Back Pain - Swimming and Lacrosse

McKayla Schmitt. *University of Minnesota, Minneapolis, MN.*
(Sponsor: Suzanne Hecht, FACSM)
(No relevant relationships reported)

HISTORY: A 17-year-old senior swimmer and lacrosse player has had 6 months of low back pain. She had no acute injury but reports gradual onset of pain that has progressed causing her to be unable to participate in her sports. She has almost nightly awakening secondary to back pain. She denies numbness, tingling, weakness, or radiation of pain into her lower extremities.

She has a history of celiac disease. There is a family history of hypothyroidism, celiac disease, and rheumatoid arthritis.

PHYSICAL EXAMINATION: Exam revealed bilateral, left greater than right, paraspinal muscle tightness from T10-L5. She had full forward flexion, extension, rotation, and lateral flexion. She had a negative straight leg raise, slump test, and stork test, bilaterally. No neurological signs or symptoms.

DIFFERENTIAL DIAGNOSIS:

1. Strain of lumbar paraspinal muscles
2. Spondylolysis
3. Spondyloarthritis

TESTS AND RESULTS:

Thoracic and lumbar spine anterior-posterior and lateral radiographs:

--Spondylolysis with spondylolisthesis at L5-S1
 Lumbar spine MRI:
 --Anterolisthesis with spondylolysis of L5 on S1.
 --Desiccation at the level of L5-S1 with mild loss of disc height
 HLA-B27: negative
 TSH: 0.86 (normal)
 Vitamin D: 37
 CBC: within normal limits
 CRP: 6.8 (normal)
 ESR: 16 (normal)

FINAL/WORKING DIAGNOSIS:

Spondyloarthritis

TREATMENT AND OUTCOMES:

1. Referral to rheumatology
2. Initiation of Methotrexate and Humira
3. Returned to swimming within 4 weeks of initiation Methotrexate, and 2 weeks of initiation of Humira, with significant reduction in low back pain

2918 May 31 4:35 PM - 4:55 PM**Elite Weightlifter With Acute Back Pain**

Taoufik Bel Fekih, Nidal Hammad, Louis Holtzhausen, FACSM, Yasin Al Makhadma. *Aspetar, Doha, Qatar*. (Sponsor: Louis Holtzhausen, FACSM)

Email: taoufik.belfekih@aspetar.com

(No relevant relationships reported)

HISTORY: An 18 years old male, elite weightlifter sustained a sudden onset of sharp pain in the low back during back squat training (150 kg), with an episode of numbness of posterior right thigh which quickly resolved.

The pain was localized in the right lateral L4/L5 area, with intensity rated 8/10 on a Numerical Pain Scale.

Training history: Weightlifting and resistance training 6 days (30 hours)/week.

PHYSICAL EXAMINATION: No gait abnormality

No neurological deficit, Straight leg raise test negative

Para-spinal muscular spasm and a mildly limited ROM in right rotation, lumbar spine extension, lateral flexion to the right.

Pain-free sacroiliac joint.

Tenderness on palpation of spinous process and L4-L5 facet area on the right side.

Neurological examination normal, including motor function, sensory and reflexes.

DIFFERENTIAL DIAGNOSIS: A simple "lumbago"

Intervertebral disc prolapse

Burst fracture

Spondylolysis

Acute deterioration of spondylolisthesis

TEST AND RESULTS: Standard X-rays showed probable L5 pars lesion, Loss of disc height at L4-L5. An osseous fragment overlying the L4-L5 neural foramina.

The MRI images showed an apophyseal ring fracture involving the postero-inferior L4 vertebral body, with mild bone edema. There was no clear root impingement. There was an L5-S1 disc hernia.

CT scan with 3D rendering confirmed the presence of L4-L5 (acute) ring fracture; and an older fracture at L5-S1.

Laboratory tests showed: Vitamin D deficiency (<10 ng/ml for range 30-80 ng/ml)

Bone densitometry (L4 and 5): Minus 2 (Osteopenia)

FINAL WORKING DIAGNOSIS: Posterior apophyseal ring fracture.

Psycho-social status:

High anxiety levels because of fear of missing an upcoming international competition.

TREATMENT AND OUTCOMES: A "conservative" approach was followed.

Including:

NSAID's

Use a lumbar brace for 4 weeks.

Abstain from weight-lifting for 8 weeks (reviewed regularly)

Vitamin D supplementation: 50.000 IU, 1tab/week

Calcitonin IM injections 100 UI/dayx10 days

Graded exercise rehabilitation, including incident-free progressive weight loading.

The athlete returned to previous level of activity after 8 weeks.

He could back squat 260 kg at 3 months' post injury, and won the Junior World Championships in his weight class.

F-41 Rapid Fire Platform - Vascular Function

(No relevant relationships reported)

Data have demonstrated that an acute bout of resistance exercise (ARE) reduces vagal modulation. However, only a handful of studies have evaluated differences between resistance-trained (RT) and untrained (UT) individuals in response to an ARE.

PURPOSE: To compare alterations in vagal modulation during recovery from ARE in RT and UT individuals. **METHODS:** Eighteen RT individuals (Mean±SD; Age: 23±3yrs; Ht: 1.7±0.1m; Wt: 75.2±15.6kg) and eight UT individuals (Age: 24±3yrs; Ht: 1.6±0.09m; Wt: 61.9±10.8kg) volunteered to participate. Vagal modulation was assessed using heart rate variability (HRV) in the frequency domain [High-frequency power (lnHF)], as well as heart rate complexity [sample Entropy (SampEn) and Lempel-Ziv entropy (LZEn)]. Data were collected at rest, 15 minutes (Rec1) and 30 minutes (Rec2) during recovery from ARE and a control (CON). The ARE utilized 3 sets of 10 repetitions at 75% 1-repetition maximum (1RM) and 2 minutes of rest between sets and exercises on the chest press, leg press, latissimus dorsi pulldown, leg curl and leg extension. A 2x2x3 repeated measures ANOVA was used to examine groups (RT, UT) across conditions (CON, ARE) on the repeated factor of time (rest, Rec1, Rec2). **RESULTS:** The groups were similar (p≥0.05) for age, and height, but not weight. The 1RMs on all the exercises were different (p≤0.05) between groups. At rest, all measures of vagal modulation were similar between groups. In addition, there were no 3-way interactions for any measures of vagal modulation. There were significant time x condition interactions for lnHF (ARE: rest: 7.5±1.2ms2; Rec1: 5.8±2.2ms2; Rec2: 4.5±1.2ms2; p=0.0001), SampEn (ARE: rest: 1.5±0.4; Rec1: 1.3±0.4; Rec2: 1.4±0.4; p=0.022), and LZEn (ARE: rest: 0.8±0.08; Rec1: 0.7±0.1; Rec2: 0.7±0.2; p=0.001). LnHF and LZEn were reduced at Rec1 and Rec2 compared to rest, with similar responses between the resistance-trained and untrained groups. SampEn was reduced only at Rec1 compared to baseline, with no difference between groups. **CONCLUSIONS:** These data demonstrate that both resistance-trained and untrained individuals have similar reductions in vagal modulation in response to an acute bout of resistance exercise using weight machines.

2922 May 31 3:25 PM - 3:35 PM**Influence of Cardiorespiratory Fitness on Central and Local Arterial Stiffness During Acute Inflammation**

Elizabeth C. Schroeder¹, Thessa IM Hilgenkamp¹, Wesley K. Lefferts¹, Amanda V. Sardeli², Stacy Arriola¹, Tracy Baynard, FACSM¹, Bo Fernhall, FACSM¹. ¹University of Illinois at Chicago, Chicago, IL. ²Campinas University, Campinas-SP, Brazil. (Sponsor: Bo Fernhall, FACSM)

Email: eschro7@uic.edu

(No relevant relationships reported)

Acute inflammation is associated with increased cardiovascular (CV) risk. Aortic stiffness, a risk factor for CV disease, increases during acute inflammation. However, whether inflammation affects the aorta and carotid similar has not been determined. High cardiorespiratory fitness is cardio-protective and associated with lower central artery stiffness and inflammation. Thus, cardiorespiratory fitness may be protective and attenuate increases in arterial stiffness during acute inflammation. **PURPOSE:** Determine the effect of acute inflammation and fitness on arterial stiffness. **METHODS:** Arterial stiffness was assessed in 11 low fit (6 male, 24 ± 5 yrs, 22.8 ± 4.3 kg/m², 34.5 ± 2.9 ml/kg/min) and 12 high fit (VO₂peak >75th age- and sex-specific percentile; 5 male, 27 ± 4 yrs, 22.6 ± 1.9 kg/m², 56.4 ± 9.7 ml/kg/min) participants at baseline and 24h-post typhoid vaccination. Aortic pulse wave velocity (PWV) and brachial blood pressure were assessed with the Mobilograph device. Carotid β-stiffness was assessed via ultrasound with echo-tracking. Carotid pressure and wave reflections were obtained via tonometry (SphygmoCor) and calibrated to brachial mean and diastolic pressure. C-reactive protein (CRP) and interleukin-6 (IL-6) were assessed via ELISA. **RESULTS:** Acute inflammation was induced as evident by increases in CRP

and IL-6 ($p < 0.01$; Table). Mean arterial pressure and PWV were unaltered ($p > 0.05$), and heart rate increased at 24h ($p < 0.05$). β -stiffness and pulse pressure increased in high fit participants, with no change in low fit (interaction, $p = 0.02$). Carotid wave reflections were reduced at 24h in both groups ($p < 0.05$). **CONCLUSION:** While neither fitness nor acute inflammation altered aortic stiffness, fitness may alter the sensitivity of the carotid artery to acute inflammation. Future research is necessary to examine the mechanism of these differential stiffness responses during acute inflammation and their implications for the cerebrovasculature.

The Influence Of Habitual Moderate-Vigorous Physical Activity Levels Versus Aerobic Fitness On Age-Related Endothelial Function

Jarrett A. Johns¹, Myles W. O'Brien¹, Amanda Bungay¹, Said Mekary², Derek S. Kimmerly¹. ¹Dalhousie University, Halifax, NS, Canada. ²Acadia University, Wolfville, NS, Canada. Email: j.johns@dal.ca

(No relevant relationships reported)

Older adults (OA) have reduced vascular function, as assessed via flow-mediated dilation (FMD). However, it is unknown whether OA also have reduced low flow-mediated constrictor (L-FMC) responses than younger adults (YA). Further, we have previously demonstrated in OA that FMD responses are influenced more by habitual moderate-vigorous physical activity (MVPA) levels than aerobic fitness. It is unclear whether differences in habitual MVPA levels between YA and OA contribute to age-related declines in vascular function. **PURPOSE:** To test the hypotheses that: 1) YA would have superior brachial (BA) and popliteal (POP) FMD and L-FMC versus OA, and 2) that habitual MVPA levels would have a greater influence on endothelial function than age- and sex- aerobic fitness levels. **METHODS:** FMD and L-FMC were measured via duplex ultrasonography in 9 YA (5 ♀, 24±3 yr) and 9 OA (5 ♀, 68±4 yr) matched for body mass index, as well as age- and sex-related aerobic fitness categories (Poor-Excellent). L-FMC and FMD were quantified as the percent decrease in diameter (from baseline) during the last 30-s of a 5-min distal cuff occlusion and the percent increase in diameter during a 5-min post-cuff deflation period, respectively. Peak oxygen consumption was measured via indirect calorimetry using an incremental cycle ergometer test. MVPA was quantified over at least 7-d using a PiezoRx® physical activity monitor. **RESULTS:** Compared to OA, YA spent more time engaged in MVPA (426±178 vs. 260±91 min/week, $p = 0.03$), had higher BA-FMD (8.0±2.8 vs.

5.6±1.7%, $p = 0.04$) and POP-FMD (5.8±0.8 vs. 3.2±1.2%, $p < 0.01$). However, both groups had similar BA L-FMC (YA, -1.5±1.7 vs. OA, -0.8±1.1%, $p = 0.35$) and POP L-FMC responses (YA, -1.7±1.7 vs. OA, -0.6±1.9%, $p = 0.19$). MVPA was moderately correlated to BA-FMD ($r = 0.64$, $p < 0.01$) and POP-FMD ($r = 0.53$, $p = 0.03$). However, age-/sex-specific aerobic fitness categories were not correlated to BA-FMD ($p = 0.28$) or POP-FMD ($p = 0.30$). **CONCLUSION:** Based on age- and sex-related aerobic fitness categories, our results suggest that lower weekly MVPA time may have a greater influence on age-related declines in endothelial-dependent vasodilation than aerobic fitness status *per se*. However, neither BA nor POP endothelial-dependent vasoconstrictor responses were altered with aging.

(No relevant relationships reported)

Diagnosis and treatment for coronary artery disease (CAD) includes angiography and/or percutaneous coronary intervention. However, catheterization may result in acute artery dysfunction and damage. Whilst exercise training is recommended for CAD patients following catheterization, it is not known if there is an acute period when exercise may be detrimental due to the prior catheterization. In support of this, animal models have demonstrated exercise-induced paradoxical vasoconstriction post catheterization. **PURPOSE:** This study, for first time in humans, aims to examine the vascular responses to acute exercise following catheterization. **METHODS:** 24 CAD patients (age: 66.1±7.1 years 31.9±7 kg/m², 83.3% males) undergoing transradial catheterization were assessed pre and 1 week post intervention. Endothelial function was assessed by radial artery (RA) flow mediated dilation (FMD) in both catheterized and control arm. Bilateral RA diameter and blood flow were assessed during handgrip exercise (HE), 3min stages at 5%, 10%, 15% of maximum voluntary contraction. Differences pre-post catheterization, between the catheterized and control arm, and between HE intensities were determined using mixed-linear model (SPSS 25). **RESULTS:** FMD was impaired in the catheterized arm [6.4% (5.0, 7.7) to 4.3% (2.9, 5.6)] but not in the control arm [6.5% (5.2, 7.8) to 6.5% (5.2, 7.9)], post catheterization (time*arm $p < .05$). There was a significant dose-dependent increase in blood flow with incremental exercise ($p < .001$). However, there was no difference in the exercise responses between arms or pre-post catheterization. Baseline RA diameter was higher in the catheterized arm post catheterization [0.28cm (0.26, 0.30) to 0.29 (0.28, 0.31) $p < .001$]. There was no dilation in the RA, in any condition, with increasing exercise intensity ($p > .05$). **CONCLUSION:** Endothelial function, assessed by FMD, was impaired 1 week post catheterization. Interestingly, the RA's ability to dilate with increased blood flow was not apparent pre or post catheterization. This suggests either that the artery does not dilate at these exercise intensities, or that these patients have an inherent impaired vasodilation. Further work is needed to examine this with different exercise intensities/modes and in different groups following catheterization.

Effect of Acute Hyperglycemia on Microvascular Hemodynamics and Tissue Oxygenation during Handgrip Exercise

Shane M. Hammer, Andrew M. Alexander, Kaylin D. Didier, Lillie M. Huckaby, Camryn N. Webster, Thomas J. Barstow, FACS. Kansas State University, Manhattan, KS.

(No relevant relationships reported)

Acute hyperglycemia elicits endothelial dysfunction at rest through reactive oxygen species-mediated damage to the endothelial surface layer (ESL). The ESL is associated with many of the mechanisms responsible for appropriate microvascular adjustments to exercise. **PURPOSE:** We tested the hypotheses that acute hyperglycemia would lead to 1) an 'overshoot' in deoxygenated heme concentration (deoxy-[heme]) at exercise onset reflecting greater fractional oxygen extraction and 2) less increase in total heme concentration (total-[heme]) during exercise reflecting less increase in microvascular hematocrit. **METHODS:** Three healthy young men (26 ± 4 yr) completed a 10-minute constant-load handgrip exercise test at 40% of peak power (9.6 ± 0.7 W) under control conditions (CON) and during acute hyperglycemia (HGL), i.e., 90-minutes after oral consumption of a 10 ounce solution containing 75g of dextrose. Near-infrared spectroscopy was used to measure deoxy-[heme] and total-[heme] of the flexor digitorum superficialis (FDS) continuously at rest and during exercise. **RESULTS:** Deoxy-[heme]_{CON} and total-[heme]_{CON} were significantly greater during exercise (189 ± 28 μM and 341 ± 34 μM, respectively) compared to rest (164 ± 13 μM and 302 ± 17 μM, respectively) ($p < 0.01$). Deoxy-[heme]_{HGL} and total-[heme]_{HGL} were significantly greater during exercise (181 ± 14 μM and 322 ± 27 μM, respectively)

compared to rest ($168 \pm 26 \mu\text{M}$ and $313 \pm 16 \mu\text{M}$, respectively) ($p < 0.01$). As a percent of steady-state (SS) values, deoxy-[heme]_{CON} was greater than deoxy-[heme]_{HGL} from 35s until 75s of exercise ($p < 0.05$). Deoxy-[heme]_{CON} and deoxy-[heme]_{HGL} were not different at SS. Total-[heme]_{HGL} was significantly lower than total-[heme]_{CON} at SS ($p < 0.01$). **CONCLUSION:** These data suggest that acute hyperglycemia leads to 1) increased fractional oxygen extraction at the onset of moderate-intensity handgrip exercise reflecting impaired perfusive oxygen delivery and 2) less of an increase in microvascular hematocrit reflecting impaired diffusive oxygen conductance during exercise steady state.

2926 May 31 4:05 PM - 4:15 PM

A Longitudinal Investigation On The Effect Of Age And Sex On Flow-mediated Dilatation In Children

Joey P. Bacauanu¹, Katharine D. Currie², Nicole A. Proudfoot¹, Brian W. Timmons¹, Maureen J. MacDonald¹. ¹McMaster University, Hamilton, ON, Canada. ²Michigan State University, East Lansing, MI.

Email: bacauaj@mcmaster.ca

(No relevant relationships reported)

Flow-mediated dilation (FMD) is a non-invasive assessment of arterial endothelial function. Previous cross-sectional analysis suggests resting arterial diameter and FMD increase throughout childhood, with no sex-based differences in FMD until girls exceed that of boys at 17-18 years old. No previous investigations included longitudinal examinations of the change in FMD over time, between boys and girls. **PURPOSE:** To assess the effects of age and sex on arterial diameters and FMD in school-aged children annually over a 3-year period. We hypothesized that resting arterial diameters will be larger in boys compared to girls at every time point and will increase each year, in both sexes. We also hypothesized that there would be no difference in FMD in girls versus boys over all 3 years as all of the children were tested younger than 17-18 years. **METHODS:** This observational study assessed 100 participants initially aged 8.5 ± 1.1 years, (range 6-10 years, 53 boys) annually for 3 years from the School-age Kids' health from early Investment in Physical activity (SKIP) study. The primary outcome was brachial artery FMD, which was measured using ultrasound technology. **RESULTS:** One-way repeated measures ANOVA was followed up with paired-sample t-test to compare mean differences between years. Two-way repeated measures ANOVA with sex as the between subjects' factor was used to determine interaction effects. Resting arterial diameter was largest across the cohort at year 3 ($2.8 \pm 0.28\text{mm}$) compared to year 1 ($2.7 \pm 0.30\text{mm}$, $p < 0.001$) and year 2 ($2.7 \pm 0.30\text{mm}$, $p < 0.001$). Contrary to our hypothesis, allometrically scaled FMD for boys was larger than girls (boys: 6.4 ± 3.09 , girls: $6.2 \pm 3.17\text{mm}$, $p = 0.002$) and no time differences were observed between years 1, 2 and 3 (year 1: 6.2 ± 3.11 , year 2: 6.2 ± 3.14 , year 3: $6.35 \pm 3.15\%$, $p = 0.67$). On average, boys had a larger resting arterial diameter compared to girls (boys: 2.8 ± 0.3 , girls: 2.6 ± 0.24 , $p = 0.001$). **CONCLUSION:** Differences observed in resting arterial diameter are driven by year 3 data and allometrically scaled FMD was larger in boys compared to girls, which may be explained by boys having larger resting arterial diameters compared to girls, and may also be accounted for by rapidly changing growth patterns in children. Funded by CIHR.

HIITing The Brain Enhances Cerebrovascular Shear Stress; The Link To Neuroprotection?

Damian M. Bailey¹, Takuro Washio², Kazuya Suzuki², Shigehiko Ogoh, FACSM². ¹University of South Wales, Pontypridd, United Kingdom. ²Toyo University, Kawagoe, Japan.

Email: damian.bailey@southwales.ac.uk

(No relevant relationships reported)

High-intensity interval exercise training (HIIT) is considered a more time-efficient alternative to moderate-intensity continuous training (MICT) that can optimize metabolic and cardiovascular health though its impact on the cerebrovasculature is unknown.

PURPOSE: Pilot examination to characterise local cerebrovascular shear stress responses during an acute bout of HIIT and MICT.

METHODS: Following ethics approval, 2 physically-active males (21-23 yrs) were randomly assigned to HIIT or MICT (semi-recumbent cycling) preceded by a standardized warm-up and separated by sufficient time to allow for full haemodynamic recovery. During HIIT, subjects performed 3 intervals (each consisting of 2 mins at 60W and 2 mins at 100W) and for MICT, isovolume work performed continuously at 80W for 12 mins. Diameter, blood flow and shear rate in the internal carotid artery (ICA) were measured using Doppler ultrasound at rest and averaged over the final 4 min of HIIT and MICT. The end tidal partial pressure of carbon dioxide (PET_{CO2}), heart rate (HR), mean arterial pressure (MAP) and oxygen uptake (VO₂) were recorded continuously photoplethysmography and respiratory gas analysis.

RESULTS: Exercise-induced increases in HR, MAP and VO₂ were comparable between HIIT and MICT and were accompanied by an equivalent, progressive

reduction in PET_{CO2}. In contrast, ICA diameter decreased more markedly during HIIT [Δ (exercise minus rest) HIIT: -0.15 mm vs. Δ MICT: -0.01 mm] with increased velocity (Δ HIIT: $7.75 \text{ vs. } \Delta$ MICT: $3.39 \text{ cm}\cdot\text{s}^{-1}$) and corresponding elevation in shear rate (Δ HIIT: $38 \text{ vs. } \Delta$ MICT: 9 s^{-1}).

CONCLUSIONS: These findings, albeit proof-of-concept, provide preliminary evidence highlighting a fourfold greater elevation in local cerebrovascular shear stress during HIIT compared to an equivalent volume of MICT. This is primarily attributable to local vasoconstriction that cannot be explained by hyperventilation-induced hypocapnia though likely represents a functional response coupling cerebral O₂ delivery to demand. To what extent repeated exposure to the intermittency of HIIT-induced cerebrovascular shear stress confers enhanced neuroprotection in the long-term is currently under investigation.

Impairments In Lower Limb Microvascular Function Associated With Cycle Phases In Young Healthy Women.

Rogério N. Soares, Anmol T. Mattu, Juan M. Murias. University of Calgary, Calgary, AB, Canada.

Email: rogerio.soares@ucalgary.ca

(No relevant relationships reported)

Impairments in lower limb microvascular function associated with cycle phases in young healthy women.

Rogério N Soares, Anmol T Mattu, Juan M Murias.

University of Calgary, Faculty of Kinesiology.

Purpose: Differences in women's hormone concentrations throughout the menstrual cycle affects vascular responsiveness. Previous investigations have shown that these changes can be modulated by regular use of oral contraceptives. However, most of these studies only assessed changes in vascular function at the upper limb conduit artery level. This study investigated whether vascular function at the lower limb microvasculature of healthy young women might be affected by the phase of the menstrual cycle. **Methods:** 14 young (25 ± 5 years of age) physically active women participated in the study. The participants were assigned to two groups of seven participants each according to oral contraceptive use: non-contraceptive group (women who did not use any contraceptive within the last two years prior to the intervention - NCP) and oral contraceptive group (seven women who used oral contraceptive regularly for at least two years prior to the intervention - OCP). The participants underwent two lower limb vascular occlusion tests (5 min of baseline, 5 min of occlusion, and 8 min following cuff release) in two different phases of the menstrual cycle (follicular and luteal phase). Microvascular responsiveness was assessed by the percent of change of the NIRS-derived muscle oxygen saturation (StO₂) reperfusion slope (%/sec) of the tibialis anterior muscle. **Results:** There was no difference in the reperfusion slope of the NCP group between the follicular ($1.18 \pm 0.5 \%$ /sec) and luteal ($1.01 \pm 0.3 \%$ /sec) phases. The reperfusion slope of the OCP group was significantly steeper in the follicular ($0.85 \pm 0.2 \%$ /sec) compared to the luteal phase ($0.63 \pm 0.2 \%$ /sec). **Conclusion:** Use of oral contraceptive is associated with reduced microvascular function in the luteal phase in young physically active women.

Vertical Jump and Agility Performance Improves After 8-week Conditioning Program in Youth Female Volleyball Athletes

William D. Hale¹, Roger O. Kollock¹, Jeff Pace². ¹The University of Tulsa, Tulsa, OK. ²Titan Sports and Performance Center, Tulsa, OK.

Email: wd1231@utulsa.edu

(No relevant relationships reported)

Volleyball athletes must employ specific conditioning exercises with high levels of force, high rates of speed, and quick changes-of-direction. Volleyball sport specific vertical jumping ability can be assessed through various types of vertical jumping protocols such as the block vertical jump (BVJ), the countermovement vertical jump (CMJ), and the two-step approach vertical jump (AVJ). Sport specific agility testing for volleyball can be assessed with a 9-cone (9C) test to determine the athletes' ability to generate quick and accurate movement with change-of-direction and/or acceleration and deceleration.

PURPOSE: The purpose of this study was to determine if an 8-week combined high intensity interval training and plyometric (HIIT-PT) conditioning program improves

performance on three vertical jump protocols and agility time in youth female volleyball athletes. **METHODS:** Eleven female youth volleyball players (ages: 15±2.7 yrs.; height: 68.2±1.3 in; mass: 143.5±14.8 lbs) completed an 8-week summer HIIT-PT conditioning program. The 8-week summer conditioning program consisted of combined 2 x week (60 min each) high intensity interval exercises and 2 x week (60 min each) plyometric exercises. Three vertical jump protocols (BVJ, CMJ, AVJ) and an agility test (9C) were administered at the beginning of the first week and at the end of week 8 of the summer HIIT-PT conditioning program.

RESULTS: Prior to data comparisons, a Kolmogorov-Smirnov test of normality was performed for each of the four variables and determined to be from a normal distribution (BVJ: $p = .096$, CMJ: $p = .200$, AVJ: $p = .187$, 9C: $p = .127$). A series of paired sample t-tests were performed to compare pretest and posttest vertical jump heights (inches) and agility times (seconds). All three vertical jump protocols significantly increased (BVJ: 14.6 vs 16.1, $p.000$; CMJ: 17.3 vs 18.4, $p.000$; AVJ: 21.0 vs 23.1, $p.001$) and agility times decreased (9C: 25.3 vs 23.6, $p.000$) following the 8-week HIIT-PT summer conditioning program. **CONCLUSION:** Results from this study indicate that employing an 8-week combined HIIT-PT conditioning program may improve jumping and change-of-direction outcomes in youth female volleyball athletes.

The Talk as a Measure of Exercise Intensity in Children
 Peter T. Gittings, Carl Foster, FACSM, Debra Szma, Cristina Cortis, Andrea Fusco, John P. Porcari, FACSM. *University of Wisconsin-La Crosse, La Crosse, WI.*
 Email: cfoster@uwlax.edu
 (No relevant relationships reported)

Purpose: The purpose of this study was to determine if the Talk Test (TT) is a valid measure of ventilatory threshold (VT) in children. **Methods:** Thirteen healthy children (age 8-12 y) performed maximal incremental exercise with respiratory gas exchange and with the TT. During the last 30 seconds of each stage they read a passage containing 100-106 words and were asked if they could "speak comfortably". Gas exchange was measured and was used to identify VT. Comparison measurements occurred at the last positive (LP), equivocal (EQ), and negative (NEG) stages of the TT. **Results:** There were significant ($p<0.05$) differences in VO_2 (VT vs LP and NEG stages; 0.95 ± 0.580 vs $0.71\pm0.284^*$ and $1.17\pm0.504^*$), HR (VT vs LP, EQ, and NEG stages; $136.0\pm19.0^*$ vs $126.3\pm12.91^*$ and $152.5\pm15.40^*$ and $160.5\pm16.28^*$), and RPE (VT vs LP and NEG stages; 5.2 ± 2.70 vs $3.6\pm1.32^*$ and $7.2\pm1.09^*$). **Conclusion:** It was concluded that the EQ stage of the TT is a valid measure of the exercise intensity at VT in children, as it is already known to be in adults.

Predicting Changes in Adolescent Muscle Mass with Field Testing
 Laura S. Kabiri¹, Wayne Brewer², Alexis Ortiz, FACSM³. ¹Rice University, Houston, TX. ²Texas Woman's University, Houston, TX. ³UT Health San Antonio, San Antonio, TX.
 Email: laura.kabiri@rice.edu
 (No relevant relationships reported)

With physical training and normal adolescent growth, gains in lean muscle mass can be seen among the healthy adolescent population. Assessing these gains is crucial to monitoring and adjusting training protocols and helping with client motivation and investment. However, the ability of common field tests to accurately predict changes in muscle mass among this population has yet to be proven. **PURPOSE:** The purpose of this study was to assess the ability of the standing long jump (SLJ) and 90° push-up (PU) test to accurately predict changes in lean mass (ΔLM) among healthy adolescents aged 12-18 years. **METHODS:** Forty-five healthy adolescents completed the standing long jump, 90° push-up test, and a full-body dual energy x-ray absorptiometry (DEXA) scan twice

with 7-10 months between test sessions. The difference in each outcome was calculated and used to indicate change. Field test predictive ability was evaluated using multiple regression and accounted for age (yrs), sex (female = 0, male = 1), height (cm), body mass, and pubertal stage using the Pubertal Development Scale (PDS).

RESULTS: A mean change of 2198.82 g of lean mass (range = -1193.60, 7307.70; SD = 1816.67) was shown using DEXA. The SLJ and PU had a mean change of 5.11 cm (range = -36.00, 35.70; SD = 16.40) and 0 repetitions (range = -13, 11; SD = 5.30) respectively. Both ΔSLJ ($r = .340, p = .011$) and ΔPU ($r = .315, p = .018$) had significant moderate relationships to ΔLM . The inclusion of ΔSLJ and ΔPU in the model accounted for an additional 8.8% of the variability ($R^2 = .551$ from .463) and 4.2% ($R^2 = .593$) respectively. The overall model explained 59.3% of the variability in lean mass change and resulted in the following predictive equation: $\Delta LM = 1237.59 + (-630.44 \times \text{age}) + (-169.34 \times \text{PDS}) + (847.31 \times \text{gender}) + (33.89 \times \text{height}) + (199.04 \times \text{BMI}) + (29.07 \times \Delta SLJ) + (73.13 \times \Delta PU)$

CONCLUSIONS: Along with anthropometric developmental factors, the SLJ and PU tests can be used to estimate changes in lean muscle mass. However, these factors only account for approximately 60% of the change in lean muscle mass leaving the remaining 40% attributable to other (neural, mechanical, motivational) factors. Nevertheless, this prediction equation can assist in monitoring changes in lean muscle mass during adolescence.

Relationship Between Physical Activity and Motor Skills in 3-5 year olds: National Youth Fitness Survey
 Aaron P. Wood¹, Satomi Imai², Amy Gross McMillan², Damon Swift², Katrina D. DuBose, FACSM³. ¹University of Tennessee, Knoxville, TN. ²East Carolina University, Greenville, NC. ³East Carolina University, Greenville, NC.
 Email: awood46@vols.utk.edu
 (No relevant relationships reported)

PURPOSE: The purpose of this study was to examine what kind of physical activity would have a positive relationship with motor skills in children through secondary data analysis.

METHODS: Data from children 3-5 years old (N=352, 179 males) who participated in the National Youth Fitness Survey (2012) were used. Included in this study were demographics, anthropometrics, physical activity questionnaire by parent report, and motor skill score determined by Test of Gross Motor Development-2nd Edition. Multiple regression was conducted to examine the relationship between physical activity and motor skills controlling for sex, race, and parent's socioeconomic status. **RESULTS:** The most commonly reported activities were running (43%), playing outdoor games (35%), and riding a bike (34%). Motor skills standard scores were locomotor (Mean (SE)=9.99 (.16)), object control (Mean (SE)=8.52 (0.14)), and gross motor skill (Mean (SE)=95.57 (.68)). Participation in the following activities were positively related to gross motor skill score: riding a bike (β (SE)=5.27 (2.02), $p=0.02$), scooter riding (β (SE)=9.83 (2.59), $p=0.002$), swimming (β (SE)=4.01 (1.17), $p=0.004$), and jumping on a trampoline (β (SE)= 7.45 (3.09), $p=0.03$). With the exception of riding a bike the activities positively related to gross motor skill score had a reported range of participation between 7-12%.

CONCLUSIONS: The key findings of this study indicated that participation in specific physical activities were related to gross motor skill score in preschool aged children. Further, it showed that with the exception of riding a bike the activities that the children participated in the most were not the same as those activities that were positively related to their gross motor skill score.

Tri-Ponderal Mass Index and Fitnessgram BMI Classification In Sixth-grade Children
 John L. Walker, FACSM¹, James Eldridge², Tinker D. Murray, FACSM¹, William G. Squires, Jr., FACSM³. ¹Texas State University, San Marcos, TX. ²University of Texas at Permian Basin, Odessa, TX. ³Texas Lutheran University, Seguin, TX.
 Email: jw18@txstate.edu
 (No relevant relationships reported)

To classify the health status of children, criterion standards for body composition and body mass index (BMI) have been established by FITNESSGRAM according to gender and age. Standards for aerobic capacity (AC) have also been established to assess cardiorespiratory function. Tri-Ponderal Mass Index (TMI) has been shown to better classify overweight and obesity than BMI in youth. **PURPOSE:** The purpose of this study was to determine the association between TMI and FITNESSGRAM BMI classification in sixth-grade children. **METHODS:** Subjects were 439 sixth-grade boys and girls, ages 11-13, who completed each of the FITNESSGRAM components as a part of their yearly assessment. In addition to height and weight, subjects' AC was determined from one-mile run/walk times, age, gender and BMI. 43% percent of these students were classified within the Healthy Fitness Zone (HFZ) for BMI. 42% percent of these students were classified as High Risk for BMI. **RESULTS:** The correlation

between TMI and BMI was .98, and the correlation between BMI and AC was -.82. The correlation between TMI and AC was -.80. Receiver Operating Characteristic (ROC) analysis indicated that a TMI of 13.97 represents the best cut-off score for classifying girls within the HFZ for BMI, with 94% classified correctly, and AUC = .98. Also, a TMI of 13.41 represents the best cut-off score for classifying boys within the HFZ for BMI, with 94% classified correctly, and AUC = .98. For determining High Risk classification for BMI, a TMI of 14.90 represents the best cut-off score for classifying girls as High Risk for BMI, with 96% classified correctly, and AUC = .99. Also, a TMI of 15.24 represents the best cut-off score for classifying boys as High Risk for BMI, with 94% classified correctly, and AUC = .98. **CONCLUSIONS:** TMI is strongly associated with classification according to FITNESSGRAM BMI standards in sixth-grade children. These data suggest that a TMI of 13.97 for girls and 13.41 for boys are the best criteria for HFZ classification for FITNESSGRAM BMI. Also, a TMI of 14.90 for girls and 15.24 for boys are the best criteria for High Risk classification for FITNESSGRAM BMI. TMI is a substantial factor in determining overweight and obesity, and body size has been shown to be an important health-related outcome, especially in youth.

A Comparison Of Health-related Fitness Variables Between Youths In Singapore And Taipei

Yew Cheo Ng¹, Govindasamy Balasekaran, FACSM¹, Stanley Sai-Chuen Hui, FACSM², Visvasuresh Victor Govindaswamy³, Jolene Lim¹, Peggy Boey¹. ¹Nanyang Technological University, Singapore, Singapore. ²The Chinese University of Hong Kong, Hong Kong, Hong Kong. ³Concordia University Chicago, Chicago, IL.

Email: yewcheo@gmail.com

(No relevant relationships reported)

Health-related fitness (HRF) variables may reduce cardiovascular risk factors if detected early in youths. A comparison between two similar high-density cities may reveal more information on their health status. **PURPOSE:** To compare HRF variables between youths in Singapore (SGP) and Taipei (TP).

METHODS: A total of 1559 youths from SGP (age: 13.49 ± 1.21 years, height: 159.76 ± 8.94 cm, weight: 51.91 ± 13.38 kg, Body Fat (BF) %: 21.51 ± 10.25 %) and 1620 youths from TP (age: 13.84 ± 0.91 years, height: 160.89 ± 7.86 cm, weight: 55.57 ± 13.35 kg, BF%: 23.29 ± 10.30 %) participated in this study. Body Mass Index (BMI) was calculated and BF% was measured by bio-electric impedance analysis. Aerobic fitness, lower limb flexibility, arm strength, and abdominal endurance were tested using the 15m youth Progressive Aerobic Cardiovascular Endurance Run (PACER) test, one-legged sit-and-reach (SRT), handgrip strength (HS) test, and 1-minute sit-up test (SUT) respectively.

RESULTS: Higher percentage of youths from TP were in the normal (TP: 54.88%, SGP: 46.89%) and overweight (TP: 18.15%, SGP: 12.70%) BMI range, while there was a higher percentage of underweight youths in SGP (40.41%) compared to TP (26.98%). Significant differences were found between SGP and TP for height (SGP: 159.76 ± 8.94 cm, TP: 160.89 ± 7.86 cm, $p < 0.0005$), weight (SGP: 51.91 ± 13.38 kg, TP: 55.57 ± 13.35 kg), BMI (SGP: 20.19 ± 4.21 kg·m⁻², TP: 21.35 ± 4.28 kg·m⁻², $p < 0.0005$), BF% (SGP: 21.51 ± 10.25 %, TP: 23.29 ± 10.30 %, $p < 0.0005$), SRT (SGP: 54.14 ± 10.15 cm, TP: 51.78 ± 11.29 cm, $p < 0.0005$), SUT (SGP: 38.94 ± 11.92, TP: 33.03 ± 9.71, $p < 0.0005$) and PACER (SGP: 40.93 ± 23.90 laps, TP: 37.75 ± 18.86 laps, $p < 0.0005$). No significant difference was found in HS between youths in both countries (SGP: 25.18 ± 7.77 kg, TP: 25.45 ± 7.33 kg, $p = 0.32$), with SGP having a lower obesity rate (SGP: 12.7%, TP: 18.15%).

CONCLUSIONS: Higher BMI and BF% values were found in TP as compared to SGP. While youths in both countries had similar arm strength, SGP youths had higher abdominal endurance, better flexibility and higher aerobically fitness as compared to TP youths. Youths from both countries have differences even with similar population density and should maintain their fitness health status through physical activities as this will help to reduce the risk of cardiovascular diseases in the future.

High Intensity Interval or Moderate Continuous Training in Health Indicators of Adolescents with Central Obesity

Fabricio Boscolo Del Vecchio¹, Flávio R. Guilherme², Wilson Rinaldi². ¹Federal University of Pelotas, Pelotas, Brazil. ²State University of Maringá, Maringá, Brazil.

Email: fabricioboscolo@gmail.com

(No relevant relationships reported)

PURPOSE: To evaluate the effects of HIIT and moderate intensity continuous training (MICT) on health indicators from adolescents with central obese.

METHODS: This is a randomized clinical trial, with three evaluations: baseline, after 8 and after 16 weeks. The sample was composed by 42 participants, randomized in two groups: HIIT (n = 22) and a MICT (n = 20). After 16 weeks of training (3 sessions/

week), 34 adolescents finished the program (HIIT, n = 21; MICT, n = 13). The HIIT group performed different models of interval training, progressively organized, and the MICT trained in a fixed intensity from 60 to 80% of HRmax. Anthropometrical data ([BMI, Waist Circumference [WC], Height Waist Ratio [HWR], Body Fat Percentage [%BF]), cardiorespiratory fitness (CRF), blood pressure (systolic and diastolic) and metabolic profile (fasting blood glucose [FBG], high density lipoproteins [HDL-C], low density lipoproteins [LDL-C], total cholesterol, non-HDL cholesterol and triglycerides [TG]) were analyzed.

RESULTS: Sixteen weeks of aerobic training resulted in significant reductions in BMI (HIIT = -4.5% [ES = -0.26] vs MICT = -3.9% [ES = -0.24]), WC (HIIT = -6.9% [ES = -0.64] vs MICT = -6.6% [ES = -0.61]), HWR (HIIT = -10.5% [ES = -1.00] vs MICT = -5.2% [ES = -0.50]), %BF (HIIT = -14.3% [ES = -0.59] vs MICT = -9.8% [ES = -0.40]), FBG (HIIT = -6.1% [ES = -0.65] vs MICT = -11.1% [ES = -0.89]) and non HDL cholesterol (HIIT = -14.5% [ES = -0.44] vs MICT = -11.0% [ES = -0.37]), and increased CRF (HIIT = 13.0% [ES = 1.77] vs MICT = 10.3% [ES = 0.76]). Only HIIT improved diastolic blood pressure (-17.0%, ES=-0.87), LDL-C (-13.3%, ES=-0.34) and total cholesterol (-11.9%, ES = -0.47), but only MICT changed positively TG (-23.4%, ES = -0.44). No changes were observed for systolic blood pressure and HDL-C. No differences were found in all variables between groups. Relating to inadequacy cases, both groups changed TG (HIIT = 20 to 11, MICT 13 to 6), but only HIIT decreased the number of adolescents in inadequacy from CRF and blood pressure (from 14 to 3). **CONCLUSIONS:** 16 weeks of HIIT or MICT positively impact anthropometrical variables, metabolic profile and CRF in obese adolescents.

2962 Board #8 May 31 2:00 PM - 3:30 PM

Physiological And Anthropometric Profiles Of Elite Teenage Cyclists In The United States

Michael J. Saunders, FACSM, David N. Lenzi, Nicholas D. Luden, Stephanie P. Kurti, Katherine R. Smith, Christopher J. Womack, FACSM. James Madison University, Harrisonburg, VA.

(No relevant relationships reported)

PURPOSE: Maximal oxygen consumption (VO_{2max}), power output at VO_{2max} (W_{max}), lactate threshold (LT), and several anthropometric characteristics are related to elite cycling performance in adults. These factors may change during adolescent development, yet little is known about how values among teenage cyclists compare to their adult counterparts. Low bone mineral density (BMD) has also been reported in competitive adult road cyclists versus recreationally active controls, but BMD in younger cyclists has not been thoroughly investigated.

METHODS: We examined variables from a graded exercise test (LT, VO_{2max} , W_{max}) and anthropometric characteristics (height, weight, % fat) in 8 elite male teenage cyclists (16.8 ± 1.4 y) and compared them to junior Italian cyclists and professional cyclists in the literature. BMD was also measured via DXA, and compared to age-specific norms.

RESULTS: Our cohort possessed comparable absolute/relative VO_{2max} (4.6 ± 0.7 L/min; 74.9 ± 6.6 mL/kg/min) and W_{max} (375 ± 67 W; 6.1 ± 0.7 W/kg) values to previously studied junior Italian cyclists, with inter-study differences potentially explained by different rider specializations and competitive-levels, and methodological differences between studies. Our teenaged cyclists were smaller (176 ± 6 cm), lighter (61.5 ± 5.0 kg), and had lower absolute VO_{2max} and W_{max} than professional adult cyclists in prior studies. Total BMD values (1.142 ± 0.088 g/cm²), and values for the spine, femur, and femoral neck were all > 50th percentile for age/sex.

CONCLUSIONS: The largest differences in exercise responses between competitive teenage and adult cyclists were in absolute aerobic power (rather than per kgBW), which would presumably diminish with any further increases in size/mass with maturation in young cyclists. The healthy BMD levels in this group could be related to age, or to mountain biking and other cross-training completed by this group of athletes.

The Chinese Assessment Of Motor Quotient: Methods For Children In 7 To 9 Years Old

Jindong Chang¹, Xiaolei Liu², Wei Liu³, Naiqing Song⁴. ¹Southwest University, Chongqing, China. ²High School Affiliated to Southwest University, Chongqing, China. ³Xuzhou Kindergarten Teachers College, Xuzhou, China. ⁴The Branch of the Collaborative Innovation Center of Assessment toward Basic Education Quality at Southwest University, Chongqing, China.

Email: changlai@163.com

(No relevant relationships reported)

PURPOSE: Motor quotient is described as an index of the present rate of development and, possibly, predicts future development. As such, it is expected that those who have greater motor quotient would be more likely to obtain the health benefits offered by habitual physical activity. A theoretical model and assessment frame, the Chinese

Assessment of Motor Quotient (CAMQ), for the assessment of childhood motor quotient had been proposed in theory, but validity data were lacking. The purpose of this study was to explore validity evidence for the CAMQ among children 7 to 9 years.

METHODS: The CAMQ validity was evaluated through two analyses that utilized cross-sectional data obtained through local schools in Chongqing, China. A confirmatory factor analysis (CFA) compared the data to the theoretical model. Patterns of association between age and gender and the CAMQ total and domain scores were examined using regression models. The CAMQ was completed by 572 children (53 % male) in 7 to 9 years (mean 8.2 years), with all guardian of children approached agreeing to participate.

RESULTS: The CAMQ model included three domains: physical competence (fitness), athletic performance (motor skill) and motor behavior (motivation). Using CFA analyzed the validity data 557 children with complete raw scores. The results showed the $\chi^2/df=2.79$, GFI = 0.96, CFI=0.95, NFI=0.93, TLI= 0.95, RMSEA=0.05. Regression models showed that interpretive categories, developed from age and gender-adjusted normative data, were not associated with age indicating that the CAMQ is suitable for use across this age range. Children's gender was associated with physical competence and athletic performance domain scores, indicating that further research is required regarding the gender adjustment of the raw CAMQ scores.

CONCLUSIONS: The CAMQ offers a comprehensive assessment of physical competence, athletic performance, and motor behavior as components of children motor quotient (7 to 9 years). Monitoring of these measures enhances our understanding of children's motor quotient and assists with the identification of areas where additional supports are required.

ACKNOWLEDGEMENT: Supported by NPOSS 15CTY011, Humanities and Social Sciences by Ministry of Education 17YJC890020, and Fundamental Research Funds for the Central Universities 1709240.

(No relevant relationships reported)

Poor health status in childhood has been documented to persist into adulthood, reducing quality of life. **PURPOSE:** To understand the fitness levels in adolescents between three countries that share similarities in race and culture.

METHODS: A total of 4736 healthy adolescents (age: 13.79 ± 0.93yrs, height: 162 ± 8.21cm, weight: 54.79 ± 12.82kg, BF%: 22.25 ± 10.00%) were recruited for the intervention from Shanghai (SH) (n=1586), Hong Kong (HK) (n=1530) and Taipei (TP) (n=1620). Anthropometric measurements were taken on the same day. Participants took their percent body fat (BF%) with a bio-impedance analysis, and handgrip strength test (HGS) with a hand dynamometer. Flexibility, abdominal muscular strength, and cardiovascular fitness (CF) were measured with one-legged sit and reach test (SRT), one-minute sit-up test, and 15m PACER test respectively.

RESULTS: One-way ANOVA showed significant differences between the three countries for height (SH: 164.4 ± 7.83cm, HK: 160.7 ± 8.40cm, TP: 160.89 ± 7.86cm; p < 0.0005), weight (SH: 56.48 ± 12.24kg, HK: 52.2 ± 12.44kg, TP: 55.58 ± 13.35kg; p < 0.0005), BF% (SH: 22.23 ± 9.64%, HK: 21.16 ± 10.00%, TP: 23.3 ± 10.30%; p < 0.0005), HGS (SH: 55.53 ± 14.09kg, HK: 51.94 ± 13.90kg, TP: 50.86 ± 14.67kg; p < 0.0005), abdominal muscular strength (SH: 36.20 ± 9.24 reps, HK: 30.56 ± 10.14 reps, TP: 33.03 ± 9.71 reps; p < 0.0005) and CF (SH: 40.11 ± 16.05 laps, HK: 35.48 ± 18.44 laps, TP: 37.77 ± 18.86 laps; p < 0.0005). Kruskal-Wallis Test analyzed results of SRT showed significant difference between the three countries (SH: 54.96 ± 9.70cm, HK: 49.61 ± 12.03cm, TP: 51.79 ± 11.29cm; p < 0.0005). Significant differences were observed in the inverse relationship between BF% and CF (r = -0.46; p < 0.0005), BF% and abdominal strength (r = -0.30; p < 0.0005) and a positive linear relationship between abdominal strength and CF (r = 0.54; p < 0.0005).

CONCLUSIONS: Adolescents from Shanghai, Hong Kong and Taipei are vastly different in all health-related fitness variables which could be attributed to environmental and social factors. However, they are generally healthy and fit with good BF% level and CF. Adolescents should continue to be exposed to regular physical activities to maintain and improve fitness status. This would prevent unwanted cardiovascular diseases in future which would lead to higher quality of life.

The Effects of Plyometric or Combined Training on Kicking Time in Teenager Taekwondo Athletes

Adrián Chacón Araya, Pedro Carazo-Vargas. *University of Costa Rica, San José, Costa Rica.*

Email: pedro.carazo@ucr.ac.cr

(No relevant relationships reported)

Purpose: To compare the effectiveness of a general plyometric training (GP) and a GP plus transfer exercises (GP + TE) on kicking time (KT) in cadet and junior taekwondo athletes. **Methodology:** Volunteers were 33 athletes between 12 and 17 years old and taekwondo practice experience of 3.0 ± 1.2 yr. Participants were randomly assigned to GP, GP+TE, or a control (CON) group, and underwent a 3-week intervention, training 3 times per week. The training session was divided into a stretch, a general warm-up and the treatment phase, according to the specifications for each group, each lasting approximately 10-min. Following the intervention, the athletes completed their regular training. The exercises performed by the participants only differed in the 10-min lasting the intervention. The GP group completed 8 sets of 6 repetitions of countermovement jumps (CMJ), the GP+TE completed the same exercise exercises as the GP group immediately followed by a taekwondo kicking technique on a kicking pad. The CON group only performed static stretching. A Fitlight Trainer System was used to measure before and after KT performance. For the KT drill, the athlete was instructed to use the dominant leg in a circular kick ("Bandal Chagui") and in a frontal kick ("Miroto Chagui"). The front leg was used for both kicks, and the first sensor of the measurement system was located at ankle height to start the time and a second sensor was located at the height of the performer's navel to stop the time and register the KT. A 3 x 2 (groups x measurements) general linear model ANOVA was used to analyze KT. **Results:** No significant interaction or main effects were shown on circular kick KT scores (p > 0.05). A significant measurement main effect was found on frontal kick KT (F = 4.743, Pre = 0.354 ± 0.004s vs. Post = 0.344 ± 0.004s; p < 0.037) regardless of the experimental group. **Conclusion:** The GP and the GP+TE training elicited similar improvements in frontal kick KT in cadet and junior taekwondo athletes. Circular kick KT was unaffected by training.

Which Is Better In Physical fitness Between Obese And Lean Young Children?

Kosho Kasuga¹, Takahiro Nakano², Tomoaki Sakai². ¹Gifu University, Gifu, Japan. ²Nagoya Gakuin University, seto, Japan.

(Sponsor: kiyoji tanaka, FACSM)

Email: kasuga@gifu-u.ac.jp

(No relevant relationships reported)

[Introduction] The number of children being diagnosed with infant metabolic syndrome is also on the rise. Moreover, an increase in the prevalence of lean children is also beginning to be seen in recent years.

[Purpose] This study aims to examine the characteristic of physical fitness according to level of obesity index among young children from the age of three to six by using a large-scale dataset.

[Methods] The subjects included 5640 young children (2840 boys and 2800 girls). We administered physical fitness tests comprising seven types of exercises (grip strength, standing long jump, softball throw, 25-m run, side-step, upright hand standing time, and sitting trunk flexion) to gauge the children's state of physical fitness. A T-score was calculated on the basis of the mean and standard deviation according to sex and age, and this score was used as an individual score of physical fitness. Children were divided into seven groups on the basis of the obesity index (~15%, -15%~-5%, -5%~0%, 0%~+5%, +5%~+15%, +15%~+20%, +20%~). Further, the extent of differences among children with different obesity index was examined for each type of exercise. To conduct a statistical analysis of the data, one-way ANOVA and multiple comparisons (Tukey's HSD test) were employed.

[Results]The analysis revealed a significant difference among the groups for all the exercises. In the 25-m run, standing long jump, and upright hand standing time, "+20% or more" group had the lowest scores. In the softball throw, sitting trunk flexion, side-step, grip strength, and overall physical fitness, "-15% or less" group scored the lowest.

[Discussion]The physical fitness of obese (+20%~) and lean (~15%) children was found to be poor. In the lean children, the reason is thought to be low muscle mass and underdevelopment due to a lack of physical activity. Moreover, their low expenditure of energy is suspected to result in a low appetite, which can lead to poor nutrition. On the other hand, the severely obese children (+20 or more) may be undeveloped due to their lack of physical activity and excessive and imbalanced diet. However, the mildly obese (up to +15%) are not physically underdeveloped at infancy. They do not need extreme obesity prevention measures, and it is important for them to acquire a "play a lot, eat a lot" lifestyle.

Unit Characteristics Of Physical Activity Intensity In Physical Education Lesson Among Elementary School
 Kenta Otsubo¹, Kosho Kasuga². ¹*Gifu University graduate school, Gifu, Japan.* ²*Gifu University, Gifu, Japan.* (Sponsor: Kiyoji Tanaka, FACSM)
 (No relevant relationships reported)

[PURPOSE] This study aimed to measure the intensity of a given physical exercise during an elementary school level physical education class.
 [METHODS] The subjects of this study were 28 elementary school children (16 boys and 12 girls) in the 5th grade. To measure exercise intensity, a Lifecorder GS (manufactured by SUZUKEN Co., Ltd) was used. There were five target units of exercise including long jump, expression, tag rugby, hurdle run, and Tee-ball. The length of each class as well as the proportion of each exercise were measured according to the period recording method (Instruction, Management, Motor learning, Cognitive learning). To assess the difference in intensity across each of the five units of exercise, the coefficient of variation (CV) was calculated. A corresponding one-way analysis of variance and a multiple comparison test were used for clarification. In addition, when Bartlett's test was applied and a significant main effect was observed, a test of equal variances between the two groups was used.
 [RESULTS] Regarding individual differences in exercise intensity, significant differences were found between tag rugby and both tee balls and long jump, as well as between expression and long jump. The coefficient of variation was calculated as follows: expression (29%), tag rugby (27%), Tee-ball (25%), hurdle run (18%), long jump (17%). In addition, differences in units were significantly higher in exercise intensity between hurdle run and tag rugby, expression and tee ball, as well as between long jump and Tee-ball.
 [CONCLUSIONS] In physical education classes, there is a difference in physical activity among the five exercises measured, and it is presumed that the magnitude of these differences varies depending on the individual exercise. That such individual differences exist in physical education classes is, in itself, not a problem. However, this would become undesirable in any situation in which the difference becomes large, thus failing to ensure consistency in the amount of physical activity and potentially resulting in children performing less physical activity. In order to secure a consistent level of activity intensity in physical education lessons, it is necessary to take measures for children with less physical activity.

Physical Fitness Level And Personality Traits At Age Six: Longitudinal Relationship With The Big Five
 Hiromu Nozue¹, Kosho Kasuga². ¹*Gifu University graduate School, Gifu, Japan.* ²*Gifu University, Gifu, Japan.* (Sponsor: kiyoji tanaka, FACSM)
 (No relevant relationships reported)

[PURPOSE] To examine the longitudinal change of the Big Five factors of personality in children aged six years with high and low physical fitness (PF) levels.
 [METHODS] The participants were 186 six-year-old children (87 boys, 99 girls). To measure PF level, PF tests for young children were conducted. Principal component analysis was performed for the seven PF test parameters, and the first principal component scores were converted into T scores classified by sex and age (categories spanning 0.5 years), which were treated as overall PF scores. To investigate children's personalities with regard to the Big Five factors of personality, a questionnaire survey was administered to the children's teachers. The five main factors of personality traits were "openness(O)," "conscientiousness(C)," "neuroticism(N)," "extraversion(E)," and "agreeableness(A)." Based on the overall PF score at age six we divided the participants into a higher PF level group (upper 25%, 47 participants) and lower PF level group (lower 25%, 47 participants). We conducted a two-factor analysis of variance (PF level × age) that corresponded to only one factor concerning the evaluation. When a significant main effect was observed, multiple comparison test (Tukey's HSD) was conducted. The statistical significance level of this study was less than 5%.
 [RESULTS] "O" was significantly higher in the higher PF level group at ages five and six. "C" and "E" were significantly higher in the higher PF level group at ages four and six. "A" was significantly higher at ages four, five, and six in the higher PF level group. For "A," a significant difference was found between the age of four and six and five and six in both groups, and for "E," a significant difference was observed only in the higher PF level group, between the ages of four and five, four and six, and five and six.
 [CONCLUSION] It was suggested that "A" and "E" are particularly fostered from the ages of five to six. It was inferred that personality characteristics were nurtured through physical activities such as athletic play, which involve communicating with multiple persons and obeying rules.

Relationship Between Physical Fitness Characteristics Of Girls And Attitudes And Preference For Exercise
 Azusa Hamaguchi¹, Kosho Kasuga². ¹*Gifu University Graduate School, Gifu, Japan.* ²*Gifu University, Gifu, Japan.* (Sponsor: Kiyoji Tanaka, FACSM)
 (No relevant relationships reported)

PURPOSE: The purpose of this study is to investigate the relationship between physical fitness characteristics of girls and their attitudes toward and preference for exercise and physical education.
 METHODS: The participants of this study were 181 public elementary school girls, ranging from third grade to sixth grade. Eight items of a physical fitness test were divided by grade, and we calculated T-scores; the average T-scores of the eight items was taken as the total physical fitness score. An upper group of physical fitness was established for those that scored in the upper 25% (45 people); the lowest 25% (45 people) made up the lower group of fitness. These two groups were analyzed. A questionnaire survey was conducted using a five-point scale for the investigation of attitude and preference of exercise and physical education.
 In order to investigate the difference between the attitudes toward and preference for exercise and physical education between the two groups, an independent t-test was used.
 RESULTS: Statistical analysis of survey results demonstrated that 31 out of 40 items showed a significant difference. Among them, for items such as "I don't want to get tired," "I am not interested in exercise," "I dislike feeling inferior," "I don't want people to know about my abilities," and "I don't want my friends to get angry when I can't do something well," the lower group reported higher scores than the upper group.
 CONCLUSIONS: Based on physical fitness level, the upper group and the lower group displayed very different thinking processes about exercise and physical education. It is particularly conceivable that girls with inferior physical fitness have negative thoughts about exercise. In addition to this, girls with inferior physical fitness was suggested that tends to extremely dislike to be seen movement and to be evaluated by someone.

Physical Activity And Physical Fitness Characteristics Of Young Children With Extended-hours Childcare
 Kirara Minami. *Gifu University Graduate School, Gifu, Japan.* (Sponsor: kiyoji tanaka, FACSM)
 (No relevant relationships reported)

[Purpose] This study aimed to clarify the difference between the amount of physical activity obtained and the physical fitness characteristics of infants in extended child care and those not in extended childcare.
 [Method] Forty-two aged 6years-old children enrolled in a private kindergarten participated with 21 of those having used extended childcare for two years or three years (the use group), and 21 who had not used it (the non-use group). The amount of physical activity the infants engaged in was measured using Panasonic's Day calorie. For physical fitness and exercise ability, we conducted an infant physical fitness test and calculated the T score by gender and age (0.5 year categorizations) from the results of the seven items measured; the average T score of seven items was taken as the total physical fitness score. A t-test that did not correspond to the comparison between the number of steps and the total physical fitness score within the normal amount of childcare time of the use group and the non-use group was applied. In addition, Pearson's correlation coefficient was used to examine the relationship between the use group and the non-use group's physical activity levels and overall physical fitness scores.
 [Results and Discussion] The results of the analysis found that there was no significant difference in amount of physical activity and physical strength/exercise ability between the use group and the non-use group. Regardless of whether extended-hours childcare use is used or not, it appears that the same tendency was shown because all of the children are doing the same activities during regular childcare hours. On the other hand, the extended-hours childcare children showed 2,335.84 steps per hour, so it is possible that extended-hours childcare is playing an important role in securing the amount of physical activity.

Seasonal Variation In Physical Activity Levels Among Elementary School Children In The Arctic Areas.
 Karin H. Danielsen, Gunnar E. Mathisen, Thilde K. Vårnes, Edvard H. Sagelv, Kim Arne Heitmann. *UiT The Arctic University of Norway, Tromsø, Norway.*
 Email: karin.danielsen@uit.no
 (No relevant relationships reported)

PURPOSE

To compare elementary school children's physical activity levels during two different seasons in Northern Norway.

METHODS:

Elementary school children from 1st, 3rd, 5th and 7th grade were recruited to wear an accelerometer (GT3X-BT, ActiGraph, LLC, Pensacola, United States) for seven consecutive days during two different seasons: The winter season in November ($n=235$), and the summer season in June ($n=214$). The primary physical activity outcome was measured as total counts per minute and time spent at different activity intensities. We defined moderate-to-vigorous physical activity (MVPA) as >2000 counts per min, as previously used (Ekelund et al., 2004).

RESULTS

Girls had more counts per min during the measured week in the summer season (616 ± 380.5) compared to the winter season (589 ± 124.8) ($p<0.001$), while there was no significant differences among boys. Boys spent more time in MVPA during the winter season (71.5 minutes \pm 26.7) compared to the summer season (61.5 minutes \pm 12.9) ($p<0.05$). Children in 7th grade spent more time in MVPA during the winter season (64.6 minutes \pm 26.1) compared to the summer season (44.9 minutes \pm 23.6) ($p<0.001$). There were no differences between sexes for time spent in MVPA or counts per min ($p<0.05$) during the winter season, except for counts per min in 1st grade ($p<0.05$). During weekdays in the winter season, 53.1% of the children reached MVPA of ≥ 60 minutes physical activity daily. In weekdays during the summer season, 62.5% of the children reached MVPA ≥ 60 minutes.

CONCLUSION Girls had more counts per minute during the summer season compared to the winter season, but there were no differences in time spent in MVPA. Boys spend more time in MVPA during the winter season compared to the summer season. 62.5% met the recommended 60 min per day of MVPA during the summer compared to the winter where 53.1% met the recommendations.

2972 Board #18 May 31 2:00 PM - 3:30 PM Associated Factors To Health Risk Behaviors in Adolescent's Athletes

Jhonatan Gritten Campos, Michael Pereira da Silva, Thiago Silva Piola, Ana Beatriz Pacifico, Nicolau Augusto Malta Neto, Wagner de Campos. *Universidade Federal do Paraná, Curitiba - Paraná, Brazil.* (Sponsor: Carlo Baldari, FACSM)
Email: jhonatantec@hotmail.com

(No relevant relationships reported)

PURPOSE: To verify associated factors with health risk behaviors (HRB) in Brazilian adolescents' athletes. **METHODS:** Cross-sectional study, with 367 athletes (15.68 \pm 0.78 years) from Curitiba/PR/Brazil. The HRB evaluated were: insufficient levels of physical activity, high TV and videogame time, low consumption of fruits and vegetables, consumption of alcohol, tobacco and illicit drugs, sexual and violent behavior. Investigated associated factors were: sex, age, socioeconomic status, type of sport, years of training and weekly training volume, evaluated through questionnaires. Poisson regressions analyzed the factors associated with HRB, adopting $p<0.05$. **RESULTS:** The collective sport (PR: 3.11, 95% CI: 1.13-8.58) and years of practice (PR: 1.14, 95% CI: 1.01-1.29) were positively associated to high TV time. For the high videogame time, inverse associations were seen for age (PR: 0.59, 95% CI: 0.39-0.89) and for the weekly training volume (PR: 0.92, 95% CI: 0.86-0.99), but not for years of practice (PR: 1.12, 95% CI: 1.01-1.25). For vegetable consumption, inverse associations were seen for the weekly training volume (PR: 0.98, 95% CI: 0.96 - 0.99). Age was positively associated with mild (PR: 1.64, 95% CI: 1.32-2.03) and excessive (PR: 1.82, 95% CI: 1.34-2.48) alcohol consumption. On the other hand, inverse associations were seen for the weekly training volume and mild (PR: 0.95, 95% CI: 0.92-0.99) and excessive (PR: 0.94, 95% CI: 0.89 - 0.99) alcohol consumption. Positive associations were seen for age (PR: 9.59; 95% CI: 3.36-27.38) and weekly training volume (PR: 1.20; 95% CI: 1.01-1.45) for tobacco consumption, and age for illicit drug use (PR: 18.08; 95% CI: 3.38-56.65). Girls were less likely to have sexual (PR: 0.28, 95% CI: 0.08-0.94) and violent (PR: 0.23, 95% CI: 0.08-0.62) risk behaviors. **CONCLUSIONS:** It was observed that characteristics of sports practice, such as years of practice and weekly training volume may favor healthy behaviors such as a lower videogame time, alcohol consumption and increased consumption of vegetables in adolescent's athletes.

2973 Board #19 May 31 2:00 PM - 3:30 PM Comparison Of Physical Activity, Cardiovascular Endurance And Perception Of Quality Of Life Between Adolescents Engaged And Non-engaged In After School Sports Program

Ana Beatriz Pacifico¹, Edina Maria De Camargo¹, Thiago Silva Piola¹, Jhonatan Gritten Campos¹, Gislaiane Cristina Vagetti², Valdomiro De Oliveira¹, Wagner De Campos¹. ¹Universidade Federal do Paraná, Curitiba - Paraná, Brazil. ²Universidade Estadual do Paraná, Curitiba - Paraná, Brazil. (Sponsor: Carlo Baldari, FACSM)
Email: ana_pacifico@hotmail.com

(No relevant relationships reported)

Objective: To compare the level of physical activity, cardiovascular endurance and perception of quality of life of male and female adolescents, of three different groups: 1) engaged in after school sports programs; 2) engaged in any other type of regular physical exercise; 3) not engaged in any type of formal physical exercise. **Methods:** The sample consisted of 374 adolescents, 198 boys (16.35 \pm 0.65) and 176 girls (16.19 \pm 0.67). The QAFA questionnaire was used to evaluate the level of physical activity (min/week) and the Pacer test for cardiovascular endurance (VO_{2max}). The KIDSCREEN-52 was used to evaluate perception of quality of life. Anova's One-way and post hoc Scheffé were used for the comparisons, with $p<0.05$. **Results:** non-exercising adolescents presented lower levels of physical activity (Boys: 471.72 \pm 570.07 min/week; Girls: 332.09 \pm 359.22 min/week) and cardiovascular endurance (Boys: 36.41 \pm 4.70 ml/kg/min; Girls: 31.16 \pm 3.23 ml/kg/min) when compared to those engaged in after school sports programs (Boys: 1074.17 \pm 733.98 min/week; 40.15 \pm 6.50 ml/kg/min; Girls: 985.00 \pm 634.95 min/week; 33.46 \pm 4.70, respectively) and other type of regular physical exercise (Boys: 866.89 \pm 572.45 min/week; 38.49 \pm 5.45 ml/kg/min; Girls: 635.43 \pm 467.78 min/week; 32.96 \pm 4.5 ml/kg/min, respectively), $p<0.01$. Boys (77.51 \pm 8.45 points) and girls (74.84 \pm 8.90 points) engaged in after school sports program had higher scores for perception of quality of life when compared to boys (72.74 \pm 9.15 points) and girls (74.18 \pm 6.95 points) engaged in other type of physical exercise and non-exercise boys (72.18 \pm 10.31 points) and girls (69.98 \pm 9.35 points), $p<0.05$. **Conclusion:** adolescents engaged in after school sports programs presented higher levels of physical activity, cardiovascular endurance and better perception of quality of life. Support: Fundação Araucária

2974 Board #20 May 31 2:00 PM - 3:30 PM Relationship Between Physical Fitness Level At Age 6 And Motivation And Perseverance

Rio Kojima¹, Kosho Kasuga². ¹Gifu University graduate school, Gifu, Japan. ²Gifu University, Gifu, Japan. (Sponsor: Kiyoji Tanaka, FACSM)

(No relevant relationships reported)

[Purpose]

The purpose of this study was to investigate the relationship between physical fitness (PF) level at the age of 6 and longitudinal change of motivation (M) and perseverance (P).

[Methods]

The participants were 186 young children (87 boys and 99 girls). For measuring PF, PF tests for young children were conducted. Principal component analysis was performed for the seven PF test parameters, and first principal component scores were converted into T-scores classified by sex and age (categories spanning 0.5 years), which were treated as overall PF scores. The upper 25% of the overall PF scores was classified as a higher PF level group (47 participants), and the lower 25% of the overall PF scores was classified as a lower PF level group (47 participants). In addition, in order to objectively investigate young children's personalities with regard to "M" and "P", a questionnaire survey was administered to the young children's schoolteachers.

A two-factor analysis of variance (PF level group \times grade) that corresponded to only one factor concerning the evaluation was conducted. Multiple comparison tests (Tukey's HSD) were performed for all observed significant main effects. The statistical significance level of this study was less than 5%.

[Results]

With respect to "M" and "P", the results showed no significant interaction between PF level and grade; however, a significant main effect was observed between the PF level groups and grade.

The multiple comparison test between the PF level groups showed that "M" and "P" were significantly higher in the higher PF level group, and it is motivated at the ages of 4 (0.477), 5 (0.631), and 6 (0.870), the patience. In terms of strength, the effects increased at the ages of 4 (0.655), 5 (0.904), and 6 (1.232).

The multiple comparison test between the grade levels showed that both "M" and "P" were significantly higher in the higher PF level group at age 6 than at age 4 and at age 5.

[Discussion]

Infants with high PF at the age of 6 show high "M" and "P" at the age of 4. Further, the difference widens with successive grade levels, thereby suggesting that the bipolarization of "M" and "P" originates in early childhood.

and are negatively influenced by BF. Further studies addressing the variation in growth characteristics and health behaviors that potentially influence muscle power during childhood are needed. Supported in part by FIPI/DEGI/UPRRP.

Acute Cardiometabolic Responses to Integrative Neuromuscular Training in Children

Avery D. Faigenbaum, FACSM, Jie Kang, FACSM, Nicholas A. Ratamess, Anne Farrell, Mina Belfert, Sean Duffy, Cara Jensen, Jill A. Bush, FACSM. *The College of New Jersey, Ewing, NJ.*
Email: faigenba@tcnj.edu

(No relevant relationships reported)

Integrative neuromuscular training (INT) is a method of conditioning that includes strength and conditioning exercises which are designed to enhance both health- and skill-related components of physical fitness. While previous investigations have examined the effects of INT on performance, the acute cardiometabolic responses to INT have not been examined. **PURPOSE:** To examine the acute cardiometabolic responses to a specific INT protocol and to compare these responses to a bout of moderate intensity treadmill (TM) walking in children. **METHODS:** 14 children (10.7±1.1 yr) were tested for peak oxygen uptake (VO_2) and peak heart rate (HR) on a maximal TM test and subsequently participated in 2 experimental conditions on nonconsecutive days: a 12-min INT protocol of 6 exercises and a 12-min TM walking protocol at 50% $\text{VO}_{2\text{peak}}$. The INT protocol included balance board squats (EX1), medicine ball squats with toss (EX2), planks with side step (EX3), medicine ball forward lunges (EX4), battling rope double arm waves (EX5) and medicine ball slams (EX6). Each INT exercise was performed twice for 30 sec with a 30-sec rest interval between sets and exercises. Participants performed the INT and TM protocols while connected to a metabolic system and HR monitor. **RESULTS:** Throughout INT mean HR significantly increased from 121.1±9.0 b·min⁻¹ during EX1 to 183.5±7.9 b·min⁻¹ during EX6 and mean VO_2 significantly increased from 14.9±3.6 ml·kg⁻¹·min⁻¹ during EX1 to 33.3±6.0 ml·kg⁻¹·min⁻¹ during EX6 ($p<0.05$). Mean HR and VO_2 values during INT ranged from 60.9% to 92.4% of HRpeak and from 28.1% to 63.0% of $\text{VO}_{2\text{peak}}$, respectively. During the TM condition, mean HR and VO_2 values ranged from 121.1±11.7 b·min⁻¹ to 150.4±17.3 b·min⁻¹ and from 19.2±2.5 ml·kg⁻¹·min⁻¹ to 26.8±6.2 ml·kg⁻¹·min⁻¹, respectively. Mean HR and VO_2 values were significantly higher during EX5 and EX6 of INT than during the same time intervals of TM walking ($p<0.05$). **CONCLUSION:** These data indicate that INT can pose a moderate to vigorous cardiometabolic stimulus in children, and selected INT exercises are more intense than moderate intensity walking.

Longitudinal Assessment of Peak Power During Childhood

José M. Santo Domingo-Vélez¹, Farah Ramírez-Marrero, FACSM², Lucia del R Martínez-Colón². ¹University of Puerto Rico - Bayamon, Bayamón, Puerto Rico. ²University of Puerto Rico - Rio Piedras, San Juan, Puerto Rico. (Sponsor: Farah Ramírez-Marrero, FACSM)
Email: jose.santodomingo1@upr.edu
(No relevant relationships reported)

Factors influencing peak power (PP) during childhood are still unclear. Even though physical activity in children consist mostly of high intensity short burst movement, there are limited longitudinal studies assessing PP during childhood. **PURPOSE:** To evaluate PP in children and identify the possible influence of sex and body fat (BF). **METHODS:** Forty-four children (24 girls and 20 boys), were evaluated in 1st grade and for the next four consecutive years (mean group age on the first and last evaluation: 6.4±0.5, and 10.5±0.5 years respectively). Counter-movement vertical jump height (JH) was determined using an electronic platform and converted to PP(W) using Canavan & Vescovi's equation. Height and weight were measured, and triceps and calf skinfolds were also measured for BF estimate. Repeated measures ANOVA were performed to determine differences in all variables by grade and Pearson correlations to evaluate relationships between BF, JH, PP and relative peak power (RPP). Independent sample t-test was used to detect differences between sex. **RESULTS:** JH increased between grades, being significant between 2nd, 3rd and 4th grade (27.1±4.3, 28.4±4.2, 29.9±4.9, 31.7±6.0, 32.7±7.0 cms, for 1st, 2nd, 3rd, 4th and 5th grade respectively, $p<0.05$). PP (W) also increased significantly, except from 3rd to 4th grade (1009.7±41.9, 1177.8±35.5, 1537.7±86.3, 1587.9±46.3, 1812.3±47.3 W for 1st, 2nd, 3rd, 4th, and 5th grade respectively, $p<0.01$). No differences were found in JH or PP between boys and girls in any grade. Negative correlations were found between BF and JH ($r = -.48, -.59, -.71, -.63, -.46$ for the 1st, 2nd, 3rd, 4th and 5th grade respectively, $p<0.01$), also between BF and RPP (W/Kg) ($r = -.61, -.67, -.69, -.77$, for the 1st, 2nd, 4th and 5th grade respectively, $p<0.001$). **CONCLUSION:** These results suggest that JH and PP increase similarly between boys and girls as they move from 1st to 5th grade

Criterion-related Validity Of A Cadence Rope Skipping Test For Estimating $\text{VO}_{2\text{peak}}$ In Adolescents

Stanley Sai-chuen Hui, FACSM, Weidong Gao. *The Chinese University of Hong Kong, Shatin, Hong Kong, Hong Kong.*
Email: hui2162@cuhk.edu.hk

(No relevant relationships reported)

Rope skipping is a fun and excellent moderate to vigorous physical activity (MVPA) for school students especially for elementary and junior high schools. Studies demonstrate that prolonged rope skipping exercise could effectively improve aerobic fitness. Considering the specificity principle in fitness evaluation, it is desirable to develop a rope-skipping specific exercise testing for evaluating aerobic fitness. **Purpose** The purpose of this study was to develop a prediction model to estimate peak oxygen uptake ($\text{VO}_{2\text{peak}}$) from a sub-maximal cadence rope skipping test among secondary school students. **Methods** A total of 58 secondary school students (38 boys, 20 girls, age=13.8±/1.1 yrs) completed two different forms of rope-skipping exercises (free-style skipping & Gallop-style skipping, in randomized order) with a steady cadence of 60 skips per min, for 3 min each and at least 20 min apart. Exercise heart rates (EHR) throughout the 3-min skipping and additional 1-min post-exercise HR (PHR) were monitored continuously using Polar HR monitor. Students also completed a treadmill $\text{VO}_{2\text{peak}}$ test using calibrated direct VO_2 metabolic measuring system (COSMED K4b2). Moderate to vigorous physical activity habits (MVPA), in term of average min per day were assessed by questionnaire. $\text{VO}_{2\text{peak}}$ was then correlated with HER and PHR at various time points, as well as MVPA, BMI, age, and gender, using stepwise regression, to determine criterion-related validity. **Results** Regardless of skipping style, $\text{VO}_{2\text{peak}}$ was best correlated with PHR at 20s after the exercise, followed by MVPA, gender, and BMI. The best equation was: $\text{VO}_{2\text{peak}} = 70.422 + (7.542 * \text{gender}) + (.126 * \text{MVPA}) - (.470 * \text{BMI}) - (.167 * \text{PHR@20s})$; $R = .870$, $\text{SEE} = 4.54 \text{ ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$, using the free-style rope skipping test. Both free-style and Gallop-style rope skipping gave similar level of criterion-related validity. **Conclusion** A 3-min free-style cadence rope skipping submaximal test was effective to estimate $\text{VO}_{2\text{peak}}$ of secondary school students using post-exercise heart rate at 20 seconds after the exercise, and gender, MVPA, and BMI. This test is particularly suitable for athletes of rope skipping to evaluate aerobic fitness due to its' good validity and specificity.

Acute Physiological And Perceptual Responses To Body-weight Circuit And Treadmill-based High-intensity Interval Exercise In Children

Jeanette M. Ricci¹, Rami Stanbouly¹, Emily L. Kryaska¹, Todd A. Astorino². ¹Michigan State University, East Lansing, MI. ²California State University - San Marcos, San Marcos, CA.
(Sponsor: Karin A Pfeiffer, FACSM)

(No relevant relationships reported)

Research examining acute responses to non-laboratory-based high-intensity interval exercise (HIIE), such as body-weight exercise, in children is lacking. **PURPOSE:** To compare the acute physiological and perceptual responses between body-weight circuit (CIRC) and treadmill high-intensity interval running (TM) in children. **METHODS:** Physically active boys (n=17; age = 9.7 ± 1.3 years) completed a graded exercise test to determine maximal heart rate (HR_{max}), peak oxygen uptake ($\text{VO}_{2\text{peak}}$) and maximal aerobic speed (MAS). Time-matched (8-min) CIRC and TM were completed in a randomized order on separate days within a 1 to 2-week period. CIRC consisted of two sets of 4 bouts of 30 s of maximal repetitions of mountain climbers, jump squats, jumping jacks, and burpees, whereas TM included 30 s bouts at 100% MAS. Both had a 30 s recovery between bouts. HR and gas exchange data were continuously assessed using a portable metabolic analyzer and HR monitor, and blood lactate concentration (BLA) was measured pre- and post-exercise. Global affect (PANAS) and exercise enjoyment (PACES) were assessed at baseline and post-exercise. Rating of perceived exertion (RPE), affect (Feeling Scale) and enjoyment (Exercise Enjoyment Scale) were recorded pre- and post-exercise and at 38% and 75% of session completion. **RESULTS:** Mean peak HR and VO_2 were 87% HR_{max} and 74% $\text{VO}_{2\text{peak}}$ for CIRC and 89% HR_{max} and 80% $\text{VO}_{2\text{peak}}$ for TM, with a significant difference in peak VO_2 between regimens ($p<0.05$). Yet, there were no differences in session HR, VO_2 or V_E ($p>0.05$). Post-exercise BLA was significantly higher following CIRC vs. TM (mean difference = 3.0 ± 2.2 mM, $p<0.05$). RPE, affect and enjoyment responses did not differ between regimens during exercise, and affect did not differ from pre- to post-exercise within or between regimens ($p>0.05$). Post-exercise enjoyment was significantly lower after CIRC vs. pre-exercise (mean difference = 3.9 ± 1.1, $p<0.05$). **CONCLUSION:** Although HR was similar, there was a higher peak VO_2 in response to TM, paralleling previous work in adults. The greater BLA accumulation in CIRC may be explained by

greater muscle recruitment required for multi-joint, dynamic movements and could explain the reduced post-exercise enjoyment. Future research should investigate higher volume protocols utilizing different body-weight exercises.

The Effect Of Comprehensive Coordination Training On Children's Cognitive Function

Xin Liu¹, Yang Li¹, Yi Liu¹, Xiaolei Liu², Jindong Chang³.
¹Southwest University, Chongqing, China. ²High School Affiliated to Southwest University, Chongqing, China. ³The Branch of the Collaborative Innovation Center of Assessment toward Basic Education Quality at Southwest University, Chongqing, China.
 Email: 595754247@qq.com
 (No relevant relationships reported)

PURPOSE: The aim of this study was to investigate the impact of comprehensive coordination training on children's cognitive function by adding two extracurricular exercises per week.

METHODS: A sample of 120 children aged 7-9 years old who participated in the "MQ101" program were randomly divided into two groups. The experimental group consisted of 58 people and the control group of 62 people. The experimental group participated in extracurricular comprehensive coordination training for 12 weeks, 2 times a week, and 1 hour each time. The control group did not participate in specialized training courses (not limiting students' self-exercise). The height, weight, 50-meter run, Body Comprehensive Coordination Test (BCCT) and the Eriksen Flanker test were tested in the pre-post experiment. The independent sample T-test and factor analysis were used to analyze the change values between the experimental group and the control group.

RESULTS: The two groups had no significant demographic differences in age, gender, height, weight, physical fitness tests or BCCT before the experiment. After the experiment, height, weight, and 50-meters-run had significantly changed in two groups ($p < 0.05$). However, regarding a body comprehensive coordination test, only the experimental group has significant differences before (29.75 ± 6.75) and after (32.80 ± 5.21) the experiment ($p < 0.05$). The results of Flanker test indicated that the post-test period had a higher accuracy rate in both congruent ($95.27\% \pm 9.76$) and incongruent ($91.03\% \pm 6.97$) trials compared with those in the pre-test period ($84.7\% \pm 10.29$ and $73.69\% \pm 7.79$, respectively) in the experimental group. Additionally, no significant differences were found in the reaction time between the experimental group and the control group.

CONCLUSIONS: Comprehensive coordination training has a great impact on the development of children's coordination skills. In addition, behavioral testing results also suggest that coordinative training may specifically benefit prefrontal-dependent tasks in the immature brain state of children aged 7-9 years old by increasing the allocation of attention resources and enhancing the efficiency of neurocognitive processing. (This study was supported by NPOSS Grant 15CTY011.)

Clarify The Influence Of Changing Parental Consciousness On Opportunities Of Children's Exercise

Shintaro Furuta. *Gifu University Graduate Student, Gifu, Japan.*
 (Sponsor: Kiyoji Tanaka, FACSM)
 (No relevant relationships reported)

PURPOSE: This study was to clarify the influence of changing parental consciousness on children's exercise opportunities.

METHODS: We urged a change in parental consciousness by showing them how pleasantly children exercised in various exercise programs. The participants included 32 children and their parents. The selection method firstly extracted the lowest 50% ranked by three test (50 m run, standing long jump, and soft ball throw) total scores out of the 103 elementary school 1st and 2nd graders who intending to participate in the program. We then used based on the results of a questionnaire on extracted person, "children who do not like exercising and have few opportunities to exercise" were selected. Various exercise programs were conducted seven times in total. The program also consisted of playful activities in addition to basic physical activities such as running, jumping, and throwing. We tried a questionnaire on the first and last day of the program. We examined the following three issues using the collected data: whether parents intending to increase opportunities for children to get exercise actually did it, whether the presence of a playground is related to intention of parents to increase those opportunities, and whether the presence or absence of a place is relevant to the increase in children's exercise opportunities.

RESULTS: The findings revealed that although 96% of the parents intended to increase opportunities for children to get exercise, only 25% were actually able to increase it. Further, 56% of those who intended to increase such opportunities had an appropriate playground near their houses, although 69% of them could not actually increase it.

CONCLUSION: The number of parents intending to create more opportunities for children to exercise increased. However, this change in consciousness did not necessarily lead to an actual increase. The result suggests that other factors are involved in increasing opportunities for children to exercise, such as time and environment. This study was limited by time constraints. Therefore, it is necessary to continue the program over a longer period of time and analyze further changes in parental consciousness to determine the influence on opportunities for children's exercise activities.

 (No relevant relationships reported)

PURPOSE: To describe the anthropometric and fitness profiles of 6-8 grade students who participated in 2-3 days/week of PE classes during the academic year.

METHODS: Data was collected on all willing 6-8 graders from the years 1992 to 2002, for a total of 10 years. Subjects included 1374 6th graders (height 59.33 ± 3.3 in, weight 102.6 ± 28.2 lbs), 1267 7th graders (height 62.4 ± 3.0 in, weight 117.7 ± 31.4 lbs), and 634 8th graders (height 63.1 ± 3.2 in, weight 125.7 ± 29.7 lbs) at a Chambersburg, PA junior high school. Participants completed fitness markers (height, weight, one-mile run, and curl ups) once in a year. Descriptive/frequency statistics were used to examine dependent variables for each participant, analyzing by grade and gender. Values were compared to the normative healthy fitness zones (HFZ) by FITNESSGRAM. **RESULTS:** 6th grade boys had a mean body mass index (BMI) of 19.7 ± 3.7 kg/m², one-mile run of 9.4 ± 2.3 minutes, and curl ups of 45.8 ± 10.1 ; 63.9% met the HFZ for BMI, 77.5% met the HFZ for one-mile run, and 96.5% met the HFZ for curl ups. 6th grade girls had a mean BMI of 20.6 ± 4.8 kg/m², one-mile run of 10.7 ± 2.3 minutes, and curl ups of 39.9 ± 10.7 ; 57.5% met the HFZ for BMI, 70.0% met the HFZ for one-mile run, and 94.7% met the HFZ for curl ups. 7th grade boys had a mean BMI of 20.2 ± 3.8 kg/m², one-mile run of 9.0 ± 2.6 minutes, and curl ups of 49.7 ± 11.6 ; 71.9% met the HFZ for BMI, 72.2% met the HFZ for one-mile run, and 97.1% met the HFZ for curl ups. 7th grade girls had a mean BMI of 21.5 ± 5.0 kg/m², one-mile run of 10.7 ± 2.6 minutes, and curl ups of 41.3 ± 10.7 ; 63.8% met the HFZ for BMI, 69.2% met the HFZ for one-mile run, and 98% met the HFZ for curl ups. 8th grade boys had a mean BMI of 21.1 ± 3.7 kg/m², one-mile run of 9.2 ± 3.3 minutes, and curl ups of 50.9 ± 11.6 ; 67.2% met the HFZ for BMI, 53.1% met the HFZ for one-mile run, and 85.3% met the HFZ for curl ups. 8th grade girls had a mean BMI of 22.6 ± 4.9 kg/m², one-mile run of 10.5 ± 1.8 minutes, and curl ups of 38.0 ± 9.6 ; 54.0% met the HFZ for BMI, 59.7% met the HFZ for one-mile run, and 80.1% met the HFZ for curl ups. **CONCLUSIONS:** Many junior high aged children are not meeting standards that are accepted regarding BMI, one-mile run, and curl ups. More work is needed to decrease BMI and obesity in children. More physical activity/sports involvement outside of PE programs may be needed for children not meeting these HFZ standards.

The Role of Growth and Maturation During Adolescence on Team Selection and Short-Term Sports Participation

Adam Baxter-Jones, Donovan Dale, Leah Ferguson, Kent Kowalski, Louise Humbert. *University of Saskatchewan, Saskatoon, SK, Canada.*
 (No relevant relationships reported)

Older (born in a month at the start of the team selection year; termed relative age (RA)), more mature adolescent athletes are more likely to be selected onto youth teams. However, little is known as to whether selection onto a team influences an individual's short-term sports participation. **Purpose:** (i) to investigate the relationship of RA, anthropometrics, and maturity on team selection and (ii) the short-term (3 years) consequence of selection on sports participation. **Methods:** 851 participants were recruited from six bantam team sport try-outs: soccer, football, basketball, volleyball, baseball and hockey. Parental heights, date of birth, date of test, height, sitting height and weight were recorded and age at peak height velocity (APHV) and final adult height predicted. Athletes were placed in month quartiles for month of birth. Reference standards were used to create z-scores. Sports participation was recorded at try outs and at 3 year follow-up. Analysis included chi-squared and ANOVA. **Results:** The sample showed an over representation of the first and second birth month quartiles ($p < 0.05$). Z-scores for height ranged from 0.1 (1.1) to 1.8 (1.2) and were significantly different between sports ($p < 0.05$). Some height and APHV differences

were found between selected and non-selected athletes ($p < 0.05$). 4% of non-selected athletes dropped out of all sport participation. 84% of selected athletes were still in the same sport compared to 68% of athletes still in the same sport but who were not selected. **Discussion:** In general athletes at try-out were already taller than the general population, in some sports were maturing earlier, and were born early in the selection year. If not selected a large percentage changed sports. Coaches should be aware of the consequences of selecting the oldest, tallest and more mature athletes on continued sports participation.

An Evaluation of the Irish Life Schools Fitness Challenge

Kevin D. O'Brien, Sarah M. Kelly, Mark Roantree, Andrew McCarren, Brona Furlong, Niall M. Moyna. *Dublin City University, Dublin 9, Ireland.* (Sponsor: Michael Harrison, FACSM)

Email: kevin.obrien7@mail.dcu.ie

(No relevant relationships reported)

BACKGROUND: Children and adolescents with high levels of cardiorespiratory fitness (CRF) have a favourable cardiovascular risk profile and a reduced risk of myocardial infarction, stroke, and mortality in adulthood. Furthermore, levels of CRF tend to track from adolescence to adulthood. The 20m shuttle run test (20mSRT) is the most widely-used test to estimate CRF in adolescents. The Irish Life Health Schools Fitness Challenge is a national initiative designed to improve CRF levels among first year students attending Irish secondary-level schools.

PURPOSE: To assess the effect of the annual Irish Life Health Schools Fitness Challenge on CRF in 12-year old boys and girls between 2012 and 2017.

METHODS: Participating schools used a 20mSRT to assess CRF levels before and after a 6-week exercise intervention. The exercise intervention was designed and implemented by teachers in each school. The 20mSRT involved running back and forth between two lines 20m apart, keeping in time with a series of audio signals. The starting speed was 8.5 km.hr⁻¹ and increased by 0.14 m.sec⁻¹ every min. The test was terminated if a participant stopped voluntarily, or was unable to maintain the set pace.

RESULTS: Mean 20mSRT score was significantly higher in boys than girls at baseline ($p < 0.001$) and 6 weeks ($p < 0.001$). Mean 20mSRT score (total number of shuttles) increased ($p < 0.001$) by 16% (53.5 ± 14.7 vs. 62.0 ± 15.4) in boys ($n=14,378$) and 19% (37.2 ± 11.8 vs. 44.1 ± 12.6) in girls ($n=14,698$) ($p < 0.001$).

CONCLUSIONS: A 6-week school-based exercise intervention designed and implemented by teachers resulted in a significant improvement in 20mSRT performance in 12-year old boys and girls.

Presence Of The Pediatric Inactivity Triad (PIT) In 4th And 5th Graders.

Kristofer C. Grant, Jeremy Davis, Carlie Pierce, Alexis Moore, Elizabeth Bailey, Stephen Bailey, FACSM. *Elon University, Elon, NC.*

(No relevant relationships reported)

The Pediatric Inactivity Triad (PIT) has recently been proposed as new way to examine the relationships between physical inactivity and impaired health in youth. Physical inactivity, dynapenia, and physical illiteracy are believed to be the primary determinants of PIT. **PURPOSE:** The purpose of this investigation is to determine if important relationships exist between the proposed determinants of PIT with anthropometric and psychometric measures. **METHODS:** Thirty children (10 females, 20 males) completed a series of tests and questionnaires to assess physical activity (Evaluation of Physical Activities in Youth: EASY), muscular strength and power (hand grip, vertical leap), physical literacy (Physical Literacy Assessment for Youth: PLAY Basic), body image (Social Physique Anxiety Scale for Children: SPAS) and anthropometrics (BMI, waist circumference). **RESULTS:** One third of participants (10 out of 30) were identified as not being competent by the PLAY Basic. 40% of participants did not achieve the federal guideline for physical activity in youth. 37% of participants were in the lowest 25th percentile for hand grip and vertical leap. 5 (17%) participants displayed physical inactivity, dynapenia, and physical illiteracy. SPAS was correlated with BMI ($r=0.38$, $p=0.04$) and PLAY Basic ($r=-0.42$, $p=0.02$). PLAY Basic was also correlated with EASY ($r=0.44$, $p=0.01$) and vertical leap ($r=0.39$, $p=0.04$). **CONCLUSIONS:** The results of this investigation suggest that it may be possible to identify individuals impacted by PIT. Several of these determinants are interrelated, so it may be possible to positively impact PIT by designing interventions to address specific outcomes.

Sex-Based Differences in the Upper Body Musculature May Influence Rate of Force Development in High School Students

Erica R. Goldstein¹, Michael J. Redd², Tristan M. Starling-Smith², Alison M. Redd³, Jeffrey R. Stout², David H. Fukuda².

¹University of Central Florida, Oviedo, FL. ²University of Central Florida, Orlando, FL. ³Keiser University, Orlando, FL.

Email: egoldstein@knights.ucf.edu

(No relevant relationships reported)

Changes in skeletal muscle occur during the process of maturation that influence the expression of muscular strength. The isometric mid-thigh pull (IMTP) is used to measure force-time characteristics [peak force (PF) and rate of force development (RFD)], while the bioelectric properties of body tissues can be used to estimate lean body mass (LBM) and cellular health via phase angle. **PURPOSE:** To evaluate the contributions of segmental LBM, phase angle, and potentially relevant developmental indicators on IMTP performance in adolescents. **METHODS:** Twenty-three high school students (14 girls and 9 boys; age=15.4±0.8y; height=1.7±0.7m, body mass=68.9±14.9kg) underwent anthropometric measurements to determine somatic maturity and multi-frequency bioelectrical impedance analysis to determine whole body phase angle (50 kHz), overall LBM, and segmental LBM of the arms, legs, and trunk. Participants performed an IMTP with a custom-built rack and force plates to determine peak RFD, absolute PF, and PF relative to body mass. Stepwise linear regression was used to determine the relationships between IMTP performance and segmental LBM as well as specific developmental indicators (chronological age and somatic maturity). Independent sample t-tests were used to evaluate sex-based differences. Pearson correlations were also used to compare IMTP performance with overall LBM and whole body phase angle. **RESULTS:** Sex-based differences ($p < 0.05$) were shown for maturity offset (female: 2.5±0.6y; male: 0.9±0.8y), whole body LBM (female: 101.3±15.9kg; male: 117.8±18.3kg), arm LBM (female: 10.2±2.6kg; male: 12.7±2.7kg), RFD (female: 1596.17N*s⁻¹; male: 2742.41N*s⁻¹). RFD was significantly associated with arm LBM ($r^2=0.239$; $p < 0.05$) while the addition of trunk LBM improved the model ($r^2=0.454$; $p < 0.05$). Neither chronological age nor somatic maturity were associated with any of the IMTP variables, while RFD was significantly correlated with both whole body phase angle ($r=0.495$) and overall LBM ($r=0.476$). **CONCLUSION:** Significant sex-based differences in the upper body musculature likely influence RFD in high school students despite girls displaying greater somatic maturity than boys. Phase angle may also play a role in the rate of muscular strength expression in adolescents.

2986 Board #32 May 31 2:00 PM - 3:30 PM

Physiological and Perceptual Responses to Step-Wise and Ramp Graded Exercise Tests in Children

Meral Culver, Thomas Hilb, Kelly E. Johnson, Jakob D. Lauver, Justin P. Guilkey. *Coastal Carolina University, Conway, SC.*

Email: mnculver@coastal.edu

(No relevant relationships reported)

Step-wise graded exercise tests are common protocols to measure aerobic fitness in children but have limitations due to the nature of the increments. Modifying these tests to a ramp protocol could overcome some of these limitations. **PURPOSE:** To examine physiological and perceptual responses to step-wise and ramped graded exercise tests in children ($n = 8$; age = 13.3 ± 2.2 yrs.). **METHODS:** The standardized James protocol (STEP) and a modified-ramp James protocol (RAMP) were performed on a cycle ergometer on separate days. Protocol order was counterbalanced. STEP commenced with three 3-min stages, followed by 1-min stages. Work rate increases were based on body surface area. For RAMP, work rate was ramped to match the 3-min and 1-min stages of STEP. Work rate was increased until volitional exhaustion for both tests. Oxygen consumption ($\dot{V}O_2$), heart rate (HR), respiratory exchange ratio (RER) and OMNI ratings of perceived exertion for chest (RPE-chest), legs (RPE-legs) and overall (RPE-overall) were recorded at the end of each 3-minute stage and peak exercise. Physiological and perceptual responses between tests were compared using two-way repeated-measure ANOVAs and test time (TT) and peak power (PP) were compared using repeated measure t-tests. Significance was established at $p < 0.05$. **RESULTS:** The physiological and RPE responses were similar between tests at the end of each 3-min submaximal stage ($p > 0.05$). At peak exercise, absolute and relative $\dot{V}O_2$ for STEP were 2.17 ± 0.67 L·min⁻¹ and 42.5 ± 5.9 ml·kg⁻¹·min⁻¹. For RAMP, absolute and relative $\dot{V}O_{2peak}$ were 2.33 ± 0.89 L·min⁻¹ and 45.3 ± 8.9 ml·kg⁻¹·min⁻¹. The differences were not significant. There were no differences between STEP and RAMP for peak HR (196.3 ± 9.8 bpm vs. 196.1 ± 9.7 bpm) and peak RER (1.24 ± 0.11 vs. 1.21 ± 0.06). At peak exercise, RPE-chest, RPE-leg and RPE-overall were similar between STEP (4.8 ± 4.0 , 8.4 ± 2.1 and 7.6 ± 3.0 , respectively) and RAMP (5.6 ± 3.4 , 8.5 ± 2.3 and 8.0 ± 1.8 , respectively) ($p > 0.05$). TT and PP for STEP were 11.3 ± 2.5 min and 196.8 ± 70.7 W and 12.4 ± 2.4 min and 210.3 ± 65.5 W for RAMP ($p = 0.11$ and $p = 0.12$, respectively) **CONCLUSION:** Although limitations in step-wise protocols

exist, submaximal and peak physiological and perceptual responses were similar to a ramp protocol. Both protocols may be appropriate in children to measure aerobic fitness.

