nerve preparation. **RESULTS:** T2D rats exhibited hyperglycemia after overnight fasting (104 ± 5 vs. 161 ± 10 mg/dL, $P<0.05$). Compared to control, capsaicin administration evoked significantly greater increases in RSNA (0.3 μg : 36 ± 25 vs. $92\pm17\%$; 1.0 μg : 55 ± 26 vs. $246\pm72\%$, $P<0.05$) and MAP (0.3 μg : 15 ± 8 vs. 45 ± 9 mmHg; 1.0 μg : 23 ± 9 vs. 70 ± 5 mmHg, $P<0.01$) in T2D rats. The discharge of group IV muscle afferents to 1 μM capsaicin exposure was likewise significantly greater in T2D rats compared to control (0.8 ± 0.3 vs. 2.9 ± 0.7 Hz, $P<0.05$). **CONCLUSIONS:** These findings suggest that the heightened cardiovascular response to exercise in T2D may be caused by an exaggerated muscle metaboreflex made operative via a potentiation in muscle afferent responsiveness to chemical stimulation. Change In Cardiorespiratory Fitness And Prevalence Of Metabolic Syndrome After An Exercise Program

Matthew Riccardi, *Ball State University, Muncie, IN.*
 Email: mpriccardi@bsu.edu
 (No relevant relationships reported)

Metabolic syndrome (MetSyn) is defined as the clustering of multiple risk factors associated with an increased risk for cardiovascular disease (CVD) and type II diabetes. We, and others, have shown that cardiorespiratory fitness (CRF) is associated with the prevalence of MetSyn, however, it is unknown if a change in CRF with exercise training is related to reduced prevalence of MetSyn. **PURPOSE:** To examine the relationship between the change in CRF and the change in number of MetSyn risk factors following a self-referred exercise program. **METHODS:** Maximal cardiopulmonary exercise (CPX) tests and MetSyn risk factors were analyzed prospectively from 364 adults aged 46.1 years (45% women). MetSyn was defined according to the National Cholesterol Education Program- Adult Treatment Panel III criteria as updated by the American Heart Association/National Heart, Lung, and Blood Institute. Correlations and logistic ordinal regression were used to assess the relationship between the change in CRF and the change in number of MetSyn risk factors following ~6 months of participation in a self-referred, community-based exercise program. **RESULTS:** Overall prevalence of MetSyn decreased from 25% to 15%, while CRF improved 15% (30.9 ± 8.1 vs. 35.5 ± 8.9 mL/kg/min, $P<0.001$) following the exercise program. Measured change in CRF had a significant, inverse relationship with the change in number of MetSyn risk factors ($r=-0.211$; $P<0.001$). Subjects who improved CRF had a 52% reduction in likelihood of gaining MetSyn risk factors when compared to subjects who did not improve CRF (Odds ratio=0.474; $P=0.030$). **CONCLUSION:** This prospective analysis indicates that there is an inverse relationship between the change in CRF and the change in MetSyn risk factors in a self-referred cohort participating in an exercise program for approximately 6 months. Participating in a community-based, self-referred exercise program yields significant improvements on CRF, the MetSyn risk factors, and the overall prevalence of the MetSyn and therefore should be emphasized as a primary prevention strategy for MetSyn.

 (No relevant relationships reported)

Individuals with arterial hypertension often have an autonomic nervous system (ANS) imbalance with predominance of sympathetic ANS. This predominance can lead to injury of several organs affecting its functioning. There is evidence that performing high intensity resistance training (RT) with heavier loads and a lower number of repetitions results in lower cardiovascular stress when compared with lighter loads and a higher number of repetitions. However, the effects of different protocols of RT in autonomic modulation are not known specially using nonlinear analyses methods.

PURPOSE: Analyze and compare the effects of different protocols of high intensity of effort RT on autonomic cardiac modulation of hypertensive women using nonlinear methods. **METHODS:** A randomized crossover design clinical trial was conducted with 15 postmenopausal hypertensive women who underwent a control session and two high intensity RT protocols involving 6 and 15 repetition maximum (RM). The nonlinear variables that compose Heart Rate Variability (HRV) were collected pre, immediately post, 1 h post, and 24 h post each protocol. Repeated-measures ANOVA were used.

RESULTS: The SD1 indices that represent parasympathetic activity in the system were lower in 15RM protocol immediately after the exercise (9.32 ± 11.40) when compared with 6RM (16.38 ± 13.15) and control (19.39 ± 13.40) ($p<0.05$). The SD2 indices that represent a global variability in the system also were lower in 15RM protocol especially immediately after (13.84 ± 9.57) the exercise when compared with 6RM (24.19 ± 17.50) and control (29.32 ± 17.41) ($p<0.05$). For the 6RM protocol no relevant clinical changes were observed.

CONCLUSIONS: Performing high intensity RT with lower loads and a higher number of repetitions decreases parasympathetic ANS activity, which may be related to an increased cardiovascular stress. On the other hand, heavier load and lower repetition RT did not have a significant impact upon autonomic modulation when compared to a control session.

Effects Of Sleep-inducing Mixed Juice On Sleep Quality And Cardiac Vagal Regulation In Adults With Disturbed Sleep

Hye-Young JUNG, Maengkyu KIM, Choun-Sub KIM, Min-Ghyu SUN, Yong-Woo KIM. *Kyungpook National University, Daegu, Korea, Republic of.*
 Email: kimmk@knu.ac.kr
 (No relevant relationships reported)

PURPOSE: To investigate whether the consumption of sleep-inducing juice would effect on sleep quality and cardiac vagal regulation in adults with sleep disorders. **METHODS:** This randomized and cross-over design study was conducted on twenty-three adults (24.26 ± 1.39 yrs; 15 females, 8 males) who complained with difficulty in initiating and/or maintaining sleep (PSQI \geq cutoff score of 5). On feeding session (FS), subjects had received sleep-inducing juice (250ml) twice a day for 8 wks while non-feeding session (N-FS) maintained usual daily life without no juice intake. 2 wks washout was given between two sessions. Anthropometrics and hemodynamic index were taken before and after FS and N-FS. Sleep parameters (e.g. sleep latency) and amount of physical activity had recorded through Actigraph GTX3+ while Pittsburgh sleep diary has completed for consecutive 7 days. For evaluation of cardiac autonomic regulation, heart rate variability (HRV) at resting and during sleep had recorded through Polar RS800CX. In addition, self-reported Pittsburgh sleep quality index (PSQI) and fatigue severity scale (FSS) had completed before and after FS and N-FS. **RESULTS:** Anthropometrics, hemodynamic index, and amount of physical activity had no significant differences between sessions including baseline. Sleep latency, total counts/night, and sleep fragmental index had significant decreases after FS whilst total sleep time and sleep efficiency had significant increase ($p<0.001$, respectively) compared to post N-FS. Moreover, PSQI had significantly decreased after FS ($p<0.001$) coincided with significant decline of FFS ($p<0.001$). Furthermore, vagal activity index (e.g. HF, rMSSD, and SD1) had significant improvement followed by FS ($p<0.05$, respectively) yet there were no significant differences in N-FS. On the contrary, sympathetic nerve activity index (LF/HF ratio) had significant decrease after FS while there was no significant difference after N-FS. **CONCLUSIONS:** Major findings has suggested that consumption of sleep-inducing juice is effective to improve sleep quality accompanied with enhancement of cardiac vagal tone at resting and during sleep. Thus, sleep-inducing juice might be of benefit for managing sleep in adults with disturbed sleep.

Gavin, FACSM¹. ¹Purdue University, West Lafayette, IN. ²Indiana University-Purdue University Indianapolis, Indianapolis, IN. ³Indiana University School of Medicine- West Lafayette, West Lafayette, IN.
(No relevant relationships reported)

Obesity is associated with chronic inflammation characterized by increased levels of inflammatory cytokines. Exosomes are small microvesicles secreted by cells that contain a variety of molecules including microRNAs (miR), mRNAs, and proteins. Typically, miRs act through post-transcriptional regulation of mRNA targets via mRNA degradation and/or translational repression. Exercise training reduces chronic inflammation. **PURPOSE:** The current study examined if obesity and concurrent exercise training alter skeletal muscle: (1) exosomal miR content, and (2) inflammatory signaling. **METHODS:** Vastus lateralis biopsies were obtained from sedentary lean (LN) and obese (OB) (N=8/group) men and women for analysis of targeted whole skeletal muscle mRNA, miR, and protein; and skeletal muscle derived exosomal miR (via small RNA-seq) before and after seven days of concurrent aerobic and resistance training. Significance at $p \leq 0.05$. **RESULTS:** Pathway analysis of skeletal muscle derived exosomal miR indicated: 1) obesity increases miR targeting cancer, Wnt/ β -catenin, and neuroinflammation in which transforming growth factor β receptor 1 (TGF β R1) is common; 2) exercise training decreases miR targeting IL-10, IL-8, toll like receptor signaling (TLR), and NF- κ B pathways in which RELA, an NF- κ B subunit, is common. In whole skeletal muscle, IL-8 mRNA was reduced 50% (LN: Pre=1.0, Post=0.57; OB: Pre=0.89, Post=0.37) and Jun mRNA was reduced 25% after exercise training (LN: Pre=1.0, Post=0.75; OB: Pre=0.98, Post=0.76) consistent with the anti-inflammatory effects of exercise on skeletal muscle. **Conclusion:** These data suggest that obesity and seven days of exercise training both alter skeletal muscle-derived exosomal contents. The target cells for skeletal muscle derived exosomes and the physiological relevance requires further investigation.

(No relevant relationships reported)

Consumption of alcohol after resistance exercise (RE) is a common practice and might have negative effects on muscle recovery. Separately, alcohol and RE have opposite effects on signaling through mTOR complex 1 in skeletal muscle, a key pathway involved in muscle protein synthesis. **Purpose:** To investigate the effect of alcohol consumption after heavy RE on the phosphorylation of key proteins upstream of mTOR in skeletal muscle of resistance trained men. **METHODS:** Eleven recreationally resistance-trained men (24 \pm 2 y, 178 \pm 7 cm, 78.3 \pm 8.6 kg) completed 2 sessions of 6 sets of 10 repetitions of Smith machine back squats at 80% of 1 repetition maximum with 2 min of rest between sets. Immediately after exercise participants consumed 30 g of whey protein, followed by a drink (10 min after exercise) containing either alcohol (ALC: 1.09 g EtOH/kg fat free body mass⁻¹) or no alcohol (PLA). Muscle samples were obtained using biopsy before exercise (PRE) and 2 hrs after exercise (2H) and analyzed for phosphorylation at mTOR^{S2448}, TSC2^{S939}, TSC2^{S1387}, and AMPK^{T172} using western blotting. Blood was collected at PRE and 24 hours after exercise (24H) and analyzed for creatine kinase (CK) activity. **RESULTS:** Significant ($p < 0.05$) main effect of time was observed for mTOR^{S2448}, mTOR phosphorylation was (2.9 \pm 1.3) times greater at 2H compared to PRE ($F_{(1,10)} = 77.758, p < 0.001, \eta^2 = 0.774$). No significant main or interaction effect was observed for TSC2^{S939}, TSC2^{S1387}, or AMPK^{T172}. A significant main effect of time with a large eta squared effect size was observed for CK activity. CK activity was greater at 24H (312 \pm 137 U·L⁻¹) compared to PRE (135 \pm 69 U·L⁻¹) ($F_{(1,10)} = 28.856, p < 0.001, \eta^2 = 0.558$) indicating that the exercise protocol effectively induced a modest amount of muscle damage on both trials. **CONCLUSION:** Ingestion of a large bolus of alcohol after heavy resistance

exercise did not affect phosphorylation at mTOR^{S2448}, TSC2^{S939}, TSC2^{S1387}, or AMPK^{T172} at 2 hours after exercise in resistance-trained men. Supported in part by grants from the National Strength and Conditioning Association Foundation and the Texas Chapter of the American College of Sports Medicine

(No relevant relationships reported)

Autophagy is an evolutionary conserved cellular degradation system implicated in maintaining health and promoting longevity. Few human data exist investigating the autophagic response to exercise; however, acute moderate-intensity, continuous exercise (MICT) has been shown to stimulate autophagy in skeletal muscle. Presently, it is unknown whether high-intensity interval training (HIIT) exercise induces autophagy. **PURPOSE:** The purpose of this study was to compare the autophagy response of an acute bout of HIIT exercise (treadmill running) to MICT exercise in human skeletal muscle. **METHODS:** Using a crossover design, ten recreationally-active males (n=5) and females (n=5) performed a bout of MICT (60 minutes at 55% of max velocity [V_{max}]) and HIIT (6 bouts of 1 minute at 100% V_{max} and 1 minute at 3 MPH, followed by 5 minutes at 3 MPH, followed by 6 bouts of 1 minute and 100% V_{max} and 1 minute at 3 MPH). Muscle biopsies from the vastus lateralis were taken pre- and 3 hours post-exercise. Exercise bouts were separated by ≥ 72 hours and performed after abstaining from alcohol for ≥ 24 hours and food and caffeine for ≥ 8 hours. Subjects also refrained from food, energy-containing beverages, and caffeine during the 3-hour post-exercise period prior to the muscle biopsy. Muscle tissue was analyzed for protein expression of markers of autophagy (LC3I, LC3II) and autophagy signaling (p38MAPK) via western blot analysis. **RESULTS:** No differences were detected for LC3I, LC3II, and p38MAPK protein content measured 3 hours post-exercise compared to pre-exercise in both HIIT and MICT bouts ($p > 0.05$). LC3II:LC3I ratio increased 3 hours post-exercise in HIIT (162.4 \pm 45.9%), which was significantly higher than MICT at 3 hours post-exercise which decreased from pre-exercise (48.8 \pm 9.4%; $p < 0.05$). **CONCLUSION:** Our findings show that despite discrepant durations and intensities, HIIT stimulates autophagy in human skeletal muscle, however, in a distinct fashion compared to MICT. Our data also add to the current literature demonstrating that autophagy is activated by continuous (≥ 60 minutes), moderate-intensity (55 – 70% VO_{2max}) exercise.

Senescent Skeletal Muscle Satellite Cell Exosomes Induce Endothelial Cell Senescence and Impair Angiogenesis
Christopher K. Kargl, Purdue University, West Lafayette, IN.
(Sponsor: Timothy Gavin, FACSM)
(No relevant relationships reported)

Introduction: Cellular senescence is a state of irreversible cell cycle arrest associated with aging that occurs in many cell types including endothelial cells (EC) and skeletal muscle satellite cells (SC). Senescent cells exhibit an increase in secretion of cytokines and chemokines, often referred to as the senescence associated secretory phenotype (SASP). SCs and ECs co-exist in the muscle niche and cross-talk occurs between the two cell types. Small extracellular vesicles (exosomes) have been implicated as important contributors to the SASP. **Purpose:** Determine if exosomes from human, primary, senescent muscle satellite cells impact human endothelial cell growth, angiogenesis, and senescence. **Methods:** Senescence in primary human skeletal muscle satellite cells (n=6) was induced via incubation with 200 μ m hydrogen peroxide (H₂O₂). Exosomes were collected from normal and H₂O₂ treated satellite cells (NML-EXO and SEN-EXO, respectively). Human umbilical vein endothelial cells (HUVECs) were treated with 50 μ g/ml of NML-EXOs or SEN-EXOs. HUVEC growth and senescence was evaluated using EdU and β -galactosidase staining. HUVEC angiogenesis was measured via matrigel tube formation, wound healing and transwell migration assays. **Results:** After 48-hours, there was a decrease in proliferation (NML-EXO: 22% vs SEN-EXO: 18% EdU⁺ cells) and an increase in senescence (NML-EXO: 40% vs SEN-EXO: 53 % β -gal⁺ cells) in the SEN-EXO treated HUVECs. SEN-EXOs also impaired HUVEC wound healing following a scratch assay by 32.4%. There were no differences in HUVEC tube formation or transwell migration between the two EXO treatments. **Conclusion:** Exosomes harvested from senescent muscle satellite cells appear to transfer a senescent phenotype to HUVECs, resulting in impaired growth and

migration. This study provides evidence that exosomes function as part of the SASP in satellite cells and may propagate a senescent phenotype to neighboring endothelial cells in skeletal muscle with aging.

Effects Of Different Doses Of D-galactose On Skeletal Muscle In C57bl/6j Mouse

Yuta Sato¹, Yuki Tamura¹, Masafumi Noda², Karina Kouzaki¹, Koichi Nakazato¹. ¹Nippon Sport Science University, Tokyo, Japan. ²The University of Tokyo, Tokyo, Japan.

(No relevant relationships reported)

PURPOSE: Pharmacologically inducible models of aging could help to understand the pathogenesis of sarcopenia and to establish better exercise prescriptions for the elderly. Administration of D-galactose (50-150 mg/kg) has been used to induce aging phenotype including accumulation of oxidative stress, muscle atrophy, and cognitive impairment. A recent paper has shown that a higher dose of D-galactose (500 mg/kg/day) accumulated greater oxidative stress, compared with the commonly used dose (100 mg/kg/day). These observations suggest that there might be room to reconsider the optimal dose of D-galactose. We hence examined whether higher dose of D-galactose (above 100 mg/kg/day) exacerbate skeletal muscle atrophy. **METHODS:** Male C57BL/6J mice (8 weeks old) were divided into 4 groups as follow: 1) Control (0 mg/kg/day, n=10), 2) D-Galactose (150 mg/kg/day, n=10), 3) D-Galactose (1000 mg/kg/day, n=10), and 4) D-Galactose (2000 mg/kg/day, n=10). We intraperitoneally injected D-galactose solution at indicated dose every day for 8 weeks. On the day before tissue collection, we performed grip strength measurement. Twenty-four hours after the final injection, we collected and weighed gastrocnemius muscle, and then conducted histochemical analysis to measure cross-sectional area. **RESULTS:** We first confirmed that body weight and food intake during the intervention were not different among any doses of D-galactose. There were also non-detectable changes in muscle mass and grip strength among groups. We found that D-galactose injection decreased muscle fiber cross-sectional area at 150 mg/kg/day (-13.7%, P=0.03), but not at 1000 mg/kg/day (-11.5%, P=0.10) and 2000 mg/kg/day (-9.8%, P=0.19). **CONCLUSIONS:** Daily injection of D-galactose at 150 mg/kg/day sufficiently induces muscle fiber atrophy. Even if the dose was increased up to 1000 or 2000 mg/kg/day, the muscle fiber atrophy was not aggravated but rather alleviated.

Exercise Activate Tendon Cells through HGFA

James H-C Wang, Kentaro Onishi, Jianying Zhang, Feng Li. University of Pittsburgh, Pittsburgh, PA. (Sponsor: Brian A. Davis, MD., FACSM)

Email: wanghc@pitt.edu

(No relevant relationships reported)

Regular exercise enhances the musculoskeletal systems including tendon strengthening. Tendon cells, consisting of tendon stem/progenitor cells (TSCs) and tenocytes, are essential for the maintenance and repair of tendinous tissues when injured. Previously, we showed that TSCs increase in their number and quality after mice underwent moderate treadmill running. However, the molecular mechanisms underlying the activation of tendon cells by exercise are unknown. Hepatocyte growth factor activator (HGFA) is known to be a systemic factor that can activate skeletal muscle stem cells. **PURPOSE:** To test the hypothesis that HGFA is elevated and activates tendon cells in response to exercise. **METHODS:** Total 18 mice were equally divided into cage control and exercise groups. Exercise was mimicked by one-time treadmill running (OTR), with which mice ran at 13 meter/min for 6 hrs. Twelve hours before OTR, both groups of mice were injected with 1 mg of bromodeoxyuridine (BrdU) per mouse to determine cell proliferation. One day after OTR, all mice were sacrificed and Achilles and patellar tendons were harvested. The HGFA levels in both tendons and serum were measured using ELISA, and BrdU incorporation was assayed by immunofluorescence staining. Student *t*-test was performed to assess statistical significance. **RESULTS:** OTR increased HGFA levels in both Achilles and patellar tendons of OTR mice compared to cage control mice (Fig. 1A). HGFA levels in serum were also significantly increased after OTR (data not shown). Moreover, more BrdU positive cells were present in patellar tendons in OTR group than control group (Fig. 1B), indicating that quiescent tendon cells were activated from G₀ to G_{Alter} by exercise, possibly through HGFA. **CONCLUSION:** Exercise-elevated HGFA possibly may be responsible for the activation of tendon cells. This new molecular mechanism may explain the beneficial effects of exercise on tendon strengthening by stimulating synthesis.

Fig. 1 (A) HGFA is elevated by exercise (OTR) in Achilles (AT) and patellar (PT) mouse tendons (* $p < 0.05$); **(B)** OTR increases the number of tendon cells that incorporated BrdU, indicating that many tendon cells are activated from G₀ to G_{Alter} at one day after exercise.

(No relevant relationships reported)

Peripheral artery disease (PAD) is a significant medical condition caused by blockages in the arteries of the leg. Some PAD patients progress to critical limb ischemia (CLI) and major amputation. While recent regenerative medicine approaches on collateral vessel formation have made some progress, the myopathy and dysregulation of the skeletal muscle in CLI have not been thoroughly investigated. **PURPOSE:** To determine the regenerative mechanism of the muscle stem cell (MuSC) and its niche components in response to ischemic insults, we assessed interactions between MuSC, vascular- and neural-network, and myofibers at different time points. **METHODS:** The femoral artery ligation mouse model of PAD on different reporter mice were used in the study. Immunofluorescence, single fiber staining, and biochemistry blotting from harvested hindlimb muscles were used for data analysis. One-way ANOVA with Tukey's *post hoc* test and a paired two-tailed *t*-test were performed to determine differences following CLI injury. **RESULTS:** Skeletal muscle regeneration persisted up to 56 days while the number of eMHC⁺ fibers ($p < 0.01$) was highest 14 days following CLI surgery compared to the contralateral sham control. In addition, muscle regeneration was accompanied by significant alterations in the motor unit, as demarcated by the presence of denervated synapses, regeneration of the neuromuscular junction (NMJ), and increased number of subsynaptic nuclei ($p < 0.05$). Furthermore, the size of the myonuclear domain was decreased at 7 and 14 days ($p < 0.01$), corresponding to greater RNA content ($p < 0.001$) and MuSC frequency ($p < 0.05$) while the mitochondrial domain was increased 28 days ($p < 0.01$) following CLI injury. **CONCLUSION:** Overall, these data indicate that as a regenerative response to critical limb ischemia, the neurovascular network of myofibers are remodeled and newly regenerated myofibers exhibit MuSC-derived myonuclear expansion to allow enhanced transcriptional support and an increase in mitochondrial content for a bioenergetic need of the energy-demanding tissue regeneration. Supported by NIH R21AR072287 (YJC) and Regenerative Engineering and Medicine research grant.

Increased Muscle 5alpha-dihydrotestosterone By Acute Resistance Exercise Contributes To Muscle GLUT4 Signaling In Diabetic Rats

Naoki Horii, Natsuki Hasegawa, Masataka Uchida, Motoyuki Iemitsu. Ritsumeikan University, Kusatsu, Japan. (Sponsor: Izumi Tabata, FACSM)

(No relevant relationships reported)

Our previous study showed that 5 α -dihydrotestosterone (DHT), an active androgen, can be synthesized in skeletal muscle by 5 α -reductase. Recently, we revealed that the increase in muscle DHT level by resistance training was associated with improvement of glycemic control in type 2 diabetic rats. Acute resistance exercise activates signaling pathway such as AMPK/TBC1D1 and Akt/AS160 in skeletal muscle, resulting in enhancement of GLUT4 translocation. However, it is still unclear whether an increase in muscle DHT secretion by acute resistance exercise contributes to up-regulation of

these signaling pathways in type 2 diabetes. **PURPOSE:** This study aimed to clarify whether acute resistance exercise-induced increase in muscle DHT level contributes to muscle glucose metabolism-related signaling pathway in type 2 diabetic rats. **METHODS:** Male 20-week-old type 2 diabetic (OLETF) rats were randomly divided into 8 groups: resting control and immediately, an hour and three hours after acute resistance exercise (climbing ladder) with and without treatment of 5 α -reductase inhibitor (N=6 each group).

RESULTS: Muscle 5 α -reductase protein expression and DHT level were significantly increased immediately and an hour after acute resistance exercise ($p<0.05$), whereas these exercise responses were significantly suppressed by the treatment of 5 α -reductase inhibitor ($p<0.05$). Muscle AMPK^(Thr172), TBC1D1^(Ser237) and Akt^(Ser473) phosphorylation were significantly increased at immediately and an hour after acute resistance exercise ($p<0.05$). In addition, muscle AS160^(Thr642) phosphorylation and GLUT4 translocation were significantly increased one and three hours after resistance exercise ($p<0.05$). However, the treatment of 5 α -reductase inhibitor was significantly suppressed the up-regulations of GLUT4 translocation and Akt/AS160 phosphorylation ($p<0.05$), but did not alter the AMPK/TBC1D1 phosphorylation.

CONCLUSIONS: These results suggest that the increase in DHT secretion by acute resistance exercise may partially contribute to enhancement of muscle GLUT4 translocation via activation of Akt/AS160 phosphorylation in type 2 diabetic rats. Supported by Grants-in-Aid for Scientific Research (#17H02182 and #16K13059, M. Iemitsu).

The Development of Cancer Cachexia Negatively Impacts Skeletal Muscle Extracellular Matrix Remodeling

Wesley Haynie, Jacob Brown, David Lee, Megan Rosa-Caldwell, Richard Perry, Lemuel Brown, Nicholas Greene, Tyrone Washington. *University of Arkansas, Fayetteville, AR.* Email: wsh001@uark.edu

(No relevant relationships reported)

Cancer-cachexia is the largely irreversible wasting of lean body mass as a result of cancer progression, affecting ~80% of all cancer patients with as much as ~40% of cancer-related deaths being attributed directly to cachexia. Cachexia has been associated with increased fibrosis and reduced physiological function in cardiac muscle, but the possible role and development of fibrosis and associated extracellular matrix (ECM) remodeling in skeletal muscle has lacked evaluation. **PURPOSE:** To examine the effects of cancer cachexia on ECM remodeling and the development of fibrosis in skeletal muscle. **METHODS:** 40 C57BL/6J mice were injected with either Lewis Lung Carcinoma cells or a PBS control into their hind-flank at 8 wks of age. The tumor was allowed to develop for 1, 2, 3, or 4 wks (n=8 per group). Tibialis anterior (TA) muscle was extracted and immediately frozen for morphology and mRNA abundance analysis using RT-qPCR. **RESULTS:** There were no changes in TA muscle weight until 4 wks post-tumor implantation which resulted in a ~22% lower muscle wet weight compared to PBS control ($p<0.05$). Sirius Red staining of TA muscle sections resulted in no change in collagen abundance in all groups with the exception of a 2-3-fold increase at 4 wks relative to all other groups ($p<0.05$). Collagen 1 gene expression was ~50% and ~60% lower than control at 3 and 4 wks post tumor injection, respectively. ($p<0.05$). Collagen 1 gene expression was ~2-fold higher at 1 and 2 wks but there was no difference at 3 or 4wks, all relative to control ($p<0.05$). The ratio of Collagen 3:1 gene expression decreased ~30-50% from 1-3wks compared to control ($p<0.05$), but there was no difference at 4-wks. MMP-2 gene expression was ~50% higher at 1-wk compared to control ($p<0.05$), but was not different 2-4wks from control ($p<0.05$). MMP-9 gene expression was 3 and 6-fold greater than control at 3 and 4-wks post-injection, respectively ($p<0.05$). There was a main effect of tumor implantation to reduce TIMP-1 gene expression ~20-70% ($p<0.05$). **CONCLUSION:** The development of cancer cachexia results in dysregulation of ECM remodeling and increased collagen deposition within skeletal muscle. This dysregulation could negatively affect skeletal muscle's ability to maintain muscle mass and respond to other environmental stressors.

(No relevant relationships reported)

Skeletal muscle ion regulation may affect exercise tolerance during intense muscle work. However, the inter-play between different sarcolemmal ion transport proteins is not well described in trained skeletal muscle. **PURPOSE:** To examine associations between protein expression of Kir6.2, a key subunit of the ATP-sensitive K⁺ channel (K_{ATP} channel), and exercise performance, as well as different ion regulators and fiber type profile in trained skeletal muscle. **METHODS:** Seventeen competitive women soccer players (age; 23±4 yrs; height; 166±5 cm, weight; 60.2±7.5 kg; VO_{2max}; 50.5±5.1 ml·min⁻¹·kg⁻¹), participated. Participants has a muscle biopsy obtained from m. vastus lateralis. The Western Blot technique was applied to determine muscle protein expression of Kir6.2, different ion transporters involved in Na⁺, K⁺, Cl⁻, H⁺ and La⁻ sarcolemmal transport, a myriad of metabolic enzymes and muscle fiber type character. Finally, exercise performance capacity was assessed with a VO_{2max} test, a repeated sprint test (RST), as well as the Yo-Yo Intermittent Endurance, level 1 (YYIE1). Inter-individual relationships between selected variables were evaluated by Pearson's product-moment correlation coefficients. **RESULTS:** Muscle Kir6.2 and monocarboxylate transporter 4 (MCT4) correlated ($r=0.59$; $P<0.05$) with MCT4 explaining 35% of the variance in Kir6.2 protein. Moreover, the ratio of MCT4/Kir6.2 muscle protein expression correlated ($r=0.50$; $P<0.05$) to YYIE1 performance. Kir6.2 protein expression also correlated ($P<0.05$) with muscle Na⁺-K⁺ATPase β 1 and the FXDY1 subunits ($r=0.42$ and 0.50 , respectively). Kir6.2 correlated to the expression of Myosin Heavy Chain I (MHCI; $r=0.51$) and Phosphofructokinase (PFK) protein ($r=0.45$). In contrast, no relationship was observed between Kir6.2 and oxidative enzymes. Σ Na⁺-K⁺ATPase subunits correlated ($r=0.46$; $P<0.05$) to Kir6.2 protein expression. The sum of all ion transporters correlated to VO_{2max} ($r=0.58$), RST ($r=0.45$) and YYIE1 performance ($r=0.42$). **CONCLUSIONS:** Skeletal muscle K_{ATP} channel abundance appears to associate with the capacity to regulate ions such as H⁺ and K⁺. Moreover, the capacity to regulate ion homeostasis is associated with exercise tolerance in trained human skeletal muscle.

LINE-1 Retrotransposition Increases with Age in Rodent Skeletal Muscle

Pety W. Mumford¹, Matthew A. Romero¹, Shelby C. Osburn¹, Paul A. Roberson¹, Kaelin C. Young², Michael D. Roberts¹. ¹Auburn University, Auburn, AL. ²Edward Via College of Osteopathic Medicine-Auburn Campus, Auburn, AL.
Email: pwm0009@auburn.edu
(No relevant relationships reported)

Long interspersed nuclear element-1 (LINE-1 or L1) is termed a genomic parasite due to its ability to randomly copy and paste itself back into the genome. Studies have shown that L1 accounts for roughly 17-18% of the total human genome. However, due to various mutations in most of the L1 elements, only approximately 100 copies are functionally active. L1 has been shown to increase with age in mice skeletal muscle tissue. However, there is no data regarding the effects of aging on L1 activity in rat skeletal muscle tissue. **PURPOSE:** To identify the effects of aging on L1 expression in rat skeletal muscle tissue. **METHODS:** Sedentary male fischer 344 rats were fed ad libitum and were aged to 3, 12, and 24 months (mo) (n=9 per age group) and then sacrificed. Primer sets for qPCR were designed for the youngest most active form of L1 (L1.3), and older L1 elements (L1.Tot). Gastrocnemius skeletal muscle was harvested and then processed for RNA and DNA isolation. Thereafter, the following analysis ensued: L1 mRNA expression, L1 DNA copy number, L1 promotor methylation and ORF1 protein. Additionally, a subset of the tissues from 3 mo (n=8) and 24 mo (n=8) were shipped to LC Sciences for RNA sequencing to analyze L1 related genes. **RESULTS:** Primer sets designed for both L1.3 and L1.tot significantly increased with age (L1.3, $p=0.003$; L1.Tot, $p=0.003$), and was higher at 24 mo compared to 3 mo ($p<0.01$). L1.3 integration into the genome was significantly higher at 24 mo compared to 3 mo ($p=0.021$). ORF1 protein expression significantly increased with age ($p<0.001$), and was higher in both the 12 and 24 mo compared to 3 mo ($p<0.05$). There was no statistical difference for L1 promotor methylation. From RNA sequencing CTCF was significantly higher in 24 mo compared to 3 mo ($p=0.011$). **CONCLUSION:** L1 gene expression appears to increase with age, which leads to more random insertions back into the genome. This may be a result of an increase in

CTCF binding, acting as a co-activator at the L1 promotor, but this hypothesis needs validation. Additionally, L1 promotor methylation, while not statistically significant, was numerically lower with age and this decrease could be contributing to the increase in L1 gene expression. Thus, we provide novel insight as to how L1 gene regulation is altered with age, but more research is needed to test how L1 is affecting skeletal muscle health.

