RESULTS: Compared with SIT, only WALK8 significantly attenuated 2-h breakfast postprandial triglyceride total area under the curve (tAUC; SIT: median [Q1, Q2], 2.12 mmol·h·L⁻¹ [1.46, 3.67] vs WALK8: 2.01 [1.25, 3.34], p = 0.041). The tAUC for 2-h dinner postprandial triglyceride and for both 2-h dinner and breakfast postprandial NEFA were not significantly changed in the three-activity break conditions. However, compared with SIT, the three-activity break conditions significantly increased the pre-dinner NEFA concentrations on day 1 (WALK3 52%, WALK5 36%, and WALK8 75%; all p < 0.05), but only WALK8 increased the fasting NEFA concentration on day 2 (25%; p < 0.05). No significant differences in all the above-mentioned indicators were found among the three-activity break conditions.

CONCLUSIONS: The 8-min brief bouts every 70 min attenuated the postprandial triglyceride response measured about 24 h after, not immediately after, the intervention phase. Supported by the Shanghai Science and Technology Committee (No. 16080503300).

Physical Activity Level And Prescription Pattern Of Physical Activity Among Physicians In Santiago De Chile.

Alejandro Quijada. Universidad Mayor, Santiago, Chile.

Email: doctorquijada@gmail.com

(No relevant relationships reported)

PURPOSE: The aim of this research was to determine the level of physical activity (PA) and prescription pattern (PP) of physical activity among physicians in their private practices. **METHODS:** An analytical cross-sectional study analyzed 341 physicians (182 males, 159 females; mean age 39.7 years) of 13 different private health care centers in Santiago de Chile, South America. Data of PA was collected using the short form of the International Physical Activity Questionnaire (IPAQ-SV) and the data of the PP was collected using the Exercise Is Medicine (EIM) questionnaire developed in Latin America. **RESULTS:** 30% of the participants reported low level of physical activity (≤600-MET min/week). Higher physical activity levels were found among male physicians compared to female physicians (9% versus 6%). 80% of the physicians reported prescribing PA to their patients (always 37%; almost always

43%), but only 8% fully knew the international PA recommendations for health. When asked why they do not prescribe PA, among those who do not do it regularly, the main cause was because they do not know the PA current guidelines (12%), and among those who knew the guidelines, the "lack of time within the consultation" was the most common cause (39%), followed by the doctor's preconceived notion that "the patient will not comply with the prescription given" (19%). Although both national and international guidelines establish PA as the first line of treatment of chronic non-communicable diseases, 92% of physicians do not prescribe PA in accordance with these recommendations. Among these, 46% of them refer not to know these recommendations and something that in our opinion is even more worrisome is that 21% of the doctors surveyed, had knowledge of the guidelines, but do not apply them. **CONCLUSION:** data suggested a relationship between the level of knowledge of PA recommendation, the prescription pattern in clinical practice, and the practice of PA itself among doctors.

Large vs Small Skeletal Muscle Mass Training: a Pilot Study on Solid Organ Transplanted Recipients

Alessio del Torto¹, Roberto Peressutti², Umberto Baccarani³, Adriana De Silvestre², Amici Giampaolo⁴, Stefano Lazzer¹.
¹University of Udine, Udine, Italy. ²Friuli-Venezia-Giulia Regional Transplant Coordination Center, Udine, Italy. ³General Surgery and Transplantation Unit, Department of Medicine, University of Udine, Udine, Italy. ⁴Nephrology Centre of AAS3, Gemona del Friuli, Gemona del Friuli, Italy.
(No relevant relationships reported)

Kidney (KTR) and liver (LTR) transplanted recipients suffer from a reduced exercise capacity ($\dot{V}O_{2peak}$) and performance. Several studies pointed out the skeletal muscle as the main responsible for the low peak work rate (WR_{peak}) and reduced $\dot{V}O_{2peak}$ in KTR and LTR, rather than the central factors (e.g. maximal O_2 delivery) (Williams & McKenna, 2012). Indeed, skeletal muscle dysfunctions and atrophy seem to be a common scenario in the post-transplant period (Kempeneers et al., 1990; Kallwitz, 2015).

PURPOSE: The aim of the present study is to determine if endurance training (ET) involving a small muscle mass, e.g. single leg cycling (SLC), might induce the development of higher $\dot{V}O_{2peak}$ and WR_{peak} than ET with large muscle masses, e.g. double leg cycling (DLC), in KTR and LTR.

METHODS: 9 sedentary patients were enrolled (KTR=6; LTR=3) and divided into SLC (n=5; age 50±10.3 yrs; time post transplant 11±14.8 yrs; BMI 25±3.0) and DLC (n=4; age 58.5±0.7 yrs; time post transplant 4.3±1.5 yrs; BMI 26.3±2.9) groups. Subjects completed DLC incremental test to determine $\dot{V}O_{2peak}$ and WR_{peak} on an electronically braked ergometer. Pulmonary gas exchange was measured using breath-by-breath analyses. All subjects were asked to attend 24 ET sessions: the DLC group trained both leg at the same time and the SLC group performed the first half of the session with one leg and the second half with the other limb.

RESULTS: 2 subject in the DLC group did not complete the ET regimen due to health-related issues, thus were excluded from the analysis. SLC (n=5) and DLC (n=2) groups completed 20±2.5 and 23±1.4 ET sessions, respectively. SLC and DLC groups increased significantly (p: 0.025) the $\dot{V}O_{2peak}$ of 2.5±2.0 and 3.0±2.3 mL·min⁻¹·kg⁻¹, respectively. SLC and DLC groups improved (p: 0.053) the WR_{peak} of 18.0±14.4 and 10.0±7.1 W, respectively.

CONCLUSION: These preliminary results suggest that SLC training elicited a similar change in $\dot{V}O_{2peak}$, but slightly higher improvement in WR_{peak} with respect to the DLC training. This might suggest the key role of skeletal muscles in limiting peak exercise performance. The results are promising, but the low sample sizes prevent us from drawing firm conclusions.

Recalled Age at Menarche from The Michigan State University Motor Performance Study

Shannon R. Siegel, FACSM¹, Karin A. Pfeiffer, FACSM², Larissa True³, Eric M. Martin⁴, Christine Pacewicz², Crystal Branta², Rebecca Battista, FACSM⁵. ¹University of San Francisco, San Francisco, CA. ²Michigan State University, East Lansing, MI. ³SUNY-Cortland, Cortland, NY. ⁴Boise State University, Boise, ID. ⁵Appalachian State University, Boone, NC.
Email: ssiegel@usfca.edu
(No relevant relationships reported)

Background: Many growth studies have assessed age at menarche to quantify biological maturation, as it is related to several physiological and performance variables. Begun in 1967, the Michigan State University Motor Performance Study (MPS) tested youth on a battery of physical growth, maturation, and motor performance tasks twice yearly for 32 years. One maturation marker, age at menarche, was collected for female participants and their mothers. In a follow-up study to investigate participants' adult health outcomes, females again reported age

at menarche. **Purposes:** 1- Determine whether recalled age at menarche (up to 20 years after the fact) was related to a more timely assessment of age at menarche, and 2-Determine whether daughters' and mothers' ages at menarche were related to each other. **Methods:** During the MPS, a letter was sent to participants' mothers asking for age at menarche for themselves (n = 118) and their daughters (n = 99). At the follow-up, 127 females provided their recalled age at menarche; 25 of these respondents were matched with their earlier recall data. Descriptive statistics and correlations were calculated. **Results:** Age at menarche assessed during the MPS for the daughters was (mean ± sd) 13.13 ± 1.1 years (minimum-maximum = 11.2-16.7 years). At the follow-up, the recalled age at menarche was 13.11 ± 1.4 years (minimum-maximum = 10.2-18.0 years). For the 25 participants who had both MPS and follow-up data for age at menarche, the correlation was positive and strong: $r = 0.75$, $p < 0.001$. A moderate positive relationship between mothers' and daughters' ages at menarche was also found, $r = 0.39$, $p < 0.001$. Mothers of the MPS participants reported a slightly younger mean age at menarche than their daughters (12.83 ± 1.4 years). **Discussion:** Many studies have examined the accuracy of recalled age at menarche, with the relationship between actual and recalled age at menarche ranging from $r = 0.70$ -0.81. Results from this small sample showed that MPS participants remembered their ages at menarche with similar reliability. Given that the original results were based on the recall from their mothers, the agreement between the two recalls is particularly noteworthy. The current sample is consistent with previous work which found a significant correlation of $r = 0.25$ between mothers' and daughters' ages at menarche.

Time Spent In Moderate- to Vigorous-intensity Physical Activity Is Associated With Intramuscular Adipose Tissue Content In Young Men

Madoka Ogawa¹, Noriko Tanaka¹, Akito Yoshiko², Hiroshi Akima¹. ¹Nagoya University, Nagoya, Japan. ²Chukyo University, Nagoya, Japan. (Sponsor: Katsumi Asano, FACSM)
Email: d0c0dem0.mad020@gmail.com
(No relevant relationships reported)

Physical inactivity induces decreases of skeletal muscle mass and increases content of the adipose tissue in humans. However, it is not well known that the relationships between daily physical activity and various types of adipose tissues such as intramuscular adipose tissue (IntraMAT), intermuscular adipose tissue (InterMAT) or subcutaneous adipose tissue (SAT). **PURPOSE:** To investigate relationship between daily physical activity and contents of IntraMAT, InterMAT and SAT in the thigh for young men.

METHODS: Twenty healthy young men (24.5±4.8 years) participated in this study. Axial images of the mid-thigh were taken using magnetic resonance imaging. The cross-sectional area (CSA) of IntraMAT, InterMAT, SAT and skeletal muscle were measured. Daytime physical activity time was measured using an accelerometer on 14 consecutive days and summarized the activity time of two intensities; light-intensity (1.1-2.9 METs), and moderate- to vigorous-intensity (3.0-7.0 METs).

RESULTS: In the accelerometer data, time spent in light-intensity physical activity was 672.4±74.6 min/day, and time spent in moderate-to vigorous-intensity physical activity was 96.6±30.5 min/day. Light-intensity physical activity time was not significantly correlated with contents of all adipose tissues in the thigh. The moderate-to vigorous-intensity physical activity time was correlated with IntraMAT content ($r = -0.739$, $P < 0.01$). On the other hand, moderate- to vigorous-intensity physical activity time was not significantly correlated with contents of InterMAT and SAT. Stepwise regression analysis was performed, with IntraMAT content as a dependent variable and age, body mass index, SAT CSA/body weight, skeletal muscle CSA/body weight, light-intensity physical activity time, moderate- to vigorous-intensity physical activity time as independent variables. As a result, skeletal muscle CSA/body weight and moderate- to vigorous-intensity physical activity time were independent variables ($R^2 = 0.655$).

CONCLUSIONS: These results suggest that moderate- to vigorous-intensity physical activity time was related to IntraMAT content only, skeletal muscle size and moderate- to vigorous-intensity physical activity time could be a major determinant of IntraMAT content in young men.

Association Between BMI And Health Perceptions In Preservice Teachers

Lesley S. Leonard. College of Coastal Georgia, Brunswick, GA.
Email: lleonard@ccga.edu
(No relevant relationships reported)

Schools play an important role in shaping the dietary and physical activity behaviors of children, and teachers are increasingly called to deliver health-related information in the school setting. No study has examined the association between body mass index (BMI) and health perceptions in preservice teachers in elementary education programs. **PURPOSE:** To determine the association between perceptions of physical activity, healthy weight, and healthy eating in a sample of preservice teachers in elementary

education programs. **METHODS:** Participants included 341 preservice teachers enrolled in elementary education programs in the state of Florida. Individuals ranged in age from 18 to over 50, with 93% of the participants in the age range of 18 to 29. Females accounted for 91% of the participants. All participants provided self-report height and weight information and responded to statements regarding perceptions of physical activity, healthy weight, and healthy eating. Participants also provided the number of days per week they engaged in at least 30 minutes of moderate to vigorous physical activity. **RESULTS:** Bivariate correlations showed lower BMI was associated with the perceptions of a more physically active lifestyle ($r = -0.25, p < .01$), healthier weight ($r = -0.66, p < .01$), and healthier eating choices ($r = -0.26, p < .01$). In terms of exercise, higher BMI was associated with fewer days per week of at least 30 minutes of moderate to vigorous physical activity ($r = 0.16, p < .01$). **CONCLUSION:** The current findings indicate that BMI is associated with perceptions of health in preservice teachers in elementary education programs. Should they be replicated, such findings encourage researchers to examine the ways in which health promotion programs should be delivered to preservice teachers to improve their health and enhance their ability to promote healthy eating and physical activity to their future students.

Physical Activity and Body Composition in Adults

Robert Buresh, FACSM, Brian Kliszczewicz, FACSM, Jennifer Julian, Katy Hayes. *Kennesaw State University, Kennesaw, GA.*
(No relevant relationships reported)

Rates of overweight and obesity have risen significantly since the 1980's, while levels of physical activity have declined. Reductions in physical activity may explain much of the increased body fatness realized over the past several decades, and increases in physical activity may contribute to improved body composition and weight management.

PURPOSE: To examine the relationships among markers of energy expenditure and body composition in adults. **METHODS:** Participants arrived at the laboratory between 6:00 and 9:00 a.m., having fasted for at least 10 hours. Height and body mass (BM) were measured, and 4-compartment body composition (percent body fat [%BF], fat mass [FM] and fat-free mass [FFM]) was determined using data derived from bioelectric impedance analysis and dual energy x-ray absorptiometry. Resting metabolic rate (RMR) was determined via indirect calorimetry. Participants were then provided with accelerometers to allow for measurement of various markers of physical activity (PA), including physical activity energy expenditure (PAEE), sedentary time (SED), time spent in moderate- to vigorous-physical activity (MVPA), and step counts (STEPS). Accelerometers were worn for 21-28 days, and associations between markers of PA and body composition were analyzed. **RESULTS:** Absolute expressions of PA (e.g., PAEE, STEPS) were not associated with body composition. However, expressions of PA relative to various fractions of BM were significantly correlated with %BF in both men and women. The strongest predictor of %BF was STEPS·kgFM⁻¹·day⁻¹. Power regression analysis yielded the model, 2907.1(STEPS·kgFM⁻¹·day⁻¹)^{-0.778} in men (R² = 0.91), and 820.25(STEPS·kgFM⁻¹·day⁻¹)^{-0.546} in women (R² = 0.82). **CONCLUSIONS:** Physical activity expressed per unit of FM strongly predicted %BF. These findings suggest relative expressions of PA (e.g., STEPS·kgBM⁻¹·day⁻¹ or STEPS·kgFM⁻¹·day⁻¹) may be more efficacious than absolute expressions of PA in developing PA prescriptions for weight management.

What is the Effectiveness of HIIT Body Work on Energy Expenditure in Active Male Adults

Alexandre F. Machado¹, Roberta L. Rica¹, Fábio L. Ceschini¹, Victor M. Reis², Aquiles Y. Silva³, Danilo S. Bocalini⁴, Aylton F. Junior¹. ¹University São Judas Tadeu, São Paulo, Brazil. ²Research Center in Sports Sciences, Vila Real, Portugal. ³University Mayor, Santiago, Chile. ⁴University Federeal of Espírito Santo, Vitória, Brazil.
 Email: xdmachado@gmail.com
(No relevant relationships reported)

INTRODUCTION: The High Intensity Interval Training (HIIT) has been identified as an important strategy in fitness by improving the cardiometabolic function in adults. However, different models of HIIT performed with body weight, known as HIIT body work (HBW) in blocks with maximum intensity, still lack information namely the energy demand imposed in training. **PURPOSE:** Assessment the energy expenditure in a single session of HBW in healthy male adults. **METHODS:** 12 male adults (33.3 ± 12 years old) performed an all-out protocol with 30 seconds effort x 30 seconds recovery, amounting 20 minutes in the total session. The session exercises were Jumping Jack (JJ), Burpee (BP), Mountain climber (MC) and Squat Jump (SJ), performing 5 sets for each set. The energy expenditure was determined by indirect calorimetry with K5, gas analyser throughout the entire session. Heart rate was also measured as well as the rating of perceived exertion (0-10 Borg scale). Repeated measures ANOVA, followed by Tukey (0.05) post hoc test, were performed to compare the differences between exercises. All analysis were performed using SPSS

software. **RESULTS:** The session mean VO₂ was 35.31 ± 5.21 ml.kg.min⁻¹, total energy expenditure was 250.78±27.41 kcal; mean heart rate was 164±8bpm and mean RPE was 8.92±0.68. The mean and standard deviation for the blocks of the different exercises are described in the table below, values followed by the same letter do not differ significantly from each other. Table – Mean VO₂ and energy expenditure per exercise and per minute of exercise.

| | JJ | BP | MC | SJ |
|------------------------------|---------------------------|---------------------------|---------------------------|--------------|
| EE (kcal) | 50.27 + 8.23 ^a | 73.66 + 8.84 ^b | 62.60 + 8.2 ^c | 64.24 + 6.55 |
| EE (kcal.min ⁻¹) | 10.5 + 1.65 ^a | 14.73 + 1.77 ^b | 12.52 + 1.64 ^c | 12.85 + 1.31 |

Note: a and b = significantly different from every other exercise (p<0.05); c = significantly different from JJ and BP (p<0.05). **CONCLUSION:** The burpee exercise is the most demanding exercise in terms of aerobic energy expenditure. Contrarily, the jumping jack exercise was the least demanding. Aerobic energy expenditure seems consistent with the use of this type of workout to promote weight loss and / or fat loss.

Mechanical Efficiency After High Intensity Interval Training In HIV+ Hispanic Women

Farah A. Ramirez-Marrero, FACSM¹, Marcos A. Amalbert-Bririel², Jorge L. Santana-Bagur³, Valerie Wojna³, Walter Frontera, FACSM³. ¹University of Puerto Rico, Rio Piedras, San Juan, Puerto Rico. ²University of Massachusetts, Amherst, MA. ³University of Puerto Rico, Medical Sciences, San Juan, Puerto Rico.
 Email: farah.ramirez1@upr.edu
(No relevant relationships reported)

High intensity interval training (HIIT) is known to improve cardiorespiratory fitness (VO_{2peak}) and exercise capacity in healthy and living with chronic disease adults. Mechanical efficiency (energy demand at a given workload) also helps improve exercise capacity; however, few studies have evaluated mechanical efficiency resulting from HIIT; and none with HIV+ adults. **PURPOSE:** To compare mechanical efficiency in HIV+ and HIV- women after a low volume HIIT intervention. **METHODS:** A group of 20 HIV+ and 11 HIV- Hispanic women completed a graded exercise test (GXT) on a bicycle ergometer with increments of 25W until volitional fatigue, during which measures of VO₂ and HR were obtained. GXT were conducted before and after a low volume-HIIT intervention (1:1 intervals) 3 days/wk. for 6 weeks (2 wks. (16 min total) at 80%, and 4 wks. (20 min total) at 90% of HR reserve). Percent VO_{2peak} and %HRpeak were determined at 25, 50, 75, and 100W. T-tests and Wilcoxon Ran Sum tests were used to detect pre to post-test differences within each group. **RESULTS:** Compared with HIV-, HIV+ had lower VO₂ at 100W workload during pre-test (20.4±1.9 vs. 17.5±1.9 ml·kg⁻¹·min⁻¹, P=0.01), and also at 75W and 100W during post-test (16.9±1.7 vs. 14.8±2.4, P=0.02; 21.0±2.8 vs. 17.3±3.4 ml·kg⁻¹·min⁻¹, P=0.01; respectively). Reduced metabolic demand (%VO_{2peak}) was observed at 25W in HIV- (46.4±15.4 vs. 37.9±10.5 %, P=0.01), at 50W in both HIV- and HIV+ groups (60.8±16.5 vs. 53.6±13.4, P=0.02; 62.8±13.3 vs. 59.5±11.2 %, P=0.04; respectively), and at 75W in HIV+ (81.3±13.8 vs. 75.9±13.7%, P=0.04). **CONCLUSION:** Although VO₂ was lower at near maximal workloads in HIV+ compared with HIV-, both groups increased their mechanical efficiency at various submaximal workloads; thus, improving exercise capacity with HIIT. Supported by NIMHD S21MD001830, R21MH095524, U54MD007587-04, and R25MD007607.

Weight Loss Decreases Dyspnea on Exertion and Unpleasantness in Obese Adults

Vipa Bernhardt¹, Dharini M. Bhammar², Rubria Marines-Price³, Tony G. Babb, FACSM⁴. ¹Texas A&M University-Commerce, Commerce, TX. ²University of Nevada-Las Vegas, Las Vegas, NV. ³Parkland Health and Hospital System, Dallas, TX. ⁴Institute of Exercise and Environmental Medicine, Texas Health Presbyterian Hospital Dallas and UT Southwestern Medical Center, Dallas, TX. (Sponsor: Tony G Babb, FACSM)
 Email: vipa.bernhardt@tamuc.edu
(No relevant relationships reported)

PURPOSE: We have previously shown that weight loss improved dyspnea on exertion in obese, otherwise healthy, women. Dyspnea is a multidimensional symptom comprised of at least two distinct domains: sensory-perceptual (i.e., dyspnea intensity) and affective distress (i.e., unpleasantness and emotional response). Both domains may lead individuals to avoid exercise. In this retrospective study, we investigated the effects of weight loss in obese women and men on these dyspnea domains. **METHODS:** Twenty-one participants (12 M/9 F, 33 ± 7 yrs, 169 ± 12 cm, 102 ± 18 kg, 35 ± 4 kg/m², 41 ± 7% body fat) underwent a 12-week weight loss program. Pre-

and post-intervention measurements included a submaximal cycling test at 60W for women and 105W for men. Participants rated their perceived breathlessness (RPB, 0-10 Borg scale) as well as unpleasantness, depression, anxiety, frustration, anger, and fear associated with their breathlessness (visual analog scales, 0-10 cm) at the end of the test. Paired t-tests were used to analyze difference between pre- and post-intervention. **RESULTS:** Significant decreases were achieved in body weight by 9 ± 4 kg ($9 \pm 4\%$), BMI by 3 ± 1 kg/m², and body fat by $5 \pm 10\%$ ($p < 0.05$). RPB dropped by 1.5 ± 1.8 ($p < 0.05$). Significant decreases in ratings of unpleasantness (-2.3 ± 2.2), anxiety (-1.2 ± 1.8), frustration (-0.8 ± 1.9), and fear (-0.4 ± 1.0) were observed, while ratings of depression and anger were unchanged. **CONCLUSIONS:** Moderate weight loss alleviated not only dyspnea on exertion, but also the unpleasantness and negative emotional response related to the dyspnea. Supported by NIH Grant R01 HL096782 and King Charitable Foundation Trust.

Prior Baby Jumper Use Is Correlated With Children's Parent-Reported Physical Activity Level

Toyin Ajisafe, Poonam Mankar. *Texas A&M University - Corpus Christi, Corpus Christi, TX.*

Email: toyin.ajisafe@tamucc.edu

(No relevant relationships reported)

PURPOSE: Baby jumpers are ubiquitous in the infant equipment selection.

Anecdotally, while some parents link them to enhanced motor development, others link them with delayed walking onset. Baby jumper use involves successive vertical push-offs (rebounds) against the floor with the feet. The resulting raising and lowering of the body's center of mass is consistent with movements that require leg stiffness regulation. Leg stiffness has been shown to be positively related to maximum sprint velocity in adults and adolescents. Yet, no studies (to our knowledge) have investigated relationships between prior baby jumper use and current locomotor and physical activity (PA) behaviours in young typically developing children. This pilot study investigated these relationships.

METHODS: Parents of 45 children (age: 4 ± 2.3 years; height: 97.5 ± 25.6 cm; mass: 17.2 ± 9.4 kg) completed a 24-item survey administered through Qualtrics software. Questions included prior use of a baby jumper, age at walking onset, current fundamental locomotor behavior and PA level. Questions on the degree of a behavior level were on a 5-point Likert scale. Surveys were excluded, if a parent indicated that the child was born preterm or diagnosed with an intellectual or developmental disability. Bivariate correlations were used to evaluate the directionality of relationships between previous baby jumper use and locomotor and PA behaviors. A Mann-Whitney U test was used to compare age at walking onset between children who used and did not use a baby jumper.

RESULTS: Of the sample, 64% previously used a baby jumper. The proportions of the sample that were underweight, healthy weight, overweight, and obese, were 14%, 51%, 17%, and 17% respectively. Prior use of a baby jumper was moderately positively correlated with children's parent-reported PA level ($\rho = .545$, $p = .013$) and running pace (compared to peers their age and sex) ($\rho = .348$, $p = .019$). There was no significant difference in age at walking onset between the groups ($U = 231.0$, $p = .981$).

CONCLUSIONS: Prior baby jumper use may be linked with running performance and PA level and may promote physical activity in young children. These relationships should be further investigated and modeled using objective measures of locomotor and PA behaviors. Prior baby jumper use did not delay walking onset in the sample.

Overall Mortality, Survival, And Causes Of Death In Former US Olympians

Juliana Antero¹, Hirofumi Tanaka², Quentin D. Larochelambert¹, Maja Pohar-Perme³, Jean-François Toussaint¹. ¹The French National Sports Institute (INSEP), Paris, France. ²The University of Texas at Austin, Austin, TX. ³The University of Ljubljana, Ljubljana, Slovenia.

Email: juliana.antero@insep.fr

(No relevant relationships reported)

United States (US) send a greatest number of athletes to Olympic Games but their longevity and specific causes of deaths have not been examined.

PURPOSE: To quantify US Olympic athletes' longevity and to determine the impact of specific causes of deaths (CoD) on Olympians life duration in relation to the general population.

METHODS: Female ($n = 2,301$) and male ($n = 5,823$) US athletes who have participated at least once in the summer or winter Olympic Games between 1912 and 2012 were followed up to 2016. Their life status and CoD were certified by the National Death Index. The years-saved method was applied to quantify longevity gains/losses in former US Olympians in comparison to the general population.

RESULTS: Former US Olympians lived on average ~ 5 years longer (95% CI 4.3 to 6) than their referents in the general population, based on the 2,309 deaths observed out of 8,124 former athletes. The burden of each CoD was distributed according to

its impact on the total number of years of life saved: cardiovascular diseases (CVD), 2.2 years (1.9 to 2.5); cancer, 1.5 years (1.3 to 1.8); respiratory diseases, 0.8 years (0.7 to 0.9); and external causes, 0.5 (0.4 to 0.6). Nervous system diseases and mental disorders mortality rates were not significantly different from their peers in the general population.

CONCLUSION: US Olympians live ~ 5 years longer than their referents in the general population, advantage mainly driven by lower risks of CVD and cancer. Nervous system diseases and mental disorders do not appear to contribute to the extended longevity that Olympians display.

Years of life saved among US Olympic athletes per causes of death

1990 Board #146 May 30 3:30 PM - 5:00 PM

Elevated Serum Uric Acid And Heart Failure In U.S. Adults: 2007-2016 NHANES

Michelle L. Stone, Michael R. Richardson, Larry Guevara, Bethany G. Rand, James R. Churilla, FACSM. *University of North Florida, Jacksonville, FL.* (Sponsor: Dr. James Churilla, FACSM)

(No relevant relationships reported)

There is limited evidence examining the relationship between elevated serum uric acid (UA) concentration and heart failure (HF) in U.S. adults. **Purpose:** Examine the associations between elevated UA and HF using a nationally representative sample of U.S. adults. **Methods:** The final sample with complete data for this analysis ($N=17,412$) included men and women aged ≥ 40 years who participated in the 2007-2016 National Health and Nutrition Examination Survey. Self-reported diagnosis of HF was assessed via interview. Elevated UA was defined as values >6.0 mg/dL for women and >7.2 mg/dL for men. Multivariable gender-stratified logistic regression was utilized to examine the odds of HF. **Results:** The estimated prevalence of HF was 3.85% and 3.39% among men and women, respectively. Age adjusted analysis revealed significantly increased odds of HF in men (odds ratio [OR], 2.78; 95% confidence interval [CI] 2.09-3.71, $P < 0.01$) and women (OR, 3.25; 95% CI 2.37-4.45, $P < 0.01$) with elevated UA. Significance remained following adjustment for education, income, race, body mass index, alcohol consumption, hypertension, diabetes, physical activity, and creatinine in men (OR, 1.59; 95% CI 1.04-2.43 $P = 0.03$) and women (OR, 2.03; 95% CI 1.33-3.08, $P < 0.01$). **Conclusions:** In a representative sample of U.S. adults, having an elevated UA concentration was associated with significantly increased odds of HF when compared to adults with normal UA.

1991 Board #147 May 30 3:30 PM - 5:00 PM

Modernization of a Developing Country: Effect on Body Mass Index

Cynthia Villalobos¹, William E. Herrin¹, J. Mark VanNess¹, Norah Madaya², Margaret E. Ciccolella¹, Courtney D. Jensen¹. ¹University of the Pacific, Stockton, CA. ²Uganda Bureau of Statistics, Kampala, Uganda.

(No relevant relationships reported)

Modernization provides technology and resources that commonly displace physical activity (PA) from the daily routine; in time, body mass index (BMI) trends upward.

Given the host of deleterious consequences precipitated by poor body composition, it may be helpful to isolate specific factors that predict the largest elevations in BMI. Uganda is an appropriate location to evaluate this. Over 5 years, the percentage of women classified as overweight or obese increased from 19% to 24%; men increased from 4% to 9%. During this time, PA underwent considerable change while nutrition was relatively stable. **PURPOSE:** To evaluate the impact of modernization on BMI in Uganda. **METHODS:** We analyzed the 2016 Demographic and Health Surveys of Uganda, Household Members database. 11,577 subjects met inclusionary criteria. We conducted descriptive statistics to characterize this population, linear regression to examine the effect of modernization on BMI, and logistic regression to test these factors on the odds of overweight (BMI \geq 25) or obesity (BMI \geq 30). **RESULTS:** Mean age was 28.7 \pm 10.2 yr; BMI was 22.0 \pm 3.7; 16.0% of subjects were either overweight (n=1,405) or obese (n=440). More subjects owned a bicycle (40.6%) than a motorcycle (12.6%) or car (4.3%); more subjects owned mobile phones (79.7%) than computers (4.3%); 28.8% of households had electricity and 16.2% had television. Linear regression ($R^2=0.160$; $p<0.001$) found BMI to be increased when a household had a refrigerator ($\beta=0.483$; $p<0.004$), electricity ($\beta=0.409$; $p<0.001$) and television ($\beta=0.961$; $p<0.001$). Additionally, ownership of a car ($\beta=0.421$; $p<0.016$) and a mobile phone ($\beta=0.625$; $p<0.001$) predicted increases in BMI, while ownership of a bicycle ($\beta=-0.330$; $p<0.001$) and a land-line phone ($\beta=-0.657$; $p<0.034$) predicted decreases in BMI. Logistic regression (pseudo $R^2=0.21$; $p<0.001$) found the odds of being overweight or obese increased when a household had electricity (79%; $p<0.001$) and television (107%; $p<0.001$). Additionally, ownership of an automobile (41%; $p=0.002$) and a mobile phone (147%; $p<0.001$) increased the odds of being overweight or obese. **CONCLUSIONS:** Specific features of modernization associate with increases in BMI. As developing countries continue their development, public health interventions are warranted to promote the maintenance of PA.

1992 Board #148 May 30 3:30 PM - 5:00 PM
Effects of Division I Cross-Country Training on Iron Markers and Systemic Inflammation
 Chandler McDonald, Noah John Erb, David Aguilar-Alvarez.
Weber State University, Ogden, UT.
 Email: cmcdonald.pt@gmail.com
(No relevant relationships reported)

Inflammatory cytokine and immune cell production is modulated by iron status including storage measured by ferritin levels. Cross-country athletes have an elevated risk of iron depletion; the effects of long term cross country training on inflammatory cytokine profile and its relationship with iron storage markers have yet to be elucidated.

PURPOSE: To determine the influence of cross-country training on markers of inflammation and iron storage and to interpret potential mechanisms underlying these relationships.

METHODS: Twelve NCAA division 1 cross-country athletes, ages 18 to 25 years old, were followed for two years. Blood was collected at the beginning of the season and analyzed by complete blood count (CBC) and ferritin levels were assessed by enzymatic spectrophotometry. Cytokines IL-1 β , IL-2, IL-4 IL-5, IL-6, IL10, TNF- α and IFN- γ were measured with the LumineX[®] MAGPIX[®] system. Dependent samples t-test was used to compare ferritin cytokines and CBC mean difference between first and second year measurements. Pearson correlations were conducted to assess associations between ferritin and immune cells/inflammatory cytokines. IBM[®] SPSS Statistics 22 software was used to analyze the data.

RESULTS: TNF- α levels increased from the 1st to the 2nd year (98.60 \pm 11.17 vs. 121.41 \pm 11.93 pg/dL, $p=0.006$). Platelets (253.63 \pm 12.28 vs 267 \pm 13.43 K/ μ L, $p=0.041$), Neutrophils (44.46 \pm 1.26 vs 50.46 \pm 2.70) K/ μ L, $p=0.045$) and Monocytes (8.58 \pm 1.90 vs 10.61 \pm 2.70 K/ μ L, $p=0.003$) also significantly increased from the 1st to the 2nd year. Ferritin levels were positively correlated with TNF- α both years ($r=0.716$ $p=0.009$, $r=0.595$ $p=0.04$).

CONCLUSIONS: One year of cross-country training seems to influence increases in pro-inflammatory cytokines and immune cell concentrations in NCAA Division 1 Athletes. Although there were no significant changes on ferritin levels over the years of study, ferritin increases were linked to increases in pro-inflammatory cytokine TNF- α .

1993 Board #149 May 30 3:30 PM - 5:00 PM
Relationship Between Weight History and Depression in U.S. Adults
 Larry Guevara, Michael R. Richardson, Robert J. Zeglin, Christopher J. Joyce, Bethany G. Rand, Michelle L. Stone, Tammie M. Johnson, James R. Churilla, FACSM. *University of North Florida, Jacksonville, FL.*
(No relevant relationships reported)

PURPOSE: Explore the relationship between changes in weight over time and subsequent depression status using a nationally representative sample of U.S. adults. **METHODS:** The study sample (n=20,505) included male and female adults (\geq 36 years of age) who participated in the 2007-2016 National Health and Nutrition

Examination Survey. Weight history examined fluctuations of weight, mainly gain in weight, from self-reported current weight and self-reported weight 10 years ago. Depression status was assessed using the PHQ-9 utilizing a cut point of \geq 10 to assign a depression score. Logistic regression analysis was utilized to examine odds of depression across ranges of weight gain. **RESULTS:** Overall prevalence of depression among U.S. adults aged 36 years and older was found to be at 7.5% (95% Confidence Interval [CI] 6.9-8.2). Following adjustment for gender, race, education, smoking, and physical activity, those who gained 20 or more lbs. had significantly greater odds of having depression (OR 1.45; 95% CI, 1.26-1.67) compared to those gaining <5 lbs. (referent). A similar relationship was not revealed for other weight gain ranges: 5-9lbs. (OR 0.84; 95% CI, 0.62-1.14), 10-14lbs. (OR 0.90; 95% CI, 0.70-1.15), 15-19lbs. (OR 0.93; 95% CI, 0.66-1.31). **CONCLUSION:** Findings revealed that weight gain of 20lbs. or more resulted in significantly greater odds of a PHQ-9 score indicative of depression.

1994 Board #150 May 30 3:30 PM - 5:00 PM
Cardiorespiratory Fitness, Serum 25-hydroxyvitamin D, and Risk of Metabolic Syndrome Among Men: The Cooper Center Longitudinal Study
 Stephen W. Farrell, FACSM, Carolyn E. Barlow, Benjamin L. Willis, David Leonard, Andjelka Pavlovic, Laura F. DeFina, William L. Haskell, FACSM. *The Cooper Institute, Dallas, TX.*
(No relevant relationships reported)

PURPOSE: We examined the individual and joint associations among cardiorespiratory fitness (CRF), serum vitamin D [25(OH)D], and metabolic syndrome (MetSyn). **METHODS:** Between 2006 and 2018, 14349 apparently healthy men completed a comprehensive health examination. Measures included CRF based on a maximal treadmill exercise test, components of MetSyn, and 25(OH)D. Participants were classified into categories of low (quintile 1), moderate (quintiles 2-3), and high (quintiles 4-5) CRF by age group, as well as by clinical cut points for MetSyn and 25(OH)D. We examined mean 25(OH)D levels in men with and without MetSyn. We calculated odds ratios (OR) of MetSyn across levels of CRF and 25(OH)D, and also examined joint associations among these three variables. **RESULTS:** The prevalence of 25(OH)D deficiency and MetSyn was 16.9% and 22.2%, respectively. Mean 25(OH)D levels were 30.9 \pm 11.6 and 26.3 \pm 10.7 ng/mL in men without and with MetSyn, respectively ($p<0.001$). Prevalence of MetSyn was inversely associated with ordered categories of CRF and 25(OH)D (p for trend <0.001 for both). Men with normal 25(OH)D had lower odds of MetSyn than men who were vitamin D deficient (OR=0.29, 95% CI=0.26-0.33). Men with moderate (OR=0.31, 0.27-0.35) or high CRF (OR=0.08, 0.07-0.09) had lower odds of MetSyn than men with low CRF. Joint associations between CRF, 25(OH)D, and MetSyn revealed significantly greater prevalence of MetSyn in unfit men when compared to fit men within each category of 25(OH)D ($p<0.001$). Each 5 ng/mL increment of 25(OH)D, and 1 MET increment of CRF was associated with a 16.0% and 31.3% lower prevalence of MetSyn, respectively. **CONCLUSION:** There are strong individual and joint associations between CRF, 25(OH)D, and MetSyn. Although these observed associations are cross-sectional, it seems prudent to recommend increased levels of physical activity and vitamin D intake in men with low CRF, vitamin D deficiency, and/or MetSyn.

1995 Board #151 May 30 3:30 PM - 5:00 PM
Effect Of Fitbit Alone Compare To Fitbit And Kinesiology-Dietitian Counseling In Sedentary Men: Preliminary Report
 Tommy Chevrette¹, Priscilla Beaupr¹, Marie-Ève Larrivée¹, Claudie Émond¹, Jacques Plouffe¹, Étienne Dubois², Patricia Blackburn¹. ¹UQAC, Chicoutimi, QC, Canada. ²Hexfit Solution inc., Québec, QC, Canada.
(No relevant relationships reported)

The scientific literature has shown increased data on the FitBit ambulatory self-monitoring device but little is known about its effects on sedentary adult men. **PURPOSE:** The purpose of this pilot study was to evaluate the impact of FitBit-HR2 (G1) and FitBit-HR2 with kinesiology - Dietitian counseling (G2) on the number of steps taken per day. **METHODS:** 12 sedentary men aged between 18-35 yld were asked to wear a Fitbit watch for 60 days. Six men using FitBit (mean=25.7 \pm 3.2 years old, BMI 21.8 \pm 3.7 kg/m²) were compared to 6 men using FitBit while also receiving kinesiology - Dietitian counseling (mean=27.3 \pm 5.0 years old, BMI 25.2 \pm 8.3 kg/m²) in their respective ecological environments. The participants in G2 received four 60-minute individual counseling sessions. **RESULTS:** Both groups appear to have significantly increased the number of steps they take per day during the study. Participants in G1 took 5838.9 \pm 1035.0 steps on average at week 1 and 9029.0 \pm 2529.4 steps at week 7 (Cohen's $d = 1.65$; $p<0.001$). Participants in G2 took 3708.2 \pm 1340.2 steps on average at week 1 and 8942.9 \pm 4456.6 steps at week 7 (Cohen's $d = 1.59$; $p<0.01$). While G2 mean Steps difference (week 7-week 1) is bigger than that of G1, it is too early to suggest that counseling sessions combine with FitBit had an increased value. **CONCLUSION:** It appears that using a self-monitoring ambulatory device

by itself is likely to help sedentary men to increase the step per day number. Future research should involve more sedentary men and women of all ages to help conclude the impact of either FitBit alone and FitBit and counseling.

1996 Board #152 May 30 3:30 PM - 5:00 PM
Heart Rate Characteristics for Male Chinese College Students of Different PA-Level during 3000 Meters Running

Jingmin Liu¹, Jian Guan². ¹Division of Sport Science and Physical Education, Tsinghua University, Beijing, China. ²Tsinghua Affiliated Middle School of Chiang Tai Road, Beijing, China.
 Email: ljm_th@tsinghua.edu.cn
 (No relevant relationships reported)

PURPOSE: To explore the Heart Rate load variation for male Chinese college students of different physical activity level during 3000 meters running, providing a reference for training load monitoring and security.

METHODS: Real-time heart rate of 475 Chinese undergraduate students in Tsinghua University were test with Team 2 Polar tester during 3000-meter-run test. The physical activity was investigated by an international questionnaire. All subjects were grouped three by PA levels. Data calculated by SPSS 20.0.

RESULTS: 1. There were significant difference in heart rate among students with different levels of physical activity during 3000-meter-run. The mean of maximum heart rate in group with lower PA level was the highest 202.4±8.9, while that of the group with good PA level was the lowest 198.7±6.4(P<0.05). 2. The heart rate has relation to the time during 3000-meter-run. The average speed of first three laps has a significant linear relationship to the average heart rate(R=0.875). The heart rate reached a plateau in the last four laps. The heart rate of all reached the maximum in the end of test. 3. The maximum heart rate of 20% individual students reached or exceeded the summit value of maximum heart rate (220-age), and continued for a several minutes within a relatively dangerous range.

CONCLUSIONS: Mean of maximum and average heart rate of Chinese male college students with good PA level group was lower than that of poor PA level group in 3000-meter-run test. There is a high risk factor for poor PA level Chinese male students when running continuously in the maximum heart rate level. Study was supported by The Chinese General Administration of sports (2015B075)

Monitor Type: Participant Evaluations of Two Types of Activity Tracking Devices during a Walking Intervention

Anna I. Rinaldi-Miles¹, Ann Miller¹, Lauren von Schaumburg¹, Bhibha M. Das². ¹Illinois State University, Normal, IL. ²East Carolina University, Greenville, NC. (Sponsor: David Q. Thomas, FACSM)
 Email: aimiles@ilstu.edu
 (No relevant relationships reported)

Commercial physical activity tracking devices have gained popularity both in the lay population and in research settings, however, research examining the effectiveness of commercial physical activity monitors has been mixed. One potential factor to the mixed results may be participants' perceptions and preferences of the type of activity monitor. **PURPOSE:** The purpose of the study is to investigate usage and adoption issues as well as the perceived impact for two types of activity trackers. **METHODS:** A 2-arm randomized trial was used to compare the influence of type of data engagement on activity with two types of activity monitors: 1) a hip accelerometer (New Lifestyles 1000) (n = 19) requiring manual logging (MANUAL) and 2) a wrist accelerometer (Fitbit Charge 2) (n = 19) with digital logging (DIGITAL).

Participants wore the activity trackers for four weeks with instructions to attempt to meet daily step goals. At the end of the study they completed an online questionnaire evaluating their experiences with the activity trackers. The open-ended question responses for each participant were analyzed qualitatively by a content analysis. Meaning units (n = 166) from responses were coded and organized into categories and sub-categories. **RESULTS:** For both MANUAL and DIGITAL groups, the top identified categories regarding the perceived impact of the devices were 1) awareness of daily activity patterns (n = 28), 2) influenced motivation (n = 15), and 3) enhanced intuitive understanding of activity (n = 14). Differences between groups were found in prominent themes related to usage and adoption. The MANUAL users identified three themes equally: 1) concern about security of device while wearing (n = 8), 2) issues with ease of wearability (n = 8), and 3) positive experiences (n = 8). The DIGITAL users identified top themes: 1) no issues (n = 8) and usability problems (n = 8) equally, and 3) questioning accuracy (n = 6). **CONCLUSION:** Participants in both groups identified similar themes related to the impact of the devices indicating the both types of trackers were found to be perceived similarly impactful. Differences emerged in usage and adoption. Users of both types of trackers identified negatives and positives to tracker type indicating the importance of matching tracker type with personal preferences to maximize usage.

1998 Board #154 May 30 3:30 PM - 5:00 PM
The Downfall of Sitting: The Relationship between Sedentary Time and Blood Pressure

Megan L. Conner, Grace Shin, Jamie C. Clark. University of Central Oklahoma, Edmond, OK.
 (No relevant relationships reported)

One third of the population is affected by hypertension, and previous research has shown that sitting for extended amounts of time can be detrimental to a person's health. **PURPOSE:** The purpose of this study was to evaluate the correlation between self-reported sitting time and blood pressure. It was hypothesized that sedentary time was significantly related to blood pressure. **METHODS:** The study included faculty or staff that were ambulatory and full-time equivalent. The participants were given a self-reported physical activity questionnaire (The International Physical Activity Questionnaire [IPAQ]) to determine sedentary time. Resting blood pressure (systolic and diastolic) was assessed using a stethoscope and sphygmomanometer, after sitting quietly in a chair for 5 minutes. Data was analyzed with a bivariate correlation test. **RESULTS:** There was a significant, positive, moderate relationship between sedentary time and systolic blood pressure (n = 10, r = .705, p = .01) and a significant, positive, strong relationship between sedentary time and diastolic blood pressure (n = 12, r = .810, p = .001). **CONCLUSION:** Self-reported sedentary time was positively related to blood pressure. In other words, the greater the individual's sitting time, the higher the systolic and diastolic blood pressure was found to be. Engaging in physical activity and reducing sedentary time may decrease the likelihood of developing hypertension. Future research should focus on the effects of programming to decrease sedentary time on measures of health.

1999 Board #155 May 30 3:30 PM - 5:00 PM
Self-Reported Sedentary Behavior Is Associated With Total, Visceral, And Segmental Body Fat In Adults

Megan C. Nelson, Christopher Alfiero, Rachel Midence, Chantal A. Vella, FACSM. University of Idaho, Moscow, ID.
 Email: megann@uidaho.edu
 Reported Relationships: M.C. Nelson: Industry contracted research; InBody USA.

Regional body fat deposition, particularly visceral fat, may be an important mechanistic link between sedentary behavior and cardiometabolic disease risk with advancing age. **PURPOSE:** To examine the associations of sedentary behavior and screen time with total, visceral, and segmental body fat in middle to older aged adults. **METHODS:** 47 adults (mean±SD: age 53.5±11.2 y; body fat 30.5±10.6%; men 38.3%) self-reported sedentary behavior and moderate-to-vigorous physical activity (MVPA) using the Sedentary Behavior Questionnaire and International Physical Activity Questionnaire, respectively. Leisure screen time was defined as television viewing, video games and computer games. Total, visceral, and segmental body fat were estimated with the InBody770 bioelectrical impedance analyzer. Waist circumference was measured at the top of the iliac crest. Multiple regression assessed the associations of sedentary behavior and screen time with total and regional fat distribution, controlling for age, sex and MVPA. **RESULTS:** Average sedentary time was 7.5±2.3 h·d⁻¹ with 1.3±0.9 h·d⁻¹ reported as screen time. Sedentary time was associated with total fat mass (R²=0.19, β=0.33, p=0.02), visceral fat (R²=0.20, β=0.31, p=0.03), trunk fat (R²=0.17, β=0.36, p=0.01), waist circumference (R²=0.23, β=0.39, p<0.01) and leg fat (R²=0.24, β=0.30, p=0.03) independent of age and sex. When MVPA was added to the model total fat mass (R²=0.20, β=0.30, p=0.04), trunk fat (R²=0.17, β=0.34, p=0.03) and waist circumference (R²=0.25, β=0.36, p=0.01) remained significant. Screen time was associated with trunk fat (R²=0.13, β=0.30, p=0.04) and waist circumference (R²=0.23, β=0.38, p<0.01) independent

of age and sex, with the association of trunk fat attenuated after accounting for MVPA. **CONCLUSIONS:** Our findings suggest self-reported sedentary behavior is independently associated with the accumulation of excess total body fat, visceral fat, and fat within the trunk and legs in middle to older-aged adults. However, the association between sedentary behavior and visceral fat is attenuated by MVPA, indicating MVPA may be important for preventing the accumulation of visceral fat. Our findings also suggest total sedentary behavior is more strongly associated with regional fat deposition than screen time in this sample.

2000 Board #156 May 30 3:30 PM - 5:00 PM
Knowledge of Heart Disease and Indices of Physical Activity in Health and Non-Health Based Majors
 Kailyn R. Sanchez, Emily Dunston, Christi Brewer. *Eastern Washington University, Spokane, WA.*
 (No relevant relationships reported)

Cardiovascular disease (CVD) is the leading cause of mortality and is associated with modifiable lifestyle factors, such as physical activity (PA). Research has examined CVD knowledge (CVDK) and PA level in undergraduate students; however, no research has examined the relationship between CVDK and PA in this group. **PURPOSE:** To examine differences in CVDK and indices of PA between sex and major (health (HB) or non-health (NHB) based) and potential associations between CVDK and PA. **METHODS:** Students (N=241) completed an online survey including the 30-item Heart Disease Knowledge Questionnaire and 7-item International Physical Activity Questionnaire. Twenty-four outliers were removed prior to statistical analyses (n=217; 21.1±2.7 yrs; 145 females, 141 HB majors). Independent samples t-tests were conducted to test for differences in total (TK), dietary (DK), epidemiological (EK), medical (MK), risk factor (RFK), and symptom (SK) knowledge, as well as weekly frequency and duration of moderate PA (MPA), vigorous PA (VPA), and total MET-min/week of MVPA between sex and major. Alpha was adjusted for multiple comparisons. Pearson's r was used to test for linear associations between TK and PA indices. **RESULTS:** Sixty-seven percent of students met recommended PA guidelines with a minimum of 500 MET-min/week of MVPA. Females had greater RFK than males (4.6±1.6 vs. 4.0±1.6, p=0.006). HB majors had significantly higher TK (18.4±5.0 vs. 15.3±5.3, p<0.001), DK (3.7±1.7 vs. 3.1±1.9, p=0.007), EK (2.8±1.1 vs. 2.4±1.2, p=0.006), MK (4.4±1.5 vs. 3.3±1.4, p<0.001), and RFK (4.6±1.6 vs. 3.9±1.5, p=0.002) than NHB majors. There were no significant differences in SK between majors (p>0.05). Males reported significantly higher levels of MVPA than females (2300.7±2377.7 vs. 1441.9±1348.6 MET-min/week, p<0.01). There were no associations between TK and any PA index (p>0.05). **CONCLUSION:** HB majors had greater knowledge than NHB majors in all areas except SK; however, there were no differences in PA levels between majors. This suggests that CVDK may not translate to increased PA levels in undergraduates. Future research should investigate relationships between CVDK and risk reduction behaviors in this population.

2001 Board #157 May 30 3:30 PM - 5:00 PM
Association Between Objectively Measured Body Fat Percentage And Two Indirect Measures Of Adiposity
 Christopher M. Bopp, Oliver W.A. Wilson, Zack Papalia, Melissa J. Bopp, FACSM. *Pennsylvania State University, University Park, PA.* (Sponsor: Melissa Bopp, FACSM)
 (No relevant relationships reported)

Body mass index (BMI), calculated using height and weight, is used clinically to diagnose obesity. The ability of BMI to estimate adiposity is limited in the general population and unknown in college aged individuals. Relative fat mass (RFM) has been proposed as an alternative technique to BMI for diagnosis of obesity. RFM accounts for mass stored in the lower portion of the torso by incorporating height and waist circumference into the equation. **PURPOSE:** The purpose of this study was to compare rates of obesity determined by BMI, RFM and objectively measured percent body fat (BF%) via bioelectrical impedance analysis (BIA) in a large cohort of college aged men and women. **METHODS:** 3804 college students completed an objective fitness assessment, where they self-reported their age and sex, and height, weight, waist circumference, and BF%, were assessed. Correlation and chi-square tests for independence analyses examined the relationships and differences in rates of obesity between each method. **RESULTS:** The mean age of the sample was 21.2±1.1, and the majority (n = 2406, 63%) identified as male. Significant correlations were found between BMI and BF% for men (r=0.79, p<0.001) and women (r=0.84, p<0.001); BMI and RFM for men (r=0.85, p<0.001) and women (r=0.83, p<0.001); and, BF% and RFM for men (r=0.74, p<0.001) and women (r=0.76, p<0.001). Differences were found between the observed and expected classification of normal adiposity or obesity by BMI, RFM and BF% for men and women (for all p<0.001). Among men, comparing BF% vs. BMI and RFM vs. BMI, more obese men via BF% or RFM were classified as normal via BMI (BF%; $\chi^2=665$, p<0.001; RFM; $\chi^2=1189$, p<0.001). For women, comparing BF% vs. BMI and RFM vs. BMI, more women who were obese via %BF and RFM were classified as normal via BMI (%BF $\chi^2=576$, p<0.001; RFM $\chi^2=108$, p<0.001). Comparing RFM and BF%, more men and women classified as

obese by RFM were considered normal by %BF ($\chi^2=626$, p<0.001; $\chi^2=246.5$, p<0.001). **CONCLUSION:** Strong associations are observed among BMI, RFM and objectively measured %BF in college students. Despite these strong relationships, discrepancies were observed between obesity classifications between BF%, BMI and RFM.

2002 Board #158 May 30 3:30 PM - 5:00 PM
Physical Activity and Health Habits Among Emergency Medical Technician Students
 Kristi L. Storti, Hayden D. Gerhart, Amy B. Fiorentini, Robert E. Alman, Louis Pesci, Madeline P. Bayles, FACSM. *Indiana University of Pennsylvania, Indiana, PA.*
 Email: klstorti@iup.edu
 (No relevant relationships reported)

Of the recognized emergency medical service professionals, the least is known about EMTs and EMT students. One known study suggests that EMT-B students have some level of predisposition to conditions such as high blood pressure, low exercise tolerance, obesity, and poor health-habit decision-making with regard to tobacco and alcohol use. **PURPOSE:** To determine the prevalence of health risk, physical activity and sedentary behaviors among students enrolled in an Emergency Medical Technician Certification Program. **METHODS:** Sixty EMT students (mean age 24.9 ± 8.3 years, 46.7% female, 98.4% Caucasian) completed risk behavior surveys including physical activity, health status, smoking, and alcohol use modeled after the Centers for Disease Control and Prevention (CDC) Behavioral Risk Factor Surveillance System (BRFSS) and a Modifiable Activity Questionnaire (MAQ) to assess leisure-time physical activity and sedentary behavior. **RESULTS:** The median (25th, 75th percentile) METmin/week of self-reported physical activity from the MAQ for all participants was 558 (228, 1074) and by gender 660 (246, 1074) males and 480 (375, 1098) females. When categorized as meeting or not meeting the current US Physical Activity Guidelines, 56.7% met or exceeded the ≥ 500 METmin/week guideline. Median BMI for all participants was 25.6 (22.9, 30.1) kg/m² with approximately 28.3% of the population considered overweight and 25% obese. Among reported health conditions, 41.7% rated their general health as very good or excellent; 20.0% percent reported being diagnosed with asthma and 16.7% reported being diagnosed with a depressive disorder. With regard to smoking and alcohol, 11.7% reported currently smoking, 15.0% reported current use of chewing tobacco or snuff and 43.3% reported ever vaping or using an e-cigarette. Additionally, participants reported a mean (standard deviation) of 4.4 (4.6) days per month of drinking at least one drink of alcohol and drinking 2.5 (2.4) drinks when they drank. **CONCLUSION:** Among EMT students, over half are meeting the current US Physical Activity Guidelines. Prevalence of overweight/obesity, smokeless tobacco use, and reported depression may put this population at risk for comorbid conditions as they transition from student to professional EMT.

Accelerometer-determined Sedentary Time And Physical Activity Across Standard Occupational Categories In CARDIA
 Tyler D. Quinn¹, Kelley Pettee Gabriel, FACSM², Juned Siddique³, David Aaby³, Kara Whitaker⁴, Abbi Lane-Cordova⁵, Steve Sidney⁶, Barbara Sternfield⁶, Bethany Barone Gibbs¹.
¹University of Pittsburgh, Pittsburgh, PA. ²UT Austin, Austin, TX. ³Northwestern University, Chicago, IL. ⁴University of Iowa, Iowa City, IA. ⁵University of South Carolina, Columbia, SC. ⁶Kaiser Permanente, Oakland, CA. (Sponsor: Kelley Pettee Gabriel, FACSM)
 Email: tylerquinn@pitt.edu
 (No relevant relationships reported)

PURPOSE High accumulated sedentary time with inadequate physical activity is a common behavioral profile in the United States. Examining differences in activity patterns across occupational categories can distinguish target populations for intervention. **METHODS** This cross-sectional analysis of Year 20 CARDIA data (2005-6) included participants who had valid accelerometry data (≥4 days with ≥10 hours), reported job and job duties, and were not currently a student (n=2,050). Uniaxial accelerometry data (ActiGraph 7164), including leisure and occupational time, were expressed in 60 second epochs and summarized as: average counts per minute (CPM) and time spent (hours/day) in total sedentary behavior (SED), light physical activity (LPA), and moderate-to-vigorous physical activity (MVPA) using Freedson cutpoints. Self-reported job and job duties were categorized into the 23 major groups of 2010 Standard Occupational Classification (SOC) using Occucoder v2.7 followed by adjudication by a trained researcher. Military and forestry categories were excluded because <5 participants reported jobs in those categories. Omnibus group differences were analyzed using ANCOVA adjusted for sex, race, age, education, wear time, center, and BMI. **RESULTS** Table 1 shows the least and most favorable three SOC groups in each activity category with mean (standard error) reported. P-values represent overall group

difference across occupational categories. Building/grounds maintenance had the highest CPM while office and admin support had the lowest. Architecture/engineering had the highest SED while food preparation had the lowest. Food preparation had the most LPA and legal had the least. Construction had the highest MVPA while healthcare support had the lowest.

CONCLUSION Activity patterns have large variation across occupational categories, justifying occupation as an important determinant of activity and the workplace as a potential intervention setting.

Table 1 – Occupational Categories with the Least and Most Favorable CPM, SED, LPA, and MVPA

| | Least favorable 3 categories | mean (SE) | Most favorable 3 categories | mean (SE) | p-value |
|--------------|-----------------------------------|--------------|-------------------------------|--------------|---------|
| CPM | Office and Administrative Support | 338.2 (7.6) | Food Preparation and Serving | 416.6 (19.9) | <.0001 |
| | Healthcare Support | 341.7 (27.3) | Construction and Extraction | 425.3 (17.7) | |
| | Architecture/Engineering | 351.0 (20.9) | Building/Grounds Maintenance | 428.4 (22.3) | |
| SED (hrs/d) | Architecture/Engineering | 9.18 (0.22) | Personal Care and Service | 7.58 (0.16) | <.0001 |
| | Legal | 9.07 (0.21) | Building/Grounds Maintenance | 6.88 (0.24) | |
| | Computer/Mathematical | 9.03 (0.15) | Food Preparation and Serving | 6.64 (0.21) | |
| LPA (hrs/d) | Legal | 3.83 (0.14) | Personal Care and Service | 4.79 (0.11) | <.0001 |
| | Computer/Mathematical | 3.86 (0.10) | Healthcare Support | 4.87 (0.19) | |
| | Arts/Entertainment/Sports/Media | 4.00 (0.10) | Food Preparation and Serving | 5.25 (0.14) | |
| MVPA (hrs/d) | Healthcare Support | 0.45 (0.08) | Life/Physical/Social Sciences | 0.71 (0.05) | 0.0479 |
| | Office and Administrative Support | 0.50 (0.02) | Building/Grounds Maintenance | 0.72 (0.06) | |
| | Community and Social Service | 0.52 (0.05) | Construction and Extraction | 0.73 (0.05) | |

CPM=counts per minute; SED=total sedentary behavior; LPA=light physical activity; MVPA=moderate-to-vigorous physical activity

Association Between Cardiorespiratory Fitness And Continuous Cardiometabolic Syndrome Risk Score In Korean Men

Hyun Jeong Kim¹, Min Jeong Cho¹, Eun sun Yoon¹, Yoon-Ho Choi², Sae Young Jae¹. ¹University of Seoul, Seoul, Korea, Republic of; ²Samsung Medical Center, Seoul, Korea, Republic of.

Email: hjeong7305@naver.com

(No relevant relationships reported)

PURPOSE: We examined the hypothesis that cardiorespiratory fitness (CRF), defined as maximal oxygen uptake, predicts the risk of incident cardiometabolic syndrome (CMS) defined as having ≥ 3 relevant risk factors and is prospectively associated with continuous CMS risk score in healthy men. **METHODS:** Participants were 2,742 Korean men who underwent general health examinations and had no evidence of CMS, cardiovascular diseases, diabetes, and hypertension at baseline. Baseline CRF was directly measured by peak oxygen uptake (VO_{2peak}) and divided into quartiles. Incident CMS was defined as participants having ≥ 3 CMS components, and continuous CMS risk score was computed as the sum of z-score of five risk factors at follow-up. **RESULTS:** During a median follow-up of 5 years, 946 (34.5%) men developed CMS. The relative risks (RR) and 95% confidence interval (CI) of incident CMS in the highest quartile (>38.1 ml.kg.min) vs. the lowest quartiles of peak oxygen uptake (<31.8 ml.kg.min) was 0.62 (95% CI: 0.52-0.75) after adjusting for age, body mass index, smoking and alcohol intake. Baseline peak oxygen uptake was independently associated with continuous CMS risk score at follow up after adjusting for covariates ($\beta=-0.092$, $p<0.001$). **CONCLUSION:** The independent association between CRF and incident CMS and continuous CMS risk score, suggesting that improving CRF should be considered as an additional risk factor to predict the future likelihood of CMS in Korean men.

2005 Board #161 May 30 3:30 PM - 5:00 PM
Differential Impacts Of Exercise Systolic Blood Pressure Response On The Risk Of Sudden Cardiac Death In Men With And Without A History Of Cardiovascular Disease

Sae Young Jae¹, Jari Laukkanen², Barry Franklin, FACSM³, Bo Fernhall, FACSM⁴. ¹University of Seoul, Seoul, Korea, Republic of; ²University of Eastern Finland, Kuopio, Finland. ³William Beaumont Hospital, Royal Oak, MI. ⁴University of Illinois at Chicago, Chicago, IL.

Email: syjae@uos.ac.kr

(No relevant relationships reported)

PURPOSE: Although exercise systolic blood pressure (ESBP) response has been associated with different prognosis in men with and without known or suspected coronary artery disease, it remains unclear whether ESBP is associated with an increase or a decrease in the risk of sudden cardiac death (SCD) in both groups. We tested the hypothesis that ESBP would be associated with differential outcomes of SCD in men with and without a history of cardiovascular disease. **METHODS:** This prospective study was based on a population sample of 2,410 men, aged 42-61 years, who were followed up in the Kuopio Ischemic Heart Disease cohort study. Excessive ESBP was defined by a maximal SBP ≥ 210 mmHg during progressive bike exercise testing to volitional fatigue. Participants were stratified by men with (n=884)

and without (n=1,526) a history of cardiovascular disease at baseline. **RESULTS:** During a median follow-up of 25 years, 226 SCDs occurred. After adjusting for age, each 10 mmHg increase in ESBP was associated with an increased or decreased risk for SCD in men without (HR=1.14, 95% CI 1.06-1.24) and with (HR=0.94, 95% CI 0.89-0.99) a history of cardiovascular disease, respectively. After adjusting for age, BMI, resting SBP, smoking, alcohol intake, LDL-C, HDL-C, family history of heart disease, diabetes, and maximal oxygen uptake, an increased risk of SCD was observed with excessive ESBP response in men without a history of cardiovascular disease (HR 1.73, 95% CI 1.07-2.82). A trend for a reduction in the SCD risk was observed with excessive ESBP response in

men with history of cardiovascular disease (HR 0.92, 95% CI 0.60-1.41).

CONCLUSION: Our findings indicate that ESBP response was associated with the risk of SCD in both groups. However, the heightened risk of SCD associated with excessive ESBP response appeared in men without a history of cardiovascular disease, whereas excessive ESBP response may have opposite results in men with a history of cardiovascular disease.

2006 Board #162 May 30 3:30 PM - 5:00 PM
Moderators Of The Relationship Between Worksite Walkability And Physical Activity

Jane C. Hurley, Mike Todd, Christine B. Phillips, Hannah Hook, Steven P. Hooker, FACSM, Punam Ohri-Vacaspati, Marc A. Adams. Arizona State University, Phoenix, AZ. (Sponsor: Steven Hooker, FACSM)

Email: jchurley@asu.edu

(No relevant relationships reported)

Purpose: This study examined traditional and novel moderators (i.e., age, sex, race, income, # of children <18 yrs, ratio of cars to drivers, home walkability) of the relationship between worksite neighborhood walkability (WNW) and physical activity (PA).

Methods: Participants (n = 512, mean 44 yrs, 59% female, 70% White) were employed (not at home) during the baseline phase of a larger trial. Measures included self-reported PA (total min/week, min/week of transport-PA inside (TPAin) and outside (TPAout) the home neighborhood; NPAQ) and Actigraph-measured PA (min/week moderate-to-vigorous PA in bouts [MVPA] and sedentary-light PA [SLPA]). GIS-assessed WNW (500m network buffer of residential, intersection, and transit densities; land use mix). Negative binomial regression estimated associations of WNW with PA, each moderator, and WNW x moderator (i.e., age, sex, race, income, # of children <18, car:driver ratio, home walkability) interactions. Alpha level set at 0.10 to probe conditional effects. Main effects of covariates (residence tenure, distance to work, reason moved to residence, total household members; and in accelerometer models, wear time) were included.

Results: Sex and # of children <18 yrs moderated relationships of WNW with MVPA and SLPA. Race moderated the relationship of WNW with TPAout. For women, the conditional effect of WNW on MVPA was positive (p = .04) while the conditional effect of WNW on SLPA was negative (p = .04); effects not different from zero for men. For adults with no children <18, the conditional effect of WNW on MVPA was positive (p = .01) while the conditional effect of WNW on SLPA was negative (p = .01); not different from zero for those with at least 1 child. For White participants, the conditional effect of WNW on TPAout was negative (p = .07); not different from zero for non-Whites. No other moderators (age, income, car:driver ratio, or home walkability) interacted with WNW.

Conclusions: For women, adults without young children, and Whites (but not men, those with young children, and non-Whites), PA is influenced by walkability of worksite environments in mostly expected directions. An underexplored aspect of behavioral ecological models is identifying who is sensitive to the environmental conditions that can bolster health promotion efforts.

Association of Leisure Time Physical Activity and Back Pain in Brazilian adults

Italo R. Lemes¹, Rômulo A. Fernandes¹, Bruna C. Turi-Lynch², Jamile S. Codogno¹, Henrique L. Monteiro³. ¹São Paulo State University, Presidente Prudente, Brazil. ²Faculty of Dracena, Dracena, Brazil. ³São Paulo State University, Bauru, Brazil.

Email: itolemes@hotmail.com

(No relevant relationships reported)

Leisure time physical activity (PA) may reduce the risk of back pain. A recent meta-analysis found that moderate to high PA during leisure time protects against low back pain by up to 16%. However, there is no study investigating this association in a developing country like Brazil (the biggest nation in Latin America).

PURPOSE: To investigate the association of leisure time PA and back pain in adults from the Brazilian National Health System (NHS).

METHODS: Data were obtained from 557 adults (410 women) enrolled in the Brazilian NHS in 2016. Participants were 50 years or older, registered for at least

one year in the NHS, and received at least one medical visit in the past six months. Leisure time PA was estimated using the Baecke questionnaire. Participants were classified according to tertiles of PA score: active, moderately active and insufficiently active. Presence of back pain was assessed through standardized questionnaire about health condition. Binary logistic regression was used to estimate values of odds ratios (ORs) and 95% confidence intervals (95% CIs). Reference group was the bottom tertile. Health status, sociodemographic and behavioural covariates were potential confounders.

RESULTS: In overall sample, mean age was 69.0 ± 8.40 years, 214 (38.4%) were physically active, 189 (33.9%) were moderately active and 154 (27.6%) were insufficiently active. Back pain was present in 344 (61.8%) adults. In the adjusted model, physically active participants were less likely to have back pain when compared to insufficiently active group (OR: 0.59; 95%CI = 0.36 to 0.95).

CONCLUSION: In this sample, leisure time PA was inversely associated with the presence of back pain.

Agreement Between Measured BMI and Reported BMI Obesity Definitions in a Brazilian Civil Servants

Mayda Silva¹, Daniel Saint-Martin¹, Fernanda Silva², Graciele Lemos², João Paulo¹, Edgard Von Koenig Soares¹, Rosenkranz Maciel Nogueira¹, Guilherme Eckhardt Molina¹, Luiz Guilherme Grossi Porto¹. ¹University of Brasilia and GEAFS, Brasilia, Brazil. ²University of Brasilia - UnB, Brasilia, Brazil.
 (No relevant relationships reported)

Body mass index (BMI) is a worldwide used method for obesity identification. It is an easy and low-cost method recommended for large samples assessment. Concerns exist regarding the risk of misclassification when BMI is calculated based on reported height and weight as compared to the measured height and weight for BMI calculation.

PURPOSE: We compared the prevalence of obesity categorized by measured BMI (m-BMI) and reported BMI (r-BMI) among Brazilian civil servant. **METHODS:** We evaluated 398 randomly selected volunteers (42.2% men), aged 44.8±8.7 yrs, m-BMI: 25.6±4.7 kg/m², from a federal labor court. Volunteers reported weight and height in a health questionnaire without knowing that they would be subsequently measured in an anthropometric scale (Welmy-RI W200). Both m-BMI and r-BMI were calculated using the Quetelet formula: BMI = (weight in kg)/(height in m²). Obesity was defined as BMI ≥30.0 kg/m². Due to lower sensitivity among women, a BMI ≥29.0 kg/m² alternative cut-off point was also tested. Agreement analyses was done considering m-BMI as reference, using following indices: 1) total agreement (TA) as the sum of the percentage of true positive and true negative values (TA=TP+TN); 2) sensitivity = [TP / (TP+FN)] X 100, were FN is false negative; 3) specificity = [TN / (TN+FP)] X 100. All indices were calculated as their point value and 95% interval of confidence (95%IC). **RESULTS:** Agreement indices are shown on Figure 1. When the 29.0 kg/m² cut-off point was used in the r-BMI, we found a much higher sensitivity (88.2%) with small reductions on TA (-1.4%) and specificity (-3.1%). **CONCLUSION:** We observed very high agreement between r-BMI as compared to m-BMI in the total sample and among men. The accuracy of r-BMI to identify obesity among women was lower than among men, probably affected by its lower prevalence. Using the 29.0 kg/m² alternative cut-off point for women resulted on a sensitivity as good as in men. r-BMI also showed to be a highly specific method to exclude obesity.

Figure 1. Agreement between measurement BMI (kg/m²) and reported BMI in Brazil civil servant (n= 398)

| | | Measurement BMI | | | Total | |
|-----------------------|-----|-----------------------|----------------|-----|-------|--|
| | | ≥30 kg/m ² | | | | |
| Reported BMI | Yes | Yes | No | | N (%) | |
| | | No | | | | |
| ≥30 kg/m ² | Yes | 55 (94.8%) | 3 (5.2%) | 58 | | |
| | No | 10 (2.9%) | 330 (97.1%) | 340 | | |
| Total | | 65 | 333 | 398 | | |

| | |
|-----------------------|---------------------------|
| MEN AND WOMEN | |
| Agreement: | 96.7% (95%CI 94.5–98.1) |
| Sensitivity: | 84.6% (95%CI 73.9–91.4) |
| Specificity: | 99.1% (95%CI 97.4–99.7) |
| MEN (n= 168) | |
| Agreement: | 98.2% (95%CI 94.9–99.4) |
| Sensitivity: | 90.3% (95%CI 75.1–96.6) |
| Specificity: | 100.0% (95%CI 97.3–100.0) |
| WOMEN (n= 230) | |
| Agreement: | 95.7% (95%CI 92.2–97.6) |
| Sensitivity: | 79.4% (95%CI 63.2–89.6) |

The Overwatch League: A Pilot Study of Professional Video Gamers

Erich Groezinger, Garrett Loomer. *Massachusetts General Hospital, Boston, MA.*
 Email: erichgroezinger@gmail.com
 (No relevant relationships reported)

A pilot study of professional video gamers reveals the presence of subclinical cardiovascular disease

PURPOSE:

Sedentary behavior in contemporary society is typically coupled with extended screen time (i.e. hours spent in front of a television / computer screen). In November 2016, the commercial video game developer, Blizzard Inc.™, announced the creation of the Overwatch League (OWL), an international e-gaming association built on the model of a traditional professional sports league.

The purpose of this pilot study was to establish the feasibility of a larger project and to evaluate for the presence of subclinical pathology in members of the OWL team representing Boston.

METHODS:

The members of the Boston Uprising (n=10, age=20±2) were tested using electrocardiography, cardiac imaging (echocardiography), vascular function testing (applanation based tonometry) and multiple neurocognitive tests (testmybrain.org). Additionally, a questionnaire was administered that obtained information on health history as well as gaming history of the young subjects.

RESULTS:

All participants were in their first season of professional e-gaming and reported e-game screen time exposure of 54±14 hours/week over the last 12 months with <1 day/month with complete freedom from screen time. Cardiovascular health metrics derived from the study document evidence of subclinical cardiovascular disease. Specifically, 50% of the subjects had either pre-hypertension (n=4, SBP >120 mmHg) or hypertension (n=1, SBP >140 mmHg). Additionally, 40% of the subjects measured in the 80th percentile for age and height in measured vascular stiffness (assessed by pulse wave velocity).

CONCLUSION:

This study demonstrates the feasibility of onsite data collection in an OWL team and suggests the presence of subclinical cardiovascular disease in these young individuals. Larger scale study is planned, and confirmation of the findings would indicate that this group of young individuals requires attention to cardiac risk factor modification and may benefit from a regular exercise routine being incorporated into their ‘training.’ These findings may have a public health impact given the large number of sedentary Americans with high amounts of screen time.

Age-related Health State Over European Countries: The Context May Be The Difference

Pedro Bezerra¹, Filipe Manuel Clemente¹, Marton Dvorak², João Camões¹. ¹Polytechnical Institute of Viana do Castelo, Viana do Castelo, Portugal. ²University of Physical Education, Budapest, Hungary.
 Email: pbezerra@esdl.ipv.pt
 (No relevant relationships reported)

The age-related life quality in aged population has been widely reported in literature including muscular functioning and self-reported health state. The EQ-5D-5L questionnaire is widely used at population level and comprises five dimensions including mobility, self-care, usual activities, pain/discomfort and anxiety/depression. Grip strength and walking ability are known to be associated with muscular functioning and activities of daily living. Little research has examined the differences throughout European countries. **Purpose:** this study aimed to investigate the relationship between the health state and health predictors, among elderly from 4 different European countries [Portugal (PT), Italy (IT), Bulgaria (BL) and Hungary (HU)]. **Methods:** 324 (81 PT, 119 IT, 76 BL and 48 HU) older adults (68.9±6.3 yrs, 73.6±12.7 Kg, 1.61±0.08 m), male (24%) and female (76%), were recruited from local population. The subjects completed the EQ-5D-5L and were assessed as handgrip test (HandT), 6 minutes walking test (6MW). EQ-5D-5L index (EQ_index) was calculated to assess the quality-adjusted life years (QALYs). ANOVA was performed to detect country group differences. Pairwise comparisons was executed with Tukey post hoc test and Cohen D. Pearson coefficient of correlation was used to assess relationship between determinants. Significance was set at p<0.05. **Results:** Pairwise comparisons showed that BL has lower scores than HU, IT and PT in EQ_index (differences ranged between -17% to -28%, p<0.05, d=0.80 to 1.30), HandT (differences ranged between -29% to -69%, p=0.000; d=2.60 to 3.98); and 6MW (differences ranged between -72.33% to -82%, p=0.000; d=4.58 to 12.03), for both sexes. In all countries the EQ_index was moderately and positively correlated with HandT (r=0.453; p=0.000) and 6MW (r=0.533; p=0.000). However the pattern was not cross-country homogeneous, as HU showed lowest correlations (r=0.124; p=0.400; 6MW, r=-0.016; p=0.913).

Conclusions: Different environments promote different life quality in aged population. BL evidences poorer quality of life and fitness status than other European countries. HU seems to well promote healthy life style. Further investigation is need to better understand the present findings.

Impact Of Physical Activity On N-glycan Profile In Older Adults

Fawzi Kadi¹, Andreas Nilsson¹, Aurelia Santoro², Claudio Franceschi². ¹Örebro University, Örebro, Sweden. ²University of Bologna, Bologna, Italy.
 Email: fawzi.kadi@oru.se
 (No relevant relationships reported)

The biological mechanisms underlying the beneficial effects of regular physical activity (PA) on prevention of chronic diseases are not fully understood. It is currently suggested that N-linked enzymatic glycosylation, a post-translational modification modulating the biological function of several proteins, may contribute to disease development. Nevertheless, the influence of PA on N-glycans in humans has never been explored. **PURPOSE:** To explore serum N-glycan profile in a sample of community-dwelling older women with different objectively assessed PA levels and metabolic risk status. **METHODS:** Components of the metabolic syndrome (MetS) and serum N-glycans analyzed using DSA-FACE technology were assessed in 109 older community-dwelling women (65-70 yrs). Ten peaks, each representing a unique N-glycan structure were detected. Adherence to PA guidelines was determined using accelerometry. Participants daily engaged in 30 minutes of MVPA were classified as meeting PA guidelines.

RESULTS: Significant differences in N-glycan peaks were indicated when comparing women adhering to the PA guideline to those less active: when adjusted by MetS, a 12% ($p = 0.006$) and a 13% ($p = 0.004$) lower level of NA3 (peak 8) and NA4 (peak 10), respectively, were evident among the physically active women compared to those less active. In contrast to findings based on the MVPA threshold, no differences in N-glycan peaks were observed between PA groups when based on the lower intensity threshold, which may indicate that the influence on N-glycan levels by PA is intensity-sensitive.

CONCLUSIONS: Adherence to PA guidelines is related to a favorable N-glycan profile, regardless of metabolic risk status. This proposed effect on N-glycans only occurs above the moderate PA-intensity threshold. Our findings support the promotion of a physically active lifestyle as a supporting non-pharmacological public health approach.

Post-exercise Cooling Impairs Muscle Protein Synthesis Rates In Healthy Young Males

Cas J. Fuchs, Imre W.K. Kouw, Tyler A. Churchward-Venne, Joey S.J. Smeets, Joan M. Senden, Wouter D. van Marken Lichtenbelt, Lex B. Verdijk, Luc J.C. van Loon. *Maastricht University, Maastricht, Netherlands.* (Sponsor: Janice Lee Thompson, FACS M)
 Email: cas.fuchs@maastrichtuniversity.nl
 (No relevant relationships reported)

Protein ingestion and cooling are strategies employed by athletes to improve post-exercise recovery and, as such, to facilitate muscle reconditioning following exercise. However, whether post-exercise cooling affects postprandial protein handling and subsequent muscle protein synthesis rates during recovery from exercise has not been studied.

Purpose: This study assessed the impact of post-exercise cooling on acute postprandial (hourly) and prolonged (daily) myofibrillar protein synthesis rates during recovery from resistance-type exercise over a 2-week period.

Methods: Twelve healthy, male adults (age: 21 ± 1 y) performed a single session of resistance-type exercise followed by water immersion of both legs for 20 min. One leg was immersed in cold water (8°C : CWI) while the other leg was immersed in thermoneutral water (30°C : CON). After water immersion, a beverage was ingested containing 20 g intrinsically L-[1-¹³C]-phenylalanine and L-[1-¹³C]-leucine labelled milk protein with 45 g of carbohydrates. In addition, primed continuous L-[ring-²H₃]-phenylalanine and L-[1-¹³C]-leucine infusions were applied, with frequent collection of blood samples and muscle biopsies to assess myofibrillar protein synthesis rates *in*

vivo over a 5-h recovery period. In addition, deuterated water (²H₂O) was ingested with the collection of saliva, blood and muscle biopsies over 2 weeks to assess the effects of post-exercise cooling with protein intake on myofibrillar protein synthesis rates during more prolonged resistance-type exercise training.

Results: Incorporation of dietary protein-derived L-[1-¹³C]-phenylalanine into myofibrillar protein was significantly lower in CWI compared to CON (0.016 ± 0.002 vs 0.021 ± 0.002 MPE; $P = 0.016$). Post-exercise myofibrillar protein synthesis rates were lower in CWI compared to CON based upon L-[1-¹³C]-leucine (0.058 ± 0.003 vs $0.072 \pm 0.005 \cdot \text{h}^{-1}$, respectively; $P = 0.024$) and L-[ring-²H₃]-phenylalanine (0.042 ± 0.003 vs $0.053 \pm 0.004 \cdot \text{h}^{-1}$, respectively; $P = 0.025$). Daily myofibrillar protein synthesis rates assessed over 2 weeks were significantly lower in CWI when compared to CON (1.48 ± 0.05 vs $1.67 \pm 0.11 \cdot \text{d}^{-1}$, respectively; $P = 0.042$).

Conclusion: Cold-water immersion during recovery from resistance-type exercise impairs myofibrillar protein synthesis rates.

 (No relevant relationships reported)

PURPOSE: The effects of consuming a normal or high-protein diet containing isolated whey protein (IWP) in conjunction with resistance training (RT) is little known. This study aimed to determine the effects of IWP on performance, biochemical, hormonal and tissue parameters in rats completing a vertical ladder training protocol.

METHODS: Thirty-two 45-day-old male Wistar rats were divided into four groups (n=8/group): normal protein diet (14% IWP) sedentary (NS) and trained (NT); high-protein diet (35% IWP) sedentary (HS) and trained (HT). RT consisted of 8 vertical ladder climbs/3x a week, over 6 weeks. In weeks 1-2, rats carried a load equivalent to 70% of the maximal load, determined by a maximal load test (MLT), performed on the first and last days of training. The load was adjusted to 80% and 85% of the MLT, respectively, every 2 weeks. At the conclusion of the study, the animals were anesthetized and euthanized after 12h of fasting. Quadriceps (Q), anterior tibial, gastrocnemius (G), soleus and long finger extensor, kidneys, liver and heart tissues were excised and weighed (g).

RESULTS: Performance values (g) on the last MLT improved in HT (964.8 ± 117.6) compared to HS (730.6 ± 89.7), NT (472.6 ± 72.7) and NS (323.0 ± 63.7). There was no difference in plasma levels of testosterone, IGF-1, hepatic enzymes, creatinine, and β -hydroxybutyrate, as well as hematological parameters. Levels of HDL-c ($p < 0.001$) were higher in HT (104.4 ± 26.0) and HS (100.7 ± 21.2) compared to NS (73.9 ± 15.7) and NT (60.8 ± 12.0). There was an observed difference in the relative weights of the kidneys (HS= 0.72 ± 0.05 , HT= 0.70 ± 0.04 , > NS= 0.58 ± 0.04 , NT= 0.59 ± 0.02 , $p < 0.0001$), liver (HT= 2.93 ± 0.21 > NS= 2.62 ± 0.19 , NT= 0.59 ± 0.02 , $p = 0.004$) and heart (HS= 0.32 ± 0.02 > NS= 0.28 ± 0.02 , NT= 0.27 ± 0.01 , $p = 0.003$). In relation to the relative muscle weight of G ($p = 0.05$) and Q ($p = 0.02$), HT (1.16 ± 0.09 ; 1.67 ± 0.09) showed higher values in comparison to NT (1.04 ± 0.08 ; 1.53 ± 0.09).

CONCLUSIONS: A high-protein diet of 35% IWP in combination with RT improved performance as well as increased muscle and organ weight without damaging tissues related to protein metabolism (confirmed by unchanged hematological parameters). This finding may help to minimize the risk of developing cardiometabolic disorders in certain populations.

Satiating Effect Of High Protein Diets On Resistance-trained Individuals In Energy Deficit.

Justin Roberts¹, Anastasia Zinchenko², Krishna Mahbubani³, James Johnstone¹, Lee Smith¹, Vivianne Merzbach¹, Miguel Blacut⁴, Oscar Banderas⁴, Luis Villanor⁴, Fredrik Varvik⁴, Menno Henselmans⁴. ¹Anglia Ruskin University, Cambridge, United Kingdom. ²University of Cambridge, Cambridge, United Kingdom. ³Addenbrookes Hospital, Cambridge, United Kingdom. ⁴International Scientific Research Foundation for Fitness and Nutrition, Amsterdam, Netherlands.
 Email: justin.roberts@anglia.ac.uk
 (No relevant relationships reported)

Short-term energy deficit strategies are employed by weight class and physique athletes to enhance strength:body-mass and body composition during training or prior to competition. During such phases, athletes may consume very high protein intakes to maximise satiety, maintain caloric deficit and minimise lean muscle losses despite

a paucity of research supporting any benefits. **PURPOSE:** To compare the satiating effect of two protein diets on resistance-trained individuals in short-term energy deficit. **METHODS:** Following University ethical approval, 16 resistance-trained participants (age: 28±2years; height: 1.72±0.03m; body-mass: 88.83±5.54kg; body-fat: 21.85±1.82%) were randomly assigned to a moderate (PRO_{MOD}: 1.8 g·kg⁻¹·d⁻¹) or high protein (PRO_{HIGH}: 2.9 g·kg⁻¹·d⁻¹) matched calorie-deficit diet for 7 days in a cross-over manner, including 4-week wash-out. Venous samples were collected (time-points T0, 60, 120mins) for assessment of plasma ghrelin and protein YY concentrations to a fixed-protein (0.7g·kg⁻¹) meal, along with perceived satiety ratings, following each diet. **RESULTS:** Following PRO_{MOD} mean ghrelin concentration (pg·ml⁻¹) significantly reduced post-meal (T0: 972.8±130.4, T60: 659.7±86.4, T120: 613.6±114.3; p≤0.003 compared to T0). Similar observations were reported for PRO_{HIGH} (T0:1088.2±158.8, T60: 786.6±117.3, T120: 850.6±147.7; p≤0.015). However, T120 responses differed between conditions, and further confirmed when data were normalised for relative change (PRO_{MOD}: -0.40±0.06, PRO_{HIGH}: -0.26±0.06; p=0.015). PYY concentrations (pg·ml⁻¹) increased post-meal across time-points (PRO_{MOD}: 84.9±8.9 to 147.1±11.9 and PRO_{HIGH}: 100.6±9.5 to 143.3±12.0; p<0.001), with no differences reported between diets. Perceived 'hunger', 'fullness' and 'satisfaction' were comparable between diets (p>0.05). However, 'desire to eat' remained significantly blunted at T120 post-meal for PRO_{MOD} only (p=0.048). **CONCLUSIONS:** PRO_{HIGH} does not confer additional satiating benefits in resistance-trained individuals during short-term energy deficit. Ghrelin response to a test-meal support the contention that satiety was sustained with PRO_{MOD} with implication that high protein meals may be adequate to increase acute satiety when following a PRO_{MOD} energy-restricted diet.

2015 Board #171 May 30 2:00 PM - 3:30 PM
Effect Of Branched-chain Amino Acid Plus Glucose Supplement Timing On DOMS And Related Indicators After Eccentric Exercise
 Junqiang Qiu, Guoqiang Geng, Mengrou Panyang, *Beijing Sport University, Beijing, China.*
 Email: qiuqj001@sina.com
 (No relevant relationships reported)

PURPOSE: Nutrient timing is a strategic approach to maximize training effects, reduce risk of injury, and help with recovery. The present study examined the effect of BCAA plus Glucose on markers of muscle damage and Inflammation after eccentric exercise in male college students.

METHODS: 18 healthy college students were divided into control group (PLA) group and supplement (BCAA+G) group randomly. Each group was randomly assigned 4 people for pre-exercise supplementation and 4 people after exercise for the first time, and changed for the second time. Before or after supplementation, volunteers performed an eccentric exercise protocol. Muscle soreness(VAS), creatine kinase (CK), C-reactive protein (CRP) and interleukin-6 (IL-6) and 3-methylhistamine (3MH) assessments were performed before exercise and after 30min, 24, 48 hours.

RESULTS: The VAS score of the subjects increased significantly 24 hours after high-intensity eccentric exercise (2.86 vs 1.66, p<.05), and the increase of serum CK level (364.45 vs. 151.02U/L), CRP (4.77 vs. 3.28mg/L) and IL-6 (279.00 vs. 110.63pg/ml) increased significantly (p<.05); BCAA plus G supplement significantly reduced the VAS score (1.27 vs 2.86, p<.05) and CK (258.74 vs. 364.45U/L), CRP (3.75 vs. 4.77mg/L), IL-6 (164.09 vs. 279.00pg/ml) levels (p<.05), compared with pre-supplementation group, post-supplementation had lower VAS score (1.27 vs. 2.63), CRP (3.75 vs. 4.26mg/L) and IL-6 (164.09 vs. 226.66pg/ml) and 3MH (105.07 vs. 131.67umol/L) response at 24 h after eccentric exercise (p<.05). **CONCLUSIONS:** High-intensity eccentric exercise caused DOMS with the elevation of damage and inflammatory markers as CK, CRP and IL-6. BCAA plus G supplementation can effectively reduce the level of DOMS, decrease muscle damage and inflammatory factors and protein breakdown. Compared with pre-exercise supplementation, post-exercise supplementation has a better effect on reducing inflammatory factors and protein breakdown caused by DOMS.

 Email: sh0099vp@ed.ritsumei.ac.jp
 (No relevant relationships reported)

Combined resistance exercise (RE) and nutrient intake synergistically interacts with muscle hypertrophic effect (MHE) (Phillips et al., 2006). Indeed, muscle breakdown (MB) is suppressed with acute RE and proper nutrient (amino acid + carbohydrate), reflected by decreases in 3-methylhistidine (3-MH), a MB marker in 24h urine collection. The study also suggested that the response of MB marker upon acute RE may reflect MHE in chronic RE training (Bird et al., 2006). However, the effect of the order of nutrient intake and RE on acute MB response remains unclear. Given that MB

acutely responds to RE (Louis et al., 2007), it is important to assess acute changes in MB markers upon nutrient intake and RE. **PURPOSE:** The aim of this study was to investigate the effect of the order of nutrient intake and RE on acute changes in urinary MB marker and thus MHE.

METHODS: Twelve healthy men were divided into three conditions: 1) nutrient intake before RE condition (Pre), 2) nutrient intake after RE condition (Post), and 3) RE without nutrient intake condition (No). They performed 5 types of multiple RE at 70%RM intensity. In all conditions, RE was performed from 8:30 to 9:30. The time of nutrient intake in the Pre was at 7:00, while in the Post was at 9:30. The standard Japanese lunch menu with 21 g of whey protein and 200 ml of milk (total energy, 1019 kcal; Protein, 53.4 g; fat, 25.1 g; carbohydrate, 139.5 g) was provided. Urinary samples were collected at 7:00, 10:00, 12:00, 15:00, and 18:00, and urea nitrogen (UN), creatinine (Cre), and 3-MH concentrations were measured, and 3-MH and UN, were normalized by Cre. **RESULT:** The acute responses of MB markers were validated by the result that the time-course change in the total amount of UN and UN normalized by Cre were consistent at any given time point. The area under the curve (AUC) of 3-MH was significantly higher in Pre than that in No (P < 0.01). There was no significant difference between Post and No in the AUC of 3-MH. The AUC of UN was significantly higher in Pre than that in Post (P < 0.05) and No (P < 0.01). **CONCLUSION:** These results suggest that nutrient intake before RE may have no substantial MHE. Supported by Grant-in-Aid for Scientific Research from the Japanese Ministry of Education, culture, Sports Scientific, and Technology (Grants 26702029 and 15KK0358).

Different Amounts Of Protein Intake Influence Body Composition And Performance In Elite Cyclists
 Antonio Paoli¹, Tatiana Moro², Giuseppe Marcolin¹, Paulo Gentil³, Antonino Bianco⁴. ¹University of Padova, Padova, Italy. ²University of Texas Medical Branch, Galveston, TX. ³Federal University of Goias, Goiana, Brazil. ⁴University of Plermo, Palermo, Italy.
 Email: antonio.paoli@unipd.it
 (No relevant relationships reported)

PURPOSE: The ideal amount of protein intake for endurance athletes has been poorly investigated. The aim of our study was to evaluate the physiological impact of different dietary protein intakes on body composition and performance outcomes in a group of elite cyclists. **METHODS:** Thirty-four elite cyclists (1600-1800 km/month) participated to the study. Subjects were divided in 4 groups with different levels of protein intake: normal (NP, 1.2 g/kg), moderate (MP, 1.6 g/kg), high (HP, 2.0 g/kg) or very high (VHP 2.4 g/kg) protein for 8 wk. In the diets fats were maintained constant whilst energy from carbohydrate and protein was modified to maintain an isocaloric diet. Body composition was assessed via Dual X Ray Absorptiometry (DXA) and via ultrasound to calculate cross sectional area (CSA) of the anterior thigh. VO₂max, peak power output and 1 RM half squat test were also performed. **RESULTS:** After two months both HP and VHP showed a significant improvement of 1 RM (HP pre 133±14 Kg vs post 141±12 Kg, p<0.001; VHP pre 137±12 Kg vs post 144±11 Kg, p<0.001), PPO (HP pre 505±78 W vs post 534±67 W, p<0.001; VHP pre 512±55 W vs post 541±76 W, p<0.001), and VO₂max (HP pre 62.1±5.8 mlO₂/Kg vs post 64.5±5.9 mlO₂/Kg, p<0.001; VHP pre 61.2±5.5 mlO₂/Kg vs post 64.1±7.6 mlO₂/Kg, p<0.001), without differences between groups. There were no significant changes of 1 RM and VO₂max for both NP and MP whilst NP showed a significant decrease of PPO. Both HP and VHP showed a significant increase of lean body mass (LBM) (HP pre 64.72±1.9 Kg vs post 65.99±2.2 Kg, p<0.001; VHP pre 65.52±2.0 Kg vs post 67.61±1.7 Kg) whilst both NP and MP showed a significant decrease (NP pre 63.31±2.1 Kg vs post 62.4±2.3, p<0.05; MP pre 66.88±1.8 Kg vs post 65.80±2.9). HP and VHP showed a significant increase of anterior thigh CSA (HP pre 50.5±7.8 cm² vs post 53.4±6.7 cm², p<0.001; VHP pre 51.2±5.5 cm² vs post 54.1±7.6 cm²). No changes of blood values are detected.

CONCLUSIONS: Our data suggest that a higher protein intake (2.0 and 2.4 g/Kg) may help elite cyclists to improve performance and to increase muscle mass without differences between the two levels of protein intake. Instead 1.2 and 1.6 g/Kg of protein seemed to be not sufficient and could impair performance and muscle mass.

The Association Between The Number Of Meals With Adequate Protein Intake And Maximal Deadlift Strength

Alejandro Gaytan-Gonzalez, Roberto Gabriel Gonzalez-Mendoza, Sergio Alejandro Copado-Aguila, Juan Antonio Jimenez-Alvarado, Marisol Villegas-Balcazar, Francisco Torres-Naranjo, Juan R. Lopez-Taylor. *Universidad de Guadalajara, Guadalajara, Mexico.*
 Email: alejandro.gaytan@cucs.udg.mx
 (No relevant relationships reported)

PURPOSE: To analyze the association between the number of meals with adequate protein intake and maximal deadlift strength in college athletes.
METHODS: We evaluated 250 (107 women) college athletes previous to a national contest. Maximal strength was assessed with one repetition maximum (1RM) on deadlift and was adjusted for body mass (kg lifted weight/kg body mass). The protein intake per meal was assessed with 24-h dietary recalls. The reported protein intake was expressed as absolute (g) and relative (g/kg body mass). Adequate protein intake per meal was deemed as ≥ 20 g and ≥ 0.3 g/kg. Next, we calculated the number of meals that achieved these thresholds and were grouped as $\leq 1, 2, 3, \geq 4$ meals for each criterion. Then, 1RM was compared between groups with and without adjustment for covariables (age [years], lean body mass [kg, bioelectrical impedance], height [cm], sex, relative protein intake [g/kg/d]) for each criterion.
RESULTS: For ≥ 20 g criterion, the ≥ 4 meals group showed significantly higher 1RM than ≤ 1 group for the unadjusted model. When it was corrected for age, lean body mass, height, and sex, it remained significant. However, the differences were no longer significant when the model was also adjusted for relative protein intake. As the model was adjusted, the number of meals decreased their contribution to the model. The same pattern was observed with the ≥ 0.3 g/kg criterion (Table).
CONCLUSIONS: The number of meals with adequate protein intake is associated with higher deadlift 1RM. However, its importance decreased when were adjusted for relative protein intake. Therefore, the association between protein intake and deadlift 1RM could be mediated by total relative protein intake, and the number of meals with adequate protein intake could serve as a strategy to eat more protein rather than playing a “timing” role.

Table. Comparison of maximal deadlift strength by number of meals with adequate protein intake.

| | ≤1 | Number of meals with adequate protein intake | | | | p | R ² | R ² # |
|---------------|----------------|--|----------------|----------------|---------------|-------|----------------|------------------|

Correlation Between Dietary Protein Intake And Grip Strength In Inactive Vegetarian And Vegan Females

Eric Bartholomae, April Incollingo, Maricarmen Vizcaino, Christopher Wharton, Carol Johnston. *Arizona State University, Phoenix, AZ.*
 (No relevant relationships reported)

More than 5% of U.S. adults 18-35 y self-identify as vegetarian or vegan. While health benefits, including reduced risk for cardiometabolic diseases are promoted, concern remains over the potential of lower protein intake, which can lead to reduced muscle mass and strength.
PURPOSE: To examine the relationship between dietary protein and grip strength in inactive vegetarian and vegan female adults.
METHODS: Thirty-three self-reported inactive (<150min exercise/wk) female vegetarians and vegans (31y±9.6; n=23 vegan) of at least 1 year were recruited for this study. A 24hr dietary recall was administered by a trained researcher and protein intake calculated using Food Processor software. Dominant handgrip strength was measured 3 times using a handheld dynamometer, and greatest score recorded. An *a priori* α of 0.05 was used and partial Pearson Product Moment correlation was determined between protein intake and grip strength when controlling for diet type (vegetarian vs. vegan). Independent samples t-tests were conducted to compare protein intake and grip strength in vegetarians vs. vegans.
RESULTS: Results showed significantly greater grip strength in vegans (26.7±4.7 kg) as compared to vegetarians (23.5±2.9 kg), t(2.046) p<.050, and no difference in protein intake between groups t(-.368) p=.716. Results show no correlation between protein intake (43.7±15.2 g PRO/d) and grip strength (25.7±4.4 kg) while controlling for diet type (r(30)=.118, n=33, p=.520). It is noteworthy that mean grip strength in the sample was significantly below the reference value for North American females (31 kg).
CONCLUSION: This study provides evidence that there was no significant association between protein intake and grip strength in inactive female vegetarians; yet, the grip strength for this population fell significantly below region/gender-specific reference ranges.

2020 Board #176 May 30 2:00 PM - 3:30 PM
Combining Whey Protein Isolate with Eccentric Training Improved Quadriceps Strength in Patients with ACL Rupture

Xiaoyuan Zhang¹, Hongshi Huang², Jie Yang², Yuanyuan Yu², Zixuan Liang², Stephen H.S. Wong, FACSM¹, Cuiqing Chang².
¹The Chinese University of Hong Kong, Hong Kong, Hong Kong.
²Peking University Third Hospital, Beijing, China. (Sponsor: Stephen H.S. Wong, FACSM)
 Email: 1155115922@link.cuhk.edu.hk
 (No relevant relationships reported)

Anterior cruciate ligament (ACL) rupture results in significant quadriceps weakness, which will then cause abnormal gait and knee instability. Eccentric training (ET) can produce larger effects on muscle strength than concentric training¹, which may be further augmented by protein supplement². **Purpose** To examine the effects of combining whey protein supplement with preoperative isokinetic ET on quadriceps strength and function after ACL rupture. **Methods** Thirty-seven male subjects aged 18-40 years with ACL rupture were randomly assigned to isokinetic ET (IET, N=19) group or isokinetic ET with whey protein isolate (IET+WP, N=18) group. Both groups received preoperative isokinetic ET for six weeks, containing 3-4 sets per day with 8-10 repetitions for each set, twice a week. Subjects in IET+WP consumed whey protein isolate 22 g per day. Cross-Sectional Area (CSA) of quadriceps was scanned by MRI, and strength and knee function were measured before and after the trials. **Results** After intervention, CSA of the involved quadriceps increased by 3.7% (NS) in IET and 7.6% (P=0.012) in IET+WP. The ratio of side-to-side increased by 3.9% (NS) in IET and 4.8% (P=0.002) in IET+WP. The peak torque of quadriceps during eccentric contraction at 60 degree/s, concentric contraction at 60, 180 and 300 degree/s increased by 27.9% (P<0.001), 35.9% (P<0.001), 34.3% (P=0.002) and 27.3% (P=0.003) in IET, and increased by 44.2% (P<0.001), 42.3% (P<0.001), 37.4% (P=0.002) and 36.7% (P<0.001) in IET+WP, respectively, with no differences between the two groups. Lysholm and IKDC2000 knee function score in IET+WP increased by 24.7% (P=0.001) and 12.9% (P=0.001). **Conclusions** Combining whey protein supplement with ET tends to be more effective on improving CSA of quadriceps, knee function and quadriceps strength when compared to ET alone after ACL rupture, even though the results did not reach statistical differences. **References** [1]. The Effect of Protein Supplementation on Recovery From Exercise-Induced Muscle Damage

Brooke E. Starkoff, Elizabeth Lenz, Craig O. Mattern, Danny Too, and Heidi K. Byrne. *The College at Brockport- SUNY, Brockport, NY; Valparaiso University, Valparaiso, IN* Macronutrient consumption is a crucial component to recovery from vigorous physical activity. Specifically, carbohydrates and protein play a substantial role in recovery from strenuous physical activity. **PURPOSE:** To determine whether or not a carbohydrate plus protein (CHO-P) supplement (containing branched chain amino acids) invoked improved recovery from exercise-induced muscle damage (EIMD) when compared to an isocaloric carbohydrate (CHO) only control supplement, while simultaneously controlling for diet. **METHODS:** Twenty resistance-trained college males (22.1±3.9 yrs, 176.0±6.9 cm, 84.2±17.6 kg) participated in a ten-day, double-blind, randomized trial. Subjects consumed a provided diet (60±5% carbohydrate, 25±4% fat, 15±3% protein) and a daily supplement of 60 g carbohydrates or 40 g carbohydrates plus 20 g protein for eight days. On the fifth day, subjects completed a 100-box jump EIMD protocol. Measures of creatine kinase and myoglobin were obtained prior to EIMD and at 12, 24, 48, and 72 hours post exercise. Muscle soreness and lower body muscle force production were measured pre-EIMD and at 24, 48, and 72 hours post-EIMD. **RESULTS:** Creatine kinase levels (U/L) were elevated at 12 (227.1±18.5), 24 (216.1±17.0), 48 (189.6±18.3), and 72 (168.1±18.0) hours post-EIMD when compared to baseline (121.4±15.2). Myoglobin levels (ng/mL) were elevated at 12 (60.4±56.6) hours post-EIMD when compared to baseline (8.745±6.3). Although the elevations in creatine kinase and myoglobin indicate that EIMD was produced, there were no significant differences in creatine kinase or myoglobin between CHO and CHO-P groups at any time points measured. Although muscle soreness was increased at all time points post-EIMD, there were no significant differences between the CHO and CHO-P conditions. **CONCLUSION:** These data suggest that a CHO-P supplement does not elicit greater recovery from EIMD when compared to a CHO supplement alone.

Associations Among Dietary Protein Intake, Physical Activity, and Muscle Quality in Young Adults

Chester Sokolowski¹, Simon Higgins², Megha Vishwanathan³, Michael Schmidt³, Richard Lewis³, Ellen Evans³. ¹Florida State University, Tallahassee, FL. ²Elon University, Elon, NC. ³University of Georgia, Athens, GA.
 Email: cs18s@my.fsu.edu
 (No relevant relationships reported)

It is well established that moderate-vigorous intensity physical activity (MVPA) and resistance training (RT) positively influence muscle capacity and quality and health across the lifespan. Dietary protein intake is also known to influence muscle health. Data suggest that MVPA, RT, and dietary protein intake differ in young men and women, which may impact muscle capacity and quality; however, research in recreationally active young adult cohorts is lacking. **PURPOSE:** The aim of this study was to determine the associations between dietary protein intake quantity and source and muscle capacity (MC) and quality (MQ), controlling for MVPA and RT, in young men and women. **METHODS:** Young adults (n=122; 18-22 yr; 54% female) were assessed for a) total, animal and plant protein intakes via 3-day diet recall with analysis by Nutrition Data Systems for Research software; b) body composition via DXA scans, and c) knee extensor muscle strength (MC-S) and power (MC-P) via isokinetic dynamometry and Nottingham leg extensor power rig, respectively. Muscle quality was calculated as strength (MQ-S) and power (MQ-P) relative to leg lean mass. MVPA was determined using accelerometry and RT was determined from questionnaire. **RESULTS:** Compared to females, males ingested more animal protein when normalized per body weight, as a percentage of total kcal, and as a percentage of total protein intake (all p<.05). Males also had more lean mass and greater MC-S, MC-P, and MQ-S than females (all p<.05); however, there was no sex difference in MVPA, RT, or MQ-P (all p>.05). Additionally, males had a significant relationship between total protein, total animal protein, and total plant protein intake and MC-S whereas females did not. Controlling for sex, MVPA, and RT, higher total dietary protein and total animal protein intake were associated with greater MC-S (r = .29 and .25, respectively, both p<.05). Higher relative animal protein intake was positively related, whereas higher relative plant protein intake was inversely related to MQ-P (both p<.05). **CONCLUSIONS:** This data suggests that young adult males and

females differ in their dietary protein intake patterns. Moreover, dietary protein intake is modestly related to muscle capacity and quality with effects being stronger in males compared to their female counterparts.

2023 Board #179 May 30 2:00 PM - 3:30 PM
Association of Protein Intake at Three Meals With Muscle Mass in Healthy Young Subjects

Jun Yasuda, Mai Asako, Takuma Arimitsu, Satoshi Fujita. *Ritsumeikan University, Shiga, Japan.*
 (No relevant relationships reported)

PURPOSE: In addition to importance of total daily protein intake for regulation of muscle mass, protein intake over 0.24 g/body weight (BW) from each meal may be necessary to maximize postprandial muscle protein synthesis in young population. Therefore, we hypothesized that if individuals do not achieve protein intake over 0.24 g/BW at least one of three meals (breakfast, lunch, and dinner), muscle mass can be decreased. This cross-sectional study examined the association of protein intake at three meals with muscle mass among healthy young subjects. **METHODS:** We collected 3-day dietary records to evaluate dietary intake. We calculated total fat free mass (FFM) and appendicular (AppFFM) with dual-energy X-ray absorptiometry, and TotalFFM% and AppFFM% were also calculated as FFM relative to BW. The 266 subjects were categorized into two groups: AP group, achieving over 0.24 g/BW of protein intake at all three meals; or NP group, not achieving 0.24 g/BW of protein intake at least one meal. **RESULTS:** There was no linear association between total protein intake above the recommended dietary allowance (RDA) and both TotalFFM% and AppFFM%. Consequently, we examined the association of protein intake at three main meals with muscle mass in subjects consuming total daily protein intake above the RDA. Regardless of potential confounders (e.g. sex, physical activity, and energy intake), we demonstrated that TotalFFM% (77.0 ± 0.5 vs 75.2 ± 0.4%, P = 0.008) and AppFFM% (34.7 ± 0.3 vs 34.1 ± 0.2%, P = 0.058) in AP group was greater than in NP group consuming total protein intake above the RDA. **CONCLUSION:** This finding suggests that even if individuals achieve total protein intake above the RDA, not achieving protein intake over 0.24 g/BW at least one meal may lead to decreased muscle mass in young population. This work was supported by the Japanese Council for Science, Technology and Innovation (SIP, Project ID 14533567), and the grant "Technologies for creating next-generation agriculture, forestry and fisheries" (funding agency: Bio-oriented Technology Research Advancement Institution, NARO).

Effects Of Soy Milk Ingestion On Running Anaerobic Sprint Test (RAST) Performance

Govindasamy Balasekaran, FACSM, Pan Shi Yu. *Nanyang Technological University, Singapore, Singapore.*
 Email: govindasamy.b@nie.edu.sg
 (No relevant relationships reported)

PURPOSE: Pre-exercise feeding is crucial in ensuring individuals are well-fuelled and able to perform at high intensities. Soy protein supplementation have shown to improve performance and recovery, in endurance or resistance exercises. However, there is sparse research on its effects in the repeated anaerobic sprint test (RAST) which is a valid and reliable method in measuring anaerobic capacity. The purpose was to investigate the effects of soy milk ingestion on anaerobic performance using the RAST. **METHODS:** 10 males (age: 23.2 ± 1.23 years, height: 174.3 ± 5.84 cm, weight: 65.39 ± 6.44 kg) participated in the study. They performed two RAST with a soy milk intervention (SOY: 500mL soy milk + 4g stevia sweetener) and a placebo control (CON: 500 mL water + 4g stevia sweetener) over a 7-day period. The RAST consisted of six 35 m sprints with 10 seconds recovery between each sprint; sprint times, heart rate (HR), rating of perceived exertion (RPE), hunger and fullness, blood glucose and lactate levels, mean power output (MP) and fatigue index (FI) were measured. **RESULTS:** The total effort time(seconds) was not significant between SOY (32.77 ± 1.23) and CON (33.28 ± 1.71), p = 0.179. FI in SOY (31.64 ± 5.20) was significantly lower than CON (37.30 ± 5.70), p = 0.023. MP (Watts) (Soy: 499.27 ± 62.72; Con: 486.39 ± 86.13, p = 0.410) and relative power output (Watts)(Soy: 9.34 ± 1.02; Con: 9.55 ± 1.51, p = 0.461) were not significant. No significance were found between trials for the peak blood lactate (PBL) (mmol.L⁻¹) (Soy: 9.75 ± 1.61; Con: 10.24 ± 1.90, p = 0.488) and peak blood glucose (PBG) (mmol.L⁻¹) (Soy: 23.94 ± 3.90; Con: 25.09 ± 4.61, p = 0.497) levels. PBL (r = - 0.654) and PBG (r = - 0.662) concentrations were inversely associated with MP in the SOY trial. No significance were found in mean HR (SOY: 111 ± 40.43; CON: 112 ± 38.69, p = 0.448) and median RPE (p = 0.391) between both trials. There were no significant differences in the ratings for hunger (p = 0.844) and fullness (p = 0.853) between both trials. **CONCLUSIONS:** The soy milk intervention in RAST significantly lowered the FI, but had no significance in any of the variables investigated. The significant decrease in FI and earlier peak lactate levels post-exercise may indicate the possibility of soy milk reducing fatigue. Future studies are required to examine the ergogenic effects of soy milk.

Effects Of Menstrual Cycle On Branched-chain And Aromatic Amino Acids During Endurance Exercise In Female Athletes
 Mikako Sakamaki-Sunaga, Kayoko Kamemoto, Mizuki Yamada, Tomoka Matsuda, Hazuki Ogata. *Nippon Sport Science University, Tokyo, Japan.*
 Email: sunaga@nittai.ac.jp
 (No relevant relationships reported)

Cyclic fluctuations in ovarian hormone (estrogen and progesterone) levels that play an important role in reproductive function are a unique characteristic of adult women. However, these changes in ovarian hormone levels affect physical and mental condition. Previous studies have reported that levels of branched-chain amino acids (BCAA) and aromatic amino acids (AAA) in the blood are related to fatigue. **PURPOSE:** This study investigated the effects of the menstrual cycle on the concentration of BCAA and AAA during endurance exercise and the recovery period in female athletes. **METHODS:** Seven eumenorrheic female athletes (lacrosse players; age, 21.7 ± 0.5 years; height, 157.4 ± 5.1 cm; weight, 52.7 ± 4.6 kg), who usually exercised 4 h/day, 5 days/week, were recruited. Subjects performed endurance exercise on a cycle ergometer for 60 min at 65% of their $\dot{V}O_{2peak}$, measured in a preliminary trial, during the follicular phase (FP) and luteal phase (LP) of their menstrual cycles. After exercising, subjects rested in a chair for 60 min and their post-exercise recovery was observed. Blood samples were taken: pre-exercise (0 min); 30 min after the start of exercise (30 min); 45 min after the start of exercise (45 min); immediately post-exercise (60 min); 30 min post-exercise (90 min); and 60 min post-exercise (120 min). Levels of estradiol, progesterone, BCAA (valine, leucine, isoleucine), and AAA (tyrosine, phenylalanine) in the blood were assessed. The Fischer ratio(BCAA/AAA) was calculated using the following formula: BCAA/AAA = (valine + leucine + isoleucine)/(tyrosine + phenylalanine). **RESULTS:** Estradiol and progesterone levels were significantly lower in the FP than in the LP (estradiol: 40.2 ± 15.4 pg/mL vs. 170.8 ± 75.2 pg/mL, $p < 0.01$; progesterone: 0.5 ± 0.1 ng/mL vs. 11.3 ± 6.5 ng/mL, $p < 0.05$). The Fischer ratio significantly decreased from exercise initiation to exercise conclusion during both phases (FP: 3.6 ± 0.4 (0 min), 3.2 ± 0.3 (60 min), $p < 0.05$; LP: 3.6 ± 0.4 (0 min), 3.3 ± 0.6 (60 min), $p = 0.05$); however, no significant differences were observed between the FP and LP. **CONCLUSION:** No differences in the levels of BCAA and AAA in the blood were observed between the FP and LP of the menstrual cycle pre-, during, or post-exercise.

Semantic Memory fMRI in Healthy Older Adults After Acute Exercise and Rest
 Junyeon Won¹, Alfonso Alfini², Lauren Weiss¹, Corey Michelson¹, Daniel Callow¹, Sushant Ranadive¹, Rodolphe Gentili¹, J. Carson Smith, FACSM¹. ¹University of Maryland at College Park, College Park, MD. ²John's Hopkins University, Baltimore, MD. (Sponsor: J. Carson Smith, FACSM)
 Email: won25@umd.edu
 (No relevant relationships reported)

An extent literature suggests that regular participation in long-term exercise enhances cognitive function. However, less is known about the beneficial effects of acute exercise on semantic memory.

PURPOSE: This study investigated brain activation during a semantic memory task after a single session of exercise in healthy older adults (ages 55-85) using functional magnetic resonance imaging (fMRI). **METHODS:** We used a within-subjects counterbalanced design where 26 participants (ages 55-85) underwent two experimental visits on separate days. During each visit, participants engaged in 30 minutes of rest or stationary cycling exercise immediately prior to performing recognition of Famous names and Non-Famous names during fMRI scanning. **RESULTS:** There were no significant differences in the Famous Name Task (FNT) response time (RT) or accuracy after exercise and rest. Acute exercise was associated with significantly greater semantic memory activation (Famous > Non-Famous) in bilateral middle temporal gyrus, right cerebellum, and left fusiform gyrus. A post-hoc analysis showed significantly greater activation in the bilateral hippocampus after exercise compared to rest. **CONCLUSIONS:** Greater brain activation following a single session of exercise suggests that exercise may increase neural processes underlying semantic memory activation in healthy older adults. These effects were

localized to the known semantic memory network, and thus do not appear to reflect a general or widespread increase in brain blood flow. Coupled with our prior exercise training effects on semantic memory-related activation, these data suggest the acute increase in neural activation after exercise may provide a stimulus for adaptation over repeated exercise sessions.

The Effects Of Continuous and Interval Exercise on Cognitive Performance in Young Adults
 Emily Tagesen¹, David Bellar², Ellen L. Glickman, FACSM¹.
¹Kent State University, Kent, OH. ²University of Louisiana Lafayette, Lafayette, LA.
 (No relevant relationships reported)

Exercise has been shown to increase cognitive performance. However, there are few studies that have compared exercise types to determine different effects. **PURPOSE:** The purpose of the present investigation was to compare changes in cognitive function after two different forms of work matched exercise. **METHODS:** The participants were 22 healthy college age males. Participants were randomly assigned an order of treatment consisting of work matched continuous (CONT) and interval exercise (INT) protocols. The continuous exercise treatment consisted of 20:24 min of 50% $\dot{V}O_{2max}$ on the cycle ergometer. The interval exercise treatment consisted of 6 cycles of 2:00 min 40% $\dot{V}O_{2max}$ and 1:00 min 90% $\dot{V}O_{2max}$ on the cycle ergometer for a total of 18 minutes. Pre and post exercise blood samples were collected to quantify brain-derived neurotrophic factor (BDNF) and participants completed a battery of assessments on the CogState software platform. The cognitive function battery exam included tests of reaction skills, memory skills, psychomotor skills, visual attention, working memory, and spatial working memory. Additionally, blood pressure was continuously measured during the 2 hours post exercise using a non-invasive finger cuff system. **RESULTS:** Repeated measures ANOVA analysis did not reveal any difference in serum BDNF levels by time ($F = 0.237$, $p = 0.629$; pre: 388.9 ± 196.4, post: 464.3 ± 222.4) or treatment by time ($F = 0.896$, $p = 0.349$). Non-parametric analysis of cognitive data revealed significant ($p < 0.02$) changes in attention (identification speed test) in both CONT and INT (baseline: 460.6 ± 69.3 sec, post CONT: 513.8 ± 99.2 sec, post INT: 504.5 ± 85.6 sec). For the executive function (Groton's maze) only the INT resulted in a significant increase ($p < 0.01$) from baseline (baseline: 48.2 ± 11.7, post INT: 38.4 ± 13.8). There were significant correlations between systolic blood pressure during recovery for both INT and CONT and improvements in executive function (CONT $r = 0.567$, $p < 0.01$; INT $r = 0.570$, $p < 0.01$). **CONCLUSION:** It appears that both CONT and INT exercise promote some increases in cognitive function related to elevated recovery systolic blood pressure and independent of serum BDNF. Moreover, INT exercise may increase executive function more than aerobic exercise, though more investigation into this effect is warranted.

The Effects Of A 30-min Moderate Aerobic Exercise On Autonomic And Inhibitory Control - ERP Study
 Yiu Man Lee, Stanley Sai-chuen HUI, FACSM. *Chinese University of Hong Kong, Hong Kong, Hong Kong.* (Sponsor: Prof. Stanley Sai-chuen HUI, FACSM)
 (No relevant relationships reported)

PURPOSE: The current study aimed at exploring whether inhibitory control would be changed after a 20-min bout of moderate cycling exercise plus 5-min warm-up and 5-min cool-down. The study hypothesized that subjects who demonstrated greater high frequency heart rate variability (HF-HRV) reactivity (i.e. larger HF-HRV decrease) under a mental stress evoked by a Stroop color-word test, would perform better on the Stroop tasks after acute aerobic exercise. **METHODS:** 40 young male adults (age = 21.3 ± 2.1 yrs. old) were randomly assigned to either an exercise intervention or no exercise (control) condition. Participants of intervention were asked to engage in a 20 min cycling exercise at 60% $\dot{V}O_{2max}$, while computerized Stroop color-word test was conducted before and after the cycling to examine the acute effects of aerobic exercise on inhibitory control. HRV was measured during the Stroop tasks by using the Electrocardiogram (ECG), which was recorded via two bipolar electrodes that were placed on the left and right chest of the participants. The electroencephalogram (EEG) signal was recorded continuously from a 32 scalp electrodes arranged according to the International 10-20 system. The EEG data was re-referenced offline to average of mastoid electrodes, and bandpass filtered at 0.1 to 20 Hz. Target-locked ERP analysis was restricted to the frontocentral midline electrodes (Fz, Cz, Pz) as Stroop interference effect were known to be maximum at the midline. **RESULTS:** Two-way repeated measures MANOVA showed significant Intervention X Time interaction on Stroop interference at Pz location ($p < 0.03$). Meanwhile, significant Intervention X Time interaction on HF-HRV differences was revealed between the exercise intervention and control groups on the Stroop tasks ($p < 0.01$). Exercise group performed significantly lower score on Stroop interference and lower HRV reactivity at post-test than the control group ($p < 0.05$). Lower scores reflecting more adaptive response and enhanced cognitive performance.

CONCLUSIONS: A 30-min acute moderate aerobic exercise could elicit inhibitory control for young adults. The studies manifested the potential physiological mechanism between central nervous system and autonomous nervous system which were reflected by HRV index.

Aerobic and Muscular Fitness Associations with Adolescent Cognitive Control

Tatsuya T. Shigeta¹, Angus A. Leahy², Jordan J. Smith², Narelle Eather², David R. Lubans², Charles H. Hillman¹. ¹Northeastern University, Boston, MA. ²University of Newcastle, Callaghan, New South Wales, Australia.
Email: shigeta.t@husky.neu.edu
(No relevant relationships reported)

Purpose: Physical activity supports greater cardiorespiratory fitness (CRF); a correlate of cognitive control. The relation of muscular fitness (MF) and cognitive control are less clear. The present study investigated the differential relationship of CRF and MF with cognitive control in older adolescents; a population subjected to social and academic stressors.

Methods: Students (15-17 years, N = 289, 122 females) from ten secondary schools completed tests of inhibition, working memory (WM), CRF (PACER), and MF (standing long jump, push-ups).

Results: Stepwise regression analyses accounted for demographic factors in step 1, and either CRF or MF in step 2. CRF predicted flanker response accuracy (RA) and reaction time (RT) across congruency conditions (β 's ≥ 0.14 , p 's < 0.05). In the 1-back WM task, CRF predicted greater RA, greater d' , and shorter non-target RT (β 's ≥ 0.15 , p 's < 0.05). In the 2-back WM task, CRF predicted greater non-target RA and d' (β 's ≥ 0.14 , p 's ≤ 0.05). Comparatively, MF only predicted 2-back target accuracy ($\beta = 0.14$, $p = 0.02$). Follow-up 3-step regressions assessed significant outcomes from the 2-step models to account for the contrasted fitness variable in step 2, and the fitness variable of interest in step 3. CRF remained a significant predictor for most cognitive outcomes (β 's ≥ 0.17 , p 's ≤ 0.05). However, with MF entered in step 2, CRF marginally predicted incongruent flanker RA and 1-back non-target accuracy (β 's ≤ 0.16 , p 's ≥ 0.06), and no longer predicted greater 2-back d' ($\beta = 0.11$, $p = 0.20$). Comparatively, MF marginally predicted 2-back target accuracy with CRF accounted for ($\beta = 0.12$, $p = 0.09$).

Conclusion: MF was unrelated to cognitive performance, especially with CRF included in the model. CRF's predictability of WM decreased with MF accounted for, particularly during conditions requiring greater WM demands. CRF was generally related to faster processing speed and greater RA during a task modulating inhibitory demands, suggesting that increased CRF may improve cognition via modulation of older adolescents' inhibitory control. Such findings highlight physical activity's value in aiding cognition underlying older adolescents' academic performance. Project funded by the National Health and Medical Research Council (APP1120518).

Cortical Activation during Walking While Smartphone Texting: a Dual Task Based fNIRS Study

Kun Wang, Zhangyan Deng, Qian Gu, Jimeng Zhang, Tao Huang, Zuosong Chen. Shanghai Jiao Tong University, Shanghai, China.
Email: wangkunz@sjtu.edu.cn
(No relevant relationships reported)

BACKGROUND: Previous studies demonstrated that gait performance was decreased when walking while performing a cognitive task such as texting on a smartphone, which reflects a cognitive-motor dual-task interference. The neural bases of the interference are not well studied. **PURPOSE:** To investigate the cortical activation during a dual task of walking while smartphone texting in young healthy adults using the functional near-infrared spectroscopy (fNIRS). **METHODS:** In a crossover study design, 39 right-handed college students (21.3 \pm 2.5 years, 46.1% females) randomly undertook the following three task conditions separated by a minimum of 48 hours: smartphone texting only (T task), walking only (W task), and dual task of smartphone texting while walking (TW task). Cortical oxygenation during the three tasks was monitored using a 38-channel fNIRS (NIRx Medical Technologies LLC, USA). Walking was conducted on a treadmill with a speed of 2.0 km/hour. Texting task was performed with a typing APP on a smartphone. **RESULTS:** There was no significant difference in texting speed between T task and TW task (71.7 \pm 10.4 vs. 71.0 \pm 12.9 chars/min, $P > 0.05$). Texting enhanced hemodynamic response in frontopolar area (eg, Ch1_{T task vs. W task} 1.10 \pm 1.93 vs. -0.12 \pm 0.14 a.u., $P < 0.01$; Ch1_{TW task vs. W task} 0.89 \pm 1.05 vs. -0.12 \pm 0.14 a.u., $P < 0.01$) dorsolateral prefrontal cortex (e.g., Ch6_{T task vs. W task} 0.24 \pm 0.43 vs. -0.15 \pm 0.42 a.u., $P < 0.01$; Ch6_{TW task vs. W task} 0.21 \pm 0.33 vs. -0.15 \pm 0.42 a.u., $P < 0.01$) and Broca's area (e.g., Ch35_{T task vs. W task} 0.99 \pm 0.81 vs. 0.47 \pm 0.75 a.u., $P < 0.01$). In addition, W task evoked an increased activation in temporopolar area (e.g., Ch8_{T task vs. W task} 0.04 \pm 0.12 vs. 0.75 \pm 1.30 a.u., $P < 0.01$) and superior temporal gyrus (e.g., Ch15_{T task vs. W task} 0.22 \pm 0.64 vs. 0.76 \pm 0.84 a.u., $P < 0.01$) than T task. There were no significant differences in those regions between T task and TW task. **CONCLUSIONS:** The

findings indicated that walking on a low speed requires less cognitive resources from the prefrontal cortex, while the temporal lobe is involved. When walking while texting on a smartphone, the brain areas (temporopolar area and superior temporal gyrus) involved in gait were activated, and areas in prefrontal cortex were also activated. Thus, more cognitive resources were allocated to smartphone texting during the dual task.

2031 Board #187 May 30 2:00 PM - 3:30 PM

Can Repeated Bouts Of Exercise Improve Equally Post-exercise Inhibitory Control As Single Bout Of Exercise?

Takeshi Sugimoto¹, Tadashi Suga¹, Hayato Tsukamoto², Tadao Isaka¹, Takeshi Hashimoto, FACSM¹. ¹Ritsumeikan University, Kusatsu, Shiga, Japan. ²University of South Wales, Pontypridd, United Kingdom. (Sponsor: Takeshi Hashimoto, FACSM)
Email: sh0150rs@ed.ritsumei.ac.jp
(No relevant relationships reported)

PURPOSE: We previously demonstrated that post-exercise improvements of inhibitory control (IC) are associated with increase in exercise volume (Tsukamoto et al. Med Sci Sports Exerc. 2017). Previous studies reported that repeated bouts of moderate-intensity exercise (Repeated), which is performed with a short rest interval during exercise program, may be a useful strategy in improving metabolic function, potentially by enhancing lipid metabolism compared with volume-matched single bout of moderate-intensity exercise (Single) (Goto et al. J Appl Physiol. 2007). However, it remains unknown whether Repeated would be effective in improving post-exercise IC. In this study, we compared the effect of Repeated and Single on post-exercise IC. **METHODS:** Fifteen healthy men (age: 20.6 \pm 0.4 years) performed Repeated and Single in randomized order. The Repeated was consisted of twice moderate-intensity cycling exercise (60% $\dot{V}O_{2\text{peak}}$) for 20 min which was separated by a 20-min sitting rest, while the Single was performed for 40 min without rest. To evaluate IC, the Stroop task was administered before exercise, immediately after exercise, and every 10 min during the 30-min post-exercise recovery period. At the same time points, blood was collected for glucose and lactate measurement, and psychological arousal level was assessed by the felt arousal scale. **RESULTS:** The exercise-induced increase in mean arterial pressure was significantly lower in Repeated than in Single ($P < 0.05$), but not heart rate and ratings of perceived exertion. Psychological arousal level in post-exercise recovery did not differ significantly between the two conditions. Similarly, there were no significant differences for blood glucose and lactate immediately after exercise and post-exercise recovery between conditions. IC was significantly improved immediately after both Repeated and Single ($P < 0.05$), but it did not differ significantly between two conditions. **CONCLUSION:** The present findings suggest that Repeated can similarly elicit IC improvements as Single.

The Differential Relationships Between Physical Activity and Adiposity with Cognitive Function in Preadolescent Children.

Nicole E. Logan¹, Lauren B. Raine¹, Rebecca J. Shorin¹, Naiman A. Khan², Arthur F. Kramer¹, Charles H. Hillman¹. ¹Northeastern University, Boston, MA. ²University of Illinois, Champaign Urbana, IL.
Email: logan.n@husky.neu.edu
(No relevant relationships reported)

PURPOSE: To identify the effects of adiposity and a physical activity (PA) intervention on cognitive and neuroelectric indices of inhibitory control in preadolescent children. **METHODS:** Children were randomly assigned to either a 9-month afterschool physical activity (PA) or a wait-list control (CON) group. Children completed a task that manipulated inhibitory control at pre- and post-test while measures of task performance and the P3-event related potential (ERP) were assessed. Children were further grouped according to weight category. 76 children with obesity (39 PA; 37 CON) completed testing. A sample of normal weight children (NW) (n=76) were matched to the sample of children with obesity based on treatment allocation and demographic variables of age, sex, IQ, SES, and fat-free $\dot{V}O_{2\text{max}}$. Changes in adiposity measures included whole body percent fat (%Fat), subcutaneous abdominal adipose tissue (SAAT), and visceral adipose tissue (VAT). The influence of physical activity and adiposity on task performance and brain function was examined. **RESULTS:** Children in the PA group decreased %Fat from pre- to post-test ($p=.011$); an effect not observed in the CON group. Children in the CON group gained SAAT and VAT from pre- to post-test ($p \leq 0.001$), whereas children in the PA group did not. The PA group showed larger P3 amplitude from pre- to post-test ($p=.026$); an effect not seen in the CON group. P3 amplitude did not differ between groups at pre-test for children with obesity; however, the PA group demonstrated larger P3 amplitude compared to the CON group at post-test ($p=.006$). Children with obesity in the CON group had smaller P3 amplitude at post-test compared to pre-test ($p=.003$), an effect not seen in NW children. Results suggest that physically inactive children with obesity

have increased adiposity and smaller P3 amplitude over 9 months. Furthermore, results suggest that a PA intervention may be particularly beneficial for children with obesity, as they showed increased P3 amplitude from pre- to post-test. **CONCLUSION:** PA is beneficial for brain function in pre-adolescent children, especially in those with obesity. Given that childhood obesity is a public health concern with an array of health complications, these results have important implications for the physical and cognitive health of children.

Association of School Day Segmented Physical Activity with Children's Physical and Cognitive Health
 Xiangli Gu¹, Tao Zhang², Priscila M. Caçola¹, Xiaoxia Zhang¹, Jing Wang¹. ¹University of Texas at Arlington, Arlington, TX. ²University of North Texas, Denton, TX.
 Email: xiangli.gu@uta.edu
 (No relevant relationships reported)

Purpose: Around 32% of children are overweight or obese and do not meet the 60-minute moderate-to-vigorous physical activity recommendation (MVPA; SHAPE America, 2016). Given that physical activity is highly variable between children across the school day and during specific segments (CDC, 2013), it is unclear which segmented MVPA during school contributes the most physical and cognitive health benefits. This study aimed (1) to investigate associations between time spent in MVPA during recess, lunch, physical education (PE), and physical fitness components (BMI, cardiorespiratory and muscular fitness), as well as cognitive health, respectively; and (2) to test the indirect effect of segmented MVPA on cognitive health through physical fitness among 8-9 years old children.

Methods: Participants were 340 8-9 years old children ($M_{age} = 8.40$, $SD = 0.49$) recruited in the southwest region of the U.S. Time spent in MVPA during recess (RE_MVPA), lunch (LU_MVPA) and PE (PE_MVPA) segments were measured by accelerometers across five school days. The FITNESSGRAM® test battery was used to assess physical fitness components including PACER, curl-up, push up, and BMI. Children's cognitive health was measured by also the 6-item PedsQL™ Cognitive Functioning Scale (Varni et al., 2011).

Results: The time spent in MVPA during recess was positively associated with physical fitness (cardiorespiratory and muscular fitness; $r = .27$, $r = .40$, $p < .01$) and had low, but positive correlation with cognitive function ($p < .05$). Both cardiorespiratory ($r = .26$, $p < .01$) and muscular fitness ($r = .12$, $p < .05$) were significantly related to cognitive health. The structural equation modeling analyses suggested a significant indirect effect of time spent in MVPA during recess and PE on children's cognitive function through physical fitness with sound goodness-of-fit indices: $\chi^2/df = 109.46/58$, CFI = .93, RMSEA = .051; (90% CI [0.04, 0.07]).

Conclusion: The results suggest that school segmented MVPA in PE and recess provide children with opportunities to maintain appropriate levels of physical fitness and cognitive health. This study fills the research gap by identifying unstructured physical activity periods such as recess that can provide greater room to implement physical activity and health promotion strategies in school-age children.

Relationship Between Fitness and Active-Sedentary Behavior with Cognitive and Emotional Recognition in Elderly: Core Study
 Andrés Vivas, Paulo C. Freire, Juliana L. Sousa, Marcyo C. Silva, Henrique Bortolotti, Eduardo C. Costa, Hassan M. Elsangedy, Eduardo B. Fontes. *Federal University of Rio Grande do Norte, Natal, Brazil.*
 Email: andresviv69@gmail.com
 (No relevant relationships reported)

The decline in cognitive function and emotional regulation in aging have broad negative implications for independence, social competence and behavior that affect health. These impaired conditions can be exacerbated by increased sedentary behavior (SB) and lower levels of physical activity (PA) and fitness. However, it is not clear which of these have a higher relationship with cognitive function and emotional regulation in elderly.

PURPOSE: To investigate the relationship between cognitive function and emotional regulation with physical fitness, PA and SB in the elderly.

METHODS: This preliminary analysis of the Cardiovascular, Cognitive and Exercise Study in the Elderly (CORE) included 60 volunteers (64 ± 3.47 years; female n: 39), who performed a cognitive task (Wisconsin cards sorting test) and an emotional facial recognition task, physical fitness test (senior fitness test and handgrip strength), PA level (Minnesota Leisure-time Physical Activity Questionnaire) and sedentary behavior questionnaire (Longitudinal Aging Study Amsterdam). Bivariate correlations using Spearman's rho (ρ) were used with statistical significance set at 5%.

RESULTS: Significant relationship between cognitive performance with, leg strength (total correct response, $\rho = 0.28$; total errors, $\rho = -0.28$; and non-perseverative errors, $\rho = -0.28$), 6-min walking test (total correct response, $\rho = 0.31$; total errors, $\rho = -0.31$;

and non-perseverative errors, $\rho = -0.30$) and SB (perseverative errors $\rho = -0.27$). Also, the reaction time (RT) during the emotional facial recognition had a significant relationship with upper body strength (RT positive $\rho = -0.26$; RT negative $\rho = -0.33$) and PA level (MET, hr/w) (RT negative $\rho = -0.31$). Also, a significant relationship between worse cognitive performance with handgrip strength (non-perseverative errors, $\rho = 0.26$) and SB (perseverative errors, $\rho = -0.27$).

CONCLUSIONS: These preliminary results suggest that physical fitness and SB are associated with cognitive performance. Also, PA level and upper body strength are associated with emotional performance. These findings suggest the importance between the balance of maintaining an active behavior and the inclusion of aerobic and resistance exercises to improve cognition and emotional regulation in the elderly.

Cardiovascular Risk Moderates Aerobic Training Efficacy on Executive Function in Older Adults
 Lauren Marcotte, Cindy K. Barha, Robin Hsiung, Teresa Liu-Ambrose. *University of British Columbia, Vancouver, BC, Canada.*
 Email: lauren.marcotte@alumni.ubc.ca
 (No relevant relationships reported)

PURPOSE: To examine whether the Framingham Cardiovascular Risk Profile Score (FCRP) moderates the effect of a 6-month progressive aerobic training program (AT) on executive function in older adults with mild subcortical ischemic vascular cognitive impairment.

METHODS: This is a secondary analysis of a proof-of-concept randomized controlled trial in 71 older adults, who were randomized to either a 6-month, thrice-weekly, progressive AT program (AT), or usual care plus an education program (CON). At baseline and trial completion, three executive processes were measured: 1) response inhibition by Stroop Colour Word Test; 2) working memory by digits backward test, and 3) set shifting by the Trail Making Test (B-A). Baseline cardiovascular risk was calculated using the FCRP, and participants were classified as either low risk (<20% FCRP score; LCVR) or high risk (>20% FCRP score; HCVR). A complete case analysis (n=57) was conducted using an analysis of covariance (ANCOVA) to evaluate between-group differences in the three executive processes. Age, baseline Montreal Cognitive Assessment score, education, and baseline score for the outcome variable were entered as covariates in all models.

RESULTS: A significant interaction was found between FCRP and group (AT or CON) for the digit span backward ($F(1,49) = 4.67$, $p = 0.03$) and the Trail Making Test ($F(1,50) = 4.09$, $p = 0.04$). There was no significant interaction for the Stroop Colour Word Test ($F(1,48) = .802$, $p = .38$). On the digit span backward test, AT improved performance compared to CON ($3.74 \pm .33$ vs. $2.75 \pm .46$) in those with LCVR, while in those with HCVR, AT did not improve performance compared to CON ($2.97 \pm .45$ vs. $3.76 \pm .41$). Similarly, for the Trail Making Test (B-A), AT improved performance compared to CON (52.66 ± 13.27 vs. 80.12 ± 17.82) in those with LCVR, while AT was not beneficial compared to CON in those with HCVR (98.80 ± 18.06 vs. 59.92 ± 17.09).

CONCLUSION: We found that cardiovascular risk significantly moderates the efficacy of aerobic exercise on working memory and set shifting in older adults with vascular cognitive impairment. Our findings highlight the importance of intervening early in the disease course of vascular cognitive impairment, when cardiovascular risk may be lower, to reap maximum benefits of aerobic exercise.

A Single Bout of Exercise Improves Accuracy in Video Gaming: a Pilot Study
 Bernat de las Heras, Orville Li, Lynden Rodrigues, Jean-Francois Nepveu, Marc Roig. *McGill University, Montreal, QC, Canada.*
 Email: bernatdelas@gmail.com
 (No relevant relationships reported)

There are 2.3 billion of video gamers worldwide and this number is expected to grow to more than 2.7 billion by 2021. Research has demonstrated negative associations between the number of hours spent in front of a screen and physical inactivity. Video gamers are thus at a great risk of experiencing long-term health issues associated to excessive sedentarism. Cardiovascular exercise has been proven to be an effective intervention in reducing the risk of cardiometabolic clinical conditions as well as enhancing brain health and function. However, whether exercise has positive effects on video game performance is not known.

PURPOSE: To investigate the effects of a single bout of cardiovascular exercise on the performance of "League of Legends" (LoL), a video game played daily by more than 30 million players. **METHODS:** 14 healthy young (18-28 yo) LoL gamers played an individual LoL task of 20 min preceded by either 15 min of a high-intensity interval exercise or rest. The two conditions were administered on two separate days in a counterbalanced fashion. Video game performance was assessed as the number of targets destroyed, as well as accuracy, defined as the ability to destroy a target with only one attack. Attacks that required more than one attempt to destroy a target

were counted as accuracy errors. **RESULTS:** Exercise improved the capacity of participants to successfully destroy targets, but differences between exercise (119.43 [4.23]) and rest (111.50 [3.98]) did not reach statistical significance (paired t-test; $t=1.81$; $p=0.094$). Exercise enhanced accuracy, with fewer errors after exercise than after rest (paired t-test; $t=-2.38$; $p=0.033$). Self-reported sitting time was negatively associated with total score after the rest condition ($r=-0.55$; $p=0.040$). Neither other variable (cardio-respiratory fitness, BMI, cognitive level) was associated with game performance. **CONCLUSION:** Exercise performed before playing LoL improves video game performance increasing accuracy. The fact that players with less sitting time showed better performance reinforces the importance of reducing sedentary behaviors in this group. The implementation of exercise routines in video gamers may improve their general health and their gaming performance. Supported by FRQS Junior I Salary Award (MR) and by the McGill Faculty of Medicine (OL).

ASsocation Between Cognitive Funtion And Handgrip Strength In Physical Education College Students

Héctor Reynaldo Triana Reina¹, Kely Johana Bonilla Vargas², Jesús Astolfo Romero¹. ¹Universidad Santo Tomas, Bogotá, Colombia. ²Universidad de Rosario, Bogotá, Colombia. Email: hecortriana@usantotomas.edu.co
 (No relevant relationships reported)

PURPOSE: To analyze the association between cognitive function and handgrip strength in a sample of university students of Physical Culture in Bogotá, Colombia. **METHODS:** the cross-sectional study included a total sample of 104 voluntary university students of Physical Culture, 18 - 25 years old, from Bogotá, Colombia. The handgrip strength was determined by the digital dynamometer and the cognitive function was evaluated individually by trained personnel through the Paced Auditory Serial Addition Test (PASAT), to evaluate the speed and flexibility of the processing of auditory information, the sustained and divided attention, as well as the calculation capacity, a standardized audio was used in the speed of the stimulus, presenting the individual digits every 3 seconds (PASAT-3), adding each new digit to the previous one immediately. The shorter stimulus intervals were used in 2 seconds (PASAT-2), increasing the difficulty. The association between cognitive function and handgrip strength adjusted for weight, was performed using the linear logistic regression model in the statistical package SPSS v25. **RESULTS:** The sample was middle-aged (Age=19.8±2.4yrs; N=87 men). The logistic regression model showed a strong association between hand grip strength adjusted to weight and cognitive function, through the stimulation of PASAT-2 ($p = 0.026$, Beta = 0.219), compared with PASAT-3 ($p = 0.062$; Beta = 0.184) where no significant difference was found, however a low tendency is identified. **CONCLUSION:** the results of this study show that hand grip strength is associated with a better cognitive response in speed and flexibility of processing in college students of Physical Culture of Bogotá, Colombia, for which it is suggested to promote the regular practice of exercise physical that stimulates muscle strength, in order to improve cognitive performance in college students.

2038 Board #194 May 30 2:00 PM - 3:30 PM
Exercise Intensity Influences Prefrontal Cortex Oxygenation During Cognitive Testing

Terence Moriarty, Kelsey Bourbeau, Bryanne Bellovary, Micah Zuhl. *University of New Mexico, Albuquerque, NM.* Email: moria1ta@unm.edu
 (No relevant relationships reported)

Various types of exercise therapies, including high and low intensity aerobic exercise, along with mind-body exercise (e.g., yoga) have been implemented into treatment for those suffering from psychological disorders and traumatic brain injury. The prefrontal cortex (PFC), which houses key cognitive constructs is responsive to exercise, and is commonly measured using functional near infrared spectroscopy (fNIRS). Evidence suggests that exercise mediates neural adaptation through increased blood flow and neurogenesis, which enhances neural activation leading to improved cognitive performance. However, the type and intensity of exercise that has the most robust impact on brain blood flow is currently unknown. **PURPOSE:** Therefore, the primary aim of the study is to compare PFC activation during cognitive tasks performed after low-intensity, high intensity, and yoga exercises. We also aim to determine if markers of cardiovascular and metabolic stress influence brain activity after each exercise bout. **METHODS:** Eight subjects (4 male, 4 female), aged 35 ± 5 years completed a control, high intensity, low intensity, and yoga exercise trial followed by administration of a cognitive task (NIH Toolbox Fluid Cognition). Left and right PFC oxygenation were measured during the post-exercise cognitive assessment using fNIRS technology. **RESULTS:** Oxygenation during the cognitive task was higher in the left PFC region after low intensity exercise compared to all other trials (control, high intensity, yoga). Regression model analysis showed that a 10% increase in %HRmax up to 70% intensity predicts an increase in left PFC oxygenation by 2.11 umol. No relationship

was detected between PFC oxygenation and cognitive performance or the lactate response among participants in the current study, however a relationship between control levels of brain derived neurotrophic factor (BDNF) and processing speed was detected. **CONCLUSIONS:** Acute exercise below 70% aerobic intensity increased brain blood flow during a post-exercise cognitive task. Therefore, it may be beneficial for those who engage in any cognitive related activity to perform a brief bout of low intensity exercise prior to the task. This may include people who participate in academic-based testing, cognitive behavioral therapy, or motor training.

2039 Board #195 May 30 2:00 PM - 3:30 PM
Exploring The Relationships Between Personality And High-intensity Exercise-affect In Men And Women

Shelby E. Dietz, Allyson G. Box, Annmarie Chizewski, Steven J. Petruzzello, FACSM. *University of Illinois Urbana-Champaign, Urbana, IL.* (Sponsor: Steven J. Petruzzello, FACSM)
 (No relevant relationships reported)

In general, men are more likely to meet physical activity guidelines in comparison to women, and tend to report exercising at higher-intensities. However, less is understood in regards to how men and women differ in feeling states (e.g., core affect) during a high-intensity exercise bout. **PURPOSE:** Determine whether sex differences exist in personality traits and high-intensity exercise-affect. **METHODS:** Male (M; n=63) and female (F; n=101) undergraduates (n=164, 20±2yrs, 24±4 body mass index (BMI), 62% female, 82% regular exercisers) completed several personality surveys along with a 15-minute high-intensity circuit (HIC). Core affect (via Feeling Scale & Felt Arousal Scale) was assessed prior to, every 3-minutes during, and 20-minutes post (P20) condition. **RESULTS:** Multivariate ANOVAs revealed significant differences ($P < 0.05$) in the personality traits extraversion (F= 46.2, M= 42.2, $d = .894$), neuroticism (F= 47.4, M= 45.1, $d = .644$), openness (F= 14.5, M= 15.6, $d = -.496$), intensity-preference (F= 26.4, M= 29.0, $d = -.535$) and intensity-tolerance (F= 25.2, M= 28.4, $d = -.651$). No sex differences ($P > 0.05$) were observed for exercise-affect prior to, during, and following the HIC. **CONCLUSIONS:** Although sex differences exist in various personality traits, these differences did not influence how one felt prior to, during, and following a HIC. These findings support the notion that men and women respond similarly to exercise stimuli. More research is needed to understand why women exercise less and at lower-intensities in comparison to men.

2040 Board #196 May 30 2:00 PM - 3:30 PM
Acute After-School Screen Time in Children Decreases Impulse Control: A Randomized Crossover Trial

Bruce W. Bailey, Mary Efraim, Chance McCutcheon, Hunter LaCouture, Harrison Marsh. *Brigham Young University, Provo, UT.* Email: bruce.bailey@byu.edu
 (No relevant relationships reported)

PURPOSE: This study examined the effect of three hours of after school active play vs. sedentary screen time on executive function in children. **METHODS:** This study used a crossover design with treatment conditions that were randomized and counter-balanced. There were two experimental conditions: three hours of active play compared to three hours of sedentary screen time. Participants included 32 boys and girls age 8-9 yrs. Physical activity patterns were measured using an actigraph accelerometer. Executive control was measured using the Stroop color and word test. **RESULTS:** The mean age and BMI were 8.7 ± 0.4 years and 16.9 ± 2.2. On the active day, children spent 95 ± 28 minutes in MVPA after school compared to 3 ± 3 minutes on the sedentary day (F = 252.1, P < 0.0001). There was no difference between days in the Stroop Task performance for word reading or color naming. However, there was a significant difference between conditions for the incongruent task, with children performing better on the active day (F = 6.79, P = 0.0150). **CONCLUSIONS:** The results of this study demonstrate that active play after school improves executive function in children by increasing their ability to inhibit cognitive interference.

Acute Exercise Alters Functional Connectivity During Cognitive Task

Soichi Ando¹, Sota Saito¹, Nobuaki Mizuguchi², Mizuki Sudo³, Kazunori Ohkawara¹, Atsushi Senoo¹. ¹The University of Electro-Communications, Tokyo, Japan. ²Keio University, Tokyo, Japan. ³Meiji Yasuda Life Foundation of Health and Welfare, Tokyo, Japan. ⁴Tokyo Metropolitan University, Tokyo, Japan. Email: soichi.ando@uec.ac.jp
 (No relevant relationships reported)

PURPOSE: There is a growing body of evidence to show that acute aerobic exercise improves cognitive performance. Nevertheless, it remains largely unknown how acute

exercise improves cognitive performance. The purpose of this study was to test if alteration in functional connectivity is involved in improving cognitive performance induced by acute exercise.

METHODS: Participants were 10 healthy right-handed young men (age: 21.6 ± 1.4 yr., peak oxygen uptake = 46.5 ± 8.7 ml/kg/min). Experiments were conducted in a randomized crossover design. In the Exercise condition, subjects cycled at 40% peak oxygen uptake for 30 minutes. In the Control condition, subjects rested for 30 minutes without exercise. In both conditions, participants performed cognitive task (Go/No-Go task) before and after exercise (rest). We first analyzed regions specifically activated by exercise as region of interest. Then, we identified regions where functional connectivity was altered before and after exercise. We also identified regions where amount of alteration in functional connectivity was correlated with that of reaction time (RT).

RESULTS: RT was reduced in the Exercise condition (Pre: 420 ± 77 ms, Post: 388 ± 65 ms, $p = 0.02$), while it did not change in the Control condition (Pre: 416 ± 79 ms, Post: 417 ± 78 ms, $p = 0.82$). We observed significant increases in activation in the opercular and triangular parts of the left inferior frontal gyrus (IFG) and anterior cingulate cortex ($p < 0.01$, uncorrected). We observed an increase in functional connectivity between the opercular part of the left IFG and the left putamen (Pre: 0.02 ± 0.11 , Post: 0.12 ± 0.13 , $p = 0.08$). Alteration in the functional connectivity between these regions was negatively correlated with the alteration in RT ($r = -0.44$, $p = 0.06$).

CONCLUSIONS: Alteration in functional connectivity may be associated with improvement of cognitive performance after acute exercise.

The Effects Of Exercise Intensity On Auditory Processing Speed And Flexibility: A Randomized Crossover Study.

Ciera Batholomew, Michael Larson, Hunter LaCouture, Kaylie Carbine, Chance McCutcheon, Harrison Marsh, Bruce W. Bailey, Jr. *Brigham Young University, Provo, UT.*
Email: cieralb12@gmail.com

(No relevant relationships reported)

PURPOSE: The purpose of this study was to determine how exercise, at a moderate and vigorous intensity, alters auditory processing speed and flexibility, and calculation ability. **METHODS:** One hundred and thirty-six men and women between the ages of 18-45 were recruited for this randomized crossover study. Participants were randomly assigned to each of the following exercise conditions: moderate (35% VO₂ max), vigorous (70% VO₂ max), and sedentary (no exercise). Each condition lasted 40 minutes and was separated by 7 days. After the exercise condition, a battery of cognitive tests were administered. The Paced Auditory Serial Addition Test (PASAT) was one of these tests and was used to measure the relationship between exercise intensity and auditory processing speed and flexibility. **RESULTS:** Eighty-one men (age=23.2, BMI=23.9 ± 3.2) and fifty-five women (age=20.9, BMI=22.4 ± 2.8) completed the study. There was no main effect of condition for the number of problems answered correctly ($F = 1.24$, $P = 0.2900$), the number of problems attempted ($F = 1.48$, $P = 0.2291$) and the percent of problems correctly answered ($F = 1.69$, $P = 0.1865$). There was a main effect for gender for the number of problems answered correctly ($F = 21.7$, $P < 0.0001$), the number of problems attempted ($F = 19.5$, $P < 0.0001$) and the percent of problems answered correctly ($F = 7.06$, $P = 0.0084$). However, there was no significant gender by condition interaction for any variable of interest ($P > 0.05$). **CONCLUSIONS:** The results of this study show that there is no significant relationship between exercise and auditory processing speed and flexibility, and calculation ability post exercise. These results suggest that exercise at a moderate or vigorous intensity does not hinder a person's ability to perform complex cognitive processing tasks.

2043 Board #199 May 30 2:00 PM - 3:30 PM
The Effects Of Acute Aerobic Exercise On BDNF Levels And Cognition In Postmenopausal Women

Ryan Wiet, Kenneth Sparks, Dough Wajda, Jeremy Genovese, Emily Kullman. *Cleveland State University, Cleveland, OH.*

(No relevant relationships reported)

PURPOSE: The purpose of this study was to examine how menopausal status affects choice reaction time and peripheral BDNF levels after aerobic exercise. It was hypothesized that exercise would affect peripheral BDNF levels and choice reaction time similarly among pre and postmenopausal women. **METHODS:** The subjects consisted of 14 active females (7 premenopausal and 7 postmenopausal). Subjects went through two different trials: an exercise trial and a controlled reading trials. The exercise trial consisted of running on a treadmill at 75% of VO₂max for 30 minutes. The control trial consisted of a reading session. A computerized Stroop test was given to assess choice reaction time, and blood samples were obtained before, immediately after, and 30 minutes after the exercise and control trials. **RESULTS:** Exercise did not lead to a significant change in BDNF in either group. However, there was a statistical interaction ($P = 0.041$) between pre and postmenopausal women over time between

pre and post timepoints, with premenopausal women trending towards an increase in BDNF, and postmenopausal women trending towards a decrease in BDNF. There was a large effect size within this interaction represented with a partial eta squared value of .265. A Post Hoc test was done to further investigate the interaction. There was not enough statistical power ($P = .164$) to state that there was a difference in BDNF levels (pre to post) but that there appears to be a trend. Both age and FSH had indirect relationships with BDNF ($p < 0.05$); the greater the age or FSH, the lower the peripheral BDNF levels. There was a positive correlation between age and Stroop Test time over all time points ($P = .039$, $.089$, and $.027$; pre, post, and post30 exercise respectively). This indicated an age-related decline in choice reaction time capabilities. **CONCLUSION:** Within the study, there was not statistical evidence that acute exercise affects BDNF levels nor choice reaction time for the Stroop incongruent test, regardless of menopausal status. However, a clear decline in choice reaction time was noted with increase age. Additionally, there appears to be a blunting of exercise-induced increases in BDNF in postmenopausal women. Further investigation is required to clarify this relationship.

2044 Board #200 May 30 2:00 PM - 3:30 PM

Chronic Effect of Exercise on Working Memory in Children And Adolescents: A Meta-Analysis of Randomized Controlled Trials

Sonia Montero-Briceño, Isaura M. Castillo-Hernández, Gerardo A. Araya-Vargas. *University of Costa Rica, San José, Costa Rica.* (Sponsor: Ellen M. Evans, FACSM)
Email: soniamonterob@yahoo.es

(No relevant relationships reported)

INTRODUCTION: Working memory (WM), generally considered executive function, is gaining attention due to its role in contributing to children and adolescents' academic achievement, especially verbal and quantitative reasoning, and sports-related tactical memory. Quantitative reviews regarding the effect of exercise interventions (EX) on this higher-level cognitive skill in these important cohorts are lacking.

PURPOSE: The aim of the study was to assess the chronic effect of EX on WM in children and adolescents and to evaluate potential moderators of this effect using a meta-analytic approach.

METHODS: A computerized literature search was conducted based on seven databases: SPORTDiscus, Google Scholar, PubMed, ScienceDirect, Dialnet Plus, SciElo, and MEDLINE. Studies needed to meet the following inclusion criteria: 1) a RCT design in children or adolescents, 2) EX with mode description, 3) published in English, Spanish, or Korean 4) WM as dependent variable, and 5) reported descriptives that permitted effect size (ES) calculation. The quality score was defined using a scale from 1 to 5. A random-effects model with a within-group design was used to calculate the ES. One-way analysis of variance of independent groups or Pearson's correlation coefficients were used to examine moderators.

RESULTS: 6207 articles published before Nov. 2016 were found, of which 10 studies representing 60 ES's and totaling 806 participants (males and females, 9.93 ± 8 yo) were included in the analysis. The mean quality for the studies was 4.4 ± 7 . An overall ES of .85 was found ($p \leq .001$; $CI_{95\%} = .47$ to 1.24 ; $z = 4.35$; $Q = 419.50$; $I^2 = 94.28\%$) suggesting a positive high effect of the EX to enhance WM. Age ($r = -.34$; $p = .048$), number of sessions ($r = .42$; $p = .03$), and sex ($F_{statistic} = 3.6$; $p = .04$), significantly moderated the effect. Neither a) quality of the studies ($r = .24$; $p = .17$), b) min/session ($r = -.28$; $p = .15$), c) weeks of intervention ($r = .24$; $p = .17$), nor d) type of exercise (i.e., aerobic, anaerobic, neuromotor; $r = .41$; $p = .53$) were significant moderators. No bias was found according to Egger's regression analysis ($p = .39$).

CONCLUSIONS: EX has a positive significant effect on children and adolescents' WM compared with their control peers. Different types of exercise appeared to be equally effective strategies for improving WM in these cohorts.

2045 Board #201 May 30 2:00 PM - 3:30 PM

Motivational Differences Between Crossfit And Traditional Resistance Training Participants

Douglas P. Marin¹, Luis Felipe T. Polito², Denis Foschini³, Hirian C. Souza⁴, Natalia Rodrigues⁵, Jobert M. Ferreira⁵, Rosemari Otton¹. ¹Universidade Cruzeiro do Sul, São Paulo, Brazil. ²Universidade Metodista de São Paulo, Sao Bernardo do Campo, Brazil. ³Universidade Federal de São Paulo, São Paulo, Brazil. ⁴Universidade Metodista de São Paulo, São Bernardo do Campo, Brazil. ⁵Universidade Metodista de São Paulo, São Paulo, Brazil.
Email: douglas.marin@metodista.br

(No relevant relationships reported)

PURPOSE: To investigate the motivational factors, behavioral regulations based on self-determination theory framework, and the relationships between basic psychological need satisfaction and actual exercise behaviors of CrossFit and resistance training (RT) participants.

METHODS: Have been evaluated 493 subjects (males = 351, females = 148), RT (n = 365, 279 males, 86 females) and CrossFit (n = 128, 69 males, 59 females) completed the follow online questionnaires: Behavioural Regulation in Exercise Questionnaire, Exercise Motivations Inventory-2, The Basic Psychological Needs in Exercise Scale. **RESULTS:** The CrossFit participants presented higher levels of enjoyment, stress management, social recognition, affiliation, competition, and weight management. Conversely, RT participants reported higher motives for appearance. Intrinsic regulation to exercise was significantly higher in CrossFit, whereas RT clients scored higher controlled motivation. The CrossFit group reported higher levels of relatedness, while RT group presented more perception of autonomy. There was no significant difference between weekly exercise volume between groups; therefore, correlation and mediation analysis were conducted with pooled data. Autonomy and competence were significantly associated with more autonomous forms of motivation. Exercise frequency and weekly exercise volume were positively related to intrinsic motivation. When mediating model was evaluated, the social motives to exercise and intrinsic motivation were found to mediate the relationship between competence and weekly exercise volume (95% BCa CI of 2.47 to 11.91). **CONCLUSIONS:** These findings suggested that CrossFit members attend the gym/CrossFit box predominantly for intrinsic reasons and social motives as compared to RT participants. Exercise professionals may consider the development of programs to increase social motives and exercise-related identity (e.g., interest, affiliation, and enjoyment) to promote intrinsic regulation in individuals from fitness centers.

2046 Board #202 May 30 2:00 PM - 3:30 PM
Neuroelectric Indices of Attentional Processing are Reduced During Low-Intensity Cycling

Kaitlyn E. Carmichael¹, David J. Cleveland², Alyssa G. Vigil², Megan E. Ruhland², Ryan L. Olson². ¹University of Georgia, Athens, GA. ²University of North Texas, Denton, TX.
 (No relevant relationships reported)

Acute aerobic exercise exerts a small beneficial effect on cognition. A majority of studies have examined cognitive function following acute bouts of exercise, while very few have evaluated changes that may occur during exercise. The limited research that has been conducted in this area is mixed, demonstrating differential effects on cognitive performance depending on methodological decisions including exercise intensity and duration. **PURPOSE:** The primary purpose of this study was to examine the effects of low-intensity cycling on cognitive function, measured by behavioral performance (response accuracy and reaction time) and neuroelectric indices of attentional processing (P3 amplitude and latency). **METHODS:** Twenty-seven (Mage = 22.9 ± 3.0 years old) college-aged individuals were counterbalanced into low-intensity exercise (EX) and seated control (SC) conditions. During each condition, participants completed a 10-minute resting baseline period, 20 minutes of either sustained cycling or seated rest, and a 20-minute recovery period. Electroencephalography (EEG) data were recorded during a modified oddball paradigm in order to assess primary cognitive outcome measures at 10-minute intervals (5 blocks total) throughout each condition. **RESULTS:** Individuals in EX and SC conditions displayed lower accuracy to rare trials across time, $F(4,23) = 4.54, p = .008, \eta^2_p = .44$, suggesting reductions in performance to more difficult trials as testing sessions progressed. There were no significant differences in reaction time between EX and SC conditions. Significant reductions in P3 amplitude were observed only during the 20-minute cycling period compared to seated rest, $F(4,23) = 3.50, p = .023, \eta^2_p = .38$, while no differences in P3 latency were observed between EX or SC conditions. **CONCLUSIONS:** Taken together, results indicate that exercise at lower doses may have small but significant effects on behavioral and neuroelectric outcomes of cognitive performance. These changes may be due in part to the shifting of attentional resources from the cognitive task to the maintenance of exercise. Information gathered from this study may aid in the development of appropriate exercise prescription for populations looking to specifically target cognitive function deficits through acute aerobic exercise.

2047 Board #203 May 30 2:00 PM - 3:30 PM
Impact of Stress on Resting Skeletal Muscle Oxygen Consumption with and without Prior Exercise

Melissa J. McGranahan, Edward S. Green, Kevin K. McCully, FACSM, Nathan T. Jenkins. University of Georgia, Athens, GA. Email: mmmcg91@uga.edu
 (No relevant relationships reported)

The effects of acute exercise on muscle metabolism are well established, however the impact of mental stress (MS) on muscle metabolism is not well understood. **PURPOSE:** To assess muscle oxygen consumption (mVO2) after acute MS and evaluate the effect of acute exercise prior to MS on mVO2. **METHODS:** Participants (N=15 males, 22± 2 yr, VO2peak 40.8 ± 5.7 ml/kg/min) served as their own control in a randomized counter balanced design. Participants completed a total of three visits over 3-5 weeks. On the initial visit, a maximal oxygen uptake test on a cycle ergometer was performed. Near-infrared spectroscopy (NIRS) was used during a five-minute

cuff occlusion and the initial slope during the occlusion was used to assess mVO2 in the gastrocnemius muscle. mVO2 was assessed at baseline (BL), after rest (CON) or exercise (EX), and after mental stress (MS). On two separate days, participants either rested for 25 minutes (CON) or completed 25 minutes of exercise (EX) at 90% ventilatory threshold on cycle ergometer. MS was evoked by a serial subtraction test administered by two research assistants dressed in white lab coats. Data were analyzed using a 2x3 repeated measures ANOVA with Fishers LSD post hoc tests, and are presented as mean percent change +/- SD. **RESULTS:** A significant interaction effect of Condition x Time on mVO2 was observed ($F=6.3 p<0.05, \eta^2=0.326$). Post hoc comparisons indicated mVO2 was significantly increased after EX compared to CON by 21.8±/ 26.0% ($p<0.05$). Within CON, MS increased mVO2 by 12.6 +/- 10.2% ($p<0.001$). In EX, there was an increase in mVO2 from BL to after EX by 12.6 +/- 16.0% ($p<0.05$) and from BL to after MS by 18.2 +/- 64.1% ($p=0.053$). **CONCLUSION:** To our knowledge, these data are the first to suggest that acute MS increases the metabolic rate of resting skeletal muscle. Interestingly, the combination of prior EX and MS does not further augment metabolic activity beyond MS alone.

Affective and Perceptual Responses to High-Intensity Interval Training: Comparing Graded Walking to Ungraded Jogging

Abby Fleming, Nic Martinez, Maureen Chiodini-Rinaldo, Larry Collins, Candi Ashley, Marcus Kilpatrick, FACSM. University of South Florida, Tampa, FL. (Sponsor: Marcus Kilpatrick, FACSM)
 Email: arfleming@mail.usf.edu
 (No relevant relationships reported)

Benefits associated with high-intensity interval training (HIIT) are well-established. Research has also demonstrated that HIIT can be well-tolerated in a variety of populations, protocols, and modalities. Treadmill-based HIIT has almost exclusively included running interspersed with walking. Research to date has not investigated the delivery of HIIT by way of graded walking interspersed with ungraded walking. **PURPOSE:** Compare the effects of ungraded jogging to graded walking as a modality of HIIT on perceived exertion, affect, and enjoyment. **METHODS:** Nine healthy participants (5 males, 4 females; mean BMI = 25; mean age = 26) completed two 20-minute counterbalanced HIIT trials after completion of maximal testing. Both trials alternated between workloads associated with 85% of VO2max and a brisk and comfortable walking speed (mean = 3.2 mph). The interval portions of the trials were performed at elevated grade (mean = 17%) for the WALK-HIIT trial and elevated speed (mean = 6.7 mph) for the RUN-HIIT trial. Affect, enjoyment, and perceived exertion, both overall (RPE-O) and legs only (RPE-L), were measured throughout each trial. Enjoyment was measured upon completion of each trial. **RESULTS:** Data was analyzed using dependent t-tests. RPE-O, RPE-L, affect, enjoyment, and HR (all p-values > 0.05; all ES values < 0.50) were not significantly different for the WALK-HIIT and RUN-HIIT trials. **CONCLUSIONS:** Findings indicate that WALK-HIIT and RUN-HIIT trials produce similar perceptual and affective responses, with each providing a significant exercise stimulus sufficient to improve cardiometabolic health. The production of relatively similar responses suggests that graded walking is a viable alternative to running for the delivery of the many benefits associated with interval-based exercise without negative impacts on the exercise experience.

The Impact of Qigong Baduanjin on Cognitive Function & Mental State in Patients with type 2 Diabetes

Yan Zhao. Chengdu Sport Institute, Chengdu, China.
 (No relevant relationships reported)

PURPOSE: This study aims to assess the clinic efficacy of Qigong Baduanjin (QBDJ) on cognition and mental status in patients with type 2 diabetes. **METHODS:** sixty-seven type 2 diabetic patients with mild cognitive impairment (MCI) (31 males and 36 females; aged 47-68 years; the educational background of all participants were above middle school) were screened and randomly divided into two groups: the QBDJ group (n=34), and the control group (n=33). Both groups were based on the routine treatment of diabetes. The QBDJ group received Baduanjin exercise forty minutes a time and five times per week for three months, whereas the control group without special exercise intervention. Montreal Cognitive Assessment (MoCA) and Hamilton Anxiety Scale (HAMA) were used to evaluate the change of cognitive function and mental status in all patients. All data were analyzed using SPSS Statistics for Windows v 17.0. Group differences in baseline characteristics were tested using the χ^2 test and the T test. For the outcome measures, independent-sample T test was performed to compare the changes between the QBDJ and control groups. The paired T test was used to compare the effects before and after treatment. The level of significance was established at $p<0.05$. **RESULTS:** There was no significant difference in the scores of MoCA and HAMA between two groups before the intervention. After 3 months of Baduanjin practice, the total score of MoCA, the score of visuospatial/executive, and the score of delayed recall were significantly higher in the QBDJ group than in the

control group ($P < 0.05$). QBDJ training also contributed to improving the ability of emotion regulation. Compared with the control group, participants in the QBDJ group had significantly lower total HAMA score ($P < 0.05$). **CONCLUSIONS:** These results indicate that regular QBDJ exercise can effectively improve cognitive function and produce positive effects on mental state in type 2 diabetic patients with MCI.

TABLE 1. COMPARISON OF SCORES FOR ALL MoCA SUBTESTS IN TWO GROUPS

| | Control group(n=33) | | QBDJ group(n=34) | |
|------------------------|---------------------|--------------------|---------------------|--------------------|
| | Before intervention | After intervention | Before intervention | After intervention |
| Visuospatial/executive | 3.01 ± 0.74 | 3.06 ± 0.82 | 3.04 ± 0.57 | 3.98 ± 1.04** |
| Naming | 2.51 ± 0.63 | 2.53 ± 0.71 | 2.48 ± 0.59 | 2.55 ± 0.91 |
| Attention | 4.43 ± 0.75 | 4.46 ± 1.01 | 4.44 ± 0.63 | 4.62 ± 0.88 |
| Language | 2.02 ± 0.46 | 2.04 ± 0.53 | 2.03 ± 0.57 | 2.11 ± 0.70 |
| Abstraction | 0.98 ± 0.27 | 1.01 ± 0.36 | 1.02 ± 0.33 | 1.15 ± 0.54 |
| Delayed recall | 1.94 ± 0.66 | 2.02 ± 0.71 | 1.91 ± 0.58 | 3.37 ± 0.89** |
| Orientation | 5.78 ± 0.53 | 5.81 ± 0.42 | 5.73 ± 0.64 | 5.89 ± 0.76 |
| Total score | 20.83 ± 1.34 | 21.14 ± 1.52 | 20.59 ± 1.21 | 23.63 ± 1.63** |

When the difference is significant ($p < 0.05$), the P value is marked with * (QBDJ group vs. Control group) and @ (compared with before intervention in QBDJ group)

TABLE 2. COMPARISON OF HAMA SCORE IN TWO GROUPS

| | Control group(n=33) | | QBDJ group(n=34) | |
|------|---------------------|--------------------|---------------------|--------------------|
| | Before intervention | After intervention | Before intervention | After intervention |
| HAMA | 15.44 ± 3.58 | 16.25 ± 4.03 | 15.83 ± 3.32 | 10.63 ± 3.71** |

When the difference is significant ($p < 0.05$), the P value is marked with * (QBDJ group vs. Control group) and @ (compared with before intervention in QBDJ group)

Self-Reported Physical Activity and Memory Performance among Adolescent Cannabis Users

Ileana Pacheco-Colón, Maria J. Salamanca, Raul Gonzalez.
 Florida International University, Miami, FL.

Email: ipach008@fiu.edu

(No relevant relationships reported)

Prior work has found that heavy cannabis use (CU) is associated with learning and memory impairments, whereas physical activity (PA) has been linked to enhanced memory and cognition.

PURPOSE: To determine whether PA moderates the link between CU and memory among adolescents, such that CU leads to greater memory deficits in those who report less PA.

METHODS: Participants were 387 adolescents (ages 15-19) from a larger study, 198 of whom completed the Sports & Activity Involvement Questionnaire added after study onset. We used minutes reported in the past 6 months as our measure of PA. Frequency of CU (in days) was assessed over the last 6 months; 70% endorsed some CU. Participants completed the California Verbal Learning Test-II and Wechsler Memory Scales-IV Logical Memory and Designs subtests. We used composite scores from these tests' immediate and delayed free recall trials to derive latent constructs of immediate and delayed memory, respectively.

We examined the independent influence of CU and PA on our latent constructs of immediate and delayed memory in separate regression models. To assess whether PA moderates the association between CU and memory performance, we ran separate models for each memory construct with both predictors and their interaction term. We repeated these analyses controlling for lifetime alcohol, nicotine, and CU frequency to isolate the effects of recent CU.

RESULTS: Greater past 6-month CU frequency was associated with poorer immediate, $\beta = -.22, p < .001$, and delayed memory, $\beta = -.23, p < .001$. However, past 6-month PA was not associated with immediate, $\beta = -.01, p = .90$, or delayed memory, $\beta = .07, p = .19$. The PA X CU interaction effect was not significant for either immediate, $\beta = .03, p = .88$, or delayed memory, $\beta = .03, p = .85$. Results were unchanged after controlling for other substance use and lifetime CU frequency, which accounted for significant variance on immediate, $\beta = -.27, p = .03$, but not delayed memory, $\beta = -.11, p = .39$.

CONCLUSION: Our findings replicate the well-established link between CU and memory. However, self-reported PA did not influence this association in our adolescent sample. Future work should employ objective measures of PA to account for factors like activity intensity, aerobic fitness, and social biases inherent in self-report. Supported by NIH Grants R01 DA031176 & U01 DA041156.

Action Boundary Perception Across 30 Days in an Isolated and Confined Environment

Alice LaGoy¹, Aaron Sinnott¹, Kellen Krajewski¹, Richard J. Simpson², Joanne L. Bower³, Candice A. Alfano⁴, Christopher Connaboy¹. ¹University of Pittsburgh, Pittsburgh, PA. ²University of Arizona, Tucson, AZ. ³De Montfort University, Leicester, United Kingdom. ⁴University of Houston, Houston, TX.
 Email: adl59@pitt.edu

(No relevant relationships reported)

Successful execution of operational tasks requires accurate and efficient action boundary perception. An action boundary is the task- and individual-specific threshold where an action is possible. The inability to accurately perceive changes in action possibilities due to changing action boundaries may increase the risk adopted during a task, possibly compromising mission success. Astronauts must maintain effective operational performance in isolated, confined and extreme (ICE) environments for extended timeperiods, similar to those expected on the proposed mission to Mars. It is unknown how these environments affect action boundary perception. **PURPOSE:** Investigate changes in action boundary perception behavior during a 30-day Human Exploration Research Analog (HERA) mission. **METHODS:** Sixteen subjects completed six trials of the perception-action coupling task (PACT), a novel tablet-based action boundary perception task, in the afternoon of days 3, 10, 17, 24 and 5 days post-mission. The 15-minute PACT presents a series of virtual balls and apertures varying in ball to aperture size ratio (B-AR) from 0.2 to 1.8 with a ratio of 1.0 representing the action boundary. Subjects determined whether the ball could fit through the aperture, then responded based on their perception of this action possibility. 8 (ratio) x 5 (time) repeated measures ANOVAs were performed to assess changes in response time (RT), accuracy (ACC) and lapses. **RESULTS:** No significant ratio x time interactions were observed. RT ($F_{4,60} = 3.631, p = 0.010, \eta^2_p = 0.195$) was faster on day 24 (0.738 ± 0.088s) than day 17 (0.768 ± 0.092s). No differences were observed between other timepoints. ACC and lapses did not vary during the mission ($p > 0.05$). RT ($F_{2,583,38,742} = 42.815, p < 0.001, \eta^2_p = 0.741$) and ACC ($F_{1,423,21,341} = 42.815, p = 0.002, \eta^2_p = 0.407$) were sensitive to changes in B-AR; responses were slower and less accurate near the action boundary. **CONCLUSION:** Minimal change in action boundary perception performance was observed in HERA ICE analog, with improvements in RT detected. Faster RT may reflect more efficient responses or behavioral changes due to ICE environments, suggesting action boundary perception is not compromised by a 30 day ICE analog assessment. This material was based on work supported by NASA (NNX15AC13G) PIs: Alfano and Simpson

Associations Of Cognition With Physical And Vascular Function In Patients With Chronic Kidney Disease.

Ulf G. Bronas¹, Mary Hannan¹, James P. Lash¹, Joe X. Zhou¹, Alana Steffen¹, Melissa Lamar². ¹University of Illinois at Chicago, Chicago, IL. ²Rush University Medical Center, Chicago, IL.

Email: Bronas@uic.edu

(No relevant relationships reported)

Cognitive impairment is prevalent in patients with chronic kidney disease (CKD), but little is known about its relationship with physical and vascular function.

Purpose: To investigate the relationship between cognitive function, and physical and vascular function in older adults with stage 3-4 CKD and preclinical cognitive impairment. We hypothesized that physical and vascular function would be related to cognitive function. **Methods:** Participants (n=28) with CKD and preclinical cognitive impairment (57% female, 68% black, eGFR 43.7, age 68) completed the Trail Making Test (TMT-A: psychomotor speed, and TMT-B executive control), and digit symbol coding (DSC) (visuomotor speed/complex attention). These are standard measures that are sensitive to cognitive decline. Physical function was determined via the short physical performance battery test (SPPB) and the 6-minute walk test (6MWT). Vascular function was determined via brachial artery flow mediated vasodilation (FMD) following 5-minutes of forearm occlusion. Correlations were assessed via Pearson's bivariate correlation. **Results:** All participants scored below the fiftieth percentile of age and sex specific normative values on the TMT; 32% scored below the tenth percentile on the TMT-A and 50% scored below the tenth percentile for TMT-B. Age, years of education, sex, or race did not correlate with TMT-A, TMT-B, or DSC. TMT-A were inversely correlated with 6MWT ($r = -.5, p = .007$), SPPB score ($r = -.65, p < .001$), and FMD ($r = -.4, p = .04$). TMT-B was inversely correlated with 6MWT ($r = -.39, p = .04$), but not with SPPB, or FMD. DSC was correlated with 6MWT ($r = .47, p = .01$), but not with SPPB, or FMD. **Conclusion:** In patients with CKD, psychomotor speed is associated with indicators of physical function and fitness levels, and with vascular function. Executive control, visuomotor speed, and complex attention was associated with physical fitness levels. These results indicate a concomitance between higher levels of fitness, physical, and vascular function, and higher scores in psychomotor speed and executive control in patients with CKD. The clinical

implications of our work remains to be further explored, but interventions to improve fitness levels, and physical and vascular function may contribute to lessening the impact of CKD-associated cognitive alterations.

Effects Of Three Months Of A “Playing Actively And Learning” Program On Selective Attention Performance In Boys And Girls

Isabela A. Ramos¹, Eduardo B. Fontes², Claudia Dias³, Gustavo L. Guedes⁴, Carmen S G Campbell⁴, Rodrigo A V Browne². ¹University Catholic of Brasilia, Brasilia, Brazil. ²Federal University of Rio Grande do Norte, Natal RN, Brazil. ³UniProjeção, Brasilia, Brazil. ⁴Catholic University of Brasilia, Brasilia, Brazil.

(No relevant relationships reported)

Physical education classes provide an opportunity for students to be physically active and also to help in school learning. **PURPOSE:** To compare the effects of physical education program combined with scholar contents named “Playing actively and Learning (PAL)” on selective attention in boys and girls. **METHODS:** 39 children with low academic achievement (9.5±0.9yr) from an elementary public school of vulnerability area at Brasilia - Brazil, undertook Stroop test before and after intervention. The anthropometric data (weight and stature) were assessed for characterization of the sample. The stimuli at Stroop test GO/No-go was a colored bar and a colored word in congruent (e.g., RED in red ink) or incongruent (e.g., RED in blue ink) color ink. The participants had to match the color of the bar to the meaning of the word and press the correct key as soon as the stimuli appeared at computer screen. Nineteen boys (BG; n=19; 32.1±4.5 kg; 138±0.4 cm; 16.7±1.7 kg.m²⁽⁻¹⁾) and twenty one girls (GG; n=21; 31.1±7.3; 137±0.4 cm; 16.4±3.5 kg.m²⁽⁻¹⁾) participated on the study. Both BG and GG attended to 24 classes (60 min, twice a week for three months) during school journey. At those classes they learned the content of Portuguese and Mathematics while doing active plays (running, jumping and aerobic dance) (PAL) at moderate intensity (154.6±17.2 bpm). ANOVA mixed was used to compare data before and after intervention. **RESULTS:** No differences were observed in congruent or incongruent conditions between groups. The reaction time decreased in incongruent Go condition in both groups after intervention for boys (958.3±113.3ms to 877.9±105.6ms; P=0.004) and girls (976.6±91.5ms to 904.6±86.7ms; P=0.005) (Figure 1). **CONCLUSION:** Three months of PAL resulted in improvement in a similar way in boys and girls at the most difficult part of Stroop test. To support these results studies with a neuroelectric analysis (i.e. event related potential component) can be recommended.

Figure 1. Improvement of Reaction Time in the congruent and incongruent Go condition of the Stroop test after PAL program in boys and girls.

Physical Activity from Childhood to Adulthood and Cognitive Performance in Midlife

Juuso O. Hakala¹, Suvi P. Rovio¹, Katja Pahkala¹, Jaakko Nevalainen², Markus Juonala³, Nina Hutri-Kähönen², Olli J. Heinonen¹, Mirja Hirvensalo⁴, Risto Telama⁴, Jorma SA Viikari³, Tuija H. Tammelin⁵, Olli T. Raitakari¹. ¹University of Turku, Turku, Finland. ²University of Tampere, Tampere, Finland. ³Turku University Hospital, Turku, Finland. ⁴University of Jyväskylä, Jyväskylä, Finland. ⁵LIKES Research Centre for Physical Activity and Health, Jyväskylä, Finland.
 Email: juolahak@utu.fi

(No relevant relationships reported)

The prevalence of cognitive deficits is increasing worldwide, making risk factor reduction a crucial target on the global public health agenda. Adulthood physical activity (PA) is suggested to protect against old-age cognitive deficits, but the independent role of childhood / youth PA for adulthood cognitive performance is unknown.

PURPOSE: We investigated the association between PA from childhood to adulthood and midlife cognitive performance.

METHODS: This study is a part of the Cardiovascular Risk in Young Finns Study. From 1980, a population-based cohort of 3,596 children (baseline age 3-18 years) have been followed-up for 31 years in 3-9-year intervals. PA was queried in all study phases. Cumulative PA was determined in childhood (age 6-12 years), adolescence (age 12-18 years), young adulthood (age 18-24 years) and adulthood (age 24-37 years). Cognitive performance was assessed using computerized neuropsychological test in 2011 among 2,026 participants aged 34-49 years.

RESULTS: High PA level in childhood (β 0.119, 95% confidence interval (CI) 0.055-0.182, $p=0.0002$), adolescence ($\beta=0.125$ SD, 95% CI 0.063-0.188, $p<0.0001$), young adulthood ($\beta=0.135$ SD, 95% CI 0.063-0.207, $p=0.0002$) and adulthood ($\beta=0.045$ SD, 95% CI 0.013-0.077, $p=0.006$) was independently associated with better reaction time in midlife. Additionally, an independent association between high PA level in young adulthood (β 0.101, 95% CI 0.001-0.200, $p=0.048$) and adulthood ($\beta=0.064$ SD, 95% CI 0.018-0.110, $p=0.006$) and better visual processing and sustained attention in midlife was found among men. Associations for other cognitive domains were not found.

CONCLUSIONS: Cumulative exposure to PA from childhood to adulthood was found to be associated with better midlife reaction time both in men and women. Furthermore, cumulative PA exposure in young adulthood and adulthood was associated with better visual processing and sustained attention in men. These associations were independent of PA levels in other measured age frames. Therefore, physically active lifestyle should be adopted already in early childhood, and continued into midlife to ensure the plausible benefits of PA on midlife cognitive performance. Concluding, this study provides novel insight into cost-effective and well-timed promotion of cognitive health.

Patient Perceptions of a Cancer Rehabilitation Program Which Provides 12 Weeks Of Individualized Exercise Prescription

Travis Yahner¹, Karen Wonders, FACSM², Stephen LoRusso¹. ¹Saint Francis University, Loretto, PA. ²Maple Tree Cancer Alliance, Dayton, OH.
 Email: tpy100@francis.edu

(No relevant relationships reported)

Purpose: The purpose of this study was to determine why cancer patients choose to participate and remain in an exercise rehabilitation program. **Methods:** 79 participants in a cancer rehabilitation program were asked to complete a questionnaire consisting of 6 open ended questions asking 1. Who referred them, 2. What did they follow through with the referral, 3. Why they have chosen to remain in the program, 4. What their initial thoughts of the program were, 5. What their current thoughts about the program are, and 6. Are they satisfied with the program. This study was approved by the Saint Francis University IRB. **Results:** 38% of clients were referred by either an oncologist or family doctor, 25% by hospital staff, 24% by friend or support group and 13% by media outlets. 59% of clients followed through for their health, and 15% for supervision of their exercise sessions. 51% of clients continued in the program because of the results they obtained and 25% because they had not yet met their goals, while 24% continued because of their cancer exercise trainer. 73% of clients had positive thoughts about the program, and 99% had the same or improved thoughts. Finally 94% of clients were satisfied with the program. **Conclusion:** The majority of clients were referred by their oncologist, or hospital staff indicating the power that physicians and hospital staff have in providing guidance for their clients. Further, once clients join a cancer rehabilitation program the benefits motivate them to continue in the program.

Clearly they are satisfied with the program which is a program which provides individualized personalized exercise prescription and a cancer trainer for support and motivation.

D-64 Free Communication/Poster - Hydration/Fluid Balance

Thursday, May 30, 2019, 1:00 PM - 6:00 PM

2056 Board #212 May 30 2:00 PM - 3:30 PM Impact of Nutrient Intake During Exercise on Hydration Markers Following Exercise and Rehydration

Colleen X. Munoz¹, Evan C. Johnson², Laura J. Kunces³, Amy L. McKenzie⁴, Michael Winger¹, Cory Butts⁵, Aaron Caldwell⁶, Adam Seal⁶, Brendon P. McDermott, FACSM⁶, Jakob L. Vingren, FACSM⁷, James Boyette⁷, Colin Melford⁸, Abigail Colburn⁸, Skylar Wright⁸, Ekow Dadzie⁸, Virgilio Lopez⁸, Lawrence E. Armstrong, FACSM⁸, Elaine C. Lee⁸. ¹University of Hartford, West Hartford, CT. ²University of Wyoming, Laramie, WY. ³Thorne Research, Summerville, SC. ⁴Virta Health, San Francisco, CA. ⁵University of Arkansas, Fayetteville, AR. ⁶University of Arkansas, Fayetteville, AR. ⁷University of North Texas, Denton, TX. ⁸University of Connecticut, Storrs, CT. (Sponsor: Lawrence Armstrong, FACSM)
(No relevant relationships reported)

Endurance athletes commonly strive for optimal hydration status during and after events, and have vast nutrition options available to support performance and well-being. **PURPOSE:** We aimed to evaluate relationships among nutrients consumed during exercise and markers of hydration status. **METHODS:** Fifty-one cyclists (age mean=51y and range=21-72y; 49 males, 2 females) completing a 161km event (mean=26°C, 76%RH; maximum=30°C, 93%RH) recorded all dietary intake during the ride. Five hydration markers (urine color and specific gravity, plasma osmolality (P_{osm}), plasma copeptin (P_{cop}), and body mass change (BM) were collected before and after (POST) the ride, and one hour after a 650mL water bolus (POST_{1h}). Linear regressions tested associations between hydration markers and eight predictor terms derived from nineteen nutrients merged into a reduced-dimensionality dataset through serial k-means clustering. As an indicator of water retention signaling, P_{cop} tertiles were analyzed via two-way ANOVA to evaluate nutrient intake influence. **RESULTS:** Five predictor clusters were significantly associated to hydration markers (number of associated hydration markers in parenthesis): 1) glycemic load + carbohydrates + sodium (one), 2) protein + fat + zinc (one), 3) magnesium + calcium (two), 4) pinitol (three), and 5) water (four); caffeine, potassium, fiber, betaine, and three sugar-alcohols did not associate with hydration markers. All hydration markers (except P_{osm}) associated to at least one nutrient predictor. P_{cop} POST tertiles (13.5±5.9, 34.4±7.4, and 76.8±40.0 pmol/L, respectively) differed by sodium (1st vs. 3rd tertile p=0.0047; 2217±1295 and 1747±1214 mg, respectively) and water intake (1st vs. 3rd and 2nd vs. 3rd, all p<0.0001; 1st=4910±1722, 2nd=4887±1011, 3rd=3837±1097 g). P_{cop} POST_{1h} tertiles (7.4±3.0, 22.0±5.4, and 54.2±36.7 pmol/L, respectively) differed by water intake (1st vs. 3rd and 2nd vs. 3rd, all p<0.0001; 1st=4921±1652, 2nd=4953±1063, and 3rd=3759±1072 g). **CONCLUSION:** These data suggest that some nutrients impact fluid-electrolyte balance and hydration markers. Nutrient intake appears to mediate urinary markers more than P_{cop} , and P_{cop} more than BM. Further, sodium and water appear to best mitigate water retention signaling following exercise and rehydration.

2057 Board #213 May 30 2:00 PM - 3:30 PM Effects of Caffeine Dose Timing on Total Urine Excretion during Sodium-Aided Hyperhydration Protocols.

Shelby L. Greene¹, Elizaveta Roslanova², Phillip Wickenheiser¹, David M. Morris¹. ¹University of Texas, Odessa, TX. ²University of Texas, Odessa, TX.
Email: shelbylgreene@outlook.com
(No relevant relationships reported)

When used alone, both caffeine and sodium-aided hyperhydration (SAH) can be ergogenic. Although caffeine use in conjunction with SAH promotes diuresis, hyperhydration can be achieved, albeit at lower levels compared to SAH alone. Previous caffeine and SAH work has suggested most of the caffeine induced diuresis occurs within 15 min of consumption of a bolus of caffeine, sodium and water. This response suggests that caffeine-induces diuresis for only 15 min following its consumption, and/or that the diuretic effects of caffeine are dependent on hydration levels. **PURPOSE:** to determine the effects of caffeine, consumed at different

time-points, on diuresis during SAH protocols. **METHODS:** Subjects were 17 healthy males (23 ± 5 yr, 177 ± 8 cm, 83.4 ± 15.3 kg). Each performed 4, 90 min hyperhydration trials in a randomized, double-blind fashion. Protocols began with a bladder void and measurement of urine specific gravity (USG) followed by ingestion of 15 mL H₂O · kg⁻¹ · bm⁻¹ with one of four treatments: Placebo (PL), 70.5 mg NaCl · kg⁻¹ · bm⁻¹ (Na), or a combination of NaCl and caffeine consumed in two different strategies: 70.5 mg NaCl + 5 mg caffeine · kg⁻¹ · bm⁻¹ taken at the start of the trial (NaCaf0), or 70.5 mg NaCl · kg⁻¹ · bm⁻¹ taken at the start and 5 mg caffeine · kg⁻¹ · bm⁻¹ taken at 75 min of the trial (NaCaf75). After consuming the water, subjects rested for 90 min performing a measured bladder void every 15 min. Total urine excreted (TUE) was expressed as a percentage of the total fluid consumed during the hyperhydration protocols. USG and TUE were compared using one-way repeated measures ANOVA with Sidak post hoc analyses. Levels of significance were set *a priori* at P < 0.05. **RESULTS:** USGs were 1.007 ± 0.003 (PL), 1.008 ± 0.003 (Na), 1.007 ± 0.004 (NaCaf0), and 1.009 ± 0.004 (NaCaf75) (P > 0.05). TUE for PL (87 ± 30%) was significantly higher than all other protocols (P < 0.05). TUE for NaCaf0 (73 ± 16%) was significantly higher than Na (56 ± 18%, P = 0.02) and NaCaf75 (52 ± 13% P < 0.01). NSD in TUE was observed between Na and NaCaf75. **CONCLUSION:** The results reaffirm that, when caffeine is consumed at the beginning of a SAH strategy, hyperhydration can be achieved, but at a lower level compared to SAH without caffeine. The results also suggest that waiting to consume caffeine until 75 min after water is consumed does not result in caffeine induced diuresis during a SAH protocol.

2058 Board #214 May 30 2:00 PM - 3:30 PM Dehydration Impairs Accuracy and Increases Brain Activity During a Rhythmic Bimanual Choice Reaction Time Task

Matthew T. Wittbrodt¹, Michael N. Sawka, FACSM¹, J. C. Mizelle², Regan R. Lawson¹, Lewis A. Wheaton¹, Mindy L. Millard-Stafford, FACSM¹. ¹Georgia Institute of Technology, Atlanta, GA. ²East Carolina University, Greenville, NC.
(Sponsor: Mindy L. Millard-Stafford, FACSM)
(No relevant relationships reported)

Dehydration impairs motor coordination but the influence on other fundamental cognitive-motor functions is unclear. **PURPOSE:** To determine the impact of dehydration on rhythmic bimanual choice performance (accuracy & reaction time) and brain function (electroencephalography). **METHODS:** Ten aerobically fit men (22.4 ± 2.5 y) completed three experimental sessions: control (seated rest; CON), dehydration (EHS-DEH) induced by 2.5 h intermittent walking in the heat (45°C, 15% RH), and euhydration (EHS; 2.5 h intermittent walking in the heat but matching sweat loss with water ingestion). Performance during a bimanual probabilistic choice reaction time task (PCRT; 32 min) consisting of randomly presented dominant (~67%) and non-dominant (~33%) stimuli was examined concurrently with visual evoked potentials. Perceived PCRT mental workload (NASA-TLX, 21-point scale) was assessed following task completion. **RESULTS:** PCRT reaction time was not different (p = 0.40) averaged across trials (CON: 538.3 ± 37.7, EHS: 542.6 ± 39.2, DEH: 532.6 ± 39.2 ms). EHS-DEH (67.3 ± 14.1%) reduced PCRT accuracy during non-dominant (less frequent) responses vs. CON (83.7 ± 5.8 %; p = 0.04) but not compared with EHS (74.6 ± 11.0 %; p = 0.18). Accuracy during dominant stimuli were not different across trials (p > 0.05). N1 amplitude in the occipital electrodes (perceptual processing) was higher following EHS-DEH (385.2 ± 141.3 uV*ms) compared to CON (241.8 ± 168.6 uV*ms; p = 0.001) but not vs. EHS (300.3 ± 171.1 uV*ms; p = 0.60). EHS and CON were not different from each other (p = 0.60). No differences (p > 0.05) were observed among trials for the contingent negative variation (movement anticipation) or N2 (stimulus categorization). EHS-DEH (6.4 ± 5.0) elicited greater levels of perceived effort vs. CON (3.7 ± 2.4; p = 0.03) and frustration vs. EHS (11.8 ± 5.0, 7.5 ± 5.1; p = 0.0004). **CONCLUSIONS:** Dehydration increased perceived effort, frustration, and perceptual processing demands, resulting in impaired accuracy for this cognitive-motor task requiring vigilance during prolonged fine motor movements. Prevention of dehydration during exercise-heat stress preserved cognitive-motor performance, brain activity, and mental workload similar to control conditions.

Dehydration Has No Influence on Simulated Motor-race Performance Despite Greater Cardiovascular and Thermoregulatory Demand

Justin J. Holland¹, Christopher Irwin², Tina L. Skinner³, Michael D. Leveritt³. ¹Queensland University of Technology, Kelvin Grove, Australia. ²Griffith University, Gold Coast, Australia. ³The University of Queensland, St Lucia, Australia. (Sponsor: Professor Jeff Coombes, FACSM)

 (No relevant relationships reported)

Purpose: Motor-racing drivers compete in hot compensable environments imposing high physiological strain. Dehydration may impact a driver's health, safety and race performance. This study examined the effect of heat-induced dehydration on performance and physiological outcomes during a simulated motor-race.

Methods: Fifteen healthy men [age: 25.2±5.4 y, body mass: 84.8±10.7 kg, $\dot{V}O_{2peak}$: 43.7±7.8 mL.kg⁻¹.min⁻¹ (mean±SD)] participated in this controlled crossover study. Participants were randomised (counter-balanced) to a no fluid trial [1.9±0.1% body mass loss (BML) via sauna exposure (wet bulb globe temperature (WBGT): 43.6±2.8°C)] and fluid trial [1.0±0.5% body mass gain via room temperature water consumption every 10 min during sauna exposure]. All participants completed ~60 min of Australian simulated motor-racing in a heated (WBGT: 33.7±0.7°C) laboratory with no fluid provided to both trials which resulted in a 1.3±0.4 and 0.9±0.2% BML for the fluid and no fluid trials respectively. Lap time, physiological strain, heart rate and core/skin temperature were measured throughout the task. Urine [specific gravity (USG) and osmolality (Uosm)], body mass, and serum [sodium (Na), osmolality (Sosm), and plasma volume (PV)] samples were collected pre- and post- sauna and race.

Results: Mean lap time was not different between trials (fluid=134.981±2.402 s, no fluid=134.718±2.147 s; $p=0.293$). The no fluid trial resulted in significantly higher ($p<0.05$) peak heart rate (129±16 vs. 121±16 beats.min⁻¹), core temperature (38.0±0.2 vs. 37.7±0.3°C), physiological strain (4.1±1.1 vs. 3.5±1.1), Sosm (310±4 vs. 300±4 mOsm.kg⁻¹), Na (138.7±2.1 vs. 135.8±4.5 mmol.L⁻¹), USG [median(interquartile range): 1.025(1.024-1.027) vs. 1.006(1.004-1.013)], U_{osm} [942(879-1010) vs. 221(186-497) mOsm.kg⁻¹], total body mass loss (2.7±0.3 vs. 0.9±0.4%) and change in PV (-7.9±4.2 vs. -3.3±4.2%) than the fluid trial.

Conclusion: Dehydration of ~2.7% BML without fluid replacement had no influence on simulated race performance measured by mean lap time, despite significantly greater cardiovascular and thermoregulatory demand. Further research is warranted to assess the impact of greater cardiovascular and thermoregulatory demand from dehydration on the safety, health and well-being of drivers.

2060 Board #216 May 30 2:00 PM - 3:30 PM
Self-Reported Changes in Thirst and Alertness during Variable Prescribed Fluid Intake

Hillary A. Yoder¹, Ainsley E. Huffman¹, Carson L. Keeter¹, Shane McCullough¹, Erica T. Perrier², Alberto Dolci², Evan C. Johnson¹. ¹University of Wyoming, Laramie, WY. ²Danone Research, Palaiseau, France.
 Email: hillaryyoder@gmail.com
 (No relevant relationships reported)

PURPOSE: To evaluate the relationship between self-reported thirst and alertness in people drinking variable amounts of prescribed water. **METHODS:** Subjects (n = 115, 59 males, 32 ± 10 y; 24.6 ± 4.4 kg·m⁻²) visited the lab 3 times over 10 days: V1, a baseline visit that prior to participants were drinking *ad libitum*; V2, following 3 days of fluid restriction (1 L·d⁻¹, of which 250 mL was consumed in the morning prior to the visit); and V3, the morning following a prescribed increase in water intake. The increase in water intake at V3 varied by group assignment: a control group (CON) maintained 250 mL of morning water consumption, while LOW and HIGH intake groups (n = 45 each) consumed 496 ± 82 mL and 878 ± 125 mL, respectively. At each visit, which occurred after the morning water consumption period, subjects indicated on an open-ended visual analog scale (VAS) how thirsty and alert they felt. Two-way ANOVA for thirst and alertness between groups from V1 to V2 and V2 to V3 were completed. Repeated measures correlation procedure was completed for change in alertness and thirst from V1 to V2 and V2 to V3. **RESULTS:** Groups were similar at baseline (V1) for fluid intake, thirst and alertness (all $p \geq 0.17$). Fluid restriction (V2) resulted in a main effect of time for both thirst and alertness (both $p < 0.01$), with no main effect of group. On average, thirst increased (35 ± 35 mm) and alertness decreased (-19 ± 31 mm) from V1 to V2. The prescribed increase in water intake (V3) revealed a significant interaction of time and group for both thirst and alertness (both $p < 0.01$). Independent-samples t-tests revealed that HIGH reduced thirst (-38 ± 37 mm) and increased alertness (18 ± 25 mm) significantly more than both LOW (thirst, -7 ± 37 mm; alertness -1 ± 24 mm) and CON (thirst, -6 ± 23 mm; alertness 0 ± 23 mm; all $p < .01$). There was no difference between LOW and CON (both $p > 0.92$). Repeated measures correlation analysis showed a negative relationship between change in alertness and thirst ($R^2 = 0.29$, $p < 0.01$). **CONCLUSION:** An inverse relationship

was observed between self-reported alertness and thirst. Following fluid restriction, drinking a larger volume of water (750-1000 mL) in the morning decreased thirst and increased alertness.

Exercise Induced Hypohydration Reduces Subsequent Ad-libitum Food Intake

Lewis J. James¹, Katie McMillan², Emma Davies², Ruth M. James². ¹Loughborough University, Loughborough, United Kingdom. ²Nottingham Trent University, Nottingham, United Kingdom. (Sponsor: Prof Craig Sale, FACSM)
 Email: L.James@Lboro.ac.uk

Reported Relationships: **L.J. James:** Industry contracted research; Funding from PepsiCo and LucozadeRibenaSuntory, with funds paid to the institution.

The relationship between hydration status and appetite regulation/energy intake is unclear. Animal models suggest hypohydration/reduced water availability suppresses food intake, but the effects in humans are less clear, with a paucity of research examining exercise-induced hypohydration. **PURPOSE:** To investigate the effects of exercise-induced hypohydration with or without post-exercise rehydration on *ad-libitum* energy intake, as well as selected appetite regulatory gut peptides.

METHODS: Twelve recreationally active, non-obese males (mean (SD) age 22±3 y; height 1.77 (0.06) m; body mass 77.7 (9.8) kg; $\dot{V}O_{2peak}$ 47 (9) mL/kg/min) completed a 75 min treadmill run at 65% $\dot{V}O_{2peak}$ in 24.5 (0.8) °C and 82 (4) % relative humidity without fluid intake, inducing body mass loss of 1.7 (0.4) %. Over the subsequent hour, subjects either rehydrated with water equivalent to 100% of body mass loss (REHY) or consumed no water so they remained hypohydrated (HYPO). A multi-item *ad-libitum* buffet lunch was then served, with subjects instructed to eat until 'comfortably full and satisfied'. Venous blood samples were taken before and after exercise and before lunch. **RESULTS:** Serum osmolality was higher, whilst plasma volume was lower pre-lunch during HYPO vs REHY ($P<0.05$). *Ad-libitum* energy intake at lunch was lower in HYPO (1149 (638) kcal vs 1399 (712) kcal; $P=0.024$), whilst *ad-libitum* water intake from drinks (733 (243) mL vs 344 (288) mL; $P=0.008$) and from food and drinks combined (1113 (330) mL vs 737 (366) mL $P=0.011$) were higher in HYPO. Additionally, fat ($P=0.042$) and salt ($P=0.046$) intake were lower in HYPO, whilst carbohydrate ($P=0.064$) and protein ($P=0.099$) intake tended to be lower in HYPO. Pre-lunch, acylated ghrelin concentration was lower in HYPO (48.7 (35.3) pg/mL vs 62.7 (33.5) pg/mL; $P=0.038$), but there was no difference between trials for PYY ($P=0.157$) or GLP-1 ($P=0.379$) concentrations. **CONCLUSION:** These data suggest that in healthy, non-obese males, exercise induced hypohydration without subsequent rehydration reduces acylated ghrelin concentration, as well *ad-libitum* energy intake. Exercise-induced changes in hydration should be carefully considered in situations where adequate post-exercise energy and nutrient replenishment are important. This project received no funding.

2062 Board #218 May 30 2:00 PM - 3:30 PM
Influence Of Different Hydration Levels On Artistic Gymnastics Performance In Preadolescent And Adolescent Gymnasts

Costas Chryssanthopoulos¹, Eirini Charikleia Ragkousi¹, Georgia Kapodistria¹, Georgios Dallas¹, Giannis Galeros¹, Aikaterini Giannikopoulou¹, Ionas Papasotiriou¹, Ioannis Lambropoulos², Maria Maridaki¹. ¹National and Kapodistrian University of Athens, Athens, Greece. ²Biomedizin, Diagnostic and Research Laboratories, Marousi, Greece.
 Email: chryssan@phed.uoa.gr
 (No relevant relationships reported)

The effect of different hydration levels in artistic gymnastics performance has not been studied. **PURPOSE:** To examine the possible influence of different hydration levels in artistic gymnastics performance in preadolescent and adolescent gymnasts. **METHODS:** Eleven male preadolescent and adolescent artistic gymnasts [12.1 ± 0.8 (range 10-15) years old, 2.8 ± 0.2 (range 2-3.5) Tanner Stage; mean ± SE] performed two 3-hour identical training sessions separated by one week, while they ingested artificially sweetened water equivalent to either 50% (Low Volume; LV) or 150% (High Volume; HV) of the fluid lost in training. After training, in both trials participants performed the same programs in 3 apparatuses and were evaluated by an international level judge via the assistance of video. The fluid lost in training was identified during three similar preliminary training sessions, where gymnasts drank water *ad libitum*, and was observed that they replaced about 50% of their fluid lost. Hydration, dietary and training status were controlled before LV and HV trials which were performed in a random order and under similar environmental conditions (23.4 ± 0.3 °C and relative humidity 53-54 ± 2% in both LV and HV). Pre and post exercise differences between trials were analyzed using two-tailed t-tests, whereas responses over time were examined by 2-way ANOVA. **RESULTS:** The different volumes of

fluid provided established different hydration levels as indicated by the different urine specific gravity (USG) levels post-exercise (LV: 1.017 ± 0.002 vs. HV: 1.002 ± 0.001 ; $p < 0.001$), while pre-exercise USG were similar between conditions (LV: 1.018 ± 0.002 vs. HV: 1.015 ± 0.001 ; $p = 0.09$). The percentage of fluid lost was higher in LV ($1.2 \pm 0.2\%$) compared to HV ($0.4 \pm 0.1\%$) ($p = 0.02$), however, mean performance evaluation in the 3 apparatuses was not different between conditions (LV: 8.72 ± 0.21 vs. HV: 8.68 ± 0.20 ; $p = 0.57$). **CONCLUSIONS:** By ingesting fluid equivalent to about 50% of the fluid lost during a 3-hour training session, artistic gymnasts of about 12 years old maintain short-term hydration levels and avoid excessive dehydration ($> 2\%$). Ingesting a higher amount of fluid equivalent to about 1.5 times the fluid lost does not provide an additional benefit in terms of performance evaluation.

2063 Board #219 May 30 2:00 PM - 3:30 PM
The Effects of Mode of Rehydration on Subsequent Exercise-heat Challenge Performance

Linda M. Yamamoto¹, Elaine C. Lee², Brendon P. McDermott³, Kathleen N. Beasley², Holly Emmanuel², Jeff S. Volek⁴, Douglas J. Casa, FACSM², Lawrence E. Armstrong, FACSM², William J. Kraemer, FACSM⁴, Carl M. Maresh, FACSM⁴. ¹Central Connecticut State University, New Britain, CT. ²University of Connecticut, Storrs, CT. ³University of Arkansas, Fayetteville, AR. ⁴The Ohio State University, Columbus, OH. (Sponsor: Carl M. Maresh, FACSM)
 Email: lindayamamoto@hotmail.com
 (No relevant relationships reported)

PURPOSE: Athletes and soldiers routinely exercise in the heat for extended periods of time without matching fluid intake to sweat rate, risking impaired physiologic function and performance decrements. Intravenous and oral rehydration are both used to overcome performance decrements associated with dehydration. The purpose of this study was to examine the efficacy of mode of rehydration using athletically relevant dehydration-rehydration-exercise scenarios.

METHODS: Ten healthy, active men (age 23.3 ± 1.1 yr; height, 177.8 ± 2.8 cm; body mass, 81.4 ± 1.3 kg; body fat, $11.0 \pm 1.0\%$, $\dot{V}O_{2max}$, 58.8 ± 1.3 ml·kg⁻¹·min⁻¹) completed four trials consisting of overnight dehydration, exercise dehydration, rehydration, observation and an exercise-heat challenge (EHC) in a hot environment (35.6 ± 0.2 °C, $35.0 \pm 1.8\%$ relative humidity) differing only in rehydration mode. Participants were rehydrated to -2% of baseline weight over 30 minutes with intravenous (IV), oral (ORAL), $\frac{1}{2}$ IV + $\frac{1}{2}$ ORAL (I+O), or *ad libitum* (ADL) half-normal saline. For the EHC subjects completed a 25 min submaximal run followed immediately by an all-out maximal 0.5 mile run, five minutes rest, and five minutes of repetitive box lifting (RBL). Run time and number of boxes lifted per minute were recorded. Performance data was analyzed with a two-way repeated measures ANOVA.

RESULTS: Total number of boxes lifted was significantly lower in the ADL and ORAL trials (47.1 ± 9.5 , 46.3 ± 11.8 , respectively) compared to I+O (52.3 ± 11.1), but not IV (49.9 ± 12.2). Boxes lifted during minutes 1 and 5 were significantly higher than minutes 2, 3, and 4 for all trials. Performance times for the 0.5 mile run were not different among trials.

CONCLUSIONS: Partial rehydration via IV and oral fluids appears to have an ergogenic effect on high-intensity, total-body exercise in the heat possibly due to a combination of more rapid plasma volume restoration, oropharyngeal and gastric cues, as well as reduced gastric distention discomfort due to a lesser amount of oral fluids. These findings suggest a synergistic benefit to total-body performance with I+O between exercise bouts in the heat.

2064 Board #220 May 30 2:00 PM - 3:30 PM
Hydration And Gender Differences In Terms Of Non-oxidative Performance

Jessica Sudock¹, Vincent Paolone, FACSM¹, Cristina Winter¹, Thomas Dodge². ¹Springfield College, Springfield, MA. ²International Institute for Athletic Development, Simsbury, CT. (Sponsor: Dr. Sam Headley, FACSM)
 Email: jsudock@springfieldcollege.edu
 (No relevant relationships reported)

Nonoxidative performance is vital to the performance of many high level athletes (Armstrong, Johnson, McKenzie, Ellis, & Williamson, 2015; Chamari, Chaouachi, & Racinais, 2015). Many athletes are voluntarily hypohydrated through training as they do not properly rehydrate after a training session (Cengiz, 2015). The decrease in performance that accompanies changes in hydration can negatively impact athletes (Cengiz, 2015). **PURPOSE:** The present study examined the effect of hydration status on nonoxidative performance and to examine differences between the genders in terms of nonoxidative performance. **METHODS:** Twelve subjects, 6 males and 6 females, completed three sessions where a Wingate test was performed and lactate was measured. All subjects were NCAA Division III club or varsity athletes. The subjects completed a familiarization trial, a trial in the hypohydrated state and a trial in the hydrated state. The hypohydrated trial was completed after a 12 hr water restriction

in order to induce a 2-4% decrease in body weight. No weight was lost prior to the hydrated trial and urine specific gravity was below 1.010. **RESULTS:** No significant difference was found in terms of hydration and nonoxidative performance ($p = .082$, $\eta^2 = .27$). A significant difference was found in terms of gender and nonoxidative performance. Males had a higher nonoxidative capacity (9.01 W/kg ± 0.37 vs. 6.58 W/kg ± 0.37 , $p = .001$), nonoxidative power (13.51 W/kg ± 1.12 vs. 9.18 W/kg ± 1.12 , $p = .021$) and fatigue index compared to females (24.84 W/s ± 3.86 vs. 10.28 W/s ± 3.86 , $p = .024$). **CONCLUSION:** The results from this study indicate that hydration does not influence non-oxidative performance in NCAA Division III club or varsity athletes. Female athletes within this study had a decreased nonoxidative performance compared to the male athletes. These results contradict previous findings that indicated that relative measures of nonoxidative performance did not vary between the genders when represented in relative terms (Maud & Shultz, 1986; Van Praagh, Fellman, Bedu, Falgairette & Coudert, 1990). Future research can be performed to look at differences in fat mass between the genders and the impacting collegiate athletes in terms of non-oxidative performance.

2065 Board #221 May 30 2:00 PM - 3:30 PM
Effects Of Caffeine Dose Timing On The Time-course Of Diuresis During Sodium-aided Hyperhydration.

David M. Morris¹, Shelby Greene¹, Elizaveta Roslanova², Phillip Wickenheiser¹. ¹University of Texas, Odessa, TX. ²University of Texas, Odessa, TX.
 Email: morris_da@utpb.edu
 (No relevant relationships reported)

When used alone, both caffeine and sodium-aided hyperhydration (SAH) can be ergogenic. Caffeine, when used with SAH, promotes diuresis, but hyperhydration can be achieved, albeit at lower levels than with SAH alone. In previous caffeine and SAH work, caffeine induced diuresis occurred only within 15 min of consumption of a bolus of caffeine, NaCl, and H₂O. This suggests that caffeine-induced diuresis may occur for only 15 min after its consumption, and/or that the diuretic effect of caffeine is dependent on hydration levels. Caffeine has been shown to be ergogenic when taken as little as 5 min before exercise; thus, determining the temporal aspects of caffeine induced diuresis in conjunction with SAH may lead to better pre-exercise nutritional strategies. **PURPOSE:** To determine the effect of caffeine, consumed at different time-points, on diuresis over a 90 min SAH protocol. **METHODS:** Subjects were 17 males (23 ± 5 yr, 177 ± 8 cm, 83.4 ± 15.3 kg). Each performed 2, 90 min SAH trials beginning with a bladder void and measurement of urine specific gravity (USG) followed by ingestion of 15 mL H₂O · kg⁻¹ · bm⁻¹ with one of two treatments: 70.5 mg NaCl + 5 mg caffeine · kg⁻¹ · bm⁻¹ taken at the start of the trial (NaCaf0), or 70.5 mg NaCl · kg⁻¹ · bm⁻¹ taken at the start and 5 mg caffeine · kg⁻¹ · bm⁻¹ taken at 75 min of the trial (NaCaf75). After consuming the H₂O, subjects performed a measured bladder void every 15 min for 90 min. USGs were compared using a paired t-test. Urine excretions (UE) for each bladder void of the trials were expressed as a percentage of the total H₂O consumed and compared with a two-way repeated measures ANOVA and Sidak post hoc analyses. **RESULTS:** USGs were 1.007 ± 0.004 (NaCaf0), and 1.009 ± 0.004 (NaCaf75) ($P = 0.30$). UE for NaCaf0, and NaCaf75, respectively at the urine collection points were $15 \pm 9\%$, $7 \pm 6\%$ (15 min, $P < 0.01$), $15 \pm 5\%$, $9 \pm 2\%$ (30 min, $P < 0.01$), $18 \pm 5\%$, $14 \pm 4\%$ (45 min, $P = 0.05$), $15 \pm 5\%$, $11 \pm 6\%$ (60 min, $P = 0.05$), $10 \pm 5\%$, $8 \pm 6\%$ (75 min, $P = 0.25$), and $7 \pm 5\%$, $6 \pm 3\%$ (90 min, $P = 0.88$). **CONCLUSIONS:** Although consuming caffeine at the start of the trial resulted in significantly greater diuresis for the first 30 min of the trial, waiting to consume caffeine until 75 minutes after the consumption of the water and NaCl did not result in caffeine induced diuresis 15 min after consumption of the caffeine.

2066 Board #222 May 30 2:00 PM - 3:30 PM
Racial Differences in 24 Hour Urinary Hydration Markers

William M. Adams, Gabrielle S. Glenn, Megan L. Haskins, Derek J. Hevel, Amber Huntsinger, Eleni M. Karras, Jaclyn P. Maher, Jared T. McGuirt, Stacey L. Walton. University of North Carolina at Greensboro, Greensboro, NC.
 Email: wmadams@uncg.edu
 Reported Relationships: W.M. Adams: Consulting Fee; Clif Bar & Company, BSX Technologies, Samsung. Industry contracted research; Statim Technologies, LLC.

Prior literature has investigated racial/ethnic differences in hydration status based on spot urine samples, however, no literature has examined these differences using 24 h urinary hydration measures.

PURPOSE: To examine 24 h urinary hydration markers in college-aged non-Hispanic White (WH) and non-Hispanic Black (BL) men and women.

METHODS: Thirteen men (BL, n=6; WH, n=7) and nineteen women (BL, n=16; WH, n=3) (mean \pm SD; age, 20 \pm 4y; height, 169.2 \pm 12.2cm; body mass, 71.3 \pm 12.2kg; body fat, 20.8 \pm 9.7%), combined from two separate research projects were included.

Participants provided a 24 h urine sample across 7 (n=13) or 3 (n=19) consecutive days (148 d total) for assessment of urine volume (U_{VOL}), urine osmolality (U_{OSM}), urine specific gravity (U_{SG}), and urine color (U_{COL}). Differences in 24 h hydration status between sex and ethnicity were assessed using linear mixed effects models with associated Bonferroni post hoc analyses. Significance was set a-priori at $p < 0.05$.

RESULTS: U_{VOL} was significantly lower in BL (0.85 ± 0.43 L) compared to WH college students (2.03 ± 0.70 L) ($p < 0.001$). Conversely measures of U_{OSM} , U_{SG} , and U_{COL} were significantly greater in BL (716 ± 263 mOsm \cdot kg $^{-1}$, 1.020 ± 0.007 , and 4.2 ± 1.4 , respectively) compared to WH college students (473 ± 194 mOsm \cdot kg $^{-1}$, 1.013 ± 0.006 , 3.0 ± 1.2 , and respectively) ($p < 0.05$). Independent of race, women were significantly less hydrated than men by measures of U_{VOL} (MD [95% CI]: -0.56 L [-0.823 , -0.308], $p < 0.001$), U_{OSM} (107 mOsm \cdot kg $^{-1}$ [24, 190], $p = 0.012$), U_{SG} (0.003 [0.001, 0.005], $p = 0.017$), and U_{COL} (-0.6 [-1.2, -0.1], $p = 0.012$).

CONCLUSIONS: Based on 24 h urinary hydration markers, college-aged non-Hispanic Black men and women were inadequately hydrated compared to their non-Hispanic White counterparts when assessed over consecutive days. Furthermore, women were significantly less hydrated than men, independent of racial background. Given the importance of hydration on acute and long-term health, identifying populations that are inadequately hydrated may allow for the development of targeted strategies to improve habitual fluid intake. Future research examining 24 h hydration status coupled with fluid intake behaviors across a broader sample of races or ethnicities is warranted to further understand the determinants that guide drinking behaviors.

Hydration Knowledge and Behavior in Youth Mountain Bike Teams

Natasha A. Brand¹, Stavros A. Kavouras, FACSM², Erin K. Howie Hickey¹, Dean R. Gorman¹. ¹University of Arkansas, Fayetteville, AR. ²Arizona State University, Phoenix, AZ. (Sponsor: Stavros Kavouras, FACSM)
 Email: nbrand@uark.edu
 (No relevant relationships reported)

Many youth sports organizations recognize the importance of educating on hydration practices and awareness, however, according to recent research current hydration education is not translating to effective practices. **PURPOSE:** The purpose of this study was to assess and describe the hydration knowledge and behavior of student-athletes participating in competitive youth mountain bike teams. **METHODS:** One hundred thirty-three student-athletes, 11-18 years were surveyed on hydration knowledge and behavior. Participants were apparently healthy and active members of a National Interscholastic Cycling Association Mountain Bike Team. **RESULTS:** The mean score for knowledge was 9.3 ± 1.5 (out of 15). Less than 30% of participants scored higher than 70% (≥ 10.5 out of 15). Adequate knowledge was described as $\geq 70\%$ of a maximal score of 15. Over 98% of participants understood the importance of fluids on performance, however, only 65% of participants received hydration education. Knowledge scores were significantly higher ($P < 0.05$) in those receiving hydration education; however mean knowledge scores were still low (9.5 ± 1.5). Mean knowledge scores increased by year in school but were still low. Post-exercise weight loss knowledge was varied between answers. Of those who felt their fluid intake during training or races was adequate, 70% had low knowledge scores. Girls reported they were less certain about being adequately hydrated than boys (Girls: 63%, Boys: 37%). Stopping in a race due to an excessive feeling of heat was significantly higher in boys (60%) than in girls (40%). **CONCLUSION:** Despite understanding the importance of keeping hydrated, mean knowledge scores indicated inadequate knowledge, while hydration behavior indicated inconsistency in translation of knowledge.

 (No relevant relationships reported)

While daily hydration is best assessed in a 24-h urine sample, using a urine spot sample can be more practical for healthcare professionals, researchers, and individuals. Although urine product is subject to circadian variation, 24-h urine concentration reported to be approximated from a mid- to late-afternoon spot urine sample in adults. However, no data exists in children. **PURPOSE:** To identify time windows during which spot values of urine osmolality (UOsm) is representative of 24-h values in healthy children.

METHODS: Among 541 healthy children (age: 3-13 y, female: 45%, BMI: 17.7 ± 4.0 kg \cdot m $^{-2}$), equivalent test was performed by comparing UOsm from specific time windows [morning (0600-1159), early afternoon (1200-1559), late afternoon (1600-1959), evening (2000-2359), overnight (2400-0559), and first morning (0600-0959)] to 24-h urine sample. The equivalency was determined when the mean difference and the confident interval between the spot and 24-h urine sample fell below the bound of 80 mmol \cdot kg $^{-1}$. The analysis was performed by using the first spot urine sample from each time window. Other spot urine samples after the first spot urine within each time window were not used to avoid unequally weighting data.

RESULTS: Equivalence test showed that the late afternoon (1600-1959) spot urine sample UOsm value was equivalent to the 24-h UOsm value in children ($P < 0.05$; mean difference: 62; CI: 45-78). The overall diagnostic ability of urine osmolality assessed at late afternoon (1600-1959) to diagnose elevated urine osmolality (> 800 mmol \cdot kg $^{-1}$) on the 24-h sample was "good" (area under the curve: 87.4%; sensitivity: 72.6%; specificity: 90.5%; threshold: 814 mmol \cdot kg $^{-1}$).

CONCLUSIONS: These data suggest that in free-living healthy children, 24-h urine concentration can be approximated from a late afternoon spot urine sample.

Comparison of Skin Cleaning Methods for Measurement of Regional Sweat Electrolyte Concentrations

Shyretha D. Brown¹, Kelly A. Barnes¹, Ryan P. Nuccio¹, Corey T. Ungaro¹, Adam J. Reimel¹, Peter D. De Chavez², Lindsay B. Baker, FACSM¹. ¹Gatorade Sports Science Institute, Barrington, IL. ²PepsiCo R&D, Barrington, IL.

Reported Relationships: S.D. Brown: Salary; Gatorade Sports Science Institute, PepsiCo Inc. The views expressed in this abstract are those of the authors and do not necessarily reflect the position or policy of PepsiCo, Inc..

Various skin preparation methods, ranging from MINIMAL (alcohol wipes) to more THOROUGH (e.g., shaving and cleaning), have been used to remove surface contamination prior to patch application for sweat electrolyte measurements. Using MINIMAL cleaning methods could improve athlete participation and the efficiency of sweat testing in the field, but it is unknown if this would result in higher sweat [Na^+], [Cl^-], and [K^+] due to insufficient removal of surface contamination. **PURPOSE:** To compare the effect of MINIMAL vs. THOROUGH skin cleaning methods on regional sweat [Na^+], [Cl^-], and [K^+].

METHODS: Thirteen subjects (7 male, 6 female; 23-45 y; 74.6 ± 15.8 kg) cycled at $\sim 80\%$ HR_{max} in a warm laboratory (30°C, 50% rh) while sweat was collected from right (RDF) and left (LDF) dorsal forearms with absorbent patches (3M™ Tegaderm+Pad). Prior to patch application (20 min before exercise), the RDF was shaved, cleaned with alcohol, wiped with deionized water, and dried with gauze (THOROUGH). The LDF was cleaned with alcohol wipes only (MINIMAL). Patches were removed upon adequate sweat absorption (0.60 ± 0.15 g, 57 ± 15 min). Sweat from absorbent patches was extracted via centrifuge and subsequently analyzed for [Na^+], [Cl^-], and [K^+] by ion chromatography. Regional sweating rate (RSR) was determined via gravimetry. **RESULTS:** There were no differences between MINIMAL and THOROUGH for sweat [Na^+] (54.4 ± 24.7 vs. 53.4 ± 23.8 mM, $p = 0.06$) or sweat [Cl^-] (45.2 ± 23.2 vs. 44.4 ± 22.2 mM, $p = 0.13$). Bland Altman 95% limits of agreement (LOA) were 4.0 to -2.2 mM and 4.8 to -3.0 mM for sweat [Na^+] and [Cl^-], respectively. Sweat [K^+] was higher with MINIMAL vs. THOROUGH cleaning (5.0 ± 0.8 vs. 4.5 ± 0.6 mM, $p = 0.001$; LOA: 1.3 to -0.3 mM). RSR was not different between cleaning methods (0.973 ± 0.411 vs. 0.954 ± 0.406 mg/cm 2 /min, $p = 0.75$; LOA: 0.435 to -0.397 mg/cm 2 /min).

CONCLUSIONS: MINIMAL cleaning of the skin with alcohol results in similar regional sweat [Na^+] and [Cl^-] compared with more THOROUGH preparation that includes shaving of hair and cleaning with alcohol and deionized water. Sweat [K^+] is statistically (but not practically) higher when MINIMAL cleaning is conducted. THOROUGH skin preparation prior to sweat testing may not be warranted; although future research in field conditions is needed to confirm that MINIMAL cleaning is adequate.

Epifluidic Colorimetric Patch for On-Skin Analysis of Regional Sweat Chloride Concentration during Laboratory-based Exercise

Lindsay B. Baker, FACSM¹, Ryan P. Nuccio¹, Corey T. Ungaro¹, Shyretha Brown¹, Adam J. Reimel¹, Alexander J. Aranyosi², Stephen P. Lee², Jeffrey B. Model², Roozbeh Ghaffari², Kelly A. Barnes¹. ¹Gatorade Sports Science Institute, Barrington, IL. ²Epicore Biosystems Inc, Cambridge, MA.
Email: lindsay.baker@pepsico.com

Reported Relationships: **L.B. Baker:** Salary; Gatorade Sports Science Institute, PepsiCo Inc. *The views expressed in this abstract are those of the authors and do not necessarily reflect the position or policy of PepsiCo, Inc.*

Assessing regional sweat electrolyte concentrations using standard patch techniques requires post-collection benchtop harvesting and analysis of sweat, which precludes real-time feedback to athletes. A technique enabling on-skin analysis is needed to advance the practicality of sweat testing. **PURPOSE:** To determine the accuracy and reliability of a novel epidermal microfluidic patch with built-in colorimetric assay (Epifluidic patch) to measure regional sweat [Cl⁻].

METHODS: Twenty-three subjects (15 male, 8 female; 18-42 y; 72.3±11.2 kg) cycled at 85% HR_{max} in a warm laboratory (30°C, 50% rh) while sweat was collected from the right and left ventral forearms with an Absorbent patch (3M Tegaderm+Pad) and Epifluidic patch (Epicore Biosystems, Inc.), respectively. A subset of subjects (n=9) completed two identical trials 2-4 days apart to determine test-retest reliability. Immediately after removal of the Absorbent patch, an image was taken of the Epifluidic patch on-skin with a digital single-lens reflex camera for analysis of [Cl⁻] via colorimetry. Sweat from the Absorbent patch was extracted via centrifuge and subsequently analyzed for [Cl⁻] by ion chromatography. Data are shown as mean±SD. **RESULTS:** There was no difference in sweat [Cl⁻] between Absorbent and Epifluidic patches (32.9±16.8 vs. 34.5±19.6 mmol/L, p=0.21). Bland-Altman Limits of Agreement between methods was -10.1 to 13.3 mmol/L. There was a significant correlation between patches (r=0.96, p<0.0001) and the coefficient of determination (r²) for predicting Absorbent from Epifluidic patch [Cl⁻] was 0.92. Based on Deming regression analysis, the slope and intercept of the regression line describing Absorbent vs. Epifluidic patch sweat [Cl⁻] were not different than 1 and 0, respectively. Sweat [Cl⁻] was not different between repeat trials for the Absorbent (1.4±4.4 mmol/L, p=0.36) or Epifluidic patch (-0.4±1.6 mmol/L, p=0.51) and test-retest CVs were 12% and 4%, respectively.

CONCLUSIONS: The Epifluidic patch provides accurate and reliable data for forearm sweat [Cl⁻] estimation during exercise in controlled laboratory conditions. Future research is needed to evaluate the Epifluidic Colorimetric Patch for on-skin analysis of sweat [Cl⁻] at other regional sites as well as during live practices and games.

2071 Board #227 May 30 2:00 PM - 3:30 PM

Skin Tattoos Do Not Affect Exercise-induced Sweat Rate Or Sodium Concentration.

Ethan Rogers¹, Gregory Cox², Chris Irwin¹, Danielle McCartney¹, Ben Desbrow¹. ¹Griffith University, Gold Coast, Australia. ²Bond University, Gold Coast, Australia. (Sponsor: Louise Burke, FACSM)
Email: ethan.rogers@griffithuni.edu.au
(No relevant relationships reported)

PURPOSE: Skin tattoos have been shown to reduce sweat rate and increase sweat sodium concentration when sweating is artificially stimulated. This study investigated whether similar responses are observed with exercise-induced sweating.

METHODS: Twenty-two healthy individuals (25.1±4.8 y (Mean±SD), 14 males) with a unilateral tattoo ≥11.4 cm² in size, >2 months in age, and shaded ≥50% participated in this investigation. Participants undertook 20 min of intermittent cycling (4 x 5 min intervals) on a stationary ergometer in a controlled environment (24.6±1.1°C, RH 64±6%). Resultant sweat was collected into absorbent patches applied at two pairs of contralateral skin sites (pair 1: Tattoo vs. Non-Tattoo; pair 2: Control 1 vs. Control 2 (both non-tattooed)), for determination of sweat rate and sweat [Na⁺]. Paired samples t tests were employed to determine differences between contralateral sites.

RESULTS: Tattoo vs. Non-Tattoo: Neither sweat rate (Mean±SD: 0.92±0.37 vs. 0.94±0.43 mg·cm⁻²·min⁻¹, respectively; p=1.000) nor sweat [Na⁺] (Median(IQR): 36(32-53) vs. 37(31-45) mM·L⁻¹, respectively; p=0.827) differed. Control 1 vs. Control 2: Neither sweat rate (Mean±SD: 1.19±0.53 vs. 1.19±0.53 mg·cm⁻²·min⁻¹, respectively; p=0.917) nor sweat [Na⁺] (Median(IQR): 29(26-41) vs. 31(25-43) mM·L⁻¹, respectively; p=0.147) differed. The non-significant differences for Tattoo vs. Non-Tattoo were within the range of normal variability (sweat rate CV=5.4%; sweat [Na⁺] CV=4.4%).

CONCLUSIONS: Skin tattoos do not appear to alter rate or [Na⁺] of exercise-induced sweat. The influence of skin tattoos on thermoregulatory responses to exercise may have been over-estimated.

2072 Board #228 May 30 2:00 PM - 3:30 PM

Comparison of Sports-Oriented Sweat Prediction Equation Performances During Running

Kurt J. Sollanek¹, Mia Liu¹, Andrei Carballo¹, Samuel N. Cheuvront, FACSM². ¹Sonoma State University, Rohnert Park, CA. ²Sports Science Synergy, LLC, Franklin, MA.
Email: sollanek@sonoma.edu

Reported Relationships: **K.J. Sollanek:** Other (please describe); Travel support for Dr. Sollanek provided by Sports Science Synergy, LLC.

PURPOSE: This study compared the performance of three sports-oriented sweat prediction equations against measurements made during outdoor running or indoor treadmill running with adequate airflow.