Determinant Factors of Cellular Health Among Adolescent Girls and Boys

Raquel David Langer¹, Anderson M. Marques², Erika K. Hussey³, Gil Guerra-Junior¹, Ezequiel M. Goncalves¹.
¹University of Campinas, Campinas, Brazil. ²Pontifical Catholic University of Campinas, Campinas, Brazil. ³US Army, NSRDEC, Medford, MA.
 Email: raqueldlanger@gmail.com
 (No relevant relationships reported)

Several studies have demonstrated that cardiorespiratory fitness (CRF) and body adiposity are strong indicators of health during childhood and adolescence. However, it is not known if these parameters are associated with cellular health. For example, phase angle (PhA) is used to evaluate nutritional status and is an indicator of cellular health. **PURPOSE:** In this study, we test if body composition and CRF have an influence on cellular health among adolescents of both genders. **METHODS:** 203 girls (12.7 ± 1.3 years) and 221 boys (12.8 ± 1.3 years) were evaluated. The peak of height velocity (PHV) was used as an indicator of somatic maturation. The percentage of fat mass (%FM) was calculated based on skinfold thickness (triceps and calf). CRF was assessed with the Leger test. Bioelectrical impedance analysis provided parameters to calculate the values of PhA and fat-free mass (FFM). Bivariate correlation was used to verify the association between PHV with PhA, %FM, FFM and CRF. We used partial correlation to evaluate if PHV was a mediator of the relationship between PhA, %FM and CRF. A linear regression analysis adjusted by PHV was used to verify if variables (%FM, FFM and CRF) influenced cellular health among adolescents of both genders. **RESULTS:** The PHV showed a significant positive correlation with FFM in girls (r = 0.83, p<0.001) and boys (r = 0.83, p<0.001); with PhA in girls (r = 0.24, p<0.01) and boys (r = 0.38, p<0.001); and with %FM but only in girls (r = 0.15, p<0.05). PHV was negatively correlated with CRF in girls (r = -0.54, p<0.001) and boys (r = -0.20, p<0.01). Linear regression of the PhA adjusted by the PHV had an effect on %FM in girls (β = 0.233, p<0.05) but not in boys (β = 0.013, p=0.834), on CRF in boys (β = 0.166, p<0.05) but not in girls (β = 0.007, p=0.931), and on FFM in girls (β = 0.697, p<0.001) and in boys (β = 0.614, p<0.001). **CONCLUSION:** We discovered that PhA when controlled by somatic maturation seems to be more influenced by %FM in girls, CRF in boys, and FFM in both genders of adolescents. Interestingly, cellular health and CRF (for girls) and %FM (for boys) were not associated with PhA. This has implications for physical activity behavioral for improved health in adolescents of both genders. Supported by CAPEs (No. 23001.000422/98-30)

Resting Energy Expenditure and Metabolic Equivalents in Youth: Impact of Inconsistent Operational Definitions

Paul Hibbing, Scott Crouter, FACSM. University of Tennessee, Knoxville, Knoxville, TN.
 Email: phibbing@vols.utk.edu
 (No relevant relationships reported)

Youth metabolic equivalents (MET_y) are multiples of resting energy expenditure (REE), but there are different operational definitions for REE, including basal metabolic rate (BMR) and resting metabolic rate (RMR). **PURPOSE:** To compare MET_y defined as multiples of BMR (MET_{yBMR}) versus RMR (MET_{yRMR}). **METHODS:** Data from two studies (N = 255, 47.4% male, mean ± SD age 10.2 ± 1.5 years) were analyzed. For all participants, BMR was predicted using Schofield's equations. RMR was assessed during 30-min supine rest while wearing a portable metabolic unit (Cosmed K4b²). Participants also performed structured physical activities (PA) ranging from sedentary behaviors (SB) to vigorous PA. MET_{yBMR} and MET_{yRMR} were calculated by dividing steady state oxygen consumption by BMR and RMR, respectively. Values were compared using two-way (Activity X MET_y calculation) analysis of variance on a mixed-effects model. Post-hoc tests were performed with Bonferroni correction (α = 0.05). MET_{yBMR} and MET_{yRMR} values were also classified as SB (≤1.50 MET_y), light PA (1.51-2.99 MET_y), moderate PA (3.00-5.99 MET_y), or vigorous PA (≥6.00 MET_y). Classifications were compared with a confusion matrix. **RESULTS:** There was a significant interaction (F(30) = 19.1, p < 0.001) between activity and MET_y calculation. MET_{yBMR} and MET_{yRMR} differed significantly for 20 of 31 activities (64.5%), with differences ranging from 0.2 MET_y for supine rest to 4.8 MET_y for the running course (p < 0.001). For intensity classification, MET_{yBMR} and MET_{yRMR} gave the same classification in 61.4% of cases (see table). **CONCLUSION:** MET_{yBMR} and MET_{yRMR} are comparable (within 0.5 MET_y) for SB, but MET_{yBMR} becomes progressively higher than MET_{yRMR} as intensity increases, reaching differences >40%. MET_{yBMR} and MET_{yRMR} are not interchangeable units, and care is necessary when interpreting and comparing the findings of studies that use MET_y.

| MET _{yBMR} | MET _{yRMR} | | | |
|---------------------|---------------------|----------|-------------|-------------|
| | SB | Light PA | Moderate PA | Vigorous PA |
| SB | 342 | 6 | 0 | 0 |
| Light PA | 180 | 220 | 10 | 0 |
| Moderate PA | 14 | 265 | 561 | 23 |
| Vigorous PA | 0 | 34 | 301 | 204 |

Comparative Study On Body Composition Distribution Between Obese And Normal Children In China

Zhengyan Tang, Jingmin Liu, Yujie Liu, Xiao Hou. Tsinghua University, Beijing, China.
 Email: tzy0565@sina.com
 (No relevant relationships reported)

The prevalence of obesity among Chinese children is on the rise, and Asian are more likely to have centripetal obesity. **PURPOSE:** To compare the body composition and distribution of obese children and normal children, and to find out the changing rules among different ages. **METHODS:** We recruited 219 Chinese children (12.18±3.05 yr.; height: 155.24±15.66 cm; mass: 48.60±14.41 kg; boys: 48.4%). The age ranges from 7 to 17, and is divided into three age groups, including 7-9, 10-13 and 14-17. According to national standards, <Screening for overweight and obesity among school-age children and adolescents>, they are divided into normal group(n=161) and obesity group(n=58). Their body composition was measured using dual-energy X-ray absorptiometry (DEXA), the main indicators were bone mineral content (BMC), fat mass(FM) and lean mass(LM) of trunk and limbs, and body fat percentage(BFP), trunk fat Percentage(TFP), trunk LM Percentage(TLP),trunk BMC Percentage(TBP). Paired samples t test and correlation analysis with age control was used for statistics. **RESULTS:** BFP and FM in obesity group were higher than those in normal group with significant difference (p<0.01). BMC and FM were higher in obesity groups, but there was no significant difference. The TFP of normal group was significantly lower than that of obesity group in each sex. (p < 0.01), Boys TBP normal group was significantly lower than obesity group(p<0.05), and TLP had no significant difference. Girls have completely opposite results. In 7-9 years old group, there was no significant difference in all indexes between obesity group and normal group. In 10-13 years old group, TFP in obesity group was higher than that in normal group(boys p<0.01, girls p=0.51), and in 14-17 years old group, there was no significant difference in TFP ratio between obesity group and normal group. There was a moderate negative correlation between FM and BMC in the trunk of overweight women (r=-0.515, p<0.05). TFP was negatively correlated with LM in obesity group(boys r=-0.460,p<0.01, girls r=-0.545,p<0.01),but there was no correlation in normal group. **CONCLUSIONS :** TFP was higher in obese children, and the trend of fat centripetal distribution increases first and then decreases with age. Children with centripetal obesity tend to have lower LM, and girls also have lower BMC.

2990 Board #36 May 31 2:00 PM - 3:30 PM
Systolic Blood Pressure Mediates the Relationship Between Body Mass Index and Inhibitory Control in Children

MARIA LUIZA M. REGO¹, DANIEL ARANHA R. CABRAL¹, HENRIQUE BORTOLOTTI¹, KELL G. DA COSTA¹, GLEYDCIANE A. FERNANDES¹, MENNA J. PRICE², EDUARDO B. FONTES¹. ¹Federal University of Rio Grande do Norte, Natal, Brazil. ²Swansea University, Swansea, United Kingdom.
 (No relevant relationships reported)

Increased body mass index (BMI) and systolic blood pressure (SBP) have been shown to be associated with poorer inhibitory cognitive control throughout childhood and impact children's health. Further statistical procedures may help to understand the nature of relationship between these variables in children. **PURPOSE:** Here, we verify the mediation role of the SBP in the relationship between BMI and inhibitory control. **METHODS:** Twenty non-normotensive (NNT) children (age: 10.86 (10.18-10.98) years; 8 hypertensive stage I; 1 hypertensive stage II and 11 pre-hypertensive) were paired with 20 normotensive (NT) children (age: 10.40 (9.86 – 10.69) years) by cardiorespiratory fitness, BMI, somatic maturation, scholar performance and age. They differed on SBP (NNT: 120.53±6.73 mmHg vs NT: 106.64±7.04 mmHg; p<0.01) and diastolic blood pressure (DBP) (NNT: 75.83±8.81 mmHg vs NT: 64.80±4.94 mmHg; p<0.01). BP was calculated by the average of three measures with a two-minute interval between them. Inhibitory control was measured by a food specific inhibitory Go/ No-go task. The Go stimuli were presented as office and bathroom pictures, whereas the No-go (inhibition) stimuli were food and toys images. Performance

was evaluated based on number of errors during No-go stimuli. T-tests were applied to verify differences between independent variables and cognitive performance. Thereafter, a four step mediation was applied using SBP as a mediator of the relation between BMI and number of errors. **RESULTS:** NNT group had higher number of errors compared to NT one (4.14 ± 0.92 vs. 2.43 ± 0.54 ; $p = 0.002$). In addition, a relationship between BMI and number of errors ($\beta = 0.38$, $SE = 0.16$, $p = 0.02$) was found. However, when considering SBP, this relationship was no longer statistically significant ($\beta = 0.24$, $SE = 0.16$, $p = 0.13$). The bootstrapped unstandardized indirect effect was 0.13 and the 95% confidence interval ranged from 0.02 to 0.35. This indicates SBP as a full mediation of the relation between BMI and inhibitory control. **CONCLUSION:** We confirm the relationship between body mass index and cognitive inhibitory control in children and for the first time present systolic blood pressure as a mediating mechanism.

Examining the Relationship Between Physical Activity and Cardiometabolic Biomarkers in Youth with Overweight or Obesity

Justin B. Moore, FACSM¹, M. Rosa Bernal López², Joseph A. Skelton¹, Andrew M. South¹, Antonio Vargas-Candela², Ricardo Gómez-Huelgas³, Javier Benítez-Porres⁴. ¹Wake Forest School of Medicine, Winston-Salem, NC. ²Institute of Biomedical Research in Malaga (IBIMA), University Hospital of Malaga (Regional Hospital), Málaga, Spain. ³Institute of Biomedical Research in Malaga (IBIMA), University Hospital of Malaga (Regional Hospital), Málaga, Spain, Málaga, Spain. ⁴University of Málaga, Málaga, Spain.
 Email: jusmoore@wakehealth.edu
 (No relevant relationships reported)

While physical activity is known to have beneficial effects in youth, including short-term improvements in adiposity, little is known regarding the association of physical activity with cardiometabolic biomarkers among youth. This is especially true in youth with overweight or obesity. **PURPOSE:** To determine the relationship between achieving 30 minutes of moderate-to-vigorous physical activity (MVPA) per day and markers of cardiometabolic health in youth with overweight or obesity. **METHODS:** Eighty-one children (mean age $6.7\text{yrs} \pm 1.2$, 54% male, 47% with overweight, 53% with obesity), who are participating in a longitudinal intervention to increase physical activity and cardiometabolic health provided data on physical activity (via accelerometer), body composition (via DXA), blood pressure, and fasting biomarkers (insulin, glucose, triglycerides, & cholesterol). A series of ordinary least squares regressions were conducted examining the relationship between the various markers and achieving 30 minutes of MVPA, while controlling for age and sex (model one) and age, sex, and percent body fat (model two). **RESULTS:** Our results indicated that percent body fat was negatively associated with achieving 30 minutes of MVPA ($b = -2.98$, $P < .01$) after controlling for age and sex. Of the remaining biomarkers, only fasting insulin was associated with achieving 30 minutes of MVPA ($b = -3.81$, $P < .05$), but this relationship became non-significant ($b = -2.36$, $P = .16$) when adding percent body fat to the model ($b = 0.50$, $P < .01$). **CONCLUSIONS:** Achieving 30 minutes of MVPA was negatively associated with adiposity, but other cardiometabolic biomarkers were not associated with achieving 30 minutes of MVPA among youth with overweight and obesity.

Negative Impact of Icing Treatment on Qualitative Recovery of Injured Soleus Muscle in Rats

Tsubasa Shibaguchi¹, Claudia Pérez-López¹, Takao Sugiura², Kazumi Masuda¹. ¹Kanazawa University, Kanazawa, Japan. ²Yamaguchi University, Yamaguchi, Japan.
 (No relevant relationships reported)

PURPOSE: Although the RICE (Rest, Ice, Compression, and Elevation) treatment has been recognized as the gold standard of first aid treatment for sports injuries, we and the others previously demonstrated that a transient icing treatment immediately after skeletal muscle injury impaired muscle regeneration. However, the information

about the influence of icing treatment following skeletal muscle injury remains limited. This study was, therefore, to investigate the impact of icing as a first-aid treatment on qualitative recovery of damaged muscle in terms of fibrosis and myosin heavy chain (MyHC) profile.

METHODS: Male Wistar rats (9-10 weeks of age) were randomly assigned to control (Con), injured, and injured with icing groups (Ice). Bupivacaine (BPVC) was injected into slow soleus muscles bilaterally in order to induce muscle injury in the two injury groups. Application of icing treatment (ice pack, 0°C for 20 min) to the icing group was carried out immediately after the BPVC injection. At 3 days-4 weeks after BPVC injection, soleus muscles were removed and analyzed.

RESULTS: Compared with the Con group, a significant increase in fibrotic area was observed after 2 weeks following injury in the injured groups, but after 1 week following injury in the Ice group ($P < 0.05$). This area was also tended to be higher in Ice than in injured animals during 1-4 weeks of recovery period. In addition, the number of Tcf4-positive nuclei, a fibroblast marker, located in interstitial spaces in both injured groups markedly increased 1 week after BPVC injection. The numbers were tended to be more magnified in the Ice group than in the injured group, then their number in both injured groups gradually decreased thereafter. Injury-related de novo appearance of embryonic, neonatal, IId/x, and IIb MyHC isoforms was noted in both injured groups 1 week after BPVC injection. These MyHC isoforms were significantly decreased toward the undetectable level thereafter. However, the embryonic MyHC isoform was still detectable in icing, but not in injured, animals 4 weeks after BPVC injection.

CONCLUSIONS: Our results suggested that icing treatment following skeletal muscle injury will have a negative impact on recovery process (fibrosis and normalization of MyHC profile) of regenerating muscle.

Stressed Outover Stress Fractures? Potential Predictive Model To Determinethose At Risk

Timothy M. Dekker, Mayo Clinic, Jacksonville, FL. (Sponsor: George Pujalte, FACSM)
 Email: dekker.timothy@mayo.edu
 (No relevant relationships reported)

PURPOSE: Stress fractures are injuries caused by cumulative, repetitive stress that leads to abnormal bone remodeling. There are two causes of stress fractures, excessive stresses causing weakening of bone material and typical stresses acting on abnormal bone. Stress fractures are more common in certain populations including women, military personnel, high-level athletes, and the middle aged/elderly. Stress fractures have a large socioeconomic impact as they cause prolonged periods away from competition and a significant amount of healthcare spending. A reliable, reproducible method to determine which individuals are most susceptible within the predisposed populations would provide cost-effective prevention strategies. Advanced numerical simulation tools may be key to modeling the mechanical behavior of bones under different loading conditions.

METHODS: Method: The hybrid finite-discrete element method (FDEM) combines aspects of the finite element method to model the elastic behavior of materials and the discrete element method to model the initiation and propagation of fractures. The FDEM is used to simulate the deformation and fracturing in materials such as bone and rock. This can capture the transition of a solid from a continuous to a discontinuous state by directly simulating fracturing processes. See the Image 1 for further explanation of methods.

RESULTS: Refer to Image 2 for graphs and model results.

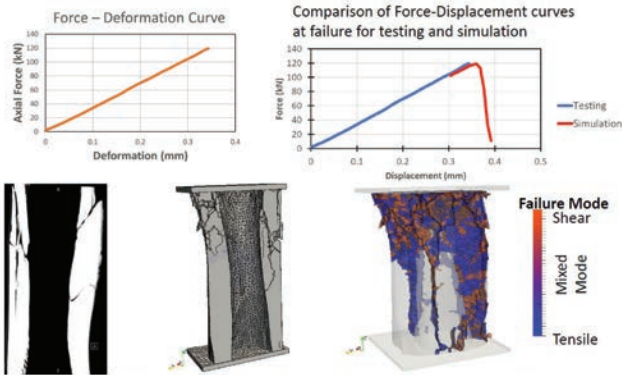

CONCLUSION: The FDEM model shows promise to help predict stress fractures. Further studies are needed; including realistic bone loadings to real life situations.

An initial simulation study was done in which prepared bovine tibiae without surrounding soft tissue was first imaged using computed tomography (CT). Following CT imaging, the bones were loaded in compression to the point of failure.

The tibiae were then re-imaged with CT. The initial CT data provided a three-dimensional model that could be used in the simulation software.

The 3D model, along with the compression test, were used to calibrate a FDEM numerical model. Once calibrated, a numerical simulation of the compression test was conducted. The strength, stiffness, and fracture patterns from the physical testing and numerical simulation were then compared.

Comparison of testing and simulated fracture patterns. Both methods showed the predominant failure mechanism was axial splitting with fractures forming parallel to the applied forces. There was an encouraging agreement between physical tests and numerical simulations.

made software was used to align the talus and calcaneus of the uninjured and injured side based on principal axis of inertia and moments of inertia. Thereafter, the curvature radius and arch length of each talus and calcaneus were measured in coronal and sagittal plane. Paired sample t test was used to compare the results in uninjured and injured side.

RESULTS: The analysis of the calcaneus have showed that there was no difference between uninjured and injured cases for curvature radius neither in coronal plane (60±10 mm vs. 61±11 mm, respectively) nor in sagittal plane (58±16 mm vs. 60±12 mm) (p>0.05). In addition, there was not statistical difference between uninjured and injured cases for the arch length neither in coronal (23±3 mm vs. 21±3 mm) nor in sagittal plane (19±5 mm vs. 17±5 mm) (p>0.05). The analysis of talus has shown that there was not significance between uninjured and injured side for the curvature radius measured in coronal plane (55±7 mm vs. 56±8 mm) and in sagittal plane (34±4 mm vs. 34±7 mm) (p>0.05). Additionally, there was not significance between uninjured and injured side for the arch length measured in sagittal plane (29±4 mm vs. 28±4 mm) (p>0.05). Importantly, there was statistical significance between uninjured and injured side for the arch length measured in coronal plane (29±4 mm vs. 21±4 mm) (p<0.05).

CONCLUSIONS: Microfractures of the talus and consequent decrease in its arch length measured in the coronal plane may be a predictor of the foot injuries.

Association Between Femoral Cartilage Deformation and Pain Following Running
 Hyunjae Jeon, Abbey Thomas. *University of North Carolina at Charlotte, Charlotte, NC.*
 Email: hjeon2@unc.edu
 (No relevant relationships reported)

Patellofemoral pain (PFP) is a multifactorial knee pathology and prevalent in physically active individuals. Running is one of the most popular forms of exercise accounting with nearly 17 million runners in the US. Despite the health benefits, running may lead to injury with more than 20% of runners injured annually. Of those, 10% develop PFP. Emerging evidence suggests chronic PFP may lead to patellofemoral osteoarthritis, a condition characterized by cartilage breakdown. However, little is known about how activities that cause the symptoms of PFP influence cartilage health. Diagnostic ultrasound imaging is an emerging technique to measure cartilage thickness immediately after physical activity. No research has analyzed femoral cartilage deformation followed by running in patients with PFP.
PURPOSE: To determine if 30 minute running changes cartilage thickness and joint pain in patients with PFP compared to healthy adults.
METHODS: As part of an ongoing investigation, 6 adults (n=3 PFP, age: 21.3±0.6yrs, body mass index[BMI]: 20.5±3.2kg/m²; n=3 healthy, age: 21.0±1.0yrs, BMI: 21.9±1.4kg/m²) participated. A GE LOGIQe diagnostic ultrasound machine with a 12MHz linear probe was used to obtain the knee cartilage images before and after 30 minutes running. Perceived pain level was measured using a 10cm Visual Analog Scale (VAS). Correlation between percent cartilage thickness change and VAS was performed to measure the association between two variables and a simple regression analysis was performed to determine the predictability of cartilage thickness measure according to the pain level change.
RESULTS: Pain level change and cartilage deformation showed a strong correlation (r=0.85, p=0.033), and pain level change explained 72% of the variance in cartilage thickness (R²=0.72, p = 0.03)
CONCLUSIONS: Though continuation of this investigation is needed to confirm our findings, the strong positive association between pain level and cartilage deformation implies that measuring pain by VAS before and after physical activities may be an easy and effective means for clinicians to evaluate cartilage deformation.

Intratendinous Distribution Of Achilles tendinosis, A retrospective Study.
 michael bultheel. *ku Leuven, Leuven, Belgium.*
 Email: michaelbultheel@gmail.com
 (No relevant relationships reported)

Background. Achilles tendinopathy is a very common condition. The pathology of overuse tendinopathy has been described as a continuum that comprises 3 stages: reactive tendinopathy, tendon disrepair and degenerative tendinopathy with tendinosis. The precise location of tendinosis in the Achilles tendon tends to vary from patient to patient: musculotendinous, insertional, anteriorly or posteriorly in the tendon.
Aim. This study describes the variation in the location of the intratendinous zone of tendinosis in the Achilles tendon.
Patients and methods. All ultrasound scans of all patients who presented with pain in the Achilles region were retrospectively analyzed and classified. In this respect, classification occurred into the following three categories: tendinosis, reactive tendinopathy or other (e.g. normal scan, peritendinopathy, bursitis,...). The tendinosis group was subdivided according to the location of the tendinosis zone into proximal or insertional, which were further subdivided into anterior, posterior or both.
Results. In total we recorded and examined the ultrasound scans from 395 tendons from 325 patients, meaning 70 patients had bilateral complaints. 209 of them were men and the mean age of this population was 43 years. In 41 patients we found two zones of tendinosis. In 55,5% of the patients with pain in the Achilles region tendinosis was seen, in 18,8% reactive tendinopathy and in 25,7% something else. The results showed that in 68,2% of the sample the tendinosis zone was proximal, whereas in 31,8 % it was insertional. The proximal tendinosis zone was mostly found right across the width of the tendon (57%), but also anteriorly (15,2%) and posteriorly (27,8%). The insertional tendinosis zone, however, was mostly found posteriorly (49,3%), followed by anteriorly (27,3%) and across the width of the tendon (23,4%).
Conclusions. Although we already know that the tendinosis zone in Achilles tendinopathy occurs at different locations, the relative distribution of these zones remained relatively unclear. The distribution described raises concern about the fact that all these patients are often treated with the same protocol. Further research is needed to determine whether a difference in approach according to the location of the tendinosis zone is appropriate.

Side Differences in the Y-Balance Test Performance in Patients with Unilateral Low Back Pain
 Yousef M. Alshehre, Khalid Alkhatami, Kelli Brizzolara, Sharon Wang-Price. *Texas Woman's University, Dallas, TX.*
 Email: yalshehre@twu.edu
 (No relevant relationships reported)

PURPOSE: Diminished balance is a well-recognized impairment in individuals with low back pain (LBP). Clinically, the Y-balance test (YBT) has been recommended as an outcome measure to assess dynamic balance deficits in the LBP population. Specifically, the reach distances of the 3 testing directions collected from both limbs often are averaged to represent a patient's balance performance. However, it is unclear if these patients perform the YBT differently when they stand on their painful limb versus on their non-painful limb. The purpose of the study was to compare the differences in the YBT between the painful versus non-painful limbs of patients with LBP under two separate conditions: performing the YBT on the dominant leg and on the non-dominant leg. **METHODS:** Thirty-one right-leg-dominant adults (37.1 ± 12.5 years) with unilateral LBP completed the study, including 14 participants with LBP on the right side (9 men, 5 women) and 17 participants with LBP on the left side (8

men, 9 women). Each participant stood on one leg unsupported, with the opposite foot reaching as far as they could without losing balance in 3 directions: anterior (ANT), posteromedial (PM), and posterolateral (PL). Each participant performed a total of 9 trials for each direction and for each limb, but only the last 3 trials were measured and normalized to the corresponding leg length for later statistical analysis. Two separate 2 (group) x 3 (direction) ANOVAs with repeated measures were used to determine differences between groups, one for the dominant (right) leg, and the other for the non-dominant (left) leg. **RESULTS:** There were no significant differences in age and body mass index ($p > .05$) between groups. When standing on the dominant (right) leg, there was a significance difference ($p = 0.037$) in the PM reach distance between groups, with the left LBP group (86.1 ± 4.7 cm) reaching a shorter distance than the right LBP group (101.6 ± 5.2 cm). There were no significant differences in the ANT and PL directions. In addition, there were no differences in all directions between groups when standing on the non-dominant (left) leg. **CONCLUSIONS:** The results of the study suggest that using a composite score may fail to show dynamic balance deficits. The PM reach direction appears to be the most challenging testing component for patients with LBP.

2998 Board #44 May 31 2:00 PM - 3:30 PM
Skeletal Muscle Size, Quality And Function In Patients With Several Years After Total Hip Arthroplasty

Akito Yoshiko¹, Kohei Watanabe¹, Toshio Moritani, FACSM², Moroe Beppu³, Ryoichi Izumida⁴, Takuya Otani⁵, Hideaki Shiratsuchi⁶, Naonobu Takahira⁷. ¹Chukyo University, Nagoya, Japan. ²Kyoto Sangyo University, Kyoto, Japan. ³Japan Hip Joint Foundation, Tokyo, Japan. ⁴Edogawa Hospital, Tokyo, Japan. ⁵The Jikei University, Tokyo, Japan. ⁶Funabashi Orthopedic Hospital, Chiba, Japan. ⁷Kitasato University, Kanagawa, Japan. (Sponsor: Toshio Moritani, FACSM)
 Email: yoshiko@lets.chukyo-u.ac.jp
 (No relevant relationships reported)

Total hip arthroplasty (THA) leads decrease of physical activity and muscle function, and it would induce asymmetric motor performance in daily life since most cases of THA are applied to one side. For prevention of muscle dysfunction, some sports activities such as golf, walking, swimming and so on are recommended after THA. Recently, muscle quality, i.e. fat and/or connective tissue within skeletal muscle, has been used as one of important factors to determine muscle function. **PURPOSE:** The purpose of this study was to compare muscle size, quality and function between the operated and non-operated legs in patients with one side THA with several year's exercise habits after THA. **METHODS:** Fourteen men and women (67.1 ± 5.3 years; height, 161.3 ± 6.8 cm; body mass, 65.5 ± 18.5 kg) with exercise habits, such as golf, participated in this study. They had THA surgery in either side several years ago (4.9 ± 2.5 years). B-mode transverse images of rectus femoris were taken using ultrasound system (Logiq e Premium, GE Healthcare, USA), and isometric knee extension strength (KE) was measured in both operated and non-operated legs. Muscle thickness as an index of muscle size, echo intensity as an index of muscle quality and KE were compared between operated leg and non-operated leg. **RESULTS:** There were no differences between operated leg and non-operated leg in muscle thickness (1.4 ± 0.5 cm vs. 1.4 ± 0.4 cm, $P > 0.05$), echo intensity (88.7 ± 17.8 a.u. vs. 88.9 ± 17.3 a.u., $P > 0.05$) and KE (38.3 ± 13.8 kg vs. 41.3 ± 12.3 kg, $P > 0.05$). **CONCLUSION:** As the result of several years passing after THA, the difference of high muscle size, quality and function was not shown between operated and non-operated leg. Several year's exercise habits can improve not only muscle size and function but also muscle quality.

2999 Board #45 May 31 2:00 PM - 3:30 PM
Effects of Deep Oscillation Therapy on Symptoms Associated with Eccentric Exercise-Induced Delayed Onset Muscle Soreness

Kacey Ohlemeyer¹, Steele Morris¹, Heriberto Zamora Jr¹, Allison B. Smith¹, Dawn M. Emerson², Toni M. Torres-McGehee¹. ¹University of South Carolina, Columbia, SC. ²University of Kansas, Lawrence, KS.
 (No relevant relationships reported)

Delayed onset of muscle soreness (DOMS) has debilitating symptoms that produces muscle damage and performance deficits among athletes. Deep oscillation therapy (DOT) is a therapeutic intervention that utilizes an electrostatic wave to create a deep oscillation massage at the cellular level with proposed physiological benefits. There is little evidence to support the use of DOT on exercise-induced DOMS. **Purpose:** Examine the effects of DOT on girth, pain pressure threshold (PPT), perceived pain, strength, and range of motion (ROM) following a bout of eccentric exercise-induced DOMS when compared to control. **Methods:** Moderately active participants (age: 22 ± 2.5 years; male: $n=5$, female: $n=5$) completed an eccentric exercise protocol for the elbow flexors to induce DOMS as part of a randomized counter-balance design study [Control group (C: no treatment) and a treatment group (T: DOT)]. T group received a 20-minute DOT treatment for 6 days. Visual analog scale assessed pain and

a manual algometer assessed PPT and girth was measured at 3 sites on the bicep (5, 9, 13 cm proximal from the antecubital line). A goniometer assessed ROM for extension and flexion. Isokinetic dynamometer measured strength for 2 maximum voluntary isometric contractions at 3 angles (30° , 90° , 130°). A 2 x 6 repeated measures ANOVA to examine differences for girth, PPT, perceived pain, ROM, maximum voluntary isometric contraction (MVC) and maximum isokinetic contraction (MIC). **Results:** A significant main effect was found for perceived pain and PPT between groups ($P \leq 0.01$; $P = 0.002$); with significant interactions between days ($P \leq 0.01$; $P \leq 0.01$). Both displaying improvements for the T group. Girth was significantly different over time for both C and T (2.55 vs. 1.42 , $P = 0.03$) and T resulted in a reduction for days 2-6 ($P = 0.04$). Mean ROM significantly changed over time, with Days 2-6 significantly less than Day 1 ($P < 0.05$), but no significant differences occurred between groups. No differences were found in MVC and MIC at any angles over time or between groups. However, MIC at 30° was decreased over time (5.68 and $.41$, $P = 0.001$), with Day 2 significantly lower than Day 1 (mean difference 14.5 ± 4.8 , $P = 0.008$), with a resulting increase for T when compared to C. **Conclusion:** There are positive effects from DOT on symptoms of exercise-induced DOMS.

3000 Board #46 May 31 2:00 PM - 3:30 PM
Effects of Testosterone and Resistance Training on Anabolic and Inflammatory Biomarkers Following Spinal Cord Injury

Ashraf S. Gorgey, FACSM¹, Refka E. Khalil¹, Ranjodh Gill¹, Christopher P. Cardozo², Robert A. Adler¹. ¹Hunter Holmes McGuire VA Medical Center, Richmond, VA. ²James J. Peters VA Medical Center, Bronx, NY.
 Email: ashraf.gorgey@va.gov
 (No relevant relationships reported)

Resistance training (RT) evokes skeletal muscle hypertrophy via increasing insulin growth factors-1 (IGF-1) after spinal cord injury (SCI). Muscle hypertrophy increases basal metabolic rate (BMR) following 16 weeks of RT; increase in BMR is also linked positively to adiponectin after SCI. The effects of combining testosterone replacement therapy (TRT) and RT on circulating growth factors, adiponectin and inflammatory biomarkers are still unclear. **PURPOSE:** To examine the effects of TRT+RT on IGF-1, insulin growth factors binding protein-3 (IGFBP-3), adiponectin and interleukin-6 (IL-6) compared to TRT only in men with SCI. **METHODS:** Twenty-two men with motor complete SCI were randomized into either 16 weeks of TRT+RT ($n = 11$) or TRT ($n = 11$). After overnight fast, IGF-1, IGFBP-3, adiponectin and IL-6 were measured. Evoked progressive RT using neuromuscular electrical stimulation (2 lbs. increments) was administered twice weekly. Daily TRT patches (2-6 mg/day) were applied on both shoulders at bedtime for 16 weeks. **RESULTS:** IGF-1 showed a decrease ($P = 0.008$) in both TRT+RT ($n=11$; B2: 169.5 ± 96.5 to P1: 101.5 ± 28 ng/ml) and TRT only ($n=11$; B2: 136 ± 74 to P1: 99 ± 36 ng/ml) groups. IGFBP-3 increased significantly ($P = 0.0001$) in both TRT+RT ($n=11$; B2: 1764 ± 665 to P1: 2548.5 ± 853 ng/ml) and TRT ($n=11$; B2: 1918.5 ± 587 to P1: 2778 ± 967 ng/ml). A significant interaction was noted between TRT+RT and TRT groups in the circulating adiponectin ($P = 0.024$). IL-6 decreased ($P = 0.039$) in TRT+RT ($n=8$; B2: 5.5 ± 5.6 to P1: 2.9 ± 5.4 pg/ml) and TRT ($n=11$; B2: 5.9 ± 6.0 to P1: 3.9 ± 4.4 pg/ml) groups. **CONCLUSION:** Greater adipose tissue in men with SCI may have resulted in aromatization of testosterone to estradiol that has been previously shown to decrease IGF-1 and increase IGFBP-3. Increased circulating testosterone following TRT+RT may be responsible for suppressing adiponectin but not in the TRT group. Finally, administering TRT with or without RT may elicit anti-inflammatory effects after SCI.

Effectiveness of One-Year FMS Based Training on Physica Function and Fitness of College Pilot Trainees

Heng Li¹, WEIMO ZHU, FACSM². ¹Nanjing University of Aeronautics and Astronautics, Nanjing, China. ²Nanjing University of Aeronautics and Astronautics University of Illinois at Urbana-Champaign, URBANA, IL. (Sponsor: WEIMO ZHU, FACSM)
 (No relevant relationships reported)

PURPOSE: The fitness and health of airline pilots are essential for the safety of billions of the people traveling on commercial airlines around the world every year. Yet, no effective intervention has been developed to improve pilots' fitness using a

simple and easy approach. Using a randomized controlled trial design, we examined the effectiveness of 1-yr. supervised FMS (functional movement system) based training.

METHODS: 122 male, healthy college pilot trainees (20.1 ± 0.3 yr.) were randomly assigned to FMS training (n = 62) and regular physical education control (n = 60), 178.99 times, about 192 hours in total, during one year, and their height, weight and a set of fitness were measured before and after the study.

RESULTS: Overall adherence to prescribed exercise sessions was 178.99±12.95 times or a 93±6% adherence rate, and there is no difference between groups. FMS scores in the training group increased by 29.7% (from pretest of 13.8 ± 1.44 to posttest of 17.9 ± 1.03), but only 5.1% improvement in the control group (from 13.7 ± 1.28 to 14.4 ± 1.06). Similar changes were observed in weight, BMI, hand-grip (HG), stand-long-jump (SLJ) and Sit-&-Reach (S&R), which are summarized in the table below (M±SD):

| Differences between Posttest and Pretest in Selected Fitness Variables | | | | | | | |
|--|-------------|-------------|-----------|-----------|-----------|----------|-----------|
| Group | Weight (kg) | Height (cm) | BMI | FMS | HG (kg) | SLJ (m) | S&R (cm) |
| Control | 0.05±1.50 | 0.02±.1 | 0.13±.49 | 0.70±.81 | 1.83±1.69 | 0.10±.07 | 2.42±1.05 |
| Training | -0.92±2.04 | 0.06±.3 | -0.31±.66 | 4.10±1.36 | 4.11±2.17 | 0.18±.06 | 4.42±1.19 |
| Effect size | -.26 | .089 | -.66 | .84 | .51 | .49 | .67 |
| F | 7.386* | 5.177 | 6.886* | 18.649*** | 41.83*** | 1.045 | 2.153*** |

*p<0.05, **p<.01, ***p<.001.

CONCLUSIONS: The FMS based training can effectively improve FMS and other physical fitness of college pilot trainees.

KEY WORDS: exercise intervention, randomized controlled trial, college students

Low-volume High-intensity Interval Training On Cardio-metabolic Health And Adherence-related Psycho-perceptual Responses In Overweight/obese Middle-aged Adults

Eric Tsz Chun Poon¹, Jane Jie Yu¹, Sinead Sheridan², Ka Wing Chan¹, Stephen H.S. Wong, FACSM¹. ¹The Chinese University of Hong Kong, Hong Kong, Hong Kong. ²The University of Hong Kong, Hong Kong, Hong Kong.
 Email: ericpoontc@gmail.com
 (No relevant relationships reported)

High-intensity interval training (HIIT) has been proposed as a time-efficient protocol to improve metabolic health. However, its practical efficacy in terms of cardio-metabolic and adherence compared with higher-volume moderate-intensity continuous exercise (MICE) remains unclear.

PURPOSE: To compare the training effects between low-volume HIIT and higher-volume MICE on cardio-metabolic and psycho-perceptual responses in overweight/obese middle-aged men.

METHODS: Twenty overweight/obese men (mean age: 48.0 ± 5.7 years) were randomly assigned to undertake either HIIT (n=10) or MICE (n=10) training for 8 weeks (3 sessions/week). HIIT sessions consisted of ten 1-minute intervals of exercise at 80-90% HR_{max} separated by 1-minute active recovery. MICE sessions involved 50-minute continuous exercise at 65-70% HR_{max}. Health-related variables including cardiovascular fitness (VO_{2max}), body composition and cardio-metabolic blood markers were assessed before and after the intervention. Adherence-related psycho-perceptual variables including enjoyment and self-efficacy were also assessed after the intervention. Paired-sample t-tests were used to compare changes within a group before and after the intervention. Analyses of Covariance were used to compare the group difference in outcome variables after controlling for baseline values.

RESULTS: Both groups showed similar VO_{2max} increase over the 8-week intervention (HIIT: 32.5 ± 5.6 to 36.0 ± 6.2 ; MICE: 36.3 ± 6.0 to 21.5 ± 40.2 ± 5.1 mL kg⁻¹min⁻¹, both p < 0.05). Both groups had significant fat% loss (HIIT: 24.5 ± 3.4 to 23.2 ± 3.5; MICE: 23.0 ± 4.3 to 21.5 ± 4.1, both ps < 0.05) and there was a trend favoring MICE (p = 0.054). Compared to the baseline, MICE group significantly decreased weight, body mass index (BMI), waist circumference and glycated hemoglobin whereas HIIT increased high-density lipoprotein after the intervention. However, these variables did not differ significantly upon group comparison. The self-efficacy and enjoyment responses were found similar between HIIT and MICE (both ps > 0.05).

CONCLUSIONS: Our findings suggest that low-volume HIIT elicits a similar improvement of cardiovascular fitness and adherence-related psycho-perceptual responses as traditional higher-volume MICE in overweight/obese middle-aged men.

Features of Gaseous Metabolism during Exercise Tolerance Testing in Overweight Women

Peizhen Zhang. Beijing Sport University, Beijing, China.
 (Sponsor: Xiangrong Shi, FACSM)
 (No relevant relationships reported)

PURPOSE: To reveal differences of gas metabolism indexes between overweight and normal weight women when they did exercise under different load, instruct overweight women to do exercise scientifically.

METHODS: Women between 20 and 30 years were divided into normal weight(NW) group(N=15, BMI=18-23.9kg/m²) and overweight(OW) group(N=15, BMI>24kg/m²). After the baseline test, using modified Bruce treadmill protocol, the air metabolism indexes of two groups were determined by Cortex MetaMax 3B portable gas metabolic analyzer, including VO₂, minute ventilation(MV), breathing frequency(BF), expiratory end-tidal CO₂ concentration(ETCO₂), expiratory end-tidal O₂ concentration(ETO₂), arterial blood carbon dioxide partial pressure(PaCO₂), VCO₂, oxygen pulse and maximal voluntary ventilation(MMV), etc.

RESULTS: Most of indexes such as VO₂, VCO₂, and MV rose gradually with the load increase during exercise tolerance testing except for ETO₂ and PaCO₂. PaCO₂ and VCO₂ of OW group at grade 4 and grade 5 was significant lower than NW group by 5.6 mmHg and 0.6L/min separately. ETCO₂ of OW group at grade 3 and 4 were significant lower than NW group about 0.5% and 0.6% respectively. During recovery stage, most of indexes decreased gradually, while ETO₂ presented a rising trend. During the recovery stage, ETCO₂ of OW group was significantly lower than NW group(5.3% vs 5.8%), while MMV, MV and oxygen pulse were significantly higher than NW group. MMV of OW group at 2, 3 and 4 minutes were significant lower than NW group by 1L/min, 1L/min and 0.9L/min; MV of OW group were significant lower than normal weight group by 17.8L/min, 20.1L/min and 16.9L/min. The oxygen pulse of OW group during whole 5 minutes recovery period were significantly higher than NW group by 2.7L/min, 3.9L/min, 3.9L/min, 2.9L/min and 2.0L/min. The gaseous metabolism between two groups was significantly different when they did 7.1 and 10.2 METs exercise.

CONCLUSIONS: Although there was no difference in gas metabolism between overweight and normal weight women in resting state, the respiratory function of overweight women was weaker than normal weight women during exercise, especially at the intensities of 7.1 and 10.2 METs. After exercise tolerance testing, the recovery rate of gas metabolism in overweight adult women was slower than that of normal weight women.

3004 Board #50 May 31 3:30 PM - 5:00 PM
Effects of two Different Stretching Methods Program on Range of Motion in Militaries

Paula Paraguassu Brandão¹, Carlos José Nogueira², Adriane Oliveira Sampaio², Alisson Gomes Da Silva², Mário César Conceição³, Gilmar Weber Senna⁴, Estélio Henrique Martin Dantas⁵. ¹Celso Lisboa University, Rio de Janeiro, Brazil. ²Air Force - FAB - Air Cadets Preparatory School, Barbacena, Brazil. ³Federal University of the State of Rio de Janeiro, Rio de Janeiro, Brazil. ⁴Catholic of Petropolis University, Petrópolis, Brazil. ⁵Tiradentes University, Aracaju, Brazil.
 (No relevant relationships reported)

The proprioceptive neuromuscular facilitation and stretching methods are commonly applied in warm-up routines, often with the aim of injury prevention. **PURPOSE:** to investigate the effect of a 12-week program of flexibility training on range of motion (ROM) of shoulder and lumbar spine joints in male militaries. **METHODS:** 90 young male militaries (17.02 ± 1.24 years old), of a universe of 500 students from Air Cadets Preparatory School, were randomly assigned in 3 groups with 30 subjects each one: stretching (SG), proprioceptive neuromuscular facilitation (FNPG) and control (CG). The ROM was measured by goniometry based on LABIFIE protocol in three moments: before, during (6-week) and after training (12-week). The experimental groups performed 3 sets with 5 seconds rest intervals, 5 times a week, for shoulder horizontal flexion (SHF), shoulder horizontal extension (SHE) and lumbar spine flexion (LSF). The scale of perceived exertion in the Flexibility (PERFLEX) (0 - 110) was used to control the intensity in both groups, SG (31 - 60) and FNPG (61 - 80). The exercise duration was 5 seconds for the SG and 8 seconds for each phase (contraction-relaxation) for the FNPG. **RESULTS:** There were no significant differences among 3 groups in the ROM baseline values. The comparative analysis of ROM rates, defined through one-way ANOVA combined with Tukey post-hoc test, showed significant differences in the following movements to the FNPG: SHF (Δ% = 4.6, p < 0.001); SHE (Δ% = 8.6, p < 0.002); LSF (Δ% = 56.1, p < 0.001). **CONCLUSION:** It was concluded that the program of flexibility training by FNP resulted in higher rates of development of ROM when compared to the stretching.

3005 Board #51 May 31 3:30 PM - 5:00 PM
Step Count Targets Corresponding to China Physical Activity Guidelines for the Preschool Children
 Kai Xu, Nianyun Zhang, Wenxian Yang, Yihan Liu, Yunkun Zhang. *Nanjing Sport Institute, Nanjing, China.*
 Email: xkaon@msn.com
 (No relevant relationships reported)

Chinese Preschool Children (3-6 years old) Physical Activity Guidelines (2018 ed) recommends that preschool children should accumulate at least 180 minutes of physical activity (PA) at any intensity throughout the day, including no less than 60 minutes of Moderate-to-Vigorous PA (MVPA).

PURPOSE:

Step count(SC) targets corresponding to these recommendations to assist parents and childcare workers, who will guide children to achieve the PA goal.

METHODS:

903 preschool children were instructed to wear the ActiGraph GT3x accelerometers sensor for more than 4 days, including at least 3 workdays and 1 weekend, for at least 8 hours per day. Sedentary Behavior (SB), Light PA (LPA), Moderate PA (MPA), Vigorous PA (VPA), MVPA, Total PA (TPA) and SC were obtained by GT3x. Receiver operating characteristic curve (ROC) was applied to analyze the thresholds for SC associated with MVPA and TPA, as well as sensitivity and specificity. The statistical analysis was performed by SAS JMP 13.

RESULTS:

The survey obtained valid data from 795 participants. The total wearing days were 4520, with the wearing time of 765.16±122.96min. The time of SB, LPA, MPA, VPA, MVPA, TPA and SC was 470.27±150.24min, 245.66±74.52min, 42.99±20.53min, 16.27±12.50min, 59.26±30.91min, 304.93±94.65min and 8005±3160 steps, respectively. In 4520 days, 43.94% of MVPA reached to 60min and 90.44% of TPA reached to 180min. Only 3 days which contained 60min or more MVPA did not reach to 180min of TPA. The consistency test result was $Kappa = 0.9987$ ($P < 0.0001$). Thus, the evaluation of MVPA was more valuable.

The study also carried out ROC analysis of SC and MVPA which reached to 60min or not. The result showed the Area Under Curve was 0.8671. The maximum Youden index was 0.5900, corresponding to the SC of 7686 steps. The specificity was 0.8505 and sensitivity was 0.7395. When setting the SC standard as 8000, which is close to 7686 steps, the consistency test result was $Kappa = 0.5715$ ($P < 0.0001$), and it was acceptable.

CONCLUSION:

Based on the data, we suggest that SC target of 8000 steps per day can be used to determine whether Chinese preschool children meet the PA recommendations by the national guideline.

Online Walking- Really? Comparing Online Activity Courses With Traditional Face To Face Courses.
 Keith Randazzo, Suzanne McDonough, Christopher Washam. *Mississippi College, Clinton, MS.*
 Email: kdrandazzo@mc.edu
 (No relevant relationships reported)

As female students enter college they are given many opportunities to be physical active including fitness classes and student gym memberships. Despite many benefits and opportunities, many female college students are not achieving the recommended 10,000 steps per day (Clemente et al, 2016). Activity trackers provide additional short and long term motivation for becoming physically active (Fritz, 2014). An online activity tracker based course possesses unique opportunities to increase student autonomy and exercise self-efficacy. Both of which are related to physical activity levels. Findings will provide valuable insight into benefits and drawbacks of online activity courses. **PURPOSE:** This study sought to examine effects of an online fitness course on psychosocial aspects of physical activity (i.e. exercise self-efficacy and intention to be physically active) in female college students. **METHODS:** Participants ($N=42$, mean age = 20.1 ± 1.5 years) college undergraduate students. Study consisted of three groups. Experiential group contained 14 students enrolled in online walking. Control group one had 14 females students enrolled in face to face activity course and the other contain 14 students who never took an activity course. Each group was given a survey measuring exercise self-efficacy and intention to exercise at the start of the semester and then 15 weeks later.

RESULTS: Two 3(group) X 2 (time) RMANOVA were run to test the interactions. There were significant group by time interactions for both intention to continue exercising [$F(2, 39) = 9.26, p < .001, \eta_p^2 = .27$] and exercise self-efficacy [$F(2, 39) = 23.03, p = .001, \eta_p^2 = .17$] and both indicated large effect sizes (Cohen, 1969). The group by time interactions indicated that participating in activity courses whether online or face to face positively affected students' intention to exercise as well as their exercise self-efficacy. Control group had no significant changes.

CONCLUSIONS: The results of this study provided two valuable insights. First, this study provided evidence of the effectiveness of online courses in influencing students' intention to continue exercising and exercise self-efficacy. Second, these results demonstrated students can receive similar benefits from online courses as they receive from face to face activity courses.

Health-Related Fitness Knowledge, Physical Activity, and Instructional Practices Among Male and Female Physical Educators
 Ben D. Kern, Stacy Imagbe, James M. Clemons, David Bellar. *University of Louisiana at Lafayette, Lafayette, LA.*
 Email: benkern@louisiana.edu
 (No relevant relationships reported)

Lifelong physical activity (PA) is an important outcome of physical education (PE) programs. To effectively promote student PA, educators must possess adequate health-related fitness knowledge (HRFK), utilize effective instructional practices related to HRFK, and model a physically active lifestyle. Research among US adults shows that females tend to be less physically active than male counterparts, however, no research has documented gender differences in HRFK nor instructional practices related to HRFK.

PURPOSE: To determine the relationship of HRFK, PA, and HRFK instructional practices among female and male physical educators.

METHODS: A three-part questionnaire was administered to physical educators ($N = 796$; 409 female) from seven US states. Part 1 of the questionnaire included the *International Physical Activity Questionnaire* (I-PAQ), measuring vigorous, moderate, and light PA min/wk. Part 2 included 10-items from *PE Metrics* Standards 3 & 4 Assessment, measuring participants' HRFK. Part 3 included the *Physical Education Curriculum Analysis Tool* (PECAT) to determine the extent to which participants teach and assess student HRFK. Survey responses were adapted to a 5-point likert scale. One-way ANOVA along with post-hoc t-tests were conducted and gender comparisons made.

RESULTS: Female physical educators scored significantly higher in HRFK (85% HRFK, $F[2,794]=4.17, t=2.85, p=.002$ [$r=.102, d=.21$]), and reported less weekly minutes of vigorous PA (142.2 min/wk, $F[2,794]=2.78, t=1.98, p=.024, [r=.08, d=.14]$) than male counterparts (82% HRFK, 157.5 min/wk vigorous PA). Females also reported significantly greater teaching of HRFK (14.8 vs. 13.9, $F[2,794]=3.09, t=2.37, p=.009, [r=.09, d=.17]$) and assessment of HRFK than male physical educators, approaching significance (9.7 vs. 9.3, $F[2,794]=1.24, t=1.57, p=.058, [r=.06, d=.11]$). No differences in moderate and light PA were observed.

CONCLUSIONS: In spite of participating in less weekly vigorous PA, female physical educators in the study demonstrated greater HRFK and emphasized teaching and assessing HRFK more, thus may be more effective in promoting health-related fitness and lifelong student PA.

3008 Board #54 May 31 3:30 PM - 5:00 PM
An Educational Intervention Expands Sports Nutrition Knowledge in Division II Athletic Staff
 Rachel L. Darr, Savannah Feldpausch, Jeremy Glaser. *Saginaw Valley State University, University Center, MI.*
 Email: rldarr@svsu.edu
 (No relevant relationships reported)

College athletic staff are confronted with numerous day to day perils in attempting to advance the performance of their athletes with suitable nutrition playing a dynamic role in that task. Having adequate nutrition knowledge is key to providing satisfactory and appropriate information to improve performance. The ideal providers of such knowledge are Registered Dietitians with a specialty in Sports Dietetics who may not be obtainable or have scarce contact to athletes on a smaller, less resourced Division II campus. **Purpose.** First establish the knowledge base of those that have regular contact, who consistently provide nutrition education to athletes and formally explore if 3 nutrition education sessions can advance that knowledge. **Methods.** Division II athletic staff were asked 20 sports nutrition knowledge questions focusing on macronutrients, micronutrients, supplements, weight management, eating disorders, and hydration relating to sport performance in an online pre-survey. Three nutrition education sessions focusing on the survey material were administered to athletic staff by a Registered Dietitian. Succeeding education, post-surveys (same as pre-surveys) were taken online. Total percent correct finalized survey results. A Likert scale range measured self-efficacy, 1-not at all confident to 4-very confident. Pearson correlations and linear regressions were utilized to compare pre-/post-survey results and self-efficacy. **Results.** Twenty-six pre-surveys were completed (39.7±13.6 yo). There were no relationships with pre-surveys to age, gender, or title of participants. Ten pre-survey participants (41.7±12.9yo) likewise completed post-surveys. Percent total scores improved from pre-surveys (64.5±6.9) to post surveys (76.0±9.4), $p=0.017$. Self-efficacy increased from pre-surveys (2.7 ±0.4) to post-surveys (3.0±0.4), $p=0.012$. No differences in knowledge were seen between gender, title, or education level, in pre- vs

post-survey results. **Conclusion.** Educating an athletic staff with 3 nutrition education interventions amplifies their knowledge base and self-efficacy; regardless of gender, title, or education level. This study warrants the need for further research to examine the implementation of this new knowledge base from the athletic staff to the athletes.

3009 Board #55 May 31 3:30 PM - 5:00 PM
Gender Differences in Golf Performance After Various Warm-ups

Andrea Fradkin, FACSM. *Bloomsburg University, Bloomsburg, PA.*
 Email: afradkin@bloomu.edu
 (No relevant relationships reported)

Distinct injury differences exist between genders in golf, however, performance improvement benefits have not been studied.

PURPOSE: To examine golf performance differences by gender following individual and combined warm-up components.

METHODS: Sixty-five (31 male, 34 female) proficient golfers performed 5 baseline swings, followed by 10 swings after seven randomly ordered warm-up combinations (aerobic exercise (AE); stretching (ST); specific activity (SP); aerobic exercise & stretching (AE+ST); aerobic exercise & specific activity (AE+SP); stretching & specific activity (ST+SP); and all 3 components (ALL)), on non-consecutive days. Club and ball flight characteristics were measured.

RESULTS: Clubhead speed (CHS) improved following AE, SP, AE+ST, AE+SP, ALL ($p \leq 0.001$), ST, and ST+SP ($p \leq 0.05$). Carry distance (CD) improved after AE, AE+ST, AE+SP, ALL ($p \leq 0.001$), SP, ST ($p \leq 0.01$), and ST+SP ($p \leq 0.05$). Significant improvements were also seen in ball speed (BSPEED) for AE, AE+ST, AE+SP, ALL ($p \leq 0.001$), SP, and ST ($p \leq 0.01$), however, ST+SP showed non-significant increases. For launch angle (LA), AE, ST, SP, AE+SP, and ALL (female) showed non-significant increases, whereas ST+SP, AE+ST, and ALL (male) showed non-significant decreases. Finally, in backspin (BSPIN), AE, ST, SP, AE+SP, ST+SP (male), and ALL (female) showed non-significant increases, whereas AE+ST, ST+SP (female) and ALL (male) had non-significant decreases.

CONCLUSION: There were no significant gender differences following a warm-up. AE was the most valuable element to complete for performance improvement, with the greatest increases seen after AE+SP, AE, and ALL. ST significantly decreased CD, BSPEED, and CHS, however, ST+SP showed significant increases in CD and CHS, suggesting that 30 seconds of SP off-sets any negative effects of static stretching. Performance also significantly increased with AE+ST, suggesting that pre-warming the body may also negate any harmful effects of static stretching. The overall reliability was high (0.831-0.989), suggesting golfers had consistent swings, thus the performance changes were a result of the warm-up components. This was further supported by significant changes in CHS and BSPEED but not LA or BSPIN, indicating that CD improved solely as a result of increased BSPEED attributed to increased CHS.

3010 Board #56 May 31 3:30 PM - 5:00 PM
Actions of The Nasf-ab In a City of The Extreme North of Brazil

Ana Paula de Azevedo Albuquerque¹, Paula Paraguassú Brandão², Valderi Nascimento Viana¹, Thiago Santos Cardoso¹, Isadora Canto³, Rodrigo Gomes de Souza Vale⁴. ¹Universidade Federal do Amapá, Faculdade de Macapá-FAMA, Macapá, Brazil. ²Universidade Federal do Estado do Rio de Janeiro, Rio de Janeiro, Brazil. ³Coordenadora do Núcleo Ampliado de Saúde da Família e Atenção Básica, Macapá, Brazil. ⁴Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil.
 (No relevant relationships reported)

PURPOSE: Analyze if the teams the Núcleo Ampliado de Saúde da Família e Atenção Básica (NASF-AB) - Extended Core of family health and primary health care - of Sistema Único de Saúde do Brasil (SUS) - Unified Health System - of Brazil, of the city of Macapá in the State of Amapá, It's act in accordance with what is proposed by the Ministry of health.

METHODS: The present study is a descriptive and explanatory research. It includes both qualitative and quantitative character. Which is used the monthly reports of the teams of the Extended Core of family health and primary health care from May to September 2018. The reports used to analyze belongs to 8 teams of NASF-AB that exist in the city of Macapá in the State of Amapá, how that teams work through matrix support each of which is composed of six distinct areas professionals among there are the Physiotherapist, social worker, nutritionist, psychologist, speech therapist and physical education professional.

RESULTS: The results obtained from the documentary survey allow a good analysis about NASF-AB professionals' actions, It was analyzed 3 among 9 available which are health actions, individualized care and home visits accompanied with the Estratégia Saúde da Família (ESF) - The family health strategy. The analysis took into account all the professionals that compose the teams and their actions of the

selected items. Among the data obtained it is essential to emphasize that of all health actions only 7.5% of them had participation of the physical education professional, while the psychologist was 23.8%. When analyzing the number of individualized care in absolute terms there is a large difference between the number of attendances of the psychology professional, which was 1625 individuals, and the social work professional, which in 5 months took care of 632 users.

CONCLUSION: The research evidenced that the attendances made by the NASF-AB teams, among the 3 items analyzed, It is below the expected level of what should be, especially when it's considered that the teams should work using the matrix support, which probably does not occur, If a chosen area is taken into account and the population selected It is understand that the population reach is still restricted. In front of exposed believes that should provide greater training for these professionals.

 (No relevant relationships reported)

PURPOSE: To investigate the effects of lipid profile and anthropometric measures in obese children based on a seven day participation at a health education camp (KIDS).

METHODS: Twenty children were enrolled in the KIDS (12 girls; 8 boys; 9.97±1.27 yrs.; 52.5±10.3 kg; 143.6±10.94 cm). The KIDS team was composed by a Physical Educator, Nutritionist, Psychologist, Physiologist and a Pedagogo which developed the multidisciplinary activities for parents and children. The parents attended the KIDS on the first two days to raise awareness about the healthy habits for the whole family. The children stayed for another five days. The blood sample for lipid profile and anthropometric data were collected before and after KIDS. The Student t test was applied to compare pre and post KIDS data. The level of significance was set at $p < 0.05$. **RESULTS:** The results are presented at table 1. **Table 1-** Anthropometric data and lipids profile (Mean±SD) before and after seven-day KIDS (n=20).

| Parameters | PRE | POST | Δ (%) | p |
|-------------------------------|--------------|-------------|-------|--------|

Recommendations for the Implementation of Physical Activity Intervention Evaluations in Leisure Centres

Nadja A. Willinger¹, James Steele², Gary Liguori, FACSM³, Steve Mann⁴, Lou Atkinson⁵, Alfonso Jimenez⁶, Elizabeth Horton¹. ¹Coventry University, Coventry, United Kingdom. ²Solent University, Southampton, UK, ukactive Research Institute, London, United Kingdom. ³University of Rhode Island, Kingston, RI. ⁴Places for People Leisure, London, United Kingdom. ⁵Aston University, Birmingham, United Kingdom. ⁶GO fit LAB, Ingesport, Madrid, Spain; Coventry University, Coventry, United Kingdom.
 (No relevant relationships reported)

Introduction: Conducting physical activity research in a real-world setting, such as leisure centres (LC's), faces many barriers. Because of this, most applied research has a limited scope of both setting and population. This research explores the barriers and possible solutions for implementing research into real-world settings.

Methods: During January 2018, a multicentre Randomized Controlled Trial aimed at increasing PA levels and member retention rates of LC's was piloted. The research was conducted at six different LC across England. In February and March of 2018, semi-structured telephone interviews with 12 total staff from the different LC's were conducted. Interviews were meant to gather feedback on the implementation of research study processes in the LCs and staff were prompted to reflect on specific barriers and success to the research implementation process. Data were analysed thematically using NVivo.

Results: Feedback indicated that communication between exercise professionals (EP), the sales staff, LC staff, and research team was impaired, largely due to the compartmentalized nature of the LCs and busy working hours. It was criticised that both recruitment procedure and delivery of intervention sessions were described in the same manual, therefore confusing staff as to which procedure was to be carried out by the sales team or EP's. Additionally, compared with sales teams, EPs were overall more confident in recruiting research participants.

Discussion: Based on these qualitative interviews, primary suggestions to aid the implementation of intervention studies in the leisure industry include 1) the necessity of appointing a study manager per LC, 2) scheduling regular conference calls between research staff and LCs to aid the intra- and inter-organisational exchange of information, and 3) the involvement of EPs in study recruitment and intervention delivery. To improve the staff's understanding of all study processes, the distribution of separate manuals for the recruitment procedures and intervention delivery is suggested. **Conclusion:** These recommendations can aid research implementation into real-world settings, and eventually translate into higher rates of LC use and increased PA at the population level.

The Effect of Foam Rolling and Vibrating Foam Rolling on Exercise-Induced Muscle Fatigue

Yuanpeng Liao, Yihua Ying, Yinghong Ying. ChengDu Sports Institute, ChengDu, China.
 Email: lyppercy@163.com
 (No relevant relationships reported)

PURPOSE: To evaluate the effectiveness of foam rolling (FR) and vibrating foam rolling (VFR) on the rehabilitation of exercise-induced muscle fatigue (EIMF).

METHODS: Sixty-six male college students (age: 24.5±2.5 yrs) were randomly divided into three groups: a control group (n=22), a FR group (n=22) and VFR group (n=22). All subjects performed a bout of bottom-up squats for obtaining EIMF. All subjects were measured for peak torque (PT), peak torque/body weight (PT/BW), average peak torque (APT) and total work (TW) by using an isokinetic test system and do the Visual Analogue Scale (VAS) before, 0.5h, 24h, and 48h after the squats. The only difference among groups was that the FR group and VFR group performed a 1-min FR exercise protocol and VFR exercise protocol separately before each post-EIMF protocol measurement (at 0.5h, 24h, and 48h). The data was analyzed by one-way ANOVAs with LSD post-hoc tests, and independent t-tests.

RESULTS: See below table for all results. At 0.5h after the EIMF protocol, PT, PT/BW, APT and TW significantly decreased in FR group, VFR group and control group (all p<0.01), and there were no significant group differences in these variables. At 24h after the EIMF protocol, T, PT/BW, APT and TW tended to be higher in the FR group and VFR group than in the control group, and there were significant group differences between FR group, VFR group and the control group (p<0.01), although there were no significant group differences between FR group and VFR group (P>0.05). At 48h after the EIMF protocol, PT, PT/BW, APT and TW were significantly higher in the FR group and VFR group than in the control group (P<0.01, p<0.05), there were significant group differences between FR group and VFR group (P<0.05).

CONCLUSIONS: Foam rolling and Vibrating Foam Rolling resulted in a faster recovery in muscle strength and muscle work following a bout of bottom-up squats.

In the same condition, the VFR seems to be better in the recovery in muscle strength and muscle work following a bout of bottom-up squats than the FR. The potential mechanism needs to be further investigated.

Moving Beyond Healthcare To Health: A Preliminary And Descriptive Statistical Report On The Health Peers Programme In The War On Diabetes In Singapore In 2017

Fadzil Hamzah, Loh Win Nie, Michelle Lauw, Felicia Kua, Valencia Lim. Changi General Hospital, Singapore, Singapore.
 Email: fadzil_hamzah@cgh.com.sg
 (No relevant relationships reported)

INTRODUCTION: The Health Peers Programme illustrates how healthcare providers from multiple disciplines work together to pilot a community health programme in partnership with community stakeholders supported by government health initiatives in the early intervention of diabetes. **PURPOSE:** To determine the impact of a multidisciplinary community health programme focusing on early intervention of diabetes in individuals who are at risk or who have been diagnosed with diabetes.

METHODS: 137 volunteers were trained as Health Peers in 2017 through a structured programme developed by a sports physician, a dietician and a clinical psychologist to coach those at-risk or diagnosed with diabetes. Each health peer reached out to at least 2 residents in a housing estate within 6 months. An outreach included an initial house visit with face-to-face interactions and two subsequent contact sessions, involving face-to-face interaction sessions, online text messaging or teleconversation. The competency and confidence of the Health Peers to conduct health coaching were assessed post-training. A survey was conducted at 6 months post-outreach to assess the extent of translation from knowledge and awareness, to lifestyle changes by the residents. **RESULTS:** All Health Peers showed improvement in their competency post-training. Their confidence levels in health coaching showed increasing trends throughout the period of assessment. 88.9% of the residents reported an overall positive experience when interacting with the Health Peers. All of them reported that they would consult the Health Peers for assistance in their health goals. 87.3% agreed that the Health Peers have impacted their knowledge and awareness of diabetes and healthy living. 83.3% made positive changes to their eating habits and exercise based on the national recommendations after 6 months of health coaching. **CONCLUSION:** A successful and sustainable community health programme must aim to appeal and evoke ownership of its participants to champion chronic disease management and prevention by engaging them through their own experiences. This is achieved through a dynamic and structured programme developed by various expertise within the healthcare profession in collaboration with community stakeholders and supported by government health initiatives.

Effect of 6-week Hypoxic Training on Plasma Metabolites in Overweight Females

Ge Hu, Hui Cao, Jianmin Cao, liwen Lian, Kunshun Guo.
 Beijing Sport University, Beijing, China.
 Email: wizardhuge@outlook.com
 (No relevant relationships reported)

Overweight female population in China ranks first in the world. Overweight is a risk factor for many diseases. Hypoxic training can reduce body weight and improve metabolism. However, the mechanism of weight loss in hypoxia remains unclear.

PURPOSE: To examine the effect of hypoxic training on plasma metabolites in overweight females. **METHODS:** 40 overweight females (age: 31.30±5.15 years, body mass index: 30.11±4.35 kg/cm²) were selected and grouped into hypoxic training group (HT, n=20) and normoxic training group (NT, n=20). All subjects underwent a 6-week training, which included resistance training and endurance training for 30 minutes each, 3 times a week. Resistance training: dumbbells with 12RM, 8 actions, 2 groups for each action. Endurance training: treadmill with slope 0° at 60%-70% maximum heart rate. The HT group was trained under normobaric hypoxia (16% O₂). The NT group was trained in normoxia. The diet was not restricted. Body composition was detected before and after training. Plasma metabolites were analyzed by using liquid chromatography/mass spectrometry and principal component analysis. **RESULTS:** After training, the body fat and serum total cholesterol in HT group reduced more than that in NT group on average (8.37% vs 3.60%, p=0.035; 4.95% vs -14.28%, p=0.005). The metabolic characteristics were significantly different between HT and NT group, there were 50 endogenous metabolites (VIP>1 and p<0.05), of which 33 were increased and 17 were decreased. Major metabolites that changed with hypoxic training included sphingosine, sphingomyelin, phosphatidylcholine, L-valine, linoleic acid and oleic acid. **CONCLUSION:** Hypoxic training has a marked effect on the plasma metabolites in overweight females, which can improve the lipid metabolism by regulating the metabolic pathway of linoleic acid. These findings may lead to a better understanding of the mechanism of hypoxic training in weight loss.

Figure 1. PLS-DA model of LC/MS metabolomics data for post-training between HT and NT group

Top Down 1RM Testing May Facilitate Higher and More Reliable Maximal Strength Values Than Traditional <Bottom Up> Methodologies

Andrew N. Buskard, Joseph F. Signorile. *University of Miami, Coral Gables, FL*. (Sponsor: Dr. Kevin Jacobs, FACSM)
 Email: andrewbuskard@miami.edu
 (No relevant relationships reported)

PURPOSE: Accurate determinations of individuals' maximal strength (1RM) are critical when evaluating the effectiveness of exercise interventions involving progressive resistance training. 'Bottom-up' testing methods (BT), involving progressions from low to maximal loads, are commonly employed in clinical and laboratory environments. Concerns about the reliability of this method in novice exercisers suggest that a different technique may be more effective. This study compared the reliability and effectiveness of BT testing to that of 'top down' 1RM testing (TDT), in which the initial testing load is greater than individual's 1RM and loads are progressively reduced until a successful repetition is completed. **METHODS:** 70 healthy adults (age = 45.03 ± 25.64 y) with diverse strength training experience were randomized into a reliability testing trial (n=33) or an optimal method trial (n=27) following a familiarization visit designed to introduce subjects to the pneumatic chest press (CP) and leg press (LP) and to determine their approximate 1RM using a sub-maximal method. Subjects in the reliability trial performed either TDT or BT 1RM testing on 3 occasions separated by at least 3 days, while subjects in the optimal method trial performed each method once in random order on different days. **RESULTS:** No between-group differences were identified at baseline with respect to age, BMI, previous training experience, or predicted leg and chest press 1RM for either trial. For the reliability trial, no significant between-group differences were identified in coefficient of variation over the three testing days for either the CP or LP. However, the BT group produced significantly higher CP and LP 1RM values on the second testing day (Cohen's *d* = -.67, *p* = .014; Cohen's *d* = -.70, *p* = .011, respectively). For the optimal method trial, no order effect across days was identified between BT or TDT. However, significantly higher CP 1RM values were obtained using TDT (Cohen's *d* = .92, *p* = .015). Untrained individuals in this sample obtained significantly higher LP 1RM values using TDT (Cohen's *d* = 2.72, *p* = .001) and older individuals obtained significantly higher CP values (Cohen's *d* = 1.37, *p* = .028) using TDT. **CONCLUSION:** TDT may produce higher and more reliable 1RM values than BT across a wide spectrum of ages and experience levels.

Comparison between Caloric Expenditure Sitting on a Standard Chair, Stability Ball, and Balanced Active Sitting

Emily L. Langford, Ronald L. Snarr. *Georgia Southern University, Statesboro, GA*.
 Email: el02241@georgiasouthern.edu
 (No relevant relationships reported)

Chronic sedentary behaviors can be detrimental to health and increase the risk of mortality. Products, such as stability balls and active balanced sitting chairs, have recently emerged as a way to reduce sedentary behaviors in office settings. **PURPOSE:** To determine if differences in caloric expenditure and heart rate exist between a standard chair (SC), a stability ball (SB), and an active balanced sitting chair (ST). **METHODS:** Participants (n=20) performed a 10 minute reading task while sitting on a standard chair, a stability ball, and an active balanced sitting chair. All three conditions were randomized for each participant. Caloric expenditure and heart rate were monitored via a portable metabolic cart and a heart rate strap, respectively. Conditions were compared using a repeated measures ANOVA and significant comparisons were assessed through Bonferroni post-hoc analyses. **RESULTS:** Heart

rate response was greater on the ST (84±15 bpm) when compared to the SC (75±12 bpm; *p*<.001) and SB (73±12 bpm; *p*<.001). Total caloric expenditure on the ST (27.4±7.07 kcal) was greater than SC (16.55±3.07 kcal; *p*<.001) and SB (16.85±2.54 kcal; *p*<.001); however, no difference existed between SC and SB. Caloric expenditure per minute was greater on the ST (2.73±0.71 kcal) versus the SC (1.64±0.28 kcal; *p*<.001) and SB (1.69±0.26 kcal; *p*<.001). Additionally, the ST required increased MET values (2.35±0.49 METs) than the SC (1.437±0.28 METs; *p*<.001) or the SB (1.50±0.33 METs; *p*<.001). No significant differences were observed between the SB and SC for any of the comparisons. **CONCLUSION:** The ST produced a greater heart rate response and caloric expenditure than the SC or SB, indicating that active balanced sitting may be a feasible way to reduce sedentary office behaviors. Consistent with previous literature, there were no differences in heart rate or caloric expenditure between the SB and the SC during any condition. These results suggest that active sitting, which includes a strong balance component, may be crucial to increasing energy expenditure beyond that of sitting on a SC.

Different Frequencies Of High-intensity Interval Training On Aerobic Fitness And Fatness In Overweight/obese Young Adults

Edwin C. Chin, Parco M. Siu, FACSM. *The University of Hong Kong, Hong Kong, Hong Kong*. (Sponsor: Parco M Siu, FACSM)
 Email: edwincyc@connect.hku.hk
 (No relevant relationships reported)

PURPOSE: To compare the effect of high-intensity interval training (HIIT) on aerobic fitness, body composition, and blood pressure. **METHODS:** Forty-seven overweight/obese young men aged between 18 to 30 years were randomly allocated to non-interventional control (CON; n=14), three HIIT sessions weekly (HIIT×3; n=14), two HIIT sessions weekly (HIIT×2; n=10), and one HIIT session weekly (HIIT×1; n=9). Each HIIT session consisted of 12 × 1-minute of 30-meter shuttle runs at 90% of heart rate reserve (HRR) and interspersed with 11 × 1-minute bouts of jogging at 70% HRR. Aerobic fitness, body fatness, and blood pressure were examined before, after 4 weeks and 8 weeks of the intervention. Aerobic fitness was measured by 20-meter shuttle multistage run test, body fatness was measured by bioelectrical impedance analyzer, and blood pressure was assessed by electronic sphygmomanometer. **RESULTS:** Aerobic fitness in all HIIT groups were significantly higher than CON at post-test. Percent body fat mass, absolute body fat mass, trunk fat mass, and systolic blood pressure in all HIIT groups were significantly lower than CON at post-test. The change of aerobic fitness (Δ% total running distance: *r* = 0.6, *p* < 0.01) was positively correlated with the exercise frequency of HIIT. The Δ% percent body fat mass (*r* = -110.5, *p* < 0.01), Δ% absolute body fat mass (*r* = -0.5, *p* < 0.01), Δ% absolute trunk fat mass (*r* = -0.4, *p* < 0.01) and Δ% systolic blood pressure (*r* = -0.4, *p* < 0.05) showed negative correlation with the exercise frequency of HIIT. **CONCLUSIONS:** Dose-response in the improvement of aerobic fitness, reduction of body fatness, reduction of systolic blood pressure among different exercising frequencies of HIIT were observed. HIIT, even with lower frequency (once weekly), improved aerobic fitness, body fatness, and blood pressure in overweight or obese young adults.

3019 Board #65 May 31 3:30 PM - 5:00 PM

The Experiences of College Students Enrolled in a Fitness Walking Class with Shelter Dogs

Melanie L. Sartore-Baldwin, Bibha M. Das, Stacey R. Altman. *East Carolina University, Greenville, NC*. (Sponsor: Katrina DuBose, FACSM)
 Email: sartorem@ecu.edu
 (No relevant relationships reported)

Many four-year colleges and universities no longer require physical activity courses as part of student curricula but continue to offer elective physical activity courses. These elective courses are important given the benefits associated with physical activity, the low levels of physical activity found within the college student population, and the importance of establishing lifelong physical activity habits at earlier life stages. College and universities also stress the importance of community engagement within their courses. In the physical activity context, service-learning curricula has been used to teach responsibility, life skills, and values to students suggesting that addressing the physical activity needs of others, such as shelter dogs, within activity-based courses may benefit multiple entities. **PURPOSE:** The purpose of this study was to examine the experiences of students enrolled in a service-learning fitness walking course in which students walk local shelter dogs. **METHODS:** Data were collected over six full semesters and three summer sessions. During this time, the course was offered twelve times and a total 66 reflection papers

were submitted. These papers were guided by five questions constructed to assess the objectives of the course. Adopting a grounded theory approach, the papers were inductively analyzed first using open coding, followed by focused and axial coding. **RESULTS:** One central theme emerged under which several subthemes was identified. The central theme was the importance of walking to shelter dog physical and emotional well-being. As one subtheme, students described feeling motivated and obliged to attend class regularly so the dogs could get physical activity. Other subthemes included the importance of walking for humans, the importance of patience, enjoyment of interacting with the dogs, learning about the physical activity needs of dogs, and deconstructing stereotypes of shelter animals. **CONCLUSIONS:** The results of this study suggest that students enjoyed engaging in regular walks for the wellbeing of the shelter animals. While students did acknowledge that they were also getting physical activity, this was secondary. Findings suggest that multiple entities can benefit from service-learning physical activity courses and be sources of motivation for students.

3020 Board #66 May 31 3:30 PM - 5:00 PM
A Survey of HBCU Nutritional Habits, Attitudes About Health and Risk Perception

Jennifer J. Brown, Trevian D. Long, Jonquin L. Elliott, Kelly N. Brewer, Demond L. Holley, Samara D. Hauser. *Elizabeth City State University, Elizabeth City, NC.*
 Email: jjbrown@ecsu.edu
 (No relevant relationships reported)

PURPOSE: The purpose of this study was to explore nutritional habits, attitudes about health, and risk perception in an HBCU population of rural northeastern North Carolina. Specific targets of assessment included nutritional status, perceptions surrounding health risks, environmental risks and risk perception related to common diseases such as prediabetes (PD), high blood pressure (HBP), stroke, asthma, cancer and cardiovascular disease (CVD).

METHODS: A total of 300 university students, faculty and staff ($N = 300$, $M = 143$, $F = 157$, ages 18-65 yrs, $Mean = 23.39$ yrs, $SD = 8.40$ yrs), of any activity level, from all parts of campus were surveyed utilizing the REAP-S and RPS-DD instruments. SPSS correlations and Chi Square tests were used to analyze survey and demographic data.

RESULTS: A strong positive correlation was demonstrated between the beliefs of "I feel I have very little control over risks to my health" and "If I am going to get diabetes, there is not much I can do about it" ($N = 293$, $R = .524$, $p < .001$). Beliefs that exercising regularly could reduce risk strongly correlated to controlling weight gain ($N = 293$, $R = .737$, $p < .001$), as did eating healthy and reducing the risk of diabetes ($N = 292$, $R = .627$, $p < .001$). Increased consumption of sweets ($N = 295$, $R = .157$, $p < .007$) and processed meals ($N = 295$, $R = .125$, $p < .032$) correlated with beliefs related to a lack of control. A negative correlation was demonstrated between this perception and a willingness to make change ($N = 287$, $R = -.123$, $p < .036$), and beliefs that personal efforts would help control risk ($N = 294$, $R = -.192$, $p < .001$). Perceived risk for heart disease correlated with family CVD diagnosis ($N = 292$, $R = -.507$, $p < .001$), perceived cancer risk ($N = 287$, $R = .537$, $p < .001$), perceived HBP risk ($N = 283$, $R = .389$, $p < .001$), perceived stroke risk ($N = 289$, $R = .556$, $p < .001$), and perceived asthma risk ($N = 286$, $R = .340$, $p < .001$).

CONCLUSIONS: Findings suggest perceived control is a powerful indicator of perceptions of the effectiveness of positive health behaviors, and engagement in management behaviors. Family CVD diagnosis strongly impacted personal perceptions of risk for cancer, HBP, stroke, and asthma risk. Future research should evaluate effective interventions centered around healthy exercise and nutrition practices, with an emphasis on internal locus of control.

Differences In Strategic Constructs Of The Transtheoretical Model Across The Levels Of Sitting Time

Ho Han¹, Heontae Kim², Harold W. Kohl, FACSM³. ¹Oklahoma State University, Stillwater, OK. ²The University of Mississippi, University, MS. ³University of Texas Health Science Center at Houston, Austin, TX. (Sponsor: Harold W. Kohl III, FACSM)
 Email: hohan@okstate.edu
 (No relevant relationships reported)

Differences in Strategic Constructs of the Transtheoretical Model across the Levels of Sitting Time

Ho Han, Heontae Kim, Harold W. Kohl II, FACSM
 Oklahoma State University, Stillwater, OK, The University of Mississippi, University, MS, University of Texas Health Science Center at Houston, Austin, TX
 The strategic constructs, such as processes of change, self-efficacy, and decisional balance, of the Transtheoretical Model (TTM) have been relatively neglected by researchers in spite of the fact that they potentially provide important insight into the content of behavior change interventions. As most criticisms of the TTM are targeted at the central organizing construct, the stages of change, due to its arbitrary stage

classification, the direct comparison between objective values attaching to a specific behavior and the strategic constructs is warranted. **PURPOSE:** To investigate the differences in strategic constructs of the TTM across objectively measured sitting time. **METHODS:** A total of 201 college students conducted a TTM questionnaire for sedentary behavior and worn an accelerometer for seven consecutive days in order to obtain objective sitting time. Multivariate analyses of variances (MANOVA) with post-hoc pairwise comparisons were conducted to determine mean differences in the strategic constructs across quintiles of sitting time. Tests for linear trends were conducted using orthogonal polynomial coefficients. A two-sided $P < 0.05$ was considered statistically significant. **RESULTS:** Compared with participants in higher quintiles of sitting time, 7 out of 10 processes of change (e.g., mostly consciousness raising [$\eta^2_p = 0.09$], followed by social liberation [$\eta^2_p = 0.08$], contingency management [$\eta^2_p = 0.08$], etc.) were used significantly more frequently by those in the lowest quintile ($p < 0.05$) with negative linear trends ($p_{trend} < .05$). No significant differences were found in the constructs of self-efficacy and decisional balance across the quintiles. **CONCLUSION:** Based on this preliminary analysis it appears that the use of certain processes of change would be more beneficial to reduce sitting time or to protect their current sitting time from relapse.

3022 Board #68 May 31 3:30 PM - 5:00 PM
Influence Of Non-cognitive Ability Scores On Physical Fitness Improvement: An Examination Using Longitudinal Data

Takahiro Nakano¹, Tomoaki Sakai¹, Kosho Kasuga². ¹Nagoya Gakuin University, Nagoya, Japan. ²Gifu University, Gifu, Japan. (Sponsor: Kiyoji Tanaka, FACSM)
 Email: taka@ngu.ac.jp
 (No relevant relationships reported)

Recently, many activities have been conducted to improve physical fitness owing to the decline in children's physical fitness observed in Japan. Such activities have led to gradual improvements in physical fitness. With the commencement of a study to examine the educational effect of exercise promotion, this program entered a new stage. Specifically, we focused on motivation, perseverance, and positive attitudes that are emphasized in young children. These non-cognitive abilities are considered indispensable for future social success. A few studies have examined the relationship between physical fitness and non-cognitive abilities. Last year, we also presented findings of a study on the relationship between non-cognitive abilities and physical fitness of children using cross sectional data, and identified the need to examine the longitudinal relationship. **PURPOSE:** The present aimed to examine the influence of non-cognitive abilities on physical fitness improvement using longitudinal data. **METHODS:** We conducted physical fitness tests and a non-cognitive ability survey on 264 young children. Data were collected during the same period for 2 years. Participants were classified into the improved and non-improved groups based on the extent of change in their ranking in the class. Differences in non-cognitive ability scores in the first and second year were examined using a three-way ANOVA with physical fitness improvement, sex, and grade as factors. **RESULTS:** No significant interaction was confirmed between gender, grade, and physical fitness improvement in any year. A significant main effect of sex, grade, and physical fitness improvement was observed in the first year, and of sex and physical fitness improvement in the second year. Girls' non-cognitive ability score was significantly higher than that of boys. Among 4-year-olds, the non-cognitive ability score was significantly higher in the first year as compared to that in the second year. The non-cognitive ability score of participants in the improved group was significantly higher than that of participants in the non-improved group. **CONCLUSIONS:** The present findings confirmed that non-cognitive abilities have a positive effect on the extent of improvement in physical fitness.

Breaking Up Prolonged Sitting Improves Cognitive Function In Qatari Females

Bryna C.R. Christmas¹, Lee Taylor, FACSM², Anissa Cherif², Suzan Sayegh², Daniel P. Bailey³. ¹Qatar University, Doha, Qatar. ²ASPETAR - Orthopaedic and Sports Medicine Hospital, Doha, Qatar. ³University of Bedfordshire, Bedford, United Kingdom. (Sponsor: Dr Lee Taylor, FACSM)
 Email: bchristmas@qu.edu.qa
 (No relevant relationships reported)

Within Qatar, 83% of the population participate in little or no physical activity (PA). A sedentary lifestyle is associated with impaired cognitive function. However, cultural barriers [i.e. Islamic traditional clothing (e.g. Abaya)], as well as the climate (i.e. hot and humid), reduce the ability of Qatari females to engage in PA. **PURPOSE:** Examine the effects of an ecologically valid PA intervention on cognitive function in Qatari females. **METHODS:** Eleven sedentary (sitting ≥ 7 h/day) females [median (minimum - maximum) age 27 (21 - 44) y; height 1.64 (1.57 - 1.74) m; body mass 57.8 (47.0 - 87.4) kg; body fat 36 (24 - 45) %] completed three trials. Trial one was a

familiarization. Trials two and three were identical, except in one visit the participants remained seated for 5-h (SIT), and in the other visit they interrupted their sitting time every 30-min with a 3-min walk (WALK) on a motorized treadmill at a moderate walking speed (rating of perceived exertion 12 - 14). Cognitive function was assessed using the Computerized Mental Performance Assessment System (COMPASS) at 15-min before baseline (-15-min), and then at 2.5-h and 5-h. The following tests were completed; serial-3 subtractions (2 min), serial 7 subtractions (2 min), simple reaction time (50 stimuli), rapid visual information processing [RVIP (5 min)], choice reaction time (50 stimuli), and Stroop (60 stimuli). The visual analogue scale for fatigue (VAS-F) was completed at the same time intervals. Linear mixed models were used to examine differences in COMPASS and VAS-F for condition (SIT, WALK), and time (-15-min, 2.5-h, 5-h). Data is reported as effect size; $\pm 90\%$ confident limit. **RESULTS:** There was a greater number of RVIP correct scores in WALK compared to SIT (0.84; ± 0.66). There was a quicker reaction time (RT) for RVIP in WALK compared to SIT (-0.66; ± 0.70). RVIP false was lower in WALK compared to SIT (-0.51; ± 0.73). Stroop RT was quicker in WALK compared to SIT (-0.96; ± 0.05). RT for congruent Stroop was quicker in WALK compared to SIT (-0.92; ± 0.68). VAS-F was lower in WALK compared to SIT (-0.40; ± 0.68). **CONCLUSION:** Interrupting prolonged sitting with moderate intensity walking offers an ecologically valid intervention to enhance cognitive function in Qatari females. Supported by Qatar University CHSS SEED grant (CHSS-SF-16-2).

The Effects Of Regenerative Injection Therapy Compared To Corticosteroids For The Treatment Of Lateral Epicondylitis

Julie B. Barnett¹, Madison N. Bernacki¹, Jessica L. Kainer¹, Hannah N. Smith¹, Annette M. Zaharoff², Sandeep Subramanian¹. ¹UT Health San Antonio Texas, San Antonio, TX. ²The Non-Surgical Center of Texas, San Antonio, TX. Email: barnettj3@uthscsa.edu
(No relevant relationships reported)

BACKGROUND: The lateral epicondyle is a common site for chronic tendinosis, a condition characterized by overuse and degeneration of a tendon due to repeated microtrauma. This leads to pain and functional limitations. There is a growing interest in non-surgical forms of treatment for this condition including provision of corticosteroid injections and regenerative injection therapy (provision of autologous blood and platelet rich plasma injections).

PURPOSE: The study objective was to compare the effectiveness of corticosteroids compared to regenerative injection therapy for the treatment of chronic tendinosis at the lateral epicondyle (i.e. lateral epicondylitis).

METHODS: Researchers systematically reviewed randomized controlled trials published in English language from 2008-2018. Databases used included PEDRO, Scopus, Pubmed, and CINAHL. Ten articles met our selection criteria as an RCT level of evidence with a total of 682 patients. Sackett's ratings adapted to include PEDRO scores helped assess study quality. Analyzed results focused on pain, function and follow-up time. Primary outcome instruments used included Visual Analog Scale, (VAS) and Disabilities of the Arm, Shoulder and Hand, (DASH).

RESULTS: The corticosteroid groups demonstrated greater benefits in the short-term follow up (36 months; level 1A) and the regenerative injection therapy groups (both autologous blood and platelet rich plasma) demonstrated greater long-term improvements lasting for a period of about 2 years (1A level). One hundred subjects were randomized to receive corticosteroid (n = 49) or platelet rich plasma (n = 51) injections in a double blind RCT. A greater proportion of people reported a reduction of pain and DASH scores by >75% (clinically significant) in the platelet rich plasma group at the 6 months and one-year assessment period.

CONCLUSIONS: Regenerative injection therapy results in greater long-term pain relief and improved function for people with lateral epicondylitis.

3025 Board #71 May 31 3:30 PM - 5:00 PM

Evaluation of Intervention Effects of Different Exercise Modes on Non-alcoholic Fatty Liver Disease

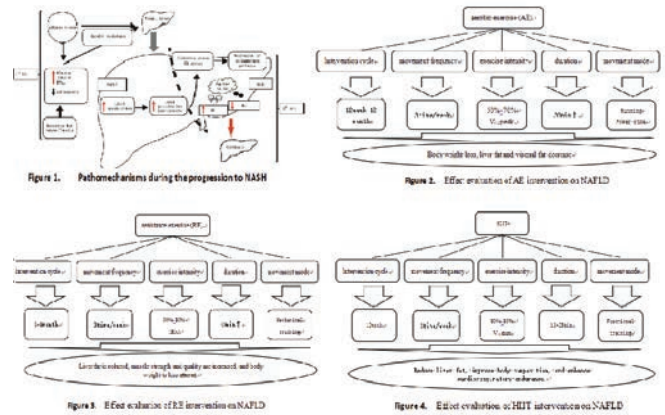

Zhiping Zhen¹, Chao Luo¹, Liangyi Hu¹, Hanran Li², Yuhan Cao¹, Qixian Chen¹, Qingjia Song¹, Dan Xu¹, Yiqing Lan¹, Chenlin Zhao¹. ¹Beijing normal university, beijing, China. ²China University of Mining and Technology, beijing, China. Email: zpzxt@bnu.edu.cn
(No relevant relationships reported)

PURPOSE: Based on the analysis of more than 1000 documents in the past 5 years and visiting physical activity experts, coaches and athletes, this paper discusses aerobic exercise (AE), resistance exercise (RE), and high-intensity interval training (HIIT) in non-alcoholic fatty liver disease (NAFLD). Discuss The main differences of intervention methods, intervention time, and intervention effects among the NAFLD people, To explore the targeting and dose-response relationship of different exercise models intervention in NAFLD.

METHODS: (1)Through searching in Pubmed,Web of science and other databases, articles were selected for analysis according to the corresponding inclusion criteria and exclusion criteria.(2)Expert survey.(3)Interview method.

RESULTS: (1) AE, RE and HIIT can reduce hepatic steatosis and improve liver histology in NAFLD people, but their intervention effects are different. AE stands out in reduce body weight; RE stands out in reduce hepatic fat, decreases insulin resistance (IR) and increases muscle strength; HIIT has a significant effect in reducing hepatic fat and enhancing cardiovascular fitness. (2) the frequency, duration, and intervention period of AE and RE are similar; achieve the same or better intervention effect, HIIT only requires the 1/3 exercise time of the previous two.(3) People of different age, gender, physical fitness and disease degree have different choices in sports mode. Scientific monitoring and medical supervision are necessary conditions for improving the relationship between the dose and effect of exercise.

CONCLUSIONS:RE may be more effective than AE in patients with poor cardiovascular fitness, sarcopenia, and NAFLD who are unable to tolerate or participate in AE; HIIT has certain advantages in the time-effect and dose-effect due to less exercise time and smaller amount of exercise, This is easy for the NAFLD people to accept, and it will facilitate long-term adherence in the future.

Visualization Analysis of International Research of Physical Activity Promoted built environment

Zhenduo Liu¹, Liping Jiang², Yuning Jia¹, Penghui Xie¹, Yanan Wang¹, Joonyoung Lee³, Brooke Doherty³. ¹East China Normal University, Shanghai, China. ²Tongji University, Shanghai, China. ³University of North Texas, Denton, TX.
(No relevant relationships reported)

Background: Recently, studies regarding the relationship between the building environment, physical activity, and health have flourished in the areas of public health promotion among urbanized countries. (Chen, 2014). The researchers found that land use structure, residential density, and street connectivity were positively correlated with the amount of daily moderate physical activity (Frank, 2005). Although the importance of building environment to promote physical activity has been emphasized, very little is known about the development trend and "hotspots" in this field.

Purpose: Through sorting out the process of studies focused on international physical activity promoting-type built environment, this paper aimed to reveal the basic characteristics and research "hotspots" in this field through software analysis and to provide suggestions for future research.

Methods: Based on the literature about international physical activity promoting-type building environment from the Web of Science, The researchers searched 3,678 research papers and references in the field of health promotion during 2004—2018 and used Citespace Version 5.2 (Chen, 2018) for bibliometric analysis and visualized analysis.

Results: The results revealed that: (1) current studies mainly come from western countries (i.e., primarily the United States, Canada, and Australia); (2) the research "hotspots" focus on different forms of physical activity, obesity, and body mass index control in built environment.

Conclusion: Transportation planning and management, urban planning, and behavioral science have focused on building environments that can promote physical activity. Majority of the research has mainly emphasized the relationships between health and built environment and physical activity assessments. While facing the serious problem of childhood obesity, it is important to consider building environment construction as one of the main solutions.

Health and Wellness Coaching as a Promising Strategy to Better Health and Quality Of Life

Paula Helena Dayan, Luciana Oquendo Pereira-Lancha, Antonio Herbert Lancha Junior. *University of São Paulo, São Paulo, Brazil.*

Email: paulinha.dayan@gmail.com

(No relevant relationships reported)

Health and wellness coaching (HWC) is a promising strategy and potentially highly effective approach for weight loss in short term and healthy behavior change. As a partnership process between the coach and the client, it emphasizes behavior change to better client health. Coming up as a new approach that focus on behavioral change without a diet prescription, HWC seems to be likely to promote body weight loss and improve quality of life. **PURPOSE:** The aim of this study is to present and evaluate HWC in promoting changes in body composition and to improve the self-assessment of quality of life. **METHODS:** 13 subjects completed the intervention. Body composition (Bodpod®) and quality of life (WHOQOL-bref) were assessed at baseline (P1) and after 12 weeks of HWC (P2). 12 HWC sessions were completed, which were held weekly (1 hour each) + 36 Physical Activity sessions (1 hour each, 3 times a week). No diet was prescribed during the whole process. Data was collected at the School of Physical Education and Sport, University of São Paulo. **RESULTS:** In P2, HWC sessions were associated with reductions in body weight (-2,16 kg) and fat mass (- 1,91 kg). From P1 to P2, we also observed little reduction in fat free mass (-0,25 kg). Great improvement in all aspects of self-rated quality of life was also shown (physical health, psychological domain, social relationship, environment and overall quality of life). These outcomes emphasize the effectiveness of HWC in promoting fat loss and behavioral changes with high impact in quality of life. **CONCLUSIONS:** HWC was able to promote weight loss, fat loss, to maintain fat free mass and to improve quality of life in a 12 week program, combined with an exercise program. Therefore, the strategy was effective in promoting better health, once it empowers individuals to take actions for their own health.

3028 Board #74 May 31 3:30 PM - 5:00 PM
Power Outputs During Performance of a Simple Transfer Task

Jessica Elise Kuhn, Jeonghoon Oh, Keri Strand, Moataz Eltoukhy, Joseph Signorile. *University of Miami, Coral Gables, FL.*

(No relevant relationships reported)

PURPOSE: The Gallon Jug Shelf Test (GJST) is a validated assessment of an older persons' capacity to transfer moderately heavy objects from a knee-high to a shoulder high shelf. Since power is a major determinant of performance during activities of daily living, we calculated power during the performance of the GJST.

METHODS: Subjects performed the GJST in a three-dimensional motion capture laboratory while standing with both feet on force plates. The task was performed in an open unit with immovable shelves to allow visualization of movement. The work done during when lifting a stationary gallon jug from low shelf to high shelf was calculated as shown in equation (1). $\Delta Work = m(a+g) \times \Delta h$ (1) Where: m: the mass of the gallon jar (kg); a: the jar's average acceleration (m/s^2); g: gravitational acceleration ($9.81 m/s^2$); Δh : difference in height between the bottom and top shelves (m) The power was calculated as the change in the work over the change in time (equation 2). $\Delta Power = \Delta Work / \Delta t$ (2) Where: Δt : the time spent lifting the jar between the two shelves (s) **RESULTS:** A mixed ANOVA was used to examine differences in work and power among trials and across repetitions (reps). For work, a Huynh-Feldt analysis revealed a significant difference across repetitions ($p=.050$, $\eta^2=.068$), while pairwise comparisons revealed significantly less work by the fourth (rep 2: $Mdiff=.016 \pm .005$; rep 3: $Mdiff=.012 \pm .005$) and fifth repetition (rep 2: $Mdiff=.01 \pm .007$; rep 3: $Mdiff=.014 \pm .007$) ($p<.05$). Similarly, a trend toward significance for differences in power across sets was detected ($p=.067$, $\eta^2=.064$). Pairwise comparisons showed significant declines in power between repetition 2 and repetitions 4 ($Mdiff=.002 \pm .001$; $p=.004$) and 5 ($Mdiff=.002 \pm .001$; $p=.015$), and between repetitions 3 and 4 ($Mdiff=.001 \pm .001$; $p=.004$; $p=.029$).

CONCLUSIONS: The GJST is a viable test of object transfer power and work that can also be used to evaluate fatigue in older persons.

3029 Board #75 May 31 3:30 PM - 5:00 PM
Differences In Male Vs Female Regional Body Composition Changes With Resistance Training

Cory Mahan¹, Bharath Selvaraj¹, Amy Givan¹, Adam Doedtman², Jacayln McComb, FACSM³, Eneko Larumbe-Zabala⁴, Maria Fernandez-del-Valle¹. ¹Southern Illinois University Edwardsville, Edwardsville, IL. ²Southern Illinois University Carbondale, Carbondale, IL. ³Texas Tech University, Lubbock, TX. ⁴Texas Tech University Health Sciences Center, Lubbock, TX.

(No relevant relationships reported)

Purpose: The purpose of this study is to analyze the effects of resistance training on regional body composition in normal-weight males and females.

Methods: A total of 31 (n=14 males) young volunteers were randomized to intervention (9 females, 7 males) and control groups (8 females, 7 males). Females had a body mass index (BMI) of $22.6 \pm 1.95 \text{ kg/m}^2$, and percentage of body fat (%BF) of $32.3 \pm 7.8 \%$; males had a BMI of $22.95 \pm 1.55 \text{ kg/m}^2$ and %BF of $18.14 \pm 6.22\%$. Body composition measurements were recorded using a dual-energy X-ray absorptiometry (DXA), and a maximal strength test was used on both upper and lower body at pre and post intervention. Left and right trunk, arms, and legs lean body mass (LBM) and body fat (BF) were recorded and percentage of change (% Δ) was calculated for each variable. The resistance training protocol consisted of 3 sessions per week for 3 weeks, using 7 exercises (i.e. bench press, barbell back squats, leg press, sit-ups, dead lifts, barbell rows, and jump squats) consisting of 10 repetitions per exercise for 3 sets.

Results: Non-parametric tests showed a statistically significant difference in exercising males ($p=0.001$) in left leg $\% \Delta \text{LBM}$ ($3.05 \pm 1.68\%$) when compared to controls ($-2.32 \pm 2.14\%$). No statistically significant differences were found in any of the body composition variables for females in the resistance training group compared to the control group.

Conclusions: Our results suggest that males and females exhibit different regional body composition changes in response to the same resistance training program. Further research is needed to increase the understanding of sex-related differences in resistance training-induced regional body composition changes.

3030 Board #76 May 31 3:30 PM - 5:00 PM
Impact Of Sit-to-stand And Treadmill Work-station Use On Self-reported Musculoskeletal Pain.

Gregory Cloutier¹, Diego Arguello¹, Alvin Morton², Dinesh John¹. ¹Northeastern University, Boston, MA. ²Northeastern University, Knoxville, TN.

(No relevant relationships reported)

Purpose: This study examined the effects of a one year work-station intervention on perceived musculoskeletal pain. **Methods:** Sixty-six sedentary overweight office workers (mean \pm SD: age = 45.3 ± 12.3 years, BMI = $32.4 \pm 5.8 \text{ kg/m}^2$) participated in this 12-month study. Participants were cluster randomized to a control (C), (N = 21), a sit-stand desk (D), (N = 23), or a treadmill desk (T), (N = 22) group. Group T was asked to accumulate 2 h of walking and 1 h of standing at the workstation in bouts of 10 to 30 min daily. Group D was asked to accumulate standing for 3 h/day in bouts of 10 to 30 min. Group C did not receive a workstation that enabled behavior change at work and was encouraged to meet the federal physical activity guidelines during the study. All participants self-reported regional musculoskeletal pain using the Modified Nordic Musculoskeletal questionnaire at baseline and month 12. Musculoskeletal regions included the lower back, upper extremity (neck and shoulders), wrist and forearm, and lower extremity (knees, ankles, and feet). Random intercept logistic regression models accounting for repeated measures and the effects of cluster randomization were used to determine change in the likelihood (odds ratio-OR) of self-reporting the presence or absence of pain. Post-hoc pairwise comparisons with Tukey-Kramer corrections (for multiple hypotheses testing) were conducted to determine the location of any significant change. **Results:** There were no significant between group differences in self-reported OR for musculoskeletal pain at baseline. The 12-month intervention did not result in a significant change in self-reported pain in the two experimental conditions in any region. Participants within Group D had a significantly lower likelihood ($p = 0.027$; effect size = 0.10) of self-reporting upper extremity pain at month 12 (OR = 1.29) compared to baseline (OR = 1.78). **Conclusion:** While workstation interventions to decrease sedentary behavior yielded no reductions in self-reported pain over 12-months, increasing daily accumulated standing and/or walking time did not introduce new musculoskeletal pain in seated office workers. These findings may help alleviate concerns associated with change in musculoskeletal pain when introducing ergonomic solutions to break continuous workplace sitting.

3031 Board #77 May 31 3:30 PM - 5:00 PM
The Effect Of 10-week Walking Program On Self-regulation And Exercise Adherence In Sedentary Workers
 Mynor G. Rodriguez-Hernandez¹, David D. Pascoe, FACSM², Danielle D. Wadsworth². ¹University of Costa Rica, San Ramon, Costa Rica. ²Auburn University, Auburn, AL. (Sponsor: David D. Pascoe, FACSM)
 Email: mynor.rodriguez@ucr.ac.cr
 (No relevant relationships reported)

PURPOSE: The present study examined changes in self-regulation and self-efficacy in sedentary employees participating in a 10-week walking intervention.

METHODS: 68 sedentary employees were enrolled in a 10-week walking intervention. Subjects were randomly assigned (based on initial BMI and gender) to one of three groups consisting of two walking protocols: intermittent walking (Age = 46±9, BMI= 30.33±5.79 kg/m²) continuous walking (Age = 48±9, BMI= 30.53±6.17 kg/m²) or control group (Age = 42±10, BMI= 27.66±5.11 kg/m²). The two experimental groups received self-paced walking programs that were time and intensity matched, as well as, a mobile health intervention with weekly strategies to improve self-efficacy and self-regulation skills via text messages, e-mails and videos. The control group received a self-pace walking program only. All groups completed a self-regulation and self-efficacy measured by questionnaire and walking behavior measured by a wrist worn accelerometer at baseline, week 6 and week 11.

RESULTS: Results from the mixed ANOVA showed group and time interaction $F(4,130) = 8.017, p < .001$, and a large effect $\eta^2 = .198$. The continuous group significantly improved overall self-regulation and its sub-scales from pre-test to week 6 and post-test ($p < 0.05$). Self-efficacy decreased significantly from pre-test to week 6 ($p = .047$) and post-test ($p = .008$) for all groups. Walking activity changed significantly $F(4,130) = 2.526, p = .044, \eta^2 = .072$, with the continuous walking group significantly increasing walking from pre-test to week 6 ($p = .033$), and a significant higher percentage of change compared to the control group from pretest to post test ($p = 0.042$).