Exercise-induced Changes In Circulating Follistatin And GDF-15 Are Intensity- And Duration-dependent
 Melissa M. Markofski¹, Forrest L. Baker¹, Richard J. Simpson, FACSM², Nadia H. Agha¹. ¹University of Houston, Houston, TX. ²University of Arizona, Tucson, AZ.
 Email: mmarkofs@central.uh.edu
 (No relevant relationships reported)

Follistatin inhibits the actions of the TGFβ family to oppose inhibition of skeletal muscle growth, whereas growth and differentiation factor (GDF) 15 may inhibit muscle growth. The **PURPOSE** of this project was to determine if predominately aerobic exercise can induce changes in concentrations of circulating follistatin and GDF-15, and if these changes are dependent on exercise intensity and/or duration. **METHODS:** Fifteen recreationally trained young (28.3±2.0 years) males (n=8) and females (n=7) participated in two bouts of treadmill running: a vigorous intensity/short duration (ViSd) bout at +15% ventilatory threshold for 30 minutes and a moderate intensity/long duration (MiLd) bout at -5% ventilatory threshold for 90 minutes. Blood was collected pre-exercise, 15 minutes from the start of exercise, mid-exercise, and immediately, 1hr-, 2hr-, and 3hr-post exercise. Serum was analyzed with commercially available ELISA kits for follistatin and GDF-15.

RESULTS: At 15 minutes into the exercise bout follistatin was higher (p<0.0001) in MiLd (8.12±4.7 ng/mL) than ViSd (5.28±4.3 ng/mL), and GDF-15 was higher (p=0.0002) in MiLd (209.3±40.8 ng/mL) than ViSd (183.7±31.2 ng/mL). Follistatin was higher in ViSd 1hr post-exercise (MiLd 9.7±3.1 ng/mL vs. ViSd 12.1±7.3 ng/mL; p<0.0001), and higher in MiLd 2hr post-exercise (MiLd 11.2±3.4 ng/mL vs. ViSd 7.6±4.2 ng/mL; p0.0008) and 3hr post-exercise (MiLd 10.1±3.3 ng/mL vs. ViSd 8.8±4.9 ng/mL; p<0.0001). GDF-15 was higher in MiLd immediately post-exercise (MiLd 335.0±75.9 units vs. ViSd 193.5±34.0 units; p=0.0265), 1hr post-exercise (MiLd 461.0±84.7 ng/mL vs. ViSd 225.2±45.7 ng/mL; p<0.0001), and 3hr post-exercise (MiLd 338.2±70.2 ng/mL vs. ViSd 224.3±44.8 ng/mL; p<0.0001).

CONCLUSIONS: The differences at the 15 minutes into exercise time point suggest that the exercise-induced follistatin and GDF-15 response is intensity-dependent. The differences post-exercise imply that there may also be a duration effect. Intensity and duration need to be considered to increase follistatin in response to running.

1880 Board #36 May 30 2:00 PM - 3:30 PM
Effect of Mechanical Loading of Aged Myotubes on their Myogenic Lineage Progression and Apoptosis
 Athanasios Moustogiannis¹, Evangelos Zevolis¹, Orjona Taso², Antonios Chatzigeorgiou¹, Michael Koutsilieris¹, Anastasios Philippou¹. ¹National And Kapodistrian University of Athens, Athens, Attiki, Greece. ²University College London, London, United Kingdom.
 (No relevant relationships reported)

PURPOSE: The process of myogenesis is gradually declined and cells apoptosis increases with aging. However, mechanical loading of aged skeletal muscle can ameliorate its impaired myogenic and survival potential. Yet, the molecular responses of aged muscle cells to mechanical loading are still elusive. This study examined the effects of mechanical loading of aged differentiated myoblasts (myotubes) on the signaling and gene expression responses associated with the progression of their myogenic lineage and survival. **METHODS:** C2C12 myoblasts were cultured for 50 consecutive days (68 cell cycles) in order to acquire aging properties, while normal myoblasts were used as a control condition. Subsequently, control and aged C2C12 cells were cultured on elastic membranes until their 9th day of differentiation (myotubes) and then underwent a passive, cyclic stretching (2.2% elongation, at a frequency of 0.25Hz, for 12h). Phosphorylation of signaling proteins ERK1/2 and Akt, as well as the expression of the myogenic factor MyoD were determined by immunoblotting of cell lysates derived from stretched and non-stretched myotubes. Real Time-PCR was used to measure changes in expression levels of the myogenic regulatory factors (MRFs; MyoD, Myogenin, MRF4), growth factors (IGF-1 isoforms: IGF-1Ea, IGF-1Eb), apoptotic factors (Foxo, Fuca, p53) and atrophy factors (Murf1, Atrogin, Myostatin) in response to mechanical loading of the differentiated C2C12 cells. **RESULTS:** Mechanical loading of the myotubes resulted in significant activation of Akt and increase in MyoD protein levels (p<0.05). mRNA expression levels of IGF-1 isoforms (IGF-1Ea: 2.1-fold, IGF-1Eb: 1.2-fold) and MRFs (Myogenin: 11-fold, MRF4 1.2-fold) were increased significantly (p<0.05), while MyoD (0.8-fold), apoptotic factors (FOXO: 0.7-fold, FUCA: 0.3-fold, p53: 0.6-fold) and atrophy factors (Atrogin: 0.09-fold, Myostatin: 0.7-fold, Murf1: 0.09-fold) decreased (p<0.05).

CONCLUSIONS: Upregulation of myogenic and anabolic factors, along with the downregulation of apoptotic and atrophy factors by mechanical loading suggests an amelioration of myogenic and survival ability of the aged myotubes.

1881 Board #37 May 30 2:00 PM - 3:30 PM
Nutrients Stimulate Mitochondrial Biogenesis Via PGC-1α-targeting miRNAs In C2C12 Myotubes.
 Claudia Pérez López, Tsubasa Shibaguchi, Kazumi Masuda. Kanazawa University, Kanazawa, Japan.
 (No relevant relationships reported)

Purpose: Several studies have demonstrated that small nutrients, such as Caffeine (CAFF) and branched chain amino acids, especially Leucine (Leu), induce mitochondrial biogenesis through diverse mechanisms that converge in the activation of PGC-1α, leading to enhancing transcriptional activity and mitochondrial remodeling. Micro-RNAs (miRNAs) have been known to act as powerful negative modulators of gene expressions involved in essential cellular processes. Recent evidence suggests that miR-494, miR-696, and miR-761 are involved in mitochondrial biogenesis by negative modulation of PGC-1α signaling. However, it remains unclear whether these miRNAs are regulated individually or cooperatively by nutrients stimulation. Therefore, our study was focused on the effect of Leu and CAFF on these miRNAs functions and how it affected its downstream effectors, and ultimately, mitochondrial biogenesis. **Methods:** Following 5 days of differentiation period, C2C12 myotubes were treated with Leu (1 and 3mM) or CAFF (3mM) containing Dulbecco's modified Eagle's medium (DMEM) without serum and Leu for 24h. The serum and Leu-Free DMEM with a 2% H₂O was used as a control. After 24h of each treatment, the cells were harvested and then, DNA, RNA, and protein (whole fraction) were isolated for immunoblotting and qPCR analyses. Micrographs of four fields per condition were randomly captured before and 24h after treatment to measure myotube diameter. **Results:** Mitochondrial DNA copy number increased significantly 24h after Leu addition, and especially in the CAFF treatment (p < 0.05), compared with the control cells. Similarly, myotube diameter was significantly larger in two Leu-treated groups (≥ 20%, p < 0.05), as well as CAFF supplementation (~10%, p < 0.05), than in control and pre-treatment groups. PGC-1α protein level and phosphorylation rate of p70S6K were also augmented in both treatment groups. Conversely, miR-494, miR-696, and miR-761 levels were downregulated in the Leu-treated groups, but only miR-761 levels were decreased in the CAFF-treated group. **Conclusion:** These results suggested that nutrients such as Leu or CAFF can regulate the expression of PGC-1α-targeting miRNAs, which then leads to inducing mitochondrial biogenesis.

Changes In Phb1 Modulate Effects Of Different Exercise Modes On Skeletal Muscular Mitochondrial Function in rats
 Wen Fang¹, Ze Li², Hong Feng². ¹Tsinghua University, Beijing, China. ²Tianjin University of Sports, Tianjin, China.
 Email: fangwen5702175@163.com
 (No relevant relationships reported)

PURPOSE: ATP synthesis plays the most important role. ATP synthesis is closely related to the structural and functional integrity of mitochondria. To investigate the effects of PHB1 expression changes on skeletal muscle mitochondrial function in rats of different exercise modes. **METHODS:** 160 healthy male SD rats were randomly divided into four groups: normal control(NC), moderate intensity exercise(MIE), excessive fatigue exercise(EFE), and acute exhaustive exercise(AEE) groups. NC and AEE: routinely raised. MIE: 10 minutes per day at 10m/min for the first week and increased for 10 minutes every day until the end of the second week. From the third week, rats run at 15m/min for 60min every day until the end of the 8th week. Slope: 10%. EFE: From the first week of training, the speed of the running platform is 15m/min, increased by 5m/min per week to 30m/min. Training time is 30 minutes and increased by 20 minutes per week until 110 minutes. Slope: increase by 5% per week until 15%. The EFE and AEE groups were trained for 6 days per week for 8 weeks. AEE: The rats were subjected to acute exhaustive exercise after 8 weeks. They were killed after 48h of the last experiment. Mitochondrial respiratory control rate (RCR), ATP content, ROS level, complex V activity and PHB1 expression were measured. **RESULTS:** Compared with NC, in MIE group, RCR (+73%, P<0.001), ATP content (+48%, P<0.05), complex V activity (+79%, P<0.05), PHB1 expression (+42%, P<0.01) were increased, and ROS level (-75%, P<0.001) was reduced; In OFE group, RCR (-39%, P<0.01), ATP content (+50%, P<0.05), complex V activity (+293%, P<0.001), PHB1 expression (+28%, P<0.01) and ROS level (+62%, P<0.001) were increased; In AEE group, the RCR (-58%, P<0.05), ATP content (-55%, P<0.05), complex V activity (-56%, P<0.001), PHB1 expression (-31%, P<0.01) decreased, and ROS (+79%, P<0.05) level increased. Correlation analysis showed that PHB1 expression was positively correlated with ATP content in three groups. **Conclusion:** Changes in PHB1 expression were consistent with changes in mitochondrial function under different motion modes.

It is suggested that there may be interaction between PHB1 and ATP synthase. PHB1 participates in the stabilization of mitochondrial structure, changes mitochondrial function and affects the body's ability to exercise.

Resistance Exercise And Doxorubicin Treatment: Effects On Antioxidant Enzyme Expression In Type II Muscle
 Salaheddin Sharif¹, David S. Hydock¹, Kelsey A. Daehlin¹, Mackenzie D. Twaddle², Allison T. Tigner², Meghan K. Wagner², Eric C. Bredahl². ¹University of Northern Colorado, Greeley, CO. ²Creighton University, Omaha, NE.
 Email: salaheddin.sharif@unco.edu
 (No relevant relationships reported)

Doxorubicin (DOX) is a chemotherapy drug used to effectively treat a variety of cancers. Its clinical use, however, is limited by its toxicities commonly attributed to increased oxidative stress in cardiac and skeletal muscle. The DOX-induced rise in oxidative stress can overwhelm endogenous antioxidants yet exercise (both endurance and resistance) has shown promise in attenuating this decline. Little information, however, is available on how DOX and resistance exercise affect antioxidant enzymes in type II skeletal muscle. **PURPOSE:** To determine the effects of resistance training before and during DOX treatment on superoxide dismutase (SOD) 1 and SOD2 expression in the primarily type II extensor digitorum longus (EDL) muscle. **METHODS:** Thirty-six male Sprague-Dawley rats were randomly assigned to one of four groups: sedentary+saline (SSS), sedentary+DOX (SSD), resistance training+saline (RRS), or resistance training+DOX (RRD). The resistance training protocol incorporated a raised cage model where food and water were elevated progressively which provided hind limb loading 10 weeks prior to DOX injection and 4 weeks during DOX treatment. Groups treated with DOX received 3 mg/kg DOX weekly for 4 weeks (12 mg/kg cumulative), and saline-treated groups received 0.9% NaCl as a placebo. Five days following the final DOX or saline injection, EDL muscles were excised, and Western blotting was performed to quantify SOD1 and SOD2 expression. **RESULTS:** Although no significant drug effects, activity effects, or drug x activity interactions were observed with SOD1 and SOD2 expression ($P > 0.05$), a trend toward SSD expressing less SOD1 and SOD2 than SSS was observed (-25% and -37%, respectively). This same trend in SOD1 and SOD2 expression, however, was not observed in RRD (+3% and -3%, respectively vs SSS). **CONCLUSIONS:** The DOX dosing regimen used in the current study had no effect on SOD1 and SOD2 expression in the EDL muscle, and the resistance training protocol also did not affect SOD1 and SOD2 expression. These results suggest that resistance exercise may play a limited role in modulating oxidative stress of DOX in type II skeletal muscle.

Mechanisms Through Which Agents Of Muscle Fatigue, Acidosis And Phosphate, Inhibit Muscle Myosin Function.
 Mike Woodward, Edward P. Debold. *University of Massachusetts Amherst, Amherst, MA.*
 Email: mkwoodwa@kin.umass.edu
 (No relevant relationships reported)

PURPOSE: During muscle fatigue from intense activity, elevated concentrations of hydrogen ions (acidosis) and inorganic phosphate (Pi) inhibit muscle's ability to generate force and motion. However, it is not clear exactly how these metabolic by-products reduce the force and enzymatic function of muscle's molecular motor, myosin. **METHODS:** To determine these mechanisms we directly measured the effect of these fatigue agents on the force generating capacity of isolated myosin in a laser trap assay and on its ability to hydrolyze ATP in an ATPase assay. **RESULTS:** Acidosis (pH 7.4 vs. 6.5) in a mini-ensemble laser trap assay reduced myosin's average force production by 20% ($p < 0.05$) due to a slowed rate of actomyosin binding. This conclusion was supported by the observation that acidosis slowed myosin's ability to hydrolyze ATP by roughly 90% ($p < 0.05$) in a solution assay. By contrast elevated levels of Pi (0 vs. 10-15mM), in the presence of low pH (6.5), caused a similar reduction in force. However, this was likely due to an accelerated rate of myosin's detachment from actin, because myosin's ATPase rate also recovered back toward the control value (pH 7.4, no Pi) when Pi was added. **CONCLUSION:** Thus, these data provide unique insight into the molecular mechanisms that underlie the loss of muscle function during fatigue. In our current work we are using these findings to explore methods to mitigate these effects *in vitro* in a first step toward attenuating fatigue in diseases such as chronic heart failure.

Molecular Implications of Active and Passive Recovery Following High Volume Resistance Training

Christopher Vann¹, Cody Haun², Shelby Osburn¹, Matthew Romero¹, Paul Roberson¹, Petey Mumford¹, Carlton Fox¹, Jordan Moon³, Kaelin Young¹, Michael Roberts¹. ¹Auburn University, Auburn, AL. ²LaGrange College, LaGrange, GA. ³ImpediMed, Carlsbad, CA.
 Email: cgv0001@auburn.edu
 (No relevant relationships reported)

PURPOSE: Deloading is widely practiced in the strength and conditioning community as a method to augment recovery; however, there is little molecular signaling data to fully explain the details of why this practice is beneficial. **METHODS:** Recreationally-trained, college-aged males ($n = 30$) underwent 6 weeks of volume based training, after which the participants were split into active recovery (AR) and passive recovery (PR) groups with deload lasting 7 days. Participants donated a muscle biopsy from the vastus lateralis prior to week 1 (PRE), post training (POST), and post deload (DL). Protein expression for mTOR, AMPK, 4EBP1, and p70S6k was evaluated via western blotting. Additionally, blood was obtained via venipuncture, and serum levels of creatine kinase (CK), testosterone (TEST), and cortisol (CORT) were evaluated using commercially available assay kits. **RESULTS:** There was an effect of time for phosphorylated (p) 4EBP1 ($p = 0.014$) where PRE ($p = 0.003$) and POSTDL ($p = 0.004$) expression of p-4EBP1 were significantly higher than POST. CK activity also had an effect of time ($p = 0.016$) where CK at POST was significantly higher than at DL ($p = 0.007$). There was a significant group*time interaction of proteasome activity ($p = 0.040$) where post-hoc analysis revealed the AR group exhibited higher proteasome activity DL than the PR group ($p = 0.051$). Differences in protein expression for pan and phosphorylated mTOR, AMPK, p70S6K, and pan 4EBP1 were not significant ($p > 0.05$). Additionally, there were no significant differences in serum testosterone and cortisol levels ($p > 0.05$). **CONCLUSION:** AR may stimulate the PI3K/AKT pathway resulting in the phosphorylation of 4EBP1 potentially allowing hypertrophic adaptation to occur. Additionally, proteasome activity being upregulated with AR POSTDL may be beneficial in cleaving damaged protein structures. More research is needed to further investigate molecular signaling after deloading paradigms.

PGC-1/ERR-Induced Regulator in Muscle (PERM1) Increases Mitochondrial Respiratory Capacity in Culture Muscle Cells
 Trace Thome, Terence E. Ryan, Fabian F. Berru. *University of Florida, Gainesville, FL.*
 Email: trthome@ufl.edu
 (No relevant relationships reported)

Peripheral arterial disease is the third leading cause of death of atherosclerotic cardiovascular mortality in the United States and the incidence of PAD increases with age. Previous studies have shown that PAD displays impaired mitochondrial respiration, decreased expression of mitochondrial enzymes, increased oxidative stress, and mitochondrial DNA mutations within their ischemic limb muscles. We identified a potential transcriptional regulator of mitochondrial gene expression, PGC-1/ERR-induced regulator in muscle (PERM1) which is reduced 85% in patients with severe PAD. Interestingly, PERM1 regulates the expression of only a subset of genes induced by PGC-1a or ERRs expression in C2C12 myotubes, suggesting that PERM1 selectively functions in specific PGC-1/ERR-driven pathways. **Purpose:** The purpose of this study is to determine whether PERM1 is a potential gene target to aid in tissue recovery and regeneration from hypoxia in C2C12 myotubes. **Methods:** We generated AAVs to overexpress the PERM1 gene or a green fluorescent protein (ZsGreen1). Following AAV infection, C2C12 myoblasts were differentiated into mature myotubes for assessments of mitochondrial biogenesis, mitochondrial respiration, and myogenesis were performed. To determine if PERM1 plays a role in recovering myotube respiration and myotube atrophy from hypoxia, C2C12 myotubes infected AAV-PERM1 were placed in hypoxia for 6-hours and mitochondrial respiratory function, content, and myosin heavy chain area were assessed during the recovery from hypoxic insult. **Results:** AAV-PERM1 resulted in a ~16-fold increase in mRNA expression which drove a ~20% increase in complex I-supported respiration compared to the control cells ($P < 0.05$, $n=6$). Increased expression of PERM1 did not change the myotube fusion index (an indicator of myogenesis) ($P=0.32$, $n=4$). **Conclusion:** Our results indicate that PERM1 is a strong regulator of mitochondrial biogenesis in skeletal muscle cells, capable of increasing both mitochondrial content and respiratory function. Based on these observations, future studies should be aimed at understanding the therapeutic potential of PERM1 for improving muscle energetics in conditions with impaired muscle metabolism, including peripheral arterial disease. Partially supported by AHA Grant 18CDA34110044 to TER.

Xbp1 Promotes Skeletal Muscle Regeneration And Growth In A Cell Non-autonomous MannerKyle R. Bohnert¹, Ashok Kumar². ¹St. Ambrose University, Davenport, IA. ²University of Louisville, Louisville, KY.
(No relevant relationships reported)Kyle R. Bohnert^{1,2} and Ashok Kumar¹¹University of Louisville²St. Ambrose University

Purpose: Skeletal muscle exhibits a remarkable capacity for regeneration following injury. However, the molecular mechanisms governing skeletal muscle regeneration remain poorly understood. X-box binding protein (XBP1) is a downstream target of the endoplasmic reticulum (ER) stress inducer inositol-requiring enzyme 1 (IRE1). The purpose of this study was to determine the role of XBP1 in regulation of skeletal muscle regeneration and growth.

Methods: To investigate the role of XBP1 in the regulation of skeletal muscle regeneration and growth, we generated muscle-specific knockout (KO) mice of XBP1. Control and KO mice were then injected with 100 µl of 1.2% BaCl₂ into the tibialis anterior muscle to induce a necrotic injury. In a separate experiment, control and KO mice were subjected to the synergistic ablation model of overload hypertrophy of the plantaris muscle. Skeletal muscle was collected and analyzed using histological and biochemical techniques.

Results: Protein levels of XBP1 are increased in regenerating muscle fibers (1 ± 0.21 vs. 17.66 ± 13.9, p < 0.05). Moreover, genetic deletion of XBP1 inhibits regeneration due to reducing the number 2 or more centrally nucleated fibers (44.2 ± 2.8 vs. 30.7 ± 1.7, p < 0.05) and the number of satellite cells per 100 myofibers (26.5 ± 2.4 vs. 19.3 ± 1.4, p < 0.05). Furthermore, targeted ablation of XBP1 inhibits increases in cross-sectional area of myofibers due to a functional overload in adult mice (2266.3 ± 304.4 µm² vs. 1779.5 ± 150.9 µm², p < 0.05). Interestingly, XBP1 does not affect the rate of protein synthesis during muscle growth. Rather, deletion of XBP1 prevents skeletal muscle hypertrophy through reducing the total number of satellite cells per 100 myofibers (9.5 ± 1.1 vs. 5.8 ± 0.8, p < 0.05).

Conclusions: The results of the present study suggest that XBP1 is necessary for skeletal muscle regeneration and adult skeletal muscle hypertrophy. Furthermore, XBP1-mediated signaling in myofibers promotes satellite cell proliferation and fusion in a non-cell autonomous manner. More investigations are needed to further understand the mechanisms, especially gene network that XBP1 regulates during skeletal muscle formation and growth.

Effects of Obesity and Acute Resistance Exercise on Skeletal Muscle Intercellular Communication PathwaysRon T. Garner¹, Yaohui Nie², Shihuan Kuang², Timothy P. Gavin, FACSM². ¹Husson University, Bangor, ME. ²Purdue University, West Lafayette, IN.
Email: garnerr@husson.edu
(No relevant relationships reported)

Obesity (OB) disrupts cellular communication consistent with lower skeletal muscle capillarization. Exosomes, small microvesicles, transport and deliver mRNA, miRNA, and proteins in an endocrine manner and are released by muscle during aerobic exercise. The effects of resistance exercise (REX) on exosome biogenesis is unknown.

PURPOSE: Investigate if resistance exercise increases skeletal muscle exosome biogenesis pathways and if this response is impaired in obesity.

METHODS: Lean (LN) and obese (OB) (n=8/group) sedentary men and women performed 3 sets of 8-12 repetitions/set of acute, single leg knee extension resistance exercise at 80% of 1-RM. Vastus lateralis biopsies were obtained at rest and at 15 min, and 3 hr post-exercise. Muscle mRNA, protein expression, fiber typing, and capillary staining were measured.

RESULTS: The gene expression of the exosome biogenesis components hepatocyte growth factor-regulated tyrosine kinase (HGS) and vacuolar protein sorting mutant (VPS4a) were lower in OB than LN at rest (~25%) and at 15 min post- (~20%), but not 3 hr post-exercise. Expression of exosome surface markers apoptotic linked gene-2 interacting protein X (Alix) was lower (OB ~35% and LN ~20% 15min post-exercise) and tumor susceptibility gene-101 (TSG-101) was higher (OB ~50% and LN ~40% 3hr post-exercise) in response to REX in both groups. Acute resistance exercise increased vascular endothelial growth factor (VEGF) mRNA similarly in LN and OB. Interestingly, anti-angiogenic thrombospondin-1 (TSP-1) mRNA was increased by acute REX only in OB (~230% 3hr post-exercise). miR-130a (angiogenesis), miR-206 (myoblast to myotube differentiation) and miR-503 (repressor of cell proliferation) were increased in OB at rest and following exercise. Type II fiber size was greater and capillary density was lower in OB.

CONCLUSION: Obesity alters skeletal muscle exosome biogenesis, angiogenic, and muscle differentiation pathways possibly contributing to greater muscle fiber size and lower muscle capillarization. Resistance exercise alters skeletal muscle exosome marker expression similarly in both lean and obese.

Cancer Cachexia is a devastating syndrome that affects around 50-80% of cancer patients and is characterized by a rapid, drastic fat and muscle mass loss. The APC^{Min/+} mouse strain is a well-studied mouse model of human colorectal cancer and cancer cachexia. The branched-chain amino acid leucine is known to stimulate muscle growth/maintenance through activation of mTOR and protein synthesis.

PURPOSE: To examine the effects of chronic leucine supplementation on cancer cachexia development in APC^{Min/+} mice. **METHODS:** 7 APC^{Min/+} mice (APC) and 11 wild-type (WT) were used for this study. The animals were assigned to the following groups: WT no leucine (WTNL, n=5), WT leucine (WTL, n=5), APC^{Min/+} no leucine (APCNL, n=5) and APC^{Min/+} leucine (APCL, n=2). Mice were given ad libitum access to food and water. Mice in the leucine groups received 1.5% leucine-rich water. Plantaris muscles and tibias were excised at 20 weeks of age. Tissue was immediately frozen for morphology and gene expression analysis using RT-qPCR. **RESULTS:** The number of polyps increased in APC^{Min/+} compared to WT (46.57 ± 2.44 vs 0.00 ± 0.00). The number of polyps < 1 mm was increased (14.33 ± 1.45 vs. 7.75 ± 2.05) in APCL compared to APCNL (p<.05). There was a main effect for APC^{Min/+} to have lower body mass than WT (p<.0001). There was a main effect of genotype to decrease plantaris weight/tibia length in APC^{Min/+} mice vs. WT mice (p<.0001) and a main effect of leucine to decrease plantaris weight/tibia length in APC^{Min/+} mice (p<.05), which appeared to be driven by the APC (interaction p=.0841). There was an ~8-fold increase in *atrogin-1* gene expression in APCNL compared to WTNL (p<.05). *Atrogin-1* gene expression was ~7-fold lower in APCL compared to APCNL (p<.05). There was a main effect of genotype to increase *MuRF1* expression in APC^{Min/+} mice compared to WT (p<.05) and a main effect of leucine to decrease *MuRF1* expression (p<.05), which appeared to be driven by the APC genotype (interaction p=.0560). No difference was found in *MyoD* or *Myogenin* gene expression. **CONCLUSION:** The preliminary data suggest deleterious effects of leucine in cancer cachexia, which need to be affirmed by further studies. Based on gene expression of the E3 ubiquitin ligases, this loss in muscle mass may be independent of protein degradation.

(No relevant relationships reported)

Muscle antioxidant enzymes may be upregulated in parallel with increased exercise training status and capacity for reactive oxygen species (ROS) formation. **PURPOSE:** To examine associations between antioxidant protein expression and different physiological markers of endurance exercise in trained women athletes. **METHODS:** Seventeen competitive women soccer players (age; 23±4 yrs; height; 166±5 cm, weight; 60.2±7.5 kg; VO_{2max}; 50.5±5.1 ml·min⁻¹·kg⁻¹) participated. Participants had a muscle biopsy taken from m. vastus lateralis, which was analyzed for protein expression of superoxide dismutase 1 and 2 (SOD1 and 2), several metabolic enzymes and muscle fiber type profile. Participants also performed a VO_{2max} test, a repeated sprint test (RST), as well as the Yo-Yo Intermittent Endurance, level 1 (YYIE1) and Recovery test, level 1 (YYIR1). Inter-individual relationships between selected variables were analysed using Pearson's product-moment correlation coefficients. **RESULTS:** VO_{2max} and SOD2 correlated (P<0.05) with VO_{2max} explaining 24% of the variance in SOD2 protein expression. Myosin Heavy Chain I (MHCI) and IIa (MHCIIa) explained 26 and 25%, respectively, of the variance in SOD2 protein. Oxidative enzymes such as citrate synthase, isocitrate dehydrogenase and cytochrome

c oxidase correlated ($P < 0.05$) with SOD2 explaining 24, 31 and 17% of the variance, respectively. Finally, SOD2 protein expression correlated ($P < 0.05$) to monocarboxylate transporter 4 (MCT4; $r = 0.67$) and phosphofructokinase (PFK; $r = 0.62$). No statistical relationship was observed between SOD2 protein and neither $\text{Na}^+\text{-K}^+\text{ATPase}$ subunits, Na^+/H^+ exchanger, Acetyl-CoA carboxylase, PECAM-1, nor YYIE1, YYIR1 and RST performance. SOD1 protein expression displayed an inverse correlation with MHCIIa ($r = 0.61$; $P < 0.05$), but did not correlate with any other variable assessed in muscle or physical capacity. **CONCLUSIONS:** Skeletal muscle antioxidant capacity associates with markers of endurance exercise such as maximal aerobic power, type I and IIa muscle fibers, and mitochondrial function. However, strong relationships were additionally observed between antioxidant profile and lactate production as well as transport capacity, supporting a link between lactate and ROS generation.

Determining The Role Of Cellular Senescence In Skeletal Muscle Regeneration

Laura V. Young, Michel G. Arsenault, Craig S. Campbell, Kiera Rigby, Emma Moore, Alasdair Cameron, Adam P.W. Johnston. *University of Prince Edward Island, Charlottetown, PE, Canada.*

Email: lvyoung@upe.ca

(No relevant relationships reported)

Satellite cells drive skeletal muscle regeneration in response to injury, a process regulated by factors released into the local muscle environment. However, the cellular sources of this trophic support are poorly defined. In this regard, recent work on skin and bone repair has revealed a surprising supportive role for cells termed "senescent cells" which are commonly associated with aging and pathology. However, the role of senescence in skeletal muscle repair is currently unknown. The **PURPOSE** of this study is to determine the presence and contribution of senescent cells in skeletal muscle repair following acute injury. **METHODS:** The tibialis anterior (TA) of C57BL/6 mice was injured with cardiotoxin (CTX) and collected 5, 7, 10, 14, and 21 post-injury for histological/ immunohistochemical (IHC) and gene expression analysis. To examine the function of senescent cells during muscle repair, mice were treated with a senolytic compound (ABT-263) following injury to selectively ablate senescent cells. **RESULTS:** Senescent cell number (as revealed using the senescence-associated beta-galactosidase (SA- β -gal) assay) increased significantly following injury ($p < 0.05$) and returned to baseline by day 21 post-injury, a time-course that is coincident with the repair process. In agreement with this, qPCR analysis of putative senescence pathways including p16 and p21 and p53 as well as secreted factors commonly secreted by senescent cells such as IL1 and MMP13 were significantly upregulated in injured compared to control tissue ($p < 0.05$). Preliminary IHC analysis demonstrated that at 5 days post-injury, 58% of senescent cells were positive for macrophage marker F480, while at 10 days post-injury, 43% of senescent cells were F480+ and 9% were CD31 positive; an endothelial cell marker. Identification of other cell types is under investigation. Senolytic treatment was effective at removing senescent cells as a significant 44% reduction in the number of SA- β -gal+ cells was observed, the consequences of which on muscle repair are currently under analysis. **CONCLUSION:** Senescent cells are a newly identified component of the muscle repair environment which may influence skeletal muscle repair and satellite cell function.