METHODS: Eleven open literature studies were identified where runner sweating rates (L/h) were carefully measured and reported from changes in body mass (n = 109). For studies that did not correct for non-sweat losses of body mass, a standardized correction of 0.20 g/kcal was subtracted from the reported sweating rates. Body mass, air temperature, relative humidity, running speed and distance or duration was provided in the published reports. A prospective field study of n = 37 volunteers was completed with n = 40 separate sweating rate observations made. Outdoor track testing was completed through a range of environmental conditions (temperature range: 10-31.3°C). The performance of three sports-oriented sweat prediction equations (H2QTM, Putnam, and Barr & Costill) was compared to measured sweating rates.

RESULTS: Measured sweating rates from the literature ranged from 0.417 to 2.129 L/h; track sweating rates ranged from 0.293 to 1.739 L/h. Agreement between measured (x-axis) and predicted (y-axis) sweating rates were assessed using the concordance correlation coefficient (CCC; ≥ 0.800). The relative error (RE; < 1.000) and accuracy (percent agreement; ≥ 70%) were also assessed using 0.250 L/h as an error acceptance threshold. For retrospective data (n = 109), the CCC ranged from 0.377 to 0.809; RE from 0.732 to 1.208; accuracy from 43 to 70%. For prospective data, the CCC ranged from 0.455 to 0.882; RE from 0.564 to 1.105; accuracy from 58 to 88%. In all instances the three equations performed better on the more highly controlled prospective data set. One equation (H2QTM) performed best on all three agreement parameters and on both data sets.

CONCLUSIONS: These results illustrate the difficulty of accurately predicting sweating rates in runners, but also the possibility of achieving good accuracy with the right equation.

2073 Board #229 May 30 2:00 PM - 3:30 PM

Validity And Reliability Of The CorTempTM Telemetric Pill During 50 H Of Reuse.

Jonathan Gosselin, Eric D.B. Goulet. University of Sherbrooke, Sherbrooke, QC, Canada.

Email: jonathan.gosselin2@usherbrooke.ca

(No relevant relationships reported)

Continuous measurement of rectal temperature using a telemetric pill (TP) inserted as a suppository has been validated. However, the use of TP may remain limited because of its high cost and single use. We have determined in our laboratory that the CorTempTM TP can be used repeatedly over time; in fact, it has a large battery autonomy, can be turned on and off at will and easily survives high-level disinfection. Reuse of the TP is made possible using a technique involving inserting the TP inside a condom, attaching it to a dental floss and introducing the TP inside the rectum with an over-the-counter suppository applicator. **PURPOSE:** The aim of the study was to examine the validity and reliability of CorTempTM TPs during repeated use in a water bath for a duration of 50 h. **METHODS:** Three TPs already used for less than 5 h each in a previous human study were tested in a water bath during 20 trials ranging from 1 to 5 h each, for a total of 50 h and with temperature variations ranging from 37 to 40°C. Trials were conducted in a randomized manner and temperatures of the TPs were compared to those of a wired rectal probe (YSI 401, WRP). After each trial, TPs were placed in a 2.5% glutaraldehyde solution for 20 min to achieve high-level disinfection, as recommended when a probe is used with a condom. The WRP and each TP were calibrated before the start of the experiment. Acceptable agreement between sensors was taken as a bias ≤ 0.2°C (sum of both instrument measurement errors). **RESULTS:** 50 h mean biases and random errors between TP 1, 2 and 3 and the WRP were of -0.09°C±0.12°C, -0.10°C±0.14°C and -0.12°C±0.15°C, respectively. Mean biases and random errors at 17 h, 34 h and 50 h of reuse were of respectively -0.10°C±0.11°C, -0.06°C±0.11°C and -0.11°C±0.11°C for TP 1 vs. WRP, -0.09°C±0.13°C, -0.08°C±0.12°C and -0.13°C±0.16°C for TP 2 vs. WRP and -0.14°C±0.17°C, -0.10°C±0.13°C and -0.11°C±0.12°C for TP 3 vs. WRP.

CONCLUSION: Our results indicate that the CorTempTM TP can be reused up to at least 50 h while still providing valid and reliable temperature readings. Furthermore, the CorTempTM TP can undergo high-level disinfection repeatedly while maintaining full structural and functional integrity.

2074 Board #230 May 30 2:00 PM - 3:30 PM
Validity of Calculated Core Temperature From Heart Rate Measured by an Electronic Vest

James M. Pivarnik, FACSM, Montana L. Pruett, David P. Ferguson. *Michigan State University, East Lansing, MI.*
(No relevant relationships reported)

Recent technology has included development of ingestible pills and vests designed to monitor core and skin body temperatures. If accurate, they can be ideal in many field settings. However, little research has been performed to demonstrate the accuracy (validity) of this new technology. **PURPOSE:** We compared these new technologies with traditional modalities during 60 min of continuous cycle ergometer exercise at room (20° C) temperature. **METHODS:** Study participants included a convenience sample (N=18, 14 female, age:23.8±3.4 yr, wt: 70.4±11.6 kg, ht: 175.5±9.3 cm). Intensity for the first 30 min was set at a Power (watts, W) corresponding to individual participant RPE values of 12-13. Intensity increased to an RPE of 15-16 for the final 30 min of cycling, and W were adjusted accordingly. Heart rate (HR) was measured continuously (Polar). Core temperature was measured via a rectal (PROBE-C) thermistor and an ingestible pill (PILL). Skin temperature (PROBE-S) was measured at the arm, chest, thigh, and calf, and a mean value was calculated (Ramanathan, 1964). Core and skin temps were also estimated from a sensor electronics module located in a vest (VEST, Equivital) worn by each participant. Vest temperatures were calculated according to equations developed previously (Buller et al., 2013). Repeated measures ANOVA, Pearson correlations, and dependent t-tests were used to examine relationships among the various temperature measurement modalities (Alpha = p<0.05). **RESULTS:** HR averaged 125±25 and 151±18 b/min for the first and second 30 min of exercise, respectively. Likewise, Power averaged 81±22 and 97±22 W. While core temperatures were nearly identical at onset of exercise (~37.3° C), the three modalities differed after 60 min of cycling (PROBE-C; 37.9±0.8, PILL; 38.3±0.3, VEST; 38.6±0.4° C (p<0.05). Skin temperatures differed between PROBE-S and VEST at both beginning (31.2± 1.1 vs 33.8±1.2° C) and end (32.9± 1.5 vs 37.0±0.6° C) of exercise (p<0.01). Correlations among the various modalities were significant (p<0.05) and ranged from R=0.51 - 0.77, but did not differ from each other. **CONCLUSION:** The major study finding was that the vest estimated higher core and skin temperatures during exercise compared to traditional temperature measuring devices, overestimating work intensity at study ambient conditions.

2075 Board #231 May 30 2:00 PM - 3:30 PM
Physiological Strain Index Of Female Wheelchair Basketball Players During Competition

Heather M. Logan-Sprenger. *UOIT, Oshawa, ON, Canada.*
 (Sponsor: Lawrence Spriet, FACSM)
 Email: heather.sprenger@uoit.ca
(No relevant relationships reported)

Purpose: The purpose of this study was to assess the thermoregulatory responses and physiological strain of elite wheelchair (WC) basketball players during international competitions. **Methods:** Eleven female (n=11; 7 SCI and 4 Non-SCI) national team WC basketball players volunteered for the study. Testing occurred during a four-game series against the same international competitor (temp 22.1±1.2° C, RH 55±2%). Hydration habits were monitored and gastrointestinal temperature (Tc), heart rate, and skin temperature (SkT) were recorded in real-time. **Results (mean±SD):** Athletes arrived hydrated for all games (urine specific gravity, 1.014±0.002). Players lost a mean of 0.5±0.1% body mass due to sweat loss and replaced ~69% of fluid losses. SCI athletes played 21±4 min and Non-SCI athletes played 14±6 min. SCI athletes had a mean SkT throughout the game of 35.2±0.2° C and Non-SCI of 36.2±0.2° C. SCI SkT rose a mean of 6.3±1.1° C and Non-SCI 6.8±0.9° C. SCI Tc rose a mean of 1.0±0.2° C and Non-SCI a mean of 0.9±0.4° C. 2/10 players reached a Tc>39° C (SCI athlete class 1, 39.4° C; Non-SCI class 4.5 athlete, 39.5° C). Mean physiological strain index (PSI) was 5.1±0.7 (range, 2.6-7.9). Athletes who played >50% of the game (n=4) had a mean PSI of 6.7±0.8 compared to athletes who played <50% of the game (n=6) who had a PSI of 3.9±0.7, with the greatest contribution to PSI from core temperature. **Conclusions:** Monitoring Tc and PSI during competition is encouraged to understand competition specific responses and identify athletes more at risk of heat-related fatigue due to injury level and high playing time.

2076 Board #232 May 30 2:00 PM - 3:30 PM
Effects of Passive Heating on Perfusive and Diffusive Microvascular Oxygen Delivery

Kaylin D. Didier, Lillie M. Huckaby, Andrew M. Alexander, Shane M. Hammer, Camryn N. Webster, Thomas J. Barstow, FACSM. *Kansas State University, Manhattan, KS.*
(No relevant relationships reported)

Previous studies have demonstrated that passive heating has led to increases in endothelial function and vasodilation of the brachial artery. The increase in

vasodilation is thought to originate from increased nitric oxide bioavailability, thus increasing blood flow into the limb. However, the different aspects of the downstream microvascular oxygen delivery (i.e. perfusive and diffusive) to the exercising muscle have yet to be described. **PURPOSE:** The purpose of this study was to determine the effect of seven days of passive heating on oxygen delivery during handgrip exercise. We tested the hypothesis that, 7 days of passive heating would result in a decrease in the diffusive oxygen delivery (total-[heme]) and an increase in the perfusive oxygen delivery (deoxy-[heme]) in the exercising muscle. **METHODS:** Three participants (2 women, 23.0 ± 1.0 yrs, 70.9 ± 15.7 kg, 171 ± 10.1 cm) participated in this study. Peak power was determined by an incremental two-hand handgrip exercise test. Subjects performed 10 minutes of dynamic handgrip exercise at 40% peak power pre and post 7 days of passive heating. Absolute concentrations of deoxy-[heme] and total-[heme] of the flexor digitorum superficialis muscle were measured continuously via frequency-domain multi-distance near-infrared spectroscopy (OxiplexTS, ISS). The passive heating protocol consisted of immersion up to the shoulder in a 40°C hot tub until rectal temperature reached 38.5°C or increased by 1°C for 60 minutes. Data reported as mean ± SE. **RESULTS:** From baseline to the last 30 seconds of exercise there was no significant difference in the Δ deoxy-[heme] (perfusive oxygen delivery) for pre (52.3 ± 2.2 μM) and post passive heating (47.6 ± 16.4 μM; p=0.822). However, the Δ total-[heme] (diffusive oxygen delivery) was significantly lower following passive heating (p<0.001). Pre and post passive heating Δ total-[heme] was 75.1 ± 13.8 μM and 30.7 ± 13.3 μM, respectively. **CONCLUSION:** The significant decrease in Δ total-[heme] after passive heating suggests that the diffusion of oxygen into the exercising muscle was reduced. This finding, along with no change in the perfusive oxygen delivery as represented by the Δ deoxy-[heme], suggests that the oxygen uptake of the exercising muscle was decreased.

2077 Board #233 May 30 2:00 PM - 3:30 PM
Effect of Heat and Humidity on the Inflammatory Response During Aerobic Exercise

Kylene Boka¹, Brandon M. Gibson¹, Jeremiah A. Vaughn², Brittany N. Followay³, Elliott Arroyo¹, Joseph A. Laudato¹, Ellen L. Glickman, FACSM¹, Adam R. Jajtner¹. ¹Kent State University, Kent, OH. ²Bemidji State University, Bemidji, MN. ³Ripon College, Ripon, WI. (Sponsor: Ellen L. Glickman, FACSM)
(No relevant relationships reported)

PURPOSE: The purpose of this study was to examine the inflammatory responses via classical and trans signaling in response to aerobic exercise during exposure to different environmental conditions. **METHODS:** Recreationally active men (n=12, 24.4±3.1 yrs, 1.81±0.07m, 81.5±8.0kg, 47.2±4.8ml/kg/min) completed 5 experimental trials: a VO₂max test and cycling trials in 22°C/45% RH (MTMH), 22°C/70% RH (MTHH), 35°C/20% RH (HTLH), and 35°C/45% RH (HTMH). In each condition, participants cycled for 60 minutes at 60% VO₂max, rested for 15 minutes, cycled at 90% VO₂max until exhaustion (TTE), then recovered for 60 minutes. Blood was obtained before exercise (PRE), after the hour of cycling (60), after the TTE (90), and after recovery (REC). Blood was assessed for serum IL-6, IL-10, IL-1ra, TNF-α, sIL-6r, and IL-1β. Data were analyzed with repeated measures or Friedman's ANOVA. **RESULTS:** Main effects of time (F=97.13, p<0.001) and condition (F=4.08, p=0.018) were observed for IL-6. IL-6 increased from PRE (0.67±0.07 pg/ml) to 60 (4.79±0.77; p<0.001pg/ml) and 90 (p<0.001; 6.69±0.89 pg/ml), and decreased from 90 to REC (2.90±0.37 pg/ml; p=0.001). Concentrations were elevated during HTLH (4.16±0.54 pg/ml) compared to MTMH (3.42±0.53 pg/ml; p=0.037) and MTHH (3.30±0.43 pg/ml; p=0.041), and HTMH (4.17±0.34 pg/ml) compared to MTHH (p=0.038). A time effect for IL-10 (F=14.49, p=0.001) was observed with increases from PRE (0.34±0.04 pg/ml) to 90 (0.71±0.09 pg/ml; p=0.002), and no difference between conditions. An interaction was observed for IL-1ra (F=3.73, p=0.015), with concentrations increasing from PRE (276.67±29.28 pg/ml) to 90 (356.12±45.63 pg/ml; p=0.002), before peaking at REC (571.80±83.26 pg/ml; p<0.001). Changes were greater (p<0.05) during HTLH (467.81±78.82 pg/ml) and HTMH (440.29±61.85 pg/ml) than MTMH (295.06±21.08 pg/ml) or MTHH (325.45±60.03 pg/ml). An interaction was also observed for TNF-α (F=5.73, p=0.001) with increases during HTLH and HTMH from PRE (0.10±0.06 pg/ml) to 60 (1.06±0.07 pg/ml; p=0.002) and 90 (1.09±0.06 pg/ml; p<0.001). **CONCLUSIONS:** Data suggests high temperatures will initiate a pro-inflammatory response that may be countered by contraction-induced IL-6 response, and downstream increases in IL-1ra and IL-10.

Study partially funded by the Kent State University Research Council.

Examining the Impact of a Prospective WBGT Heat Policy on High School Football Practices

Rebecca M. Lopez, Patrick Gorrell, Gianluca Del Rossi.
University of South Florida, Tampa, FL. (Sponsor: Douglas Casa, FACSM)
 Email: rlopez@health.usf.edu
 (No relevant relationships reported)

A wet bulb globe temperature (WBGT) policy with suggestions for practice modifications can potentially help decrease the number of exertional heat illnesses (EHIs) reported in high school football. It is unknown what impact such a policy would have on the number of outdoor football practices that would be cancelled or modified. **Purpose:** To assess WBGT during a full season of football at various high schools in Florida to determine how a regional WBGT policy would have impacted football practices. **Methods:** Environmental data was collected daily throughout the duration of the regular football season by athletic trainers stationed at 10 high schools in west central Florida. WBGT measures were recorded at approximately 4PM (R1) and again at 6PM (R2) to correspond with practice start and end times. These measures were then allocated into 5 previously defined, regional WBGT categories which corresponded to different activity modifications ranging from no modifications (WBGT < 27.8°C) to no outdoor practices (WBGT ≥ 33.4°C). An ANOVA was used to determine differences in WBGT between schools and across the various months during football season. **Results:** There were no statistical differences in the WBGT measures between the 10 schools at the R1 (P=0.655) and R2 (P=0.446) timepoints. Nearly 39% (n=169) of all WBGT measures at R1 (~4PM) across the 10 schools were < 27.8°C and would not have required any practice modifications. Only 7.5% (n=33) of the measures for this same R1 timepoint were ≥ 33.4°C which would have resulted in cancellation of practice. Fifty-seven percent (n=208) of R2 WBGT measures were < 27.8°C while only 1.1% (n=4) were ≥ 33.4°C. Also, the maximum WBGT measurement in August (33.1 ± 0.7°C) was significantly higher than in October (28.6 ± 0.7°C; P=0.000) but similar to maximum WBGT in September (32.7 ± 0.9°C) and November (31.0 ± 1.9°C; P>0.05). **Conclusion:** Our findings revealed that if existing regional heat guidelines would have been applied in Florida during our study, the policy would have resulted in the cancellation of outdoor practices on only a few days. It is also clear that the risk of dangerously elevated WBGT was not limited to preseason practices in August. Finally, delaying practices to later in the afternoon would likely decrease the risk of EHI and minimize the number of practices affected by a heat policy.

An Evaluation of Race Car Cockpit Temperature as an Indicator of Thermal Strain in Race Car Drivers

Samuel C. Barthel, David P. Ferguson. *Michigan State University, East Lansing, MI.*
 Email: samuelbarthel45@gmail.com
 (No relevant relationships reported)

Under current Federation Internationale de l'Automobile (FIA) rules, in endurance sports car racing, if ambient temperatures inside the cockpit of a racing car exceed 32°C, then the maximum time a driver spends in the race car is reduced. However, teams have instituted air conditioning in the car which may render this rule obsolete. **PURPOSE:** To evaluate if cockpit temperature of a racing car effects the thermal strain of racing driver with and without an air conditioning (AC) system. **METHODS:** Four male racing drivers had heart rate (HR), core temperature (T_{core}), physiological strain index (PSI) measured continuously during over 38 driving sessions including testing, practice, qualifying and a race. **RESULTS:** Cockpit temperature elicited a positive relationship, with each measured variable (slope ± SE, r₂, p-value); HR (1.842 ± 0.01655, 0.62, <.0001), T_{core} (0.08519 ± 0.002723, 0.32, <.0001), PSI (0.1899 ± 0.007706, 0.24, <.0001). There were no significant differences in slope with AC on or AC off when compared in each variable. HR with AC on (1.867 ± 0.0191) displayed no significant difference to AC off (1.784 ± .05187, p = 0.1332). T_{core} with AC on (0.8546 ± 0.002751) exhibited no change compared to AC off (0.7572 ± 0.01899, p = 0.6118). Lastly, PSI with AC on (0.1910 ± .007686) showed no difference with AC off (0.1561 ± 0.06305, p = 0.5828). **CONCLUSIONS:** Air conditioning systems that are administered through the driver's helmet do not change the thermal strain caused by an increase in cockpit temperature. This concludes that the FIA's current use of cockpit temperature remains the most accurate way to estimate the thermal strain on the driver.

Relationships between Body Temperatures Changes with Exercise Performance

Adam R. Jajtner¹, Brittany N. Followay², Jeremiah A. Vaughan³, Elliott Arroyo¹, Brandon M. Gibson¹, Joseph A. Laudato¹, Ellen L. Glickman, FACSM¹. ¹Kent State University, Kent, OH. ²Ripon College, Ripon, WI. ³Bemidji State University, Bemidji, MN.
 (Sponsor: Ellen Glickman, FACSM)
 (No relevant relationships reported)

Purpose: To examine the relationship between changes in body temperature, and time spent above critical temperatures with aerobic performance and drinking behavior. **Methods:** 12 recreationally active men (24.4 ± 3.1 yrs; 1.81 ± 0.07m; 81.5 ± 8.0kg; 47.2 ± 4.8 ml/kg/min) completed five experimental visits: a VO₂ max test, and a cycling trial in 23°C/45%RH, 23°C/70%RH, 34°C/20%RH and 34°C/45%RH. During each cycling trial, participants completed 60 minutes of cycling at 60% VO₂max, a 15min rest and a time to exhaustion (TTE) at 90% VO₂max. Water intake, and TTE performance was collected in each condition. During each exercise session, participants were monitored continuously for their rectal temperature (T_{re}) and skin temperatures at five locations: Chest, Triceps, Forearm, Thigh and Calf. Total skin temperature (T_{sk}) and whole body temperature (T_{wb}) were calculated using weighted averages. The Area Under the Curve with respect to increase from baseline (AUCi) was then calculated for T_{re}, T_{sk} and T_{wb}. Data were analyzed as Pearson Product Moment Correlations between AUCi for T_{re}, T_{sk} and T_{wb} with water intake and TTE performance. Furthermore, the time spent above specific critical temperatures for T_{re} (37.5, 38.0, 38.5 and 39.0°C) and T_{wb} (35.0, 36.0, 37.0 and 38.0°C) were related to water intake at TTE performance using stepwise linear regression. **Results:** Significant correlations were observed between water intake with T_{sk} (r = 0.469; p=0.003) and T_{wb} (r = 0.511; p=0.001), though no significant correlation was observed for T_{re} (p=0.059). Time spent with a T_{wb} above 35°C related to total water intake (r = 0.521; p=0.001), though no critical T_{re} temperature was observed. TTE performance was significantly correlated with and T_{wb} (r = -0.338; p=0.036), but not with T_{re} (p=0.179) or T_{sk} (p=0.058). Time spent with a T_{wb} above 37°C and T_{re} above 38.5°C was related to TTE performance (r = 0.409; p=0.010; r = 0.481; p=0.002, respectively). **Conclusions:** Data indicate that total water intake is driven by T_{wb}, and likely not influenced by T_{re}. TTE performance, however, is influenced by both T_{wb} and T_{re}. Future research should focus on establishing critical body temperatures to determine the points at which performance declines on an individualized basis. *This investigation was partially funded by Kent State University Research Council.*

Comparison of Physiological Strain Index and Core Temperature Rise for Classifying Heat Tolerance Among Warfighters

Jay H. Heaney¹, Andrew J. Ordillie², Katherine M. Wilson³, Douglas M. Jones³. ¹Naval Health Research Center, San Diego, CA. ²Innovative Employee Solutions, San Diego, CA. ³Leidos Inc., San Diego, CA.
 (No relevant relationships reported)

The heat tolerance test (HTT) is used by the military to assist with return-to-duty decisions for heat-injured warfighters. Criteria for determining heat tolerance are generally accepted as core temperature (T_{core}) < 38.6°C and heart rate (HR) < 160 bpm during 120 min of treadmill walking in a compensable heat stress environment. Additional information for classifying heat tolerance may be gained by evaluating the final 60 min of an HTT, as Druyan et al. (2013) determined a limit of < 0.45°C T_{core} increase during the final 60 min (ΔT_{coreF60}). Use of calculations that encompass both T_{core} and HR, such as the physiological strain index (PSI), may also provide useful information to aid in return-to-duty decisions. **PURPOSE:** To determine the validity of PSI increase during the final 60 min (ΔPSI_{F60}) of an HTT for classifying heat tolerance and compare it with the ΔT_{coreF60} criterion established by Druyan et al. **METHODS:** Using traditional HR and T_{core} criteria, 15 males were classified as heat-tolerant (HT) (age: 27 ± 5 yrs, height: 177.2 ± 6.5 cm, weight: 82.4 ± 10.1 kg) and 15 males were classified as heat-intolerant (HI) (age: 27 ± 7 yrs, height: 177.3 ± 7.6 cm, weight: 86.7 ± 14.5 kg). ΔPSI_{F60} values were calculated for all subjects and compared with a previously determined ΔPSI_{F60} limit of 1.82 to confirm validity. Additionally, ΔPSI_{F60} was calculated for a sample of 77 male warfighters (age: 25 ± 5 yrs, height: 178.5 ± 7.1 cm, weight: 84.8 ± 10.1 kg) who were classified as HT/HI according to ΔPSI_{F60} and ΔT_{coreF60} thresholds. The number of misclassifications for ΔPSI_{F60} and ΔT_{coreF60} (Druyan et al.) were then compared. **RESULTS:** ΔPSI_{F60} threshold of 1.82 was validated by comparing it to ΔPSI_{F60} for HT and HI warfighters (HT: 0.54 ± 0.64, p < .001; HI: 1.95 ± 0.72, p = .318). Misclassifications of HT/HI for ΔPSI_{F60} and ΔT_{coreF60} were 8 (10%) and 7 (9%), respectively. Sensitivity and specificity of the proposed ΔPSI_{F60} HT/HI criterion were 97% and 54%, respectively, versus 95% and 70% for ΔT_{coreF60}. **CONCLUSION:**

Findings suggest that 1.82 $\Delta\text{PSI}_{\text{F60}}$ and 0.45°C $\Delta\text{T}_{\text{coreF60}}$ thresholds to determine heat tolerance yield a similar number of misclassifications. Future work should aim to refine these techniques to reduce the number of HT/HTI misclassifications.

2082 Board #238 May 30 2:00 PM - 3:30 PM
Establishing a Physiological Strain Index Criterion During the Final Sixty Minutes of Heat Tolerance Testing

Douglas M. Jones¹, Andrew J. Ordille², Katherine M. Wilson¹, Jay H. Heaney³. ¹Leidos, Inc., San Diego, CA. ²Innovative Employee Solutions, San Diego, CA. ³Naval Health Research Center, San Diego, CA.

(No relevant relationships reported)

The heat tolerance test (HTT) assesses cardiorespiratory and thermoregulatory capacity during heat stress using heart rate (HR) and core temperature (T_{core}) as pass/fail criteria, where HR and T_{core} may not exceed 160 bpm and 38.6°C, respectively. Additional information regarding physiological stress and heat tolerance may be derived from the physiological strain index (PSI), which provides a singular physiological strain value using HR and T_{core} measurements. To our knowledge, the change in PSI during the final 60 min of an HTT ($\Delta\text{PSI}_{\text{F60}}$) has not been evaluated as a potential criterion for classifying heat tolerance/intolerance during HTT. **PURPOSE:** The purpose of this study was to establish a criterion threshold for $\Delta\text{PSI}_{\text{F60}}$ and report on its ability to classify heat tolerance/intolerance during an HTT. **METHODS:** Seventy-seven US military men (age: 25 ± 5 yr, ht: 178.5 ± 7.1 cm, wt: 84.8 ± 10.1 kg) completed up to 120 min of continuous treadmill walking (3.3 mph, 4.0% grade) in 40°C and 40% relative humidity and were classified for their heat tolerance (n = 64) or heat intolerance (n = 13) using established T_{core} and HR criteria. A $\Delta\text{PSI}_{\text{F60}}$ was calculated for, and compared between, heat tolerant (HT) and heat intolerant (HI) subjects using an independent sample *t*-test. A maximal normal accepted value for $\Delta\text{PSI}_{\text{F60}}$ was calculated by taking the mean value of $\Delta\text{PSI}_{\text{F60}}$ for HT subjects plus two standard deviations. **RESULTS:** $\Delta\text{PSI}_{\text{F60}}$ was significantly less in HT subjects than in HI subjects (0.54 ± 0.64 vs 1.95 ± 0.72; *p* < .001). For HT subjects, a $\Delta\text{PSI}_{\text{F60}}$ maximal normal accepted value was determined to be 1.82. **CONCLUSION:** Findings indicate that $\Delta\text{PSI}_{\text{F60}}$ appropriately differentiated HT from HI subjects during an HTT in this population of military personnel. Therefore, we report that exceeding a $\Delta\text{PSI}_{\text{F60}}$ of 1.82 may serve as an additional criterion for classifying heat intolerance during HTT. Further work on the validation of this maximal normal accepted value for $\Delta\text{PSI}_{\text{F60}}$ is needed.

Interpretations of Physiological Strain Index During Heat Tolerance Testing

Andrew J. Ordille, Douglas M. Jones, Katherine M. Wilson, Jay H. Heaney. Naval Health Research Center, San Diego, CA.
 Email: a.ordille94@gmail.com

(No relevant relationships reported)

The heat tolerance test (HTT) assesses cardiorespiratory and thermoregulatory capacity during heat stress using core temperature (T_{core}) and heart rate (HR) as pass/fail criteria. Additional information regarding physiological stress and heat tolerance may be derived from the physiological strain index (PSI), which provides a representation of total physiological strain using T_{core} and HR measurements. Currently, there is minimal information available on the efficacy of various PSI interpretations, with respect to accurately identifying differences in physiological strain between those that have passed and failed an HTT. **PURPOSE:** To report different methods to evaluate physiological strain during HTT using PSI. **METHODS:** Eighty-two military personnel (age: 25 ± 5 yrs, height: 178.2 ± 7.2 cm, weight: 84.5 ± 9.9 kg) completed up to 120 min of continuous treadmill walking (3.3 mph; 4.0% grade) in 40°C and 40% relative humidity. PSI was calculated from T_{core} and HR measurements that were recorded every 5 min. PSI was then interpreted as trial mean, end of test (EOT), slope, and time-weighted (0 min - EOT) area under the curve (AUC) for subjects that passed and failed an HTT and compared using independent samples *t*-tests (*p* < .05). **RESULTS:** The trial mean PSI was significantly less in those that passed compared with those that failed the HTT (3.7 ± 0.7 vs. 4.8 ± 0.3; *p* < .001). Similarly, EOT PSI was significantly less for subjects that passed compared with those that failed (4.7 ± 1.1 vs. 6.8 ± 0.6; *p* < .001). Graphed as a function of time, the slope of the best-fit line for PSI was less in those that passed compared with those that failed (0.02 ± 0.01 vs. 0.07 ± 0.03; *p* < .001). PSI was also calculated as AUC (pass: 416 ± 141, fail: 453 ± 87; *p* = .299) and, when adjusted for trial time, resulted in a significantly lower PSI value for those that passed compared with those that failed (3.8 ± 0.7 vs. 4.8 ± 0.3; *p* < .001). **CONCLUSION:** Findings indicate all PSI parameters investigated appropriately differentiated between subjects that passed and failed the HTT, resulting from either cardiorespiratory stress, thermoregulatory stress, or a combination of the two. Further work on the use of this index and its evaluation is warranted, as there are no defined criteria for HTT fail using PSI as an integrative value of total thermal strain.

2084 Board #240 May 30 2:00 PM - 3:30 PM
Thermal Behavior Does not Differ Between Sexes During and Following High Intensity Aerobic Exercise

Randi L. Snopkowski¹, Nicole Vargas¹, Christopher Chapman¹, Blair Johnson¹, Rob Gathercole², Zachary Schlader, FACSM¹.

¹University at Buffalo, Buffalo, NY. ²lululemon athletica inc., Vancouver, BC, Canada. (Sponsor: Zachary Schlader, FACSM)
 (No relevant relationships reported)

Females utilize thermal behavior more than males during low intensity aerobic exercise. Core temperature is elevated during high vs. low intensity aerobic exercise because of greater heat production. Thus, thermal behavior is greater during high intensity exercise because of the heightened stimulus to behave. It is unknown if sex modulates thermal behavior during high intensity exercise.

Purpose: Test the hypothesis that thermal behavior differs between males and females during high intensity exercise and recovery.

Methods: 10 males (M) and 10 females (F) (23±3y) underwent 30 min of cycling exercise at a power output that elicited 80±5% (F) and 78±4% (M) of $\text{VO}_{2\text{peak}}$ (*P*=0.28) followed by 120 min seated recovery in a 27±1°C, 21±2% relative humidity environment. Subjects were instructed to maintain a thermally comfortable neck temperature throughout using a custom-made neck device. Neck device temperature provided an index of thermal behavior. Mean skin (10 site) and core (intestinal) temperatures, mean skin wettedness (8 site), neck device temperature, skin blood flow (laser Doppler) and local sweat rate (ventilated capsule) were measured continually.

Results: There were no sex differences in heat production during exercise (F: 399±68, M: 429±62 W/m², *P*=0.39). During exercise, core and mean skin temperatures, skin wettedness, skin blood flow and local sweat rate increased, while neck device temperature decreased (all *P*<0.01). There were no sex differences in core (F: 37.7±0.2, M: 37.9±0.3°C, *P*≥ 0.50), mean skin (F: 32.6±0.3, M: 32.6±0.3°C, *P*≥0.99) or neck device (F: 12.1±10.6, M: 11.9±10.2°C, *P*≥0.25) temperatures, mean skin wettedness (at 30 min: F: 0.50±0.06, M: 0.53±0.04 au, *P*≥0.99), skin blood flow (F: 163±50, M: 172±36 PU, *P*≥0.99) or local sweat rate (F: 0.72±0.20, M: 0.85±0.27 mg/cm²/min, *P*≥0.33) during exercise (data reported at 30 min). During recovery, core and mean skin temperatures, mean skin wettedness, skin blood flow and local sweat rate decreased, and neck device temperature increased back towards pre-exercise levels (all *P*<0.01). There were no differences in the dynamics of these changes between sexes (all *P*≥0.16).

Conclusions: Thermal behavior during and following high intensity aerobic exercise does not differ between males and females.

This study was funded by lululemon athletica inc.

Exercise Intensity Independently Modulates Thermal Behavior During Exercise Recovery, But Not During Exercise

Nicole T. Vargas¹, Christopher L. Chapman¹, Blair D. Johnson¹, Rob Gathercole², Zachary J. Schlader, FACSM¹. ¹University at Buffalo, Buffalo, NY. ²lululemon athletica inc., Vancouver, BC, Canada. (Sponsor: Zachary Schlader, FACSM)
 Email: nt Vargas@buffalo.edu

(No relevant relationships reported)

Purpose: High intensity (HI) exercise stimulates greater heat production than moderate intensity (MI) exercise, but also reduces perceptual thermal sensitivity. Thus, thermal behavior may differ between HI and MI exercise. We tested the hypothesis that thermal behavior is greater during HI compared to MI exercise and recovery.

Methods: In a 27.0±0.4°C, 21±3% RH environment, 20 subjects (10 females) cycled for 30 min at MI (53±6% $\text{VO}_{2\text{peak}}$) or HI (78±6% $\text{VO}_{2\text{peak}}$), followed by 120 min seated recovery. Mean skin (10 site) and core (telemetry pill) temperatures, and mean skin wettedness (8 site) were recorded continuously. Participants maintained a thermally comfortable neck temperature throughout using a custom-made device. Neck device temperature provided an index of thermal behavior. The weighted average of mean skin and core temperatures, and mean skin wettedness provided an indication of the mean afferent stimulus to thermally behave.

Results: Mean skin (by +0.4±0.7°C, *P*<0.01) and core (by +0.4±0.3°C, *P*<0.01) temperatures were higher at end exercise in HI. Mean skin temperature was not different between trials by 10 min recovery (*P*≥0.96). Core temperature was higher in HI until 90 min recovery (*P*≤0.01). Mean skin wettedness (by +0.04±0.06 a.u., *P*=0.03) and the mean afferent stimulus (by +2.5±3.5 a.u., *P*=0.01) were greater at 10 min of exercise in HI, and remained until 60 min into recovery (*P*<0.01). The decrease in neck device temperature was greater in HI during exercise (at 30 min: by -4.9±9.6°C, *P*≤0.06), but did not differ after 20 min recovery (*P*≥0.60). There were negative relationships between the mean afferent stimulus and neck device temperature for exercise (HI: *r*=-0.91, MI: *r*=-0.96, both *P*<0.01) and recovery (HI: *r*=-0.98, MI: *r*=-0.96, both *P*<0.01). During exercise, there were no differences in the slope (HI: -0.93±0.31; MI: -0.87±0.14°C/a.u., *P*=0.49) or y-intercept (HI: 43.4±11.6 a.u., MI:

43.8±4.9°C a.u., $P=0.91$). During recovery, the slope was steeper (-0.94 ± 0.06 vs. $-0.77\pm 0.78^\circ\text{C}/\text{a.u.}$, $P<0.01$) and y -intercept higher (49.3 ± 2.0 vs. $41.7\pm 2.3^\circ\text{C}$, $P<0.01$) in HI.

Conclusions: Thermal behavior is greater during HI exercise due to a greater afferent stimulus to behave. However, the withdrawal of thermal behavior is augmented following HI versus MI exercise.

Circulating Mcp-1 Associated With Prolonged Cycling In Hot Temperature

cody dulaney¹, Eliott Arroyo¹, Emily Tagesen¹, Joseph Laudato¹, Ellen Glickman, FACSMT¹, Adam Jajtner¹, Brittany Followay², Jeremiah Vaughan³. ¹Kent state university, Kent, OH. ²Ripon College, Ripon, WI. ³Bemidji State University, Bemidji, MN. (Sponsor: Ellen G. Glickman, FACSMT)
Email: cdulanel1@kent.edu

(No relevant relationships reported)

Purpose: The purpose of this investigation was to examine the recruitment of classical monocytes during prolonged aerobic exercise in high temperature and humidity conditions. **Methods:** Seven recreationally active men (23.4 ± 3.0 yrs; 180.9 ± 5.8 cm; 85.1 ± 11.3 kg; 3.7 ± 0.27 L·min⁻¹) completed five trials: a graded exercise test, and four cycling trials in 37°C/23% Relative Humidity (RH)(HTLH), 37°C/33%RH (HTMH), 24°C/38%RH (MTMH), and 24°C/51%RH (MTHH) in a counterbalanced fashion. During the exercise protocol, participants rested supine for 15 minutes before completing 60-min of cycling at 60% $\dot{V}O_{2\text{max}}$, a 15-min rest, and cycling until exhaustion at 90% $\dot{V}O_{2\text{max}}$ (TTE), before 60 minutes of recovery. Blood samples were obtained prior to exercise (PRE), after 60 minutes of cycling (60), after the TTE (90) and following one hour of recovery (REC). Blood was assessed for plasma concentrations of Monocyte Chemoattractant Protein 1 (MCP-1) via ELISA, and CCR2 expression on classical monocytes (CD14+CD16-) via flow cytometry. Briefly, CCR2 expression was determined as fold change over fluorescence minus one (FMO). Data were analyzed using within-subjects repeated measures ANOVA. **Results:** A main effect for time was observed ($F = 8.9$; $p = 0.003$; $\eta^2_p = 0.560$) for MCP-1 in circulation. MCP-1 increased from PRE (183.8 ± 59.7 pg·mL⁻¹) to 60 (215.8 ± 74.1 pg·mL⁻¹; $p = 0.009$), 90 (231.6 ± 83.8 pg·mL⁻¹; $p = 0.006$), and REC (216.0 ± 88.3 pg·mL⁻¹; $p = 0.019$). Concentrations also increased from 60 to 90 ($p = 0.018$). A main effect of time was also observed ($F = 11.6$; $p = 0.009$; $\eta^2_p = 0.659$) for CCR2 expression on classical monocytes. No differences in CCR2 expression were observed between PRE (147.4 ± 50.6), and 60 (146.0 ± 70.8 ; $p = 0.869$), however decreases from PRE were observed at 90 (131.1 ± 39.7 ; $p = 0.023$), and REC (102.2 ± 37.1 ; $p < 0.001$). **CONCLUSION:** These data indicate that high temperature and/or humidity conditions do not impact recruitment of classical monocytes. Furthermore, prolonged cycling appears to increase circulating MCP-1 and decrease CCR2 expression on classical monocytes. Collectively, this may indicate a limited effect of aerobic exercise on the overall recruitment of classical monocytes, although further research is warranted.

This investigation was partially funded by the Kent State University Research Council.

Heat Acclimation Causes Profound Post-Exercise Hypotension and Favorable Improvements in Lipid and Immune Profiles

Eric Rivas¹, Oscar E. Suman, FACSMT², Vic Ben-Ezra³. ¹Texas Tech University, Lubbock, TX. ²University of Texas Medical Branch, Galveston, TX. ³Texas Woman's University, Denton, TX. (Sponsor: Oscar E. Suman, FACSMT)
Email: eric.rivas@ttu.edu

(No relevant relationships reported)

Purpose: We have previously reported that passive hyperthermic exposure causes an acute hypotensive response. The animal literature has shown that chronic heat stress causes alterations in metabolic and lipid metabolism. However, it is unknown if heat acclimation also causes chronic blood pressure and lipid responses in humans. This project tested the hypothesis that 10-day exercise-heat acclimation (HA) would cause greater post-exercise hypotensive responses and alter metabolic, lipid, and immune profiles compared to 10-day exercise under neutral conditions (CON). **METHODS:** Twelve healthy sedentary subjects (7M/5F, 28±6y, 78±17kg), completed a 10-day (90min/day exercise bout) clamp controlled (internal work-rate) hyperthermia HA (42°C, 28% RH) and control (CON: 23°C, 42% RH) protocols in a counterbalanced design separated by at least 2 months. Pre- and post-exercise HA/CON blood pressure was taken post-exercise over 1 hour after day 1 and day 10 exercise. Metabolic, lipid and immune panels were taken pre-post HA/CON. **RESULTS:** Exercise under heat stress had greater post-exercise hypotension (systolic; -6mmHg, diastolic -8mmHg; and mean arterial pressure, -7mmHg) on day 1 and day 10 compared to exercise under neutral conditions (main effect for condition,

$P<0.004$). Only from pre-to-post HA, total cholesterol (170 ± 22 to 152 ± 15 ; $P<0.02$) and triglycerides (130 ± 63 to 93 ± 27 ; $P<0.03$) were reduced. A trend for changes in glycemic control (%A1c; 5.4 ± 0.3 to 5.3 ± 0.4 ; $P<0.06$) neutrophils ($52.3\pm 5.6\%$ to $57.5\pm 4.0\%$; $P<0.09$), lymphocytes ($37.9\pm 5.7\%$ to $32.9\pm 3.0\%$; $P<0.07$), and eosinophils (2.4 ± 1.7 to 3.1 ± 0.1 ; $P<0.06$) were found after HA.

CONCLUSIONS: These preliminary data indicate that HA causes a profound post-exercise hypotensive response and favorable metabolic, lipid, and immune profile changes. Further examination of heat acclimation on vascular, metabolic, and immune responses will offer insight for benefits in other clinical populations with vascular, metabolic and immune dysfunction.

Quantifying the Environmental Thermal Conditions that Exist During Summer Track Meets in South Texas

Juan Gonzalez. The University of Texas Rio Grande Valley, Edinburg, TX. (Sponsor: Alexis Ortiz, FACSMT)

(No relevant relationships reported)

PURPOSE: To quantify the environmental thermal conditions that track & field officials, volunteers and track & field athletes are exposed during June and July in south Texas. **METHODS:** Five summer track meets were selected from the Texas Amateur Athletic Federation (TAAF) competition season during June and July for analysis. Air temperature, heat stress index, web bulb globe temperature, relative humidity, thermal work limit, and ultraviolet index (UVI) were recorded at 8 a.m., 10 a.m., Noon, 2 p.m., and 4 p.m. with a handheld wet bulb globe temperature (WBGT) Kestrel 0854TAN Heat Stress Tracker (TEquipment.net). **RESULTS:** The mean temperature reading, standard deviation, and standard error for the five track meets throughout the duration of the track meets were 8 am: $81.4^\circ\text{F} \pm 2.02$ (0.9); 10 am: $86.36^\circ\text{F} \pm 3.73$ (1.7); Noon: $91.68^\circ\text{F} \pm 5.20$ (2.3); 2 pm: $91.84^\circ\text{F} \pm 6.34$ (2.8); and 4 pm: $92.38^\circ\text{F} \pm 10.16$ (4.5). The mean heat stress values were 8 a.m. 89.56 ± 2.82 (1.3); 10 a.m. 98.66 ± 9.40 (4.2); Noon. 106.22 ± 9.27 (4.1); 2 p.m. 102.68 ± 8.19 (3.7); and 4 p.m. 103.68 ± 10.49 (4.7). The mean wet bulb globe temperature readings were 8 a.m. 76.8 ± 2.94 (1.3); 10 a.m. 82.2 ± 4.65 (2.1); Noon. 81.4 ± 4.98 (2.2); 2 p.m. 80.32 ± 7.62 (3.4); and 4 p.m. 78.76 ± 5.95 (2.7). The mean relative humidity readings were 8 a.m. 80.32 ± 4.75 (2.1); 10 a.m. 72.8 ± 6.89 (3.1); Noon. 55.92 ± 7.97 (3.6); 2 p.m. 54.52 ± 11.03 (4.9); and 4 p.m. 59.08 ± 9.76 (4.4). The mean thermal work limit readings were 8 a.m. 161.56 ± 12.06 (5.4); 10 a.m. 155.8 ± 17.76 (7.9); Noon. 139.54 ± 26.98 (12.1); 2 p.m. 152.2 ± 46.21 (20.7); and 4 p.m. 166.56 ± 33.78 (15.1). The mean UVA index readings were 8 a.m. 0.1 ± 0.0 (0.0); 10:00 a.m. 2.68 ± 1.11 (0.5); Noon. 8.14 ± 1.60 (0.7); 2 p.m. 8.56 ± 2.23 (1.0); and 4 p.m. 6.66 ± 2.11 (0.9). **CONCLUSIONS:** Data suggests that the thermal conditions from June to July in south Texas are considered "low alert" based on the Event Alert System used by the ACSM and other organizations, such as the Bank of America Chicago Marathon. Based on UVA index data, participants and track meet officials should wear sunscreen. Although data suggest "low alert," track & field officials should consider starting summer track meets at 4 p.m. when heat variables begin to diminish.

Metabolic Recovery Response During Seated Rest In Hot Environment

Jeremiah A. Vaughan¹, Brittany N. Followay², Adam R. Jajtner³, Ellen L. Glickman, FACSMT⁴. ¹Bemidji State University, Bemidji, MN. ²Ripon College, Ripon, WI. ³Kent State University, Kent, OH. ⁴Kent State University, Kent, OH. (Sponsor: Ellen L. Glickman, FACSMT)

Email: jeremiah.vaughan@bemidjistate.edu

(No relevant relationships reported)

Purpose: The purpose of this study was to examine the metabolic recovery response during seated rest in a hot and moderate environmental condition after a prolonged cycling bout. **Methods:** Eleven recreationally active men (23.6 ± 2.6 yrs; 180.9 ± 6.8 cm; 85.3 ± 10.8 kg; 3.8 ± 0.42 L·min⁻¹) completed a recovery session under two conditions: 22°C/45%RH (MT) and 35°C/45%RH (HT). Prior to recovery session, each participant completed a 60-min cycling trial at 60% $\dot{V}O_{2\text{max}}$ and a time-to-exhaustion trial at 90% $\dot{V}O_{2\text{max}}$. Data were collected during the 3min (M3), 15min (M15) 30min (M30), and 60min (M60) of the 60-min recovery. Metabolic variables assessed were $\dot{V}O_2$, RER, VE, and HR. Data were analyzed using within-subjects repeated measures ANOVA. **Results:** A significant interaction was observed for $\dot{V}O_2$ ($F = 2.788$, $p = 0.043$, $\eta^2 = 0.258$). Post-hoc analysis indicated a main effect of time during MT ($F = 8.097$, $p < 0.001$, $\eta^2 = 0.503$), but not HT condition ($F = 2.433$, $p < 0.065$, $\eta^2 = 0.213$). Specifically, during the MT, $\dot{V}O_2$ was significantly lower at M15 ($p < 0.001$), M30 ($p = 0.015$), M45 ($p < 0.001$) and M60 ($p < 0.001$) compared to M3. Furthermore, $\dot{V}O_2$ was significantly lower during the HT condition compared to MT during M60 ($p < 0.001$). No significant interaction was observed for VE ($F = 1.384$, $p = 0.261$, $\eta^2 = 0.148$). A significant main effect of time was observed ($F = 11.818$, $p < 0.001$, $\eta^2 = 0.596$). M15, M30, M45, and M60 were significantly lower compared to M3 ($p = 0.05$). No significant interaction was observed for RER ($F = 1.566$, $p = 0.207$,

$\eta^2 = 0.164$). A significant main effect of time was observed for RER ($F = 3.319, p = 0.022, \eta^2 = 0.293$). M15, M30, M45 and M60 were significantly lower compared to M3 ($p = 0.05$). A significant interaction was observed for HR ($F = 2.702, p = 0.046, \eta^2 = 0.231$). Post-hoc analysis indicated a main effect of time during both MT ($F = 21.441, p < 0.001, \eta^2 = 0.704$) and HT ($F = 11.022, p < 0.001, \eta^2 = 0.524$). Specifically, during both MT and HT, HR was significantly lower at M15, M30, M45, and M60 ($p < 0.05$) compared to 3M. Furthermore, HR was significantly lower during the MT compared to the HT condition during all time points ($p < 0.05$), except M30 ($p = 0.081$).

Conclusion: Data suggests recovery is moderately impacted in a high temperature conditions compared to a moderate condition after a submaximal and maximal exercise bout determined by elevated HR.

Wireless Real-Time Transistor-Based Skin Temperature Data Acquisition System

Audrey Johnson, Nisha Charkoudian, FACSM. *USARIEM, Natick, MA.* (Sponsor: Nisha Charkoudian, FACSM)
(No relevant relationships reported)

Environmental physiology studies rely on the accurate measurement of skin and internal temperatures. Many traditional skin temperature systems utilize thermistor or thermocouple measurements. However, utilizing a transistor-based sensor allows for a more linear data set, which could provide more stability, thus allowing for a more robust and accurate measurement over a range of environmental conditions. Field Programmable Gate Arrays (FPGA) are relatively low cost and low power consuming programmable hardware devices that allows for a signal to be processed and viewed in real time. Combining the processing power of the FPGA and the heightened accuracy of transistor-based analog temperature sensors, a modernized data acquisition (DAQ) system could provide linearized real time data.

PURPOSE: To design a wireless patch-type transistor-based skin temperature DAQ system that will provide a more accurate and linear set of data for measurement in hot/humid/cold/altitude environments, and will be sufficiently robust for outdoor field studies.

METHODS: We designed and built a prototype wireless transistor-based skin temperature DAQ that implements a precision analog temperature sensor to acquire skin temperature and FPGA technology for signal processing. The tested accuracy for the precision analog temperature sensor is ± 0.05 - 0.1°C in a temperature range of 20°C to 42°C . By utilizing FPGA technology, the system will process, pack, and wirelessly send data to a computer for real time monitoring.

RESULTS: In preliminary testing, the FPGA system showed an overall lower power consumption in addition to less variability in Voltage (V), the signal upon which temperature measurements depend. Over a 5°C temperature change it was seen that the FPGA system had a variance of 3.7×10^{-11} V, while a thermistor based temperature system had a variance of 1.3×10^{-3} V. In most settings, this will result in a substantially lower power consumption using our new system.

CONCLUSION: Our data suggest that our new FPGA approach is superior to traditional skin temperature measurements in its ability to rapidly attain and maintain accurate temperature readings. Next steps include field testing the device over a wide range of temperature, wind and humidity conditions.

Prefrontal Cortex Oxygenation and Haemodynamics during a Long Duration Incremental Exercise Protocol while wearing Personal Protective Equipment

Lynneht Stuart-Hill¹, Cory Coehoorn¹, Patrick Neary², Olave Krigolson¹. ¹University of Victoria, Victoria, BC, Canada.
²University of Regina, Regina, SK, Canada.
(No relevant relationships reported)

Heat stress has been shown to effect cerebral oxygenation and haemodynamics. There is although limited research evaluating the effects of rapid and uncompensable core temperature (T_c) acquisition, as which occurs when one is wearing personal protective equipment (PPE), on cerebral oxygenation and haemodynamics. **PURPOSE:** To determine the effects of rapid and uncompensable T_c acquisition on cerebral oxygenation and haemodynamics. **METHODS:** Fourteen male subjects (33.6 ± 12.1 years) performed an incremental treadmill test to a termination point in a control session (CON) and an experimental session (PPE). Changes in oxy-haemoglobin (O_2Hb), deoxy-haemoglobin (HHb), total haemoglobin (tHb), and tissue oxygen saturation index (TSI %) were monitored in the left and right prefrontal cortex (PFC) using near-infrared spectroscopy (NIRS). Heart rate (HR), thermal comfort scale (TCS) and thermal sensation (TS) were also recorded at each 0.5°C increase in T_c . **RESULTS:** Time to termination (TTT) was significantly different ($p \leq 0.05$) between CON (77.3 ± 22.8 min) and PPE (50.3 ± 12.4 min). Subjects also showed significantly lower ($p \leq 0.05$) HR throughout CON (pre = 76.8 ± 8.6 bpm; post = 161.1 ± 20.7 bpm) when compared to PPE (pre = 86.5 ± 9.3 bpm; post = 179.6 ± 11.7 bpm). Significant differences were also between CON and PPE end-exercise T_c (CON = $38.57 \pm 0.3^\circ\text{C}$;

PPE = $39.01 \pm 0.3^\circ\text{C}$), TCS (CON = 3.57 ± 0.6 ; PPE = 4.63 ± 0.3), and TS (CON = 7.57 ± 0.5 ; PPE = 8.67 ± 0.3). Lastly, there was a $0.04^\circ\text{C}/\text{min}$ increase in T_c during PPE and a $0.02^\circ\text{C}/\text{min}$ increase in T_c during CON. Important NIRS results were a plateau in left-side O_2Hb and tHb at $T_c 38^\circ\text{C}$ in both CON and PPE, 80% of TTT in CON, and 60% of TTT in PPE. Additionally, there was increased left-side PFC activation during PPE as indicated by a significant decrease ($p \leq 0.05$) in TSI % from start to end of exercise (Start = $70.9 \pm 4.9\%$; End = $68.2 \pm 5.9\%$) and double the decrease in TSI %/min in PPE when compared to CON. **CONCLUSION:** These data suggest that rapid and uncompensable T_c acquisition causes an altered cerebral oxygenation and haemodynamic response in the left-side PFC. There were no changes in the cerebral oxygenation and haemodynamic response during CON. The left-side response during PPE could have implications for cognitive processes during and/or following exercise in the heat.

The Effect of Rapid and Slow Heat Acquisition on Body Weight and Blood Glucose Levels

Rozhin Mohammadrezaei, Cory Coehoorn, Lynneht Stuart-Hill. *University of Victoria, Victoria, BC, Canada.*
(No relevant relationships reported)

Body water loss due to thermoregulation during exercise in a hot environment may cause a significant decrease in body mass, affecting blood plasma volume and consequently parameters such as blood glucose (BG) concentration. It is not known if the increased rate of thermal acquisition that occurs as a result of exercise in a microclimate such as personal protective equipment impacts BG concentrations differently than a slower rate of thermal acquisition. **PURPOSE:** The purpose of this study was to determine if rapid heat acquisition impacts body mass, urine specific gravity (USG) and BG concentration differently than slow heat acquisition during exercise. **METHODS:** Fourteen healthy male subjects (mean age, 33.6 ± 12.1 years) performed an incremental exercise test to a termination criterion in a control session (CON) and an experimental session (PPE). Body mass, USG and BG were measured before and after each trial. **RESULTS:** Rate of thermal acquisition was significantly different ($p < 0.001$) between CON (0.02 ± 0.04 %/min) and PPE (0.04 ± 0.19 %/min). Time to termination (TTT) was also significantly different between CON (77.3 ± 22.8 min) and PPE (50.3 ± 12.4 min) and subjects also showed a lower HR throughout CON (pre = 76.8 ± 8.6 bpm; post = 161.1 ± 20.7 bpm) when compared to PPE (pre = 86.5 ± 9.3 bpm; post = 179.6 ± 11.7 bpm). Both conditions resulted in an identical and significant loss of total body mass (1.45 ± 0.62 kg; $p < 0.05$), with a corresponding increase in USG ($p < 0.01$). Despite body water loss, no significant change in blood glucose concentration occurred pre- to post-exercise in either condition ($\text{BG}_{\text{CON}} = -0.04 \pm 853$ mmolL^{-1} ; $\text{BG}_{\text{PPE}} = 0.34 \pm 93$ mmolL^{-1}). **CONCLUSION:** This data suggests that constant levels of blood glucose concentration are maintained regardless of rate of heat acquisition and despite body water loss that would affect plasma concentration.

Effect of Dietary Nitrate Supplementation with Beet Root Juice on Thermoregulatory and Cardiovascular Responses to Extreme Heat in Aged Humans

Matthew N. Cramer, Mu Huang, Michinari Hieda, Gilbert Moralez, Craig G. Crandall, FACSM. *Institute for Exercise and Environmental Medicine, Dallas, TX.* (Sponsor: Craig Crandall, FACSM)
Email: matthewcramer2@texashealth.org
(No relevant relationships reported)

PURPOSE: To test the hypothesis that dietary nitrate supplementation with beet root juice attenuates cardiovascular and thermal strain in aged individuals during prolonged non-encapsulated environmental heat stress. **METHODS:** Study participants were eight healthy, normotensive, non-obese, aged individuals (66 ± 5 years; BMI: 24.6 kg/m^2 ; five females). Before (PRE) and after (POST) 1 week of daily nitrate supplementation with concentrated beet root juice (140 ml twice daily), participants were exposed to 42.5°C and 35% relative humidity conditions for 2 h. Core and skin temperatures, arterial blood pressures, heart rate, cutaneous blood flow and vascular conductance, and forearm blood flow and vascular conductance were measured throughout the exposure. **RESULTS:** Following nitrate supplementation, mean arterial pressure decreased from 88 ± 5 to 80 ± 7 mmHg ($P = 0.02$) in thermoneutral conditions. During a subsequent heat stress, mean arterial pressure was significantly lower POST vs. PRE (treatment x time interaction: $P < 0.01$); however, this effect was limited to the first 30 min of the heat exposure. No effect of dietary nitrate supplementation was observed on core temperature, mean skin temperature, heart rate, cutaneous blood flow, cutaneous vascular conductance, forearm blood flow, and forearm vascular conductance throughout heat stress ($P > 0.05$). **CONCLUSION:** Our results indicate that in aged individuals, dietary nitrate supplementation does not attenuate thermal strain, and only transiently reduces cardiovascular strain, during extreme heat stress.

Effects On Skin Temperature of Marathon Running in a Hot Humid Environment

Daniel Rojas-Valverde¹, Randall Gutiérrez-Vargas¹, Braulio Sánchez-Ureña¹, Jeffrey M. Mjaanes². ¹National University, Heredia, Costa Rica. ²Northwestern University, Evanston, IL. (Sponsor: Jeffrey M. Mjaanes, FACSM)
 Email: drojasv@hotmail.com
 (No relevant relationships reported)

Participating in marathons in hot and humid weather may lead to fatigue, syncope, injuries or even death. In the diagnosis and monitoring of delayed onset muscle soreness and fatigue status, infrared thermography (IRT) has been used as a non-invasive method for the assessing skin temperature as a response of muscle hyperthermia after exercise.

Purpose: Analyze the effect of running a marathon in a hot and humid environment on skin temperature.

Methods: Seventeen amateur runners (age 35.82 ± 7.03 years, weight 66.79 ± 11.97 kg, height 168.44 ± 10.59 cm, VO_{2peak} 52.88 ± 7.09 ml/kg/min) had their lower limb skin temperature measured using trough IRT (FLIR T450) after running a marathon (0-80 m.a.s.l.) in a hot (thermal index 28.34 ± 3.27 °C) and humid environment (~81%), the measures were taken in a temperature controlled room (23°C). Both dominant (DLL) and non-dominant (NDLL) lowers limbs were divided for analysis into fourteen different areas and mean temperature of each area was used for analysis. A one-way ANOVA were used to compared thermal images taken 15 days and before marathon and 24 hours and 6 days after marathon.

Results: We found significant differences in skin temperatures: knee (DLL: $F_{(3,48)}$: 5.14, $p=0.004$); Vastus lateralis (DLL: $F_{(3,48)}$: 7.191, $p<0.01$; NDLL: $F_{(3,48)}$: 4.883, $p=0.005$); Rectus femoris (DLL: $F_{(3,48)}$: 5.956, $p=0.002$; NDLL: $F_{(3,48)}$: 5.521, $p=0.002$); Vastus medialis (DLL: $F_{(3,48)}$: 5.079, $p=0.004$; NDLL: $F_{(3,48)}$: 7.214, $p<0.001$); Adductor (DLL: $F_{(3,48)}$: 4.097, $p=0.011$; NDLL: $F_{(3,48)}$: 5.702, $p=0.002$); biceps femoris (DLL: $F_{(3,48)}$: 18.952, $p<0.01$; NDLL: $F_{(3,48)}$: 15.105, $p<0.01$); popliteal fossa (DLL: $F_{(3,48)}$: 11.103, $p<0.01$; NDLL: $F_{(3,48)}$: 11.598, $p<0.001$); semitendinosus (DLL: $F_{(3,48)}$: 14.382, $p<0.01$; NDLL: $F_{(3,48)}$: 15.000, $p<0.01$); lateral gastrocnemius (DLL: $F_{(3,48)}$: 15.007, $p<0.01$; NDLL: $F_{(3,48)}$: 10.316, $p<0.01$); and medial gastrocnemius (DLL: $F_{(3,48)}$: 7.567, $p<0.01$). Significant differences in all areas mentioned were found between measures: pre 15d < post 24h, pre marathon < post 24h > post 6d.

Conclusions: Running a marathon in hot, humid environment leads to significant increases in lower limb skin temperature and the temperature levels returned to baseline values after 6 days of recovery.

Myokine Responses To Resistance Exercise In Prader-Willi Syndrome

Naama W. Constantini, FACSM, Varda Gross-Tsur, Yanir Sabag, Yehuda Pollack, Shachar Nice, Harry J Hirsch. *Shaare Zedek Medical Center, Jerusalem, Israel.*
 Email: naamacons@gmail.com
 (No relevant relationships reported)

Background: Caloric restriction and daily exercise are needed to prevent morbid obesity in individuals with Prader-Willi Syndrome (PWS). Resting and activity energy expenditure are lower in PWS than in BMI-matched controls. Hypotonia, decreased muscle mass, and cognitive impairment make exercise particularly challenging for this population. Myokine responses to RT may have beneficial metabolic effects and promote caloric expenditure.

PURPOSE: Determine if young PWS adults can perform a RT program and evaluate their myokine response compared to age & BMI-matched controls. **METHODS:** Each study group included 11 participants (7 men and 4 women), ages 30.7±4.6 & 30.1±4.3 years, and BMI 28.3±4.3 and 28.2±4.2 kg/m² for PWS & controls respectively (NS). Blood samples for glucose, creatine kinase (CK), lactate, HbA1C, and myokines were obtained before and after performing a program of eight resistance exercises of large muscle groups (3-4 sets of 12 repetitions). Additional blood samples were drawn 30 & 60 minutes after completing the RT. Myokines were assayed using a multiplex myokine panel (Mercke). Paired t-test was used for comparing results for PWS vs controls. The unpaired t-test was used for comparing peak laboratory values with basal levels.

RESULTS: Basal levels of glucose, HbA1C, and lactate were similar for PWS & controls but CK was lower in PWS vs controls (62±54 vs 322±333 U/L, $p<0.04$).

Peak lactate was 3.7±2.2 in PWS vs 7.3±2.2 in controls ($p<0.001$). Interleukin-6 (IL-6) increased by 41±52 percent over baseline in PWS ($p<0.03$) and by 35±32 percent in controls ($p<0.007$). Following exercise, peak brain-derived neurotrophic factor (BDNF) levels were 44±47 percent over baseline in control males ($p<0.006$) but did not increase in PWS males or in females. Positive responses of BDNF and irisin were associated with greater exertion compared to non-responders. **CONCLUSIONS:** PWS young adults are capable of performing strength-building exercise. IL-6 responses to exercise were similar in both PWS and controls but BDNF increased only in control males. Further studies of myokine levels in PWS may contribute to understand unique metabolic responses in this population.

Endocrine Responses After Aerobic Exercise Under Inhibition/ Stimulation Of Hpa Axis In Healthy Adult Males.

Maria Dourida Mitarachi. *National and Kapodistrian University of Athens, Athens, Greece.* (Sponsor: Kathryn Schmitz, FACSM, FACSM)

Email: maria@mitarakis.gr

(No relevant relationships reported)

Exercise affects the homeostatic mechanisms of the human body, depending on the type, duration, intensity and frequency of exercise. The endocrine responses to acute and excessive exercise are comparable to those related to "stress". **PURPOSE:** Analysis of the hormonal responses under inhibition/stimulation conditions of the Hypothalamo-Pituitary Adrenal (HPA) axis after a selected aerobic protocol was performed in healthy male volunteers. **METHODS:** Eight healthy male volunteers (age: 29.2±3.1 yrs, body mass: 84.5±5.2kg, height: 1.81±0.03m) performed a single bout of 30 min aerobic exercise at 70% VO_{2max} on a treadmill, on three different conditions [control, HPA axis inhibition (induced by exogenous glucocorticoid administration), HPA axis stimulation (induced by exogenous ACTH administration)], following standard diet. Blood samples were collected before (t0), at the end of the exercise bout (t30), and 30 min later (t60). Serum cortisol (COR), adrenocorticotropic hormone (ACTH) and growth hormone (GH) were measured. Two-way ANOVAs were used for statistics. Data are presented as mean±SE. **RESULTS:** COR levels significantly decreased 30 min after exercise ($p<0.05$) (13.2±1.4; 10.8±1.5; 7.2±1.6 µg/dl; at t0, t30 and t60, respectively). ACTH significantly decreased 30 min after exercise ($p<0.01$) (25.2±2.9; 20±2.9; 15.7±2.1 pg/ml; at t0, t30 and t60, respectively). GH significantly increased after exercise ($p<0.05$) (0.1±0.1; 5.7±1.2; 2.3±1.1 ng/ml; at t0, t30 and t60, respectively). Under HPA axis stimulation conditions, COR significantly increased immediately after exercise ($p<0.001$) and remained increased 30 min after exercise ($p<0.001$) (15.7±1.6; 30.8±1.2; 32.4±5.4 µg/dl; at t0, t30 and t60, respectively). GH significantly increased immediately after exercise ($p<0.001$) and decreased 30 min after exercise (0.1±0.1; 9.4±3.5; 3.2±1.2 ng/ml; at t0, t30 and t60, respectively). This decrease between the end of exercise (t30) and 30 min after exercise (t60) was significant ($p<0.01$). **CONCLUSION:** This exercise regimen does not appear to trigger significant effects on the stress axis other than an HPA axis-independent increase of GH. Prescription of specific training programs should be characterised by stress-induced parameters before recommended for healthy and diseased population groups.

Modeling Growth Hormone Dynamics through Indices of Cardiac Control at Rest and Exercise

Nathaniel T. Berry, Chris K. Rhea, Laurie Wideman, FACSM. *University of North Carolina at Greensboro, Greensboro, NC.* (Sponsor: Laurie Wideman, FACSM)

Email: nberry11@gmail.com

(No relevant relationships reported)

Growth hormone (GH) is released in a pulsatile manner from the anterior pituitary and these secretory dynamics provide important context to the functioning of the hypothalamic-pituitary (HP) axis. Similarly, heart rate variability (HRV) provides important context to cardiac control. These two systems are often investigated separately, however, evidence suggests that they share a common attractor. The **PURPOSE** was to examine how changes in cardiac-dynamics during daytime hours during rest and exercise could be used to predict GH output through machine-learning algorithms. **METHODS:** Seven-healthy males (25.4±2.6 yr, 174.7±7.8 cm) completed two 24hr profiles separated by a minimum of 8-weeks. Participants were randomly assigned to an exercise (5x30s sprints; 3-min of rec) and resting condition [Exercise: 71.2±10.8 kg, 9.8±3.3 %BF, VO_{2max} 71.2±11.2 ml/kg/min; Rest: 69.8±12.1 kg, 9.0±2.7 %BF, VO_{2max} 67.8±9.0 ml/kg/min]. Serum was collected via intravenous catheter every 10-min and RR-intervals were collected continuously. The 24hr RR-interval was split into 3-min epochs taken every 10-min throughout the 24hr period; providing an index of acute cardiac regulation throughout the 24hr period. The sample entropy of each of these epochs was used to create an additional time-series (SampEn_{EP}) that was used to predict changes in GH output. A long-short-term-memory (LSTM) network was

used to model and predict GH output over time. The LSTM was trained on the first 14hr of each of the exercise and resting profiles using lagged GH and $SampEn_{Exp}$. Five iterations of each model were run and the root mean square of the error (RMS) from each of these iterations were compared across conditions. RESULTS: The LSTM models trained on the exercise profiles provided significantly better fit compared to the resting condition ($RMS_{EX}=0.28\pm 0.29$; $RMS_{REST}=0.41\pm 0.26$; $p=0.02$), resulting in more accurate prediction of the nighttime changes in GH than resting profiles. CONCLUSIONS: The ability of these models to learn the relationship and accurately predict GH output based on the patterned regulation of cardiac control throughout the day represents a shared hierarchical regulation between the HP and cardiac axes. These methods capture the more rapid time-dependent relationships that are currently missed with common assessment techniques.

Evidence tying ultraviolet (UV) light exposure to endogenous vitamin D synthesis presents a possibility for naturally enhancing serum testosterone via endogenous vitamin D. PURPOSE: 1) Determine the effect of an acute bout of UV light exposure on post-resistance exercise serum testosterone in older men and, 2) to investigate whether serum testosterone was influenced by endogenous vitamin D. METHODS: Six older adult men (age 62 ± 1.79 yrs., height 179.92 ± 1.12 cm., body mass 83.79 ± 3.12 kg., BMI 25.95 ± 1.15 kg/m²) participated in two identical resistance exercise sessions followed by a 30-minute recovery. Sessions were approximately one week apart and the exercise protocol consisted of 4 sets of 10 repetitions of leg press, chest press, and back row with one minute of rest between sets. After the second exercise session, participants were exposed to an UV light source during the first 10 minutes of recovery. Serum testosterone and vitamin-D were measured pre- and post-resistance exercise in 5-minute increments during the 30-minute recovery. RESULTS: Exercise alone did not significantly affect serum testosterone or vitamin D. Exercise combined with acute UV light exposure significantly increased serum testosterone area under the curve ($p<0.05$) but did not significantly alter serum vitamin D. CONCLUSION: These findings suggest that acute UV light exposure may positively impact serum testosterone response following a single bout of resistance exercise in older adult men.

Effects Of Exercise On The Expression Changes Of Kiss-1/gpr54 In Testis Of Rats In Growth Phase

JUNPENG FENG, YI YAN. *BEIJING SPORT UNIVERSITY, BEIJING, China.*

Email: bsufengjunpeng@163.com

(No relevant relationships reported)

PURPOSE: To investigate the localization and expression level of KISS-1/GPR54 in testis and effects of exercise during the growth period of male rats. METHODS: 21D old weanling rats were randomly divided into group C (n=60) and group CE (n=65). CE group took 5-weeks trained (60-70% vVO₂max, 1h/day, 5days/week). The rats of two groups were killed on the 21st D, 35th D, 43rd D, and 56th D old. The localization, mRNA expression and protein expression of KISS-1/GPR54 in the testis of each group were tested. RESULTS: From 21st D to 56th D, KISS-1 and GPR54 were expressed firstly in rat testicular Spermatogenic cells, and then they expressed both in Spermatogenic cells and Leydig cells. Following the growth, the expression of testis KISS-1 mRNA peaked at 35D, ($p < 0.01$), and then decreased without significantly difference. But the protein level of Kiss-1 increased continuously and peaked at 56D ($p < 0.01$). The expression of GPR54 mRNA and protein peaked at 43D ($p < 0.01$), and then decreased without significantly difference. Exercise intervention had no effect on the localization of KISS-1 and GPR54, but induced the decrease of KISS-1 and GPR54 mRNA during the growth period, which were no significant difference compared with group C. After exercise intervention, the expression of KISS-1 protein in rats testis in each time point had the same trend as group C, but the expression level were significantly lower than group C ($p < 0.01$). The expression of GPR54 protein in rats testis of group CE were almost unchanged from 21D to 35D and increased significantly from 35D to 43D, then decreased from 43D to 56D. The GPR54 protein of 56th D was significantly lower than that of group C at 56th day ($p<0.01$). CONCLUSIONS: During the growth period, the localization of KISS-1 and GPR54 expressed have stage characteristics, and the expression level of KISS-1 and GPR54 increases gradually, with some temporal characteristics. Although exercise will not influence the change trends of KISS-1 and GPR54, it will decrease their level.

2100 Board #256 May 30 3:30 PM - 5:00 PM
Effects Of Exercise On Hypothalamic Kisspeptin/gpr54 Signaling Pathway Of High-fat-diet-feeding Growing Rats

Yi Yan, XU Rui. *Beijing Sport University, Beijing, China.*

Email: yanyi22@sina.com

(No relevant relationships reported)

Hypothalamic Kisspeptin/GPR54 system is the "control switch" for the onset of puberty. Obesity induced by high-fat diet and/or physical inactivity is a leading cause of precocious puberty. PURPOSE: To observe the effect of high-fat diet on the hypothalamic expression of KiSS-1, the G-protein coupled receptor (GPR) 54 and GnRH mRNA and explore the modulatory role of moderate-intensity exercise in the high-fat-diet feeding male rats, which are in growth period. METHODS: Male weanling rats (21std) were fed high-fat-die were randomly assigned to chow diet sedentary (CS, n=24), chow diet exercise (CE, n=24) and high-fat diet sedentary (HS, n=24), high-fat diet exercise (HE, n=24) groups. SE and FE groups did the 60%-70% V(•)O₂ max treadmill training (5 days/week, 1 hour/day). The V(•)O₂ max of exercise groups were remeasured every two weeks. 6 rats of each group were killed on the 35th day, 42nd day and 56th day. The hypothalamic expression of KiSS-1, GPR54 and GnRH mRNA were tested in each group. RESULTS: During the growth period, the Kiss-1 mRNA of FS group increased continuously, which was opposed with CS group. The GPR54 mRNA of FS group got to the maximum level on 42nd day, which was similar with CS group. Both in CS and FS groups, GnRH mRNA decreased significantly before 56th day, which had the trend of increase. Both in CE and HE groups, the mRNA of Kiss-1 and GPR54 got the maximum levels on 42nd day, which opposed with the lowest level of GnRH mRNA. CONCLUSIONS: The changed trend of kisspeptin/GPR54 signaling pathway during the growth period were obvious increase in high-fat diet rats. Exercise could change the trend of kisspeptin/GPR54 signaling pathway induced by high-fat diet especially after puberty.

2101 Board #257 May 30 3:30 PM - 5:00 PM
Salivary and Serum Cortisol Proportion Dynamics Are Impacted by High-Intensity Exercise

Travis Anderson, Nathaniel T. Berry, Laurie Wideman, FACSM. *University of North Carolina at Greensboro, Greensboro, NC.*

Email: t_ander2@uncg.edu

(No relevant relationships reported)

Salivary cortisol (C_{sal}) represents the free cortisol concentration of serum cortisol (C_{ser}). It has been suggested that C_{sal} is approximately 5-10% of total C_{ser} , however, the impact of diurnal variation in C_{sal} and how this pattern affects the proportion of C_{ser} and C_{sal} (C_{prop}), has yet to be explored. PURPOSE: Therefore, the purpose of this study was to assess the diurnal changes of C_{sal} , and the extent to which a high-intensity exercise bout may impact this relationship. METHODS: Male (n = 7) college-aged students (26.3 ± 2.8 yrs, 176.5 ± 8.1 cm, 73.6 ± 12.6 kg, 9.9 ± 3.2 BF(%), VO_{2max} : 68.9 ± 9.5 ml.kg⁻¹.min⁻¹) completed two 24-hour (rest and exercise) cortisol profiles. Subjects had a catheter inserted at 0600hr and blood and saliva samples were collected simultaneously every 120 mins. During the exercise condition, subjects performed 5x30s sprinting intervals on the cycle ergometer, at a resistance of 7.5% of body mass. Subjects were permitted 3-min of passive recovery between bouts. C_{sal} and C_{ser} were analyzed via competitive-binding assay. C_{prop} was calculated as proportion of C_{sal} relative to C_{ser} at each time point. Multilevel growth models with varying fixed/random coefficients were tested and compared (AIC). The final cubic growth model controlled for condition and freely estimated the intercept, velocity, and acceleration terms while the initial trajectory of C_{prop} was fixed across all individuals. RESULTS: The IQR of C_{prop} was 3.56-6.29%. The greatest C_{prop} values were consistently observed during nighttime sampling with the magnitude of C_{prop} being greatest at 2300hr. The cubic growth models were determined to best-represent 24-hr changes in C_{prop} . The final model showed a significant effect for exercise ($\beta = -1.37$, $p = 0.036$; AIC = 1030.781). CONCLUSION: The greatest C_{prop} at 2300hr appears to be driven primarily by elevations in C_{sal} . This shift may be influenced by night time cortisol secretion interactions with binding proteins, alterations in salivary flow rate, or salivary gland enzymatic activity. Exercise appears to influence C_{prop} dynamics, especially during late afternoon and nighttime hours. It is therefore recommended that cortisol profiles be constructed from both total and free C_{ser} for the most accurate monitoring of the HPA-axis, especially within an exercise context.

Effect of the Menopausal Transition on Physical Performance: A Longitudinal Study

Dmitriy Bondarev¹, Tajja Finni¹, Pauliina Aukee², Katja Kokko¹, Urho M. Kujala¹, Vuokko Kovanen¹, Eija K. Laakkonen¹, Sarianna Sipilä¹. ¹University of Jyväskylä, Jyväskylä, Finland. ²Central Finland Central Hospital, Jyväskylä, Finland.
Email: dmitriy.d.bondarev@jyu.fi
(No relevant relationships reported)

Low muscle strength and decline in the power are associated with low walking speed and with mobility limitations, disabilities and falls among older populations. Whether menopause per se accelerates decline in physical performance in women and in this way contributes to functional limitations in later years remains controversial. **PURPOSE:** The aim of this study was to examine changes in physical performance in women aged 47 to 55 following the menopausal transition. **METHODS:** This longitudinal study is a part of the Estrogenic Regulation of Muscle Apoptosis study. Women aged 47 to 55 were randomly selected from the Finnish National Registry ($n=6878$) and perimenopausal women ($n=228$) were followed until postmenopausal. The baseline menopausal status was defined based on menstrual cycle diary and follicle stimulating hormone (FSH) level. The progression of menopausal transition was followed at three-to-six months' intervals for early perimenopausal and late perimenopausal women, respectively. When FSH >30 IU/l was recorded, the measurement was repeated within two-to-four weeks and if FSH was determined in two consecutive blood samples to be elevated and no bleeding had occurred in past 6 months participant was considered to be postmenopausal. To capture a comprehensive understanding of the physical performance, measures of muscle power (vertical jump), muscle strength (grip and knee extension), aerobic capacity (6min walking distance), and walking speed were carried out. **RESULTS:** A significant decline in hand grip force for -2.9 % (95%CI -4.5, -1.1; $d=0.20$) in knee extension force for -3.1% (95%CI -4.8, -1.3; $d=0.23$) and in vertical jumping height for -3.24 % (95CI -4.6, -1.7; $d=0.28$) was observed following the menopausal transition. Walking distance significantly increased for 1.9 % (95%CI 1.2, 2.7, $d=0.38$) while in walking speed changes were 0.24 % (95%CI -1.1, 1.6; $d=0.02$) non-significant. **CONCLUSIONS:** The menopausal transition influences muscle strength and power, whereas the influence on mobility/ walking was less evident and may follow after. Supported by the funding from the European Union's Horizon 2020 research and innovation Programme under the Marie Skłodowska-Curie grant agreement No675003, and by the Academy of Finland (ERMA study grant agreement 275323).

The Relationship Between Oral Contraceptive Use With Total Hydroxyvitamin D And Its Metabolites In Young Adult Women

Julie P. Greeves¹, Jonathan CY Tang², Sarah Jackson¹, Neil P. Walsh, FACSM², Rachel M. Izard⁴, William D. Fraser². ¹Army Headquarters, Andover, United Kingdom. ²University of East Anglia, Norwich, United Kingdom. ³Bangor University, Bangor, United Kingdom. ⁴Army Recruiting and Initial Training Command, Upavon, United Kingdom. (Sponsor: Professor Neil Walsh, FACSM)
Email: julie.greeves143@mod.gov.uk
(No relevant relationships reported)

Vitamin D deficiency, defined as total hydroxyvitamin D (25(OH)D) <50 nmol/L, is associated with poor bone health, impaired muscle function and increased risk of some diseases. The biologically active form of vitamin D is dihydroxyvitamin D (1,25(OH)₂D), but there is emerging evidence that the relative proportion of 1,25(OH)₂D to the catabolic metabolite (24,25(OH)₂D) determines biological activity. In women, higher 25(OH)D concentrations have been reported in oral contraceptive pill (OCP) users, but the influence of OCP and other hormonal contraceptives (HC) on vitamin D metabolites and their ratio is unknown. **PURPOSE:** To examine the relationship between vitamin D metabolites, the vitamin D metabolite ratio (VMR) and HC use in young adult women. **METHODS:** 512 female Army recruits, mean (SD) age 23 (3.2) years, height 1.66 (0.06) m, and body mass 64.8 (7.9) kg, volunteered to provide a venous blood sample at the start of basic military training. Samples were analysed for 25(OH)D, 1,25(OH)₂D, 24,25(OH)₂D, intact parathyroid hormone (iPTH), and albumin adjusted calcium (aCa). Participants had passed Army selection including medical screening and physical performance testing. Hormonal contraceptive use was assessed by questionnaire, and later verified from medical records. **RESULTS:** 163 women using vitamin D supplements were excluded from the analysis. Remaining participants were subdivided into groups: no-HC ($n=157$); OCP ($n=95$); progesterone-only pill (POP, $n=25$); injection ($n=13$); and, implant ($n=59$). There were no differences in participant characteristics between groups ($p>0.05$). Compared with no-HC, OCP users had higher 25(OH)D (61 (28) vs 73 (31) nmol/L), 1,25(OH)₂D (159 (38) vs 177 (50) pmol/L), 24,25(OH)₂D (6 (3) vs 7 (4) nmol/L), and lower iPTH (3.64 (1.04) vs 3.22 (1.05) pmol/L) ($p<0.01$). There were no differences in the VMR (25(OH)

D:24,25(OH)₂D and 1,25(OH)₂D:24,25(OH)₂D), or in aCa, between groups ($p>0.05$). iPTH and 25(OH)D:24,25(OH)₂D VMR were lower, and aCa was higher, in POP than in no-HC users ($p<0.05$). **CONCLUSION:** Oral contraceptive pill users have higher 25(OH)D, possibly from the stimulation of vitamin D binding protein and increased bioavailability of 25(OH)D, but the balance between the active and catabolic vitamin D metabolites is not dependent on HC use.

2104 Board #260 May 30 3:30 PM - 5:00 PM

Changes in Salivary Cortisol and Iga Levels are Associated with Fatigue after Acute Endurance Exercise.

Natsuka Hashizume¹, Natsuki Hasegawa¹, Naoki Horii¹, Maki Yoshikawa¹, Katsunori Tsuji², Masataka Uchida¹, Keiko Iemitsu¹, Takeshi Hashimoto¹, Kiyoshi Sanada¹, Masao Kanamori¹, Kohei Watanabe³, Motoyuki Iemitsu¹. ¹Ritsumeikan University, Kusatu, Japan. ²National Cancer Center Research Institute, Tokyo, Japan. ³Chukyo University, Aichi, Japan.
(No relevant relationships reported)

Several studies have investigated markers for exercise-induced fatigue. Physical and mental fatigues induce a secretion of salivary cortisol, and this hormone affects immunosuppression such as reduction of salivary immunoglobulin A (IgA) secretion. However, it is unclear whether the secretions of salivary cortisol and IgA levels in response to different exercise volumes are related to subjective fatigue and exercise performance. **PURPOSE:** The aim of this study was to investigate relationships among salivary cortisol and IgA levels, subjective fatigue, and exercise performance after acute endurance exercise.

METHODS: Nine healthy young males voluntarily participated in this study. All subjects randomly performed the following three sessions: cycling exercise at 70% VO₂max for 20-min (20-min session), cycling exercise at 70% VO₂max until exhaustion (exhaustive session), and resting control for 20-min (resting session). Salivary cortisol and IgA levels, visual analog scale on subjective fatigue, and maximum voluntary contraction (MVC) in knee extensor muscle groups were measured before and immediately, 30, 60, and 120 min and 24 hours after each session.

RESULTS: In the 20-min and exhaustive sessions, subjective fatigue increased at immediately after exercise and decreased 60, 120 min and 24 hours after exercise. However, MVC showed no change throughout the all sessions. In the resting sessions, no significant differences in salivary cortisol levels before and after exercise were observed. In the 20-min and exhaustive sessions, salivary cortisol levels were significantly higher 30 min after exercise as compared with before exercise and after then gradually decreased until 120 min after exercise. ($p<0.05$). No significant differences in salivary IgA levels before and after exercise were observed in all sessions. Additionally, salivary cortisol and IgA levels were positively correlated with the subjective fatigue (cortisol; $r=0.243$, $p<0.05$, IgA; $r=0.167$, $p<0.05$), but were not correlated with the MVC.

CONCLUSIONS: These findings suggest that the changes in salivary cortisol and IgA levels may be related to increase in acute exercise-induced subjective fatigue. Supported by Grants-in-Aid for Scientific Research (#17H02182 and #16K13059, M. Iemitsu).

Body Height Trajectories in Pediatric Competitive Athletes

Gal Dubnov-Raz¹, Ran Efrati², Shiran Leib², Amir Rimon², Miri Gelbart², Yoni Yarom³, Tomer Ziv-Baran². ¹Sheba Medical Center, Tel Hashomer, Israel. ²Tel Aviv University, Tel Aviv, Israel. ³Medix Sport Medicine Center, Tel Aviv, Israel.
Email: gal-d@bezeqint.net
(No relevant relationships reported)

PURPOSE: There is a significant concern that competitive sports in children and adolescents might hinder growth. Currently available data are limited and conflicting. The purpose of this study was to examine the trajectories of body height in competitive pediatric athletes.

METHODS: Data on all child and adolescent athletes that underwent annual pre-participation examinations in a sports medicine center from 2007-2018 were extracted. Data included sport type, age, sex, weight and height. Height was transformed to age-

and sex- specific standard deviation scores (SDS) using the CDC growth charts. In athletes with >1 examination, generalized estimating equations were used for repeated measures analyses of height SDS changes over time.

RESULTS: Data on 2,287 athletes were available, of which 693 had >1 height measurement and formed the study population (70.4% males, mean age 11.5±2.4 years, range 6-18, from 46 sport types). The median duration between the first and last examinations was 1.9 years (IQR 0.99-2.93 years) with a maximum of 9.3 years. Height SDS was not significantly changed throughout the follow-up period in the total cohort (-0.13 per year, 95%CI -0.52-0.03, p=0.51), see Figure. In subgroup analyses, no significant change in height SDS was seen among athletes aggregated from classic height-advantageous sports (basketball, volleyball, tennis and swimming, p=0.73), basketball players (p=0.84) or gymnasts (p=0.24). No significant change in height SDS over time was seen when participants were stratified by first measurement age (<9, 9-12, 12+ years) and sex.

CONCLUSIONS: In this large cohort of pediatric athletes with repeated physical examinations, competitive sports were not associated with significant changes in body height relative to age. This finding remained true regardless of age at first measurement and sex, as well as when focusing on sports with typically tall or short statures. Competitive sports do not seem to hinder growth in children.

2106 Board #262 May 30 3:30 PM - 5:00 PM
Effects Of Collagen Gene Polymorphisms On Ligament Injury In Weight-lifting Athletes

Yusuke Sekimoto, Yota keduka, Yuto Mizutome, Keisuke Takahashi, Naoki Kikuchi. *Nippon sport science university, Tokyo, Japan.*
 Email: sport-0411yu@outlook.jp
 (No relevant relationships reported)

Previous studies have been reported that polymorphism is associated with injury in athlete and general populations. Some studies suggested that COL5A1 polymorphism is one of the risk factors of ligament and tendon injury in professional soccer players and others.**PURPOSE:** To investigate the association between COL1A1, COL5A1, COL11A1 and COL22A1 gene polymorphisms and ligament injury in Japanese weight-lifting athletes.

METHODS: A total of 174 Japanese weight-lifting athletes (Male: n=111, Height: 168.4 ± 6.8. Weight: 81.0±18.8, Age: 21.3 ± 6.2, Female: n=63, Height: 153.8 ± 20.2, Weight: 61.9 ± 11.0, Age: 20.5 ± 3.1) participated in present study. Subjects were divided into 2 groups based on their results of questioners (ligament injury group and no ligament injury group). Genotyping results were analyzed using the TaqMan approach for the COL1A1, COL5A1, COL11A1 and COL22A1 polymorphism.

RESULTS: the genotype frequency of the CC, CT, and TT genotypes in the COL5A1 gene were 0, 29 and 71 % in the no injury group and 5, 28, and 67 % in the injury group. COL5A1 CC genotype frequency was lower tendency in no injury group compared with injury group. However, there was no significant association between COL1A1, COL5A1, COL11A1, COL22A1 polymorphisms and ligament injury.

CONCLUSIONS: Our results suggested that COL5A1 CC genotype has tendency of low risk factor of ligament injury, however, there is no association between Each polymorphisms and ligament injury in Japanese weight-lifting athletes.

The Effect Of FTO rs9969309 Polymorphism On Body Composition in Chinese adults

Chunbo Qin¹, Xi Jin², Ji Li¹, Daixi Xie¹, Xin Zhao³, Mark Loftin, FACSM². ¹Shenzhen University, Shenzhen, China. ²The University of Mississippi, University, MS. ³The Sixth Hospital of Shenzhen, Shenzhen, China. (Sponsor: Mark Loftin, FACSM)
 Email: 67696054@qq.com
 (No relevant relationships reported)

The FTO (fat mass and obesity associated) gene, the first common obesity susceptibility gene in a Caucasian population, was reported by GWAS (genome-wide association studies) in 2007. **PURPOSE:** The aim of this study was to explore the effect of genotypes of FTO rs9969309 polymorphism on body composition related traits in Chinese adults. **METHODS:** Forty-three Chinese adults aged from 19 to 55 years old (32 males and 11 females) were recruited from Shenzhen University and a running club of local community. The subjects participated in physical activity at least three times per week with thirty minutes each session. Body composition related traits, including body weight (BW), hip circumference (HC), abdomen circumference (AC), waist-hip ratio (WHR), percentage of body fat (PBF), fat mass (FM), fat free mass (FFM) and body mass index (BMI), were analyzed by bioelectrical impedance analyzer (BH-380 in Beijing Acemeway Company). The genotypes of FTO rs9969309 were analyzed by the Beijing Genomics Institute. One-way ANOVA was used to compare between genotypes and body composition related data. **RESULTS:** There were three genotypes (TT, AT and AA) in rs9969309 polymorphism, in which 24 individuals with TT genotype, 16 individuals with AT genotype and 3 individuals with AA genotype. The body composition related traits, including HC, AC, BMI and FM, were significantly lower in TT genotypes than those in AA genotypes (p=0.017, p=0.004, p=0.002, p=0.006, respectively), and were significantly lower in TT genotypes than those in AT genotypes (p=0.025, p=0.023, p=0.010, p=0.041, respectively). Also, there was a significant difference only between TT and AA genotypes in WHR (p=0.015). No significant differences were found in the three genotypes with BW, PBF and FFM. **CONCLUSION:** The results indicate differences in several body composition parameters regarding the FTO rs9969309 polymorphism in a small sample of Chinese adults.

The Association Between Mct1 T1470a And Ace I/d Polymorphisms And Athletic Status In Climbing Athletes

Mika Saito, Jou Takahira, Sakura Daiku, Souichiro Miyauchi, Naoki Kikuchi. *Nippon sport science university, Tokyo, Japan.*
 Email: sa123ka.v@gmail.com
 (No relevant relationships reported)

Previous studies have shown a relationship between MCT1 T1470A polymorphism and blood lactate concentration during and after high-intensity intermittent exercise. In addition, the I allele seems associated with endurance-orientated events, while the D allele seems like to be the opposite with power- orientated events in the ACE I/D polymorphism. Sports climbing also required muscle power and endurance performance, therefore we hypothesis that MCT1 T1470A and ACE I/D polymorphisms associated with athletic performance in climbing athletes.

PURPOSE: To investigate the effects of the MCT1 T1470A and ACE I/D polymorphisms on athletic achievements (national or regional level) in climbing athletes.

METHODS: Sixty-nine climbers (49 men and 20 women) were genotyped for the MCT1 T1470A genotype (rs1049434) and ACE I/D (rs4341) using the TaqMan@Assay. All climbers were assigned to two groups (35 national level climbers and 34 regional level Climbers) based on their results of competitions.

RESULTS: The genotype frequency of the AA, TA, and TT genotypes in the MCT1 gene were 43%, 49% and 8% in the national level and 44%, 32%, and 24% in regional level. TT genotype frequency was lower tendency in national level athletes (8%) compared with regional level athletes (24%) (P=0.089). The genotype frequency of the DD, ID, and II genotypes in the ACE I/D gene were 16%, 38% and 46% in the national level and 3%, 38%, and 59% in regional level. There was no significant differences of frequency of the DD, ID, and II genotypes in the ACE I/D.

CONCLUSIONS: Conclusions: results were suggested that MCT1 T1470A polymorphism may associated with athletic performance in climbing athletes. The MCT1 T1470A and ACE I/D genotypes can provide useful information (e.g., talent selection and genotype-based customization for training) for athletes, especially well-trained men and their strength and conditioning coaches and sports coaches.

2109 Board #265 May 30 3:30 PM - 5:00 PM
Association Between Mitochondrial Dna Sequence, Heteroplasmy, And Indels With Response To Aerobic Exercise Training

Heather L. Vellers¹, Kirsten C. Verhein², Steven R. Kleebarger², Adam B. Burkholder², J. Timothy Lightfoot, FACSM³, Jacqui Marzec², Claude Bouchard, FACSM⁴. ¹Texas Tech University, Lubbock, TX. ²National Institute of Environmental Health Sciences, Research Triangle Park, NC. ³Texas A&M University, College Station, TX. ⁴Pennington Biomedical Research Center, Baton Rouge, LA. (Sponsor: J. Timothy Lightfoot, Ph.D., FACSM)
 Email: Heather.Vellers@ttu.edu
 (No relevant relationships reported)

PURPOSE: Aerobic exercise training provides numerous biological and physiological health benefits towards the prevention and treatment of various chronic diseases. However, not all individuals increase cardiorespiratory fitness (CRF) with exposure to a given dose of aerobic training: some individuals are highly trainable and increase CRF, while others respond poorly. Genetic background is known to contribute to interindividual variation in adaptations to aerobic training. Our current understanding of genetics and exercise is limited primarily to the nuclear genome as only a few laboratories have investigated the role of the mitochondrial genome. The purpose of this study was to determine whether mitochondrial DNA (mtDNA) sequence, heteroplasmy, and indels differed among individuals previously characterized as elite endurance athletes, and high- or low-responders to aerobic training.

METHODS: DNA was isolated from whole blood in healthy subjects part of the GENATHLETE (world class endurance athletes; n=15) and HERITAGE (CRF response levels: high responders n=15; low responders n=15) study cohorts. mtDNA was amplified by long-range polymerase chain reaction, then tagged with Nextera libraries and sequenced on a Miseq instrument. Unique mtDNA sequence variants were called when at least two individuals in a group had the variant.

RESULTS: Compared to athletes and high-responders, low-responders had unique mtDNA single nucleotide polymorphisms (SNPs) in D-loop (displacement-loop) hypervariable region (HVR) 2 at positions 72, 152, 185, 188, 228, 295, 462, and 489. Of the HVR2 positions, position 188 was unique only to low-responders. Indels were unique to athletes and high-responders and located in D-loop HVRI (16179, 16182, 16188, 16192), HVR2 (302), and HVR3 (567) positions. mtDNA Heteroplasmy was not different between groups.

CONCLUSIONS: Our results highlight an area of the mitochondrial genome responsible for DNA replication and transcription that may contribute to an individual's ability to improve CRF with aerobic training. Ongoing work aims to 1) confirm present findings in low responders through increasing sample size from the HERITAGE cohort, and 2) test for interactions between mitochondrial and nuclear genomes associated with response to a given dose of aerobic training.

Circulating DNA As A Monitoring Tool In Professional Soccer

Nils Haller, Tobias Ehlert, Sebastian Schmidt, Perikles Simon. *Sports Medicine, Mainz, Germany.*
 Email: nhaller@uni-mainz.de
 (No relevant relationships reported)

PURPOSE: Player monitoring in elite sports settings is becoming increasingly important. Questionnaires or biomarkers, such as circulating, cell-free DNA (cfDNA) are possible approaches for load monitoring. cfDNA concentrations were shown to increase dependent on total distance covered in soccer and cfDNA was associated with overtraining in weightlifters. Thus, the purpose of this study was to examine whether cfDNA is feasible as a monitoring tool in elite soccer Players.

METHODS: Capillary blood from 22 elite male soccer players was collected on 40 time points during 4 months of a regular season. Moreover, 2 time points during pre-season were included. Blood samples were drawn on the day before and on days after season games. Players filled in a Visual-Analogue-Scale questionnaire (VAS) including the items "general perceived exertion" and "muscular fatigue". Performance was recorded by a GPS based (training) or a camera based (games) tracking system.

RESULTS: We observed a significant increase in mean cfDNA concentrations from the start of pre-season to the end of pre-season (1.6-fold, p=0.02). Moreover, cfDNA concentrations were significantly elevated in players on the day after regular season games (1.4-fold; p<0.001) in line with the VAS scores. cfDNA showed significantly higher values during weeks that included an additional midweek game (1.3-fold, p<0.001). While cfDNA concentrations correlated with performance data of the training, the VAS scores were correlated with the tracking of the season games. However, cfDNA concentrations and VAS scores did not significantly correlate with each other.

CONCLUSIONS: Here, we show that cfDNA concentrations at rest and VAS scores are influenced by previous load in professional soccer players. Moreover, a higher load

due an additional midweek game led to significantly higher cfDNA concentrations. Future studies will reveal the full potential of cfDNA as a monitoring tool for player load in soccer Players.

 (No relevant relationships reported)

Endurance-oriented athletes have a high proportion of slow-twitch muscle fibers (MF), whereas muscles of sprinters and strength athletes predominantly consist of fast-twitch MF. The heritability of the MF composition was estimated at 45%.

PURPOSE: To perform a genome-wide association study for MF composition and to validate the results in additional studies using sport-related phenotypes. **METHODS:** MF composition of M. vastus lateralis in 168 physically active healthy Russian subjects (55 females, 113 males) was evaluated with immunohistochemistry. The case-control study involved 241 elite Russian athletes (89 sprinters, 49 strength athletes vs 103 endurance athletes). Twenty male wrestlers participated in the Wingate anaerobic test. Micro-array analysis (for detection of 700 K - 1.1 M single nucleotide polymorphisms (SNPs)) or whole-genome sequencing (wrestlers only) was used for genotyping. **RESULTS:** We first identified 929 SNPs that were associated (P<0.05) with the proportion of fast-twitch MF both in males and females. Next, we found that of the 929 SNPs, 37 variants were associated with sprinter athlete status (i.e. alleles associated with increased proportion of fast-twitch MF were over-represented in sprinters compared to endurance athletes). Of those, sprinter-related alleles of 4 SNPs (rs7669580, rs1247330, rs2048968, rs2369665) were also over-represented in strength athletes (vs endurance athletes). Only rs7669580 SNP located in the *LDB2* gene (encodes cytoskeletal protein) was found to be associated with the relative peak power in wrestlers. **CONCLUSION:** We have identified the A allele of the *LDB2* rs7669580 SNP that was associated with increased proportion of fast-twitch MF (P=0.00046), ability to become a sprinter (P=0.021) or a strength athlete (P=0.016) and increased peak power of wrestlers (P=0.0187). The study was supported by grant from the Russian Science Foundation (Grant 17-15-01436).

2112 Board #268 May 30 3:30 PM - 5:00 PM
Genetic Modulation of Hypothalamic Pituitary Adrenal Function in Specialized Military Men

Marcus K. Taylor, FACSM¹, Lisa M. Hernández¹, D Christine Laver¹, Douglas A. Granger². ¹Naval Health Research Center, San Diego, CA. ²University of California, Irvine, Irvine, CA.
 (No relevant relationships reported)

Hypothalamic-pituitary-adrenal (HPA) hormone profiles are informative mediators of health status. Existing studies link candidate genetic variants in the corticosteroid and serotonin systems to basal cortisol function in diverse populations. Potential connections of such variants to the HPA end-product, dehydroepiandrosterone (DHEA), is essentially unexamined and virtually nothing is known of their effects in military populations. **PURPOSE:** To determine whether candidate genetic variants in the mineralocorticoid receptor (MR [i.e., -2C/G]), glucocorticoid receptor (GR [i.e., BcII]), and serotonin transporter (i.e., 5HTTLPR, triallelic version) modulate daily HPA function (cortisol and DHEA) of specialized military men. **METHODS:** Seventy-three elite military men were studied (mean ± SE age = 33.2±0.7 yrs). Salivary cortisol and DHEA were collected on 2 consecutive weekdays at wake, wake + 30 min, wake + 60 min, 1600, and 2100. TaqMan® genotyping assays were performed for BcII and -2C/G. Variable number tandem repeat analyses were conducted for 5HTTLPR. Unique and combined associations of the genetic variants were assessed with respect to daily patterns of salivary cortisol and DHEA. **RESULTS:** Homozygous GG carriers of -2C/G had higher DHEA concentrations across the day in comparison to C carriers (F(1, 55) = 8.7, p = .005). Homozygous SS carriers of 5HTTLPR had higher DHEA concentrations at wake + 30 and 60 min, followed by convergence with the L carrier profile in the afternoon and evening (interaction effect, F(2.4, 132) = 4.2, p = .011).

Combined effects on DHEA patterns: $-2C/G + 5HTTLPR$ (interaction effect, $F(7.3, 126.3) = 3.7, p < .001$), $-2C/G + BclI$ (group effect, $F(3, 53) = 4.2, p = .01$), and $5HTTLPR + BclI$ (interaction effect, $F(7.8, 134.8) = 3.7, p < .001$). Salivary cortisol profiles were not modulated by candidate variants. **CONCLUSION:** Whereas MR's affinity for cortisol and aldosterone is well researched, the link between $-2C/G$ and DHEA helps to resolve equivocal literature regarding MR's potential compatibility with DHEA. Also, the connection between $5HTTLPR$ and DHEA implies the signaling between serotonergic and HPA systems extrapolates beyond the primary end-product, cortisol. Finally, this study demonstrates that genetic modulation of salivary DHEA profiles is additive, if not synergistic.

2113 Board #269 May 30 3:30 PM - 5:00 PM
Effects of Collagen Gene Polymorphisms on Tendon And Ligament Inflammations in Japanese Male Endurance Athletes.

Ayami Numa¹, Keiko Iemitsu¹, Shumpei Fujie², Natsuki Hasegawa¹, Naoki Horii¹, Masataka Uchida¹, Izumi Tabata, FACSM¹, Yasushi Shinohara¹, Motoyuki Iemitsu¹. ¹Ritsumeikan University, Kusatsu, Japan. ²University of Tsukuba, Ibaraki, Japan.
 (No relevant relationships reported)

In endurance athletes, chronic mechanical stress to tendon and ligament induces local inflammation, leading to tendon and ligament injuries. Type 1, 5 and 12 collagen is the major structural component of tendon and ligament and other component is type 3 and 6 collagen. Several studies were identified the relationship between tendon or ligament injures and collagen gene polymorphisms such as, rs1800012 in COL1A1, rs12722 and rs3196378 in COL5A1, rs1800255 in COL3A1 and rs35796750 in COL6A1. However, effect of tendon and ligament inflammations on collagen-related gene polymorphisms remains unclear in Japanese endurance athletes. **PURPOSE:** This study aimed to clarify whether single nucleotide polymorphisms (SNPs) within the collagen genes were associated with the incidence of tendon and ligament inflammations in Japanese male endurance athletes.

METHODS: Twenty-four Japanese elite male long-distance runners participated in a cross-sectional study. All subjects were investigated the onset number of tendon and ligament inflammations in the student period of the university by using a questionnaire. SNPs of rs1800012 in COL1A1 gene, rs12722 and rs3196378 in COL5A1 gene, rs1800255 in COL3A1 gene and rs35796750 in COL6A1 gene were determined by real-time PCR with Taqman probe.

RESULTS: All subjects had GG genotype of rs1800012 in COL1A1 gene. The onset number of tendon and ligament inflammations in the student period of the university was significantly higher in CC genotype of rs12722 in COL5A1 gene as compared with CT and TT genotype individuals ($P < 0.05$) and was significantly higher in CC genotype of rs3196378 in COL5A1 gene as compared with CA and AA genotypes individuals ($P < 0.05$). Moreover, the onset number of tendon and ligament inflammations in the AA and AG genotype of rs1800255 in COL3A1 gene was tended to be higher than that in GG genotype individuals ($P = 0.078$). However, the rs35796750 in COL6A1 gene polymorphism had no impact on differences of the onset number of tendon and ligament inflammations.

CONCLUSIONS: These results suggest that SNPs of rs12722 and rs3196378 in COL5A1 gene and rs1800255 in COL3A1 gene may affect incidence of tendon and ligament inflammations in Japanese male endurance athletes. Supported by Grants-in-Aid for Scientific Research (#17H02182 and #16K13059, M. Iemitsu).

2114 Board #270 May 30 3:30 PM - 5:00 PM
KCNA4 Gene Variant is Auxiliary in the Complex Phenotype of Endurance Running Performance Level

Keven Flecha-Velazquez¹, Thomas D. Fahey², Juan L. Martinez-Barreda³, Juan R. Lopez-Taylor⁴, Miguel A. Rivera¹. ¹University of Puerto Rico, San Juan, Puerto Rico. ²California State University, Chico, Chico, CA. ³Hospital Civil de Culiacan, Culiacan, Mexico. ⁴University of Guadalajara, Guadalajara, Mexico.
 (No relevant relationships reported)

To the best of our knowledge, the pertaining sources of information on the Potassium Voltage-Gated Channel Subfamily A Member 4 (KCNA4) gene do not evidence a single study evaluating the possible association between its genotypic and allelic frequencies with endurance performance. **PURPOSE:** We tested the hypothesis of an association between the prevalence of the genotypic and allelic frequencies distribution of the KCNA4 gene rs1323860 (C/T transition) and endurance performance level in Hispanic male marathon runners (MR). **METHODS:** The present is an observational study following a genetic epidemiology model using a case-control design. The subjects (n=1876) were adult Hispanic male MR. Fast-MR (Cases; n=938) were finishers in the top 3rd percentile. Slow MR (Controls; n=938) were finishers in the lowest 3rd percentile of their respective age. Genomic DNA was purified from a whole blood sample. Polymerase chain reaction was used to amplify a KCNA4 SNP which

consists of a C/T (rs1323860) transition. The observed genotype frequencies, in both Cases and Controls, met Hardy-Weinberg equilibrium (χ^2, P **RESULTS:** Genotype and allele frequencies were statistically different ($P < 0.01$) between cases and controls. Odds ratio revealed that the C allele was 1.33 times more likely prevalent in the cases than in the controls (95% CI; 1.17, 1.51; $P < 0.001$). The magnitude of the statistical power for the present study was 0.86. **CONCLUSIONS:** The findings strongly suggest that KCNA4 gene rs1323860 (C/T transition) is auxiliary in the complex phenotype of endurance running performance level in Hispanic male marathon runners.

2115 Board #271 May 30 3:30 PM - 5:00 PM
Association Of Circulating Cell-free Dna Released During Physical Exercise With Extracellular Vesicles

Elmo Neuberger, Alexandra Brahmer, Berin Boztepe, Eva-Maria Krämer-Albers, Perikles Simon. University of Mainz, Mainz, Germany.
 Email: neuberge@uni-mainz.de
 (No relevant relationships reported)

Introduction Circulating cell-free DNA (cfDNA) has emerged as an important target for liquid biopsies including performance diagnostics. Extracellular vesicles (EVs) are important mediators of cell-to-cell communication and are demonstrated to deliver bioactive material, such as proteins, lipids and nucleic acids, via the circulation. The ability of EVs to transport DNA and, thus, contribute to the pool of cfDNA is controversially discussed. **Purpose** To gain more detailed information of the release mechanisms of cfDNA during physical exercise by estimation of the proportion of cfDNA associated with EVs. **Methods** Platelet-free plasma was collected prior and immediately after an incremental cycling test to exhaustion from a single healthy male athlete. Using size exclusion chromatography (SEC), 2 ml of plasma were separated into 16 fractions of 1 ml. cfDNA concentration in plasma and SEC fractions was measured by direct quantitative real-time PCR of the LIPA2-repeat sequence with or without prior treatment of the fractions with DNaseI. To take pre-analytical considerations into account, the analysis was performed on freshly prepared plasma in a technical duplicate, and frozen SEC fractions. Vesicular fractions 4 to 7 were defined by the presence of the genuine EV markers CD9 and CD63 as well as the platelet-EV marker CD41b in western blot analysis. **Results** Plasma cfDNA concentration increased from 14.05 ng/ml plasma Pre to 157.01 ng/ml Post the cycling test. The amount of DNA, recovered in differently prepared SEC samples (fraction 1-16), was 8.8 ± 0.9 ng in the pre samples and 108.8 ± 22.8 ng post samples. The run of the cfDNA curve in the SEC samples was very similar in the pre and post samples ($r = 0.90, 95\% \text{ CI: } 0.82-0.94; p < 0.001$). In the vesicular fractions (SEC 4-7) $23.8 \pm 1.9\%$ of the recovered DNA occurred. DNaseI treatment only slightly decreased the amount of DNA in fractions (4-7) from 2.18 ± 0.15 ng to 1.72 ± 0.52 ng in the Pre samples and from 24.9 ± 7.0 to 20.3 ± 0.4 ng in the Post samples. In the remaining SEC fractions $79.9 \pm 6.4\%$ of the DNA was digested. **Conclusion** About 24% of the cfDNA in human plasma occurs in the vesicular Sec fractions. The larger amount seems to be independent of EVs and is prone to DNaseI digest. Further experiments are required to clarify if the DNA is inside of EVs or on the outside, protected from DNaseI.

D-68 Free Communication/Poster - Concussion II

Athletic Training Educator Concussion Symptomology Prioritization for Clinical Decision-Making Compared to Typical Symptom Presentation

Melissa C. Kay, Bridget M. Sturch, Johna K. Register-Mihalik. University of North Carolina - Chapel Hill, Chapel Hill, NC. (Sponsor: Kevin Guskiewicz, FACSM)
 Email: mkay@email.unc.edu
 (No relevant relationships reported)

Athletic training education program directors (PDs) are often tasked with setting the tone of their curriculum and prioritizing items of focus for students. Given the current attention on concussion, it is important to understand PDs' concussion knowledge and strategies for decision making. PDs personal strategies may influence educational content and student practices, implicating clinical practices for new athletic trainers (AT). **PURPOSE:** To determine whether educator-identified prioritized symptoms for removing an athlete from play align with common concussion-related symptoms experienced by athletes. **METHODS:** PDs from 32 professional-level athletic training education programs (n = 25 undergraduate; age = 43.8 ± 8.2 ; yrs experience = 21.1 ± 9.2) completed a validated survey examining concussion knowledge and the three symptoms most likely to cause them to remove an athlete from play. Participants responded to questions regarding symptoms and consequences of concussion on the

scale of 1 (definitely not a symptom/consequence) to 4 (definitely is). Total knowledge was summed for a possible range of 25-100. **RESULTS:** PDs' concussion knowledge was moderate (81.1 ± 6.7), primarily due to lack of confidence ("probably" vs. "definitely" is a symptom/consequence) in some items as opposed to being incorrect. The primary symptom reported by PDs as indicating necessary removal from play was headache ($n = 23/32$) followed by a three-way tie ($n = 14/32$ each): 1) amnesia/trouble remembering, 2) trouble understanding/confusion, and 3) visual disturbances. Dizziness was the fifth most common symptom causing removal from play ($n = 11/32$). Previous literature supports headache as the most common symptom experienced by athletes, then dizziness and difficulty concentrating. Although after headache, most common symptoms may vary; however, memory problems, confusion, and visual disturbances are typically reported as some of the most common symptoms. **CONCLUSION:** These data suggest that in general, PDs are prioritizing the most common symptoms experienced for their removal from play decisions. This is encouraging as it suggests that PD's knowledge on key symptoms is appropriate. Future research should further investigate the role AT knowledge and symptom prioritization plays on content in educational programs.

2117 Board #273 May 30 3:30 PM - 5:00 PM
No Effect Of Randomizing Concussion Symptom Presentation On Symptom Number Or Severity Reporting
 Kathryn L. O'Connor, Lauren Dougherty, Griffin J. Feinberg, Andrew Lapointe, Steven Broglio, FACSM. *University of Michigan, Ann Arbor, MI.* (Sponsor: Steven P Broglio, FACSM)
 Email: kloconn@umich.edu
 (No relevant relationships reported)

Purpose: Concussion symptom evaluations are the most common tool used by clinicians to diagnose an injury. However, the most common post-concussion symptoms reported are also the symptoms that appear first on the Standardized Concussion Assessment Tool (SCAT) symptom list. The purpose of the current study was to evaluate whether SCAT symptom order influenced symptom reporting in healthy young adults with and without a prior concussion.

Methods: Previously concussed and non-concussed young adults completed a survey consisting of demographics, medical history, and SCAT symptoms. Participants were randomized to either complete the original SCAT form or the SCAT with randomized symptom order. Since the individuals were healthy, many participants reported zero symptoms. Thus, logistic regression and zero inflated negative binomial models compared the symptoms scores of the first 5 SCAT symptoms to determine whether presentation order influenced symptom reporting. The first five symptoms evaluated were headache, pressure in the head, dizziness, neck pain, and nausea.

Results: A total of 13 ($n = 6$ Female) participants completed the surveys who had an average age 25.07 ± 4.73 . Participants who completed the randomized SCAT consisted of 2 females (33.3%), 5 males (71.4%), there was no significant effect of sex on likelihood of receiving the randomized SCAT order ($p > 0.05$). Three participants (60.5%) out of five with a concussion completed the randomized SCAT order. There was no significant effect of prior concussion on likelihood of receiving the randomized SCAT order ($p > 0.05$). Logistic regression and zero inflated negative binomial models yielded no significant effect of SCAT order on the likelihood to report symptoms or the severity of symptoms (all p 's > 0.05).

Conclusions: In this small sample size of healthy young adults, SCAT symptom presentation does not appear to influence symptom reporting or severity. Follow up analyses should evaluate for this effect in a larger sample and in acutely concussed individuals.

2118 Board #274 May 30 3:30 PM - 5:00 PM
Adult Perception of a Child's Sport Concussion Risk
 Allyssa K. Memmini¹, Kathryn L. Van Pelt¹, Alissa H. Wicklund², Steven P. Broglio, FACSM¹. ¹*University of Michigan, Ann Arbor, MI.* ²*Orthopaedic and Spine Center of the Rockies, Fort Collins, CO.* (Sponsor: Steve Broglio, FACSM)
 (No relevant relationships reported)

Purpose: With increased media coverage on sport-related concussions (SRC), there has been a growing concern about the risks associated with contact sports. Previous literature reports a decrease in participation numbers stemming from increased perception of concussion risk in contact sports such as football. The purpose of this study was to evaluate the effect of adult profession and perception of their child's concussion risk while participating in contact sports. We hypothesized that adults with a medical background would be more educated about the consequences of SRC, and thus would be less inclined to choose high-contact sports participation for their own children compared to those without medical backgrounds. **Methods:** Data were collected through an anonymous electronic Qualtrics survey administered to faculty and staff at a large midwest university and associated medical center between 2017 to 2018 ($n=5849$, age= 39.519 ± 13.802 years). Respondents indicated their gender, age, highest degree awarded, whether or not they were a medical professional, and

in what sports they would allow their children to participate. Sports were subdivided into four categories (high-contact, partial-contact, non-contact, and all of the above) and analyzed using chi-square tests, followed by a logistic regression to investigate any differences between professional categories and rate of selection of high-contact sports. **Results:** Preliminary chi-square tests indicated no difference between medical (MP) and non-medical professionals (NMP) and the four sport subdivisions ($\chi^2=5.58$, $p=0.23$). Between-group nominal logistic regression was non-significant ($p=0.20$) in examining the effect of profession and selection of sports. More specifically, there was insignificance between professions and likelihood of choosing high-contact sports ($p=0.092$). **Conclusion:** Initial analyses suggest no difference in the choice of sport participation among children with parents in medical and non-medical backgrounds despite an increased attention on concussion in recent years. Future analyses will investigate the specific sports chosen, as well as additional covariates such as parental sport participation and concussion history.

2119 Board #275 May 30 3:30 PM - 5:00 PM
Changes in Fixational Eye Movements following Concussion
 Anthony P. Kontos¹, Bianca T. Leonard¹, Valerie C. Snyder¹, Cyndi Holland¹, Min Zhang¹, Ethan S. Bensinger², Christy K. Sheehy³, Michael W. Collins¹, Ethan A. Rossi¹. ¹*University of Pittsburgh, Pittsburgh, PA.* ²*UC Berkeley, Berkeley, CA.* ³*UCSF, San Francisco, CA.* (Sponsor: Matthew Ganio, FACSM)
 Email: akontos@pitt.edu
 (No relevant relationships reported)

Concussions can affect smooth pursuit, saccadic, and vergence eye movements. Fixational eye movements (FEMs) - the small, involuntary motion of the eye that occurs while focusing on a target - are affected by Alzheimer's, Parkinson's, and mild cognitive impairment. However, little is known about changes in FEMs following concussion.

Purpose: To compare FEMs in concussed patients to controls using a retinal image-based eye tracking device.

Methods: Participants included 50 patients with a concussion and 39 age- and gender-matched controls aged 13-27 years. FEMs were measured with a tracking scanning laser ophthalmoscope (TSLO) that tracks retinal image motion at 480 Hz with accuracy of ~ 0.2 arcmin. Eye traces were analyzed offline to compute microsaccadic amplitude, peak velocity, and peak acceleration. Fixational spread, using bivariate contour ellipse area (BCEA), intersaccadic intervals, blink rate, and total blink time were also analyzed. Concussed patients completed the Vestibular Oculomotor Screening (VOMS), Post-concussion Symptom Scale (PCSS), and Immediate Post-Concussion Assessment and Cognitive Test (ImPACT) for comparison with FEMs.

Results: Microsaccades were larger (amplitude - controls: 0.397° SD 0.32, concussion: 0.597° SD: 0.45; $p < 0.001$) and faster (peak velocity: control: $27.9^\circ/\text{sec}$ SD: 22.2; concussion: $39.7^\circ/\text{sec}$ SD: 30.3; $p < 0.001$; peak acceleration: control: $6.27^\circ/\text{sec}^2$ SD: 9.29; concussion: $9.47^\circ/\text{sec}^2$ SD: 14.1) in concussed participants. Although concussed patients and controls made equal numbers of microsaccades during a 30 sec recording, concussion patients had a greater proportion of larger, faster microsaccades - with 19% more microsaccades at amplitudes greater than 0.75° and 22% more microsaccades $\geq 30^\circ/\text{sec}$. The BCEA was 221% larger in concussed patients (0.56°) compared to controls (0.26°).

Conclusions: These findings support changes in FEMs following concussion as measured using retinal image-based eye tracking. Microsaccades in concussed patients were larger in amplitude, peak velocity, and peak acceleration compared to controls. Specifically, fixation is less precise, with a larger spread (i.e., increased BCEA). Retinal imaging and eye-tracking of FEMs may be useful in identifying and monitoring recovery following concussion.

2120 Board #276 May 30 3:30 PM - 5:00 PM
Examining Persistent Deficits in Gait Utilizing Inertial Measurement Units
 Griffin J. Feinberg, Andrew P. Lapointe, Kathryn L. Van Pelt, Lauren A. Dougherty, Allyssa Memmini, Katherine M. Breedlove, Steven P. Broglio, FACSM. *University of Michigan, Ann Arbor, MI.* (Sponsor: Steve Broglio, FACSM)
 (No relevant relationships reported)

Purpose: The effects of concussion on gait have been studied using three-dimensional motion capture technology. However, the equipment expense may not be feasible for all clinicians and researchers. Inertial Measurement Units (IMU) are inexpensive, portable, and have been used to evaluate gait. The purpose of this study is to utilize IMU's to evaluate gait deficits in concussed participants (CON) (time > 1 year since concussion incidence) compared to non-concussed participants (NC). **Methods:**

Fourteen participants (n=6 CON 22.87 ± 2.13 years, 3.16 ± 2.14 concussions, 4.49 ± 1.66 years from concussion, n=8 NC 26.42 ± 5.25 years) completed the 2-Minute Walk (2Walk), and Timed Up and Go (TUG) gait tasks while equipped with 10 IMU's. Exclusion criteria included no orthopedic injuries in the past year or condition that impedes gait, or the ability to jump. Additionally, control participants were excluded if they presented with any concussion history. Independent t-tests were utilized to examine the relationship between concussion history and motor function utilizing turn velocity, angle and duration, as well as double support gait percentage and TUG duration. For all TUG variables, the results from the participants' three trials were averaged before computation. **Results:** There was a significant difference amongst groups for turn duration (p<0.01), turn velocity (p=0.04), during the TUG gait task. Additionally, there was a significant difference for percentage of gait cycle in double support for the 2Walk (p=0.011). Turn velocity was faster for the concussed participants (mean CON= 238.4°/sec, NC= 208.2°/sec) while turn duration was shorter (mean CON=1.66 ± 0.1sec, NC=1.90 ± 0.13 sec) compared to controls. Concussed participants spent approximately 3.5% less of their gait cycle in double support during the 2Walk. However, no significant differences were noted in turn velocity and duration in the 2Walk task. **Conclusion:** Preliminary findings show altered gait and turning strategies among those with a concussion history. These differences may be explained by concussion history. Alternatively, differences in activity levels and sporting experience may also contribute. Future analyses will reassess these changes in addition to other kinematic metrics as sample size increases.

2121 Board #277 May 30 3:30 PM - 5:00 PM
Interrater And Intrarater Reliability Of The Standard Assessment Of Tackling Technique (SATT) On Secondary School Football Athletes

Scott Dietrich¹, Braden Lawson², Jane McDevitt³. ¹Kansas State University, Manhattan, KS. ²Independent, Manhattan, KS. ³Temple University, Philadelphia, PA.
 Email: sdietrich@ksu.edu
 (No relevant relationships reported)

BACKGROUND: Eighteen years after Guskiewicz et al. (2000) began studying sport related concussion in college and high school football players, head and spine injuries remain a very serious concern for the sport. An upward trend in serious catastrophic brain and spinal cord injuries still exists (Meehan and Landry, 2015), despite greater awareness of signs and symptoms, improved injury evaluation, more accurate symptom assessment, cautious return to play decisions, better helmet technology, new tackling styles, updated coach education, and rule changes limiting contact in practice (Yang et al., 2017). A consistent, cost effective method to evaluate and screen unsafe tackling behaviors has yet to be established. The Standard Assessment of Tackling Technique (SATT) is an observational tool designed to score movement proficiency on five critical elements of an American football tackle. Each element is rated on a four step, ordinal scale from zero - did not occur to three - performed with proficiency. **PURPOSE:** of this study was to evaluate interrater and intrarater reliability of the SATT. **METHODS:** Fifteen healthy subjects were videotaped while performing a tackle proficiency assessment (TPA) drill on a square blocking dummy. Twelve players (n=12) completed all three TPA sessions spaced 7 days apart, three players did not complete all trials and their data was removed. A total of 36 videos were independently scored by two, trained raters. Training required completion of a forty-five-minute session with explanation of the scoring rubric and scoring sample videos until 80% scoring agreement was obtained. **RESULTS:** Interrater reliability was good for sessions 1 (ICC = 0.801; 95% confidence interval [CI]: 0.446-0.938) and 2 (ICC = 0.856; 95% CI: 0.575-0.956) and moderate for session 3 (ICC = 0.602; 95% CI: 0.076-0.867). The individual SATT components showed Arm Rip was the least reliable component (ICC = 0.40; 95% CI: 0.31-0.51) and leg drive was the most reliable component (ICC = 0.95; 95% CI: 0.92-0.97). Intrarater reliability was moderate to good for both raters (ICC = 0.57 - 0.79). **CONCLUSIONS:** The results showed that the SATT can be independently scored by two raters, following a 45 minute training session and more experienced raters demonstrate increased intrarater reliability.

Effects Of 3D Multiple Object Tracking On Head Impacts During A Collegiate Ice Hockey Season

Anna Sessa, Daniel Antonoff, Jordan Goss, Taylor Langevin, Christina Renodin, Lee Spahr, John Rosene. *University of New England, Biddeford, ME.*
 Email: asessa@une.edu
 (No relevant relationships reported)

Player-to-player contact is the most frequent head impact mechanism in collegiate ice hockey. Training with three-dimensional multiple object tracking (3D-MOT) could potentially reduce the quantity and severity of head impacts by enhancing player

anticipation of these impacts. **PURPOSE:** The purpose of this study was to utilize 3D-MOT training as a tool to reduce the quantity and severity of head impacts in NCAA Division III men's and women's ice hockey players. **METHODS:** Collegiate men's and women's ice hockey players (N = 33; men = 17, women = 16) were randomly assigned to a 3D-MOT group (3D-MOT = 17) or control group (C = 16). 3D-MOT training occurred twice per week for 12 weeks throughout one regular season. Quantity, location, linear acceleration, and rotational velocity of head impacts were measured in practices and games. Independent samples t-tests compared peak linear acceleration and peak rotational velocity between groups. Pearson chi square analysis compared the quantity of impacts between groups. Independent groups ANOVAs compared peak linear acceleration and peak rotational velocity of impacts between player positions and peak linear acceleration and peak rotational velocity at five different helmet locations between groups. **RESULTS:** 3D-MOT forwards sustained head impacts with greater mean peak linear acceleration (3D-MOT = 41.33 + 28.54g; C = 38.03 + 24.30g) and mean peak rotational velocity (3D-MOT = 13.59 + 8.18 rad.sec-1; C = 12.47 + 7.69 rad.sec-1) in games, and greater mean peak rotational velocity in practices versus control forwards (3D-MOT = 11.96 + 6.77 rad.sec-1; C = 10.22 + 6.95 rad.sec-1). Conversely, 3D-MOT defensemen sustained fewer in-game head impacts (3D-MOT = 181 head impacts; C = 282 head impacts) and head impacts with a mean peak rotational velocity less than control defensemen (3D-MOT = 11.54 + 6.76 rad.sec-1; C = 13.65 + 8.43 rad.sec-1). There was no significant difference for all other parameters analyzed between 3D-MOT and control groups. **CONCLUSION:** 3D-MOT training reduced the quantity and severity of head impacts for defensemen in games, but not for forwards. Player position may play an important role in future interventions to reduce quantity and severity of head impacts in collegiate ice hockey.

2123 Board #279 May 30 3:30 PM - 5:00 PM
Concurrent Validity and Reliability of the XLNTbrain Balance Test with the Balance Error Scoring System

Ashley Santo, Danielle Brown. *Towson University, Towson, MD.*
 (No relevant relationships reported)

Background: The Balance Error Scoring System (BESS) is a commonly used balance assessment, because it is cost-effective and requires minimal equipment. The XLNTbrain Balance Test, was recently developed and uses smartphone accelerometer technology to provide clinicians with a more objective measure. While the objective nature of the test is promising, the validity and reliability of the XLNTbrain Balance Test is unclear. **Purpose:** To determine the concurrent validity and reliability of the XLNTbrain Balance Test compared to the BESS. **Methods:** Thirty-seven physically active participants (15 males, 22 females, 20.73 ± 2.02 yrs, 169.60 ± 10.28 cm, 70.12 ± 14.15 kg) completed the BESS and XLNTbrain Balance Test in a counterbalanced order. A subset of the sample (n=33) repeated the tests one week later. Concurrent validity was established through correlation analysis examining the relationship between scores on the BESS and XLNTbrain Balance Test. Reliability was established using paired-samples t-tests and Intraclass Correlation Coefficients (ICC_{3,1}) computed for the BESS and XLNTbrain Balance Test. **Results:** A significant moderate relationship was found between the total scores of the BESS and XLNTbrain Balance Test (r_s=0.43, p=0.008), and between the firm tandem stance condition of the BESS and the eyes closed tandem stance condition of the XLNTbrain Balance Test (r_s=0.41, p=0.013). There were no statistically significant differences in scores between testing sessions for the BESS total score (Time 1: 16.44 ± 8.01, Time 2: 14.64 ± 6.38, t₃₂ = 1.64, p=0.11), or the XLNTbrain total score (Time 1: 12.85 ± 5.89, Time 2: 14.77 ± 10.30, t₃₂ = -1.02, p=0.31). There was a moderate reliability score for the BESS total score (ICC_{3,1}=0.54, p<0.005) and a low reliability score for the XLNTbrain Balance Test (ICC_{3,1}=0.17, p=0.17). **Conclusions:** Although the XLNTbrain Balance Test appears to demonstrate moderate concurrent validity against the BESS, it did not demonstrate improved reliability. Future research should determine if the XLNTbrain Balance Test demonstrates validity against force plates. Additionally, the sensitivity of the BESS and XLNTbrain Balance Test to the effects of concussion should be explored.

Balance And Cognitive Recovery Following Concussion Injury Is Associated With Initial Symptom Severity

Christopher G. Neville¹, Michael VanNostrand¹, Andrew Brindle², Brian Rieger¹. ¹Upstate Medical University, Syracuse, NY. ²Quadrant Biosciences Inc, Syracuse, NY.
 Email: nevillec@upstate.edu
 (No relevant relationships reported)

Introduction: Symptoms remain a primary way to monitor recovery from concussion injury. However, the association between subjective symptoms and objective measures of balance and cognition is not entirely understood.

Purpose: To examine the association between objective and subjective measures during recovery from concussion injury. The primary hypothesis is to describe changes in cognition, balance, and symptom severity over a one month timeframe following concussion injury. A secondary hypothesis is that symptom severity at time of injury will be associated with objective measures during the recovery period.

Methods: Fifty-one young adults (18.01±5.96 years old) who recently sustained a concussion completed a battery of four cognitive tests, eight balance tests, and a 22 item symptom report using a commercially available assessment tool (ClearEdge, Quadrant Biosciences Inc; Syracuse, NY). All subjects completed test 1, on average, 5.45 ± 3.53 days after injury, and test 2, 23.06 ± 10.92 days following test 1. Group comparisons (repeated measures ANOVA or T-Test) and effect sizes (Cohen's d) were used to compare recovery across time. To address the secondary hypothesis, those within the group reporting low symptom severity (symptoms <10; n=18) and high symptom severity (symptoms > 40; n=14) were compared.

Results: Across the sample, symptom severity at initial testing ranged from 0-89. Statistically significant differences between test 1 and 2 were seen for all cognitive tests (p<0.001) and 1 of the 8 balance tests (p=0.028). When comparing symptom severity groups, significant differences (p<0.05) at the first testing session were seen on 3 cognitive tests and 2 balance tests. No differences were seen between groups at test 2. The low symptom severity group had no changes in cognitive or balance scores between test 1 and 2. The high symptom group had large effects sizes towards improvement on Tandem Stance Eyes Closed (d=1.16), and Simple Reaction Time 2 (d=1.36).

Conclusion: Symptom severity is associated with objective measures of balance and cognition during the recovery period. The low symptom group appears to have reached full recovery prior to initial testing. The high symptom group showed signs of injury at initial testing with large changes in cognitive and balance performance at re-test.

Reliability of the Stability Evaluation Test Over Consecutive Annual Baseline Assessments

Theresa L. Miyashita¹, Eleni Diakogeorgiou². ¹Concordia University - Chicago, River Forest, IL. ²Southern Connecticut State University, New Haven, CT.

Email: theresa.miyashita@cuchicago.edu
(No relevant relationships reported)

PURPOSE: It is recommended athletes receive annual concussion baseline testing that includes an assessment of postural control. Research has found concussion history does not correlate to baseline Balance Error Scoring System (BESS) scores. However, the BESS is not as sensitive in detecting postural control changes when compared to force plate measurements. The Stability Evaluation Test (SET) on the VSR Sport™ by NeuroCom® is an instrumented BESS and measures sway velocity. The purpose of this study was to determine the reliability of baseline sway velocity measurements taken during consecutive annual baseline screenings in Division I lacrosse players.

METHODS: 44 healthy Division I Lacrosse Players (14 females, 30 males; age = 20.57 ± 0.99; height = 69.59" ± 3.38"; weight = 169.73lbs ± 31.24) from one university participated in the study. All players were medically cleared for full participation and did not have a history of a concussion in the last 12 months. At the start of each season, players performed the standard 3 stances of the BESS test (double leg, single-leg, tandem) on two surfaces, firm and foam, while standing on the VSR Sport™ force plate.

RESULTS: A Pearson correlation analysis of the 2017 and 2018 sway velocities during each stance of the Stability Evaluation Test, found that none of the stance trials met the a priori threshold of r ≥ 0.70 to indicate good test-retest reliability.

CONCLUSIONS: There is not a strong correlation between baseline balance measurements taken at the start of consecutive seasons. To ensure the reliability of measurements, it is recommended annual baseline measurements be taken even in the absence of a concussion. An individualized approach is ideal in the management of a concussion injury, and baseline accuracy should be considered a critical component.

| Mean Sway Velocity Scores & Stance Correlations | | | | | | | |
|---|------------------|------------------|--------------|------------------|------------------|--------------|-----------------|
| | Double Leg, Firm | Single Leg, Firm | Tandem, Firm | Double Leg, Foam | Single Leg, Foam | Tandem, Foam | Composite Score |
| 2017 Mean Sway Velocity | .69 | 2.19 | 1.31 | 1.75 | 4.88 | 5.40 | 2.69 |
| 2018 Mean Sway Velocity | .63 | 2.18 | 1.38 | 1.58 | 3.60 | 3.61 | 2.17 |
| Correlation (r) | .49 | .40 | -.01 | .41 | .18 | .30 | .34 |

2126 Board #282 May 30 3:30 PM - 5:00 PM

Relationship Of Vestibular/ocular Motor Symptoms And Impairment On State Anxiety In Athletes With Sport-related Concussion

R.J. Elbin¹, Mallory McElroy¹, Melissa Womble², Katie Stephenson-Brown¹, Nathan D'Amico¹, Anthony Kontos³.

¹University of Arkansas, Fayetteville, AR. ²Inova Sports Concussion Program, Fairfax, VA. ³University of Pittsburgh, Pittsburgh, PA. (Sponsor: Matthew Ganio, FACSM)

(No relevant relationships reported)

PURPOSE: This study 1) compared state anxiety scores between concussed athletes with and without vestibular/ocular motor symptoms/impairment, 2) documented changes in state anxiety throughout SRC recovery, and 3) examined the role that state anxiety has on SRC recovery in athletes with vestibular/ocular symptoms/impairment.

METHODS: Thirty-nine concussed athletes (17.23 ± 2.30 yrs, 62%-F) with vestibular/ocular motor symptoms/impairment (total symptoms ≥2 on any component) (VESTIB) and 40 concussed athletes (16.48 ± 1.15 yrs, 30%-F) without vestibular/ocular motor symptoms/impairment (NO VESTIB) completed the Vestibular/Ocular Motor Screening within 30 days of SRC. The State-Trait Anxiety Inventory (STAI) was administered at initial and clearance visits. Analysis of covariance (ANCOVA), controlling for symptoms, was used to examine state anxiety scores between groups, and a paired samples t-test was used to examine changes across time. Chi-square analyses with odds ratios (ORs) assessed the association of vestibular/ocular motor symptoms/impairment on clinical levels of state anxiety (STAI score ≥40) and prolonged SRC recovery (≥21 days). **RESULTS:** The VESTIB group reported higher state anxiety scores (38.95±11.15) than the NO VESTIB group (30.60±9.98) (F [1,79] = 5.58, p =.02, η² = .07). State anxiety scores improved from the initial (35.11±11.83) to clearance visit (26.01±8.15)(t (73) = 6.30, p<.001). The VESTIB group was 3.64 times more likely to exhibit clinical levels of state anxiety at the initial visit (χ²[1, 79] = 6.35, p=.01, 95% CI = 1.30 - 10.29). Athletes in the VESTIB group with clinical levels of anxiety were 4.24 times more likely to have prolonged recovery than without (χ²[1, 38] = 3.75, p=.05, 95% CI = .94 - 19.26). **CONCLUSIONS:** Athletes with vestibular/ocular motor symptoms/impairment may experience higher anxiety following SRC, which may influence recovery. Clinicians should assess vestibular/ocular motor and anxiety domains following SRC.

Comparison of Whole and Regional Body Composition Testing Devices

Rachel N. Tauber, Shuqi Zhang, Clayton L. Camic, Peter J. Chomentowski III. Northern Illinois University, DeKalb, IL.

Email: rtauber1@niu.edu
(No relevant relationships reported)

Obesity has increased exponentially within the last three decades and is now widely recognized as one of the leading health threats due to its association with such as type 2 diabetes, cardiovascular disease, and hypertension. In recent years, there have been advances in technology such as bioelectrical impedance analysis (BIA), dual-energy X-ray absorptiometry (DEXA), and air-displacement plethysmography that has been used to categorize individuals into percent fat categories. However, there are still concerns with the validity of these devices. **PURPOSE:** The purpose of this study was to analyze the validity of an 8-point electrode BIA, DEXA, and air-displacement plethysmography methods compared to hydrostatic weighing. **METHODS:** 32 male (mean age ± SD= 22.4 ± 2.5 years) and 30 female subjects (mean age ± SD= 21.9 ± 2.3 years) performed body composition testing using BIA, DEXA, air-displacement plethysmography, and hydrostatic weighing. All tests were conducted in one continuous two-hour session for each subject. Subjects were instructed prior to testing to refrain from eating for a minimum of five hours but no more than ten, to avoid consuming alcohol within twelve hours of testing, to avoid caffeine within three hours of testing, to avoid large amounts of liquid within four hours of testing, and to refrain from exercising within 8 hours of testing. **RESULTS:** The one-way ANOVA with repeated measures and follow-up paired samples t-tests indicated that percent body fat estimated from DEXA (mean ± SD = 31.0 ± 8.9%) resulted in significantly greater values than hydrostatic weighing (23.3 ± 9.2%), air-displacement plethysmography (23.3 ± 10.8%), and BIA (23.6 ± 10.5%). In addition, the constant error (CE) and total error (TE) values of predicting hydrostatic weighing percent body fat from DEXA (CE = -7.7%, TE = 8.2%) was significantly greater than those associated with

THURSDAY, MAY 30, 2019

air-displacement plethysmography (CE = 0.1%, TE = 3.2%) and BIA (CE = -0.3%, TE = 8.2%). **CONCLUSION:** These findings indicated that the air-displacement plethysmography and BIA methods provided acceptable estimates of body composition when compared to hydrostatic weighing. The DEXA method, however, displayed large CE and TE values and thus was not an accurate measure of percent body fat.

Relationship Between Cardiorespiratory Fitness and Arterial Stiffness in Healthy Adults
 Hannah E. Remington, Daniel R. Elston, Bradley S. Fleenor, Matthew P. Harber, FACSM. *Ball State University, Muncie, IN.*
 (No relevant relationships reported)

Aortic stiffness and cardiorespiratory fitness (CRF) are independent predictors of cardiovascular disease (CVD), cardiovascular (CV) events, and early mortality. However, the relationship between arterial stiffness and CRF is largely unknown. **PURPOSE:** To examine the relationship between arterial stiffness and CRF in apparently healthy adults. **METHODS:** Two hundred three subjects—97 men (aged 50±21 years) and 106 women (aged 47±20 years)—visited the Human Performance Lab to complete one round of testing. Each performed a maximal cardiopulmonary exercise test to determine CRF (i.e., $\dot{V}O_{2max}$). Aortic stiffness was measured via carotid-femoral pulse wave velocity (cfPWV). Data were checked for normality, and Pearson-product moment correlations were performed to determine the association between CRF and arterial stiffness. **RESULTS:** $\dot{V}O_{2max}$ for the entire cohort was 32.8±12.0 ml/kg/min (range 11.4-66.4). The entire cohort had a cfPWV (m/s) of 7.3±1.6 (range 4.8-12.2). cfPWV was moderately associated with CRF ($r = -0.585, p < 0.001$). **CONCLUSION:** Arterial stiffness is inversely related to CRF. These data suggest that the beneficial effects of CRF on cardiovascular-related outcomes may be mediated, at least partially, through arterial stiffening.

Relationships Among Muscle Function, Skeletal Muscle Mass, and Arterial Stiffness
 Olivia E. Jones, Daniel E. Elston, Bradley S. Fleenor, Matthew P. Harber, FACSM. *Ball State University, Muncie, IN.* (Sponsor: Matthew P. Harber, FACSM)
 (No relevant relationships reported)

Skeletal muscle function (MF), skeletal muscle mass (SMM) and arterial stiffness are independent risk factors for all-cause mortality and cardiovascular events. Decreases in SMM are negatively associated with arterial stiffness, however, the relationship between MF and arterial stiffness remains unclear. **PURPOSE:** To examine the relationship between MF and SMM with arterial stiffness. **METHODS:** Participants (N=203, 97 males/106 females) were apparently healthy adults (Age 48.3 ± 20.2 years, BMI 26.8 ± 4.9 kg/m², $\dot{V}O_{2max}$ 32.8 ± 12.0 ml/kg/min). Arterial stiffness was assessed through carotid-femoral pulse wave velocity (cfPWV). SMM was assessed through dual-energy X-ray absorptiometry (DXA), while handgrip strength was measured with a hand dynamometer. Relationships for the entire cohort were analyzed using Pearson correlations between cfPWV, SMM, and MF. **RESULTS:** Inverse associations for the entire cohort were observed with MF and cfPWV ($r = -0.343, p = 0.001$) while SMM was not associated with cfPWV ($r = -0.007, p = 0.911$). All associations remained significant when divided into groups based on sex ($p < 0.05$). **CONCLUSIONS:** These data suggest that muscle function, specifically handgrip strength, but not SMM are associated with arterial stiffness irrespective of sex. Interventions to improve arterial health should target measures of muscle function instead of skeletal muscle mass.

2130 Board #286 May 30 3:30 PM - 5:00 PM
Effect Of Exercise On Reserve Of Repolarization And Blood Stress Markers
 Alllan H. Goldfarb, FACSM, Joseph Starobin, Blair Wisco, Kerry Martin, Alexis Slutsky, Kirsten Ward. *Univ., of North Carolina Greensboro, Greensboro, NC.*
 Email: ahgoldfa@uncg.edu
 (No relevant relationships reported)

Reserve of repolarization of the heart (RoR) is a non-invasive method to monitor the heart's response to stress. RoR assess stability of cardiac membranes and when excitation becomes unstable. Previous studies reported RoR as a useful tool to determine cardiac risk in cardiac patients. In this study we compared two cohort groups, posttraumatic stress disorder (PTSD) which has a strong association with CVD and a group of apparently healthy subjects (AH). **Purpose:** To determine if RoR and blood stress markers in AH and PTSD cohorts are different at rest and in response to a graded exercise test to 85% HRmax. **Methods:** Ten young women with documented PTSD (23.2 ± 1.4 yrs.) and 8 AH individuals (24.1 ± 1.7 yrs) with normal BP arrived after overnight fast (7-9 am) and rested for 20 minutes. ECG's (12 lead)

were monitored before, during and after exercise to obtain RoR. Blood was taken at rest and after exercise. Plasma samples were analyzed for stress proteins. **Results:** Resting HR's were statistically higher in the PTSD group compared to AH group (77.2 ± 3.1; 67.7 ± 2.6 bpm, $P < 0.0001$). Resting RoR between groups was not significantly different (AH=81±7%, PTSD = 78±5%, $P > 0.2$). RoR at the final exercise stage in AH group had significantly greater reserve (RoR = 40.4% compared to PTSD = 32.6%, $P = 0.02$) despite greater workload. Brain natriuretic peptide (BNP) increased in PTSD (pre = 139.8 ± 27.8, post = 232.8 ± 47.8 pg/ml, $P = 0.02$) whereas AH showed no change (pre = 123.9 ± 30.2, post = 138 ± 44.2 pg/ml). Plasma TnI was not different between groups at rest ($P > 0.3$) but increased significantly ($P = 0.03$) only in PTSD group with no changes in blood creatine kinase between groups and across time. **Conclusions:** These data suggest that PTSD individuals have less RoR in response to graded exercise compared to AH individuals. In addition, PTSD group had increased plasma BNP, and TNI suggesting an increased risk of having a cardiac event. It is suggested that this procedure may be useful as a screening process to help identify individuals with a risk of a coronary event.

Poor Cardiorespiratory Fitness is Associated with Higher Risk of Infectious Events in Kidney Transplant Recipients
 Sara Ortolan, Daniel Neunhaeuserer, Alessandro Patti, Francesca Battista, Mattia Grassi, Andrea Gasperetti, Lucrezia Furian, Andrea Ermolao. *University of Padova, Padova, Italy.*
 Email: sara.ortolan88@gmail.com
 (No relevant relationships reported)

Kidney Transplant Recipients (KTRs) have a reduced cardiorespiratory fitness, which is a well-known independent predictor of overall mortality in the general population and in patients with different chronic diseases. Although it is known that infections are one of the main cause of death in these patients, the possible correlation between cardiorespiratory fitness and the incidence of infectious events remains unexplored. **PURPOSE:** To investigate parameters of cardiorespiratory fitness as possible prognostic markers for infectious events in KTRs. **METHODS:** KTRs were evaluated at our outpatient clinic with an incremental, maximal CardioPulmonary Exercise Test (CPET), 3-12 months after transplantation. Cardiorespiratory fitness was analyzed with peak oxygen consumption ($\dot{V}O_{2peak}$) and the oxygen uptake efficiency slope (OUES). Laboratory data, drug therapy and history of infectious events were collected. The results of the study analysis were obtained with multivariate regression models. **RESULTS:** 157 KTRs (age 51±13 years, 64% men) were included in this study, with a mean BMI of 24.2±3.3 Kg/m². Glomerular Filtration Rate of 57±19 mL/min/1.73m², and hemoglobin concentration of 123.5±16.7 g/L. During a mean follow-up period of 33 months after the CPET, at least one infectious event occurred in 72 subjects (46%). The mean $\dot{V}O_{2peak}$ of the entire population was 25.6±6.9 mL/Kg/min, corresponding to 81.3±21.6% of the $\dot{V}O_{2peak}$ predicted for age and gender. 14.7% (n=22) of our patients had a $\dot{V}O_{2peak}$ below the 5th percentile of a matched healthy population based on the FRIEND study results. This subgroup demonstrated an increased risk of infectious events with a Hazard Ratio of 2.11 (CI 95%, 1.19-2.73, $p = 0.01$), which was independent of age, hemoglobin and immunosuppressive regimen. **CONCLUSION:** To our knowledge, this is the first clinical study associating a poor cardiorespiratory fitness with a higher risk of infectious events in KTRs. It can be speculated that an increased cardiorespiratory fitness, obtained by specific aerobic exercise training, may thus reduce infectious events and improve prognosis in this specific population.

<Effect Of Menstrual Cycle On Resting, Exercise And Post-exercise Heart Rate In Healthy Women>
 Giovanna M. R. Cunha, Luiz Guilherme Grossi Porto, Daniel Saint Martin, Edgard Soares, Giliard Lago Garcia Lago Garcia, Carlos Janssen Cruz, Guilherme Eckhart Molina. *Universidade de Brasilia, Brasilia, Brazil.*
 Email: giovannamrcunha@hotmail.com
 (No relevant relationships reported)

Spontaneous heart rate (HR) is an important physiological measurement in the clinical and exercise contexts, however, it is not totally clear whether spontaneous HR could be influenced by menstrual cycle. **PURPOSE:** Our objective was to investigate the effect of menstrual cycle (Follicular and Luteal phases) on the HR at rest, during the maximal treadmill exercise (MTE) and post-exercise recovery in a clinically healthy woman. **METHODS:** We evaluated 11 healthy women (24.1 ± 4.4 years, BMI 22.5 ± 0.6 kg/m²) with menstrual cycle lasting 28 ± 1.1 days. At rest, the HR was recorded in the supine and orthostatic positions. During the MTE, we recorded the chronotropic reserve with Maximum Heart Rate and Heart rate at the beginning of the test ($HR_{max} - HR_{initial}$) and in the post-exercise recovery we recorded the HR recovery (HRR) at the 1st, 3th, and 5th min following MTE. The HR recovery coefficient refers to equation ($HR_{max} - HRR_{min} / HR_{max} - HRI$) x 100; HRRmax: higher values on the stress test; HRRmin: Heart Rate Values at each minute of recovery and HRI: initial test heart rate.

The evaluations were performed in the follicular phase between the 9th and 11th day and in the luteal phase between the 19th and 21st day after the beginning of the menstrual cycle. Statistical analysis employed parametric tests with two-tailed *p* value set at 5%. **RESULTS:** At rest, HR was [supine: 64 ± 2.8 bpm - 64.7 ± 1.9 bpm, ($p > 0.05$)] and [orthostatic: 82.6 ± 3.4 - 82.1 ± 3.4 bpm ($p > 0.05$)] in during the follicular and luteal phases, respectively. Chronotropic reserve was not different ($p > 0.05$) during Follicular (86.4 ± 2.2 bpm) and Luteal (86.9 ± 3.8 bpm) phases. Also, absolute HRR, $\Delta\%$ HRR and HRR Coefficient did not show any difference between both phases of menstrual cycle ($p > 0.05$).

| Variables | Follicular | | Lutea | <i>p</i> | | | |
|-----------------------------|------------|---|-------|----------|---|-----|------|
| HR _{INITIAL} (bpm) | 96 | ± | 3,3 | 95,18 | ± | 4,4 | 0,84 |
| HR _{MAX} (bpm) | 182,5 | ± | 3,2 | 182,1 | ± | 2,9 | 0,93 |
| C.R. (bpm) | 86,4 | ± | 2,2 | 86,9 | ± | 3,8 | 0,91 |
| | | | | | | | |

CONCLUSIONS: We concluded that HR responses during rest, maximal treadmill exercise and 5 minutes post-exercise were not affected by the menstrual cycles, even with all physiological changes that occur during Follicular and Luteal phases.

2133 Board #289 May 30 3:30 PM - 5:00 PM

A Pilot Observational Study Investigating The Impact Of Glycogen Storage Disease III On Aerobic Capacity

Philip J. Hennis¹, David Tomlinson², Gurinder Rayat³, Elaine Murphy⁴. ¹Nottingham Trent University, Nottingham, United Kingdom. ²Manchester Metropolitan University, Manchester, United Kingdom. ³Southampton NHS trust, Southampton, United Kingdom. ⁴National Hospital for Neurology and Neurosurgery, London, United Kingdom. (Sponsor: Prof. Craig Sale, FACSM) (No relevant relationships reported)

Glycogen storage disease 3 (GSDIII) is a rare inherited metabolic disorder caused by glycogen debranching enzyme (GDE) deficiency which primarily affects the liver, skeletal muscle and heart and results in muscle weakness and profound exercise limitation. Despite exercise intolerance being a major complication associated with the disease, the influence of GSDIII on aerobic capacity is largely unstudied. **PURPOSE:** To preliminary describe the impact of GSDIII on aerobic capacity and investigate potential mechanisms responsible for any impairment. **METHODS:** In this descriptive study 5 patients (3 female) (39 ± 11 years) with GSDIIIa underwent an incremental cycle exercise test to volitional exhaustion. During exercise breath-by-breath gas analysis took place to determine oxygen utilisation (VO₂), carbon dioxide production (VCO₂), and minute ventilation (VE) and heart rate (HR) was measured continuously. The study received institutional and NHS ethics approval. **RESULTS:** Peak VO₂ was lower in the GSDIII patients than predicted based on their demographic data (16.9 ± 8.4 ml/kg/min, 52 ± 23% of predicted), as was peak work rate (WR) (86 ± 59 watts, 52 ± 30% predicted), peak HR (139 ± 26 bpm, 77 ± 11% predicted), and VE peak (30 ± 19 L/min, 36 ± 13% predicted). Peak RER was low for a test completed to maximal exertion (0.90 ± 0.07). **CONCLUSION:** VO_{2peak} is lower in patients with GSDIII than would be expected for their age, height, mass and sex. The mechanisms responsible for this impairment are yet to be fully determined, but the small data set presented here indicate a reserve in respiratory and central cardiovascular function. Previous literature has identified energy deficiency as a primary cause of exercise intolerance in GSDIII due to impaired glycogen breakdown, and these results are supported here by the low RER values at peak exercise.

2134 Board #290 May 30 3:30 PM - 5:00 PM

Inflammation and Muscle Oxygen Saturation are Associated with Exercise Pressor Response in Peripheral Artery Disease

Polly Montgomery, Marcos Kuroki, Ming Wang, Danielle Jin-Kwang Kim, Andrew Gardner. Penn State University, Hershey, PA.

(No relevant relationships reported)

Purpose: To determine whether calf muscle oxygen saturation (StO₂) and vascular biomarkers of inflammation and oxidative stress were associated with an exercise pressor response during treadmill walking in patients with symptomatic peripheral artery disease (PAD). **Methods:** A total of 179 patients were characterized on demographic variables, comorbid conditions, cardiovascular risk factors, ankle/brachial index, peak walking time (PWT), claudication onset time (COT), and calf muscle oxygen saturation (StO₂) during a graded maximal treadmill test. The exercise pressor response was measured as the change in blood pressure from rest to the end of the first 2-minute treadmill exercise work stage (2 mph, 0% grade). Patients were further characterized on endothelial effects of circulating factors present in the sera using a cell culture-based bioassay on primary human arterial endothelial cells, and on circulating inflammatory and vascular biomarkers. **Results:** During the maximal

treadmill test, patients experienced COT at 197 ± 164 seconds (mean ± SD) and PWT at 395 ± 254 seconds. There was a wide range in the change in systolic blood pressure (-46 to 50 mm Hg) and in diastolic blood pressure (-23 to 38 mm Hg), with mean increases of 4.3 mm Hg and 1.4 mm Hg, respectively. In multiple regression analyses, significant predictors of systolic blood pressure included glucose ($p < 0.001$) and insulin ($p = 0.039$). The significant predictors of diastolic blood pressure included cultured endothelial cell apoptosis ($p = 0.019$), the percentage drop in exercise calf muscle StO₂ ($p = 0.023$), high sensitivity C-reactive protein ($p = 0.032$), and glucose ($p = 0.033$). **Conclusion:** Higher levels in pro-inflammatory vascular biomarkers, impaired calf muscle StO₂ during exercise, and elevated blood glucose were independently associated with greater exercise pressor response in patients with symptomatic PAD. The clinical implication is that exercise and nutritional interventions designed to improve inflammation, microcirculation, and glucose metabolism may ameliorate the exercise pressor response in patients with symptomatic PAD.

Effects of Combined Exercise on Vascular Inflammatory Markers and Arterial Stiffness in Elderly Women

Jung-Sook Kim¹, Soo-Min Ha¹, Soo-Jin Hyun¹, Do-Yeon Kim¹, Jong-Won Kim². ¹Pusan National University, Busan, Korea, Republic of. ²Busan National University of Education, Busan, Korea, Republic of.

(No relevant relationships reported)

Women become more likely to develop chronic diseases as their metabolic function decreases after menopause. Vascular disease is a major problem for elderly women. The problem of these elderly women is due to a decline in health status due to lack of physical activity.

Purpose: The purpose of this study was to analyze the effects of a combined exercise training regimen on vascular inflammatory markers (WBC, CRP, fibrinogen) and arterial stiffness (blood pressure, pulse wave analysis and velocity) in elderly women.

Methods: Forty-five healthy elderly female volunteers, aged 75.44 ± 5.30 years, were randomly assigned to combined exercise group (EX; $n = 24$) trained for 12-week or to a "non-exercise" control (CON; $n = 21$) group. The variables of vascular inflammatory markers, BP, PWA and PWV were measured in all the subjects before and after the 12-week combined exercise training. The 60 minute combined exercise program (aquatic exercise 1 time, strength exercise 2 times/week) was performed 3 times per week for 12 weeks, and the intensity was progressively increased every four weeks (1-4 weeks: RPE 12 to 13, 5-8 weeks: RPE 13 to 14, 9-12 weeks: RPE 14 to 15). **Results:** The vascular inflammatory markers were as follows; All variables showed interaction effects and there was a significant difference in delta values between the two groups. WBC and CRP levels significantly decreased in the EX ($p < .05$). But control group CRP ($p < .05$) and fibrinogen ($p < .01$) levels significantly increased in the CON. SBP showed interaction effect and significant difference in delta-value. CON had significantly increased. However, there was no significant difference between PWA and PWV. **Conclusion:** Our findings indicate that regular aquatic and resistance exercise were effective in improving the serum vascular inflammatory markers and blood pressure of the elderly women with lower cardiovascular disease risk, which are all due to the decreased physical activities. Therefore, if senior citizens continuously improve their efficiency of exercise, they can get the benefit of improving anti-inflammation and delaying the aging process with aging so that they can improve their level of healthy life in the old age.

Olympic Distance Amateur Triathlete Chronotype Profile

Paulo Puccinelli¹, Vânia D'Almeida¹, Giscard Lima¹, Claudio Lira², Moises Cohen¹, Marilia Andrade¹. ¹UNIFESP, São Paulo, Brazil. ²UFG, Goiânia, Brazil.

Email: paulopuccinelli@hotmail.com

(No relevant relationships reported)

It seems that the athletes tend to select and pursue sports that suited their chronotype. Elite triathletes show to comprise high proportions of morning-types (MTs), differently from general population. Possibly the early morning training sections, characteristics in

this sport modality, favors athletes presenting morning types profile. There are no data about amateur triathletes chronotype, but probably there are also a high percentage of morning type, mainly because the training sessions occur even earlier, once amateurs need to work after the training. As the training sessions occur early in the morning, it is possible for morning-type athletes are able to develop higher intensity trainings and thus having better physiological adaptations. However, there are no data about chronotypes and physiological profile.

PURPOSE: Characterize the chronotype profile in a group of triathlon amateur competitors who participate in the Olympic distance triathlon race. Verify if there are association between chronotype profile and physical fitness in amateur triathletes.

METHODS: Thirty-nine men and six women who had subscribed to compete in the sixth stage of the 26th Brazil Triathlon Trophy (26^o Troféu Brasil de Triathlon) in the Olympic distance participated in this cross-sectional observational study. Participants were evaluated for anthropometric characteristics (body mass, height, and body composition through [DXA]), aerobic physical fitness (maximum oxygen consumption [V O₂max], anaerobic threshold and respiratory compensation point, maximum aerobic velocity [MAV] and running economy [RE]). Chronotype profile was evaluated using Horne-Ostberg morning-eveningness questionnaire.

RESULTS: According to the chronotype questionnaire 66.7% of the volunteers (69.2% men and 50.0% women were classified as morning profiles (22.2% definite morning and 44.4% as moderate morning) and only 6.7% were classified as evening profiles. There were no significant correlations between chronotype profiles and the physical fitness variables.

CONCLUSIONS: Amateur triathletes show to comprise high proportions of morning-types, but the physiological profile is similar between the different existing chronotypes.

concentration and utilization at rest and exercise. Changing patterns in substrate availability and utilization can have effects on metabolism, cognitive functioning and circadian rhythms. **Purpose:** The purpose of this study was to evaluate the effects of TRF on overall physiological functioning, specifically sleep, resting energy expenditure (REE), resting respiratory quotient (RQ), and likelihood of depression.

Methods: A longitudinal design was used to examine physiological changes associated with four weeks of TRF among 34 healthy adults between the ages of 18-60 years. Sleep was evaluated via self-report logs given to participants at testing sessions. REE and RQ were measured using a metabolic cart while subjects were in a fasted state.

The Brief Anxiety and Depression Survey was administered, and each subject was given a score indicating their likelihood of depression at each testing session. Variable differences within subjects were determined using a repeated measures ANOVA or a paired samples T-test. **Results:** A significant decrease in total sleep ($p = 0.034$) and BADS scores ($p = .046$) occurred between non-TRF and TRF. Analysis revealed that resting RQ values experienced a significant increase ($p = .002$) between testing non-TRF and TRF testing periods ($p = .034$) and pre-test and TRF testing sessions ($p = .008$). Direct correlations were found between BADS, total sleep and resting RQ.

Conclusion: TRF may influence glucose utilization during rest. Past studies have shown that different forms of intermittent fasting, such as TRF, enable an organism to create more regulated circadian rhythms, allowing less reliance on glucose, resulting in benefits in prevention and treatment of various diseases. The results of the present study are in opposition of previous literature and may provide insight into how glucose utilization affects other physiological processes. Increased glucose utilization may have been a factor in the decrease in total sleep and depression in the patients in the study. Future research is needed to verify if increased utilization of carbohydrates at rest influences changes of circadian rhythms and depression occurrence.

The Effect Of Time Of Day On Jump Potentiation In Distance Runners

Elaine Vieira, Ilanna Maria Holanda Almeida, Daniel Alexandre Boullousa, Sebastian Del Rosso, Stephany Melo Vieira, Filipe Brandão Santos, Douglas Araújo Vargas, Luiz Djalma Rodrigues Filho, John Robert dos Santos Silva. *Catholic University of Brasília, Brasília, Brazil.*

Email: elaine.vieira@ucb.br

(No relevant relationships reported)

The Effect of Time of Day on Jump Potentiation in Distance Runners.

Time of day is a key factor that influences athletic performance. No study has specifically investigated the effect of early morning vs. late afternoon training on jump potentiation in distance runners. This is important because circadian rhythms and alterations in sleep patterns can affect training adaptations and athletic performance.

PURPOSE: To determine whether the time of day influence jump potentiation in distance runners. **METHODS:** We recruited 18 male runners that were divided into two groups: novice runners (NOV) with ≤ 3 years of racing experience ($n=6$; age 34.7 ± 6.4) and experienced runners (EXP) with ≥ 3 years of experience ($n=12$; age 34.5 ± 5.1). Chronotypes were identified using the Horne-Ostberg's Morningness-Eveningness questionnaire and sleep quality was assessed with the Pittsburgh Sleep Quality Index. Counter movement jump (CMJ) was determined with the My Jump App. CMJ height was measured after 5 min warm-up and after 30 min test (70% HRR) of running on a treadmill at 8:00 am and 8:00 pm. Following the 30 min test treadmill CMJ height was measured at 0, 3, 6 and 9 minutes of recovery. **RESULTS:** The overall sleep quality of the athletes were poor (5.4 ± 3.8 , $n=18$). The NOV group were poor sleepers (6.5 ± 3.6 , $n=6$) whereas the EXP group were at the limit score to become poor sleepers (4.8 ± 3.9 , $n=12$). The majority (77.3%, $n=14$) of the runners were morning types and 22.2% ($n=4$) were intermediate types. CMJ height in the EXP group was increased at 0 min of recovery and was decreased to warm-up levels at 3, 6 and 9 min ($p < 0.01$) during morning test. Interestingly, jump potentiation only occurred in the morning while no significant increases were observed in the evening in the EXP group ($p=0.6$). The NOV group had no changes in jump potentiation in both morning and evening tests. **CONCLUSION:** We conclude that jump potentiation could be only observed during morning in experienced distance runners probably because of their chronotypes.

2139 Board #295 May 30 3:30 PM - 5:00 PM

Circadian Phase Is Associated With Self-reported Chronotype In Young, Sedentary Adults

J. Matthew Thomas, Julie S. Pendergast, W. Scott Black, Philip A. Kern, Jody L. Clasey, FACSM. *University of Kentucky, Lexington, KY.*

(No relevant relationships reported)

Chronotype, which is an individual's preferred timing of sleep and activity across the 24-hour day, is regulated by genetics, environmental exposure, and age. Chronotype is measured by subjective questionnaires that query the timing of daily behaviors. Late chronotype has been previously associated with lower level of physical activity, higher body mass index (BMI), and increased risk of type 2 diabetes and the metabolic syndrome. A well-established measure of an individual's circadian timing, or phase, is the onset of melatonin secretion measured in dim light conditions (dim light melatonin onset; DLMO). Despite previous investigations, the associations between DLMO and chronotype, as well as body composition, have not been fully elucidated in young, sedentary adults. **PURPOSE:** To examine the association between DLMO and chronotype; and the association between DLMO and body composition measures in young, sedentary adults. **METHODS:** Fifty-two adults (19 male, 25.8 ± 6.0 yrs; BMI 26.1 ± 5.4 kg/m²; %Fat $34.2 \pm 8.8\%$) participated in this study. All subjects were sedentary (< 2 hrs weekly structured exercise), non-smokers, and did not use medication. Circadian phase was measured by DLMO (time of day when saliva melatonin ≥ 4 pg/ml). Chronotype was measured as the midpoint of sleep on free days (free of vocational responsibilities, corrected for sleep debt; MSFsc) calculated from the Munich Chronotype Questionnaire (MCTQ) and a composite score calculated from the Morningness-Eveningness Questionnaire (MEQ; range: 16-86). Percentage body fat (%Fat) was determined by total body DXA scanning. Pearson's correlation analysis was used to determine if significant ($p < 0.05$) associations were observed between DLMO and MSFsc, MEQ, BMI, and %Fat. **RESULTS:** DLMO ($21:42 \pm 01:31$) was significantly associated with MSFsc ($04:34 \pm 01:11$; $r = 0.66$; $p < 0.001$) and MEQ (50.0 ± 9.0 ; $r = -0.52$; $p < 0.001$). No significant associations were observed between DLMO and BMI ($r = -0.13$) or %Fat ($r = 0.04$). **CONCLUSION:** An objective measure of circadian phase was associated with subjective measures of chronotype. However, neither BMI nor %Fat was associated with DLMO in young sedentary adults. Supported by the University of Kentucky Pediatric Exercise Physiology Laboratory Endowment, the University of Kentucky, and the NIH TL1TR001997 and UL1TR001998.

Social Jetlag Is Associated With Higher Eveningness Index

Stephanie Witzel Esteves Alves, Olivia Francisco Antunes, Marcos Mônico-Neto, Hanna Karen Moreira Antunes. *Universidade Federal de São Paulo, São Paulo, Brazil.*

Email: stephanie.witzel@gmail.com

(No relevant relationships reported)

Currently, the social demands imposed by work, school and academic activities prevent youth and adults from maintaining an ideal sleep routine. This situation causes

sleep restriction, reducing sleeping hours per night and leading to numerous health damages. This phenomenon has been conceptualized as social JetLag (SJL). **Purpose:** Investigate the association between chronotype and mood profile in presence of SJL of young adults. **Methods:** Participated in this study 68 male subjects (mean age 25.43±6.64 years, and BMI 24.59±4.25) and physically active. In a transversal study approved by our institutional ethics committee (n° 2.263.382), the subjects answered a sleep questionnaires battery composed by Pittsburgh Sleep Quality Index (PSQI), Morningness-Eveningness Questionnaire (MEQ), Munich Chronotype Questionnaire (MCTQ), Epworth sleepiness scale (ESS) and Brunel Mood Scale to determine a mood profile (subscales: anger, confusion, depression, fatigue, vigor, tension). The SJL was categorized in accord to MCTQ results in 3 groups: a) No SJL (≤ 30 min), b) SJL until 1 h (31- 60 min), c) SJL more than 1h (>61 min). **Results:** The groups were compared, and no differences were found between all subscales of Brunel. Moreover, we didn't find any differences regard the sleep quality and diurnal excessive sleepiness. On the other hand, the groups were different on sleep duration and chronotype. Longer SJL is associated to higher Eveningness index ($F(2,65)=7.48; p=0.001$). **Conclusions:** Our finds suggest that the presence of SJL didn't impact the volunteer's humor profile and longer SJL is associated to higher eveningness index.

 (No relevant relationships reported)

Melatonin is a hormone which controls sleep, inflammation, and oxidative stress. Aerobic physical exercise can influence melatonin in normoxia. However, there is controversy about the effects of exercise on the melatonin level in hypoxia, which is characterized by impaired sleep. **PURPOSE:** This work evaluated the effects of aerobic physical exercise on melatonin under hypoxic conditions. **METHODS:** Forty healthy men were randomized into 4 groups: Normoxia (N) - (22.1 ± 3.1 y, 69.1 ± 1.1 kg); Hypoxia (H) - (23.2 ± 2.1 y, 67.2 ± 4.1 kg); Exercise under Normoxia (EN) - (26.1 ± 3.2 y, 71.1 ± 3.2 kg); and Exercise under Hypoxia (EH) - (24.1 ± 3.1 y, 72.3 ± 2.1 kg). The observation period for all groups was 36 hrs, beginning with a first night devoid of any intervention. The normobaric hypoxia condition was conducted in a room equipped for altitude simulation that can reach up to 4,500 m (normobaric chamber, CAT - Colorado Altitude Training™ / 12 CAT-Air Unit, USA). Aerobic exercise was performed by the EN and EH groups on a treadmill at 50% of VO_{2peak} for 60 minutes. Venous blood samples for the melatonin measurement were obtained on the 1st and 2nd days at 7:30 AM as well as on the 1st and 2nd nights at 10:30 PM. Data are reported as mean ± standard deviation. A repeated measures and one-way analysis of variance (ANOVA) followed by the Tukey's post hoc test were used to detect significant differences between groups. The accepted significance level was $p \leq 0.05$. **RESULTS:** On the 2nd night, melatonin was higher in the H group compared to the N group (48.3 ± 2.2 vs. 26.1 ± 1.1, $p < 0.05$); low in the N group compared to the EH group (26.1 ± 1.1 vs. 59.2 ± 2.1, $p < 0.05$); low in the H group compared to the EH group (48.3 ± 2.2 vs. 59.2 ± 2.1, $p < 0.05$); and low in the EN group compared to the EH group (37.2 ± 1.0 vs. 59.2 ± 2.1, $p < 0.05$). On the 2nd day, melatonin was higher in the H group compared to the N group (39.1 ± 3.1 vs. 28.1 ± 2.1, $p < 0.05$); low in the N group compared to the EH group (28.1 ± 2.1 vs. 46.2 ± 2.0, $p < 0.05$); and high in the EH group compared to the H group (46.2 ± 2.0 vs. 39.1 ± 3.1, $p < 0.05$). **CONCLUSIONS:** Hypoxia acutely increases melatonin. Diurnal remission of the nocturnal increase in melatonin seems to be delayed by hypoxia and to an even greater extent if acting together with exercise.

Investigations of Sleep Quality Disturbances and Its Associations with Respiratory Functions and Depression Level among Young Adults with Down's Syndrome

Ertugrul Safran, Hikmet Ucgun, Meltem Ramoglu, Hulya Nilgun Gurses. *Bezmialem Vakif University, Istanbul, Turkey.*
 Email: ertugrulsafraan@hotmail.com
 (No relevant relationships reported)

Individuals with Down Syndrome (DS) have a broad range of respiratory problems. These problems are important cause of morbidity, mortality and may increase tendency to sleep disturbances. Also depression has been frequently reported in individuals with DS.

PURPOSE: To investigate of sleep quality disturbances and its associations with respiratory parameters and depression levels in young adults with DS. **METHODS:** 50 individuals with DS (28 male, 22 female; 21.5±3.39 year) were included in the study. Sleep quality components (subjective sleep quality, sleep latency, sleep duration, habitual sleep efficiency, sleep disturbances, use of sleeping medications, and daytime dysfunction) evaluated with Pittsburgh Sleep Quality Index (PSQI). According to PSQI guidelines, good sleep quality is indicated by a composite score of <5 (possible total=21), and poor sleep quality by a score of >5 . Forced vital capacity (FVC), forced expiratory volume in one second (FEV1) and peak expiratory flow (PEF) values were recorded using with spirometry. Pearson correlation was used to relate variables.

RESULTS: Sleep quality parameters, respiratory values and depression scores of participants showed in Table 1. A total of % 52 (n=26) of participants have poor sleep quality. % 10 of participants (n=5) in severely depressed status. We found significant correlations of sleep quality parameters (habitual sleep efficiency; sleep disturbances, total PSQI) to depression level ($r=0.68, r=0.75; r=0.72, p<0.05$). Significant correlations were found between PEF values and total PSQI scores; habitual sleep efficiency ($r=0.86; r=0.69 p<0.05$).

CONCLUSIONS: Our study suggest that sleep quality has a important effects on depression level. Also suggest that sleep quality and respiratory parameters are correlated, especially with PEF. All of this three parameters may affect each other. Further studies with bigger populations and controls needed for better results.

| Table 1. Values of Sleep Quality, Respiratory Functions and Depression Scale | |
|--|---------------------------------|
| Pittsburgh Sleep Quality Parameters | Values(mean±standart deviation) |
| Sleep duration | 0.47±0.28 |
| Sleep latency | 1.22±0.40 |
| Subjective sleep quality | 0.92±0.31 |
| Habitual sleep efficiency | 1.45±0.73 |
| Sleep disturbances | 0.97±0.6 |
| Daytime sleep dyssfunction | 0.52±0.25 |
| Use of sleep medications | 0.1±.23 |
| Total | 6.72±2.23 |
| Respiratory Parameters | % |
| Forced Expiratory Volume in 1 Second (FEV1) | 64.83±20.11 |
| Forced Vital Capacity (FVC) | 69.33±16.93 |
| Peak Expiratory Flow (PEF) | 42.66±24.67 |
| Self-Depression Scale | Score |
| | 60±28.75 |

Elastic Band Resistance Training Effects on Strength and Sleep of Shift Workers

Marco T. de Mello, Diego A. Borba, Lucas A. Facundo, Fernanda V. Narciso, Addressa Silva. *Universidade Federal de Minas Gerais, Belo Horizonte, Brazil.*
 Email: tmello@demello.net.br
 (No relevant relationships reported)

PURPOSE: To determine the effect of elastic band resistance training in strength, muscle mass and sleep of shift workers. **METHODS:** Twelve sedentary workers with weekly work schedule of 12 hours of work for 36 hours of rest (Age: 42.3±8.8 years, Body Mass Index: 27.6±3.7 Kg), performed 16 elastic band training sessions (2 sets until failed; 3 times by week, for 16 weeks). The initial training load was determined by color and/or number of elastic band test to 10RM (shoulder abduction and biceps curl) and 20RM to seated low row exercise. The push up exercise no used elastic band. In following training sessions, the participants were instructed to perform the four exercises in the maximal number of repetition possible each new session. The estimated arm muscle area, exercises repetition number and sleep (sleep duration, sleep latency, sleep efficiency and weak after sleep onset) were assessment pre and post-training. The sleep variables were determined by actigraphy technique for during seven days. The pre and post-test comparisons were made using paired t test. **RESULTS:** The arm muscle area, was improved after training (7015.5±1859.3 vs. 7571.179±1723.625, p<0.05) as well as exercises repetition number (shoulder abduction: 10.3±0.6 vs. 22.3±4.7; push up: 11.2±3.2 vs. 19.8±6.7; seated low row: 20.2±1.0 vs. 37.1±8.4; biceps curl: 10.2±0.6 vs. 23.7±7.7, p<0.001). There is no change in sleep variables after training (Sleep Duration: 386.3±36.7 vs. 384.6±43.8 min; Sleep Latency: 28.5±32.7 vs. 14.0±15.0 min; Sleep Efficiency: 86.7±7.7 vs. 86.5±7.5%; Weak after sleep onset: 34.4±22.2 vs. 38.3±23.7 min, p>0.05). **CONCLUSIONS:** Elastic band resistance training improved the strength and muscle mass of shift work without to change their sleep quality of shift workers. Supported by UFMG, FAPEMIG, MAFRE Foundation, CAPES and CNPQ.

Impact Of Sleep Deprivation On Flexibility Performance

Fernanda Veruska Narciso, Beatriz M. Pereira, Addressa Silva, Mauro H. Chagas, Matheus M. Reis, Carlos Amaral Costa, Valdenio M. Brant, Lucas A. Facundo, Aline A. Cruz, Marco Tulio de Mello. *Universidade Federal de Minas Gerais, Belo Horizonte, Brazil.*
 (No relevant relationships reported)

PURPOSE: The purpose of this study was to verify the impact of sleep deprivation in flexibility of young adults. **METHODS:** Ten sedentary male young adults (Mean age: 24.3 ± 3.8 years old, body mass index: 24.8 ± 2.5 kg/m²) wore wrist actigraph before and during the 36-h of sleep deprivation to measure sleep-wake cycle, and Passive Maximal Range of Motion (PROM_{max}) was evaluated by the modified knee extension test with a fleximeter in 4 different moments: at onset of sleep deprivation (8:00am, day 1 = baseline), and after 12h (8:00pm, day 1), 24h (8:00am, day 2) and 36h (8:00pm, day 2) of sleep deprivation. Volunteers lay back with the hip flexed at 90°, and the initial knee ROM (0°) was considered as 90° right knee flexion. PROM_{max} was measured 06 times, and mean values at the 03 lasts was analysed. Analyzes of Paired-Samples Variance were used to compare the variables in four moments, and statistical significance set at p< 0.05. **RESULTS:** PROM_{max} values showed significant difference (F_{1,38} = 51.148, p < 0.001) after 12h (71.7 ± 0.27°; CI_{95%} = 66.2-77.2), 24h (71.0 ± 2.6°; CI_{95%} = 65.8-76.3) and 36h (69.8 ± 2.6°; CI_{95%} = 64.5-75.1) of sleep deprivation compared with baseline (73.0 ± 2.7; CI_{95%} = 67.6-78.4). Moreover, there was decrease of PROM_{max} (F_{1,38} = 17.951, p < 0.001) from 12 h to 36 h and from 24 h to 36 h of sleep deprivation. **CONCLUSION:** Our findings suggest that sleep deprivation may have a negative impact on PROM_{max}. Furthermore, 12 h and 36 h after baseline moment showed reduction of the PROM_{max}, even as the time of maximal circadian rhythm values (acrophase) have generally observed between 4:00pm and 8:00pm. The duration of sleep deprivation and the circadian time are important in determining the impairment in passive flexibility performance. Acknowledgment: CAPES, CNPQ, FAPEMIG, CEMSA, CEPE.

Effects Of Sleep Deprivation On Histopathological Changes And Oxidative Damage In Different Type Muscle Fibers

Marcos Mônico-Neto¹, Kil Sun Lee¹, Daniel Araki Ribeiro², Caroline Margonato Cardoso², Luciana Le Sueur Maluf², Hanna Karen Moreira Antunes¹. ¹*Federal University of Sao Paulo, Sao Paulo, Brazil.* ²*Federal University of Sao Paulo, Santos, Brazil.*
 Email: marcosmoniconeto@gmail.com
 (No relevant relationships reported)

Previous studies has shown that sleep deprivation (SD) induces muscle atrophy and histopathological changes, however, these effects may be different considering the type muscle fiber. **PURPOSE:** to analyze histopathological changes and oxidative damage after SD in different types of muscle fibers (oxidative and glycolytic) of rats. **METHODS:** 20 Wistar male rats (3 months, 300-350 g) were distributed in two groups, control group (CTL, n=10) and SD by 96 h group (SD96, n=10). The SD96 group was sleep deprived on consecutive 96 h, while the CTL group remained in the housing box. At the end of SD, the soleus and plantar muscles were analyzed for lipid peroxidation by concentrations of malondialdehyde (MDA), oxidative damage to DNA by nuclear labeling of 8-OHdG and histopathological changes. **RESULTS:** it was observed increased MDA concentrations in the soleus of SD96 compared to CTL (0.0134±0.0009 vs 0.0121±0.0009 mmol/mg, P=0.01). Comparison between muscles revealed that the soleus had higher concentrations of MDA than plantar to both groups (P<0.001 for both). Regarding 8-OHdG, there was increased nuclear labeling to the plantar muscle in the SD96 compared to CTL (25.4±3.6 vs 7.2±1.9 positive cells, P<0.001). In the soleus, greater nuclear labeling was observed in SD96 compared to CTL (60±13.6 vs 9.6±3.6 positive cells, P<0.001), already the comparison between the muscles revealed a greater nuclear labeling of 8-OHdG in the soleus muscle compared to plantar in the SD96 group (P<0.001). The histopathological evaluation of the soleus revealed the presence of interstitial edema in SD96 compared to CTL (19.5±4.2% vs 0%, P<0,001), associated with intense cellular infiltration, alterations in the arrangement of muscle fibers, as well as areas of tissue degeneration and reduction of muscle parenchyma (72,7±2,7 vs 92,4±1,6%, P<0,01). In the plantar muscle, the changes were more subtle, with slight increase in cellularity in the SD96 and fibers presenting smaller cross-sectional area in SD96 group. **CONCLUSIONS:** SD induces degenerative process and oxidative damage in the skeletal muscle, being more intense in type I fibers.

The Effect of Acute Sleep Restriction on Running Mechanics during an Exhaustive Run

Reiley T. Bergin, Nicholas R. Heebner, Cheyenne DeRaymond, Amanda C. Glueck, John Abt, FACSM, Stuart Best. *University of Kentucky, Lexington, KY.* (Sponsor: John Abt, FACSM)
 (No relevant relationships reported)

Purpose: Inadequate sleep is a known risk factor for injury, but the mechanisms by which sleep restriction increases injury risk remain unknown. The purpose of this study was to determine if running mechanics during an exhaustive run, including average peak impact accelerations between the tibia and the forehead, would be altered following one night of sleep restriction. **Methods:** Two male and seven female subjects (21 ±3yrs, 55 ±10kg) completed an exhaustive treadmill run following either 8 hours (well-rested, WR) or 3 hours of sleep (sleep-restricted, SR) in a randomized crossover design, separated by at least one week. The exhaustive treadmill run was performed at an intensity equal to the subject's ventilatory threshold until volitional fatigue. Wireless inertial measurement units (IMUs) were placed on the right tibia and forehead. Average right tibia peak impact accelerations (RtPk), average head peak impact accelerations (HdPk), and shock attenuation (ratio of RtPk to HdPk) were measured for 3 minutes during the first 2-5 minutes and final 3 minutes. Paired t-tests were used to compare each dependent variable (shock attenuation, RtPk, HdPk) between conditions (WR vs SR). **Results:** Time to exhaustion during the exhaustive treadmill test was not significantly different between the WR and SR conditions respectively (38.5 ±15.3 minutes, 40.0 ±14.7 minutes, p = 0.69). There were no significant differences in shock attenuation between conditions during the first 2-5 minutes (WR: 58.96 ±7.09, SR: 57.72 ±7.33, p = 0.55) and final 3 minutes (WR: 58.00 ±8.73, SR: 57.53 ±7.58, p = 0.84). No significant differences were found between conditions for RtPk (WR: 5.19 ±0.73g, SR: 5.07 ±0.92g, p = 0.49, WR: 5.38 ±0.87g, SR: 5.29 ±0.96g, p = 0.64) and HdPk (WR: 2.12 ±0.44g, SR: 2.11 ±0.37g, p = 0.79, WR: 2.22 ±0.45g, SR: 2.20 ±0.36g, p = 0.76) during the first 2-5 minutes and final 3 minutes respectively. **Conclusion:** Running mechanics were not altered following one night of sleep restriction. These data suggest that one night of inadequate sleep is not sufficient to alter running mechanics, however more research is needed to understand the possible effects of chronic sleep restriction and its potential influence on injury risk during running.

2147 Board #303 May 30 3:30 PM - 5:00 PM
Landing Mechanics And Muscular Strength Are Not Altered Following Acute Sleep Restriction

Stuart Best, Reiley Bergin, Cheyenne DeRaymond, Nicholas R. Heebner, Amanda C. Glueck, John Abt, FACSM. *University of Kentucky, Lexington, KY.* (Sponsor: John Abt, FACSM)
 Email: stuart.best@uky.edu

(No relevant relationships reported)

PURPOSE: Inadequate sleep is associated with an increased risk of injury, however it is unknown what physical risk factors for injury are altered by inadequate sleep. We hypothesized that one night of sleep restriction would affect reaction times and landing mechanics but not leg strength. **METHODS:** Ten healthy subjects (5 males, 5 females, 21 ± 3 yrs, 1.67 ± 0.11 m, 59.8 ± 11.8 kg) completed cognitive testing, strength testing and a series of jump assessments following 8 hours (well-rested, WR) or 3 hours sleep (sleep-restricted, SR) in a randomized crossover design. Subjects woke at the same time for each assessment and testing was conducted at the same time of day, in the same order, and separated by at least one week. Reaction time was assessed using the computerized Automated Neuropsychological Assessment Metrics (ANAM) assessment. Strength testing (isokinetic dynamometer-60°/s) included maximal knee extension (KE) and flexion (KF) strength for each leg. Subjects completed 5 trials of a double leg drop-landing task, as well as 5 trials on each leg of a single leg stop-jump task. Peak knee flexion angles (PkKF) were captured using 3D motion capture. Vertical ground reaction forces (VGRF) for each leg were captured with two flush mounted force plates. **RESULTS:** There were no significant differences between conditions for reaction time ($p=0.894$), or KE ($p=0.882$, $p=0.568$) and KF ($p=0.295$, $p=0.156$) in the left or right legs respectively. VGRF was not significantly different between the WR and SR conditions during the drop-landing task (Left: $p=0.216$, Right: $p=0.082$). Although not significant, a trend of greater PkKF was found (Right WR: $68.7 \pm 32.7^\circ$, SR: $49.5 \pm 34.4^\circ$, $p=0.068$) (Left WR: $68.8 \pm 32.1^\circ$, SR: $51.1 \pm 34.2^\circ$, $p=0.097$), when comparing the WR to the SR condition during the drop-landing task. The difference in VGRF during the single leg stop-jump task approached significance for the left leg (WR: 2.52 ± 0.41 , SR: 2.72 ± 0.44 , $p=0.052$). No other significant differences in VGRF or PkKF were observed during the single-leg stop-jump task (all $p>0.362$). **CONCLUSIONS:** No significant differences in strength and landing mechanics were observed following one night of sleep restriction. Knee flexion angle data trends suggest additional nights or chronic sleep restriction may be required to significantly alter movement mechanics.

Parameters Associated with Abnormal Cardiac Conditions in Adolescent Athletes: Analysis using Simon's Heart Heartbytes Registry

Jacob Jones¹, Dai Sugimoto¹, Gregory Kobelski¹, Prashant Rao², Stanton Miller², Chris Koiler², Gian Corrado¹, David Shipon². ¹*Boston Children's Hospital, Boston, MA.* ²*Jefferson University, Philadelphia, PA.*

Email: jacob.jones@childrens.harvard.edu

(No relationships reported)

PURPOSE: To determine clinical parameters that are related to abnormal cardiac conditions in the physically active youth. **METHODS:** We used the Simon's Heart Heartbytes National Youth Cardiac Registry to collect cardiac related data from middle and high school athletes in southeastern Pennsylvania. We collected age, race/ethnicity, symptoms suggestive of abnormal cardiac conditions, past medical history, medication use, caffeine intake and family history. We also obtained height, weight, blood pressure, and cardiac murmur findings, as well as an ECG in all individuals. Binary logistic regression analysis was performed to identify an independent association between abnormal cardiac symptoms and potential indicators (all collected variables). The odds ratio (OR), 95% confidence interval (95% CI), and p-values were used as critical statistical values. **RESULTS:** There were a total of 887 athletes (543 males and 344 females, age= 16.9 ± 2.1 , height= 166.9 ± 11.4 , weight= 62.0 ± 16.0). There was an independent association between abnormal symptoms and presence of significant past medical history (OR: 4.75, 95% CI: 3.17, 7.10, $p=0.001$) and prescribed medication use (OR: 1.71, 95% CI: 1.04, 2.79, $p=0.034$). Although the association between the presence of abnormal symptoms and African-American race (OR:2.01, 95% CI: 0.95, 4.28, $p=0.069$) and average daily

consumption of at least 2 types of caffeine drinks (soda, energy drinks, tea, and coffee) (OR:2.11, 95% CI: 0.87, 5.07, $p=0.097$) were not significant, there was a trend to reach the a priori significance level.

CONCLUSIONS: The current study identified several clinical parameters that are associated with symptoms suggestive of abnormal cardiac conditions. Further research needs to be done on a larger scale to better sort out the clinical history that may contribute to false positives in an effort to reduce false positives at heart screenings.

Evaluation of Shoulder Health of Collegiate Wheelchair Basketball Athletes

Matthew T. Santa Barbara, Jacqueline M. Spangenberg, Monica E. Rho. *Shirley Ryan AbilityLab, Chicago, IL.*
 Email: santabam@gmail.com

(No relationships reported)

Shoulder pain is the most commonly reported musculoskeletal complaint among manual wheelchair users. Wheelchair basketball athletes may be at a higher risk of shoulder injury given the additional demands of their sport, but there is little research on the prevalence of shoulder injuries in this population. Shoulder injuries affect both sport participation and ability to perform activities of daily living for manual wheelchair users. Identifying shoulder injuries in wheelchair basketball athletes is important to provide better context in injury treatment and prevention. **PURPOSE:** Determine the prevalence of shoulder injuries using questionnaires, physical exams, and ultrasound evaluations in collegiate wheelchair basketball athletes. **METHODS:** Observational cross-sectional study of collegiate wheelchair basketball athletes at a single institution. Inclusion criteria were participation on a collegiate wheelchair basketball team and use of a manual wheelchair for $\geq 50\%$ of mobility. Each athlete completed a baseline questionnaire that included a Visual Analog Scale (VAS) for shoulder pain in the last month, the American Shoulder and Elbow Surgeons Score (ASES), the Wheelchair User's Shoulder Pain Index (WUSPI) and then underwent a physical exam and musculoskeletal ultrasound evaluation of both shoulders. The Ultrasound Shoulder Pathology Rating Scale (USPRS) was used to grade pathological ultrasound findings. 2-tailed t-tests were used to compare shooting arms to non-shooting arms. **RESULTS:** Seven males and eight females completed the study. Ten of the fifteen athletes had experienced shoulder pain or an injury during the time they had used a wheelchair. Mean VAS in the shooting arm was $2.78 (\pm 2.24)$ and non-shooting arm was $1.50 (\pm 1.89)$ ($p=.11$). Mean ASES score was $89.92 (\pm 11.28)$. Mean WUSPI was $7.12 (\pm 9.46)$. There were nineteen positive physical exam findings in the shooting arms, compared to eight in the non-shooting arms ($p=.05$). Mean USPRS for the shooting arm was $2.13 (\pm 1.73)$ and non-shooting arm was also $2.13 (\pm 1.25)$ ($p>.99$). **CONCLUSIONS:** Shoulder injury and pain are prevalent in wheelchair basketball athletes based on questionnaires, physical exams and ultrasound findings. Supported by the Craig Neilsen Foundation.

2150 Board #306 May. 30 3:30 PM - 5:00 PM
Descriptive Analysis of Youth American Football Quarterback Injuries: A 15-years of Retrospective Data Study

Luke C. Radel, Gregory P. Kobelski, Michael J. O'Brien, William P. Meehan, III, Dai Sugimoto. *Boston Children's Hospital, Boston, MA.*

Email: luke.radel@childrens.harvard.edu

(No relationships reported)

PURPOSE: To describe the common injuries of youth American football (FB) quarterbacks (QBs) within the last 15 years. **METHODS:** A retrospective chart review of all patients cared for in a sports medicine clinic of an academic pediatric medical center between 01/01/2003 - 10/01/2018. Patients were identified using the search engine *HoundDog* to search the term "quarterback." Records were then reviewed to identify all QBs ≤ 18 years of age. Injuries that were not associated with FB participation were excluded. Main outcome variables were injured anatomic locations, injury types, surgical status, and settings in which the injury was sustained. Descriptive statistics were used to analyze the outcome variables. **RESULTS:** A total of 374 male QBs (mean age: 14.6 ± 2.1) sustained a total of 423 injuries. The top 5 injured anatomic locations (Figure 1) were shoulder (22.2%), knee (15.5%) head/neck (14.5%), elbow (13.6%), and wrist/hand/lower arm (11.3%). The injuries consisted of 64.3% in acute mechanism and 35.7% chronic in nature. The acute injuries occurred during game competition (55.5%), practice (14.3%), and off-season (6.7%); for the remaining 23.5% there was not sufficient documentation in the medical record to determine the setting. Of the chronic injuries, 47.0% occurred during off-season and 34.4% occurred in-season; for 15.2% of the chronic injuries there was not sufficient documentation in the medical record to determine the setting. Among all injuries, 22.9% were surgical cases, and the top 3 anatomic locations of surgery were knee (35.0%), shoulder (20.7%), and elbow (18.7%). **CONCLUSIONS:** The shoulder is the most commonly injured body part among young QBs seeking care in a specialty sports medicine clinic,

although the knee is the most commonly injured body part that requires surgery. Quarterback injuries are primarily acute in mechanism, and the majority of these acute injuries occur during game competition.

Spine Injuries and Concussions among Figure Skaters**

Kristen M. Lambrinakos-Raymond, Gregory Kobelski, Ellen Geminiani, Dai Sugimoto, William P. Meehan, III. *Boston Children's Hospital, Boston, MA.*
(No relationships reported)

PURPOSE: To determine the prevalence and mechanism of spine injuries and concussions among a sample population of figure skaters. To assess for potential risk factors for these injuries.

METHODS: This is a cross-sectional analysis of spine injuries and concussions reported by figure skaters. Data was obtained through an anonymous, confidential online questionnaire distributed to members of participating figure skating clubs. The main outcomes included diagnoses, mechanism and source of medical care. Simple descriptive statistics were used; Fisher's exact test was used to assess for statistical differences in categorical variables between groups. SPSS was used for all analyses.

RESULTS: Thus far, 88 participants have completed questionnaires (recruitment ongoing). The mean age of participants is 25.2 years (SD 17.1). Most (79%) respondents are female. Most (85%) practice figure skating year-round; 85% participate in competitions. Some skaters participate in more than one discipline including singles (n=68), pairs (n=3), ice dance (n=21), synchronized skating (n=29), theatre on ice (n=17). More than a quarter (27%; n=24) of participants reported spine injuries/back pain. The most common diagnosis was muscular back pain. Treatment was primarily guided by primary care (n=10), sports medicine (n=13), physical therapists (n=14) and athletic trainers (n=10). Almost half of those who reported back pain did not present to a health care provider (HCP) (45%; n/N=11/24). All injuries occurred in practice. More than a quarter of participants (27%; n=24) sustained at least one concussion; 7 sustained two concussions. Several (42%; n/N=10/24) skaters did not present to a HCP for evaluation of their first concussion. All concussions occurred during practice and most (92%; n/N=22/24) were during on-ice activities. The most common mechanism of injury was a fall (62%; n/N=15/24). The sex of the skater was not associated with either mechanism of spine injury or history of concussion.

CONCLUSIONS: Nearly a third of skaters sustained a concussion or spine injury, yet nearly half did not report their injuries to a HCP. Our findings warrant further investigation into the reasons for such a low reporting rate among figure skaters and the potential effect on injury outcomes.

Development and Evaluation of an Electronic Preparticipation Physical Evaluation System: A Pilot Feasibility Study**

Jordan Knox¹, Daniel Cushman¹, Matthew Brobeck¹, Masaru Teramoto¹, Kimberly Harmon, FACSM², Stuart Willick, FACSM¹. ¹University of Utah, Salt Lake City, UT. ²University of Washington, Seattle, WA. (Sponsor: Stuart Willick, FACSM)
Email: jordan.knox@hsc.utah.edu
(No relationships reported)

The preparticipation physical evaluation (PPE) is important for athlete health and safety, and is required for participation in collegiate sports and the majority of US high schools. The vast majority of PPEs are completed using a paper PPE form. Previous work had developed an ePPE system and found it was efficient and yielded good athlete compliance and high physician satisfaction. Another study showed ePPE's value for collecting and analyzing college athlete injury and illness data, suggesting strong potential for the ePPE to improve injury analysis as well as efficiency of the PPE. Despite these reports, use of electronic PPE forms has not become widespread. **PURPOSE:** 1) to develop and implement an ePPE system for collegiate athletes that simultaneously serves as a relational database for research purposes, 2) to assess perceptions of providers on the ePPE system compared to paper PPE forms, and 3) to demonstrate the research potential of an ePPE system by conducting a sample epidemiologic analysis using electronically collected data.

METHODS: In this pilot feasibility study, researchers developed an ePPE system using REDCap, a HIPAA-compliant web application designed for academic research purposes. The ePPE form had the identical contents and questions as the paper PPE form already in use at the NCAA Division I institution. Athletes on three teams at were randomized to use the ePPE (n = 22) or the paper PPE (n = 21) form. Providers and athletes were later surveyed regarding their perceptions of the two systems. A sample epidemiologic analysis using ePPE data was conducted.

RESULTS: The ePPE system was successfully developed and implemented. All athletic trainers and physicians preferred the ePPE over the paper PPE, and felt that the ePPE was more efficient. Data were easily extracted for analysis from the ePPE system. A sample epidemiologic analysis established concerns about concussions

sustained by athletes (27.3% of athletes) and some behavioral and psychological symptoms reported by athletes (trouble sleeping, depression, and anxiety; 13.6-22.7% of athletes).

CONCLUSIONS: While this was only a pilot feasibility study involving relatively small teams, we show that development and implementation of an ePPE system is technically feasible, is preferred by users, and facilitates sports research.

Psychological Factors Related to Return to Sport After ACL Reconstruction in Adolescents**

Aubrey Armento, David Howell, Alexia Gagliardi, Jay Albright, Stephanie Mayer. *University of Colorado School of Medicine, Aurora, CO.* (Sponsor: John Hill, FACSM)
Email: aubrey.armento@childrenscolorado.org
(No relationships reported)

PURPOSE: The present study aimed to assess the relationship between psychological factors, including perceived social support and pre-operative expectations, and return to sport after ACL reconstruction in adolescents.

METHODS: 56 participants completed the Hospital for Special Surgery Pediatric Functional Activity Brief Scale (HSS Pedi-FABS), the Psychovitality (PV) questionnaire, and the Multidimensional Scale of Perceived Social Support (MSPSS) prior to undergoing ACL reconstruction. We performed a multiple linear regression to assess if MSPSS score was associated with confidence in returning to sport (total PV score). Additionally, we divided participants into competitive and non-competitive groups based on their response to the HSS Pedi-FABS. Outcome variables obtained from the PV questionnaire addressing pre-operative expectations of returning to sport following surgery were compared between the competitive and non-competitive groups using a series of Chi-square analyses.

RESULTS: Among all participants, 86% (n=48) reported that they expected to return to sport within less than six months of surgery. A higher proportion of competitive athletes (81%) expected to return to sport within six months post-operatively compared to the non-competitive athletes (63%; p=0.18). In addition, a significantly lower proportion of competitive athletes (14%) compared to non-competitive athletes (39%) reported that they would be content returning to an activity level that was less than their pre-injury activity level (p=0.037) and would be willing to settle for a less strenuous sport than their pre-injury sport (16% vs 42%; p=0.034). There was no significant association between MSPSS total score (mean= 6.22±0.375, range= 4-7) and PV total score (mean= 13.8±3.0, range= 8-18; β coefficient= -0.63, 95% CI= -1.77, 0.52, p = 0.28).

CONCLUSIONS: The majority of all participants reported the expectation of returning to sport within six months of surgery. A significantly lower proportion of competitive athletes compared to non-competitive athletes reported that they would be content returning to a lesser activity level or less strenuous sport. There was no significant association between perceived social support and confidence in returning to sport.

A Review of the Injury Pattern of the 2018 Chicago Marathon**

Valerie Rygiel, Hallie Labrador. *NorthShore/University of Chicago, Chicago, IL.* (Sponsor: Carrie Jaworski, FACSM)
(No relationships reported)

Marathon racing is increasingly popular and it is estimated that 25 out of every 1000 finishers will seek medical help during their race. Some studies have shown that the most common injuries are musculoskeletal and the volume of runners seeking medical care increases as the race progresses. However, there is a lack of information that illustrates a specific injury pattern along a race course.

PURPOSE: To measure the volume and types of injuries sustained by 2018 Chicago Marathon runners at the various medical stations to determine the impact that distance has on injury pattern.

METHODS: In this retrospective chart review of records collected at the 2018 Chicago Marathon (N=1016), the diagnoses of runners seeking medical care was taken at 21 course medical tents and 2 finish line tents and categorized as either musculoskeletal, medical, wound care, or other. The data was divided into quartiles: miles 0-10, 10-18, 18-26.2, and finish line. The rate of each diagnosis was then compared between the quartiles using a chi-square analysis.

RESULTS: 3.8% of the runners visited the medical tents. Visit volumes had a bimodal distribution in the 2nd and 4th quartiles. 41.6% of runners seeking medical help did so at the finish line compared to 8.6%, 32.8%, and 17.0% in the first three quartiles respectively. 50.6% of all complaints were musculoskeletal, followed by 15.2% medical, 7.9% wound care, and 15.1% other. The percentage runners with musculoskeletal complaints were 24%, 75%, 16%, and 51% in the first, second, third, and fourth quartile respectively. Conversely, the percentage of medical complaints peaked in the 4th quartile with percentages of 1.1%, 5.8%, 1.7%, and 31.0%

respectively. When comparing the diagnosis of musculoskeletal, medical, wound care, and other complaints, there was a statistically significant difference in incidence with $p < 0.001$.

CONCLUSIONS: The most common presenting complaints were musculoskeletal, followed by medical, other, and then wound care. The largest number of runners seeking medical care were at the finish line and halfway point of the race and so the majority of resources should be focused at these locations. While there was a larger proportion of musculoskeletal complaints near the halfway point of the course, the higher percentage of medical complaints was at the finish line.

2155 Board #311 May. 30 3:30 PM - 5:00 PM
Iron and Vitamin D Deficiency in D1 Female Track & Field Athletes

Kristopher J. Paultre, William Cade, Hannah Ellis, Thomas M. Best, FACSM. *University of Miami, Miami, FL*. (Sponsor: Dr. Thomas Best, FACSM)
 Email: kristopher.paultre@jhsMiami.org
 (No relationships reported)

PURPOSE: To identify the prevalence of Iron and Vitamin D deficiency in D1 female track and field (T&F) athletes

METHODS: In a retrospective review of medical records at a single institution, laboratory data were reviewed for female T&F athletes [BT1] from 2013 to 2019. Labs were acquired as part of the entrance pre-participation physical (PPE) including ferritin, hemoglobin, and Vitamin D. Iron deficiency was defined as serum ferritin below 30ng·mL⁻¹ with severe deficiency below 13 ng·mL⁻¹. Vitamin D was classified as; below 15 ng/mL - deficient, 16-29 ng/mL insufficient, and above 30 ng/mL sufficient. Anemia was defined as hemoglobin (Hgb) < 11.1 g·dL⁻¹.

RESULTS: Seventy-seven student-athletes were screened, 48% were iron deficient, and a further 13 % had severe iron deficiency. Of those with iron deficiency (ferritin <30, n= 37), four had anemia (n=3). For Vitamin D, 7% were deficient, 24% were insufficient, and 69% were sufficient. **CONCLUSIONS:** When compared to the prevalence of iron deficiency in the general US female population ages 16-49 (11%), there was an increased prevalence in our sample (48%). Interestingly, we noted a similar prevalence of iron deficiency anemia (3-5% general population vs. 4.3% in our sample). Furthermore, our results showed a 24% prevalence for Vitamin D Insufficiency consistent with the general US female population of similar age at 24-26%. The prevalence of Vitamin D deficiency was higher in the US population at 10-11% when compared to our study at 7%. The effects and benefits of screening, intervention, and performance outcomes are a topic of ongoing investigation.

2156 Board #312 May. 30 3:30 PM - 5:00 PM
The Impact of Clinical Factors in Physician and ATC Decision Making for Concussion Return to Play: Insight from a Policy Capturing Study

Darwin McKnight, Vicki Nelson, Franklin Sease, RG Gilliland. *Greenville Health System, Greenville, SC*. (Sponsor: Franklin Sease, FACSM)
 (No relationships reported)

PURPOSE: To scrutinize the role of several clinical factors in physician and clinical athletic trainer (ATC) return-to-play (RTP) decision making in high school athletes who sustained a concussion.

METHODS: Sports Medicine physicians and ATCs completed a policy capturing survey of 50 clinical scenarios and rated how likely they were to clear the athlete for RTP. Nine factors were randomly varied within the scenarios: age, gender, sport, prior concussion, initial symptom score, symptom duration, and ImPACT performance. Participants then ranked how important each variable was in their decision making process.

RESULTS: 16 physicians (87.5% CAQSM, 12.5% Fellows, mean 9.2 concussions managed per month) and 29 ATCs (mean 4.8 concussions managed per month) participated. ImPACT testing was the most significant contributor in RTP decisions. Physicians and ATCs weighed ImPACT changed from baseline (β 0.42±0.23 and 1.28±1.18 respectively) and ImPACT compared to normative values (0.39±0.24 and 1.38±0.90 respectively) most heavily. Respondents self-ranked prior concussion and age as most influential in their RTP decision making. There was no correlation between participants self-ranking of importance and the observed contribution of a variable to decision making.

CONCLUSIONS: Respondents displayed poor insight to the role of various clinical factors in their management of concussion RTP. ImPACT testing has a greater influence on RTP decisions than physicians and ATCs realize. Despite having low self-ranked importance, variables related to ImPACT results were among the most influential. Self-ranking importance of clinical variables is similar between physicians and ATCs; however, symptom duration is less important to ATCs compared to physicians. Although age was considered important in self-ranking it was not a significant contributor to RTP decision making.

2157 Board #313 May. 30 3:30 PM - 5:00 PM
Evaluating Patient Reported Outcomes in a Pediatric Sports Medicine Practice: A Look at the FAAM

Alissa Conde, Adam Kiefer, Christy Reed, Katherine Cieslak, Paul Gubanich, FACSM. *Cincinnati Children's Hospital Medical Center, Cincinnati, OH*. (Sponsor: Dr. Paul Gubanich, FACSM)
 Email: alissa.conde@cchmc.org
 (No relationships reported)

Purpose: Foot and ankle injuries account for up to 30% of all pediatric sports medicine visits. Self-reported outcome measures can be utilized to capture the patient's perspectives on their injury and monitor recovery, however, this has not been well studied in youth athletics. The objective of this study is to examine the relationship between patient injury characteristics and FAAM scores. **Methods:** A retrospective cross-sectional pilot study was conducted on patients that completed the Foot and Ankle Ability Measure (FAAM) survey as standard of care for either their first clinic or physical therapy visit. Factors of interest include age, sex, diagnosis and type of rehabilitation program. Descriptive statistics and multiple linear regression models were performed. **Results:** In this pilot study, 457 individuals were identified as having completed the FAAM over the 3 year review period. A sample of 36 patients with 42 distinctive injuries were reviewed. The average age of the sample was 16.38 years, 53% were female. Only 8 athletes (22%) identified as participating in multiple sports. Soft tissue injury was the most common diagnosis (65% of encounters) and more than half of the patients were referred to physical therapy. The average time from injury to presentation was 63 days (RNG: 1-694 days). The average initial FAAM score was 0.52 (SD ± 0.28, RNG: 0.03-0.96). Multiple linear regression models showed no significant predictors. Only time from injury to initial FAAM score approached a p-value of 0.10. **Conclusions:** The use of the FAAM may provide insight into patient perception of function and recovery from a musculoskeletal injury. Our study unveils characteristics of one cohort of adolescents from a pediatric sports medicine clinic with foot and ankle injuries. Time to presentation was significantly longer than expected but perceived level of dysfunction was higher. The multiple linear regression models showed no strong predictors of FAAM scores, however, this pilot study was underpowered. Future efforts will focus on further evaluation of this entire cohort and the interaction between injury characteristics, management recommendations, and FAAM scores.

2158 Board #314 May. 30 3:30 PM - 5:00 PM
Application of Quantitative Balance Testing to Office Based Concussion Care: A Feasibility Study

Brady Bowen, Ian D. Hutchinson, Kelly Russo, Hamish A. Kerr, FACSM. *Albany Medical Center, Cohoes, NY*. (Sponsor: Hamish Allister Kerr, FACSM)
 (No relationships reported)

PURPOSE

Assessment of concussion in the office should be multimodal, including a clinical interview, neurocognitive and balance assessment. Access to baseline, pre-injury measures have been identified as having greater clinical utility than single assessments. Our institution offers baseline ImPACT neurocognitive assessment to pediatric contact sport athletes. The goal of this study was to determine the feasibility of quantitative balance testing of individuals to improve quality of our concussion care.

METHODS

Following Institutional Review Board (IRB) approval, patients were offered objective balance assessment using a modified Balance Error Scoring System (mBESS) conducted using a combination motion analysis video/force plate of postural stability (Equilibrate; Balance Engineering LLC, Henrietta, NY). Baseline balance testing obtained was compared to published normative data (Howell & Meehan, J Pediatr Orthop, 2016); results were segmented by age and gender using unpaired Student-t test with significance set at $p < 0.05$.

RESULTS

80 patients (December 2014-present) conducted a balance assessment: (43 Female/ 37 Male); age (14.5±4.1 yrs); Body Mass Index (21.7±5.6 Kg/m²), previous concussion 7/80 (9%) and history of lower extremity musculoskeletal injury 15/80 (19%). 18 patients over the age of 18 years were excluded from comparative analysis to published pediatric normative data, leaving 62 patients. Two stances were directly compared and analyzed: double leg stance and tandem stance (non-dominant behind) with eyes closed. There were significantly better performances in our study groups in tandem stance for 16-18 yrs females, 8-12 yrs males and females compared to the normative data (Table. 1).

CONCLUSION

Quantitative baseline balance testing was deliverable in our office and our results indicate better performance for some populations than previously published normative data.

Specific Dietary Practices In Female Athletes And Their Association With Disordered Eating

Celina Francesca de Borja, Lauren M. McCall, Bryan Holtzman, Laura Moretti, Nicole Farnsworth, Kathryn E. Ackerman. *Boston Children's Hospital, Boston, MA.* (Sponsor: Kathryn Ackerman, FACSM)
 Email: celina.deborja@childrens.harvard.edu
 (No relationships reported)

PURPOSE: Health and weight management benefits may influence athletes' decisions regarding specific dietary practices. Eating disorders/disordered eating (ED/DE) are highly prevalent in the athletic population. The purpose of this study was to determine if following specific diets correlated with a greater likelihood of responding positively to ED/DE screening tools compared to not adhering to a diet. **METHODS:** 1000 female athletes (15-30 yrs) were asked to complete a comprehensive health and wellness survey. Athletes were asked to specify their diet and completed 3 ED/DE screening tools: the Brief Eating Disorder in Athletes Questionnaire, the Eating Disorder Screen for Primary Care, and self-reported current or past history of ED/DE. We hypothesized that athletes adhering to specific diets were more likely to score positively on ED/DE screening tools than those not following a diet. The most common diets were included in the analyses: vegan, vegetarian, pescatarian, gluten free, low carbohydrate, low dairy, and ≥ 2 diets. Athletes following diets for health issues (e.g. Celiac disease) were excluded. Descriptive statistics were calculated for all study measures and Chi-square testing was performed to assess relationships between athletes' dietary practices and their responses to ED/DE screening tools. **RESULTS:** 234 of 1000 female athletes reported adherence to specific diets; 766 reported no diet adherence. 69 of the 234 athletes were excluded due to medically-related dietary practices or vague dietary descriptions. 133 athletes reported following 1 of the diets and 32 athletes reported following ≥ 2 diets. Of the diet-adherent athletes, 67.9% responded positively to ≥ 1 of the 3 ED/DE screening tools. Athletes practicing vegetarian, vegan, low carbohydrate, low dairy, or ≥ 2 diets were more likely to respond positively to ≥ 1 ED/DE screening tool vs. athletes without dietary restrictions (70.0%, 77.8%, 79.5%, 60.0%, and 65.6%, respectively vs. 41.8%; $p \leq 0.048$). **CONCLUSION:** Specific diet adherence in female athletes is associated with greater likelihood of positive screening for ED/DE using survey self-report. Health practitioners should consider further ED/DE questioning of athletes reporting specific diet adherence in order to enhance nutritional knowledge and help treat and prevent ED/DE.

2160 Board #316 May. 30 3:30 PM - 5:00 PM
Concussion Symptom Reporting Across Age Levels

Eric M. Bankert, Franklin Sease, FACSM, Vicki Nelson. *Greenville Health System Steadman Hawkins Clinic of the Carolinas, Greenville, SC.* (Sponsor: Franklin Sease, FACSM)
 Email: Ericbankert@gmail.com
 (No relationships reported)

Purpose: To evaluate differences in concussion symptom reporting across age levels **Methods:** Between 2008-2018 post-concussion symptoms were reported by Middle School (MS), High School (HS) and Collegiate athletes (CA) utilizing the post-concussion symptom scale after a concussive injury. Repeat evaluations and initial evaluations with a symptom score of zero were excluded. ANOVA was performed assessing total symptom scores and number of symptoms reported by age group and gender. **Results:** 1,748 athletes (65.2% male, 22 sports) were included: Middle School (6.3%, n=110), High School (86.4%, n=1511) and Collegiate (7.3%, n=127). Significant differences were found in total symptom scores ($p=0.006$) and number of symptoms reported ($p=0.00003$). Symptom scores were highest in High School athletes (23.37, SD 20.2) compared to MS (mean 17.78, SD 18.5) and CA (20.13, SD 21.3). Total number of symptoms reported was also highest in High School athletes (9.73, SD 6.1) compared to MS (7.55, SD 5.4) and CA (8.02, SD 5.9). High School females report significantly higher symptom scores (27.5+/-22.5 vs 21.6+/-18.9, $p < 0.0001$) and number of symptoms (10.7+/-6.1 vs 9.4+/-6.1, $p=0.0002$) relative to male peers. **Conclusion:** In student athletes who have suffered a concussion, the post injury symptom scores and total number of symptoms and individual symptoms reported varied significantly across age levels, with significantly less symptoms being reported in the middle school athletes.

2161 Board #317 May. 30 3:30 PM - 5:00 PM
The Role of Resistance Training Dosing on Pain and Quality of Life in Individuals with Knee Osteoarthritis: A Systematic Review

Meredith N. Turner, Daniel O. Hernandez, Christopher P. Emerson, William Cade, John Reynolds, Thomas M. Best, FACSM. *University of Miami, Coral Gables, FL.*
 (No relationships reported)

Purpose: To determine whether resistance training effects pain and quality of life in individuals with knee osteoarthritis (OA), and whether or not a dose-response relationship exists. Secondly, we will investigate if the effects of resistance training are influenced by KL grade or location of OA (tibiofemoral and/or patellofemoral). **Methods:** A systematic literature search of three electronic databases (PubMed, CINAHL, and EMBase) was performed for English studies to identify RTCs comparing resistance interventions with no intervention or education in knee OA and reporting changes in pain and physical function. Articles meeting inclusion criteria were assessed independently by two reviewers for methodological quality using the CONSORT 2010 scale and bias assessed by the Cochrane Collaboration's tool for assessing risk of bias. **Results:** Four hundred and sixty-nine studies were found in the initial search. Fourteen were included for analysis after screening. Thirteen trials were rated with high methodological quality based on the CONSORT scoring system. One study was excluded due to poor CONSORT score (9). Thirteen eligible trials with 1,521 participants were therefore included in the subsequent analysis. The average CONSORT quality score was 20.3 (range 17 to 24.5). Evidence from eleven studies revealed resistance training significantly improved pain and/or quality of life. No trends were identified with maximum strength, and frequency of exercise sets or repetitions, and thus trends between strength training outcomes and location or KL grade of knee OA were unable to be evaluated. **Conclusion:** This systematic review suggests that resistance training improves pain and quality of life for patients with knee OA, but specific optimal dosing strategies remain unknown. Further high quality prospective studies with homogenous populations and interventions aimed to investigate precise dosing parameters are needed.

2162 Board #318 May. 30 3:30 PM - 5:00 PM
Distribution of Sonographically Guided Injections of the Subgluteus Minimus and Medius Bursae in Cadaveric Model

Brittany J. Moore¹, Wade Johnson², Jonathan T. Finnoff, FACSM², Jay Smith¹, Jacob L. Sellon¹. ¹Mayo Clinic, Rochester, MN. ²Mayo Clinic, Minneapolis, MN. (Sponsor: Dr. Jonathan Finnoff, FACSM)
 (No relationships reported)

PURPOSE: The primary purpose of this investigation was to describe and validate sonographically guided techniques for injecting the subgluteus minimus bursa (SGMinB) and subgluteus medius bursa (SGMedB) in a cadaveric model. **METHODS:** A single experienced operator completed all injections under ultrasound guidance in 12 unembalmed cadaveric specimens. SGMinB injections (N=12) placed 3mL of diluted blue latex into the bursa using an in-plane, anterior-inferior to posterior-superior approach in short axis (SAX) to the gluteus minimus (GMin) tendon. SGMedB injections (N=12) placed 3 mL of diluted yellow latex into the bursa using an in-plane, anterior to posterior approach in SAX to the gluteus medius (GMed) tendon. For comparison with more commonly performed injections, the same operator completed sonographically guided injections into the subgluteus maximus bursa (SGMaxB, N=12) and sonographically guided intraarticular hip injections (N=2) in the same 12 specimens. 10 specimens were subsequently dissected and 2 specimens were frozen and cut into cross sections. **RESULTS:** All 12 SGMinB injections accurately placed latex deep to the GMin tendon without intraarticular communication. All 12 SGMedB injections accurately placed latex deep to the GMed tendon. In 3/12 specimens some latex communicated between SGMinB and SGMedB, 2 of which occurred in the setting of pre-injection documented tendinosis. No injections communicated with the SGMaxB or intraarticular space. **CONCLUSIONS:** Sonographically guided SGMinB and SGMedB injections can accurately target specific locations of tendon-bursa pathology in patients with greater trochanteric pain syndrome. In the presence of tendon pathology, communication between SGMinB and SGMedB may occur.

Field Of View: A Football Player With Acute Visual Changes

Samantha Smith, James J. Kinderknecht. *Hospital for Special Surgery, New York, NY.*
(No relationships reported)

HPI

A 23 year old professional football player self-reported abnormal vision during a game. He had two episodes of blurriness in the superior visual field of the right eye lasting 15-20 minutes each and separated by 15 minutes. He had no eye pain or headache. No identified head trauma preceding symptoms. He was not removed from play.

Exam

At halftime: Blood pressure 130/83. Normal appearing conjunctiva and clear corneas. Pupils equal, round, and reactive to light. Normal extra-ocular movements. Visual fields full to confrontation. Decreased visual acuity in right eye. Undilated fundoscopic exam revealed crisp vessels and normal optic discs. Neurologic exam normal. Post-game: Normal visual acuity and remainder of exam normal.

Differential Diagnosis

1. Retinal detachment
2. Retinal vessel occlusion
3. Acephalgic migraine
4. Concussion
5. Optic nerve lesion

Tests and Results

Athlete referred to ophthalmology for full eye exam the day following the game.

Ophthalmology Findings:

- normal intraocular pressure
- bilateral AV nicking consistent with hypertensive retinopathy
- right retinal venous engorgement with few dot blot hemorrhages consistent with central retinal vein occlusion
- no retinal detachment

Carotid artery ultrasound and transthoracic echocardiogram were unremarkable. Laboratory tests for coagulopathy and systemic inflammatory disease were negative. Sleep study was notable for severe supine obstructive sleep apnea with associated episodic hypoxia and severe sleep fragmentation.

Final/Working Diagnosis

Central retinal vein occlusion and hypertensive retinopathy, likely associated with obstructive sleep apnea, an association described in the literature, with no other identified etiology.

Treatment and Outcomes

- Athlete did not miss any football practices or games
- Vision remained normal and follow up retina exam was unchanged
- Blood pressure monitored frequently without any documented daytime hypertension
- Began to use CPAP at night
- Reported improved sleep quality and reduced daytime fatigue

2164 Board #320 May. 30 3:30 PM - 5:00 PM

It's More Than A Headache

Juan M. Guzman, Jr., Darin Rutherford, Dennys Maldonado.
Mercyhealth, Janesville, WI.
Email: micajg@glink.drexel.edu
(No relationships reported)

HISTORY:

15yo male high school soccer player with headache and dizziness following injury 1 month prior.
Event was soccer ball striking right temporal area with fall to the ground without secondary head trauma or loss of consciousness. On rising, patient was knocked down by the opponent. He removed himself from the game due to symptoms of headache, balance problems, dizziness, sensitivity to light and noise, irritability, feeling slowed down, feeling mentally foggy, difficulty concentrating, and having visual problems. He had associated neck pain, numbness and tingling in the left upper extremity and left lower extremity after the injury.
No weakness in the upper or lower extremities.
No retrograde or anterograde amnesia reported.
He continued to play the game.
Reported his symptoms to the coach and licensed athletic trainer (LAT) when the game finished.

History of congenital C2-C3 autofusion, concussion 4 years prior with loss of consciousness, and posterior tension-like headaches with coughing and laughing.
PHYSICAL EXAM:

NECK: Neck supple without rigidity. FROM without tenderness on movement or palpation

NEURO: alert, oriented, normal speech. Normal neurological exam of arms.

Normal DTRs, motor, sensory exam.

No focal findings or movement disorder noted.

Finger to nose testing normal.

Cranial nerves II-XII intact.

Motor and sensory grossly normal bilaterally, normal muscle tone, no tremors, strength 5/5

GAIT: normal

Post Concussion Symptom Scale: 46

DIFFERENTIAL DIAGNOSIS:

1. Post-concussion syndrome
2. Cervical Spinal Stenosis
3. Cerebral Herniation

TEST & RESULTS:

MRI of brain & C-spine: Chiari 1 malformation with cerebellar tonsils extending 2 cm below the foramen magnum. Dens angled posteriorly, increasing the degree of crowding at and below the foramen magnum. There is associated slight indentation of the ventral aspect of the upper cervical spinal cord. Congenital partial fusion of C2 and C3. The posterior arch of C1 appears incomplete. No spondylololsthesis.

FINAL WORKING DIAGNOSIS

Chiari Type 1 malformation

TREATMENT & OUTCOMES

1. Avoid athletic activities and referred to neurosurgery for treatment.
2. Neurosurgery performed posterior fossa decompression and duraplasty procedure successfully.
3. Discharged from hospital to home after 3 days with full resolution of headaches and symptoms.

2165 Board #321 May. 30 3:30 PM - 5:00 PM

When Leg Pain In A Runner Does Not Mean Stress Fracture Or Shin Splints

Sayedmajid Reza Alavi Dehkordi, Carlos R. Rodriguez. *Bayfront Health System, St. Petersburg, FL.*
Email: alavidehkordi@hotmail.com
(No relationships reported)

HISTORY: A 17-year-old male participating in high school middle-distance running presented with a 6-week history of lower left leg pain and limp. The pain was getting worse with increased training. He was running an average of 12-15 miles per day five days a week. This was evenly split on streets and cross-country roads. Although he had taken analgesics, the pain did not improve. He had no pain at rest but had noted some occasional pain at night. There was no history of antecedent trauma and the remaining history did not reveal any significant abnormalities.

PHYSICAL EXAMINATION: Local examination revealed diffuse tenderness over the anterior aspect of the lower left leg. There was no bruising or palpable swelling noted. The musculature and strength was normal. The range of motion of the left knee and ankle joints was normal and there was no neurovascular deficit noted. General physical examination did not reveal any significant abnormalities.

DIFFERENTIAL DIAGNOSIS: 1-Shin Splint 2-Stress Fracture 3-Brodie Abscess 4-Osteoid Osteoma

TEST AND RESULTS: Plain radiographs revealed cortical thickening in the middle 3rd of medial cortex of Tibia(Figure-1). The central nidus and the surrounding sclerosis of the bony lesion was apparent on the CT scan (Figure-2).

FINAL/WORKING DIAGNOSIS: Osteoid Osteoma

TREATMENT AND OUTCOMES: The patient underwent surgical en bloc excision as an outpatient procedure. A shark bite excision of cortical lesions along with the surrounding sclerotic bone was performed under image guidance. The specimens were sent for histopathological examination which was consistent with Osteoid Osteoma. He was kept partial weight bearing for 6 weeks, followed by gradual progression to full weight bearing. Three months post-surgery, the patient was completely asymptomatic. Follow-up radiographs revealed a well-healed excision site and no evidence of recurrence. He returned to his running without problems .

2166 Board #322 May. 30 3:30 PM - 5:00 PM

Doc, My Leg Is Numb.

Justin R. Thompson¹, P. Patrick Mularoni², Sayedmajidreza Alavidehkordi¹. ¹Bayfront Health, Saint Petersburg, FL. ²Johns Hopkins All Childrens Hospital, Saint Petersburg, FL.
(No relationships reported)

HISTORY: An 18 year old, high school, football kicker suffers a leg injury during his last regular season game. He kicked his last PAT of the game when he reported tightness in his anterior leg. During the following kick off, he felt a pop in his right upper thigh as he kicked the ball. He reported immediate pain and difficulty walking. He was able to independently limp off the field. That night he elevated and iced his leg. He reported that he fell asleep with his leg elevated with ice on the area. Upon waking the next morning he felt numbness in the outside of his right thigh. He continued experiencing the soreness in the anterior portion of his thigh, but reported it was no worse than the day before. He denied any back pain, prior back injury, or history of trauma to his back. **PHYSICAL EXAMINATION:** General: NAD, crutch assisted ambulation, athletic build CV: 2+ dorsalis pedis pulses bilaterally, warm extremities Pulm: no dyspnea GI: abdomen soft, non-tender Skin: no bruising Neuro: decreased sensation subjectively along the outer right thigh from hip to knee MSK: Pain to palpation along proximal hip flexors and AIIS, no defect in muscle palpated, full AROM, PROM of hips. 4/5 strength of right hip flexion secondary to pain, 5/5 on left. 5/5 strength bilaterally with hip extension, adduction, abduction, as well as knee flexion and extension. No spinous process or SIJ tenderness to palpation, no step offs appreciated. **DIFFERENTIAL DIAGNOSIS:** 1. Avulsion fracture of AIIS with associated nerve injury 2. Hip flexor strain with meralgia paresthetica 3. hip flexor strain with direct nerve injury from ice 4. FAI with acute hip labral tear 5. Lumbar disc herniation **TEST AND RESULTS:** Pelvis XR: Normal radiographic examination of the hips and the remainder of the pelvis **FINAL/WORKING DIAGNOSIS:** Hip flexor strain with associated meralgia paresthetica **TREATMENT AND OUTCOMES:** 1. Rest from kicking over the following 10 days. 2. Active recovery with ATC at school 3. Numbness resolved at time of follow up in clinic, strength was returning without pain with hip flexion 4. Released to increase kicking distance from PAT to less than 30 yards with plans to increase as tolerated, recommended no kick offs for the remainder of playoffs 5. Athlete had complete resolution of symptoms and was back to full kicking duties approximately 4 weeks after initial injury

2167 Board #323 May. 30 3:30 PM - 5:00 PM

"Not Just Another Ankle Sprain"-an Interesting Case Of Chronic Ankle Pain

Cole C. Budinsky. *Nationwide Children's Hospital, Columbus, OH.*
(No relationships reported)

HISTORY: 22-year-old female presented with progressively worsening ankle pain, swelling, catching, and locking over a five year period. She denied recent or prior trauma. Her limitation was inability to stand throughout a full work day. Past medical history was significant for morbid obesity s/p sleeve gastrectomy 4 years ago. She was seen in the past and told it was "just another ankle sprain" or "from her weight". The pain has worsened despite claims it would improve "once she lost weight". **PHYSICAL EXAMINATION:** Mild circumferential swelling with moderate pes planus noted. Tenderness: talar dome, post.-tib. tendon, posterior talar processes. Full ROM, with 4/5 strength appreciated in all planes. Able to walk on heels and toes, with a limp. Unable to hop. Anterior Drawer: positive w/excessive laxity and crepitus. Talar Tilt: positive. Anterior impingement and impaired proprioception noted. Sensation and pulses intact. **DIFFERENTIAL DIAGNOSIS:**
1. Talar Stress Fracture
2. Tarsal Coalition
3. Os Trigonum
TEST AND RESULTS:
Radiographs: 3-view Left Ankle
-Degenerative changes of the tibiotalar joint.
-Osteochondral lesions of the medial talar dome and medial shoulder of the tibial plafond.
-Hypertrophic changes concerning for enthesitis about the tendinous insertions.
MRI: Left Ankle:
-Chronic OCD lesion to medial talar dome with large subchondral cysts, measuring 16mm x 8mm.
-Talar Dome collapse with Outerbridge Grade 3/4 articular cartilage loss of the overlying tibial plafond and talar dome.
-Enthesophytes of the dorsal and plantar calcaneus.
FINAL/WORKING DIAGNOSIS:
Large medial talar dome OCD lesion with subchondral cysts (Grade 5 Hepple MRI Staging) and evidence of enthesitis and degenerative talonavicular changes concerning for longstanding inflammatory arthritic condition.
TREATMENT AND OUTCOMES:

1. Tall walking boot and ice therapy, with work modifications to limit weight bearing status
2. Ortho Foot and Ankle referral to address operative management in process.
3. Referral to Rheumatology after case discussion given concern for inflammatory arthritis.
4. Final Outcome pending; patient has yet to consult with either of the above.

2168 Board #324 May. 30 3:30 PM - 5:00 PM

Tumbling Triceps in Gymnastics

Alecia Gende, Mederic Hall. *University of Iowa, Iowa City, IA.*
Email: alecia-gende@uiowa.edu
(No relationships reported)

HISTORY: 21 year old female, D-1 gymnast, with 2 weeks of tight and achy right triceps pain. Athlete noted pain after practice, denies specific injury. Her pain is worse with resisted elbow extension. She is treating conservatively, rehabbing with ATC with strengthening both shoulder and arm, and is now tolerating forward tumbling, but soreness remains with backward tumbling. She feels she has plateaued in progress. **PE:** Grossly unremarkable, no ecchymosis or swelling. She has tenderness to triceps muscle belly without palpable muscle defect. ROM and strength are intact at her shoulder and elbow. She is neurologically intact distally. **DDX:** Triceps tear, triceps tendinopathy, shoulder pathology **TEST & RESULTS:** MSK US-proximal, mid belly of long head of triceps muscle fiber disruption with 2 cm fiber gap and hematoma. Extensive hyperemia in zone of injury and 8 cm of fascial thickening. Active contraction demonstrates fiber gap without contraction at zone of injury and abnormal contraction of surrounding fibers. **FINAL/WORKING DX:** Acute tear of right triceps, long head, grade 2b **TREATMENT & OUTCOMES:** Platelet-rich plasma injection into triceps tear followed by compression and 2 days rest. Progressive, sport-specific, pain-free strengthening with ATC guidance. Athlete avoided weight bearing on hands and stretching of triceps. She tolerated dance and trampoline work without issue. Upon reaching 80% speed/power without pain or functional limitation, 2 weeks after diagnosis, we performed serial US exams to evaluate tissue healing and guide progressive muscle loading. 2 week US demonstrated decreased fascial thickening, 2 cm fiber gap w/hyperemia persisted. Absent contraction at site of injury remained, abnormal contraction of surrounding fibers was improved. Continued rehab, did not progress beyond 80% at this time regardless of pain-free status. 4 week US revealed resolution of hematoma and fascial edema. Mild hyperemia remained at zone of injury. Some abnormal contraction at site of injury present, and normalized contraction of surrounding fibers. Athlete was released to gradually RTP under ATC guidance. Athlete progressed overhead loading, reached 100% power/speed and was advanced to forward and eventually backward tumbling. She tolerated full RTP 8 weeks after initial US. Athlete remains without re-injury.