CONCLUSIONS: For sedentary employees a continuous walking program is a better approach to improve self-regulatory skills and may provide a more feasible approach to prescribing exercise in sedentary office employees. Intermittent physical activity may have some positive impact on self-regulatory skills, however the amount of time and frequency of the bouts need to be tested to determine a feasible approach to include physical activity and meet daily obligations as well.

3032 Board #78 May 31 3:30 PM - 5:00 PM
Self-efficacy To Reduce Sedentary Behavior: Differences Between Depressed And Healthy Populations
 Maria Perez, Jeni E. Lansing, Jacob D. Meyer, Gabriel Cruz-Maldonado, Laura D. Ellingson, FACSM. Iowa State University, Ames, IA. (Sponsor: Laura Ellingson, FACSM)
 (No relevant relationships reported)

Excessive sedentary behavior (SB) is associated with increased health risks, including risks of poor mental health, such as depression. Previous research demonstrates depressed individuals exhibit increased barriers to health-related behaviors, such as exercise, compared to non-depressed individuals. Examining differences in self-efficacy to overcome barriers to reduce SB in depressed versus non-depressed populations is necessary to design effective SB interventions. **Purpose:** To examine how self-efficacy for overcoming barriers to reduce SB differs between depressed and non-depressed adults. **Methods:** Participants with self-reported major depressive disorder (MDD, $n = 144$) and healthy adults ($n = 1,243$) completed an online survey regarding self-efficacy to overcome barriers to reduce sedentary behavior on a Likert scale ranging from 1 (not at all confident) to 10 (100% confident). Questions examined barriers related to social norms, time, fatigue, motivation, pain/health, resources/environment, and mood. Barriers were compared between depressed and healthy adults with independent-samples t-tests and effect sizes (Cohen's d). **Results:** Participants with MDD reported significantly lower self-efficacy compared to healthy individuals ($p < 0.05$) for overcoming each barrier. The largest difference between groups was seen for mood ($d = 0.75$). Patients with MDD also reported lower self-efficacy for overcoming barriers related to motivation ($d = 0.48$), fatigue ($d = 0.45$), environment/resources ($d = 0.43$), pain/health ($d = 0.34$), social norms ($d = 0.23$) and time ($d = 0.20$). For MDD, self-efficacy to overcome barriers was lowest for mood while social norms was the lowest for healthy adults. **Conclusion:** As confidence in overcoming barriers for reducing SB differs between depressed and healthy adults, intervention strategies that are effective in healthy adults may not be effective for those with depression. It may be necessary to consider the relatively larger impact of mood, motivation, and fatigue on confidence to reduce SB in depressed populations. Future research is needed to examine how addressing low self-efficacy for overcoming different barriers influences the ability to reduce SB in those with depression.

3033 Board #79 May 31 3:30 PM - 5:00 PM
Research and Commercial Utilization of Wearables Among Healthy Adults: An Exploratory Comparative Analysis
 Zakkoyya H. Lewis¹, Emma Sypes², Milagro JeanMarie-Tucker¹, Anton-Luigi Picazo¹, Lauren Pritting¹. ¹Loyola Marymount University, Los Angeles, CA. ²University of Guelph, Guelph, ON, Canada.
 Email: zakkoyya.lewis-trammell@lmu.edu
 Reported Relationships: Z.H. Lewis: Salary; Beachbody.

Electronic activity monitors, commonly known as wearables, have proliferated both in research and in consumer use. However, there is limited reports on how wearables are operationalized in physical activity interventions in comparison to how they utilized by consumers. **PURPOSE:** To describe and evaluate the findings of two studies that evaluated the use of wearables among generally healthy individuals. **METHODS:** Study 1—Medscape, Medline, PsycInfo and Cochrane databases were searched in 2017. Included studies were assessed using an intensity scale that measured the extent of wearable usage. The intensity scale assessed duration, personalization, reach, and frequency of the wearable within the intervention with a higher intensity score reflecting higher usage. Study 2—Participants ($n = 33$, 78.8 % Female, 51.5% aged 18-24 years, 56.3% White, 27.07±6.7 kg/m²) were recruited to participate in an online survey. Participants were eligible if they were an adult and if they owned a wearable device aimed to promote physical activity. The intensity scale utilized in Study 1 was used in Study 2. Independent T-Tests were performed to compare intensity scores between Study 1 (effective interventions only) and Study 2. **Summary of RESULTS:** Study 1—22 citations, reporting on 25 unique interventions arms, met the inclusion criteria. Of these, 7 found significant group differences in physical activity and/or weight loss outcomes. These studies utilized several wearable features (86.7%) and allowed participants to interact with the wearable at their own discretion (51.1%). Study 2—72.7% and 42.4% reported positive physical activity and weight outcomes after using their wearable. Participants often use their device daily (87.9%) and use multiple wearable features (75.8%). The intensity scores from Study 2 (18.2 ± 2.7) were higher than Study 1 (15.4 ± 3.9) ($t = -5.6, p < 0.05$). In particular, consumers reported higher frequency of use than effective research interventions ($t = -5.7, p < 0.01$). **CONCLUSION:** Wearables are not utilized similarly within interventions as they are with commercial consumers. Interventions should consider more mandated use of the wearable in the study design to reflect the consumer experience. This will aid in determining the effectiveness of wearables to promote physical activity and weight loss.

3034 Board #80 May 31 3:30 PM - 5:00 PM
Exploring the Physical Activity Counselling Practices of Foundation Doctors: A Qualitative Study
 Jimisayo Osinaike. Manchester Metropolitan University, Manchester, United Kingdom.
 Email: Jimisayoosinaike@gmail.com
 (No relevant relationships reported)

Purpose: Physician have an enormous role in physical activity (PA) promotion for the purpose of prevention and management of non-communicable diseases. Thus, this study explored the PA counselling practices of medical doctors when in their foundation year as this is the time that serves as a bridge between medical school and specialty/general practice training.

Methods: A qualitative study was undertaken amongst 11 Foundation Doctors (FD) in the Manchester University National Health Service (NHS) Trust using a purposive sampling approach. In-depth interviews were conducted, transcribed verbatim and analysed thematically

Results:

| Codes | Sub-Themes | Overarching themes | Quotes |
|--|--------------------------------|--------------------------------------|--|
| FD PA levels | PA Practise | PA COUNSELLING ATTITUDE AND PRACTISE | 'In secondary care I will say the PA advice is more of the physios role because we don't have time. I think we get them medically fit for discharge while the therapy team can encourage physical activity' |
| Involvement of other health professionals | PA Role Perception Belief | | |
| PA Recommendations and Guidelines Health Benefits of PA Exercise and/PA type | Knowledge about PA | | |
| Clinical Settings | Level of Care | | |
| Patient Body Size | Obesity and PA counselling | BARRIERS | 'We are very busy, often staying late. I think it is put lower down the priority order compared to other jobs' |
| Lack of Undergraduate Teaching and Role Model | Limited Knowledge and Guidance | | |
| Patients Knowledge about PA and Health | Public Awareness | FACILITATORS | Lot of people think PA is important but they have not really thought about talking to patient about it. So highlighting it in a teaching session might bring FD to a consciousness of it and hopefully inculcate it in practise' |
| Foundation Teaching Sessions Clinical Settings | Favourable setting | | |

Conclusion: FD PA counselling practise is low and attitude was particularly poor while in the hospital setting. Lack of training and support from consultants were major hindrances noted. Unexplored opportunities exist for foundation doctors to champion PA both in primary and secondary care

3035 Board #81 May 31 3:30 PM - 5:00 PM
Are Fitness Club Members More Likely To Meet Physical Activity Guidelines Than The General Adult Population?

Christina Gjestvang, Trine Stensrud, Bjørge Herman Hansen, Elin Kolle, Lene Annette Hagen Haakstad. *Norwegian School of Sports Sciences, Oslo, Norway.*
 Email: christina.gjestvang@nih.no
 (No relevant relationships reported)

PURPOSE: There is a need for research examining if having a fitness club membership is associated with meeting the physical activity recommendations. Hence, the aims of the present study were 1) to assess total physical activity level at onset and after 12 months of fitness club membership and 2) investigate if having a fitness club membership is associated with increased physical activity and higher prevalence of meeting current physical activity recommendations than the general population. In addition, we wanted to identify demographic and social-economic variables and compare this in participants with high and low exercise involvement.
METHODS: The participants (n=250) answered an electronic questionnaire at inclusion covering demographic and social-economic factors. Self-reported exercise involvement at the fitness club was obtained after three, six and 12 months. Total physical activity level was measured by ActiGraph GT1M in a sub-cohort (n = 125) at inclusion and after 12 months. Adherence to current physical activity recommendations was defined as ≥150 minutes/week of moderate to vigorous physical activity (MVPA) in bouts of ≥10 minutes.
RESULTS: At both time-points, more than half of the participants had low physical activity level. No significant changes in total physical activity level were found from inclusion to 12 months. Although, daily bouts of MVPA increased with 8.9% (p = ≥0.05). Muscle-strengthening activity were reported by 54.4% (in mean 1.9 (± 1.0) days/week) and 44.3% (in mean 1.5 (± 1.0) days/week) at inclusion and after 12 months, respectively. The prevalence of meeting 150 minutes of weekly MVPA increased with 9.9% from inclusion to 12 months, with no significance changes (p = ≥0.05). After three, six and 12 months, few differences in demographic and socio-economic variables were shown between participants with high and low exercise involvement.
CONCLUSIONS: Fitness club members have higher prevalence of meeting the current physical activity recommendations compared to the adult population. Although,

more than half of the participants had low physical activity level at both inclusion and after 12 months, suggesting that a fitness club membership in itself might not be sufficient to meet the current physical activity recommendations.

3036 Board #82 May 31 3:30 PM - 5:00 PM
How Best to Use Your Limited Cardiovascular System Training Equipment Budget: A Case Study

Megan Boshard, Michael Bohne, Ellis Jensen. *Utah Valley University, Orem, UT.*
 Email: ellis.jensen@uvu.edu
 (No relevant relationships reported)

PURPOSE: The Student Life and Wellness Center (SLWC) at Utah Valley University (UVU) spent \$300,540 on its current fleet of 46 pieces of cardiovascular system training equipment (cardio equipment). UVU students pay for gym equipment from student fees. SLWC managers want to know how to use their cardio equipment budget and gym space efficiently to benefit students most. **METHODS:** All the cardio equipment was purchased from Life Fitness (Rosemont, IL). The equipment reports usage data to Life Fitness, and we retrieved that data from their Halo Fitness Cloud. All the equipment has been in use for 24 months except the treadmills which have only been in use for 3 months. **RESULTS:** Overall use (distance, hours, and workouts) was compared. Use/month/dollar was compared, in order to best understand the value and popularity of each device.

| Equipment | Price | Distance/month | Distance/month/dollar | Hours/month | Hours/month/dollar | Workouts/month | Workouts/month/dollar |
|-------------------------|------------|----------------|-----------------------|---|--------------------|----------------|-----------------------|
| Number | \$ | Miles | Miles | Hours | Hours | Number | Number |
| Treadmill (15) | \$6,880.23 | 261.722 @ * | .038 @ * | 54.662# * | .008* | 231.267# * | .034# * |
| Elliptical (12) | \$5,710.30 | 211.143 @ * | .037 @ * | 37.699+ * | .007 * | 133.333+ * | .023 * |
| Upright Bike (6) | \$5,999.00 | 513.352+## | .086+## | 35.400+ * | .006 * | 148.667+ * | .025 * |
| Recumbent Bike (7) | \$6,499.00 | 534.197+## | .082+## | 41.834 * | .006 * | 180.286 * | .028 * |
| PowerMill Climber (4) | \$6,999.00 | 569.440+## | .081+## | 77.990+## @* | .011+## @* | 402.000+## @* | .057+## @* |
| FlexStrider Trainer (2) | \$9,665.00 | 31.580+## @ | .003+## @ | 5.415+## @ | .001+## @ | 31.500+## @ | .003+## @ |
| | | | | @, p<.05 compared to Recumbent Bike #, p<.05 compared to Elliptical +, p<.05 compared to Upright Bike | | | |

DISCUSSION: Powermills are the most used equipment in our sample: whether measured as distance, hours, or workouts. They are also the best overall value. FlexStriders cost the most money and were used the least. **CONCLUSION:** Through simple analysis of automatically-recorded data, UVU can use student money effectively. Students will have the equipment they like to use, and less student fees will be needed as costly unpopular equipment will not be purchased in the future. Gym managers should be able to serve their clientele better with similarly-simple analyses.

3037 Board #83 May 31 3:30 PM - 5:00 PM
Utilizing Technological Devices to Enhance Prevention of Type II Diabetes Mellitus

Alissa M. Underhill. *Pacific Lutheran University, Tacoma, WA.*
 Email: aunderhill@plu.edu
 (No relevant relationships reported)

PURPOSE: To evaluate the inclusion of technology, a Fitbit Flex and smartphone, into the popular lifestyle modification program: the Diabetes Prevention Program - Group Lifestyle Balance Program (DPP - GLB). The DPP - GLB Program has shown great success in reduction of progression toward T2DM. However, it was unknown how integrating technology would affect overall program outcomes, which included the attainment of 150 minutes of physical activity (PA)/week and weight loss trending toward 7%.
METHODS: Men and women over the age of 40, and at risk for prediabetes, were recruited. The study included an initial four weeks of baseline PA testing, followed by 12 weeks of lifestyle intervention. Individualized weight loss and PA goals were set. Participants self-randomized to the control (N = 11) or the technology group (N = 13). Session participation was high. Technology participants missed 8.3% of sessions, while control participants missed 18.2% of sessions.
RESULTS: Participants were aged 66.24 (SD = 7.38) years. At baseline, 21% of participants were overweight, and 79% were obese. Using a generalized estimating

equation to estimate average weight lost, participants lost 0.46 lbs/week. One hundred percent of technology participants lost weight, while 73% of control participants lost weight. Only 7.7% of technology participants reached the 7% weight loss goal, while 27.2% of control participants reached the 7% weight loss goal. Both groups lost similar amounts of weight in averages, with technology participants losing an average of 7.35 lbs and control participants losing an average of 7.79 lbs. At study conclusion, 37% of participants were overweight, and 63% were obese. Although statistical significance was not found, we believe clinical significance was found. The majority of participants (63%) self-reported inactivity during the initial meeting. Technology participants averaged PA tracking for 72.5 days while the control group averaged 47.7 days of PA tracking of 77 days available.

CONCLUSIONS: Monitoring PA with technology can reinforce positive lifestyle changes to encourage users and increase activity due to instant feedback from the device. Participants can be successful with weight loss by going through the GLB Program, with or without technology, reinforcing the importance of lifestyle modification.

3038 Board #84 May 31 3:30 PM - 5:00 PM
The Correlative Relationship Between Fitness Goals and Wearable Usage: An Observational Double-Blind Study

Anton-Luigi L. Picazo. *Loyola Marymount University, Los Angeles, CA.*
 Email: apicazo1@lion.lmu.edu
 (No relevant relationships reported)

Background:

Wearable devices, such as Fitbits, Apple Watches, and numerous fitness devices, have become an increasing trend in those attempting to improve and/or monitor their physical activity. These devices incorporate various features that may elicit behavior change, however there is limited information on which features are utilized most. In addition, there is limited information on whether the usage of wearables varies by fitness goals. The present study observes wearable users and examines any correlative relationships between wearable usage and individual fitness objectives.

Methods

Consenting males and females ages 18 and older who owned any variation of wearable devices were given a 15-minute survey containing questions regarding the type of wearable owned, wearable usage, fitness activity, fitness goals, and opinionated questions. Descriptive statistical analysis using means and frequencies were utilized to describe the sample. Spearman correlation analyses were used to determine the relationship between the participant's reported fitness goal and reported usage of various wearable features. All analyses were conducted using IBM SPSS Version 25.

Results

Of the participants to complete the survey (n=33), the majority were female (78%) and were between 18 and 24 years old (51.5%). Most participants worked out 3-4 times a week (37%) and used their wearable daily (87.9%). Participants reported that their primary fitness goal was to lose weight (42.4%), build muscle (21.2%), lose fat (18.2%), and improve mobility (18.2%). The most prevalent features used were the virtual rewards/badges (69.7%), exercise alert notifications (62.5%), and goal-based challenges (42.5%). The correlation analyses showed a weak correlation between the fitness goal and reported device utilization (r<1.0 on all utilization variables).

Conclusion

Our preliminary analyses show weak correlations between reported fitness goal and usage of wearables. These results suggest that how individuals use their wearable device (which impacts the exposure to embedded behavioral change techniques) negligibly impacts and is negligibly affected by their fitness goal. However, more research is needed to further evaluate the relationship between these variables.

The Effects of a Pilot Translational Health In-School Program on Physical Fitness and Health Outcomes

Natasha Cruz, Emily W. Flanagan, Gina Zito, Arlette Perry, FACSM. *University of Miami, Miami, FL.* (Sponsor: Arlette Perry, FACSM)
 Email: nxc220@miami.edu
 (No relevant relationships reported)

Low levels of physical activity and physical fitness are associated with adverse medical conditions including type 2 diabetes and cardiovascular disease. Significant declines in physical activity are most notable in children as they transition to adolescence in middle school making this a critical age to promote a physically active lifestyle that confers health benefits. Several existing programs have used multiple courses and activities to promote active lifestyle behaviors in middle school adolescents. We theorized that a single in-school elective course may be an effective strategy to promote health outcomes in adolescents. **PURPOSE:** To examine the effects of a multidimensional translational health in nutrition and kinesiology (THINK) in-school

pilot program encompassing nutrient/exercise physiology education, laboratory experiences, and structured physical activities on physical fitness, physical literacy, and nutrition knowledge.

METHODS: Participants from a public middle school were enrolled in the THINK elective course (n=33, 22 males; 11 females; 11.97±0.03 yrs). The program was administered two hours/day, two days/week for 16 weeks. Participants were evaluated at baseline and post-intervention for physical fitness, elements of physical literacy, and nutrition knowledge. **RESULTS:** THINK students evidenced a 5.88 mmHg reduction in mean arterial pressure (p=0.05), along with the following improvements in physical fitness: a 4.55 lb increase in muscular strength, a 72.19 ft increase in distance covered during the NIH 2-minute walk test, a 2.34 in increase in lower body power, and 3.64 increase in the number of sit-ups performed in one minute (p≤0.01 for all). There were no significant changes in BMI or flexibility. Additionally, THINK students exhibited significant increases in nutrition and kinesiology (p<0.01) signifying a better understanding of the value of physical activity and nutrition for health promotion/disease prevention. **CONCLUSIONS:** A multidisciplinary THINK program employing kinesiology/nutrition science education, laboratory skills, and physical activities in one course can result in significant improvements in physical fitness, physical literacy, and nutrition science education.

3040 Board #86 May 31 3:30 PM - 5:00 PM
Perceived Quantity of Physical Activity as a Reflective Measure in Muscle and Bone Strength

Kirstie Huynh¹, Karen Serrano Vides², Kimberly Espartero¹, Rebekkah Reichert¹, Maria Alvarez¹, Priscilla Franson¹, Arianna Mazzarini¹, Andrew Denys¹, Vanessa Yingling, FACSM¹.
¹California State University, East Bay, Garden Grove, CA.
²California State University, East Bay, Hayward, CA. (Sponsor: Vanessa Yingling, FACSM)
 (No relevant relationships reported)

Perception plays a powerful role in shaping health outcomes. An active lifestyle, provides mechanical load needed to strengthen and maintain both muscle and bone health. Many recommendations on the quantity of physical activity needed for health benefits exist however it is unclear if individuals perception of their activity habits relates to muscle and bone strength benefits. **PURPOSE:** To determine if those who perceived that they get the right amount or more than needed amount of exercise, have greater muscle and bone strength.

METHODS: 79 participants, 41 females and 38 males (age (yrs) 29.2 + 10.8, height (cm) 166.5 + 9.2, body fat % 24.6 + 9.3) performed a relative grip strength (RGS) test using a hand grip dynamometer, 1 repetition maximum leg extension test (IRM), and a vertical jump test using a Vertec (PP). Bone Strength Index (compression) (BSIc) and polar Strength-Strain Index (SSIp) were measured using peripheral Quantitative Computed Tomography (pQCT). A questionnaire stated "Do you feel you get too much exercise, too little exercise, or about the right amount of exercise?" Welch's t-tests detected differences in muscle function and bone strength based on perception of exercise quantity (Above and Below).

RESULTS: 41 participants perceived they got the "right amount of exercise or above" (Above) and 29 participants reported that they got below the right amount of exercise (Below). Perception of the Above group resulted in greater muscle function tests compared to the Below group (Average PP: 11.5% (p=0.004), RGS: 5.7% (p=0.004). "Right amount of exercise or above" resulted in greater bone strength (SSIp) at both the radius (11.7% (p=0.055) and tibia (13.3% p=0.02).

CONCLUSIONS: Participants' perception on quantity of exercise reflected their bone and muscle strength. Those who perceived that they get the appropriate or a higher amount of exercise had greater bone and muscle strength values compared to participants' who perceived they exercised less. Perception of getting the "right amount of exercise or above" compared to "below right amount of exercise" was a good indicator of greater bone and muscle strength.

Investigating the Relationship Between Social Media Use and Reported Rates of Exercise

Lauren Pritting, Anton-Luigi Picazo, Milagro JeanMarie-Tucker, Zakkoyya H. Lewis. *Loyola Marymount University, Los Angeles, CA.*
 Email: lauren.pritting@gmail.com
 (No relevant relationships reported)

Purpose: Social media has a large impact on body image and confidence. This study aims to gather information and examine correlations on the relationship between social media use and reported rates of exercise.

Methods: An observational study of participants (n=33) that own a wearable fitness device was conducted. Approximately 79% of participants were female, 52% of participants were aged 18-24, 30% aged 25-34, 12% aged 35-54, and 6% aged 55 and older. Participants completed a questionnaire asking them to describe their exercise and social media habits. Participants classified themselves as having an intermediate

(51.5%), advanced (33.3%) or beginner (15.2%) proficiency in exercise. Descriptive statistics with means and frequencies were used to identify trends in social media use and exercise frequency. The relationship between social media use and exercise frequency were assessed through Spearman Correlation and Chi-Squared procedures. All analyses were conducted using IBM SPSS Version 25.

Results: Participants reported exercising once a week (3.0%), 1-2 times per week (24.2%), 3-4 times per week (39.4%), 5 or more times per week (30.3%), or not currently exercising (3.0%). The preferred exercise type was aerobic (69.7%), followed by resistance (21.2%) and balance (9.1%). No participants reported posting their exercise to their social media accounts but 27.3% follow a fitness model or blog. There was a strong correlation between exercise frequency and following a fitness model or blog ($r=-0.3$, $p=0.05$) but the direct relationship was nonsignificant ($\chi^2=5.4$, $p=0.3$).

Conclusion: Our results suggest that there is a correlation between people who follow fitness models or exercise blogs and exercise frequency. Our research also suggests that there may be an underlying mediating variable driving this relationship. We plan to conduct a focus group to ask specific questions regarding social media's influence on exercise. Future research should look at the mediating relationship between social media use and exercise frequency.

3042 Board #88 May 31 3:30 PM - 5:00 PM
Incarcerated Young Women's Exercise and Sleep Behaviors: A Needs and Feasibility Study

Diane L. Elliot, FACSM¹, Kristi Racer², Wendy McGinnis¹, Carol Defranchesco¹, Leslie Leve³, Kerry Kuehl¹. ¹Oregon Health & Science University, Portland, OR. ²Oregon Youth Authority, Salem, OR. ³University of Oregon, Eugene, OR.
 Email: elliotd@ohsu.edu

(No relevant relationships reported)

Incarcerated young women (ages 16 to 21 yo) are at high risk for future drug abuse. Both regular exercise and adequate restorative sleep have been shown to reduce drug use and other harmful behaviors. Existing programs for incarcerated youth to reduce future drug use do not address healthy lifestyles or incorporate Positive Youth Development models. Implementing such a program requires understanding these young women's current physical activity and sleep attitudes and behaviors.

PURPOSE: Determine whether wearable technology can be applied in a close custody setting. Establish current attitudes and behaviors related to sleep and physical activity of incarcerated young women. **METHODS:** Incarcerated young women completed an anonymous survey concerning physical activity and sleep attitudes and behaviors, using a 5-point agreement response scale. 46 of approximately 75 young women consented to participate. Descriptive statistics are presented. A convenience sample of 9 young women wore a Fitbit for a week. **RESULTS:** No regular physical activity program is provided for these young women. However, the majority felt that they were "built for exercise" and "have the skills for exercise." There was strong agreement that "when active they enjoy it" at 4.2 ± 0.8 . The majority of girls felt that they "needed more sleep." And being "sleepy" significantly correlated with self-reported being "grumpy" (p less than 0.001). Girls do not have access to computers, and we were able to implement a system of recharging and downloading the wearable units that was feasible and acceptable for staff. Girls used the Fitbits as directed. Only 2 of 9 girls achieved the goal of at least 8 hours sleep per night, despite the prescribed lights out and awakening times that should allow more than 9 hours sleep each night. Only one girl achieved more than 10,000 steps each day. **CONCLUSION:** Incarcerated young women's sleep and physical activity do not meet recommended guidelines. Both are domains where these high-risk emerging adults still can make choices despite close custody. A Positive Youth Development program to enhance these behaviors and increase their self-efficacy for health choices could add to existing programs to deter future drug use and other harmful behaviors. Supported by the Paul R. Vogt endowment and Ramona and Thomas McDonald donations.

3043 Board #89 May 31 3:30 PM - 5:00 PM
Listening To Music While Exercising Increases The Risk For Noise-Induced Hearing Loss

Gabriella Messina, Alicja Stannard, Jamie Marotto. Sacred Heart University, Fairfield, CT.
 Email: messinag@mail.sacredheart.edu

(No relevant relationships reported)

Music has an ergogenic effect on exercise performance, improves motivation, decreases exertion, and delays the onset of fatigue. However, loud sound levels from music can cause permanent damage to the inner ear resulting in noise-induced hearing loss (NIHL).

PURPOSE: The purpose of this study was to assess the risk of NIHL among students utilizing campus recreational facilities and examine whether music used as a motivator was associated with increased risk for NIHL.

METHODS: One hundred and nineteen students were recruited from the main fitness center on college campus. Physical activity level was recalled using a modified short version of the International Physical Activity Questionnaire. Music intensity levels

were assessed by a sound pressure level mannequin with a built-in microphone. Thirty second samples were taken in 5 second intervals using participant's personal listening devices. Average, minimum, and maximum sound levels were recorded in decibels (dBA). The estimated risk for NIHL was established based on the average sound level and duration of exposure using NIOSH criteria. Participants indicated whether music was a motivator during a workout. Descriptive statistics were performed for all variables. Chi-square analyses evaluated relations between risk for NIHL, gender, and music as a motivator. T-tests assessed the difference in average loudness level and gender.

RESULTS: Participants were college students (51.3% males, 48.7% females). Majority of participants (89.1%) used music as motivation while exercising (93.4% male and 84.5% female, $p>0.05$). Twenty four percent of participants were at risk for NIHL, approaching statistical significance for gender (29.5% males vs 19% females, $p=0.056$). The average sound levels for the participants were 88.8 ± 10.3 dBA and statistically significant for gender (90.9 ± 10.6 dBA for males, 86.5 ± 9.4 dBA for females, $p=0.017$).

CONCLUSIONS: Every fourth college student listening to music while exercising was at risk for NIHL. NIHL is an avoidable cause of permanent hearing impairment. Recommendations for safe use of personal listening devices during workouts include keeping volume at a safe level, below 85 dBA, and limiting time spent using the device during workouts.

3044 Board #90 May 31 3:30 PM - 5:00 PM
Connected Health Exercise Consultation Case Study: A Weight Management Strategy Post Gastric Bypass Surgery

Frank Paul¹, Regis Fernandes¹, Minako Katayama¹, Matthew Buras¹, Donna Cataldo², Robert Scales¹. ¹Mayo Clinic, Scottsdale, AZ. ²Arizona State University, Phoenix, AZ.

(No relevant relationships reported)

Weight regain is not uncommon post gastric bypass surgery (GBS). A connected health (CH) platform has the potential to improve adherence to lifestyle recommendations to support long-term weight management.

Purpose: Describe the process of delivering a CH intervention to support in-person exercise consultations in a case study example. **Methods:** A sedentary 59-year old female (18-years post GBS) with a BMI=37.9 kg/m² was assessed at baseline, 12 and 24-weeks with the 6-minute walk test (6-MWT), 17-item Block Brief Dietary Fat Intake Screener and the 10-item Block Fruit-Vegetable-Fiber Screener. An activity monitor worn on the wrist tracked the daily physical activity (PA) level and a chest strap Heart Rate monitor recorded structured exercise (SE) over the 24-weeks. Bluetooth technology downloaded PA and SE related data to a smartphone using a fitness application with CH capability. The CH intervention consisted of two 30-minute in-person exercise consultations (Week 1 and 4) plus six follow-up telephone calls (Weeks 5-24) with individualized feedback and guidance from a clinical exercise physiologist. Short-term progressive PA and SE goals were negotiated over the 24-week period with an initial prescription (Weeks 1-4) of 8,000+ steps/day and SE on 2+ days/week (60-90 minutes/week). **Results:** The mean daily step count was 12604 and 14630 steps/day and the mean SE minutes were 106 and 90 minutes/week for Weeks 1-12 and Weeks 13-24 respectively. Baseline, 12, and 24-week 6-MWT distances were 514.6, 567.7, and 630.9 meters, predicted daily values for total fat were 87.1, 75.1, and 72.7 grams, fruit/vegetable servings were 4.8, 2.6, and 4.4/day and dietary fiber were 12.5, 7.1, and 10.2 grams respectively. Body weight was 94.6, 80.6, and 71.6 kg respectively. **Conclusion:** In this case study example, the subject demonstrated adherence to using wearable technology to track PA related behavior and participate in this CH intervention. **Future directions:** CH may provide a process to remotely deliver weight management support between in-person clinical visits. Research is required to evaluate the impact of CH interventions in a bariatric patient population. Supported by Mayo Clinic and Arizona State University Project Honeybee

University Staff Physical Activity Inventory (USPAI)

Kristianna M. Altamirano, Brent M. Peterson, Kelsely L. Miller, Jacob K. Gardner. Biola University, La Mirada, CA.
 Email: kristianna.altamirano@biola.edu

(No relevant relationships reported)

The work-related environment has been implicated as a factor involved in the declines of physical activity (PA) in the United States and abroad. Although, the collective literature would suggest that reductions of risk for multiple chronic health conditions has been associated with physically active lifestyles meeting or exceeding 150 minutes/week. Staff in a University setting may experience unique work-related challenges that may inhibit his-or-her ability to achieve recommended daily levels of PA. Few studies exist; however, that have evaluated PA among University staff members. **PURPOSE:** To explore self-reported levels of PA among staff members at Biola University.

METHODS: Eligible survey respondents (N = 320) were men (n = 108, 40.3 ± 13.1 years of age, 168.0 ± 8.5 cm in height, 74.8 ± 14.3 kg in weight, and an average body

mass index (BMI) of 26.4 ± 4.7 kg/m² and women ($n = 212$, 39.7 ± 13.3 years of age, 164.2 ± 8.1 cm in height, 69.8 kg in weight, and an average body mass index (BMI) of 26.03 ± 6.5 kg/m²) who reported being staff members from Biola University. Participants completed the International Physical Activity Questionnaire (IPAQ), using the Survey Monkey® platform. Workers were grouped by type of job (administration, staff and facilities). Total daily sitting time and metabolic equivalent (MET) minute activity-specific (leisure, household, occupational, and transport) and total weekly PA were calculated. **RESULTS:** A Multivariate Analysis of Variance MANOVA revealed significant ($p < 0.05$) main effects for job type, total minutes of PA per week, and grand total PA per week. Post-hoc analyses revealed facilities had significantly greater minutes of work PA and total weekly PA than staff and administration. There was no significant ($p > 0.05$) difference between job types in quantity of leisure, transport, and household PA. An independent T-test was employed to evaluate gender differences for total minutes of work PA and overall minutes of weekly PA. Significant ($p < 0.05$) differences were observed for gender and total work PA, but not for overall PA. Men were significantly more active at work than women. **CONCLUSION:** Mean weekly minutes of overall PA exceeded minimal weekly recommendations among all job titles and sexes.

3046 Board #92 May 31 3:30 PM - 5:00 PM
Physical Therapy Students Knowledge And Attitudes of Nutrition

Jordan D. Day, MS, Eric Jones, PhD, Dustin Joubert, PhD, Sarah Drake, MS, RD, LD, Todd Whitehead, PhD, Stephen F. Austin State University, Nacogdoches, TX. (Sponsor: Thomas J. Pujol, FACSM)

(No relevant relationships reported)

PURPOSE: Physical therapy has incorporated health promotion as a part of practice, which includes nutrition. A search of university curriculum within the state of Texas revealed no nutrition courses within entry-level doctoral physical therapy programs or at prerequisite level. Furthermore, little research has been conducted on the knowledge and attitudes of nutrition in physical therapists. Therefore, the purpose of the present study was to determine knowledge and attitudes of nutrition in current physical therapy students. **METHODS:** Subjects included doctoral physical therapy students from across the range of years of study in professional preparation programs. This research was conducted online (Qualtrics), which included a Nutrition Knowledge Test (NKT) (32 possible points) and an attitude scale (55 possible points). The survey was disseminated by doctoral physical therapy program directors to students and analyzed using ANOVA. **RESULTS:** A complete sample of $n = 605$, the mean NKT score was 22.43 ± 3.43 (70.1%). Though there was no correlation between attitudes and knowledge of nutrition ($.026, p = .526$), physical therapy students revealed high regard for nutrition with the mean attitude score being 47.13 ± 4.32 (85.7% agreeableness with positive nutrition statements). There was also a significant difference in NKT scores when comparing groups who had taken a nutrition course and those who had not, 22.81 ± 3.56 and 21.66 ± 3.46 ($p < .001$), respectively. Those individuals who had completed 3 or more nutrition courses showed the largest improvement on the NKT (~7%). Additionally, the Midwestern region presented with the most students' programs having a nutrition course, held the highest NKT scores (22.67 ± 3.19), highest regard towards nutrition (47.44 ± 4.22) and were most satisfied with level of understanding of nutrition (69.8%). It is important to note that though there was an increase in NKT scores with increase in nutrition courses, the difference was only 2.36 points on the NKT. **CONCLUSION:** Based on relatively small changes in NKT and desires expressed during this survey, integrating nutrition competencies within current required courses may be the most appropriate intervention.

3047 Board #93 May 31 3:30 PM - 5:00 PM
Relationship Between Socialization and Weight Changes Using Among Individuals That Use Wearable devices

Milagro JeanMarie-Tucker, Anton-Luigi Picazo, Lauren Pritting, Zakkoyya H. Lewis. Loyola Marymount University, Los Angeles, CA.

Email: mjeanmar@lion.lmu.edu

(No relevant relationships reported)

Over the past few years, the use of fitness-tracking wearable devices, or wearables, has increased. They have many features that allow users to monitor their activity, measure pulse rate, and communicate their progress with other users. Accessible and streamlined user interfaces assist individuals in weight management while sharing their results with others in their social groups. Prior research has shown evidence for a positive association between weight loss and in-person socialization during workouts. However, research on virtual socialization within wearable devices and changes in weight is limited.

PURPOSE: To investigate the relationships between socialization and changes in body weight after wearable use.

METHODS: Individuals that owned a wearable device were eligible for this observational study. Surveys were completed electronically via Qualtrics Online Survey Platform. Participants accessed the survey through social media, email, and in-person recruitment ($n=33$, 78.8% Female, 51.5% aged 18-24 years, 56.3% White, 27.07 ± 6.7 kg/m²). Data was analyzed using SPSS Version 25. Chi-square tests and Spearman correlations were used to evaluate the relationship between changes in weight and in-person socialization (e.g. work out buddies) or device socialization (e.g. interactions with likes, comments, leaderboards, etc.).

RESULTS: Participants reported both an increase (33.3%) and a decrease (66.7%) in weight since using their wearable. There was prevalent use in the various socialization techniques (in-person = 42.4%, likes and comments = 30.3%, and leaderboards = 27.3%). In accordance with previous studies, there was a moderate association between in-person socialization and weight loss ($r = -0.49, p = .02$). There were no significant associations between changes in weight and usage of leaderboard features ($r = -0.18, p = 0.42$) or likes and comments features ($r = -0.07, p = 0.77$).

CONCLUSIONS: Our analysis did not find a significant relationship between reported weight change and virtual socialization. However, there was a moderate relationship between reported weight change and reports of working out with a partner. Due to the small sample size, no definite conclusions can be drawn but future research should continue to investigate in-person versus virtual socialization on weight outcomes.

3048 Board #94 May 31 3:30 PM - 5:00 PM
Exercise is Medicine Programs: Public versus Private Healthcare Provider Interest and Needs

Aidan M. Murray¹, Emi B. Hayashi¹, Richard W. Christiana², Gina M. Besenyi¹. ¹Kansas State University, Manhattan, KS. ²Appalachian State University, Boone, NC. (Sponsor: Craig A. Harms, FACSM)

(No relevant relationships reported)

Purpose: Park Prescriptions (ParkRx) incorporating healthcare provider referrals for park-based physical activity (PA) are a type of Exercise is Medicine (EIM) program to improve patient physical and mental health through outdoor PA. This study explored public vs private healthcare provider 1) PA counseling practices, 2) knowledge/interest in ParkRx, and 3) barriers and resources needed to implement ParkRx programs. We anticipate private providers to be more receptive to ParkRx.

Methods: An e-survey was administered in Spring/Summer 2018 to healthcare providers in Kansas, Missouri and North Carolina. Participants were recruited via flyers, emails, community-healthcare partnerships, and snowball sampling techniques. Modified validated survey items examined PA counseling practices, knowledge/interest in ParkRx programs, and barriers and resources needed. Descriptive statistics and independent samples t-tests explored study objectives including differences by public (i.e., Hospital, HMO, VA) versus private (i.e., consultant; solo/group) practice.

Results: Providers ($n=223$) were mostly public (57.4%) versus private (42.6%). The majority of providers ask about patient PA habits (75.0%) in a lot/all of check-ups ($M=5.0, SD=1.5$). However, private providers ask about PA habits and provide verbal counseling more often than public providers, $t(168.4) = -2.10, p = 0.038, t(168.10) = -3.20, p = 0.002$ respectively. Very few providers give written PA prescriptions (10.8%). Few providers knew about ParkRx programs (13.9%), but 81.6% expressed interest in program development. Public providers were more willing to implement a ParkRx program $t(181.9) = 2.40, p = 0.017$. When implementing ParkRx, public providers place greater importance on evidence of park-based PA $t(221) = 2.40, p = 0.017$, evidence of patient interest $t(221) = 2.30, p = 0.022$, a patient portal with PA resources $t(221) = 2.84, p = 0.005$, and incorporation into EHR electronic $t(178.9) = 2.55, p = 0.012$.

Conclusions: Healthcare providers underutilize written PA prescriptions and awareness of EIM programs such as ParkRx is limited. EIM initiatives should target both public and private healthcare providers, but remain cognizant of differences in implementation needs.

3049 Board #95 May 31 3:30 PM - 5:00 PM
The Effects of Sit To Stand Workstations on Perceived Leisure

Constance Haynes, Cara Daniels, Larissa Boyd, Melissa Powers. University of Central Oklahoma, Edmond, OK.

(No relevant relationships reported)

With the increase in sedentary behaviors, workplaces are using new ways to improve activity by giving employees the option to stand while working. However, research has not fully examined the impact of workplace wellness initiatives on participants' perceived freedom to participate in leisure activities. **PURPOSE:** The purpose of this study was to evaluate the effects of a sit-to-stand (STS) workstation intervention on leisure function over 12 months. **METHODS:** Faculty and staff volunteers from a university ($N=24$) were randomly assigned to a control group ($n=11$) or STS group ($n=13$). STS participants were required to stand at the desk for a minimum of two hours per workday. The Leisure Diagnostic Battery (LDB)-Function was used to assess perceived freedom in leisure. The LDB includes a 25-item survey regarding social comfort, environment, decision making, and communication with others. A

repeated measures ANOVA was used to analyze results. **RESULTS:** Two outliers were removed from analysis. All assumptions were met. A significant difference occurred between groups ($F_{2,22}=5.14, p=.01$). A significant time effect did occur from pre-test to 6 ($p=.02$) and pre-test to 12 months ($p=.02$). The main effect for group was not significant ($p>.05$). The CG decreased by .05 points from baseline to 6 months and increased by .09 from 6 to 12 months ($p>.05$). A dependent t -test revealed the STS group significantly decreased by .26 points from baseline to 12 months ($p=.00$). **CONCLUSION:** The STS group decreased feeling less free to engage in leisure activities from baseline to 12 months. Similar to current research, this data demonstrates that workplace interventions may not improve leisure activity participation. However, this study only measured self-reported freedom in leisure. Future research should objectively measure leisure activity participation.

ACKNOWLEDGEMENTS: This project was funded by the University of Central Oklahoma, Research and Sponsored Programs office.

3050 Board #98 May 31 3:30 PM - 5:00 PM
Associations Between Neighborhood-level Measures Of Socioeconomic Status And School-reported Health-related Physical Fitness.

Noe DeAnda, Toyin Ajisafe. *Texas A&M University - Corpus Christi, Corpus Christi, TX.*
 Email: toyin.ajisafe@tamucc.edu
 (No relevant relationships reported)

PURPOSE

We previously reported pervasive musculoskeletal fitness deficits and high obesity prevalence at a proxy predominantly Hispanic elementary school in Corpus Christi, Texas. It's unclear whether these are linked with neighborhood level measures of socioeconomic status (SES). This study investigated associations between school-reported health related physical fitness and neighborhood-level measures of SES, i.e., area deprivation index (ADI), median household income, park density, and number of park amenities that support physical activity (PA).

METHODS

The study sample consisted of 41 elementary and middle schools in Corpus Christi Independent School District (student enrollment is 79% Hispanic). Percentages of students who achieved healthy fitness zone (HFZ) classification on FitnessGram® outcomes in 2016-2017 was generated from Texas Education Agency database. School zip codes, corresponding median household incomes, park density, and park amenities that support physical activity were retrieved using Google search engine, US Census Bureau American FactFinder tool, and Geographic Information System (GIS) mapping tools, respectively. ADI was obtained using Neighborhood Atlas. Park density was the ratio of the number of parks to land area (in square kilometers) of respective zip codes. Land area was measured using GIS tools. Linear regression models and resulting standardized beta coefficients informed the magnitudes of associations between outcomes. Statistical significance was set at $p < .05$.

RESULTS

Median household income was negatively associated with the percentage of students who achieved HFZ on the measure of cardiorespiratory fitness ($\beta = -.406; p = .006; 95\% \text{ CI } [.000, .000]$). The number of park amenities that support physical activity ($\beta = .524; p = .000; 95\% \text{ CI } [.003, .008]$) and ADI ($\beta = -.420; p = .004; 95\% \text{ CI } [-.027, -.005]$) were positively and negatively associated with the percentage of students who achieved HFZ classification on BMI, respectively.

CONCLUSION

The current findings suggest that park authorities should invest and ensure equity in the number park amenities that support physical activities across neighborhoods with low and high deprivation indices. The association between median household income and cardiorespiratory fitness warrants further investigation.

Medical Students' Knowledge and Attitudes to Physical Activity and Health and to Physical Activity Counseling

Eszter Füzéki, Winfried Banzer, FACSM. *Goethe University Frankfurt, Frankfurt am Main, Germany.* (Sponsor: Prof. Winfried Banzer, FACSM)
 Email: fuezeki@sport.uni-frankfurt.de
 (No relevant relationships reported)

PURPOSE: Physical activity (PA) counseling in the health care setting is regarded as a promising avenue to increase population level PA. Equipping future physicians with the necessary knowledge is crucial. The aim of this survey was to assess the knowledge on and attitude towards PA and health, as well as PA counseling at a large German Medical School.

METHODS: a 15-item online survey was conducted. The study has been approved by the University Ethics Committee.

RESULTS: 145 students (106 females, 73%) returned the questionnaire. 118 (81%) reported not knowing the WHO PA recommendations. Only 15 (10.3%) respondents could identify the recommendations correctly. 108 (74%) reported having learnt

anything on the health effects of PA. 106 (73%) wished more information on this topic. 97% and 96% of respondents considered PA to be important or very important in the prevention and therapy of chronic diseases respectively. 99% judged PA counseling to be physicians' task. Weekly reported PA was as follows: 9 (6%) no exercise, 19 (13%) > 1 hr, 47 (32%) 1-2 hrs, 41 (28%) 2-4 hrs, and 29 (20%) < 4 hours. 32 (22%) respondents were in the entry phase of their studies, 87 (60%) in the midphase and 26 (18%) in their final, practical year. Gender was not associated with the importance of PA in prevention and therapy, with physicians' PA counseling role and with perceived need for more information on PA and health. High overall PA volume was only associated with physicians' PA counseling role (Spearman's rho .224, $p > 0.01$). The importance of PA in therapy was associated with the importance of PA in prevention (Spearman's rho .595, $p > 0.01$). PA counseling as physicians' role was associated with PA in prevention (Spearman's rho .402, $p > 0.01$) and PA in therapy (Spearman's rho .406, $p > 0.01$) respectively. **CONCLUSIONS:** Medical students are interested in learning about the health effects of PA, consider PA important in the prevention and therapy of chronic diseases, and see PA counseling as physicians' task, with no difference between males and females and students according to their study phase. Also no association was found between respondents' PA and health related views and their volume of PA. A self-selection bias in respondents cannot be ruled out.

3052 Board #98 May 31 3:30 PM - 5:00 PM
Comparison Of Energy Expenditure Of Overground And Motorized Treadmill Running In Healthy Chinese Young Adults

Shuo Li¹, Jingjing Xue², Zihong He², Shuai Jiang³, Xu'nan Tan³, Ping Hong⁴. ¹Shanghai University of Sport, Shanghai, China. ²China Institute of Sport Science, Beijing, China. ³Beijing Sport University, Beijing, China. ⁴Winter sports management center of the general administration of sport of China, Beijing, China.
 Email: lishuo1018@126.com
 (No relevant relationships reported)

PURPOSE: Overground and motorized treadmill running are popular types of exercise training. Compared to motorized treadmill running, overground running has no external motor and depends on subject's own motor to acceleration and deceleration. However, it is still unexplored for the difference of cardiometabolic demands of overground running when compared with treadmill running at the same speed. The purpose of this study was to compare the oxygen consumption at the same speed of overground and treadmill running in Chinese young adults. **METHODS:** 40 healthy Chinese young adults (21 male, 24.8±2.04 years; 19 female, 23.8±1.95 years) volunteered to participate in the study. After the anthropometric data collection, body composition assessment, 6 min running bouts energy costs of different speed (7km/h, 8km/h, 9km/h) of overground and treadmill running were measured. The energy costs of subjects were measured by a portable gas analyzer (MetamaxTM 3B, German). Overground trials were completed in an indoor sports stadium, and treadmill (Rodby RL3500E, Sweden) running were completed in the same stadium to minimize environmental influences on performance. The variables including heart rate, oxygen consumption (VO₂) and RPE were collected within 6 minutes during each overground and treadmill running test. **RESULTS:** The gross overground running metabolic energy cost of male at 7km/h, 8km/h and 9km/h was higher when compared to the treadmill testing mode (0.242 ± 0.02 vs. 0.225 ± 0.02 ml/kg/m, $P < 0.01$; 0.249 ± 0.02 vs. 0.219 ± 0.02 ml/kg/m, $P < 0.01$; 0.244 ± 0.02 vs. 0.215 ± 0.02 ml/kg/m, $P < 0.01$). We also found significant differences of female between the two modes with the treadmill being lower (0.231 ± 0.02 vs. 0.217 ± 0.02 ml/kg/m, $P < 0.01$; 0.232 ± 0.02 vs. 0.213 ± 0.01 ml/kg/m, $P < 0.01$; 0.228 ± 0.02 vs. 0.207 ± 0.01 ml/kg/m, $P < 0.01$) at speed of 7 km/h, 8km/h and 9km/h. **CONCLUSIONS:** The results demonstrate that, for all experimental velocities in men and women, the energy cost of overground running is higher than the treadmill running. It is critical that these differences are taken into account when prescribing training intensities on whether the overground running or the treadmill running to a training protocol.

Comparison of Progressive Single and Multiple Sets of Resistance Training on Muscle Strength and Power

Kyoungseo seo, Male, Jiyeon Kim, Female, Joungbo Ko, Male, Jonathon Martinez, Male, Sukho Lee, Male. *Texas A&M university San Antonio, San Antonio, TX.* (Sponsor: Minsoo Kang, FACSM)
 Email: kseo@tamusa.edu
 (No relevant relationships reported)

Controversial research findings have yet to determine whether single or multiple sets of resistance training protocol is more effective than the other. **PURPOSE:** To compare the effects of low volume progressive single set and traditional multiple sets of resistance training on muscle strength, power, and field tests in the upper and lower

body. **METHODS:** Total 20 participants were randomly assigned to single set (ST, n=10), and multiple sets groups (MT, n=10). The ST group trained for one set with a maximum of six reps. The first rep started at 70% of one repetition maximum (1RM) and increased by 5% after each rep until they reached 90% of their 1RM and then the last rep was performed at 100% of 1RM. The MT group trained at 70% of 1RM for 10 reps with 3 sets. Both groups trained 3 times per week for 8 weeks using the squat and chest bench press. 1RM squat, 1RM bench press, anaerobic power, vertical jump, and medicine ball throw in upper and lower body were measured at baseline and after 8 weeks of training. Two-way repeated measures ANOVA were used to determine an interaction effect between trial and treatment groups factors for each dependent variable. Main effects of trials and the treatment groups were also tested. **RESULTS:** There was no significant interaction effect between trial and treatment groups for all dependent variables. Main effect results show that both ST (percentage change = 20%, $p < .001$) and MT (24.05%, $p < .001$) groups significantly increased 1RM squat, compared to their baseline. 1RM bench press was also increased in both ST (6.82%, $p < .005$) and MT (13.9%, $p < .002$) groups. No significant differences in 1RM squat and 1RM bench press were found between the two training groups. Anaerobic power in ST (22.8%, $p < 0.001$) and MT (8.6%, $p < .002$) groups was significantly increased, compared to their baseline. However, there were no significant differences in anaerobic power of upper body. Vertical jump in ST (13.54%, $p < .001$) and MT (6.43%, $p < .049$) groups was significantly increased, compared to their baseline. There was no significant increase in the medicine ball throw from both groups. **CONCLUSIONS:** The results imply that low volume progressive single set training (ST) protocol is as effective as traditional multiple sets training (MT) protocol for increasing muscle strength and power.

Effects of a Multifactorial Exercise Intervention on Falls Risk Factors: Comparing Age and Falls History
 Jessica Pope¹, Steven Morrison², Amanda Estep³, Jatin P. Ambegaonkar¹, Shane V. Caswell¹, Nelson Cortes¹. ¹George Mason University, Manassas, VA. ²Old Dominion University, Norfolk, VA. ³Austin Peay State University, Clarksville, TN.
 Email: ncortes@gmu.edu
 (No relevant relationships reported)

In the US, older adults experience an estimated 29 million falls per year resulting in 7 million injuries. Multifactorial exercise interventions (INT) are effective in reducing falls risk. Yet, it remains poorly understood how age and previous history of falls impacts INT aimed to reduce falls risk.

PURPOSE: To compare the effects of a multifactorial exercise INT on time (pre, post), age group (50-59, 60-69, 70-79, 80+ years), and faller status [fallers (1 or more falls in past year), non-fallers] on right & left leg strength (RLS & LLS), foot & hand reaction time (FRT & HRT), 30 second sit-to-stand (STS), and timed up and go (TUG). **METHODS:** One hundred eighty-three older adults (71.0±6.6 years, 1.7±1 m, 81.5±17.2 kg) participated in a multifactorial INT, Stay Active and Independent for Life (SAIL). Participants met for 1h, 3x/week for 10 weeks; exercises included aerobic, balance, strength, and stretching exercises. RLS & LLS (normalized to body mass), FRT & HRT (ms), STS (number of repetitions) and TUG (s) were assessed pre and post-INT. A 2 (time) x 4 (age group) x 2 (faller status) MANOVA was conducted to assess differences among factors. Post-hoc analysis was conducted for significant interactions ($\alpha < 0.05$).

RESULTS: Main effects were attained for time and age group ($p < 0.05$). Participants were stronger (RLS, pre=24±.08, post=28±.09; LLS, pre=23±.08, post=27±.09) and improved leg endurance (STS, pre=12.36±3.22, post=14.54±4.01) after INT. FRT was faster from pre (306.6±49.8) to post (299.6±43.6). For age group, 60-69 had greater RLS and LLS (.26±.10, .26±.09) than 70-79 (.25±.09, .24±.08). In 60-69 (14.32±3.94) group, STS was higher than 70-79 (12.96±3.4) and 80-90 (11.66±3.87). TUG scores were faster for 60-69 (7.00±1.52) compared to 70-79 (7.73±1.54) and 80-89 (9.09±2.12). No other statistically significant differences were found ($p > 0.05$). **CONCLUSION:** In line with previous literature, SAIL was effective at reducing falls risk factors, supporting SAIL to be an effective INT. Multifactorial INT are an effective strategy to combat falls as they target multiple risk factors. Outcomes of 60-69 age group suggest INT should be adjusted for advanced age. However, including falls efficacy and quality of life may give more insight into improvements. Supported by grant from Potomac Health Foundation.

Virtual Reality Exercise on College Students' Mood and Rating of Perceived Exertion
 Wenxi Liu¹, Nan Zeng², Zachary C. Pope¹, Daniel McDonough¹, Zan Gao, FACSM¹. ¹University of Minnesota Twin Cities, Minneapolis, MN. ²Colorado State University, Fort Collins, CO.
 (Sponsor: Zan Gao, FACSM)
 Email: liux4443@umn.edu
 (No relevant relationships reported)

PURPOSE: This study examined differences in college students' mood and rating of perceived exertion (RPE) during immersive virtual reality (VR), non-immersive VR, and traditional biking sessions.

METHODS: Forty-nine college students (34 females; $M_{age} = 23.6$) completed three separate 20-minute biking exercise sessions: 1) immersive VR biking on VirZoom VR bike using PlayStation 4; 2) non-immersive VR biking on Gamercize bike using Xbox 360; and 3) traditional biking on Spirit Fitness XBU55. Their mood was assessed via the Brunel Mood Scale (anger, confusion, depression, fatigue, tension, and vigor) during each session. RPE was evaluated by the Borg Rating of Perceived Exertion every 4 minutes. Repeated measures ANOVA was used to compare the mean differences in mood and RPE among these 3 exercise sessions.

RESULTS: Overall, significant differences were observed between biking sessions for mean RPE [$F(2, 98) = 3.58, p = 0.03, \eta^2 = 0.07$] and all mood variables [$F(2, 96) = 3.84 - 278.56, p < 0.05, \eta^2 = 0.07 - 0.85$], except for tension ($p > 0.05$). Post hoc Bonferroni comparisons indicated immersive VR had significantly higher anger compared to non-immersive VR (1.09 ± 0.21 vs 1.5 ± 0.66, $p < 0.01$); non-immersive VR had significantly higher confusion compared to immersive VR (1.51 ± 0.69 vs 1.26 ± 0.53, $p = 0.01$) and traditional biking (1.51 ± 0.69 vs 1.20 ± 0.4, $p < 0.01$), respectively; immersive VR had significantly lower depression compared to traditional biking (1.07 ± 0.18 vs 1.34 ± 0.68, $p = 0.03$); both immersive VR (1.86 ± 0.72 vs 2.47 ± 0.87, $p < 0.01$) and non-immersive VR (1.81 ± 0.74 vs 2.47 ± 0.87, $p < 0.01$) had significantly lower fatigue compared to traditional biking; immersive VR had significantly higher vigor compared to non-immersive VR (3.70 ± 0.93 vs 1.30 ± 0.47, $p < 0.01$) and traditional biking (3.70 ± 0.93 vs 1.15 ± 0.38, $p < 0.01$), respectively; immersive VR had significantly lower mean RPE compared to traditional biking (10.18 ± 1.84 vs 12.86 ± 2.13, $P < 0.01$).

CONCLUSIONS: Findings suggest a commercially-available VR-based exercise bike (VirZOOM) may be a motivating interesting and enjoyable physical activity promotion tool for healthy young adults.

High Intensity Interval Training in a Natural Setting: An Intrapersonal Perspective
 Maureen W. Howard, Debra M. Vinci. University of West Florida, Pensacola, FL.
 Email: mhoward4@uwf.edu
 (No relevant relationships reported)

High intensity interval training (HIIT) is an extremely challenging workout associated with negative affect for participants (Ekkekakis et al., 2011; Foster et al., 2015). HIIT is often perceived as appropriate only for people who are experienced and relatively fit exercisers and as a poor option for deconditioned or previously sedentary exercisers (Hardcastle et al., 2014). Almost all HIIT research has been conducted in controlled, laboratory settings and focused on physiological adaptations. Little is known about the affective experiences of HIIT participants in real-life settings.

PURPOSE: To examine the experiences of HIIT participants in a real-life outdoor boot camp.

METHODS: Qualitative interviews were conducted with 16 boot camp participants whose length of time participating in HIIT ranged from two months to eight years.

RESULTS: Three main findings: 1. People of widely varying fitness levels, ages, body types, and exercise backgrounds were able to enjoy and successfully perform HIIT workouts. According to body mass index categories, 64% of study participants were either overweight or obese. Ages ranged from 26 to 58 years; 2. Participants reported the alternating intensity levels were motivating and allowed them to work at near maximal intensity for short intervals, knowing low intensity intervals would soon provide needed recovery. The ability to customize the intensity and duration of intervals made HIIT workouts easier to complete than moderate intensity workouts extending over long periods of time; 3. Social support within the boot camp was crucial to successful performance and enjoyment of HIIT workouts. Participants reported that social support enabled them to endure workouts at higher intensity levels than would have been possible if exercising alone.

CONCLUSIONS: HIIT is appropriate for people of varying fitness levels and exercise experience. Built-in recovery intervals motivate people to maximize effort during high intensity intervals. Social support during HIIT was central to participants' ability to complete difficult workouts.

3057 Board #103 May 31 3:30 PM - 5:00 PM

The Effect of a Behavioral Weight Loss Intervention With or Without Exercise on Depressive Symptoms

Kelliann Davis, FACSM, Renee Rogers, John Jakicic, FACSM.
University of Pittsburgh, Pittsburgh, PA.
 Email: kkd2@pitt.edu
 (No relevant relationships reported)

Depressive symptoms have been associated with less weight loss in some behavioral weight loss interventions (BWL), and although it has been speculated that adding moderate-to-vigorous physical activity (MVPA) may improve outcomes, the relationship is not well understood. **PURPOSE:** To examine the relationship between weight loss, MVPA participation, and depressive symptoms over time in subjects enrolled in a BWL.

METHODS: Secondary analyses of depressive symptoms and weight loss in sedentary subjects ($n=379$; 45.0 ± 7.9 years; $BMI=32.4\text{kg}/\text{m}^2\pm 3.8$) enrolled in a BWL and randomized to a reduced calorie diet (DIET, $N=104$), diet plus a moderate dose of MVPA (MOD-EX, $N=97$), or diet plus a high dose of MVPA (HIGH-EX, $N=102$) were completed. All groups reduced energy intake (1200-1800 kcal/day), received weekly intervention sessions (months 1-6), followed by 2 group and 2 telephone contacts per month (months 7-12). MOD-EX was prescribed unsupervised MVPA that progressed to 150 min/wk, and HIGH-EX was progressed to 250 min/wk. Depressive symptoms (CES-D) and weight were assessed at 0, 6, and 12 months.

RESULTS: Weight decreased [6mo: $-9.18\pm 5.9\text{kg}$; 12mo: $-10.0\pm 7.8\text{kg}$] and depressive symptoms modestly increased from baseline to 6 months [BL: 6.45 ± 2.34 ; 6mo: 7.05]($p<0.001$) and baseline to 12 months [BL: 6.45 ± 2.34 ; 12mo: 6.93]($p<0.05$), with no significant differences between randomized groups. There was a modest, yet significant correlation between baseline CES-D score and weight change at months 6 ($r=.126$) and 12 months ($r=.122$)($p<0.05$). Subjects who completed 6 months of the intervention ($n=337$) had significantly lower baseline CES-D scores compared to the non-completers ($n=42$)($p<0.05$), but there were no differences for 12 month completers ($p=.49$).

CONCLUSIONS: The data revealed an inverse relationship between baseline depressive symptoms and success in the BWL. This relationship was not different between DIET, MOD-EX, and HIGH-EX, indicating that exercise participation may not influence this relationship. While depressive symptoms increased slightly over time regardless of group assignment, the 6 month completers had lower baseline depressive symptoms than non-completers. Thus, baseline depressive symptoms may be an important marker of both success and attrition in a BWL.

Cardiorespiratory Effects Of A Multicomponent Exercise Program On Individuals Diagnosed With Alzheimer's Disease: Pilot Study

Flávia B. Machado, Óscar Ribeiro, Joana Meireles, Arnaldina Sampaio, Joana Carvalho. *University of Porto, Porto, Portugal.*
 Email: f_93_machado@live.com.pt
 (No relevant relationships reported)

Dementia, particularly Alzheimer's disease (AD), is one of the major causes of impairment and dependence in the world. Besides the cognitive decline, that characterize AD, this neurodegenerative disease progresses along with functional impairment, and adversely affects physical conditioning. Recent guidelines reinforce the need to implement effective interventions to mitigate the impact of AD. Physical exercise could be significant in improving functional and cognitive performances in these individuals. Cardiorespiratory fitness has been directly associated with different health-related parameters, brain health, neurocognitive performance and ability to perform daily activities. Submaximal incremental treadmill tests have been used to measure aerobic fitness in healthy older adults and seems to be appropriate for those diagnosed with dementia. **PURPOSE:** The aim of this study was to evaluate the impact of a multicomponent exercise program on peak oxygen consumption.

METHODS: According to the 2011 *NINCDS-ADRDA* criteria, and in a mild to moderate stage of disease, 15 community-dwelling individuals diagnosed with probable AD were referred from the Neurology Department of a Hospital Centre to participate in this study. VO₂ peak was measured through an incremental treadmill test using a modified Bruce protocol, designed for older individuals, previously tested with AD subjects. **RESULTS:** Results from Wilcoxon Signed Rank test revealed a slight increase on VO₂ peak [19,11(3,61); 20,60(4,40)]; $p=0,594$] and on time to reach it [5,58(1,48); 6,17(2,23)]; $p=0,575$] which may be explained by a potential benefit of exercise on peripheral factors such as muscular resistance and coordination, both essential to success on endurance tests. **CONCLUSIONS:** Data from both evaluation moments suggest that AD subjects cardiorespiratory fitness is under the established partners for independent healthy older adults. These results reinforced the importance to create cost-effective strategies, and to use gold standard evaluation instruments, to mitigate or prevent the physical conditioning decline, determinant to their autonomy on activities of daily living.

Sedentary Time and Physical Activity Pattern in Women after an Interdisciplinary Program to Treat Obesity

Camila A M de Oliveira, Mariana C. Villani, Caio B. Messias, Amanda S. Moraes, Silvano S. Gil, Maria Gabriela S. Cuesta, Luiz Henrique L. Affonso, Suzana M R Teixeira, Cauê V. La Scala Teixeira, Ricardo J. Gomes, Danielle A. Caranti. *Universidade Federal de São Paulo, Santos, Brazil.*
 Email: camila.a.m.oliveira@gmail.com
 (No relevant relationships reported)

The result of interventions for body weight reduction is not rare disappointing. Adjustments in daily-life physical activities and in sedentary time in response to exercise may undermine the negative energy balance caused by the interventions, reducing their efficacy.

Purpose: To determine the effects of an interdisciplinary program (IP) to treat obesity on sedentary and physical activity (PA) time. **Methods:** A total of 14 obese women (39.33 ± 5.77 years and $BMI 34.14\pm 2.99$) participated in a 16-week program consisting of 3 sessions/week lasting 2 hours each. Physical exercise was carried out for 1 hour in every session, followed by psychological, nutritional or physical therapy intervention. For sedentary time and PA determination participants wore an accelerometer for seven consecutive days before and during the last week (LW) of IP. The difference between Pre and LW values was determined by repeated measure one-way ANOVA. Pearson's correlation test was also performed. Significance was set at 5%. The protocol was approved by Unifesp Ethics Committee (#2.579.851). **Results:** Following IP, body weight change ranged from -5.90 to $+2.40$ Kg. However, the program failed ($p>0.05$) in promoting a significant mean reduction on body weight (Pre 94.06 ± 8.35 ; Post 93.07 ± 8.56 Kg). Neither the time (min/day) spent sedentary (Pre: 568 ± 63 ; LW: 600 ± 75), in light (Pre: 257 ± 47 ; LW: 267 ± 64) or moderate/vigorous (Pre: 24 ± 10 ; LW: 24 ± 14) PA nor the number of steps/day (Pre: $6,392\pm 1,530$; LW: $6,808\pm 2,874$) changed in LW compared to the period pre-intervention ($p>0.05$). The correlation between changes in body weight with changes in time in sedentary (-0.068), light (-0.233), moderate/vigorous (-0.292) PA and steps/day (-0.289) was also not significant ($p>0.05$). **Conclusion:** Even though we did not find a significant correlation between variation in body weight and variation in time sedentary/active, the lack of change in sedentary and PA time despite the addition of 3 sessions of exercise/week suggests the occurrence of a compensation to minimize the increase in daily energy expenditure caused by exercise, contributing to the resistance to body weight reduction. Our results also demonstrate a failure in adopting a more active life style after participating in an IP.

Financial Support: FAPESP 2015/06630-1, 2017/04528-0 and CAPES.

Water Intake During Resistance Training Affects Arterial Stiffness In Normotensive Healthy Adults

Daniel Rodriguez¹, Nakazato Koichi², Naoki Kikuchi², Gustavo Allegretti¹, Francisco Luciano Pontes Jr.³, Aylton Figueira Jr.¹.
¹São Judas Tadeu University, São Paulo, Brazil. ²Nippon Sports Science University, Tokyo, Japan. ³University of São Paulo, São Paulo, Brazil.

Email: d-rodriguez@uol.com.br

(No relevant relationships reported)

Resistance training (RT) may induce arterial stiffness (AS) which is associated with increased risk of myocardial infarction and stroke, the two leading causes of death in the developed world. However, there are a lot of variables and situations that can influence AS such as water intake (WI).

PURPOSE: To determine the influence of WI during RE on arterial stiffness. **METHODS:** Young adult men ($n=17$, 23.1 ± 6.3 years old; 174.0 ± 5.4 cm height; 76.4 ± 13.3 kg weight) with at least 1 year of previous experience in RT and previously hydrated performed in two different occasions (one week interval between them) an RT session (3 sets, 8-12 repetition of 12 exercises for all major muscle groups at 70-80% of 1RM) with [WI session (500ml of water)] and without (NWI session) water intake. Aortic stiffness was measured before, immediately after, and 30 and 60 min after the RT session via Ankle-brachial pulse wave velocity (PWV). Repeated measures ANOVA was conducted to compare RT sessions differences (Rest, after, 30min, 60 min). Between-RT sessions differences at each moment were examined using appropriate post hoc analyses.

RESULTS: Increase in post-exercise PWV for the NWI session compared to rest was observed. Moreover WI values were lower than NWI for all post-exercise measures. Table 1. Pulse wave velocity (PWV) in meters per second (m/s) before, immediately after, 30 and 60 min after WI and NWI resistance training sessions.

| RT session | Rest | After | 30 min | 60 min |
|------------|-----------|-----------|-----------|-----------|
| No water | 11.3±1.5 | 12.3±1.1 | 12.3±1.2 | *12.5±1.0 |
| Water | 11.5± 0.6 | *11.5±1.2 | *11.3±1.2 | *11.8±1.1 |

* Significant difference between no water and water sessions ($p < 0.05$). #Significant RT session by time interaction/difference in relation to Rest ($P < 0.05$). Results are presented in mean and standard deviation.

CONCLUSION: WI during RT may be beneficial to reduce the negative impact of RT on arterial stiffness. This was evidenced by the maintenance of PWV values after WI session and increased values after NWI. From this investigation alone we cannot determine whether WI is influencing the PWV measurement or which physiological mechanisms were influenced by WI.

Outcomes On Physical Activity Levels By Minimal Contact Intervention At A University Setting: Preliminary Results

Cristina Ascanio-Sandoval, Edna Elvira Jauregui-Ulloa, Juan Antonio Jimenez-Alvarado, Aldo Rene Palafox-Renteria, Marisol Villegas-Balcazar, Juan R. Lopez-Taylor. *Universidad de Guadalajara, Guadalajara, Mexico.*
 (No relevant relationships reported)

PURPOSE: To compare the effects of an intervention program of minimal contact using Whatsapp® and Fitbit® over the levels of physical activity on a university population.

METHODS: We designed a 12-week intervention program of minimal contact on a university population. Participants were randomly assigned into two groups: intervention (IN) and control (CO). From a total of 177 participants, 19 (11 men, 8 women, aged 18 - 32) completed the program and had the complete accelerometry information measured with the wGT3X-BT® accelerometer. The program consisted of messages sent by Whatsapp® every week based on The Canadian 24 hrs movement: sweat, step, sleep and sit. All the messages were based on the motivational self-determination theory. The participants also wear a portable Fitbit Flex® 2 for 12 weeks. We evaluated the moderate to vigorous physical activity (MVPA) levels and sedentary behaviors in minutes/day and percentage of weekly wearing time by accelerometry using the IPEN criteria. We compared the outcomes by group (t-test, U Mann-Whitney) and time (paired T-test, Wilcoxon).

RESULTS: Both groups met the recommendations of MVPA in high proportion (IN=83.3%, CO=85.7%, >150 min/w). There were no significant differences in MVPA nor sedentary levels between groups at baseline and after 12 weeks. MVPA (in time and percentage) and time in sedentary activities decreased, however, the percentage of sedentary activities increased in IN group but decreased in the CO group. Nonetheless, these differences were not significant. Sedentary behaviors were very high in both groups. Independently of the intervention and the assessment moment, subjects spent more of the 60% of the wearing time on sedentary activities (Table).

CONCLUSIONS: This intervention was not effective to increase MVPA levels or decrease sedentary behaviors. Probably more time is needed to improve the entire 24 hrs movement component and/or the minimal contact should be more supervised in this sample.

| | Pre | | | Post | | |
|---------------------|-----------------------|-----------------|-------|-----------------------|-----------------|-------|
| | Intervention (n = 12) | Control (n = 7) | p | Intervention (n = 12) | Control (n = 7) | p |
| MVPA (min/day) | 46.7 ± 21.9 | 50.1 ± 23.4 | 0.755 | 45.9 ± 21.1 | 49.7 ± 18.5 | 0.698 |
| MVPA (%) | 5.6 ± 2.5 | 5.8 ± 3.0 | 0.966 | 5.5 ± 2.6 | 5.7 ± 2.4 | 0.862 |
| Sedentary (min/day) | 536 ± 67.5 | 573.1 ± 64.7 | 0.257 | 529.5 ± 76.0 | 558.8 ± 87.7 | 1.0 |
| Sedentary (%) | 63.6 ± 5.1 | 66.1 ± 6.8 | 0.383 | 64.6 ± 7.8 | 64.2 ± 3.1 | 0.904 |

Data expressed as mean ± standard deviation. There were no significant differences for pre vs post assessments ($p > 0.05$). MVPA: Moderate to vigorous physical activity; (min/day): Average daily time on that activity; (%): Percentage of the whole week spent on that activity.

 (No relevant relationships reported)

A single exercise session evokes blood pressure (BP) reductions that are immediate and persist for ≥24hr, termed *postexercise hypotension* (PEH). Self-monitoring of PEH may foster positive outcome expectations of exercise, and thus, enhance exercise adherence among adults with hypertension. **PURPOSE:** To compare the efficacy of self-monitoring of exercise (EXERCISE) versus exercise plus PEH (EXERCISE+PEH) for exercise adherence and BP control among adults with hypertension. **METHODS:** Adults with high BP were randomized to EXERCISE (n=12) or EXERCISE+PEH (n=12). Subjects underwent supervised, moderate intensity aerobic exercise training for 40-50min/session, 3d/wk for 12wk, and were encouraged to exercise unsupervised at home ≥30min/d, 1-2d/wk. All subjects self-monitored exercise using a calendar recording method. EXERCISE+PEH also self-monitored BP before and after exercise. Adherence was calculated as [(# of exercise sessions performed ÷ # of possible exercise sessions) X 100%]. BP was measured pre- and post-training. **RESULTS:** Healthy, middle-aged (52.3±10.8y) men (n=11) and women (n=13) with hypertension (136.2±10.7/85.2±8.9mmHg) completed exercise training with 87.9±12.1% adherence. EXERCISE+PEH demonstrated greater adherence to supervised training (94.3±6.6%) than EXERCISE (81.6±13.2%; $p=0.007$). In addition, EXERCISE+PEH performed 32.6±22.5min/wk more unsupervised home exercise than EXERCISE ($p=0.004$), resulting in greater overall study exercise adherence (107.3±18.7%) than EXERCISE (82.7±12.2%; $p=0.002$). Post- versus pre-training, BP was reduced -7.4±11.3/-4.9±9.9mmHg ($ps < 0.025$) with no statistical difference between EXERCISE (-5.2±13.3/-3.6±6.1mmHg) and EXERCISE+PEH (-9.9±11.3/-6.1±6.9mmHg; $ps > 0.344$). **CONCLUSIONS:** This study is the first to demonstrate that PEH self-monitoring is an efficacious tool to improve exercise adherence among adults with hypertension. Future research among a larger, more diverse sample is needed to confirm these novel findings and determine whether EXERCISE+PEH translates to better BP control relative to EXERCISE self-monitoring alone.

 (No relevant relationships reported)

PURPOSE: To observe longitudinal changes in health and fitness among deconditioned professional American firefighters using High Intensity Functional Training (HIFT). **METHODS:** This HIFT was part of a credit-bearing educational experience (course-based) in which 13 undergraduate students participated in a service activity that met the needs of a community partner (Fire Services) and allowed them to gain deeper understanding of course objectives, knowledge and skills at a Committee on Accreditation for the Exercise Sciences accredited university, under the supervision of two ACSM exercise physiologists and one CSCS certified professors. Behavior change (BCG transtheoretical model), body composition (BC skinfolds, waist/hip ratio, circumferences), aerobic capacity (AC Bruce, step test), balance (BL, BESS), muscular strength (MS, handgrip), muscular endurance (ME, push-up, leg press), and flexibility (FX, seat-reach) measures were collected among 23 male firefighters (mean ± SD, age = 33.3 ± 10.2 yrs; height, 182.3 ± 6.5 cm; body mass index, 29.9 ± 4.9) at baseline, at 10 and 20 weeks. **RESULTS:** Measures of BCG, BC, AC, BL, MS, ME and FX significantly changed over time (RMANOVAs; $p < 0.05$). Follow-up post hoc analyses indicated that all measures significantly improved from baseline to the end of training ($p < 0.05$). **CONCLUSIONS:** The results of the current longitudinal HIFT suggest that measures of health and fitness among deconditioned U.S. firefighters significantly improved over 20 weeks. These results highlight the importance of (1) developing

an exercise programming that is designed for the active-duty firefighter population to maintain the beneficial adaptations in health and fitness and (2) including exercise science majors in relevant community experiential learning service activities.

3064 Board #110 May 31 3:30 PM - 5:00 PM

Effects of a Weight Management Intervention on Holiday Weight Change And Body Image in Inactive Overweight Midlife Postmenopausal Women

Isaura M. Castillo-Hernández, Megha Vishwanathan, Ellen M. Evans, FACSM. *University of Georgia, Athens, GA.* (Sponsor: Ellen M. Evans, FACSM)
Email: imc28001@uga.edu

(No relevant relationships reported)

INTRODUCTION: The holiday season is linked to weight gain which has also been related to distress about self-attitudinal aspects of body image (BI) inclusive of physical appearance and perceptions about physical fitness and health. The impact of a weight management intervention on holiday weight change and BI in midlife females has not been investigated.

PURPOSE: This study aimed to examine the effects of an 11-week weight management intervention on holiday weight change and BI in inactive overweight postmenopausal women. **METHODS:** Females (n=18; 54.7±3.9 yrs; BMI=30.5±4.5 kg/m²) completed an 11-week weight management program (supervised exercise with nutrition education) with three phases: 1) Pre-Holiday (PreH; 5 weeks), 2) Holiday Period (HP; Thanksgiving 2017 through New Year's Day 2018; unsupervised social media support only), and 3) Post-Holiday (PostH; 6-weeks). Weight and BI [Multidimensional Body-Self Relations Questionnaire subscales] were assessed at four times: 1) Baseline 1 (B1); 2) Follow-up 1 (F1; post PreH); 3) Baseline 2 (B2; post HP, baseline for PostH); and 4) Follow-up 2 (F2; final measure after PostH). Data analysis utilized one-way repeated measures ANOVAs and Pearson's correlations.

RESULTS: Weight change was highly variable from B1 to F2 (range=-6.0 to 5.1 kg) although no significant changes occurred (B1=79.5±12.7 kg; F1=79.2±12.4 kg; B2=79.9±12.8 kg; F2=79.9±12.4 kg; p=.33, ES_{B1-F2}=.03). Contrarily, Appearance Evaluation (B1=2.4±0.6, F1=2.5±0.8, B2=2.6±0.9, F2=2.7±0.8; p=.01; p=.004; ES_{B1-F2}=.52), Fitness Orientation (B1=2.7±.6; F1=3.0±.7; B2=2.9±.5; F2=3.0±.7; p=.013; ES_{B1-F2}=.43), and Health Orientation (B1=3.1±.7; F1=3.4±.6; B2=3.4±.6; F2=3.5±.6; p < .001; ES_{B1-F2}=.65), increased. No changes in the subscales of Body Areas Satisfaction, Overweight Preoccupation and Self-Classified Weight subscales were detected (all p ≥ .05). Change in weight was related to change in both Fitness and Health Orientation (B1 to F2; r=-.50; p=.03; and r=-.54; p=.02; respectively), but it was not related to changes in Appearance Evaluation (r=-.22, p=.37). **CONCLUSIONS:** Our preliminary pilot study suggests that the 11-week weight management intervention attenuated holiday weight gain while positively influencing body image in overweight midlife females.

3065 Board #111 May 31 3:30 PM - 5:00 PM

Association between Quadriceps Strength and Self-Reported Physical Activity in Individuals with Knee Osteoarthritis

Malia N. M. Blue, Abbie E. Smith-Ryan, FACSM, Hope C. Davis, Troy Blackburn, Brian Pietrosimone, FACSM. *University of North Carolina, Chapel Hill, NC.* (Sponsor: Abbie Smith-Ryan, FACSM)

Email: mmm3303@email.unc.edu

(No relevant relationships reported)

Limited quadriceps strength is common with knee osteoarthritis (OA) and may lead to activity avoidance and low physical activity (PA) levels. **PURPOSE:** To investigate the association between quadriceps strength and self-reported PA in individuals with knee OA. Secondary analyses evaluated the association between a change (Δ) in quadriceps strength and self-reported PA following a 4-week physical therapy intervention designed to improve lower extremity strength. **METHODS:** Ninety individuals with radiographic knee OA were enrolled in the current study (43% male; Kellgren-Lawrence grade: 2-4). Assessments occurred at baseline, post intervention, and 4 weeks after intervention completion. At each testing visit, participants completed the Physical Activity Scale for the Elderly (PASE), the Western Ontario and McMaster Universities Arthritis Index pain subscale, and a quadriceps maximal voluntary isometric contraction (MVIC) performed at 70° of knee flexion measured with an isokinetic dynamometer. Multiple regression analyses were conducted to assess the association between MVIC normalized to body mass (nMVIC - predictor variable) and PASE after accounting for age, body mass index, radiographic OA severity, and pain. **RESULTS:** For all participants at baseline, there was a significant association between greater nMVIC and greater PASE ($\Delta R^2=0.049$, $p=0.033$) after accounting for covariates. When stratified by sex, nMVIC was not associated with PASE (Males: $\Delta R^2=0.045$, $p=0.197$; Females: $\Delta R^2=0.011$, $p=0.432$). There was no association between the Δ nMVIC and Δ PASE following the intervention (Total: $\Delta R^2=0.043$, $p=0.072$; Males: $\Delta R^2=0.071$, $p=0.106$; Females $\Delta R^2=0.008$, $p=0.585$), or

4 weeks post intervention (Total: $\Delta R^2=0.001$, $p=0.845$; Males: $\Delta R^2=0.009$, $p=0.629$; Females: $\Delta R^2=0.002$, $p=0.773$). **CONCLUSIONS:** Although greater quadriceps strength was associated with greater self-reported PA, nMVIC only explained 4.9% of the variance in PASE. Post intervention, a change in strength was not associated with a change in PA. Therapeutic interventions aimed at increasing strength may not lead to a subsequent increase in PA. Future studies should investigate the influence of interventions incorporating PA and strength on health and physical function in individuals with knee OA.

Effect Of Hiit On Bmd And Body Composition For College Female Students With Eating Disorder

Shan-Shan MAO, Su-Hang XIE. *Beijing Sport University, Beijing, China.*

Email: ss.mao@163.com

(No relevant relationships reported)

Purpose: To study the effect of high intensity interval training (HIIT) on bone mineral density (BMD) and body composition for college female students with high risk of eating disorder for improvement of physical status. **Methods:** A total of 97 female college students (20.40 yrs) were invited to join the EDI-3 estimate, and 23 of them were judged to have high risk of eating disorder. The 23 students were randomly divided into two groups, the HIIT group (n=12) and the control group (n=11). The HIIT group performed 12 weeks HIIT program particularly designed for them: vehemently pedaling bike for 30 seconds and then resting for 10 seconds, repeating the circle for three times. The training was carried out every other day during the 12 weeks. In contrast, no intervening was taken for the control group during the 12 weeks. Before and after 12 weeks, BMD of total body of all subjects was detected by DEXA, and body composition was measured by BIA. **Results:** 12 weeks later, (1) the BMD of the HIIT group increased significantly ($p<0.05$), from 1.897±0.097 to 1.928±0.126 for the head, from 1.778±0.060 to 1.800±0.065 for the trunk, and from 1.943±0.066 to 1.962±0.128 for the legs. The total body showed a very significant increase ($p<0.01$), from 1.926±0.058 to 1.968±0.107 g/cm². (2) Their averaged weigh was increased from 58.863±6.698 to 60.463±6.651, muscle mass was increased from 38.650±3.144 to 39.125±2.92, and BMI also varied obviously ($p<0.05$). Moreover, the basal metabolism was increased from 1259.375±72.018 to 1269.50±66.345 for the training group students. However, fat mass had no change ($P>0.05$). **Conclusions:** 12 weeks HIIT for female college students with high risk of eating disorder could make their BMD and body composition to improve obviously.

3067 Board #113 May 31 3:30 PM - 5:00 PM

Impact Versus Resistance Training For Bone In Young Women: Preliminary Findings Of The OPTIMA-Ex Trial

Conor Lambert, Belinda R. Beck, FACSM, Amy T. Harding, Steven L. Watson, Benjamin K. Weeks. *Griffith University, Gold Coast, Australia.*

(No relevant relationships reported)

PURPOSE: The OPTIMA-Ex (Osteoporosis Prevention Through Impact and Muscle-loading Approaches to Exercise) trial aims to compare bone responses to two known osteogenic stimuli - impact exercise and resistance training in young women with lower than average bone mass.

METHODS: The trial is a three-arm, single-blind, single-centre, randomised controlled exercise intervention targeting healthy but sedentary women aged 18-30 years with lower than average bone mass (T-score ≤ 0). Participants were randomised to a 10 month, twice-weekly, either supervised high intensity impact training (IT), high intensity resistance training (RT) or home-based low intensity exercise (active control) (CON). Preliminary DXA (Medix DR) outcomes for lumbar spine (LS), dominant (D) and non-dominant (ND) femoral neck (FN); D and ND distal 1/3 radius (RAD) areal bone mineral density (aBMD) have been examined per-protocol, using repeated-measures ANCOVA adjusted for compliance, age, height, weight, total lifetime physical activity, dietary calcium and baseline values. DXA results are reported as mean difference \pm SE, statistical significance set at $p \leq 0.05$.

RESULTS: A total of 51 women (age=22.2±3.6 years; height=1.64±0.62 m; weight=58.1±8.7 kg) have been randomised (IT=17, RT=17, CON=17) with no between-group differences at baseline. Follow-up data is available for 22 participants (IT=6, RT=8, CON=8). Compliance currently differs between groups (IT=66.5±17.2%, RT=67.3±12.3%, CON=87.5±13.7%; $p=0.011$). There are no between-group differences in aBMD at any site. However, there are significant within-group differences in our primary outcome of LS aBMD for both IT (0.046±0.020 g/cm²; $p=0.044$) and RT (0.049±0.018 g/cm²; $p=0.019$). Additional within-group differences are present for ND FN (0.031±0.012 g/cm²; $p=0.027$) and ND RAD (0.047±0.020 g/cm²; $p=0.036$) aBMD for RT. A significant within-group difference is evident for ND (0.057±0.023 g/cm²; $p=0.027$) and D (0.061±0.024 g/cm²; $p=0.029$) RAD aBMD for CON.

CONCLUSIONS:

Although minimal statistical power limits the conclusions that can be drawn from these preliminary data, results indicate both RT and IT improve spine bone mass, while RT may provide a broader osteogenic stimulus in young adult women with lower than average bone mass. Data collection is ongoing.

3068 Board #114 May 31 3:30 PM - 5:00 PM

The Feasibility and Efficacy of a Behavioral Intervention to Promote Appropriate Gestational Weight Gain

Rebecca A. Schlaff, Meghan Baruth, Samantha J. Deere. *Saginaw Valley State University, University Center, MI.* Email: raschlaf@svsu.edu

(No relevant relationships reported)

Nearly half of all women gain above gestational weight gain (GWG) recommendations and physical activity (PA) has been shown to decline during pregnancy. Much work remains in understanding how to promote appropriate GWG and PA during pregnancy. **PURPOSE:** This study assessed the feasibility and efficacy of a pilot behavioral intervention on GWG and PA behaviors. **METHODS:** Women (n=45) 14-20 weeks gestation enrolled in a behavioral intervention. Physicians "prescribed" the intervention to low risk patients. The intervention included self-monitoring, support, and optional walking groups. Process evaluation measures regarding usage and acceptability of study components were obtained. PA was objectively measured at baseline and 35 weeks. The percentage of participants with appropriate GWG was calculated. Control data was obtained from the same clinic where participants were recruited. **RESULTS:** Overall, the intervention was acceptable to participants; attrition was low (6.7%), weekly contact was high (87%), and self-monitoring was high (Fitbit worn on 82% of intervention weeks; weekly weighing on 81%). Facebook (40% of weeks) and study website use (19%) was low, as was walking group attendance (7% attended a single group). Participants reported a lack of discussions about the study with their physician. Results showed no significant difference between intervention and control participants in the percentage who gained excess weight (p=0.37). There was a significant decrease in moderate-to-vigorous PA in intervention participants (p<0.0001). **CONCLUSION:** Continued efforts for promoting PA and appropriate GWG are needed. Although acceptable, the intervention was not efficacious. Future intervention research should consider/report feasibility and acceptability indices through process evaluation. Trainings for, or input from, prenatal healthcare providers on how to best encourage and support patients' engagement in healthy behaviors, such as PA, are warranted.

3069 Board #115 May 31 3:30 PM - 5:00 PM

Blood Lipid Profile Differences After a 12-Month Sit-to-Stand Workstation Intervention

Cara Daniels, Constance Haynes, Larissa Boyd, Jacilyn Olson, Melissa Powers. *The University of Central Oklahoma, Edmond, OK.*

(No relevant relationships reported)

A reduction in sedentary behavior has been associated with improvements in metabolic health. Because a disproportionate number of working hours for office-based employees are spent engaged in sedentary behavior, an increase in workplace activity is substantiated. **PURPOSE:** The purpose of this study was to determine if the use of a sit-to-stand workstation (STS) effected blood lipid profiles following a 12-month intervention. **METHODS:** Participants of the study included volunteer faculty and staff of the University of Central Oklahoma who were randomly assigned to a control group (CG) or an intervention group (IG). A STS was provided to the IG with participants being instructed to stand at least 2 hours every work day. Blood lipid profiles were used to measure high-density lipoprotein cholesterol (HDL), low-density lipoprotein cholesterol (LDL), total cholesterol (TC), and blood glucose (BG) at baseline, 6, and 12-months of the intervention. The data was analyzed using a repeated-measures ANOVA. **RESULTS:** No significant differences were found between groups (p>.05). Small, non-significant improvements occurred for the IG in HDL and LDL over time and a significant change in BG across all groups took place over time (F_{2,23}=8.05, p=.00). Descriptive statistics can be found in Table 1. One outlier was removed from analysis. **CONCLUSION:** Significant differences did not occur between STS participants and those using a typical workstation; however, some benefits may be gained from breaking up bouts of sedentary behavior. Future research may examine the effects of longer standing time to ascertain the efficacy of the STS. Table 1

Blood Lipid Profile Statistics at Baseline, 6 months, and 12 months

| | Intervention Group | | Control Group | |
|-----------------------|--------------------|----------------|---------------|----------------|
| | n | M (SD) | n | M (SD) |
| HDL pre (mg/dL) | 13 | 60.54 (19.84) | 11 | 58.64 (16.33) |
| HDL 6 months (mg/dL) | 13 | 58.54 (17.13) | 11 | 58.55 (15.69) |
| HDL 12 months (mg/dL) | 13 | 60.69 (18.03) | 11 | 63.27 (16.47) |
| LDL pre (mg/dL) | 12 | 104.50 (46.25) | 9 | 97.00 (20.06) |
| LDL 6 months (mg/dL) | 12 | 105.67 (36.89) | 9 | 96.78 (29.88) |
| LDL 12 months (mg/dL) | 12 | 104.25 (46.38) | 9 | 93.22 (35.35) |
| TC pre (mg/dL) | 15 | 175.91 (24.08) | 11 | 175.91 (24.08) |
| TC 6 months (mg/dL) | 15 | 182.29 (36.95) | 11 | 180.00 (26.26) |
| TC 12 months (mg/dL) | 15 | 187.07 (39.53) | 11 | 191.91 (23.91) |
| BG pre (mg/dL) | 14 | 95.73 (8.66) | 11 | 90.73 (10.08) |
| BG 6 months (mg/dL) | 14 | 89.53 (5.88) | 11 | 85.82 (12.05) |
| BG 12 months (mg/dL) | 14 | 91.53 (11.51) | 11 | 89.00 (11.22) |

Effects of a Brief Lifestyle Intervention for Office Workers

Cassandra M. Beattie, Lucas J. Dudgeon, Sarah J. Cosgrove, Katie M. Heinrich. *Kansas State University, Manhattan, KS.* Email: cbeattie@ksu.edu

(No relevant relationships reported)

PURPOSE: Our study assessed the impact of a brief lifestyle intervention (LI) using a novel fitness application on body composition and fitness in office workers. **METHODS:** Insufficiently active office workers (n = 22) participated in a four-week randomized pilot trial. Individuals were randomized to either information-only control (CON; n = 10, age = 34.3 ± 14.6 years, 63.6% female, 80% white) or intervention (LI; n = 12, age = 37.6 ± 14.8 years, 91.7% female, 100% white) groups. CON was provided access to online physical activity and nutrition information with short assessments. LI was trained in-person on a mobile fitness application, that provided short (~2 minutes) daily workouts, alternating muscle groups each day; daily logging of waist circumference, and a tracking system for "treats" (i.e., high sugar/starch foods). In person measures were conducted pre- and post-intervention. Anthropometric measures included height, weight, body fat percentage, and waist circumference (WC). Fitness was measured via handgrip dynamometry (strength), sit-and-reach (flexibility), and 30-second chair stand test (muscular endurance). Independent-samples t-tests were used to examine group differences on baseline characteristics. Both within-group (paired-samples t-tests) and between-group (ANCOVA with baseline scores as covariate) changes scores were analyzed. **RESULTS:** No significant baseline differences were found between groups. Significant changes were found for LI on WC (mean Δ = -3.2 ± 4.3 cm; t = 2.57, p < 0.05), chair stand (mean Δ = 4.9 ± 4.8 repetitions; t = 3.52, p < 0.01), and flexibility (mean Δ = 2.9 ± 3.6 cm; t = 2.84, p < 0.05). Significant changes were found for CON for chair stand (mean Δ = 2.9 ± 3.1 repetitions; t = 2.92, p < 0.05). No significant between group differences were found for change scores. **CONCLUSION:** Our data suggest the novel fitness application could be a viable option to improve body composition and fitness among insufficiently active office workers. Future investigations should aim to validate our pilot study with larger sample sizes and consider additional measures of health and fitness.

Muscle Damage and Inflammatory Response from Volume-Equated Resistance Exercise with Short vs Long Rest Interval

Gilmar W. Senna¹, Paula P. Brandão², Estevão Scudese³, Matheus Baffi⁴, Luiz Claudio P. Ribeiro³, Estélio H.M. Dantas⁵. ¹Catholic of Petropolis University, Petrópolis, Brazil. ²Celso Lisboa University, Rio de Janeiro, Brazil. ³Federal University of State of Rio de Janeiro, Rio de Janeiro, Brazil. ⁴Catholic of Petrópolis University, Petrópolis, Brazil. ⁵Tiradentes University, Aracajú, Brazil.

(No relevant relationships reported)

Resistance exercise is considered the most efficient method for the improvement of muscular strength, power and endurance. However, it is not possible to explain in their entirety the mechanisms that bring the benefits of neuromuscular fitness levels. **PURPOSE:** The aim was to analyze the effects of rest period length between resistance exercise (RE) sets on inflammatory response (cytokines and leukocyte)

and muscle tissue damage. **METHODS:** Ten trained men with at least one year of consistent resistance training experience were selected to participate (26.40 ± 4.73 years, 80.71 ± 8.95 kg, 176.03 ± 6.11 cm, $9.86 \pm 3.25\%$ body fat, bench press relative strength: 1.27 ± 0.27 kg/kg-1 of body mass) and to perform two workouts sessions separated by one week. Each session consisted of five sets of 10 repetitions performed at 85% of 10 repetition maximum on barbell bench press followed by the leg press exercise, with either 1- or 3-minute of rest between sets. Circulating concentrations of creatine kinase (CK), lactate dehydrogenase (LDH), Interleukin 6 (IL-6), and tumoral necrosis factor alfa (TNF- α), were measured at pre-exercise (Pre), and post 3h (except for IL-6), 6h, 12h and 24h. The rate of perceived exertion (RPE) was recorded after each set on both visits. **RESULTS:** After the statistical analysis, we found increases triggered by the 1-minute of rest period length in CK main-effect for time-points ($p = 0.0001$) and rest conditions ($p = 0.0014$), occurring in from 6h to 24h post-exercise compared with the Pre-exercise. For CK the AUC did differ ($p = 0.0005$) between the 1-minute (4572.4 ± 1169.5 u/L.h⁻¹) and 3-minute (3330.1 ± 715.9 u/L.h⁻¹) rest conditions. In addition, we observed an increase in TNF- α for different time-points, mainly in 6h and 12h. Similarly, increases in IL-6 were observed for all post-exercise time-points (6h, 12h and 24h) compared to Pre-exercise data. For the RPE, the short rest period length demonstrated significant increases compared to the longer rest condition (SH, $p < 0.001$; LP, $p < 0.001$). **CONCLUSION:** The short rest condition promoted a greater overall damage of muscle tissue with a longer duration of the inflammatory process of this tissue. Supported by CAPES Brazil: 2.034.476.

Exergaming Intervention in Sedentary Middle-Aged Adults Improves Cardiovascular Endurance, Balance and Lower Extremity Functional Fitness

Daniel Rosney, Sr.¹, Peter Horvath². ¹Temple University, Philadelphia, PA. ²State University of New York at Buffalo, Buffalo, NY.

(No relevant relationships reported)

BACKGROUND: Interactive video game technology has been extensively utilized in rehabilitative settings. However, few studies have explored the potential benefits of interactive video games as an exercise instrument for middle-aged adults who do not have a gym membership or who otherwise cannot regularly make it to their local fitness center. Features of interactive "exergaming" (modeling proper exercise biomechanics, increasing self-monitoring of behavior, encouraging participants to set health-related goals, and rewarding regular use) may help promote physical activity and consequently improve balance, cardiovascular endurance and functional fitness.

PURPOSE: To compare balance, cardiovascular health and functional fitness in relation to exercise tests in sedentary adults before and after exergaming ($n = 12$, 56 ± 4 yrs, 162.1 ± 10.9 cm, 79.2 ± 19.1 kg, $39.6 \pm 7.7\%$ fat mass).

METHODS: Subjects initially underwent balance, cardiovascular endurance and functional fitness tests before engaging in exergaming for 20 min/3d/wk. After 8 weeks, balance, cardiovascular health and functional fitness were retested.

RESULTS: Exergaming improved Single-Leg-Stand time (3.2 ± 0.4 s to 7.9 ± 1.4 s, $p < 0.05$), Sit-To-Stand repetitions (14.2 ± 1.7 to 16.8 ± 1.3 , $p < 0.05$) and YMCA 3-Minute Step Test heart rate recovery (103 ± 7.9 to 95 ± 3.2 , $p < 0.05$) while eliciting an habitual voluntary moderate-intensity exercise level in previously sedentary individuals.

CONCLUSIONS: Exergaming increased cardiovascular endurance, balance and lower extremity functional fitness while meeting American College of Sports Medicine guidelines for moderate-intensity exercise. Exergaming should be considered a viable option for home exercise programs to meet ACSM physical activity recommendations and improve overall quality of life.

Effects Of Yoga And Tai Chi On Mental Health, Pain, And Balance In College Students

shiqi Yu, Jingle Xu, Tara Bridgeman, Cecile Craft, Gloria Duke, Sarah Sass, Xuanliang Dong, Yong Tai Wang, FACSM, Danita Alfred. University of Texas at Tyler, Tyler, TX. (Sponsor: Yong Tai Wang, FACSM)

Email: 976748974@qq.com

(No relevant relationships reported)

Psychological disorders affect up to 50% of college students. Mind-body exercises such as tai chi and yoga have been effective for decreasing mental distress and pain and improving balance, but little is known about these outcomes in the college-aged population.

Purpose: This primary aim of this study was to determine the effectiveness of yoga and tai chi on mental health, pain, and balance in college students. **Methods:** Participants included 46 undergraduate students (13 males, 33 females; age: $M = 23.9$ years, $SD = 7.4$) enrolled in a yoga class (15), tai chi class (16), or a lecture class for the control group (15). Measures of depression, anxiety, stress, pain, and balance were administered at baseline (before the classes began) and at the middle (7 weeks) and end of the semester (14 weeks). A repeated-measures ANOVA was used with time

(baseline, mid, end) and Group (yoga, tai chi, control) to examine the effects of the interventions. In addition, focus group interviews were conducted at the end of study. **Results:** At baseline, the yoga group had higher anxiety and depression scores than the tai chi group. No other differences were apparent at baseline. Over time, yoga group showed decreased anxiety and depression from baseline to 14 weeks, and in depression from baseline to 7 weeks. Though no other significant differences were noted, there was a pattern of decreasing means across all measures of mental health and pain and improvement in balance in the yoga and tai chi groups. Additionally, focus group findings revealed students favored yoga over tai chi. Tai chi benefits included brief distraction from school and possibly improved sleep but was found to be boring and at times more stressful due to time being taken away from academic work and with learning the sequential steps. Yoga was the "bright spot" in the week and more students felt it decreased stress, minimized potential for anxiety attacks, served as a disconnect from the external world, improved pain and mobility and served as a way to connect with friends. **Conclusion:** The preliminary results suggest that implementation of yoga is acceptable and feasible in college students and has the potential of playing a protective or preventive role in promoting mental health.

The Impact of Text Messaging on Baccalaureate Nursing Students' Physical Activity: Single Case Design

Ashley Shuzhu He-Rinicker. Hardin Simmons University, Abilene, TX. (Sponsor: Dennis G O'Connell, FACSM)

Email: sxh05f@acu.edu

(No relevant relationships reported)

PURPOSE: Find the effect of text messaging on physical activity (PA), physical fitness (PF), and physical activity self-efficacy (PASE) of nursing students.