Skeletal Muscle Stress Protein mRNA Response to Aerobic Exercise in Different Environmental Temperatures

Megan J. Johnson, Rebecca L. Cuthbert, Robert J. Shute, Dustin R. Slivka, FACSM. *University of Nebraska Omaha, Omaha, NE.*

(Sponsor: Dustin R. Slivka, Ph.D., FACSM)

(No relevant relationships reported)

Stress proteins protect skeletal muscle from internal and external stress. Heat shock proteins respond to temperature, exercise and oxidative stress. Cold shock proteins respond to temperature and hypoxia in animals or in cell cultures but have not been studied in humans. The response of cold shock proteins to exercise and physiologically-relevant environmental temperature in human skeletal muscle is not known. **PURPOSE:** The purpose of this study was to determine the early mRNA response of human cold shock and heat shock stress proteins to endurance exercise and environmental temperatures. **METHODS:** Seven recreationally trained males (age: 24 ± 1.2 years; height: 178 ± 1.7 cm; weight: 76.8 ± 1.9 kg; $\text{VO}_{2\text{peak}}$: 4.5 ± 0.2 $\text{L}\cdot\text{min}^{-1}$; W_{peak} : 290 ± 7.8 W) cycled for 1 hour at 60% W_{peak} in 7 °C, 20 °C, and 33 °C environmental temperature. Gene expression for heat shock and cold shock proteins were analyzed using qRT-PCR on muscle biopsy samples taken from the *vastus lateralis* pre- and 3 hours post-exercise. **RESULTS:** RBM3 mRNA was reduced 1.43 ± 0.10 fold ($p = 0.006$) and there was a trend for CIRP to decrease 1.27 ± 0.14 fold (p

$= 0.059$) from pre- to 3 h post-exercise. CIRP and RBM3 mRNA were not different between temperatures ($p = 0.273$ and $p = 0.686$, respectively). HSP70 mRNA was 2.27 ± 0.23 fold higher 3 h post-exercise when compared to pre-exercise ($p = 0.002$) but was not significantly different between temperatures ($p = 0.103$). HSP27, HSP90, and HSF1 mRNA did not change from pre- to post-exercise ($p = 0.052$, $p = 0.324$, $p = 0.795$) and were not different between temperatures ($p = 0.247$, $p = 0.134$, $p = 0.808$). **CONCLUSIONS:** These data indicate that exposure to mild heat and cold during aerobic exercise have limited effect on the skeletal muscle mRNA expression of heat shock and cold shock proteins. However, this novel study found cold shock protein mRNA of skeletal muscle decreases, whereas HSP70 mRNA increases in response to a low to moderate intensity aerobic exercise bout. Supported by the National Institute for General Medical Science, Nebraska IDeA Networks for Biomedical Research Excellence (INBRE), and the University of Nebraska at Omaha Committee on Research and Creative Activity.

Purpose: It is well known that "Exercise is Medicine". Exercise is a publically recognized and effective intervention strategy for a series of chronic diseases including obesity, diabetes, sarcopenia, and aging-related cognitive dysfunction. However, its molecular mechanisms for the beneficial prevention and treatment of chronic diseases and health promotion have not been systematically explored and elucidated. Since autophagy has been gained extensive attention in the field of medical science, the Nobel Prize in Medicine has been awarded to Yoshinori Ohsumi in 2016 as the pioneer scientist due to his achievements of autophagy in the prevention and treatment of diseases, health promotion, anti-aging, and lifespan extension. Therefore, elucidating the mechanisms of chronic diseases through exercise-induced autophagy and exploring its potential applications are highly desired.

Methods: A series of animal models were established for evaluating exercise intervention efficacy of chronic diseases, and exploring the underlying mechanisms and potential applications through western blotting, RT-PCR and TSM techniques.

Results: Our studies have confirmed that appropriate exercise intervention is a promoter of autophagy, which can rescue the dysfunctional status of autophagy and abnormal mitochondrial energy metabolism in chronic diseases. The autophagy or microRNA-mediated autophagy regulates insulin sensitivity and increases mitochondrial quality control, thereby realizing the prevention, treatment and rehabilitation of chronic or aging-related diseases.

Conclusion: Exercise-induced autophagy is benefit for the prevention and treatment of chronic diseases and health promotion. These promising studies also provide clear targets to develop novel drug candidates, food supplements, or mimic exercise pills for the prevention and treatment of chronic diseases, and health promotion.

Mitochondrial Ant2 And Ucp2 Expression In Mouse Liver During Colon-26 Tumor-induced Cachexia

Adrianna J. Castro, Gabriel S. Pena, Hector G. Paez, Jessica L. Halle, Nishant P. Visavadiya, Michael C. Zourdos, Michael A. Whitehurst, FACSM, Andy V. Khamoui. *Florida Atlantic University, Boca Raton, FL.*

(No relevant relationships reported)

Cancer cachexia is a life-threatening paraneoplastic condition characterized by unintended weight loss and skeletal muscle atrophy. Recent frameworks describe cancer cachexia as a systemic disease in which several non-muscle organs are reprogrammed or remodeled. The liver exerts major control over systemic metabolism yet has been relatively unexplored in cancer cachexia. Previous reports indicate loss of oxidative phosphorylation (OXPHOS) coupling efficiency in the cachectic liver, through currently undefined mechanisms. **PURPOSE:** To investigate mitochondrial Ant2 and Ucp2 expression in the liver during colon-26 tumor-induced cachexia, and their relationship to OXPHOS coupling efficiency. **METHODS:** Balb/c males (10 wks) were assigned to receive an injection of sterile PBS or 10^6 colon-26 (C26) tumor cells. Tissues were collected from PBS-injected weight-stable mice (PBS-WS), C26 mice that were weight-stable (C26-WS), and C26 mice with moderate (10% weight loss, C26-MOD) and severe cachexia (20% weight loss, C26-SEV) ($n = 4-7$ per group). The liver was analyzed by high-resolution respirometry and immunoblotting to determine mitochondrial respiration and protein expression, respectively. Citrate

synthase activity was assayed as a proxy for mitochondrial density. The respiratory control ratio (RCR), an index of OXPHOS coupling efficiency, was determined in the complex I-linked state. **RESULTS:** RCR was ~25-60% lower in all C26 groups compared to PBS-WS ($p<0.05$). C26-SEV also had lower RCR than C26-MOD ($p<0.05$). Together this may signify an early loss of liver OXPHOS coupling efficiency due to cancer, that subsequently worsens when severe cachexia develops. Citrate synthase activity was not different between groups ($p>0.05$), suggesting the impairment of respiratory function to be independent of mitochondrial mass. Ucp2 expression was not different between groups ($p>0.05$). However, Ant2 expression was greater in C26-SEV compared to PBS-WS, C26-WS, and C26-MOD, by 15-30% ($p<0.05$). Ant2 expression related inversely with RCR in the liver ($r=-0.547$, $p<0.05$), implying higher liver Ant2 content to be associated with uncoupling of OXPHOS. **CONCLUSION:** We highlight an under-recognized role of liver mitochondria in cancer cachexia, and suggest hepatic mitochondrial function to be a therapeutic target.

Leptin Gene Polymorphism, Plasma Leptin Levels And Aerobic Capacity In Response To Intense Exercise

Tamara P. Mancilha, Cyntia F. Oliveira, Magna C.F. Passos, Josely C. Koury. *RIO DE JANEIRO STATE UNIVERSITY, Rio de Janeiro, Brazil.*
Email: tamara.mancilha@hotmail.com
(No relevant relationships reported)

PURPOSE: The aim of the present study was to determine the association between single nucleotide polymorphisms (SNPs) in the leptin (LEP) and leptin receptor (LEPR) genes, and body composition, plasma leptin levels, and aerobic capacity in response to 48 h of intense exercise.

METHODS: Male Brazilian Army cadets ($n=163$; 21.6 ± 0.4 years) were genotyped for the LEP 19G>A (rs2167270) and -2548G>A (rs7799039), and LEPR 668A>G (rs1137101) polymorphisms. Anthropometric, hormonal and aerobic capacity parameters were measured 48 h after intense military exercise.

RESULTS: Sixty-seven percent of participants were classified as having superior aerobic conditioning ($VO_{2max}=55.2\pm 0.2$ mL·kg⁻¹·min⁻¹), and had lower plasma leptin levels (36%, $P=0.008$) than subjects classified as having excellent aerobic conditioning. Considering all subjects VO_{2max} correlated negatively with fat mass ($r=-0.212$; $P=0.007$), whereas plasma leptin level correlated positively with body fat ($r=0.642$, $P=0.005$) and fat mass ($r=0.723$, $P=0.001$), and negatively with VO_{2max} ($r=-0.223$, $P=0.005$). Only individuals homozygous for the wild-type homozygote for LEP -2548G>A SNP had higher plasma leptin values (59%), body fat (85%), and fat mass (82%) ($P<0.05$) compared to those with a GA genotype. LEP -2548G>A SNP was a positive predictor for plasma leptin levels ($B=-0.217$, $P=0.02$), after adjusting for fat mass, and therefore, genotype effects may affect leptin levels.

CONCLUSIONS: Polymorphism in the leptin promoter gene may influence plasma leptin levels, but not aerobic capacity, in response to intense physical exercise. Additional studies are needed to show the precise contribution of the SNPs on aerobic capacity. Financial support FAPERJ.

(No relevant relationships reported)

Dual energy X-Ray absorptiometry (DXA) determined lean tissue mass has long been regarded as a criterion method for determining and monitoring changes in whole body and appendicular skeletal muscle mass. However, its utility is limited and restrictive due to patient size limitations, cost, specialized operator training and patient radiation exposure. **PURPOSE:** Herein, we sought to compare measurements of whole-body fat free tissue mass (FFTM) determined by a new standing bioimpedance spectroscopy

(BIS) device as well as DXA before and after six weeks of progressive resistance training. **METHODS:** Twenty-three resistance-trained males (mean \pm SD, age: 21.6 ± 2 , height: 178.4 ± 7.8 cm, weight: 80.9 ± 10.5 kg) underwent six weeks of resistance training. DXA (Lunar Prodigy iDXA, G.E.) and BIS (SOZO, ImpediMed Inc.) were administered pre and post-intervention with participants in a fasted and normally-hydrated state wearing a t-shirt and athletic shorts for determination of whole body FFTM. Agreement between methods for determination of whole body FFTM at each time point and across time were determined by Bland and Altman plot analysis (mean difference and 95% limits of Agreement), bivariate linear regression analysis and dependent samples t-tests with statistical significance set at $p\leq 0.05$. **RESULTS:** Bland and Altman plot analysis revealed good agreement between methods producing a mean difference and 95% LOA of 1.9 ± 2.3 kg, respectively. Regression analysis revealed a strong and significant relationship ($r=0.96$, $r^2=0.92$, $SEE=2.2$ kg, $p<0.001$) between DXA and BIS-derived FFTM. Both DXA and BIS-derived FFTM significantly ($p<0.001$) increased post-training (pre vs post, 63.2 ± 7.9 vs 65.8 ± 7.4 and 65.2 ± 8.3 vs 67.6 ± 7.2 kg, respectively). Importantly, mean FFTM delta scores were not statistically different between DXA and BIS (2.6 ± 1.4 vs 2.4 ± 2.6 kg, $p=0.57$). Furthermore, regression analysis revealed a significant relationship between DXA and BIS-derived FFTM delta scores ($r=0.72$, $r^2=0.52$, $SEE=1.01$ kg, $p<0.001$). **CONCLUSIONS:** BIS-derived FFTM agrees well with DXA-derived FFTM for single measurements as well as following resistance training-induced skeletal muscle hypertrophy and is an accurate and acceptable alternative to DXA.

Body Composition and Aerobic Capacity in NCAA Division I Cross-country Athletes Across a Season

Takudzwa A. Madzima, Svetlana Nepocatykh, Daniel A. Baur, Kirtida Patel, Walter R. Bixby, FACSM. *Elon University, Elon, NC.*
Email: tmadzima@elon.edu
(No relevant relationships reported)

Body composition has several implications for the overall health and performance of athletes. Changes in body composition can serve as indication of the physical demands of a competitive season as well as provide valuable feedback of the training adaptations from different training regimens. **PURPOSE:** To evaluate the pre- to post-season changes in body composition and maximal aerobic capacity in male (MXC) and female (WXC) Division I cross-country athletes. **METHODS:** Eleven MXC (age: 18 ± 1 yrs; body fat: $9.8\pm 4\%$) and 13 WXC (age: 18 ± 1 yrs; body fat: $19.8\pm 4\%$) participated. Body composition [(lean mass, LM; leg lean mass (LLM); fat mass, FM, body fat% and bone mineral density, BMD) were measured pre- and post-season by DXA. Regional BMD of the total body, lumbar spine (L1-L4), hip (femur), LM and FM were obtained for analysis. The appendicular skeletal muscle adjusted by squared height (ASM index; kg/m²) and the lean mass index (LMI = (LMpost-LMpre)/(FMpre-FMpost)) were calculated to assess body composition changes. A self-paced maximal oxygen uptake (VO_{2MAX}) test was used to assess aerobic capacity. Participants completed 5 \times 2-min stages at a self-selected speed for each stage corresponding to ratings of perceived exertions of 11, 13, 15, 17 and 20, respectively. ANOVAs were used for analysis with significance accepted at $p<0.05$. **RESULTS:** Total body LM increased significantly in both MXC and WXC, with MXC increasing to greater extent than WXC ($+1.37\pm 0.9$ vs $+0.56\pm 0.9$ kg; $p<0.05$). The ASM and LLM increased significantly in both MXC and WXC from pre- to post-season ($p<0.05$), with no differences between genders. Further, the LMI did not differ between groups ($+2.15\pm 3.9$ vs $+1.33\pm 3.7$ kg). There were no gender by time and no time effects for FM, body fat% and regional BMD. There were no pre- to post-season changes in VO_{2MAX} for both MXC (70.3 ± 4.3 to 69.5 ± 3.9 ml/kg/min) and WXC (56.6 ± 3.9 to 58.3 ± 5.3 ml/kg/min). **CONCLUSIONS:** Results suggest highly trained cross-country athletes experience positive changes in total and regional LM with no changes in FM, body fat% and BMD. Aerobic capacity was maintained across the season despite increases in LM. Results highlight the seasonal changes in body composition in collegiate distance runners that may inform strength and conditioning coaches and athletic trainers.

Low Carbohydrate Diet On Body Composition Of Trained Crossfit Individuals

Andreia Naves, Mariane Iori, Renata Carnauba, Ana Beatriz Baptistella. *VP Research Institute, São Paulo, São Paulo, Brasil.*
Email: andreia.naves@vponline.com.br
(No relevant relationships reported)

Effects of low carbohydrate diet on body composition of trained Crossfit individuals

Purpose: To evaluate the influence of low carb diet on body composition of trained individuals. **Methods:** Twenty eight CrossFit practitioners (M:13, W:15, age range: 19-59 years) for at least 6 months followed a personalized diet plan for 2 months. The diet had 27% of energy from carbohydrate, 50% of energy from fat and 23% of energy from protein, and consisted of 5 meals per day, comprising mainly of fruits and vegetables, complex carbohydrates (cereals and tubers) and animal proteins (red meat limited to 3 times/week). The body weight was measured to the nearest 0.01 kg using electronic scales and body composition (including percent body fat, muscle, and fat mass) was evaluated by portable ultrasound during the days 1, 30 and 60 of the dietetic program. The collected measures were chest, triceps, subscapular, medial axillary, suprailiac, abdomen and medial thigh. The equations developed by Jackson and Pollock were used for the calculation of body density. Waist and hip circumference were also measured. Samples were tested for normal distribution and groups were compared by either paired Student's t-test or Mann-Whitney test. The type I error was set at $p < 0.05$. **Results:** There was a significant reduction in body weight and hip circumference after 30 (weight: 79.8 ± 15.4 vs 77.5 ± 14.4 , $p < 0.001$; hip circumference: 107.6 ± 6.9 vs 104.9 ± 7.3 , $p = 0.007$) and 60 days (weight: 79.8 ± 15.4 vs 77.0 ± 14.6 , $p < 0.001$; hip circumference: 107.6 ± 6.9 vs 105.58 ± 8.3 , $p = 0.007$) of dietary intervention. Additionally, was observed a significant reduction of total fat and %body fat after 30 (total fat: 23.8 ± 16.1 vs 20.4 ± 15.6 , $p = 0.004$; % body fat: 25.1 ± 6.5 vs 21.5 ± 5.3 , $p < 0.001$) and after 60 days (total fat: 23.8 ± 16.1 vs 19.9 ± 15.3 , $p < 0.001$; %body fat: 25.1 ± 6.5 vs 20.0 ± 5.5 , $p < 0.001$) and a significant gain of body fat-free mass after 60 days (59.1 ± 12 vs 60.9 ± 13 , $p = 0.01$). When subgroup analyses were performed by sex, it was found that the relative loss of body fat was similar. Thus, there was no difference between lean mass gain between men and women. **Conclusion:** The low carbohydrate diet promoted body weight, total fat and % body fat reduction and fat-free mass gain, independently of sex, after 30 and 60 days, in trained Crossfit individuals.

Body Composition and Muscle Contractile Properties in Male Professional Soccer Players
 Ashley Jones¹, Karen Hind², Ian Entwistle¹, Hannah V. Wilson¹, Peter Francis¹. ¹Musculoskeletal Health Research Group, Leeds, United Kingdom. ²Wolfson Research Institute, Durham, United Kingdom.
 Email: Ashley.D.Jones@leedsbeckett.ac.uk
 (No relevant relationships reported)

PURPOSE: Lower limb muscle injury accounts for >50% of all injuries in professional soccer. Despite this, there is an absence of body composition and muscle function reference ranges in professional players. The purpose of this study was to generate lower limb reference ranges for lean tissue mass (LTM) and muscle contractile properties, which could be used to monitor associations with injury risk in prospective cohort studies. **METHODS:** Professional soccer players ($n=193$; age: 21.6 ± 4.4 years, height: 180.2 ± 10 cm, weight: 78 ± 11.2 kg), free from illness and injury, from the English Soccer League participated in this study. Whole body and lower limb LTM ($n=130$) was estimated using Dual X-Ray Absorptiometry (DXA; Lunar iDXA™, GE Healthcare, WI). Lower limb (Adductor Magnus (AM), Bicep Femoris (BF), Gastrocnemius Lateralis (GL), Gastrocnemius Medialis (GM), Gluteus Maximus (GT) and Rectus Femoris (RF) muscle contractile properties ($n=193$) were assessed using Tensiomyography (TMG); GK 40, Panoptik d.o.o., Ljubljana, Slovenia). Maximal muscle displacement (Dm) and contraction time (Tc) were estimated for all muscles. **RESULTS:** Soccer players were homogenous in whole body (76.7 ± 8.8) and lower limb (21.7 ± 2.5 kg) LTM. Midfielders had lower RF-Tc than Goalkeepers (29.2 ms vs 32.8 ms; $P=0.034$). Forwards had lower GT-Dm than Defenders (9.1 mm vs 10.7 mm; $P=0.042$). There was no difference in lower limb LTM or contractile properties between dominant and non-dominant limbs ($P > 0.05$). Increasing lower limb LTM was associated with a reduction in Dm (right= $-.375$, left= $-.394$; $P < 0.05$). Lower limb muscle contractile properties normalised to lower limb LTM were higher in forwards compared to other outfield playing positions ($P < 0.05$). **CONCLUSIONS:** Our findings suggest players are homogenous in terms of the total amount of LTM and contractile function regardless of leg (dominant vs. non-dominant) studied. Differences in muscle contractile properties between playing positions may represent differences in positional demands. Increasing LTM might have been expected to produce increasing Dm; however, an increase in LTM is associated with an increase in non-contractile tissue that may lead to an overall reduction in contractile mass.

Electromyographic Evidence of Excessive Achilles Tendon Elongation During Isometric Contractions After Achilles Tendon Repair
 Malachy P. McHugh, FACSM, Karl F. Orishimo, Ian J. Kremenec, Julia Adelman, Stephen J. Nicholas. *Nicholas Institute of Sports Medicine and Athletic Trauma, Lenox Hill Hospital, New York, NY.*
 Email: mchugh@nismat.org
 (No relevant relationships reported)

PURPOSE: Increased tendon elongation after Achilles repair is thought to contribute to selective weakness in end-range plantarflexion (PF). Excessive tendon elongation during maximum voluntary contraction (MVC) means greater muscle fiber shortening. Since mean frequency (MF) of the electromyogram (EMG) increases with decreasing fiber length, it was hypothesized that MF would be higher on the involved (Inv) versus non-involved (Non) side during isometric PF MVCs. The purpose of this study was to examine MF during isometric MVCs in patients with Achilles tendon repairs. **METHODS:** Isometric PF MVC was measured at 20°, 10°, 0° dorsiflexion (DF), and 10°, 20° PF, in 17 patients (age, 39 ± 9 years; 15 men, 2 women) 43±24 months after surgery. Surface EMG signals were recorded during MVCs. MF was calculated from Fast Fourier Transforms of medial gastroc (MG) lateral gastroc (LG) and soleus (S) EMG signals. Effect of weakness on MF was assessed using analysis of variance. **RESULTS:** Patients had weakness in 20° PF (deficit $28 \pm 18\%$, $P < 0.01$; 14 of 17 deficit >20%) but no weakness in 20° DF (deficit $8 \pm 15\%$, $P = 0.20$; 4 of 17 deficit >20%). MF increased moving from DF to PF ($P < 0.001$) but was not different between Inv and Non ($P = 0.22$). At 10° PF 8 of 17 patients had weakness (>20% deficit). MF was significantly higher on Inv versus Non, across all angles, in patients with weakness versus no weakness at 10° PF (side by group $P = 0.014$; Table 1). MF was 13% higher on Inv versus Non in patients with weakness ($P = 0.012$) versus 3% lower in patients with no weakness ($P = 0.47$). **CONCLUSIONS:** Higher MF for Inv versus Non in patients with PF weakness is consistent with greater muscle fiber shortening. This indicates that weakness was primarily due to excessive lengthening of the repaired Achilles tendon. If weakness were simply due to atrophy, a lower MF would have been expected.

| Table 1 | MG MF (Hz) | | | S MF (Hz) | | | LG MF (Hz) | | |
|--------------|------------|--------|---------|-----------|--------|---------|------------|--------|---------|
| | Inv | Non | Inv/Non | Inv | Non | Inv/Non | Inv | Non | Inv/Non |
| Weak (n=8) | 193±34 | 169±34 | P=0.02 | 181±21 | 168±23 | P=0.13 | 185±47 | 157±27 | P=0.04 |
| Strong (n=9) | 165±31 | 170±23 | P=0.63 | 165±20 | 168±24 | P=0.70 | 154±26 | 162±38 | P=0.54 |

Spatial Resolution Of The Medial Gastrocnemius Mechanomyograph Resolved By Time-frequency And Principle Pattern Analysis
 William J. Armstrong. *Western Oregon University, Monmouth, OR.*
 (No relevant relationships reported)

PURPOSE: The purpose of the present study was to examine the mechanomyograph of the medial gastrocnemius spatially using a grid of nine accelerometers during electrically-invoked contractions. **METHODS:** 16 (8M, 8F) moderately-active volunteers (mean age = 21 ± 3 y) with measurable H-reflexes participated. The tibial nerve was stimulated in 2V increments with 10-second rest intervals, and data where the peak-to-peak M-wave amplitude exceeded the H-reflex were analyzed. Peak-to-peak MMG (MMG_{pp}) data were subjected to the intensity analysis, and total intensity, the peak total intensities (Max), and time to Max (TTMax) were determined. Maps of the dependent variables were plotted across a 9-accelerometer grid for each stimulus for each participant to be analyzed. The MMG intensity analyses were subjected to a principle pattern analysis (p-space) and p-values ($P, n = 5$) were compared intra-subject. Pearson's r among the dependent variables and repeated measures ANOVA were calculated for P, MMG_{pp}, Max, and TTMax, by stimulus (Stim) and accelerometer (ACC) using R open source software (www.r-project.org). Statistical significance was set at $\alpha = 0.05$. **RESULTS:** A significant correlation existed only for MMG_{pp} and Max ($r = 0.9434$, $p < 0.0001$). RM-ANOVA demonstrated significant effects of Stim for MMG_{pp} and Max; ACC for MMG_{pp}, Max, and TTMax; and Stim by ACC for TTMax ($p < 0.001$). Progression of the MMG acceleration maps varied across individuals and ACCs. P-space analysis revealed significant differences between p-values for all participants ($p < 0.001$), significant effects for ACC ($p < 0.01$) in

eight participants, and Stim ($p < 0.05$) in five participants. In addition, there were significant interactions for Stim by P ($n = 6$, $p < 0.01$) and ACC by P ($n = 1$, $p < 0.01$). **CONCLUSIONS:** MMG varies spatially for the medial gastrocnemius and between individuals. Mapping the MMG acceleration may allow researchers to identify characteristic differences among individuals, as well as individual muscles (e.g., soleus). More research is suggested to identify such differences.

Effect Of Ballet Dance On Knee Joints Muscle Strength Based On The Isokinetic Research

Rou Wen¹, Jingjing Xue², Yanjing Ren¹, Mi Zhang¹, Jing Li¹.
¹Beijing Dance Academy, Beijing, China. ²China Institute of Sport Science, Beijing, China.
 Email: rouwen66@sina.com
 (No relevant relationships reported)

PURPOSE: Several researches have revealed that dance training increases muscle strength. By comparing the muscle strength of knee joints of ordinary college students with ballet dance students', the differences between the two groups were analyzed and the influence of dance on muscle strength was explained.

METHODS: 48 healthy college students volunteered to participate in the study. Experimental group consisted of 24 Ballet students (12 male, 21.5±0.9years; 12 female, 20.9±1.8years); control group consisted of 24 non-dance students (12male, 20.7±0.9years, 12 female, 20.6±0.8years). German ISOMED2000 Isokinetic test device was used to test the knee joints strength of all participants, with the concentric contraction test going first and then following the eccentric contraction test, with the testing angular of 60°/s, 180°/s. The test variables include peak torque, relative peak torque and the peak torque ratio of flexion and extension. **RESULTS:** The result showed that the female and male Ballet students have significantly higher peak torque (N·m) and relative peak torque (Nm/Kg) at all angular of knee flexion and extension than non-dance students (All peak torque flexion at 60°/s and 180°/s: 81.805±10.84 vs. 58.725±7.34 and 68.055±9.22 vs. 46.875±8.78; both $p < 0.01$. All peak torque extension at 60°/s and 180°/s: 178.335±25.88 vs. 124.2±19.54 and 128.465±14.96 vs. 92.505±16.41; both $p < 0.01$. All relative peak torque flexion at 60°/s and 180°/s: 1.29±0.14 vs. 1.02±0.14 and 1.08±0.14 vs. 0.81±0.13; both $p < 0.01$. All relative peak torque extension at 60°/s and 180°/s: 2.84±0.43 vs. 2.17±0.38 and 2.04±0.25 vs. 1.61±0.28; both $p < 0.01$). However, there is no significant difference in peak torque ratio of flexion and extension between two groups ($P > 0.05$).

CONCLUSIONS: The results indicated that long-term ballet training can obviously improve the control strength and outbreak power of knee flexion and extension. Ballet training leads to a balanced effect impact on hamstring and quadriceps, which helps to avoid knee injuries and improve the dance movements. **Acknowledgements:** This work was supported by Beijing philosophy and social science foundation research (Grants No.14JDWYB011).

Ankle Related Musculotendinous Stiffness in Individuals With and Without Chronic Ankle Instability

Kyeongtak Song, Troy Blackburn, Erik A. Wikstrom, FACSM.
 University of North Carolina at Chapel Hill, Chapel Hill, NC.
 Email: ktsong@email.unc.edu
 (No relevant relationships reported)

Chronic ankle instability (CAI) is a multifaceted condition linked to life-long residual symptoms and post-traumatic ankle osteoarthritis. Musculotendinous stiffness (MTS) is a vital component of joint stability but to date, only passive joint stiffness has been quantified in those with CAI. **PURPOSE:** To compare ankle related musculotendinous stiffness between CAI patients and uninjured controls. **METHODS:** 20 CAI (18F, 2M; 20±1 years, 172±7cm, 68±13kg) and 20 uninjured healthy controls (18F, 2M; 20±1 years, 69±8cm, 60±8kg) volunteered to participate. CAI participants had experienced at least one lateral ankle sprain (3±1 sprains), at least two episodes of giving way within the past 6 months (6±4 episodes), ≥ 11 on the Identification of Functional Ankle Instability, $\leq 90\%$ on the Foot & Ankle Ability Measure (FAAM) (87.3±8.9%), and $\leq 80\%$ FAAM-Sport (73.3±14.9%). Active plantar flexor and peroneal muscle stiffness were estimated using the damped oscillation method. Participants were seated on a custom-made loading device with the hip, knee, and ankle joints at 90°. Participants were instructed to maintain the ankle in a neutral position by activating the plantar flexors or evertors isometrically to a level only strong enough to support the applied load which was adjusted to produce 30 ± 5% MVIC. A perturbation was then applied by dropping a ball onto the loading device from the height of 110cm in order to produce the series of oscillations of the shank about the ankle. Torsional stiffness (k) was calculated using the equation $k = 4\pi^2 r^2 m f^2$, where f is the damped frequency of oscillation, r is the system radius, and m is the total mass of the system. Independent t-tests assessed group differences with an alpha level of $p < 0.05$. **RESULTS:** Plantar flexor stiffness was lower in CAI group (123.6 ± 20.5 N/m/kg) compared to healthy control (141.6 ± 28.0 N/m/kg) group ($p = 0.04$). However, there was no difference in peroneal muscle stiffness between CAI (5.85 ± 1.2 N/m/kg) and control (5.84

± 1.4 N/m/kg) groups ($p = 0.98$). **CONCLUSION:** Those with CAI have reduced plantar flexor stiffness compared to the uninjured controls, which may be a potential underlying factor for CAI associated sensorimotor impairments. This lower plantar stiffness may influence ankle joint stiffness during activities, which may be a risk factor for recurrent ankle sprains.

Influence Of Plyometric Training On Tendinous Tissue Elongation During Initial Phase Of Explosive Power Exertion

Chihiro Edamatsu, Tomiko Odagaki, Kazuki Kusumoto.
 Kurashiki University of Science and the Arts, Kurashiki, Japan.
 Email: edamatsu@kusa.ac.jp
 (No relevant relationships reported)

PURPOSE: The sharp rise of the ground reaction force due to high pre-activation of muscles upon drop jump (DJ) contributes to increases in the reactive strength index (RSI). In our previous studies, in a comparison between athletic long jumpers and general men, the long jumper showed a significant increase in Achilles tendon tissue elongation immediately after DJ contact due to high pre-activation of the gastrocnemius muscle. In this study, we aimed to clarify the influence of plyometric training on Achilles tendon tissue elongation dynamics immediately after DJ contact. **METHODS:** Five men (age, 21.0 ± 0.7 y; height, 172.2 ± 4.6 cm; weight, 67.6 ± 3.8 kg) volunteered to participate in this study. The subjects were asked to undergo plyometric training (maximum hopping 10 reps × 3 sets, 3 times a week, 12 weeks). Experiments were conducted before and after training and after 12 weeks of detraining. Changes in the Achilles tendon tissue length of the gastrocnemius medialis (the distance from the muscle tendon junction to the calcaneus along the line of action of the tendon) during DJs from a height of 0.3 m were measured using a high-speed camera and ultrasonography equipment. Electromyographic parameters and ground reaction force were measured in synchrony with the camera and ultrasonography equipment.