2169 Board #325 May. 30 3:30 PM - 5:00 PM

Knee Pain in a 7th Grade Runningback

Michael Bradburn¹, E. Ray Stewart¹, E. Lyle Cain². ¹The University of Alabama, Tuscaloosa, AL. ²Andrews Sports Medicine and Orthopaedic Center, Birmingham, AL.
(No relationships reported)

Authors: Michael J. Bradburn, E. Ray Stewart, E. Lyle Cain
Affiliation: The University of Alabama, Tuscaloosa, AL, Andrews Sports Medicine and Orthopaedic Center, Birmingham, AL
Title: Knee pain in a 7th Grade Runningback
Case History: Patient is a 13-year-old male 7th grade runningback who sustained a left knee injury at practice. He reported running the football and dragging a defender who was holding onto the patient's left leg. He felt a pop in his knee and reported immediate swelling. He was evaluated later that night at the Varsity football game and was referred to the sports medicine office in Tuscaloosa for evaluation.
Physical Exam
Inspection: non-weight bearing left lower extremity, assistance with crutches
Mild ecchymosis, severe effusion, maximal tenderness: lateral joint line, medial patellar, moderate swelling
Tests: left knee: negative Lachman's, guarded medial and lateral McMurray's. Negative valgus and varus stress, negative anterior and posterior drawer
Range of motion left knee: painful active and passive range of motion, 45 degrees of flexion active and passive, 0 degrees extension active and passive
Positive patellar apprehension on left
Lower extremity strength is normal
Lower extremity neurovascular exam is normal
Differential Diagnosis
#1: patellar subluxation
#2: femoral condyle fracture
#3: lateral collateral ligament sprain
#4: lateral meniscus tear
#5: femoral / tibial bone contusion
Tests and Results

THURSDAY, MAY 30, 2019

X-ray Knee 4 views Left: avulsion fracture of lateral femoral condyle – minimally displaced

MRI Left knee without contrast: popliteus tendon rupture with retraction. Edema surrounding ACL

Final/Working Diagnosis

Left popliteus tendon femoral avulsion

Discussion

Isolated popliteus tendon rupture is a rarely reported finding in the literature. The vast majority of popliteus tendon ruptures occur in combination with other ligamentous injuries specifically in the posterolateral structures of the knee. Generally, reported cases are treated non-operatively with a high rate of return to play at previous level.

Outcome

Patient was evaluated by an orthopedic surgeon at Andrews Sports Medicine and Orthopaedic Center in Birmingham, AL and underwent arthroscopic left popliteus tendon repair

Return to Activity and Follow Up

After surgery the patient followed an ACL rehabilitation protocol, weight bearing as tolerated in a controlled motion brace, locked in extension for two weeks and began physical therapy after his initial post-operative appointment two weeks after surgery. At his 2-week post-operative appointment he could wean off crutches and weight bear as tolerated with his knee brace locked in extension. Physical therapy following ACL rehab protocol was initiated for the next 4 weeks, allowing for range of motion exercises out of the brace. After six weeks total he was released to return to full activities.

2170 Board #326 May. 30 3:30 PM - 5:00 PM Hurting Humeri in a Teenage Fencer

Jacob Jones, William Meehan, III. *Boston Children's Hospital, Boston, MA.*

Email: jacob.jones@childrens.harvard.edu

(No relationships reported)

HISTORY: Patient is a 13-year-old right-hand-dominant male fencing athlete who presented with one year of intermittent right upper arm pain without a specific injury. The pain was diffuse throughout the entire upper arm. The dull, aching pain rated 5/10 and last weeks at a time. The pain was worse at night, causing him to cry. Advil and BenGay helped with the pain. PT did not seem to help. He had seen by two other physicians previously and had a working diagnosis of referred pain from the shoulder. He had shoulder x-rays that were reportedly normal. After initial evaluation and imaging, the patient rested from fencing and restarted upper extremity PT. At 2 month follow-up, he endorsed similar symptoms on his left upper extremity, despite not using the arm for any strenuous activities apart from PT **PHYSICAL EXAMINATION:** Normal cervical ROM. Normal posture. Bilateral upper extremities: No scapular dyskinesia. No pain with palpation over clavicle, SC joint, AC joint, biceps tendon, humerus, elbow. Full ROM of both shoulders and elbows. Negative rotator cuff, AC, labrum provocative tests. Nerves intact. **DIFFERENTIAL DIAGNOSIS:** Biceps/Triceps strain, Humeral stress injury, Cervical spine radiculopathy, Thoracic Outlet Syndrome, Leukemia

TEST AND RESULTS: Right humerus xray: Cortical thickening of the right mid humeral shaft, with subtle periosteal reaction. Mottled cortical thickening which could represent an atypical stress reaction location. Left humerus xray: Unremarkable. Right humerus MRI: Diffuse, primarily diaphyseal marrow and periosteal edema of the right humerus. Findings could be consistent with chronic stress injury. Left humerus MRI: Diffuse bone marrow edema of the left humerus, with adjacent periosteal and mild muscular edema, consistent with left humeral stress reaction with no fracture line. Labs: BMP, Mg, TSH, Free T4, PTH, Vit D, Celiac panel are normal. Phos mildly elevated. **FINAL/WORKING DIAGNOSIS:** Bilateral humeral stress reactions **TREATMENT AND OUTCOMES:** PT to work on upper extremity strengthening. Rest from fencing for 3 months. Recommended formal evaluation by bone specialist but family declined. Patient returned to full fencing activity 5 months after his initial right arm stress injury diagnosis without any return of symptoms

2171 Board #327 May. 30 3:30 PM - 5:00 PM Different Strokes for Different Folks

Shannon Carroll. *Edward Via College of Osteopathic Medicine at Auburn University, Auburn, AL.*

(No relationships reported)

HISTORY: A 21 year-old right-hand dominant Division I women's golfer presented with gradual onset right wrist pain starting July 2018 without change in equipment, technique, grip or shaft, but did increase tournament play over the summer. She was initially diagnosed with radiocarpal impingement and treated with posterior interosseous nerve injection at the fourth dorsal compartment. Shortly after she began to have right medial elbow pain with associated fourth and fifth digit numbness and tingling. She had an injection of the cubital tunnel as well with immediate pain relief, though the pain returned shortly after injection and continued to worsen. Particularly noted pain was worsened with full extension mid-swing. She had minimal playing time

through the fall season (unable to chip and putt secondary to pain) and has been unable to participate in spring practice for more than 10 minutes at a time without pain. At this time she is also having resting pain.

PHYSICAL EXAMINATION: Right Wrist/Hand: No muscular atrophy, full range of motion active and passively, non-tender to palpation, ligamentously stable Right Elbow: No soft tissue swelling, bruising, or muscle atrophy, tender to palpation over the flexor pronator mass, medial epicondyle, and sublime tubercle with resisted digital and wrist flexion as well as pronation, stable in varus and valgus at 0 and 30 degrees, positive Tinel's test and elbow flexion test, negative subluxable ulnar nerve, negative moving valgus test, negative Milking maneuver, decreased sensation in the distribution of the ulnar nerve, negative Froment sign, negative Scott Earl test, negative Wartenberg syndrome. **DIFFERENTIAL DIAGNOSIS:** 1. Medial Epicondylitis 2. Cubital Tunnel Syndrome 3. Flexor Pronator Syndrome **TEST AND RESULTS:** 1/2/19 MRI Right Elbow - minimal tendinopathy of the common flexor tendon without tear, small spurring at the sublime tubercle with subtle marrow edema, possibly reflecting low-grade stress reaction, intact UCL, anconeus epitrochlearis identified T2-weighted axial images 11-12 1/10/19 Right Upper Extremity EMG/NCV - no evidence of right cervical radiculopathy or ulnar neuropathy 2/19 Right Upper Extremity Dynamic EMG/NCV - no significant change in activity, recruitment or motor unit seen pre- or post-exertion of right upper extremity; parenthetically despite normal studies, significant tenderness palpated in the area of the anconeus/flexor carpi ulnaris origin on the median elbow region **FINAL/WORKING DIAGNOSIS:** Dynamic Compression of Ulnar Nerve secondary to Anconeus Epitrochlearis with Medial Epicondylitis **TREATMENT AND OUTCOMES:** Surgical cubital tunnel release with anterior subcutaneous nerve transposition with a nerve protection wrap, neurolysis of the posterior medial antebrachial cutaneous nerve and excision of the Flexor Carpi Ulnaris. Post-operatively she will be in a long arm splint for two weeks followed by a removable long arm splint with 30 degrees extension at the wrist and 90 degrees flexion at the elbow. Continue progression at 4 weeks post-operatively to full active range of motion, then 6 weeks full passive range of motion if indicated. At 8 weeks patient can begin sport-specific activity with full return to play after 12 weeks of post-operative recovery.

2172 Board #328 May. 30 3:30 PM - 5:00 PM An Unusual Presentation of an Increasingly Common Infection

Erica Martin. *The University of Michigan, Ann Arbor, MI.*

(Sponsor: Keri Denay, FACSM)

Email: erma@med.umich.edu

(No relationships reported)

HISTORY: 20-year-old female collegiate basketball player with no medical history presented to training room for 1 day history of epigastric abdominal pain. Pain initially generalized but then localized to epigastric region with nausea and non-bloody diarrhea but no emesis or urinary symptoms. Patient's last menstrual period ended 2 days prior to presentation, was normal. She is sexually active but uses condoms inconsistently. No vaginal complaints. She tried ibuprofen for pain which helped somewhat. No history of GERD, but given location of her symptoms and benign examination, treated with Tums with follow up in 1-2 days. She presented to the emergency department that evening as pain acutely increased.

PHYSICAL EXAMINATION: (in emergency department)

General: fatigued, moderate distress

HEENT: dry mucus membranes

Gastrointestinal: tender in the bilateral upper quadrants, normal bowel sounds, no rebound or guarding.

Psychiatric: appropriate affect

DIFFERENTIAL DIAGNOSIS:

1. Gastroesophageal reflux
2. Viral gastroenteritis
3. Anxiety

TESTS AND RESULTS:

1. Negative labs: comprehensive metabolic panel, lactate, blood cultures (eventually)
2. Abnormal labs: complete blood count (CBC) (high white blood cell count)
3. Imaging studies: abdominal ultrasound unremarkable, CT of abdomen and pelvis negative.

FINAL/WORKING DIAGNOSIS:

Gonorrhea

TREATMENT AND OUTCOMES:

Two days after initial emergency room (ER) visit, patient returned and was feeling a bit better, but was still having abdominal pain in the right upper and bilateral lower quadrants. Examination reassuring, but repeat CBC obtained given leukocytosis in ER and sexually transmitted infection (STI) testing ordered. White blood cell count decreased. Prior to STI testing resulting, patient's abdominal pain increased and she was directed again to the ER. There, she had pelvic examination which revealed yellow cervical discharge. STI testing done, in addition to urine pregnancy testing. Transvaginal ultrasound was negative. At the time of discharge from the ER, STI test results pending. Treated empirically in ER for STI with azithromycin and ceftriaxone.

Both STI tests (from training room and ER) positive for gonorrhea after discharge from ER. In follow up with patient, she is feeling better and has returned to normal activities.

A Narrow Wrestling Decision

Tyler K. Drewry¹, Richard Okragly¹, Jaideep Chunduri².
¹TriHealth, Cincinnati, OH. ²Beacon Orthopaedics, Cincinnati, OH. (Sponsor: Henry Stiene, MD, FACSM)
Email: kdrewry88@gmail.com
(No relationships reported)

HISTORY: A 25 year-old male college wrestler presented to the training room the day after a wrestling match complaining of neck soreness. He had unintentionally fallen backwards on the mat and sustained a hyperextension injury of his neck. Immediately after the trauma, he felt an “electrical sensation” traveling down both of his arms into his hands, which resolved within 24-48 hours. At the time of evaluation, he denied any weakness, bowel or bladder retention or incontinence, or numbness or tingling. His only complaint was residual neck pain which was previously treated with oral prednisone and NSAIDS.

PHYSICAL EXAMINATION: A young healthy male in no distress. Normal ambulation. Neck range of motion demonstrated full flexion, but 50% in extension, right and left rotation and lateral tilting. Pain reproduced with neck extension. There was left and right cervical paraspinal tenderness to palpation with no step-off or crepitus noted. Bilateral upper and lower extremity strength, sensation, and reflex testing were normal. No clonus and negative Babinski, Spurling’s, and Hoffman’s signs.

DIFFERENTIAL DIAGNOSIS:

1. Cervical paraspinal muscle strain
2. Cervical Cord Neurapraxia
3. Fracture of cervical vertebrae
4. Congenital Cervical Stenosis

TEST AND RESULTS:

Cervical Spine AP and Lateral Radiographs: Seven cervical vertebrae seen in AP view. Pedicle shadows intact. Lateral view shows loss of cervical lordosis. Intervertebral disc spaces are well maintained.

CT Cervical Spine WO Contrast: No evidence of fracture or subluxation. Mild congenital cervical canal stenosis.

MRI Cervical Spine WO Contrast: No evidence of acute injury. Multilevel cervical spondylosis with congenital stenosis with the diameter of the spinal canal measuring 6-7 mm. No significant CSF surrounding the spinal cord.

Torg ratio measured on all imaging had values of 0.7 or less.

FINAL/WORKING DIAGNOSIS:

Congenital Cervical Stenosis with associated Cervical Cord Neurapraxia and Cervical strain

TREATMENT AND OUTCOMES:

Based off of imaging and Torg ratio of 0.7 or less, the athlete was not cleared to return to participation. Although he had wrestled for 20 years without issues, he did sustain a transient spinal cord injury necessitating a visit to the ER. He was referred for a second opinion to a neurosurgeon regarding clearance for return to play.

2174 Board #330 May. 30 3:30 PM - 5:00 PM

A Jaw Crushing Line Drive in a Baseball Pitcher

Joshua I. Wilner, Michael Fong, Kaiser Permanente, Los Angeles, CA. (Sponsor: Aaron Rubin, FACSM)
(No relationships reported)

Title: A Jaw Crushing Line Drive in a Baseball Pitcher

Authors: Joshua Wilner, MD, Michael Fong, MD (Sponsor: Aaron Rubin, FACSM)
Institutions: Kaiser Permanente Los Angeles

History: A 23 year old collegiate baseball pitcher sustained a line drive off the right body of his mandible. The patient had a few seconds in which he reported loss of consciousness. After regaining consciousness, he found the baseball at his feet and threw to first in time for the out. At initial medical evaluation, patient complained of pain and bleeding at the right body of his mandible where the baseball made struck him. However, the site of maximal pain was the left superior mandible, where there was no direct trauma. The patient also had concussion symptoms, including headache, confusion, and photophobia.

Physical Examination: Examination on the field indicated a superficial laceration over the right body of the mandible. There was tenderness and swelling at the right body and left subcondylar aspect of the mandible. He had trismus, but no dysphagia or malocclusion. Patient had a positive concussion evaluation. There was no dental or oral trauma. There was no airway compromise or cervical spine abnormalities. There were no neurological deficits. The patient was sent to the emergency room for further evaluation and imaging.

Differential Diagnosis:

1. Mandible fracture
2. Mandible contusion

3. Mandible dislocation

Test and Results:

CT Scan Head and Mandible:

1. Non-displaced left subcondylar mandible fracture
2. No fracture of right body of mandible
3. No acute intracranial hemorrhage or pathology

Final Diagnoses:

Non-displaced, closed left subcondylar mandible fracture
Concussion
Facial laceration

Treatment and Outcomes:

1. Mandible fracture was treated with observation and soft diet for 4 weeks.
2. All concussion symptoms resolved within 4 days, and the patient graduated return to play protocol.
3. The laceration was treated with simple interrupted suture repair for 7 days. There were no wound complications.
4. The patient returned to full baseball activities 4 weeks after date of initial injury.

2175 Board #331 May. 30 3:30 PM - 5:00 PM

A Real Pain in the Neck: A Football Player with Atypical Post-Traumatic Neck Pain

James Suchy, Doug McKeag, FACSM, OHSU, Portland, CA.
Email: jtsuchy@gmail.com
(No relationships reported)

HISTORY:

18 yo M football player presented to college training room clinic with painful right-sided neck swelling after blunt neck trauma from another player’s shoulder pad 2 weeks prior. He had presented to ER 2 days after the incident with acute neck pain and limited ROM, headaches, and difficulty concentrating. CT head & cervical spine were unremarkable. Diagnosed with concussion and SCM strain. He started concussion and muscle strain rehab. Concussion symptoms improved over the next two weeks, but his cervical pain and ROM didn’t, and his neck became more swollen. He denied recent illness, cough, rash, fever, chills, dyspnea, dysphagia. POCUS was performed before referral to ER. **PHYSICAL EXAMINATION:** VS: Normal; Gen: No acute distress HEENT: tender 5 x 3 cm subcutaneous mass on the antero-lateral neck, no bruits appreciable; MSK (Neck): tenderness to palpation along the entire right SCM, no spinous process tenderness, decreased lateral flexion and rotation towards the contralateral side; Card: Regular rate and rhythm, no murmurs; Resp: Clear bilaterally **DIFFERENTIAL DIAGNOSIS:** Occult cervical spine fracture, Intramuscular infection, Ruptured sternocleidomastoid, Internal jugular thrombosis, Arterial pseudoaneurysm

TEST AND RESULTS: POCUS: diffuse heterogenous regions throughout the SCM musculature, increased vascularity; ED Labs: WBC: 15.40; ED CT Neck with Contrast: diffuse inflammation of the right SCM muscle with multiple intramuscular abscesses collections in the deep aspect, largest measuring 2.1 x 2.4 x 6.0 cm with associated narrowing of the right internal jugular vein. **FINAL/WORKING DIAGNOSIS:** Traumatic SCM myositis with intra-muscular abscesses

TREATMENT AND OUTCOMES:

Hospitalized and started on IV Unasyn and Decadron. Ultrasound guided needle aspiration collected 2 cc purulent fluid that grew 2+ strep pyogenes. Symptoms didn’t improve, so sent to OR for I&D where purulent fluid was drained from cavities superficial to and within the SCM. Neck swelling, pain, and range of motion improved. Repeat neck CT confirmed resolution of infection. Discharged on oral Augmentin. Over several weeks rehabbed to full strength and range of motion in the neck. Given the duration of time away from sport, patient decided to red-shirt the rest of his football season.

2176 Board #332 May. 30 3:30 PM - 5:00 PM

Atypical Shortness of Breath in Division 1 Athlete

David M. Baxter, Crozer-Keystone Health System, Springfield, PA. (Sponsor: Thomas Kaminski, FACSM)
Email: david.baxter@crozer.org
(No relationships reported)

HISTORY: This patient a 20-year-old NCAA Division 1 Field Hockey player who presented with shortness of breath, early fatigue, weakness, and achiness with aerobic training for the past several years. She had symptoms almost immediately with aerobic conditioning that would progress as she continued to exercise. Our athlete reported a trial of pre-exercise albuterol which did not improve her symptoms or exercise tolerance.

PHYSICAL EXAMINATION: Lungs were clear to auscultation bilaterally, with appropriate inspiratory and expiratory effort and normal lung sounds. The patient was able to speak in full sentences without hoarseness. Pulse oximetry 99% and resting

heart rate was 64. There was no cyanosis or clubbing of the nails, with normal capillary refill. Cardiac exam revealed regular rate and rhythm without murmurs, rubs, gallops. PMI was not displaced.

DIFFERENTIAL DIAGNOSIS:

1. Reactive Airway Disease 2. Exercise Induced Bronchospasm 3. Valvular Heart Disease 4. Vocal Cord Dysfunction **TEST AND RESULTS:**

Chest X-rays —no focal consolidation, trachea is midline, no masses, no pneumothorax, full inspiratory effort. EKG —within normal limits. Echocardiogram —within normal limits, preserved ejection fraction and without significant stenosis or regurgitation Spirometry —Pre albuterol administration - FVC 3.33L, FEV1 3.01L, FEV1% 90.5% —Post albuterol administration - FVC 3.4L, FEV1 3.00L, FEV1% 88.9% —Normal lung volumes Flexible Laryngoscopy —appropriate vocal cord movement with respiration and phonation. **FINAL/WORKING DIAGNOSIS:**

Exercise-Induced Laryngeal Obstruction, Vocal Cord Dysfunction

TREATMENT AND OUTCOMES:

1. Referred to Otolaryngologist for diagnosis and treatment; diagnosed with Exercise-Induced Laryngeal Obstruction as diagnosis of exclusion 2. Treated with botox to the bilateral thyro-arytenoid muscles on 3 separate occasions separated by 4 months with positive clinical response. 3. Regular behavioral voice/speech therapy with Speech Language Pathologist tolerated well. 4. Sport psychology counseling was utilized and subjectively helpful to address the underlying anxiety associated with her dyspnea. 5. Patient with improved exercise tolerance, although continues to have symptoms and was unable to return to NCAA Division 1 competition level.

2177 Board #333 May. 30 3:30 PM - 5:00 PM

Eosinophilic Fasciitis Presenting as Benign Subcutaneous Emphysema

Karim Elghawy, Aditya Mehta, Karen Bovid, Robert Baker, FACSM. *Western Michigan University, Homer Stryker MD School of Medicine, Kalamazoo, MI.* (Sponsor: Robert J. Baker, FACSM)

(No relationships reported)

HISTORY: A previously healthy 12 year old female presented with left forearm pain and subcutaneous crepitus of one week duration. She sustained a minor fall 6 weeks ago where she scratched her forearm against a wooden deck. No bruising, cut wounds or penetrating injury. Few days later she developed dull aching pain and subcutaneous crepitus at the front of her left forearm. No redness, warmth, swelling or limitation of movement. X-rays showed air under the skin. She was started on oral antibiotic without improvement. Ten days later, she was admitted to the hospital and started on IV antibiotics with partial improvement. After 2 days she was discharged on oral antibiotics. Symptoms resolved within 10 days of discharge. A week from finishing antibiotics, she presented with similar symptoms without new injuries. No fever, malaise, weight loss or joint pains. She has family history of JIA in a 19 year old brother and Psoriasis in a 15 year old sister.

PHYSICAL EXAM: She looked non-ill and non-toxic with normal vital signs. There was a mildly tender palpable crepitus over the antero-lateral aspect of her left forearm. No localized swelling, erythema or fluctuation. Normal active range of motion at shoulder, elbow, forearm and wrist. Intact sensation to light touch. Intact radial pulse and brisk cap refill.

DIFFERENTIAL DIAGNOSIS:

1. Necrotizing fasciitis
2. Benign subcutaneous emphysema
3. Autoimmune disease

TESTS AND RESULTS:

Forearm AP and lateral radiographs:

-Moderate subcutaneous gas in the left volar forearm

MRI left forearm:

-Subcutaneous, muscle as well as superficial and deep fascial edema suggestive of cellulitis, myositis and fasciitis. Multiple foci of gas within the subcutaneous tissues and deep fascia-No osteomyelitis or abscess

CBC, CRP and ESR:

-Normal

Tissue biopsy and cultures:

-Severe eosinophilic inflammation, no bacterial growth

FINAL/WORKING DIAGNOSIS:

Eosinophilic fasciitis

TREATMENT AND OUTCOMES:

1. Surgical I&D. No fluid or gross tissue abnormality was noted
2. No antibiotics post-operatively, only one prophylactic dose intra-operatively after cultures were collected
3. Her symptoms resolved and she remained symptom free for 2 months
4. Symptoms recurred without new injury
5. She was referred to pediatric rheumatology for further management
6. Symptoms resolved spontaneously within 2-3 weeks

2178 Board #334 May. 30 3:30 PM - 5:00 PM

Tunneling Away Lateral Ankle Pain

Geoffrey Dreher, David Webner, Kevin DuPrey. *Crozer-Keystone Health Newtowrk, Springfield, PA.* (Sponsor: Thomas Kaminski, FACSM)

Email: geoffrey.dreher@gmail.com

(No relationships reported)

TITLE: Tunneling Away Lateral Ankle Pain

AUTHORS: Geoffrey M. Dreher, DO; David Webner, MD; Kevin DuPrey, DO
ACSM Sponsor (if you accept): Thomas Kaminski, PhD, ATC (kaminski@udel.edu)

HISTORY:

60-year-old boilermaker presented with 2-month insidious onset left lateral ankle pain, localized to the lateral malleolus, described as achy and throbbing, 7/10, worse with walking, stairs and climbing ladders. No relief with Acetaminophen or NSAIDs.

PHYSICAL EXAMINATION:

Left ankle: no edema or ecchymosis, full range of motion with pain in active dorsiflexion and plantarflexion. Strength 5/5, gross sensation intact and 2+ dorsalis pedis and posterior tibial pulses. Tenderness to palpation along the lateral malleolus extending distally approximately 5 cm along lateral ankle.

DIFFERENTIAL DIAGNOSIS:

1. Chronic lateral ankle instability
2. Peroneal tendinosis with subluxation
3. Lateral malleolar stress fracture
4. Ankle osteoarthritis
5. Talar osteochondral lesion

TEST AND RESULTS:

• Left ankle 3 view x-ray: Normal.
• Left ankle MRI: Anatomic variant involving conjoined peroneus brevis and longus tendons, located along the anterolateral aspect of distal fibula. Deficient/absent peroneal groove along posterior fibula, which also suggests congenital abnormality. Mild conjoined tendinosis, without surrounding edema.
• Left lateral ankle ultrasound: Intact peroneal tendon overlying the lateral malleolus with trace fluid in sheath. The peroneal tendons split just before brevis insertion onto base of 5th metatarsal.

FINAL/WORKING DIAGNOSIS:

1. Conjoined left peroneal tendon subluxation with tenosynovitis and absence of fibular groove.

TREATMENT AND OUTCOMES:

1. Physical therapy for 6 weeks led to improved balance and walking mechanics, but no change in pain.
2. Immobilization in CAM boot for 6 weeks caused no improvement in pain or swelling out of boot.
3. Corticosteroid injection to peroneal tendons at level of lateral malleolus lead to no improvement.
4. Podiatry referral and surgery including tubularization of peroneal tendons, creation of 6mm fibular groove and repair of peroneal retinaculum. 3 months post-operatively, the patient was full weight bearing pain free with daily activities in lace-up ankle brace.

2179 Board #335 May. 30 3:30 PM - 5:00 PM

Shoulder Pain in a Weightlifter

Kelly Joy Valignota, Terry Nicola, FACSM, Melody Hrubes. *UIC Sports Medicine, Chicago, IL.* (Sponsor: Dr. Terry Nicola, FACSM)

Email: kj.valignota@gmail.com

(No relationships reported)

HISTORY: A 20-year-old male weightlifter presented as a new patient to a sports medicine clinic with left shoulder pain. Pain began five months prior while the patient was performing overhead presses with a 205 lb barbell. While pushing up into his 5th repetition, he felt a “shift” in his left shoulder. He did not have a significant amount of pain at the time. In the following weeks, he began to have more pain in the left shoulder and decreased his weight during overhead presses and chest presses due to pain and weakness. He tried taking two weeks off from lifting, but when he resumed

he was unable to complete any overhead or chest work due to pain. The pain is focal over the anterior-lateral shoulder with no radiation. No numbness or tingling. He is unsure if his weakness is due to pain or a separate issue.

PHYSICAL EXAMINATION: There was no bony abnormality or muscle atrophy. Patient had full active range of motion of the left shoulder in forward flexion and abduction, with mild pain at end range. Passively, he had 85 degrees of external rotation and 85 degrees of internal rotation with arm abducted to 90 degrees. There was tenderness to palpation along the distal clavicle and acromion, as well as over the supraspinatus, infraspinatus, teres minor/major, biceps, and anterior deltoid. Jobe's test positive for pain and weakness. Positive cross-arm test. Negative Hawkin's, Neer's, O'Brien's, Speed's, and Yergason's. Pain with resisted external rotation and shoulder abduction. Strength was 5/5 at bilateral deltoid, biceps, triceps, wrist extensors, finger flexors, and finger abductors, but 4/5 during resisted left glenohumeral external rotation due to pain.

DIFFERENTIAL DIAGNOSIS: 1) Glenohumeral subluxation 2) Rotator cuff tear 3) Labral tear 4) AJ joint sprain/separation 5) Clavicle fracture
TESTS AND RESULTS: 1) XR Chest from ER visit for unrelated incident: Visualized left clavicle normal, shoulder not visualized. 2) MRI left shoulder without contrast: Nondisplaced fracture of the distal clavicle with associated bony edema of the clavicle and acromion at the AC joint with mild surrounding soft tissue edema. Low grade tendinosis of the infraspinatus and supraspinatus with suspicion for a tiny undersurface tear without retraction.

3) XR Clavicle: Clavicle is intact and negative for fracture.
FINAL/WORKING DIAGNOSIS: Nondisplaced fracture of distal clavicle
TREATMENT AND OUTCOMES:

- Given no signs of fracture healing after 5 months, ordered laboratory work which revealed Vitamin D deficiency. Patient started on Vitamin D 1200mg and Calcium 800mg daily.
- Activity modified to abstain from weight bearing exercises through the left upper extremity until next follow up visit.

2180 Board #336 May. 30 3:30 PM - 5:00 PM
Is it Friction? A Rare cause of Medial Knee Pain

Wade Johnson, Jeffrey Payne. *Mayo Clinic, Minneapolis, MN.*
 (Sponsor: Jonathan Finnoff, FACSM)
 (No relationships reported)

HISTORY: A 22-year-old male with no significant past medical history presents with reports of two weeks of progressive medial knee pain, after beginning training for a sprint triathlon. Prior to starting his training, he primarily lifted weights and ran only sporadically. He increased his running significantly up to 3 to 4 miles 4 to 5 times per week. Pain was initially only present while running, but became present with any activity including swimming, especially with a frog-leg kick, after cycling, and finally with day-to-day walking. He notes mild swelling in the medial knee. He denies any catching, locking, buckling, or give-way of the knee. He denies any paresthesias in the right lower extremity.

PHYSICAL EXAMINATION: Pain in the right medial knee with single leg squat on the right. No knee effusion, however, there is mild swelling located just below the medial joint line over the proximal medial tibia on the right. Knee range of motion is full bilaterally. Ligamentous exam stable. Pain with valgus stress testing at 30 degrees on the right without laxity. No tenderness over the medial or lateral joint lines. Tenderness to palpation over the proximal medial tibia a few centimeters distal to the joint line and over the MCL in this region. No tenderness to palpation over the proximal MCL or pes anserine bursa. **DIFFERENTIAL DIAGNOSIS:** 1. Medial tibial plateau stress reaction 2. Distal MCL sprain 3. Pes anserine bursitis

TEST AND RESULTS: Plain radiographs: — No acute osseous abnormality. MRI right knee: — focal subcortical marrow edema within the medial aspect of the tibia 2.5cm below the joint line at the site of a bony protuberance compatible with prominent medial tibial crest — No fracture line, or soft tissue mass
FINAL/WORKING DIAGNOSIS: Medial tibial crest friction syndrome
TREATMENT AND OUTCOMES:

- Voltaren gel and activity modification with cessation of cycling, and reduction in training volume, with reported improvement.
- Patient wanted to return to training for a triathlon and ultrasound-guided corticosteroid injection, deep to the MCL over the tibial protuberance, was performed.
- Patient reported complete resolution of pain immediately after injection that was maintained at 2 weeks.
- Patient completed his sprint triathlon without development of pain and he was instructed to follow-up should his symptoms recur.

2181 Board #337 May. 30 3:30 PM - 5:00 PM

Osteitis Pubis: A Career Ending Diagnosis?

Stephen Sanker, Amanda Goodale. *TriHealth, Cincinnati, OH.*
 (Sponsor: Henry Stiene, FACSM)
 (No relationships reported)

HISTORY:

A 19-year-old Division III collegiate basketball player presents with gradual onset of right groin pain during training. There is no known acute injury. He notes increasing pain during basketball workouts which occurs with running, squatting, and standing from a seated position. There are no radicular symptoms. No numbness, tingling. No genital pain or bulges in the groin. Of note, patient had similar symptoms in high school which reportedly never fully subsided. Treatment has included occasional NSAIDs and intermittent rest.

PHYSICAL EXAMINATION:

Skin intact. No warmth, erythema, or swelling
 Full active and passive range of motion of bilateral hips, pain at extremes of external rotation
 Tender anteriorly at bilateral groin and over pubic symphysis. Mildly tender proximal adductor tendons.
 Pain with FADIR and FABER testing, resisted straight leg raise, and abdominal crunch 5/5 strength of major muscle groups of the lower extremity

NVI

DDX:

- Hip flexor strain / tear
- Adductor strain
- Femoroacetabular impingement syndrome
- Osteitis pubis

Athletic pubalgia

TESTING:

AP and lateral Xrays of right hip:

- No acute osseous abnormalities. No signs of degenerative changes
 MRI of the pelvis:

- Symmetric stress edema on either side of pubic symphysis consistent with osteitis pubis.

FINAL/WORKING DIAGNOSIS:

Osteitis pubis

TREATMENT AND OUTCOMES:

- Several weeks of rest and oral NSAIDs with mild improvement in symptoms, followed by athletic trainer supervised therapy focused on core and pelvic strengthening.
- Corticosteroid injection of pubic symphysis two months after initial presentation with modest improvement in symptoms, though short-lived.
- Patient continues to have significant pain with any increased levels of activity.
- Recently prescribed topical NSAID.
- Consult with local surgeon recommended against surgical intervention at this time. Discussed further work-up and treatment options with patient including: protected weight-bearing with crutches, repeat MRI with athletic pubalgia protocol, diagnostic femoroacetabular injection, MRI arthrogram of hips evaluating for labral pathology, platelet rich plasma injections, pubic symphysis excision. Patient has recently been only exercising in limited fashion, and is not currently participating in collegiate athletic due to pain.

2182 Board #338 May. 30 3:30 PM - 5:00 PM

Left Knee Pain In A 9-year-old Female

Branden Turner. *Kaiser Los Angeles Sports Medicine, Los Angeles, CA.* (Sponsor: Aaron Rubin, FACSM)
 Email: branden.turner@kp.org
 (No relationships reported)

HISTORY: 9yo female presents with 2 years of recurring left knee pain. Patient is unable to extend the knee and has pain with ambulation. History of a fall, 1 year ago and worsening pain at the lateral patella. Patient worked with PT after initial fall with resolution of symptoms. Subsequently, the patient had multiple episodes of acute pain and decreased extension of knee with no acute trauma. Patient was referred to Sports Medicine for further evaluation. There is a 2-year history of symptoms since onset. Patient with 2/10 left lateral knee pain with sensation of pressure and inability

to completely extend knee. Denies acute trauma. Pain is improved with massage and stretching. Occasionally taken NSAIDs for pain management. Denies numbness, tingling, weakness, swelling, redness, fever, or chills XR and US performed in clinic. Subsequently, MRI of left knee was ordered.

PHYSICAL EXAMINATION: LEFT KNEE Symmetric, no quadriceps atrophy No effusion No TTP over quadriceps tendon, patella, patella tendon, medial joint line, MCL or LCL Left: Active ROM: 5-135, PROM 0-135 Right: Active ROM: -3-135 Clark Inhibition: neg Bounce test: neg Patella grind: neg Varus stress 0 and 30: neg Valgus stress 0 and 30: neg Lachman: neg Anterior drawer: neg Posterior drawer: neg Mc Murray: + palpable lateral knee click without pain Thessaly/Apley: neg Ober: very flexible at level of hip Short and hypertonic hamstrings on left, w/o tenderness to palpation No tenderness along IT band Thomas: positive Strength 5/5: hip and knee flexion and extension Sensation intact to light touch

DIFFERENTIAL DIAGNOSIS: Hamstring hypertonicity, Mass/tumor, Reactive arthropathy, Enteropathic arthropathy, Meniscus tear

TEST AND RESULTS: X-ray left knee, standing: flattening of the lateral tibial plateau and tibial spines, no acute fracture, no joint disease, open physis US left knee: normal hamstring tendon and muscle no fluid appreciated along tendon sheath, no pes anserine bursitis, no IT band bursitis, no effusion, meniscus not visualized

MRI Left knee: discoid lateral meniscus with horizontal tear

FINAL/WORKING DIAGNOSIS: Discoid meniscus with tear

TREATMENT AND OUTCOMES: Left discoid meniscus saucerization and Physical therapy for rehabilitation. Patient doing well after surgery, with return to full activity without pain or other symptoms

D-75 Clinical Poster/Reception - Clinicians' Reception with Poster Presentations

Thursday, May 30, 2019, 6:00 PM - 7:00 PM
Room: Hotel-Signature 1 Meeting Room

2197 Board #1 May 30 6:00 PM - 7:00 PM The Relationship between Bone Mineral Accrual and Changes of Body Composition in Competitive Girl Runners

Norimitsu Kinoshita¹, Eriko Uchiyama¹, Kenta Okuyama².
¹Hosei University, Tokyo, Japan. ²Shimane University, Shimane, Japan.
(No relevant relationships reported)

Low bone density is a complication of a long-term strict weight control during adolescence in women.

PURPOSE: To assess whether decrease in percent body fat (%BF) is associated with an impaired bone mineral accrual in girl runners.

METHODS: Consecutive 22 freshmen girl runners (15y/o, 158cm, 45kg) during 7 years in competitive high school teams were evaluated over 2 years of training. DXA was performed at the preparatory phase (baseline) and repeated after 23 ± 2 months (follow-up). The runners were divided into 2 groups; negative (DEC, n=11) or positive (GAIN, n=11) changes of %BF (Δ %BF) during the period. The effect of the period and the group on the changes in bone mineral content (BMC) and density (BMD) of total body less head and z-score were analyzed by 2-way repeated measures ANOVA. As for lean soft tissue mass (LSM) and fat mass (FM), paired t-test was used to compare between baseline and follow-up. Bivariate correlation analysis was used to examine the relationship between bone mineral accrual (Δ BMC and Δ BMD) and Δ %BF as well as the changes of FM (Δ FM) and LSM (Δ LSM). Written informed consent was obtained from the runners and their parents. P<0.05 was considered as statistically significant.

RESULTS: %BF changed from 17.4 to 14.3 (DEC) and 15.0 to 18.4 % (GAIN). The period had significant effects on BMC, BMD, and z-score without interactions. Contrast showed significant increases in those variables, while the group of Δ %BF had no significant effect, indicating the values of DEC and GAIN were similarly increased; 1.57 to 1.64 and 1.66 to 1.77 kg, 0.98 to 1.00 and 1.00 to 1.03 g/cm², and -0.25 to -0.20 and 0.04 to 0.22, respectively. The DEC runners gained LSM (34.2 to 36.1 kg) and reduced FM (7.7 to 6.4 kg) significantly, while the GAIN runners significantly increased FM (6.9 to 9.0 kg) without LSM change (36.6 to 37.0 kg). Neither Δ %BF nor Δ FM, but Δ LSM was significantly correlated with Δ BMC (r=0.45) and Δ BMD (r=0.55).

CONCLUSIONS: Bone mineral was equally accrued among the runners of which %BF increased or decreased, where the accretion was associated with LSM gain. Competitive distance runners would develop leanness by not only losing FM but also gaining LSM (i.e., skeletal muscle) along with long-term exercise training. This would ameliorate an impairment of bone mineral acquisition by strict weight control.

2198 Board #2 May 30 6:00 PM - 7:00 PM Pre-Race Risk Screening and Stratification Predicts Adverse Events - SAFER Study In 76654 Distance Runners

Martin Schwellnus¹, Sonja Swanevelder², Esme Jordaan².
¹SEMLI, University of Pretoria, Pretoria, South Africa. ²South African Medical Research Council, Capetown, South Africa.
(No relevant relationships reported)

PURPOSE: The purpose of this study was to determine if a pre-race medical screening and risk stratification program predicts adverse events (ability of a runner to finish the race, or develop a medical complication) during an endurance running event.

METHODS: This prospective study, conducted during the Two Oceans marathon races (21.1km and 56km) in South Africa over 4 years, involved 76654 consenting race entrants. Race entrants completed a pre-race medical screening questionnaire at registration (3-4 months before the race), and were risk stratified into four groups: very high risk (VHR; existing cardiovascular disease - CVD), high risk (HR; risk factors for CVD), intermediate risk (IR; existing other chronic disease, medication use or injury), and low risk (LR). All runners in the VHR and HR categories were provided with educational information to decrease the risk of medical complications, and were also advised to undergo a pre-race medical assessment. Runners were tracked from registration to starting and finishing the race, and medical encounters (ME) were documented. Main outcome variables were the did-not-start rate (DNS; % runners registering but not starting) and the adverse event rate (AE) [defined as % starters that did-not-finish (DNF) or had an ME] in each risk category.

RESULTS: The DNS rate (%: 95% CI) for runners was similar in all risk categories (VHR=19.5; 17.9-21.2, HR=18.8; 18.0-19.7, IR=18.4; 18.0-18.9, and LR=18.6; 18.2-19.1)(p=0.604). The DNF rates in the VHR (2.2; 1.6-3.0)(p=0.005), HR (1.8; 1.5-2.1)(p=0.017), and IR (1.9; 1.8-2.1)(p<0.001) were significantly higher compared to the LR (1.4; 1.2-1.5). The overall AE rates for runners in the VHR (2.3; 1.8-3.0) (p=0.0017), HR (1.8; 1.5-2.1)(p=0.0323), and IR (2.0; 1.9-2.2)(p<0.001) were significantly higher compared to the LR (1.5; 1.3-1.6).

CONCLUSIONS: A pre-race medical screening, risk stratification and educational intervention program did not change the DNS in the risk categories. However, runners in the higher risk categories, that chose to start the race, were more likely to suffer an adverse event (not finish the race or present with a medical encounter) compared with runners in the lowest risk category.

2199 Board #3 May 30 6:00 PM - 7:00 PM Impact of Silver Ion Laundry Treatment on Athletic Gear and Environmental Pathogens and Athlete Health

Priya Balachandran¹, John J. Openshaw².
¹Applied Silver, Hayward, CA. ²Stanford University, Palo Alto, CA.
(No relevant relationships reported)

Community-acquired infections caused by *Staphylococcus* and MRSA can spread easily through sharing towels, gear and contaminated surfaces. The resulting skin infections can lead to athlete disqualifications, cancellations of competitions and potential impact on team performance. In this study, we evaluate a residual antimicrobial textile treatment as an environmental hygiene and infection control strategy through improved textile cleanliness and reduced athlete risk for infection.

PURPOSE: To determine the impact of silver-based residual antimicrobial textile treatment on *Staphylococcus* and MRSA levels on athletic gear, environmental surfaces, athlete infection rates and number of missed play days. **METHODS:** The study, conducted at a professional sports facility over a six-month period, included pre-season and regular season use. Residual antimicrobial silver ion laundry additive was injected onto textiles during the final rinse stage of the facility's standard laundry process. Bioburden data for *Staphylococcus* and MRSA was collected approximately every 4 weeks using contact plates. Athletes' shirts, shorts, jerseys, girdles and towels, and locker room surfaces including carpets, upholstery and other hard surfaces were sampled. Infection rates and number of days missed pre- and post-laundry treatment are also being recorded. Samples collected before initiating the silver ion textile treatment served as the control data set. **RESULTS:** Prior to silver-ion treatment implementation, significant levels of *Staphylococcus* were measured on athlete textiles (average 75 CFU/100 sq. cm.) and on environmental surfaces (average 16 CFU/100 sq. cm.). Silver ion treatment of the textiles resulted in dramatic decreases in *Staphylococcus* by 77% on textiles and by 37.5% on environmental surfaces. Similar trends were also observed with MRSA. The overall bioburden levels continue to trend downward during the period of treatment. **CONCLUSIONS:** The current results demonstrate that a normal laundry process augmented with an active antimicrobial treatment provide athletic gear and a locker room environment that are and stay cleaner. Final data related to cleanliness, infection rates and player days will be tallied at the close of 2018.

2200 Board #4 May 30 6:00 PM - 7:00 PM
Association Between Sport Specialization and Low BMD Among Female High School Distance Runners
 Mitchell J. Rauh¹, Michelle T. Barrack², Adam S. Tenforde³, Michael D. Rosenthal¹, Jeanne F. Nichols, FACSM⁴, ¹San Diego State University, San Diego, CA. ²California State University Long Beach, Long Beach, CA. ³Spaulding Rehabilitation Hospital/Harvard Medical School, Charlestown, MA. ⁴University of California San Diego, La Jolla, CA.
 (No relevant relationships reported)

Sport specialization has become increasingly common and has been related to sports injury and menstrual dysfunction among female high school distance runners. The association between sport specialization and low bone mineral density (BMD) is poorly described in this population. **PURPOSE:** To determine the association between sports specialization and low BMD in female high school distance runners. **METHODS:** Participants consisted of 64 female runners (age 15.6 ± 1.4y), not currently on birth control medication, who competed in interscholastic cross-country and distance track events in southern California. Each runner completed a survey on sport participation and menstrual function, and had her height and weight measured. Each runner's spine and hip BMD were assessed using DXA, standardized to BMD Z-score by age and sex normative values. Sport specialization classifications were: low specialization (distance running sport(s) for ≤8 months/year and participation in ≥1 other non-running high school sports); moderate specialization (only distance running sport(s) for ≤8 months/year, or participation in distance running sport(s) ≥9 months/year and ≥1 other non-running sports); and high specialization (participation in distance running sport(s) for ≥9 months/year and no other sports. Multivariable logistic regression was performed to determine the adjusted odds ratio (OR) and 95% confidence interval (CI), adjusting for BMI and gynecological age. **RESULTS:** Overall, 21.9% of the runners were high sport specialists, and 37.5% and 40.6% were moderate and low sport specialists, respectively. Twenty-three (35.9%) runners had low BMD (Z-score < -1.0). After adjusting for gynecological age and BMI, high sport specialists were five times more likely (OR=5.4, 95% CI: 1.3-23.3; p=0.02) to have low BMD than low sport specialists. **CONCLUSIONS:** Our findings indicated that high sport specialization was associated with low BMD among female high school distance runners. Further investigation of this association is warranted as low BMD has been related to increased risk of stress fracture.

2201 Board #5 May 30 6:00 PM - 7:00 PM
The Effects Of Subconcussive Impacts On The Neurocognitive Function Of Men's Collegiate Lacrosse Players From Pre-season To Post-season
 Caroline Varlotta (Sponsor: Dr. Gerard P Varlotta, FACSM), Joshua Giordano, Joseph Miceli, Brandon Burg, Haille Zwibel, Matthew VarlottaHeller. *NYIT-COM, Old Westbury, NY.*
 (No relevant relationships reported)

There is an estimated 1.6 to 3.8 million sports-related mild traumatic brain injuries (mTBI) per year in the United States. Football is more commonly studied than other sports, even though men's lacrosse has almost as great of a risk of mTBI. Since many players of this age group are in schools of higher education, mTBI can inhibit their ability to learn in the classroom. **PURPOSE:** To examine the effects of total number of impacts, cumulative magnitude, and cumulative rotation, as measured by accelerometer, on neurocognition, as measured by time to complete the Trails A task in pre- and post-season. **METHODS:** We examined 10 male freshmen NCAA Division II collegiate lacrosse players in pre- and post-season (January and May). Subjects wore the Vector mouthguard, which contains accelerometers, during full contact practices and 18 games. Vector mouthguard recorded impact number and magnitude. Subjects' cognition was evaluated by C3logix Trails A test. **RESULTS:** The data was analyzed by comparing athletes' mean scores of Trail A between pre- and post-season with paired samples t-test and correlating it with the total number of impacts, cumulative impact, and cumulative rotation with computation of Pearson correlation coefficients. Statistical significance was determined by p-value<.05. The association between completing the Trails A task and the following variables was statistically significant with a positive Pearson coefficient: total number of impacts (0.80, 0.006), cumulative impact (0.74, 0.014) and cumulative rotation (0.71, 0.022). **CONCLUSIONS:** The athletes took longer to complete the Trails A task in post-season if they experienced an increased total number of impacts, cumulative impact, or cumulative rotation. These changes may indicate the number of impacts, cumulative impact, and cumulative rotation affects athletes' cognitive abilities without clinical symptoms or reporting of mTBI. The results of this pilot study suggests further investigation is warranted.

2202 Board #6 May 30 6:00 PM - 7:00 PM
International Clinical Scholar Award - Effects of Mistletoe Extract Supplementation on Inflammation Markers after Strenuous Exercise in Rowers
 Soo-Min Ha¹, Jung-Sook Kim¹, Bo-Sung Kim¹, Jeong-Ah Lee², Yoon-Jung Choi¹, Do-Yeon Kim¹. ¹Pusan National University, Busan, Korea, Republic of. ²Kyungsung University, Busan, Korea, Republic of.
 (No relevant relationships reported)

Excessive long-term training and extensive exertion during exercise can inflammatory cytokine expression. Various measures have been explored to minimize this, and dietary supplements having anti-inflammatory and antioxidant functions can help athletes recover from repetitive intensive exercises, thereby preventing reduced vitality. **Purpose:** This study aimed to identify the effect of mistletoe extract consumption on inflammatory markers of university male rowing athletes for 8 weeks during the winter training period. **Methods:** This study included 20 male rowing athletes divided into the Korean Mistletoe extract supplement group (KME, n = 10) and the control group (CON, n = 10). The KME group took 110 mL of mistletoe extract every morning and evening after meals (total of 220 mL) for eight weeks. Before and after taking mistletoe for eight weeks, 2,000 m rowing performance capabilities were measured, and KME group took 110 mL of mistletoe extract after recovery from the rowing exercise. Blood samples were collected during the rest, immediately after exercise, and after 30 min of recovery. Among inflammatory markers, IL-6 and TNF-α were analyzed. **Results:** Both groups showed a significantly reduced 2,000-m rowing time (KME; p<0.001, CON; p<0.01), and the total number of strokes were significantly fewer in the KME group than in the CON group (p<0.05). After supplementation the levels of IL-6 and TNF-α were lower in the KME group than in the CON group in all periods of the rest (p<0.001), immediately after exercise (IL-6; p<0.01, TNF-α; p<0.001), and after 30 min of recovery (p<0.01). **Conclusion:** Therefore, mistletoe extract intake can reduce the serum inflammatory cytokine levels (which are otherwise increased due to high-strength exercise) among active individuals, indicating improved anti-inflammatory activity.

2203 Board #7 May 30 6:00 PM - 7:00 PM
Specific Dietary Practices In Female Athletes And Their Association With Disordered Eating
 Celina Francesca de Borja, Lauren M. McCall, Bryan Holtzman, Laura Moretti, Nicole Farnsworth, Kathryn E. Ackerman, FACSM. *Boston Children's Hospital, Boston, MA.*
 (No relevant relationships reported)

PURPOSE: Health and weight management benefits may influence athletes' decisions regarding specific dietary practices. Eating disorders/disordered eating (ED/DE) are highly prevalent in the athletic population. The purpose of this study was to determine if following specific diets correlated with a greater likelihood of responding positively to ED/DE screening tools compared to not adhering to a diet. **METHODS:** 1000 female athletes (15-30 yrs) were asked to complete a comprehensive health and wellness survey. Athletes were asked to specify their diet and completed 3 ED/DE screening tools: the Brief Eating Disorder in Athletes Questionnaire, the Eating Disorder Screen for Primary Care, and self-reported current or past history of ED/DE. We hypothesized that athletes adhering to specific diets were more likely to score positively on ED/DE screening tools than those not following a diet. The most common diets were included in the analyses: vegan, vegetarian, pescatarian, gluten free, low carbohydrate, low dairy, and ≥2 diets. Athletes following diets for health issues (e.g. Celiac disease) were excluded. Descriptive statistics were calculated for all study measures and Chi-square testing was performed to assess relationships between athletes' dietary practices and their responses to ED/DE screening tools. **RESULTS:** 234 of 1000 female athletes reported adherence to specific diets; 766 reported no diet adherence. 69 of the 234 athletes were excluded due to medically-related dietary practices or vague dietary descriptions. 133 athletes reported following 1 of the diets and 32 athletes reported following ≥2 diets. Of the diet-adherent athletes, 67.9% responded positively to ≥1 of the 3 ED/DE screening tools. Athletes practicing vegetarian, vegan, low carbohydrate, low dairy, or ≥2 diets were more likely to respond positively to ≥1 ED/DE screening tool vs. athletes without dietary restrictions (70.0%, 77.8%, 79.5%, 60.0%, and 65.6%, respectively vs. 41.8%; p≤0.048). **CONCLUSION:** Specific diet adherence in female athletes is associated with greater likelihood of positive screening for ED/DE using survey self-report. Health practitioners should consider further ED/DE questioning of athletes reporting specific diet adherence in order to enhance nutritional knowledge and help treat and prevent ED/DE.

2204 Board #8 May 30 6:00 PM - 7:00 PM
The Impact of Clinical Factors in Physician and ATC Decision Making for Concussion Return to Play: Insight from a Policy Capturing Study
 Darwin McKnight, Vicki Nelson, Franklin Sease, FACSM, Rg Gilliland. *Greenville Health System, Greenville, SC.*
(No relevant relationships reported)

PURPOSE: To scrutinize the role of several clinical factors in physician and clinical athletic trainer (ATC) return-to-play (RTP) decision making in high school athletes who sustained a concussion.

METHODS: Sports Medicine physicians and ATCs completed a policy capturing survey of 50 clinical scenarios and rated how likely they were to clear the athlete for RTP. Nine factors were randomly varied within the scenarios: age, gender, sport, prior concussion, initial symptom score, symptom duration, and ImPACT performance. Participants then ranked how important each variable was in their decision making process.

RESULTS: 16 physicians (87.5% CAQSM, 12.5% Fellows, mean 9.2 concussions managed per month) and 29 ATCs (mean 4.8 concussions managed per month) participated. ImPACT testing was the most significant contributor in RTP decisions. Physicians and ATCs weighed ImPACT changed from baseline (β 0.42±0.23 and 1.28±1.18 respectively) and ImPACT compared to normative values (0.39±0.24 and 1.38±0.90 respectively) most heavily. Respondents self-ranked prior concussion and age as most influential in their RTP decision making. There was no correlation between participants self-ranking of importance and the observed contribution of a variable to decision making.

CONCLUSIONS: Respondents displayed poor insight to the role of various clinical factors in their management of concussion RTP. ImPACT testing has a greater influence on RTP decisions than physicians and ATCs realize. Despite having low self-ranked importance, variables related to ImPACT results were among the most influential. Self-ranking importance of clinical variables is similar between physicians and ATCs; however, symptom duration is less important to ATCs compared to physicians. Although age was considered important in self-ranking it was not a significant contributor to RTP decision making.

2205 Board #9 May 30 6:00 PM - 7:00 PM
Spine Injuries and Concussions among Figure Skaters
 Kristen M. Lambrinakos-Raymond, Gregory Kobelski, Ellen Geminiani, Dai Sugimoto, William P. Meehan, III. *Boston Children's Hospital, Boston, MA.*
(No relevant relationships reported)

PURPOSE: To determine the prevalence and mechanism of spine injuries and concussions among a sample population of figure skaters. To assess for potential risk factors for these injuries.

METHODS: This is a cross-sectional analysis of spine injuries and concussions reported by figure skaters. Data was obtained through an anonymous, confidential online questionnaire distributed to members of participating figure skating clubs. The main outcomes included diagnoses, mechanism and source of medical care. Simple descriptive statistics were used; Fisher's exact test was used to assess for statistical differences in categorical variables between groups. SPSS was used for all analyses.

RESULTS: Thus far, 88 participants have completed questionnaires (recruitment ongoing). The mean age of participants is 25.2 years (SD 17.1). Most (79%) respondents are female. Most (85%) practice figure skating year-round; 85% participate in competitions. Some skaters participate in more than one discipline including singles(n=68), pairs(n=3), ice dance(n=21), synchronized skating(n=29), theatre on ice(n=17). More than a quarter (27%; n=24) of participants reported spine injuries/back pain. The most common diagnosis was muscular back pain. Treatment was primarily guided by primary care(n=10), sports medicine(n=13), physical therapists(n=14) and athletic trainers(n=10). Almost half of those who reported back pain did not present to a health care provider (HCP) (45%; n/N=11/24). All injuries occurred in practice. More than a quarter of participants (27%; n=24) sustained at least one concussion; 7 sustained two concussions. Several (42%; n/N=10/24) skaters did not present to a HCP for evaluation of their first concussion. All concussions occurred during practice and most (92%; n/N=22/24) were during on-ice activities. The most common mechanism of injury was a fall (62%; n/N=15/24). The sex of the skater was not associated with either mechanism of spine injury or history of concussion.

CONCLUSIONS: Nearly a third of skaters sustained a concussion or spine injury, yet nearly half did not report their injuries to a HCP. Our findings warrant further investigation into the reasons for such a low reporting rate among figure skaters and the potential effect on injury outcomes.

2206 Board #10 May 30 6:00 PM - 7:00 PM
Lisa S. Krivickas Clinician/Scholar Travel Award: Characterizing the Prevalence of Cam-Type Hip Impingement in Women's Professional Ice Hockey Players
 Cordelia W. Carter, Darryl Whitney, Matthew Kingery, Samuel Baron, Guillem Gonzalez-Lomas. *NYU-Langone Medical Center, New York, NY.*
(No relevant relationships reported)

Purpose Recent studies have demonstrated an increased prevalence of femoroacetabular impingement (FAI) in elite men's ice hockey players, yet little is known about the hips of players in the National Women's Hockey League (NWHL). The primary purpose of this study was to determine the prevalence of radiographic cam-type FAI in women's professional ice hockey players. The secondary purpose was to analyze the relationship between the presence of cam deformity and hip ROM; clinical impingement signs; and age of menarche.

Methods Clinical, radiographic and demographic data were collected for NWHL players during pre-participation physicals. Alpha angles were measured on 45° Dunn radiographs, with alpha angles >55° defined as cam-positive. Spearman correlations were performed to analyze the relationship between alpha angle and both ROM measurements and menarchal age. Players were grouped into those with and without cam lesions and group differences were assessed using the student's t-test.

Results Twenty-seven athletes were included. Nineteen (70%) had alpha angles >55°; 14 (52%) had bilateral cam deformity. Average menarchal age was 13.9 ±1.5 years. There was a significant association between age of menarche and alpha angle (right hips, p=0.01; left hips, p=0.04). There was no significant association between alpha angle and either hip ROM or clinical impingement signs.

Conclusion This study suggests that elite female ice hockey players have a higher prevalence of cam-type morphology than the general population. The positive association between alpha angle and age of menarche lends additional support to the etiological hypothesis of the cam lesion resulting from activity-related stress at the proximal femoral physis; players with earlier menarche (and therefore earlier physeal closure) seem to be less vulnerable to the development of cam deformity of the proximal femur. Thus, professional women's ice hockey players have a high risk of developing cam-type morphology of the proximal femur, although each player's age of menarche may mediate her individual risk for cam lesion development.

E-05 Thematic Poster - Cardiac

(No relevant relationships reported)

While it is widely accepted that chronic endurance exercise training leads to cardiac remodeling called 'athlete's heart', the effects of high intensity interval training on left ventricular (LV) structure and function remain equivocal.

PURPOSE: To determine whether the most extreme form of high intensity interval training, namely sprint training, leads to significantly different LV structure and function at rest and during exercise. We hypothesized that sprint athletes (SPR) would have similar systolic wall stress but reduced diastolic function because of the reduced compliance of smaller hearts compared with endurance athletes (ET).

METHODS: Eleven male ET and nine SPR were examined at rest and during progressive exercise (30, 40 & 50% of peak power output). To estimate differences in peripheral blood flow demand, the change in skeletal muscle oxyhaemoglobin saturation (sMO₂) during exercise was quantified with near-infrared spectroscopy. LV systolic and diastolic function were assessed using echocardiography (2D, speckle tracking, color M-mode). Modification of Laplace's Law allowed for the estimation of LV wall stress across the entire systolic period of the cardiac cycle. A quadratic model for continuous data was applied, reported as (Rest; slope with exercise).

RESULTS: Despite a greater peripheral blood flow demand in SPR (Δ sMO₂, $P < 0.0001$) and smaller hearts than ET (LV mass at rest: 95 ± 12 vs. 73 ± 7 g/m², $P < 0.0001$), cardiac index was similar (2.37 ± 0.15 vs. 2.55 ± 0.23 L/min/m², $P = 0.65$; slope $P = 0.16$) but total systolic wall stress per min was consistently lower in SPR (163 ± 14 vs. 115 ± 21 a.u., $P = 0.03$; slope: $P = 0.39$). In contrast, diastolic relaxation, as represented by the validated LV untwisting rate, increased more during exercise in SPR (-103 ± 12 vs. -94 ± 19 degrees/s, $P = 0.64$; slope: $P = 0.04$), but LV blood dynamics, as per intra-ventricular pressure gradients, were comparable (2.79 ± 0.29 vs. 2.55 ± 0.44 mmHg, $P = 0.44$; slope: $P = 0.89$).

CONCLUSION: Compared to ET, the similar cardiac output with lower LV wall stress and a greater LV relaxation with similar filling dynamics in sprint athletes indicates a specific 'athlete's heart' that is characterized by different associations between demand, haemodynamics and LV mechanical function. Future investigations in patient populations are warranted.

2229 Board #2 May 31 9:30 AM - 11:30 AM**Exercise-Induced Cardiac Fatigue is Similar Across Increasing Trail-Running Race Distances**

Alexandra M. Coates¹, Katharine D. Currie², Trevor J. King¹, Philip J. Millar¹, Jamie F. Burr¹. ¹University of Guelph, Guelph, ON, Canada. ²Michigan State University, East Lansing, MI.
(Sponsor: Jamie Burr, FACSM)

(No relevant relationships reported)

A transient reduction in cardiac function following prolonged endurance exercise, termed exercise-induced cardiac fatigue, has previously been reported following events ranging from 2-40hrs. Right-ventricular dysfunction has been demonstrated to occur prior to left-ventricular dysfunction and, similarly, diastolic impairments may occur prior to systolic impairments. While highly-trained athletes are more fatigue-resistant than lesser-trained subjects, the timing and magnitude of cardiac alterations following prolonged racing is unclear. **PURPOSE:** The aim of this study was to investigate the effects of varying distance trail running races on cardiac function in recreational runners of varying fitness levels, to determine the dose-response of cardiac fatigue. **METHODS:** Forty-three distance runners competing in the Sulphur Springs trail races (25k,n=9; 50k,n=13; 80k,n=13; 160k,n=8) completed pre and post testing measures

including resting echocardiography, and an incremental running test to determine maximal oxygen consumption (VO₂max). **RESULTS:** Mean race durations were as follows: 25k: 2.5 ± 0.3 hrs, 50k: 6.0 ± 2.0 hrs, 80k: 11.6 ± 1.8 , and 160k: 25.2 ± 3.6 hrs (all $P < 0.001$). Echocardiographic results indicated diastolic impairments of both ventricles, with minimal systolic impairments, across all race distances post-race. Of the parameters investigated, only early-to-late diastolic filling ratio (E/A) was different between groups such that the 160k racers did not have as great of a reduction (mean Δ -0.51±0.50, 160k Δ -0.20±0.45, $P = 0.02$). All racers had decreased blood pressure (MAP pre: 94 ± 10 vs post: 83 ± 9 mmHg, $P < 0.0001$), and elevated heart rates (pre: 55 ± 8 vs post: 78 ± 12 b/min, $P < 0.0001$) post-race. Fitness (VO₂max) and age were not related to changes in cardiac function, whereas race duration was related to changes in E/A ratio ($r = 0.37$, $P = 0.02$) only. Changes in diastolic blood pressure were related to many changes in cardiac function including peak longitudinal strain ($r = 0.34$, $P = 0.03$).

CONCLUSIONS: Prolonged trail-races appear to alter diastolic function regardless of race duration, and fitness, likely due to similar reductions in blood pressure post-race. A clear relationship between race duration and level of cardiac impairment is not apparent.

2230 Board #3 May 31 9:30 AM - 11:30 AM**Cardiovascular Adaptations During the Hormonal Transition of a Male-to-Female Transgender Athlete**

Shannon L. Wilson¹, Andrew C. D'Lugos¹, Nathan Serrano¹, Theresa M. Jorgensen¹, Joanna Harper², Glenn A. Gaesser, FACSM¹, Jared M. Dickinson, FACSM¹, Siddhartha S. Angadi, FACSM¹. ¹Arizona State University, Phoenix, AZ. ²Providence Portland Medical Center, Portland, OR.

(No relevant relationships reported)

PURPOSE: Cardiovascular consequences of female sex hormone exposure on human male biology are currently unknown. This level of investigation is critical given potential adverse outcomes reported in rodent models. This case study aimed to comprehensively assess cardiovascular phenotypes before and during estrogen treatment for gender reassignment.

METHODS: This is the case of a biologically male, distance runner (28 yr) undergoing male-to-female gender reassignment. Two baseline assessments were made prior to initiation of hormone treatment. Testing following initiation of estrogen treatment took place at 4-8 week intervals depending on subject's availability. Testing included resting echocardiography for assessment of biventricular function, dual energy x-ray absorptiometry (DXA), and central vascular blood pressures and stiffness assessments. Treadmill-based VO_{2,peak} and running economy, as well as non-invasive cardiac output and a-vO₂ difference at rest and at peak exercise were quantified at each visit.

RESULTS: Throughout the first 12 months of treatment, stroke volume decreased (136 to 80 ml/beat) with an initial reduction in peak heart rate (ranged 188-180 bpm). Consequently, peak cardiac output declined (28.4 L/min to 15.5 L/min) while a-vO₂ difference increased (11.6 to 19.9 ml O₂/100 ml blood). This resulted in only a minor decrease in absolute VO_{2,peak} (3.3 to 3.1 L/min). Ejection fraction (calculated using modified Simpson's method via echocardiogram) decreased (61% to 57%) along with left ventricular diastology (mitral valve E/e 6.0 to 4.1). Right Ventricular Fractional Area change was unaffected (53% to 53%), while measures of right heart diastology increased (tricuspid valve E/e 3.9 to 4.6). Both right ventricular (RV) and left ventricular (LV) strain initially improved with the addition of estrogen, before worsening over the course of hormone treatment (RV strain ranged from -36 to -31.5%; LV strain ranged from -23.5 to -19%). **CONCLUSIONS:** Therapeutic estrogen administration and testosterone blockade may adversely affect cardiopulmonary fitness via reduction in myocardial performance at peak exercise. This may be associated with a worsening of LV and RV strain at rest. More research is needed to examine the long-term effects of gender reassignment therapy on cardiovascular function.

2231 Board #4 May 31 9:30 AM - 11:30 AM**Cardiovascular Disease Risk In Middle-Aged Ultra-Endurance Athletes**

(No relevant relationships reported)

It is widely accepted that aerobic exercise reduces cardiovascular disease (CVD) risk. However, recent studies suggest that volumes of exercise that greatly exceed physical activity guidelines may be damaging to the heart. Currently, it is unclear if individuals who train for ultra-endurance races have an elevated risk of developing CVD compared to those that perform lower amounts of physical activity. Additionally, little work has been done to examine vascular function in these athletes. **PURPOSE:** To evaluate cardiovascular function and calculate CVD risk to determine if individuals that train for ultra-endurance races have a greater risk compared to individuals that engage in moderate physical activity. **METHODS:** We examined cardiovascular

function in athletes (ATH, 14M/11F, 50±1 y) that had been training for ultra-endurance events for 10+ years and controls (CON, 9M/9F, 49±2 y) that were meeting current ACSM physical activity guidelines. We used cardiac computed tomography (CT) to calculate coronary artery calcium scores (CACS) and contrast-enhanced magnetic resonance imaging (MRI) to identify myocardial fibrosis (MF). Carotid-femoral pulse wave velocity (cFPWV) was used to evaluate aortic stiffness and ultrasound assessment of carotid intima-media thickness (CIMT) was used to determine vascular structure of the carotid artery. Additionally, we used Doppler ultrasound to assess vascular endothelial function by measuring flow-mediated dilation (FMD) of the brachial artery. Finally, we used a risk score calculator to determine 10-year CVD risk. **RESULTS:** CACS > 0 was observed in 8 ATH and 2 CON; however, the presence of CAC was not significantly different between groups (P>0.05). Additionally, no participant in ATH or CON had MF. ATH had lower cFPWV compared to CON (6.2±0.2 vs 6.9±0.2 m/s, P<0.05), while no difference in CIMT (ATH; 0.64±0.02 vs CON; 0.62±0.03 mm, P>0.05) or FMD (ATH; 3.6±0.8 vs CON; 5.6±1.2 %, P>0.05) was observed. Furthermore, there was no group difference in calculated CVD risk (ATH; 2.4 ± 0.6 vs CON; 1.6 ± 0.3 %, P>0.05). **CONCLUSION:** Middle-aged ATH with 10+ years of training for ultra-endurance races are not at a greater risk of developing CVD than individuals that are meeting current physical activity guidelines.

(No relevant relationships reported)

An acute bout of high-volume high-intensity exercise, such as marathon running, can increase cardiac biomarker concentrations. It is unknown whether these biomarker elevations are related to myocardial micro-damage.

PURPOSE: To assess cardiomyocyte damage following a marathon run using troponin I and novel magnetic resonance imaging (MRI) techniques including T1, T2 mapping and diffusion tensor imaging (DTI), and subsequently relate troponin I to MRI parameters of cardiomyocyte damage.

METHODS: Cardiac MRI was performed at 3T in 12 male participants of the 2017 Amsterdam Marathon. MR data and blood samples were collected during 3 study visits: I) 1 week before, II) 4±2 hrs post-marathon and III) 2 weeks post-marathon. We measured troponin I, cardiac function (ejection fraction, strain, torsion) and morphology (volumes, T1 and T2 maps, and DTI).

RESULTS: 11 men (51 [50-56] years) finished the race (42.195km) in 236±35 min at 89±5% of their predicted maximum heart rate. Troponin I increased post-exercise (from 0 [0-0] at baseline to 57 [16-82] ng/L), but returned to baseline values after 2 weeks recovery (0 [0-0] ng/L). Cardiac ejection fraction and morphology (volumes, T1, T2 maps) did not change following the marathon run (native T1:1214±23 at baseline, 1221±26 4hrs post-marathon and 1206±24 ms 2 weeks post-marathon, p=.15; T2: 50 [48-51] vs. 50 [48-52] vs. 50 [48-52] ms, p=.44). Left ventricular basal strain became less negative from baseline (-25±2%) to post-marathon (-22±2%) and did not completely recover after 2 weeks (-23±3%, p=.003). Extracellular volume fraction (24.6±2.9 vs 26.5±2.6 vs 25.0±3.4 %, p=.37), mean diffusivity (1.49±0.09 vs 1.60±0.16 vs 1.48±0.08 mm²/s, p=.09) and fractional anisotropy (.37 [.33-.39] vs .38 [.37-.40] vs .38 [.34-.40], p=.76) did not significantly change post-marathon. Post-exercise troponin was positively associated with changes in mean diffusivity (r=.62, p=.04).

CONCLUSION: We observed elevations in cardiac troponin I after marathon running, which were significantly associated with higher mean diffusivity of myocardial tissue water. These findings suggest that cardiac biomarker elevations may result from exercise-induced myocardial micro-damage such as disruption of cardiomyocyte integrity and associated edema. Recovery largely occurred within 2 weeks.

Right Ventricle Systolic And Diastolic Function In Renal Transplant Recipients after 12 Months Of Unsupervised Exercise Training

Laura Stefani¹, Beatrice Leone², Elena Zappelli², Gianni Pedrizzetti³, Giorgio Galanti¹, Pietro Amedeo Modesti⁴. ¹Sports Medicine-FIMS (Italian Federation of Sport Medicine), Florence, Italy. ²Sports Medicine, Florence, Italy. ³Engineering and Architectural department -University of Trieste, Florence, Italy. ⁴Sports Medicine-Center University of Florence, Florence, Italy.

Email: laura-stefani@tiscali.it

(No relevant relationships reported)

Purpose: RV function is strongly associated with clinical outcomes in the population at high cardiovascular risk. The RV chamber has been largely studied especially in the cardiopulmonary disease as predictive aspect for a reduced exercise capacity. More recently particularly deformation parameters as Speckle tracking echocardiography (STE) is applied as imaging technique for an accurate evaluation. Renal Transplant Recipient (RTR) is the new category involved in the physical activity program despite the high CV risk. The study aims to assess the global RV function in the RTR regularly submitted to physical activity (PA) at moderate intensity for 1 yr. **Methods:** a group of 50 RTR, aged 50 ±5, was trained for 1 year following a mixed exercise program 30 subjects with an high quality of image and trained for at least 3 times a week, were followed by echocardiographic exam every 6 months. They were investigated by 2D RV standard parameters and strain analysis by X-Strain software with the measurement of the Free Wall (FW) of the RV at T0, T6, and T12 months. **Results:** RTR had at initial phase, low values of RVFW strain with respect of the normal range and vs to the HC; The RVFW strain was found significantly (P<0.01) increased at the end of the exercise program, restoring the normal range. The RV diastolic function maintained normal with a significant (p<0,05) and progressive adjustment of the E/A ratio in RTR only. No significant variations in controls.

| RTR (30) | T0 | T6 | T12 | HC (12) T0 | T6 | T12 |
|------------------|------------|------------|-------------|------------|-------------|-------------|
| RV FW strain % | -20,48±6,3 | -23,55±4,9 | -25,06±6,07 | -28,43±4,9 | -31,53 ±5,2 | -30,23± 3,1 |
| RV mean strain% | -18,73±6,3 | -23,02±4,6 | -25,52±6,7 | -26,50±5,7 | -29,52±4,5 | -29,52± 4,5 |
| RVAC % | 40,28±8,4 | 41,2±8,1 | 41,5±7,9 | 45,5±8,2 | 43,4±6,7 | 46,3±2,9 |
| RV Diameter mm | 23,38±0,71 | 22,71±1,41 | 22,81±0,2 | 22,09± | 21,5±0,3 | 21,77± 0,5 |
| E/A | 1,4±0,07 | 1,21±0,6 | 1,42±0,2 | 1,58±0,5 | 1,54±0,4 | 1,43±0,4 |
| E/A ¹ | 1,1±0,5 | 1,06±0,3 | 1±0,04 | 1,2±0,4 | 1,1±0,33 | 1,04±0,0 |

Conclusions: One year of moderate intensity of unsupervised physical exercise improves the RV chamber performance. The investigation of both of the systolic and diastolic parameters and by the strain analysis can contribute to a correct follow-up in RTR patients. This approach could be proposed especially in case of complete asymptomaticity and during physical exercise program. More data will be necessary in future to support this hypothesis.

Cardiac Reinnervation Affects Blood Pressure and Cardiorespiratory Adaptation to Exercise after Heart Transplant

Emmanuel G. Ciolac¹, Rafael E. Castro², Awassi Y. Ggomane¹, Ariane A. Viana¹, Fernando Bacal², Edimar A. Bocchi², Guilherme V. Guimarães². ¹São Paulo State University - UNESP, Bauri, Brazil. ²University of São Paulo - USP, São Paulo, Brazil.

(No relevant relationships reported)

PURPOSE: To investigate the hemodynamic and cardiorespiratory adaptation to exercise in individuals with heart transplantation (HTx) with (CR group) versus without evidence of cardiac reinnervation (NOCR group).

METHODS: Sedentary individuals with HTx (age = 45.5 ± 2.2 years; time elapsed since surgery = 6.7 ± 0.7 years) were allocated to the CR (N = 16) and NOCR (N = 17) group according to their heart rate response to cardiopulmonary exercise testing (CPX). 24-h ambulatory blood pressure (BP), carotid-femoral pulse wave velocity (PWV) and cardiorespiratory fitness were assessed before and after 12 weeks of a thrice-weekly exercise program (5 min of warm-up, 30 min of aerobic exercise, 1 set of 10-15 reps in 5 resistance exercises, and 5 min of cool-down).

RESULTS: The CR group had reduced (P < 0.01) 24-h systolic/diastolic BP (7/9 mmHg), daytime systolic/diastolic BP (9/10 mmHg) and nighttime diastolic BP (6

mmHg) after training (Figure). The NOCR group reduced ($P < 0.05$) only 24-h (5 mmHg), daytime (5 mmHg) and nighttime (6 mmHg) diastolic BP after training. Hourly analysis showed that the CR group reduced systolic/diastolic BP for 10/21 hours, while the NOCR group reduced systolic/diastolic BP for only 3/11 hours (Figure). The CR group also improved both maximal oxygen consumption (10.8 %) and exercise tolerance (13.4 %) after training, but the NOCR group improved only exercise tolerance (9.9 %). PWV did not change in both groups. **CONCLUSIONS:** Greater improvements in ambulatory BP and maximal oxygen consumption in the CR than NOCR group. These results suggest that CR affects hemodynamic and cardiorespiratory adaptations to exercise training in individuals with HTx.

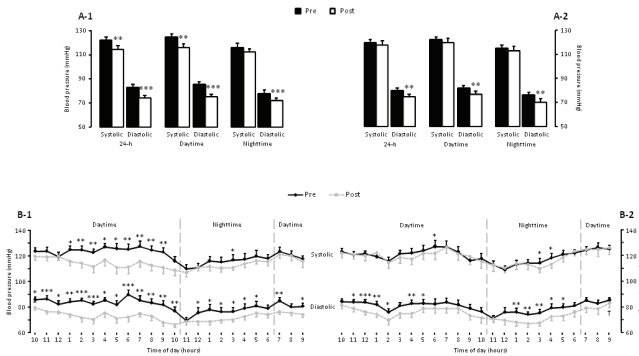

Figure. Ambulatory blood pressure before (pre) and after (post) 12 weeks of exercise training. A: Average 24-h, daytime and nighttime systolic and diastolic blood pressure. B: Hourly averages of systolic and diastolic blood pressures. 1: individuals with clinical evidence of cardiac reinnervation. 2: individuals without clinical evidence of cardiac reinnervation. Asterisks denote significant difference from pre-intervention in the same group (*: $P < 0.05$; **: $P < 0.01$; ***: $P < 0.001$). Dagger denotes significant difference from the CR group during the same period (†: $P < 0.05$).

The Effect Of Cold-water Immersion On Joint Power During Drop-landings

Henry Wang, Yuii Nomoto, D. Clark Dickin. *Ball State University, Muncie, IN.*
Email: hwang2@bsu.edu

(No relevant relationships reported)

Exposure to cold environments results in pronounced alterations in many physiological systems. Military exercises, recreational situations, and popular winter sports could introduce large changes in tissue temperatures of the lower body. To date, the effect of cold exposure on joint mechanics during high impact activities (e.g. drop-landings) remains unknown. It is unclear whether cold exposure could reduce joints' ability to absorb landing impact, which may increase risks of landing related injuries. **Purpose:** To determine the effect of cold-water immersion on lower-extremity joint power during drop-landings. **Methods:** On four separate occasions, 11 female recreational athletes (22±2 yr, 65±7 kg, 1.67±0.06 m) performed drop-landings (single-leg and double-leg landings) from a 0.6-m height following 30-minute immersion in thermoneutral water (CON) (34 °C) to the hip-joint level and in cold-water (20 °C) to the ankle- (LOW), knee- (MED), and hip- (HIGH) joint levels. 3D motion capture was conducted. Lower-extremity joint power was calculated. One way repeated measures ANOVA was used to determine differences among the four conditions. **Results:** No significant differences in peak power absorption among all testing conditions for either the single-leg landing ($p > 0.05$) or double-leg landing ($p > 0.05$). For single-leg landing, the mean±SD of the power absorption (W/kg) during water-immersions (CON, LOW, MED, and HIGH) were 22.1±3.4, 21.9±2.9, 22.0±3.1, 22.8±3.1, for the ankle, respectively, and 34.7±7.1, 34.4±6.3, 33.3±6.2, 34.4±7.5, for the knee, respectively, and 39.1±8.9, 39.9±11.3, 38.4±5.1, 39.5±8.3, for the hip, respectively. For double-leg landing, the power absorption during water-immersions (CON, LOW, MED, and HIGH) were 18.7±2.9, 19.2±2.8, 18.8±1.9, 18.6±2.8, for the ankle, respectively, and 32.6±6.0, 32.5±5.6, 31.5±4.0, 33.3±7.4, for the knee, respectively, and 33.3±14.1, 31.9±16.6, 29.9±12.8, 31.8±16.0, for the hip, respectively. **Conclusion:** For recreational athletes, drop-landing engages sub-maximal eccentric effort at leg's muscle-tendon units to absorb

impact. Although cold-water lowers tissue temperature, the ability of lower-extremity joints to absorb landing impact remains intact. Thus, the risk of landing related injuries may not be elevated due to cold exposure.

Landing Mechanics Differences between the Drop Vertical Jump and Stop Jump

Robin M. Queen, FACSM, Kristen Renner, Alexander Peebles. *Virginia Tech, Blacksburg, VA.*
Email: rmqueen@vt.edu

(No relevant relationships reported)

ACL injury prevention studies have used both the drop vertical jump (DVJ) and the stop jump (SJ) to assess ACL injury risk. Given the anterior motion in the SJ, it may better mimic movement patterns present at the time of ACL injury. Previous studies have not directly compared the landing mechanics between a SJ and DVJ in order to determine which task would be better to use when assessing ACL injury risk and during evaluations of return to sport readiness. **PURPOSE:** To investigate sex-specific differences in lower extremity landing mechanics between the SJ and DVJ. **METHODS:** Fifty healthy participants, 26 male (23±3 years, 1.79±6.4m, 78.8±10.7kg) and 24 female (23±3 years, 1.67±5.9m, 61.4±6.5kg), were recruited and signed informed consent. Participants performed seven trials per task (SJ and DVJ). Data was collected using a modified Helen Hayes marker set and a ten-camera motion capture system (120 Hz) time synchronized with 2 embedded force plates (1440 Hz). Peak posterior GRF (pGRF), vertical GRF (vGRF), peak knee flexion (KF) and abd/adduction (KA) angles, KF and KA range of motion (ROM), and peak knee extension (pKEM) and abduction moments (pKAM) were quantified for the dominant limb. To examine the sex-specific differences and the differences between the landing tasks, a 2x2 mixed model, repeated measures ANOVA was conducted in SPSS ($\alpha = 0.05$). **RESULTS:** No main effects or interactions were found for the pKEM or KA ROM. Main effects for landing and sex were found for peak KA moment and angle (Table 1). Interactions between sex and landing type existed for the remaining variables of interest (Table 1). **CONCLUSION:** Landing mechanics are different between the SJ and the DVJ with and these responses are sex dependent. Therefore, selection of the landing task could influence results and needs to be considered when assessing injury risk as well as return to sport readiness.

Table 1: Sex and landing task differences.

| Variable | Female SJ | Male SJ | Female DVJ | Male DVJ | Interaction | ME Landing | ME Sex |
|-----------------------------------|--------------|--------------|--------------|--------------|-------------|------------|--------|
| Peak KA Angle (add (+), abd (-)) | -7.4 ± 9.8 | 7.7 ± 8.7 | -5.4 ± 9.6 | 9.8 ± 8.8 | 0.888 | 0.003 | <0.001 |
| Peak KA Moment (add (+), abd (-)) | 0.8 ± 0.5 | 0.2 ± 1.3 | 0.3 ± 1.1 | -0.3 ± 1.0 | 0.755 | 0.022 | 0.006 |
| vGRF (BW) | 1.5 ± 0.3 | 1.7 ± 0.4 | 1.8 ± 0.4 | 1.8 ± 0.3 | 0.015 | 0.001 | 0.459 |
| pGRF (BW) | 0.4 ± 0.1 | 0.5 ± 0.1 | 0.4 ± 0.2 | 0.4 ± 0.1 | 0.032 | 0.125 | 0.936 |
| Peak KF Angle | 85.6 ± 12.5 | 94.2 ± 14.0 | 90.2 ± 11.2 | 94.2 ± 15.4 | 0.021 | 0.023 | 0.097 |
| KF ROM | 104.8 ± 14.5 | 120.8 ± 18.8 | 107.1 ± 12.3 | 115.4 ± 23.0 | 0.012 | 0.297 | 0.016 |

Biomechanical Loading Magnitude Differences During Landing in Male Athletes with and without Patellar Tendinopathy

Laura S. Pietrosimone¹, J Troy Blackburn², Erik Wikstrom, FACSM², David Berkoff², Sean Docking³, Jill Cook³, Darin Padua². ¹Duke University, Durham, NC. ²University of North Carolina at Chapel Hill, Chapel Hill, NC. ³LaTrobe University, Bundaroo, Australia. (Sponsor: Erik Wikstrom PhD, ATC, FACSM)

Email: laura.pietrosimone@duke.edu

(No relevant relationships reported)

Mechanical loading of the patellar tendon (PT) is considered a primary factor associated with tendinopathy in jumping athletes. Prior research has not established if overloading or underloading movement profiles are present in symptomatic and asymptomatic athletes with PT structural abnormality (PTA) compared to healthy athletes. **PURPOSE:** To compare involved limb landing biomechanics between male athletes with and without patellar tendinopathy. **METHODS:** 43 males were grouped based on PT pain and ultrasound imaging of the proximal PT: symptomatic with PTA (SYM-PTA; n=13; 20±2yrs; 1.8±0.1m; 84±5kg), asymptomatic with PTA (ASYM-PTA; n=15; 21±2yrs; 1.8±0.1m; 82±13kg), and healthy control (CON; n=15; 20±2yrs; 1.8±0.1m; 79±12kg). 3D biomechanics were collected during double-limb jump-landing trials from a 30cm box placed 50% of participant height from 2 force plates. Kinematic (knee flexion angle (KF)) and kinetic (vertical ground reaction force (vGRF); internal knee extension moment (KEM); patellar tendon force (F_{PT})) variables were analyzed as continuous waveforms during stance phase. Mean values were calculated for each 1% of stance, normalized over 202

data points across stance phase (0-100%), and plotted with 95% confidence intervals for each group. Statistical significance was defined as a lack of 95% CI overlap for ≥ 3 consecutive %; average mean differences (MD) were calculated.

RESULTS: SYM-PTA had lesser KF than CON over stance phase (8-76%, MD: 15.8±2.7°). ASYM-PTA had lesser KF than CON in the early (8-13%, MD: 8.0±0.4°; 21-24%, MD: 11.11±0.32°) and late (74-94%, MD: 9.6 ± 1.1°) stance phase. SYM-PTA group had lesser KEM than CON in early stance (6.5-9%, MD: 0.04 ± 0.004 Nm[kgm]⁻¹), as well as ASYM-PTA in mid-stance (38-56%, MD: 0.03 ± 0.001 Nm[kgm]⁻¹). SYM had lesser F_{PT} in early stance (6-9%, MD: 0.9 ± 0.2BW) than CON and in mid-stance (36-60%, MD: 0.7 ± 0.1BW) than ASYM-PTA. There were no differences in VGRF between groups.

CONCLUSIONS: Male athletes with SYM-PTA demonstrated a PT load-avoidance profile during a double-limb landing task compared to ASYM-PTA and CON athletes. ASYM-PTA did not show evidence of overloading compared to CON. Our findings support the use of individualized treatments for athletes along the continuum of patellar tendinopathy to maximize load-bearing capabilities of tendon.

2239 Board #4 May 31 9:30 AM - 11:30 AM
Is Visual-Cognitive Loading During Jumping A Potential Risk Factor For Sports Injuries?

Jan Wilke, Florian Giesche, Daniel Niederer, Tobias Engeroff, Sebastian Barabas, Saskia Tröller, Lutz Vogt, Winfried Banzer, FACSM. *Goethe University Frankfurt, Frankfurt am Main, Germany.*

Email: wilke@sport.uni-frankfurt.de
 (No relevant relationships reported)

PURPOSE: Failed jump landings represent a key mechanism of musculoskeletal trauma. It has been speculated that cognitive dual-task loading during the flight phase may moderate the injury risk. This study aimed to explore whether increased visual distraction can compromise landing biomechanics.

METHODS: Twenty-one healthy, physically active participants (15 females, 25.8±0.4 years) completed a series of 30 counter-movement jumps (CMJ) onto a capacitive pressure platform. In addition to safely landing on one leg, they were required to memorize either one (1N), two (2N) or three (3N) jersey numbers shown during the flight phase. Conditions were randomly selected and equally balanced over all jumps. Outcomes included the number of recall errors as well as landing errors and three variables of landing kinetics (time to stabilization/TTS, peak ground reaction force/pGRF, length of the centre of pressure trace/COPT). Differences between the conditions were calculated using Friedman tests and post hoc Bonferroni-Holm corrected Conover tests.

RESULTS: Regardless of the condition, the number of landing errors remained unchanged ($p=.46$). In contrast, increased visual distraction resulted in a higher number of recall errors (median 1N: 1, 2N: 2, 3N: 3; $p=.001$). Higher cognitive loading, furthermore, appeared to negatively impact the total (1N: 323 mm, 2N: 340 mm, 3N: 332 mm; $p=.05$) and mediolateral (1N: 261 mm, 2N: 273 mm, 3N: 270 mm; $p=.01$) COPT. TTS and pGRF ($p=.84$) and time to stabilization ($p=.78$) were unaffected.

CONCLUSIONS: A simple visual distraction in a controlled experimental setting is sufficient to adversely affect landing stability and task-related short-term memory during CMJ. The ability to precisely perceive the environment during movement under time constraints may, hence, represent a new risk factor of musculoskeletal injury and should be investigated in a prospective trial.

2240 Board #5 May 31 9:30 AM - 11:30 AM
Effects of Arm Swing and Overhead Target on Vertical Jump Performance in Children and Adolescents

Zachary M. Gillen, Marni E. Shoemaker, Brianna D. McKay, Nicholas A. Bohannon, Alegria I. Mendez, Lacey E. Jahn, Joel T. Cramer, FACSM. *University of Nebraska-Lincoln, Lincoln, NE.* (Sponsor: Joel T. Cramer, FACSM)

(No relevant relationships reported)

PURPOSE: To examine the effects of including an arm swing and overhead target on vertical jump performance in children and adolescents.

METHODS: Young males ($n=21$, mean±95% confidence interval, age=12.1±1.1 years) performed counter-movement vertical jump testing with (CMJA) and without (CMJ) the use of an arm swing and overhead target on force plates sampled at 1 kHz. For both conditions, participants stood in the middle of the force plates, performed a rapid counter-movement of self-selected depth, and immediately finished with a maximal, explosive vertical jump. For the CMJA, participants were instructed to visually focus on the overhead target (Sports Imports, Freestanding Vertec Jump Trainer, Hilliard, OH, USA), use the arms to swing during the countermovement phase, and use the dominant hand to reach for the overhead target. For the CMJ, participants kept their hands on their hips and eyes forward. Vertical ground reaction forces from force plates under each foot were summed to provide total vertical ground reaction forces (N). Performance outcomes included peak force (PF, N), peak rate of

force development (pRFD, N·s⁻¹), peak power (PP, W), concentric impulse (CON, Ns), and eccentric impulse (ECC, Ns). Five separate one-way repeated measures ANOVAs were used to compare means between CMJA and CMJ conditions.

RESULTS: There were no differences between CMJA and CMJ for PF (CMJ=712.1±183.6 N, CMJA=716.3±151.9 N, $p=0.941$), pRFD (CMJ=6209.3±1628.4 N·s⁻¹, CMJA=6456.2±2082.1 N·s⁻¹, $p=0.657$), or CON (CMJ=133.4±20.9 Ns, CMJA=134.6±27.6 Ns, $p=0.849$). PP was greater during the CMJA (CMJ=2136.2±550.9, CMJA=2632.6±558.4 W, $p=0.014$), and ECC was greater during the CMJ (CMJ=102.5±17.6 Ns, CMJA=88.1±17.5 Ns, $p=0.015$).

CONCLUSIONS: Including an arm swing and reaching for an overhead target resulted in 23% greater PP with 14% less ECC during the vertical jump test. Reducing eccentric pre-loading, while increasing power production is optimal for youth performance testing. Since PF, pRFD, and CON were not different, while ECC was lower during the CMJA, complex underlying mechanisms involving movement velocity may be responsible for the greater power output during the CMJA, which is consistent with previous studies in adults.

Physical and Psychological Predictors of Single-leg Drop Landing Biomechanics ACL Reconstruction.

Christopher Kuenze, Thomas Birchmeier, Jeffrey Kovan, Caroline Lisee. *Michigan State University, East Lansing, MI.*

Email: kuenzech@msu.edu
 (No relevant relationships reported)

Physical function, psychological factors, and biomechanical adaptations all play roles in risk of second ACL injury after ACLR. However, a gap in knowledge exists regarding the predictive relationships between modifiable risk factors that can be evaluated early in the recovery process and biomechanical adaptations during sport-specific tasks.

PURPOSE: To assess the ability of involved limb knee extension maximal voluntary isometric contraction (MVIC) strength, psychological readiness for sport, and self-reported knee function to predict sagittal plane single-leg drop landing (SLL) kinematics and kinetics after ACLR.

METHODS: Fifty-two participants (19 M/33 F, age=22.6±4.4 yrs, height=1.7±0.1 m, weight=73.5±11.9 kg, time since surgery=37.8±23.8 mo.) with unilateral ACLR were included in this cross-sectional study. Participants completed involved limb knee extension MVIC torque (Nm/kg) assessment, the ACL Return to Sport After Injury (ACL-RSI) Scale to assess psychological readiness for sport, and the International Knee Documentation Committee (IKDC) subjective knee evaluation to assess knee-related function. Peak sagittal plane hip and knee joint moments and joint angles were assessed during three SLL trials. Separate multivariable linear regression models with forward entry were used to assess the ability of physical and psychological outcomes to predict sagittal plane kinematics and kinetics.

RESULTS: Knee extension MVIC strength, but not ACL-RSI score or IKDC score, significantly predicted peak knee flexion angle ($R^2 = 0.43$, $p=0.001$) and internal knee extension moment ($R^2 = 0.31$, $p=0.001$) during the SLL. Knee extension MVIC strength was positively correlated with ACL-RSI score ($r = 0.30$, $p = 0.03$) and IKDC score ($r = 0.39$, $p = 0.01$).

CONCLUSIONS: Poor quadriceps strength is associated with high-risk, "stiff" sagittal plane kinematics during a SLL task; however, psychological readiness for return to sport and self-reported knee function did not significantly contribute to the predictive models. Therefore, addressing quadriceps strength deficits throughout recovery may be important to reducing biomechanical risk factors for secondary ACL injury while addressing psychological readiness for sport may play a greater role promoting return to sport following ACLR.

Static Loading of the Knee Joint Results in Modified Single Leg Landing Biomechanics

Michael W. Olson, FACSM. *Southern Illinois University Carbondale, Carbondale, IL.*

Email: mwolson@siu.edu
 (No relevant relationships reported)

PURPOSE: The purpose of this study was to examine the mechanical and neuromuscular responses to single leg drop landing perturbations before and after passive loading of the knee joint.

METHODS: Participants' (male [$n=7$] and female [$n=14$], 21.3 ± 2.1 yrs, 1.69 ± 0.09 m, 69.3 ± 13.0 kg) right hip, knee, and ankle kinematics were captured with a 3D motion capture system. Electromyography (EMG) signals were recorded from rectus femoris (RF), vastus lateralis (VL), vastus medialis (VM), semimembranosus (SM), and biceps femoris (BF) muscles. EMG were normalized to maximum voluntary efforts. Participants performed 10 single leg landings from a 30 cm height onto a force platform before and after static knee loading. Participants were seated and secured to a chair while the right knee was flexed and secured at 35° during static loading. A load (150 N/females, 200 N/males) was applied at a 90° angle to the proximal leg for

10 min. Maximum, minimum, range of motion (ROM), and angular velocities were assessed for the hip, knee, and ankle joints, while normalized average EMG (NAEMG) and average vertical ground reaction forces (aVGRF) were calculated over the initial 200 ms of landing. Rate of force development (RFD) was calculated during the landings. One-way ANOVAs analyzed kinematics variables, NAEMG during loading, aVGRF and RFD; while a two-factor ANOVA (condition x muscle) analyzed NAEMG. Alpha level was set at 0.05.

RESULTS: Maximum hip flexion velocity decreased (87.1 ± 56.9 vs. 56.9 ± 63.4 °/s, $p < 0.01$). Minimum knee flexion velocity increased (-14.9 ± 25.2 vs. -27.9 ± 34.2 °/s, $p < 0.02$). Minimum knee ad/abduction velocity decreased (-528.5 ± 127.5 °/s vs. -399.9 ± 129.3 °/s, $p < 0.001$). Ankle ROM decreased (56.2 ± 8.5 vs. 52.6 ± 8.5 °, $p < 0.001$). aVGRF decreased (1297.1 ± 392.4 N vs. 1231.3 ± 392.4 N, $p < 0.02$). RFD had a non-significant trend ($16,602 \pm 1057$ N/s vs. $17,368 \pm 1447.6$ N/s, $p = 0.076$). NAEMG was significant between muscle groups (RF: $46.4 \pm 28.9\%$ vs. VL: $26.2 \pm 27.7\%$, $p < 0.01$; VM: $56.3 \pm 46.6\%$ vs. VL: $26.2 \pm 27.7\%$, BF: $38.8 \pm 27.8\%$, and SM: $32.4 \pm 23.0\%$, $p < 0.02$).

CONCLUSIONS: Changes in velocity parameters are attributed to the altered mechanical behavior of the knee joint tissues and may contribute to changes landing mechanics. Overall, results indicate modified hip and knee control in response to potential reduction in knee joint stiffness.

Relationship Between Fear Of Reinjury And Single-Leg Landings In ACL Reconstructed Individuals

Elisabeth C. Holt¹, Anh-Dung Nguyen¹, Brooke A. Smith¹, David R. Bell², Stephanie M. Triggsted². ¹High Point University, High Point, NC. ²University of Wisconsin Madison, Madison, WI.
 Email: eholt@highpoint.edu

(No relevant relationships reported)

High fear of reinjury following ACL reconstruction (ACLR) is related to lower rates of return-to-sport (RTS) and altered neuromuscular and biomechanical patterns during double-leg landings that increase the risk of secondary ACL injury. However, single-leg landings are observed as an ACL injury mechanism and used for RTS decisions following ACLR. Whether fear of reinjury is related to landing patterns on a single limb in ACLR individuals is unknown. **PURPOSE:** To determine the relationship between fear of reinjury and lower extremity muscle activation and biomechanics during single-leg landings in individuals with ACLR. **METHODS:** Thirty-six females (18.9±1.5yrs, 168.7±6.5cm, 67.2±10.0kg) with a history of ACLR completed the Tampa Scale of Kinesiophobia-11 (TSK-11) and three trials of a single-leg hop for distance. 3D motion capture recorded lower extremity biomechanics. Surface electromyography recorded the average peak root mean square (RMS) amplitude of 6 muscles [gluteus medius, gluteus maximus, biceps femoris, semitendinosus, vastus lateralis, rectus femoris] 50ms prior to initial contact (PRE) and during landing (LAND), and was normalized to peak RMS. Spearman's rank correlations examined the relationship between total TSK-11 scores and lower extremity landing muscle activation and biomechanics. **RESULTS:** Fear of reinjury was not related to any lower extremity single-leg landing muscle activation or biomechanics. Specifically, there was no significant relationship to knee kinematics ($r_{s(\text{range})} = -0.251 - 0.000$, $P_{\text{range}} = 0.146-0.999$) or kinetics ($r_{s(\text{range})} = -0.273-0.249$, $P_{\text{range}} = 0.150-0.705$), hip kinematics ($r_{s(\text{range})} = -0.055-0.182$, $P_{\text{range}} = 0.295-0.753$) or kinetics ($r_{s(\text{range})} = -0.091-0.161$, $P_{\text{range}} = 0.355-0.602$), or lower extremity muscle PRE activation ($r_{s(\text{range})} = -0.129-0.190$, $P_{\text{range}} = 0.274-0.861$), or LAND activation ($r_{s(\text{range})} = -0.234-0.283$, $P_{\text{range}} = 0.100-0.852$). **CONCLUSIONS:** Caution should be used when assessing RTS readiness using single-leg landings. ACLR individuals who demonstrate proper single-leg landings may still be at risk of secondary ACL injury if they have a high fear of reinjury. To comprehensively assess RTS readiness, single-leg landings should be used in conjunction with measures that effectively identify fear of reinjury.

The Effects of Resistance Training On Cardiac Muscle Function During Cancer Cachexia

Ashton Legenza¹, Chase Reyes¹, Matthew Dovgan¹, Allison Tigner¹, Wisam Najdawi¹, Eric Bredahl¹, Jacob Siedlik¹, Joan Eckerson, FACSM¹, Kristen Drescher². ¹Creighton University, Omaha, NE. ²Creighton University School of Medicine, Omaha, NE. (Sponsor: Joan Eckerson, FACSM)
 Email: ashtonlegenza@creighton.edu

(No relevant relationships reported)

It is estimated that half of all patients with cancer will eventually develop a condition called cachexia that is characterized by systemic inflammation, negative protein and energy balance, and an involuntary loss of cardiac and skeletal muscle. It is a dangerous syndrome that not only has a dramatic impact on patient quality of life but is also associated with poor responses to chemotherapy and decreased survival. **PURPOSE:** To investigate the effects of resistance training (RT) on cancer cachexia-induced cardiac muscle loss. **METHODS:** All procedures were done in accordance with an IACUC approved protocol. Male-Wistar rats (n=48) were randomly assigned to a sedentary (SED), RT, SED+cancer, and RT+cancer group. Animals assigned to RT groups trained for a total of 13 weeks using an elevated food model to simulate low intensity RT. SED animals were placed in standard animal housing for an equivalent amount of time. At week 10, animals were injected with Walker 256 mammary carcinoma cells (10⁶ cells) or an equivalent amount of 0.9% saline. Left ventricular morphology was measured using echocardiography prior to injection and at the end of the 13-week experiment. Animals were anesthetized with isoflurane during imaging. Differences in ventricular thickness and diameter between groups were analyzed using one-way ANOVA. Significance was set at $\alpha=0.05$. **RESULTS:** There were no significant findings for ventricular morphology between or within groups. **CONCLUSIONS:** The findings suggest that RT had no effect on cancer-cachexia induced cardiac muscle loss. Since the Walker 256 mammary carcinoma cells did not provide a significant cardiotoxic effect, future studies are warranted using different cancer cell lines or incubation periods to induce cardiotoxicity. This work was funded through a Haddix research grant.

Repetitive Activation Compromises Motoneuron Excitability During Fatiguing Exercise

Vincent P. Georgescu, Joshua C. Weavil, Taylor S. Thurston, Hsuan-Yu Wan, Russell S. Richardson, Markus Amann.
 University of Utah, Salt Lake City, UT.
 Email: vincent.georgescu@hsc.utah.edu

(No relevant relationships reported)

Although fatiguing exercise is known to decrease motoneuronal excitability, the mechanisms underlying this impact remain unclear. **PURPOSE:** To investigate the role of repetitive motoneuron activation in determining the decrease of motoneuronal excitability during fatiguing exercise. **METHODS:** On 2 separate days, healthy young subjects (26 ± 6 yrs) performed intermittent isometric knee extensions (at 20% of maximal voluntary quadriceps torque): 1) voluntarily (VOL; i.e. requiring repetitive motoneuron activation), and 2) electrically-evoked (EVO, femoral motor nerve stimulation at 20 Hz; no motoneuron activation). The exercise consisted of 50 s contractions followed by 10 s breaks during which potentiated twitches (Qtw) were assessed to monitor the development of peripheral fatigue during each trial. Exercise continued in each trial until the goal of achieving a similar ~40% reduction in Qtw (ΔQtw) was reached. Before and immediately after exercise, cervicomedullary stimulations (CMS) were used to elicit unconditioned (CMS only) and conditioned (transcranial magnetic stimulation followed by CMS, 100 ms interval) cervicomedullary motor-evoked potentials (CMEPs). All CMEPs were normalized to M-waves and evoked during a constant electromyographic (EMG) activity corresponding to 20% of the EMG obtained during pre-exercise MVCs. **RESULTS:** In both trials, ΔQtw was, per design, comparable (~40%; $P = 0.9$) and unconditioned CMEPs were similar before and after exercise ($P = 0.23$). Conditioned

CMEPs were decreased following VOL (-79%, $P < 0.05$). While conditioned CMEPs were also significantly decreased following EVO (-62%), the exercise-induced reduction was substantially smaller compared to VOL.

CONCLUSION: Repetitive activation of the motoneurons contributes to the decrease in motoneuronal excitability during voluntary exercise. It remains unclear whether motoneuronal responsiveness to synaptic input and/or the efficacy of the corticomotoneuronal synapse account for the repetitive activation-related depression. However, as motoneuron excitability still falls during evoked exercise, other mechanisms, potentially related to neural feedback, also contribute to the exercise-induced fall in motoneuronal excitability.

Dietary Nitrate Supplementation Attenuates Fatigue in Rat Skeletal Muscle

Donnie Howell, Sydney C. Shank, Alex J. Glogoza, William L. Sexton, FACSM. *A.T. Still University of Health Sciences, Kirksville, MO.* (Sponsor: William L. Sexton, FACSM)
 Email: sa199610@atsu.edu
 (No relevant relationships reported)

Nitrate supplementation via oral beetroot juice (BR) has been shown to increase the partial pressure of oxygen in the interstitial space (PiO_2) in rat skeletal muscle. PiO_2 reflects the balance between oxygen delivery and oxygen consumption, and BR is thought to increase PiO_2 and to slow PiO_2 on-kinetics via increased nitric oxide availability. However, it is not known whether nitrate supplementation via BR enhances skeletal muscle contractile performance. **PURPOSE:** The purpose of this study was to 1) validate the effect of oral BR juice on PiO_2 in the rat extensor digitorum longus muscle (EDL) and 2) to determine whether nitrate supplementation attenuates fatigue in the EDL. **METHODS:** Twenty female Sprague Dawley rats (~270g) were randomly divided into three groups: beet juice (BR, n=7), nitrate depleted beetroot juice (dBR, n=8), and water (CON, n=5). BR rats received beetroot juice in their drinking water (1 mmol/kg/day; Beet It, James White, UK) for 5 days before experimentation while dBR rats received an equivalent volume of nitrate depleted BR. CON rats received water *ad libitum*. After pentobarbital anesthesia (50 mg/kg ip), the EDL muscle was isolated and attached to a load cell interfaced with a muscle tension analyzer. PiO_2 was measured using the phosphorescent quenching method. **RESULTS:** The EDL was first stimulated at 1 (Hz, 6 V, 2 ms) to elicit isometric contractions. Resting PiO_2 was not different among the groups (BR, 26 ± 2 ; dBR, 21 ± 1 ; CON 25 ± 3 mmHg). However, the rate of fall of PiO_2 at the onset of contractions (on-kinetics) as reflected by the mean response time, was slower in BR rats (BR, 23 ± 3 s; dBR, 12 ± 2 s; CON, 12 ± 1 s; $p < 0.002$). Second, the EDL was stimulated at 3 Hz to elicit fatigue. There was no difference in peak tension development among the groups (BR, 0.18 ± 0.01 ; dBR, 0.23 ± 0.02 ; CON, 0.14 ± 0.01 g/mg). However, percent fatigue was less in the BR rats (BR, 18 ± 3 ; dBR, 30 ± 3 ; CON, 28 ± 4 %; $p < 0.05$). There was also a decrease in the peak positive dT/dt during contractions (BR, 14.8 ± 1.4 ; dBR, 19.7 ± 1.9 ; CON, 18.9 ± 1.0 s; $p < 0.05$). **CONCLUSION:** These findings validate the observation that nitrate supplementation with oral BR slows PiO_2 on-kinetics in rat skeletal muscle. Although developed tension was not different, muscle fatigue was less in the BR treated rats which may be attributable to the slower PiO_2 on-kinetics.

Exercising Skeletal Muscle Blood Flow is Diminished in a Rat Model of Pulmonary Arterial Hypertension

Gary M. Long¹, Andrea Frump², Ashley Troutman¹, Melissa Mailand¹, Kaylee Ann Ellis¹, Amanda Fisher², Keith Avin¹, Andrew R. Coggan, FACSM¹, Tim Lahm², Mary Beth Brown¹.
¹Indiana University, Indianapolis, IN. ²Indiana University School of Medicine, Indianapolis, IN.
 (No relevant relationships reported)

PURPOSE: Skeletal muscle dysfunction including a shift toward glycolytic metabolism has been suggested to contribute to exercise intolerance in pulmonary arterial hypertension (PAH) but an exercise perfusion limitation of skeletal muscle has not been identified. Therefore, we performed novel characterization of skeletal muscle blood flow response to exercise in a rat model of PAH. **METHODS:** Treadmill running at 50% VO_{2max} was performed by male Sprague-Dawley rats (368 ± 13 g) injected with monocrotaline (MCT, 60mg/kg) to elicit a severe PAH phenotype (MCT, n=7), or vehicle control (saline) (CON, n=7). Fluorescent microspheres injected during run and rest bouts were utilized to determine blood flow via photo spectroscopy of harvested skeletal muscles. VO_{2max} was measured prior to terminal blood flow studies to characterize exercise capacity of each rat and determine relative exercise intensity for flow analysis. Echocardiographic determination of right ventricular (RV) morphometry and function was also performed. Values are mean \pm SE. **RESULTS:** As expected, MCT exhibited RV hypertrophy (as elevated ratio of RV to LV+S mass, $p = 0.002$, and RV wall thickness in echocardiography, $p = 0.004$), higher RV systolic pressure ($p = 0.02$) and lower VO_{2max} ($p = 0.03$) vs. CON. During exercise, blood flow (expressed as as

ml/min per 100g tissue) of the vastus lateralis, semitendinosus, gastrocnemius and biceps femoris was significantly reduced ($p = 0.02$) in MCT (0.187 ± 0.07) compared to CON (0.662 ± 0.17) concomitant with higher ($p = 0.008$) whole blood lactate in MCT (10.44 ± 1.65 mmol/L) vs. CON (4.33 ± 0.72 mmol/L). Further, exercising blood flow was inversely related to blood lactate at exercise ($r = -0.603$, $p = 0.03$), and positively related to cardiac output ($r = 0.61$, $p < 0.05$). At rest, there was a tendency for both blood flow reduction ($p = 0.06$) and higher lactates ($p = 0.09$) in MCT (0.053 ± 0.01 , 5.98 ± 2.48 mmol/L) vs. CON (0.148 ± 0.04 , 1.82 ± 0.19 mmol/L). **CONCLUSIONS:** Exercising blood flow is reduced in a rat model of PAH and may contribute to metabolic limits to exercise capacity. Future studies will explore ways to augment skeletal muscle exercising blood flow in PAH, with the hope of improving tolerance for exercise in patients. Funding: NIH-NHLBI R-15 (MB Brown)

Low-load Resistance Exercise During Inactivity is Associated With Greater Fibre Area and Satellite Cell Expression in Older Skeletal Muscle

Adam Johnston¹, Ryan P. Kelly¹, Michaela Devries², Tyler Churchward-Venne³, Stuart Phillips, FACSM⁴, Gianni Parise⁴, Daniel M. Moore⁵. ¹University of Prince Edward Island, Charlottetown, PE, Canada. ²University of Waterloo, Waterloo, ON, Canada. ³McGill University, Montreal, QC, Canada. ⁴McMaster University, Hamilton, ON, Canada. ⁵University of Toronto, Toronto, ON, Canada.

 (No relevant relationships reported)

Age-related sarcopenia is accelerated by physical inactivity. Low-load resistance exercise (LLRE) counters inactivity-induced muscle atrophy in older adults, but changes in muscle fibre morphology are unstudied. The **PURPOSE** of this study was to determine the impact of LLRE during short-term inactivity (step-reduction) on muscle fibre size, satellite cell (SC) and capillarity content in older skeletal muscle. **METHODS:** Fourteen older (~71 years) male adults underwent 14 days of step reduction (<1500 steps/day) while performing six sessions of LLRE (~30% maximal strength) with one leg (SR + EX) while the contralateral leg served as an untrained control (SR). Seven healthy ambulatory age-matched male adults (~69 years) served as a comparator group (COM). Muscle biopsies were taken from the vastus lateralis after 14 days, and immunohistochemical analysis was performed to determine muscle fibre cross-sectional area (CSA), myonuclear content, SC content (PAX7⁺ cells), and total (C:F) and fibre type-specific (C:Fi) capillary-to-fibre ratios. **RESULTS:** Type I and II fibre CSA was greater in SR + EX compared with SR. Whereas there were no differences across fibre types between SR + EX and CON, type II fibre CSA was significantly lower in SR compared with COM. Type II myonuclear domain was greater in SR + EX compared with COM and SR. Pax7⁺ cells associated with type I and II fibres were lower in SR compared with SR + EX. Type II PAX7⁺ cells were also lower in SR compared with COM with a similar trend for type I fibres. There were trends for a lower C:Fi in SR compared with SR + EX for both fibre types with no differences for each compared with COM. Minimal LLRE during a period of decreased physical activity is associated with greater muscle fibre CSA, SC content, and capillarization. **CONCLUSION:** These results support the use of LLRE as an effective countermeasure to inactivity-induced alterations in muscle morphology with age.

Skeletal Muscle Fatigue: Mechanisms And Mitigation At The Cellular And Molecular Levels In Older Adults

Aurora D. Foster, Chad R. Straight, Edward P. Debold, Mark S. Miller. *University of Massachusetts, Amherst, Amherst, MA.*
 Email: arougeau@umass.edu
 (No relevant relationships reported)

Skeletal muscle fatigue, or the contraction-induced decline in whole muscle force or power, decreases physical function in older adults. Fatigue primarily results from elevated hydrogen (H^+) and phosphate (P_i) altering myosin-actin interactions; however, which steps of the myosin-actin cross-bridge cycle are altered and whether these changes are reversible at the molecular and cellular levels are unclear. **PURPOSE:** The study objectives were to: 1) Examine the effects of simulated fatigue on molecular and cellular function, and 2) Test the ability of deoxyadenosine triphosphate (dATP), an alternative energy to adenosine triphosphate (ATP), to reverse fatigue-induced changes. **METHODS:** Maximal force production, myofibril mechanics and cross-bridge kinetics were measured in single fibers (20 per person) from the vastus lateralis of 8 (4 men) healthy, sedentary older adults (65-75 years) under normal (5 mM P_i , pH 7.0), fatigue (30 mM P_i , pH 6.2) and fatigue with dATP conditions. ANOVAs with post-hoc tests were used to evaluate differences between means by fiber-type and results were considered significant at $P \leq 0.05$. **RESULTS:** Force declined with fatigue in slow- (myosin heavy chain (MHC) I, 22%) and fast-contracting (MHC II, 30%) fibers due to a reduced number or stiffness of strongly bound myosin heads (30-36%) and slower cross-bridge kinetics (longer myosin attachment times (18-31%) and

reduced rates of force production (17-37%). MHC I myofilaments became stiffer with fatigue (59%), suggesting a fiber-type specific mechanism to partially mitigate fatigue-induced force reduction. Fatigue with dATP moderately improved force production similarly in both fiber types (10-12%) compared to fatigue with ATP. In MHC I fibers, fatigue with dATP returned the number or stiffness of myosin heads and cross-bridge kinetics to normal values. In MHC II fibers, fatigue with dATP left the number or stiffness of myosin heads similar to fatigue conditions, while the cross-bridge kinetics were 19-22% faster than normal. **CONCLUSION:** These results identify novel fiber-type specific changes in myosin-actin interactions and myofilament stiffness that help explain fatigue-related force reduction in older adults as well as an alternative energy source that partially reverses the effects of fatigue.

Eccentric Overload during Strength Training: A Stimulus for Enhanced Satellite Cell Activation

Michaela Wehrstein¹, Axel Schöffel¹, Nadine Weiberg¹, Theresa Betz¹, Thomas Gwechenberger², Mareike Rittweg², Helmut Müller², Birgit Friedmann-Bette¹. ¹University Hospital Heidelberg, Heidelberg, Germany. ²Olympic Training Center Heidelberg, Heidelberg, Germany.

(No relevant relationships reported)

The effective stimulation of satellite cells (SCs) is crucial for muscular adaptations to various forms of exercise. **PURPOSE:** to find out if strength training with eccentric overload (CON/ECC⁺), which is known to cause microtraumata in skeletal muscle, induces enhanced SC activation, proliferation and differentiation to new myofibers. **METHODS:** 30 recreationally active male subjects were randomly assigned to one bout of intense leg-extension strength training performed as conventional concentric/eccentric resistance exercise (CON/ECC, $n = 15$, 23.3 ± 3.5 yr, 181 ± 5 cm, 74.5 ± 7.6 kg) or as CON/ECC⁺ ($n = 15$, 24.7 ± 3.3 yr, 182 ± 6 cm, 77.4 ± 8.9 kg). Biopsies from the vastus lateralis muscle were obtained in rested condition and again 7 days after the resistance exercise from the contralateral leg. Immunohistochemical analyses of cryosections were performed for myosin heavy chain isoforms I, II and neonatal (MHC_{neo}) as well as for total SC number (DAPI/Pax7; SC_{tot}) and for activated SCs (DAPI/Pax7/MyoD; SC_{act}). CK and myoglobin were determined in venous blood. **RESULTS:** CK (CON/ECC⁺: 4587 ± 7069 vs. 142 ± 55 U · L⁻¹; CON/ECC: 3942 ± 5422 vs. 128 ± 51 U · L⁻¹) and myoglobin (CON/ECC⁺: 720 ± 1335 vs. 41 ± 20 µg · L⁻¹; CON/ECC: 796 ± 1248 vs. 34 ± 12 µg · L⁻¹) were significantly ($P \leq 0.005$) increased after resistance exercise. Only after CON/ECC⁺, significant increases in total SC number per myofiber (0.13 ± 0.05 vs. 0.10 ± 0.03 , $P = 0.017$) and related to type II fibers (0.13 ± 0.04 vs. 0.10 ± 0.05 , $P = 0.009$) were observed. Also, the proportion of activated SCs went up after CON/ECC⁺ only (from 13.2 ± 8.9 to 20.7 ± 9.2 % of SC_{tot}, $P = 0.008$), the average 8 % increase being significantly ($P = 0.026$) different from the non-significant 0.5 % decrease after CON/ECC (from 11.0 ± 10.1 to 10.5 ± 7.4 %). After CON/ECC⁺, the proportion of SC_{act} was significantly correlated with the maximal values for CK ($r = 0.607$, $P = 0.016$) and myoglobin ($r = 0.679$, $P = 0.005$). No change occurred in the low number of MHC_{neo} positive myofibers in either group. **CONCLUSION:** The considerable increases in CK and myoglobin suggest substantial myofiber damage after both forms of intense resistance exercise. However, only CON/ECC⁺ induced a significant activation and proliferation of SCs. With regard to the lack of increase in MHC_{neo} expression, there was no evidence for de-novo synthesis of myofibers.

Doublets Initiating Low Frequency Stimulation Improve Dynamic Contractility Without Exacerbating Fatigue

Kristian Overgaard, Katja K. Pedersen, Ole B. Nielsen. Aarhus University, Aarhus, Denmark.

Email: overgaard@ph.au.dk

(No relevant relationships reported)

Purpose: Doublets, two action potentials (AP) with a very short inter-impulse interval, frequently occur initially in impulse trains from motor nerves during muscle activation. Such doublets improve dynamic contractile parameters such as rate of force development (RFD), velocity and power. In addition, previous studies have shown delayed fatigue development from repeated isometric contractions when a doublet initiates a *sub-tetanic* train compared with constant frequency stimulation. However, these comparisons were not matched for impulse number, train duration and work, which may have confounded the interpretations. Furthermore, it is unknown how doublets would affect endurance during *dynamic* contractions. We, therefore, compared the development of fatigue from repeated shortening contractions activated with *doublet-initiated sub-tetanic* train (DT) or constant-frequency *sub-tetanic* train (CFT) using protocols matched for work, AP and train duration.

Methods: EDL muscles were isolated from 4 week old rats and incubated at 30°C in Krebs Ringer buffer. To induce fatigue, 100 shortening contractions were elicited either by a *doublet-initiated sub-tetanic* train (DT; 60 Hz) or a constant-frequency

sub-tetanic train (CFT; 71 Hz). Contractions in the two groups were matched for work, train duration and pulse number. Isometric contractility was tested before and immediately after fatigue.

Results: Work of each contraction was similar in DT- and CFT-stimulated muscles both initially (368 ± 10 vs 369 ± 13 µJ, respectively) and after 100 fatiguing contractions (202 ± 9 vs 193 ± 8 µJ, respectively). However the contraction force and shortening developed faster in the DT-fatigued than the CFT-fatigued muscles: Initial values (RFD 20 ± 0.7 vs 13 ± 0.3 N/s and shortening velocity 48 ± 2 vs 41 ± 1); fatigued values (RFD 16 ± 0.7 vs 10 ± 0.4 N/s, velocity 29 ± 2 vs 23 ± 1 mm/s). Isometric tetanic force was equally affected in both groups; DT-fatigued muscles decreased to 73 ± 2 % and CFT-fatigued muscles to 75 ± 1 % of initial force.

Conclusion: The results indicate that during repeated contractions matched for total work, stimulation duration and pulse number, an initiation by a doublet does not exacerbate fatigue development, but provides an activation strategy for muscles to produce a higher RFD and shortening velocity.

Walking Efficiency as a Predictor of Brain Atrophy with Aging

Jennifer A. Schrack¹, Amal A. Wanigatunga¹, Vadim Zipunnikov¹, Yang An², Adam P. Spira¹, Christos Davatzikos³, Eleanor M. Simonsick², Susan M. Resnick². ¹Johns Hopkins University, Baltimore, MD. ²National Institute on Aging, Baltimore, MD. ³University of Pennsylvania, Philadelphia, PA. Email: jschrack1@jhu.edu

(No relevant relationships reported)

Purpose: Emerging evidence suggests decreasing gait speed may precede declining cognitive function with age. Rising energetic costs of walking precede age-related declines in gait speed, making poor walking efficiency a potential early marker of changes in brain structure and function. The purpose of this study was to examine whether diminished walking efficiency precedes aging-related changes in brain structure.

Methods: Longitudinal data from 767 participants (mean age 64.8 ± 14.8 years, 51% women) enrolled in the Baltimore Longitudinal Study of Aging neuroimaging substudy over up to 7 years (range 1-7) were examined using linear mixed models to estimate the effects of baseline walking efficiency on brain volumes at the most recent visit. Energy expended during 2.5 minutes of usual paced overground walking was assessed using a portable, indirect calorimeter and standardized per meter walked to derive walking efficiency (ml/kg/m). Using MRI scans, brain volume measurements (cm³) were derived with semi-automated region-of-interest algorithms.

Results: In models adjusted for baseline age, sex, time since baseline, race, education, BMI, intracranial volume, and mild cognitive impairment/dementia status, a 0.01 ml/kg/m higher baseline cost of walking was associated with lower total brain volumes ($\beta = -1.2$ cm³), white matter ($\beta = -0.9$ cm³), gray matter ($\beta = -0.7$ cm³), and larger ventricular volumes ($\beta = 0.4$ cm³) at follow-up ($p < 0.03$ for all). Standardized coefficients indicated these associations tended to be strongest for white matter, particularly in the frontal and temporal lobes.

Conclusion: As walking efficiency declines with age, there is associated brain atrophy explained by an observed increase in ventricle volume and shrinkage of total brain, gray and white matter, independent of cognitive impairment and dementia. These findings suggest that rising inefficiencies related to mobility may precede brain atrophy that occurs with aging and serve as novel targets for future interventions that may improve brain health through adaptive motor learning and/or skill development.

Exercise type and intensity in older women: Preliminary results of community-based interventions on functional capacity

Gabriel de Souza Zanini, Vanessa Teixeira do Amaral, Gabriel Falcão, Emmanuel Gomes Ciolac

São Paulo State University - UNESP, School of Sciences, Physical Education Department, Exercise and Chronic Disease Research Laboratory

PURPOSE: To assess the effect of different community-based exercise interventions on functional capacity in older women.

METHODS: 80 sedentary or insufficiently active older women (69.2 ± 7.9) were randomly assigned to perform a twice-weekly community-based moderate-intensity continuous aerobic training plus resistance training (MICT+RT)(N=28), high-intensity interval training plus resistance training (HIIT+RT)(N=24) or resistance training (RT) (N=28) programs. Anthropometric (weight, height and BMI) and functional capacity (seat-and-reach, handgrip, sit-up, timed up-and-go (TUG), and 6-minute walking (6MW) tests) were assessed before and after 12 weeks of follow-up.

RESULTS: Weight, BMI and seat-and-reach did not change significantly during follow-up in any group. Handgrip strength improved ($P < 0.05$) after MICT+RT and RT, but not after HIIT+RT. Sit-up, TUG and 6MW performance improved ($P < 0.05$) similarly between groups during follow-up (Table 1).

CONCLUSION: The present preliminary results suggest that community-based exercise programs are effective to improve functional capacity in older women, independent of their type and intensity.

Table 1. Functional capacity before and after follow-up.

Longitudinal Relationship between Energy Reserves and Brain Atrophy

Amal A. Wanigatunga¹, Yujia Qiao¹, Yang An², Christos Davatzikos³, Vadim Zipunnikov¹, Adam P. Spira¹, Eleanor M. Simonsick², Susan M. Resnick², Jennifer A. Schrack¹. ¹Johns Hopkins Bloomberg School of Public Health, Baltimore, MD. ²National Institute on Aging Intramural Research Program, Baltimore, MD. ³University of Pennsylvania, Philadelphia, PA.
(No relevant relationships reported)

Purpose: Energy reserves for ambulation deteriorate progressively with age due to climbing energy costs and declining peak energy capacity. We examined whether declines in energy reserves necessary for gait contribute to brain atrophy.

Methods: We studied 597 cognitively-intact participants (mean age 69 years, 54% women) in the Baltimore Longitudinal Study of Aging neuroimaging study with repeated energetic and neuroimaging measures. Energy expenditure was measured using indirect calorimetry. Energetic reserve was defined as a cost ratio between the average VO_2 (ml/kg/min) expended during a slow-paced (0.67 m/s) treadmill walking

test and peak VO_2 (ml/kg/min) expended during a rapid-paced 400m walk, with a higher cost ratio representing lower energetic reserve. Using MRI brain scans, brain volumes were derived using an automated multi-atlas approach to define regions-of-interest. Multivariable mixed-effects models were used to estimate whether: 1) baseline and 2) longitudinal changes in cost ratio were associated with annual changes in brain volumes.

Results: In fully-adjusted baseline models, a 10% higher baseline cost ratio was associated with a 0.18 cm^3 ($\text{SE}=0.04$; $p<0.001$) annual increase in ventricular volume. Additionally, baseline cost ratio was inversely related to parahippocampal gyrus volume averaged over time (main effect= -0.05 (0.02) cm^3 , $p=0.001$). In fully-adjusted longitudinal models, an annual 10% increase in cost ratio was associated with a 0.04 (0.01) cm^3 ($p=0.002$) annual decrease in parahippocampal gyrus volume. Though not statistically significant, increased cost ratios were observed with declines in all other regions.

Conclusion: As the energetic cost of walking approaches energetic capacity, associated brain atrophy is explained by increased ventricle volume and shrinkage of the parahippocampal gyrus in cognitively-intact individuals. These findings suggest that declines in energy reserves may contribute to brain atrophy with aging.

Device Measured Physical Activity And Sedentary Behavior In Chilean Older Adults: The Latin American Cities For Healthy Aging Study

Nicolas Aguilar-Farias, Damian Chandra-Poblete, Pia Martino-Fuentealba. *Universidad de La Frontera, Temuco, Chile.*

(Sponsor: Wendy J Brown, FACSM)

Email: nicolas.aguilar@ufroterra.cl

(No relevant relationships reported)

PURPOSE: To describe device measured physical activity (PA) and sedentary behaviour (SB) in older adults from Temuco, Chile.

METHODS: Community-dwelling adults aged 60 and older were recruited from 17 different neighbourhoods in Temuco, Chile. The participants were asked to wear an ActiGraph GT3X+ accelerometer on the hip for 7 consecutive days. A sleeping and a non-wear-time algorithms were used to detect daily wearing time. Accelerometer data were considered valid if the participant wore the device for at least 8 hours on any 4 days of the week. Accelerometer vector magnitude counts (cpm) were used to classify all worn time as either SB (<200 cpm), light (LPA, 200-2689 cpm), moderate (MPA, 2690-6166 cpm), vigorous (VPA, 6167-9642 cpm), very vigorous PA (VVPA, ≥ 9643 cpm) and moderate-to-vigorous PA (MVPA, ≥ 2690 cpm) using a combination of Aguilar (2014) and Sasaki (2011) cut-points. For those participants who were unable to provide 7 complete days, total time spent in different activity intensities was calculated as: ($5 \times \text{mean weekday time} + 2 \times \text{mean weekend day time}$)/7, thus providing an average day estimate for each behavior. PA recommendation compliance was defined as accumulating either ≥ 150 min/week of MVPA or 30 min/day of MVPA on at least 5 days. Multivariate regressions were used for analysis. **RESULTS:** 316 participants were recruited, but 228 provided valid accelerometer data (69.5 ± 6.86 years, 32% male). On an average day the participants spent 303.7 ± 87.1 min/day in SB, 375.4 ± 88.5 min/day in LPA and 40.8 ± 29.3 min/day in MVPA. In relative terms, the older adults spent $42.3 \pm 11.5\%$ of their waking hours in SB and only $5.6 \pm 3.9\%$ in MVPA per day. Age was negatively associated with time spent in MPA ($\beta = -0.75$ min/day, $p = 0.003$) and MVPA ($\beta = -0.78$ min/day, $p < 0.001$). Being male was positively associated with MPA ($\beta = 14.7$ min/day, $p < 0.001$), VPA ($\beta = 1.0$ min/day, $p < 0.001$) and MVPA ($\beta = 15.7$ min/day, $p < 0.001$). 33.3% of the sample met the PA recommendations with no differences by gender. The oldest old were less likely to meet PA recommendations (OR=0.93, $p = 0.003$). **CONCLUSIONS:** This study provides relevant information for reinforcing strategies to promote PA in elderly population, considering that the oldest old and women were less likely to engage in MVPA. Moderate Intensity Walking Cadence (Steps/min) in 61-85 Year Old Adults

Catrine Tudor-Locke, FACSM, Scott Ducharme, Aston K. McCullough, Christopher C. Moore, Colleen J. Sands, Zachary R. Gould, Marcos Amalbert-Birriel, Elroy J. Aguiar, John M. Schuna, Jr., Tiago V. Barreira, Stuart R. Chipkin. *University of Massachusetts Amherst, Amherst, MA.*

(No relevant relationships reported)

Consistent evidence supports a strong relationship between walking cadence (steps/min) and intensity. However, this relationship has primarily been examined in young adults. **PURPOSE:** To identify a heuristic (evidence based, reasonable, rounded) cadence threshold associated with absolutely-defined moderate intensity defined as 3 METs (metabolic equivalents; $\text{MET} = 3.5 \text{ mL/kg/min}$) in older adults (61-85 years of age). **METHODS:** Thirty-seven participants (23 women; age= 71.6 ± 14.0 years; $\text{BMI} = 25.8 \pm 4.7 \text{ kg/m}^2$) completed a progressive treadmill walking test. The protocol

included 5 minute bouts increasing by 0.5 mph increments from 0.5 to 6.0 mph until: 1) the participant naturally selected to jog or run, 2) reached >75% of their age-predicted maximum heart rate, or 3) reported a Borg scale rating of perceived exertion (RPE) >13. Oxygen consumption (VO_2 ; mL/kg/min) was measured using indirect calorimetry and cadence was determined by dividing directly-observed steps by bout duration. METs were calculated as the average VO_2 over the last two minutes of each bout, divided by 3.5 mL/kg/min. Receiver Operator Characteristic (ROC) curves and Youden's index were used to determine moderate intensity based on cadence. Additionally, the cadence-intensity relationship was evaluated using a segmented regression model with random coefficients. **RESULTS:** All but three participants reached at least 3 METs during treadmill walking. The ROC cadence threshold for absolutely-defined moderate intensity was 100.3 steps/min. Specificity and sensitivity values were above 85% for moderate intensity. The cadence-intensity relationship was also explained by bi-linear relationship with a breakpoint at 94.4 steps/min, where cadence explained 74% of the variance. The cadence threshold for absolutely-defined moderate intensity was 101.3 (95% Prediction Intervals=68.2-112.8). **CONCLUSION:** A growing number of studies have provided evidence supporting the utility of 100 steps/min as a reasonable heuristic threshold value associated with absolutely-defined moderate intensity walking in younger adults. This study confirms that 100 steps/min is also as an appropriate proxy threshold of absolutely-defined moderate intensity in ambulatory and ostensibly healthy older adults. **FUNDING:** NIH-NIA-5R01AG049024

 (No relevant relationships reported)

Exergaming is a new and popular exercise regimen that can combine physical exercise and cognitive training, and has the potential to improve cognitive function and dual-task mobility among older adults. **PURPOSE:** To test whether an 8-week exergaming program that utilizes custom Microsoft Kinect-based motion-tracking exergames would improve cognitive function and dual-task mobility compared to a traditional physical exercise program among older adults at risk for falling. **METHODS:** A quasi-experimental intervention study was conducted with adults aged ≥ 65 years living in senior living communities and reporting mobility difficulties or a fall in the past year were enrolled to an exergaming program or a traditional physical exercise program, offered twice weekly for 8 weeks. Cognitive function and dual-task mobility were measured before and after the 8-week intervention. A Wilcoxon rank-sum test was used to compare the group difference and further adjust for exercise intensity (ratings of perceived exertion, RPE) using a rank transform method. **RESULTS:** Twenty-nine participants (age 77 ± 7 yrs) completed either the exergaming program ($n=15$) or the traditional physical exercise program ($n=14$). Statistically significant group differences in Trail Making Test Part A (TMT-A, $p<0.05$) and single-task gait speed, stride length, and stride width (all $p<0.05$) and marginal group differences in Mini-Mental State Examination (MMSE, $p=0.06$) were observed, all favoring the exergaming program. After adjusting for RPE, effects remained statistically significant for most single-task gait measurements (all $p \leq 0.05$), and marginal group differences in TMT-A ($p=0.06$) and MMSE ($p=0.07$) were observed. There were no statistically significant group differences in dual-task gait performance. **CONCLUSIONS:** Exergaming marginally improved global cognitive status and had a protective effect against declines in executive function and single-task gait measurements compared to traditional physical exercise. The findings support the need for larger studies to determine cognitive and mobility benefits related to exergaming.

PURPOSE: Few studies have evaluated whether associations with health risks differ between accelerometer and questionnaire measures of physical activity (PA) and sedentary behavior (SB), which was the objective of this study. **METHODS:** We followed 5,992 women (mean age 79 yr; 49.8% white, 33.3% black, 16.9% Hispanic) for all-cause mortality in the Objective PA and Cardiovascular Health Study. Vector magnitude counts/15 sec epoch from a hip worn ActiGraph GT3X+ triaxial accelerometer (required ≥ 4 of 7 days with ≥ 10 hr/d wear) were used to define time spent in SB (<19 counts/15 sec), light (19-518), moderate to vigorous (MVPA; ≥ 519), and total PA (≥ 19). The CHAMPS and CARDIA questionnaires were used to obtain detailed self-reports on PA and SB, respectively. Cox regression was used to estimate hazard ratios (HR) and 95% confidence intervals (CI) for a 30-min/day increment in PA or SB, controlling for age, race-ethnicity, education, smoking, number of comorbidities, self-rated health and SF36 physical function score (and awake wear time for accelerometer model). **RESULTS:** Mean time (min/d) from the accelerometer (wear time adjusted) and questionnaire were 337.9 and 600.4 for total PA, 287.3 and 337.8 for light PA, 50.7 and 222.6 for MVPA, and 555.7 and 482.7 for SB. Wear time-adjusted Spearman correlations between these measures were 0.29, 0.16, 0.34, and 0.28 for total, light, MVPA, and SB, respectively. There were 706 (11.9%) deaths documented during a mean 4.5 year follow-up. HRs (95% CIs) for accelerometer and questionnaire were 0.88 (0.87, 0.91) and 0.98 (0.97, 0.99) for total PA; 0.88 (0.85, 0.91) and 0.98 (0.97, 0.99) for light PA, 0.65 (0.59, 0.72) and 0.98 (0.97, 0.99) for MVPA, and 1.14 (1.10, 1.17) and 1.02 (1.01, 1.03) for SB. Associations did not meaningfully differ when stratified on categories of race-ethnicity (white, black, Hispanic) or age (<80 vs ≥ 80 year). **CONCLUSIONS:** Associations with all-cause mortality risk are stronger for accelerometer compared with questionnaire measures of PA and SB. The differences in strength of associations and the modest correlations between accelerometer and questionnaire measures suggest less precision with questionnaires and that accelerometer measures are capturing health-promoting aspects of movement in older women that are not captured in widely used questionnaires.

E-09 Thematic Poster - Resistance Training

Eccentric and Blood Flow Restriction Exercises in Women Induce Hypertrophy

Jennifer Bunn, Elizabeth Wells, Danielle Eustace, Stuart Gupton, Greg Dedrick. *Campbell University, Buies Creek, NC.* (Sponsor: Michael J Webster, FACSM)
 Email: bunnj@campbell.edu
 (No relevant relationships reported)

Blood flow restriction (BFR) is a new clinical method used to induce hypertrophic responses with low mechanical loads. However, women have been largely under-represented in this area of research. **PURPOSE:** To assess the mechanical and metabolic effects of eccentric (ECC) exercise and BFR therapy on the elbow flexors in recreationally trained females. **METHODS:** Seventeen healthy, recreationally trained females (ECC: 30.0 ± 7.6 yrs, 165.6 ± 5.4 cm, 67.1 ± 8.5 kg; ECC+BFR: 24.4 ± 2.2 yrs, 163.7 ± 9.3 cm, 67.6 ± 12.2 kg) were randomly assigned to either the ECC+BFR group or the ECC group. Testing was conducted at weeks 0 and 4, and included: body composition via bioelectrical

impedance analysis, cross-sectional area (biceps brachii) and thickness of the elbow flexors via ultrasound measures, arm circumference, 1-rep max (1-RM) of a bicep curl, and maximal reps of an inverted row. All participants underwent training of the elbow flexors twice per week for four weeks. The ECC+BFR group trained at 30% 1-RM, 3 x 20 repetitions and the ECC group trained at 60% 1-RM, 3 x 10 repetitions. Participants performed an eccentric bicep curl with the technician lifting the participant's arm from the bottom of the bicep curl to return to the starting position. Thirty seconds of rest was provided in between sets with occlusion maintained for the ECC+BFR group. Rate of perceived exertion (RPE) was taken following each set and blood lactate measurements were taken at the end of the second training session each week. **RESULTS:** There was no significant group difference for any of the variables ($p>0.05$). A training effect was shown with both groups increasing right arm circumference ($p=0.004$), muscle thickness ($p<0.001$), cross-sectional area ($p=0.001$), 1-RM for the right ($p=0.001$) and left arms ($p=0.014$), and inverted rows ($p=0.001$). Both groups showed significant decreases in lactate ($p=0.047$) and RPE ($p<0.001$) over time. **CONCLUSION:** Training at a lower percentage of 1-RM with BFR can induce significant changes in muscle mass composition that equate to functional gains (inverted rows completed) similar to training at a higher percentage of 1-RM without BFR. BFR is a viable option for female patients who are unable to lift 70% 1-RM due to surgical protocols or other medical restrictions and was shown to not be more physically demanding to the patient.

Muscular Morphological Adaptations Following Two High Intensity Interval Training Configurations

Masoud Moghaddam, Carlos A. Estrada, Bert H. Jacobson, FACSM. *Oklahoma State University, Stillwater, OK.* (Sponsor: Bert H. Jacobson, FACSM)
 Email: masoud.moghaddam@okstate.edu
 (No relevant relationships reported)

High intensity interval training (HIIT) refers to a group of short bouts separated by rest periods. It has been suggested that HIIT activates fast-twitch muscles; the shorter and more intense the burst is, the more it targets fast-twitch fibers. **PURPOSE:** To compare the effects of ultrashort (UH) versus short (SH) functional HIIT on muscular adaptations of rectus femoris (RF) and vastus lateralis (VL). **METHODS:** Thirty-four recreationally active participants were randomly assigned to SH (8 males and 9 females) and UH (8 males and 9 females) groups to complete 6 cycles of 6 exercises at all-out intensity (i.e. kettlebell snatches; step-up jumps; jumping jacks; goblet squat; burpees; high knees) 3 d/wk for 4 weeks. SH was performed with 20s:10s work-to-rest ratio, and a 2-minute recovery between cycles, while UH was completed with 10s:5s work-to-rest ratio, and 1-minute recovery after each cycle. Muscle thickness (MT), fat thickness (FT), cross-sectional area (CSA) and echo intensity (EI) of RF and VL were assessed via ultrasound before and after 4-week interventions. The MT and FT scans were captured in sagittal plane, while the CSA and EI were taken in transverse plane. Two-way mixed factorial ANOVAs were used for analyses. **RESULTS:** No significant differences between groups were observed following training. The results displayed no significant ($p>0.05$) change in EI of the RF and VL. However, both groups significantly ($p<0.05$) increased RF CSA (UH: 12.1 ± 4.2 to 13.0 ± 4.3 cm², SH: 11.5 ± 3.1 to 12.1 ± 3.2 cm²), as well as VL CSA (UH: 26.2 ± 6.6 to 28.4 ± 7.0 cm², SH: 24.6 ± 5.8 to 27.0 ± 5.2 cm²). Additionally, the thicknesses of RF (UH: 1.3 ± 0.3 to 1.5 ± 0.4 cm; FT = 0.6 ± 0.3 to 0.5 ± 0.3 cm, SH: 1.2 ± 0.3 to 1.4 ± 0.3 cm; FT = 0.5 ± 0.2 to 0.4 ± 0.2 cm) and VL (UH: 1.3 ± 0.4 to 1.4 ± 0.3 cm; FT = 0.5 ± 0.3 to 0.4 ± 0.2 cm, SH: 1.4 ± 0.4 to 1.5 ± 0.4 cm; FT = 0.5 ± 0.3 to 0.3 ± 0.2 cm) significantly ($p<0.05$) improved in both groups. **CONCLUSION:** To date current literature has shown functional HIIT to be an effective protocol to improve anaerobic and aerobic performances. However, in the present study, both groups similarly improved muscular morphology of the RF and VL by performing functional HIIT. Furthermore, these findings suggest that the UH protocol induces benefits comparable to those of the SH protocol, while reducing the total exercise time to 50 percent.

Resistance Training With Or Without Load Promotes Similar Changes In Electromyography Activity But Not In Blood Lactate

Rafael Ribeiro Alves, Sr., Bruno Cavalcante Gomes, Murilo Augusto Soares de Araújo, Carlos Alexandre Vieira, Vitor Alves Marques, Thayná Coelho Guimarães, Claudio André Barbosa de Lira, Douglas de Assis Teles Santos, Paulo Roberto Viana Gentil. *Federal University of Goiás, Goiânia, Brazil, Goiânia, Brazil.*
 Email: alves.rafael.ribeiro@gmail.com
 (No relevant relationships reported)

PURPOSE: to comparison the changes in peak electromyography (EMG) activity and levels of blood lactate (mmol/L) during a specific resistance exercise by three different moments, with extra load (TL), no load (TWL) and no load but with visual feedback (TLF). **METHODS:** twenty healthy men (age: 26.5 ± 4.8 height: 1.77 ± 0.1

weight: 80.6 ± 12.9) volunteered to participate in the study. Participants were scheduled in two visits on laboratory, a) 10 repetition maximum test (10-RM test) and b) performance of three aleatory and different situations of a knee extension (1 - extra load, 2 - no load and 3 - no load with visual feedback) with movement velocity of a 2-second to concentric and eccentric phase (controlled by a mobile app metronome) and 10 minutes of rest between then. Blood lactate was measure before and after each situation. EMG activity was evaluated on vastus medialis (VM), vastus lateralis (VL) and rectus femoris (RF). A significance level of $p \leq 0.05$ was adopted for all statistical tests. **RESULTS:** There were an increase in blood lactate after all the moments when compared to before exercise performance ($p<0.05$) and the blood lactate was higher in post situation TL ($p<0.05$) when comparison TWL and TLF (8.2 ± 2.9 , 4.2 ± 1.8 , 4.3 ± 1.7 , respectively). Additionally, significant difference was found between in all moments ($p<0.05$). The significant difference on EMG activity ($p<0.05$) only occurred on rectus femoris in TL set when compared to TWL (775.9 ± 325.1 , 492.7 ± 262.5 , respectively), but not significant difference ($p>0.05$) in the TLF situation (573.2 ± 219.7). **CONCLUSIONS:** Performing exercise using no load can be efficient to promote increase in EMG activity and metabolic responses being an important training strategy when extra load is not possible.

Effects Of A Rugby Training On Anthropometric And Fitness Of Female Adolescents With High Physical Performance

Camila B. Müller, Gabriel Gustavo Bergmann, Eraldo Pinheiro. *Federal University of Pelotas, Pelotas, Brazil.*
 Email: camilaborges1210@gmail.com
 (No relevant relationships reported)

PURPOSE: To verify the effects of a program of tactical, technical and physical training of rugby and the behavior of maturity in anthropometric and physical fitness variables of female adolescents with high physical performance for this sport. **METHODS:** 30 female adolescents (14.00 ± 0.53 years old) were selected from a database of a youth program for sportive development. Adolescents ($n=15$) with high physical performance for rugby (more than percentile 80 in speed, agility and power - MORE80) were divided into two groups: intervention (INT) ($n=8$), with two weekly sessions during 16 weeks of rugby training, and control (CON) ($n=7$), without participation of systematized training. Fifteen students without high physical performance for rugby (less than percentile 80 in speed, agility and power) were randomly selected from the program database (LESS80). A battery of physical tests and anthropometric measures were evaluated before and after the intervention period as well the maturity measurement was performed. For statistical analysis, two-way ANOVA with repeated measures were used to compare the anthropometric and physical variables between groups, with Bonferroni post-hoc to identify the significant differences (moment, group and interaction) and independent Student's T test to verify differences between MORE80 and LESS80. **RESULTS:** The variables that presented significant differences between the pre and post moments ($p<0.05$), in both INT and CON groups, were increase in height and wingspan and reduction in sum of skinfolds for anthropometric parameters, and improvement in countermovement jump, sprints in 10 and 20m and 5-m multiple

shuttle test for fitness variables. Squat jump, mean power and peak power generated in tests of ability to repeat sprints and test of speed of change of direction showed significant interactions, with improvement of the INT group between moments. Body mass did not present significant differences. In addition, MORE80 showed greater maturity deviation than LESS80.

CONCLUSIONS: Tactical-technical and physical rugby training can produce increment in specific variables of the modality, anthropometric variables are not influenced by the training and maturity is more advanced in female adolescents with high physical performance for rugby.

The Effects of a Short-Term Guideline Recommended Hypertrophy Training versus Blood Flow Restriction Training on Pulse Wave Velocity

Murat Karabulut, FACSM¹, Ulku Karabulut¹, Michael G. Bembem, FACSM². ¹University of Texas Rio Grande Valley, Brownsville, TX. ²University of Oklahoma, Norman, OK.
 Email: murat.karabulut@utrgv.edu

(No relevant relationships reported)

PURPOSE: To determine the effects of guideline recommended hypertrophy and blood flow restriction training protocols on pulse wave velocity in recreationally active males.

METHODS: Fourteen male subjects (age= 23.7±2.6) were randomly assigned to one of two groups that trained the knee flexors, extensors, and split squat for 6 weeks. The two training groups included: a blood flow restriction group (BFR, N=8) and hypertrophy (HYP, N=6). All training groups began with subjects warming up on the cycle ergometer at 50 rpm with 2.0 kg resistance and subjects were then lead through the resistance training programs that remained constant for each session thereafter. The HYP group followed NSCA guideline for recommended intensity, set, and rest period. The HYP group performed exercise for 4 sets of 10 repetitions 3x/wk at 75% of 1RM with 90 second rest between each set. The BFR group performed exercises for 4 sets of 30, 15, 15, 15 reps 3x/wk at 40% of 1RM with 30 second rest between each set. Each training session was monitored by a trained individual to make sure the correct breathing pattern were maintained during lifts to avoid the Valsalva maneuver. As for pre and post testing sessions, fasted subjects (for at least 8 hours) reported to the lab and hydration level was assessed by clinical urine refractometer before testing sessions. PWV was measured non-invasively using applanation tonometry, in which a probe was used on the surface of the skin over the carotid, radial, femoral, and pedal arteries to obtain segmental measures.

RESULTS: One-way ANOVA found no between-group differences in any of the outcome measures of interest at baseline. There were no significant condition main effects for carotid-radial (CR), carotid-femoral (CF), femoral-distal (FD), however a significant time main effect was detected for CF ($p < 0.05$). CF-PWV significantly decreased from baseline to post testing.

CONCLUSIONS: The findings of the study suggest that both BFR and HYP training programs are similarly effective in decreasing the central arterial stiffness. The data also indicates that avoiding the Valsalva maneuver may be necessary for positive changes in aortic stiffness and BFR training protocol can be used an alternative method for those who can't or do not want to lift high loads to improve central arterial elasticity.

2267 Board #6 May 31 9:30 AM - 11:30 AM
Effects of an 8 Week Upper Body Resistance Training Program on Aerobic Capacity in Untrained Females

Jennifer Bossi¹, Emily Pitts², Adam Keath². ¹Winthrop University, Rock Hill, SC. ²Anderson University, Anderson, SC.
 (Sponsor: Janet Wojcik, FACSM)
 Email: bossij@winthrop.edu

(No relevant relationships reported)

PURPOSE: VO₂peak and 1RM in untrained females were compared before and after an eight week upper body strength training plan to determine the effect of upper body strength training on aerobic capacity.

METHODS: Twelve untrained college females completed a VO₂peak and 1RM bench press test. The subjects were then randomly split into 2 groups of 6. Both groups maintained their normal aerobic exercise routine with the exception of the treatment group, who completed an upper body strength training protocol twice a week for eight weeks. VO₂peak and 1RM were reassessed immediately following the eight week period.

RESULTS: A one-way repeated measures ANOVA was conducted to determine whether a statistically significant difference existed in VO₂peak, RERmax, HRmax, final time, and 1RM over the course of the 8 week strength training program. A change did occur in VO₂peak for the treatment group from pre to post exercise intervention (34.22 mL/kg/min pre to 35.37 mL/kg/min post). In addition, 1RM increased in the training group from 70.83 lbs to 75.83 lbs. However, the exercise intervention did not

elicit statistically significant changes in measures of training variables over time, $F(5, 6) = .540, p = .742$, partial $\omega^2 = .310$. No change was seen in either VO₂peak or 1RM in the control group.

CONCLUSIONS: Although not statistically significant, a slight overall increase in VO₂peak in the treatment group was observed, while no change in the VO₂peak of the control group occurred. A longer resistance training period could result in more significant differences in both 1RM and aerobic capacity. Therefore, upper body resistance training alone will not impact aerobic capacity dramatically in untrained athletes, especially when done short term. Resistance training may, however, be beneficial in competitive athletes where even a slight difference in performance could be the difference between winning and losing. Future researchers should look at how upper body resistance training impacts running biomechanics specifically, and if a direct connection exists with running economy.

2268 Board #7 May 31 9:30 AM - 11:30 AM
Effects of Dynamic or Static Stretching Performed Before Resistance Training on Muscle Adaptations in Untrained Men

João B. Ferreira-Júnior¹, Ricardo P. C. Benine¹, Suene F. N. Chaves¹, Hugo M. Costa², Eduardo D. S. Freitas³, Michael G. Bembem, FACSM³, Carlos A. Vieira⁴, Martim Bottaro⁵. ¹Federal Institute of Sudeste of Minas Gerais, Rio Pomba, Brazil. ²Catholic Pontiff University of Minas Gerais, Belo Horizonte, Brazil. ³University of Oklahoma, Norman, OK. ⁴Federal University of Goiás, Goiania, Brazil. ⁵University of Brasília, Brasília, Brazil.

(No relevant relationships reported)

Stretching and resistance exercises are often recommended due to their positive effects on health and quality of life. Stretching exercises are frequently performed before a session of resistance exercise, however, muscle stretching has been shown to acutely reduce muscular strength, and impair chronic muscular adaptations to training. However, the chronic effects of static stretching exercises performed prior to bouts of resistance exercise are conflicting. Additionally, the chronic effects of dynamic stretching on muscle adaptations to resistance training remain unknown.

Therefore, research that evaluates the chronic effects of both static and dynamic muscle stretching before resistance exercise is needed. **PURPOSE:** To evaluate the chronic effects of dynamic and static stretching performed before resistance training on muscle adaptations in untrained young men. **METHODS:** Forty-five untrained young men (21.2±0.5 yrs., 72.2±5.6 kg and 178±1 cm) were randomly assigned to one of three groups: 1) static stretching (SS, n= 14) in which subjects performed 80s of static stretching prior to resistance exercise; 2) dynamic stretching (DS, n= 13) that included 80s of dynamic stretching prior resistance exercise; or 3) control group (CON, n= 18) in which subjects performed no stretching prior to exercise. All subjects performed 4 sets of 8-12RM (repetition maximum) of knee flexion exercise two days per week for 8 weeks, with a period of at least 48 h between sessions. Unilateral knee flexor maximal isometric strength (MIS) and posterior leg muscle thickness (MT) were measured before and after the training period. Data normality was confirmed by the Shapiro-Wilk test and a two-way repeated measures ANOVA (group x time) was performed. Statistical significance was set a priori at $p \leq 0.05$. **RESULTS:** There were significant increases in MIS (SS= 48.3%, DS= 37.6%, CON= 49.4%, $p < 0.05$) and MT (SS= 13.3%, DS= 13.1%, Control= 11.4%, $p < 0.05$) with no significant differences across groups ($p > 0.05$). **CONCLUSIONS:** Eighty seconds of static or dynamic muscle stretching performed prior to bouts of resistance exercise did not affect the training-induced muscular adaptations in untrained young men.

2269 Board #8 May 31 9:30 AM - 11:30 AM
The Impact of Volume-Matched, Heavy vs Moderate Weight Resistance Training on Inflammation and Muscular Damage

Lee J. Winchester¹, Patton Allen², Teresa Wiczynski², Scott Arnett², Scott Lyons, FACSM². ¹University of Alabama, Tuscaloosa, AL. ²Western Kentucky University, Bowling Green, KY. (Sponsor: Scott Lyons, FACSM)
 Email: ljwinchester@ua.edu

(No relevant relationships reported)

Background: It is well documented that resistance exercise training improves muscular strength and hypertrophy. Heavy loads greater than 65% of 1 repetition maximum (1RM) are typically required for optimal induction of muscular hypertrophy. Heavy loads tend to induce greater muscular damage and repair, resulting in enhanced muscular hypertrophy. However, there is little information comparing intensities

of hypertrophy inducing resistance loads on muscular damage and inflammatory response. The purpose of this study was to compare heavy vs moderate hypertrophy loads on markers of post exercise muscular inflammation and damage.

METHODS: 11 resistance-trained, college-aged males were recruited for this study. Participants were asked to complete 3 data collection sessions, each 1 week apart. During session 1, a baseline venous blood draw was collected, followed by evaluation of 1RM barbell squat. With sessions 2 and 3, participant performed volume-matched barbell squats at 2 different intensities using a counter-balanced design: 5 sets of 5 reps at 85% (High) or 3 sets of 11 reps at 67% (Low). Blood draws were taken 1 hour post-exercise for sessions 2 and 3. Plasma was isolated and evaluated via ELISA assay.

RESULTS: There were no significant changes ($p < .05$) in plasma C-Reactive Protein (CRP) for any of the 3 time points (358.78 ± 180.32 , 454.52 ± 520.68 , 322.01 ± 188.02 ng/mL for Baseline, High, Low, respectively). Myoglobin, a marker of muscular damage, is awaiting analysis.

CONCLUSIONS: Current results suggest that the utilized volume of hypertrophy resistance training, at either load, does not induce detectable changes in inflammation in the plasma.

Testosterone Determines Erythropoiesis And Changes In Hemoglobin Mass During Adolescence

Erica Mabel Mancera¹, Edgar Cristancho¹, Diana Ramos¹, Walter Schmidt², Lohover Duque³, Joel Rojas³. ¹Universidad Nacional de Colombia, Bogotá, Colombia. ²Bayreuth University, Bayreuth, Germany. ³Unidad Central del Valle, Tuluá, Colombia. (Sponsor: William Byrnes, FACSM)

Email: emmanceras@unal.edu.co

(No relevant relationships reported)

In prepubertal stage, total hemoglobin mass (Hbmass) is similar in boys and girls. With the beginning of puberty, Hbmass increases in boys, while it stagnates in girls. This divergence might be explained by the selective increase in androgen production in males which has, however, not yet been studied.

PURPOSE: To study the relationship between the blood testosterone concentration and hemoglobin mass in boys and girls. A second aim was to find out the impact of altitude and training status.

METHODS: In total, 313 children and adolescents with different endurance training status and different altitude of residence entered the study (age 9 to 18 yrs; females $n=94$, males $n=219$; low altitude (1000m) $n=150$, moderate altitude (2500m-3000m) $n=163$; endurance trained $n=190$, untrained $n=123$). The sexual maturation was estimated by the scale of Tanner (stage I-V). Hbmass and blood volume (BV) were determined by the optimized CO-rebreathing method. Testosterone (Test) and erythropoietin (EPO) were measured in cubital venous blood. For statistical purposes multiple linear regression analyses and regression trees (CART) were used.

RESULTS: While [Test] was low in all females (0.2 ± 0.6 ng/ml) it markedly increased from Tanner stage III (stage I/II: 0.4 ± 0.8 ng/ml, stage III: 2.7 ± 2.0 ng/ml, stage IV/V: 4.2 ± 2.1 ng/ml). In the whole group (males and females) a strong correlation was found between [Test] and absolute Hbmass ($r = 0.8$, $p < 0.001$) as well as relative Hbmass (Hbmass/kg, $r = 0.6$, $p < 0.001$). In the male group, the increase in [Test] by 1 ng/mL was associated with an increase of 34.2 ± 4.3 g of Hbmass ($p < 0.001$), the training status with 45.8 g and altitude with 32.1 g. Highest Hbmass values (15.3 ± 0.7 g/kg) were observed in the trained group with altitude with [Test] > 4.9 ng/ml. The general impact of [Test] on Hbmass was 45%, of biological maturation 34.4%, of training 16.0%, and of altitude 5.0%. A strong correlation of [Test] with BV was found ($r = 0.7$, $p < 0.001$). There was no correlation between [Test] and EPO ($r = 0.04$, $p = 0.5$).

CONCLUSION: In boys there is a strong increase in [Test] from Tanner stage III, which considerably stimulates erythropoietic processes. We suggest testosterone being the determining factor for the different development of Hbmass in girls and boys during puberty and explaining the gender differences in adults.

(No relevant relationships reported)

The benefits of physical activity (PA) on aerobic fitness are well known. What is not so well understood is the nature of this relationship, i.e., is the association between PA and fitness linear or curvilinear and does the dose-response rates vary in different populations? **PURPOSE:** To explore the dose-response rate and association between VO₂max and self-reported physical activity, and to assess whether this association varies by sex, age and weight status. **METHODS:** VO₂max was assessed in 8,002 (10.0-15.9-year olds) children (3,775 girls) using the 20-metre shuttle-run test. Physical Activity was assessed using the Physical Activity Questionnaire for Adolescents (aged >11 years, PAQ-A) or for Children (aged <11 , PAQ-C). The associations between VO₂max and PAQ were analyzed using ANCOVA adopting PAQ and PAQ² as covariates, allowing the intercepts but more importantly the slope parameters of PAQ and PAQ² to vary with the categorical variables sex, age group and weight status. **RESULTS:** ANCOVA identified a significant quadratic polynomial association between VO₂max and PAQ (entered as both a linear PAQ and PAQ² terms), where the positive linear PAQ term varied by weight status and sex but the quadratic PAQ² term was negative (-0.39 ; 95% CI -0.57 to -0.21), common to all groups. The curvilinear (inverted U) association suggests that the benefits of increasing PA (same dose) on VO₂max is greater when children report low levels of PA compared to children who report higher levels of PA. These dose-response rates were also steeper for boys, and steeper in lean compared with overweight/obese children. **CONCLUSIONS:** In this paper we demonstrate, for the first time in children, that the dose response between physical activity and VO₂max is curvilinear in nature, i.e., the benefit of increasing physical activity on aerobic fitness is greater in children who report low levels of habitual physical activity. This has important public-health implications, in that getting sedentary children active is likely to have a disproportionately greater benefit to their health and fitness.

(No relevant relationships reported)

Previous research has suggested that age-related decline in mitochondrial enzymes consequently results in reduction of skeletal muscle oxidative function. Limited research exists investigating effects of healthy aging on these observed changes, especially with middle-aged individuals. **Purpose:** The purpose of this study was to investigate the effects of healthy aging on changes in tissue oxygenation in skeletal muscle (SmO₂) during a self-paced VO₂max (SPV) test in younger and middle-aged subjects. **Methods:** This study included seven younger (ages 18-35 years, 4 males, BMI 28.1 ± 3.4 kg/m²) and nine middle-aged (ages 40-55 years, one male, BMI 25.1 ± 3.8 kg/m²) healthy, recreationally active individuals. Subjects visited the lab once to complete the SPV test on a Wattbike cycle ergometer. The Moxy sensor, which uses near-infrared spectroscopy, was used to estimate SmO₂. Four Moxy sensors were used and were placed on the right and left quadriceps (vastus lateralis), and right and left gastrocnemius muscles. The SPV test was exactly ten minutes in length, with five 2-minute stages. Each stage was perceptually regulated using the 6-20 rating of perceived exertion (RPE) scale: 11, 13, 15, 17, and 20 (in that order). Repeated-measures ANOVAs were used to compare SmO₂ between anatomical sites and stages of the SPV. Age group was used as a between-subjects factor. **Results:** Measured VO₂max was 48.33 ± 7.56 ml/kg/min for the younger and 38.10 ± 7.45 ml/kg/min for the middle-aged subjects. For SmO₂ there was no main effect of anatomical site ($p=0.170$) and no differences between age groups ($p=0.906$). A main effect was present for SPV stages ($p < 0.001$); values remained steady until the last two stages, where they decreased in both groups (younger: 71.0 ± 3.1 , 69.5 ± 3.5 , 67.9 ± 3.7 , 63.6 ± 4.5 , 58.3 ± 5.9 percent; middle-aged 69.4 ± 2.8 , 70.4 ± 3.1 , 70.4 ± 3.3 , 65.4 ± 4.0 , 56.1 ± 5.3 percent). **Conclusion:** Since no age-related differences were found in SmO₂ during the exercise test, healthy aging (i.e. regular aerobic exercise) can be seen as an effective intervention for maintenance skeletal muscle blood flow and a profound influence for sustaining quantity and quality of mitochondria function. Future research should determine whether the same findings occur with healthy, active elderly subjects.

High Intensity Exercise Training for High Functioning Children with Autism Spectrum Disorder Improves Physical Performance

Karl F. Kozlowski, Clancy Seymour, James P. Donnelly, Marcus L. Thomeer, Christopher Lopata. *Canisius College, Buffalo, NY.*
 (Sponsor: Frank J. Cerny, FACSM)
 Email: kozlow13@canisius.edu

(No relevant relationships reported)

PURPOSE: This study assessed the effectiveness of a five-week high intensity exercise program offered over two years for high-functioning children with autism spectrum disorder (HFASD). **METHODS:** Children with HFASD ($n=56$, M age: 10.22 ± 1.5 yr) engaged in a 1 hr exercise session, 4 d/wk for 5 weeks. Each session included an instruction period, warm-up, high intensity workout, related game, and cool-down to be completed in either an individual (I) or cooperative (CO) format. Child satisfaction surveys (7-pt. Likert) assessed perceived enjoyment, level of support, physical benefits, etc. Staff satisfaction surveys assessed their enjoyment of running the session(s), and clarity and utility of the training. Fidelity of implementation (accuracy) was assessed in 64.9% of all sessions. Biometric (i.e., height, weight, waist circumference, BMI) and physical performance data (i.e., strength, flexibility, aerobic fitness, power, physical activity intensity) were also collected. Paired t -tests were used to assess pre to post program performance differences. **RESULTS:** Results indicated that the program was implemented accurately (94%). Satisfaction ratings indicated that the overall feeling about the program was very positive from both the participants (M : 6.4) and staff ($n=14$, M : 6.93). There was no difference in post-satisfaction ratings between the I and CO formats (I $M = 5.81$, CO $M = 5.45$, $p = .30$). Pre-posttest comparisons yielded statistically significant improvements in sit-ups in 60 sec ($M \Delta = 3.5$ reps, 95%CI = 1.41, 5.59), squats in 60 sec ($M \Delta = 4.4$ reps, 95%CI = 1.67, 7.15), and standing long jump ($M \Delta = 4.0$ in., 95%CI = -.79, 7.21). Additionally, the rounds completed on repeated parallel workouts improved significantly ($M \Delta = 2.3$, 95%CI = 1.49, 3.07). Significant improvements in percentage of time in moderate-vigorous activity were observed in both the I and CO exercise formats (I $M \Delta = 4.1\%$, 95%CI = 3.19, 5.06; CO $M \Delta = 1.9\%$, 95%CI = -.59, 3.24). The I format produced significantly greater improvement in activity level (% time) than the CO format across the 5-weeks ($M \Delta = 2.22\%$, 95%CI = .63, 3.81). There were no significant changes in biometric measures. **CONCLUSION:** A high intensity exercise program for children with HFASD is feasible (high fidelity, satisfaction) and improves physical performance.

2276 May 31 10:30 AM - 10:45 AM

Talent Identification in Elite Youth Sports

Kewei Zhao¹, Andreas Hohmann², Binghong Gao¹. ¹*Shanghai University of Sport, Shanghai, China.* ²*University of Bayreuth, Bayreuth, Germany.*

Email: zhao_kw@hotmail.com

(No relevant relationships reported)

Several talent selection programs in elite sport schools are based on motor diagnostics for the purpose of recommending or transferring promising talents to general groups of sports; game sports, combat sports or endurance sports, and to more concrete sports such as gymnastics, skiing, or tennis. However, in most sports, the predictive value of such testing is unclear.

PURPOSE: The aim of the talent prediction was to assign each individual of the Under-15 athletes to his own sport. **METHODS:** The sample consisted of $N = 97$ youth athletes from Shanghai Elite Sport school belonging to six different sports including basketball ($n = 7$), fencing ($n = 23$), judo ($n = 20$), swimming ($n = 10$), table tennis ($n = 15$), and volleyball ($n = 22$). The performance diagnosis took place between September 2016 and March 2017, and comprised eighteen anthropometric parameters, two motor tests on back strength and complex reaction speed, five physiological measurements of the heart rate at rest, vital capacity, systolic and diastolic blood pressure, and hemoglobin concentration in the blood. The prognostic validity of the morphological, motor, and physiological tests was determined using linear discriminant analysis and nonlinear neural networks (multilayer perceptron). **RESULTS:** The between-sports differences in a battery of generic anthropometric, motor, and physiological tests allow one to distinguish the young athletes' talents according to their individual sport provenience. The linear and nonlinear statistical methods that were used in parallel to identify the most relevant talent characteristics of each of the six sports by means of the leave-one-out procedure reversely confirmed the quality of the results. **CONCLUSION:** All diagnostic methods exhibited medium to high validity to discriminate between the six different sports. The relevance of the eighteen body dimensions, five physiological measures, and two motor tests for talent identification was confirmed.

2277 May 31 10:45 AM - 11:00 AM

Physical Literacy Levels Of Canadian Children In Grades 7-9 (12-16 Years): Descriptive Results

Joël Blanchard¹, Nadine Van Wyk², Anastasia Alpous³, Emily Ertel³, Patricia E. Longmuir¹. ¹*Children's Hospital of Eastern Ontario Research Institute, University of Ottawa, Ottawa, ON, Canada.* ²*Mount Royal University, Calgary, AB, Canada.* ³*Children's Hospital of Eastern Ontario Research Institute, Ottawa, ON, Canada.*

(No relevant relationships reported)

PURPOSE: The Canadian Assessment of Physical Literacy (CAPL) is the first validated protocol to accurately and reliably assess the physical literacy level of children between 8 and 12 years of age. However, a ceiling effect was found when using the CAPL in older children, within the knowledge/understanding domain and in the Canadian Agility and Movement Skill Assessment, one component of the physical competence domain. The purpose of this study was to evaluate the validity of a modified version of the CAPL for older children.

METHODS: The modified CAPL (CAPL 789) was used to assess physical literacy among Canadian youth in grades 7-9 (aged 12-16 years). Data were collected from schools and recreation facilities in the provinces of Alberta and Ontario (Canada), yielding a sample of 245 participants (129 girls, mean age 13.7 ± 0.9 years). Descriptive statistics were calculated for all CAPL assessments. Age and gender effects were examined to establish the validity of the CAPL 789 within this age group.

RESULTS: Physical competence increased significantly with age ($p < 0.05$), the means in grades 7 to 9 being 19 ± 3 , 21 ± 4 and 21 ± 3 respectively. Gender did not influence most scores. For example, the Canadian Agility and Movement Skill Assessment total score (/36) showed no significant difference ($p > 0.05$) between boys (25 ± 5) and girls (25 ± 4). Girls scored significantly higher ($p < 0.05$) than boys (6.6 ± 1.2 vs. 6.3 ± 1.3) in the knowledge assessment (/10). There was also a significant increase ($p < 0.05$) in knowledge scores among girls as they got older.

CONCLUSIONS: This study described the physical literacy of youth in grades 7 to 9 (12-16 years old). Gender did not influence physical competence, a result different from the data for younger children. Knowledge increased with age among girls but not boys. Future research might be necessary to identify if these unexpected results can be explained by different rates of maturation at this age, unique characteristics of this sample or that the CAPL 789 requires additional protocol modifications.

2278 May 31 11:00 AM - 11:15 AM

Associations of Awareness of National Physical Activity Recommendations and Self-Reported Physical Activity Behaviors among Students

Taylor A. Wahl¹, Benjamin T. Pope¹, Jennifer R. Ricketts¹, Naofumi Yamamoto², Nobuko Hongu, FACSM¹. ¹*The University of Arizona, Tucson, AZ.* ²*Ehime University, Matsuyama, Japan.*

(Sponsor: Nobuko Hongu, FACSM)

Email: twahl@email.arizona.edu

(No relevant relationships reported)

PURPOSE: College students majoring in nutritional sciences are taught the national recommendation of weekly moderate-vigorous physical activity within their curriculum. The objective of this study was to examine 1) the awareness of the national physical activity recommendation for moderate-vigorous exercise (150 min/week), 2) where nutrition students obtain their recommendations, and 3) if their awareness and knowledge affected their physical activity behaviors. **METHODS:**

Using a 10-question survey, 331 introductory level nutrition students and 89 upper division nutrition students were asked an array of questions. The questions involved demographic questions, the number of days of their regular physical activity, if they knew the weekly physical activity recommendation, and where they have acquired most of their physical activity knowledge from. **RESULTS:** Of the total student responses, 70.9% (n=295) responded that they did not know the national physical activity recommendation, leaving 29.1% (n=121) saying that they did. Of the 121 students who responded saying that they did know the recommendation, 18% of these students (n=22) knew the recommended minutes (150 minutes), with an additional 36 students overestimating the recommendation. The results showed that male students exercised significantly more often than female students ($p < 0.001$). Additionally, looking at ethnicity as a factor, African Americans exercised significantly less than Whites ($p = 0.02$). There was a significant positive association between the amount of people who exercised and whether they knew the recommendation ($p = 0.0031$). Students were obtaining their knowledge of physical activity from a vast variety of sources. A positive association was also observed between the amount of people who exercised and whether they had the recommendation correct or not ($p = 0.0041$). **CONCLUSION:** Nutrition students who are not exercising do not know the physical activity recommendation, despite being taught the recommendation in their curriculum. Further studies need to find more effective ways to communicate the physical activity recommendation to college students.

E-11 Clinical Case Slide - Knee III

ACL Injury Prevention Program-Recreational Softball
Doug W. Dendy, C Roger James, FACSM, Toby J. Brooks. *Texas Tech University Health Sciences Center, Lubbock, TX.* (Sponsor: C. Roger James, FACSM)
Email: doug.dendy@ttuhsc.edu
(No relevant relationships reported)

HISTORY: A 13-year-old female athlete went through a 7 week ACL injury prevention program (IPP) during a recreational softball season consisting of movement preparation skills and drills intended to assist the athlete in learning to dynamically stabilize the knee.

PHYSICAL EXAMINATION: Athlete's anthropometric measurements were as follows body mass 68.6 kg, body height 1.83 m, leg length 0.94 m bilaterally, and knee width 0.96 m bilaterally. Field agility examination demonstrated the patient did not have any impairment or diagnosis that would preclude her from participating in the IPP.

DIFFERENTIAL DIAGNOSIS-FINAL/WORKING DIAGNOSIS: The athlete exhibited typical neuromuscular control patterns for her age during sports participation. She did not exhibit any obvious high-risk behaviors such as excessive knee valgus or asymmetry.

TESTS AND RESULTS: The athlete performed three double-leg drop vertical jumps (DVJ) from each of two landing heights (30, 50 cm). Performance was recorded using a motion capture system. Biomechanical measures were obtained at the beginning and end of the season. At post-test, the athlete demonstrated 13.7° greater maximum hip flexion and 7.3° less maximum ankle dorsiflexion bilaterally from both heights. She also demonstrated 2.3° greater ankle inversion bilaterally from both heights, as well as 20.1° greater maximum right knee valgus from 50 cm.

TREATMENT AND OUTCOMES: The IPPs consisted of 15 minutes of stretching and agility focusing on improved neuromuscular control and cues for ACL injury prevention that were emphasized during practices and games. In addition, 2-3 fielding drills were incorporated into practices to work on controlling knee mechanics.

A 7-week IPP during a softball season affected positive changes in hip and ankle mechanics during landing from both heights, but not in the right knee from the higher height.

Negative changes at the right knee were likely a consequence of an immature motor pattern resulting from learning a new skill. In addition, right knee valgus could reflect a weakness in the right hip or that more neuromuscular training is needed. The athlete was recommended for more IPP training with a continued focus on improving knee mechanics. More investigation is needed to address neuromuscular control over a longer period using the IPP in this and other athletes.

2283 May 31 9:50 AM - 10:10 AM
Knee Injury - Dancer

Kevin Huang, Samuel Chu. *Northwestern/Shirley Ryan AbilityLab, Chicago, IL.* (Sponsor: Joseph Ihm, FACSM)
(No relevant relationships reported)

HISTORY: A 20 year old female dance instructor was performing split jump lunges when she developed acute onset of pain and swelling in the medial left knee while loading the leg in the posterior position. She reported feeling a tearing sensation and was unable to immediately weight bear. On presentation to the emergency room was partially weightbearing. Initial left knee radiographs were negative for acute fracture. She was given a soft knee sleeve, started ibuprofen 600mg TID, and initially used ice. She presented to outpatient sports medicine clinic 1 week later with persistent 7/10 pain and swelling in the medial knee. She denied locking or buckling of the knees.

PHYSICAL EXAMINATION: Exam revealed mild-to-moderate effusion of the left knee and restricted range of motion due to pain (flexion to 100 degrees, extension to 10 degrees). There was tenderness to palpation over the medial joint line and pain with valgus stress testing. Anterior drawer with bilateral mild laxity but symmetric. McMurray's was limited by guarding and restricted range of motion. Gait was antalgic with limited knee flexion on the left. Hip abduction strength 4-/5 bilaterally.

DIFFERENTIAL DIAGNOSIS:

1. Medial meniscus tear
2. Medial collateral ligament injury
3. Anterior cruciate ligament injury
4. Patellar dislocation/subluxation
5. Osteochondral injury

TESTS AND RESULTS:

Left Knee X-ray:

- No acute osseous findings
- Suggestive of lateral patellar tilt and subluxation

Left Knee MRI:

- Sequela of prior transient lateral patellar dislocation and medial patellar retinaculum rupture
- Osseous contusions of the medial patella and lateral femoral condyle
- Shallow trochlear groove with minimal lateral patellar subluxation

FINAL/WORKING DIAGNOSIS:

Acute lateral patellar dislocation and medial patellar retinaculum rupture in setting of trochlear dysplasia

TREATMENT AND OUTCOMES:

1. Left knee immobilizer started 1-week post-injury.
2. Isometric quadriceps strengthening exercises started 1-week post-injury.
3. Improved range of motion, swelling, and gait at 1 month follow up.
4. Started in physical therapy for knee range of motion, strengthening and stabilization exercises, hip abduction strengthening, and progression to return to dance/exercise.
5. Discussed orthopedic referral if no further improvement or recurrent dislocation.

2284 May 31 10:10 AM - 10:30 AM
Knee Injury-football

Ankur Verma¹, Jeremy Burnham², Vincent Shaw¹, Jerrica Watson². ¹*Baton Rouge General, Baton Rouge, LA.* ²*Bone & Joint Clinic of Baton Rouge, Baton Rouge, LA.* (Sponsor: Mary Lloyd Ireland, FACSM)
Email: ankur2222@gmail.com
(No relevant relationships reported)

HISTORY: A 16-year-old male high-school football player presents to the sports medicine clinic with left leg weakness and numbness. He was injured during a game three weeks previously when another player collided with the lateral aspect of his knee. At an after-hours clinic post-game, he was placed in a hinged knee brace and sent to the ED for CT angiogram to evaluate for arterial injury and US to evaluate for DVT. Both were negative. However, he has since developed swelling, stiffness, and left foot drop, which prompted his appearance at our clinic. He also complains of decreased sensation in his foot. The symptoms are worsened with sitting and weight-bearing.

PHYSICAL EXAMINATION: Left knee: Large effusion present. ROM is from 5- to 85-degrees. MJL, LJL, and fibular head tenderness. Gapping with varus stress. Stable

to valgus stress. Increased ER with the dial test. Positive Lachman's. 0/5 EHL and tibialis anterior strength, otherwise 5/5. Absent sensation to light touch along the deep and superficial peroneal nerve distributions.

DIFFERENTIAL DIAGNOSIS: ACL tear, LCL tear, Meniscus tear, Peroneal nerve injury, PCL tear **TEST AND RESULTS:** XR: Intra-articular calcifications near ACL tibial attachment. No other fractures identified.

MRI: Full-thickness tear of the ACL without definitive evidence of fracture, Full-thickness tear of the biceps femur tendon at the fibular insertion with 3.2 cm of proximal retraction, disruption of the fibular collateral ligament, interstitial tearing of the distal popliteus tendon.

FINAL WORKING DIAGNOSIS: Left ACL tear, Left LCL tear, Left partial popliteus tear, left knee hamstring avulsion of the biceps femur, left complete foot drop with peroneal nerve injury.

TREATMENT AND OUTCOMES: 1. Placed in a brace and referred to orthopedic surgery 2. Surgery done for ACL/PLC/LCL reconstruction, distal hamstring repair, popliteus tendon reconstruction, and decompression of the peroneal nerve as scar tissue was noted around the nerve 3. NWB in a boot for 6 weeks with limited ROM from 0-90 degrees 4. Referred for PT 5. Referred for EMG 6 weeks post-surgery He eventually developed 1+ strength of the EHL. Sensation in the deep and superficial peroneal distribution significantly improved. He was placed in a custom AFO. He understands it is unlikely he will be able to play football at the same level again.

2285 May 31 10:30 AM - 10:50 AM

Atraumatic Recurrent Knee Effusion in a Collegiate Athlete - Soccer

Darwin R. McKnight, Vicki R. Nelson, Wayne F. Sease.
Greenville Health System, Greenville, SC. (Sponsor: Wayne Sease, FACSM)
Email: dmcknight@ghs.org

(No relevant relationships reported)

HISTORY: An 18-year-old male sophomore collegiate soccer player presented to training room with a 2 month history of recurrent atraumatic left knee effusion and lateral knee pain. He reported multiple episodes of swelling that lasted several days before resolving. An X-ray obtained after initial evaluation was unremarkable and patient was advised to use ice, compressive dressing and take oral anti-inflammatories which improved symptoms temporarily and allowed him to participate with team. Two weeks later, he reported intense sharp anterior pain while walking down the steps with subsequent inability to bear weight. During follow up evaluation he was given crutches, allowed to partial weight bear and MRI was ordered.

PHYSICAL EXAMINATION: No angular deformity of either lower extremity. Left knee has moderate effusion. Full extension with flexion to 90°. Tenderness present over patella facets and lateral joint line. He has no medial joint line tenderness. No increased anterior/posterior translation or varus/valgus instability. He reports lateral sided pain with McMurray and Thessaly. Full range of motion and strength at the left hip and ankle.

DIFFERENTIAL DIAGNOSIS:

1. Synovitis (reactive vs pigmented villonodular)
2. Chondromalacia
3. Patella chondral flap tear
4. Occult Fracture/Loose Body
5. Meniscus Tear
6. Osteochondritis Dissecans
7. Arthritis (RA vs SLE)

TEST AND RESULTS:

2 cm x 2.3 cm x 5 mm osteochondral defect in lateral femoral condyle with large effusion, synovial thickening, vertical signaling within posterior medial meniscus, lateral meniscus extrusion, medial compartment chondromalacia and popliteus strain

FINAL WORKING DIAGNOSIS: Osteochondritis Dissecans Lesion

TREATMENT AND OUTCOMES: The patient was seen by Orthopedic Surgery and underwent arthroscopic surgery. Two screws were placed intra-operatively for internal fixation. There was no evidence of meniscal injury intra-operatively. Patient will sit out the remainder of soccer season.

2286 May 31 10:50 AM - 11:10 AM

Atraumatic Calf Swelling in Recreational Cyclist

Brian Hill, Stephen Spadafore, Kyle Knierim, Morteza Khodaei, FACSM. *University of Colorado, Denver, CO.*

(No relevant relationships reported)

HISTORY: 51 year-old male presented with intermittent left calf pain and swelling for the past 2 months. The pain and swelling became constant the week preceding his presentation. He had no known injury but first noticed the pain after a spin class 2 months ago. The pain was worse with cycling, jogging, and swimming and at the end of the day. He had no knee pain, ankle pain, or hip pain. He denied lower extremity weakness or numbness. The pain did not radiate.

PHYSICAL EXAMINATION: There was a soft tissue enlargement in posterior medial aspect of left calf that was mildly tender to palpation, soft, and non-mobile. Transillumination of the area was positive. No overlying erythema or skin changes were noted. Calf musculature and strength were normal. There was no tenderness along the rest of the gastrocnemius or Achilles tendon and no pretibial edema was present. Neurovascular examination was unremarkable.

DIFFERENTIAL DIAGNOSIS:

1. Deep Vein Thrombosis
2. Synovial Cyst
3. Abscess
4. Morel-Lavallée lesion
5. Lipoma
6. Hematoma

TESTS AND RESULTS:

- Knee x-rays: Grossly normal; generally preserved joint space, with osteophyte formation and mild patellofemoral arthritis
- Bedside ultrasound of calf: Large, hypoechoic, cystic appearance; connected with a small stalk to the posterior knee joint capsule (popliteal); no vascularity seen on Color Flow Doppler

- Fluid analysis: Yellow, hazy; no crystals seen; minimal nucleated cells

FINAL/WORKING DIAGNOSIS: Synovial cyst connected to the popliteal aspect of the knee joint

TREATMENT AND OUTCOMES:

1. Bedside ultrasound evaluation
2. Aspiration of popliteal cyst, 85cc of straw-colored fluid, sent for analysis
3. ACE wrap recommended in attempt to prevent re-accumulation of fluid
4. Orthopedic evaluation due to re-accumulation of fluid, recommended continued monitoring given asymptomatic nature
5. Could consider surgical excision if becomes symptomatic

Electrocardiogram Abnormal Finding During a Pre-participation Screening in an Asymptomatic Professional Soccer Player

Iliana E. Quintero-Raygoza, José A. Garza, Tomás J. Martínez-Cervantes, Karina Salas-Longoria, Oscar Salas-Fraire. *Hospital Universitario, Monterrey, Mexico.*

Email: ilibet_e@hotmail.com

(No relevant relationships reported)

HISTORY: A 17-year-old asymptomatic male soccer player undergoes a pre-participation physical evaluation which consists of a resting electrocardiogram (ECG), ECG monitored exercise stress test, and an aerobic capacity fitness measurement. He has a family history of hypertension in his father. He denied any family history of other diseases. He denies any episodes of syncope, heart palpitations, dyspnea, cyanosis, or chest pain during exercise or at rest. He does not take any medications.

PHYSICAL EXAMINATION: Normal neurological assessment, no neck adenopathy, no carotid bruit or jugular vein distention. Respiratory assessment was normal, with symmetric chest expansion. The cardiac auscultation had a normal S1 and S2, with regular rate and rhythm, no splitting of the heart sounds heard, and no murmur. There was a normal palpation of peripheral pulses in extremities, with regular rate and rhythm. Blood pressure at rest was 110/80 mmHg in right arm and 105/60 mmHg in

right leg. Heart rate was 62 beats per minute and respiratory rate of 14. Body weight was 58.3 kg with a height of 1.75 meters, body mass index (BMI) of 19 kg/m². Resting electrocardiogram: sinus rhythm, 71 beats per minute, right axis deviation, right bundle branch block, right ventricular hypertrophy and early repolarization pattern.

DIFFERENTIAL DIAGNOSIS: 1. Borderline electrocardiogram findings in athlete 2. Congenital heart defects (atrial septal defects or primary cardiomyopathies)

TEST AND RESULTS: Treadmill Exercise Stress Test: Attained 98% of age-predicted maximum heart rate, Normal exercise ECG. Transthoracic Echocardiogram: Normal left ventricular function with an ejection fraction of 58%. Bicuspid aortic valve, left sided aortic arch, image suggestive of turbulent blood flow in descending aorta with a pressure gradient of 12 mmHg. CT Coronary Angiogram: Post-ductal coarctation of the aorta

FINAL WORKING DIAGNOSIS:

Bicuspid aortic valve and Post-ductal coarctation of the aorta

TREATMENT AND OUTCOMES:

Conservative treatment without interruption of physical activity, with a yearly medical evaluation. Pre-participation screening in athletes may detect diseases and lower morbidity and mortality rates in sports related activities.

2291 May 31 9:50 AM - 10:10 AM

Menstrual Dysfunction - Cross Country/Track

Bryan Holtzman¹, Kathryn E. Ackerman, FACSM². ¹*Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA.* ²*Boston Children's Hospital, Boston, MA.* (Sponsor: Kathryn E. Ackerman, FACSM)

Email: bryan.holtzman@gmail.com

(No relevant relationships reported)

History

A 16.5 year old biologically female, privately self-identifying male high school junior distance runner presented for evaluation of menstrual dysfunction, history of eating disorder, and guidance about being a transgender high school and future NCAA athlete. The patient would like to hold off on hormonally and potentially socially transitioning to male until after college to compete as a female. The patient was hospitalized for an eating disorder 2.5 years previously. The patient uses sertraline 75 mg/day for anxiety, OCD, and depression. The patient achieved menarche at age 15 and reports menstruating 3-4 times per year since (with amenorrhea during weight nadir 2 years ago).

Physical exam

Patient dresses with a male gender expression. Ht 159.8 cm, Wt 48.75 kg, BMI 19.1 kg/m², BP and pulse non-orthostatic. Skin: no hirsutism, acne, skin discoloration, rashes, or Russell's signs. Tanner stage: 4/5 breasts, 3+ axillary hair, 5/5 pubic hair. Normal external genital exam. Musculoskeletal exam is wnl.

Differential diagnosis

1. Female athlete triad/relative energy deficiency in sport
2. Anorexia nervosa
3. Polycystic ovary syndrome/hyperandrogenism

Nutritional evaluation by registered sports dietitian

Grazing throughout day, leading to inadequate energy intake and insufficient protein and fat intake while running 60 miles per week

Tests and results:

Normal TSH (1.07 uIU/mL), 25-OH vitamin D (38.8 ng/mL), WBC (5.7 K/uL), ferritin (43 ng/mL)

DXA Z-scores:

Total body less head: -0.2

Lumbar spine: -0.1

Percent body fat: -2.0

Final working diagnosis

Oligo-amenorrhea from dietary insufficiency/over-exercising in the setting of a transgender biological female not wanting to menstruate or develop secondary sex characteristics

Treatment and outcomes

1. Discussion with athlete and family about transgender sports participation options at high school, collegiate, and national level
2. Dietary optimization through meetings with registered sports dietitian
3. Continued psychological counseling regarding gender dysphoria/gender incongruence
4. 4.75 kg weight gain in less than a year (BMI increase from 19.1 to 20.5 kg/m²)
5. Resumption of monthly menses
6. Maintenance of normal lab values; extensive work-up unnecessary
7. Plans to run in college as a female but to transition socially to male gender

2292 May 31 10:10 AM - 10:30 AM

Bone Health - Running. Can You Outrun Your Past?

Karin VanBaak, MD¹, Kimberly Detwiler, MS ATC². ¹*University of Colorado School of Medicine, Aurora, CO.* ²*University of Colorado, Boulder, CO.* (Sponsor: Morteza Khodae, FACSM)
Email: karin.vanbaak@ucdenver.edu

(No relevant relationships reported)

HISTORY: A 20 year-old female distance runner with a history of recurrent bone stress injuries was referred for evaluation of back pain. Diagnostic workup revealed a left sacral stress fracture. Her workup was expanded to address her significant injury history. She had recently returned to her typical training volume of 70 miles/week following a left fibula stress fracture. She had a history of 2 prior stress fractures - left tibia & left sacrum. She reached menarche at age 17 & reported fewer than 6 periods per year. A short trial of oral contraceptives was discontinued 6 months prior to presentation. She had not had a menstrual cycle since that time. She had a history of Celiac Disease, diagnosed during a workup of iron deficiency as a teenager. She reported compliance with a gluten free diet since age 16. She had no history of disordered eating, chronic illness, or chronic medication use.

PHYSICAL EXAMINATION: The patient was a well appearing, fit female. Her BMI was 21 kg/m². She exhibited no acne or signs of hirsutism including abnormal weight distribution or hair growth. Single leg hop test was positive. **DIFFERENTIAL**

DIAGNOSIS: 1. Uncontrolled Celiac Disease 2. Overtraining Syndrome 3. Vitamin D

Deficiency 4. Hyperthyroidism Hyperparathyroidism **TEST AND RESULTS:** DXA: - Total Body Z-score: -0.3 - L1-4 Z-score: -1.8 - L/R femoral neck Z-score: -0.3/-0.5 - Total body fat: 18.3% Lab workup: - TTG IgG 19 U/mL, TTG IgA 2 U/mL, ferritin 53 ng/mL - Estradiol 24 pg/mL, FSH 5.8 mIU/mL, LH 3.1 mIU/mL, Prolactin 4.3 ng/mL, total Testosterone 21 ng/dL, DHEA 400 ng/mL, TSH 1.5 uIU/mL, Free T3 2.5 pg/mL - Vitamin D 56 ng/mL - 24 hour urine Ca:Cr ratio 167, BS Alk Phos 22.2 mcg/mL, PTH 21 pg/mL, Ca 10.1 mg/dL **FINAL WORKING DIAGNOSIS:** Recurrent bone stress injuries due to: - Low bone density secondary to uncontrolled Celiac Disease during time of adolescent bone mass accrual. - Functional hypothalamic amenorrhea due to current low energy availability.

TREATMENT AND OUTCOMES:

1. Treatment for sacral stress fracture, running progression started at 9 weeks with MRI evidence of fracture healing.
2. Biomechanical assessment & rehabilitation.
3. Medically modified training plan.
4. Monitoring by Sports Nutrition.
5. Discussion with patient of treatment with transdermal estrogen. This was deferred given return of menses during stress fracture treatment.

2293 May 31 10:30 AM - 10:50 AM

Lung Function - Ultraendurance Marathon

Courtney M. Wheatley¹, Caitlin C. Fermoye², Glenn M. Stewart², Bryan J. Taylor³, Loic Chabridon⁴, Alice Gavet⁴, Briana L. Ziegler², Jesse C. Schwartz¹, Paul Robach⁴, Bruce D. Johnson². ¹*Mayo Clinic, Scottsdale, AZ.* ²*Mayo Clinic, Rochester, MN.* ³*University of Leeds, Leeds, United Kingdom.* ⁴*Ecole Nationale des Sports de Montagne, Chamonix, France.*
Email: wheatley.courtney@mayo.edu

(No relevant relationships reported)

HISTORY: An experienced 39-year-old male ultraendurance runner started experiencing shortness of breath, coughing and inspiratory difficulties 80km into the 170km Ultra-Trail du Mont Blanc. He was able to finish the race by reducing his exercise intensity and was examined ~2 hours after crossing the finish line.

PHYSICAL EXAMINATION: The runner appeared weak, pale, with breathing shallow and constrained and oxygen saturation reduced from 97 to 92%. Resting respiratory rate and heart rate were elevated pre vs. post-race at 15 vs. 8 breaths and 52 vs. 103 beats per minute respectively. Lung auscultation found diffuse crackling in both lungs, but no wheezing.

DIFFERENTIAL DIAGNOSIS:

1. Exercise-induced asthma/bronchoconstriction
2. Pulmonary edema

TEST RESULTS:

Pulmonary function testing:

- FVC and FEV₁ dropped 3L from baseline, with coughing making PFTs difficult

Lung Diffusion:

- DLCO dropped 25%, higher than the 13-16% range seen in other racers

- Alveolar-capillary membrane conductance (Dm) fell 50%, this was not observed in other racers

- Pulmonary capillary blood volume (Vc) dropped 28% from baseline, this was typical of the group

Resting Echocardiography:

- Post-race stroke volume was reduced, but cardiac output remained elevated compared to baseline (SV: 70 vs. 56mL; Q: 3.9 vs. 4.8L/min)

- RV diastolic area and RA area both increased post-race and RV function was reduced (RV area: 22.7 vs. 26.1 cm²; RA area: 16.7 vs. 19.6 cm²; RV FAC: 37.9 vs. 30.7%)

Blood work:

- 38-fold increase in CK-MB (3.7 to 142.7 pg/mL)
- 8-fold increase in cTnl (0.00 to 0.08 ng/mL)
- 4-fold increase in BNP (15 to 64 pg/mL)

FINAL/WORKING DIAGNOSIS:

Runner exhibited evidence of acute injury to the heart and skeletal muscle. The race, which was characterized by intermittent altitude exposure, likely induced a substantial pressure-volume overload. Further, the reduction in pulmonary function and lung diffusion with the unique reduction in Dm, along with desaturation and lung sounds suggested mild pulmonary edema.

TREATMENT AND OUTCOMES:

1. Rest
2. Within 24 hours, everything was recovering: saturation returning to 97%, PFT close to predicted and lung diffusion improving, but not back to baseline
3. Runner reported it taking about a week for his lungs to feel normal again
4. He has returned to training at normal intensity

2294 May 31 10:50 AM - 11:10 AM

Intermittent Dizziness & URI Symptoms in a Young Athlete

James Pearson¹, Jonathan Siu², Hamed Shalika¹. ¹*Citrus Valley Family Medicine Residency Program, West Covina, CA.* ²*Kaiser Permanente, Fontana, CA.* (Sponsor: Aaron Rubin, FACSM)
Email: j7pearson@gmail.com
(No relevant relationships reported)

HISTORY:

A 21-year-old female division 1-track athlete presented multiple times with episodes of lightheadedness and headache with visual symptoms. Also reported recurrent rhinitis, residual cough and chest congestion. Symptoms were intermittent during periods of increased activity and relieved by rest. She missed multiple practices and workout sessions. Pt. was seen in 2013, 2016, 2017 and 2018 with dx including migraine, URI, influenza, and concussion with prolonged recovery respectively. She was empirically treated with albuterol and antibiotics without relief. Initial CXR negative but given the ongoing symptoms, serial x-rays noted a prominent main pulmonary artery.

PHYSICAL EXAMINATION:

Over the course of multiple examinations:

- NAD
 - Nasal congestion and cough present
 - RRR with normal heart sounds
 - No respiratory distress but decreased breath sounds in the left lung's upper and middle field. No rales/wheezes
 - Neuro exam was unremarkable
 - Skin was warm and dry
- DIFFERENTIAL DIAGNOSIS:**
- 1) Recurrent Upper Respiratory Tract Infection
 - 2) Asthma (EIB)
 - 3) Vocal Cord Dysfunction
 - 4) Migraine
 - 5) Cardiovascular abnormality unspecified
 - 6) Concussion with prolonged symptoms

TESTS AND RESULTS:

- 9/2016: Labs: wnl, EKG: NSR, no acute ischemic change
- 2/2017: CXR: wnl
- 4/2018: Repeat CXR: normal heart size, prominent main pulmonary artery
- 5/2018: EKG: wnl, TTE: pulmonic valve not well seen, tricuspid regurgitation with PA systolic pressure of 32
- 6/2018: MRA chest w/o contrast: mild diffuse cardiomegaly, prominent right atrium & main pulmonary outflow. Partial anomalous right pulmonary venous return to right-sided SVC.
- 7/2018: EKG wnl, TEE: Moderate increased right ventricular size & right atrial enlargement.
- 8/2018: Cath noted PAPVR of entire right lung to azygous vein with large left to right shunt.

FINAL/WORKING DIAGNOSIS

Partial v. Total Anomalous Pulmonary Venous Return

TREATMENT AND OUTCOMES

- 1) Referral placed to pediatric cardiac surgery for repair.
- 2) Exercise stress test to quantify exercise tolerance.
- 3) Counseled and encouraged to participate in steady-state aerobic exercise.
- 4) Counseled on approximately 5% chance of passing on congenital heart disease to her offspring and fetal echo is indicated at 20 weeks.
- 5) Infective endocarditis prophylaxis not indicated.

E-13 Clinical Case Slide - Wrist and Hand

2298 May 31 9:30 AM - 9:50 AM

Forearm Pain- Ice Hockey

Melissa Lau, William Pease. *Ohio State University, Columbus, OH.*

(No relevant relationships reported)

History

The patient is a 21 year old right hand dominant female who plays collegiate ice hockey. Past medical history includes remote left shoulder dislocation. One year prior, she had insidious onset of constant and dull left wrist pain without any precipitating event. Over time, it progressed to numbness and paresthesias that radiated to the radial and dorsal aspects of her forearm; she denied swelling or discoloration. It was worse in the morning and after exercise. She denied pain, trauma or weakness involving her neck, shoulder, elbow, wrist or hand. She failed conservative measures including rest, NSAIDs, bracing and ice.

Physical Exam

- Extensor more than flexor musculature slightly tender to palpation
- Nontender palpation of: left triangular fibrocartilage complex, ulnar/radial styloids, distal radioulnar joint, medial/lateral epicondyles
- Trace left forearm musculature fullness but overall with soft compartments
- Full and painless active/passive range of motion
- 5/5 upper limb strength (including pincer, grip strength)
- Painless resisted wrist extension
- Negative Phalen's, Finkelstein tests
- Neurovascularly intact (pulses, capillary refill, sensation, reflexes)

Differential Diagnosis

- Posterior interosseous nerve (PIN) entrapment/neuritis
- Radius or ulna stress reaction/fracture
- Intersection syndrome
- Lateral epicondylitis
- Exertional compartment syndrome

Tests and Results

- XR (left wrist, forearm): unremarkable
- Ultrasound (left forearm): trace fluid around tendons in second compartment
- MRI (left forearm with and without contrast): unremarkable, with normal appearing radial and posterior interosseous nerves
- EMG (left arm): unremarkable
- Compartment testing (mmHg):
- *pre-exercise: volar 25, dorsal 11, mobile wad 26
- *post-exercise: volar 35, dorsal 33, mobile wad 45

Final Diagnosis

Exertional compartment syndrome

Treatment and Outcomes

- Failed 5-day prednisone burst and ultrasound-guided tendon sheath injection for possible intersection syndrome
- Referred to orthopedic hand specialist who measured compartment pressures
- Underwent successful 4-compartment fasciotomy
- 2 weeks post-op: Weight bear as tolerated; OT/PT referral for ROM, stretches, soft tissue mobilization and strengthening
- 6 months post-op: Started new ice hockey season

2299 May 31 9:50 AM - 10:10 AM

Little Finger Injury - Football

Andre A. Abadin¹, Raul A. Rosario-Concepcion¹, John Cicciaro², George Pujalte, FACSM¹, Kristina DeMatas¹. ¹Mayo Clinic, Jacksonville, FL. ²University of St. Augustine for Health Sciences, St. Augustine, FL.

(No relevant relationships reported)

HISTORY: A 16-year-old, high school football running back, sustained a left 5th finger injury while catching a football at practice. He ran a route to his right and caught a low pass thrown to him. He initially reported pain and then noticed that his left little finger bone was sticking out of the skin. The mechanism of the injury was unclear. He did not recall whether he hit his finger on his leg or the football hit his finger while attempting to catch the ball.

PHYSICAL EXAMINATION: Examination revealed swelling of the left 5th digit with a two-centimeter laceration over the palmar side of the proximal phalanx. The left 5th proximal interphalangeal phalanx (PIP) joint appeared superficial to the musculature and skin, exposing the PIP joint. There was no evidence of fracture or any additional deformity of the finger. He was unable to move the PIP and DIP joint actively with normal MCP range of motion.

**DIFFERENTIAL DIAGNOSIS**

Interphalangeal open dislocation
Interphalangeal fracture
Interphalangeal collateral ligament strain

TEST AND RESULTS

Left hand x-rays pre-reduction
Left PIP 5th finger dislocation
No acute or healing fracture
Soft tissue swelling of the fifth digit
Left hand x-rays post-reduction
No acute or healing fracture
Soft tissue swelling of the fifth digit
Alignment of the PIP joint was normal

FINAL/WORKING DIAGNOSIS

Unusual volar PIP open dislocation of the left 5th finger without fracture

TREATMENT AND OUTCOMES

Reduction of left 5th digit PIP joint in the emergency department
2-cm laceration repair with sutures
Placed an extension block splint and on cephalixin antibiotic for 10 days
Referred to Hand Orthopedic Surgery for evaluation of PIP post-reduction
Orthopedic surgeon recommended diagnostic hand ultrasound to evaluate any ligament or tendon damage
Ongoing evaluation

2300 May 31 10:10 AM - 10:30 AM

Musculoskeletal Injury - Weightlifting - More Than Just a Hand Injury in a World Champion

Joseph Medellin¹, Ryan Rompolo², Mark E. Lavallee, FACSM¹. ¹WellSpan York Hospital Sports Medicine, York, PA. ²Franciscan Health Sports Medicine, Lafayette, IN. (Sponsor: Mark E. Lavallee, MD, CSCS, FACSM)

Email: joemedellinmd@gmail.com

(No relevant relationships reported)

HISTORY: LB, a 51-year-old female competing for team USA at the International Weightlifting Federation (IWF) World Masters Championships in Barcelona, Spain on August 20, 2018 was on her third attempt (70kg) in the clean and jerk when she sustained intense pain in her right hand on the bottom of the jerk which caused her to not complete the lift. She came directly to medical area for evaluation.

EXAMINATION: Right Hand: Sensation intact, 2+ radial pulse, <2 second capillary refill of first finger. The first finger extended posteriorly angulated off the metacarpophalangeal (MCP) joint.

DIFFERENTIAL DIAGNOSIS: 1. Dislocation of MCP joint of 1st finger 2. Ulnar collateral ligament of thumb injury 3. First finger fracture

TEST AND RESULTS: None obtained

FINAL WORKING DIAGNOSIS: Dislocation of MCP joint of first finger

TREATMENT AND OUTCOMES: Reduction of first finger MCP joint dislocation was achieved in the medical area at the competition with normal exam post reduction. The patient then found out her prior lift of the clean and jerk (66kg) was enough to secure her the World Championship title for her weight class. We then found out her complete medical background, which included an ongoing battle with breast cancer for the past two years, diagnosed in the fall of 2016. Due to the aggressive nature of the cancer, she has undergone a bilateral radical mastectomy (including resection of both pectoralis major muscles), partial right lung resection, partial diaphragm resection and partial gastrectomy in November 2017. The operation kept her from training for 8 months. She has undergone chemotherapy and radiation as her cancer has metastasized to her brain and bone. In February 2018, 6 months prior to the competition, she sustained a pelvic fracture after a fall. Despite this, she continued to train in her garage in Arizona leading up to the Master's competition.

Her finger was completely healed two weeks after competition. LB, the IWF Master's World Champion for the Female 90kg Class, had another surgery one month after the competition with radiation to follow. Upon completion of surgery, her first question to the surgeon was, "when can I start lifting?" Despite the 8 months her Oncologist has given her, LB is hopeful, kind spirited and a World Champion.

2301 May 31 10:30 AM - 10:50 AM

Sports-Related Wrist Pain In A Musician

Svetlana Dani. University of Maryland, Baltimore, MD.

Email: lana.pustilnikova@gmail.com

(No relevant relationships reported)

HISTORY:

23-year-old man, fell on an outstretched left wrist while playing flag football 5 months prior to presentation. He developed ulnar wrist pain was told he had a fracture of one of the carpal bones at an urgent care center. He followed up at an orthopedic center, where a congenital carpal coalition was noted. He wore a wrist brace for a month. He returned to regular activity until 2 months prior to presentation when he had a repeat injury to the left wrist and developed recurring pain on the ulnar aspect of his left wrist. He wore a brace for another month with improvement. Two weeks prior to presentation, he felt a popping sensation on the ulnar aspect of the left wrist while lifting. He only has pain with loading activities. No numbness or tingling. He is a trombone player and a music major and plans on using his hand for his career.

PHYSICAL EXAMINATION:

MSK: Left wrist: Skin is dry, clean, intact. Wrist range of motion is 70 degrees of extension and 75 degrees of flexion with full pronation and supination. Non-TTP over the ECU or TFCC. Mildly tender over the triquetrum. Painful click reproduced with volarly-directed pressure on the triquetrum. Strength 5/5 in FPL, EPL, interossei and FDP. Grip strength on left side is 70 lbs and 130 lbs on the right side.

DIFFERENTIAL DIAGNOSIS:

Extensor carpi ulnaris tendinopathy and subluxation
Triangular fibrocartilage complex injury
Triquetral, hook of hamate or ulnar styloid fracture
Ulnar nerve entrapment at Guyon's canal
Ulnorcarpal abutment syndrome
Lunotriquetral ligament injury
Lunotriquetral coalition with injury
Ulnar styloid impaction syndrome
Pisotriquetral or ulnocarpal arthrosis

TESTS AND RESULTS:

MRI of the left wrist:

Lunotriquetral coalition, likely fibrocartilaginous. Fluid signal within the synchondrosis and stress edema within lunate and triquetrum, suggesting instability. Scapholunate ligament, TFCC and FCU tendon and ulnar nerve are intact.

FINAL WORKING DIAGNOSIS:

Congenital left-sided lunotriquetral coalition with an injury resulting in instability.

TREATMENT AND OUTCOMES- Discussed fusion of the lunotriquetral joint

- Wrist brace for several weeks
- NSAIDs
- Use grips for wrist-loading activities
- Possibility of a cortisone injection if no improvement with conservative measures

2302 May 31 10:50 AM - 11:10 AM

Fifth Metacarpal Pain With Extensor Lag In An 18 Year Old Football Player

Ryan Robin, Brittany Moore, Karen Newcomer, FACSM. *Mayo Clinic, Rochester, MN.* (Sponsor: Karen Newcomer, FACSM) *(No relevant relationships reported)*

HISTORY: An 18-year-old high school football player presented to the clinic following an in-game injury to his left 5th digit during a tackling attempt. History is significant for 2 previous football injuries to the same digit. The initial injury occurred 1 year prior with pain and swelling of the 5th PIP joint with limited range of motion. He returned to normal following weeks of buddy taping. Second injury occurred 2 weeks prior to current injury, after direct, traumatic contact to the PIP joint. Again there was pain, swelling, and improvement with buddy taping. The final injury requiring medical attention occurred during a tackling attempt with unclear mechanism. There was no sensation of dislocation. Pain localized to the dorsal MCP joint (MCPJ) without radiation.

PHYSICAL EXAMINATION: On inspection, there was mild soft tissue swelling about the dorsal 5th MCPJ. Maximal tenderness to palpation was over the dorsal MCPJ, with secondary tenderness at the ulnar and radial PIP. On active ROM his 5th digit was unable to extend from the flexion biased natural resting hand position, which created an extensor lag of 1-2cm from the horizon at the MCP and extensor lag of 15° at the DIP. Active flexion was limited at the MCPJ and DIPJ by 10-15° compared to the normal, contralateral side. There was 0.5cm flexion lag of the 5th digit making a fist. Strength was 4/5 for FDS and FDP with pain reproduction. He had difficulty firing the extensor digiti minimi

DIFFERENTIAL DIAGNOSIS: 1. Metacarpal fracture 2. Proximal phalanx fracture 3. Mallet finger 4. MCP extensor sheath injury

TEST AND RESULTS: Hand X-rays: Small avulsion fracture off the volar aspect of the base of the 5th middle phalanx. MSK Ultrasound: Intact distal extensor mechanism MRI hand: Distal 5th metacarpal bone contusion without acute fracture, MCPJ capsular sprain with low-grade partial tear of the ulnar collateral ligament, and joint effusion.

FINAL WORKING DIAGNOSIS: Left 5th MCPJ capsule sprain, partial tear of the 5th MCP ulnar collateral ligament, and 5th metacarpal bone contusion

TREATMENT AND OUTCOMES: 1. Immobilization with hand based intrinsic plus splint encompassing the 4th + 5th MCP for 4 weeks 2. No contact sports due to osseous edema and risk of fracture until 4 week follow up 3. Follow up in 4 weeks for x-rays 4. More follow up to be presented at the conference as patient returns

E-14 Rapid Fire Platform - Biomechanics in Fatigue

Friday, May 31, 2019, 9:30 AM - 10:40 AM
Room: CC-Hall WA2

The Biomechanical Effects of Fatigue on Drop-Jump Performance in Basketball Athletes

Warren C. Ondatje, Guillermo J. Noffal, Pablo B. Costa, Jared W. Coburn, FACSM. *California State University Fullerton, Fullerton, CA.* *(No relevant relationships reported)*

Anterior Cruciate Ligament (ACL) injuries have high occurrences in the sport of basketball due to the high amounts of landing, cutting, and other sudden deceleration maneuvers. During landing, studies have prospectively linked insufficient amounts of knee flexion, greater knee valgus angles, and greater knee valgus moments accompanied by greater vertical ground reaction force to increased risk of ACL injuries. These mechanisms have shown to be increased in a fatigued state therefore

suggesting an athlete may be at greater risk for ACL injury when they are fatigued. Research to support this claim, however, is inconclusive. **PURPOSE:** To examine the difference in peak knee flexion angle (pKFA), peak knee valgus angle (pKVA), peak knee valgus moment (pKVM), and peak vertical ground reaction force (vGRF) pre and post fatigue during the landing phase of a drop jump task in basketball athletes. **METHODS:** Twenty-five subjects participated in the study and performed three drop jump trials before and after a fatigue protocol involving repeated counter movement jumps touching a customized target specific to each subject. Data was captured using a Qualisys 9-camera motion capture system sampling at 240-Hz and two AMTI force plates sampling at 2400-Hz. **RESULTS:** Paired t-tests showed subjects landed with significantly greater pKFA post fatigue ($p < .05$) while pKVA, pKVM, and pGRF showed no difference pre- and post-fatigue ($p > .05$). **CONCLUSION:** Subjects in this study adopted a safer landing strategy post fatigue, hence, suggesting our study did not support the claim that athletes would be at greater risk for ACL injuries in a fatigued state.

Dynamic Postural Stability During Rested and Fatigued Backwards Single-Leg Jump-Landings

Colin W. Bond, Benjamin C. Noonan. *Sanford Health, Fargo, ND.*
Email: colin.bond@sanfordhealth.org
(No relevant relationships reported)

Poor time to stabilization (TTS) during backward single-leg jump-landing (BSLJL) is a risk factor for injury. **PURPOSE:** The purpose of this study was to assess the reliability of TTS and effect of fatigue on TTS. It was hypothesized that TTS would demonstrate adequate reliability, and that fatigue would worsen TTS. **METHODS:** Nine active subjects (4 F, 5 M, 24.8 ± 3.4 y, 1.77 ± 0.08 m, 74.7 ± 15.3 kg) performed BSLJL on the dominant (D) and non-dominant (ND) leg. BSLJL was performed barefoot by jumping backwards on the test leg over a 0.15 m hurdle, landing on the test leg on a force plate with hands on the hips, and stabilizing as quickly as possible. During session 1, subjects performed 10 trials without familiarization. During session 2, subjects performed 3 trials (PRE), rested for 5 minutes, and re-performed 3 trials (POST). During session 3, subjects completed a 5 to 7 minute fatigue protocol consisting of step-ups, L-drills, vertical jumps, and agility ladder drills between PRE and POST instead of resting. Sessions 2 and 3 were completed in a randomized order. TTS was quantified as time from initial contact to when vertical ground reaction force remained within 5% of the subject's body mass for 1 s. RMANOVA and paired t-tests were used to compare TTS, and typical error (TE) was used to quantify reliability. Significance was set to $p \leq 0.05$. **RESULTS:** During session 1, BSLJL TTS did not improve over 10 trials on D ($p = 0.18$) or ND ($p = 0.49$). During session 2, TTS was similar PRE and POST on D (1.12 ± 0.47 vs 1.17 ± 0.40 s, $p = 0.81$) and ND (1.27 ± 0.53 vs 1.05 ± 0.57 s, $p = 0.09$), and had a within-day TE of 0.02 and 0.16 s, respectively. During session 3, TTS was similar PRE and POST on D (1.21 ± 0.32 vs 1.60 ± 1.05 s, $p = 0.22$), but greater at POST compared to PRE on ND (1.21 ± 0.51 vs 1.60 ± 0.58 s, $p = 0.04$). The between-day TE assessed using PRE TTS from session 2 and 3 was 0.36 s on D and ND. **CONCLUSION:** BSLJL learning effects are negligible, although familiarization trials are likely needed. Between-day reliability does not appear adequate. Using TTS to longitudinally monitor injury risk may be inappropriate. Fatigue appears to degrade TTS, but does not affect all subjects equally, and effects may be masked by large inter-subject variation in TTS. Identifying factors related to susceptibility to fatigue induced decrements may improve injury prevention measures.

2306 May 31 9:50 AM - 10:00 AM

Fatigue Increases Center of Pressure Sway

Gustavo Sandri Heidner, Caitlin O'Connell, Nicholas Murray, J. C. Mizelle, Patrick Rider, Zachary J. Domire. *East Carolina University, Greenville, NC.*
Email: sandriheidnerg17@students.ecu.edu
(No relevant relationships reported)

Posture and stability are key components in the accurate performance of a myriad of physical tasks. Recent research suggests that fatigue may lead to an increase in center of pressure (COP) oscillation, but the conditions in which balance is impaired are unclear. **PURPOSE:** To investigate the effects of fatigue and other perturbation conditions on the sway of the COP. **METHODS:** Eighteen participants completed three trials under each condition, pre- and post-fatigue protocol. The conditions were eyes open (EO), eyes closed (EC), single leg stand (SL), subtraction of seven (SS), unstable surface (US), virtual reality baseline (VB) and virtual reality perturbation (V2). The x- and y-axis COP coordinates were measured using a Bertec force plate. After the first 21 trials, the participants walked on a treadmill at a RPE of 14 for 30 minutes while carrying a 25 kg weighted backpack. Anterior-posterior (APd) and medio-lateral (MLd) displacement of COP were calculated. Results are presented in millimeters (Mean ± SD). A two-factor mixed-design ANOVA was used to test for statistically significant differences ($\alpha = .05$). **RESULTS:** APd increased under EC

(12.79 ± 2.91, $p < .001$), SS (17.01 ± 5.63, $p = .004$), and V2 (9.80 ± 2.78, $p = .001$). MLD increased under SL (11.76 ± 5.82, $p = .050$) and SS (14.54 ± 5.74, $p = .015$). There were no differences in COP sway when vision remained unimpaired, even on unstable surface. **CONCLUSION:** Fatigue appears to increase COP sway only when other mechanical or cognitive perturbations are present. Supported by: the Office of Naval Research (N00014-17-1-272).

2307 May 31 10:00 AM - 10:10 AM
Effect of Sex on Neural Excitability and Central Fatigue for a Submaximal Elbow Extensor Task

Alexandra F. Yacyshyn, Chris J. McNeil. *The University of British Columbia, Kelowna, BC, Canada.* (Sponsor: Charles L. Rice, FACSM)

(No relevant relationships reported)

Compared to other muscle groups (e.g., elbow flexors), few studies (two) have investigated the role of sex on muscle fatigue of the elbow extensors (EE). The greater fatigability usually seen for males compared to females was not observed, so the EE warrant further study. **PURPOSE:** To investigate the effect of sex on peripheral, motoneuronal, and cortical excitability as well as central fatigue with a submaximal EE task. **METHODS:** To date, 13 participants (7 females) have performed a 15min sustained isometric EE contraction at the level of electromyographic activity (EMG) recorded at 15% of maximal torque, followed by recovery contractions over 5min. Pre- and post-fatigue as well as at the end of each minute, evoked potentials were recorded from triceps brachii in response to transcranial magnetic stimulation of the motor cortex (TMS; motor evoked potentials, MEPs), cervicomedullary stimulation (cervicomedullary motor evoked potentials, CMEPs) and brachial plexus stimulation (maximal M-wave; Mmax). MEPs and CMEPs were elicited 100ms after a conditioning TMS pulse. To assess central fatigue, voluntary activation (VA) was calculated pre- and post-fatigue using superimposed and resting tetani evoked via trains of 5 stimuli (100Hz) delivered over triceps brachii. **RESULTS:** During fatigue, Mmax area did not change. The CMEP (normalized to Mmax) was reduced to 46.9±15.6% and 50.1±36.9% of the control ratio in females and males, respectively. The MEP (normalized to CMEP) was facilitated to 153.8±95.8% in females and 260.9±195.1% in males. At 5min of recovery, the normalized CMEP remained depressed in females and males (57.1±31.8% and 47.6±34.0%, respectively), whereas the normalized MEP remained facilitated at 220.1±106.4% in females and 184.5±101.3% in males. VA decreased from 97.0±1.8% to 84.3±18.0% in females and 95.5±3.4% to 76.7±21.0% in males at task termination, and showed incomplete recovery at 5min (89.0±6.9% females and 84.6±13.0% males). **CONCLUSIONS:** Apart from a trend toward greater central fatigue in males, the preliminary results support published findings, which show negligible sex differences with isometric fatigue of the EE. Additional research is needed to ascertain why the EE differ from other muscle groups in this regard. Supported by NSERC, CFI, and BCKDF

The Impact of Mental Fatigue on Force and Motor Unit Firing Variability in Young Adults

Katie L. Kowalski, Anita D. Christie. *University of Western Ontario, London, ON, Canada.*
 Email: kkowals7@uwo.ca

(No relevant relationships reported)

Mental fatigue leads to declines in performance of tasks such as cycling time trial performance and skill-based outcomes such as soccer shot accuracy. The neuromuscular mechanisms leading to these declines are not well understood. Although force variability has been shown to increase under dual-task conditions, it is not known if these results extend to conditions of mental fatigue. **PURPOSE:** The purpose of this study was to assess the impact of mental fatigue on variability in motor output in healthy, young individuals. Specifically, we sought to determine if a task that induces mental fatigue has effects on force and motor unit firing variability. **METHODS:** Nineteen participants (10 female, 9 male) performed 10-s isometric contractions at 20 and 50% maximum voluntary contraction (MVC) before, during, and after completing 20 min of the psychomotor vigilance task (PVT). The PVT is a sustained attention task that induces mental fatigue, as indicated by increases in reaction time (RT) to visual stimuli. Force and indwelling motor unit (MU) firings were measured prior to and immediately following performance of the PVT (single task), and within the first and final minutes of PVT performance (dual task). Subjective ratings of fatigue were also obtained using a 10-point Likert scale before and after the PVT. **RESULTS:** Reaction time increased by 14% from the beginning of the PVT (276.14 ± 31.54 ms) to the end (314.15 ± 37.74 ms, $p < 0.001$). Subjects also subjectively reported greater levels of fatigue following the PVT (4.95 ± 1.84) compared to before (3.00 ± 1.20, $p < 0.001$), indicating successful induction of mental fatigue. For the coefficient of variation (CV) of force there was no significant main effect of time ($p = 0.14$) or contraction intensity ($p = 0.33$), and no significant interaction

($p = 0.51$). For the CV of the MU interspike interval there was a main effect of contraction intensity with a greater CV of the interspike interval during the 50% MVC (19.51 ± 3.84%) than the 20% MVC (14.87 ± 3.59%, $p < 0.001$) contractions. However, there was no significant main effect of time ($p = 0.83$) and no significant interaction ($p = 0.23$). **CONCLUSION:** Inducing mental fatigue did not lead to changes in the variability of force production or motor unit firing during isometric contractions at 20 and 50% MVC as a single-task or during a concurrent cognitive task.

Impact Mechanics in Female Runners with Single and Multiple Stress Fractures Following Fatigue

Jerome Outerleys¹, Kristin L. Popp², Sara E. G. Rudolph³, Signe Caska³, Kathryn E. Ackerman, FACSM², Mary L. Boussein², Irene S. Davis, FACSM¹. ¹Spaulding National Running Center, Harvard Medical School, Cambridge, MA. ²Harvard Medical School, Cambridge, MA. ³Massachusetts General Hospital, Boston, MA. (Sponsor: Dr. Irene Davis, FACSM)

Email: jouterleys@partners.org

(No relevant relationships reported)

Stress fractures are common injuries in runners and military recruits, with females at greater risk than their male counterparts. Impact variables including peak axial tibial shock and vertical average load rate during running have been shown to be higher in females with a history of tibial stress fractures and increase with fatigue. However, the relationship between mechanics and injury in those with multiple lower extremity stress fractures has not been examined. **PURPOSE:** To investigate whether impacts increase with fatigue in runners with no history of stress fractures (CON), one (1SFX), and 3 or more (3SFX) stress fractures. **METHODS:** Impact variables were calculated for 43 females (14 CON, 14 1SFX, and 15 3SFX) at a speed of 2.67 m/s before and after a fatigue run. Variables included peak axial and resultant tibial shock (VTA, RTA) and vertical average and instantaneous loading rates (VALR, VILR). The fatigue run was performed at a 5 km predicted pace and stopped when a RPE reached ≥ 18. Absolute change comparisons were made using one-way ANOVAs and post-hoc tests. **RESULTS:** 3SFX had larger changes (i.e. increased values) after fatigue than CON or 1SFX for all variables (Table 1), although after post-hoc tests only VILR for 3SFX was statistically higher than 1SFX ($p < 0.05$), with VALR, VTA, and RTA not reaching significance. Additionally, subjects with the largest changes in these variables exhibited a change in their foot strike towards a more posterior strike pattern. **CONCLUSION:** Females with multiple stress fractures showed larger changes in load rates after fatigue, compared to those with history of one stress fracture. Change in foot strike pattern greatly influences impact mechanics before and after fatigue. The Effects Of Running Form On Hip Kinetics During Running Fatigue On An Instrumented Treadmill

Michael Bohne, Tamarie Wagstaff, Kainalu Nitta, Kirsten Howe, Kristen Terry, Jason Thomas. *Utah Valley University, Orem, UT.* (Sponsor: Scott Drum, FACSM)

Email: michael.bohne@uvu.edu

(No relevant relationships reported)

PURPOSE: The purpose of this study was to assess movements and forces applied to the hip and pelvis to determine its relationship to running form. **METHODS:** 23 participants (11 male, 12 female; ages 18-39) were organized into 3 groups and by gender. They participated in a two day data collection. Day one consisted of a standardized VO2max protocol obtained using a Cosmed K5 portable metabolic cart system (Cosmed Inc., Albano Laziale, Italy) and a Bertec instrumented treadmill (Bertec, Inc., Columbus, Ohio). Participants were given a day between test days and were required to not engage in any form of exercise. On the second day, participants ran at 80% of their recorded VO2max scores until fatigued. Each participant ran with

reflective markers that were used by high speed motion capture cameras (Vicon, Inc., Oxford, UK) to record kinematic data. All data was analyzed statistically using a MANOVA ($\alpha=0.05$).

RESULTS: Significance for the medial-lateral GRF was found when analyzed between gender ($F(1,14)=6.682, p=0.022$; Female mean = 0.043 BW (Body weight), Male mean=0.024 BW). Significance for the anterior-posterior GRF was found between times ($F=13.208, p=0.001$): start (0.214 BW) and end (0.248 BW; $p=0.002$). The vertical GRF showed significance between start (2.236 BW) when compared to end (2.499 BW; $p=0.034$). Lateral pelvic ROM significant differences were found between start (7.813 degrees) and end (9.267 degrees; $p=0.010$). Data analysis for pelvic rotation ROM showed significant differences between gender (Female=11.299 and Male=6.726; $p<0.001$) and time: start (8.153 degrees) and end (9.695 degrees; $p=0.026$).

CONCLUSIONS: Results showed significant changes in ground reaction forces between beginning of steady state running and a fatigued state during the selected running protocol, but no significant changes in hip joint moments. Thus, the data suggests fatigue influenced a change in form, as evidenced by the significant changes in ground reaction forces. However, the lack of significant changes in hip joint moments suggest that additional compensation is happening with the running form. Further research is needed to examine segmental kinematics and muscle EMG around the hip to fully understand the relationship between the compensation during fatigued running form and hip/pelvic kinematics and kinetics.

E-29 Free Communication/Poster - Performance

Friday, May 31, 2019, 7:30 AM - 12:30 PM
Room: CC-Hall WA2

2337 Board #1 May 31 9:30 AM - 11:00 AM Mild Dehydration Protocol Impairs Lightweight Rowing Performance: Exploring Differences in Dehydration Technique

Dayton J. Kelly, Liana E. Brown. *Trent University, Peterborough, ON, Canada.*
Email: daytonkelly@trentu.ca
(No relevant relationships reported)

Dehydration is an acute weight loss technique used by lightweight rowers to become eligible for competition. While rowing allows a two-hour window between weigh-ins and racing that athletes can use to rehydrate, it is unclear what effect this procedure may have on performance. **PURPOSE:** To determine whether mild dehydration with rehydration, as a weight reduction strategy for lightweight rowers, compromises rowing performance. **METHODS:** Experienced rowers ($N=14$) twice performed a 2000 m rowing ergometer time trial and visuomotor battery: once euhydrated and once after mild dehydration (mean $-1.68 \pm .23\%$ body mass reduction). Weight loss was achieved through a combination of 12-hour fluid restriction and subsequent sauna exposure. **RESULTS:** Participants were significantly slower on the 2000 m rowing trial in the dehydration condition than in the euhydrated condition (2.44 ± 4.5 s, $p<0.05$). Hierarchical linear regression analyses revealed that these rowing performance decrements were better explained by dehydration achieved through fluid restriction ($r^2=.504, p<0.01$) than by dehydration achieved in the sauna or total dehydration magnitude ($r^2=.025, n.s.$). Hierarchical regression revealed that dehydration-related changes in visuomotor function were also explained by dehydration by fluid abstinence but not sauna exposure and were predictive of dehydration-related rowing performance decrements ($r^2=.310, p<0.01$). **CONCLUSION:** These findings suggest that rowing time-trial performance can be negatively affected by relatively small changes in hydration status and that the technique by which dehydration is achieved is important. Performance losses were associated with fluid abstinence and not with sauna dehydration. Reduced motor control may explain resulting declines in performance following dehydration and rehydration.

2338 Board #2 May 31 9:30 AM - 11:00 AM Progression of World Records in Master Swimming

Tiago M. Barbosa¹, Henrique P. Neiva², Flavio A.S. Castro³, Daniel A. Marinho². ¹Nanyang Technological University, Research Centre in Sports, Health and Human Development, Polytechnic Institute of Bragança, Singapore, Singapore. ²University of Beira Interior, Research Centre in Sports, Health and Human Development, Covilhã, Portugal. ³University Federal Rio Grande do Sul, Porto Alegre, Brazil.
(No relevant relationships reported)

Master sports is increasingly popular and arguably becoming more competitive worldwide. Engagement in master sports has a positive impact on athlete's health &

fitness. Master swimming is a good proxy of overall master sports as it is deemed to have one of the highest number of competitive participants. Several fitness components are performance determinants in master swim. However, it is unknown the progression of World Records (WRs) in master swim over time. It can provide insight on the overall trend of master swimmers' fitness level and competitiveness over the past decades. **PURPOSE:** To analyze the progression of WRs in master swim in the past decades. **METHODS:** The WRs in all men's freestyle events (50m, 100m, 200m, 400m, 800m and 1500m) in all age-groups (from 25-29 to 100-104 years-old) between 1984 and 2016 were extracted from FINA database. To enable comparisons across events, WRs were converted into swim speed. For each event and age-group the percentage of change in the swim speed between Olympic cycles was calculated. Then, it was computed the relative variability within-cycle and within-event. Small, moderate and large worthwhile effects of time between Olympic cycles were calculated as well. Finally, the chance that time (i.e. Olympic cycle) and events had a substantial effect on the WRs progression was computed. **RESULTS:** The within-cycle variability was moderate-high ($15.98<CV<148.46\%$; 1996-2000 and 1984-1988, respectively); whereas the within-events variability was high ($33.93<CV<128.38\%$; 400m and 800m events, respectively). Small, moderate and large worthwhile effects between-cycles were 0.16%, 0.47% and 0.93%, respectively. Chances that time had a substantial effect on the WRs progression ranged between 97.5% (in the 50m events) and 100% (800m). Chances that event had a substantial effect ranged from 80.9% (in 2012-2016) and 100% (in 1984-1988 and 1992-1996). **CONCLUSIONS:** Master swim WRs showed largest progressions in the first Olympic cycles than recently. Middle- and long-distance events denoted higher percentage of change than sprints. Supported by: Portuguese Foundation for Science and Technology (UID/DTP/04045/2013); European Fund for regional development (FEDER)-COMPETE 2020 (POCI-01-0145-FEDER-006969).