METHODS: A single-case design, concurrent 4-randomized baselines across subjects, and an 8-week text-messaging intervention were used. Participants (Ps) were selected based on results from PA health risk factors, the International Physical Activity Questionnaire (IPAQ), the Physical Activity Appraisal Inventory-Adolescence and Young Adult Version (PAAI). Selected Ps had high or low PA and PASE, and low or moderate PA health risk. Ps (P1-P5: 1 male, 4 female, mean age = 21) were randomized to 5, 7, 10, or 13 day baselines (BL) and completed 3 or 4 BL PF tests and 4 PF retests in week 2 (W2), 4 (W4), 6 (W6), 8 (W8) of intervention. PF tests were resting and post-walk HR and BP, weight, height, BMI, waist-hip ratio (WHR), hand grip strength, VO_2 max from the treadmill 6-minute walk test (T6MWT). PA and PASE were measured by the IPAQ and PAAI at W4 and W8 of intervention. All Ps wore pedometers to measure objective PA throughout the intervention. The 2-SD-band method was used to compare BL data with W2, W4, W6, and W8 data. **RESULTS:** Self-reported PA increased from BL in P2, P3, P4, and P5 by 9.5, 2.9, 11, and 7.8 hrs, respectively. Statistically significant increases were noted in PF in 4 Ps. P1: Resting HR (BL-W6-W8 $\downarrow 9.3$ b/min); Resting SBP (BL-W6-W8 $\downarrow 8$ mmHg); WHR (BL-W6-W8 $\downarrow 4\%$), post-walk SBP (BL-W4-W6-W8 $\downarrow 16.7$ mmHg), distance traveled in T6MWT (BL-W4-W6-W8 $\uparrow 53.7$ m), VO_2 max (BL-W6-W8 $\uparrow 1.7$ mL/kg-min). P2: resting SBP (BL-W2-W6-W8 $\downarrow 9$ mmHg); WHR (BL-W6-W8 $\downarrow 0.04$); post-walk HR (BL-W2-W4-W6-W8 $\downarrow 6.8$ b/min), post-walk SBP (BL-W2-W6-W8 $\downarrow 22.5$ mmHg). P4: resting HR (BL-W6-W8 $\downarrow 5.8$ b/min); weight (BL-W6-W8 $\downarrow 0.5$ kg); post-walk -SBP (BL-W6-W8 $\downarrow 25.3$ mmHg). P5: WHR (BL-W2-W6-W8 $\downarrow 0.03$); post-walk HR (BL-W2-W4-W6-W8 $\uparrow 23.8$ b/min), post-walk SBP (BL-W4-W6-W8 $\uparrow 19.4$ mmHg); distance traveled in T6MWT (BL-W2-W4-W6-W8 $\uparrow 53.7$ m). PASE increased from BL in P1, P2, P3, and P5: 40, 100, 360, 710, respectively. **CONCLUSIONS:** The results suggested that text-messaging may be effective in increasing nursing students' PA, PF, and PASE.

3075 Board #121 May 31 3:30 PM - 5:00 PM
Effects Of Sit-to-stand Desk And Treadmill Workstations On Sedentary Behavior And Physical Activity

Diego J. Arguello¹, Gregory Cloutier¹, Alvin Morton², Dinesh John¹. ¹Northeastern University, Boston, MA. ²University of Tennessee Knoxville, Knoxville, TN.

Email: arguello.d@husky.neu.edu

(No relevant relationships reported)

Purpose: To compare the efficacies of treadmill and sit-to-stand workstations in decreasing daily sedentary behavior (SED) during a 12-month, cluster-randomized trial with an intent to treat design in sedentary overweight office workers. **Methods:** Sixty-six office workers (7 male, 59 female, age \pm SD = 45.3 ± 12.3 y., BMI \pm SD = 32.5 ± 5.7 kg/m²) were cluster randomized to one of 3 groups: (i) seated desk control (C) (N=21), (ii) sit-to-stand desk (D) (N=23), or (iii) treadmill desk (T) (N=22). Change in mean daily SED, standing and stepping time were measured using activPAL™ accelerometers adhered to the dominant thigh at baseline (B), month-3 (M3), month-6 (M6) and month-12 (M12). Inclusion in analyses required ≥ 4 valid accelerometer wear days (i.e., ≥ 10 h. of wake wear time). Missing mean daily SED, standing and stepping

hours were imputed using multiple-imputation. Between and within group differences in mean daily wake-time spent SED, standing, and stepping after M3, M6 and M12 were analyzed with random intercept mixed linear models accounting for repeated measures and clustering effects. Bonferroni corrections were used during pairwise post-hoc comparisons to correct for multiple hypotheses testing. **Results:** Mean monitoring time (i.e., mean sensor wear days and daily time) did not significantly vary between or within groups. There were no significant within group changes in mean daily SED time. Mean daily standing time significantly increased in group D from B to M3 (Mean \pm SD = 1.03 \pm 2.24 h [7.72%], $p = 0.03$, Cohen's D = 0.46), which was sustained through M12. Similarly, group T increased mean standing time from B to M3 (Mean \pm SD = 1.23 \pm 2.56 h [13.28 %], $p = 0.025$, Cohen's D = 0.48), but these increases were negated at M12. Mean daily stepping time increased significantly in group D from B to M12 (Mean \pm SD = 0.81 \pm 1.61 h [2.65 %], $p = 0.019$, Cohen's D = 0.50). No significant between group differences in SED, standing or stepping time were observed at M3, M6, or M12. **Conclusion:** Workstation-based workplace interventions may result in moderate short-term daily reductions in SED and increased physical activity among seated office workers. Sustaining these short-term behavioral improvements may not be achievable through passive environmental modifications alone, and may require additional active behavior change strategies.

3076 Board #122 May 31 3:30 PM - 5:00 PM
Impact Of 12 Week Pedometer Based Interventionson Long Termincrease In Physical Activity Inpreviously Sedentary Adults

Venkata K. Puppala¹, Elise Nelton¹, Amberly Branum¹, Kwang Woo Ahn¹, Scott J. Strath², Mobin Malik³, Michael E. Widlansky¹. ¹Medical College of Wisconsin, Milwaukee, WI. ²University of Wisconsin, Milwaukee, WI. ³Cleveland Clinic, Cleveland, OH.
 (No relevant relationships reported)

PURPOSE: Sedentary life style increases the risk of cardiovascular disease. In previous studies we have demonstrated that 12 week pedometer based interventions aimed at increasing physical activity by 10% each week to achieve a goal of 10,000 steps/day resulted in increase in moderate physical activity (MPA) among sedentary adults at the end of 12 weeks. We wanted to study if this increase in MPA has been sustained in the long term in these adults.

METHODS: A total of 55 adults aged > 50 years were randomized to be in three groups. Group 1 with no intervention, Group 2 received pedometer only and Group 3 with pedometer plus interactive motivational website which provides strategies to increase their physical activity by 10% each week for 12 weeks. A 7 day log of duration and intensity of physical activity using an accelerometer (Actigraph GTX3) were obtained in all the three groups at baseline, 12 and 52 weeks. Data was analyzed with repeated measures ANOVA including group, time, and interaction between group and time was conducted to account for repeated measurements over three time points. False discovery rate control under dependency of Benjamin and Yekutieli was employed to adjust for dependent multiple tests

RESULTS: There is no significant change in physical activity at the end of 12 weeks or 52 weeks in the control group. There is a statistically significant increase in amount of time spent in MPA, and amount of time spent in bouts (10 minutes of MPA) at the end of 12 weeks compared to baseline in Pedometer and pedometer + website group. These gains were however not seen at the end of 52 weeks with the exception of physical activity in bouts. There is statistically significant increase in the physical activity in bouts at the end of 12 and also at 52 weeks compared to baseline in both pedometer and pedometer +website groups.

CONCLUSIONS: 12 week pedometer based interventions have shown long term increase activity in physical activity in bouts at the end of 52 weeks.

3077 Board #123 May 31 3:30 PM - 5:00 PM
Barefoot Running As A Treatment For Plantar Fasciitis In The Runner: A Case Series

Cassie Oddy¹, Alexandra Walker², Peter Francis¹. ¹Leeds Beckett University, Leeds, United Kingdom. ²University of St. Mark and St. John, Plymouth, United Kingdom.
 Email: c.oddy@leedsbeckett.ac.uk
 (No relevant relationships reported)

PURPOSE: Plantar fasciitis is the most common running related injury associated with the foot and represents ~8% of all running injuries. The median recovery time for plantar fasciitis is ~5-months. Following the failure of conservative management for a female runner with plantar fasciitis, we trialled an alternate day treatment strategy of barefoot running on a grass surface (10 - 15 minutes). This approach was successful and was published as a medical case report. This abstract aims to describe the results of an emerging case series (n=4) using a similar approach.**METHODS:** Four amateur runners (2 male, 2 female, age 27-45 years) were diagnosed as having plantar fasciitis. In all cases, the failure of conservative management led to them being prescribed a

barefoot running intervention on grass. Patients were instructed to complete 10-15 minutes (dependent on pain tolerance) of barefoot running every second day and record pain scores using the visual analog scale (VAS) every morning. **RESULTS:** Mean pain intensity (scored out of 10) at the beginning of the intervention was 5.4 \pm 1.5 (range 3.5 - 7). After 6 sessions of barefoot running, mean pain intensity had reduced to 2.0 \pm 1.6 (range 2.0 - 4.0). All patients demonstrated an improvement in pain intensity after 4-sessions. Three patients sustained this improvement up to session 6 and one patient reverted to their original pain score (4). The two female patients demonstrated an immediate and sustained reduction in pain. The two male patients initially remained unchanged or increased pain intensity before improving. **DISCUSSION:** The results of this emerging case series suggest that this intervention is at least well tolerated in runners with chronic plantar fasciitis. The fact that the intervention contains the activity known to worsen symptoms may suggest this approach has some promise. However, it is not possible to infer cause and effect from a case series and the improvements shown in this series may be due to other factors such as the passage of time or a reduction in fear avoidance behaviour.

3078 Board #124 May 31 3:30 PM - 5:00 PM
Aquatic High Intensity Interval Training Improves Cardiorespiratory Fitness of Sedentary Adults

Brittany B. McDaniel, Mildred R. Naquin, Bovorn Sirikul, Robert R. Kraemer, FACSM. *Southeastern Louisiana University, Hammond, LA.* (Sponsor: Dr. Robert R. Kraemer, FACSM)
 Email: rkraemer@selu.edu
 (No relevant relationships reported)

PURPOSE: The purpose of this study was to determine the effects of five weeks of aquatic high intensity interval training (HIIT) on cardiorespiratory fitness and body composition in sedentary young adults. **METHODS:** Eleven participants [9 female (20.0 \pm 0.71 yr), 2 male (23.5 \pm 2.12 yrs)] completed 18 sessions: A) a pre-program testing session; B) a familiarization session; C) 15 exercise sessions; and D) a post-program testing session. The participants completed 3 sessions per week for 5 weeks. Each session consisted of a 5-minute warm-up, 25 minutes of exercise, and a 5-minute cool down. The exercise portion consisted of 25 exercise intervals lasting 10-30 seconds and used combinations of 8-12 different exercises. Twenty-two standard aquatic upper body, lower body, and full body aerobic exercises, most of which utilized aquatic dumbbells or hand paddles, were used in an HIIT protocol during each exercise session. The HIIT intervals during the first week were 10 seconds and increased by 5 seconds each week ending with 30-second HIIT durations during the fifth week. The active recovery intervals were 50 seconds during the first week and decreased by 5 seconds each week ending with 30-second recovery durations during the fifth week. **RESULTS:** Significant improvements in body composition, submaximal and peak heart rate, submaximal VO₂, and peak VO₂ occurred from pre- to post-program. **CONCLUSION:** To our knowledge, this is the first study to evaluate the effectiveness of standard aquatic aerobic exercises in a HIIT protocol. Improvements in cardiorespiratory fitness and exercise economy were observed in sedentary individuals. This form of exercise may be more tolerated in obese individuals or patients with physical limitations for land-based exercise.

Table 1. Data are mean \pm SD.

| Variable | Baseline | 5 weeks | p-value |
|---|-------------------|-------------------|---------|
| Body Composition (% body fat) | 32.55 \pm 5.57 | 30.55 \pm 6.31 | 0.004 |
| GXT VO ₂ Peak (mL/kg/min) | 30.53 \pm 4.38 | 31.95 \pm 5.08 | 0.035 |
| GXT Stage 1 VO ₂ (mL/kg/min) | 15.72 \pm 2.18 | 14.11 \pm 2.30 | 0.013 |
| GXT Stage 1 HR (bpm) | 138.91 \pm 5.58 | 136.64 \pm 5.22 | <0.001 |
| GXT Stage 2 VO ₂ (mL/kg/min) | 21.74 \pm 3.11 | 19.25 \pm 3.50 | 0.031 |
| GXT Stage 2 HR (bpm) | 169.18 \pm 5.72 | 164.45 \pm 5.56 | <0.001 |
| HR Peak (bpm) | 198.91 \pm 3.45 | 192.00 \pm 5.22 | <0.001 |

3079 Board #125 May 31 3:30 PM - 5:00 PM
Active Video Gaming: Appropriate Tool to Improve Fitness in Pediatric Renal Transplant Recipients?

Sandra Weigmann-Fassbender¹, Kathrin Pfeil¹, Burkhard Tönshoff¹, Gerhard Huber², Klaus Weiß², Theresa Betz¹, Birgit Friedmann-Bette¹. ¹University Hospital Heidelberg, Heidelberg, Germany. ²University of Heidelberg, Heidelberg, Germany.
 (No relevant relationships reported)

Renal transplanted children are at increased risk for cardiovascular diseases due to reduced cardiovascular fitness. **PURPOSE:** 1) To evaluate cardiovascular fitness, motor coordination, physical activity and health-related quality of life (HRQL) in pediatric renal transplant recipients and 2) to find out, if active video gaming provides a sufficient stimulus for an improvement in these items. **METHODS:** Twenty renal

transplant recipients (TX, 13.5 ± 3.4 yr; 152.0 ± 21.1 cm; 52.2 ± 20.5 kg) and 33 healthy controls, matched for sex, pubertal stage, regular physical activity and attended school (CON, 13.1 ± 3.2 yr; 157.2 ± 17.7 cm; 49.0 ± 15.9 kg) completed a cycling or treadmill spiroergometry, a motor coordination and a maximal hand grip strength test. HRQL was determined with a validated questionnaire and activity of daily life was recorded as steps per hour with a physical activity monitor. Thirteen patients out of TX (12.9 ± 3.4 yr; 152.1 ± 21.5 cm; 53.8 ± 22.2 kg) participated in a 6-week exercise video game intervention. They were instructed to exercise 3x/week at home and were contacted weekly for adherence. All tests were repeated after the intervention. **RESULTS:** Cardiovascular fitness ($\dot{V}O_{2peak}$: 28.6 ± 7.8 vs. 41.7 ± 8.5 mL·min⁻¹·kg⁻¹; $P < 0.001$), motor coordination (MQ_{total} : 59.7 ± 17.5 vs. 105.8 ± 14.9; $P < 0.001$), physical activity (steps·h⁻¹: 458 ± 171 vs. 687 ± 280; $P = 0.001$) and HRQL (75.0 ± 14.9 vs. 85.2 ± 7.58; $P = 0.017$) were significantly reduced in TX compared to CON. Maximal hand grip strength was similar in both groups. After six weeks of exergaming, daily physical activity significantly increased from 481 ± 176.5 to 602 ± 226 steps·h⁻¹ ($P = 0.043$). However, compliance turned out to be low and cardiovascular fitness, motor coordination and HRQL remained unchanged. **CONCLUSION:** Cardiovascular fitness, motor coordination, physical activity and HRQL are markedly reduced in pediatric renal transplant recipients. Despite low compliance, six weeks of active video gaming provided a stimulus for an increase in daily physical activity in these patients, but did not improve fitness.

3080 Board #126 May 31 3:30 PM - 5:00 PM
Effect of Dual-Task Performance Among Young Adults

Yeonhak Jung, Brett Baker, Preeti Chopra, Darla M. Castell.
University of Texas at Austin, AUSTIN, TX.
 Email: yeonhak.jung@utexas.edu
 (No relevant relationships reported)

Numerous studies have shown that dual-task demands involving exercise lead to a decline in performance on one or both tasks, but the direct effects of exercise intensity and type are less known. **PURPOSE:** To examine the dual-task performance of reaction time while standing or walking or fast-paced walking on a treadmill while completing tasks of varying complexities. **METHODS:** Using within-subject and a repeated measures design a total of 32 participants (Male=21.03±2.79; Female=17) performed six different conditions involving Go/No-Go (GNG) movement tasks while treadmill standing/walking/fast-pace walking (2 task - congruent/incongruent x 3 intensities). Dual-task reaction time was measured during GNG movement task required subjects to strike virtual stimulus that is green while avoiding the red target. The directions were then reversed to create an incongruent condition. All participants performed 3 minutes of each exercise condition on a Motek-instrumented V-gait treadmill integrated with a 180° virtual reality projection screen which created the environment of GNG task. **RESULTS:** A repeated measures ANOVA with a Greenhouse-Geisser correction showed that mean reaction time differed significantly between exercise conditions, $F(3.425, 106.177) = 14.157, p < .01$. Post hoc tests using the Bonferroni correction revealed that Go-task while walking condition was faster than Go-task while standing an average of .039 ($p < .01$), NoGo-task while standing an average of .074 ($p < .01$), NoGo-task while fast-paced walking an average of .031 ($p < .01$). There were no significant differences between Go-task while walking, fast-paced walking and NoGo-task while walking. **CONCLUSIONS:** This novel research methodology suggests that walking-induced physiological arousal may lead to improved dual-task performance over a standing position (Schaefer et al., 2010). Further study with group comparison is warranted.

3081 Board #127 May 31 3:30 PM - 5:00 PM
Implementation of Exercise Training Programs in Dialysis Patients

Spela Bogataj¹, Jernej Pajek¹, Jadranka Buturovic Ponikvar¹, Maja Pajek². ¹UMC Ljubljana, Ljubljana, Slovenia. ²University of Ljubljana, Ljubljana, Slovenia.
 Email: sspelabogataj@gmail.com
 (No relevant relationships reported)

PURPOSE:

To determine the effect of functional exercise guided by a kinesiologist in addition to the basic exercise program of cycling during dialysis on dialysis treatment adequacy (Kt/V) and physical performance of dialysis patients. **METHODS:** 29 dialysis patients participated in the study. We tested their condition with 6-minutes walking test (6MWT), 10 repetitions sit-to-stand test (STS10), handgrip strength test (HG) and with measurement of their Kt/V. We randomized patients in two groups - one experimental (EXP) and one active control group (CON). The exercise program for both groups was performed three times per week over the course of two months. The EXP group attended a guided functional exercise before the dialysis procedure and after that performed a cycling session during dialysis. CON participated in equal intradialytic exercise program as EXP without prior functional exercise. After two months we repeated the baseline tests. **RESULTS:**

27 patients completed the study. Both groups have a significant increase in 6MWT ((EXP (510.08 ± 68.69 m vs. 561.62 ± 94.98 m; $p=0.002$), CON (456.86 ± 78.86 m vs. 487.07 ± 76.16 m; $p=0.000$)) and in STS10 ((EXP (27.94 ± 5.98 s vs. 17.46 ± 4.52 s; $p=0.000$), CON (31.40 ± 7.80 s vs. 26.13 ± 8.85 s; $p=0.000$)) compared with baseline values. In HG there was a significant difference only in EXP (30.46 ± 8.4 kg vs. 36.00±9.76 kg; $p=0.000$), with no significant difference in CON (baseline: 26.14 ± 4.87 kg vs. 26.79 ± 4.26 kg; $p=0.295$) when comparing with their baseline values. Both groups also increased their Kt/V score. EXP improve their score from 1.49 to 1.65 ($p=0.006$) and CON from 1.59 to 1.81 ($p=0.001$) When comparing both groups, we can see a greater increase in EXP in STS10 ($p=0.004$) and in HR ($p=0.000$) compared to the CON. There were no statistically significant difference between groups in 6MWT ($p=0.053$) and in Kt/V ($p=0.00$). **CONCLUSION:** Both types of exercise are effective in improving aerobic endurance and strength of lower limbs. However we believe that, if we want to improve various motor skills, cycling during dialysis alone is not enough. Our research showed us that functional training led by kinesiologist in dialysis centre is practical, feasible and effective in improving the physical function of hemodialysis patients combined with well established practice of intradialytic cycling.

Maximal Oxygen Uptake Responders Versus Non-responders Show Differing Cognitive Responses to Movement-based Video Game Training

Christian Thompson¹, Brigid Larkin¹, Josh Volponi², Alexander Simon², Joaquin Anguera², Adam Gazzaley². ¹University of San Francisco, San Francisco, CA. ²University of California - San Francisco Medical Center, San Francisco, CA.
 (No relevant relationships reported)

There is evidence that aerobic exercise training improves cognitive control including working memory, attention, and goal management via improved brain perfusion, exercise-induced neurogenic factors, and structural adaptations. There is also evidence that cognitive training itself has beneficial effects on cognition via plasticity in neural networks and structural adaptations. However, it is unclear if these adaptations are found equally in those who experience increases in maximal aerobic capacity versus those that do not. **PURPOSE:** Determine cognitive adaptations associated with older adults performing 8 weeks of training on a video game (BBT) that combined cognitive and physical training. It was hypothesized that positive cognitive adaptations would be greater in participants increased maximal aerobic capacity as compared those who did not. It was also hypothesized that participants would show an improvement in cognitive function after the intervention regardless of whether maximal aerobic capacity improved or not. **METHODS:** Fifteen lightly active older (67.6 ± 4.4 yrs) participants completed 8 weeks of training, 3 days per week (24 sessions total) on BBT. Physical task difficulty was adaptive in the game based on real-time heart rate measurements. Cognitive task difficulty was adaptive and included task switching, selective attention and working memory challenges. Participants were assigned to either a maximal aerobic capacity responder group (Responders) who increased $\dot{V}O_{2max}$ ($n=7$) or a non-responder group (Non-Responders) that did not increase $\dot{V}O_{2max}$ ($n=8$). Cognitive assessments included behavioral and neural measures of working memory, sustained attention and goal management. **RESULTS:** Analysis of Covariance (ANCOVA) did not reveal any differences in post-test cognitive variables between Responders and Non-responders. However, when groups were combined, Paired T-Tests showed improvements in the following cognitive variables: Reaction Time Variability in working memory tasks ($p < .05$) and Impulsivity in attention-based tasks ($p < .05$). **CONCLUSION:** Participants who increased maximal aerobic capacity did not experience greater improvements in cognitive control variables as compared to participants who did not. However, the group as a whole did improve measures of cognition.

PURPOSE: To examine sex differences in postprandial glucose (PPG) during moderate intensity stair climbing of various durations following consumption of a mixed meal. The PPG response is strongly associated with cardiometabolic disease risk and women remain understudied in biomedical science. **METHODS:** Five males (24.0±3.9y) and nine females (23.7±2.7y) consumed a mixed meal containing 675 kcal (33% fat, 53% carbohydrate, 14% protein) and glucose levels were monitored for 1 hour. On three subsequent visits, participants consumed an

identical meal combined with either 1min, 3min, or 10min of stair-climbing, all ending 28 min after subjects finished the meal. Fingertick blood glucose measurements were taken at baseline and every fifteen minutes thereafter for one hour.

RESULTS: All results were normalized for body weight. There was no difference in post-exercise PPG at 30min for any of the trials in men (Δ -0.05 \pm 0.12 to 0.28 \pm .23mg/dL/kg, p = 0.69 to 0.29). In women there was a significant difference in post-exercise PPG at 30min for the 10min trial (Δ -0.537 \pm 0.074mg/dL/kg, p <0.001) but not for the 1min or 3min trials. There was no difference in glucose area under the curve (AUC) or incremental area under the curve (iAUC) for any of the trials in men (Δ -2.22 \pm 4.39 to 5.32 \pm 5.68 mg/dL/kg/min, p = 0.64 to 0.40 and Δ -0.86 \pm 2.749 to 5.70 \pm 7.76 mg/dL/kg/min, p = 0.77 to 0.38). In women there was a significant difference in AUC for the and iAUC for the 10min trial (Δ -11.45 \pm 2.22mg/dL/kg/min, p <0.001 and Δ -10.51 \pm 2.99mg/dL/kg/min, p <0.01) but not for the 1min or 3min trials. No interaction was seen between trial and sex for post-exercise PPG at 30min (p =0.65, η_p^2 =0.15), AUC (p =0.70, η_p^2 =0.13), or iAUC (p =0.80, η_p^2 =0.09)

CONCLUSIONS: Men and women showed a similar responses in PPG following moderate intensity stairclimbing of various durations.

Club Fit: A Physical Activity, Education, and Mentoring Service Learning Program

Erika Kenley, Christine Galvan. *California State University, Long Beach, Long Beach, CA.*
 Email: erika.kenley@gmail.com
 (No relevant relationships reported)

INTRO: In the United States, obesity affects about 12.7 million children and adolescents, with minority and low-income populations at an increased risk. Development of a positive association and regular engagement in physical activity at a young age promotes the transition of these habits into adulthood. School-based physical activity programs benefit communities as well as students and schools. The implementation of a physical activity based service learning program provides a mutually beneficial partnership between pre-service teachers and the elementary students. **PURPOSE:** The purpose of this study was to determine the effect of a 9-week fitness intervention and education program for under-served 5th grade students. **METHODS:** Club Fit! consists of a 9-week program with bi-weekly 60-minute exercise sessions. Physical Education Teacher Education pre-service teachers (n =21) served as mentors to 5th grade students (n =35) enrolled at a local elementary school. The pre-service teacher/mentor to student/mentee ratio was 1:1 - 1:2. Pre-service teachers alternated leading lessons focused on health and skill-related physical fitness components, such as paddle tennis, yoga, jumping rope, and locomotor skills. Basic educational concepts from the components of physical fitness were incorporated, including comparing heart rate before and after activity and distinguishing between muscular strength and endurance. Each session concluded with journal questions reflective of the day's concepts and activities. Prior to the program, pre-service teachers trained to use the FitnessGram assessment protocols and Healthy Fitness Zone standards (HFZ). Four FitnessGram Performance Standards were assessed pre- and post-program: Back Saver Sit and Reach, One Mile Run, Curl-Ups, and Push-Ups. Paired t-tests were used to assess the pre and post values for all four FitnessGram Performance Standards. **RESULTS:** Students improved performance in all measured FitnessGram components: Back Saver Sit and Reach (Left: p = 0.00922=, Right: p = 0.00319); One Mile Run (p = 2.279E-7); Curl-Ups (p = 0.000261); Push-Ups (p = 0.00159). **CONCLUSION:** Students improved in all four FitnessGram components and HFZ standards were met for all comparable components. The fitness intervention increased levels of health-related fitness.

The Effect of Multimodal Training on Mobility in MCI Patients: A Pilot Randomized Controlled Trial

Felipe de Oliveira Silva¹, José Vinícius Ferreira¹, Jéssica Plácido¹, Paula Sant'Anna¹, Valeska Marinho¹, Jerson Laks², Andrea Deslandes¹. ¹UFRJ, Rio de Janeiro, Brazil. ²Unigranrio, Rio de Janeiro, Brazil.
 Email: prof.felipeoliveira@gmail.com
 (No relevant relationships reported)

Due a growing number of new cases of dementia and the lack of pharmacological treatment for prodromal stages of dementia, the study of non-pharmacological interventions becomes more necessary. Although Mild Cognitive Impairments (MCI) patients begins to show mobility decreases, especially in dual-task (DT), some studies exams if the physical exercises can improve this deficit. **PURPOSE:** To investigate the effect of multimodal training (MT) on mobility in single task (ST) and DT in elderly with MCI. **METHODS:** Fifteen MCI patients, aged \geq 60 years-old, participated in this pilot randomized controlled trial. At baseline, patients were submitted to three visits: (1) anthropometric measurements, anamnesis and neuropsychological tests; (2) cardiovascular test on treadmill; (3) mobility tests: 8-foot up and go (8UG) in ST and DT (motor and cognitive tasks). Ten participants were randomized and allocated

to an experimental group (EG = 5), with multimodal physical training, including aerobic exercises, strength, balance and stretching; or in a control group (CG = 5). After three months of intervention, both groups were reevaluated. An independent t-test and effect size (ES) analysis were performed through the deltas (post-pre) of the groups. **RESULTS:** The EG presented improvements in general mobility (SMD=0.71 [moderate], 95%CI=0.06, 1.37) and in all mobility tests compared to the CG (TS 8UG: SMD=0.62 [moderate], 95%CI=0.65, 1.90; coefficient of variability (CoV) 8UG: SMD=0.14 [trivial], 95%CI=-1.10, 1.38; DT 8UG: SMD=1.12 [large], 95%CI= 0.23, 2.48; cost of DT (CDT) 8UG: SMD=1.09 [large], 95%CI= 0.26, 2.44). **CONCLUSION:** MT has a positive effect on mobility in elderly patients with MCI, mainly in DT, contributing to the preservation of functional mobility in this group. Supported by CNPq (301483/2016-7) and FAPERJ (E-26/ 203.193/2016).

The Role Of A Sit-to-stand Workstation And Its Effects On Work Productivity

Alexander J. London, Matthew Green, Jamie Clark, Melissa Powers, Jacilyn Olson, Larissa Boyd. *University of Central Oklahoma, Edmond, OK.*
 Email: alondon3@uco.edu
 (No relevant relationships reported)

The prolonged sedentary nature of office work has been shown to induce high levels of discomfort, leading to decreased worker productivity. Many modalities, including ergonomic-adjustable chairs, treadmill desks, and light-activity promotion have been used as interventions to combat worker distress and productivity. The sit-to-stand (STS) workstation is another tool aimed at improving workers' focus and productivity. **PURPOSE:** Therefore, the purpose of this study is to evaluate the efficacy of a STS workstation on work productivity. **METHODS:** All participants were volunteer faculty and staff of the University of Central Oklahoma randomly assigned to a control (n =10) or STS workstation intervention (n =8) group. Both groups filled out the *Health and Work Performance Questionnaire* at the base-line, 6-month, and 12-month mark of the study to measure productivity. Absolute productivity is a subjective measure of an employee's work output. Relative productivity is a subjective comparison of the employee's work output to another employee in a similar position. The control group was instructed to continue their day as normal while the intervention group was instructed to stand at least 2 hours per work day, if possible. **RESULTS:** There was no interaction effect for absolute productivity ($F_{2,15}$ =.91, p =.42) from baseline to 12 months with a moderate effect size (0.68). However, a decrease was seen in the control group from baseline (85 +/- 7.07) to post-test (73.08 +/- 28.07) with a strong effect size (1.69), while the STS workstation group increased from baseline (86.25 +/- .88) to post-test (88.75 +/- 8.35). Relative productivity showed no interaction effect as well ($F_{2,15}$ = .89, p = .44) from baseline to 12 months. The control group saw a decrease from start (1.09 +/- .17) to finish (1.07 +/- .10) while the intervention group saw an increase from start (1.10 +/- .12) to finish (1.19 +/- .26). **CONCLUSIONS:** Overall, the STS workstation did not show a significant improvement in work productivity compared to the control group. However, a positive trend was seen in the intervention group towards perceived greater work production. **ACKNOWLEDGEMENTS:** This study was funded by the University of Central Oklahoma, Research and Sponsored Programs office and Areawide Aging Agency.

3087 Board #133 May 31 3:30 PM - 5:00 PM
College Students' Acute Sedentary Behavior, Step Counts, and Situational Interest during Virtual Reality

Daniel J. McDonough¹, Zachary C. Pope¹, Nan Zeng², Wenxi Liu¹, Zan Gao, FACSM¹. ¹University of Minnesota - Twin Cities, Minneapolis, MN. ²Colorado State University, Fort Collins, CO. (Sponsor: Zan Gao, FACSM)
 Email: mcdo0785@umn.edu
 (No relevant relationships reported)

PURPOSE: This study examined differences in college students' acute sedentary behavior, steps, and situational interest during immersive virtual reality (VR), non-immersive VR, and traditional stationary biking sessions. **METHODS:** Forty-nine college students (34 females; \bar{X}_{age} = 23.6 \pm 3.4 years; \bar{X}_{BMI} = 23.8 \pm 3.1 kg/m²) completed three separate biking sessions: 1) immersive VR bike (VirZoom VR bike, PlayStation 4); 2) non-immersive VR bike (Gamerize bike, Xbox 360); and 3) traditional stationary bike (Spirit Fitness XBU55 bike). Participants' percentage of sedentary time (%ST) and steps were tracked using ActiGraph GT3X+ accelerometers, with situational interest examined using the validated Situational Interest Scale. One-way MANOVA examined differences for all outcomes between the three exercise sessions. **RESULTS:** Significant differences were observed for all outcomes between the three exercise sessions, $F(1, 135) = 67.9-277.2$, $p < 0.01$; $\eta^2 = 0.42-0.79$, except for %ST ($p > 0.05$). In detail, immersive VR resulted in significantly higher steps than non-immersive VR and traditional biking, respectively (2,033.8 \pm 423.4; 1,412.7 \pm 193.5; 1,546.4 \pm 288.0). Moreover, participants reported significantly higher situational

interest during immersive VR (3.5 ± 0.4) than non-immersive VR (2.1 ± 0.5) and traditional biking (1.7 ± 0.4). Specifically, immersive VR compared to non-immersive VR and traditional biking, respectively, observed significantly greater novelty (3.78 ± 0.4 ; 2.2 ± 0.7 ; 1.3 ± 0.4), challenge (3.7 ± 0.4 ; 2.9 ± 0.6 ; 2.3 ± 0.7), attentional demand (3.2 ± 0.6 ; 1.5 ± 0.7 ; 1.5 ± 0.5), exploration intention (3.7 ± 0.5 ; 2.3 ± 0.5 ; 1.9 ± 0.6), and instant enjoyment (3.1 ± 0.6 ; 2.2 ± 0.7 ; 1.3 ± 0.4). Noteworthy, non-immersive VR was observed to be significantly higher than traditional biking in all 5 subscales of situational interest as well.

DISCUSSION: Observations suggested immersive VR biking to promote greater steps and situational interest over non-immersive VR and traditional biking, with non-immersive VR observed superior to traditional biking for situational interest, suggesting VR biking may be an attractive exercise modality in this population. Future experimental designs assessing these outcomes are warranted.

 (No relevant relationships reported)

Purpose

The purpose of this study was to determine the short-term effects of resistance training (RT) on arterial compliance and physical fitness in obese women with normal blood pressure.

Methods

A total of 16 participants (10 control/6 intervention) were included in the analyses (age: 23.5 ± 4.1 years; body mass index: 33.6 ± 2.9 m/kg²). Pre- and post-intervention assessments included cardiorespiratory tests, arterial stiffness assessments, and leg press (LP) and bench press (BP) one repetition maximum tests (1RM). Trainings consisted of seven strength exercises performed at an intensity of 80% 1RM until 550 calories have been expended.

Results

Analysis of variance (ANOVA) showed significant interaction effects (time \times group) in LP ($p=0.001$) and BP ($p=0.001$) tests. Further, pairwise comparisons showed significant increases in LP ($p<0.001$) and BP ($p<0.001$) total weight lifted in the RT group after the intervention (20.55 ± 12.22 kg and 6.1 ± 4.54 kg respectively), but not in the control group (-2.26 ± 8.96 kg and 0.58 ± 2.26 kg respectively). There were no statistically significant changes found for arterial compliance.

Conclusions

Short-term high intensity RT had positive effects on muscle strength in obese women with normal blood pressure with no negative effects on arterial compliance.

3089 Board #135 May 31 3:30 PM - 5:00 PM
Weekly Activity Maintained While Adding Training Among Post Bariatric and Obese Participants

David L. Wenos, Kristen Byrne, Brittany Rood, Elizabeth Edwards, Jeremy Akers, Trent Hargens, FACSM. James Madison University, Harrisonburg, VA.
 (No relevant relationships reported)

It is suggested that a barrier to weight loss during exercise training is associated with increased compensatory sedentary activity (CSA). While studies report a positive association between physical activity and improved weight loss in post bariatric (PB) and obese individuals, the effectiveness for the different types of physical activity interventions and CSA reported is often equivocal. **Purpose:** To evaluate if vigorous or moderate continuous exercise regimens maintain or increase energy expenditure of individuals during exercise training. **Methods:** Eight PB individuals [7 female, 1 male; Body Mass Index (BMI) = 34.95 ± 7.6] and ten obese individual [7 female, 3 male; BMI = 38.99 ± 6.5] participated in a supervised 12 week three days per week treadmill exercise training program. The PB high intensity interval group exercised at 80% of their age adjusted heart rate reserve (HRR) for 4 one minute intervals interspersed with 4 minute recovery bouts at 50% of the HRR for weeks 3 through 6. Exercise was increased to 6 one minute bouts at the same HRR intensity and recovery time for weeks 7 through 12. The obese continuous moderate intensity group exercised for 20 minutes at 60% HRR for weeks 3 through 6 and 20 minutes at 65% HRR for weeks 7 through 12. Both exercise interventions included a 2-week run-in to avoid injuries. Energy expenditure (MET-hrs) was measured using micro activPALs for the pre-exercise week and weeks 3, 9 and 12. **Results:** Overall, there were no significant differences between groups for MET-hrs for any week. MET-hrs increased ($p < .05$) from the pre-exercise week (212.1 ± 4.96) during the intervention (week 3: 221.87 ± 8.01 ; week 9: 218.22 ± 11.19), and remained elevated post-intervention (week 12: 216.35 ± 7.5). Post-intervention MET-hrs had decreased from week 3, but were not significantly different from week 9 MET-hrs. There was 85% compliance for all

training sessions for both groups. **Conclusion:** Post Bariatric surgery patients increased METs from vigorous intensity exercise intervention similar to obese individuals in moderate continuous exercise training. Although METs for week 12 declined for both groups, it remained above baseline and appears there was no evidence of CSA for either group.

Supported by Sentara RMH Hospital and CHBS

3090 Board #136 May 31 3:30 PM - 5:00 PM
Efficacy of a Virtual Reality Fitness Program for Enhancing Muscular Fitness and Body Composition

Kenneth Delcastillo, Andrew Alto, Ramon Belliard, Brad Schoenfeld. Lehman College, Bronx, NY.

Reported Relationships: K. Delcastillo: Industry contracted research; The study was funded by an industry grant.

PURPOSE: The purpose of this study was to compare the effects of a time-efficient virtual reality (VR) training system versus a traditional exercise (TE) program on measures of muscular fitness, body composition, and enjoyment.

METHODS: Nineteen untrained young men (height: 175.8 ± 4.2 cm; weight: 81.9 ± 15.8 ; age: 23.3 ± 3.9) were randomly assigned to 1 of 2 experimental groups: A virtual reality (VR) protocol consisting of a computer-guided exercise-based program using a cable pulley resistance that took a half hour to complete ($n = 10$), or; a traditional exercise (TE) protocol, consisting of a combination of resistance training and cardiorespiratory training that took 1.5 hours to complete ($n = 9$). The training intervention lasted 8 weeks. Testing was carried out pre- and post-study for changes in measures of maximal muscle strength (1 repetition maximum [1RM] for the bench press and leg press), upper body muscular endurance (50% of 1RM for the bench press), and body composition (fat free mass, skeletal muscle mass, and body fat percentage) assessed via multifrequency bioelectrical impedance analysis. The level of enjoyment of the respective exercise programs was assessed post-study using the modified 8-item Physical Activity Enjoyment Scale.

RESULTS: Main effects for time were observed for 1RM bench press ($F = 71.030$; $p < 0.001$), 1RM leg press ($F = 64.021$; $p < 0.001$), upper body muscular endurance ($F = 43.059$; $p < 0.001$), lean body mass ($F = 5.345$; $p = 0.034$) and skeletal muscle mass ($F = 6.968$; $p = 0.017$). No main effects for time were noted with respect to changes in body fat. A time-group interaction was observed for tests of 1RM leg press ($p = 0.004$) and upper body muscular endurance ($p = 0.033$), with TE showing significantly greater increases compared to VR. No between-group differences were noted for any other outcome variable.

CONCLUSIONS: Despite greater improvements in some performance-related measures for TE, our findings suggest that the specific VR program studied is a viable strategy to improve muscular fitness and lean mass while requiring a limited time commitment in a young, untrained population. Moreover, participants in VR reported a high level of enjoyment with the program, which may help to foster long-term adherence.

3091 Board #137 May 31 3:30 PM - 5:00 PM
Student Engagement in Classroom Physical Activity Breaks

Jeanne Barcelona¹, Yen Chen², Darla Castelli¹. ¹Wayne State University, Detroit, MI. ²University of Texas at Austin, Austin, TX.

(No relevant relationships reported)

Purpose: Students are sedentary for approximately 92% of the day. Classroom physical activity (PA) breaks are known to decrease sedentary behavior (SB). However, little consideration has been given to the environmental and behavioral factors influencing how students engage in classroom PA breaks. Therefore the purpose of this study was to understand how perceived classroom climate and sedentary behavior impact students' total moderate to vigorous physical activity (MVPA).

Methods: Students ($n=112$) housed in 1st and 2nd grade classrooms across two school districts participated in a one-day study protocol using a classroom climate survey and accelerometers to investigate student engagement in a five minute classroom PA break. Descriptive statistics, bivariate correlation analyses between variables and mediation analyses using linear regression were conducted to explore direct and indirect effects.

Results: Over half of the students were females (56.3%) and second graders (51.8%). Correlations were found between perceived classroom climate to sedentary behavior ($r = -.31$, $p = .001$) and total MVPA ($r = .34$, $p < .001$). Sedentary behavior was negatively correlated with total MVPA ($r = -.71$, $p < .001$). The mediation model explained 27% of the total MVPA variance ($p < .001$). Perceived classroom climate had a direct effect on sedentary behavior ($B = -.04$, $SE = .01$, $t = -3.09$, $p < .05$). Sedentary behavior had a direct effect on total MVPA ($B = -.45$, $SE = .06$, $t = -7.69$, $p < .05$). Student perceived classroom climate did not have a significant direct effect on total MVPA ($p = .09$) but did have significant indirect effect through sedentary behavior (indirect effect = .02, bootstrap $SE = .007$, 95% bootstrap $CI = .005$, .030), meaning that a participant who scores 1 point higher on perceived classroom climate survey, on average, .02 minutes higher on total MVPA through sedentary behavior.

Grade, sex, and PA break type were controlled in the analyses. **Conclusions:** Providing students with classroom PA breaks may not be enough. Student's PCC shape how they engage in classroom PA breaks. Teachers must develop a positive classroom climate where PA is encouraged and affirmed.

Osteogenic Response After Six Months of High-Intensity, Low-Impact Exercise

Malcolm Jones, Alberto F. Vallejo, E. Todd Schroeder, FACSM.
University of Southern California, Los Angeles, CA.
(No relevant relationships reported)

Purpose: Lagree Fitness exercise offers high-intensity, low impact workouts that combine resistance, endurance, core, and cardio training. These classes are offered as alternatives to traditional weight bearing resistance training; however, it is unknown whether this training method has osteogenic effects on bone similar to traditional resistance training. To provide such insight, we assessed changes in bone after six months of the high-intensity training using the Lagree Fitness Megaformer in men and women.

Methods: 31 healthy participants began a 6 month, 3x per week, 25 minute group lead, Lagree Fitness training course on the Megaformer. The data from 19 women and 4 men (45.1 ± 20.9 years of age), weight (150.5 ± 41.5 lb), height (66.5 ± 6.5 in) were analyzed; eight participants did not complete the course and were excluded from data analysis. All participants completed a lumbar spine, bilateral hip, and total body scan on a GE Lunar iDXA dual-energy x-ray absorptiometer at baseline and within 10 days of completing 72 training sessions.

Results: There were no significant osteogenic effects on lumbar spine bone mineral density (BMD) (P=.102), femoral neck BMD (P=.519), or total hip BMD (P=.481) in this sample. There was also no significant changes in total body bone mineral content (BMC). While there were no statistically significant changes in total body BMD (P=.186), total arm BMD (P=.125) and total leg BMD (P=.111), there were apparent positive increases that may be promising and suggests the necessity for further data collection with a larger sample. There were similar positive effects on total arm BMC (P=.292) with statistically significant increases in total leg BMC (P<.035). The increase from baseline of total arm lean mass (LM) (P<.009) was significant, and increases in total body LM (P=.069) approached significance. Change in total leg LM (P=.382) was not significant.

Conclusion: In the absence of weight bearing exercise, high-intensity exercise on the Lagree Fitness Megaformer provided significant increase in total leg BMC, and promising increases in BMC and BMD across other body regions. However, there were no significant osteogenic effects on the hips and lumbar spine typically of importance in osteopenic populations.

3093 Board #139 May 31 3:30 PM - 5:00 PM
Physical Activity Breaks in the College Classroom: Student Engagement Factors

Maria del Mar Chavarria-Soto¹, Megan Babkes Stellino¹, Lyndsie M. Koon², Jessica B. Kirby¹, Taylor Polson¹. ¹*University of Northern Colorado, GREELEY, CO.* ²*University of Illinois, Champaign, IL.*
 Email: mariadelmcr@yahoo.com
(No relevant relationships reported)

Most college classes require long periods of sedentary behavior and attention demanding tasks. College students, as emerging adults, are moving through a key developmental stage, in which it is critical to instill lifelong health behaviors. Physical activity breaks (PABs) in college settings are novel, but have been shown to be potentially beneficial regarding concentration and academic performance (Babkes Stellino, et al., 2017). **PURPOSE:** To explore college students' barriers to, and reasons for, engagement in a PABs intervention. **METHODS:** College students were invited to participate in video-led or live instructor-led PABs consisting of cardio-strength based exercises or yoga during a 6-week summer college course. Students were asked to write out the reason(s) they chose to engage in the PAB, or not, each day a PAB was offered. At the end of the 6-week course, students also completed an open-ended survey intended to understand their overall reasons for engagement, and barriers to participation in PABs. Basic thematic analysis was conducted to explore why students chose to engage in PABs or chose to opt out. **RESULTS:** Common reasons reported for engaging in PABs were enjoyment, needing a break from lecture, and contributing to the research. Enjoyment levels were higher when various modes of PABs were offered. Students mentioned a greater personal connection, and a desire to put forth more effort when a live instructor led the activity, particularly for yoga PABs. PABs were viewed as a break from class, and considered a valid exercise bout for some students. This was motivating for some students, but reported as a limitation for others who had already exercised or were going to exercise later that day. Not feeling well, being unprepared or just not wanting to participate, were reported as the main barriers to engagement in the PABs. **CONCLUSION:** It is important to understand what motivates college students to engage, or not, in PABs, in order to better tailor future

programs that will appeal to a greater majority of students. Findings will contribute to the continued exploration of the benefits that PABs can have for college students in the college classroom.

Effects Of Exercise Intensity Provided In The Exercise Classes On The Establishing Exercise Habits

Yasutomi Katayama, Kenta Kitamura. *Kogakkan University, Ise, Japan.* (Sponsor: Kiyoji TANAKA, FACSM)
 Email: katayama@kogakkan-u.ac.jp
(No relevant relationships reported)

We provided Japanese adult women who have not been having exercising regularly habits and through an exercise intervention (group exercise class like a fitness sports club) succeeded in establishing exercise habits. We considered that providing vigorous intensity exercise, presence or absence of a goal setting, and social support might be effective in establishing exercise habits. In particular, there are indications that low exercise intensity is preferable for establishing exercise habits. However, success experiences of difficult (vigorous intensity) exercise enhance confidence, which may contribute to establishing exercise habits in Japanese adult women.

PURPOSE: To examine the effects of differences in exercise intensity provided in the exercise classes on the establishing exercise habits and changing in self-efficacy of exercise and health-literacy related to behavioral changing such as health and exercise habits.

METHODS: We recruited 27 participants (volunteers) in this intervention (exercise classes). Participants were 20-64-year-old healthy Japanese women who have not been having exercising regularly habits, confidence in physical fitness, and athletic ability. They separated randomly moderate- to vigorous-intensity (2-8 METs) exercise class (MV group, n=14) and low- to moderate-intensity (2-4 METs) exercise class (LM group, n=13). We instructed 90 min/session some exercises 24 sessions (twice a week for 3 months) and lectured about association with health and physical activity (exercise) for both groups.

RESULTS: There were 4 participants (28.6%) in MV group and 5 participants (38.5%) in LM group who dropped-out. The establishing exercise habits after the 1-yr from the end of intervention were not significantly different between two groups (20%, 50%). Self-efficacy (11.8 ± 2.5 → 11.5 ± 3.4 points, 8.8 ± 3.5 → 9.4 ± 2.7 points) and health-literacy (18.3 ± 2.9 → 18.5 ± 2.1 points, 16.5 ± 4.0 → 17.0 ± 5.1 points) did not significantly different from baseline and differ significantly interaction between the two groups.

CONCLUSION: It was concluded that exercise intensity contributed little to increasing self-efficacy, health-literacy and establishing exercise habit. It may be important to definite goal setting (goal contents) or social support to improve them.

Accuracy Of Dual Task To Distinguish Elderly With Alzheimer's From Healthy Controls

Juliana L. Araujo, Jessica Plácido, José Vinicius Ferreira, Felipe Oliveira, Renato Sobral Monteiro-Junior, Jerson Laks, Andrea C. Deslandes. *UFRJ, Rio de Janeiro, Brazil.*
(No relevant relationships reported)

Alzheimer's disease (AD) is the most prevalent dementia in the world. Indeed, the expectations are that this number will triple in the coming decades. Clearly, accessible interventions to prevent and treat the disease have been crucial, as well as, identify preclinical individuals. Despite clinical diagnosis are still focused on episodic memory deficits as the gold standard for AD, some studies suggest that because of the damages caused by the disease in prefrontal and temporal areas, along with, impairment in executive function AD could also have a motor signature that could be access through gait and Dual task (DT) tests. the accuracy of these tests to distinguish healthy from AD elderlies.

PURPOSE: To verify the sensitivity and specificity of DT and DT cost to distinguish elderly with AD from healthy controls.

METHODS: We evaluated older adults over sixty years old. DT performance was measured by gait velocity (m/s), DT cost (DTC= ([single task - dual task] / single task) × 100)) and the number of evoked words (DTanimals). We also included Sit to Stand, 8 Foot up and go and STEP test to measure functional capacity. Cognitive functions were evaluated through MMSE, RAVLT and Trail (A and B). T test and Mann-Whitney test were used to compare the two groups. The sensitivity and specificity of the tests were explored through the ROC curve. **RESULTS:** The final sample consisted of 82 participants, being 39 healthy elderly and 43 diagnosed with AD. There was a significant difference between the Healthy and AD groups in all DT variables and MMSE; DT (p < 0.001), DT cost (p < 0.001), MMSE (p < 0.001). Moreover MMSE (area = 0.974; sensitivity = 92.9%; specificity = 82.1%; p < 0.001) showed better accuracy than DT (area = 0.901; sensitivity = 80.5%; specificity = 86.8%; p < 0.001) and DTC variables (area = 0.816; sensitivity = 82.7%; specificity = 76.3%; p < 0.001). The cut-off point of DT was 9.55.

CONCLUSIONS: DT analysis was able to differentiate AD from Healthy elderly with great accuracy and a moderate sensitivity and specificity. Performance in dual task should be more investigated as a possible motor biomarker of AD.

Effects Of Bingocize® On Quality Of Life, Fall Risk, And Health Knowledge In Community-Dwelling Older Adults

Alyssa Kathryn Dispennette¹, Brian Focht, FACSM¹, Brian Clark², Mark Schafer², Matthew Shake², Gretchen Macy², Jason Crandall². ¹The Ohio State University, Columbus, OH. ²Western Kentucky University, Bowling Green, KY. (Sponsor: Brian Focht, FACSM)

(No relevant relationships reported)

Quality of life (QOL) is an important aspects of overall well-being in older adults. QOL is associated with functional, physical, and psychological health; all of which can be improved with increased physical activity. A high fall risk is associated with low physical function and QOL. One in four older adults experiences a fall each year, making it necessary to focus public health interventions towards decreasing fall risk and improving QOL in older adults. Bingocize® is a health promotion program designed to promote health, health knowledge, physical activity, and social engagement among older adults. **PURPOSE:** The purpose of this study was to determine the effects of the new version of Bingocize® on QOL and fall risk in community-dwelling older adults (N=36; mean age 73.63 ± 6.97). **METHODS:** Participants were clustered and randomly assigned to (a) experimental (n=19; participating in Bingocize® program, which included the bingo game, exercise, and health education) or (b) control (n=17; only played bingo). Each group completed a 12-week intervention that consisted of two 45-60 minute sessions per week. Pre and post data assessments included the TUG, 30-second chair stand, 4-staged balance, handgrip strength, WHOQOL-BREF, PANAS, and a health knowledge quiz. A mixed design analysis of variance (ANOVA) was used to compare intervention effects. Associations were significant at p≤0.05. **RESULTS:** There were no significant interactions for any of the variables, with the exception of positive affect (PA) (F (1,34) = 5.66, p = 0.02, power = 0.64) and handgrip strength (F (1,34) = 8.31, p = 0.007, power = 0.80). There was also a significant main effect for time for health knowledge. Post hoc analysis using independent samples t-tests were conducted on PA (t (33) = 2.39, p = 0.023, two-tailed) and handgrip strength (t (34) = 2.85, p = 0.007, two-tailed). **CONCLUSION:** Participating in the Bingocize® health promotion program can produce a meaningful and detectable change in handgrip strength and PA in community-dwelling older adults.

Tailored Domain-Specific Sedentary Behavior Intervention on Reducing Sedentary Time

Heontae Kim, Minsoo Kang, FACSM. *The University of Mississippi, Mississippi, MS.*
 Email: hkim35@olemiss.edu

(No relevant relationships reported)

PURPOSE: To continue the advancement of sedentary behavior intervention, it is important for researchers to design the intervention based on the theoretical model and contextual information of sedentary behavior. Therefore, the purpose of this study is to identify the feasibility of tailored domain-specific sedentary behavior intervention on reducing sedentary behavior time using contextual information of sedentary behavior. **METHODS:** A total of 43 adults (age ≥ 18) were participated in this study. A randomized controlled trial with a covariate adaptive randomization was used. Participants were randomly assigned to three groups: 1) tailored domain-specific intervention group; 2) standard intervention group; and 3) control group. Behavioral strategies to reduce sedentary behavior included educational meeting and materials, goal setting and feedback, and self-monitoring based on theoretical background for two intervention groups. Additionally, contextual information of sedentary behavior was given to tailored intervention group. Participants' sedentary behavior time was measured at baseline, 1st and 2nd intervention week by accelerometers, and contextual information of their sedentary behavior was obtained from the Sedentary Behavior Record instrument. Two-way (Group × Time) repeated measures analysis of variance was conducted for comparison for changes in total time spent in sedentary behavior among the three groups.

RESULTS: Thirty-six out of 43 participants who wore the Actigraph during at least 10 hours per day for at least four days were included in this study. There was a significant interaction between group and time, F(3.9, 63.6) = 3.94, G-G p = .007, $\eta_p^2 = .193$. Simple effect analysis results showed that sedentary behavior time at each time point were not significantly different for the control group, F(1.7, 18.9) = 0.48, G-G p = .597, $\eta_p^2 = .042$, and the standard intervention group, F(1.8, 20.1) = 1.76, G-G p = .198, $\eta_p^2 = .138$. The sedentary behavior time, however, differed among three times for tailored domain-specific intervention group, F(1.7, 18.8) = 14.00, G-G p < .001, $\eta_p^2 = .560$.

CONCLUSIONS: The tailored domain-specific sedentary behavior intervention using contextual information of sedentary behavior was effective, reducing sedentary behavior time for adults.

Stage Ofbehavior Change In Regards Of Physical Activity, Health And Quality Of Life Among Health Professionals From Health Institutions

Amauri dos Santos, Carolina Gonzalez Beltran, João Pedro da Silva Júnior, Victor Keihan Matsudo. *CELAFISCS, Brazil.*

(No relevant relationships reported)

Purpose: To analyze the factors associated to the stage of behavior change among professionals from health institutions. **Methods:** The sample consisted of 1054 professionals (247 male and 807 female). The dependent variable was the irregularly active group of the behavioral stage questionnaire (proposed by Prochaska, 1988). The independent variables were: gender, physical activity, steps number, sleep, negative mood, presence of diseases, health perception, and quality of life. **Statistical analysis:** Binary Logistic Regression Odds Ratio (OR) and its respective 95% confidence intervals (CI) were used to associate the study variables. **Results:** Factors associated with irregularly active behavior change were: gender, physical activity, sleep, negative mood, presence of disease, health perception and quality of life. On the other hand, steps number was not associated with the stage of irregularly active behavior change (see table below). **Conclusion:** The irregularly active group had a positive association with female sex, as well as a higher probability of belonging to groups that did not comply with the recommendation of physical activity, dissatisfaction with sleep, with a higher frequency of negative mood, with diseases, negative health perception and a low quality of life.

Factors associated with irregularly active stages of behavior change (Pre-Contemplative, Contemplative, Preparation) with gender, physical activity, factors related to health and quality of life

| Variable | Significant (p ≤ .05) | OR | CI 95% | Variable | Significant (p ≤ .05) | OR | CI 95% |

The Effect of a Foot Exercise Protocol on Intrinsic Muscle Volume

Ulisses T. Taddei¹, Alessandra B. Matias¹, Fernanda IA Ribeiro¹, Irene S. Davis, FACSM², Isabel CN Sacco¹. ¹Universidade de Sao Paulo - Faculdade de Medicina, Sao Paulo, Brazil.

²Spaulding National Running Center, Cambridge, MA. (Sponsor: Irene S. Davis, FACSM)

Email: utaddei@gmail.com

(No relevant relationships reported)

Musculoskeletal injuries of the foot may be partially attributed to weakness of the intrinsic muscles, which are crucial to foot stability during dynamic activities. Perhaps because of their small size, the potential for strengthening these muscles is highly under-appreciated. Therefore, treatment of foot problems is often focused on externally supporting the foot rather than strengthening it. **PURPOSE:** To determine the effect of a foot exercise intervention on the volume of plantar intrinsic foot muscles.

METHODS: 34 recreational runners were randomly assigned to either a Control (CON) or Foot Strengthening (FS) group. The CON group was assigned to a placebo lower limb stretching protocol while the FS group performed a foot exercise protocol for 8 weeks. Running mileage and training pace were controlled weekly throughout the study for both groups. The right foot of all subjects was imaged using MRI at baseline (T0), as well as at week 8 (T8). Cross-sectional areas (CSA) of the whole length of the Abductor Hallucis (AbH), Abductor Digiti Minimi (AbDM), Flexor Hallucis Brevis (FHB), and Flexor Digitorum Brevis (FDB) were measured by a researcher blinded to both group assignment and time (T0 or T8) The Intraclass Correlation values for repeatedly measuring CSA for this tester was ICC_{3,1} = 0.97 (0.96–0.98). **RESULTS:** There was a significant difference in volume and CSA for all muscles measured for the FS group between T0 and T8 (p<0.05). Muscle volume in the FS group increased

by 22.4% for the AbH, 17.1% for AbDM, 17.7% for FHB, and 8.8% for FDB. No changes were noted in the CON group. **CONCLUSION:** The foot exercise protocol significantly increased the volume of intrinsic foot muscles in a healthy and physically active population of recreational runners. This study was financed in part by the Coordenação de Aperfeiçoamento de Pessoal de Nível Superior - Brasil (CAPES) - Finance Code 001, FAPESP 2015/14810-0.

Changes in muscle volume in the CON and FS groups (positive indicates an increase in size and negative indicates a decrease in size). * Significant difference from CON (p<0.05).

3100 Board #146 May 31 3:30 PM - 5:00 PM
The Effect Of Exercise Training And Increasing Non-exercise Physical Activity On Glyca Levels

Damon L. Swift¹, Joshua E. McGee¹, Lesley D. Lutes². ¹East Carolina University, Greenville, NC. ²University of British Columbia Okanagan, Kelowna, BC, Canada.
 Email: swift@ecu.edu
 (No relevant relationships reported)

Purpose: Aerobic training has been shown to have a beneficial effect on GlycA, which is a marker of inflammation. However, it has not been previously reported if an intervention with aerobic training and increasing non-exercise physical activity can further reduce GlycA. Thus, the purpose of the present study is to determine the impact of the combination of aerobic training and increasing non-exercise physical activity on GlycA levels compared to aerobic training alone in obese adults. Methods: Obese adults (N=30) were randomized to an aerobic training, (AERO), aerobic training and increasing non-exercise physical activity, (AERO-PA) or a control (CON) group for 6 months. Both exercise groups performed supervised aerobic training (50%-75% VO2 max) at a dose of 12 kcals per kg per week. Along with exercise training, the AERO-PA group had the goal of increasing non-exercise physical activity ~3,000 steps above baseline levels. Archived blood samples were obtained at baseline and at follow-up and subsequently analyzed by LipoScience for GlycA after the completion of the study (LabCorp, Morrisville, NC). An ANCOVA was used to evaluate the change in GlycA across the intervention groups with adjustment for the baseline value. Person correlations were run to evaluate the change in GlycA with weight, body composition, and fitness variables. Results: Significant within groups reductions in GlycA were observed in the AERO (-43.1 μmol/L, CI: -74.1 to -12.2) and the AERO-PA groups (-31.2 μmol/L, CI: -61.2 to -1.1), but this change was not significant compared to the CON group (-15.4 μmol/L, CI: -41.8 to 11.0). The change in GlycA in exercisers was not associated with the change in fitness (r=-0.18, p=0.47), waist circumference (r=-0.37 p=0.13), weight (r=-0.31, p=0.21), body fat (r=-0.28, p=0.26) or change in steps of non-exercise physical activity (r=0.35, p=0.16). Conclusion: Neither aerobic exercise training or aerobic training and increasing non-exercise physical activity reduced inflammation levels in obese adults measured by GlycA. Changes in GlycA are not associated with body composition, non-exercise physical activity, or fitness changes associated with aerobic exercise training.

Power and Strength Training Produce Similar Improvements in Performance in Individuals with Parkinson's Disease

Nicholas P. Cherup, Kirk B. Roberson, Andrew N. Livingston, Kerri L. Strand, Emma R. Michiels, Jessica Kuhn, Francisco A. Lopez, Joseph F. Signorile. *University of Miami, Miami, FL.*
 (Sponsor: Kevin Jacobs, FACSM)
 (No relevant relationships reported)

PURPOSE: Loss of motor function is a cardinal symptom associated with Parkinson's disease (PD), with many studies indicating that muscular strength and power decrease as the illness progresses. Although literature supports the efficacy of resistance training to improve motor function in persons with PD, no study has compared the impact of strength and power training on measures of strength, power, balance and functional movement in PD patients. **METHODS:** Thirty-five participants diagnosed with mild to moderate PD were randomized into a 12-week strength or power training program (2 times per week). Measures of muscular strength (1RM), peak power (PP_{rel}), balance (Berg balance assessment, dynamic posturography, modified falls efficacy scale), and functional movement (timed up-and-go) were assessed before and after training. **RESULTS:** No significant group effect was found. Significant increases in leg press (MD = 54.89 kg ± 7.41; η²=.749; p < .0001) and chest press (MD = 7.33 kg ± 3.46; η²=.518; p < .0001) strength, as well as in leg press (MD = 106.89 W ± 24.73 η²=.358; p < .0001) and chest press power output (MD = 52.12 W ± 13.51; η²=.299; p < .0001) were seen for the entire sample. There was also a significant decrease in Berg scores for the sample (MD = -1.68 ± .551; η² =.192, p = .009). No other differences were detected across the training period. **CONCLUSION:** Strength and power training produced similar improvements in measures of strength and power in individuals diagnosed with PD. Although Berg scores decreased significantly following training, these declines were not considered clinically significant. We postulate that the lack of improvement in balance and functional movement scores for either intervention may be due to the failure to include movement-specific drills in the training protocol. Future research should continue to examine the differential effects produced by strength and power training in PD patients and should include a functional training phase designed to elicit improvements in balance and daily function.

The Impact Of A Workplace Wellness Program On Employees In A University Setting

Bhibha M. Das¹, Thomas M. Halloran², Charles D. Kemble¹, Melanie Sartore-Baldwin¹, Katrina D. DuBose, FACSM¹.
¹East Carolina University, Greenville, NC. ²Architech Sports & Physical Therapy, Charlotte, NC. (Sponsor: Katrina D. DuBose, FACSM)
 Email: dasb@ecu.edu
 (No relevant relationships reported)

The Affordable Care Act of 2010 contained incentives for worksites to develop workplace wellness programs and employee wellness programs, which have shown positive outcomes to companies in various dimensions of wellness. Historically, studies have examined one dimension of wellness and typically within a corporate setting. **PURPOSE:** To evaluate the effectiveness of an educational wellness intervention on overall well-being based on the eight dimensions of wellness in university faculty and staff. **METHODS:** Employees (N = 12, 72.7% female; 81.8% white) underwent an 8-week intervention called the Employee Wellness Institute. Employees met once a week with each session highlighting one of the eight dimensions of wellness. Demographics, anthropometrics, physical activity, nutrition, and overall wellness were pre and post intervention. Statistical analysis utilized a paired-t test and Cohen's d for effect size. **RESULTS:** Within each dimension of wellness there was an average increase of 8% in Physical, 3% in Emotional, 3% in Social, 2% in Occupational, 4% in Spiritual, and both Environmental and Intellectual had the largest increase at 9% which was statistically significant (p=0.011). **CONCLUSION:** Data supports the hypothesis that employees would improve their proficiency within the 8-dimensions of wellness as well as physical activity, although not all improvements were statistically significant. Within a short 8-week intervention, employees had increase their overall wellness up to 9% in some dimensions. If the employees had access to a year-round program that continuously strived to improve their wellness, or if more employees had access to such a program, the overall wellness of an entire faculty/staff of a university may improve. Thus, future research and practice efforts should implement and evaluate year-long worksite wellness programs for university employees.

Efficacy Of A Recess-based Intervention On Academic And Health Outcomes In Elementary School Children
 Christine St Laurent, Sarah Burkart, Sofiya Alhassan, FACSM.
University of Massachusetts Amherst, Amherst, MA. (Sponsor: Sofiya Alhassan, FACSM)
 Email: cstlaurent@umass.edu
 (No relevant relationships reported)

Both cardiorespiratory and muscular fitness are important for overall health and may benefit academic related outcomes in children. However, few intervention studies have examined the impact of an intervention that has emphasized both components on academic or cognitive outcomes. Furthermore, school recess may be an ideal time to promote physical activity and fitness and has been a relatively understudied setting in relation to these outcomes. **PURPOSE:** To evaluate the preliminary efficacy of a 3-month recess-based combined fitness intervention (INT; consisting of both aerobic and muscular fitness activities) on cognition (inhibition and working memory), classroom behaviors (engaged and off-task behaviors), fitness (cardiorespiratory and muscular), and moderate to vigorous physical activity (MVPA) in elementary school-age children. **METHODS:** Schools (n=2) were randomized to either the INT (n=27, sex: 66.7% male, age: 8.8±0.1 years) or control group (CON; n=27, sex: 42.3% male, age: 9.4±0.1 years). Baseline and post-intervention measures included a flanker test (inhibition), list sorting test (working memory), classroom behavior observation (on- and off-task behaviors), 20-meter shuttle run (cardiorespiratory fitness), muscular fitness battery (muscular fitness), and accelerometry (MVPA). Process evaluation measures were recorded daily, weekly, and post-intervention. ANCOVA models were adjusted for baseline score, age, and other covariates. An independent samples *t*-test was used to compare percent of time spent in MVPA during recess between schools. **RESULTS:** Percent of time spent in MVPA during recess was significantly higher in the INT compared to the CON group (INT=41.7±2.1%; CON=30.4±0.2, *p*<0.001). No other significant differences were observed. Although participant enjoyment and INT acceptability was high, the average participation in INT sessions was 19.4% (ranging from 0 to 95.6%). **CONCLUSION:** This pilot study demonstrated some preliminary support that offering a combined fitness program is feasible and can increase percent of time spent in MVPA during recess. Future research is warranted to determine if the INT can impact academic or cognitive outcomes. Supported by: University of Massachusetts Amherst Graduate School Dissertation Research Grant

The Associations between Maternal Body Mass Measures and Macronutrient Intake on Insulin Sensitivity Measures during Late Pregnancy
 Brittany R. Allman, Aline R. Andres, Eva C. Diaz Fuentes, Elisabet Borsheim. *Arkansas Children's Nutrition Center, Little Rock, AR.*
 Email: ballman@uams.edu
 (No relevant relationships reported)

PURPOSE: To determine associations between maternal body mass measures (body mass index [BMI], gestational weight gain [GWG]) and macronutrient intake (protein, carbohydrate [CHO], fat) on insulin sensitivity (IS) and fasting glucose (GLU) in late pregnancy in normal weight (NW, n = 87), overweight (OW, n = 67) and obese (OB, n = 31) women. **METHODS:** Participants were recruited early in pregnancy (<10 wk). A 100-gram oral glucose tolerance test (OGTT) was done following an overnight fast at 30 wks to calculate the metabolic clearance rate of glucose (MCR, mg·kg⁻¹·min⁻¹). Dietary intake of animal (AP) and plant (PP) protein (g·kg⁻¹·d⁻¹), fat (g) and CHO (g) were estimated using 3-d food records. Correlations between GLU and MCR with AP, PP, fiber, fat, CHO, GWG, and early pregnancy BMI were assessed using Pearson correlations. Multiple linear regression was used to model MCR and GLU with the independent variables. Data are mean ± SD. **RESULTS:** MCR (NW: 10.1 ± 0.8; OW: 8.3 ± 1.1; OB: 6.7 ± 1.0 mg·kg⁻¹·min⁻¹, *p* < 0.0001) and PP (NW: 0.39 ± 0.12; OW: 0.32 ± 0.09; OB: 0.27 ± 0.09 mg·kg⁻¹·min⁻¹, *p* < 0.0001) differed between groups. Fasting GLU was higher in OW compared to NW (NW: 79 ± 6; OW: 83 ± 7 mg/dL, *p* = 0.008), and AP was lower in OB compared to NW groups (NW: 0.67 ± 0.25; OB: 0.52 ± 0.18 g, *p* = 0.004). CHO intake was higher in NW vs. OB (*p* < 0.05). MCR correlated with AP (*r* = 0.21, *p* = 0.047) and BMI (*r* = -0.62, *p* < 0.0001) in NW, and with fat (*r* = -0.39, *p* = 0.001) and BMI (*r* = -0.58, *p*

< 0.0001) in OW. GLU correlated with BMI (*r* = 0.37, *p* = 0.001) in NW, with fat (*r* = 0.29, *p* = 0.025) and BMI (*r* = 0.31, *p* = 0.016) in OW, and with PP (*r* = -0.41, *p* = 0.035) in OB. Most parsimonious models: In OW, fat (β = -0.02, *p* < 0.001) and BMI (β = -0.41, *p* < 0.0001) were associated with MCR; and PP (β = -30, *p* = 0.008) and fat (β = 0.14, *p* = 0.002) associated with GLU. In OB, PP (β = 5.8, *p* = 0.011) and fat (β = -0.02, *p* = 0.005) were independently associated with MCR; and PP (β = -44.6, *p* = 0.003) and CHO (β = 0.03, *p* = 0.043) associated with GLU. **CONCLUSIONS:** Higher fat intake and BMI, and low PP intake in OW pregnant women is associated with lower IS. Higher fat and CHO intake, and low PP intake in OB pregnant women is associated with decreased IS. Thus, to improve insulin regulation and glucose metabolism, OW and OB pregnant women may benefit from increasing PP intake and ensure optimal macronutrient intake.

Maternal Exercise and DHA Levels During Pregnancy Influences Infant Body Composition
 Cody J. Strom, Christy Isler, Kelley Haven, Ed Newton, Kimberly Kew, Blake R. Rushing, Samantha McDonald, Linda E. May. *East Carolina University, GREENVILLE, NC.*
 Email: stromc17@students.ecu.edu
 (No relevant relationships reported)

Nearly 14% of U.S. children aged 2-5 years are obese. Evidence indicates that obesity develops *in utero* and is affected by several maternal factors. Maternal exercise is shown to reduce the risk of delivering high-birthweight infants. However, previous studies restricted their exercise exposure to aerobic training; thus, the effects of other common exercise modes on infant body composition are unknown. Maternal diet, specifically DHA levels, is also suspected to affect infant size. Maternal DHA is shown to improve infant birth weight and decrease fat mass. However, it is unclear as to whether this association is affected among exercising mothers. **PURPOSE:** To determine the relationships between different maternal exercise modes and maternal plasma levels of DHA on infant body composition. **METHODS:** Thirty-six healthy, low-risk, women with a singleton pregnancy (<16 weeks) were randomized to one of four intervention groups: aerobic (n=13), resistance (n=4), circuit (n=6)(aerobic + resistance) or non-exercising control (n=13) group. Participants exercised 3x/week for 50 minutes at moderate intensity for ~20 weeks. Maternal plasma was collected at 16 and 36 weeks of gestation and analyzed for DHA levels using liquid chromatography/mass spectrometry. At one month of age, infant body composition was assessed via skinfold technique. ANCOVA models were performed to determine independent associations between maternal exercise mode, maternal DHA levels, and infant percent body fat (%BF). **RESULTS:** Infants born to aerobic- or circuit-trained mothers had significantly lower %BF compared to infants born to resistance-trained mothers (*p*=0.045, *p*=0.048), respectively. After controlling for infant sex, 16-week maternal DHA levels, and fasted state, maternal exercise exhibited no effect on infant %BF (*F*, 0.57; *p*=0.6865). Maternal DHA levels at 16 weeks (*F*, 1.30; *p*=0.2887), 36 weeks (*F*, 1.13; *p*=0.3742) or across pregnancy (~20 weeks) (*F*, 1.27; *p*=0.3026) did not associate with infant %BF, after controlling for maternal exercise mode, sex, and fasted state. **CONCLUSION:** The current data supports the relationship between maternal exercise modes with aerobic activity on infant body composition. The data suggests that exercise mode may be a more important modulator of infant body composition than maternal DHA levels.

The Effects of Exercise Mode During Pregnancy on Maternal Metabolism
 Samantha Michelle McDonald, Christy Isler, Kelly Haven, Edward Newton, Linda E. May, Cody Strom. *East Carolina University, Greenville, NC.*
 Email: mcdonaldsa18@ecu.edu
 (No relevant relationships reported)

Maternal metabolism is the strongest predictor of fetal growth and development; thus, it is imperative that women maintain a healthy pregnancy to ensure optimal health of their offspring. Evidence demonstrates that chronic exercise training exhibits potent metabolic effects (e.g., insulin sensitivity), indicating a healthier metabolic profile. In healthy pregnancies, however, the effects of prenatal exercise and various modes of exercise on maternal metabolism are unclear. **PURPOSE:** To determine the effects of exercise mode on maternal metabolism during pregnancy, in a sample of healthy women with singleton pregnancies. **METHODS:** At 16 weeks gestation, healthy pregnant women were randomized to one of four intervention groups: aerobic (AT), resistance (RT), circuit (CT) and non-exercising control (CON). Supervised exercise sessions consisted of 50 minutes of moderate-intensity (40-59% VO_{2peak}) exercise, three times per week. Fasting blood samples were collected via venipuncture and fingerstick at 16 and 36 weeks gestation to assess maternal glucose and lipid profiles. ANOVA models were performed to determine the effects of exercise mode on maternal glucose, total cholesterol (TC), triglycerides

(TG), high-density lipoprotein (HDL), low-density lipoprotein (LDL) and lactate (LT) at 36 weeks and the change from the 2nd to 3rd trimester. **RESULTS:** Seventeen pregnant women had complete metabolic data. Prenatal exercise exhibited no effect on glucose or lipid profiles at 36 weeks (glucose: p=0.48; TC: p=0.29; TG: p=0.48; HDL: p=0.25; LDL: p=0.79; LT: p=0.96) or their change between the 2nd and 3rd trimesters (glucose: p=0.45; TC: p=0.87; TG: p=0.31; HDL: p=0.65; LDL: p=0.81; LT: p=0.37). Similarly, no effects were found for exercise modes at 36 weeks (glucose: p=0.76; TC: p=0.41; TG: p=0.24; LDL: p=0.49; LT: p=0.69) or across pregnancy (glucose: p=0.83; TC: p=0.40; TG: p=0.32; LDL: p=0.61; LT: p=0.70), with the exception of HDL at 36 weeks. CT mothers exhibited lower HDL levels compared to controls (p=0.04). **CONCLUSIONS:** In healthy pregnancies, prenatal exercise and various modes of exercise do not appear to positively nor negatively affect maternal metabolism. Further research should include larger samples and more rigorous assessments of glucose and lipid metabolism (e.g., HbA_{1c}, HOMA-IR, CRP).

3107 Board #153 May 31 2:00 PM - 3:30 PM
Effects of Evidence-Based Materials and Local Resources on Knowledge/Beliefs and Physical Activity Levels During Pregnancy

Rachel A. Tinius¹, Kolbi Edens¹, Bailey Pitts¹, Kristin Yoho¹, Jill M. Maples², T. Scott Lyons, FACS¹, Kim Link¹, M. Susan Jones¹, Kevin J. Pearson³. ¹Western Kentucky University, Bowling Green, KY. ²University of Tennessee, Knoxville, TN. ³University of Kentucky, Lexington, KY. (Sponsor: T. Scott Lyons, FACS¹)
 Email: rachel.tinius@wku.edu
 (No relevant relationships reported)

PURPOSE: Physical activity (PA) during pregnancy is safe and effective for improving maternal and infant health; however, only 23% of pregnant women exercise in accordance with guidelines, and this number is likely even lower in rural Kentucky. The purpose of this study is to determine the impact of evidence-based educational materials and access to local resources on PA levels and knowledge/beliefs about PA during pregnancy. **METHODS:** Women were recruited from a rural obstetric clinic (8-12 weeks gestation). PA levels were assessed using a fitness tracker and the Pregnancy Physical Activity Questionnaire. Knowledge/beliefs about PA during pregnancy were assessed via surveys. Stage of readiness to exercise was assessed using the transtheoretical model. Participants were randomly assigned to an intervention (IG) or control group (CG). The IG received evidence-based educational information regarding PA during pregnancy and free access to six local fitness facilities. All baseline assessments were repeated during late pregnancy (32-39 weeks). To assess obstetric outcomes, a survey was emailed to each participant after delivery. **RESULTS:** 63 women enrolled in the study (age=29.7±4.9 years, pre-pregnancy BMI= 26.2±6.3 kg/m², household income=\$78,589, average step count in 1st trimester=7,108 steps), and 45 have completed the study (follow-ups are ongoing). There were no differences in baseline variables between groups. In the IG, 13 women utilized PA services (prenatal yoga: 8, gym: 2, both: 3). There was no difference between groups in PA (assessed via change in step counts from early to late pregnancy) (p=.81). However, there was a trend for the IG to accumulate less sedentary time compared to the CG during late pregnancy(p=0.12). There were no differences in knowledge (p=0.8) or beliefs (p=0.3) regarding PA during pregnancy between groups. The IG was at a later stage of the transtheoretical model than women in the CG during late pregnancy (p=0.04). **CONCLUSION:** The intervention was unsuccessful at significantly increasing PA levels and knowledge/beliefs. Yoga was the most commonly utilized activity among IG women, and while beneficial, is unlikely to alter step counts. Future interventions need more than educational materials and access to resources in order to have a substantial impact on PA-related outcomes.

Strategies And Challenges In Recruiting Overweight/ Obese Pregnant Women For A Behavioral Lifestyle Intervention Program

Lara Schneider, Jihong Liu, Ellen Wingard, Sara Wilcox, Judith Burgis, Alicia Dahl. University of South Carolina, Columbia, SC.
 (No relevant relationships reported)

Pregnancy may serve as a unique window for lifestyle behavioral change because of increased concern for health and well-being in expectant mothers. **PURPOSE:** To report the recruitment efforts and results undertaken in a behavioral lifestyle intervention administered during and after pregnancy. **METHODS:** The Health in Pregnancy and Postpartum (HIPP) Study is an ongoing randomized controlled trial that targets excessive weight gain during pregnancy and promotes weight loss after delivery. The target population includes overweight or obese women who are pregnant ≤ 16 weeks, white or African American, aged 18-44 years, and do not have exercise contraindications. Women are recruited through OB/GYN clinics in metropolitan Columbia, SC. Interested women who meet the initial inclusion criteria (i.e., age, race,

gestational age, and pre-pregnancy BMI) are screened by phone for medical exclusions or other study exclusions. A script based on principles of motivational interviewing is used to ensure women consider pros and cons of each study condition, and if still interested in participating, they are scheduled for baseline visit. **RESULTS:** Of the 1,547 women initially eligible and interested, only 822 (53.1%) could be reached by phone for further screening and 161 (19.6%) were found ineligible. Of the 661 eligible women screened by phone, 387 (58.5%) scheduled baseline measurements. Top reasons women were ineligible include: incompetent cervix (3.3%), insulin-dependent diabetes (3.0%), and doctor contraindicated exercise during pregnancy (2.7%). After accounting for cancelled or no show (n=126) and in progress (n=4) appointments, 257 (66.2%) women have completed the in-person portion of baseline measurements, resulting in the overall recruitment yield of 16.6% (257/1547). Women who cancelled or did not show up at baseline visits were less likely to have their own cell phone (p=0.02) or a smart phone (p<.004), receive <20 texts/day (p<.0001), have access to a computer (p=.007), or have ever downloaded a podcast (p=.0008); women were more likely to miss or cancel appointments in April, July, and December (p<.0001). **CONCLUSION:** Recruitment of women in early pregnancy for a behavioral lifestyle intervention appears challenging, particularly among women with limited phone access.

Evidence-based Educational Brochures Influenced Beliefs And Improved Knowledge Regarding The Benefits Of Exercise During Pregnancy

Mark A. Schafer¹, Madison Alvis¹, Cody Morris², Tiana Garrard¹, Abigail Hughes¹, Laura Hunt¹, Megan Koester¹, India Yocum¹, Rachel Tinius¹. ¹Western Kentucky University, Bowling Green, KY. ²The University of Alabama at Birmingham, Birmingham, AL, AL. (Sponsor: Scott Lyons, FACS¹)
 Email: mark.schafer@wku.edu
 (No relevant relationships reported)

Purpose: Women who are pregnant report receiving little or no advice about physical activity during pregnancy from their provider. The purpose of this study was to assess the effectiveness of an evidence-based educational brochure on both immediate and two-week retention of knowledge about exercise during pregnancy. **Methods:** Thirty-two women of childbearing age (age: 25.0 ± 4.0 years, body mass index: 29.5 ± 6.5 kg/m²) completed a survey before exposure to an evidence-based educational brochure regarding exercise during pregnancy. Post surveys were taken immediately after viewing the educational brochure and again 2-weeks later. **Results:** After exposure to educational brochures, survey scores on both surveys were significantly higher immediately-post and two-weeks post compared to baseline survey scores [Survey 1 (assessing beliefs) – pre: 79.2±8.9%, post: 92.6±7.4%, 2-weeks post:92.0±6.5%, p < 0.001; Survey 2 (assessing knowledge) – pre: 65.3±16.4%, post: 81.3±14.9%, 2-weeks post:78.8±12.4%, p < 0.001]]. No significant differences detected between immediate post and 2-weeks post for either Survey 1 (p = 0.72) or Survey 2 (p = 0.52); suggesting the information was retained. **Conclusion:** An evidence-based educational brochure is effective for improving and retaining information regarding exercise during pregnancy. Health care providers should consider providing patients with this information in order to improve knowledge and patient-provider communication on this topic.

Maternal Water Exercise And Its Effects On Weight Gain And Fetal Outcomes: A Meta-analysis

Roberta Bgeginski, Taniya S. Nagpal, Michelle F. Mottola, FACS¹. The University of Western Ontario, London, ON, Canada. (Sponsor: Michelle F. Mottola, FACS¹)
 Email: robertabg@gmail.com
 (No relevant relationships reported)

Physical activity during pregnancy is known to bring benefits not only for the mother but also for the fetus. Water-based exercises have been recommended as an adequate modality of exercise during pregnancy, however, no meta-analysis has analyzed the effects of water exercise programs on maternal weight gain and fetal outcomes including birthweight. **PURPOSE:** To conduct a systematic review and meta-analysis of randomized controlled trials to investigate the effects of prenatal water-based exercise on maternal weight gain and fetal outcomes. **METHODS:** Eligible trials were identified by a structured search of MEDLINE, EMBASE, ISI Web of Science, Scopus, and SportDiscus up to October 2018. Data were retrieved comparing standard care with standard care plus prenatal water exercise (at least once a week) for at least one of the following outcomes: maternal weight gain, gestational age at delivery, and/or fetal birthweight. Study selection and data extraction were performed by two independent reviewers. Random-effects meta-analysis was conducted for mean difference between exercise and control groups (PROSPERO registration: CRD42016039473). **RESULTS:** Our search yielded 1846 publications of which 1562 were assessed for eligibility. In total, 9 studies were eligible and included in the meta-analysis. Pregnant

women who engaged in a water exercise program showed a significant difference in total maternal weight gain (5 RCTs, n=561, OR -1.00 [95% CI -1.55, -0.45], p<0.001) compared to standard care only. No significant effects on gestational age at delivery (8 RCTs, n=1442, OR 0.04 [95% CI -1.02, 1.10], p=0.94) and birthweight (8 RCTs, n=1427, OR -24.32 [95% CI -86.44, 37.80]) were found. **CONCLUSION:** Water exercise during pregnancy controls maternal weight gain without influencing the duration of pregnancy or baby weight. Health care providers can consider suggesting water-based exercises during pregnancy to promote appropriate weight gain.

Ripple Effect Of Lifestyle Interventions During Pregnancy On Untreated Partners' Weight

Todd Hagobian, FACSM¹, Suzanne Phelan¹, Andrew Schaffner¹, Anna Brannen¹, Angelica McHugh², Maxine Ashby-Thompson³, Amy Gorin⁴, Xavier Pi-Sunyer³, Dymna Gallagher³, Rena Wing⁵. ¹California Polytechnic State University, San Luis Obispo, CA. ²Brown Medical School, The Miriam Hospital, Providence, RI. ³Columbia University College of Physicians and Surgeons, New York, NY. ⁴University of Connecticut, Storrs, CT. ⁵Brown Medical School, The Miriam Hospital, Providence, RI. Email: thagobia@calpoly.edu

(No relevant relationships reported)

Weight loss interventions have a positive "ripple effect" on untreated partners, but ripple effects in pregnancy are unknown. **PURPOSE:** To determine whether prenatal lifestyle interventions that reduced gestational weight gain in pregnant women had a positive "ripple" effect on untreated partner weight. **METHODS:** To determine whether prenatal lifestyle interventions that reduced gestational weight gain in pregnant women had a positive "ripple" effect on untreated partner weight. **RESULTS:** 122 partners (100% male, 23% Hispanic, 82% married, 48% obese) were randomized to intervention (N=59) or usual care (N=63). There was no intervention or intervention by time interaction effect on partner weight (P = 0.7953). Partner weight trended higher, but weight changes were not statistically significant (P = 0.1204) from study-entry to 35 weeks' gestation (Mean 0.19 kg; 95% CI -0.73 to 1.24) or to 12 months postpartum (Mean 0.82 kg; 95% CI: -0.84 to 1.12 kg). **CONCLUSIONS:** There was no evidence of a ripple effect on partner weight. Partner weight gain was 0.82 kg from pregnancy to 12-months postpartum. Partners of pregnant women appear not to experience sympathy weight gain. Supported by National Institutes of Health Award Number R01HL118208.

The Effectiveness of Tai Chi For Rehabilitation Of Post-stroke Patients: A Meta-analysis

Jiao Lu, Lin Liu, Ya Wei Song, Yan Chen, Juan Wei. Nanjing Sport Institute, Nanjing, China. Email: lj_sus@163.com

(No relevant relationships reported)

Stroke has been a growing public health concern that affects 33 million patients each year worldwide. Most seriously, stroke's prevalence rate increases each year worldwide. In recent years, tai chi is becoming an increasingly popular means of improving balance function and gait in patients with stroke. However, the clinical effects of tai chi beyond conventional physical therapy remain controversies. **Purpose:** To systematically evaluate the effectiveness of tai chi for rehabilitation of post-stroke patients. **Methods:** Randomized controlled trials (RCTs) examining the effects of a tai chi training during 4 to 12 weeks for patients with stroke were included by searching 11 electronic databases until September 2018. Two reviewers independently extracted data and scored methodological quality by using the Physiotherapy Evidence Database scale. **Results:** 18 RCTs involving 1080 patients were identified for meta-analysis. Meta-analyses were performed using RevMan 5.3 and Stata 12.0. **Results:** Our work showed that tai chi was superior to usual rehabilitation for balance function (standard mean difference [SMD], 1.90; 95% confidence interval [CI], 1.14 to 2.66; P < 0.00001), gait speed (mean difference [MD], 0.25 m/s; 95% CI, 0.05 to 0.45; P = 0.01), Fugl-Meyer assessment (SMD, 1.22; 95% CI, 0.15 to 2.30; P = 0.03) and ADL (SMD, 2.21; 95% CI, 0.57 to 3.85; P = 0.008). **Conclusion:** Based on the current evidence and heterogeneity among studies, tai chi

with duration of 4 to 12 weeks can be cautiously recommended to effectively enhance the balance function, gait speed, motor ability of lower extremities, and activities of daily life of post-stroke patients.

3113 Board #159 May 31 2:00 PM - 3:30 PM

Exercise Effects On Cognitive Function And Adls In Alzheimer'S Disease: A Meta-analysis

Alex Angeli, Catherine G. R. Jackson, FACSM, Dawn K. Lewis, Stephanie D. Moore. California State University, Fresno, CA. (Sponsor: Catherine G. R. Jackson, FACSM) Email: alex.angeli@outlook.com

(No relevant relationships reported)

BACKGROUND: Alzheimer's Disease (AD) is the worldwide leading cause of senile dementia and affects approximately 5.3 million Americans. It is a healthcare issue which is accelerating at a rapid pace. While categorized as a disorder which cannot be cured or slowed, a convincing body of evidence has revealed protective effects of physical activity in mitigating symptoms and delaying progression of the disease.

PURPOSE: To investigate the effects of physical activity interventions on cognitive function and Activities of Daily Living (ADLs) in patients with AD. Based on these results, the design of exercise programs for individuals affected by AD are suggested. **METHODS:** A Meta-Analysis was performed to analyze the effectiveness of different exercise modalities in ameliorating cognitive and functional symptoms of AD. Seven specific inclusion criteria were developed to include studies which contained exercise programs designed to improve or maintain aerobic fitness, strength, ADL performance or any combination of thereof.

RESULTS: Fourteen studies, which included 769 patients diagnosed with AD who were 65 years of age or older met the inclusion criteria for the analysis. Calculations for Effect Size (ES) and Confidence Interval (CI) showed that exercise interventions had a moderate positive effect on cognitive function (ES=0.52; CI=0.15-0.89; p<0.001), and a large positive effect on performance of ADLs (ES=0.76; CI=0.19-1.33; p<0.001). Furthermore, interventions that included an aerobic component (Aerobic Training and Multimodal Training) positively influenced cognitive function, while interventions that included resistance and functional training (Resistance Training and Multimodal Training) improved performance in ADLs.

CONCLUSION: While a large variability was found in study design, intervention, duration, and assessment measures, exercise was usually shown to have positive effects on measures of decline in AD. Exercise programs should be incorporated in the management of AD patients. The choice of exercise modality should include both aerobic and strength/functional components to achieve maximum benefit in cognitive function and ADLs performance. Multimodal Training, which includes activities across the metabolic spectrum, shows the greatest promise as an exercise intervention in AD.

3114 Board #160 May 31 2:00 PM - 3:30 PM

Insulin Resistance Adaptations To High-Intensity Interval Versus Moderate-Continuous Training In Health And Disease: A Meta-Analysis

Felipe Mattioni Maturana, Peter Martus, Andreas M. Niess. University Hospital of Tuebingen, Tuebingen, Germany. Email: felipe.mattioni@med.uni-tuebingen.de

(No relevant relationships reported)

Besides the well-known physical fitness benefits of high-intensity interval training (HIIT) over moderate-intensity continuous training (MICT), the effect on other cardiometabolic risk factors, such as insulin resistance, is not yet well defined. **PURPOSE:** to investigate the overall effects of HIIT and MICT on insulin resistance as well as subgroups analyses in i) population: healthy (H), overweight/obese (O), metabolic syndrome (MetS), type-2 diabetes (T2D); ii) age: < 30 y, 30-50 y, > 50 y; iii) training duration: < 5 wk, 5-10 wk, > 10 wk; iv) men ratio: < 0.4, 0.4-0.6, > 0.6; and v) type of exercise: cycling vs running. **METHODS:** randomized controlled trials were identified through a systematic search in PubMed. After the selection, 17 studies were included. Small-study effects were analyzed through contour-enhanced funnel plots and the Egger's test. The standardized mean difference (Cohen's d) was the outcome used, it was calculated with the random-effects model, applying the DerSimonian-Laird estimator for the between-study variance (τ^2). Effect sizes (ES) were classified as trivial (d < 0.2), small (d = 0.2 - 0.5), medium (d = 0.5 - 0.8), and large (d > 0.8). A sensitivity analysis was performed using the leave-one-out cross-validation method. Positive and negative ES represent a favorable effect for HIIT and MICT, respectively. **RESULTS:** the overall effect presented a medium ES (d = 0.53, p = 0.035), with a τ^2 = 0.85 and significant small-study effect (p = 0.01). The population subgroup had a large ES for O (d = 1.77, p = 0.02), trivial ES for H (p = 0.8), and MetS (p = 0.7), and small ES for T2D (p = 0.6). The age subgroup had a large ES for 30-50y (d = 0.87, p = 0.09), and trivial ES for < 30 y (p = 0.5) and > 50 y (p = 0.5). The training duration subgroup had a large ES for < 5 wk (d = 0.97, p = 0.055), trivial ES for 5-10 wk (p = 0.6), and small ES for > 10 wk (p = 0.6). The men ratio subgroup had a large ES for > 0.6 (d = 1.43, p = 0.03), and trivial ES for < 0.4 (p = 0.9) and 0.4-0.6 (p = 0.8). The type of exercise subgroup had a large ES for cycling (d = 0.83, p = 0.02) and trivial

ES for running ($p = 0.5$). **CONCLUSIONS:** despite a medium overall ES, the effects of HIIT and MICT on insulin resistance vary considerably. HIIT may be superior to MICT in improving cardiometabolic health in an overweight/obese population, men, and cycling exercise.

3115 Board #161 May 31 2:00 PM - 3:30 PM
An Alternative Model For A Meta-analysis On Exercise And Blood Pressure In Older Adults

George A. Kelley, FACSM, Kristi Sharpe Kelley. *West Virginia University, Morgantown, WV.*
Email: gkelley@hsc.wvu.edu
(No relevant relationships reported)

PURPOSE: Using a traditional random-effects model, a recent meta-analysis by Herrod et al. (2018) reported statistically significant reductions in both resting systolic blood pressure (SBP) and diastolic blood pressure (DBP) as a result of aerobic, resistance, and combined aerobic and resistance exercise in adults with a mean age of 65 years and older. However, a recently proposed and alternative method, the inverse heterogeneity model (IVhet), has been shown to provide more robust findings. The purpose of this study was to apply the IVhet model to these previous meta-analytic findings. **METHODS:** Data from 41 randomized controlled trials representing 96 groups (52 exercise, 44 control) were pooled using the IVhet model. In addition, absolute and relative differences between the IVhet and random-effects model were calculated. Data were reported using the mean difference (exercise minus control) with non-overlapping 95% confidence intervals considered statistically significant. **RESULTS:** Using the IVhet model, statistically significant reductions in resting blood pressure were found as a result of aerobic exercise (SBP, -4.7 mmHg, 95% CI, -7.7 to -1.8; DBP, -2.0 mmHg, 95% CI -3.13 to -0.89), SBP but not DBP for resistance training (SBP, -7.0 mmHg, 95% CI, -10.5 to -3.4; DBP, -1.2 mmHg, 95% CI -2.7 to 0.31), and both SBP and DBP for combined aerobic and resistance training (SBP, -5.5 mmHg, 95% CI, -8.3 to -2.7; DBP, -3.7 mmHg, 95% CI -4.8 to -2.7). When compared to the random-effects model, findings from four of the six mean differences in blood pressure were smaller, ranging from -0.82 to -0.19 mmHg (6.1% to 41.0%) while all six 95% CI were wider, ranging from 0.24 to 1.56 mmHg (11.5% to 36.8%). **CONCLUSIONS:** These findings suggest that with the exception of changes in DBP as a result of resistance training, exercise (aerobic, resistance, combined aerobic and resistance) reduces resting SBP and DBP in older adults. Importantly, these findings are generally smaller than those previously reported, a factor that could have practical implications. Future studies should consider using the IVhet model when conducting an aggregate data meta-analysis.

The Effect Of Qigong On Chronic Obstructive Pulmonary Disease: A Systematic Review And Meta-analysis

Ming Yang¹, Yunsai Chen¹, Xiaolei Liu², Jindong Chang³.
¹Southwest University, Chongqing, China. ²High School Affiliated to Southwest University, Chongqing, China. ³The Branch of the Collaborative Innovation Center of Assessment toward Basic Education Quality at Southwest University, Chongqing, China.
Email: yangm_svu@163.com
(No relevant relationships reported)

PURPOSE: This review aims to investigate the effect Qigong on chronic obstructive pulmonary disease (COPD).

METHODS: All randomized controlled clinical trials published in English or Chinese and involving the use of Qigong by patients with COPD were searched in PubMed/MEDLINE, Cochrane Library, Embase, PsycINFO, Cambase databases, CNKI, and WanFang databases from their respective inception to June 2018. The meta-analysis was conducted using the Revman 5.3. The quality of the included trials was assessed using the Jadad rating scale. Two researchers independently completed the inclusion, data extraction, and quality assessment.

RESULTS: Fourteen RCTs with 1274 COPD patients met the inclusion criteria. The meta-analysis revealed that the FEV1, FEV1%, FEV1/FVC% and 6MWD was significantly enhanced in the experimental group (FEV1 mean difference [MD] = 0.29, 95%CI: 0.09 to 0.48; FEV1% MD=6.09, 95% CI: 3.15 to 9.04; FEV1/FVC% MD=4.20, 95% CI: 1.88 to 6.51; 6 months: MD=57.52, 95% CI: 17.48 to 97.57) than the control group. There was no significant difference in FVC between the experimental group and the control group ($P > 0.05$).

CONCLUSION: Qigong exercise can improve the lung function and exercise ability of COPD patients. However, future research with better quality RCTs needs to explain the mechanism of the positive effect of Qigong on COPD. (This study was supported by Fundamental Research Funds for the Central Universities at SWU Grant 1709240.)

Evidence for Kinesio Taping in Management of Myofascial Pain Syndrome: A Systematic Review and Meta-analysis

Lin Liu¹, Jiao Lu¹, Yan Chen¹, Juan Wei¹, Xue-Feng Zhang², Bin-Bin Wang². ¹Nanjing Sport Institute, Nanjing, China. ²Dongguan Shilong People's Hospital Affiliated Southern Medical University, Dongguan, China.
Email: liulin1989@126.com
(No relevant relationships reported)

Myofascial pain syndrome (MPS) is one of the most common neuromuscular system diseases and is also easily misunderstood in pain clinic. And kinesio taping has been gradually used by physiotherapists or pain clinicians in the pain clinic as a clinical support treatment for MPS. However, no evidence-based medical data is available to support the advantageous effect of kinesio taping on MPS over other treatments at post-intervention and follow-up. **PURPOSE:** To evaluate the effectiveness of kinesio taping for managing MPS in terms of pain intensity, pressure pain threshold, range of motion (ROM), muscle strength and disability. **METHODS:** PubMed, EBSCO, ScienceDirect, Web of Science, Cochrane Library and Physiotherapy Evidence Databases were searched from database inception to January 2018. Randomised controlled trials (RCTs) that used kinesio taping as the main treatment protocol for participants diagnosed with MPS were included. Two reviewers independently screened articles, scored methodological quality by using Cochrane risk-of-bias tool and extracted data. The primary outcomes were pain intensity, pressure pain threshold and ROM at post-intervention and follow-up. The secondary outcomes were muscle strength and disability at post-intervention and follow-up. **RESULTS:** Meta-analyses of 15 RCTs involving 713 patients, showed that kinesio taping was more effective than other treatments in improving pain intensity (mean difference [MD] = 0.94 cm, 95% confidence interval [CI]: -1.55 cm to -0.32 cm, $p=0.003$) and ROM (standardised mean difference [SMD] = 0.32, 95% CI: 0.12 to 0.52, $p=0.002$) at post-intervention. Kinesio taping was also superior to other non-invasive techniques in relieving pain intensity at follow-up (MD = -0.68 cm, 95% CI: -1.22 cm to -0.13 cm, $p=0.02$). **CONCLUSION:** The latest evidence statistically supports the use of kinesio taping over other treatments for relieving the pain intensity and range of motion of patients with myofascial pain syndrome at post-intervention. Kinesio taping is also statistically superior to other non-invasive techniques in relieving pain intensity at follow-up. However, no significant superiority of kinesio taping was found in pressure pain threshold, muscle strength and disability.

Sprint Interval Training or High-intensity Interval Training to Improve VO_{2max} In Sedentary Individuals? A Meta-analysis.

Stephanie P. Waletzko, Donna J. Terbizan, FACSM. *North Dakota State University, Fargo, ND.* (Sponsor: Donna J. Terbizan, FACSM)
Email: stephanie.waletzko@ndsu.edu
(No relevant relationships reported)

PURPOSE: To evaluate improvements in VO_{2max} in sedentary adults aged 18-55 comparing sprint interval training (SIT) vs high intensity interval training (HIIT) vs continuous cardiovascular training (CCVT).