RESULTS: The RSI increased significantly after training (1.89 ± 0.35) and after detraining (1.78 ± 0.46) compared to that before training (1.49 ± 0.43). The elongation of Achilles tendon tissue immediately after the grounding of DJ was significantly increased by training (+ 2.99 ± 2.36 mm), and the training effect disappeared after detraining (- 0.23 ± 2.50 mm). On the other hand, there was no significant effect on the maximum elongation of tendon tissue in the push-off phase. In other words, the elongation of tendon tissue during the initial phase of explosive power exertion is more important than the maximum elongation of the tendon tissue.

CONCLUSIONS: Plyometric training increases tendon tissue elongation immediately after the DJ grounding and increases the RSI. These results suggest that the increase in tendon tissue elongation during the initial phase is one of the factors to increase explosive power exertion.

1905 Board #61 May 30 2:00 PM - 3:30 PM
Reliability Of Isokinetic Eccentric Hamstring To Concentric Quadriceps Torque Ratio Between Velocities, Sexes, And Limbs

Sean P. Langan, Georgia Southern University-Armstrong, Savannah, GA.
 (No relevant relationships reported)

The ratio of eccentric hamstring strength to concentric quadriceps strength has recently been suggested to potentially have utility for prospectively identifying risk for injury. However, there has been little research on the reliability of these ratios and furthermore, the differences and reliability of this ratio between different velocities, sex, and limbs. **Purpose:** To establish the reliability of eccentric hamstring to concentric quadriceps ratios, and determine any differences between ratios at different angular velocities, sex, and limbs in healthy and physically active young adults.

Methods: Following a standardized warmup, 20 women (23.3±3.5 years) and 20 men (25.3±3.0 years) performed concentric (e60 and e240 degrees·s⁻¹) and eccentric (e30 and e120 degrees·s⁻¹) knee flexion and extension protocols using both the dominant (D) and non-dominant (ND) limbs. Average peak torque from each set was used to create two ratios of eccentric hamstring to concentric quadriceps strength: e30/c240 and e120/c240. **Results:** For both sexes, the intraclass correlation coefficient (2,1) for the e30/c240 ratios (\bar{r} : .66 -.68, \bar{r}_D : .62 -.71) were slightly higher than the e120/c240 ratios (\bar{r} : .45 -.59, \bar{r}_D : .46 -.51). The Standard Error of Measurement (SEM) was similar across the two ratios within each sex; however, the SEM was smaller for men (4.5-5.0%) compared to women (5.2-7.3%). The D ($P = .001$, 95% CI_{diff}: .03 to .10) and ND ($P = .035$, 95% CI_{diff}: .003 to .09) e30/c240 ratios for the women demonstrated a significant systematic decrease across the two sessions. There were no limb differences for either of the ratios ($P > .05$); however, the e30/c240 ratio for the women was significantly higher ($P = .046$) than the men (95% CI_{diff}: .01 to .72).

Conclusion: No potent reliability differences appeared between the two ratios, which may be attributable to using average peak torque across repetitions without considering

location of peak torque or sustained torque throughout range of motion (angular work). Partially explaining sex differences in absolute reliability and session changes could be experience with maximal effort muscular activation (e.g. resistance training).

1906 Board #62 May 30 2:00 PM - 3:30 PM
Regional Activation of Supraspinatus, Infraspinatus and Periscapular Musculature during Strengthening Exercises with Elastic Bands

Talia Alenabi, Ranjit Joseph, Tea Lulic, Clark Dickerson.
University of Waterloo, Waterloo, ON, Canada. (Sponsor: Dr. Lyle Micheli, FACSM)
 Email: talia.alenabi@gmail.com
 (No relevant relationships reported)

PURPOSE: Strengthening of the rotator cuff and periscapular muscles is crucial for appropriate neuromuscular control of the mobile glenohumeral and scapulothoracic joints. The aim of the current study was to quantify and compare the regional activation of supraspinatus (SUP), infraspinatus (INF) and some periscapular muscles during shoulder strengthening exercises with elastic bands.

METHODS: 27 right handed healthy volunteers (22.5 ± 2.7 years old) were recruited. Four fine wire electrodes were inserted into the anterior and posterior regions of SUP and the superior and middle regions of INF under ultrasound guidance. Four paired surface electrodes collected data from the upper, middle and lower trapezius and serratus anterior (UT, MT, LL, SERR respectively). Participants performed four resistance exercises (in Y, T, W and L postures) with elastic bands while maintaining good form and cadence. Kinematics were recorded synchronously by Vicon motion tracking system. Electromyography values were presented as % of maximal voluntary isometric contraction (MVIC) and compared across exercises using ANOVA.

RESULTS: Rotator cuff and periscapular muscles showed similar activation profiles throughout the Y, W and T exercises. The peak activation of SUP anterior occurred in 20% of L exercise cycle while for other regions it occurred in 40-60% of time cycle. Mean activations of all rotator cuff partitions were over 40% MVIC during four exercises, except middle INF during T exercise (29.3% MVIC). LT was activated >80% MVIC during all four exercises, with no significant differences across exercises while MT was significantly more active in T exercise. The activations of SERR and UT were significantly higher during Y exercise. **CONCLUSIONS:** YTWL exercises induced moderate to high activation in supraspinatus and infraspinatus partitions, and very high activation in lower trapezius. These exercises are appropriate for strengthening of some rotator cuff and periscapular muscles and can potentially be useful for rehabilitation of scapular dyskinesia and shoulder impingement. However, caution should be taken while prescribing Y exercise for these pathologic conditions as this exercise may induce high activation in UT. Providing additional strengthening exercises for SERR to this exercise package is recommended.

The Effect Of Knee Joint Angle Difference On The Compartment Neuromuscular Activation In Rectus Femoris

Hiroku Mitsuya¹, Koichi Nakazato¹, Kohei Watanabe², Takashi Okada¹. ¹*Nippon Sport Science University, Tokyo, Japan.*
²*Chukyo University, Aichi, Japan.*
 (No relevant relationships reported)

Bi-articular muscles play an important role to smooth movement in human. However, the biomechanics and physiological function of those muscles is unclear. Thus, this study investigates the function of rectus femoris as a famous bi-articular muscle in lower limbs.

PURPOSE: The purpose of this study is to unravel the compartment neuromuscular activation of rectus femoris during isometric knee extension and hip flexion in different knee angles.

METHODS: Subjects were eight healthy men. Knee extension with hip flexion were performed in isometric contraction. Knee angle was set up at 90, 60, 30, and 0 degree. Also, there were three contractions as follow: Maximum voluntary contraction (MVC), 80%MVC and 60%MVC. Muscle activation of rectus femoris was measured by using multi-channel surface electromyography, and calculated the average rectified value (ARV). We evaluated the ARV of rectus femoris divided into proximal, medium and distal compartment. We evaluated the ARV of rectus femoris divided into proximal, medium and distal compartment.

RESULTS: In the proximal region at 30 degrees knee angle, averaged ARV value in the MVC (0.113 mV) was significantly higher than those of other two contraction groups (80%MVC: 0.071 mV, $p < 0.05$ vs MVC; 60%MVC: 0.047 mV, $p < 0.01$ vs MVC). There was no significant differences in ARVs both in medium and distal compartments.

CONCLUSIONS: Proximal region of rectus femoris has the role of knee extension and hip flexion in slightly flexed knee joint position. We conclude that the difference of knee angle affects the compartment neuromuscular activation in rectus femoris.

Effect of neuromuscular training on rate of force development and joint stability. Williams, C.D. & Herring, B.
 Department of Kinesiology, Sport Studies, and Physical Education
 The College at Brockport
 Contact: cwilliams@brockport.edu

Abstract

Neuromuscular adaptations to training are primarily responsible for explosive movements through increases in neural drive and efficiency, which increases recruitment of fast twitch muscle fiber and rate of force development (RFD). Increases in RFD allow an individual to produce more force in shorter time durations, and are expected to increase joint stability. The purpose of this study was to determine the effects of neuromuscular training on RFD and joint stability. A training group and a control group were used. Using a multi-joint isokinetic dynamometer, a 4-week training program was developed. Ten participants performed squat, leg drive, lateral squat, and deadlift exercises twice a week, for three sets of ten seconds each, at 50% of maximal velocity. Pre and post-tests measured RFD using a squat exercise at 50% of maximal velocity, and measured joint stability using the Landing Error Scoring System in Real Time (LESS-RT). Results indicated no significant differences between pretest measures of RFD or LESS-RT between the training and the control groups; nor were differences found between pre and post test measures of RFD and LESS-RT for the control group. Results indicated a significant increase in RFD ($t_{(9)} = -2.652, p = .026$) and a significant decrease in scores ($t_{(9)} = 3.648, p = .005$), indicating an increase in RFD and joint stability after training, and suggesting a decreased risk of injury.

Shoulder Muscle Activity Changes in Patients After Injection and Physical Therapy

Holly B. Rittenberry, Jennie L. Cooper, Andrew R. Karduna.
University of Oregon, Eugene, OR.
 Email: hrittenb@uoregon.edu
 (No relevant relationships reported)

INTRODUCTION

Shoulder pain is a common orthopedic ailment, with multiple potential sources of pain and dysfunction. A combination of treatments may be used. While treatment has generally shown to be effective, it does not resolve the syndrome for all patients. **PURPOSE** To determine the effect of a standardized treatment protocol on the neuromechanics of the shoulder. It is hypothesized that rotator cuff activation will increase with both pain relief and physical therapy.

METHODS

Seven subjects, who were diagnosed with subacromial impingement, and seven healthy controls were recruited. At the first testing session, the subject was instrumented with six surface electromyography sensors and two fine-wire sensors.

Subjects elevated their arm in the scapular plane, while kinematics and EMG were recorded. EMG data were normalized to a reference contraction.

Following a subacromial injection, the subject repeated elevation motion. Following the testing session, the subjects completed six weeks of physical therapy. The subjects returned for additional testing following the same protocol. For patients, the three testing periods were designated T1 (before injection), T2 (after injection), and T3 (after physical therapy). For healthy controls, only the original time point was analyzed.

RESULTS

Figure 1 shows the supraspinatus activity of seven patients during humeral elevation in the scapular plane. At baseline, it appears that muscle activation in the patients is lower than controls, but in most cases, increases over time. There also are potential differences in activity between patients and control subjects at the three time points, as well as changes associated with the subacromial injection or with physical therapy.

CONCLUSIONS

Immediately following the subacromial injection, activation levels appear to have remained relatively constant. However, after physical therapy, activation levels show a pattern of increase. Data collection and analysis are continuing.

Figure 1: Supraspinatus activity at 30°, 60°, 90° and 120° of humeral elevation (n = 7, means +/- sd).

Muscle Thickness And Strength Relationships In Patients With Patellofemoral Pain Before And After Rehabilitation

L. Colby Mangum¹, Neal R. Glaviano², David Hryvniak³, Joseph M. Hart, FACSM³, Jay Hertel, FACSM³, Susan A. Saliba³.
¹University of Central Florida, Orlando, FL. ²University of Toledo, Toledo, OH. ³University of Virginia, Charlottesville, VA.
 (Sponsor: Jay Hertel, FACSM)
 Email: L.Colby.Mangum@ucf.edu
 (No relevant relationships reported)

The gluteus maximus (Gmax) and medius (Gmed) have shown altered strength and activation in patients with patellofemoral pain (PFP) and have been addressed commonly in rehabilitation programs. However, the relationship between strength and a visual method of quantifying muscle activation through ultrasound imaging has not been explored. **PURPOSE:** To determine relationships between muscle thickness (at rest and during contraction) and strength using hand-held dynamometry of the Gmax and Gmed in various positions (side-lying, bipedal stance, unipedal stance) before and after a 4-week impairment-based rehabilitation program. **METHODS:** 19 patients with PFP (23.7±4.8yrs, 168.7±6.8cm, 69.6±15.1kg, 14F) completed 12 sessions of supervised impairment-based rehabilitation focused on lower extremity range of motion, strength, functional movement, and core stability. Ultrasound imaging and strength of Gmax and Gmed was performed before and after rehabilitation. Ultrasound images were collected at rest while side-lying, during side-lying hip abduction, bipedal stance, and unipedal stance. Both strength and thickness measures were normalized to body mass (kg). **RESULTS:** There were no significant relationships found between strength and muscle thickness at the pre-rehabilitation session. Following rehabilitation, both Gmax and Gmed exhibited significant relationships between strength and muscle thickness during side-lying positions. For Gmax, side-lying at rest, there was a moderate relationship ($r=0.50, p=.03$) and during side-lying hip abduction ($r=0.46, p=.05$). Gmed revealed similar relationships following rehabilitation with side-lying at rest ($r=0.65, p=.003$) and during hip abduction ($r=0.46, p=.046$). **CONCLUSION:** Muscle thickness, as captured with ultrasound imaging, increases as strength increases for both the Gmax and Gmed in individuals with PFP, while side-lying, and only following rehabilitation. The strongest relationship was found in the Gmed, which is supported by the positioning being the same for both thickness and strength measures. The concentric nature of the Gmed contraction during side-lying hip abduction could also be a major contributor to this relationship.

Classifying Upper Extremity Exercises Using Biomechanics Captured with an Inertial Measurement Unit-based Device

Andrew Hua, Pratik Chaudhari, Nicole Johnson, Joshua Quinton, Bruce Schatz, David Buchner, FACSM. University of Illinois at Urbana-Champaign, Champaign, IL.
 Email: ahua5@illinois.edu
 (No relevant relationships reported)

Exercise adherence and physical activity can be difficult to measure. Current methods often rely upon self-report surveys which are susceptible to error. Machine learning methods can be applied to biomechanical data to classify and identify activity. Each

exercise has a unique “fingerprint” of biomechanical data in that there is a unique combination of motion in each joint. Inertial measurement units (IMU) can move biomechanical analysis from the lab to real world environments allowing for more ecologically valid measurements. **PURPOSE:** The purpose of this study is to develop a machine learning algorithm for classifying nine different upper extremity exercises, based upon biomechanics captured from an IMU-based device. **METHODS:** 50 participants (mean age = 21.9 years) were recruited. Participants performed one compound and eight isolation exercises with their right arm while wearing the device. Each exercise was performed ten times for a total of 4500 trials. The device consists of a small, self-contained computer and four 3-axis IMUs. IMUs were placed on the hand, forearm, upper arm, and torso. Joint angles were calculated using relative rotations between pairs of IMUs. A modified Hampel filter and Savitzky-Golay filter were applied to remove outliers and noise. Random Forests were trained on 50% of the data and tested on the remaining 50%. **RESULTS:** The model performed well with an overall classification accuracy of 92.4%. Figure 1 shows the class confusion matrix where the numbers represent the proportion of true cases that were predicted. **CONCLUSION:** The results suggest upper extremity exercises can be classified using biomechanics data captured with a novel IMU-based device. These findings set the basis for more objective activity logs which can be used for measuring exercise adherence, physical therapy, and physical activity levels. Ultimately, the device may be used to create activity profiles for health screening and health status.

Effect of a Period of Cervical Flexion on Upper Extremity Muscle Strength

David T. Uher¹, Gregory Anoufrie², Michael E. Toczko².
¹Columbia University, New York, NY. ²Appalachian State University, Boone, NC. (Sponsor: Scott Collier, FACSM)
 Email: dtu2102@tc.columbia.edu
 (No relevant relationships reported)

As daily technology use increases, there is an increase in periodical cervical flexion, which can cause a strain on the neck and muscles of the upper extremity. It has been studied that on average people regularly experience cervical flexion of 45 degrees during handheld technology use. **Purpose:** Examine the effect that 30 minutes of cervical flexion has on upper extremity muscle strength, specifically the biceps brachii, triceps brachii, and middle deltoid. **Methods:** Twenty-four participants (12 male, 12 female) (n=24; height= 173.1±9.3 cm; weight=73.33±22.58 kg) were measured before and after 30 minutes of 45 degrees of cervical flexion in a seated position using a MicroFET2 Hand Held Digital Muscle Tester to isometrically test each muscle. Paired Samples T-test was used to determine overall strength changes and percent strength decreases. **Results:** Significant changes in muscle strength were evident in the left biceps brachii (254.1±101.5 vs 239.87±103 N, p<0.05), right biceps brachii (270.67±96.23 vs 254.53±102 N, p<0.05), left middle deltoid (140.82±54.27 vs 125.42±51.27 N, p<0.05), and right middle deltoid (129.2±46.1 vs 122.89±49.76 N, p<0.05). No significant strength changes were measured in either triceps muscle. Minimal changes were seen across contralateral arm muscles and across genders. When comparing dominant to non-dominant arms, significant changes in percent strength change were found in the dominant biceps brachii (272.8±100.77 vs

THURSDAY, MAY 30, 2019

269.15±109 N, p<0.05), non dominant bicep brachii (251.94±96.59 vs 235.25±95.74 N, p<0.05), dominant triceps brachii (151.63±54.59 vs 141.34±51.32 N, p<0.05), dominant middle deltoid (132.6±47.92 vs 124±49.13 N, p<0.05), and non dominant middle deltoid (137.44±53.21 vs 124.27±51.92 N, p<0.05). **Conclusion:** A normal daily degree of cervical flexion will decrease some upper extremity strength over the course of 30 minutes.

Effects Of An Exercise And Kinesiotape Intervention On Forward Head/Rounded Shoulder And Scapular Dyskinesia

Michelle A. Sandrey, Luke Klaviter. *West Virginia University, Morgantown, WV.* (Sponsor: Jean L. McCrory, FACSM)
 Email: msandrey@mail.wvu.edu
 (No relevant relationships reported)

Improper posture including forward head, rounded shoulder and scapular dyskinesia have been linked to neck and shoulder pain. Treatment for forward head posture (FHP), rounded shoulder posture (RSP), and scapular dyskinesia has consisted of an exercise protocol. Kinesiotape (KT) has recently emerged as a treatment method but there is a lack of research on the effectiveness, or whether exercise or KT is better than the other. **PURPOSE:** To compare a KT intervention to a strengthening and stretching program for correction of FHP, RSP, and scapular dyskinesia in a healthy, non-athletic, college age population. **METHODS:** Twenty healthy college-aged subjects with forward head, rounded shoulder posture and scapular dyskinesia completed the study. There were 10 subjects (7 females, 3 males, 20.30±.82 yr, ht=171.07±11.82 cm, wt=79.47±13.79 kg) in the exercise group and 10 subjects (7 females, 3 males, 20.40±1.43 yr, ht=166.61±11.99 cm, wt=69.40±11.48 kg) in the KT group. Subjects were randomized into two intervention groups undergoing a four-week program. One group participated in a strengthening and stretching exercise protocol (EG) based on the current literature, while the other group had KT applied to the upper back and shoulders for a duration of five days with two days of no tape in a seven-day period. Pre-and post-test measurements included the craniocervical angle (CVA) in degrees, forward shoulder angle (FSA) in degrees, and scapular dyskinesia as assessed using scapular dyskinesia scoring (0-3, maximum combined score = 6) for each scapula. **RESULTS:** There was a significant time main effect for the scapular dyskinesia score (SDS) as both groups improved pre-to-post intervention (F=12.5, P<.01; EG=4.8±1.14 vs 5.3±.949, KT=4.10±1.59 vs 4.9±1.01). Time effect sizes were small to moderate for CVA (KT=.13 to EG=.53), RSA (EG=.15 to KT= -.46) and SDS (EG=.44 to KT=.50) in both groups. Group effect sizes were small for CVA (0.24), RSA (0.25) and SDS (0.36). Minimal-detectable-change-scores were achieved for the CVA (EG=3.90, KT=.80) and SDS (EG=.50, KT=.80) for both groups, indicating clinical improvement. No other results were significant. **CONCLUSIONS:** Both groups improved pre-to-post intervention for the three measurements, even though only SDS was significant. Thus, either treatment could be used.

Stimulation Techniques used to Assess Corticospinal Excitability Alters an Attentional Focus Maximal Voluntary Contraction of the Elbow Flexors.

Shawn A. Wiseman, Behzad Lahouti, Israel Halperin, Duane Button. *Memorial University of Newfoundland, St. John's, NL, Canada.*
 (No relevant relationships reported)

PURPOSE: To investigate the role of attentional focus on force output by assessing 1) force output during maximal voluntary elbow flexion contractions, 2) corticospinal excitability and 3) motor unit activation patterns. **METHODS:** 7 resistance-trained males completed two experimental sessions. Each session consisted of 12 maximum voluntary contractions (MVC) with 180s rest of recovery between MVC. Participants were given counter-balanced external and internal attentional focus conditions prior to each MVC to direct attention. Force output and electromyography (EMG) of the biceps brachii, triceps brachii, and brachioradialis were recorded for both sessions. Transcranial magnetic stimulation, transmastoid electrical stimulation, and brachial plexus electrical stimulation were used to produce motor evoked potentials (MEPs), cervicomedullary motor evoked potentials (CMEPs) and maximal M-waves (M_{max}) in the biceps brachii during each MVC in one of the two sessions. All MEPs and CMEPs were normalized to M_{max}. **RESULTS:** Forces produced during the stimulation session were not significantly different between external and internal focus conditions (p = 0.20). However, forces produced during the non-stimulation session were 19.9% higher with an external cue compared to internal cues (p < 0.05). As well, forces produced with external cues were 13.2% greater during the non-stimulation session compared to the stimulation session. (p<0.05). EMG activity was not found to be significantly different between attention focus cues (p≥0.1). **CONCLUSIONS:** The usage of stimulation techniques likely distracted participants from the attentional focus cues provided during the stimulation session. Therefore,

we were unable to successfully assess changes in corticospinal excitability between focus cues. However, we were still able to show that external cues direct greater force production of the elbow flexors compared to internal cues.

The Comparison of Children Active Travel Mode Time Under the Different Air Quality

JiaChuan Xue, Gang He. *Capital University of Physical Education and Sports, Beijing, China.*
 Email: de3an@hotmail.com
 (No relevant relationships reported)

There are sufficient evidence to confirm the adverse effects of air pollution and the positive effects of active travel mode on the health. However, few studies have research on the impact of different air quality on children active travel mode time, especially in Asia country like China. **PURPOSE:** By comparing the active travel mode time of children under the different air quality areas to show the impact on air quality of children active travel mode time. **METHOD:** Through Beijing Municipal Environmental Protection Bureau to record the past year daily AQI (air quality index) data of different areas in Beijing, and according to the data to select two schools in good air quality (the AQI is 91 and 96) and two schools in poor air quality (the AQI is 102 and 120), all totals of 407 students (boys = 217, age = 10.78 ± 0.93 yrs). Using the questionnaire to record the children active travel mode time, including the time of children to go to school or other places on foot during the weekdays and weekend, and the time of children to go to school or other places by bike during the weekdays and weekend. The data were analyzed by using one-way ANOVA. **RESULT:** By comparing the active travel mode time of children in two schools with AQI of 91 and 96 (68.67±111.38 vs. 117.30±137.68mins, P<0.05); By comparing the active travel time of children in two schools with AQI of 91 and 102 (68.67±111.38 vs. 154.66.30±249.61mins, P<0.05). **CONCLUSION:** Air quality may have an impact on children active travel mode time, the children in the best air quality areas have relatively less active travel mode time. Future studies should consider the more factors that may impact the children active travel mode time.

1916 Board #72 May 30 3:30 PM - 5:00 PM
Physical Activity, Sedentary Time, Body Composition and Cardiorespiratory Fitness In 4th Grade Hispanic Children

Luis A. Torres-Villela¹, Lucia del R Martinez¹, Carmen Nevarez², Mercedes Rivera¹, Farah A. Ramirez-Marrero, FACSM¹.
¹University of Puerto Rico - Río Piedras Campus, San Juan, Puerto Rico. ²University of Puerto Rico - Medical Sciences Campus, San Juan, Puerto Rico.
 (No relevant relationships reported)

Physical activity (PA) positively influences health parameters such as cardiorespiratory fitness (CRF) and body composition in children and adolescents. However, evidence of these associations, including sedentary time (ST), among Hispanic children is insufficient. **PURPOSE:** To determine associations between PA, ST, body composition, and CRF in 4th grade Hispanic children in Puerto Rico. **METHODS:** A group of 70 boys (n=33) and girls (n=37), 9.4±0.5 years of age completed a CRF test (PACER) and body composition evaluation (height, weight, calf and triceps skinfolds) using the FITNESSGRAM protocol, and wore an accelerometer for 7-consecutive days. T-tests and Wilcoxon rank-sum tests were conducted to test for sex differences when appropriate, and correlation analyses by sex to test for associations between variables. **RESULTS:** Compared with boys, girls were less active (238.7±48.1 vs. 199.4±72.4 min/day of moderate to vigorous PA, P=0.01; 18528±4539 vs. 15003±5883 steps/day, P=0.01) and more sedentary (6.8±1.2 vs. 7.8±1.8 hrs/day, P=0.01). Boys and girls were not different in their mean BMI (18.0±5.0 vs. 18.5±3.6 kg/m², P=0.63), %fat (22.6±11.0 vs. 25.2±8.1 %, P=0.26), max steps/min (133±14.4 vs. 131±18 steps, P=0.57), and CRF test (34.2±21.2 vs. 26.5±17.1 laps, P=0.11). CRF in boys was inversely correlated with BMI and %fat (rho= -0.39 (P=0.04), -0.42 (P=0.02); respectively), and directly correlated with vigorous PA (rho=0.40, P=0.03); while in girls, CRF was directly correlated with maximal steps/min (rho=0.34, P=0.04). **CONCLUSION:** Although boys and girls appear sufficiently active, lower PA and higher ST among girls should be addressed to promote healthier lifestyles. Also, the

THURSDAY, MAY 30, 2019

influence of PA intensity and body composition on CRF appear to differ by sex, a consideration for future PA interventions in this population. Supported in part by FIPI/DEGI/UPRRP.

Effects of Exergaming on Motor Skill Competence, Perceived Competence, and Physical Activity in Preschool Children

Zan Gao, FACSM¹, Nan Zeng², Zachary C. Pope¹, Ru Wang³, Fang Yu¹. ¹University of Minnesota, Minneapolis, MN. ²Colorado State University, Fort Collins, CO. ³Shanghai University of Sport, Shanghai, China.
 Email: gaoz@umn.edu
 (No relevant relationships reported)

PURPOSE: Few school settings offer structured physical activity (PA) opportunities for preschool children, with little study conducted examining exergaming's effectiveness on health outcomes in this age group. This study's purpose, therefore, was to examine a school-based exergaming intervention's effect on preschool children's perceived competence, motor skill competence and PA versus usual care (recess), as well as examine gender differences for these outcomes.

METHODS: Sixty-five preschoolers (33 girls; $M_{age} = 4.45 \pm 0.46$; $M_{BMI_{percentile}} = 59.05 \pm 32.04$) from 2 underserved urban elementary schools in a Midwestern U.S. state were enrolled and then assigned to 1 of 2 conditions, with school as experimental unit: (1) usual care recess group (8 weeks of 100 minutes [5 days x 20 minutes] recess/week); and (2) exergaming intervention group (8 weeks of 100 minutes [5 days x 20 minutes] school-based exergaming/week). All children underwent identical perceived competence, motor skill competence and moderate-to-vigorous PA (MVPA) assessments at baseline and at the end of the 8th week. A multivariate analysis of variance with repeated measures was employed to examine preschool children's changes in perceived competence, motor skill competence and MVPA over time.

RESULTS: A significant Group by Time effect was observed for MVPA ($F(1, 52) = 4.37, p = 0.04, \eta^2 = 0.04$), but not perceived competence ($F(1, 52) = 0.83, p = 0.37, \eta^2 = 0.02$) or motor skill competence ($F(1, 52) = 0.02, p = 0.88, \eta^2 = 0.00$). Specifically, intervention children displayed significantly greater increased MVPA at 8 weeks than the comparison children (4.05 vs. -1.99 minute). Additionally, there was a significant Time effect for motor skill competence ($F(1, 52) = 15.61, p < 0.01, \eta^2 = .23$) and Gender effect for MVPA ($F(1, 52) = 5.06, p = 0.02, \eta^2 = 0.09$). In detail, while all preschoolers' motor skill competence improved over time, boys demonstrated higher MVPA than girls at both time points.

DISCUSSION: Exergaming showed a positive effect in promoting preschool children's MVPA at school and has the potential to enhance perceived competence and motor skill competence. More research with larger sample sizes and longer study durations is warranted.

1918 Board #74 May 30 3:30 PM - 5:00 PM
The Effect of Extracurricular Coordinated Physical Education on the Development of Basic Motor Skills of Children aged 7-9 Years Old

Yan Li¹, Hanbing Song¹, Jindong Chang², Ming Yang¹.
¹Southwest University, Chongqing, China. ²The Branch of the Collaborative Innovation Center of Assessment toward Basic Education Quality at Southwest University, Chongqing, China.
 Email: 871857030@qq.com
 (No relevant relationships reported)

PURPOSE: The purpose of this study was to analyze the effect of the extracurricular physical education program through a 12-week-coordination on the development of basic motor movements for children of 7-9 years.

METHODS: A sample of 120 children of the elementary school period, 58 of whom were in the experimental group and 62 of whom were in the control group, were incorporated into the study in line with their own consent after their guardian had also informed. The program lasted for 12 weeks in the form of 2 days and 2 hours a day. The control group was not involved in any extracurricular physical education program. A research model of "pretest-posttest" was used. The "independent t" and the "paired samples t" statistical package program were used to analyze the data.

RESULTS: The study results indicated that transfer coordination ($t=2.89, p<0.05$), click-to-click ($t=2.76, p<0.05$), climbing obstacles ($t=4.47, p<0.05$), and rolling skills ($t=3.81, p<0.05$) that four indicators were significantly higher in the experimental group. The rolling skill was a significant change pre-and post-experiment in the control group ($t=2.13, p<0.05$), no significant differences in other variables.

CONCLUSIONS: As the results of this study, it follows that apart from clearly mentioning the importance of physical pricing practices. The extracurricular physical education program through long-term proper practices will enable children to develop their basic motor skill. (This study was supported by NPOSS Grant 15CTY011.)

1919 Board #75 May 30 3:30 PM - 5:00 PM
Comparisons Of In-school And Out-of-school Physical Activity Among Chinese Elementary School Children

Zheng Zhu, Chen Sun, Sheng Zhao, Zhen-Bo Cao. Shanghai University of Sport, Shanghai, China.
 (No relevant relationships reported)

PURPOSE: Relatively little is known regarding children's physical activity (PA) during school and outside of school. Therefore, the objective of this study was to compare in-school and out-of-school PA among Chinese elementary school children.

METHODS: A cross-sectional study was conducted among 360 (4th grade) children recruited from 3 elementary schools in Shanghai, China. PA was measured in 5 consecutive school days by accelerometers. Minutes per hour (min/h) of moderate-to-vigorous PA (MVPA) and total PA (TPA) were calculated using established cut points. Children's in-school and out-of-school MVPA and TPA were compared using paired *t* test. Gender differences in MVPA and TPA across the two study settings were also examined using independent *t* test.

RESULTS: 242 participants (boys: 45.5%, mean age: 9.6 ± 0.3 years, weight: 35.0 ± 7.6 kg, height: 139.8 ± 6.1 cm, body mass index: 17.8 ± 2.9 kg/m²) provided valid accelerometer data (defined as ≥ 2 days, ≥ 10 h/day) and were included in the study. Results showed a higher level of in-school MVPA compared to out-of-school MVPA (3.1 min/h vs 2.3 min/h, $P<0.001$) and of in-school TPA compared to out-of-school TPA (17.3 min/h vs 15.1 min/h, $P<0.001$). There were no difference in out-of-school MVPA and TPA across gender but boys showed a higher level of in-school MVPA (3.1 min/h vs 2.3 min/h, $P<0.001$) and TPA (18.3 min/h vs 16.6 min/h, $P<0.001$) compared to girls.

CONCLUSION: Chinese elementary school children spent more time engaging in in-school PA compared to out-of-school PA with boys showing a higher level of in-school PA compared to their counterpart girls. Findings suggest that PA promotion strategies should focus on developing out of school, community-based programs and that maximizing in-school PA among girls.