Are Changes in Physical Work Capacity Related to Changes in Associated Physiologic Measures?

Derek Crawford. *Pittsburg State University, Pittsburg, KS.*
Email: dcrawford@pittstate.edu
(No relevant relationships reported)

High intensity functional training (HIFT) is a novel exercise intervention that may test body systems in a balanced and integrated fashion through challenging individuals' abilities to complete mechanical work; however, research has not determined if work capacity (WC) is a unique measure of fitness. **PURPOSE:** To determine if change in WC is related to change in the underlying physiologic measures. **METHODS:** Twenty-five healthy men ($n=13$; age = 22.6 ± 3.5 ; body mass = 86.1 ± 13.9 kg; height = 182.8 ± 8.1 cm) and women ($n=12$; age = 21.0 ± 1.5 ; body mass = 70.5 ± 11.3 kg; height = 165.6 ± 5.7 cm) completed a six-week (5 days/week) HIFT intervention with WC and various physiologic measures of fitness assessed pre- and post-intervention. Physiologic variables assessed included aerobic capacity ($\dot{V}O_{2max}$); one-repetition maximums for back squat, shoulder press, and deadlift exercises; peak power and fatigue index from a 30-second Wingate bout; and WC (i.e., the maximal amount of mechanical work performed in a given time domain). **RESULTS:** At baseline, all physiologic measures of fitness were significantly associated with WC and this relationship was even stronger at post-intervention assessment (all $p < 0.05$). Further, there were significant improvements across these measures in response to the HIFT intervention (all $p < 0.05$). However, a multiple regression model using the change in these measures did not significantly predict the change in WC induced by HIFT ($F = 0.330$; Sum of Squares = 637.3; $df = 5$; $p = 0.908$; $R^2 = 0.141$). In addition, no single measure of fitness was significantly associated with the change in WC (Table 1). **CONCLUSION:** HIFT may be a unique challenge to individuals' fitness beyond traditional exercise programs; as evidenced by the independence of changes in WC from changes in the associated physiologic components. Elucidating the translational impact of increasing WC via HIFT may be of great interest to health and fitness practitioners.

Athletic Profile Of Elite Alpine Skier Racers: A Systematic Review And Meta-analysis

Pierre-Marc Ferland, Alain Steve Comtois. *UQÀM, Montreal, QC, Canada.*
Email: pm.ferland@hotmail.com
(No relevant relationships reported)

ACSM Abstract
PURPOSE

The purpose of this study was to review all anthropometric and physical test results performed on alpine ski racers that were published in the scientific literature to build an athletic profile specific to the skier's sex and level as well as to quantify the effect size of presented factors on alpine ski racing performance.
METHODS

Four electronic databases were systematically searched using the following key words: *alpine skiing physiology*. The manual search was performed through the reference list of all suitable publications, the author's personal collection and the proceedings of the *International Congresses on Science and Skiing*.

SUMMARY OF RESULTS

The search and selection strategy permitted to gather data from 28 peer reviewed publications that was collected on a total of 1107 skiers coming from 11 different countries to build the athletic profile as well as 6 peer-reviewed publications that presented suitable correlations for the meta-analysis. Results of this study present the athletic profile, review the different testing protocols, present correlations between physiological factors and alpine ski racing performance and combine them to present the overall effect size of these factors on alpine ski racing performance. Findings show that men generally present higher tests result than woman, that higher level ski racers generally present higher test results than lower level ski racers and that age, weight, body fat % and lower limb power presented significant effects on alpine ski racing performance (-0,52 [95% IC : -0,73; -0,31] ($p < 0,0001$); -0,57 [95% IC : -0,78; -0,36] ($p < 0,0001$); -0,25 [95% IC : -0,43; -0,07] ($p = 0,0055$) and 0,8 [95% IC : 0,44; 1,17] ($p < 0,0001$) respectively).

CONCLUSION

The present review should serve as guidelines for professionals working with alpine ski racers since some of the factors presented in the athletic profile have been shown to be related with performance. Further research should include more details on the testing protocols used, be directed towards female athletes, present results from groups of athletes of the same sex and clearly identified as established at a certain level and be directed on the effect of physiological factors on alpine ski racing performance. These measures could help support further theoretical investigations.

2341 Board #5 May 31 9:30 AM - 11:00 AM Are Conditional Abilities Related to ATP Rank in Tennis Players?

Enrique O. Prada, Aldo F. Longo, Mariela B. Arangio, Gustavo D. Aquilino, Victor M. Paris, José L. Tripodi, Gustavo Bagnasco, Claudio A. Gillone, Marcelo L. Cardey. *CeNARD, Buenos Aires, Argentina.*

(No relevant relationships reported)

PURPOSE: The purpose of this research was to explore for associations between a group of conditional abilities and the position in the ATP ranking in adult tennis players.

METHODS: Thirteen Argentine male tennis players were studied (Age = 27.7 ± 4.1 yr, BMI = 23.3 ± 1.2 kg·m⁻²; mean ± SD). The participants ranked from 26th to 462nd in the ATP ranking at the time of being tested. A set of physical fitness tests was carried out: Handgrip strength (HAST), Abalakov jump (ABJ), Maximal oxygen uptake ($\dot{V}O_{2max}$), Sit and reach flexibility (SARF), Simple and Complex reaction time of hands and feet to visual stimuli (Simple eye-hand reaction time (SEHRT), Complex eye-hand reaction time (CEHRT), Simple eye-foot reaction time (SEFRT) and Complex eye-foot reaction time (CEFRT)), and Peripheral vision reaction time (PVRT). The Spearman's rank correlation coefficient (r_s) was employed to test associations between the performances in the physical fitness tests and the ATP rank. Additionally, the relationships among the conditional abilities were analyzed, by means of the Pearson's product-moment correlation coefficient (r). The statistical significance level was set at $p < 0.05$.

RESULTS: A moderate but significant negative correlation was found between PVRT and ATP rank ($r_s = -0.58$; $p = 0.047$). And among the conditional abilities, a marked positive correlation was identified between $\dot{V}O_{2max}$ and SARF ($r = 0.64$; $p = 0.02$). The mean and SD values of HAST, ABJ, $\dot{V}O_{2max}$ and SARF were, respectively: 47.3 ± 7.0 kgf, 47.1 ± 4.4 cm, 58.1 ± 4.2 ml·kg⁻¹·min⁻¹ and 13.0 ± 5.0 cm. And the mean and SD values corresponding to the eye-motor reaction time tests were (in ms): 206 ± 16 for SEHRT, 313 ± 48 for CEHRT, 487 ± 36 for SEFRT, 603 ± 60 for CEFRT and 982 ± 168 for PVRT.

CONCLUSIONS: Tennis level as measured by the ATP ranking showed to be significantly correlated to Peripheral vision reaction time. The sign of this correlation indicates that the players with higher ATP ranks tended to show lower performances in Peripheral vision reaction time.

2342 Board #6 May 31 9:30 AM - 11:00 AM The Influence of Bout Duration and Rule Modification in Small-Sided Games

Richard Hauer¹, Antonio Tessitore², Harald Tschan¹. ¹University of Vienna, Vienna, Austria. ²University of Rome "Foro Italico", Rome, Italy.

(No relevant relationships reported)

PURPOSE: Small-sided games (SSG) are an established training method to develop aerobic capacity in team sports (1). However, there is still a lack of knowledge about

the variety of variables that influence the outcomes of SSG (2). Therefore, the present study was designed to investigate the influence of changes in bout durations and rules on physiological and technical parameters in men's lacrosse.

METHODS: Data of 12 elite male Austrian lacrosse athletes were collected. Prior to the intervention athletes maximum heart rate (HR) and aerobic capacity was evaluated. According to results athletes were assigned to 4 even strength teams. Each team participated in 8 SSG training sessions. SSG consisted of 3 vs. 3 self-regulated match-play on a basketball field with small goals at the end lines. Each team performed two sessions of two different bout (3x6 and 6x3-minute) and rule modification (body/non-body contact) regimes. %HRmax for total session time, time spent in 4 different HRzones, rating of perceived exertion (RPE), and technical actions were collected. Statistical significance was set at $p \leq 0.05$ and for an estimate of effects Cohen's ES was calculated.

RESULTS: Physical and technical parameters showed no difference nor effect between different bout regimes (BR). On the other hand, non-contact regimes (NCR) had lower RPE (15.8 ± 0.3; $p = 0.01$; $d = 2.04 \pm 1.56$) values, but didn't show difference in %HRmax for total sessions. NCR spent more time in HRzone 2 (128.0 ± 26.5s; $p = 0.04$; $d = 1.37 \pm 1.32$) and 3 (245.4 ± 77.0s; $p = 0.05$; $d = 1.41 \pm 1.56$) compared to the contact regime (CR). Similarly, number of total events (761.5 ± 56.3; $p = 0.00$; $d = 2.92 \pm 1.74$), passes (254.3 ± 26.7; $p = 0.00$; $d = 2.39 \pm 1.34$), and shots (47.3 ± 9.0; $p = 0.04$; $d = 1.51 \pm 1.62$) were higher in NCR.

CONCLUSION: The findings show no influence on technical and physical parameters between different BR. Further, rule modifications show effects on intensity and technical actions in SSG. Results indicate less intensity (time spent in HRzones and RPE) and more technical actions when no-body contact is allowed. According to the findings, we recommend to implement NCR into sport specific lacrosse training programs to change the outcome of SSG sessions.

2343 Board #7 May 31 9:30 AM - 11:00 AM Training Level Does Not Affect The Negative Effect Of Mental Fatigue On Visuomotor Performance.

Bart Roelands¹, Jeroen Van Cutsem¹, Samuele Marcora², Romain Meeusen, FACSM¹. ¹Vrije Universiteit Brussel, Brussels, Belgium. ²Kent University, Kent, United Kingdom. (Sponsor: Romain Meeusen, FACSM)

Email: bart.roelands@vub.be

(No relevant relationships reported)

PURPOSE: Mental fatigue has been shown to impair multiple visuomotor related skills in sport-specific and non-sport-specific settings. Further, it has recently been reported that professional road cyclists have superior inhibitory control and resistance to mental fatigue than recreational cyclists. We sought to assess whether badminton players also have superior executive functions and whether they are more resistant to mental fatigue than controls on an open-skill visuomotor task.

METHODS: Eleven untrained healthy controls (mean ± SD; age: 25 ± 4y; 6 females, 5 males) and nine healthy badminton players (age: 23 ± 3y; 4 females, 5 males) performed two experimental trials in a randomized crossover order. Participants completed a baseline visuomotor task (~6min30sec), followed by a Flanker task. Next, they performed either a mentally fatiguing task (90 minutes Stroop task; MF) or watched a documentary for 90 minutes (CON). Immediately thereafter again the Flanker task and the visuomotor task were completed. Accuracy and reaction time were followed up in all tasks but the documentary. Multiple physiological and psychological measures were assessed during the protocol.

RESULTS: Badminton players' and controls' accuracy during the Stroop task dropped over time ($p = 0.023$). Subjectively, both groups perceived the Stroop task as more mentally demanding than the documentary ($p < 0.001$). In addition, higher mental fatigue was perceived in MF compared to CON, independently from group ($p = 0.029$). In the visuomotor task, controls as well as badminton players reacted significantly slower on the complex stimuli when mentally fatigued (~7%; $p < 0.001$). Badminton players (1109 ± 251ms) outperformed controls (1299 ± 227ms; $p = 0.022$) in the visuomotor task.

CONCLUSIONS: Mental fatigue ensued in both badminton players and controls after a 90 minutes Stroop task and impaired open skill-visuomotor performance in both groups. More specifically participants responded on average 7% slower when mentally fatigued. Firstly, this shows that athletes are indeed not immune to mental fatigue. Secondly the present results substantiate mental fatigue does not only impair endurance performance, but also impairs open skill-visuomotor performance.

2344 Board #8 May 31 9:30 AM - 11:00 AM
Physiological Determinants of Peak Power Output in Elite Cyclists
 Glyn Howatson, FACSM¹, Mehdi Kordi¹, Stuart Goodall¹, Nicos Haralabidis², Tejal Patel², Tom Maden-Wilkinson³, Jonathan Folland, FACSM⁴. ¹Northumbria University, Newcastle-upon-Tyne, United Kingdom. ²University of Bath, Bath, United Kingdom. ³Sheffield Hallam University, Sheffield, United Kingdom. ⁴Loughborough University, Loughborough, United Kingdom.
 Email: glynhowatson@hotmail.com
 (No relevant relationships reported)

Despite the importance of peak power output (PPO) to many cycling disciplines, particularly in sprint events, little is known about the structural and functional determinants of PPO in elite cyclists. **PURPOSE:** To determine the relationship and contribution, in elite cyclists spanning a range of disciplines, of putative neuromuscular determinants with cycling PPO during sprint cycling. **METHODS:** Thirty-five elite male cyclists volunteered to take part in the study (mean \pm SD age, 22 \pm 4 yr; stature, 179.1 \pm 5.9 cm; mass, 77.4 \pm 11.3 kg) and conducted a series of isovelocity sprints to assess PPO on two separate occasions. Surface EMG (sEMG) of the gluteal, hamstring and quadriceps muscles were recorded during the PPO test. Muscle volume was assessed and quantified using MRI and muscle architecture of the vastus lateralis (pennation angle [PO_{VL}] and fascicle length [FI]) were assessed with ultrasound. Bivariate correlation analyses were conducted to assess relationships; significant correlations were included in a step-wise regression to predict PPO performance. **RESULTS:** Positive bivariate relationships were found for quadriceps volume ($r = 0.87$; $P < 0.001$), hamstring volume ($r = 0.71$; $P < 0.001$) and PO_{VL} ($r = 0.81$; $P < 0.001$) with PPO. The remaining measures (FI, and sEMG) were unrelated to PPO. A step-wise multiple regression analysis was conducted with the three predictor variables; 87% of the variability in PPO between cyclists ($P < 0.001$) was explained by two variables, quadriceps volume (76%) and PO(11%). **CONCLUSION:** These data provide valuable information on the characteristics of elite cyclists. Importantly, determinants of PPO in this elite population have been identified as muscle volume of the quadriceps and pennation angle of the VL. These data provide a basis that allows coaches and practitioners to understand the contributing factors to cycling PPO performance. Consequently, it is recommended that athletes, coaches and practitioners use this information to target these physical qualities to inform training programme design of elite cyclists to maximise pennation angle and quadriceps volume.

2345 Board #9 May 31 9:30 AM - 11:00 AM
The Influence of Fatiguing Exercise on Power Output
 Lena K. Perry, J. Mark VanNess, William P. Lydon, Joey Rossi, Courtney D. Jensen. *University of the Pacific, Stockton, CA.*
 Email: l_perry2@u.pacific.edu
 (No relevant relationships reported)

Physical fatigue impairs performance during high power, short duration activities. As technological developments permit new methods of measuring this effect, it is important to validate existing paradigms. **PURPOSE:** To determine if kinetic measurements from vertical jump (VJ) tests are influenced by fatigue based on explosive power outputs. **METHODS:** A sample of athletes (9 men, 26 women) from a Division I NCAA sports program completed testing. To establish baseline VJ kinetics, athletes performed a controlled warm-up and then completed 6 jumps on a SpartaTrac force plate, each separated by 15s rest. Sparta software computed 3 outputs: Load, Explode, and Drive. After baseline VJ calculation, all athletes performed an anaerobic fatigue protocol on a mechanically-braked cycle ergometer: 3 sprints lasting 15s separated by 10s rest. Peak and mean power were recorded from the cycle trials. Subjects then repeated the VJ protocol. This pattern was repeated until 6 sets of VJ were recorded. Repeated measures ANOVA tested differences between successive VJ performances. **RESULTS:** Male athletes were 20.8 \pm 1.5 years old, weighed 175.8 \pm 14.0 lbs, had a baseline VJ of 46.9 \pm 3.6 cm, Load of 53.6 \pm 13.3, Explode of 49.4 \pm 6.6, and Drive of 49.4 \pm 11.9. Female athletes were 20.2 \pm 1.2 years old, weighed 142.3 \pm 13.2 lbs, had a baseline VJ of 32.7 \pm 4.3 cm, Load of 49.8 \pm 46.1, Explode of 40.7 \pm 8.0, and Drive of 63.1 \pm 49.7. The only differences between men and women were weight ($p < 0.001$), VJ ($p < 0.001$), and Explode ($p = 0.006$). ANOVA found VJ height to decrease between baseline and trial 2 ($p < 0.001$); there was no difference between men and women ($p = 0.210$); between trials 2 and 6, VJ height was consistent ($p > 0.400$). Load was not affected by the fatigue protocol across the total sample ($p = 0.418$) or by sex ($p = 0.239$). Explode was not affected by fatigue across the sample ($p = 0.233$) or by sex ($p = 0.406$). Drive was affected by fatigue ($p = 0.040$), decreasing in successive trials; there was no interaction with sex ($p = 0.742$). **CONCLUSION:** VJ is more sensitive to fatigue than SpartaTrac force plate calculations. An initial fatiguing insult was sufficient to compromise performance, whereas accumulated fatigue did not have an additive effect. Drive was the only variable in SpartaTrac outputs that was affected by fatigue.

2346 Board #10 May 31 9:30 AM - 11:00 AM
Variations in Athletic Profiles Between Division I All-Girl and Co-Ed Competition Cheerleaders
 Nia Y. Hicks, Michelle L. Eisenman, Emily L. Langford, Barry Munkasy, Ronald L. Snarr, Greg A. Ryan. *Georgia Southern University, Statesboro, GA.*
 (No relevant relationships reported)

On a Co-Ed cheer team, a female's primary role is a flyer. In contrast, an All-Girl team allows females to be either a flyer, base, or back spot. Although strength, power, and proprioception are required of all positions, these metrics, in addition to individual anthropometrics, may influence a coach's decision on squad placement. **PURPOSE:** The purpose was to compare anthropometric and performance variables between All-Girl (AG) and Co-Ed (CE) Division-I female cheerleaders. **METHODS:** Thirty-three (AG: $n = 24$; CE: $n = 9$) cheerleaders were assessed for: height (H), weight (W), body composition (BF%), vertical jump (VJ), upper body power (UP), and dominant (DHG) and non-dominant (NDHG) hand-grip strength. The greater of two trials for VJ, UP, NDHG, and DHG were used for statistical analysis. BF% was determined via air displacement plethysmography on the same visit to the laboratory. Due to unequal group sizes, non-parametric Mann-Whitney U Tests were run comparing the athletic profile between AG and CE. **RESULTS:** Significant differences were noted in: H (median: AG: 63.5in, CE: 61.0in; $p < 0.01$); W (AG: 135.0lb, CE: 121.0lb; $p < 0.01$); UP (AG: 89.5in, CE: 80.0in; $p = 0.02$); DHG (AG: 25.5kg, CE: 20.0kg; $p = 0.04$); and NDHG (AG: 24.0kg, CE: 18.0kg; $p = 0.04$). No significant differences were present in BF% ($p = 0.14$) or VJ ($p = 0.42$). **CONCLUSION:** In addition to being taller and heavier, the AG team cheerleaders demonstrated greater upper body strength and power when compared to females on the CE team. These differences may be attributed to the variety and physical demand of positions available for females on the AG team. This information may be particularly useful to coaches when assigning squad placement or when designing training programs.

Relationship Between Bone Mineral Density and Vertical Jump Performance in Collegiate Athletes
 Sarah N. Lanham, Michelle L. Eisenman, Emily L. Langford, Ronald L. Snarr. *Georgia Southern University, Statesboro, GA.*
 Email: sl03888@georgiasouthern.edu
 (No relevant relationships reported)

Resistance training has been shown to increase bone mineral density (BMD) in athletes due to the increased repetitive loading and stress applied to bone as compared to the general population. Furthermore, plyometric training, a common strength and conditioning modality in most sports, may enhance this loading and stressor effect on bone formation. **PURPOSE:** To compare the relationship between BMD and lower body power, via vertical jump performance, in collegiate male and female athletes. **METHODS:** Seventy-eight (males: $n = 45$, females: $n = 33$) Division-I collegiate athletes, from various sports, performed two trials of squat (SJ) and countermovement (CMJ) akimbo jumps, with the best effort included for analysis. BMD was collected via whole body dual-energy x-ray absorptiometry. Pearson correlations were conducted to determine the relationship between BMD and vertical jump performances (i.e., SJ and CMJ) as a group and within each gender. **RESULTS:** For the entire group, a significant, positive, moderate correlation existed between BMD and SJ ($r = 0.58$, $p < 0.01$), as well as between BMD and CMJ ($r = 0.64$, $p < 0.01$). When factored by gender, there was no significant correlation between BMD and vertical jump for males (SJ: $r = 0.17$, $p = 0.27$; CMJ: $r = 0.28$, $p = 0.07$). However, females retained a significant, positive, low-to-moderate correlation between BMD and both jumps (SJ: $r = 0.35$, $p = 0.04$; CMJ: $r = 0.41$, $p = 0.02$). **CONCLUSION:** Lower body power appears to be positively associated to BMD in a collegiate athletic population, particularly in female athletes. Due to the diverse nature of the sports included in the analysis (e.g., basketball, swimming, cheerleading, tennis, soccer), results may not reflect specific BMD adaptations for those sports requiring increased plyometrics and vertical loading.

Variations in Physiological Fitness Of Starters Vs Non-starters During A Collegiate Women'S Basketball Season
 Monica Taylor¹, Erica Thomas². ¹University of the Sciences, Philadelphia, PA. ²St. Ambrose University, Davenport, IA.
 (Sponsor: Patrick Davitt, FACSM)
 Email: m.taylor@uscience.edu
 (No relevant relationships reported)

Introduction: The ability to maintain strength and conditioning components related to performance throughout an entire competitive season are an important aspect of training for athletes and coaches alike. Currently little is known about the ability of

trained athletes to maintain performance components over the course of the season. **Purpose:** To examine potential changes between pre-season and post-season measures of speed, agility, power, and endurance between players who averaged 20 or more minutes per game and those that averaged less. **Methods:** 14 female collegiate basketball players (average age 18.7±0.21 years) participated. Participants engaged in 2 separate testing periods (end of pre-season and end of competitive season). During each testing period speed, agility, strength, endurance, anaerobic condition, and power were tested using 40-yard dash, Pro-agility test, squat, mile run time, and beep test, respectively. Paired t-tests were used to determine significant differences between testing period 1 and 2. Athletes were also identified as being either a starter (ST), which was an indicator of playing time averaging greater than 20 minutes per game, or non-starter (NST). **Results:** Performance components were measured at the beginning and end of the basketball season. At season start, ST and NST players were statistically similar in regards to all reported tests of performance. Of the components tested at the post-season time point, only two were found to change significantly. Pro-agility scores improved over the course of the season for both ST (pre-season 5.5±0.1, post season 5.1±0.07, $t(5)=2.43$, $p=0.04$) and NST (pre-season 5.6±0.07, post season 5.2±0.07, $t(5)=2.85$, $p=0.01$) players. NST players demonstrated a significant decrease in performance on the 40-yard-dash (pre-season 5.5±0.06, post-season 5.8±0.07, $t(5)=-2.8$, $p=0.02$) while ST players had no difference. For the mile run, NST athletes demonstrated a significant increase in time (3%) when compared to the ST players (0%), with a $p=0.05$. **Conclusion:** These findings demonstrate the ability of female collegiate basketball athletes to maintain, and even improve upon, certain performance related components. For athletes with less playing time, some measures may suffer over the course of the season.

Confirming The Coach's Bias: Power Begets Performance At The Plate

Kento J. Moriguchi, Nathaniel J. Holmgren, J. Mark VanNess, William P. Lydon, Courtney D. Jensen. *University of the Pacific, Stockton, CA.*
Email: k_moriguchi@u.pacific.edu
(No relevant relationships reported)

Baseball coaches value specific traits in their batters; this is reflected in starting lineups. The success of those batters depends on their ability to produce base hits. This is a complex skill affected by many factors, but a key component is the kinematic fingerprint of the swing. **Purpose:** To test which biomechanical domains of a baseball swing predict entry into the starting lineup, and which associate with the likelihood of getting base hits. **Methods:** We enrolled 13 batters from a D1 baseball team (7 starters, 6 non-starters) and conducted 3D analyses of swing mechanics using Proteus (Boston Biomotion, USA). Each athlete performed six sets of five swings at increasing loads between 11b and 9lbs of magnetic resistance. Independent-samples t-tests measured the difference in performance between starters and non-starters, with special attention paid to mean swing power (MSP) and mean swing consistency (MSC, i.e., how accurately successive swings are replicated in 3D space). Logistic regression tested how MSP and MSC affected the odds of being in the starting lineup. Linear regressions measured the effect of MSP and MSC on the number of hits in a season and hits per at-bat. **Results:** Players in the starting lineup had 0.27 ± 0.03 hits per at-bat; non-starters had 0.17 ± 0.15 ($p=0.170$). Starters exhibited a weak trend for lower consistency ($p=0.092$) but generated more power ($p=0.003$) and achieved greater bat speed ($p=0.009$). MSP and MSC were not significant predictors of starting status: for each additional point of MSP, the odds of being a starter increased 29% ($p=0.106$); for each additional point of MSC, the odds were decreased by 24% ($p=0.123$). Owing to a small sample, power was not significantly different throughout the lineup, but consistency was lowest in batters 3-5 ($p=0.048$). Linear regressions found each additional point of MSC to predict 2.1 fewer hits per season ($p=0.029$) while each additional point of MSP predicted an increase of 0.7 hits per season ($p=0.014$). When measuring these effects per at-bat, significance was lost. A post hoc power analysis revealed a need for 6 additional athletes to achieve significance. **Conclusions:** Even in a small sample, analysis of swing mechanics is helpful in determining performance. An increase in swing power associated with more hits and an increase in consistency associated with fewer.

Intervention Of Cordyceps Sinensis On Exercise Fatigue

wenjuan zhen. *Chengdu Sport University, CHENGDU, China.*
Email: 1286245074@qq.com
(No relevant relationships reported)

Purpose: To investigate the intervention of Cordyceps sinensis on exercise fatigue and search for the reasons of such phenomena. **Methods:** Forty 6-week SD rats were randomly divided into two groups: control group ($n=15$) and medicine group ($n=15$) treated with corduceps sinensis (0.004g/ml).

lasted for 10 days, then all rats were trained to swim until exhaustion. Immediately after the exhaustion, test its exhausting time and some biochemical indexes, such as BUN, Blood testosterone and Lactic acid.

Results: Compared with the control group, Exhausted time of medicine group was significantly prolonged (108.23 ± 42.12 vs. 199.05 ± 62.18 min. $p < 0.001$); the blood lactate level was higher (6.75 ± 1.68 vs. 9.35 ± 2.01 mmol/L); the blood testosterone level was higher (0.201 ± 0.098 vs. 0.315 ± 0.068 nmol/L, $p < 0.05$); and the urea nitrogen level was lower (1.89 ± 0.20 vs. 1.52 ± 0.34 nmol/L, $p < 0.05$).

Conclusions: Cordyceps sinensis has the ability to improve the exercise capacity of rats, increase the threshold of lactate, increase the secretion of serum testosterone, inhibit the catabolism of protein, and prevent the decline of lean body mass.

2351 Board #15 May 31 9:30 AM - 11:00 AM
No Changes in Depth Jump Height but Longer Ground Contact Times as Box Height Increases

Cameron D. Addie¹, Emily E. Grammer¹, Marisa K. Straughn¹, Giovanna C. Ramos¹, Tyler J. Neltner¹, Jeffrey D. Simpson¹, Ludmila Cosio Lima¹, Eric K. Greska², Lee E. Brown, FACSM¹.
¹University of West Florida, Pensacola, FL. ²University of Delaware, Newark, DE.
(No relevant relationships reported)

Depth jumps (DJ) are commonly implemented in plyometric training programs in an attempt to enhance lower extremity jump performance. However, it is unknown how different box heights affect jump height (JH) and ground contact time (GCT). **Purpose:** To assess JH and GCT of depth jumps from various box heights. **Methods:** College students who engaged in plyometric training ($M=13$, $F=7$; age: 22.8 ± 2.7 y, height: 175.65 ± 11.81 cm, mass: 78.32 ± 13.50 kg) performed DJs from 30cm (DJ30), 45cm (DJ45), 60cm (DJ60), 76cm (DJ76), and 91cm (DJ91). A 16 camera Vicon system was used to track reflective markers bilaterally to calculate JH (ASIS, PSIS), while a Kistler force plate was used to measure GCT. JH and GCT were compared using separate 2x5 (sex x box height) repeated measures ANOVAs. **Results:** There was no interaction but there was a significant main effect for sex where both JH ($M > F$) and GCT ($F > M$) showed a significant M bias. There was no box height main effect for JH (DJ30 $.4934 \pm .1126$ m, DJ45 $.5003 \pm .1134$ m, DJ60 $.4936 \pm .1195$ m, DJ76 $.4957 \pm .1105$ m, DJ91 $.4783 \pm .1162$ m) but there was for GCT where DJ30 ($.358 \pm .097$ s), DJ45 ($.360 \pm .105$ s) and DJ 60 ($.372 \pm .104$) were not significantly different from each other but were all less than DJ76 ($.396 \pm .116$) and DJ91 ($.420 \pm .115$). **Conclusion:** Increasing box height beyond 60cm increased GCT but did not affect JH. Therefore, practitioners designing plyometric training programs to increase JH that implement DJs may utilize box heights between 30 and 60cm. This would insure minimal GCT which might be vital in other power and speed events.

2352 Board #16 May 31 9:30 AM - 11:00 AM

Effect of Sex on Pacing Behaviour in Elite 1500m Short-Track Speed Skating Competitions

Lars van Leeuwen¹, Marco J. Konings², Florentina J. Hettinga, FACSM³. ¹Rijksuniversiteit Groningen, Groningen, Netherlands. ²University of Essex, Colchester, United Kingdom. ³Northumbria University, Newcastle upon Tyne, United Kingdom. (Sponsor: Dr Florentina Hettinga, PhD, SFHEA, FECSS, FACSM)
(No relevant relationships reported)

Purpose: The aim of this study is to examine the effect of sex on pacing behavior during elite 1500m short-track speed skating events. **Methods:** In short-track speedskating, a 1500m race is 13.5 laps. Lap times from 13805 skating performances from World Cups, World and European Championships and the Olympics in the seasons 2012/2013 up until 2017/2018 were collected from the ISU website and examined using ANOVA statistical analysis in which lap velocities were chosen as dependent variables and sex was chosen as independent variable ($p < .05$). In order to compare men (M) and women (W), the data were normalized by calculating individual mean velocities, and dividing those by the actual lap velocity. This gave percentage of mean velocity as outcome variable. **Results:** Pacing behavior of both sexes is shown in figure 1. The absolute velocities male short-track speed skaters achieved are significantly higher than female skaters achieved in every lap ($p < .001$). Examining the normalized lap velocities, significant differences occurred as well. Men demonstrated relatively higher velocities up until lap 5 (lap 1 to 5, M: 0.86 ± 0.08 , W: 0.85 ± 0.09 , $p < .001$). In lap 6, no significant difference in velocity was found (M: 1.04 ± 0.07 , W: 1.04 ± 0.08 , $p = .109$). Nonetheless, in lap 7 until the final lap 14, women demonstrated relatively higher velocities than men (for lap 7 to 14, M: 1.11 ± 0.20 , W: 1.12 ± 0.10 , $p < .001$). **Conclusion:** Elite men are faster than elite women in absolute velocity. Additionally, elite men and women short-track speed skaters show different pacing behavior in a 1500m race in which men start more aggressively and finish slower than women do.

Quantitative Impact Of Individual Lower Limb Muscle Volumes On Athletic Performances

Xue Feng¹, Tianyuan Xie¹, Craig Meyer², Silvia Blemker², Joseph M. Hart, FACSM². ¹Springbok, Inc, Charlottesville, VA. ²University of Virginia, Charlottesville, VA. (Sponsor: Joe Hart, FACSM)
 Email: xfeng@springbokanalytics.com
 Reported Relationships: X. Feng: Ownership/interest/stock; Springbok, Inc.

Lower limb skeletal muscles play an important role in athletic performances. However, due to the difficulty in obtaining detailed information of each individual muscle, their quantitative impact on performance is unknown. High resolution magnetic resonance imaging (MRI) of the muscles can be used for accurate measurements of the volumes of each muscle and study their quantitative impact on performances. **PURPOSE:** To develop an accurate muscle volume measurement tool using MRI and use it to study the quantitative impact of individual volume on performances of jump and sprint on basketball players. **METHODS:** 10 male varsity basketball players and 8 club players were recruited in this study. MRI was performed on a Siemens 3T Trio scanner using a customized sequence based on the spiral k-space sampling method. Proton-density weighted images of the entire lower limb from T12 to the ankle were acquired with multiple stacks. Manual segmentation was performed to delineate the boundary for all 35 muscles on each leg, followed by volume calculation and normalization to account for differences in body size. All subjects were instructed to perform various jump and sprint tests. Correlations between muscle volumes and each performance metric were studied on both the varsity and club groups. Feature selection was used to reduce the number of relevant muscles, followed by a linear regression model to study the quantitative impact of the selected muscles on each performance metric. **RESULTS:** Vastus medialis and semimembranosus were selected as the most important muscles for jump while adductor longus and vastus medialis were selected for sprint. Strong correlations ($r=0.833$) between the selected muscles and associated performances were found for varsity players and moderate correlations ($r=0.507$) were found for club players. **CONCLUSIONS:** MRI can provide accurate quantitative measurements of muscle volumes, which have heterogeneous impact on different athletic performances. This information can be used for an improved training scheme that targets specific muscles, especially for high level athletes.

Andrew R. Hill^{1,2}, Daniel L. Laudermilk¹, Soon-Mi Choi¹. ¹Midwestern State University, Wichita Falls, TX, ²Endunamoo Strength & Conditioning, Wichita Falls, TX.

Post activation potentiation (PAP) is defined as a short-term improvement in performance as a result of using a resistance exercise. The phenomenon of PAP has been shown to acutely increase athletic performance with back squats as an effective modality. **PURPOSE:** This study investigated acute effects of different back squat intensities on the countermovement vertical jump (CMJ). **METHODS:** Participants were 13 to 18-yr-old healthy male ($n=8$) and female ($n=3$) who participated in regular resistance training for at least 6 months and have played in a University

Interscholastic League (UIL) within the past 6 months. One Repetition Maximum (1-RM) was measured within 4 weeks before testing and all participants abstained from strenuous exercise for 48 hours prior to testing. Each participant performed a standard warm-up for 5 minutes and measured a baseline (PRE) CMJ by a Vertec®. One minute of resting interval time was provided after PRE test. The CMJ performed by a randomized counterbalanced order with repeated measures under five different barbell back squat trials: 70, 75, 80, 85, and 90% of 1-RM. Between each barbell back squat trial and CMJ test, the participants rested for one minute. Peak power values were estimated by equation (Harman Formula): Peak power (W) = 61.9 · jump height (cm) + 36.0 · body mass (kg) + 1,822. All Data were represented mean and standard deviation and analyzed by one-way ANOVA with repeated measures. **RESULTS:** There was no significant difference at 70, 85, and 90% of 1-RM. The CMJ increased significantly in 1-RM 75% (PRE: 51.3 ± 13.9 cm, 75%: 52.8 ± 13.6 cm, $p=.036$). At 1-RM 80%, increasing tendency was shown (PRE: 51.3 ± 13.9 cm, 80%: 52.8 ± 14.5 cm, $p=.069$). **CONCLUSION:** The results may indicate that barbell back squat at 75-80% of 1-RM can improve a CMJ performance acutely in adolescence who plays in UIL level.

Comparison Of Exercise Intensity Between Folk Dance And Walking In Healthy Female

Kumiyo Kai. Nihon Fukushi University, Mihama, Japan.
 Email: kumiyo@n-fukushi.ac.jp
 (No relevant relationships reported)

Dance promotes physical health, mental health, and social health. Dance has gained popularity especially by women of all ages as an activity for health and fitness. In Japan, dance is a part of requirements in middle school PE core curriculum. Hip-hop dance, creative dance and folk dance are recommended to teach in PE. However, the research on physical aspects of folk dance is still few. **PURPOSE:** To measure the heart rate and the exercise intensity while dancing folk dance and compare those to walking. **METHODS:** Heart rate of 7 healthy female (21.1±0.4 yrs) were recorded using the heart rate monitor (Polar, RC3GPS) while 1) dancing folk dance "Virginia Reel" with music (duration 7min 30sec, 116 bpm) and 2) walking for the same duration with same music in their own pace (the average speed was 83.7±8.6m/min). Exercise intensity was calculated by using maximum heart rate (%HRmax) and heart rate reserve (%HRR). Perceived exertion was measured by the Borg Rating of Perceived Exertion (RPE) 6-20 Scale. Independent t-test was performed with p value under 0.05 considered significant. **RESULTS:** The heart rate while dancing was significantly higher than that of walking (dance 118.9±7.2bpm, walking 93.9±9.5bpm, $p<.05$). %HRmax and %HRR of dance were significantly higher than those of walking (%HRmax dance 59.5±3.5%, walking 47.0±4.7%, $p<.05$; %HRR dance 39.0±4.4%, walking 20.2±5.5%, $p<.05$). RPE of dance was significantly higher than that of walking (dance 13.1±1.2, walking 10±1, $p<.05$). The maximum heart rate during trial was 153±6.8bpm in dance and 111.2±26.5bpm in walking. According to ACSM classification of exercise training intensity, intensity of dance was light to moderate (intensity moderate in %HRmax, light in %HRR, moderate in RPE) and walking intensity was light in all three measures. **CONCLUSION:** Although heart rate, %HRmax, and %HRR of dance are higher than those of walking, the exercise intensity of dance is light to moderate. Dance can be a beneficial physical activity for beginners but we need to consider the pace of dance to meet sufficient intensity.

VO_{2peak} Associated With Breath Hold Capacity In Surfers

Cory J. Greever, Kaden Groseclose, April Denny, Adele Looper, Danielle Jones. California Polytechnic State University, San Luis Obispo, CA.
 Email: greever@calpoly.edu
 (No relevant relationships reported)

Competitive surfing is a growing sport with evolving performance and safety demands. One particular challenge surfers face is the need to endure long breath holds following bouts of surf paddling. **PURPOSE:** The purpose of this study was to examine the association between aerobic fitness markers, such as VO_{2peak}, and ventilatory thresholds, and post-paddling breath hold capacity in competitive surfers. **METHODS:** Eleven male collegiate level competitive surfers completed both a maximal graded exercise test and a simulated post-paddling breath hold challenge on a modified paddling ergometer. Associations between markers of aerobic fitness and post-paddling breath-hold capacity were tested using linear regression modeling. **RESULTS:** The overall regression model indicated a positive linear association between the assessed markers of aerobic fitness and post-paddling breath-hold capacity ($r = .828$, $r^2 = 0.686$, $p = 0.035$). This association was explained by differences in VO_{2peak} ($\beta = 0.975$, $p = .034$). **CONCLUSION:** These findings suggest that VO_{2peak} may be an important training target for programs aimed at improving breath hold capacity in surfers.

Shoulder Range Of Motion: Comparison Between Dominant And Non-dominant Sides In Elite Young SwimmersSandra L. Prieto¹, Juan C. Mazza², Mauricio Serrato¹, Raúl R. Festa², Patricia Cosolito². ¹Colombia State University, Bogotá D.C., Colombia. ²Biosystem Institute Sports Sciences, ROSARIO, Argentina.

Email: sanlilipri@hotmail.com

(No relevant relationships reported)

The joint range of motion (ROM) is related to flexibility, constituting a physical quality that influences in technical skills and biomechanical economy of movement; however, this physical ability has been little investigated in different sport's disciplines, so they are unknown normative ranges for specialties and competition level, especially related with dominance of the athletes. The shoulder complex of swimmer is submitted to a high number of repetitions, especially overhead, to achieve propulsion and overcome aquatic drag, requiring joint's symmetry of movement, from side to side. **PURPOSE:** To describe active and passive ROM, testing shoulder complex, identifying differences between side to side, in elite young swimmers that belong to Bogotá State's Team. **METHODS:** Fifty one healthy young swimmers participated in a cross-sectional study (23 males, 28 females; age: 16.51±1.10 yr; weight: 59.86±7.74 kg; height: 167.32±9.05 cm). We include subjects with no previous shoulder injuries. Seven tests were performed for Active and Passive ROM (flexion, abduction and extension; horizontal adduction and abduction; medial and lateral rotation). Mean and standard deviations (SD) values were calculated by dominant and non-dominant shoulder, for all ROM measurements. We applied paired t-test to determine statistical differences (sd) between dominant and non-dominant shoulder, at $p < 0.05$. **RESULTS:** Analyzing shoulder active ROM in males, we have found sd for Active medial rotation between dominant (93.74±13.97°) and non-dominant (99.09±16.23°) sides ($p < 0.05$); also sd for Active lateral rotation between dominant (97.83±11.24°) and non-dominant (91.70±6.12°) sides ($p < 0.0001$). In females, we have found sd for Active medial rotation between dominant (87.21±13.91°) and non-dominant (89.5±7.70°) values ($p < 0.05$); also sd for Active lateral rotation between dominant (101.14±9.18°) and non-dominant (97.46±9.74°) values ($p < 0.003$). No sd were found in Active and Passive ROM, for other variables measured. **CONCLUSIONS:** We found symmetrical shoulder ROM's values, side to side, for elite young swimmers, except for Active medial and lateral rotation, in both genders. Probably, this evidence does not allow load balance and should be considered as a risk factor of "swimmer's shoulder" painful.

Performance Across Quarters In An International Field Hockey TournamentJohn G. Morris¹, Luke E. Hazell¹, Nick Shedd², Caroline D. Sunderland¹. ¹Nottingham Trent University, Nottingham, United Kingdom. ²USA Field Hockey, Colorado Springs, CO.

Email: john.morris@ntu.ac.uk

(No relevant relationships reported)

In 2014 the structure of international field hockey matches moved from 2 x 35-minute halves to 4 x 15-minute quarters. The intention was to create a higher intensity, faster paced and more exciting game. The physical challenges presented by the new game structure are largely unknown. **PURPOSE:** This study examined the presence and extent of performance decrements across quarters in matches during an international women's field hockey tournament. **METHODS:** Twenty international, female field hockey players (mean ± SD: age 23.0 ± 2.9 y, body mass 59.9 ± 4.9 kg, height 161.5 ± 4.8 cm) participated in the study. Seven matches from one international tournament were analysed. Based on global positioning satellite data, locomotor activities were categorised into three bands corresponding to low (0.00 - 1.68 m s⁻¹), moderate (1.69 m s⁻¹ - 4.18 m s⁻¹), and high (4.19 m s⁻¹ - > 5.27 m s⁻¹) speed running. Data were analysed using a two-level repeated measures multi-level model, with match number at level 1 and player at level 2. Model fit was assessed using the -2*loglikelihood statistic. **RESULTS:** During the tournament the total distance completed by players was 1778 (258), 1620 (229), 1613 (225), 1501 (255) m in quarters 1 to 4 respectively (mean and standard deviation). The corresponding averages for high speed running were 376 (181), 297 (146), 310 (135), 276 (125) m respectively. When controlling for position, the decrement in high-speed distance covered in quarter 2, 3 and 4 compared with quarter 1 was -78, -64 and -98 m respectively (all $P < 0.05$ compared with quarter 1). **CONCLUSIONS:** This study demonstrates that players cover their maximum total distance and high-speed distance during quarter 1, but are unable to maintain this performance level in the remaining quarters of a match during an international hockey tournament.

Performance-Related Variables That Are Associated With Finish Time in an Olympic Distance TriathlonTodd Buckingham¹, Rebecca W. Moore², David P. Ferguson¹, Nicholas D. Myers¹, Karin Pfeiffer, FACSM¹. ¹Michigan State University, East Lansing, MI. ²Eastern Michigan University, Ypsilanti, MI.

Email: buckin21@msu.edu

(No relevant relationships reported)

Wearable devices allow athletes to track an abundance of sports performance variables. However, the amount data can be overwhelming. Most triathletes wear these devices during training and racing. This technology could allow researchers to obtain performance-related variables during triathlon competition from the three disciplines to improve performance. **PURPOSE:** Determine if/which performance-related variables from wearable devices are associated with better in-race performance in each discipline (swim, bike, run), and overall, during an Olympic distance triathlon for amateur triathletes.

METHODS: Participants were amateur triathletes who completed an Olympic distance triathlon during 2016 or 2017 and used a Garmin multisport watch that recorded race performance. Participants completed a questionnaire and included a data file from their Garmin watch that linked to an Olympic distance triathlon race where performance-related variables could be analyzed. One variable was examined for each discipline: SWOLF, cycling cadence, and running stride length. All triathlon times were obtained from the website of the race that each participant completed. Pearson correlations assessed relationships between the performance-related variables and time in each of the three disciplines, and overall finish time. A multiple linear regression was performed to determine percent variance accounted for in overall finish time by the performance-related variables. Covariates were age and sex.

RESULTS: One-hundred thirty triathletes (37.7±10.4 years, 34.6% female) submitted complete questionnaires. SWOLF ($r = 0.788$, $p < 0.01$; $r = 0.600$, $p < 0.01$), cycling cadence ($r = -0.401$, $p < 0.01$; $r = -0.477$, $p < 0.01$), and running stride length ($r = -0.871$, $p < 0.01$; $r = -0.822$, $p < 0.01$) were all significantly related to their respective discipline and overall. The multiple linear regression revealed that the three performance-related variables accounted for 71% of the variance in official finish time ($R^2 = 0.710$).

CONCLUSIONS: By determining the three performance-related variables that are most strongly correlated with individual discipline and overall Olympic distance triathlon finish time, triathletes can now focus on these variables to produce faster race times.

Assessing the Differences Between a Governed and Non-Controllable Focal Point on Male Broad Jump PerformanceAndy Bosak¹, Robert Sanders², Hannah Nelson¹, Madeline Phillips¹, Branden Ziebell¹, Russell Lowell¹, Jared Feister¹. ¹Liberty University, Lynchburg, VA. ²The University of Mississippi, Oxford, MS. (Sponsor: James Schoffstall, FACSM)

Email: ambosak@liberty.edu

(No relevant relationships reported)

Prior studies have investigated the manipulation of a visual target (i.e. sport specific focal point, non-controllable, or governed focal point) on vertical jump performance, yet few studies have examined factors that directly impact broad jump performance. The broad jump (BJ) test is often utilized to determine how far a person can jump and is a measurement of an individual's horizontal power ability. A previous focal point broad jump study utilizing female subjects suggested that BJ performance may slightly increase when using a governed focal point. However, this has not been evaluated using a male population. **PURPOSE:** To examine the impact of a governed (i.e. set focal point) vs. non-governed (i.e. no set focal point) focal point on broad jump performance in active males. **METHODS:** Thirty-three no less than averagely fit collegiate males had their descriptive data (Ht. = 174.97 ± 6.82 cm, Wt. = 81.85 ± 10.52 kg, BF% = 15.22 ± 5.76%, age = 22.00 ± 1.70 yrs) collected. Subjects completed an 8 min dynamic warmup and then received a four minute passive recovery (PR) period. Subjects then completed four familiarization broad jumps (ie. a jump series). After another four minute PR period, subjects completed two series of jumps (ie. four trials apiece with 60 seconds of PR between each jump) in a counterbalanced order with either a governed focal point (FP) or non-governed focal point (NFP) being utilized for each jump. The FP and NFP jump series were separated by 4 min of PR. The farthest jump for FP vs. NFP was compared using Paired-Samples t-Tests with significant differences occurring at $p \leq 0.05$. **RESULTS:** Significant differences ($p = 0.015$) occurred between FP (235.46 ± 21.59 cm) and NFP (233.33 ± 22.49 cm). Also, nineteen subjects highly benefited from utilizing a governed focal point with a mean jump increase of 5.26%. **CONCLUSION:** It appears that using a focal point (FP) may elicit a farther jump in no less than averagely fit males as compared to utilizing a non-controlled focal point (NFP). Further research may be required to evaluate the impact

of a sport specific focal point vs. a generic set focal point on broad jump performance with males and females who participate in sports where horizontal power is highly associated with improved sport performance.

Relationship of Lumbopelvic-hip Stability on Ball Speed in Female Windmill Softball Pitchers

P. T. Williams, J. W. Barfield, G. D. Oliver, FACSM. *Auburn University, Auburn, AL.* (Sponsor: Gretchen Oliver, FACSM)
 Email: ptw0007@tigermail.auburn.edu
 (No relevant relationships reported)

The dynamic movement of the windmill softball pitch requires the body acting as a kinetic chain working in a proximal to distal manner. Optimal energy transfer from the lower to upper extremity requires the stability of the lumbopelvic-hip complex (LPHC). **PURPOSE:** To examine the differences in knee valgus between LPHC stability groups, defined by knee valgus while performing a single leg squat (SLS), and if knee valgus could predict ball speed during the windmill softball pitch. **METHODS:** Eleven right-handed softball pitchers (13.7 ± 2.1 yrs; 163.8 ± 8.0 cm; 66.3 ± 11.0 kg; 48.4 ± 5.1 mph) volunteered to participate. Kinematic data were collected via an electromagnetic tracking system. Participants performed a SLS on their stride leg (left leg) and threw 3 fastballs for strikes to a catcher (43 ft). Stride leg knee valgus was assessed at 45° of knee flexion during the SLS and top of back swing (TOB), foot contact (FC), and ball release (BR). **RESULTS:** There was no statistical differences in knee valgus between groups (stable vs unstable) at the pitching events of TOB ($F_{(1,10)}=0.03$; $p=0.86$); FC ($F_{(1,10)}=0.01$; $p=0.91$); and BR ($F_{(1,10)}=0.23$; $p=0.64$). Examining knee valgus at the pitching events as a predictor of ball speed revealed no significance ($F_{(3,7)}=0.64$, $p=0.62$, $R=0.46$, $R^2=0.21$). **CONCLUSION:** In this study, there was no difference in knee valgus between LPHC stability groups as determined in the SLS. Overall knee valgus, at the pitching events, did not predict ball speed. As knee valgus is an outcome of an unstable LPHC, the authors postulated that having less knee valgus during the pitching cycle would have assisted in energy transfer and thus increased ball speed in windmill softball pitching. Limitations to this study include the small sample size used. Future studies should consider a multivariable model to determine LPHC stability and examine the influence of the trunk at events within the windmill softball pitching cycle to determine their effect on increasing ball speed.

Mean and standard deviations of knee valgus (in degrees) and ball speed (mph)

| LPHC stability | Pitching events | Mean(SD) |
|----------------|-----------------|-------------|
| Stable | TOB | -4.15(10.5) |
| | FC | -3.53(10.6) |
| | BR | 2.35(6.2) |
| Unstable | TOB | -5.17(5.5) |
| | FC | -4.21(5.3) |
| | BR | 0.27(8.2) |
| Ball speed | Stable | 50.4(3.1) |
| | Unstable | 44.7(6.3) |

Effects of Optimizing the Respiratory Pump on Performance During a Simulated Ice Hockey Period

Peggy A. Plato¹, Kurtis Rayfield¹, Victor A. Convertino², Craig J. Cisar, FACSM¹. ¹San Jose State University, San Jose, CA. ²US Army Institute of Surgical Research, Fort Sam Houston, TX.
 Email: Peggy.Plato@sjsu.edu
 (No relevant relationships reported)

Ice hockey requires high-intensity activity during shifts with inactive recovery between shifts. During recovery periods, blood may pool in the legs, reducing central blood volume and the ability to clear lactic acid. Impedance threshold devices (ITD) were developed to treat conditions of central hypovolemia, such as hemorrhage. By creating a negative intrathoracic pressure, venous return is enhanced, increasing stroke volume and cardiac output. **PURPOSE:** To determine the effects of breathing with an ITD during recovery periods between simulated ice hockey shifts. **METHODS:** Five male collegiate ice hockey players skated a course, the Peterson On-Ice Repeated Sprint Test, eight times (shifts) with 90 s recovery between each shift. Each athlete completed two test sessions separated by 48 hr, one while breathing freely during the recovery periods (control condition) and one while breathing with the ITD during the recovery periods. **RESULTS:** Performance, measured as time to skate the course, was similar between conditions ($p > .05$). Average time to complete each shift was 22.10 ± 0.74 s (SEM) and increased with successive shifts. After shift 4, lactate was 12.0 ± 0.8 mM

(control) and 11.0 ± 2.0 mM (ITD). After skating eight shifts, lactate continued to increase during the control condition (14.0 ± 0.4 mM) and was 28% higher than the ITD condition (10.9 ± 1.5 mM). Ratings of perceived exertion increased from shift 1 to shift 8 with the average slope of increase greater for the control condition (0.87, 95% CI 0.80-0.94) than the ITD condition (0.65, 95% CI 0.60-0.70, $Z = -7.54$, $p < .001$). **CONCLUSIONS:** Breathing with the ITD during recovery periods did not affect skating performance measured as time to complete each shift, but lactate was lower after shift 8 and athletes rated their exertion lower during the ITD condition. Thus, use of an ITD has potential to enhance recovery during repeated bouts of high-intensity, intermittent exercise.

Influence of Loaded Lunge Performance on Functional Movement Screen Deep Squat Performance in Physically Active Individuals

Eric P. Scibek, Matthew F. Moran, Mary C. Hemmer, Louis R. Castro. *Sacred Heart University, Fairfield, CT.*
 Email: scibeke@sacredheart.edu
 (No relevant relationships reported)

The Functional Movement Screen Deep Squat (DS) is used to assess the quality of fundamental movement patterns. Specifically, the DS assesses musculoskeletal stability and mobility at the ankle, knee, and hip. The DS score is added to a composite score to identify individuals at risk for musculoskeletal injury. **PURPOSE:** To examine the influence of ankle range of motion (ROM), as measured during a weight bearing lunge, on the individual scoring criteria and overall score for the DS. **METHODS:** Twenty-two college aged, physically active subjects (11 M, 11 F, 20.3 ± 1.0 yo) were recruited and completed testing. Bilateral peak weight bearing ankle dorsiflexion ROM was measured with a digital inclinometer during the loaded lunge test, with the lower bilateral scores being retained. Participants performed three trials of the DS with their feet flat and three trials with their heels elevated on a 2x6 block. Standard FMS scoring criteria were applied to assign a score of 3, 2, or 1. Successful completion of the DS requires: 1. torso to be parallel with the tibia or toward vertical, 2. femur to be parallel with the floor or below, 3. knees to track over the toes, & 4. dowel cannot move beyond the toes. A one-way ANOVA with a Bonferoni post hoc test and independent t-tests were used to determine significance ($p \leq 0.05$) for the influence of ankle dorsiflexion ROM on DS scores and the presence of the four individual DS dysfunctions respectively. **RESULTS:** There was a significant difference in ankle dorsiflexion for DS scores [$F(2, 19) = 5.20$, $p=0.016$]. Post hoc testing revealed a significant difference in dorsiflexion ROM between a score of 3 ($51.4^\circ \pm 9.7^\circ$) and a score of 1 ($39.5^\circ \pm 5.6^\circ$). There was a significant difference ($p=0.001$) in ankle dorsiflexion for participants that met the torso/tibia criteria ($51.0^\circ \pm 7.6^\circ$) compared to participants that did not meet the criteria ($40.1^\circ \pm 5.0^\circ$), and for participants that met the dowel position criteria ($50.5^\circ \pm 5.0^\circ$) compared to those that did not meet the criteria ($41.5^\circ \pm 6.3^\circ$) ($p=0.016$). **CONCLUSION:** Participants with limited weight bearing ankle dorsiflexion ROM are more likely to score a 1 and exhibit a forward lean and bar position during the DS. This information will guide a clinician's corrective exercise approach for individuals that exhibit these DS dysfunctions.

Could Hip Joint Position Induce Different Metabolic and Muscular Responses After Knee Extension?

Marco A. Dourado¹, Denis C. L. Vieira¹, Lucas Ugliara¹, Lee E. Brown, FACSM², Martim Bottaro¹. ¹University of Brasilia, Brasilia, Brazil. ²California State University, Fullerton, CA.
 (Sponsor: Lee E. Brown, FACSM)
 Email: profmarcodourado@gmail.com
 (No relevant relationships reported)

The positioning of the back of the seated knee extension exercise alters hip joint position, which in turn modifies the muscle length of the rectus femoris. The increase the angle between the seat and the back of the chair allows a greater stretching of the rectus femoris a condition that theoretically may have an influence on knee extensors force production and consequently may have an impact on muscle metabolic response. It has been hypothesized that acute muscle thickness (MT) swelling in response to exercise may occur due to an increase in intracellular osmotic concentration secondary and byproduct accumulation. Thus, hip angle position may also have an impact on knee extensors metabolic responses. **PURPOSE:** This study investigated the acute effects of two different hip joint position during seated knee extension training on MT swelling and torque production in young individuals. **METHODS:** Seven healthy men (25 ± 4 yrs) underwent two sessions of isokinetic training in different hip joint positions (0° and 90°, 0° full extension). Participants performed 5 sets of 10 repetition of concentric isokinetic exercise at 60%/s; with 1-minute rest between sets. Sessions were 72h apart. Muscle thickness (MT) were measured by ultrasound before and after the exercises session. **RESULTS:** Paired t-test showed no significant differences for the PT at 90° hip position (252.81 ± 21.32 N.m) and 0° (251.38 ± 17.18 N.m). There was no significant difference ($p>0.05$) on MT of rectus femoris and vastus

lateralis between positions. Rectus femoris MT increased from 31.08 + 3.09 mm to 35.74 + 2.78 mm at 90°, and from 29.76 + 3.48 mm to 34.46 + 2.40 mm at 0°. Vastus lateralis MT increased from 31.37 + 6.05 mm to 33.35 + 7.04 mm at 90°, and from 31.45 + 6.32 mm to 32.72 + 6.14 mm at 0°. **CONCLUSION:** Resistance trained men experience same metabolic and muscular responses of the knee extensors following the two different hip joint positions exercises. Thus, the practice of using different hip positions in an attempt to maximize metabolic responses may be discontinued.

Cardiorespiratory Assessment of Professional Brazilian Surfers

Franz H. Burini¹, Rafael Rezende¹, Pedro Rodstein¹, Thales Messoria¹, Angelo Tadayoshi¹, Paulo Mendes². ¹UNESP Medical School, Botucatu, Brazil. ²Surf Co., São Paulo, Brazil. (Sponsor: Roberto C Burini, FACSM)
Email: fburini@fmb.unesp.br
(No relevant relationships reported)

Surfing demands multifactorial physical fitness and continuing interaction with environmental variables. Sports specific assessment is mandatory in elite athletes and should focus on fitness variables such as cardiorespiratory, muscle strength, power and balance.

PURPOSE: The purpose of this study was to evaluate 10 elite Brazilian surfers for cardiorespiratory fitness during a specific sport protocol.

METHODS: 9 elite surfers (19±4 years) were evaluated for cardiorespiratory fitness using a portable metabolic analyzer (K4b²-COSMED®) for VO₂max on a pool. The protocol was structured to increase load every 2 minutes with different elastic rubber bands (8 bands with different increasing elastic capacity each) fixed on athletes surfing board, and the test was considered maximum within voluntary fatigue (BORG scale) or VO₂ plateau or RQ>1.1. Values were expressed as Mean ± standard deviation.

RESULTS: Mean values for VO₂max were 47±9 mL/kg.min⁻¹ (43-59 mL/kg.min⁻¹). None of the athletes reported clinical symptoms of cardiovascular considerations.

CONCLUSIONS: Surfers athletic performance should be focused on a multifactorial matter, and fitness evaluation should consider specific demands. For VO₂ analyses, this specific protocol would be considered feasible and should be encouraged.

Effective Stretching Position for the Tightness of Posterior Shoulder Capsule Determined by Shear Wave Elastography

Naoya Iida, Keigo Taniguchi, Kota Watanabe, Hiroki Miyamoto, Tatsuya Taniguchi, Mineko Fujimiya, Masaki Katayose. Sapporo Medical University, Sapporo, Japan.
Email: iidan0512@gmail.com
(No relevant relationships reported)

PURPOSE: Stretching is often used to treat and prevent the posterior shoulder capsule tightness; however, effective stretching positions remain unclear. We aimed to identify stretching positions that applied greatest passive force on the posterior shoulder capsule by evaluating elastic characteristics in various stretching positions via ultrasound shear wave elastography (SWE). **METHODS:** Nine fresh-frozen shoulders (age 86.6±7.7 years) without osteoarthritis or rotator cuff tears were investigated. All posterior shoulder tissues including muscle and skin were preserved intact. The shear elastic moduli of the middle and inferior posterior shoulder capsules were evaluated via SWE. Shear elastic modulus measurements were performed in 9 stretching positions using a combination of several shoulder elevation planes (frontal, sagittal, scapular) and elevation angles (-30°, 0°, 30°, 60°). Torque of 4 Nm for shoulder internal rotation or horizontal adduction was applied in each stretching position. Shear elastic moduli were measured in resting positions at 0° of elevation with neutral shoulder internal/external rotation. The shear elastic moduli in all stretching and resting positions were compared using one-way repeated-measures analysis of variance ($p < .05$). **RESULTS:** Shear elastic modulus values for middle posterior capsules in internal rotation at 30° of scapular plane elevation (86.1±43.0 kPa, $p = .01$) and horizontal adduction at 60° of elevation (93.2±39.3 kPa, $p < .001$) were significantly higher than the values in the resting position (33.1±21.9 kPa). Additionally, the shear elastic modulus value for the inferior posterior capsule in internal rotation at 30° of flexion was significantly higher than the value in the resting position (117.1±51.9 vs. 46.1±41.6 kPa, respectively; $p = .004$). **CONCLUSION:** We demonstrated that effective middle posterior shoulder capsule stretching positions were shoulder internal rotation at 30° of scapular plane elevation and horizontal adduction at 60° of elevation. Shoulder internal rotation at 30° of flexion was the most effective position for the inferior posterior shoulder capsule. Stretching in these positions to relieve tightness of posterior shoulder capsules could contribute to treatment and prevention of throwing shoulder injuries.

Phase Change Material Cooling Reduces Indices of Muscle Damage and Does Not Inhibit Acute Adaptation

Susan Y. Kwiecien¹, Malachy P. McHugh, FACSM¹, Denis J. O'Hara¹, Glyn Howatson, FACSM². ¹Nicholas Institute of Sports Medicine and Athletic Trauma, Lenox Hill Hospital, New York, NY. ²Northumbria University, Newcastle upon Tyne, United Kingdom. (Sponsor: Glyn Howatson, FACSM)
 Email: susan@nismat.org
 (No relevant relationships reported)

Phase change material (PCM) cooling has been shown to decrease muscle damage and accelerate recovery. However, the effects of cryotherapy on the adaptive response to exercise are not well understood. The repeated bout effect (RBE) is a protective adaptation to an initial bout of eccentric exercise and serves as a model to examine acute adaptation.

PURPOSE: To examine (1) the effect of PCM cooling on muscle damaging eccentric exercise, and (2) whether application of PCM cooling blunts the adaptive RBE response.

METHODS: Twenty males (24±5 yo) performed 120 eccentric quadriceps contractions on each leg at 90% of isometric strength and were randomized to receive PCM packs frozen at 15°C (treatment) or melted packs (control) worn inside shorts for 6 h post exercise. Prior to exercise, and on each of the subsequent 3 days, pain, strength, creatine kinase activity (CK) and high sensitivity C-reactive protein (hsCRP) were measured. The protocol was repeated 2 weeks later with all subjects receiving melted PCMs after the repeated exercise bout. Treatment and RBE were assessed using treatment and/or bout x time ANOVA.

RESULTS: The exercise caused pain in both groups (P = 0.0001) with less pain in the PCM group (P = 0.021). There was an RBE for pain (P = 0.0001) with no difference between treatments (P = 0.38). There was an increase in strength in the PCM group (P = 0.001; treatment x time effect P = 0.035) with no strength loss in the control group (P = 0.90). The RBE for strength differed between treatments (P=0.005); strength increased after the initial bout in the PCM group but not after the repeated bout (P=0.006), while strength was unchanged in the control group (P=0.55). CK was elevated in both groups (P < 0.01) with no difference between groups (P = 0.46). There was a RBE for CK (P = 0.0001) with no difference between groups (P = 0.84). The exercise did not elevate hs-CRP (P = 0.49) with no difference between groups (P = 0.94).

CONCLUSIONS: PCM cooling reduced pain following damaging exercise. While the protocol was insufficient to cause strength loss, it is notable that PCM cooling elevated strength on the days after eccentric exercise. Importantly, the RBE was not compromised by PCM cooling.

Effects Of Photobiomodulation Therapy On Fatigue And Muscle Damage In Judo Athletes

Rafael Kons¹, Lucas Bet da Rosa Orsatto², Raphael Luiz Sakugawa¹, Jorge Nelson Junior¹, Fernando Diefenthaler¹, Daniele Detanico¹. ¹Federal University of Santa Catarina, Florianópolis, Brazil. ²Queensland University of Technology, Brisbane, Australia.
 Email: rafakons0310@gmail.com
 (No relevant relationships reported)

PURPOSE: Photobiomodulation therapy (PBMT) has emerged as an effective non-invasive strategy to attenuate fatigue and muscle damage when applied before different types of exercises; however, there is no evidence regarding PBMT effects on fatigue and muscle damage in judo athletes. Thus, the aim of our study was to investigate the PBMT effect on fatigue and muscle damage in judo athletes.

METHODS: This was a randomized, triple-blind, placebo-controlled trial study. Sixteen judo athletes (four purple, five brown and seven black belts; 23.1±3.8 years, body mass 77.9±14.9 kg, height 173.1±8.9 cm, 17.5±7.3% of body fat, and 12.9±5.0 time of practice) had their preferred and non-preferred lower limbs randomized for PBMT, while the contralateral limb received placebo at knee extensors, flexors, and plantar flexors muscles (total dose=450J). They performed a protocol of 10 sets of 10 reps (1 min rest) of maximal countermovement jumps (CMJ) to induce muscle fatigue and damage. *Rectus femoris* echo intensity (EI_{RF}), unilateral CMJ, and muscle soreness were assessed for each lower limb in different time points: before, during (5th set), post (immediately after), and 24 and 48 h after the protocol, as presented in Table 1. Two-way ANOVA repeated measures compared treatment-time interaction with Bonferroni post hoc when appropriate (p<0.05).

RESULTS: There was no treatment-time interaction for any of the investigated variables (F=0.690, p>0.262), while time effect was observed (F=15.009, p<0.001). Table 1 shows the mean and standard deviation and depicts time differences.

Table 1. CMJ impulse, rectus femoris echo intensity (EIRF), and muscle soreness for placebo and PBMT.

| Variables | Treatment | Baseline | 5 th set | Post | 24h | 48h |
|------------------------------|-----------|----------------------|---------------------|----------------------|----------------------|----------------------|
| CMJ _{IMPULSE} (N's) | Placebo | 136±20 ^A | 121±18 ^B | 115±20 ^B | 130±24 ^C | 126±33 ^C |
| | PBMT | 141±27 ^A | 120±20 ^B | 117±25 ^B | 137±18 ^C | 134±28 ^C |
| EI _{RF} (a.u.) | Placebo | 124±11 ^A | - | - | 151±19 ^B | 149±20 ^B |
| | PBMT | 127±12 ^A | - | - | 148±15 ^B | 152±16 ^B |
| Muscle soreness (a.u.) | Placebo | 0.0±0.0 ^A | - | 2.1±2.3 ^B | 4.2±2.4 ^C | 3.6±1.6 ^C |
| | PBMT | 0.0±0.0 ^A | - | 1.8±1.9 ^B | 4.2±2.4 ^C | 3.5±1.7 ^C |

Different letters within the same line are significantly different (p<0.05).

CONCLUSIONS: The fatigue protocol (10 sets of 10 reps CMJ) was efficient to induce fatigue and muscle damage immediately after, 24h, and 48h. However, the adopted PBMT parameters applied before exercise has no effect to attenuate lower limbs fatigue, muscle damage, and soreness in judo athletes.

Heart Rate Recovery Assessment in Elderly and Young Men: a Comparison Between Types of Exercise

Clara I. Monteiro¹, Guilherme P.T. Arêas², Sonia L. Rivera³, Audrey Borghi-Silva¹, Ramona Cabiddu⁴, Renata Gonçalves Mendes¹. ¹Federal University of Sao Carlos, Sao Carlos, Brazil. ²Federal University of Sao Carlos, São Carlos, Brazil. ³Industrial University of Santander, Santander, Colombia. ⁴Università degli Studi di Milano, Milano, Italy.
 (No relevant relationships reported)

Post-exercise heart rate (HR) recovery (HRR) is considered a potential marker of cardiac health. Cardiorespiratory fitness, aging effect and, specifically, the type of physical exercise are able to exert an influence on HRR. However, is not clear the behavior of the HRR in the resistance exercise (RE). **PURPOSE:** To analyze HRR after RE and non-resistance exercise (NRE) in healthy male subjects. **METHODS:** Twenty-two subjects were evaluated and divided in two groups: Young (GY, n=11), 26.0 ± 4.4 ys and Elderly (GE, n=11), 66.5 ± 5.0 ys. A symptom-limited cardiopulmonary exercise test on a cycle ergometer and a symptom-limited resistance test at 70% of 1RM on a Leg Press 45° device were performed as NRE and RE, respectively. HR was recorded after exercise using a cardiofrequencimeter (Polar s810). HRR indices were calculated by subtracting the first (HRR-1), second (HRR-2) and third-minute (HRR-3) HR from the maximal value achieved in both exercises. An ANOVA Two Way test was performed (p<0.05). **RESULTS:** The analysis revealed no interaction between age and exercise factors on HRR. However, independent of exercise, an age effect with faster recovery was observed for GY (higher HRR values were found in the 1st and 2nd minutes of recovery). Besides, an effect of age and exercise was observed for NRE (higher values for GY after NRE in the 3rd minute of recovery) (Table 1). **CONCLUSION:** Cardiovascular adjustments investigated through HRR are attenuated in the elderly after RE and NRE. These results provide an interesting insight into a deeper understanding of CV restoration after different exercise modalities and age; Regardless of the type of exercise, the effect of aging prevails in determining the individual's HRR response to exercise.

Table 1. Interaction between group (Elderly vs. Young) and type of exercise (CEPT vs. load at 70% 1 RM).

| | Elderly | | Young | | Age | Type | Interaction |
|------------------|--------------|---------------|---------------|---------------|-----|------|-------------|
| | NRE | RE | NRE | RE | | | |
| HRR-1 min | 24.36 ± 12.6 | 17.73 ± 13.07 | 32.64 ± 6.65 | 35.82 ± 21.51 | * | NS | NS |
| HRR-2 min | 42.18 ± 11.2 | 28.36 ± 16.85 | 52.64 ± 8.3 | 50.45 ± 20.51 | * | NS | NS |
| HRR-3 min | 48.82 ± 11.5 | 31.64 ± 18.07 | 61.36 ± 10.88 | 59.27 ± 20.52 | * | * | NS |

Mean ± standard deviation. NRE: non-resistance exercise; RE: resistance exercise; HRR: heart rate recovery. *p<0.05. NS: Not Significant.

The Effects of Sport Massage and Foam Rolling on Running Efficiency in Female Collegiate Distance RunnersKent D. Johnson, FACSM, Avery Franklin, Rebecca Robertson, Kade Hinkle. *Lipscomb University, Nashville, TN.*
Email: kent.johnson@lipscomb.edu

(No relevant relationships reported)

Foam Rolling and Sport Massage techniques have become increasingly popular methods to help athletes prepare for and recover from bouts of intense exercise. Distance runners in particular use Foam Rolling prior to and after strenuous workouts potentially to improve athletic performance and flexibility, reduce workout-related soreness and decrease recovery time. While these activities are common in intercollegiate athletics (especially distance running circles), there is equivocal evidence that supports the effectiveness of either method, especially when used prior to exercise. **PURPOSE:** To compare running efficiency following a bout of Sport Massage and Foam Rolling in female Collegiate distance runners. **METHODOLOGY:** Nine healthy NCAA D-1 female Cross Country runners volunteered for the study (age=20.89±1.97yrs; WT=54.25±7.15kg; HT=163.02±5.67cm; Percent Fat=15.29±5.72; BMI=20.26±2.01). Volunteers reported to the laboratory and completed an initial $\dot{V}O_{2max}$ test (7.0mph with a 3% grade increase every 3 minutes until exhaustion; $\dot{V}O_{2max}$ =55.73±2.11 ml/kg/min). Subjects then performed three separate randomized treadmill runs (7.0mph at 3% grade for 10 minutes) following either no intervention (NI), Sport Massage (SM) or a Foam Rolling (FR) session. To estimate running efficiency, heart rate (HR), rate of perceived exertion (RPE) and lactate samples were taken every two minutes throughout the three 10-minute steady state runs. **RESULTS:** Results showed there were no significant differences ($p>0.05$) between NI, SM or FR for RPE (NI=10.25±2.31; SM=10.50±2.67; FR=10.63±2.56) or lactate (NI=2.7±1.23; SM=2.84±0.90; FR=2.90±0.97). However, there was a significant difference ($p=0.028$) for HR between NI (149.88±15.33) and FR (144.75±13.79). SM (147.50±14.43) was not significantly different ($p>0.05$) from NI or FR for HR. **CONCLUSION:** These results indicate that FR prior to a steady state submaximal run may have a beneficial cardiovascular effect (improved efficiency) in well trained female distance runners.

Accelerated Recovery of Muscle Function in Baseball Pitchers Using Post-Game Phase Change Material CoolingMichael J. Mullaney¹, Susan Y. Kwiecien¹, Andrew Fink², Malachy P. McHugh, FACSM¹. ¹Nicholas Institute of Sports Medicine and Athletic Trauma, Lenox Hill Hospital, New York, NY. ²Mullaney & Associates Physical Therapy, Matawan, NJ. (Sponsor: Malachy P. McHugh, FACSM)

Email: mchugh@nismat.org

(No relevant relationships reported)

PURPOSE: No studies have documented recovery of strength in baseball pitchers nor interventions to accelerate strength recovery on the days after a pitching performance. The objectives of this study were to (1) document indices of recovery following a pitching performance, and (2) determine if recovery can be accelerated by providing prolonged post-game phase change material (PCM) cooling to the shoulder.

METHODS: Shoulder strength, pain and plasma creatine kinase (CK) levels were measured in 11 college baseball pitchers 48 h prior to a game, and 12 h and 36 h afterwards. Players were randomized to wearing PCM cooling packs (15°C) within a compression shirt for 3 h post game (PCM treatment), versus no treatment (control) and received the opposite post-game treatment one week later (randomized crossover design). Strength in internal rotation (IR), external rotation (ER) and empty can test (EC) was assessed using a hand-held dynamometer. Pitchers threw 45 pitches on each occasion. Effect of PCM cooling on strength, pain and CK was assessed with repeated measures analysis of variance.

RESULTS: There was IR strength loss in the control condition (18% at 12 h, 11% at 36 h, $P<0.01$) but no strength loss in the PCM condition ($<1\%$ at 12 h and 36 h; Treatment effect $P=0.06$, Treatment by Time $P=0.03$). Similarly, there was ER strength loss in the control condition (14% at 12 h, 11% at 36 h, $P<0.01$) but less strength loss in the PCM condition (8% at 12 h, 7% at 36 h; Treatment effect $P<0.01$, Treatment by Time $P=0.58$). Pitching had no effect on EC strength (Time effect $P=0.97$). CK and pain were elevated on the days after the game (Time effects $P<0.01$) with no difference between treatments (Treatment effect: CK $P=0.79$, pain $P=0.73$; Time by Treatment: CK $P=0.92$; pain $P=0.70$).

CONCLUSIONS: Strength loss, pain and elevated CK were evident 12-36 h post game. PCM cooling protected against strength loss but not pain or CK. Pain (peak 3 out of 10) may have been too low to have been affected by the intervention. This is the first study to document impairments in muscle function on the days after a baseball pitching performance. PCM cooling packs provides a practical means of delivering prolonged post-game cooling after pitchers have departed the training room.

Sports Compression Garments Enhance Recovery Hemodynamics and Subsequent Time-Trial PerformanceDaniel Chi Wo Lee. *The Chinese University of Hong Kong, Hong Kong, Hong Kong.*

Email: dcwlee@cuhk.edu.hk

(No relevant relationships reported)

Sports compression garments (CG) has been proposed to accelerate post-exercise recovery by enhancing blood metabolite clearance and reducing muscle soreness. However, limited information exists on CG-induced hemodynamic responses during recovery and their potential impact on subsequent time-trial (TT) performance.

PURPOSE: We examined the effect of wearing thigh-high sports CG (1) on hemodynamic responses, during passive recovery between exercise using Doppler ultrasound (USCOM®), 2) on subsequent TT performance and 3) to investigate any associated perceptual and affective responses in physically active healthy individuals. **Methods:** Thirteen physically active healthy males (age=20.9±1.4 years; weight=65.9±7.8 kg; height=173.3±4.8 cm) underwent two cycling trials separated by one week. Each trial consisted of a 20-min fatiguing preload cycling followed by 60-min of passive recovery whilst wearing either thigh-high sports CG or gymnastic pants (CON). A 5-min TT was subsequently conducted and power output and cadence were recorded. Cardiac output (CO) and stroke volume (SV) were measured using Doppler ultrasound (USCOM®); heart rate (HR), blood lactate (BLa⁻), ratings of perceived exertion (RPE), leg muscle soreness (LMS), non-invasive blood pressure (MAP), and systemic vascular resistance (SVR) were monitored at 5, 15, 30, 45, 60 min during passive recovery. **Results:** CG exerted a lower body pressure of 28.6±9.4 mmHg in a semi-reclined position. During the subsequent 5-min TT, power output (215.2±24.0 vs. 210.8±21.5 W, CG vs. CON) and cadence (72.5±3.8 vs. 71.2±4.8 rpm, CG vs. CON) were significantly higher in CG than CON ($P<0.05$). SV was higher at 15, 30 and 45 min ($P<0.05$), CO was higher at 5 and 45 min ($P<0.05$), HR was lower at 15 and 30 min ($P<0.05$), BLa⁻ was lower at 5 and 15 min ($P<0.05$) during passive recovery with CG, and LMS was lower at all timepoints ($P<0.05$), compared to CON. **Conclusion:** Thigh-high sports CG improves subsequent TT performance by enhancing hemodynamic responses and attenuating perceived muscle soreness during passive recovery in physically active healthy males.

Exercise Recovery with Cold and Thermoneutral Water Immersion and Performance in AthletesHana Marmura, Matthew Palmer. *St. Francis Xavier University, Antigonish, NS, Canada.*

Email: hmarmura9@gmail.com

(No relevant relationships reported)

Cold water immersion (CWI) is commonly used to expedite recovery from strenuous exercise. However, it is unclear whether recovery with CWI confers any added performance or perceptual benefits during subsequent exercise vs. thermoneutral water immersion (TWI). **PURPOSE:** To investigate the potential for CWI and TWI in recovery from strenuous exercise to improve subsequent performance in athletes. **METHODS:** Ten varsity athletes (age 22 ± 2 yrs; height 177.9 ± 10.5 cm; weight 70.6 ± 9.6 kg; $\dot{V}O_{2max}$ 53.9 ± 6.8 ml/kg/min) performed pre-recovery (PRE) and post-recovery (POST) exercise protocols. The 20 min recovery period involved 10 min of either CWI (14.7 ± 0.3 °C), TWI (34.8 ± 0.8 °C) or room air control (CON) (28.7 ± 0.8 °C) in a randomized, crossover design. The exercise protocols required participants to cycle for 20 min at 57 ± 1% $\dot{V}O_{2max}$ (WARM) and immediately complete a 10 min work-based time trial (TT) at ~75% $\dot{V}O_{2max}$ in heat (30 ± 0.1 °C, 59 ± 0.3% r.h.). This was followed by performance tests of upper and lower body reaction time, maximal countermovement jump height (CMJ), maximum voluntary isometric contraction (MVIC) of the knee flexors, and questionnaires outlining mood states and belief score. Heart rate (HR) and ratings of perceived exertion (RPE) were recorded every 1 min during the TTs and in recovery. **RESULTS:** No differences between groups were observed for any PRE variable. Mean workloads were higher for every min of the POST TT in the CWI trial compared to TWI and CON trials. There was a trend for CWI to minimize the % change in mean TT workload vs. TWI and CON (-1.1 ± 1.9 vs. -4.6 ± 1.4 and -7.2 ± 2.3%, $p=0.11$). Mean POST-WARM $\dot{V}O_{2}$ did not differ between CWI, TWI or CON trials (2.2 ± 0.2, 2.2 ± 0.2 and 2.2 ± 0.1 L/min). However, mean POST-WARM HR was significantly lower in the CWI trial vs. TWI and CON trials (151 ± 3 vs. 159 ± 3 and 159 ± 4 bpm, $p<0.05$). Mean increase in TT RPE was blunted in the CWI trial vs. TWI and CON trials (0 ± 1 vs. 1 ± 1 and 1 ± 1, $p<0.05$). Belief score correlated with the change in TT workload in the CWI trial only ($R^2=0.35$, $p<0.05$). No significant differences in CMJ or MVIC were observed between trials. **CONCLUSION:** Ten minutes of CWI in recovery from intense exercise in the heat reduced mean HR and RPE during a post-recovery exercise test, which may have contributed to the trend of a higher mean workload in the post-recovery TT vs. TWI or CON.

Effect Of Electromagnetic Treated Water Combined With Infrared Radiation On Post-exercise Recovery Of Elite Gymnasts
 Tienan Wu¹, Xin Wang², Ziang Song³, Chi Zhang⁴, Bing Hu⁵, Yahua Zi⁶, Huiping Yan⁷, Yifan Lu⁷. ¹Heihe University, Heihe, China. ²Guangdong Junfeng BFS Technology Co., Ltd., Guangzhou, China. ³Beijing University of Posts and Telecommunications, Beijing, China. ⁴General Administration of Sport of China, Beijing, China. ⁵Yantai Sport Research Center, Yantai, China. ⁶Shanghai University of Sport, Shanghai, China. ⁷Beijing Sport University, Beijing, China.
 Email: tienan_wu@hotmail.com
 (No relevant relationships reported)

Gymnasts are required to complete a series of highly difficult routines that need excellent physical condition and plenty of training time, the post-exercise recovery is crucial. Electromagnetic Treated Water (ETW) is very small water molecule clusters caused by the electromagnetic field which can benefit human body in different ways. Infrared radiation (IR) is commonly used in the recovery period of training.

Purpose: The aim of the study is to assess the effect of ETW combined with IR on post-exercise recovery.

Methods: Twenty gymnasts from China men's national gymnastics team were randomized to the experimental group (EG, N=10) or the control group (CG, N=10). The CG continued with their daily training, the EG received 3-dimensional IR in a specific cabin for 30 minutes after training and drank no less than 1500 mL ETW per day for 12 weeks. Both groups followed the same training plan, diet and nutritional supplements. Blood parameters, including Routine Blood Test (RBT), Creatine Kinase (CK), Blood Urea Nitrogen (BUN), Dopamine (DA), Serotonin (5-HT) and Blood Lactate Acid (BLA), were detected before (t1), after (t2) and 1 hour later (t3) of training at D1, D42 and D84. In addition, Athlete Burnout Questionnaire (ABQ) and Pittsburgh Sleep Quality Index (PSQI) were collected.

Results: Comparing with CG, BLA(t3) and 5-HT(t3) was significantly decreased at D1 (0.73±0.26 vs. 1.21±0.34 mmol/L, 160.36±26.96 vs. 189.27±40.24 ng/mL, p<0.01, respectively), BUN(t1) was lower at D84 (4.22±0.98 vs. 5.88±1.07 mmol/L, p<0.01), as were Physical/Emotional Exhaustion (9.4±2.80 vs. 13.0±2.49, p<0.01) and Sport Devaluation (9.3±2.75 vs. 12.1±2.02, p<0.05). PSQI was significantly improved at D42 (5.0±1.33 vs. 6.9±2.38, p<0.05) and D84 (3.5±1.65 vs. 6.6±2.55, p<0.01). BLA(t3) were significantly decreased compared with BLA(t2) in EG at D1, D42, D84 (0.73±0.26 vs. 2.50±0.83, 2.40±1.26 vs. 8.21±5.09, 2.05±0.63 vs. 3.46±1.33 mmol/L, p<0.01, respectively).

Conclusion: The result of the present prospective study confirmed that ETW combined with IR can eliminate the BLA efficiently, reduce fatigue accumulation, improve sleep quality and decrease athlete burnout, that all can promote the post-exercise recovery.

Impact of a Chronic Foam Rolling Protocol on Bunkie Test Scores
 Elizabeth O'Neill, Maura Bergan, Tracey Matthews. *Springfield College, Springfield, MA.*
 Email: eoneill@springfieldcollege.edu
 (No relevant relationships reported)

The role of fascial tissue relative to muscle function and performance has garnered increased interest in recent years. Foam rolling (FR) has become a very popular form of self-myofascial release; however, the impact of chronic FR on the fascia is not well established. **PURPOSE:** To examine the impact of a FR protocol on myofascial function assessed via the Bunkie test (BT). **METHODS:** Participants were randomly assigned to a control group (CG; n = 17) or foam rolling group (FRG; n = 17). FRG completed a 14-day FR protocol. CG subjects were instructed not to FR. Participants completed the BT at baseline and following the 14 days. The BT consists of 5 plank positions held bilaterally to assess myofascial function. Positions include the anterior power line (APL), lateral stabilizing line (LSL), posterior power line (PPL), posterior stabilizing line (PSL), and medial stabilizing line (MSL). Positions were held for as long as possible with proper form and the time recorded. **RESULTS:** Factorial MANOVAs with repeated measures were utilized to examine how BT Scores changed across time (pre/post), between side of body (left and right) and treatment group (FRG, CG). Two MANOVAs were performed, one for power (APL and PPL) and the other for stabilization (MSL, LSL, and PSL). A significant time by treatment interaction was found ($\lambda = .74$, $p < .01$, $\eta^2 = .26$) and a significant side effect was found ($\lambda = .81$, $p < .04$, $\eta^2 = .19$) for power. Univariate analyses for the time by treatment interaction revealed that the APL was significant ($F(1,32) = 7.14$, $p = .01$, $\eta^2 = .18$). No significant differences existed for FRG from pre to post test. The CG group had significantly higher scores at pretest (37.82 ± 3.62) than post test (30.95 ± 3.49). For the significant main effect of side, PPL was significant. The right side (22.15 ± 2.48) was significantly less than the left side (24.59 ± 2.53). For MSL, LSL, and PSL, no significant interactions or differences existed for group, time and side. **CONCLUSION:** The

14-day FR protocol did not have an influence on BT scores, possibly indicating chronic FR does not influence myofascial function. Given that the results do not appear to identify consistent trends, the efficacy of the BT to assess myofascial dysfunction should be explored further.

Recovery From Unaccustomed Strenuous Exercise In Young And Older Endurance-trained Adults
 Koichiro Hayashi¹, Miriam E. Leary², Stephen J. Roy², Jitanan Laosiripisan², Evan P. Pasha², Hirofumi Tanaka, FACSM². ¹Kokugakuin University, Yokohama, Japan. ²The University of Texas at Austin, Austin, TX. (Sponsor: Hirofumi Tanaka, FACSM)
 Email: k-hayashi@kokugakuin.ac.jp
 (No relevant relationships reported)

There is a well-conceived notion that rate of recovery from strenuous exercise gets slower with advancing age. It is not clear whether older adults who exercise habitually and are apparently healthy demonstrate slower rates of recovery from unaccustomed eccentric exercise. **Purpose:** The aim of the present study was to determine if older adults who are physically active demonstrate slower rates of recovery from unaccustomed strenuous eccentric exercise compared with younger peers. **Methods:** A total of 39 apparently healthy men and women were studied; young sedentary (n=10, 28±2 years), young endurance-trained (n=15, 27±2 years), and older endurance-trained (n=14, 58±2 years) groups. Subjects performed 45 min (15 min x 3 times with 5 min resting periods) of downhill running (at -16% gradient) at a speed corresponding with 65% of their maximal oxygen consumption. Visual analog pain scale, isometric muscular strength, joint range of motion (ROM), and serum myoglobin concentration were measured at baseline as well as 24h, 48h, and 72h after the downhill running protocol. **Results:** Compared with baseline, pain scores of each muscle group were greater at 24h, 48h, and 72h in all 3 groups (p<0.05). Isometric muscular strengths decreased following downhill running (p<0.05), but the pattern of this response and recovery did not differ among the three groups. The ROM for hip extension decreased after downhill running (p<0.05), with the most pronounced decline seen in the young sedentary group. ROM gradually increased to baseline levels in all 3 groups. Serum myoglobin concentrations increased at 24h and returned to baseline values at 48h in both the young and older trained groups. **Conclusion:** The present findings are not consistent with the prevailing notion that older trained adults have a slower rate of recovery from strenuous exercise compared with young adults.

 (No relevant relationships reported)

PURPOSE: The use of compression garments during exercise to enhance performance has been endorsed by many athletes. The aim of this study was to determine if compression garments would improve consecutive-day exercise performance in a dose-dependent manner in young athletes.

METHODS: A single-blind crossover design with three experimental conditions [loose-fitting gym attire (CON), low compression (LOW-CG) and high compression (HIGH-CG)] was employed. Recreationally active male cyclists (n=10; 21±2 yo) underwent preliminary baseline testing for linear force calculation followed by counter-balanced conditions using a multi-day cycle ergometer protocol [Day 1 = severe intensity sprint cycle protocol followed by 24-h of controlled rest and experimental condition (CON, LOW-CG or HIGH-CG); Day 2 = 8km time trial]. Prior to each exercise bout, subjective discomfort and muscle soreness were assessed via questionnaire and blood pressure was measured. During the sprint and time trial conditions a) power output (LEM software), oxygen uptake (metabolic cart; Vyntus CPX) and heart rate (HR; Polar) were assessed continuously. Venepuncture blood samples were drawn pre-, at the end of exercise, and 15, 30 and 60 min post-exercise during rest to determine plasma lactate, creatine kinase (CK), and myoglobin using a Cobus 6000 e-modul. Data was analysed using repeated measures ANOVA. **RESULTS:** Plasma lactate was lower at 30 and 60 min post-exercise on Day 1 in HIGH-CG compared with CON group (HIGH-CG: 8.4±2.5mmol; 3.8±1.4mmol vs. CON: 13.4±5.13, 6.5±2.6mmol, p=.25 and p=.15, respectively with no other significant interactions observed. Compared to Day 1, diastolic (CON: 1±10%; LOW-CG: 1±9%; HIGH-CG: -12±4%) and mean arterial pressure (CON: -4±5.1%; LOW-CG: -3±8.1%; HIGH-CG: -5.5±3.4%) decreased on Day 2 in HIGH-CG only (p<.05). Time trial completion was decreased (p<.05) during HIGH-CG (948±304s) compared

to both LOW-CG (988±319s) and CON (1010±364s). HR at 30s of exercise was lower in HIGH-CG compared to CON (120±11 vs. 132±16 bpm; $p<.038$). No differences occurred for oxygen uptake kinetics, CK, or subjective outcomes on Day 1 or 2. **CONCLUSIONS:** These results suggests that degree of pressure influences the effectiveness of compression garments for both multi-day cycling and performance recovery in young males.

Assessing the Impact of Passive Vs. Active Recovery on Broad Jump Performance in Collegiate Females
 Madeline Phillips, Branden Ziebell, Moroni de Moors, Abraham Frech, Hannah Nelson, Russell Lowell, Anna Blackley, Andy Bosak. *Liberty University, Lynchburg, VA.* (Sponsor: Dr. James Schoffstall, FACSM)
 (No relevant relationships reported)

The broad jump test is widely utilized to assess an individual's horizontal power ability. Traditionally, the type of recovery between subsequent broad jumps is of the passive nature, yet prior studies utilizing other modes of power assessment have evaluated the impact of active recovery on power production. However, to the best of the researchers' knowledge no prior study has evaluated the impact of passive (PR) vs. active recovery (AR) on broad jump (BJ) performance. **PURPOSE:** To investigate the potential differences between an PR vs. AR on BJ performance in no less than averagely fit college-age females. **METHODS:** After having descriptive data (Ht. = 165.07 ± 5.56, Wt. = 62.68 ± 6.78, BF% = 23.99 ± 4.96, age = 21.08 ± 1.74) recorded, 24 averagely fit college-age females participated in an 8 min dynamic warm-up. Subjects were then given a four minute passive recovery period after the warm up and then completed four familiarization jumps (ie. trials). After another four minute passive recovery period, subjects completed two series of jumps (ie. four trials apiece) in a counterbalanced order with either an PR or AR between each jump. The AR period consisted of subjects completing stepping exercises for 60 seconds utilizing a 20cm step height, while PR had subjects stand still until their next jump. The PR and AR jump series were separated by a standardized four minutes passive recovery period. Excluding the first jump of each series, the farthest jump for PR vs. AR was compared using Paired-Samples t-Tests with significant differences occurring at $p \leq 0.05$. **RESULTS:** Significant differences ($p = 0.030$) occurred between PR (178.32 ± 21.17 cm) and AR (175.74 ± 18.73 cm) with 75% of the subjects benefiting from the PR vs. AR. **CONCLUSION:** The results suggest that PR may contribute to a further jumping distance vs. AR using no less than averagely fit college-age females. Future research may be required to assess the impact of an PR vs. AR on broad jump performance using no less than averagely fit college-age males. Additional research may need to occur in order to assess the specific type of activity that occurs between an active recovery period and its potential impact on broad jump performance.

2379 Board #43 May 31 9:30 AM - 11:00 AM
The Effects of Stretching on Blood Lactate Concentration after Anaerobic Exercise
 Anna Blackley, Brianna Tummons, Kaitlyn Dombrowski, Bradee Davis. *Liberty University, Lynchburg, VA.* (Sponsor: Dr. James Schoffstall, FACSM)
 (No relevant relationships reported)

Blood lactate (BLa) concentration is believed to be one of the contributing factors of muscular fatigue and muscle soreness when lactate is converted into lactic acid. Because of these decrements associated with BLa accumulation during exercise, multiple methods to remove BLa have been investigated. However, the results on the effects of stretching remain inconclusive. Although BLa returns to resting levels within 30-60 minutes after exercise, the primary focus of this study was to further explore the effects of stretching on BLa recovery. **PURPOSE:** This study aimed to assess the benefits of stretching on BLa levels (mmol/L) after performing a maximal anaerobic exercise compared to sitting down after the same anaerobic maximal exercise. **METHODS:** After measuring descriptive data (age, ht., wt., age), 15 subjects (age 22 ± 1 years; ht. 1.76 ± 0.09 m; wt. 83 ± 15 kg) performed a Wingate Cycle Ergometer Test, on two separate occasions, followed by two different 10-minute protocols in counterbalanced order: sitting or (active and passive) stretching. BLa levels were measured before and after performing the Wingate test and then 10 minutes after the test. **RESULTS:** The difference in BLa levels before ($p = 0.815$) and after ($p = 0.212$) exercise were similar and showed no significant difference ($p < 0.05$). However, there was a statistically significant difference in BLa levels between the two post 10-minute protocols ($p = 0.002$). **CONCLUSIONS:** The current results indicate that stretching after a maximal bout of anaerobic exercise can be statistically significant in lowering BLa accumulation.

2380 Board #44 May 31 9:30 AM - 11:00 AM
Comparison of Perceived Exertion and Recovery Status Scores in Collegiate Male Soccer Players and Coaches
 Michelle L. Eisenman, Emily L. Langford, Ronald L. Snarr, Greg A. Ryan. *Georgia Southern University, Statesboro, GA.*
 (No relevant relationships reported)

Perceived Recovery Status (PRS) and Rating of Perceived Exertion (RPE) are two subjective methods coaches, athletes, and sport scientists have used to quantify training load and recovery to improve athletic performance. While these values are important to monitor, these tools are more useful if there is an agreement between coaches and players. **PURPOSE:** To assess subjective measures (PRS and RPE scores) received from athletes and coaches during the course of a preseason. **METHODS:** PRS scores prior to, and RPE scores after, each of 18 preseason practices (Pr) were collected on 26 Division I male soccer players (P) and 3 coaches (C). Athletes provided scores away from other athletes and coaches. Coaches were instructed to provide answers to PRS and RPE as to how their athletes felt. Due to the categorical nature of the data, nonparametric Mann-Whitney U Tests were run comparing P to C data for each Pr. **RESULTS:** P and C RPE were not significantly different ($p > 0.05$) for 17 of the 18 practices. The only statistically significant difference occurred in Pr8 (median P: 8.0, C: 7.0; $p = 0.04$). PRS comparisons were slightly more variably different (4 of 18) through preseason training: Pr2 (P: 7.5, C: 9.0; $p = 0.02$); Pr5 (P: 7.0, C: 9.5; $p = 0.02$); Pr14 (P: 7.0, C: 5.0; $p = 0.01$) and Pr15 (P: 4.5, C: 1.5; $p = 0.04$). **CONCLUSION:** Results indicate that perception of intensity of practice and recovery were fairly similar throughout preseason. As preseason progressed, a shift in PRS from C overestimating P recovery, to underestimating recovery, especially following scrimmages occurred. This is an important consideration for coaching and training staffs in determining practice schedules for athletes during preseason training.

A Comparison of Physical Activity Behaviors and Sleep in Female NCAA Division-I Athletes versus Controls
 Dillon C. Frisco, Jesse A. Goodrich, Jeffrey Higdon, Kenneth Wright, William C. Byrnes, FACSM. *University of Colorado, Boulder, CO.* (Sponsor: William Byrnes, FACSM)
 Email: Dillon.Frisco@colorado.edu
 (No relevant relationships reported)

Physical activity behaviors and sleep patterns influence health in the general population but have not been evaluated in collegiate student athletes. For these individuals the demands of academics and athletics alter these parameters but have not been fully characterized or compared to students who are not collegiate athletes. **Purpose:** This study compared physical activity (PA) behaviors and sleep patterns of female NCAA D I student-athletes (Athletes) to recreationally active female students (Controls). **Methods:** Across three consecutive semesters, subjects were recruited for one to three weeks of monitoring. Sleep was monitored with Activatches. PA was monitored using ActivPals. Forty-five females were recruited from the University of Colorado, Boulder. Athletes were recruited from the Golf (n=6) and Tennis teams (n=8). Controls were recruited from the general student body (n=31). Subjects were instructed to wear devices at all times except during competitions. Travel days and days with less than 90% waking wear time were removed from analysis. Time spent in Sedentary (SED), Low Intensity (LIT) and Moderate-Vigorous Physical Activity (MVPA) are presented as percent of waking day. **Results:** Mean days recorded per individual was: Controls 15.1; golf 10.2; and tennis 15. Compared to Controls, Athletes had higher daily step counts (12,040 ± 6498 vs 8,992 ± 5240, $p<.01$), less SED (63.5±15.0 vs 71.4±13.3, $p<.05$), higher LIT (26.4 ± 12.9 vs 21±10.8, $p<.05$) and higher MVPA (9.7 ± 3 vs 7.6 ± 3.3, $p<.01$). For both groups, weekends had higher LIT (+3.0%, $p<.01$), decreased MVPA (-.75%, $p<.05$), and a trend toward decreased SED (-2.3%, $p=.0563$) compared to weekdays. There were no differences in PA between Golf and Tennis. Sleep was not significantly different in Athletes versus Controls, including duration of sleep (07:04 ± 00:49 vs 7:32 ± 00:42, $p=.6$) and sleep midpoint. Yet, midpoint was significantly later on weekends vs. weekdays in both groups (04:35 ± 01:01 vs 04:03 ± 00:55, $p<.01$) **Conclusion:** Female Athletes had higher physical activity demands than Controls. Yet both groups, on average, slept only slightly more than the American Academy of Sleep Medicine recommended 7-hours. This may negatively impact overall health. Research is needed on how these sleep and activity behaviors influence academic and athletic outcomes.

Influence of Whole-Body Vibration and Air Compression on Lactate Removal
 Parker B. Marson¹, William Armstrong², Megan T. Rose¹.
¹Western Oregon University, Monmouth, OR. ²Western Oregon University, Tualatin, OR.
 (No relevant relationships reported)

PURPOSE: The purpose of the present study was to examine potential benefits and outcomes of whole body vibration (WBV) and air-compression boot as a recovery modality from lactate-producing exercise. Previous study had demonstrated potential benefits for these modalities on lactate removal in D-II Collegiate cross-country runners. **METHOD:** Ten recreationally-active participants (6 M; 4 F; mean age = 24 ± 5 y) participated in three lactate-producing protocols (two 30-s Wingate anaerobic (WAnT) tests separated by 2-min rest) followed by 5 minutes of either WBV (at 40 Hz), air compression boot, or rest. Participants were subjected to ≤ 3 finger pricks [pre-WAnT (Pre), post-WAnT (Post-0), and post-modality (Post-Mod)] to draw a drop of blood to be analyzed for blood lactate concentration ([La]). Consent was obtained and all participants were informed that participation in the research was voluntary. WAnT measures (peak-power output, PPO; relative peak power, RPP; anaerobic fatigue, FI) were computed. Statistical analyses (t-tests and ANOVA) were performed using R Studio (www.rstudio.com) at the significance level of $\alpha < 0.05$. **RESULTS:** The work was sufficient to elevate [La] and there were no significant differences between WAnTs (PPO, RPP, FI; $p > 0.05$). [La] was significantly greater from Pre to Post-0 ($p < 0.001$). While there were no statistically significant effects for modalities, the compression boot appeared to have a slight advantage over WBV and rest. Rates of [La] removal were: compression boot (mean = 0.360 ± 0.325 mmol/min), the WBV (mean = 0.320 ± 0.525 mmol/min), and seated rest (mean = 0.167 ± 0.370). **CONCLUSION:** These data suggest that the compression boot and WBV modalities are worthy of further study and consideration as effective means of increasing the rate of [La] clearance post-training and post-competition.

2383 Board #47 May 31 9:30 AM - 11:00 AM
The Acute Effects of Yoga on Physiological and Psychological Measures of Stress in College Students
 Charles J. Fountaine, FACSM, Hannah Garrett, Kelley Phillips.
 University of Minnesota Duluth, Duluth, MN.
 Email: cfountain@d.umn.edu
 (No relevant relationships reported)

College students commonly report high levels of stress due to academic pressures and social challenges. Subsequently, the use of yoga as a form of stress-relief has become increasingly popular among college students. **PURPOSE:** to determine the acute effects of yoga on physiological and psychological measures of stress in college students. **METHODS:** Participants (n=20, 16 female) were initially assessed for baseline proxy measures of psychological and physiological stress. Psychological stress was assessed via the Positive and Negative Affect Schedule (PANAS) Questionnaire. Physiological stress was assessed by outfitting each subject with a five-lead EKG Holter monitor to measure heart rate variability (HRV). HRV was determined as the time interval between R-R waves (ms). Once baseline levels of stress were recorded, participants then completed a 20 min video of a Vinyasa Flow Sun Salutation yoga practice, while supervised by a certified yoga instructor. After the conclusion of the yoga session, participants' post-baseline stress levels were re-assessed via PANAS and HRV. **RESULTS:** There was a statistically significant increase in positive affect scores from pre (26.7 ± 8.79) to post (31.0 ± 8.47), $p = 0.004$. The mean increase in positive affect scores (4.30 ± 5.9) indicated a moderate effect size, $d = 0.73$. There was a statistically significant decrease in negative affect scores from pre (15.95 ± 4.74) to post (11.35 ± 4.21), $p < 0.001$. The mean decrease in negative affect scores (4.6 ± 3.76) indicated a large effect size, $d = 1.22$. —There was a statistically significant increase in HRV scores from pre (665.5 ± 104.36 ms) to post (924.3 ± 122.98 ms), $p < 0.001$. The mean increase in HRV score (258.8 ± 102.32 ms) indicated a large effect size, $d = 2.52$. **CONCLUSIONS:** The results of this study indicated that a 20 min yoga practice resulted in a significant improvement in positive affect scores (16%), a significant decrease in negative affect scores (29%), and a significant improvement in HRV (39%), all indicative of a reduction in psychological and physiological measures of stress levels.

Effects of Moderate versus Variable High Intensity Cycling on Metabolic Responses During Recovery.
 Matthew Wolfe, Jenna Thompson, Meral Culver, Kelly E. Johnson, Justin P. Guilkey. Coastal Carolina University, Conway, SC.
 Email: mhwolfe@coastal.edu
 (No relevant relationships reported)

PURPOSE: Examine oxygen consumption (VO₂), energy expenditure and respiratory exchange ratio (RER) during recovery following moderate-intensity exercise (MIE) and variable high-intensity exercise (VIE) in healthy adults (n=5; age = 20.2 ± 5.7 yrs). **METHODS:** Two experimental conditions (MIE and VIE) were randomized and performed on separate days in the fasted state. Both conditions commenced with a 15-min seated rest, followed by the assigned exercise. MIE consisted of continuous moderate-intensity exercise at 40% of WRmax. VIE consisted of sixteen 10-sec supramaximal sprints (120% WRmax), sixteen 20-sec high intensity bouts (60% WRmax) and low-intensity recovery (20% WRmax) interspersed throughout the exercise. Total duration and total work were matched between conditions. Following exercise, there was 75 minutes of seated recovery. Resting VO₂ was averaged over the final 10 min of rest. VO₂ and respiratory exchange ratio (RER) were recorded during exercise and every 15-minutes of recovery. NetVO₂ was calculated as the VO₂ above resting VO₂. Energy expenditure (EE) and fat oxidation rate (FatOx) were calculated. VO₂ and RER responses between conditions were compared using a 2-way repeated measure ANOVAs and EE and FatOx between conditions were compared using paired t-tests. Significance was established if $p < 0.05$. **RESULTS:** During recovery, net VO₂ decreased in both conditions from exercise (VIE = 1184.2 ± 247.0 ml·min⁻¹; MIE = 1005.8 ± 222.1 ml·min⁻¹) to 75 minutes (VIE = 40.3 ml·min⁻¹ ± 23.6; MIE = 16.1 ± 10.2 ml·min⁻¹). There were no differences in net VO₂ between conditions during recovery. Net EE during recovery from VIE and MIE were 10.8 ± 6.7 kcals and 5.5 ± 3.9 kcals, respectively ($p = 0.13$). During VIE and MIE, RER was 1.02 ± 0.4 and 0.96 ± 0.06, respectively ($P = 0.06$). During recovery, RER was lower in VIE compared to MIE at 30 (0.81 ± 0.07 vs. 0.89 ± 0.07) and 45 minutes (0.85 ± 0.11 vs. 0.95 ± 0.09) but was similar at 15 and 60 minutes. At the end of recovery, RER for VIE and MIE were 0.89 ± 0.08 and 0.95 ± 0.09, respectively ($p = 0.08$). FatOx at the end of recovery was significantly greater in VIE (0.05 ± 0.04 g·min⁻¹) than MIE (0.01 ± 0.03 g·min⁻¹). **CONCLUSION:** Although, NetVO₂ and EE were similar during recovery, VIE appears to alter fuel utilization patterns during recovery towards a lower RER and greater fat oxidation.

Subconcussive Impacts in Youth Players and Their Possible Impairment in Cognitive Functions
 Luis R. Lopez-Roman¹, Yarimar I. Diaz-Rodriguez².
¹Universidad del Sagrado Corazon, San Juan, PR. ²Universidad Maimónides, Buenos Aires, Argentina.
 (No relevant relationships reported)

In United States at least 2.5 million children under 14 years old play soccer (1 million under 10 years; 1.5 million between 10 and 14 years old). At his age they receive at least one subconcussive impact when heading the ball at different game situations. Subconcussive impacts are impacts to the head or body that cannot be diagnosed as a concussion on clinical grounds or with neuroimaging studies (MRI, CT-Scan or PET Scan). A subconcussive impact may alter cognitive functions such rapid processing without any recognizable trace. Processing speed is the ability to perform automatic thinking tasks while maintaining focused attention especially when pressured. Processing speed is related to phonetic recognition, hearing comprehension and interpretation, rapid naming, respond to environment changes and knowledge application. Accelerometers can measure the magnitude of a blow to the head live in the field. The ImPACT Pediatric® is a neurocognitive test that provide pre and post information of cognitive changes. **PURPOSE:** To identify the relationship between subconcussive impact magnitude (G) and rapid processing score difference after at least one blow to the head in youth soccer players. **METHODS:** A group of 15 youth male soccer athletes between 9 to 11 years old (9.9 ± 0.6 years) wear a head accelerometer in a specialize headband. Each participant was encouraged to perform normally in the game. Descriptive statistics was used to assess subconcussive impacts. T-test was used for the neurocognitive pre and post-test to assess differences in rapid processing. **RESULTS:** Range of acceleration was from 16 g to 60g (Ave = 23.8 ± 9.1g). T-Test showed differences in rapid processing for males ($p = 0.01$). However, although there is a significant difference between the pre-test and the post-test, there is no relationship between the difference in values between the pre- and post-tests of rapid processing and the magnitude of the impact received ($r = 0.04$). **CONCLUSION:** These results suggest that males that play soccer and receive a subconcussive impact can reflect significantly changes in rapid processing. However, the magnitude of the impact does not appear to be the obvious factor in creating greater differences or major changes in rapid processing.

Active and Passive Recovery Following High Volume Resistance Training: Markers of Molecular Gene Expression

Carlton D. Fox¹, Christopher G. Vann¹, Cody T. Haun², Shelby C. Osburn¹, Matthew A. Romero¹, Paul A. Roberson¹, Petey W. Mumford¹, Jordan R. Moon³, Kaelin C. Young⁴, Michael D. Roberts¹. ¹Auburn University, Auburn, AL. ²Lagrange College, LaGrange, GA. ³Impedimed, Lexington, KY. ⁴Edward Via College of Osteopathic Medicine - Auburn Campus, Auburn, AL. (No relevant relationships reported)

Purpose: Deloading is a common practice in the strength and conditioning community; however, there is a lack of data analyzing the effects of deloading on genes associated with muscle growth. **Methods:** Resistance-trained, college-aged males, (n=30; training age 5±3 yrs) completed 6 weeks of high-volume resistance training, after which the participants were split into active and passive recovery groups, with the deload period lasting 7 days. A muscle biopsy was obtained from the vastus lateralis prior to week one (PRE), after week 6 (POST), and after a week of either passive (PS) or active (AC) deloading (DL). Biopsy samples were used to evaluate messenger ribonucleic acid (mRNA) expression via real-time polymerase chain reaction (PCR) of the following markers: Atrogin-1, Muscle RING Finger Protein-1 (MURF-1), Mechano Growth Factor (MGF), Myosin Heavy Chain Ia (MHC-I), Myosin Heavy Chain IIa (MHC-IIa), Myosin Heavy Chain IIx (MHC IIx) and Myostatin. **Results:** MHC IIa exhibited a significant group ($p = 0.029$) and time effect ($p < 0.001$), and a GxT interaction was also observed ($p=0.048$). The expression of MHC IIa was significantly higher in AC at POST and DL compared to PS. A significant time effect was observed in MURF-1, MGF, MHC I, MHC IIa, MHC IIx, and Myostatin expression ($p < 0.05$). Atrogin-1 exhibited no significant effect of time or group. **Conclusion:** Active recovery during a deloading period after the completion of a high-volume resistance training phase may increase the mRNA expression of MHC IIa, but further research into the protein expression of the MHC IIa isoform is necessary to better understand relationships between deloading, gene, and protein expression.

Post-Natal Moderate Exercise Reduces the Harms of Protein Deprivation on the Cardiac Oxidative Stress Biomarkers

Diorginis José S. Ferreira¹, Anderson Pedroza², Diego Araújo², Cristiane Freitas², Talitta Lima², Mariana Fernandes³, Claudia Lagranha³. ¹Federal University of São Francisco Valley, Petrolina, Brazil. ²Federal University of Pernambuco, Recife, Brazil. ³Centro Acadêmico de Vitória, Vitória De Santo Antão, Brazil. Email: diorginisoares@hotmail.com (No relevant relationships reported)

Purpose: A maternal diet low in protein results in morphologic and functional damage to the offspring's hearts. Moderate exercise, on the other hand, is thought to improve heart metabolism and function, improving the overall health in adulthood. Thereby, we speculate that moderate exercise performed during early post-natal development could ameliorate the cardiac damage resulted from a perinatal protein deprivation. **Methods:** We used a rat model of protein restriction during gestation and lactation to assess the effect of moderate post-lactation physical exercise on oxidative stress parameters in the heart. Pregnant rats were divided into two groups: normoprotein (NP) receiving 17% casein in the diet, and low-protein (LP), receiving 8% casein. At 30 days of age, the male offspring born to each group were further subdivided into control (NP and LP) and exercised (ENP and ELP) groups. At 55 days of age, the rats were sacrificed and blood and heart were collected for biochemical analysis. The data were analyzed using the ANOVA two-way followed by the Tukey's multiple comparisons test. **Results:** We observed significant increases in the lipid (NP: 33.27 ± 5.01 vs. LP: 67.13 ± 5.68 μ M/mg prot; $p < 0.0001$) and protein oxidation (NP: 3.01 ± 0.48 vs. LP: 6.32 ± 0.26 μ M/mg prot; $p < 0.0001$) with concomitant reduction in the enzymatic anti-oxidant systems, superoxide dismutase (NP: 11.51 ± 0.03 vs. 9.46 ± 0.48 U/mg protein; $p < 0.01$), and catalase (NP: 9.53 ± 0.34 vs. LP: 7.79 ± 0.36 U/mg prot; $p < 0.01$) in the un-exercised rats on LP group. Application of moderate exercise to this group, however, resulted in significant > 2-fold reductions in both lipid (LP: 67.13 ± 5.68 vs. ELP: $26.5 \pm$

1.6 μ M/mg prot; $p < 0.0001$), and protein oxidation (LP: 6.32 ± 0.26 vs. ELP: 1.65 ± 0.19 μ M/mg prot; $p < 0.0001$) that correlated with an increase in non-enzymatic antioxidant defense (LP: 11.12 ± 1.13 vs. ELP: 28.19 ± 5.14 Redox status; $p < 0.001$), and a significant decrease in serum triglycerides (LP: 202.58 ± 19.25 vs. ELP: 122.11 ± 11.57 mg/dL; $p < 0.05$). **Conclusions:** We suggest that cardiac damage occurring in children born to mothers lacking protein during early childhood development could be ameliorated to an extent with moderate physical exercise designed to improve cardiac oxidative balance.

Circulating Angiogenic Cell and Microparticle Response to Prolonged Sitting

William S. Evans¹, Daniel D. Shill¹, Rian Q. Landers-Ramos², Lee Stoner, FACSM³, Quentin Willey³, Daniel Credeur⁴, James M. Hagberg, FACSM¹, Steven J. Prior¹, Erik D. Hanson³. ¹University of Maryland, College Park, MD. ²Baltimore Veterans Affairs Geriatric Research, Education and Clinical Center, Baltimore, MD. ³University of North Carolina, Chapel Hill, NC. ⁴University of Southern Mississippi, Hattiesburg, MS. Email: wsevans@terpmail.umd.edu (No relevant relationships reported)

Prolonged sitting increases the risk for cardiovascular disease. However, markers of vascular repair and damage such as circulating angiogenic cell (CAC) populations and microparticles (MP) have not been characterized with prolonged sitting or sitting with intermittent activity. **PURPOSE:** To examine the effects of 3h of sitting with or without calf raises on CD34⁺, CD62E⁺, and CD31⁺/42b⁺ MP populations which are linked to endothelial activation, apoptosis and CAC paracrine activity, respectively, and CD14/31⁺, CD3/31⁺, and CD34⁺ CACs which are linked to endothelial repair. **METHODS:** After familiarization, sedentary subjects (n=18) sat still for 180 minutes (control condition) or sat for 180 minutes but performed 10 calf raises every 10 minutes (experimental condition) in a random order. Blood samples were obtained at baseline and at 180 minutes for analyses. CACs and MPs were isolated and analyzed using multicolor fluorescent flow cytometry. Data were analyzed with repeated measures ANOVA and are presented as mean \pm standard error. **RESULTS:** There was a main effect of sitting to decrease CD34⁺ MPs (119 ± 8 vs. 106 ± 7 events/ μ l, $p < 0.01$) and CD62E⁺ MPs (53 ± 6 vs. 34 ± 4 events/ μ l, $p < 0.001$) regardless of condition. There were no significant differences in CD31⁺/42b⁺ MPs (50 ± 7 vs. 38 ± 12 events/ μ l), CD14/31⁺ cell frequency (85 ± 3 vs. 87 ± 2 % of parent), CD34⁺ cell frequency (704 ± 169 vs. 560 ± 122 per 500,00 events) or CD3/31⁺ cell frequency (52 ± 3 vs. 50 ± 2 % of parent) after sitting or between conditions. **CONCLUSION:** Contrary to our hypothesis, a three-hour bout of sitting with or without calf raises was not sufficient to affect CAC numbers. Furthermore, sitting decreased MP markers linked to endothelial activation and CAC paracrine activity, and calf raises did not ameliorate these changes. Future studies assessing longer durations of sitting with a more potent stimulus (e.g., intermittent walking) should be done to further understand the effects of sitting on the CAC and MP response.

Differences in CD31+ Circulating Angiogenic Cell Subtypes Between Endurance Trained and Sedentary Younger Adults

Rian Q. Landers-Ramos¹, Ryan M. Sapp², Daniel D. Shill², James M. Hagberg, FACSM², Steven J. Prior². ¹Towson University, Towson, MD. ²University of Maryland, College Park, MD. Email: rlandersramos@towson.edu (No relevant relationships reported)

Circulating angiogenic cells expressing the CD31 surface marker promote neoangiogenesis and vascular repair. Additional surface markers present on CD31⁺ cells may dictate the physiological function of these cells and their ability to contribute to vascular repair. **PURPOSE:** To determine if regular endurance exercise influences the composition of CD31⁺ cells by comparing total CD31⁺ number and subtypes in endurance trained and sedentary younger adults. **METHODS:** Fasted blood was obtained from healthy endurance exercise trained (n=12) and sedentary men (n=11) 18-39 years old. Peripheral blood mononuclear cells were isolated, FcR blocked and immunostained with antibodies specific to CD31-BB515, CD14-PECy5, CD11b-Pacific Blue, CD3-APC and CD34-Alexa Fluor700 and fixed in paraformaldehyde. The forward-side-scatter plot was used to identify the lymphocyte and monocyte gates from a total of 100,000 events/sample using a LSR II flow cytometer. Total CD31⁺ cells and the number of events with positive co-expression of CD31 and CD14, CD3, CD11b, or CD34 surface markers were quantified. **RESULTS:** No significant differences between groups were observed in total CD31⁺ number in both mono-lymphocytic (P=0.09) and lymphocytic (P= 0.1) populations. Within the mono-lymphocytic population, CD31⁺/CD3⁺ cells were 52% higher in the endurance trained compared to the sedentary individuals (P= 0.04). No differences between groups were

observed in the CD31+/CD14+ (P=0.3), CD31+/CD11b+ (P=0.5) or CD31+/CD34+ (P=0.17) subtypes. In the lymphocytic population, 48% more CD31+/CD34+ cells were observed in the endurance trained compared to the sedentary group (P=0.03). CD31+/CD34+ cell number was 60% higher in the endurance trained group compared to the sedentary group (P=0.06) and a trend was also observed for higher CD31+/CD14+ cells in the endurance trained compared to the sedentary group (88% higher, P=0.07). No differences in CD31+/CD11b+ were observed between groups (P=0.7). **CONCLUSION:** Despite no significant differences in total CD31+ cell number, a higher proportion of CD31+ cells from endurance trained men were found to have pro-angiogenic markers compared to sedentary men which may improve their functional capacity and angiogenic potential. Differential Cardiovascular and Mitochondrial Adaptations in Humanized P53 R72P Knock-In Mice

Junchul Shin¹, Soo-Young Choi¹, Soon-Gook Hong¹, Jacqueline Sayoc¹, Meghan Rath¹, Minsoo Kang, FACSM², Michael D. Brown, FACSM³, Maureen Murphy⁴, Joon-Young Park¹. ¹Temple University, Philadelphia, PA. ²University of Mississippi, Mississippi, MS. ³Auburn University, Auburn, AL. ⁴The Wistar Institute, Philadelphia, PA.

(No relevant relationships reported)

We previously demonstrated that tumor suppressor p53 plays a crucial role in mitochondrial biogenesis and mtDNA quality control by transcriptional regulation of mitochondrial transcription factor A (TFAM) gene. Human P53 gene contains a common polymorphism at codon 72 (p53R72P), which has been shown to be associated with mitochondrial integrity and their function. **PURPOSE:** Here, we investigate whether p53Arg72Pro is associated with exercise response with respect to cardiovascular and mitochondrial functions using humanized p53 knock-in mouse model. **METHODS:** Humanized P53 Knock-In mice (HUPKI) containing either the human version of P53R72 or P53P72 genes were randomly assigned to sedentary or a 9-week voluntary wheel running exercise (VW) group. Angiotensin II (1 mg/kg/day) was infused for 4 weeks before mice were euthanized. Maximal aerobic capacity was measured by a motorized treadmill running test. Blood pressure was measured using a radio-telemetry apparatus. Muscle mtDNA copy number was measured by qPCR. Muscle capillary density was measured by immunostaining. **RESULTS:** Aerobic exercise capacity was similar between R72 HUPKI vs P72 HUPKI in sedentary group. However, R72 HUPKI showed greater aerobic exercise capacity compared to P72 HUPKI mice in VW group compared to the R72 HUPKI (R72, 2584.2±536.0 vs. P72, 2015.3±359.4, sec, p=0.004). In the skeletal muscle, mtDNA content (P72, 0.98±0.28 vs. R72, 1.49±0.18, p=0.007) and capillary density (R72, 4.2±0.3 vs P72, 3.4±0.4, p=0.006) were significantly higher in R72 HUPKI compared to P72 HUPKI in VW group (p<0.05). In addition, R72 HUPKI showed significantly greater reduction in blood pressure after VW compared to P72 HUPKI (MAP, R72: 114.9±9.5 vs. P72: 128.5±17.9, mmHg, p=0.006). **CONCLUSION:** Data suggest that p53 codon 72 arginine allele may have a greater cardiovascular and mitochondrial adaptations to aerobic exercise training. Origin of Extracellular Vesicles Released During Exercise

Perikles Simon¹, Alexandra Brahmmer¹, Nils Haller¹, Leona Esch-Heisser², Elmo W. Neuberger¹, Eva-Maria Krämer-Albers². ¹Institute for Sports Science, Johannes Gutenberg-University Mainz, Mainz, Germany. ²Institute of Developmental Biology and Neurobiology, Johannes Gutenberg-University Mainz, Mainz, Germany.

Email: simonpe@uni-mainz.de

(No relevant relationships reported)

Physical activity triggers a wide range of multi-systemic adaptations that promote mental and physical health. Adaptation requires a massive cellular cross-talk between organs and extracellular vesicles (EVs) have been proposed as contributors to exercise-associated adaptive systemic signaling. Recent work demonstrated that exercise triggers the release of EVs into the circulation, but the subtype and the origin of EVs remained unknown.

PURPOSE: To apply detailed EV-phenotyping analysis exploring the cellular origin and subtypes of EVs released by exercise.

METHODS: 21 healthy male participants were subjected to an incremental cycling test until exhaustion and blood was drawn before, at a respiratory exchange ratio of 0.9 (RER 0.9), and immediately after the test. Different EV-subtypes were isolated from plasma by immunobead-based purification separately directed against the three EV-associated tetraspanins (CD9, CD63, CD81) and by size exclusion chromatography.

Analysis of EV-count was done by nano-particle tracking analysis followed by EV-subtype surface analysis by western-blotting and by multiplexed flow cytometry analysis.

RESULTS: Average load at RER 0.9 was 206 Watt and maximal load was 330 Watt. Markers found with significant fold-change increases were highly congruent between CD9⁻, CD63⁻ and CD81⁻EVs suggesting that the contributing cells release EVs containing all three tetraspanins. Strongest exercise related increases were obtained for CD81⁻EVs for platelet specific markers CD41b 2-fold; CD42a 2.2-fold, CD62P 2.9-fold, lymphocyte markers CD4 9.6-fold, CD8 1.8-fold, MHC-I 2.9-fold, markers specifying antigen-presenting cells MHCII 3.4-fold, CD40 2.9-fold, and endothelial markers CD31 2.5-fold, CD105 4.3-fold, CD146 3.3-fold. Overall, markers exhibited a trend to increase at RER 0.9 - probably indicating the onset of EV-release - with the endothelial marker CD105 on CD81⁻EVs as the only significantly 1.4-fold (95% CI: 1.1-1.9; p<0.05) elevated candidate following only 15min of aerobic exercise.

CONCLUSIONS: EVs released during exercise originate from a diverse group of cell types that are in direct contact with the blood stream and may preferentially contribute to signaling mechanisms affecting angiogenesis, coagulation, adaptive immunity and tissue repair.

Ablating The Rab-GTPase Activating Protein TBC1D1 Predisposes Rats To High Fat Diet-Induced Cardiomyopathy

Pierre-Andre Barbeau, Jacy M. Houad, Jason S. Huber, Sabina Pagliarlunga, Laelie A. Snook, Eric A.F. Herbst, Zane Chorney, Jeremy A. Simpson, Graham P. Holloway. University of Guelph, Guelph, ON, Canada. (Sponsor: Dr. Jamie Burr, FACSM) Email: pbarbeau@uoguelph.ca

(No relevant relationships reported)

While the pathogenesis of diabetic cardiomyopathy is poorly understood, impaired insulin signalling within the heart is thought to contribute to the development of this pathology. TBC1D1, a Rab-GTPase activating protein, is involved in glucose homeostasis and substrate metabolism within skeletal muscle, however, the function of TBC1D1 within the heart is relatively unknown.

PURPOSE: To examine the role of TBC1D1 in overall cardiac morphology and substrate utilization using a rat knock-out (KO) model.

METHODS: 7 weeks of high-fat feeding was provided as a metabolic perturbation to further elucidate the interaction between TBC1D1 and diet-induced cardiac contractile function. Experiments were conducted at 12 weeks of age, with the exception of cardiomyocyte isolation, which was conducted at 7 weeks of age. Animals were anaesthetized with 2.5% isoflurane before assessments of cardiac function, or surgical removal of the left ventricle. The left ventricle was immediately utilized for bioenergetics assessments, fixed for histology or immediately frozen in liquid nitrogen for Western blotting.

RESULTS: In chow-fed animals, TBC1D1 ablation increased plasma membrane GLUT4 content and glucose uptake, as well as plasma membrane FABPpm content and palmitate oxidation, consistent with activating cellular trafficking through the ablation of TBC1D1. While echocardiograms suggested indices of cardiac function were unaltered in chow fed KO animals, when challenged with a 7 week high-fat diet, TBC1D1 KO rats displayed a 4-fold increase in fibrosis in association with attenuated stroke volume, cardiac output and end diastolic volume, suggesting a predisposition to diet-induced cardiomyopathy. Mitochondrial respiratory capacity and substrate sensitivity to pyruvate and ADP were not altered by diet or TBC1D1 ablation, nor were rates of mitochondrial hydrogen peroxide emission, or markers of oxidative stress. **CONCLUSIONS:** Altogether, ablation of TBC1D1 improves indices of cardiovascular function in rats fed a standard diet, but increases fibrosis and compromises indices of cardiac function in rats consuming a high-fat diet. Therefore, TBC1D1 may exert cardioprotective effects in the development of diabetic cardiomyopathy. This research is supported by NSERC funding.

The “Syringe Potentiometer”: A Low-cost Solution For Accurate and Precise Calibration Of Pneumotachographs

Troy J. Cross, Eli Kelley, Timothy Hardy, Bruce Johnson. *Mayo Clinic, Rochester, MN.*
Email: cross.troy@mayo.edu
(No relevant relationships reported)

Pneumotachographs typically display highly nonlinear “pressure-flow” behavior. As such, a constant calibration factor (*K*) is inadequate for these devices, and a nonlinear *K* curve is preferred. Two methods have been described to produce nonlinear *K* curves for pneumotachographs: the weighted averaging method described by Yeh *et al.* (*J Appl Physiol*, 53: p280, 1982); and the polynomial approach forwarded by Tang *et al.* (*J Appl Physiol*, 95: p571, 2003). These methods, however, do not incorporate measurements of a flow “reference” and, subsequently, a direct measure of their flow accuracy and precision has not yet been provided.

PURPOSE: To modify a standard 3-L calibration syringe to provide a valid reference flow signal.

METHODS: A standard 3-L syringe was modified to incorporate a 3D-printed linear-slide mechanism affixed to the plunger. A string potentiometer was attached to a fixation point on the linear-slide-plunger assembly which provided a voltage signal in proportion to the plunger length and, consequently, volume. The first derivative of this signal provided a “reference” flow. Nonlinear *K* curves were obtained via the weighted averaging (WA) and polynomial (POLY) approaches, and from dividing the “reference” flow by the analog signal from the pneumotachograph (REF). The flow accuracy (average error) and precision (standard deviation of errors) of each method were compared over low (<1 L·s⁻¹), medium (≥1-3.0 L·s⁻¹), high (≥3.0-6.0 L·s⁻¹) and very high (≥6.0-16.0 L·s⁻¹) flow rates. Over 180 strokes were recorded from the syringe.

RESULTS: The accuracy of the WA, POLY, and REF methods displayed high accuracy (<±25 ml·s⁻¹) over the low, medium and high flow ranges. However, the WA and POLY methods yielded modest underestimates of flow (75-100 ml·s⁻¹) in the very high flow range, while the REF method remained within ±25 ml·s⁻¹. The precision of each method was <25 ml·s⁻¹ for low to high flow rates. At very high flows, the REF method displayed the best precision (60 ml·s⁻¹) compared with the POLY (80 ml·s⁻¹) and WA (>120 ml·s⁻¹) methods.

CONCLUSIONS: While all 3 calibration methods displayed comparable performance up to 6.0 L·s⁻¹, the “syringe potentiometer” and, by extension, the REF method provided the best accuracy/precision at very high flow rates (i.e., ≥6.0-16.0 L·s⁻¹).

(No relevant relationships reported)

Pulmonary function and inspiratory muscle strength decrease with advancing age. In healthy young subjects, it has been reported that there is a positive correlation between maximal inspiratory pressure (P_{imax}) as an index of inspiratory muscle strength and diaphragm thickness (T_{di}), which is assessed by ultrasonography. Therefore, we hypothesized that T_{di} in elderly subjects would be thinner than in young subjects, accompanied by a reduction of P_{imax}. **PURPOSE:** The aim of this study was to characterize the inspiratory muscle strength and diaphragm thickness in elderly women. **METHODS:** Nine healthy elderly females (67.6±1.2 yrs) and fourteen young females (18.9±0.3 yrs) volunteered for this study. Pulmonary function (vital capacity, forced vital capacity and maximal voluntary ventilation) and P_{imax} were determined using computerized spirometry system with a hand-held mouth pressure meter. T_{di} was monitored at functional residual capacity (FRC) and total lung capacity (TLC) by B-mode ultrasound: the probe was held between the 7th, 8th, or 9th intercostal spaces on the right side. **RESULTS:** Pulmonary function and P_{imax} were significantly lower in the elderly than those in young individuals. There were no significant differences in T_{di} at FRC (elderly women: 2.8±0.3 mm, young women: 2.5±0.1 mm) and TLC (elderly women: 4.9±0.2 mm, young women: 4.5±0.2 mm) between the two groups. Additionally, no significant correlation was found between P_{imax} and T_{di}.

CONCLUSIONS: These results suggest that inspiratory muscle strength in women reduces with advancing age, which is not accompanied by a decrease in diaphragm thickness.

(No relevant relationships reported)

PURPOSE: Previous research indicates the importance of cysteinyl leukotrienes (cyst-LTs) in the pathogenesis of exercise-induced bronchoconstriction (EIB) and asthma. As a result of airway hyperresponsiveness, mast cells, airway epithelial cells, and other inflammatory cells produce cyst-LTs which leads to airway inflammation and subsequent bronchoconstriction. Urine analysis of cyst-LTs is a common noninvasive technique but has poor repeatability among studies. Exhaled breath condensate (EBC) has been suggested as an alternative, more reliable measurement of cyst-LTs. Therefore, the aim of this study was to determine if EBC is an accurate method for detecting changes in cyst-LT production following a eucapnic voluntary hyperventilation (EVH) challenge. **METHODS:** Twenty-two subjects [age (mean ± SD) = 20.1 ± 2 yr; 6 men, 16 women] with physician diagnosed asthma (mild- to moderate-) and established EIB participated in this study. All subjects experienced a > 10% drop in FEV₁ following an EVH challenge. Subjects then completed baseline pulmonary function tests at rest followed by 10 mins of baseline EBC collection. Subjects then performed an EVH challenge and pulmonary function was administered at 5, 10, 15, and 20min post-EVH. EBC was collected from 0-10 mins post-EVH and urine samples were collected pre- and 60 min post-EVH challenge. **RESULTS:** The concentration of cyst-LTs in EBC increased significantly (p<0.01) post-EVH challenge, resulting in a 97% increase from baseline. In addition, urinary cyst-LT concentrations were significantly different pre- and post-EVH challenge (p=0.04) increasing 21% from baseline. A significant correlation was found between EBC and urine concentrations of cyst-LTs both pre- and post-EVH. However, no significant correlation (p>0.05) was discovered between the change in cyst-LT concentration pre- to post-EBC and urine. **CONCLUSIONS:** The present study suggests that EBC is a sensitive, non-invasive method for assessing changes in cyst-LTs and the inflammation status of the airways following an EVH challenge.

Email: wheatley.courtney@mayo.edu
(No relevant relationships reported)

Ultraendurance events induce prolonged physiological stress that can cause perturbations in heart and lung function due to the elevated workloads. Variations in race distance and environmental conditions alter the length of time this stress is experienced, which when long enough, can also result in sleep deprivation. Beyond spirometry, whether the duration of this stress affects the degree of change in lung health remains somewhat unknown. **Purpose:** To evaluate the effects of moderate altitude (course range: 1000-2800m) ultraendurance trail running and the influence of distance on pulmonary function, lung mechanics and respiratory muscle strength. **Methods:** Spirometry, force oscillation and maximal inspiratory and expiratory pressures (MIP/MEP) assessments were performed 24-72hrs prior and 1-3hrs post-completion of either a 100km (CCC; n=9, 2 females, age= 43±12, finishing time= 21±4h) or 171.5km (UTMB; n=9, 2 females, age= 40±8y, finishing time= 38±9h) trail running race. **Results:** Pulmonary function was significantly reduced from baseline after both CCC and UTMB, but the magnitude of decline was not different between races (CCC vs. UTMB: ΔFVC= -158±331 vs. -257±463mL; ΔFEV₁= -245±240 vs. -302±398mL/s; ΔPEF= -981±976 vs. -803L/min; ΔFEF₂₅₋₇₅= -493±1140 vs. -484±669mL/s; ΔVC= -204±478 vs. -500±910mL, p<0.05 different from zero for all, p>0.05 CCC vs. UTMB respectively for all). Efficiency of ventilation (reactance=X_{rs}) decreased at all frequencies (5-11-19Hz), whereas as obstruction (resistance=R_{rs}) in

the peripheral lung (5Hz) increased following both the CCC and UTMB ($\Delta Xrs5insp = -0.14 \pm 0.33$ vs. $-0.43 \pm 0.38 \text{ cmH}_2\text{O/L/s}$; $\Delta Rrs5insp = 0.23 \pm 0.53$ vs. $0.78 \pm 1.32 \text{ cmH}_2\text{O/L/s}$). Neither MIP nor MEP was reduced relative to baseline following CCC and UTMB. **Conclusions:** Participation in an ultraendurance trail race resulted in acute reductions in lung function and lung mechanics without a reduction in respiratory muscle strength. Further, these changes in lung health were not aggravated by a longer race distance and stress duration.

Muscular Strength, Exercise Capacity and Body Composition of Alpha-1 Antitrypsin Deficient COPD Patients

Eóin Durkan¹, Aidan J. Brady¹, Tomás Carroll², Noel G. McElvaney³, Niall M. Moyna¹. ¹Dublin City University, Dublin, Ireland. ²Alpha One Foundation, Dublin, Ireland. ³Royal College of Surgeons, Dublin, Ireland. (Sponsor: Micheal Harrison, FACSM)
Email: eoin.durkan@dcu.ie
(No relevant relationships reported)

PURPOSE: Alpha-1 antitrypsin deficiency (AATD) is the most common genetic disorder affecting people of European descent. The condition often results in the development of emphysema, leading to chronic obstructive pulmonary disease (COPD) in the third/fourth decade of life. Breathlessness, resultant deconditioning and exercise intolerance are often the most troublesome symptoms reported by patients with COPD and are linked to poor quality of life (QoL). Typically, patients with AATD COPD are assessed by pulmonary function test (PFT). However, exercise capacity (EC) cannot be reliably predicted from PFTs. Deconditioning is associated with reduced EC and QoL. The current study examines differences in PFTs, body composition, muscular strength, EC and QoL between AATD COPD patients (ZZ) and alpha-1 antitrypsin replete COPD patients (MM). **METHODS:** 29 ZZ patients, (m/f 20/9, age 60 ± 8 , FEV1/FVC: 0.47 ± 0.12 , FEV1%pred. 51 ± 22 , DLCO%pred. 73 ± 21) were recruited from the National Centre of Expertise for AATD in Beaumont Hospital, Ireland. Patients performed spirometry and diffusing capacity for carbon monoxide (DLCO) was assessed. Body mass index (BMI) and waist:hip (W:H) ratio were calculated. QoL and symptom perception were examined using the SF-36 questionnaire (SF-36) and St. George's Respiratory Questionnaire (SGRQ), respectively. EC was assessed via 6 minute walk test (6MWT), upper body strength via handgrip dynamometer (HG) and lower body strength via 30 sec sit to stand test (30STS). 9 MM patients (m/f 2/7, age 65 ± 5 yr, FEV1/FVC: 0.47 ± 0.15 , FEV1%pred. 58 ± 29 , DLCO%pred. 72 ± 17) completed the same protocol. Continuous data are presented as mean \pm SD. Mean group differences were compared using an independent t-test. **RESULTS:** There was a significant group difference for handgrip strength (ZZ 38 ± 10 vs MM 29 ± 7 p=0.009) and SGRQ scores for Symptoms (ZZ 41.2 ± 20.9 vs MM 60.0 ± 13.8 p=0.023), Impacts (ZZ 24.4 ± 17.4 vs MM 43.2 ± 20.8 p=0.014), and Total (ZZ 35.6 ± 18.2 vs MM 54.5 ± 14.5 p=0.011). SF-36 Vitality score was higher in ZZ than MM (58.2 ± 21.5 vs 40.5 ± 19.6 p=0.035). **CONCLUSIONS:** For the same level of COPD and similar body composition, fitness and upper body strength, ZZ patients present with significantly lower SGRQ scores and significantly higher SF-36 scores than MM patients.

2398 Board #62 May 31 9:30 AM - 11:00 AM

Observations of Late-Onset Exercise Oscillatory Ventilation

Jessica D. Berg, Joshua R. Smith, Thomas P. Olson, FACSM. Mayo Clinic, Rochester, MN. (Sponsor: Thomas Olson, FACSM)
(No relevant relationships reported)

Exercise oscillatory ventilation (EOV) is characterized by regular waxing and waning of ventilation without apnea during exercise. In patients with heart failure (HF) development of EOV is a robust predictor of mortality. EOV is typically reported during the early stages of exercise and dissipates during the later stages of exercise. We have recently identified a cohort of diagnostically diverse patients that present EOV during the late stages of exercise. This late-onset pattern is contradictory to the common pattern of EOV, thus we termed it late-onset EOV. **Purpose:** To retrospectively analyze clinical characteristics, demographics and breathing patterns of patients who presented with late-onset EOV. **Methods:** The medical records of eleven patients (6M/5F, 53 ± 19 yrs, BMI: 29 ± 12 kg/m²) demonstrating late-onset EOV during clinically indicated cardiopulmonary exercise testing were retrospectively analyzed. The amplitude of cycles were calculated as peak \dot{V}_E minus nadir \dot{V}_E during each cycle. The period of each cycle was calculated measuring the time from nadir to nadir. \dot{V}_E/VCO_2 slope was calculated as $(\dot{V}_{E_{peak}} - \dot{V}_{E_{nadir}}) / (VCO_{2_{peak}} - VCO_{2_{nadir}})$. Late-onset EOV was defined as ≥ 3 amplitudes of $\geq 25\%$ of the average \dot{V}_E for 3 consecutive cycles with the EOV originating $\geq 50\%$ $\dot{V}O_{2peak}$. **Results:** Diagnoses included heart failure (n=6), diabetes (n=4), exercise induced arrhythmia (n=7), hypertension (n=4) and hyperlipidemia (n=4) and medications included beta-blockers (n=7), aspirin (n=6), diuretics (n=5) and statins (n=5); however, no diagnosis or medication were common across all patients. The $\dot{V}O_{2peak}$ was

20 ± 7 mL/kg/min ($72 \pm 28\%$ predicted $\dot{V}O_{2peak}$). None of the patients demonstrated oscillatory ventilation at rest, while all of the patients exhibited EOV at $>50\%$ $\dot{V}O_{2peak}$ (amplitude of mean $\dot{V}_E = 44.7\%$, period=40.4s). \dot{V}_E/VCO_2 slope had a positive correlation with EOV amplitude ($r=0.74$, $p=0.01$). The % predicted $\dot{V}O_{2peak}$ had a negative relationship with EOV period ($r=-0.64$, $p=0.04$). **Conclusion:** Our data demonstrate, in a diverse patient population, that the onset of EOV can occur during late stages of exercise and is related to metrics of exercise intolerance. No clear diagnosis or medication was common among these patients. Additional research is required to elucidate the mechanisms contributing to late-onset EOV.

Limitations To $\dot{V}O_{2max}$ In Competitive Swimmers

Curtis S. Goss, Joel T. Greenshields, Stephen D. Husch, Robert F. Chapman, FACSM, Joel M. Stager, FACSM. Indiana University - Bloomington, Bloomington, IN. (Sponsor: Robert Chapman, FACSM)
(No relevant relationships reported)

PURPOSE: Literature containing $\dot{V}O_{2max}$ values for competitive swimmers is sparse and has generally reported modest values for competitive swimmers when compared with other endurance athletes. The purpose of this investigation was 1) to pool the findings of previous research to provide a reference value for the $\dot{V}O_{2max}$ of competitive swimmers and 2) to examine primary data to suggest a basis for the modest values reported to date. **METHODS:** Values obtained from the literature from swimmers age 17 years or older described as "trained," "highly-trained," "collegiate," "national-level," "international-level," or "elite," and completing incremental, open-flow, indirect calorimetry swimming protocols were included in the analysis. A mean and 95% CI were calculated for each sex using a random-effects model. Additionally, in our laboratory, swimming $\dot{V}O_{2max}$ data were collected on national- and international-level women and men swimmers in a swimming flume using a continuous, incremental weight-loading protocol at a constant speed. These data were compared to $\dot{V}O_{2max}$ data from national-level runners (7 men) who completed an incremental grade increase treadmill protocol in our lab. **RESULTS:** Eight articles utilizing swimming protocols ($k=9$, $n=70$ women; $k=13$, $n=121$ men) were analyzed. The relative $\dot{V}O_{2max}$ (mL·kg⁻¹·min⁻¹; mean \pm 95% CI) was 50.2 ± 1.3 for women and 54.9 ± 0.5 for men. Our $\dot{V}O_{2max}$ data (4 women; 10 men) agree with the literature values (mean \pm SD; 51.0 ± 5.0 women; 53.6 ± 4.7 men). There was a strong ($r=0.75$) and significant ($p=0.01$) correlation between breathing frequency (f_b ; breaths·min⁻¹) at max and relative $\dot{V}O_{2max}$ in the men swimmers that was not evident in the running cohort ($r=-0.41$; $p=0.34$). Relative $\dot{V}O_{2max}$, minute ventilation ($\dot{V}_{E_{BTPS}}$; L·min⁻¹), and f_b at max were significantly different ($p < 0.01$; $p < 0.01$; $p = 0.01$) between men swimmers ($\dot{V}_{E_{BTPS}} = 135.7 \pm 16.1$; $f_b = 47.1 \pm 9.1$) and runners ($\dot{V}O_{2max} = 73.9 \pm 3.5$; $\dot{V}_{E_{BTPS}} = 169.7 \pm 16.6$; $f_b = 58.6 \pm 7.6$). **CONCLUSIONS:** The relationship between f_b and $\dot{V}O_{2max}$ in swimmers suggests that $\dot{V}O_{2max}$ for competitive swimmers could be compromised at least in part by f_b and presumably \dot{V}_E by extension. The absence of this same relationship in runners suggests that this could be due to constraints specific to swimming, such as phase-locked breathing.

2400 Board #64 May 31 9:30 AM - 11:00 AM

The Effects of Cold Water and Cold Sports Drink Consumption on Resting Lung Function

Sandra Tecklenburg-Lund, Seth C. Brauman, Rhiannon M. Seneli. St. Ambrose University, Davenport, IA.
Email: lundsandrat@sau.edu
(No relevant relationships reported)

Resting pulmonary function (PFT) is known to have important effects on ventilation, gas exchange and breathing mechanics during and after exercise. Previous research has shown that consumption of 1L of cold water affects resting lung function, but no other beverages have been examined. Because athletes frequently consume cold water or sports drink, it is important to understand the effects of these beverages on pulmonary function. **PURPOSE:** Therefore, the purpose of this study was to determine whether cold water or cold sports drink would decrease resting PFTs in healthy individuals. **METHODS:** Nine healthy (6 men, 3 women), individuals (age 22 ± 1 yrs) visited the laboratory on two separate occasions to complete an experimental trial consisting of either 1L of cold water (-4°C) or 1L cold sports drink (-4°C). PFTs were performed before and at 5, 10, and 15 min after beverage ingestion. Data were analysed using paired t-tests. **RESULTS:** The cold water significantly reduced forced vital capacity (FVC) from pre- to post- ingestion by 3.7% (4.96 ± 1.17 L to 4.78 ± 1.12 L) ($p=0.002$). Similarly, the cold sports drink significantly reduced FVC from pre- to post- ingestion by 3.7% (5.09 ± 1.17 L to 4.93 ± 1.24 L) ($p=0.02$). Maximum drop in FVC was not significantly different between water and sports drink ($p=0.99$). Forced expiratory volume in 1 second (FEV₁) significantly decreased by 3.5% from pre- to post- water ingestion

(4.35 ± 1.05 L/min to 4.22 ± 0.96 L/min) ($p = 0.04$). Sports drink also significantly decreased FEV₁ by 5.0% from pre- to post ingestion (4.34 ± 1.09 L/min to 4.16 ± 1.08 L/min) ($p = 0.015$). There was no significant difference in maximum drop FEV₁ from pre- to post-ingestion between water and sports drink ($p=0.29$). **CONCLUSIONS:** The ingestion of cold water and cold sports drink decreased pulmonary function in healthy individuals, but changes in PFTs were not different between the two beverages. This suggests that cold fluid intake can influence PFT measurement and could be an important consideration for individuals planning fluid intake strategies pre-, during, and post-exercise.

Peripheral Chemosensitivity To Hypoxia And Hypercapnia Is Not Attenuated In Symptomatic Concussed Athletes

Emma L. Reed, James R. Sackett, Suman Sarker, Zachary J. Schlader, FACSM, John J. Leddy, Blair D. Johnson. *The State University at Buffalo, Buffalo, NY.*
Email: elreed@buffalo.edu

(No relevant relationships reported)

Central chemosensitivity to hypercapnia is attenuated in symptomatic concussed athletes (CA) compared to healthy controls (HC). Activation of the peripheral chemoreceptors is needed to elicit the full ventilatory response to hypercapnia. However, it is unknown if peripheral chemosensitivity (PCS) is attenuated in CA. **Purpose:** We tested the hypothesis that PCS is lower in symptomatic CA versus HC. **Methods:** PCS to hypoxia (PCS_{O₂}) and hypercapnia (PCS_{CO₂}) were assessed in 7 symptomatic CA (4 females, age: 20 ± 2 y) and 10 HC (3 females, age: 23 ± 2 y). CA were tested within 5 ± 2 days of injury. Ventilation (V_E), heart rate (HR), mean arterial pressure (MAP), arterial oxygen saturation (%S_{pO₂}), and the partial pressure of end tidal CO₂ (PETCO₂) were recorded continuously. For PCS_{O₂}, participants inhaled 2-6 breaths of 100% N₂, followed by 3 min of room air breathing, 10 separate times. For PCS_{CO₂}, participants inhaled 1 breath of 13% CO₂, 21% O₂, and 66% N₂, followed by 3 min of room air breathing, 10 separate times. We determined the mean of the three highest consecutive V_E values, the peak HR and MAP, the nadir %SaO₂, and the peak PETCO₂ within 2 min following each hypoxic or hypercapnic administration. The PCS_{O₂} and PCS_{CO₂} data are reported as the slope of the linear regression line of V_E vs. %SaO₂ or PETCO₂, respectively. The peak HR and MAP responses following hypoxia were also plotted against the nadir %SaO₂ and the slope of the resulting linear regression lines represented the cardiovascular responses (PCS_{HR} and PCS_{MAP}, respectively) to hypoxia mediated by the PCS. **Results:** Baseline HR (59 ± 14 vs. 66 ± 7 bpm; $P = 0.10$), MAP (97 ± 15 vs. 89 ± 10 mmHg; $P = 0.09$), DBP (74 ± 13 vs. 69 ± 4 mmHg; $P = 0.16$), PETCO₂ (44 ± 2 vs. 45 ± 2 mmHg; $P = 0.11$), and %SpO₂ (98 ± 3 vs. $97 \pm 1\%$; $P = 0.27$) did not differ between CA and HC, respectively. Baseline SBP was higher in CA (129 ± 19 vs. 117 ± 8 mmHg; $P = 0.05$). There were no differences in PCS_{O₂} (0.40 ± 0.21 vs. 0.38 ± 0.36 L/min/%S_{pO₂}; $P = 0.45$), PCS_{MAP} (0.58 ± 0.38 vs. 0.67 ± 0.52 mmHg/%S_{pO₂}; $P = 0.35$), PCS_{HR} (0.88 ± 0.73 vs. 1.34 ± 1.53 bpm/%S_{pO₂}; $P = 0.24$), or PCS_{CO₂} (0.07 ± 0.11 vs. 0.07 ± 0.04 L/min/mmHg; $P = 0.44$) between CA and HC, respectively. **Conclusions:** These data indicate that PCS is not lower in symptomatic CA vs. HC. It is unlikely that the peripheral chemoreceptors contribute to the reduced ventilatory response to hypercapnia in CA.

Do Faster Ultra-endurance Runners Have A Pulmonary Phenotype?

Caitlin Jorgenson¹, Glenn Stewart¹, Courtney Wheatley¹, Paul Robach², Alice Gavet², Briana Ziegler¹, Jesse Schwartz¹, Bryan Taylor³, Loïc Chabridon², Pierre Bouzat⁴, Bruce Johnson¹. ¹Mayo Clinic, Rochester, MN. ²Ecole Nationale de Sports de Montagne, Chamonix, France. ³University of Leeds, Leeds, United Kingdom. ⁴Grenoble University Hospital, Grenoble, France.
(No relevant relationships reported)

Purpose: The cardiopulmonary system of ultramarathon runners is exposed to prolonged periods of increased cardiac output and ventilation during exercise, which can stress the alveolar-capillary membrane. In order to determine if an adaptive pulmonary phenotype exists in ultramarathon runners, we tested the hypothesis that individuals who can sustain a faster race pace have superior pulmonary function and lung diffusing capacity. **Methods:** Twenty-seven runners were assessed prior to a 100km ultramarathon at two different rates (Hong Kong 100, N=19, CCC, N=8). Forced vital capacity (FVC) and forced expiratory volume in 1s (FEV₁) were assessed via spirometry. Lung diffusing capacity for carbon monoxide (DLCO) and nitric oxide (DLNO) were measured using a single-breath technique at rest and during 3 stages of low level exercise. The DLNO/DLCO was calculated to assess the relative contribution of membrane conductance to capillary blood volume. The cohort was split into a faster group with an average finish time under 15 hours and a slower group with an average finish time above 21 hours to compare differences in pulmonary function. **Results:** Baseline FVC and FEV₁ were not different in the faster runners (FVC= 5.2 ± 0.5 L;

FEV₁= 4.2 ± 0.5 L) compared to the slower runners (FVC= 5.2 ± 1.1 L; FEV₁= 4.1 ± 0.8 L), and did not differ from normative values, with overall percent predicted FVC and FEV₁ at 105% and 92%, respectively. DLCO and DLNO did not differ between groups (fast, DLCO= 33.2 ± 6.0 mmHg, DLNO= 160.2 ± 26.0 mmHg; slow, DLCO= 30.2 ± 5.5 mmHg, DLNO= 155.2 ± 27.6 mmHg), however the ratio of DLNO/DLCO was lower in the faster group at rest (4.9 vs. 5.2 , $p=0.018$) and during exercise (stage3: 4.9 ± 0.2 vs. 5.3 ± 0.4 , $p<0.01$). **Conclusions:** Resting lung function was not enhanced in faster runners, however the altered DLNO/DLCO ratio with light exercise suggests a greater relative contribution of capillary blood volume to membrane conductance might be associated with ultraendurance performance.

The Effects of Single versus Multiple Sets of Leg Presses on Myocardial Energy Expenditure

Junhai Xu¹, Arnold G. Nelson, FACSM². ¹Louisiana State University, BATON ROUGE, LA. ²Louisiana State University, Baton Rouge, LA. (Sponsor: Arnold G Nelson, FACSM)

(No relevant relationships reported)

A popular trend in exercise regimes is to maximize the amount of work done in a minimum amount of time or maximize work by minimizing rest intervals. It is hoped that reduced rest time will result in dramatic fitness gains. To date, however, no differences in total energy expenditures have been found between high and low rest interval protocols. Unfortunately, total energy expenditures do not reflect the metabolic strain experienced by the cardiac tissue. Rather, the rate pressure product [RPP = Systolic blood pressure \times heart rate/1,000] has been recommended as a good index to assess cardiovascular metabolic stress, and to help determine the intensity and duration of exercise in developing fitness. **PURPOSE:** To determine if cardiac energy expenditure (i.e. RPP) differs between high rest (multiple sets) and low rest (single set) exercise protocols. **METHODS:** 14 untrained college students (5 male, 9 female; Age: 21.1 ± 0.2 years) participated in the study. Exercise intervention consisted of 2 days of multiple sets (4 sets, 10 reps @ 150% body weight, 3 min interser rest) and 2 days of single set (40 reps @ 150% body weight) leg presses, randomly assigned in a balanced crossover order. At least 2 days separated each session and all sets were completed as fast as possible. HR and SBP were obtained on the right arm with an automated blood pressure machine at both pre-exercise and immediate post set completion. A paired T-test was used to compare the difference between the average final post set RPP of two trials of each exercise type. **RESULTS:** Multiple sets RPP (13.7 ± 0.8) was significantly less ($t=6.5 \times 10^{-5}$, $p<0.05$) than the single set RPP (17.5 ± 0.8). **CONCLUSION:** Contrary to total body energy expenditure research, a single set of exercise exerts more metabolic stress on the cardiovascular system than doing the same work with several rest intervals. Thus, single set of exercise could be used to train when attempting to train cardiac tissue, but multiple sets of exercise is recommended for people with compromised cardiovascular systems.

Associations between Time Spent in Sedentary Behaviors and Cardiometabolic Disease Risk Factors in Young Adults

Katrina Taylor¹, Megan C. Nelson², Chantal A. Vella, FACSM². ¹Eastern Washington University, Cheney, WA. ²University of Idaho, Moscow, ID.

Email: ktaylor31@ewu.edu

(No relevant relationships reported)

Research suggests that sedentary behavior is associated with cardiometabolic disease (CMD) risk factors but much of this research has relied on self-report measures of sedentary time. **PURPOSE:** To determine the associations between sedentary time and CMD risk factors in young adults. **METHODS:** Undergraduate students ($n=95$; age 20.4 ± 1.3 y; BMI 23.9 ± 2.9 kg.m⁻²) wore an accelerometer during waking hours for 7 consecutive days to measure sedentary time (<150 counts/min) and moderate-to-vigorous physical activity (MVPA, $\geq 2,690$ counts/min). Body composition, waist circumference, blood pressure (BP), and fasting glucose, triglycerides, high-density lipoprotein (HDL), and low-density lipoprotein (LDL) were measured and lipid accumulation product (LAP) was calculated. Multiple regression analyses were used to assess associations among variables, while controlling for sex, race/ethnicity, smoking, family history of diabetes, study time, and MVPA. Analysis of covariance was used to compare CMD risk factors across tertiles of sedentary time. **RESULTS:** On average,

students spent 8.4 ± 1.5 h.d⁻¹ in sedentary behaviors. Sedentary time was associated with diastolic BP ($R^2=0.22$, $\beta=0.35$, $p=0.001$), fat mass ($R^2=0.39$, $\beta=0.22$, $p=0.02$), triglycerides ($R^2=0.11$, $\beta=0.24$, $p=0.04$), waist circumference ($R^2=0.15$, $\beta=0.23$, $p=0.04$), and LAP ($R^2=0.17$, $\beta=0.30$, $p=0.008$) independent of all covariates. There were no associations between sedentary time and systolic BP, glucose, HDL, or LDL ($p \geq 0.05$). Waist circumference was different across tertiles of sedentary time (tertile 1: 79.8 ± 14.3 cm vs. tertile 3: 85.2 ± 14.5 cm, $p=0.02$). Further, diastolic BP ($p=0.007$), LDL ($p=0.002$), fat mass ($p=0.04$) and LAP ($p=0.01$) were significantly different across tertiles of sedentary time with less favorable outcomes as sedentary time increased. **CONCLUSIONS:** Our findings suggest that sedentary time is independently associated with markers of CMD in young adults. Further, those who engage in 8 hours or more of sedentary behavior per day have significantly less favorable outcomes across a range of CMD risk factors. These findings support the need to develop public health recommendations regarding minimizing sedentary behaviors, particularly in young adults. Translational Designed HIIT Protocol Improves Peak VO₂ In A Preclinical HCM Model Without Adverse Events

Jonathan J. Herrera¹, Kate Szczesniak¹, Danielle L. Szczesniak¹, Jaime Yob¹, Jil C. Tardiff², Sharlene Day¹. ¹University of Michigan, Ann Arbor, MI. ²University of Arizona, Ann Arbor, MI.
 Email: jonjoe@med.umich.edu
 (No relevant relationships reported)

Exercise training improves cardiorespiratory capacity (peak or pVO_2) in healthy and cardiac disease states. High Intensity Interval Training (HIIT) is a prominent strategy in cardiac rehab do to superior pVO_2 improvements. Reduced pVO_2 in patients w/hypertrophic cardiomyopathy (HCM) powerfully predicts adverse outcomes, including mortality and heart transplant. Participation in vigorous exercise, however, is controversial in HCM patients given concerns of sudden cardiac death even though recent data suggests risks are much lower than previously thought. **PURPOSE:** Evaluate the effects of HIIT on pVO_2 in a preclinical transgenic cardiac troponin T delta160E (TG) HCM mouse model. **METHODS:** C57Bl/6 non-transgenic (NTG) ($n=6$ F, $n=5$ M) and TG ($n=4$ F, $n=8$ M) mice (13-16mos) underwent a translationally parallel cardiac rehab HIIT protocol. One treadmill training bout included 4-4min high intensity intervals (~85% pVO_2) interspersed by 5-3min recovery intervals (~50% pVO_2) for 31 total mins. Bouts were repeated 3 times/wk for 10wks. Compliance was measured as % of total training time completed. Randomized pre and post pVO_2 (metabolic treadmill testing) and body composition (NMR) were measured by a blinded technician. Unpaired and paired t-tests were used for data analysis. **RESULTS:** Training compliance b/w TG and NTG did not differ ($921.90 \text{ min} \pm 4.24$, 99.13% vs $928.95 \text{ min} \pm 1.05$, 99.90% ; $p=0.14$). Pre and post HIIT pVO_2 were significantly lower in TG mice than NTG (pre: $102.36 \text{ mL/kg/min} \pm 2.04$ vs. $119.20 \text{ mL/kg/min} \pm 5.57$, $p<0.01$; post: $120.89 \text{ mL/kg/min} \pm 4.19$ vs $140.03 \text{ mL/kg/min} \pm 4.18$, $p<0.01$). Paired analysis detected a significant increase in pVO_2 following HIIT training in both TG and NTG groups ($p<0.01$). TG mice had significantly greater pre and post % lean mass (pre: $69.96\% \pm 1.11$ vs $66.46\% \pm 1.09$, $p<0.05$; post: $70.73\% \pm 0.56$ vs $68.47\% \pm 0.79$, $p<0.05$), and significantly less pre and post % fat mass (pre: $11.89\% \pm 1.12$ vs $15.22\% \pm 1.08$, $p<0.05$; post: $11.74\% \pm 0.52$ vs $13.86\% \pm 0.76$, $p<0.05$). Post-HIIT 24hr ambulatory activity did not differ b/w groups (TG: 334.5 beam crosses ± 33.3 vs. NTG: 534.8 beam crosses ± 101.8 , $p=0.070$). **CONCLUSION:** HIIT training increased pVO_2 in a HCM mouse model without adverse consequences, providing the rationale to explore exercise as a positive disease modifier in HCM patients.

E-34 Free Communication/Poster - Vascular Function

Friday, May 31, 2019, 7:30 AM - 12:30 PM

High Blood Flow Restriction Pressure is Necessary to Induce Vascular Adaptations with Very Low-Load Training

Kevin T. Mattocks¹, J Grant Mouser², Matthew B. Jessee³, Scott J. Dankel⁴, Samuel L. Buckner⁵, Zachary W. Bell⁴, Takashi Abe⁴, John P. Bentley⁴, Jeremy P. Loenneke⁴. ¹Lindenwood University - Belleville, Belleville, IL. ²Troy University, Troy, AL. ³University of Southern Mississippi, Hattiesburg, MS. ⁴University of Mississippi, University, MS. ⁵University of South Florida, Tampa, FL.
 (No relevant relationships reported)

Vascular conductance is increased to a similar extent following low load (30% of one repetition maximum (1RM)) resistance training with and without blood flow restriction (BFR). It is unclear, however, if very low force (<30% 1RM) contractions require BFR to produce this effect. It is also relatively unknown if or how the venous system changes following chronic BFR as this type of training causes blood to dam up in the veins during BFR.

Purpose: To examine the vascular responses to lifting a very low-load (15% 1RM) with and without different pressures (40 and 80% arterial occlusion pressure) and how it compares to high load (70% 1RM) training in the lower body.

Methods: Forty non-resistance trained individuals performed two of four conditions (one in each leg): 1) 15% 1RM, no BFR (15/0), 2) 15% 1RM, 40% arterial occlusion pressure (15/40), 3) 15% 1RM, 80% arterial occlusion pressure (15/80), and 4) 70% 1RM, no BFR (70/0). Participants performed 4 sets of unilateral knee extension to failure (up to 90 repetitions) with 30 (15% 1RM) or 90 (70% 1RM) seconds of rest between sets, twice a week for 8 weeks. Before and after the training protocol, vascular conductance and venous compliance were measured. Data displayed as mean change (95% CI).

Results: There was a significant time by condition interaction for vascular conductance ($p=0.04$). Conditions 15/80 [7.9 (3.4 , 12.3) flow $\cdot 10^2$ mmHg] and 70/0 [7.2 (2.7 , 11.7) flow $\cdot 10^2$ mmHg] increased vascular conductance while conditions 15/0 [-1.2 (-5.7 , 3.3) flow $\cdot 10^2$ mmHg] and 15/40 [-0.864 (-5.6 , 3.9) flow $\cdot 10^2$ mmHg] did not change. There was no interaction ($p=0.335$), nor were there main effects of condition ($p=0.684$) or time [0.001 (-0.001 , 0.004) ml/100 ml/mmHg, $p=0.204$] for venous compliance.

Conclusion: A high BFR pressure (80% arterial occlusion pressure) combined with a very low-load produces similar vascular responses to that of high load resistance training. It may be that lifting a load of 15% 1RM without BFR and that the application of a moderate pressure (40% arterial occlusion pressure) does not disrupt blood flow enough to impact vascular conductance. These results add to the hypothesis that a higher restriction pressure is necessary to induce certain peripheral adaptations when utilizing a load less than 30% 1RM.

2407 Board #71 May 31 11:00 AM - 12:30 PM
High Pressure Blood Flow Restriction Is Necessary For Peripheral Vascular Adaptations With Very Low Loads

J G. Mouser¹, Kevin T. Mattocks², Matthew B. Jessee³, Samuel L. Buckner⁴, Scott J. Dankel⁵, Zachary W. Bell⁵, Takashi Abe⁵, John P. Bentley⁵, Jeremy P. Loenneke⁵. ¹Troy University, Troy, AL. ²Lindenwood University - Belleville, Belleville, IL. ³University of Southern Mississippi, Hattiesburg, MS. ⁴University of South Florida, Tampa, FL. ⁵University of Mississippi, University, MS.
 Email: jmouser@troy.edu
 (No relevant relationships reported)

Low-load resistance exercise combined with blood flow restriction (BFR) has the ability to increase muscle mass following periods of training. Peripheral vascular adaptations to this type of exercise have been examined at loads commonly used [30% of one-repetition maximum (1RM)]. Vascular adaptations occur through flow-induced shear stress, mechanical compression due to muscular contraction, and circumferential strain induced by pressure waves. Loads lower than 30% 1RM (i.e. 15% 1RM) may not induce enough mechanical stress to stimulate adaptation, and higher BFR pressures may be required. **Purpose:** To examine the peripheral vascular response to eight weeks of training using very low loads combined with differing BFR pressures in the upper body. **Methods:** Forearm blood flow (FBF), vascular conductance (FVC), and venous compliance (FC_v) were measured using strain-gauge plethysmography before and following eight weeks of 2x/week resistance training of the elbow flexors

using 15% IRM combined with either no BFR [15/0], 40% of arterial occlusion pressure (AOP) [15/40], or 80% of AOP [15/80], and were compared to high load resistance exercise at 70% IRM [70/0] in 20 men and 20 women. Results reported as Mean (SE). **RESULTS:** FBF exhibited a condition x time interaction ($P=.043$). The training response to 15/80 and 70/0 were greater ($+0.520$ (0.22), $+0.616$ (0.22) $\text{ml}\cdot\text{min}^{-1}\cdot 100\text{ml}^{-1}$, respectively) than 15/0 and 15/40 (-0.077 (0.22), -0.137 (0.21) $\text{ml}\cdot\text{min}^{-1}\cdot 100\text{ml}^{-1}$, respectively). A similar interaction existed for FVC ($P=.032$), with 15/80 and 70/0 showing a greater response ($+8.286$ (2.66), $+8.595$ (2.6) $\text{ml}\cdot\text{mmHg}^{-1}$, respectively) than did 15/0 and 15/40 ($+1.813$ (2.66), -0.413 (2.6) $\text{ml}\cdot\text{mmHg}^{-1}$, respectively). FC_v displayed only a main effect of time ($P=.044$), increasing 0.003 (0.002) % mmHg^{-1} . **CONCLUSIONS:** At very low loads (15% IRM), FBF and FVC were increased only in the high pressure group in a manner not different from high load, lending support to the conclusion that circumferential strain on arterioles can lead to vascular adaptation. The lack of difference in the FC_v response implies that even very low loads affect compliance. Future research should examine the possibility of capillarization occurring following repeated exposure to high pressure BFR.

 (No relevant relationships reported)

Childhood obesity is strongly associated with cardiovascular disease (CVD) development. It is necessary to combat unfavorable outcomes of obesity at a young age by utilizing effective interventions, such as exercise. **PURPOSE:** To examine the effects of a jump rope exercise program on CVD risk factors, including body composition, vasoactive substances, inflammation, and vascular function in prehypertensive adolescent girls. **METHODS:** Forty girls (age 14-16) were recruited and randomly assigned to a jump rope exercise group (EX, n=20) or control group (CON, n=20). Body composition, nitrate and nitrite levels, endothelin-1 (ET-1), c-reactive protein (CRP), systolic blood pressure and diastolic blood pressure (SBP, DBP), and arterial stiffness were measured before and after 12 weeks. **RESULTS:** There were significant group by time interactions following the 12-week program for body composition (from 33.8±3.6 to 30.2±3.1%), central adiposity (from 86.4±4 to 83.3±5 cm), SBP (from 126±3.3 to 120±2.1 mmHg), and brachial-to-ankle pulse wave velocity (from 8.2±1.0 to 7.4±0.2 m/s). Nitrate/nitrite levels increased (from 54.5±5.1 to 57.2±5.2 μmol) along a reduction in CRP levels (from 0.5±0.4 to 0.2±0.1 mg/L). There were no significant changes in ET-1 ($P=.022$). **CONCLUSIONS:** These findings indicate that jump rope exercise may be an effective intervention to improve these CVD risk factors in prehypertensive adolescent girls. Jumping rope is an easily accessible exercise modality that may have important health implications for CVD prevention in younger populations.

Muscle Blood Flow is not Dependent upon Conduit Artery Diameter following Prior Vasodilation

Timothy R. Rotarius¹, Jakob D. Lauver², John R. Thistlethwaite³, Barry W. Scheuermann⁴. ¹Adrian College, Adrian, MI. ²Coastal Carolina University, Conway, SC. ³Ohio Dominican University, Columbus, OH. ⁴University of Toledo, Toledo, OH.
 (No relevant relationships reported)

At the onset of exercise in humans, muscle blood flow increases to a new steady-state that closely matches the metabolic demand of the exercise. This increase has been attributed to the skeletal muscle pump and rapid vasodilatory mechanisms. Yet, most research in this area has focused on using the conduit artery as the measurement site for blood flow. It is possible that the conduit artery does not reflect the same hyperemic response as the microvascular level during exercise. **Purpose:** Therefore, we attempted to dissociate the matching of oxygen delivery and oxygen demand by administering 0.4 mg glyceryl trinitrate (GTN) prior to handgrip exercise resulting in significant vasodilation at the level of the conduit artery. **Methods:** 8 healthy males (29 ± 9 yrs) performed 2 trials of rhythmic handgrip exercise (30 contractions/min at 5% of 1RM) for 6 minutes, for each control (CON) and GTN condition. Brachial artery (BA) diameter and blood velocity were measured using Doppler ultrasonography. Central hemodynamic variables (i.e. heart rate and mean arterial pressure) were measured using finger plethysmography. **Results:** Administration of GTN resulted in a 12% increase in resting BA diameter that persisted throughout exercise (CON: 0.50 ± 0.01 cm; GTN: 0.56 ± 0.01 cm, $p < 0.05$). Resting forearm blood flow (FBF) was significantly higher following GTN administration compared to control (CON: 144.9 ± 62.4 mL/min; GTN: 212.1 ± 116.5 mL/min, $p < 0.05$); however, any differences in FBF disappeared after the onset of muscle contractions (End-exercise FBF: CON: 561.3 ± 173.1 mL/min; GTN: 525.0 ± 133.4 mL/min, $p > 0.05$). Vascular conductance

was not significantly different between CON and GTN. **Conclusion:** Our results indicate that the matching of oxygen delivery and oxygen demand is unencumbered by prior vasodilation, so that any over-perfusion is corrected at the onset of exercise. This could be attributed to a greater retrograde flow observed following GTN administration, indicating a greater resistance to blood flow downstream of the conduit artery. Thus, the results of this study provide evidence that the regulation of vascular tone within the microvasculature may be independent of that in the conduit artery and therefore, adaptations within the microcirculation function to match oxygen delivery to oxygen demand during exercise.

Lower Extremity Venous Compliance in Newly Injured Individuals with Spinal Cord Injury

Matthew T. Maher, MS, CEP¹, James M. LiMonta, BS¹, Andrew D. Delgado, MS², Kristell Taylor, BS², Thomas N. Bryce, MD², Miguel Escalon, MD², Vincent Huang, MD², Jill M. Wecht, EdD¹. ¹James J. Peters VA Medical Center, Bronx, NY. ²Icahn School of Medicine at Mount Sinai, New York, NY.
 (No relevant relationships reported)

Venous occlusion plethysmography (VOP) has been used as a non-invasive measure to compare lower extremity venous vascular function in individuals with chronic spinal cord injury (SCI) to healthy controls. Our group has previously reported significantly reduced lower extremity venous compliance (LEVC) in persons with SCI compared to healthy controls, which we speculate may relate to long standing paralysis and limited daily orthostatic challenge. However, to our knowledge LEVC has not yet been reported in the newly injured SCI population.

PURPOSE: The purpose of this investigation was to evaluate changes in LEVC during acute in-patient rehabilitation following SCI.

METHODS: VOP was used to determine changes in LEVC, which was assessed shortly after admission to the inpatient unit and a few days prior to discharge. VOP was acquired in the supine position at the widest calf circumference using a mercury strain gauge. Brachial blood pressure was monitored in the supine position during the VOP and a thigh cuff was inflated to 20 mmHg below the diastolic blood pressure (BP) and an ankle cuff was inflated to 100 mmHg above the systolic BP. Cuff inflation was maintained for 3 minutes and LEVC was estimated from changes in calf girth divided by thigh cuff occlusion pressure.

RESULTS: Eleven participants were enrolled, 35±11 years old (range: 19-52 years), 73% (n=8) male with acute SCI (34±17 days from injury; range 14-69 days). Injury levels ranged from C4 to T12 and 82% were motor complete. On average, participants were admitted 30±17 days after injury and the average length of stay (LOS) was 46±14 days. Neither calf circumference nor LEVC changed significantly over the LOS. However, the number of days between injury and the baseline VOP assessment was significantly associated with LEVC change ($r^2=0.57$; $p<0.01$) and change in LEVC differed significantly between those admitted within 30 days of injury (-3.6±2.7 %) and those admitted 31 days or more from injury (7.8±8.7%; $p<0.05$).

CONCLUSION: These data suggest that LEVC continues to be lost 30 days after injury during inpatient rehabilitation hospitalization following SCI. However, capturing baseline VOP data more than 30-days after injury, likely underestimates this venous vascular adaptation to paralysis.

Prolonged Sitting Increases Arterial Stiffness in Healthy Adults

Lauren C. Bates¹, William S. Evans¹, Quentin Willey¹, Daniel P. Credeur², Lee Stoner, FACSM¹, Erik D. Hanson¹. ¹University of North Carolina Chapel Hill, Chapel Hill, NC. ²University of Southern Mississippi, Hattiesburg, MS. (Sponsor: Lee Stoner, FACSM)
 Email: lbates15@live.unc.edu
 (No relevant relationships reported)

Chronic sedentary behavior increases risk for cardiovascular disease, which is the leading cause of death globally. Sitting impairs leg vascular health. Simple perturbations to increase leg blood flow prevent impairments, however, the effects on central cardiovascular health are unknown. Arterial stiffness (AS) is an indicator of CVD, and Pulse Wave Velocity (PWV) is a non-invasive measure of arterial compliance. Pulse Wave Analysis (PWA) measures augmentation index (AIx) and central pressure provides additional information about AS. **Purpose:** To investigate the effects of prolonged sitting, with and without calf raises on aortic AS (carotid-femoral PWV) central blood pressure (CBP), and AIx. **Methods:** After familiarization, sedentary participants (n=20, 21.7 yrs (2.9), BMI 25.7 m/kg² (5.3), 70% female) sat for 180 minutes with and without performing 10 calf raises every 10 minutes in a random order. Following 20 min of supine rest, baseline vascular measures were collected. Measures of CBP and AIx were recorded at 10, 90, and 170 min of sitting. Near-infrared spectroscopy (NIRS) was used to assess total hemoglobin (tHb) concentration

in the gastrocnemius muscle (index of blood pooling). Data were analyzed with a linear mixed model and are presented as mean difference (SE). **Results:** PWV increased significantly (0.30 m/s (0.46), $p < 0.001$) while AIx significantly decreased (-9.2% (11.0), $p < 0.001$). tHb tended to increase with sitting (0.9 (1.0), $p = 0.082$) and in the control condition (2.1 (1.0), $p = 0.084$). **Conclusions:** Sitting increases aortic AS but decreases AIx, an effect which may be mediated by blood pooling in the lower leg. Intermittent calf raises are insufficient to alter AS, as PWV increased by 0.30 m/s acutely. Despite being below the clinical threshold of 1.0 m/s with chronic inactivity, the acute increases in PWV in 3 hours may increase heart burden and become meaningful over time.

Acute Effects Of Oral Ascorbic Acid On The Vascular Endothelial Function Under Heat-not-burn Tobacco Smoking

Ayako Azuma, Hajime Miura, Mizuki Ishikawa, Yasuaki Tamura. *Institute of Socio-Arts & Science, Tokushima University, Tokushima, Japan.*

Email: ayakkuma32@gmail.com

(No relevant relationships reported)

PURPOSE: Heat-not-burn (HNB) tobacco smoking has spread through the market. While it is suggested that HNB tobacco smoking reduces the vascular endothelial function and is associated with a high risk of developing cardiovascular disease, oral administration of ascorbic acid benefits the endothelial function and redox states of HNB tobacco smoking patients remains unclear. In the present study, we examined the effect of the oral administration of ascorbic acid on the endothelial function and oxidative stress markers after HNB tobacco smoking in healthy young adults.

METHODS: Eight healthy men smoked one HNB tobacco cigarette in 2 conditions: the VC trial took ascorbic acid (1000 mg) before smoking, while the P trial took a placebo before smoking. The flow-mediated dilatation (FMD) at the brachial artery and biological antioxidant potential (BAP) levels were measured 15 minutes before smoking and immediately, 60, and 120 min after smoking.

RESULTS: In the P trial, the FMD immediately after smoking ($5.0 \pm 0.7\%$) was significantly decreased in comparison to before smoking ($8.5 \pm 1.0\%$). The VC trial showed quicker recovery of the FMD after smoking than the P trial. At 60 min after smoking, a significantly difference was noted in the BAP values of the 2 trials (VC: 1920 ± 139.1 vs. P: 1833 ± 131.2 U CARR, $p < 0.05$).

CONCLUSIONS: In HNB tobacco smoking, the oral administration of ascorbic acid was associated with a significant improvement in the oxidative stress marker levels in comparison to a placebo. These findings support that ascorbic acid may be an important factors for reducing the risk of cardiovascular disease in HNB tobacco smoking.

Limb Specificity And Near-infrared Spectroscopy Assessment Of Reactive Hyperemia: The Potential Impact Of Oral Capsaicin

Alexs A. Matias¹, Meghan Lynch¹, Brian Lora¹, Gaia Giuriato², Massimo Venturilli², Stephen J. Ives¹. ¹Skidmore College, Saratoga Springs, NY. ²University of Verona, Verona, Italy.

Email: amatias1@skidmore.edu

(No relevant relationships reported)

BACKGROUND: Cardiovascular disease (CVD) is a leading cause of morbidity and mortality in developed nations, therefore, there exists clinical importance in assessing vascular function, both causal and correlative of CVD, and in developing strategies to mitigate dysfunction. Capsaicin, the pungent ingredient in chili peppers (*Capsicum*), has been demonstrated to improve vascular function in mice through activating vascular endothelial transient receptor potential vanilloid type 1 channels (TRPV₁) increasing nitric oxide (NO), promoting vasodilation. Further, recent work has suggested Near-Infrared Spectroscopy (NIRS) provides insight into vascular function, however, whether the reperfusion slope is limb specific is unknown. **PURPOSE:** To determine if there is limb specificity (forearm vs. quadriceps), and whether acute oral capsaicin (780 mg, Cayenne Pepper extract), influences the NIRS-derived oxygen saturation (StO₂) reperfusion slope. **METHODS:** Using a counterbalanced, single-blind crossover design, total hemoglobin (Hb_{tot}), oxyhemoglobin (HbO₂), muscle tissue oxygenation (saturation; StO₂%), and deoxyhemoglobin (HHb) were assessed in 14 healthy young males (21 ± 3 yrs.) using NIRS, at rest, during 5 mins of suprasystolic cuff inflation and during reactive hyperemia. The StO₂ deoxygenation and reperfusion slopes were calculated during the first 10-second window of cuff occlusion and reactive hyperemia, respectively. **RESULTS:** No significant ($p < 0.05$) differences were observed in treatment (capsaicin vs. placebo) during cuff occlusion of the quads (CQ) or forearm (CFA). However, StO₂ slope during CQ was significantly ($p < 0.05$) greater than CFA for both treatments (capsaicin: -2.32 ± 0.37 vs. -1.10 ± 0.05 %/s; placebo: -2.13 ± 0.27 vs. -1.19 ± 0.15 %/s; respectively). Similarly, only a significant ($p < 0.05$) difference between upper and lower body microvascular function was

found for StO₂ slope during cuff release (CR) (capsaicin: 0.81 ± 0.10 vs. 0.32 ± 0.03 %/s; placebo: 0.86 ± 0.11 vs. 0.26 ± 0.10 %/s; quadriceps vs. forearm; respectively). **CONCLUSION:** Capsaicin, at this dose, does not alter the StO₂ reperfusion slope in the upper or lower limbs. However, the NIRS-derived StO₂ deoxygenation and reperfusion slopes appear to be limb specific, warranting further study to elucidate the mechanisms.

Changes in Arterial Adropin Levels by Age and Aerobic Training Is Related to Arterial Vasodilation

Shumpei Fujie¹, Natsuki Hasegawa², Naoki Horii², Masataka Uchida², Seiji Maeda¹, Jaime Padilla³, Luis A. Martinez-Lemus³, Motoyuki Iemitsu². ¹University of Tsukuba, Tsukuba, Ibaraki, Japan. ²Ritsumeikan University, Kusatsu, Shiga, Japan. ³University of Missouri, Columbia, MO.

(No relevant relationships reported)

Adropin promotes nitric oxide (NO) production via increases in endothelial NO synthase (eNOS) in endothelial cells. In a recent study, we showed that circulating adropin levels, elevated by aerobic exercise training (AT), are related to reductions in arterial stiffness via increased NO production in middle-aged and older adults. However, it is unclear whether changes in arterial adropin levels by AT are related to vasodilation via increases in arterial NO production. **PURPOSE:** This study aimed to examine whether changes in arterial adropin levels by age and AT are related to vasodilation via arterial NO production.

METHODS: Male 38-week-old senescence-accelerated mouse prone 1 (SAMP1) mice were divided into 2 groups; aged-sedentary control and aged-AT. Additionally, male 13-week-old SAMP1 mice were used as a young-sedentary control group. AT consisted in voluntary wheel running for 12 weeks. Mouse aortic rings were isolated for the evaluation of vasodilatory responses to acetylcholine (ACh, endothelium-dependent), sodium nitroprusside (SNP, endothelium-independent), adropin, and the combination of adropin with the NOS inhibitor, L-NAME, using an organ bath system. Furthermore, serum and arterial adropin, arterial nitrite/nitrate (NOx), and eNOS phosphorylation levels were measured. The expression of arterial adropin mRNA was measured using real-time RT-PCR.

RESULTS: ACh-induced vasodilation, as well as that induced by adropin were significantly impaired with aging and AT restored them both ($P < 0.05$). Moreover, adropin-induced vasodilation was significantly inhibited by the administration of L-NAME in all groups, while no significant differences in SNP-induced vasodilation between the three groups were observed. Aging was associated with reductions in serum and arterial levels of adropin, arterial adropin mRNA expression, arterial NOx level, and eNOS phosphorylation, whereas AT significantly increased these parameters ($P < 0.05$).

CONCLUSIONS: These results suggest that the changes in arterial adropin mRNA and protein levels that occur with age and AT are related to vasodilation via arterial NO production.

Nocturnal Hypertension Status and C-Reactive Protein Levels Before and After AEXT

Adelola O. Adeyemo, Michael D. Brown, FACSM. Auburn University, Auburn, AL.

Email: aoa0005@auburn.edu

(No relevant relationships reported)

C-Reactive Protein (CRP) is an inflammatory biomarker linked to endothelial dysfunction, resulting hypertension, and cardiovascular events. 24-hr ambulatory blood pressure monitoring (ABPM) is the gold standard for diagnosing hypertension, with recent evidence showing a superior predictive value of asleep nighttime values, in particular, for cardiovascular outcomes. **PURPOSE:** To assess whether circulating CRP levels differ between nighttime hypertensives and normotensives and examine the ability of exercise training to affect CRP levels.

METHODS: Non-smoking, middle-to-older age, sedentary African Americans underwent an aerobic exercise training (AEXT) program for 24 weeks. Various modes of AEX were included, with intensity progressing up to 60% VO₂ max. Participants underwent 6 weeks of dietary stabilization and were required to maintain a constant weight for the study's duration. CRP and blood pressure (BP) were measured from fasted blood samples and 24-hour ABPM, respectively, before and after the AEXT program. Upon study completion, subjects were divided into groups based on average asleep ABPM values (O'Brien et al 2013) and baseline circulating CRP levels.

RESULTS: At baseline, normotensive subjects had significantly lower circulating CRP than those classified as hypertensives based on nighttime systolic BP (2.95 vs 4.74 mg/L, $p < .01$). Although there was no difference between normotensives and hypertensives classified as at low (<1mg/L) or high (>3mg/L) risk for cardiovascular disease based on CRP levels, there was a difference in circulating CRP between groups

at average risk ($p < .05$). CRP did not significantly decrease ($p = .095$), however, after 6 months of AEXT the hypertensive group experienced a significantly greater decrease in CRP than the normotensive group ($p = .01$).

CONCLUSIONS: Our results suggests that nighttime hypertensive status may correspond to cardiovascular disease risks predicted by the classic biomarker CRP. Nocturnal SBP may be a discriminating additive factor to consider for health by those at average risk for future events by CRP levels. For both hypertensives and normotensives, AEXT may alter CRP, with hypertensives likely to see a greater effect. Supplementary studies are needed to examine the relationship between additional variables and nocturnal hypertension.

2416 Board #80 May 31 11:00 AM - 12:30 PM
Integrated Effects of Sympathetic Vasoconstriction and Local Vasodilation in Human Skeletal Muscle and Skin Microvasculature

Masashi Ichinose¹, Mikie Nakabayashi², Yumie Ono². ¹Meiji University, Tokyo, Japan. ²Meiji University, Kanagawa, Japan.
 (No relevant relationships reported)

Both sympathetic vasoconstriction and locally-mediated vasodilation play important roles in regulation of blood flow to skeletal muscle and skin during exercise. However, the integrated effects of these two vascular regulatory mechanisms in microcirculation are unclear. **Purpose:** We aimed to investigate integration of sympathetic vasoconstriction and local vasodilation in the skeletal muscle and skin microvasculature in humans. **Methods:** In 39 healthy volunteers, we measured blood flow index of flexor carpi radialis muscle using diffuse correlation spectroscopy and monitored skin blood flow at the proximal site by laser-Doppler flowmetry, simultaneously. We examined the effects of acute sympathoexcitation by forehead cooling on relatively weak or robust vasodilatory responses during post-occlusive reactive hyperemia (PORH) induced by 70 s or 10 min arterial occlusion at upper arm, respectively. To increase sympathetic tone during PORH, forehead cooling was begun 60 s before the occlusion release and ended 60 s after the release. **Results:** The acute sympathoexcitation diminished the peak and duration of vasodilation in both skeletal muscle and skin in 70 s occlusion trials [peak skeletal muscle vascular conductance (MVC): 5.6 ± 0.4 vs. 4.1 ± 0.3 , peak cutaneous vascular conductance (CVC): 3.4 ± 0.2 vs. 2.9 ± 0.2 AU, 50 % decay time of MVC: 19 ± 0.8 vs. 13 ± 0.6 , 50 % decay time of CVC: 17 ± 1.0 vs. 14 ± 1.0 s, $p < 0.05$]. The sympathetic inhibition of vasodilation was blunted under robust vasodilatory stimuli produced by 10 min occlusion. This blunt of the sympathetic inhibition was greater in skeletal muscle than in skin, especially in those initial and peak vasodilation. Indeed, the sympathoexcitation reduced the peak vasodilation only in skin (peak MVC: 10.2 ± 0.9 vs. 9.7 ± 0.9 , $p > 0.05$, peak CVC: 7.7 ± 0.5 vs. 6.5 ± 0.5 AU, $p < 0.05$) while it accelerated the initial vasodilation selectively in skeletal muscle (area of MVC during first 15 s of PORH: 75.2 ± 6.5 vs. 83.0 ± 6.9 , $p < 0.05$, area of CVC: 51.6 ± 2.7 vs. 51.7 ± 3.4 AUs, $p > 0.05$). **Conclusion:** We conclude that, in humans, the integration of sympathetic vasoconstriction and local vasodilation has different effects in skeletal muscle and skin. Such different effects would be importantly involved in selective control of perfusion in microcirculation of different tissues.

2417 Board #81 May 31 11:00 AM - 12:30 PM
Influence Of Arm cranking Exercise With Electrical Stimulation On The Vascular Endothelial Function

Mizuki Ishikawa, Hajime Miura, Ayako Azuma, Yasuaki Tamura. Tokushima university, Tokushima city, Japan.
 Email: miduki_0609@yahoo.co.jp
 (No relevant relationships reported)

PURPOSE: Arm-cranking exercise may not result in reduction in ba-PWV. Electrical muscle stimulation (EMS) has been shown to be able to increase the blood flow and the peripheral circulation. Arm-cranking exercises with EMS may therefore be able to increase the arterial function. However, less is known about the effect of submaximal arm-cranking exercise with EMS on the vascular endothelial function.

METHODS: Eight healthy adult men were studied under two experimental trials (arm-cranking exercise with EMS; A+E trial, arm-cranking exercise without EMS; A trial). In the A+E trial, submaximal arm-cranking exercise at 50%VO_{2max} with both lower leg and thigh muscles were sequentially stimulated at 4-Hz for 20min. Before and after each trial, the brachial systolic and diastolic blood pressure (SBP/DBP) were measured in the supine position. The vascular endothelial function of the right brachial artery was also assessed by flow-mediated dilation (FMD).

RESULTS: In the A+E trial, the FMD increased immediately after ($9.7 \pm 0.8\%$) and 30 min after ($8.4 \pm 0.7\%$) compared with rest ($6.0 \pm 0.7\%$). The FMD in the A trial, increased immediately after ($8.0 \pm 1.2\%$) compared with rest ($6.4 \pm 0.4\%$), however, no significant differences were found in 30min after ($6.4 \pm 1.0\%$). Immediately after and 30 min after each trial, significant differences in the FMD were found between the A+E and A trials ($p < 0.05$). The SBP and DBP were not significantly different between the both trials.

CONCLUSIONS: Acute arm-cranking exercise with EMS increases the vascular endothelial function. These results suggest that chronic arm-cranking with EMS might be useful for reduction the risk of cardiovascular disease.

The Age-dependent Changes In Cardiovascular Risk Factors Associated With Endothelial Function In Women Of Han Nationality With Ace D/I Polymorphism In Beijing

Yuanyuan LYU¹, Lingxiao HE², Kaiyu XIONG¹, Li ZHAO*¹.
¹Beijing Sport University, Beijing, China. ²KU Leuven Faculty of Kinesiology and Rehabilitation Sciences, Leuven, Belgium.
 Email: lvyuanyuan2938@aliyun.com
 (No relevant relationships reported)

PURPOSE: Angiotensin converting enzyme (ACE) I/D polymorphism influences ACE activity, with the D allele associated with higher angiotensin II production, which can have adverse effects on endothelial function through the promotion of vasoconstriction. Age is an independent risk factor for endothelial dysfunction, and postmenopausal women because estrogen deficiency affects their endothelial function. The present study was to investigate the trend of cardiovascular risk factors for endothelial function with aging in Han nationality women with ACE D/I polymorphism in Beijing.

METHODS: A total of 391 females, age from 22 y to 75 y, were selected for analyzing the relationship between ACE I/D polymorphism and cardiovascular risk factors for endothelial function, (Ages 20-44: 120; Ages 45-59: 150; Ages 60-75: 121). Body composition, serum lipids metabolism, endothelial function, endothelium-derived relaxing factor and contracting factor were analyzed.

RESULTS: The distribution characteristics of ACE I genotype and D genotype in han Chinese women in Beijing were as follows: Ages 20-44: 63.74% and 36.26%; Ages 45-59: 67.33% and 32.67%; Ages 60-75: 64.34% and 35.66%. There was no age associated with differential expression. Along with the women aging, DI/II genotype had higher TG level, higher chance of hyperglycemia and lower HDL level. The percentage of body fat and visceral fat significantly increased than DD type did. FMD, blood pressure, baPWV and IMT increased earlier and DBP abnormality rate, IMT, IMT thickening rate had more severe increases than DD type. The decrease of NO and NO/ET-1 and the increase of ET-1 and AngII were more significant compared with DD type. The interaction between age and ACE gene D/I polymorphisms could remarkably affect vascular endothelial function.

CONCLUSIONS: There was no age associated with differential expression in ACE D/I polymorphism in Women of Han nationality in Beijing. The interaction between age and ACE D/I polymorphisms plays a key role in endothelial dysfunction, in which DI/II genotype is vulnerable to endothelial dysfunction and arteriosclerosis with aging.

The Effects Of Pilates Training On Vascular Function In Obese Premenopausal Women With Elevated Blood Pressure

Michelle Walters-Edwards¹, Alexei Wong¹, Song-Young Park², Javad Mehrabani³, Majid Koozechian⁴, Arturo Figueroa, FACSM⁵. ¹Marymount University, Arlington, VA. ²University of Nebraska, Omaha, NE. ³University of Guilan, Rasht, Iran, Islamic Republic of. ⁴Jacksonville State University, Jacksonville, AL. ⁵Texas Tech University, Lubbock, TX. (Sponsor: Arturo Figueroa, FACSM)
 Email: michelle.walters-edwards@marymount.edu
 (No relevant relationships reported)

Obesity is associated with vascular dysfunction, including an increase in blood pressure (BP), arterial stiffness (pulse wave velocity, PWV) and pressure wave reflection [augmentation index (AIx)]. Therefore, effective interventions targeting improvements in arterial function for obese individuals are critical for the prevention of hypertension (HTN) and cardiovascular events at a young age. Previous studies have shown that pilates training (PT) decreases AIx and aortic BP in young normotensive individuals. However, the possibility of PT improving arterial function in obese women with elevated BP is currently unknown. **PURPOSE:** The purpose of this study was to examine the effects of PT on BP, PWV and AIx in obese women with elevated BP. **METHODS:** Twenty-eight obese premenopausal women [age (23 ± 1 years), body mass index (34.1 ± 0.7 kg/m²), systolic BP (127 ± 2 mmHg) and diastolic BP (75 ± 2 mmHg)] were randomized to either PT (n= 14) or no-exercise control group (n= 14) for 12 weeks. PT consisted of 12 exercises per session 3 x week (approx 60 mins duration per session). Two sets of 6-10 repetitions were performed for each exercise. Supine BP, brachial to ankle PWV (baPWV), AIx, and heart rate (HR) were measured at baseline and after 12 weeks. **RESULTS:** There were significant group-by-time interactions ($P < 0.05$) for systolic BP, diastolic BP, baPWV and AIx. There were significant decreases ($P < 0.05$) in systolic BP (-5 ± 1 mmHg), diastolic BP (-4 ± 1 mmHg), baPWV (-0.6 ± 0.2 m/s), and AIx ($-4 \pm 1\%$) in the PT group compared to

no changes after control. No significant changes were observed in HR after 12 weeks for both groups. **CONCLUSIONS:** Pilates exercise led to reductions in BP, arterial stiffness and wave reflection in obese premenopausal women with elevated blood pressure and may therefore be an effective intervention in the prevention of HTN and cardiovascular events at a young age in obese women.

2420 Board #84 May 31 11:00 AM - 12:30 PM
Effects Of Acute Cycling With Electric Muscle Stimulations Of Lower Limb On The Endothelial Function

Hajime Miura, Miduki Ishikawa, Ayako Azuma, Yasuaki Tamura. *Tokushima University, Tokushima, Japan.*
 Email: hajime-m@tokushima-u.ac.jp
 (No relevant relationships reported)

The combination of exercise and electrical muscle stimulation (EMS) has been shown to potentially improve energy expenditure or glycogen metabolism. However, few attempts have been made to identify the effects of exercise with EMS on the arterial function. **PURPOSE:** The aim of this study was to evaluate the effects of acute endurance cycling with EMS on the vascular endothelial function determined by flow-mediated vasodilation (FMD). **METHODS:** Nine healthy adult men performed 2 experimental trial: 20 min cycling at 50W with EMS (EMS+C), and the same exercise without EMS (C). In the EMS+C trial, both lower leg and thigh muscles were sequentially stimulated at 4 Hz for 20 min during exercise. The stimulation current was at the highest intensity that did not cause discomfort. Before and after each trial, the brachial systolic and diastolic blood pressure (SBP and DBP, respectively) were measured. The FMD in the right brachial artery was obtained using a high-resolution ultrasound device, determining the percent change in the arterial diameter over the baseline value at maximum dilation during reactive hyperemia. **RESULTS:** In the EMS+C trial, the FMD was significantly elevated immediately after (12.1±0.7%) and at 30 min after EMS (11.1±0.6%) compared with rest (8.7±0.6%). However, there were no significant changes in the C trial (8.9±0.8% at rest, 9.9±0.7% immediately after the C trial, and 9.2±0.6% at 30min after the C trial). Immediately and 30min after each trial, significant differences in the FMD were found between the EMS+C and C trials ($p<0.05$). No significant changes were found in the SBP/DBP in either trial. **CONCLUSIONS:** Acute endurance cycling with EMS results in a larger improvement of the vascular endothelial function than the same exercise without EMS. These findings suggest that low-intensity cycling with EMS might be useful for reducing the risk of cardiovascular disease.

Effect of Heating Duration on Brachial Artery Endothelial Function in Humans

Jem Cheng, Maureen MacDonald. *McMaster University, Hamilton, ON, Canada.*
 Email: chengjl2@mcmaster.ca
 (No relevant relationships reported)

In humans local heat stress elicits arterial vasodilation through two known mechanisms: axon reflexes responsible for the initial rise in skin blood flow (SkBF), and heat shock protein (HSP)-mediated release of nitric oxide (NO) responsible for the prolonged plateau in SkBF. The effect of selective targeting of these mechanisms, through local heating protocols of varying durations, on endothelial function is unknown. **PURPOSE:** To determine the effect of 10 minutes (axon reflexes) vs. 30 minutes (axon reflexes + HSP-mediated NO release) of local forearm heating on brachial artery (BA) endothelial function. **METHODS:** Five young, apparently healthy, recreationally active males (21±2 years old) were recruited. In separate visits, heating was applied to the left forearm using a commercially available heating pad set to *high* for either 10 minutes (HEAT10, 41.7±0.8 °C) or 30 minutes (HEAT30, 43.5±2.0 °C). Endothelial function was measured before and after each heating intervention through a BA flow-mediated dilation (FMD) test. **RESULTS:** Allometric scaling was performed on the entire data set to account for the increased arterial diameter observed after heating in the 30-minute condition. A generalized estimating equations analysis with an exchangeable correlation structure revealed a main effect of time on BA FMD (rest: 6.4±1.3 vs. HEAT: 7.7±2.2%, $P = 0.027$), suggesting that both 10-minute and 30-minute heating protocols improved endothelial function. **CONCLUSION:** These findings suggest that BA FMD is improved similarly with 10 minutes or 30 minutes of local heat stress applied to the forearm; and that the addition of local NO release to axon reflex-mediated vasodilation may not further enhance the acute endothelial function responses. Supported by NSERC DG #238819-13.

Passive Leg Movement Technique for Assessing Vascular Function: Further Defining the Distribution of Blood Flow

Katherine L. Shields¹, Ryan M. Broxterman¹, Catherine L. Jarrett¹, Angela V. Bisconti², Soung Hun Park¹, Russell S. Richardson¹. ¹University of Utah, Salt Lake City, UT. ²University of Milan, Milan, Italy.
 Email: Katherine.Shields@hsc.utah.edu
 (No relevant relationships reported)

PURPOSE: It has yet to be quantified how passive leg movement (PLM)-induced hyperemia, an index of vascular function, is distributed beyond the common femoral artery (CFA), into the deep femoral (DFA) and the superficial femoral (SFA) arteries, which supply blood to the thigh and lower leg, respectively. Furthermore, the impact of cuffing the lower leg, a common practice, especially with drug infusions during PLM, on the hyperemic response is, also, unknown. **METHODS:** Therefore, PLM was performed with and without cuff-induced blood flow (BF) occlusion to the lower leg in 10 healthy subjects, with BF assessed by Doppler ultrasound. **RESULTS:** In terms of BF distribution during PLM, of the 380±60 ml of BF that passed through the CFA, 266±45 ml (~70%) was directed to the DFA while only 114±18 ml (~30%) passed through the SFA. Cuff occlusion of the lower leg significantly attenuated the PLM-induced hyperemia through the SFA (~30%), which was reflected by a fall in BF through the CFA (~20%), but not through the DFA. Additionally, cuff occlusion significantly attenuated the PLM-induced peak change in BF (ΔBF_{peak}) in the SFA (324±50 to 214±36 ml/min), which was, again, reflected in the CFA (1019±138 to 833±150 ml/min), but not in the DFA. **CONCLUSIONS:** Thus, the PLM-induced hyperemia predominantly passes through the DFA. However, as a fraction of the PLM-induced hyperemia does pass through the SFA, cuffing the lower leg during PLM should be considered to emphasize the DFA specific hyperemia in the PLM assessment of vascular function. Vasodilatory And Metabolic Capacity With Advancing Age: Evidence Of Interdependence In The Human Vasculature

Soung Hun Park¹, Oh Sung Kwon¹, Song-Young Park², Joshua C. Weavil¹, Jay R. Hydrén¹, Robert H. I. Andtbacka¹, John R. Hyngstrom¹, Van Reese¹, Russell S. Richardson¹. ¹University of Utah, Salt Lake City, UT. ²University of Nebraska, Omaha, NE.
 Email: soung.hun.park@utah.edu
 (No relevant relationships reported)

PURPOSE: Vasodilatory capacity declines with advancing age, however, the role of vascular mitochondrial function in this process is unclear. Therefore, this study sought to examine the link between vascular and mitochondrial respiratory function with advancing age. **METHODS:** Skeletal muscle feed arteries (SMFAs) were harvested from young (35±6yrs, n=9) and old (71±9yrs, n=15) subjects. Using pressure myography, vasodilation in SMFAs was assessed in response to flow-induced shear stress, acetylcholine (ACh), and sodium nitroprusside, and mitochondrial respiration was measured by respirometry in permeabilized smooth muscle fibers. Free radical production was assessed by electron paramagnetic resonance spectroscopy. **RESULTS:** Endothelium-dependent vasodilation was significantly attenuated in the old, induced by both flow (young: 92±3, old: 45±4%) and ACh (young: 92±3, old: 54±5%), while endothelium-independent vasodilation was not altered by age. Complex I and I+II, state 3 respiration was significantly lower in the old (CI young: 10.12±0.83, old: 7.02±0.37 pmol/s/mg; CI+II young: 12.34±0.64, old: 7.6±0.43 pmol/s/mg). Although state 4 respiration and mitochondrial-specific free radical production were not different between groups, both tended to be higher in the old. The respiratory control ratio (RCR), was also significantly attenuated in the old (young: 2.25±0.14, old: 1.11±0.06). State 3 (CI+II) and 4 respiration, as well as RCR, were significantly correlated ($r=0.49-0.86$) with endothelium-dependent, but not endothelium-independent capacity. Free radical levels were related to endothelium-dependent ($r=0.4$, $p=0.06$), but not endothelium-independent ($r=0.06$) vasodilation. **CONCLUSION:** The age-related decline in vasodilatory capacity is related to a concomitant attenuation in mitochondrial respiratory capacity and may be a consequence of augmented free radical production. Supported by The National Heart, Lung, and Blood Institute at the National Institute of Health (PO1 HL1091830) and Veteran's Administration Rehabilitation Research and Development Service (E6910-R, E1697-R, E1433-P, E9275-L, and E1572-P).

Comparison Of Endothelial-dependent Vasodilatory And Vasoconstrictor Responses Between Upper- And Lower-Limb Arteries In Older Adults

Myles O'Brien¹, Myles W. O'Brien¹, Jarrett A. Johns¹, Susan A. Robinson¹, Said Mekary², Derek S. Kimmerly¹. ¹Dalhousie University, Halifax, NS, Canada. ²Acadia University, Wolfville, NS, Canada.

Email: my594690@dal.ca

(No relevant relationships reported)

Low-flow mediated constriction (L-FMC) provides important information about the acute effects of reduced shear stress on endothelial function. L-FMC has been mainly tested in upper-limb arteries, where an inverse association with VO_{2peak} has been observed in younger adults. It is unclear if an L-FMC response exists in lower limb arteries, which are exposed to larger fluctuations in shear stress during traditional modes of aerobic exercise than the upper-limb. Furthermore, it is uncertain whether the same inverse relationship between L-FMC and VO_{2peak} exists in older adults (OA). **PURPOSE:** Based on known differences in flow-mediated dilation (FMD) between upper- and lower limbs, we tested the hypothesis that heterogeneous L-FMC responses exist between the brachial- (BA) vs. popliteal (POP) arteries. We also expected that OA with greater aerobic fitness would have larger L-FMC responses in both arteries. **METHODS:** FMD and L-FMC were assessed in 47 OA (67±5 yr; 30F) using high-resolution duplex ultrasonography with commercial edge-detection and wall-tracking software. L-FMC was defined as the % decrease in lumen diameter in response to 5-min of distal ischemia. FMD was calculated as the % increase in lumen diameter following a reactive hyperemia. **RESULTS:** Larger FMD responses were observed in the BA vs. POP (4.7±1.6% vs. 3.3±2.0%; $P<0.001$), which were moderately correlated to each other ($r=0.54$; $P<0.001$). When allometrically scaled, the BA exhibited a greater L-FMC response than the POP (-1.3±1.6% vs. -0.4±1.6%; $P=0.03$). L-FMC responses in the BA vs. POP were not correlated with each other ($r=0.22$; $P=0.14$). As expected, VO_{2peak} was associated with both BA-FMD ($r=0.59$; $P<0.001$) and POP-FMD ($r=0.48$; $P=0.001$). VO_{2peak} was moderately correlated to BA L-FMC ($r=0.52$; $P<0.001$) but strongly correlated to POP L-FMC ($r=0.73$; $P<0.001$). **CONCLUSION:** The heterogeneous L-FMC responses between the BA and POP indicates that upper limb L-FMC responses do not represent a systemic measure of vasoconstrictor capacity. The stronger association between VO_{2peak} and POP L-FMC suggests that larger local shear stress responses, induced by traditional lower-limb modes of aerobic exercise, may result in greater adaptations to low flow-mediated endothelial vasoconstrictor responsiveness.

Physical Activity Ameliorates Endothelial NLRP3 Inflammasome in Obese Mice Aorta

Yoonjung Park, Jonghae Lee, Junyoung Hong, Michihisa Umetani, Emily LaVoy. University of Houston, Houston, TX.

Email: ypark10@uh.edu

(No relevant relationships reported)

PURPOSE: The NLR family, pyrin domain-containing 3 (NLRP3) regulates a release of pro-inflammatory cytokine interleukin (IL)-1 β via caspase-1-mediated pyroptosis, thereby plays a pivotal role in vascular pathology in obesity. Physical activity ameliorates the obesity-associated inflammation and vascular dysfunction. Thus, we examined the beneficial effect of physical activity on the NLRP3 inflammasome-associated signaling pathways in high fat diet-induced obese mice aorta and its potential underlying mechanisms.

METHODS: We had four groups of male mice, C57BL/6J: (1) wild-type control with low-fat diet (LF-SED), (2) LF diet with free access to a voluntary running wheel (LF-RUN), (3) high-fat diet (HF-SED; 45% of calories from fat), and (4) HF-RUN. We determined the effects of voluntary running on the NLRP3, caspase-1, IL-1 β , adiponectin, nitric oxide (NO), and oxidative stress in the obese mice aorta using RT-qPCR and immunohistochemistry.

RESULTS: Voluntary running decreased cleaved caspase-1 and IL-1 β expression in aortic endothelium of obese mice. Physical activity restored a high fat diet-induced decrease in endothelial adiponectin expression and NO production. Intracellular superoxide production in the aorta was significantly higher in HF-SED compared to LF-SED and LF-RUN while it was lower in HF-RUN.

CONCLUSIONS: Our findings indicate that physical activity rescues high fat diet-induced overexpression of NLRP3 inflammasome/oxidative stress and downregulation of adiponectin/NO in mice aorta.

(No relevant relationships reported)

Accumulating evidence indicates that prolonged sedentary time (SED) is associated with cardiovascular disease (CVD) morbidity and mortality, potentially independent of moderate- to vigorous-intensity physical activity (MVPA). However, the mechanisms underlying the SED-CVD link have yet to be fully elucidated. Endothelial dysfunction, an early pathogenic process underlying atherosclerosis, is purported to be a contributing factor based on findings from acute lab-based studies. However, few studies have examined whether habitual SED (indicative of more chronic exposure to SED) is linked to endothelial dysfunction.

PURPOSE: To examine the association of accelerometer-derived habitual SED with markers of endothelial cell health. **METHODS:** Apparently healthy adults (n=83; 43% male; 25.5±5.8 yrs) residing in New York City were examined. SED and MVPA were measured for 7 days using a thigh-mounted accelerometer/inclinometer. Endothelial function measures included endothelium-dependent vasodilation [reactive hyperemia index (RHI)], endothelial microparticles (EMPs) [CD62E+ and CD31+/CD42- surface markers], and endothelial progenitor cells (EPCs) [CD34+/CD133+/KDR+ surface markers], all collected under fasting conditions. Participants were categorized into high (≥ 9.8 h/day) or low SED (< 9.8 h/day) groups by median split. **RESULTS:** No significant differences between the high and low SED groups were detected for any of the endothelial cell markers including RHI (high: 2.38 ± 0.14 vs. low: 2.47 ± 0.14; $p=0.68$), CD62E+ EMPs (high: 699.9 ± 48.3 vs. low: 826.3 ± 57.0 counts/ μ l; $p=0.12$), CD31+/CD42- EMPs (high: 486.9 ± 37.5 vs. low: 533.3 ± 41.6 counts/ μ l; $p=0.44$), CD34+/KDR+ EPCs (high: 100.8 ± 0.1 vs. low: 79.4 ± 0.1 %; $p=0.37$), and CD34+/CD133+/KDR+ EPCs (high: 2.4 ± 0.0 vs. low: 2.0 ± 0.0 %; $p=0.75$) after adjustment for age, sex, race, ethnicity, education, and MVPA. **CONCLUSION:** Among healthy adults, habitual SED was not associated with markers of endothelial cell health. Mechanisms other than endothelial dysfunction should be explored as a potential link between prolonged SED and CVD.

Short-term Cycling Restores Endothelial Dysfunction After Resistance Exercise

Takuma Morishima¹, Motoyuki Iemitsu², Eisuke Ochi¹. ¹Hosei University, Tokyo, Japan. ²Ritsumeikan University, Kusatsu, Japan. (Sponsor: Jill Kanaley, FACSM)

(No relevant relationships reported)

PURPOSE: Resistance exercise impairs endothelial function. Therefore, it is of paramount importance to devise an effective strategy for restoring endothelial function after resistance exercise. Herein, we tested the hypothesis that resistance exercise-induced endothelial dysfunction would be restored by short-term cycling.

METHODS: Seventeen young healthy subjects completed two randomized experimental trials: 1) resistance exercise (RE) only trial; 2) cycling after the RE trial (RE + C). Following baseline brachial artery flow-mediated dilation (FMD), subjects performed the resistance exercise. Following the resistance exercise, subjects were asked to rest in the supine position for the assessments of FMD. Subjects in the RE only trial maintained this supine position for 60 min, whereas those in the RE + C trial performed 10 min of self-paced cycling (67.0 ± 1.7 % HRmax) after the resistance exercise. Subjects were again asked to rest in the supine position after cycling. FMD was then repeated at 30 and 60 min after the resistance exercise in both trials.

RESULTS: In the RE only trial, the significant increased blood flow relative to baseline ($P < 0.05$) was disappeared after 30 min of resting in the supine position (54.2 ± 8.1 ml/min, 150.6 ± 30.0 ml/min, 94.2 ± 17.0 ml/min, 72.1 ± 12.9 ml/min at baseline, 10, 30 and 60 min after the resistance exercise, respectively), but were maintained at 30 min after the resistance exercise in the RE + C trial due to subsequent cycling (47.0 ± 7.4 ml/min, 139.5 ± 24.4 ml/min, 112.0 ± 17.9 ml/min, 55.9 ± 9.0 ml/min at baseline, 10, 30 and 60 min after the resistance exercise, respectively). Both trials caused a significant impairment in FMD at 10 min after the resistance exercise (6.5 ± 0.3 % vs. 3.5 ± 0.5 % in the RE only trial, 6.5 ± 0.2 % vs. 2.9 ± 0.5 % in the RE + C trial, $P < 0.05$). This decline was sustained for 60 min in the RE only trial (3.8 ± 0.6 % and 4.3 ± 0.3 % at 30 and 60 min after the resistance exercise, $P < 0.05$ vs. baseline). However, the impaired FMD was restored in the RE + C trial (7.2 ± 0.7 % and 7.0 ± 0.6 % at 30 and 60 min after the RE, $P > 0.05$ vs. baseline).

CONCLUSIONS: In conclusion, impaired endothelial function after the resistance exercise can be restored by 10 min of cycling.

2428 Board #92 May 31 11:00 AM - 12:30 PM
Application Of A Tourniquet During Venous Blood Collection From The Forearm Reduces Plasma Nitrite Concentration

Chris Easton¹, Luke Liddle¹, Mia C. Burleigh¹, Chris Monaghan¹, David J. Muggeridge². ¹University of the West of Scotland, Blantyre, United Kingdom. ²University of the Highlands and Islands, Inverness, United Kingdom. (Sponsor: Professor Jason Allen, FACSM)
 Email: chris.easton@uws.ac.uk
 (No relevant relationships reported)

Dietary nitrate (NO₃⁻) supplementation increases nitric oxide (NO) availability and can reduce blood pressure and improve exercise performance. While plasma nitrite [NO₂⁻] provides the best marker of NO availability, the use of a tourniquet during blood collection may be problematic due to the established effects of hypoxia on NO metabolism. **PURPOSE:** This study compared measurements of plasma NO₂⁻ and NO₃⁻ where blood was collected via venepuncture and from an indwelling intravenous cannula. **METHODS:** Fifteen participants (mean ± standard deviation: age 27 ± 4 years, body mass 71 ± 11 kg) completed two experimental trials in a randomized order. In one trial, participants ingested 140 ml of NO₃⁻-rich beetroot juice (BR; ~8.4 mmol NO₃⁻) 2.5 h prior to sample collection. No supplementation was given in the other (CON). In both trials, a blood sample was collected from a forearm vein using a venepuncture needle 40 s after the application of a tourniquet to the upper arm. Simultaneously, a blood sample was collected from the opposite arm via an indwelling intravenous cannula with no restriction to blood flow. A second blood sample was collected from the cannula 40 s after a tourniquet was attached to the upper arm. Near-infrared spectroscopy was used to assess deoxygenation of the flexor muscles through changes in total (tHb), deoxy- (HHb), and oxy- (HbO₂) haemoglobin. Samples of plasma were analyzed for [NO₂⁻] and [NO₃⁻] using gas-phase chemiluminescence. **RESULTS:** The application of a tourniquet increased tHb, HHb, and HbO₂ suggesting deoxygenation of the local forearm muscles (all *P*<0.05). Plasma [NO₂⁻] was significantly higher when sampled from the unrestricted cannula (CON: 179 ± 67 nM, BR: 473 ± 164 nM) in comparison to venepuncture (CON 112 ± 51 nM, *P*=0.03; BR 387 ± 136 nM, *P*<0.001) and the cannula during tourniquet application (CON 109 ± 43 nM, *P*=0.02; BR 384 ± 124 nM, *P*<0.001). Plasma [NO₃⁻] was not different between sample sites in either trial (all *P*>0.05). **CONCLUSIONS:** The application of a tourniquet for venous blood sampling causes ischemia, localized hypoxia, and reduces plasma [NO₂⁻], possibly due to an increased conversion to NO or greater uptake of NO₂⁻ by the tissue. Researchers should ensure consistency in blood collection methodologies and consider how the use of a tourniquet may influence NO metabolism.

Associations Among Indices of Insulin Resistance and Vascular Reactivity in Older, Obese Adults

Matthew D. Doyle, Vincent M. Simth, Gabrielle A. Volk, Kevin D. Ballard, FACSM, Kyle L. Timmerman, FACSM. *Miami University, Oxford, OH.*
 Email: ballarkd@miamioh.edu
 (No relevant relationships reported)

Insulin resistance (IR), estimated by calculating the homeostasis model assessment of IR (HOMA-IR), independently predicts incident cardiovascular disease (CVD) events. Further, HOMA-IR is inversely associated with brachial artery flow-mediated dilation (FMD) in non-diabetics, suggesting that IR may contribute to vascular dysfunction that increases CVD risk. **PURPOSE:** We sought to determine associations among indices of IR/glucose control and vascular reactivity in older, obese adults. We hypothesized that brachial artery FMD and hyperemic shear rate area under the curve (AUC) would be inversely associated with indices of IR/glucose control. **METHODS:** Preliminary data are from older, obese adults [*n* = 20 (16 women); age = 64.2 ± 4.8 y; BMI = 35.3 ± 5.3 kg/m²] participating in an ongoing clinical study. Brachial artery FMD and hyperemic shear rate AUC were assessed by a trained technician using high-resolution ultrasonography following an overnight fast. Additionally, fasting blood glucose (FBG) and serum insulin concentrations, HOMA-IR, hemoglobin (Hb)A1c, and postprandial blood glucose responses (i.e., 2 h AUC) to mixed meal ingestion (0.3 g protein/kg lean body mass + 0.5 g glucose/kg lean body mass) were measured to assess IR/glucose control. Partial correlations (controlling for age and sex) were used to examine associations among these variables. **RESULTS:** Participants were insulin resistant (HOMA-IR = 3.7 ± 2.2) but not diabetic (FBG = 99.5 ± 9.5 mg/dL, HbA1c = 5.5 ± 0.2%). Fasting brachial artery FMD (3.4 ± 1.6%) was not correlated (all *P*≥0.44) with FBG (*r* = -0.18) or serum insulin (14.2 ± 7.5 μIU/ml; *r* = -0.07), HOMA-IR (*r* = -0.13), HbA1c (*r* = -0.19), or 2 h blood glucose AUC (13,430 ± 2,298 mg/min/dL; *r* = -0.23). Hyperemic shear rate AUC was not correlated with indices of IR/glucose control (all *P*≥0.11). **CONCLUSIONS:** Preliminary data from our ongoing clinical study show that indices of IR/glucose control are not associated with vascular reactivity in older,

obese adults. Continued recruitment of participants will more definitely determine the potential contribution of IR to vascular dysfunction and CVD risk. Supported by National Institute on Aging (1R15AG055923-01).

 (No relevant relationships reported)

Institutions:¹ Universidade Nove de Julho - São Paulo SP, Brazil; ² Faculdade de Medicina da Universidade de São Paulo - SP, Brazil.

Deep venous thrombosis (DVT) is a disease characterized by an acute thrombus formation in deep veins. It is unclear whether DVT chronically impairs muscle metabolism during exercise.

Purpose: To analyze the impact of DVT on muscle oxygen saturation (STO₂) during exercise.

METHODS: Ten patients with chronic unilateral DVT were recruited. Patients were submitted to two submaximal walking exercise tests to assess STO₂ in calf. In one test the leg with previous DVT was assessed and in the other test the counter lateral leg was assessed. Onset, at the end, maximal, minimal and average STO₂ during exercise were obtained.

RESULTS: Onset (DVT leg:64(14)% vs. Control leg: 67(6)%, *p*=0.117), at the end (DVT leg:72(4)% vs. Control leg: 74(5)%, *p*=0.099), maximal (DVT leg:73(10)% vs. Control leg: 73(5)%, *p*=0.878), minimal (DVT leg: 59(14)% vs. Control leg: 61(24)%, *p*=0.678), and average (DVT leg: 66(9)% vs. Control leg: 66 (9)%, *p*=0.678), were similar between legs.

CONCLUSION: DVT does not affect muscle STO₂ during exercise.

Key words: Venous thrombosis, exercise, lower extremity.

Does 24-hour Ambulatory Blood Pressure Monitoring Act as Ischemia Preconditioning and Influence Endothelial Function?

Brandon G. Fico, Weili Zhu, Hirofumi Tanaka, FACSM. *The University of Texas at Austin, Austin, TX.* (Sponsor: Dr. Hirofumi Tanaka, FACSM)
 Email: bfico@utexas.edu
 (No relevant relationships reported)

Ischemic preconditioning can exert a powerful protection against a subsequent period of ischemia in a variety of organs, via repeated inflation and deflation of a blood pressure cuff. Most often, damages of ischemia reperfusion injury and benefits of preconditioning are evaluated via endothelial function. The ambulatory blood pressure device takes repeated blood pressure measurements and constitutes repeated bouts of ischemia for 24 hours. In practice, measurements of endothelial function and ambulatory (24-hour) blood pressure are often combined. **PURPOSE:** We determined whether repeated bouts of ischemia accumulated for 24 hours through 24-hour ambulatory blood pressure monitoring influence endothelial function. **METHODS:** Twenty-two apparently healthy non-medicated middle-aged subjects (41±8 years, 12 males and 10 females) participated in the study. Flow-mediated dilation (FMD; index of endothelium-dependent vasodilation) was measured twice 30 minutes apart at baseline to confirm test-retest reliability. Subsequently, subjects were fitted with an ambulatory (24 hour) blood pressure monitoring device. Blood pressure was measured every 15 minutes during the daytime and 20 minutes at nighttime. Upon returning after 24 hours, FMD was remeasured. Shear rate and reactive hyperemia were also measured simultaneously. **RESULTS:** The ambulatory blood pressure monitoring device went through an average of 110±13 inflation/deflation cycles, which resulted in 46±6 minutes of cumulative ischemic stimuli. Two measurements of FMD at baseline were not different, showing the measurement stability. Following 24-hours of ambulatory blood pressure monitoring, FMD did not change significantly (6.6±2 vs. 6.8±3%). Similarly, shear rate (4.4±2.6 vs. 5.1±5.9 cm/s) and reactive hyperemia (13.7±12.1 vs. 17.6±21.1 cm/s) were unchanged (all *p* > 0.05). **CONCLUSIONS:** Ambulatory blood pressure monitoring and the associated ischemia repeated for 24 hours, did not influence endothelium-dependent vasodilation acting via ischemic preconditioning.

THE IMPACT OF POSTTRAUMATIC STRESS DISORDER ON PERIPHERAL VASCULAR FUNCTION

J. Weggen, A. Hogwood, B. Imthurn, A. McIntyre, A. Darling, K. Decker and R. Garten. Virginia Commonwealth University, Richmond, VA
 The physiological manifestations of posttraumatic stress disorder (PTSD) have been associated with an increase in risk of cardiovascular disease (CVD) independent of negative lifestyle factors. Peripheral vascular dysfunction may be a mechanism by which PTSD increases CVD risk via increases in oxidative stress, inflammation, and/or sympathetic nervous system activity. **PURPOSE:** This study sought to examine peripheral vascular function in those with PTSD compared to age-matched controls. **METHODS:** Eight individuals with PTSD (5 women, 3 men; age 22 ± 2 years), and sixteen healthy controls (CON; 10 women, 6 men, 23 ± 2 years), participated in the study. Leg vascular function was assessed via passive leg movement (PLM) technique and evaluated with Doppler ultrasonography. PLM-induced increases in leg blood flow were quantified as peak change in blood flow from baseline (Δ Peak LBF) and blood flow area under the curve (LBF AUC). **RESULTS:** Significant differences in leg vascular function were revealed between groups. The PTSD group reported significantly lower Δ Peak LBF (PTSD: 294.16 ± 54.16 ; CON: 594.78 ± 73.70 ml·min⁻¹; $p = 0.01$) and LBF AUC (PTSD: 57.23 ± 24.37 ; CON: 169.92 ± 29.84 ml; $p = 0.02$) when compared to the CON group. **CONCLUSION:** This study revealed that lower limb vascular function is impaired in individuals with PTSD when compared to healthy counterparts.

Measurement of Peripheral Pulse Wave Velocity Responses to Prolonged Sitting: Influence of Posture

PURPOSE: Prolonged sitting acutely increases (worsens) pulse wave velocity (PWV), a measure of arterial stiffness. Though the effect of prolonged sitting on PWV would be best captured while maintaining a seated posture, measurement of PWV is recommended to be performed in a supine posture. We examined whether peripheral PWV responses to a simulated workday of prolonged sitting differed when measured in a seated vs. supine posture. **METHODS:** Adults with overweight or obesity (BMI ≥ 25.0 kg/m²) and elevated blood pressure participated in an 8-hr simulated workday of prolonged sitting (only necessary restroom and meal breaks allowed). Carotid-radial (crPWV) and carotid-ankle (caPWV) PWV were both measured using tonometry at baseline, mid-day, and afternoon. At each timepoint, participants rested for 10 minutes in a seated posture followed by seated PWV, then rested for 10 minutes in a supine posture followed by supine PWV. Generalized linear mixed models evaluated main effects of posture and time, and their interaction on PWV. **RESULTS:** Participants ($n=25$) were 42 ± 12 years old, 64% self-reported as male, had a systolic blood pressure of 132 ± 9 mmHg and diastolic blood pressure of 83 ± 8 mmHg, and mean BMI 32 ± 5 kg/m². Participants took an average of 3.7 ± 1.3 restroom breaks. For crPWV ($n=23$ with valid data), there was no posture x time interaction ($\beta = -0.03$ m/s; $P = 0.840$); the main effect of posture was significant ($\beta = 0.47$ m/s; $P = 0.001$) but the main effect of time was not ($\beta = 0.095$ m/s; $P = 0.241$). For caPWV ($n=21$ with valid data), the interaction was not significant ($\beta = -0.64$ m/s; $P = 0.074$); there were significant main effects of time ($\beta = 0.24$ m/s; $P = 0.017$) and posture ($\beta = 1.94$ m/s; $P = 0.001$). **CONCLUSION:** Peripheral PWV was higher when measured while seated vs. supine. However, the effect of prolonged sitting over time on PWV was not statistically different across postures. Especially for crPWV, seated and supine measurement of PWV appear to capture similar responses to prolonged sitting.

The Acute Effects of Aerobic, Resistance, and Integrated Concurrent Exercise on Blood Pressure and Arterial Stiffness
 Gregory Spicer, Susan Sotir, Kristen Oullette, Tracey Matthews, Garrett Abel, Samuel Headley. *Springfield College, Springfield, MA.* (Sponsor: Vincent Paolone, FACSM)
 Email: gspicer@springfieldcollege.edu
 (No relevant relationships reported)

While the acute peripheral and central blood pressure responses to aerobic and resistance exercise have been well documented, a comparison between these types of exercise and integrated concurrent exercise has not yet been investigated. **PURPOSE:** To investigate the acute peripheral and central blood pressure, and arterial stiffness (augmentation index) responses following an aerobic, resistance, and integrated concurrent exercise sessions. **METHODS:** Ten resistance trained males ($M = 20.8 \pm 1.69$) performed aerobic exercise (AER), resistance exercise (RES), and integrated concurrent exercise (ICE) sessions in random order following a familiarization session. The AER session consisted of 45 min of stationary cycling at 70% HR reserve (HRR) ($M = 156.13 \pm 2.93$ cpm), while the RES and ICE sessions consisted of the performance of 5 resistance exercises preceded by 2 min of seated rest or stationary cycling at 70% HRR respectively. Cardiovascular parameters including central and peripheral systolic and diastolic blood pressures (cSBP, cDBP, pSBP, and pDBP respectively) and augmentation index (AIx) were collected prior to and 0, 15, 30, 45, and 60 minutes post exercise with pulse wave analysis using the Sphygmocor Xcel System. Five 3x6 Repeated Measures Factorial ANOVAs were used to examine the presence of an interaction effect or main effects with respect to exercise condition (AER, RES, ICE) and time for cSBP, cDBP, sSBP, sDBP, and AIx. No significant interaction or main effect for condition was found for any of the dependent variables. Significant differences were found for time across the dependent variables cSBP, pSBP, and AIx ($p \leq .05$). These differences represented typical physiological responses to exercise. AIx was significantly elevated following RES 0 and 15 min post exercise ($p \leq .05$) but was not found to significantly increase following AER or ICE. Regardless of exercise condition, acute cardiovascular responses in terms of peripheral and central blood pressures were similar. **CONCLUSION:** Integrated concurrent exercise resulted in similar acute cardiovascular responses compared to aerobic and resistance exercise; however, the aerobic component of ICE may possibly blunt the acute increase in arterial stiffness elicited by RES performed in isolation.

Aerobic Training And Vascular Protection: Insight From Altering Blood Flow Patterns
 Ashley Darling, Jennifer Weggen, Kevin Decker, Austin C. Hogwood, Austin Michael, Brandon Imthurn, Andrew McIntyre, Ryan S. Garten. *Virginia Commonwealth University, Richmond, VA.*
 (No relevant relationships reported)

Adequate blood flow patterns are essential in maintaining vascular homeostasis. Exercise-induced increases in antegrade, or forward, blood flow is a major modulator of vascular health; however, as vascular function in the conduit arteries is normalized as aerobic training progresses it is unknown if aerobically-trained vessels can adequately counteract vascular insults. **PURPOSE:** The study sought to determine the ability of aerobically-trained individuals to counteract an acute vascular insult (increased retrograde shear). **METHODS:** Ten young male trained rowers (20 ± 1 yrs) and ten male recreationally active controls (24 ± 1 yrs) were recruited for this study. Subjects completed two brachial artery (BA) flow mediated dilation (FMD) tests separated by a 30 minutes of sub-diastolic cuff inflation (60 mmHg) of the forearm. BA diameter, blood flow, and shear rate were evaluated prior to and throughout both FMD tests. **RESULTS:** The sub-diastolic cuff inflation intervention resulted in significant increases in retrograde shear rate ($p < 0.001$) and oscillatory shear index ($p < 0.001$) over time (pre- to post-FMD measures). Significant reductions across time were revealed in brachial artery (BA) dilation (absolute: $p = 0.008$; relative change: $p = 0.011$) and the post-cuff release hyperemic response (BA blood flow AUC: $p < 0.001$; BA shear rate AUC: $p = 0.001$), but no group differences were observed in these variables. **CONCLUSIONS:** This study revealed that individuals with prior upper limb training were unable to attenuate the vascular dysfunction associated with acute increases in retrograde shear.