METHODS: A systematic literature search (key terms: HIIT, endurance, interval training, SIT, and VO2) was conducted of electronic databases (PubMed, Scopus, Sport Discus, Science Direct, Web of Science, Google Scholar) to ascertain appropriate studies. The inclusion properties for the studies were: sedentary individuals between the ages of 18-55 free of comorbidities other than being overweight or obese; included a continuous training group; completed a pre and post VO_{2max} graded exercise test. These search criteria yielded 20 studies evaluating HIIT protocols totaling 527 subjects in the interval group and 214 subjects in the CCVT group. There were nine studies studying a SIT protocol with 111 total subjects in the interval group and 85 subjects in the CCVT group.

RESULTS: Statistics and effect sizes were calculated using G*Power software (Heinrich-Heine-Universität Düsseldorf) with a post-hoc two-tailed designed t-test with α error at .05. Training, regardless of type, increased VO_{2max} . HIIT increased VO_{2max} by 11.421%, whereas SIT increased it by 10.353%, followed by CCVT with an increase of 7.361%. Cohen's d provided effect sizes comparing HIIT, SIT, and CCVT training groups. Both HIIT and SIT had large Cohen's d effect sizes at 1.053 and 0.764, respectively, compared to a moderate effect size of 0.506 for the CCVT group. **CONCLUSIONS:** Both HIIT and SIT are valid options for increasing the VO_{2max} of sedentary individuals with a relatively small commitment time needed. This could have implications for participant adherence to the protocol. Both HIIT and SIT had a significantly positive effect on the participant's VO_{2max} when compared to the CCVT group. However, CCVT also improved their VO_{2max} . Therefore, any sustained physical activity is beneficial for sedentary adults to improve VO_{2max} .

3119 Board #165 May 31 2:00 PM - 3:30 PM
Aerobic Exercise And Balance In Adults Over 50 Years: Meta-analysis Of Randomized Controlled Trials

Tyrone Loría Calderón. *Universidad de Costa Rica, San Ramón, Costa Rica.*

(No relevant relationships reported)

Various interventions have combined aerobic exercise with strength, power or balance training and the direct effect on balance in older adults. The specific effect of aerobic exercise on balance is unclear. **PURPOSE:** The purpose of this study was to analyze the effect of aerobic exercise on balance in older adults. **METHODS:** The systematic search was made on academic scientific bases: Academic Complete Search, ProQuest, PubMed, Science Direct and Sport Discuss, using the Boolean phrase: (aerobic exercise OR aerobic training) AND (adult* OR aging* OR senior* OR older adult*) AND (balanc*) NO (diet or nutrition) NO (Animal) And random*. The inclusion criteria were: publications in English or Spanish, full text, older adult (people and women), people over 50 years, experimental and quasi-experimental studies, treatment focused on aerobic exercise and dynamic or static balance indistinctly of the type of test. We analyzed 4496 studies and only 11 investigations met the inclusion criteria, obtaining 56 effect sizes (TE) in 590 subjects. The moderator variables were age, sex, level of physical activity, health condition, N per study, duration of the session and exercise modality. **RESULTS:** The overall effect size for the experimental conditions was $TE = 1.083$, ($p \leq 0.05$) (95% CI: 0.63 - 1.53, $Q = 679.07$, $p = 0.00$, $I^2 = 99.55$); the effect size of the control group was $TE = 0.056$, ($p = 0.685$) (95% CI: -0.14, .25, $Q = 11.48$, $p = 0.009$, $I^2 = 73.88$). There were no differences in differences between the control groups of TE ($n = 16$) and experimental group ($n = 40$) ($F = 2.73$, $p = .104$). The Cochran's Q test for the experimental group presents values that indicate that the calculated effect sizes have high heterogeneity according to Borenstein, et al. (2009). In addition, the Egger test was applied and this gave the following data $t = 4.55$, $gI = 54$, $p = 0.000$ *, accepting the alternative hypothesis indicating that there is asymmetry; procedure that detected a publication bias. **CONCLUSION:** Aerobic exercise (AE) exerts a positive effect on the balance of older adults; therefore, AE training is a valid strategy to counteract the loss of balance in older adults.

NCAA Division III Football Players Dietary Intake: In Season vs. Off Season

Elizabeth J. DeFrang¹, Wendy ES Repovich, FACSM², Janet T. Peterson, FACSM¹. ¹Linfield College, McMinnville, OR. ²Eastern Washington University, Cheney, WA. (Sponsor: Janet Peterson, FACSM)

(No relevant relationships reported)

Excess caloric intake leads to weight gain which contributes to an increase in health risks such as those associated with metabolic syndrome. **PURPOSE:** The purpose of this study was to examine the diet of division III football players in and off season and to identify the differences between skilled and unskilled players. **METHODS:** Twenty-two players [18.9 + 0.79 yr] completed in (F, Fall) and off season (S, Spring) testing. Data included height, weight, body composition and a 24 hour diet recall using the 5-pass method. Nutrition data were analyzed using Food Processor software. In and off season data were compared using a paired sample t-test. Repeated measures ANOVA was used to test for differences between skilled and unskilled players. This study was approved by the Linfield College Institutional Review Board. **RESULTS:** All players gained weight (F: 86.1 ± 13.1 kg; S: 92.0 ± 12.8 kg, $p = 0.033$) by spring. The weight gain was associated with an increase in percentage body fat (F: 13.8 ± 4.6 ; S: 16.3 ± 4.4 , $p = 0.028$). All players decreased total caloric intake in the spring (F: 5553 ± 1922 kcal; S: 3972 ± 1384 kcal, $p = 0.0008$). There were no differences in the macronutrient distribution (%kcal) at either time point (Fat: F: $37.3 \pm 5.9\%$; S: $37.3 \pm 9.1\%$; Carbohydrate F: $47.5 \pm 6.8\%$, S: $46 \pm 11.0\%$ Protein F: $15.2 \pm 3.8\%$; S: $16.87 \pm 4.5\%$). The player's relative protein intake (g/kg) was lower in the off season (F: 2.60 ± 1.36 ; S: 1.87 ± 0.97 ; $p = 0.036$). Sodium and cholesterol consumption decreased from F to S but remained above the daily recommended intake for all players. There were no differences in total calories, macronutrient composition, relative protein intake, sodium or cholesterol between the skilled and unskilled players. A majority of the players meals were consumed at the college dining hall. **CONCLUSION:** Body weight and percent body fat increased from F to S with an associated increased caloric intake during the season. The players consumed large amounts of calories with a high percentage of fat during the season. All players decreased caloric intake in the off season. The change in body weight and body composition may increase health

risks in the long run. It is important for players to make dietary choices to maximize performance and reduce long term health risks within the constraints of eating at the college dining hall.

Rapid Weight Loss Negatively Affects Body Composition and Serum Creatinine in Elite Judokas

Patrik Drid¹, Sasa Krstulovic², Marko Erceg², Tatjana Trivic¹, Marko DM Stojanovic¹, Sergej M. Ostojic¹. ¹University of Novi Sad, Novi Sad, Serbia. ²University of Split, Split, Croatia.

Email: patrikdrid@gmail.com
 (No relevant relationships reported)

The most frequently used rapid weight loss (RWL) methods in weight-sensitive sports were dehydration and decreased energy intake, with RWL accompanied by many adverse health effects. **PURPOSE:** To evaluate the effects of 7-day RWL intervention on body composition and biomarkers of creatine metabolism in eight elite judokas during a pre-competition period. **METHODS:** The participants voluntarily participated in this study. Strategy of weight loss included restriction of fluid and food intake, and started 7 days before competition. During the first six days, dietary changes included restricted intake of fluids and macronutrients (35% reduction in total caloric intake), followed by a total food restriction on the last day (a weigh-in day). **RESULTS:** RWL induced a significant drop in weight (81.7 ± 10.7 kg at baseline vs. 76.8 ± 10.3 kg at follow-up; $P < 0.001$), fat mass (12.6 ± 5.6 kg vs. 9.2 ± 4.0 kg; $P = 0.003$) and fat-free mass (69.1 ± 7.3 kg vs. 67.6 ± 7.7 kg; $P = 0.05$), accompanied by an increase in serum creatinine levels at follow up (104.0 ± 10.5 $\mu\text{mol/L}$ vs. 114.9 ± 10.2 $\mu\text{mol/L}$; $P = 0.009$). **CONCLUSIONS:** An acute restriction of food and fluid intake appears to negatively affect fat-free mass and indices of kidney function in judokas. Decreased tubular secretion of creatinine due to poor fluid intake (and excretion) might be a possible cause of elevated serum creatinine and a potential kidney stress after RWL, which requires further investigation. This project was partly supported by the Serbian Ministry of Education, Science and Technological Development (175037 and 179011), the Provincial Secretariat for Higher Education and Scientific Research (142-451-2473 and 114-451-710) and the Faculty of Sport and Physical Education, University of Novi Sad (2018 Annual Award).

Intentions Matter When it Comes to Body Composition Changes in DIII Athletes Over Summer Break

Justin Mehrer, Christopher Vangsnes, Jessica L. Kutz. Shenandoah University, Winchester, VA.
 Email: jmehrer14@su.edu

(No relevant relationships reported)

In Division III, coaches cannot require athletes to report summer workouts, but can suggest what should be done to be ready the upcoming season. Coaches also cannot cut an athlete based on knowledge of a lack of summer workouts. **PURPOSE:** To determine whether athlete intentions lead to efficacious outcomes in DIII athletes over summer break. It was hypothesized that due to lack of accountability, body composition intentions over summer break would not be achieved. **METHODS:** Fifty-one student athletes (32 women, 19 men; 20 ± 1 years old) had their body composition assessed in May in addition to their intention(s) regarding body composition changes over summer break (increase muscle mass and/or decrease fat mass or no change). Body composition was again assessed in August of the following school year. **RESULTS:** Only an intention to increase muscle mass or decrease body fat mass led to no significant change in either variable. When athletes had the combined intention of increasing muscle mass and decreasing fat mass, a significant decrease in body fat percentage was observed (-1.8 ± 2.3%; $p = 0.017$). Independently, the increase in muscle mass ($+1.33$ ± 2.3kg; $p = 0.063$) and decrease in fat mass (-1.1 ± 2.2kg; $p = 0.094$) were not significant. **CONCLUSIONS:** Thus, these data suggest in order to achieve a decrease in fat mass, that has a significant impact on percent body fat, this intention should be combined with the intention to increase muscle mass. Additionally, singular intentions did not evoke intended body composition changes.

3123 Board #169 May 31 2:00 PM - 3:30 PM
The Effect of Feedback on Pre-Game Hydration Status of Division II Collegiate Basketball Players.

Daniel Poel, Jason C. Dorman, Elizabeth H. Kasperek, Thayne A. Munce, FACSM. *Sanford Sports Science Institute, Sioux Falls, SD.* (Sponsor: Thayne Munce, FACSM)
 Email: daniel.poel@sanfordhealth.org
 (No relevant relationships reported)

Proper hydration is vital to peak athletic health and performance. Although hydration status is relatively simple to monitor, regular hydration testing is rarely implemented in sport regardless of competition level. Consequently, many athletes enter competition unaware of their hydration status, preventing opportunities to begin in an optimal state of readiness. **PURPOSE:** To evaluate the effect of hydration testing and simple feedback on pre-game hydration status of collegiate basketball players. **METHODS:** Twenty men's collegiate basketball players from a single NCAA Division II university participated in this study during the 2016-17 (N = 14) and 2017-18 (N = 12) seasons. In Season 1, players' urine specific gravity (USG) and body weight (BW) were assessed 1-2 hours prior to the start (PRE) of eight pairs of regular season conference games (16 games total) played on consecutive days (Fri & Sat). In Season 2 (10 games), players' USG was assessed 4-5 hours before game time, at which time they were provided feedback about their hydration status. USG was reassessed 1-2 hours prior to game time, along with BW. USG was measured using a hand-held clinical refractometer. Hydration status was defined as: hyperhydrated (HYP; USG < 1.005), euhydrated (EUH; 1.005 ≤ USG < 1.020), moderately hypohydrated (MOD; 1.020 ≤ USG < 1.025), and severely hypohydrated (SEV; USG ≥ 1.025). BW was measured using a digital scale, with players wearing similar clothing each time. **RESULTS:** PRE hydration status, based on proportional distribution, was significantly different between Season 1 and Season 2 (P < 0.001). In Season 1, 41.4% of players were EUH and 24.9% were MOD at PRE compared to 82.3% and 4.6% in Season 2, respectively. While 27.1% of players were SEV at PRE in Season 1, no players were SEV at PRE in Season 2. There was no change in PRE USG from Fri (1.018 ± 0.008) to Sat (1.019 ± 0.008) in Season 1 (P = 0.077), but PRE USG on Sat (1.010 ± 0.005) was significantly lower than on Fri (1.011 ± 0.006) in Season 2 (P = 0.015). **CONCLUSION:** The implementation of hydration testing and simple feedback significantly improved pre-game hydration status of collegiate basketball players compared to hydration testing alone. Athlete monitoring, when combined with proper feedback and education, can be used effectively to optimize athletic readiness.

Perceptions of Food Group Recommendations in Division II Athletes

Janet Kupperman, FACSM. *Rockhurst University, Kansas City, MO.*
 Email: janet.kupperman@rockhurst.edu
 (No relevant relationships reported)

PURPOSE: The purpose of the project was to conduct a needs assessment in order to make targeted nutrition education available to athletes at an NCAA Division II university. **METHODS:** 82 athletes (10 males, 72 females) completed a survey designed to explore eating patterns, to assess basic nutrition knowledge, and to determine nutrition topics about which participants wanted to receive nutrition information. Survey items included nutrition education preferences, gender, height, weight, activity level, nutrition knowledge questions, as well as how many servings of fruits, vegetables, grains, dairy and protein they typically consumed and how many servings they thought they needed. Guidelines for quantities and examples were provided. **RESULTS:** Hydration and protein were the topics most frequently requested (74% and 72% of those making requests). Daily caloric and food group needs were estimated using information from the 2015-2020 Dietary Guidelines based on age, gender, and activity level. Consumption patterns (C) and perceived needs (PN) were compared to recommendations (R). C < R for vegetables (81.7%), fruits (41.5%), protein (61%), grains (86.6%), and dairy (81.7%). PN < R for vegetables (29.3%), fruits (9.8%), protein (53.7%), grains (85.4%), and dairy (48.8%). PN < C for vegetables (6.1%), fruits (15.9%), protein (67.1%), grains (43.9%), and dairy (13.4%). **CONCLUSION:** Since athletes were aware that their consumption of vegetables was lower than recommended, they may be receptive to strategies for incorporating vegetables into their diets. Awareness of the need for information about protein was reflected by their requesting information on the topic and by the consistency of the percentage of athletes with protein C<R and PN<R. Apparently low consumption of and awareness of the need for carbohydrates such as grains may be affecting performance among these athletes. Dairy consumption was lower than the perceived need for dairy, suggesting the need for information in this area. Basic nutrition education relating to food groups is relevant for this group of NCAA Division II athletes.

3125 Board #171 May 31 2:00 PM - 3:30 PM
Food Servings Ingested Before And After An Intervention Program In A University Setting

Sergio Alejandro Copado-Aguila, Sayra Nataly Muñoz-Rodríguez, Juan R. Lopez-Taylor, Edna Elvira Jauregui-Ulloa, Marisol Villegas-Balcazar. *Universidad de Guadalajara, Guadalajara, Mexico.*
 (No relevant relationships reported)

PURPOSE: To compare the food servings ingested by food groups after a 12-week intervention program to promote physical activity in a university setting. **METHODS:** 66 (32 men, 34 women) subjects belonging to the university community (teachers, students, administrative staff) of three different University Centers of the University of Guadalajara were evaluated on their food habits. They were asked about their daily food intake employing a food frequency questionnaire by standardized staff during the interview process. Each subject described how many days per week he/she usually ate each food and the usual amount they consumed on those days. A daily average of food group servings was calculated. Servings' size were determined according to Mexican System for Equivalent Foods. The sample was divided into three groups: Device group (D, participants wore an accelerometer), Device plus counseling group (DC, participants wore an accelerometer and received a series of tips by a website to promote the physical activity and to change health-related behaviors), and Control group (CO, participants received no intervention). Comparisons were considered significant at a p-value < 0.05. **RESULTS:** Subjects' age, body weight, and stature were: 24 ± 7 y 21 ± 7 years, 69.9 ± 12.9 y 57.9 ± 13.0 kg; y 172.1 ± 8.4 y 160.1 ± 8.4 cm, for men and women, respectively. Cereals was the food group most consumed and Legumes the less one for all groups. Considering the average, the intake of Fats increased for all groups. However, Seeds group decreased significantly in the D and CO groups only. No other significant difference was observed. **CONCLUSIONS:** The addition of non-contact counseling was associated with no change in Seeds group in comparison with the other groups. Maybe this kind of intervention might not be effective to modify food intake in this population.

Table. Food servings ingested by Food Group in the studied Groups (n=66)

| | Device (n = 25) | | Device plus counseling (n = 25) | | Control (n = 16) | |

Collegiate Athletes That Consumed Adequate Energy Post-concussion Reported Fewer Days Of Concussion-related Symptoms

Matthew Frakes, Melinda W. Valliant, Marshall Crowther, John Michel, Kate Callaway, Becca Morgan, Corbit Franks, Andrew Beyke. *The University of Mississippi, University, MS.*
 Email: mrfrakes@go.olemiss.edu
 (No relevant relationships reported)

PURPOSE: To determine whether meeting overall calorie intake impacts the number of days an athlete has concussion-related symptoms following diagnosis.
METHODS: Fourteen Division I collegiate athletes with a mean age of 20.14 (SD=1.027) who were diagnosed with a concussion were randomly placed in a control group (n=7) or intervention group (n=7). In both groups, daily caloric intake was compared to total daily caloric needs and the individual was coded as met or did not meet energy needs. Concussion related symptoms were assessed using the Sports Concussion Assessment Tool (SCAT5) Symptom Evaluation Form. For the intervention group, four single serving packets of a carbohydrate supplement were provided following immediate impact at the suspicion of a concussion or within 30 to 60 minutes of diagnosis (two servings immediately at suspicion or following diagnosis of concussion, and one serving every other hour within the first 4 hours following the initial servings), and two single serving packets during daily concussion protocol evaluation until the athlete reported no symptoms. A 2x2 Factorial ANOVA was conducted on the total number of days of concussion symptoms with respect to daily average calories being met (AvgCalories) and comparing the control and intervention groups (Controllntervention).
RESULTS: Statistically significant differences were found in a number of days of concussion symptoms between those who met average daily calorie needs and those who did not, F(1, 14) = 7.826, p<.05. No statistically significant difference was seen in the number of days of concussion symptoms between athletes who were in the control group and the intervention group, F(1, 14) = 0.936, p=.356. Although a statistical significance was not observed in the number of days of athlete symptoms, an average decrease in the number of days was observed in the intervention (M = 4.43, SD = 2.37) when compared to the control (M = 8.57, SD = 5.09), t(7) = 2.357, p = .151.
CONCLUSION: In this population, athletes that meet their daily calorie needs had fewer days that they experienced concussion related symptoms compared to the subjects that did not meet their caloric needs. This preliminary research suggests that it is beneficial to assure that individuals are aware of their caloric needs and strive to meet them following the diagnosis of a concussion.

3127 Board #173 May 31 2:00 PM - 3:30 PM
Body Composition And Food Consumption Of A Group Of Trekkers Of sãO Paulo - Sp, Brazil

Marcia Nacif, Gabriela Soares, Juliana Masami Morimoto. *Universidade Presbiteriana Mackenzie, São Paulo, Brazil.*
 Email: marcia.nacif@mackenzie.br
 (No relevant relationships reported)

The demand for physical activities in the nature has increased a lot and one of the most practiced modalities in Brazil is the trail. The trail is characterized by open paths amidst nature and it is considered the main form of access to preservation areas and lush landscapes. Due to the lack of national literature regarding trekkers, it is justified the importance of studying these sportsmen. **PURPOSE:** Evaluate the body constitution and the food consumption of a group of trekkers of São Paulo, Brazil.
METHODS: Cross-sectional study, approved by the Research Ethics Committee of the Mackenzie Presbyterian University, performed with trekkers of both sexes, who consented to participate in the research. To assess body composition showed the weight, height, skinfolds and body circumferences. The percentage of body fat was calculated by the Body Density (D) calculation proposed by Durnin and Womersley (1974) and subsequent conversion of D by the Siri's equation (1961). The body fat percentage classification was made according to Lohman et al. (1992). The food consumption was evaluated by a 24-hour Recall. The macronutrients, fatty acids, vitamins A, C, E, calcium, magnesium and iron were calculated using Avanutri® Software version 4.0. We used the recommendations of the Institute of Medicine (2001) and the Brazilian Society of Cardiology (2013). The analysis of the average difference between nutrients and anthropometric variables was made by Student's t test and Analysis of Variance (ANOVA). **RESULTS:** 14 trekkers were evaluated with an average age of 29 years, 50% female and 50% male. It was observed that 35.71% of the participants were overweight and 50.0% showed a high fat percentage. Men had higher stature and weight, while women presented higher fat percentage and biceps skinfold (p <0.001). It was found adequate intake of macronutrients, but the consumption of saturated fats and cholesterol was high. There was also a high prevalence of inadequacy about calcium consumption and greater intake of lipids by men (p <0.05). **CONCLUSIONS:** It is recommended that the trekkers search for guidance on food and nutrition, seeking a good performance and greater utilization of this experience with nature.

3128 Board #174 May 31 2:00 PM - 3:30 PM
Association Of The Adequate Intake Of Macronutrients Between Strength Levels From 1RM In University Athletes

Sayra Nataly Muñoz-Rodriguez, Alejandro Gaytan-Gonzalez, Sergio Alejandro Copado-Aguila, Roberto Gabriel Gonzalez-Mendoza, Joaquin Ojeda-Robles, Juan R. Lopez-Taylor, Marisol Villegas-Balcazar. *Universidad de Guadalajara, Guadalajara, Mexico.*
 (No relevant relationships reported)

PURPOSE: To analyze the association between the proportions of athletes with adequate macronutrient intake with one repetition maximum (1RM) on bench press in college athletes.
METHODS: 164 (103 men, 61 women) college athletes from different sports were evaluated. 24-h dietary recalls were administered to estimate the macronutrient intake. Carbohydrate (CHO), protein (PRO) and fat (FAT) intake were calculated and adjusted for body weight (g/kg/day). Consumption was classified as "adequate" if the athlete consumed the recommended minimum amounts for each macronutrient: 5 g/kg/day of CHO, 1.2 g/kg/day of PRO, and 0.5 g/kg/day of FAT. Bench press 1RM test was performed to determine the maximal strength. Then, 1RM was classified into sex-specific quartiles: (Men: Q1 <57.8 kg, Q2 57.8 - 66.8 kg, Q3 66.9 - 80.3 kg, and Q4 >80.3 kg; Women Q1 <35.1 kg, Q2 35.2 - 39.6 kg, Q3 39.7 - 48.8 kg, and Q4 >48.8 kg) of displaced weight (kg). The proportion of athletes with an adequate intake of each macronutrient was compared between 1RM quartiles and analyzed by sex. Similarly, the proportion of subjects with adequate intake were compared between macronutrients within quartiles. Chi-square and multiple Z tests (with Bonferroni adjustment) were used to determine significant differences between groups. Significant differences were deemed at a p-value ≤0.05.
RESULTS: There were no significant differences in the proportions of adequate intake between 1RM quartiles for all three macronutrients, for both men and women (p>0.05). However, while analyzing the proportion of subjects with adequate macronutrient intake within quartiles, CHO was the one with the lowest proportion on men for all quartiles. The same pattern was observed in women except for Q1 (Table).
CONCLUSIONS: No association between adequate macronutrients intake and 1RM bench press strength levels were observed. However, CHO was the macronutrient with the lowest proportion of athletes achieving the minimum recommended intake.

| | | Q1 | Q2 | Q3 | Q4 | p-value |
|-------|---------|-------------|--------------|--------------|--------------|---------|
| Men | PRO | 13 (93%) ab | 28 (90.3%) a | 27 (84.4%) a | 24 (92.3%) a | 0.734 |
| | FAT | 14 (100%) b | 29 (93.5%) a | 30 (93.8%) a | 24 (92.3%) a | 0.786 |
| | CHO | 8 (57%) a | 20 (64.5%) b | 18 (56.2%) b | 11 (42.3%) b | 0.412 |
| | p-value | 0.005 | 0.004 | 0.001 | <0.001 | |
| Women | PRO | 7 (70%) | 20 (83.3%) a | 13 (86.7%) a | 10 (83.3%) a | 0.744 |
| | FAT | 9 (90%) | 21 (87.5%) a | 15 (100%) a | 10 (83.3%) a | 0.483 |
| | CHO | 6 (60%) | 6 (37.5%) b | 4 (26.7%) b | 2 (16.7%) b | 0.166 |
| | p-value | 0.303 | 0.001 | <0.001 | 0.001 | |

Data expressed as frequencies (%). Different letters denote significant differences between nutrients within quartiles (p<0.05).

3129 Board #175 May 31 2:00 PM - 3:30 PM
A Comparison Study of Energy Expenditure and Nutrition Intake in Amateur Athletes in Long Distance Running

xintang wang, Yu Ji. *Beijing Sport University, Beijing, China.*
 Email: wangxintang@bsu.edu.cn
 (No relevant relationships reported)

PURPOSE: By analyzing the energy expenditure figures of each group (training group, marathon group and cross-country running group) and their nutrition intake figures, some reasonable suggestions were given to solve the problem of nutrition intakes in daily training or competition.
METHODS: The energy expenditure data were collected by wearing 3-axis accelerometer (ActiGraph GT3X, USA) when 10 amateurs did 10km training, 6 amateurs did marathon competition, and 6 amateurs did 50-100 km cross-country running. They were asked to recall and record all the foods and beverages during competition or training. After measuring energy expenditure during their exercises, and recording the process of nutrition supplement, we compared the differences in energy expenditures of different groups, and analysis the relativity between energy expenditures and nutrition intakes.

RESULTS: (1) The energy expenditure figure of training group was 0.66 ± 0.10 kcal/kg/km, which was observably less than those of marathon group (1.22 ± 0.32 kcal/kg/km) and cross-country group (1.20 ± 0.18 kcal/kg/km) ($P < 0.01$); however, there was no any obvious difference between the marathon group and cross-country group ($p > 0.05$); (2) The calorie of supplement intakes was 756.17 ± 387.80 kcal/kg/km, which was significant lower than the calories of energy expenditure (2331.61 ± 939.30 kcal/kg/km) in 22 amateurs. However, there was a positive correlation between energy expenditure and supplement intake among the 22 amateur athletes ($r = 0.950, P < 0.01$). **CONCLUSIONS:** (1) The energy expenditure level during daily training was obviously lower than which during competition in amateur runners; (2) The nutrition intake didn't meet the demand of energy cost during long distance running although the runners had followed the principle of "the more energy cost, the more supplement will need".

The Exercise Microbiome Project: An 8 week Cardiovascular Intervention on the Human Gut Microbiome

Arron M. Shiffer, Anthony Santos, Kyle Winfree, Shari Kyman, Emily Cope, J. Gregory Caporaso, Dierdra Bycura. *Northern Arizona University, Flagstaff, AZ.* (Sponsor: Dr. Timothy Behrens, FACSM)
 Email: shiffy35@gmail.com
 (No relevant relationships reported)

INTRODUCTION: The effects of diet and exercise are well studied in connection with human health. However, the relationship between the human gut microbiome (HGM) and exercise is not well understood. **PURPOSE:** The purpose of this study was to examine possible changes to the HGM diversity and composition resulting from an 8-week intervention of cardiovascular exercise (CVE). **METHODS:** Twenty-seven participants (20 F and 7 M) aged 18-25 years were recruited. Inclusion/exclusion criteria were determined using the AHA/ACSM pre-screening questionnaire along with screening for historical factors that might impact the microbiome. Fecal samples for HGM profiling were collected weekly, during three phases of the project: baseline (4 wks; no CVE), intervention (8 wks; CVE 3x wk), and washout (4 wks; no CVE). Pre/post VO_2 max and body composition analyses were conducted. Heart rate ranges for the CVE intervention were pre-determined by the subject's VO_2 max test. Gut microbiota were profiled using 16S rRNA gene sequencing. Microbiome sequence data were analyzed with the QIIME 2 bioinformatics platform. **RESULTS:** To track changes in each subject's HGM, community richness and composition were compared to the week 1 (baseline) values for each subject. One week after the CVE began there was a significant change ($p = 0.0001$) in the HGM composition. This change persisted through week 11, when the CVE program stopped and microbial compositions abruptly returned to baseline values. Interestingly, in week 8, some individuals seem to have returned to a composition similar to baseline. Reasons for this anomaly are unclear. Additionally, each individual's community richness and compositions were compared to the prior week to understand week-to-week changes, demonstrating a significant shift ($p = 0.0002$) in composition at week 8, indicating settlement into a novel HGM composition. The week to prior week community richness showed significant decreases in weeks 7-9 ($p = 0.02$). This was followed by a significant increase in week 12 ($p = 0.017$). **CONCLUSION:** The CVE intervention showed significant changes in HGM richness and composition that correlated with the beginning and the end of the CVE intervention. These changes indicate that exercise has a clear impact on the HGM and further studies are needed to uncover the underlying mechanism.

Oral Calcium Loading Before Exercise Influences PTH and CTX Responses

Sarah J. Wherry¹, Meryl Wastney², Christine M. Swanson¹, Toby Wellington¹, Rebecca S. Boxer¹, Connie M. Weaver², Wendy M. Kohrt, FACSM¹. ¹University of Colorado Anschutz Medical Campus, Aurora, CO. ²Purdue University, West Lafayette, IN. (Sponsor: Wendy Kohrt, FACSM)
 Email: sarah.wherry@ucdenver.edu
 (No relevant relationships reported)

Timing of calcium (Ca) ingestion relative to exercise may attenuate observed increases in parathyroid hormone (PTH) and c-terminal telopeptide of type I collagen (CTX, a marker of bone resorption). Controlled Ca supplementation studies have typically used doses of ≥ 1000 mg, but it is not known how much Ca is absorbed. **PURPOSE:**

to quantify Ca absorption during exercise when preceded by a high (H: 1015 mg) or low (L: 215 mg) Ca-containing meal and determine effects on serum PTH, CTX, ionized Ca (iCa), and total Ca (tCa). **METHODS:** Healthy, cycling-trained men ($n = 10$, aged 20-45 y) underwent two identical 1-hour cycling bouts at $\sim 75\%$ HRmax. In a randomized, cross-over design utilizing dual calcium tracers, participants were provided with a H or L Ca meal 2 hours before exercise. Each meal included 15 mg of $^{44}\text{CaCO}_3$. A bolus dose of 2.5 mg of $^{42}\text{CaCl}_2$ was administered 4 hours before exercise followed by a constant infusion of $^{42}\text{CaCl}_2$ at 0.0125 mg/hr that continued through exercise and a 1-hour recovery. Gut absorption was determined from the appearance of the oral tracer in plasma relative to the rate of disappearance of the IV tracer using compartmental modeling. Blood was sampled every 15 minutes during exercise and recovery. Urine was collected prior to the meal, immediately before exercise, and at the end of recovery. **RESULTS:** Ca absorbed was 2.5 times higher with H versus L (H: 295 ± 158 mg; L: 116 ± 50 mg; $p = 0.007$); there was no difference in urinary Ca excretion (H: 22 ± 15 mg; L: 21 ± 18 mg). Changes in iCa during exercise were not different (H: -0.03 ± 0.11 mg/dL; L: -0.08 ± 0.24 mg/dL; $p = 0.46$). H prevented the increase in CTX during exercise (H: -0.03 ± 0.04 ng/mL; L: 0.02 ± 0.05 ng/mL; $p = 0.03$), but the increase in PTH during exercise (H: 12.7 ± 16.7 pg/mL; L: 11.3 ± 16.5 pg/mL; $p = 0.80$) did not differ for H and L. During recovery, CTX was lower for H (H: 0.03 ± 0.05 ng/mL; L: 0.10 ± 0.06 ng/mL; $p = 0.003$); PTH did not differ (H: -10.3 ± 14.9 pg/mL; L: -9.5 ± 14.5 pg/mL; $p = 0.88$). There were no differences between H and L for iCa during recovery or tCa during exercise or recovery. **CONCLUSION:** Ca absorption was higher in H versus L, but there was no difference in urinary excretion, suggesting that absorbed Ca was retained. The H Ca load was effective in attenuating the increase in CTX despite no attenuation of the PTH response. Supported by DoD Grant W81XWH-12-1-0364.

3132 Board #178 May 31 2:00 PM - 3:30 PM
Short-Term Low Choline Intake May Not Negatively Affect Strength Gains in Older Adults

Chang Wook Lee¹, Vincent CW Chen², Steve Bui³, Teak V. Lee⁴, Steven E. Riechman, FACSM⁵. ¹University of Houston-Victoria, Victoria, TX. ²Georgian Court University, Lakewood, NJ. ³Dixie State University, St. George, UT. ⁴Pierce College, Woodland Hills, CA. ⁵Texas A&M University, College Station, TX.
 (No relevant relationships reported)

PURPOSE: The micronutrient choline is a precursor to acetylcholine (ACh), which mediates skeletal muscle contraction and force production. We previously reported that 12 weeks of low choline consumption ($\sim 50\%$ of Adequate Intake [AI]) impaired strength gains in older adults in response to resistance exercise training. The purpose of this study was to investigate whether low choline consumption for a shorter period of time has negative effects on muscle responses to resistant exercise (RE) in older adults. **METHODS:** Thirty one, 50-to-65-year-old, generally healthy men and women were randomly assigned to one of three choline intake groups (Low, 3.6 ± 0.6 mg/kg/d, $n = 10$; Med, 6.0 ± 0.6 mg/kg/d, $n = 11$; High, 8.8 ± 0.8 mg/kg/d, $n = 10$) and underwent 3 weeks of diet and RE intervention (leg press and extension, 2x/week, 3 sets, 8-12 reps, 75% of maximum strength [1RM]; 4 bouts of maximal isometric force production on leg extension). 1RM and EMG tests were performed before and after intervention. **RESULTS:** While all three groups experienced significant increases in strength, there was no difference between choline groups in changes in 1RMs (Leg press, Low: $12.4 \pm 12.0\%$, Med: $17.5 \pm 10.7\%$, High: $15.8 \pm 10.7\%$, $p = 0.588$; Leg extension, Low: $17.9 \pm 13.0\%$, Med: $15.3 \pm 18.8\%$, High: $5.9 \pm 12.2\%$, $p = 0.209$). Similarly, no differences were observed in EMG amplitudes or average/peak isometric force outputs between groups. **CONCLUSION:** These data suggest that less than a month of low or high choline intake may not affect strength gains in older adults. It appears that only a prolonged period of low choline intake may have negative effects on muscle responses to RE.

Vitamin D Status and Biobehavioral Health in U.S. Navy Explosive Ordnance Disposal Operators

Lisa M. Hernandez¹, Edward D. Gorham², Marcus K. Taylor, FACSM². ¹Leidos/Naval Health Research Center, San Diego, CA. ²Naval Health Research Center, San Diego, CA. (Sponsor: Marcus K. Taylor, FACSM)
 Email: lisa.m.hernandez75.ctr@mail.mil
 (No relevant relationships reported)

Vitamin D (VITD) is essential for musculoskeletal health and, thus, plays a critical role in human performance, especially in specialized military groups such as U.S. Navy Explosive Ordnance Disposal (EOD). As the premier combat force for countering explosive hazards, EOD must perform optimally in the most austere environments. Accumulating evidence also indicates that VITD may help to prevent certain diseases and reduce all-cause mortality risk. To safeguard health and EOD mission success, it is critical to evaluate factors that influence biobehavioral health in this elite group. **PURPOSE:** The primary purpose of this study was to assess VITD status

in EOD operators. A secondary purpose was to evaluate the associations between VITD and biobehavioral correlates (i.e., body composition, mood). **METHODS:** In 72 EOD operators (86% Caucasian), VITD was measured using a blood test (25-hydroxyvitamin D3). Body fat percentage (BF%), bone mineral content (BMC), maximal volume of oxygen uptake (VO_{2max}), muscular strength (one-repetition max; back squat, bench press), blood lipids, blood pressure, posttraumatic stress disorder symptoms, and depression symptoms were also assessed. Pearson product-moment correlation analyses were used to evaluate associations between VITD and biobehavioral characteristics. **RESULTS:** Mean \pm SE were as follows: age = 34.2 \pm 0.8 y; BF% = 17.6 \pm 0.4; VITD = 39.0 \pm 1.0 ng/mL; and VO_{2max} = 47.9 \pm 0.7 ml/kg/min. Associations with VITD were: BF% ($r = -.33$) and android fat ($r = -.36$), both $p < .01$; VO_{2max} ($r = .24$), blood triglycerides (TGs; $r = -.30$), and diastolic blood pressure (DBP; $r = -.25$), all $p < .05$. No correlations were observed with strength, BMC, other blood lipids, or behavioral health. **CONCLUSION:** EOD operators in this study were generally healthy with respect to VITD levels and all other measures. The negative association between VITD and BF% is consistent with accruing data in both military and athletic populations. It also reflects the prevailing hypothesis that in overweight individuals, VITD can become sequestered within fat tissue. Inverse relationships with android fat, TGs, and DBP are in line with reports that VITD deficiency is linked to cardiovascular disease risk factors. Future studies will evaluate VITD status with neurocognitive function and genetic variants of stress physiology.

3134 Board #180 May 31 2:00 PM - 3:30 PM
**Influence Of Vitamin D Status On The Post-exercise
 Hepcidin And Interleukin-6 Response In Trained
 Athletes**

Alexandra L. Shill¹, Molly Collinson¹, Mark Palmer¹, William D. Fraser², Jonathan Tang², Richard J. Burden³, Nicolette C. Bishop¹. ¹Loughborough University, Loughborough, United Kingdom. ²University of East Anglia, Norwich, United Kingdom. ³English Institute of Sport, Loughborough, United Kingdom.
 (No relevant relationships reported)

PURPOSE: Iron deficiency and reduced iron status have potential negative performance implications for athletes, particularly endurance runners. Hepcidin has a key role in iron homeostasis and is known to be influenced by interleukin (IL)-6. Emerging research from clinical populations indicates that vitamin D supplementation can reduce both circulating hepcidin and IL-6 levels hence could improve iron availability and increase performance. Exercise is known to increase both IL-6 and hepcidin levels, but the influence of vitamin D status on this response is unknown.

METHODS: Twenty trained participants (24 \pm 4 years; 184.3 \pm 6.5 cm; 79.8 \pm 7.5 kg; 55.7 \pm 6.5 mL/min/kg) divided into 3 activity groups (endurance runners n=6; resistance trained n=6; team sports n=8) gave informed consent to take part in this study. Following an overnight fast, participants completed a sub-maximal and graded treadmill test to volitional exhaustion. Venous blood samples were collected pre, post, 1 h and 3 h post-exercise. Blood was analysed for serum total 25-hydroxy vitamin D at pre-exercise only; plasma hepcidin-25, plasma IL-6 and serum iron concentrations were assessed at all time points.

RESULTS: Pre-exercise vitamin D values were similar between groups (90.2 \pm 32.5 nM, $p = 0.563$). Hepcidin increased significantly after exercise ($F_{(1,1,18,4)} = 36.81$ $p < 0.001$) with values peaking at 3 h post-exercise (pre 17.13 \pm 12.15 ng/mL; 3 h post-exercise 38.44 \pm 23.92 ng/mL). Both iron and IL-6 concentration increased significantly in response to exercise ($F_{(1,9,32,2)} = 44.1$ $p < 0.001$ and $F_{(2,1,36,4)} = 18.92$ $p < 0.001$, respectively). No significant interactions or group differences were found for hepcidin ($p = 0.121$ and $p = 0.409$), iron ($p = 0.529$ and $p = 0.297$) or IL-6 ($p = 0.709$ and $p = 0.175$). There was a significant negative correlation between peak hepcidin and relative VO_{2peak} ($\rho = -0.468$ $p = 0.038$). There was a trend for a negative relationship between vitamin D values and % change in hepcidin from pre-exercise to 3 h post-exercise ($r = -0.431$ $p = 0.058$) and a trend for a positive relationship between vitamin D and peak IL-6 values ($r = 0.410$ $p = 0.072$).

CONCLUSIONS: Higher serum Vitamin D levels have the potential to reduce the post-exercise hepcidin response and therefore could have positive implications on athletes' post-exercise iron status.

**Evaluation of Vitamin K Intake and Its Relation to Bone
 Mineral Density**

Julia M. Rovera, Joseph R. Stanzione, Sinclair A. Smith, Stella L. Volpe, FACSM. Drexel University, Philadelphia, PA. (Sponsor: Stella L. Volpe, FACSM)
 Email: jmr83@drexel.edu
 (No relevant relationships reported)

Vitamin K is a required nutrient important in bone health. Some researchers have reported that vitamin K can help to prevent bone fractures. **PURPOSE:** To explore whether a relationship exists between vitamin K intake and bone mineral density (BMD) among athletes, 18 to < 35 years of age and \geq 35 years of age. **METHODS:**

This was a cross-sectional study, where 198 athletes were measured for total body BMD (TBBMD), lumbar spine BMD (LBMD), and dual femoral neck BMD (FNBMD) with dual-energy X-ray absorptiometry (DXA). Athletes also completed a food frequency questionnaire (FFQ) to determine their average daily intake of Vitamin K intake, as phyloquinone (also known as vitamin K₁). Athletes were separated into two age groups: 18 to < 35 years of age (57 women; 42 men) (28.10 \pm 3.86 years of age) and \geq 35 years of age (60 women; 39 men) (46.21 \pm 8.80 years of age). Pearson correlation models were used to correlate all three BMD sites with vitamin K intake. Alpha levels were set *a priori* at $p < 0.05$. **RESULTS:** In the 18 to < 35 years of age group, mean vitamin K intake was 370.75 \pm 265.82 mcg/day. Significant correlations were reported between all three BMD sites and vitamin K intake in this age group (n=99): TBBMD $r = -0.254$, $p < 0.05$; LBMD $r = -0.248$, $p < 0.05$; FNBMD $r = -0.278$, $p < 0.05$. In the \geq 35 years of age group, mean vitamin K intake was 406.27 \pm 267.99 mcg/day. There was no significant correlation between vitamin K intake and any of the three BMD sites in the \geq 35 years of age group (n=99). **CONCLUSION:** Our results demonstrate that the average vitamin K intake in these athletes was over 300% of the Dietary Reference Intakes (DRI), where 97.1% of female athletes and 79.2% of male athletes met and exceeded their respective DRI (90 mcg/day for women, 120 mcg/day for men). It is unclear, however, why a negative relationship existed between vitamin K intake and BMD in athletes 18 to < 35 years of age, and no relationship existed in athletes \geq 35 years of age. A prospective study should be conducted to better elucidate these relationships. This study was not funded.

**Short Term High Intensity Resistance Exercise-
 induced Muscle Soreness Is Attenuated with Dietary
 Cholesterol**

Vincent C. Chen¹, Chang Woock Lee², James D. Fluckey³, Steven E. Riechman, FACSM⁴. ¹Georgian Court University, Lakewood, NJ. ²University of Houston-Victoria, Victoria, TX. ³Texas A&M University, College Station, TX. ⁴Texas, College Station, TX.
 Email: vchen@georgian.edu
 (No relevant relationships reported)

Inflammation plays an important role in muscle soreness after the high-intensity resistance exercise. Cholesterol is essential for mediating inflammation through regulating membrane homeostasis and facilitating cell signaling. **PURPOSE:** The purpose of this study was to investigate the effects of dietary cholesterol on the exercise-induced soreness levels. **METHODS:** 16 untrained, healthy young men (n=12) and women (n=4) performed a short-term high-intensity resistance exercise consisting of unilateral leg press and extension with 5 sets and repetitions until failure at 85% 1RM in the Resistance Exercise (RE) sessions and 3 sets/10 repetitions at 50% 1RM in the Light Exercise (LE) sessions. The RE was performed on the starting day (day 0) and day 9 while the LE was performed on day 3 and 6. Participants were randomly assigned to either a Low Cholesterol Intake (LC, n=7) or a High Cholesterol Intake (HC, n=9) group. Soreness levels were recorded with a Soreness Visual Analogue Scale. Overall soreness was defined as the average soreness from Day 1 to 12. **RESULTS:** The overall soreness levels in LC were 91.6 \pm 3.6% higher than HC ($P = 0.044$). Two days after the first RE, soreness levels reached to the highest point in both groups and were higher in LC than HC ($P = 0.028$). The soreness in LC on Day 10 was lower than Day 2 ($P = 0.021$). There was no significant difference between groups after the second RE. **CONCLUSIONS:** The soreness levels peaked at two days after the first resistance exercise in both groups, which is consistent with the Delayed Onset Muscle Soreness. The lower overall soreness in HC than LC might suggest that the higher level of dietary cholesterol promoted a more efficient recovery via the regulation of inflammation and thus lowered the soreness levels. However, the levels of the biomarkers such as creatine kinase and C-reactive protein were unknown and should be analyzed in future studies to investigate the effects of cholesterol on the exercise-induced inflammation.

* $P < 0.05$, significant difference between HC and LC groups on the day. Data are Mean \pm SEM.

F-61 Free Communication/Poster - Nutrition and Children

Friday, May 31, 2019, 1:00 PM - 6:00 PM

Effects of Fruit and Vegetable Consumption on Physical Activity Levels in Elementary School-Aged Children**

Megan Reynolds. *University of Central Florida, Orlando, FL.*
(No relevant relationships reported)

PURPOSE: This study will examine the association of fruit and vegetable consumption at school on physical activity and academic achievement among children from disadvantaged backgrounds. Concern for this topic arose from the awareness that childhood obesity and the diseases that accompany it such as diabetes and hypertension are continuing to rise, all while participation in physical activity is declining. Meals served in school could potentially intervene and help to reverse these statistics, especially for underprivileged children where many rely on this food to satisfy their daily nutritional needs. This project seeks to discover relationships between these factors in order to optimize the success of young students from different backgrounds. **METHODS:** This is a cross-sectional, mixed-methods study designed to compare the association of fruit and vegetable consumption on physical activity and academic performance in a sample of underserved grade-school children. The student sample will come from the UCP Beta Downtown campus. There will be 50 student subjects from each grade 3 to 5 that will be selected from each class roster, using systemic random sampling. Teachers and parents of participants will also be asked to participate in focus groups and fill out short multiple-choice questionnaires. **RESULTS:** Results showed that children in the 3rd - 5th grades spend over 70% of their day being sedentary, roughly 20% of time throughout the day was spent participating in light physical activity, and less than 10% of daily living was spent participating in moderate-to-vigorous physical activity (MVPA). These same children also did not meet the recommended dietary intake for fruit and vegetable consumption, as on average they consumed less than one fruit or vegetable serving per day. **CONCLUSIONS:** It is necessary to educate the nation's children on healthy eating options, as well allow more opportunity for higher intensity physical activity. School-based interventions are critical to reach children of diverse backgrounds. These interventions could help begin the reversal of current trends in the fight against obesity.

**3138 Board #184 May 31 2:00 PM - 3:30 PM
Preschool Children in Childcare Settings Do Not Consume Healthy Snacks Despite Menus That Meet Recommended Dietary Standards**

Stacie M. Kirk, Erik P. Kirk, FACSM. *Southern Illinois University Edwardsville, Edwardsville, IL.*
Email: skirk@siue.edu
(No relevant relationships reported)

Preschool snack menus must meet the Dietary Guidelines for Americans, however, what is actually served and consumed by children is not restricted, potentially affecting consumption of a healthy diet.

PURPOSE: Compare preschool snack menus that meet recommended dietary guidelines to what is served and consumed by children. **METHODS:** Fifty-two preschool children (mean±SD, age 3y 9m ± 4m) from a university early childhood center participated in a 10-week study. Dietary intake was measured by trained investigators using direct observation for pre and post snack analysis. Energy and nutrient content was completed using Food Processor Nutrition Analysis by ESHA. Food color was determined by observation during analysis to determine if the color of food affected consumption of certain snacks. A food preference survey was administered orally by investigators to children immediately after each snack. **RESULTS:** There was a significant ($p<0.05$) difference for total kilocalories (kcal) between menu (168 ± 48), served (269 ± 129) and consumed (179 ± 137). There was a significant ($p<0.05$) difference for grams of carbohydrate between menu (23.9 ± 8.5g), served (39.9 ± 18.7g) and consumed (27.1 ± 19.6g). There was a significant ($p<0.05$) difference for grams of fat for menu (5.7 ± 3.2g) and consumed (5.4 ± 5.8g), compared to served (8.5 ± 5.7 g). There was a significant ($p<0.05$) difference for grams of protein for menu (5.7 ± 2.0g) and consumed (5.8 ± 4.2 g) compared to served (8.7 ± 4.2g). The majority of food served was white (47.4%), brown (14.0%), or orange (19.0%) in appearance indicating a larger amount of processed/prepackaged foods consumed. Minimal food was served with the colors of yellow (4.7%), red (9.0%) or green (2.2%); colors normally associated with fruits, vegetables, and lean meats. Children consumed about 23.1% of meats and 50% of vegetables that were served to them,

which was significantly ($p<0.05$) lower than dairy (75.2%), fruits (72.6), and grains (77.0%). Children consumed a high amount (84.2%) of the fats/sweets served to them. Children described the snack food as yummy (85.3%), okay (6.4%), or yucky (8.3%). **CONCLUSIONS:** The results indicate that snack menus meeting recommended dietary standards may not match what children are served or consuming for snack, potentially contributing to long-term health consequences.

Construction And Validation Of a Digital Instrument For The Evaluation Of Children Nutritional Status**

Elisa P. Ferrari¹, Silvana dos Santos¹, Larissa A. Maciel², Fernando L. Cardoso³. ¹Catholic university of Brasilia, Brasilia, Brazil. ²Catholic university of Brasilia, Brasilia, Brazil. ³Santa Catarina State University, Florianópolis, Brazil.
Email: elisa.ferrari@ucb.br
(No relevant relationships reported)

BACKGROUND: Self-assessment of body image refers to the internal representations of their body structure and physical appearance in relation to themselves and others. Silhouette scales can be an alternative to assess the nutritional status in children.

PURPOSE: Develop and indicate metrical qualities of a digital instrument for evaluation of nutritional status in children.

METHOD: 414 children, aged between seven and 10 years old were assessed for the following measures, Circumferences (neck, shoulder, chest, relaxed arm, wrist, waist, abdomen, hip, proximal thigh, medial thigh, distal thigh, leg, ankle); diameters (biliocrystal and biacromial); stature; body weight. Descriptive statistics were performed using simple frequency, position and dispersion measurements. The normality of the data was tested by Kolmogorov Smirnov test was used. The inferential tests were performed, validity coefficient of content, Spearman's correlation, using SPSS version 20.0® and considering $p<0.05$.

RESULTS: The instrument is composed of nine three-dimensional body figures developed from average values of body measurements of 200 children aged 7 to 10 years. These figures represent a continuum of excessive thinness (BMI 12.0 kg/m²) to severe obesity (BMI 29.0 Kg/m²). The application of this instrument consists of the presentation of the figures, with the following instructions, 1) (real) and 2) (ideal). The dissatisfaction with the body image is obtained by subtracting the real from the ideal. The validity coefficient of content presented values higher than 0.90 for the image clarity, practical relevance and representativeness of the item, obtained through the evaluation of 10 judges. For the validation of the criterion, the children with excess weight indicated the greatest real figures, as well as the highest values of discrepancy, regardless of gender, boys ($r=0.36$, $p<0.01$) and girls ($r=0.52$, $p<0.01$). **CONCLUSION:** It is concluded that the developed instrument demonstrated good psychometric qualities, becoming a viable option for evaluating children's body image.

**3140 Board #186 May 31 2:00 PM - 3:30 PM
Low Cruciferous Vegetable Intake is Associated with Elevated Inflammation in Preadolescent Girls**

Jennifer W. Bea¹, Lindsay Kohler¹, Megan Hetherington-Rauth², Janet Funk¹, Nora Carranza¹, Vinson Lee¹, Robert Blew¹, Scott B. Going¹. ¹University of Arizona, Tucson, AZ. ²University of Lisbon, Lisbon, Portugal.
Email: jbea@uacc.arizona.edu
(No relevant relationships reported)

Subclinical chronic inflammation, measured by C-reactive protein (CRP), is strongly linked to cardiovascular disease (CVD) in adults. CRP has been shown to be elevated in some children and is considered a potential risk factor for early onset CVD.

Strategies to reduce chronic inflammation among children is paramount. In adults, higher cruciferous vegetable intake has been associated with lower inflammation.

PURPOSE: To examine the relation between cruciferous vegetable intake and CRP among preadolescent girls.

METHODS: Among girls aged 9-12 yrs (N=296), cruciferous vegetable intake was measured by the Youth/Adolescent Questionnaire and categorized as >0-0.25, 0.26-0.50, >0.50 servings per day. Fasting serum CRP (mg/L) was measured by the Beckman Coulter AU5812 Clinical Chemistry Analyzer. Girls with CRP values >10mg/L were excluded. CRP levels were categorized by normal, moderately increased risk, and high risk for CVD according adult cut-offs (CRP <1, ≥1-3, >3 mg/L). Multinomial logistic regression with covariates of BMI percentile, maturation, and physical activity was used to evaluate CRP category relation with cruciferous vegetable intake.

RESULTS: Mean age, BMI, and CRP levels were 10.8±1.1 yrs, 20.7±5.1 kg/m², and 1.3±1.8 mg/dl, respectively. The proportion of girls in the normal, moderate, and high risk CRP categories were (N%): 218 (69.2%), 50 (15.9%), 47 (14.9%). Average cruciferous vegetable intake was 0.27±0.3 servings/day. Low cruciferous vegetable intake (>0-0.25 servings/day) was significantly associated with a CRP level of 1-3mg/L (RRR=3.5, 95% CI 1.1-11.3; P=0.04).

CONCLUSIONS: Cruciferous vegetable intake among girls aged 9-12 years was low overall. The lowest intake was associated with the CRP risk category considered to confer a moderately elevated risk of CVD among adults. Enrichment of the diet with cruciferous vegetables is an intervention strategy that should be tested in girls to reduce inflammation and CVD risk early, regardless of BMI status. Supported by National Institute of Child Health and Human Development (HD074565) and the National Cancer Institute (P30CA023074)

(No relevant relationships reported)

Pathology Classification and Exercise Adherence: a JTA Educational Approach to Providing Community-Based Exercise Programs

PURPOSE: The purpose of this study was to determine if pathology classification is a significant predictor of adherence to a community-based exercise program. **METHODS:** A cohort study design was implemented, evaluating the Lyndon Health/Fitness Intervention Program (HFIP). Subjects ($N = 44$) had a mean age of 65.82 ($SD = 10.00$) years, participated in a 6-week exercise program consisting of 60 min per session, two days per week. Each subject's Primary Healthcare Provider identified the pathology classification and exercise adherence was defined as the number of sessions attended out of 12 possible sessions. Data were analyzed via an independent groups 2-way analysis of variance (2-way ANOVA), simple linear regression, and multiple linear regression. **RESULTS:** No significant interaction was found for Pathology x Gender in regards to exercise adherence ($F(1,2) = 0.363, p = .698$). There was no significant difference between exercise adherence for gender ($F(1,1) = 0.299, p = .588$), or for pathology ($F(1,4) = 1.823, p = .146$). Pathology classification was found to be significant predictor of exercise adherence ($F(1,31) = 4.560, p = .041$). **CONCLUSION:** While pathology classification was a statistically significant predictor of exercise adherence, only 10.0% of the variance in adherence could be predicted from this model (adjusted $R^2 = .100$). Necessary future research in this area should consider larger and more diverse samples, longer duration exercise programs, and following-up with subjects after program conclusion. Furthermore, the Lyndon HFIP was facilitated in conjunction with a senior-level, undergraduate exercise science course, and served as an applied means to elucidate imbedded ACSM Job Task Analyses (JTA) required of Commission on Accreditation of Allied Health Education Programs (CAAHEP) accredited exercise science programs. The Lyndon HFIP appeared to be a feasible means to promote student learning while expanding community-based exercise opportunities.

3142 Board #188 May 31 2:00 PM - 3:30 PM Program Directors' Perspectives On Coaes-mediated Caahep Accreditation For The Exercise Sciences

Carlton R. Insley, III¹, Susan M. Muller¹, Sidney R. Schneider¹, William Coale². ¹Salisbury University, Salisbury, MD. ²Committee on Accreditation for the Exercise Sciences, Indianapolis, IN. (Sponsor: Walt Thompson, FACSM, FACSM)
Email: rcinsley@salisbury.edu

Reported Relationships: **C.R. Insley:** Other (please describe); Not sure if this constitutes a required disclosure. The authors Insley and Muller volunteer services at the CoAES (ACSM). The author Coale is a part-time employee at the CoAES (ACSM).

For viability, college medical faculty must provide quality programs in an enrollment-competitive market. Accreditation, credentialing, and licensure contribute to health practice prosperity. Kinesiology-related domain programs (exercise science, exercise physiology etc.) have incomplete achievement in program accreditation, credentialing, and licensure.

PURPOSE: To assess Program Directors' perspectives on CoAES-mediated CAAHEP accreditation for the Exercise Sciences. **METHODS:** A 19-question survey was developed and validated by an expert committee. Upon IRB approval, an exploratory study was conducted. Results were anticipated to offer data clarifying the Program Directors' perspectives, and enabling CoAES insight to forward a more positive accreditation path. Electronically solicited, 75 individuals from approximately 500

commercially identified Kinesiology-related programs (undergraduate and graduate) with published e-mail addresses, offered responses. Utilizing descriptive statistics, response analyses were performed in context of survey items. **RESULTS:** The following data graphs represent salient features of survey results:

CONCLUSION: Respondents indicated several major barriers; one of which being 40% of faculty had never discussed pursuing accreditation. The CoAES is challenged to disseminate accreditation information to promote accreditation discussions, and mitigate barriers perceptions. Data support CoAES' Accreditation Ambassador/Mentor Program, which addresses noted needs.

3143 Board #189 May 31 2:00 PM - 3:30 PM Retrieval Practice Improves the Recall and Transfer of Learning of Physiology Information.

John L. Dobson. *Georgia Southern University, Statesboro, GA.*
Email: jdobson@georgiasouthern.edu
(No relevant relationships reported)

PURPOSE: It is well-documented that retrieval practice can enhance the recall of both complex and simple information when compared to more typical methods of learning such as repeated studying (i.e., reading). Evidence is also accumulating that retrieval practice can enhance higher orders of thinking, such as the ability to critically evaluate research articles (Dobson, Linderholm and Perez, 2018) and transfer of learning (Butler, 2010). One purpose of this investigation was to explore the effects of retrieval practice on transfer of learning with physiology information. A second purpose was to compare recall and transfer of physiology information following retrieval practice versus a judgment of learning task (JOL) that may be easier for students to implement on their own. **METHODS:** Participants were randomly assigned to learn three short (~500 words) physiology texts using each of the following strategies: 1. studying a text four consecutive times (SSSS), 2. studying and then retrieving a text two consecutive times (SRSR), and 3. studying a text four consecutive times while completing multiple JOL during the second and fourth repetitions (SJSJ). Recall and transfer of learning were both assessed one week after the participants learned the texts, and the results were analyzed using repeated measures ANOVAs. **RESULTS:** The SRSR strategy facilitated significantly greater recall than the SSSS strategy (21.35 ± 1.08 vs. $17.35 \pm 0.86, p < 0.05$), and both the SRSR and SJSJ strategies lead to significantly greater transfer than the SSSS strategy (44.60 ± 2.55 and 41.79 ± 2.63 , respectively, vs. $36.07 \pm 2.40, p < 0.05$). **CONCLUSION:** These results demonstrate that retrieval practice enhances both recall and higher order thinking about physiology information and that covert retrieval, as experienced in a JOL task, may provide similar benefits.

3144 Board #190 May 31 2:00 PM - 3:30 PM Effects Of A Situated Environment On Classroom Community, Connectedness, And Learning In Exercise Science Students

Amy A. Crawley, Ludmila Cosio-Lima, Byron Havard, Nancy B. Hastings. *University of West Florida, Pensacola, FL.*
Email: acrawley@uwf.edu
(No relevant relationships reported)

Clinical exercise science programs require rigorous academic preparation often taught in traditional classroom and lab settings. However, employers also require students to develop strong interpersonal professional skills necessary to be successful in the field. Incorporating situated learning in the exercise science classroom provides opportunities for students to develop social interaction, theory application, critical thinking, and problem solving skills. A greater sense of classroom community is understood to significantly enhance students' internalization of learning and the development of these desired professional skills. **PURPOSE:** The purpose of this research is to explore students' perceptions of overall classroom community, connectedness, and learning in both a situated and traditional classroom environment. **METHODS:** 53 undergraduate exercise science students (age [yrs] = 22.21 ± 2.96 , males = 35.8%; females = 62.3%) who had participated in either a situated learning course or a traditional learning course completed Rovai's (2002) Classroom Community Survey at the end of the semester. A one-way ANOVA was performed to

determine if there were any significant differences between the two groups ($\alpha = .05$). **RESULTS:** The results demonstrated significant differences between the groups across all three variables of overall classroom community ($p < .00$), connectedness ($p = .02$), and learning ($p < .00$). The situated learning group demonstrated significantly higher mean scores. **CONCLUSIONS:** Students' perceive higher levels of overall classroom community, connectedness, and learning when participating in a situated learning experience. Incorporation of these types of learning environments in exercise science degree programs may enhance professional skill development and successful employment within the field.

3145 Board #191 May 31 2:00 PM - 3:30 PM

Contemporary Conflict Management in the Sports Medicine Setting

Rodiel Kirby Baloy¹, Katelyn Davenport², Charles Lindberg², Elizabeth Tinch². ¹The College of St. Scholastica, Fort Hays State University, Duluth, MN. ²Fort Hays State University, Hays, KS.

Email: rbaloy@css.edu

(No relevant relationships reported)

Purpose. Conflict management is an important aspect in the administration and organization of sports medicine teams. Health care professionals attempt to exert personalities, influences, biases that may create points of misunderstanding within everyday team operations. **Methods.** This review gathers contemporary information and theories towards conflict and conflict management, including definitions of current terminology and current concepts. This study also identifies opportunities that team members may utilize when dealing with conflict. Four main types of conflict are discussed and are juxtaposed with sports medicine scenarios. These types include: goal related conflict, affective conflict, procedural conflict, and cognitive conflict. A review of recent literature also provides strategies for dealing with conflict and creating commitment within team members. **Results.** Potential effects and benefits of various conflict management approaches are discussed. Evidence is then presented to further understand and appreciate the elements involved with conflict when intertwining healthcare professionals in a sports medicine setting. **Conclusion.** In conflict management, recognizing that all team members have differing viewpoints can serve as a resolution point which encourages team members to embrace their differences. Finally, a case study summarizes the theories for conflict management.

3146 Board #192 May 31 2:00 PM - 3:30 PM

The Promotion Of Physical Activity By Craft Breweries In Knoxville, Tennessee

Kelley Strohacker, FACSM, Eugene C. Fitzhugh, Paula-Marie M. Ferrara, Cory T. Beaumont. *University of Tennessee, Knoxville, TN.*

Email: kstrohac@utk.edu

(No relevant relationships reported)

A growing body of research supports a positive relationship between physical activity (PA) and alcohol consumption within various sample populations. Anecdotally, producers of craft beer appear to specifically market to active consumers via sponsorship competitions, charity biking, and hosting of regular PA events (e.g., group runs). Currently, no empirical data exists regarding the promotion of PA promotion by craft breweries. **PURPOSE:** Determine the prevalence and type of PA promoted by craft breweries located in a single community. **METHODS:** Operators of 13 craft breweries located in Knoxville, TN were solicited to complete an electronic survey capturing type and frequency of common PA-related events (e.g., running, biking, fitness classes) hosted over an average month, as well as associated promotions (e.g., discounted beers). Census tract data was tabulated for each brewery location. Descriptive statistics and frequency scores were computed to quantify the promotion of PA across surveyed craft breweries. **RESULTS:** A response rate of 77% was achieved. Participating breweries (N=10) were located in areas that are populated by predominately white (80.9±14.0%), young-to-middle aged adults (35±5y), and that generally consist of a higher proportion of renter-occupied housing units (63.1±18.8%). All respondents indicated that the respective establishment hosted at least one type of PA event. Over an average month, 25 group runs (mean=4±1), 18 group fitness classes (6±3), and 16 group biking events (3±1) were held across seven, three, and five breweries, respectively. In nine of the ten breweries, patrons attending active events are eligible for one or more of the following promotions: \$1USD off all beers (50%), discounted first beer (30%), discounted two beers (10%), and one free beer (20%). **CONCLUSIONS:** A majority of craft breweries in Knoxville, TN host one or more types of group activities multiple times per month, with specific beer promotions for participating patrons. These data provide preliminary evidence for the promotion of PA by craft breweries within a community setting. Further research is necessary to determine the impact and reach of such events, as well as operators' motivations to pair the promotion of PA with the consumption of craft beer.

3147 Board #193 May 31 2:00 PM - 3:30 PM

Effects of Exercise Habits on Working Memory of College Students

Yuan Yang¹, Tian Li², Shoufu Yan¹. ¹Capital University of Physical Education and Sports, Beijing, China. ²YueZhiJian Education Institute, Beijing, China.

Email: yangyuan.0115@foxmail.com

(No relevant relationships reported)

PURPOSE: Working memory is the process of storing information by human body and processing by way of thinking. Relevant studies have shown that exercise have positive impacts on working memory of human body, but previous studies mostly focused on the forms of exercise, and the subjects were mostly children or elderly people. So, this study aimed to explore whether exercise can affect the working memory of college students by comparing who have the exercise habit with who have been sedentary.

Methods: 12 students from the Capital University of Physical Education and Sports were taken as subjects. According to the exercise habits, 6 subjects with exercise habits were divided into exercise group and 6 subjects with sedentary were divided into control group. The E-prime software was used to program the 2-Back task to measure the working memory of subjects. The experimental procedure was divided into four blocks. The first and third blocks were simple tasks, the second and fourth blocks were complex tasks. The SPSS23.0 was used to analyze the experimental data.

RESULTS: The behavior data were analyzed with 2 (exercise habit group)*2 (task type) repeated measurement ANOVA to investigate the responsiveness of different exercise habits to 2-Back task. The results showed that for accuracy, the main effect of task type was not significant $F(1,10)=2.923, p=.118$, and the interaction effect between task type and group was significant $F(1,10)=6.245, p=.032$, indicating that the subjects with exercise habits had higher accuracy than those who with sedentary, but there was no difference in accuracy when performing simple and complex tasks. For the response time, the main effect of task type was not significant $F(1,10)=.125, p=.731$; the interaction effect of task type and group was not significant $F(1,10)=.048, p=.831$, indicating that there was no difference in response time between subjects in the process of two tasks, and there was no significant difference in the reaction time between subjects with exercise habits and sedentary.

Conclusion: Exercise habits may have positive effects on working memory of college students, especially on accuracy of completing working memory process, and the related brain mechanisms need to be further studied.

Reduced Cardiorespiratory Fitness and Greater Body Fatness Will Develop As A Consequence of Chronic Ankle Instability

Michael J. Turner, FACSM, Aregash Theodoros, Anyea King, James Joyner, Tricia Hubbard-Turner, FACSM. *UNC Charlotte, Charlotte, NC.*

Email: miturner@uncc.edu

(No relevant relationships reported)

Our laboratory has recently reported significant declines in daily physical activity (PA) performed in humans and mice as a result of Chronic Ankle Instability (CAI), which will likely accelerate the development of unhealthy characteristics. **PURPOSE:** To assess the impact of CAI on cardiorespiratory fitness and body composition. **METHODS:** Thirty-four subjects participated in the study. Seventeen subjects with CAI were matched for sex (10 females, 7 males/group), age (22.1±2.6yr and 22.2±3.0yr; Mean±SD), height (167±8cm and 168±8cm), and weight (70.5±7.3kg and 66.7±7.5kg), to subjects with no history of ankle injury, respectively. Subjects reported to the Health Risk Assessment Lab for one session. Subjects completed the foot and ankle ability measure (FAAM and FAAMSport) and the NASA physical activity questionnaire. Subject's body composition was assessed by DEXA. Afterward, subjects performed a treadmill maximal exercise test. Every minute of the treadmill test the subjects rated their exertion using the Borg RPE scale (6-20 scale). For the treadmill test we used a two-minute progressive test until volitional fatigue was attained. **RESULTS:** No differences were observed between groups for age ($p=0.86$), height ($p=0.79$), and weight ($p=0.15$). Body composition was different ($p=0.0002$) between the CAI and Control group (33.9±6.0% and 24.6±6.8%, respectively). VO2max (ml/kg/min) was significantly different ($p<0.0001$) between CAI and Control groups (30.2±4.8 and 49.2±7.5, respectively). Time to maximal exercise test completion ($p=0.02$) and VEmax ($p=0.008$) were different between groups. Maximal

HR was not different ($p=0.96$) between groups however resting HR was different ($p=0.0001$) between the CAI and Control groups (77.3 ± 7.5 bpm and 64.9 ± 8.1 bpm, respectively). FAAM ($p<0.0001$), FAAMsport ($p<0.0001$) and NASA ($p<0.0001$) were all observed to indicate differing activity levels between the groups. **CONCLUSIONS:** CAI in college-aged adults results in significantly reduced PA and cardiorespiratory fitness levels accompanied by significantly greater body fatness. Our findings suggest these serious negative health outcomes will rapidly develop as a consequence of the recurrence of this musculoskeletal injury as a young adult.

3149 Board #195 May 31 3:30 PM - 5:00 PM
Early Brace Progression Following Anterior Cruciate Ligament Reconstruction Leads to Improved Knee Range of Motion

Lauren N. Erickson, Kathryn C. Lucas, Cale A. Jacobs, Darren L. Johnson, Mary L. Ireland, FACSM, Brian Noehren, FACSM. *University of Kentucky, Lexington, KY.*
 Email: Lauren.Erickson@uky.edu
 (No relevant relationships reported)

Loss of passive knee extension (KE) following anterior cruciate ligament (ACL) reconstruction is a common deficit after surgery, and has been associated with prolonged pain, quadriceps weakness, and gait impairments. Recent literature indicates that it is also predictive of an increased risk of osteoarthritis due to altered knee kinematics. Post-operative bracing may limit the ability to achieve full terminal KE; however, the effects of various brace progressions have received little attention. **PURPOSE:** To quantify the time to achieve baseline KE and knee flexion (KF) after ACL reconstruction following an early versus delayed brace progression. **METHODS:** 18 ACL-reconstructed subjects were allocated into an early brace progression ($n=9$; 4F, 5M; 21.2 ± 4.9 y; 27.6 ± 5.1 kg/m²) or delayed brace progression ($n=9$; 3M, 6F; 22.8 ± 5.6 y; 24.4 ± 3.0 kg/m²) group. The delayed group was weight bearing as tolerated (WBAT) with a post-operative brace locked in full extension for ambulation for 4 weeks. After 4 weeks, the brace was unlocked with a transition to a hinged knee sleeve at 2 months. The early group was WBAT with the post-operative brace locked in full extension for 1-2 weeks. Subjects were gradually weaned from crutches at 1-3 weeks with complete discontinuation of the brace at 3-6 weeks. KE and KF were measured with a goniometer. Independent t-tests were used to compare differences between groups ($\alpha<0.05$). **RESULTS:** There were no significant differences between groups for baseline KE (early: $-5.7\pm 2.2^\circ$; delayed: $-4.6\pm 3.5^\circ$; $p=0.43$) and KF (early: $142.6\pm 5.2^\circ$; delayed: $142.4\pm 8.6^\circ$; $p=0.97$). There were significant differences between groups post-surgery in time to achieve baseline KE (early: 12.8 ± 9.3 days; delayed: 40.4 ± 16.6 days; 68.4% difference; $p<0.001$) and KF (early: 31.6 ± 8.8 days; delayed: 55.6 ± 13.8 days; 43.2% difference; $p<0.001$). No subjects were noted to have increased knee laxity. **CONCLUSIONS:** Early brace progression was more effective than delayed brace progression in reducing the time to restore baseline KE and KF. Early restoration of knee motion following ACL reconstruction may limit post-operative complications, such as knee stiffness, anterior knee pain, delay in strength recovery, and gait impairments. Adjustment of post-operative brace protocols can have a profound impact on clinical outcomes.

3150 Board #196 May 31 3:30 PM - 5:00 PM
The Detection of Knee Joint Sounds under Different Loading Conditions using Vibroarthrography

Kristin Kalo¹, Rainer Sus², Daniel Niederer¹, Volker Gross², Winfried Banzer, FACSM¹, Lutz Vogt¹. ¹Goethe University Frankfurt, Frankfurt am Main, Germany. ²University of Applied Sciences, Giessen, Germany.
 Email: kalo@rz.uni-frankfurt.de
 (No relevant relationships reported)

Creptus of the knee may mirror structural changes of the joint during motion. Although the magnitude of these sounds increases with greater cartilage damage, it is unclear whether knee joint sounds also reflect joint loading. **PURPOSE:** To reveal whether the magnitude of knee joint sounds differs across defined dynamic loading conditions using vibroarthrography. **METHODS:** Twelve healthy volunteers (26 ± 3.59 years, 7 females) participated in the randomized-balanced crossover study. Knee joint sounds were recorded (linear sampling, 5512 Hz) by means of two acoustic sensors (microphones), one placed on the medial tibial plateau and one on the patella. Two activities of daily life (standing up from and sitting down on a bench; descending stairs) and three open kinetic chain (OKC) knee extension-flexion cycles (passive movement, 10% and 40% loading of the individual one repetition maximum) were performed. Each participant carried out three sets of five repetitions and three sets of 15 steps downwards (stairs), respectively. For data analysis, the mean noise volume for each loading condition was determined. The resulting values were expressed as relative difference to the individual OKC passive movement value. Friedman test and Bonferroni-Holm adjusted post-hoc test were performed to detect differences between conditions. **RESULTS:** The OKC passive movement sound ranged from .0001 to .003 a.u. ($\pm 43.6 - 69.3$ dB) at the medial tibia and from .001 to .03 a.u. ($\pm 60.6 -$

87.7 dB) at the patella. Significant differences between joint sound amplitudes for all movements, both measured at the medial tibial plateau ($\text{Chi}^2=20.7$, $p<0.001$) and at the patella ($\text{Chi}^2=27.6$, $p<0.001$) were obtained. The corresponding median differences for the tibia sensor were: stand/sit: 236%, stairs: 675%, OKC_{10} : 291%, OKC_{40} : 384%; and for the patella sensor: stand/sit: 158%, stairs: 260%, OKC_{10} : 75%, OKC_{40} : 78%. **CONCLUSION:** Overall, the larger the supposed knee joint loading was, the louder was the recorded knee creptus. Consequently, vibroarthrographically assessed knee joint sounds can differ across knee joint loading conditions. Future studies should further support these findings using inverse dynamics as a measurement of knee joint loading.

3151 Board #197 May 31 3:30 PM - 5:00 PM
Glenohumeral And Hip Range Of Motion Are Associated In Softball: Implications For Performance And Injury

Mallory Faherty, Carolyn Killelea, Morgan Skidmore, Robert Zarzour, Timothy Sell, FACSM. *Duke University, Durham, NC.*
 (Sponsor: Timothy Sell, FACSM)
 (No relevant relationships reported)

Effective ball release during throwing requires coordination between the upper extremity (UE) and lower extremities. Deficits in UE and lower extremity (LE) range of motion (ROM) have been associated with decreased throwing performance and musculoskeletal injury. **PURPOSE:** To determine the association between glenohumeral and hip ROM in softball athletes. **METHODS:** 28 NCAA Division I female softball athletes participated (Age: 18.8 ± 1.5 years, Height: 168.1 ± 6.8 cm, Weight: 70.6 ± 9.3 kg). ROM tests included: glenohumeral internal rotation (GIR) and external rotation (GER), hip internal rotation (HIR) and external rotation (HER). All ROM tests were completed bilaterally and an average of three trials was utilized for data analysis. ROM measurements were analyzed individually, as well as a total ROM for the UE (TGROM) and LE (THROM). Data was stratified by pitcher vs. position players, dominant (DOM) vs. non-dominant (NDOM) UE and LE. Normality was assessed using a Shapiro-Wilk test. Correlations between UE and LE ROM were analyzed utilizing Pearson correlations or Spearman-Rho correlations, as appropriate. Significance was set *a priori* at $p<0.050$. **RESULTS:** Pitchers demonstrated significant correlations between DOM GIR and DOM HIR (Correlation: 0.845, $P=0.017$), as well as between DOM GIR and NDOM HER (Correlation: 0.79, $P=0.034$). Pitchers also demonstrated correlations between DOM GIR and DOM THROM (Correlation: 0.770, $P=0.043$), as well as DOM GIR and NDOM THROM (Correlation: 0.785, $P=0.036$). Position players did not demonstrate any significant correlations between glenohumeral and hip ROM. **CONCLUSION:** Pitchers demonstrated significant correlations between glenohumeral and hip ROM, while position players did not. The positive correlation in pitchers may indicate that effective pitch performance is dependent on efficient coordination between the glenohumeral joint and hip. Proper hip ROM is necessary for an athlete to effectively transfer energy to the glenohumeral joint. Changes in hip ROM may lead to adaptations in glenohumeral ROM, both positive and negative; future research should focus on understanding these possible adaptations.

3152 Board #198 May 31 3:30 PM - 5:00 PM
Return To Play Testing In Individuals With ACL-Reconstructed Knees: Does Timing Of The Assessment Matter?

Stephan G. Bodkin, Margaret H. Rutherford, Stephen F. Brockmeier, David R. Diduch, Joseph M. Hart, FACSM. *University of Virginia, Charlottesville, VA.* (Sponsor: Joseph Hart, FACSM)
 Email: sgb3d@virginia.edu
 (No relevant relationships reported)

Context: Traditional return to play assessments following anterior cruciate ligament reconstruction (ACLR) identify large muscular deficits at 6 months post-surgery. This is concerning with majority of patients being cleared for sports on time alone. It is unknown if individuals post-ACLR show improved outcomes if assessed later than 6 months post ACLR. The purpose of this study was to examine patient function in individuals stratified by months post-ACLR. **Methods:** A total of 293 individuals with ACLR (23.2 ± 10.1 years, 142 Female, 6.4 ± 9 mo post-ACLR) participated in the study. Participants were stratified based on the timing of their evaluation in months since ACLR: 5-6 mo: $n=122$, 6-7 mo: $n=102$, 7-8 mo: $n=43$, 8-9 mo: $n=26$. Subjective knee function was assessed through the International Knee Documentation Committee (IKDC) Subjective Form. Mass-normalized maximal voluntary isometric contraction (MVIC) and limb symmetry indexes (LSI) were collected on knee extensor and flexor muscle groups. Non-parametric statistics were run due to violation of the assumption of normality. Measures of subjective and muscular function were compared through Kruskal-Wallis with *post-hoc* partial eta squared values for effect sizes.

Results: There were significant difference between the 5-6 mo. vs 6-7 mo groups ($\eta^2=.04$) and the 5-6 mo vs 8-9 mo groups ($\eta^2=.04$) for subjective function ($P=.04$). There were significant differences between the 5-6 mo vs 8-9 mo groups ($\eta^2=.07$) and the 6-7 mo vs 8-9 mo groups ($\eta^2=.04$) for MVIC Extension ($P=.14$). No differences were seen between groups for MVIC for knee extension ($P=.14$) or flexion ($P=.97$) or knee flexor LSI ($P=.60$) (Table 1).

Conclusions: There are significant differences which demonstrate progressively increasing subjective function and knee extension symmetry when tested at later timepoints from surgery. However, the observed values are low suggesting even at 9-months post ACLR patients are demonstrating deficits that may be improving.

Table 1: Between Group Differences: Median (IQR)

| Mo. Post-ACLR | 5-6 | 6-7 | 7-8 | 8-9 | P-Value | Effect Size (η^2) |
|------------------------|------------------------------------|-----------------------------------|----------------------|------------------------------------|--|--------------------------------------|
| IKDC | 79.7 ^{ab} (70.1, 88.5) | 83.9 ^a (74.5, 92.0) | 79.3 (73.6, 88.8) | 89.1 ^b (75.8, 92.3) | .019 ^a .026 ^b | .04 ^a .04 ^b |
| MVIC Extension (Nm/kg) | 1.46 (1.16, 1.87) | 1.60 (1.26, 2.03) | 1.59 (1.23, 2.07) | 1.65 (1.39, 2.05) | - | - |
| MVIC Flexion (Nm/kg) | .737 (.51, 1.01) | .76 (.59, .98) | .77 (.57, .89) | .66 (.51, 1.11) | - | - |

The Effect of Icing with Varying Degrees of Compression on Quadriceps Intramuscular Temperature

Stephen Mathew¹, Susan Y. Kwiecien¹, Glyn Howatson, FACSM², Malachy P. McHugh, FACSM¹. ¹Nicholas Institute of Sports Medicine and Athletic Trauma, Lenox Hill Hospital, New York, NY. ²Northumbria University, Newcastle upon Tyne, United Kingdom. (Sponsor: Malachy P McHugh, FACSM)
Email: susan@nismat.org
(No relevant relationships reported)

Clinically, compression is often applied in combination with ice. Amongst practitioners, elastic wrap is the most common type of external compression, while plastic wrap has become increasingly popular because it can be discarded without returning it to the treatment facility. However, few studies have investigated the magnitude of tissue cooling among different types of external compression applied to an ice bag.

PURPOSE: To evaluate and compare the cooling effectiveness of wetted ice bag applied with elastic wrap compression or held in place with plastic wrap but with no added compression on intramuscular and skin surface temperatures.

METHODS: Ten male participants (36±9 yo) received ice packs made with wetted ice applied simultaneously to a standardized area on the anterior aspect of the quadriceps for 30 minutes. The ice pack was secured with low compression (plastic wrap) to the right anterior thigh and high compression (elastic wrap) to the left anterior thigh. Skin and intramuscular (1 and 2 cm plus one-half skinfold measurement) temperatures of the vastus lateralis were measured continuously during a 10-minute baseline period, 30-minute treatment period, and a 60-minute recovery period.

RESULTS: Intramuscular temperatures decreased from baselines of 35.1 ± 1.1°C at 3 cm and 34.4 ± 1.3°C at 1 cm, to 23.1 ± 4.9°C at 3 cm and 17.8 ± 5.2°C at 1 cm by the end of the elastic compression treatment. Intramuscular temperatures decreased from baselines of 35.4 ± 0.9°C at 3 cm and 34.4 ± 0.9°C at 1 cm, to 24.5 ± 6.7°C at 3 cm and 17.9 ± 4.4°C at 1 cm by the end of the plastic wrap control treatment (Fig. 1). Although the mean difference between compression treatments was 45.1 ± 8.3 mm Hg ($P = 0.0001$), no difference was observed between treatments in terms of the magnitude of reduction in skin and intramuscular temperature at both 1 cm ($P = 0.475$) and 3 cm ($P = 0.421$) regardless of compression pressure.

CONCLUSIONS: The magnitude of temperature reduction was comparable using either elastic wrap with high compression or plastic wrap with minimal compression. Plastic wraps are a practical alternative for clinicians as they may be disposed of by the patient or athlete without having to stay at the treatment facility.

Impact of Musculoskeletal Injury and Pain in Lacrosse Officials: Implications for Clinical Care and Preparedness

Heather K. Vincent, FACSM¹, Michelle Bruner¹, Charlie Obermayer², Bruce Griffin³, Kevin R. Vincent, FACSM¹. ¹University of Florida, Gainesville, FL. ²US Lacrosse, Officials Development Program, Sparks, MD. ³US Lacrosse, Center for Sport Science, Sparks, MD.
Email: vincehk@ortho.ufl.edu
(No relevant relationships reported)

PURPOSE: Lacrosse officials come from different backgrounds, ages and training levels, but all function as athletes while refereeing. Anecdotal evidence shows that mild-to-severe musculoskeletal pain is common in this population. We need to understand the scope of the problem to help keep these adults active over the long-term and engaged in the sport. The purposes of this study were to: 1) determine the prevalence, location and impact of musculoskeletal pain, and 2) identify physical or training-related correlates of pain. **METHODS:** A specific anonymous survey was developed and distributed to members of the national US Lacrosse Officials Development Program and 1,441 were returned complete. Respondents were 52.0 ± 12.9 yrs, 79.5% male and 63.5% represented east coast regions. 51.1% never played lacrosse, and 37.8% of former players participated through post-collegiate years. Pain sites and severity (0-10 numerical pain rating), previous injuries and current impact of pain on officiating duties were captured. **RESULTS:** Pain was present in 18.1% - 40.1% of officials primarily at the foot, shoulder, back and knee. Pain severity during rest and exercise averaged 4.3 - 4.6/ 10 pts, respectively. A total of 437 officials reported diagnoses of osteoarthritis ([OA]; knee 48.7%, hip 10.5%, spine 10.1%, shoulder 8.0%) and 247 reported OA in more than one joint. Correlates of these pain symptoms included former lacrosse injury (22.6% have long-term pain today) and weight gain in last five years (r range = -.053-.186; all $p < .05$). Current participation in running as a sport was inversely related to pain symptoms. Officials with any diagnosis of OA more often reported frequent or continual difficulties with a) running the entire field distance, b) starting and stopping on the field, c) keeping pace, d) focusing on multiple actions of players at once, and e) enjoying the officiating duties than officials with no OA (Mann Whitney U tests all $p < 0.0001$). **CONCLUSION:** Officials are unrecognized athletes, and many may benefit from clinical care support at the field before, during and after games to help manage musculoskeletal pain, especially during regulation games or tournaments. Pain relief may translate to better engagement in lacrosse officiating duties, improvement in player safety and enjoyment of the officiating role.

3155 Board #201 May 31 3:30 PM - 5:00 PM

Age Related Error of the Measurement of the Tibialis Posterior Muscle via Ultrasound Imaging

Victoria A. Violette, Keisha V. Perkins, Christopher L. Thompson, A. W. Johnson. Brigham Young University, Provo, UT. (Sponsor: Pat Vehrs, FACSM)
(No relevant relationships reported)

PURPOSE: The tibialis posterior (TP) is a key muscle in controlling foot function and is associated with several lower extremity pathologies. Being able to assess the strength, activity and size of the TP across ages plays an important role in treating and understanding pathologies associated with the TP. It may be more difficult to image the TP of older individuals due to fatty infiltration and fibrosis. The purpose of this study evaluated the reliability of ultrasonic measurements of the TP in young and older adults. **METHODS:** Legs of 23 individuals (older (O) n=7; younger (Y) n=16) were imaged via ultrasound (6-15ML probe, GE Logiq S8) and the cross-sectional area (CSA) and thickness of the TP was recorded. To measure the TP, the probe was held at a point 30% and 50% between the knee joint line and the inferior tip of the lateral malleolus. Subjects inverted their foot and videos of the contraction cycle were recorded. Two separate still-shots of the muscle at rest were saved from the recorded videos at each location to make size measurements. This process was performed on both anterior and posterior sides of the leg. To assess reliability, intraclass correlation coefficients (ICC) and the standard error of the measurement (SEM) were calculated. An independent t-test was used to determine differences in the measurement error between age groups. **RESULTS:** The average TP CSA at the 30% point for the anterior view was 3.96 ± 1.05 cm², and the posterior was 4.00 ± 1.06; at the 50%, the anterior was 3.43 ± 1.09 cm², and the posterior was 3.55 ± 1.09. Excellent reliability was seen when comparing repeated measurements for anterior and posterior area and thickness measurements for both younger and older individuals (ICC=.937-.999), however, there was a significant difference in the SEM for TP thickness (O = 0.06 ± 0.02cm; Y = 0.035 ± 0.01cm, $p=.008$) and CSA (O = 0.11 ± 0.07cm; Y = 0.046 ± 0.01cm, $p=.02$). **CONCLUSIONS:** Repeated measurements showed excellent reliability in both groups. There was a greater error in the measurement in the older adults. Despite

showing excellent reliability, these results show that age does affect the accuracy of the measurement of the TP muscle size assessed by ultrasound imaging; however, it would also be beneficial to be able to assess quality of muscle tissue.

No Differences in Sub-Cortical Motor Region Activity for Knee Motor Control Following Anterior Cruciate Ligament Reconstruction
 Christopher Ballance¹, Dustin Grooms², James Onate¹. ¹The Ohio State University, Columbus, OH. ²Ohio University, Athens, OH.
 Email: ballance.4@osu.edu
 (No relevant relationships reported)

PURPOSE: Emerging research has indicated that anterior cruciate ligament reconstruction (ACL-R) is associated with neuroplasticity. It has been speculated that these findings may have future implications on rehabilitation and ACL-R outcomes. However, most of this research has focused on cortical plasticity rather than sub-cortical plasticity. The purpose of this project was to determine the effects of ACL-R on sub-cortical portions of the cortical-subcortical motor loop. **METHODS:** A healthy group of active participants (n=16, age=23.2±3.5 years, height=1.7±0.1 m, weight=69.7±14.3 kg) and a left ACL-R group (n=15, age=21.7±2.7 years, height=1.7±0.1 m, weight=70.4±15.8 kg, 38.1±27.2 months' post-surgery) were locally recruited. Functional magnetic resonance imaging (fMRI) and T1 structural imaging were performed to analyze brain activation during a unilateral left (involved) 45° knee extension/flexion at a rate of 1.2 Hz for 4 blocks of 30 seconds interspersed with 30 seconds of rest. The right putamen and right sub-thalamic nuclei (STN) served as seed regions, and the two groups were contrasted using a mixed-effects general linear model with a *a priori* cluster threshold of p<.05. **RESULTS:** Compared to the control group, the ACL-R group displayed no differences in right putamen and right STN activation during the unilateral motor task. **CONCLUSION:** These results indicate that ACL-R may not influence the motor control loop at the sub-cortical level. Therefore, motor control and motor learning, as it relates to the subcortical structures, may not be affected by ACL-R. As a result, neurorehabilitation after ACL-R should use priming techniques to target specific cortical regions that previous studies have indicated as being affected by ACL-R.

Performance and Return to Sport Following Latissimus Dorsi and Teres Major Tears in Professional Baseball Pitchers
 Kevin Ma¹, Brandon Erickson², Peter Chalmers³, John D'Angelo¹, Anthony Romeo². ¹MLB, New York, NY. ²Rothman Orthopaedic Institute, Tarrytown, NY. ³University of Utah, Salt Lake City, UT.
 Email: Brandon.Erickson@rothmanortho.com
 (No relevant relationships reported)

Purpose: Determine the performance and return to sport (RTS) rate in professional baseball pitchers following LD/TM tears treated operatively and non-operatively, and to compare RTS rate and performance between pitchers who sustained a LD/TM tear and matched controls. The authors hypothesize there is a high RTS rate in professional baseball pitchers following LD/TM tears with no significant difference in RTS rate or performance, specifically related to primary outcome performance variables: WHIP ((walks +hits)/innings pitched), fielding independent pitching (FIP), and wins above replacement (WAR)) between cases and controls for both operative and non-operative treatment. **Methods:** All professional baseball pitchers who sustained a LD/TM tear between 2011-2016 were included. Demographic and performance data (pre and post injury) for each player was recorded. Performance metrics were then compared between cases and matched controls within both operatively non-operative treatment. **Results:** Overall, 120 pitchers had a documented LD/TM tear; (42 (35%) were major league players). Most players (107 (89.2%)) were treated non-operatively. Average time to return to the same level of competition for pitchers treated non-operatively was 170.7 +/- 169.7 days while for those treated operatively was 406 +/- 146.83 days. The RTS rate among players treated non-operatively and operatively was identical at 75%. Players treated non-operatively had no change in FIP or WAR following injury but had a higher (i.e. worse) WHIP after injury (p=0.039), and performed significantly worse in several secondary performance metrics, including number of games played per year (p<0.001). Players treated operatively had no change in any measured performance metrics following surgery. No difference existed between cases and controls in the primary performance variables. **Conclusion:** LD/TM tears occur more frequently in professional pitchers than previously recognized and reported. The majority of LD/TM tears are treated non-operatively. RTS rate for professional baseball pitchers following LD/TM tears treated operatively or non-operatively is 75%. Players treated non-operatively saw a decline in several performance metrics while players treated operatively had no significant difference in performance after surgery.

Characterizing the Prevalence of Cam-Type Hip Impingement in Women's Professional Ice Hockey Players
 Cordelia W. Carter, Darryl Whitney, Matthew Kingery, Samuel Baron, Guillem Gonzalez-Lomas. NYU-Langone Medical Center, New York, NY.
 Email: cordeliawcarter@gmail.com
 (No relevant relationships reported)

Purpose Recent studies have demonstrated an increased prevalence of femoroacetabular impingement (FAI) in elite men's ice hockey players, yet little is known about the hips of players in the National Women's Hockey League (NWHL). The primary purpose of this study was to determine the prevalence of radiographic cam-type FAI in women's professional ice hockey players. The secondary purpose was to analyze the relationship between the presence of cam deformity and hip ROM; clinical impingement signs; and age of menarche. **Methods** Clinical, radiographic and demographic data were collected for NWHL players during pre-participation physicals. Alpha angles were measured on 45° Dunn radiographs, with alpha angles >55° defined as cam-positive. Spearman correlations were performed to analyze the relationship between alpha angle and both ROM measurements and menarchal age. Players were grouped into those with and without cam lesions and group differences were assessed using the student's t-test. **Results** Twenty-seven athletes were included. Nineteen (70%) had alpha angles >55°; 14 (52%) had bilateral cam deformity. Average menarchal age was 13.9 ±1.5 years. There was a significant association between age of menarche and alpha angle (right hips, p=0.01; left hips, p=0.04). There was no significant association between alpha angle and either hip ROM or clinical impingement signs. **Conclusion** This study suggests that elite female ice hockey players have a higher prevalence of cam-type morphology than the general population. The positive association between alpha angle and age of menarche lends additional support to the etiological hypothesis of the cam lesion resulting from activity-related stress at the proximal femoral physis; players with earlier menarche (and therefore earlier physeal closure) seem to be less vulnerable to the development of cam deformity of the proximal femur. Thus, professional women's ice hockey players have a high risk of developing cam-type morphology of the proximal femur, although each player's age of menarche may mediate her individual risk for cam lesion development.

Clinical Outcomes of Ultrasound-Guided Percutaneous Patellar Tendon Scraping
 Evan Plunkett, Michael Baria, Meghan Miller, Robert Magnussen. Ohio State University, Columbus, OH.
 (No relevant relationships reported)

Purpose: To report the clinical outcomes of patients with patellar tendinopathy treated with ultrasound-guided percutaneous patellar tendon scraping. **Methods:** Design: Retrospective case series
 Setting: Academic sports medicine clinic
 Patients: Nine patients with patellar tendinosis (total of 10 tendons). Six patients had primary patellar tendinosis and three had persistent pain despite surgery. Mean age was 21.2 years old. Four were competitive athletes, 4 were recreational athletes and 1 has ceased sport participation.
 Interventions: All patients underwent ultrasound-guided patellar tendon scraping using a 14-gauge needle, followed by a brief rehabilitation period before returning to sport.
 Main Outcome Measures: Patient reported outcome measures (PROM), including the Victoria Institute of Sport Assessment Questionnaire-Patellar Tendon and Lower Extremity Functional Scale; time to return to sport and; adverse events.
Results: All patients with primary patellar tendinosis met the minimal clinically important difference (MCID) for their PROM with 1 patient experiencing a symptom relapse. The average time to return to competitive sport was 2.67 weeks. In the post-surgical group, one of the three patients experienced a significant clinical improvement durable for 16 months. No adverse events were reported for any patient.
Conclusions: Ultrasound-guided percutaneous patellar tendon scraping may result in improved patient-reported outcome scores and facilitate a safe, rapid return to sports in cases of primary patellar tendinopathy. Results were less reliable for persistent pain after surgery.

Initial/Repeat Triamcinolone Acetonide Extended-Release (TA-ER) Reduces Osteoarthritis Knee Pain Regardless of Prior Intra-Articular Corticosteroids (IACS)

Kim M. Huffman¹, John Richmond², Andrew Spitzer³, Andreas Gomoll⁴, Deryk G. Jones⁵, Virginia B. Kraus¹, Amy Cinar⁶, Joelle Lufkin⁶, Scott Kelley⁶. ¹Duke University School of Medicine, Durham, NC. ²New England Baptist Hospital, Dedham, MA. ³Cedars-Sinai Orthopaedic Center, Los Angeles, CA. ⁴Hospital for Special Surgery, New York, NY. ⁵Ochsner Sports Medicine Institute, Harahan, LA. ⁶Flexion Therapeutics, Inc., Burlington, MA. (Sponsor: 7960, FACSM)
Email: kim.huffman@duke.edu

(No relevant relationships reported)

PURPOSE: Repeat IACS are common in the management of knee osteoarthritis (OA), but efficacy may diminish over time, and recurrent use has been associated with articular damage. This post hoc analysis of a Phase 3b, single-arm, open-label study was designed to evaluate repeat injection of TAER in patients with knee OA who had received prior IACS. **METHODS:** Patients ≥40 y with symptomatic knee OA for ≥6 mo received the 1st TA-ER injection on Day 1 and the 2nd injection at the first visit (Wk 12, 16, 20, or 24) at which repeat dose criteria were met (benefit from and tolerated the 1st injection without safety concerns and clinical indication to receive the 2nd injection). Patients who received 2 injections were evaluated every 4 wks up to 52 wks after the 1st injection. Treatment-emergent adverse events (TEAEs) and index knee radiography were evaluated. Exploratory efficacy endpoints included Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) A (pain). **RESULTS:** Of 208 enrolled patients, 179 received 2 injections. Of these, 95 (53.1%) had prior index knee IACS. Median time to 2nd injection was 16.4 wks (prior IACS) and 16.9 wks (no prior IACS); in both subgroups ~20% did not need the 2nd injection until Wk 24. Mean WOMAC-A scores were comparable in both groups and decreased ~50-75% following each injection (Figure). Incidences of serious and Grade 3/4 TEAEs were low and similar in both groups. There were no indications of chondrolysis, osteonecrosis, subchondral insufficiency fractures, or clinically significant subchondral bone changes in either group. **CONCLUSION:** TA-ER provided substantial analgesia for 12-24 wks postinjection that did not diminish with repeat administration and/or prior IACS use. Safety profiles were consistent with the overall population and previous reports. TA-ER may be a potential long-term nonoperative management strategy for knee OA pain.

Figure. Comparison of mean WOMAC-A (pain) scores following the 1st and 2nd TA-ER injections for patients with and without prior index knee IACS.

IACS, intra-articular corticosteroid; TA-ER, triamcinolone acetonide extended-release; WOMAC, Western Ontario McMaster Universities Osteoarthritis Index.

Acute and Longitudinal Effects of Pitching on Passive Range of Motion in Division I Athletes

Jacob D. Jelmini, Michael P. Price, Casey J. Meyer, Lori D. Greenwood. Texas A&M University, College Station, TX.
Email: jjelmini@tamu.edu

(No relevant relationships reported)

PURPOSE: To assess passive range of motion (ROM) measurements acutely over time and how this acute change alters over the course of a baseball season. **METHODS:** Seven healthy male NCAA Division I baseball pitchers were measured prior to the start of the season. Each pitcher was assessed for passive shoulder and elbow ROM, with measurements taken after each pitching bout during the season.

Pitching bouts were allotted to early season, mid-season, or late season. In addition to ROM measurements, pitch volume, pitch type, and ball velocity were also collected for analysis.

RESULTS: Following a pitching bout, passive shoulder external rotation decreased by 7% ($p = 0.000$) during the early season. However, passive shoulder internal rotation was significantly reduced during the early season (-37%; $p = 0.001$), mid-season (-30%; $p = 0.000$), and late season (-42%; $p = 0.000$). Further, total motion also decreased during the early season (-12%; $p = 0.000$), mid-season (-6%; $p = 0.000$), and late season (-9%; $p = 0.000$). In terms of pitch type, increasing the volume of fastballs thrown had a moderate correlation with loss of passive shoulder external rotation during the late season ($r = -0.705$). Increasing the volume of curveballs thrown had a moderate correlation with total motion lost during the late season ($r = -0.665$) as well as with passive elbow extension lost during mid-season ($r = -0.760$).

CONCLUSIONS: Passive ROM is significantly impacted immediately after throwing. This decrease continues to be present throughout all parts of the baseball season. Moreover, a moderate correlation of fastballs and curveballs to losses in passive ROM indicates that attention to pitch type may be warranted, particularly during the middle and latter parts of the baseball season.