1920 Board #76 May 30 3:30 PM - 5:00 PM
Predictors of Return to a Childhood Healthy Eating and Active Living Obesity Clinic

Karissa L. Peyer¹, Joani Jack², Greg W. Heath, FACSM¹.
¹University of Tennessee at Chattanooga, Chattanooga, TN.
²University of Tennessee College of Medicine Chattanooga and Children's Hospital at Erlanger, Chattanooga, TN.
 (No relevant relationships reported)

PURPOSE: To identify predictors of program retention among children enrolled in a multifactorial obesity treatment clinic designed to support behavior change in physical activity and healthy eating to combat unhealthy weight levels. **METHODS:** Children age 2-18 years old ($n = 285$) attended a baseline visit at a childhood healthy eating and active living (CHEAL) clinic. Parents completed a behavioral survey and height, weight, blood cholesterol and blood glucose were objectively measured. Weight status was reflected as the Percent Over the 50th Percentile for age and sex based on CDC reference values (BMI50). Survey items included questions about prenatal and infancy history, family medical history, and eating and activity behaviors as well as desire to make changes and discuss nutrition behaviors with a dietician. All survey and objective measures were first evaluated with univariate analysis (Chi-Square and t-test) to identify differences between Returners and Non-Returners. Variables identified as having a significant relationship with returning for a second clinic visit were then entered into logistic regression models using forward selection. Four different models were constructed, with Model 4 containing all variables that were significant in univariate analyses.

RESULTS: Significant variables in univariate analyses included BMI50, sex, age, baseline cholesterol, sugar sweetened beverage (SSB) consumption, willingness to meet with a dietician, and the mother gaining more than 35 pounds during pregnancy. In logistic regression, children who consumed SSB once per week were more likely to return for a second clinic visit than those consuming SSB every day (OR 4.5 (95% CI: 1.9 - 10.5)) and older children were less likely to return than younger children (OR 0.9 (95% CI: 0.8 - 0.99)).

CONCLUSIONS: The predictors identified support theories associated with the importance of readiness for change (SSB consumption, willingness to meet with a dietician) and suggest that engaging families when children are young may improve retention rates for clinic-based interventions targeting healthy weight or energy-balance behaviors.

1921 Board #77 May 30 3:30 PM - 5:00 PM
Evidence for Compensation or Synergy of Children's Activity During Outdoor and Indoor Preschool Time
 Michael J. Wierenga, Kimberly A. Clevenger, Karin A. Pfeiffer, FACSM. *Michigan State University, East Lansing, MI.*
(No relevant relationships reported)

INTRODUCTION: Evidence for physical activity (PA) compensation (e.g., high PA leads to low PA in another part of the day) and synergy (e.g., building on times of high PA with additional high PA) in school-aged youth has been reported, but has not been studied in preschoolers. **PURPOSE:** To determine if preschoolers exhibit evidence of compensation or synergy in indoor and outdoor PA during child care. **METHODS:** Children (N=44; 3-4 y) in three preschools wore an accelerometer on their right hip for two school days. PA intensity was determined using Pate cut-points (counts/15sec). A proximity tagging beacon was placed in each classroom, and children's accelerometers acted as receivers. Lack of communication between beacons and receivers indicated that children were outdoors. Outdoor and indoor time (min/hr) in light, moderate, vigorous, or total PA was determined. Paired t-tests were used to identify if time in each intensity (for indoor/outdoor time) significantly differed between days ($p < 0.05$). Difference in time in each intensity between days was calculated and Pearson correlations were performed to compare between-day changes in outdoor and indoor light, moderate, vigorous, and total PA (e.g., correlation between change in outdoor total PA vs. change in indoor total PA). Positive associations support synergy, while inverse associations support compensation. **RESULTS:** No differences in time in each intensity between days were found. Change in outdoor light ($r = 0.02$, $p = 0.883$), moderate ($r = -0.17$, $p = 0.279$), and total ($r = -0.14$, $p = 0.369$) PA were not significantly related to change in indoor light, moderate, and total PA, respectively. Change in outdoor vigorous PA was positively related to change in indoor vigorous PA ($r = -0.40$, $p = 0.007$). For total PA, 59% of children exhibited evidence of compensation and 41% exhibited evidence of synergy. For vigorous PA, 45% of children exhibited evidence of compensation, and 55% exhibited evidence of synergy. **CONCLUSION:** Results suggest that vigorous intensity exercise may be more synergistic in nature. The weak-to-moderate, negative correlations among light, moderate and total PA warrant evidence for PA compensation at these intensities; however, results should be further examined in future studies using a larger sample size. **Funding:** ACSM Foundation, MWACSM, NASPEM, SHAPE

The Effectiveness Of High-intensity Interval Training Versus Moderate-intensity Continuous Training On Cardiometabolic Risk Factors In Childhood Obesity: A Meta-analysis
 Jing-xin Liu¹, Lin Zhu². ¹*Shanghai University of Sport, Shanghai, China.* ²*Guangzhou Sport University, Guangzhou, China.*
 Email: liujx102@163.com
(No relevant relationships reported)

Exercise training is mainly prescribed for obese children to decreased cardiometabolic risks, however, studies examining the difference between high-intensity interval training (HIIT) and moderate-intensity continuous training (MICT) are limited. **PURPOSE:** The purpose of this study was to determine if HIIT differentially impacted on cardiovascular risk factors compared with MICT in obese children. **METHODS:** The relevant literature was searched from the databases of PubMed, Web of Science, Embase, the Cochrane library, and CNKI, which was completed in September 2018. Only randomized controlled trials involving both HIIT and MICT on obese children were included, and studies involving only one intervention would be excluded. Two researchers independently performed literature screening, literature quality evaluation, and data extraction according to inclusion and exclusion criteria. **RESULTS:** A total of 9 study with 309 obese children were included. Compared with baseline, both HIIT and MICT can significantly reduce body weight (BW), body mass index, systolic blood pressure, diastolic blood pressure, and increase VO₂peak. Similar results were also found with respect to fasting glucose (FG) and fasting insulin in HIIT, while MICT is not significant. HIIT showed a small but significant effect on BW (mean difference (MD): -0.797 kg, 95%CI -1.018 to -0.575, $p = 0.0001$), total cholesterol (standardized mean difference (SMD) = -0.877, 95%CI -1.733 to -0.022, 0.044), HOMA-IR (MD = -0.620 mmol/L, 95%CI -1.234 to -0.006, 0.048), FG (MD = -0.391 mmol/L, 95%CI -0.608 to -0.173, 0.001) compared than MICT did. The main difference between HIIT and MICT is that HIIT is more effective for VO₂peak (MD: 3.364 ml/kg/min, 95% CI 1.902 to 4.826, $p = 0.0001$). **CONCLUSIONS:** Our meta-analysis of randomized controlled trails indicates that both HIIT and MICT can significantly reduce cardiovascular risk factors in obese children, while HIIT with greater improvement observed in cardiorespiratory fitness.

The Effects Of Active Video Games And SPARK PE On Children's In-school Physical Activity
 Han Chen¹, Haichun Sun², Jiling Liu³, Peng Zhang⁴. ¹*Valdosta State University, Valdosta, GA.* ²*University of South Florida, Tampa, FL.* ³*Texas A&M University, College Station, TX.* ⁴*East Stroudsburg University, East Stroudsburg, PA.*
 Email: hanchen@valdosta.edu
(No relevant relationships reported)

PURPOSE: Active video games (AVGs) is a technology tool that allows participants to engage in physical activity (PA) while playing video games. Research has shown that AVGs may serve as a "gateway" to increase individuals' PA. A physical education (PE) curriculum, Sport, Play, And Recreation for Kids (SPARK), is also designed to promote students' fitness and PA. The purpose of the study is to compare the effects of the two interventions (AVGs vs. SPARK PE) in increasing participants' in-school moderate to vigorous PA (MVPA).

METHODS: Both third (n=29, 34.5% for boys, 65.5% for girls, mean age = 9.1; SD = .6) and fourth grade (n=36, 41.7% for boys, 58.3% for girls, mean age = 10.2; SD = .5) students from a public school located in the South Georgia region participated in the study. Participants from third grade were enrolled in AVGs group while fourth graders were engaged in SPARK PE class. Both interventions lasted for six weeks with three 40-min sessions each week. A total of six Kinect AVG stations were set up with six participants practicing dance games at each station. Students in the SPARK PE group were taught by a student teacher who is familiar with SPARK K-5 curriculum. All participants were pre- and post-tested on their in-school PA for three days prior to and after the intervention using ActiGraph GT3X+. Everson's cut points were applied to generate the percentage of time engaged in MVPA. A two-way mixed ANOVA was conducted to examine the effects of interventions (between-subjects) and time (within-subjects) on participants' in-school MVPA percentage.

RESULTS: There was no significant main effect of time ($F(1, 63) = .72$, $p > .05$, partial $\eta^2 = .01$) on participants' in-school MVPA percentage. There was, however, significant main effect of interventions ($F(1, 63) = 23.5$, $p < .001$, partial $\eta^2 = .27$) on students' in-school MVPA percentage, with SPARK PE group (mean = 3.9) had higher percentage than did the Kinect AVG group (mean = 2.7). In addition, there was no significant interaction between time and intervention groups ($F(1, 63) = 1.60$, $p > .05$, partial $\eta^2 = .03$).

CONCLUSIONS: Neither Kinect AVG nor SPARK PE changed participants' in-school MVPA percentage. The effect of PA interventions on children's in-school MVPA need to be explored in future studies.

Predictors and Acceptability of Shared Physical Activity in Parent-Child Dyads
 Patrick M. Filanowski¹, Sarah M. Camhi, FACSM², Jessica A. Whiteley², Ronald J. Iannotti³, Laurie A. Milliken, FACSM². ¹*Xavier University, Cincinnati, OH.* ²*University of Massachusetts Boston, Boston, MA.* ³*CDM Group, Inc., Bethesda, MD.*
 (Sponsor: Laurie Milliken, FACSM)
 Email: FILANOWSKIP@XAVIER.EDU
(No relevant relationships reported)

PURPOSE: To identify significant predictors and assess the acceptability of shared physical activity (PA) in young children and their parents.

METHODS: Twenty-eight parent-child dyads (mean±SD; age, parents: 38.0±6.6, children: 6.0±1.7) completed sessions in a fitness center that included five different shared PAs (brisk walking, dancing, tag games, body-weight exercises, and jumping games) and were instructed to try to complete at least one PA per day in the following week at home. One week later, parents reported their dyad's participation in the shared PAs. Parents reported demographic characteristics, family chaos, parent PA self-efficacy, parental PA self-efficacy for their child, and average min/week of shared PA. A forward stepwise regression was used to determine the optimal model to predict the total number of minutes parent-child dyads spent completing each PA together at home. McNemar's test was used to determine differences between perceived acceptability and completion of the five PAs as a dyad during shared time.

RESULTS: Lower family chaos (B=-19.41, $p = 0.034$), higher parent body mass index (BMI) (B=7.65, $p = 0.003$), and higher annual household income (B=11.85, $p = 0.023$) significantly predicted minutes of shared PA at home. The proportion of parents who perceived brisk walking as an acceptable PA was not different ($p = 0.125$) than those who briskly walked with their child. The proportion of parents who perceived jumping games, body-weight exercises, dancing, and tag games as acceptable PAs was greater than those who completed these PAs with their child (all, $p < 0.05$).

CONCLUSIONS: Shared PA participation may be higher when participants have lower family chaos, higher parental BMI, and higher annual household income. Brisk walking could be considered in future family-based PA programs since it was perceived as acceptable and was completed in the home environment, whereas the other shared PAs were perceived as acceptable but not completed at home.

The Effects of Playground Zoning on Physical Activity During Recess in Elementary-Aged Children.

Jillian Barnas, MS, Stephen Ball, PhD. *University of Missouri, Columbia, MO.* (Sponsor: Jill Kanaley, PhD, FACSM)
 (No relevant relationships reported)

While many factors contribute to the development of obesity, a sedentary lifestyle plays a significant role in this epidemic. Epidemiological data indicates that 50% of children aged 6-11 years old and approximately 92% of adolescents aged 12-18 years old are not meeting the recommended health guideline of 60 minutes of moderate-to-vigorous physical activity (MVPA) per day. Therefore, the most effective interventions for combating inactivity and childhood obesity should target children before inactivity develops in their adolescent years. Due to the increasing youth obesity rates, schools have been identified as ideal environments to promote physical activity (PA). **PURPOSE:** The purpose of this study was to compare changes in physical activity in youth, measured by accelerometry, during recess with a playground zoning intervention. **METHODS:** The sample included 433 third-, fourth-, and fifth-grade boys and girls from two elementary institutions. PA was observed during recess using systematic observation of play and leisure activity in youth (SOPLAY) and measured using Actigraph-GT3X accelerometers on a subset of students ($n = 78$). Baseline data were collected for one week prior to playground zoning. Afterwards, the playgrounds were zoned into six various activities for two weeks and PA data was observed and measured. **RESULTS:** A repeated measures ANOVA detected a significant main effect with the zoning and decreased time spent in sedentary activity ($p = .013$) and moderate activity ($p = .027$). A significant cross-over interaction was detected with zoning and an increase in time spent in vigorous activity ($p = .017$) and MVPA ($p = .006$) for third graders, whereas fifth graders significantly decreased the time spent in MVPA ($p < .001$). Furthermore, third grade boys accumulated 204 more steps on the zoned playground compared to baseline measurements ($p = .001$). A McNemar test revealed a 5% increase in observational PA on zoned playgrounds ($p < .001$). **CONCLUSION:** Zoned playgrounds are an applicable, manageable, and effective program that can help improve PA during recess for young children. However, a different intervention may be needed to improve PA in older children.

Influence of Parents' Physical Activity on Children's Physical Activity And Cardiopulmonary Endurance

Shousheng Xu, Yan Wang, Yu Jing, Zhengzhen Wang, FACSM, Juan Wang. *Beijing Sport University, Beijing, China.* (Sponsor: Zhengzhen Wang, FACSM)
 (No relevant relationships reported)

It is reported that parents have important influences on the children's physical activity (PA) and health fitness, but such research has hardly been found in China nowadays. **PURPOSE:** To investigate PA level, health fitness and economic status among the children of 7-9 yrs and their parents; to assess the influence of parents' PA level, economic, educational condition and so on.

METHODS: The subjects were selected from Huilongguan Centre Primary School in Beijing. The children are 7-9 yrs and their parent who brought up them with age of 30-39 yrs. Through self-designed questionnaire, the study made investigation of economics and educational status on the subject families, and the other main contents including medical history, family history, PA and sports. It was obtained the PA data of the children by the revised PAQ-A, and the parents' PA level were measured by accelerometer (ActiGraph GT3X+). Health fitness examination adopted the national standard for pupil's fitness measurements.

RESULTS: 36 families completed the examination totally. According to daily average time of MVPA, whether one person or two of the couple, less than 30 mins was regarded as PA insufficient family (iPAf), and more than 30 mins was PA sufficient family (sPAf). (1) The data proved 20 sPAf and 16 iPAf in the study. (2) There were different in the children's scores between sPAf (3.02 ± 0.53) and insufficient ones (2.61 ± 0.58) ($P < 0.05$), and the BMI of the two groups (15.63 ± 1.95 vs 17.77 ± 3.67) showed great difference ($P < 0.01$). (3) The time of 50m*4 shuttle-run between the two children groups were different (119.35 ± 29.42 vs 127.56 ± 21.14 , $P < 0.05$); (4) The sedentary time everyday of the husband and wife in a family were moderately correlated ($r = 0.516$, $P = 0.023$), and the light PA time displayed low positive correlation ($r = 0.362$, $P = 0.046$), while the correlation was not found between the time of their moderate and more intensity PA ($r = 0.145$, $P = 0.093$). **CONCLUSIONS:** (1) The findings indicated that the higher PA level the parent had, the higher PA level their children did; and the children's cardiopulmonary endurance are higher similarly, whereas with the lower obesity extent. (2) The PA level of the husband and wife were interdependent and interactive. Supported by Central Universities and Colleges Basic Scientific Research Funds Special Funding (2016ZX016).

Preschool Children's Cognition is Associated With Motor Skill Competence and Cardiovascular Fitness

Jung Eun Lee¹, Nan Zeng², Zachary C. Pope³, Daniel McDonough³, Wenxi Liu³, Zan Gao, FACSM³. ¹University of Minnesota-Duluth, Duluth, MN. ²Colorado State University, Fort Collins, CO. ³University of Minnesota, Minneapolis, MN.
 (Sponsor: Zan Gao, FACSM)
 (No relevant relationships reported)

PURPOSE: While the early years are a critical window for the development of a healthy lifestyle, it is the period of growth for which we know the least about evidence linking physical activity with health outcomes in this population. This cross-sectional study examined the associations among physical activity (PA), motor skill competence (MSC), perceived physical competence (PPC), cardiovascular fitness (CF), and cognition in preschool children.

METHODS: Sixty-five preschool children (33 girls; 27 White, 21 Black, 10 Hispanic, 7 other; $\bar{X}_{age} = 4.45 \pm 0.46$; $\bar{X}_{BMI\text{percentile}} = 59.05 \pm 32.04$) were recruited from two local elementary schools in Minneapolis, Minnesota. Children's 3 days PA during school time included moderate-to-vigorous PA (MVPA) and steps were assessed via Actigraph Link; MSC was measured via the Test of Gross Motor Development-Second Edition; PPC was assessed via the Pictorial Scale of Perceived Competence and Social Acceptance; CF was assessed via a modified YMCA 3-Minute Step Test; and cognition was assessed via the computer-administered NIH Toolbox. Multiple linear regression was performed to determine the associations among outcome measures.

RESULTS: Preschool children's MVPA was not significantly related to MSC ($r = 0.182$, $p > 0.05$), PPC ($r = 0.121$, $p > 0.05$), CF ($r = -0.141$, $p > 0.05$), cognition ($r = -0.095$, $p > 0.05$), but step counts were significantly positively related to MSC ($r = 0.282$, $p < 0.05$), and preschool children's MSC was a significant predictor of step counts [$F(4, 63) = 4.65$, $\beta = 0.12$, $p < 0.05$, $R^2 = 0.24$] after age, gender, and BMI were adjusted. In addition, PPC was significantly positively correlated with MSC ($r = 0.366$, $p < 0.01$), and was a significant predictor of MSC [$F(4, 63) = 2.66$, $\beta = 0.26$, $p = 0.04$, $R^2 = 0.15$]. Preschool children's cognition was significantly positively correlated with MSC ($r = 0.266$, $p < 0.01$) and CF ($r = 0.372$, $p < 0.01$), respectively, but only CF seemed to be a significant predictor of cognition [$F(2, 62) = 4.52$, $\beta = 0.35$, $t = 2.73$, $p = 0.01$, $R^2 = 0.14$].

CONCLUSIONS: The findings support the need for effective strategies that simultaneously promote motor skill competence, cardiovascular fitness, cognition, and physical activity behaviors in early childhood. Future research with larger and more diverse samples is warranted.

Physical Literacy Competency Among Elementary and Middle School Children

Lindsay J. DiStefano, Emma F. Zuk, Eleanor M. Beltz, Julie P. Burland, Zachary Malone, Shauna Bolton, Hayley J. Root. *University of Connecticut, Storrs, CT.* (Sponsor: Douglas Casa, FACSM)
 Email: lindsay.distefano@uconn.edu
 (No relevant relationships reported)

Physical literacy addresses the ability, confidence and desire needed to optimize physical activity participation. Ability to perform, or competency in, fundamental movement skills, has not been recently evaluated among children in the United States, which is essential for identifying needs for intervention.

PURPOSE: To compare physical literacy competency between sexes and age groups in children. **METHODS:** 288 children (134 males, 153 females; age 9 ± 2 years; height 132 ± 36 cm; mass 41 ± 14 kg) from 6 schools volunteered to participate. Participants completed tasks in a randomized order to assess five domains of physical literacy competency: locomotor, running, balance, upper extremity (UE) and lower extremity (LE) object control. Trained raters evaluated competency using a standardized, valid and reliable assessment (PLAYfun; Canadian Sport for Life). Participants were divided into age groups (Elementary: grades K-4; Middle: grades 5-8). Competency on all tasks was measured using a 0-100 continuous scale. Total average score and domain average scores were compared between sexes and age groups using a multivariate analysis of variance ($\alpha < .05$). **RESULTS:** There were no significant interactions between sexes and age groups ($p > .05$). Regardless of age, males demonstrated greater competency than females for overall score (mean \pm SE points: males = 71.5 ± 1.0 , females = 63.7 ± 1.0 ; $p < .001$), running (males = 75.4 ± 1.8 , females = 63.72 ± 1.80 ; $p < .001$), UE object control (males = 73.32 ± 1.71 , females = 56.4 ± 1.7 ; $p < .001$), and LE object control (males = 66.9 ± 2.0 , females = 52.3 ± 2.0 ; $p < .001$). Regardless of sex, Middle had greater competency than Elementary for overall score (Middle = 62.2 ± 1.0 , Elementary = 73.0 ± 0.9 ; $p < .001$), locomotor (Middle = 75.3 ± 1.17 , Elementary = 65.0 ± 1.3 ; $p < .001$), balance (Middle = 77.4 ± 1.3 , Elementary = 62.1 ± 1.3 ; $p < .001$), UE object control (Middle = 70.0 ± 1.6 , Elementary = 59.8 ± 1.8 ; $p < .001$), and LE object control (Middle = 67.9 ± 1.9 , Elementary = 51.2 ± 1.8 ; $p < .001$). **CONCLUSIONS:** Sex differences in physical literacy are present among children in the United States, especially in

tasks involving object control. Similarly, over 20% of children in middle school lack competency in object control tasks. These areas need to be addressed in order to optimize long-term physical activity.

Classroom-based Strategies to Reduce Disparities in Physical Activity Among Children with Asthma
 Tiwaloluwa Ajibewa, Toby Lewis, Lexie R. Beemer, Lauren Allport, Shreya Bahl, Emma Weston, Maysa Damen, Ben Ransier, Darin Stockdill, U. Sean Vance, Richard Dopp, Rebecca E. Hasson, FACSM. *University of Michigan, Ann Arbor, MI.*
 (Sponsor: Rebecca Hasson, FACSM)
 (No relevant relationships reported)

PURPOSE: Children with asthma often experience physical activity (PA) induced symptoms 5-10 minutes following the start of exercise, with symptoms peaking 5-10 minutes post-activity. Classroom PA breaks provide shorter bouts of PA (4 minutes), and may represent a novel strategy to promote PA participation in this clinical population. Using a classroom-based PA intervention, we tested the feasibility of 5, 4-minute PA breaks to promote PA participation in children with asthma. **METHODS:** Nine, 3-6th grade classrooms at an elementary school in Detroit, MI (79% Hispanic; 80% on free/reduced lunch; 31% prevalence of asthma and asthma-like symptoms) participated in the 20-week intervention. Asthma status was self-reported via the International Study of Asthma and Allergies in Childhood (ISAAC) questionnaire in conjunction with nurse documentation. PA participation, exercise intensity (sedentary (SED), low-intensity physical activity (LPA), moderate-to-vigorous intensity physical activity (MVPA)), and asthmatic symptom occurrence were assessed via direct observation. **RESULTS:** All students accumulated approximately 19 total minutes (4.5±0.8 PA breaks x 246±8.0 seconds) of activity per day during PA breaks. Throughout the intervention, a greater percentage of children with asthma participated in MVPA during the PA breaks compared to children without asthma (asthma: 52.9±1.5% vs. non-asthma: 46.1±1.3%; p=0.001). In contrast, a greater percentage of students without asthma participated in LPA during PA breaks (non-asthma: 30.2±1.1% vs. asthma: 25.8±1.2%; p=0.006). There were no differences in the percentage of students who were SED during PA breaks (asthma: 21.3±1.7% vs. non-asthma: 23.7±1.8%; p=0.155). Out of 294 observations, six instances of asthmatic symptoms (coughing) were observed post PA break. **CONCLUSIONS:** Classroom-based interventions that incorporate short bouts of PA, represent safe exercises for children with asthma. Given the higher participation in MVPA among children with asthma, classroom interventions may be effective in reducing PA disparities in school settings.

Wearable Activity Monitors as Part of a Childhood Obesity Treatment Program
 Whitney M. Holeva-Eklund¹, Taylor Lane¹, Hendrik De Heer¹, Timothy K. Behrens, FACSM¹, Anthony Gobe², Sherry Walka².
¹Northern Arizona University, Flagstaff, AZ. ²Northern Arizona Healthcare, Flagstaff, AZ. (Sponsor: Timothy K. Behrens, PhD, FACSM)
 (No relevant relationships reported)

PURPOSE: It is well known that childhood obesity has become a common issue in the United States (1), and that obesity contributes to a multitude of chronic diseases and negative health conditions (2). One of the biggest challenges in the treatment and prevention of childhood obesity is that the goal of these programs is primarily to modify behaviors that occur outside of the program space. The purpose of this study was to summarize the findings from a 6-month program that used wearable activity monitors (WAM) as part of a clinical obesity treatment program for fifteen children in Arizona (USA) between December 2015 to November 2017. **METHODS:** Obese children were referred to participate in this program by their pediatrician. Participants were provided a WAM that was used to monitor their physical activity (PA) levels, heart rate, and sleep habits. For the first week, participants were instructed not to change their behaviors so that baseline PA data could be collected. Subsequently, appropriate step and heart rate zone goals were set and progressively increased each week that a participant met their previous goal. **RESULTS:** Adherence to wearing the WAM was high, with only about 1.3% of activity data and 3% of sleep data missing throughout the entire program. Three children dropped out of the study before the program was completed. For the children who completed the program, modest improvements were noted for step count, and healthy sleep habits were found to be positively correlated with PA. In baseline data collection, the children walked on average 8,900 steps per day. In the final week, the children recorded 9,784 daily steps on average, representing approximately a 10% increase in the average number of steps taken. **CONCLUSIONS:** Overall, childhood obesity treatment programs focus heavily on modifying behaviors that occur outside of the clinic setting. A WAM appears to be a feasible approach to continuously monitor and increase the PA of obese children. Including WAM and progressive goal setting in a clinical obesity treatment program

for children may be an effective method to increase PA levels outside of the clinical setting. Further exploration of the link between healthy sleep habits and PA could yield additional findings useful to childhood obesity treatment and prevention.

- 1931** Board #87 May 30 3:30 PM - 5:00 PM
Association of Sports Participation with Intake of Fast Food for Family Meals Among Rural Children
 Brooke Wagner, Daheia J. Barr-Anderson, FACSM, Sarah Friend, Marc Vacquier, Jayne A. Fulkerson. *University of Minnesota - Twin Cities, Minneapolis, MN.*
 (No relevant relationships reported)

After-school sports participation is common among children, and the busy lives of families could lead to challenges to prepare healthful family meals. This often results in families seeking the convenience of fast food for their evening meal. However, there is a scarcity of research, particularly among families in rural areas, examining whether children's sports participation is associated with families' intake of fast food as their evening family meal. **PURPOSE:** To examine associations between sports participation and fast food intake of rural children. **METHODS:** Baseline data from the childhood obesity prevention, randomized controlled trial, NU-HOME, were analyzed. Children (n=60; age=8.95±0.89 years; 62% female; 60% normal weight) and their parents reported on sociodemographics, child's sports participation (activities in the last year and frequency after school and in evenings) and family's intake of fast food as the evening meal. Logistic regression analyses were performed. **RESULTS:** Mean sports participation in the past year was 2.36±1.27 activities, with children reporting engaging in after-school and evening activities on 2.19±1.66 and 2.61±2.21 days, respectively, over the past week. Of their evening family meals in the past week, parents reported that 1.2±1.01 meals were considered fast food. Although sports participation in the past year was correlated with socioeconomic status, there was no statistically significant association between sport participation and fast food as evening family meal (p>0.05). **CONCLUSIONS:** Although sports participation was not associated with fast food intake as evening family meal in this study, future research should explore this relationship in other populations, particularly in larger studies. Furthermore, the possibility of lower availability of fast food options in rural areas compared to more urban settings could be an important caveat.

The Association Between Sex and Directly Observed Physical Activity in Preschool-Age Children
 Camille LeCompte, Sarah Burkart, Sofiya Alhassan, FACSM.
University of Massachusetts Amherst, Amherst, MA.
 Email: clecompte@umass.edu
 (No relevant relationships reported)

Sex disparities in physical activity (PA) are evident in preschool-age children (2.9 – 5 years old). Preschool-age boys have been reported to participate in more PA during free play. However, it is unknown if this disparity is evident when participating in a structured PA intervention. **Purpose:** To examine the association between sex and directly observed PA levels in preschool-age children while participating in a PA intervention. **Methods:** This study utilized data from the Short bouts of Exercise for Preschoolers (STEP) study. STEP was a 6-month cluster randomized controlled study that examined the effects of short bouts of structured PA implemented within the classroom setting as part of designated gross motor playtime in ten preschool centers. STEP consisted of structured PA during the first 10 minutes of gross motor playtime followed by 20 minutes of free playtime. PA levels during the 10-minute intervention session were measured using a modified Observational System for Recording Physical Activity in Children-Preschool Version. PA intensity was classified as sedentary, light, or moderate-to-vigorous (MVPA). This secondary analysis focused on the baseline and 3-month data of participants randomized to the intervention group (preschool centers, n = 5; participants, n = 75; age = 3.9 ± 0.67 years). Spearman correlations were used to examine the association between sex and PA intensity during the intervention. Repeated measures ANOVAs were used to examine the effect of sex on PA intensity. **Results:** Participants spent similar percent of intervals in MVPA at baseline (boys, 41.77±6.59; girls, 38.27±5.16) and 3-months (boys, 46.61±7.59; girls, 43.89±7.55). There were no significant associations between sex and directly observed MVPA at baseline (r=-0.035, P=0.37) or 3-months (r=-0.039, P=0.81). Similarly, there were no significant effects of sex on any PA intensity (all P > 0.80) during the intervention. **Conclusion:** In this sample, sex was not associated with or impacted the number of intervals that preschool-age children spent in MVPA during the structured PA intervention. Future studies are needed to determine if these trends remain the same in a larger sample size.

**Patterns of Physical Activity Change during
 Playground and Gardening Activities in Young Children**

Dawn P. Coe, FACSM, Scott E. Crouter, FACSM, Ashlyn N. Schwartz. *The University of Tennessee, Knoxville, TN.*
 Email: dcoe@utk.edu

(No relevant relationships reported)

Previous research shows a decline in activity intensity during outdoor free play in young children, with the pattern of decline varying between boys and girls. However, this area has not been studied in other outdoor locations (i.e., garden) or during semi-structured play. **PURPOSE:** To determine if a time course change in intensity level, defined as a change in youth MET (MET_y), occurs during outdoor play on a natural playground and in a garden setting in preschool children. **METHODS:** Twenty-six children (4.5 ± 0.7 y; 13 boys) wore an ActiGraph GT3X+ accelerometer on the right hip during two 30 min free living conditions; free play on a natural playground and semi-structured play in a garden. The Pate et al. equation was used to calculate VO₂ from accelerometer data. MET_y values were calculated by dividing predicted VO₂ by predicted basal metabolic rate (Schofield equation). Hierarchical linear models were used to demonstrate the changes in MET_y over time (level one variable = time, level 2 variable = individual child, predictor variables = sex (boy or girl) and location (garden or playground)). There was a three-way interaction among time, location, and sex (F(1, 725.984) = 7.858, p<0.001), thus separate models were run for each sex. **RESULTS:** For boys, there was no time by location interaction (F(1, 387.174) = 1.038, p=0.309) and no main effects for time (F(1, 177.036) = 3.115, p=0.268) or location (F(1, 384.913) = 1.234, p=0.078). For girls, there was a significant time by location interaction (F(1, 313.624) = 9.925, p=0.002), yielding the following equation: MET_y = 2.81 - 0.44 (location; playground = 0, garden = 1) - 0.02 (time) + 0.02 (location*time). The figure represents the average change in MET_y for each location and by sex.