Influence Of Acute Inflammation On Central Hemodynamics During A Mild Sympathoexcitatory Stimulus.

Neil J. McMillan, Elizabeth C. Schroeder, Wesley K. Lefferts, Thessa I.M. Hilgenkamp, Bo Fernhall, FACSM. *University of Illinois at Chicago, Chicago, IL.* (Sponsor: Bo Fernhall, FACSM)
 (No relevant relationships reported)

Acute inflammation is associated with an increased risk of cardiovascular events. Acute inflammation causes vasodilation and impairs vascular sensitivity to sympathetic stimuli, which could impact wave reflections and central blood pressure. **PURPOSE:** Determine the effect of acute inflammation on central hemodynamics during a mild sympathoexcitatory stimulus. **METHODS:** Central hemodynamics were assessed in 22 apparently healthy young adults (12 males, 25.3 ± 4.4 years, 22.8 ± 3.2 kg/m²) before and during a mild sympathoexcitatory stimulus (-20 mmHg lower body negative pressure [LBNP]) at baseline and 24h following a typhoid vaccination. Central pressure and augmentation index (AIx) were obtained via radial tonometry and a validated generalized transfer function. Aortic pulse wave velocity (PWV) and reflection index were also measured. Measures were calibrated to brachial mean and diastolic pressure measured via oscillometric cuff. C-reactive protein (CRP) and interleukin-6 (IL-6) were assessed via standard ELISA techniques. **RESULTS:** Acute inflammation was induced with significant increases in IL-6 (1.12 ± 0.53 to 2.38 ± 1.33 pg/mL; p < 0.001) and CRP (1.11 ± 2.03 to 2.81 ± 3.79 mg/L; p = 0.001). No changes were observed for heart rate or pulse wave velocity in response to inflammation. Acute inflammation resulted in reductions in diastolic and mean arterial pressure, and central augmentation index (AIx) (p<0.05), while reflection index was not altered (p > 0.05). There were no effects of LBNP, and no effect of inflammation on LBNP responses (interactions > 0.05). **CONCLUSION:** Acute inflammation lowered mean pressure as well as global wave reflections, suggesting peripheral vasodilation. Central hemodynamic control during a sympathoexcitatory stimulus is preserved during acute inflammation in young, apparently healthy adults.

Greater Reliance On Carbohydrates During Single Leg Versus Double Leg Cycling

Sarah G. Kearney, Shane Draper, John McDaniel. *Kent State University, Kent, OH.*
 Email: skearne5@kent.edu
 (No relevant relationships reported)

Small muscle mass exercise allows for greater muscle specific blood flow and tissue perfusion. This increase in oxygen delivery should allow individuals to tolerate a greater muscle specific workload which potentially would result in greater reliance on carbohydrate oxidation. However, the metabolic consequences of manipulating active muscle mass is not fully understood. **PURPOSE:** To determine if there is a difference in carbohydrate and fat oxidation between single-leg and double-leg

cycling at the same rate of whole body oxygen consumption. **METHODS:** Eight healthy college aged men (n=5) and women (n=3) completed the study. Participants arrived fasted and completed two conditions across two days (matching for oxygen consumption): 30-minute single leg cycling and 30-minutes double leg cycling. Oxygen consumption (VO₂), respiratory exchange ratio (RER), kilocalories (kcal), carbohydrate oxidation (CHO), fat oxidation (FTO), and power (PWR) were recorded throughout the entire bout of exercise. Paired samples t-tests were performed to find differences in all dependent variables across both conditions. **RESULTS:** Matching for oxygen consumption (1.6 ± 0.39 versus 1.58 ± 0.38 L/min) required slightly lower PWR (t=3.08, p=0.015) in SL (86.58 ± 25.26 W) than DL (94.23 ± 30.67 W) while still maintaining the same energy expenditure (239.38 ± 75.64 versus 232.19 ± 74.65 kcal). However, participants had a greater rate of carbohydrate oxidation (t=7.61, p<0.001) during SL (1.46 ± 0.45 g/min) compared to DL (1.01 ± 0.49 g/min). This is further demonstrated with significantly greater RER values (t=5.28, p=0.001) in SL (0.92 ± 0.03) than DL (0.86 ± 0.05) and reduced FTO in SL (t=5.47, p<0.001; 0.22 ± 0.06 g/min) than DL (0.36 ± 0.09 g/min). **CONCLUSION:** Despite the same global intensity based on oxygen consumption and energy expenditure within both conditions, there was an increase in CHO and decrease in FTO during SL cycling. This suggests that there is a potential for smaller muscle mass activities (i.e. single leg exercise training) to have greater impact on post-prandial blood glucose control compared to larger muscle mass activities. Future research should consider participants with metabolic disease.

The Effect Of An Antioxidant Cocktail On Flow-Mediated Dilation In Endurance Athletes

Trevor J. King, Heather L. Petrick, Philip J. Millar, Jamie F. Burr, FACSM. *University of Guelph, Guelph, ON, Canada.* (Sponsor: Jamie Burr, FACSM)
 (No relevant relationships reported)

Flow-mediated dilation (FMD) is a measure of endothelial function, and an FMD response can be initiated by different blood flow induced shear stimuli (e.g. sustained vs. transient exposure), each testing a different aspect of endothelial function. Excessive reactive oxygen species (ROS) are known to impair FMD, but low levels of ROS may be involved in endothelial cell signaling. Endurance exercise bombards the endothelium with ROS and may induce an adaptive response in the endothelium of trained individuals. However, it is unknown whether ROS are involved in the FMD response among endurance trained athletes. **PURPOSE:** To identify the involvement of ROS in the FMD response of trained endurance athletes to a variety of shear stimuli. **METHODS:** 10 trained runners and cyclists (n=3 women) performed an incremental exercise test and two experimental FMD visits. An antioxidant cocktail (AOC) or inactive placebo was given prior to each experimental visit (1 g vitamin C, 600 IU vitamin E, 600 mg alpha lipoic acid). Each identical experimental visit involved 3 FMD tests. FMD was measured as reactive hyperemia (RH)-FMD (transient stimulus), sustained stimulus (SS)-FMD (6-min of 9 kg rhythmic handgrip squeezing), and progressive (p)-FMD (rhythmic handgrip squeezing at 3, 6, and 9 kg). **RESULTS:** Mean VO_{2max} was 58 ± 5 ml·kg⁻¹·min⁻¹. Within each FMD method (RH-, SS-, and p-FMD) shear rate was not different between AOC and Placebo (all p > 0.4). SS-FMD was not altered by AOC (PLA = 2.3 ± 1.0 mm, AOC = 2.6 ± 1.6 mm, p = 0.44), and the FMD/shear rate slope created using p-FMD was not altered by AOC (PLA = 0.018 ± 0.002 mm·s, AOC = 0.017 ± 0.001 mm·s, p = 0.78). There was a trend for a reduction in RH-FMD following AOC consumption (PLA = 3.1 ± 0.8 mm, AOC = 2.5 ± 1.4 mm, p = 0.08), and the RH-FMD response to AOC was significantly different from the SS-FMD response to AOC (p = 0.04). Following covariation for baseline diameter, SS-FMD (p = 0.003) and RH-FMD (p = 0.04) were significantly reduced following AOC consumption, and there was a trend for a difference in response to AOC between methods (p = 0.06). **CONCLUSIONS:** These preliminary data suggest that ROS may be involved in the FMD response of trained endurance athletes, and the degree of involvement may vary based on shear stress stimulus. *NSERC, CFI, ERA-OMRIS.*

High Intensity Endurance and Resistance Training Does Not Improve Orthostatic Tolerance Compared to Recreationally Active

Courtney E. Wheelock¹, Hayden W. Hess¹, Zachary J. Schlader, FACSM¹, David Hostler, FACSM². ¹University at Buffalo, Buffalo, NY. ²University at Buffalo, Buffalo, NY. (Sponsor: Dave Hostler, FACSM)
 Email: cwheeloc@buffalo.edu
 (No relevant relationships reported)

Endurance-trained adults often display a relative inability to maintain blood pressure during orthostatic challenges. In contrast, resistance-trained adults often have augmented orthostatic tolerance. However, little is known about the effects of concurrent high intensity endurance and resistance training (CT) on orthostatic

tolerance. **PURPOSE:** To test the hypothesis that CT will have a greater orthostatic tolerance compared to recreationally active (RA) adults. **METHODS:** Twelve subjects (26 ± 4 y), six (3 males) CT (76.5 ± 14.0 kg; fat free mass (FFM) = 66.5 ± 15.1 kg) and 6 (3 males) RA adults (78.5 ± 26.5 kg; FFM = 64.1 ± 22.5 kg) underwent body composition testing (air displacement) followed by a progressive lower body negative pressure (LBNP). The LBNP test began at 20 mmHg and decreased 20 mmHg every 3 min until pre-syncope. Heart rate (ECG; HR), mean arterial pressure (Penaz method; MAP), stroke volume (Modelflow; SV), and changes in leg blood volume measured by calf circumference (plethysmography) were recorded continuously. Orthostatic tolerance was quantified via cumulative stress index (CSI), calculated as the sum of the product of LBNP stage and duration of that stage (e.g., 20 mmHg*3 min + 40 mmHg*3 min, etc.). **RESULTS:** Baseline HR (RA: 66 ± 91 bpm, CT: 62 ± 10 bpm p=0.72), SV (RA: 99 ± 29 mL, CT: 100 ± 30 mL p=0.96), and MAP (RA: 82 ± 28 mmHg, CT: 83 ± 8 mmHg p=0.95) did not differ between groups. During LBNP, SV and MAP decreased, while HR and calf circumference increased (all p<0.01). There were no differences in HR, SV, MAP, and calf circumference between groups over time or at pre-syncope (HR- RA: 108 ± 24 bpm; CT: 116 ± 20 bpm p=0.54; SV- RA: 32 ± 20 mL, CT: 30 ± 22 mL, p=0.90; MAP- RA: 41 ± 18 mmHg, CT: 57 ± 21 mmHg, p=0.20; calf circumference- RA: 1.8 ± 1.8%, CT: 3.7 ± 1.6%, p=0.08). CSI did not differ between groups (RA: 575 ± 383 mmHg*min, CT: 800 ± 530 mmHg*min, p=0.42). **CONCLUSIONS:** Orthostatic tolerance did not differ between combined high intensity endurance and resistance trained adults when compared to recreationally active adults. Combined endurance and resistance training does not improve nor hinder orthostatic tolerance compared to that of recreational exercise.

2440 Board #104 May 31 11:00 AM - 12:30 PM

Attenuated Pulsatile Load During Metaboreflex Activation is Associated with Excess Adiposity in Dynapenic Postmenopausal Women

Arun Maharaj¹, Salvador J. Jaime², Stephen M. Fischer¹, Arturo Figueroa, FACS¹. ¹Texas Tech University, Lubbock, TX. ²University of Wisconsin - La Crosse, La Crosse, WI. (Sponsor: Dr. Arturo Figueroa, FACS) Email: arun.maharaj@ttu.edu (No relevant relationships reported)

The age-related loss in muscle strength (dynapenia) is associated with elevated blood pressure (BP) and fat mass (FM). Aortic pulse pressure (PP), rather than brachial PP, more closely relates to cardiovascular events because it represents left ventricular pulsatile load, which is particularly important in older women. **PURPOSE:** To examine the impact of dynapenia and adiposity on aortic BP responses to metaboreflex activation (post-exercise muscle ischemia, PEMI) in postmenopausal women. **METHODS:** 71 postmenopausal women [(dynapenic, n=41, 57±1 years), (non-dynapenic, n=30, 59±1 years)] were included in this study. FM, percent body fat (BF%) and percent lean mass (LM%) were measured using Dual Energy X-Ray Absorptiometry. Normalized handgrip strength (nMVC) was calculated as maximal voluntary contraction/body weight. Dynapenia was classified as an nMVC ≤ 0.30 kg/kg. Heart rate and aortic BP (radial applanation tonometry) were measured at rest and during 3-min PEMI following 2-min isometric handgrip exercise at 30% MVC. **RESULTS:** Resting BP was similar in both groups. The dynapenic group had significantly lower nMVC (0.24 ± 0.01 vs 0.38 ± 0.01 kg/kg, p < 0.001) and LM% (51.5 ± 0.6 vs 60.9 ± 0.9, p < 0.001), and higher FM (44.5 ± 1.7 vs 26.5 ± 1.3 kg, p < 0.001) and BF% (48.5 ± 0.6 vs 39.1 ± 0.9, p < 0.001) compared to the non-dynapenic group. The dynapenic group exhibited a blunted brachial PP (9 ± 2 vs 16 ± 2 mmHg, p < 0.05) and aortic PP (9 ± 2 vs 15 ± 2 mmHg, p < 0.05) response to PEMI without differences in heart rate response to PEMI (3 ± 1 vs 3 ± 1 beats/min) compared to the non-dynapenic group. In the dynapenic group, attenuated brachial and aortic PP responses to PEMI were related (all p < 0.05) to FM (r = -0.48; r = -0.47) and BF% (r = -0.51; r = -0.49). **CONCLUSIONS:** Pulsatile load responses to PEMI were blunted in dynapenic postmenopausal women. Excess adiposity contributes to the attenuated pulsatile response to metaboreflex activation in dynapenic postmenopausal women.

Lower Leg Lean Mass Is Associated With Reduced Pulse Pressure Amplification In Postmenopausal Women

Stephen M. Fischer¹, Arun Maharaj¹, Salvador J. Jaime², Arturo Figueroa, FACS¹. ¹Texas Tech University, Lubbock, TX. ²University of Wisconsin-La Crosse, La Crosse, WI. (Sponsor: Arturo Figueroa, FACS) (No relevant relationships reported)

Sarcopenia, the age-related loss of skeletal muscle mass, has been associated with increased arterial stiffness (pulse wave velocity, PWV). Lower leg muscle mass has been associated with increased brachial-ankle PWV (baPWV), a measure of systemic arterial stiffness. Pulse pressure (PP) is lower in the aorta compared to the brachial artery (PP amplification, PPA), in healthy individuals. PPA decreases with aging due

to increased aortic stiffening. Lower PPA is an independent predictor of cardiovascular death. It is unknown whether leg muscle mass is associated with lower PPA in postmenopausal women. **PURPOSE:** To examine relationships between leg lean mass (LegLM), PPA, and baPWV in postmenopausal women.

METHODS: 93 postmenopausal women (aged 48 - 71 years; BMI: 30 ± 7) underwent vascular function and body composition testing. Aortic PP was determined using applanation tonometry. baPWV and brachial PP were measured using an oscillometric device with cuffs placed on the arms and ankles. LegLM was measured by dual-energy x-ray absorptiometry. Handgrip strength was measured as the maximal voluntary contraction (MVC). The relationships between these variables were analyzed using Pearson's correlations. Significant correlations were subsequently analyzed using multiple linear regression.

RESULTS: LegLM was correlated with baPWV (r = -.218, p = .034) and PPA (r = -.298, p = .004). PPA was also negatively correlated with baPWV (r = -.261, p = .01). LegLM was positively associated with PPA (β = 0.216, t = 2.320, p = .023) after adjusting for age, MVC, systolic pressure, and heart rate.

CONCLUSIONS: Low leg lean mass was related to vascular dysfunction measured as increased systemic arterial stiffness and reduced PPA. Greater muscle mass in the legs may be protective against increased systemic arterial stiffness and reduced PPA associated with aging.

2442 Board #106 May 31 11:00 AM - 12:30 PM
Aerobic Training-induced Increase In Follistatin-like 1 Secretion Is Associated With eNOS Phosphorylation In Diabetic Rats.

Kenichiro Inoue¹, Natsuki Hasegawa¹, Shumpei Fujie², Naoki Horii¹, Masataka Uchida¹, Motoyuki Iemitsu¹. ¹Ritsumeikan University, Kusatsu, Shiga, Japan. ²University of Tsukuba, Tsukuba, Ibaraki, Japan. (Sponsor: Takeshi Hashimoto, FACS) Email: sh0118es@ed.ritsumei.ac.jp (No relevant relationships reported)

INTRODUCTIN: Aerobic exercise training reduces arterial stiffness via elevation of nitric oxide (NO) production in type 2 diabetes. Follistatin-like 1 (FSTL1) is a muscle-derived myokine and stimulates protein kinase B (Akt)/endothelial nitric oxide synthase (eNOS) signaling via binding to receptor (DIP2A) in endothelial cells. However, it is unclear whether FSTL1 secretion induced by aerobic exercise training is related to a reduction of arterial stiffness in type 2 diabetic rats. **PURPOSE:** This study aimed to investigate whether FSTL1 secretion induced by aerobic exercise training is related to a reduction of arterial stiffness with activation of aortic eNOS phosphorylation in type 2 diabetic rats. **METHODS:** Twenty-week-old male type 2 diabetic (OLETF) rats were randomly divided into sedentary control (OLETF-Con: n=7) and aerobic exercise training (OLETF-Ex: treadmill running for 60min at 25m/min, 5days/week: n=7) groups. In addition, 7 male LETO rats were used as healthy sedentary control. After 8-week experiment, we measured carotid-femoral pulse wave velocity (cfPWV: as an index of arterial stiffness), and thoracic aorta was isolated after collection of blood. **RESULTS:** Fasting blood glucose and cfPWV significantly increased (p<0.05) and aortic Akt and eNOS phosphorylation levels, plasma nitrate/nitrite (NOx) level, and serum FSTL1 protein level significantly decreased (p<0.05) in OLETF-Con as compared to LETO. OLETF-Ex showed significant decrease in fasting blood glucose and cfPWV (p<0.05), and significant increase in aortic Akt and eNOS phosphorylation, plasma NOx, and serum FSTL1 protein levels (p<0.05) as compared to OLETF-Con. However, no significant difference in aortic DIP2A protein level among three groups was seen. Serum FSTL1 protein level was positively correlated with aortic eNOS phosphorylation level (p<0.05, r=0.630), and plasma NOx level was negatively correlated with cfPWV (p<0.05, r=-0.546). **CONCLUSION:** The results suggest that the increase in FSTL1 secretion induced by aerobic exercise training is associated with the reduction of arterial stiffness via activation of arterial NO production-related signaling pathway in type 2 diabetic rats. Effects of Somatosensory Afferent on Cerebral Hemodynamics during Orthostatic Stimulation

Marina Fukuie¹, Yuka Ninomita², Takayuki Yamabe¹, Seiji Maeda¹, Tsubasa Tomoto³, Takashi Tarumi², Jun Sugawara². ¹University of Tsukuba, Ibaraki, Japan. ²National Institute of Advanced Industrial Science and Technology (AIST), Ibaraki, Japan. ³Institute for Exercise and Environmental Medicine, Texas Health Presbyterian Hospital Dallas, Dallas, TX. (No relevant relationships reported)

PURPOSE: The effect of somatosensory afferent on the cerebral circulatory control is not clear. This study aimed to reveal whether the somatosensory input from lower extremities can affect cerebral hemodynamic regulation during orthostatic stimulation. **METHODS:** Eleven young adults (4 women) underwent two consecutive 6-min

lower body negative pressure (LBNP) stimulations (-30 mmHg and -50 mmHg) under following two conditions: hanging up the body by a harness (leg-free) and bracing feet on the wood board in the LBNP chamber with slight knee flexion (leg-resisted) against suction. These conditions were conducted in random order. Heart rate (HR), mean arterial pressure (MAP), cardiac output (CO), end-tidal CO₂ (EtCO₂), and cerebral blood flow velocity (CBFv) from the middle cerebral artery were continuously recorded. Dynamic cerebral autoregulation (dCA) was evaluated by transfer function analysis. **RESULTS:** HR was significantly higher, and CO and EtCO₂ were significantly lower during -50 mmHg of LBNP stimulation than each baseline value irrespective of leg conditions, whereas MAP and mean CBFv remained at similar levels throughout the LBNP stimulation under both leg conditions. Power spectral density of mean CBFv in the low-frequency range (0.07-0.2 Hz) significantly increased at -30 and -50 mmHg of LBNP stimulations in the leg-resisted condition (from 1.41 ± 0.62 to 5.42 ± 3.27 and 5.19 ± 3.46) but not in the leg-free condition. Likewise, transfer function gain in the low-frequency range were significantly augmented at -30 and -50 mmHg of LBNP stimulations in the leg-resisted condition (from 1.22 ± 0.34 to 1.58 ± 0.39 and 1.56 ± 0.43) but not in the leg-free condition. **CONCLUSIONS:** These results suggest that somatosensory afferent from lower extremities may modify cerebral hemodynamic regulation during orthostatic stimulation.

Relationship Between Arterial Stiffness And Cardiac Function In Athletes
 Yuto Hashimoto¹, Takanobu Okamoto². ¹Graduate school of Nippon Sport Science University, Tokyo, Japan. ²Nippon Sport Science University, Tokyo, Japan.
 Email: 18pda06@nittai.ac.jp
 (No relevant relationships reported)

Arterial function and left ventricular (LV) function are inter-related. In fact, increased arterial stiffness increases afterload and causes decrease in LV diastolic function in elderly hypertensive patients. The high arterial stiffness causes increased myocardial workload for compensation. However, the relationship between arterial stiffness and cardiac function in athletes remain unknown.

PURPOSE: The present study aimed to determine the relationship between aortic stiffness and LV function in athletes.
METHODS: The participants in this study were 16 male college athletes (age 21.5 ± 0.9 yrs). Carotid-femoral pulse wave velocity (cfPWV), which reflects aortic stiffness, was measured using an automatic oscillometric device. In addition, cardiac function was measured using an ultrasound echography. Color Doppler, Pulsed Doppler, and Tissue Doppler images were recorded and used to assess LV diastolic function, evaluated as the early and late mitral inflow velocity ratio (E/A ratio) and early septal mitral annulus movement velocity (e'). The "E/A ratio" is a classical method of assessing LV diastolic function and is influenced by afterload. On the other hand, "e'" is an index of myocardial stiffness, but is not influenced by afterload. We examined the correlation between cfPWV and each indicator of LV diastolic function. Data analysis was performed using Spearman's rank correlation coefficient.
RESULTS: A negative correlation between cfPWV and E/A ratio (r = -0.557, p = 0.02) was observed. However, there was no correlation between cfPWV and e' (r = -0.076, p = 0.772).
CONCLUSION: These results suggested that higher aortic stiffness causes decreased LV diastolic function in athletes, regardless of LV myocardial stiffness.

Effects Of Habitual Isometric Handgrip Exercise On Arterial Function & Cognitive Function In Older Adults
 Takanobu Okamoto, Yuto Hashimoto. Nippon Sport Science University, Tokyo, Japan.
 Email: tokamoto@nittai.ac.jp
 (No relevant relationships reported)

Physical exercise is important for prevention of cardiovascular diseases and cognitive impairment and for decreasing its rate of progression. Isometric handgrip exercise can effectively decrease peripheral blood pressure (BP). However, the effects of isometric handgrip exercise on arterial function and cognitive function remain unknown.
PURPOSE: The present study aimed to determine whether habitual isometric handgrip exercise decreases arterial stiffness and improves cognitive function in older adults.
METHODS: Eleven males and females (mean age 75 ± 3 y; ± SEM) who were not actively involved in regular resistance or endurance training. The isometric handgrip exercise comprised four unilateral 2-min isometric contractions at 30% of maximal voluntary contraction using a programmed handgrip dynamometer with 1-min rest periods for five days per week for 8 weeks. Heart-carotid pulse wave velocity (hcPWV), carotid systolic BP (cSBP), brachial systolic BP (bSBP), and brachial diastolic BP (bDBP) were non-invasively measured after resting in the supine position for at least five minutes in both groups before (baseline) and after four weeks of

training using an arterial applanation tonometry system. Trail making test (TMT) Part A, which measures processing speed, and Part B, which assesses task shifting, were used to determine processing speed and flexibility in task switching and cognition.
RESULTS: cSBP and bSBP after training were significantly lower than baseline values, decreasing from 148 ± 6 to 138 ± 5 mmHg and from 140 ± 5 to 132 ± 4 mmHg, respectively (p < .01, for both), although bDBP did not change significantly before and after training (from 81 ± 3 to 78 ± 3 mmHg). TMT-A and TMT-B after training were significantly lower than baseline values, decreasing from 34.73 ± 3.04 to 26.41 ± 2.33 and from 60.52 ± 5.25 to 49.39 ± 4.51 sec, respectively (p < .05 for both). A significant positive correlation was observed between the amount of change in hcPWV and the amount of change in TMT-A (r = 0.595, p < .05). In addition, a significant positive correlation was observed between the amount of change in hcPWV and the amount of change in TMT-B (r = 0.589, p < .05).
CONCLUSIONS: These results demonstrate that isometric handgrip exercises exert a beneficial effect on arterial and cognitive function.

Effect of Musclin on Aerobic Training-induced Reduction of Arterial Stiffness in Obese Rats
 Yuta Toyama¹, Natsuki Hasegawa¹, Naoki Horii¹, Kenichiro Inoue¹, Keiko Iemitsu¹, Shumpei Fujie², Masataka Uchida¹, Motoyuki Iemitsu¹. ¹Ritsumeikan University, Kusatsu, Japan. ²University of Tsukuba, Ibaraki, Japan. (Sponsor: Hashimoto Takeshi, FACS M)
 (No relevant relationships reported)

Aerobic exercise training (AT) reduces arterial stiffness with elevation of arterial nitric oxide (NO) production via activation of endothelial NO synthase (eNOS) phosphorylation even in obesity. Secretion of musclin, a myokine which binds to natriuretic peptide receptor-C (NPR-C) and leads to vasoconstriction, accelerates in obese patients. However, it remains unclear whether AT attenuates musclin secretion and NPR-C levels, thereby decreasing arterial stiffness with the activation of arterial NO production pathway in obese rats. **PURPOSE:** This study aimed to clarify whether AT-induced attenuation of arterial musclin and NPR-C protein levels are related to reduction of arterial stiffness with NO production pathway in obese rats.
METHODS: Twenty-week-old male obese rats were randomly divided into two groups; sedentary control and aerobic exercise training (treadmill running for 60min at 25m/min, 5days/week) (n=7 each group), and seven male LETO rats were used as healthy sedentary control. After 8 weeks experiment, we measured carotid-femoral pulse wave velocity (cfPWV, an index of arterial stiffness), arterial nitrate/nitrite (NOx), musclin, NPR-C, eNOS phosphorylation (p-eNOS), and Akt phosphorylation (p-Akt) levels.
RESULTS: In sedentary obese rats, cfPWV and arterial NPR-C protein levels increased, and arterial NOx, p-eNOS and p-Akt levels decreased compared to LETO (each p < 0.05). In contrast, AT in the obese rats induced reduction of arterial stiffness and arterial NPR-C protein level, and elevation of arterial NOx, p-eNOS and p-Akt levels (each p < 0.05). AT reduced an augmented arterial musclin level by obesity. Arterial NPR-C protein level was negatively correlated with arterial p-eNOS (r = -0.501, p < 0.05) and NOx (r = -0.645, p < 0.05).
CONCLUSIONS: The results suggest that AT-induced attenuation of arterial musclin and NPR-C protein levels may participate in reduction of arterial stiffness with increased NO production pathway (i.e., Akt/eNOS signaling). Impact of a High Fat Meal Combined with Prolonged Sitting on Central and Peripheral Arterial Stiffness; A Pilot Study
 Simon Fryer¹, Keeron J. Stone¹, Craig Paterson¹, Meghan A. Brown¹, Aitor Martinez Aguirre-Betolaza², Daniel P. Credeur³, James Faulkner⁴, Gabriel H. Zieff⁵, Elizabeth Kelsch⁵, Kathryn Burnet⁵, Lee Stoner, FACS M⁵. ¹University of Gloucestershire, Gloucester, United Kingdom. ²University of Basque Country (UPV/EHU), vitoria-gasteiz, Spain. ³University of Southern Mississippi, Hattiesburg, MS. ⁴University of Winchester, Winchester, United Kingdom. ⁵University of North Carolina at Chapel Hill, Chapel Hill, NC. (Sponsor: Dr Lee Stoner, FACS M)
 Email: dr.s.fryer@gmail.com
 (No relevant relationships reported)

Acute sedentary behavior, such as prolonged sitting, has a detrimental impact upon markers of central and peripheral arterial health, including arterial stiffness. Similarly, a high-fat meal can also negatively impact post-prandial measures of central and systemic arterial stiffness. However, the interaction between prolonged sitting and high-fat meal consumption and its effects on central and peripheral arterial health has not been investigated.

PURPOSE: To determine the effects of 3 hours of prolonged sitting, with and without a high fat meal on central and peripheral arterial stiffness.

METHODS: Five young healthy males (Age: 22.8±2.5 yrs, BMI: 25±4.4 kg/m²), from a target of 18, have been recruited. Following familiarization, participants visited the laboratory on two occasions and completed a 3 hour period of prolonged sitting following the consumption either a high-fat (HF) or low-fat (CON) meal, in a randomized order. Visits were separated by a minimum of 2, and maximum of 7 days. Before and after prolonged sitting, supine central (carotid-femoral pulse-wave velocity [cfPWV]) and peripheral (femoral-ankle pulse-wave velocity [faPWV]) arterial stiffness were measured. High (60g of fat) and CON (10 g of fat) meals were matched for macronutrient content and volume. Data was analyzed using two-way repeated measures analysis of variance. Alpha was set at $P < 0.1$ *a priori* for preliminary analyses.

RESULTS: A significant interaction effect was observed for cfPWV (Group x Time, $P = 0.079$); *post hoc* analysis revealed that cfPWV increased following HF (Pre = 5.7±0.6 m/s vs. Post = 6.1±0.6; $p < 0.05$, $\eta^2_p = 0.71$) but was unchanged following CON (Pre = 6.2±0.8 m/s vs. Post = 6.2±0.6; $p > 0.05$, $\eta^2_p = 0.016$). No interaction ($P = 0.643$) or group ($P = 0.175$) effect was observed for faPWV, but faPWV did significantly decrease following sitting (Pre = 9.7±0.4 m/s vs. Post = 8.9±0.5; $p < 0.05$, $\eta^2_p = 0.641$).

CONCLUSIONS: The preliminary findings of this study suggest that, in young healthy adults, a high-fat meal, in combination with prolonged sitting may lead to a greater increase in central arterial stiffness than sitting combined with a low fat meal. Further, prolonged sitting may differentially impact central and peripheral arterial stiffness.

 Email: t.wasshie@gmail.com
 (No relevant relationships reported)

The previous study reported that flow-mediated dilation in peripheral conduit arteries decreased following an acute bout of isometric exercise. On the other hand, it remains unknown whether an acute isometric exercise affects cerebrovascular endothelial function. **PURPOSE:** The purpose of the present study was to examine the effect of acute isometric handgrip (IHG) exercise on hypercapnia-induced shear-mediated dilation in the internal carotid artery (ICA). **METHODS:** Four subjects participated in the present study and performed four 2-min IHG exercises at 25% of maximum voluntary contraction. Shear-mediated dilation in the ICA was induced by hypercapnia (target end-tidal carbon dioxide; +10mmHg from individual baseline value) and was calculated as the percent rise in peak diameter from baseline value. **RESULTS:** ICA blood velocity and diameter did not change after acute IHG exercise protocol compared with resting value. Also, shear-mediated dilation in the ICA was unchanged by IHG exercise protocol (4.4±2.0 vs. resting value, 4.5±1.9, $P = 0.84$). **CONCLUSIONS:** In the present study, the IHG exercise trials did not change cerebrovascular endothelium function. These findings suggest that the response of cerebral endothelial function to IHG exercise is different from that of the peripheral endothelial function.

The Impact Of Pulsed Electromagnetic Field Therapy On Blood Pressure And Circulating Nitric Oxide Levels: A Double-blind, Randomized Study In Subjects With Metabolic Syndrome.

Dongwook Yeo¹, Courtney Wheatley², Glenn Stewart¹, Win-Kung Shen², Jesse Schwartz², Bruce Johnson¹, Chul-Ho Kim¹. ¹Mayo Clinic, Rochester, MN. ²Mayo Clinic, Phoenix, AZ.
 (No relevant relationships reported)

Regulation of blood pressure (BP) is important in reducing the risk for cardiovascular disease. There is growing interest in non-pharmacological methods to treat BP including a novel approach using pulsed electromagnetic field therapy (PEMF). PEMF therapy has been proposed to impact physiological function at the cellular and tissue level and one possible mechanism is through an impact on endothelial function and nitric oxide (NO) related pathways

PURPOSE: The purpose of this study was to evaluate the therapeutic effect of PEMF on BP and NO in subjects with metabolic syndrome

METHODS: 23 subjects (PEMF group, Age: 58±12yrs, Ht: 169.7±11.9cm, Wt: 93.2±17.7kg) underwent PEMF therapy (Biomobility Inc., Shanghai, China) and 21 subjects (SHAM group, Age: 59±10yrs, Ht: 167.3±10.7cm, Wt: 87.5±18.1kg)

underwent sham therapy. The protocol for therapy included 16-min sessions, 3 sessions/day for 12 wk using both hands and feet. BP was measured at rest and near the end of submaximal exercise pre and 12 wk post therapy. Moreover, NO was measured at similar time points

RESULTS: There were no changes in wt in either group over the 12 wk of therapy. The PEMF demonstrated a trend toward increases in NO after therapy but SHAM did not ($p = 0.09$). For resting BP, there were no differences in systolic BP (SBP), diastolic BP (DBP) or mean arterial pressure (MAP) between groups ($p > 0.05$). During exercise, the PEMF had a reduction in pk SBP ($p = 0.04$), but not SHAM ($p = 0.57$). However the PEMF demonstrated a significant relationship between baseline SBP and change in SBP following therapy ($r = -0.71$, $p < 0.01$) and between MAP and change in MAP following therapy ($r = -0.60$, $p < 0.01$), but there were no such relationships found in SHAM ($r = -0.040$, $p > 0.05$ and $r = -0.043$, $p > 0.05$ respectively). Subjects with resting hypertension (defined as BP > 140 SBP) in the PEMF ($n = 11$) had significant reductions in SBP, DBP and MAP when compared to SHAM with HTN ($n = 9$) ($p < 0.05$). In this sub-group analysis, PEMF demonstrated lowered pk SBP ($p = 0.04$) at a given exercise load ($p = 0.40$) but SHAM did not ($p > 0.05$)

CONCLUSIONS: PEMF may increase plasma NO availability and improve BP at rest and during exercise. This indicates that PEMF may be a therapeutic technique to regulate BP in metabolic syndrome. However, this beneficial effect appears to be limited to subjects with existing high blood pressure

Sleep Metrics are Associated with Markers of Cardiovascular Disease Risk in Youth

Elissa K. Katulka, Alexandra E. Hirt, Michele N. D'Agata, Felicia R. Berube, Melissa A. H. Witman. University of Delaware, Newark, DE.
 Email: ekatulka@udel.edu
 (No relevant relationships reported)

There is accumulating evidence identifying relationships between insufficient sleep in children and adolescents and negative cognitive, psychosocial, and metabolic health consequences. However, the relationship between childhood sleep metrics and cardiovascular (CV) risk profile is less clearly defined.

PURPOSE: To characterize the relationship between sleep and CV health in young, healthy children through traditional risk factor assessment and vascular function assessments.

METHODS: Sleep metrics and habitual physical activity assessments were performed on 12 young, healthy boys and girls (12.3 ± 1 years) using wrist-worn accelerometry for 7 days and nights. Sleep onset latency (SL) was calculated as the mean time of transition from wakefulness to sleep, while sleep efficiency (SE) was calculated as the mean percentage of time spent asleep between sleep onset and wake onset. Central blood pressures and markers of wave reflection were assessed using pulse wave analysis (PWA) with an oscillometric device. Arterial stiffness was assessed through pulse wave velocity (PWV) measurements obtained using applanation tonometry and volumetric displacement. Vascular function was assessed using Doppler ultrasound measurements of femoral artery hemodynamics and diameter during passive leg movement (PLM).

RESULTS: SL was significantly associated with body mass index ($r = 0.66$, $p < 0.05$) and PWV ($r = 0.64$, $p < 0.05$) and tended to show moderate relationships with leg blood flow (LBF) responses during PLM (Δ LBF from baseline to peak, $r = -0.45$; LBF area under the curve, $r = -0.50$). SE was significantly associated with systolic blood pressure (SBP) ($r = -0.58$, $p < 0.05$) and aortic SBP ($r = -0.57$, $p = 0.05$). Subjects whose SE was >85% had lower aortic SBP (86.9 ± 1 vs. 93.7 ± 2, $p < 0.05$) and tended to have lower percent body fat, more steps per day, and better blood flow responses during PLM compared to those whose SE was <85%.

CONCLUSIONS: Preliminary findings suggest that metrics indicative of better sleep quality, such as greater SE and reduced SL, are associated with more favorable CV profiles in children. These results support the usefulness of assessing sleep as a potential approach for early prevention of CV disease risk during youth.

Investigating the Effect of a High Fat Meal and Prolonged Sitting on Executive Function: A Pilot Study
 Craig Paterson¹, Keeron J. Stone¹, Lee Stoner, FACSM², Daniel P. Credeur³, Aitor Martinez-Aguirre-Betolaza⁴, Joseph Festa⁵, Meghan A. Brown¹, John K. Parker¹, Simon Fryer¹. ¹University of Gloucestershire, Gloucester, United Kingdom. ²University of North Carolina at Chapel Hill, Chapel Hill, NC. ³University of Southern Mississippi, Hattiesburg, MS. ⁴University of Basque Country (UPV/EHU), vitoria-gasteiz, Spain. ⁵Loughborough University, Loughborough, United Kingdom. (Sponsor: Dr Lee Stoner, FACSM)
 (No relevant relationships reported)

Prolonged periods of sitting have been shown to reduce cerebral blood flow and autoregulation, which may subsequently impair executive function. Similarly, the consumption of a high-fat diet can negatively impact cerebral perfusion. However, whether prolonged sitting combined with a high fat meal additionally impairs both executive function and cerebral perfusion is unknown.

PURPOSE: To investigate the effects of consuming a high-fat meal followed by 3 hours of prolonged sitting on executive function and cerebral perfusion.

METHODS: Five young healthy males (Age: 22.8 ± 2.9 yrs; stature 177.7 ± 6.4 cm; mass 78.9 ± 14.3 kg), from a target of 18, were recruited. Following familiarisation, participants completed two randomised sessions of 3 hours of prolonged sitting following the consumption of a high-fat (HF) and low-fat (LF) meal. Each visit was separated by a minimum of 2 and maximum of 7 days. Participants completed a Stroop test (containing both congruent and incongruent trials) and trail-making test (TMT) both pre- and post- sitting period. The TMT consists of two parts, A and B. Continuous wave near-infrared spectroscopy (cw-NIRS) was used to measure cerebral perfusion at AF4 both before (baseline) and throughout each trial. Data was analyzed using two-way repeated measures analysis of variance. Alpha was set at $P < 0.1$ a priori for preliminary analyses.

RESULTS: There were no significant differences between or within trials for completion time for Stroop and TMT part A. Completion time for TMT part B was significantly ($p = 0.078$, $d = 2.2$) faster in the low-fat condition compared to HF condition (16.4 ± 4 s vs. 21.6 ± 0.7 s). There were no significant differences in cerebral perfusion between or within groups ($p = 0.201$).

CONCLUSIONS: These preliminary findings suggest that the consumption of a high-fat meal may negatively impact core executive functions measured by TMT Part B, namely working memory and task-switching ability. However, cerebral perfusion, as measured by cw-NIRS, failed to identify a mechanism. This may be a consequence of limited statistical power given the sample size, or uncertainties regarding the sensitivity of cw-NIRS when measuring cerebral perfusion.

Serial Lower Limb Occlusion and Reperfusion Augments Muscle Oxygen Saturation despite Attenuated Cardiac Hemodynamics
 Afton D. Seeley, Natasha Cruz, Jesse S. Brenman, Kevin A. Jacobs, FACSM. University of Miami, Miami, FL. (Sponsor: Kevin Jacobs, FACSM)
 Email: ads129@miami.edu
 (No relevant relationships reported)

INTRODUCTION: Remote ischemic preconditioning (RIPC) involves brief, serial manually-imposed blood flow restriction of the limbs. The alternating periods of occlusion and reperfusion lead to endothelial adaptations, capable of enhancing blood flow and oxygen delivery. An understanding of the cardiovascular, ventilatory, and local metabolic adjustments to RIPC is essential to optimize the technique as a physiological stimulus. **PURPOSE:** To investigate reactive and sustained changes in cardiac hemodynamics, local muscle oxygen saturation, and ventilation in response to serial RIPC application. **METHODS:** Ten (M:4, F:6) recreationally aerobically trained college students (22 ± 2 y, 170.4 ± 9.8 cm, 73.6 ± 8.7 kg, 19.8 ± 6.4 % BF, VO_{2peak} : 45.5 ± 5.0 mL·kg⁻¹·min⁻¹ at 208 ± 31 W) received 5-min of alternating-leg blood flow occlusion using a blood pressure cuff (220 mmHg) placed on the upper thighs for a total of 40 min in a supine position. Muscle oxygen saturation (SmO₂) was measured continuously using a portable NIRS-based sensor placed over the vastus lateralis. Cardiac hemodynamics were measured continuously using impedance cardiography. Continuous ventilatory changes in response to RIPC were measured in a small subset (n=4) using a metabolic cart. **RESULTS:** Serial occlusion resulted in a more rapid decrease in SmO₂ over time (15.13 ± 2.95 vs. 16.67 ± 2.12 %·min⁻¹), and a lower heart rate (61 ± 9 vs. 58 ± 7 bpm) and cardiac output (5.1 ± 0.8 vs. 4.9 ± 0.7 L·min⁻¹) from occlusion 1 to 4. Serial reperfusion resulted in a greater reactive peak SmO₂ (86.7 ± 2.4 vs. 88.3 ± 2.8 %), and a lower peak heart rate (74 ± 9 vs. 70 ± 10 bpm) and cardiac output (6.6 ± 0.8 vs. 6.2 ± 0.8 L·min⁻¹) from reperfusion 1 to 4. Ventilatory data suggest a decrease in oxygen consumption from the first to last occlusion (-0.046 ± 0.013 L·min⁻¹) and from the first to last reperfusion ($-0.030 \pm$

0.009 L·min⁻¹). **CONCLUSIONS:** Both the occlusion and reperfusion stimuli appear less physiologically stressful when applied serially, despite a heightened peak SmO₂ following reperfusion. The serial reperfusion response indicates vascular modulation and/or lower local metabolic demand, rather than cardiac hemodynamics, may be responsible for enhancement of local muscle oxygen saturation.

Arterial Smooth Muscle Cell PAQR7 Activation Attenuates Myogenic Tone In Pressurized Cerebral Arteries
 Jacob A. Goldsmith, Kirk W. Evanson. Florida State University, Tallahassee, FL. (Sponsor: Heidi Kluess, FACSM)
 (No relevant relationships reported)

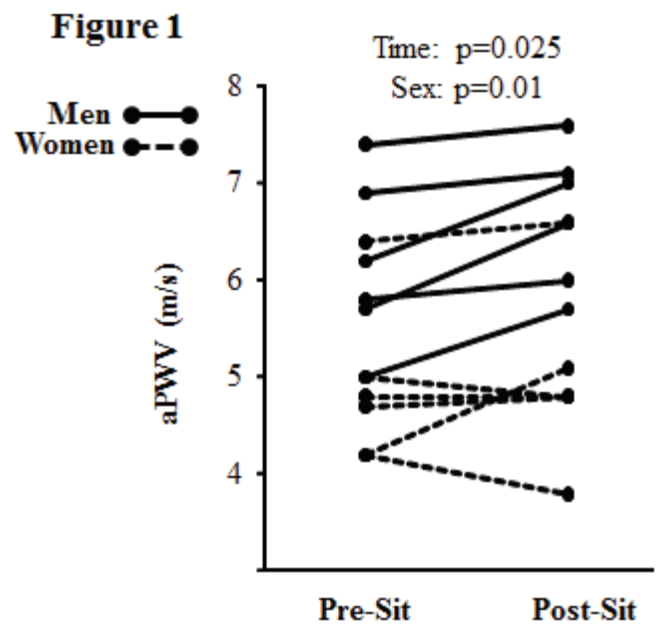

Sex steroid hormones (estrogen, progesterone) are regulators of arterial contractility. Specifically, progesterone exerts rapid, nongenomic vasodilation via membrane receptors termed membrane progesterone receptors (mPR) belonging to the GPCR-like family of Progesterin & Adiponectin Q Receptors (PAQR). Moreover, PAQR7 (mPR α) is reportedly expressed in smooth muscle cells (SMC) of human conduit vessels and has a putative role in vasodilation. However, the expression and function of PAQR7 in pressurized resistance size arteries, arteries that regulate local blood flow and blood pressure, have not been investigated. **PURPOSE:** To examine the expression and physiological function of PAQR7 in cerebral resistance size arteries. **METHODS:** RT-PCR was performed on whole cerebral arteries and isolated arterial SMCs to detect PAQR7 mRNA expression. Western blotting was performed on whole cerebral arteries to examine PAQR7 protein expression. Pressurized artery myography was performed on endothelium-intact and -denuded cerebral arteries to examine the role of SMC PAQR7 in vasodilation using the PAQR7-specific agonist, Org OD 02-0. **RESULTS:** PAQR7 mRNA (whole artery and isolated arterial SMCs) and protein were detected in resistance size cerebral arteries (n=4). Interestingly, there were no significant differences in vasodilation between endothelium-intact and -denuded arteries at any concentration (10^{-9} M to 10^{-6} M, n=4). **CONCLUSION:** These data suggest that arterial smooth muscle PAQR7 activation elicits vasodilation in pressurized resistance size arteries.

Modification of Vascular Function after Acute Handgrip Exercise Training in College Students
 Arturo A. Arce-Esquivel, Ashley N. Tulloch, Joyce E. Ballard, FACSM. The University of Texas at Tyler, Tyler, TX. (Sponsor: Joyce E. Ballard, FACSM)
 Email: aarce@uttyler.edu
 (No relevant relationships reported)

Structural and functional changes in the arterial system following exercise training are well documented. These adaptations are associated with reduced vascular resistance, improved blood delivery and diffusion in the contracting muscles. Training-induced adaptations (i.e., regional vascular improvements) have been reported following one week of exercise training. **PURPOSE:** To examine the influence of an acute unilateral exercise training protocol on microvascular function. **METHODS:** Eleven apparently healthy young college students (age: 22 ± 1.43 years) participated in this study. Microvascular function was assessed (fingertip Digital Thermal Monitoring of vascular reactivity), before and at the end of 5-day training program. Training consisted of a unilateral handgrip training protocol (nondominant arm) at 60% of maximal voluntary handgrip strength, performed for 5 days, 20 min per session, and a cadence of one contraction per 4 sec. **RESULTS:** After training, handgrip strength increased significantly by 14.40 % (pre-training = 36.1 ± 8.7 kg; post-training = 41.3 ± 1.7 kg, $p < 0.05$) in the trained arm. The participants experienced a significant 36% increase in Vascular Reactivity Index (VRI) from baseline (2.60 ± 0.40 to 3.53 ± 0.42 , $p < 0.05$). **CONCLUSIONS:** These data indicate that a localized acute isometric exercise program results in significant improvements in microvascular function among healthy college students. The unilateral improvements in vasoreactivity, once again, confirm the concept of specificity of training.

 (No relevant relationships reported)

Prolonged periods of uninterrupted sitting (i.e., 3 hours) can negatively affect markers of central vascular health, including aortic arterial stiffness. It is unclear whether individual differences, particularly biological sex, can modify the central vascular health response to prolonged periods of sitting. **PURPOSE:** To test the hypothesis that prolonged sitting will increase (worsen) central arterial stiffness, a response that will be greater in men as compared to women. **METHODS:** Twelve relatively healthy participants (i.e., free of diagnosed disease; women=6) completed a 3-hour bout of uninterrupted sitting. Before and after sitting (supine), assessments of heart rate (HR), mean arterial pressure (MAP), and aortic pulse wave velocity (aPWV) were measured via surface electrocardiography, cuff oscillometry, and applanation tonometry, respectively. **RESULTS:** Participants were similar in age (men=25±2 vs. women=25±3 yrs; $p=0.93$) and BMI (men=29±2 vs. women=25±2 kg/m²; $p=0.17$). Prior to sitting, HR and MAP were similar, but men had a higher aPWV ($p=0.021$). Following sitting, there was a significant reduction in HR (-5±2 bpm; $p=0.027$), with no change occurring in MAP ($p=0.916$). In response to sitting, there was a time ($p=0.025$) and sex ($p=0.010$) effect for aPWV; aPWV increased in men (pre-sit=6.2±0.4 vs. post-sit=6.7±0.3; $p=0.011$) but not in women (pre-sit=4.9±0.3 vs. post-sit=5.0±0.4 m/s; $p=0.55$) (Figure 1). **CONCLUSIONS:** These preliminary findings suggest that prolonged periods of uninterrupted sitting augment central arterial stiffness, a response that appears to be apparent in men, but not in women.

The Reliability of Lower-Limb Pulse-Wave Velocity Assessments Using an Oscillometric Technique
 Jake C. Diana¹, Elizabeth Kelsch¹, Katie Burnet¹, Daniel Creuder², Simon Fryer³, Keeron Stone³, Lee Stoner, FACSM¹.
¹University of North Carolina at Chapel Hill, Chapel Hill, NC. ²University of Gloucestershire, Gloucester, United Kingdom. ³University of Southern Mississippi, Hattiesburg, MS. (Sponsor: Lee Stoner, FACSM)
 (No relevant relationships reported)

Sedentary behavior appears to target the athero- and arterio-sclerotic susceptible vasculature of the lower extremities. For example, vascular function in the leg is acutely impaired following periods of prolonged sitting. **PURPOSE:** Studies have

relied on techniques which are challenging to perform, therefore impeding further study. Consequently, there is a pressing need to identify precise (reliable), yet simple, techniques for evaluating lower extremity vascular health. Oscillometric assessment of pulse-wave velocity (PWV) in the leg may be one potential solution. The current study aimed to determine the between-day reliability of femoral-ankle PWV (faPWV) in supine and seated positions using the oscillometric-based SphygmoCor XCEL device. **METHODS:** 15 participants (22.1 y, 80% F; BMI 22.7) were tested on three mornings in a fasted state, separated by a maximum of 7 days. In a balanced, randomized order, faPWV was measured in sitting and supine positions using SphygmoCor XCEL. Carotid-femoral PWV (cfPWV) was also assessed for quality control. **RESULTS:** The intra-class correlation coefficient (ICC) for supine faPWV (ICC = 0.89) was above the 0.75 criterion, but not for seated (ICC = 0.54). The standard error of measurement (SEM) was 0.42 m/s and 0.95 m/s in the supine and seated positions, respectively. Similarly, reliability measures for cfPWV met the criterion in the supine (ICC = 0.75, SEM = 0.42 m/s) but not seated positions (ICC = 0.66, SEM = 0.48 m/s). **CONCLUSIONS:** These findings indicate that, in a healthy cohort, faPWV can be determined in supine position with acceptable precision using SphygmoCor XCEL. The next step is to measure precision in populations of varying age and health states. The use of these devices may provide researchers with a simple and precise way of investigating the impact of sedentary behaviors.

Effects of Acute Capsaicin on the Central and Peripheral Hemodynamic Response to Passive Leg Movement
 Stephen J. Ives¹, Gaia Giuriato², Massimo Venturelli², Meaghan Lynch¹. ¹Skidmore College, Saratoga Springs, NY. ²University of Verona, Verona, Italy.
 Email: sives@skidmore.edu
 (No relevant relationships reported)

Previous work in vitro and animal models suggests, capsaicin, the pungent ingredient in peppers, which acts on transient receptor potential vanilloid type 1 channels improves vascular function, in an endothelium and nitric oxide (NO) dependent manner. Recently, topical capsaicin has also been shown to attenuate the metaboreflex in humans. Thus, whether acute oral capsaicin improves an NO-dependent measure of vascular function, or the mechanoreflex response to PLM, remains elusive. **Purpose:** to determine the effects of capsaicin on the vascular and mechanoreflex responses to continuous PLM. **Methods:** In a single blind crossover design, 13 young healthy men (21±3 yr, 177±7cm, and 73±12kg) underwent continuous PLM at 1 hz for 2 min after taking placebo (800 mg fiber) or capsaicin (780 mg pepper extract, ~2mg Capsaicin). At baseline and during PLM, Near-infrared spectroscopy (NIRS) of v. lateralis continuously measured tissue oxygen saturation (StO₂), total hemoglobin concentration (THb), oxyhemoglobin concentration (HbO), and deoxyhemoglobin concentration (Hb), as estimates of microvascular function. Central hemodynamic responses (stroke volume, SV; heart rate, HR; cardiac output, CO; and mean arterial pressure, MAP) were measured using finger photoplethysmography. **Results:** The individual absolute peak change in StO₂ (4.9 ± 1.2 vs 4.0 ± 0.7%), THb (22 ± 15 vs 11 ± 4 ΔμM), HbO (22 ± 16 vs 10 ± 4 ΔμM), and Hb (-2.5 ± 1.3 vs -1.2 ± 1.1 ΔμM), were all unaffected by capsaicin ($p>0.05$, placebo vs. capsaicin, respectively). Exploring the area under the curve (AUC) in StO₂ (301 ± 128 vs 155 ± 85), THb (1491 ± 1032 vs 758 ± 386 μM), HbO (1549 ± 1102 vs 707 ± 318 μM), and Hb (-59 ± 89 vs 51 ± 129 μM) were not different between placebo and capsaicin (all, $p>0.05$). Peak changes in CO (1.3 ± 0.5 vs 1.1 ± 0.2 ΔL/min), and HR (10 ± 4 vs 8 ± 3 Δbeats/min), tended to be lower, while SV and MAP were not different between conditions ($p>0.05$). Post hoc analysis of potential racial differences, people of color and Caucasian's elicited similar individual absolute peak change in StO₂ (3.0 ± 1 vs 3.4 ± 1%), but tended to have lower AUC (108 ± 68 vs. 251 ± 83, $p=0.09$). **Conclusion:** In the current model, using a modest acute dose in young healthy males, capsaicin does not alter the central or peripheral hemodynamic responses to PLM, but warrants further work with aging or disease.

Arterial Stiffness Is Unaffected By Acute Hyperglycemia And Menstrual Cycle Phase In Premenopausal Women.
 Kaitlyn R. Liu, Jennifer S. Williams, Taylor Stimpson, Joshua C. Tremblay, Alyssa M. Fenuta, Kyra E. Pyke. Queen's University, Kingston, ON, Canada.
 Email: kaitlyn.liu@queensu.ca
 (No relevant relationships reported)

BACKGROUND: Acute hyperglycemia results in transient increases in arterial stiffness in healthy males and postmenopausal women. However, research in premenopausal women is lacking and the impact of menstrual phase (early follicular (EF) and late follicular (LF)) on vulnerability to acute hyperglycemia-induced increases in arterial stiffness is unknown. It is hypothesized that increases in arterial stiffness in the EF phase will be attenuated in the LF phase. **PURPOSE:** To examine

the impact of acute hyperglycemia on arterial stiffness in premenopausal women in the early and late follicular phases of the menstrual cycle. **METHODS:** Seventeen healthy, naturally menstruating women (21±1 years) participated in three experimental visits. During two visits ($EF_{Glucose}$, $LF_{Glucose}$), arterial stiffness was assessed via central and peripheral (arm and leg) pulse wave velocity (PWV) before and 15-, 45-, 75-, and 105-minutes after consuming an oral glucose challenge (75g glucose/300mL solution). Blood samples were taken to assess blood glucose (BG), insulin (BI), estrogen, progesterone and blood viscosity levels. During a third visit in the EF phase, participants ingested 300mL of water to act as a time-control for PWV ($EF_{Control}$). **RESULTS:** BG and BI levels increased 30 minutes post-glucose ingestion ($p < 0.001$), with no difference between visits ($p = 1.00$, $p = 0.577$, respectively). Both central and peripheral PWV measurements were unchanged across visits and time. **CONCLUSION:** These results suggest that acute hyperglycemia and menstrual phase do not impact central and peripheral PWV. Premenopausal women may experience protection from acute hyperglycemia-induced increases in arterial stiffness previously observed in men and postmenopausal women.  (No relevant relationships reported)

Endothelial function is one of the early markers of atherosclerosis and thus consecutively of cardiovascular disease risks. Brachial Artery Flow-Mediated Dilatation (DILA) is an indicator of endothelial function that can be obtained by a non-invasive technique. Physical exercise is a non-pharmacological therapy that has the benefit of homeostasis of endothelial function. **PURPOSE:** To evaluate the effects of resistance training with restriction of blood flow on endothelial function and total occlusion pressure in elderly. **METHODS:** The elderly were invited to participate of the study in the written informed consent term. We selected 37 elderly women who were divided into 3 groups (placebo control (C), 60% restriction of blood flow (R60) and 80% restriction of blood flow (R80)), and were submitted to the DILA protocol, which is a test that verifies the total artery occlusion pressure through an ultrasound and an inflatable cuff, with endothelial control function and the total vascular occlusion pressure, so that the training pressure restriction is determined. All were submitted to a maximum load protocol (1RM), to determine the training load (20% of 1RM) with blood flow with duration of 8 weeks. Comparison of data was done through two-way ANOVA. **RESULTS:** Significant differences were found only in the group that trained with 60% blood flow restriction when compared to all groups in the post-training (C: 0.0213 ± 0.0160 cm vs. R60: 0.0503 ± 0.0180 cm vs. R80: 0.0306 ± 0.0200 cm, $*p \leq 0.05$) and with pre-training of group R60 (0.0190 ± 0.0135 cm vs. 0.0503 ± 0.0180 cm $*p \leq 0.05$). In occlusion pressure, the group which trained with 60% of flow restriction had a difference significant before and after the training R60 (186.67 ± 10.33 mmHg vs. 156.66 ± 16.32 mmHg, $*p \leq 0.05$). **CONCLUSION:** Resistance training with blood flow restriction is able to increase brachial artery dilatation and reduce the pressure of occlusion in elderly women who trained with 60% blood flow restriction.

Effect Of A Two-week Exercise Intervention On Postprandial Extracellular Vesicles In Adults With Prediabetes

Natalie ZM Eichner, Nicole M. Gilbertson, Emily M. Heiston, Luca Musante, Sabrina LaSalvia, Arthur L. Weltman, FACSM, Uta Erdbrügger, Steven K. Malin, FACSM. *University of Virginia, Charlottesville, VA.* (Sponsor: Steven Malin, FACSM)
 Email: nze8bz@virginia.edu
 (No relevant relationships reported)

PURPOSE: Postprandial hyperglycemia is a stronger predictor of cardiovascular disease (CVD) compared to fasting glucose, but the mechanism remains unclear. Extracellular vesicles (EVs) are potential bio-effectors that impact CVD, and exercise is known to modify fasting EVs. However, the effect of exercise on EVs in the postprandial state in relation to CVD risk is unknown. **METHODS:** Twelve older (64.7±2.3 yrs), obese (BMI: 31.1 ± 1.7 kg/m²) and sedentary (19.3 ml/kg/min) adults were screened for prediabetes using ADA criteria (75 g OGTT and/or HbA_{1c}). Subjects

underwent 12 bouts of supervised cycle ergometer training at 70%HR_{peak} for 60 min/d. Annexin V- total EVs, platelet EVs (CD31⁺/CD41⁺), endothelial EVs (CD105, CD31⁺/CD41⁺) and leukocyte EVs (CD45⁺/CD41⁺) were collected at fasting and 2-hr during a 75g OGTT from fresh plasma. EVs were analyzed via imaging flow cytometry pre-/post-intervention. CVD risk factors including BMI, VO_{2peak}, glucose, systolic (SBP), diastolic (DBP), arterial pressure (AP), and arterial stiffness (augmentation index; AIx) were assessed at fasting and 2-hr during the 75g OGTT. **RESULTS:** Exercise tended to decrease BMI ($P=0.06$) and postprandial AIx assessed at 2-hr (trend: $P=0.08$) and tAUC₁₂₀ (trend: $P=0.11$), but had no significant effect on VO_{2peak} ($P=0.19$) or 2-hr glucose ($P=0.26$). All AV- EVs except CD31⁺/CD41⁺ increased post-training (all $P < 0.001$). However, when accounting for changes in fasted EVs following training, only AV-CD105 remained significantly elevated at 2-hr post-training ($P=0.01$). Increases in postprandial total AV- EVs correlated with reductions in postprandial AP ($r=-0.73$, $P=0.03$) and AIx ($r=-0.75$, $P=0.02$) while postprandial AV- CD31⁺/CD41⁺ was related to lowered SBP at 2-hr ($r=-0.71$, $P=0.05$). **CONCLUSION:** Although exercise training may modify the postprandial AV- EV response in adults with prediabetes, this response appears to be driven by alterations in fasted EVs. Future work should consider the physiological and clinical relevance of EVs in the fasted versus postprandial state to elucidate the physiologic underpinnings by which postprandial hyperglycemia confers CVD risk.

Cardiorespiratory And Cerebrovascular Function Of Long-neck Karen Women In Thailand

Pattawan Lapo. *Chulalongkorn University, Bangkok, Thailand.*
 Email: pattawanlapo@hotmail.com
 (No relevant relationships reported)

Karen Kayan women live in the deep forest of northern Thailand. They wear brass coils around their necks all their lives starting from 5-7 years of age. The coils are replaced by a longer one as they grow older. There is only scarce information regarding the physiological and health impact of lifelong wearing of the neck brass coils in these women. **PURPOSE:** To determine the influence of wearing brass neck coils on cardiorespiratory and cerebrovascular function in long-neck Karen tribes. **METHODS:** A total of 28 Karen women (23 – 66 years) living in Mae Hong Son Province (at high altitude) in the northern Thailand were studied. Fourteen Karen women who had been wearing neck brass coils were compared with 14 Karen women who had not been wearing brass neck coils. We also studied 14 age-matched women living at sea level. **RESULTS:** There were no significant group differences in body fat percentage, resting heart rate, and brachial-ankle pulse wave velocity (measure of arterial stiffness). Both systolic and diastolic blood pressure was greater and maximal oxygen consumption was lower in both Karen women than in the sea level controls (all $p < 0.05$). Karen women wearing neck coils demonstrated lower flow-mediated dilation (index of endothelium-dependent vasodilation), lung functions, including forced vital capacity and forced expiratory volume during the first second, and cerebral blood flow velocity than Karen women without neck brass (all $p < 0.05$). **CONCLUSIONS:** Karen women wearing neck brass coils demonstrate reduced endothelial and lung functions as well as cerebral perfusion compared with age-matched Karen women without coils living in the same villages. Karen women wearing brass neck coils may be at elevated risks of developing cardiopulmonary and cerebrovascular diseases. Supported by the 90th Anniversary of Chulalongkorn University, The Ratchadaphisek Somphot Fund and Faculty of Sports Science's Scholarship for Research 2018.

 Email: power3g@cmich.edu
 (No relevant relationships reported)

Insulin resistance contributes to endothelial dysfunction establishing a causal link between type 2 diabetes and cardiovascular disease. An acute bout of exercise has been shown to enhance insulin sensitivity and endothelium function potentially contributing to a commonly observed reduction in blood pressure post-exercise. However, the underlying molecular mechanism(s) for these improvements in smooth muscle remains unclear. **PURPOSE:** To examine blood pressure response and key signaling proteins involved in insulin sensitivity and endothelial function following an acute session of exercise in aged rodents. **METHODS:** Based on body mass, aged (~12 months) female Sprague-Dawley rats (n=50) were assigned to one of four groups: 1) sedentary control group without insulin injection (CON-ins), 2) control group with insulin injection (10mU/g; CON+ins), 3) exercise group without insulin injection (EX-ins), and 4) exercise group with insulin injection (EX+INS). Insulin or saline injections were administered 5-min prior to sacrifice. Under isoflurane anesthesia, blood pressure was assessed and the descending aorta was harvested. Exercise cohorts

were sacrificed 3-hr after a 60-min swimming protocol. Western immunoblotting was used to determine phosphorylated Akt (p-Akt^{Ser473}), phosphorylated AMPK (p-AMPK^{Thr172}), and phosphorylated eNOS (p-eNOS^{Ser1177}). **RESULTS:** Blood pressure was significantly lower following exercise compared to sedentary conditions (EX-ins and EX+ins vs. CON-ins and CON+ins, $p < 0.05$). p-Akt^{Ser473} was significantly ($p < 0.05$) higher under insulin stimulated compared to non-insulin stimulated conditions, and this effect was also attenuated with exercise (CON+ins > EX+ins; $p < 0.05$). Although not statistically significant, there was a trend for a difference between groups in p-eNOS^{Ser1177} (CON+ins: 1.29, CON-ins: 0.80, EX+ins: 1.31, EX-ins: 0.65, $p = 0.11$). No significant differences were observed in p-AMPK. **CONCLUSION:** The post-exercise improvement in blood pressure is at least partially mediated by enhanced insulin sensitivity via Akt signaling and potentially p-eNOS signaling in smooth muscle.

Sex Differences In Sitting-induced Vascular Dysfunction: Evidence Of Augmented Antioxidant Defense.

Kevin Decker, Patrick Feliciano, Morgan Kimmel, Austin Hogwood, Jennifer Weggen, Ashley Darling, Austin Michael, Ryan Garten. *Virginia Commonwealth University, Richmond, VA.*
 Email: deckerkp@vcu.edu
 (No relevant relationships reported)

PURPOSE: This study sought to examine the role of oxidative stress in sitting-induced vascular dysfunction across genders. **METHODS:** On two separate occasions, ten males (25±5 yrs) and eleven females (23±3 yrs) had leg vascular function assessed using passive leg movement (PLM) technique before and after 1.5 hours of sitting. Superficial femoral artery (SFA) blood flow and shear rate patterns, heart rate, mean arterial pressure (MAP), and calf circumference (CC) were measured throughout sitting. One gram of vitamin C (VC) or placebo (PL) was consumed 1.5 hours prior to each sitting trial. **RESULTS:** All subjects ($n = 21$), regardless of condition (PL or VC), reported significantly decreased SFA blood flow (-28.6 ± 41.8 ml/min; $p < 0.01$) and shear rate (-11.3 ± 15.5 s⁻¹; $p < 0.01$) as well as a significant increase in MAP (3.6 ± 5.1 mmHg; $p < 0.01$) and CC (1.2 ± 0.3 cm; $p < 0.01$) after 1.5 hours of sitting. In the PL trial, a significant decline in leg vascular function, evaluated as ΔPLM_{PEAK} , was evident in males, but not females [-210 ± 51 Aml/min] v. [-43 ± 46 Aml/min]; $p = 0.02$] after 1.5 hours of sitting. In the VC trial, both groups revealed no significant declines in ΔPLM_{PEAK} [-17 ± 51 Aml/min] v. [-81 ± 46 Aml/min]; $p = 0.33$]. **CONCLUSION:** This study revealed that females, but not males, display a resistance to sitting-induced lower limb vascular dysfunction. The vascular dysfunction was significantly attenuated with antioxidant supplementation in males, but not females, which implies a greater inherent antioxidant defense and vascular protection in the lower limb vasculature of females.

The Relationship Between Body Mass Index and Aortic Stiffness in Females Across the Lifespan

Allison P. Keller¹, Wesley K. Lefferts², Jaqueline A. Augustine³, Jacob P. DeBlois¹, Qiu Wang¹, Kevin S. Heffernan¹. ¹Syracuse University, Syracuse, NY. ²University of Illinois at Chicago, Chicago, IL. ³The State University of New York at Cortland, Cortland, NY. (Sponsor: Bo Fernhall, FACS M)
 (No relevant relationships reported)

Obesity, classified by a body mass index (BMI) >30 kg/m², continues to be a health concern for women in the United States across all ages. Obesity is a traditional risk factor for the development of cardiovascular disease (CVD). One novel non-traditional predictor of future CVD risk is aortic stiffness. Obese individuals have increased aortic stiffness compared to those of normal body size. **PURPOSE:** Determine the relationship between BMI and aortic stiffness in 476 women between the ages of 9-83 years old. **METHODS:** Girls ($n = 123$, age 9-12 years (yrs), BMI 21 ± 5 g/m²), young women ($n = 138$, age 18-39 yrs, BMI 24.89 ± 4.46 kg/m²), middle age women ($n = 137$, age 40-59 yrs, BMI 26.73 ± 4.22 kg/m²) and older women ($n = 78$, age 60-83 yrs, BMI 26.34 ± 4.26 kg/m²) participated in the study. BMI was calculated as weight (kg) / height (m)². Aortic stiffness was measured as carotid-femoral pulse wave velocity (PWV) using applanation tonometry (SphygmoCor; Sydney, Australia). **RESULTS:** According to results from linear regression, BMI was a significant predictor of PWV for the female children ($\beta = 0.387$, $p < 0.01$, 95% CI 0.03 – 0.076), young women ($\beta = 0.635$, $p < 0.01$, 95% CI 0.156 – 0.237) and middle age women ($\beta = 0.508$, $p < 0.01$, 95% CI 0.113 – 0.210). BMI was not a significant predictor of PWV in the older women ($\beta = 0.107$, $p = 0.20$, 95% CI -0.073 – 0.178). When exploring age-group by BMI interaction terms, significant group differences were detected in the relation between BMI and PWV. Using the young women as a reference group – there was no significant difference between the slopes of the regression lines for BMI and PWV between the young and middle age women ($\beta = -0.03$, $p = 0.36$, 95% CI -0.11 – 0.04). There were significant differences between the slopes of the regression lines between the young women and girls ($\beta = -0.14$, $p < 0.01$, 95% CI -0.21 – -0.08) and between the young

women and older women ($\beta = -0.14$, $p < 0.01$, 95% CI -0.23 – -0.06). **CONCLUSION:** Our data suggest that the relationship between BMI and aortic stiffness changes with advancing age. BMI is a significant predictor of aortic stiffness in females between the ages of 9-59 yrs, but not in elderly females (>60 yrs). In older females changes in body composition (i.e. increases in body fat and decrease in muscle mass) may change the relationship between BMI and aortic stiffness.

Differing Impact of Weight Cycling on Ambulatory Blood Pressure Versus Conventional Blood Pressure Assessment: A Possible Explanation to Controversy
 Zachary Zeigler, Danielle Akin, Trevor Nordin. *Grand Canyon University, Mesa, AZ.*
 Email: zachary.zeigler@gcu.edu
 (No relevant relationships reported)

BACKGROUND: Weight Cycling (WC) is a widespread behavior associated with deleterious cardiovascular (CV) health, including elevated blood pressure (BP). Yet, a 2010 review analyzing the effects of WC on BP concluded there was not enough quality evidence to draw any sort of decisive conclusions. Ambulatory BP (ABP) monitoring is recognized as a superior method of measurement and predictor of the CV state when compared to traditional laboratory BP assessment. The impact that WC may have on ABP per se is unknown. **METHODS:** Impact of self-reported WC history on ABP was assessed via a causal comparative non-experimental design. Sixty-five women completed the Weight and Lifestyle Inventory questionnaire (WALI). The WALI has been shown to be a reliable index of WC ($r = .87$, $P < 0.001$). Subjects were classified as weight cyclers (WC) if they reported a weight loss of ≥ 4.5 kg at least 3 times followed by weight regain. Those who reported less than this were classified as non-weight cyclers (NWC). Main outcome was mean differences between groups on laboratory BP and ABP. **RESULTS:** WC ($n = 31$) were older (39.7 ± 8.9 vs 33.1 ± 11.3 yr), had a higher percent body fat (47.1 ± 6.2 vs 41.4 ± 7.8 (%)), and were less fit (21.2 ± 5.4 vs 26.7 ± 7.6 ml.kg⁻¹.min⁻¹) than NWC ($n = 34$). No significant differences were found for laboratory BP values. WC women had higher systolic (130.1 ± 13.6 vs 122.0 ± 8.2 mmHg, $P = 0.006$) and diastolic (76.2 ± 8.9 vs 70.0 ± 9.0 mmHg, $P = 0.011$) ABP values than NWC women. Systolic (23% versus 17%, $P < 0.001$) and diastolic (13% versus 9%, $P < 0.001$) BP load was higher for WC compared to NWC women. **CONCLUSION:** WC may deleteriously impact BP outcomes that might only be witnessed when ABP monitoring is used.

 (No relevant relationships reported)

Individuals with Down syndrome (DS) exhibit autonomic dysfunction, which causes significant reductions in aerobic capacity (VO_{2peak}). Autonomic dysfunction alters central regulation of the cardiovascular system in DS, demonstrated by reduced peak heart rate and cardiac contractility. Vascular function, especially arterial stiffness, is inversely related to aerobic capacity and is a well-known cardiovascular disease risk factor. However, there is very limited information regarding vascular function in response to moderate intensity exercise in individuals with DS. **Purpose:** To investigate the hemodynamic and vascular response to moderate intensity exercise in individuals with and without DS (control). **Methods:** Thirty-eight volunteers (DS=19, age=24 yr for each group) participated in this study. Central hemodynamic variables (aorSBP, aorDBP, aorPP, AIx@75) and pulse wave velocity (PWV) were measured with an ambulatory blood pressure monitor. Carotid ultrasonography was used to obtain arterial stiffness indices β -stiffness and elastic modulus (Ep). All measures were performed at baseline and immediately- and 30-min post moderate intensity treadmill exercise. **Results:** Individuals with DS had significantly lower VO_{2peak} (DS: 28.3 ml/kg/min; Control: 40.8 ml/kg/min). There were no group differences in the hemodynamic response (aorSBP, aorDBP, aorPP) to exercise between DS and controls ($p > 0.05$ for all). Furthermore, no group differences were observed in arterial stiffness variables, AIx@75, β -stiffness, PWV and Ep, in response to exercise ($p > 0.05$ for all). **Conclusions:** Our results suggest that individuals with DS do not exhibit different arterial stiffness and altered hemodynamic responses to moderate intensity exercise when compared individuals without DS.

The Influence of Habitual Physical Activity on Arterial Baroreflex Sensitivity in Healthy Young Adults

Joseph C. Watso, Austin T. Robinson, Matthew C. Babcock, Kamila U. Migdal, William B. Farquhar, FACSM. *University of Delaware, Newark, DE.* (Sponsor: William Farquhar, FACSM)
 Email: jwatso@udel.edu
 (No relevant relationships reported)

The arterial baroreflex is an essential component of beat-to-beat blood pressure (BP) regulation, and impaired baroreflex function is associated with cardiovascular disease states. Exercise training in at-risk populations improves (increases) sympathetic baroreflex sensitivity (sBRS) and cardiac vagal baroreflex sensitivity (cBRS). While high habitual physical activity (PA) has cardioprotective benefits, it is unknown if high habitual PA is associated with improved arterial baroreflex function in healthy young adults. **PURPOSE:** We tested the hypothesis that high habitual PA is associated with greater sBRS and cBRS. **METHODS:** Seventeen non-obese adults (sex: 7F/10M, age: 24±3 years, BP: 110±12/60±8 mmHg) underwent muscle sympathetic nerve activity (MSNA; microneurography, n=12), beat-to-beat BP (finger photoplethysmography), and heart rate (single-lead ECG) measurements throughout ten minutes of quiet supine rest. The sequence method was used to estimate spontaneous cBRS using beat-to-beat time series of systolic BP and R-R interval (HemoLab v8.9). Briefly, baroreflex sequences were identified when systolic BP and R-R interval changed in the same direction in four or more consecutive cardiac cycles. Overall cBRS was determined by combining up and down sequences (increase/decrease in both systolic BP and R-R interval, respectively). Spontaneous sBRS was estimated using beat-to-beat time series diastolic BP (3mmHg bins) and MSNA burst area. Step count and moderate-to-vigorous PA (MVPA) were assessed via accelerometry (ActiGraph vGT3X) over seven consecutive days. **RESULTS:** Among participants, mean step count was 8766±3778 steps/day (4884-18520 steps/day) and mean MVPA was 79±31 min/day (45-140 min/day). Overall cBRS was 30±14 ms/mmHg (up: 30±20 ms/mmHg; down: 37±24 ms/mmHg) and spontaneous sBRS was -1.3±0.6 AU MSNA/beat/mmHg diastolic BP (mean±SD for all). Higher step count ($r=-0.62, p=0.03$) and MVPA ($r=-0.68, p=0.02$) were associated with greater spontaneous sBRS. Higher step count ($r=0.43, p=0.12$) and MVPA ($r=0.41, p=0.14$) were not significantly associated with greater overall cBRS. **CONCLUSIONS:** These preliminary findings suggest that high habitual PA is associated with greater sympathetic, but not cardiac vagal, baroreflex sensitivity in healthy young adults.

PURPOSE: The aim of this cross-sectional study was to determine if bone-loading physical activity was positively related to arterial stiffness and body composition in healthy college-aged students. **METHODS:** Healthy college-aged women (n=56, 20.3±1.3 years) and men (n=47, 21.0±1.2 years) between the ages of 18 and 25 years were recruited from the University of Massachusetts Lowell. The total bone-specific physical activity questionnaire (tBPAQ, average of past and current BPAQ) was used to obtain a comprehensive account of lifetime bone-loading physical activity. We

measured the carotid to femoral pulse wave velocity (cf-PWV) to evaluate arterial stiffness using a novel oscillometric device (SphygmoCor XCEL). Dual energy X-ray absorptiometry was used to measure lean mass (kg) and percent body fat (%BF) for this study. **RESULTS:** Pearson's correlation tests showed a significant inverse relationship between tBPAQ and cf-PWV ($r=-0.338, p=0.011$) in college-aged women; however, this relationship was not found in college-aged men ($p>0.05$). There were significant negative correlations between tBPAQ and %BF in both college-aged women ($r=-0.265, p=0.048$) and men ($r=-0.306, p=0.036$). No significant relationships were found between tBPAQ and lean mass in both groups ($p>0.05$). **CONCLUSION:** We found that bone-loading physical activity was negatively associated with arterial stiffness measured by the cf-PWV in college-aged women, but not in men. The %BF was inversely related to tBPAQ scores in both college-aged women and men. Thus, high impact bone-loading physical activity could be recommended to improve arterial stiffness and reduce %BF in young college-aged students.

Characterization Of Exercise Blood Pressure Responses In Adolescents With A Chronic Inflammatory Condition

Katharine D. Currie¹, Joyce Obeid², Maureen J. MacDonald², Brian W. Timmons². ¹Michigan State University, East Lansing, MI. ²McMaster University, Hamilton, ON, Canada.
 Email: currie4@msu.edu
 (No relevant relationships reported)

Exaggerated blood pressure (BP) responses to exercise are prognostic of cardiovascular disease (CVD) in adults. There are no criteria to define exaggerated BP responses in children, yet higher exercise BPs have been shown to be associated with CVD risk factors. Therefore, exercise BPs may provide important prognostic information in children, especially those at higher risk for CVD. **PURPOSE:** The study sought to characterize the exercise BP responses in an "at-risk" sample of adolescents with a chronic inflammatory condition. **METHODS:** Twenty-one adolescents (7 males; 14.7 ± 1.8 years) with a confirmed single diagnosis of chronic kidney disease, cystic fibrosis, inflammatory bowel disease, juvenile idiopathic arthritis or type 1 diabetes mellitus participated in this study. Brachial BP was assessed using a motion-tolerant automated auscultatory device every 2 minutes during the McMaster All-Out Progressive Continuous cycling test, using pediatric-specific criteria for test termination at "maximal" effort. Maximal BPs were compared to (1) sex-specific reference values for healthy adolescents, and (2) exaggerated BP criteria for adults. **RESULTS:** Maximal systolic BPs for males and females were 184 ± 35 and 172 ± 19 mmHg, respectively. Maximal diastolic BPs for males and females were 71 ± 11 and 74 ± 9 mmHg, respectively. Two males (29%) had a maximal BP above reference values with one having a higher systolic BP and the other having a higher diastolic BP. Nine females (64%) had a maximal BP above reference values with five exceeding the systolic BP reference, one exceeding the diastolic BP reference, and three exceeding both BP references. An exaggerated BP response occurred in two males and two females. **CONCLUSION:** Approximately half of our sample of adolescents with a chronic inflammatory condition reached higher exercise BPs compared to healthy adolescent reference values. Elevated exercise BPs were also more common in females compared to males, and 19% of our sample met the adult-criteria for exaggerated BP responses. Collectively our observations of elevated exercise BPs in an "at-risk" population highlight the importance of examining BP responses in children, including research on its potential prognostic value.

A Comparison of Whole Blood Viscosity and Hematocrit Levels between Yoga Practitioners and Sedentary Adults

James Shadiow. *Texas State University, San Marcos, TX.*
 Email: jamesshadiow@gmail.com
 (No relevant relationships reported)

Alterations in rheological measures such as elevations in whole blood viscosity (WBV) and hematocrit (Hct), have been linked with increased risk of cardiovascular disease (CVD). Endurance training has been demonstrated to lower WBV and Hct; however, evidence supporting the efficacy of yoga in modulating WBC and Hct is sparse. **PURPOSE:** The purpose of this trial was to determine the effect of a regular yoga practice on WBV and Hct. **METHODS:** A cross-sectional study was conducted examining WBV at multiple shear rates and Hct levels among yoga practitioners with a minimum of 3 months of consistent practice and sedentary, healthy adults. Fasting blood samples were collected from an antecubital vein from a total of 42 participants: 23 sedentary adults and 19 regular yoga practitioners. Brachial arterial blood pressure (BP) was measured and the averages of 3 measures were reported. **RESULTS:** Yoga practitioners had significantly lower WBV at 45 s⁻¹ ($p < 0.01$), 90 s⁻¹ ($p < 0.01$), 220 s⁻¹ ($p < 0.05$), and 450 s⁻¹ ($p < 0.01$) than sedentary participants. No significant group differences in Hct ($p = 0.38$) were found. A tendency toward lower systolic BP ($p=0.06$)

was observed in the yoga practitioner group; however, no significant group differences in BP were exhibited. **CONCLUSION:** Although a consistent yoga practice was associated with lower WBV, a health indicator related to CVD risk, yoga was not associated with changes in Hct, a major determinant of WBV.

E-35 Free Communication/Poster - Bone and Bone Mineral Density

Friday, May 31, 2019, 7:30 AM - 12:30 PM
Room: CC-Hall WA2

2471 Board #135 May 31 11:00 AM - 12:30 PM Bone Health in Elite Norwegian Endurance Cyclists and Runners: A Cross-Sectional Study

Oddbjørn Klomsten Andersen¹, Benjamin Clarsen², Ina Garthe², Morten Mørland², Trine Stensrud¹. ¹Norwegian School of Sport Sciences, Oslo, Norway. ²Norwegian Olympic Training Centre, Oslo, Norway.

Email: o.k.andersen@nih.no

(No relevant relationships reported)

Athletes who compete in non-weight-bearing activities such as swimming and cycling are at risk of developing low bone mineral density (BMD). Athletes in long distance running are at risk of low BMD.

PURPOSE: 1. To evaluate the bone health in Norwegian male and female national-elite road cyclists and middle- and long distance runners, and to identify cases of low BMD, classified as having a Z-score ≤ -1 , according to ACSM criteria. 2. To identify possible risk factors associated with low BMD.

METHODS: Twenty-one runners, 11 females and 10 males, and 19 road cyclists, 7 females and 12 males were enrolled in this cross-sectional study. DXA measurement of BMD in total body, femoral neck and lumbar spine was measured. Participants completed a questionnaire regarding training, injuries, calcium intake and health variables.

RESULTS: The cyclists had lower BMD for all measured sites compared to the runners ($p \leq 0.05$). Ten of 19 cyclists were classified as having low BMD, despite reporting to train heavy resistance training on the lower extremities. One male cyclist had a Z-score ≤ -2 . Low BMD was site-specific, having occurred in the lumbar spine and the femoral neck, and was not confined to females. Type of sport was the only factor significantly associated with low BMD.

CONCLUSIONS: National elite Norwegian road cyclists had lower BMD compared to runners, and a large proportion were classified as having low BMD, despite having performed heavy resistance training. Interventions to increase BMD in this population should be considered.

2472 Board #136 May 31 11:00 AM - 12:30 PM Relationship of Bone Mineral Density and Body Composition in Student Athletes and College Aged Students

(No relevant relationships reported)

Introduction: Bone health and body composition (BC) provide insights into the risk factors for fracture and other bone related disease. Peak bone development is thought to be achieved in the young adult years of an individual's life and can be indicative of the risk of osteoporosis later in life. Regular physical activity can be a major factor in healthy bone development. **Purpose:** To elucidate the relationship between bone mineral density (BMD) and BC measurements between a college aged non-student athlete (NA) population and a student-athlete (ATH) population. **Methods:** Bone mineral density (BMD) and BC measurements from NA population ($n = 61$) and from ATH population ($n = 39$) were collected using the Dual Energy X-ray Absorptiometry (DEXA). Furthermore, sex specific differences between and within the subgroups were evaluated. The variables compared between groups for the two-sample t-tests included BMD, weight (WT), fat mass (FM), lean mass (LM), and bone mineral content (BMC). Statistical analysis was performed using Minitab 18 software. **Results:** No statistical difference was found for BMD, WT, LM, and BMC between subgroups. However, sex-specific differences were present for all variables of interest (BMD Females: 1.170 ± 0.07 g/cm² vs Males: 1.277 ± 0.105 g/cm²; WT Females: 132.0 ± 20.3 lbs vs Males: 169.1 ± 25.7 lbs; FM Females: 36.1 ± 13.5 lbs vs Males: 27.0 ± 16.0 lbs;

LM Females: 90.3 ± 13.1 lbs vs Males: 135.0 ± 18.0 lbs; BMC Females: 5.61 ± 0.87 lbs vs Males: 7.3 ± 1.07 lbs). Pearson's correlation coefficient results indicate that there was a moderate to strong relationship between BMD and lean mass for all groups.

Conclusions: Activity may play a role in the relationship between BMD and BC. The results of this study can help direct future studies on bone health and BC. Data from this study could be utilized in the formation of a predictive model for the development and interactions of osteoporosis and obesity. Such a model would help in the identification of risk factors early in life so appropriate intervention can be put in place. Quantitative bone health and BC data can help coaches and medical professionals prescribe appropriate training and medical interventions if necessary for subjects who are at risk for developing bone or metabolic diseases. Small sample size and lack of activity data were limitations of this current study.

2473 Board #137 May 31 11:00 AM - 12:30 PM Regional Lumbar Bone Mineral Density Differs In Cricket Fast Bowlers With Lumbar Bone Stress Injury

Peter Alway¹, Nicholas Peirce², Robert Kerslake³, Mark King¹, Katherine Brooke-Wavell¹. ¹Loughborough University, Loughborough, United Kingdom. ²England and Wales Cricket Board, Loughborough, United Kingdom. ³Nottingham University Hospitals Trust, Nottingham, United Kingdom.

Email: P.Alway@lboro.ac.uk

(No relevant relationships reported)

Lumbar bone stress injuries (LBS) are among the most serious sustained by fast bowlers in cricket, with symptoms often indistinguishable from low back pain.

They most often occur in the non-dominant lumbar spine in response to the unique lumbar loading characteristics of fast bowling. It is not known whether lumbar spine bone mass differs according to current or previous LBS. **PURPOSE:** To determine differences in lumbar bone mineral density (BMD) between current LBS, previous LBS and never LBS fast bowling groups. **METHODS:** 58 fast bowlers (mean \pm SD: age: 21.23 ± 4.21 years; height: 1.88 ± 0.06 m; body mass: 84.13 ± 9.14 kg) declared as fit to bowl received a lumbar MRI scan (3.0T Discovery MR750w, GE Healthcare, Milwaukee, WI), an AP lumbar DXA scan (Lunar iDXA, GE Healthcare, USA), and had their medical history and MRI scans reviewed for historical incidence of LBS. MRI scans were analysed to determine current LBS. DXA scans were analysed to measure specific bone accrual of dominant (ipsilateral to bowling arm) and non-dominant sides of the lumbar spine. Rectangular custom regions of interest (Lunar enCORE v 17.0) were added to the lateral 33% of each lumbar vertebral body, to exclude the spinous process, and BMD of these regions were calculated. One-way ANOVA determined if groups differed in age, height, body mass, and whole vertebra BMD. Two-way mixed repeated measures ANOVA determined within and between group differences between sides. **RESULTS:** MRI and medical history demonstrated 19 current, 23 never and 16 previous LBS fast bowlers. Age was significantly greater ($p < 0.05$) in previous LBS (23.71 ± 4.80) compared with current (19.52 ± 2.22) and never LBS (20.90 ± 4.36). No significant differences were found between groups for height, body mass or whole vertebra BMD ($p > 0.05$). BMD was higher at the non-dominant than dominant side of the vertebrae (1.63 vs. 1.50 g/cm², $p < 0.001$) and this differed between vertebra ($3.0 - 30.8\%$, $p < 0.001$) and groups ($p = 0.03$). BMD on the dominant side was higher in current (+4.4%) and previous (+3.7%) than never LBS. BMD on the non-dominant side was lower in current (-2.3%) and previous (-0.8%) than never LBS. **CONCLUSION:** Bone mineral accrual differs between current, never and previous LBS groups possibly due to differences in bowling technique, workload and maturation, and may identify those at risk of LBS.

2474 Board #138 May 31 11:00 AM - 12:30 PM Biometric, Dietary And Training Influences On Bone Mineral Content In Competitive Triathletes

Email: bmclclhn@memphis.edu

(No relevant relationships reported)

PURPOSE: Physical activity is important for optimal bone development, however, biometric, training, and dietary practices may compromise bone health. The purpose of this study was to explore potential influences on bone mineral content (BMC) in competitive triathletes.

METHODS: Participants were 12 male and 13 female triathletes. Standard protocols were used to determine BMC (DXA), weight (digital scale), training volume (self-reported exercise duration X intensity) caloric intake (7 day dietary recall) and calcium intake (7-day dietary recall).

RESULTS: Participants were 25 adult triathletes. Males ($n=12$) had an average weight of 169 lbs (± 18.9), BMC of 2,737g (± 507.4), training volume of 44,948 ($\pm 18,433$), total lean mass of 62,686 g (± 6083.6), kcals of 2,776 (± 774.1), and calcium intake of 991.5 (± 577.2). Females ($n=13$) had an average weight of 127.8 lbs (± 17.3),

BMC of 2,092 (\pm 239.8), training volume of 30,934 (\pm 11,377.8), total lean mass of 42,727 (\pm 3958.8), average kcals of 1,987.4 (\pm 386.0), and calcium intake of 755.0 (\pm 365.9). Results of bivariate correlations for males indicated significant positive associations among BMC and weight ($r = 0.85, p < .001$), and total lean mass ($r = 0.72, p < .001$). There were no significant correlations among BMC and calories, calcium or training volume. Preliminary analyses using multiple linear regression indicated that weight, caloric intake, calcium, total lean mass, and training volume did not significantly explain potential influences on BMC for males. For females results of the bivariate correlations found significant positive associations among BMC and weight ($r = 0.74, p < .01$), and total lean mass ($r = 0.49, p < .05$). There were no significant correlations among BMC and calories, calcium or training volume. Preliminary analyses using multiple linear regression indicated that weight, caloric intake, calcium, total lean mass, and training volume explained 74.4% of the variance in BMC for females ($p < .05$). Weight ($\beta = 0.97$) was the only significant predictor at the univariate level.

CONCLUSION: Given the critical role that optimal bone development plays in overall health, it is important to consider potential influences on BMC, particularly in long endurance athletes. Further studies with more participants are needed to better understand the current findings.

Several studies have been reported, the positive effects of basketball playing on the bone system. (Rodrigues 2017; Agostinete 2016; Tarmo 2016).

PURPOSE: We described - in a cross-sectional study - the physical development and bone status of 172 basketball players. Our hypothesis is the growth of the bone mass - in the examined age period - does not necessarily parallel with the developmental pattern of the bone structure.

METHODS: The sample divided into age groups: U12 (10.9 \pm 0.3 years), U14 (12.1 \pm 0.6 years), U16 (14.1 \pm 0.7 years), U18 (16.1 \pm 0.7 years), U19 (17.4 \pm 0.4 years). The biological maturity defined by estimating the bone age and morphological age. The bone age estimated with Sunlight Bone Age ultrasound scanner and the morphological age estimated on specific anthropometric measure, Mészáros-Mohácsi method (Mészáros 1983). Bone structure measured by GE Lunar Prodigy DEXA scanner with Medimaps TBS inSight software. Statistical analysis completed with IBM SPSS Statistics 21 software. The measurements carried out between March 2017 and September 2018.

RESULTS: The bone mass (BMC) increase significantly ($p < 0.05$) correlated ($r = 0.92$) with the changes of the longitudinal parameters of the players. The change pattern is similar to the change of the body weight. Most of the bone density (BMD) value found in the normal range. The mean values of the age groups showed the BMD developmental pattern is different from the change of the BMC. We observed the mean values of the bone structure between the U12 and U14 age groups were located at the lower edge of the normal range. Surprisingly, increase of the BMC followed by the change of the bone structure at U14 and later age groups (during the late phase of puberty). The BMD values stagnate at age U16 and U18. Mean values of the BMD were the upper part of the normal range after the age of U18, it also means the structure of the bone reached the status of the adults.

CONCLUSIONS: Our results confirm our hypothesis about the structural change in the growing bone mass is non-linear. After the intensive growing period there is a delay in bone density development. We observed increased number of the bone fracture during the examination period, it could be explained by the above finding.

2476 Board #140 May 31 11:00 AM - 12:30 PM
Sedentary Time Predicts 2-Year Longitudinal Bone Strength in Hispanic Girls

Victoria L. Bland, Vinson Lee, Jennifer W. Bea, Robert M. Blew, Scott B. Going, University of Arizona, Tucson, AZ.

(No relevant relationships reported)

Physical activity during adolescence is important for optimizing bone strength during this rapid period of bone mineral accrual. However, most adolescent females do not meet the physical activity guidelines of 60 min moderate to vigorous physical activity (MVPA) per day and sedentary time has been associated with decreased bone mineral density (BMD) and bone strength. The effect of sedentary time on longitudinal bone strength has not been established in adolescent Hispanic females.

PURPOSE: To determine if baseline sedentary time predicts 2-year longitudinal tibia and femur bone strength in Hispanic girls. **METHODS:** A cohort of primarily Hispanic adolescent females ($n = 112$), age 9-12 years, wore tri-axial accelerometers

for seven consecutive days at baseline. Evenson cut points were used to classify sedentary activity. Femoral and tibial bone strength strain index (SSI) was assessed using peripheral quantitative computed tomography (pQCT) at 2-year follow up. We used linear regression analysis to test associations between sedentary time and SSI after controlling for relevant variables (baseline SSI, lean soft tissue mass, height, maturity offset, and ethnicity). **RESULTS:** Average daily sedentary time was 865 \pm 84 minutes. Sedentary time was negatively associated with femur and tibia SSI, although the association was only significant for tibia SSI ($p = 0.029$). **CONCLUSION:** Higher levels of baseline sedentary time are associated with lower longitudinal (2-year follow-up) SSI in the tibia and femur. Interventions to decrease sedentary time in adolescent females may improve bone outcomes.

Sponsored by: NIH Grant 5R01HD074565-05

Lower Limb Peak Power and Cortical and Trabecular Bone Strength in the General Population

Vanessa R. Yingling, FACSM, Kirstie Huynh, Karen Serrano Vides, Kimberly D. Espartero, Andrew Denys, Rebekkah J. Reichert, Maria G. Alvarez, Priscilla Franson, Arianna M. Mazarini, California State University, East Bay, Hayward, CA.

Email: vanessa.yingling@csueastbay.edu

(No relevant relationships reported)

Physical activity is beneficial to both the skeletal and muscular systems. The connection between muscular forces and bone strength is explained by the Mechanostat Theory (bone responds to forces applied to them). Therefore, muscle function tests may provide a non-invasive measure of bone strength. Recent studies report significant correlations between lower limb muscle power and bone strength (Janz, 2015, Yingling, 2017).

PURPOSE: To assess the relationship between lower limb power and bone strength in the cortical and trabecular bone of the radius and tibia in a healthy (non-athletic) population.

METHODS: 40 females (age (yrs) 31.6 + 12.5, height (cm) 160.7 + 6) and 37 males (age (yrs) 26.8 + 7.7, height (cm) 172.8 + 7.7) performed a vertical jump test. Peak Power (PP) was calculated from vertical jump height (Sayers, 1999). Peripheral Quantitative Computed Tomography (pQCT) was used to quantify bone strength at the radius and tibia for both cortical and trabecular sites. Cortical site measures included Moment of Inertia (J), Cortical Area (Ct.Ar), cortical Bone Mineral Density (cBMD), Strength-Strain Index (SSI). Bone Strength Index (BSIc), Total Area (T.Ar.tb), trabecular volumetric Bone Mineral Density (vBMD.tb), and trabecular volumetric Bone Mineral Content (vBMC.tb) were measured. Pearson's correlation analyses were run $p < 0.05$.

RESULTS: PP measures were associated with cortical and trabecular bone strength parameters in the tibia and radius. Strong associations were found in cortical bone sites except for cBMD as indicated by the correlation coefficients (r) [tibia - J (0.7374), Ct.Ar (0.7650), SSI (0.7344), radius - J (0.7028), Ct.Ar (0.7830), SSI (0.6788)]. Similar results were found in the trabecular region for both the tibia and radius respectively [BSIc (0.6199), T.Ar.tb (0.5204), vBMc.tb (0.6016), vBMD.tb (0.4415) and BSIc (0.7950), T.Ar.tb (0.5943), vBMc.tb (0.7371), vBMD.tb (0.7188)].

CONCLUSIONS: PP is associated with cortical and trabecular bone strength parameters in the radius and tibia for a diverse population of healthy adults. PP seems to have the greatest effect on bone strength and structure for both the cortical and trabecular sites, but is not associated with cortical BMD. Lower limb muscle power could provide a means to monitor bone health in a general population.

Body Composition, Bone Mass and Bone Geometry in Adolescent Athletes

Raiany R. Bergamo¹, Humberto M. de Carvalho², Gil Guerra-Junior¹, Anderson M. de Moraes³. ¹University of Campinas (UNICAMP), Campinas, Brazil. ²Federal University of Santa Catarina (UFSC), Santa Catarina, Brazil. ³Pontifical Catholic University of Campinas (PUC-Campinas), Campinas, Brazil. Email: raianyrbergamo@hotmail.com
 (No relevant relationships reported)

Sports practice is a strong osteogenic stimulus promoting bone mineral accrual, and growing bones have more responsive improvements to high-impact sports.

PURPOSE: To analyze the influence of exposure to soccer and basketball practice on body composition, bone mass, and bone geometry in adolescent male athletes, accounting for maturity-associated variation on body composition. **METHODS:** Three hundred and eighty young athletes (soccer: $n = 235$, age = 14.2 ± 0.94 years, body mass = 57.1 ± 9.7 kg, stature = 169.1 ± 10.3 cm; basketball: $n = 145$, age = 14.7 ± 0.13 years; body mass = 68.6 ± 16.4 kg; stature = 177.1 ± 13.8 cm). Body composition, bone mineral content (BMC) and bone mineral density (BMD) of whole body, posteroanterior lumbar spine (L1-L4), femoral neck and geometric variables, such as strength index, buckling ratio, section modulus, cross-sectional moment of inertia (CSMI) and cross-sectional area (CSA) were evaluated by Dual-energy X-ray absorptiometry (model iDXA, GE Healthcare Lunar, enCore™ software version 13.60, 2011, Madison, WI, USA). Estimated peak height velocity was based on the protocol by Moore (2015). Analysis of covariance (Quade), for non-parametric ANCOVA, was used to examine the variation on body composition, bone mass, and bone geometry of players grouped by sport. **RESULTS:** There was a significant difference between the modalities only for femoral neck parameters [BMO ($F_{\text{ANCOVA}}: 11.237$; $p=0.001$), BMC ($F_{\text{ANCOVA}}: 6.676$; $p=0.010$)] and Bone Geometry [Strength Index ($F_{\text{ANCOVA}}: 51.407$; $p<0.001$), Buckling ratio ($F_{\text{ANCOVA}}: 50.189$; $p<0.001$), Section Modulus ($F_{\text{ANCOVA}}: 175.874$; $p<0.001$), CSMI ($F_{\text{ANCOVA}}: 164.921$; $p<0.001$) and CSA ($F_{\text{ANCOVA}}: 165.230$; $p<0.001$)]. All parameters were higher for basketball, except for Strength Index. **CONCLUSION:** Our results suggest that youth basketball practice may promote a higher effect on bone parameters (BMD, BMC and geometry) related to the femur in contrast to soccer, probably due to the specificity of the modality.

Table 1. Results for the variables of body composition, bone mass and bone geometry according to modality.

| Parameters | Variables | Basketball (n=145) | | | | Soccer (n=235) | | | |
|-------------------------|-------------------------------------|--------------------|---------|---------|----------|----------------|---------|---------|----------|
| | | Mean | SD | Min | Max | Mean | SD | Min | Max |
| Body composition | Fat Mass (Kg) | 13.40 | 5.12 | 5.61 | 36.92 | 8.61 | 2.49 | 5.03 | 22.57 |

Non-dominant Hand-grip Strength Is Positively Associated With Areal Bone Mineral Density In College-aged Women

Eliana Casamassima, Karen Roa, Julie Ballo, Theresa Poon, SoJung Kim. University of Massachusetts, Lowell, MA. Email: eliana_casamassima@student.uml.edu
 (No relevant relationships reported)

Previous studies have focused on the relationship between areal bone mineral density (aBMD, g/cm²) and non-dominant hand-grip strength in older populations; however,

there is a lack of research analyzing this relationship in the younger college-aged population. **PURPOSE:** The purpose of this study was to demonstrate the relationship, if any, between aBMD and non-dominant hand-grip strength in healthy college-aged students. **METHODS:** One hundred and four participants aged 18-25 (57 women, 20.3 ± 1.3 years; 47 men 21.0 ± 1.2 years) were recruited from the University of Massachusetts Lowell. aBMD of the non-dominant side of femur (FN: femoral neck, TH: total hip) and lumbar spine (L1-L4) was measured by dual energy X-ray absorptiometry (DXA). JAMAR Dynamometer was used to measure non-dominant hand-grip strength (kg) and body composition (lean mass, kg) was measured by DXA. The total bone-specific physical activity (tBPAQ, average of past and current BPAQ) score was used to obtain a comprehensive account of lifetime physical activity related to bone health. **RESULTS:** Pearson's correlation tests showed positive correlations between non-dominant hand-grip strength and aBMD of the non-dominant FN ($r=0.559$, $p=0.001$), TH ($r=0.523$, $p=0.001$), and lumbar spine ($r=0.430$, $p=0.001$) in college-aged women. These relationships were not observed in college-aged men ($p>0.05$). There were positive relationships between non-dominant hand-grip strength and lean mass in both college-aged men ($r=0.540$, $p=0.001$) and women ($r=0.647$, $p=0.001$). No significant relationships were found between BPAQ scores and aBMD in both groups. **CONCLUSION:** This study presents evidence that aBMD is positively correlated with non-dominant hand-grip strength in college-aged women, but not in college-aged men. Further analysis is needed to better understand the factors associated with this relationship.

Muscular Fitness And Bone Health In Athletes And Non-athletes

Duarte Henriques-Neto, João Pedro Magalhães, Diana Aguiar Santos, Gil Rosa, Fátima Batista, Luís B. Sardinha. University of Lisbon, Lisbon, Portugal.
 (No relevant relationships reported)

Abstract

Muscular fitness has been associated with several health-related outcomes including bone health. However, evidence on this relationship considering sport participation is scarce. **Purpose:** To examine associations between several expressions of muscular fitness and bone speed of sound (SoS) in young people of both sexes according to current sport participation (ATHL-athletes engaged in formal competition vs. Non-ATHL - non-athletes). **Methods:** Participants were 184 boys (11.1-18.9 yrs old; 90 athletes) and 198 girls (12.2-18.8 yrs old; 45 athletes) at and above the age of peak height velocity (PHV). Bone SoS evaluation was conducted by quantitative ultrasound (QUS) at the distal radius (R-SoS) and midshaft tibia (T-SoS) of the non-dominant limbs. Muscular fitness included the handgrip strength (HG), the vertical jump (VJ), agility (shuttle-run 4x10m), and speed (20-m sprint test). All statistical analyzes were performed separately for boys and girls and adjusted for maturity (yrs from the age of PHV), body mass index (WHO z-BMI), and daily calcium intake. **Results:** The ANCOVA revealed superior muscular fitness in athletes compared to non-athletes ($p<0.05$) in both sexes, with the exception of HG strength in which no differences were observed. There were no dissimilarities in bone SoS between the athletes and non-athletes, except for the tibia in which the male athletes showed lower SoS than the non-athletes (ATHL: 3743.78 ± 8.90 m/s vs. Non-ATHL: 3775.33 ± 8.71 m/s, $p=0.013$). In both sexes, multiple linear regression showed a greater number of muscular fitness predictors of bone SoS in non-athletes than in athletes: in non-athletes, the HG strength associated with the T-SoS ($\beta=5.36$, $p=0.002$) and the speed with the R-SoS ($\beta=-58.97$, $p=0.001$) in girls and the VJ height ($\beta=3.01$, $p=0.017$) and speed ($\beta=-71.69$, $p=0.022$) associated both with the T-SoS in boys. In athletes, HG strength associated with R-SoS ($\beta=1.99$, $p=0.049$) in girls and the sprint associated with the T-SoS ($\beta=-65.78$, $p=0.020$) in boys. **Conclusion:** Despite higher values of muscular fitness, athletes did not reveal higher bone SoS than non-athletes and showed less associations between these variables. In young people, muscular fitness appeared to be a better marker of bone health in non-athletes compared to athletes.

Relationship Of Physical Activity With Bone Parameters In Young Hispanic Girls

Diego W. Blew, Vinson R. Lee, Robert M. Blew, Jennifer W. Bea, Victoria L. Bland, Scott B. Going. University of Arizona, Tucson, AZ.
 (No relevant relationships reported)

Increased levels of moderate-to-vigorous physical activity (MVPA) are associated with enhanced bone mass/density development in non-Hispanic children, which may prevent osteoporosis later in life. This relationship has not been established in Hispanic females; as osteoporosis rates increase, an understanding of this relationship across populations is vital. **PURPOSE:** To determine the impact of MVPA on bone density, content, structure and strength in young Hispanic girls. **METHODS:** Young, primarily Hispanic female subjects ($N=320$), age 9-12 yr., wore accelerometers for

seven consecutive days. Wear time was classified into sedentary, light, moderate, and vigorous activity based on Evenson cut points. Femoral and tibial bone density, content, strength, and architecture were assessed using peripheral quantitative computed tomography (pQCT). Whole body soft tissue composition was measured by DXA. Associations between each bone variable and average daily MVPA were determined using multivariate regression, adjusting for maturity offset, BMI, and ethnicity. **RESULTS:** Average height, weight, and percent fat were 145.8±9.6 cm, 44.1±14.7 kg, and 32.5±9.8%, respectively. Multiple linear regression resulted in consistently significant ($p<0.05$) or trends toward significant associations between bone parameters and daily MVPA. Average daily MVPA was 22.3±63.1 minutes. Femur 20% periosteal circumference, strength-strain index (SSI), 4% tibia average bone strength index, average periosteal circumference, average cortical thickness, and 66% tibia cortical content, periosteal circumference, and SSI all had significant associations with average daily minutes of MVPA, while other pQCT measures approached significance. The variance explained by MVPA ranged from approximately 0% to 4.8%. Together, BMI, maturity offset, and ethnicity explained 2.6% to 70.2% of the variance in the models. **CONCLUSION:** There is a significant positive relationship between average daily MVPA levels and bone content and strength in Hispanic girls. Physical activity interventions could lead to enhanced bone development and strength, as shown in non-Hispanic populations. Sponsored by: NIH Grant 5R01HD074565-05

Middle School Recreational Sport Participation as a Determinant of Adult Muscle and Bone Strength

Karen Serrano Vides, Kirstie Huynh, Kimberly Espartero, Rebekkah Reichert, Maria Alvarez, Priscilla Franson, Arianna Mazzarini, Andrew Denys, Vanessa Yingling, FACSM.
California State University, East Bay, Hayward, CA. (Sponsor: Vanessa Yingling, FACSM)

(No relevant relationships reported)

Physical activity during adolescence promotes the development of skeletal strength and muscle function. Musculoskeletal adaptations result from mechanical forces common in sporting activities. Recent studies have reported strong positive correlations between muscle power and bone strength (Janz, 2015, Yingling, 2017).

PURPOSE: To determine if participation in middle school sports (self-report questionnaire) resulted in greater muscle and bone strength later in life.

METHODS: 79 participants, 41 female and 38 male (age (yrs) 29.2 + 10.8, height (cm) 166.5 + 9.2, body fat (%) 24.6 + 9.3) performed a Relative Grip Strength (RGS) test using a hand grip dynamometer, 1 Repetition Maximum leg extension test (1RM), and a vertical jump test. Peak Power (PP) was calculated from jump height (Sayers, 1999). Peripheral Quantitative Computed Tomography (pQCT) was used to measure bone strength (polar Strength-Strain Index (SSI_p)) in the cortical region of the tibia and radius. A questionnaire completed by participants stated "Did you participate in recreational sports during middle school (Grades 6-8)?" Welch's t-test determined differences in the muscle function tests and bone strength measures based on middle-school sports participation.

RESULTS: 55 individuals participated in recreational sports during middle school, 16 individuals did not. Those who participated in sports during middle school had an average relative PP of 55.41 W/kg, RGS of 6.46 N/kg, 1RM of 2.86 RW/BM, radial SSI_p of 279.31 mm³, and tibial SSI_p of 2036.13 mm³. Individuals that did not participate in recreational sports during middle school had an average PP of 49.12 W/kg, RGS of 5.58 N/kg, 1RM of 2.45RW/BM, radial SSI of 268.49 mm³, tibial SSI of 1957.50 mm³. Middle school sports participation resulted in significantly greater PP ($p = 0.008$), RGS ($p = 0.010$) and 1RM ($p = 0.018$) but no differences were found for bone strength in either the radius or tibia.

CONCLUSIONS: Adolescence is a key time for bone and muscle strength adaptation. However, the results suggest that self report of middle school recreational sport involvement may not be an optimal way to predict muscle and bone strength in adulthood. Evaluating past activity by survey has limitations with self-reported activity including the inability to determine the intensity of activity.

Morning Downhill Exercise Reduces Bone-resorption Marker After Midday, But Not After Morning Meal.

Katarina T. Borer¹, QingYun Zheng², Adam I. Daoud³, Thomas Kernozek, FACSM⁴, Melissa M. Gross¹. ¹University of Michigan, Ann Arbor, MI. ²East China Normal University, Shanghai, China. ³Harvard University, Cambridge, MA. ⁴University of Michigan, La Crosse, WI.

Email: katarina@umich.edu

(No relevant relationships reported)

PURPOSE: In view of the importance of nutrient intake in suppressing markers of bone resorption, our aim was to find out the time course of changes in plasma concentrations of markers of bone formation (osteocalcin (OS) and C1CP, C-terminal

propeptide of type 1 collagen) and resorption (CTX, C-terminal telopeptide of type 1 collagen), relative to 40 minutes of downhill or uphill exercise performed at 8-8:40 h, and to three isocaloric meals eaten at 7, 13, and 19 h.

METHODS: Twenty postmenopausal women, 58 y old, were assigned to walk on either an uphill (slope 8 to 12 °) or -6° downhill treadmill for 40-minutes (40 UP, 40 Down) or to remain sedentary. Ground reaction forces (GRF) were measured with mechanosensitive Novel Pedar shoe inserts, and physical effort as % VO₂max with a metabolic cart. Hourly measurements of anabolic growth (GH) and parathyroid (PTH) hormones, catabolic cortisol and bone markers served to assess the metabolic responses relative to timing of meals and exercise. An osteogenic index was calculated as percent change in the C1CP/CTX ratio.

RESULTS: Peak GRFs were significantly higher in downhill (1097 N) than uphill (814 N) exercise while relative effort was significantly higher during uphill than downhill exercise (74.6% vs 46.6% VO₂ max, respectively) exercise. In the 40 Down trials, the osteogenic C1CP/CTX ratio rose between 13 and 20 h with a peak between 15 and 17 h and produced a 55% greater area under the curve relative to 40 Up and SED trials. There was a significant correlation between the C1CP/CTX and the GRFs ($r^2=0.708$, $F=15.55$, $p<0.0009$), as was the case for the OS/CTX ratio. The GH/cortisol ratio was elevated between 15 and 20 h, and the PTH/cortisol ratio between 16 and 22 h in 40 Up compared to 40Down and SED groups. Cortisol concentration was elevated in 40 Up trial. There was no correlation between the osteogenic and anabolic endocrine indices.

CONCLUSIONS: Greater mechanical loading in downhill morning exercise increases the osteogenic bone-marker and anabolic hormone indices after the start of midday meal, but not after the morning meal. No such anabolic effect is seen after uphill exercise which produces lower mechanical loading, higher VO₂ max and high cortisol response. This suggests that optimal anabolic responses to morning loading exercise require energy intake during the midday meal.

Racial/Ethnic Differences in Bone Health, Bone Free Lean Mass, and Fat Mass in Young Women

Japneet Kaur, Ryan M. Miller, Eduardo D.S. Freitas, Aaron Heishman, Debra A. Bembien, FACSM, Michael G. Bembien, FACSM. *University of Oklahoma, Norman, OK.*

Email: Japneet.Kaur-1@ou.edu

(No relevant relationships reported)

The burden of osteoporosis and fracture incidence varies significantly with race/ethnicity. Caucasians are reported to have a lower bone mineral density (BMD) than African-Americans, and a higher, lower, or similar BMD than Asians. However, majority of these studies are focused on East-Asians, with few well-defined studies focusing on South-Asians, who are culturally and geographically different from East-Asians. **PURPOSE:** The purpose of the current study is to evaluate bone mineral density/content, bone free lean mass (BFLM) and strength, and fat mass in young women belonging to Caucasian, East-Asian and South-Asian descent. **METHODS:** Twenty-nine young women aged 18-30 years self-identified themselves as Caucasian (Cau; n=13), South-Asian (SA; n=11), and East-Asian (EA; n=5). Quadriceps (Q) angle was measured using a hand-held goniometer. Body composition (fat, BFLM, and bone mineral content) and total and regional BMD were measured using Dual Energy X-Ray Absorptiometry, while handgrip, jump test, and 1Repetition-Maximum (1-RM) leg press were used to quantify lower limb muscle strength and power. Ethnic differences in each outcome variable were determined using one-way ANOVA, and Pearson correlation coefficients quantified relationships between variables. Statistical significance was set at $p<0.05$. **RESULTS:** Q-angle was significantly higher in SA in comparison to Cau ($p<0.05$). Muscle strength tests revealed that Cau had considerably higher values for 1-RM leg press than SA ($p=0.027$). Jump height ($p=.002$) and time in air ($p=.003$) were considerably higher for Cau and EA compared to SA. Additionally, SA had a significantly higher percent body fat and fat mass at the total body and in the lower limbs ($p\leq0.001$). Though non-significant, BFLM was highest in Cau, followed by EA, and least in SA ($p=0.068$). **CONCLUSION:** Our preliminary data indicates an increased adiposity in SA, without a concurrent increase in muscle mass. Such a phenotype is deteriorative for bone, and suggestive of an early, sub-clinical form of osteosarcopenic obesity. We also see differences in percent body fat and muscle strength between EA and SA, emphasizing the need to consider these two groups separately while assessing the bone-muscle-fat unit.

Tibia Bone and Soft Tissue Characteristics in Oral Contraceptive Users and Non-Users

Hoang Van M. Nguyen¹, Pragma Sharma-Ghimire², Samuel R. Buchanan¹, Debra A. Bembem, FACSM¹. ¹The University of Oklahoma, Norman, OK. ²Lander University, Greenwood, SC. (Sponsor: Debra A. Bembem FACSM, FACSM)
 Email: Hoang.v.nguyen-2@ou.edu
 (No relevant relationships reported)

Oral contraceptives (OC) contain different formulations of the synthetic estrogen, ethinyl estradiol (EE), and progesterin; these sex steroids can exert metabolic effects on bone, muscle, and fat tissues. OC use affects body composition and bone density; however, its effects on muscle quality are not clear. Increased fat infiltration within the muscle associated with OC use could negatively impact muscle quality and performance. **PURPOSE:** To compare tibia bone and soft tissue variables assessed by pQCT in OC users and Non-users. **METHODS:** Women ages 20-30 were divided into low dose OC users (<20 ug EE, n=18), high dose OC users (>20 ug EE, n=15) and Non-users (n=22). Bone variables (vBMD, geometry, strength) were measured at 4%, 38%, and 66% of the non-dominant tibia by pQCT. Muscle and fat densities and areas were analyzed by BoneJ software at the 66% site. **RESULTS:** There were no significant differences between low dose and high dose OC users for any variables. Low dose and high dose OC groups did not differ from Non-users in age, height, BPAQ scores, or calcium intake. Weight-adjusted comparisons determined low dose OC users had lower total BMC (p=0.046), total area (p=0.003), Peri C (p=0.003), cortical area (p=0.048), and SSI (p=0.022) than Non-users at the 38% site. High dose OC users had lower muscle area (p=0.041), total fat density (p=0.039), and subcutaneous fat density (p=0.030) than Non-users at the 66% site. **CONCLUSION:** Our findings suggest that OC formulated with EE concentrations > 20 µg affect tibia soft tissue characteristics while OC pills containing < 20 µg affect bone variables. Further investigations are needed examining multiphasic combined OC to provide a more comprehensive picture of OC effects on soft tissue and bone characteristics.

Table 1. Bone and Soft Tissue Characteristics in OC Users and Non-Users (Mean ± SD)

| Variables | Non-Users (n=22) | Low Dose OC Users (n=18) | High Dose OC Users (n=15) |

Hip Structural Analyses Characteristics Based on Physical Activity Status in Young and Middle-aged Premenopausal Women

Pragma Sharma Ghimire¹, Michael Bembem, FACSM², Debra Bembem, FACSM². ¹Lander University, Greenwood, SC. ²The University of Oklahoma, Norman, OK. (Sponsor: Dr. Debra Bembem, FACSM)
 Email: psharmaghimire@lander.edu
 (No relevant relationships reported)

Mechanical loading associated with physical activity (PA) is important for optimizing hip bone health. Bone cells are inherently mechanosensitive and adapt to the mechanical environment. Bone adaptation to loading is regulated by the Wnt signaling pathway, which is inhibited by several glycoproteins including sclerostin (Scl) and Dickkopf-1 (DKK-1). Elevated Scl levels are associated with low bone mineral density and increased risk for hip fracture. **PURPOSE:** This study compared age and PA level differences in hip structural analyses (HSA) variables [SI (strength index);

SM (sectional modulus); BR (buckling ratio); and CSMI (cross-sectional moment of inertia)] in young (20-30 yrs, n=25) and middle-aged premenopausal women (35-45 yrs, n=25). The relationships between Scl and DKK-1 with HSA variables were also studied. **METHODS:** Fasting morning blood samples were analyzed for serum Scl and DKK-1 by ELISA. HSA variables were measured at dual femur site by DXA. PA levels were classified as low moderate-active (LM) and health enhancing physical activity-active (HA) based on the International Physical Activity Questionnaire. **RESULTS:** Two-way ANOVA showed a significant age group effect for Lt SM, which was lower in middle-aged women (p<0.05). Significant main effects of age and PA (p<0.05) were found for Rt BR, which was higher in middle-aged and lower in HA women. HSA variables were not correlated with serum Scl and DKK-1 levels (p>0.05). **CONCLUSIONS:** Lower SM and higher BR in middle-aged women support an age-related decrease in hip bone strength. Based on our findings, HSA variables are not related to Wnt signaling inhibitors.

Table 1. HSA variables based on Age and PA Levels (Mean ± SD)

| Variables | Young (n=25) | | Middle-aged (n=25) | |
|----------------------------|-----------------|------------------|--------------------|------------------|

Six-month Assessment Of Biomarkers, Skeletal Attributes, Body Composition, And Performance In Collegiate ROTC Members

Breanne S. Baker, Samuel R. Buchanan, Alison Balderas, Hoang Van M. Nguyen, Cameron S. Combs, Christopher D. Black, FACSM, Michael G. Bembem, FACSM, Debra A. Bembem, FACSM. *University of Oklahoma, Norman, OK.* (Sponsor: Dr. Debra Bembem, FACSM)
 Email: bakerbre@health.missouri.edu
 (No relevant relationships reported)

Physical activity has been associated with greater areal bone mineral density (aBMD) and reduced fracture rates, however, active military personnel report high rates of bone injuries. Current assessment tools, DXA, pQCT, and serum biomarkers, have not been consistently correlated with injury status in this cohort. **PURPOSE:** To follow ROTC and matched controls over six months and study changes in parathyroid hormone (PTH) and sclerostin concentrations, bone density and quality, and body composition. **METHODS:** Collegiate ROTC members (n=16) were matched to active sex, age (±2yrs), and body mass (±5lbs) controls (n=15). Participants completed testing in November (fall), January (pre), March (mid), and April (post). ROTC participants engaged in an exercise training intervention from pre to post testing periods. Total body, lumbar spine, dual hip aBMD and BMC, and body composition were measured by DXA, while tibial volumetric BMD (vBMD) was measured by pQCT. ELISA kits were used to measure PTH and sclerostin. **RESULTS:** At baseline no significant group differences existed (all p≥0.052). Significant (group × time) interactions were found in the dominant hip (Table 1). Significant interactions were also found at the 4% and 66% tibia. From fall to post, controls decreased mean total vBMD 4.221 mg/cm³ and increased mean total area and mean periosteal circumference 18.30 mm² and 1.0 mm respectively (all p≤0.018). Mean 66% muscle cross-sectional area significantly increased from pre to post 645.1 mm² in ROTC only (p<0.001). PTH did not change but sclerostin significantly increased from fall to pre (p=0.001) and then leveled off from pre to post in both groups (p>0.278). **CONCLUSIONS:** Over time ROTC measures of bone density and quality either improved or did not change, while controls lost aBMD at the dominant hip. Additionally, sclerostin, but not PTH, significantly changed throughout the study.

Table 1. Significant (group × time) interactions in dominant hip aBMD (g/cm³) variables (means±SD).

| Variable | ROTC (n=16) | | | Controls (n=15) | | |

Sex Differences in Muscle-Bone Interactions in Chinese Men and Women

Alison Balderas¹, Zhaojing Chen², Meihua Su¹, Samuel Buchanan¹, Breanne Baker³, Michael Bembem, FACSM¹, Debra Bembem, FACSM¹. ¹University of Oklahoma, Norman, OK. ²California State University San Bernardino, San Bernardino, CA. ³University of Missouri, Columbia, MO. (Sponsor: Debra A. Bembem FACSM, FACSM)
Email: alisonkelley@ou.edu
(No relevant relationships reported)

Muscle-bone interactions are important for bone health as mechanical forces from muscular contraction place large stresses on bone. Little is known about sex differences in bone and muscle characteristics in Asians. **PURPOSE:** To examine sex differences in bone characteristics, grip strength, and lower body strength and power in Chinese adults (n=53). **METHODS:** Chinese males (n=28) and females (n=25) had body composition and aBMD (total body, lumbar spine, dual femur) assessed by DXA, and bone geometry (4%, 38%, 66%) of the non-dominant tibia measured by pQCT. Leg strength (two-leg press) and power (jump mat) and maximal grip strength (handgrip dynamometer) were measured. **RESULTS:** There were no sex differences in physical activity or calcium intake. After adjusting for height and weight, males had significantly greater leg press 1RM, grip strength, jump height, jump time, lumbar spine aBMD, 4% total BMC, 4% total area, and 4% bone strength index (BSI) (p<0.05) than females. In males, leg 1RM was positively correlated with total body aBMD (r=0.427), and left femoral neck aBMD (r=0.445), and jump power was positively correlated with total body aBMD (r=0.580) and all hip aBMD variables (r=.487 to 0.646) (all p< 0.05). Females generally had stronger correlations between muscle and bone variables: leg 1RM (all p<0.05) and jump power (all p<0.003) were positively related to all aBMD variables (r=0.432 to 0.819). Jump power and BSI were positively correlated (r=0.378, p=0.048) in males, whereas jump power and leg 1RM showed moderate to strong correlations with 4% total BMC, total area, and total BSI (r=0.460 to 0.836, p<0.05) in females. **CONCLUSION:** Based on our findings, Chinese males had greater bone size, bone strength, and muscle strength than females; however, females exhibited more and stronger relationships between muscle and bone variables than males.

Table 1. Sex Differences in Muscle and Bone variables (unadjusted Means ± SD)

| Variable | Females (n=25) | Males (n=28) |
|-------------------------------|----------------|----------------|
| Leg Press 1RM (kg) | 110.2 ± 17.3 | 187.2 ± 15.9** |
| Maximal Grip Strength (kg) | 27.8 ± 1.2 | 42.1 ± 1.1** |
| Jump Height (in) | 13.2 ± 0.6 | 18.6 ± 0.6** |
| Jump Time (s) | 0.51 ± 0.01 | 0.62 ± 0.01** |
| 4% Tibia | | |
| Total BMC (g) | 330.2 ± 10.2 | 384.4 ± 9.4* |
| Total Area (mm ²) | 1047.0 ± 29.8 | 1165.6 ± 27.4* |
| BSI (mg/mm ³) | 104.9 ± 6.4 | 128.6 ± 5.9* |

*p<0.05 vs. females, **p<0.01 vs. females

Added Load Alters Ankle And Knee Joint Moments During Stair Ascent

William G. Robinson¹, Alexis K. Nelson¹, Jake A. Melaro¹, Alexander M. Carnall¹, Rachael Ard¹, Victoria White¹, Derek Beeler², Spring Glover², Cris Stickley², Douglas W. Powell, FACSM¹. ¹University of Memphis, Memphis, TN. ²University of Hawaii at Manoa, Honolulu, HI. (Sponsor: Douglas W. Powell, FACSM)
(No relevant relationships reported)

INTRODUCTION: Approximately 66% of the United States is overweight or obese. Obesity is associated with many negative health conditions including osteoarthritis. Research has investigated the effects of increased mass on gait biomechanics, however weight-related changes stair locomotion biomechanics are less understood.

PURPOSE: to assess changes in lower extremity joint moments associated with acutely added body mass during stair ascent. **METHODS:** Ten college aged participants performed 5 stair ascent trials in each of 5 loading conditions: body weight (BW), BW+5%, BW+10%, BW+15%, and BW+20%. Mass was added using a weighted vest. An 18-camera motion capture system (240 Hz) and embedded force platform (1200 Hz) were used to collect kinematics and ground reaction forces simultaneously. **Commercial software** was used to calculate ankle, knee and hip joint moments during the stance phase of second step of a five-step stairway. Univariate ANOVAs with Tukey’s post-hoc tests were used to compare peak ankle, knee and hip joint moments from each weighting condition. **RESULTS:** Ankle plantarflexion and knee extension moments increased with added load (Table 1). Hip extension moments were not altered with added load. **DISCUSSIONS/CONCLUSION:** The ankle joint is the primary contributor to increased lower extremity joint moments in response to added load during stair ascent. Though an omnibus effect of added load was observed at the knee, only one post-hoc comparison was statistically different (BW vs. BW+15%) suggesting that the knee is not responsible for increased propulsion in response to added load during stair ascent. Interestingly, no changes in peak joint moments were observed at the hip joint. A limitation of this study was that the acutely added load was not similar in location or physical properties to the increased load associated with obesity which may limit the generalizability of these findings to obese individuals.

Table 1. Mean ankle, knee and hip joint moments during stair ascent in the control and added load conditions. P-value represents omnibus findings of the univariate ANOVA.

| | BW | BW+5% | BW+10% | BW+15% | BW+20% | P-value |
|-------|------------|-------------------------|-------------------------|-------------------------|-------------------------|---------|
| Ankle | -1.4 (0.4) | -1.5 (0.4) ^a | -1.6 (0.4) ^a | -1.6 (0.4) ^a | -1.7 (0.4) ^a | 0.002 |
| Knee | 1.1 (0.4) | 1.2 (0.3) | 1.2 (0.4) | 1.3 (0.3) ^a | 1.3 (0.3) | 0.024 |
| Hip | -0.6 (0.2) | -0.7 (0.2) | -0.7 (0.3) | -0.7 (0.3) | -0.7 (0.3) | 0.620 |

Note: ^a – denotes significantly different than BW, ^b – significantly different than BW+5%, ^c – denotes significantly different than BW+10%, ^d – denotes significantly different than BW+15%.

Examination of the Influence of Lead Leg Recovery Mechanics on Slip Induced Outcomes

Andrew L. Crawford¹, Tyler Donahue², Chris Hill², Caleb Williams³, Jeff Simpson⁴, Harish Chander⁵, Chip Wade⁶, Sydni Wilhoite¹, Kristen Neitz¹, Josh Pascal¹, Ariana Haynes¹, Kelsey Lewis¹, Abigail Johnson¹, Barry Munkasy¹, LI Li, FACSM¹, John Garner⁷, Dwight Waddell², Sam Wilson¹. ¹Georgia Southern University, Statesboro, GA. ²University of Mississippi, Oxford, MS. ³LaGrange College, LaGrange, GA. ⁴University of West Florida, Pensacola, FL. ⁵Mississippi State University, Starkville, MS. ⁶Auburn University, Auburn, AL. ⁷Troy University, Troy, AL. (Sponsor: LI, LI, FACSM)
Email: ac08610@georgiasouthern.edu
(No relevant relationships reported)

INTRODUCTION: Slips and falls have serious implications on one’s health. Nearly every 10 seconds, an adult is treated in the hospital for fall related issues. Further, injury and mortality rates are on the rise across all populations when slips or falls are involved. Other studies have analyzed different corrective responses. However, how the recovery response may fail during a slip that results in a fall is still unclear. **PURPOSE:** To examine lead leg slip recovery corrective responses between falls and recoveries following an induced slip perturbation. **METHODS:** One hundred participants were recruited for this study. Participant’s lower extremity gait kinematics and kinetics were collected during normal gait and an unexpected slip. The variables of interest were mean sagittal moments about the ankle, knee, and hip, during stance phase. Peak moments, and time to peak moments. The slip was classified as either a fall or a recovery. Once classified, corrective responses were examined between groups using independent t-tests. Additionally, prediction equations for slip outcome were created using a binary logistic regression model. **RESULTS:** After exclusions, the final analysis included 64 participants, this included 39 trials classified as recoveries, and 25 trials classified as falls. The results from the logistic regression model suggest that increased time to peak hip extension (OR = 1.006, CI: 1.00-1.01) and ankle dorsiflexion (OR = 1.005, CI: 1.00-1.01) moments increased the odds of falling. While the average ankle moment was negatively associated with falling (OR = 0.001, CI: 0.001-0.005). **CONCLUSIONS:** After analyzing lower extremity gait during unexpected slip perturbations the results suggest that the slipping hip’s recovery

FRIDAY, MAY 31, 2019

response is a key factor in preventing falls. Future work focused on slip training may benefit from targeting this primary hip response of the slipping leg in order to mitigate fall risk.

Lead Leg Corrective Responses to Varying Slip Severity

Joshua Pascal. *Georgia Southern University, Statesboro, GA.*
 (Sponsor: Dr. Li Li, FACSM)
 Email: jp26238@georgiasouthern.edu
 (No relevant relationships reported)

Slips and falls account for large rates of injury and mortality in multiple populations. While previous research has examined the corrective responses elicited, it is still unclear which responses may break down during more severe slips. **PURPOSE:** To examine lead leg slip recovery corrective responses across slip severity following an induced slip. **METHODS:** One hundred participants were recruited for this study. Participant's lower extremity gait kinematics and kinetics were collected during normal gait and an unexpected slip. The variables of interest were mean sagittal moments about the ankle, knee, and hip, during stance phase. Peak moments, and time to peak moments. The slip was classified based on slip severity, using heel slip distance, and velocity. Once classified, corrective responses were examined between groups using independent t-tests. Additionally, prediction equations for slip severity were created using a binary logistic regression model. **RESULTS:** After exclusions, the final sample included 64 participants for analyses, consisting of 37 non-hazardous slips, and 27 hazardous slips. The results from the logistic regression model suggest that as the average ankle moment increases in the slip period, the odds of experiencing a hazardous slip decrease (OR = 0.01, CI: 0.01-0.03). Further, as the time to peak hip extension (OR = 1.007, CI: 1.000-1.013) and knee extension moments (OR = 1.001, CI: 0.997-1.004) increase, the odds of experiencing a hazardous slip increase. **CONCLUSIONS:** Rapid lower extremity corrective responses appear critical in arresting the slip. While there are various strategies for slip recovery, our findings suggest that the primary recovery mechanism at the slipping hip may play a vital role in preventing the severe slip.

Added Load Alters Ankle And Knee Joint Moments During Stair Descent

Jake A. Melaro¹, Alexis K. Nelson¹, William G. Robinson¹, Alex M. Carnall¹, Rachael A. Ard¹, Rachael A. Arnwine¹, Victoria White¹, Derek Beeler², Spring Glover², Cris Stickley², Douglas W. Powell, FACSM¹. ¹University of Memphis, Memphis, TN. ²University of Hawaii at Manoa, Honolulu, HI. (Sponsor: Douglas W Powell, FACSM)
 (No relevant relationships reported)

INTRODUCTION: Combat forces perform a number of tasks with a rigid load added to the trunk including walking, running and stair ascent and descent. Though a number of studies have investigated the effect of added loads on joint biomechanics during over ground and treadmill walking, less focus has been applied to negotiating stairs. Changes in lower extremity biomechanics during stair descent may be associated with excessive joint loading. **PURPOSE:** to quantify changes in joint kinetics when descending stairs with increasing loads. **METHODS:** Ten healthy adults (age: 18 - 30) performed 5 stair descent trials in each of 5 loading conditions: body weight (BW), BW+5%, BW+10%, BW+15%, and BW+20%. Mass was added using a modular vest and metal plates. An 18-camera motion capture system (240 Hz) and embedded force platform (1200 Hz) was used to collect kinematics and ground reaction forces simultaneously. Commercial biomechanical software was used to calculate ankle, knee and hip joint moments during the stance phase of second step of a five-step stairway. Univariate ANOVAs with Tukey's post-hoc tests were used to compare peak ankle, knee and hip joint moments from each loaded condition. **RESULTS:** Ankle plantarflexion moments increased at BW+15% and BW+20% (Table 1). Hip and knee extension moments were not altered with added load. **DISCUSSIONS/CONCLUSION:** The ankle joint is the primary contributor to increased lower extremity joint moments only in response to added load at or exceeding +15% BW during stair descent. Interestingly, no changes in peak joint moments were observed at the knee and hip joint, suggesting that neither joint is responsible for increased energy absorption in response to added load during stair descent. Further research may seek to investigate the effects of fatigue on joint kinetics during stair descent.

Table 1. Mean ankle, knee and hip joint moments during stair descent in the control and added load conditions. P-value represents omnibus findings of the univariate ANOVA.

| | BW | BW+5% | BW+10% | BW+15% | BW+20% | P-value |
|-------|-----------|-----------|-----------|--------------------------|------------------------|---------|
| Ankle | -0.9(0.2) | -1.0(0.2) | -1.0(0.3) | -1.0(0.2) ^{a,b} | -1.1(0.3) ^a | 0.025 |
| Knee | 1.4(0.3) | 1.5(0.4) | 1.5(0.5) | 1.6(0.4) | 1.6(0.4) | 0.142 |
| Hip | -0.2(0.2) | -0.1(0.1) | -0.2(0.3) | -0.1(0.2) | -0.1(0.2) | 0.485 |

Dual Tasking Using a Treadmill Desk Affects Middle-Aged but Not Young Adults

Rebecca R. Rogers, Mallory R. Marshall. *Samford University, Birmingham, AL.*
 (No relevant relationships reported)

PURPOSE: Young adults have the capacity to manage dual task conditions with minimal impairment to either the cognitive or the motor task; however, this ability decreases with age. Previous research on dual tasking has primarily examined over ground walking and minimal information is available on dual tasking on a treadmill. The purpose of this study was to examine the effect of dual tasking using a treadmill desk on changes in cognitive performance and gait parameters in young adults (YA) and middle-aged adults (MA). **METHODS:** YA (n=24; mean age 21.1±1.6 yrs) and MA (n=25; mean age 53.0±5.3 yrs) were recruited to participate in this study. Participants completed five cognitive tests (Stroop Word Color Test, phoneme monitoring, typing test, Sternberg working memory test, and serial 7 subtractions) in a single task (ST) and dual task (DT) condition in a randomized and counterbalanced order. Participants were seated at a desk for ST and walked on a treadmill desk at self-selected speed (mean speed YA=1.5±0.4 mph; MA=1.4±0.5 mph) during DT. An OptoGait system recorded gait parameters of step length, stride length, and coefficient of variation. **RESULTS:** There were no significant differences in gait parameters or test scores in YA when comparing DT and ST conditions (p>0.05). MA performed worse on word recall score (89.7±11.3 vs 96.6±7.5%, p=0.03), typing speed (44.9±11.2 vs 49.9±13.3 wpm, p=0.00), and Sternberg reaction time (1.5±2.0 vs 1.0±1.9 s, p=0.00) during the DT compared to the ST condition. MA stride length decreased during DT in the Sternberg test (37.7±5.9 vs 36.5±5.3 in, p=0.01) and serial 7 subtractions (37.2±5.7 vs 36.5±5.3 in, p=0.00). MA showed detriments in reaction times on the Stroop test (0.8±1.2 vs 0.6±0.9 s, p=0.00) and Sternberg test (1.5±2.0 vs 0.9±1.5 s, p=0.02) and decreased word recall score (89.7±11.3 vs 97.5±7.0%, p=0.04) compared to YA during the DT condition. **CONCLUSION:** The impairments in gait and cognitive test scores in MA but not YA suggest that the ability to simultaneously process cognitive demands and treadmill walking requirements decreases with age. Using a treadmill desk might affect work-related performance or gait parameters in middle-aged adults.

The Effects of Postural Control Measures on Induced Slip Outcomes

Ariana Haynes¹, Tyler Donahue², Chris Hill², Caleb Williams³, Jeff Simpson⁴, Harish Chandar⁵, Chip Wade⁶, Abigail Johnson¹, Sydney Wilhoite¹, Kristen Neitz¹, Kelsey Lewis¹, Joshua Pascal¹, Andrew Crawford¹, Barry Munkasy¹, Li Li, FACSM¹, John Garner⁷, Dwight Waddell², Sam Wilson¹. ¹Georgia Southern University, Statesboro, GA. ²University of Mississippi, University, MS. ³LaGrange College, LaGrange, GA. ⁴University of West Florida, Pensacola, FL. ⁵Mississippi State University, Mississippi State, MS. ⁶Auburn University, Auburn, AL. ⁷Troy University, Troy, AL.
 Email: ah07573@georgiasouthern.edu
 (No relevant relationships reported)

Slips and falls are a major health concern in the United States. Injury incidence rates have increased in recent years and now the leading cause of non-fatal injuries and the third leading cause of fatal injuries in the U.S. are due to falls. During an unexpected slip, sensory information is used to elicit an appropriate recovery. Therefore, increased

fall risk has been associated with declines in sensory system integrity. Previous research has suggested that decreased balance scores were associated with more hazardous slips yet measures of postural control between individuals who fall or recover after an induced slip have not been investigated. **PURPOSE:** To examine differences in slip detection using postural control measures between individuals who fall or recover after an induced slip. **METHODS:** One hundred participants were recruited for this study. Standing postural control measures were recorded under six different sensory conditions: eyes open, eyes closed, eyes open with sway referenced vision, eyes open with sway referenced support, eyes closed with sway referenced support, and eyes open with sway referenced vision and support. Variables of interest were sway velocity components and the root mean square of the center of pressure (CoP) in the medial-lateral and anterior-posterior directions. After postural control testing, participants completed testing involving a normal gait and an unexpected slip trial. The slip was classified as either a fall or a recovery. Once classified, standing postural control measures were examined between groups using independent t-tests. Additionally, prediction equations for slip outcome were created using a binary logistic regression model. **RESULTS:** The final analysis sample included 73 participants, with 48 trials classified as recoveries and 25 trials as falls. Postural sway when the proprioceptive (OR = 0.02, 95% CI: 0.01-1.34) and vestibular (OR = 0.60, 95% CI: 0.26-1.39) systems were relied on were negatively associated with odds of falling while visual system reliance resulted in a positive association (OR = 3.18, 95% CI: 0.887-11.445). **CONCLUSIONS:** The data suggests that visual sensory information may have a greater influence on dynamic stability and slip outcomes. Additionally, postural control measures may provide insight into task selection during recovery.

Novel Evidence Of Cortical Control In Severe Slip Responses

Sam Wilson¹, Tyler Donahue², Chris Hill³, Caleb Williams³, Jeffrey Simpson⁴, Harish Chander⁵, Chip Wade⁶, Sydni Wilhoite¹, Kristen Neitz¹, Ariana Haynes¹, Joshua Pascal¹, Kelsey Lewis¹, Andrew Crawford¹, Barry Munkasy¹, Li Li, FACSM¹, John Garner⁷, Dwight Waddell¹. ¹Georgia Southern University, Statesboro, GA. ²University of Mississippi, University, MS. ³LaGrange College, LaGrange, GA. ⁴University of West Florida, Pensacola, FL. ⁵Mississippi State University, Mississippi State, MS. ⁶Auburn University, Auburn, AL. ⁷Troy University, Troy, AL. Email: sjwilson@georgiasouthern.edu
(No relevant relationships reported)

Slips and falls are a major cause of injury and death in the United States. During a human slip response, an ensemble of muscular activations appear in an attempt to maintain balance and prevent a fall. The slip response has several key events that appear reflexive in nature. Though, the temporal nature of these responses may suggest cortical involvement as well. Indeed, some other forms of postural perturbations have provided evidence of cortical control in the recovery response. However, there is little information regarding cortical contribution to the slip response. **PURPOSE:** To examine corticospinal activity in lower extremity slip recovery corrective responses across slip severity. **METHODS:** One hundred participants were recruited for this study, and after exclusions the final analysis included 73 participants. Participant's lower extremity gait kinematics, kinetics, and electromyography (EMG) on the quadriceps (Q), hamstrings (H), dorsiflexors (TA), and plantarflexors (MG) were collected during normal gait (NG) and an unexpected slip (US). The slip was classified based on slip severity, using heel slip distance, and velocity. Once classified, EMG spectral power was examined in the Piper frequency band between gait trials, and groups using a mixed model analysis of variance. **RESULTS:** Spectral power showed no differences in NG trials. However, spectral power in the Piper frequency band was increased in the Q and H, during the US trial for severe slips, but not minor slips. For the quadriceps, a significant gait by slip severity interaction was observed ($F(1,70) = 9.934, p = 0.002, \eta^2 = 0.124$). Simple effects revealed a significant increase in activation between normal gait and unexpected slips for those who experienced hazardous slips ($p < 0.001$), but no differences for non-hazardous slips ($p = 0.364$). For the hamstrings, a significant interaction was also observed ($F(1,70) = 5.076, p = 0.027, \eta^2 = 0.069$). The simple effects revealed a significant increase in activity between gait trials, in the hazardous slips ($p = 0.002$), but not in the non-hazardous slips ($p = 0.651$). **CONCLUSIONS:** We show here novel contributions of the corticospinal pathway to the slip recovery response, particularly in musculature used in the recovery response.

Influence Of Prediction Equations On The Produced Power In The Sit To Stand Movement

Christopher Marang, Robert Gregory, Marc Robertson, Robert Axtell, FACSM. Southern Connecticut State University, New Haven, CT. (Sponsor: Robert Axtell, FACSM)
(No relevant relationships reported)

The sit-to-stand movement (STS) has been used as a tool to evaluate both lower extremity power and function in elderly individuals. Field tests of lower extremity power specific to the STS provide practitioners with clinically meaningful insight into functional capacity across the lifespan. For these field tests to be a useful tool, normative values must be established across the age continuum. **PURPOSE:** To compare the mechanical power produced during a field-based STS test in young adults utilizing two different methods of analysis. **METHODS:** Eighteen participants (20.7 ± 3.0 yrs, 72.3 ± 14.7 kg, 1.70 ± 0.1 m) between 18 and 30 years performed three sets of five self-paced STS repetitions on two side-by-side force platforms, one for each lower extremity. Hip and knee angles were set at 90° with the feet positioned on the two force platforms; foot width was standardized based on the distance between the individual's right and left anterior superior iliac spines. Power was analyzed during the rising phase of the force-time curve using an established power equation ($E1, P = FxS/T$) and a modified power equation ($E2, P = FxS/T$); P = mechanical power, F = bodyweight, S = standing minus seated height, = femur length, T = time. Differences in mechanical power calculated by E1 and E2 were determined using a dependent t-test. A Pearson product moment coefficient of correlation (r) was used to examine the relationship between power calculated by E1 and E2. The level of significance was set at $p < 0.05$. **RESULTS:** The calculated power during the rising phase of the STS was significantly greater using E1 compared to E2 (350.96 ± 138.93 W vs. 344.28 ± 138.79 W, $p < 0.0001$). The two methods for calculating power demonstrated a strong correlation ($r = 0.99$). **CONCLUSION:** The two methods used to calculate power were shown to be highly related, demonstrating both are clinically appropriate for use in a field-based setting. This relationship showed that although the two methods provided different values of power, the power differences across all participants changed in the same manner independent of the method used. The difference in calculated power can be explained by the variation in S determination. The results of this study demonstrate that both equations allow for the accurate determination of mechanical power during the rising phase of a field-based STS test.

The Relationship between Cervical Tilt Angle and Upper Body Position in Upright and Slump Sitting

Sicong Ren¹, Ming Zhang², Weimo Zhu, FACSM¹. ¹University of Illinois Urbana-Champaign, Champaign, IL. ²The Hong Kong Polytechnic University, Hong Kong, Hong Kong. Email: sicongr2@illinois.edu
(No relevant relationships reported)

Malposition of the cervical vertebra caused by poor sitting postures could lead to the development of cervical musculoskeletal disorders. It has been well documented that there is a positive correlation between over-tilted angles and abnormal load-carrying on cervical vertebrae. However, intrinsic cervical angles are difficult to measure without computed tomography or magnetic resonance imaging. **PURPOSE:** This study aimed to assess the cervical tilt angle at the C5C4 level based on upper body position in both upright and slump sitting postures. **METHODS:** Eight participants (Male: $n = 4, 50\%$; Age: 26.0 ± 2.9 yr; Height: 171.9 ± 10.3 cm; Weight: 60.1 ± 11.8 kg) with no history of documented cervical injuries were recruited for this study. An eight-camera, infrared motion analysis system and two force platforms were used to capture the three-dimensional posture and ground reaction forces of a seated human. A musculoskeletal model with detailed neck constructed in the AnyBody Modelling System was used to calculate cervical tilt angles. The correlations between cervical tilt angle at the C5C4 level and sternoclavicular elevation and glenohumeral abduction were examined by sitting postures separately and combined. **RESULTS:** Correlations between C5C4 tilt angle and sternoclavicular elevation and glenohumeral abduction in upright and slump sitting are summarized below:

| | Sternoclavicular Elevation | Glenohumeral Abduction |
|------------------------------------|----------------------------|------------------------|
| C5C4 Tilt Angle in Upright Sitting | 0.587 | -0.340 |
| C5C4 Tilt Angle in Slump Sitting | 0.660 | -0.432 |
| Combined | 0.516 | -0.215 |

CONCLUSION. Overall, C5C4 tilt angle has a moderate and positive correlation with sternoclavicular elevation, but a low and negative correlation with glenohumeral abduction. Therefore, sternoclavicular elevation may be useful to predict the C5C4 tilt angle in upright and slump sitting.

The Effects of Shoe Type on Muscle Activity During Step Up and Step Down Motions
 Shayla Maniowabi-Huebner, Ashley VanSumeren, Sarah Breen. *Northern Michigan University, Marquette, MI.*
 (No relevant relationships reported)

Hiking is a popular activity with many health benefits. Evidence suggests that 75% of hiking related injuries are of the lower extremities and that footwear choice may play a role in these injuries. **PURPOSE:** To evaluate the connection between footwear choice and lower extremity muscle activity during step-up and step-down movements, specifically the vastus medialis (VM), tibialis anterior (TA), biceps femoris (BF), and gastrocnemius (G). **METHODS:** Eleven male and female hikers (26 ± 5 years, 80.3 ± 12.6 kg, 1.8 ± 0.08 m) performed three step-up and step-down trials on three AMTI force platforms in both hiking boots and hiking shoes. Footwear weights were standardized. Surface electrodes recorded EMG data of the four muscles of interest on the dominant leg during each trial. Maximal voluntary isometric contractions (MVIC) were conducted for each muscle and used to normalize EMG. Paired t-tests were used to compare differences in muscle activity between footwear. **RESULTS:** Mean EMG amplitude (% MVIC) of BF were 11.37 ± 5.65% in boots and 11.61 ± 5.93% in shoes. Mean EMG of G in boots were 27.08 ± 25.61% and 43.28 ± 44.30% in shoes. Mean EMG of VM in boots were 41.26 ± 18.53% and 41.34 ± 18.55% in shoes. Mean EMG of TA in boots were 16.83 ± 6.46% and 15.71 ± 5.59% in shoes. No significant differences were found in muscle activity between footwear. **CONCLUSION:** Muscle activation is not affected by footwear, therefore the user can choose either hiking boots or hiking shoes in a stepping task and not overwork any specific musculature. These results may be valuable for hikers, military personnel, or firefighters when choosing footwear.

Influence of Lower Extremity Strength on Chair Rise Functional Demand in Older Female Cancer Survivors
 Victoria M. Bandera, Dain P. LaRoche, FACSM. *University of New Hampshire, Durham, NH.*
 Email: vmb1005@wildcats.unh.edu
 (No relevant relationships reported)

Functional demand (FD) is the ratio of the muscular force required by a physical task to the maximal force capacity of the muscle, which is greater in older individuals. Measuring FD in older adult cancer survivors can determine whether functional activities, such as a chair rise, are more exhaustive than for healthy older adults without history of cancer diagnoses. **PURPOSE:** To quantify the differences in hip (HE) and knee extension (KE) strength, the primary muscles used to complete a chair rise, and FD during chair rise, between older female cancer survivors (CS) and older females with no history of cancer (NC). **METHODS:** Eleven NC (65.9 ± 6.6 yr, 75.4 ± 26.9 kg, 1.60 ± 0.04 m, 29.5 ± 10.8 kg·m⁻²) and nine CS who completed chemotherapy and/or radiation treatments within 10 years (57.1 ± 6.6 yr, 75.5 ± 23.1 kg, 1.68 ± 0.07 m, 27.0 ± 9.2 kg·m⁻²) performed 3 maximal isokinetic contractions on a dynamometer at 30 deg·s⁻¹ to measure HE and KE strength. Retroreflective markers were placed on the lower extremity using the Helen Hayes model and a 3D video motion capture system and an in-ground force plate were used to record kinematic and kinetic data during chair rise. The HE and KE moments during chair rise were calculated by inverse dynamics using Visual3D software; FD was calculated as the ratio of joint moment during chair rise to available strength and expressed as a percentage. Analysis of Covariance was used to compare NC and CS with age and BMI as covariates. Data are reported as estimated population means (95% CI) adjusted for age and BMI. **RESULTS:** KE strength was similar in CS, 1.20 Nm·kg⁻¹ (0.84-1.56 Nm·kg⁻¹), and NC, 1.67 Nm·kg⁻¹ (1.36-1.99 Nm·kg⁻¹, p=0.082). HE strength was lower in CS, 2.12 Nm·kg⁻¹ (1.59-2.64 Nm·kg⁻¹) than in NC, 3.01 Nm·kg⁻¹ (2.55-3.46 Nm·kg⁻¹, p=0.029). Peak knee FD was greater in CS, 131% (92-171%), than in NC, 51% (17-86%, p=0.012). Peak hip FD was similar in CS, 78% (28-128%), and NC, 41% (-2, 85%, p=0.31). **CONCLUSIONS:** Compared to NC, older female CS had significantly lower HE strength and greater knee FD during chair rise, and had a trend for lower KE strength and greater hip FD, which may help explain the greater fall risk and mobility limitation observed in this at-risk clinical population. Resistance training should be incorporated in cancer rehabilitation programs to increase strength and functional reserve capacity.

Reliability and Minimum Detectable Difference of Tibial Acceleration during Running
 Clare E. Milner, FACSM, Jillian L. Hawkins, Kevin Aubol. *Drexel University, Philadelphia, PA.*
 Email: clare.e.milner@drexel.edu
 (No relevant relationships reported)

Tibial acceleration is often measured in runners and may be related to injury risk. To evaluate differences between conditions, reliability and minimum detectable difference of common variables are needed. **PURPOSE:** To determine the test-retest reliability and minimum detectable difference of peak axial and peak resultant tibial acceleration during running in the laboratory and on a treadmill. **METHODS:** We recruited 19 runners (31 ± 6 years; 1.70 ± 0.08 m; 68.6 ± 11.6 kg; 10 women) who provided written informed consent. Tibial acceleration was collected at 1000Hz in the laboratory and 1023Hz on the treadmill via a research grade tri-axial accelerometer firmly attached to the anteromedial distal tibia during running at 3.0m/s. In the laboratory, foot contact was made on a synchronized force platform in 2 sessions for 5 trials each. Participants also ran on a treadmill for one minute following a self-directed warm up. Peak axial and peak resultant acceleration during stance were determined for 2 sets of: 5 steps in the laboratory, and both 5 and 10 steps on the treadmill. Interclass correlations (ICC(3,5) and ICC (3,10)) indicated reliability and minimum detectable differences were calculated. **RESULTS:** Test-retest reliability was excellent for both peak axial and peak resultant acceleration during laboratory and treadmill running. Minimum detectable differences were less than 2g. Averaging over 10 trials instead of 5 did not improve reliability.

Table 1: Reliability and minimum detectable difference for peak axial and peak resultant tibial accelerations during laboratory and treadmill running

| Variable | Mean (SD) (g) | ICC (95% CI) | Standard error of measurement (g) | Minimum detectable difference (g) |
|------------------------------------|---------------|---------------------|-----------------------------------|-----------------------------------|
| Peak axial acceleration | | | | |
| Lab 5 trials | 6.1 (2.0) | 0.988 (0.968-0.995) | 0.7 | 2.0 |
| Treadmill 5 trials | 6.1 (2.4) | 0.949 (0.833-0.982) | 0.7 | 2.0 |
| Treadmill 10 trials | 6.1 (2.4) | 0.963 (0.841-0.988) | 0.6 | 1.7 |
| Peak resultant acceleration | | | | |
| Lab 5 trials | 8.3 (3.2) | 0.945 (0.859-0.958) | 0.2 | 0.6 |
| Treadmill 5 trials | 8.5 (3.3) | 0.949 (0.833-0.982) | 0.5 | 1.5 |
| Treadmill 10 trials | 8.6 (3.3) | 0.963 (0.841-0.988) | 0.5 | 1.4 |

CONCLUSION: A difference of at least 1.5g for peak resultant acceleration and 2g for peak axial acceleration is needed to be sure that the difference exceeds measurement error. Smaller differences may simply be due to measurement error and may not reflect meaningful change.

Running For Two: A Case Study On Running Throughout Pregnancy
 Kara N. Radzak, Jessica Tom, Brianna Borgia. *University of Nevada, Las Vegas, Las Vegas, NV.*
 Email: kara.radzak@unlv.edu
 (No relevant relationships reported)

The American College of Obstetricians and Gynecologists supports physical activity during pregnancy. Healthy women with normal pregnancies can continue running, but only 31% run into their third trimester. Many physiological and anatomical changes during pregnancy, such as increased body mass, hyperlordosis, and ligamentous laxity, can alter movement. While pregnancy related gait changes in walking have been reported, how running is altered remains unknown. **PURPOSE:** This case study biomechanically examined a 32 year old woman running throughout her pregnancy. **METHODS:** Data collection occurred once every four weeks, from the 13th week of pregnancy, until the 39th week. The participant was medically cleared to continue running monthly. Lower body kinematics and kinetics were recorded using a motion

capture system while the participant performed five self-selected velocity trials over a force platform embedded walkway. **RESULTS:** Mean values were calculated for each variable of interest (Table 1). Pelvic motion changes from the second to third trimester were visually pronounced (Figure 1a-c). **CONCLUSION:** Changes in biomechanical variables were seen throughout pregnancy, but were pronounced from the second to third trimester. Altered movement patterns may be acquired to improve gait safety, dynamic stability, and counter pregnancy related anatomical changes.

| Variable | 3 months* | 4 months* | 5 months* | 6 months* | 7 months [†] | 8 months [‡] | 9 months [‡] |
|------------------------------|-----------|-----------|-----------|-----------|-----------------------|-----------------------|-----------------------|
| Self-Selected Velocity (m/s) | 3.64 | 2.64 | 2.89 | 2.70 | 2.14 | 1.79 | 1.40 |
| Stride Length (m) | 2.37 | 2.43 | 2.66 | 2.46 | 2.03 | 1.63 | 1.54 |
| Stride Width (m) | 0.05 | 0.07 | 0.07 | 0.10 | 0.09 | 0.13 | 0.11 |
| Ankle ROM during stance (°) | 49.07 | 42.38 | 39.73 | 42.18 | 36.11 | 43.44 | 29.36 |
| Knee ROM during stance (°) | 23.63 | 24.40 | 23.80 | 20.28 | 17.29 | 15.19 | 18.57 |
| Hip ROM during stance (°) | 35.32 | 38.13 | 43.45 | 40.66 | 37.07 | 32.29 | 22.19 |

Altered Lower Extremity Joint Work Profiles During Inclined Running At Iso-efficiency Speeds

Douglas W. Powell, FACSM¹, Tyler Standifird², Andrew Creer², Lauren Williams², Joseph Christensen², Max R. Paquette¹.
¹University of Memphis, Memphis, TN. ²Utah Valley University, Orem, UT.
 (No relevant relationships reported)

Inclined running is a common component of many runners' training programs in the form of hill repeats. Runners are often forced to slow their running pace, iso-efficiency speed (ISO), during inclined running to maintain their metabolic effort. Though commonly used in training, little is known regarding the changes in joint kinetics associated with running on an inclined treadmill at an ISO speed. **PURPOSE:** To evaluate changes in lower extremity joint work when running on increasing inclines at ISO speeds. **METHODS:** Eleven NCAA Division I runners performed five 5-second treadmill running trials during each of three ISO speed inclined conditions: 0% incline, 4% incline, and 8% incline. ISO speed was confirmed using oxygen consumption (VO₂) using indirect calorimetry. Kinematics and ground reaction forces were recorded simultaneously using an 8-camera motion capture system (100 Hz, Qualisys Inc.) and instrumented treadmill (1000 Hz, Bertec), respectively. Visual 3D was used to calculate ankle, knee and hip joint powers while custom software (MATLAB, MathWorks) calculated positive and negative joint work as joint power integrated with time. A repeated measures ANOVA with Tukey's post-hoc was used to determine the effect of treadmill incline on joint work. **RESULTS:** Negative ankle joint work increased while negative knee and hip joint work decreased with increasing treadmill incline (Table 1). Positive ankle and hip joint work increased while positive knee work decreased with increasing treadmill incline (Table 1). **CONCLUSIONS:** Our findings suggest that even at ISO speeds (i.e., reduced speeds to maintain effort), inclined treadmill running increases eccentric demands on plantarflexors, and concentric demands on knee and hip extensors. These data may support altered training prescriptions for athletes recovering from joint-specific muscular injuries to minimize training-related stresses placed on those tissues.

Table 1. Mean positive and negative ankle, knee and hip joint work values in the 0% Incline, 4% Incline and 8% Incline conditions.

| Joint | Negative | | | p-value | Positive | | |
|--------------|------------|------------|------------|---------|------------|------------|------------|
| | 0% Incline | 4% Incline | 8% Incline | | 0% Incline | 4% Incline | 8% Incline |
| Ankle (J/kg) | -4.0 (1.0) | -4.8 (1.3) | -5.2 (1.3) | <0.001 | 9.8 (3.2) | 10.9 (2.6) | 12.1 (2.2) |
| Knee (J/kg) | -6.2 (2.3) | -4.8 (2.0) | -3.8 (1.9) | <0.001 | 6.5 (2.4) | 5.6 (2.4) | 4.2 (2.3) |
| Hip (J/kg) | -8.6 (4.1) | -4.5 (3.9) | -2.9 (3.3) | <0.001 | 1.4 (0.3) | 2.8 (1.7) | 6.9 (2.7) |

Note: P-values represent omnibus testing while superscripts represent post-hoc testing. * - denotes significantly different than 0% Incline condition, † - denotes significantly different than 4% Incline condition.

The Association Between Trunk Lean and Running Kinetics in Competitive Distance Runners

Tyler J. Moffit¹, Derek N. Pamukoff². ¹California State University, Bakersfield, Bakersfield, CA. ²California State University, Fullerton, Fullerton, CA.
 Email: tmoffit@csub.edu
 (No relevant relationships reported)

The annual injury rate among competitive distance runners is over 50%. The vertical loading rate (vLR) and posterior ground reaction force (GRF) are associated with running-related injuries. Knee and lower limb injuries are the most commonly reported sites of injury. Greater forward trunk lean during running contributes to lower knee joint loading. However, it is unclear if trunk lean is associated with GRF characteristics. **PURPOSE:** The purpose of this study was to determine the association between forward trunk lean, GRF, and knee joint loading characteristics in competitive distance runners. **METHODS:** Thirty-six competitive distance runners were recruited for this study (72% male, age=20±1.5 years, height=1.74±0.02 m, mass=61.6±1.4 kg, forefoot strike=58%, 1500m personal best=83.3±3.5% world record). 3-Dimensional biomechanics were recorded during 5 running trials at self-selected speed (±5%) over a force plate. Forward trunk lean was calculated as the angle of the trunk segment relative to the vertical axis of the global coordinate system. GRF characteristics included instantaneous vLR, and peak vertical and posterior GRF. Knee joint kinetics included the peak internal knee extensor moment and sagittal plane knee joint stiffness. Partial correlation, controlling for speed and foot strike angle, was used to assess the association between trunk lean and gait kinetics. **RESULTS:** Trunk lean at foot contact (r=-0.45, p<0.01), Peak trunk lean (r=-0.38, p=0.03), and average trunk lean (r=-0.50, p<0.01) were negatively associated with vLR. Peak trunk lean was positively associated with vertical GRF (r=0.34, p=0.05). Trunk lean angles were not associated with posterior GRF, knee extensor moment, or knee joint stiffness. **CONCLUSIONS:** Runners with a lesser forward trunk lean angle had a greater vLR. Forward trunk lean may allow runners to position their foot under their center of mass to assist in attenuating vLR. Greater forward trunk lean was also associated with larger vertical GRF, which may allow runners to increase the total force imparted into the ground to propel themselves. Forward trunk lean is a modifiable gait characteristic that may be useful for injury prevention and performance enhancement of competitive distance runners.

Comparison of Running Power to Metabolic Cost at Various Submaximal Running Speeds and Inclinations

Randolph E. Hutchison, Scott Murr, Mason J. Coppi, Jake T. Ogden, Frank Lara, Lee F. Shearer. Furman University, Greenville, SC. (Sponsor: Anthony Caterisano, FACSM)
 Email: Randolph.Hutchison@furman.edu
 (No relevant relationships reported)

Running pace is one of the primary measures of running intensity, however, variations in grade limit quantifying intensity solely based on pace. With the advent of wearable running power meters, runners can address the external work stimulus inclusive of pace and grade. **PURPOSE:** The purpose was to compare running power measured by a Running Power Meter to the metabolic cost of running at different speeds and inclinations. **METHODS:** 5 collegiate cross country runners (male n=2, age=21±1.414 yrs, weight=69.8±3.960 kg, height=180±4.243 cm; female n=3, age=19.67±0.577 yrs, weight=54.07±2.290 kg, height=164.33±10.263 cm) participated in 10 trials of submaximal running at different speeds and inclinations. Subjects first completed an LT test to determine submaximal running speed with lactate collected and analyzed (Lactate Pro) via blood samples taken by finger prick. During subsequent submaximal running trials, metabolic and ventilatory measures were collected with a portable breath-by-breath analyzer (COSMED K5). Speed was controlled by a rider on a bicycle that was equipped with a speedometer. Spearman's Correlation was run between relative VO₂ values and running power for males, females, and all subjects. **RESULTS:** There is a statistically significant, strong positive correlation between relative VO₂ and running power for male (R=0.778; P<0.001), female (R=0.846; P<0.001), and combined male and female collegiate cross country runners (R=0.602; P<0.001). **CONCLUSIONS:** The results support that running power is positively related to VO₂, which may indicate a strong relationship with running intensity.

| Correlation between Running Power and VO2 | | |
|---|-------------------------|--------------|
| Subject | Correlation Coefficient | Significance |
| Male 1 | 0.963 | P<0.001 |
| Female 1 | 0.964 | P<0.001 |
| Male 2 | 0.988 | P<0.001 |
| Female 2 | 0.960 | P<0.001 |
| Female 3 | 0.782 | P<0.01 |
| Males | 0.778 | P<0.001 |
| Females | 0.846 | P<0.001 |
| Combined | 0.602 | P<0.001 |

Is Peak Resultant Acceleration A Substitute For Peak Axial Acceleration During Running?

Jillian L. Hawkins, Kevin Aubol, Clare E. Milner, FACSM.
Drexel University, Philadelphia, PA. (Sponsor: Clare Milner, FACSM)

(No relevant relationships reported)

Peak resultant and peak axial acceleration have been used interchangeably in the literature in relation to tibial load. However, they have not been directly compared to establish if this is appropriate.

PURPOSE: To determine the relationship between peak resultant acceleration and peak axial acceleration during running in healthy adults. **METHODS:** Nineteen (10 women) healthy rearfoot striking runners (mean (SD): age: 31 (6) years; height: 1.7 (0.1) m; weight: 68.6 (11.6) kg) who ran at least 10 miles per week were recruited. A tri-axial accelerometer was tightly secured to the distal anteromedial aspect of the right tibia of each runner. Participants completed 10 running trials over ground in the laboratory at 3.0 m/s ($\pm 5\%$). Accelerometer and force plate data were synchronized and recorded at 1000 Hz. Stance was determined from force plate data and peak resultant and peak axial acceleration were extracted for each step. A Wilcoxon-signed rank test determined any group difference between the variables. A simple linear regression was performed to assess the relationship between peak resultant acceleration and peak axial acceleration. **RESULTS:** Peak resultant acceleration (median (IQR)): 8.1 (5.4) g was significantly higher than peak axial acceleration (median (IQR)): 6.3 (3.6) g ($p<0.001$; ES=0.88). Peak resultant acceleration is higher because it is the combined acceleration from all three axes. From the regression, $R^2=0.566$ ($p<0.001$, 95%CI= 0.4 to 0.7), which indicates that peak resultant acceleration accounts for about half of the variance in peak axial acceleration. **CONCLUSION:** Since the peak resultant acceleration was consistently higher and only accounts for about half of the variance in peak axial acceleration, they should not be used interchangeably. Care should be taken when making comparisons between studies reporting tibial acceleration using different dependent variables.

Study funded by College of Nursing and Health Professions Research Award

Peak axial acceleration vs peak resultant acceleration during running

Postpartum Runners: Is There A Difference In Running Kinematics And Kinetics Compared To Controls?

Shefali Christopher, Rebba Maylone, Lindsey Bauer, Haley Barak, Srikant Vallabhajosula. *Elon University, Elon, NC.*
 (Sponsor: Stephen Bailey, FACSM)
 Email: schristopher3@elon.edu

(No relevant relationships reported)

A recent study found that 70% of elite female runners ran during their pregnancy. Most resumed running within 2 months after childbirth. Despite the increased prevalence of running in women before and after childbirth, there is very little research on the physical changes and impairments experienced by these runners. Pregnancy and childbirth lead to well-established unique anatomical and physiological changes that more than likely influence running kinematics (joint excursion) and kinetics (landing forces). No studies have investigated running gait in this population; however, a few studies have reported the presence of pain in this population. **PURPOSE:** To identify differences in running kinematics and kinetics between postpartum (PP) women and controls. **METHODS:** Four PP and 4 age-matched women without children (CON) ran on a treadmill at their self-selected speed. All participants were pain-free. Five 5s trials were collected after warm-up. A 3D motion capture system was used to determine hip and knee joint angles. Participants also performed 6 overground running trials. Impact peak and vertical loading rates were calculated from the ground reaction forces during overground running. An independent samples t-test was used to compare the 2 groups. **RESULTS:** Hip range of motion (CON: $48.63\pm 7.68^\circ$; PP: $52.67\pm 4.65^\circ$), Knee range of motion (CON: $70.26\pm 10.57^\circ$; PP: $78.74\pm 16.70^\circ$), peak knee flexion during stance (CON: $43.48\pm 6.40^\circ$; PP: $38.47\pm 8.91^\circ$), peak impact force normalized to bodyweight (CON: 1.90 ± 0.47 ; PP: 2.04 ± 0.50), average vertical loading rate (CON: 55.85 ± 15.69 s⁻¹; PP: 55.47 ± 25.60 s⁻¹) were not significantly different between the groups. **CONCLUSION:** Though there were no significant differences, postpartum runners had greater hip and knee range of motion but lesser peak knee flexion during stance compared to age-matched controls. Further, the PP group had similar vertical loading rates but greater variability in their rate of loading when compared to their age-matched controls. These preliminary findings could indicate that runners two months into postpartum show similar running biomechanics compared to age-matched women who did not have a child. These results could have implications on guidelines for postpartum women returning to running. A larger sample size is required to confirm these findings.

Loud Music Via Earphones Alters Men's Running Mechanics, Not Women's: The Impact Factor Trial

Andrea Manca¹, Lucia Cugusi², Giorgio Altavilla³, Eleonora Zocca³, Martina Zocca³, Francesco Bussu⁴, Luca Pomidori³, Michele Felisatti³, Franca Deriu¹. ¹University of Sassari, Sassari, Italy. ²University of Cagliari, Cagliari, Italy. ³Centro Esercizio Vita, Ferrara, Italy. ⁴Otolaryngology Division, Azienda Ospedaliero-Universitaria di Sassari, Sassari, Italy.
 Email: andmanca@uniss.it

(No relevant relationships reported)

PURPOSE: Listening to music during exercise yields a number of positive and measurable physiological effects. However, to date the possible influence of music listening on the amount of impact forces during running has not been investigated yet. The present pilot trial examined the effects of different volumes of background music on jogging and running mechanics. **METHODS:** A total of 50 recreationally active healthy volunteers (22 women, 28 men; age 23 ± 7 yrs; weight 69.7 ± 11.6 kg) performed 2-minute running stints on a sensorized treadmill integrated with a 3D-gait analysis system over 3 different randomly assigned experimental conditions (running while listening via earphones to 80- or 85-dB music, or no music) at 3 different velocities (8, 10 and 12 km/h). Measures of average and peak ground pressure force along with kinematic and kinetic parameters describing the running mechanics were recorded by the sensorized treadmill during the experimental conditions. **RESULTS:** Running while listening to 85-dB music resulted in significantly greater impact loading at 8 ($p=0.0005$) and 10 km/h ($p=0.04$) but not at 12 km/h ($p=0.35$) and not with a volume of 80-dB. Gender-based analysis revealed significant Condition*Gender interactions only for the comparison "85-dB music" versus "no music". After correcting by body weight, Bonferroni-adjusted comparisons revealed significant music-induced increases in impact loading only for the male group at 8 km/h (men: $+4.1$ kg/cm², $p<0.0005$; women: $+0.8$ kg/cm², $p=0.47$) and 10 km/h (men: $+3.3$ kg/cm², $p=0.004$; women: $+0.8$ kg/cm², $p=0.51$) but not at 12 km/h. Gender-based comparisons also revealed in the female group significantly reduced knee ROM at 8 km/h (-5° , $p=0.008$) and stride length both at 8 (-5 cm; $p<0.0005$) and 10 km/h (-4 cm; $p<0.0005$). **CONCLUSIONS:** Data indicate that, in physically active male subjects, running while listening to loud music results in increased impact forces. This is not the case for women, who showed no changes in impact in response to music. We offer that the lack of effect of music in women may be related to their different morphology of pelvis and lower limb,

which may be accounted for the significant changes in kinematic and kinetic running parameters observed. The present findings introduce music listening during exercise as a new potential risk factor for injury.

Effects of Spinal Coupling and Marker Set on Tracking of Spine Models During Running

Nelson A. Glover¹, Rumit S. Kakar², Ajit MW Chaudhari, FACSM¹. ¹The Ohio State University, Columbus, OH. ²Ithaca College, Ithaca, NY.
Email: glover.nelson.a@gmail.com
(No relevant relationships reported)

Running is a complex motion producing many muscle and joint forces that cannot be directly measured. Musculoskeletal simulation enables estimation of these muscle and joint forces, but to have confidence these simulations and processes must be biofidelic. Most models include a rigid spine, but prescribing motion with a coupled spine model may allow more accurate inverse kinematics tracking of experimental data and allow truer resulting intervertebral force and muscle activation estimations. **PURPOSE:** To determine the effects of spinal coupling and the quantity of experimental data available on the tracking of experimental running data through use of a rigid and a coupled lumbar spine model. **METHODS:** Two subjects ran on a treadmill and 3 motion capture trials at different speeds were collected with 13 markers placed on the spine and 46 other markers placed over the rest of the body. The Full Body Lumbar Spine model has 30 degrees of freedom (DoF), including a lumbar spine with coupling constraints resulting in a net of 3 DoF among those 5 vertebral bodies. Two iterations of this model were used, one with the coupling of the lumbar spine enabled (CS), and one where the coupling was locked resulting in a rigid lumbar spine (RS). Inverse Kinematics (IK) was executed using six different combinations of spinal markers as tracking inputs for both models. The marker error after IK was computed at each frame, and the root-mean-square (RMS) error computed for the full trial. Effects of the model, subset of tracking markers used as input, and subject were analyzed with multiple regression and differences between tracking subsets were analyzed with Tukey pairwise comparisons. **RESULTS:** Choice of model (CS or RS) had a significant effect on the RMS error of the markers ($p < 0.001$). The average RMS error across all spinal markers was 1.35 ± 0.30 cm for the CS vs. 1.64 ± 0.29 cm for the RS. The multiple regression showed a significant effect of tracking subsets, and subject ($p < 0.001$). Tukey pairwise comparisons showed that the two best tracking subsets were one weighting all 13 spinal markers and one weighting two lumbar markers (L2, L4), two thoracic markers (T10, T4), and the C7. **CONCLUSION:** The CS model exhibits lower RMS errors than the RS model, and this error can be further minimized by the inclusion of additional thoracic and lumbar spine markers.

Does Step Rate Affect Running Injury Incidence? An Observational Study with 12-Month Follow-Up

ELIZA SZYMANEK¹, Erin Miller², Amy Weart², Donald Goss². ¹Madigan Army Medical Center, Tacoma, WA. ²Keller Army Community Hospital, West Point, NY.
(No relevant relationships reported)

PURPOSE: The primary aim of our study was to observe preferred step rate in military runners and observe injury incidence over one calendar year. **METHODS:** Subjects were recruited prior to the Army Physical Fitness Test (APFT) at West Point, NY and asked to run at their self-selected pace for a timed 2-mile event. Two-dimensional frontal plane video was collected during over ground running from two stationary high-speed cameras sampling at 30 Hz to assess preferred step rate. One-year clinical injury surveillance was conducted among all runners with a full medical record review using the Armed Forces Health Longitudinal Technology Application (AHLTA), an electronic medical record system. Sub-clinical injuries for which medical treatment was not sought were collected via semi-monthly email surveys over one year. Combined clinical and sub-clinical injury incidence was assessed among runners who completed all email surveys over the course of one year. **RESULTS:** Overall, 372 runners (mean age 22.6 ± 6 years, height 163.8 ± 36.8 centimeters, weight 78.5 ± 30.4 kilograms) participated in this study. Out of 372 runners, 16 sustained a clinical injury. Mean step rate for healthy runners was 173.6 and mean step rate for clinically injured runners was 172.7 steps/min. An independent t-test comparing step rate of clinically injured and non-injured runners yielded a non-significant p value: $p = 0.773$. 95 out of 372 runners completed all 4 sub-clinical injury surveys (95/372 = 26%). Out of 95 runners, 19 sustained a clinical or sub-clinical injury. An independent t-test comparing step rate of injured and non-injured runners yielded a non-significant p-value = 0.08, with a mean of 174.5 ± 12.3 for the uninjured group and a mean step rate of 172.4 ± 8.2 for those in the combined injury group. These results demonstrate no clinically meaningful or statistically significant difference in step rate with clinical or sub-clinical injury risk in our population. **CONCLUSIONS:** In this study, self-selected step rate during a timed 2-mile APFT in Department of Defense runners did not influence lower extremity injury rates. Future

studies are needed to further investigate the relationship between step rate and lower extremity injuries, and whether step rate can be a useful screening tool to prevent running related injury.

Comparisons of Running Mechanics Between Injured and Non-injured Cross-country Runners

Julien Mihy, Kristyne Wiegand, Julia Freedman Silvernail. University of Nevada, Las Vegas, Las Vegas, NV. (Sponsor: John Mercer, FACSM)
(No relevant relationships reported)

PURPOSE: The purpose of this study was to compare ankle power, peak plantarflexion moment, and ankle range of motion (ROM) between injured and uninjured Division-I cross-country athletes. **METHODS:** Six Division-I female cross-country athletes (height 164.7 ± 4.1 cm; weight 52.0 ± 3.1 kg) reported prior to the start of the cross-country season. Upon providing informed consent, athletes completed 5 running trials at a preferred pace over a 15-m runway in a laboratory equipped with ten 3D motion capture infrared cameras. Kinetic data were collected using three embedded force platforms within a 15-m runway. Ankle ROM, peak plantarflexion moment, and average ankle plantarflexion power were calculated. Injury reports were obtained from the team's certified athletic trainer at the end of the season. These reports allowed for the stratification of athletes into injured and uninjured groups. Data from six athletes were used for the current analysis, thus Hedges' *g* measures were used to identify effect size. **RESULTS:** Three athletes sustained left foot injuries during the season. Injury status had a small effect prospectively on plantarflexor power ($g=0.25$) and ankle ROM ($g=0.25$), and a medium effect on peak plantarflexor moment ($g=0.68$) of the injured ankle. Injured athletes exhibited lower magnitudes of the variables of interest compared to uninjured athletes: average plantarflexor power (274.8 ± 53.5 and 306.1 ± 101.4 Nm/s respectively), less ankle ROM (41.5 ± 4.3 and $44.1 \pm 8.3^\circ$), and lower peak plantarflexor moments (124.1 ± 12.3 and 140.0 ± 17.8 Nm). **CONCLUSIONS:** Based on the results of the current study, the measured variables, particularly peak plantarflexion moment, may be of interest when investigating foot injury risk. The athletes in the current study may already be altering their motion to protect the at-risk limb. Longitudinal studies with additional data points and robust sample sizes are necessary to determine changes in running gait which may indicate increased risk of injury. This information has the potential to inform pre-screening gait analyses and subsequent coaching and clinical interventions.

Achilles Tendon Stress and Backward Running

Naghme Gheidi, UWL, LA CROSSE, WI. (Sponsor: Tom W Kernozek, FACSM)
Email: ngheidi@uwlax.edu
(No relevant relationships reported)

Naghme Gheidi, Thomas W. Kernozek, Alexis. Mehr, Lauren Strommen, Alexis Mehr, Carolyn Apfelbach, Drew Rutherford. University of Wisconsin-La Crosse, La Crosse, WI.
Backwards running (BR) has a greater cardiovascular demand and requires greater balance compared to forward running (FR). Previous literature has reported a lower patellofemoral joint compressive forces during BR. Therefore, BR has been recommended as a good rehabilitation exercise for patellofemoral pain patients as an intermediate progression from walking to FR. However, the effects of BR on Achilles tendon (AT), a common site of running injury, has not been investigated. To our knowledge, there have been no studies conducted comparing AT stress between FR and BR. **Purpose:** Identify differences in AT stress during FR and BR patterns. **Methods:** 22 healthy males (Age: 21 ± 1.6 years, Height: 181.4 ± 6.6 cm, Mass: 77.92 ± 7.12 kg) participated. Ultrasound imaging of AT cross sectional area (CSA) was measured with the ultrasound probe placed transversely between medial and lateral malleoli with the dominant ankle in a neutral position. After a 5 minute warm-up to familiarize themselves with the different running patterns, each performed 5 trials of both FR with a heel strike pattern and BR on a 20 meter runway with a running velocity between 2.8-3.4 m/s. Kinematic data were collected using a 15 camera motion capture system with a capture rate of 180 Hz using 47 reflective markers. Ground reaction force data were collected at 1800 Hz using a force platform. Human Body Model (HBM) was used to estimate muscle forces through static optimization based on inverse dynamics. AT force was determined from summing medial and lateral gastrocnemius and soleus muscle forces. AT stress was estimated by dividing AT force by AT CSA. Multivariate repeated measures analysis of variance was performed with an alpha value set to 0.05. **Results:** AT stress, force, ankle range of motion, and plantar flexor moments were greater during BR ($p < 0.001$). **Conclusion:** Higher AT loading occurred during BR compared to FR. The increased AT force production and AT stress during BR may prove to be problematic as a rehabilitation exercise for individuals experiencing AT related pathologies.

Impact Of Footwear On Running Mechanics In Older Individuals: A Pilot Study
 Brianne Borgia, Kara N. Razak, Julia Freedman Silvermail.
University of Nevada, Las Vegas, Las Vegas, NV. (Sponsor: John Mercer, PhD, FACSM)
 Email: borgia@unlv.nevada.edu
 (No relevant relationships reported)

While previous investigations have extensively examined running biomechanics in different types of footwear, there is a paucity of work examining these differences in an older habitual running population. **PURPOSE:** The purpose of this study was to examine the effects of maximalist and conventional footwear on running mechanics in older runners. **METHODS:** Five participants (Age: 58.8 ± 6.72 years; BMI: 25.14 ± 2.18; Miles/week: 24.3 ± 16.7) participated in this preliminary investigation. Participants were provided with a neutral laboratory shoe and a maximal cushioning laboratory shoe in their self-reported size. In addition, participants were asked to bring a pair of their own running shoes to represent a third footwear condition. Shoe characteristics are shown in Table 1. Running kinematics were captured using a 10-camera motion capture system while participants ran at a controlled pace of 4.0 m/s (± 5%) over a 10-m runway with force platforms collecting kinetic data. Participants ran in each of the three footwear conditions, the order of which was randomized. Five successful trials from each condition were chosen for analysis. A one-way repeated measures ANOVA assessed differences in mean kinematic and kinetic variables of interest between shoe conditions ($\alpha < 0.05$). **RESULTS:** Mean values for shoe characteristics and gait variables are shown in Table 1. **CONCLUSION:** Preliminary data shows no differences between footwear conditions, suggesting that participants maintain their preferred movement patterns in all three shoes. As the study continues we will be able to ascertain whether this lack of difference is a result of our small current sample size or reflective of the participant's adaptations while running.

| Variable | Neutral Shoe | Maximal Shoe | Own Shoe |
|-----------------------------|------------------|------------------|------------------|
| Shoe Characteristics | | | |
| Material Thickness (mm) | 32.18 ± 0.94 | 41.51 ± 1.107 | 29.94 ± 7.73 |
| Peak g | 10.13 ± 0.02 | 8.52 ± 0.21 | 11.48 ± 3.54 |
| Peak Force (N) | 844.37 ± 2.47 | 710.70 ± 17.93 | 956.89 ± 295.04 |
| Time to Peak Force (ms) | 19.97 ± 0.48 | 23.51 ± 0.72 | 17.43 ± 3.86 |
| Kinematics | | | |
| Ankle ROM (°) | 46.85 ± 8.69 | 41.63 ± 7.34 | 44.57 ± 8.62 |
| Knee ROM (°) | 29.96 ± 5.69 | 29.68 ± 4.81 | 30.13 ± 5.26 |
| Hip ROM (°) | 25.99 ± 6.78 | 27.09 ± 6.87 | 25.06 ± 8.06 |
| Ankle angle at IC (°) | 1.13 ± 8.26 | 4.17 ± 10.89 | 3.72 ± 6.73 |
| Knee angle at IC (°) | 23.41 ± 4.31 | 19.31 ± 5.34 | 23.21 ± 5.97 |
| Hip angle at IC (°) | 16.24 ± 7.69 | 12.57 ± 9.93 | 13.61 ± 7.41 |

An Investigation of Factors Affecting Dynamic Postural Stability in Collegiate Cross Country Runners
 Emily A. Fonke¹, David A. Guthrie¹, Andrew C. Montenyohl¹, Srikant Vallabhajosula¹, Timothy C. Sell, FACSM², Mallory Flaherty³, Shefali M. Christopher¹. ¹Elon University, Elon, NC. ²Duke University, Durham, NC. ³Duke University, Durham, NC.
 (Sponsor: Dr. Timothy Sell, FACSM)
 Email: efonke@elon.edu
 (No relevant relationships reported)

Injury rates for NCAA cross country runners between 2009 and 2014 were 4.7-5.9/1000 athlete exposures. Prevalence of running-related injuries in the general population has been shown to be between 18-92%. Injury could lead to impaired balance which is a common aspect of return-to-sport rehabilitation programs, and various methods of its assessment have been proposed. The Dynamic Postural Stability Index (DPSI) was introduced to measure variability in tri-axial ground reaction forces during specific tasks. DPSI has been shown to be increased in injured runners and predict athletic performance in soccer players. DPSI has been correlated to ankle range of motion and strength in military personnel. These variables have not been measured in healthy collegiate runners. **PURPOSE:** To investigate how previous injury affects DPSI and explore relationship between ankle range of motion and strength with DPSI in collegiate runners. **METHODS:** Twenty-seven Division I collegiate cross country athletes (age: 19.8±1.3 years) participated. Those with an injury in the past 3 years were categorized in the injured group (IG). Athletes jumped over a hurdle on to a force

plate and landed on a single leg. Three trials were performed on each leg. DPSI was calculated for the first 3s after landing. Ankle range of motion was assessed via active dorsiflexion and gastrocnemius length measurement. Ankle and hip strength were measured using a handheld dynamometer. An independent samples t-test was used to determine differences in DPSI between IG and uninjured group (UG). Pearson's correlation coefficient was used to determine relationships between DPSI and other variables. **RESULTS:** No significant difference was found for DPSI on left (IG: 0.30±0.03 vs. UG: 0.32±0.04) and right (IG: 0.30±0.03 vs. UG: 0.31±0.03) sides. There was a significant moderate negative correlation between dorsiflexion range of motion and DPSI (right side $r = -0.605$, $p = 0.001$; left side $r = -0.452$, $p = 0.001$). There were no correlations between strength and DPSI except for right inversion strength and right DPSI ($r = 0.446$, $p = 0.020$). **CONCLUSION:** DPSI seems to be influenced to a greater extent by ankle dorsiflexion than strength or previous injury in a collegiate running population; therefore, improving ankle dorsiflexion may be used as a rehabilitation strategy to improve DPSI.

Relationship between Stance Frontal Plane Kinematics and Initial Impact forces in Runners: Asymmetry Implications
 Deborah Fortino, Amanda Leon, Monique Mokha. Nova Southeastern University, Ft. Lauderdale, FL.
 Email: df1021@mynsu.nova.edu
 (No relevant relationships reported)

Rearfoot eversion (REV) and contralateral pelvis drop (CPD) play a crucial role in force absorption at impact during running. Controlling and adequately absorbing the repetitive vertical ground reaction force (vGRF) at impact is essential in injury prevention. **PURPOSE:** This study aimed to examine the relationships between vGRF and REV, and vGRF and CPD bilaterally in collegiate runners. **METHODS:** Eleven asymptomatic (5 females, 6 males) NCAA Division II cross country runners (age, 19.1 ± 1.1 yrs; height, 174.2 ± 11.2 cm; mass 62.2 ± 6.2 kg; 38.3 ± 15.9 miles/wk, treadmill speed, 3.6 ± 0.5 m/s) underwent 3D motion analysis during a 7 minute steady state run on an instrumented treadmill. vGRF, REV and CPD were evaluated bilaterally for association via Pearson Correlation coefficients, $p < 0.05$. **RESULTS:** Mean (±SD) peak angles of REV and CPD, and vGRF during left stance were 3.6 ± 6.5°, -5.4 ± 3.8°, and 1.8 ± 0.6 body weights (BW), respectively. Mean peak angles of REV and CPD, and vGRF during right stance were 2.51 ± 2.5°, -4.9 ± 4.9°, and 1.6 ± 0.4 BW, respectively. Significant high negative correlation was found for REV and vGRF during left stance [$r(9) = -.967$, $p = 0.03$] while CPD and vGRF during right stance were significantly highly positively correlated [$r(9) .714$, $p = 0.02$]. **CONCLUSION:** Despite the low number of subjects, we conclude that frontal plane kinematics are associated with impact force magnitude during running, and the associations appear to be asymmetrical necessitating a bilateral examination of running mechanics.

Effect Of Arch Characteristics On Pain In Minimally-shod vs Traditionally Shod Runners
 Jean L. McCrory, FACSM¹, Lauren E. Davis¹, Lauren K. Cline¹, Erica M. Casto². ¹West Virginia University, Morgantown, WV. ²University of Massachusetts Amherst, Amherst, MA.
 Email: jlmccrory@hsc.wvu.edu
 (No relevant relationships reported)

Minimalist running became popular due to the purported rationale of lowering overuse injury rates. The efficacy of wearing minimalist shoes to prevent injury has been greatly debated. We previously reported that arch height (pes cavus, normal, pes planus) influences lower extremity pain in minimalist runners; however, no clear relationship has been established between either arch height index (AHI) or arch rigidity index (ARI), running shoe type, and pain. The **PURPOSE** of this study was to examine self-reported pain in the lower limbs in minimally and traditionally shod runners with various AHIs and ARIs. **METHODS:** Following consent, 60 experienced runners (age 26.88 ± 9.2 yrs, hgt 171.6 ± 9.8 cm, mass 68.7 ± 15.1 kg, gender: 40F/20M) completed a visual analog scale (VAS) about pain in five common sites of injury: knee, ankle, calf, shin, and foot (VAS ≥ 3/10 was considered pain). AHI was categorized as high (n=30), normal (n=60), and low (n=30). ARI was categorized as rigid (n=30), normal (n=60), and flexible (n=30). A series of 3-factor chi-square analyses determined if shoe type (minimalist, traditional) and AHI (high, normal, and low arch) were related to overall and site specific pain (yes, no). ($\alpha = 0.05$). Additional 3-factor chi-square analyses determined if ARI (rigid, normal, and flexible) and shoe type (minimalist, traditional) were related to pain (yes, no). ($\alpha = 0.05$). **RESULTS:** More minimalist runners with a normal AHI (70.%; $p = 0.028$) reported pain in at least one site when compared to traditional runners with a normal AHI (40.0%; $p = 0.028$). All minimalist runners with a rigid arch reported pain in at least one site (100%; $p = 0.003$) while reported pain in runners in traditional shoes was less common (28%; $p = 0.003$). However, the interaction between site specific pain, arch characteristics, and shoe type

is not as clear as the results varied between the different AHI/ARI, shoe type, and site specific pain combinations. **CONCLUSIONS:** Generalizations about site specific pain in minimally or traditionally shod runners with high/low or flexible/rigid arches are difficult because the results are combination specific. Runners with a rigid arch may not be able to absorb ground reaction forces as well when wearing minimal shoes and may fare better in a traditional shoe that offers more support during ground contact.

Impact of Progression Run on Sagittal Plane Stance Phase Kinematics

Jordan Garman¹, Jeff T. Wight¹, Jaclyn A. O'Loughlin¹, David R. Hooper¹, Michelle C. Boling², Ryan S. Sloan¹. ¹Jacksonville University, Jacksonville, FL. ²University of North Florida, Jacksonville, FL.
 Email: runjordanrun@gmail.com
 (No relevant relationships reported)

The impact of fatigue on distance running kinematics is commonly studied by having runners complete exhaustive runs that alter joint kinematics quite dramatically. In this study, we attempt to assess minor changes that occur during a non-exhaustive progression run, by comparing sagittal plane joint-angle plots for the entire stance phase. **PURPOSE:** Compare baseline and final stance phase kinematics for a 16-minute treadmill progression run to determine if there are significant differences among the hip, knee and ankle. **METHODS:** Nineteen runners participated (18-45 years). Kinematic data were collected using 6 Vicon motion-analysis cameras. During testing, baseline data were collected during a 4-minute run at self-selected marathon pace. Then, a 16-minute progression run was completed, that ended at marathon pace. The first 10 clean strides were analyzed during the last minute of the 4-minute run and the last minute of the 16 minute progression run. Stance phase data for each stride was normalized to 101 points. Average joint angle curves for the baseline run were compared to those from the end of the progressive run (for all 101 points). The mean difference score was calculated to quantify kinematic change for the entire phase. Parvo metabolic testing was completed simultaneously to confirm that the progression run caused the heart rate and VO₂ to increase significantly. A one-way ANOVA was used to test for joint differences. **RESULTS:** Kinematic change was calculated for the hip (1.9±1.0°), knee (3.4±2.7°) and ankle (1.8±0.8°). There was a significant joint difference (p < 0.05). Post-hoc analysis revealed the knee kinematic change to be significantly greater than the hip and ankle. **CONCLUSIONS:** The submaximal progression run appeared to alter knee kinematics the most. Overall, the kinematic changes were minor, but it is important to note that the knee changes were approximately 80-85% greater than the hip and ankle. This analysis may help to better understand performance and/or injury.

Effects Of Assistance And Resistance Elastic Bands On Short Distance Sprinting In Women

Kailey Goins, Bryan Riemann. Georgia Southern University, Savannah, GA.
 Email: krgoins5@gmail.com
 (No relevant relationships reported)

Despite the prevalence using resistance bands to add resistance or assistance to sprinting, there is little research to validate the use as a training modality. **PURPOSE:** To determine the effects of elastic resistance and assistance on forward and backward sprinting velocity, stride time and stride length. **METHODS:** Eight high-school and college (19.9±3.5 years) women soccer players voluntarily ran six maximal effort 10m forward and backward sprints under three conditions, resistance, assistance and body weight. During the resistance/assistance conditions, 3m elastic bands (Super Bungie Cordz, West Warwick, RI), marketed as providing 333N of force when fully stretched, were secured to a pelvic belt. During the sprints, bilateral lower extremity kinematic data was recorded with custom footswitches embedded in standardized laboratory shoes (Asics T2F9N) indicating ground contact/off. Sprinting velocity, stride time and stride length were computed for each sprint in the same 1.5m space relative to the start position. Separate direction by condition repeated measures analysis of variance for each outcome measure were followed by simple main effect post hoc tests. **RESULTS:** Sprint direction had significantly different effects on sprint velocity (P<.001, η_p²=0.746), stride time (P=.007, η_p²=0.504), and stride lengths (P<.001, η_p²=0.760) between the three conditions. Post hoc results are provided in Table 1. **CONCLUSIONS:** When sprinting with only body weight, similar characteristics exist in each direction, whereas the effects of sprinting with resistance and assistance was different between the directions. By quantifying the changes in sprinting velocity and stride time/length with elastic resistance and assistance, these results provide practitioners with insight regarding training specificity.

Physiological and Biomechanical Differences Between a Traditional Treadmill and a 360 Degree Virtual Reality Treadmill

Jessica L. Kutz, Alyssa Carter, Austin McCarron, Andrew Sartain. Shenandoah University, Winchester, VA. (Sponsor: Jody Greaney, FACSM)
 Email: jessica.kutz21@gmail.com
 (No relevant relationships reported)

Virtual reality opportunities are booming as technology has advanced to provide a truly immersive experience. Soon virtual reality exercise experiences may be readily available to the public; thus, the exercise equipment that companies produce need to be assessed for use and safety. **PURPOSE:** Fifteen college students (8 women, 8 men; 20 ± 1 years old) walked for 5 minutes on a traditional treadmill (TT) and a 360-degree virtual reality treadmill (VR) with no headset to determine the physiological [heart rate (HR), oxygen consumption (VO₂), rate of perceived exertion (RPE), respiratory exchange ratio (RER)] and biomechanical [step rate (SR), step length (SL), knee angle (KA), tilt] differences at self-selected paces as well as to a pace of 97 steps per minute set by a metronome (TTM vs VRM). **RESULTS:** VO₂ (TT:11.6 ± 1.2 vs VR:16.8 ± 3.5 ml/kg/min, p < 0.005), RER (TT:0.81 ± 0.5 vs VR:0.89 ± 0.5, p < 0.005), HR (TT:91.3 ± 16.3 vs VR:113.1 ± 22.3 bpm, p < 0.005) and RPE (TT:2.1 ± 0.8 vs VR:4.7 ± 1.5, p < 0.005) were all significantly lower while walking on a traditional treadmill (TT) compared with a VR360 treadmill (VR) at a self-selected pace. This same pattern was observed when asked to walk at a specific cadence (97 steps/min) except RER was not different between the traditional treadmill and the VR360 treadmill (TTM: 0.89 ± 0.05 vs VRM: 0.94 ± 0.06, p=0.146). SR was significantly higher on the traditional treadmill (TT:107.1 ± 6.0 vs VR:76.9 ± 14.8 steps/min, p < 0.005), as well as SL (TT:0.42 ± 0.07 vs VR:0.22 ± 0.14 m, p < 0.005). KA was significantly lower on the VR360 treadmill, forcing a more knock-kneed walking position (TT:174.2 ± 3.9 vs VR:139.9 degrees, p < 0.005) The 360 treadmill induced a bent over position, causing a significantly greater tilt (TT:175.8 ± 3.0 vs VR:156.5, p < 0.005). **CONCLUSION:** Walking on a virtual reality treadmill is more strenuous from a physiological and biomechanical perspective than a traditional treadmill, at a self-selected and forced pace. Shorter exercise bouts using virtual reality treadmills may be a more practical use of this exercise modality.

Not All Forefoot Striking Is Equal

Alessandra Matias¹, Jereme Outerleys¹, Isabel Sacco², Irene Davis, FACSM¹. ¹Spaulding Running National Center, Cambridge, MA. ²Faculdade de Medicina FMUSP, Universidade de Sao Paulo, Sao Paulo, Brazil. (Sponsor: Irene Davis, FACSM)
 Email: alessandra.matias@usp.br
 (No relevant relationships reported)

Rearfoot strike (RFS) runners typically exhibit an impact peak in their vertical ground reaction force caused by heel impact. This impact is associated with high load rates that have been linked to running injuries. The vast majority of forefoot strike (FFS) runners do not exhibit this impact peak and have significantly lower load rates compared with RFS runners. However, some FFS runners do exhibit an impact peak and load rates similar to RFS. The heel descent after initial contact in FFS could help further explain this phenomenon. **PURPOSE:** To investigate the relationship between heel kinematics and vertical average loading rate (VALR) in FFS runners. **METHODS:** 30 habitual FFS runners from an ongoing study were included (5F, 25M; age: 35.6±9.3). Ground reaction forces and heel kinematics were collected on an instrumented treadmill at 2.6±0.4m/s. Pearson correlations between VALR and heel height at initial contact (HIC), time to heel contact (THC), heel descent acceleration

(HDA) and heel descent excursion (HDE) were extracted. These variables were also compared between runners who exhibit an impact peak (n=9) and those that did not (n=21).

RESULTS: VALR was significantly (all $p < 0.01$) correlated with HIC ($r = -0.514$), THC ($r = -0.783$) and HDA ($r = 0.612$). A trend was found for the correlation with HDE ($r = -0.33$, $p = 0.08$). FFS runners with an impact peak exhibited significantly lower HIC, a shorter THC and higher HDA (Table 1). A trend for lower HDE was noted in this group as well.

CONCLUSIONS: Lower heel at initial contact, decreased time to heel contact, and higher heel descent acceleration were significantly correlated with greater VALR and were observed by FFS with vertical impact peaks. This suggests that FFS runners with these impacts should be trained to land with more plantarflexion and greater eccentric control of their heel descent to reduce their landing impacts. Supported by FAPESP (2017/26844-1).

Table 1. Mean (SD) of VALR and heel kinematics for FFS runners with and without Impact Peaks

| | No Impact Peaks | Impact Peaks | p |
|-------------|-----------------|---------------|--------|
| n | 21 | 9 | |
| VALR (BW/s) | 36.13 (10.33) | 58.02 (18.56) | <0.001 |
| HIC (mm) | 77.15 (12.09) | 63.18 (8.13) | 0.004 |
| THC (ms) | 56.06 (11.70) | 39.79 (9.55) | 0.001 |
| HDA (m/s/s) | 17.62 (5.32) | 21.77 (3.51) | 0.042 |

Approximately 50% of runners sustain an injury each year that requires a cessation of training. Lower extremity stiffness has been identified as a potential contributor to lower extremity injury. However, recent research has suggested that the skeletal and muscular contributions to stiffness may be more indicative of injury mechanisms [1]. Research has also suggested that both footwear and foot strike pattern may also play a role in injury rates. **PURPOSE:** to assess the effect of footwear and strike pattern on skeletal and muscular contributions to leg stiffness. **METHODS:** Thirteen runners (aged 18 to 30) performed 8 over ground running trials at preferred running velocity in each of four experimental conditions: barefoot forefoot (BF-FF), barefoot rearfoot (BF-RF), shod forefoot (S-FF) and shod rearfoot (S-RF). Kinematics (240 Hz, Qualisys, Inc.) and ground reaction forces (GRFs, 960 Hz, AMTI Inc.) were collected simultaneously. Leg stiffness (kLeg) was calculated as the ratio of peak GRF magnitude divided by shortening of the limb. Skeletal (kSkel) and muscular contributions (kMusc) were calculated as previously described [1]. Three 2x2 repeated measures ANOVAs with Tukey's post-hoc tests were conducted to determine the effect of footwear and strike pattern on kLeg, kSkel and kMusc. **RESULTS:** Significant footwear by strike pattern interactions were observed for kLeg, kSkel and kMusc (Table 1). Post-hoc comparisons of kLeg, kSkel and kMusc revealed significant differences between S-RF and BF-FF, BF-RF, S-FF. **CONCLUSIONS/DISCUSSION:** These data demonstrate that both footwear and strike pattern alter leg stiffness as well as muscular and skeletal contributions to stiffness. Though previous research has identified that stiffness may contribute to lower extremity injury, no clear relationship has been identified. Further research is necessary to determine how the components of leg stiffness may be related to injury mechanisms. [1] Powell, Paquette & Williams 2017.

Table 1. Mean stiffness values for leg stiffness (kLeg) as well as skeletal (kSkel) and muscular (kMusc) components of stiffness.

| | BF-FF | BF-RF | S-FF | S-RF | Interaction | Footwear | Strike Pattern |
|-------|----------|----------|----------|-------------------------|-------------|----------|----------------|
| kLeg | 18.9±3.7 | 18.3±3.6 | 17.8±5.1 | 23.8±7.3 ^{abc} | <0.001 | 0.088 | 0.012 |
| kSkel | 15.4±3.6 | 14.8±3.1 | 14.2±4.4 | 19.2±6.6 ^{abc} | <0.001 | 0.174 | 0.028 |
| kMusc | 3.5±8.0 | 3.5±1.0 | 3.5±1.0 | 4.6±1.1 ^{abc} | <0.001 | 0.005 | 0.001 |

Note: a – denotes significantly different than BF-FF, b – denotes significantly different than BF-RF, c – denotes significantly different than S-FF.

Impact of Fatigue on Stride to Stride Variability of Sagittal Plane Joint Kinematics

David R. Hooper¹, Jeff T. Wight¹, Jaclyn O'Loughlin¹, Jordon Garman¹, Ryan S. Sloan¹, Michelle C. Boling². ¹Jacksonville University, Jacksonville, FL. ²University of North Florida, Jacksonville, FL.
 Email: dhooper4@ju.edu
(No relevant relationships reported)

With recent improvements in motion-analysis, it has now become much easier to assess multiple distance running strides to determine how consistent a runner's kinematics are. Thus, the impact of factors such as fatigue on running technique can now be evaluated. **PURPOSE:** To determine if stride-to-stride variability (SSV) of sagittal plane stance phase joint angles at the hip, knee, and ankle are altered by a 16-minute submaximal progression run. **METHODS:** Nineteen runners (18-45 yrs) participated in this study. Six Vicon Bonita cameras were used to collect kinematic data at 200 Hz. A Parvo metabolic cart was used to confirm the progression run caused fatigue. Baseline data were collected utilizing a 4 minute run at self-selected marathon race pace. After a 5-minute rest period the runners completed a 16-minute progression run, with increases in intensity at 4 minute intervals, which ended at marathon pace for the final data collection. Ten strides were used for SSV calculations. Stance phase joint angles were normalized to 101 data points. SSV was then determined for each joint by calculating the standard deviation (SD) across the 10 consecutive strides. The baseline and final SSV were compared using a 2-way ANOVA. **RESULTS:** The progression run increased the heartrate significantly (158.6±13.4 bpm to 169.6±14.3 bpm), thus confirming significant fatigue. Baseline and final SSV data were compared for the hip (1.23±0.37° vs. 1.17±0.37°), knee (1.47±0.39° vs. 1.51±0.44°), and ankle (1.20±0.50° vs. 1.21±0.40°). ANOVA and post-hoc testing revealed the knee to be the most variable joint overall. However, there were no significant increases in SSV between baseline and final measures. **CONCLUSIONS:** Despite experiencing metabolic and kinematic changes, the runners maintained the consistency of their running technique. Future research may want to evaluate SSV under greater to levels of fatigue to assess whether a fatigue threshold exists that will lead to an altered consistency of running technique.

The Effects of Sampling Frequency on Studying Peak Tibial and Sacral Accelerations in Running

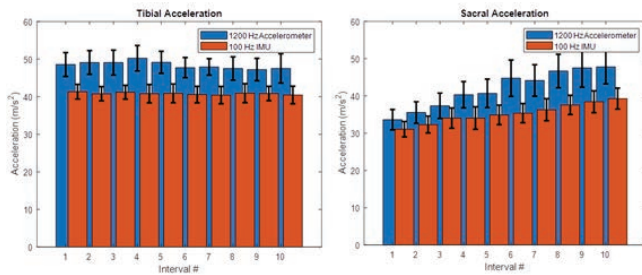

Michel Klaassen¹, Allison H. Gruber², Ashley B. Nguyen², Marit A. Zandbergen¹, Jaap H. Buiurke¹, Jasper Reenalda¹. ¹Roessingh Research and Development, University of Twente, Enschede, Netherlands. ²Indiana University, Bloomington, IN. (Sponsor: Joseph Hamill, FACSM)

(No relevant relationships reported)

Tibial impact (peak tibial acceleration, PTA) is often studied in relation to running injuries such as tibial stress fractures. The magnitude of impacts after initial contact give insight into how well the body is able to mitigate shock propagation. The ratio between PTA and peak sacral acceleration (PSA) is used for shock attenuation. Sample frequencies of 1000-1200 Hz are used to measure PTA and PSA in the lab. Considering the trend for using accelerometers in devices like cell phones and sport watches, measuring at a lower frequency is favorable for battery life, measurement duration, and monetary costs.

PURPOSE: To study the effects of reduced sampling frequency on PTA and PSA magnitudes during an exertive 20 min. treadmill run. **METHODS:** A healthy subject (M, 23 yrs, 1.75 m, 75 kg) was equipped with two wired accelerometers (1200 Hz) and two inertial measurement units (IMU) (100 Hz) on the tibia and sacrum. The subject ran for 20 minutes at 3.8 m/s on a treadmill. RPE (Borg) at end of run was 17. PTA and PSA were obtained using a custom Matlab algorithm. The 1200 Hz signal was filtered using a low-pass filter (cutoff freq. = 60 Hz). Delta peak of PTA and PSA between the first and last interval of the run was calculated for each sensor. A T-test was used to test for the statistical difference. **RESULTS:** PTA and PSA were greater over each interval during the run for the 1200 Hz sensor than the IMU (Figure 1a, 1b). Delta peak values of the IMU and 1200 Hz sensor were not different for PTA, but were for PSA ($p < 0.05$).

CONCLUSIONS: The trend in PTA and PSA during the run was similar between higher and lower resolution devices. However, the IMU cannot be used for absolute impact values, given the underestimation. These data suggest wearable technology is suitable to measure signal changes in PTA and PSA out-of-the-lab measurements but we caution interpretation of absolute values. The subject did not have "high" PTA, thus more work is needed to assess if lower res. devices are appropriate for those with greater PTA.

Figure 1: Peak tibial (a) and sacral (b) acceleration for running 20 minutes on a treadmill

2523 Board #187 May 31 9:30 AM - 11:00 AM Differences In Indoor, Outdoor, And Treadmill Walking In Healthy Young Adults

Abigail C. Schmitt, Sidney L. Baudendistel, Ania L. Lipat, Tatiana White, Chris J. Hass, FACSM. *University of Florida, Gainesville, FL.* (Sponsor: Christopher J Hass, FACSM)
(No relevant relationships reported)

The ability to ambulate within one's environment is an important skill for everyday life, however, traditional methods of assessing gait involve walking in controlled settings that may not represent performance in real-world environments. Laboratory and clinically-based quantitative gait assessments are often conducted in a sterile and uniform environment and treadmill walking assessments, used to collect a large amount of walking data, are conducted with an externally driven speed and fixed environment. As such, gait demonstrated in these assessments may not reflect gait performance in the real-world environment. **PURPOSE:** To compare gait behavior among overground indoor, outdoor, and treadmill walking in healthy adults. **METHODS:** 16 healthy young adults (5M, 11F, 21±2yrs) performed three walking trials (500m each) at a self-selected pace: indoors around a gymnasium (IN), outdoors along a sidewalk (OUT), and on a treadmill (TM). Data were collected using wearable sensors and the following variables were calculated for each trial: cadence, gait velocity, double support %, step time, stride length. Two repeated-measures MANOVAs were used to compare mean values and variability (standard deviation (SD)) across conditions. **RESULTS:** Significant differences were found across the conditions for both mean values ($\Lambda^*=0.38$, $F(10,6)=15.18$, $p=.002$), and variability ($\Lambda^*=0.37$, $F(10,6)=15.41$, $p=.002$). Univariate tests showed differences in mean values between all three conditions for cadence, gait velocity, step time, and stride length ($p<.003$), and greater double support time in the TM condition than the IN or OUT conditions ($p=.006$). Univariate tests for variability measures failed to detect statistically significant differences ($p>.01$). The TM condition had a lower gait velocity SD than IN or OUT ($p=.001$). **CONCLUSION:** Healthy young adults adopt different walking strategies while walking indoors, outdoors, and on a treadmill.

| | Outdoors | Treadmill | Indoors |
|---------------------|---------------|---------------|---------------|
| Cadence (steps/min) | 115.04 ± 7.23 | 104.53 ± 9.71 | 111.76 ± 7.36 |
| Gait velocity (m/s) | 1.30 ± 0.17 | 0.99 ± 0.26 | 1.19 ± 0.17 |
| Double support % | 18.22 ± 3.21 | 22.00 ± 3.89 | 19.18 ± 3.30 |
| Step time (s) | 0.52 ± 0.03 | 0.58 ± 0.05 | 0.54 ± 0.03 |
| Stride length (m) | 1.36 ± 0.13 | 1.13 ± 0.20 | 1.27 ± 0.14 |

2524 Board #188 May 31 9:30 AM - 11:00 AM Effect of Mobile Texting and Walking Speed on Gait Characteristics of Normal and Obese Adults

Jongil Lim, Jiyeon Kim, Kyoungseo Seo, Cindy M. Trinh, Jonathon Martinez, Sukho Lee. *Texas A&M University - San Antonio, San Antonio, TX.* (Sponsor: Minsoo Kang, FACSM)
(No relevant relationships reported)

Studies have shown that obesity is associated with increased biomechanical loads, poorer motor control abilities, and impaired cognition. However, less is known if

there is an augmented effect on obese population when both biomechanical loads and cognitive function are required at the same time such as texting while walking. **PURPOSE:** To examine how usage of mobile devices while walking affects walking characteristics of normal and obese populations. **METHODS:** A total of 32 participants were recruited in this study: 16 normal-weight (NW; age = 26.6±4.2 years, BMI = 23.4±3.1 kg/m²) and 16 obese participants (OB; age = 27.3±6.1 years, BMI = 34.4±3.5 kg/m²). Two conditions were employed (No-texting and Texting). In each condition, subject performed two 60 sec walking trials at three speeds (90% (PSF-10), 100% (PSF), and 110% (PSF+10) of a preferred step frequency (PSF) measured in baseline) along a rectangular walkway (8 x 12 m). At each step frequency condition, participants were asked to walk while matching a preferred foot strike to the beat of an auditory metronome. Gait parameters including spatial and temporal step characteristics were measured from wireless inertial sensor system. Three-way repeated measures ANOVA's were performed for all dependent variables, with texting condition and walking speed as within-subjects variables and obesity as a between-subjects variable. **RESULTS:** A significant texting by walking speed interaction in matching the target step frequency was observed ($F(2,56)=39.85$, $p<.001$, $\eta p^2=.58$) in both groups, showing the interference effects of texting on retaining cadence rhythm at fast walking speed (% change from target step frequency = No-texting: 2.1±.5 % at PSF-10, .28±.3 % at PSF, -1.5±.4 % at PSF+10; vs. Texting: 2.4±.7 % at PSF-10, -2.8±.8 % at PSF, -8.2±.8 % at PSF+10). OB exhibited longer double support time (NW=17.7±0.5, OB=22.0±0.5 % of the gait cycle time (%GCT); $p<.001$), stance time (NW=59.0±0.2, OB=61.1±0.2 %GCT; $p<.001$), and turn duration (NW=1.59±0.05, OB=1.78±0.05 sec; $p=.006$) compared to NW. **CONCLUSION:** Overall, the results provide further evidence of dual-task effects of texting on walking characteristics. The study further highlights the specificity of reduced gait function as a function of speed of walking as well as body composition under dual-task situation.

2525 Board #189 May 31 9:30 AM - 11:00 AM Comparison of Brain Hemodynamic Responses to Forward versus Backward Walking among People Post-Stroke

Justin Shamunee, Eunbi Lee, Kai Sun, Angelica Alberto, Danica Tolentino, Taeyoung Jung. *California State University, Northridge, Northridge, CA.*
(No relevant relationships reported)

Hemiparetic gait is frequently observed in people post-stroke, which is characterized by gait asymmetry. Forward walking (FW) and backward walking (BW) are commonly used to restore gait in stroke rehabilitation. The two forms of locomotion have been investigated via physiological and biomechanical methods. Limited studies have incorporated neurocognitive methods to investigate the specific underlying neural mechanisms associated with FW and BW in people post-stroke. **PURPOSE:** To compare the cortical hemodynamic responses of the motor cortex to FW and BW in people post-stroke.

METHODS: 11 individuals post-stroke participated in this cross-sectional study. All participants completed two walking conditions on a treadmill. They performed the test conditions on separate days in a random order. After 30 seconds of quiet standing, participants completed 30-second walking trials five times for each condition at a matched speed. The functional near-infrared spectroscopy (fNIRS) system was utilized to measure oxyhemoglobin (oxyHb) levels during the walking trials. **RESULTS:** Paired t-tests showed that there was a statistically significant difference in the level of oxyHb between FW and BW (p -value $<.05$). BW elicited a higher level of cortical hemodynamic activity by showing a 467% greater rate of change in oxyHb as compared to FW. In addition, regional comparisons of brain activity patterns demonstrated significant differences. During BW, participants post-stroke increased oxyHb levels in the primary motor cortex higher than the supplementary motor cortex. However, FW showed the opposite trend of brain activity patterns in the motor cortex. **CONCLUSIONS:** Our findings suggest that walking backward can increase the levels of brain activity and stimulate different areas of the brain as compared to the conventional mode of walking forward. Our results indicate that BW can be incorporated into stroke rehabilitation which may help promote neuroplasticity. Future studies should examine the effects of BW training on cognitive functions in people post-stroke.

2526 Board #190 May 31 9:30 AM - 11:00 AM Does Wearable Crutch Walking Excessively Load the Hip Joint?

Karl F. Orishimo, Amir Shapira, Ian J. Kremenic, Malachy P. McHugh, FACSM, Stephen J. Nicholas. *Nicholas Institute of Sports Medicine and Athletic Trauma, Lenox Hill Hospital, New York, NY.* (Sponsor: Malachy P. McHugh, FACSM)
Email: karl@nismat.org
(No relevant relationships reported)

PURPOSE: As an alternative to using traditional axillary crutches for non-weightbearing, the use of a wearable crutch has been associated with better functional

outcomes. However, hip and back pain have been reported as side effects. This may be due to the reduced ability of the lower extremity to attenuate ground reaction forces. The primary objective was to compare compressive forces at the hip between wearable crutch walking, normal walking and axillary crutch walking. It was hypothesized that hip forces would be higher with wearable crutch walking compared with normal walking and axillary crutch walking.

METHODS: Three-dimensional kinematics and ground reaction forces were measured in 12 healthy subjects (11 men, 1 woman, age 36±10 yr) during normal gait, axillary crutch ambulation and wearable crutch walking (iWalk 2.0). Hip and trunk range of motion, as well as peak vGRF and peak hip and low back compressive force during the stance phase, were compared for the three conditions using repeated-measures ANOVA.

RESULTS: Gait speed while wearing the wearable crutch was reduced 44% compared to normal gait and 33% compared to crutch ambulation ($P < 0.001$). Frontal and sagittal plane hip range of motion were both significantly reduced during both crutch conditions compared to normal gait ($P < 0.001$). Trunk range of motion in both planes was greatest during wearable crutch walking compared to both normal gait and crutch ambulation ($P < 0.001$). Peak vGRF while wearing the hands-free crutch was 12% lower than normal gait ($P < 0.001$) and 30% lower than crutch ambulation ($P < 0.001$). Peak compressive hip force during wearable crutch walking was 11% lower than during normal walking ($P = 0.026$) and 30% lower than during axillary crutch walking ($P < 0.001$). Low back compressive force during wearable crutch walking was 18% higher than during normal walking ($P = 0.03$) but not different than during axillary crutch walking (1.4% difference $P > 0.05$).

CONCLUSIONS: Despite a reduction in the shock-absorbing ability of the lower extremity, vGRF and compressive hip forces were not increased during wearable crutch walking. Although low back compressive force did increase with this device, it did not exceed the forces during axillary crutch walking. Therefore, the wearable crutch seems to be safe for patients who are required to be non-weightbearing.

2527 Board #191 May 31 9:30 AM - 11:00 AM
Effect Of New Walking Exercise With Two Poles For Upright Posture In Back-knee Case

Kiyomi Izumi¹, Yumi Ito², Kana Hashimoto¹, Shinji Kameda³, Takemasa Kawahara¹. ¹General Incorporated Association Kenkou-Jumyou Sekaichii, Higashiosaka, Japan. ²Funbarukun Co., Ltd., Higashiosaka, Japan. ³Arigatou Works Co., Ltd., Kyoto, Japan.

 (No relevant relationships reported)

Back-knee is knee deformation with hyperextension, and observed leaning forward, and adduction and internal rotation of hip joint during walking instead of hip and knee flexion. Therefore, we have adopted exercise with new walking style using two poles to avoid leaning forward. **PURPOSE:** To study the effect of the walking exercise using two poles on posture and gait in a back-knee case. **METHODS:** Subject: 70's female, with back-knee on both legs, using two T-canes in everyday life. Intervention: The walking exercise was conducted using two poles for 15 to 30 minutes once a week for 10 months. Same exercise was done every day at home. Equipment: A set of poles with the grips bending towards the thumb side (radial deviation), setting the length 10 cm or longer than the general Nordic walking pole. Walking style: (i) Stick the pole vertically at about 10 cm or more from the toe of the foot you stepped. (ii) Put the legs shoulder-width forward, land the step from the heel, kick out with a toe and walk. **MEASUREMENT:** The joint angles were measured during the walking using two T-canes before intervention and with this walking style after 45-week exercise. **RESULTS:** At the loading response, the trunk bending against a vertical axis were decreased from 20° (before intervention) to 8° (after 45 weeks). The hyperextension of the knee joint were decreased from 42° to 30°. Posterior hip joint extension was not observed before intervention, but it showed 17° extension after 45 weeks. Also, when raising the legs, the hip flexion angle against a vertical axis were 35° before intervention and 50° after 45 weeks, showing the motion range for hip flexion-extension extended. **CONCLUSION:** This walking style with two poles is thought to have the effect to gain the upright posture, making it easier to put forward the legs.

2528 Board #192 May 31 9:30 AM - 11:00 AM
The Effect Of Stride Length Training On Muscular Activity And Energy Cost During Walking

Hae Ryoung Chung¹, Travet Witherspoon¹, Moroni DeMoors¹, Jin Hee Jeong², Chris Pitsikoulis³. ¹Clayton State University, Morrow, GA. ²Augusta University, Augusta, GA. ³Aurora University, Aurora, IL.
 Email: hchung@clayton.edu
 (No relevant relationships reported)

Human bipedalism is the most unique locomotive form in the terrestrial environment and can be performed for a prolonged period of time. To maintain this form of locomotion humans have adopted physiological and mechanical strategies to minimize and conserve their stored energy. The self-selected locomotive pace in humans is that at which the most efficient energy cost can be maintained. **PURPOSE:** To study the effects of stride length alteration training on the electromyographic (EMG) activity of the quadriceps muscle group and hamstring muscle group and oxygen consumption. **METHODS:** Male (n=8) subjects (age =21years) recruited for this study. Heart rate, and oxygen consumption (VO₂), and EMG activity (quadriceps and hamstring) were continuously measured during walking at self-selected speed at the following stride length: (1) self-selected (s-s) (2) 10% below s-s, (3) 20% below s-s, (4) 10% above s-s, (5) 20% above s-s, and (6) 30% above s-s stride-length. Subjects then trained 3 days per week for 8 weeks on a treadmill starting at 20% above their s-s speed. Each week, speed was increased by 0.1 miles per hour (mph) until the subject was unable to maintain a walking gait (one foot must remain on the treadmill). Post-testing was conducted after completion of the training sessions. Repeated measures ANOVA were used to determine differences between sessions. **RESULTS:** Post s-s speed and length and VO_{2max} were significantly higher than pre-test ($p=0.05$ for all). Both pre- and post- heart rate, VO₂, and EMG activity were significantly lower at s-s stride length than all below and above s-s stride lengths ($p=0.05$ for all). Post- VO₂ and EMG activity at s-s stride length were significantly higher than pre-test ($p=0.05$). **CONCLUSIONS:** Oxygen consumption and EMG activity levels showed a U-shaped curve with the lowest at s-s stride lengths and higher at below and above s-s speed before and after 8 weeks of stride length alteration training. This indicates walking energy cost is optimal at s-s stride lengths regardless of the training-induced change in s-s stride length. Stride length alteration training shifted the U-shaped curve for oxygen consumption and EMG to the right indicating increased overall walking energy cost that is related to increased s-s stride length.

2529 Board #193 May 31 9:30 AM - 11:00 AM
Effects of Percent Body Fat on Foot Pressure Characteristics during Walking in Weight-Matched Male Adults

Hyejung Choi, Jongil Lim, Sukho Lee. Texas A&M University - San Antonio, San Antonio, TX.
 (No relevant relationships reported)

Increased body weight is associated with increased magnitude of pressures under the feet in obese population. Although body mass index (BMI) has been used in the assessment of overweight/obesity, BMI does not differentiate between muscle and adipose tissue, which may play a role in characterizing walking patterns. **PURPOSE:** To compare foot pressure characteristics during walking between obese and weight-

matched controls. **METHODS:** Sixty male adults were assigned to normal group (NG; n=30, age: 48.64 ± 6.24 years, percent body fat (%BF): 21.18 ± 3.51 %) and obese group (OG; n=30, age: 47.71 ± 6.45 years, %BF: 29.81 ± 4.12 %) based on %BF. Body compositions including %BF, fat mass, muscle mass, and BMI were measured by bioelectrical impedance method. Foot pressure and gait parameters were recorded with a force-distribution-measure treadmill system during walking at the preferred speed. An independent t-test was performed to compare the differences of dependent variables between the groups. A p < .05 was considered statistically significant. **RESULTS:** No differences were observed between the groups in weight (NG: 72.21 ± 9.04 kg, OG: 75.03 ± 8.52 kg, p=.254) and BMI (NG: 24.54 ± 2.17 kg/m², OG: 25.65 ± 2.59 kg/m², p=.073). OG showed significantly greater %BF (NG: 21.18 ± 3.51 % fat, OG: 29.81 ± 4.12 %, p < .001) and fat mass (NG: 14.18 ± 3.74 kg, OG: 21.64 ± 3.52 kg, p < .001), but lower muscle mass (NG: 31.64 ± 4.81 kg, OG 28.56 ± 2.70 kg, p < .05) despite the same weight. The speed of walking did not differ between the groups (NG: 3.47 ± 0.86 km/h, OG: 3.20 ± 1.02 km/h, p = .261), but OG walked with a wider step width (NG: 14.29 ± 4.07 cm, OG: 16.66 ± 3.73 cm, p < .05). The line of the force application point was longer in NG for both stance-phase (NG: 250.88 ± 63.62 mm, OG: 213.13 ± 55.41 mm, p < .05) and single-limb support phase (NG: 130.38 ± 41.03 mm, OG: 106.42 ± 37.75 mm, p < .05). Maximum pressure at the heel was also greater in NG (24.64 ± 6.29 N/cm²) than OG (20.93 ± 6.56 N/cm²) (p < .05). **CONCLUSION:** The results demonstrated substantially different force application patterns during walking between obese and weight-matched control group, indicating a potential influence of %BF on foot pressure characteristics in walking. The comprehensive evaluation of obesity including %BF, therefore, should be administered for the prescription of safe physical activity.

Response of Femoral Articular Cartilage Throughout a 5,000 Step Walking Protocol Using Ultrasound
 Steven J. Pfeiffer, Hope C. Davis, Brett Pexa, Jessica Szymczak, Catherine Wistreich, Rachel Sorensen, Erik A. Wikstrom, FACSM, Troy Blackburn, Brian Pietrosimone, FACSM.
University of North Carolina at Chapel Hill, Chapel Hill, NC.
 Email: stevenpf@email.unc.edu
(No relevant relationships reported)

Femoral cartilage cross-sectional area (CSA) demonstrates changes following a standardized walking protocol of varying durations when assessed using ultrasonography (US). However, it is unclear if a certain step threshold exists beyond which no further changes in CSA are observed. Similarly, it is unclear how changes in cartilage CSA progress with an increasing number of steps.
PURPOSE: To evaluate changes in femoral cartilage CSA between baseline and 1,000, 2,000, 3,000, 4,000, and 5,000 steps, respectively using US.
METHODS: Thirty-two healthy individuals (63% female, age = 22 ± 3 yr, BMI = 24 ± 3 kg/m²) completed a single testing session. Habitual walking speed was assessed over a 6-meter walkway using infrared timing gates. Participants rested with their knees extended on an examination table for 45-minutes to unload their knee cartilage prior to the walking protocol. US was used to acquire images of the femoral cartilage prior to the walking protocol. Immediately following US acquisition, participants walked on a treadmill at their average, over ground walking speed for 1,000 steps, after which additional US images of the femoral cartilage were acquired. This process was repeated at 2,000, 3,000, 4,000, and 5,000 step time points. A one-way repeated-measures analysis of variance was used to compare femoral cartilage CSA across the 6 time points. Multiple Bonferroni corrected planned comparisons (0.05/5) were used to evaluate pair-wise comparisons if a statistically significant ANOVA model was identified.
RESULTS: Significant differences in femoral cartilage CSA were observed across time points ($F_5=23.60$, p<0.001). Femoral cartilage CSA was significantly greater at the 2,000 (Mean Difference [MD] = +1.25mm, p=0.01), 4,000 (MD = +0.95mm, p<0.001), and 5,000 (MD = +2.14mm, p<0.001) step points compared to baseline. Conversely, femoral cartilage CSA was significantly lesser at the 3,000 step point (MD = -1.12, p=0.001) compared to baseline.
CONCLUSIONS: Changes in femoral cartilage CSA following walking may be dependent on the number of steps taken during a session of physical activity. Future research should determine mechanisms related to the increase and decrease in femoral cartilage CSA found in response to walking, as these mechanisms may be linked to the number of steps taken.

Preliminary Analysis: The Effects of Gait Interventions on Knee Joint Contact forces in Healthy Adults
 Matthew Prebble, Qi Wei, Oladipo Eddo, Bryndan Lindsey, Shane V. Caswell, Nelson Cortes. *George Mason University, Manassas, VA.*
 Email: ncortes@gmu.edu
(No relevant relationships reported)

The effects of gait modifications (GM) are of interest as a non-invasive strategy to slow the progression of knee osteoarthritis. Previous research has found a reduction in knee adduction moment (KAM) as a result of GM. However, there is conflicting research regarding the relationship between KAM and joint contact forces. **Purpose:** To compare the effects of two GMs on the estimated joint contact forces in the medial and lateral knee compartments. **Methods:** 5 healthy volunteers (27.8 ± 4.1 years, 1.74 ± 0.10 m, 74.98 ± 13.7 kg) completed 10 trials each of walking with a normal gait (NG) and with 2 different interventions: foot progression (FP) & lateral trunk lean (TL). During each trial GM parameter magnitude (1-5 SD relative to baseline) was estimated using Visual3D and real time visual feedback was provided to participants. Data was collected using a motion capture system (200Hz) while participants walked across a ~6-meter walkway; 4 in-line force plates (1000Hz) captured ground reaction force and speed was controlled for during each trial. Data was imported into OpenSim to estimate the joint contact forces in the knee of the dominant leg. Differences between the 3 GMs were analyzed using an ANOVA ($\alpha<0.05$). **Results:** Average peak joint contact force for both the medial and lateral knee compartments are summarized in table 1. A one-way ANOVA found no statistical differences (p>0.05) between gait strategies for all conditions. **Conclusion:** While no significant differences were found it may be due to the small preliminary sample size. It also plausible that the OpenSim model of the knee joint may not be able to accurately reflect the in-vivo biomechanics of the knee in the frontal plane due to the model's degree of freedom. Further research should be conducted to verify these findings in a larger sample.