Long-Term Characteristics of Injured Shoulders in Overhead Sports: A Gender Comparison

Youngwook Kim¹, Adam B. Rosen². ¹Utah State University, Logan, UT. ²University of Nebraska at Omaha, Omaha, NE.
Email: ywkimac@gmail.com

(No relevant relationships reported)

Overhead sports require high levels of mobility and force produced by the shoulder joint. Additionally, gender differences in glenohumeral joint mobility and upper extremity strength are apparent in various athletic populations. Previous studies have found relationships in shoulder range of motion (ROM) and strength in several shoulder injuries. However, data are lacking regarding the long-term effects of shoulder injuries and considerations with respect to gender. **PURPOSE:** To determine the long-term effects of shoulder injuries on shoulder ROM and strength and examine gender differences in collegiate overhead athletes. **METHODS:** 35 male (age: 20.3 ± 1.2 yr, mass: 84.1 ± 9.7 kg) and 25 female (age: 19.6 ± 0.8 yr, mass: 70.8 ± 10.9 kg) overhead athletes fully participating in NCAA division I baseball, softball, volleyball, or tennis were recruited and divided into injury history group and healthy group depending on the existence of a history of shoulder injury. Active ROM of shoulder internal rotation (IR), external rotation (ER) and horizontal adduction (HAD) were measured using a digital inclinometer. Isometric shoulder IR and ER strength were assessed using a hand-held dynamometer and normalized by body mass. A two (group) by two (gender) factorial ANOVA was used to evaluate the dominant shoulder ROM and strength. Cohen's d effect sizes were calculated to assess the magnitude of differences. **RESULTS:** Females showed significantly lower IR ROM ($p = .03$, $d = 0.88$), IR strength ($p = .04$, $d = 0.83$), and ER strength ($p = .04$, $d = 0.86$) in the injury history group versus the healthy group, whereas there were no group differences in males ($p > .05$). Additionally, male overhead athletes had lower IR ($p = .01$, $d = 0.67$) and HAD ROM ($p = .01$, $d = 0.85$) and greater IR strength ($p = .02$, $d = 0.64$) compared to female overhead athletes. **CONCLUSION:** The results of this study indicate that shoulder injuries may have longer-lasting effects in female overhead athletes compared to male athletes. Furthermore, male overhead athletes demonstrated larger differences in posterior shoulder tightness and rotator cuff strength imbalances compared to female overhead athletes. This study may have significant implications for protocols aimed at preventing shoulder reinjury for specific genders in overhead sports.

Skin Combatibility with 3d Printed Splints And Casts

Diana Hall¹, Dean Miller¹, Suprit Singh², Yue Li³, Bill Bentley³, Lex Schultheis³. ¹ActivArmor, Pueblo, CO. ²University of Central Florida School of Medicine, Orlando, FL. ³University of Maryland, College Park, MD.
Email: diana.hall@activarmor.com

(No relevant relationships reported)

PURPOSE: 3D printed limb orthotics offer hygienic advantages over traditional technology because no padding is needed. We investigated biocompatibility and chemical profile of 3D printed material in contact with skin. **METHODS:** Patient-specific 3D printed ABS polymer casts from multiple sources of feedstock were evaluated according to ISO 10993 standards used by FDA for review of biocompatibility. The effect of post-processing with acetone vapor was evaluated as an independent variable. Cytotoxicity testing using L929 fibroblast reactivity, sensitization by Kligman Maximization methods in Guinea Pigs and irritation evaluation by intracutaneous injection in New Zealand White Rabbits of 3D print extractions were conducted under GLP conditions. In addition, mass spectrometry of filament feedstock and 3D printed casts was performed on solvent extractions using DART methods. **RESULTS:** Finished casts met criteria for permanent contact with skin

and limited contact with mucosal membranes. Mass spectrometry findings indicated that changes in ABS polymer occurred with 3D printing and post-processing in both surface and internal chemistry.

However, these chemical changes did not compromise biocompatibility assessed under ISO 10993. **CONCLUSIONS:** Patient-specific 3D printed, ABS orthotics met industry standards for biocompatibility for extended patient skin contact despite changes in material chemistry from feedstock. Therefore, testing and adherence to specific manufacturing controls is necessary to assure patient safety. Mass spectrometry assessment of composition of ABS polymers may serve to continually monitor product quality of 3D printed medical devices in accordance with 21 CFR 820.30.

This work was supported in part by a CERSI grant to University of Maryland from the US FDA (U01FD005946A). Its contents are solely the responsibility of the authors and do not necessarily represent the official views of the HHS or FDA.

Pubertal Timing is Not Related to Anterior Cruciate Ligament Laxity in Young Adults.

Matthew Diehl, Andrew Froehle, Joseph Cox, Jedediah May, Sarah Kreul. *Wright State University Boonshoft School of Medicine, Dayton, OH.*
Email: diehl.27@wright.edu

(No relevant relationships reported)

Females sustain ACL injuries more often than males, especially among physically active adolescents and young adults. Studies suggest that increased estrogen during the ovulatory phase of the menstrual cycle is related to ephemeral increases in ACL laxity, and thus elevated injury risk. These hormonal factors may partially explain the sex-bias in injury risk, since males do not experience the same estrogen spikes and thus avoid these bouts of elevated risk. Little is known, however, about how variability in estrogen exposure within females affects inter-individual differences in injury risk. One factor that may play a role in cumulative estrogen exposure is age at menarche, since it relates to total number of cycles experienced. Our prior work shows links between age at menarche, pubertal growth patterns, and biomechanical risk for ACL injury. It is possible that age at menarche also has an impact on ACL injury risk through effects on laxity.

Purpose: To determine if age at menarche is related to female ACL laxity.

Methods: Subjects were recreationally active undergraduate and medical school females (N=15) and males (N=20). Males served as a control group, in which pubertal development timing was assessed as age at achieving adult height (recall). Age at menarche and current menstrual status in females were assessed by recall questionnaire. Telos™ stress radiography was used to assess ACL laxity. Statistical analysis consisted of an independent samples t-test to compare laxity in males and females. Linear regression analysis was used to determine whether laxity was related to pubertal timing within each sex.

Results: The t-test found no significant sex difference in ACL laxity (female mean \pm SD = 3.0 ± 1.8 mm; male mean \pm SD = 3.7 ± 1.7 mm; $P = 0.26$). In males, regression analysis demonstrated no relationship between age at achieving adult height and knee laxity: slope = -0.03 (95% CI: $-0.38 - 0.31$); intercept = 4.34 (95% CI: $-1.60 - 10.39$); $r^2 = 0.003$; $P = 0.83$. Similarly, females exhibited no relationship between knee laxity and age at menarche: slope = -0.17 (95% CI: $-0.95 - 0.61$); intercept = 5.15 (95% CI: $-4.87 - 15.16$); $r^2 = 0.02$; $P = 0.65$. The absence of regression relationship persisted after controlling for current menstrual cycle status.

Conclusion: ACL laxity in females appears to be unrelated to age at menarche.

Accuracy of Ultrasound Imaging of the Lisfranc Joint Complex

Meridith K. DeLuca, Bryant Walrod, Laura C. Boucher. *The Ohio State University, Columbus, OH.*
Email: deluca.84@osu.edu

(No relevant relationships reported)

Lisfranc injuries account for 1 in 55,000 injuries yearly and are associated with poor outcomes and high complication rates. Superficially connecting the medial

cuneiform and second metatarsal, the dorsal Lisfranc ligament is easily visualized with ultrasound. Ultrasound can provide quick, cost effective diagnosis but is not currently standard in clinical practice.

PURPOSE: This study sought to compare measurement accuracy of the dorsal Lisfranc ligament using ultrasound, external software, and gross anatomic dissection, with an additional anatomic study of the joint complex. **METHODS:** Ultrasound images of 22 embalmed cadaveric feet (13 male, 9 female, 79.5 ± 13.3 years) were obtained using a 6-13MHz linear array. Dorsal Lisfranc ligament length and joint space were measured and compared between methodologies.

Images were also re-measured using ImageJ software. Specimens were dissected to evaluate dorsal, interosseous, and plantar Lisfranc ligaments. Joint complex morphology was documented. **RESULTS:** Ultrasound (8.39 ± 1.26 mm) and ImageJ measurements (8.26 ± 1.76 mm) of the dorsal Lisfranc ligament did not differ significantly, but both were significantly different ($p < 0.05$) than gross dissection (10.8 ± 1.84 mm). There were no significant differences in dorsal joint space measures between ultrasound (2.19 ± 0.49 mm) and ImageJ (2.05 ± 0.52 mm), but both were significantly different ($p < 0.05$) than dissection measurements (1.04 ± 0.24 mm).

The dissected dorsal and interosseous ligaments had consistent morphology, whereas the plantar ligament demonstrated a Y- and a fan-shaped variant. A connection between the interosseous and plantar ligaments was present in 64% of dissections.

CONCLUSION: The dorsal Lisfranc ligament is easily visualized on ultrasound with 23% of the ligament not clearly visible at the peripheral bony attachments. While visually underrepresented on ultrasound, measurements were consistent. Radiographic joint space measurement remains the diagnostic gold standard. Further research should focus on using ultrasound to measure both bony and ligament integrity.

Ligament echogenicity provides additional diagnostic information to assess more subtle joint injuries. Additionally, the plantar Lisfranc ligament variability may impact the stability of the joint in some patients.

Impact of Aerobic and Resistance Exercise on Global Shoulder Function in Breast Cancer Survivors

Frank C. Sweeney¹, Wendy Demark-Wahnefried², Kerry S. Courtney³, Nathalie Sami¹, Kyuwan Lee¹, Debu Tripathy⁴, Thomas A. Buchanan¹, Darcy Spicer¹, Leslie Bernstein⁵, Joanne Mortimer⁵, Christina M. Dieli-Conwright, FACS¹. ¹University of Southern California, Los Angeles, CA. ²University of Alabama at Birmingham, Birmingham, AL. ³University of Alberta, Edmonton, AB, Canada. ⁴The University of Texas, MD Anderson Cancer Center, Houston, TX. ⁵City of Hope National Medical Center, Duarte, CA. (Sponsor: Christina Dieli-Conwright, FACS¹)

(No relevant relationships reported)

Purpose: Treatment strategies for breast cancer including surgery, radiation, endocrine therapy and chemotherapy have contributed to improving survival rates. However, the implementation of surgical and radiation therapies precipitates adverse musculoskeletal effects in the upper extremity (UE), including decreased shoulder range of motion (ROM), weakness, and chronic pain, with 67% of breast cancer survivors (BCS) reporting upper extremity problems. The purpose of this exploratory analysis of a randomized, controlled trial was to investigate the effects of a 16-week aerobic and resistance exercise intervention on the functional mobility of the UE in BCS.

Methods: BCS were randomized to the Exercise (EX; N=50) or Control (CON; N=50) groups. The EX group underwent moderate-to-vigorous aerobic and resistance exercise sessions 3 times/week for 16 weeks. Functional mobility was assessed pre- and post-intervention by active ROM, maximal isometric voluntary strength, the Disabilities of Arm, Shoulder and Hand (DASH) questionnaire, and the Penn Shoulder Scale (PSS). Repeated-measures analyses of variance were used to compare pre- and post-intervention data in the two groups and assess between group differences.

Results: Included BCS were 53.5 ± 10.4 years old, Hispanic white (55%) with body mass index 33.5 ± 5.5 kg/m². Participants were treated with surgery (79% mastectomy) and both chemotherapy and radiation therapy (76%), including breast alone (55%) or breast + nodal radiation (45%). At baseline, EX and CON did not differ on functional mobility measures ($p > 0.05$). Post-intervention, the EX group experienced statistically significant improvements in active ROM (shoulder flexion, external rotation at 0°/90°), isometric strength (shoulder flexion, external rotation, internal rotation and horizontal adduction) and DASH/PSS scores when compared to their baseline measures ($p < 0.001$) and to the CON group ($p < 0.001$). The CON group did not experience any changes ($p > 0.05$).

Conclusions: A 16-week aerobic and resistance exercise program is associated with improved functional mobility of the UE. Clinical exercise programs should be incorporated into current rehabilitation oncology practice as a means of improving global shoulder function following breast cancer treatment.

(No relevant relationships reported)

Previous data have found that breast cancer survivors (BCS) have poorer body composition, strength, and physical function compared to age and weight matched controls. Whether these changes improve over time after treatment remains uncertain. **PURPOSE:** To compare body composition, strength, and physical function between short-term (ST; <4 years; n=17; age=57±9 yrs) and long-term (LT; >4 years; n=24; age=62±7 yrs) BCS. **METHODS:** Body composition [lean mass (LM), fat mass (FM)] was assessed using dual-energy X-ray absorptiometry. Lower body strength was assessed using the Biodex leg extension/flexion system at 60 ° isometric knee extension. Upper body strength was assessed using one repetition maximum chest press. Physical function was measured using the continuous-scale physical function performance test. Independent t-tests were used to compare ST and LT-BCS. Significance was accepted at $p \leq 0.05$. **RESULTS:** Time since treatment completion was 1.8±1.0 yrs for ST and 11.8±6.9 yrs for LT. There were no differences in body weight, LM, FM, and upper and lower body strength between groups. Total physical function (ST:64±14; LT:73±11 U) and the functional domains for endurance (ST:66±15; LT:75±12 U) and balance (ST:65±15; LT:75±12 U) were significantly lower in ST-BCS. **CONCLUSION:** Our findings indicate that without exercise, body composition and strength do not improve whereas physical function improves over time following treatment. Funding: ACSM Doctoral Student Grant; NSCA Doctoral Graduate Student Research Grant.

Effects of High-Intensity Interval Training on Body Composition in Breast Cancer Patients Undergoing Anthracycline Chemotherapy

Ellice Wang¹, Kyuwon Lee², Christina M. Dieli-Conwright, FACSM². ¹Keck School of Medicine, Los Angeles, CA. ²University of Southern California, Los Angeles, CA. (Sponsor: Christina M. Dieli-Conwright, FACSM)
(No relevant relationships reported)

Purpose: While widely used in breast cancer patients, anthracyclines induce multiple adverse side effects, including weight gain and muscle atrophy. High intensity interval training (HIIT) is a novel exercise method that improves glucose metabolism, cardiorespiratory fitness and body composition in less exercise time than traditional continuous aerobic exercise in the general population. However, the effects of HIIT on body composition when performed during chemotherapy are unknown. The purpose of this study was to examine the effects of HIIT on body composition in breast cancer patients undergoing anthracycline chemotherapy.

Methods: Thirty sedentary breast cancer patients diagnosed with stage I-III breast cancer were randomized to exercise (HIIT=15) or control (CON=15) groups. HIIT performed 3 exercise sessions per week on stationary bike for 8 weeks during anthracycline chemotherapy. Exercise intensity was individually prescribed based on peak power output (PPO) and each HIIT session included 7 alternating bouts of 90% of peak power output followed by 10% peak power output. CON was asked to maintain current levels of activity. Lean mass and fat mass were obtained at baseline (wk0) and post-treatment (wk9) from the InBody 770 bioelectrical impedance scale (Biospace, Cerritos, California). Paired t-test and repeated ANOVA were used to determine effects of HIIT on body composition within and between the two groups.

Results: At baseline, HIIT and CON groups did not differ by age (46.9±9.8yr) or BMI (31.0±7.5 kg/m²). Following 8 weeks, body composition did not significantly change in either group ($p > 0.05$). Fat mass slightly decreased in the HIIT (wk0: 37.8±13.8kg to wk9: 35.4±13.4kg, $p > 0.05$) and CON (wk0: 30.2 ± 12.6kg to wk9: 29.4±13.7kg, $p > 0.05$) groups. Lean mass slightly increased in the HIIT group (HIIT: wk0: 44.0±6.4kg to wk9: 44.7±6.4kg, $p > 0.05$) and did not change in the CON group (wk0: 44.3±8.8kg to wk9: 44.2±8.5kg, $p > 0.05$).

Conclusions: An 8-week HIIT intervention did not improve body composition in obese breast cancer patients undergoing anthracycline therapy. Longer duration interventions with a larger sample must be explored to elucidate the benefits of HIIT on body composition in this population.

Relationship Between Accelerometer Output And Oxygen Consumption In Patients With Breast Cancer After Chemotherapy Treatment

Laurien M. Buffart¹, Maïke G. Sweegers¹, Rosalie Huijsmans¹, Johannes Brug², Mai J. Chin A Paw¹, Teatske M. Altenburg¹. ¹Amsterdam UMC, Amsterdam, Netherlands. ²National Institute for Public Health and the Environment, Bilthoven, Netherlands.
Email: l.buffart@vumc.nl
(No relevant relationships reported)

PURPOSE: Currently used accelerometer cut-points to identify different intensities of physical activity are validated in the healthy population. These cut-points may not be applicable to patients with cancer due to lower fitness levels or different energy expenditure in rest. We aimed to examine the relationship between oxygen consumption and accelerometer output during different controlled activities in women with breast cancer shortly after completion of chemotherapy treatment.

METHODS: Forty women aged 50.4 (SD 9.5) years who completed chemotherapy treatment for breast cancer two to four months ago participated in this laboratory study. A cardiopulmonary exercise test was conducted to assess peak oxygen consumption (peakVO₂). Oxygen consumption in rest was assessed while lying supine for 6 minutes. Subsequently, nine activities with different intensities were performed while wearing an accelerometer on the right hip, and during which oxygen consumption was assessed. The relationship between oxygen consumption (expressed as percentage of peakVO₂) and Metabolic Equivalent of Task (MET) value) and accelerometer output (in counts per minute (cpm)) was studied with linear regression analyses.

RESULTS: PeakVO₂ was 21.5 (SD 6.1) mL/kg/min. Oxygen consumption in rest was 3.1 (SD 0.6) mL/kg/min. The accelerometer output corresponding to the cut-points for low versus moderate (40% peakVO₂) and moderate versus vigorous (60% peakVO₂) intensity physical activity were 1100 and 1868 cpm, respectively. The analyses based on MET values resulted in a cut-point of 1172 cpm to distinguish between low and moderate intensity physical activity (3 MET) and a cut-point of 2689 cpm to distinguish between moderate and vigorous intensity physical activity (6 MET).

CONCLUSIONS: The accelerometer cut-points to distinguish different physical activity intensities were lower than cut-points validated in the general population (i.e. 1952 cpm for moderate and 5724 cpm for vigorous intensity). This finding was irrespective of the method used to express oxygen consumption (%peakVO₂ versus MET). This study demonstrates that the use of accelerometer cut-points validated in the general (healthy) population underestimates the physical activity intensities in patients with breast cancer after chemotherapy treatment.

Community-Based Exercise Improves Cancer-Related Fatigue and Physical Fitness In Breast Cancer Survivors: A Preliminary Analysis

Chad W. Wagoner, Jordan T. Lee, Stephanie A. Sullivan, Erik D. Hanson, Brian C. Jensen, Lee Stoner, FACSM, Aaron Piepmeier, Kirsten A. Nyrop, Hyman B. Muss, Claudio L. Battaglini, FACSM. University of North Carolina at Chapel Hill, Chapel Hill, NC. (Sponsor: Claudio Battaglini, FACSM)
(No relevant relationships reported)

PURPOSE: A preliminary analysis was conducted to examine the potential impact of a community-based exercise program to improve cancer-related fatigue (CRF) and markers of physical fitness in breast cancer survivors (BCS) who were within a year of post primary treatment. **METHODS:** Ten early stage (I-III) BCS were included in the analysis (58 ± 11 years; 168.8 ± 7.5 cm; 74.7 ± 20.5 kg). Pre and post intervention assessments were completed for CRF via the PROMIS Fatigue 7a questionnaire, VO_{2peak}, lower and upper body strength, and subendocardial viability (SEVR). A 6-Minute Walk Test (6MWT) and Timed Up and Go (TUG) were completed to assess physical function. Participants aerobically trained on their choice of elliptical, treadmill, or stationary bike, progressively increasing intensity over the 16-weeks. Resistance training consisted of full-body circuits targeting major muscle groups. Training took place 3 days/week for 1 hour each day. **RESULTS:** CRF (-6.0 ± 3.5; $p < 0.001$), 6MWT (50.3 ± 46.5 m; $p < 0.01$), and SEVR (6.25 ± 8.3; $p < 0.05$) all significantly improved in response to the exercise intervention. VO_{2peak}, lower and upper body strength, and TUG showed small but nonsignificant improvements. Further analyses elicited inverse associations between changes in CRF and 6MWT ($r = -0.60$; $p = 0.05$) as well as CRF and SEVR ($r = -0.40$; $p = 0.25$). **CONCLUSIONS:** Preliminary analyses revealed that a community-based exercise program is effective in improving CRF while either maintaining or improving other markers of physical fitness. Community-based exercise programs have the potential to be viable alternatives for treating BCS who are presently experiencing CRF. Future studies are needed to explore relationships among CRF and markers of physical fitness as they could provide insight into potential underlying mechanisms driving CRF. Supported by funding from the Breast Cancer Research Foundation of New York.

The 24-month Follow-up Of The Optitrain Exercise Rct For Women With Breast Cancer Undergoing ChemotherapyKate A. Bolam, Sara Mijwel, Natalie Holowko, Jonas Bergh, Helene Rundqvist, Yvonne Wengström. *Karolinska Institutet, Stockholm, Sweden.*

Email: kate.bolam@ki.se

(No relevant relationships reported)

In the earlier OptiTrain randomized controlled exercise trial, we found beneficial effects of two different exercise programs on health and treatment related outcomes. **PURPOSE:** The aim of this study was to report on cancer-related fatigue (CRF), quality of life (QoL), symptoms, muscle strength, cardiovascular fitness, body mass and physical activity levels of women with stage I-IIIa breast cancer who had been involved in the OptiTrain exercise RCT, 24 months from baseline. **METHODS:** The original 16-week, supervised exercise program was a three-armed, randomized controlled trial comparing the effects of a combined program of resistance training and high intensity interval aerobic training (RT-HIIT) or a combined program of moderate intensity and HIIT aerobic exercise (AT-HIIT) to usual care among 240 women with breast cancer undergoing chemotherapy. At 24 months, 117 and 155 participants participated in the in-clinic tests and completed the self-report questionnaires, respectively. We assessed CRF, QoL, symptoms, muscle strength, estimated cardiorespiratory fitness, body mass and objectively measured sedentary behaviour and physical activity. Analyses included mixed linear effects model analyses. **RESULTS:** RT-HIIT reported lower levels of total CRF (-1.37, 95% confidence interval (CI) -2.70, -0.04, effect size (ES) = -0.38), cognitive CRF (-1.47, 95% CI -2.75, -0.18, ES = -0.44), physical symptoms (-0.23, 95% CI -2.70, -0.00, ES = -0.29) but higher muscle strength (12.09, 95% CI 3.77, 20.40, ES = -0.51) than UC at 24 months. Whereas AT-HIIT reported lower total symptoms (-0.23, 95% CI -0.42, -0.03, ES = -0.29), symptom burden (-0.30, 95% CI -0.60, -0.01, ES = -0.08 (no effect)) and body mass (-2.15, 95% CI -3.71, -0.60, ES = -0.28) than UC at 24 months. **CONCLUSIONS:** The RT-HIIT group from the OptiTrain exercise RCT reported lower levels of total and cognitive CRF, and physical symptoms but higher muscle strength at 24 months, whereas, the AT-HIIT group reported lower total symptoms, and body mass at 24 months. The clinically relevant ES in muscle strength in the RT-HIIT is particularly encouraging given the importance of muscle strength as a predictor of many relevant health outcomes. While these results are promising, effect sizes range from small to medium and the results must therefore be interpreted with caution.

3172 Board #218 May 31 3:30 PM - 5:00 PM

Effects Of Exercise Training During Breast Cancer Chemotherapy On Fitness Outcomes At 1-year Follow-upAndria R. Morielli¹, Ki Yong An¹, Dong-Woo Kang¹, Christine M. Friedenreich², Donald C. McKenzie³, Karen Gelmon⁴, John R. Mackey⁵, Robert D. Reid⁶, Kerry S. Courneya¹. ¹University of Alberta, Edmonton, AB, Canada. ²Alberta Health Services, Calgary, AB, Canada. ³University of British Columbia, Vancouver, BC, Canada. ⁴University of British Columbia & British Columbia Cancer Agency, Vancouver, BC, Canada.⁵Cross Cancer Institute, Edmonton, AB, Canada. ⁶University of Ottawa Heart Institute, Ottawa, ON, Canada.*(No relevant relationships reported)*

PURPOSE: To determine the effects of different doses and types of exercise during breast cancer chemotherapy on fitness outcomes at 1-year follow-up and to investigate the associations of physical activity during the follow-up period with fitness outcomes. **METHODS:** The Combined Aerobic and Resistance Exercise (CARE) Trial was a multicenter trial in Canada that randomized 301 breast cancer patients initiating chemotherapy to 3 days/week of supervised exercise consisting of either: (1) a standard dose of 25-30 minutes of aerobic exercise (STAN, n=96), (2) a higher dose of 50-60 minutes of aerobic exercise (HIGH, n=101), or (3) a combined dose of 50-60 minutes of aerobic and resistance exercise (COMB, n=104). At 1-year post-intervention, patients completed objective measures of aerobic fitness, muscular strength, and muscular endurance. Physical activity was collected via questionnaire at 1-year follow-up and patients were categorized as meeting (1) aerobic only, (2) strength only, (3) combined, and (4) neither exercise guideline. **RESULTS:** We obtained fitness data on 263 (87.4%) patients and self-report data on 284 (94.4%) patients at 1-year follow-up. Analyses of covariance showed that COMB was superior to HIGH for upper body muscular endurance (8.8 reps; $p = 0.020$); borderline superior to HIGH for lower body muscular strength (5.1 kg; $p = 0.05$); and borderline superior to STAN for upper body muscular endurance (6.4 reps; $p = 0.09$). Moreover, meeting the combined exercise guideline at follow-up was associated with: (1) better VO_2 peak (2.1 ml/kg/min; $p = 0.002$); upper body strength (2.8 kg; $p = 0.017$); and upper body endurance (13.4 reps; $p = 0.004$) compared to meeting neither guideline, (2) better upper body endurance (8.6 reps; $p = 0.026$); and lower

body endurance (15.2 reps; $p = 0.020$) compared to meeting the aerobic only guideline and (3) better VO_2 peak (1.7 ml/kg/min; $p = 0.041$); and lower body endurance (20.1 reps; $p = 0.036$) compared to meeting the strength only guideline. **CONCLUSIONS:** Performing combined aerobic and strength exercise during breast cancer chemotherapy resulted in longer-term improvements in muscular endurance and strength compared to aerobic exercise alone. Moreover, performing combined aerobic and strength exercise during follow-up was strongly associated with better fitness outcomes.

Effects Of Exercise During Chemotherapy On Hospitalization And Chemotherapy Completion: The OptiTrain Breast Cancer TrialSara Mijwel, Kate A. Bolam, Yvonne Wengström, Helene Rundqvist. *Karolinska Institutet, Stockholm, Sweden.*

Email: saramijwel@gmail.com

(No relevant relationships reported)

PURPOSE: Prevention of chemotherapy adverse effects may aid in reducing the number of women being admitted to the hospital. Moreover, the importance of sustaining full dose chemotherapy-intensity has been demonstrated. We previously showed that a 16-week exercise program in patients with breast cancer undergoing chemotherapy was beneficial to prevent physiological and self-reported health-related deteriorations. Here, the aim was to examine the effects of exercise on hospitalization and chemotherapy completion rates.

METHODS: 240 women scheduled for chemotherapy were randomized to 16-weeks of resistance and high-intensity interval training (RT-HIIT), moderate-intensity aerobic and high-intensity interval training (AT-HIIT) or to usual care (UC). Chemotherapy completion rate is reported as the mean relative dose intensity (RDI; $\text{mg}\cdot\text{m}^{-2}\cdot\text{wk}^{-1}$), which represents the actual received dose intensity as a fraction of the dose intensity of the originally planned chemotherapy regimen. Lymphocyte and thrombocyte concentrations were measured prior to each chemotherapy session. All data were extracted from medical records.

RESULTS: A significantly lower proportion of participants in the RT-HIIT group (3%) were hospitalized compared to participants in the UC group (15%) over the course of chemotherapy ($p=0.049$). In total, 22% of the participants in RT-HIIT, 28% in AT-HIIT, and 20% in UC required a dose adjustment with no significant between group differences ($p=0.49$). Among those that required dose adjustment, median relative dose intensity was 80% (IQR=75-87) in the RT-HIIT group, 75% (IQR=75-80) in the AT-HIIT group, and 77% (IQR=73-82) in the UC group ($p=0.25$). No significant differences were found between groups for lymphocyte or thrombocyte concentrations. **CONCLUSIONS:** A 16-week exercise intervention consisting of resistance and high intensity interval training during chemotherapy may have significant implications for the cost of cancer care due to reduced hospitalization rates, but had no effect on chemotherapy completion rates.

Inflammatory and Affective Responses to Acute Resistance Exercise of Varying Loads in Postmenopausal Women.Ciaran M. Fairman¹, Maryam B. Lustberg², Marcy L. Haynam², Anna Kimborowicz², Josh Bartels², Michael Lantz², Sarah Johnson², Carl Maresh², William J. Kraemer, FACSM², Brian C. Focht, FACSM². ¹Edith Cowan University, West Perth, Australia. ²Ohio State University, Columbus, OH. (Sponsor: Brian C Focht, FACSM)

Email: c.fairman@ecu.edu.au

(No relevant relationships reported)

Resistance exercise (RE) is increasingly recognized as a powerful behavioral intervention that can improve key metabolic and cardiovascular risk factors among aging women. The manipulation of RE variables, such as repetitions and load, may illicit differing physiological and psychological responses to acute bouts of RE. Although differential responses to acute RE may influence training adaptations and subsequent motivation for regular RE participation, the effects of acute RE upon these outcomes in postmenopausal (PMW) have yet to be evaluated. **PURPOSE:** To determine the effects of RE intensity on physiological, affective, and motivational outcomes in PMW.

METHODS: Thirteen PMW (Age: 59.23±11.3; BMI 29.99±4.55) participated in the study. Each participant completed 3 experimental conditions in a randomly assigned order. The low-load condition involved 3 sets of 12-15 reps at 55%-64% 1 repetition maximum (RM), with 60 seconds of rest between sets. The moderate load involved 3 sets of 8-12 reps at 65%-75% 1RM, with 90 seconds of rest between sets. The heavy load involved 3 sets of 3-6 reps at 80-90% 1RM, with 120 seconds of rest between sets. Assessment of inflammatory markers (IL-6, TNF- α) were obtained prior to, immediately after, 15 minutes and 30 minutes after each condition. Affective and motivational outcomes were assessed prior to, during, and at multiple timepoints following each condition.

RESULTS: Results revealed no significant ($p > 0.05$) differences in inflammatory markers or affective responses as a function of RE load. Furthermore, there was no significant differences ($p > 0.05$) in intention or self-efficacy between experimental conditions.

CONCLUSIONS: CONCLUSION: Acute bouts of RE at 55-64% 1RM, 65-75% 1RM and 80-90% 1RM yielded comparable inflammatory and affective responses in PMW. The similar responses to the varying loads of acute RE observed in this investigation may have valuable practical implications for RE prescription among PMW.

Blood Pressure Abnormalities Among NCAA Athletes**

Hannah M. Wright¹, Michael C. Meyers, FACSM¹, Mark L. Niebyski², James C. Sterling³, Shad K. Robinson¹. ¹Idaho State University, Pocatello, ID. ²World Hypertension League, Corvallis, MT. ³Baylor, Scott & White, Dallas, TX.
Email: wrighann@isu.edu
(No relevant relationships reported)

Although an athlete is routinely exposed to rigorous physical training programs leading to improved cardiorespiratory function, more recently, there has been concern with athletes presenting with hemodynamic abnormalities commonly associated with morbidity and mortality within the general population. **PURPOSE:** To quantify blood pressure (BP) abnormalities among NCAA Division I and II collegiate athletes. **METHODS:** Following written informed consent, 217 (131 male, 86 female) athletes (mean \pm SEM; age = 20.0 \pm 0.1 yr; ht = 178.7 \pm 1.1 cm; wt = 86.9 \pm 1.8 kg) underwent supine, hyperventilation, and standing BPs using a manual, hand-held sphygmomanometer as part of a preexercise evaluation prior to CPET. Supine BPs were subsequently evaluated using ACC/AHA criteria, with data analyzed by gender and race (50 African American, 167 White). **RESULTS:** MANOVAs (Wilks' λ) indicated a significant main effect across gender ($F_{2,214} = 14.987$; $P < 0.0001$), but not race ($F_{2,214} = 2.239$; $P = 0.101$). Post hoc analyses revealed that, overall, males exhibited a higher incidence of elevated BP ($BP_{sys} 121.2 \pm 0.9$ vs. 113.8 ± 1.1 ; $BP_{dias} 70.1 \pm 0.9$ vs. 74.4 ± 0.7 , $p < 0.0001$) than females, respectively. Among the 45.6% of total athletes diagnosed with elevated BP, 74.7% were males ($BP_{sys} 124.9 \pm 0.7$ / $BP_{dias} 77.8 \pm 0.7$) as compared to 25.3% of cases documented among females ($BP_{sys} 122.9 \pm 1.2$ / $BP_{dias} 76.9 \pm 1.2$). Of equal concern, was the hypertension indicated in 7.6% of male athletes ($BP_{sys} 142.8 \pm 1.9$ / $BP_{dias} 84.0 \pm 1.9$), with none reported among females. **CONCLUSION:** Findings indicated that 50.2% of NCAA Division I and II athletes in this study were diagnosed, based on ACC/AHA guidelines, with either elevated BP (BP_{sys} between 120-129 mm Hg and BP_{dias} less than 80 mm Hg) or Stage I or II hypertension (BP_{sys} greater than 129 mm Hg, and $BP_{dias} \geq 80$ mm Hg). These findings support the need for early detection, follow-up screening, and non-drug treatment of athletes to include identifying risk factors (i.e., stress) and knowledge assessment. Ongoing studies are underway to assess the breadth and long-term implications of elevated BP on the athletes' health, particularly with respect to potential cardiovascular risk.

Cardiac Etiology of Exercise Induced Hypoxemia within Elite Athletes**

Jiri Dostal¹, Josef Stasek¹, Radka Kockova², Viktor Kocka³. ¹Faculty of Medicine, Charles University, Hradec Kralove, Czech Republic. ²University Hospital Hradec Kralove, Hradec Kralove, Czech Republic. ³University Hospital Kralovske Vinohrady, Prague, Czech Republic.
Email: dostaljiri@lfhk.cuni.cz
(No relevant relationships reported)

PURPOSE: Exercise induced hypoxemia (EIH) is common finding within a group of elite athletes. It is generally thought, that the causality lies in the pulmonary. We report a group of 8 elite athletes with severe EIH (SpO₂ below 92%) examined for the origin of the EIH. The task was to perform differential diagnoses to locate the shunt into the pulmonary circulation or cardiac shunts.

METHODS: Eight consecutive national level endurance athletes (cycling, running and rowing) with severe EIH (SpO₂ reproducibly below 92) has been examined with stress transthoracic echocardiography with injection of agitated saline. The saline was administered via cubital vein during the last two steps of the stress echo and the

presence of the hypoxemia. Differential diagnoses was based on previously published reports for evaluation of cardiac shunts - number of microbubbles and latency (number of cardiac cycles) between the injection and the appearance of the microbubbles in the left heart. Trans-esophageal echo has been performed in the follow up procedure to evaluate the anatomical etiology of the shunt.

RESULTS: Four athletes presented pulmonary etiology of the hypoxemia. Four athletes have presented cardiac origin with right to left shunt causing EIH. Concurrent transesophageal echocardiography discovered one atrial septal defect and three patent foramen ovale (PFO). One athlete with patent PFO underwent successful catheterization closure of the PFO. Follow up exercise testing and stress echo confirmed no signs of shunt and no signs of presence of EIH in that patient. Also, performance measures of that athlete improved significantly. One athlete with patent PFO/ASD underwent unsuccessful catheterization closure due to anatomical challenges.

CONCLUSIONS: Exercise induced hypoxemia is generally thought to be caused by anatomical or functional shunts within the pulmonary circulation. Our findings suggest possibly higher prevalence than originally thought of cardiac etiology. Successful treatment by catheter-based closure device improves performance and eliminate other clinical signs of the right to left cardiac shunt. Further evaluation of larger group of elite athletes with EIH is warranted to understand better the real prevalence and possible treatment of the cardiac origin of the EIH.

Metabolic And Cardiovascular Effects Of Body Weight Support Treadmill Walking In Healthy Older Adults.**

Robert S. Van Zant, Wick Colchagoff, Anya Cox, Benjamin Eggleston, Andrea Griffith, Linda Harrison, Amie Newberry, Blake Price. The University of Findlay, Findlay, OH.
Email: vanzant@findlay.edu
(No relevant relationships reported)

Purpose: Body weight supported treadmill training (BWSTT) has been proven to be effective for gait re-education for patients experiencing neurologic and musculoskeletal impairments. Recently our lab showed no significant difference in cardiovascular and metabolic effects of BWSTT in healthy young adults at clinically appropriate levels of body weight support (BWS). The purpose of this study was to determine the effects of BWSTT on cardiovascular and metabolic function in older (50-80 years) healthy adults. **Methods:** A total of 20 subjects (50% female, 58.3±7.3 yr; 172.6±9.0 cm; 84.2±22.4 kg; 28.1±5.4 kg/m²) provided their informed consent for study participation. Each subject completed 3, 5-minute treadmill walking trials at a self-selected pace, with 0%, 15%, and 30% BWS, performed in a single-blind randomized fashion. Subjects rested for a minimum of 5 minutes between each trial, and did not begin a subsequent trial until HR was verified to be < 5 bpm of HR rest. Heart rate using a Polar Beat HR monitor, blood pressure (BP) via auscultation, rate of perceived exertion (RPE) using the Borg ratio scale, and oxygen uptake (VO₂) using continuous indirect calorimetry, were measured at rest, and during the 3 walking trials. Mean data from minutes 3, 4, and 5 were then analyzed for difference by repeated measures ANOVA using SPSS statistical analysis (Version 24). **Results:** At rest, HR was 70.8±8.2 bpm and BP was 126.8±12.2 / 84.3±8.6 mmHg. Mean walking speed was 67.1 m/min. All tested parameters for all exercise trials were significantly ($p < 0.05$) different from rest. Among exercise trials, VO₂ and tidal volume at 30% BWS was significantly less than 0% BWS. **Conclusion:** In contrast to previous findings in younger adults, 30% BWSTT elicits a significant reduction in VO₂ and tidal volume in older adults at self-selected walking speeds.

**3178 Board #224 May 31 3:30 PM - 5:00 PM
The Combined Effects of Whey Protein and Aerobic Exercise on Glycemic Responses**

Todd Castleberry¹, Ryan Gordon², Matthew Sokoloski², Emily Zumbro², Christopher Irvine², Aubrien Henderson², Matthew Brisebois², Vic Ben-Ezra². ¹Texas Christian University, Fort Worth, TX. ²Texas Woman's University, Denton, TX.
Email: t.castleberry@tcu.edu
(No relevant relationships reported)

BACKGROUND: An acute bout of aerobic exercise has been shown to improve glycemic responses in both healthy people and those with type 2 diabetes. More recent literature has also suggested that consuming whey protein prior to a meal or glucose challenge may decrease postprandial glucose response. To the authors' knowledge, no studies have examined the combined effects of acute aerobic exercise and whey protein on glycemic responses.

PURPOSE: The purpose of this study was to evaluate the combined effect of acute aerobic exercise and whey protein on plasma glucose, insulin, gastric inhibitory polypeptide (GIP), glucagon like peptide-1 (GLP-1), and glucagon following glucose ingestion in healthy, sedentary men.

METHODS: Eleven males (mean \pm SD, age: 24.3 \pm 5.4 years; BMI: 26.0 \pm 5.3 kg/m²; HbA1c: 5.2 \pm 0.2 %; VO_{2 max}: 38.3 \pm 6.1 ml/kg/min) completed four randomized trials:

no exercise and no whey protein (R); acute treadmill exercise (EX; 70% $\dot{V}O_2$ max for 60 min) performed ~12-14 hrs prior to a 75 g oral glucose tolerance test (OGTT); 50 g of whey protein (W) administered as a 30 min preload prior to an OGTT; and EX combined with W (EXW). Plasma samples from the OGTTs were analyzed for insulin, glucagon, GIP and GLP-1 using multiplex kits. Glucose was measured using enzyme-electrode technology. All variables are represented as incremental area under the curve (iAUC).

RESULTS: Glucose and insulin responses are represented in Table 1. GIP, GLP-1, and glucagon increased for both W and EXW compared to R ($p < .01$) and EX ($p < .03$).

| | R | EX | W | EXW |
|--------------------------|---------------|---------------|----------------|----------------|
| Glucose (mmol x 120 min) | 116.8 ± 105.3 | 155.7 ± 92.9 | -21.1* ± 103.6 | 16.2** ± 118.1 |
| Insulin (pmol x 120 min) | 40922 ± 32078 | 34176 ± 22624 | 78956* ± 36162 | 63182 ± 51780 |

* $p < .01$ vs R; * $p < .01$ vs EX

CONCLUSION: Postprandial glucose responses are reduced following the consumption of 50 g of whey protein prior to a 75 g glucose challenge. Additionally, 50 g of whey protein increased plasma GIP and GLP-1, which has been shown to stimulate insulin secretion. Based on these findings, the combination of acute aerobic exercise and whey protein provides the most benefit compared to exercise or whey alone.

Associations Among Objectively and Subjectively Measured Physical Activity in Older Adults
 Gabrielle Volk, *Miami University, Oxford, OH.*
 (No relevant relationships reported)

Less than thirty-percent of older adults (>55y) meet the physical activity requirements outlined by Centers for Disease Control and Prevention. Physical activity has been reported to reduce the risk of diseases/conditions such as hypertension, type II diabetes, coronary heart disease, depression, and cancer—highlighting its importance as a modifiable, health-related factor. Consequently, it may be clinically useful for physicians to be able to assess physical activity in their patients. Thus, the **PURPOSE** of this study was to evaluate the validity of the Community Healthy Activities Model Program for Seniors (CHAMPS) questionnaire compared to a more objective measure of physical activity using accelerometry. **METHODS:** In 58 adults ($\geq 58y$) we assessed physical activity via questionnaire (CHAMPS) and 7-day accelerometry (Actical); and body composition (bioelectrical impedance). For accelerometry, subjects were advised to continue their habitual activity level. Pre-established cut-points for accelerometry interpretation were: sedentary (<100 counts/min); light physical activity (100-431 counts/min); moderate-to-vigorous physical activity (MVPA) (>431 counts/min). MVPA for CHAMPS included activities with MET values ≥ 3.0 METs. Associations were examined utilizing partial correlations (controlling for age and sex). **RESULTS:** Mean values for these subjects included: age = 69.0 ± 6.3y; BMI = 27.4 ± 7.3 kg/m²; body fat percentage (32.8 ± 11.6%); CHAMPS MVPA = 1843.5 ± 1477.2 kcal/wk. Mean values for accelerometry were: wear time: 890.8 ± 112.3 min/day; 14.8 ± 1.9 h/day; counts/min: 110.5 ± 59.3; accelerometer MVPA = 56.7 ± 29.1 min/day. CHAMPS MVPA was significantly correlated with accelerometer counts/min ($r = 0.40$, $p = 0.003$) and accelerometer MVPA ($r = 0.29$, $p = 0.035$). CHAMPS MVPA was inversely correlated with body fat percentage ($r = -0.33$, $p = 0.015$). **CONCLUSION:** These preliminary data suggest that the CHAMPS questionnaire may provide clinicians with a suitable estimation of their patients' habitual physical activity level.

Assessment of Bilateral Asymmetry in Cycling Peak Torque in Multiple Sclerosis Patients vs. Controls
 Brian A. Pribble¹, John W. Farrell, III², Daniel J. Larson¹, Christopher D. Black, FACSM¹, Debra A. Bembem, FACSM¹, Rebecca D. Larson¹. ¹University of Oklahoma, Norman, OK. ²University of Ottawa, Ottawa, ON, Canada.
 Email: brian.a.pribble-1@ou.edu
 (No relevant relationships reported)

Bilateral asymmetry (BA) is defined as any significant differences in functional or anthropometric measures between contralateral limbs. BA in muscle function has previously been observed in persons with multiple sclerosis (PwMS), with higher levels of asymmetry in lower limb strength having a negative impact on walking capacity and quality of life. Previous methods used with PwMS have not allowed for the assessment of BA during bipedal movements. **Purpose:** The aim of the current study was to assess the levels of BA in power output in PwMS during submaximal cycling compared to healthy controls. **Methods:** Eight PwMS and 6 controls completed a cycle ergometer graded exercise test (GXT) at a self-selected cadence. Peak torque (PT) produced by each leg was assessed at 50%, 60%, and 70% of peak power output (PPO) to determine level of BA. Subjects additionally completed a 25-ft walk test (25FWT), six-min walk test (6MWT), and maximal voluntary contractions (MVCs) of the knee extensors. Group comparisons were assessed at each %PPO using a mixed factorial ANOVA. Correlations between GXT outcomes and 25FWT, 6MWT, MVC, and Expanded Disability Status Scale (EDSS) scores were assessed using Pearson's r and Spearman's rho correlations. **Results:** Non-significant effects were found for the Group x %PPO interaction ($p = 0.28$) and %PPO ($p = 0.49$) variables. Compared to controls, PwMS did not show any significant differences in BA at any %PPO. When collapsed across groups, the % difference in peak torque was found to have a weak to strong correlation with the 25FWT ($r = 0.72$, 0.80, and 0.79, all $p \leq .01$), 6MWT ($r = -0.41$ $p = 0.14$, -0.63 $p = 0.02$ and -0.73 $p = .00$), MVC ($r = 0.27$ $p = 0.35$, 0.47 $p = 0.09$, and 0.80 $p = 0.00$) and EDSS ($\rho = 0.38$ $p = 0.18$, 0.27 $p = 0.35$, 0.02 $p = 0.94$) at 50, 60, and 70% of PPO respectively. **Conclusion:** No significant differences were found for cycling peak torque asymmetry between PwMS and controls. Despite non-significance, PwMS displayed a between limbs difference of $\geq 10\%$ for peak torque at all levels of %PPO whereas controls all had differences $< 10\%$. Furthermore peak torque asymmetry was found to correlate moderately well with MS outcome measurements when collapsed across groups. Future research is needed to determine the viability of assessing BA with cycling PT measures.

The Effects of Fatigue on Peak Torque During Dorsiflexion Between Limbs in Multiple Sclerosis Patients
 David J. Lantis¹, Gregort S. Cantrell², John P. Hintz³, Cameron D. Owens³, Debra A. Bembem, FACSM³, Christopher D. Black, FACSM³, Daniel J. Larson³, Rebecca D. Larson³. ¹St. Ambrose University, Davenport, IA. ²Northern State University, Aberdeen, SD. ³University of Oklahoma, Norman, OK. (Sponsor: Christopher D. Black, FACSM)
 Email: lantisdavidj@sau.edu
 (No relevant relationships reported)

Multiple Sclerosis (MS) is a progressive immune-mediated disease that causes demyelination of the central nervous system. One of the most common symptoms in MS patients is fatigue. While strength asymmetries (SA) have been previously identified in MS patients, less is known of the impact fatigue has on SA. Fatigue of ankle dorsiflexion (AD) has the potential to limit walking function and activities of daily living (ADL) in MS patients. **PURPOSE:** To investigate the impact AD fatigue has on peak torque (PT) between limbs in MS patients compared to healthy individuals (Non-MS). **METHODS:** 26 individuals participated in the current study (MS: $n = 13$, Age = 50.3 ± 9.1 yrs, Expanded Disability Status Scale = 3.5 ± 1.8; Non-MS: $n = 13$, Age = 50.8 ± 8.5 yrs). Visit 1 & 2 consisted of test familiarization sessions. Visit 3 consisted of pre-exercise (PRE) maximal isometric contractions (MVC) of AD followed by fatiguing isometric exercise (FE) at 30% MVC until exhaustion. Immediately (POST) and 2 minutes (REC) after exercise subsequent MVCs were performed. Both limbs were tested with 15 minutes of rest between FE. Limbs were separated for analysis based on MVC PT (strong vs. weak). **RESULTS:** There was no group or limb difference in FE duration. When both limbs were collapsed for analysis,

FE duration was significantly lower in the MS group compared to the Non-MS group (161.14 ± 97.13 N vs. 226.24 ± 83.7 N, respectively; $p < 0.009$). PT significantly decreased PRE-POST, increased POST-REC, but still significantly less at REC from PRE for both limbs within each group ($p < 0.05$). The MS group showed a significant PT difference between limbs at PRE ($\Delta 4.34 \pm 5.88$ N; $p < 0.05$) and REC ($\Delta 3.94 \pm 7.14$ N; $p < 0.05$), while the Non-MS group showed no limb difference. PRE PT was significantly correlated to FE duration in the Non-MS group ($r = -0.55$; $p < 0.003$), but there were no significant correlations between PRE PT and FE duration in the MS group ($p > 0.11$). **CONCLUSION:** The MS group fatigued more quickly than the Non-MS group, however there was no fatigue asymmetries between limbs. The fatiguing exercise attenuated PT differences between limbs in the MS group but not in the Non-MS group. Strength was not related to FE duration in the MS group, but was so in the Non-MS group. The lack of a relationship between strength and fatigue in MS patients may help guide rehabilitation to improve ADLs.

Benefits Of Whole Body Vibration Exercise For Non-specific Chronic Low Back Pain: An Assessor-blind, Randomized Controlled Trial

Xueqiang Wang, Peijie Chen. *Shanghai University of Sport, Shanghai, China.*

Email: qiang897@163.com

(No relevant relationships reported)

PURPOSE: The purpose of this study was to confirm the benefits of whole body vibration (WBV) exercise for pain intensity and functional disability in patients with non-specific chronic low back pain (NSCLBP). **METHODS:** This was a 2-arm single-blind randomized controlled trial. Eighty-nine NSCLBP patients met the inclusion criteria, they were randomly allocated to either the WBV exercise group ($n=45$) or the control group ($n=44$). The WBV exercise group received WBV exercises three times a week for 12 weeks. The control group received general exercise protocol three times a week for 12 weeks. Primary outcome measures were pain intensity and functional disability measured by the visual analog scale (VAS) scores and Oswestry Disability Index (ODI). The secondary outcome measures included lumbar joint position sense, quality of life (Short Form Health Survey 36, SF-36) and overall treatment effect (Global Perceived Effect). **RESULTS:** A total of 84 NSCLBP patients completed the 12-week study program. After 12 weeks, compared with the control group, the mean VAS and ODI scores decreased by additional 1 point (95% CI, -1.22, -0.78; $P < 0.001$), 3.81 point (95% CI, -4.98, -2.63; $P < 0.001$) based on adjusted analysis in the WBV exercise group. And the WBV exercise group provided additional beneficial effects for in terms of lumbar joint position sense ($P < 0.05$), SF-36 ($P < 0.05$), and Global Perceived Effect ($P = 0.012$). **CONCLUSIONS:** The study demonstrated that WBV exercise could provide more benefits than general exercise for relieving pain and improving functional disability in patients with NSCLBP.

(No relevant relationships reported)

The Synergic Impact of Sarcopenia and Dynapenia on Depressive Symptoms in Korean Older Adults

Purpose: To examine the synergistic impact of low appendicular skeletal muscle mass (ASM) and low muscle function (MF) on the risk of depressive symptoms in community-dwellers of Korean older adults.

Methods: Data obtained from a total of 446 participants aged 65 years or older (80% women) recruited from local communities were used in this analysis. ASM and MF were assessed with dual-energy X-ray absorptiometry (DEXA) and a 30-s chair stand test, respectively. Depressive symptoms were assessed with the center for epidemiologic studies depression Scale (CES-D). Logistic regression was used to estimate odds-ratios (ORs) and 95% confidence interval (CIs) for having depressive symptoms according to ASM and MF levels. Statistical significance was tested at $p=0.05$.

Results: The overall prevalence of depressive symptoms in this study population was approximately 16.4%, with 3.6% of men and 12.8% women. With respect to depressive symptoms, individuals with low ASM alone or low MF alone had significantly higher ORs of 2.963 (95% CI=1.318-6.538, $p=0.019$) or 3.843 (95% CI=1.679-8.797, $p=0.002$), respectively, compared to individuals with normal ASM and MF (OR=1). In addition, individuals with low ASM and MF had a significantly higher risk of OR=7.907 (95% CI=3.354-18.640, $p < 0.001$) compared to individuals with normal ASM and MF (OR=1).

Conclusion: The current findings suggest that both sarcopenia and dynapenia are independently and additively associated with an increased risk of depressive symptoms in elderly Korean adults, implying an urgency of an intervention targeting at both muscle mass and function for a healthy aging.

This study was supported by the National Research Foundation funded by the Korean Government (NRF-2018R1D1A1B07048210 and NRF-2017R1A2B4007357).

Effect of Resistance Training on Muscular Function and Functional Mobility in Adults with Cerebral Palsy

Tiffany N. Raczynski, Victoria B. Kott, Pooja Pal, Areum K. Jensen. *San Jose State University, San Jose, CA.*

(No relevant relationships reported)

Cerebral Palsy (CP) is a non-progressive neurological disorder due to damage in the brain leading to musculoskeletal dysfunction and immobility. Physical deconditioning of individuals with CP appears to accelerate muscle atrophy and osteoporosis; thus, adults with CP are more prone to fall and fracture. The lower state of balance and functional mobility is also related to the higher risk of fall in the general public, and resistance training is known to improve overall muscular strength and functional mobility. However, equivocal results were reported whether resistance training has a positive effect on muscular function and balance in CP population.

PURPOSE: To determine the influence of resistance training to muscular strength and balance in adults with CP who already developed muscle atrophy and osteoporosis.

METHODS: Twenty adults with and without CP were recruited. Seven CP participants completed post-exercise experiments after performing resistance training twice a week for three months. Muscular strength (torque, work, and power) at 90, 150, and 210 °/sec were assessed in the leg using the Humac Norm Isokinetic Dynamometer. Functional mobility was assessed from the Berg Balance Test, and limits of stability test using the Biodex balance system.

RESULTS: CP group had significantly lower knee extensor peak torque (e.g., 11.8 ± 2.3 CP vs. 68 ± 12.5 control, ft-lbs, $P < 0.05$), and lower knee flexor peak torque (e.g., 6.3 ± 1.6 CP vs. 43.8 ± 7.9 control, ft-lbs, $P < 0.05$) compared to control. After 3 months of training, CP group did not show statistical differences in muscular strength [e.g., extensor peak torque (27.5 ± 17.0 pre vs. 31.5 ± 24.2 post, ft-lbs, $P > 0.05$), and flexor peak torque (9.3 ± 5.6 pre, vs. 15.0 ± 10.9 post, ft-lbs, $P > 0.05$), or balance [e.g. overall score (25.2 ± 16.1 pre vs. 24.3 ± 11.4 post $p > 0.05$) on limit of stability test, total score (18.0 ± 19.5 pre vs. 24.4 ± 21.6 $p > 0.05$) on Berg Balance test. However, individuals who improved peak torque in knee flexors and extensors also improved postural stability via the Berg balance test.

CONCLUSIONS: These preliminary findings suggest that muscular strength influences functional mobility in adults with CP only after exercise training.

3185 Board #231 May 31 3:30 PM - 5:00 PM
Differential Effect of Obesity on Muscular Strength in Adults with Cerebral Palsy

Bjorn L. Mulingtapang, Pooja Pal, Cory E. Low, Areum K. Jensen. *San Jose State University, San Jose, CA.*

(No relevant relationships reported)

Cerebral palsy (CP) is a non-progressive and permanent neurological disorder that is characterized by muscular deterioration and atrophy. The major clinical problem with CP is early development of cardiovascular disease with increased rates of mortality. Due to the inevitability of motor dysfunction adults with CP can develop health risk factors such as obesity at a higher rate compared to the general population. Limited information is available to identify levels of obesity and its relation to muscular function in adults with CP.

PURPOSE: To determine whether severity of obesity may affect muscular function and strength in adults with CP.

METHODS: We studied total of sixteen adults with and without CP. Muscular strength (i.e., torque, work, and power) during knee extension and flexion was measured at 90, 150, and 210 °/sec in the lower extremity using Humac Norm Isokinetic Dynamometer. Maximal isometric forearm muscular strength was measured using a handgrip dynamometer. Body mass index (BMI), waist to hip ratio, and whole-body scan from Dual Energy X-Ray Absorptiometry were used to identify the levels of obesity.

RESULTS: Compared to control, individuals with CP had similar BMI (26.8 ± 3.0 CP vs. 22.9 ± 1.0 control kg/m^2 ; $P > 0.05$), % body fat (35.2 ± 4.5 CP vs. 28.4 ± 3.7 control %; $P > 0.05$), and % leg fat (40.7 ± 4.3 CP vs. 30.5 ± 4.1 control %; $P > 0.05$). However, waist to hip ratio was significantly greater in CP (0.90 ± 0.02 CP vs. 0.80 ± 0.02 control; $P < 0.05$); muscular strength was significantly lower in CP compared to control (e.g., knee extensor peak torque at 90°/sec; 25.9 ± 8.1 CP vs. 72.5 ± 12.2 control ft-lb; $P < 0.05$). There was no relationship between BMI and extensor/flexor peak torque in both groups; however, there was a linear relationship between waist to hip ratio and extensor/flexor peak torque only in CP group ($R^2=0.34$). A strong inverse relationship between % leg fat and extensor/flexor peak torque was observed in both groups ($R^2=0.79$).

CONCLUSION: These findings suggest that central obesity rather than BMI appeared to influence muscular strength in CP adults. In addition, less fat in the legs rather than the total body may contribute for higher leg muscular strength in adults with CP. Supported by Central RSCA and Undergraduate Research Grant, SJSU

Effects Of Fatigue On Isometric And Isokinetic Dorsiflexion Strength Asymmetry In Multiple Sclerosis

Cameron Owens¹, Davis Lantis², Gregory Cantrell³, Debra Bemben, FACSM¹, Christopher Black, FACSM¹, Daniel Larson¹, Rebecca Larson¹. ¹University of Oklahoma, Norman, OK. ²St. Ambrose University, Davenport, IA. ³Northern State University, Aberdeen, SD.
 Email: cdowens@ou.edu
 (No relevant relationships reported)

Multiple Sclerosis (MS) is an autoimmune disease affecting the central nervous system. MS is characterized by a variety of symptoms, with fatigue being the most commonly reported symptom. Strength asymmetry (SA) of knee extensor/flexors has been documented in previous research in individuals with MS. However, SA of the dorsiflexors in MS patients has yet to be fully investigated in a fatigued state. **PURPOSE:** The aim of this study was to measure SA of the dorsiflexors during isometric/isokinetic maximal voluntary contractions (MVC/MVIC, respectively) before and after a fatigue test (FT). **METHODS:** Thirteen individuals with MS (8 Female (F), 5 Male (M), Age = 50.3 ± 9.1 yrs. and an expanded disability status scale (EDSS) score = 3.5 ± 1.8) and 13 Non-MS individuals (8 F and 5 M, Age = 50.8 ± 8.5 yrs.) participated in a three visit study. Visit 1 consisted of equipment and test procedure familiarization. The following two visits consisted of either a FT test at 30% of MVC or at 30% of MVIC. Prior to, and immediately following the FT, MVC or MVICs were performed. During each visit both legs were tested with a 15 minute break between assessments. The order of test (MVC or MVIC) and leg (left or right) was randomized. All MVIC's were performed at 60°/s. **RESULTS:** SA was calculated as the difference between limbs Pre and Post FT. Measurements of peak tension (PT), voluntary contraction time (VCT), and muscle tension maintaining capacity (MTMC) during MVC and MVIC between legs (within) and between groups were not statistically different (p>0.05). Although MVIC VCT and MVC PT between groups was not significantly different, notable effect sizes (ES) were shown between groups during MVIC for VCT (ES=0.67, MS vs. Non-MS= 0.12 ± 0.09 vs. 0.07 ± 0.06 sec, p= 0.12), and MVC for PT (ES=0.8, MS vs. Non-MS= 3.03 ± 2.67 vs. 1.35 ± 1.23 Nm, p=0.06). **CONCLUSION:** The moderate/large ES for MVC PT and MVIC VCT highlights the possibility of fatigue affecting SA and VCT differently between MS and Non-MS. In future studies, a larger sample size should be used to improve the statistical power of the analyses.

Safety And Feasibility Of Strength Training In Patients With Duchenne Muscular Dystrophy

Donovan J. Lott¹, Tanja Taivassalo², Hyun J. Park², Korey D. Cooke², Zahra Moslemi², Abhinandan Batra², Sean C. Forbes², Barry J. Byrne², Glenn A. Walter², Krista Vandeborne². ¹University of Florida, Newberry, FL. ²University of Florida, Gainesville, FL.
 Email: djlottpt@php.ufl.edu
 (No relevant relationships reported)

Duchenne muscular dystrophy (DMD) is a rapidly progressive and currently incurable neuromuscular disease. Understanding the role of exercise is important for these patients as high-intensity or eccentric actions can be damaging in DMD yet a lack of loading may exacerbate muscle dysfunction. While a few studies show submaximal exercise may be safe and potentially delay the loss of muscle function in DMD, no study has systematically examined the potential of strengthening exercise to improve muscle function or attenuate disease progression. **PURPOSE:** To examine the safety and feasibility of a pilot, in-home strengthening intervention consisting of knee extensor (KE) and flexor (KF) exercise in DMD. **METHODS:** Eight ambulatory boys with DMD [9.3 (0.8) yrs, BMI 19.0 (4.6) kg/m²] on corticosteroid therapy were recruited to undergo 12 weeks of isometric exercise training of the bilateral KE and KF. Exercise prescription consisted of 4 sets x 6 reps, 3x/week at a target intensity of 50% maximal volitional contraction (MVC). At baseline (BL), MVC testing and training familiarization were done for one week on site. The exercise equipment (custom built chair, laptop, and load cell) was subsequently shipped allowing for in-home training and supervision via live video conferencing for each session. Safety outcome measures to assess muscle damage included magnetic resonance proton transverse relaxation time (T₂) of KE and KF, pain assessment, and creatine kinase levels at BL, 1, 6, and 12wks. Peak strength (KE and KF MVC) and time to ascend/descend 4 steps were also assessed at BL and 12wks. **RESULTS:** The 7 boys who completed the strength training program had a compliance of 84.9 (9.0)% for the exercise sessions. The safety measures did not indicate signs of muscle damage [non-

significant change in mean T₂: KE=2.3 (3.6)% and KF= 0.4 (4.6)%]. Peak torque increased by 20.6% for KE (p<0.01) and 14.3% for KF (p<0.05), and the time to ascend (13.5%, p<0.05) and descend (22.7%, p<0.05) steps improved after exercise training. **CONCLUSION:** This in-home, 12-week supervised strength training program was safe, feasible, and improved strength and function in boys with DMD. Future research is required to optimize the strengthening protocol and further explore its potential efficacy and clinical application.

The Characteristics of Muscle Tone and Stiffness in Young Adults with Chronic Low Back Pain

Minjia Wang¹, Bin Yang², Guohan Wang¹, Peijie Liu¹, Yaozheng Wang¹, Jie Jing¹. ¹Chengdu Sport Institute, Chengdu, China. ²Gamma Performance, Beijing, China. (Sponsor: Tongjian You, FACSM)
 Email: 349957217@qq.com
 (No relevant relationships reported)

The prevalence of chronic low back pain (CLBP) in young adults is increasing; however, the biological mechanism of CLBP in this population remains unknown. **PURPOSE:** To observe the characteristics of muscle tone and stiffness (MTS) of relevant muscle groups in young adults with CLBP, in order to provide reference for rehabilitation and prevention of CLBP.

METHODS: Twenty six subjects with CLBP (age: 22±2 years, 14 males and 12 females) were recruited as the experimental (E) group, while 29 healthy subjects (age: 25±2 years, 16 males and 13 females) were recruited as the control (C) group. The degree of pain (Visual Analogue Scale/Score, VAS) was recorded, and the MTS (indicators including F-Frequency, D-Logarithmic Decrement and S-Stiffness) of three muscle groups (para-spinal, hamstring and tensor fascia lata muscles) was assessed using the Myoton-3 equipment. Group differences were determined by using independent-sample t-tests; within the E group, MTS was compared between gender and degree of pain (VAS) using ANOVA.

RESULTS: Compared with C group, the E group's MTS of all three muscles were significantly higher (p<0.05), and the differences were 11.4%, 10.0% and 14.9% respectively; E group showed bilateral imbalance in all three muscles, while C group did not show imbalance. With the E group, compared with female subjects, male subjects had higher MTS of tensor fascia lata and para-spinal muscles (p<0.05), and the differences were 12.8% and 20.0%, respectively; in addition, the MTS values of tensor fascia lata, hamstring and para-spinal muscles in the subjects with moderate pain (VAS 4-7) were higher than those with mild pain (VAS 1-3) (p<0.05), and the differences were 12.7%, 14.9% and 22.2% respectively.

CONCLUSIONS: MTS is associated with considerable increase of hamstring, para-spinal muscle and tensor fascia lata in young patients with CLBP; Young CLBP patients had significant bilateral MTS imbalance of all these muscles; Young male CLBP patients had higher MTS in para-spinal muscle and tensor fascia lata than female patients; The more painful, the higher of the MTS in young CLBP patients.

Differential Effect of Resistance Training on Musculoskeletal Architecture and Strength in Adults with Cerebral Palsy

Ramon C. Ronquillo, Mac G. Damoulios, Cory E. Low, Alan L. De Vera, Areum K. Jensen. San Jose State University, San Jose, CA.
 (No relevant relationships reported)

Cerebral Palsy (CP) is a neurological disorder caused by lesions in the brain and is characterized by impaired motor function, musculoskeletal deformity, and atrophy. Individuals with CP appear to develop osteoporosis at an earlier age compared to general population. Bone weakness has adverse effects on the muscular system, which causes CP population to be more prone to fractures and further immobility. Bone mineral density (BMD) improves in the general population via resistance training. However, it is still uncertain whether resistance training alters skeletal strength in the CP population and whether it influences musculoskeletal architecture and strength. **PURPOSE:** To determine the effect of resistance training on BMD, skeletal architecture, and muscular strength in adults with CP. **METHODS:** We studied 14 adults with and without CP. CP participants went through 3 months of resistance training twice per week. Dual-energy X-ray absorptiometry was used to measure local BMD at the lumbar spine (L1-L4), proximal femur, and radial/ulnar regions. Architectural differences were identified by measuring various angles and lengths on the proximal femur. Leg muscular strength was measured during knee extension and flexion using the Humac Norm Isokinetic Dynamometer. **RESULTS:** There was a significant increase in BMD at femur in CP group after 3 month exercise (0.6±0.1 CPpre vs. 0.9±0.1 CPpost g/cm²; P<0.05). BMD at lumbar and forearm regions in CP group was similar to control group even though BMD in CP group seemed to improve after training (P>0.05). Skeletal architecture and muscular strength were significantly lower in CP compared to control, but it did not change after resistance

training (architectural angle; 64±5 CPpre vs. 70±2 CPpost degree; $P>0.05$). While control group showed a strong linear relationship between femoral neck BMD and knee extensor peak torque ($R^2=0.83$), CPpre showed no relationship ($R^2=0.01$). After 3 months of training, CP participants who exhibited higher BMD appeared to develop greater muscular strength ($R^2=0.26$). **CONCLUSION:** These findings suggest that short term resistance training improved skeletal strength in CP adults without alterations in skeletal architecture. Skeletal strength appeared to play a role in enhanced muscular strength in adults with CP only after exercise training.

3190 Board #236 May 31 3:30 PM - 5:00 PM

Effects Of Eccentric Training Combined To Neuromuscular Electrical Stimulation On Electromechanical Delay Of Peroneal Muscles In Individuals With Functional Ankle Instability

Ziwen Pei, Jian Chen, Danyang Li. *Wuhan Sports University, Wuhan, China.*

(No relevant relationships reported)

The electromechanical delay (EMD) represents the time required by the muscles to provide a protective response to an injurious mechanism. Individuals with functional ankle instability (FAI) have showed longer EMD times for the peroneal muscles (EMD-P) than ankles of healthy individuals; which is thought to increase the risk of the recurrence of ankle sprains. However, there's currently no noninvasive treatment to shorten EMD-P. **PURPOSE:** The aim of this study was to investigate the effects of eccentric training combined with neuromuscular electrical stimulation (NMES) on the EMD time of peroneal muscles during eccentric muscle action in individuals with FAI. **METHODS:** This was a three-arm, single-blinded, randomized controlled trial. Thirty-nine volunteers (21 ± 3ys) with FAI were randomly assigned to control (CON; $n = 13$), eccentric training (ECC; $n = 13$), or eccentric training combined with neuromuscular electrical stimulation groups (ECC+NMES; $n = 13$). The control group received conventional rehabilitation therapy (CRT), involving strength and balance training. The ECC group performed isokinetic concentric and eccentric training of the peroneal muscles based on CRT. The ECC+NMES group received NMES simultaneous to the isokinetic training. Both groups trained 3 days/week for eight weeks. The EMD-P was calculated when peroneal muscles contracted eccentrically at 90/s using the isokinetic system before and after training. A one-way ANOVA was used to look at the differences in EMD-P between three groups. **RESULTS:** No significant differences existed for EMD-P among the groups before training ($F = 0.295$, $P > 0.05$). Compared with pre-training, the EMD-P was significantly shorter in the ECC group (133 ± 8 vs. 127 ± 8 ms, $P < 0.05$) and ECC+NMES groups (135 ± 11 vs. 119 ± 9 ms, $P < 0.05$). However, no change occurred in CON (134 ± 7 vs. 135 ± 10 ms, $P > 0.05$). The ECC group showed a significant lower EMD-P compared with CON after training (127 ± 8 vs. 135 ± 10 ms, $P = 0.027$), whilst EMD-P was shorter after training in ECC+NMES compared with ECC (119 ± 9 vs. 127 ± 8 ms, $P = 0.03$). **CONCLUSION:** Eccentric training effectively shortened the EMD-P in individuals with FAI compared with conventional treatment. However, ECC combined with NMES further enhanced the reduction in EMD-P. Therefore, ECC+NMES could be an effective treatment for FAI.

3191 Board #237 May 31 3:30 PM - 5:00 PM

Passive Hallux Adduction Decreases Lateral Plantar Artery Blood Flow in Low Arch Feet

Aaron W. Johnson¹, Julia L. Dunbar¹, Sarah T. Ridge¹, Dustin Bruening¹, Kathryn Brewerton¹, Jayson Gifford¹, Daniel Hoopes². ¹Brigham Young University, Provo, UT. ²Revere Health Orthopaedic Surgery, Provo, UT. (Sponsor: Pat Vehrs, FACSM)

(No relevant relationships reported)

PURPOSE: Due to the vital role that blood flow (BF) plays in maintaining tissue health, compromised BF can affect tissue healing. An adducted hallux, as often seen inside a narrow shoe, may put passive tension on the abductor hallucis, consequently compressing the lateral plantar artery (LPA) into the calcaneus and restrict BF. This may negatively affect the health of tissues within the foot such as the plantar fascia and may contribute to plantar fasciopathy. The purpose of this study was to compare BF within the LPA before and after passive hallux adduction (PHA). **METHODS:** Forty-five healthy volunteers (20 female, 25 male; age = 24.8 ± 6.8 yr; height = 1.7 ± 0.1 m; body mass = 73.4 ± 13.5 kg) participated in this study. Blood velocity and vessel diameter measurements were obtained using ultrasound imaging (L8-18i transducer, GE Logiq S8). The LPA was imaged deep to abductor hallucis for 120 seconds: 60 seconds at rest followed by 60 seconds of PHA. Maximal PHA was performed by applying pressure to the medial side of the proximal phalanx of the hallux. BF was then calculated in mL/min, and measurements before and during PHA were compared. Arch height index (AHI) was assessed for all volunteers.

RESULTS: Log transformed data was used to run a paired t-test between BF measured before and during PHA. The overall volume of BF over the 60 seconds during PHA was 22% lower compared to before (-0.250 ± 0.063 mL/min, $p < 0.001$), with an initial decrease of 60%. As AHI decreased, there was a greater negative Δ BF. As baseline BF increased, there was also a greater negative Δ BF.

CONCLUSIONS: Our preliminary findings of decreased BF through PHA indicate conditions that elicit PHA (e.g. wearing narrow-toed shoes) may affect BF and tissue health.

3192 Board #238 May 31 3:30 PM - 5:00 PM

A Randomized Controlled Trial Comparing Physiotherapy And Extracorporeal Shockwave Therapy In Treatment Of Plantar Fasciitis

Jade Chee¹, Charles Kon². ¹Singhealth, Singapore, Singapore. ²Changi General Hospital, Singapore, Singapore.

(No relevant relationships reported)

PurposePlantar fasciitis is postulated to arise from chronic overload. First line treatment includes non-steroidal anti-inflammatory drugs, orthotics, physical therapy and stretching exercises. Patients who do not respond to the above after a 6-month period can be considered for extracorporeal shock wave therapy (ESWT). In this study, we evaluated the outcomes of conventional physiotherapy alone versus physiotherapy together with ESWT over a 6-month period for patients diagnosed with plantar fasciitis.

MethodsPatients with heel pain who presented to the Specialist Orthopaedic Clinic from April 2017 to Apr 2018 were assessed for eligibility criteria. Enrolled patients were randomized into 2 arms: physiotherapy alone, or physiotherapy together with ESWT. Clinical and functional outcomes were evaluated using the SF 36 score, the American Orthopaedic Foot-Ankle Society (AOFAS) hindfoot score, as well as the Visual Analogue Scale (VAS) at baseline, 3 months, and 6 months. **Results**A total of 26 subjects were recruited. 1 dropped out of the study, and 5 defaulted follow-up. Results from the remaining 20 subjects were analysed. No significant difference in SF 36 score was found at 3-month follow-up (physical functioning $p=0.806$, physical limitations $p=0.624$, body pain $p=0.075$, general health $p=0.879$, vitality $p=0.119$, social functioning $p=0.419$, emotional limitations $p=0.958$, mental health $p=0.770$). The differences in AOFAS and VAS at 3-month follow-up were not statistically significant ($p=0.222$ for AOFAS, $p=0.329$ for VAS).

There was also no significant difference in SF 36 score after 6 months (physical functioning $p=0.814$, physical limitations $p=0.481$, body pain $p=0.091$, general health $p=0.427$, vitality $p=0.839$, social functioning $p=0.680$, emotional limitations $p=0.299$, mental health $p=0.416$). 6-month post-intervention AOFAS and VAS were not significantly different ($p=0.978$ for AOFAS, $p=0.372$ for VAS).

ConclusionOur study showed no significant differences in SF 36 score, AOFAS, and VAS after a 6-month period between participants who underwent physiotherapy alone as compared with those who received ESWT in addition to physiotherapy. No serious adverse events were noted at the 6-month follow-up visit. Further studies need to be undertaken with a larger sample size, and a longer follow-up period.

Effect Of A Virtual-exercise Program On Physical Function And Activity: Findings From The VERITAS Trial

Janet P. Bettger¹, Cynthia L. Green¹, DaJuanicia Holmes², Anang Chokshi³, Bryan T. Hoch⁴, Arthur J. Deleon⁴, Laura Webb², Vincent Miller², Joseph M. Smith³, Eric D. Peterson¹. ¹Duke University, Durham, NC. ²Duke Clinical Research Institute, Durham, NC. ³Reflexion Health, San Diego, CA. ⁴Duke Health, Durham, NC.

Email: janet.bettger@duke.edu

Reported Relationships: J.P. Bettger: Industry contracted research; Reflexion Health.

PURPOSE: To determine the effect of a virtual exercise program versus usual care on physical function and activity 6 and 12 weeks after total knee arthroplasty (TKA). **METHODS:** We conducted a multicenter, randomized controlled trial with adults undergoing unilateral TKA. At least 10 days before surgery, participants were randomized 1:1 to the virtual exercise program with an avatar coach, in-home 3D biometrics and weekly telehealth clinician support versus usual care (referral to home health or outpatient physical therapy as determined by the surgeon and clinical team). Intention-to-treat analysis was used for the following 6- and 12-week secondary patient-reported outcomes: physical function (in five domains of the Knee injury and Osteoarthritis Outcome Score [KOOS], higher score is better function) and minutes per week of moderate-to-vigorous physical activity (MVPA). Patient satisfaction with the virtual exercise program was assessed of intervention group patients 12-weeks after surgery. **RESULTS:** From November 2016-December 2017, 306 patients were randomized (mean age, 65 years; 62.5% women); 287 completed the trial (143 virtual, 144 usual care). At 6 weeks, there was no difference between groups in pain, symptoms, quality of life, difficulty with daily activities, and with function needed for sports and recreation ($p>0.05$). Patients in the virtual exercise group reported a mean of 119.9 (SD 197.4) min/week of MVPA at 6 weeks compared with 68.9 (SD 112.0) min/week for usual care patients ($p=0.089$). At 12 weeks, physical activity, pain, symptoms, quality of life and daily activities were not significantly different between groups but

patients in the virtual exercise group reported less difficulty with function related to sports and recreation than usual care patients (intervention 75.6 [SD 19.2] vs usual care 61.5 [28.3], $p=0.006$). Patients in the virtual exercise group reported high likelihood of recommending the program to others (mean score 9.1 ± 2.1) on a scale of 0-10.

CONCLUSIONS: Among patients receiving TKA, the virtual exercise program increased MVPA in the first 6-weeks after surgery and resulted in measurable gains to physical function for sports and recreation activities at 12-weeks.

Several evidences suggest that aerobic exercise performance decrease after sleep deprivation (SD) and psychobiology aspects could explain these effects, however, the role of anxiety on this way is poorer explored. **Purpose:** Investigate the role of anxiety-state on moderate continuous and 3-km time-trial exercise in subjects sleep deprived. **Methods:** Eleven healthy male subjects (32.72 ± 6.73 yrs; 70.93 ± 7.79 kg; 1.74 ± 0.05 m; 23.37 ± 2.74 kg/m²), were submitted to 30 min of moderate continuous exercise followed a 3-km Time-Trial test in treadmill in two conditions separated by 15 days: Normal Sleep (7-8 hours of sleep) and SD (36 consecutive hours). The subjects answered an anxiety state questionnaire (Idate Trait-State) before (B), immediately after aerobic moderate continuous exercise (AM), immediately after 3-Km time-trial (AT-T) and 30 minutes recovery (R). The time to finish the time-trial was used as performance index, and the time to partial distances was accompanied to observed strategy performance. The time-course and groups differences were compared by ANOVA repeated measures with post-hoc Duncan test, with significance $P \leq 0.05$. The protocol was approved by Unifesp Ethics Committed (#2.00.369). **Results:** The mean score of anxiety were higher in SD condition in B (34.9 vs 38.18 ; $P=0.03$), AM (31.8 vs 38.6 ; $P=0.006$) and R (30.90 vs 37.23 ; $P=0.01$) time-courses. No differences were found in the total and partial time to complete the 3-km test. The initial velocity of the time-trial test was higher in the normal sleep condition (15.45 vs 13.95 ; $p=0.005$). **Conclusion:** We observe that although the SD is not able to affect the total time to complete the 3-Km test, the score of anxiety in different time-courses (before, during and after exercise) was higher in the SD condition. In addition, the strategy used were different, demonstrated by the lower initial velocity chosen by the volunteers sleep deprived. These findings suggest that the level of anxiety associated with SD can alter strategies by underestimating the performance.

PURPOSE: To analyze the effects of bariatric surgery on cardiac autonomic modulation in morbid obese patients. **METHODS:** The study included 14 morbid obese patients that were submitted to bariatric surgery. Before and after surgery subjects were submitted to body mass index (BMI) assessment, answered, and were submitted to polysomnography. During polysomnography, AHI and cardiac autonomic modulation were assessed during sleep. **RESULTS:** After surgery BMI and AHI reduced significantly ($p < 0.05$) from 48.7 ± 5.6 kg/m² to 41.9 ± 5.7 kg/m² and from 34 ± 29 events/h to 18 ± 16 events/h, respectively. Standard deviation were used as a measure of variability in pre and postoperative period and values were calculated with pre 829.20 ± 82.84 and post 972.24 ± 146.20 with $p \leq 0.001$ demonstrating gains in HRV in all patients. [1] Additional information with the application of the spectral wavelet analysis in the frequency decomposition provided values pre 2.8775×10^5 and post 2.3440×10^5 ($p < 0.05$). **CONCLUSIONS:** Morbid obese submitted to bariatric surgery presents improvement in cardiac autonomic modulation during sleep.

3196 Board #242 May 31 3:30 PM - 5:00 PM Oxygen Desaturation in Sleep Apnea is Inversely Associated with Vascular Changes Following Exercise Training

PURPOSE: Obstructive sleep apnea (OSA) is characterized by reductions in nocturnal mean O₂ saturation (meanSpO₂) that may increase cardiovascular disease morbidity. The extent to which exercise confers cardioprotection in overweight adults with different meanSpO₂ profiles is not known. The purpose of this study was to examine the association of meanSpO₂ with vascular function changes following exercise training in adults with and without OSA. **METHODS:** At baseline, participants underwent overnight polysomnography to determine the presence and severity of OSA. Tertile-based cut-off points were used to categorize meanSpO₂ and apnea hypopnea index (AHI). Body fat was analyzed using dual energy X-ray absorptiometry. Vasoreactivity of the brachial artery was measured using flow-mediated dilation (FMD), while microcirculatory function was assessed via the total shear stress area under the curve (SSAUC) response during FMD. Body fat and vascular measures were repeated upon completion of a 6 week (3 sessions/wk; 1 hr/session) exercise training program. **RESULTS:** Thirty (age: 49 ± 9 years; BMI: 32.0 ± 3.8 kg/m²; 18 men: 12 women) adults with and without OSA completed the study. At baseline, adults in the highest tertile of meanSpO₂ were younger than those in the lowest tertile (43 ± 9 yrs vs. 53 ± 7 yrs, $p=0.017$), yet no differences in vascular measures, AHI or total body fat percentage were observed across the tertiles. No changes in brachial artery diameter or FMD were observed across tertiles following exercise. However, the change in SSAUC in the highest tertile of meanSpO₂ was greater, compared to the lowest tertile ($13,636 \pm 15,898$ A.U. vs. $-186 \pm 10,879$ A.U., $p=0.041$). Forward stepwise linear regression revealed that the highest tertile of meanSpO₂ was a significant ($F=5.15$, $p=0.036$) determinant of the increased SSAUC with exercise, independent of age and baseline SSAUC. **CONCLUSIONS:** Severe oxygen desaturation during sleep was inversely associated with improvements in microcirculatory function following exercise training.

3197 Board #243 May 31 3:30 PM - 5:00 PM Shorter Sleep Duration Is Associated With Increased Sedentary Duration In Lean, But Not Overweight Or Obese, Individuals

Saurabh S. Thosar, Isabel Katlaps, Nicole P. Bowles, Andrew W. McHill, Steven A. Shea. *Oregon Health & Science University, Portland, OR.*

Email: thosar@ohsu.edu

(No relevant relationships reported)

PURPOSE: Sedentary behavior and insufficient sleep both can independently increase the risk for chronic diseases such as obesity and cardiovascular disease. However, whether or not prior nocturnal sleep duration influences daytime sedentary behavior is not well understood. We hypothesized that total sleep duration at night will be inversely associated with the subsequent day's total sedentary time. We also explored if this relationship is different in lean compared to non-lean individuals. **METHODS:** 27 adults (10 lean, 50 ± 2 years) chose a self-selected 8-h sleep opportunity for 5-14 days ($\mu = 11$). Adherence to the self-selected sleep period was verified using a sleep diary and phone calls to a time stamped mailbox at bedtime and upon awakening. Sleep duration was manually scored from wrist actigraphy (wGT3X-BT); and activity levels and sedentary duration were scored using 'Freudon Adult' algorithm'. To test whether total sleep duration (TSD) influenced subsequent sedentary duration (SD), a mixed model analysis was conducted with TSD as the independent variable, and subject as random factor. We further tested the associations between TSD and SD separately in lean and non-lean individuals. Finally, independent sample t-tests were used to determine whether TSD and SD differed between lean and non-lean individuals. **RESULTS:** TSD was negatively associated with the subsequent day's SD [$F(1, 289) = 4.8$; $p=0.03$]. SD was significantly higher in non-lean as compared to lean individuals [mean 386 minutes vs 302 minutes per day; $t(25) = 2.9$; $p = 0.02$]. TSD was not different between groups; $p = 0.64$. When lean and non-lean groups were analyzed separately, there was a significant inverse relationship between TSD and subsequent ST in lean [$F(1, 117) = 9.69$, $p = 0.002$] but not in non-lean individuals ($p > 0.05$). **CONCLUSIONS:** We discovered that shorter sleep duration during an 8h scheduled sleep opportunity is associated with increased SD during the subsequent day. This relationship was only found in lean individuals, possibly due to the higher ST in non-lean compared to lean individuals. Experimental studies investigating the bidirectional effects of sedentary behavior and sleep and the subsequent effect on cardiometabolic physiology are recommended to better understand the effect of these behaviors on the risk for chronic disease.

3198 Board #244 May 31 3:30 PM - 5:00 PM
Associations Of Sleep Metrics, Body Composition, And Cardiorespiratory Fitness In Older Women

Erin E. Kishman, Joshua R. Sparks, Charity B. Breneman, Xuewen Wang. *University of South Carolina, Columbia, SC.*
 Email: ekishman@email.sc.edu
 (No relevant relationships reported)

Sleep duration and quality have been associated with obesity risk. Most previous studies used body mass index (BMI) as a proxy of obesity and subjectively evaluated sleep. Older adults often suffer from poor sleep quality, high body fat, and low cardiorespiratory fitness (CRF), especially women after menopause. **PURPOSE:** To investigate if sleep duration and quality are associated with BMI, body composition, and CRF in older women. **METHODS:** Older women (n= 115; age: 65.61±4.32) wore an actigraph monitor for 7 days to measure sleep metrics. Total sleep time and sleep quality, which included wake after sleep onset, activity counts during sleep, sleep onset latency, and number of awakenings, were determined using manufacturer provided software. BMI was calculated, and a dual x-ray absorptiometry scan was performed to assess body composition. A graded exercise test was used to measure CRF. Data was collected in two locations (n=89 and 26, respectively). Pearson product correlations were used to determine associations and study location was controlled for. **RESULTS:** Total sleep time negatively associated with lean mass and fat free mass (r= -0.28, p=0.012; r= -0.28, p=0.012), but positively associated with percent body fat (r=0.26, p=0.025). There were no associations between sleep metrics and CRF. **CONCLUSIONS:** Our data indicates longer total sleep time was associated with less lean mass but greater body fat in older women. This suggests in older women longer total sleep time may be linked with less physical function and worse health condition. Further examination of the association between sleep with physical function and biomarkers in this population is recommended.

3199 Board #245 May 31 3:30 PM - 5:00 PM
Sleep Restriction during 8-Week Calorie Restriction on Physical Activity and Lipoprotein Particle Concentrations and Sizes

Joshua R. Sparks¹, J. Larry Durstine, FACSM¹, Shawn D. Youngstedt², Ryan R. Porter³, Mark A. Sarzynski, FACSM¹, Xuewen Wang¹. ¹University of South Carolina, Columbia, SC. ²Arizona State University, Tempe, AZ. ³University of South Carolina School of Medicine, Greenville, SC. (Sponsor: J. Larry Durstine, FACSM)
 Email: jrsparks@email.sc.edu
 (No relevant relationships reported)

Overweight and obesity and having an abnormal lipoprotein profile are associated with increased risk of cardiovascular disease (CVD). Increased sedentary time, decreased physical activity (PA), and restricted sleep are risk factors for obesity and CVD. Calorie restriction is often used to induce weight loss. However, little information exists concerning how caloric restriction, sleep restriction, and PA interact, and their overall impact on CVD risk.

PURPOSE: To examine changes in body weight, PA, and lipoprotein particle concentrations and sizes following caloric restriction (CR) and sleep restriction (SR) intervention (CR+SR) compared to CR alone in overweight or obese adults.

METHODS: 28 adults (age=44.5±5.8 years) were randomized into an 8-week CR or CR+SR group. Both groups consumed a diet equivalent to 95% of the individual's resting metabolic rate. Participants in the CR+SR were instructed to restrict time-in-bed up to 90 minutes 5 days per week. Sedentary and PA time was measured utilizing a Sensewear Mini Armband. Fasting serum samples were collected for analysis of lipoprotein particle concentrations and sizes by nuclear magnetic resonance spectroscopy. Repeated measure analyses included a group×time interaction to compare changes in weight, sedentary and PA time, and lipoprotein particle concentrations and sizes between groups.

RESULTS: Body weight significantly decreased in both groups with no difference between groups (p=0.748; weight loss: 2.5±0.2 kg in CR and 2.2±0.5 kg in CR+SR). A significant difference in the change in total PA time between CR and CR+SR (p=0.044) was found. Total PA time significantly increased in CR (256.7±87.6 to 320.1±122.7 minutes, p=0.025) only. No differences in the changes in lipoprotein particle concentrations or sizes between CR and CR+SR were found. Large HDL particle concentration decreased in the entire sample (7.5±3.4 to 6.6±3.4 μmol/L, p=0.004). **CONCLUSIONS:** The CR+SR did not result in increased PA as in the CR; however, weight loss and lipoprotein particle concentration or size changes for the two groups were similar. These results suggest that moderate SR on 5 days a week may not significantly alter lipoprotein metabolism during weight loss, which may partly be due to compensated sleep on the other 2 days of the week. Supported by AHA Grant 14BGIA20380706

3200 Board #246 May 31 3:30 PM - 5:00 PM
Relationships Among BMI, Estradiol, And Sleep-wake Behavior In Women

Shannon K. Crowley, Julia Rebellon, Abigail J. Leonard, Christina Huber, Lyndsay Wolfe, Andrea Tobar, Sierra Hayden, Daniel Henderson, Meir Magal, FACSM. *North Carolina Wesleyan College, Rocky Mount, NC.*
 Email: scrowley@ncwc.edu
 (No relevant relationships reported)

PURPOSE: It has been estimated that women are at 40% increased risk for developing clinically significant sleep disturbances (such as insomnia) compared to men. Reproductive-related hormones, such as estradiol (E2), have been shown to play a key role in sleep-wake behavior in women, and pharmacological interventions which target the regulation of E2 have been shown to improve sleep in women. Importantly, body mass index (BMI) has been shown to be inversely associated with E2 levels in premenopausal women, and previous studies have also suggested that women who are overweight or obese are significantly more likely to report clinically-significant sleep disturbances. Thus, this study aimed to examine associations between BMI, E2, and sleep disturbances in premenopausal women in order to identify a non-pharmacological, physical activity (PA) related modifiable target for the prevention of clinically significant sleep problems in women. **METHODS:** Following a two-tiered screening process, 28 healthy women (18-45y, mean age: 24.6y) who were medication-free and had regular menstrual cycles completed: (1) enrollment visit, (including mood and sleep assessment and assessment of cardiorespiratory fitness via maximal oxygen consumption during exercise); (2) one-week sleep monitoring period (objective and subjective measures of sleep-wake behavior); and (3) saliva collection for the assessment of salivary E2 levels. Saliva collection occurred during the follicular phase of the menstrual cycle to control for ovarian cycle E2 fluctuations. **RESULTS:** Higher BMI was significantly associated with lower E2 levels (r = -.38, p = 0.04), and also longer objectively-measured sleep onset latency (SOL) duration (r = .51, p = 0.004). Consequently, lower E2 levels were significantly associated with increased objectively-measured wake after sleep onset (WASO) duration (r = -.43, p = 0.03) and increased number of awakenings during the sleep period (r = -.48, p = 0.01). **CONCLUSIONS:** Results suggest that, in premenopausal women, higher BMI may be associated with increased sleep disturbances, and that this relationship may be mediated by E2 levels. It is therefore possible that regular PA, which has been shown to be inversely associated with BMI, may improve sleep via its positive effects on adiposity and associated regulation of E2.

Associations Among Sedentary Time, Feeding Duration, And Sleep Duration In Adults With Overweight And Obesity

Corey A. Rynders¹, Sheila Steinke¹, Elizabeth Kealey¹, Emma Tussey¹, Isaac Debache², Audrey Bergouignan¹, Adnin Zaman¹, Elizabeth Thomas¹. ¹University of Colorado - Anschutz Medical Campus, Aurora, CO. ²CNRS IPHC UMR7178, Strasbourg, France. (Sponsor: Edward Melanson, PhD, FACSM)
 Email: corey.rynders@ucdenver.edu
 (No relevant relationships reported)

PURPOSE: Reducing daily sedentary time, decreasing daily feeding duration, and increasing total sleep duration are important lifestyle targets for improving the metabolic health of adults undergoing weight loss. However, objective methods for simultaneous measurement of sedentary time, meal timing, and sleep in free-living adults are lacking and it is unclear how these variables are related in overweight adults or change in response to weight loss.

METHODS: Thirty-two overweight and obese adults were recruited to participate in an ongoing weight loss study (90% female, Age= 36.4±6.4 yr, BMI= 33.4±5.5 kg/m²). Participants simultaneously wore an activPAL accelerometer on the thigh and an Actiwatch on the non-dominant wrist for 7 days in a free-living environment to assess waking sedentary behavior and nighttime sleep, respectively. A cell phone application (MealLogger) was used to photograph and timestamp all caloric events during the 7-day period to determine daily feeding duration which was verified using a continuous glucose monitor. Assessments were performed at baseline and will be repeated at 12 weeks following completion of the weight loss intervention. Correlation analyses were performed on baseline data to determine associations among sitting time during waking hours, daily feeding duration, sleep duration, and sleep timing.

RESULTS: On average participants were sedentary for 67.5±8.5 % of waking hours, consumed energy over 11.0±1.9 hours during the day and slept for 7.2±0.7 hours at night. Sedentary time (as a percent of the waking day) was negatively correlated with sleep duration (Spearman rho=-0.48, P=0.006) but was not related to later sleep timing (sleep midpoint), longer feeding duration, or timing of the last meal.

CONCLUSIONS: Using a novel set of methods, we show that higher levels of sedentary time during waking hours are associated with shorter total sleep duration in adults beginning a weight loss intervention, however cause and effect cannot be

established in this analysis. Our future studies are aimed at understanding whether reducing sedentary time leads to increased sleep duration (or vice versa) and measuring how sleep, activity, and meal timing change with weight loss.

G-11 Highlighted Symposium - Make No Bones About It: Bone Loading in Relation to Bone Stress Injuries

Saturday, June 1, 2019, 9:00 AM - 11:00 AM
Room: CC-303

The skeleton adapts and responds to repetitive mechanical loading. The same loading features that induce favorable bone adaptation can also lead to bone stress injuries, including stress fractures. This symposium will discuss the loading and response of bone as it relates to bone stress injuries.

3220 June 1 9:40 AM - 9:55 AM Changes in Bone Microarchitecture and Estimated Bone Strength Over 12 Months After Tibial Stress Fracture Diagnosis: Implications for Return to Sport

Kristin L. Popp¹, Sara G. Rudolph², Signe Caksa², Amy Yuan², Julie M. Hughes³, Kathryn E. Ackerman, FACSM⁴, Adam S. Tenforde⁵, Chun Xu⁶, Ginu Unnikrishnan⁶, Jaques Reifman⁶, Mary L. Bouxsein⁷. ¹Massachusetts General Hospital, Harvard Medical School, United States Army Research Institute of Environmental Medicine, Boston, Natick, MA. ²Massachusetts General Hospital, Boston, MA. ³United States Army Research Institute of Environmental Medicine, Natick, MA. ⁴Massachusetts General Hospital, Harvard Medical School, Boston Children's Hospital, Boston, MA. ⁵Spaulding Rehabilitation Hospital, Boston, MA. ⁶High Performance Computing Software Applications Institute, Frederick, MD. ⁷Massachusetts General Hospital, Harvard Medical School, Beth Israel Deaconess Medical Center, Boston, MA.

(No relevant relationships reported)

Stress fractures (SF), common injuries among athletes, have been reported in up to 20% of track and field athletes. Typically, after a period of unloading and gradual return to weight-bearing activities, athletes return to unrestricted participation in their given sport 12-14 weeks after SF diagnosis. However, the time course of the recovery of mechanical competence of the bone is not well characterized, and reinjury rates are high. **PURPOSE:** To determine changes in bone microarchitecture and estimated bone strength over 12 months following tibial SF diagnosis. **METHODS:** We enrolled 30 women, ages 18-35, with a tibial SF (grade 2 or higher) for this prospective observational study. Participants completed a baseline visit within 3 weeks of SF diagnosis. At baseline, 6, 12, 24, and 52 weeks following SF diagnosis, we collected high-resolution peripheral quantitative computed tomography (HR-pQCT) scans of the ultradistal tibia (4% of tibia length), background and lifestyle questionnaires, and a physical activity assessment. **RESULTS:** Over the initial 12 weeks, total volumetric bone mineral density (vBMD) declined by 1.2% ($p=0.001$), trabecular vBMD by 1.2% ($p=0.006$), cortical thickness by -1.0% ($p=0.007$), and bone volume/total volume by 1.2% ($p=0.008$). At 24 weeks, mean values for all bone parameters were nearing baseline values, and by 52 weeks, mean values had surpassed baseline values. A similar trend was seen in estimated bone strength, though changes did not reach statistical significance. Of the 30 participants, 7 incurred a subsequent SF during the course of the 12 month-follow up and 2 incurred ≥ 2 subsequent SFs. **CONCLUSION:** Persisting decrements in bone microarchitecture and estimated bone strength suggest bone mechanical integrity does not return to baseline for 3-6 months after tibial SF diagnosis. This, coupled with the high rate of recurrent SFs, suggests more conservative return to sport guidelines may be in order.

The opinions and assertions contained herein are the private views of the authors and are not to be construed as official or as reflecting the views of the U.S. Army or of the U.S. Department of Defense. This abstract has been approved for public release with unlimited distribution.

Changes in Tibial Bone Microarchitecture in Response to 8 Weeks of US Army Basic Combat Training in Men and Women: A Preliminary Analysis from a Large Field Study

Julie M. Hughes¹, Katelyn I. Guerriere¹, Kathryn M. Taylor¹, Kristin L. Popp², Ronald W. Matheny, Jr.¹, Stephen A. Foulis¹, Mary L. Bouxsein³. ¹United States Army Research Institute of Environmental Medicine, Natick, MA. ²United States Army Research Institute of Environmental Medicine, Massachusetts General Hospital, Natick, MA. ³Massachusetts General Hospital, Harvard Medical School, Beth Israel Deaconess Medical Center, Boston, MA.

(No relevant relationships reported)

Stress fractures are overuse injuries in bone tissue that are common during Army Basic Combat Training (BCT) when recruits undergo a period of heightened physical activity. The pathophysiology and mechanoadaptive biology that underlie stress fracture development and prevention continue to be characterized. Mechanoadaptation to BCT has been demonstrated in the tibial microarchitecture of female military recruits. Whether male military recruits are able to mount an analogous response to BCT remains to be determined. **PURPOSE:** To analyze preliminary data from a large prospective field study (427 men and women from a larger cohort of ~4000 recruits to be studied) with the goal of characterizing changes in tibial bone microarchitecture in male and female recruits as a result of 8 weeks of BCT. **METHODS:** We collected high-resolution peripheral quantitative computed tomography images of the distal tibia (4% from the distal tibial plateau) before and after BCT and analyzed data on 303 male and 124 female recruits who volunteered and completed BCT. Linear mixed models were used to estimate the mean difference for each outcome from pre- to post-BCT, while controlling for race/ethnicity, age, and body mass index. **RESULTS:** Mean age of male (20.7 ± 3.4 yrs) and female (20.6 ± 3.6 yrs) recruits was similar. At the distal tibia, cortical thickness, trabecular thickness, bone volume/total volume, and total, trabecular, and cortical volumetric bone mineral density (vBMD) increased significantly by 0.50-2.28% (all $p < 0.0001$) over the BCT period in women and by 0.32-1.84% (all $p < 0.0001$) in men. **CONCLUSIONS:** This preliminary view of data collected to date found that following BCT, both men and women mounted an adaptive response in tibial trabecular bone microarchitecture, indicative of de novo trabecular bone formation. The responses in tibial bone microarchitecture were of greater magnitude in women than in men, which may be due to lower average baseline values in bone microarchitectural properties in women, and therefore potentially greater loading stimuli. Other lifestyle and demographic factors may also influence the adaptive bone response to BCT and will be investigated in the larger sample following study completion.

Effects Of An Online Sports Nutrition Curriculum On Biomarkers Of Iron Status In Youth Athletes

Marni E. Shoemaker, Zachary M. Gillen, Brianna D. McKay, Nicholas A. Bohannon, Alegria I. Mendez, Joel T. Cramer, FACSM. *University of Nebraska-Lincoln, Lincoln, NE.*
 (Sponsor: Dr. Joel T. Cramer, FACSM)

(No relevant relationships reported)

Online nutrition education curricula framed around concepts of sports nutrition may improve accessibility as well as engagement, awareness, and adherence for active high school athletes.

Purpose: Examine the effects of an online sports nutrition curriculum on ferritin, soluble transferrin receptor (sTfR), and hemoglobin (Hb) biomarkers of iron status in high school athletes.

Methods: One hundred twenty-three male (n=56, age: 17 ± 1 y, stature: 76 ± 20 kg, mass: 176 ± 6 cm) and female (n=67, 16 ± 1 y, 67 ± 16 kg, 164 ± 6 cm) high school athletes were tested for ferritin, sTfR, and Hb concentrations before and after participating in seven online sports nutrition modules (~1 module per week) focused on macronutrients, micronutrients, performance plate, energy balance, nutrient timing, and supplements. Pre- and post-education prevalence of poor iron status for each biomarker was calculated, while individual subject's iron status classification was tracked. Mixed factorial ANOVAs (time x sex) compared mean biomarker concentrations.