CONCLUSIONS: Boys' MET_y level was consistent across time in both locations. Girls' MET_y level declined in the playground but increased in the garden. For girls, semi-structured activity in a garden may result in sustained higher MET_y activity during play.

**Recess And Overweight And Obesity In Children 5-11
 Years Of Age: 2013-2016 Nhanes**

Chakene D. Rogers, Michael R. Richardson, James R. Churilla, FACSM. *University of North Florida, Jacksonville, FL.*
 (Sponsor: James R. Churilla, FACSM)

(No relevant relationships reported)

There is limited evidence examining reported weekly volume of recess and odds of overweight and obesity using large nationally representative samples of U.S. children. **PURPOSE:** Examine the associations between reported weekly volume of recess, and overweight and obesity in a nationally representative sample of U.S. children. **METHODS:** The study sample included male (n=1,434) and female (n=1,409) children 5 to 11 years of age who participated in the 2013-2016 National Health and Nutrition Examination Survey. Overweight and obesity were defined using the 85th and 95th percentile of body mass index of the same age and sex. Proxy respondents answered interview questions regarding the number of days/week and minutes/day that the child participates in recess. **RESULTS:** Compared to a referent group participating in recess five days/week for > 30 minutes/day, analysis revealed significantly higher odds of obesity in females reporting no recess participation (Odds Ratio 1.81; 95% Confidence Interval, 1.03-3.16, P=0.0397). This relationship was independent of age and race/ethnicity. A similar relationship was not revealed for prediction of overweight in females or overweight and obesity in males. **CONCLUSION:** In a large nationally representative sample of U.S. children, reporting no recess was associated with significantly higher odds of obesity in females.

**Game-Play Characteristics by Field Size in Boys Youth
 Lacrosse**

Matthew Johnson¹, Patricia M. Kelshaw², Lisa H. Hepburn³, Andrew E. Lincoln³, Reginald E. Dunn³, Shane V. Caswell¹.

¹Colby College, Waterville, ME. ²George Mason University, Manassas, VA. ³MedStar Sports Medicine, Baltimore, MD.

(No relevant relationships reported)

US Lacrosse's Athlete Development Model (LADM) currently encourages small-sided game (SG) field dimensions to increase development and skill acquisition for youth athletes. No studies have evaluated changes in game-play subsequent to SG participation in boys' youth lacrosse (BYL). **PURPOSE:** To describe game-play characteristics during SG (35-45 yd) and full-field games (FG, 60-70 yd) in BYL. **METHODS:** Data was collected from 33 BYL players in Virginia (8.5±0.5 years, 138.3±5.7 cm, 35.9±6.5kg) on SG (n=15) and FG (n=18) teams. All games were filmed using a digital camera affixed to a camera lift system. Game-play characteristics were measured by reviewing the game video and coding for characteristics of unsuccessful passes, successful passes, shots on goal, goalie saves, changes of possession, loose balls, and intercepted passes. Descriptive statistics were reported (Frequency, Mean) for all observed game-play characteristics. **RESULTS:** Teams participated in 12 games total with 159 total athlete-exposures. Total game-play characteristics were: unsuccessful passes (SG=587, FG=399), successful passes (SG=165, FG=347), shots on goal (SG=81, FG=143), goalie saves (SG=28, FG=79), changes of possession (SG=419, FG=335), loose balls (SG=799, FG=670), and intercepted passes (SG=31, FG=24). The average characteristic per game were: unsuccessful passes (SG=97.8, FG=66.5), successful passes (SG=27.5, FG=57.8), shots on goal (SG=13.5, FG=23.8), goalie saves (SG=4.7, FG=13.2), changes of possession (SG=69.8, FG=55.8), loose balls (SG=133.2, FG=111.7), and intercepted passes (SG=5.2, FG=4.0). Further characteristics included: percent successful passes (SG=22%, FG=47%) and percent of successful shots on goal (SG=60%, FG=41%). **CONCLUSION:** Generally, FG had a greater percentage of successful passes than SG with comparable attempts per game between the two groups. In addition, SG had a greater successful shot percentage on less shots but had fewer goalie saves per game. Lastly, the SG team had more unsuccessful passes, loose balls, and turnovers. Further research is required to understand the effects of all aspects of the LADM on player development in BYL.

**Increased Acute-chronic Training Load Ratio Is
 Associated With Time-loss Injury In Elite-youth Female
 Soccer Athletes**

Darin A. Padua, Barnett Frank, Megan Mathes. *University of North Carolina at Chapel Hill, Chapel Hill, NC.*

(No relevant relationships reported)

Prior research demonstrates that elevated acute (1-week) relative to chronic (3-4 weeks) training load (TL) ratios are associated with increased injury risk. However, there is no existing research examining this relationship in youth female soccer athletes, who are at high risk for certain injuries during sport, such as anterior cruciate ligament injury. **PURPOSE:** To investigate the association between acute-to-chronic TL (A:C) ratio measures with time-loss injury in elite-youth female soccer athletes. **METHODS:** Forty-three elite-youth female soccer athletes participated in the study. Daily measures of training load, measured by self-reported (0-10 scale) rating of perceived exertion (RPE) multiplied by training duration (minutes), were recorded within 30-minutes of practices and games from pre-season (August 2017) until the end of the fall competitive season (December 2017) using a customized phone app. Following completion of the competitive season, the athletes completed a survey to determine their history of experiencing a time-loss injury during the season. A:C ratios were calculated at week-9 relative to weeks 5 through 8, as this was the most intensive TL period of the season. Binary logistic regression examined the association between A:C ratio and time-loss injury status. Receiver operator curve (ROC) analyses was performed to select a A:C TL cutpoint, followed by computation of sensitivity, specificity and area under the curve (AUC). Odds ratios (OR) were calculated and compared between those with and without time-loss injury. **RESULTS:** Nineteen athletes reported to miss ≥1 day of practice or game due to injury. Logistic regression demonstrated greater A:C ratio was associated with increased risk of time-loss injury (OR = 12.65 [95% CI=1.51, 105.27], Wald=5.49, P=0.019). ROC curve analysis identified an A:C ratio cutpoint of 1.62 to have optimal screening properties: sensitivity=73.3%, specificity=87.5%, AUC=0.76. The OR for an A:C ratio of 1.62 or higher compared to less than 1.62 was 19.25 (95% CI=3.64, 101.77). **CONCLUSIONS:** Elevated A:C ratios (>1.62) are associated with increased risk of suffering time-loss injury in elite-adolescent female soccer athletes. Monitoring and managing A:C TL may be an important injury prevention strategy in this population.

Physical Education Enrollment Trends of Youth with Obesity in a Large Midwestern Metropolitan Area
 Amanda Gier, Philip Khoury, Shelley Kirk, Christopher Kist, Robert Siegel. *Cincinnati Children's, Cincinnati, OH.*
 Email: amanda.gier@cchmc.org
 (No relevant relationships reported)

PURPOSE: To determine physical education (PE) enrollment trends of youth with obesity in primary and secondary schools in a large Midwestern metropolitan area.
METHODS: Data from 71 months of clinical visits to a pediatric weight management program were extracted from electronic medical records. Entries were refined to include only school-aged children, ages 6-18 years old. Multiple encounters per subject were included if the encounters occurred during separate school years. Information regarding frequency (days per week) and duration (length of school year) of PE class was used to determine what percent of total school days a subject was enrolled in PE. Data were analyzed to determine trends in PE enrollment by age, gender, race, ethnicity and socioeconomic status.
RESULTS: Data were obtained for 6221 patient encounters (3514 females, 2706 males). Of these, 31.4% of patients were not enrolled in PE during the school year of the encounter. The most common frequencies of PE enrollment overall were 20% (29.4%) and 40% (16.3%) of total school days. There was no significant difference in PE enrollment between the age groups of 6-11 years and 12-13 years (26.6% vs. 26.5%). Students ages 14-18 years old were enrolled in PE a lower percentage of school days (18.5%, $p<0.0001$). Of students ages 14-18 years, males were enrolled in PE significantly more than females (21.2% vs. 16.7%, $p=0.002$). Subjects with government-funded health insurance were enrolled in PE more than students with private health insurance (25.2% vs. 22.0%, $p<0.0001$). Differences between race and ethnicity were not significant.**CONCLUSION:** PE enrollment in this population falls below previously reported national averages for elementary and middle school students and slightly above average for high school students. The majority of school-aged youth with obesity in this metropolitan area do not acquire enough physical activity through PE to meet recommended daily physical activity guidelines.

1938 Board #94 May 30 3:30 PM - 5:00 PM
BMI, Body Composition and Race are Associated with Decreased Bicycling Ability in Youth with Obesity.
 Christopher Kist, Amanda Gier, Phil Khoury, Shelley Kirk, Robert Siegel. *Cincinnati Children's Hospital, Cincinnati, OH.*
 (No relevant relationships reported)

PURPOSE: To evaluate which factors may decrease the ability to ride a bike in youth with obesity.
METHODS: Data from 71 months of clinical visits to a pediatric weight management program were extracted from electronic medical records. Demographics and anthropometric measures, along with patient response to the question, "Are you able to ride a bike?" were analyzed to determine which factors limit a patient's ability to ride a bike. Levels of continuous variables for riders vs non-riders were compared using Wilcoxon rank sums tests. Fisher's Exact tests were used to compare proportions. Stepwise logistic regression was used to determine independent predictors of ability to ride.
RESULTS: Data were obtained from 4276 patients (2409 females, 1876 males). Mean age was 12.2 ± 3.2 years. Mean BMI was 33.5 ± 9 kg/m². Overall, 78.9% of the subjects were able to ride a bike. Males were more able to ride than females (79.4% vs. 78.6%, $p=0.54$). Caucasians were more able to ride than African Americans (80.0% vs. 76.9%, $p=0.0491$). Older aged subjects were more able to ride than younger aged subjects (12.6 ± 3 vs. 11.9 ± 3.8 years, $p<0.0001$). Subjects with a higher BMI were less able to ride (34.8 ± 9.3 vs. 33 ± 8.8 kg/m², $p<0.0001$). Subjects with a higher percent body fat (PBF) were less able to ride (46.4 ± 6.1 vs. 43.4 ± 6.7 , $p<0.0001$). Body fat mass was also significantly higher in the group that was unable to ride (41.1 ± 25.5 kg vs. 37.3 ± 15.1 kg, $p<0.0001$).
CONCLUSIONS: Many different factors contribute to the ability to ride a bike in youth with obesity. Gender, race, age, BMI and body composition were all associated with the ability to ride a bike. Youth with greater amounts of obesity and body fat may struggle more to ride a bike. Being unable to ride a bike limits options for active transportation and moderate-to-vigorous play in youth with obesity.

1939 Board #95 May 30 3:30 PM - 5:00 PM
Game-Play Characteristics by Field Size in Girls' Youth Lacrosse
 Patricia M. Kelshaw¹, Matthew Johnson², Lisa H. Hepburn³, Andrew E. Lincoln³, Reginald E. Dunn³, Shane V. Caswell¹.
¹George Mason University, Manassas, VA. ²Colby College, Waterville, ME. ³MedStar Sports Medicine, Baltimore, MD.
 (No relevant relationships reported)

To facilitate player development, the Lacrosse Athlete Development Model (LADM) recommends the use of small-sided games (SG) and fewer players on the field. Yet, no studies have evaluated if SG change game-play in girls' youth lacrosse (GYL).
PURPOSE: To describe game-play characteristics during SG and full-field games (FG) in GYL. **METHODS:** Female athletes (N=28, 8.5 ± 0.5 years, 132.4 ± 3.6 cm, 31.4 ± 1.7 kg) participated on either a small-sided (SG, n=13) or a full-field (FG, n=15) 10U level team within a single GYL league in Virginia. Both SG and FG teams participated in 6 games during the season. All games were filmed using a digital camera affixed to a camera lift system. Game-play characteristics were measured by reviewing game video and coding the frequency of observed activities (e.g. successful passes, changes of possession, intercepted passes, shots on goal, and loose balls). Descriptive statistics (Frequency, Mean) for game-play characteristics were calculated.
RESULTS: A total of 137 athlete-exposures (AE) occurred across 12 games (SG=59AE, FG=78AE). Total characteristics for the season were: unsuccessful passes (SG=476, FG=378), successful passes (SG=59, FG=110), shots on goal (SG=183, FG=189), goalie saves (SG=58, FG=79), changes of possession (SG=333, FG=281), loose balls (SG=625, FG=575), and intercepted passes (SG=17, FG=10). Average characteristics per game were: unsuccessful passes (SG=79.3, FG=63.0), successful passes (SG=9.83, FG=18.3), shots on goal (SG=30.5, FG=31.5), goalie saves (SG=9.7, FG=13.2), changes of possession (SG=55.5, FG=46.8), loose balls (SG=104.2, FG=95.8), and intercepted passes (SG=2.8, FG=1.7). Further, the FG team had a larger proportion of successful passes (23%) than the SG team (11%). However, the SG team had a larger proportion of successful shots on goal (63%) than the FG team (54%).
CONCLUSION: A greater proportion of successful passes were observed in FG than SG with comparable attempts and slightly fewer intercepted passes per game. Further, SG was observed to have a greater proportion of successful shots on goal despite FG having slightly more attempted shots on goal and more goalie saves. Additional research is needed to better understand how all aspects of LADM guidelines affect player development and skill acquisition in GYL.

1940 Board #96 May 30 3:30 PM - 5:00 PM
Physical Activity Among Youth Lacrosse Players: Full vs. Modified Field Play
 Christopher Anderson¹, Lisa H. Hepburn², Andrew E. Lincoln², Reginald E. Dunn², Shane V. Caswell³, Patricia Kelshaw³, Bruce D. Griffin⁴.
¹Georgetown University School of Medicine, Washington DC, DC. ²MedStar Sports Medicine, Baltimore, MD. ³George Mason University, Manassas, VA. ⁴US Lacrosse, Sparks, MD.
 Email: cga31@georgetown.edu
 (No relevant relationships reported)

PURPOSE: US Lacrosse developed the Lacrosse Athlete Development Model (LADM) to provide every athlete the opportunity to enter, enjoy and excel by learning and playing lacrosse in a way that's best for each stage of growth and development. Evaluation is essential to determine whether the LADM achieves the stated goals. The study aim was to assess whether players' physical activity (PA) was greater during games played on modified (Mod) fields than full-sized (Full) fields.
METHODS: This prospective cohort study involved two boys' and two girls' youth lacrosse teams who participated in six full or modified games. 61 youth players between the ages of 8-10 (U10) were selected via a convenience non-probability sample. Full field games were played on 60x110 yard fields; modified field games were played on 35x60 yard fields; games were 50-54 minutes long. Players wore the Actigraph Wgt3X-BT, a triaxial accelerometer that recorded PA over time in units of Metabolic Equivalents (1 MET = 3.5 ml O₂·kg⁻¹·min⁻¹). Data were categorized by PA level and analyzed using Chi-square tests to assess differences in PA by play (Full vs. Mod).
RESULTS: Boys' median PA was 3.0 METs (Full) and 2.8 METs (Mod). Girls' median PA was 2.9 METs (Full) and 3.2 METs (Mod). Among boys, vigorous physical activity was higher in full field games (13.9%) compared to modified field games (9.4%). ($p<0.001$) Among girls, moderate physical activity was higher in full field games (12.6%) compared to modified field games (10.3%) ($p<0.001$).
CONCLUSIONS: There were modest differences in activity level by game type among youth (U10) boys and girls lacrosse players when playing on the modified (smaller) field compared to the full field games. Although statistically significant, differences may be attributable to the following factors: • Higher player-field density on the modified fields (i.e., less open space on the modified fields); • More experienced and talented players participating in full field play; • Relatively more players on the

bench for more of the game on the modified fields than full size fields; • Coaches stopping the game on multiple occasions to provide instructions to inexperienced players in the modified field game; • Local (rather than US Lacrosse) rules were used, allowing more players on the field and longer game times.

 (No relevant relationships reported)

Purpose: to investigate whether a physical activity (PA) promotion program in overweight/obese (OW/OB) youngsters is favorable to changes in PA levels, vitamin-D (VIT-D) and metabolic profile and the correlations between those changes. **Methods:** This was an intervention study performed twice a week, over a period of six months with 57 OW/OB youngsters (31 girls). PA promotion program aimed to increase children and adolescent's moderate-vigorous PA levels. It was performed evaluation of body composition, physical activity, maturational stage and biochemical variables (HDL, LDL and VLDL cholesterol, glucose, insulin and VIT-D). For statistical analysis, Paired sample t-tests and partial correlations were used. **Results:** Significant differences between baseline and post intervention were observed for body composition, lipid profile and PA levels. Furthermore, Δ VIT-D was positively correlated with the Δ HDL ($r=0.30$), while negative correlations were found with metabolic risk factors. Δ VPA showed significant correlations with Δ VIT-D ($r=0.37$) and Δ HDL ($r=0.34$). **Conclusions:** After a PA program, OW/OB youth presented positive changes in body composition, vitamin D, metabolic profile and PA levels, indicating that interventions involving physical exercise should be promoted as an important component of a healthy lifestyle. This study was supported by FCT :UID/DTP/00617/2013

Investigating the Impact of Daily Physical Education on Fitness Levels of Underserved Minority Youth

Molly C. Finnan, Julian A. Reed, Caroline Stanton. *Furman University, Greenville, SC.* (Sponsor: Anthony Caterisano, FACSM)
 Email: molly.finnan@furman.edu
 (No relevant relationships reported)

PURPOSE: To investigate the impact of a 45-minute daily physical education intervention on overall fitness among underserved, minority elementary school youth. **METHODS:** An analysis of variance (ANOVA) mixed effect linear model was used to evaluate the effectiveness of 45 minutes of daily physical education on the Progressive Aerobic Cardiovascular Endurance Run (PACER), push-ups, and curl-ups among elementary school youth attending Legacy Early College, a Title I school in the southeastern US. Gain scores (final post-test assessment in May 2018 - original pre-test assessment in September 2017) were calculated and analyzed for significance. The interaction between school and time was estimated for each outcome. Each analysis was stratified by gender and adjusted by age to control for baseline differences by school. A Title I control school that provided physical education only one day per week was used as a comparison. **Summary of RESULTS:** Legacy students had significantly greater increases in curl-ups (Gain Score=12.23, $F=31.323$, $p=.000$) and PACER laps (Gain Score=6.18, $F=9.502$, $p=.002$). Legacy males and females observed greater increases in their fitness levels than controls. Legacy male and female students performed significantly better than controls in curl-ups, push-ups and PACER laps (Gain Scores=11.46, 3.14, 5.22, $F=71.695$, 51.126, 9.51, $p=.000$, .000, .002 respectively). **CONCLUSION:** Implementing 45 minutes of daily physical education in underserved elementary schools could improve childrens' overall fitness levels. Supported by Campbell Young Leaders.

Using Dance to Promote Physical Activity and Fitness Among Adolescent Girls with Intellectual Disabilities

Heidi Stanish¹, Aviva Must², Carol Curtin³, David Tybor², Linda Bandini³. ¹University of Massachusetts Boston, Boston, MA. ²Tufts University School of Medicine, Boston, MA. ³University of Massachusetts Medical School, Worcester, MA.
 Email: heidi.stanish@umb.edu
 (No relevant relationships reported)

Girls with intellectual disabilities (ID) exhibit poor fitness and low physical activity (PA) levels, and are considered a vulnerable, at-risk population. Girls with ID have limited access to many PA opportunities, but dance is accessible, widely available, and perceived as enjoyable. **PURPOSE:** To evaluate the feasibility and preliminary efficacy of a 12-week dance intervention to promote engagement in moderate to vigorous PA (MVPA) and increase cardiorespiratory (CR) fitness among girls with ID ages 16-21. **METHODS:** The intervention was implemented in 3 urban communities and included two 75-minute weekly dance sessions. Dance styles included hip hop, jazz, and modern; the choreography and session structure were designed to promote MVPA. Continuous heart rate (HR) monitoring (Polar® E600) was used for motivation and to record time spent below/in/above each girl's target HR (THR) zone (60-80% HR_{max}). Pre- and post-test CR fitness was measured by the 6-minute walk test (6MWT). Survey items assessed enjoyment and satisfaction. **RESULTS:** 18 adolescent girls (17.3 ± 2.7 y) with ID completed the intervention. Attendance was high; girls attended an average of 87% of dance sessions (range 67% - 100%). Overall, girls spent 52% (± 23%) of each session engaged in MVPA; defined as in or above their individual THR zone. Engagement level was quite variable; one girl averaged 4% of the dance session in her THR zone and another averaged 94%. When queried weekly about their PA intensity during the sessions, 11 of 18 girls reported that they worked "really hard" at every session. We observed a mean increase of 74.6 feet in distance walked on the 6MWT baseline to post-test ($n=14$); however, this difference was not significant ($p=0.17$). Post-intervention surveys indicated that girls "liked" the dance program (14 of 17), perceived improved fitness (15 of 17), and wished to continue dancing (15 of 17). Most girls reported a preference for a girls-only dance program and a program exclusively for those with ID. **CONCLUSION:** Participants engaged in dance at an MVPA intensity level for over half of the 75-minute sessions, supporting that dance is viable for promoting PA for girls with ID. Girls expressed their enjoyment of the program and wanted to continue beyond the 12-week program. More frequent training is likely needed to increase CR fitness.

1944 Board #100 May 30 3:30 PM - 5:00 PM
Relationship Between Physical Activity, Sedentary Time, Cardiorespiratory Fitness And Academic Achievement In Norwegian Adolescents.

Runar Solberg¹, Jostein Steene-Johannessen¹, Ulf Ekelund, FACSM¹, Geir Kåre Resaland², Sindre M. Dyrstad³, Tommy Haugen⁴, Sveinung Berntsen⁴, Elin Kalle¹. ¹Norwegian School of Sports Sciences, Oslo, Norway. ²Western Norway University of Applied Sciences, Sogndal, Norway. ³University of Stavanger, Stavanger, Norway. ⁴University of Agder, Kristiansand, Norway. (Sponsor: Ulf Ekelund, FACSM)
 (No relevant relationships reported)

Background: There is increasing evidence of positive associations between physical activity (PA), cardiorespiratory fitness (CRF) and academic achievement. Some studies have found an inverse association between sedentary time and academic achievement, however, the findings are mixed and the literature is inconclusive. **Purpose:** To examine the associations between objectively assessed PA, sedentary time, CRF and academic achievement in a sample of Norwegian adolescents. **Methods:** This cross-sectional study included 1518 adolescents aged 13.9 years (53.8% girls) from 29 schools in Norway. We assessed PA and sedentary time by accelerometry (Actigraph GT3X+). Intensity thresholds for sedentary time and MVPA were <100 counts per minute (CPM) and >2000 CPM, respectively. CRF was measured with an intermittent shuttle run test. Academic achievement in reading and numeracy were assessed using standardized national academic tests. We used a multiple linear mixed model analysis including school as random effect to account for clustering, adjusted for covariates (age, sex, socio economic status (SES) and accelerometer wear time). Additionally, the analyses modelling sedentary time and MVPA as exposure variables were mutually adjusted.

Results: Mean achievement in reading and numeracy were 55.9 (Standard deviation (SD) 10.0) and 55.8 (SD 9.7) points, respectively. Achievement in reading was positively associated with sedentary time ($B=0.044$, 95% CI: 0.027; 0.062), time spent in MVPA ($B=0.050$, 95% CI: 0.018; 0.083) and CRF ($B=0.014$, 95% CI: 0.009; 0.019). Achievement in numeracy was positively associated with sedentary time ($B=0.033$, 95% CI: 0.016; 0.050), time spent in MVPA ($B=0.033$, 95% CI: 0.014; 0.065) and CRF ($B=0.013$, 95% CI: 0.009; 0.018). **Conclusion:** Achievement in reading and numeracy are positively and independently associated with sedentary time, time spent in

MVPA and CRF. The results suggest that accumulating 10 minutes more in MVPA or sedentary per day, is associated with improved achievement in reading and numeracy by approximately 0.5 and 0.3 points, respectively. However, due to the cross-sectional design and the small magnitude of the associations, the practical implications of these results should be interpreted with caution.

1945 Board #101 May 30 3:30 PM - 5:00 PM
Intervention With Exergames For Adolescents Promote Moderate To Vigorous Physical Activity

Catiana L. P. Romanzini, Mileny C. M. de Freitas, Ruan F. de Morais, Jefferson G. da Silva, Sérgio M. C. Rocha, Marcelo Romanzini. *Londrina State University, Londrina, Brazil.*
 Email: clpssamai@uel.br
 (No relevant relationships reported)

Both the decline in moderate to vigorous physical activity intensities (MVPA) and the increase in sedentary behavior (SB) have different deleterious effects on the health of adolescents. **PURPOSE:** Verify a 10-week intervention using exergames with adolescents was able to promote levels of physical activity from moderate to vigorous intensities (MVPA) and compare the time in MVPA between the group with more or less participation in sessions. **METHODS:** Twenty adolescents (11 boys and nine girls) with an average age of 11.7 ± 0.9 years participated in an intervention with 10 sessions of exergames on the school, twice a week for about 40 to 60 minutes. XBOX 360 equipment was used with Kinect and the pair of adolescents practiced the games using an ActiGraph accelerometer. The analyzes included the total time and time of involvement in MVPA at each session. Descriptive statistics analyzes and the independent student T test were used. The level of significance was 5%. **RESULTS:** Of the 20 adolescents, three participated in all the sessions (10), six participated in nine sessions and seven participated in eight sessions, representing 80% of effective participation in the intervention. Only 20% of the students participated in only four to six sessions per week. Approximately half the time of each session was spent with MVPA (20.7min vs. 24.4min), in favor of the group with the largest participation in sessions with active video games. This same group presented up to the ninth session with longer mean time in MVMA compared to the group that participated in fewer sessions. **CONCLUSION:** It was possible to observe that a 10-week intervention using exergames with adolescents was able to promote levels of physical activity of moderate to vigorous intensities (MVPA), mainly in the group that have more participation in sessions.

Twelve Years Follow Up - Prevalence Trends Of Physical Inactivity And Overweight In Brazilian Adolescents

Fabio Ceschini¹, Sandra Mahecha², Erinaldo Andrade³, Gustavo Alegretti⁴, Aylton Figueira Júnior⁴. ¹Sao Judas Tadeu University and Traveling Through Physiology, são paulo, Brazil. ²Major University - Chile, Santiago, Chile. ³Uninove University, são paulo, Brazil. ⁴Sao Judas Tadeu University, são paulo, Brazil.
 Email: fabio.ceschini@hotmail.com
 (No relevant relationships reported)

PURPOSE: Determine the physical inactivity and overweight prevalence in adolescents living at São Paulo State (Brazil) from 2005 to 2017. **METHODS:** We evaluated 3,845 adolescents as part of a cohort study that started in 2005 in São Paulo city. In this study we analyzed 2,012 both sex adolescents that were followed in 2005, 2009, 2013, 2015 and 2017. In 2005, adolescents were from 15 to 18 years of age. We assessed the habitual physical activity practice by International Physical Activity Questionnaire (IPAQ-short-8 version) considering active (AT) the adolescents that accumulated at least 300 minutes per week of moderate-vigorous PA and inactive (INA) if less than 300 min/week were reported. Body weight (kg) and height (m) were self-reported by questionnaire. BMI was calculated and the respective criteria for overweight classification were considered for Brazilian adolescents

(CONDE and MONTEIRO, 2006). The anthropometry tendency changed overtime, and a linear regression model was designed to express the annual physical inactivity prevalence average and the excess of body weight. The significance was $p < .05$.

RESULTS: In general, the prevalence of physical inactivity in 2005 was 50.4%, with significant increase to 53.2% (2009); 56.7% (2013); 59.2% (2015) and 60.2% (2017), with 0.91% annual increase. Higher variation was observed in girls than boys (1.32% x 0.89% per year). The overweight prevalence followed similar trend: 2005 (16.7%); 21.2% (2009); 25.8% (2013); 28.2% (2015) and 29.3% (2017) with 1.29% increase per year ($p < .05$). Girls presented significantly and higher percentage change than boys (1.56 vs. 1.15% per year).

CONCLUSIONS: Data showed progressive trend of high physical inactivity and body fat increase, leading to an incidence of obesity in the next 10 years around 71.0% of all adolescents living in Sao Paulo State 37.2% of physically inactive behavior. These data suggests an early development of cardiovascular disease, with higher impact in girls than boys. Also data strongly suggest to effectiveness of public health policies towards the physical inactivity prevention and the excess of body mass among adolescents are related to unhealthy behaviors of eating, drinking and PA.

Compliance With The 24-h Movement Guidelines In Hong Kong Adolescents: Associations With Body Mass Index

YAN SHI¹, Wendy Y. Huang², Jane J. Yu¹, Stephen H.S. Wong, FACSM¹. ¹The Chinese University of Hong Kong, Hong Kong, Hong Kong. ²Hong Kong Baptist University, Hong Kong, Hong Kong.
 (No relevant relationships reported)

The evidence-based 24-h Movement Guidelines (MG) for children and youth was launched in 2016, shifting the thinking from one single movement behavior to an integration of three behaviors under the 24-h circle: physical activity (PA), screen time (ST), and sleep. A low compliance rate of meeting these combined recommendations has been reported for children. However, few studies have focused on adolescents, and its association with health outcomes such as body weight status is largely unknown.

PURPOSE: To examine compliance with the 24-h MG among Hong Kong adolescents and their associations with body mass index (BMI).

METHODS: 1,039 adolescents (11-18 yrs) wore the waterproof activPAL™ for 24-h over 7 consecutive days to assess PA and sleep duration. ST was measured using items from the validated Chinese version of the Children's Leisure Activities Study Survey. Participants were classified into 8 categories depending on the adherence to the 3 recommendations: none, single recommendation (PA, ST or sleep), two recommendations (PA & ST, PA & sleep, or ST & sleep) and all three recommendations. BMI was calculated as weight (kg) / height (m)². Linear mixed models were used to examine the associations of BMI with the 8 categories and the number of guidelines met (0-3), adjusted for age, sex and school clustering effects.

RESULTS: The analytic sample consisted of 656 adolescents (48% of girls) who provided valid activPAL™ data for at least 4 days and completed questionnaire. Only 1.1 % of the adolescents met the overall 24-h MG, while 38.7% met none of them. The proportion of meeting one single recommendation of PA, ST and sleep was 9.9%, 30.3% and 39.2%, respectively. Adolescents who did not meet the PA recommendation ($b = 1.34$; 95% CI, 0.32 to 2.36; $p = 0.007$) and those who did not meet the combination of PA and sleep recommendations ($b = 2.15$; 95% CI, 0.49 to 3.82; $p = 0.011$) had higher BMI than those who met the respective recommendations. No significant association was found between number of recommendations met and BMI.

CONCLUSIONS: Compliance with the 24-h MG was alarmingly low among Hong Kong adolescents. Meeting PA recommendation and the combination of PA and sleep recommendations were more likely to have a healthier body weight. Supported by the General Research Fund of the Research Grants Council, Hong Kong, China (#14501415).

The Effects Of HIIT And LIT On Weight Loss In Obesity Children/adolescents: A Systematic Review And Meta-analysis

Zhao Xiaochen, Cao Chunmei, Li Qing. *Tsinghua university, Beijing, China.*
 Email: 18614222993@163.com
 (No relevant relationships reported)

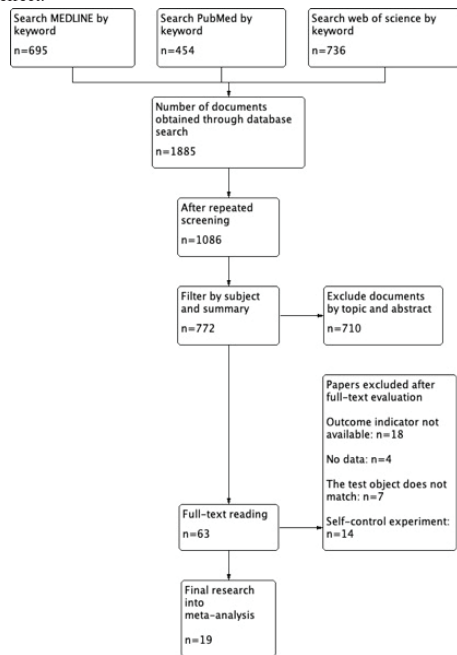

PURPOSE: To explore the effect of high-intensity interval training and low-intensity training on weight loss in obese children and adolescents.