Table 1: Simulated Knee Joint Contact Forces Normalized by Bodyweight (mean±sd)

| | NG | FP | TL |
|--------------------------------|-----------|-----------|-----------|
| Medial Compartment (1st Peak) | 2.38±0.58 | 2.58±0.95 | 2.44±0.94 |
| Medial Compartment (2nd Peak) | 3.95±0.58 | 3.34±1.86 | 3.25±1.85 |
| Lateral Compartment (1st Peak) | 0.73±0.20 | 0.80±0.33 | 0.93±0.24 |
| Lateral Compartment (2nd Peak) | 0.51±0.20 | 0.45±0.20 | 0.51±0.22 |

Gait Analysis Of Patients With Distal Radius Fracture Using A Novel Laser-tug System
 Koji Fujita¹, Hiroataka Iijima², Atushi Okumura³, Yosuke Yao³, Akimoto Nimura¹, Ryuichi Kato⁴, Atsushi Okawa¹, Masaki Takahashi². ¹*Tokyo Medical and Dental University, Tokyo, Japan.* ²*Keio University, Kanagawa, Japan.* ³*Kawaguchi General Hospital, Saitama, Japan.* ⁴*JA Kyosai Research Institute, Tokyo, Japan.*
 Email: fujiorth@tmd.ac.jp
(No relevant relationships reported)

BACKGROUND: Patients with distal radius fracture (DRF) are at risk of consequent fragility fracture. Gait analysis of patients with DRF can provide useful information to prevent a fall and resultant fracture. The timed up and go test (TUG) is a clinical test, most often used to evaluate functional mobility; however, the detailed information of steps during the test is not well assessed. **PURPOSE:** To analyze the gait characteristics of patients with DRF during TUG using a newly developed Laser-TUG system. **METHODS:** We developed the Laser-TUG system, which enables us to assess the detailed gait information during TUG without using any instruments on patients. The system uses a single laser range sensor, and can track both legs and measure the foot contact positions to obtain the walking parameters, such as stride length and step length. Using the Laser-TUG system, we compared the gait of 20 patients with DRF who had surgery up to 2 weeks prior (the fracture group), and 40 age-matched healthy non-fractured volunteers (the non-fracture group). **RESULTS:** The total time of TUG in the fracture group was lesser (8.5 vs. 7.4 seconds, P=0.03). The length of stride was smaller (0.51 vs. 0.62 meter, P<0.01), and the number of steps in total was greater (14.3 vs. 11.7, P<0.001), especially at the turning around phase (3.2 vs. 2.3, P=0.04) in the fracture group. The distance from the turning point (0.53 vs. 0.46 meter, P=0.02) was also farther in the fracture group. **CONCLUSION:** With this system, gait can be visualized without the use of a sensor on the patients. The time of TUG in the fracture group was less than 10 seconds, which implies normal gait speed; however, they walked with more steps and experienced difficulty turning around during TUG. These results suggest the cause underlying the tendency to fall in patients with DRF.

Single-Parameter Gait Modifications Cause Involuntary Secondary Gait Changes

Bryndan Lindsey, Oladipo Eddo, Matthew Prebble, Shane V. Caswell, Ana M. Azevedo, Nelson Cortes. *George Mason University, Manassas, VA.*
 Email: ncortes@gmu.edu
 (No relevant relationships reported)

Gait modification (GM) using real-time biofeedback (RTB) has shown success reducing 1st peak knee abduction moment (KAM) which is associated with knee osteoarthritis. Most studies have used single parameter GMs; though, evidence suggests that GMs can induce additional involuntary gait changes. **PURPOSE:** To compare the effects of 3 single parameter GMs [foot progression (FP), medial knee thrust (MKT), and trunk lean (TL)] designed to reduce KAM on secondary gait variables. **METHODS:** 10 healthy individuals volunteered for this study (26.7 ± 4.7 years, 1.75 ± 0.1 m, 73.4 ± 12.4 kg) with the dominant limb being used for analyses. Mean and standard deviation (SD) for KAM and frontal plane trunk, knee, and transverse plane foot angles were calculated from 10 baseline trials. Joint angles were used to provide RTB for corresponding GMs (i.e. foot angle and FP). Five trials were completed for each GM using RTB with the joint angle falling within a range (3-5 SD) relative to baseline. Visual 3D was used to calculate KAM (Nm/kgm) and angles (°) at KAM. Repeated measures ANOVA were conducted to assess differences in dependent measures (p<0.05). **RESULTS:** All GMs reduced KAM, with some causing involuntary changes to secondary gait variables (Table 1). Specifically, FP increased peak knee abduction angle, MKT reduced foot angle and increased trunk angle, and TL increased stride width (P<0.05). **CONCLUSIONS:** All single parameter GMs reduced PKAM but resulted in additional involuntary gait changes such as increased knee abduction, internal foot rotation and trunk lean, and stride width during FP, MKT, and TL, respectively. Hence, a modification scheme that employs multiple GMs at once is likely more beneficial to reduce KAM.

Table 1. Means ± SD for dependent measures. Kinetic and kinematic variables were measured at KAM.

| | Group Main Effect | | Gait Modification | | | | | | |
|--------------------------|-------------------|--------|-------------------|---------------|-------|---------------|-------|--------------|-------|
| | F | P | Base-line | FP | d | MKT | d | TL | d |
| KAM (Nm/kgm) | 15.43 | <0.001 | -0.27 (0.05) | -0.25 (0.06)* | 0.52 | -0.17 (0.09)* | 1.43 | -0.25 (0.09) | 0.27 |
| Foot Angle (°) | 25.04 | <0.001 | -3.54 (4.32) | 4.59 (5.20)* | 1.70 | 2.10 (9.90)* | 0.74 | -4.10 (4.90) | -0.12 |
| Knee Angle (°) | 8.31 | <0.001 | 3.41 (2.61) | 2.87 (2.60)* | -0.21 | 2.23 (3.05)* | -0.41 | 3.59 (3.08) | 0.06 |
| Trunk Angle (°) | 40.37 | <0.001 | 1.48 (3.01) | 1.48 (3.06) | 0.00 | 2.77 (4.07)* | 0.36 | 6.91 (2.21)* | 2.06 |
| Stride Width (m) | 1.69 | 0.02 | 0.13 (0.03) | 0.14 (0.03) | 0.28 | 0.14 (0.04) | 0.24 | 0.15 (0.04)* | 0.56 |
| Stride Length (m) | 3.54 | 0.18 | 1.41 (0.19) | 1.40 (0.20) | -0.07 | 1.45 (0.16) | 0.21 | 1.42 (0.17) | 0.09 |

*Indicates statistically significant difference from baseline (p<0.05). Reduced foot angle and trunk lean towards the dominant limb is positive while knee abduction is negative.

Case-Control Investigation Of Speed And Gait After An Incomplete Spinal Cord Injury

Amanda J. Wakeman, Whitley J. Stone, Braden A. Younkin, Dustin W. Davis, Matthew J. Garver, H Scott Strohmeyer. *University of Central Missouri, Warrensburg, MO.* (Sponsor: Scott Lyons, FACSM)
 (No relevant relationships reported)

Individuals with an incomplete spinal cord injury (iSCI) present with an array of compensatory gait mechanistic changes. Appraising these changes may help clinicians better prescribe treatment plans to improve quality of movement. **PURPOSE:** The primary purpose of this investigation was to compare gait measures between someone with an iSCI and an age-, sex-, and height-matched non-limited control (CON). A secondary purpose was to quantify changes in movement when walking at different speeds. **METHODS:** This case-control study included a participant with iSCI and a CON. Three-dimensional motion analysis was used to determine gait speed and lateral deviation (LD) for preferred normal walking (NW) and fast walking (FW) tests. LD was determined by movement of 7th cervical spinal process (C7) marker along the frontal plane. **RESULTS:** Case-control differences were observed: gait speed NW (iSCI: 0.20m/s; CON: 1.37m/s), gait speed FW (iSCI: 0.33m/s; CON: 1.91m/s), LD NW (iSCI: 0.43m; CON: 0.09m), and LD FW (iSCI: 0.39m; CON: 0.10m). **CONCLUSIONS:** In the clinical setting, LD is often indicative of an abnormal walking pattern, but is not typically quantified for objective reassessments. The participant with iSCI and CON increased gait speed from a NW to FW 26.92% and 38.72%, respectively. LD did not change as expected, with iSCI decreasing (-7.85%) and CON increasing (4.99%) when increasing speed. These preliminary data may reflect the need to evaluate more segmental responses in addition to C7 deviation to fully gain insight on compensatory mechanisms adopted during NW and FW after iSCI. Future investigations may consider evaluating the relationship between C7, pelvic response, trunk flexion, and metabolic cost as walking speed changes to better direct therapeutic attention to the component most responsible for the dysfunction. Although not fully explanatory, it is common for clinicians to view crude LD as reflective of sub-optimal walking. Rehabilitation specialists may consider implementing a more objective view of C7 movement when assessing pathologic gait, as it is clearly impacted by altering walking speed.

Hip Mechanics during Gait in Sedentary Adults

Devin K. Kelly, Kristyne Wiegand, Janet S. Dufek, FACSM, Julia Freedman Silvernail. *UNLV, Las Vegas, NV.* (Sponsor: Janet S. Dufek, FACSM)
 Email: devin.kelly@unlv.edu
 (No relevant relationships reported)

Obesity is a known risk factor for osteoarthritis (OA). Studies investigating how gait changes that are associated with obesity lead to the development of OA often lack a measure of level of physical activity. It is well established that sedentary behavior leads to obesity and therefore it may also influence the progression of OA. Investigating hip mechanics during gait in sedentary obese and sedentary normal weight adults may offer insight into the effect of physical activity behavior on

biomechanical factors associated with the development of hip OA. **PURPOSE:** To assess hip biomechanics during gait in normal weight and obese adults to explore the effect of a sedentary lifestyle on the progression of hip OA. **METHODS:** Gait analyses were performed on 18 sedentary young adults. Participants were separated into two groups based on body mass index. Group 1 consisted of sedentary normal weight adults (n=9) and group 2 consisted of sedentary obese adults (n=9). Three-dimensional kinematic and kinetic data were collected at 200 Hz and 1000 Hz respectively as participants walked 12 meters at their preferred velocity. Hip joint angles and moments were calculated. Average range of motion and peak moments were determined and assessed for statistically significant differences between groups using independent t-tests with the alpha level set at 0.05. **RESULTS:** The two groups walked at similar preferred velocities ($3.15 \pm .30$ m/s; $3.16 \pm .25$ m/s; $p = 0.96$). Range of motion in the sagittal ($40.31 \pm 4.68^\circ$; $41.11 \pm 6.05^\circ$; $p = 0.48$) and transverse planes ($13.48 \pm 3.29^\circ$; $13.27 \pm 4.15^\circ$; $p = 0.78$) were similar between groups. Coronal plane range of motion was significantly greater in group 1 than group 2 ($13.94 \pm 2.68^\circ$; $12.63 \pm 2.60^\circ$; $p = 0.02$). Average peak hip extension moments were also similar between groups (50.60 ± 13.72 Nm/kg; 51.44 ± 14.63 Nm/kg; $p = 0.78$). **CONCLUSIONS:** Sedentary normal weight and sedentary obese individuals had similar sagittal range of motion and peak extension moment at the hip. The literature shows that individuals with hip OA experience limited sagittal range of motion and reduced extension moment. Taken together, current results suggest that sedentary behavior, regardless of body weight, may contribute to the development of hip OA.

Gait Mechanics between a Lower Body Positive Pressure and Regular Treadmill

Pedro Migliano¹, Rebecca Greenwood¹, Alexis Ortiz, FACSM².
¹TWU - Houston, Houston, TX. ²UT Health - San Antonio, San Antonio, TX.
 Email: pmigliano@twu.edu
 (No relevant relationships reported)

Lower Body Positive Pressure Treadmills (LBPPT) allow for unweighted running and are often used as a tool for gait re-training or running load management. To our knowledge no study has examined differences in gait mechanics during walking and running between LBPT 100% WB and a regular treadmill (TM). **PURPOSE:** The purpose of this study is to examine differences in cadence, stance time, maximal heel strike force (HS), and maximal metatarsal force (MT) between a LBPT at 100% BW and a regular treadmill as measured through an in-shoe pressure sensor system (PSS). **METHODS:** 7 participants (mean age: 31.14 ± 6.03 , mean weight: 83.89 ± 10.61) donned the PSS and were set-up in the LBPT. The subjects performed a running protocol which had stages from 3 mph to 6 mph at 1 mph increments at 100% BW. Following the running protocol on the LBPT the participants completed the same running protocol on the TM. Cadence, average stance time between both legs, HS, and MT were recorded with the PSS at each stage of the test with each stage lasting 15 seconds. **RESULTS:** A 2x4 repeated measure ANOVA and Intra-class correlations were run to examine the data for any significant differences and level of agreement. For cadence, there was no significant main effect of device ($F(1,5) = 5.68$, $p = .06$) and both devices showed a good level of agreement ($ICC = .83$). For stance time, there was a significant main effect of device ($F(1,5) = 8.69$, $p = .03$), a significant main effect of speed ($F(3,15) = 39.59$, $p \leq .0005$), and both devices showed an excellent level of agreement ($ICC = .93$). For HS, there was a significant interaction of device and speed ($F(3,15) = 3.58$, $p = .04$) with post-hoc comparisons with Bonferroni adjustment showing a difference between 3 and 4 mph on the TM (mean difference = 24.33 , $p = .04$). HS showed an excellent level of agreement between devices ($ICC = .93$). For MT, there was a significant effect of speed ($F(3,15) = 5.67$, $p = .01$) but no significant effect of device ($F(1,5) = .31$, $p = .60$). MT showed a good level of agreement between devices ($ICC = .89$). **CONCLUSIONS:** Our results show that while there was a significant difference between LBPT and TM for ST, the overall level of agreement and lack of difference between devices for cadence, MT and HS show that the LBPT can be used at 100% BW with little deviation in gait mechanics compared to a TM.

2537 Board #201 May 31 9:30 AM - 11:00 AM
Validation of a Built-In Gait Analytics System for Lower Body Positive Pressure Treadmills

Alexis Ortiz, FACSM¹, Pedro Migliano², Rebecca Greenwood².
¹UT Health San Antonio, San Antonio, TX. ²Texas Woman's University, Houston, TX.
 Email: ortiza7@uthscsa.edu
 (No relevant relationships reported)

Lower Body Positive Pressure Treadmills (LBPT) allow for unweighted running, giving the user the choice to adjust their bodyweight from 100% to 20%. Some LBPT's have added the option for a built-in gait analytics system (GAS) which provide real-time gait analysis data including weight bearing symmetry, step length, stance time, and cadence.

PURPOSE: To validate the LBPT GAS compared to an in-shoe pressure sensor system (PSS). **METHODS:** 8 subjects (mean age: 30.80 ± 6.98 , mean weight: 69.54 ± 15.53) donned the PSS and were set-up in the LBPT. The subjects performed a running protocol which had stages from 3 mph to 6 mph at 1 mph increments from 80% bodyweight to 20% body weight (20% increments) at each speed setting. Weight bearing symmetry, stance time, and cadence were recorded with the PSS and GAS at each stage of the test with each stage lasting 15 seconds. **RESULTS:** Pearson correlations and Intra-class correlations were used on weight bearing symmetry, stance time on both the left and right leg, and cadence acquired from the GAS and PSS. Weight bearing symmetry was not correlated between devices, $r = -.06$, $p = .53$, $r^2 = .01$, $ICC = -.13$. Right stance time was found to have a small significant correlation, $r = .37$, $p \leq .001$, $r^2 = .14$, $ICC = .40$. Left stance time was found to have a small to moderate significant correlation, $r = .43$, $p \leq .001$, $r^2 = .19$, $ICC = .37$. Cadence was found to have a small significant correlation, $r = .37$, $p \leq .001$, $r^2 = .14$, $ICC = .18$. **CONCLUSIONS:** These findings are unable to support the LBPT GAS as a valid gait analysis tool related to weight bearing symmetry, stance time and cadence due to relatively poor agreement and correlations when compared to direct measures from an in-shoe pressure sensor system.

2538 Board #202 May 31 9:30 AM - 11:00 AM
Effects Of Arm Weight On Gait Performance In Hemiparetic Stroke And Healthy Subjects

Hyung Suk Yang¹, C. Roger James, FACSM², Lee T. Atkins³, Steven F. Sawyer², Phillip S. Sizer, Jr.², Neeraj A. Kumar², Jongyeol Kim². ¹University of South Dakota, Vermillion, SD. ²Tech University Health Sciences Center, Lubbock, TX. ³Angelo State University, San Angelo, TX.
 (No relevant relationships reported)

PURPOSE: The purpose was to investigate the effects of arm weights on arm swing amplitude, gait performance, and muscle activity in stroke patients and healthy subjects. **METHODS:** Nine hemiparetic stroke and nine healthy subjects participated. Subjects walked at their preferred speed under different weight carriage conditions (stroke/healthy group; C1: no weight; C2: uninvolved/dominant arm weight; C3: involved/non-dominant arm weight; C4: bilateral arm weights). **RESULTS:** In stroke patients, gait speed ($P = 0.048$, C1: 0.639 ± 0.259 (M \pm SD); C2: 0.662 ± 0.259 ; C3: 0.700 ± 0.246 ; C4: 0.689 ± 0.267 m/s) and involved side tibialis anterior integrated EMG (iEMG) values ($P = 0.018$, C1: 49.588 ± 13.300 ; C2: 44.998 ± 12.713 ; C3: 43.291 ± 13.961 ; C4: 44.876 ± 13.892 μ V) exhibited changes with the arm weights that were statistically inconclusive ($\alpha_{adjusted} < P < 0.05$) using Hochberg correction. In healthy subjects, non-dominant side posterior deltoid iEMG was statistically inconclusive ($P = 0.022$, C1: 24.985 ± 29.955 ; C2: 25.374 ± 28.518 ; C3: 30.126 ± 31.652 ; C4: 28.877 ± 33.346 μ V). When individual subject gait speeds were explored using descriptive statistics and effect sizes, some subjects exhibited a potentially clinically meaningful improvement. **CONCLUSIONS:** The observed increases in gait performance demonstrated encouraging results for higher functioning stroke patients who exhibit gait impairment and asymmetry. The addition of arm weights merits further investigation as a potential rehabilitation intervention in people with stroke-related gait disturbances.

2539 Board #203 May 31 9:30 AM - 11:00 AM
Application of the Cervical Flexion Relaxation Ratio to Investigate the Impact of Torso-borne Load Redistribution

Marina Carboni, John Ramsay, Jonathan Kaplan. *Natick Soldier Research Development and Engineering Center, Natick, MA.*
 Email: marina.g.carboni.civ@mail.mil
 (No relevant relationships reported)

Students and military personnel often carry heavy torso loads (e.g. backpacks) which can lead to pain in the shoulders and back. To minimize pain associated with torso loads, load redistribution devices have been developed to off-load weight from the shoulders to the hip. Previous studies have used the cervical flexion relaxation ratio (cFRR), a measure of muscle activity between the extension and flexion phase of forward head motion, to correlate backpack loads with the potential of developing neck pain. **PURPOSE:** Using the cFRR, assess the impact of redistributing torso-borne loads and whether changes in cFRR are observed following prolonged load carriage. **METHODS:** Twelve volunteers walked at $1.34 \text{ m} \cdot \text{s}^{-1}$ at 0% grade for 40 min while wearing a torso-borne baseline load of 27 kg and two load distribution conditions to offload shoulder pressure. Flexible pressure sensors monitored pressure distribution at the shoulders and hips. To capture cFRR, bilateral EMG sensors with integrated tri-axial accelerometers were placed on the cervical erector spinae muscle bellies. EMG data were sampled at 2 kHz, demeaned, band pass filtered from 30 to 500 Hz, and full

wave rectified. cFRR (Table 1) was measured pre-walk and post-walk and outcomes were submitted to repeated measures ANOVA based on load conditions, side of body and time. **RESULTS:** The average pressure measured at the shoulders for the baseline load ($3.76 \pm .90$ kPa) was significantly higher than the two load distribution conditions (1.55 ± 1.68 kPa, $p = .001$; 1.72 ± 1.12 kPa, $p < .0005$, respectively). There were no main effects due to load condition or body side ($p > .074$). However, there was a significant main effect of time ($p = .033$).

CONCLUSION: The load distribution equipment successfully shifted pressure from the shoulders to the hips, however this did not correlate with an improvement in cFRR. Changes in cFRR were observed pre- vs. post-walk indicating that the cFRR measure is sensitive to load carriage over time.

Table 1. cFRR.

| FRR | Baseline Load | | Load Distribution 1 | | Load Distribution 2 | |
|------------|---------------|------------|---------------------|------------|---------------------|------------|
| | Pre | Post | Pre | Post | Pre | Post |
| Right Side | 1.74 ± .66 | 1.55 ± .66 | 1.49 ± .36 | 1.3 ± .36 | 1.52 ± -.35 | 1.4 ± .37 |
| Left Side | 1.7 ± 1 | 1.57 ± .71 | 1.35 ± .3 | 1.27 ± .37 | 1.35 ± .17 | 1.23 ± .22 |

Functional Sarcopenia Biomarkers In 56 To 80 -Yr Old-Men And Women

Jhon F. Ramírez-Villada¹, Leonardo Rodríguez-Perdomo², Annie Tibaduiza-Romero¹, Jorge-Jaime Márquez-Arabia¹, Jaime Ortiz-Silva¹, Nery C. Molina-Restrepo¹, Carlos Mario Arango-Paternina¹. ¹University of Antioquia, Medellín, Colombia. ²SENA, Bogotá, Colombia.
 Email: jhonramirezvillada@gmail.com
 (No relevant relationships reported)

PURPOSE: Age-associated loss of skeletal muscle mass and function has considerable importance for those activities related with disease prevention, health promotion, and care planning. The aim of the study was to examine several biomarkers of sarcopenia in older women, and its relation to functional deterioration

METHODS: Body composition, muscle strength, and gait performance indicators were measured in 179 healthy women (56 to 76 -yr- old) to examine the relationship among those parameters as biomarkers of functional sarcopenia. All subjects were carefully familiarized with the evaluation tests. First, morphological variables such as lean/height² (kg/m²), appendicular lean/height² (kg/m²), lean body mass (% LBM), and others were estimated by Dual-energy X-ray absorptiometry (DXA). Second, functional indicators related to explosive force (power, take-off time, flight time, and maximum height achieved) were evaluated using a contact equipment. Third, isometric strength was tested by handgrip dynamometer. Finally, fast gait performance was evaluated using different indicators (distance, velocity, stride length, double support, contact phase, propulsion phase, velocity displacement) by photocell system.

RESULTS: Using two criteria, prevalences of sarcopenia were 57% (Lean/Height² (kg/m²); 95%-CI: 0.48-0.65), and 42% (Appendicular Lean/Height² (kg/m²); 95%-CI: 0.34-0.51). Nevertheless, a low prevalence to handgrip strength (16%, 95%-CI: 0.10-0.24) and gait performance (8.72%, 95%-CI: 0.05-0.14) were observed, contrary to power deterioration of lower limbs (31%, 95% CI: 0.22-0.41). Also, those subjects with lower levels of explosive strength (odds ratio (OR): 4.66 (95% CI: 1.098 to 12.561; P<0.05) had risk of having a higher adiposity level (≥25%), and lower results of fast gait performance.

CONCLUSIONS: Despite a wide variety of tests and tools is now available for characterization of sarcopenia in practice and in research, health professionals must be careful to avoid an inadequate clinical and functional diagnosis.

Comparison of Injury in Male and Female Amateur Rugby Union

Ian C. Kenny, Caithriona Yeomans, Roisin Cahalan, Giles Warrington, FACSM, Liam G. Glynn, Mark J. Campbell, Mark Lyons, Andrew J. Harrison, Kevin Hayes, Thomas M. Comyns. University of Limerick, Limerick, Ireland. (Sponsor: Giles Warrington, FACSM)
 Email: ian.kenny@ul.ie
 (No relevant relationships reported)

PURPOSE: Despite recent growth in game popularity worldwide, Women's Rugby Union is currently lacking rigorous, comprehensive injury surveillance programs (World Rugby). This long-term study aimed to monitor injury trends, that may emerge, which will aid future implementation of evidence-based injury prevention strategies to minimize injury risk and enhance player welfare, for the female and male game.

METHODS: Using a bespoke web-based injury recording system (IRISweb), 15 male and 4 female national league clubs were recruited for a full season of monitoring in Ireland, representing 479 male and 129 female players. Each club nominated an 'injury recorder', who was a team physician or physiotherapist trained in use of the IRISweb system. In 10% of clubs the head coach, qualified in first aid, recorded injuries.

In all cases the team physician reviewed all injuries for 'return to play' ensuring classification validity. Measures included injury incidence, type, timing, severity, and playing position.

RESULTS: The most commonly reported match injuries for men's clubs were concussion (12%), followed by ankle ligament sprains (11%); for women, it was ankle ligament sprains (11%) and concussion (11%). Concussion injuries resulted in an average of 30 days absence from Rugby match or training activities for men and 23 days for women. Timing of all injuries showed incidence rate (per 1000 player hours) for men of 7.6/10.6/19.1/11.5 for 1st/2nd/3rd/4th match quarter respectively, and 7.1/12.8/12.8/11.5 for women, showing an early 2nd quarter peak for women. The position with the highest proportion of injury was openside flanker forward (no.7) for men and inside centre back (no.12) for women. The majority of injuries for both sexes were moderate or severe (greater than eight days absence). Women presented with a significantly lower rate (13.5 Vs 18.5; p<0.05) of severe injuries.

CONCLUSIONS: The amateur women's game in Ireland has presented with both similarities and differences in injury occurrence compared to the men's game. Marked differences surround an earlier match timing of women's injury, and less severe occurrence of women's injury. Practitioners should note the most common injuries occurring and the playing positions most frequently injured and develop welfare and prevention strategies around this knowledge.

Incoming NCAA athletes must be tested for the presence of hemoglobin (Hb) S but the prevalence with positive sickle cell trait (SCT) status at Division I institutions and their prior knowledge of status is unknown. **PURPOSE:** Determine the prevalence of athletes with SCT at a Division I university and describe their demographics, prior knowledge of status, and Hb profile. **METHODS:** A retrospective chart review of the 2010/11-18/19 academic years at one university. Main outcome measures included: actual and expected prevalence of SCT positive athletes, sex, race, sport, prior knowledge of SCT status and family history, and Hb profile (HbA, HbA2, HbS, HbF, and HbC) proportions. Expected prevalence was calculated from CDC statistics and applied to the known athlete racial breakdown per year with Fisher's Exact test utilized for comparison. **RESULTS:** Twenty-six SCT positive athletes (6±1 per academic year) were identified, accounting for ~1% of the athlete population each year. The majority were Black/African-American (n=24, 92.31%) males (n=23, 88.46%). There were less SCT positive Black/African-American athletes than expected on average per year (4 vs 13, p=0.044). Football had the greater part (n=18, 69.23%) of SCT athletes followed by men's track and field (n=3, 11.54%). Other sports included women's track and field, volleyball, baseball, men's basketball and cheerleading. Five athletes (19.23%) reported prior knowledge of their SCT status. Seven athletes (26.92%) reported a family history of SCT or sickle cell disease, three of which did not know

their own status. One athlete provided a newborn screen. Results of Hb electrophoresis testing were available for 25 (96.15%) athletes. Average values for HbA, HbA2, HbS, HbF and HbC were 57.10±2.70%, 3.13±0.47%, 39.72±2.84%, 0.23±0.83% and 0.00±0.00%, respectively, excluding one unique case with 0.00% HbA, 1.40% HbA2, 59.70% HbS, 38.90% HbF and 0.00% HbC. **CONCLUSIONS:** Athletes with SCT accounted for a small proportion of the athlete population at a Division I university and were lower than expected prevalence. The majority had no prior knowledge of personal or family history. Obtaining Hb profiles beyond solubility testing can provide health care providers with information that may affect clinical manifestation and management.

2543 Board #207 May 31 11:00 AM - 12:30 PM
Seasonal Incidence of Game-Related High School Football Trauma on Artificial Turf and Natural Grass
 Michael C. Meyers, FACSM. *Idaho State University, Pocatello, ID.*
 Email: meyersgroupinc@gmail.com
Reported Relationships: M.C. Meyers: Industry contracted research; Partial funding by FieldTurf USA.

It is commonly surmised that environmental conditions and concomitant sport use dictate the quality and degree of decline of natural grass over a season of competitive football. Although artificial turf infill systems have been purported to duplicate the playing characteristics of natural grass while maintaining surface quality throughout a season of play, no long-term studies have specifically compared injury incidence rates between the two surfaces at the high school level of competition. **PURPOSE:** To quantify seasonal incidence of game-related high school football trauma on artificial turf versus natural grass. **METHODS:** 77 high schools (4A-6A) from six states (CA, GA, MI, MT, PA, TX) were evaluated from August to December over 8 competitive seasons (2010-2017). Injury incidence rates (HIR) were calculated using injuries per 10 games = (number of injuries ÷ number of games) x 10. **RESULTS:** Of the 665 games documented, 343 games (51.6%) were played on artificial turf versus 322 games (48.4%) played on natural grass. A total of 1,241 injuries were documented with 514 (41.4%) occurring on artificial turf, and 727 (58.6%) on natural grass. Analyses per 10 games indicated a significant main effect (Wilks' Lambda F = 18.925; p<0.0001) between surfaces by month. Subsequent post hoc analyses indicated a significant lower incidence of injury while competing on artificial turf (p<0.05) during August [5.6 (95% CI, 2.7-8.1) vs 23.1 (19.9-24.8)], September [11.8 (95% CI, 10.4-12.9) vs 29.3 (27.8-29.7)], October [6.0 (95% CI, 4.9-7.0) vs 26.6 (24.5-27.6)], November/December [8.0 (95% CI, 6.6-8.9) vs 36.0 (31.4-37.4)], and by total seasonal trauma [26.6 (95% CI, 25.5-27.3) vs 31.3 (30.4-31.8)] when compared to injuries reported on natural grass, respectively. **CONCLUSION:** A significantly lower incidence of trauma was documented on artificial turf when compared to natural grass throughout all months of the competitive high school season. Further investigation is warranted to quantify seasonal surface influence across severity of injury, surface impact trauma, shoe surface-contact and noncontact trauma, specific extremity joints/muscles, and elective medical procedures in high school football. The findings of this study may be generalizable only to this level of football competition and this specific artificial surface.

2544 Board #208 May 31 11:00 AM - 12:30 PM
Injury Surveillance in Amateur Rugby Union in Ireland
 Tom M. Comyns, Caitriona Yeomans, Roisin Cahalan, Giles Warrington, FACSM, Liam Glynn, Mark Campbell, Mark Lyons, Andrew Harrison, Kevin Hayes, Ian Kenny. *University of Limerick, Limerick, Ireland.* (Sponsor: Dr Giles Warrington FACSM, FACSM)
 Email: tom.comyns@ul.ie
(No relevant relationships reported)

Rugby Union is a physically demanding, full-contact team sport that has grown in popularity. To reduce injury risk a comprehensive understanding of the incidence and nature of injuries is required. Injury surveillance systems are currently lacking in the amateur rugby game worldwide. The use of consistent injury definitions and methods of data collection are needed to provide robust epidemiological information for this cohort. **PURPOSE:** To assess the match injury incidence, nature, location and burden amongst male amateur adult players in Ireland. **METHODS:** A bespoke web-based injury surveillance system was used with 15 male adult Irish amateur national league clubs (479 players) across a full rugby season. Each club nominated an 'injury recorder', either a medical physician or physiotherapist, who was trained in use of the system. The injury definition used in this injury surveillance system aligned to the World Rugby consensus guidelines on injury definitions. Measures included match injury incidence, nature, location and injury burden, which assesses the frequency of an injury in relation to the severity of the injury (measured as the number of days absent). **RESULTS:** The match injury incidence for male adult amateur players was 49.7/1,000 player hours. The most common lower limb location of injury was the ankle (6.3/1,000 player hours), while the shoulder had the highest upper limb injury incidence rate

(9.1/1,000 player hours). Regarding the nature of match injury, strains (15.4/1,000 player hours) had the highest incidence rate followed by sprains (12.9/1,000 player hours) and haematomas/contusions (6.2/1,000 player hours). The top three injuries with the highest injury burden were hamstring strains (756 cumulative days absent), concussion (611 days absent) and anterior talo-fibular ligament sprains (605 days absent). **CONCLUSIONS:** The results from this comprehensive and robust web-based surveillance system provide detail on the incidence, nature, location and burden of match injury for male adult amateur players. This information can inform practice so that appropriate injury prevention strategies and policies can be derived to reduce injury risk in male amateur rugby and thus enhance player welfare.

2545 Board #209 May 31 11:00 AM - 12:30 PM
Relationship between Physical and Wellness Baseline Screening Measures and Seasonal Amateur Rugby Injury
 Caithriona Yeomans, Ian C. Kenny, Roisin Cahalan, Victoria Costello, Giles D. Warrington, FACSM, Liam G. Glynn, Andrew J. Harrison, Kevin Hayes, Mark Lyons, Mark J. Campbell, Thomas M. Comyns. *University of Limerick, Limerick, Ireland.* (Sponsor: Dr. Giles D. Warrington, FACSM)
 Email: caithriona.yeomans@ul.ie
(No relevant relationships reported)

There is an inherent risk of injury in Rugby, due to the physical demands and exposure to collisions. While injuries in professional Rugby are widely reported, little is known about the amateur game. Investigating relationships between physical and wellness screening measures may identify injury causal factors and aid the development of targeted injury prevention strategies. **PURPOSE:** To investigate the relationship between physical and wellness screening measures, and seasonal injury in Irish amateur Rugby. **METHODS:** One hundred and thirty-seven amateur Rugby players [male n=113 (mean age=22.7±3.9), female n=24 (mean age=25.6±4.9)] were screened in pre-season and monitored throughout the season for injury. Questionnaires included: player background history and wellness; Pittsburgh Sleep Quality Index (PSQI); Athletic Coping Skills Inventory (ACSI-28) and Perceived Available Support in Sport (PASS-Q). Physical tests included: anthropometric measurements, knee-to-wall test, straight leg raise test and adductor squeeze test. Injury incidence data were gathered using a comprehensive Rugby-specific web-based surveillance system. Data were collected and analyzed in SPSS (Version 22, IBM Corp., Armonk, N.Y., USA). Logistic regression were used to estimate odds of sustaining an injury. Baseline measurements were compared between males and females and 'Forwards' (position 1-8) and 'Backs' (position 9-15) using Student's t-tests. Significance was set a-priori at P = 0.05. **RESULTS:** Males had a higher incidence of injury than females with respective incidence rates of 51.2/1,000player hours and 42.9/1,000player hours (P<0.05). In the 'Backs', an inverse relationship between adductor strength at 0° knee flexion and groin injury was found (-0.307, P<0.05). No correlations between questionnaires and other physical measurements and injury were found. **CONCLUSIONS:** The Irish Rugby Injury Surveillance (IRIS) project is the first long-term injury surveillance system monitoring injury trends in Irish amateur Rugby. Reduced groin strength at pre-season was associated with more groin injuries during the season for 'Backs'. Further investigation of groin strength and injuries in Rugby may inform future injury prevention strategies. **Funding:** The IRIS Project is funded by the Irish Rugby Football Union.

2546 Board #210 May 31 11:00 AM - 12:30 PM
Resiliency in Collegiate Athletes: A Cross-sectional Study
 Katherine Rizzone¹, Molly McCann¹, Gwen Haffenden², Jorie Freitag². ¹*University of Rochester Medical Center, Rochester, NY.* ²*University of Rochester, Rochester, NY.*
 Email: katherine_rizzone@urmc.rochester.edu
(No relevant relationships reported)

Resiliency, the ability to recovery from a difficult circumstance, is known to impact health and well-being. It may be relate to sports-related injury in athletes, but this has not been previously investigated. **PURPOSE:** To assess resiliency levels in varsity collegiate athletes and investigate possible relationships between resiliency and other factors, including previous sports-related injuries. **METHODS:** This cross-sectional study surveyed varsity collegiate athletes, from 13 different sports, enrolled in two Division III institutions. Resiliency was assessed via the Connor Davidson Resilience Scale, a validated measure. Descriptive statistics were used to describe the study population, and bivariate analyses via Chi-square and Fisher's exact where appropriate, were used to examine differences among covariates across levels of resiliency. **RESULTS:** A total of 403 athletes participated, the majority were male (58.7%) and white (81.7%) and 72.0% were team sport athletes. Average resiliency score was 74.7 (+/-13.0, range 24-100). Analysis of the cohort demonstrated that level of

resiliency significantly differed across year in school ($\chi^2=20.2$, $p=0.001$), type of school (public/private, $\chi^2=17.4$, $p=0.002$) and type of sport (team/individual, $\chi^2=12.5$, $p=0.002$), but not across gender ($\chi^2=4.9$, $p=0.08$). Levels of resiliency did not differ by race, irrespective of gender. Among female athletes, resiliency level differed by type of sport played ($\chi^2=9.1$, $p=0.01$), however, this relationship was not observed among male athletes ($\chi^2=3.5$, $p=0.2$). Resiliency level did differ significantly by type of institution attended, for both female athletes ($\chi^2=8.1$, $p=0.02$) and male athletes ($\chi^2=8.1$, $p=0.02$). Resiliency differed by year in school for female athletes, with freshman female athletes reporting low levels of resiliency more frequently as compared to senior female athletes (14.2% vs. 6.2%, respectively; $\chi^2=16.5$, $p=0.04$). There was no statistically significant difference in resiliency levels when analyzed by previous sports-related injuries or surgeries in the overall cohort or when stratified by gender. **CONCLUSIONS:** Resiliency levels differed by type of sport, type of school and year in school. Further research is needed to investigate how resiliency may impact the injury risk of collegiate athletes.

Developing a Rugby-Specific Injury Surveillance System

Giles D. Warrington, FACSM, Caithriona Yeomans, Thomas M. Comyns, Roisin Cahalan, Liam G. Glynn, Andrew J. Harrison, Kevin Hayes, Mark Lyons, Mark J. Campbell, Ian C. Kenny.
University of Limerick, Limerick, Ireland.
(No relevant relationships reported)

Rugby Union is one of the most played and watched team sports worldwide. Despite high injury incidence rates widely reported in the literature, no long-term injury surveillance system monitoring of the incidence of injury in both male and female amateur Rugby currently exists. Unlike the professional code, amateur cohorts often have limited resources and infrequent access to medical professionals, thus the effective implementation of such systems present additional challenges. **PURPOSE:** To describe the design, development, implementation and evaluation of a comprehensive Rugby-specific injury surveillance system. This paper serves to inform the international community to help develop uniform high quality approaches to injury surveillance. **METHODS:** The four phases involved in the Irish Rugby Injury Surveillance (IRIS) Project: i) A survey establishing the current injury monitoring practices in operation in the top 58 amateur Irish clubs. These 58 clubs represent 26% of all amateur clubs in Ireland. ii) The design of a comprehensive web-based surveillance system (IRISweb) to monitor injury incidence, nature and severity. iii) Recruitment of 15 male and 5 female teams out of the top 58 amateur clubs to participate in the IRIS project. iv) A survey to evaluate the usefulness of the IRISweb system, after one season. **RESULTS:** Twenty-one clubs agreed to participate, however 2 clubs failed to provide a full season of injury data and therefore were excluded from the final analysis, giving 90% compliance. Nineteen clubs completed the evaluation survey (response rate = 90%). The overall rating and usefulness of IRISweb was rated 'good' or 'very good' by 82% of clubs. The main facilitators to injury surveillance were; increased player adherence (65%) and notifications to update the system (59%). In contrast, poor player adherence (71%) and medical staff availability (24%) were the main barriers to injury surveillance. **CONCLUSIONS:** The IRIS project is the first prospective long-term injury surveillance system in Irish amateur Rugby, effectively tracking injuries to guide evidence-based injury prevention strategies. This study outlines the development of the system, highlighting facilitators and barriers to injury surveillance within amateur sport. **Funding:** The IRIS Project is funded by the Irish Rugby Football Union.

A Systematic Review And Meta-analysis Of The Incidence Of Injury In Professional Female Soccer

Lawrence Mayhew¹, Jamie McPhee², Peter Francis¹, Gareth Jones¹. ¹Leeds Beckett University, Leeds, United Kingdom. ²Manchester Metropolitan University, Manchester, United Kingdom.
 Email: l.mayhew@leedsbeckett.ac.uk
(No relevant relationships reported)

The epidemiology of injury in male professional football is well documented and has been used as a basis to monitor injury trends and implement injury prevention strategies. There are no systematic reviews that have investigated injury incidence in women's professional football. Therefore, the extent of injury burden in women's professional football remains unknown. **PURPOSE:** The primary aim of this study was to calculate an overall incidence rate of injury in senior female professional soccer. The secondary aims were to provide an incidence rate for training and match play. **METHODS:** PubMed, Discover, EBSCO, Embase and ScienceDirect electronic databases were searched from inception to September 2018. Two reviewers independently assessed study quality using the Strengthening the Reporting of Observational Studies in Epidemiology statement using a 22-item STROBE checklist.

Seven prospective studies ($n=1137$ professional players) were combined in a pooled analysis of injury incidence using a mixed effects model. Heterogeneity was evaluated using the Cochrane Q statistic and I². **RESULTS:** The epidemiological incidence proportion over one season was 0.62 (95% CI 0.59 - 0.64). Mean total incidence of injury was 3.15 (95% CI 1.54 - 4.75) injuries per 1000 hours. The mean incidence of injury during match play was 10.72 (95% CI 9.11 - 12.33) and during training was 2.21 (95% CI 0.96 - 3.45). Data analysis found a significant level of heterogeneity (total Incidence, $X^2=16.57$ $P<0.05$; $I^2=63.8\%$) and during subsequent sub group analyses in those studies reviewed (match incidence, $X^2=76.4$ (d.f. = 7), $P<0.05$; $I^2=90.8\%$, training incidence, $X^2=16.97$ (d.f. = 7), $P<0.05$; $I^2=58.8\%$). Appraisal of the study methodologies revealed inconsistency in the use of injury terminology, data collection procedures and calculation of exposure by researchers. Such inconsistencies likely contribute to the large variance in the incidence and prevalence of injury reported. **CONCLUSIONS:** The estimated risk of sustaining at least one injury over one football season is 62%. Continued reporting of heterogeneous results in population samples limits meaningful comparison of studies. Standardising the criteria used to attribute injury and activity coupled with more accurate methods of calculating exposure will overcome such limitations.

2549 Board #213 May 31 11:00 AM - 12:30 PM
Head Impacts In Women'S Collegiate Rugby: Incidence And Force Application

Erin Tuttle, Taylor Langevin, Daniel Antonoff, Christina Renodin, Ashley Potvin-Fulford, Erin Shellene, Lee Spahr, John Rosene. *University of New England, Biddeford, ME.*
 Email: etuttle2@une.edu
(No relevant relationships reported)

With the growth in women's rugby participation, there is a need to enhance our understanding of the potential for subconcussive and concussive risk in such a physical sport. Investigating head impact exposure in women's rugby is important for understanding potential concussive risk and to develop interventions that minimize this risk. **PURPOSE:** The purpose of this study was to quantify incidence, magnitude, and distribution of head impacts throughout a collegiate women's rugby season. **METHODS:** Twenty-three collegiate female rugby athletes wore Smart Impact Monitors (SIM) within headbands during practices and games. Head impact data including number of head impacts, peak linear acceleration, peak rotational acceleration, peak rotational velocity, and location of head impacts were collected. Analyses were performed to compare these data in practices and games, first and second half of game play, and by athlete position group, including hit up forwards, outside backs, and adjustables. Paired sample t-tests, repeated measure ANOVAs, and 3-way ANOVAs with a set level of significance at $p \leq .05$ were utilized in the analysis. **RESULTS:** Players sustained 120 head impacts $\geq 15g$ (range 18.1g - 78.9g) with 1199 total athlete exposures in practices and games combined. In games, 67 head impacts were recorded with a mean of 0.40 ± 0.22 impacts per-player per-game. There were 53 head impacts recorded in forty-seven practices with a mean of 0.05 ± 0.04 impacts per-player per-practice. There were no significant differences in number or magnitude of head impacts between practices and games, first half and second half of games, or by position group ($p > 0.05$). The front and the back of the head locations had significantly more head impacts than the crown and the right side of the head ($p \leq 0.05$). **CONCLUSIONS:** Collegiate women's rugby athletes endured the same number and magnitude of head impacts in both practices and games, regardless of position or time of match. These findings give insight into the subconcussive impacts that female collegiate rugby athletes sustain during competition. Further research is necessary to develop interventions that minimize head impacts and ultimately reduce risk of head injury in women's rugby.

2550 Board #214 May 31 11:00 AM - 12:30 PM
One-year Test-retest Properties Of Binocular Vision Tests

Ian Shrier, FACSM¹, Suzanne Leclerc², Stephanie Long¹, Guowei Zhong³. ¹McGill University, Montreal, QC, Canada. ²Institut National du Sport du Quebec, Montreal, QC, Canada. ³None, Montreal, QC, Canada.
 Email: ian.shrier@mcgill.ca
(No relevant relationships reported)

PURPOSE: Binocular vision tests (BVTs) are increasingly recommended for use in concussion management, but their reliability remains unknown. Our objective was to determine the one-year test-retest reliability of 10 BVTs proposed for use in concussion management, where concussions may occur months after a baseline measure. **METHODS:** We used routinely collected data on young athletes who had two sessions of pre-season baseline testing of 10 BVTs at least 11 months apart with no intervening concussion or training that might influence BVT scores. The tests assessed: 3D vision (gross stereoscopic acuity, GSA), saccades, anatomic deviation (AD) at 30cm and 3m,

ability of eyes to move/fixate in-sync (positive fusional vergence [PFV] and negative fusional vergence [NFV] at 30cm and 3m, near point of convergence [NPC], and near point of convergence - break [i.e. double vision, (NPCb)]).

RESULTS: There were 8 males and 9 females with a mean age of 22.4 (SD = 4.6) years. The intraclass correlations (ICC) suggest good reliability for PFV (0.94) and NPV (0.72) at 30cm. There was moderate reliability for NPCb (0.58), saccade (0.57), and PFV at 3m (0.58). There was poor reliability for AD 30cm (0.34) and NPC (0.45). Reliability was essentially 0 for NPV at 3m, and GSA (0.0). Limits of agreement (LoA) were best for saccade ($\pm 25\%$) and worst for AD 30 cm ($\pm 172\%$), and ranged from $\pm 40\%$ to $\pm 114\%$ for 7 of the 8 other tests. For AD 3m, the distribution was highly skewed leading LoA to be uninformative.

CONCLUSIONS: The results indicate one-year test-retest reliability of the BVTs ranged from poor to good, with the majority being moderate. The effect of concussion must have a moderate to large effect on the scores of most BVTs to be clinically useful.

**2551 Board #215 May 31 11:00 AM - 12:30 PM
The Epidemiology of Sports Related Dislocations among Collegiate and High School Athletes**

Christy Collins, Sara Quetant, Sarah N. Morris, Erin B. Wasserman. *Datalys Center for Sports Injury Research and Prevention, Inc., Indianapolis, IN.*
(No relevant relationships reported)

Athletes are at risk of sustaining a dislocation, ranging from relatively minor with minimal time lost from play to more severe with long recovery times and costly treatments. Previous studies have examined dislocations; however, most focused on specific sports or joints.

PURPOSE: To describe dislocations sustained by collegiate and high school athletes. **METHODS:** Athletic trainers (ATs) participating in the National Collegiate Athletic Association (NCAA) Injury Surveillance Program reported athlete-exposure (AE) and injury data for 25 sports during the 2009/10-2016/17 academic years. ATs participating in the National Athletic Treatment Injury and Outcomes Network (NATION) reported AE and injury data for 27 sports during 2011/12-2013/14. Dislocations occurred during a school-sanctioned practice or competition and required medical attention. Along with dislocation characteristics, injury rates per 10,000 AEs were reported with 95% confidence intervals (CIs).

RESULTS: From 2009/10-2016/17, ATs reported 542 dislocations among NCAA athletes for an injury rate of 0.81/10,000 AEs (95% CI:0.74-0.87). Men's football (1.74; 95% CI:1.53-1.94), men's wrestling (1.53; 95% CI:0.91-2.16), and women's gymnastics (1.31; 95% CI:0.54-2.09) had the highest rate of dislocations. From 2011/12-2013/14, ATs reported 149 dislocations among high school athletes for an injury rate of 0.29/10,000 AEs (95% CI:0.24-0.34). Boys' football (0.79; 95% CI:0.62-0.95), girls' basketball (0.52; 95% CI:0.26-0.78), and boys' wrestling (0.50; 95% CI:0.22-0.79) had the highest rate of dislocations. For NCAA and high school athletes, the most commonly dislocated body parts were the hand/finger (40.2% and 25.8%) and shoulder/clavicle (36.7% and 40.3%). A greater proportion of dislocations resulted from player contact (55.8% and were non-time loss (40.9%) in NCAA athletes than high school athletes (39.6% and 25.9%). A similar proportion of NCAA and high school dislocations were recurrent (20.6% and 18.8%) and required surgery (21.4% and 15.8%).

CONCLUSION: Some characteristics of dislocations vary across collegiate and high school athletes including mechanism of injury and time loss. More research is needed to determine how to effectively reduce the incidence of dislocations among all collegiate and high school athletes.

**2552 Board #216 May 31 11:00 AM - 12:30 PM
Evaluation Of Rule Modifications On The Reduction Of Injuries In High School Boys' Lacrosse**

Stanley Guillaume¹, Andrew Lincoln², Lisa Hepburn², Shane Caswell³, Zachary Kerr⁴. ¹Orange Park Medical Center, Jacksonville, FL. ²MedStar Memorial Hospital, Baltimore, MD. ³George Mason University, Fairfax, VA. ⁴University of North Carolina, Chapel Hill, NC.
Email: stanguil6@gmail.com
(No relevant relationships reported)

The National Federation of State High School Associations previously modified two lacrosse rules: Rule 5.4 in the 2012/13 academic year to heighten the penalty for any hits to the head/face/neck (HFN); and Rule 5.3.5 in the 2013/14 academic year to minimize body checking.

Purpose: To determine if the rate of overall injury, HFN injuries, and concussions due to intentional contact (checking) differed for boys' high school lacrosse players after two rule modifications were enacted.

Methods: Data were collected from the High School RIO (Reporting Information Online) sports injury surveillance system. During the 2008/09-2016/17 seasons, athletic trainers collected injury and athlete-exposure (AE) data for high school boys' lacrosse teams. Overall and checking-related injury rates were calculated and stratified

by competition and practice settings. Overall, HFN, and concussion injury rates were further analyzed by checking mechanism (e.g., being body/stick checked or delivering body/stick check). Incidence rate ratios (IRR) with 95% confidence intervals (CI) compared rates prior to and after the enactment of the rule modifications (Rule 5.4 - 2012/13 vs. 2008/09-2011/12; Rules 5.4 and 5.3.5 - 2013/14-2016/17 vs 2008/09-2011/12).

Results: There was a significant decrease in checking-related HFN injuries (IRR, 0.29; 95% CI, 0.13-0.65) and checking-related concussions (IRR, 0.29; 95%CI, 0.12-0.70) during practice in the seasons after both rule modifications were imposed, but there were no significant decreases in any checking-related injuries during competition. When both rules were enacted together, concussion risk due to delivering body check (IRR, 0.51; 95% CI 0.29-0.91) and overall injury risk due to being body checked (IRR, 0.72; 95% CI, 0.53-0.97) decreased. By injury mechanism, there were no significant decreases after only the Rule 5.4 modification took place.

Conclusion: When both the Rule 5.4 and 5.3.5 modifications were in effect, concussion and overall injury risk decreased for the player initiating the body check and the player being body checked, respectively. However, concussion risk due to being body checked during games was not affected.

**2553 Board #217 May 31 11:00 AM - 12:30 PM
Gastrointestinal Illness Accounts for Most Days Lost per Single Illness During the Super Rugby Tournament**

Audrey Jansen van Rensburg¹, Martin P. Schwellnus, FACSM², Dina C. Janse van Rensburg, FACSM¹, Esme Jordaan³, Charl Janse van Rensburg⁴. ¹Sports Medicine, University of Pretoria, Pretoria, South Africa. ²SEMLI, University of Pretoria, Pretoria, South Africa. ³South African Medical Research Council, Cape Town, South Africa. ⁴South African Medical Research Council, Pretoria, South Africa.
(No relevant relationships reported)

Purpose: Respiratory tract (RT) and gastrointestinal (GI) illness is commonly reported in elite athletes. The purpose of this study is to determine the incidence rate, illness burden (IB), and mean training / match days lost (per single illness) for RT and GI illness in rugby union players participating in the annual Super Rugby tournaments.

Methods: A total of 868 elite rugby players from 5 South African teams that participated in the Super Rugby tournament from 2013 to 2016, were followed daily over the 20-week competition period for each year (80 167 player days over 4 years). Team physicians were 100% compliant in completing the illness log. Information included the daily squad size and illness details including the system affected and training/match days lost. We report illness incidence rate (IR=illness per 1000 player days; 95% CI), illness burden (IB=days lost per 1000 players days; 95%CI), and mean training / match days lost (per single illness) for the RT and GI systems. **Results:** 389 illnesses (RT=271; GI=78, Other=40) were reported, with an overall crude IR of illness of 4.85 (4.38-5.36). The IR of illness was significantly higher in the RT system (3.38; 2.97-3.85) vs. the GI system (0.97; 0.75-1.23) (p<0.0001). The IB for all systems over the 4-year period was 5.93 (5.40-6.48), and this was significantly higher in the RT (3.36; 2.97-3.78) compared with the GI system 1.73 (1.46-2.05) (p<0.0001). However, the days lost to a single illness was significantly higher in the GI system (1.78; 1.51-2.10) compared to the RT system (0.99; 0.88-1.12) (p<0.0001). **Conclusion:** In the elite Super Rugby tournament, illness in the RT system accounts for the highest IR and burden of illness. However, days lost per single GI illness is highest; therefore, a GI illness is more serious, resulting in more days lost to training / matches. Future studies should therefore determine specific risk markers for GI illness, so that preventative measures can be designed and implemented to protect the health of these Super Rugby players.

**2554 Board #218 May 31 11:00 AM - 12:30 PM
The Prevalence of Obesity and its Association with Previous Musculoskeletal Injury in Probation Officers**

Jacob A. Mota, Zachary Y. Kerr, Gena R. Gerstner, Hayden K. Giuliani, Eric D. Ryan. *University of North Carolina at Chapel Hill, Chapel Hill, NC.* (Sponsor: Abbie Smith-Ryan, FACSM)
Email: jamota@unc.edu
(No relevant relationships reported)

Probation officers are responsible for the supervision of criminal offenders released into the community with the high risk of violent and physically demanding interactions. Despite obesity reaching epidemic levels in many public safety occupations, probation officers remain understudied. **PURPOSE:** The purpose of the current study was to examine the prevalence of obesity and its association with previous musculoskeletal injury in probation officers. **METHODS:** The current study used data from a survey administered to all North Carolina probation officers in 2015, with 1,323 completing the entire survey (70.9%). The survey included questions on demographics, injury history, physical activity, geographical location of work, and years of employment. Body mass index (BMI) was calculated and classified per the National Heart, Lung, and Blood Institute's guidelines. A logistic regression model

estimated the odds ratios (OR) of musculoskeletal injury history within the past year. Predictor variables were age, sex, employment history, geographical location, physical activity within the past month, and BMI classification. **RESULTS:** The majority (80.8%) of the respondents were classified as overweight or obese (BMI > 25.0 kg/m²), with 49.9% classified as obese (BMI > 30 kg/m²) and 9.5% classified as severely obese (BMI > 40 kg/m²). Multivariable logistic regression modeling suggested that workers categorized as being severely obese (BMI > 40 kg/m²) were 2.5 times more likely (OR=2.56; 95% CI=1.19-5.51) to sustain a musculoskeletal injury within the past year than their normal weight colleagues. **CONCLUSION:** Given the prevalence of obesity in our sample of probation officers, and its association with previous musculoskeletal injury, public safety administrators may wish to consider workplace interventions designed to combat obesity.

2555 Board #219 May 31 11:00 AM - 12:30 PM
Graft Type And Previous ACL Injury Influence Re-rupture Rates In 1478 ACL Reconstructions With 95% 2 Year Follow-up

Ray Moran¹, Enda King¹, Chris Richter¹, Eanna Falvey¹, Siobhan Strike², Andy Franklyn Miller¹. ¹*Sports Surgery Clinic, Dublin 9, Ireland.* ²*University of Roehampton, London, United Kingdom.*
 (No relevant relationships reported)

Purpose

The aim of this study was to report outcomes relating to the patient reported outcome measure International Knee Documentation Committee questionnaire (IKDC), return to play rates and second ACL injury rates at 2 year follow up, while examining differences in second ACL injury rate relating to gender, graft type and previous ACL reconstruction (ACLR).

Methods

Prospective data was collected on 1478 consecutive ACL reconstructions for a single surgeon between 1st January 2014 and 1st October 2016. Data was collected at pre-op, intra-op, and 2 year follow up relating to IKDC, RTP and second ACL injury. ACLR was carried out with bone patellar tendon bone (BPTB, n = 1335) or 4 strand double bundle hamstring autograft (HT, n = 130). Isokinetic dynamometry and 3D biomechanical analysis of jump and change of direction tests were carried out at 3, 6 and 9 months post-surgery as able. Chi Squared test was used to analyse differences in ipsilateral and contralateral ACL injury rates relating to gender, previous ACLR and graft type.

Results

1072 male and 393 female patients with an average age of 25.6 years (± 8.7) formed the cohort. 90 had previous ACLR with 1375 no previous ACL injury. Pre-op 1262 (86.1%) stated their intention to return to the same level of sport or higher after surgery. There was 2 year follow up on 94.5% of subjects. RTP rate was 78% with 11.1% not returning because of the operated knee and 10.8% because of other reasons. The mean IKDC score was 86.2 (± 10.4). There were 40 ipsilateral injuries (2.7%) and 84 contralateral injuries (5.7%). There was a significant difference in ipsilateral injury rate between those with previous ACLR (8.5%) and those without (1.6%) (p < 0.001) with no difference in contralateral injury rates between groups. There was a significant difference in ipsilateral injury rate between graft types with higher rates in HT(9.2%) than BPTB grafts (2.1%) (p < 0.001) with no difference in contralateral injury rates. There was no difference in ipsilateral (p = 0.531) or contralateral (p = 0.370) injury rates between male and female patients.

Conclusion

This study reports excellent re-injury, RTP and IKDC scores for a single surgeon in a large cohort with 95% follow up at 2 years post reconstruction. Those with HT graft and previous ACLR had higher rates of re-injury of the ACLR limb.

2556 Board #220 May 31 11:00 AM - 12:30 PM
Frequency, Magnitude, And Location of Head Impacts In Collegiate Water Polo

Jenna J. Phreaner, Derek C. Monroe, Nicholas J. Cecchi, Steven L. Small, James W. Hicks. *University of California, Irvine, Irvine, CA.*
 (No relevant relationships reported)

Water polo is a contact sport that carries a risk of head injury, well documented in epidemiological surveys of USA Water Polo members and physician reports from international competition. However, a growing body of evidence suggests that head impacts—even those that are asymptomatic and go unreported—can produce brain injury. We know from both survey data and prospective monitoring of NCAA Division I athletes that the risk for head impacts is dependent on player position. It is unknown if these patterns extend to other levels of competition. **PURPOSE** To describe patterns of head impacts in intercollegiate club water polo (ICWP) competition. **METHODS** ICWP players (9 Men; 14 Women) were monitored during

competition for head impacts using cap-worn inertial sensors to record impact time, head locations, peak linear acceleration (PLA), and peak rotational acceleration (PRA). Video recordings of competitions were reviewed to rule out false positives. The null hypotheses that impact frequencies were equally distributed among (i) player positions, (ii) game scenarios, and (iii) head locations were tested using Chi-square 'goodness-of-fit' tests. Significant differences were decomposed by chi-square tests. T-tests were used to test for differences in PLA and PRA between men and women. All results presented are corrected for multiple comparisons. **RESULTS** Men sustained 52 head impacts and women sustained 43 head impacts over 12 games, mostly on offense [71.2%, 62.8%; p<.001] and mostly at the center position relative to perimeter positions [p<.0001]. Impacts were most often sustained at the back of the head among men and women [p<.03]. Impacts ranged from low to high magnitude for men [means(range): PLA=39.7 (17.7-94.1)g; PRA=5.21(1.00-17.40) krads/sec²] and women [means(range): PLA=33.7 (16.2-72.6)g; PRA=4.02 (.20-14.00) krads/sec²]. Magnitudes did not differ between men and women [t(93)<1.98, p>.051]. **CONCLUSION** We observed a pattern of risk among male and female ICWP players similar to a pattern previously reported in Division I men's water polo players. Considering the growing body of evidence suggesting adverse effects of repeated head impacts, our data suggest that players, particularly at the center position, might benefit from wearing protective headgear that attenuates the forces of these head impacts.

2557 Board #221 May 31 11:00 AM - 12:30 PM
The Epidemiology Of Ankle Sprains In Youth, High School, And College Lacrosse

Aliza K. Nedimyer¹, Avinash Chandran¹, Andrew E. Lincoln², Shane V. Caswell³, Thomas P. Dompier⁴, Erik A. Wikstrom, FACSM¹, Zachary Y. Kerr¹. ¹*University of North Carolina at Chapel Hill, Chapel Hill, NC.* ²*MedStar Sports Medicine Research Center, Baltimore, MD.* ³*George Mason University, Manassas, VA.* ⁴*Lebanon Valley College, Annville, PA.* (Sponsor: Erik A. Wikstrom, FACSM)

Reported Relationships: A.K. Nedimyer: Other (please describe); The NCAA Injury Surveillance Program was funded by the NCAA., HS NATION was funded by the National Athletic Trainers' Association Research and Education Foundation (NATA REF), and the Central Indiana Corporate Partnership (CICP) Foundation., Data collection for youth lacrosse was funded by National Operating Committee on Standards for Athletic Equipment (NOCSAE) and US Lacrosse..

Understanding how ankle sprain injury incidence varies by level of play in male and female lacrosse players is important in informing level- and sport-specific injury prevention strategies.

Purpose: Describe the epidemiology of ankle sprains in youth, high school (HS), and college lacrosse in the 2014/15-2016/17 seasons.

Methods: Youth data originated from 10 leagues in 5 states (21 boys' and 21 girls' team-seasons). HS data originated from the National Athletic Treatment, Injury and Outcomes Network (22 boys' and 15 girls' team-seasons). College data originated from the National Collegiate Athletic Association Injury Surveillance Program; 20 men's and 47 women's team-seasons). Athletic trainers (ATs) reported athlete-exposure (AE) and injury data from practices and competitions. Injury rate ratios (IRR) compared injury rates by level of play. Sex differences were not examined as these sports have different rules. IRRs with 95% confidence intervals (CI) excluding 1.00 were considered significant. We calculated the proportions of time loss (TL) injuries (resulting in participation restriction time ≥24 hours) and injury mechanism distributions.

Results: Ankle sprain rates per 1000AE were 0.77 (n=20), 0.36 (n=13), and 0.54 (n=62) in youth, HS, and collegiate male players, respectively, and 1.20 (n=11), 0.90 (n=20), and 0.56 (n=55) in youth, HS, and collegiate female players, respectively. Ankle sprain rates were higher in youth girls versus college women (IRR=2.15, 95%CI: 1.12-4.11), and youth boys versus HS boys (IRR=2.14, 95%CI: 1.07-4.31). Overall, 50% of ankle sprains in female lacrosse players were TL injuries; proportions of TL injuries in male lacrosse players increased with level of play (40.0%, 62.9% and 71.2%, respectively). Also, 56.2% of male ankle sprains and 39.2% of female ankle sprains were due to non-contact mechanisms. Overall, proportions of player contact-related ankle sprains increased with level of play (6.5%, 18.2%, and 29.1%, respectively).

Conclusions: Ankle sprain rates varied by level of play in male and female lacrosse players. Variations associated with TL injuries and player contact-related injuries may highlight the need for level-specific injury prevention strategies. Future research should target reducing the incidence of non-contact ankle sprains.

2558 Board #222 May 31 11:00 AM - 12:30 PM
PROMIS Physical Function Two Weeks Following Orthopaedic Surgery

Gregory Perraut, Ali Aneizi, Vidushan Nadarajah, Patrick Sajak, Michael P. Smuda, Min Zhan, Jonathan D. Packer, R. Frank Henn, III. *University of Maryland School of Medicine, Baltimore, MD.*

(No relevant relationships reported)

Many patients opt for elective orthopaedic procedures to regain physical function. However, little data exist describing early postoperative function, which limits surgeons' ability to appropriately manage their patients' expectations and recovery. **PURPOSE:** To characterize physical function level two weeks postoperative from upper and lower extremity orthopedic surgery and to determine pre-operative factors that are associated with change in physical function two weeks following surgery. **METHODS:** Patients 17 years and older undergoing elective orthopaedic surgery at one institution were enrolled prospectively and completed various questionnaires prior to surgery and again two weeks postoperatively. The questionnaires included: six of the PROMIS computer adaptive questionnaires: Physical Function (PF), Pain Interference, Fatigue, Social Satisfaction, Anxiety, and Depression; a joint-specific function questionnaire, a joint numeric pain scale, and a body numeric pain scale. Physical activity levels were measured using three legacy PRO questionnaires (Tegner, IPAQ, and Marx). Responses were analyzed using Spearman's correlation coefficient, ANOVA, and multivariate linear stepwise regression with PF as the dependent variable. **RESULTS:** 435 patients (47% female) with mean age 41.1 ± 15.7 were included in our final analysis. Mean baseline PF score was 42.1 and mean two-week PF score was 35.5 ($p < .0001$). Patients undergoing upper extremity surgery had higher PF at two weeks than those undergoing lower extremity surgery (39.1 vs 32.2 , $p < .0001$). Ethnicity, preoperative narcotic use, operative joint, injury prior to surgery, and baseline IPAQ category all had significant impact on 2 week postoperative PF score ($p < .05$). Numerous baseline and 2-week measures were correlated with postoperative PF score, with 2-week Social Satisfaction demonstrating the strongest correlation ($r = 0.604$, $p < .0001$). Multivariate regression demonstrated several independent predictors of 2-week PF score. **CONCLUSIONS:** Patients have a significant decline in physical function following orthopaedic surgery, with those undergoing lower extremity surgery having a significantly greater decline. This information can be used to properly manage patients' short-term expectations and increase patient satisfaction.

2559 Board #223 May 31 11:00 AM - 12:30 PM
State Regulations and Region Are Associated With High School Football Preseason Heat Acclimatization Guidelines Compliance

Zachary Y. Kerr¹, Samatha E. Scarneo², Andrew J. Grundstein³, Riana R. Pryor⁴, Yuri Hosokawa⁵, Douglas J. Casa, FACSM², Johna K. Register-Mihalik¹. ¹*University of North Carolina at Chapel Hill, Chapel Hill, NC.* ²*University of Connecticut, Storrs, CT.* ³*University of Georgia, Athens, GA.* ⁴*California State University - Fresno, Fresno, CA.* ⁵*Ritsumeikan University, Kusatsu, Japan.* (Sponsor: Douglas Casa, FACSM)
 Email: zkerr@email.unc.edu

Reported Relationships: Z.Y. Kerr: Other (please describe); This research was funded by a grant from the National Athletic Trainers' Association Research and Education Foundation, on which Kerr and Register-Mihalik served as co-PIs, The Korey Stringer Institute (at which Casa and Scarneo are employed) were involved in the development of the preseason heat acclimatization guidelines examined in this study.

In 2009, the National Athletic Trainers' Association Inter-Association Task Force (NATA-IATF) created preseason heat acclimatization guidelines to reduce exertional heat illness (EHI) risk. **PURPOSE:** Examine how United States (US) high school (HS) football programs' compliance with NATA-IATF guidelines in the 2017 preseason was associated with state regulations and region. **METHODS:** A sample of 1000 athletic trainers (ATs) completed an online survey assessing their HSs' compliance with 17 NATA-IATF guidelines in the 2017 preseason. ATs provided HS zip codes to generate our main exposures: (1) whether their state HS athletic associations mandated the guidelines; and (2) region based on warm season wet bulb globe temperature (WBGT). The mild Region 1 included the Pacific Coast and northern US; moderate Region 2 included the midsection of the US; and hot Region 3 included the Southern US. Our two main outcome measures were: reporting compliance with all 17 and ≥ 10 NATA-IATF guidelines. Multivariable binomial regression models estimated prevalence ratios (PR) with 95% confidence intervals (CI). Characteristics of ATs (age, sex, years experience) and HSs (student enrollment, football squad size) were considered for model inclusion via forward model building; only age was retained. **RESULTS:** Most ATs were female (54.9%), aged < 40 years (65.5%), and with < 10 years of experience (50.3%). The HSs were mostly located in Region 3 (43.8%), with 16.0% in states with

mandates. Overall, 4.0% reported compliance with all 17 NATA-IATF guidelines; 74.2% complied with ≥ 10 . Controlling for age, the prevalence of reporting compliance with all 17 guidelines was higher in states with versus without mandates (PR=2.89, 95%CI: 1.53-5.45), and in Region 3 versus Region 1 (PR=4.86, 95%CI: 1.48-16.01). Similar results were found when examining compliance with ≥ 10 guidelines (states with versus without mandates PR=1.21, 95%CI: 1.11-1.30; Region 3 versus Region 1 PR=1.31, 95%CI: 1.19-1.44). **CONCLUSIONS:** Compliance with all 17 NATA-IATF guidelines is low, though many HSs complied with ≥ 10 . Findings highlight the need to identify facilitators of proper implementation, particularly in relatively cooler areas (i.e., Region 1) where there may be less concern for EHI. State-level mandated NATA-IATF guidelines may help increase compliance.

2560 Board #224 May 31 11:00 AM - 12:30 PM
Association Between Running Shoe Characteristics and Lower Extremity Injuries in United States Military Academy Cadets

Gary L. Helton¹, Kenneth L. Cameron², Rebecca A. Zifchock³, Erin Miller², Donald L. Goss², Jinsup Song⁴, Michael T. Neary⁵. ¹*William Beaumont Army Medical Center, El Paso, TX.* ²*Baylor University-Keller Army Community Hospital Division 1 Sports PT Fellowship, West Point, NY.* ³*United States Military Academy, West Point, NY.* ⁴*Temple University School of Podiatry, Philadelphia, PA.* ⁵*Providence Community Health Center, Providence, RI.*

Email: ghelton10@gmail.com

(No relevant relationships reported)

PURPOSE: Prospectively investigate the relationship between running shoe characteristics and lower extremity musculoskeletal injury. **METHODS:** The study included 1025 of 1308 incoming United States Military Academy (USMA) cadets. Shoe length and stiffness were recorded to calculate shoe torsional stiffness while shoe heel height was also recorded. Demographic data and Army Physical Fitness Test (APFT) data were also recorded. Lower extremity injuries sustained over nine weeks during cadet basic training were documented using the Armed Forces Health Longitudinal Technology Application (AHLTA) and the Cadet Illness and Injury Tracking System (CIITS). Kaplan-Meier survival curves were estimated with time to incident of lower extremity injury as the primary outcome by level of the independent predictor variables. Risk factors and known or potential covariates were carried forward into multivariable Cox Proportional Hazards Regression Models. **RESULTS:** Approximately 18.1% of participants incurred a lower extremity injury. Cadets wearing shoes with moderate lateral torsional stiffness were 49% less likely to incur any type of lower extremity injury and 52% less likely to incur a lower extremity injury due to overuse than cadets wearing shoes with minimal lateral torsional stiffness. Risk of injury was similar among cadets wearing shoes with minimal and extreme lateral torsional stiffness. **CONCLUSIONS:** Shoes with mild to moderate lateral torsional stiffness may be appropriate in reducing risk of lower extremity injury in cadets. Shoes with minimal lateral torsional stiffness should be discouraged in this population.

E-40 Free Communication/Poster - Caffeine Supplementation

2561 Board #225 May 31 11:00 AM - 12:30 PM
Effects of Pre-exercise Caffeinated Energy Drink Consumption on Running Performance.

Angela Huber, Joe Adams, Kerri De Jonge, Adam Gist, Lesly Jeanpois, Benjamin Stayton, Kimberly Wasielewski, Wick Colchagoff, Scott Van Zant. *University of Findlay, Findlay, OH.*
 Email: hubera@findlay.edu

(No relevant relationships reported)

Purpose: The purpose of this study was to examine the effects of pre-exercise consumption of a commercially available caffeinated energy drink on running performance in healthy adult subjects. **Methods:** Eight adult subjects (50% female; Age: 31.1 ± 6.0 y, Ht: 175.3 ± 46.8 cm, Wt: 77.7 ± 7.5 kg, BMI: 25.30 ± 2.2 kg/m²) provided their informed consent for participation. All subjects had at least a 3-month history of regular running (at least 30 min, 3 times per week) and were typical consumers of caffeine (at least weekly). Subjects first completed a progressive treadmill running protocol to determine $\dot{V}O_2$ peak, with continuous measurement of $\dot{V}O_2$ (indirect calorimetry) and HR (wireless heart monitor). Blood pressure (auscultation) and RPE (Borg ratio scale) were assessed at each workload. Subjects

returned for two performance-running trials, staged at least one week apart. One hour prior to each run, subjects consumed a commercially available caffeinated drink (CAF) (Monster® Rehab®, containing 1.48 mg caffeine/kg body weight), or a similar tasting, non-caffeinated placebo drink (PLA). Both drinks contained an equal amount of carbohydrate (3 gm) per serving. Drinks were administered in a double-blind fashion. Subjects then completed a 30-minute run at a pace corresponding to 70-75% $\dot{V}O_2$ peak, and then ran at 90% $\dot{V}O_2$ peak until volitional fatigue. $\dot{V}O_2$ and HR were monitored continuously throughout the performance run. BP and RPE were obtained every 5 minutes of the first 30 minutes and at conclusion of the run. Performance time at 90% $\dot{V}O_2$ peak was recorded. Mean values for all measured variables between trials were assessed for differences ($p < 0.05$) via repeated measures ANOVA. **Results:** During the run trials, no significant differences were seen in $\dot{V}O_2$, METS, %fat used, %carbohydrate used, HR, RPE, and BP. RER at 5 min of the run was significantly ($p = 0.046$) reduced in the CAF trial. Mean run time at 90% $\dot{V}O_2$ peak (8.96 min PLA, 9.46 min CAF) was not significantly different ($p = 0.37$) or clinically meaningful (effect size = 0.08). **Conclusions:** Pre-exercise consumption of a commercially available caffeinated energy drink failed to significantly impact metabolic / cardiovascular function and performance run time in recreational adult runners.

2562 Board #226 May 31 11:00 AM - 12:30 PM
Effects of Acute Consumption of Caffeinated Gum on Anaerobic Exercise Performance

Ryan Fiddler¹, Larissa True¹, Jeff Bauer¹, Katherine Monson¹, Mathew Martone¹, Angelica Butler¹, Philip J. Buckenmeyer¹, Gary H. Kamimori, FACSM². ¹SUNY-Cortland, Cortland, NY. ²CIV USARMY MEDCOM WRAIR, Silver Spring, MD. (Sponsor: Gary H. Kamimori, FACSM)
 Email: ryan.fiddler@cortland.edu
 (No relevant relationships reported)

Athletes commonly consume caffeine to enhance sports performance. Caffeine is ingested from a variety of sports nutrition products such as sports drinks, energy drinks, gels, and bars. **PURPOSE:** The purpose of this study was to investigate the effect of caffeinated chewing gum on anaerobic exercise performance. **METHODS:** Using a double-blind, counter-balanced, repeated measures crossover design, 22 recreationally-active college-aged males and females (mean \pm SD: age = 21.0 \pm 1.1 yr; height = 172.5 \pm 9.9 cm; body mass = 74.6 \pm 13.8 kg) consumed either 200 mg of caffeinated chewing gum (CAFF, Military Energy Gum, MarketRight Inc, Plano, IL) or placebo (PL) approximately 30 minutes prior to performing the Wingate bike test. Paired-samples *t* tests were used to compare differences between the following dependent variables: mean power (MP), peak power (PP; highest power output in 5 s), fatigue index (FI), and total work (TW). **RESULTS:** There were no statistically significant differences in MP (CAFF; 7.44 \pm 1.16 vs. PL; 7.47 \pm 1.37 watts \cdot kg⁻¹, $p = 0.720$), PP (CAFF; 10.40 \pm 1.52 vs. PL; 10.52 \pm 1.34 watts \cdot kg⁻¹, $p = 0.659$), FI (CAFF; 11.80 \pm 4.58 vs. PL; 13.21 \pm 4.44 watts \cdot sec⁻¹, $p = 0.059$), or TW (CAFF; 16921.81 \pm 4943.71 vs. PL; 16971.98 \pm 5036.38 kJ, $p = 0.823$) between treatments. **CONCLUSIONS:** These results suggest that 200 mg of caffeine consumed approximately 30 min prior to the Wingate bike test does not improve anaerobic performance in recreationally-active college-aged males and females.

2563 Board #227 May 31 11:00 AM - 12:30 PM
Effects of Caffeinated Chewing Gum on Repeated Sprint Performance in Recreationally Active Individuals

Melissa A. Whidden, FACSM¹, Matthew D. Simcox¹, Brooke R. Berridge¹, Peter S. Greenland¹, Elizabeth D. Schultz¹, James J. Hauser¹, Matthew B. Hudson², Kenneth P. Clark¹. ¹West Chester University, West Chester, PA. ²University of Delaware, University of Delaware, DE.
 Email: mwhidden@wcupa.edu
 (No relevant relationships reported)

Caffeine is frequently consumed by athletes as an ergogenic aid during training and competition. It has been shown to improve performance in moderately intense-long duration endurance exercise. The mechanisms to explain caffeine's performance enhancing effects include improving nervous system activation, muscle contraction, and fuel delivery to the muscle. However, the effects of caffeine on singular or repeated bouts of short term high-intensity exercise are less clear. **PURPOSE:** To investigate the effects of caffeinated chewing gum on performance during repeated high-intensity sprints in active individuals. **METHODS:** Six recreationally active subjects (Age = 21 \pm 1 yr) completed two high-intensity experimental sessions, consisting of two sets of 60 meter sprints with three sprints per set. Caffeine (240 mg) or placebo was administered via chewing gum following the first set of sprints of each experimental session. Middle 20 meter sprint times, post sprint heart rates and post sprint ratings of perceived exertion (RPE Scale 1-10) were measured. **RESULTS:** There were no significant changes in 20 meter sprint times between the two experimental conditions across the six sprints; 2.69 \pm 0.08 secs (placebo) vs. 2.74 \pm 1.6 secs (caffeine). However, sprint times were maintained in the caffeinated trial when compared to the

placebo condition across the six sprints. There was a trend for post sprint heart rates to be lower following the fourth sprint performed (144 \pm 13 bpm placebo vs. 125 \pm 11 bpm caffeine, $P = 0.07$) but the effect did not carry over into the fifth and final sprint. There was a trend for RPE to be lower following the fifth sprint (6.33 \pm 0.5 placebo vs. 4.83 \pm 0.3 caffeine, $P = 0.06$) and it was significantly lower (6.5 \pm 0.5 placebo vs. 5.1 \pm 0.4 caffeine, $P \leq 0.05$) following the final sprint. **CONCLUSIONS:** The acute ingestion of caffeine via chewing gum appears to maintain speed during repeated, high-intensity sprints in recreationally active individuals. Furthermore, caffeinated chewing gum seems to lower post sprint heart rates and ratings of perceived exertion. Further research with additional subjects is needed to ascertain if caffeinated chewing gum taken during the later stages of high-intensity exercise helps to maintain exercise performance and attenuate fatigue.

Effect of Caffeinated Gum on Choice Reaction Time

Philip J. Buckenmeyer¹, Ryan Fiddler¹, Larissa True¹, Jeff Bauer¹, Katherine Monson¹, Angelica Butler¹, Matthew Martone¹, Gary H. Kamimori, FACSM². ¹SUNY Cortland, Cortland, NY. ²CIV USARMY MEDCOM WRAIR (US), Silver Spring, MD.
 Email: buckenmeyerp@cortland.edu
 (No relevant relationships reported)

Caffeine ingestion is a common practice for individuals seeking to feel more awake or trying to improve performance. Rather than consuming caffeinated drinks, a more recent trend is that of chewing caffeinated gum. Published research in this area, particularly in support of benefits to fine motor performance, is limited. **PURPOSE:** To determine if chewing Military Energy Gum (MEG, MarketRight Inc, Plano, IL) compared to a placebo can improve choice reaction time (CRT, MOART System, Lafayette, IN) under rested and fatigued conditions. **METHODS:** Twenty-two (12 males, 10 females), college-aged (mean \pm SD: 21 \pm 1.1 yrs; 1.73 \pm 0.10 m in ht; 74.6 \pm 14.18 kg in wt), volunteers participated in a double-blind, cross-over, placebo-based study. All subjects completed an IRB consent form. Subjects were asked to be available for testing on two non-consecutive days, for one hour. Prior to each testing period, subjects fasted from food for 7 hours and abstained from alcohol for 24 hours. Upon arrival the first day, subjects completed a brief health assessment survey, performed the CRT and the Wingate cycling power (WCP) test. Subjects performed the CRT (pre-gum CRT), were given two pieces of either 200 mg caffeinated MEG (cMEG) or placebo MEG (pMEG), chewed the gum for ten minutes, and again performed the CRT (post-gum CRT), completed the WCP test, and did CRT for third time (post-gum WCP). A mixed-methods ANOVA was conducted to determine if a group (MEG, placebo) by time (pre-gum, post-gum, post-WCP) interaction on choice reaction time existed. Significance was established at $p < 0.05$. **RESULTS:** There was no statistically significant interaction between group and time. However, CRT for the cMEG improved significantly from pre-gum (0.544 \pm .09 sec) to post-gum (0.504 \pm .07 sec), and pre-gum to post-Wingate ($M = 483 \pm .08$ sec). **CONCLUSION:** When compared to a placebo, caffeinated MEG did not significantly improve choice reaction time of college-aged participants under rested or fatigued conditions. Yet, choice reaction timing did show an improving trend during the sequential testing.

Caffeine, an adenosine receptor antagonist, has documented hypo-analgesic effects during exercise. However, there is currently a lack of research focusing specifically on the potential analgesic effects of caffeine on delayed onset muscle soreness. **PURPOSE:** The purpose of this study was to determine whether 5 mg/kg of caffeine attenuates muscle pain and improves 5k running performance following exercise-induced muscle soreness. **METHODS:** The subjects ($n = 11$) included nine males and two females who were apparently healthy adults (height: 175.9 \pm 8.4cm, body mass: 69.2 \pm 7.5 kg, age: 24.5 \pm 6.3 years, body fat: 8.5 \pm 4.7%, $\dot{V}O_{2max}$ 63.6 \pm 6.1 ml \cdot kg⁻¹ \cdot min⁻¹). Prior to participating, the subjects were asked to discontinue supplement use for 72 hours and abstain from caffeine consumption for 48 hours. Participants first performed an introductory testing and familiarization session to gain an understanding of the procedures. The study included a 30-minute downhill run on a treadmill set at -10% grade and 70% $\dot{V}O_{2max}$ to induce delayed onset of muscle soreness. Participants then returned 48 hours after to complete a 5k time trial run where they consumed either

5 mg/kg of caffeine (CAFF) or placebo (PLB). Rating of perceived exertion (RPE) and heart rate (HR) were taken every two minutes during the trial. **RESULTS:** There was no detectable statistical difference between 5k performance between trials ($p = .67$) for CAFF (1036.2 ± 92.6 sec) vs. PLB (1043.4 ± 91.9 sec). Algometer readings were similar between CAFF and PLB trials for rectus femoris (RF) muscle soreness ($p = .216$) and vastus medialis oblique (VMO) muscle soreness ($p = .679$). There was no difference detected between CAFF and PLB trials for muscle weakness or tenderness ($p = .824$). There were also no differences between trials for RPE ($p = .818$). **CONCLUSIONS:** The present study does not suggest that caffeine is effective at reducing muscle soreness, RPE or improving performance during exercise when DOMS is present.

Effects of 8 Weeks of Caffeine Supplementation on Protein Metabolism Markers in Resistance-Trained Men
 William R. Lunn, FACSM, James Gerosa. *Southern Connecticut State University, New Haven, CT.*
 Email: lunnw1@southernct.edu
 (No relevant relationships reported)

The use of caffeinated beverages and supplements is common among collegiate and recreational athletes, with 85% of people aged 18-24y consuming caffeine. The use of caffeine may influence the adaptations to resistance training by altering pathways in protein metabolism. **PURPOSE:** The purpose of this study was to determine if caffeine intake alters markers of protein metabolism, changes in strength gains, or body composition in response to an 8-week resistance training protocol. **METHODS:** Resistance-trained men ($n=20$; 22.1 ± 2.4 y; 178.1 ± 7.5 cm; 82.8 ± 15.7 kg) were randomly assigned into a caffeine (CAF; $n=10$) or placebo supplementation group (PLA; $n=10$). Participants were instructed to consume three caffeine (200 mg per capsule; 7.7 ± 1.3 mg·kg⁻¹) or placebo capsules per day. Both groups followed 4-day meat-free meal plans before study commencement, the 4th week of the protocol, and the 8th week of the protocol. Skinfold and 10-repetition max test (10RM) were performed to test body composition and strength, respectively, at each time point. Urine collection (24-hr) was performed to determine urinary 3-methylhistidine (3MH), urinary creatinine (Cr), and 3MH:creatinine (3MH:Cr). A 2x3 repeated measures MANOVA with a Bonferroni *post-hoc* test was used to test significance ($p < 0.05$). **RESULTS:** After 8 weeks of supplementation and resistance training, urinary 3MH:Cr was significantly lower in CAF than PLA (0.137 ± 0.49 vs 0.178 ± 0.48 $\mu\text{mol}\cdot\text{mmol}^{-1}$; $p = 0.016$). There were no significant differences between groups in strength or body composition. **CONCLUSION:** The results from this study demonstrated consuming caffeine does not negatively affect common adaptations to resistance training, and may improve the metabolic environment to promote muscle protein synthesis. Young, resistance-training men who habitually consume ergogenic doses of caffeine may impart proteolytic suppression that can benefit a hypertrophic training program.

 (No relevant relationships reported)

Introduction: Pre-workout supplementation has become a growing interest in the sports nutrition industry. Specifically, caffeine, creatine, and beta alanine have been combined in an effort to enhance performance. **Purpose:** The purpose of this study was to examine the effect of the consumption of the combination of caffeine (150mg), creatine (1g), and amino acids (1.6g) in habitual and non-habitual caffeine users in anaerobic performance. **Methods:** 24 recreationally active college-age students (age 21.6 ± 2 yr, ht. 176.8 ± 16 cm, body mass 73.8 ± 18.3 kg, 15♂) volunteered to participate in a randomized, double-blind crossover study. Two Wingate Anaerobic Power Test (WAPT) familiarization trials were conducted prior to entry into the study. Subjects refrained from vigorous activity 24 hours before testing, maintained their normal diet, and habitual caffeine users continued their habit, while non-habitual caffeine users did not ingest caffeine for 2 weeks prior to testing. Fasted subjects ingested either the supplement (SUP) or a taste, texture and color matched placebo (P), 30 minutes prior to WAPT with a minimum of 48 hrs between trials. Finger stick blood lactate was obtained three minutes post all trials. **Results:** Means for Peak Power (PP) was 1082.1 ± 326.1 and 1085.3 ± 357.3 watts, Mean Power (MP) was 545.2 ± 226.5 and 579.6 ± 190.6 watts, Fatigue Index (FI) was 77.4 ± 16 and $74.8 \pm 7.2\%$ and Total Work (TW) was 17227.8 ± 6211.3 was 17387.1 ± 5718.5 joules for P and SUP trials, respectively. Statistical analysis by Factorial ANOVA ($p < 0.05$) revealed no significant difference between habitual and non-habitual caffeine users across both conditions. **Conclusion:** SUP ingestion does not improve anaerobic performance regardless of previous caffeine ingestion history at the commercially available levels evaluated in this study.

The Physiological Responses of Caffeine Supplementation During Repeated-Sprint Activity
 Michael D. Belbis, Peter J. Chomentowski 3rd, Clayton L. Camic, Steven M. Howell, Shuqi Zhang. *Northern Illinois University, Dekalb, IL.*
 Email: belbismichael@gmail.com
 (No relevant relationships reported)

Caffeine is one of the most widely used drugs in the world due to its benefits of increasing mental and physical capabilities. Caffeine also is commonly used as an ergogenic aid when performing repeated-sprint activity (RSA). **PURPOSE:** The purpose of this study is to examine the effects of 200 mg of caffeine during RSA on heart rate (HR), rating of perceived exertion (RPE), blood lactate concentration (BLA), and sprint time (ST). **METHODS:** Thirty-two students (Age: 22.19 ± 2.29 years) participated in the study. The study followed a randomized crossover design, in which each participant ingested either 200 mg of caffeine or placebo 45 minutes prior to sprinting. The sprinting protocol consisted of three sets of six maximal-effort 30-meter sprints. Each sprint covered a 15-meter distance between the starting and the secondary marker, such that each subject sprinted down to the secondary and back to the starting. Each of the sprints in a set were separated by a total of 20 seconds of active recovery. Following each set, HR, BLA, ST, and RPE were recorded. **RESULTS:** The caffeine trials were not significantly different than the placebo for HR and RPE. However, for RPE, there was a main effect for time [$F(3,93) = 292.810$, $p < 0.001$]. The caffeine trials (Resting: 1.30 ± 0.52 mmol/L; Set 1: $11:33 \pm 2.38$ mmol/L; Set 2: 13.26 ± 3.02 mmol/L; Set 3: 13.67 ± 2.49 mmol/L) elicited increased BLA compared to the placebo (Resting: 1.37 ± 0.53 mmol/L; Set 1: 9.24 ± 2.43 mmol/L; Set 2: 11.46 ± 2.87 mmol/L; Set 3: 11.83 ± 2.55 mmol/L). The caffeine trials (Set 1: 6.78 ± 0.58 secs; Set 2: 6.81 ± 0.55 secs; Set 3: 6.85 ± 0.57 secs) also produced a decreased average ST compared to the placebo (Set 1: 7.00 ± 0.64 secs; Set 2: 7.02 ± 0.62 secs; Set 3: 7.12 ± 0.63 secs). For the average ST, there were significant main effects for condition [$F(1,31) = 36.839$, $p < 0.001$] and time [$F(2,62) = 5.806$, $p = 0.006$]. **CONCLUSION:** Caffeine supplementation of 200 mg elicits an increase in RSA in college-aged non-athletes.

Effects Of Caffeine On High-intensity Functional Training Performance In High- Vs. Low-caffeine Users
 Jesse A. Stein, Melitza R. Ramirez, Katie M. Heinrich. *Kansas State University, Manhattan, KS.*
 Email: jesse.stein.2@gmail.com
 (No relevant relationships reported)

Caffeine's ergogenic effects during endurance and high-intensity exercise are well-established. However, habitual caffeine use may diminish its ergogenic properties. Researchers have investigated high-intensity functional training (HIFT) which incorporates endurance, weightlifting, and gymnastics modalities performed at a relatively high-intensity. However, the effects on caffeine supplementation on HIFT performance remain unknown. **PURPOSE:** Our study aimed to determine the effects of caffeine on HIFT performance between low- and high-caffeine users. **METHODS:** 13 HIFT-trained men were recruited. Participants completed a 7-day caffeine recall to determine low- (<200mg/day, $n=7$, age= 29.3 ± 8.4 years, HIFT-experience= 5.2 ± 3.2 years, weight= 86 ± 11.3 kg) and high-caffeine users (>300mg/day, $n=6$, age= 27.7 ± 4.2 years, HIFT-experience= 2.8 ± 2.4 years, weight= 94.5 ± 8.5 kg). Using a double-blind, crossover design, participants were randomized to consume 5mg/kg body weight of caffeine or a placebo 60 minutes before a HIFT workout. The HIFT workout consisted of as-many-rounds-as possible in 20 minutes of 5 pull-ups, 10 push-ups, and 15 air squats (1 round = 30 repetitions). HIFT performance was determined by the absolute difference in repetitions between the caffeine and placebo conditions (HIFT performance = repetitions during caffeine - repetitions during placebo). An independent-samples t-test was used to determine the differences in HIFT performance between low- and high-caffeine users. **RESULTS:** Low- and high-caffeine users completed 451 ± 91 vs. 395 ± 95 and 501 ± 95 vs 415 ± 99 repetitions during the placebo and caffeine conditions, respectively. HIFT performance was not significantly different between low- and high-caffeine users (50 ± 38 vs. 20 ± 18 repetitions, $p = 0.10$). **CONCLUSION:** Caffeine's ergogenic effect was not significantly different between low- and high-caffeine users' performance, suggesting a no caffeine tolerance effect. HIFT athletes may benefit from supplementing caffeine without significant impairments from high-caffeine consumption. Future investigations should determine the effects of caffeine utilizing other HIFT workouts, and consider stratifying participants by daily caffeine consumption relative to body weight.

Low Dose of Caffeine Do Not Affect Torque and Rate of Torque Development

Lucas Ugliara¹, Martim Bottaro¹, Sávio Alex¹, Valdinar Junior², Douglas Pinheiro³, João Paulo Telo Pimenta¹, Amilton Vieira¹.

¹University of Brasilia, Brasilia, Brazil. ²National Academy of Police of Brazil, Brasilia, Brazil. ³University Center of the Federal District, Brasilia, Brazil.

Email: lucasugliaraunb@gmail.com

(No relevant relationships reported)

Higher rate of torque/force development (RTD) and peak torque (PT) are associated with sports performance, lower risk of injuries and better recovery from injury. For elderly individuals, a higher RTD and PT are often associated with independence, quality of life, and reduced risk of falls. Evidences have shown that caffeine may enhance RTD in younger adults, but no information are available for elderly.

PURPOSE: This study investigated the effect of a low dose of caffeine on PT and RTD of older (OG) and younger adults (YG).

METHODS: Fifteen older (69±6 years; 70±12 kg; 169±6 cm) and 15 younger men (27±4 years; 78±9 kg; 176±7 cm) were tested for PT and RTD of the plantar flexors using a Biodex 4 dynamometer. They were familiarized with testing conditions in the first visit to the laboratory. The two experimental (3 mg/kg of caffeine or placebo) conditions were tested in two days, separated by at least 48 h. Subjects performed four maximal isometric voluntary contractions (MIVC) before and after supplementation. PT, RTD 0 to 50 ms (RTD₀₋₅₀) and RTD 100 to 200 ms (RTD₁₀₀₋₂₀₀) were analyzed. RTD and PT were normalized by body mass for comparisons. The Shapiro-Wilk test was used to check data normality and the mixed-model ANOVA was used to investigate time and group interaction.

RESULTS: No difference ($p>0.05$) for time and group x time interactions were found for PT (OG: +0.6%; YG: +1.2%), RTD₀₋₅₀ (OG: +3.5%; YG: +4.8%), and RTD₁₀₀₋₂₀₀ (OG: - 3.1%; YG: - 2.3%). As expected, placebo did not show any significant difference.

CONCLUSIONS: A low dose of caffeine did not affect PT and RTD in older and young adults. It could be hypothesized that a greater dose of caffeine may be required to improve muscle function in young and older subjects.

The Effects of Carbohydrate and Caffeine Mouth Rinse on Upper Body Muscular Strength and Endurance

Raci Karayigit, Gülfem Ersöz. Ankara University Sport Sciences Faculty, Ankara, Turkey.

Email: racikarayigit@hotmail.com

(No relevant relationships reported)

Carbohydrate (CHO) and caffeine (CAF) are the most preferred nutritional ergogenic aids by elite athletes. CHO improves performance by sparing the muscle glycogen depots and CAF by antagonizing adenosine receptors. In recent years it has been shown that combined or separated CHO and CAF mouth rinsing can improve sprint performance. However, more research is needed to examine the effect of CHO and CAF rinsing on strength and muscular endurance performance.

Purpose : to investigate the effect of rinsing of CHO and CAF on bench press strength and endurance performance.

Metots: Twelve resistance trained men participated in this research. After the familiarization test day, participants participated in a total of 4 test days with a randomized, counterbalanced, crossover study design: 6% (1.5 gr.) weight / volume (w / v) CHO mouth rinse (CMR) with 25 ml water, mouth rinse with water (PLA), %1.2 CAF mouth rinse (CAFMR) and combined %6 CHO, %1.2 CAF mouth rinse (CCMR). After a 10-hour night fasting one repetition maximum (1RM) was determined for strength and %40 1RM strength endurance test over a 3 sets until repetition to failure with 2 seconds eccentric and 2 seconds concentric phase. Prior to strength and endurance measurements, participants rinsed the solutions in their mouths for 10 seconds. During the test protocol heart rate (hr), lactate (la), glucose (glu), felt arousal (fa) and ratings of perceived exertion (rpe) were measured. In the analysis of the data, single and two-way repeated measures analysis of variance were used.

Results: No significant differences were detected between trials as for strength, endurance, hr, glu, la, fa, rpe ($P>0.05$).

Discussion: This research has shown that orally rinsing of carbohydrate and caffeine does not have a significant effect on upper body strength and muscular endurance performance. The results of the study are in parallel with the literature. In future studies, higher doses of solutions may be rinsed in the mouth to investigate the effect on lower body strength and muscular endurance performance whose which muscle activation percentage is low during maximal voluntary contraction.

Keywords: Caffeine, carbohydrate, rinsing, ergogenic,

Effects of Caffeine on High-Intensity Functional Training Performance

Melitza R. Ramirez, Jesse A. Stein, Katie M. Heinrich. Kansas State University, Manhattan, KS.

(No relevant relationships reported)

Caffeine demonstrates an ergogenic effect on endurance exercise performance, however, limited information exists establishing its efficacy during high-intensity functional training (HIFT). HIFT is an exercise program that incorporates a variety of multi-joint movements performed at a relatively high-intensity and designed to improve parameters of general physical fitness and performance. **PURPOSE:** Our study aimed to determine the effects of caffeine on HIFT performance. **METHODS:** 13 HIFT-trained men (age = 28.5 ± 6.6 years, HIFT experience = 4.1 ± 3.0 years, body weight = 84.3 ± 9.9 kg) were randomized in a double-blind, crossover design. After consent, participants completed two HIFT sessions separated by a 7-day washout period, 60-minutes after consuming 5mg/kg of caffeine or a placebo. During HIFT sessions, participants completed as-many-rounds-as-possible in 20 minutes of 5 pull-ups, 10 push-ups, and 15 air squats, with performance measured as the number of rounds completed (30 repetitions = 1 round). Paired-samples t-tests were used to compare HIFT performance between the caffeine and placebo conditions and to test for a potential learning effect between the first and second sessions. **RESULTS:** Participants significantly improved HIFT performance during the caffeine trial (15.3 ± 3.6 rounds) as compared to placebo (14.3 ± 3.0 rounds), $t(12) = -2.783$, $p < 0.05$. The eta squared statistic (0.39) indicated a large effect size. Moreover, no significant learning effect was identified between the first and second sessions (14.9 ± 3.2 vs. 14.7 ± 3.5 rounds, $p = 0.73$). **CONCLUSION:** Caffeine elicited an ergogenic response during HIFT in HIFT-trained men, with no identifiable learning effect, which is useful for competitive HIFT athletes aiming to optimize performance. However, future investigations should establish the efficacy of caffeine during varying-duration HIFT sessions and among female HIFT athletes.

Effect Of Caffeine On Muscular Strength And Endurance In Resistance-trained College-aged Males

Nicholas Taylor, Christi Brewer. Eastern Washington University, Cheney, WA.

(No relevant relationships reported)

PURPOSE: To determine if pre-exercise caffeine consumption would significantly enhance performance during muscular strength and endurance testing in habitual caffeine users.

METHODS: Males (n=8, 22.12±.83yrs., 85.82±12.75kg) who self-reported to be habitual caffeine users volunteered for the study. All participants reported resistance training a minimum of 3 times per week for at least 3 months prior to involvement in the study. Participants abstained from caffeine for at least 48 hours prior to testing. In this double-blind, placebo-controlled, within-subjects design, participants were randomly assigned to consume either 150mg caffeine (10 oz. standardized coffee) or decaffeinated coffee (10 oz. placebo) and performed a 5-repetition (5RM) maximal effort leg press followed by a maximal effort YMCA push-up test. Participants returned 1 week after the first trial for the second treatment. A paired samples t-test was performed to test for significant differences between treatments.

RESULTS: Analysis showed significant increases in 5RM leg press weight ($p=0.029$) and push up performance ($p=0.009$) between treatment and placebo trials. An 11% improvement was seen in 5RM leg press weight (600±161 lbs) compared to the placebo (539±135 lbs). Similarly, there was a 14% improvement in push up performance (caffeine 40±10 repetitions, placebo 35±7 repetitions) between treatment and placebo testing. The relative dose of caffeine for the participants was 1.78±0.26 ml/kg of bodyweight (1.4 - 2.2 mg/kg of bodyweight).

CONCLUSIONS: Our results indicate that 150mg caffeine may improve muscular strength and endurance in resistance-trained habitual caffeine users. Further, the relative amount of caffeine consumed was less than that believed to be required for an ergogenic effect on performance. These results suggest that for habitual caffeine users that follow a washout period, a lower caffeine dosage can still elicit an ergogenic effect on muscular strength and endurance. Future research should determine whether our results are consistent across both sexes as well as determine whether the same ergogenic effect can be seen following similar dosages to those who are not habitual users.

ADORA2A, but Not CYP1A2, Genotype Influences Caffeine's Effect On Glucose Responses To A Carbohydrate FeedingNile Banks, Patrick Tomko, Ryan Colquhoun, Tyler Muddle, Mitchel Magrini, Sam Emerson, Nathaniel Jenkins. *Oklahoma State University, Stillwater, OK.*

(No relevant relationships reported)

Cytochrome P450 1A2 (CYP1A2) is a liver enzyme that is responsible for 95% of caffeine metabolism, while adenosine A_{2A} receptors (ADORA2A) are antagonized by caffeine. Functional single nucleotide polymorphisms (SNP) in CYP1A2 (-163 C>A; rs762551) and ADORA2A (1083 T>C; rs5751876) have been reported to influence various physiological responses to caffeine. **PURPOSE:** To examine if SNPs in CYP1A2 or ADORA2A influence the effect of caffeine on the postprandial glucose (GLU) response to a carbohydrate feeding (CHO). **METHODS:** Sixteen healthy males (mean \pm SD, 25 \pm 4 y, 94 \pm 15 kg, 178 \pm 6 cm) were genotyped for rs762551 (AA; n=9, AC/CC; n=7) and rs5751876 (CC; n=6, CT/TT; n=10). During two separate visits, blood draws were performed prior to and 30- and 60-min after the subject consumed either a liquid CHO meal (0.75g CHO/kg) or the same liquid CHO meal with 4 mg/kg of pharmaceutical grade caffeine (CHO + CAFF) in random order. Trapezoidal areas under the GLU curve (AUCs) were calculated for each participant in each condition and subsequently analyzed with separate two-way mixed factorial ANOVAs (Genotype [AA vs. AC/CC or CC vs. CT/TT] \times Condition [CHO vs. CHO + CAFF]). The type-I error rate was set a priori at 5%. **RESULTS:** For CYP1A2, there was no significant genotype \times condition interaction ($p=0.87$), nor main effects for genotype ($p=0.20$) or condition ($p=0.22$). For ADORA2A, however, there was a genotype \times condition interaction ($p=0.03$) (Fig 1). In the CC allele-carriers, the GLU AUC was greater during the CHO + CAFF than CHO condition ($p=0.026$, 95% CI of difference [137.8, 2132]), whereas there was no difference during the CHO + CAFF and CHO conditions for the CT/TT allele-carriers ($p=0.97$, 95% CI of difference [-842.9, 701.9]). **CONCLUSION:** The caffeine-induced impairment in postprandial glycaemia is influenced by ADORA2A 1083 T>C, but not CYP1A2 -163 C>A genotype.

Electromyostimulation Induced Changes In Intramyocellular Lipid Of Vastus Lateralis In Older Adults**Maya Hioki¹, Nana Kanehira², Teruhiko Koike¹, Akira Saito³, Hideyuki Takahashi⁴, Kiyoshi Shimaoka², Hisataka Sakakibara¹, Yoshiharu Oshida¹, Hiroshi Akima¹. ¹Nagoya University, Nagoya, Japan. ²Tokaigakuen University, Nagoya, Japan. ³University of Tokyo, Tokyo, Japan. ⁴Japan Institute of Sports Sciences, Tokyo, Japan.

Email: maya@mri.biglobe.ne.jp

(No relevant relationships reported)

Intramyocellular lipid (IMCL) is an important energy substrate during physical activity for young as well as older adults. However age-related changes in lipid metabolism can cause excess IMCL accumulation that can induce insulin resistance. Our previous studies have reported that IMCL content is inversely correlated with physical activity level in young, while it is not in the older adults (Hioki et al. 2018). In contrast, electromyostimulation (EMS) has been used to improve muscle mass, strength, and metabolism after spinal cord injury or chronic heart failure.

PURPOSE: We aimed to prove the hypothesis that EMS can induce changes in the IMCL content of the vastus lateralis (VL) in older adults.

METHODS: Fourteen physically active, non-obese older men and women were randomly assigned to an EMS group (70.4 \pm 1.8 years) or a control group (without EMS) (68.0 \pm 1.4 years) (n = 7 each). We applied EMS to the VL of the right leg for 30 min at a frequency of 30 Hz, pulse duration 300 μ s, and contraction/relaxation durations of seven seconds on and seven seconds off. IMCL content in the VL was quantified by ¹H-magnetic resonance spectroscopy before and immediately after the EMS in the EMS group, as well as in the control group. ¹H-MRS spectra with and without water suppression were taken, and calculation of IMCL contents and creatine (Cr) (mM) was performed by the LCModel software. Fasting plasma glucose and insulin values were also determined from blood samples collected before and immediately after EMS.

RESULTS: In the EMS group, values for IMCL/Cr increased significantly from 4.8 \pm 2.1 to 6.9 \pm 2.5 ($p < 0.05$) and plasma glucose decreased significantly from 96.4 \pm 4.0 to 93.0 \pm 3.4 mg/dL ($p < 0.05$); whereas, insulin did not change significantly (5.6 \pm 1.1 vs. 5.2 \pm 1.2 μ U/mL; $p = 0.43$). Values for IMCL/Cr did not change significantly after resting for 30 min in the control group (4.9 \pm 2.1 vs. 5.0 \pm 1.1, $p = 0.95$). Creatine values did not change after EMS in the EMS group (63.3 \pm 3.4 vs. 62.9 \pm 8.4 mM, $p = 0.96$) or after resting in the control group (63.3 \pm 7.4 vs. 65.6 \pm 8.9 mM, $p = 0.76$).

CONCLUSION: The findings suggested that a single bout of EMS induces an increase in the IMCL content in the VL of older adults. This study was supported by a Grant in Aid (KAKENHI No. 23650432) and the Descente and Ishimoto Memorial Foundation for the Promotion of Sports Science.

Email: sh0136se@ed.ritsumei.ac.jp

(No relevant relationships reported)

PURPOSE: Eleutherococcus senticosus (ES) is a kind of Araliaceae and used as a medical plant. The principal component of ES is a glycoside such as triterpenoid and more than 16 kinds of components exist (e.g. sesamin, eleutheroside B, isoflavidin, chlorogenic acid). Given the finding that an intake of ES for 8 weeks enhances fat utilization and endurance exercise capacity in human study (Kuo et al., 2010), it is hypothesized that, in addition to fat mobilization from adipocytes, skeletal muscle energy metabolism is increased. However, the effect of ES on metabolic profile in a skeletal muscle cells is unknown. The aim of this study was to investigate the effect of ES on expressions of metabolism-associated proteins in differentiating C2C12. **METHODS:** During and after differentiation, C2C12 cells were treated with 0.1 mg/ml, 0.2 mg/ml, 0.5 or 1.0 mg/ml ES for 72 hours. The expressions of Mitochondrial lipid related proteins and energy metabolism associated proteins were analyzed by Western blotting. **RESULTS:** The expressions of mitochondrial lipid metabolism-associated proteins such as carnitine palmitoyltransferase I (CPT I),

uncoupling protein 3 (UCP3), and cytochrome c oxidase (COX) did not change to ES treatments during and after C2C12 cell differentiation. However, the expression of phosphorylated AMP-activated protein kinase (AMPK), a metabolism-associated protein, was increased in response to 1.0 mg/ml ES ($p < 0.05$) in both during and after cell differentiation. **CONCLUSION:** The finding suggests that ES may enhance skeletal muscle energy metabolism by means of augmented AMPK activity, and may relate to elevated endurance exercise capacity. Supported by Bizen Chemical Co.,LTD

PURPOSE: Eleutherococcus senticosus (ES) is a kind of Araliaceae and used as a medical plant. The principal component of ES is a glycoside such as triterpenoid and more than 16 kinds of components exist (e.g. sesamin, eleutheroside B, isoflavidin, chlorogenic acid). Given the finding that an intake of ES for 8 weeks enhances fat utilization and endurance exercise capacity in human study (Kuo et al., 2010), it is hypothesized that fat mobilization from adipocytes is increased. However, the effect of ES on fat metabolism such as lipolysis and lipogenesis in adipocytes is unknown. The aim of this study was to investigate the effect of ES on cell differentiation, lipolytic and lipogenic activities, and those related protein expressions in differentiating 3T3-L1 adipocytes. **METHODS:** 3T3-L1 adipocytes were treated with 0.2mg/ml, 0.5 or 1.0mg/ml ES for 72 hours. Triacylglycerol (TAG) content was biochemically measured. The expressions of adipocyte differentiation-, lipolysis-, and lipogenesis-associated proteins were analyzed by Western blotting. **RESULTS:** ES treatment (1.0mg/ml ES) significantly decreased intercellular lipid accumulation (TAG content) compared with control ($P < 0.01$). The expressions of lipolysis-associated proteins such as adipose triglyceride lipase (ATGL), perilipin1 and CGI-58 were significantly lower in the ES compared with control ($p < 0.01$). On the other hand, ES significantly decreased the protein expression of peroxisome proliferator-activated receptor γ (PPAR γ) ($p < 0.01$), while enhanced AMP-activated protein kinase (AMPK), acetyl-CoA carboxylase (ACC) and Akt phosphorylation ($P < 0.05$). Furthermore, the expression of lipogenesis-associated protein (e.g., Phosphoenolpyruvate carboxykinase (PEPCK)) was lower in ES treated cells than in control ($P < 0.05$). **CONCLUSION:** These results suggest that ES suppressed intracellular lipid accumulation during adipose differentiation in 3T3-L1 adipocytes. The mechanisms underlying this effect of ES might be inhibition of adipocyte differentiation by down-regulation of PPAR γ , and suppression of fatty acid synthesis by decreased expression of PEPCK as well as augmented phosphorylation of AMPK and ACC. Funding This study was supported by grants from the Bizen Chemical Co.,LTD.

Effect of Aerobic and Resistance Exercise on Fatty Liver in Mice Model

Linlin Zhao, Xin Xu. *Shanghai University of Sport, Shanghai, China.*
(No relevant relationships reported)

The role of exercise in treatment of fatty liver has been recognized clinically, but the underlying molecular mechanism still unclear. PPAR α is a hormone activated nuclear receptor and transcription factor, which is important for lipid metabolism, adipogenesis and insulin regulation.

PURPOSE: This research was aimed to explore the effect of aerobic exercise combined with resistance training on fatty liver induced by high fat diet in mice, and the potential mechanism related with PPAR α pathway.

Methods: Thirty male 8 weeks old C57BL/6 mice were randomly divided into sedentary control group (CON), high-fat diet intervention group (HF) and high fat diet with exercise intervention group (HFE). After 16 weeks of high fat diet, HFE mice were subjected to 1 hour treadmill running at 15 m/min and 0° incline or 1-m vertical ladder with an 85° incline climbing for 16 times. Aerobic treadmill running and resistance climbing were arranged alternately for six days per week for 8 weeks. Blood samples were collected to measure the liver function. The liver tissues were stained with oil red O. PGC-1 α and PPAR α expression in liver tissue was detected by Western-blot.

RESULTS: The study found that high fat diet significantly increased body weight, liver index (32.93 \pm 0.59g vs 46.88 \pm 1.03g, 0.046 \pm 0.001 vs 0.051 \pm 0.003, $p < 0.05$), serum transaminase AST and ALT (126.33 \pm 22.49 u/L vs 249.63 \pm 17.59 u/L, 59.5 \pm 10.50 u/L vs 297 \pm 25.88 u/L, $p < 0.05$) in HF mice as compared with CON mice. While these changes were alleviated by combined exercise for eight weeks with decreasing body weight ,liver index(46.88 \pm 1.03 g vs 40.1 \pm 1.27g, 0.051 \pm 0.003 vs

0.040 \pm 0.002, $p < 0.05$) and serum transaminase AST and ALT (249.63 \pm 17.59 u/L vs 244.25 \pm 59.89 u/L, 297 \pm 25.88 u/L vs 169.88 \pm 38.67 u/L, $p < 0.05$) in HFE mice as compared with HF mice. Expression of PPAR α in HFE was increased as compared with HF mice ($p < 0.05$), while the expression of PGC-1 α was found decrease ($p < 0.05$) at the mean time.

CONCLUSION: These results indicated that combined exercise for eight weeks might ameliorate high fat diet induced hepatic lipid metabolism disorder by regulating the expression of PGC1- α and PPAR α .

Aerobic Interval Training Improve Effect of Liraglutide on Hepatic Lipid Steatosis in Diabetic Rats with NASH

Yuxiu He, Xun Li, Huan Cai. *Hebei Normal University, Shijiazhuang, China.*
(No relevant relationships reported)

PURPOSE: The nonalcoholic steatohepatitis (NASH) that is usually accompanied by type 2 diabetes, which characterized by hepatic steatosis, is roaring in the worldwide. It is clear that aerobic interval training (AIT) is an effective means to reduce visceral fat and protect liver. The liraglutide has also antidiabetic effect. Here, we are trying to explore whether AIT combined with liraglutide have a better effects on reducing hepatic lipid steatosis in diabetic rats.

METHODS: 60 Wistar male rats were divided into control group (CON), diabetes group (DM), DM+AIT group (DE), DM+Liraglutide group (DL) and DM+AIT+Liraglutide group (DLE). The diabetes model was induced by high fat diet and STZ. Liraglutide (subcutaneous injection, 0.2mg/kg/day) and AIT (treadmill, 7 min 85%-95% VO_{2max} interspersed with 3 min intervals at 50-60% VO_{2max} , 4 times/d, 5d/week) were maintained for 8 weeks. The fasting blood glucose (FBG), triglyceride (TG), was measured by enzymatic method; the serum insulin, ALT, AST, FFA and DAG in liver were analyzed by ELISA. The CD36, CPT-1A, and PPAR α expression in liver were analyzed by western blotting.

RESULTS: Compared with CON, the FFA and DAG in DM increased by 89% and 67.6% ($P < 0.01$), and with increased serum ALT and AST (174% and 78.9%, $P < 0.01$). The ALT, AST, FFA and DAG decreased by 39.33%, 19.05%, 43.02%, and 33.08%, respectively, in DLE compare to DM. There is a significant interaction between liraglutide and AIT on decreased parameters. In addition, the CD36 expression were 64%, 77% and 75% lower in DE, DL and DLE than DM ($P < 0.01$), and the CPT-1A expression was higher 120%, 141% and 86% in DE, DL and DLE than DM ($P < 0.01$), the PPAR α expression were increased by 228%, 116% and 124% in DE, DL and DLE, compare to DM ($P < 0.01$).

CONCLUSIONS: Aerobic interval training combined with liraglutide have a better effect on lipid steatosis in diabetic rats with NASH than separate AIT or liraglutide intervention.

| Comparison of liver function and lipid steatosis | | | | | |

The Effect Of Exercise On Hypothalamic Kiss-1 Of Rats With Post-weaning High Fat Diet

RUI XU¹, Yi Yan², Minhao Xie³, Biao Sun¹. ¹Nanjing Sport Institute, NANJING, China. ²Beijin Sport University, BEIJING, China. ³Sports Medicine Institute, General Administration of Sport of China, BEIJING, China.
Email: ajiuwei@126.com
(No relevant relationships reported)

Kisspeptins, encoded by the Kiss1 gene, is unanimously recognised as essential regulators of regulating gonadotropin secretion. It is mainly expressed in the arcuate nucleus in the hypothalamus, and have a direct role in regulating energy balance.

PURPOSE: To explore high fat diet(HFD) and moderate-intensity treadmill training (MIT) in modulating the hypothalamic expression of kiss-1 mRNA relative expression and kisspeptin-immunoreactivity in 3 weeks post-weaning rats. **METHODS:** The 3 weeks SD rats (weight= 58.54 \pm 2.69g) after 5 weeks high fat feeding, 30 HFD 8-weeks SD rats were randomly assigned to sedentary (HS, n=15), MIT (n=15), and 15 normal diet 8-weeks SD rats were assigned as sedentary (SS, n=15) group. During the following 5 weeks, HS group rats were continued expose to HFD. MIT group did the 60%-70% VO_{2max} treadmill training (5 days/week, 1 hour/day). RT-qPCR and

immunohistochemistry were used to test the expression of hypothalamic Kiss1mRNA and the number of kisspeptin neurons in each group. **RESULTS:** After 5-weeks high fat feeding, the HFD rats were heavier than normal diet group (308.96 ± 28.38 g vs. 324.52 ± 37.52 g, $p=0.139$), and had more expression of kiss-1 mRNA (1.55 ± 0.59 vs. 2.47 ± 0.81 , $p<0.05$) in the hypothalamic. The number of kisspeptin neurons in the ARC HFD group were also significantly higher than SS group (8.23 ± 3.17 vs. 15.46 ± 4.15 , $p<0.05$). After 5-weeks training, MIT group weighted less than HS group (300.83 ± 21.06 g vs. 324.52 ± 37.52 g, $p<0.05$). In the same conditions of HFD intervention, compared with HS group, MIT group had lower hypothalamic expression of kiss-1 mRNA (2.47 ± 0.81 vs. 1.6 ± 0.22 , $p<0.05$), and the number of kisspeptin neurons in ARC were also significantly lower than HS group (15.46 ± 4.15 vs. 12.08 ± 2.56 , $p<0.05$). **CONCLUSIONS:** High fat diet could increase the expression of kiss-1 mRNA and the number of kisspeptin neurons in ARC while increasing bodyweight; moderate-intensity treadmill training could reduce the stimulating effect of high fat diet induced weight gain and changes hypothalamic expression of kiss-1 and kisspeptin.

Effects Of Dietary And Hiit On Lipid Metabolism Of The Liver Tissue In Obese Rats

Yuan Zhang, Juan Wei, Nianyun Zhang, Lei Sheng. *Nanjing Sports Institute, Nanjing, China.*
 Email: beibei82506@126.com
 (No relevant relationships reported)

PURPOSE: This study aimed to investigate the effects of diet and High Intensity Interval Training (HIIT) on body mass gain, serum inflammatory markers and hepatic lipid metabolism of obese rats. **METHOD:** Male Sprague-Dawley rats were fed with a normal standard diet (N) or a high fat diet (H; 45% kcal as fat) for eight weeks without exercise stimuli. Obese rats were defined as increased at least 20% body weight than normal diet rats. Normal diet rats were then continue fed with a normal diet (N), and half of obese rats were fed with a normal diet (ON), while the other half were continue fed with a high-fat diet (OH). Each diet type group was then divided into two subgroups, control (NC, ONC, OHC groups) and High Intensity Interval training (NHI, ONHI, OHHI groups) ($n=10-12$). The HIIT training consisted of a swimming exercise performed over eight weeks. **RESULTS:** Obese high fat diet rats showed greater body weight, visceral adipose mass, serum lipid levels (LDL, TG, TC), and inflammatory markers (MCP-1, IL-1 β , TNF- α) in values than normal diet rats, but were significantly reduced with HIIT, but this phenomenon was not observed in obese normal diet rats, except MCP-1. In addition, compared to normal rats, OHC group rats exhibited high levels of hepatic wet weight and liver triglycerides, but not in ONC group. HIIT significantly decreased liver TG content compared with control groups, which consistent with liver oil red O stain images. Moreover, compare to the control groups, mitochondrial CS activity and the biogenesis marker PGC-1 α expression were upregulated with HIIT in obese high fat diet rats, meanwhile, the activity of mitochondrial fatty acid oxidation enzymes, include CPT-1 α , β -HAD were significantly increased in HIIT groups. However, the activity of LPL and FAT/CD36 enzymes, which are key regulators of tissue fatty acid uptake from plasma were not changed with HIIT. **CONCLUSION:** HIIT was shown to be effective in controlling body weight, adiposity levels and serum lipid contents in high-fat diet fed obese rats, HIIT displayed positive effects on mitochondrial lipid oxidation enzyme activities and significantly attenuated lipid accumulation of liver tissue in obese rats. Additionally, diet and exercise was more effective than exercise alone in reducing body weight, VAT mass, serum inflammatory and liver TG content.

Bodipy Is Superior To Oil-red-O For Detecting And Quantifying Intramuscular Triglyceride In Human Skeletal Muscle

Juliette A. Strauss¹, Daisy A. Shepherd², Emily F.P. Jevons¹, Myfanwy Macey¹, Sam O. Shepherd¹. ¹Liverpool John Moores University, Liverpool, United Kingdom. ²University of Auckland, Auckland, New Zealand.
 Email: j.a.strauss@ljamu.ac.uk
 (No relevant relationships reported)

PURPOSE: To compare the use of bodipy and oil-red-O (ORO) for quantification of intramuscular triglyceride (IMTG) content and use during exercise as well as investigation of lipid droplet (LD) morphology in human skeletal muscle. **METHODS:** Biopsies were obtained from the *m. vastus lateralis* of six fasted healthy, lean sedentary males (age: 20 ± 1 yr, BMI: 24.8 ± 1.2 kg.m², VO_{2peak} : 39.8 ± 2.4 ml.min⁻¹.kg⁻¹) prior to and immediately following 60min cycle ergometer exercise at $\sim 60\%VO_{2peak}$. Cryosections were labelled using antibodies targeting MHCI and MHCIIa. Anti-laminin was used to identify the cell membrane. LDs were labelled with either bodipy or ORO. Images were captured using confocal immunofluorescence microscopy and analysed using Image Pro Plus.

RESULTS: IMTG content (% area stained) was greater when using bodipy compared to ORO ($P=0.006$), and bodipy detected more LDs ($P=0.03$) with a greater mean LD size ($P=0.03$) than ORO. Regional distribution was also different for the two dyes with IMTG content with bodipy being greater in the central vs. peripheral region (5 μ m from plasma membrane) in both type I (central: $3.1 \pm 0.5\%$ vs. peripheral: $2.8 \pm 0.5\%$) and type IIa fibres (central: $1.4 \pm 0.3\%$ vs. peripheral: $1.3 \pm 0.2\%$; $P=0.036$). The opposite was true when using ORO, with a greater IMTG content observed in the peripheral vs. the central region in all fibre types ($P=0.013$). These regional differences in IMTG content for bodipy and ORO were attributed to differences in LD number ($P=0.039$). Following exercise, using bodipy, IMTG content was decreased in both the peripheral ($-58 \pm 21\%$, $P=0.014$) and central regions ($-63 \pm 21\%$, $P=0.016$) of type I fibres. However, using ORO only a significant decrease in IMTG content in the peripheral region of type I fibres was observed ($-85 \pm 19\%$, $P=0.021$).

CONCLUSION: Bodipy is preferable to investigate IMTG in skeletal muscle due to its superior LD detection capabilities and specificity for detecting IMTG avoiding labelling of membrane structures, compared to ORO. We demonstrate the importance of this in the context of regional distribution of IMTG detected using ORO and bodipy and differences in region-specific IMTG utilisation during exercise. Therefore, it is possible that the choice of lipid dye could impact the conclusions drawn in studies in which subcellular IMTG distribution is considered.

Pre-Exercise Ingestion of Isomaltulose Increases Energy Expenditure with Enhancing Fat Oxidation in Healthy Young Adults

Naoko Onuma¹, Daisuke Shindo¹, Miki Sakazaki², Yukie Nagai², Kentaro Yamanaka³. ¹Nihon Univ., Funabashi, Japan. ²Mitsui Sugar Co., Ltd, Tokyo, Japan. ³Showa Women's Univ., Tokyo, Japan.
 (No relevant relationships reported)

Isomaltulose, which is a disaccharide composed of glucose and fructose, is known for suppressing rapid elevation of blood glucose level and excess secretion of insulin. However, it is unclear how pre-exercise isomaltulose ingestion alters energy metabolism during subsequent exercise in young adults. **PURPOSE:** In this study, we investigated the effects of pre-exercise isomaltulose ingestion on carbohydrate, fat and energy metabolism during subsequent exercise of young adult. **METHODS:** Twelve young healthy participants (6 females and 6 males, 23.1 ± 1.3 yrs) performed three experimental trials in a randomized counterbalanced design, which consisted of 60 min of pre-exercise resting with ingesting a isomaltulose drink (ISO), a sucrose drink (SUC), or plain water (WAT), 30-min of treadmill running at an individually predetermined speed (50–60% VO_{2max}), and 60-min of post-exercise resting. During the trials, we continuously recorded heart rate (HR), blood pressure (BP), VO_{2} , and VCO_{2} . We also calculated energy expenditure (EE), respiratory quotient (RQ), carbohydrate oxidation (CHO) and fat oxidation (FO) during exercise. **RESULTS:** There were no significant effect of trial in HR and BP during exercise. Nevertheless, EE during exercise had a significant effect of trial (ISO: 377.3 ± 26.2 kcal, SUC: 345.6 ± 22.3 kcal, WAT: 318.7 ± 23.5 kcal). Also, RQ during exercise had a significant effect of trial (ISO: 0.85 ± 0.05 , SUC: 0.89 ± 0.06 , WAT: 0.85 ± 0.06). These results indicates that EE increases in the SUC trials might be attributed mainly to facilitation of carbohydrate oxidation and that EE increases in the ISO trials might be mainly due to facilitation of both carbohydrate and fat oxidation. **CONCLUSION:** These results suggest that pre-exercise isomaltulose ingestion facilitated fat oxidation and energy metabolism during subsequent exercise on healthy young adults.

The Effects Of 8-weeks Moderate Intensity Exercise In Skeletal Muscle Autophagy Of Obese Sd Rats

Youxiang Cao¹, Rui Xu², Yi Yan³, Minhao Xie⁴. ¹Beijing Sport University, Nanjing cooperaerobics Co., Ltd., Nanjing, China. ²Nanjing Sport Institute, Nanjing, China. ³Beijing Sport University, Beijing, China. ⁴Sports Medicine Institute, General Administration of Sport of China, Beijing, China.
 Email: 715708019@qq.com
 (No relevant relationships reported)

Purpose: The study aims to investigate the effect of 8 weeks of moderate intensity exercise on the level of autophagy in skeletal muscle of obese rats. Based on this, to further explore the effective exercise load for promoting the skeletal muscle autophagy, and the possible mechanism of enhanced autophagy in skeletal muscle of exercise-trained rats.

Methods: 40 11-week-old male SD rats were selected after 8 weeks adaptive feeding and divided into normal control group and high-fat group. These groups then further subdivided into exercise group (control trained group (CT), obese trained group (OT)) and sedentary groups (control sedentary group (CS), obesity sedentary group (OS)). CT

and OT did the 60%-70%•VO₂max treadmill training(5days/week,60min/day). After the 48h at the end of the last training, the LC3b,Beclin1 mRNA expression were tested in each group.

Results:After 8 weeks high fat diet intervention, the body weight of OS group was significantly higher than CS group(546.98±72.07gvs. 667.96±46.97g, p<0.01). After 8 weeks training, OS group were heavier than OT group(667.96g±46.97 vs. 586.05±32.77g,p<0.01),and OT group has more expression of LC3b mRNA(0.93±0.06 vs. 0.75±0.11, p=0.156)and Beclin1 mRNA(1.86±0.22 vs. 1.34±0.11, p=0.841).

Conclusions:8 weeks high fat diet can significantly reduce the skeletal muscle autophagy activity in obese quiet rats, whereas 8 weeks of moderate-intensity exercise intervention can improve the obese rats the skeletal muscle autophagy activity.

High Intensity Interval Training Activates Specific Site HSL Phosphorylation and Reduces Visceral Fat

Yang Liu, Jiashun Mei, Yuxiu He. *Hebei Normal University, Shijiazhuang, China.*

Email: billy_ox@163.com

(No relevant relationships reported)

Objectives:To investigate the possible underlying mechanisms of why high-intensity interval training can significantly reduce the weight of visceral fat: differences in HSL(Hormone Sensitive Lipase) phosphorylation at different Sites (subcutaneous and visceral). **Methods:** Female c57bl/6 mice were fed a high-fat diet to produce a diet-induced obesity animal model. After successful modeling, 36 obese mice were randomly divided into high-fat diet control group (HFD group), moderate-intensity continuous training group (MICT group) and high-intensity interval training group (HIIT group).The HFD group was fed a high-fat diet for 12 weeks without exercise. The MICT group continued to exercise on a treadmill of approximately 60% VO₂max with high-fat diet,while the HIIT group were given a high-intensity interval training of approximately 100% VO₂max peak intensity with high-fat diet. At the end of the 12 weeks training, mouse body weight, Lee's index, inguinal (subcutaneous) and peri-uterine (visceral) fat weights were measured. Hepatocyte fat infiltration was observed by HE staining. Serum lipids (TC, TG, HDL-C, and LDL-C) were measured by colorimetry. HSL protein expression and phosphorylation of Ser563, ser565, ser660 were measured by Westernblot. **Results:**Compared with the HFD group as the baseline, there was a significant body weight decrease in the MICT group and HIIT group (p<0.01). HIIT and MICT showed no significant difference in subcutaneous fat reduction, but compared with MICT, HIIT could significantly reduce the peri-uterine (visceral) fat (p<0.01); Liver lipid droplet infiltration of HIIT group was lower than HFD and MICT, and LDL-C of HIIT significantly decreased (P<0.05); Phosphorylation of ser563 in peri-uterine fat of HIIT was significantly higher than HFD and MICT (p<0.05). Ser660 of inguinal fat was significantly higher in MICT than in HFD HIIT groups (p<0.05). **Conclusion:** HIIT can reduce visceral fat, relieve hepatic fat lesions, and reduce LDL more than moderate-intensity continuous training. This is related to the fact that HIIT can specifically increase the phosphorylation of HSL-ser563 in visceral adipose tissue and promote fat hydrolysis.

(No relevant relationships reported)

TEXT: The lipodystrophy syndrome affects several people living with HIV under antiretroviral therapy (ART) being characterized by visceral adipose tissue accumulation and atrophy of subcutaneous adipose tissue (SAT) associated to metabolic disturbances and extracellular matrix (ECM) protein deposition and tissue fibrosis. On the other hand, concurrent training (CT) has been adopted as an efficient therapy to reduce severities caused by ART. **PURPOSE:** Hence, we aim to determine the effects of twelve weeks of CT in remodeling of adipose tissue, ECM proteins and gene expression of SAT in people with HIV. **METHODS:** Healthy non-active (HIV-, n=6) and people living with HIV (HIV+, n=6) (Brazilian Clinical Trials Registration, n. U1111-1214-3022) were submitted to a CT program (3x a week for 12 weeks), composed of aerobic (13 BORG scale, 20 min.) and resistance training (8 ex., 10-12RM). Total load lifted, aerobic performance (Vpeak) and SAT biopsies to determine adipocyte area (*Hematoxylin and eosin*), Collagen I, collagen III and Collagen total areas (*Picro-Sirius*), elastic fibers deposition area (*Weigert/NanGienson*) (µm²) and Real Time-PCR to quantify mRNA expression of the following genes: collagen I, collagen III, VEGF and Fibronectin were performed. Data were analyzed by two-way RMANOVAs. **RESULTS:** CT improved aerobic and strength performance, reduced adipocyte area (Δmean= -1144 [IC95%: -1934; -353.8]) and elastic fiber deposition

in HIV+ group (Δmean= -204.9 [IC95%: -132.5; -227.3] in HIV- and HIV+ groups (P<0.05). CT did not change Collagen I (Δmean=-2941.7 [IC95%: 3814.3; -9697.8]; F=0.229); and III (Δmean=-2241.7 [IC95%: 2476.0; -6959.5], F=2.97) deposition and gene expression (Δmean=-0.495 [IC95%: -2.401; 1.410]; F=0.53; ES= 0.02 and Δmean=-0.558 [IC95%: -1.97; 0.86]; F=1.55. ES=0.07, respectively), as well as, VEGF (Δmean= 0.07 [IC95%: -0.79; 0.95]; F=0.03; ES=0.002) and Fibronectin (Δmean=-1.62 [IC95%: -7.94; 4.70]; F=0.04; ES=0.002) (P>0.05). **CONCLUSION:** CT was able to improve adipocyte area heterogeneity and promoted a reduction of elastic fibers deposition in SAT of people living with HIV.This study was sponsored by UEM.

Differences In Energy Expenditure During Constant Speed And Interval Walking In Healthy Sedentary Adults

Myung Dong Choi, Andary Esho, Christian Maron. *Oakland University, Rochester, MI.*

Email: choi@oakland.edu

(No relevant relationships reported)

Walking represents a popular, convenient and relatively safe form of activity that can easily be incorporated into weight management programs. The energy expenditure associated with walking has been reported to be either linearly or slightly exponentially related to speed. Thus, interval walking training has been developed as a novel free-living training modality that improves physical fitness and cardiovascular risk factors in humans. **PURPOSE:** To determine the effect of interval walking exercise (INT) and constant speed walking exercise (CON) on whole body energy expenditure and fat utilization in healthy sedentary adults. We hypothesized that interval walking exercise increases whole body fat utilization and energy expenditure to a greater extent, compared with the constant speed walking exercise. **METHODS:** This study was set as randomized crossover design. Nine healthy sedentary individuals (BMI ≤ 25 kg/m² and 18-50 yrs) were recruited. Initially nine subjects were randomly assigned into CON or INT group. Then, CON became INT and INT became CON. The constant speed walking consists of a single bout of 60 min walking exercise at 45% of VO₂max on a treadmill. The interval walking consists of a single bout of 60 min walking exercise with cycles of alternating 3-min slow (30% of VO₂max), 3-min moderate (45% of VO₂max), and 3-min fast (60% of VO₂max) walking. Energy expenditure and fat usage were determined via indirect calorimetry during rest and walking exercise. Two-way ANOVA was used to determine differences in energy expenditure and fat utilization between the groups. **RESULTS:** The rate of fat utilization (g/min) was higher in INT group, compared with CON (0.276±0.01 g/min vs. 0.238±0.01 g/min, respectively, P=0.046) during 60 min walking. The rate of total calorie expenditure (kcal/min) from body fat was also higher in INT group, compared with CON (2.996±0.13 kcal/min vs. 2.564±0.13 kcal/min, respectively, P=0.028) during 60 min walking. **CONCLUSION:** Our data show that an interval type of walking pattern compared to walking at a constant speed, could be better to expend more energy from body fat. Thus, these findings may provide a better exercise strategy to maintain a healthy body weight in healthy sedentary individuals and to reduce body weight/fat potentially in obese people.

Email: cm.mcclean@ulster.ac.uk

(No relevant relationships reported)

BACKGROUND: Exercise following a high-fat meal can ameliorate lipid peroxidation but the effects on DNA single strand breaks and base oxidation currently remain unknown. **PURPOSE:** To determine the effects of moderate intensity postprandial exercise on biomarkers of DNA damage and oxidation and inflammation. **METHODS:** Twelve apparently healthy, recreationally active, male participants (21.8 ± 3.7 years; 178.6 ± 6.2 cm; 83.6 ± 14.9 kg; 51.2 ± 8.6 ml·kg⁻¹·min⁻¹) completed a randomized, crossover study consisting of two trials: (1) a high-fat meal alone (resting control) or (2) a high-fat meal 2 h before 60 mins of moderate intensity exercise (65% maximal heart rate). Venous blood was collected at baseline, prior to exercise (2 h after meal ingestion), immediately post-exercise, and at 2 and 4 h post-exercise. Biomarkers of oxidative damage (DNA single-strand breaks - comet assay); DNA base oxidation (formamidopyrimidine DNA glycosylase [FPG] - comet assay); lipid peroxidation; ascorbyl free radical metabolism and inflammation (retinol-binding protein-4 and erythrocyte sedimentation rate) were determined using conventional biochemistry techniques.

RESULTS: DNA percentage tail intensity increased following the test meal, remaining elevated at 4 h post-exercise ($p<0.05$; main effect for time). Similarly, FPG increased postprandially and remained elevated at 4 h ($p<0.05$; main effect for time). Likewise, a persistent increase in lipid hydroperoxides and in ascorbyl radical metabolism was observed ($p<0.05$; main effect for time). Erythrocyte sedimentation rate increased postprandially and remained elevated at 2 h ($p<0.05$; main effect for time) while no changes were detected in retinol-binding protein-4.

CONCLUSIONS: Ingesting a high-fat meal induced a state of postprandial oxidative stress, including DNA damage and base oxidation, that remained unaltered by one hour of postprandial exercise.

E-42 Free Communication/Poster - Behavioral Aspects of Exercise

Friday, May 31, 2019, 7:30 AM - 12:30 PM
Room: CC-Hall WA2

2589 Board #253 May 31 9:30 AM - 11:00 AM Correlates Of Workout Adherence: Golf Skill, Exercise Enjoyment, Life Satisfaction, And Mood Of Senior Golfers

Lynn A. Darby, FACSM¹, Bonnie G. Berger¹, David R. Owen².
¹Bowling Green State University, Bowling Green, OH. ²Brooklyn College of the City University of New York, Brooklyn, NY.
Email: ldarby@bgsu.edu
(No relevant relationships reported)

Many senior golfers (≥ 50 yrs of age) desire to improve their golf scores, however, they may, or may not participate in workout programs to achieve their golf goals.

PURPOSE: To investigate whether individualized, "take-home," golf-specific fitness and skill exercises would motivate golfers to work out, and to explore the relationships between workout adherence, golf fitness and skill, life satisfaction, exercise enjoyment, and mood before and after a pre-season, golf-specific training program. **METHODS:** Before and after eight weeks of golf-specific training programs, senior golfers (Age = 63.3 ± 6.8 yrs; $N=10$; 1 male, 9 females) completed assessments. These included the Titleist Performance Institute[®] TPI-fit (17 tests; one score) and Big12 (golf swing analyses and errors score), golf histories, Life Satisfaction Scale (LS), Physical Activity Enjoyment Scale (PACES), Profile of Mood States (POMS), and 6-min walk tests (6MWT). Pearson correlations and repeated measures ANOVAs were calculated (pilot study: $\alpha = 0.10$). **RESULTS:** Before and after training, TPI-fit scores were 18.1 ± 4.3 , 14.4 ± 6.9 ($M \pm SD$), and the Big12 scores were 12.7 ± 9.4 , 8.0 ± 3.7 . These scores changed in desirable directions (lower is better). The number of workouts completed by the golfers was 14 ± 9 ($M \pm SD$), or 43% of 32 workouts. After eight weeks, the number of workouts completed was positively correlated with PACES Trait ($r = .55$, $p = .05$) and Age of Beginning Golf ($r = .85$, $p = .001$), and negatively correlated with LS ($r = -.51$, $p = .07$). Those who enjoyed exercise and started golf later in life adhered to the workouts. In contrast, those who had high life satisfaction and started golf at younger ages did not adhere to the prescribed golf workouts. When measured after the eight-week training program, golfers who reported more exercise enjoyment had more desirable mood changes after the 6MWT ($r = .72$, $p = .01$), began golf at a later age ($r = .50$, $p = .07$), but had higher 9-hole scores ($r = .47$, $p = .09$). **CONCLUSION:** Senior golfers who wanted to improve their golf scores adhered to less than half of the prescribed golf-specific workouts when working out alone. Therefore, future studies of senior golfers should investigate group training for golf workouts, and examine the possible contributions of peer support and social interactions to enhance workout adherence.

2590 Board #254 May 31 9:30 AM - 11:00 AM Physical Activity Is Associated With Grit And Resilience In College Students: Is Intensity The Answer?

Emily R. Dunston, Martin Waldrip, Shelby Christ, Amber Skillingstad, Annika Vahk, Katrina Taylor. Eastern Washington University, Cheney, WA. (Sponsor: Chantal A. Vella, FACSM)
(No relevant relationships reported)

Physical activity (PA) has been positively associated with academic performance; however, as students transition from high school to tertiary education their PA levels often decrease. The transition to tertiary education is a substantial life event, requiring a combination of academic and social determinants to succeed. Little research has investigated the associations between PA and determinants of academic success, such as grit and resilience. **PURPOSE:** To determine the associations among PA, grit and resilience in undergraduate students.

METHODS: Undergraduate students ($n=244$; 165 females, age 21.1 ± 2.9 years) participated in an online survey. Self-reported PA was collected using the International Physical Activity Questionnaire. Grit was measured using the Short Grit Scale and resilience was determined with the Connor-Davidson Resilience Scale. Linear regression analyses were used to determine associations among grit, resilience, and PA. One-way ANOVAs were used to determine differences in grit and resilience across tertiles of PA.

RESULTS: Vigorous PA was positively associated with resilience ($\beta=0.17$, $p=0.01$) and the perseverance of effort grit domain ($\beta=0.19$, $p=0.004$), while being negatively associated with the consistency of interest grit domain ($\beta=-0.22$, $p=0.001$). Moderate PA was associated with both grit domains ($p \leq 0.03$) but not resilience ($p=0.38$). Further, resilience (tertile 1: 34.1 ± 5.5 vs. tertile 2: 36.8 ± 4.9 , $p=0.005$) and the perseverance of effort grit domain (tertile 1: 4.1 ± 0.7 vs. tertile 3: 4.4 ± 0.5 , $p=0.01$) were significantly higher with increased vigorous PA. Consistency of interest grit domain scores (tertile 1: 2.9 ± 0.9 vs. tertile 3: 2.6 ± 0.8 , $p=0.04$) were lower with higher levels of vigorous PA. There were no differences in grit and resilience across tertiles of moderate PA ($p>0.05$).

CONCLUSIONS: Vigorous PA was positively associated with the perseverance of effort grit domain and resilience but negatively associated with the consistency of interest grit domain. Moderate PA was also associated with grit but not resilience in this cohort. The findings suggest that intensity of PA may play a role in grit and resilience levels in students. Future research may be beneficial to determine if participation in vigorous PA can increase grit or resilience in college students.

2591 Board #255 May 31 9:30 AM - 11:00 AM

Examining Intra-Individual Variability of Perceived Physical Discomfort In Young Adults: A Potential Exercise Antecedent

Cory Thomas Beaumont, Kelley Strohacker, FACSM. The University of Tennessee, Knoxville, TN.
Email: cbeaumo1@vols.utk.edu
(No relevant relationships reported)

Ecological Momentary Assessment (EMA) allows the observation of intra-individual variance in cognitive, perceptual, psychological, and contextual variables that may impact recurrent health behaviors such as exercise. Perceptions of physiological states (e.g. pain, illness) likely influence behaviors, but most assessments are cross-sectional. **PURPOSE:** To determine preliminary estimates of intra-individual variability in perceived physiological states. **METHODS:** A secondary analysis was conducted using data from young, healthy adults ($N=29$) undergoing EMA of exercise antecedents. Participants were sent four surveys per day across 14 days (56 total surveys). The extracted variables pain, stiff, and achy were scored on a seven-point Likert scale; 0= not at all, 3= moderately, 6= extremely. Individual item scores were summed to create a "physical discomfort" score (Cronbach's $\alpha=0.847$). Data were retained from compliers who completed $\geq 75\%$ of EMA surveys. Compliers ($n=20$, 23 ± 4 years, $BMI=25.6 \pm 3.1$ kg/m^2 , 60% female) completed $89 \pm 5\%$ of surveys. Missing data were imputed with the participant's daily means for that respective variable. Two-way mixed intra-class correlation coefficients (ICC) were calculated with 95% confidence intervals (CI) for pain, stiffness, achiness, and physical discomfort across all 56 time blocks and across 14 daily means. $ICC \leq 0.5$, between 0.5-0.75, between 0.75-0.9, and ≥ 0.9 indicate poor, moderate, good, or excellent consistency. **RESULTS:** Indices of physical discomfort were generally low ($M \pm SD$): pain= 0.9 ± 1.2 ; achy= 1.3 ± 1.4 ; stiff= 1.5 ± 1.5 . Poor consistency was observed across time points for pain ($ICC=0.32$; $CI=0.21-0.51$), achy (0.44; 0.31-0.63); stiff (0.48; 0.34-0.67), and physical discomfort (0.49; 0.35-0.67). Poor-to-moderate consistency was observed across daily means for pain (0.46; 0.31-0.66), achy (0.57; 0.41-0.75), stiff (0.60; 0.45-0.77), and physical discomfort (0.59; 0.43-0.76). **CONCLUSION:** Due to the inconsistent nature of perceived pain, achiness, stiffness, and physical discomfort, more frequent assessment of physical discomfort may be necessary within EMA to capture important fluctuations. Understanding the timing, magnitude, and direction of fluctuations could expose points of vulnerability relating to exercise behavior.

2592 Board #256 May 31 9:30 AM - 11:00 AM Association Of Asian/Asian-American Immigrants' Physical Activity Behavior And Time Spent Living In The U.S.

Zi Yan¹, Bradley J. Cardinal, FACSM². ¹Merrimack College, north andover, MA. ²Oregon State University, Corvallis, OR.
(Sponsor: Brad Cardinal, FACSM)
Email: yanz@merrimack.edu
(No relevant relationships reported)

The Asian/Asian-American population comprises one of the largest ethnic/racial cohorts in the U.S. They also are reported to be among the most inactive. **PURPOSE:** To examine the potential relationship between Asian/Asian-American immigrants' leisure-time physical activity behavior and their length of time spent living in the U.S. (i.e., temporality).

METHODS: Data were obtained from the 2013-2014 National Health and Nutrition Examination Survey. Among 1,074 Non-Hispanic Asian/Asian-American participants, 541 (Female = 287, Male = 254) were age \geq 20 yr. ($M = 48.5$, $SD = 15.2$), not born in the U.S., and they reported their physical activity data. Those responding "yes" to either of the following two questions were classified into the moderate-to-vigorous physical activity (MVPA) group: (1) "In a typical week, do you do any vigorous-intensity sports, fitness, or recreational activities that cause large increases in breathing or heart rate like running or basketball for at least 10 minutes continuously?" and (2) "In a typical week do you do any vigorous-intensity sports, fitness, or recreational activities that cause large increases in breathing or heart rate like running or basketball for at least 10 minutes continuously?" Temporality groupings were as follows: <1, 1<5 years, 5-9, 10-20, and \geq 20 years.

RESULTS: All total, 306 study participants (56.56%) reported engaging in MVPA. Binary logistic regression was used to estimate the odds ratios and 95% confidence intervals of reporting participation in MVPA. After adjusting for age, gender, income, and education level, those living in the U.S. increased their odds of participating in MVPA. Specifically, compared to those who had been in the U.S. for <1 year, those who had been in the U.S. for 1<5 years, 5-9 years, 10-20 years, and \geq 20 increased their odds of MVPA participation by 145%, 139%, 189% ($p = 0.06$) and 293% ($p = 0.02$), respectively.

CONCLUSIONS: Notwithstanding the evidence of a generally inactive nation, the findings of the current study suggest that there are some positive features in American culture that facilitate and support MVPA among Asian/Asian-American adults who have immigrated and resided in the U.S. for one or especially two or more decades. Gaining deeper insight into precisely what those features are should be the focus of future research.

2593 Board #257 May 31 9:30 AM - 11:00 AM
Mental Toughness As A Moderator Of The Physical Exercise - Esports Performance Relationship: A Pilot Study.

Andreas Stamatis¹, Thomas Leif Andre², Robert Noah Padgett³, Silvio Polly Valladao². ¹SUNY Plattsburgh, Plattsburgh, NY. ²University of Mississippi, University, MS. ³Baylor University, Waco, TX. (Sponsor: Peter W. Grandjean, FACSM)
 Email: stamaand@yahoo.gr
 (No relevant relationships reported)

eSports popularity has been growing faster than any sport in history (global audience, money prizes, NCAA scholarships, part of 2022 Asian Games). Preliminary data show a positive relationship between physical exercise (PEX) and eSports performance (eSP). To date, there has been no effort to explore the effect of the player's level of mental toughness (MT) on eSports key performance indicators (KPI), such as placement in a contest.

PURPOSE: (a) To explore the perceptions of players concerning the relationship between PEX and eSP; (b) To confirm the positive aforementioned relationship; (c) to investigate the moderation effect of MT in that relationship; and (d) provide evidence for larger-scale efforts.

METHODS: Data were collected on 23 male recreational eSport competitors (>6hours per week) ($M_{age} = 20.7$, $SD = 2.1$). The eight-item Mental Toughness Index (MTI) was used to measure MT, one question with five scales (0=significantly negatively, 5=significantly positively) was used to collect information on their perceptions, number of days of exercise per week was used as an indicator of PEX, and average place on *Fortnite: Solo* matches over 3 hours was used as KPI. We investigated the moderating role of MT using regression analysis in R. Predictors were mean-centered. The interaction was probed looking at simple slopes.

RESULTS: The majority of players tended to perceive PEX as having no significant or negative effect on eSP (65%). The estimated regression model without an interaction is $KPI = 27.6 + 3.13(PEX) + 1.07(MT)$, where $R^2 = .296$. The estimated regression model with an interaction is $KPI = 26.7 + 3.36(PEX) + 0.85(MT) + 0.4(PEX \times MT)$, where $R^2 = .310$. Simple slopes of PEX conditional on MT scores +1SD, Mean, and -1SD are: 4.72, 3.29, and 1.86, respectively.

CONCLUSIONS: Contrary to the players' belief, PEX was found to be positively correlated with eSP. Furthermore, we identified a potentially enhancing moderating effect of MT on the relationship between frequency of exercise and eSP. Therefore, not only PEX but also psychological skill training (PST), such as MT training, may be beneficial for the players on their effort to place higher and win larger prizes. This pilot study offers preliminary evidence for the need for larger-scale similar projects. Future studies should recruit professional eSports players, as well.

2594 Board #258 May 31 9:30 AM - 11:00 AM
The Effects Of Aerobic, Resistance, And Combination Training On Satisfaction With Physical Function And Appearance

Liezl Mae B. Fos¹, Leanna M. Ross², Cris A. Slentz², Lucy W. Piner², Leslie H. Willis², Lori A. Bateman², Joseph A. Houmar², FACSM³, William E. Kraus, FACSM². ¹The University of North Carolina at Greensboro, Greensboro, NC. ²Duke University Medical Center, Durham, NC. ³East Carolina University, Greenville, NC.

(No relevant relationships reported)

Purpose To determine the effects of aerobic training (AT), resistance training (RT), and combination training (AT/RT) on personal satisfaction with physical function (SPF) and appearance (SPA). We also examined the sex-specific relationships between objective measures of body habitus and cardiorespiratory fitness with changes in these satisfaction scores.

Methods Participants (n=130 from the STRRIDE AT/RT randomized trial) completed one of four 8-month exercise programs: 1) AT: 14 kcal exercise expenditure per kg per week (KKW) at 75% VO_{2peak} ; 2) RT: 3 days per week, 8 exercises, 3 sets per exercise, 8-12 repetitions per set; 3) AT/RT: full combination of the AT and RT programs; 4) AT-High Amount (AT-H): 21 KKW at 75% VO_{2peak} . The Satisfaction with Physical Function and Appearance Questionnaire [7-point integer scale ranging from -3 (very dissatisfied) to +3 (very satisfied)] was administered at baseline and post-intervention. We also assessed measures of body habitus (weight, lean and fat mass, and minimal waist and hip circumferences) and cardiorespiratory fitness (VO_{2peak}). Paired t-tests determined post- minus pre-intervention change score significance within training groups ($p < 0.05$). Sex-specific correlations examined the relationship between changes in SPF and SPA with changes in body habitus and fitness.

Results After 8 months of training, all groups significantly improved their SPF scores, ranging from 1.8 (AT) to 2.8 points (AT-H), and their SPA scores, ranging from 0.8 (RT) to 2.4 points (AT-H). Change in SPF was significantly correlated with change in fat mass ($r = -0.34$) in women and change in VO_{2peak} ($r = 0.29$) in men. Change in SPA was significantly correlated with change in fat mass ($r = -0.39$), waist circumference ($r = -0.25$), and weight ($r = -0.30$) in women and change in hip circumference ($r = -0.28$), weight ($r = -0.32$), and lean mass ($r = -0.45$) in men.

Conclusions On average, all of the STRRIDE AT/RT training groups improved their self-reported satisfaction with physical function and appearance. We observed sex-specific differences in the relationships between changes in SPF and SPA with changes in body habitus and fitness. These correlative results can help inform future research targeting the mediating effects of exercise on self-perception of body image and function.

2595 Board #259 May 31 9:30 AM - 11:00 AM
Exercise-Induced Upregulation of M1 Excitability Following Motor Practice Does Not Predict Procedural Consolidation

Jing Chen¹, Jiling Liu², David L. Wright². ¹Texas A&M University, Texarkana, TX. ²Texas A&M University, College Station, TX.
 Email: jchentamut@gmail.com

(No relevant relationships reported)

A brief bout of moderate intensity cardiovascular exercise immediately after procedural learning can protect a newly acquired motor memory from interference. The present experiment examined the possibility that exercise after practice increases motor cortex (MCE) which has been argued to be a biomarker for procedural skill consolidation. **PURPOSE:** Examine if (a) offline gain in procedural skill is associated with elevated MCE following practice and (b) the MCE following practice can be modified via exercise. **METHODS:** 35 right handed young adults were assigned to an Interference (INT), Interference + Exercise (INT+EX), or a no interference, no exercise (NO) condition. All individuals practiced a target motor sequence and some (INT, INT+EX) performed additional training with an alternative motor sequence 2-hr after practice with the target. The INT+EX also included cardiovascular exercise the target sequence practice. Test performance of the target sequence occurred 6-hr after practice. MCE was assessed using transcranial magnetic stimulation prior to training and after training (every 3 min for a total of 11 post training assessments of MCE). **RESULTS:** One way ANOVA (Condition: INT, INT+EX, NO) was used to analyze the mean response time for the target sequence offline learning effect and revealed a main effect of Condition $F(1,32) = 17.01$, $p < 0.01$. The extra practice in INT led to significant forgetting (-3 ± 7 ms) compared to the NO condition (NO, $+21 \pm 7$ ms). Introducing exercise, despite the presence of interference, eliminated the forgetting observed for the INT condition (INT+EX, 30 ± 7 ms). A 3 (Condition: INT, INT+EX, NO) x 11 (Time: 1-11) ANOVA with repeated measures on the last factor conducted on the % change in the normalized CE failed to reveal any significant main or interaction effects (F 's < 1.0). **CONCLUSION:** The INT+EX condition resulted in relatively greater increase in M1 excitability after practice compared to INT and NO conditions

but this increase was not significant. Moreover, relative increase in M1 excitability did not predict the extent of procedural learning at the time of test. These data question the claim that an upregulation of excitability at M1 is a biomarker for procedural skill consolidation.

2596 Board #260 May 31 9:30 AM - 11:00 AM
Effects Of Regular Sport Activities On Stress Level In Athletic And Non-athletic University Students

Márta Szmodis¹, Annamária Zsákai², Gergely Blaskó², Piroska Fehér², Dorina Annár², Edit Bosnyák¹, Anna Farkas¹, Gábor Almási¹, Miklós Tóth¹. ¹University of Physical Education, Budapest, Hungary. ²Eötvös Loránd University, Budapest, Hungary.
 Email: szmodis.marta@tf.hu
 (No relevant relationships reported)

Regular sport activity has favourable influence on the physical and mental state. **PURPOSE:** To analyse the effects of regular sport activities on body structural parameters, cortisol level, perceived stress and psychosomatic symptoms in university students. **METHODS:** The subjects (N=200) were athletic (athletic males: n_{am}=56, athletic females: n_{af}=50; more than 7 hours sport activity per week) and non-athletic university students (non-athletic males: n_{nam}=44, non-athletic females: n_{naf}=50; less than 3 hours sport activity per week). Body composition was estimated by InBody720 analyser. Free cortisol level in saliva was quantified by using IBL ELISA kits. Subjects were divided into subgroups having low, average and high basic cortisol levels by considering the normal range of cortisol level by the time of awakening. Perceived stress levels were measured by the Perceived Stress Scale with 14 items (PSS-14). Psychosomatic symptoms were assessed by questionnaire. Differences of the subgroups were tested by Tukey's post-hoc test and Chi-square test. **RESULTS:** There were significant differences (mean±SD, p<0.01) between subgroups in body composition (fat% - am: 12.1±6.0 vs. nam: 17.9±6.8; af: 20.8±5.5 vs. naf: 25.4±5.7; muscle% - am: 50.3±3.6 vs. nam 47.6±3.9; af: 43.8±3.2 vs. naf: 41.7±3.3), in stress level (total scores - am: 21.0±5.7 vs. nam: 23.3±7.2; af: 25.5±7.0 vs. naf: 28.0±9.7), and there were gender differences in psychosomatic symptoms (total scores - am: 14.6±6.3 vs. af: 20.4±7.4; nam: 14.9±6.1 vs. naf: 19.6±8.2), i.e. athletic students had larger muscle and smaller fat components, lower level of stress. Basic level of salivary cortisol revealed significant relation with the level of physical activity: athletic students had lower level of cortisol both in the males and females. This relation is reflected in the higher frequency of students with low level of cortisol in the physically more active subgroups in both sexes (am: 29% vs. nam: 15%; af: 18% vs. naf: 5%; p<0.01) as well as in the higher frequency of female students with high level of cortisol in the non-athletic subgroup (27% vs. 11%). **CONCLUSIONS:** The regular physical activity helps to achieve physical and mental well-being. It seems that non-active females are the most vulnerable to physical-psychic exhaustion. Granted: 20769/3/2018/FEKUTSTRAT

2597 Board #261 May 31 9:30 AM - 11:00 AM
The Importance Of 'Time' Prescription To Exercise Adherence: A Meta-analysis

Elizabeth Kelsch¹, Kathryn Burnet¹, Justin Moore, FACSM², Lee Stoner, FACSM¹. ¹University of North Carolina at Chapel Hill, Chapel Hill, NC. ²Wake Forest School of Medicine, Winston Salem, NC.
 (No relevant relationships reported)

Purpose: Time is perceived to be a major barrier to exercise adherence. This meta-analysis determined the effect of manipulating the time component of FITT (frequency, intensity, time, type) on exercise adherence. **Methods:** Electronic databases were searched from inception to September 2018. Inclusion criteria were (1) adults ≥ 18 y; (2) randomized controlled trial; (3) adherence (percentage) was the dependent variable. Meta-regression quantified the association between exercise intervention duration and adherence. Random effects meta-analyses were utilized where effect sizes were reported as mean differences (MD). Standardized mean differences were also calculated to characterize the effect size: trivial (<0.2), small (0.2-0.3), medium (0.4-0.8), and large (>0.8). **Results:** Initially, 2,885 articles were identified. After evaluation of study characteristics, quality and validity, data from 9 articles (16 trials) involving 513 participants (122 male, 391 female) were extracted. There was a non-significant effect for time (MD= 1.4, 95% CI: -1.6, 4.2) on adherence across all studies. Subgroup analyses were performed to determine the importance of population type: healthy and chronic diseases. Time manipulation had a positive medium effect in the healthy sub group (MD= 7.0, 95% CI 0.4, 13.6), and a negative, but a small non-significant effect in the chronic diseased subgroup (MD= -2.3 95% CI -5.5, 0.8). Meta-regression analysis revealed a positive association between intervention duration (month) and adherence for the healthy group (β= 3.4, 95% CI: 2.5, 4.2), but not for the chronic diseases group (β = -0.2, 95% CI: -0.7, 0.2).

Conclusions: Manipulation of time is effective for promoting exercise adherence in healthy populations, but not in those with chronic diseases. Further, exercise intervention duration is positively associated with adherence in healthy populations, but not in those with chronic diseases.

Association Between Parenting Style And Adherence To The 24-hour Movement Guidelines In Adolescents

Stephen H.S. Wong, FACSM¹, Yan Shi¹, Wendy Y. Huang². ¹The Chinese University of Hong Kong, Hong Kong, China. ²Hong Kong Baptist University, Hong Kong, China.
 Email: hsswong@cuhk.edu.hk
 (No relevant relationships reported)

Previous studies have examined the influence of parental style on children's physical activity (PA), sedentary behavior, and sleep in isolation. It is largely unknown how parenting style affect these movement behaviors as a whole within a 24-hour period. **PURPOSE:** To examine the association between parenting style and adherence to the 24-hour movement guidelines among adolescents in Hong Kong. **METHODS:** 1,039 adolescents aged 11-18 years and their parents participated in this study. The adolescents wore an activPAL™ for 7 consecutive days to measure moderate-to-vigorous PA (MVPA), SB and sleep duration. Meeting the overall 24-hour movement guidelines was defined as: ≥ 60 minutes of MVPA, ≤ 2 hours of screen time (ST), and 8-10 hours of sleep a day. Parenting style was reported by the adolescents using the Parenting Styles and Dimensions Questionnaire (PSDQ) which assessed three domains (authoritarian, authoritative, and permissive). Linear mixed models were performed to assess the association between parenting styles from both parents and the numbers of recommendations met by the adolescents, adjusting for educational attainment of parents, number of siblings, and school clustering effects. The models were performed for boys and girls separately. **RESULTS:** 278 adolescents (14.6 ± 1.6 years, 48% girls) provided valid activPAL™ data and reported the perceived parental style pertaining to their mothers and fathers. Only 1.1 % of the adolescents met the overall 24-hour guidelines. The percentage of meeting the PA, ST and sleep duration recommendations was 9.4%, 27.3%, and 37.8%, respectively. Permissive parenting style of the mothers was associated with a higher number of recommendations met by their sons (b = 0.07, 95% CI = 0.01 to 0.14, p < 0.05). There was no relationship between fathers' parental style and adherence to the guidelines for adolescents. **CONCLUSIONS:** Adolescent boys were more likely to adhere to the 24-hour movement guidelines when their mothers had a more permissive parenting style. This study was supported by the General Research Fund (GRF) of the Research Grants Council (RGC) of the Government of the Hong Kong Special Administrative Region, China (#14501415).

Comparison Of Affective, Perceptual, And Heart Rate Responses To Self-paced Treadmill Versus Trail Running

Luke Haile¹, Sara Galbraith², Curt B. Dixon, FACSM². ¹Bloomsburg University, Bloomsburg, PA. ²Lock Haven University, Lock Haven, PA.
 Email: lhaile@bloomu.edu
 (No relevant relationships reported)

The biophilia hypothesis describes the innate tendency of humans to seek connections with nature and living systems. Therefore, exercise in nature may allow more positive affective responses (AR) compared to exercise indoors, which may affect preferred intensity and ratings of perceived exertion (RPE) during exercise. **PURPOSE:** To compare AR, RPE, heart rate (HR), and exercise time between self-paced indoor treadmill running and outdoor trail running conditions. **METHODS:** Ten college-aged men and women were recruited for two self-paced exercise sessions performed in a random, counterbalanced order. The indoor exercise was performed on a treadmill in the laboratory without view of nature. The outdoor exercise was performed on a wooded trail, immersed in nature. For both sessions, the first 0.25 mi was a self-paced walking warm-up, the next 1.5 mi was self-paced running, and the last 0.25 mi was a self-paced walking cool-down. AR (Feeling Scale), RPE (Adult OMNI Walk/Run Scale), and HR (Mio Alpha) were measured at the middle and end of the 1.5 mi of running. AR, RPE, and HR were compared between sessions using mixed-model ANOVA. Total exercise time was compared between sessions using a paired-samples t-test. **RESULTS:** A significant main effect indicated higher average AR during trail running compared to the treadmill (2.4 ± 0.6 v 0.6 ± 0.6, p < 0.05). A significant interaction effect (p < 0.05) indicated AR increased during trail running (2.2 ± 0.5 to 2.6 ± 0.6) yet decreased during treadmill running (1.0 ± 0.5 to 0.3 ± 0.5). Although average RPE values were similar between conditions, a significant interaction effect (p < 0.05) indicated that RPE was stable during trail running (5.4 ± 1.2 to 5.3 ± 1.6) yet

increased significantly during treadmill running (4.7 ± 1.3 to 6.2 ± 1.0). HR increased similarly during both exercise sessions, yet exercise time was significantly less for trail compared to treadmill running (17.8 ± 3.5 min v 22.1 ± 4.5 min).

CONCLUSIONS: For indoor treadmill running, RPE increased with HR as expected, yet AR declined. Outdoor trail running, although with similar increasing HR, produced stable RPE and increased AR. These results indicate that self-paced running immersed in nature can have more positive effects on mood while providing the same physiological benefit as indoor treadmill running.

Aerobic Fitness and Cardiac Autonomic Control Related to Better Cognitive Performance in Young Adults

Arlison Fernandes Mendonça de Sousa, Samuel Estevam Vidal, Daniel Tavares de Andrade, Igor Marcio Correa Fernandes da Cunha. *FACIPLAC, Brasilia, Brazil.*
Email: arilsonf@hotmail.com

(No relevant relationships reported)

Aerobic fitness has a positively relation to cognitive function, including attention. In addition, an increased aerobic fitness has been related to better cardiac autonomic control, verified by heart rate variability (HRV), a simple and non-invasive tool for verification of autonomic nervous system activity. Previous studies have shown that higher levels of HRV is related to better attention. **PURPOSE:** To compare the cognitive performance and cardiac autonomic control of young adults with different levels of aerobic fitness (high vs low). **METHODS:** 20 males young adults (aged 21.2 ± 2.1 years) participated. The criteria for participation were: not consuming tobacco, supplements, or any drug that could interfere the evaluations; being free of cardiovascular diseases and attention disorders and do not consumed alcohol or coffee several hours before the tests. The attention components were evaluated through the Attention Network Test (ANT). The aerobic capacity (VO_{2max}) was estimated according to the Astrand nomogram. Body mass and stature was used to calculate body mass index (BMI) and skin folds were performed. Cardiac autonomic control was assessed by means of the HRV time domains (RMSSD and SDNN) at rest in the sitting position for 10 minutes prior to the ANT. Participants were divided into high and low fitness groups according to VO_{2max} (46 ± 6 vs. 31 ± 2). Results of HRV and the components of ANT: alertness, orientation and conflict were verified and compared between groups. **RESULTS:** The high fitness group compared to low fitness group demonstrated greater cardiac autonomic control [SDNN (74.1 ± 36.3 vs. 47.9 ± 12.4); RMSSD (55.4 ± 32.4 vs. 33.9 ± 13)] and better executive control of attention, verified by the Conflict component of the ANT [101.3 ± 30.1 vs. 141.2 ± 46.2], respectively. VO_{2max} had a moderate and negative correlation with the Conflict ($r = -0.50$, $p = 0.04$). Correlation between Conflict and SDNN and RMSSD appear ($r = -0.56$, $p = 0.01$), and $r = -0.46$, $p = 0.05$), respectively. In addition, there was no difference in the sum of skinfolds and BMI between groups. **CONCLUSIONS:** Participants of high fitness group demonstrated greater cardiac autonomic control and executive control of attention compared to the low fitness group. Still, the greater autonomic control seems to favor the greater executive control of attention.

Principles Of Fractal Geometry As Method Of Research Of The Self-organization Of The Human Movement

Maurício T. Souza, Andressa F. de Lima, Sandra M. S. F. Freitas, Alethéa Nardini, Marcelo L. Marquezi. *Cidade de São Paulo University - UNICID, São Paulo, Brazil.*

(No relevant relationships reported)

PURPOSE: The research method applied in the studies in the practice of physical exercise has predominantly used direct and/or invasive techniques, and may cause discomfort in the participants. However, it seems appropriate to apply non-invasive methods evaluating synergies during the execution of exercises. To apply the principles of fractal geometry in the kinematic analysis of the vertical jump in the mini trampoline to demonstrate the complex process of self-organization of the jump identifying individual "pattern" of synergies in the lower limbs of female undergraduate students. **METHODS:** Five Physical Education students were submitted to consecutive vertical jump with against motion and without the aid of their arms on the mini trampoline for 120 seconds. The joints angles of the lower limbs were recorded using a Vicon Bonita camera to capture the sign of the markers. Twelve markers were placed on the right and left sides of the body (anterior iliac crest, major femur trochanter, lateral femoral epicondyle, lateral malleolus, calcaneus, and the fifth metatarsal head). The position of the markers was recorded by a motion capture system (Proreflex240, Qualisys) with an individual 100 Hz sampling rate (12000 frames). For the kinematic analysis of the articular angles (Ankle, knee, hip) the Cantor Ternary Set was applied, considering two stages of iteration ($I_0 = [0, 1]$; $I_1 = [0, 1/3] \cup [2/3, 1]$; $I_2 = [0, 9] \cup [2/9, 3/9] \cup [6/9, 7/9] \cup [8/9, 1]$), which were demonstrated by Radar geometric method

RESULTS: The first iteration demonstrated consistency in the "standard" for ankle, knee and hip, right and left side. In the second, a recursion process was verified, since the graphs showed self-similarity.

CONCLUSIONS: The application of fractal geometry principles proved to be an adequate method to verify the individual "pattern" of jump behavior in the mini trampoline, through iterativity and recursivity, indicating a synergetic behavior in the system and characterizing itself as a process of self-organization.

2602 Board #266 May 31 9:30 AM - 11:00 AM

Association Between Binge Watching TV and Physical Activity in College Students

Julie M. Cousins, Heather H. Betz. *Albion College, Albion, MI.* (Sponsor: Helaine Alessio, FACSM)

Email: juliemcousins@gmail.com

(No relevant relationships reported)

Binge television (TV) watching is a relatively new phenomenon that involves watching more than two TV episodes or multiple movies in one sitting. TV watching is a form of sedentary activity. Prolonged sedentary time has been shown to be independently associated with deleterious health outcomes regardless of physical activity (PA).

The influence of binge TV watching on PA has not been studied in college students.

PURPOSE: The purpose of this study was to examine the associations between PA with binge TV watching in male and female college students. **METHODS:** A total of 46 Albion College students (25 males age = 20.0 (1.0) years; 21 females age = 20.5 (1.0) years) participated in this study. Height (females = 167.9 (6.1) cm; males = 182.4 (6.9) cm) and weight (females = 65.5 (15.7) kg; males = 86.9 (17.6) kg) were measured. The International Physical Activity Questionnaire was used to assess PA. Binge TV watching was assessed by self-report. Statistical analysis was performed using t-test and Pearson product-moment correlations. Significance was set to $p < 0.05$.

RESULTS: 47.6% of female and 48.0% of male college students met the ACSM minimum recommendations for 30 min of moderate intensity PA 5 days per week or 20 min 3 days per week of vigorous intensity PA. 76.2% of females and 56.0% of males reported binge watching TV at least 1 time per week. 100% of females and males reported binge watching TV in the past year. Students that met the PA requirements binge TV watched on average 2.5 (2.7) times per week, while students that did not meet the PA requirements binge TV watched on average 3.2 (2.3) times per week ($p=0.20$). A significant difference ($p=0.026$) was found in the number of times males reported binge watching TV (2.1(2.3) times per week) compared to the number of times females reported binge watching TV (3.7(2.5) times per week). Physical activity was not found to be significantly correlated with binge TV watching in college students ($p=0.10$). **CONCLUSIONS:** Binge TV watching and PA were not found to be significantly associated in college students. Females binge watched TV significantly more than males. Since binge TV watching does not appear to be stopping the students from doing PA, future research should be done to determine what binge TV watching may be stopping them from doing, possibly sleeping.

Exploring the Relationship Between Planned and Performed Physical Activity: the Utility of a Smartphone App

Matthew T. Stewart, Taylor Nezhich, Joyce Lee, Rebecca Hasson, FACSM, Natalie Colabianchi. *University of Michigan, Ann Arbor, MI.* (Sponsor: Rebecca Hasson, FACSM)

Email: stewartm@umich.edu

(No relevant relationships reported)

PURPOSE: Few studies have examined day-level plans to be physically active and subsequent physical activity behavior, likely due to the feasibility of collecting this data. The purpose of this study was to test the feasibility and acceptability of a new mobile phone application (Life in a Day App: LIAD) for collecting real-time time-use data among college-aged students and to examine whether plans to be physically active (recorded in advance on an electronic calendar for the protocol period) were associated with physical activity during the study protocol (measured through the LIAD app).

METHODS: Forty-eight participants were randomly assigned to one of three protocols defined by the number of days of data collection (1, 3 or 5 days). Participants were asked to record their planned activities for the protocol period in a Gmail calendar and provided smartphones (Samsung Galaxy S5) to complete time-use entries in real time (e.g., exercise/sports, eating/cooking, school, personal care). Participants were instructed to wear an accelerometer (ActiGraph wGT3X+) on their wrist during the protocol period (i.e., 24 hours a day) in order to objectively measure physical activity. **RESULTS:** Overall compliance with the protocol was very high with all participants utilizing the LIAD app. However, not all completed the data entry in real time, which was desired. Three of the 48 participants did not complete the calendar component. Six of the 48 participants did not have sufficient accelerometry data, defined as at least 10 hours of data on each day of the protocol. The most common participant-reported feasibility issue was the difficulty in carrying two smartphones. Within the full sample, the number of days when exercise was planned in the Gmail

calendar but not executed was 18. The number days of when exercise was executed but not planned was 15, while the number of days when exercise was executed and planned was also 15. **CONCLUSION:** Overall, there was moderate congruence between plans to be physically active and executed physical activity. Despite a few challenges, the mobile app is a reasonable and practical method of collecting real-time use data and offers insight into the relationship between planned vs. executed exercise at the day-level.

The Effects Of A Six-week Boot Camp Program On Exercise-related Affects And Perceptions

Selen Razon¹, Jared M. James¹, Anna K. Schade¹, Antonia L. Battaglini¹, Alexis N. Trumbetti¹, Jamie M. Blose¹, Katie M. Cooper¹, Paul K. Stickles¹, Umit Tokac², Melissa A. Reed¹, Melissa A. Whidden, FACSM¹. ¹West Chester University, West Chester, PA. ²University of Missouri, Columbia, MO. (Sponsor: Melissa A. Whidden, FACSM)
Email: selenrazon@gmail.com
(No relevant relationships reported)

Physical inactivity is the greatest public health concern of the 21st century (Blair 2009; Kohl et al., 2012). Lack of motivation for behavior change as well as a low sense of self-efficacy for exercise are amongst the greatest contributors of the problem (Lox, 2017). While evidence suggests the effectiveness of select physical activity (PA) interventions for improving PA levels, whether these interventions can also help long term PA behavior change is unknown (Prince et al., 2014). **PURPOSE:** The purpose of this study was two-fold (1) to investigate the effectiveness of a six-week boot camp program for increasing motivations for long-term PA behavior change, self-efficacy for exercise, and improving participants' perceptions of their general health as well as 2) to gauge participants' motives for adhering to the program. **METHODS:** Twenty-seven sedentary adults ($M_{age}=30.04$, $SD=10.33$) participated in a vigorous boot camp program for a minimum of five days per week for fifty minutes a day throughout a six-week period responded to questionnaires measuring their motivation for behavior change, self-efficacy for exercise and, perceptions of general health at the onset and the completion of the program. At the completion of the program, participants also responded to a single qualitative prompt for identifying motives for continued adherence to the program. **RESULTS:** Paired sample t tests indicated a significant improvement in participants' mean scores for self-efficacy for exercise ($M=7.21 \pm 2.2$ pre vs. 8 ± 1.65 post; $t=-2.38$, $p < 0.05$) and the perception of their general health ($M=3.17 \pm 1.01$ pre vs. 3.92 ± 0.7 post; $t=-4.21$, $p < 0.05$). Results from the qualitative prompt revealed three main themes for continued adherence: (1) structured aspect of the program, (2) accountability between the participants and exercise leaders, and (3) the sense of community within the program. **CONCLUSIONS:** These findings suggest that alternative boot camp interventions can prove effective means for improving important precursors of PA behaviors. From a practical standpoint, structured approaches that can provide a supportive community as well as a sense of accountability may present critical initiatives in promoting long term PA and solving the problem of inactivity.

Sedentary Adult Characteristics and Exercise Benefits and Barriers: Associations in an Interactive Voice Response Study

Matthew C. Ainsworth, Suzanne E. Perumean-Chaney, Kevin R. Fontaine, Mohanraj Thirumalai, Laura Q. Rogers, FACSM, Dori Pekmezi. University of Alabama at Birmingham, Birmingham, AL. (Sponsor: Laura Q. Rogers, FACSM)
Email: ainswrth@uab.edu
(No relevant relationships reported)

Adults living in the Deep South suffer higher rates of cancer incidence and mortality possibly related to higher rates of physical inactivity. Hence, additional information regarding physical activity (PA) barriers and benefits is needed for targeting interventions for this at-risk population. **PURPOSE:** To examine baseline associations between participant characteristics and PA benefits and barriers in sedentary adults enrolled in an Interactive Voice Response (IVR)-supported study in the Deep South. **METHODS:** Participants ($N=63$) completed the 43-item Exercise Benefits and Barriers Scale (EBBS) and 7-day Physical Activity Recall (moderate-to-vigorous physical activity [MVPA]) prior to randomized allocation. **RESULTS:** The mean age of the sample was 43 ± 11.8 years with slightly more male (55.6%) and black or African American (58.7%) participants. On average, participants were obese (31.1 ± 6.9 kg/m²), and self-reported 40 ± 56 minutes per week of MVPA. Using Mann-Whitney test, overall barriers were significantly greater for those with annual incomes less than \$50k vs. \$50k or more (Median [Mdn] = 30.0 vs. 25.5, $p = .025$) and for those employed less than full-time vs. full-time ($Mdn = 32.0$ vs. 28.0, $p = .034$). No significant associations were indicated for benefits. For PA barrier subscales, Time Expenditure time was a less frequent barrier for African-American vs. other (Mdn

= 2.0 vs. Mdn 2.3, $p = .002$) and obese vs. non-obese ($Mdn = 1.8$ vs. 2.3, $p = .005$). Physical Exertion was a greater barrier if not employed full-time vs. employed full-time ($Mdn = 2.7$ vs. 2.3, $p = .001$). Family Discouragement barriers were greater for unmarried vs. married ($Mdn = 2.0$ vs. 1.5, $p = .014$). Exercise Milieu barriers were more frequent for those with incomes less than \$50k per year vs. \$50k or more ($Mdn = 2.0$ vs. 1.4, $p = .005$). There were no significant associations between minutes of MVPA and EBBS or subscale scores. **CONCLUSIONS:** Our results highlight demographic differences in scores of barrier items related to time expenditure, family discouragement, physical exertion, and other exercise barriers. Further study is needed to examine how barriers in this population change over the course of an IVR-supported physical activity intervention. Supported by the NCI (R03CA1775) and NHLBI (T32HL105349) of the National Institutes of Health.

Mirror Mirror On The Wall: Who Prefers You Most Of All? Individual Preferences In The Context Of Mirrored-exercise Environment

Hila Sharon David, Yonatan Sarig, Gershon Tenenbaum. Florida State University, Tallahassee, FL.
Email: hs17@fsu.edu
(No relevant relationships reported)

Although most fitness facilities have a mirror on at least one of four walls, not all exercisers may benefit from exercising in a mirrored-environment. While studies suggest that certain antecedents, such as body image concerns, may underline people's avoidance from mirrored-exercise settings, the reasons that motivate people to exercise in a mirrored-setting, remained unclear. **PURPOSE:** Through a qualitative investigation, we explored in-depth the reasons that drive people to, or prevent people from, exercising in a mirrored-setting, and the consequence of exercising with versus without a mirror, among exercisers with distinct exercise-settings preferences. **METHODS:** Semi-structured interviews were conducted with 8 mirror-preferring exercisers (MPEs; 22.75 ± 2 yrs) and 8 mirror-avoiding exercisers (MAEs; 21.9 ± 2.2 yrs) and analyzed through a thematic analysis. **RESULTS:** Themes of enjoyment and gratification from the "exerciser-look," a desire to track fitness progress, and a high reliance on mirrors' feedback to monitor "form" emerged as reasons to prefer a mirrored-exercise environment. Themes of body shame and a desire to avoid self-disgust emerged as reasons to avoid mirrored-exercise settings among female MAEs. Mastery and contents of self-confidence underlined male MAEs' preference to avoid the mirror during exercise. Among both MPEs and MAEs, themes of decline in enjoyment, motivation and performance level emerged in relation to exercising in a non-preferred mode. **CONCLUSION:** Adhering to one's preferred mode of exercise is crucial for positive exercise-related outcomes. While a mirrored-exercise environment can serve as a confidence-booster for people who derive their exercise-motivation from the visual feedback of their appearance, it may lead to mood, motivation, and performance decrements among people, specifically females, who are less satisfied with their physical appearance. Understanding people's exercise-environment preferences in initial stages of the fitness progress may aid professionals in tailoring personalized exercise programs, which in turn, may increase exercise motivation. A further empirical investigation must target the consequences of mirrors for exercisers with different needs is necessary.

Sedentary Behavior in 6-10 Year Old Children and Associations to Portable Device Use and Parental Influence

Jonathan B. Naylor¹, Jacob E. Barkley². ¹Ashland University, Ashland, OH. ²Kent State University, Kent, OH. (Sponsor: Ellen Glickman, PhD, FACSM, FACSM)
Email: jnaylor2@ashland.edu
(No relevant relationships reported)

In recent years, portable screen-based devices such as internet-connected cellular telephones (i.e., smartphones) and portable tablet computers (i.e., tablets) have increased in availability. Prior research has indicated that the use of such devices may be associated with sedentary behavior and physical activity. While such relationships have been assessed in adults and/or evaluated other types of screen-time, the relationship between portable device use and physical activity and sedentary behavior remains untested in young children.

PURPOSE: To examine screen-based media device (smartphone, tablet, television, video games, computer) use in children and their parents in relation to sedentary behavior and physical activity. **METHODS:** Parents ($N = 40$) completed validated questionnaires assessing average daily total screen use (smartphone, tablet, television, video games, computer), portable screen-based device use (smartphone, tablet), sedentary behavior, and physical activity for themselves and their children ($N = 40$, 8.7 ± 1.3 years old). Four standard regression models were used to assess the relationship between criterion variables and

the following predictor variables: child age, child sex, child average daily sedentary time, and child physical activity. Criterion variables included (a) child portable device use (Model 1), (b) child total screen use (Model 2), (c) parent portable device use (Model 3), and (d) parent total screen use (Model 4).

RESULTS: Child sedentary time was significantly ($\beta = 0.47, t = 3.30, p = 0.002$) and positively associated with child portable device use. Child sedentary time was also significantly ($\beta = 0.45, t = 2.91, p = 0.006$) and positively associated with parent total screen use. Child age and physical activity were not significantly ($p > 0.05$) related to either parent or child portable or total device use.

CONCLUSION: As found in similar studies examining young adults, child sedentary behavior was related to portable device use while physical activity was not. This suggests that children who are heavy users of portable screen-based devices allocate more time to sitting than their peers who are lower portable screen users. Furthermore, results also suggest that total screen use in parents was predictive of sitting in their children.

2608 Board #272 May 31 9:30 AM - 11:00 AM
Exercise Intensity as a Predictor of Mood States During a Group Cycling Class

Debra A. Stroiney¹, John D. Ranney², Navid Ghodddosi¹.
¹George Mason University, Manassas, VA. ²Gannon University, Erie, PA.
 Email: dstroine@gmu.edu
 (No relevant relationships reported)

Increases in positive mood states after exercise has been well documented. Group cycling classes are a popular mode of exercise in the fitness industry. There is limited research on the effect of group fitness classes on mood states and whether intensity level will have an impact on the mood enhancing benefits. **PURPOSE:** The purpose of this study was to determine if exercise intensity predicts changes in mood states during a group cycling class. **METHODS:** A total of 99 subjects, ages 18 to 25 years old, volunteered for the study. No previous experience with group cycling classes was required. The subjects participated in one group cycling class instructed by a certified cycling instructor. Prior to the cycling session the subjects filled out an informed consent, medical history, and Subjective Exercise Experience Scale (SEES). Subjects were then given a heart rate monitor, instructed on proper bike set up and how to operate the bike during class. The cycling class consisted of a 5 min warm up, a 30 min conditioning phase with a mix of sprints, hills and jumps typically performed in a cycling class. The class ended with a 5 minute cool down and 5 minute stretch off the bike. Heart rate and percent heart rate reserve (%HRR) was continuously tracked during class. After the class, subjects filled out a second (post) SEES. A hierarchical regression analysis was used to examine whether intensity measured by %HRR predicted changes in each of the 3 mood state categories on the SEES (positive well-being, psychological distress, fatigue). Three related sample t-tests were run examining changes in mood following the cycling class. **RESULTS:** % HRR was negatively related to positive well-being ($\beta = -.178, p = .046$) and positively related to fatigue ($\beta = .30, p = .003$). There were no significant differences in fatigue after the cycling class ($p > .05$), however positive well-being increased ($p = .001$) and psychological distress decreased ($p = .021$) after the class. **CONCLUSION:** The intensity level of an acute exercise session may affect the mood enhancing benefits of exercise. The group cycling class did increase positive well-being and decrease psychological distress. However, individuals who exercised at higher intensity levels had increased levels of perceived fatigue and decreased feelings of positive well-being.

What Parental Correlates Predict Children's Active Transportation to School in the Southeast USA?

Eugene C. Fitzhugh¹, Jerry Everett², Linda Daugherty².
¹University of Tennessee, Knoxville, TN. ²University of Tennessee, Knoxville, TN.
 Email: fitzhugh@utk.edu
 (No relevant relationships reported)

School-aged children in the Southeast USA have been found to have significantly lower levels of active transportation to school (ATS) via walking or biking. Parents, the main gatekeeper of children's ATS behaviors, usually weigh their perceptions of the sociocultural and the neighborhood-built environments when making their ATS decision. **PURPOSE:** To contrast the correlates of ATS decision-making behavior between parents living in the Southeast with other parents across the USA. **METHODS:** This study utilized data from 2,952 households from across the USA (50.6% from the Southeast USA) that had school-aged children (K-8th grade) who were located within a 20-minute walk to a school. Parents were surveyed during 2012-13 using a mixed-mode approach that involved telephone and web surveys. Parents self-reported their child's ATS behavior and their own attitudes, beliefs, and perceptions in five areas related to ATS - safety and convenience concerns, perceived ATS benefits, desired neighborhood active transportation characteristics, and perceived ATS social norms. In addition, parents reported the demographics and the geographical

characteristics of their home. PROC LOGISTIC in SAS was utilized to contrast correlates between the Southeast and the USA. **RESULTS:** Parents in the Southeast, compared to parents across the USA, were significantly less likely to allow their child to take ATS (12.9% vs. 33.3%, respectively) (OR=0.46; 95% CI=0.36-0.59). ATS correlates, regardless of USA region, included decreases in ATS with increasing age (OR=0.97; 95% CI=0.96-0.99), and increases in ATS if parents perceived ATS to be the norm (OR=2.57; 95% CI=2.23-2.96). Correlates linked to increases in ATS, which were limited to only parents living in the Southeast, were being black (OR=1.68; 95% CI=1.31-2.60) and being single, (OR=1.71; 95% CI=1.15-2.54). The only correlate association related to a decrease in ATS specific to the Southeast was heightened safety concerns (OR=0.44; 95% CI=0.23-0.84). **CONCLUSIONS:** Among households located near schools in the Southeast, interventions that allay parental ATS safety concerns might lead to increased ATS. In addition, programs that promote physical activity among adults in the Southeast might indirectly lead to increases in ATS among households with children.

Determinants of Change in Sedentary Behaviour In Young Children: a Systematic Review

Liane B. Azevedo¹, Esther M.F. van Sluijs², Helen J. Moore³, Kathryn Hesketh⁴.
¹Teesside University, Middlesbrough, United Kingdom. ²University of Cambridge, Cambridge, United Kingdom. ³Durham University, Durham, United Kingdom. ⁴University College London, London, United Kingdom.
 Email: l.azevedo@tees.ac.uk
 (No relevant relationships reported)

High levels of sedentary behaviour have been suggested to be harmful in young children and appear to track from early to middle childhood years, suggesting the need to intervene before the behaviour becomes embedded. **PURPOSE:** To identify determinants of change in sedentary behaviour in young children (≤ 6 years old). **METHODS:** Eleven databases were searched up to March 2018. Duplicate paper selection focussed on the inclusion of longitudinal and intervention studies which: a) targeted sedentary behaviour in young children (≤ 6 years old); b) assessed a within-child change in objectively-measured sedentary behaviour; and c) reported on at least one determinant of sedentary behaviour. Intervention components were coded according to the cluster of behaviour change technique (BCT). Data synthesis was guided by the socio-ecological model and Harvest plots and included duplicate quality assessment. **RESULTS:** Sixteen studies (4 longitudinal and 12 intervention studies) met the inclusion criteria out of 14,966 papers identified in searches. Five determinants were identified from four longitudinal studies and 21 determinants (i.e. BCT components) were identified from 12 intervention studies. Studies were considered to be of high ($n=9$) or intermediate ($n=7$) quality. Interventions targeted a mean of 3.6 (SD 2.4) BCT clusters. The BCT cluster "shaping knowledge" and "antecedents" were targeted in 11 and 8 out of the 12 studies respectively. The following determinants at the interpersonal level were associated with a decrease in sedentary behaviour: goals and planning (i.e. behavioural contract), repetition and substitution (i.e. graded tasks) and reward and treat (i.e. incentives). In single studies, two environmental-level determinants were associated with an increase in sedentary behaviour: afterschool period and transition from childcare to school. **CONCLUSION:** A limited range of determinants of change in young children's sedentary behaviour have been studied. Of these, only a few were associated with objectively measured change in sedentary behaviour. There is a need for more evidence, particularly from interventions targeting sedentary behaviour only to provide more robust evidence and to support the development of future interventions.

Exercise Dependence, Eating Disorder Symptoms and Biomarkers of Relative Energy Deficiency among Male Endurance Athletes

Anna K. Melin¹, Ida L. Fahrenholtz², Mia Lichtenstein³, Monika K. Torstveit⁴.
¹University of Copenhagen, Copenhagen, Denmark. ²University of Agder, Kristiansand, Norway. ³University of Southern Denmark, Odense, Denmark. ⁴Agder, Kristiansand, Norway.
 Email: aot@nexs.ku.dk
 (No relevant relationships reported)

Exercise dependence (ED) is characterized by a craving for physical training, uncontrollable excessive exercise behavior with inability to reduce exercise amounts, and potential harmful consequences, such as injuries, impaired social relations and depression. The condition is often associated with eating disorder pathology and perfectionism among women. Whether an association between ED and eating disorder symptoms among male endurance athletes exists, is less known. **PURPOSE:** The aim of this study was to explore possible associations between ED, eating disorder symptoms, and biomarkers of Relative Energy Deficiency in Sports (RED-S) among male athletes. **METHODS:** Fifty-three healthy well-trained male cyclists,

triathletes, and long-distance runners recruited from regional competitive sports clubs were included in this cross-sectional study. The protocol comprised the Exercise Dependence Scale (EDS) consisting of 7 sub-scales, the Eating Disorder Examination Questionnaire (EDE-Q), measurements of body-composition, resting metabolic rate, energy intake and -expenditure, and blood analysis of hormones and glucose.

RESULTS: Subjects with higher EDS score displayed a more negative energy balance compared to subjects with lower EDS score ($p < 0.01$). EDS total score was positively correlated with EDE-Q global score ($r = 0.41$, $p < 0.05$) and the subscale score for *Restraint eating* ($r = 0.34$, $p < 0.05$) and *Weight concern* ($r = 0.35$, $p < 0.05$). EDS total score and the subscales *Lack of control* and *Tolerance* were positively correlated with cortisol ($r = 0.38$, $p < 0.01$, $r = 0.39$, $p < 0.01$, and $r = 0.29$, $p < 0.05$, respectively). The EDS subscales *Withdrawal* and *Tolerance* were negatively correlated with fasting blood glucose ($r = -0.31$ and $r = -0.32$, $p < 0.05$, respectively), while *Intention effect* was negatively correlated with testosterone:cortisol ratio ($r = -0.29$, $p < 0.05$) and positively correlated with cortisol:insulin ratio ($r = 0.33$, $p < 0.05$). **CONCLUSION:** In this sample of healthy male athletes we found positive associations between higher EDS scores, eating disorder symptoms and biomarkers of RED-S, such as a more pronounced negative energy balance and higher cortisol levels. More studies are needed to elucidate ED as a possible contributor to the syndrome of RED-S.

Parental Rewards for Children's Physical Activity: A Quantitative and Qualitative Analysis

Tyler J. Kybartas, Paula-Marie M. Ferrara, Dawn P. Coe, FACSM, Kelley Strohacker, FACSM. *University of Tennessee, Knoxville, TN.*

(No relevant relationships reported)

School-based intervention studies have used rewards to promote physical activity (PA) in children. However, little research has examined parental incentivization of children's PA including reasons and types of rewards. **PURPOSE:** To investigate parent-selected rewards for children's PA in terms of prevalence, type, and motivation to incentivize or not. **METHODS:** Parents ($N=90$, mean \pm SD; 39.3 \pm 6.0 y) of children (8.7 \pm 2.1 y) completed a web-based survey that included items regarding moderate-to-vigorous PA (MVPA, min \cdot week $^{-1}$), use of PA rewards, and demographic characteristics. Open-ended questions were used to determine the type of activity rewarded, type of reward given, and parents' reasoning for not using PA rewards. Independent sample t-tests were used to determine differences between reward groups (reward, no reward) and parent-reported children's MVPA. Qualitative data underwent content and thematic analysis. **RESULTS:** Over half (55%) of the respondents provided PA rewards. There was no significant difference between reward groups for MVPA (reward: 321 \pm 195 min \cdot week $^{-1}$; no reward: 344 \pm 180 min \cdot week $^{-1}$; $t(88)=0.862$, $p>0.05$). Two underlying themes as to why parents did not give rewards were deemed "Expectation" (e.g. being active is expected, should be part of everyday life) and "Intrinsic Motivation" (e.g. already active, already enjoy PA). Rewarded PA's were thematized as "Non-Exercise" (e.g. chores, good behavior, homework), "Sport" (e.g. performance, participation/effort), and "Non-Sport Activity" (outdoor play, structured PA, bike riding, miscellaneous PA). There were two themes for types of rewards including "Tangible" (e.g. money, food, other) and "Non-Tangible" (e.g. verbal praise, electronic time, family activities). **CONCLUSION:** Rewarding children's PA is prevalent within this sample of parents. Substantial variety exists regarding the type of PA incentivized and the type of reward provided. Motivations should be further explored to inform intervention design.

Social Network of Friends and Physical Activity in University Students

Carlos M. Arango¹, Jason Cardona¹, Diana I. Muñoz², Victor H. Arboleda¹, Sandra M. Hincapié², Fredy A. Patiño¹. ¹*Universidad de Antioquia, Medellin, Colombia.* ²*Universidad CES, Medellin, Colombia.*

Email: cmarangop@gmail.com
(No relevant relationships reported)

PURPOSE: To identify associations between different parameters of social networks with sedentary behavior and physical activity in university students **METHODS:** A social network analysis was carried out in a cross-sectional study in 475 university students. Sedentary behavior and physical activity were measured using self-report questionnaires, and participants were asked to nominate their best friends within the university. A multivariate analysis was performed using logistic regression models, separately for sedentary behavior and physical activity. In all the models, predictive variables included network density, cluster of friends, centrality, popularity, and friend behaviors. These models were adjusted including sociodemographic variables. Analysis of the information was carried out taking a significance level of less than 5% ($p < 0.05$) and a reliability of 95% with the SPSS V24 program and the Ucinet software for social network data **RESULTS:** It was found that 17.6% of participants reported high TV viewing (2 or more hours per day of TV viewing) and 76% were physically active (150 minutes-

week of moderate physical activity or 75 minutes-week of vigorous physical activity). High TV viewing was negatively associated with popularity, and physically active participants received a greater number of friendship nominations compared with inactive students. Likewise, in women, the increase of 10 percentage points in active friends was positively associated with being physically active (OR: 2.3, CI 96% 1.1 - 5.0). By the contrary, an increase of 10 percentage points of friends with high TV viewing was associated with less probability of being physically active (OR: 0.4, CI 96% 0.1 - 0.9). For men, any of the associations were statistically significant **CONCLUSIONS:** Social network of friends affects sedentary behavior and physical activity levels of women university students. Social dynamics are important correlates for sedentary behavior and physical activity in university students

2614 Board #278 May 31 9:30 AM - 11:00 AM
Mood Response To Aerobic Exercise In The Tiger Study

Graham D. Salmun¹, Molly S. Bray¹, Rodney K. Dishman². ¹*University of Texas at Austin, Austin, TX.* ²*University of Georgia, Athens, GA.*

Email: gsalmun@utexas.edu
(No relevant relationships reported)

The mood response to exercise may play a major role in exercise adherence and has a high degree of inter-individual variability. The difference between a positive and a negative affective mood response to exercise may influence the likelihood of regular participation in exercise.

Purpose: To determine how mood states change from pre- to post-exercise in sedentary individuals. **Methods:** The Training Interventions and Genetics of Exercise Response (TIGER) Study is a prospective cohort study, in which sedentary subjects (18-35 y, <30 min/wk for 30 days prior to enrollment) participated in a 15-week program, exercising within a prescribed (65-85% maximum heart rate reserve) target heart rate zone for 3 d/wk. Before and after each exercise session, a subset of subjects ($n=312$) completed a 10 cm visual analog scale (VAS: 0-100) for four mood states: fatigue, tension, depression, and hunger. Mean change in response to exercise for each mood state was analyzed using a paired t-test. Linear and logistic regression were used to examine associations between mood and exercise. Change was also examined by obesity status (BMI > 30kg/m²). **Results:** Exercise was associated with reductions in feelings of fatigue (mean pre: 53.41, post: 50.62); tension (mean pre: 43.56, post: 39.93); depression (mean pre: 38.79, post: 34.02); and increased hunger (mean pre: 51.81, post: 57.47). Mean change values from pre- to post-exercise: fatigue: -2.78, tension: -3.65, hunger: 5.67, & depression: -4.82. Non-obese subjects displayed a significantly greater hunger response to exercise (7.41 vs 4.89 respectively, $p<0.05$) and greater (but non-significant) reductions in depression following exercise (-5.91 vs -4.33 respectively, $p=0.07$) compared to obese subjects. Change in fatigue score was significantly and negatively associated with exercise intensity ($p<0.001$). An increased hunger score was significantly associated with increased risk of exercise dropout ($p<0.04$), even after controlling for obesity status. **Conclusions:** Exercise elicits reductions in feelings of fatigue, tension, and depression, while increasing hunger. Non-obese versus obese subjects display a significantly greater hunger response to exercise and a trend of reduced depression. Mood states following exercise may influence both exercise intensity and adherence.

Sedentary Behavior & Health Variables in People with Type 2 Diabetes

Shaima Alothman, Aqeel Alenazi, Mohammed Alshehri, Jason Rucker, Patricia Kluding. *The University of Kansas Medical center, Kansas city, KS.*

(No relevant relationships reported)

Sedentary Behavior and Health Variables in People with Type 2 Diabetes

Shaima Alothman¹, Aqeel Alenazi^{1,2}, Mohammed Alshehri^{1,3}, Jason Rucker¹, Patricia Kluding¹

¹University of Kansas Medical Center, Kansas City, Kansas; ²Prince Sattam Bin Abdulaziz University, Alkharj, Saudi Arabia; ³Jazan University, Jazan, Saudi Arabia **PURPOSE:** The purpose of this study is to examine the relationships between sedentary behavior (SB), glycemic control, well-being, fatigue, and physical function in people with type 2 diabetes (T2D). These modifiable health variables have been shown to be 1) affected in people with T2D, and 2) associated with SB in older adults. However, the relationships between these variables and SB in people with T2D are uncertain. **METHODS:** A cross-sectional study design was used to assess the relationship between SB (total sitting time) with glycemic control (HbA1c), well-being (WBQ-22), fatigue (Fatigue Severity Scale), and physical function (Senior Fitness Test). An activPAL3™ activity monitor was used to assess SB in people with T2D aged from 50 to 75 years. **RESULTS:** Data from 59 participants were included in the final analysis. Study participants were obese (33.4 ± 5.5 kg/m²) and sedentary (11.08 \pm 2.31 Hours/day). Multiple linear regression examining the effect of the assessed variables on SB showed that poorer glycemic control ($\beta = 0.40$; 95% IC: 14.43, 58.13) was associated with higher level of SB, independent of moderate to vigorous physical

activity. No other significant relationships were observed. **CONCLUSION:** Glycemic control was a significant predictor of SB level. Understanding these relationships are important in designing and implementing interventional programs. Future studies are needed to explore this relationship further, as both glycemic control and SB are modifiable factors and could be used as main target for interventions aimed to improve health outcomes in people with T2D.

Psychometric Evaluation of the Physical Activity Appraisal Inventory: Adolescence and Young Adult Version

Barbara Haas¹, Shuzhu Rinicker², Belinda Deal¹, Zhaomin He¹, Dennis O'Connell, FACSM². ¹University of Texas at Tyler, Tyler, TX. ²Hardin-Simmons University, Abilene, TX. (Sponsor: Dennis O'Connell, FACSM)

Email: bhaas@uttyler.edu

(No relevant relationships reported)

PURPOSE: To develop and perform initial psychometric testing of a specially designed scale: Physical Activity Appraisal Inventory--Adolescence and Young Adult Version (PAAI-AYA).

METHODS: The PAAI was validated in two separate studies: study one, elderly female patients with cancer (n=219); study two, elderly female with cancer (n=73) or without cancer (n=55). The PAAI-AYA was developed using the PAAI with the addition of nine-items pertaining specifically to young adults via content-expert validation. Following survey instrument finalization, it was distributed to students at three universities in the United States. Two hundred and sixty-eight students completed the survey. Survey data from 226 students (55 male and 165 female) who met age qualifications (16-25 yrs; x age = 23.5 years) were used for data analysis. Exploratory factor analysis was conducted with principal-axis factoring, parallel analysis, and promax rotation.

RESULTS: A one-factor, 21-item solution, physical activity self-efficacy, was decided on for the scale (loadings range = .63-.81, 55.4% of total variance). The scale had high reliability (Cronbach alpha = .96), acceptable item-total and inter-item correlations (.62-.79, .3-.78, respectively), and high concurrent validity with the Exercise Self-Efficacy Scale (rs = .80, p <.001), and with self-reported physical-activity levels (rs = .40, p <.001).

CONCLUSIONS: Although the scale developed in this study needs future confirmatory factor analysis, it is a reliable and promising tool. As such, it can be effectively utilized by clinicians to better understand and promote physical activity self-efficacy in late-adolescent and young-adult college populations.

2617 Board #281 May 31 9:30 AM - 11:00 AM

The Effects Of A Low-dose Mindfulness-based Intervention On Psychological/physiological Health And Acute Food Choices.

Liam A. Beasley, Francesca Cavallerio, Justin Roberts. Anglia Ruskin University, Cambridge, United Kingdom.

Email: liam.beasley@student.anglia.ac.uk

(No relevant relationships reported)

Mindfulness-based interventions (MBI) are becoming increasingly popular as a low-risk tool that engage participants in the practice of positive psychological skill training. Long-term studies demonstrate that MBIs may improve physiological/psychological well-being, and specific health behaviours, but require significant time commitment, therefore prompting development of 'low-dose' MBI's. However, the efficacy of these MBIs, particularly with modification of nutritional choices has yet to be established. **PURPOSE:** This study investigated the efficacy of a short-term MBI and its effects on psychological and physiological markers of health, in conjunction with the assessment of acute food choice. **METHODS:** Following University ethical approval, 27 healthy participants were randomly assigned to 6-weeks of either: MBI; progressive muscle relaxation [PMR] or a wait-list control [C]. Within experimental groups participants undertook a 10-minute audio-guided script for six-days per week. At baseline (T1), week 3 (T2) and 6 (T3), participants completed three psychological questionnaires assessing mindfulness state (MAAS), perceived stress (PSS) and mindful eating (MEQ), in addition to physiological measures (blood pressure (BP), heart rate variability (HRV)) and a food choice task. **RESULTS:** MBI resulted in a significant increase in MAAS (0.76 ± 0.15au; p < 0.01, $\eta^2 = 0.44$) and reduced PSS (-4.89 ± 1.22au; p = 0.05, $\eta^2 = 0.17$) by T3 compared to PMR and C. Alternatively, no differences were observed between groups at any stage for MEQ scores (p ≥ 0.05). Within-MBI only, time and frequency HRV improved T1-T3 by 8.22 ± 5.52 ms⁻¹ (p = 0.02, $\eta^2 = 0.16$) and 12.29 ± 6.16nu (p = 0.05, $\eta^2 = 0.12$) respectively. These changes were not emulated for BP variables at any stage (p ≥ 0.05). Finally, no significant effects for acute food choices were observed (positive choices p = 0.90; negative choices p = 0.30). **CONCLUSIONS:** A low-dose MBI induced improvements between-groups for MAAS and PSS, and within-condition for time and frequency HRV. Whilst this supports the efficacy of an acute MBI in self-reported measures, HRV results should

be interpreted cautiously due to the lack of between-group significance. As food choice and MEQ responses were not influenced, further research targeting nutrition-specific MBIs are warranted.

2618 Board #282 May 31 9:30 AM - 11:00 AM

SPLASH (Swimming. Positive Perceptions. Lifestyle. Activity. Strength. Healthy Habits.) Into Fitness: An Intervention for Girls

Eydie N. Kramer, Daheia J. Barr-Anderson, FACSM. University of Minnesota, Minneapolis, MN.

Email: krame640@umn.edu

(No relevant relationships reported)

Pre-teen girls are disproportionately affected by obesity, and experience reductions in positive self-regard, physical activity (PA) participation, and healthy eating habits as they age. Previous literature demonstrates that health identity developed in youth drives adult behavior. Engagement in brief interventions has enhanced psychological underpinnings (i.e., exercise identity: EI; healthy eater identity: HEI) of healthy behavior in samples of obese and normal-weight girls. However, previous studies have not examined results from a mixed BMI weight-status sample, following participation in an innovative intervention designed to develop salient health identity in the critical pre-teen years. **PURPOSE:** To determine if participation in a multicomponent intervention (1-week health camp plus randomly assigned 10-week eHealth program) will increase EI, HEI, and health behavior in pre-teen girls. Preliminary post-camp results are presented. **METHODS:** Thirty-two participants (age=10.6±0.80 years, BMI percentile=76.7±25.83, overweight/obese=53.1%) attended a camp designed to enhance health identity. Programming focused upon improving the girls' EI by teaching three modalities of PA: swimming (aerobic), strength exercises (resistance-training), and yoga (flexibility). Nutrition/culinary lessons were included to enhance HEI. The curriculum promoted positive perceptions of self, regardless of BMI classification. Data were collected at baseline and post-camp. Measures will be repeated at three-month follow-up, following randomly assigned eHealth intervention. **RESULTS:** Participants experienced a significant increase in EI role-identity (p<0.001), and moderately increased enjoyment of PA (p=0.061) at post-camp. Additionally, participation in mild PA significantly improved (p=0.020). Small increases in HEI, moderate-vigorous PA, and fruit/vegetable intake were reported post-camp; results were not statistically significant. **CONCLUSION:** Preliminary findings indicate that psychological underpinnings of healthy behavior (such as identity or enjoyment) are positively impacted in pre-teen girls following participation in a 1-week health camp. Follow-up data will elucidate upon long-term effects, dependent upon assignment to eHealth intervention or usual care control.

Investigating the Role of Perceived Willpower in Predicting Exercise Behavior- A Longitudinal Analysis on Gym Members

Navin Kaushal¹, Béatrice Bérubé¹, Martin S. Hagger², Louis Bherer¹.

¹University of Montreal, Montreal, QC, Canada. ²Curtin University, Perth, Australia.

Email: n.kaushal@umontreal.ca

(No relevant relationships reported)

PURPOSE: Implicit Theories about Willpower (ITW) propose that the beliefs of an individual's willpower as either abundant/rejuvenating or a limited resource predicts repetition of self-regulated behaviors, such as exercise. It is also theorized that willpower could be a determining factor for long-term behavioral adherence. While the ITW has demonstrated predictive validity for various health behaviors, its role in the context of exercise is limited. The purpose of the study was to test how the ITW predicts behavior among regular exercisers using an extended dual-process model. **METHODS:** Participants (n= 161) were a sample of adults (18-65) recruited across nine gym and recreation centers in a large metropolitan city and were averaging 257 min/week (SD = 171) of moderate-to-vigorous physical activity. Participants completed online surveys that were assessed monthly for six months. Multi-level structural equation modeling was used to analyze the results. **RESULTS:** The model found Intention X planning interaction to predict behavior ($\beta = .29, p < .001$), while controlling for intention ($\beta = -.08, p = .14$) and planning ($\beta = -.01, p = .85$). Specifically, high intenders with specific plans predicted behavior. Habit was also found to predict behavior ($\beta = .11, p = .005$). Intrinsic motivation predicted both habit ($\beta = .25, p < .001$), and the interaction construct ($\beta = .18, p < .001$) directly and behavior ($\beta = .17, 95\% \text{ CI } [.070, .278]$) from total direct and indirect pathways. Rejuvenating willpower predicted habit ($\beta = .11, p = .020$) and intrinsic motivation ($\beta = .11, p = .008$) directly in addition to the interaction construct ($\beta = .10, 95\% \text{ CI } [.019, .184]$) and behavior ($\beta = .09, 95\% \text{ CI } [.001, .193]$) via total pathways. The model did not find limiting willpower predict any paths. Time did not predict changes in the observed model. **CONCLUSION:** Findings add support to previous work on proposed maintenance constructs by testing them longitudinally in post-intenders. The model further advances

these findings by identifying how willpower, particularly, perceived rejuvenating willpower played a pivotal role as a proximal predictor of habit and intrinsic motivation and a distal predictor to behavior. Exercise-focused interventions that help participants cultivate rejuvenating willpower could be beneficial for behavioral maintenance.

2620 Board #284 May 31 9:30 AM - 11:00 AM
Correlates of Light Physical Activity Among Cancer Survivors

Elizabeth Fallon¹, Rakiyah Johnson², Carla Berg². ¹American Cancer Society, Atlanta, GA. ²Emory University, Atlanta, GA. (Sponsor: Melissa Bopp, FACSM)
Email: Elizabeth.Fallon@cancer.org
(No relevant relationships reported)

Emerging evidence demonstrates positive health benefits of light physical activity (LPA) for cancer survivors. Yet, little research has explored modifiable factors that facilitate or hinder LPA behavior in this population. Furthermore, studies are often underpowered for conducting sub-group analyses. **PURPOSE:** To explore modifiable correlates of LPA among cancer survivors using a social cognitive framework, and how these correlates may differ among those engaging/not engaging in moderate-to-vigorous physical activity (MVPA). **METHODS:** Self-report data from the third survey of the American Cancer Society's Studies of Cancer Survivors I (N = 1720) were analyzed. Social cognitive variables of interest reflect cognitive determinants (i.e. perceived health competence and perceived susceptibility to cancer recurrence) and environmental determinants (i.e. healthcare provider support, perceived social support, and unsupportive partner behaviors). The Leisure Time Exercise Questionnaire was used to create four LPA categories (0, 1-59, 60-119, and 120+ minutes/week). Ordinal regressions using forced entry were conducted, stratified by MVPA status (0 minutes of MVPA, ≥ 1 min MVPA). Models were adjusted for relevant covariates (i.e., demographic, cancer-related, health-related variables), missing data bias was examined, and sensitivity analyses were conducted to examine the robustness of the results.

RESULTS: Among cancer survivors reporting no MVPA (n = 747), greater provider support for PA (adjusted OR [aOR] = 1.49, p = .03), greater perceived health competence (aOR = 1.44, p = .01), and greater unsupportive partner behaviors (aOR = 1.06, p = .03) were significantly correlated with higher LPA. No constructs were correlated with LPA among cancer survivors already engaging in MVPA (n = 973). Missing data bias was small (Cramer's V/Phi < 0.1). Results were similar in unadjusted analyses, and when stratifying by insufficient and meeting MVPA recommendations. **CONCLUSIONS:** The utility of a social cognitive framework in explaining LPA among cancer survivors who do not engage in any MVPA was supported. Interventions may be more efficacious by incorporating healthcare provider support, improving health competence, and improving interpersonal skills that address unsupportive partners.

Investigating the Effect of Competition Level on Penalties and Injuries in Youth Soccer

Nicole C. Walden, Stephanie D. Walsh, Christopher P. Tomczyk, Tamerah N. Hunt, FACSM. Georgia Southern University, Statesboro, GA. (Sponsor: Tamerah Hunt, FACSM)
Email: nw06347@georgiasouthern.edu
(No relevant relationships reported)

There is an estimated 2.3 million youth soccer participants in the United States. As concern rises for the safety of youth athletes, organizations are changing the rules to make the game safer, potentially resulting in more penalized behaviors. Differences in competition levels may contribute to varying behavioral outcomes, such as foul and injury rates.

PURPOSE: Examine the relationship between competition level and behavioral outcomes, such as number of fouls and injuries, in youth soccer. **METHODS:** During the competitive season, two soccer organizations were observed to examine behaviors associated with sportsmanship, behavior, fouls, and injuries during a game situation. The organizations consisted of teams from a recreation department and a travel academy soccer club located in South Georgia. Teams consisted of male and female athletes ranging from 6-16 years old, whom were divided by pre-determined age groups within the leagues. Observational data was collected on

game statistics which included spectator, coach and athlete behavior, as well as fouls and injuries, within the soccer organizations. A total of 86 recreational (n=52) and club (n=34) games were observed.

RESULTS: Club soccer teams had a greater number of fouls (F=247; 7.26 + 5.47, ranging from 0-23 per game) compared to recreational teams (F=75, 1.44 + 1.69, ranging from 0-7 per game). The number of injuries (I) were not affected by level of competition, age or number of fouls in club (I = 26; 0.76 + 0.99, ranging from 0-3 per game) and recreation (I=31; 0.60 + 0.96, ranging from 0-4 per game) youth soccer teams.

CONCLUSIONS: This pilot study provides preliminary evidence that competition level and age may be the driving force of behaviors that lead to penalties. Regardless of the number of penalties for both organizations, the number of injuries were minuscule; thus dispelling anecdotal links between aggressive behaviors and injury in youth soccer. Ultimately, greater level of competition in youth soccer, resulted in a higher competitive nature leading to more fouls, but not more injuries. Future research should consider situational factors that may impact these findings such as coaches and parents behaviors during the game, as well as referee standards for calling fouls. Supported by Centers for Disease Control Grant CE17-002

An Exploratory Study of Mood States and Transient Emotions in Amateur Dressage Riders

Collin Pursley, Texas Christian University, Fort Worth, TX.
(No relevant relationships reported)

PURPOSE: The purpose of this study was to explore the horse rider relationship through the effect of a rider's mood on the horse's behavior in practice and competition. **METHODS:** A total of 18 Female amateur dressage riders participated in this study. The participants completed five surveys and two observations. Surveys included a demographic survey, Rotter's I-E Scale, Orientation to Life Questionnaire, and the Profile of Mood States (POMS). Observations took place at a scheduled practice and during one competition per participant. **RESULTS:** The POMS results showed increased mood disturbance from the riders (N=16, M= 9.94), p= 0.03 between practice and competition. Observation data revealed no significance in horse conflict behavior between practice and competition (M= 1.18) p= 0.95. The differences between rider TMD and horse conflict behavior pre and post competition, the results demonstrated a strong, positive, and significant correlation (r=0.868), p=0.000.

CONCLUSIONS: The results of this study can be considered at best preliminary, but highlight a potential moderator of the horse rider relationship.

Differences Between NCAA Division II Coactive And Interactive Ncaa Division Ii Athletes Motivation Types Over Time

Mindy Mayol¹, Urska Dobersek², Matthew D. Beekley, FACSM. ¹University of Indianapolis, Indianapolis, IN. ²University of Southern Indiana, Evansville, IN. ³DePauw University, Greencastle, IN.
Email: mmayol@uindy.edu
(No relevant relationships reported)

Few studies have examined motivation types in collegiate athletes over time using the Self-Determination Theory. **PURPOSE:** To investigate differences in motivation types between coactive (CAs) and interactive (IAs) athletes over three time points. **METHODS:** Overall, 530 participants from 21 teams composed of both IAs (n = 283) and a CAs (n = 247) voluntarily completed the 18-item Sport Motivation Scale II used to measure: intrinsic (IR), integrated (INTR), identified (IDR), introjected (INT), external (EXT), and amotivation (AMR) regulation. A 2x3 Mixed Analysis of Variance with Bonferroni post hoc tests were used to analyze the differences in motivation types over the pre-season (PS), in-season (IS), and off-season (OS). **RESULTS:** Main effects and post hoc results showed that, for IR, significant differences were seen in both the IS, F(1, 352) = 8.96, p = .003, and OS, F(1, 352) = 4.87, p = .028, with CAs scoring higher (M = 16.67, SD = 4.11; M = 16.81, SD = 3.84) versus IAs (M = 15.65, SD = 4.33; M = 16.17, SD = 4.25). For INTR, differences were seen in the OS, F(1, 352) = 7.44, p = .007, where CAs scored higher (M = 17.10, SD = 3.49) than IAs (M = 16.30, SD = 4.25). For IDR, differences were seen in both the IS, F(1, 352) = 7.10, p = .008, and the OS, F(1, 352) = 5.06, p = .025, with CAs scoring higher (M = 17.31, SD = 4.57; M = 16.82, SD = 4.01) versus IAs (M = 16.60, SD = 3.88; M = 16.16, SD = 4.15). For ITR, differences were seen in the PS, F(1, 352) = 12.98, p = .001, the IS, F(1, 352) = 12.98, p = .002, and the OS, F(1, 352) = 12.98, p = .018, where CAs scored higher (M = 14.25, SD = 4.21; M = 13.85, SD = 4.47; M = 13.94, SD = 4.40) than IAs (M = 13.02, SD = 4.81; M = 13.04, SD = 4.65; M = 13.06, SD = 4.91). For AMR, differences were seen in both the IS, F(1, 352) = 7.63, p = .006, and OS, F(1, 352) = 10.97, p = .001, with IAs scoring higher (M = 8.51, SD = 4.47; M = 8.38, SD = 4.93) versus CAs (M = 7.32, SD = 4.14; M = 7.32, SD = 4.14). No significant differences were seen for EXTR (p > .05). **CONCLUSIONS:** Results demonstrated that CAs exhibited higher IR, INTR, IDR and ITR scores than IAs support the hypothesis of Hollembek and

Amorose (2005) suggesting that CAs feel that they receive more autonomy support and individualized feedback from their coaches. Higher AMR scores were seen in IAs versus CAs and may be indicative of low self-determination and have been positively associated with burnout (Cresswell, 2009).

A Comparison of Motivation and Grit in NCAA Collegiate Athletes

Michael Nordvall, Nicole Viscuso, Nathan Fioramonti, Alexei Wong. *Marymount University, Arlington, VA.* (Sponsor: Arturo Figueroa, FACSM)
 Email: mnordval@marymount.edu
 (No relevant relationships reported)

Assessing self-determination to play a sport (motivation) and the strength of character or resolve (grit) in athletes is a useful tool for coaches and sports psychologists; however, gender, individual vs. team sports, and time of season differences in motivation and grit are not well documented. Whether an athlete is motivated intrinsically (more self-determined) or has sufficient grit may be the difference between athletic success or failure. Recognizing variations in motivational and grit characteristics in athletes can provide guidance towards improving individual performance and team dynamics. **PURPOSE:** To compare motivation and grit in NCAA collegiate athletes. **METHODS:** The Sports Motivation Scale II (SMS-II) and 12-Item Grit Scale were administered to 151 (87 females; 64 males; 19.2 ± 2.1 yrs) athletes spread among seven NCAA division III individual and team sports. Surveys also determined each participant's gender, class matriculation status (freshman through senior), and time of sport season (pre-, during-, off-season). Between group differences for SMS-II relative autonomy index (RAI; degree of self-determination score) and grit were made using independent T-Test and one-way ANOVA with post hoc analyses. **RESULTS:** SMS-II RAI scores (mean \pm SD) in both males and females were significantly higher/more self-determined ($p < 0.05$) in athletes on team (65.8 ± 20.0) vs. individual (53.3 ± 26.9) sports yet were significantly lower/less self-determined ($p < 0.05$) when in-season (58.5 ± 25.9) vs. pre- (65.1 ± 15.0) and post- (68.5 ± 19.8) seasons. Freshmen athletes had significantly lower/less self-determined ($p < 0.05$) RAI scores (56.3 ± 22.4) vs. sophomores (66.6 ± 18.9) and juniors (66.4 ± 23.8). 12-Item Grit Scale in both males and females revealed significantly lower/less gritty ($p < 0.05$) scores (mean \pm SD) for freshmen (3.56 ± 0.47) vs. sophomore (3.73 ± 0.41) and senior (3.76 ± 0.41) athletes. No between group gender differences were observed for RAI or grit. **CONCLUSION:** Our results are the first to compare indices of motivation and grit in a diversity of NCAA athletes and indicate several between group differences in self-determination and grit that may guide athletes towards improved individual and team performance.

2625 Board #289 May 31 9:30 AM - 11:00 AM
Relationships Among Coping Strategies And Training Intensity, Duration, And Frequency In Triathletes

Michelle B. Stockton¹, Barbara McClanahan¹, Christopher Vukadinovich². ¹*University of Memphis, Memphis, TN.* ²*St. Jude Children's Research Hospital, Memphis, TN.* (Sponsor: Lawrence W. Weiss, FACSM)
 Email: mstocktn@memphis.edu
 (No relevant relationships reported)

PURPOSE: The purpose of this study was to evaluate how coping strategies influence training volume and self-reported exercise intensity, duration, and frequency in triathletes. **METHODS:** Participants were 27 adult triathletes who established their own training regimen. Overall training volume was determined by exercise duration and intensity over 24 weeks. Exercise frequency, intensity, and duration were assessed through a physical activity recall questionnaire. Participants also completed a 41-item coping skills assessment. Total scores were calculated for positive coping strategies (range = 23-69) and negative coping strategies (range = 18-54). **RESULTS:** Overall training volume (intensity*minutes) over the 24 weeks for all participants was 38,803 ($\pm 15,704$) over 6-months. Over half of the participants (57.6%) reported exercise intensity to be vigorous with 36% reporting moderate-to-vigorous. More than 69% of the participants worked out longer than 45 minutes per session (duration) and for at least 1-2 times per week (27.3%) or more (36%) (frequency). The results of the bivariate correlations indicated that positive coping strategies was significantly associated with intensity ($r = 0.42$, $p = 0.011$), duration ($r = 0.41$, $p = 0.013$) and frequency ($r = 0.34$, $p = 0.035$). There was no significant relationship between training volume and positive coping strategies ($p = 0.300$). Interestingly, there were no significant relationships found among negative coping strategies and the other variables. Preliminary analyses using 3 separate simple linear regression were conducted to see the amount of influence positive coping strategies has on exercise intensity, duration, and frequency. Although positive coping strategies did not significantly explain the variance in exercise intensity, it approached significance ($p = 0.051$). Non-significant findings were found for duration ($p = 0.071$) and frequency (0.102). **CONCLUSIONS:** Study results illustrate the importance of understanding the

relationship between coping strategies and training for triathletes. Further research is needed to determine the use of coping strategies on all aspects of training in order to develop ideal preparation tactics for optimal performance.

2626 Board #290 May 31 9:30 AM - 11:00 AM
Personality and Trait Self-Handicapping in Baseball and Softball College Athletes

David A. Tobar, Joshua A. Cermak, Bonnie G. Berger. *Bowling Green State University, Bowling Green, OH.*
 Email: dtobar@bgsu.edu
 (No relevant relationships reported)

Self-handicapping is a learned coping strategy to minimize threats to self-esteem when a person fears potential failure for an upcoming, evaluative event, but there is a paucity of research on self-handicapping and personality in athletes. **PURPOSE:** To examine the relationship between Big Five personality traits and trait self-handicapping in male and female college athletes. **METHODS:** Data were collected from softball ($n = 15$ females; age: 19.9 yrs) and baseball ($n = 28$ males; age: 20.6 yrs) athletes at a D-I university in the Midwest. Participants completed the Self-Handicapping Scale and Big Five Inventory - 2S. Independent *t*-tests examined gender differences for trait self-handicapping (SH) and personality [extraversion (E), negative emotionality (NE), conscientiousness (C), agreeableness (A), open-mindedness (OM)]. Pearson correlations identified personality traits related ($p < .10$) to SH, and these traits were included in a stepwise multiple regression to predict SH. **RESULTS:** Female athletes scored higher than male athletes on SH ($M_s = 32.0$ vs. 23.3 , $p < .01$) and NE ($M_s = 16.7$ vs. 12.9 , $p < .05$). Due to the gender difference for SH, correlations and regression analyses were done separately for each gender. For females, SH was correlated with NE ($r = .79$, $p < .001$), C ($r = -.46$, $p = .08$), and OM ($r = .51$, $p = .05$). The regression analysis revealed that NE was the only significant predictor of SH ($R^2 = .63$, $p < .001$). For males, SH was correlated with NE ($r = .53$, $p < .005$), C ($r = -.62$, $p < .001$), and A ($r = -.51$, $p = .005$). The regression analysis revealed that C was the only significant predictor of SH ($R^2 = .38$, $p < .001$). **CONCLUSION:** Higher self-handicapping in female athletes was an unexpected finding. Since negative emotionality was strongly related to SH in all athletes, but more for females, higher NE scores for females may partially explain their higher SH scores. Conscientiousness also was related to SH in all athletes, but more for males. Thus, athletes prone to experiencing distress and being less vigilant may self-handicap if they fear failure in an upcoming event. Sport psychologists should consider assessing personality, especially negative emotionality and conscientiousness, and monitoring emotions to minimize SH behaviors and potentially improve performance and well-being in athletes.

2627 Board #291 May 31 9:30 AM - 11:00 AM
Exercise Addicted Subject Show Positive Affective Responses Both Moderate And Intense Exercise

Mario Augusto Medeiros Lucas, Marcos Monico Neto, Sergio Tufik, Hanna Karen Moreira Antunes. *Universidade Federal de São Paulo, Santos, Brazil.*
 Email: mario.medeiros@unifesp.br
 (No relevant relationships reported)

The possible differences in affective responses to moderate and intense exercise in exerciser's addiction subjects are not reported in the literature and this result can help elucidate the reasons for the deployment exercise dependence. **Purpose:** Investigate the affective responses of exercise addiction subjects and controls in moderate and intense exercise. **Methods:** 17 male subjects (34.35 \pm 5.70yrs; 73.15 \pm 9.36kg; 1.75 \pm 0.07m; 24.78 \pm 2.51kg/m²; 13.17 \pm 4.73%FatMass), were distributed into a control group ($n = 10$) composed of runners without exercise addiction symptoms and an exercise addiction group ($n=7$) composed of runners with exercise addiction symptoms. The subjects were submitted to two treadmill tests separated by 7 days: 1) 60%Vpeak; 2) 85%Vpeak. For these conditions, the subjects answered a Subjective Exercise Experiences Scale (SEES) in the following time-courses: baseline (B), immediately after (IA) and 30 minutes after finishing of the exercise (R). To evaluate the affect during effort, a Feeling Scale was recorded at last minutes of exercise to both intensities. The data were compared by two-way ANOVA with post-hoc Duncan test, with significance $p \leq 0.05$. The protocol was approved by Unifesp Ethics Committed (#2.096.523). **Results:** At 60%Vpeak, we not observed differences in SEES scale. At 85%Vpeak, the Fatigue subscale show similar responses between the groups, were an increased in IA when compared to B ($p < 0.001$ to both). The feeling Scale results show that to control group, when 60%Vpeak was compared with 85%Vpeak intensity, the first one intensity was pleasurable, while the second one was unpleasurable (3.10 \pm 2.33 vs -1.90 \pm 3.51; $p = 0.002$ respectively). To the exercise addiction group, both intensities was classified as pleasurable (3.00 \pm 1.82 vs 1.00 \pm 4.43; $p = 0.13$). **Conclusion:** The data suggest that both exercise intensities moderate and intense (independent of fatigue state) are capable to promote well-being and pleasure in exercise addiction subjects, while to the controls group, feeling pleasure was observed only in moderate intensity. **Financial Support:** AFIP, CAPES (001 financial code), CNPq (400129/2016-7).