Results: Prevalence of iron depletion (ferritin cutoffs) increased from 48 to 52% and decreased from 79 to 75%, low iron levels (sTfR cutoffs) decreased from 38 to 30% and increased from 29 to 33%, and anemia (Hb cutoffs) decreased from 20 to 14% and 29 to 23% in males and females, respectively. Subjects classified as iron depleted (n=65) did not change, one subject improved iron levels, while six subjects (6%) improved their classification from anemic (n=25) to non-anemic (n=19) from pre- to post-education. There were no interactions (p>0.05) or main effect for time (p>0.05) for ferritin (pre 28.4 ± 15.1 to post 28.0 ± 14.2), sTfR (19.0 ± 8.2 to 20.1 ± 7.4), or Hb (13.5 ± 2.2 to 13.9 ± 1.8). There was no main effect for sex (p>0.05) for sTfR (m: 19.2 ± 6.4, f: 19.8 ± 6.4), but males exhibited higher (p≤0.05) concentrations of ferritin (m: 32.5 ± 18.2, f: 23.8 ± 18.2) and Hb (m: 14.3 ± 1.7, f: 13.2 ± 1.7).

Conclusions: Females present a greater risk of poor iron status, suggesting a need to focus on dietary iron in young female athletes. Participating in the online sports nutrition curriculum did not improve mean concentrations of ferritin, sTfR, or Hb, but did improve anemia classifications for six subjects (n=3 males, n=3 females).

Acknowledgments: This study was funded by the Nebraska Beef Council.

NCAA Division I Women's Cross Country Consumes Adequate Energy Midseason Following Nutrition Education Seminars

Catherine Saenz¹, Jared A. Mallard¹, Kelsey M. Beckmann¹, Terrance Orange¹, Kevin RM Coyle¹, Kara L. Conway¹, Jeff T. Wight¹, George G.A. Pujalte, FACSM², David R. Hooper¹.
¹Jacksonville University, Jacksonville, FL. ²Mayo Clinic, Jacksonville, FL. (Sponsor: Carena Winters, FACSM)

(No relevant relationships reported)

Elite-level endurance athletes are prone to low energy availability due to the high energy demands of the sport and the propensity to emphasize low body compositions. Low energy availability may lead to nutrient-related deficiencies such as low iron and low vitamin D. Chronic deficiency in these essential nutrients may lead to health issues, including symptoms related to the female athlete triad. Women endurance athletes are at a particular risk for low energy availability mid-season due to the high energy demands. Previous studies indicate that collegiate-level women's cross country runners do not have enough knowledge on how nutrition and energy availability affect health. Little is known on how nutrition education may affect energy intake mid-season and how it may affect circulating markers commonly associated with the female athlete triad. **PURPOSE:** To observe: 1) If collegiate women cross country runners consumed adequate energy mid-season after receiving nutrition education. 2) To observe how mid-season nutrition affected serum iron and serum Vitamin D values. **METHODS:** Five women from a NCAA Division I cross-country team (age: 20.8±1.5 years, height: 169.6±5.7 cm, weight: 58.3±4.1 kg) received nutrition education starting at pre-season and continuing on throughout the season. Three-day diet records were collected and analyzed by a registered dietician. After an overnight fast, blood samples were collected and measured for total ferritin and circulating Vitamin D by immunoassay. **RESULTS:** Athletes consumed an average (95% CI) of 1980 kcal/d (1740-2220kcal/day). Dietary carbohydrate was 4.2g/kg/d (95% CI: 3.4-5.0g/kg/d), dietary fat was approximately 28% (95% CI: 25-33%), and dietary protein was 1.5g/kg/d (95% CI: 1.3-1.6g/kg/d) of the diet. Serum ferritin was 28.1 ng/mL (95% CI: 14-35ng/mL) and Vitamin D was 46.8ng/mL (95% CI: 39.6-54.6ng/mL). **CONCLUSION:** Despite the demanding training volume mid-season, collegiate women's cross country runners were able to maintain adequate calories and recommended intake for dietary fat and

dietary protein. Circulating markers commonly associated with female athlete triad were also within the recommended ranges for optimal health. A nutrition education program may help bring awareness and knowledge on how adequate energy is vital to health and performance.

Nutrition and the Female Athlete: Macronutrient Consumption and Body Composition Changes among Collegiate Volleyball Players.

Yvette L. Figueroa. *Augusta University, Augusta, GA.* (Sponsor: Arlette C. Perry, FACSM)
 Email: yfigueroa@augusta.edu

(No relevant relationships reported)

An athlete's diet and physical training have been reported to have direct positive influences on performance variables including strength and power which are strategic to athletic performance. According to nutritional recommendations, however, female athletes consume far less total calories, carbohydrates, and proteins when compared to male athletes of similar lean body mass (LBM). **PURPOSE:** To determine 1) whether collegiate volleyball players meet nutrition recommendations and 2) whether there are significant changes in macronutrient consumption and body composition after an eight-week, off-season resistance training program. **METHODS:** Eleven collegiate-level competitive female volleyball players were examined for total calorie, carbohydrate, and protein consumption using three-day food logs. A body height/weight scale and hydrodensitometry were used to compute body mass index (BMI), LBM, and percent body fat (BF). **RESULTS:** The volleyball players reported total calorie consumption 15.06% and 10.79% below recommended guidelines before and after training, respectively, while carbohydrate intake was 7.27% and 4.77% below recommended guidelines before and after training, respectively. Protein intake levels met recommended guidelines and did not change throughout the training program. Paired samples t-tests showed increases in LBM, and decreases in BMI and BF following eight weeks of training (p<0.05 for all). **CONCLUSION:** Our study showed that despite positive improvements in body composition, collegiate volleyball players are not meeting current nutritional recommendations for optimal athletic performance. These findings may have important health and performance implications specific to collegiate female athletes.

3252 Board #4 June 1 9:00 AM - 11:00 AM
Examination Of Energy Availability On The Hormonal Profile Of Endurance-trained Male Athletes

Erin M. Moore¹, Toni M. Torres-McGehee², Clemens Drenowatz³, Brittany T. Williams², Thaddeus C. Broderick², David F. Stodden², Justin M. Goins². ¹University of South Florida, Tampa, FL. ²University of South Carolina, Columbia, SC. ³Pädagogische Hochschule Oberösterreich, Linz, Austria.

(No relevant relationships reported)

Currently, there is inadequate literature existing for male athletes who participate in high-energy expenditure activities with decreased energy needs. Understanding the physiological demands and consequences of decreased energy availability (EA) in male athletes is critical for acute and long-term health and prevention of injuries and illness. **Purpose:** Examine the effect of EA on reproductive (Testosterone [T] and Luteinizing Hormone [LH]) and metabolic hormones (Insulin, Leptin, Cortisol, and Interleukin-6 [IL-6]) in male endurance-trained athletes. **Methods:** A cross-sectional design on 14 endurance trained male athletes (age: 26.4 ± 4.2 yrs.; weight: 70.6 ± 6.4 kg; height: 179.5 ± 4.3 cm, BMI: 21.9 ± 1.8, Body Fat% (BFP): 13.6 ± 3.5%) were recruited from the local community. Participants completed 2 separate training weeks (low [LV] and high [HV] training volumes) and each week included: 7-day dietary logs, 7 day-exercise logs, and 1 blood draw each week to determine concentrations for 6 hormones (reproductive and metabolic). Anthropometric measurements (height, weight, and body composition) were taken prior to data collection. LEA was defined as (≤ 20 kcal/kg FFM·d. **Results:** Participants at risk for LEA (41.2%: n = 7; HV: 50%: n = 4; LV: 33.3%, n = 3) had increased T levels (p = 0.20) and 21.7% (n = 5) (HV: 18.2%, n = 2; LV: 25%, n = 3) presented with low Leptin levels (p = 0.01). A significant difference was found between the 2 training weeks - Leptin (t₍₁₃₎ = 1.61 p < 0.001; HV: 78.6%, n=11; LV: 85.7%, n=12), EA - overall T (χ² (2) = 4.4, p = 0.04), and HV week - T (χ² (2) = 5.8, p = 0.02). A strong negative correlation was found for overall Leptin to BFP: (r₍₂₄₎ = -0.73, p < 0.001) and T-RMR (F(1, 23) = 16.23, p < 0.001). A weak negative correlation for T-EI (F(1,24) = 6.7, p = 0.02) and a strong positive correlation was found for overall T- BFP (F(1, 24) = 51.9, p < 0.001). **Conclusion:** Overall, participants who demonstrated LEA, highlighted a significant negative relationship between LEA and Leptin. Due to Leptin's negative response to EA below 20 kcal/kg FFM·d; male runners should monitor their exercise expenditure and dietary intake to maintain appropriate levels of EA (> 20 kcal/kg FFM·d). Valid and reliable predictive equations for hormones should be examined to become useful tools for clinicians whom do not have access to blood work.

3253 Board #5 June 1 9:00 AM - 11:00 AM
Sources Of Nutrition Information And Knowledge For Ultra-runners

Sara E. Mahoney, FACSM, Thomas R. Wójcicki, Andrew J. Carnes, Nigel Ouslan. *Bellarmine University, Louisville, KY.*
 Email: smahoney@bellarmine.edu
 (No relevant relationships reported)

PURPOSE: Ultra-marathon events (i.e., >42.2-km) continue to grow in popularity; however, little research exists on the typical dietary intake of ultramarathon participants, or the sources of information which influence their habits and beliefs. The objectives of this study were to characterize the acquisition of nutrition information among ultra-endurance athletes, and to determine the relationship between the use of different sources of information and nutritional knowledge (relative to current evidence-based recommendations). **METHODS:** Participants (n=196) were adults who had completed an ultramarathon at least once in the past 2 years. Measures included: a demographic questionnaire; the Sources of Nutrition Information (SONI) questionnaire, which included 7 major sources of nutrition information, as well as their credibility, accessibility, frequency, interest; and the General Nutrition Knowledge Questionnaire - Revised (GNKQ-R). Repeated measures ANOVA was used to analyze differences between items on the SONI scale. Spearman rank correlation was used to test for a relationship between sources of information and GNKQ-R score. **RESULTS:** 18% self-identified as vegan/vegetarian, 6% paleo/ketogenic, 20% traditional American diet, 54% "healthy" and 12% "other". Peer reviewed literature was reported as the most frequently used (mean score=1.64, p<0.001), credible (3.02, p<0.001), and interesting (2.62, p=0.002). Social media was the most accessible (2.81, p<0.001), but the least credible (1.87, p<0.001). A modest, significant correlation (r=0.185, p = 0.015) exists between use of peer-reviewed literature and nutrition knowledge. **CONCLUSIONS:** Ultrarunners report high usage of peer-reviewed literature for nutrition information, which is related with improved nutritional knowledge. Because of its accessibility, social media may be a promising tool to provide nutrition information to this population.

3254 Board #6 June 1 9:00 AM - 11:00 AM
Lack Of Nutrition Knowledge In Division II Athletes Associated With Limited Access To Registered Dietitians

Brian P. Reagan¹, Darby Culp¹, Christa Parkes¹, David Pierce².
¹University of Indianapolis, Indianapolis, IN. ²Indiana University - Purdue University, Indianapolis, Indianapolis, IN.
 (Sponsor: Dr. Riggs Klika, FACSM)
 Email: reaganb@uindy.edu
 (No relevant relationships reported)

Limited nutrition knowledge is prevalent among all types of athletes, which is correlated with negative health consequences. Eating disorder (ED) etiology is the most documented, dire issue facing athletes, especially those in lean-emphasized sports (LES) such as gymnastics and tennis. Primary contributor to ED in LES is athletes' lack of nutrition knowledge of carbohydrates (CHO), fats, and weight management (WM). **PURPOSE:** To assess NCAA Division II (DII) athletes' knowledge in distinct domains: (1) CHO, (2) fats, and (3) WM. **METHODS:** The Macronutrient and Energy Metabolism Expertise Survey (MEMES) was created through modification of Reagan's NET Survey. Changes included different domains (e.g. WM questions vs. Etiology) and expanding number of questions (5 to 10). An expert panel confirmed the face and construct validity of the MEMES before it was piloted. Athletes signed informed consent and then voluntarily completed the MEMES via Qualtrics in a designated computer lab on one test date. Email reminders were sent 1 month, 1 week, and 1 day prior to test date. The criterion for "Adequate Knowledge" (AK) was set at 80% for each domain and total score correct. Pearson product moment correlations were calculated between variables (e.g. percent correct, gender, sport). **RESULTS:** Eighty-eight males and eighty females completed the MEMES (35.8% return rate). Males scored significantly higher on CHO (p = 0.017) and athletes (n = 16) who reported having access to a Registered Dietitian (RD) scored significantly higher on the CHO and fat domains (p = 0.00 and 0.042, respectively). The majority (28.6%) reported "experience as an athlete" as their primary source for nutrition knowledge. The least cited source was a RD (8.9%). Also, the athletes lacked knowledge: the mean total score was 14.4 correct out of 40 or 36%, falling below the established AK of 80%. The mean of correct scores were 29.1%, 37.0%, and 41.9% for fats, CHO, and WM, respectively. **CONCLUSION:** The results suggest that athletes are at a high risk of health consequences such as ED. Likewise, they are likely to be misinformed about sound sports nutrition by relying on their self-knowledge rather than a professional advice from a RD. This challenges the notion that experience as an athlete is a source of nutrition knowledge.

3255 Board #7 June 1 9:00 AM - 11:00 AM
Evidence Of A Relationship Between Dietary Fat Intake And Inflammation Among Professional Soccer Players

Diarmuid Daniels¹, Nathan Lewis², Paul Catterson³, John Newell¹, Georgie Bruinvels⁴, Micheal Newell¹, Andrew Simpkin¹, Andrew Barr⁴, Charles R. Pedlar². ¹National University of Ireland Galway, Galway, Ireland. ²St Mary's University, Twickenham, United Kingdom. ³Newcastle United Football Club, Newcastle, United Kingdom. ⁴Orreco, Business Innovation Centre, National University of Ireland, Galway, Ireland.
 (No relevant relationships reported)

Reducing background inflammation in athletes may be a medical and performance objective. Data describing the relationship between erythrocyte membrane fatty acids (EMFA) and low grade inflammation in soccer players are absent from the literature. EMFA reflects dietary fat intake in the weeks preceding the blood test. **PURPOSE:** To investigate the strength and reproducibility of the relationship between EMFA and inflammation in a group of professional soccer players. **METHODS:** We conducted an observational study, collecting venous blood samples measuring high-sensitivity C-reactive protein (CRP) and EMFA in the early season (T1) and late season (T2). A total of 47 blood samples were collected from 29 different athletes, with 25 athletes tested at T1, and 22 athletes at T2. A cut off point of >5mg/L¹ was set to minimise the effect of acute inflammation, and these samples were removed from the analysis. Linear relationships between biomarker variables were examined using Pearson correlation tests. **RESULTS:** At T1, we report significant positive correlations between CRP and the following EMFA variables: Omega6:Omega3 ratio and the Arachidonic Acid: Eicosapentaenoic acid (AA:EPA) ratio (0.566, p< 0.003, and 0.582, p< 0.002 respectively) and significant negative correlations with the Omega 3 index and the anti-inflammatory fatty acid index (AIFAI; -0.495, p< 0.011, and -0.465, p< 0.018 respectively). However, at T2, the relationship between EMFA variables and inflammation had attenuated, with no strong linear correlations observed. The correlation analysis of all the blood samples collected (n=47) showed significant correlations between the Omega-3 Index, the AIFAI and CRP (-0.319, p< 0.028, and -0.299, p< 0.040 respectively). **CONCLUSION:** There is a relationship between inflammation and EMFA variables in professional soccer players and the strength of this relationship appears to depend on the sampling occasion. Future research should explore augmenting EMFA as an anti-inflammatory strategy.

Sex Differences in Nutrition Knowledge of Division I College Athletes

Alyssa J. Guadagni, Emily N. Werner, James M. Pivarnik, FACSM. *Michigan State University, EAST LANSING, MI.*
 (Sponsor: JAMES M. PIVARNIK, FACSM)
 Email: guadagn2@msu.edu
 (No relevant relationships reported)

Appropriate nutrition is imperative for participation in, and recovery from, exercise. However, many college athletes do not have a sufficient nutrition knowledge base to help them stay healthy during their physically taxing sports. **PURPOSE:** To assess the nutrition knowledge base of NCAA Division I college athletes using a validated nutrition knowledge survey. **METHODS:** Varsity athletes at a Division I university were recruited via word-of-mouth. A validated nutrition knowledge survey (Callella et al., 2017) that contained both general- and sport nutrition-specific sections, was administered at different settings convenient to the athletes (e.g., team meetings or training table). Participants were asked not to share answers or use any outside resources (e.g., internet). Scores were summed as +1 for a correct answer or +0 for no answer, an incorrect answer, a double-answer, or the "I don't know" option. The maximum possible score was 97. Knowledge was categorized as low (<33rd percentile), medium (33rd to 66th percentile), and high (> 66th percentile). Frequencies of knowledge categories were tallied, and an independent t-test was run to determine sex differences. Alpha level was set at p<0.05. **RESULTS:** Athletes (n=128; n=70 female, n=58 male) from eight different sports completed the nutrition knowledge survey. Frequencies of each knowledge category were 42 (n=11 female, 31 male) with low knowledge, 24 (n= 7 female, 17 male) with medium knowledge, and 62 (n=52 female, 10 male) with high knowledge. Average scores for females were 64.5±15.9, 43.1±11.0, and 21.4±5.9 for the total survey, general nutrition, and sport nutrition sections, respectively. On average, males scored significantly lower, with scores of 43.6±15.1, 27.6±10.1, and 16.0±6.7 for the total survey, general nutrition, and sport nutrition sections, respectively (p<0.001). **CONCLUSION:** Based on survey results, the majority of NCAA Division I athletes assessed fell into the high nutrition knowledge category, with most in the category being female. Future research should expand on this to assess knowledge of specific nutrition concepts.

G-18 Thematic Poster - Behavioral Aspects of Exercise

3258 Board #1 June 1 9:00 AM - 11:00 AM**The Physical and Mental Rehabilitation Effect of Healthy-mind Exercise intervention on Individuals of Illicit Drug Dependent**

Dong Zhu¹, Mei Jiang¹, Ding Xu². ¹Shanghai University of Sport, Shanghai, China. ²Shanghai Drug Administration, Shanghai, China.

Email: zhudong@hotmail.com

(No relevant relationships reported)

PURPOSE: Healthy-mind exercise is an exercise of a low-medium intensity and benefit to both physically and mentally. The exercise is composed of Tai Chi, Healthy Qi Gong and Yoga. The hypothesis of this experiment was that the healthy-mind exercise intervention is superior to the conventional physical rehabilitation methods in Shanghai compulsory detoxification and rehabilitation centers on the effect of fitness and quality of life.

METHODS: A total of 100 male individuals of illicit drug dependent who met the inclusion criteria were recruited and randomly assigned to two groups. In the experimental group (n=50), subjects practiced three times of healthy-mind exercise in the morning, noon and evening for 20 minutes for each exercise session. The total time of the exercise was 60 minutes, 5 times a week. The control group was treated with the conventional rehabilitation method (n=50). The contents of the exercises in control group included recreational gymnastics, gesture exercise, the times of daily practice, duration of each session, total duration of a day and the repetitions per week were the same as those of the experimental group. Outcomes of fitness, quality of life for drug addiction questionnaire (QOL-DA) were measured at the baseline, 3 month and 6 month. Data analysis was applied with SPSS 19.0. A two-way repeated measures analysis of variance (ANOVA) was applied to test whether the treatments were different after 6 months.

RESULTS: At baseline, no statistically significant differences were observed between two groups in terms of demographic outcomes, fitness and the scores of QOL-DA. After 6 months of exercise intervention, there were significant differences found in systolic ($F_{(2,166)}=11.77$), diastolic ($F_{(2,166)}=8.96$), heart rate ($F_{(2,166)}=7.82$), vital capacity ($F_{(2,166)}=3.08$), flexibility ($F_{(2,166)}=13.85$), aerobic endurance ($F_{(2,166)}=15.05$). The results of QOL-DA showed that there were significant differences between experimental group and control group in physical function ($F_{(2,170)}=10.32$), psychological function ($F_{(2,170)}=9.71$), symptom function ($F_{(2,170)}=6.42$), social function ($F_{(2,170)}=14.91$) and total score ($F_{(2,170)}=15.95$). **CONCLUSIONS:** This study proved that the healthy-mind exercise was suitable for substance dependent individuals.

3259 Board #2 June 1 9:00 AM - 11:00 AM**Confirmation of Self-Reported Ambulatory Exercise Bouts During Ecological Momentary Assessment**

Lindsay P. Toth, Lucas F. Sheridan, Kelley Strohacker, FACSM. The University of Tennessee, Knoxville, TN.

(No relevant relationships reported)

Ecological momentary assessment (EMA) is a method of self-report (SR) that can be used to examine how fluctuations in physical activity (PA) behavior are related to affective, contextual, and cognitive antecedents. Concurrent objective PA monitoring is recommended with EMA to supplement retrospective questions about PA. The objective PA data could be useful for confirming that SR bouts of ambulatory exercise occurred as described (timeframe, duration, intensity). To date, such a confirmation process has not been described in the literature. **PURPOSE:** Assess the use of accelerometry to confirm EMA of ambulatory exercise. **METHODS:** Participants (N=29, age 24±6y) completed four mobile surveys/d for 14-d (82% response rate) denoting exercise type and duration over the preceding 4-h. Throughout the 14-d period, participants wore an ActiGraph GT3X+ (AG) on the hip (14.0±3.5h/d). To confirm EMA reported exercise bouts, survey meta-data (date, time-stamp) and bout durations were used to guide visual inspection (VI) of AG data within the corresponding 4-h time blocks by two independent reviewers (inter-observer agreement=84% and after deliberations=100%). The Crouter 2-Regression Model (C2RM) was applied to AG counts to determine a min-to-min coefficient of variation (CV). SR bouts were confirmed when the C2RM CV ranged between 1% and 10%

continuously and step counts were above 5 steps per 10s epoch for the approximate SR duration. Descriptive statistics and frequency analyses were conducted. **RESULTS:** 93 of 128 bouts were confirmed, and the average SR bout duration (29±20min) was slightly greater than VI bouts (25±20min). Ten bouts were unable to be confirmed due to AG non-wear. In the 25 remaining unconfirmed cases, no continuous bouts matching the SR durations were observed. **CONCLUSIONS:** Processing AG data using C2RM allowed intuitive and reliable VI for confirmation of continuous ambulatory exercise bouts reported via standard EMA survey items. Feasibility of applying this process may be limited by large sample sizes.

3260 Board #3 June 1 9:00 AM - 11:00 AM**Feasibility Of A Novel Video Game-based EMG Biofeedback System In Patients With Knee Osteoarthritis**

Eileen Krepkovich¹, Colby Magnum², Susan Saliba², Matthew Lichter¹, Aaron Olowin¹, Neal Richardson¹, Joseph Hart, FACSM². ¹Barron Associates, Inc., Charlottesville, VA.

(No relevant relationships reported)

PURPOSE: Rehabilitation through quadriceps strengthening is a well-established treatment for patients with osteoarthritis (OA) of the knee. Electromyography (EMG) biofeedback units provide an interactive mechanism to increase motivation during exercise, but conventional systems are expensive, and their simplistic interface may not be engaging to the user. The purpose of this study was to compare technology acceptance and knee extension torque production using EMG biofeedback presented to patients from within a video game interface.

METHODS: A novel virtual world game system ("KneeBRIGHT") was developed that integrated electromyography (EMG) biofeedback and guided patients through quadriceps strengthening routines. Feasibility testing was completed with 19 patients with a prior diagnosis of knee joint osteoarthritis (51.9±7.5yrs, 88.7±19.8kg, 170.5±7.4cm). Participants conducted 2 testing sessions on separate days. During the first session, participants performed 3 sets of lower body exercises with emphasis on maximal muscle activation, endurance, and motor control/precision. These exercises were conducted with a commercially available EMG biofeedback unit (Pathway MR-20, Promethius Group, Dover, NH). During the second session, participants used the KneeBRIGHT game that was designed to match the exercise sets in the first session. For all sessions, knee extension torque was recorded during the isometric muscle activation exercises using a dynamometer, and patient engagement was assessed using the technology acceptance model (TAM) questionnaire. Peak torque and TAM scores obtained during the KneeBRIGHT and traditional biofeedback sessions were compared using paired t-tests.

RESULTS: Knee extension torque generated during KneeBRIGHT game exercise sessions was increased by an average of 25% compared to the torque generated during conventional EMG biofeedback sessions (2.14 Nm/kg vs. 1.77 Nm/kg, p=0.02). There was no significant difference in TAM scores between the sessions (3.42±0.4 vs 3.2±0.5, p=0.25).

CONCLUSIONS: Patients exercising with the KneeBRIGHT game produced greater knee torque than patients exercising with the conventional system, and demonstrated positive levels of engagement.

3261 Board #4 June 1 9:00 AM - 11:00 AM**Exploring Qualitative Determinants of Regular Group Indoor Cycling Participation in a Diverse Sample of Adults**

Alvin L. Morton¹, Lyndsey M. Hornbuckle¹, Miguel Aranda¹, Derrick T. Yates¹, Courtney L. Anderson². ¹University of Tennessee, Knoxville, Knoxville, TN. ²Georgia State University, Atlanta, GA.

(No relevant relationships reported)

While U.S. adults generally do not acquire adequate amounts of physical activity, non-Hispanic Blacks (NHB) obtain less physical activity than non-Hispanic Whites (NHW). Identifying reasons why NHB regularly participate in a given exercise modality may help tailor future recommendations in this population. Group indoor cycling (GIC) classes have gained popularity and are offered widely in fitness facilities. **PURPOSE:** To qualitatively investigate the motivation for regular GIC class participation in a racially diverse sample.

METHODS: Women and men attending GIC classes at a rhythm-based cycling studio ≥ 1 day/week for the preceding three consecutive months were recruited. Participants completed a questionnaire that included two open-ended questions: 1) "Why do you continue to regularly choose GIC classes for exercise?" and 2) "How does the environment at this cycling studio motivate you to continue to choose GIC for exercise?" Three investigators independently analyzed data using established procedures for thematic analysis. Data from the two questions were reported in

aggregate. **RESULTS:** Seventeen adults (88% female; 71% NHB; 29% NHW; mean±SD age: 32.1±7.4 yrs.; body mass index: 26.2±3.6 kg/m²) completed the study. Five main themes emerged as reasons for regular GIC class participation in NHB and NHW, respectively: music selections (83 and 80%), studio atmosphere (67 and 40%), social support (67 and 80%), physical health (58 and 100%), and enjoyment/fun (42 and 60%). **CONCLUSIONS:** The music (majority hip-hop and rap) in this studio may have played an integral role in attracting NHB to participate in GIC classes at this studio on a regular basis. NHW participants indicated physical health as a key motivator for class attendance. More research is needed to gain a deeper understanding of cultural relevance as it relates to motivational factors for exercise, which could inform future strategies for promoting regular exercise in various populations.

 (No relevant relationships reported)

Low cardiorespiratory fitness and accumulated fat mass have been widely associated with impaired cognitive performance in children, however, their influence on creativity remains unclear. The creativity is a component of cognition and is defined as the process of identifying the difficulty, formulating hypotheses about the deficiencies and solving the problems. Actually, the creativity has become an element key to cognition because contribute to personal and professional success of the subject. **PURPOSE:** Here, we compare creativity in children with different levels of cardiorespiratory fitness (CF) and fat mass (FM), as well as their relationship. **METHODS:** In this cross-sectional study, 73 children with age ranging from 10.1 to 11.5 participated while attending two testing sessions. On the first testing session, all children had general anthropometric assessments and completed a graded shuttle run test to estimate cardiorespiratory fitness (VO₂ max). On the second session, they perform the Children's Figural Creativity Test, scholar performance test and have the fat mass (FM) measured by the Dual-energy X-ray Absorptiometry. Children were divided in two groups (Lower x Higher) separated by the median value of CF and FM. Creativity was compared between groups by a paired t test and unpaired Mann-Whitney (P<0.005). Pearson or Spearman correlations were used to compare the associations between the variables. **RESULTS:** The results demonstrate no significant differences on creativity between VO₂ max (p=0.75) and FM (p=0.56) levels. In addition, no correlation was identified between creativity with CF (r=-.031; p=.828) and FM (r=-.174; p=.218). **CONCLUSIONS:** In conclusion, creativity is similar in children with different VO₂ and FM level and there is no relationship between these variables. However, are necessary more studies with a robust creativity measurement technique, based in neurobiological markers (NIRS, fMRI).

The Relationships between Cell Phone Use and Sedentary Behavior in Samples of Japanese and American College Students

Jacob E. Barkley¹, Andrew Lepp¹, Takahiro Sato¹, Koji Yamatsu², Ellen L. Glickman, FACSM¹. ¹Kent State University, Kent, OH. ²Saga University, Saga, Japan. (Sponsor: Ellen Glickman, FACSM)
 Email: jrbarkle1@kent.edu
 (No relevant relationships reported)

Previous work from our research group has indicated a significant, positive relationship between cellular telephone (cell phone) use and sitting or sedentary behavior in college students. However, this work has been limited to only a single, large, public university in the Midwestern United States. Therefore, it remains unknown if this relationship would be present in groups of college students from different geographic regions and/or cultural backgrounds.

PURPOSE: To compare the relationship between daily cell phone use and sedentary behavior in samples of college students from Japan and the United States.

METHODS: A sample of college students (N = 808, 20.2 ± 1.8 years old) from either a university in Japan (n = 534, 19.8 ± 1.1 years old) or the United States (n = 274, 21.71 ± 2.4 years old) completed validated surveys assessing age, daily cell phone use (min) and daily total sedentary behavior (min). Surveys were administered in English for American students and Japanese for students from Japan.

RESULTS: Independent samples t-tests revealed that Japanese students reported greater daily sitting (420 ± 264 min/day) and less daily cell phone use (215 ± 125 min/day) than American students (360 ± 198 min/day sitting, 274 ± 150 min/day cell phone use). Because of these differences, Pearson's correlation analyses assessing the relationship between cell phone use and sedentary behavior were performed

for Japanese and American students separately. There were significant, positive relationships between cell phone use and sedentary behavior in both Japanese (r = 0.132, p = 0.002) and American (r = 0.166, p = 0.006) college students.

CONCLUSION: While there were differences in sedentary behavior and cell phone use in Japanese versus American college students, the relationships between these variables was positive and significant regardless of group. This finding supports previous data indicating that elevated cell phone use is predictive of greater daily sitting in college students. Furthermore, present results indicate that this relationship extends beyond American college students.

Investigating the Impact of Acute Exercise and Brain Stimulation on Cognitive Control in Healthy Adults

Erika K. Hussey¹, Eduardo B. Fontes², Nathan Ward², Daniel R. Westfall³, Shih-Chun Kao⁴, Arthur F. Kramer³, Charles H. Hillman³. ¹US Army, NSRDEC, Natick, MA. ²Tufts University, Medford, MA. ³Northeastern University, Boston, MA. ⁴Purdue University, West Lafayette, IN.
 (No relevant relationships reported)

The field of cognitive enhancement has grown in popularity in recent years. Exercise and transcranial direct current stimulation (tDCS) are two approaches for which there is some evidence of transiently improved cognitive control. Yet, no research has systematically compared both approaches, so the degree to which these techniques influence similar mechanisms of improvement remains unknown. **PURPOSE:** We parametrically compared the acute effects of aerobic exercise and tDCS over left prefrontal regions on cognitive control. **METHOD:** 96 young healthy individuals (22.4 ± 4.1 years old) completed two testing sessions. The first session included baseline measurements of cognitive control on a flanker inhibition task and an n-back working memory task, followed by a maximal graded exercise test. During the second session, participants were randomly assigned to either 20 minutes of running on a treadmill at moderate intensity (60-70% of maximal heart rate) or 20 minutes of seated rest. After a 10-minute interval, participants were randomly assigned to receive 30 minutes of active tDCS (2mA anode over left prefrontal cortex; cathode over right bicep) or sham stimulation as they completed the flanker and n-back tasks. We compared baseline-corrected cognitive control performance as a function of Exercise (running vs. seated rest) and Stimulation (active vs. sham tDCS) using linear mixed effects models. **RESULTS:** Models revealed a main effect of Condition on n-back sensitivity (nonparametric signal detection A': t=2.45, p=0.014), but no significant effects of Stimulation, and no interaction of Exercise and Stimulation. Specifically, the individuals who exercised were better able to discriminate n-back targets from nontargets compared to the seated group. We did not observe any effects of Exercise or Stimulation on flanker performance (accuracy and response times on incongruent or congruent trials). **CONCLUSION:** Whereas noninvasive brain stimulation produced no effects on cognitive control, acute aerobic exercise significantly improved working memory performance. This suggests that the neuroenhancement mechanisms impacted by short bouts of exercise and tDCS may be distinct. Further, this pattern hints that aerobic exercise may have broader effects on cognitive control than non-invasive brain stimulation.

The Individual and Combined Effect of Hypoxia and Music on Physical Performance

Kate O'Keefe, Jacob Dean, Dr. Simon Hodder, Dr. Alex Lloyd. Loughborough University, Loughborough, United Kingdom. (Sponsor: Prof. George Havenith, FACSM)
 Email: k.e.okeefe@lboro.ac.uk
 (No relevant relationships reported)

Humans ascending to high altitude are susceptible to debilitating psychological alterations which include severe mood changes, cognitive fatigue, and neuropsychological impairments. The combination of environmental stressors that occur at altitude can further inhibit both physical and cognitive performance.

PURPOSE: Music has ergogenic effects on physical performance through enhancing psychological factors such as mood, emotion and cognition. This study aimed to explore the impact of music as a tool for mitigating the performance decrements observed at altitude. **METHODS:** Following ethical approval from Loughborough University, 13 healthy males (mean ± SD; 23.9 ± 4.01 years) completed one familiarisation session and four counterbalanced experimental trials; 1) normoxia (0.209 FiO₂) and no music; 2) normoxia (0.209 FiO₂) with music; 3) normobaric hypoxia (0.13 FiO₂) and no music; 4) normobaric hypoxia (0.13 FiO₂) with music. All conditions were completed at 21°C with 50% relative humidity. Music was self-selected by each participant prior to the familiarisation session. The songs were assessed for their motivational qualities using the Brunel Music Scale Inventory (BMRI-2). Each experimental trial included a 15-min self-paced time trial on an arm bike, followed by a 60-s isometric maximal voluntary contraction (MVC) of the biceps brachii. Supramaximal nerve stimulation was used to quantify central and peripheral

fatigue with voluntary activation (VA%) calculated using the twitch interpolation method. Subjective measures included motivation (MS) and mood using the Brunel Mood Scale (BRUMS). **RESULTS:** Average power output (W) was reduced with a main effect of hypoxia ($p = 0.02$) and significantly increased with a main effect of music ($p = 0.001$). When combined the interaction was additive ($p = 0.87$). Average MVC force (N) was reduced in hypoxia ($p = 0.03$) but VA% of the biceps brachii was increased with music ($p = 0.02$). MS and BRUMS remained unchanged across all conditions ($p > 0.06$). Music reduced subjective scores of mental effort, breathing discomfort, and arm discomfort in hypoxia ($p < 0.001$). **CONCLUSION:** Music increased self-paced and maximal physical exertion through enhancing neural drive and diminishing detrimental mental processes, enhancing performance at both sea level and high altitude.

G-19 Thematic Poster - Endocrine Responses to Exercise and Occupational Stressors

Coupling of Adrenal and Gonadal Hormones: Potential Relationship to Occupational Demand

Matthew R. Schoenherr, Lisa M. Hernandez, Marcus K. Taylor, Ph.D., FACSM. *Naval Health Research center, San Diego, CA.*
(Sponsor: Marcus Taylor, PhD, FACSM)
Email: matthew.r.schoenherr.ctr@mail.mil

(No relevant relationships reported)

The positive coupling hypothesis describes the hypothalamic-pituitary-adrenal and -gonadal systems as parallel, cooperative processes that represent joint calibration to meet internal, and/or environmental, demands. We recently tested this hypothesis in Naval Special Warfare (NSW) personnel and found positive coupling between the adrenal hormones, cortisol (CORT) and dehydroepiandrosterone (DHEA), and the gonadal hormone, testosterone (TESTO).

PURPOSE: To test the positive coupling hypothesis in Explosive Ordnance Disposal (EOD) personnel; a specialized military population whose mission is to ensure that hazardous explosives are rendered safe for unit preservation and security. **METHODS:** Active duty U.S. Navy EOD operators ($N = 64$; mean \pm SD age: 34 ± 6.0 years) self-collected saliva samples in a non-deployed, free-living setting on 2 consecutive weekdays at wake, wake + 30 min, wake + 60 min, 1600, and 2100 (10 samples total). Exclusion criteria included use of any anabolic supplements within the last 3 months. Coupling hypotheses (associations between CORT, DHEA, and TESTO summary parameters) were tested with Pearson product-moment correlation analyses. Established summary parameters were determined for each hormone: highest morning value, area under the curve (with respect to ground [morning values]), and averages of morning and evening values, respectively. **RESULTS:** DHEA was positively coupled with TESTO (r range: .28-.61, $p < .05$) and also with CORT (r range: .50-.57, $p < .05$) throughout the day. Positive coupling between CORT and TESTO was only observed in the evening ($r = .32$, $p = .014$). **CONCLUSION:** This study partially replicated our prior report in NSW personnel, which demonstrated that DHEA positively coupled with TESTO as well as CORT. The evening association of TESTO and CORT is also consistent with our previous findings and likely indicative of homeostatic processes. Unlike the previous study, however; the morning values of TESTO and CORT were not coupled in the present study. This inconsistency could potentially be explained by a warfighter's specific operational demands. For example, positive coupling may be adaptive for duties that include direct engagement with the enemy. In contrast, uncoupling may be more conducive to ensuring unit safety and security.

Testosterone Status Following Short-term, Severe Negative Energy Balance Predicts Fat-free Mass Loss in U.S. Marines

Claire E. Berryman, John J. Sepowitz, Holly L. McClung, Stefan M. Pasiakos, FACSM. *US Army Research Institute of Environmental Medicine, Natick, MA.* (Sponsor: Stefan M. Pasiakos, FACSM)

(No relevant relationships reported)

Male US military personnel exposed to periods of severe negative energy balance often experience marked reductions in circulating total testosterone, and it is not uncommon for concentrations to fall below normal levels (< 300 ng/dL). However, testosterone fluctuations following severe negative energy balance are variable, and little is known about the metabolic and physiological differences between males who experience low testosterone (LT) and those who maintain normal testosterone (NT). **PURPOSE:** To determine metabolic and physiological differences between males with LT versus those with NT following 8 d of strenuous military training. **METHODS:** Male US Marines ($n = 68$) were dichotomized based on testosterone concentration ($< \text{or} \geq 300$ ng/dL) following 8 d of severe negative energy balance incurred during military training. Body composition (DEXA) and whole-body protein turnover (^{15}N alanine) were measured and blood and urine samples collected before (PRE) and after (POST) training. Linear mixed models were used to assess the effects of testosterone status, time, and their interaction on outcomes. **RESULTS:** Testosterone concentrations decreased PRE (505 ± 135 ng/dL) to POST (284 ± 115 ng/dL, $P < 0.01$). When volunteers were dichotomized by POST testosterone status (NT, $n = 24$; 407 ± 97 vs. LT, $n = 44$: 217 ± 52 ng/dL, $P < 0.01$), PRE BMI, total fat mass, and testosterone were greater in NT compared to LT ($P < 0.05$). LT lost more fat-free mass (FFM, -3.4 ± 1.3 kg) and less fat mass (-2.4 ± 1.2 kg) compared to NT (-2.4 ± 2.0 and -3.2 ± 1.6 kg, respectively; P -interaction < 0.03). Insulin ($+5.55 \pm 9.35$ $\mu\text{U}/\text{mL}$) and norepinephrine ($+0.23 \pm 0.29$ ng/mL) increased from PRE to POST in LT, whereas no changes occurred in NT ($+1.03 \pm 3.75$ $\mu\text{U}/\text{mL}$ and $+0.04 \pm 0.30$ ng/mL, respectively), resulting in significant differences between groups (P -interaction < 0.02). Independent of time, LT had greater whole-body protein synthesis, breakdown, and flux (P -status < 0.01), but not net balance (P -status = 0.2), compared to NT. **CONCLUSION:** Military personnel susceptible to operational stress-induced LT may be predisposed to greater FFM loss during periods of negative energy balance incurred during short-term, strenuous military training. Supported by US Army Medical Research and Materiel Command; authors' views not official US Army or DoD policy.

Salivary Stress Biomarkers During the Lake Placid Ironman® Ultraendurance Event

Aidan P. Fiol, Deanna M. Dempsey, Douglas J. Casa, FACSM, Jun Hashiwaki, Rebecca L. Stearns, Robert A. Huggins, Amy L. McKenzie, Colleen X. Munoz, Elaine C. Lee. *University of Connecticut, Storrs, CT.*

Email: aidan.fiol@uconn.edu

(No relevant relationships reported)

Biomarkers such as salivary IgA (sIgA) have been established as valid, reliable, and non-invasive stress markers. sIgA concentrations have been reported to decrease following periods of high physiological stress, such as that experienced during ultraendurance events. Heat shock protein 70 (HSP70), a molecular chaperone, has been assessed primarily as a plasma/serum stress biomarker. The role of HSP70 in saliva, how it responds to extremely stressful exercise events and its correlation to changes in sIgA remain unclear. **PURPOSE:** To test the hypothesis that salivary HSP70 can be used as a salivary stress biomarker correlated to sIgA during an ultraendurance event. **METHODS:** Thirty-three subjects competing in the Lake Placid Ironman triathlon participated (all data, mean \pm SD: 38 ± 8 yrs, 178.4 ± 8.9 cm, 76.3 ± 10.4 kg, $10.8 \pm 3.8\%$ body fat, finish time 708 ± 90 min). Environmental symptoms questionnaires (ESQ) were administered before (PRE) and 1 hour after the race (POST). Hydration status was assessed via urine specific gravity (USG). Saliva samples were collected PRE, POST, and 1 day post-race (AMPOST) and analyzed for IgA (Salimetrics) and HSP70 (Enzo Life Sciences) by ELISA according to manufacturer instructions. Significant differences among time points were analyzed by repeated measures ANOVA and LSD post hoc tests. **RESULTS:** Subjects experienced significant stress with completion of the race (708 ± 90 min finish time, ESQ 1hPOST (20 ± 8) vs. PRE (5 ± 3 , $p < 0.05$), POST RPE (18 ± 2)). sIgA was decreased POST (41.71 ± 20.46 $\mu\text{g}\cdot\text{ml}^{-1}$) vs. PRE (48.88 ± 17.20 $\mu\text{g}\cdot\text{ml}^{-1}$, $p = 0.05$) and vs. AMPOST (37.76 ± 27.02 $\mu\text{g}\cdot\text{ml}^{-1}$, $p = 0.006$). Salivary HSP70 was increased POST (3.91 ± 3.29 ng $\cdot\text{ml}^{-1}$) vs. PRE (1.68 ± 1.93 ng $\cdot\text{ml}^{-1}$, $p = 0.0002$). **CONCLUSIONS:** Salivary HSP70 was detectable using a commercially available ultrasensitive HSP70 ELISA. Extracellular HSP70 in the oral cavity may be a non-invasive marker of stress during an ultraendurance event and is correlated with more common salivary stress marker sIgA.

Daily Cortisol Patterns in Specialized Military Men: Replication and Refinement in a Novel Population
 Genie Leah A. Padilla¹, Lisa M. Hernández¹, Marcus K. Taylor, FACSM². ¹Leidos, San Diego, CA. ²Naval Health Research Center, San Diego, CA.
 (No relevant relationships reported)

Amassing evidence suggests that post awakening cortisol patterns are useful indicators of health status. Our lab established summary parameters of cortisol and reported excellent stability across 2 days of repeated sampling in 58 U.S. Navy SEALs. To confirm the generalizability of our original findings, there is a need to replicate procedures in another military population with unique operational demands. **PURPOSE:** To establish the summary parameters of daily cortisol patterns, the stability of repeated sampling, and the impact of salivary sampling compliance in U.S. Navy Explosive Ordnance Disposal (EOD) operators. **METHODS:** Seventy active duty, male EOD operators (mean \pm SD age = 34.9 \pm 6.5 y) self-collected saliva samples in a nondeployed, free-living setting. Samples were collected on 2 consecutive weekdays at Wake, Wake + 30 min, Wake + 60 min, 1600, and 2100. Three measures of magnitude and three measures of pattern were computed. The stability of each parameter was evaluated via correlational analyses and Cronbach's alpha (α). Compliance was evaluated via actigraphy using two alternate compliance criteria. **RESULTS:** Average salivary cortisol concentrations increased at Wake + 30 min (mean \pm SE reactivity = 48.9 \pm 6.8%), followed by a swift recovery at Wake + 60 min. Approximately 17.4% (n = 12) were classified as negative-reactors (i.e., <0% change from Wake to Wake + 30 min). The three measures of magnitude demonstrated good stability across 2 days (r value range: 0.37-0.45, ps < 0.01; α range: 0.54-0.62). Fifty-five percent of the sample was classified as compliant (defined as <15 min deviation from target sampling times) across both days; this decreased to 31% when compliance was refined to <5 min deviation. However, controlling for compliance did not convincingly influence any of the summary parameter estimations or their stability. **CONCLUSIONS:** These findings demonstrate a thorough replication and refinement of our prior report, implying that these results are generalizable across diverse military populations. The noninvasive salivary sampling protocol used in this study yields stable estimations of daily cortisol patterns in specialized military men. This sampling protocol is recommended for use as an operational health surveillance instrument for chronically stressed military members.

Cortisol Responses During a Long Duration Incremental Exercise Protocol in the Heat while Wearing Personal Protective Equipment
 Thomas Service¹, Cory Coehoorn¹, Lynne Stuart-Hill¹, Olave Krigolson¹, Patrick Neary². ¹University of Victoria, Victoria, BC, Canada. ²University of Regina, Regina, SK, Canada.
 (No relevant relationships reported)

Individuals in occupations that wear personal protective equipment (PPE) are exposed to acute heat stress on a regular basis. There is no research evaluating the effects of rapid and uncompensable core temperature (T_c) acquisition, as which occurs when one is wearing PPE, on rate and magnitude of salivary cortisol appearance. **PURPOSE:** To determine the effects of rapid and uncompensable (T_c) acquisition on the rate and magnitude of salivary cortisol appearance. **METHODS:** Fourteen male subjects (33.6 \pm 12.1 years) performed an incremental treadmill test to a termination point in a control session (CON) and an experimental session (PPE). Salivary samples were collected using an oral swab stimulated method. Saliva samples were processed and analyzed for salivary cortisol concentration using a highly sensitive enzyme immunoassay. Heart rate (HR), thermal comfort scale (TCS) and thermal sensation (TS) were also recorded at each 0.5°C increase in core temperature (T_c). **RESULTS:** There were significant differences in time to termination (TTT) (CON = 77.3 \pm 12.6 min; PPE = 50.3 \pm 6.9 min), pre-exercise HR (CON = 76.8 \pm 4.8 bpm; PPE = 86.5 \pm 5.1 bpm), post-exercise HR (CON = 161.1 \pm 11.9 bpm; PPE = 179.6 \pm 6.8 bpm), end-exercise T_c (CON = 38.57 \pm 0.3°C; PPE = 39.01 \pm 0.3°C), TCS (CON = 3.57 \pm 0.6; PPE = 4.63 \pm 0.3), and TS (CON = 7.57 \pm 0.5; PPE = 8.67 \pm 0.3). There was also a 0.04°C/min increase in T_c during PPE and a 0.02°C/min increase in T_c during CON. Significant cortisol results showed a difference in the rate of cortisol appearance (CON = 0.002 μ g dL⁻¹ min⁻¹; PPE = 0.018 μ g dL⁻¹ min⁻¹). There was a significant difference in mean cortisol values between start of exercise and the end of exercise (p \leq 0.01). There was also a significant difference (p \leq 0.05) between magnitude of salivary cortisol values at termination when comparing CON and PPE. **CONCLUSION:** Rapid and uncompensable T_c acquisition results in an elevated acute cortisol response. This will have implications for individuals who are employed in fields that are exposed to acute heat stress chronically. The acute effects of increased cortisol concentration are a decreased anabolic response, decreased cognitive performance, and decreased mood states. The chronic effects are many, but are mostly related to atherosclerosis development and subsequent cardiovascular disease.

 (No relevant relationships reported)

PURPOSE: To determine the effect of demographic, health, and treatment factors on moderate to vigorous physical activity (MVPA) in breast cancer patients undergoing chemotherapy. **METHODS:** Breast cancer patients (N=66, M_{age} = 48.3 \pm 10.0 years) undergoing chemotherapy (CT) wore an accelerometer for 24-hours (worn on the hip during the day and wrist while sleeping) for ten consecutive days (3 days pre-, day of, and 6 days post-CT dose) during three treatment phases (beginning, middle and end of chemotherapy). Mixed models were used to assess the effect of demographic, health, and treatment factors on MVPA. We assessed the effect of time point (burst), treatment status (i.e. pre-CT dose v. day of/post-CT dose), burst x treatment status interaction, age, body mass index, education, total number of comorbidities, disease stage, cumulative treatment cycle number, self-reported pre-diagnosis minutes/day of MVPA, weekend v. weekdays, and self-reported health status on daily minutes of MVPA. **RESULTS:** On average, breast cancer patients engaged in 20.8 minutes/day (95%CI:17.4,24.1) of MVPA across all bursts. Results indicate a significant decrease of 5.0 minutes/day of MVPA(95%CI:-6.5,-3.5) as time point increases, a 4.2 minute/day decrease in MVPA(95%CI:-5.8,-3.2) on day of CT dose or post-CT days compared to pre-CT dose days, a 0.9 minute/day increase in MVPA (95%CI: 0.5,1.3) as treatment cycle number increases, and a 2.2 minute/day increase in MVPA (95%CI:1.1,3.2) on weekends. **CONCLUSIONS:** Results from the current analysis suggest treatment-related factors, such as treatment day, post-treatment days, and time undergoing chemotherapy, had the greatest effect on MVPA in breast cancer patients, significantly decreasing minutes per day spent in MVPA over time. These results show the importance of tailoring future physical activity interventions to specific treatment factors in order to reduce the decline in MVPA during chemotherapy.

Overcoming Fitness, Symptom, and Behavior Barriers After A Physical Activity Intervention With Fitness Graded Motion Exergames (PAfitME) Among Head And Neck Cancer Patients
 Hsiao-Lan Wang¹, Harleah Buck¹, Tapan Padhya¹, Kristine Donovan², Laura Szalacha¹, Ellen Smith³, Srinivas Katkooori¹, Barbara Smith, FACSM¹. ¹University of South Florida, Tampa, FL. ²Moffitt Cancer Center, Tampa, FL. ³University of Michigan, Ann Arbor, MI. (Sponsor: Barbara Smith, Member# 126904, FACSM)
 Email: hwang5@health.usf.edu
 Reported Relationships: **H. Wang: Receipt of Intellectual Property Rights/Patent Holder; Exergame Grading Scheme (Copyright: TXu1-996-913).**

Purpose: Routinely engaging physical activity (PA) leads to better health outcomes in cancer survivors. Over 50% of head and neck cancer (HNC) survivors rarely engage in any type of PA because of the barriers of impaired fitness, severe symptoms, and poor self-efficacy (SE). A personalized telehealth Physical Activity intervention with fitness graded Motion Exergames (PAfitME) was designed to overcome these barriers. In our pilot study, we found the HNC patients fully adhered with the personalized exergame prescription in the 6-week PAfitME intervention. The purpose of this study was to examine changes in barriers: fitness (gait speed), symptoms, and SE among HNC patients participating in the PAfitME intervention.

Methods: A pre/post-test design was used to test the 6-week PAFitME intervention. Personalized exergame prescriptions were developed and progressed based on the social cognitive theory and exercise principal of adaptation. Fitness was measured by preferred gait speed (m/s). Symptom data were collected via the MD Anderson Symptom Inventory, Brief Pain Inventory, Pittsburg Sleep Quality Index, General Anxiety Disorder scale, and Center for Epidemiologic Studies Depression Scale. SE was measured by the PA Self-Efficacy scale (0-100%). Descriptive statistics and paired t tests were applied.

Results: A total of 10 HNC participants were recruited. Two participants dropped out due to recurrence. The mean age was 58.2 years old (n=8). Seven (88%) were male. Three (38%) had oral cancer and 5 (63%) had laryngeal cancer. Three (38%) had a feeding tube and 2 (25%) had a tracheostomy. Four (50%) had stage III/IV cancer. Mean gait speed improvement was clinically significant (0.11m/s). There were positive improvements in 17 of 20 symptoms with significant decreases in pain ($t=2.34$, $p=0.05$), in fatigue ($t=3.64$, $p=0.008$) and in difficulty with voice/speech ($t=2.35$, $p=0.05$). Seven participants (88%) had 100% SE to do their personalized exergame prescription in the post test.

Conclusions: This study shows HNC participants overcame their PA barriers after the PAFitME intervention. It also supports the need for a larger randomized clinical trial for efficacy testing. The positive impact from PAFitME will shift PA interventions from a standardized protocol to a personalized, behavioral telehealth approach.

Muscle Function And Cancer Related Fatigue In Prostate Cancer Survivors Receiving Different Treatment Regimens

Sandro Nobre Chaves¹, Filipe Dinato de Lima¹, Martim Bottaro¹, Claudio L. Battaglini, FACSM², Ricardo Jacó de Oliveira¹.
¹University of Brasilia, Brasilia, Brazil. ²University of North Carolina at Chapel Hill, Chapel Hill, NC. (Sponsor: Claudio L Battaglini, FACSM)
Email: sandronobrec@gmail.com
(No relevant relationships reported)

Prostate cancer is the most commonly neoplastic disease that affects men in the world. Androgen deprivation therapy (ADT) is the treatment regimen most used in advanced disease stages. Whereas the occurrence of late side effects induced by ADT seems well described, the long-term consequences of ADT in muscle function and fatigue have not been well documented.

PURPOSE: The purpose of this study was to assess fatigue, muscle strength, muscle thickness, and muscle quality in prostate cancer survivors undergoing to ADT.

METHODS: Ten prostate cancer patients on ADT (ADT group) (74.40 ± 5.76 years, 77.44 ± 14.75 kg and 1.63 ± 0.07 m), 8 patients not undergoing ADT (N-ADT) (69.75 ± 5.92 years, 82.25 ± 9.20 kg and 1.70 ± 0.07 m) and 18 healthy control subjects (CON) (72.17 ± 6.54 years, 77.94 ± 9.47 kg and 1.69 ± 0.07 m) participated in this study. Perceived fatigue was assessed through 20-item Multidimensional Fatigue Inventory. Muscle thickness and quality (e.g., echo intensity) were assessed through B-mode ultrasound. Muscle strength and work capacity were assessed using an isokinetic dynamometer. One-way ANOVAs with Bonferroni post-hoc were used for comparisons between groups adjustment.

RESULTS: Muscle thickness was lower in ADT than CON (21.32 ± 3.20 vs. 26.49 ± 5.10 respectively, $p = 0.021$). Peak torque was lower in ADT than CON (109.78 ± 30.36 vs. 154.67 ± 33.92 respectively, $p = 0.005$). Work capacity was lower in ADT than CON (1964.40 ± 571.71 vs. 2923.67 ± 604.39 respectively, $p < 0.001$). ADT showed greater echo intensity than CON (116.82 ± 15.98 vs. 101.23 ± 8.33 respectively, $p = 0.005$) and N-ADT (102.73 ± 11.72, $p = 0.046$). There were no differences between N-ADT and CON on muscle thickness, peak torque, work capacity, and echo intensity ($p > 0.05$). General fatigue was greater on both ADT (11.10 ± 3.41 vs. 7.83 ± 2.60, $p = 0.030$) and N-ADT (11.13 ± 3.48 vs. 7.83 ± 2.60, $p = 0.047$) compared to CON. Physical fatigue was greater on ADT than CON (13.20 ± 4.02 vs. 8.72 ± 2.87, $p = 0.006$).

CONCLUSIONS: Therefore, it appears that the nature of ADT treatment has a deeply negative effect on muscle function and fatigue when compared to patients not-undergoing ADT. Therefore, further research is needed to confirm these preliminary findings, in order to attenuate the decline of muscle function and fatigue in men undergoing ADT treatment.

Inflammation Mediates The Effects Of Exercise On Fatigue In Patients With Breast Cancer Undergoing Chemotherapy

Anouk E. Hiensch¹, Sara Mijwel², Yvonne Wengström², Anne M. May¹, Helene Rundqvist². ¹University Medical Center Utrecht, Julius Center for Health Sciences and Primary Care, Utrecht, Netherlands. ²Karolinska Institutet, Stockholm, Sweden.
Email: a.e.hiensch-2@umcutrecht.nl
(No relevant relationships reported)

PURPOSE: The randomized controlled OptiTrain trial showed beneficial effects on fatigue after a 16-week exercise program in patients with breast cancer undergoing adjuvant chemotherapy. Hypothesized underlying mechanisms include the involvement of inflammatory pathways. Here, we investigated the effects of exercise on inflammation markers and whether the positive effects on fatigue were mediated by changes in inflammation.

METHODS: 240 women scheduled for chemotherapy were randomized to 16-weeks of resistance and high-intensity interval training (RT-HIIT), moderate-intensity aerobic and high-intensity interval training (AT-HIIT) or usual care (UC). In the current mechanistic analyses, we included participants with >60% attendance and a random selection of controls (RT-HIIT = 30, AT-HIIT = 27, UC = 29). Ninety-two blood markers (e.g. IL-6, TNF α , soluble CD8A) were quantified at baseline and post-intervention. The Piper Fatigue Scale was used to assess general and physical fatigue. Mediation analyses were conducted to explore whether changes in inflammation markers mediated the effect of exercise on general and physical fatigue. ANCOVA, adjusted for menopausal status, chemotherapy treatment (taxanes/no taxanes) and baseline values of the inflammation marker and fatigue, was used to identify between-group differences in the outcome.

RESULTS: In general, chemotherapy led to an increase in inflammation. The increase in IL-6 (pleiotropic cytokine) and CD8a (T-cell surface glycoprotein) was, however, less pronounced following RT-HIIT compared to UC (-0.45 (95% CI -0.85; -0.05), $p=0.03$ and -0.28 (95% CI -0.57; 0.004), $p=0.05$, respectively). The changes in IL-6 and CD8a significantly mediated the effects of exercise on both general and physical fatigue by 32.0% and 27.7%, and by 31.2% and 26.4%, respectively. No significant between-group differences in inflammation markers at 16 weeks (post-intervention) were found between AT-HIIT and UC.

CONCLUSIONS: This study is the first showing that supervised RT-HIIT partially counteracted the increase in inflammation during chemotherapy, i.e. IL-6 and soluble CD8a, which resulted in lower fatigue levels post-intervention. Exercise might be put forward as an effective treatment to reduce chemotherapy-induced inflammation and subsequent fatigue.

3277 Board #5 June 1 9:00 AM - 11:00 AM

Differences by Activity Level in Barriers and Benefits of Exercise in Breast Cancer Survivors

Gwendolyn A. Thomas, Margaret F. Bedillion. Syracuse University, Syracuse, NY.
(No relevant relationships reported)

Physical activity is a critical component of treatment for breast cancer survivors that prevents additional cancer recurrence, comorbid chronic disease and body composition changes. However, recommended physical activity guidelines are rarely met.

PURPOSE: This study examined how barriers and benefits of exercise differ between breast cancer survivors who are not engaging in any moderate or vigorous physical activity, those doing physical activity but not meeting physical activity guidelines, and those meeting recommended physical activity guidelines. **METHODS:** 392 breast cancer survivors were recruited through the Susan Love/Army of Women, a national non-profit breast cancer organization, and completed the Exercise Barriers and Benefits Survey, the International Physical Activity Questionnaire and questions on resistance exercise activities. **RESULTS:** Multivariate ANOVAs examined whether exercise groups differed in types of exercise benefits and barriers they reported. 267 of the women (69.6%) did not meet recommended guidelines (150 minutes/week of aerobic activity and twice per week resistance exercise). The greatest perceived benefits were for physical performance and the lowest were for social interaction. There were significant differences between groups on benefits ($F = 18.981$; $df = 2, 16$; $p = .000$; $\eta^2 = .090$). Exercise benefits were not significantly different between the some exercise and exercise guidelines groups. The greatest perceived barriers were for physical exertion and the lowest were for the exercise milieu. There were significant differences between groups on barriers ($F = 54.807$; $df = 2$, $p = .000$; $\eta^2 = .222$). The some exercise group had significantly higher barriers than the exercise guidelines group ($p = .047$).

CONCLUSIONS: Despite recommendations, the majority of breast cancer survivors do not meet physical activity guidelines. Understanding which barriers and benefits are relevant to different groups of exercisers is an important avenue to prescribing exercise in an at risk population. Personalized approaches may promote exercise initiation in those not currently exercising; while targeting different barriers may help those already exercising to meet recommended physical activity guidelines.

3278 Board #6 June 1 9:00 AM - 11:00 AM**Effects Of Exercise On QoL And Fatigue of Inactive Breast Cancer Survivors, A TwiCs study**

Anne M. May¹, Roxanne Gal¹, Carla H. van Gils¹, Rolf HH Groenwold², Desirée HJG van den Bongard¹, Petra HM Peeters¹, Helena M. Verkooijen¹, Evelyn M. Monnikhof¹. ¹University Medical Center Utrecht, Utrecht, Netherlands. ²Leiden University Medical Center, Leiden, Netherlands.
Email: a.m.may@umcutrecht.nl
(No relevant relationships reported)

PURPOSE: Meta-analyses have shown beneficial effects of exercise on quality of life (QoL) and fatigue in breast cancer survivors. Methodological considerations, however, are drop out after randomization to control caused by disappointment and contamination (controls adopting the behavior of the intervention group), since blinding in exercise trials is not possible. TwiCs (Trials within Cohorts) is an alternative for conventional randomized clinical trials and might overcome these disadvantages. We studied the 6-month effectiveness of a 12-week exercise program on the QoL and fatigue in inactive breast cancer survivors using the innovative TwiCs design.

METHODS: The UMBRELLA Fit study is nested within the UMBRELLA cohort, including patients at the radiotherapy department of the UMC Utrecht. Patients were asked consent for prospective collection of medical data and patient reported outcomes, and to be randomized to future intervention studies. For UMBRELLA Fit, we randomized 260 eligible inactive (<150 min/wk moderate to vigorous leisure time and sports activities) breast cancer survivors, 12-18 months after cohort inclusion. Survivors randomized to the intervention group (n=130) were offered a twice weekly supervised moderate to high intensity aerobic and resistance exercise program. Survivors were also asked to be active for 30 min/day supported by an activity tracker. The control group (n=130) was not informed and received usual care (UC). To evaluate effects on QoL and fatigue by intention to treat ANCOVA regular cohort measurements (EORTC QLQ 30, MFI-20) were used.

RESULTS: Included breast cancer survivors aged 58±10 years and 52% (68/130) accepted the intervention. TwiCs accrual was efficient and no contamination was observed (median change in physical activity from baseline in controls was 0). At baseline, QoL was comparable to Dutch reference values and no significant between-group changes were observed. Physical fatigue was significantly lower following the exercise intervention (effect size 0.2, p<0.05) compared to UC.

CONCLUSIONS: Physical exercise has beneficial effects on physical fatigue of inactive breast cancer survivors. Future instrumental variable analysis will show influence of non-acceptance on the intervention effect. The TwiCs design seems feasible for pragmatic trials.

3279 Board #7 June 1 9:00 AM - 11:00 AM**Community-based Soccer Improves Hip BMD, Mental Health, And Reduces Hospital Admissions In Prostate Cancer Patients**

Eik D. Bjerre¹, Klaus Brasso¹, Julie Midtgaard². ¹Rigshospitalet, Copenhagen, Denmark. ²University of Copenhagen, Copenhagen, Denmark.
Email: eb@ucsf.dk
(No relevant relationships reported)

Physical exercise has been shown to improve quality of life, fitness, and physical function for men with prostate; however, research on effects of real-life interventions is warranted. **PURPOSE:** To evaluate the effects of one year of community-based soccer training on bone mineral density (BMD), body composition, mental health, and hospital admissions. **METHODS:** Design, Setting and Participants: In a pragmatic, multicentre, parallel randomised controlled trial, 214 men with prostate cancer were randomly assigned to either soccer delivered in local football clubs (FG, n=109) or usual care including referral to community-level rehabilitation (UG, n=105). **Intervention:** One hour of soccer twice weekly over one year or usual care. All participants received standardised advice in relation to physical activity guidelines. **Outcome Measurements and Analysis:** BMD, lean body mass, and fat mass were assessed with dual-energy X-ray absorptiometry. Mental health was assessed by Short Form-12 Mental Component Summary. Per-protocol population was defined as soccer participation ≥50% of training sessions over one year. **RESULTS:** Total hip BMD improved for both intention-to-treat (ITT) 0.007 g/cm² (95% CI 0.004 to 0.013, p = 0.037) and per-protocol population 0.007 g/cm² (95% CI 0.000 to 0.015, p = 0.046). The per-protocol population scored 2.9 points higher (95% CI 0.0 to 5.7, p = 0.048) on mental health, and reduced fat mass by 0.9 kg (95% CI -1.7 to -0.1, p = 0.029). No changes were observed in lean body mass. Hospital admissions were reduced in the ITT population with 20 in FG and 33 in UG (p = 0.016). In the per-protocol population odds ratio for hospital admission was 0.34 (p = 0.042) for FG compared to UG.

CONCLUSIONS: Community-based soccer improved hip BMD, and men who played regularly for one year improved mental health, lost fat mass and had fewer hospital admissions.

3280 Board #8 June 1 9:00 AM - 11:00 AM**Exercising Together® for Couples during Radiation Therapy for Prostate Cancer: A Pilot Feasibility Study**

Mary E. Medysky, Jessica C. Siteмба, Kimi Daniel, Arthur Hung, Kerri M. Winters-Stone, FACSM. *Oregon Health & Science University, Portland, OR.* (Sponsor: Kerri Winters-Stone, FACSM)

(No relevant relationships reported)

We developed Exercising Together®, a partnered strength training program, as an exercise-based approach to improve patient, spouse and relationship health for couples coping with cancer. Exercising Together® may be most effective during cancer treatment, when couples experience the most stress, but the program has only been tested in couples post-treatment. **PURPOSE:** To determine the feasibility and acceptability of Exercising Together® during a course of radiation therapy for prostate cancer and the preliminary efficacy of the program on physical function, symptoms and dyadic coping in both the patient and spouse. **METHODS:** Couples were recruited from a radiation oncology clinic to participate in group classes of Exercising Together® 3x/week throughout his treatment. Classes consisted of moderate-intensity strength training performed by the couple who worked as training partners. The Physical Performance Battery (timed walk, stance and chair stand) and 400m walk time, and anxiety (SCL-90 ANX), depressive symptoms (CES-D), intimacy (Physical Intimacy Scale) and dyadic coping (active engagement and protective buffering) were assessed at baseline and at the end of radiation, with self-report measures assessed again 8 weeks after training stopped. Independent Wilcoxon-signed rank tests were used to assess change in each patients and spouses. **RESULTS:** 10 couples were enrolled within 3-months. Retention was 100% and average adherence to prescribed classes was 78%. No adverse events occurred. Patients showed significant increases in 4m walk speed (p=0.017), reductions in anxiety (p=0.027) and more active engagement based on the dyadic coping scale (p=0.039) at the end of training. Spouses had improvements in PPB scores (p=0.023) and chair stand time (p=0.024) post-training. At 8-week follow-up no further changes occurred in men, but spouses had significant reductions in depressive symptoms (p=0.016) and nearly significant reductions in anxiety (p=0.066). **CONCLUSION:** Exercising Together® is feasible, acceptable and improved physical, mental and relationship health over a course of radiation therapy. Comparisons to a control group may further identify benefits; however, based on these data a larger, multi-site trial of Exercising Together® in the radiation oncology setting is warranted.

G-21 Thematic Poster - Muscle Damage and Injury

Saturday, June 1, 2019, 9:00 AM - 11:00 AM

3282 Board #1 June 1 9:00 AM - 11:00 AM**The Role of T Cells in Muscle Damage Protective Adaptation**

Michael R. Deyhle¹, Meghan Carlisle², Chad Hancock², Robert Hyldahl². ¹University of Florida, Gainesville, FL. ²Brigham Young University, Provo, UT.
Email: mrd.deyhle@gmail.com

(No relevant relationships reported)

Skeletal muscle rapidly adapts to contraction-induced damage such that it is subsequently resistant to damage. This phenomenon is called the repeated bout effect (RBE). Interestingly, following damaging contractions on one muscle group the contralateral analogous muscle group also acquires resistance to damage. This is known as the contralateral RBE (cRBE). The mechanisms that underlie the acquisition of the repeated bout effect are not yet fully understood, yet some studies have shown that muscle immune cell accumulation and inflammation after the initial muscle damage is necessary for the RBE to be realized. T-cells are capable of generating immunological memory, an attribute that is central to their role in adaptive immunity. Additionally, a growing body of literature highlights an important role of T-cells in muscle healing following injury. Therefore, we hypothesized that T-cells could

Abstracts were prepared by the authors and printed as submitted.

contribute to the RBE in a way reminiscent to their role in adaptive immunity. In this study, *in vivo* lengthening contractions (LC) were used to model the RBE and the cRBE. Flow cytometry was used to characterize intramuscular T-cells following single and repeated bouts of LC. Herein, we also test the hypothesis that T-cells contribute to the RBE by immunological memory. Rats that did two bouts of LC separated by 2 weeks sustained less damage after the second bout. Rats that did a repeated bout of LC on the opposite limb were not protected from damage. CD4+, CD8+ and regulatory T-cells increased in muscle muscles that sustained damage. In rats that were protected from damage a minimal increase in T-cells was observed. Adoptive transfer of T-cells from rats that had previously done muscle-damaging LC did not confer damage protection to recipient rats. In conclusion, the RBE, but not the cRBE was observed in rats, and T-cells infiltrate muscle damaged by LC, but they do not appear to contribute to the RBE in the same way that they drive adaptive immunity.

Low-Dose Rapamycin Facilitates Recovery from Exercise-Induced Muscle Injury

Christopher L. Rawdon, Christopher P. Ingalls. *Georgia State University, Atlanta, GA.*

Email: crawdon1@student.gsu.edu

(No relevant relationships reported)

Rapamycin has been shown to have a dose-dependent effect on multiple signaling proteins in skeletal muscle cells that influence protein synthesis and calcium handling. However, it has yet to be determined if a low-dose of rapamycin impacts skeletal muscle during recovery from an exercise-induced injury. **PURPOSE:** To determine if low-dose rapamycin affects the rate of isometric strength recovery, muscle ubiquitination levels and markers of autophagy compared to saline control 14 days after exercise induced injury. **METHODS:** Mice were injected with either saline (SAL; 0.9%) or low-dose rapamycin (RAP; 10 µg/kg body weight) every other day for 2 weeks before and after a single bout of 150 eccentric contractions of the left anterior crural muscles. The recovery of strength of the anterior crural muscles was measured *in vivo* immediately, 7 days, and 14 days after injury induction. The magnitude of expression of beclin-1, ubiquitin, and ubiquitinated protein in injured and contralateral control TA muscles (i.e., primary anterior crural muscle) were analyzed via Western blot at 14 days after injury. **RESULTS:** Isometric twitch torque values did not differ between groups at any time point. No group differences in peak isometric tetanic torque were observed pre-injury, post-injury or 7 days following injury. However at 14 days, RAP mice recovered to pre-injury peak isometric torque values ($P_{pre} = 2.30 \pm .07$ Nmm; $14d = 2.25 \pm 0.08$ Nmm) while SAL group was significantly lower than pre-injury. At 14 days, RAP mice generated 15.4% higher maximal torque than SAL group ($p = 0.04$). Beclin-1 and free ubiquitin expression in TA muscles were significantly increased in both SAL (1.4-fold and 2.3-fold, respectively) and RAP (2.2-fold and 8.0-fold, respectively) mice at 14 days after injury compared to the uninjured muscle. The increase in the free ubiquitin in the injured muscle was 3.3-fold greater in the RAP treatment compared to SAL ($p = 0.001$). There were no significant changes in the ubiquitination of proteins among the groups at 14 days post-injury. **CONCLUSION:** Chronic low-dose rapamycin treatment in mice enhances recovery of skeletal muscle from eccentric contraction-induced injury at the 14th day and accentuates the upregulation of free ubiquitin.

Time Course of Change in Critical Torque following Exercise-Induced Muscle Damage

Robert E. Hight, Darshit S. Patel, Jessica A. Peterson, Cameron Lohman, Jason A. Campbell, Michael G. Bembien, FACSM, Christopher D. Black, FACSM. *University of Oklahoma, Norman, OK.* (Sponsor: Christopher D. Black, FACSM)
Email: robbyhight@gmail.com

(No relevant relationships reported)

Exercise-induced muscle damage (EIMD) is a result of high-force eccentric contractions and can lead to significant alterations in the structure and function of skeletal muscles. Critical torque (CT) and the impulse above critical torque (IACT) have both been reported to decrease following EIMD. **PURPOSE:** The purposes of this study were to 1) observe the time course of change in CT and IACT up to 7-days following EIMD, and 2) to assess the extent to which central and peripheral fatigue contribute to changes in CT and IACT following EIMD. **METHODS:** Participants (males = 6, females = 4) completed 2 familiarizations and 5 experimental visits. Fatigue patterns were assessed, and CT and IACT were derived at the 1st experimental visit. The 2nd experimental visit included an EIMD protocol consisting of 100 back squats. The 3rd, 4th, and 5th experimental visits were identical to the 1st. CT and IACT were acquired through voluntary and stimulated conditions. **RESULTS:** The participant's ratings of muscle soreness were significantly elevated up to 4-days following EIMD ($p < 0.05$). Dominant leg MVIC was reduced up to 2-days ($p < 0.05$) while non-dominant leg MVIC was reduced up to 4-days ($p < 0.05$) following EIMD. Mean CT was decreased up to 4-days following EIMD in the voluntary

condition ($p < 0.05$) while decreases lasted up to 2-days in the stimulated condition ($p < 0.05$). IACT was not significantly different following EIMD in either conditions ($p > 0.05$). Voluntary activation was not significantly different following EIMD ($p > 0.05$) and these results are the same for twitch torque ($p > 0.05$). EMG RMS and twitch torque both showed a significant reduction during the voluntary CT test ($p < 0.05$). There were no changes in low-frequency fatigue after the voluntary and stimulated conditions ($p > 0.05$) or following EIMD ($p > 0.05$).

CONCLUSIONS: Even though CT was lower following EIMD, IACT was not. Additionally, our results show no contribution of central or peripheral fatigue on torque production following EIMD. These findings suggest the loss in torque production following EIMD to be a factor of EIMD's effect on muscular function and not the central and peripheral mechanisms of fatigue.

3285 Board #4 June 1 9:00 AM - 11:00 AM

Short Wave Elastography Changes in the Biceps Brachii in Response to a Muscle Damage Protocol

Jeffrey Brent Feland, Garrett Jones, Cameron Smallwood, Jon Blotter, A. Wayne Johnson. *Brigham Young University, Provo, UT.* (Sponsor: J. Ty Hopkins, FACSM)

Email: Brent_Feland@byu.edu

(No relevant relationships reported)

PURPOSE: Standard ultrasound (US) imaging can help determine structural alterations within muscle and tendon; however, it offers limited information about the intrinsic mechanical properties of muscle. Because muscle is compressible, but transversely isotropic, the most accurate measure is the shear modulus, and SWE correlates well with Young's modulus. Shear wave changes should be useful for determination of muscle lesions or intrinsic changes. To date only a couple studies have observed SWE changes in an arm undergoing DOMS with varying results. Thus, the purpose of this study was to track the changes in biceps SWE changes in kilopascals (kPa), from baseline to 1 week post muscle damage protocol.

METHODS: Standard ultrasound (US) imaging can help determine structural alterations within muscle and tendon; however, it is limited in its ability to convey information about the intrinsic mechanical properties of muscle. Because muscle is compressible, but transversely isotropic, the most accurate measure is the shear modulus, and SWE correlates well with Young's modulus. Shear wave changes should be useful for determination of muscle lesions or intrinsic changes. To date only a couple studies have observed SWE changes using velocity as the variable of interest in muscle undergoing DOMS with varying results. Thus, the purpose of this study was to track the changes in bicep SWE changes (kPa), from baseline to 1 week post muscle damage protocol.

RESULTS: All data were analyzed using a RMANOVA with post-hoc comparisons to determine significance between data points. VAS and SWE were significantly increased for the DOM group at 24 and 48 hours post exercise ($P < .0001$) with no significant difference between 24 and 48 hours for SWE ($p = 0.825$), while VAS scores increased significantly from 24-48 hours post ($p = 0.031$). There was with no significant difference between baseline VAS ($p = 0.196$) or SWE ($p = 0.087$) at 1 week.

CONCLUSIONS: SWE values increased significantly from baseline to 24 hrs and stayed elevated at 48 hours, which is contrary to data from a published study showing a decrease after 24 hours in the brachialis. This could be due to muscle position. SWE measures of the bicep in an extended position appears to follow VAS and muscle damage progression better than SWE measurements reported from DOMS in a resting position.

Vastus Lateralis Muscle Quality Deteriorates More So Than Muscle Size During Knee Joint Immobilization

Michael Sahebi, Rob J. MacLennan, Nathan Becker, Ethan Davis, David Ogilvie, John McDorman, Ernest Vargas, Matt S. Stock. *University of Central Florida, Orlando, FL.*

Email: sahebi12@knights.ucf.edu

(No relevant relationships reported)

Disuse of a muscle group, such as what occurs during bedrest, limb immobilization, and spaceflight, results in atrophy. Investigators have yet to examine the extent to which short-term disuse alters the composition of muscle tissue, which can be quantified via measures of echogenicity. **PURPOSE:** The purpose of this study was to examine the effects of two weeks of knee joint immobilization on vastus lateralis echo intensity and cross-sectional area. **METHODS:** Twelve healthy females (mean \pm SD age = 21 ± 2 years) with a body mass index ≤ 30 kg/m² voluntarily underwent two weeks of left knee joint immobilization via ambulating on crutches and use of a brace. The brace was worn at all times except during sleep, and compliance was confirmed via accelerometers secured around both ankles. Before (PRE) and after the two-week period (POST), B-mode ultrasonography was used to obtain panoramic images of the left (immobilized) and right (control) vastus lateralis in the transverse plane. Images were taken from 50% of femur length. The same investigator performed all imaging. Images were analyzed at the end of the study with ImageJ software to quantify vastus

lateralis echo intensity and cross-sectional area. Two-way (time \times limb) analyses of variance, effect size statistics, and linear regression were used to interpret the data. **RESULTS:** Echo intensity showed a significant time \times limb interaction ($F = 8.27$, $p = .015$, $\eta^2 = .429$). Follow-up analyses showed a large increase in echo intensity (i.e., decreased muscle quality) for only the immobilized limb ($p = .016$, Cohen's $d = 0.817$). Declines in muscle cross-sectional area for the immobilized limb were less consistent, as no time \times limb interaction was observed ($F = 2.90$, $p = .116$, $\eta^2 = .209$). There was, however, a significant association between the change in echo intensity and the change in cross-sectional area ($r^2 = .383$, $p = .032$). **CONCLUSION:** In healthy female participants, two weeks of knee joint immobilization resulted in considerable changes in vastus lateralis muscle quality, whereas the atrophic response was less dramatic.

The Effects of Betalain Supplementation on Indices of Muscle Damage

Steven Vitti¹, Samuel Headley, FACSM², Susan Sotir², Elizabeth O'Neill². ¹University of Illinois Springfield, Springfield, IL. ²Springfield College, Springfield, MA. (Sponsor: Samuel Headley, FACSM)
 Email: svitt2@uis.edu
 (No relevant relationships reported)

Purpose: Immediately following eccentric exercise, a pro-inflammatory and pro-oxidative state ensues to initiate the remodeling phase and subsequent repair of damaged tissue. A continued pro-inflammatory and pro-oxidative state can lead to secondary muscle damage thereby prolonging the repair and regenerative process. Betalains are bioactive pigments that are reported to have anti-inflammatory and antioxidant properties. We therefore examined the effects of a betalain-rich concentrate (BRC) on indices of muscle damage following eccentric exercise in an effort to assess muscle recovery following supplementation. **Methods:** In this counterbalanced repeated measures design, a total of 11 recreationally active males consumed 50 mg of BRC, containing 12.5 mg of betalains, 3 times per day for 3 days (initial testing day, 24 and 48 hr post-exercise), or nothing at all (control). The exercise protocol consisted of 30 maximal eccentric contractions of the elbow flexors. Each condition was separated by 2 weeks and the contralateral arm was used for the second testing session. Maximal voluntary isometric contraction (MVIC), arm circumference (AC), muscle soreness (MS), and range of motion (ROM) were measured pre, post, 24, 48, and 72 hr following the eccentric exercise. Creatine kinase (CK) was measured pre, 24, 48, and 72 hr following the eccentric exercise. **Results:** No significant differences or interactions were observed for any of the variables ($p > .05$). There was, however, a p -value approaching significance with a corresponding large effect size for the main effect of MVIC ($p = .07$, $\eta_p^2 = 0.28$). **Conclusion:** Betalain supplementation did not enhance skeletal muscle recovery following eccentric damage. However, we feel the large effect size may provide practical significance. Therefore, future studies should expand upon ours to include larger samples of recreationally active individuals using a more intense damage protocol.

Pilot Data Suggest Negative Change In Bone Mineral Content Is Related To Self-report Musculoskeletal Injury In Infantry Marines

Karen R. Kelly, Brenda Niederberger, Dale Bergquist-Turori, Andrew Jensen, Jake Bernards, Jason Jameson. *Naval Health Research Center, San Diego, CA*
 Email: karen.r.kelly8.civ@mail.mil
 (No relevant relationships reported)

Background: Prevalence of musculoskeletal injury (MSKI) is greatest in young Marines due to the high volume of vigorous exercise, especially in early training. Fitness and body composition are known to be related to injury risk; however, understanding changes in such factors over a training cycle and the risk of injury are not well understood.

Purpose: The purpose of this study was to measure changes in body composition and bone density over the 40-day infantry training and its relation to MSKI. **Methods:** Active duty, male, infantry students ($n = 50$) enrolled in the infantry training battalion located at School of Infantry-West (SOI-W) aboard Camp Pendleton were recruited to participate in this study. Pre- and post-SOI-W training (Day 1 and Day 40), Marines completed a whole body dual-energy x-ray absorptiometry (DXA); as well as, sleep, nutrition, and fitness questionnaires. Three months following graduation from SOI-W, a follow-up survey was sent regarding prevalence and type of MSKI. **Results:** Of the original Marines in the study ($n = 50$), six Marines (12%) reported sustaining an MSKI within three months of completing SOI-W. Those that were injured showed decreased bone mineral content (BMC) in both the dominant and non-dominant leg as compared to the group average whom had an increase in BMC (injured vs. non-injured right leg: $\Delta -5.5\%$ vs. $\Delta +3.3\%$; injured vs. non-injured left leg: $\Delta -3.8\%$ vs. $\Delta +1.2\%$). Additionally, of the injured Marines, 50% reported "poor" sleep quality on the Pittsburgh Sleep Quality Index and 67% reported "excessive sleepiness"

on the Epworth daytime sleepiness scale at the follow-up time point. No differences in fitness levels or dairy consumption (milk, cheese, yogurt, ice cream) were present between injured and non-injured Marines at any time point.

Conclusion: These pilot data suggest that MSKI may be related to negative changes in BMC; as well as sleep quality and daytime sleepiness. Further work is needed to determine the relationship between MSKI and BMC and sleep to elucidate mechanisms or impact on injury risk.

G-34 Free Communication/Poster - Body Composition

Accuracy of Body Fat Estimation Using Circumferences and Air Displacement Plethysmograph on Male Navy Sailors

Katherine M. Wilson, Rebecca S. Weller, Andrew J. Ordille, Douglas M. Jones, Melissa D. Laird, Jay H. Heaney. *Naval Health Research Center, San Diego, CA*
 (No relevant relationships reported)

The Department of Defense maintains fitness and body composition standards for active duty service members to maintain safety and performance as well as promote health and disease prevention. Since height/weight tables do not reflect body fat percentage (BF%), the Navy needed a technique that was quick, portable, cost effective, and scalable to a large, diverse population. An equation to calculate BF% using circumference measurements was developed in 1984, using underwater weighing as the gold standard, and has remained in use by the Navy since its implementation. **PURPOSE:** To assess the accuracy of BF% estimation on male U.S. Navy sailors obtained using circumference (Circ) and air displacement plethysmograph (ADP) techniques compared with BF% estimates using dual-energy X-ray absorptiometry (DXA) as the gold standard. **METHODS:** Same-day DXA, Circ, and ADP measurements were recorded for 45 male subjects (age: 33 ± 7 yr, height: 177.9 ± 7.8 cm, weight: 92.9 ± 15.1 kg). Circumferences were taken using a retractable tape measure placed on the skin by trained researchers. Three measurements were taken and averages were calculated and entered into the equation. Compression shorts and swim caps were worn for ADP measurements and lung volumes were predicted. DXA was completed per manufacturer specifications. **RESULTS:** Average BF% was 21.6 ± 4.8 , 21.9 ± 4.8 , and 26.2 ± 7.1 for DXA, Circ, and ADP, respectively. Differences between ADP and DXA were statistically significant ($p < .001$). Compared with DXA, BF% estimates were accurate within $\pm 1.0\%$ in 31.1% and 8.9% of subjects for Circ and ADP measurements, respectively. Circ overestimated BF% in 57.7% of subjects, while ADP overestimated BF% in 93.3% of subjects. **CONCLUSION:** When comparing the accuracy of Circ and ADP with DXA, Circ had a nearly identical average and SD, while the average was 4.6% higher for ADP with a larger SD (4.8 vs. 7.1). Circ was within $\pm 1\%$ of DXA in nearly 1 in 3 subjects, while ADP was as accurate in fewer than 1 in 10 subjects. ADP overestimated BF% in 42 of the 45 subjects. Furthermore, the highest BF% overestimation for any individual was 7.1% for Circ in contrast to 11.5% for ADP. The results of this study suggest that in a male Navy population, use of circumference measurements to estimate BF% is more accurate than ADP and in close agreement with DXA measurements.

The Influence of Gender and Body Composition on Pool-Based Anaerobic Power and Capacity

Jacquelyn N. Zera¹, Emma Connell¹, Elizabeth Nagle, FACSM², Takashi Nagai³, Mita Lovalekar², John P. Abt, FACSM⁴, Scott M. Lephart, FACSM⁴, Bradley Nindl, FACSM². ¹John Carroll University, University Heights, OH. ²University of Pittsburgh, Pittsburgh, PA. ³Mayo Clinic, Rochester, MN. ⁴University of Kentucky, Lexington, KY. (Sponsor: Elizabeth Nagle, FACSM)
 Email: jzera@jcu.edu
 (No relevant relationships reported)

Recent evidence has shown that a tethered 30-second maximal swim (TST) is a valid and reliable measure of anaerobic power and capacity in swimmers. Consistent differences between males and females exist in both land and water-based measurements of force production, with land-based differences heavily influenced by body weight and muscle mass. However, the influence of body size and composition has not been investigated for the TST. **Purpose:** To explore gender differences in anaerobic power (F_{peak}) and capacity (F_{mean}) during a TST, and to explore the influence of body total body mass (TBM), and body composition (percent body fat (%BF) and

fat free mass (FFM)) on gender differences. **Methods:** Thirteen males (Age = 22.54 ± 3.1 years; BMI = 24.63 ± 2.5 kg·m⁻²; %BF = 13.92 ± 5.1%) and fifteen females (Age = 20.67 ± 4.5 years; BMI = 23.36 ± 2.9 kg·m⁻²; %BF = 25.80 ± 7.9%) completed a TST, as previously described in the literature. Body composition was assessed via air displacement plethysmography. Independent t-tests were used to determine absolute differences between males and females for F_{peak} and F_{mean} . Additionally, the influence of TBM, %BF, and FFM on gender differences for F_{peak} and F_{mean} during a TST was determined using a backwards stepwise linear regression analysis. **Results:** Males produced significantly higher F_{peak} ($p < 0.001$) and F_{mean} ($p = 0.008$), compared to females. However, when adjusted for measures of body composition, FFM was significant for F_{peak} ($p = 0.002$) and F_{mean} ($p = 0.001$), and gender was not significant ($p = 0.694$ and $p = 0.136$, respectively). **Conclusions:** Although gender differences were observed for mean and peak force production, results of the present investigation revealed that fat free mass significantly contributed to force production, regardless of gender. Therefore, force production and sprint swimming performance may benefit from gains in muscle mass, although more research is needed in the form of training studies. Additional research should investigate the influence of the ratio of fat mass and fat free mass on buoyancy, body position, and the balance required to achieve optimal force production and sprint swimming performance.

3315 Board #3 June 1 8:00 AM - 9:30 AM
Fat-Free Mass Index in a Diverse Sample of Male Collegiate Athletes

Bradley S. Currier, Patrick S. Harty, Jessica M. Moon, Shane A. Ponder, Richard A. Stecker, Hannah A. Zabriskie, Andrew R. Jagim, Chad M. Kerkisick, FACSM. *Lindenwood University, St. Charles, MO.*

(No relevant relationships reported)

Fat-free mass index (FFMI) is a body composition metric that has been employed to assess relative muscularity, with a 28.1 kg/m² upper limit reported in male athletes. FFMI is calculated by dividing fat-free mass by squared height, though further height corrections via linear regression may be required to normalize FFMI in taller individuals. To date, only two investigations have reported height-adjusted FFMI (FFMI_{Adj}) in males. **PURPOSE:** The purpose of this study was to report height-adjusted FFMI data and natural upper limits of FFMI in male collegiate athletes. **METHODS:** The body composition of 209 male collegiate athletes from 10 sports (Mean ± SD; Age: 20.7 ± 1.9 years, Height: 182.9 ± 6.7 cm, Weight: 90.8 ± 16.8 kg, Percent Body Fat: 15.6 ± 5.3 %) was measured using dual-energy x-ray absorptiometry. The height adjustment was calculated by regressing unadjusted FFMI against height in all athletes above the median unadjusted FFMI. The slope of this line was used to adjust all FFMI values. The natural upper limit for FFMI_{Adj} in this sample was determined by calculating the 97.5th percentile of all values. FFMI_{Adj} data were assessed for normality using the Shapiro-Wilks test. One-way ANOVAs with Tukey *post-hoc* comparisons were used to determine between-sport differences. **RESULTS:** The slope of the line used in height adjustment was -0.014 ($p = 0.631$). A paired-samples t-test revealed a significant difference (0.041 kg/m², $p < 0.001$) between unadjusted and adjusted mean FFMI values. The overall mean FFMI_{Adj} was 22.8 ± 2.8 kg/m². FFMI_{Adj} was not normally distributed and was log transformed prior to analysis. Significant between-sport differences ($p < 0.001$) in FFMI_{Adj} were identified. Upper limits (97.5th percentile) for FFMI_{Adj} were found to be 28.32 kg/m² for the entire cohort while upper limits for rugby and baseball were found to be 29.1 kg/m² and 25.5 kg/m², respectively. **CONCLUSION:** This study reported FFMI_{Adj} values in a diverse cohort of male collegiate athletes, providing data for the first-time in several sports. These values can be used to guide nutritional and exercise interventions and provide coaches with standardized information regarding the potential for further fat-free mass accretion in male athletes.

3316 Board #4 June 1 8:00 AM - 9:30 AM
Gender and BMI Differences in Body Image Among College Freshmen

Ruth N. Henry, Matthew D. Ruiz, William C. Vantrease, David Bender. *Lipscomb University, Nashville, TN.* (Sponsor: Kent Johnson, FACSM)

(No relevant relationships reported)

Research in the area of body image has shown that females have more dissatisfaction with their bodies than males, but that males also have concerns with some aspects of body image. Instructors in wellness courses designed for college freshmen have the opportunity to address these challenges.

Purpose: to determine which components of body image display gender differences, and whether gender differences in certain aspects of body image are related to BMI. **Methods:** The Body Self-Image Questionnaire was administered to students in a freshman Wellness course as a part of their physical fitness assessment which included BMI (N=130 F, 50 M). Data were analyzed with a 2 x 2 factorial ANOVA to evaluate both effects of BMI and Gender and their interactions. All nine subscales of the BSIQ were included: Overall Appearance Evaluation (OAE), Fatness Evaluation

(FE), Health/Fitness Evaluation (HFE), Health/Fitness Influence (HFI), Attention to Grooming (AG), Social Dependence (SD), Height Dissatisfaction (HD), Negative Affect (NA), and Investment in Ideals (II). For the analysis, BMI values <25.0 kg/m² were classified as "normal" (NW); values ≥25 kg/m² were categorized as "overweight" (OW).

Results: In SD, there was a significant main effect for gender, with females scoring higher in the factor of social dependence ($p = 0.138$). There was a main effect for gender in HD, with males being more dissatisfied with their height than females ($p = 0.103$). An interaction existed between gender and BMI for height dissatisfaction, with a greater gender disparity in HD in normal weight students (M>F) than in OW students, where differences almost disappeared. The main effect for gender in FE indicated that females view themselves as fatter than males ($p = 0.015$); not surprisingly, there was also a main effect in FE for BMI ($p < 0.0001$; OW>Nor). A main effect for BMI existed in OAE ($p < 0.0001$; Nor>OW); II ($p = 0.0373$; Nor>OW); HFE ($p < 0.0001$; Nor>OW); and NA ($p = 0.0003$, OW>Nor). A gender-BMI interaction existed in HFI ($p = 0.0098$) indicating that OW males felt that health and fitness influenced feelings about their bodies more so than OW females; in Nor students, gender differences were very small. **Conclusion:** The belief that females have more body image concerns than males is valid in some components of body image, and BMI attenuates some gender differences.

Impact of Body Fat Percent on Heart Rate of Moderate-Intensity Aerobic Activity

Wenhao Liu, FACSM, Istvan Kovacs, Austin McClinton. *Slippery Rock University, Slippery Rock, PA.*
 Email: wenhao.liu@sru.edu

(No relevant relationships reported)

PURPOSE: To better understand the relationship between body fat percent (%BF) and aerobic capacity, this study examined how %BF would impact heart rate (HR), maximal HR% (%HRmax) and HR reserve% (%HRR) when walking at 3.0 mph among young adults.

METHODS: The three-site skinfold measure was administered to 176 university students (mean age: 20.82±1.49; 102 males and 74 females) in the US and converted to %BF using the conversion tables by Jackson et al. (1985). The ACSM satisfactory ranges of %BF (2014, 10%-22%BF for men and 20%-32%BF for women) were used to divide participants into three %BF groups: Normal, Lean, and Obese. HRmax was calculated with "220-age", resting HR (after lying on the floor for five minutes) was measured using HR monitors (Sigma PC26.14), and HRR was calculated with "HRmax-resting HR". Finally, HR at the end of a three-minute treadmill walking at 3.0 mph was measured, which was also used to compute %HRmax (HR ÷ HRmax × 100%) and %HRR [(HR - Resting HR) ÷ HRR × 100%] of the walking. One-way MANOVA was used to examine differences in HR, %HRmax, and %HRR of the three-minute walking among the three %BF groups.

RESULTS: There were 90 participants in Normal, 64 in Lean, and 22 in Obese group. No age difference ($p > .70$) was found among the three %BF groups (Normal 20.71±.90, Lean 20.94±2.79, Obese 20.95±1.50). However, significant differences (p values ranged from .000 to .003) were observed in HR, %HRmax, and %HRR for the three-minute walking at 3.0 mph among the three %BF groups. Specifically, significant differences were identified in HR in all the three pairwise comparisons: Lean (95.56±10.27) vs. Obese (112.14±9.82), Lean vs. Normal (104.58±11.24), and Normal vs. Obese; in %HRmax in all the three pairwise comparisons: Lean (48.03±5.29) vs. Obese (56.34±4.91), Lean vs. Normal (52.48±5.64), and Normal vs. Obese; and in %HRR between Lean (22.89±7.35) and Obese (30.22±6.07) and between Lean and Normal (26.85±6.99).

CONCLUSIONS: The %BF classified with ACSM %BF ranges has significant impact on HR among young adults when walking at 3.0 mph, a moderate-intensity (3.5-MET) activity. Specifically, when walking at 3.0 mph, lean individuals demonstrate significantly lower HR, %HRmax, and %HRR than normal and obese individuals; and normal individuals show significantly lower HR and %HRmax than obese individuals.

Anthropometric Characteristics Of NCAA Division III Swimmers

Heather Milton, Susan Edmond. *NYU Langone Health, New York, NY.*

Email: heather.milton@nyumc.org

(No relevant relationships reported)

There is an assumption among competitive swimmers that certain body types are predisposed to perform better. This assumption may be in part due to research on young swimmers that suggests that greater standing (StH) and seated height (SH), arm span (AS), and the surface areas of the arm and foot increase swimming speed. However, literature on these variables in adult swimmers does not exist. Further, despite literature supporting the negative correlation between body fat percentage (BF) and performance in a variety of sports, the literature on swimmers suggests BF

is not a leading contributor to faster swimming speeds. There exists a need to explore the association between anthropometric characteristics and performance among adult competitive swimmers.

PURPOSE: To evaluate the association between anthropometric characteristics of National Collegiate Athletic Association Division III (DIII) male and female swimmers and performance determined by qualifying for NCAA national competition. **METHODS:** 54 Subjects (25 F) were evaluated preseason for StH and SH, arm circumference (AS) and upper arm length (AL), hand length (HL) and width (HW), foot length (FL) and width (FW), and weight (WT) and BF in accordance with standard methods. At midseason, BF and AS were repeated. Means (M) and standard deviations (SD) for all variables among male and female swimmers were reported. Logistic regression analyses were performed to determine the association between each anthropometric measure and qualification for Nationals competition controlling for gender. **RESULTS:** Nineteen (35.2%; 11 [37.9%] male and 8 [32.0%] female) qualified for Nationals. With the exception of seated height and left hand length (p=0.05), both of which showed a positive association, regression analyses revealed that there were no statistically significant differences between anthropometric characteristics and qualification for Nationals. **CONCLUSIONS:** Results suggest that greater SH and left HL have a positive effect on swimming performance, but there was no association between any other anthropometric variable and qualification for Nationals. These findings suggest that differences in swimming performance among DIII swimmers are likely due to other factors, such as biomechanical, intrinsic physiological and psychosocial attributes.

Body Composition Changes Following NFL Combine Preparation Training
 Jeremy R. Townsend¹, Jordan LuAllen², William C. Vantrease¹, Megan D. Jones¹, Ann M. Toy¹, Ian Hunter¹, Kent D. Johnson, FACSM¹. ¹Lipscomb University, Nashville, TN. ²Ignition Athletic Performance Group, Nashville, TN. (Sponsor: Kent D. Johnson, FACSM)
 (No relevant relationships reported)

The NFL scouting combine and college pro-days implement a battery of anthropometric and performance tests to assess college football players attempting to play in the NFL. As such, athletes commonly undergo specific training and nutrition regimens to optimize combine performance to increase their chances of signing with an NFL team. **PURPOSE:** To observe body composition changes following a training program of different lengths designed to prepare athletes for NFL combine and pro-day performance. **METHODS:** Seventeen male collegiate football players (21.9±0.43 y, 1.89±0.06 m, 106.7±15.3 kg) participated in a NFL combine preparation program. The combine preparation training consisted of 4 resistance training sessions per week and 6 days per week of position and combine test-specific training. Athletes participating in this program were also provided dietary counseling by a nutritionist to improve dietary habits. Pre- and Post- training, body mass (BM), body fat percentage (BF%), fat mass (FM), total body water (TBW), and lean body mass (LBM) were assessed via bioelectrical impedance analysis (BIA). Since all athletes did not join the program on the same date we divided athlete data into two groups: (1) those that completed 7-8 weeks of training (n=10) and, (2) those that completed 4-6 weeks of training (n=7). Data were analyzed by separate repeated measures analysis of variance (ANOVA) for each variable. **RESULTS:** Regardless of group, the combine preparation training program produced significant increases in body mass (p=0.004; Δ +1.14±1.36 kg), TBW (p=0.045, Δ +1.24±2.31 kg), and LBM (p=0.041, Δ +1.67±2.97 kg). No significant (p>0.05) main effect of time was observed for BF% or FM. Additionally, there were no significant differences between groups for variable. Of the 17 participants, 3 players were drafted and were on active rosters for the 2018 NFL season, 1 participant was drafted and signed a practice squad contract, with 5 other participants signing undrafted free agent contracts with various NFL teams. **CONCLUSION:** Data suggests that significant changes in body mass, TBW, and LBM can be achieved as a result of NFL combine training even when the training program is of short duration. Furthermore, in these highly trained athletes, even 8 weeks of training may be too short to observe significant improvements in FM or BF%.