METHODS: Search database (MEDLINE, PubMed, websites of science core database), the deadline is May 20, 2018. The screening conditions were as follows: Randomized controlled trials; Writing in English; Participants in the study were obese children/adolescents between the ages of 6 and 18 ; The intervention model is HIIT or

LIT, and the training time is at least four weeks;The final results of the study should include weight (body weight), BMI, body fat ratio (% body fat), and body fat (fat weight). The risk assessment was assessed using the Jadad scale (total score of 7).

RESULTS: Compared with LIT, HIIT can significantly reduce % body fat [-1.27(95%CI=-1.87,-0.67),Z=4.14(p<0.0001)], BMI[-0.42(95%CI=-0.83,-0.01),Z=2.00(p=0.05)] and body weight. [-0.40(95%CI=-0.73,-0.06),Z=2.33(p=0.02)];Comparing the EG and the CG of HIIT and LIT respectively which is found that for the body weight index, the combined statistical effect values of the two training methods were significantly different. However, LIT is better than HIIT[HIIT=-0.27(95%CI=-0.49,-0.04)][LIT=-0.94(95%CI=-1.12,-0.75)];% body fat, HIIT is better than LIT [HIIT=-0.56(95%CI=-0.84,-0.29)][LIT=-0.45(95%CI=-0.70,-0.21)]

CONCLUSIONS: HIIT is more effective for obese children/adolescents than LIT. LIT is better for whole body weight loss, but HIIT is better for body fat reduction. For aerobic training, the training period and the number of times are not proportional to the weight loss effect.

The subgroup analysis of low intensity training

Comparing a Body Image Assessment Scale with Anthropometric Measures in Chilean Adolescents
 Maribel Parra-Saldias¹, Daniel Mayorga-Vega², Jesús Viciana³, Farah Ramírez-Marrero, FACSM⁴. ¹Pontifical Catholic University of Valparaíso, Chile, ²Vña Del Mar, Chile. ³University of Jaen-Spain, Jaen, Spain. ⁴University of Granada, Spain, Granada, Spain. ⁴University of Puerto Rico, Río Piedras, Río Piedras, Puerto Rico. (Sponsor: Farah Ramirez-Marrero, FACSM)
 Email: mparrasaldias@gmail.com
 (No relevant relationships reported)

Body image is an important marker of health and well-being among young people. Instruments to assess body image use contour images that participants use to describe their body image self-perception. These images must be culturally sensitive and adequate for different age groups. Although the Contour Drawing Rating Scale (CDRS) has been validated among adolescents in Spain, no previous studies have compared the body image CDRS with anthropometric measures among Chilean adolescents.

PURPOSE: To assess body image using the CDRS among Chilean adolescents, and compare with anthropometric measures including body mass index (BMI) and waist circumference (WC).

METHODS: A group of 156 Chilean adolescents (87 males, 69 females) aged 13-14 years old participated in the study. They completed the body image CDRS consisting of 9 images from which they selected the one representing their body image self-perception. Values for selected images ranged from 1 (underweight) to 9 (obese). Subsequently, body weight was measured with a Tanita-HD313® scale, height with a SECA-206® stadiometer, and waist circumference with a Lufkin W606PM® tape, while participants were barefoot, and wore short-sleeve t-shirts and shorts. BMI was then calculated (kg/m²). To determine sex differences, Chi-Square and t-test were used, and correlation analyses were performed to detect association between variables.

RESULTS: Body image CDRS values ranged from 2 to 8 in males, and 1 to 9 in females (Z=4.237, p<0.001). Mean (±standard deviation) BMI in males and females was 21.3±3.5, and 22.3±3.3 kg/m², respectively (Z=2.168, p<0.03). Mean (±standard deviation) waist circumference in males and females was 75.9±9.1, and 74.1±8.3 cm, respectively (Z=1.012, p>0.05). Spearman correlation coefficients showed a moderate but significant association between the CDRS score and BMI (males, rho = 0.68; females, rho = 0.49, p <0.01 for both) and waist circumference (males, rho = 0.66; females, rho = 0.52, p <0.01 for both).

CONCLUSIONS: The significant correlation between anthropometric measures and the CDRS in our group of Chilean adolescent males and females suggest that body image self-perception closely represent objective measures of body image assessment; thus, providing an adequate body image assessment tool in this population.

1950 Board #106 May 30 3:30 PM - 5:00 PM
Heavy TV Viewers Are The Heaviest Regardless Of Physical Activity: A Study Of 10,000 Preadolescents
 Elina Engberg. University of Helsinki, Helsinki, Finland.
 Email: elina.engberg@helsinki.fi
 (No relevant relationships reported)

PURPOSE: To examine 1) whether recreational sedentary TV viewing and computer use are associated with body mass index (BMI), 2) whether the associations of TV viewing and computer use with BMI are modified by physical activity (PA), and 3) whether the associations of TV viewing and computer use are similar with BMI and waist-to-height ratio (WtHR).

METHODS: We assessed time spent on TV viewing, computer use and PA with an online questionnaire in 10,228 preadolescents with a mean age of 11.1 (SD 0.8) years from the Finnish Health in Teens (Fin-HIT) study. We categorized the preadolescents into Light, Medium and Heavy TV viewers and computer users, and into groups with Low, Medium or High PA levels. BMI categories and WtHR tertiles were established based on measured weight, height and waist circumference. We used multinomial logistic regression in order to calculate odds ratios (OR) with 95% confidence intervals (CI).

RESULTS: The percentages of Heavy TV viewers and Heavy computer users were higher in the overweight/obese group (46% and 43%, respectively) than in the normal weight (35% and 34%) or underweight groups (31% and 29%) (both p<0.001). Compared with Light TV viewers, Medium and Heavy TV viewers had a lower risk of being underweight (OR: 0.8, 95% CI: 0.7 - 1.0 and OR: 0.8, 95% CI: 0.6 - 0.9, respectively, when adjusted for age, sex, language, sleep duration and PA level) and a higher risk of being overweight/obese (adjusted OR: 1.3, 95% CI: 1.1 - 1.5 and OR: 1.6, 95% CI: 1.3 - 1.8, respectively). Compared with Light computer users, Heavy computer users had a higher risk of being overweight/obese (adjusted OR: 1.4, 95% CI: 1.2 - 1.7). We observed interactions between PA level and the amount of TV

viewed ($p=0.012$) or computer used ($p=0.010$). However, Heavy TV viewers had a higher risk of being overweight/obese regardless of PA level. The associations of TV viewing and computer use were similar with BMI categories and WHtR tertiles.

CONCLUSIONS: Heavy TV viewing and computer use are associated with higher BMI and central adiposity in preadolescents. Heavy TV viewing seems to increase the risk for overweightness and central adiposity, regardless of PA level. Strategies to reduce high sedentary screen times could potentially help in preventing overweightness and adiposity among children and adolescents.

Body Composition Changes Associated With A Structured Exercise Program Among Children And Adolescents

Ashley Peart, Kameron Suire, Ali Venezia, Darby Winkler, Danielle Wadsworth. *Auburn University, Auburn, AL.*
Email: azh0078@auburn.edu

(No relevant relationships reported)

Children and adolescents in the U.S. fail to meet physical activity guidelines and health consequences associated with inactivity, such as high body fat composition, continue to impact children. Targeting children for physical activity and fitness interventions have the potential to improve body composition; however, little is known on body composition changes during a fitness-based intervention.

PURPOSE: To determine changes in body composition for children participating in a fitness-based intervention.

METHODS: 21 children (age = 9.38 ± 3.82 , BMI = 21.0, body fat percentage = 30.90) participated in an 8-week, structured fitness intervention consisting of 1-hour weekly sessions. Weekly sessions provided fitness opportunities in a fun, non-competitive environment with the purpose to elicit moderate-to-vigorous physical activity. Pre- and Post-testing using the iDXA was conducted to detail changes in body composition.

RESULTS: Results from a paired samples *t*-test showed significant increases in the following body composition measures: Left Leg Lean Mass ($t = -2.366$, $p = .028$), Right Leg Lean Mass ($t = -3.914$, $p = .001$), Lean Mass Truck ($t = -2.766$, $p = .012$), Lean Mass Total ($t = -4.575$, $p < .001$), Right Leg Bone Mass ($t = -2.500$, $p = .021$) and Bone Mass Total ($t = -3.826$, $p = .004$). **CONCLUSIONS:** Participation in an 8-week fitness intervention showed positive body composition changes for children. These changes occurred with minimal intervention (1 hour per week). Future studies should determine the duration of the effect.

Multi-Component School-Based Weight-Management Program Improve Physical Fitness and Vascular Reactivity in Obese Adolescent

Napasakorn Chuensiri¹, Kanang Srihirun¹, Saowalak Siiripanya¹, Saowaluck Suntraluck², Tussana Jaruchart³, Vijit Kanungsukkasem¹, Daroonwan Suksom¹. ¹*Chulalongkorn University, Bangkok, Thailand.* ²*Institute of Physical Education Sukhothai campus, Sukhothai, Thailand.* ³*Naresuan University, Phitsanulok, Thailand.*

Email: napas.ch@gmail.com

(No relevant relationships reported)

The prevalence of childhood obesity has increased markedly in both eastern and western countries. Development of obesity in early life could lead to serious health problems including a premature cardiovascular disease. Therefore, a primary prevention such as an effective weight management program would be needed in order to minimize the adverse effects of childhood obesity. **PURPOSE:** This study aimed to determine the effects of multi-component school-based weight-management program on body composition, physical fitness and vascular function and structure in obese adolescents. **METHODS:** Twenty-eight obese adolescents (21 males, 75%) between the ages of 13 and 15 (14.1 ± 0.8) at or above the sex-specific 90th percentile on BMI-for-age growth charts were recruited. Participants were randomly assigned into control (CON; $n=12$) and intervention (INT, $n=16$) groups. The INT group participated in a multi-component school-based intervention for 10 weeks which included supervised after-school physical activities, dietary and daily physical activities related advices. Moreover, school-health promotion environment and health education lectures for school staffs, students and parents were included in the program. Non-curricular physical activities (i.e., running, playing games and resistance training) were performed moderate to vigorous aerobic activities for 50 minutes/day, three days a week on alternate days. Body composition, physical fitness, vascular function (brachial-FMD) and structure (IMT and baPWV) were measured before and after intervention. **RESULTS:** After 10-week of multi-component school-based weight-management program, body mass (89.7 ± 8.6 vs. 88.0 ± 10.5 , $p < 0.05$) and body fat percentage (44.13 ± 5.27 vs. 41.22 ± 6.74 , $p < 0.05$) significantly decreased only in an INT group. Peak oxygen consumption (29.25 ± 2.41 vs. 31.56 ± 3.05 , $p < 0.05$) and health related physical fitness increased only in an INT group ($p < 0.05$). Moreover,

vascular reactivity of an INT group was improved after 10-week program compared with a CON group (6.81 ± 2.25 vs. 3.62 ± 1.48 , $p < 0.05$). There was no change in artery wall thickness and stiffness in any group. **CONCLUSIONS:** Multi-component school-based weight-management program may be an effective primary prevention for reducing cardiovascular disease risk factors.

Weekly Frequency Of Meeting The Physical Activity Guidelines And Cardiometabolic Risk In Youth: Nhanes 2003-2006

David A. White¹, Erik A. Willis². ¹*The Children's Mercy Hospital, Kansas City, MO.* ²*National Cancer Institute, Rockville, MD.*

Email: dawwhite@cmh.edu

(No relevant relationships reported)

The current physical activity (PA) guidelines for children and adolescents recommend accumulating 60 minutes of moderate-to-vigorous intensity physical activity (MVPA), 7 days per week. Although the time and intensity components of the PA guidelines have been rigorously studied, the days per week (frequency) component is less researched. **PURPOSE:** To examine the influence of frequency of meeting the MVPA guidelines on cardiometabolic risk in children and adolescents. **METHODS:** Accelerometer data from children and adolescents (age 6-18 years; $n=673$) with at least 4 valid days, 10 hours of wear time, and an average of ≥ 60 minutes per day of MVPA participating in the National Health and Nutrition Examination Survey 2003-2006 were used. The Evenson cut points for MVPA were applied. The proportion of valid days meeting the ≥ 60 minutes of MVPA guidelines (DMG) were calculated and used to assign subjects to quartiles. General linear modeling was used to compare associations of quartiles to individual cardiometabolic risk factors. Covariates included age, sedentary time, MVPA, sex, race/ethnicity, asthma, physical disability, assessment period, quartiles of the Healthy Eating Index, and poverty-income ratio.

RESULTS: DMG by quartile are as follows: Quartile 1 ($n=158$; DMG=43.6%; 95% CI 41.8-45.5); Quartile 2 ($n=171$; DMG 62.3%; 95% CI 61.4-63.2); Quartile 3 ($n=154$; DMG=75.3%; 95% CI 74.6-76.0); Quartile 4 ($n=194$; DMG=91.6%; 95% CI 89.2-94.1). Diastolic blood pressure was higher in Quartile 1 and Quartile 2 compared to Quartile 3 (Q1=56.8mmHg, 95% CI 51.2-62.3; Q2=56.9mmHg; 95% CI 50.4-63.4, Q3=50.2mmHg; 95% CI 43.2-57.1; $p < 0.01$ and $p < 0.05$ respectively). There were no other differences between quartiles for BMI percentile, waist circumference, waist-to-height ratio, systolic blood pressure, cholesterol, triglycerides, glucose, or insulin. **CONCLUSION:** This cross-sectional analysis found no association between proportion of DMG and cardiometabolic risk factors in children and adolescents. Achieving an overall weekly average of 60 minutes per day of MVPA appears to be sufficient for cardiometabolic health regardless of meeting the frequency component of the PA guidelines. Future studies are needed to understand optimal weekly patterns and volume of PA as well as their associations with health outcomes in youth.

Fitness In Pediatrics: Is It Adequately Carried Out?

Jorge Franchella, Facsm, Laura Alvarez, Nuria Serrano. *Hospital De Clinicas. UBA, Buenos Aires, Argentina.*

Email: jfranche19@icloud.com

(No relevant relationships reported)

INTRODUCTION: The physical fitness in the pediatric area is mandatory, prior to the realization of physical activity, whether recreational, school or competition. Regarding the increasing demand we find that each pediatrician performs them by requesting complementary studies according to their own criteria and in a routine manner.

OBJECTIVE: Show the lack of consensus when requesting studies to perform the physical aptitude in the area of pediatrics. **MATERIAL AND METHODS:** A personalized type survey was conducted; to specialists of the pediatric area in the city of Buenos Aires during the month of May of the year 2018, in which they questioned about physical fit in pediatric age in healthy children and for all kind of physical activity. The data obtained was analyzed to know what evaluations and complementary studies request to give the physical aptitude. **RESULTS:** A total of 105 pediatricians were interviewed, of which 99 of them made physical aptitudes in their daily practice, this being the total number of surveys selected, 94% were clinical pediatricians and 6% had another subspecialty (cardiology, infectology, other ones). 68% had more than 10 years in the profession, only 12% had less than 5 years of activity in the specialty; this data did not make a significant difference when deciding on the request for studies. The 60% of professionals performed daily physical fitness, being 96% for school physical activity and of these only 45% were competitive schools and sport, none of them was for high performance. In relation to studies requested, 73% asked for an electrocardiogram, 25% Rx. of chest, 21% blood count, 10% echocardiogram and 3% ergometry annually, considering for this the type of physical activity to be carried out, as well as the weekly work load of the activity. The request for studies was not greater in the cases of competitive sports nor was it influenced by the number of weekly hours of sports practice. In relation to the age to request different studies, the majority

of doctors performed it after 5 years old and it was striking that in 72% of them do it annually, despite being the whole population healthy children. **CONCLUSIONS:** Facing this result, we believe it is necessary to unify the medical criteria to request studies in relation to the needs of patients

Contribution Of In-school And Out-of-school Physical Activity Towards Meeting The Daily Recommendations.
 Neal C. Phifer, Dale D. Brown, FACSM, Susann Marcum, Emily Jones, Skip M. Williams, Dan Phelps. *Illinois State University, Normal, IL.* (Sponsor: David Q. Thomas, FACSM)
 Email: ncphife@ilstu.edu
 (No relevant relationships reported)

PURPOSE: The purpose of the study was to examine in-school and out-of-school activity in children as related to achieving daily activity recommendations for moderate-to-vigorous physical activity (MVPA) and steps. **METHODS:** Activity patterns of 346, 10-12 year old fifth-grade students in three Midwestern elementary schools were assessed during a two week period, one week during school hours only and the other week for continuous 24 hour periods. Data were collected using wrist worn activity trackers (Polar Active). Teachers distributed the devices at the start of each school day and collected at the end of each school day for the first week and provided to the students for the next week for continuous monitoring. Monitors measured MVPA, steps, and calories expended per day. Demographic and anthropometric data were also recorded (age, height, weight). All data were uploaded to the monitor's manufacturer website and then collected by the researchers. A prior study was used to determine that four days of monitoring could accurately estimate physical activity. A final sample of 186 (N=186) students who attained a 500 step minimum for the same four consecutive school days between both weeks (M-R or T-F), were identified. These data were used to determine averages for steps, minutes of daily activity, and calories expended. **RESULTS:** Results indicate students attained an average of 15319.38 steps/day. In-school activity and out-of-school activity accounted for an average of 6362.79 steps/day (41.53% of total), 8956.59 (58.47% of total) respectively. Activity minutes averaged 77.43 minutes/day. In-school and out-of-school activity accounted for an average of 33.58 minutes (43.37% of total), and 43.85 minutes (56.63% of total) respectively. Calories expended averaged 2044.66 Kcal/day. In-school and out-of-school activity accounted for an average of 1560.56 Kcal (76.32% of total), and 484.10 Kcal (23.68% of total) respectively. **CONCLUSIONS:** These results indicate that out of school activities account for most of daily steps taken and activity minutes in the fifth grades students studied during an average school day. A similar distribution of caloric expenditure was not observed between in school and out of school monitoring.

1956 Board #112 May 30 3:30 PM - 5:00 PM
The Effect of Increased Extracurricular Physical Activity on the Mathematics Achievements of Children aged 7-9 Years Old
 Hanbing Song¹, Ming Yang¹, Yan Li¹, Jindong Chang².
¹Southwest University, Chongqing, China. ²The Branch of the Collaborative Innovation Center of Assessment toward Basic Education Quality at Southwest University, Chongqing, China.
 Email: songhanbing6@126.com
 (No relevant relationships reported)

PURPOSE: The purpose of this study was to assess the impact of an increased extracurricular physical activity on mathematics academic performance for children aged 7-9 years. **METHODS:** A sample of 120 children aged 7-9 participated in the MQ101 Program. The experimental samples were randomly divided into the experimental group (58 children) and the control group (62 children). The experimental group involved in the extracurricular exercise with games as the main activity content, intervention. The activity lasted for 12 weeks, twice a week for 60 minutes each time, exercise intensity: MVPA = (220-age) × (60-69%); the control group did not participate in any intervention project. The body shape, physical fitness, and mathematics testing scores of the subjects were tested before and after the experiment. The main finding is the change in numerical scores, measured by a standardized mathematical test of 10 minutes. The secondary outcome is a change in body shape and physical fitness. **RESULTS:** The results showed that the experimental group was better than the control group in the problem solving ($t=2.87, p<0.01$), calculation speed ($t=-3.39, p<0.01$) and accuracy rate ($t=2.21, p<0.05$). The math scores of the experimental group were significantly higher than the control group ($t=4.14, p<0.01$). In addition, the changes in physical fitness of the experimental group were significantly better than the control group ($t=2.34, p<0.01$), however, the difference in body shape index was not statistically significant ($t=1.91, p>0.05$).

CONCLUSIONS: The results of this randomized trial are expected to provide schools and policy-makers with significant new insights into the potential of extracurricular PA to improve physical fitness and academic achievement in children. (This study was supported by NPOSS Grant 15CTY011.)

Influence Of Menarche On Perception, Dimension And Body Image Of Active And Insufficiently Active Girls
 Roberta L. Rica¹, Eliane F. Gama¹, Danilo S. Bocalin². ¹São Judas Tadeu University, São Paulo, Brazil. ²Federal University of Espirito Santo, Vitória, Brazil.
 Email: robertarica@hotmail.com
 (No relevant relationships reported)

Menarche causes body changes such as increased body fat and classic changes occur in secondary sexual characteristics. In this way due to body changes, the body perception also needs to be adjusted. The regular practice of physical activity has been considered a key element to improve the perception of size and body image in different populations, however, to our knowledge, the association between menarche and the level of physical activity in perception of the dimension and of the body image still unexplored. **PURPOSE:** Verify the influence of menarche in the perception of the dimension and the body image of active and inactive girls. **METHODS:** After the approval of the São Judas Tadeu University Research Ethics Committee, thirty-eight girls were distributed into two groups active and insufficiently active subjects and analyzed semiannually by 2,5 years by identification before and after menarche. Anthropometric parameters (height, body weight and body mass index), perceptions of body size (using the Image Marking Procedure) and body image (silhouettes scale) were used as evaluation parameters. **RESULTS:** After menarche, all the girls in both groups presented alteration ($p<0.05$) only in the anthropometric parameters and in the body perception index of the hip after the menarche. No significant changes were identified ($p>0.05$) between groups. **CONCLUSION:** menarche induced anthropometric alterations and perception of the hip dimension, but without promoting changes in the general perception of the body, as well as in the indication of the silhouettes and in the corporal satisfaction regardless of the level of activity physical.

1958 Board #114 May 30 3:30 PM - 5:00 PM
Habitual Physical Activity And Academic Achievements Among Undergraduate Adult Students
 Daniel S. Moran, FACSM, Julianna Aisner, Tamam Younis, Oxana Rubinstein. *Ariel University, Ariel, Israel.*
 (No relevant relationships reported)

Physical activity is associated with many physical and mental health benefits. The activity improves mood, reduces stress and anxiety and as shown previously increases academic performance with higher grades among youth and young undergraduate students. **PURPOSE:** To examine the relationship between physical activity habits and academic achievement among undergraduate adult male and female students. **METHODS:** Two hundred and thirty two male students (34.5 ± 10.2 yrs) and seventy two female students (36.5 ± 7.6 yrs) from the Faculty of Health Sciences at Ariel University volunteered to participate in this study. The cross-sectional study was conducted using a quantitative method and data was collected by a closed questionnaire, which included questions about physical activity in view of intensity, type of activity, time duration and frequency per week and was analyzed vis-à-vis academic achievements. **RESULTS:** A significant positive correlation ($p<0.03$) was found between physical activity habits and higher grades only among the male students. For the younger male students and the adult male students - the higher the physical activity time duration and frequency the higher the grades were. No correlation between adult female students' physical activity and academic grades were found ($p>0.05$). **CONCLUSIONS:** Older male students' academic grades were correlated to their physical activity habits. The awareness of the importance of physical activity habits among undergraduate male students is not limited to the younger age students but is also true for all age groups.

Assessing Hispanic College Students Knowledge Related to Metabolic Syndrome Conditions
 Ulku S. Karabulut, Lin Wang, Zasha Romero, Paloma Mendoza, Murat Karabulut, FACSM. *UTRGV, Brownsville, TX.*
 Email: ulku.karabulut@utrgv.edu
 (No relevant relationships reported)

PURPOSE: To investigate Hispanic college students' awareness and knowledge related to metabolic syndrome (MetS) conditions. **METHODS:** Hundred and thirty-nine Hispanic college students (age= 22.43 ± 4.07) volunteered to participate in the study. Each participant read and signed the consent form prior to any data collection to take place. Demographic data including age,

race, gender, and major were collected. Participants then answered 89 questions and completed MetS knowledge questionnaire (Yahia et al., 2014; Becker et al., 2008). The questionnaire was designed to assess MetS related knowledge and awareness and has seven categories: diabetes, adiposity, hypertension, high serum cholesterol, arteriosclerosis, stroke, and myocardial infarction. Students' responses were scored and interpreted as poor knowledge ($\leq 50\%$ correct), fair knowledge (51-80% correct), and good knowledge (81-100%).

RESULTS: The results showed that majority of the students had fair level of knowledge (71.80% correct) related to MetS conditions. The participants were more knowledgeable on stroke and adiposity, and least knowledgeable on cholesterol, myocardial infarction, and diabetes components. There was no significant difference between genders for the level of knowledge for adiposity, cholesterol, myocardial infarction, and diabetes component of the questionnaire. However, there was a significant difference in knowledge level for stroke component between genders ($p < 0.01$). Males had more knowledge on stroke component than females.

CONCLUSIONS: Majority of Hispanic college students have fair level of knowledge about MetS and MetS related conditions. Findings suggest that students MetS related knowledge and awareness can be improved. MetS is highly prevalent among Hispanic population. Therefore, increasing Hispanic students' awareness and knowledge related to MetS is essential to improve students' overall health. Previous studies identified colleges and universities as potential settings for health prevention and early intervention. Future studies should investigate the effects of various intervention methods on Hispanic students' MetS related knowledge and long-term health conditions.

1960 Board #116 May 30 3:30 PM - 5:00 PM
Comparison of School Meal Patterns in High School Athletes and Non-Athletes

Alison M. Redd, Jeanette M. Garcia. *UCF, Orlando, FL.*
(No relevant relationships reported)

PURPOSE: To compare differences in school meal patterns and total (both interscholastic organized sports and leisure-time) physical activity among high school athletes and non-athletes. **METHODS:** A total of 308 high school students (16.04 \pm 1.35 years old, 56.5% female, 59.4% Caucasian) completed a series of questionnaires regarding their consumption of meals provided at school (both breakfast and lunch), participation in their school's free/reduced price meal program, and reasons for not consuming school meals. Additionally, questions regarding weekly duration and frequency of organized interscholastic sports practices and leisure-time physical activity were included. Due to skewed distributions, both non-parametric and parametric analyses were conducted to compare differences among male and female athletes and non-athletes. All analyses were conducted in SAS software version 9.4 with a significance level set at $\alpha < 0.05$ software.

RESULTS: Out of the 308 participants, 56% of the sample ($n=168$, 51% female) participated in interscholastic sports, and 44% ($n=136$; 65% female) were classified as non-athletes. Student athletes participated in more overall weekly physical activity ($p=0.00$) compared to non-athletes. No differences existed between athletes and non-athletes regarding their consumption of either school breakfast (24.4% athletes vs. 18.4% non-athletes, $p=0.2$) or lunch (52.3% athletes vs 45.6% non-athletes, $p=0.24$). Additionally, there were no differences between athletes (29%) and non-athletes (34.5%) regarding participation in the school free/reduced meal program ($p=.023$). Qualitative feedback provided for avoiding consumption of school meals included students arriving to school without enough time to purchase breakfast before class, eating breakfast or lunch from home, and that school meals are not appetizing or healthy. **CONCLUSIONS:** School meals are consumed by student athletes; therefore the nutritional value of school meals should provide for the energy needs of student athletes as well as the general student population of non-athletes.

(No relevant relationships reported)

PURPOSE: Mental health concerns, like anxiety and depression, are prevalent among college students (Blanco et al., 2008). Chronic moderate-intensity exercise has been shown to improve these difficulties (Morres et al., 2018). This study evaluated changes in physical and psychological health in ethnically-diverse urban undergraduate students after a 10-week peer-led aerobic training intervention. **METHODS:** Twenty-three sedentary undergraduate students (mean age = 21 \pm 2.24 yrs) participated in a 10-week training program composed of one weekly peer-led aerobic exercise session and completed 2 additional sessions per week independently. One week prior to and following the training program, assessments of cardiovascular fitness, using

the Rockport 1-mile walk test, anthropometric measures, and psychological health, using self-report measures from the NIH Toolbox and the Patient-Reported Outcomes Measurement Information System scales, were conducted. Paired-samples t tests were used to assess pre-post program changes in these measures. **RESULTS:** Participants attended 8.3 \pm 1.26 moderate-vigorous exercise sessions under the supervision of their peer-trainer and exercised independently 2.39 \pm 1.95 d-wk⁻¹ for an average of 34.85 \pm 19.62 min-session⁻¹. Despite a significant progressive increase in intensity from the first 3 to the last 3 sessions (mean HR = 135.98 \pm 16.98 and 150.15 \pm 15.16, respectively; $p < .001$), no effect of aerobic training on cardiovascular fitness or other anthropometric measures were detected (all $p > .10$). Nevertheless, there were significant pre-post-program improvements on multiple measures of psychological functioning including perceived stress, positive affect, sadness, and emotional support (all $p < .05$). There were marginally significant trends towards improvement in measures of perceived rejection ($p = 0.055$), general life satisfaction ($p = 0.062$), and perceived hostility ($p = 0.069$).

CONCLUSIONS: These preliminary findings are consistent with the literature indicating that moderate-intensity aerobic exercise improves psychological functioning. They support the further assessment of peer-mediated aerobic exercise to alleviate stress and improve quality of life in undergraduate students representing a diverse inner-city demographic.

Relationship Between Duration and Quality of Sleep on College Student Health Behaviors and Outcomes

Anthony C. Rosso, Oliver W.A. Wilson, Zack Papalia, Michele Duffey, Melissa Bopp, FACSM. *The Pennsylvania State University, State College, PA.* (Sponsor: Dr. Melissa Bopp, FACSM)
 Email: acr5435@psu.edu
(No relevant relationships reported)

Lack of sleep among college students is currently a massive epidemic affecting millions. Sleep duration and quality is an important determinant of overall health, and is related to health behaviors (physical activity (PA) & diet) and outcomes (mental health). But little is known about these relationships among college students.

Purpose: Examine how PA, depression, body mass index (BMI), fruit and vegetable consumption (FVC), and academic performance differed based on sleep quality and duration. **Methods:** Students completed an online survey, self-reporting their sex, height, weight, grade-point average (GPA), PA levels, FVC, and also responded to questions regarding mental health and sleep. Participants were grouped into those who reported less <4 or ≥ 4 nights of restful sleep/week. Paired samples t-tests examined differences in the aforementioned PA, FVC, BMI, and GPA between groups. Chi-square tests for independence examined differences in mental health (depression and stress) based between groups. **Results:** 4380 participants responded to the sleep question, the majority of whom were women (59.2%) and non-Hispanic white (76.1%). For all participants, those who reported better sleep reported significantly higher moderate PA ($p = .045$), vigorous PA ($p < .001$), weekly MET-min ($p < .001$), and GPA ($p < .001$), whereas BMI ($p = .627$) and FVC ($p = .107$) did not differ between groups. When split by sex, the same results were revealed for women, but among men the only significant differences were in GPA ($p = .042$) and vigorous PA ($p = .019$). Those who reported better sleep also reported significantly less symptoms of depression regardless of sex ($p < .001$). **Conclusion:** A positive relationship between sleep and PA was found for women. In men, only vigorous PA was found to have a positive relationship with sleep. Though, a positive relationship between sleep and academic performance was evident for both sexes. In addition, better sleep was associated with better mental health regardless of sex. In summary, findings highlight the importance of more education on the importance in the relationship of sleep and better academic performance and mental health. Further research is required to examine the relationship, in particular directionality, between the amount PA and the duration of sleep in college students.