Student-athletes' Experience And Perception On Migration In Dual Career: The Amid Project

Andrea Fusco¹, Cristina Cortis¹, Lorian Castellani¹, Patrice Giron², Jörg Förster², Niko Niemisalo³, Heikki Hannola³, Mojca Doupona Topič⁴, Marta Bon⁴, Laura Capranica⁵, Herbert Wagner⁶, Philip X. Fuchs⁶. ¹University of Cassino e Lazio Meridionale, Cassino, Italy. ²Hochschulsport Hamburg, Hamburg, Germany. ³Lapland University of Applied Sciences, Rovaniemi, Finland. ⁴University of Ljubljana, Ljubljana, Slovenia. ⁵European Athlete Student network, Ghaxaq, Malta. ⁶University of Salzburg, Salzburg, Austria. (Sponsor: Carl Foster, FACSM)
Email: andrea.fusco@unicas.it
(No relevant relationships reported)

Migration across borders in the European Union (EU) can promote beneficial career development in many elite sports. For student-athletes pursuing tertiary education the relocation of residence could involve challenges due to the variety of national policies. To overcome drop outs and decremental performances in Dual Career (DC) migration, the identification of the challenges faced by migrating student-athletes is a crucial aspect. **PURPOSE:** To investigate student-athletes' perception on current conditions, challenges, and recommendations on migration. **METHODS:** A 50-item questionnaire, assessing demographic data, history and progress in DC, experiences in migration, support measures and their perceived effect, needs and recommendations, was developed, validated, and filled in by 223 student-athletes. Differences in quantitative data from 5-point-Likert scales were tested by means of Kruskal-Wallis ($p < .05$). **RESULTS:** 52% of the sample (age=23.5±4.1yrs, sports practice=16.8±8.2hrs/week) already relocated for the academics (26%), sports (33%), or both (41%) paths of their DC and could report their specific experiences in support measures and challenges ($\chi^2(4)=2.11, p=.72$). Among these, 49% received financial support ($\chi^2(4)=19.57, p < .001$), 38% of it from the family. Decreases in performance were found in sports when relocating for academic reasons (2.2±1.1points; $\chi^2(4)=6.65, p=.08$) and in academics when relocating for sports (3.3±1.3points; $\chi^2(4)=2.25, p=.69$). Difficulties emerged in attendance at university (69%; $\chi^2(4)=15.55, p < .01$), exam (44%; $\chi^2(4)=2.19, p=.70$) and training (37%; $\chi^2(4)=3.36, p=.50$) schedule. **CONCLUSIONS:** The high percentage of relocating student-athletes confirms the relevance of mobility in DC. Academics and sports can equally be the reason for relocation. Institutions in both fields should be aware and supportive in DC migration, especially due to a possible decrease in performance. In contrast with the targeted ideals of EU, the financial contribution from parents indicates that DC migration could be feasible mainly for wealthy parts of the society. However, major difficulties appeared also in non-financial issues that can be tackled by enhanced organization, tutoring, and cooperation between institutions. The study was co-funded by the Erasmus+ Programme

Cortisol and Testosterone Responses in Chess Players during an International Chess Tournament

Anastassios Philippou¹, Katina-Evangelia Kyriakou², Argyro Papadopetraki¹, Efstathios Efstathopoulos¹, Maria Maridaki². ¹National and Kapodistrian University of Athens, Goudi-Athens, Greece. ²National and Kapodistrian University of Athens, Dafni-Athens, Greece.
Email: tphilipou@med.uoa.gr
(No relevant relationships reported)

Chess is a strategic atypical sport and a highly cognitive task demanding mental and physical alertness, in which players are deeply committed and experience intense emotions. Evidence supports that chess elicits physiological responses and induces stress-associated hormonal changes.

PURPOSE: This study investigated potential changes in free salivary cortisol and testosterone in chess players during a tournament. **METHODS:** Thirty male active chess players participated in the study (age: 43.2±12.4 yrs, Elo score: 1903.2±341.5), competing in a 9-round chess tournament (Swiss pairing system). Unstimulated mixed saliva samples were collected in salivate swabs at 3 time points: baseline, after the 2nd and 3rd round and, for the 10 finalists also after the 6th and 7th round (19:00-23:25 pm.). The saliva samples were analyzed for cortisol and testosterone by ELISA and student T-test was used for statistics. **RESULTS:** Testosterone levels exhibited a trend of decrease, from 77.7±105.1 ng/ml at baseline to 38.7±46.6 ng/ml after the 2nd and 3rd round, to 25.3±20.7 ng/ml after the 6th and 7th round, however without reaching statistical significance ($p > 0.05$). Cortisol levels increased from 4.4±3.3 ng/ml at baseline to 7.6±6.8 ng/ml after the 2nd and 3rd round in all participants ($p < 0.05$). In the 10 finalists, however, cortisol showed no significant changes through the 3 time points (from 3.5±2.8 ng/ml to 6.0±4.8 ng/ml to 5.3±2.9 ng/ml; $p > 0.05$). Significant percentage changes of cortisol were found compared to baseline (277±384.5% ng/ml and 207.6±113.7% ng/ml; $p < 0.01$). Interestingly, in the finalists, cortisol to testosterone

ratio exhibited a significant increase only after the 2nd and 3rd round, from 1.0±0.1 to 0.4±0.3 ($p < 0.01$), contrary to the all participants' ratio, which declined from 1.4±6.8 to 0.4±0.3 ($p > 0.05$).

CONCLUSIONS: Our findings indicate that testosterone levels are not significantly affected by the stress of the game in contrast to cortisol levels, which are significantly increased. Interestingly, although cortisol levels of top chess players (finalists) did not show significant changes during the tournament, however their cortisol to testosterone ratio was elevated after the first rounds, implying an increased physiological stress of these players at the beginning of the tournament.

Association Between Menstrual Dysfunction, Bone Stress Injuries and Risk for Disordered Eating in Female Collegiate Athletes

Michelle Bugbee, MS, Stephanie Wilson, MS, Rachele Pojednic, PhD, EdM. Simmons College, Boston, MA.
(No relevant relationships reported)

Normal 0 false false EN-US X-NONE X-NONE /* Style Definitions */ table.MsoNormalTable {mso-style-name:"Table Normal"; mso-tstyle-rowband-size:0; mso-tstyle-colband-size:0; mso-style-noshadow:yes; mso-style-priority:99; mso-style-parent:""; mso-padding-alt:0in 5.4pt 0in 5.4pt; mso-para-margin-top:0in; mso-para-margin-right:0in; mso-para-margin-bottom:8.0pt; mso-para-margin-left:0in; line-height:107%; mso-pagination:widow-orphan; font-size:11.0pt; font-family:"Calibri",sans-serif;} **Purpose:** The purpose of this study is to evaluate the association between menstrual dysfunction (MD), bone stress injuries (BSI) and risk for disordered eating (DE) in female collegiate athletes. **Methods:** 79 division III collegiate female athletes, of all fields of sport, participated in a retrospective cross-sectional questionnaire where self-reported menstrual history, eating behaviors, and history of musculoskeletal injury data were collected. **Results:** 12.6% of athletes reported MD, 16.5% of athletes were found to be at risk for DE, and 17.9% reported a history of BSI. Of the 14 athletes that had a BSI, 20% (n=2) also had the presence of oligo/amenorrhea, although results were not significant. Of athletes who had DE, 30.8% (n=4) of athletes also reported having oligo/amenorrhea ($p=0.05$). 19.1% (n=9) of athletes who reported ever having used oral contraceptive pill (OCP) also reported having a BSI. 21.2% (n=11) of athletes that have ever used any hormonal contraceptive method (n=52) also reported having a BSI, however no significant difference existed between the two groups ($p=0.297$). **Conclusion:** Our data indicates one-fifth of division III female athletes with a history of MD also report a history of BSI. The statistically significant elevated risk for MD with DE observed adds to the literature demonstrating a direct correlation between triad risk factors in division III athletes. Comprehensive and structured screening methods for triad-related symptoms across all division athletics will help to prevent long-term health consequences. **Key Words:** Menstrual dysfunction, bone stress injuries, disordered eating, female athlete triad, collegiate, female athletes. <!--EndFragment-->

Risk Of Burnout Syndrome In College Athletes As A Predictor Of Anxiety And Depression

Victor Hugo Montejo-Lambaren, Sara Ramirez-Hernandez, Alejandro Gaytan-Gonzalez, Juan R. Lopez-Taylor. Universidad de Guadalajara, Guadalajara, Mexico.
(No relevant relationships reported)

PURPOSE: To identify the association between the risk of suffering Burnout syndrome with the presence of anxiety and depression.

METHODS: 403 college athletes from a high-performance program were evaluated. Trained psychologists applied a psychometrical battery conformed by two scales: Goldberg's Anxiety and Depression scale (two subscales with 9 questions each, that results in "With/Without anxiety" and "With/Without depression") and Sport Burnout Inventory - Reviewed (19 questions and 3 sub-scales: Emotional Exhaustion, Depersonalization and Reduced Personal Realization; it brings four possible conclusions: "Low Risk", "Moderated Risk", "High Risk" and "With Burnout"). A logistic regression analysis was performed to predict the presence of anxiety or depression depending on the risk of Burnout syndrome existence.

RESULTS: The logistic regression model was statistically significant for some of the classifications in the Burnout inventory. For anxiety, Depersonalization was the only dimension with a significant association. Subjects with "Moderated risk" showed a higher probability of suffering anxiety ($p=0.013$). On the other hand, all three dimensions were significantly associated with a higher risk of presenting depression problems. Emotional Exhaustion ($p=0.009$) and Depersonalization ($p=0.007$) qualified as "Moderated risk" showed high probabilities of depression. Furthermore, Emotional Exhaustion "High risk" rates were also associated with depression scores ($p=0.045$). Finally, Reduced Personal Realization was associated with presenting this problem when "High risk" was classified ($p=0.005$).

CONCLUSIONS: Subjects who reported any risk of suffering Burnout syndrome were more prone to presenting depression but no anxiety. Evaluating the risk of

suffering Burnout Syndrome in college athletes could be a good way to predict the possibility of having depression problems. Similar studies are suggested to corroborate these results.

Table. Association between Burnout Syndrome ranges and anxiety and depression presence.

| | Anxiety | | | | Depression | | | |

Relationships between Perceived Coaching Behaviors, Competitive Anxiety, and Athlete Burnout
 Seongkwan Cho¹, Kyung-Shin Park¹, Brett Nickerson¹, Youngsook Kim², Hun-Hyuk Choi³. ¹Texas A&M International University, Laredo, TX. ²Korea Institute of Sport science, Seoul, Korea, Republic of. ³Korea National University of Education, Cheongju, Korea, Republic of.
 Email: scho@tamui.edu
 (No relevant relationships reported)

Previous studies found psychological and situational factors were related to athlete burnout, and competitive anxiety in sports could have detrimental effects on performance and significant relationship with burnout in athletes. Athletes' perceptions of coaching styles were associated with competitive anxiety and athlete burnout; however, limited research has investigated the overall relationship.

PURPOSE: to investigate the relationship between perceived coaching behaviors, competitive anxiety, and athlete burnout
METHODS: A total of 376 collegiate athletes from 11 different sports, whose ages ranged from 20 to 25 years old (296 males and 80 females; Mage = 21.23yrs, SD = 1.09), completed a battery of questionnaires: a demographic questionnaire Sport Climate Questionnaire, Controlling Coach Behaviors Scale, Sport Anxiety Scale-2, and Athlete Burnout Questionnaire. Descriptive statistics were calculated, and structural equation modeling was conducted to test the hypothesized model. The bootstrap technique was used to test the mediation effect, and item and construct parceling techniques were utilized to increase the stability of the parameter estimates.

RESULTS: The hypothesized model presented an acceptable fit to the data. Specifically, $\chi^2(48) = 137.15 (p<.001)$, CFI = .97, TLI = .96, SRMR = .04, and RMSEA = .06 with 90% CI [.05, .08]. Autonomy-supportive coaching was negatively related to athlete burnout ($\beta = -.18$), whereas controlling coaching and competitive anxiety were positively related to athlete burnout ($\beta = .33$ and $.35$, respectively). Intriguingly, only controlling coaching were significantly related to competitive anxiety ($\beta = .35$). The indirect path from controlling coaching to athlete burnout via competitive anxiety was significant ($\beta = .12$).

CONCLUSION: The magnitude of the direct effects indicated controlling coaching behaviors more influenced athlete burnout than autonomy-supportive coaching behaviors. The findings suggest that coaches should understand the importance of the athletes' perception of their coaching behaviors and the effect of coaching behaviors on competitive anxiety and burnout.

2633 Board #297 May 31 9:30 AM - 11:00 AM
Psychophysiological Stress Indicators In College Athletes: Comparison Of Physiological Responses With Different Types Of Stressors
 Sara Ramirez-Hernandez, Victor Hugo Montejó-Lambaren, Alejandro Gaytan-Gonzalez, Juan R. Lopez-Taylor. *Universidad de Guadalajara, Guadalajara, Mexico.*
 (No relevant relationships reported)

PURPOSE: To compare the physiological responses to different types of stressors in college athletes.
METHODS: 20 male college athletes (17 to 23 y) were evaluated. Psychophysiological assessment of stress was done by a ProComp™ Infniti Biofeedback System. Physiological responses were recorded and categorized as "stressed" (Heart Rate [HR] >90 b/min, Electromyography [EMG] >5 μ V, Skin Conductance [SC] >5 uS and Respiration [Resp] >16 br/min) and (not stressed);

The evaluation consisted of 7 stages lasting 2 min each (BASELINE, exposed to a PHYSIOLOGICAL stressor [unpleasant sounds], 1st REST, exposed to a COGNITIVE stressor [mathematical task], 2nd REST, exposed to an EMOTIONAL stressor [talk about a stressful memory] and 3rd REST). A statistical analysis was carried out with X², Phi coefficient, and Cochran's Q test.

RESULTS: Significant changes were found in the proportion of "stressed" subjects in the physiological responses of HR and SC, and a trend towards significance in EMG throughout the evaluation. The indicators that most approached the expected response (increase with stressor and decrease at rest) during the evaluation were HR and SC; EMG tended to approach. The significant differences observed in the proportion of subjects "stressed" by stages and by indicators were in BASELINE, 1st REST and 2nd REST, and with a trend towards significance in COGNITIVE, being Resp the indicator that showed the highest proportion. The effect size for significant differences was moderate to high (Table)

CONCLUSIONS: The subjects obtained expected responses (increase/decrease) over time in most of the indicators, except in Resp, so in our sample, it was not an indicator related to stress. The proportion of subjects "stressed" during stressing stages were not significant but were different during rests, which may mean that the greater proportion of subjects increased their physiological responses in a similar way to stressors but could recover differently during rests.

Table. Proportion of "Stressed" subjects by physiological response and stage.

| | Baseline | Physio-logical | 1st rest | Cog-nitive | 2nd rest | Emo-tional | 3rd rest | p-value (Cochran's Q) |
|---------------------------|----------------|----------------|----------------|------------|----------------|------------|----------|-----------------------|
| HR | 2 (10%) a | 7 (35%) | 5 (25%) ab | 18 (90%) | 3 (15%) a | 9 (45%) | 6 (30%) | <0.001 |
| EMG | 10 (50%) bc | 7 (35%) | 13 (65%) b | 14 (70%) | 8 (40%) ab | 12 (60%) | 10 (50%) | 0.053 |
| SC | 3 (15%) ac | 5 (25%) | 3 (15%) a | 12 (60%) | 11 (55%) b | 13 (65%) | 12 (60%) | <0.001 |
| RESP | 11 (55%) b | 10 (50%) | 10 (50%) ab | 11 (55%) | 10 (50%) ab | 15 (75%) | 10 (50%) | 0.632 |
| p-value (X ²) | 0.002 | 0.430 | 0.004 | 0.082 | 0.048 | 0.267 | 0.283 | |
| Phi | 0.430 | 0.186 | 0.406 | 0.289 | 0.315 | 0.222 | 0.218 | |

Data expressed as frequencies (%), unless otherwise stated. Different letters denote significant differences between physiological responses within each stage (p<0.05). HR: Heart rate; SC: Skin conductance; RESP: Respiration; EMG: Electromyography.

The Effect Of Crossfit On Self-talk And Goal Setting In At-risk Youth: A Pilot Study.
 Mia D. Hannah, Christina Gipson, Nicole Walden, Stephanie Walsh, Tamerah Hunt, FACSM. *Georgia Southern University, Statesboro, GA.* (Sponsor: Tamerah N. Hunt, FACSM)
 Email: mh12150@georgiasouthern.edu
 (No relevant relationships reported)

At-risk youth experience limited support, lack consistency, and depend on governmental programs and could benefit from structured programs. CrossFit participants are encouraged to discuss workout goals and strategies and are reminded about workout efficiency. **PURPOSE:** Examine the effects that CrossFit has on the use of self-talk and goal setting techniques. **METHODS:** Sixteen participants identified as at-risk (e.g. living in single-parent homes or in low-income environments) participated in a CrossFit program. Participants ranging from 11 to 14 years old completed 12 weeks of CrossFit for one hour, three days per week. Participants completed two Likert-type questionnaires (Goal Setting questionnaire and Self-talk questionnaire). Survey scores served as dependent variables. Paired samples t-tests were calculated to examine changes over time on both surveys. All statistical analyses were conducted using SPSS 25.0 (IBM, Armonk, NY). Significance level was set *a priori* at 0.05. **RESULTS:** 16 participants (84%) completed both pre and post Goal Setting surveys, while 10 (52%) completed both pre and post Self-Talk questionnaire surveys. Significant differences were found between scores for total score (Mean Pre: 14.4 \pm 2.9, Mean Post: 17.9 \pm 2.5; $t_{(1,15)} = 3.13, p = 0.007$); question 2, "Once I set a goal, I don't give up until I achieve it" (Mean Pre: 1.4 \pm .13, Mean Post: 2.2 \pm .24; $t_{(1,15)} = 2.42, p = 0.029$) and question 6 "When I set a goal, I think about what I need to do to achieve that goal" (Mean Pre: 2.9 \pm .23; Mean Post: 3.7 \pm .70; $t_{(1,15)} = 2.82, p = 0.013$) with scores improving after the intervention. No significant differences were found for the Self-Talk questionnaire (n=10), total score (p>0.05). **CONCLUSION:** This pilot study provides preliminary evidence that CrossFit for at-risk youth enhances goal setting skills. The introduction of CrossFit classes appears to create structure for goal setting as strategies/goals are discussed before workouts and accomplishments/results are recorded and reviewed. However, it does not appear that CrossFit increases

self-talk which could be due to no formal instruction in the current format of CrossFit classes. Future investigations should include impacts of self-talk and goal setting with intentional training, a larger participant pool, and qualitative methods.

Preliminary Evidence Of A Relationship Between Injury And Sport Camera Use In Winter Sliding Sports

Linda Paquette, Elie Truchon, Martin Lavallière, Daniel Lalonde.
Université du Québec à Chicoutimi, Saguenay, QC, Canada.
 Email: linda_paquette@uqac.ca
 (No relevant relationships reported)

PURPOSE: The accessibility of digital technologies has led to an increased use of video cameras in sliding winter sports. However, very little is known on the risks associated with the use of such equipment. In other contexts, camera use was associated with a social facilitation effect involving an increase in performance (Yu et al., 2015). In winter sliding sports like snowboard and alpine skiing, the culture is characterized by a valorization of risk taking (Anderson, 1999). This effect could translate in greater risk taking when a camera is around (Rodrigue et al, 2012). The aim of this study was to explore the relationship between camera use and injury risk in winter sliding sports, while considering psychosocial factors associated with injuries including age, sex, perceived skill level, intentional risk taking and personality traits (impulsivity and sensation seeking). **METHODS:** The study was a self-reported follow-up survey conducted online among canadian winter sliding sports athletes before and after a winter ski season within an interval of 4 months. **RESULTS:** Among the 224 adolescents and adults (121 men and 103 women) who completed the surveys, 32,6% were aged 14-25 years, 32,3% aged 26-25 years and 36,2% aged 36 years +. Descriptive statistics indicates that 37,1% were filmed during sports practice at least once during past 12 months prior to the study an 42,0% were filmed at least once during the follow-up ski season. Among them, 25,7% reported that they take more risks when they are filmed “sometimes”, “often” or “always”. A logistic regression analysis predicting the occurrence of an injury by the end of the ski season indicates that camera use during the ski season is significantly associated with injury risk (OR = 0,25 $p < 0,001$) even after including psychosocial factors usually associated with injury risk in the model, including intentional risk taking, perceived skill level and sensation seeking also being significant predictors of injury. **CONCLUSIONS:** These results suggest a possible injury risk associated with the use of a camera on the slopes, partially explained by a social facilitation effect, but it is unclear at this moment if this risk could also involve the camera itself depending on the type of use (i.e. on a selfie stick). These results should be supported by objective data from an experimental design.

Cross-cultural Invariance Of The Mental Toughness Index Among American And Mexican Athletes

Grant B. Morgan¹, Andreas Stamatis², Pedro Julian Flores Moreno³, Lenin Tlamatini Barajas Pineda³, Adriana Isabel Andrade Sánchez³. ¹Baylor University, Waco, TX. ²State University of New York at Plattsburgh, Plattsburgh, NY. ³Universidad de Colima, Colima, Mexico. (Sponsor: Peter Walter Grandjean, FACSM)
 Email: grant_morgan@baylor.edu
 (No relevant relationships reported)

The popularity of *mental toughness* (MT) in English-speaking countries is well recognized. However, its worldwide cultural relevance remains to be fully disclosed. Gucciardi et al. (2016) and Morgan et al. (2018), using the Mental Toughness Index (MTI), reported intra-cultural invariance of MT in Australasia and in the U.S. and Greece, respectively. To date, there has been no effort to unearth the degree of the universality of the term between Mexico and USA via MTI. **PURPOSE:** To examine the invariance of MT across two different cultural groups of athletes and to further validate MTI. **METHODS:** The MTI was completed by 97 Mexican and 173 US athletes. The MTI consisted of eight items with a seven-point response scale. The U.S. samples consisted of roughly half male and half female athletes, whereas the Mexican was predominantly male (64%). The U.S. sample consisted of athletes from a number of sports, such as American football, basketball, baseball, and softball. Half of the Mexican sample reported playing soccer and almost all other sports had fewer than five athletes. Invariance testing was conducted using multiple group confirmatory factor analysis with increasingly restrictive models. We first fitted a unidimensional model within each sample to ensure good model-data fit. Then we estimated configural (equal number of dimensions), metric (configural + equal loadings), and scalar invariance models (metric + equal intercepts). Scalar invariance is the minimum type of invariance to infer cross cultural equality. To evaluate the model-data fit, we used the comparative fit index (CFI), root mean square error of approximation (RMSEA), and the differences between these indices for increasingly restrictive models.

RESULTS: The model-data fit in both samples was very good (CFI_{Greek} = .984, RMSEA_{Greek} = .08; CFI_{Mex} = .998, RMSEA_{Mex} = .03). The scalar invariance model was selected as the best fitting (CFA_{scalar} = .908, RMSEA_{scalar} = .08) but with a slightly different item intercept for two items (Item 4, < .5; Item 7, < .3). **CONCLUSION:** These analyses support partial scalar invariance of MT. As such, the analysis establishes a common metric of MT across samples, which allows comparisons to be made on their MT scores.

Relationships between Aggression and Head Impact Kinematics in Ice Hockey

Melissa S. DiFabio¹, Katherine M. Breedlove², Thomas A. Buckley¹. ¹University of Delaware, Newark, DE. ²University of Michigan, Ann Arbor, MI.
 Email: m.s.difabio@gmail.com
 (No relevant relationships reported)

Sustaining head impacts in sport regularly may be damaging to long-term neurological health. Further, some research has suggested a relationship between sports aggression and concussion, therefore, being able to identify players at-risk of sustaining these head impacts may be beneficial in monitoring their safety on ice. **PURPOSE:** To examine relationships between player self-reported aggression in ice hockey and head impacts sustained in a collegiate club season. **METHODS:** Nineteen collegiate male ice hockey (19.9±1.2 years old, 1.8±0.06 m, 78.5±5.7 kg) players completed the Competitive Anger and Aggression Scale (CAAS), a valid 12-item survey used to evaluate anger and aggression during sport competition. Penalty minutes (PM) and games played (GP) statistics were taken from the official game records. Head impact kinematics were recorded via tri-axial accelerometers (Triax, Nowalk, CT) that each player wore for games/practices. Spearman correlation was performed to examine relationships between CAAS scores, PM, GP, and head impact kinematic variables (number of impacts, mean linear and rotational acceleration, and cumulative linear acceleration). **RESULTS:** Neither CAAS scores (mean anger: 26.8±4.9, aggression: 22.2±7.3) nor PM (mean 20.9±22.7, range: 0-95) were significantly related to any other variables. GP was significantly correlated with number of impacts (r=0.606, p=0.006), mean rotational acceleration (r=0.583, p=0.009), and cumulative (r=0.542, p=0.02). Mean number of impacts was 71.5±51.6 (range: 6-168); mean linear and rotational acceleration were 36.8±3.8g and 3.5±0.7 krad/sec². **CONCLUSIONS:** The main finding is no relationship between self-reported anger and aggression during sport and/or sustaining penalty minutes and head impact kinematics, which suggests that hockey athletes who play with more intensity do not necessarily sustain more head impacts while playing. Unsurprisingly, GP was related to impacts, suggesting that more playing time is related to sustaining more and/or greater head impacts. CAAS and PM as markers of playing aggression may not be helpful in determining athletes who sustain more head impacts.

2638 Board #302 May 31 9:30 AM - 11:00 AM
Iron Supplementation and the Female Athlete Triad in High School Distance Runners

Paige Skorseth¹, Aleksei Dingel², Katie Hastings², Nicole Segovia², Emily Kraus². ¹University of Wisconsin, Madison, WI. ²Stanford University, Stanford, CA.
 Email: skorseth@stanford.edu
 (No relevant relationships reported)

PURPOSE: The female athlete triad, defined as decreased energy availability, menstrual changes, and low bone mineral density (BMD), is common in female high school distance runners. Previous research has shown that the Triad and iron deficiency are interrelated. However, there has been no data indicating how the relationship between female athlete triad, iron deficiency, and iron supplementation presents clinically in this population. **METHODS:** 38 female, high-school aged middle and long-distance runners were recruited through social media, coach contact, or direct study outreach. Evaluation included: a validated survey examining components of disordered eating (DE) and menstrual irregularities, height and weight measurements, serum lab draws (ferritin, 25-hydroxy vitamin D, estradiol, IGF-1, free T3), and dual-energy x-ray absoptometry (DXA) scan to evaluation BMD. The Female Athlete Triad Cumulative Risk Assessment Score was used to calculate a risk score on each athlete measured by DE, age of menarche, menstrual irregularities (amenorrhea or oligomenorrhea), DXA BMD, and number of bone stress injuries. Statistical method used was Mann-Whitney U tests. P-values less than 0.05 were considered statistically significant. **RESULTS:** Participants had an average ferritin of 31.0 (SD=17.6). The average cumulative risk score was 2.76 (SD=1.79), i.e. moderate risk. Of the individual components of the triad, 76% of runners displayed disordered eating/eating disorder, 22% had delayed menarche, 19.4% oligomenorrhea, 25% amenorrhea, and 37% had lumbar spine z-scores of <-1. Forty three percent of runners used iron supplementation, and serum ferritin was increased in the group when compared to

the non-supplementing athletes ($p=0.067$). The cumulative risk score in runners supplementing with iron was 3.5, while the non-supplementing group had a risk score of 2.5 ($p=0.093$).

CONCLUSIONS: Findings show that high school-aged female distance runners possess multiple components of the female athlete triad, putting them at greater risk for sustaining a bone stress injury. Runners supplementing with iron have an expected increase in ferritin iron levels compared to the non-supplementing group, however they also have increased female athlete triad risk scores compared to non-supplementing counterparts.

Effect of Competitive Training on Antiviral Immune Activity in Collegiate Gymnasts

Jessica Alley, Hilary Green, Laurel Smeins, Matt Jefferson, Ruth Litchfield, Marian Kohut. *Iowa State University, Ames, IA.* (Sponsor: Warren Franke, FACSM)
(No relevant relationships reported)

Regular moderate exercise has numerous health benefits, including positive effects on immune function, although periods of intense training may increase susceptibility to respiratory tract pathogens such as influenza virus. **PURPOSE:** To determine the effect of intense athletic training on the antiviral immune response profile and to examine the effect of ingestion of eggs on this response. **METHODS:** Female participants from a Division I varsity gymnastics team were recruited and either consumed whole eggs daily ($E; n = 7$) or maintained their normal diets ($NE; n = 6$) for the duration of the study. Blood was collected at three time points: before the high intensity pre-season training began (T1), one month into pre-season (T2), and two months after T2 at the end of pre-season (T3). Peripheral blood mononuclear cells (PBMCs) were isolated from whole blood, cultured ex vivo, and challenged with influenza A/PR/8/34 for 24 hours. Cell supernatants were analyzed using a multiplex cytokine array assay. **RESULTS:** Statistical analyses revealed lower levels of cytokines involved in both innate (IL-1 β , IL-6, TNF α) and T cell-mediated immunity (IFN γ , IL-2, IL-7) produced in response to virus stimulation at T2 (6.8, 87.3, 351, 731, 82.0, and 3.2 pg/mL, respectively) compared to T1 (12.1, 317, 534, 2469, 311, and 5.5 pg/mL, respectively) and T3 (17.4, 268, 712, 3018, 212, and 5.1 pg/mL, respectively; $p \leq 0.05$, paired t-tests). PBMCs from gymnasts who became ill during the study period ($n = 3$) produced less IFN α (427 vs. 1442 pg/mL) at T2 and more sCD40L (11.6 vs. 5.8 pg/mL) at T3 than those who remained healthy ($p \leq 0.05$, independent t-tests). When egg consumption was examined, a mixed ANOVA with repeated measures revealed a significant treatment by time interaction and follow-up post hoc tests identified differences in inflammatory cytokine production at T3 (12.3 vs. 23.3 and 496 vs. 963 pg/mL for IL-1 β and IL-6, respectively, in E vs. NE; $p \leq 0.05$). **CONCLUSION:** These preliminary data suggest that, during intense training, both innate and adaptive antiviral defenses are impaired but that egg consumption may attenuate training-associated inflammation. Increases in immunosuppressive proteins, such as sCD40L, may also increase susceptibility to illness in athletes. Funding was provided by the Iowa Egg Council and Egg Nutrition Center.

Treadmill Running Attenuates Experimental Colitis in Wild-Type Mice Fed High-Fat Diet and Dextran Sulfate Sodium

Jinkyung Cho, Donghyun Kim, Inhwan Lee, Youngyun Jin, Minjung Kang, Kwonseok Han, Taewan Kim, Hyunsik Kang. *Sungkyunkwan University, suwon, Korea, Republic of.*
(No relevant relationships reported)

Purpose: To investigate the therapeutic effect of treadmill running against ulcerative colitis induced by high-fat diet (HFD) and mild dextran sulfate sodium (DSS) in wild-type (WT) mice.

Methods: At age of 10 weeks, C57BL/6 male mice were assigned to either standard chow (SC, $n=10$) or HFD ($n=10$) or HFD+DSS (HFD+DSS, $n=10$) or HFD+exercise training+DSS (HFD+EX+DSS, $n=10$). Mice in the HFD+EX+DSS group was subjected to a moderate treadmill running with 50 minutes per session and 5 days per week for 11 weeks. Mice in the DSS groups were fed with DSS (2% w/v) in the drinking water during the last 3 weeks of the 11-week treatment period. Hepatic histology, hepatic genes of inflammation and fibrosis, and tight junction proteins in colon were assessed as primary outcomes.

Results: HFD+DSS exacerbated hepatic steatosis in conjunction with greater weight loss, shortened colon length ($p=0.02$), enlarged spleen ($p=0.03$), and greater infiltration

of neutrophils and monocytes into circulating blood ($p<0.001$ & $p<0.001$, respectively) and colon ($p<0.001$ & $p<0.001$, respectively) compared to HFD alone. The pathology of HFD+DSS-induced ulcerative colitis was accompanied by upregulated hepatic inflammatory and fibrosis genes such as Ly6d ($p=0.020$), Lgals ($p=0.021$), Timp-1 ($p<0.001$), Col1a1 ($p<0.001$) and increased serum inflammatory markers such as IL-6 ($p<0.001$), IL-17a ($p<0.001$), GRO- α ($p=0.03$), and MCP-1 ($p=0.42$), as well as downregulated colon tight junction proteins such as ZO-1 ($p=0.01$) and occludin ($p=0.01$). However, treadmill running alleviated the severity of colitis phenotypes induced by HFD+DSS treatment via suppression of upregulated hepatic inflammatory and fibrosis genes and stimulation of downregulated colon tight junction proteins.

Conclusion: The current findings suggest that exercise training alleviates the severity of HFD+DSS-induced ulcerative colitis by modulating genes of hepatic inflammation and fibrosis and colon tight junction proteins in WT mice.

Supported by the National Research Foundation funded by the Korean Government (NRF-2017R1A2B4007357).

Effect of MCT-1 Polymorphism on Lactic Acid Clearance in Resistance Trained Females

Lauren M. Branon. *University of Southern Indiana, Evansville, IN.*
Email: lbranon@eagles.usi.edu
(No relevant relationships reported)

The monocarboxylate transporter one (MCT-1) protein is a carrier protein that plays a vital role in cellular respiration. MCT-1 is known to aid in the transportation of carboxylates, including lactic acid, out of the blood stream and back into muscle tissue. There is a common single-nucleotide polymorphism (SNP) in the MCT-1 gene (T1470A)

that is believed to play a role in the clearance rate of circulating lactic acid following intense exercise. **PURPOSE:** The purpose of this study was to investigate the role of the MCT-1 SNP on lactic acid production and clearance rates in resistance trained, females. **METHODS:** Twenty-one female participants (age = 20.81 \pm 2.06 years) who resistance train three or more times per week were recruited for this study. Lactic acid measurements were taken pre-test and 0, 10, 20, 30, 40 minutes post-test. In order to induce lactic acid production, a standard thirty second Wingate test was used. The MCT-1 gene of each participant was isolated from saliva and amplified using Polymerase Chain Reactions (PCR). Once isolated and amplified, each participants MCT-1 gene was sequenced using Next Generation Sequencing. A two-way mixed factorial ANOVA [genotype (AA,TA,TT) x time (pre, 0, 10, 20, 30, 40)] was used to examine interactions between genotype and time. Three follow-up repeated measures ANOVA's (individual groups x time) were utilized to examine how each group contributed to this interaction. Alpha values were set at .05 and Bonferonni corrections were used in all analyses. **RESULTS:** Further, a significant interaction (genotype x time)

was observed ($p=0.001$). Follow-up ANOVA indicated that each had a main effect for time ($p=0.001$ for each group). Additionally, the AA group cleared lactic acid at a significantly faster rate ($p=0.01$) than the TT group for the 10-20 minute time period. **CONCLUSION:** These results indicate that the MCT-1 SNP likely plays a role in lactate clearance in resistance trained females.

2642 Board #306 May 31 11:00 AM - 12:30 PM

Exercise Preconditioning-Induced Modification of Gut Microbiota Increases Survival in Cecal Ligation and Perforation (CLP)-Induced Sepsis

Hyun-Sik Kang, Donghyun Kim, Jinkyung Cho, Youngyun Jin, Minjung Kang, Inhwan Lee, Haeryun Hong. *Sungkyunkwan University, Suwon, Korea, Republic of.*
(No relevant relationships reported)

PURPOSE: To investigate whether exercise preconditioning-induced modification of gut microbiota increases survival in cecal ligation and puncture (CLP)-induced sepsis.

METHODS: C57BL/6N male mice at age of 4 weeks were randomly assigned to either control ($n=10$) or exercise preconditioning ($n=10$). Mice in the exercise group were subjected to an 8-week-high-intensity treadmill running. Prior to sepsis, the effect of exercise preconditioning on gut microbiota was explored by 16S ribosomal RNA amplification sequencing. Survival probability, organ damage, and pro- and anti-inflammatory cytokines were assessed to investigate whether or not exercise preconditioning-induced changes in gut microbiota modulate host response to CLP-induced sepsis. **RESULTS:** Along with increased β diversity, exercise preconditioning induced the modification of gut microbiota at species level dominated by the phyla *Bacteroidetes*, *Firmicutes*, and *Verrucomicrobia* and to a less extent by the phylum *Cyanobacteria*. Preconditioned mice had higher survival ($p<0.05$) and less organ damage in sepsis compared to control mice. At 8-hr post-sepsis, the preconditioned mice had lower peritoneal interleukin (IL)-1 β ($p=0.020$) and IL-6 ($p<0.001$) but higher peritoneal interferon (IFN)- γ ($p=0.002$), IL-10 ($p<0.001$), and transforming

growth factor (TGF)-1 β ($p < 0.001$) compared to the control mice. In addition, the preconditioned mice has lower blood growth-regulated oncogene (GRO)- α ($p = 0.001$), monocyte chemoattractant protein (MCP)-1 ($p < 0.001$), macrophage inflammatory protein (MIP) 2 ($p < 0.001$), and tumor necrosis factor (TNF)- α ($p = 0.003$) compared to the control mice. At 20-hr post-sepsis, the preconditioned mice had lower peritoneal IL-1 β ($p < 0.001$) and IL-6 ($p < 0.001$) but higher peritoneal TGF-1 β ($p < 0.001$) in conjunction with higher blood IL-17A ($p = 0.002$) and TGF-1 β ($p = 0.029$) compared to the control mice. **CONCLUSIONS:** The current findings suggested that exercise preconditioning-induced modification of gut microbiota might contribute to increased survival in sepsis by modulating host response toward the establishment of a balance between pro- and anti-inflammation. Supported by the National Research Foundation funded by the Korean Government (NRF-2018R1D1A1B07048153 and NRF-2016R1A6A3A11932432).

Impact of Fitness on Receptor Expression of Monocytes Cultured with Palmitate Following Acute Exercise

Lindsay M. LaFratta, Lauren N. Pedersen, Natalie J. Bohmke, Anson M. Blanks, Virginia L. Mihalick, Morgan B. Senter, R. Lee Franco. *Virginia Commonwealth University, Richmond, VA.*
(No relevant relationships reported)

A high-fat meal elicits acute pro-inflammation noted by lipemia and an increased expression in monocyte adhesion molecules. Few studies have investigated the effect of exercise as a potential method to reduce the deleterious postprandial immune response. **PURPOSE:** Therefore, the purpose of this study was to investigate the effect of exercise on the expression of adhesion receptors on lipid-exposed pro-inflammatory monocytes in fit and unfit females. **METHODS:** 5 fit (VO₂ peak ≥ 35 mL O₂/kg/min) and 5 unfit (VO₂ peak < 30 mL O₂/kg/min) females performed 30 min of moderate intensity (60% VO₂ peak) cycling. Blood samples were obtained pre-, immediately, 1hr, and 2hr post-exercise. Whole blood was stimulated with palmitate (10 μ g/mL) and cultured for 2 and 4 h at each timepoint. Monocytes were stained with antibodies against CD14 and CD16 to identify pro-inflammatory subsets. Additionally, antibodies against CD11c, CD36, CD62L, and VLA4 and were analyzed via flow cytometry. Post-exercise changes in monocyte receptor expression following incubation with palmitate were assessed by paired sample t-tests. **RESULTS:** Within intermediate monocytes, unfit females observed a significant change in VLA-4 with 4 h palmitate incubation at 1hr post-exercise (pre % change: -21.74 \pm 20.53 vs. 1hr post % change: -6.98 \pm 13.64, $p = 0.04$). In non-classical monocytes, unfit females observed a significant change in CD11c with 2 h palmitate incubation at 2hr post-exercise (pre % change: -25.04 \pm 19.85 vs. 2hr post % change: -3.36 \pm 23.14, $p < 0.01$). Fit females observed significant changes in non-classical monocyte receptor expression of both CD36 (pre % change: 2.20 \pm 29.51 vs. post % change: -35.57 \pm 27.23, $p = 0.03$) and CD62L (pre % change: -21.47 \pm 18.71 vs. 4.66 \pm 4.71, $p = 0.034$) incubated with palmitate for 4 h immediately post-exercise. **CONCLUSION:** The impact of fitness is highlighted by a decrease in CD36 and blunted decrease in CD62L in lipid-exposed non-classical monocytes following acute exercise in fit females. The VLA-4 and CD11c decrease observed in lipid-exposed pro-inflammatory monocytes of unfit females was blunted following acute exercise. Future research is warranted that investigates the impact of exercise and fitness on the monocyte adhesion cascade following consumption of a high-fat meal.

2644 Board #308 May 31 11:00 AM - 12:30 PM
Immunoregulatory Effects of Oat Avenanthramides during Downhill Running in Young Men and Women

Tianou Zhang¹, Tong Zhao², Yuzi Zhang³, Tao Liu³, Gilles Gagnon⁴, Jacqueline Ebrahim⁴, Li Li Ji, FACSM⁵. ¹The University of Texas at San Antonio, San Antonio, TX. ²The Second Military Medical University, Shanghai, China. ³University of Minnesota, Minneapolis, MN. ⁴Ceapro Inc., Edmonton, AB, Canada. (Sponsor: Li Li Ji, FACSM)
 Email: tianou.zhang@utsa.edu
 Reported Relationships: **T. Zhang:** Industry contracted research; PepsiCo & Ceapro Inc..

PURPOSE: Avenanthramides (AVA) are a group of di-phenolic acids found only in oats, providing antioxidant protection and inhibiting inflammation. Downhill running (DR), an eccentric exercise, activates a series of peripheral immune cells and inflammatory responses in the skeletal muscle. The objective of the study is to evaluate the effects of oat AVA supplementation on eccentric exercise-induced leukocytes changes in the blood of human subjects.

METHODS: 12 male and 12 female subjects were randomly assigned to high-AVA (H-AVA) or low-AVA (control) groups. Two treadmill-based DR sessions were separated by an 8-week washout period followed by 8-weeks of oat AVA supplementation by receiving two cookies containing high (206 mg/kg) or low (0 mg/kg) AVA daily. Blood samples were collected before DR and at various time

points (0, 4, 24, 48, and 72h) after DR. Granulocyte- and Granulocyte Macrophage-Colony Stimulating Factor (G-CSF and GM-CSF) were measured using multiplex immunoassays (R&D System). Peripheral blood leukocyte sub-populations were quantified using the flow cytometer (BD Accuri C6) and presented as percentage. Data were analyzed using repeated measures ANOVA.

RESULTS: DR increased plasma G-CSF at 0h and 4h post-DR ($P < 0.05$), with a significant interaction between oat supplementation and AVA dosage ($P < 0.05$). DR did not affect GM-CSF, but H-AVA showed a trend of lower GM-CSF at 24h post-DR ($P = 0.091$). H-AVA decreased DR-induced CD11b⁺CD45⁺ leukocytes by 15% at 0h and by 14% at 4h post-DR compared to control ($P < 0.05$, time \times AVA dosage). CD14⁺CD11b⁺CD45⁺ leukocytes was elevated at 4h post-DR ($P < 0.01$), but decreased by oat supplementation at pre- and 24h post-DR by 16% and 24% respectively ($P < 0.05$, time \times oat supplementation). H-AVA showed 52% higher CD56⁺ lymphocytes than control at 4h post-DR after supplementation ($P < 0.05$). DR significantly reduced CD56⁺CD16⁺ lymphocytes at 4h post-DR ($P < 0.05$) before oat supplementation, but increased by 36% in H-AVA compared to control at pre-DR after supplementation ($P = 0.070$).

CONCLUSIONS: High AVA supplementation inhibited DR-induced colony stimulating factors (G-CSF and GM-CSF) expression. While both dietary groups decreased circulatory monocytes (CD14) activation after DR, H-AVA inhibited neutrophils (CD11b) and increased NK cells (CD56) activations.

2645 Board #309 May 31 11:00 AM - 12:30 PM
Differential Natural Killer Cell Cytotoxicity Response To Post-Exercise Autologous Serum Based On Cytomegalovirus Serostatus

Priti Gupta. *University of Houston, Houston, TX.*
 Email: tanug3110@gmail.com
(No relevant relationships reported)

Cytomegalovirus (CMV) is a beta-herpes virus present latently in most people worldwide. CMV decreases the exercise-induced mobilization of Natural Killer (NK) cells and lowers the post-exercise-increase in NK cytotoxic activity (NKCA), perhaps due to alterations in NK subsets. NKCA is also impacted by cytokines and stress hormones released into serum after exercise. Whether this effect is altered by CMV is not yet known.

PURPOSE: To determine the effect of exercise-induced changes in cell subsets, cytokines, and hormones on exercise-induced changes in NKCA in CMV+ and CMV- individuals.

METHODS: 13 physically active adults (7 women and 6 Men; age=31.9 \pm 7 years) cycled 30-min at 115% of their lactate threshold power. Peripheral blood was collected pre-, post-, and 1h post-exercise. Mononuclear cells isolated from pre-exercise blood were incubated with target cells (K562 or U266) in the presence of autologous serum from pre-, post-, and 1h post-exercise for 4h. NKCA was calculated from number of lysed target cells. CMV serostatus was determined by ELISA. The effect of CMV and time on NKCA was assessed by linear mixed models.

RESULTS: Eight subjects were CMV+. 1h post-exercise autologous serum significantly enhanced NKCA per cell against U266 cells in CMV+ individuals (Pre vs. post vs. 1h post = 0.283 \pm .053 vs. 0.331 \pm .053 vs. 0.468 \pm .053, $p < 0.05$). Incubating pre-exercise NK cells with post-exercise or 1h post-exercise serum did not impact NKCA in CMV- individuals (Pre vs. post vs. 1h post = 0.367 \pm .037 vs. 0.297 \pm .037 vs. 0.397 \pm .037, $p > 0.05$).

CONCLUSIONS: CMV status impacted the ability of serum from the recovery from exercise to enhance NKCA/cell. Future experiments will identify whether CMV status impacts glucocorticoids and cytokines concentration in 1h post-exercise serum.

Carbohydrate Intake Attenuates Post-Exercise Plasma Levels of Cytochrome P450-Generated Oxylipins

David C. Nieman, FACSM¹, Nicholas D. Gillitt², Guan-Yuan Chen³, Qibin Zhang³, Camila Sakaguchi³, Ella H. Stephan⁵. ¹Appalachian State University, Boone, NC. ²Dole Nutrition Research Laboratory, Kannapolis, NC. ³UNC-Greensboro, Kannapolis, NC. ⁴Federal University of São Carlos, São Carlos, Brazil. ⁵UNC-Chapel Hill, Chapel Hill, NC.
 Email: niemandc@appstate.edu
(No relevant relationships reported)

Oxylipins are bioactive oxidation products derived from n-6 and n-3 polyunsaturated fatty acids (PUFAs) in the linoleic acid and α -linolenic desaturation pathways.

PURPOSE: This study determined if carbohydrate intake during prolonged and intensive cycling countered post-exercise increases in n-6 and n-3 PUFA-derived oxylipins. **METHODS:** The research design utilized a randomized, crossover, counterbalanced approach with cyclists (N=20, overnight fasted state, 7:00 am start) who engaged in four 75-km time trials while ingesting two types of bananas (Cavendish, mini-yellow), a 6% sugar beverage, and water only. Carbohydrate intake was set at 0.2 g/kg every 15 minutes, and blood samples were collected pre-exercise

and 0 h-, 0.75 h-, 1.5 h-, 3 h-, 4.5 h-, 21 h-, 45 h-post-exercise. Oxylipins were measured with the Vanquish UHPLC coupled to a Quantiva triple quadrupole mass spectrometer (Thermo Fisher Scientific, Haverhill, MA) using reference standards. **RESULTS:** Significant and substantial fold-increases (immediately post-exercise/pre-exercise) were measured for plasma levels of arachidonic acid, eicosapentaenoic acid (EPA), docosahexaenoic acid (DHA), and 43 of 45 oxylipins. Significant interaction effects (4 trials x 8 time points) were found for plasma arachidonic acid ($P<0.001$) and DHA ($P<0.001$), but not EPA ($P=0.255$), with higher post-exercise values found in the water trial compared to the carbohydrate trials. Significant interaction effects were measured for 12 of 45 oxylipins. The data supported a strong exercise-induced increase in plasma levels of these oxylipins during the water trial, with carbohydrate ingestion (both bananas types and the sugar beverage) attenuating oxylipin increases, especially those (9 of 12) generated from the cytochrome P-450 (CYP) enzyme system. These trials differences were especially apparent within the first three hours of recovery from the 75-km cycling bout. **CONCLUSIONS:** Prolonged and intensive exercise evoked a transient but robust increase in plasma levels of oxylipins, with a strong attenuation effect linked to acute carbohydrate ingestion, especially those generated through the CYP enzyme system.

Effects of Exercise in Different Environmental Conditions on Leukocyte Counts and Subsets

Tricia L. Hart¹, Elliott Arroyo¹, Brittany N. Followay², Jeremiah A. Vaughan³, Ellen L. Glickman, FACSM¹, Adam R. Jajtner¹.
¹Kent State University, Kent, OH. ²Ripon College, Ripon, WI.
³Bemidji State University, Bemidji, MN.

(No relevant relationships reported)

PURPOSE: To observe the effects of aerobic exercise in different environmental conditions on leukocyte counts. **METHODS:** Recreationally active men ($n=7$; 23.9 ± 2.4 yrs; 182.9 ± 5.6 cm; 12.8 ± 3.6 %BF; 47.3 ± 5.9 ml·kg⁻¹·min⁻¹) volunteered to complete four exercise trials; a maximal graded exercise test, and an aerobic exercise protocol in low temperature (LT; 5°C), moderate temperature (MT; 22°C), and high temperature (HT; 35°C). The exercise protocol consisted of a 60-minute cycling trail at 60% VO_{2max}, a 15-minute rest period, and a time to exhaustion trail at 90% VO_{2max} (TTE). Blood draws were completed before (PRE) and after (60P) the 60-minute trial; immediately after TTE (90P), and one hour post-TTE (REC). Leukocyte count (WBC); lymphocyte number and ratio (LY# and LY%); monocyte number and ratio (MO# and MO%); and granulocyte number and ratio (GR# and GR%) were analyzed via hematology analyzer. Changes were analyzed using a two factor within-subjects repeated measures ANOVA. **RESULTS:** A significant time effect was observed for WBC ($F=2.68$, $p=0.046$, $\eta^2_p=0.348$). Post hoc tests indicated WBC increased at all time points relative to PRE in all trials combined ($p=0.001-0.026$). A significant interaction was observed for LY# ($F=6.59$, $p=0.001$, $\eta^2_p=0.568$), with significant increases from PRE to 60P during HT ($p=0.015$), but not during LT or MT ($p>0.05$). LY# was also elevated at 90P relative to PRE in each trial ($p=0.002-0.011$). A significant time effect was observed for MO# ($F=4.09$, $p=0.026$, $\eta^2_p=0.45$) and GR# ($F=25.51$, $p<0.001$, $\eta^2_p=0.836$). With trials combined, MO# increased from PRE to 90P ($p=0.019$) and GR# increased at each timepoint relative to PRE ($p=0.001-0.008$). A significant time effect was observed for LY% ($F=21.31$, $p<0.001$, $\eta^2_p=0.81$), MO% ($F=8.73$, $p=0.001$, $\eta^2_p=0.636$), and GR% ($F=27.37$, $p<0.001$, $\eta^2_p=0.846$). With trials combined, LY% decreased at REC ($p>0.001$) relative to PRE, MO% decreased at all timepoints relative to PRE ($p<0.001-0.015$), and GR% increased at all timepoints relative to PRE ($p<0.001-0.047$). **Conclusion:** Temperature may not impact acute exercise-induced increases in total leukocytes, however, exercise in the heat (35°C) may increase circulating lymphocyte count when compared to exercise in moderate (22°C) and cold (5°C) temperatures.

Identification Of Blood Biomarkers Of Mild Traumatic Brain Injury In Collegiate Football Players

Eunhan Cho¹, Nathan Lemoine¹, Bailey Theall¹, Amy Turner¹, Jack Marucci¹, Shelly Mullenix¹, Derek Calvert¹, Michael MacLellan², Nikita Kuznetsov¹, Brian A. Irving, FACSM¹, Neil M. Johannsen¹, Guillaume Spielmann¹.
¹Louisiana State University, Baton Rouge, LA. ²University of Prince Edward Island, Charlottetown, PE, Canada. (Sponsor: Brian Irving, FACSM)
Email: echo3@lsu.edu

(No relevant relationships reported)

Football has one of the highest incidence rates of mild traumatic brain injury (mTBI) compared to other contact sports, but on field identification relies on sub-optimal subjective assessments. **Purpose:** We aimed to characterize changes in blood biomarkers of mTBI in NCAA Division I football players in response to repeated head-impacts during a competitive season. **Method:** We studied 30 collegiate football players (21 linemen; 9 non-linemen). Resting serum samples drawn prior to pre-season camp, at the end of pre-season camp, and at the end of the competitive season, were analyzed for biomarkers of mTBI including S100B, GFAP, NSE, UCHL1, NFL, and BDNF by ELISA. The frequency and magnitude of game and practice head-impacts were recorded using helmet-accelerometers. Changes in serum biomarkers of mTBI between linemen and non-linemen across the different timepoints were analyzed by repeated measures ANOVA. When significant differences were found, *Pearson's* correlation coefficients were used to determine linear correlations between biomarkers of mTBI and the frequency and magnitude of head impacts. **Results:** All players had similar levels of S100B before the start of the season (pre-camp, $p>0.05$), however linemen exhibited higher levels of S100B than non-linemen after camp and at the end of the season (post-camp; 30.6%, post-season: 22.5%; $p<0.05$). While both linemen and non-linemen had greater levels of serum BDNF and NSE at the end of the season, when compared to pre- and post-camp levels ($p<0.05$), the largest increases were seen amongst linemen ($p<0.05$). In the linemen group, the average magnitude of head impacts across the 2 weeks of pre-season camp was positively correlated with serum BDNF ($r=0.806$, $p=0.009$). The increase in serum S100B observed in linemen at the end of the season was highly correlated with both maximum ($r=0.794$, $p=0.011$) and average gyroscopic forces ($r=0.669$, $p=0.049$) experienced by players between the post-camp and post-season timepoints. **Conclusion:** Linemen exhibited a greater increase in serum biomarkers of mTBI than non-linemen where repeated low-moderate head-impacts are less frequent. Furthermore, S100B was highly associated with the frequency and magnitude of head-impacts during a college football season, suggesting a potential role as diagnostic tool for mTBI in contact sports.

Evaluating Acute Sport-related Concussion In The Primary Care Setting: Are We Dropping The Ball?

Weston T. Northam, Michael J. Cools, Michael Boyd, Jason P. Mihalik, Kevin M. Guskiewicz, FACSM, Kevin A. Carneiro.
University of North Carolina, Chapel Hill, NC. (Sponsor: Kevin Guskiewicz, FACSM)
Email: weston.northam@unchealth.unc.edu

(No relevant relationships reported)

Concussed athletes are increasingly introduced into the medical care continuum via the primary care setting. As such, primary care physicians (PCPs) are expected to make more decisions regarding return-to-play, symptom management, and specialist referral than ever before. Concussion-specific history and physical examination is vital for this decision-making process.

PURPOSE: To review clinic documentation and determine how PCPs are evaluating concussed athletes in clinic relative to published consensus and guidelines.

METHODS: We conducted a retrospective records review for all patients evaluated by PCPs with no formal sports medicine training at a single large academic medical center. We restricted our review to pediatric patients (7-18 yrs) diagnosed with sport-related concussion between 2014-2017. **RESULTS:** We included 490 patients (age= 14.7 ± 2.2 years; 184 females). Patients presented most frequently to pediatricians (60%) at a median of 3 days from injury (range 0-64 days, IQR 1-6). Most patients participated in football (25.9%), soccer (19.8%), and basketball (15.1%). Prior concussion history was documented in 28.8% of visits. Providers documented headache presence or absence in 94% of patients, compared with nausea (52.2%), dizziness (51.8%), vision changes (45.7%), cognitive complaints (45.7%), emotional changes (17.1%), sleep difficulties (15.8%) and neck pain (13.5%). Basic

neurologic examination was documented in 95.5% of visits compared to detailed neurologic assessment including strength, sensation, cranial nerves, and cerebellar function (26.9%), clinical cognitive assessment (13.5%), balance testing (41%), and neck exam (45.7%). Return-to-play was frequently discussed (94.5% of visits) and 13.1% of PCPs referred the patient to a dedicated sports medicine provider. **CONCLUSIONS:** Symptom-based return-to-play algorithms cannot be effective if the signs and symptoms driving their decision-making aren't being properly evaluated and documented. The PCPs caring for the patients in our retrospective study often omit important components of the history and physical examination for concussed athletes. New tools are needed to empower PCPs to more completely evaluate and manage these patients, and PCPs should be encouraged to thoroughly document the care provided.

2650 Board #314 May 31 11:00 AM - 12:30 PM
Single Versus Dual-Task Performance Using a Novel Dual-Task Assessment in a Healthy Sample

Nicholas K. Erdman¹, Juliana Jimenez¹, David R. Howell², Thomas A. Buckley³, Jacob E. Resch¹. ¹University of Virginia, Charlottesville, VA. ²University of Colorado at Denver, Denver, CO. ³University of Delaware, Newark, DE. (Sponsor: Joe Hart, FACSM)

(No relevant relationships reported)

PURPOSE: The dual-task (DT) paradigm consists of concurrent performance of a cognitive and motor task. Varying DT methodologies have been used to observe subtle changes associated with sport concussion (SC). However, previously employed DT methodologies may not be translatable to the clinical setting. The purpose of the current study was to compare performance on commonly used cognitive and motor tasks administered separately and concurrently in a healthy collegiate sample.

METHODS: Participants consisted of 60 (32 female, 28 male) recreationally active adults (Age: 20.5 ± 1.34 years, Height: 171.7 ± 9.33 cm, Mass: 69.25 ± 12.23 kg). Participants completed the single task (ST) assessment which consisted of the Standardized Assessment of Concussion (SAC) and four trials of the timed tandem gait (TTG) test separately. Participants then completed the SAC and TTG concurrently for the DT assessment. For the SAC, paired t-tests were used to compare ST and DT performance for immediate recall (10-item list), concentration (digit span, months in reverse order), and delayed recall domains as well as the composite score. For the TTG test, paired t-tests compared the best (fastest) time of the ST trials to the average values for each SAC domain. All analyses were performed with α = 0.05.

RESULTS: SAC composite scores significantly improved by 2.3 ± 3.61 points from ST to DT performance (p < 0.001). Comparisons of all ST and DT domain and composite scores for the SAC and TTG are presented in Table 1.

CONCLUSION: The DT assessment resulted in improved cognitive performance and decreased (slower) motor performance as compared to ST performance. Our findings align with related literature using more sophisticated assessment tools. The current findings suggest altered allocation of cognitive resources using commonly used clinical measures of cognition and motor control prior to and following a SC. Future research should investigate the current DT methodology in concussed athletes.

Table 1. Comparison of Single Task (ST) and Dual-Task (DT) Domain and Composite Scores for the SAC and TTG Performance. (μ ± SD)

| Domain | ST | DT | Mean Difference | p |
|---|--------------|-------------|-----------------|---------|
| SAC (points) | | | | |
| Immediate Recall | 24.4 ± 2.46 | 26.7 ± 2.98 | 2.3 ± 2.82 | < 0.001 |
| Concentration | 4.5 ± 0.72 | 4.1 ± 1.06 | 0.4 ± 1.03 | 0.004 |
| Digits | 3.5 ± 0.72 | 3.3 ± 0.87 | 0.2 ± 1.16 | 0.32 |
| Months | 1.0 ± 0.00 | 0.8 ± 0.44 | 0.3 ± 0.44 | < 0.001 |
| Delayed Recall | 8.5 ± 1.35 | 8.8 ± 1.21 | 0.4 ± 1.10 | 0.013 |
| Composite | 37.3 ± 3.58 | 39.6 ± 4.18 | 2.3 ± 3.61 | < 0.001 |
| Time to Complete TTG (sec) | | | | |
| Immediate Recall | 11.3 ± 2.02* | 14.4 ± 3.00 | 3.1 ± 2.09 | < 0.001 |
| Concentration | 11.3 ± 2.02* | 12.0 ± 2.21 | 0.7 ± 2.98 | 0.08 |
| Digits | 11.3 ± 2.02* | 11.8 ± 2.24 | 0.5 ± 1.62 | 0.019 |
| Months | 11.3 ± 2.02* | 12.8 ± 2.52 | 1.4 ± 2.09 | < 0.001 |
| Delayed Recall | 11.3 ± 2.02* | 13.1 ± 2.47 | 1.8 ± 1.94 | < 0.001 |
| *All DT TTG values were compared to the best (fastest) time achieved during ST performance. | | | | |

The Performance of Adolescent Athletes on Baseline Concussion Assessments

Matthew S. Propst¹, Adam W. Kiefer², Timothy S. Foster³, Christy Reed², Paul J. Gubanich, FACSM². ¹CHI St. Joseph Health, College Station, TX. ²Cincinnati Children's Hospital Medical Center, Cincinnati, OH. ³University of Cincinnati, Cincinnati, OH. (Sponsor: Paul Gubanich, FACSM)

Email: mpropst@st-joseph.org
 (No relevant relationships reported)

PURPOSE: The purpose of this study is to examine the baseline performance of adolescent athletes on the King-Devick test (KD), modified Balance Error Scoring System (mBESS), and Post Concussive Symptom Inventory (PCSI) to determine whether age or sex significantly influence performance or reporting on these assessments. **METHODS:** A retrospective cohort study was conducted on athletes' baseline concussion assessments as completed as part of their school or organizations' concussion surveillance program. Testing was recommended prior to or at the start of each sports season and included a concussion history and risk factor questionnaire, KD, mBESS, and PCSI. The influence of age, sex, and correlations between tests were also examined. **RESULTS:** Data from eight schools and one sports organization was available for review. Data collected from 389 athletes (64% M, 36% F) were included in the analysis. The average age was 15.9 (+/-1.5), range 12.1-19.2). The average KD score was 47.6 (+/- 9.7, range 28.0-88.6 s), mBESS 25.8 (+/- 3.2, range 12-30), and PCSI score was 5.2 +/- 8.2, range 0-52). Gender did not influence test performance on any of the measures. Only KD was influenced by age with improved performance noted at older ages (p<0.01). Overall, the three test measures showed poor correlation among these athletes. **CONCLUSIONS:** KD, mBESS, and PCSI baseline performance is reported in a cohort of adolescent athletes. Test performance was not influenced by gender and only KD was associated with age. The poor correlation between tests supports the need for a comprehensive baseline concussion surveillance program. Further studies are necessary to examine the utility of these measures in managing recovery from injury in this population.

Cardiovascular Autonomic Changes Following a Bout of Low-intensity Exercise in Recently Concussed and Healthy Athletes

Phillip R. Worts¹, Marcos Sanchez-Gonzalez², Michael J. Ormsbee, FACSM³, Lynn B. Panton, FACSM³, Cathy W. Levenson³, Scott O. Burkhardt⁴, Jeong-Su Kim, FACSM². ¹Tallahassee Orthopedic Clinic, Tallahassee, FL. ²Larkin Community Hospital, South Miami, FL. ³Florida State University, Tallahassee, FL. ⁴Children's Health Andrews Institute, Plano, TX. (Sponsor: Jeong-Su Kim, FACSM)
 Email: prw13@my.fsu.edu

(No relevant relationships reported)

Concussion can negatively impact several physiological processes, one of which is the cardiovascular system. While measurements of heart rate variability (HRV) in concussed patients may appear similar to healthy controls at rest, physiological stressors such as exercise may expose cardiovascular autonomic dysfunction present after injury. **PURPOSE:** To compare cardiovascular autonomic modulation of sport-related concussion (SRC) participants with age- and sex-matched healthy controls (CON) during 10' of rest, 20' of exercise and 20' of recovery. **METHODS:** Student-athletes (15.9 ± 1.3 years; N=12, 8 SRC + 4 CON) were assigned to a 20' exercise bout of treadmill walking at 40% age-predicted HRmax. SRC participants exercised between Day 3 and Day 7 following their concussion. HRV and blood pressure were collected throughout the testing session. Descriptive statistics, a series of two-way mixed ANOVAs, and post hoc pairwise comparisons with Bonferroni correction were performed using SPSS 22. **RESULTS:** There was no significant interaction between injury and mean arterial pressure (MAP) ($p = 0.07$). The main effect of time showed recovery MAP was significantly lower than during exercise, $F(2,844,28.442) = 6.412$, $p = 0.002$, partial $\eta^2 = 0.391$ and the main effect of group showed that the SRC group had a significantly higher MAP than CON, $F(1,10) = 13.103$, $p = 0.005$, partial $\eta^2 = 0.567$. The main effect of time showed that low-frequency normalized units (LFnu) was significantly higher at seated rest and during exercise than recovery, $F(2,852,28.522) = 11.485$, $p < 0.001$, partial $\eta^2 = 0.535$ with no differences between SRC and CON ($p = 0.578$). There was no significant interaction between injury and time for LFnu ($p = 0.797$). **CONCLUSIONS:** SRC participants exhibit subtle differences in cardiovascular autonomic responses during a bout of treadmill walking. A greater MAP in SRC compared to CON suggests a blunted post-exercise hypotensive response. These data may indicate that, at least acutely, concussion impacts cardiovascular autonomic modulation responses to low-intensity aerobic exercise. The aforementioned findings could have clinical implications for the management of concussions in adolescent athletes.

2653 Board #317 May 31 11:00 AM - 12:30 PM
Systolic Blood Pressure Response to Orthostasis after Concussion is Related to ADRA2A Gene Receptor Subtypes

Michael F. La Fountaine, FACSM¹, Asante N. Hohn¹, Caroline L. Leahy¹, Anthony J. Testa¹, Joseph P. Weir, FACSM². ¹Seton Hall University, Nutley, NJ. ²University of Kansas, Lawrence, KS.

Email: michael.lafountaine@shu.edu

(No relevant relationships reported)

Orthostasis causes a gravity-dependent redistribution of blood volume to the lower extremities. The baroreflex coordinates effector organs of the cardiovascular autonomic nervous system (CV-ANS) to produce a proportional response to mitigate an aberrant change in systolic blood pressure (SBP). In autonomic dysfunction (AD), there may be a lag or impaired accommodation leading to dramatic changes in SBP. Growing evidence indicates that AD is a part of the post-injury period after concussion. The impact of genetic variability of CV-ANS receptors including that of alpha-2 adrenoceptor (ADRA2A) gene polymorphisms remains undefined. **Purpose:** To evaluate the effect of ADRA2A gene variants on SBP responses to orthostasis in recently concussed athletes. **Methods:** A prospective study was performed in 13 concussed college athletes (gender: 10 female, 3 male; age: 20±1 yrs; height: 1.70±0.11 m; weight: 74±17 kg). Beat-to-beat SBP was assessed digitally at rest for 10 minutes in the supine (SUP) position and then for 3 minutes in the standing (STND) position within 48 hours (48H) of concussion; SBP was averaged and a change score computed (Δ SBP = STND SBP - SUP SBP). Fast-Fourier transform was performed and power calculated for the low frequency (LF) spectra in each position (e.g., SUP LF-SBP, STND LF-SBP); the variables were \log_{10} transformed for parametric analyses. A saliva sample was obtained from each participant and a commercial laboratory identified the ADRA2A single nucleotide polymorphism (rs1800544) using PMR-array. **Results:** Data are presented as group mean (±SD). There were no ADRA2A [C/C: n=5; C/G: n=5; G/G: n=3] group differences for demographics, SUP and STND SBP or LF-SBP. A significant group main effect ($p < 0.05$) was observed for Δ SBP and post-hoc tests revealed that the G/G [-21(±3)] response was significantly ($p < 0.05$)

lower than the C/G [7(±18)] group. A 3 X 2 RMANOVA for LF-SBP was performed. A significant group, position and interaction effect ($p < 0.05$) was observed; post-hoc tests were not significant, but trending for an effect in the G/G group. **Conclusion:** The ADRA2A receptor, whose activation is known to inhibit the release of norepinephrine and reduce peripheral vasoconstriction, contributed to a blunted SBP response to orthostasis in G/G homozygotes compared to other variants within 48H of concussion.

2654 Board #318 May 31 11:00 AM - 12:30 PM
Moderate Intensity-interval-training With Blood Flow Restriction And Body Cooling For People With Post-concussion Syndrome

Yi-Ning Wu¹, Jessica Gravel², Matthew White², Josh Avery², Terrie Enis², Caroline Stark¹, Robert C. Cantu, FACSM².

¹University of Massachusetts Lowell, Lowell, MA. ²Emerson Hospital, Concord, MA. (Sponsor: Robert C. Cantu, FACSM)
 Email: yining_wu@uml.edu

(No relevant relationships reported)

PURPOSE: To examine the effects of a 12-session aerobic exercise program with blood flow restriction (BFR) and body cooling (BC) on people diagnosed with post-concussion syndrome (PCS) less than a year.

METHODS: A single blind randomized controlled trial of aerobic exercise with BFR and BC was conducted. Twenty-five adults with PCS were assigned to the experimental group (n=14, 8 females and 6 males, 38±11 yrs) or the control group (n=11, 9 females and 2 males, 33±10 yrs). Both groups rode a recumbent elliptical machine for 21 minutes at moderate intensity (60% of predicted maximum heart rate) twice a week for six weeks, but only the experiment group received BFR and BC while riding. PCS Symptom Checklist (26 items with a total score of 156) was used daily to track the number and severity of PCS symptoms during the 6-week intervention and the 6-week follow-up period. To examine the fluctuations of symptom number and severity, the variance of overall checklist scores and sub-domain scores for each individual during the 6-week intervention and the 6-week follow-up period was calculated. Mann-Whitney U test was used to test the group differences.

RESULTS: The fluctuation of overall symptom severity during the 6-week intervention was significantly less in the experimental group ($p = 0.03$). Less variations of severity in cognition and mood domains were observed in the experimental group ($p = 0.02$ respectively). During the 6-week follow-up period, the number of PCS symptoms remained more stable in the experimental group ($p = 0.02$). There is a trend that after the intervention ended, less symptom severity fluctuation was observed in the experimental group ($p = 0.05$). The number of PCS symptoms in the cognition and sleep domains reduced after the 6-week intervention ended and remained stable during the 6-week follow-up period ($p = 0.007$ and $p = 0.02$). Furthermore, the severity of mood and sleep symptoms remained more stable in the experimental group ($p = 0.04$ for both domains).

CONCLUSIONS: Aerobic exercise with BFR and BC alleviated the post-concussive symptoms of people who suffered PCS less than a year. More stable recovery was found in individuals who exercised at 60% of predicted maximum heart rate under BFR and body cooling as compared to those who underwent the exercise without BFR and BC.

Comparison of Baseline Concussion Tests in Youth and Collegiate Football Players

Jason C. Dorman, Daniel N. Poel, Thayne A. Munce, FACSM. Sanford Sports Science Institute, Sioux Falls, SD. (Sponsor: Thayne A. Munce, FACSM)

Email: jason.dorman@sanfordhealth.org

(No relevant relationships reported)

As proper medical care for sports concussions is increasingly emphasized, administering baseline testing can be a valuable component of a comprehensive concussion management strategy, especially for athletes who participate in contact/collision sports. **PURPOSE:** To compare baseline measurements of Youth (middle school) and Collegiate (NCAA Division II) American football players on three tests used for the evaluation of sports concussion. **METHODS:** Sixty-two healthy football players (31 Youth: 13.2 ± 0.5 yr; 31 Collegiate: 20.3 ± 1.6 yr) performed baseline concussion testing before their respective seasons. Testing included balance (BAL; twenty second, bipedal standing on a Wii Balance Board for four conditions; eyes open [O], eyes open + cognitive task [OC], eyes closed [C], eyes closed + cognitive task [CC]), oculomotor function (KD; King-Devick) and multiple object tracking (MOT; NeuroTracker). Postural sway values (95% Ellipse Area [EA]) for each BAL condition, KD total time and MOT speed thresholds (Core 1, 2 & 3) for each group were compared. **RESULTS:** EA was significantly lower in three (O, C, CC) of the four BAL tests in Collegiate vs. Youth players (O: 0.83 ± 0.70 vs. 1.48 ± 1.08 cm², $P = 0.006$; C: 1.20 ± 1.00 vs. 2.20 ± 1.16 cm², $P < 0.001$; CC: 1.29 ± 1.53 vs. 6.18 ± 13.20 cm², $P = 0.045$). EA was not different between Collegiate and Youth players in

the OC condition (1.63 ± 3.04 vs. 5.85 ± 15.96 cm², $P = 0.153$). KD total time was significantly faster in Collegiate vs. Youth players (38.44 ± 6.18 vs. 51.47 ± 10.04 s, $P < 0.001$). Collegiate players had faster speed thresholds on two (Core 1 & 2) of the three MOT tests (Core 1: 5.55 ± 0.84 vs. 4.90 ± 1.27 m·s⁻¹, $P = 0.020$; Core 2: 3.29 ± 0.82 vs. 2.89 ± 0.75 m·s⁻¹, $P = 0.047$). Speed threshold was not different between the Collegiate and Youth players in Core 3 of MOT (2.21 ± 0.45 vs. 2.00 ± 0.63 m·s⁻¹, $P = 0.143$). **CONCLUSION:** Collegiate players had better baseline scores on a majority of the clinical concussion tests. These findings highlight the importance of recurrent baseline testing and/or use of age-specific normative values in concussion evaluation. Moreover, youth players had greater variability in their test results, thus medical personnel should exercise caution when relying solely on normative scores to evaluate the neurologic function of youth suspected of having a concussion.

The Effects of Test Duration on Concussion Evaluation Outcomes

Adam Kremer, Douglas M. Kleiner, FACSM. *Center for Sports Concussion, Jacksonville Beach, FL*. (Sponsor: Douglas Kleiner, FACSM)

(No relevant relationships reported)

There are many forms of evaluating traumatic brain injury in sports medicine. This may include "paper and pen" neuropsychological tests, ...which often lend themselves to the sports medicine environment. A reliable, and inexpensive test that can be used on the sideline without any additional devices is highly desirable. However, the chosen "length" (number of questions/tasks) of these instruments are rarely justified, if at all. **PURPOSE:** The purpose of this experiment was to determine if duration of testing makes a difference in outcomes. From our experiences as clinicians, we have observed the frustration build in the injured athlete as the test continues. We hypothesize that there is an optimal duration to the test, and as such, with an extended and unnecessary duration, we contend that lower scores may be present due to other extrinsic variables including boredom and frustration. **METHODS:** A convenience sample of 55 subjects (mean height=175.8 cm, mass=88.2 kg) were each given a 30-question and a 70-question version of the Stroop test, and a 30-question and a 120-question version of the Symbol Digit Modalities Test (SDMT). Each had their mental status assessed by each version of the test. **RESULTS:** Fifty-five subjects completed the Stroop test long version (70 questions). The time for testing averaged 81 sec and number of missed questions averaged 1.5. With regard to the short version (30 question) Stroop test, 28 subjects took the test. Results averages 32 seconds to take the test, and number missed averaged 1.0 questions. As for the SDMT short version (45 question test), 47 subjects completed the test in an average of 47.1 sec while missing an averaged 0.4 questions. The long version of the SDMT contained 120 questions. Twenty-five subjects completed the test with an average of 0.62 questions missed. Time was not obtained in this trial segment due to a technical error. **CONCLUSIONS:** This preliminary study suggests that the duration of testing time may in fact alter the performance of the subject. Further research on this topic is warranted.

2657 Board #321 May 31 11:00 AM - 12:30 PM
The Effects Of Subconcussive Impacts On The Neurocognitive Function Of Men's Collegiate Lacrosse Players From Pre-season To Post-season

Caroline Varlotta, Joshua Giordano, Joseph Miceli, Brandon Burg, Haille Zwiibel, Matthew Heller. *NYIT-COM, Old Westbury, NY*. (Sponsor: Dr. Gerard P Varlotta, FACSM)

Email: cvarlott@nyit.edu

(No relevant relationships reported)

There is an estimated 1.6 to 3.8 million sports-related mild traumatic brain injuries (mTBI) per year in the United States. Football is more commonly studied than other sports, even though men's lacrosse has almost as great of a risk of mTBI. Since many players of this age group are in schools of higher education, mTBI can inhibit their ability to learn in the classroom. **PURPOSE:** To examine the effects of total number of impacts, cumulative magnitude, and cumulative rotation, as measured by accelerometer, on neurocognition, as measured by time to complete the Trails A task in pre- and post-season. **METHODS:** We examined 10 male freshmen NCAA Division II collegiate lacrosse players in pre- and post-season (January and May). Subjects wore the Vector mouthguard, which contains accelerometers, during full contact practices and 18 games. Vector mouthguard recorded impact number and magnitude. Subjects' cognition was evaluated by C3logix Trails A test. **RESULTS:** The data was analyzed by comparing athletes' mean scores of Trail A between pre- and post-season with paired samples t-test and correlating it with the total number of impacts, cumulative impact, and cumulative rotation with computation of Pearson correlation coefficients. Statistical significance was determined by p-value < .05. The association between completing the Trails A task and the following variables was statistically significant with a positive Pearson coefficient: total number of impacts (0.80, 0.006), cumulative impact (0.74, 0.014) and cumulative rotation (0.71, 0.022). **CONCLUSIONS:** The athletes took longer to complete the Trails A task in post-season if they experienced an

increased total number of impacts, cumulative impact, or cumulative rotation. These changes may indicate the number of impacts, cumulative impact, and cumulative rotation affects athletes' cognitive abilities without clinical symptoms or reporting of mTBI. The results of this pilot study suggests further investigation is warranted.

The Reliability of a Companion KEMS Concussion Test

Douglas M. Kleiner, FACSM. *The Center for Sports Concussion, Jacksonville Beach, FL*.

Email: kleiner@tacmedics.com

(No relevant relationships reported)

The Kleiner Evaluation of Mental Status (KEMS) instrument was developed 8 years ago and has undergone continual evaluation and improvement. This instrument has previously been shown to be brief, reliable valid, and discriminating, as well as "practical for the sidelines". For the past 8 years we have evaluated many instruments for validity, specificity, and discriminating qualities of each task. **PURPOSE:** The purpose of this study was to alter the sequence and content of the instrument without affecting its accuracy. We sought to produce a "Version B" of the KEMS instrument, and to evaluate it against our initial and well-studied counterpart, thus creating a second reliable instrument to be used in pre- and post-testing, and for serial assessments. Both versions are equally-weighted, 12-question, cognitive assessment tools that include; simple orientation (SO), complex orientation (CO), immediate recall (IR), delayed recall (DR), concentration (C), and staged commands (SC). **METHODS:** A convenience sample of 48 subjects (mean height=177.3 cm, mass=89.8 kg) were divided into two equal groups. Each had their mental status assessed by one version of KEMS before, and the other version after, competing in an amateur boxing bout. The sequence of KEMS-A vs. KEMS-B was determined a priori. Descriptive data are presented as percentage (%) of responses. **RESULTS:** The mean percent of correct answers for Version A was 86.3%, vs. 87.5% for Version B. The number correct per category were the same for both versions (SC, IR, IR, CO, SO, SO, SC, CO, C, C, DR, and DR), indicating an acceptable instrument. **CONCLUSIONS:** We conclude that this instrument, along with other modalities, should be part of the standard protocol to assess concussion in athletes.

Lifestyle Behaviors and Common Injuries Among Collegiate eSport Athletes

Hallie Zwiibel, Ravi Chinsky, Joanne DiFrancisco-Donoghue. *NYITCOM, Old Westbury, NY*. (Sponsor: Gordon Schmidt, FACSM)

Email: hzwibel85@gmail.com

(No relevant relationships reported)

eSports is a \$1.5 billion industry with over 250 million viewers globally. Although there is controversy over its qualifications as a sport, the International Olympic Committee (IOM) has deemed eSports a sporting activity and over 80 colleges and universities have varsity eSports teams with 22 offering scholarships. Despite its success little is known on the health, injury concerns, and management, of eSports players.

PURPOSE: To understand lifestyle behaviors, exercise habits, and common injuries of eSports players in the collegiate setting.

METHODS: A survey was developed based on a literature review assessing gaming habits. The survey was administered to collegiate varsity eSport players between the ages of 18-22 years of age from 9 colleges and universities in various geographic settings across the United States. Facts were collected anonymously. Descriptive statistics were used to determine frequencies, averages, and standard deviations.

RESULTS: 63 subjects completed the survey 94% (n=59) male and 6% (n=4) female. The most common complaints were eye fatigue 51% (n=32), back/neck pain 41% (n=26), wrist pain 35% (n=22) and hand pain 30% (n=19). The majority of individuals practiced between 3-6 hours/day 59% (n=37) and 16% (n=10) >7 hours/day. Time spent in game play before a standing break diverged from 1 hour in 38% (n=24), to 2-3 hours in 40% (n=25), and >4 hours 19% (n=12). The majority of participants report being conscientious about diet 68% (n=43) and exercise 64% (n=40) with 65% (n=41) exercising ≥30 minutes/day and averaging 3 (SD=1.7) days exercising/week. However, 24% (n=15) reported no exercise at all. Average cups of a caffeine beverage a day was 1 (SD=0.8).

CONCLUSION: The health and injury profiles of eSports players are similar to sedentary workers as opposed to traditional athletes. The assessment and management

of eSports players must be reflective of their healthcare needs. Pre-participation examinations should evaluate vision and eye strain, assess social/addictive behavior, and evaluate physical activity and nutrition habits. Healthcare teams may include primary care Physicians, Physical/Occupational therapists, Athletic Trainers, Exercises Physiologists, Psychologists/Psychiatrists, Optometrist/Ophthalmologists and Registered Dietitians.

2660 Board #324 May 31 11:00 AM - 12:30 PM
Varsity Swimming Programs in China and U.S.: A Comparison Study

Fan Guo¹, Xiaobo Cai¹, Hai Yan², Weimo Zhu, FACSM².
¹Southeast University, Nanjing, China. ²University of Illinois at Urbana-Champaign, Urbana, IL. (Sponsor: Weimo Zhu, FACSM)
 Email: fanfan12334@126.com
 (No relevant relationships reported)

PURPOSE: To examine the difference between varsity swimming programs in two universities, one in China and one in US.

METHODS: 14 varsity female swimmers, 1 physical therapist, 1 academic counselor, 2 coaches, and 1 athletic directors from the University of Illinois at Urbana-Champaign (UIUC), U.S. and 14 varsity swimmers (female=7), 1 coach, and 1 athletic directors from the Southeast University (SEU), China were voluntarily for a semi-structure interview each ranging from 30 to 50 minutes. The interview questions include recruitment procedures, training and competition, support system, budget, coaches' training philosophy and swimmers' motivation for training. All of interviews were tape-recorded, transformed to transcript, coded and analyzed.

RESULTS: Key features and difference between two programs are summarized below:

| Items | SEU | UIUC |
|---------------------------------------|--|--|
| Recruitment | Using one single swimming test to determine the selection | Long-term monitoring for selection; two-side communications available between coaches and swimmers |
| Training (Hours; Load) | 10 hours per week; 20000-26000 yards per week | 20 hours per week; 50000-70000 yards per week |
| Competition (Dual meet; Championship) | 0 times per season; 2-3 times per season | 7-8 times per season; 2-3 times per season |
| Support Team | The coach takes duty for all aspects | Consist of 1 athletic trainer, 1 physical therapist, 1 nutritionist and 1 psychologist |
| Budget | 44,000 \$ per year | 260,000 \$ per year |
| Coaches' Training Philosophy | Improvement of athletic performance and academic achievement | Improvement of athletic performance and academic achievement; whole-person development |
| Swimmers' Motivation for Training | External motivation: Reward Internal motivation: Athletic spirit and self-improvement | Internal motivation: Interest of swimming, self-challenging, responsibility for team, and the sense of achievement |

CONCLUSION: A variety of differences were found between China and US varsity swimming programs, which should explain the swimming performance level differences between two countries at both the university and national levels.

2661 Board #325 May 31 11:00 AM - 12:30 PM
Pre-Race Risk Screening and Stratification Predicts Adverse Events - SAFER Study In 76654 Distance Runners

Martin SchwelInus, FACSM¹, Sonja Swanevelder², Esmé Jordaan². ¹SEMLI, University of Pretoria, Pretoria, South Africa. ²South African Medical Research Council, Cape Town, South Africa.
 (No relevant relationships reported)

PURPOSE: The purpose of this study was to determine if a pre-race medical screening and risk stratification program predicts adverse events (ability of a runner to finish the race, or develop a medical complication) during an endurance running event.

METHODS: This prospective study, conducted during the Two Oceans marathon races (21.1km and 56km) in South Africa over 4 years, involved 76654 consenting race entrants. Race entrants completed a pre-race medical screening questionnaire at registration (3-4 months before the race), and were risk stratified into four groups: very

high risk (VHR; existing cardiovascular disease - CVD), high risk (HR; risk factors for CVD), intermediate risk (IR; existing other chronic disease, medication use or injury), and low risk (LR). All runners in the VHR and HR categories were provided with educational information to decrease the risk of medical complications, and were also advised to undergo a pre-race medical assessment. Runners were tracked from registration to starting and finishing the race, and medical encounters (ME) were documented. Main outcome variables were the did-not-start rate (DNS; % runners registering but not starting) and the adverse event rate (AE) [defined as % starters that did-not-finish (DNF) or had an ME] in each risk category.

RESULTS: The DNS rate (%: 95% CI) for runners was similar in all risk categories (VHR=19.5; 17.9-21.2, HR=18.8; 18.0-19.7, IR=18.4; 18.0-18.9, and LR=18.6; 18.2-19.1)(p=0.604). The DNF rates in the VHR (2.2; 1.6-3.0)(p=0.005), HR (1.8; 1.5-2.1)(p=0.017), and IR (1.9; 1.8-2.1)(p<0.001) were significantly higher compared to the LR (1.4; 1.2-1.5). The overall AE rates for runners in the VHR (2.3; 1.8-3.0) (p=0.0017), HR (1.8; 1.5-2.1)(p=0.0323), and IR (2.0; 1.9-2.2)(p<0.001) were significantly higher compared to the LR (1.5; 1.3-1.6).

CONCLUSIONS: A pre-race medical screening, risk stratification and educational intervention program did not change the DNS in the risk categories. However, runners in the higher risk categories, that chose to start the race, were more likely to suffer an adverse event (not finish the race or present with a medical encounter) compared with runners in the lowest risk category.

2662 Board #326 May 31 11:00 AM - 12:30 PM
High School Sport Specialization and Prior Injury in Collegiate Football Players

Lace E. Luedke¹, Turner W. Geisthardt¹, Mitchell J. Rauh, FACSM². ¹University of Wisconsin - Oshkosh, Oshkosh, WI. ²San Diego State University, San Diego, CA. (Sponsor: Mitchell J Rauh, FACSM)

(No relevant relationships reported)

Sport specialization has become more common in young athletes and recent evidence suggests sport-specialized training is related to an increased risk of sports injury.

PURPOSE: The purposes of this study were to 1) assess the percent of high school sport specialization among collegiate football players and 2) determine whether sport specialization was related to rate of prior injury.

METHODS: 101 NCAA Division III Collegiate Football players (Age: 20.38±1.35 years, height 1.83±0.06 m, body mass 96.12±14.95 kg) participated in the study. At the beginning of their intercollegiate season, the players completed a survey about high school sport specialization participation and prior high school and college sport injuries. Sport specialization was classified as low, moderate or high based on the players' responses to questions on a) playing a primary sport in high school, b) quitting other sports to focus on the primary sport and c) training for football >8 months/year in high school.

RESULTS: In this study sample, 25.7% (n=26) of players reported being highly sport specialized and 40.6% (n=41) being moderately sport specialized in high school. Football was the primary high school sport reported for 67.3% (n=68) of players. Prior injury that limited or stopped their sports participation was reported in 83.2% (n=84) of players. While the collegiate football players classified as moderate and high sport specialists reported a higher incidence of prior injury relative to players classified in low sport specialization, the association was not statistically significant (Odds Ratio=2.66 (95% CI 0.92-7.67), p=0.07). The number of all prior injuries reported by moderate or high sport specialists (2.15±1.45) was not significantly greater than low sport specialists (1.74±1.62) (p=0.20). Similarly, the number of high school injuries reported by moderate or high sport specialists (1.30±1.30) was not significantly greater than low sport specialists (0.85±1.08) (p=0.09).

CONCLUSIONS: The prevalence of high school sport specialization in this sample of football players was consistent with prior reports of football players. While results support previous findings of higher mean numbers of prior injury with increasing sport specialization, the association was not statistically significant.

2663 Board #327 May 31 11:00 AM - 12:30 PM
Classification of Collegiate Athletes Based on Their Injury History

Heather L. Shirley, Taeyeon Oh, Minsoo Kang, FACSM, Minjung Kim, Heontae Kim, Joshua Hogg, Shannon Singletary, Melinda Valliant. University of Mississippi, University, MS.
 (No relevant relationships reported)

Sports-related injuries can have a significant impact on an athlete's performance and career. While some injuries are inevitable, many can be prevented. Cluster analysis is a useful statistical technique that can assign individuals into groups (i.e., latent subgroups) based on common characteristics. **PURPOSE:** To utilize cluster analysis to 1) identify the latent subgroups based on athletes' injury history; and 2) examine the characteristics of latent subgroups among athletes. **METHODS:** A total of 1,538 college athletes competing in the South Eastern Conference in NCAA division I were segmented by three criteria; 1) Injury parts indicate the body part sustaining the injury,

2) Injury types describe the detail of their injury status such as strain, contusion or tendonitis. 3) Injury duration refers to how long the athlete was unable to participate in training. K-means clustering analysis with the Euclidean similarity of injury log vectors was conducted to label players. The number of groups(k) was determined by applying the average silhouette method. The characteristics of clusters were analyzed descriptively, and the sports were allocated to each group followed by the athlete clusters. **RESULTS:** Five clusters were identified by the maximum average silhouette coefficient (0.153) among coefficients for randomly drawn k's between 2 to 20. The first group, mainly baseball, men's basketball, and men's tennis, had injury to their ankle, arm, and hamstring for contusion and strain for a few weeks. The second group was mostly from football, with injury to their ankle, knee, and shoulder with the most extended injury durations. The third group, mostly football or track and field, were the athletes likely to have knee inflammation, and the duration was nearly half of a year. The injured body parts of the fourth group were back, finger, and hamstring, and the types of injuries were fracture and tendonitis. This cluster was mainly women's basketball and track and field athletes. The members of the last group had head injury (e.g., concussion), and were soccer, softball or volleyball athletes. **CONCLUSION:** This study may help practitioners in recognizing the likelihood of an athletes' injury according to their sport. Additionally, coaches could also consider this information in daily practices.

2664 Board #328 May 31 11:00 AM - 12:30 PM
Ready To Tri: Characteristics Of Recreational Triathletes
 Carolyn M. Kienstra, William H. Cade, II, Thomas M. Best, FACSM. *University of Miami, Miami, FL.*
 Email: ckienstra@med.miami.edu
(No relevant relationships reported)

Purpose: The sport of triathlon has been increasing in popularity, especially among recreational athletes. As triathletes compete in races ranging from around 16 miles to 140.6 miles or more and train in 3 disciplines simultaneously, it is difficult to identify consistent risk factors for injury among these athletes. The aim of this study was to evaluate characteristics of a group of recreational triathletes in regards to their medical history, training habits, and musculoskeletal injuries.

Methods: Endurance athletes were recruited for participation from local triathlon clubs and upon presentation to the University of Miami Sports Medicine clinic. Triathletes over the age of 18 years were considered for participation. After consenting, they were sent a link via e-mail to complete an online survey.

Results: Twenty-two triathletes completed the survey. The average age was 46.5 years old (range 24-60 years). Seventy-three percent reported an injury in the past year, and 32% reported multiple injuries. The lower extremity represented 66% of injuries. The knee accounted for 27%, followed closely by the hip at 23%. The back and shoulder accounted for 15% each. Other reported locations of injuries were the foot, ankle, leg, and neck. Athletes spent the most training time per week biking at 4.9 hours, followed by running at 3.9 hours, and then swimming at 2.3 hours. Almost 60% reported weight training for an average of 2 hours per week. Of these, 77% reported at least 1 injury, but only 23% had multiple injuries. Only 14% participated in some type of yoga or Pilates. The majority of athletes, 59%, trained with the help of a coach. Only 18% reported working with a nutritionist, and less than 5% reported working with a sports psychologist. Thirty-six percent reported having a current, chronic medical condition. The most common conditions were asthma and anxiety. Sixty-four percent used some type of vitamin or supplement, with multivitamins being the most common (35%). A gluten free diet was followed by 21%, and 16% reported following a vegetarian or vegan diet.

Conclusion: Establishing a better understanding of the characteristics of recreational triathletes along with trends in their training habits can help guide further research on injury risks and lead to training recommendations for injury prevention.

2665 Board #329 May 31 11:00 AM - 12:30 PM
Caregiver Awareness of Safe Pitching Recommendations in Youth Fastpitch Softball Pitchers
 Michael Smith, Giorgio Zeppieri, Bryan Prine, Kevin Farmer, Stephanie Brombacher, Heather K. Vincent, FACSM, Jason L. Zaremski, FACSM, Michelle Bruner. *University of Florida College of Medicine, Gainesville, FL.* (Sponsor: Heather K Vincent, FACSM)
 Email: smithms@ortho.ufl.edu
(No relevant relationships reported)

PURPOSE: Fastpitch softball is one of the fastest growing sports among young females in the US. The current participation rate is similar to that of youth baseball. While there are published guidelines for safe pitching practices in softball, these guidelines are not well publicized like those in baseball, and thus may not be well monitored or enforced by caregivers or coaches. A potential consequence could be compromised safety and increased injury incidence among young softball pitchers.

The purposes of this study were to: 1) evaluate caregivers' knowledge of safe pitching guidelines for youth fastpitch softball, and 2) obtain pitching and injury data for youth fastpitch softball pitchers

METHODS: A 30-item study-specific survey was administered to caregivers of youth softball pitchers in 10U-18U age brackets. Knowledge of safe pitching practices, arm pain and injury, and pitching volume and type. 115 surveys were completed, 50.4% of which were completed by the player's mother.

RESULTS: Only 14.7% of caregivers reported knowledge of published softball pitching guidelines while 16.5% relied on safe pitching guidance from coaches, internet, or USSA-ASA recommendations. Of the 115 respondents, 57.4% pitched year round. Caregivers estimated that 26.1% pitched less than 65 pitches per game, 60.8% pitched more than 66 pitches per game, and 13% did not know how many pitches were thrown per game. 74% surveyed stated pitches were counted by the caregiver, spouse, or coach, but 26% of caregivers did not know whether pitches were counted or not during play. A total of 76 softball players reported arm pain, 33% of which were shoulder pain, 13.9% were upper arm pain, and 11.3% were elbow pain. 22% of respondents sought medical care for arm pain. Of 16U and 18U players who reported arm pain, 72.1% missed play due to arm pain

CONCLUSIONS: Caregivers need to be a primary target for education of pitching guidelines. Protection of pitching volume-related arm pain or injuries may be possible through increased awareness efforts at the national, regional and local levels. Increased involvement of caregivers in monitoring pitching volume may also positively impact early detection or prevention of chronic arm injuries and missed play in youth softball pitchers.

2666 Board #330 May 31 11:00 AM - 12:30 PM
The Ability of Internal and External Workload to Predict Injuries in College Female Soccer Players
 Ai Ishida, Pamela D. Swan, FACSM, Joshua S. Beaumont, Jesse Vezina. *Arizona State University, Downtown Phoenix, AZ.*
 (Sponsor: Pamela D. Swan, FACSM)
(No relevant relationships reported)

Wearable micro-technology devices like heart rate (HR) monitors and global positioning system (GPS) units enable sport medicine teams to monitor athlete workloads during training and games. These data are valuable to help optimize sport performance and prevent injuries. Previous research has evaluated the utility of workload parameters such as internal load (IL) and external load (EL) to predict injury risk in male athletes, but it is unknown if these same variables are applicable in females. **PURPOSE:** To investigate the correlation between IL and EL measured by micro-technology in female college soccer players and examine their utility to predict risk of injury on lower limbs. **METHODS:** Twenty-three NCAA Division One women soccer players 19.2 ± 1.2 years old, 168.2 ± 7.3 cm, and 64.0 ± 7.8 kg were recruited. Data were collected during all practice and game play over the 14-week season.

Workload measures were categorized as being either acute (A) or chronic (C) and were derived by a HR monitor (Polar Team 2, Polar Electro OY, Kempele, Finland) and GPS unit (Optimeye S5, Catapult Innovation, Melbourne, Australia). IL consisted of ratings of average HR (Avg-HR), training impulse (TRIMP i.e., HR x time), age estimated maximum HR (Max HR), and perceived exertion (S-RPE). EL consisted of total distance (TD), average speed (Avg-Spd), high speed running distance (HSR), and estimated maximum speed (Max Speed). **RESULTS:** There were significant correlations between S-RPE and TD (r = .82, p < .001), TRIMP and TD (r = .75, p < .001), Avg-HR and Avg-Spd (r = .80, p < .001) and high HR zone and HSR (r = .60, p < .001). Seven, lower limb injuries were recorded, primarily consisting of hip and knee strain. Acute Avg-HR and A to C ratio of Avg-Spd were significantly (p < .05) higher in injured as compared to the non-injured group. **CONCLUSION:** IL and EL were significantly correlated in this group of female soccer players. The injured group had overall higher intensity values prior to injury than the non-injured group. However, both very high and very low workload variables preceded injury incidents. Sport medicine teams are advised to consider individualizing training protocols to maximize performance and minimize injury as both very high and very low workloads may predict injury in female college soccer players.

2667 Board #331 May 31 11:00 AM - 12:30 PM
State-level Implementation of Health and Safety Policies Within Secondary School Athletics: 2018 Update

Samantha E. Scarneo¹, William M. Adams², Yuki Murata³, Rebecca L. Stearns¹, Douglas J. Casa, FACSM¹. ¹University of Connecticut, Storrs, CT. ²University of North Carolina at Greensboro, Greensboro, NC. ³Nagoya University, Nagoya, Japan. (Sponsor: Douglas J. Casa, FACSM)
 Email: samantha.scarneo@uconn.edu

(No relevant relationships reported)

In 2017, a study released the findings of state-level implementation of health and safety policies to prevent catastrophic injuries within secondary school athletics. However, it is unknown if improvements have been made since this initial review.

PURPOSE: To provide an update on the assessment of state-level health and safety policies pertaining to the leading causes of sudden death and catastrophic injuries within secondary school athletics in the United States.

Methods: Utilizing the methodology described in Adams et al. (2017), we aimed to provide an update to the current policies adopted at the state level for the 2017-2018 academic year. State high school athletic association policies, enacted legislation and Department of Education policies were reviewed for all 50 states and the District of Columbia. States that mandated policies within the rubric created by Adams et al. (2017) were awarded points (0-100) and ranked from 1 (best) to 51 (worst). The median and mean percent was calculated and the rankings were updated.

Results: Twenty-one states were found to mandate new policies in the 2017-2018 academic year (results are as of August 15, 2018). The median is now 47.75% (+0.65% change). The mean from 2017 was 47.65% (not originally reported), and is now 49.61% (+1.96%). States ranked 1 through 10 were New Jersey, North Carolina, Massachusetts, Kentucky, Florida, Missouri, South Dakota, Washington, Wisconsin and Hawaii. New Jersey has obtained the first-place rank (+11.99%, +3 spots in the ranking), while Florida is now ranked 5th (+14.2%, +18 spots in the ranking). Other substantial changes included Nebraska (+10%, +17 spots in the ranking), Kansas (+10.6%, +12 spots in the ranking) and South Carolina (+6.37%, +6 spots in the ranking). States ranked 40 through 51 were Louisiana, Connecticut, Oklahoma, Michigan, Minnesota, North Dakota, Iowa, Wyoming, New Hampshire, Montana, California, Colorado.

Conclusion: Many states continue to make positive changes with the implementation of health and safety policies for managing the leading causes of sudden death and catastrophic injury in sport. However, continued advocacy for the initiation, development and implementation of these policies are warranted to optimize the health and safety of secondary school athletes.

2668 Board #332 May 31 11:00 AM - 12:30 PM
Relative Age And Sports Performance In Elite Athletes According To Gender And Sport Modality

(No relevant relationships reported)

The effect of relative age is a topic to consider in the selection of elite athletes to ensure that a good detection of sporting talents is being carried out during the athlete's growth and maturation phase.

PURPOSE: Evaluate the relationship of relative age with sport performance of elite athletes according to gender and sports modality of sports and to evaluate differences between men and women.

METHODS: We analyzed the data of 1285 athletes who were selected and attended the High Performance National Center in Chile between 1992 and 2017. The athletes came from different sports disciplines which were divided into Combat Sports, Sports with Ball, Strength and Resistance and Art and Precision sports. Only athletes presenting complete data on date of birth and sports discipline were included, while all Paralympic athletes were excluded. The age of the athletes varied from 8 to 49 years old, with a total of 59.4% men. With the data of month of birth and sports discipline we organized athletes in 4 quartiles. Athletes were classified by sport discipline and gender, and statistical analysis was carried out through Chi square to see differences between the groups.

RESULTS: No effect of relative age was observed in the overall sample, however there was a slight decrease in those born in the 4th quartile, with a total of 23% of the total births, without significant differences between the quartiles without variation when analyzing by gender and sports performance. Of the 4 sports disciplines, Strength and Resistance and Combat sport showed an increase of those born in the first quartile and a decrease of those born in the last 3 months of the year, without significant differences between the groups. In sports with a balloon, this effect was not observed, while in Art and Precision sports a slight increase was observed in those born in the last months.

CONCLUSIONS: Although an effect of relative age was not observed in elite athletes who train in High Performance Center in Santiago, an important decrease was found in those born in the last 3 months, especially in strength and endurance and combat sports, leaving the doubt if younger athletes are being considered during the selection of sports talents and if they are having the same opportunities to compete as their peers who were born a few months earlier.

Muscular Strength and Lean Mass Development of Young Male and Female Swimmers Throughout Adolescence

Taline Santos da Costa, Pedro Murara, Rodrigo Vancini, Claudio Andre Barbosa de Lira, Marília Santos Andrade. *Federal University of São Paulo, São Paulo, Brazil.*
 Email: costa.taline@gmail.com

(No relevant relationships reported)

The Knowledge of differences in strength and lean mass development across chronological ages may help to understand the relationship between both in each sex and to guide training programs. **PURPOSE:** To compare the strength and muscle mass between different ages categories and sexes in young swimmers. **METHODS:** Cross-sectional study. 74 swimmers (55 males and 21 females) aged between 10 to 20 years old were evaluated. They were divided according to the training categories (category 1: 12-13 years; category 2: 14-15 years; category 3: 16 years or more). The athletes underwent evaluation of lean mass (Kg) using the dual-energy X-ray absorptiometry (DXA) method, and evaluation of knee extensor muscular peak torque (Nm) and total work (J), using an isokinetic dynamometer. **RESULTS:** Category 1 for male athletes presented lower values than category 2 for knee extensors peak torque (81.9±17.0 vs 128.0±32.9Nm, p<0.05), total work (99.2±24.5 vs 165.9±49.2J, p<0.05) and lean mass (29.1±5.1 vs. 42.8±9.7kg, p<0.05). Moreover, category 2 for male athletes presented lower values than category 3 for knee extensors peak torque (128.0±32.9 vs. 182.4±26.6Nm, p<0.05), total work (165.9±49.2 vs 238.8±40.2J, p<0.05) and lean mass (42.8±9.7 vs 56.9±3.5kg). In the female group, there were difference only between category 1 and 3 for peak torque (76.7±12.2 vs 128.5±17.0Nm, p<0.05) and total work (95.3±19.1 vs 168.3±21.9J, p<0.05). There were no differences for lean mass between the female categories. There was no significant difference between sexes for lean mass, peak torque and total work in category 1. Only lean mass was significantly higher (p<0.05) in males than in females in category 2, and peak torque, total work and lean mass were higher (p<0.05) in males than in females in category 3. **CONCLUSIONS:** The increase in muscle strength is coincident with the increase in boys' muscle mass. Unlike the boys, the girls' muscle mass was not different between age categories evaluated, but the muscle strength became higher during the time, probably due to neuromuscular adaptation. After 15 years of age, the difference in muscle performance between the sexes became significant. Separating training sections after 15 years old might be important since their levels of muscle strength and lean mass are significantly different.

Knowledge about Sports Injuries, Their Risk Factors and Prevention Among University Football players, 2018

Abubakr O. Ali. *University of Khartoum, Faculty of Medicine, Khartoum, Sudan.*
 Email: abkan7@gmail.com

(No relevant relationships reported)

PURPOSE: In Sudan, football is the most prevalent sport amongst youth. Sport injuries amongst young football players are common. In order to design effective sports injury prevention strategies it is important to know the knowledge and understand the attitudes of players about sports injuries.

METHODS: This study was descriptive cross-sectional institutional based study in the University of Khartoum. Total coverage of football teams of faculties of medicine, dentistry, pharmacy, engineering, economy and business was performed and data was collected through an author designed self-administered questionnaire comprising of socio-demographic data, knowledge, and attitude about common sports injuries experienced in football players. Data was analysed with SPSS version 24.

RESULTS: The study included 90 football players from 6 colleges. 50% have experienced a sport injury in the last 2 years and 50% haven't. Inadequate warm-up exercise (27%) and over practice (12%) were selected by participants as the major risk factors of sports injury in football players. Regarding the knowledge about common sports injuries 49% players have average knowledge, 31% players poor and only 20% players have good knowledge. Faculty of medicine team showed the highest amount of knowledge. Faculty of engineering and faculty of business showed the lowest level of knowledge. General attitude of football players towards sport injuries and their prevention show 72% players with positive attitude. A significant association between the knowledge and attitude of the players (P=0.013) was found. 74.4% of the players do not their current educational curriculum adequately addresses sport injuries, their

risk factors and prevention. **CONCLUSIONS:** University football teams need to be educated on sports injuries and their prevention through relevant trainings or courses that increase students' knowledge and influence their attitudes motivating safe practice in sports.

(No relevant relationships reported)

PURPOSE: To determine the effects of pre-meal exercise mode and/or intensity on postprandial energy expenditure, substrate partitioning, and blood substrate and hormone concentrations in persons with spinal cord injury (SCI).
METHODS: Nine adult men with chronic (≥ 1 yr) thoracic SCI consented to participation. Following assessment of neuromuscular strength and cardiorespiratory fitness, participants completed four experimental trials. On the first trial before the meal, participants completed ~42.5 min of circuit resistance exercise (CRT). The CRT energy cost was measured and subsequent exercise trials were designed to be isocaloric. Participants then completed seated control (CON), high intensity interval arm cycling (HIIT), and moderate intensity continuous arm cycling (MICT) trials in randomized order. Immediately after exercise or sitting, trial participants consumed a liquid mixed meal. During exercise and for 150 min following the meal, expired gases were collected continuously and analyzed via indirect calorimetry and blood samples were taken every 30 min.
RESULTS: Participants exercised at 52±6, 53±7, and 65±5 %VO_{2peak} for a cost of 120±19, 120±22, and 122±33 kcal during MICT, CRT, and HIIT, respectively. Only CRT appeared to have an elevated EE at 150 min post-exercise (1.43±0.15 vs 1.34-1.32 kcal·min⁻¹ in other conditions). The greatest increases in accumulated whole-body fat oxidation during recovery were seen in CRT and HIIT (15.1±3.2 and 13.3±4.8 g·150 min⁻¹, respectively) compared to MICT and CON (11.9±4.7 and 10.6±4.1 g·150 min⁻¹, respectively). As with energy expenditure, only CRT appeared to have elevated fat oxidation at 150 min post-exercise (83.1±19.1 vs 64.8-67.9 mg·min⁻¹ in other conditions). In accordance, integrated area under the curve (iAUC) of blood triglycerides and glycerol was lowest and highest, respectively, in CRT. Blood glucose was similar in all conditions, but CRT showed the lowest iAUC for insulin.
CONCLUSIONS: Pre-meal exercise changed postprandial energy metabolism in persons with SCI. Independent of exercise energy expenditure, intensity is an important determinant of post-exercise energy expenditure. Furthermore, exercise mode incorporating resistance and high intensity exercise appears to stimulate greater fat oxidation during recovery.

BLOOD PRESSURE IN RESPONSE TO HAND GRIP EXERCISE IN INDIVIDUALS WITH INTELLECTUAL DISABILITIES

Thessa I.M. Hilgenkamp¹, Elizabeth C. Schroeder¹, Tracy Baynard FACSM¹, Bo Fernhall FACSM¹
¹University of Illinois at Chicago, Chicago, IL
Individuals with intellectual disabilities (ID) have limited work capacity, potentially due to autonomic dysfunction. Preliminary data suggests a blunted heart rate response to exercise in this population, and potentially altered hemodynamics. **PURPOSE:** To compare the hemodynamic response to 2-minutes of isometric handgrip exercise (HGE) at 30% of maximal voluntary contraction in individuals with ID to a control group without ID. **METHODS:** Adults with ID (n=15, age 30±8yrs, BMI 25±3 kg/m²) and adults without ID (n=16, age 30±8yrs, BMI 26±6 kg/m²) had heart rate and blood pressure continuously recorded via an ECG-lead and finger-plethysmography

in the seated position. Isometric Recordings were acquired for the last 2 min of quiet rest, HGE, and the first 2 min of recovery. Spontaneous baroreflex sensitivity (BRS) and sympathetic activation (SAP LF) were calculated. **RESULTS:** Individuals with ID showed smaller increases compared to individuals without ID for diastolic blood pressure and mean arterial pressure (interaction, p<0.01; Table), and no significant increase in systolic pressure or pulse pressure, in contrast to the control participants (interaction p<0.01). Heart rate, BRS and SAP LF response to HGE were not different between groups (p>0.05). **CONCLUSION:** Individuals with ID exhibit a blunted blood pressure response to isometric HGE compared to individuals without ID, and this may explain the limitations these individuals experience with performing exercise. The research leading to these results has received funding from the People Programme (Marie Curie Actions) of the European Union's Seventh Framework Programme (FP7/2007-2013) under REA grant agreement n°625455.

Hematological Biomarkers are Associated With Cardiorespiratory Fitness and Level of Lesion in Individuals With Spinal Cord Injury**

Tom E. Nightingale¹, Gurjeet S. Bhangu¹, James LJ Bilzon², Andrei V. Krassioukov¹. ¹University of British Columbia, Vancouver, BC, Canada. ²University of Bath, Bath, United Kingdom.
Email: Tnightingale@icord.org
(No relevant relationships reported)

PURPOSE Spinal cord injury (SCI) is characterised by low cardiorespiratory fitness (CRF) levels and an increased risk of cardiovascular (CV) disease. We aimed to assess: (1) differences in hematological biomarkers between individuals with tetraplegia (TETRA) and paraplegia (PARA) and, (2) associations between hematology profile and cardiorespiratory fitness (CRF).
METHODS Cross-sectional data from 67 participants (TETRA; n = 21; age: 42 ± 11 yrs, 6F/15M. PARA; n = 46; age: 43 ± 10 yrs, 9F/37M) with chronic SCI (>1 yr) were collected at two research centers. Peak oxygen uptake (VO_{2 peak}) was determined using an upper-body arm-crank exercise test to volitional exhaustion and hematological biomarkers measured using an automated hematology system, respectively.
RESULTS RDW was significantly (P < 0.01) higher in TETRA (13.9 ± 0.6%) compared to PARA (13.0 ± 1.1%). Besides mean corpuscular hemoglobin concentration (tetraplegia = 336 ± 8 vs. paraplegia = 349 ± 15, P < 0.01) there were no other significant differences in hematological outcomes between injury groups. Large negative associations were found between absolute (Fig. 1A) and relative (Fig. 1B) VO_{2 peak} with RDW. Multiple linear regressions accounting for sex as a co-variate did not influence the strength of these associations. Classifying participants by population-specific absolute (Fig. 1C) and relative (Fig. 1D) VO_{2 peak} revealed significant differences in RDW.
CONCLUSION These strong negative associations between CRF and RDW in individuals with SCI parallel those previously observed in able-bodied individuals. Higher RDW values (i.e. anisocytosis) is an independent risk factor for increased CV mortality, heart failure, and coronary heart disease and may reflect several underlying

exacerbated metabolic responses such as oxidative stress and systemic inflammation. These data emphasize the importance of maintaining a high CRF in individuals with SCI.

group during isometric handgrip (HG) exercise. **METHODS:** Individuals with (n=13; 30±7yrs, 27.0±6.9kg/m²) and without ID (n=19; 28±7yrs, 25.5±3.7kg/m²) had cardiac autonomic function assessed via heart rate variability (HRV) in two-minute sections, before, during, and after seated isometric HG exercise at 30% of maximal voluntary contraction. ECG recordings were acquired and analyzed in the time (root mean square of successive differences (RMSSD) and percentage of RR intervals differing by <50ms (PNN50)), and frequency domains (low and high frequency (LF, HF), and LF/HF ratio). Data were log-transformed in the case of non-normal distribution, but raw data are presented below. **RESULTS:** HG exercise elicited a decrease in RMSSD, LF, and HF (p<0.05) in both groups that returned to baseline values during recovery. Controls reduced pNN50 during HG and recovered to values higher than seated, however, no changes were observed in ID (interaction, p=0.03). LF/HF ratio did not change in either group. **CONCLUSION:** Individuals with ID appear to have attenuated cardiac autonomic responses (i.e., depressed sympathetic tone or incomplete vagal withdrawal) to a sympathoexcitatory task, such as isometric HG exercise. These data suggest that autonomic dysfunction likely exists among individuals with ID even during submaximal intensities and may contribute to the low work capacity in this population. However, a greater sample size is required to fully elucidate these findings.

Over-ground Walking Economy In Hemiparetic Stroke
 Alyssa D. Stookey, Fredrick M. Ivey, Leslie I. Katzel. *Baltimore VA Medical Center, Baltimore, MD.*
 Email: alyssa.stookey@va.gov
 (No relevant relationships reported)

Hemiparetic stroke causes residual gait deficits that impair gait economy/efficiency. Although gait economy is traditionally assessed during sub-maximal treadmill walking, natural over-ground gait mechanics and associated over-ground economy cannot be ascertained using this method, as walking on a treadmill artificially distorts the extent of hemiparetic gait inefficiency by altering gait mechanics. **PURPOSE:** To examine economy of over-ground walking in those with chronic, hemiparetic stroke. Additionally, we sought to determine whether gait speed and distance walked relates to over-ground gait economy in this population. **METHODS:** Twenty-five chronic, hemiparetic stroke survivors underwent a peak exercise test with metabolic monitoring and two 6-minute walk (6MW) tests both with and without a portable metabolic measurement system. Gait economy was calculated as measured VO₂ during the 6MW divided by predicted VO₂ for non-stroke age-matched subjects, according to a standard estimation equation utilizing ground speed. **RESULTS:** 6MW distance covered with the portable system (306.3 ± 138.8 meters) was highly correlated (r=0.93, P<0.001) to distance walked without the system (282.8 ± 113.2 meters), indicating that the lightweight equipment did not impede walking performance. Mean VO₂ during the 6MW (12.5 ± 3.2 ml/kg/min) was 67% of mean VO₂ peak (18.63 ± 5.42 ml/kg/min) and all subjects had impaired gait economy, according to commonly accepted criteria for gauging economy deficits, as the mean measured VO₂ was 45% higher than the average predicted VO₂ (8.6 ± 2.3 ml/kg/min) (p < 0.001). Results further demonstrated a moderate association between gait economy and both gait speed (r = -0.5, P < 0.05) and distance walked (r = -0.49, P < 0.05). **CONCLUSION:** Stroke disability substantively impairs over-ground gait economy, with hemiparetic walking economy associated with walking speed and distance walked. Future research should focus on determining the extent to which economy of gait in over-ground walking can be improved with exercise rehabilitation, as well as determining which types of exercise training and therapy modalities are most beneficial to improving gait efficiency after disabling stroke.  Email: ssherm5@uic.edu
 (No relevant relationships reported)

Individuals with intellectual disability (ID) are at a greater risk for co-occurring health conditions, such as cardiovascular disease (CVD). Previous research has indicated autonomic dysfunction, an important contributor to CVD risk, to be present in individuals with ID. However, autonomic dysfunction and its potential impact on work capacity has not been thoroughly investigated in individuals with ID. **PURPOSE:** To assess cardiac autonomic function between individuals with ID and a matched control

2676 Board #340 May 31 11:00 AM - 12:30 PM Cardiac Autonomic Function and Sleep Duration Changes Due to Time-of-Day Practices/Conditioning in College Football Players

Portia B. Resnick, William D. Hale. *The University of Tulsa, Tulsa, OK.*
Email: portia-resnick@utulsa.edu
(No relevant relationships reported)

Sleep duration (SD) is critical for exercise recovery, however collegiate student athletes are typically sleep deprived secondary to early morning workouts, class responsibilities, late day competitions and travel. Optimal cardiac autonomic function (CAF) is indicative of an athlete's ability to recover and handle the next practice/conditioning session. Measures of CAF include heart rate variability (HRV) and resting heart rate (RHR) that can be obtained during the last cycle of sleep. **PURPOSE:** The purpose of this study was to compare the impact of time-of-day practices/conditioning during two six-week periods on HRV, RHR, and SD in college football players. The two six-week periods compared were off-season early morning (6:00 am) summer conditioning and in-season fall afternoon (3:30 pm) practices. **METHODS:** Thirteen male college football players were fitted with WHOOP wearable activity/recovery tracking devices that use photoplethysmography and accelerometry to determine HRV (RMSSD), RHR (bpm), and SD (hrs/day). Both HRV and RHR are measured during the last sleep cycle to determine CAF. The WHOOP device was worn throughout the entire day and night, including during practices, conditioning, and sleep. Data were downloaded to the user's smartphone daily then uploaded into SPSS for statistical analyses. The six-week summer conditioning occurred at 6:00 am while the six-week fall practices occurred at 3:30 pm. **RESULTS:** A series of three paired sample t-tests were performed to compare HRV, RHR, and SD between the two six-week time periods for time-of-day comparisons. Both HRV (100.2 vs 82.2, p.002) and SD (4.5 vs 5.3, p.002) were significantly different between the two six-week practice/conditioning time periods while RHR was not significantly different (56.6 vs 58.2, p.201). **CONCLUSIONS:** Both SD and one measure of CAF (HRV) differed based on time-of-day practices/conditioning in college football players. Athletes appeared to have higher CAF (HRV) during the six-week summer conditioning (6:00 am) period, while increased SD during the fall six-week practice (3:30 pm) period. Supported by The American Athletic Conference Research Consortium Grant

2677 Board #341 May 31 11:00 AM - 12:30 PM Immediate and Residual Effects of Sleep Extension on Performance and Motivation in Tactical Athletes

(No relevant relationships reported)

PURPOSE: Investigate the immediate and residual impacts of sleep extension on performance in tactical athletes. **METHODS:** A randomized controlled trial (Sleep extension = EXT vs Control = CON) was conducted on 50 (EXT: 20.12 ± 2.01 years vs CON: 19.76 ± 1.09 years) tactical athletes enrolled in the Reserve Officers' Training Corps. Participants wore actigraphs for 15 consecutive nights and completed a cognitive/motor battery after 7 habitual sleep nights, after 4 sleep extension nights, and after the resumption of habitual sleep for 4 nights. The CON group remained on habitual sleep schedules for the duration of the study. **RESULTS:** During the intervention, the EXT group significantly increased mean sleep time (1.36 ± 0.71 hours, p < .001). After sleep extension, there were significant between-group differences on the mean score change since baseline in Psychomotor Vigilance Test reaction time (p = .026), Trail Making Test - B time (p = .027), standing broad jump (SBJ) distance (p < .001), and motivation to perform the cognitive tasks (p = .003) and the SBJ (p = .009), with the EXT group showing a greater enhancement in performance/motivation. After resuming habitual sleep schedules, significant between-group differences on the mean score change since baseline persisted on SBJ distance (p = .001) and motivation to perform the SBJ (p = .035), with the EXT showing greater enhancement in performance/motivation. **CONCLUSION:** Increasing sleep duration resulted in immediate performance benefits in psychomotor vigilance, executive functioning, standing broad jump distance, and motivation levels. Benefits on motor

performance and motivation were evident four days after resumption of habitual sleep schedules. Sleep duration appears to positively impact performance and motivation levels in tactical athletes. 2678 Board #342 May 31 11:00 AM - 12:30 PM Sleep Quality and Psychosocial Variables Predict Common Cold in Marathon Runners

Sophie E. Harrison, Jason P. Edwards, Ross Roberts, Neil P. Walsh, FACSM. *Bangor University, Bangor, United Kingdom.*
(Sponsor: Neil P. Walsh, FACSM)
Email: s.harrison@bangor.ac.uk
(No relevant relationships reported)

General population studies show that poor sleep and psychological stress predict common cold and recent work shows that early life adversity can have long lasting effects on immunity across the lifespan. However, the influence of these lifestyle and psychosocial factors on common cold in athletes remains poorly understood (Walsh NP, 2018, *Eur J Sports Sci*, **18**: 820-31). **PURPOSE:** To investigate the influence of sleep quality and psychosocial variables on upper respiratory symptoms (URS) in runners before and after a marathon. **METHODS:** In a cohort, observational study 305 runners (68% male, age: 45 ± 9 years) were monitored during the 2-weeks before and after the Snowdonia marathon that takes place in the fall. URS incidence was monitored daily using Jackson common cold questionnaire; whereby, criteria for a URS bout was a symptom score ≥ 6 on two or more consecutive days. Criteria for a repeated URS bout in the same participant required at least five consecutive days with a symptom score of zero between URS bouts. Participants completed questionnaires assessing personality, trait anxiety, perceived stress and the occurrence of early life adversity. Training load (weekly) and self-reported sleep quantity and quality (daily) were monitored. Chi-square analyses compared pre and post marathon URS. Logistic regression was used to determine predictors of URS pre and post marathon. **RESULTS:** URS incidence was similar in the two weeks pre- and post-marathon (P > 0.05; 39 vs. 42 URS bouts, respectively). When accounting for sex, age and prior illness, participants who experienced early life adversity were twice-as-likely to report a URS bout pre-marathon (OR, 2.20; P < 0.05). Other significant predictors of URS incidence pre-marathon were lower emotional stability (OR, 0.77; P < 0.05), higher perceived stress (OR, 1.08; P < 0.05) and higher trait anxiety (OR, 1.05; P < 0.01). During the two weeks after the marathon, participants were twice as likely to suffer a URS bout if they reported lower sleep quality (OR, 2.34, P < 0.01). Higher state anxiety immediately before the race (OR, 1.04, P < 0.05) also predicted URS post-marathon. **CONCLUSION:** Self-reported sleep quality and early life adversity predict common cold in marathon runners.

2679 Board #343 May 31 11:00 AM - 12:30 PM Effects of Nap After Morning Exercise on Afternoon Performance and Overnight Sleep in Athletes

Karina Ando¹, Hiroyuki Sagayama², Masako Hoshikawa¹, Masaki Takahashi³, Shigenobu Shibata³, Hideyuki Takahashi¹. ¹Japan Institute of Sports Sciences, Tokyo, Japan. ²Japan Society for the Promotion of Sciences, Tokyo, Japan. ³Waseda University, Tokyo, Japan.

(No relevant relationships reported)

One-half of Japanese athletes have problems with sleep and daytime sleepiness. Nap is used to reduce mental and physical fatigue and improve afternoon performance. However, the impact of nap on athletes' performance is not clear. Few studies have been reported on how to spend a day towards the afternoon performance as recovery after morning exercise. **PURPOSE:** To examine the effects of a 90-min daytime nap after morning high-intensity exercise on afternoon performance and nocturnal sleep. **METHODS:** Eight healthy athletes were recruited for this study. They performed high-intensity intermittent exercise in the morning. The exercise session began at 10:30-11:00. The high-intensity intermittent exercise consisted of 12 sets, 1-min bouts of cycling at 100% of VO₂max and 4-min bouts at 0% of VO₂max at 60 rpm, and then continuous cycling at 100% of VO₂max until exhaustion. After the exercise session, the participants consumed lunch at 13:00. Nap/no-nap trials were performed at 14:30-16:00 randomly for cross-over design and were separated by at least 1 week. The participants consumed dinner at 19:30. The bedtimes and wake-up times were adapted to each participant and kept consistent between the nap/no-nap trials. The sleep efficiencies of the daytime nap and nocturnal sleep were monitored using a sheet-shaped body vibrometer. Sleepiness, reaction time, and blood samples were measured before and after the nap/no-nap trials. Each measurement before trials and after trials was compared by two-way repeated measures of analysis of variance. **RESULTS:** The sleep efficiency in the daytime nap trial was 84.4 ± 4.1%. In the nap trial, sleepiness

was significantly reduced (nap score, -4.1 ± 1.4 ; no-nap score, 0.9 ± 1.2 score; $P < 0.05$) and the reaction time was significantly shortened (nap, -6.9 ± 3.7 ms; no-nap, 7.1 ± 4.3 ms; $P < 0.05$). In addition, growth hormone (nap, 0.8 ± 0.3 ng/mL; no-nap, 0.0 ± 0.0 ng/mL; $P < 0.05$), histidine, and cystine levels increased significantly in the nap trial. The nocturnal sleep efficiencies following the daytime nap were not disturbed (nap, 93.6 ± 1.5 %; no-nap, 94.9 ± 1.7 %; $P > 0.05$). **CONCLUSION:** The present study suggested that a 90-min daytime nap after morning high-intensity exercise reduces sleepiness, shortens reaction times and does not disturb nocturnal sleep in athletes.

2680 Board #344 May 31 11:00 AM - 12:30 PM
Sleep Profile And Performance Of Young Futsal Athletes

Jorge Fernando Tavares de Souza, Rafael Ferreira de Castilho, Hanna Karen Moreira Antunes. *Universidade Federal de São Paulo, São Paulo, Brazil.*
 Email: jorge.fernando22@hotmail.com
 (No relevant relationships reported)

Futsal is characterized as a high intensity game, which requires good physical conditioning, reaction speed and decision-making in a short time. In this scenario, sleep is an important factor to promote a good physical and cognitive recovery. However, studies show that adolescents suffer from interrupted or sleep deprivation, which damages their physical and psychological recovery. **Purpose:** To investigate the sleep pattern of futsal athletes and their performance during the competitive futsal game. **Methods:** 26 futsal players, male, aged 13-17 years were recruited. Volunteers answered sleep questionnaires, including Pittsburgh Sleep Quality Index, Epworth Sleepiness Scale and Morningness-Eveningness Questionnaire. Before and after the match, they answered the Sleep Diary. Separated by category, the athletes played an official futsal game, in which was held assembling a scout of each athlete during the match (passes, assists, shots, interceptions, fouls, yellow/red card). A descriptive analysis and distribution of relative frequencies were performed. In addition, Student t-test was used and a significance level at $P < 0.05$. The study was approved by UNIFESP Ethics Committee (#1130/2015). **Results:** The athletes had 15.08 ± 1.44 years and BMI 20.85 ± 2.21 kg/m², being 38.46% (n=10) of U-14, 34.62% of U-16 (n=9) and 26.92% of U-17 (n=7). Most of the athletes present good quality sleep (84.62%), low daytime sleepiness (65.38%) and indifferent chronotype (69.23%). In the sleep diary, no significant difference was observed in sleep quality score (pre = 7.15 ± 2.88 vs post = 7.07 ± 2.81 ; $p=0.90$) and total sleep time (pre = 551.19 ± 95.95 min vs post = 548.92 ± 112.78 min; $p=0.93$) before and after the game. However, pre-game 34.62% reported having a sleep quality equal to the usual, 42.31% had a better sleep and 23.08% had a worse night's sleep. In the post-game, 50% reported having a night of sleep as usual, 26.92% had better sleep and 23.08% had a worse night's sleep. In the scout analysis, the athletes presented positive performance (positive points minus negative points) 19.23 ± 16.4 even losing the match. **Conclusions:** We concluded that there are no changes in the sleep pattern of young futsal athletes at pre and post-game. In addition, although the performance of the athletes was positive, this was not enough for them to win.

2681 Board #345 May 31 11:00 AM - 12:30 PM
Sleep-wake Cycle Analysis of Wheelchair Rugby Athletes During Two Phases of The Season

Victor Sanz-Milone¹, Fernanda Versuka Narciso², Marco Tulio De Mello², Andressa Silva², Milton Misuta¹, Andrea Maculano Esteves¹. ¹Universidade Estadual de Campinas (UNICAMP), Campinas, Brazil. ²Universidade Federal de Minas Gerais (UFMG), Belo Horizonte, Brazil.
 (No relevant relationships reported)

PURPOSE: Sleep is directly responsible for the recovery of energy spent during wake period, besides being fundamental in the development and maintenance of metabolic activities of the organism. The objective of the study was to evaluate the wake-sleep cycle of wheelchair rugby athletes during two stages of the regular season of the sport. **METHODS:** Six professional wheelchair rugby athletes of the Minas Quad Rugby team of Belo Horizonte (MG/BR), this team has national relevance being two times national champions and having players that are frequently called to represent the Brazilian national team during official competitions. The athlete used the actigraph, a watch like equipment responsible for measuring the wake-sleep cycle utilizing an accelerometer and noninvasive procedure. It is considered to be gold standard to this kind of measure. The equipment was used for 10 consecutive days in two moments: 1) pre-season; 2) competitive period with the actigraph the athletes also received the sleep diary, it is a registration of any occurrences while using the equipment. The actigraph provided the following measurements: time he laid down, time he slept, time he woke up, time he got up, also sleep latency, sleep efficiency, total sleep time and wake after sleep onset. In addition, the players still responded to an anamnesis, and the questionnaires of daytime sleepiness (Epworth), subjective quality of sleep (Pittsburgh) and chronotype. **RESULTS:** Results showed that wheelchair rugby athletes had

poor sleep quality in both stages. The athletes also demonstrated oscillations in the sleep-wake cycle depending on their routines, that is during the rest days the players presented different sleep measurements when compared with training session days and with competition days, at this time of the study there were significant results found analyzing the following variables: total sleep time ($p=0.04$), sleep efficiency ($p<0.01$) and wake after sleep onset ($p=0.01$). GLM-ANOVA.

CONCLUSIONS: With the current study it can be concluded that professional wheelchair rugby players have poor sleep quality and their sleep oscillates during the regular season of the sport, even more, the athletes have sleep oscillations depending on the characteristics of their routine.

Poor Sleep Quality is Associated with Elite Soccer Injuries

Andressa Silva, Fernanda V. Narciso, Igor Soalheiro, Fernanda Viegas, Luísa S. Freitas, Adriano Lima, Bruno A. Leite, Haroldo Christo-Aleixo, Marco T. De Mello. *Universidade Federal de Minas Gerais, Belo Horizonte, Brazil.*
 Email: silvaddressa@gmail.com
 (No relevant relationships reported)

PURPOSE: The present study proposed to investigate a relationship between sleep quality and quantity and muscular injuries in elite soccer players.

METHODS: The current investigation was a prospective cohort study of elite soccer players competing for two teams at the highest level of Brazilian competition. Data were collected for 23 players for one season (6 months). The players' sleep behavior was monitored using self-report sleep diaries and a wrist activity monitor the actigraph Actiwatch 2 (Philips Respironics®, Andover, MA) was used to continuously measure athletes rest-activity or sleep-wake cycles. The actigraph was worn on the non-dominant wrist of each athlete beginning on the first day of the assessment and remained there for 10 consecutive days. A specific database for injury recording was assembled and completed in conjunction with the medical team of each team on the day of the athlete's injury. Spearman's correlation coefficient was used to calculate the correlation between the variables. **RESULTS:** Our results indicated a moderate negative correlation between sleep efficiency and injury characteristics of the 23 soccer players (Absence time: $r=-0.524$, $p=0.01$; Injury severity: $r=-0.674$, $p<0.01$; Amount of injury: $r=-0.624$, $p<0.01$). The linear regression analysis indicated that for each increase in the score for sleep efficiency, amount of injury (number) decreased 0.06 ($R^2 = 0.44$) and absence time after injury (days) decreased 1.43 ($R^2 = 0.23$). Additionally, the results showed that for each increase in the Wake After Sleep Onset, amount of injury increased 0.02 ($R^2 = 0.30$).

CONCLUSIONS: It can be concluded that soccer players with poor sleep quality or nonrestorative sleep are prone to the risks of musculoskeletal injuries. Supported by UFMG, FAPEMIG, CAPES and CNPQ.

Growth or Destruction: Bone Marrow Edema Pathways**

Arya Minaie, Karen Myrick, Bernadette Mele, Richard Feinn, Thomas Martin, Juan Garbalosa. *Quinnipiac University, Hamden, CT.*

Email: arya.minaie@quinnipiac.edu

(No relevant relationships reported)

PURPOSE: Bone Marrow Edema (BME) is a common incidental finding on MRI in athletes. While the etiology and composition are not well understood, it has been linked to potential long-term adverse events such as osteoarthritis. The purpose of this study was to 1) describe the fat fraction (FF) of BME lesions in female athletes and 2) establish if demographic risk factors can predict magnetic resonance spectroscopy (MRS) compositional results.

METHODS: A prospective cohort of Division I female athletes, without previous ligamentous tears or surgery of the knee, were recruited to undergo a 1.5T screening MRI of each distal femur. Three readers assessed the MRI's separately for the presence of BME as well as a quantitative KOSS score. Subjects were invited two weeks later, to be scanned using a 3T MRI with Single-voxel 1H Spectra to evaluate the fat: water ratio of the BME lesions using the aid of the readers to guide voxel placement to avoid the femoral cortex and target the zone of maximal BME. Measured peaks were reported as FF = (Fat Content / (Fat Content + Water Content)) * 100. A multilevel linear mixed model was used to determine significant findings in bone marrow composition.

RESULTS: Seven female athletes (mean age: 19.1 ± 1.2 years, weight: 69.7 ± 10.0 kg, height: 166.9 ± 5.0 cm, and BMI: 25.0 ± 3.3 kg/m²) met our inclusion criteria. Eight knees were positive for BME, with 6 negative, demonstrating a total KOSS distribution between 0-2 (median; 1.0). There were no differences in water or fat content by BME status, however, positive knees had a higher FF than negative knees (p=0.058; 12.4% ± 1.3% vs. 11.0% ± 0.8%). The effect size of the difference was very large (d=1.30). In two athletes with unilateral BME, the FF of the knee with BME was greater than that of the knee without BME. BMI, sport, leg dominance, and KOSS score were not significantly correlated with FF.

CONCLUSIONS: To the best of our knowledge, this study is the first of its kind to describe the FF of knees with and without BME in female athletes. The increased FF found in BME-positive knees supports the case for the sequential development of fat metaplasia following acutely transient BME. Future research should be aimed at following individuals with BME over time with T1-weighted MRI imaging to look for non-age related changes in FF.

(No relevant relationships reported)

Both leptin (Lep) and estradiol (E2) influence bone formation. However, the combinatory effects of Lep and E2 on bone microstructure require further elucidation. Purpose: To investigate whether central Lep gene expression and/or systemic E2 treatment alter cancellous bone microstructure in male rodents. Methods: 3-month-old male Sprague-Dawley rats (n=28) were assigned to the following groups: 1) Vehicle-Lep (Veh-Lep) (n=7), 2) E2-Lep (n=9), 3) Veh-green fluorescence protein control (Veh-GFP) (n=5), or 4) E2-GFP (n=7). Lep or GFP (control) were delivered into the third ventricle of the brain at a dose of 1 mL of rAAV1 (2.3 x 10¹³ vg/mL). E2 (25 µg/kg diluted in 0.5 ml/kg sesame oil) or Veh (sesame oil, 0.5 ml/kg) were injected subcutaneously on a daily basis. At day 24, femurs were excised and analyzed via ex vivo micro-CT. The outcomes reported were: 1) cancellous bone volume/total volume (cBV/TV, %), 2) trabecular thickness (Tb.Th, mm), 3) trabecular number (Tb.N, #/mm), 4) trabecular separation (Tb.Sp, mm), and 5) trabecular pattern factor (Tb.Pf). Separate One-Way ANOVAs were performed and Tukey's post hoc tests were used when appropriate. Results: Both E2 treated groups exhibited directionally higher cBV/TV when compared with Veh-GFP (controls), while Veh-Lep displayed

directionally lower cBV/TV vs controls, although, these values did not reach the level of statistical significance. In comparison, the Veh-Lep group exhibited 40% lower cBV/TV vs E2-GFP, characterized by 35% lower Tb.N and 64% higher Tb.Sp (all p<0.05). Veh-Lep also exhibited higher Tb.Pf than E2-GFP (p<0.01), indicating a less connected trabecular network. Correspondingly, Veh-Lep displayed 36% lower cBV/TV and higher Tb.Pf values compared to E2-Lep (p<0.05). No significant differences were observed between the E2-GFP and E2-Lep groups for any cancellous outcome. Conclusion: Our data indicate that neither the combination nor individual administration of E2 and Lep produced higher cancellous bone outcomes than Veh-GFP controls. However, E2 treated groups exhibited higher cBV/TV than Lep treated groups. Further investigation is necessary to determine whether E2 stimulated bone accretion and/or whether Lep suppressed bone gain in our male rodent model.

(No relevant relationships reported)

The osteogenic index (OI) has been used to estimate the potential effectiveness of an exercise protocol on bone adaptations. It is speculated that splitting a training program into multiple daily sessions while incorporating rest periods in between loading sessions is more advantageous than all loading occurring during a single bout of exercise.

PURPOSE: To test the hypothesis that two (2EX) vs one (1EX) session per day of ballistic resistance exercise produces greater adaptations in markers of bone turnover when equated for total exercise volume but differing in OI.

METHODS: Seventeen healthy individuals (6M/11W; 21.7 ± 3.7 y (mean ±SD), body mass (kg): 67.3 ± 11.2; height (cm): 165.2 ± 11.6; body fat (%): 31.3 ± 9.0) volunteered for the study. Participants performed ballistic non-linear periodized resistance training three days per week in either the 1EX (3M/8W) or 2EX (3M/3W) group. An acute exercise test (AET; 10 sets of 10 plyo-jumps; Plyopress 625 III) was done at pre- (PreTr) and post-intervention (PostTr). Serum markers of bone turnover were analyzed immediately prior to (PreEx) and following (0 and 60 minutes PostEx) the AET using immunoassays. These included markers of bone formation (BAP, Osteocalcin, P1NP) and resorption (TRAP, CTx), and a hormonal marker (Vitamin D). PreTr vs PostTr changes in biomarker AET-induced responses were compared across groups using integrated area under the curve (AUC) analyses from the 90 minutes surrounding the AET (PreEx to 60 minutes PostEx) and 2x2 RMANOVA using GraphPad Prism software.

RESULTS: There were no significant group × time interactions for any bone biomarker (p≥0.05). However, there were significant main training effects for BAP and P1NP, such that AUC concentrations increased by 9.9% and 14.3% respectively, following training (Mean ± SD; BAP PreTr: 2002 ± 1653 vs. PostTr: 2201 ± 1783 U/L*90min, p=0.01; P1NP PreTr: 5898 ± 7321 vs. PostTr: 6742 ± 7124 µg/L*90min, p=0.03).

CONCLUSION: Exercise-induced markers of bone formation increased following 12 weeks of ballistic periodized resistance training, with no differences between exercise programs differing in OI. Markers of bone resorption did not change following training. This indicates that the ballistic exercise training program stimulated favorable changes in bone turnover, regardless of training frequency.

Cortical and Trabecular Bone Morphology in Response to Exercise and a Ketogenic Diet**

Matthew C. Scott¹, Scott E. Fuller², James D. Watt³, Michelle L. Osborn⁴, Neil M. Johannsen¹, Brian A. Irving, FACSM¹, Robert C. Noland⁵. ¹Louisiana State University, Baton Rouge, LA. ²University of Louisiana at Lafayette, Lafayette, LA. ³Louisiana State University School of Medicine, New Orleans, LA. ⁴Louisiana State University School of Veterinary Medicine, Baton Rouge, LA. ⁵Pennington Biomedical Research Center, Baton Rouge, LA. (Sponsor: Brian Irving, FACSM)

Email: mscot26@lsu.edu

(No relevant relationships reported)

Adopting a ketogenic diet (KD) is becoming increasingly popular, partly due to favorable impacts on blood glucose and body composition. Recent research has demonstrated possible negative effects of a KD on bone morphology in mice, but interactions with exercise, which sometimes accompanies health-oriented diet changes, have not been examined. **PURPOSE:** To determine the effects of a KD and aerobic

exercise on cortical and trabecular bone morphology in mice. **METHODS:** Forty C57BL6 mice were randomized into 4 groups (n=10/group); 2 groups were fed a low-fat control diet (16% protein, 72% carbohydrate, 12% fat) with one group performing vigorous intensity (blood lactate >4mM post-exercise) daily treadmill exercise (CEX), while the other served as sedentary controls (CSED). The remaining 2 groups were fed a high-fat, carbohydrate-deficient KD (16% protein, 84%fat) with one exercise group (KEX) and one sedentary control group (KSED). Treatment diets began 6 weeks pre-euthanasia and the exercise intervention occurred during the final 3 weeks. Femurs were analyzed for bone morphology using micro-computed tomography. Analysis variables included bone volume, ratio of bone to total volume, thickness, and bone mineral density (BMD) for both cortical and trabecular bone; trabecular number, spacing, and connectivity were also included. **RESULTS:** Two-way factorial ANOVA revealed an exercise effect on trabecular thickness (p=0.002) and an interaction between diet and exercise for trabecular BMD (p=0.038). Post-hoc analysis showed 5.8% thicker trabeculae in exercise groups, CEX & KEX, compared to sedentary groups, CSED & KSED, (47.7±0.6µm vs. 45.1±0.5µm, p<0.05). Trabecular BMD was 3.0% higher in CEX compared to CSED (776.7±5.8mgHA/cm³ vs. 754.0±5.2mgHA/cm³, p<0.05), whereas trabecular BMD was statistically similar between KEX and KSED (757.5±6.2mgHA/cm³ vs. 759.5±5.5mgHA/cm³, p=0.99). No other significant effects or interactions were found. **CONCLUSION:** The positive effect of exercise on bone morphology shown in this research is in line with that found in the literature. Our results did not identify any detriments in bone morphology in response to a ketogenic diet alone, but BMD changes induced by exercise in mice fed a control diet were negated by the ketogenic diet.

 (No relevant relationships reported)

PURPOSE: Habitual mechanical loading during pubertal stages has consistently been associated with current and future anabolic effects on bone characteristics. However, the specific aspects of mechanical loading that bring about anabolic effects are yet to be established. The present study investigated the relationship between soccer specific loading patterns and subsequent bone adaptation in youth soccer players.

METHODS: 17 elite adolescent soccer players (mean ± SD = age: 16.3±0.5 years; height: 1.79±0.07m; body mass: 74.9±6.7 kg) gave informed consent to take part in a study approved by the National Research Ethics Service. Peripheral quantitative computed tomography scans of the tibia of the dominant leg were taken at the beginning of pre-season training and 12-weeks later. Tibial mass (g), trabecular area (mm²), cortical area (mm²) and density (mg/cm³), periosteal circumference (mm) and strength strain index (SSI) (mm³) at the 4, 14, 38 and 66% sites were measured. During the 12 week training period, workload was quantified using a global positioning system (GPS). The following metrics were analysed: session duration (min), total distance covered (m), and high-speed running distance (17.0 km·h⁻¹). Changes in bone characteristics were assessed using paired sample t-tests, and associations between GPS metrics and bone adaptation were assessed using Person's correlation coefficient. **RESULTS:** Tibial mass increased by 2.9, 1.2 and 0.7% at the 4, 14 and 38% tibial sites (P < .05). SSI (38%; 2337.1±340.9 compared to 2383.1±317.3, P = .05) and cortical area (38%; 380.9±23.2 mm² compared to 383.1±30.8 mm², P = .02) increased following 12-weeks of soccer specific training. Average session duration was positively correlated with increased trabecular area (4%; P=.02, r=0.61) and periosteal circumference (38%; P=.03, r=0.55). Average high-speed running was positively correlated with changes in SSI (14%; P=.05, r=0.51) and cortical density (38%; P=.05, r=0.52).

CONCLUSIONS: Soccer specific training increases tibial bone characteristics at the 4, 14 and 38% sites. Moreover, session duration and high-speed running were associated with increased tibial strength, size and density following 12-weeks of soccer specific training. These factors should be considered when recommending exercise for bone health.

Circulating Sclerostin and MicroRNA-21 Are Predictors of Bone Mineral Density in Postmenopausal Women

Zhaojing Chen¹, Samuel R. Buchanan², Michael G. Bembem, FACSM², Debra A. Bembem, FACSM². ¹California State University, San Bernardino, San Bernardino, CA. ²University of Oklahoma, Norman, OK. (Sponsor: Debra Bembem, FACSM)
 Email: zjchen@csusb.edu
 (No relevant relationships reported)

Sclerostin is a potent inhibitor of the Wnt signaling pathway, which inhibits osteoblasts to form new bone (Turner et al., 2009). MicroRNAs (miRNAs) are short, non-coding RNAs that fine tune posttranscriptional gene expression. Recent research has shown that some circulating miRNAs (c-miRNAs) are upregulated in osteoporotic fracture individuals (Seeliger et al., 2014). Since both sclerostin and miRNAs regulate signaling pathways in bone, together they may be potential biomarkers of bone health. **PURPOSE:** To examine the relationships between serum sclerostin and specific c-miRNAs and to predict bone mineral density (BMD) based on circulating sclerostin and miRNA levels. **METHODS:** Seventy-three postmenopausal women aged 60 to 85 years old participated in this study. Body composition and aBMD of the total body, lumbar spine and hips were measured by DXA. Osteoporosis was determined using aBMD T-scores at lumbar spine, femoral neck, or total hip according to WHO criteria (aBMD T-score ≤ -2.5). Serum levels of sclerostin and bone resorption markers (CTX, TRAP5b) were measured by ELISA. Total RNA was extracted from serum, and relative expression levels of c-miRNAs (miR-21, -23a, -24, -100, -125b) were analyzed using miRNA assays and real-time PCR. **RESULTS:** There were no significant correlations between serum sclerostin and c-miRNAs. Serum sclerostin was significantly negatively correlated with CTX (r = -0.252, p<0.05). Sclerostin levels were significantly lower in the osteoporotic group (n=10, 0.560 ± 0.158 ng/mL) compared to the normal BMD group (n=14, 0.776 ± 0.190 ng/mL) (p<0.05). Stepwise regression analysis showed that miR-21 and sclerostin levels were significant predictors of BMD at all sites (standardized coefficient β (sclerostin)= 0.398 to 0.520, standardized coefficient β (miR-21)= -0.248 to -0.317, adjusted R²= 0.238 to 0.332, p<0.001). **CONCLUSION:** Our results indicate that circulating sclerostin and miR-21 are significantly associated with bone mineral density in postmenopausal women. Further studies are needed to examine the common signaling pathways that sclerostin and miR-21 regulate in bone metabolism.

 (No relevant relationships reported)

BACKGROUND: The Physical Activity Guidelines for American Adults recommend the equivalent of 150 minutes of moderate intensity aerobic activity each week without specifying the exercise modality. Running (weight bearing) and cycling (non-weight bearing) are common aerobic activities. However, they differ in their mechanical impact on the bone. Bone turnover (formation & resorption) can be reflected by circulating bone markers, bone specific hormones and cytokines (osteokines) released from the dynamic remodeling of bone. **PURPOSE:** To compare the bone marker response to running versus cycling at the same moderate-intensity target Heart Rate (HR). **METHODS:** 13 healthy male adults (23.7 ± 1.0 yr.) completed 4 laboratory visits. Participants performed two progressive exercise tests to exhaustion on cycling ergometer (CE) and treadmill (TM) to determine peak VO₂ and peak HR. On subsequent separate days, in a randomized order, participants performed a 30-min constant exercise challenge at 70% HR reserve (HRR) on CE and TM. Blood was drawn before (Pre), immediately post (IP) and 1h into recovery (Rec) and analyzed for lactate, osteocalcin, sclerostin and parathyroid hormone (PTH). Two-way ANOVA was used to evaluate within-person differences with time (Pre/IP/Rec) and exercise modalities.

RESULTS: 70% HRR was successfully clamped during CE and TM (CE 156.7 ± 0.4; TM 159.3 ± 0.7 bpm). Exercise on CE elicited higher IP lactate (6.2 ± 1.1 Vs 2.9 ± 1.1 nmol/l, p<0.01) and 13.7% lower O₂ uptake. At IP sclerostin increased significantly (p=0.0007) only in TM (49% Vs. 16% p=0.004). PTH had similar transient increase at IP in both modalities (p<0.001). No significant changes were observed in osteocalcin in both modalities.

CONCLUSIONS: 30 min of running and cycling at 70% HRR lead to a metabolic bone response immediately after the exercise in both modalities. While PTH, an essential factor for calcium metabolism and bone formation, increased significantly

and similarly at IP in both modalities, sclerostin (inhibitor of bone formation) increased significantly only in TM. This may reflect higher impact on the bone during running compared to cycling.

Bone Mineral Density Comparisons Between Contact and Non-Contact Male and Female Collegiate Athletes
 Dalton E. Cousin, Michelle L. Eisenman, Emily L. Langford, Ronald L. Snarr, Greg A. Ryan. *Georgia Southern University, Statesboro, GA.*
 Email: dc08163@georgiasouthern.edu
 (No relevant relationships reported)

Bone mineral density (BMD) and bone mineral content (BMC) have been suggested to be greater in athletes than non-athletes. However, less research has been done comparing the nature of the sport and the impact that has on BMD and BMC in male and female collegiate athletes. **PURPOSE:** To determine the effects of BMD and BMC between full contact (FC), limited contact (LC) and non-contact (NC) sports in male and female athletes. **METHODS:** Data from 45 male (FC [football]: 18, LC [basketball, baseball, soccer]: 21, NC [cheer, tennis, golf]: 6) and 33 female (FC: 0, LC [basketball, softball, soccer]: 16, NC [cheer, tennis, volleyball, swimming, rifle, track]: 17) Division I athletes was collected via whole body dual-energy x-ray absorptiometry (DXA). One-way ANOVAs (male and female) were run to compare BMD, BMC and, body fat percentage (BF%) between sports. **RESULTS:** A main effect significant difference was noted between BMD ($F(2,44) = 9.79, p < 0.01$) and BMC ($F(2,44) = 12.15, p < 0.01$) in male athletes. Post-hoc LSD analysis revealed that significance in all variables was between FC (BMD: 1.46 ± 0.09 g/cm³) compared to LC (1.36 ± 0.89 g/cm³, $p < 0.01$) and NC (1.31 ± 0.11 g/cm³, $p < 0.01$). Similarly, difference in BMC were between FC (4322.9 ± 564.3 g) compared to LC (3639.6 ± 485.0 g, $p < 0.01$) and NC (3403.3 ± 295.6 g, $p < 0.01$). BF% was not significantly different between any group ($p = 0.09$). No significant differences were noted with female athletes in any of the variables: BMD (LC: 1.22 ± 0.07 g/cm³, NC: 1.24 ± 0.07 g/cm³, $p = 0.29$); BMC (LC: 2797.6 ± 382.7 g, NC: 2883.8 ± 361.7 g, $p = 0.51$); BF% ($p = 0.29$). **CONCLUSION:** The nature of the sport may have an impact on an athlete's BMD and BMC, but only if the athlete competes in a FC sport, where sufficient sustained compression occurs to increase bone formation.

Head Impact Exposure Alters Neural Synchrony and Complexity in Collegiate Athletes
 Derek C. Monroe, Nicholas C. Cecchi, James W. Hicks, Steven L. Small. *University of California, Irvine, Irvine, CA.*
 Email: dcmonroe@uci.edu
 (No relevant relationships reported)

White matter connects neighboring and distant cortical regions and is the basis for brain circuits. Regular exercise strengthens these connections, but athletes participating in contact sports, including water polo, are at risk for repeated head impacts capable of damaging white matter and impairing brain circuit function. One way of measuring functional connectivity of these circuits is through resting-state electroencephalography (EEG). **PURPOSE:** To test the hypothesis that repeated head impact exposure reduces fast-rhythm ('gamma') synchrony and an associated increase in slow-rhythm complexity. **METHODS:** Intercollegiate water polo players (9 Men; 10 Women) were tested before and after the season. During the testing, each player sat with eyes closed for five minutes wearing a 32 dry-electrode EEG cap (sampling rate = 500 Hz). From the pre-processed EEG data, we computed debiased weighted phase lag index (dWPLI) as a measure of gamma (30-50 Hz) synchrony and multiscale entropy (MSE) as a measure of neural complexity. Athletes were monitored during competitions for head impacts using cap-worn inertial sensors to quantify peak linear acceleration (PLA), rotational acceleration (PRA), and rotational velocity (PRV). Cumulative exposure (twPCA) was computed per athlete by summing principal component 'magnitude' scores (representing PLA, PRA, and PRV) weighted by time (1/days) relative to post-season assessment. Mediation analysis was performed using

a series of linear regression analyses to test the relationships among twPCA, gamma dWPLI, and MSE at fine (500 Hz), moderate (33-250 Hz), and coarse (12-30 Hz) timescales. **RESULTS:** Greater twPCA was associated with a loss of gamma dWPLI [$r(17) = .709, p < .001$]. There was a significant indirect effect of twPCA on MSE across moderate time-scales [$\beta = 0.456$; 95% CI(0.048, 1.0432), $p = 0.04$]. Approximately 25% of the variance in MSE was accounted for by the mediator, gamma dWPLI ($R^2 = 0.247$). There was no mediation effect on MSE at fast or course time-scales ($p > .06$). **CONCLUSIONS:** One season of repeated head impact exposure altered brain dynamics in a dose dependent manner. The loss of fast-rhythm synchrony in athletes sustaining the greatest exposure contributed to a loss of complexity that could represent distributed and inefficient information processing at rest.

Concussion History Impairs Cerebrovascular Reactivity in Special Operations Forces Personnel
 Patricia R. Combs¹, Avinash S. Chandran¹, Nikki E. Barczak¹, Stephen M. DeLellis², Cassie B. Ford¹, Marshall L. Healy², Shawn F. Kane, FACSM², James H. Lynch, FACSM², Gary E. Means², Jason P. Mihalik¹. ¹*University of North Carolina at Chapel Hill, Chapel Hill, NC.* ²*United States Army Special Operations Command, Fort Bragg, NC.*
 Email: pcombs@live.unc.edu
 (No relevant relationships reported)

Concussion has been an increasingly prevalent blast-related injury in Special Operations Forces (SOF) personnel over the last decade. Recent studies suggest physiological deficits, such as cerebrovascular function, may outlast clinical recovery following injury. Cerebrovascular reactivity (CVR) measures the cerebral blood flow response to variations in carbon dioxide partial pressures. Understanding how concussion history affects CVR may better inform physiological assessment and long-term outcome management following concussion. **PURPOSE:** To investigate how concussion history influences CVR in SOF personnel. **METHODS:** Thirty-nine SOF personnel completed a demographic survey self-reporting concussion history (concussion history = 22 (56.4%); age = 34.3yrs \pm 3.7 yrs) They were instrumented with transcranial Doppler (TCD) ultrasound to assess middle cerebral artery velocity (MCAv). Baseline TCD data were collected for 2 minutes. Changes in MCAv were measured in response to 5 breath-holding trials (30s breath-hold/30s rest) and 5 hyperventilation trials (30s hyperventilation/30s rest). We employed mixed effects models with quadratic mean structures to assess group differences in MCAv response to breath-holding and hyperventilation tasks. **RESULTS:** Baseline resting MCAv did not significantly differ ($t_{33} = -0.47, p = 0.64$) between those with (MCAv = 50.8 ± 7.7 cm/s) and those without (MCAv = 49.6 ± 8.1 cm/s) concussion history. The MCAv response did not differ between those with and without concussion history during breath-holding ($F_{1,1909} = 0.20, p = 0.90$) or hyperventilation ($F_{1,1909} = 0.31, p = 0.58$). Among SOF personnel with concussion history, those with ≥ 3 had significantly diminished CVR response relative to those with 1-2 concussions during the breath-holding ($F_{1,1125} = 4.84, p = 0.03$) and the hyperventilation ($F_{1,1125} = 5.07, p = 0.02$) tasks. **CONCLUSIONS:** Changes in MCAv did not differ under resting conditions; however, SOF personnel with a greater concussion history showed impaired CVR when tested with physiological breathing stressors. While long-term neurophysiological effects of blast-related injury are currently unknown, assessing CVR response may provide further insight into cerebrovascular function and overall physiological health following blast exposure.

2720 Board #3 May 31 1:00 PM - 3:00 PM
Prefrontal Cortex Neural Function and Decision-making Performance Following a Long Duration Incremental Exercise Protocol in the Heat while Wearing Personal Protective Equipment
 Cory Coehoorn¹, Lynne Stuart-Hill¹, Olave Krigolson¹, Patrick Neary². ¹*University of Victoria, Victoria, BC, Canada.* ²*University of Regina, Regina, SK, Canada.*
 (No relevant relationships reported)

There is no research to date evaluating the effects of rapid and uncompensable core temperature (T_c) acquisition, as which occurs when one is wearing personal protective equipment (PPE), on neural function in prefrontal cortex and decision-making performance. **PURPOSE:** To study the effects of rapid and uncompensable T_c acquisition on neural function in prefrontal cortex and decision-making performance during a pre-and post-exercise Go/No-go test. **METHODS:** Fifteen male subjects (mean age, 32.7 \pm 12.2 years) performed an incremental exercise test to a termination criterion in CONTROL and GEAR. Electroencephalography (EEG) data was recorded during a Go/No-go test pre- and post-exercise. Decision-making performance was also monitored during the pre-and post-exercise Go/No-go test. Heart rate (HR), thermal comfort scale (TCS), thermal sensation (TS), and rating of perceived exertion (RPE) were recorded at each 0.5°C increase in T_c. **RESULTS:** There were significant differences in time to termination (TTT) (CONTROL = 77.3 \pm 12.6 min; GEAR = 50.3

± 6.9 min), pre-exercise HR (CONTROL = 76.8 ± 4.8 bpm; GEAR = 86.5 ± 5.1 bpm) and post-exercise HR (CONTROL = 161.1 ± 11.9 bpm; GEAR = 179.6 ± 6.8 bpm). Additionally, there were significant differences between CONTROL and GEAR end-exercise Tc (CONTROL = 38.57 ± 0.3°C; GEAR = 39.01 ± 0.3°C), TCS (CONTROL = 3.57 ± 0.6; GEAR = 4.63 ± 0.3), and TS (CONTROL = 7.57 ± 0.5; GEAR = 8.67 ± 0.3). Lastly, there was a 0.04°C/min increase in Tc during GEAR and 0.02°C/min increase in Tc during CONTROL. An analysis of frontal theta EEG power results showed a significant decrease when comparing pre- and post-exercise values during a Go/No-go test in GEAR ($F_{(1,14)} = 6.069, p = 0.027$). There was also a significant difference when evaluating incorrect responses between pre- and post-exercise values in GEAR ($F_{(1,14)} = 5.515, p = 0.026$). These differences were not observed during CONTROL. **CONCLUSION:** These data suggest that a long duration incremental exercise test while wearing PPE in the heat results in decreased cognitive control. This could have implications individuals in occupations that wear PPE and need to make critical decisions while experiencing rapid and uncompensable Tc heat storage.

Concussion and the Pupillary Light Reflex: Implications for Special Operations Forces Personnel

Christina B. Vander Vegt¹, Cassie B. Ford¹, Johna K. Register-Mihalik¹, Stephen M. DeLellis², Marshall L. Healy², Shawn F. Kane, FACSM², James H. Lynch, FACSM², Gary E. Means², Jason P. Mihalik¹. ¹The University of North Carolina at Chapel Hill, Chapel Hill, NC. ²United States Army Special Operations Command, Fort Bragg, NC.

Email: cbv33@email.unc.edu

(No relevant relationships reported)

Pupillary light reflex (PLR) is regulated by smooth radial muscles differentially innervated by sympathetic and parasympathetic pathways. The PLR has been posited as an autonomic nervous system (ANS) function index and a concussion biomarker. Few studies have examined static and dynamic PLR parameters in Special Operations Forces (SOF) combat and combat support soldiers. **PURPOSE:** To examine cross-sectional relationships between concussion history and PLR parameters in SOF personnel with and without concussion history. **METHODS:** The SOF personnel self-reported age and concussion history (0, 1, 2, and ≥3), and completed an assessment battery including PLR. We measured seven PLR parameters including initial and final pupil diameters, constriction and dilation velocities, constriction latency, time to 75% initial diameter recovery, and average maximum constriction velocity. These parameters were averaged across both eyes and separately regressed on concussion frequency while controlling for age (*a priori* $\alpha = 0.05$). **RESULTS:** The SOF personnel ($n = 76$; mean age = 33.5 ± 3.6 years) reported the following concussion histories: ≥3 concussions ($n = 19$; 25%), two ($n = 8$; 10.5%), one ($n = 7$; 9.2%), and none ($n = 42$; 55.3%). Initial ($\beta = -0.07$; 95% CI: -0.13, -0.02) and final ($\beta = -0.05$; 95% CI: -0.09, -0.004) pupil diameters were smaller with age increases in SOF personnel, controlling for concussion history. Similarly, those who reported ≥3 concussions had significantly smaller initial pupil diameter compared to those without concussion history, controlling for age ($\beta = -0.53$; 95% CI: -0.98, -0.08). Those who reported ≥3 concussions also exhibited slower average ($\beta = 0.46$; 95% CI: 0.07, 0.84) and maximum ($\beta = 0.64$; 95% CI: 0.12, 1.15) constriction velocities than those without a concussion history, controlling for age. **CONCLUSIONS:** The SOF personnel with greater head injury history had altered static and dynamic pupillary light responsivity, which may indicate prolonged ANS dysfunction. Our group's previous neuroimaging findings demonstrate prolonged physiological deficits beyond self-reported symptom resolution and clinical recovery from concussion. The PLR is a rapid, non-invasive, cost effective tool that may assess deficits warranting further clinical investigation.

Development of a Lower Body Negative Pressure Device to Reduce Intracranial Pressure in Hospitalized Patients with Traumatic Brain Injury

Dean Palmer¹, Justin Lawley¹, Tony Whitworth², Bert Vargas². ¹IEEM, Dallas, TX. ²Parkland Hospital, Dallas, TX. (Sponsor: Benjamin D. Levine, FACSM)

(No relevant relationships reported)

Elevations of intracranial pressure (ICP) are common in patients with a severe traumatic brain injury (TBI) with sustained elevations predicting morbidity and mortality. Aggressive management of elevated ICP is recommended and there is a need for non-invasive treatments that are complementary to existing surgical options. Using direct invasive recordings of ICP in three healthy subjects via implanted Ommaya reservoirs, this laboratory observed a robust reduction in ICP during lower body negative pressure (LBNP) in the head-down tilt (HDT) position. **PURPOSE:** Develop a novel LBNP device that is suitable for use with hospitalized patients, which will be safe and well tolerated by patients with TBI, and will improve intracranial stability, patient disability and reduce the time from admission to discharge from the ICU. **METHODS:** Working with a team of ICU nurses, neurointensivists, engineers

and physiologists, a comfortable, stable LBNP chamber was developed with sufficient access to the patient to allow standard of care for severe TBI patients. Studies to test this device in the ICU are ongoing and will impose low level LBNP (-20mmHg) 8 hours/day for 3 days. Throughout all interventions, hemodynamics and cerebral perfusion pressure will be monitored to maintain perfusion greater than 60mmHg and ICP will be carefully monitored for changes in intracranial pulse pressure. **RESULTS:** See figure for ICU based LBNP chamber design.

CONCLUSION: Previous work by our group (Petersen et al, J Physiol 2018) showed that low level LBNP can reduce ICP safely in healthy controls. We have built a novel LBNP chamber for use with hospitalized patients that may lower ICP non-invasively in patients, thus improving patient outcomes.

Locus of Control Ratings do not Predict Concussion Reporting Intentions in Intercollegiate Athletes

Melissa Anderson, L. Stephen Miller, Michelle L. Weber, Julianne D. Schmidt. University of Georgia, Athens, GA.

Email: melissa.anderson@uga.edu

(No relevant relationships reported)

Identification of all sport-related concussion continues to be challenging in part due to the lack of reporting by athletes. It is estimated that approximately 50% of all sport-related concussions at the collegiate level go unreported, however, reasons for failing to disclose a potential concussion are still unclear. In order to improve concussion reporting, we must identify factors that contribute to an athletes' intentions to report. Student-athletes that identify as having more control over the outcomes in their life may feel a stronger sense of control over whether they will report a suspected concussion to a medical professional.

PURPOSE: To examine the relationship between locus of control ratings and concussion reporting intentions in student-athletes.

METHODS: Student-athletes from three universities were invited to complete a Qualtrics survey ($n=206/498$ response rate = 41.36%, male=34.46%). The Levenson Multidimensional Locus of Control (LOC) scale is a 24 item survey that measures Internal Locus of Control (8 items), Powerful Others (8 items), and Chance (8 items). All items were answered on a six-point Likert scale ranging from 1 (strongly disagree) to 6 (strongly agree). Three separate Spearman's rank-order correlations were used to determine whether LOC sub-scores (Internality, Powerful Others and Chance) correlated concussion reporting intentions ($\alpha=0.05$).

RESULTS: Locus of control sub-score ratings did not significantly correlate direct intentions; Internality ($r_s = .055, p = .545$), Powerful Others ($r_s = -.125, p = .169$), or Chance ($r_s = -.065, p = .474$). In addition, indirect intentions were not related to the LOC subscales; Internality ($r_s = .082, p = .367$), Powerful Others ($r_s = -.111, p = .223$), or Chance ($r_s = -.062, p = .497$).

CONCLUSION: Although LOC plays a role in predicting sport-related injuries risk and outcomes, it does not seem to significantly correlate with concussion reporting intentions in the current study. Results of this study suggest the importance of considering the multiple factors that may explain an athletes intentions to report concussions beyond just how much control they perceive to have over the outcomes in their life.

2724 Board #7 May 31 1:00 PM - 3:00 PM
Acute Exercise Effects on Fatigue in Individuals Living With Post-Traumatic Stress

Daniel R. Greene¹, Steven J. Petruzzello, FACSM². ¹Augusta University, Augusta, GA. ²University of Illinois at Urbana-Champaign, Urbana, IL. (Sponsor: Steven J. Petruzzello, FACSM)

(No relevant relationships reported)

Evidence has emerged highlighting the beneficial effects of exercise in reducing symptoms of Post-Traumatic Stress (PTS) and comorbid psychological conditions (e.g., anxiety, depression). However, most of these studies fail to address the effects of exercise on other disabling symptoms of PTS. **Purpose:** Examine changes in self-reported fatigue following an acute bout of moderate intensity continuous aerobic exercise (MICE) and a bout of high-intensity interval exercise (HIIE), relative to a no-exercise inactive control (SED), in participants with subsyndromal PTS. **Methods:** Using a within-subjects design, participants [*N*= 25, 16 females; age (*M* ± *SD*); 25.6 ± 9.1 yrs] completed three randomly ordered 35-min conditions (HIIE, MICE, SED). Participants reported an average PCL-5 score of 47.64 (exceeds cut-point for probable PTS of 33). Additionally, participants reported having at least one symptom in each of the major DSM-5 clusters of PTS. Fatigue was assessed before (Pre), immediate after (Post0), 20-min after (Post20), and 40-min after (Post40) each condition. **Results:** Significant Condition, Time, and Condition x Time effects were seen [all *P*s < 0.001]. For HIIE, fatigue increased from Pre to Post0 [Cohen's *d* = 0.90], decreased from Post0 to Post20 [*d* = 0.67], and decreased from Post20 to Post40 [*d* = 0.42]. Fatigue was not different Pre to Post40 HIIE [*P* = 0.31]. For MICE, Fatigue increased slightly from Pre to Post0 [*d* = 0.33], decreased from Post0 to Post20 [*d* = 0.91], and showed no change from Post20 to Post40 [*P* = 0.36]. Fatigue was reduced from Pre to Post40 MICE [*d* = 0.29]. Finally, fatigue decreased from Pre to Post0 SED [*d* = 0.48], showed no change from Post0 to Post20 or from Post20 to Post40, and was marginally reduced Pre to Post40 [*d* = 0.32]. **Conclusion:** Participants reported elevated fatigue Post0 HIIE, but fatigue returned to baseline by Post40. While fatigue was elevated Post0 MICE, at Post40 fatigue was reduced relative to Pre. The present study provides evidence that both HIIE and MICE result in immediate increases in fatigue in individuals living with PTS, but such increases are short-lived. Future studies need to assess chronic exercise effects on fatigue, as fatigue is a disabling symptom of PTS.

2725 Board #8 May 31 1:00 PM - 3:00 PM
Feasibility of Resistance Exercise Training in Gulf War Veterans with Widespread Pain

Jacob Ninneman¹, Aaron J. Stegner¹, Patrick J. O'Connor, FACSM², Jacob B. Lindheimer¹, Neda E. Almassi¹, Nicholas P. Gretzton¹, Ryan J. Dougherty¹, Kevin M. Crombie¹, Stephanie M. Van Riper¹, Dane B. Cook, FACSM³. ¹University of Wisconsin-Madison, Madison, WI. ²University of Georgia, Athens, GA. ³William S. Middleton Memorial Veterans Hospital, Madison, WI. (Sponsor: Dane B. Cook, FACSM)

(No relevant relationships reported)

Roughly 25-33% of US Veterans of Operations Desert Shield or Desert Storm report a constellation of chronic symptoms including fatigue, confusion and widespread pain. Although exercise is routinely prescribed, and found to be efficacious, for many chronic pain conditions; Veterans' reports of post-exertional exacerbation of symptoms complicates the question of whether exercise should be used as an adjunct treatment to standard care.

Purpose: To determine the safety and efficacy of a resistance exercise training (RET) program in Gulf War Veterans (GV) with chronic widespread musculoskeletal pain (CMP).

Methods: Gulf Veterans suffering medically unexplained CMP lasting at least 3 months (*N*=50) were randomized to either 16 weeks of twice weekly RET or wait-list control (WLC). Training was supervised by exercise specialists and consisted of 10 exercises targeting major muscle groups. The program started at a very low intensity [25-35% of estimated 1-repetition maximum (1-RM)] and progressed in small (≤5%) increments. Thus, training was both individualized and standardized. Testing of 1-RM was completed at baseline and reevaluated at 16 weeks. The McGill Pain Questionnaire (MPQ) and Profile of Mood States (POMS) were completed at weeks 1, 6, 12 and 16. Exercisers not completing >50% of training were excluded from statistical analyses (*n*=4). Average 1-RM values were compared using dependent t-tests, and MPQ and POMS data were evaluated using repeated-measures ANOVAs.

Results: The final sample consisted of 22 GV in the RET group, with >90% adherence, and 20 WLC Veterans. No drop outs were due to negative complications with exercise. Following RET, participants on average lifted 67 kg/kg of body weight and significant (*p*<0.05) 1-RM increases were observed in all 8 lifts. Estimated 1-RM increased by at least 20% for 7 of 8 lifts. Mood scores significantly improved in both groups over the course of the trial with no significant difference between groups. No time or group effects (*p*>0.05) were observed in MPQ scores.

CONCLUSIONS: RET significantly increased strength in GV with CMP. It resulted in no exacerbation of pain symptoms and did not increase mood disturbance. Resistance exercise appears safe and efficacious for Gulf Veterans with widespread pain. Supported by Dept. of Veterans Affairs grant: IO1-CX000383.

F-08 Thematic Poster - Physiological Responses in Firefighters

Friday, May 31, 2019, 1:00 PM - 3:00 PM

Exploring Factors Related To Blood Pressure Increase After A 12-hour Shift-work In Firefighters

Rosenkranz M. Nogueira¹, Edgard Soares¹, Eugênio Cesar Nogueira¹, Janssen Gomes¹, Guilherme E. Molina¹, Keila E. Fontana¹, Maria Korre², Denise Smith³, Stefanos N. Kales⁴, Luiz Fernando Junqueira Jr¹, Luiz Guilherme G Porto¹. ¹UNB, BRASILIA, Brazil. ²HAVARD, SARATOGA SPRINGS, NY. ³Skidmore College, Saratoga Springs, New York, SARATOGA SPRINGS, NY. ⁴Harvard T. H. Chan School of Public Health, Boston, MA, BOSTON, MA, MA.

(No relevant relationships reported)

Firefighters' job-related activities may expose firefighters (FF) to an elevated cardiac strain. **Purpose:** To evaluate the effect of a routine 12-hour shift work on blood pressure (BP) among career FF. **Methods:** We evaluated 30 male FF, aged 40±3.2 yrs, BMI = 26.3±3.1 kg/m². BP was measured in a basal condition on an off-duty day (Eva1) and before (Eva2) and after (Eva3) a 12-h shift work, in resting supine (SUP) and orthostatic (ORT) postures. A 3-way repeated measures ANOVA (BP, body position, time) with Bonferroni post-hoc was performed. A BP increase ≥4 mmHg was considered meaningful. To understand BP responsiveness we use independent T-tests between subgroups (overweight, obese, cardiorespiratory fitness (CRF) ≥12METs and by age). On-duty task effect on BP was performed with a sub analysis on those who increased diastolic BP. **Results:** ANOVA showed a significant effect of time, BP and position with significant mean BP increase of 3.5 mmHg from Eva 2 to 3. FF >40 yrs had a larger mean systolic BP increase than younger (12 vs 1 mmHg; *p*<0.01-Table 1). No differences were observed for those who had CRF≥12 METs, were overweight or obese. 5 FF (17%) had their systolic and diastolic BP meaningfully increased in SUP and ORT conditions: 12.2, 14.8, 10.2, 14.4 respectively. 4 of them (80%) participated in firefighting or emergency medical service (EMS). 16 FF showed a mean meaningful increase of 10.1 mmHg in diastolic BP during ORT condition, 14(88%) of them participated in EMS or firefighting. FF who performed fire fighting or a EMS had a 3.9 (95%CI 0.7-21.7) higher odds of having their diastolic BP meaningfully increased. **Conclusion:** There was an important relationship between FF on duty emergency tasks and cardiovascular strain. Older FF seemed more susceptible to present a negative cardiovascular response after 12-h shift work. The increase on BP was meaningful in most cases, especially diastolic BP, which could be associate to non-fatal cardiovascular events in susceptible firefighters.

| Table 1. Comparison of BP in SUP and ORT position, in all 3 conditions, in two groups divided by med | | | | |
|--|---------|--------------|--------------|--------------|
| | | EVA 1 | EVA 2 | EVA 3 |
| Age > 40 | SBP SUP | 125.4 ± 10.9 | 125.4 ± 11.6 | 129.0 ± 10.7 |
| | SBP ORT | 125.9 ± 14.1 | 120.7 ± 11.7 | 132.7 ± 18.5 |
| | DBP SUP | 79.0 ± 11.2 | 78.5 ± 6.0 | 78.8 ± 8.1 |
| AGE ≤ 40 | DBP ORT | 83.5 ± 10.3 | 80.7 ± 8.2 | 85.3 ± 10.7 |
| | SBP SUP | 120.3 ± 9.6 | 119.1 ± 8.2 | 120.1 ± 11.6 |
| | SBP ORT | 116.6 ± 11.6 | 119.0 ± 12.2 | 117.8 ± 15.6 |
| | DBP SUP | 72.4 ± 8.7 | 69.5 ± 6.1 | 74.0 ± 7.1 |
| | DBP ORT | 76.4 ± 11.3 | 77.6 ± 12.7 | 80.7 ± 10.9 |

Heart Rate Response Relative to Body Weight/Body Fat and Fire Gear During Walking Protocol

John P. Isaacs. *eastern kentucky university, richmond, KY.*
 (No relevant relationships reported)

INTRODUCTION: Fire gear serves a specific purpose in protecting individuals from the harsh environments around them when combating fires. Little research has been done on how gear weight relative to an individual's lean body mass (LBM) and body fat (BF) affects heart rate (HR). Being conscious of how the encumbrance of gear affects one's HR is important because over-exertion from load carriage could possibly cause a decrease in performance and increase the risk of a cardiac event. **PURPOSE:** To assess HR response among individuals based on LBM and BF relative to the weight of different combinations of fire gear during a walking protocol.

METHODS: 22 recreationally trained college students (age 22±3 y/o, wt. 81±17kg, ht. 177±10 cm) performed a walking protocol in personal protective equipment (PPE 9.1 kg.), oxygen pack and mask (PM 11.3 kg.), and full gear (FG, combination of PM and PPE 20.4 kg.). Each subject completed 3 sessions total. Gear was determined using a randomized cross-over design. Subjects were tested for BF via air displacement plethysmography and weighed before the protocol. The original Bruce protocol was adjusted to (stage 1) 3 minutes (min) at 0.8 m/s and 0% grade (GR), (stage 2) 3 min at 0.76 m/s and 10% GR, (stage 3) 3 min at 1.1 m/s and 12% GR, (stage 4) 3 min at 1.5 m/s and 14% GR, and (stage 5) 4 min cool down at 0.8 m/s and 0% GR. HR was recorded during each minute of the protocol until completion. Results were analyzed using Linear Regression to identify the effect of BF and LBM on HR. Stage 4 HR's were selected because the intensity is most comparable to actual situations.

RESULTS: R² of change reported 0.47 for both LBM and BF in FG, .065 in PM, and 0.52 in PPE. For LBM only, R² of change reported 0.36 (P=0.003) for FG, 0.60 (P < 0.001) for PM, and 0.52 (P < 0.001) for PPE. BF only, reported 0.08 (P = 0.216) for FG, 0.02 (P = 0.529) in PM, and less than 0.01 (P = 0.908) for PPE.

CONCLUSIONS: The data suggests that more LBM and less BF can be advantageous in relation to HR during encumbered walking. Firefighters should focus on increasing their LBM to increase their overall performance during training or in real life high stress situations.

Physiologic Strain of SCBA (Maze) Training Compared to Circuit Training and Live Fire Training

Andrea F. Wilkinson¹, Alexs A. Matias¹, Cassandra I.K. Eddy¹, Jeffery L. King², Edgard MKVK Soares³, Denise L. Smith, FACSM¹. ¹Skidmore College, Saratoga Springs, NY. ²Houston Fire Department, Houston, TX. ³University of Brasilia, Brasilia-DF, Brazil. (Sponsor: Denise L. Smith, FACSM)
 Email: awilkins@skidmore.edu
 (No relevant relationships reported)

Firefighting is a dangerous occupation and even training carries substantial risk. In fact, about 10-12% of firefighter line of duty deaths occur in training—most due to sudden cardiac death. Self-contained breathing apparatus (SCBA) maze training (also known as SCBA confidence courses) are a common training exercise, and it is often assumed that this type of drill is less physically taxing because there is no "live-fire". However, little is known about the physiologic strain associated with SCBA maze training.

Purpose: To compare the physiological strain of SCBA maze training to live fire training and circuit training among cadets at a training academy.

Methods: Cadets (N=40) wore physiologic status monitors to assess heart rate (HR) and estimated core temperature (ECT) during circuit training, live fire training and SCBA maze training. SCBA maze training occurred in full personal protective equipment (PPE) and took place in an air conditioned building. Live fire training occurred in a specialized training structure, and the circuit training workout occurred in a large equipment bay. Age-predicted maximum (APM) HR was calculated using the 220-age formula. Data were analyzed using repeated measures ANOVA and Bonferroni post-hoc.

Results: Data from 40 cadet firefighters (31±3 yrs. old) were analyzed. No significant difference (p>0.05) was observed between SCBA maze training and live fire training for HR or ECT (see Table 1). However, HR and ECT differed significantly between circuit training and both SCBA maze training and live fire training.

Conclusions: Even though SCBA maze training was performed under controlled environment it involved a physiological strain above circuit training and as high as live fire training, reaching age predicted maximum HR. SCBA maze training should be considered as physiologically stressful as live fire training of similar duration.

Table 1. Physiologic characteristics of academy training among cadets (N=40)

| | Circuit Training | SCBA Maze | Live Fire Training |
|--------------------|------------------|-------------|--------------------|
| Duration (minutes) | 33 | 38 | 36 |
| Peak HR (bpm) | 182 ± 9* | 193 ± 10 | 194 ± 17 |
| APMHR | 82.6 ± 5.2* | 103.0 ± 4.1 | 104.4 ± 12.1 |
| Peak ECT (°C) | 38.6 ± 0.4* | 39.3 ± 0.7 | 39.3 ± 0.6 |

Variables are means ± SD; HR = heart rate; ECT = estimated core temperature; APMHR = Age predicted maximum heart rate.

* p<.05 vs SCBA and Live Fire Training

Effects of Wearing a Self-Contained Breathing Apparatus on Blood Oxygen Saturation During Exercise in Firefighters

Brandon S. Pollock¹, Jason Springer², Tom Burgasser³, Tim Berczik⁴, Keith Burns¹, Jackie Novak¹. ¹Walsh University, North Canton, OH. ²Cleveland Clinic - South Pointe Hospital, Cleveland, OH. ³Massillon Fire Department, Stark County, OH. ⁴Jackson Fire Department, Stark County, OH.
 Email: bpollock@walsh.edu
 (No relevant relationships reported)

PURPOSE: Firefighters face a number of risks as part of their occupation. The self-contained breathing apparatus (SCBA) protects from smoke inhalation; however, the effects of the SCBA on blood oxygen saturation during exercise are unclear. The purpose of this study was to look at the effects of the SCBA on blood oxygen saturation during exercise.

METHODS: Nine healthy male firefighters (35 ± 5 years, 180.2 ± 24.9 pounds, 69.8 ± 3.8 inches) completed a physical activity readiness questionnaire (PARQ+) to determine eligibility for the study. Participants performed an incremental treadmill test to estimate their VO₂ max. One week later, participants exercised at 50% of their VO₂ max wearing their SCBA (SCBA). One week later, participants exercised at 50% of their VO₂ max not wearing their SCBA for the same duration (CON). Blood oxygen saturation was recorded at the lowest point (SO₂Low) and at the end of each exercise session (SO₂End). Heart rate (HR), blood lactate (LA) and rating of perceived exertion (RPE) were also measured and the end of each exercise session. For all variables, paired samples t-tests were used to compare differences between exercise sessions.

RESULTS: There was a significant difference in SO₂Low between the exercise sessions (p = 0.006; SCBA: 90.6 ± 3.5%; CON: 94.1 ± 1.4%). There was no significant difference in SO₂End between the exercise sessions (p = 0.01; SCBA: 94.3 ± 2.3%; CON: 95.7 ± 1.1%). Although not significant, there was a large difference in LA between the exercise sessions (p = 0.06; SCBA: 4.0 ± 3.0 mmol/L; CON: 1.9 ± 1.0 mmol/L). There were no significant differences in HR (p = 0.82; SCBA: 165 ± 21 bpm; CON: 164 ± 22 bpm) and RPE (p = 0.8; SCBA: 13 ± 1; CON: 13 ± 1) between the exercise sessions.

CONCLUSIONS: During exercise blood oxygen saturation was significantly reduced while wearing SCBA compared to CON. It is possible that while wearing SCBA the partial pressure of respired oxygen is reduced, resulting in oxygen not being diffused as efficiently.

2731 Board #5 May 31 1:00 PM - 3:00 PM
Exertional Strain and Task Performance Consequences of a Reduction in Protection in Structural Fire Fighter PPE - A Pilot Study

Emiel A. DenHartog. *North Carolina State University, Textile Protection and Comfort Center, Raleigh, NC.* (Sponsor: Dr Lacy Alexander, FACSM)
 Email: eadenhar@ncsu.edu
 (No relevant relationships reported)

PURPOSE: A major concern for working in structural firefighter PPE is the heat strain that is caused by the heat protection it provides. This is a multi-faceted challenge that requires studying heat protection, firefighter strain and task performance. To initialize this a pilot study on the consequences of reducing firefighter heat and flame protection on thermal strain, task performance and overall experiences of user safety was conducted at a firefighter training facility in The Netherlands.

METHODS: Ten experienced firefighters between the ages of 25 and 50 participated in a protocol approved by the local ethical committee. They performed a simulated rescue of two dummies in a small kitchen fire in a current structural firefighters garment (S) and in a one layer FR coverall with Reduced protection (R), both with

full safety gear, including SCBA. Measurements were conducted on heart rate, skin temperatures (4 sites), core temperature, task performance (speed, rescue result), mood and comfort sensations.

RESULTS: In all conditions all firefighters were able to execute the rescue in the R-gear as well as in the S-gear with no differences in time, on average 8.5 min. There were significant reductions in heart rate in the R-gear versus the S-gear ($p=0.02$) and in core temperature increase: 1.69 (0.80 °C/hr) in R-gear versus 2.52 (1.20) °C/hr in S-gear ($p=0.04$). Mean skin temperature was slightly higher in the R-gear, possibly due to the reduction in protection (35.1°C (R) versus 34.3°C (S), $p=0.009$). But it did not reach dangerous levels, none of the maximum skin temperatures was higher than 37°C. Comfort and strain ratings were lower in the R-gear, but there was an increase in the R-gear just prior to entering the room with the fire.

CONCLUSIONS: This pilot study addressed multiple aspects of the balance strain, protection and performance, all crucial to ensure safety and health for structural firefighters. The results showed that a small fire scenario could be addressed by the gear as effectively as the current gear, which was unexpected. The R-gear is expected to further reduce strain in most of the firefighter day-to-day work activities. The results also indicated that experienced firefighters would need to build confidence in the activities that can be executed safely in this clothing.

Firefighters Do Not Exhibit Postexercise Hypotension Following a Bout of Vigorous Exercise

Paul M. Parducci¹, Beth A. Taylor, FACSM¹, Amanda L. Zaleski¹, Adam R. Blanchard¹, Yeongjin Gwon¹, Ming-Hui Chen¹, Burak T. Cilhoroz¹, Paul D. Thompson, FACSM², Linda S. Pescatello, FACSM¹. ¹University of Connecticut, Storrs, CT. ²Hartford Hospital, Hartford, CT. (Sponsor: Beth A. Taylor, PhD, FACSM)

(No relevant relationships reported)

Firefighters have a higher than normal prevalence of cardiovascular disease (CVD) and accompanying risk factors such as hypertension. These CVD risk factors may increase the risk of sudden cardiac death (SCD), which accounts for 45% of all on-duty firefighter deaths. Exercise confers protection against CVD risk, in part due to the immediate blood pressure (BP) reductions of 5-7 mmHg following exercise, termed *postexercise hypotension* (PEH). PEH in firefighters has not been studied. **PURPOSE:** To examine PEH after sudden vigorous physical exertion simulated by a maximal cardiopulmonary stress test (GEST) among career firefighters. **METHODS:** Firefighters ($n=19$ men) performed non-exercise control (CONTROL) and GEST on separate days followed by attachment to an ambulatory blood pressure (ABP) monitor for 19hr. Ambulatory systolic BP (ASBP) and diastolic BP (ADBP) were recorded at hourly intervals over awake (11hr), sleep (8hr), and 19hr. Additionally, other CVD risk factors and SCD biomarkers were measured as possible correlates of PEH. **RESULTS:** Firefighters were middle-aged (39.5±8.9yr) and overweight (29.2±4.0kg·m⁻²) men with high resting BP (123.1±9.6/79.8±10.4mmHg). Compared to CONTROL, ASBP after the GEST increased over awake (18.2±12.9mmHg, $p<0.01$), sleep (14.6±10.3mmHg, $p<0.01$), and 19hr (16.5±11.7 mmHg, $p<0.01$). Compared to CONTROL, ADBP increased after the GEST over awake (4.4±3.1mmHg, $p=0.02$), sleep (7.6±5.4mmHg, $p<0.01$), and 19hr (5.9±4.1mmHg, $p<0.01$). Resting SBP explained up to 25.6% of variance in the ASBP response over awake ($r=0.51$, $p=0.03$) and up to 30.0% over 19hr ($r=0.55$, $p=0.02$), while blood glucose levels explained up to 72.8% of variance over sleep ($r=0.85$, $p<0.01$). Resting DBP explained up to 52.9% of variance in the ADBP response over sleep ($r=0.73$, $p<0.01$), while resting DBP and medication use explained up to 76.1% of variance over awake ($r=0.87$, $p<0.01$) and up to 76.5% over 19hr ($r=0.88$, $p=0.02$). **CONCLUSIONS:** Sudden vigorous exertion evoked *postexercise hypertension* as opposed to PEH among firefighters with elevated resting BP, which was largely explained by the positive relationship between resting BP and the increase in ABP following exercise. These unexpected findings indicate that reducing hypertension is critically important to the CVD health of career firefighters.

The Effect of Rapid and Slow Heat Acquisition on Heart Rate Variability

Brandon Cotton, Cory Coehoorn, Lynne Stuart-Hill. University of Victoria, Victoria, BC, Canada.

(No relevant relationships reported)

Autonomic tone (AT), measured by heart rate variability (HRV), has shown to be linked to the risk of cardiovascular and other diseases. Firefighters are chronically exposed to environments and tasks that put them under acute bouts of thermal and cardiovascular stress, acutely affecting AT. HRV has been shown to respond to both heat stress and heavy exercise though it is not known if rapid heat acquisition caused by the microclimate of personal protective equipment (PPE) affects tonal response magnitude during exercise. **PURPOSE:** The aim of this study was to determine if PPE-induced rapid heat acquisition affected HRV differently than standard heat acquisition. **METHODS:** 15 healthy male subjects (mean age, 31.3 ± 11.7 years)

completed an incremental graded treadmill walking test until a core temperature of 39.5°C, volitional maximum, or a 2-hour time limit was obtained in both an experimental (PPE) and a control (CON) test in a random crossover design. Pre- and post-exercise, participants completed a 10-minute supine rest period, during which heart rate and R-R intervals were continuously collected. HRV data was filtered and analyzed in the frequency domain. Low (LF) and high frequencies (HF) were reported in normalized units (nu) along with the VLF (very-low frequency), LF, HF, and LF/HF ratio as a unit of power (ms²). **RESULTS:** Post-exercise LFnu was significantly increased in both CON (pre=73.3±3.5, post= 80.7±3.6, $p<0.05$) and PPE (pre=7.4±230.1, post=84.2±2.4, $p<0.01$) conditions while HFnu was significantly lower (CON; pre=26.7±3.5, post= 19.2±3.6, $p<0.05$ and PPE; pre= 31.6±4.5, post= 15.7±2.4, $p<0.01$). LF/HF ratios were also significantly different pre- to post-exercise in both conditions (CON; pre= 3.9±0.7 ms², post= 7.3±1.2 ms², $p<0.05$; PPE: pre= 3.9±0.6 ms², post= 7.7±1.0 ms², $p<0.01$). There was no difference between the two conditions either pre- or post-exercise for any of the variables measured in ms² except for post-exercise VLF which was significantly higher in PPE compared to CON. **CONCLUSION:** Results from the current study suggest that regardless of the rate of thermal acquisition, HRV response is similar, however the shift of HRV into the VLF domain during the PPE condition may have masked the magnitude of sympathetic response by lowering the LF frequency domain.

Validity of the Pregnancy Physical Activity Questionnaire for Maternal Physical Activity Recall

Michelle R. Conway¹, Mallory R. Marshall², Rebecca A. Schlaff³, Nicole M. Talge³, Karin A. Pfeiffer, FACSM⁴, James M. Pivarnik, FACSM⁴. ¹Western State Colorado University, Gunnison, CO. ²Samford University, Birmingham, AL. ³Saginaw Valley State University, University Center, MI. ⁴Michigan State University, East Lansing, MI.

(No relevant relationships reported)

The Pregnancy Physical Activity Questionnaire (PPAQ) is a commonly utilized self-report assessment of physical activity (PA) during pregnancy, but its validity when evaluating women's PA historically after the pregnancy ends is unknown. **PURPOSE:** To evaluate the validity of the PPAQ for long-term recall of PA at two time points during pregnancy and once postpartum. **METHODS:** Between 2010 and 2018, 48 women completed the PPAQ at 21 and 32 weeks gestation and 12 weeks postpartum about their previous week's PA. These same women were emailed three separate PPAQs between two months and eight years after originally completing the questionnaires to recall their PA during those same time periods. Of these 48 women, 40 completed the follow up recall questionnaires (83%). Total number of metabolic (MET) minutes per week and percent time spent in light, moderate, and vigorous activity were compared between the original and long-term recall PPAQ values using paired sample t-tests or Wilcoxon Rank tests and Spearman correlation coefficients (SCC). The participants were then separated into two groups via a median split: those who originally completed the PPAQs ≥ five years ago and < five years ago. The paired sample t-tests, Wilcoxon Sign Rank tests, and SCC were repeated. **RESULTS:** Total MET-minutes per week and percent time spent in moderate activity were underestimated by 3000 – 4000 MET-minutes per week and 6%, respectively, and percent time in light activity was overestimated by 4-6%, when comparing long-term recall to original values. Women reported spending little time in vigorous intensity activity at both time points during pregnancy (2-4%). Twenty-one of the 36 comparisons were significantly different (58%). SCC values were lower for women who recalled PA ≥ five years postpartum compared to women who recalled their PA < five years postpartum for most time points and intensities. **CONCLUSION:** It is important to continue to assess the long-term validity of self-report methods, such as the PPAQ. On average, participants tend to underestimate total and moderate PA and overestimate light PA, but by relatively small amounts (3561 MET-minutes per week, 6%, 4-6%, respectively) when recalling their activity up to eight years previously.

2736 Board #2 May 31 1:00 PM - 3:00 PM
Morphometric Response of Overweight and Obese Women to Resistance Training during Pregnancy
 Olga Roldan-Reoyo¹, Christy Isler², Kelley Haven², Edward Newton², Linda E. May². ¹Swansea University, Swansea, United Kingdom. ²East Carolina University, Greenville, NC.
 Email: olga.roldanreoyo@swansea.ac.uk
 (No relevant relationships reported)

Resistance exercise (RE) has increased in popularity among pregnant women being the third most popular activity in previously active women. However, most of the RE interventions have been focused on birth outcomes from normal weight (NW) pregnant women or in overweight or obese (OWOB) pregnant women with pregnancy-related disease. Currently, we do not know how RE can influence morphometric measures in healthy OWOB pregnant women. **PURPOSE:** To determine the effect of RE during pregnancy of OWOB women on maternal morphometric measures. **METHODS:** 33 OWOB (25-Control group (CG) vs 8-RE group (REG)) healthy, low-risk, women with a singleton pregnancy have been analyzed for this study. All women signed an informed consent and agreed to participate in the study, which involves 3-exercise protocols (aerobics, resistance and aerobics+resistance) and a CG. Participants in the REG trained 3x/week, 50min, moderate intensity for ~20 weeks using machines, free weights and swiss balls. Maternal skinfolds and anthropometric measures were collected at 16 and 36 weeks of gestation. Student t test was performed to determine differences between groups. **RESULTS:** Analysis does not show significant differences in most variables measured at 16 and 36weeks ($p > 0.05$): weight16 (CG=86,9kg vs REG=85kg), weight36 (CG=96,7kg vs REG=94,1kg), percentage of body fat16 (%BF) (CG=36,2 vs REG=36,3), %BF36 (CG=37,1 vs REG=39,2), gestational weight gain (GWG) (CG=10kg vs REG=9,2kg), waist to hip ratio (WHR) at 16 (CG=0,79 vs REG=0,82). Significant differences were found in WHR36 weeks (CG=0,84 vs REG=0,77). 40% percent of the women in the CG exceeded their GWG recommendation vs 37,5% of REG women ($p > 0.05$). Birth weight was not significantly different between groups ($p > 0.05$): (CG=3,6kg vs REG=3,5kg). **CONCLUSION:** RE was not effective to prevent excessive GWG or to decrease %BF for OWOB pregnant women. The data suggest that, another exercise protocols should be evaluated between this population to test for the best efficacy. American Heart Association #15GRNT24470029

Oxygen Uptake Kinetics During the Different Phases of the Menstrual and Oral Contraceptive Cycles
 Anmol T. Mattu, Danilo Iannetta, Patricia K. Doyle-Baker, Juan M. Murias. University of Calgary, Calgary, AB, Canada.
 Email: atmattu@ucalgary.ca
 (No relevant relationships reported)

PURPOSE: To examine whether oxygen uptake ($\dot{V}O_2$) kinetics changes across the phases of the menstrual and oral contraceptive cycles. **METHODS:** Fourteen highly active women who were either non-oral contraceptive users ($n=7$, 28 ± 6 yrs.) or monophasic oral contraceptive users ($n=7$, 22 ± 3 yrs.) participated in the study. The time-constant of the $\dot{V}O_2$ kinetics response ($\tau\dot{V}O_2$) was determined by ensemble-averaging the $\dot{V}O_2$ response measured during three consecutive step-transitions in work rate, from 20 Watts (W) to a moderate-intensity work rate of 80 W. Each step was six minutes in duration. The test was completed during the menstruation phase of the cycles (follicular phase for non-oral contraceptive users or "inactive pill" phase for oral contraceptive users) and repeated during the respective non-menstruating phase (luteal phase or "active pill" phase). An ovulation test was used to validate the menstrual cycle phase. A metabolic cart was used to continuously measure expired gas concentrations and ventilatory rates. A one-way repeated-measures ANOVA was used to compare the differences in $\dot{V}O_2$ kinetics across cycle phases between non-oral contraceptive and oral contraceptive users. Statistical significance was set at $p < 0.05$. **RESULTS:** The time constant for the adjustment of $\dot{V}O_2$ was affected by cycle phases, regardless of contraception use, whereby $\tau\dot{V}O_2$ was greater in the menstruation phases of the non-oral contraceptive and oral contraceptive cycles (24 ± 7 s) compared to the non-menstruating phases (19 ± 5 s) ($p < 0.05$). **CONCLUSION:** The speed of the $\dot{V}O_2$ kinetics response is affected by the phases of the menstrual and oral contraceptive cycles, such that a greater $\tau\dot{V}O_2$ is observed during the menstruation phase. Anmol T. Mattu was supported by the NSERC Alexander Graham Bell Canada Graduate Scholarship.

The Impact Of Pms And Pmdd On Physical Performance In Female Track And Field Athletes
 Reiko Momma¹, Yuriko Tochigi¹, Ai Hamasaki¹, Koichiro Tanahashi¹, Akari Takahashi², Tomohito Sato¹, Atsumu Yokota¹, Noboru Mesaki¹, Seiji Maeda¹. ¹University of Tsukuba, Tsukuba, Japan. ²Japan Sport Council, Kita-ku, Japan.
 (No relevant relationships reported)

Previous studies showed that menstrual cycle is associated with physical performance and subjective condition in female athletes. It is also known that premenstrual syndrome (PMS) and premenstrual dysphoric disorder (PMDD) affect subjective condition in female athletes. However, the relationships among PMS, PMDD and physical performance in female athletes are not clarified yet. **Purpose** To investigate the impact of PMS and PMDD on physical performance in female track and field athletes. **Methods** Sixteen female track and field athletes with regular menstrual cycles participated in this study. Participants were measured body composition and physical performance test in follicular phase (no PMS and PMDD phase) and luteal phase (PMS and PMDD phase). As a physical performance test, Counter Movement Jump: CMJ, Rebound Jump: RJ, and Wingate test were performed. PMS and PMDD were evaluated by questionnaire survey of premenstrual syndrome (ACOG practice bulletin, 2000) and premenstrual dysphoric disorder (DSM-5, APA, 2013). **Results** In all subjects, there were no significant differences in body composition and physical performance between follicular phase and luteal phase. However, subjects who had breast tenderness of PMS decreased more greatly than non-symptom subjects in jump height of CMJ ($p=0.038$) and RJ index ($p=0.015$). Also, subjects who had anxiety of PMS decreased more greatly than non-symptom subjects in jump height of CMJ ($p=0.05$). Moreover, subjects who had overeating of PMDD increased more greatly than non-symptom subjects in HR max during Wingate test ($p=0.042$). **Conclusions** In this study, we showed that some symptoms of PMS and PMDD were associated with suppressed physical performance in female track and field athletes. Thus, PMS and PMDD may lead to decrease the physical performance in female track and field athletes.

Physical Activity Influences the Relationship between BMI and Adiposity Differently in College Males and Females
 Ginny M. Frederick¹, Bhibha M. Das², Michael V. Fedewa³, Rachele M. Reed¹, Rachel E. Salyer¹, Michael D. Schmidt¹, Ellen M. Evans, FACSM¹. ¹University of Georgia, Athens, GA. ²East Carolina University, Greenville, NC. ³University of Alabama, Tuscaloosa, AL. (Sponsor: Ellen M. Evans, FACSM)
 Email: vmf04863@uga.edu
 (No relevant relationships reported)

G.M. Frederick¹, B.M. Das², M.V. Fedewa³, R.M. Reed¹, R.E. Salyer¹, M.D. Schmidt¹, E.M. Evans¹, FACSM. ¹University of Georgia, Athens, GA 30602. ²East Carolina University, Greenville, NC 27858. ³University of Alabama, Tuscaloosa, AL 35487. **PURPOSE:** Body mass index (BMI) is often used as a surrogate measure of adiposity (%Fat). It is well-established that physical activity (PA) influences body composition. In addition to the well-established sex differences in body composition, college-age males also typically engage in more PA than their female counterparts. This difference in PA could potentially impact the relationship between BMI and %Fat. Therefore, the aim of this study was to determine if PA differentially influences the relationship between BMI and %Fat in college-age males compared to females. **METHODS:** BMI was calculated from weight and height measured using standard clinical protocols. PA was measured in steps/day using the NL-1000 accelerometer. %Fat was measured via DEXA. **RESULTS:** Males ($N = 124$; 18.4 ± 0.5 yrs, 23.2 kg/m^2) and females ($N = 282$; 18.3 ± 0.5 yrs, 23.0 kg/m^2) were nearly identical in age and BMI (both $p > 0.05$). As expected, males were leaner (18.4 ± 5.1 %Fat vs. 32.2 ± 5.7 %Fat, $p < 0.001$) and accumulated more PA ($11,625 \pm 2930$ vs. $10,866 \pm 3467$ steps/day, $p = 0.03$) compared to females. Because of the known sex difference in %Fat, separate linear regression models were evaluated to explore the prediction of %Fat from BMI, PA, and BMI x PA. BMI explained 50.2% of the variance in %Fat among females and only 18.3% of the variance in males ($p < 0.001$ for both). Adding PA to the model significantly increased the variance in %Fat explained in both females and males ($\Delta R^2 = 3.4\%$ and 3.5% , respectively, both $p < 0.05$). The addition of the BMI x PA interaction term improved the model in females ($\Delta R^2 = 1.3\%$, $p = 0.005$), but not males ($\Delta R^2 = 0.0\%$, $p = 0.933$). **CONCLUSION:** Weight management is of high public health importance, especially for young adults who have an increasing risk for obesity during this stage of life. While many health promotion efforts focus on weight management with BMI as a primary outcome, it is important to account for sex differences with respect to the relationships among BMI, PA, and %Fat when using BMI for program evaluation in the young adult population.

(No relevant relationships reported)

Percentage Body Fat Predicted by Body Mass Index, Waist Circumference and Age in Different Racial and Gender Groups
 Studies have shown that percentage body fat (%BF) is highly correlated with the body-mass index (BMI) and waist circumferences (WC) in different age, race, and gender. However, taking ethnicity factor into account to predict %BF has not been established. **PURPOSE:** We explored the equations of %BF predicted by BMI, WC, and age in different racial and gender groups. **METHODS:** We use National Health and Nutrition Examination Survey (NHANES 2003-2004) data with sample weighing 488058396 in five race groups including Mexican American (MA), other Hispanic (OH), Non-Hispanic White (NHW), Non-Hispanic Black (NHB), and other Race - including Multi-Racial (OR). %BF was measured by dual-energy X-ray absorptiometry (DXA). Prediction equation of %BF was developed based on different race and gender groups with predictors of WC, BMI, and age (20 and older). **RESULTS:** There was a statistically significant interaction between groups. The results of the regression equation in different race and gender groups are as the following table:

| Race | MA | OH | NHW | NHB | OR | |
|-------------------------------|---------------|---------------|---------------|---------------|---------------|--------|
| Gender | Male | | | | | |
| %BF (Mean, SD) | 28.276, 4.848 | 27.280, 5.602 | 28.640, 5.942 | 26.152, 6.663 | 27.726, 5.485 | |
| R-square | 0.675 | 0.766 | 0.704 | 0.717 | 0.585 | |
| Standardized CoefficientsBeta | WC | 0.766 | 0.845 | 0.855 | 0.812 | 1.146 |
| | BMI | 0.061 | -0.042 | -0.054 | 0.022 | -0.442 |
| | Age | -0.004 | 0.139 | 0.109 | 0.057 | 0.074 |
| Gender | Female | | | | | |
| %BF (Mean, SD) | 41.362, 5.738 | 39.991, 5.302 | 40.006, 6.849 | 40.872, 6.765 | 38.182, 6.193 | |
| R-square | 0.633 | 0.566 | 0.689 | 0.678 | 0.709 | |
| Standardized CoefficientsBeta | WC | 0.187 | 0.113 | 0.199 | 0.165 | 0.239 |
| | BMI | 0.586 | 0.569 | 0.594 | 0.644 | 0.600 |
| | Age | 0.159 | 0.326 | 0.207 | 0.160 | 0.082 |

For all, $p = 0.000$
CONCLUSION: Formulating prediction equations in different gender and race groups does not improve the prediction of %BF. Further analyses such as cross-validation based on split training and testing datasets are needed.

2741 Board #7 May 31 1:00 PM - 3:00 PM
Differences in Determining Exercise Intensity in Males and Females

Jozelyn Rascon, Elizabeth Trujillo, Francisco J. Morales Acuna, Alvaro N. Gurovich, FACSM. *The University of Texas at El Paso, El Paso, TX.*
 Email: jrascon3@miners.utep.edu
(No relevant relationships reported)

Even though there are physiological differences between males and females, heart rate (HR), rate of perceived exertion (RPE), power output (PO), oxygen consumption (VO₂), and blood lactate (BL) levels have been used as measures of exercise intensity independently of the sex. **PURPOSE:** To determine if there are differences between sexes in different exercise intensity models. **METHODS:** Thirty (15 females) young, healthy individuals (age range 19-33 y) were scheduled for two testing visits 48-72 hours apart. During the first testing visit, a graded exercise test (GXT) was administered on a stationary bicycle. HR, RPE, PO, VO₂, and BL were obtained at the end of each exercise step and peak PO and VO₂max were recorded at the end of the test. BL during the GXT was used to determine 3 5-min steady-state workloads (low: 0-2 mmol/l; medium: 2-4 mmol/l; and high: >4 mmol/l) for the second test. HR, %HRmax (HR/(220-age)), RPE, PO, %POmax, VO₂, %VO₂max, and BL were also obtained at the end of each steady-state workload. A two-way repeated measures ANOVA was performed to compare all exercise intensity variables obtained during the second test between males and females ($\alpha=0.05$).

RESULTS: Only RPE, %PO, and BL did not differ between sexes on all 3 exercise intensities (Table). HR, %HR, and PO differ between sexes on at least 2 exercise intensities. VO₂ and %VO₂max differ between sexes on at least 1 exercise intensity.

| Workload | Variable | Females (n=15) | Males (n=15) | p |
|---------------------|-----------------------------|----------------|--------------|-------|
| Low (0-2 mmol/l) | HR (bpm) | 115.9 ± 14.4 | 96.8 ± 14.2 | 0.004 |
| | %HR (%) | 68.7 ± 7.5 | 59.4 ± 8.8 | 0.002 |
| | RPE | 7.7 ± 2.0 | 7.5 ± 1.6 | 0.796 |
| | PO (Watts) | 61.3 ± 20.3 | 67.3 ± 15.3 | 0.440 |
| | %PO (%) | 44.1 ± 11.2 | 36.4 ± 9.7 | 0.051 |
| | VO ₂ (ml/Kg/min) | 15.1 ± 3.7 | 15.7 ± 3.6 | 0.731 |
| | %VO ₂ max (%) | 54.0 ± 9.8 | 45.6 ± 8.4 | 0.010 |
| Medium (2-4 mmol/l) | BL (mmol/l) | 1.5 ± 0.4 | 1.3 ± 0.4 | 0.439 |
| | HR (bpm) | 143.4 ± 15.8 | 127.9 ± 19.9 | 0.053 |
| | %HR (%) | 84.9 ± 6.2 | 75.4 ± 6.7 | 0.000 |
| | RPE | 10.5 ± 2.4 | 10.8 ± 2.4 | 0.711 |
| | PO (Watts) | 93.3 ± 22.0 | 116.7 ± 19.5 | 0.017 |
| | %PO (%) | 67.6 ± 10.3 | 62.1 ± 8.3 | 0.086 |
| | VO ₂ (ml/Kg/min) | 20.1 ± 4.2 | 24.7 ± 5.1 | 0.034 |
| High (>4 mmol/l) | %VO ₂ max (%) | 71.9 ± 10.0 | 71.3 ± 6.7 | 0.760 |
| | BL (mmol/l) | 2.6 ± 0.6 | 2.8 ± 0.7 | 0.367 |
| | HR (bpm) | 164.0 ± 15.6 | 149.0 ± 17.0 | 0.016 |
| | %HR (%) | 97.0 ± 3.7 | 91.1 ± 7.3 | 0.017 |
| | RPE | 13.7 ± 2.4 | 14.1 ± 2.4 | 0.594 |
| | PO (Watts) | 123.7 ± 23.0 | 166.0 ± 29.2 | 0.001 |
| | %PO (%) | 89.9 ± 8.6 | 87.8 ± 8.2 | 0.414 |
| High (>4 mmol/l) | VO ₂ (ml/Kg/min) | 26.3 ± 5.5 | 31.0 ± 5.6 | 0.074 |
| | %VO ₂ max (%) | 93.3 ± 7.4 | 89.6 ± 5.5 | 0.212 |
| | BL (mmol/l) | 4.7 ± 0.7 | 4.8 ± 1.1 | 0.657 |

CONCLUSIONS: As previously reported, females have higher HR and %HR than males for similar %PO. However, and contradicting previous reports, RPE was similar between males and females for similar %PO. Based on the current results, traditional exercise intensity models are different between males and females. BL and %PO appear to be the models that might be used independently of sex.

2742 Board #8 May 31 1:00 PM - 3:00 PM
The Relationship Between Maternal Physical Activity during Late Pregnancy and Infant Motor Development

Nikitha Rajendran¹, Karen Furgal¹, Lauren Miller¹, Kolbi Edens¹, Kristin Yoho¹, Jill M. Maples², Rachel A. Tinius¹.
¹Western Kentucky University, Bowling Green, KY. ²University of Tennessee, Knoxville, TN.
 Email: nikitha.rajendran028@topper.wku.edu
(No relevant relationships reported)

BACKGROUND: Physical activity is beneficial for pregnant women and their offspring. Exercise during pregnancy may elicit improvements in the brain/neurodevelopment of offspring; however, it is unknown whether or not physical activity during pregnancy is connected to infant motor development. The purpose of this study was to determine the relationship between maternal physical activity during late pregnancy and infant motor development at four months of age. **METHODS:** Physical activity was objectively assessed during late pregnancy (32-39 weeks gestation) via a wrist worn accelerometer. The amount of time spent sedentary and participating in light and moderate exercises were calculated for one week. Within 48 hours of birth, surveys were given to participants to complete prospectively with information on time their infant spends in different positions (supine, prone, supported sitting and standing), infant feeding practices (breastfed vs. formula-fed), and other factors that could contribute to infant motor development during the first 4 months of life. Between 4 and 4.5 months of age, the motor development of the child was assessed by a board-certified pediatric physical therapist using the well-validated Alberta Infant Motor Scale (AIMS). **RESULTS:** Thirty women-infant pairs participated in the study (n=30). Infant motor development percentiles were not correlated to time spent sedentary ($r=-.02$, $p=.94$), time spent participating in light activity ($r=-.03$, $p=.88$), or time spent participating in moderate activity during late pregnancy ($r=.04$, $p=.85$). In addition, there was not a significant relationship between infant motor scores and the total time an infant spent in prone ("tummy time") ($r=.06$, $p=.81$). Interestingly, infants who were exclusively breastfed at 4 months had a significantly higher mean motor score percentiles compared to those who were on formula (19.0 vs. 15.8, $p=0.003$). **CONCLUSIONS:** There was no relationship between maternal physical activity levels during late pregnancy and infant motor development at four months of age. However, infants who were still breastfed at 4 months of age had higher motor development percentiles. The long-term implications of these data are substantial as motor performance in infancy is linked to an improved-cognitive function in school-age children.

F-10 Thematic Poster - Sports Injury: New Epidemiological Insights

Sport-Specific Associations of Sport Specialization and Sport Volume with Overuse Injury in Youth Athletes

Eric G. Post¹, Kevin M. Biese², Daniel A. Schaefer², Andrew M. Watson², Timothy A. McGuine², M. Alison Brooks², David R. Bell². ¹San Diego State University, San Diego, CA. ²University of Wisconsin-Madison, Madison, WI.
Email: epost@sdsu.edu
(No relevant relationships reported)

Year-round participation in a single sport at the exclusion of other sports, also known as sport specialization, is associated with increased risk of overuse injury in youth athletes. To reduce this risk, several recommendations for participation volume have been developed. However, risk of overuse injuries may be dependent on specific movement profiles required by a given sport.

PURPOSE: To examine sport-specific associations of sport specialization and exceeding sport volume recommendations with overuse injuries in adolescent basketball, soccer, and volleyball athletes.

METHODS: 716 youth athletes (70.8% female, age 14.21.5 years old, 43.2% basketball, 19.4% soccer, 37.4% volleyball) were recruited to complete an anonymous questionnaire regarding their sport participation patterns and previous injury history. Sport specialization status was classified as low, moderate, or high using a widely utilized 3-point scale. Self-reported sport volume was used to classify athletes as either meeting or exceeding sport volume recommendations (playing their primary sport >8 months/year, hours/week of organized sport > age, days of sport participation per week >5). Multivariable logistic regression analyses were utilized to examine associations between variables of interest and overuse injury in the previous year.

RESULTS: Highly specialized volleyball athletes were more likely to report an overuse injury compared to low specialization volleyball athletes (OR [95% CI]: 2.3 [1.1-4.8], p<.01). Volleyball athletes who trained: more than 8 months per year (OR [95% CI]: 2.0 [1.1-3.5], p<.05), more hours per week than their age (OR [95% CI]: 2.0 [1.2-3.4], p<.01), or more than 5 days per week (OR [95% CI]: 2.1 [1.2-3.9], p<.05) were more likely to report an overuse injury compared to volleyball athletes who did not violate these recommendations. No significant associations were observed in soccer or basketball athletes (P>0.05).

CONCLUSIONS: The association between sport specialization, excessive sport volume, and overuse injuries may be specific to sports that are more repetitive or technical in nature, such as volleyball. Dissemination of sport-volume recommendations should be focused towards athletes, parents, and coaches in these sports.

2745 Board #2 May 31 1:00 PM - 3:00 PM
A Seven-year Epidemiological Analysis Of Ankle Injuries In U.S. Rugby-7s

Victor Lopez Jr¹, Christian Victoria², Richard Ma³, Meryle G. Weinstein⁴, Michael S. Youseff⁵, Mariana E. Adieb⁵, Answorth Allen⁶. ¹Rugby Research and Injury Prevention Group, Hospital for Special Surgery, New York, NY. ²Urban Epidemiology Lab, College of Global Public Health, New York University, New York, NY. ³Missouri Orthopaedic Institute & Thompson Laboratory for Regenerative Orthopaedics, Columbia, MO. ⁴Steinhardt School of Culture, Education and Human Development, New York University, New York, NY. ⁵City College, City University of New York, New York, NY. ⁶Sports Medicine and Shoulder Service, Hospital for Special Surgery, New York, NY.
Email: drvictorlopezjr@gmail.com

Reported Relationships: V. Lopez Jr: Salary; Officer Salary. Industry contracted research; Grant National Operating Committee on Standards for Athletic Equipment (ID 44-16), Chapel Hill, NC, USA., Grant USA Rugby's Empire and New England Geographic Union Rugby Football

Unions.

PURPOSE: There is a lack of injury data on the collision sport of U.S. Rugby-7s, the aim was to determine match ankle injury-incidence and risk-factors in U.S. Rugby-7s. **METHODS:** This was a prospective epidemiology study of players at USA Rugby Club 7-a-side competitive regional circuits and USA Rugby-7s Championships (2011-2016). Injury data were captured via the Rugby Injury Survey & Evaluation (RISE) Report. **RESULTS:** Overall injuries were found at 9.9/1000ph (n=313) (time-loss 2.5/1000ph, n=78; medical attention 7.4/1000ph, n=235; P<0.001). Females (3.5/1000ph; 12.3%; n=112) encountered fewer overall ankle injuries than males (7.6/1000ph; 10.8%; n=239; P=0.477). Backs (59%) more frequently than forwards (35%). Ankle injury severity, days absent was found at 41.5 days mean severity (CI: 24.4-58.6) with 68% follow-up. Overall injuries acutely (95%), occurred during the tackle (61%, 5.2/1000ph) and open play (29%, 2.5/1000ph). Lateral ligament sprains (3.7/1000ph) occurred more frequently than medial (0.9/1000ph). Risk factors among time-loss injuries and impact were frequent (direct-contact=1.7/1000ph, 68%; n=53; non-contact=0.8/1000ph; 32%; n=25; p=0.002). Contact injuries were higher among women (64%). New time-loss injuries (71.8%) occurred more often than recurrent-time-loss ankle injuries (28.2%). Recurrent ankle injuries occurred more frequently at greater-than-12-months (delayed-recurrence=12.8%) followed by a 2-month (early-recurrence=10.3%). Recurrent injuries occurred most frequently among elite players at a late-recurrence rate (2-12-months=28.6%) as compared to non-elite players at a delayed-recurrence (>12-months=14.1%). **CONCLUSIONS:** Ankle injuries are a frequent concern in collision sports. This is compounded when return-to-sport protocols are not adhered and may be a risk-factor for subsequent injury. U.S. Rugby-7s community ankle injury rates were lower compared to International elite Rugby-7s play at 7.1-25/1000ph (time-loss). Appropriate proprioception and agility training awareness, would benefit all levels of play. This emerging population may benefit from education on return-to-sport protocols and post-tournament injury care which would decrease recurrent injury rates seen in this U.S. amateur population.

2746 Board #3 May 31 1:00 PM - 3:00 PM
Prospective Injury Surveillance during the Wheelchair Basketball World Championships 2018

Karsten Hollander¹, Sascha Kluge², Franziska Glöer¹, Astrid Zech³, Astrid Junge⁴. ¹University of Hamburg, Hamburg, Germany. ²BG Trauma Hospital of Hamburg, Hamburg, Germany. ³Friedrich-Schiller-University of Jena, Jena, Germany. ⁴Medical School Hamburg, Hamburg, Germany.
(Sponsor: Irene S. Davis, FACSM)
Email: karsten.hollander@uni-hamburg.de
(No relevant relationships reported)

Standardized injury surveillance projects have been conducted in several Olympic sports, and the information has been used to develop preventive strategies to reduce injury risk. In contrast, injury surveillance in Paralympic sports has been executed rarely, and in depth information on injury epidemiology of specific elite Paralympic sports are scarce. **PURPOSE:** To investigate the rate and characteristics of injuries prospectively during the 2018 Wheelchair Basketball World Championships in Hamburg (Germany). **METHODS:** The physicians or physiotherapists of all participating female and male teams were asked to report daily all newly incurred injuries on a standardized injury report form during the 11 days of the tournament. Incidence rates were calculated, and injury characteristics compared using chi-squared tests. **RESULTS:** A total of 100 injuries were reported from 132 players, equivalent to 77.2 injuries per 1000 athlete days (95%CI: 62.1 to 92.3). About two thirds of the injuries occurred during matches, and 32 during training sessions. The rate of match injuries was 76.6 (95%CI 61.6 to 91.6) per 1000 athlete-days, the rate of training injuries 78.4 (95%CI 63.0 to 93.8) per 1000 athlete-days. Eight time-loss injuries were documented, equivalent to 6.2 (95%CI 5.0 to 7.4) time-loss injuries per 1000 athlete-days, all were classified as minor. Most injuries occurred at the upper limb (shoulder 14%, elbow 11%, hand/fingers 10%) and back (cervical spine 16%; thoracic spine 15%). The predominant injury types were muscle spasms (25%) and contusions (16%). About half of the injuries were classified as overuse injuries (52%). Injury mechanisms differed between training and match (p<0.05), and between female and male players (p<0.05). **CONCLUSIONS:** The injury rates were higher than reported during other major tournaments (Paralympic Games) or during regular wheelchair basketball seasons. Reasons are most probably due to the high number of reported non-time-loss injuries. Possible preventive strategies should focus on shoulder, hand and back. Muscle spasms could be prevented using adequate rehydration and electrolyte substitution, while the special requirements of players' disabilities need to be considered. Future research should include illnesses in the prospective monitoring.

2747 Board #4 May 31 1:00 PM - 3:00 PM
Gender Differences In The Risk Of Head, Neck & Face Injuries In US Rugby-7s
 Christian Victoria¹, Victor Lopez, Jr.², Danielle C. Ompad¹, Richard Ma³, Meryle G. Weinstein¹, Answorth A. Allen⁴, Robert C. Cantu, FACSM⁵. ¹New York University, New York, NY. ²Rugby Research and Injury Prevention Group at Hospital for Special Surgery, New York, NY. ³Missouri Orthopaedic Institute & Thompson Laboratory for Regenerative Orthopaedics, Columbia, MO. ⁴Hospital for Special Surgery, New York, NY. ⁵CTE Center at Boston University School of Medicine, Boston, MA. (Sponsor: Robert C. Cantu, FACSM)
 Email: cv985@nyu.edu
 (No relevant relationships reported)

A high incidence of head injuries, including concussions, has been documented in a growing US rugby playing population. However, few studies have focused on describing common risk factors associated with head injuries. **PURPOSE:** The purpose of this study was to identify risk factors associated with head, neck, and face injuries (HNFI) among amateur U.S. rugby-7s players and investigate risk differences between genders. **METHODS:** Data were used from the Rugby Research and Injury Prevention Group's injury registry (January 2010-2016). Anthropometric data, mechanism of injury, and other injury risk factors were tabulated by HNFI and gender. Logistic regression determined the relation between gender and HNFI. The final multivariable model was used to calculate the probability of HNFI and highlight gender differences. **RESULTS:** The final study sample consisted of 1,307 (68.2% men, 31.8% women) U.S. rugby-7s players and 1,679 (68.1% men, 31.9% women) injuries. From 2010-2016, 474 (28.2%) HNFI were documented. The most commonly injured body part and injury type were the head (47.7%) and concussions (40.3%), respectively. The final model revealed gender, age, position during contact, contact surface, and play legality were significantly associated with HNFI. Controlling for play legality and position during contact, under 18 (U18) boys injured during contact with an opposing player had the highest probability of HNFI (51%) and a higher probability than U18 girls (p=0.004). However, women 18-24 (p=0.019) and over 30 (p=0.042), injured during contact with the ground, had a higher probability of HNFI than men. **CONCLUSIONS:** Identifying gender-specific risk factors of injury will allow for a more effective injury prevention plan that addresses the specific needs of men and women of different levels of competitive play. Our analyses suggest there are differences in risk of HNFI in amateur Rugby-7s as it relates to player age, gender, and play legality. Age group analyses may help identify gender-specific HNFI risk factors within each age group.

 (No relevant relationships reported)

Rugby-7s is a popular collision sport that is played by both sexes in the U.S. Collisions that occurs during Rugby are responsible for the majority of injuries during competition. **PURPOSE:** The objective of this study is to evaluate gender differences in match injuries among men and women amateur U.S. Rugby-7 athletes. **METHODS:** A prospective epidemiology study on Rugby-7s competitions (USA Rugby and USA Sevens tournaments) over 2010-2015 was performed. Injury rate (per 1000 player-hour (ph)) and biomechanism of injuries were recorded using the Rugby Injury Survey & Evaluation (RISE) report. Direct (injury from collision with an opposing player) and indirect mechanism (injury from the body part making contact with another factor such as playing surface) were recorded. Severity of injuries (days (d) absent from play) were determined. Comparative analysis between sexes were performed with statistical significance set a P<0.05. **RESULTS:** A total of 1223 contact match injuries were seen during the study period (men: 852 injuries; women: 371 injuries). There was no significant differences in incidence of contact injuries for U.S. men vs. women Rugby-7 athletes (men: 55.4/1000ph; women: 59.0/1000ph; P=0.31). Female players however had a higher incidence of indirect injuries than males (women: 23.1/1000ph; men: 17.4/1000 ph, P=0.007). Female Rugby-7s players also sustained more severe contact injuries than males (women: 56.7d; men: 40.1d, P=0.03). In terms of incidence of injury per body region, female players had a higher incidence of lower extremity injuries than males (women: 24.2/1000ph; men: 18.0/1000 ph, P=0.004). Female Rugby-7s athletes also missed a significant more time with contact head/neck (women:

55.1/1000ph; men: 29.4/1000 ph, P<0.009) and lower extremity injuries (women: 70.7/1000ph; men: 41.2/1000 ph, P=0.01). **CONCLUSIONS:** Significant differences in rate and mechanism of injuries exist between U.S. men and women Rugby-7 athletes in our study population. Female players are more likely to sustain certain types of injuries and missed substantially more time after an injury when compared to their male counterparts. Gender differences in sports are important to consider when evaluating injury risk and formulating population-specific prevention programs.

2749 Board #6 May 31 1:00 PM - 3:00 PM
Evaluation Of The Rate Of Orthopedic Injuries Of Concussed And Non-concussed Players In The NFL
 Emily M. Wittrup, Lucas A. Fox, Katherine M. Breedlove, Andrew P. Lapointe, Steven P. Broglio, FACSM. University of Michigan, Ann Arbor, MI. (Sponsor: Steve Broglio, FACSM)
 (No relevant relationships reported)

Evaluation of the Rate of Orthopedic Injuries of Concussed and Non-Concussed Players in the NFL
 Concussions may increase the risk of musculoskeletal injury during the 90 day period after return to play. Previous work has evaluated this effect in collegiate players with consistent results. **PURPOSE:** To examine possible increased risk of orthopedic injury among National Football League players 12 weeks (90 days) after return to play from an incident concussion compared to an incident orthopedic injury. **METHODS:** Weekly NFL injury data from 2012 through 2017 was collected from public websites and weeks 3-10 of the regular season were analyzed. Players with upper extremity (UE) and lower extremity (LE) orthopedic injuries were matched to each concussed player on position, team, and week of return to play. Concussed players were excluded if they sustained an orthopedic injury concurrently with a concussion or if there was no matched orthopedic control. Additional players were excluded from the study if they were on the injury logs for any other reason. This study analyzed 194 concussed players, comparing them with 187 LE and 105 UE injuries. An additional 444 non-injured controls with no injuries spanning 3 weeks prior were also evaluated. The rate of orthopedic injury was calculated as the number of orthopedic injuries during the 12 week period following return to play from their initial injury divided by 12 weeks. UE and LE injuries were evaluated separately against the concussion group using a Wilcoxon Rank Sum test. **RESULTS:** In the 12 week period following return to play from injury, players who sustained a concussion had an average of 0.030.06 orthopedic injuries, while players who sustained a LE injury or uninjured controls had a rate of 0.010.04 and 0.002.01 orthopedic injuries respectively. There was a significant difference between the orthopedic injury rate among the concussed and LE injury groups (Z = 2.22, p-value = 0.03). In addition, the difference in orthopedic injury rate between the controls and concussed groups was significant (Z=9.79, p-value = 1.55e-22). No relationship between concussed and UE injury was found. **CONCLUSION:** The results of this study suggest a relationship between concussions and subsequent orthopedic injuries in NFL players compared to those with an incident LE injury or no incident injury.

Volleyball-Related Injuries in Adolescent Female Players
 Joseph G. Wasser, Brady Tripp, Michelle L. Bruner, Daniel R. Bailey, Rachel S. Leitz, Jason L. Zaremski, Heather K. Vincent, FACSM. University of Florida, Gainesville, FL. (Sponsor: Dr. Heather K. Vincent, FACSM)
 Email: wassejg@ortho.ufl.edu
 (No relevant relationships reported)

Purpose: This study determined the prevalence and type of musculoskeletal injuries and potential contributing risk factors to injury among adolescent volleyball players. **Methods:** Female volleyball players (n=300; 10-18 yrs), with any level of volleyball experience were recruited. Participants completed a study-specific survey about their overall sport training type and volume, volleyball experience level (beginner, intermediate, advanced) and position, annual volume of volleyball play and injuries accrued during volleyball. **Results:** Over 65% of participants reported sustaining one or more injuries, with ankle (38.8%), knee (19.7%), finger (18.8%), and shoulder (14.5%) injuries being most frequently-reported. Among injured players, 21.1% reported missing more than one month of play. Annual volume of volleyball play increased as skill level progressed from beginner to advanced (179.7 units to 478.1 units p<0.05). Also, the prevalence of injuries sustained by players increased as skill level increased from beginner to advanced (7.7% to 72.3%; p<0.05). Players who ranked themselves as 'intermediate' experience had higher odds of sustaining an elbow injury compared to other skill levels (OR 6.59; p=0.02). Outside hitters, defensive specialists, and those who play multiple positions were more likely to participate in multiple conditioning methods such as weight training, endurance and flexibility (OR 1.81, 1.93, 1.74, respectively; p<0.05) with advanced players indicating a trend to higher odds of participating in multiple conditioning methods (OR 1.49, p=0.085). Only 46.1% of participants

reported playing other sports, with those participating in basketball indicating a 49% decreased odds of sustaining an injury compared to participating in other sports (OR 0.510, $p < 0.05$)

Conclusion: An interpretation of these data is that adolescent players may incur injuries due to underdeveloped neuromuscular systems capable of sustaining progressively higher volumes of play as experience and competition level increase. Participation in a secondary sport like basketball may protect against injury by conferring cross-sport benefits of jump-landing, cutting and body positioning. Position-specific injuries suggest technique-driven risk factors that should be further investigated biomechanically.

2751 Board #8 May 31 1:00 PM - 3:00 PM

Determinants of Concussion Symptomology and Resolution Time in US High School Soccer Players

Avinash Chandran¹, Zachary Y. Kerr¹, Angelo Elmi², Heather Young², Loretta DiPietro, FACSM². ¹University of North Carolina at Chapel Hill, Chapel Hill, NC. ²The George Washington University, Washington DC, DC. (Sponsor: Dr. Loretta DiPietro, FACSM)

Email: avinashc@email.unc.edu

Reported Relationships: A. Chandran: Other (please describe): The National Athletic Treatment, Injury and Outcomes Network (HS NATION) data were provided by the Datalys Center for Sports Injury Research and Prevention., HS NATION was funded by the National Athletic Trainers' Association Research and Education Foundation (NATA REF), and the Central Indiana Corporate Partnership (CICP) Foundation.

Concussions are a concern among soccer players of all ages. However, determinants of concussion symptomology and other sequelae have not been examined in high school soccer players.

Purpose: Examine the impact of sex, injury history, injury mechanism, and setting on concussion symptomology and resolution time among HS soccer players.

Methods: The NATION-SP captured soccer-related injury data collected by athletic trainers (ATs) during the 2011/12-2013/14 academic years. We specifically examined injuries diagnosed as concussions. Outcomes of interest included symptoms reported with concussions as well as resolution time, categorized as resolved in 7 days, 14 days, 28 days and > 28 days. Exposures of interest included sex, injury history, injury mechanism associated with concussion, and setting (competition vs. practice). We used multivariate logistic regression models to assess the odds of reporting specific symptoms as a function of exposures, as well as other observed symptoms. We then used ordinal logistic regression models to assess exposure effects on the odds of reporting a longer symptom resolution time. Odds Ratio (OR) estimates with 95% confidence intervals (CI) excluding 1.00 were deemed significant.

Results: A total of 189 concussions were reported, with most observed in girls (56%). Symptoms resolved within 7 days in 41% of reported concussions. Interestingly, we detected several symptom dependencies, such as higher odds of light sensitivity (OR=20.71, 95% CI: 8.58, 50.00) with concurrent noise sensitivity, and higher odds of irritability (OR=9.04, 95% CI: 3.74, 21.85) and drowsiness (OR=7.46, 95% CI: 3.48, 15.98) with concurrent insomnia. We also observed lower odds of longer symptom resolution time in concussions due to player contact mechanisms than those due to non-player-contact mechanisms (Adj. OR=0.33, 95% CI: 0.18, 0.59).

Conclusions: Determinants of soccer-related concussions and their sequelae appear to be multifactorial. The observed symptom dependencies may encourage clinicians to evaluate players for specific symptoms in the presence of others while also indicating common neurological pathways affected by trauma in this context. Injury mechanism may also be associated with concussion outcomes, although future investigation is warranted.

F-11 Free Communication/Slide - Carbohydrate Metabolism

Email: jrs484@drexel.edu

(No relevant relationships reported)

Substrate utilization as an indicator of exercise performance is a growing topic of interest for athletes. Athletes and sports science professionals are using substrate utilization to determine appropriate exercise programs and dietary interventions. However, evidence supporting the "typical" sports-specific metabolic profile is lacking. **PURPOSE:** To predict time of substrate change using respiratory exchange ratio (RER) >0.85 from heart rate (HR), percent $\dot{V}O_{2\max}$ (% $\dot{V}O_{2\max}$), sex, carbohydrate intake (CHO), fat intake (FAT) and protein intake (PRO). We also explored whether differences in substrate utilization existed among sport types during a $\dot{V}O_{2\max}$ test in Masters Athletes. **METHODS:** This was a cross-sectional study where 70 Masters Athletes (35 women; 35 men; 39±11 years of age) were measured for RER during a $\dot{V}O_{2\max}$ treadmill test. A food frequency questionnaire (FFQ) was completed to determine average nutrient intake. Athletes from four sport types were included in our analyses: runners (20), triathletes (20), rowers (19) and CrossFit athletes (11). A multivariate linear regression model of least squares was used to predict time to RER of >0.85 from HR, % $\dot{V}O_{2\max}$, sex, CHO, FAT and PRO. A one-way ANOVA was used to determine whether differences existed among sport types. Bonferroni correction procedures were used to control the familywise error rate and maintain alpha levels at $p < 0.05$. **RESULTS:** Significant correlations were found between time and HR ($r=0.632$, $p < 0.001$), time and % $\dot{V}O_{2\max}$ ($r=0.616$, $p < 0.001$), time and sex ($r=0.257$, $p=0.021$), time and CHO ($r=-0.290$, $p=0.010$), time and FAT ($r=-0.272$, $p=0.015$), time and PRO ($r=-0.270$, $p=0.016$) and were included in our multivariate model. HR, % $\dot{V}O_{2\max}$, sex, CHO, FAT, PRO significantly predicted time to RER ($R^2=0.467$, $p < 0.001$). We also found significant differences in time to RER >0.85 between runners (4:16 ± 0:58) and CrossFit athletes (2:52 ± 1:03) ($p=0.014$), posthoc. **CONCLUSION:** We found a significant relationship between HR, % $\dot{V}O_{2\max}$, sex, CHO, FAT, PRO and time to RER in Masters Athletes of various sports. We also found that significant differences existed in time to RER >0.85 between runners and CrossFit athletes. Future studies that are prospective and include diverse exercise intensities are needed. This study was not funded

Transcriptional Regulation Of Substrate Metabolism Following Carbohydrate Ingestion During Exercise Initiated With Different Glycogen Concentrations

Stefan M. Pasiakos, FACSM, Marques A. Wilson, Claire C. Whitney, Christopher T. Carrigan, Nancy E. Murphy, Adrienne M. Hatch, Scott J. Montain, Lee M. Margolis. *United States Army Research Institute of Environmental Medicine, Natick, MA.* Email: stefan.m.pasiakos.civ@mail.mil

(No relevant relationships reported)

BACKGROUND: Starting aerobic exercise with low muscle glycogen content elicits greater fat and less carbohydrate utilization than exercise started with high muscle glycogen content, even when exogenous carbohydrate is ingested during exercise. The mechanisms contributing to greater fat utilization despite ingesting carbohydrate during exercise initiated with low glycogen are not delineated.

PURPOSE: Characterize transcriptional regulation of substrate metabolism in response to carbohydrate ingestion during steady-state exercise initiated with low muscle glycogen.

METHODS: In a randomized, crossover design, 12 men (mean ± SD, age, 21 ± 4 y; body mass, 83 ± 11 kg; $\dot{V}O_{2\text{peak}}$, 44 ± 3 mL/kg/min) completed two cycle ergometry glycogen depletion trials, followed by a 24 h period of either high fat (1.5 g/kg carbohydrate, 3.0 g/kg fat) or high carbohydrate (6.0 g/kg carbohydrate, 1.0 g/kg fat) isocaloric refeeding to elicit low (LOW) or adequate (AD) glycogen content the following morning before initiating 80-min of cycle ergometry (64 ± 3% $\dot{V}O_{2\text{peak}}$) while

ingesting 146 g of carbohydrate. Transcriptional regulation of substrate metabolism was assessed using RT-qPCR in vastus lateralis biopsy samples obtained before (PRE) and after (POST) the 80-min exercise bout.

RESULTS: PRE glycogen synthase kinase 3 α expression was 40% lower ($P<0.05$; time-by-treatment interaction) in LOW than AD. GLUT4, hexokinase 2, phosphofructokinase, and pyruvate kinase expression were not different between LOW and AD. PRE fatty acid translocase was 40% higher ($P<0.05$; time-by-treatment interaction) in LOW than AD. Independent of time, fatty acid binding protein, carnitine palmitoyltransferase 1A, and hydroxyacyl-CoA dehydrogenase/3-ketoacyl-CoA expression were each ~40% higher ($P<0.05$; time effect) in LOW than AD. In LOW, POST peroxisome proliferator-activated receptor δ was 177% higher ($P<0.05$ time-by-treatment interaction) than PRE, with no change in AD.

CONCLUSION: Initiating aerobic exercise with low muscle glycogen content upregulates the transcriptional control of fat oxidation without modulating intramuscular regulation of glucose metabolism, even when exogenous glucose is ingested during exercise.

2755 May 31 1:30 PM - 1:45 PM

Effect Of Breaking-up Sedentary Activity On Metabolic Flexibility And Glycemia In Free-living Overweight/obese Adults

Laura Schreck, Nathan DeJong, Andrew Lange, Carlos Mendez, Thomas Glazer, David A. Goldstrohm, Edward L. Melanson, FACSM, Corey Rynders, Josiane Broussard, Daniel Bessesen, Audrey Bergouignan. *University of Colorado, Anschutz Medical Campus, Aurora, CO.* (Sponsor: Edward L. Melanson, FACSM) Email: laura.schreck@colostate.edu
(No relevant relationships reported)

PURPOSE: Sedentary behavior (SB) triggers an inability to adjust substrate use to substrate availability (metabolic flexibility, MF), which may precede glucose intolerance in the pathogenesis of insulin resistance. We and others have shown that frequent interruptions in SB leads to improved glycemic control, however the underlying role of MF in this process is unknown. This study examined the effects of breaking up SB on MF and glucose metabolism in free-living overweight and obese adults. To distinguish effects of breaking up SB from being physically active, we also studied a group where participants performed a single energy matched continuous bout of exercise. **METHODS:** Physically inactive, adults (12F/7M, mean \pm SD; 33 \pm 8 yrs, BMI = 29.5 \pm 3.3kg/m²) were randomly assigned to a 4 week intervention consisting of brisk walking for 5 min each hour for 10h, 5 d/wk (MICRO), or 4 weeks of an intervention consisting of one continuous 45 min bout of exercise per day, 5d/wk (ONE). Outcomes assessed at baseline and after each intervention included: MF (waking respiratory quotient, RQ, minus sleeping RQ as measured in a whole room calorimeter), insulin sensitivity (SI, IVGTT), 24h glycaemia (continuous glucose monitor), 24h glucose oxidation (U13C glucose tracer), SB, time spent stepping, and performing moderate to vigorous activity (MVPA; ActivPAL and ActiGraph). Groups were similar on all outcome variables at baseline. Linear mixed models evaluated intervention and intervention-by-group effects. **RESULTS:** MICRO and ONE decreased time sitting (-43.5 \pm 93.4 min), increased time stepping (+26.3 \pm 44.0 min) and time spent in MVPA (+9.8 \pm 17.6 min) ($p<0.05$ for all). No significant changes were observed in SI, but both interventions decreased fasting insulin and HOMA IR ($p<0.05$ for both). Compared to ONE, MICRO improved the acute insulin response to glucose (AIRg), lowered 24h glycemic variability, maintained exogenous glucose oxidation, and improved MF (interaction: $p<0.05$ for all). Improvements in MF were positively associated with changes in SI ($r=0.59$, $p=0.02$). **CONCLUSIONS:** Independent of time sitting and stepping, breaking up SB improves glucose homeostasis and MF. The effects of such an intervention in persons with type 2 diabetes warrants further study.

2756 May 31 1:45 PM - 2:00 PM

Low Muscle Glycogen Content Does Not Alter Exogenous Carbohydrate Oxidation During Aerobic Exercise

Lee M. Margolis, Marques A. Wilson, Claire C. Whitney, Christopher T. Carrigan, Nancy E. Murphy, Adrienne M. Hatch, Scott J. Montain, FACSM, Stefan M. Pasiakos, FACSM. *United States Army Research Institute of Environmental Medicine, Natick, MA.* (Sponsor: Stefan M Pasiakos, FACSM) Email: lee.m.margolis.ctr@mail.mil
(No relevant relationships reported)

BACKGROUND: Initiating aerobic exercise with low muscle glycogen content promotes greater fat and less endogenous carbohydrate oxidation during exercise. However, whether oxidation of exogenous carbohydrate increases when exercise is initiated with low muscle glycogen is not well defined.

PURPOSE: Determine if exogenous carbohydrate oxidation during aerobic exercise is affected by the level of muscle glycogen at the onset of exercise.

METHODS: Using a randomized, crossover design, 12 men (mean \pm SD, age: 21 \pm 4 y; body mass: 83 \pm 11 kg; VO_{2peak} : 44 \pm 3 mL/kg/min) completed 2 cycle ergometry glycogen depletion trials separated by 7-d, followed by a 24-h period of high fat (1.5 g/kg carbohydrate, 3.0 g/kg fat) or high carbohydrate (6.0 g/kg carbohydrate, 1.0 g/kg fat) refeeding to elicit low (LOW) or adequate (AD) glycogen stores. Participants then performed 80-min of steady-state cycle ergometry (64 \pm 3% VO_{2peak}) while ingesting 146 g of carbohydrate (95 g glucose + 51 g fructose; 1.8 g/min). Substrate oxidation (g/min) during exercise was determined by indirect calorimetry and tracer techniques with ¹³C-glucose and ¹³C-fructose. Muscle glycogen (mmol/kg dry wt) was determined by fluorimetric assays from vastus lateralis biopsies obtained before and after glycogen depletion and before (PRE) and after (POST) steady-state exercise trials.

RESULTS: Muscle glycogen concentrations were the same between treatments before (LOW: 467 \pm 95, AD: 472 \pm 109) and after both depletion exercise bouts (LOW: 207 \pm 99, AD: 210 \pm 145). Following 24-h refeeding, PRE glycogen was lower in LOW (217 \pm 103) compared AD (396 \pm 70; $P<0.05$). POST glycogen in AD (229 \pm 94; $P<0.05$) was lower than PRE but remained higher than LOW (137 \pm 131; $P<0.05$). Glycogen did not change PRE to POST in LOW. Exogenous carbohydrate oxidation rate was not different between LOW (0.84 \pm 0.14) and AD (0.87 \pm 0.16; $P>0.05$). Fat oxidation was higher, and total and endogenous carbohydrate oxidation was lower in LOW (0.55 \pm 0.10, 1.59 \pm 0.40, and 0.75 \pm 0.29) compared to AD (0.38 \pm 0.13, 2.03 \pm 0.36, 1.17 \pm 0.29; all $P<0.05$).

CONCLUSION: These data show that initiating steady-state aerobic exercise with low muscle glycogen content does not cause greater reliance on exogenous carbohydrate for fuel.

Energy Metabolism With Or Without Slow Or Rapid Absorption Carbohydrate In Trained Endurance Runners

Patrick Davitt, FACSM. *University of the Sciences, Philadelphia, PA.* Email: pdavitt@uscience.edu
(No relevant relationships reported)

The ability for carbohydrate (CHO) to provide sustained energy availability and stable blood glucose is important in prolonged endurance. **PURPOSE:** To examine energy metabolism, total and exogenous CHO utilization, blood glucose and performance after consuming different isocaloric glucose beverages before a sustained treadmill run. **METHODS:** 10 male experienced endurance runners (32.4 \pm 1.9 yr; 73.5 \pm 3.1 kg; %bf 15.3 \pm 2.1; VO_{2max} = 55.9 \pm 1.5 mL/kg/min) participated in a crossover-designed study, on 3 occasions: Slow digestion CHO (S), Fast digestion (F), and Water (C). Participants consumed a single 50g dose of either S or F prior to running 3hrs at 58% VO_{2max} . Pulmonary gas exchange and plasma glucose were assessed at -15, 0 (run-start), 30, 60, 90, 135, 180 min for glucose, metabolic rate, and CHOox. Breath CO₂ was analyzed for exogenous C13 rate of appearance. Immediately post-run participants completed a time-to-fatigue test at 110% VO_{2max} . **RESULTS:** There were no significant differences in VO_2 between groups during the run ($p=0.46$). There was a significant difference in CHOox for C vs. S and F (C 1.0; S 1.33; F 1.45 \pm 0.1 g/min) ($p=0.12$). There was a significant difference in breath ¹³CO₂ appearance for C vs. S and F, as well as S vs. F (C 0.0002; S 0.0012; F 0.0009 \pm 0.0001 mmol/min) ($p<0.001$), in addition to a significant time x trial for C and S vs. F ($p<0.001$). There was a significant difference in AUC CHO dose oxidized to CO₂ for S vs. F (S 1.09; F 1.41 \pm 0.2 mmol) ($p=0.03$). There was a significant difference in plasma glucose for C vs. S, but not for F (C 89.1; S 95.9; F 93.5 \pm 1.9 mg/dL) ($p=0.001$), in addition to a significant time x trial difference for C and S vs. F ($p<0.001$). There was no significant time-to-fatigue between any trial (C 161.1; S 223.7; F 156.1 \pm 34.4 sec) ($p=0.18$). **CONCLUSION:** The consumption of a single bolus of CHO beverage prior to a 3hr run elicits significant alterations in energy metabolism compared to just water, with S CHO burning significantly less total carbohydrate and more fat than a rapidly digested carbohydrate. The S CHO provided a more stable and consistent energy metabolism profile, in addition to the most stable glucose concentration during the run. These findings provide evidence that S CHO provides a consistent blood glucose and sustained exogenous energy supply during a sustained endurance run.

The Addition Of A Sodium Alginate-pectin Hydrogel To A Carbohydrate Beverage Significantly Enhances Gastric Emptying In Humans

Shaun Sutehall¹, Stuart Galloway², Andrew Bosch¹, Yannis Pitsiladis, FACSM³. ¹University of Cape Town, Cape Town, South Africa. ²University of Stirling, Stirling, United Kingdom. ³University of Brighton, Brighton, United Kingdom. (Sponsor: Prof Yannis Pitsiladis, FACSM)
Email: STHSHA011@myuct.ac.za

(No relevant relationships reported)

PURPOSE: To investigate the effect of CHO encapsulation and osmolarity on the rate of gastric emptying while at rest

METHODS: Eight healthy males were recruited to take part in this randomised, double blind, cross-over study. A 500 mL bolus of an experimental drink was instilled while seated, and gastric emptying measured using the double aspiration method every 10 min for 90 min. The three drinks consisted of 180 gL⁻¹ maltodextrin and fructose (POLY, ~700 mOsmkg⁻¹), 180 gL⁻¹ glucose and fructose (MON, ~1300 mOsmkg⁻¹) and 180 gL⁻¹ maltodextrin, fructose, sodium alginate and pectin (ENCAP, ~700 mOsmkg⁻¹). All drinks also contained 1.5 gL⁻¹ of sodium and had a CHO ratio of 1:0.8 (maltodextrin/glucose:fructose). Arterialised venous blood samples were collected prior to drink instillation and at regular intervals thereafter and analysed for glucose and non-esterified fatty acid (NEFA) concentration.

RESULTS: Time to empty half of the ingested bolus was faster for ENCAP (21.2 ± 8.5 min) than for POLY (36.3 ± 8.0 min, *P*<0.003), which was faster than for MON (52.4 ± 16.5 min, *P*<0.03). During the first 10 min, ENCAP emptied more than MON (ENCAP: 157 ± 50 vs MON: 41 ± 50 mL, *P*<0.05) but not more than POLY (108 ± 58 mL, *P*=0.28). Thereafter, ENCAP emptied more than POLY and MON, reaching significance at 20 min (ENCAP: 258 ± 68, POLY: 182 ± 44 and MON: 141 ± 42 mL, *P*<0.05) and 30 min (ENCAP: 307 ± 58, POLY: 196 ± 37, MON: 177 ± 50 mL, *P*<0.01) after instillation. After 40 minutes, there were no longer significant differences between ENCAP and POLY. ENCAP and MON remained significantly different until 70 min but were not significantly different thereafter (458 ± 34 vs 406 ± 51 mL, respectively, *P*=0.07). After 60 min, POLY had emptied significantly more than MON (380 ± 39 vs 290 ± 82, respectively, *P*<0.05). Serum glucose concentration increased to a similar level on all trials, while serum NEFA concentration continually decreased over the 90 min to a similar extent on all trials.

CONCLUSIONS: These findings suggest that encapsulating CHO in alginate hydrogel is an effective method to enhance gastric emptying.

2759 May 31 2:30 PM - 2:45 PM

Acute Carbohydrate Consumption On The Iron-regulatory Response To Exercise In Elite Keto-adapted Endurance Athletes

Burke, FACSM³. ¹University of Western Australia, Perth, Australia. ²University of Canberra, Canberra, Australia. ³Australian Institute of Sport, Canberra, Australia. ⁴Australian Catholic University, Melbourne, Australia. ⁵Australia Institute Sport, Canberra, Australia. ⁶Radboud University Medical Center, Nijmegen, Netherlands. ⁷Radboud University Medical Center, Nijmegen, Australia.

Email: alannah.mckay@ausport.gov.au

(No relevant relationships reported)

It has been demonstrated adherence to a low carbohydrate (CHO) high fat (LCHF) diet can alter markers of iron metabolism in endurance athletes. **PURPOSE:** To investigate the impact of CHO re-introduction in athletes previously adapted to a LCHF diet on subsequent inflammatory and hepcidin responses to exercise. **METHODS:** In the three weeks prior to the exercise trials, twenty-three elite race walkers adhered to either a CHO-rich (n=14) or LCHF diet (n=9). A 19-25 km race walking protocol was performed while the race walkers were still adhering to their allocated dietary intervention (Adapt). A second exercise test was performed three days later, where the LCHF consumed CHO 2 h prior to, and during the exercise protocol (in line with sports nutrition guidelines) for the first time in 3.5 weeks (CHO Restoration). Venous blood samples were collected pre-, post- and 3 h post-exercise and analysed for serum ferritin, interleukin-6 (IL-6) and hepcidin-25. **RESULTS:** Serum ferritin concentration was similar between trials (p=0.48) and dietary groups (p=0.93). The post-exercise IL-6 increase was greater in LCHF (p<0.001) during both Adapt (LCHF: 13.1-fold increase; CHO: 8.0-fold increase) and CHO Restoration (LCHF: 18.5-fold increase, CHO: 6.3-fold increase); outcomes were not different between trials (p=0.84). Hepcidin-25 levels increased 3 h post-exercise (p<0.001), however, they

did not differ between trials (p=0.46) or diets (p=0.84). **CONCLUSIONS:** Strenuous exercise undertaken following chronic adaptation to a LCHF diet is associated with a greater post-exercise IL-6 response than when exercise is undertaken with high CHO availability. The elevated IL-6 response in athletes adapted to a LCHF diet is not attenuated by an acute increase in exogenous CHO availability. Despite diet-induced differences in IL-6 responses, no differences in hepcidin levels were evident, suggesting IL-6 is likely not the primary factor determining the magnitude of post-exercise hepcidin levels. Baseline iron status may be a more dominant factor regulating this response. Increased IL-6 levels may negatively influence other body processes, and the long-term impact of adhering to LCHF on other health outcomes warrants further investigation. Funded by the ACU Research Fund and the AIS High Performance Sport Research Fund.

No Correlations Between Gastrointestinal Complaints, Gut Injury Markers, And Carbohydrate Ingestion During a 60 Km Ultramarathon

Floris C. Wardenaar¹, Niek van Venrooij², Daan Hoogervorst², Joan M.G. Senden³, Kaatje Lenaerts³, Kristin L. Jonvik². ¹Arizona State University, Phoenix, AZ. ²HAN University of Applied Sciences, Nijmegen, Netherlands. ³Maastricht University, Maastricht, Netherlands. (Sponsor: Barbara Ainsworth, FACSM)

Email: Floris.wardenaar@asu.edu

(No relevant relationships reported)

PURPOSE: It has been speculated that exercise-induced GI injury is associated with gastro-intestinal complaints. Ingesting carbohydrates (CHO) have been shown to blunt GI injury, although high CHO intakes also have been associated with GI complaints. The aim of this study was to investigate the relation between GI injury, -complaints and CHO intake.

METHODS: As part of a cross-sectional observation study 33 runners (28 males, 5 females) participating in a 60 km ultramarathon (4 April 2017, Texel, the Netherlands) provided a pre- and a post-race blood sample, and nutritional intake and (GI) complaints were assessed using a questionnaire after the race. Plasma intestinal fatty acid binding protein (I-FABP) levels, as a marker for GI injury, and inflammatory markers (CRP, IL-6, IL-8 and TNFα) were compared between pre- and post-race blood samples. GI complaints were scored on a 10-point scale and categorized as serious if scored ≥ 5. CHO intake (g/h) was calculated using predefined product ingredient declarations. Data were analyzed (SPSS 24.0) using Wilcoxon signed-rank tests and Spearman correlations tests and were presented as median [IQR]. Statistical significance was set at *P*<0.05.

RESULTS: Plasma I-FABP levels did not significantly change pre- to post-race (1375 [1264-2073] to 1726 [985-3287] pg/mL; *P*=0.33). CRP, IL-6, IL-8 and TNFα all increased from pre- to post-race (*P*<0.001). GI complaints were reported by 73% of the runners, of which 20% reported serious complaints. CHO intake was 60 [37-90] g/h. There were no significant correlations between ΔI-FABP levels and the sum of GI complaints (*r*_{sp}: -0.05; *P*=0.79), or between GI complaints and CHO intake (*r*_{sp}: 0.21; *P*=0.26). No correlation was found between ΔI-FABP and CHO intake (*r*_{sp}: -0.32; *P*=0.080), but dividing subjects into tertiles for ΔI-FABP levels revealed a significant difference in CHO intake between groups (*P*=0.027).

CONCLUSION: Despite substantial GI complaints during the ultramarathon, there were no evident signs of GI injury indicated by a minimal change in plasma IFABP levels. Prevalence of GI complaints were not correlated with change in I-FABP levels or CHO ingestion during exercise, but higher CHO intakes may potentially attenuate the degree of GI injury.

The project was supported by Eat2Move and Friesland Campina.

Are Lower-leg and Thigh Muscle Resistance Training Methods Equally Effective to Dynamic Balance for Community-Dwelling Elderly Females?

Hiroshi Kohno. *Toyo University, Asaka-Shi, Japan.*
Email: kohno@toyo.jp

(No relevant relationships reported)

PURPOSE: To compare the magnitude of lower-leg training program and thigh muscle training program to dynamic balance ability changes for community-dwelling elderly Japanese women.

METHODS: After giving written informed consent, the subjects, unable to stand on one leg for more than 25 seconds with their eyes open, were divided into a lower-leg training group (LLG; 10 females, 72.9±4.2 yrs, BMI 22.1±1.8) and a thigh muscle training group (TMG; 10 females, 70.6±2.5 yrs, BMI 22.1±1.2). The program was 60min. two times per week for 16 weeks. Each training program consisted of three parts. At first, participants learned about management skills for their physical stiffness. Secondly, they learned each resistance program. LLG participated in the program using unstable disk and elastic band. TMG learned program was to strengthen their thigh muscles with elastic band. Finally, both groups learned a three-minute arm and leg combined exercise program with music. Participants were asked to follow their learned management skill program and resistance program every day and check it on the card. Dynamic balance ability was measured by one-leg standing time with their eyes open, the area covering and total length of the center of gravity sway(COP) with eyes open or close by stabilometer. Knee extension strength was evaluated. Each measurement items were assessed before and after the intervention period. Student's t-test and two-way repeated measures ANOVA were used to test the effectiveness.

RESULTS: The class participation rates were 82± 4% and 81± 8% and home participation rates were 76± 10% and 72± 15% respectively. One-leg standing time with their eyes open (LLG: 14.0±3.0 to 19.9±2.2 sec., TMG: 12.4±2.5 to 15.9±2.2sec, F=5.01,P=0.038), area covering of COP with eyes open (LLG: 14.1±41 to 8.2±6.5 cm², TMG: 15.1±3.3 to 18.8±9.0cm²,F=8.54, P=0.009), total length of COP (LLG: 143.1±33.1 to 95.6±18.9 cm., TMG: 144.9±26.4 to 135.7±37.2cm,F=3.92, P=0.046) improved significantly in LLG. TMG knee extension strength improved significantly(P=0.029).

CONCLUSIONS: Lower-leg muscle training was found more effective to improve dynamic balance ability than thigh muscle training for community-dwelling females.

Using Gamification to Enhance Student Participation in Classroom Activity Breaks

Lexie R. Beemer, Lauren Allport, Tiwaloluwa A. Ajibewa, Shreya Bahl, Emma Weston, Maysa Damen, Ben Ransier, Darin Stockdill, U. Sean Vance, Rebecca E. Hasson, FACSM. *University of Michigan, Ann Arbor, MI.* (Sponsor: Rebecca E. Hasson, FACSM)

Email: abeemer@umich.edu

(No relevant relationships reported)

PURPOSE: Classroom-based interventions implemented in elementary schools have the potential to establish life-long physical activity habits in children. However, lower rates of participation have been observed among children in socioeconomically disadvantaged schools. The purpose of this study was to test the effectiveness of gamifying activity breaks (AB) to enhance student participation, enjoyment, and confidence during AB in low-income schools. **METHODS:** Nine, 3rd through 6th-grade classrooms (approximately 300 students) in one elementary-middle school in Detroit, Michigan (79% Hispanic; 80% qualified for free/reduced lunch) participated in this 20-week intervention where teachers implemented 5, 4-minute AB/day (100 minutes/week). Gamification of AB occurred during weeks 13-20 of the intervention and included the use of game design elements and classroom goals for the percentage of students engaging in moderate-to-vigorous physical activity (MVPA). Students had the opportunity to win daily, weekly, and post-intervention prizes for meeting

their classroom goal. Student AB participation was measured via direct observation. Student AB enjoyment was measured via the Physical Activity Enjoyment Scale questionnaire. Student AB confidence was measured via a single-item question from the Physical Activity Self-Efficacy Scale. **RESULTS:** Compared to the standard intervention (weeks 6-12), the gamified intervention resulted in a significant increase in student MVPA (standard: 38±2.3% vs. gamified: 60±2.1%, p=0.01) and student enjoyment (standard: 3.6±0.1 vs. gamified: 3.8±0.1, p=0.01) during an AB, with no change in student confidence (standard: 7.1±0.2 vs. gamified: 7.2±0.2, p=0.90). **CONCLUSIONS:** Gamification increased student MVPA participation by 86% and enjoyment of AB by 6%. This equated to students accumulating approximately 21 minutes of classroom activity per day, 13 of which were MVPA. These findings suggest gamification may be a key tool to increasing classroom activity and physical activity enjoyment in children attending low-income schools.

Comparing Health Improvements Achieved Through Different Pathways Of A Community-based Motivational Interviewing Physical Activity Programme

Matthew Wade¹, Nicola Brown², James Steele¹, Bernadette Dancy², Anne Majumdar². ¹*ukactive Research Institute, London, United Kingdom.* ²*St Mary's University, London, United Kingdom.*

Email: matthewwade@ukactive.org.uk

(No relevant relationships reported)

Benefits of regular physical activity (PA) are well documented, however physical inactivity remains a global public health challenge. The National Institute for Health and Care Excellence recommend brief advice to elicit positive PA behaviour change.

PURPOSE: Assess PA and mental wellbeing impact of signposting [SP] and Social Action [SA] group pathways of a motivational interviewing (MI) community-based PA intervention. **METHODS:** Participants (18-74 years, BMI of 28-35 kg/m²) from Essex, UK, were invited to take part in a community-based, primary care PA programme which uses MI techniques. Self-reported PA (IPAQ) and mental wellbeing (Short Warwick Edinburg Mental Wellbeing Scale) data were collected at baseline (following an initial 30 minute MI appointment), 12 weeks, 6 months, and 12 months. Participants were assigned to receive activity SP after the initial MI appointment or attend a SA group (weekly healthy lifestyle support for 12 weeks) depending on their GP surgery. Multilevel modelling were used to derive point estimates and 95% CIs for each time point and change scores (i.e. time x - time y). **RESULTS:** 2084 participants attended a baseline appointment (61% women, mean age 61 years (SD 12), 95% White or White British, 68% disabled). Mean total PA (MET-min/week) was significantly greater at baseline for the SP group (SP: 1439, 95%CI [1323-1556]; SA: 1126, 95%CI [1045-1207]). Both pathways significantly increased the amount of total PA at 12 weeks, 6 months, and 12 months. However, there were no significant differences in the changes between pathways. No significant differences in mental wellbeing between pathways at any of the four time points. Mental wellbeing significantly increased for both pathways from baseline to 12 weeks, remaining constant at 6 months. Non-significant reduction in mental wellbeing from 6 months to 12 months for the SP pathway (-1.1, 95%CI [-2.5-0.4]), but a significant increase for the SA pathway (1.3, 95%CI [0.1-2.4]). No significant differences in the changes between pathways. **CONCLUSION:** Both pathways produced similar improvements in PA and mental wellbeing suggesting MI based PA interventions with SP or SA are both effective in improving health outcomes. However, no difference in the results indicate SP should be recommended, especially as the SA group requires more resource.

Effects Of A Teacher-led Movement-training Program On Physical Fitness, Motor Skills, And Physical Activity In Third And Fourth Grade Students

Brittany Masteller, John R. Sirard, FACSM. *University of Massachusetts Amherst, Amherst, MA.* (Sponsor: John Sirard, FACSM)

Email: brittanymasteller@gmail.com

(No relevant relationships reported)

PURPOSE: FUNDamental Integrative Training (FIT) is a circuit-style strength training approach designed to be implemented in conjunction with a physical education program. The purpose of this study was to evaluate the effects of a 12-week, FIT program on physical fitness, fundamental movement skills, physical activity, and psychosocial mediators among children in third and fourth grade classrooms.

METHODS: A total of seven classrooms in one school were randomly assigned to the intervention (INT, n=4) or control (CON, n=3) group. The INT classrooms received a 12-week, teacher-led FIT intervention. The CON group continued participation in regular physical education. At baseline, mid-point, and immediately post intervention, physical fitness (curl-up, push-up, sit & reach), motor skills (hop, jump, throw, catch), objectively measured weekly physical activity and sedentary time, and psychosocial factors (self-efficacy, enjoyment, social support) were measured for all participants.

Kruskal-Wallis rank-sum tests were used to compare pre-post changes between the INT and CON groups for all variables. **RESULTS:** Sedentary time decreased for the INT group (-19 minutes) and increased slightly for the CON group ($p=0.04$). No significant differences were observed between groups for any of the physical fitness, motor skill, or physical activity variables. **CONCLUSIONS:** The current study adds valuable insight into the efficacy of delivering a FIT intervention into an existing PE curriculum. Future studies should continue to explore the relationships between physical activity, fitness, and motor skills in children to identify causal pathways and intervene appropriately.

Changes On Non-exercise Physical Activity Are Related To Improvements In Mitochondrial Function Independently Of Structured Intentional Exercise

Elvis Alvarez Carnero, Robert Standley, Giovanna Distefano, Paul M. Coen, Bret H. Goodpaster. *Florida Hospital. Translational Research Institute, Orlando, FL.*

Email: Elvis.carnero@flhosp.org

(No relevant relationships reported)

Whether exercise interventions increase or reduce non-exercise physical activity (NEPA) is controversial. Few studies have examined this potential effect on relevant physiological outcomes, particularly in the context of randomized controlled trials. **PURPOSE:** To determine the effects of a structured exercise program on NEPA, and the independent association between NEPA and both cardiorespiratory fitness (VO_{2max}) and mitochondrial capacity within skeletal muscle. **METHODS** Thirty-seven older (age=69±5yrs) obese ($BMI=35±3kg/m^2$) adults were randomized to one of the following 6-month interventions: Health education (CON: n=12), diet induced weight-loss (DIWL: n=12, or Weight-loss and exercise (WLEX: n=15). CRWL and WLEX participants had a goal of 10% weight-loss through calorie restriction. Subjects in the WLEX group completed a supervised combined aerobic and resistance exercise program. We quantified components of PA by a multisensory device. VO_{2max} was determined by cycle ergometry. Maximal oxidative phosphorylation (OXPHOS) and maximal uncoupled respiration (ETS) of permeabilized myofibers from biopsies was evaluated by high-resolution respirometry. Repeated measures analysis was performed to compare differences between the three groups pre and post intervention. Adjusted correlations to weight loss (WL) between NEPA and VO_{2max} , ETS and OXPHOS were performed. **RESULTS:** After the intervention WLEX increased significantly NEPA compared with the other groups (NEPA: WLEX= 89.6±84.5 min/day; DIWL= 3.7±42.4 min/day; CON= -10.5±63.6 min/day; $F=8.87$ for time x group interaction, $P<0.001$). Change in NEPA was positively correlated with change in mitochondrial capacity (OXPHOS, $r=0.453$ and $r=0.468$; $P<0.05$ for both) and absolute VO_{2max} ($r=0.453$, $P<0.05$). Both DIWL and WLEX experienced a significant WL (WLEX= -10.1±5.0 min/day and DIWL= -7.2±5.5 min/day; $P<0.05$). **CONCLUSIONS:** In addition to the beneficial effects of structured intentional exercise on cardiorespiratory fitness and mitochondrial capacity within muscle, exercise programs in older obese adults may also increase non-exercise physical activity, which in turn appears to independently correlate with improved aerobic capacity. These results highlight the concurrent effect of exercise and NEPA to improve health outcomes.

Intervention Effects Of A Kindergarten-based Health-promotion Programme On Physical Activity, Bmi Percentiles And Endurance Capacity

Susanne Kobel, Olivia Wartha, Christine Lämmle, Jens Dreyhaupt, Daniela Schmid, Jürgen M. Steinacker, FACSM. *Ulm University, Ulm, Germany.* (Sponsor: Jürgen M. Steinacker, FACSM)

(No relevant relationships reported)

PURPOSE: In recent decades, the prevalence of childhood overweight has increased worldwide and became a public health concern. One reason for this is children's insufficient engagement in physical activity (PA) which may lead to deficient motor skills, which are interdependent. Therefore, early health promotion such as the kindergarten-based health promotion programme "Join the Healthy Boat" is necessary. **METHODS:** In order to evaluate the programme's effectiveness on children's BMI percentiles (BMIPCT), PA and endurance capacity, a randomised controlled trial including intervention (IG) and control group (CG) was conducted. 973 kindergarten children (3.6±0.6 years; 47.1% male) in 57 kindergartens were assessed at baseline and 558 of them at follow-up. Anthropometrics and endurance capability (3-minute-run) were assessed on site. PA behaviour and socio-economic data were assessed using parental report. Linear regression models were used to determine intervention effects for all health outcomes, adjusting for baseline values, age, gender, BMIPCT and socio-economic variables. **RESULTS:** After one year, a significant positive intervention effect on children's BMIPCT was found ($p<0.04$). Further, children in the IG spent significantly more

days in sufficient PA than children in the CG (3.1±2.1 days vs. 2.5±1.9 days; $p<0.005$). Children in the IG also performed significantly better in the three minute endurance run than their counterparts in the CG (305.8±46.2m vs. 286.9±43.2m; $p<0.001$). **CONCLUSIONS:** This teacher-centred health promotion using a low-dose bottom-up approach with action alternatives achieved significant positive effects in the reduction of BMIPCT and significant increases in endurance capacity and daily PA. The programme is therefore ideal for integrating health promotion more intensively into the everyday life of children.

Comparing Physical Activity Levels across Differing Physical Education Class Modules in Middle Schools using SOFIT

Stuart McCrory¹, Bryndan Lindsey¹, Monica Guerra¹, Carol Pierce², Shane Caswell¹, Nelson Cortes¹, Jatin Ambegaonkar¹. ¹SMART Laboratory, George Mason University, Manassas, VA. ²Parkside Middle School, Prince William County Public Schools, Manassas, VA.

(No relevant relationships reported)

Over 1/3rd of school-age children are overweight or obese. To address this problem, school-age children are recommended to take part in 60 minutes of daily moderate-to-vigorous physical activity (MVPA), with 30 minutes of this daily MVPA being in-school. Physical education (PE) classes offer ideal opportunities for physical activity (PA) as they utilize varying modules including team sports, general fitness, and social (e.g. dance). Yet, how much overall PA and MVPA occurs over these differing PE class modules remains unclear. The System for Observing Fitness Instruction Time (SOFIT) is a simple observational tool that PE instructors can use to calculate PA.

PURPOSE: To observe student PA levels across multiple PE modules using SOFIT. **METHODS:** A modified SOFIT was used to assess PA over 15, 90-minute PE classes ($N=124$) across 3 modules: team sports (8 sessions), general fitness (3 sessions), and dance (4 sessions) in a single middle school. PA was coded from 1-5 corresponding to lying down, sitting, standing, walking, and vigorous, respectively. The same observer recorded PA in the last minute of a 5-minute interval based on activity in the prior 4 minutes. Separate 1-way ANOVA examined differences in MVPA (i.e. scores > 4) and overall PA across modules with Tukey-Kramer post hoc analyses as appropriate. **RESULTS:** Overall PA differed significantly across modules ($p=.02$), with team sports producing higher PA (3.80±.36) than dance (3.19±.39; $p=.04$). MVPA was similar across all modules (team sports: 4.29±.43, general fitness: 4.06±.28, dance: 3.70±.41; $F_{2,12}=2.83$; $p=.09$).

CONCLUSION: Although team sports produced greater overall PA, all modules (team sports, fitness, and dance) produced similar MVPA. As MVPA is suggested to be the preferred component of overall PA for improving overall health, all these modules are viable options for producing MVPA during PE classes in this population. To improve adherence to these different activities, future researchers should compare enjoyment levels for students across these activities. Overall, as PE classes are the greatest contribution to in-school PA for students, PE instructors and school health administrators can use our findings to choose appropriate modules to teach children PE and, concurrently, positively address the childhood obesity epidemic.

Cardiovascular, Metabolic, and Perceived Effort In A Simulated Commute On A Regular And Electric Bicycle

Helaine M. Alessio, FACSM, Tim Reiman, Brett Kemper, Courtney Kemper, Ryan Mullen, McKenna DiRe, Winston Von Carlowitz, Arden McMath, Rachel Pugh, Kyle Timmerman, FACSM. *Miami University, Oxford, OH.*

Email: alessih@miamioh.edu

(No relevant relationships reported)

Use of electric bicycles (e-bikes) with battery powered assist when pedaling, may incentivize active transport for people who may not be fit enough to ride several miles to school, work, or for leisure. E-bikes may enhance one's daily physical activity levels, possibly create a cardiovascular and metabolic health benefit and be an environmentally friendly transportation option. **PURPOSE:** To compare metabolic, cardiovascular, and ratings of perceived effort (RPE) when riding an e-bike for 3 miles at two different assist levels (boosts that vary in intensity), in comparison with a regular bicycle. **METHODS:** Male ($n=16$) and female ($n=14$) subjects, aged 19-61 yr, completed a YMCA submaximal test and three outdoor 3-mile bike rides, simulating a typical commute, at their own pace on a standard bicycle and on an e-bike at both E-2 assist, and E-3 assist levels. Participants wore a heart rate (HR) monitor and COSMED that recorded HR and oxygen consumption (VO_2). RPE on a 6-20 Borg scale was reported at the end of each 3-mile ride. A linear mixed effects model estimated the differences within subjects and between bicycle types on variables of interest at the 95% confidence level. **RESULTS:** In every model, for every variable, a significant difference ($p<0.05$) existed between riding a regular bicycle compared with an e-bike at both assist levels: HR (Reg=133 vs E-2=124 and E-3=114 beats·min⁻¹), % of VO_2

max (Reg=56 vs E-2=48 and E-3=40%, RPE (Reg=12.3 vs E-2=9.8 and E-3=8.4, respiratory quotient (Reg=.89 vs E-2=.85 and E-3=.85), METS (Reg=6.7 vs E-2=5.8 and E-3=4.8), caloric expenditure (Reg=519 vs E-2=436 and E-3=359 kcal•hr⁻¹), time (Reg=13.7 vs E-2=11.8 and E-3=10.3 min) and VO₂ (Reg=23.6 vs E-2=20.3 and E-3=16.8 ml•kg⁻¹•min⁻¹). CONCLUSIONS: Compared with regular bicycles, riding e-bikes at assist levels 2 and 3 resulted in 2.5 - 3.9 min faster 3-mile times and lower perceived efforts from somewhat hard for regular bicycle to very light for either e-bike assist levels. Speed and lower RPE may incentivize people to ride e-bikes which may contribute to environmentally friendly active transport. Compared with regular bicycling, 10-20% lower metabolic and cardiovascular responses associated with e-bikes, if performed regularly, may still benefit fitness and health.

F-13 Free Communication/Slide - Foot and Ankle

Differences In Foot Kinematics Between Forefoot Strikers In Minimalist And Conventional Running Shoes

Tryntsje Fokkema¹, Jereme Outerleys², Alessandra Bento Matias², Adam C. Clansy², Irene S. Davis, FACSM². ¹Erasmus MC University Medical Center, Rotterdam, Netherlands. ²Harvard Medical School, Cambridge, MA.
Email: t.fokkema@erasmusmc.nl
(No relevant relationships reported)

Forefoot strike (FFS) runners in conventional shoes exhibit higher posterior and medial ground reaction force loadrates than FFS runners in minimal shoes. This results in higher resultant loadrates when forefoot striking in conventional shoes. The elevated cushioned heel and lateral outsole flare of a conventional shoe may predispose the foot to greater plantarflexion (PF) and inversion (INV) at footstrike. This position may result in the increase in posterior and medial loading. PURPOSE: To determine the foot kinematic differences in the sagittal and frontal planes of FFS runners who are habituated to either conventional shoes (FFS-C) or minimal shoes (FFS-M). METHODS: This is an ongoing study of which 9 FFS-M and 15 FFS-C have been recruited to date. Kinematic and kinetic data were collected as runners traversed a 30-m runway at 3.31 (±5%) m/s, while wearing their habitual type of shoe. Foot and ankle kinematics at footstrike as well as ground reaction force loadrates were compared between groups, using Mann-Whitney U tests. Pearson correlations between kinematics and instantaneous load rates (ILR) in posterior and medial directions were calculated. RESULTS: FFS-C exhibited more plantarflexion at footstrike in the foot and ankle compared to FFS-M (Table 1). There were moderate correlations between the posterior ILR and the amount plantarflexion at footstrike in the foot and ankle (r=-0.511, p=0.011 and r=-0.582, p=0.003 respectively), where more PF resulted in a higher posterior ILR. There were no differences between FFS-C and FFS-M in the frontal plane at footstrike. Additionally, inversion at footstrike was not correlated with medial ILR (r=0.220, p=0.301). CONCLUSION: Based upon these preliminary results, running with a FFS pattern in conventional shoes promotes greater PF at footstrike, which is associated with greater posterior load rates. While greater INV at footstrike was not noted, medial load rates were greater.

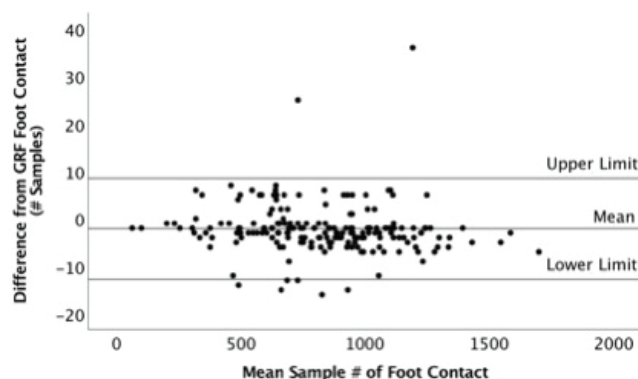

Table 1. Mean (SD) comparison of kinematic and kinetic variables between FFS-M and FFS-C

| | FFS-M | FFS-C | p value |
|----------------------------------|-------------|--------------|---------|
| | (n=9) | (n=15) | |
| Foot PF at initial contact (°) | -3.41 (2.4) | -8.94 (3.4) | <0.001 |
| Ankle PF at initial contact (°) | -6.05 (4.1) | -15.3 (5.5) | <0.001 |
| Peak ankle DF velocity (°/s) | 444 (90.0) | 579 (87.1) | 0.004 |
| Foot INV at initial contact (°) | 16.7 (4.6) | 16.0 (5.7) | 0.861 |
| Ankle INV at initial contact (°) | 12.5 (4.5) | 12.9 (5.5) | 0.976 |
| Peak ankle EV velocity (°/s) | -333 (86.7) | -465 (124.0) | 0.012 |
| Peak posterior load rate (BW/s) | 15.5 (5.7) | 26.5 (10.8) | 0.022 |
| Peak medial load rate (BW/s) | 7.12 (2.5) | 9.51 (2.7) | 0.055 |
| Peak resultant load rate (BW/s) | 55.7 (12.0) | 66.4 (17.8) | 0.114 |

2772 May 31 1:15 PM - 1:30 PM
Foot Contact Identification Using A Tibial Mounted Accelerometer During Running

Kevin Aubol, Jillian L. Hawkins, Clare E. Milner, FACSM. *Drexel University, Philadelphia, PA.* (Sponsor: Clare Milner, FACSM)
Email: kga43@drexel.edu
(No relevant relationships reported)

It is often necessary to identify foot contact when analyzing running biomechanics data, but most techniques are restricted to use in the laboratory. The accurate identification of foot contact from a single triaxial accelerometer mounted on the tibia may be useful for in-field measurements of gait. PURPOSE: To determine criterion-related validity of a new technique for determining foot contact from the resultant acceleration of the distal tibia compared to foot contact determined from vertical ground reaction force. METHODS: As part of a larger study, 19 runners (10 female, 9 male; 31 ± 6 years; 1.70 ± 0.08 m; 68.6 ± 11.6 kg) participated. Synchronous tibial acceleration and ground reaction force data were recorded at 1000 Hz using a triaxial accelerometer mounted to the skin over the distal antero-medial tibia and a force plate embedded in the floor. Participants completed 10 running trials at 3.0 m/s. Resultant acceleration was calculated and foot contact was determined using a custom algorithm that identified a minimum prior to peak resultant acceleration. Foot contact was also determined as the time at which vertical ground reaction force exceeded a threshold of 20 N. 95% limits of agreement between the two methods were calculated. RESULTS: On average the resultant acceleration identified foot contact 2.1 ± 5.4 ms earlier than ground reaction force. The 95% limits of agreement were -8.5 to 12.8 ms. With this approach 95% of foot contacts identified from resultant acceleration were within 10 ms of foot contact identified from ground reaction force. CONCLUSION: Identifying foot strike from resultant tibial acceleration measured using a single triaxial accelerometer is a valid technique for foot contact identification in the field. Study funded by College of Nursing and Health Professions Research Award

Impact Of Reduced Plantar Sensation On Balance Control

Caitlin O'Connell, Gustavo Sandri Heidner, Nicholas Murray, J. Chris Mizelle, Patrick Rider, Zachary Domire. *East Carolina University, Greenville, NC.*
Email: oconnellca17@ecu.edu

(No relevant relationships reported)

PURPOSE: Balance control has often been used to examine neural function. Given the robustness of balance control, perturbation is often needed to allow for more sensitive measurement. Our previous work has shown that balance is perturbed when a participant is placed in a moving virtual reality environment (VR). This situation creates a sensory mismatch between plantar sensation and visual feedback. The purpose of this study was to examine balance control when plantar sensation was reduced by cooling the plantar sole. We hypothesized that reducing plantar sensation would increase sway displacement, velocity and approximate entropy in a moving VR. **METHODS:** Six healthy young adults completed baseline balance tests: quiet standing (QS) and challenged by an anterior-posterior sinusoidal movement of a 360° projected picture of the lab within the VR headset. After the baseline balance test, participants placed the bottom of their feet in an ice bath until the plantar sole reached a temperature of 10-15°C. Reduced plantar sensation (RPS) was confirmed using a monofilament test. Balance tests were then repeated with participants standing on a cold steel plate with a temperature below 15°C to ensure consistent temperature of the plantar sole. Statistical analysis was performed on anterior-posterior center of pressure displacement, velocity and approximate entropy to determine differences between baseline and RPS balance tests within each balance condition ($\alpha=0.05$). **RESULTS:** Displacement increased when plantar sensation was reduced during the VR condition ($p = 0.04$, Baseline = 1.8 ± 0.8 cm, RPS = 2.4 ± 0.9 cm). There were similar trends that velocity ($p = 0.08$, Baseline = 5.1 ± 2.0 cm/s, RPS = 6.5 ± 2.6 cm/s) and approximate entropy ($p = 0.1$, Baseline = 0.13 ± 0.06 , RPS = 0.10 ± 0.03) were greater when plantar sensation was reduced during the VR condition. There was no difference between reduced plantar sensation and baseline balance during QS. **CONCLUSIONS:** Reducing plantar sensation elicited increased sway with a more consistent pattern (increased approximate entropy) when balance was perturbed by a moving visual environment, suggesting that participants had reduced balance control capabilities due to the sensory mismatch. Funding provided by the Office of Naval Research (N00014-17-1-272).

The Effects of Ankle Taping on Double Leg Balance after Plyometric Exercises

Russell Lowell¹, Jackson Roper¹, Madeline Phillips¹, Abby McCarthy¹, Hannah Nelson¹, Anna Blackley¹, Abrahan Frech¹, Moroni de Moors¹, Branden Ziebell¹, Jared Hornsby¹, Will Peveler¹, Jeff Simpson², David Titcomb¹, Andy Bosak¹. ¹*Liberty University, Lynchburg, VA.* ²*University of West Florida, Pensacola, FL.* (Sponsor: Dr. James Schoffstall, FACSM)
(No relevant relationships reported)

Ankle taping (AT) is a common preventative method to decrease the likelihood of ankle ligament injuries. Many athletic trainers use AT for athletes involved in high volume jumping sports to increase ankle stability. Ankle proprioception and postural control can be altered due to the restriction caused by AT and therefore, athletes need to be aware of the potential changes. **PURPOSE:** To compare AT center of pressure displacement (COPDsp) vs no ankle taping (NT) COPDsp, in the X- and Y- direction, before and after a fatiguing plyometric protocol. **METHODS:** Descriptive data (Ht. = 178.67 ± 8.88 , Wt. = 79.69 ± 9.55 , BF% = 12.20 ± 4.38 , age = 22.81 ± 2.56) was measured for 16 averagely fit college-age males. AT and NT sessions were prescribed in a counterbalanced order. Both sessions were separated by no less than 72 hours and no more than 96 hours of recovery. Each subject completed the same plyometric protocol and balance testing on a force plate pre- and post- fatigue with eyes closed (EC) and open (EO) trials. Significant differences for COPDsp between pre- and post- fatigue and both taping sessions were measured using a 2x2x2 repeated-measures ANOVA. Statistical significance was set at $p \leq 0.05$ for all analyses. **RESULTS:** The interaction between AT PRE EC (.137 cm) and AT POST EC (.166 cm) trials in the X direction were significant, $p = .041$. Significant differences also occurred between AT PRE EO (.133 cm) and AT POST EO (.175 cm) trials in the X direction, $p = .039$. No significant differences occurred in the Y direction for AT PRE-POST EC trials ($p = .507$) or AT PRE-POST EO trials ($p = .196$). No significant differences occurred in all NT PRE-POST EC and EO trials, $p > .05$. **CONCLUSIONS:** The current results suggest AT caused an increase in the COPDsp X direction, while there was no difference in the Y direction. Future studies may seek to evaluate collegiate athletes with experience wearing AT and the resulting effects during a dynamic balance test.

2775 May 31 2:00 PM - 2:15 PM

Effects of Shock Pad and Synthetic Turf on Ankle Biomechanics in a 90° Cutting Movement

Songning Zhang, FACSM¹, Thomas Elvidge¹, Kevin Valenzuela². ¹*The University of Tennessee, Knoxville, TN.* ²*California State University, Long Beach, CA.*
Email: szhang@utk.edu

(No relevant relationships reported)

Shock pad (PAD) is a popular choice underlayment installed under a synthetic turf (TURF) field. The effects of PAD on impact attenuation and injury risks of human movements are still relatively unknown.

PURPOSE: To examine impact attenuation related ankle biomechanical characteristics of a 90° cutting movement on synthetic turf with shock pad compared to synthetic turf only.

METHODS: Twelve recreational football and soccer players performed five successful trials of 90° cutting movement in each of two approaching speed conditions: 3.0 ± 0.3 (SLOW) and 4.0 ± 0.4 (FAST) m/s on each of TURF and PAD surface conditions. Three-dimensional kinematic and ground reaction force (GRF) data were collected simultaneously. A 2" monofilament synthetic turf with 1/2" stitch gauge was used in TURF and PAD conditions. A foam-based shock pad was used in PAD condition.

RESULTS: No significant surface main effect or surface by speed interactions were found for any ankle kinematic and kinetic variables and peak GRFs ($p > 0.05$). Increased peak ankle eversion moment (0.65 vs. 0.84 Nm/kg, $p < 0.001$) and inversion loading range of motion (ROM, 13.7 vs. 18.6 deg, $p = 0.001$) were seen in FAST compared to SLOW. Increases for peak ankle sagittal-plane concentric pushoff power, and frontal-plane eccentric and concentric power were also observed in FAST compared to SLOW. Peak vertical (2.04 vs. 2.31 BW, $p = 0.023$) and medial loading (0.79 vs. 1.11 BW, $p = 0.002$) GRFs were higher in FAST than SLOW. Additionally, peak pushoff medial GRFs were increased from SLOW to FAST (0.91 vs. 1.20 BW, $p = 0.025$), but pushoff vertical GRFs were decreased slightly (2.24 vs. 2.11 BW, $p = 0.011$).

CONCLUSIONS: The lack of significant differences between TURF and PAD and their interactions for examined ankle and GRF variables suggest that adding a form-based shock pad does not impede cutting performance. These results also seem to indicate there is a neuromuscular accommodation in cutting mechanics on PAD surface, which cannot be reflected loading variables using inverse dynamics. As cutting speed increased, greater increases in medial peak GRFs, and frontal-plane peak ankle moment and ROM were observed compared to those in sagittal-plane, suggesting increased mediolateral loading to ankle complex in fast cut movement. Supported in part by Brock International.

2776 May 31 2:15 PM - 2:30 PM

Gluteus Medius Activation During Gait Is Altered With Chronic Ankle Instability: An Ultrasound Imaging Study

Alexandra F. DeJong¹, L. Colby Mangum², Jay Hertel, FACSM¹. ¹*University of Virginia, Charlottesville, VA.* ²*University of Central Florida, Orlando, FL.* (Sponsor: Jay Hertel, FACSM)
Email: afd4au@virginia.edu

(No relevant relationships reported)

Altered gait mechanics are frequently reported in individuals with chronic ankle instability (CAI), and increasing information suggests proximal muscle adaptations occur in this population. Ultrasound imaging (USI) offers a visual means to evaluate muscle activation during movement, and overcomes limitations of electromyography to detect hip muscle activity.

PURPOSE: To identify gluteus maximus (GMAX) and medius (GMED) muscle activation using USI throughout walking gait in individuals with and without CAI.

METHODS: A descriptive laboratory study was conducted to evaluate gluteal muscle activation throughout walking on 40 total participants during a single session. Twenty young adults with CAI (21.6 ± 2.4 years, 10 males) and 20 healthy participants (21.2 ± 2.8 years, 10 males) walked on a treadmill at 1.35 m/s while researchers obtained 10-second clips of bilateral USI of the GMAX and GMED. USI clips were reduced to 55 frames consisting of 11-points over five full gait cycles. Muscle thickness values during walking were normalized to quiet bipedal standing USI images to obtain functional activation ratios (FARs). FARs with 90% confidence intervals (CI) were plotted at 10% intercludes from 0-100% of the gait cycle to compare groups and limbs. Group mean differences and Cohen's *d* effect sizes were used to assess the extent of differences.

RESULTS: The CAI group had decreased GMED activation bilaterally from 0-40% of walking gait compared to healthy counterparts with large effect sizes ($d: 0.62-0.95$). CAI group FARs were below quiet stance levels (FARs < 1.0) throughout the entire gait cycle. There were no differences noted between groups or limbs for GMAX measures. **CONCLUSIONS:** Proximal stabilizing musculature was altered bilaterally in CAI individuals compared to healthy counterparts, which may contribute to movement

dysfunction through centrally mediated adaptations. Previous studies using electromyography have not detected gluteal muscle alterations in CAI groups during stance phases of gait, however these findings suggest USI was able to detect proximal alterations during walking in this population.

The Effect Of Persistent Pain Following Ankle Sprain On Lower Extremity Kinematics During Walking

Kazandra M. Rodriguez¹, Stephen C. Cobb². ¹University of Michigan, Ann Arbor, MI. ²University of Wisconsin-Milwaukee, Milwaukee, WI.

Email: kazandra@umich.edu

(No relevant relationships reported)

Persistent pain is the most common complaint reported by those with chronic symptoms following ankle sprain with its prevalence peaking in middle-aged adults. Despite the high prevalence rate and associated adverse effects on mobility, quality of life, and physical activity, the influence of persistent ankle pain on lower extremity function during gait in middle-aged adults has not been examined. **PURPOSE:**

To identify the modifiable lower extremity kinematic dysfunction during walking gait associated with persistent ankle pain in middle-aged adults. **METHODS:** Ten individuals with persistent ankle pain (9F, 1M; 55.4 ± 6.52 years; 166.80 ± 6.73 cm; 78.24 ± 25.05 kg) and nine matched uninjured controls (8F, 1M; 53.0 ± 5.79 years; 168.2 ± 6.06 cm; 75.81 ± 24.46 kg) volunteered for the study. Three-dimensional lower extremity kinematics and kinetics were collected during five barefoot walking trials at a self-selected speed. Lower extremity sagittal and frontal joint positions were used to calculate joint ROM and maximum joint position during 1st double-limb support, single-limb support, and 2nd double-limb support. Position at initial contact in the sagittal and frontal plane was also calculated. MANOVA tests assessed group differences with an alpha level of $p < 0.05$. Significant tests were followed by independent t-tests with Bonferroni corrections. **RESULTS:** Rearfoot ankle inversion is significantly increased in those with persistent ankle pain compared to controls during overground walking ($p < 0.05$). Persistent ankle pain subjects were in an inverted position at initial contact ($2.91 \pm 4.32^\circ$), while controls were in an everted position at initial contact ($-3.75 \pm 3.25^\circ$). No other group differences were noted. **CONCLUSIONS:** Persistent ankle pain subjects demonstrate significant increases in rearfoot inversion at initial contact compared to controls. This altered movement pattern may result in further stress of the ankle joint structures, which may contribute to their persistent ankle pain. Additional research with a larger sample size and greater male representation is needed to further explore the effects of ankle pain on gait. This project was supported by the College of Health Sciences Student Research Grant Award at University of Wisconsin-Milwaukee.

2778 May 31 2:45 PM - 3:00 PM

Subjects with Chronic Ankle Instability Exhibit Less Loading Absorption After Drop Jump and Drop Landing

Oscar Achiardi, Tomás Castillo, Jaime Hernández, Josefa Robert, Catalina Sepúlveda. Pontificia Universidad Católica de Valparaíso, Valparaíso, Chile.

Email: oscar.achiardi@gmail.com

(No relevant relationships reported)

Chronic Ankle Instability (CAI) is a condition characterized by neuromuscular, range of motion, and postural control deficits that predispose subjects to reinjure. Different kinematic landing strategies have been identified in people with CAI when compared to healthy controls. Whether these adaptations result in similar loading patterns than those without CAI, has not been documented. This knowledge would be of much use for programming physical rehabilitation protocols to prevent the progression of CAI. **PURPOSE:** To compare ground reaction force (GRF) parameters between subjects with and without CAI, after a drop jump (DJ) and a drop landing (DL). **METHODS:** After informed consent was obtained, 19 young participants (height 164.8 ± 7.4 cm; body mass 68.1 ± 12.0 Kg) were assessed, classified in a group of subjects with CAI (CAI, $n = 14$) and a control group (CON, $n = 5$), according to the recommendations of the International Ankle Consortium. Groups were similar in height, body mass and gender distribution. Each participant performed 5 DJ and 5 DL from a platform of 40 cm height, landing on a force plate recording GRF at a frequency of 100 Hz. The order of all 10 jumps for each subject was determined by an online random generator. The signal corresponding to the vertical GRF was low pass filtered (4th order Butterworth, 20 Hz), normalized to body weight, and then processed to calculate the maximal GRF (FMax) and the loading rate (LR) from the time of initial contact to when FMax was achieved. Comparisons among groups were performed using unpaired t test with normal distributed data; otherwise Mann-Whitney test was used. A p value < 0.05 was considered as significant.

RESULTS: FMax was larger for CAI after DJ (CAI: 3.35 ± 0.57 N*N⁻¹ v/s CON: 3.03 ± 0.29 N*N⁻¹; $p < 0.01$), but was not different from CON after DL (CAI: $3.50 \pm$

0.59 N*N⁻¹ v/s CON: 3.39 ± 0.39 N*N⁻¹; $p = 0.57$). LR was larger for CAI after both DJ (CAI: 35.74 ± 13.26 N*N⁻¹*s⁻¹ v/s CON: 24.54 ± 10.01 N*N⁻¹*s⁻¹; $p < 0.01$) and DL (CAI: 41.33 ± 10.43 N*N⁻¹*s⁻¹ v/s CON: 35.03 ± 5.94 N*N⁻¹*s⁻¹; $p < 0.01$)

CONCLUSION: According to our preliminary results, subjects with CAI exhibit less GRF absorption after dropping from a medium altitude, which might contribute as a risk factor for ankle reinjure. Patients with CAI might benefit from including loading absorption strategies in their rehabilitation protocols.

F-14 Rapid Fire Platform - Mental Health & Athletic Performance

Friday, May 31, 2019, 1:00 PM - 2:20 PM

Room: CC-Hall WA2

Changing the Tide: Psychological Outcomes Among Active Duty Service Members Following a Surf Therapy Program

Kristen H. Walter, Nicholas P. Otis, Travis N. Ray, Lisa H. Glassman, Alexandra L. Powell, Matthew A. Humphreys, Betty Michalewicz-Kragh, Cynthia J. Thomsen. Naval Health Research Center, San Diego, CA.

Email: kristen.h.walter.ctr@mail.mil

(No relevant relationships reported)

Surf programs for individuals with psychological conditions exist; however, data evaluating such programs are limited. **PURPOSE:** This study examined psychological outcomes among active duty service members participating in a surf therapy program at Naval Medical Center San Diego. **METHODS:** Seventy-four active duty service members completed self-report questionnaires before and after the 6-week program and before and after each surf therapy session. **RESULTS:** Multilevel modeling results demonstrated that total scores for symptoms of depression ($\beta = -2.31$, $p < .01$), anxiety ($\beta = -3.55$, $p < .001$), posttraumatic stress disorder (probable PTSD subgroup only; $\beta = -14.55$, $p < .001$), and negative affect ($\beta = -6.40$, $p < .001$) significantly decreased from pre- to post-program, while positive affect significantly increased ($\beta = 9.46$, $p < .001$). Within each session, depression/anxiety symptoms significantly lessened ($\beta = -3.35$, $p < .001$) and positive affect significantly improved ($\beta = 8.97$, $p < .001$). Within-session changes did not differ across sessions ($p > .05$). Results for subgroups with probable PTSD or major depressive disorder were comparable to those of the full sample. **CONCLUSION:** Immediate benefits of surf therapy included significantly reduced depression/anxiety and increased positive affect. As a complementary intervention, surf therapy may improve depression, anxiety, and PTSD symptoms, with potentially unique benefits on affect.

2781 May 31 1:10 PM - 1:20 PM

Resilience and Mental Health Screening in Collegiate Athletes

Vicki Nelson, Franklin Sease, FACSM. Greenville Health System, Greenville, SC.

Email: vnelson2@ghs.org

(No relevant relationships reported)

Screening for mental health disorders common in collegiate athletes can be challenging due to time constraints and concerns about the willingness of athletes to report given the need for multiple screening tools to cover the broad spectrum and concerning stigma surrounding mental health. **PURPOSE:** This study evaluates the Brief Resilience Scale (BRS) as a tool to identify mental health conditions in collegiate athletes. The BRS is a 6-question screening tool assessing one's ability to recover from stress.

METHODS: Collegiate athletes were anonymously surveyed completing BRS and mental health screening tools including the Patient Health Questionnaire-2 (PHQ-2) for depression, Generalized Anxiety Disorder Assessment (GAD-7), Adult ADHD Self-Report Scale (ASRS), SCOFF eating disorders questionnaire and Pittsburgh Sleep Quality Index (PSQI). Correlations between BRS and the screening tools were determined using Pearson's correlation. Mean BRS scores among athletes screening positive or negative with the screening tools were compared by t-test.

RESULTS: 468 athletes (67.1% male, 34.6% division I, 37.4% division II, 39.3% division III) participated in the survey with 392 (84%) completing all 6 screening tools. Significant differences in the mean BRS were seen among athletes screening negative vs. positive on 4/5 mental health screening instruments (PHQ-2: 3.08 ± 0.70 v

3.56 ± 0.65, $p=0.01$; GAD-7: 3.20 ± 0.57 v 3.57 ± 0.66, $p=0.0002$; ASRS: 3.05 ± 0.54 v 3.56 ± 0.66, $p=0.00004$; PSQI: 3.27 ± 0.63 v 3.81 ± 0.60, $p=5.2 \times 10^{-16}$). A significant difference was not seen with the SCOFF tool (3.30 ± 0.63 v 3.55 ± 0.66, $p=0.06$). Significant correlations were seen between BRS and all 5 screening instruments (GAD-7 $r=-.303$, $p=1.02 \times 10^{-9}$; PHQ-2 $r=-.221$, $p=1 \times 10^{-5}$; ASRS $r=-.244$, $p=1 \times 10^{-6}$; SCOFF $r=-.157$, $p=0.002$; PSQI $r=-.400$, $p=1 \times 10^{-15}$). Overall, the BRS had a sensitivity of 26% and specificity of 98% for individuals that screened positive on at least 1 screening instrument.

CONCLUSIONS: Resilience (BRS) shows significant correlation with mental health screening instruments in athletes. As a short survey that avoids the stigma of many mental health questions, BRS may provide an efficient and effective alternative screening instrument to identify those athletes most at risk and in need of further specific screening.

2782 May 31 1:20 PM - 1:30 PM

Examination of Anger Prevalence In Ncaa Division I Student-athletes

Robert M. Madden, Samantha R. Weber, Toni M. Torres-McGehee, Allison Smith. *University of South Carolina, Columbia, SC.*

(No relevant relationships reported)

Anger may have an impact on performance. Once anger is triggered, it may not allow an athlete to move beyond whatever prompted the anger and in turn may decrease their concentration and focus on continued performance. Research is limited in the collegiate athletic population. **Purpose:** To examine the prevalence of anger in collegiate NCAA Division I athletes; and to investigate differences between sex, academic status (i.e., freshman, senior) and sport type (e.g., football, soccer, cheerleading). **Methods:** As part of a larger study, collegiate athletes ($N=616$, age: 19.5±1.3 years; males: $n=234$, height: 183.5±14.3 cm, weight: 91.2±19.5 kg; females: $n=382$, height: 168.6±7.4 cm, weight: 63.4±9.8 kg) were recruited over a 3-year period from a NCAA Division I institution. Demographic information (e.g., age, self-reported height and weight, sex, academic status, sport type) and the Anger Index Self-Test were collected via SurveyMonkey. **Results:** Chi-squared analysis revealed a significant difference between the anger index and sex [$X^2(2, N=613) = 20.3, P \leq 0.01$]. Overall 37.7% ($N=232/616$) reported high risk for anger with males 47.9% ($n=112/234$) and females 31.4% ($n=120/382$). Chi-squared analysis revealed a significant difference between the anger index and sport type [$X^2(42, N=616) = 61.3, P \leq 0.03$], with the highest percentages reporting high risk for anger within football 55.2% ($n=64/116$) and baseball 50% ($n=19/38$). Overall, 54.7% ($N=337/616$) revealed moderate risk for anger and sport type. No significant differences were found for anger risk and academic status [$X^2(10, N=616) = 5.220, P > 0.88$]. **Conclusions:** Male collegiate athletes demonstrated a higher risk for anger than female collegiate athletes; however, most athletes displayed moderate risk for anger across different sports. Anger across academic status was not significant, therefore, this may imply anger management and/or coping skills were not learned or taught throughout college. Further examination is necessary to investigate the prevalence of risky behaviors in combination with anger among this population. Considering the high prevalence of anger among collegiate athletes; institutions should work to establish a screening for all student-athletes and direct those at risk to a qualified mental health professional for intervention.

2783 May 31 1:30 PM - 1:40 PM

Examination of Mental Health Risks and Injury Prevalence in NCAA Division I Collegiate Athletes

Jane Sweeney, Toni M. Torres-McGehee, Samantha R. Weber, Robert Davis Moore, Jacob Kay. *University of South Carolina, Columbia, SC.*

(No relevant relationships reported)

Research in mental health for student-athletes is a growing topic among healthcare professionals. Studies examining pre-existing mental illness risk (e.g., depression (DEP), anxiety, attention deficit hyperactivity disorder (ADHD)) and injuries are limited. **Purpose:** To examine the effects of psychoaffective (PA) disorders (DEP, anxiety) and neurodevelopmental (ND) disorder (ADHD) risks and injury status (yes/no), injury type (acute/chronic), and multiple injury status (yes/no) in NCAA Division I student-athletes. **Methods:** A retrospective analysis of student-athlete medical records from 2013-2014 ($n=218$) and 2015-2016 ($n=174$) academic years was used from a NCAA Division I institution. Mental health screening medical records from pre-participation exams (e.g., Center for Epidemiologic Studies Depression Scale, State-Trait Anxiety Inventory, Behavioral and Emotional Screening System) identified mental health risks. Athena electronic medical records identified injury data. Descriptive statistics and chi-square analysis were used to identify the distribution of "at risk" and injury status, multiple injuries and injury type. **Results:** Student-athletes (34.7%) were at risk for at least 1 neuropsychiatric disorder (PA disorders: 17.6%, $n=69$; ND disorders: 8.9%, $n=35$; comorbid disorders: 7.9%, $n=31$). Student-athletes (34.4%) reported at least 1 injury throughout the respective academic year. Of those at risk for PA disorders (46.4%), ND disorders (25.7%) and comorbid disorders (29%)

also reported sustaining an injury. Those at risk for PA disorders (14.5%) and ND disorders (8.6%) had a higher prevalence of sustaining multiple injuries than those not at risk (7.8%). Acute injuries were sustained more commonly across all groups regardless of mental health status. PA risk group sustained 29.0% ($n=20$) acute and 17.4% ($n=12$) chronic injuries, the ND group sustained 14.3% ($n=5$) acute and 11.4% ($n=4$) chronic injuries, and the comorbid group sustained 19.4% ($n=6$) acute and 9.7% ($n=3$) chronic injuries. **Conclusions:** Neuropsychiatric disorder risks may affect injuries in NCAA Division I student-athletes, especially those with a PA disorder risk. Student-athletes at risk for neuropsychiatric disorders during preseason should be referred to a mental health professional for further evaluation.

2784 May 31 1:40 PM - 1:50 PM

Examination of Eating Disorder Risk among Recreational Athletes

Nancy A. Uriegas¹, Toni M. Torres-McGehee¹, Allison B. Smith¹, Dawn M. Emerson², Kelly Pritchett³. ¹University of South Carolina, Columbia, SC. ²University of Kansas, Lawrence, KS. ³Central Washington University, Ellensburg, WA.

(No relevant relationships reported)

With fitness becoming a new trend (e.g., Pure Barre, Zumba, CrossFit, Mudrun, marathons, etc.) the general adult recreational athlete may be engaging in the same physical demands and mental stressors associated with organized sport. In turn, this may predispose the recreational athlete to being at risk for disordered eating (DE)/eating disorders (ED).

Purpose: To examine the prevalence of Eating Disorder (ED) risk across gender in male and female recreational athletes.

Methods: Data from a larger cross sectional study was used. A convenience sample of male and female recreational athletes ($n=58$; age: 26.4±6.1 years; males: $n=34$; height: 179.1±6.2 cm; weight: 78.3±10.4 kg; females: $n=24$, height: 164.9±6.6 cm, weight: 65.4±9.0 kg) from the southeastern region of the United States participated in the study. Participants completed a basic demographic survey, the Eating Disorder Inventory-3 (EDI-3), and the EDI-3 Symptoms Checklist (SC). Basic descriptive statistics were used for demographic information. Cross-tabulations were used to examine the proportion of participants classified as "at risk for EDI-3 and EDI-3 SC" across gender.

Results: Significant differences were found between ED risk and gender [$X^2(3, N=58) = 11.8, P=0.008$]: within gender groups for EDI-3 (males: 17.6%, $n=6$; females: 4.2%, $n=1$), EDI-3 SC (males: 17.6%, $n=6$; females: 45.8%, $n=11$), and both EDI-3 and EDI-3 SC (males: 26.5%, $n=9$; females: 41.7%, $n=10$). Overall, significant differences were found between pathogenic behaviors and gender for dieting (males: 20.7%, $n=12$; females: 29.3%, $n=17, P=0.008$) and purging (males: 0.0%, $n=0$; females: 5.2%, $n=3, P=0.034$). No significant differences were found for exercise 50-100% of the time to lose weight (males: 3.4%, $n=2$; females: 5.2%, $n=3$); binge eating (males: 15.5%, $n=9$; females: 15.5%, $n=9$), laxatives (males: 3.4%, $n=2$; females: 0.0%, $n=0$), diet pill use (males: 5.2%, $n=3$; females: 8.6%, $n=5$), and use of diuretics (males: 1.7%, $n=1$; females: 1.7%, $n=1$).

Conclusion: ED risk was prevalent for both male and female recreational athletes; however females displayed an overall higher risk for EDs and pathogenic behaviors such as dieting and purging. In this new and growing population education, prevention, and clinical interventions from qualified healthcare professionals should be accessible.

2785 May 31 1:50 PM - 2:00 PM

Sport Differences In Resiliency Development Of Men's NCAA Football And Basketball Athletes

Justin R. Geijer, Connie A. Mettelle. *Winona State University, Winona, MN.*

(No relevant relationships reported)

The National Collegiate Athletic Association (NCAA) has recently identified mental health as a primary health concern for student-athletes. Each sport contains its own unique stressors, which may require sport-specific stress reduction and resiliency-building techniques.

PURPOSE: The purpose of this investigation was to identify the differences in stress impacts and resiliency in men's NCAA football and basketball athletes.

METHODS: Thirteen NCAA Division II men's basketball athletes 32 NCAA Division II men's football athletes were surveyed before and after the 2016-2017 competition season. The survey contained 35 questions, which were selected from the College Student Health Survey (Boynnton Health, University of Minnesota, Minneapolis, MN). The survey addressed aspects of physical health, drug and alcohol use, screen time, relationships, sleep, stress management, and resiliency. Post-season surveys were analyzed to determine differences between sports in stress management and resiliency. Independent t-tests were used to determine differences between survey question responses. Alpha levels were set at 0.05.

RESULTS: Football athletes reported significantly better ability to respond to adversity ($p < 0.001$), and withstand difficult situations ($p < 0.001$). No significant difference existed between the sports in regards to the number of days their physical health ($p = 0.58$) or mental health ($p = 0.95$) was negatively impacted in the past 30 days. **CONCLUSIONS:** While no significant differences existed in the number of days in which mental or physical health was negatively impacted, significant differences were found in the football and basketball athletes' perceived abilities to respond to stressful situations. Future research should investigate the development and efficacy of sport-specific resiliency-building techniques.

2786 May 31 2:00 PM - 2:10 PM

A Comparison Of Depression, Anxiety, And Stress Levels Of Basketball Athletes In Different Collegiate Divisions

Jessica E. Jochum, Lauren Blyly, Kendall Beckstein, Mallory Meyers. *University of Indianapolis, Indianapolis, IN.* (Sponsor: Amy Jo Sutterluety, FACSM)
Email: jochumj@uindy.edu
(No relevant relationships reported)

Participating in sports helps to promote a healthy lifestyle. However, as competition level increases so do physical, emotional, and mental demands placed on the athletes. These increased demands could also increase susceptibility to depression, anxiety, and stress. **PURPOSE** To investigate differences in self-reported in-season levels of stress, anxiety and depression in collegiate men's and women's basketball players from collegiate levels of NCAA Division I, II, III and the NAIA. **METHODS** 102 collegiate basketball players completed the Depression Anxiety and Stress Scale 42 (DASS-42) and demographic information questionnaire including variables measuring hours of sleep, credit hours enrolled and history of injury. The DASS-42 is a self-reported questionnaire that uses three scales to measure an individual's emotional state of depression, anxiety, and stress; each scale has fourteen items. Of the 102 athletes, 26 were from a NCAA Division I, 31 from Division II, 23 from Division III, and 22 from the NAIA, ($n_{male} = 54$ (52.9%), $n_{female} = 48$ (47.1%)). An alpha level of $p \leq .05$ was set for statistical significance. The Kruskal-Wallis test was used to compare by division level and the Mann-Whitney U test was used to compare gender and credit hours. The Pearson chi-square test was used to compare gender and hours of sleep. **RESULTS** There was not a statistically significant difference in stress, anxiety and depression scores by division levels (DI, DII, DIII and NAIA), $p = .965$, $p = .383$, $p = .729$, respectively. However, differences were found between males and females, with females reporting higher levels of stress compared to males (median score 4.0 and 13.0, respectively; $p < .001$), anxiety (median score 3.0 and 6.0, respectively; $p < .001$) and depression (2.0 and 5.0, respectively; $p = .003$). A comparison of hours of sleep by gender revealed males were likely to get more sleep, however the difference was not statistically significant ($p = .182$). Similarly there was also not a statistically significant difference between males and females for the number of credit hours currently taken ($p = .221$), but females were more likely to take more credit hours. **CONCLUSION** Comparison revealed no statistical difference between collegiate settings. However, female athletes are at greater risk of depression, anxiety, and stress than males.

2787 May 31 2:10 PM - 2:20 PM

Screening Athletes For Disordered Eating: Are We Asking The Right Questions?

Franklin Sease, FACSM, Vicki Nelson. *Greenville Health System, Greenville, SC.*
(No relevant relationships reported)

PURPOSE: Little data is available to evaluate the performance of preparticipation screening questions in practice. The performance of consensus PPE questions was examined in comparison to the validated 5-question SCOFF screening tool to detect eating disorders. **METHODS:** 230 collegiate athletes (194 male) completed an anonymous survey including 3 consensus PPE questions regarding eating habits (prior history of eating disorder, adherence to a special diet, and current attempts to gain or lose weight) and the SCOFF screening tool. **RESULTS:** 10 athletes (4.3%, 3.6% of males, 8.3% of females) screened positive for an eating disorder using the SCOFF tool. The standard PPE questions combined to identify 43% of athletes as having concerning dietary habits (sensitivity 50%, specificity 59%, positive predictive value 5%, negative predictive value 98%). One athlete self-reported a diagnosed eating disorder. This individual was detected using the SCOFF tool and was not detected using the PPE questions. An analysis of the component questions identified the single question "Do you worry that you have lost control over how much you eat?" from the SCOFF tool to be the most sensitive and specific (70%, 100%) to detect disordered eating in collegiate athletes. **CONCLUSIONS:** Our results suggest that the current consensus PPE screening questions are neither sensitive nor specific to detect eating disorders in collegiate athletes. Further studies are needed to determine the appropriate questions for screening in the collegiate athlete population.

F-31 Thematic Poster - Baseball

Friday, May 31, 2019, 3:15 PM - 5:15 PM
Room: CC-101A

Quantification of Ground Reaction Forces for Skilled Versus Recreational Baseball Hitting

Ethan Stewart¹, Megan Smidebush¹, Jeffrey Simpson², Adam Knight¹, Harish Chander¹, Robert Shapiro³. ¹Mississippi State University, Mississippi State, MS. ²University of West Florida, Pensacola, FL. ³University of Kentucky, Lexington, KY.
Email: ems664@msstate.edu
(No relevant relationships reported)

PURPOSE: Successfully hitting a baseball requires the hitter to properly use ground reaction forces (GRFs) in all three directions. The normal pattern of the GRFs during the baseball swing and the importance of the timing of those GRFs have been identified, but have not been compared among hitters across various competition levels. Therefore, the purpose of this study was to investigate how the peak GRFs in the medial-lateral direction (GRFx), anterior-posterior direction (GRFy), and vertical direction (GRFz), as well as time to reach peak GRFs for the lead and trail legs may vary between athletes who play at the collegiate level and those who have not. **METHODS:** Active baseball players were recruited and separated into two groups, recreational ($n = 6$) and skilled ($n = 6$), with the skilled players competing at the NCAA level. Each athlete performed three swing trials while standing in their normal hitting stance on two force platforms sampling at 1000 Hz. The dependent variables included the peak GRFx, GRFy, and GRFz normalized to bodyweight, and the time to peak GRFx, GRFy, and GRFz in milliseconds before ball contact for the lead and trail legs, as determined by Visual3D software. Values were averaged for each respective group and compared using independent sample t-tests ($p < 0.05$). **RESULTS:** The skilled group demonstrated a significantly lower posterior peak GRF (Recreational = -0.26 ± 0.03 BW, Skilled = -0.23 ± 0.03 BW, $p = 0.02$), a significantly higher vertical peak GRF (Recreational = 0.97 ± 0.03 BW, Skilled = 1.03 ± 0.02 BW, $p = 0.005$) and a reduction in time to vertical peak GRF in the trail leg (Recreational = -0.40 ± 0.06 ms, Skilled = -0.54 ± 0.11 ms, $p = 0.028$) in comparison to the recreational group. **CONCLUSION:** The ability of the skilled athletes to control their trail leg peak GRFy, while creating a significantly higher peak GRFz and reaching the peak GRFz faster helps to both facilitate velocity of the swing and control their body movement. Combining these three distinct kinetic differences in the swing could lead to differences in bat velocity and skill level between these two groups.

2845 Board #2 May 31 3:15 PM - 5:15 PM
Performance and Injury Correlates of X-Factor Among Baseball Hitters

Eric M. Berkson, James Michaud, Shannon Linderman, Robert C. McCunney, Donna M. Scarborough. *Massachusetts General Hospital, Boston, MA.*
Email: eberkson@mgh.harvard.edu
(No relevant relationships reported)

PURPOSE: Abdominal strains related to trunk torsional forces commonly occur during baseball batting. A large degree of trunk rotation, or X factor (XF), is proposed to increase bat speed. However, baseball swing initiation is driven by pelvis rotation, which requires adequate hip joint mobility. This study investigates the correlations between XF, bat speed, passive hip range of motion, and dynamic hip rotation during the baseball swing. **METHODS:** 22 players (3 professional, 1 amateur, 5 college, 13 high school), mean age 18.09 ± 3.90 years, underwent 3D biomechanical baseball swing analysis. XF (resultant transverse angle of the intersecting rays through both shoulder joints and the pelvis midpoint) and lead and trail hip rotation angles were measured for 1 swing. Passive, prone hip rotation was assessed via goniometer. Spearman rho correlations and one-way ANOVA were performed. **RESULTS:** Peak XF and XF at the top of the back swing did not correlate with peak bat speed ($p = 0.088$ and $p = 0.832$). There was no significant difference in peak XF across level of play [$F(2,19) = 2.637$, $p = 0.098$] (Figure 1). Passive internal trail hip rotation differed between college and high school players ($p = 0.049$) and was inversely correlated with bat speed at ball contact ($r_s = -0.526$, 0.029). Peak bat speed positively

correlated with max trail hip rotation angle during the swing ($r_s=0.570$, $p=0.006$). No correlation of peak XF and passive hip rotation measures or hip rotation angles during the swing reached significance set at $p < 0.05$.

CONCLUSIONS: Findings do not support the use of XF as an indicator of bat speed. The variation in XF values may result from coaching differences or joint mobility compensation patterns. Athletes with limited hip rotation may attempt to compensate through generation of a large XF, possibly increasing the risk of back and oblique abdominus injuries. Clinicians caring for baseball players should screen for trail hip joint rotational mobility limitations.

2846 Board #3 May 31 3:15 PM - 5:15 PM
UCL Stiffness Response to a Moderate Pitching Bout
 Christopher J. Curran, Henry W. Zale, Patrick M. Rider, Anthony S. Kulas, Zachary J. Domire. *East Carolina University, Greenville, NC.*
 Email: curranh15@students.ecu.edu
 (No relevant relationships reported)

Purpose: The effect of a single pitching bout on the material stiffness of the ulnar collateral ligament (UCL) was investigated in five competitive baseball pitchers (age: 20.0 ± 2.6 years). Differences in the response were compared between one pitcher with arm trouble and four asymptomatic pitchers. **Methods:** Shearwave ultrasound elastography was used to measure the material stiffness of the UCL prior to, and on the four days following, a moderately-intense pitching bout. The pitching bout consisted of a minimum of 50 full-effort pitches in either a practice or game situation. Pitch velocity was measured and maintained within 10% of expected maximum velocity to ensure full effort was given. Participant arm health was measured using the Kerlan-Jobe Orthopaedic Clinic Shoulder and Elbow Score (KJOC) prior to the first imaging session. **Results:** Four pitchers reported “playing without any arm trouble” with a mean KJOC score of 90.4 out of 100.0. One pitcher reported “playing, but with arm trouble” and had a KJOC score of 60.2. Each of the asymptomatic pitchers showed an immediate increase in UCL stiffness (mean increase = +15.99%) compared to baseline followed by a marked decrease and trend towards returning to baseline values on days 2-4. The UCL stiffness of the symptomatic pitcher showed a different immediate response (-29.47%) before returning towards baseline values on days 2-4. **Conclusions:** UCL material stiffness in a pitcher with arm trouble responded differently to a moderate pitching bout compared to a small sample of asymptomatic pitchers. A decrease in material stiffness of the UCL immediately following a pitching bout may be evidence of elbow distress and be useful in the identification of pitchers with increased injury risk.

2847 Board #4 May 31 3:15 PM - 5:15 PM
Does The Kinematic Sequence Of A Curveball Pitch Vary Within Baseball Pitchers?

Donna M. Scarborough, Shannon Linderman, Pablo Colon, Eric M. Berkson. *Massachusetts General Hospital, Boston, MA.*
 Email: dscarborough@mgh.harvard.edu
 Reported Relationships: D.M. Scarborough: Salary; figur8.

PURPOSE: The performance of a proximal-to-distal transfer of segmental angular velocity (or kinematic sequence) is reported to reduce stress on musculoskeletal structures of the overhand baseball pitcher’s throwing arm and maximize ball velocity. The commonly asserted risk for injury of curveball pitching has not been demonstrated biomechanically. This study evaluates the kinematic sequence (KS), and their variability, of a curveball pitch in an effort to better characterize the stress on the arm during this pitch.

METHODS: 3D biomechanical pitch analyses using high-speed motion capture cameras (360Hz) were performed on 71 curveball pitches (5-6 pitches per pitchers) from 14 baseball pitchers (4 high school, 8 collegiate and 2 professional) with a mean age 19.21 ± 2.94 years. The peak angular velocity of five body segments: pelvis, trunk, arm, forearm and hand were analyzed to determine the kinematic sequence patterns for each curveball pitch.

RESULTS: None of the 71 pitches demonstrated the proximal-to-distal KS order. Eleven different KS patterns were demonstrated, and the most prevalent order was pelvis-> trunk-> arm and hand segments peaking simultaneously -> forearm. No players performed only 1 KS pattern among the curveball pitches. An average of 3 different KSs were observed per pitcher.

CONCLUSIONS: Deviation from the proximal-to-distal KS during pitch delivery results in an inefficient movement. The KS patterns of the fastball pitch have recently been described. This study evaluated the KS patterns of the curveball pitch. The most frequently performed KS during the curveball is with the forearm segment generating peak velocity simultaneously after the hand and shoulder velocity peaks. It is not known how the stresses across the shoulder and elbow are associated with this KS. Variation in KSs performed throwing curveballs may help prevent injury to the throwing arm, in particular if some KS patterns create more stress on the throwing arm than others.

Table 1. Pitcher characteristics and number of curveball kinematic sequences performed per pitcher. *LOP- Level of Play (P- professional, C- collegiate, HS- high school)

| ID | LOP | Throwing hand | Ball speed (MPH) | # pitch trials | # of KS |
|----|-----|---------------|------------------|----------------|---------|
| 1 | P | Right | 68.64 | 3 | 5 |
| 2 | P | Left | 71.68 | 4 | 5 |
| 3 | C | Right | 59.24 | 3 | 5 |
| 4 | C | Right | 63.96 | 4 | 5 |

Induced Power Analysis Of Sequential Body Motion And Elbow Valgus Load During Baseball Pitching

Arnel Aguinaldo¹, Rafael Escamilla, FACSM². ¹Point Loma Nazarene University, San Diego, CA. ²California State University Sacramento, Sacramento, CA.
 Email: arnelaguinaldo@pointloma.edu
 (No relevant relationships reported)

The flow of mechanical energy of segmental motion provides a mechanism by which the throwing arm is accelerated during baseball pitching. Muscles can indirectly influence the energy level of distal segments to which they are not attached by way of the interaction torques transferring energy up the kinetic chain. No study to date, however, has addressed these causal components of mechanical power, specifically in relation to valgus loading at the elbow, which is prone to pitching-related injuries.

PURPOSE: To determine the components of muscle and velocity-dependent torques that contribute to the power of throwing arm segments when the elbow is under valgus load during pitching.

METHODS: The throwing motions of 10 adult pitchers (age = 22.9 ± 4.1 years, height = 1.87 ± 4.93 m, and mass = 86.5 ± 7.4 kg) were biomechanically measured using 3D motion capture after written informed consents were provided by the participants.

The resulting kinematic and kinetic data were included in a state-space power analysis using a 10-DOF model. The contributions of the torque-induced components to the mechanical work of the forearm were determined by integrating the power curves in time between the instants of front foot contact (FC) and maximum external rotation (MER) of the throwing shoulder.

RESULTS: Pitchers threw with a maximum elbow valgus torque of $70.1 \pm 2.2 \text{ N}\cdot\text{m}$. The trunk flexion (r1) and rotation (r3) components of the muscle-induced torque were the greatest positive contributors to the work of the forearm. Muscle torques contributed a total of $44.5 \pm 23.4 \text{ J}$ while velocity-dependent torques absorbed $69.6 \pm 37.1 \text{ J}$, representing 61% of the total work (114.1 J) of the distal arm segments during the arm-cocking phase (Figure 1).

CONCLUSIONS: Trunk motion in the early part of the arm-cocking phase appears to drive the power of accelerating the throwing elbow in valgus via velocity-dependent torques.

2849 Board #6 May 31 3:15 PM - 5:15 PM
Glenohumeral-Rotation-Deficits In High School, College, And Professional Baseball Pitchers With And Without An Mucl Injury
 Rafael F. Escamilla, FACSM. *California State University, Sacramento, Sacramento, CA.*
 Email: rescamil@csus.edu
 (No relevant relationships reported)

PURPOSE: To assess if a glenohumeral-internal-rotation-(IR)-Loss (GIRLoss), a glenohumeral-external-rotation-(ER)-gain (GERGain) or a total-rotational-motion-(TRM)-deficit (TRMD) predict medial ulnar-collateral-ligament (MUCL) injury-risk among high-school (HS), college (COLL), and professional (PRO) baseball-pitchers with-and-without-MUCL-injury. It was hypothesized that pitchers with MUCL injury would have >GIRLoss and TRMD compared to pitchers without MUCL injury, with no differences in IR, ER, TRM, GIRLoss, GERGain, and TRMD. **METHODS:** Two-hundred-sixteen-male HS, COLL, and PRO pitchers were equally divided into MUCL-injury-group (n=108) and control-group (n=108) without MUCL injury. Control-group was matched with the MUCL-injury-group according to number, level & age. Bilateral shoulder passive IR/ER were measured and GIRLoss, GERGain, TRM, and TRMD calculated. A two-way-analysis-of-variance ($p < 0.05$) was employed to assess shoulder-rotational-differences among the two-groups and three-pitching-levels. **RESULTS:** Compared to control-group, MUCL-injured-group had >GIRLoss ($21^\circ \pm 14^\circ$ -versus- $13^\circ \pm 8^\circ$; $p < 0.001$), GERGain ($14^\circ \pm 9^\circ$ -versus- $10^\circ \pm 9^\circ$; $p = 0.004$), and TRMD ($7^\circ \pm 13^\circ$ -versus- $3^\circ \pm 9^\circ$; $p = 0.008$). For all pitching levels ~60% of subjects in MUCL-injury-group had GIRLoss > 18° , compared to ~30% of subjects in control-group. ~60% of subjects in MUCL-injury-group had TRMD > 5° , compared to 50% of subjects in control group. No differences were observed among HS, COLL, and PRO pitchers for GIRLoss ($16^\circ \pm 12^\circ, 17^\circ \pm 11^\circ, 19^\circ \pm 13^\circ$, respectively; $p = 0.131$), GERGain ($11^\circ \pm 9^\circ, 11^\circ \pm 10^\circ, 13^\circ \pm 10^\circ$, respectively; $p = 0.171$), TRMD ($5^\circ \pm 11^\circ, 6^\circ \pm 11^\circ, 5^\circ \pm 14^\circ$, respectively; $p = 0.711$), throwing shoulder ER ($111^\circ \pm 10^\circ, 111^\circ \pm 11^\circ, 113^\circ \pm 9^\circ$, respectively; $p = 0.427$), throwing shoulder IR ($50^\circ \pm 11^\circ, 49^\circ \pm 11^\circ, 48^\circ \pm 10^\circ$, respectively; $p = 0.121$), & throwing shoulder TRM ($162^\circ \pm 14^\circ, 160^\circ \pm 15^\circ, 161^\circ \pm 14^\circ$, respectively; $p = 0.770$). **CONCLUSIONS:** Greater GIRLoss, GERGain, and TRMD in MUCL-injured-pitchers compared to uninjured-pitchers implies these variables may be related to increased-MUCL-injury-risk, especially since GIRLoss > 18° and TRMD > 5° demonstrate an increased MUCL injury risk. Shoulder rotational motion and deficits do not vary among HS, COLL, and PRO levels of pitchers.

Kinematic Factors that Contribute to Batting Performance in Collegiate Baseball
 Alexia E. Amo, William P. Lydon, Nathaniel J. Holmgren, J. Mark VanNess, Courtney D. Jensen. *University of the Pacific, Stockton, CA.*
 Email: l_amo@u.pacific.edu
 (No relevant relationships reported)

To remain competitive in collegiate athletics, sports teams now employ advanced analytical tools to identify improvable domains. In baseball, technological limitations have precluded comprehensive interpretation of swing mechanics. Recent developments in technology now permit more complex assessments. **PURPOSE:** To test how kinematic factors of bat swing associate with in-season batting performance in college athletes. **METHODS:** We enrolled 13 batters from a D1 baseball team in Northern California and used Proteus (Boston Biomotion, USA) to conduct three-dimensional analyses of swing mechanics. Each athlete performed six five-repetition sets of swings at increasing loads of magnetic resistance: 1lb, 2lb, 3lb, 5lb, 7lb, and 9lb. Proteus software computed explosiveness (rate of power production) and endurance (replication of power production in successive swings). Players were tracked through the 2017 season and all batting statistics were recorded. Linear regressions tested the effects of explosiveness and endurance on in-season batting performance. Significance was set at $p < 0.05$; owing to a small sample and the novel equipment, trends ($p < 0.08$) were considered. **RESULTS:** 11 of 13 players had a base hit during the study season; these 11 constituted the study sample. They played 40.1 ± 13.2 games and batted $.264 \pm .048$. Mean swing explosiveness was 313.7 ± 59.3 and endurance was 97.7 ± 1.4 . Batting average was positively related to swing endurance ($R = 0.638$); an additional point of endurance predicted an 8.7% increase in batting average ($p = 0.047$). Runs ($R = 0.869$), triples ($R = 0.628$), and home runs ($R = 0.585$) per at-bat were positively correlated with swing explosiveness; in each at-bat, an additional point of explosiveness predicted a 0.2% increase in runs ($p = 0.001$), 1.3% increase in triples ($p = 0.052$), and 0.8% increase in homeruns ($p = 0.075$). Neither explosiveness ($p = 0.121$) nor endurance ($p = 0.529$) associated with games played. **CONCLUSIONS:** In three-dimensional analyses of swing mechanics, increased explosiveness and endurance predicted an improved batting average, more extra base hits, and more runs scored per at-bat. Scouts may be wise to consider swing mechanics in their estimations of a player's value. Likewise, players and coaches may choose training programs that optimize mechanics accordingly.

Relationship Between Ground Reaction Force and Wrist Velocity in Skilled and Novice Baseball Pitchers
 Kurt Kornatz, Christopher Wendt, Kevin Ritsche. *Winston-Salem State University, Winston-Salem, NC.* (Sponsor: Mike McKenzie, FACSM)
 (No relevant relationships reported)

While throwing, skilled performers transmit forces in a precisely coordinated manner from the foot through the kinetic chain ultimately manifesting in a large velocity of the wrist. Accordingly, stride-leg ground reaction forces have been used to predict wrist velocity in skilled baseball pitchers. However, the relationship between ground reaction force and wrist velocity in novice pitchers is less clear. **PURPOSE:** The purpose of this study is to compare the relationship between peak vertical ground reaction forces of the stride leg (Fzpeak) and wrist velocity in skilled and age-matched novice baseball pitchers. **METHODS:** Ten collegiate baseball pitchers and ten recreationally active college-aged novice throwers completed one laboratory testing session in which they were asked to throw a baseball as fast and accurately as possible after a standardized instruction and warmup. Each subject performed a total of 15 throws, collected as part of a larger study in which stride-length was altered (comfortable $\pm 10\%$), on a dimensionally correct pitching mound equipped with a force platform (1200 Hz). Marker trajectory data (32 reflective markers) was tracked from 10 high-speed cameras at 240 frames/sec. Fzpeak was normalized for body weight (N/BW); wrist velocity (m/s) was measured at ball release. **RESULTS:** Skilled pitchers demonstrated larger FzPeak (1.61 ± 0.19 vs. 1.34 ± 0.13 N/BW, 16% difference, $p < 0.01$) and higher wrist velocity (18.11 ± 0.94 vs. 13.96 ± 1.04 m/s, 23% difference, $p < 0.01$) compared to novice participants. Furthermore, Fzpeak and wrist velocity were correlated for skilled pitchers only ($r = 0.47$, $p < 0.01$ vs. $r = -0.18$, $p > 0.1$). **CONCLUSIONS:** Skilled pitchers are more efficient than novice throwers at generating and transmitting ground reaction force through the kinetic chain in order to maximize wrist velocity.

The Impact of Varying Exercise Protocols on Neurogenesis and Angiogenesis in the Dentate Gyrus

Darrin A. Lenhart^{1,2}, Chad A. Witmer¹, Shala E. Davis¹, Gavin Moir¹, Christopher Esposito¹, Sharhan Perez¹. ¹East Stroudsburg University, East Stroudsburg, PA, ²Seton Hall University, South Orange, NJ

Exercise is being considered for associations with improved neuronal health and longevity, synaptic plasticity, increased cerebral blood volume and angiogenesis, overall brain volume, and neurogenesis which collectively may have the power to forestall neurodegenerative disease. **PURPOSE:** To investigate the effects of varying exercise protocols on indices of neurogenesis and angiogenesis in the dentate gyrus of the hippocampus to inform efforts to forestall cognitive decline associated with neurodegenerative disease. **METHODS:** The indices of neurogenesis and angiogenesis were assessed using the surrogate measures of maximal oxygen uptake (VO_{2max}), cognitive function as assessed by the Rey auditory verbal learning test (RAVLT), and urinalysis of brain-derived neurotrophic factor (BDNF) concentration taken just prior to and just after a six-week training protocol. Twelve college-aged males were randomized into either high intensity interval training group (HIIT) or a steady-state training group (SS) and were compared to six sedentary controls over the course of a six-week supervised training study. **RESULTS:** Findings reflect an association between exercise and improved cognitive function. Specifically, cognitive function improved significantly with HIIT training (Δ RAVLT=3.66, $p=0.045$) and a significant correlation between cognitive function and improved VO_2 from HIIT training was also shown ($r=0.98$; $p=0.010$). Cognitive function and neurotrophin concentration both increased significantly with steady state training compared to controls (Δ RAVLT=4.40, $p=0.011$; Δ BDNF=54.00pg/ml, $p=0.007$). **CONCLUSION:** varying exercise protocols have a varying impact on cognitive function as assessed by the RAVLT, urine BDNF, and VO_2 . Findings hold implication for pathologies that involve cognitive decline.

Not Just for Joints: Physical Activity is Associated with Greater Cortical Thickness among Adults with Osteoarthritis**

Ryan Stanley Falck, John R. Best, Chun L. Hsu, Anna R. Egbert, Linda C. Li, Lynne C. Feehan, Teresa Liu-Ambrose. *University of British Columbia, Vancouver, BC, Canada.*

Email: ryan.falck@hiphealth.ca

(No relevant relationships reported)

PURPOSE: Preliminary evidence suggests osteoarthritis (OA) is a risk factor for dementia. One potential reason is 87% of adults with OA are inactive, and low moderate-to-vigorous physical activity (MVPA) and high sedentary behaviour (SB) are each risk factors for brain atrophy. While regular MVPA and low SB are thus critical for brain health, it is unclear 1) what aspects of brain structure are associated with these behaviours among adults with OA; and 2) whether the relationships of MVPA and SB with brain structure are independent of each other. Hence, we investigated the independent relationships of MVPA and SB with brain structure in adults with knee OA. **METHODS:** This was a secondary cross-sectional analysis of a six month, proof-of-concept randomized controlled trial (RCT) to promote MVPA and reduce SB among adults with knee OA. At study entry, we objectively measured MVPA and SB for 7 days using the SenseWear Mini. Following this observation period, participants (N= 30) underwent a 3T magnetic resonance image (MRI) scan, wherein T₁-weighted structural MRIs were performed to measure cortical thickness. We performed regression analyses using a surface-based cluster size exclusion method for multiple

comparisons within the FreeSurfer neuroimaging software to determine if 1) MVPA was associated with greater cortical thickness independent of SB; and 2) SB was associated with less cortical thickness independent of MVPA.

RESULTS: Participants had a mean age of 61 years (SD= 9 years), and 80% were female. Higher MVPA was associated with greater cortical thickness in the temporal pole (cluster size= 855 mm²; $p< 0.05$) and superior frontal area (cluster size= 1204 mm²; $p< 0.05$) of the left hemisphere independent of SB. SB was not associated with greater cortical thickness in any region independent of MVPA.

CONCLUSIONS: Higher MVPA is associated with greater cortical thickness in adults with OA, however SB does not appear to be strongly associated with brain structure. Promoting MVPA among adults with OA may thus be an important strategy for maintaining cognitive health among this population.

Fitness Trumps Fatness: An Examination of Cognition and Cerebral Volume**

Julian M. Gaitán, Sarah R. Lose, Ryan J. Dougherty, Jennifer M. Oh, Catherine L. Gallagher, Cynthia M. Carlsson, Howard A. Rowley, Yue Ma, Sanjay Asthana, Mark A. Sager, Bruce P. Hermann, Sterling C. Johnson, Barbara B. Bendlin, Dane B. Cook, FACSM, Ozioma C. Okonkwo. *University of Wisconsin - Madison, Madison, WI.*

(No relevant relationships reported)

PURPOSE: To determine whether cardiorespiratory fitness (VO_{2peak}) is related to cognition and cerebral volume in the presence of fatness in a late-middle-aged cohort at risk for Alzheimer's disease (AD). **METHODS:** 127 enrollees in the Wisconsin Registry for Alzheimer's Prevention (age = 64.1 ± 5.8 years, N = 127, 43 male) underwent a graded maximal exercise test, anthropometric measurement, neuropsychological examination, a structural brain MRI scan, fasting venipuncture to assess insulin resistance (HOMA-IR), and APOE genotyping. Subjects were categorized as high vs low on VO_{2peak} using age- and sex- specific cutoffs from normative data and high vs low on waist-to-height ratio using sex-specific cutoffs. This resulted in four groups: Low fit/High fat (Lofit-Hifat; n = 43); Low fit/Low fat (Lofit-Lofat; n = 11); High fit/High fat (Hifit-Hifat; n = 28); High fit/Low fat (Hifit-Lofat; n = 41). Four cognitive domains were examined: Verbal Learning & Memory, Immediate Memory, Speed & Flexibility, and Working Memory. Cerebral volume was computed from MRI scans as the ratio of cerebrospinal fluid to the sum of gray and white matter. MANCOVA and follow-up ANCOVAs (adjusted for HOMA-IR, APOE, and in a secondary analysis, sex) were used to test whether fitness/fatness group associated with cognition and cerebral volume. **RESULTS:** There was a significant main effect of group on Verbal Learning & Memory ($p = .003$). Compared to the Lofit-Hifat group, Hifit-Lofat and Hifit-Hifat ($\beta = 0.476$, $p = .013$; $\beta = 0.719$, $p = .001$) performed better, whereas Lofit-Lofat did not ($\beta = 0.023$, $p = .939$). There was a significant main effect of group on cerebral volume ($p = .012$). Relative to the Lofit-Hifat group, Hifit-Hifat had significantly greater cerebral volume ($\beta = -0.052$, $p = .007$) while Hifit-Lofat and Lofit-Lofat were not different ($\beta = -0.027$, $p = .151$; $\beta = 0.020$, $p = .451$). When sex was added to the statistical models, there was no longer an effect of group on cognition or cerebral volume. **CONCLUSION:** In a cohort at risk for AD, cardiorespiratory fitness is associated with better cognition in Verbal Learning & Memory and greater cerebral volume even in the presence of high fatness, while sex may impact the relationships. Cardiorespiratory fitness may be more important than achieving a favorable body habitus for preserving cognition and brain health.

Brain Activity For Food Inhibition In Children With Higher Cardiorespiratory Fitness: An Fmri Study**

Kell Grandjean da Costa¹, Henrique Bortolotti¹, Kaline Brito¹, Galtieri Medeiros¹, Fernanda Palhano-Fontes², Daniel Aranha Cabral¹, Maria Luiza Medeiros¹, Gleydiane Fernandes¹, Menna Price³, Eduardo Bodnariuc Fontes¹. ¹Federal University of Rio Grande do Norte, Natal, Brazil. ²Brain Institute, Onofre Lopes University Hospital, Federal University of Rio Grande do Norte, Natal, Brazil. ³Swansea University, Swansea, United Kingdom. Email: kellgrandjean@gmail.com

(No relevant relationships reported)

Inhibitory cognitive control in children has been associated with future educational attainment, healthy body composition and eating behavior. Regular practice of aerobic exercise has shown to improve inhibitory cognitive control in children, however the brain areas involved in this cognitive domain, in particular those related to the inhibition of high caloric food, are unclear. **PURPOSE:** To identify the effects of enhanced cardiorespiratory fitness on brain activity involved in food-specific inhibitory control in children. **METHODS:** 22 children (10±1.4 years old) participated in this study by completing general anthropometric assessments, a graded shuttle run test to estimate cardiorespiratory fitness (VO_{2max}) and a food-specific cognitive task while acquiring functional magnetic resonance imaging (fMRI) data by a 1.5 T MRI scanner.

During the scanner children performed a Go/No-go task. Pictures of objects (neutral) were used as Go stimulus and caloric food and toys pictures as No-go stimulus. The entire protocol consisted in three blocks No-go food, and three No-go toy. Each block contained 50 trials (80% Go stimulus). Children were divided in two groups (Lower fitness x Higher Fitness) separated by the median value of $\dot{V}O_{2max}$. Unpaired Student's t-tests were used to compare cognitive performance between groups. Food specific-inhibitory control was assessed comparing which brain areas were more activated during No-Go conditions (Food) between groups by a two sample t-test. **RESULTS:** No differences were found between groups for the cognitive performance (number of errors) and general anthropometric variables ($p > 0.05$). However, children with higher cardiorespiratory fitness during the food-specific cognitive task had greater activation of areas related to cognition (prefrontal cortex and inferior parietal lobule), motor control (primary motor cortex and primary somatosensory cortex) and homeostatic regulation (insular cortex) ($T = 2.89$; $p < 0.005$). **CONCLUSION:** Cardiorespiratory fitness might influence the brain activity during inhibition control of high caloric food in children. This finding suggests that regularly performed aerobic exercise by children may promote functional adaptations on the brain that could affect future eating behaviors.

Prefrontal Hemodynamics And Affective Responses To Incremental Exercise

Mark E. Hartman, Matthew Ladwig, Panteleimon Ekkekakis, FACSM. *Iowa State University, Ames, IA.* (Sponsor: Panteleimon Ekkekakis, FACSM)
Email: mhartman@iastate.edu
(No relevant relationships reported)

Neuroimaging investigations in non-exercise contexts have shown that the dorsolateral prefrontal cortex (dlPFC), medial PFC and anterior cingulate, are engaged when individuals attempt to cognitively control negative affect. Moreover, there are indications that aversive interoceptive stimuli preferentially activate the right hemisphere. We theorized that affective responses to incremental exercise would be regulated by the same prefrontal network implicated in non-exercise affect regulation. We hypothesized that there would be preferential right-dlPFC activation, among individuals with low tolerance to exercise intensity and, therefore, less positive affective responses to challenging intensities of exercise (i.e., above ventilatory threshold, VT). **PURPOSE:** To investigate dlPFC activation and affective responses during incremental exercise. **METHODS:** Thirty-eight participants (15M, 21F, Age: 23.7 ± 6.9 y; BMI: 24.0 ± 4.8 kg·m⁻²; $\dot{V}O_{2max}$: 32.8 ± 7.8 ml·kg⁻¹·min⁻¹) completed an incremental cycling test to volitional termination. They were divided into low- and high-Tolerance groups based on a median split of their Tolerance scores (Preference for and Tolerance of the Intensity of Exercise Questionnaire). Near-infrared spectroscopy was used to assess changes from rest in the Tissue Oxygenation Index (ΔTOI) in the left (AF3) and right (AF4) dlPFC. Affective valence ratings (Feeling Scale; FS) were collected each min. **RESULTS:** Tolerance scores were positively correlated with FS ratings above VT ($r = 0.33$, $p = .04$), such that lower-Tolerance individuals reported lower FS ratings. For ΔTOI , a significant interaction was found between Tolerance group (low-high) and Hemisphere (left-right), $p = .02$, $\eta_p^2 = .129$. ΔTOI in the right dlPFC was larger for low- vs high-Tolerance individuals ($p = .03$). **CONCLUSION:** Low self-reported tolerance for exercise intensity is associated with lower ratings of affective valence above VT and larger increases in right-dlPFC oxygenation from rest. These results suggest that the prefrontal regulation of negative affective responses to increasing exercise intensity may exhibit similarities to the regulation of negative affective responses in non-exercise contexts.

Acute Exercise Alters Brain Activation In Older Adults: What Is The Role Of Sleep?

Alfonso J. Alfini¹, Adam P. Spira¹, Lauren R. Weiss², Junyeon Won², Casandra Nyhuis¹, Corey S. Michelson², Caroline Simon², Daniel D. Callow², J. Carson Smith, FACSM. ¹*Johns Hopkins University, Baltimore, MD.* ²*University of Maryland, College Park, MD.* (Sponsor: J. Carson Smith, FACSM)
(No relevant relationships reported)

Insufficient sleep is associated with altered brain activation and poor cognitive performance. Aerobic exercise training enhances neural efficiency and improves cognition.

Purpose: To examine sleep's role in the effect of acute aerobic exercise on brain functional activation and cognitive performance. **Methods:** We studied healthy, physically active older adults ($n = 31$; mean age = 66.2 ± 7.4 years (range = 55-81); 74.2% women; 93.6% > high school education; body mass index = 25.7 ± 4.2). During two counterbalanced study visits, participants engaged in 30 minutes of moderate-intensity bicycle exercise or seated rest, followed by a functional MRI scan. While in the scanner, participants completed the Erikson Flanker Task. Prior to the first study visit they also completed 7.9 ± 3.3 nights of wrist actigraphy. Actigraphic sleep indices

included total sleep time (TST), sleep efficiency (SE), wake after sleep onset (WASO), and average wake bout length (WBL). **Results:** Compared to rest, acute exercise significantly increased functional activation in the right superior parietal lobule (SPL; beta = 0.14, $p = 0.011$) and decreased activation in the left anterior cingulate cortex (ACC; beta = -0.09, $p = 0.012$). After adjustment for age, sex, race, and education, greater WASO was associated with less exercise-induced change in SPL activation (beta = -0.05, $p = 0.001$). There were no significant associations between TST, SE, or WBL and exercise-induced changes in functional activation. Acute exercise did not significantly affect Flanker Task performance. **Conclusions:** Acute moderate-intensity exercise alters functional activation in brain regions involved in executive function and inhibitory control, which align with previous exercise studies showing a conflict-related shift from ACC to SPL activity. Our findings suggest that the short-term effects of acute exercise may accumulate and promote the cognitive improvements linked to exercise training. Moreover, our findings suggest that greater time awake after initial sleep onset (i.e., sleep fragmentation) may attenuate the benefits of aerobic exercise on functional activation in the aging brain. Randomized controlled trials are necessary to further evaluate the interactive effects of sleep and acute exercise in older adults.

The Effect of Exercise on Neural Activation in Older Adults

Alexis B. Slutsky, Jarod Vance, Laurie Wideman, FACSM, Jennifer L. Etnier, FACSM. *University of North Carolina at Greensboro, Greensboro, NC.* (Sponsor: Jennifer L. Etnier, FACSM)
Email: abslutsk@uncg.edu
(No relevant relationships reported)

Acute exercise (EX) affects neural activation, assessed with functional magnetic resonance imaging (fMRI), and is a suggested mechanism in the effects of EX on behavioral measures of cognition. **PURPOSE:** We investigated the effect of EX on neural activation during a set switching task (SST). **METHODS:** Six healthy, right-handed older adults ($M = 71.4 \pm 5.1$) completed two separate visits [EX; 30-min of cycling at 55-65% Heart Rate Reserve and rest (RS); 30-min of seated rest]. After EX or RS participants completed a SST during an fMRI. SSTs are a measure of executive function where participants shift attention between sets of rules during the task. Switch cost (cost) is the performance difference between switching (i.e. A, B, A) and repeat trials (i.e. A, A, A). The conditions included rest, a high switching block [70% switching, 30% repeat trials (HS)], and a low switching block [20% switching, 80% repeat trials (LS)]. fMRI analyses using FSL included assessment of main effects of activation during HS and LS blocks during EX and RS and a comparison of activation with reaction time cost. **RESULTS:** Across both HS and LS and EX and RS, participants similarly activated the lateral occipital cortex and frontopolar area. In addition, there was significant activation of the superior and inferior frontal gyri, middle frontal gyrus, cerebellum VIIb, thalamus, caudate, and insula following RS in HS and LS. There were no unique areas of activation in HS following EX, however in LS there was activation in the temporal occipital fusiform gyrus, inferior frontal gyrus, and middle frontal gyrus. In relation to performance, cost during HS was associated with activation of the cerebellum VIIb following EX and activation of the thalamus and occipital pole following RS. Further, cost during LS was associated with activation in the frontopolar area after EX and activation in the thalamus following RS. **CONCLUSION:** Similar activation during HS and LS following rest and EX suggests a common network for SSTs. During the HS blocks, EX did not elicit additional unique activation, as seen following RS or the LS block, suggesting EX-induced efficiency. More research is needed to better understand the implication of differential activation. Results presented at ACSM will include additional participants; findings and conclusions will reflect the final analyses.

Association of Sleep Duration with Exercise-Induced Reductions in Default Mode Network Connectivity in Healthy Older Adults

Lauren R. Weiss¹, Alfonso J. Alfini², Junyeon Won¹, Casandra Nyhuis², Corey S. Michelson¹, Caroline Simon¹, Daniel D. Callow¹, Adam P. Spira², J. Carson Smith, FACSM. ¹*University of Maryland, College Park, MD.* ²*Johns Hopkins University, Baltimore, MD.* (Sponsor: J. Carson Smith, FACSM)
Email: lrweiss@terpmail.umd.edu
(No relevant relationships reported)

Exercise promotes neuroprotective effects in several large-scale brain networks that are vulnerable to dysregulation in aging and disease. Aging-related changes in sleep may also disrupt functional connectivity within these networks, including the default mode network (DMN), in which beta-amyloid aggregates in Alzheimer's disease (AD). **PURPOSE:** To determine the effect of moderate-intensity acute exercise on resting-state DMN functional connectivity (DMN-rSFC) in the brains of healthy older adults, and how this might be altered by poor sleep.

METHODS: On separate days, 32 physically active older adults (24F, 66.3 ± 7.3 years) completed 30 minutes of moderate-intensity cycling (RPE 14-15) or rest in a counterbalanced order prior to resting-state BOLD fMRI data acquisition. Actigraphic sleep indices, including total sleep time (TST) and sleep efficiency (SE; proportion of time in bed spent asleep), were calculated using wrist actigraphy data from 8 ± 3.5 nights prior to the first study visit. We utilized a seed-based correlation analysis (seed: left posterior cingulate cortex [PCC], MNI 2 -54 26) to determine the effect of exercise on DMN-rsFC. We tested the association of TST and SE with residualized exercise-induced change in DMN-rsFC (Δ DMN-rsFC) with multiple linear regression.

RESULTS: A paired-samples *t*-test revealed decreased DMN-rsFC in the left inferior parietal lobule (IPL; MNI -41 -51 45, $k = 108$, 864 mm³) after exercise compared to rest. TST and SE explained 25% of the variance in exercise-induced Δ DMN-rsFC ($R^2 = .253$, $F(29) = 4.91$, $p = .015$). Every 30-minute increase in TST was associated with a $\beta = 0.019$ -unit decrease in DMN-rsFC between the left PCC and left IPL ($t(29) = -3.13$, $p = .004$).

CONCLUSION: Our findings suggest that acute moderate-intensity cycling exercise reduces functional connectivity between the left PCC and left IPL, two core DMN regions. Shorter sleep duration was associated with attenuated exercise-induced reduction in functional connectivity between these regions. Given the vulnerability of DMN regions to beta-amyloid deposition, our finding that exercise-induced effects on DMN-rsFC are modulated by sleep duration may have implications for optimizing results of exercise-based interventions aimed at preventing AD. Further research is needed to investigate this possibility.

F-33 Thematic Poster - New Findings in Children and Youth

Neighborhood Resources Supporting Physical Activity: Perceived Access and Weight-Related Health Status in Youth

Elizabeth Ackley, Peyton Rohrbaugh, Hannah Kolcz. *Roanoke College, Salem, VA.*

Email: ackley@roanoke.edu

(No relevant relationships reported)

Previous authors have demonstrated that the availability of neighborhood parks and greenspace is positively associated with physical activity engagement and health outcomes in youth. Yet, given the documented influence of *perceptions* of neighborhood safety, cleanliness, and traffic calming measures on physical activity participation in youth, further investigation is needed to consider the impact of perceived park access on youth health outcomes. **PURPOSE:** To examine the relationship between perceived access to neighborhood resources supporting physical activity and weight-related health status in youth. **METHODS:** Data from 17 urban public elementary schools, representing 733 students (mean age = 7.32 ± 1.78 years; males = 372, females = 361) was collected from the 2016-2017 Roanoke Valley Community Healthy Living Index. A correlation analysis examined the relationship between perceived access to resources supporting physical activity and BMI-for-age *z*-scores. **RESULTS:** A significant negative relationship was found between perceived access to resources supporting physical activity and weight-related health status in youth, $r(731) = -0.08$, $p = .01$. **CONCLUSIONS:** As perceptions of access to neighborhood-level resources supporting physical activity increased, weight-related health status in youth improved. These findings contribute to the existing literature on neighborhood-level correlates to health by considering the impact of family perceptions of access to healthy-living resources on youth health outcomes.

(No relevant relationships reported)

The benefits of school garden programs are far-reaching; however, few studies have assessed the impact of school gardens on PA levels in a youth population.

PURPOSE: To assess the impact of school gardens on physical activity (PA) levels in a youth population. **METHODS:** Data were obtained from 62 low-income 4th grade students in a central Texas school participating in TX Sprouts—a large, school-based gardening, nutrition, and cooking randomized controlled trial. A wall-mounted stadiometer and Tanita scale were used to measure students' height, weight, and body fat percentage, respectively. ActiGraph wGT3X+BT accelerometers captured student PA on garden days and non-garden days. Evenson (2008) cut points were used to calculate time spent in sedentary (SED) and in moderate-to-vigorous PA (MVPA). Total step counts (TLSC), and energy expenditure (kcal) were also obtained. Linear mixed modeling was used to determine the effect of TX Sprouts on PA, controlling for age, sex, and BMI. **RESULTS:** Students were 60.3% female, 59.7% Hispanic with a mean age of 9.2 ± 0.4 years, and 45% of students were affected by overweight/obesity. When compared to non-garden days, on garden days students demonstrated greater MVPA ($\beta = 2.96$, $p < 0.001$), TLSC ($\beta = 551.45$, $p < 0.001$), kcal ($\beta = 18.04$, $p < 0.001$), and a reduction in SED ($\beta = -9.21$, $p < 0.0001$). This equates to an increase of approximately 3 minutes MVPA, 549 steps, 17.6 kcal, and a decrease of 9.4 minutes TMESD.

CONCLUSION: Results showed increased PA for students on garden days vs. non-garden days. While findings reflect PA during one hour of a school day, garden lessons could have a substantial and meaningful impact on children's PA if incorporated multiple times throughout the school week.

(No relevant relationships reported)

Previous studies have suggested that sedentary behaviors and physical inactivity might be independent risk factors for executive dysfunction.

PURPOSE: To examine the independent and combined relationships of after-school sedentary time (ST) and daily physical activity (PA) with executive function in children and tentatively explore which these two behaviors had greater impact on children's executive function. **METHODS:** A total of 4,304 children aged 6-12 years were recruited in 2017. ST, PA and executive function were assessed using the International Physical Activity Questionnaire Short Form (IPAQ-SF) and the Behavior Rating Inventory of Executive Function (BRIEF), respectively. Subgroups were identified as: low ST, after-school ST < 2 hours/day; high ST, after-school ST ≥ 2 hours/day; low PA, moderate-to-vigorous physical activity (MVPA) < 60 minutes/day; high PA, MVPA ≥ 60 minutes/day. Participants were categorized into 4 groups: 1) low ST, high PA; 2) low ST, low PA; 3) high ST, high PA; 4) high ST, low PA. **RESULTS:** The mean age of the participants was 9.01 ± 1.72 years. Children in group 4 had the highest T-scores of BRIEF indices (48.23 ± 8.44, increased symptom), followed by those in group 3 (47.10 ± 8.05), group 2 (45.81 ± 7.78), and group 1 (44.41 ± 7.31), with $P < 0.05$ for each pairwise comparisons except for that between group 1 and 2. Multiple linear regressions showed that ST was positively related to the T-score of all indices, independent of MVPA ($P < 0.05$). However, MVPA was negatively associated with the T-score of metacognition index (MI) and global executive composite (GEC) only in the high ST subgroup ($P < 0.05$). **CONCLUSION:** Children with both low ST and high PA may have beneficial influence on their executive function. Notably, children with high ST and low PA demonstrated more significant deficits on the BRIEF than those with low ST and low PA, which suggested that intervention efforts should be paid more on reducing ST in addition to promoting PA.

Age for Onset of Walking May Predict Physical Activity in Childhood; The Norwegian Mother and Child Cohort Study

Guro Pauck Bernhardsen¹, Trine Stensrud¹, Wenche Nystad², Ulf Ekelund, FACSM¹. ¹Norwegian School of Sport Sciences, Oslo, Norway. ²Norwegian Institute of Public Health, Oslo, Norway.
 Email: g.p.bernhardsen@nih.no
 (No relevant relationships reported)

Physical activity (PA) is associated with a wide range of health benefits in children and youth. Identifying factors that might influence activity level is important to aim future public health strategies. Cross-sectional studies have demonstrated an association between motor skills and PA in childhood, however few studies have examined whether early motor development in infancy is associated with PA in childhood. **PURPOSE:** To examine whether age for onset of walking predicts PA in 7 year olds. **METHODS:** We used data from the Norwegian Mother and Child Cohort Study (MoBa), which is an ongoing population-based birth cohort study. The mothers reported age for onset of walking (months) and PA at 7 years (frequency of participation per week in moderate-to- vigorous PA [MVPA]) through questionnaires. The PA-questionnaire's validity is tested against accelerometer assessed MVPA (spearman's rho=0.38). We used multiple regression analyses and adjusted the analyses for gestational age, sex and weight at 1 year and parental education as a marker for socio-economic status. A formal test showed no evidence of an interaction by sex. **RESULTS:** A total of 33013 participants are included in the analysis (49% girls), and the mean age (sd) were 7.1 (0.14) years at follow-up. The average age (sd) for onset of walking were 12.9 (1.86) months, and average participation rate (sd) were 4.3 (2.45) times/week in MVPA. We observed a negative association between age for onset of walking and participation in MVPA in childhood ($B=-0.08$, 95%CI=-0.10, -0.07) independent of confounding factors. **CONCLUSION:** This finding indicate that earlier age for onset of walking may predict PA in childhood. However, while the association may be considered weak, i.e. each month earlier onset of walking is associated with 0.08 higher participation rate in MVPA (frequency per week), self-reported PA is likely prone to random measurement error attenuating the true association.

An 8-week Fundamental Motor Skill Program Improves Skill Proficiency and Reduces Sedentary Time in Pre-schoolers

Alexander Engel¹, Carolyn Broderick¹, Rachel Ward¹, Nancy Van Doorn¹, Karine Perreault², Abbey Van Capelle¹, Belinda Parmenter¹. ¹University of NSW, Sydney, Australia. ²Université de Sherbrooke, Sherbrooke, QC, Canada.
 Email: alexander.engel@unsw.edu.au
 (No relevant relationships reported)

PURPOSE: Fundamental motor skills (FMS) are the building blocks for physical activity (PA), with higher FMS proficiency associated with increased PA. Time spent in sedentary behaviours (SB) are increasing, and PA levels declining in children leading to higher rates of adult onset lifestyle diseases. This study aims to assess the effectiveness of an 8-week FMS program on FMS, PA and SB in children. We hypothesised that an 8-week supervised FMS program will improve object control and locomotor skills in children aged 3-5 years, and that improvements will be associated with improvements in PA and/or SB. **METHODS:** Children aged 3-5 years were recruited from a FMS program and child care centres. Children from the FMS program participated in a supervised program aimed at developing FMS through sporting activities and games. This involved one-hour training sessions, once a week for 8 weeks. Children in the control group (CG) continued usual pre-school activities. FMS were assessed using the Test for Gross Motor Skill Development-2 and PA levels using the parent completed Pre-school Physical Activity Questionnaire at baseline, and 8 weeks. An analysis of variance was used to assess between group differences. Simple linear regression was used to identify any relationships between FMS and PA. **RESULTS:** Forty-six children participated in the study with 24 allocated to the CG (mean age 4.2±0.6 yrs) and 22 to the intervention group (IG) (mean age 3.9±0.7 yrs). After 8 weeks of FMS training the children in the IG were significantly better than the CG in the gallop ($p=0.04$) and strike ($p=0.02$), as well as locomotor ($p=0.01$), object control ($p=0.01$) and gross motor quotient ($p=0.007$) percentiles. In addition, children in the IG spent reduced time in SB ($p=0.03$), with the change being inversely and significantly associated with gallop skill performance ($r=-0.34$, $p=0.04$) and gross motor quotient ($r=-0.35$, $p=0.03$). **CONCLUSIONS:** An 8-week supervised FMS program is associated with an improvement in locomotor and object control skill proficiency, and improvements are associated with a reduction in time spent in SB. Further research is needed to explore if the improvements made during the program are maintained over time and whether children who attended the program are more likely to remain physically active throughout childhood.

The Effect Of Exercise In Addition To A Lifestyle-intervention On Hepatic Fat In Overweight Children

María Medrano Echeverría¹, Lide Arenaza¹, Cristina Cadenas-Sanchez², Maddi Osés¹, Beatriz Rodríguez-Vigil³, Francisco B Ortega⁴, Idoia Labayen¹. ¹Institute for Innovation & Sustainable Development in Food Chain (IS-FOOD), Public University of Navarra, Pamplona, Spain. ²PROFITH "PROMoting FITness and Health through physical activity" Research Group, University of Granada, Granada, Spain. ³Osatek, University Hospital of Alava (HUA), Vitoria-Gasteiz, Spain. ⁴PROFITH "PROMoting FITness and Health through physical activity" Research Group, University of Granada, Granada, Spain.
 (No relevant relationships reported)

PURPOSE: To compare the prevalence of responders (R) and non-responders (NR) for hepatic fat content and liver enzyme levels between overweight children participating in a family-based lifestyle intervention (LS) or in a family-based lifestyle plus exercise intervention (LS+Ex).

METHODS: This study included 102 overweight children (8-12 y; 55% girls; 57% with obesity according WOF criteria) that completed the 22 weeks of the EFIGRO (ClinicalTrials.gov ID: NCT02258126) two arms parallel intervention trial. The LS group (N=53; 10.6±1.1 y; 55% girls; 55% with obesity) attended a family-based lifestyle-and psycho-educational program composed by 11 sessions of 90 minutes. The LS+Ex group (N=49, 10.5±1.1 y; 55% girls; 59% with obesity) attended the same educational program and additionally participated in an exercise program that included aerobic and strength exercises, 3 days/week, 90 mins/session. Before and after the intervention, hepatic fat content was measured by magnetic resonance imaging, and alanine aminotransferase (ALT), aspartate aminotransferase (AST) and gamma-GT were measured in fasting plasma samples. Children were categorized as R when the effect size (d-cohen) was ≥ 0.2 , and as NR when d-cohen was < 0.2 .

RESULTS: Regarding hepatic fat content, there was a significantly higher prevalence of R ($P=0.035$) in the LS+Ex group (54%), than in the LS group (34%). Moreover, the difference in the prevalence of R between the two groups was also significant for GGT (69% and 38% of R, for the LS+Ex and LS groups, respectively, $P=0.002$), while there were no significant difference in the prevalence of R in changes in ALT (45% vs. 37% of R, for the LS+Ex and LS groups) and AST/ALT (40% vs. 35% of R, for the LS+Ex and LS groups) between the two groups (all $P>0.05$).

CONCLUSIONS: There was a higher prevalence of responders for hepatic fat content and GTT levels in the group of children with overweight that participated in the family-based multicomponent intervention program that included exercise. These results suggest that lifestyle intervention programs for improving obesity associated comorbidities in children should include exercise training to improve their hepatic health.

Parental Perceptions of Their Children's Physical Activity

Emily R. Shull, Chelsea L. Richard, Marsha Dowda, FACSM, Russell R. Pate, FACSM. University of South Carolina, Columbia, SC.
 Email: ershull@email.sc.edu
 (No relevant relationships reported)

Despite known health benefits, most children are not meeting the recommended physical activity (PA) guidelines. Parents play a critical role in supporting and encouraging their children's PA and it is essential to understand parents' perceptions of the factors that may influence their children's PA. **PURPOSE:** To describe, in a representative, statewide sample, South Carolina parents' perceptions of their children's PA behaviors. **METHODS:** Items from the 2013 statewide Children's Health Assessment Survey pertaining to children's PA, sport participation, outdoor activity, screen time, recreational time and coordination were analyzed for a total of 711 parent-reported children (342 males, 369 females) ages 5-17 years. Weighted percentages were calculated for the total sample and population subgroups (age, parent education, race, and weight status) and for the children's health-related PA behaviors items; weighted percentages for reported children's health-related PA behaviors stratified by meeting PA requirements. Age, parent education, race, and weight status were controlled in the analyses. **RESULTS:** Over half of the youth were reported as being active on ≥ 5 d/wk. Males were reported accumulating ≥ 60 min/d of PA as compared to females (80.5% and 72%). The 5-10-year-old age group reportedly had the highest percentage of accumulating ≥ 60 min/d of PA (90%), choosing PA during recreational time (64%), and a higher percentage (80%) spent < 120 min/d engaged in screen time compared to the other age groups. For the total group, those reportedly meeting the guideline were more likely to be active ≥ 5 d/wk (47%), choose PA during recreational time (44%), participate in sports and/or PA classes (52%), spend

≥ 60 min outside on weekdays (70%), and weekend days (64%) than the alternative behaviors. Both the younger (74% vs 16%) and middle age groups (64% vs 11%) who reportedly met the 60 min of PA guideline were more likely to spend ≥ 60 min outside on weekends. **CONCLUSIONS:** Children reportedly meeting the PA guidelines, are more likely to engage in other PA behaviors, as perceived by their parents. Active encouragement of parents and their children to be more physically active, engage in sports and outdoor time, as well as decreasing time using electronics and other sedentary behaviors should be advocated.

Association Between Meeting Physical Activity, Sleep, And Dietary Guidelines And Cardiometabolic Risk Factors And Adiposity In Adolescents
 Chelsea L. Kracht, Peter T. Katzmarzyk, FACSM, Amanda E. Staiano, Chelsea L. Kracht. *Pennington Biomedical Research Center, Baton Rouge, LA.* (Sponsor: Peter T. Katzmarzyk, FACSM)
 Email: chelsea.kracht@pbrc.edu
 (No relevant relationships reported)

INTRODUCTION: Obesity is a complex disease that may be influenced by physical activity (PA), sleep, and diet; though little is known if individual behavior guidelines are related to cardiometabolic risk factors. **PURPOSE:** To examine the association between meeting PA, sleep, and dietary guidelines and cardiometabolic risk factors and adiposity in adolescents. **METHODS:** Adolescents, ages 10 to 16 years, wore an accelerometer for 7 days, including overnight to capture PA and sleep. The PA guideline was defined as ≥ 60 minutes of moderate-to-vigorous PA per day. The sleep guideline was 9-11 hours (10-13 years of age) or 8-10 hours (14-16 years of age) per night. The dietary guideline was based on the Healthy Eating Index 2015 score calculated from a self-administered dietary recall. Scores ≥70 were classified as meeting guideline. Cardiometabolic risk factors were assessed in a clinical setting including body mass index percentile (BMIP); waist circumference (WC); DXA for total body fat; abdominal MRI for visceral adipose tissue (VAT); resting blood pressure (BP); and a fasting blood draw for high-density lipoprotein cholesterol, triglycerides, and glucose. Generalized linear regression was used to assess meeting the guidelines and cardiometabolic risk factors, with adjustment for age, sex, race, and other guidelines. **RESULTS:** Of the 342 participants, 239 (69%) provided complete measures. Adolescents were 12.4 ± 1.9 years of age, most were white (61%), had overweight or obesity (47%), and slightly more were girls (53%). Many met the sleep guideline (50%), but few met the PA (11%) or dietary (3%) guidelines. Most met 1 (50%) or no guidelines (43%), and few met 2 or more guidelines (6%). In adjusted models, meeting the PA guideline was associated with a lower BMIP, diastolic BP, WC, VAT, and total body fat; and meeting the sleep guideline was associated with a lower WC ($p < 0.05$ for all). Meeting one guideline was associated with a lower BMIP, WC, VAT, and total body fat; and meeting 2 guidelines was associated with lower diastolic BP ($p < 0.05$ for all). There were no other associations between meeting guidelines and risk factors. **CONCLUSIONS:** Adiposity was lower for those who met the PA or sleep guidelines, and very few met the dietary guideline. Multidisciplinary strategies are needed to ensure healthy behaviors for all adolescents.

The Association of Protein Intake and Change in Lean Mass During 9-mos. of Resistance Training
 Lauren T. Ptomey¹, Felicia L. Steger¹, Erik A. Willis², Debra K. Sullivan¹, Jeffery J. Honas¹, Joseph E. Donnelly, FACSM¹, Richard A. Washburn, FACSM¹. ¹University of Kansas Medical Center, Kansas City, KS. ²National Cancer Institute, Bethesda, MD.

 (No relevant relationships reported)

PURPOSE: The purpose of the study was to assess the association of protein intake with change in lean mass (LM) during a 9-mo. resistance training (RT) protocol.

METHODS: Normal/overweight sedentary, previously untrained young adults ($n = 78$, age ~22 yrs. BMI ~ 25 kg/m²) completed a 9-mo., supervised efficacy trial (1 or 3-sets RT, 9 exercises, 3 d/wk.) Participants were required to complete ≥80% scheduled RT sessions and asked maintain usual ad-libitum diets. Body composition (DEXA) and dietary intake (digital photography plus recall) were assessed at baseline, 4.5 and 9 mos. Multiple linear regression models were used to examine the associations between protein intake and changes in LM. Intake variables from the assessment periods were aggregated over the 9-month intervention. Protein intake was examined by using the nutrient residual energy-adjustment method, in which the protein residuals obtained by regressing absolute protein intake on total energy intake are added to mean protein intake and used as the independent variables. Models were adjusted for age, sex, race, randomization group, baseline LM, and height. To allow determination of whether the associations were independent of change in overall mass, models were also adjusted for changes in FM.

RESULTS: Participants completed 92 ± 6% of scheduled RT sessions. LM increased significantly from baseline to 9 mos. (1.2 ± 1.7 kg, $p < 0.0001$) with high inter-individual variability (range = - 2.0 to 6.2 kg). Grams of total protein ($\beta = 0.01$ SE=0.01, $p = 0.34$), animal protein ($\beta = 0.02$ SE= 0.02, $p = 0.15$), vegetable protein ($\beta = -0.03$ SE=0.04, $p = 0.44$), and isoleucine ($\beta = 3.4$ SE=1.97, $p = 0.09$), were not associated with changes in total LM per unit of energy-adjusted protein intake. However, leucine ($\beta = 1.8$ SE=1.2, $p = 0.03$) and valine ($\beta = 3.7$ SE=1.4, $p = 0.01$) were positively associated with changes in total LM per unit of energy-adjusted protein intake.

CONCLUSIONS: There was no association with total protein intake and changes in LM in young adults enrolled in a 9-month RT intervention. However, there was a positive association with two of the branch chain amino acids, leucine and valine. Thus, the type of protein may be more important than total protein intake for increasing LM during a long-term RT intervention.

Whey Protein Consumption Before, Rather than Within a Post-Exercise Meal Increases the Postprandial Aminoacidemia

Ruth M. James¹, Ian Varley¹, Mark P. Funnell², Carl J. Hulston², Lewis J. James². ¹Nottingham Trent University, Nottingham, United Kingdom. ²Loughborough University, Loughborough, United Kingdom. (Sponsor: Prof Craig Sale, FACSM)
 Email: ruth.james@ntu.ac.uk
 (No relevant relationships reported)

Rapidly digested and absorbed proteins enhance the muscle protein synthesis response following resistance exercise, with the degree of hyperaminoacidemia suggested to be an important consideration. However, most studies have used supplemental protein sources, with little focus on how consumption of protein within a mixed meal influences postprandial amino acid (AA) responses. **PURPOSE:** To examine the pattern of postprandial AA responses to consuming whey protein isolate before or within a mixed meal after resistance exercise. **METHODS:** Eight resistance trained men (age 21 (1) y; body mass 80.2 (8.4) kg; body fat 13 (6) %) completed two trials in a randomized order. Trials consisted of ~1 h lower-body resistance exercise, a 30 min post-exercise feeding period and a further 150 min supine rest period. Post-exercise nutrition was identical in composition (400 mL water at 0 min; an oat flapjack + 600 mL water at 15-30 min) and included 20 g of whey protein isolate, which was either consumed in the drink at 0 min (SUPP) or mixed into the oat flapjack consumed at 15-30 min (MEAL). Blood samples were taken every 15-30 min post-exercise to determine amino acid, glucose and insulin concentrations. **RESULTS:** Compared to MEAL, leucine and essential AA (EAA) concentrations were higher at 15-50 min and lower at 120-180 min in SUPP ($P < 0.05$), whilst total AA (TAA) concentrations were higher at 30-50 min and lower at 150 min in SUPP. Peak leucine (SUPP 414 (70) mmol/L; MEAL 216 (40) mmol/L; $P < 0.001$), EAA (SUPP 2404 (411) mmol/L; MEAL 1502 (235) mmol/L; $P < 0.001$) and TAA (SUPP 4860 (759) mmol/L; MEAL 3450 (467) mmol/L; $P < 0.01$) concentrations were all greater during SUPP vs MEAL, with peak concentrations also achieved earlier in SUPP. Total postprandial area under the curve for leucine, EAA and TAA concentrations were all greater during SUPP ($P < 0.05$). There were no between-trial differences for glucose or insulin responses ($P > 0.05$). **CONCLUSIONS:** Consumption of protein in supplemental form prior to, rather than within a mixed meal, facilitates a more rapid and pronounced postprandial aminoacidemia following resistance exercise. This might offer some advantage where maximizing the anabolic effect of resistance exercise is desirable. This project received no funding. The whey protein isolate was provided by Volac International Ltd.

Does Exclusive Consumption of Plant-based Dietary Protein Impair Resistance Training-induced Muscle Adaptations?

Victoria Hevia-Larrain¹, Igor Longobardi¹, Alan F. Lins¹, Rosa M. Pereira¹, Guilherme Artioli¹, Stuart M. Phillips, FACSM², Bruno Gualano¹, Hamilton Roschel¹. ¹University of São Paulo, São Paulo, Brazil. ²McMaster University, Hamilton, ON, Canada.

Email: victoriahevia@usp.br

(No relevant relationships reported)

Dietary protein consumption maximizes the anabolic response during resistance training (RT) by triggering muscle protein synthesis and providing the indispensable amino acids for a net positive protein balance. Leucine is considered the key amino acid in this process, suggesting that differences in protein quality may influence RT-induced gains in muscle mass and strength. In this respect, despite acute evidence on lower anabolic properties of plant- vs. animal-based protein, the effects of an exclusive plant-based dietary protein diet on RT-induced adaptations are currently unknown. **PURPOSE:** To investigate the impact of dietary protein source (plant- vs. mixed diet-based protein) on RT-induced changes in muscle mass and strength in total protein-matched young healthy men. **METHODS:** Nineteen vegan (VEG 26±5 y; 72.7±7.1 kg, 1.78±0.05 m) and nineteen omnivorous (OMN 26±4 y; 73.3±7.8 kg, 1.76±0.06 m) physically active young men were enrolled in a 12-week, twice weekly, lower-limb RT program. Daily protein intake was adjusted to 1.6g/kg/day in both groups via supplementing either soy (VEG) or whey (OMN) protein. Leg lean mass (LLM, by DXA) and lower-limb maximal strength (leg-press one-repetition-maximum, 1-RM) were determined PRE and POST intervention. Six 24-hour dietary recalls were performed at baseline (for habitual protein intake determination) and three during the intervention, for monitoring purposes. **RESULTS:** Significant increases in LLM were observed in both VEG (PRE=18.9±2.2 kg and POST=20.1±2.2 kg, Δ%=6.4±5.8 %, p<0.0001) and OMN (PRE=19.1±2.4 kg and POST=20.3±2.7 kg, Δ%=6.1±3.9 %, p<0.0001). Similarly, 1-RM was significantly increased in both VEG (PRE=258±59 kg and POST=354±81 kg, Δ%=38.1±5.9 %, p<0.0001) and OMN (PRE=261±63 kg and POST=381±73 kg, Δ%=49.0±21.6 %, p<0.0001). No group by time interactions were found. Finally, total protein intake was similar between groups (VEG=1.68±0.14g/kg/d and OMN=1.72±0.10g/kg/d, p=0.30). **CONCLUSION:** A higher protein-content (~1.6g/kg/day) exclusive plant-based (including soy) protein diet is similarly effective as a mixed-diet in supporting RT-induced muscle adaptations, suggesting that total protein, rather than protein quality, may be more important for muscle adaptation in young individuals. Supported by FAPESP grant 2016/22083-3.

Leucine Co-Ingestion Augments the Muscle Protein Synthetic Response to the Ingestion of 15 g Protein During Recovery from Resistance Exercise in Older Men

Andrew M. Holwerda, Kevin J.M. Paulussen, Maarten Overkamp, Joy P.B. Goessens, Irene-Fleur Kramer, Will K.W.H. Wodzig, Lex B. Verdijk, Luc J.C. van Loon. *Maastricht University, Maastricht, Netherlands.* (Sponsor: Janice L. Thompson, FACSM)

Email: andy.holwerda@maastrichtuniversity.nl

(No relevant relationships reported)

PURPOSE: Older adults have shown an attenuated post-exercise increase in muscle protein synthesis rates following ingestion of smaller amounts of protein when compared to younger adults. Consequently, more protein may be required to increase post-exercise muscle protein synthesis rates in older as compared to younger men. The present study investigated whether co-ingestion of 1.5 g free leucine with a single, 15 g bolus of protein augments the muscle protein synthetic response during recovery from resistance-type exercise in older men. **METHODS:** Twenty-four healthy older men (67±1 y) were randomly assigned to ingest 15 g milk protein concentrate (MPC80) with (15G+LEU; n=12) or without (15G; n=12) 1.5 g free leucine after performing a single bout of resistance-type exercise. Post-prandial protein digestion and amino acid absorption kinetics, whole body protein metabolism, and post-prandial myofibrillar protein synthesis rates were assessed using primed, continuous infusions with L-[ring-2H5]-phenylalanine, L-[ring-2H2]-tyrosine and L-[1-13C]-leucine combined with the ingestion of intrinsically L-[1-13C]-phenylalanine labeled milk protein. **RESULTS:** A total of 70±1% (10.5±0.2 g) and 75±2% (11.2±0.3 g) of the protein-derived amino acids were released in the circulation during the 6-h post-exercise recovery phase in 15G+LEU and 15G, respectively (P<0.05). Post-exercise myofibrillar protein synthesis rates were 16% (0.058±0.003 vs 0.049±0.002 %·h⁻¹; P<0.05; based upon L-[ring-2H₅]-phenylalanine) and 19% (0.071±0.003 vs 0.060±0.003 %·h⁻¹; P<0.05; based upon L-[1-¹³C]-leucine) greater in 15G+LEU when compared with 15G. **CONCLUSIONS:** Leucine co-ingestion augments the post-exercise muscle protein synthetic response to the ingestion of a single 15 g bolus of protein in older men.

PRE-SLEEP CONSUMPTION OF CASEIN PROTEIN ON RESTING METABOLIC RATE AND APPETITE IN PREMENOPAUSAL WOMEN

C.M. Schattinger¹, J.R. Leonard¹, A.L. Artese², M.J. Ormsbee¹, C.L. Pappas¹, L.B. Pantan¹. ¹Florida State University, FL. ²Roanoke College, VA.

PURPOSE: To determine the acute effects of nighttime pre-sleep consumption of casein protein (CP) and a placebo (PLA) supplement on next-morning measures of resting metabolic rate (RMR) and appetite in sedentary premenopausal women. **METHODS:** This study was a randomized crossover double-blind placebo-controlled trial. Seven premenopausal (age: 19.9±1.2 yrs, BMI= 23.1±2.6 kg/m²) women participated. Subjects had body composition (DXA), RMR (indirect calorimetry), and appetite (visual analog scale; VAS) measured. Subjects consumed either CP (35 g, 130 kcal) or PLA (7.2g, 10 kcal) 30 min prior to bed time on two separate occasions separated by 48-hours. RMR and measures of hunger, desire to eat, and satiety were analyzed using Paired T-tests. Significance was accepted at p<0.05. **RESULTS:** RMR (CP:1383±162; PLA:1340±159 kcal/day) and relative oxygen consumption (CP:3.41±0.44; PLA 3.36±0.38 ml/kg/min) were not different between CP and PLA. There were also no effects of CP and PLA on measures of appetite (Hunger: CP: 3.8±3.0; PLA: 3.1±2.7 cm; Satiety: CP: 4.1±3.4; PLA: 4.7±2.7 cm; Desire to Eat: CP:3.7±3.4; PLA:2.8±2.1 cm). **CONCLUSION:** There were no differences in RMR and measures of appetite between CP and PLA. There is growing evidence that a small snack before sleep (150-200 kcal) is not harmful to metabolism or appetite. This study was supported with product by Dymatize Nutrition.

(No relevant relationships reported)

PURPOSE: It has recently been speculated that protein supplementation may further augment the adaptations to prolonged endurance exercise training. We assessed the impact of protein supplementation during prolonged endurance exercise training on whole-body oxidative capacity (VO_{2max}) and endurance exercise performance.

METHODS: Sixty recreationally active males (age: 27±6 y; BMI: 23.8±2.6 kg·m⁻², VO_{2max} 47±6 mL·min⁻¹·kg⁻¹) were subjected to 12 weeks of triweekly endurance exercise training. After each session and each night prior to sleep, participants ingested either a protein supplement (PRO; 29 g casein protein) or an isocaloric carbohydrate placebo (PLA). Before and after the 12 weeks of training, VO_{2max} and endurance exercise performance (~10-km time-trial) were assessed on a cycle ergometer. Muscular endurance (total workload achieved during 30 reciprocal isokinetic contractions) was assessed by isokinetic dynamometry and body composition by DXA. Dietary intake was assessed at baseline and during the intervention period. Repeated measures ANOVA was applied to assess whether training adaptations were different between groups.

RESULTS: Protein intake increased in PRO (1.2±0.4 to 1.6±0.3 g·kg⁻¹), but not in PLA (1.3±0.4 to 1.2±0.3 g·kg⁻¹, time x treatment interaction, P<0.001). Endurance exercise training induced an 11±6% increase in VO_{2max} (time effect, P<0.001), with no differences between groups (PRO: 48±6 to 53±7 mL·min⁻¹·kg⁻¹; PLA: 46±5 to 51±6 mL·min⁻¹·kg⁻¹; time x treatment interaction, P=0.50). Time to complete the time-trial was reduced by 14±7% (time effect, P<0.001), with no differences between groups (time x treatment interaction, P=0.15). Muscular endurance increased by 6±7% (time effect, P<0.001), with no differences between groups (time x treatment interaction, P=0.84). Whole body lean mass was unchanged over time (P=0.097). However, leg lean mass showed an increase following endurance exercise training (P<0.001), which tended to be greater in PRO (PRO: 0.5±0.7 kg; PLA: 0.2±0.6 kg; time x treatment interaction, P=0.073).

CONCLUSION: Protein supplementation after exercise and before sleep does not further augment the gains in whole-body oxidative capacity and endurance exercise performance following prolonged endurance exercise training in healthy, young males.

Higher Protein Intake does Not Potentiate Resistance Training-Induced Muscular Adaptations in Middle-aged Adults

Rafael A. Alamilla, Colleen F. McKenna, Amadeo F. Salvador, Susannah Scaroni, Isabel G. Martinez, Joseph W. Beals, Scott A. Paluska, FACSM, Nicholas A. Burd. *University of Illinois at Urbana/Champaign, Urbana, IL*. (Sponsor: Scott A. Paluska, FACSM)

(No relevant relationships reported)

Maintenance of muscle strength helps preserve functional capacity and independence in aging populations. Protein intake above the current recommended dietary allowance (RDA) is believed to optimally facilitate resistance training adaptations; however, the suitability of consuming these protein amounts for middle-aged adults remains unclear. **PURPOSE:** To determine whether dietary protein ingestion above the RDA modulates muscle strength and body composition to resistance exercise training in middle-aged adults. **METHODS:** 27 participants were randomly assigned to consume either the RDA of protein (0.8-1.0 g/kg/d; 50 ± 2 y, BMI = 27.9 ± 0.1 kg/m²) or twice the RDA (1.6-1.8 g/kg/d; 52 ± 2 y, BMI = 28.1 ± 0.9 kg/m²) during a 10-wk progressive resistance training program. Participants were counseled on equal distribution of protein, and consumed either 15g or 30g protein in the immediate post-exercise period and nightly before sleep, respectively. Body composition was assessed by dual-energy x-ray absorptiometry. One repetition maximum assessments were used to determine muscular strength for both lower and upper body exercises. Strength assessments were performed at baseline and after the 10-wk intervention. **RESULTS:** There was a significant increase ($P < 0.05$) in muscle strength in all exercises for both groups across time (Table 1). However, there was no significant difference in strength between groups ($P > 0.05$) after the intervention. Body fat % was not significantly different from baseline in either group ($P > 0.05$), or after intervention ($P > 0.05$). Lower body lean body mass significantly improved ($P < 0.05$) with resistance training in both groups with no group differences ($P > 0.05$). **CONCLUSION:** Dietary protein intake comparable to the RDA coupled with moderate post-exercise and nightly protein doses is adequate to support training-induced muscle strength and mass gains in middle-aged adults.

Are Changes In Running Economy Associated With Changes In Performance In Runners? A Systematic Review and Meta Analysis

Ian J. O'Sullivan¹, Mark I. Johnson¹, Sarah B. Clarke², Peter Francis¹. ¹*Leeds Beckett University, Leeds, United Kingdom.* ²*Northern Michigan University, Marquette, MI.*

Email: i.osullivan7595@student.leedsbeckett.ac.uk

(No relevant relationships reported)

Improvements in running economy (RE) are thought to lead to improvements in running performance (P). The identification of modifiable factors that affect RE and by association, P has been the focus of a significant body of research in recent years. Modifiable factors affecting RE are broadly classified as, biomechanical, anthropometric, physiological, extrinsic and training related. Interventions have been used to alter one or more of these factors with a view to improving RE. The underlying assumption is that an improvement in RE will also lead to an improvement in P. **PURPOSE:** The aim of this study was to assess the effect of interventions of at least 2-weeks' duration on RE and P and to determine whether there is a relationship between changes in RE (Δ RE) and changes in running performance (Δ P). **METHODS:** A database search was carried out in Web of Science, Scopus and SPORTDiscus. In accordance with a PRISMA checklist 10 studies reporting 12 comparisons between interventions and controls were included in the review. **RESULTS:** There was no correlation between percentage Δ RE and percentage Δ P ($r = 0.46$, $P = 0.936$, 12 comparisons). There was a low risk of reporting bias in relation to incomplete data sets. There was an unclear risk of selection bias associated with random allocation to intervention and control groups and reporting of baseline differences in RE and P between intervention and control groups. There was also an unclear risk of performance bias relating to the monitoring of non-intervention training, detection bias associated with differences in determination of the performance outcome measure and attrition bias associated with reporting of participant dropout. Meta-analyses found no statistically significant differences between interventions and control for RE (SMD (95% CI) = -0.37 (-1.43, 0.69), 204 participants, $p = 0.49$) or for P (SMD (95% CI) = -0.65 (-26.02, 24.72), 204 participants, $p = 0.99$). **CONCLUSIONS:** Methodologies for subject allocation to intervention and control groups and the reporting of differences in baseline characteristics of control and intervention groups and reporting of participant dropout were infrequently applied in the included studies. Studies of greater statistical power, with standardised measures of performance and greater control of non-intervention training are required.

Running Economy Strongly Related to Ground Contact Time Imbalances

Dustin P. Joubert, Nicholas A. Guerra, Eric J. Jones, Erica G. Knowles, Aaron D. Piper. *Stephen F. Austin State University, Nacogdoches, TX.* (Sponsor: Stephen F. Crouse, FACSM)

Email: joubertd@sfasu.edu

(No relevant relationships reported)

Running economy (RE) can be defined as the oxygen consumption or caloric unit cost required to move at a specific velocity. In addition to a runner's maximal oxygen uptake (VO₂max) and lactate threshold (LT), RE is a key endurance performance determinant. Better RE is advantageous as it represents the ability to run at a lower relative percentage of VO₂max at a given speed and reduces the rate of energy depletion. Ground contact time (GCT) has been associated with RE, however it has not been established how GCT imbalances between feet impact economy. **Purpose:** Determine the relationship between cadence, GCT, and GCT imbalances and RE. **Methods:** 11 NCAA Division I distance runners (7 male: 21±2 years, 15.8±3.4% fat; 4 female: 19±1 years, 22.1±5.2% fat) completed a graded exercise test on a treadmill to determine LT and VO₂max. Subjects ran with a heart rate monitor capable of measuring cadence, GCT, and GCT balance between left and right feet. VO₂ and the respiratory exchange ratio (RER) were monitored continuously, and the average VO₂ and RER over the last minute of the 5 minute stages was used for determining caloric cost. Caloric unit cost (kcal·kg⁻¹·km⁻¹) was calculated for the stage determined to be just below the LT (prior to >4mmol/L), and the relationship between this measure of

RE was correlated with cadence, GCT, and GCT imbalance by Pearson correlations. **Results:** The average VO₂max among the runners was 68.6±4.9 ml·kg⁻¹·min⁻¹ and 59.3±1.1 ml·kg⁻¹·min⁻¹, and the average LT was 80±8% and 83±5% VO₂max for men and women, respectively. The relationship between RE at the LT and the measured running dynamics is displayed in Table 1. There was a very strong, positive correlation between GCT imbalances and the caloric cost of running. **Conclusion:** GCT imbalances were a stronger determinant of RE than GCT or cadence. Future research should determine how to improve GCT imbalances and if doing so can improve economy and performance.

| | | Cadence | GCT | GCT Imbalance |
|---|---------------------|---------|------|---------------|
| Caloric Cost kcal·kg ⁻¹ ·km ⁻¹ | Pearson Correlation | -.454 | .492 | .874* |
| | Sig. (2-tailed) | .161 | .124 | <.001 |
| | N | 11 | 11 | 11 |

Reactive Strength And Leg Stiffness Correlates Running Economy In Well-Trained Long Distance Runners

Fei LI, YUE SHI, Haiyong Ding. *ShangHai University of Sport, ShangHai, China.*
 Email: felix_2008@foxmail.com
 (No relevant relationships reported)

Purpose: Neuromuscular factors play critical role in running economy (RE), the present study was to investigate the relationship between leg stiffness, relative maximal strength, Counter movement jump height (CMJ), drop jump height (DJ), reactive strength index (RSI) and RE.

Methods: Twenty-eight male long-distance runners (23.1±3.8years; BMI:20.5±2.6kg·m⁻²; VO₂max: 66.4±7.0 mlO₂·kg⁻¹·min⁻¹) were participated in this study. Each subject performed two-day test including 12, 14 and 16km·h⁻¹ RE test, 1RM back squat test, CMJ and DJ test on the first day, and performed leg stiffness measurement using three-dimensional (3D) motion capture experiments on the second day, The data were analyzed using Pearson correlation coefficients.

Results: A statistically significant negative correlation was found between DJ and 16km·h⁻¹ RE (r=-0.67, p<0.01). RSI was related to RE at 14 and 16km·h⁻¹ speeds (r=-0.72 and -0.76, p<0.01, respectively). In addition, there were a significant negative correlations (r=-0.81 and -0.84, p<0.01, respectively) observed between leg stiffness and RE at 14 and 16km·h⁻¹ speeds. There were no significant correlations between relative maximal strength, CMJ and RE.

Conclusions: The present data highlight that reactive strength and leg stiffness maybe most important neuromuscular factors related to the better RE. Strength training such as heavy resistance training and plyometric exercises should be considered as a component to neuromuscular function for developing RE in long-distance runners.

Cardiometabolic and Perceptual Responses to Maximal Exercise: Comparing Graded Walking to Ungraded Running

Marcus Kilpatrick, FACSM, Abby Fleming, Taylor Smith, Balea Schumacher, Brian Waddell, A'Naja Newsome, Amber D'Oliveira. *University of South Florida, Tampa, FL.*
 Email: mkilpatrick@usf.edu
 (No relevant relationships reported)

Graded exercise testing for determination of aerobic capacity can be conducted in numerous ways with treadmill testing representing the primary modality. Achieving maximal effort on a treadmill can be accomplished by increasing speed and/or grade. Research to date comparing graded walking maximal tests to ungraded running tests is limited. **PURPOSE:** Compare the cardiometabolic responses to two treadmill-based maximal tests, namely graded walking and ungraded running. **METHODS:** 20 healthy participants (11 females, 9 males; mean BMI = 25; mean age = 24) completed two counterbalanced cardiometabolic exercise tests. The WALK trial started with a brisk and comfortable walking speed and increased grade by 2% every minute until exhaustion and the RUN trial started with a comfortable walking speed and increased by 0.5 mph every minute until exhaustion. Expired gases, HR, overall RPE (RPE-O), and legs only RPE (RPE-L) were assessed during the test. **RESULTS:** Data was analyzed using dependent t-tests. The RUN and WALK trials produced similar maximal values for RPE-O, RPE-L, and VO₂ (all p-values > 0.05; all ES values < 0.2), though HR was significantly higher in the RUN trial (p < 0.05; ES = 0.4), and RER was significantly higher in the WALK trial (p < 0.01; ES = 0.8). **CONCLUSIONS:**

Findings indicate that both walk-based and run-based exercise tests produce similar perceptual responses that indicate maximal effort, and similar VO₂max values despite very different approaches to creating intense work. The observed difference in HR suggests that a run-based maximal exercise test produces a greater cardiovascular response, while the higher RER value within the walk-based maximal exercise test suggests greater metabolic acidosis. Results support treadmill exercise testing as a flexible multiple assessment modality.

Effects of Marathon Training on Maximal Aerobic Capacity and Running Economy in Experienced Marathon Runners

Emma J. Lee, Eric M. Snyder, FACSM, Christopher J. Lundstrom. *University of Minnesota, Minneapolis, MN.*
 (Sponsor: Eric M. Snyder, FACSM)
 Email: leex4357@umn.edu
 (No relevant relationships reported)

Maximal aerobic capacity (VO₂max) and running economy (RE) are markers of running performance. A valid evaluation of RE may occur through allometric scaling of body mass (alloVO₂; ml kg^{-0.66} min⁻¹), energy cost (EC; kcal kg⁻¹ km⁻¹), or percent of VO₂max (%VO₂max). Little is known about physiological changes that occur in competitive runners over a marathon training cycle. The VDOT score, incorporating VO₂max and RE, enables comparison of race performances under different temperature conditions. **PURPOSE:** To determine whether VO₂max and measures of RE change with marathon training; to evaluate the relationship between these variables and VDOT. **METHODS:** Eight runners (age 34±2 years; marathon <3:00 males, <3:30 females; five females) completed treadmill marathon-intensity-effort (MIE) and VO₂max tests at 10 and 1-2 weeks pre-marathon. Body composition (%BF) was determined using hydrostatic weighing. Paired t-tests were used to compare pre- and post-training values. The alpha level for significance was set at 0.05. **RESULTS:** Body fat decreased from 18.7±1.5% to 16.7±1.6%, VO₂max increased from 51.6±2.4 to 63.9±1.1 ml kg⁻¹ min⁻¹, and %VO₂max during the MIE decreased from 82.1±2.0 to 72.3±3.2% (p < 0.05 for all). VDOT was significantly associated with alloVO₂ (r = -0.779, p = 0.039) but not with VO₂max (r = 0.071, p = 0.867). **CONCLUSIONS:** Experienced competitive runners may increase VO₂max and decrease %BF after a marathon-specific training cycle. The decrease in %VO₂max in a MIE is likely due to a higher VO₂max, as other measures of RE did not change significantly. In this cohort, alloVO₂ was negatively related to race performance.

The Influence of AlterG Treadmill Training on Cardiorespiratory Performance in Cross Country Runners

Tracy A. Dierks¹, Trent E. Cayot², Vincent C. Nittoli³, Todd W. Arnold³, Joseph Stimler¹. *¹Indiana University, Indianapolis, IN. ²University of Indianapolis, Indianapolis, IN. ³St. Vincent Sports Performance, Indianapolis, IN.* (Sponsor: Robyn Fuchs, FACSM)
 Email: tdierks@iu.edu
 (No relevant relationships reported)

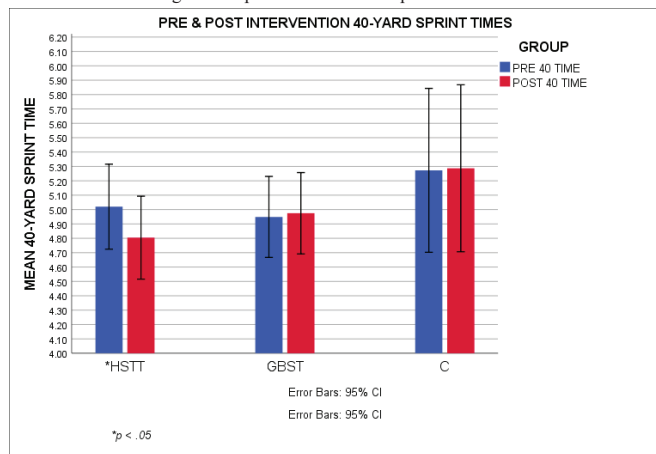

Running on an AlterG® Treadmill (AGT) at reduced bodyweight allows runners to aerobically train with reduced orthopedic stress. However, to maintain the training stimulus, the speed must be increased if heart rate (HR) response is to match overground running. This allows one to run at faster speeds for longer durations, without increasing impact forces or HR intensity beyond typical training. Yet it is unknown how this speed intensity chronically influences cardiorespiratory performance. **PURPOSE:** Investigate the effect of an AGT training program on cardiorespiratory performance. **METHODS:** As an offseason supplement, 19 healthy uninjured high school boy cross country runners replaced 2 overground running sessions/week for 6 weeks with AGT runs at 80-85% of bodyweight. Speed was increased to elicit a HR intensity and distance/time consistent with each runner's mile pace for that day. Pulmonary gas exchange and HR data were collected during treadmill graded exercise tests (GXT) at pre and post AGT training program. Paired t-test were used to assess pre-post changes in cardiorespiratory and HR variables from the GXT (p<0.05). **RESULTS:** The mean speed of AGT runs was 9.0 ± 0.5 mph at a mean distance of 4.2 ± 0.6 miles. The mean of the fastest speed for each runner was 9.8 ± 0.6 mph (range 8.6-11.4) at a mean run time of 27.6 ± 8.4 min. (range 16-40 minutes). HR [180 ± 9 vs. 167 ± 10 bpm] significantly decreased while oxygen uptake remained unchanged [46.6 ± 3.6 vs. 47.0 ± 3.2 ml/kg/min] at the anaerobic threshold (AT) post AGT training. However, peak oxygen uptake [60.8 ± 6.4 vs. 62.7 ± 5.0 ml/kg/min], peak minute ventilation [124.7 ± 22.6 vs. 132.2 ± 24.9 L/min], and peak respiratory frequency [61 ± 10 vs. 64 ± 11 breaths/min] significantly improved post AGT training, while peak HR remained unchanged [196 ± 20 vs. 192 ± 12 bpm]. **CONCLUSION:** AGT training with reduced bodyweight at faster speeds had little influence on cardiorespiratory performance variables occurring at lower levels of

intensity (AT). However, all peak cardiorespiratory performance variables at higher levels of intensity improved, likely due to training at faster than normal speeds. This would benefit runners by allowing training to occur with reduced orthopedic loading at typical HR intensities, and yet still concurrently improve peak cardiorespiratory performance.

High-Speed Treadmill vs Ground-Based Training for Sprint Speed Among College Athletes

Keith A. Coury, Monica O'Rourke. *California Baptist University, Riverside, CA.*
 Email: keith@questspeed.com
 (No relevant relationships reported)

Introduction: Practitioners often debate as to which speed-training method is most effective for improving speed. Ground-Based Speed Training (GBST) has been the predominant method, however with technological advances, High Speed Treadmill Training (HSTT) has been implemented and used (Hauschildt, 2010; Jerome-Koral, Herrera, & Millet, 2018; Johnson, Eastman, Feland, Mitchell, Mortensen, & Egget, 2013; Ross et al., 2009). **Purpose:** This study compared HSTT and GBST for improving speed and reducing 40-yard sprint times among collegiate athletes. **Methods:** Twenty-one collegiate football and baseball players were randomly assigned to HSTT ($n = 7$), GBST ($n = 7$) or control group ($n = 7$). Experimental groups completed 8 specialized training sessions 2 times a week for 4 weeks. HSTT group trained using PerformX Tred-X30 high-speed treadmill in each session with inclines of 5% to 30%. GBST group performed sprints that involved resisted and assisted training modalities: tow sled, uphill running, partner runs and downhill running. **Results:** Pre-test 40-yard sprint-time scores indicated no significant difference between groups prior to intervention ($F(2,18) = 1.059, p = .367, \eta^2 = .105$). Post-intervention indicated there was a 19.3% difference in times between the three groups ($F(2,18) = 2.152, p = .145, \eta^2 = .193$). HSTT group exhibited a significant difference among pre-intervention 40-yard sprint time ($M = 5.02, SD = .320$) to post-intervention ($M = 4.80, SD = .312$), $t(6) = 5.418, p = .002$ while GBST group did not; pre-intervention ($M = 4.95, SD = .305$) to post-intervention ($M = 4.97, SD = .306$), $t(6) = -0.488, p = .67$. **Conclusions:** HSTT group increased linear speed and decreased sprint times over GBST and control groups. HSTT may be an effective way to improve sprint speed for times over various distances in a shorter period of training time than GBST and these improvements can be transferred to collegiate and professional athletic performance.

Correction Factor to Improve the Accuracy of Iso-Efficient Treadmill Velocity During Inclined Treadmill Running

Lauren Williams¹, Michael Dial¹, Joseph Christensen¹, Tyler Standifird¹, Andrew Creer¹, Douglas Powell, FACSM². ¹Utah Valley University, Orem, UT. ²The University of Memphis, Memphis, TN. (Sponsor: Douglas Powell, FACSM)
 Email: lauren.williams523@gmail.com
 (No relevant relationships reported)

As inclined treadmill running becomes more popular among trained runners, the ability to maintain a metabolic iso-efficient velocity has gained importance. Treadmill velocity (TMV) for a specific incline and intensity can be determined by solving the ACSM running equation for speed as opposed to relative VO_2 , but this may underestimate iso-efficient TMV in trained runners as they may respond to speed and grade differently from the general population. **Purpose:** The purpose of this study was to identify

an appropriate correction factor to improve iso-efficient TMV identification during inclined running in trained runners. **Methods:** 11 collegiate distance runners (7 male, 4 female; 63.2 ± 9.5 kg; 174.8 ± 7.5 cm; 64.6 ± 6.5 $\text{mlO}_2/\text{kg}/\text{min}$) completed three 4-min treadmill runs at 0%, 4%, and 8% incline with a 4 min recovery period between runs. Expired gases were collected during the final minute of each run to determine relative VO_2 . Actual TMV at 0% was inserted into the ACSM running equation to determine predicted VO_2 for the 0% run [$\text{VO}_2 = (\text{Sx}0.2) + (\text{SxGx}0.9) + 3.5$]. That value was then divided by the actual VO_2 measured at 0% to develop a correction factor. TMV for the 4% and 8% trials was determined by inserting the measured 0% VO_2 value into the ACSM equation [$\text{S} = (\text{VO}_2 - 3.5) / (0.2 + 0.9\text{G})$] and multiplying the resultant velocity by the correction factor to maintain iso-efficiency. Differences within 0%, 4%, and 8% values were assessed using a paired sample t-test, while a one-way ANOVA compared VO_2 values between grades ($p < 0.05$). **Results:** Actual VO_2 at 0% grade was 15% lower than predicted by the ACSM equation (55.2 ± 2.7 vs. 46.8 ± 5.0 $\text{mlO}_2/\text{kg}/\text{min}$; $p < 0.05$), resulting in a correction factor of 1.2 ± 0.1 . Predicted TMV at 4% (183.6 ± 21 m/min) and 8% (159.3 ± 18.3 m/min) was 18% lower ($p < 0.05$) than the corrected velocities for each grade (216.9 ± 2 and 188.2 ± 10.4 m/min). VO_2 values for each grade were 46.8 ± 5 , 46.6 ± 4.8 , and 48.0 ± 4.9 $\text{mlO}_2/\text{kg}/\text{min}$, respectively, with the 8% VO_2 being greater than 4% ($p < 0.05$). **Conclusion:** The ACSM running equation may underestimate TMV when attempting to maintain metabolic iso-efficiency during incline running. These data suggest that application of a correction factor to the TMV derived from the ACSM equation may provide a closer approximation of TMV to maintain iso-efficiency during incline running.

F-36 Free Communication/Slide - Energy Balance-Weight Control

 (No relevant relationships reported)

Overeating and emotional eating can lead to weight gain. While exercise may help protect against weight gain, the mechanisms through which exercise aids in weight control are poorly understood. **PURPOSE:** This efficacy trial tests the hypothesis that exercise training impacts eating behaviors, specifically through a reduction in overeating and internal disinhibition (the tendency to eat in response to cognitive or emotional cues), in a sample of women who are overweight or obese. **METHODS:** Participants were inactive at baseline and self-identified as 'stress eaters' (eating more than usual when 'moderately' or 'extremely' stressed). They were randomized to 12 weeks of exercise training (EX) or to a no-exercise control (CON). EX participants were given an exercise goal of 200 min/wk of combined supervised and home-based exercise (30% supervised; home-based exercise was confirmed via accelerometry). No dietary instructions were provided to any participants. Assessments occurred at baseline and 12 weeks. Overeating episodes were measured over 14 days at each assessment using ecological momentary assessment (EMA; 5 surveys/day delivered randomly via smartphone). Internal disinhibition was assessed questionnaire. **RESULTS:** 39 participants (EX: $n = 19$, CON: $n = 20$) completed the study (age: 40.8 ± 10.3 years BMI: 31.6 ± 3.9 kg/m^2). Adherence to the exercise intervention was high (99.4% of all prescribed exercise was confirmed via accelerometry) and 12-week weight change did not differ by condition (EX: $-1.1 \pm 3.5\%$ vs. $0.4 \pm 2.0\%$, $p = 0.11$). At week 12, the proportion of eating episodes that were characterized as overeating episodes was 18.4% in EX vs. 24.5% in CON ($p = .01$). The odds of an overeating episode were lower in EX relative to CON and became more pronounced over time (condition*time = $-.005$, $\text{SE} = .002$, $p = .01$). Specifically at week 12, the odds of having an overeating episode among EX participants was 0.58 times the odds of having an overeating episode within CON's. Internal disinhibition decreased in EX (pre: 4.1 ± 2.2 , post: 2.8 ± 1.8), but not CON (4.3 ± 2.6 to 4.2 ± 2.3 , $p = .02$). **CONCLUSIONS:** Exercise

training reduced the likelihood of overeating, and eating in response to emotional or cognitive cues, in women who self-identified as stress eaters. Thus, this may be one pathway by which exercise impacts body weight.

Compensatory Reduction in Non-Exercise Energy Expenditure Among Weight-Stable Overweight and Obese Adults

Gregory A. Hand, FACSM¹, Daniel P. O'Connor, FACSM², Robin P. Shook³, Stephanie Burgess⁴, Steven N. Blair, FACSM⁴.
¹West Virginia University, Morgantown, WV. ²University of Houston, Houston, TX. ³Children's Mercy, Kansas City, MO. ⁴University of South Carolina, Columbia, SC.
(No relevant relationships reported)

PURPOSE: Increasing total daily energy expenditure is a critical component of weight management strategy. There is disagreement as to a potential compensatory reduction in non-exercise energy expenditure that could blunt the anticipated increase in total daily energy expenditure (TDEE) resulting from exercise participation. The purpose of the present study was to examine the effect of varying doses of exercise energy expenditure (EEx) on TDEE and non-exercise energy expenditure when body weight is maintained. **METHODS:** Seventy healthy, but overweight or obese, young adult women and men participated in a 26-week exercise intervention. Based on the individual daily EEx, participants were stratified into tertiles (T1, T2, T3) of increasing EEx. Paired sample t-tests determined significant within-tertile differences between pre/post data for each variable. Linear regression models, adjusted for age, sex and race, determined the significance of changes over time in selected variables. **RESULTS:** Average daily EEx was different among tertiles (39.9±9.7, 175.5±9.8, 282.9±9.8 kcal, respectively; $p < 0.001$). No main effect of tertile was found for change in sedentary activity EE ($p = 0.228$), moderate/vigorous EE ($p = 0.698$), or TDEE ($p = 0.762$). A negative main effect of tertile was found for a change in light activity EE ($p = 0.016$) and for non-exercise energy expenditure ($p = 0.012$), with a greater decrease in non-exercise energy expenditure in T3 ($p = 0.009$). **CONCLUSION:** These data indicate that, when body weight is maintained, participation in the exercise program resulted in a compensatory reduction in light and non-exercise moderate/vigorous energy expenditure, as well as a less-than-expected increase in TDEE. These findings suggest that maintenance of non-exercise energy expenditure is critical for correctly estimating the caloric deficit anticipated from participation in exercise as part of a weight loss program. Supported by an unrestricted grant from the Coca Cola Company.

The Effects of Steady State and High Intensity Exercise on Compensatory Eating Behaviors and Appetite

Emily J. Sauers, Sarah E. Myles, Chad A. Witmer, Shawn N. Munford, Shala E. Davis, FACSM. East Stroudsburg University, East Stroudsburg, PA. (Sponsor: Shala Davis, FACSM)
Email: esauers@esu.edu
(No relevant relationships reported)

Exercise is often prescribed for weight control; however, it is not uncommon that weight loss is less than expected. Unexpected results may be influenced by compensatory eating behaviors following exercise. **PURPOSE:** The aim of this study was to examine differences in eating behaviors after steady state (SS) and high intensity (HI) active females. **METHODS:** Nine, recreationally active college-aged females participated in this study. Prior to testing, subjects completed a VO_{2max} test to individualize exercise. Subjects completed three trials in a randomized order: control (CON), HI exercise, or SS exercise. Each trial took place during the first week of the luteal phase of their menstrual cycle. During the CON trial, subjects remained seated for 30 minutes. During SS, subjects ran on a treadmill at 70% VO_{2max} for 33 minutes. During the HI, trial subjects ran on a treadmill at 90% VO_{2max} for 1 minute then 50% VO_{2max} for 1 minute for 34 minutes. Food intake was recorded 24 hours before and up to 72 hours after each trial. Resting metabolic rate (RMR) was measured prior to and 24, 48, and 72 hours following each trial. A visual analog scale was used to assess appetite before and immediately following each trial. **RESULTS:** Caloric expenditure was higher during SS (302.78±28.40kcal) and HI (278.39±24.94kcal) compared to CON (68.10±2.94kcal) ($p < 0.001$); however, no differences existed between exercise trials ($p = 0.53$). Caloric intake was not different ($p = 0.82$) between SS (1505.56±135.41kcal), HI (1562.67±118.91kcal), and CON (1485.89±136.52kcal) 24 hours post exercise. Differences in caloric intake were not observed 48 ($p = 0.42$) and 72 hours ($p = 0.60$) post exercise. There were no differences ($p = 0.55$) in RMR 24 hours after SS (1598.98±197.80 kcal), HI (1426.57±66.23 kcal), or CON (1430.83±68.93 kcal). Differences were not observed ($p = 0.72$) in change in appetite following SS (2.89±7.13 mm), HI (8.22±10.57 mm), and CON (0.11±3.74 mm). **CONCLUSION:** Caloric intake and RMR were not different after SS or HI exercise. Appetite did not significantly change after exercise though large individual variability was observed; the

largest change in appetite was observed following HI exercise. Compensatory eating may be highly individualistic and appetite following exercise should be considered further, particularly following HI exercise.

The Energy Cost Of Sitting versus standing In Man.

James A. Betts, FACSM¹, Harry Smith¹, Drusus Johnson-Bonson¹, Tom Ellis¹, Joseph Dagnall¹, Aaron Hengist¹, Harriet Carroll¹, Dylan Thompson¹, Javier Gonzalez¹, Gregg Afman².
¹University of Bath, Bath, United Kingdom. ²Westmont College, Santa Barbara, CA.
Email: J.Betts@bath.ac.uk
(No relevant relationships reported)

Abstract

PURPOSE: Prolonged sitting is a major health concern, targeted via government policy and the proliferation of height-adjustable workstations and wearable technologies to encourage standing. Such interventions have the potential to influence energy balance and thus facilitate effective management of body/fat mass. It is therefore remarkable that the energy cost of sitting versus standing naturally remains unknown. **METHODS:** Metabolic requirements were quantified via indirect calorimetry from expired gases in 46 healthy men and women (age 27±12 y, mass 79.3±14.7 kg, body mass index 24.7±3.1 kg·m⁻², waist:hip 0.81±0.06) under basal conditions (i.e. resting metabolic rate; RMR) and then, in a randomized and counterbalanced sequence, during lying, sitting and standing. Critically, no restrictions were placed on natural/spontaneous bodily movements (i.e. fidgeting) to reveal the fundamental contrast between sitting and standing *in situ* whilst maintaining a comfortable posture. **RESULTS:** The mean [95% CI] increment in energy expenditure was 0.18 [0.06 to 0.31] kJ·min⁻¹ from RMR to lying, 0.15 [0.03 to 0.27] kJ·min⁻¹ from lying to sitting and 0.65 [0.53 to 0.77] kJ·min⁻¹ from sitting to standing. The observed energy cost of each posture above basal metabolic requirements exhibited marked inter-individual variance, which was inversely correlated with resting heart rate for all postures ($r = -0.5$ [-0.7 to -0.1]) and positively correlated with self-reported physical activity levels for lying ($r = 0.4$ [0.1 to 0.7]) and standing ($r = 0.6$ [0.3 to 0.8]). **CONCLUSION:** Interventions designed to reduce sitting typically encourage 30-120 min·d⁻¹ more standing *in situ* (rather than perambulation), so the 12 % difference from sitting to standing reported here does not represent an effective strategy for the treatment of obesity but may have a role in primary prevention by maintaining long-term energy balance.

Change in Visceral Adiposity with a 12-Month Behavioral Weight Loss Intervention with Varying Doses of Physical Activity: The Heart Health Study

Renee J. Rogers¹, Sara J. Kovacs², Katherine A. Collins¹, John M. Jakicic, FACSM¹. ¹University of Pittsburgh, Pittsburgh, PA. ²Temple University, Philadelphia, PA. (Sponsor: John M. Jakicic, FACSM)
Email: r.j.rogers@pitt.edu
(No relevant relationships reported)

Visceral adipose tissue (VAT) is considered to have biochemical characteristics that influence several pathophysiological processes of the body and high levels are associated with increased risk for metabolic syndrome, cardiovascular disease, and certain cancers. There is data to suggest that supervised aerobic exercise may reduce VAT in the absence of caloric restriction.

PURPOSE: To examine whether VAT is reduced within the context of a comprehensive weight management program, varied by prescribed levels of home-based moderate-to-vigorous physical activity (MVPA) in adults who were overweight or obese across 12 months.

METHODS: Data were examined from sedentary adults (N=309; BMI: 32.3±3.8 kg/m²; age=45.1±7.9 years) enrolled in a behavioral program and randomized to a reduced calorie diet (DIET, N=107), diet plus a moderate dose of MVPA (MOD-EX, N=101), or diet plus a high dose of MVPA (HIGH-EX, N=101). All groups received weekly intervention sessions in months 1-6 followed by 2 group and 2 telephone contacts per month in months 7-12, and were prescribed a diet to reduce energy intake (1200-1800 kcal/day). MOD-EX was prescribed unsupervised MVPA that progressed to 150 min/wk, whereas HIGH-EX was progressed to 250 min/wk. Body composition and VAT were measured by DXA (GE Lunar iDXA, Corescan) along with weight at 0, 6 and 12 months.

RESULTS: Weight significantly decreased in all groups at 6 months (DIET: -9.0±5.9 kg, MOD-EX: -10.2±6.4 kg, HIGH-EX: -9.4±5.3 kg; $p < 0.001$) and 12 months (DIET: -10.0±8.3 kg, MOD-EX: -11.1±8.1 kg, HIGH-EX: -9.7±6.9 kg; $p < 0.001$), with no significant difference between groups. A similar pattern was observed for percent body fat (Baseline: 43.3±5.5%, 6-month: 38.3±7.0%, 12-month: 37.7±7.6%; $p < 0.001$) with

no difference between groups. VAT decreased across time (Baseline: 1518±907cm³, 6-month: 1018±617cm³, 12-month: 971±648cm³; p<0.001) with no difference between groups.

CONCLUSIONS: The interventions were successful at reducing body weight and improving body composition in adults with obesity. The lack of additional weight loss, reductions in body composition and VAT with participation in MVPA at two different doses may suggest that there is a compensatory response in factors influencing energy balance that warrant further investigation. Impact of Intermittent Fasting on Energy Balance and Associated Health Outcomes in Lean Adults

Iain Templeman¹, Sue Reeves², Jean-Philippe Walhin¹, Harry Smith¹, Harriet Carroll¹, Peter J. Rogers³, Jeffrey M. Brunstrom³, Leonidas G. Karagounis⁴, Kostas Tsintzas⁵, Dylan Thompson¹, Javier Gonzalez¹, James A. Betts, FACSM¹. ¹University of Bath, Bath, United Kingdom. ²University of Roehampton, London, United Kingdom. ³University of Bristol, Bristol, United Kingdom. ⁴University of St Mark and St John, Plymouth, United Kingdom. ⁵University of Nottingham, Nottingham, United Kingdom. (Sponsor: Dr James A Betts, FACSM)

(No relevant relationships reported)

PURPOSE: To establish the effects of a diet combining intermittent fasting (IMF) with calorie restriction on energy expenditure and metabolic health, and to isolate the relative contributions of fasting and negative energy balance to any observed effects. **METHODS:** After a 4-week control phase, 36 lean adults (mean±SD; age = 42±11 y, BMI = 23.9±2.1 kg/m²) were randomised to one of three conditions for 20 days; 1) daily calorie restriction (75:75; 75% of habitual intake daily), 2) IMF with calorie restriction (0:150; alternating 24-h periods of fasting and feeding to 150% of habitual intake), 3) IMF without calorie restriction (0:200; alternating 24-h periods of fasting and feeding to 200% of habitual intake). In the IMF groups, transitions from feeding to fasting and vice versa occurred at 15:00 each day. In addition to free-living measures of energy intake (weighed record) and physical activity (combined heart rate/accelerometry), body composition (DEXA), metabolic rate and substrate oxidation (indirect calorimetry), fasted health markers and postprandial metabolic responses were measured at pre- and post-intervention.

RESULTS: Energy intake was reduced in the two energy-restricted groups (75:75 = -2602±904 kJ/d, 0:150 = -2105±1105 kJ/d; p=0.24) and maintained by 0:200 (+63±1439 kJ/d; p<0.01 v 75:75, p<0.01 v 0:150), a pattern mirrored by changes in body mass (75:75 = -1.9±1.0 kg, 0:150 = -1.6±1.1 kg, 0:200 = -0.5±1.1 kg; p=0.46 75:75 v 0:150, p=0.01 75:75 v 0:200, p=0.04 0:150 v 0:200). However, the decrease in fat mass with 75:75 (-1.8±0.8 kg) was greater than the decrease accompanying 0:150 (-0.8±0.9 kg, p=0.01 v 75:75), both of which differed from the stability seen following 0:200 (-0.1±0.7 kg, p<0.01 v 75:75, p=0.05 v 0:150). Furthermore, physical activity energy expenditure decreased following 0:150 when compared to 0:200 (0:150 = -410±707 kJ/d, 0:200 = +247±594 kJ/d; p=0.07) but was unaffected by 75:75 (+4±527 kJ/d; p=0.24 v 0:150, p=0.31 v 0:200). Despite these differences, metabolic rate, substrate oxidation, fasting biochemistry and postprandial metabolism were all unaffected.

CONCLUSIONS: In lean adults, restricting calories through a complete alternate-day approach to IMF attenuated reductions in fat mass and prompted declines in physical activity, whilst metabolic health was unaffected.

2894 May 31 4:45 PM - 5:00 PM

Changes In Health-related Quality Of Life In A 12-month Behavioral Weight Loss Intervention: The Heart Health Study

Katherine A. Collins, Renee J. Rogers, John M. Jakicic, FACSM. University of Pittsburgh, Pittsburgh, PA. (Sponsor: John Jakicic, FACSM)

(No relevant relationships reported)

Overweight and obesity have been shown to adversely affect health-related quality of life (HRQOL). HRQOL has been shown to improve with weight loss. However, it is important to examine whether physical activity in conjunction with weight loss has an added benefit for improvement in HRQOL. **PURPOSE:** To examine whether HRQOL improves with a lifestyle intervention for weight loss with varying doses of moderate-to-vigorous physical activity (MVPA) in adults who are overweight or obese. **METHODS:** Participants (N=270; age=45 ± 7.95 years; BMI=32.2 ± 3.7 kg/m²) engaged in a 12-month behavioral weight loss intervention. Participants were randomized to reduced calorie diet (DIET; N=), diet plus 150 min/week MVPA (DIET+PA150; N=), or diet plus 250 min/week MVPA (DIET+PA250; N=). All groups received weekly in-person intervention sessions for months 1-6, with combined in-person and telephonic sessions for months 7-12. Diet was prescribed at 1200-1800 kcal/day. Assessment of body weight and HRQOL (SF-36) were measured at baseline, 6 months, and 12 months. **RESULTS:** Weight significantly decrease in all groups at

12 months (DIET: -9.2±5.8 kg, DIET+PA150: -10.2±6.4 kg, DIET+PA250: -9.5±5.4 kg; p<0.001) with no significant difference between groups. There were significant improvements in HRQOL components of physical function, energy and fatigue, and change in health (Table); however, these did not differ by group. There were no significant changes in social function, mental health, pain, and general health. **CONCLUSION:** The addition of moderate or higher levels of physical activity to an energy restricted diet for weight loss did not improve quality of life compared to the diet alone. These results demonstrate the positive benefits that weight loss may have on HRQOL regardless of whether physical activity is included as a component of the intervention. (Supported by: NIH (R01 HL103646)

2895 May 31 5:00 PM - 5:15 PM

Reductions in Energy Expenditure After Aerobic and Resistance Exercise in Resistance-trained Males

George L. Grieve¹, J. Mark Davis, FACSM², J. Larry Durstine, FACSM², Marco Geraci², Xuewen Wang², Jackson S. Ritchey², Clemens Drenowatz³, Mark A. Sarzynski, FACSM². ¹Valdosta State University, Valdosta, GA. ²The University of South Carolina, Columbia, SC. ³University of Education Upper Austria, Linz, Austria. Email: glgrieve@valdosta.edu

(No relevant relationships reported)

PURPOSE: The purpose of this study was to examine the effects of exercise mode and intensity on energy expenditure (EE) during and after five time-matched aerobic and resistance exercise protocols in resistance-trained (RT) males. **METHODS:** Fourteen RT males (mean±SD; age:24.2±4.0 yrs; body mass:84.7±13.3 kg; height:181.2±8.8 cm; and body fat:15.9±4.6%) completed five separate protocols on separate days ≥48 hrs apart in random order, each lasting 40 min in duration: continuous aerobic (continuous), high intensity interval aerobic (HIIT), strength endurance (2x20), traditional resistance (3x10), and high intensity resistance (4x6). EE was measured before, during, immediately post- (0-30 min), and delayed post-exercise (60-90 min) using indirect calorimetry. **RESULTS:** No significant differences in exercise EE were seen between aerobic protocols. EE during both aerobic protocols was significantly greater (p<0.0001) than any of the three resistance protocols. EE during 4x6 was significantly greater than 3x10 and 2x20 by 38±10 kcal (p=0.04) and 67±8 kcal (p<0.001), respectively. From 0-30 min post-exercise, a mean increase in EE of 6.2% was seen only following the 2x20 protocol as compared to baseline pre-exercise (p<0.05). From 60-90 min post-exercise, the 3x10, 4x6, and HIIT protocols showed significant mean reductions in EE of 10.7%, 8.7%, 7.1% (p<0.05) as compared to baseline pre-exercise, respectively. The combined EE from during and after exercise resulted in the same rank order as during exercise (least to greatest: 2x20, 3x10, 4x6, continuous, and HIIT). **CONCLUSIONS:** Significant reductions in EE were found in the 3x10, 4x6, and HIIT protocols from 60-90 min post-exercise as compared to baseline pre-exercise. Continuous and HIIT protocols had the greatest EE during exercise when compared to the resistance protocols. These results have important implications on EE during and after exercise and should be considered when designing exercise training programs. Given the reductions found in EE 60-90 min post-exercise in the 3x10, 4x6, and HIIT protocols, special consideration should be given to post-exercise nutrition to avoid energy deficits which could negatively impact recovery. Supported by an ASPIRE I Grant from the University of South Carolina.

Cytokine Response to Traditional and Cluster Sets in Resistance-trained Women

Sungwon Chae¹, Margaret T. Jones, FACSM², Jennifer B. Fields², Jonathan M. Oliver³, James C. Boyett¹, Felipe C. Vechin¹, Jonathan L. Nicholson¹, Spencer A. Moses¹, Jakob L. Vingren, FACSM¹. ¹University of North Texas, Denton, TX. ²George Mason University, Fairfax, VA. ³Texas Christian University, Fort Worth, TX. (Sponsor: Jakob L. Vingren, FACSM)
Email: chaecool89@naver.com
(No relevant relationships reported)

Resistance exercise that incorporates intra-set rest between repetition blocks (i.e., cluster sets [CS]) can produce a smaller metabolic stress and endocrine response than traditional sets (TS). **PURPOSE:** To examine the effect of CS on the acute cytokine response in resistance trained women. **METHODS:** 12 resistance-trained women (mean ± SE; 23.7 ± 1.1 years; 160.1 ± 1.5 cm; 62.5 ± 1.7 kg; 5 ± 1 years training) completed 3 sessions in the follicular phase. One-repetition maximum (1RM) back squat (BS) (98.7 ± 4.1 kg), and BS:body mass (1.6 ± 0.1) were determined in Session 1. For Session 2 (3 days post Session 1) and Session 3 (7 days post Session 2), subjects were randomly assigned to either 4 sets of 10 reps with 120 seconds (s) inter-set rest (TS) or 4 x (2 x 5 reps) with 30s intra-set rest and 90s inter-set rest (CS). All performed both protocols at 70% 1RM BS. Instructions were to perform every rep “as explosively as possible”. Blood was collected pre-exercise (PRE), immediately after sets 1, 2, 3, 4 (IP), and at 5 (+5), 15 (+15), 30 (+30), and 60 (+60) min post-exercise and analyzed for interleukin (IL)-1β, IL-2, IL-6, IL-8, IL-10, and IL-15. Data were analyzed using repeated measures ANOVAs (2 × 9). **RESULTS:** A significant main effect of time (*p*<0.05) was found for IL-1β, IL-2, IL-8, IL-10, and IL-15. Concentration of IL-1β was smaller at +5 (3.9 ± 0.4 ng/mL), +15 (3.6 ± 0.4) +30 (3.5 ± 0.3), and +60 (3.7 ± 0.4) compared to IP (4.1 ± 0.4). IL-2 was greater after set 1 (10.8 ± 1.0 ng/mL), and set 2 (11.0 ± 1.2) compared to PRE (10.2 ± 1.0), and smaller at +30 (9.9 ± 1.0) compared to IP (11.0 ± 1.0). IL-8 was greater after set 1 (8.4 ± 0.6 ng/mL), set 2 (8.6 ± 0.7), and set 3 (8.5 ± 0.7) compared to PRE (8.0 ± 0.6). IL-10 was smaller at +30 (31.3 ± 7.4 ng/mL) compared to PRE (34.0 ± 7.4), and also smaller at +15 (32.6 ± 7.9) +30 (31.3 ± 7.4), and +60 (33.4 ± 8.6) compared to IP (38.0 ± 8.6). IL-15 was greater at IP (15.5 ± 4.0 ng/mL) compared to PRE (13.4 ± 3.5), and smaller at PRE (13.4 ± 3.5), +30 (11.9 ± 3.3), and +60 (11.6 ± 3.2) compared to IP (15.5 ± 4.0). No condition × time point effects were observed. **CONCLUSIONS:** Both TS and CS induced an acute cytokine response in resistance-trained women; incorporating intra-set rest (CS) did not appear to affect this cytokine response. Supported in part by a grant from the National Strength and Conditioning Association Foundation.

The Relationship between Increased Cytokine Concentrations with Body Temperature Changes

Brandon M. Gibson¹, Kylene Boka¹, Brittany N. Followay², Jeremiah A. Vaughan³, Elliot Arroyo¹, Joseph A. Laudato¹, Adam R. Jajtner¹, Ellen L. Glickman, FACSM¹. ¹Kent State University, Kent, OH. ²Ripon College, Ripon, WI. ³Bemidji State University, Bemidji, MN. (Sponsor: Ellen Glickman, FACSM)
Email: bgibso24@kent.edu
(No relevant relationships reported)

Purpose: To identify relationships between cytokines and time spent above critical body temperatures in response to aerobic exercise in various environments. **Methods:** 12 recreationally active men (24.4 ± 3.1 yrs; 1.81 ± 0.07m; 81.5 ± 8.0kg; 47.2 ± 4.8 ml/kg/min) completed five experimental visits: a VO₂ max, and a cycling trial in 23°C/45%RH, 23°C/70%RH, 34°C/20%RH and 34°C/45%RH. After supine rest, exercise conditions consisted of 60mins of cycling at 60% VO₂max, a 15min rest, and a time to exhaustion (TTE) trial at 90% VO₂max. Blood was obtained before exercise (PRE), after 60min cycling (60), and after TTE (90). Serum concentrations of IL-1β, IL-1ra, IL-6, IL-10 and TNF-α were analyzed via ELISA. Participant’s rectal (T_{re}) and skin temperatures (T_{sk}) at five locations: Chest, Triceps, Forearm, Thigh and Calf

were monitored continuously. Whole body temperature (T_{wb}) and T_{sk} were calculated via weighted averages. Area Under the Curve with respect to increase (AUCi) was calculated for T_{re}, T_{wb} and T_{sk}. Data were analyzed as Pearson Product Moment Correlations between AUCi for T_{re}, T_{sk} and T_{wb} with changes in cytokine concentration. Time spent above specific critical temperatures for T_{re}, T_{sk} and T_{wb} were related to changes in cytokine concentrations from PRE-60 and PRE-90 using stepwise linear regression. **Results:** Correlations were observed between TNFα PRE-60, and PRE-90 with T_{sk} (*r*=0.576 *p*<0.001; *r*=0.515 *p*=0.001, respectively) and T_{wb} (*r*=0.611 *p*=0.001; *r*=0.516 *p*=0.001, respectively) but not T_{re}. Time spent with T_{sk} above 33.5°C and 35°C were predictive of increases seen in TNFα PRE-60 (*r*=0.695, *p*<0.001). TNFα PRE-90 was related to time spent above 33.5°C for T_{sk} (*r*=0.593, *p*<0.001). Time spent with T_{wb} above 38°C was correlated to, but not predictive of increases seen in TNFα from PRE to 60 and PRE to 90 (*p*=0.030, *p*=0.020). Time spent above 38.5°C for T_{re} displayed significant correlations with increases seen in IL-6 PRE-60 (*r*=0.470, *p*=0.002). No other correlations or relationships were observed with changes in cytokine concentration and body temperature. **Conclusions:** Data indicate that changes in TNFα may be related to time spent above critical T_{sk} of 33.5°C and 35°C. Increases in IL-6 appear to be related to time spent above T_{re} of 38.5°C.

Exercise Suppresses Prostate Tumor Aggressiveness by Modulating Inflammatory Cytokines

Darpan I. Patel, Kira Abuchowski, Roble Bedolla, Paul Rivas, Nicolas Musi, Robert Reddick, A. Pratap Kumar. *University of Texas Health Science Center at San Antonio, San Antonio, TX.*
Email: pateld7@uthscsa.edu
(No relevant relationships reported)

Inflammatory cytokines are thought to be at the root of prostate tumor progression. Exercise has been shown to be beneficial in men with prostate cancer (PCa), however, the impact of exercise on tumor physiology is not clearly understood. **PURPOSE:** Test the hypothesis that exercise inhibits tumor progression and modulates pro-tumorigenic cytokine concentrations in the transgenic adenocarcinoma of mouse prostate (TRAMP) model. **METHOD:** Thirty, 10-week old TRAMP mice were randomized to either voluntary wheel running (VWR) or control group. Palpable tumors and VWR activity were monitored weekly. Mice were sacrificed at 4, 8, 12 and 20-weeks to assess time point differences. Excised tumors were paraffin embedded, sectioned, and stained with hematoxylin and eosin. Sectioned tumor slides were scored by a pathologist blinded to the groups. Serum collected from mice sacrificed at the 4-week and 20-week time points were assayed in duplicate using a 32 panel Mouse Cytokine Magnetic Multiplex Assay. Analysis of variance was performed to determine significant differences between treatment groups. **RESULTS:** Control mice presented first with palpable tumors at 14 weeks of age. VWR significantly delayed the presence of palpable tumors by 5 weeks (19 weeks old; *p*=0.05). No significant pathological changes were observed as a function of time; therefore, data were pooled for analysis. A treatment effect was observed with VWR mice having significantly lower number of high-grade tumors compared to controls. Specifically, 71% of control mice had high grade tumors compared to only 17% in the VWR group (*p*<0.001). Of the 32 cytokines measured, VWR significantly lowered concentrations of tumor modulating cytokines cotaxin (pre: 1291.2±310; post: 702.2±273; *p*=0.03), IL-1α (pre: 457±97; post: 167±161; *p*=0.03), IL-5 (pre: 4.7±0.2; post: 1.9±0.4; *p*=0.001), IL-12(p40) (pre: 16.9±1.5; post: ND; *p*=0.001) and VEGF (pre: 1.37±0.3; post: 0.31±0.3; *p*=0.004). No changes were observed in the control group. After 20 weeks, VWR group had significantly lower IL-5 (Con: 3.75±0.7; VWR: 1.9±0.4; *p*=0.01) and VEGF (Con: 1.72±0.7; VWR: 0.31±0.3; *p*=0.02) compared to controls. **CONCLUSIONS:** These results suggest VWR suppresses tumor aggressiveness by altering the inflammatory cytokine profile. Further research on mechanisms of action is needed.

2900 May 31 4:00 PM - 4:15 PM
Circulating Mcp-1 Is Not Related To Self-reported Moderate To Vigorous Physical Activity.

Bradley W. Macdonald, Chad Dolan, Avery N. Love, Melissa M. Markofski. *University of Houston, Houston, TX.*
(No relevant relationships reported)

PURPOSE: Monocyte chemoattractant protein-1 (MCP-1) is a key chemotactic signal which influences the recruitment and infiltration of circulating monocytes and macrophages. The purpose of this study was to examine the relationship between physical activity and circulating MCP-1 and monocytes in healthy, young adults. **METHODS:** Fourteen young (22.4±0.58 years), healthy adults were recruited for study. Subjects were asked to self-report their activity and were divided into two groups: high physical activity and moderate physical activity. Physical activity was confirmed with accelerometers (ActiGraph). A resting blood sample was collected from each subject. MCP-1 levels were analyzed via ELISA while classical (CD14+CD16-) and non-classical (CD14+CD16+) monocyte levels were analyzed via flow cytometry. **RESULTS:** Self-reported active subjects (N=9, VO₂max: 50.3±2.7

mL·kg⁻¹·min⁻¹, Average Weekly MVPA: 712.7±69.5 min) had higher ($p<0.05$) VO_{2max} and weekly MVPA measures from the self-reported inactive group (N=5, VO_{2max} : 35.6±4.2 mL·kg⁻¹·min⁻¹, Average Weekly MVPA: 548.2±64.6 min). There were no significant differences observed between the self-reported active and inactive groups for MCP-1 serum concentration, classical monocyte percentage or non-classical monocyte percentage and no correlation was observed between MCP-1 and circulating monocytes subsets. Based on ActiGraph data recorded from subjects over the course of one week, the active and inactive groups were adjusted based on average weekly MVPA. The MVPA active group (N=8, VO_{2max} : 50.8±2.9 mL·kg⁻¹·min⁻¹, Average Weekly MVPA: 797.9±35.7 min) had higher ($p<0.05$) VO_{2max} and weekly MVPA measures from the MVPA inactive group (N=6, VO_{2max} : 37.5±4.2 mL·kg⁻¹·min⁻¹, Average Weekly MVPA: 462±44.6 min). No significant differences in MCP-1 serum concentration, classical monocyte percentage or non-classical monocyte percentage were observed between the groups divided by MVPA level. **CONCLUSION:** Differences in MCP-1 concentration based on amount of regular physical activity may not exist in a cohort of healthy young adults. All participants, even those who did not report regular physical activity, had at least 150 minutes of MVPA as confirmed by accelerometry and not having a true physically inactive group may have influenced the results.

2901 May 31 4:15 PM - 4:30 PM

Acute Heavy Resistance Exercise Protocol Induces Significant Physiological Stress Elevating Extracellular Heat Shock Protein

Jacob Bowie¹, Adam J. Sterczala¹, William J. Kraemer, FACSM², Carl M. Maresh, FACSM², Brett A. Comstock¹, Shawn D. Flanagan¹, Tunde K. Szivak¹, David R. Hooper¹, Elaine C. Lee¹.

Email: jacob.bowie@uconn.edu

(No relevant relationships reported)

Cytoprotective protein HSP70 is important in recovery from stress and exercise, but has not been well-characterized in response to muscle damaging resistance exercise protocols.

PURPOSE: To characterize the physiological response to a high stress acute heavy resistance exercise protocol (AHREP) in blood biomarkers including extracellular HSP70 (eHSP70). **METHODS:** Healthy, resistance-trained men (n = 10, 24±4.5 years, 176.8±5.5 cm, 84.65±12.78 kg, 17.6±6.3% body fat, 145±18 kg 1RM) completed an AHREP (6x10RM). Blood samples were collected pre-exercise (PRE), immediately post (IP), and at 15, 30, 60, 120 minutes (min) and 24, 48, 72 hours (h) post-exercise. Samples were analyzed for stress biomarkers including lactate, creatine kinase (CK), complete blood count, cytokines, and eHSP70. The results were analyzed with a rANOVA and post hoc t tests. **RESULTS:** Plasma lactate was elevated 12 fold (vs. PRE 0.880 ± 0.296 mmol·L⁻¹) immediately after the AHREP (12.15±3.19) and remained elevated (vs. PRE, $p\leq0.0002$) at 120 min. Muscle damage was demonstrated by significantly ($p < 0.01$) elevated CK (vs. PRE 126±29 IU·L⁻¹) at 24h post-exercise (439±151). CBC indicated changes in leukocyte populations that were coincident with post-exercise increases ($p<0.05$) in chemoattract cytokine IL-8 (PRE 4.77±2.73%, IP 6.38±3.53). eHSP70 levels were increased ($p<0.05$, vs. PRE 0.391±0.244 ng·mL⁻¹) at IP (0.567±0.366) and 15 min post-exercise (0.515±0.345). **CONCLUSIONS:** The AHREP caused significant physiological stress that coincided with increases in circulating eHSP70 that returned to baseline levels within minutes post-exercise. eHSP70 likely responds with different kinetics during resistance exercise than as has been well-characterized during aerobic exercise.

A Single High-Intensity Exercise Bout Reduces Tumour Hypoxia in Mice.

Simon Lønbro¹, Pernille Byrialsen Elming², Thomas Wittenborn², Michael R. Horsman². ¹Aarhus University, Aarhus C, Denmark. ²Aarhus University Hospital, Aarhus C, Denmark.
Email: loenbro@oncology.au.dk

(No relevant relationships reported)

INTRODUCTION: Low blood perfusion and hypoxia are characteristic features of tumors and are factors of resistance to radiation and chemotherapy. A few rodent studies show that aerobic exercise, that has no severe side effects, may improve perfusion and reduce hypoxia but the significance of exercise intensity is unknown. **METHODS:** Female CDF1 mice were injected with the C3H mammary carcinoma in the mammary fat pad and allocated to either a Control group (no exercise) or a group performing low (6 m/min), moderate (12 m/min) or high intensity (18 m/min) treadmill running for 30 minutes (n=11/group). Prior to running, all mice were injected with Pimonidazole and immediately after exercise injected with Hoechst 33342 before being sacrificed 1 minute later. Tumors were excised, and histological sections prepared. Hypoxia was determined from the degree of Pimonidazole binding, while

analysis of the Hoechst 33342 staining enabled analyses of perfused vessels in the tumor (latter analyses ongoing. Data not presented). **RESULTS:** The mean hypoxic fraction was 9.0±5.2% for mice exposed to the high intensity running schedule and was significantly lower compared with the hypoxic fraction in tumors from the control group (14.2±6.2%, Student's T-test $p=0.046$) and low intensity group (13.6±4.0%, $p=0.034$) but not the moderate intensity group (12.6±7.0%, $p=0.19$). **CONCLUSION:** High intensity for 30 minutes may reduce tumor hypoxic fraction in mice and our current studies investigate the duration of the reduction in hypoxia after exercise cessation and examine the effect of this exercise regime on tumor radiation response.

F-38 Clinical Case Slide - Rehabilitation Issues: Older Adults

2906 May 31 3:15 PM - 3:35 PM**The Effects of a Linearly Progressed Resistance Training Program on a Previously Sedentary 86 Year Old Woman**

John Petrizzo¹, Jeremy Koppel², Erica Christen², Inna Koppel², Robert M. Otto, FACSM¹, John Wygand, FACSM¹. ¹*Adelphi University, Garden City, NY.* ²*Feinstein Institute for Medical Research, Manhasset, NY.* (Sponsor: Robert M. Otto, FACSM)
Email: jpetrizzo@adelphi.edu

(No relevant relationships reported)

History:

86 year old previously sedentary female agreed to participate in a linearly progressed resistance training program for six months. Prior to participation, the subject was evaluated by a physician and cleared to participate in the program. Medical history revealed a history of atrial fibrillation, hypothyroidism, hypertension, glaucoma, osteoarthritis, as well as peripheral edema. The subject reported the use of Norvasc, Losartan Potassium, Hydralazine Hcl, and Doxazosin Mesylate for her hypertension, Xarelto for her atrial fibrillation, Levothyroxine for her hypothyroidism, Latanoprost for her glaucoma as well as Lasix for her peripheral edema. Prior to initiation of the resistance training intervention, the subject's only self-reported physical activity was walking. She reported walking, on average, 1 - 3 hours per week. The subject also reported sleeping, on average, less than 5 hours per night.

Physical Examination:

The subject completed the Short Physical Performance Battery (SPPB) prior to initiating the resistance training intervention. Results of the subject's initial SPPB showed that she was unable to maintain a semi-tandem or tandem stand for 10 seconds, required the use of a walker to ambulate a distance of four meters, and was unable to transfer from sit-to-stand without the use of her upper extremities.

Test and Results:

Initial SPPB score of 2/12, consistent with poor balance, gait speed, and lower extremity functional strength

Initial Leg Press calculated 1RM = 23.1 kg

Initial Lat Pulldown calculated 1RM = 8.6 kg

Initial Bench Press calculated 1RM = 7.7 kg

Intervention:

A linearly progressed resistance training program comprised of the leg press, barbell bench press, and lat pulldown machine was implemented an average of twice per week for 6 months. The goal of the resistance training program was to make a small increase in the training load used on each of the three exercises as often as possible.

Outcomes:

Improvements of calculated 1RM of 209.8%, 268.4%, and 94.1% were noted for the leg press, lat pulldown, and bench press respectively. SPPB score double from 2/12 to 4/12. Additionally, the subject was also able to successfully transfer from sit-to-stand without the use of her upper extremities for assistance and no longer required the use of a walker during ambulation.

2907 May 31 3:35 PM - 3:55 PM**Complications Post Unicompartmental Knee Arthroplasty and Physical Therapy Manual Therapy**

Julie B. Barnett. *UT Health San Antonio Texas, San Antonio, TX.*
Email: barnettj3@uthscsa.edu

(No relevant relationships reported)

HISTORY: 65 year old male underwent an initial medial unicompartmental knee arthroplasty and physical therapy manual therapy and exercise. The patient had significant increase in pain after physical therapy manual techniques in extension and exercises interventions. Subsequently, the patient underwent a total knee arthroplasty after a lateral tibial plateau fracture was revealed.

PHYSICAL EXAMINATION: Patient had approximately minus 10 degrees of knee extension at eight weeks post unicompartmental medial arthroplasty.

DIFFERENTIAL DIAGNOSIS: Joint adhesions vs muscular restrictions vs fracture.

TEST AND RESULTS: Passive range of motion measurements taken during physical therapy with restrictions in knee extension passive range of motion. 2nd MRI revealing lateral tibial plateau fracture

FINAL WORKING DIAGNOSIS: Lateral tibial plateau fracture per MRI

TREATMENT AND OUTCOMES: Total knee arthroplasty performed and patient eventually gained full range of motion of the knee joint, normal gait, and reduction in pain.

2908 May 31 3:55 PM - 4:15 PM**Transplant Frailty Prehabilitation**

Demitri Constantinou, Keegan Willemse. *University of the Witwatersrand, Wits, South Africa.* (Sponsor: Yoganathan Coopoo, FACSM)

Email: demitri.constantinou@wits.ac.za

(No relevant relationships reported)

HISTORY: 72 year old male, liver problem of non-cirrhotic portal hypertension and esophageal varices treated with ligation. Developed sudden onset Klebsiella pneumonia septicaemia, with atrial fibrillation whilst hospitalised and cardioverted pharmacologically. Whilst investigating, liver tumor identified on CT scan. Diagnosed as hepatoma. Treatment included 2 x chemoembolization. Lost 15 kg in the previous 8 months. Previous DVT following torn Achilles tendon repair. Insulin resistance. Ex-smoker. Activity - walking and golf. Minimal alcohol use. Medication - Prazolol, furosemide, spironolactone. Referred for prehabilitation whilst awaiting liver transplant.

PHYSICAL EXAMINATION: Colour - ashen/pallor. HR = 62 bpm, regular, good volume. BP = 96/74 mmHg. Cor - NAD Lungs - NAD. Abdomen - NAD. Clinically balance reduced, generalised muscle weakness.

DIFFERENTIAL DIAGNOSIS: Anemia, paraneoplastic syndrome, chemotherapy / oncology deconditioning, cardiac dysfunction

TEST AND RESULTS: Lab results - marginally raised liver enzymes. No current anemia. Staged treadmill test using modified Bruce Protocol with ECG monitoring and mobile metabolic measurements. The results showed pre-exercise HR = 60 bpm, regular, pre exercise BP = 94/76 mmHg; maximum BP post exercise expected increases with peak RPE of 15/20 although physically could not continue. ECG normal at rest and with effort. Peak heart rate = 184 (112% of predicted). Exercise time = 9.58 minutes. Maximum load to stage 5 = 17 mets. Peak Vo2 = 18.8 ml/min/kg at 08.30 minutes. RER reached 1 at 3.15 mins. Ventilatory equivalent was high, and occurred early - implying early anaerobic dependent metabolism, likely from compromised aerobic energy system. Liver dysfunction with effects on glycogenolysis and gluconeogenesis unknown.

FINAL WORKING DIAGNOSIS: General deconditioning of multiple etiologies related to liver tumor

TREATMENT AND OUTCOMES: Exercise prehabilitation for transplant to improve aerobic function, muscle strength and balance. Exercise sessions three times per week, with significant improvements in objective outcome measures and subjective energy levels, function and quality of life.

2909 May 31 4:35 PM - 4:55 PM**Age and Gender Specific Issues - Power Based Exercise Program in a Postmenopausal Female**

Michele Aquino, John Wygand, FACSM, Robert M. Otto, FACSM, John Petrizzo. *Adelphi University, Garden City, NY.* (Sponsor: John Wygand, FACSM)

Email: maquino@adelphi.edu

(No relevant relationships reported)

History:

70 year old female with Osteoporosis was referred to Physical Therapy for gait and balance training. The patient denies any prior history of cancer, diabetes, neurological history, prior orthopedic injuries/surgeries, or major cardiac events/surgeries. Her

current prescribed medications include Lipitor, Norvasc, Hyzaar and Lexapro. The patient further mentions a history of osteopenia, but a recent DEXA scan classified the patient as Osteoporotic at femoral neck with a T-score of -2.5. The patient was prescribed 70 mg of Fosamax QD and continued with supplemental Calcium with Vitamin D. The patient reported reduction of balance with day to day activities and reported a fear of falling, but denied any falls.

Physical Examination:

Postural assessments demonstrated excessive forward head posture, with increased thoracic kyphosis along with excessive lumbar lordosis. Neurological assessment and ROM at the lumbar spine and hips were all within normal limits. Limited muscular strength was noted in bilateral lower extremities. Deficits in static balance were also noted with tandem stance.

Test and Results:

Dynamic Gait Index Score of 15/24, consistent with an increased fall risk.

DEXA results at femoral neck: T-Score: -2.5; BMD: .572 gr/cm²

DEXA results at lumbar spine: T-Score: -2.2; BMD: .807 gr/cm²

Intervention:

A Progressive Resistive Functional Power based exercise program was conducted an average two times per week for one year. A treadmill warm-up followed by progressive functional activities such as sit to stands for speed, forward step ups for speed, hip abduction and hip extension for speed were included. Progressions consisted of increased resistance and increased speed of movement.

Outcomes:

DEXA scan demonstrated BMD improvements of 29% (742 gr/cm²) and 24% (1.003 gr/cm²), as well as improvements in T-score to -2.1 to -1.5 at her femoral neck and lumbar spine, respectively. The changes attenuate fracture and mortality risk. Furthermore, a 7 point change in her Dynamic Gait Index score was noted post intervention, resulting in a decreased risk of falling. The patient has continued to be independent with a home exercise program along with continued use of her prescribed medications.

2910 May 31 4:15 PM - 4:35 PM

Mitochondrial Myopathy, The Use Of Resistance, Mobility And Neuromuscular Exercise Training In A Community Clinic.

Catherine R. Moss. *Optimize Health Ltd; The University of Auckland, Auckland, New Zealand.*

(No relevant relationships reported)

History:

A Female 68 yrs old was presented to the exercise rehabilitation clinic with:

Mitochondrial Disease (ragged red muscle fibers, excessive mitochondria)

POLG-associated CPEO

Osteoporosis

Physical examination:

Extreme muscle weakness

Low BMI

No eye movement tracking, eyelids paralyzed

Fatigue

Differential Diagnosis:

Severe cervical kyphosis and mild thoracic kyphosis and anterior pelvic tilt, low muscle strength.

Testing and Results:

A continuous recumbent cycle protocol with peak power of 28 Watts, peak blood pressure 168/74 mmHg, 110 bpm.

Functional testing findings: 30-second Sit to stand test: 3 reps in 30 seconds; Dumbbell bicep curl test (60 seconds): Left arm was 30 reps, Right arm was 20 reps; Romberg (eyes open): <3 seconds for each leg, Tandem stance balance test: not possible without modification.

Results

- Post 8 week test results

30-second Sit to stand test: 6 reps in 30 seconds (100% increase); Dumbbell bicep curl test (60 seconds): Left arm was 47 reps (17 rep increase), Right arm was 41 reps (21 rep increase); Romberg (eyes open): Left leg was 4.50 seconds (~2 second improvement) and right leg was 5.46 seconds (~3.5 second improvement), Tandem stance balance test: Left leg was 6.12 seconds and right leg was 5.59 seconds (and increase on both sides from 0 seconds). Working Diagnosis:

Mitochondrial myopathy with POLG-associated CPEO and osteoporosis with associated poor muscular strength, poor balance and posture.

Treatment and Outcomes:

The client attended a community clinical exercise rehabilitation program for 8 weeks, 2 x week 30 minutes. After a 5-minute warm up on a recumbent cycle (28-30 Watts), the client went through a one-on-one resistance & mobility training session focusing on variations of: Strength training, proprioception training, upper body & neck mobility & posture, co-ordination and muscle activation, functional balance training

Outcomes: A low intensity progressive resistance program that incorporates a variation of balance, proprioception, flexibility and muscle activation as well as upper back

mobility training is recommended for the mitochondrial myopathy conditions. Program should be continued for a further 10-12 weeks, 2 x per week of ~30 minutes with slow to moderate intensity progression.

F-39 Clinical Case Slide - Spine II

Friday, May 31, 2019, 3:15 PM - 4:55 PM

Room: CC-202C

2911 **Chair:** Sherrie L. Ballantine-Talmadge, FACSM. *CU Sports Medicine and Performance Center, Boulder, CO.*

(No relevant relationships reported)

2912 **Discussant**

Dina C. Janse van Rensburg, FACSM. *University of Pretoria, Pretoria, South Africa.*

(No relevant relationships reported)

2913 **Discussant**

Lindsay Ramey. *University of Texas Southwestern Medical Center, Dallas, TX.*

Progressive Asymmetric Low Back Pain in a Young Basketball Player

Marianne Luetmer, Edward Laskowski, FACSM. *Mayo Clinic, Rochester, MN.*

Email: luetmer.marianne@mayo.edu

(No relevant relationships reported)

History: A 23 year old otherwise healthy male basketball player developed acute onset of sharp right-sided low back pain upon landing after performing a slam dunk. He had no lower extremity radicular pain, focal weakness, or sensory loss; no constitutional symptoms. At first presentation he was diagnosed with mechanical low back pain. The prescribed physical therapy intervention was beneficial however his pain progressed. He returned to Sports Clinic one year later; the pain had spread to his right gluteal region and was exacerbated by impact exercise. He could no longer play basketball and pain interfered with daily activities.

Physical Examination:

On initial examination: tight hip internal and external rotators bilaterally, negative Stinchfield and FABER tests bilaterally, and tenderness to palpation over right lumbar paraspinals with an otherwise normal exam. One year later: strength, sensation, and reflexes remained intact. Focal tenderness over right SIJ. Normal lumbar ROM.

FABER and Stinchfield tests reproduced right-sided SI region pain. FADIR and labral scour maneuvers negative.

Differential Diagnosis:

1. Mechanical low back pain
2. Spondylolysis
3. Sacroiliitis
4. Femoral acetabular impingement
5. Labral pathology
6. Avascular necrosis

Tests and Results:

-Lumbar radiographs, year 2017: Normal.

-Pelvic radiographs, 2018: Mild iliac-sided sclerosis and irregularity bilateral SIJs, more prominent on right. No fracture or dislocation.

-Lumbar and pelvic MRI, 2018: Extensive subchondral marrow edema right SIJ; right SIJ effusion with changes suggesting enthesitis. Compatible with marked asymmetric sacroiliitis. Normal lumbar spine.

-HLA-B27 positive. ESR and CRP normal.

Final Working Diagnosis: Axial spondyloarthritis

Treatment and Outcomes:

1. Trial of naproxen 500 mg BID
2. Fluoro-guided right SIJ corticosteroid injection
3. Low-impact aerobic conditioning; core and back strengthening exercises with emphasis on optimal technique

Back Pain in a Multi-Sport High School Athlete

John Diefenderfer, Rob Stevens. *Maine General Sports Medicine, Augusta, ME.* (Sponsor: James Dunlap, FACSM)
(No relevant relationships reported)

HISTORY: A 15 year old male football player presented with low back pain that was worse on the left side. His injury occurred about 3 weeks ago during practice where he dove to tackle another teammate and had sharp pain in his lower back. He stated running/sprinting, jumping, twisting to throw the football, and sometimes bending forward all worsened the pain. Rest seemed to help, but he continued to have a dull ache in his low back that was fairly constant. He has tried heat and stretching before practice. He denies numbness, tingling, or weakness. He denies any bowel/bladder incontinence. He denies previous back injury or trauma. He is a year round athlete and also participates in basketball and hockey.

ROS: pertinent negatives include no fevers, rash, recent weight loss/gain, or joint pains. **PHYSICAL EXAMINATION:** Height: 5'7" Weight 133 lbs. Gen: no acute distress. Gait: normal, able to effectively toe and heel walk, tandem gait intact. Lumbar Spine Exam: Skin / Lymph: normal, no scars, mild stretch marks superficially midline around T10-12. Tenderness: midline L5-S1 as well as adjacent on the left, no step-offs noted, TTP SI joints bilaterally. Flexion: 60 degrees with pain. Extension: 20 degrees. Moderate to severe bilateral hamstring tightness.

Strength/reflexes/sensation/distal pulses of both LE intact. Special testing: Seated/Supine SLR, FABER, FADIR negative bilaterally. Stork testing positive bilaterally.

DIFFERENTIAL DIAGNOSIS: Lumbar muscle strain, Iliolumbar ligament sprain, SI joint dysfunction, Spondylolysis with or without spondylolisthesis, Ankylosing Spondylitis.

TEST AND RESULTS: X-rays lumbar spine: Bilateral pars defect L5 with mild Grade 1 spondylolisthesis of L5/S1. MRI lumbar spine without contrast - Acute bilateral pars defects at L4. At L5/S1 there are bilateral L5 pars defects which appear chronic and have no associated edema. There is resultant uncovering of the disc and some mild bilateral foraminal narrowing at L5/S1. No spondylolisthesis at L4/5.

FINAL WORKING DIAGNOSIS: Multilevel Bilateral Spondylolysis, acute at L4, with grade 1 spondylolisthesis L5/S1

TREATMENT AND OUTCOMES:

Physical therapy without bracing due to patient choice. Relative rest and discontinuation of contact sports while in PT. Discussion about further return to play will take place upon completion of PT.

2916 May 31 3:55 PM - 4:15 PM

Fragile Bones in a Horseback Rider

Jacob Wessels. *University of Minnesota, Minneapolis, MN.*
(Sponsor: Suzanne Hecht, FACSM)
Email: wesse074@umn.edu
(No relevant relationships reported)

HISTORY: A 55-year-old postmenopausal female presents with back pain that started when landing a jump while horseback riding. The jump was a routine jump and she felt sharp immediate pain in her mid-back. She has been riding more infrequently but no other change to her landing. This felt similar to a compression fracture five years ago she sustained sitting while on a boat ride. She has reported general fatigue and sleeping more than usual. Some heat and cold intolerance. No kidney stones. She has history of vitamin d deficiency, heartburn on omeprazole and moderate alcohol use, never smoker.

PHYSICAL EXAMINATION: P: 90 BP: 128/76 Height: 66.5in Weight: 156lb

Gen: pleasant well appearing female in no distress

Neck: no thyromegaly or palpable mass

Heart: rrr, no murmur

Back: no deformity, normal posture, tender to palpation over T6-T9 spinous processes, tender over adjacent paraspinal muscles. Forward flexion and back extension reproduces pain, no radiation down legs or to abdomen.

Neuro: reflexes 2+, strength 5/5 in upper and lower extremity.

DIFFERENTIAL DIAGNOSIS:

1. Primary osteoporosis
2. Hyperparathyroidism
3. Hypothyroidism
4. Pituitary dysfunction
5. Multiple myeloma

TEST AND RESULTS:

DXA: L1-L3 t-score -2.2BMP: Na 140, K 4.4, Cl: 105, CO2: 28, Creatinine 0.59, GFR >90, Glucose: 97, Calcium 9.8

TSH: 0.04 (0.40 - 4.00 mU/L) T4: 0.30 (0.76 - 1.46 ng/dL)

PTH: 19 (18 - 80 pg/mL)

Vita D 37 (20 - 75 ug/L)

Further Labs:

Free T3: 2.0 (2.3-4.2 pg/mL)

FSH: 100.1 LH: 23.8 Prolactin 5 (3-27ug/L)

Insulin Growth Factor 1: 89 (49 - 234 ng/ml)

Cortisol stimulation test: (850AM) 16.3, 30 min: 22.5, 1 hour: 26.0 (8 AM Reference Range 4-22 ug/dL, 30-60 minutes post stim: >20 ug/dL)

Tissue Transglutaminase IgG: <1

Lumbar X-ray: Anterior vertebral compression deformity involving T7, T8, and T9 vertebral bodies. There is also anterior wedging of T10 vertebral body which may be physiologic.

MRI Head/Brain: No focal abnormality of the pituitary gland.

FINAL WORKING DIAGNOSIS: Osteoporosis with insufficiency fracture and isolated central hypothyroidism

TREATMENT AND OUTCOMES:

1. Calcitonin nasal spray for acute pain control
2. Levothyroxine replacement to T4 in normal range
3. Yearly pituitary laboratory evaluation
4. Follow up when euthyroid for osteoporosis treatment
5. Repeat DXA in 1-2 years