 Email: mmaldar1@fitchburgstate.edu
(No relevant relationships reported)

Research suggests that many undergraduates do not achieve the minimum recommended amounts of physical activity (PA). Furthermore, the link between college students' attitudes toward PA and participation are unclear. **PURPOSE:** The purpose of this investigation was to qualitatively examine student experiences and attitudes about PA while enrolled in a conceptually-based, mandatory, health and fitness course. **METHODS:** Semi-structured interviews were performed individually

with a subset of 10 (6 female, age 18-21years, 70% Caucasian) students who were enrolled in a larger study (n=135) investigating learning and behavioral outcomes from participation in a health and fitness course. Interviews were audio recorded and transcribed verbatim. Thematic analysis was used to identify predominant themes. **RESULTS:** Interviewees described their experiences and learning outcomes from the course. In regards to PA attitudes and practices, three themes emerged: (1) Self-Consciousness. Participants reported feeling embarrassed and awkward in the fitness center when using equipment that was unfamiliar to them. (2) Friend/Family Influences. The majority of interviewees reported exercising with friends as a strategy to improve motivation. Additionally, many identified family members as either having a positive or negative influence on PA behaviors. (3) Motivational Factors. The primary factors participants cited as influencing PA motivation were health, and maintenance of body weight. **CONCLUSIONS:** Results show that several factors influence college students' motivations, attitudes, and adherence to PA participation. It is recommended that health educators consider implementing practices to ensure that physical activity courses meet the specific needs of college students. This study was funded by a Fitchburg State University Special Projects Grant.

Effects Of A 13-week Yoga Class On College Aged Student's Flexibility, Body Image, And Mood

Suet Hon. *The Chinese University of Hong Kong, Hong Kong, Hong Kong.* (Sponsor: Professor Stanley Hui S.C., FACSM)
Email: hon1102suet@gmail.com

(No relevant relationships reported)

PURPOSE: Yoga has been practiced as a low to moderate intensity physical activity in recent years and evidence suggests that yoga practices can bring beneficial effects on physical and mental health. The present study examined whether a 13-week yoga practice of postures, breathing, and relaxation techniques can improve the flexibility, body image and mood of college aged students. **METHODS:** A sample of 60 students was recruited from university to participate in a 13-week yoga class. A pre-post test design was used for this study. Measurement on the physical aspects included the flexibility test and whereas the mental aspects included body image questionnaire (Body Appreciation Scale-2) and mood questionnaire (The Positive and Negative Affect Scale). Data were analyzed at the significance level of $p < .05$ for one group pre- and post-test of two data sets. **RESULTS:** The Mann-Whitney showed significance at the $p < .01$ for the sit and reach flexibility test and significance at the $p < .05$ for the body image and mood questionnaire. Sixty students (19 ± 2 years; 1.60 ± 0.15 m; 52 ± 8.4 kg) reported improved flexibility (ranged from 3% to 9%), increased body appreciation (mean value from 3.8 to 4.2) and positive mood (mean value from 3.9 to 4.3) after the 13-weeks class. The majority students desired to participate in more yoga classes in the future. **CONCLUSIONS:** This study suggests that a 13-week yoga class showed improvements of flexibility, increasing positive body image and enhancing mood who are novice yoga practitioners. Since the participants in this study were all girls and future study can examine the gender difference on the topic.

Associations between Parents' Physical Activity and Young Children's Health Outcomes

Nan Zeng¹, Susan L. Johnson², Richard E. Boles², Laura L. Bellows¹. ¹Colorado State University, Fort Collins, CO. ²University of Colorado Anschutz Medical Campus, Aurora, CO.
(No relevant relationships reported)

PURPOSE: While parents play an important role in child development, little is known about the influence of parents' physical activity (PA) on young children. This study examined the associations between parents' PA and their preschoolers' body mass index (BMI), PA, and fundamental movement skills (FMS). **METHODS:** Of 257 parent-child dyads recruited across 3 cohorts from 4 Colorado Head Start/preschool centers from 2010-2012, 109 children (57 girls, 36 Hispanic, $\bar{X}_{age} = 4.69 \pm 0.34$, $\bar{X}_{BMIz} = -0.49 \pm 1.14$) and parents had complete data were included in the analysis. Parents' and children's PA on 4 weekdays and 2 weekends were assessed by pedometers and calculated as steps per hour. Children's BMI and sex- and age-adjusted BMIz scores were calculated using 2000 CDC Growth Charts for the United States. Children's FMS was assessed via the Bruininks-Oseretsky Test of Motor Proficiency—2nd Edition (BOT-2), including 1) Balance, 2) Running Speed and Agility (locomotor skills), 3) Upper-Limb Coordination (object control skills), and 4) Strength. Bivariate correlation and linear regression were used to examine the associations between parents' PA and children's BMI, PA, and FMS.

RESULTS: Bivariate correlation indicated that parents' PA was positively associated with children's locomotor skills ($r = 0.19$, $p < 0.05$), strength ($r = 0.21$, $p < 0.05$) ($r = 0.34$, $p < 0.01$), and inversely related to children's BMI ($r = -0.23$, $p < 0.05$). Linear regression further suggested that parents' PA was a significant predictor of children's locomotor skills [$F(5, 108) = 2.45$, $\beta = 0.13$, $p < 0.05$, $R^2 = 0.11$], PA [$F(5, 108) = 2.95$, $\beta = 0.32$, $p < 0.05$, $R^2 = 0.13$], and BMI [$F(5, 108) = 2.97$, $\beta = -0.16$, $p < 0.05$, $R^2 = 0.13$], but not a significant predictor of strength [$F(5, 108) = 1.35$, $\beta = 0.18$, p

$= 0.25$, $R^2 = 0.06$], after children's age, sex, ethnicity, and school site were adjusted. **CONCLUSIONS:** The findings suggest that parents' physical activity behavior is directly associated with their children's BMI, PA, and FMS—setting the stage for the development of experimental trials seeking to promote improvements in preschool children's FMS and overall health. Future research with larger and more diverse samples investigating the influence of parents' PA intensity (i.e., light, moderate, and vigorous) on preschool children's other health outcomes is warranted.

1966 Board #122 May 30 3:30 PM - 5:00 PM

Effects Of A Peer-led Aerobic Training Program On Physical Activity Behavior Of Urban College Students

Galila Werber-Zion¹, Olga G. Berwid¹, Gregory Klimaytis², Ricky Melendez¹, Yesenia M. Echevarria², Alana I. Johnson¹. ¹York College, City University of New York, Jamaica, NY. ²Queens College, City University of New York, Queens, NY.
Email: gwerber@york.cuny.edu

(No relevant relationships reported)

PURPOSE: Peer-based education is commonly used on college campuses to provide health information. Using it to introduce physical activity to ethnically-diverse sedentary students attending an urban commuter college has not been explored. We examined the impact of a 10-week peer-based aerobic-exercise (AE) training program on urban college students' leisure physical activity behavior. **METHODS:** Inactive students ($N = 23$, mean age: 21 ± 2.24 yrs) participated in a 10-week training program consisting of approximately 3 weekly AE sessions. Once-per-week sessions led by a peer-student trainer included a short lecture on exercise's health benefits followed by 30 mins of AE (55%-65% HRR); participants were instructed to complete 2 other AE sessions independently per week and completed weekly online journals to assess adherence. Pre- and post-training evaluations of AE behavior patterns [International Physical Activity Questionnaire (IPAQ)] were conducted in the weeks prior to and following the exercise program and one month (30-IPAQ) and 90 days (90-IPAQ) after the conclusion of training. Descriptive statistics describing program participation and adherence are presented. Paired-samples t-tests were conducted comparing pre- and post-training cardiovascular fitness. **RESULTS:** Each week 19.1 ± 1.66 participants attended a peer-led session, training at THR of 142.61 ± 22.88 . Participants completed a mean of 8.3 ± 1.26 sessions out of the expected 10. They completed a mean of 2.39 ± 1.95 d-wk⁻¹; 34.85 ± 19.62 min-session⁻¹ independently. Twenty (86.96%) participants completed the 90-IPAQ thus, students' leisure physical activity analysis included only these 20 participants. Pre-IPAQ data demonstrated that 25% of participants engaged in leisure physical activity at a mean of 164 ± 120 MET-min-wk⁻¹. One month following the training period 60% of participants exercised at a mean of 434.38 ± 395.76 MET-min-wk⁻¹; 90-IPAQ data demonstrated 55% of participants continued to engage in leisure physical activity at 488.73 ± 381.33 MET-min-wk⁻¹ on average. There was no significant effect of aerobic training on participants' cardiovascular fitness level. **CONCLUSION:** Participation in a peer-led aerobic training program may serve as a gateway to adopting a low level of leisure physical activity by urban college students.

Association of Sleep Quality and Physical Activity among Chinese College Students

Xiangyu Zhai, Qian Gu, Mei Ye, Tao Huang, Kun Wang, Xiang Fan. Shanghai Jiao Tong University, Shanghai, China.
Email: zxy530@sjtu.edu.cn

(No relevant relationships reported)

Sleep plays a critical role in the growth of youth. However, increasing studies suggest that the sleep quality (SQ) in Chinese youth is in a worrying situation. Meanwhile, SQ is associated with lifestyle factors, such as physical activity (PA). Therefore, this study will particularly focus on the association between PA level and SQ in Chinese college students, a special youth group who are under academic pressure.

PURPOSE: The present study is aimed to determine the correlation between SQ and PA level in Chinese college students.

METHODS: In 2017, 4330 college students (male: 60.1%; female:39.9%) aged 17-24 years were randomly sampled from Shanghai Jiao Tong University, China. SQ, PA level, academic pressure and lifestyles of students were collected via a questionnaire. SQ and PA level were evaluated by Pittsburgh Sleep Quality Index (PSQI) and International Physical Activity questionnaire, respectively. SQ dichotomizes two levels: good SQ (PSQI score ≤ 5) and poor SQ (PSQI score > 5). PA was also divided into two levels: sufficient PA and insufficient PA according to World Health Organization moderate-to-vigorous physical activity (MVPA) recommendations.

RESULTS: Average MVPA time was 43.5 ± 37.5 min/day (males: 47.0 ± 39.6 min/day; females: 38.1 ± 33.2 min/day). About 25.5% of participants met MVPA recommendations (males: 29.0%; females: 20.1%). Average SQ score was 7.81 ± 1.89 (males: 7.67 ± 1.86 ; females: 8.06 ± 1.91). About 89.5% of participants had poor SQ (males: 87.9%; females: 91.8%). Males with sufficient PA had better SQ (7.42 ± 1.87) than those with insufficient PA (7.74 ± 1.85 , $P < 0.05$). But no significant correlation was found in females. The linear regression results showed that insufficient PA was

associated with higher SQ score ($B=0.24, P<0.01$) among males. Other health-related factors such as dietary habits and academic pressure also showed significant correlation with SQ. However, regarding the females, no significant correlation between PA and SQ was observed. Furthermore, after adjustment for the demographic variables and health-related factors, the results of binary logistic regression showed that males with insufficient PA had higher odds of poor SQ ($aOR=1.44, 95\%CI=1.12-1.86, P<0.01$) compared with the others.

CONCLUSION: Better SQ was related to higher PA level in male college students.

Associations Between Physical Activity, Diet, And Substance Use With Academic Performance

Peter J. Matthews, Oliver W. A. Wilson, Zack Papalia, Michele Duffey, Melissa Bopp, FACSM. *Pennsylvania State University, State College, PA.* (Sponsor: Dr. Melissa Bopp, FACSM)
Email: pjm5690@psu.edu

(No relevant relationships reported)

Physical inactivity, poor diet, and alcohol/substance abuse are common health behaviors among college students. However, little is known about the relationship between these health behaviors and academic performance. **Purpose:** To examine differences in grade point average (GPA) based on physical activity (PA) levels, fruit and vegetable consumption (FVC), and use of alcohol and substances. **Methods:** Students completed an online survey self-reporting demographics (age, sex, race/ethnicity), PA (min/week of moderate and vigorous PA), FVC (servings/day), use of alcohol and substances (yes/no), as well as GPA. Independent samples t-tests were used to examine differences in GPA between those who did/not meet PA and FVC recommendations, and those who did/not use alcohol and substances. **Results:** Data was collected from 3738 participants (women, 57.8%, non-Hispanic white, 77.2%). For all participants, GPA differed significantly between those who did (3.40±.40) and did not (3.36±.48) accumulate 500 weekly MET-min ($p=.034$), and those who did (3.42±.40) and did not (3.34±.46) meet FVC recommendations ($p<.001$). GPA also differed significantly between tobacco users (3.26±.41) and non-users (3.40±.42, $p<.001$), as well as cigarette users (3.30±.40) and non-users (3.41±.42, $p<.001$), but not based on alcohol use, for all participants. **Conclusion:** Findings indicate that those who utilize substances, are less physically active and display unhealthy eating habits, tend to have poor academic performance. This provides insight to students and campus health professionals regarding how their health behaviors may be affecting their GPA.

Pilates Connect: A Program To Support The Transition Of Student-athletes To Lifetime Activity

Melinda B. Smith, Erin J. Reifsteck, Pam Kocher Brown, Diane L. Gill, FACSM. *University of North Carolina at Greensboro, Greensboro, NC.*

Email: mbsmith9@uncg.edu

(No relevant relationships reported)

Student-athletes face challenges maintaining physical activity when they transition beyond college athletics, including loss of team support, few specific goals and strong athletic identities with weaker exercise identities (Fuller, 2014; Reifsteck, Gill, & Labban, 2016). Resources that prepare final-year student-athletes for meaningful lifetime physical activity support physical and psychological wellness. **Purpose:** To implement the *PILATES Connect* program for final-year student-athletes and evaluate their experiences and program support in the transition to lifetime physical activity. **Methods:** Twelve final-year student-athletes participated in *PILATES Connect*, once each week for six weeks. The sessions included 35 minutes of Pilates training, 15 minutes of reflection and discussion, and 10 minutes of evaluation. Measures included attendance, session and program evaluations, and focus groups. **Results:** Final-year student-athletes strongly adhered to the program, with an overall attendance rate of 94.4%. In session evaluations (1=not at all true, 7=very true), participants agreed that they were pretty good at Pilates ($M=4.8$), did the activity because they wanted to ($M=6.6$), and felt like they could trust the other participants ($M=6.4$). Participants agreed that *PILATES Connect* supported their confidence in the transition to lifetime activity ($M=5.5$), greater control over activity choices ($M=5.9$), and connection to other participants ($M=6$). They would recommend *PILATES Connect* to other student-athletes ($M=6.8$) and consider participating in Pilates or other group exercise in the future ($M=6.8$). Focus group responses highlighted increased confidence through progression in a new form of activity and recognition of different options for activity after graduation. Student-athletes enjoyed discussing the transition with peers and felt less alone. They recommended more sessions and promoting the program through word of mouth and feedback from past participants. **Conclusion:** The six-week *PILATES Connect* program was feasible, as evidenced by strong adherence rates and positive feedback from participants. Final-year student-athletes agreed that the program supported their competence, autonomy, and relatedness in physical activity as they approached the transition to alumni.

Gunter Submission

Evan Hilberg¹, Katherine B. Gunter, FACSM¹, Patrick Ahi Nader². ¹*Oregon State University, Corvallis, OR.* ²*Universite de Moncton, Moncton, NB, Canada.*

Email: evan.hilberg@oregonstate.edu

(No relevant relationships reported)

Purpose: To learn if different physical activity (PA) promotion approaches for boys compared to girls are needed in rural elementary school settings, we evaluated sex differences in total physical activity (TPA) and moderate-to-vigorous physical activity (MVPA) among 1st - 5th graders attending six rural schools in Oregon.

Methods: We assessed the PA levels of 1739 students (835 girls and 901 boys) over four consecutive school days using Walk4Life MVP pedometers in fall 2015. Devices were worn above the right hip for the duration of the school day (6.5 hours/day) and programmed to measure PA time at any intensity (i.e. no minimum requirement for step rates/min). Time spent in MVPA was evaluated using a pre-specified step rate (≥ 120 steps/min). Teachers distributed and collected devices daily, recorded wear time, and reported daily classroom schedules (e.g. time for recess, lunch, etc.). At the end of day 4, data were downloaded, screened for outliers (daily step counts <500 or >15000 , incorrect MVPA settings) and adjusted for transport time. Linear mixed effects models were used to assess relationships between TPA and MVPA, and child sex and grade level. To examine the school and teacher influence, we utilized teachers nested within schools as a random effect in the model. All analyses were run in R.

Results: Analyses were done on data from 577 boys and 552 girls. There were significant sex and grade-level differences in the volume of TPA and MVPA accrued throughout the school day ($p<0.001$). Boys accrued more TPA and MVPA than girls, and younger children accrued more TPA and MVPA than older children ($p<0.001$). There was a significant grade by sex interaction. Specifically, for both MVPA and TPA, girls in 2nd through 4th grades accumulated fewer minutes than similarly aged boys, and this difference was attenuated as children got older. By grade 5, boys and girls were accruing similar levels of TPA and MVPA during school hours.

Conclusions: Physical activity levels at school declined for all students from 1st through 5th grade. Girls in 2nd through 4th grades exhibited lower TPA and MVPA levels than boys. Preliminary findings suggest different approaches to increase PA among elementary school girls may be warranted. More data are needed to learn where to target those approaches.

Supported in part by USDA NIFA, Grant #2011-68001-30020.

Effect Of 10-week Flag Football Intervention On Physical Activity Of Overweight And Obesity Children

Jie Zhuang¹, XinZhao Cao¹, DongNing Liu¹, Jun Wu², JunYu Wang¹, Yong Gao³. ¹*Shanghai University of Sport, Shanghai, China.* ²*Shanghai Liuyi elementary school, Shanghai, China.* ³*Boise State University, Boise, ID.*

Email: zhuangjie@sus.edu.cn

(No relevant relationships reported)

Purpose: To investigate the effect of 10-week flag football exercise and regular physical education class on daily physical activity (PA) levels in elementary school students.

Methods: A total of 48 9-10yr students (mean age in yr: 9.73 ± 0.55 ; 24 males, 24 female) was divided into either a flag football intervention group or a conventional physical education group. The intervention group received a 35-minute flag football exercise session, twice a week, for 10 weeks. The physical education group received a 35-minute/day routine session, including gymnastics and sports games. Daily PA was measured before and after 10 weeks for both groups using ActiGraph GT3X+ (wore on right hip) for seven consecutive days. The cut-points established by Evenson et al. were used to convert Actigraph counts data into PA in minutes in different intensity levels (sedentary: 0-25 counts/15 seconds, light: 26-573 counts/15 seconds, moderate-to-vigorous: ≥ 574 counts/15 seconds). Differences in PA between intervention and control groups before and after the 10-week intervention period were compared by a series of mixed model repeated measures ANOVAs. Data were expressed as mean \pm standard deviation; Significant level was set at 0.05. **Results:** The intervention group spent less sedentary time than the control group after the 10-week intervention (Table 1). **Conclusions:**

Flag football exercise could help reduce overweight and obesity elementary school students' daily sedentary time. Meanwhile, it was noticed that daily MVPA levels of most of these students were significantly below 60 min/d. This study was supported by National Social Science Fund of China (No. 18BTY095)

Table 1 Group differences in weekday PA levels (min/d)

The Effect Of Extracurricular Physical Activities In The Development Of Coordination Of Children Aged 7 To 9 Yearsold
 Yunsai Chen¹, Ming Yang¹, Jingdong Chang². ¹Southwest University, Chongqing, China. ²The Branch of the Collaborative Innovation Center of Assessment toward Basic Education Quality at Southwest University, Chongqing, China.
 Email: yunsaiCHEN@qq.com
 (No relevant relationships reported)

PURPOSE: The purpose of this study was to assess the effects of extracurricular physical activities on the physical coordination in children aged 7-9 years.
METHODS: A sample of 120 children aged 7-9 years (52% boys) was enrolled for a 12-week experimental intervention study. The sample was divided into an experimental group (58 children) and control group (62 children) by random number method. The experimental group participated in extracurricular intervention courses twice a week for 1 hour. The content of the course was mainly game, medium exercise intensity. The control group did not participate in the extracurricular exercise. The "Chinese Children Coordination Test (CCCT) developed by the project team was used to conduct the coordination test before and after the experiment. The raw data was standardized and compared according to age and gender.
RESULTS: After 12 weeks of extracurricular intervention, the results showed that the scores of the experimental group in the transfer coordination ($t=2.89, p<0.05$), click-to-click ($t=2.76, p<0.05$), climbing obstacles ($t=4.47, p<0.05$), and rolling skills ($t=3.81, p<0.05$) were significantly higher than the control group. The experimental group was significantly higher than the control group ($t=2.90, p<0.05$) in the standardized comprehensive score. **CONCLUSION:** Extracurricular physical activity intervention could significantly improve the coordination ability of children, and the density of extracurricular physical activities should be strengthened in this age group.
ACKNOWLEDGEMENT: Supported by NPOSS Grant 15CTY011, Humanities and Social Sciences by Ministry of Education Grant 17YJC890020.

Globally, 80.3% of school-aged children do not engage in the recommended 60 minutes of daily moderate-to-vigorous physical activity (MVPA; Hallal et al., 2012). Motor skill competence is fundamental to a child's physical activity and cognitive development (Stodden et al., 2008), and thus may explain the lack of MVPA engagement among children.

Purpose: This study aimed to examine the effects of a fundamental motor skills (FMS) intervention program on physical and cognitive health outcomes among elementary children.

Methods: Participants were 31 K-2 students (19 girls, 12 boys; $M_{age} = 6.65$) from three public elementary schools in the southwestern U.S. They were randomly assigned to either the intervention (1 school, $n = 20$) or the control group (2 schools, $n = 11$). During two separate 8-week periods in 2017 and 2018, children in the intervention group (13 girls, 7 boys) joined the FMS intervention for three times per week (60

minutes each time), while children in the control group (6 girls, 5 boys) followed a traditional afterschool program (e.g., free play). Children's pre- and post-intervention data were collected using the Test of Gross Motor Development - 2nd edition (TGMD-2; Ulrich et al., 2000), accelerometers (Actical), and a cognitive function questionnaire (PedsQLTM; Varni et al., 2011). To examine the intervention effect, a 2 × 2 repeated measures MANOVA was used, with group as the between-subjects variable and time as the within-subjects variable.

Results: The MANOVA showed significant differences between the intervention and the control group over time, $F(4,26) = 16.83, p < .001$, partial $\eta^2 = .72$. Follow-up univariate tests for the group × time effect indicated significant differences ($p < .05$) in locomotor skills (intervention: $M_{T1} = 25.4$ vs. $M_{T2} = 37.98, d = 8.31$; control: $M_{T1} = 29.73$ vs. $M_{T2} = 30.32, d = 0.25$), object-control skills (intervention: $M_{T1} = 24.68$ vs. $M_{T2} = 39.78, d = 7.07$; control: $M_{T1} = 27.05$ vs. $M_{T2} = 27.59, d = 0.19$), and MVPA (intervention: $M_{T1} = 143.62$ vs. $M_{T2} = 170.06, d = 2.54$; control: $M_{T1} = 166.24$ vs. $M_{T2} = 155.17, d = 0.79$), but not in cognitive function ($p > .05$).

Conclusion: The FMS intervention showed significant improvements in FMS and MVPA, compared to a traditional afterschool program. Findings highlight the importance of FMS for motor skill competence and MVPA promotion among school-aged children.

Evaluation Of A Physical Activity Level And And Physical Fitness In Obese Children: Health Educational Program For Children (hepchild)
 Henrique L. Ribeiro, Suliane B. Rauber, Carmen S. Campbell.
 Universidade Católica de Brasília, Águas Claras, Brazil.
 (No relevant relationships reported)

PURPOSE: This study aimed to investigate the impact of a Health Educational Program for Children (HEPchild) being 5 days of Camp and 12weeks follow-up on the physical activity level (PAL) and physical fitness (PF) in obesity children.
METHODS: The HEPchild was designed for obese children and developed in two phases: The Phase 1 consisted of Pre assessments and five-day camp (CAMP); and Phase 2 corresponded to the 3 months follow-up. Twelve children attended to CAMP as well as PAL and PF tests

RESULTS: After 12 weeks, 25% of children became more active (> 1500 and < 3000 METs per week). In contrast the amount of sedentary children (< 600 METs per week) decreased by 15% and the insufficiently active (> 600 and < 1500 METs per week) increased by 15%. No child was classified as very active (> 3000 METs per week) in any time. The PAL leisure time during the week and during the weekend increased 26.06% and 14.1%, respectively, when comparing pre CAMP to the end of 12 weeks follow-up. SB during the week and the weekend showed a significant mean reduction of 177.14 and 41.43 minutes respectively. A significant improvement was observed in the subjects' sit and reach flexibility, upper limb strength, and lower limb strength.

CONCLUSIONS: The HEPchild contributed to increase PAL and reduction of sedentary behavior and improve physical fitness in obesity children.

PURPOSE: Assess the feasibility, acceptability & costs of delivering a physically active lessons (PAL) training program to secondary school teachers & explore preliminary effectiveness for reducing pupils' sedentary time. **METHODS:** Two mixed-sex, non fee-paying schools were randomised as intervention ($n=1$; received PAL training) & control ($n=1$; no training) schools. Training was delivered to all subject teachers in two after school sessions & focused on integrating movement into lessons. Feasibility & acceptability of PAL training were assessed with quantitative & qualitative measures. Student outcomes (including accelerometer assessed activity) were assessed at baseline & 8 weeks post training for 107 & 98, 11-14 year olds at intervention & control schools, respectively. The study received ethical approval.

RESULTS: 29 of 33 teachers attended both training sessions. Teachers' feedback indicated low acceptability of PAL training & a need to revise certain training components, e.g., outdoor PAL training & increasing the learning challenge of the PAL strategies. The assistant head teacher echoed teacher's concerns about the training but suggested the concept was acceptable for secondary schools. At follow up, teachers had increased PAL delivery & students received an average of 6.9 PAL/

week. Of the pupils who recalled being in a PAL (58%), >90% wanted teachers to continue teaching PAL. Delivering the training cost £901 (£451 staff time, £450 equipment). Change in student's sedentary time (95% CI) was +5.1(-1.3,11.5) & +1.3(-6.2,8.7) minutes at control & intervention schools, respectively. **CONCLUSION** As most PAL evaluations focus on primary schools, this study makes a valuable contribution to the literature. Delivering PAL training to teachers was feasible, and delivering & participating in PAL was acceptable for teachers & students. However, low acceptability of PAL training & no evidence of effectiveness on student outcomes indicate the need to review the training. Receiving 6-7, 60 minute PAL/week has the potential to reduce adolescent's sedentary time, although the amount of activity introduced by PAL requires review. Results do not support PAL implementation or progression to a full trial with the current program. Further research could explore if different PAL training elicits more promising results.

SOFIT Studies of Physical Education in U. S. and International Schools

Nicole J. Smith¹, Thomas L. McKenzie, FACSM². ¹CSU Fresno, Fresno, CA. ²San Diego State University, San Diego, CA.

Email: njsmith@csufresno.edu

(No relevant relationships reported)

There is growing interest in assessing physical education programs worldwide in order to improve program quality. To this end, SOFIT (System for Observing Fitness Instruction Time) is a valid and reliable tool for assessing physical education, and it has been used to evaluate physical education programs worldwide since 1991. **PURPOSE:** To compare and contrast the characteristics of SOFIT studies of PE conducted in U.S. schools and in other countries. **METHODS:** Following guidelines outlined by PRISMA, we searched 10 library databases for SOFIT studies conducted worldwide. We located a total of 800 distinct records (233 U.S.; 567 non-U.S.) and evaluated a total of 305 full-texts (137 U.S.; 168 non-U.S.) for eligibility. Studies were selected if they (a) were published in English in peer review journals; (b) used the standard SOFIT protocol; and (c) assessed physical education in preK-12 schools. **RESULTS:** Fifty-eight studies met the inclusion criterion, including 29 in the U.S. and 29 in other countries. U.S. studies included nearly five times more lessons as non-U.S. studies (12,256 vs 2,703 lessons). All 58 studies described physical activity, 83% described physical activity and lesson context, and 53% included physical activity, lesson context, and teacher behavior. Interobserver reliabilities consistently exceeded 85% agreement for all main variables. The most common analyses in U.S. studies were for teacher preparation (48%), lesson location (38%), and student gender (31%). In contrast, in non-U.S. studies the most common analyses were for student gender (59%), teacher preparation (34%), and lesson location (21%). Mean lesson MVPA% was below the 50% public health objective in most studies worldwide. There was substantial diversity both within and among studies in the allocation of time to different contexts. Less than 30% of studies assessed MVPA% within lesson contexts. **CONCLUSIONS:** SOFIT has been reliably used to assess physical education internationally since 1991. There was substantial diversity in study characteristics and how data were analyzed and reported. Increased consistency in implementing the SOFIT protocol and the reporting of data could improve the generalizability of results and provide a clearer worldwide picture of the conduct of physical education.

Accumulating 10,000 Steps/Day Using a Wristband Activity Monitor May Not Meet Step Guidelines.

Laramy S. Millen, Joshua P. Muench, Gavin Connolly, Kristina Hasanaj, Rachael K. Nelson. Central Michigan University, Mt Pleasant, MI.

Email: mille3ls@cmich.edu

(No relevant relationships reported)

Physical activity (PA) guidelines aimed at accumulating 10,000 steps/day through exercise (EX) and activities of daily living (ADL) has become increasingly common with the advent of wristband PA monitors. Yet, accumulated "steps" with wristband PA monitors may not equal validated pedometers. Consequently, there is a need for evaluating and developing guidelines for step counts using wristband PA monitors for the general population. **PURPOSE:** To compare pedometer and wristband PA monitor steps accumulated through EX and ADL designed to mimic real-world behavior using a diverse participant population. **METHODS:** 24 males and 35 females, age: 18-65 yrs., BMI: 19-45 kg/m², including exercisers and non-exercisers, were recruited for this

two-day study. On Day 1 participants completed 30 minutes of EX on a treadmill at 64-74% of their age-predicted HR_{max} wearing a pedometer and wristband PA monitor. Pedometer and wristband PA monitor steps were recorded after EX and pedometer steps were subtracted from 10,000 to determine the remainder of steps participants needed to accumulate 10,000 steps through ADL on Day 2 (ADL pedometer steps = 10,000 steps - exercise pedometer steps). Next, participants were sent home with a pedometer and wristband PA monitor. On Day 2, participants were instructed to accumulate the remainder of steps needed to reach 10,000 steps through ADL. Once participants accumulated their ADL pedometer steps, step counts on both devices (i.e., wristband PA monitor and pedometer) were recorded. Total step counts were calculated as: EX steps on Day 1 plus ADL steps on Day 2 for devices. **RESULTS:** Significantly fewer wristband PA monitor steps were accumulated than pedometer steps during treadmill EX (3864±68 vs. 3573±81 steps; P<0.01) on Day 1 by 7.5%. Conversely, on Day 2, accumulated wristband PA monitor steps were significantly greater than pedometer steps during ADL (7973±275 vs. 6255±72 steps; P<0.01) by 27.5%. Consequently, total steps were significantly higher for wristband PA monitor steps than pedometer steps (11546±281 vs. 10119±57 steps; P<0.01). **CONCLUSION:** In order to achieve to the equivalent of 10,000 pedometer steps using a wristband activity monitor through treadmill exercise and activities of daily living, wristband activity monitor users should strive for closer to ~11,500 "steps" per day.

Effects of Three Regular Activity Breaks on Postprandial Triglyceride Response in Healthy Young Adults

Sheng-Xia Ma, Xiao-Mei Liu, Yan-Yu Lin, Li-Qiong Ma, Sheng Zhao, Zheng Zhu, Zhen-Bo Cao. Shanghai University of Sport, Shanghai, China.

Email: msx-27@163.com

(No relevant relationships reported)

PURPOSE: To determine whether interrupting prolonged sitting with three kinds of regular walking activity breaks has an immediate or delayed effect on postprandial triglyceride response.

METHODS: In a randomized crossover trial, 16 inactive healthy adults (7 men, aged 21-30 years) completed four 26-h (from 8:00 AM on day 1 to 10:00 AM on day 2) laboratory conditions. Except for the 9-h intervention phase, the same procedure was used in the following four trials: (1) 9-h prolonged sitting (**SIT**); (2), (3), and (4) sitting with 3, 5, and 8 minutes of brisk walking (60% VO_{2max}) every 35, 50, and 70 minutes, respectively (**WALK3**, **WALK5**, and **WALK8**). Postprandial serum triglyceride (TG) and nonesterified fatty acid (NEFA) were measured for 2-h dinner immediately on day 1 and for 2-h breakfast on day 2. Meals and meal times were standardized across the conditions for all the participants.