3320 Board #8 June 1 8:00 AM - 9:30 AM
Skinfold Thickness As A Predictor Of 3200m Performance For Trained, Male Runners
 Jake Till, Nathan Goslin-Klemme, Preston Kauder, Elaina Biechler. Loras College, Dubuque, IA. (Sponsor: Vincent Paolone, FACSM)
 Email: jacob.till@loras.edu
 (No relevant relationships reported)

Greater levels of adiposity have traditionally been linked to a decrease in distance running performance, as excess weight and body fat have been seen to increase energy expenditure and power output necessary to complete the task of efficient locomotion.

The researchers of the current study hypothesized runners with less appendicular fat would have a biomechanical advantage over runners predisposed to appendicular fat storage. **PURPOSE:** To determine the predictive power of traditional skinfold sites, including chest, midaxillary, triceps, subscapular, abdomen, suprailliac, thigh, calf, and biceps, on performance in a 3200m time trial for trained male distance runners. **METHODS:** Participants were 22 members of a NCAA Division 3 men's cross country team. Skinfold measurements were recorded for each of the nine-sites on each of the athletes using a skin caliper. The athletes then completed a 3200m time trial. This data was then used to run a multiple-regression to determine the importance of each site to time trial performance. **RESULTS:** The subjects had an average body fat percentage of 12.8%, ±4.5%, and an average 3200m time of 10:48 ±48s. The regression analysis revealed that 58.1% of the variance in 3200m time trial performance was predicted by the model using the nine sites (biceps, suprailliac, thigh, chest, subscapular, calf, midaxillary, abdomen, and triceps) as predictors (p<0.05). When co-varied out, chest, midaxillary, and abdomen were significant (p<0.05) predictors of 3200m performance. Increased chest and abdomen fat storage significantly predicted increased finish time (p=0.037, B=0.206 min) and (p=0.023, B=0.117 min). Increased midaxillary fat storage significantly predicted decreased finish time (p=0.023, B=-0.166 min). When co-varied out, triceps, calf, biceps, subscapular, suprailliac and thigh fat storage were not significant predictors (p > .05). **CONCLUSIONS:** Skinfold thickness in the chest, midaxillary, and abdomen were significant predictors of 3200m performance in trained college males, while skinfold thickness in the triceps, subscapular, suprailliac, thigh, calf, and biceps were not. Appendicular fat storage may not be as important to performance as hypothesized in homogeneous well trained male endurance runners.

Bilateral Lean Mass and Dynamic Balance Asymmetry in Collegiate Athletes
 Guadalupe Herrera, Vipa Bernhardt. Texas A&M University-Commerce, Commerce, TX.
 (No relevant relationships reported)

Introduction: Laterality, or lateral dominance may lead to asymmetry in muscle mass and strength, which in turn could lead to differences in stability and balance. Muscular asymmetry and dynamic balance asymmetry have been independently linked with increased injury risk. For example, athletes with >4cm anterior reach distance differences (ΔARD) were found to be at significantly higher risk to incur injuries. However, it is unknown if there is an association between muscle mass asymmetry and dynamic balance. Nor is it known if these factors change throughout the sports' seasonal periods (i.e., off-, pre-, and post-season). The purpose of this preliminary analysis was to analyze differences between lower body lean mass and dynamic balance in collegiate athletes and to examine if associations exist between the two variables during different seasons. Methods: NCAA Division II student-athletes were recruited in their respective off- or pre-season. Lean mass was assessed via dual energy x-ray absorptiometry. Dynamic balance was assessed via lower quarter Y Balance Test and ΔARD was calculated. Pearson correlation was used to examine associations. Results: 109 athletes (67W/42M) from six sports have been recruited (see table). There were no significant correlations (p > 0.05) between differences in lower body lean mass and ΔARD in either off- or pre-season (r²=0.003 and r²=0.001, respectively). 51% of athletes in off-season and 48% in pre-season exhibited >4cm ΔARD. Conclusion: In this preliminary report, no correlation was found between lower body lean mass asymmetry and dynamic balance asymmetry. Concerning was our finding that about half of the athletes showed dynamic imbalances, indicating higher injury risk. Further data collection will determine the extent of the changes in muscle mass and dynamic balance asymmetry over one full competitive season.

| Subject characteristics | | | |
|-------------------------|----|-------------|--------------|
| Sport | n | Height (cm) | Weight (kg) |
| Football | 18 | 185.8 ± 5.7 | 106.8 ± 18.1 |
| Softball | 18 | 167.0 ± 5.3 | 76.5 ± 10.8 |
| Basketball (W) | 6 | 174.9 ± 9.1 | 69.5 ± 10.3 |
| Basketball (M) | 5 | 192.5 ± 8.3 | 88.3 ± 8.0 |
| Track & Field (W) | 20 | 168.2 ± 7.8 | 63.2 ± 9.8 |

Effects Of Oral-contraceptive Use On Strength, Power And Body Composition In Trained Women
 Vargas Salvador¹, Romance Ramón², Petro Jorge L.³, Espinar Sergio⁴, Bonilla Diego A.⁵, Schoenfeld Brad J.⁶, Kreider Richard B., FACSM⁷, Benítez-Porres Javier². ¹EADE-University of Wales Trinity Saint David, Málaga, Spain. ²University of Málaga, Málaga, Spain. ³Universidad de Córdoba, Montería, Colombia. ⁴BetterbyScience, Málaga, Spain. ⁵Universidad Distrital Francisco José de Caldas, Bogotá, Colombia. ⁶CUNY Lehman College, New York, NY. ⁷Texas A&M University, Texas, TX. Email: salvadorvargasmolina@gmail.com
 (No relevant relationships reported)

Oral contraceptives consumption has been identified as a usual strategy for birth control among athletes. Nevertheless, its impact on body composition and sports performance remains unknown due to the heterogeneity in the formulation of these products and individual factors such as the menstrual cycle, age or sports discipline. **PURPOSE:** The aim of this study was to evaluate the effect of oral-contraceptive use on strength and body composition changes in trained women undergoing regimented resistance training (RT). **METHODS:** Twenty-three resistance-trained women (age 27.4±3.4 years; height 162.7±6.1 cm; body weight 60.5±7.8 kg; BMI 22.9±2.7 kg·m⁻²) were randomized to either a non-oral contraceptive (n=11, NOC) or an oral contraceptive (n= 12, OC) group. After a 3-week familiarization period, all participants performed four sessions of RT per week over the course of an 8-week non-linear program. Dual X-ray absorptiometry was used to measure lean body mass and fat mass. Muscle power was measured by the countermovement jump (CMJ) test using a jump contact mat, and maximal strength was assessed by the one-repetition maximum (1RM) test in the back squat (SQ) and bench press (BP). **RESULTS:** OC significantly increased lean body mass [1.4±1.4(CI: 0.5, 2.3) kg; p= 0.007]; however, no changes were observed in the NOC group [0.7±1.1(-0.2, 1.5) kg; p= 0.0741]. No significant changes were seen in regard to fat mass in both OC [0.4±1.8(-0.7, 1.5) kg; p=0.437] and NOC [0.3±0.8(-0.2, 1.0) kg; p= 0.220]. Both OC and NOC increased upper-body 1RM [6.7±3.6(4.4, 8.9) kg; p<0.01] and [4.8±1.8(3.4, 6.1) kg; p<0.01], respectively; likewise, increased lower-body 1RM [11.9± 6.7 (7.7, 16.2) kg; p< 0.01] and [15.6±5.4 (11.7, 19.4) kg; p< 0.01], respectively. No significant changes were found in CMJ in both OC and NOC [0.7±1.1 (-0.1, 1.6) cm; p= 0.911] and [0.7±1.1(-0.1, 1.6) cm; p= 0.69], respectively. **CONCLUSIONS:** OC use in conjunction with RT produces similar increases in measures of strength and power compared to NOC in trained women and has potentially beneficial effects on lean body mass. Supported by University of Málaga (Campus of International Excellence Andalucía Tech).

3323 Board #11 June 1 8:00 AM - 9:30 AM
Relationships Of Waist Circumferences Measured At Different Anatomical Sites With Body Fat In Chinese Adults
 Lin Wang, Chaoran Yang. *Shanghai University of Sport, Shanghai, China.* (Sponsor: Stanley Sai-chuen HUI, FACSM) Email: wanglin.sus@gmail.com
 (No relevant relationships reported)

In large-scale population surveys and public health screenings, the use of simple anthropometric indices has become popular for identifying individuals who are overweight and obesity. Waist circumference (WC) has been extensively investigated as an indicator of abdominal obesity and health risks among adults. However, standardized protocols for WC measurement have yet to be established. **PURPOSE:** This study aims to determine relationship between body fat and different WC sites in Chinese adults. **METHODS:** A total of 213 Chinese adults aged 18-35years old participated in the study. WC was measured at five sites: immediately above the iliac crest (WC1), immediately below the lowest rib (WC2), midpoint between the lowest rib and the iliac crest (WC3), 1 cm above the umbilicus (WC4), and at the narrowest waist (WC5). Body fat mass (FM), body fat percentage (%BF), abdominal fat mass (FM in abdominal) and abdominal percentage fat (%BF in abdominal) were determined through dual-energy X-ray absorptiometry. Pearson correlation was used to analyze the relationships of WCs with FM, %BF, FM in abdominal, and %BF in abdominal. Levels of significance were set at P < 0.05. **RESULTS:** For males, the measured WCs were strongly correlated with FM and FM in abdominal (p < 0.001), and significantly correlated with %BF and %BF in abdominal (p < 0.001). For females, the WCs were significantly correlated with FM, %BF, and %BF in abdominal (p < 0.001). **CONCLUSIONS:** The WCs were correlated significantly with FM, %BF, FM in abdominal, and %BF in abdominal both in Chinese males and in Chinese females.

3324 Board #12 June 1 8:00 AM - 9:30 AM
Association Between Body Composition and Bone Mineral Density in Elite Collegiate Athletes
 Jordan N. Brown. *Georgia Southern University, Statesboro, GA.* Email: jb17162@georgiasouthern.edu
 (No relevant relationships reported)

Individuals, such as collegiate athletes, that engage in increased levels of strenuous exercise often possess a lower body fat percentage (BF%) and increased fat-free mass (FFM). Additionally, repetitive progressive resistance training and participation in high-impact sports has been demonstrated to increase bone mineral density (BMD). Because collegiate athletes experience a high amount of repetitive loading, it may be expected that BMD would yield a relation to body composition. **PURPOSE:** The purpose of this study was to examine the relationship between body composition and BMD in elite college athletes. **METHODS:** Male (n = 45) and female (n = 33) athletes (ages 18-21 years) from a range of sports, including baseball, football, softball, and volleyball, participated in the study. Total BMD and body composition (i.e., BF% and FFM) were measured using dual-energy x-ray absorptiometry. Pearson's product moment correlations were used to assess all relationships between BMD, BF%, and FFM. **RESULTS:** In terms of males, Pearson's product correlation demonstrated a significant moderate-to-strong positive association between FFM and BMD (r = 0.79, p < 0.01). BF% showed a significant positive low-to-moderate correlation with BMD (r = 0.35, p = 0.02). For females, FFM showed a moderately positive association with BMD (r = 0.58, p < 0.01), while BF% provided a non-significant inverse correlation with BMD (r = -0.21, p = 0.23). **CONCLUSION:** FFM in both male and female collegiate athletes was positively associated with BMD. However, males displayed a positive BMD and BF% relationship, while females a non-significant, inverse association. These findings may reflect the diversity of female athletes (i.e., various sports) that were included within the analysis. For instance, sports that require a greater body mass to enhance performance and those that require a leaner physique were both included within one group which may have affected the BMD and BF% relationship.

3325 Board #13 June 1 8:00 AM - 9:30 AM
Comparison of Air Displacement Plethysmography and Multi-Frequency Bioelectrical Impedance Analysis for Body Composition Assessment
 Benjamin T. Gordon¹, Andrea Y. Arikawa², Kristin Gerkens², Andriana Gonzalez², Sara Boyd², Amber Baskin², Michele Bednarzyk². ¹Radford University, Radford, VA. ²University of North Florida, Jacksonville, FL. (Sponsor: Larry Durstine, FACSM)
 (No relevant relationships reported)

Body composition is a crucial component of health-related fitness. Two methods that are frequently used in clinical settings are air displacement plethysmography (ADP) and multi-frequency bioelectrical impedance (MF-BIA). ADP has been thoroughly validated relative to other various criterion methods. MF-BIA is newer technique relative to ADP, and does not have a substantial amount of validation. **PURPOSE:** To determine the correlation between ADP and a new model of MF-BIA. **METHODS:** The current project was a part of The RISE study, which is aimed at determining the associations between dietary supplement intake and biological and psychosocial measures, including body composition, inflammatory markers, dietary intake, stress, anxiety, and sleep. The current project aims to validate a new model of MF-BIA as a means of estimating body composition when compared to the more established ADP in adults who participate in the RISE study. The current sample consisted of 50 healthy and active individuals, 21 males with mean age 24.3 and 29 females with mean age 24.4. Mean body mass index was 25.2 kg/m² for males and 23.3 kg/m² for females. Participants were asked to come in for one study visit to measure their body composition sequentially using both methods of body composition. **RESULTS:** Average body fat percentages measured by the ADP were 28.8% (females) and 16.6% (males). For MF-BIA the average body fat percentages were 27.8% (females) and 16.9% (males). Further, average fat free mass estimated by ADP was 18.2 kg (females) and 13.8 kg (males). For MF-BIA average fat free mass was 18.3 kg (females) and 14.0 kg (males). A high correlation (Pearson's correlation coefficient, r=0.87) between the two methods was established. **CONCLUSIONS:** These findings indicate that there is a strong correlation between the two methods and MF-BIA provides comparable measurements of body composition in relation to an established method in ADP.

3326 Board #14 June 1 8:00 AM - 9:30 AM
Comparing a 3-Compartment Model to Criterion Measures for Estimating Body Composition in Athletes

Nicole C. Dahlenburg, Bryce Willian, Emily L. Langford, Ronald L. Snarr, Greg A. Ryan. *Georgia Southern University, Statesboro, GA.*

(No relevant relationships reported)

Multi-compartment models are emerging as a criterion method of analyzing body composition, thereby reducing the error associated with standalone laboratory measures. **PURPOSE:** The purpose of this study was to compare a 3-compartment model (3-C) with two gold standard lab measures (i.e., air displacement plethysmography (ADP) and dual-energy x-ray absorptiometry (DEXA)). **METHODS:** Sixty-nine male and forty-eight female athletes completed three body composition measures (i.e., DEXA, ADP, and bioelectrical impedance spectroscopy (BIS)). Body fat percentage (BF%) was calculated using a 3-compartment (3C) model, consisting of total body water (via BIS), body volume (via ADP), and body weight. For statistical analysis, a repeated measures ANOVA was used to compare ADP and DEXA against a 3-C model for all within gender comparisons. **RESULTS:** For males, results showed a significant mean difference when comparing 3-C (13.2±7.0%) and DEXA (16.5±9.5%; $p < 0.01$), but no difference between 3-C and ADP (12.0±8.0%; $p = 0.09$). For females, a significant mean difference was seen with 3-C (23.5±7.2%) and DEXA (28.5±6.6%; $p < 0.01$); however, there was no difference between 3-C and ADP (22.2±7.1%; $p = 0.34$). **CONCLUSION:** DEXA may provide overestimates of BF% for both male and female athletes, while ADP provided no significant differences when compared to a multi-compartment model.

Body Composition Comparisons Via Dual Energy X-Ray Absorptiometry and Air Displacement Plethysmography in College Athletes

Greg A. Ryan, Stephanie A. Gibson, Michelle L. Eisenman, Emily L. Langford, Ronald L. Snarr. *Georgia Southern University, Statesboro, GA.*

Email: gryan@georgiasouthern.edu

(No relevant relationships reported)

Body composition is a highly important metric in regards to overall physical activity as well as sports performance. Most body fat percentage (BF%) measurements are recorded using two-compartment models, such as skinfold analyses, bioelectrical impedance analysis, or more accurately, via hydrostatic weighing or air displacement plethysmography (ADP). However, research has suggested that three-compartment models, like dual energy x-ray absorptiometry (DEXA), may provide more accurate recordings of BF%. However, limited research exists in comparing BF% obtained via two- and three-compartment models in collegiate athletes. **PURPOSE:** To compare BF% recordings via DEXA and ADP in Division-I collegiate male and female athletes. **METHODS:** Seventy-eight athletes (Male: $n = 45$ [age = 18.4 ± 1.0 y, height = 161.9 ± 55.5 cm, weight = 77.3 ± 32.5 kg]; Female: $n = 33$ [age = 18.0 ± 0.7 y, height = 146.3 ± 56.9 cm, weight = 55.9 ± 23.8 kg]) from multiple sports underwent BF% testing via DEXA and ADP. Both tests were completed on the same visit under supervision by the same test administrator. Hydration status was measured before testing to ensure that all athletes were properly hydrated prior to the test. Athletes were instructed to dress in accordance to the recommended protocols for both tests. Individual paired sample t-tests were run for BF% comparisons for whole group, male athletes, and female athletes. **RESULTS:** A significant mean difference existed for all athletes between DEXA (21.6 ± 10.3%) and ADP (16.4 ± 9.2%) when comparing BF% ($p < 0.01$, ES = 0.53). When factored for gender, male BF% exhibited a significant mean difference between DEXA (16.3 ± 9.5%) and ADP (11.8 ± 8.0%) ($p < 0.01$, ES = 0.51). Additionally, a significant mean difference for BF% was found in the female athletes between DEXA (28.5 ± 6.6%) and ADP (22.2 ± 7.1%) ($p < 0.01$, ES = 0.92). **CONCLUSION:** These results, which are consistent with previous research, indicate significantly greater BF% values for DEXA when comparing athletic populations.

Resting Energy Expenditure And Body Composition In Crossfit

Marcio Souza¹, Maraline Sena², Andressa Lima³, Valden Capistrano Junior³, Monica Pinheiro³, Ana Paula Abdon³.

¹Federal University Of Minas Gerais, Belo Horizonte, Brazil. ²V Clinica De Nutricao, Fortaleza, Brazil. ³Federal University Of Ceara, Fortaleza, Brazil.

Email: marcionutricionista@yahoo.com.br

(No relevant relationships reported)

Crossfit is a training program created by Greg Glessman in 1995 and consists of performing high intensity functional movements. Some studies have already reported reduction of body fat and increase of metabolic rate. **PURPOSE:** To investigate differences in body composition and resting energy expenditure (REE) in CrossFit beginners and athletes using electrical bioimpedance (BIA) and indirect calorimetry (IC), respectively. **METHODS:** 28 individuals (14 male) aged 20-34 years were selected in CrossFit boxes and divided into two groups: CrossFit athletes (GA) and CrossFit beginners (GI). In baseline and after 4 weeks, participants were submitted to body composition and metabolic evaluation. Fat-free mass (FFM), fat mass (FM) and body fat percentage (BFP) were evaluated by BIA and REE and oxygen consumption (VO_2) were investigated using IC. Participants continued to perform their CrossFit training, usually in accordance with the spreadsheet prescribed by their coaches. Statistical analyses used: Kolmogorov-Smirnov and T of Student. **RESULTS:** There were no differences between groups in baseline. After 4 weeks, female GA showed higher REE (1656.0 ± 78.7 vs 1455.7 ± 157.8, $P = 0.02$) and higher VO_2 (240.4 ± 11.6 vs 211.3 ± 22.9, $P = 0.02$) when compared to female GI. Only female GA showed a significant increase in baseline energy expenditure (1415.0 ± 236.7 vs 1656.0 ± 78.7, $P = 0.03$) and a significant decrease in baseline body fat percentage (26.4 ± 1.7 vs. 25.2 ± 2.2, $P = 0.05$) between baseline and 4 weeks. In female GI, a reduction in fat mass (15.8 ± 5.7 vs 14.3 ± 5.7, $P = 0.05$) was observed, with no differences in others parameters. Among male groups, male GA showed higher REE (2275.0 ± 286.5 vs 1843.3 ± 336.8, $P = 0.03$) and greater VO_2 (330.0 ± 41.2 vs 267.2 ± 48.6, $P = 0.03$) when compared to male GI after 4 weeks. But there were no differences for body composition and metabolic characteristics in the same male group, comparing baseline and 4 weeks evaluation. **CONCLUSIONS:** This study showed that 4 weeks of CrossFit training positively influenced REE and BFP, especially in female athletes when compared to beginners. Body composition was improved in both female groups. Among men, there were no differences and, probably, four weeks represent a short period to observe changes in body composition and resting energy metabolism in male groups.

3329 Board #17 June 1 8:00 AM - 9:30 AM
An Examination Of Upper Body Power And Fat-free Mass In Division-I Cheerleaders

Abigail C. Johnson, Michelle L. Eisenman, Emily L. Langford, Ronald L. Snarr, Gregory A. Ryan. *Georgia Southern University, Statesboro, GA.*

(No relevant relationships reported)

The sport of cheerleading requires extended bouts of great physical strength and coordination, particularly at the collegiate level. Upper body power (UBP) is vital to cheerleading performance, as many stunts require athletes to lift and propel themselves or teammates into the air. Additionally, large proportions of fat-free mass (FFM) may provide the ability for cheerleaders to execute advanced movements during competition. **PURPOSE:** The purpose of this study was to examine the association between UB and FFM in Division-I cheerleaders. **METHODS:** Male ($n = 12$) and female ($n = 33$) collegiate cheerleaders were assessed for height (cm), weight (kg), UB, and FFM. UB was determined using the medicine ball put test in which participants sat on an exercise bench at a 45-degree recline and were instructed to throw a medicine ball from the chest for maximum distance. Females and males used 15-lb and 20-lb medicine balls, respectively and completed two trials with a one-minute rest in between. FFM was assessed on the same visit to the laboratory via air displacement plethysmography. Spearman's rho correlations were used to determine all associations with FFM and UB for the entire group and genders. **RESULTS:** Results indicated a significant, strong, positive correlation ($r_s = 0.79$, $p < 0.01$) between UB and FFM for the entire group. Separating the participants by gender produced a significantly, strong, positive correlation for the female population ($r_s = 0.71$, $p < 0.01$); while the males demonstrated a non-significant, moderate correlation ($r_s = 0.45$, $p < 0.45$). **CONCLUSION:** Results suggest that FFM and UB are positively correlated in collegiate cheerleaders, although this relationship was exhibited particularly among females. The demand of UB associated with the sport may require greater amounts of FFM in order to properly execute advanced movements during competition.

3330 Board #18 June 1 8:00 AM - 9:30 AM

Body Composition and Muscle Characteristics of Junior Track and Field AthletesJanel S. Bailey, Rachael Irving, Eon Campbell. *University of the West Indies, Mona, Kingston, Jamaica.* (Sponsor: Melanie Poudevigne, FACSM)

Email: Janel_bailey@yahoo.com

(No relevant relationships reported)

PURPOSE: To characterize and evaluate the body composition and muscle characteristics profile of junior track and field athletes in the athletic preseason and postseason.**METHODS:** The study included 55 junior athletes. Age, height and weight ranged from 12-19 yrs, 157-191 cm, and 42.88-100.88kg, respectively. Body composition and muscle characteristics were measured using ultrasound technology. The two-compartmental model which divides the body into fat mass (FM) and fat free mass (FFM) was used for the analysis of body composition. Muscle cross sectional area (mCSA), muscle thickness (MT) and echo intensity (EI) were used to analyze muscle characteristics. Performance ($\dot{V}P$) was quantified using the IAAF scoring system, where each time/distance, was assigned a score and $\dot{V}P$ calculated. Athletes were categorized into two groups, based on $\dot{V}P$: (Group A- increase in performance, Group B- decrease in performance in terms of time or distance).**RESULTS:** Group B athletes had higher mean values for body % fat in the preseason. However, there was no significant change in %fat or regional fat thickness between preseason and postseason, irrespective of performance group. Though not significant, ($p > 0.05$) % fat and waist circumference increased in group B athletes, but decreased in group A athletes. Significant correlations were found between change in muscle cross sectional area in the waist ($p < 0.05$, $r = 0.63$) and thigh ($p < 0.05$, $r = 0.87$), with performance in all athletes**CONCLUSIONS:** Significant differences in body composition parameters between group A and group B athletes at preseason, highlights the importance of maintaining optimal body composition in the offseason. Changes in muscle characteristics in preseason and post-season may influence athletic performance more than changes in body composition over the same period.

3331 Board #19 June 1 8:00 AM - 9:30 AM

Seasonal Body Composition Changes in Division I Cross Country RunnersKatie R. Hirsch, Malia N.M. Blue, Gabrielle J. Brewer, Austin M. Peterjohn, Abbie E. Smith-Ryan, FACSM. *University of North Carolina at Chapel Hill, Chapel Hill, NC.* (Sponsor: Abbie Smith-Ryan, FACSM)

Email: ktrose23@live.unc.edu

(No relevant relationships reported)

Body composition can significantly impact performance and injury risk, particularly in cross country, where a small build and low percent body fat are typically desirable. Body composition goals for an athlete may vary year-to-year, depending on training goals, years of competitive training, and access to specialized training staff. Tracking body composition throughout a collegiate career is important for optimal health and performance. **PURPOSE:** To evaluate changes in body composition across a first, second, third, or fourth year of competition in Division I cross country runners.**METHODS:** Pre and post season measures of body composition were evaluated in first season (N=25), second season (N=24), third season (N=13), and fourth season (N=10) Division I National Collegiate Athletic Association cross country runners (Total: N=46; male=25; female=21) between the years of 2014 to 2017. Total and regional body composition (fat mass [FM], percent body fat [%BF], lean mass [LM], bone mineral content [BMC], and armLM, legLM) was assessed using dual-energy x-ray absorptiometry. **RESULTS:** First year runners significantly increased weight (change [A] \pm SD; 1.6 ± 2.2 kg; $p=0.001$), LM (1.6 ± 1.3 kg; $p<0.001$), BMC (0.03 ± 0.05 kg; $p=0.008$), and armLM (0.1 ± 0.3 kg; $p=0.047$). Second year runners significantly increased weight (1.1 ± 1.8 kg; $p=0.005$), LM (1.2 ± 1.2 kg; $p<0.001$), armLM (0.1 ± 0.3 kg; $p=0.019$), and had a small but significant decrease in BMC (-0.02 ± 0.03 kg; $p=0.002$). There were no significant changes in body composition in third or fourth year runners. **CONCLUSIONS:** First and second season Division I cross country runners experience significant changes in body composition, primarily increases in LM, while third and fourth year runners experience minimal changes. Changes are likely influenced by the addition of strength and conditioning and nutrition staff that are not available in high school. The first two seasons may be key times for developing body composition characteristics in runners that can maximize performance and minimize injury throughout their career.

3332 Board #20 June 1 8:00 AM - 9:30 AM

Multi-Frequency Bioimpedance Reliability and Validity for Assessing Total and Segmental Body Composition in College-Aged MalesSaori Braun¹, Alexa Hayes¹, Garrett Stadler¹, Tucker Goesch¹, Morgan Goldammer¹, Steven Fleck, FACSM². ¹University of Wisconsin-Eau Claire, Eau Claire, WI. ²Andrews Research and Education Foundation, Gulf Breeze, FL.

Email: braunsi@uwec.edu

*Reported Relationships: S. Braun: Industry contracted research; InBody USA.*Bioimpedance analysis (BIA), which may be affected by hydration status, is frequently used to assess total and segmental body composition for research purposes. However, the reliability and validity of BIA in determining body composition in all populations including well hydrated college aged males has not been determined. **PURPOSE:** To determine the reliability of direct segmental multi-frequency BIA and its validity against dual energy x-ray absorptiometry (DXA) in a population of normally hydrated college-aged males. **METHODS:** Body composition was measured in the early morning 3 times in the following order: 1) BIA, 2) DXA, and 3) BIA, all in the same session lasting < 30 minutes. Immediately prior to body composition measurement, a urine sample was collected and analyzed for urine specific gravity (USG). To ensure normal hydration, a USG of 1.022-1.028 encompassing slightly dehydrated, euhydrated, and well hydrated statuses was required for study participation.**RESULTS:** A total of 102 males (mean age = 20.35 ± 1.38 years) were included in the analyses. Intra-class correlations between the two BIA determined fat free mass (FFM) of total body, right arm, left arm, trunk, right leg and left leg were .974, .961, .965, .963, .994, and .994, respectively. Two-tailed paired samples *t*-tests showed all comparisons of DXA FFM (bone mineral content [BMC] + lean mass) compared to the average of the two BIA FFM (comparable to DXA BMC + lean mass) to be significantly different ($p < .001$) except for the trunk ($p = .242$). Segmental BIA FFM underestimated segmental DXA FFM by ≤ 1.05 kg, while total body BIA FFM overestimated total body DXA FFM by 2.2kg. **CONCLUSIONS:** Multi-frequency BIA is reliable in determining total and segmental FFM. The significant differences between DXA and BIA in determining segmental FFM may be due to body composition derived from DXA is based on attenuation of x-ray to determine BMC, lean tissue, and fat mass while; body composition derived from BIA is based on impedance of body water content.

3333 Board #21 June 1 8:00 AM - 9:30 AM

Test-retest Reliability Of Bioimpedance Spectroscopy For The Analysis Of Body Composition In Physically Active MalesTyler W.D. Muddle, Patrick M. Tomko, Ryan J. Colquhoun, Mitchel A. Magrini, Nile F. Banks, Nathaniel D.M. Jenkins. *Oklahoma State University, Stillwater, OK.*

(No relevant relationships reported)

No previous studies, to our knowledge, have examined the reliability of bioimpedance spectroscopy (BIS) for the evaluation of body composition. **PURPOSE:** To evaluate the test-retest reliability of BIS for the assessment of total body water (TBW), extracellular water (ECW), and intracellular water (ICW) content, as well as fat mass (FM), fat-free mass (FFM), and body fat percentage (BF%) in physically active males. **METHODS:** Sixteen males (Mean \pm SD, 25 ± 3 y, 90 ± 11 kg, 176 ± 6 cm) were assessed at two visits, separated by 2 – 7 days. During each visit, participants rested quietly for 3 – 5 min in a supine position with their arms abducted $\geq 30^\circ$ away from their torso and legs separated prior to their assessment. Two single-tab electrodes were placed on the right side of the body 5 cm apart on both the dorsal surface of the wrist and dorsal surface of the ankle, respectively. The BIS device was used to estimate TBW, ECW, and ICW (liters; L) based on Cole modelling with Hanai mixture theory, which were then used to calculate FM (kg), FFM (kg), and BF%. Reliability was examined by calculating the intraclass correlation coefficient (ICC; model 2,1) and standard error of measurement (SEM). The coefficient of variation (CV) was calculated by expressing the SEM relative to the grand mean (%). The 95% confidence interval (CI) for each ICC was calculated and used to test the null hypothesis that each ICC was equal to zero. Systematic variability was assessed for each variable via a paired *t*-test. **RESULTS:** Reliability statistics are displayed in Table 1. None of the dependent variables displayed systematic variability ($p > 0.05$). 'Excellent' relative and absolute reliability was observed among all body water (ICC = $0.91 - 0.99$; CVs = $1.08 - 3.50\%$) and body mass (ICC = $0.95 - 0.99$; CVs = $1.10 - 6.99\%$) measurements. **CONCLUSION:** These results indicate that the BIS device used in this study allows for the reliable assessment of TBW, ECW, ICW, FM, FFM, and BF% in physically active men.**Table 1.**

| | Visit 1 | Visit 2 | p-value | ICC _{2,1} | SEM (MS _E) | CV (%) | 95% CI |
|-----------------|------------|------------|---------|--------------------|------------------------|--------|-------------|
| TBW (L) | 52.0 ± 5.9 | 51.8 ± 6.0 | 0.34 | 0.99 | 0.56 | 1.08% | 0.97 – 1.0 |
| ECW (L) | 20.6 ± 2.5 | 20.7 ± 2.4 | 0.72 | 0.99 | 0.25 | 1.20% | 0.97 – 1.0 |
| ICW (L) | 31.4 ± 3.5 | 31.6 ± 4.1 | 0.62 | 0.91 | 1.10 | 3.50% | 0.77 – 0.97 |
| FM (kg) | 18.2 ± 5.5 | 18.8 ± 6.3 | 0.26 | 0.95 | 1.29 | 6.99% | 0.87 – 0.98 |
| FFM (kg) | 71.1 ± 8.1 | 70.8 ± 8.1 | 0.40 | 0.99 | 0.78 | 1.10% | 0.97 – 1.0 |
| BF% | 20.2 ± 4.7 | 20.3 ± 4.9 | 0.52 | 0.97 | 0.80 | 3.98% | 0.92 – 0.99 |

Comparison of Bioelectric Impedance Analysis for Tracking Body Composition Changes Across a Basketball Season
 Jana L. Arabas¹, Liz Jorn¹, Monica L. Hunter¹, Jerry L. Mayhew¹, William F. Brechue, FACSM². ¹Truman State University, Kirksville, MO. ²A. T. Still University, Kirksville, MO. Email: jlarabas@truman.edu
 (No relevant relationships reported)

Body composition assessment has become an integral part of the year-round training schedule for athletes. This may be especially important in women athletes due to the potential for disordered eating. Development of low-cost bioelectric impedance analysis devices (BIA) make them attractive for determining changes in body composition components at different times in the training cycle. Question remains concerning the accuracy of these devices to track body composition changes over the yearly training and competitive cycle compared to a standard laboratory procedure. **PURPOSE:** To compare the accuracy of selected BIA devices compared to dual-energy X-ray absorptiometry (DEXA) for tracking body composition across a college women's basketball season. **METHODS:** Twelve NCAA Division-II women basketball athletes (age = 20.1 ± 1.2 yr, height = 175.0 ± 5.6 cm, weight = 70.2 ± 4.4 kg, % fat = 27.8 ± 2.8%) were measured prior to the season (T1), after pre-season conditioning (T2), at mid-season (T3), and at the end of the season (T4) using 7 single-frequency BIA devices and DEXA. **RESULTS:** Repeated-measures ANOVA indicated that body mass (p = 0.19) and DEXA %fat (p = 0.08) did not change significantly over the course of the season. A method x trial factorial ANOVA of %fat and fat-free mass (FFM) with repeated measures over the second factor indicated that 2 BIA devices were not significantly different from corresponding DEXA values while all others significantly underestimated DEXA %fat. Lin's concordance correlation between BIA devices and DEXA were varied at each phase from low of $\rho_c = 0.17$ to high of $\rho_c = 0.84$, with no consistence across time. Rank-order correlations of BIA devices with DEXA were also inconsistent across time ranging from $r = 0.40$ to $r = 0.72$. **CONCLUSIONS:** Compared to the DEXA standard, single-frequency BIA devices may not provide adequate tracking of %fat or FFM in women across a basketball season.

Using Skinfolts and Bioelectrical Impedance for Tracking Body Composition across a Soccer Season
 Liz Jorn¹, Jacob Gunn¹, Ian McCluskey¹, Jerry L. Mayhew¹, William F. Brechue, FACSM². ¹Truman State University, Kirksville, MO. ²A. T. Still University, Kirksville, MO. Email: ljorn@truman.edu
 (No relevant relationships reported)

Assessment of body fat (%fat) is common across yearly training cycles for many athletes, although questions remain concerning the accuracy of assessment methods. **PURPOSE:** To compare various methods for determining body composition in male soccer players across a yearly cycle. **METHODS:** Body composition was assessed in collegiate male soccer players (n = 13; age: 20.2 ± 1.2 yrs) prior to winter resistance training (Phase 1), following 8-weeks of resistance training (Phase 2), 8-weeks of spring skills training (Phase 3), and 14-weeks of a summer individualized training program (Phase 4). %Fat was determined at each phase using dual-energy X-ray absorptiometry (DEXA), 6 athletic SKF equations, and two bioelectrical impedance devices (arm: A-BIA; leg: L-BIA). SKF sites were measured by one experienced investigator throughout. **RESULTS:** A phase x method factorial ANOVA of %fat with repeated measures over the second factor indicated all prediction methods significantly, but consistently underestimated DEXA %fat (average difference =

11.8 ± 2.1%) despite moderate to high correlations with DEXA (r = 0.57 to 0.81). Of the SKF equations, a 7-SKF model, previously produced in our laboratory using DEXA as the criterion measure, had the closest %fat estimate (16.5 ± 3.0%) but a low correlation (r = 0.64) with actual %fat (DEXA: 18.0 ± 3.9%). Jackson-Pollock 3-, 4-, and 7-sites equations significantly underestimated %fat by 8.9% to 9.2% with the highest correlation resulting from the 4-site equation (r = 0.81). A-BIA (13.6 ± 4.9%) and L-BIA (13.4 ± 5.8%) comparably underestimated %fat (-4.8 ± 4.4%) with similar correlations against DEXA (r = 0.57 and 0.59, respectively). Significant negative correlations for differences between SKF predicted %fat and DEXA %fat (r = -0.66 to -0.94) indicated greater underestimation by SKF occurred at higher %fat and body mass values. A similar tendency was noted for differences between BIA %fat and DEXA %fat (r = -0.58 to -0.89). **CONCLUSIONS:** All prediction techniques produced significantly lower estimates of %fat in male college soccer players across a year-long training cycle. Despite underestimation, each method provided consistent measure by phase and can be used to effectively track changes across a season. Prediction errors were typically greater at greater DEXA %fat and body mass values.

3336 Board #24 June 1 8:00 AM - 9:30 AM
A Matter Of Fat? Body Composition In Relation To Vo2max Improvements In Division II Female Athletes
 Kallie LaValle, Joseph D. Ostrem. Concordia University - St. Paul, St. Paul, MN.
 (No relevant relationships reported)

PURPOSE: Body composition is a significant factor in the determination of relative maximal oxygen consumption (VO2max) (Kenney, Wilmore, & Costill, 2015). Historically, O2 consumption reported in ml/kg/min considers O2 consumption related to fat free mass (FFM). A training program that facilitates an increase in FFM and/or a decrease in fat mass (FM) and body fat percentage (BF%) would inherently increase relative aerobic capacity and may optimize performance throughout the competitive season (Castagna, et al. 2013). The purpose of the study was to determine the relative aerobic capacity response via Graded Exercise Testing (GXT) in relation to body composition changes in female Division II collegiate athletes following a pre-season conditioning program. **METHODS:** Nine female college athletes (age = 20±1 yrs) participated in the study. Subjects performed a modified Balke GXT assessment on a treadmill to failure. Prior to performing the modified Balke GXT, subjects had their body composition assessed utilizing a Bod Pod (COSMED, Rome, Italy). All laboratory assessments were performed in the kinesiology lab at Concordia University - St. Paul, MN. Aerobic fitness and body composition were assessed before and after an 8-week pre-season interval training program. Paired t-tests evaluated mean differences for pre- and post-training variables within body composition and GXT assessments. **RESULTS:** The measured VO2max via GXT (43.7 vs. 44.0 ml/kg/min, P=0.57) was not significantly increased and body composition components (FFM: 51.3 vs. 51.8 kg, P=0.49; FM: 16.0 vs. 15.9 kg, P=0.93; BF%: 23.9 vs. 23.5%, P=0.78) were also not significantly affected over the 8-week pre-season training period. **CONCLUSIONS:** The 8-week pre-season conditioning program showed improvements, although not significant, among VO2, FFM, FM, and BF%. Further studies with a greater number of participants could provide appropriate power to accurately determine the anthropometric and physiological changes experienced throughout the program.

3337 Board #25 June 1 8:00 AM - 9:30 AM
Comparison of Regional and Global Bone Mineral Densities in Male and Female College Athletes
 Monica L. Hunter¹, Jana L. Arabas¹, Liz Jorn¹, Brianne R. Morgan¹, Jerry L. Mayhew¹, William F. Brechue, FACSM², Laurel M. Wentz³. ¹Truman State University, Kirksville, MO. ²A. T. Still University, Kirksville, MO. ³Appalachian State University, Boone, NC. Email: mlh7428@truman.edu
 (No relevant relationships reported)

The advent of dual-energy X-ray absorptiometry (DEXA) has prompted an increase in research concerning the response of bone to exercise training. Previous investigations have focused mainly on female athletes and their susceptibility to stress fractures and low bone mineral density (BMD). Recent information suggests that male athletes may also suffer from relative energy deficiency in sports which could affect their bone health. However, direct comparisons of sport-specific differences and sex-differences in BMD within specific sports have not been fully explored. **PURPOSE:** To compare regional and total BMD between men and women athletes in comparable sports. **METHODS:** NCAA Division-II men (n = 115) and women athletes (n = 95) in four sports [soccer (SOC), basketball (BB), cross-country (XC), swimming (SW), and baseball/softball (BS)] were measured for regional and total BMD and lean mass (LM) using (DEXA). Inactive men (n = 23) and women (n = 27) served as a control group (CON). **RESULTS:** Men were taller and heavier and had greater regional and

LM than women. A sex x sport multivariate ANOVA, with the influence of height and weight removed by covariance, revealed that men had significantly greater regional BMD ($p < 0.005$) than women in the arms, legs, pelvis, and total body. XC and SW had significantly lower BMD than CON which were lower than SOC, BS, and BB with no significant difference among the latter groups. The sex x sport interaction was not significant ($p = 0.15$), except for leg BMD where women swimmers (1.153 ± 0.081 g/cc) had a significantly lower value than other groups (1.405 ± 0.151 gm/cc). BMD had a nonsignificantly higher correlation with LM ($r = 0.61$) than with body mass ($r = 0.58$) when sex was held constant.

CONCLUSIONS: Regional BMD appears to be uniquely dependent on sport participation and sport-specific training, but the pattern of bone development appears independent of sex. Men and women athletes in sports that require more intense ground contact and perhaps more resistance training have greater regional and total BMD, suggesting varying levels of bone stress are associated with training for different sports. The degree of stress on bones of the arms does not seem sufficient to differentiate between these sports or inactive individuals.

Comparison of Abdominal Fat among Positions and Ethnicities in College Football Players

Brianne R. Morgan¹, Monica L. Hunter¹, Richard M. Schumacher¹, Laurel M. Wentz², Jerry L. Mayhew¹, William F. Brechue, FACSM³. ¹Truman State University, Kirksville, MO. ²Appalachian State University, Boone, NC. ³A. T. Still University, Kirksville, MO.
Email: brm7215@truman.edu
(No relevant relationships reported)

Body types in American football vary dramatically, but the underlying premise is one of achieving greater size within any position. In order to reach the theoretical size required for a given position, players may perform extensive resistance training and consume large quantities of food without much concern for body composition. Recent investigation has suggested that the accumulation of abdominal or visceral fat may have serious long-term health consequences. However, limited information is available on the extent of abdominal fat accumulation in collegiate football players. **PURPOSE:** To compare the level of android adiposity among Caucasian and African-American football players in different playing positions. **METHODS:** Backs (BA, $n = 57$) and linemen (LM, $n = 47$) were measured for body composition using by dual-energy x-ray absorptiometry (DEXA). Android fat (AF) was identified as the region from the iliac crest to a height 20% distance below the chin. Ethnicity was categorized as Caucasian (CAU, $n = 74$) and African-American (A-A, $n = 30$) based on self-report. **RESULTS:** There was a significant difference ($p < 0.001$) in %fat between linemen ($27.4 \pm 7.5\%$) and backs ($16.8 \pm 4.3\%$) but not between ethnicities (CAU = $22.1 \pm 8.1\%$ vs A-A = $20.4 \pm 7.7\%$), with no significant interaction ($p = 0.96$). The same pattern was evident in AF with a significant difference between positions (LM = 3.03 ± 1.56 kg vs BA = 1.37 ± 1.75 kg), a non-significant difference between ethnicities (CAU = 2.32 ± 1.98 vs A-A = 1.63 ± 1.42 kg), and a non-significant interaction ($p = 0.54$). When body mass was held constant by covariance, there was no significant difference between positions (LM = 1.75 ± 1.95 vs BA = 2.26 ± 1.804 kg), ethnicities (CAU = 2.23 ± 1.35 vs A-A = 1.79 ± 1.371 kg), or for interaction ($p < 0.14$). AF was more highly correlated with body mass in LM ($r = 0.90$) than in BA ($r = 0.26$) and more highly correlated with body mass in A-A ($r = 0.91$) than CAU ($r = 0.63$).

CONCLUSIONS: These findings suggest that the amount AF in college football players is largely related to body size. Accounting for difference in body size eliminates the difference between playing positions and ethnicities. Further research should compare athletes to nonathletes of different ethnicities and sizes to determine if similar patterns exist.

3339 Board #27 June 1 8:00 AM - 9:30 AM

Comparison of Various Body Composition Measures for Division-I Collegiate Male Athletes

Gina R. Hogan, Michelle L. Eisenman, Emily L. Langford, Ronald L. Snarr, Greg A. Ryan. Georgia Southern University, Statesboro, GA.
(No relevant relationships reported)

Estimates of body composition are critical for athletic populations as variations in body fat percentage may impact performance, power, and general overall health. However, most laboratory and field-based devices estimate body composition using algorithms based upon and intended for general populations. Therefore, these algorithms may not be applicable to special populations, specifically male athletes. **PURPOSE:** The purpose of this investigation was to compare various field and laboratory measures of body composition in division-I male athletes against a criterion of air displacement plethysmography (ADP). **METHODS:** Sixty-nine Division-I collegiate male athletes, from various sports, performed five body composition measures (i.e., bioelectrical impedance spectroscopy (BIS), hand-to-foot bioelectrical impedance analysis (HF-BIA), foot-to-foot bioelectrical impedance analysis (FF-BIA), three site skinfold

(SF), and ADP). Each participant performed all measures on the same visit to the laboratory. A repeated measures ANOVA was used to determine differences between body composition measures against the criterion of ADP. **RESULTS:** When compared to ADP ($12.2 \pm 1.1\%$), results indicated a significant mean difference with BIS ($18.1 \pm 6.8\%$; $p < 0.01$) and HF-BIA ($18.5 \pm 6.0\%$; $p < 0.01$). There were no statistical differences between ADP and FF-BIA ($12.1 \pm 6.5\%$; $p = 1.0$) or ADP and SF ($13.2 \pm 8.6\%$; $p = 1.0$). **CONCLUSION:** Results indicate that field measures of body composition (i.e., FF-BIA and SF) may be applicable to athletic populations; whereas, laboratory measures (i.e., BIS and HF-BIA) may tend to overestimate body composition in male athletes. Therefore, new algorithms estimating body composition in athletes may be warranted for laboratory based devices.

3340 Board #28 June 1 8:00 AM - 9:30 AM

Utility of Anthropometric Indices to Estimate Changes in Adiposity in Response to an Exercise Intervention

Jacob E. Erickson¹, Michael Fedewa², Elizabeth Hathaway³, Simon Higgins⁴, Ellen Evans, FACSM¹, Michael Schmidt¹. ¹University of Georgia, Athens, GA. ²University of Alabama, Tuscaloosa, AL. ³University of Tennessee-Chattanooga, Chattanooga, TN. ⁴Elon University, Elon, NC.
Email: jericks219@gmail.com
(No relevant relationships reported)

In cross-sectional analyses, anthropometric measures are generally well correlated with clinical measures of adiposity such as those from dual-energy X-ray absorptiometry (DXA). However, it is unclear whether anthropometric measures are sensitive enough to accurately quantify longitudinal changes in central and whole-body adiposity in response to short term exercise interventions with minimal weight change. **PURPOSE:** To examine the relative agreement between anthropometric and DXA measures of change in adiposity following a 6-week cycling exercise intervention. **METHODS:** Overweight/obese women ($n = 53$, 18-24 years old, 66% White, 17% Black, 17% Other) participated in the exercise intervention. Anthropometric measures included body mass index (BMI) and natural waist (NW) circumference. DXA measures included absolute trunk fat (TrkFat), whole body absolute fat (TotFat), and percent fat (%Fat). Baseline anthropometric and DXA measures were compared using Pearson correlations, as were changes (Δ) in each measure across the intervention. **RESULTS:** Mean \pm SD at baseline for each of the measures were: NW (88.7 ± 10.8 cm), BMI (30.5 ± 5.0 kg/m²), TrkFat (16923.3 ± 5991.3 g), TotFat (35826.4 ± 9813.2 g), %Fat ($44 \pm 5.8\%$). Δ for each of the measures were: NW (-0.8 ± 0.4 cm), BMI (-0.2 ± 1.0 kg/m²), TrkFat (-482 ± 1029.8 g), TotFat (-693.6 ± 1773.6 g), %Fat ($-0.8 \pm 1.3\%$). The association between baseline NW and TrkFat was much stronger at baseline ($r = .93$, $p \leq .001$) compared to the correlation between post-intervention Δ ($r = .57$, $p \leq .001$). Similarly, correlations between baseline BMI and DXA measures were stronger (TotFat: $r = .90$, $p \leq .001$; %Fat: $r = .68$, $p \leq .001$) than correlations between Δ measures (TotFat: $r = .68$, $p \leq .001$; %Fat: $r = .34$, $p = .013$). **CONCLUSION:** Anthropometric indices may not accurately reflect Δ in body composition during short duration lifestyle interventions. This may be due to factors such as cumulative intra-rater measurement errors when assessing waist circumference and the inability of BMI to differentiate changes in lean and fat mass over time. More direct measures (e.g., DXA) may be needed to accurately assess Δ in body composition, especially when these changes are of modest magnitude.

Body Composition Characteristics and Knee Injury Prevalence of NCAA Division I Women's Soccer and Lacrosse

Gabrielle J. Brewer, Malia N.M. Blue, Katie R. Hirsch, Austin M. Peterjohn, Samantha A. Kelchner, Darin A. Padua, Abbie E. Smith-Ryan, FACSM. University of North Carolina - Chapel Hill, Chapel Hill, NC. (Sponsor: Dr. Abbie E. Smith-Ryan, FACSM)
Email: gjbrewer@live.unc.edu
(No relevant relationships reported)

Body composition is directly linked to athletic performance and may influence injury risk and recovery. Female Division I soccer and lacrosse players are at a high risk for lower limb injuries specific to the knee joint throughout their competitive careers. Return to play criterion vary; evaluation of body composition may be an important element of clearance. **PURPOSE:** The purpose of this study was to characterize pre-season body composition and injury prevalence among female Division I soccer and lacrosse players using dual-energy x-ray absorptiometry (DEXA). **METHODS:** Sixty Division I Women's Soccer ($n = 27$) and Lacrosse ($n = 33$) athletes (Mean \pm SD: age: 19.8 ± 1.4 yrs, height, 167.3 ± 6.2 cm, weight, 64.9 ± 8.0 kg.) completed a whole body DEXA scan to determine fat mass (FM), percent body fat (%fat), lean mass (LM), segmental lean mass [right leg lean mass (RLM); left leg lean mass (LLM)], and bone mineral content (BMC). History of lower extremity injury (ACL and other knee injuries) throughout a career was self-reported using a validated questionnaire. Measurements were taken pre-season (August 2018). **RESULTS:** Soccer and lacrosse

players combined (n=60) demonstrated the following body composition characteristics: total body FM (15.23 ± 4.8 kg), total body LM (46.96 ± 4.7 kg), and BMC (2.78 ± 0.3). There were significant differences between sports in %fat and segmental LM (LLM and RLM). Lacrosse athletes had higher %fat compared to soccer athletes: (mean difference [MD] ± SD: 2.5 ± 2.3%; p=0.034). Segmental leg LM (LLM, RLM) was higher in both legs of soccer athletes (LLM MD: 0.08 ± 0.54kg; p=0.004, RLM MD: 0.89 ± 5.2kg; p=0.001). In the full sample, there was no significant difference (p=0.139) between RLM and LLM. When evaluating injured vs. not injured athletes in the full sample, 45% of athletes reported a knee injury; %fat was significantly higher for athletes with no injury history (MD: 2.5±2.4%; p=0.046). **CONCLUSIONS:** These findings suggest that Division I soccer and lacrosse players who have returned to play following a lower extremity injury do not experience differences in segmental leg lean mass between the left and right leg. Based on the elite level of these teams, these data could portray optimal characteristics of successful athletes returned to play.

3342 Board #30 June 1 8:00 AM - 9:30 AM

Parental Socioeconomic Status and Skeletal Muscle Mass among Chinese College Students

Cong Huang¹, Cheng Li², Ying Tian³, Qiang Wang³, Zhengxue Song³. ¹Zhejiang University, Hangzhou, China. ²Chonnam National University, Gwangju, Korea, Republic of. ³Shenyang Normal University, Shenyang, China.
Email: hcngman@yahoo.com
(No relevant relationships reported)

PURPOSE: The purpose of this study was to determine the association between parental socioeconomic status and skeletal muscle mass in college students.

METHODS: A cross-sectional study including 2194 college freshmen (537 males; 1657 females) was conducted in Shenyang, China. Data on body composition, health check-up, and self-reported questionnaire were available from all participants. Skeletal muscle mass assessment was performed by bioelectrical impedance analyzer (TANITA BC-420 MA). Information on parental socioeconomic status (educational levels, annual income, occupational status) was collected via questionnaires. Educational levels were divided into 4 categories: primary school, middle school, high school, and ≥ college. Annual income was divided as <15000, 15000-29999, 30000-49999, and ≥50000 CNY. Occupational status was classified into 4 groups: non-employment, self-employment, blue-collar workers, and white-collar workers. Analysis of covariance was used to adjust the confounding effect of sex, age, ethnicity, hometown location, smoking status, alcohol use, sleep duration, and body mass index.

RESULTS: Mean (standard deviation) body muscle mass was 54.9 (7.8) kg in male students and 39.2 (4.3) kg in female students. Multivariate analysis showed that college freshmen with higher paternal (mean [95% confidence interval]: primary school, 42.2 [41.7, 42.7]; middle school, 42.9 [42.6, 43.2]; high school, 43.6 [43.2, 43.9]; ≥ college, 43.2 [42.8, 43.5], *P* for trend < 0.001) and maternal (primary school, 42.2 [41.7, 42.7]; middle school, 42.9 [42.6, 43.2]; high school, 43.5 [43.1, 43.8]; ≥ college, 43.4 [43.1, 43.8], *P* for trend < 0.001) educational level tended to have higher skeletal muscle mass after adjustment for potential confounding factors. On the other hand, skeletal muscle mass was not associated with parental annual income and occupational status in this study.

CONCLUSIONS: Our study found a positive association between parental educational level and body muscle mass in Chinese college students. Further longitudinal studies on association of parental socioeconomic status with youth muscular mass and function are needed.

3343 Board #31 June 1 8:00 AM - 9:30 AM

Diagnostic Accuracy of Adipose Evaluation Indexes to Identify Obesity and Predict Osteoporosis in Chinese Adults

Wei Luo¹, Lei Ai², Yue Zhou³, Biao Sun⁴. ¹Nanjing Sport Institute, Nanjing, China. ²Jiangsu Research Institute of Sports Science, Nanjing, China. ³Beijing Sport University, Beijing, China. ⁴Nanjing Sport Institute, Nanjing, China.
(No relevant relationships reported)

Objective: To develop more appropriate indicators and cutoffs for different sexes and ages in Chinese adults for earlier prevention of obesity and osteoporosis.

Design: Obesity detection difference was analyzed by chi-square test. Correlation analysis was used between adiposity evaluation indexes and body fat percentage (BF%)

and bone mineral density (BMD). Receiver operating characteristic curves detected BF%-defined obesity and BMD-defined osteoporosis. Diagnostic accuracy was assessed. Optimal cutoffs by sex and age group were determined by area under the curve, Youden index, and sensitivity.

Setting: Physical examination sites in Chinese urban areas.

Subjects: Representative samples from Han adults (702 men and 915 women) aged 20-59.

Results: Obesity prevalence increases from 7.73% (body mass index, BMI) to 26.16%

(BF%). BMI, waist-to-hip ratio (WHR), obesity degree (OBD), and BF% were correlated in all subjects ($r=0.7$, $P<0.01$). OBD thresholds of 20.5% and 14.65% for both sexes, respectively, are most applicable to 20-39-year-olds. BMI and WHR thresholds of 26.45 kg/m² and 0.9, respectively, are most applicable to 40-59-year-olds. WHR threshold of 0.9 is most applicable to 40-59-year-old women. The correlation was satisfactory between weight, BMI, OBD, and BMD in men. BMI and weight thresholds of 23.3 kg/m² and 70.55 kg are respectively most applicable to 20-39 and 40-59-year-old men.

Conclusions: BMI, OBD, and WHR are valuable for obesity diagnosis in young people and women. Traditional cutoffs should be revised by sex and age. The most applicable index differed by sex and age. Weight, BMI, and OBD are valuable for men in osteoporosis screening.

3344 Board #32 June 1 8:00 AM - 9:30 AM

The Relationship Between Body Composition with Peak Force and Anaerobic Power in Collegiate Baseball Players

Jeremy R. Pearson, Tanuj Wadhi, Jacob T. Rauch, Justin Thiel, Jody C. Andersen, Jay O'Sullivan, Eduardo O. De Souza. *The University of Tampa, Tampa, FL*.
Email: jeremy.pearson@spartans.ut.edu
(No relevant relationships reported)

While total lean body mass accretion (TLBM) has been shown to have a positive association with performance in professional baseball players (Hoffman et al., 2009), there is a paucity of data demonstrating the relationship between body composition with power performance in collegiate athletes. **PURPOSE:** To investigate the relationship between multiple body composition parameters with peak force and anaerobic power in division II collegiate baseball players. **METHODS:** This was a retrospective study in which four years of body composition data was analyzed to determine its association with peak force and anaerobic power performance for 95 collegiate baseball players (age: 21.1±1.0 yrs.; height: 1.84 ±0.05m; body mass: 87.9±11.1kg). Each subject performed a DEXA scan as well as a performance test of either a countermovement vertical jump (CMJ) (n=66) and/or a Wingate test (WIN) (n=43). Pearson's correlation coefficient was used to analyze the association between body composition parameters (i.e., TLBM, lower body lean mass [LBLM], body fat percentage [BF] and body mineral component [BMC]) with vertical jump peak force (CMJPF) and anaerobic power (i.e., absolute peak power [PP] and absolute average power [AP] on the Wingate test). **RESULTS:** TLBM was strongly correlated to WIN (PP: $r=0.777$; $p<0.0001$, AP: $r=0.808$; $p<0.0001$), but only moderately correlated to CMJ (CMJPF: $r=0.488$; $p<0.001$). LBLM was also strongly correlated to WIN (PP: $r=0.0660$; $p<0.0001$, AP: $r=0.738$; $p<0.0001$) but only moderately correlated to CMJ (CMJPF: $r=0.467$; $p=0.002$). BF had a weak correlation with WIN (PP: $r=0.244$; $p=0.049$, AP: $r=0.295$; $p=0.042$) and no significant correlation with CMJ (CMJPF: $r=0.026$; $p=0.869$). BMC was strongly correlated to WIN (PP: $r=0.713$; $p<0.0001$, AP: $r=0.776$; $p<0.0001$) and moderately correlated to CMJ (CMJPF: $r=0.519$; $p<0.0001$). **CONCLUSION:** Our data suggests a strong positive relationship between lean body mass, including bone, with anaerobic power but only a moderate relationship with peak force. Moreover, BMC was strongly correlated to performance probably because athletes with more TLBM had greater BMC. Surprisingly, there was no association between body fat percentage and performance.

3345 Board #33 June 1 8:00 AM - 9:30 AM

Weight Change and Hydration Status in Elite Puerto Rican Wrestlers in Preparation for the National Championship

Enid C. Rivera-Velázquez¹, Carmen Nevárez-Alonso², Farah A. Ramirez-Marrero, FACSM¹, Lucía del R. Martínez-Colón¹. ¹University of Puerto Rico, Rio Piedras Campus, San Juan, Puerto Rico. ²University of Puerto Rico, Medical Sciences Campus, San Juan, Puerto Rico.
(No relevant relationships reported)

Rapid weight loss is a very common strategy used in weight class sports, such as wrestling. Risky weight loss methods like fasting, fluid restriction and increased sweating are very common practices used to attain competitive weight. Acute weight gain, as a recovery strategy, after the weigh-in day has also been observed. **PURPOSE:** To determine weight change and hydration status of elite Puerto Rican wrestlers in preparation for the 2015 National Wrestling Competition. **METHODS:** Wrestlers of the national adult pre-selection (15 males, 9 females, ages 17-34 years) were evaluated. Body weight (BW) and hydration status based on urine specific gravity (USG) were determined one week before, the day of the official weigh-in and one hour before on the day of the competition. Questionnaires were administered to evaluate methods used to "make weight". Repeated measures ANOVA (post-Hoc Bonferroni) was used to identify changes in BW and USG between the measurement times. Independent sample t-test was used to detect differences between sex. **RESULTS:** Body weight decreased from 68.9±14.0 to 66.95±13.5 kgs from the week

before the competition to the day of the weigh-in, and then increased to 68.2±13.8 kgs from weigh-in to the day of the competition (F= 27.33, p<.001). USG increased significantly from 1 week before to the weigh-in (1.024±0.006 vs. 1.028 ±0.007 g/ml) and decreased on the competition day (1.025±.0073) (F=4.32, P=.019). No differences were found between sex in relative weight change (%) and USG. More than 80% of the athletes were classified as significantly dehydrated (USG >1.020) during the evaluations. Fasting, exercise with plastic suits and fluid restriction, were among the most common weight loss methods reported. **CONCLUSION:** These results indicate that wrestlers of the national adult pre-selection of Puerto Rico did not accomplish adequate hydration status on the day of the competition, even though partial weigh gain was achieved. Education programs for adequate weight and hydration management is highly recommended.

Predicting Percent Body Fat from Waist-to-Height Ratio Using a Regression Model

Stephanie Gerlach, Ann Gibson, FACSM. *University of New Mexico, Albuquerque, NM.*

(No relevant relationships reported)

Relative body fat (%BF) is a predictor of health status. Waist-to-height ratio (WtHR) better indicates disease outcome and adiposity-related disorders than does BMI or waist circumference (WC). **PURPOSE:** Develop a %BF prediction equation from WtHR, weight (wt), age and sex. **METHODS:** White, black, and Hispanic adults (70 men, 71 women; 30±10 yr; 79.6±20.5 kg; 171±12 cm) volunteered for the IRB-approved study. Participants gave written consent and followed pre-test guidelines. Duplicate measurements of WC (narrowest portion of torso), barefoot height (cm) and wt (kg) were averaged. Dry land residual volume (RV) was assessed via helium dilution; the average of 2 values ± 0.1L were used to correct body volume (Vb) from hydrostatic weighing (HW). Tare weight, water density, the average of the 3 heaviest underwater weights within 0.1kg, and RV were included in the Vb calculation. Body density (dry weight/Vb) was converted to %BF using the Siri (1961) formula. A multiple regression analysis was performed to establish a prediction equation from WtHR, wt, age and sex. Statistical analyses were conducted using R; p<.05 indicated significance. **RESULTS:** WtHR, wt, age and sex were significant predictors of %BF (p<.005). For each sex, %BF increased with each unit increase in WtHR, kg body wt, and yr of age. Wt and WtHR were negatively correlated with sex (r = -.145 men; r = -.434 women, p<.05); %BF and WtHR were positively correlated with age (r = .461 men; r = .389 women, p<.05). For the sample, %BF = 19.415 + 0.544* WtHR + 0.130*wt + 13.650 *sex (men = 0; women = 1) + 0.259*age. For the women, %BF was higher at all ages (b=13.65, SE_b=1.356, p<.001). Weight has a stronger effect (p<.001) and WtHR has a lower effect (p<.01) on %BF in women than men and all participants combined. The resulting sex-specific equation for women is: %BF = 31.65 + 0.42*WtHR + 0.23*wt + 0.25*age. For the men, wt is a lower and age a stronger predictor of %BF than in women. The resulting sex-specific equation for men is: %BF = 20.85 + 0.55*WtHR + 0.08*wt + 0.27*age. **CONCLUSION:** Sex-specific %BF prediction equations for men and women have been established from WtHR, weight, age and sex. These equations await validation with an independent sample. Regardless, %BF can be easily predicted from simple anthropometric data collected in most any setting by technicians needing minimal training.

3347 Board #35 June 1 8:00 AM - 9:30 AM
The Relationship Between BMI, Lean Mass, and Body Fat Percentage with Balance in Collegiate Archers

Branden Ziebell, Jared Feister, Andy Bosak, Russel Lowell, Madeline Phillips, Hannah Nelson, Taylor Sanders. *Liberty University, Lynchburg, VA.* (Sponsor: Dr. James Schoffstall, FACSM)

(No relevant relationships reported)

For shooting sports, static balance and stability can have a dramatic impact on successful athletic performance and may be a key contributing factor in determining the difference between an elite vs an intermediate archer. More specifically, archers need to have a firm foundation and adequate balance during practice and competition. Prior studies, using various types of athletes, have evaluated the relationship between body composition and flexibility, coordination, etc. However, there appears to be no prior studies that compared BMI, body fat percentage (BF%), leg lean mass (LLM), and trunk lean mass (TLM) with balance in archers. **PURPOSE:** To investigate the potential relationship between BMI, BF%, LLM, and TLM on balance in collegiate archers in order to determine if archers should consider incorporating training to improve body mass or segment lean mass. **METHODS:** After having height (170.73 ± 7.48 cm), weight (71.02 ± 13.31 kg), and age (20 ± 1.55 yrs) recorded, 11 (7 males, 4 females) collegiate archers had their body composition (ie. BF%, LLM, TLM, and BMI) assessed. Then, after the completion of a general dynamic warm-up and a series of flexibility tests (ie. sit and reach, back scratch test, and trunk extension), subjects had their balance, with a balance system, evaluated via an athletic single leg assessment feature. During that assessment, the individual performed a single leg

stance on a platform that decreased the amount of friction underneath the platform over 30 seconds and scoring was determined by how much movement occurred with the center of pressure. **RESULTS:** There was no relationship between balance and BF% (p = .790 r = -.091) and a low correlation occurred with balance and BMI (p = .387 r = .290). However, there was a moderately high correlation between balance and TLM (p = .028 r = .656) and a high correlation between balance and LLM (p = .003 r = .801). **CONCLUSIONS:** BF% appears to have no relationship with balance, while BMI has very little impact. Yet, LLM and TLM may influence static balance. Future research may be required to evaluate LLM and TLM with balance using a larger population in order to further explore this potential relationship and perhaps further understand the factors that affect balance.

Relationship Between Physical Activity Level With Body Composition And Physical Fitness Of Students From Ilhabela, Brazil

José Matheus O. Estivaleti¹, Carolina Gonzalez², Tatiane Figueiredo², Maurício dos Santos², Luís Oliveira¹, José D.S. Guedes³, Victor K. R. Matsudo². ¹*Nove de Julho University (UNINOVE), São Paulo, SP, Brazil.* ²*Center of Studies of the Physical Fitness Research Laboratory from Sao Caetano do Sul (CELAFISCS), São Caetano do Sul, SP, Brazil.* ³*School of Medical Sciences of Santa Casa de São Paulo (FCMSCSP), São Paulo, SP, Brazil.*

(No relevant relationships reported)

Low level of physical activity in children and adolescents has several negative implications for health, such as overweight and decreased physical fitness. **PURPOSE:** Describe and compare the body composition and physical fitness of schoolchildren according to the recommendation of physical activity, measured by accelerometry. **METHODS:** The sample consisted of 73 schoolchildren, 37 boys and 36 girls, from 9 to 11 years of age, participating in the Mixed-Longitudinal Project of Growth, Development and Physical Fitness from Ilhabela. The variables analyzed were: body weight (kg), height (cm), BMI (kg/ m²), skinfolds (mm), circumference (cm), agility (shuttle run/ sec), flexibility (sit and reach), speed (50 meters/ sec) and upper (hand grip/ kg), lower limb (vertical jump/ cm) strength, and abdominal strength (rep). The measures followed the CELAFISCS standardization. Physical activity was measured objectively by means of an accelerometer (ActiGraph, GT3X). Schoolchildren were divided into two groups: a- reached the PA recommendation (≥60min/ day), b- not reached the PA recommendation (< 60min/ day). To verify data normality, Shapiro Wilk test was used. Comparison of the schoolchildren who did or did not reach the physical activity recommendation was made by t-test and Mann-Whitney U test. The level of significance was set at p < .05. **RESULTS:** Schoolchildren who reached the recommendation had significantly lower values compared to those who did not meet, respectively for adiposity (sum of 7 skinfolds) 66.1 cm vs 100.4 cm; body weight 34.3 kg vs. 40.5 kg; height 141.1 cm vs. 144.1 cm; speed 10.1 secs. vs. 10.4 secs. and agility 12.6 secs. vs. 13.5 secs. No significant difference was found in upper and lower limb strength and abdominal strength. **CONCLUSION:** Children who fulfilled the recommendation of physical activity presented a better body composition, speed, and agility than the children who were insufficiently active.

Table 1. Comparison of the mean values of body composition and physical capacity of schoolchildren, according to compliance with the recommendation of physical activity. Mixed-Longitudinal Project of Growth, Development and Physical Fitness from Ilhabela, 2015-2018, SP, Brazil.

Anthropometry Among Non-sedentary Elderly Tendency Analysis Of Adiposity Over Three Decades

Jão da Silva Junior¹, Rafael Benito Mancini¹, Carolina Gonzalez Beltran¹, Tatiane Kosimenko Ferrari², Timoteo Leandro Araujo³, Sandra M. Matsudo⁴, José da Silva Guedes⁵, Victor K. Matsudo¹. ¹CELAFISCS, São Paulo, Brazil. ²Universidade de São Paulo- USP, São Paulo, Brazil. ³UNIFMU Faculdades Metropolitanas Unidas, São Paulo, Brazil. ⁴Universidad Mayor, Santiago, Chile. ⁵Santa Casa, São Paulo, Brazil.
(No relevant relationships reported)

Purpose: To analyze the adiposity tendency of non-sedentary elderly women over three decades. **Methods:** The study is part of the Mixed Longitudinal Project of Physical Fitness and Aging of SCS. Sample comprised female subjects, 50 years-old and older, involved in a PA program totalizing 6367 individuals. It was measured subscapular, tricipital and suprailiac skinfold. To analyze the trend, the sample was divided into age groups: 50 to 59 years, 60 to 69 years and 70 years and over. **Statistical analysis:** Polynomial regression models were estimated. In the modeling process, the mean of each one of the anthropometric variables was considered as dependent variable (Y) and the years of evaluation as independent variable (X). For each anthropometric variable, the model that presented the highest statistical significance (p) and the best accuracy measure (r²) was selected. The trend was considered significant when the estimated model obtained p < 0.05. **Results:** Triceps skinfold presented a negative trend over the three decades analyzed. In the age group of 50 to 59 years, the mean triceps skinfold decreased .01 mm every year. In the age group of 60 to 69 years, there was a decrease of .09 mm every year. In the age group of 70 years and over, the mean decreased of .16 mm. Subscapular and suprailiac and 3 skinfolds mean increased .01 mm every year in the three age groups analyzed. In the age group of 60 to 69 years, the mean of 3 skinfolds increased .01 mm. In the age group of 70 years and over, the subscapular mean increased of .16 mm in each year; while suprailiac presented an increase of .01 mm every year; and the 3 skinfold mean increased of .01 mm every year. **Conclusion:** Elderly women of all age groups showed a tendency to increase central adiposity and decrease the peripheral region, suggesting that a centripetal fat redistribution occurs with aging.

Table. Trend analysis of skinfolds among non-sedentary elderly according to age group

| | 50 to 59 years | | | 60 to 69 years | | | 70 years and over | | |
|---------------------------|-------------------|----------------|--------|-------------------|----------------|--------|-------------------|----------------|--------|
| | Model | r ² | p | Model | r ² | p | Model | r ² | p |
| Triceps skinfold (mm) | y = 23.16 - 0.01x | 0.48 | 0.0012 | y = 21.85 - 0.02x | 0.24 | 0.0090 | y = 20.45 - 0.03x | 0.36 | 0.0007 |
| Subscapular skinfold (mm) | y = 24.32 + 0.01x | 0.93 | 0.0000 | y = 21.65 + 0.02x | 0.86 | 0.0000 | y = 19.91 + 0.03x | 0.66 | 0.0000 |
| Suprailiac skinfold (mm) | y = 23.36 + 0.04x | 0.77 | 0.0000 | y = 20.72 + 0.01x | 0.73 | 0.0000 | y = 19.29 + 0.01x | 0.81 | 0.0000 |
| Mean of 3 skinfold (mm) | y = 23.34 + 0.01x | 0.90 | 0.0000 | y = 21.32 + 0.01x | 0.75 | 0.0000 | y = 19.84 + 0.01x | 0.29 | 0.0017 |

VO_{2max} and Dual Energy X-Ray Absorptiometry Results in NCAA Division I Tennis Players

Karina L. Wilson, Jason R. Lytle, Steven E. Martin, Stephen F. Crouse, FACSM. Texas A&M University, College Station, TX. (Sponsor: Stephen F. Crouse, FACSM)
(No relevant relationships reported)

Purpose: Describe VO_{2max} and body compositions using dual x-ray absorptiometry (DXA) in NCAA Division I male tennis players. **Methods:** Nine (9) male NCAA Division I tennis players (age 19.6 ± 1 yr, height 183.6 ± 5.9 cm, weight 75.6 ± 5.3 kg) who were in pre-season were tested as part of their athletic training program. Each subject underwent a DXA scan two weeks prior to their VO_{2max} test. VO_{2max} tests were conducted using the Bruce protocol (mL/kg/min). On the day of the test, athletes were instructed to consume their normal free-living breakfast and not engage in strenuous activity including team workouts prior to the test. Subjects ran to volitional exhaustion and peak exercise times and VO_{2max} numbers were recorded. Blood pressures were monitored according to the ACSM guidelines before, during, and after the exercise. After the completion of the test, data were analyzed to determine VO_{2max}, max heart rate (HR) which was recorded using a 12-lead ECG, and ventilatory threshold during exercise. **Results:** Results shown in Table 1. **Conclusion:** With respect to published norms for men that are matched to age, the players' measured VO_{2max} average would be ranked in the 90th percentile and deemed excellent for VO_{2max} based on the ACSM guidelines. The highest recorded VO_{2max} from the study is ranked in the 95th percentile and deemed superior. Based off the ACSM guidelines, the average for the body fat percentage falls in the 55th percentile and is deemed fair. The leanest player of the group is in the 80th percentile and deemed excellent.

| Player | Age (yr) | Height (cm) | Weight (kg) | % Body Fat | Lean Body Mass (lb) | Fat Mass (lb) | Measured VO _{2max} from Metabolic Cart (ml/kg/min) | Measured Max HR (BPM) | Ventilatory Threshold Heart Rate (BPM) |
|-----------|------------|-------------|-------------|------------|---------------------|---------------|---|-----------------------|--|
| 1 | 20.1 | 182.9 | 73.9 | 9.6 | 62.9 | 6.7 | 64.3 | 200 | 174 |
| 2 | 19.2 | 175.3 | 68.0 | 21.9 | 52.2 | 14.6 | 54.3 | 188 | 158 |
| 3 | 21.9 | 175.3 | 68.0 | 20.3 | 57.3 | 9.3 | 53.2 | 190 | 159 |
| 4 | 19.3 | 188.0 | 83.0 | 14.5 | 67.3 | 11.4 | 64.4 | 183 | 167 |
| 5 | 18.9 | 180.3 | 73.5 | 13.4 | 59.7 | 9.3 | 71.5 | 191 | 186 |
| 6 | 19.2 | 185.4 | 77.1 | 14.4 | 62.8 | 10.5 | 69.4 | 183 | 161 |
| 7 | 19.5 | 186.7 | 78.5 | 17.6 | 63.8 | 13.7 | 70.1 | 188 | 167 |

Effect of Moderate Intensity Physical Activity and Modality on Measures of Body Composition in Males

Brian Tyo, Kate Early, Clayton Nicks, James Davis, Cory Gibson. Columbus State University, Columbus, GA. Email: tyo_brian@columbusstate.edu
(No relevant relationships reported)

Exercise prior to body composition measures using air displacement plethysmography (ADP) and bioelectrical impedance (BIA) is generally contraindicated. Blood flow redistribution varies when using modalities such as treadmill walking (TW), leg cycling (LC) and arm cycling (AC) that may contribute to inaccuracies. Understanding the effect of physical activity using modalities on the accuracy of these devices have practical benefits. **Purpose:** To determine the effect of moderate intensity physical activity using different exercise modalities on body fat percent (BF%) measured by ADP, whole body bioelectrical impedance (WBIA), upper body bioelectrical impedance (UBIA), and lower body bioelectrical impedance (LBIA). **Methods:** Seventeen male participants (33.1 ± 9.3 y; 23.0% - 49.0% body fat) were included in the study. Participants exercised using TW, LC, and AC (45% - 55% heart rate reserve) for 30 minutes on different days including a control condition. BF% was measured pre-exercise (PreE), immediately post-exercise (PE0), 15 minutes post-exercise (PE15), 30 minutes post-exercise (PE30), 45 minutes post-exercise (PE45), and 60 minutes post-exercise (PE60) using ADP, WBIA, UBIA and LBIA at each time point. **Results:** No differences were found during the control for PreE BF% for ADP (18.2 ± 9.9%), WBIA (17.8 ± 7.6%), UBIA (17.8 ± 6.5%), and LBIA (15.6 ± 8.0%). There was no effect of time during the control on BF% except when using UBIA (p=0.03). Using ADP, BF% at PE0 was significantly less than all other time points following TW and LC (p<0.05). Following AC, PE0 was significantly different from PE15-PE60, but not PreE (p=0.06). Using LBIA, after TW only BF% measured at PE15 and PE45 was significantly less than PreE (p<0.05). **Conclusion:** BF% measured by ADP after exercise decreases with all modalities, but generally returns to PreE measures within PE15. WBIA and UBIA BF% are not affected by exercise modality over time. However, LBIA BF% tends to decrease following TM but returns to PreE measures within 60 minutes.

Comparison of Different Methods Used to Assess Body Composition in College Aged Athletes

Parker Nally, Heath Pierce, Jared Hall, Colin Shaw, Holley Sirois, Erica Blodgett, Megan Janard-Howell, Christopher Gouws, Jacob Coviello, Taylor Littlefield, MacKenzie Dwyer, Hana Laramie, Erin Tuttle, Paul Visich. University of New England, Biddeford, ME. Email: pnally@une.edu
(No relevant relationships reported)

With the prevalence of obesity increasing to almost 40% as of 2016 and the vast amount of health complications known to be associated with being overweight or obese, knowing one's body composition is increasingly important. The American College of Sports Medicine has recommended values for % body fat that places individuals into different categories (from very lean to very poor), based on sex and age. However, these categories of % body fat are based on the use of Skinfold Thickness measurements. There are now numerous ways in which to assess body composition and we don't know the variability that may exist between these methods. **PURPOSE:** The purpose of this study was to compare the most common methods of measuring body composition that are currently being used today in order to determine- 1) how much of a difference exists between the different techniques, and 2) the relationship of the different methods of measuring body composition. **METHODS:** Thirty-nine healthy males (age=20±2 y; body weight=97.38±21.26 kg; height=1.79±0.06m) had their body composition assessed five different ways. Prior to each testing day subjects completed a 10-12 hour fast, did not exercise, and had a Urine Specific Gravity of <1.02. Body composition assessments included skinfold (SF) thickness (Lange Skinfold Caliper), Dual Energy X-Ray Absorptiometry (DXA);

GE Advanced Prodigy DXA Encore V17 Software), Ultrasound Thickness (US; BodyMetrix), Bioelectric Impedance (BIA; Tanita Body Composition Analyzer, BF-350), and Underwater Weighing (UWW; Exertech Floatweight System). **RESULTS:** Body fat % for US was $17.62 \pm 6.82\%$, SF $17.69 \pm 7.59\%$, UWW $21.94 \pm 8.97\%$, BIA, $23.64 \pm 7.74\%$, and DXA $24.98 \pm 8.63\%$. In comparison to DXA, % fat was significantly greater than US, SF, and UWW ($p < 0.001$). In respect to the relationship to DXA, correlations ranged from .873 (DXA vs. BIA $p = 0.001$) to .957 (DXA vs SF $p = 0.001$). **CONCLUSIONS:** These results suggest that a difference in body fat up to 7.36% can be observed between the different methods assessed. However, the relationship between the different methods is fairly strong. Due to the large variability observed in the different body composition methods assessed, it would suggest the need for developing recommended standard ranges based on the body composition assessment utilized.

Agreement Between Two Bioimpedance Spectroscopy Devices and DXA for Body Composition

Bjoern Hornikel¹, Zackary S. Cicone¹, Clifton J. Holmes¹, Bailey A. Welborn¹, Michael R. Esco, FACSM¹, Jordan R. Moon², Todd Freeborn¹. ¹University of Alabama, Tuscaloosa, AL. ²Impedimed, Inc., Carlsbad, CA. (Sponsor: Michael R. Esco, FACSM)
Email: bhornikel@crimson.ua.edu

(No relevant relationships reported)

Bioimpedance spectroscopy (BIS) has been used as an alternative to the more expensive and invasive dual-energy x-ray absorptiometry (DXA) to estimate body composition. **PURPOSE:** To determine the agreement between two BIS devices in comparison to DXA for measuring body fat percentage (%Fat), fat-free-mass (FFM), and fat-mass (FM). **METHODS:** Ninety-five subjects ($m = 35$, $f = 60$; 30 ± 15 years; 170 ± 8.0 cm; 72.6 ± 14.8 kg) participated in the study. Both devices utilized whole body right side measurements, one device (BIS₁) in supine and the other (BIS₂) in standing position. Measurements were taken during a single visit following an 8-12 hour fast. **RESULTS:** Bland-Altman analysis revealed BIS₁ significantly underpredicted values for %Fat (mean differences $\pm 95\%$ limits of agreement: $3.09 \pm 4.97\%$) and FM (2.85 ± 5.99 kg) and significantly overpredicted FFM (1.15 ± 4.98 kg) in comparison to DXA. When compared to DXA, BIS₂ significantly underpredicted values for %Fat ($1.69 \pm 5.16\%$) and FM (1.81 ± 6.25 kg). No significant difference existed between BIS₂ and DXA for FFM (0.08 ± 5.32 kg). Correlations between both BIS₁ and BIS₂ and DXA for FM, FFM, and %Fat were very strong ($r \geq 0.92$). **CONCLUSIONS:** While BIS₁ and BIS₂ indicated some bias when calculating FM, FFM, and/or %Fat, the limits of agreement were fairly narrow, indicating both to be acceptable alternatives to DXA for clinical practice in males and females aged 18-82 years with BMIs $18-39.5$ kg/m². This study was funded by Impedimed, Inc

The Effect of Acute Exercise-Induced Fluid Loss and Fluid Consumption on Percent Body Fat

Paul T. Cutrufello, Michael J. Landram, Andrew C. Venezia. *The University of Scranton, Scranton, PA.* (Sponsor: Curt B. Dixon, FACSM)

Email: paul.cutrufello@scranton.edu

(No relevant relationships reported)

Acute exercise fluid loss, as well as fluid consumption, have been shown to impact body composition assessment using multiple methods of assessment. However, to our knowledge no study to date has examined percent body fat (%BF) using skinfold measurements (SF), air displacement plethysmography (ADP), dual energy x-ray absorptiometry (DXA), and type-A ultrasound (US) under exercise conditions while also controlling for exercise-induced fluid loss. **PURPOSE:** To determine the effect of acute exercise-induced fluid loss and fluid consumption on %BF determined by SF, ADP, DXA, and US before exercise, after exercise, and after fluid consumption. **METHODS:** Thirty-two college-aged men (20.8 ± 1.1 yrs) participated in this study and were randomly assigned to one of three groups: one group consumed water during exercise and after exercise (with water; $n = 11$), a second group consumed water only after exercise (without water; $n = 11$), and a third group served as the control group ($n = 10$). Participants reported in a euhydrated state ($U_{sg} < 1.020$). %BF was determined using SF, ADP, DXA, and US. Participants then performed 30 min. of exercise at 70% heart rate reserve (HRR) on a cycle ergometer in a room at $28.3-29.4^\circ\text{C}$. Twenty-thirty min. after exercise %BF was determined a second time. Water equal to the BM lost during exercise was consumed and %BF was measured a third time 60 min. later. **RESULTS:** Body mass (BM) was significantly reduced post-exercise in the without water group (79.7 ± 9.4 ; 78.8 ± 9.5 kg; $p < 0.001$) but not in the group exercising with water (82.5 ± 7.4 ; 82.3 ± 7.3 kg; $p = 0.210$). %BF was significantly less post-exercise compared to pre-exercise in the without water group (14.3 ± 4.4 ; 12.6 ± 4.9 %; $p = 0.017$) when using ADP. In both the with water (16.8 ± 4.5 ; 18.8 ± 4.2 %; $p = 0.001$) and without water (12.6 ± 4.9 ; 14.7 ± 5.0 %; $p = 0.011$) groups, %BF significantly increased after fluid consumption when using ADP. No significant effects were observed for DXA, US, or

SF determined %BF after exercise and fluid consumption. **CONCLUSION:** Acute exercise and fluid consumption impacted ADP determined %BF, but did not have a significant effect on %BF determined by DXA, US, and SF.

Decline In Aerobic Capacity Or Increase In BMI?

Xiong Qin, Weimo Zhu, FACSM, Zezhao Chen. *University of Illinois at Urbana and Champaign, Urbana, IL.* (Sponsor: Weimo Zhu, FACSM)

Email: xiongq2@illinois.edu

(No relevant relationships reported)

PURPOSE: Aerobic capacities, specifically $\text{VO}_{2\text{max}}$, of children and youth, have been found declining over the second half of 20th century according to the secular trend analyses (see e.g., Tomkinson et al., 2007). Since body mass index (BMI) is often a part of $\text{VO}_{2\text{max}}$ prediction, this study was to examine the impact of changed BMI on the declined $\text{VO}_{2\text{max}}$.

METHODS: First, 50th percentiles of 8-11 yr. boys and girls' BMI and 1-mile-Run-Walk (1MRW) performance in 1987 National Children and Youth Fitness Study (NCYFS II) were used to estimate their $\text{VO}_{2\text{max}}$ using the equation of Cureton et al. (1995): $\text{VO}_{2\text{max}} (\text{ml/kg/min}) = (-8.41 * \text{Time}) + (0.34 * \text{Time}^2) + (0.21 * \text{Age} * \text{Sex}) - (0.84 * \text{BMI}) + 108.94$. Second, BMIs in the prediction were replaced by the BMI 50th percentiles of 8-11 yr. boys and girls in 2015-2016 NHANES. Finally, the difference between 1987 and 2015-16 estimated $\text{VO}_{2\text{max}}$ were computed and compared.

RESULTS: Impact of BMI changes on the estimated $\text{VO}_{2\text{max}}$ by age and sex was summarized below:

CONCLUSIONS: Even when running performances stay the same, the changes in BMI between 1987 and 2015-16 could lead 1-7% decline in estimated $\text{VO}_{2\text{max}}$ of 8-11 children and youth, indicating that weight management should be a part of fitness and health promotion in children and youth.

| Impact of BMI Changes on the Estimated $\text{VO}_{2\text{max}}$ by Age and Sex | | | | | | | |
|---|-------------------------------|----------------------------------|----------------------|---|--|--------------------|----------|
| Age in Yr., Sex | BMI-1987 (kg/m ²) | BMI-2015-16 (kg/m ²) | 1987-1MRW Time (min) | 1987- $\text{VO}_{2\text{max}}$ (ml/kg/min) | 2015-16- $\text{VO}_{2\text{max}}$ (ml/kg/min) | Change (ml/kg/min) | % Change |
| 8, Male | 16.38 | 16.95 | 10.65 | 45.86 | 45.38 | -0.48 | -1% |
| 9, Male | 16.88 | 18.10 | 10.17 | 46.29 | 45.27 | -1.02 | -2% |
| 10, Male | 17.03 | 19.00 | 9.87 | 46.86 | 45.20 | -1.66 | -4% |

Regional Differences In Bone Mineral Density Vary With Whole Body Z-scores In College Track Athletes

James M. Smoliga, FACSM, Justin D. Waller, Kevin R. Ford, FACSM. *High Point University, High Point, NC.*

Email: jsmoliga@highpoint.edu

(No relevant relationships reported)

Track and field athletes are susceptible to musculoskeletal injuries due to a combination of insufficient recovery and excessive training. Stress fractures in these athletes are common, especially in distance runners, and are associated with decreased regional and whole body bone mineral density (BMD). **PURPOSE:** To determine if college track and field athletes with low BMD experience loss of BMD in the ribs (RIB) to compensate for musculoskeletal loading of the lower extremity. **METHODS:** 110 NCAA Division I track and field athletes (57 males, 53 females) underwent whole body and bilateral hip dual energy x-ray absorptiometry (DXA) scans. Whole body Z-scores and BMD for standard sub-regions, including RIB, were automatically computed by DXA software. Proximal, middle, and distal regions of the femur (F_{PROX} , F_{MID} , F_{DIST}) and tibia (T_{PROX} , T_{MID} , T_{DIST}) were objectively identified and BMD for each sub-region was computed. In the hip scans, femoral neck (F_{NECK}), Ward's triangle

(F_{WARD}), and total hip BMD were computed. The mean BMD of both sides was computed for each sub-region, and a ratio between BMD of each respective sub-region and the ribs was computed. Participants were then divided into quintiles by whole body Z-score. A linear mixed effect model was used to determine whether the sub-regional BMD parameters and ratios differed between quintile groups. Pairwise comparisons were used to determine differences between quintile groups if a main effect was significant (p<0.05). **RESULTS:** There were significant main effects for BMD to differ by each sub-region (p<0.001 for all), with the lowest quintile group always having significantly lower BMD than that of each of the upper three quintiles. However, the only significant ratios were that of F_{MID}:RIB (p=0.019) and F_{DIST}:RIB (p=0.019). Pairwise comparisons revealed the upper quintile group had significantly lower ratios for these two parameters than all other quintile groups. **CONCLUSION:** Decreased BMD in RIB and all sub-regions of the legs, combined with elevated F_{MID}:RIB and F_{DIST}:RIB ratios, suggest that BMD is lost from the ribs at a greater rate than it from specific regions of the legs in athletes with the lowest whole body Z-scores. Future research should explore the clinical implications of this finding for stress fracture risk and long-term bone health in athletes.

The Prevalence of Body Composition Criterion Methods for Validation Studies in Humans

Laurie A. Milliken, FACSM¹, Timothy G. Lohman². ¹University of Massachusetts Boston, Boston, MA. ²University of Arizona, Tucson, AZ.
Email: laurie.milliken@umb.edu
(No relevant relationships reported)

PURPOSE: To determine the recent prevalence of body composition criterion methods in validation studies of total body percent fat or fat free mass. **METHODS:** A literature search was performed to identify studies between 2013 - 2018 using the following key words: four component model, validation, body composition, and fat using Medline. Only human studies published in English were included. One person (L. Milliken) screened all articles and coded the results to identify the criterion and comparison methods used. For all studies where multi component models were used, a further note was made regarding what methods comprised those models. All methods were summarized to capture the prevalence of methods used in the literature for body composition validation studies. **RESULTS:** A total of 176 articles were identified; 128 measured total body composition or body volume articles and were included. Some studies used more than one criterion method. 10.9% of studies used a 2 component (2C) model, 67.2% used a 3C model and 10.9% used a 4C model as a criterion method. The most common 2C, 3C, and 4C models respectively were air displacement plethysmography (ADP) (9.3%), dual-energy x-ray absorptiometry (DXA) (62.5%) and ADP/DXA/total body water (TBW) (7.8%). 3.9% of studies used an inappropriate 3C or 4C model by using bioimpedance spectroscopy (BIS) in place of TBW by isotope dilution. The criterion methods used in order of prevalence were DXA (62.5%), 4C (10.9%), ADP (9.4%), isotope dilution (7.0%), magnetic resonance imaging (4.7%), 3C not including DXA (4.7%), bioelectrical impedance analysis (3.9%), and underwater weighing (1.6%). **CONCLUSIONS:** Body composition validation studies are dominated by DXA as a criterion method which may not be appropriate in all situations. Also, researchers are incorrectly using field methods rather than laboratory methods (most commonly using BIS for TBW) as part of the 4C model in validation studies. The gold standard for body composition validation studies remains the 4C model with TBW determined by isotope dilution.

3358 Board #46 June 1 8:00 AM - 9:30 AM

Body Composition in Lean Athletes: Which Ultrasound Sites Best Predict Fatness Measured by DXA?

Gabriela Alfonso. University of Colorado at Colorado Springs, Colorado Springs, CO.
Email: galfonso@uccs.edu
(No relevant relationships reported)

PURPOSE: Ultrasound (US) has been used for over 50 years as a way of measuring fat thickness comparable to skin folds in predicting body fat. Recent advances in US (Müller et al, 2016) have increased objectivity and accuracy in measuring fat thickness. This study was designed to compare the new US approach with DXA %fat as the criterion method in male and female athletes. **METHODS:** Three centers (Perth, Colorado, Lisbon) performed whole body DXA method on 16 competitive athletes (n=48; age: 23.5 ± 4.2 years, weight: 69.2 ± 11.1 kg, height: 174.4 ± 8.6 cm, BMI: 22.6 ± 2.4 kg/m²). Three ISAK Level 1 and US trained observers at each center measured 8 standardized US sites, as described by Müller et al (2016), on each athlete capturing 3 sets of measurements per subject. Observer 1 data were combined from each center for both female and male athletes to create Observer 1 sample (n=48); two other sets of data were collated by combining Observer 2 and 3 data, each n=48. Step down regression and correlational analyses were examined for relationships between DXA %Fat and all 8 US sites.

RESULTS: Significant correlations between DXA %fat and all 8 US sites (r=.52 - .87, p<0.01) were found. Using step down multiple regression analyses all 8 sites were entered into the analyses to predict DXA %fat. Three sites for females (lower abdomen (LA), medial calf (MC), distal triceps (DT); p<0.001, SEE=2.4-2.6%); and two sets of three sites for males: LA, MC, and erector spinae (ES) (p<0.01; SEE=1.8-2.2%), and upper abdomen (UA), MC, ES (p<0.01; SEE=1.9%) were found to be the best predictors.

CONCLUSIONS: These findings show that US can predict DXA %fat with low SEE's in both male and female athletes.

3359 Board #47 June 1 8:00 AM - 9:30 AM

Body Fat Assessed With Electrical Impedance Myography Compared With DXA In Professional Athletes

Juan R. Lopez-Taylor, Roberto Gabriel Gonzalez-Mendoza, Francisco Torres-Naranjo, Alejandro Gaytan-Gonzalez, Juan Antonio Jimenez-Alvarado, Edna Elvira Jauregui-Ulloa, Marisol Villegas-Balcazar. Universidad de Guadalajara, Guadalajara, Mexico.
(No relevant relationships reported)

Electrical impedance myography (EIM) has been compared with DXA in physically active subjects, but its accuracy in professional athletes has not been explored. **PURPOSE:** To compare the body fat estimated with a commercial EIM mobile device with body fat measured with DXA. **METHODS:** We evaluated the body fat percentage (BF%) of 28 professional male soccer players (19 - 34 years old, BF% 14.95 ± 2.43) with a whole body DXA scan (Hologic®) and a mobile EIM device (Skulpt® Chisel). The EIM was assessed at ten anatomical sites (abdomen, biceps, calves, chest, forearms, hamstrings, lower back, quadriceps, shoulders, and triceps). The BF% was estimated for each anatomical point and for the sum of all according to the manufacturer's instructions. We calculated mean differences in BF% (DXA - EIM) and their 95% limits of agreement. DXA and EIM BF% were analyzed for correlation with intra-class correlation coefficient and compared with ANOVA and Dunnett post hoc test. **RESULTS:** There were strong correlations between DXA BF% and EIM BF% assessed at abdomen, chest, lower back, quadriceps, hamstrings, and all sites. Moderate to low correlations were observed for shoulders and triceps. Biceps, calves, and forearms showed no significant correlation. Similarly, DXA BF% was different to EIM BF% at calves and forearms only (p<0.05). From the other anatomical sites, the lowest mean difference was observed at hamstrings and the biggest at biceps. However, the narrowest limits of agreement were observed at quadriceps and the widest at chest. BF% estimated using all sites showed similar results as obtained evaluating BF% at quadriceps (Table). **CONCLUSIONS:** The EIM mobile device was useful to accurately estimate BF%, even evaluating a single anatomical site when compared with DXA in professional soccer players. This device may be helpful for body composition assessment on the field. However, its accuracy in other athletic populations and its applicability for follow-up warrants further research.

| Anatomical site | Mean | -2SD | +2SD | ICC | Range LA |
|-----------------|--------|--------|------|-------|----------|
| All sites | 1.95 | -2.65 | 6.55 | 0.64 | 9.2 |
| Quadriceps | -1.97 | -6.07 | 2.14 | 0.61 | 8.21 |
| Triceps | -0.50 | -5.30 | 4.29 | 0.48 | 9.59 |
| Biceps | -2.34 | -7.30 | 2.61 | 0.13 | 9.91 |
| Shoulders | -0.63 | -6.46 | 5.21 | 0.50 | 11.67 |
| Hamstrings | -0.29 | -6.24 | 5.66 | 0.61 | 11.9 |
| Abdomen | 2.16 | -4.24 | 8.57 | 0.75 | 12.81 |
| Lower back | 1.33 | -5.23 | 7.89 | 0.62 | 13.12 |
| Chest | 0.62 | -6.71 | 7.96 | 0.67 | 14.67 |
| Forearms | -3.19* | -8.34 | 1.95 | 0.04 | 10.29 |
| Calves | -5.31* | -10.88 | 0.25 | 0.005 | 11.13 |

ICC: Intraclass correlation coefficient; Range LA: Absolute range on limits of agreement (95%); SD: Standard deviation. * Significant differences with DXA (p<0.05).

3360 Board #48 June 1 8:00 AM - 9:30 AM
Influence of Circumference Measurements and Body Composition on Estimating Resting Metabolic Rate in Healthy Adults

Kristi Chase, Kyle Patek, John Walker, FACSM, Joni Mettler.
Texas State University, San Marcos, TX.
 Email: klc280@txstate.edu
 (No relevant relationships reported)

Measurement of resting metabolic rate (RMR) is an important factor for weight management. Previous research has reported several variables to estimate RMR such as body size, percent fat (%BF), age, and sex; however, little is known regarding the effect of circumference measures in estimating RMR. **PURPOSE:** The purpose of this study was to develop a model to estimate RMR using waist circumference (WC), an easily obtainable measure, and cross-validate it to previously published models. **METHODS:** Subjects were 140 adult men and women, ages 18-65 years. RMR was measured through indirect calorimetry, %BF was measured through air displacement plethysmography, and fat mass and fat-free mass were determined from %BF and weight. Other variables collected were: weight, height, age, sex, ethnicity, body mass index, WC, hip circumference, waist-to-hip ratio, waist-to-height ratio, and %BF estimated from bioelectrical impedance analysis. Subjects were randomly divided into derivation and cross-validation samples. A multiple regression model was developed to determine the most accurate estimation of RMR in the derivation sample. The cross-validation sample was used to confirm the accuracy of the model and to compare the accuracy to published models. **RESULTS:** The best predictors for estimating RMR were body weight, $r = 0.70$, $p = 0.031$, age, $r = -0.30$, $p = 0.012$, and sex, $r = 0.51$, $p = 0.018$. Other factors failed to account for significant variation in the model. The derived equation for estimating RMR is: $RMR \text{ (kcal/day)} = 843.11 + 8.77(\text{weight}) - 4.23(\text{age}) + 228.54(\text{sex}, M = 1, F = 0)$, $R^2 = 0.68$, $SEE = 173 \text{ kcal/day}$. Cross-validation statistics were: $R^2 = 0.54$, $p \leq 0.05$, $SEE = 199 \text{ kcal/day}$, and total error = 198 kcal/day. In published models, R^2 ranged from 0.47 to 0.57, SEE ranged from 192 to 213 kcal/day, and total error ranged from 212 to 1311 kcal/day. **CONCLUSIONS:** Cross-validation to published models for estimating RMR were similar to those of the derived model; however, the total error in the derived equation was lower than any of the previously published models. Several published models considerably overestimate RMR compared to the current model. The results of this study suggest that RMR can be reasonably estimated with easily obtainable measures which allow for estimation and implementation of RMR for weight management in clinical practice.

Health and Fitness Differences Between Urban and Rural Costa Rican Older Adults

Luis Solano-Mora¹, Mónica Salazar-Villanea², Luis E. Araya-Ortega², Esmeralda Valdivieso-Mora³, David K. Johnson⁴, Yamileth Chacón-Araya², José Moncada-Jiménez². ¹National University, Heredia, Costa Rica. ²University of Costa Rica, San José, Costa Rica. ³University of Kansas, Lawrence, KS. ⁴University of California, Davis, CA.
 Email: jose.moncada@ucr.ac.cr
 (No relevant relationships reported)

Costa Rica has one of the highest life expectancies in America, even higher than the United States. Studies addressing health and fitness in Latin American urban and rural older adults are scarce. **PURPOSE:** The purpose of the study was to test the hypothesis that older adults from rural areas present fewer negative health conditions and higher fitness than older adults from urban zones. **METHODS:** 298 participants aged 60 to 85 (Urban n = 188, Rural n = 110) completed a 29-item chronic diseases questionnaire and performed the Senior Fitness Test: a) 6-min walking test (6-MWT), b) 30-s Chair to-Stand Test, c) 30-s Arm Curl Test, d) timed up- and go test (TUG), balance time, and handgrip strength (HGS). Categorical variables were analyzed with non-parametric Chi² and continuous variables with 2 x 2 ANOVA (residency zone x gender). **RESULTS:** Urban women reported more chest pain ($\chi^2 = 6.05$, $p = 0.014$), more pacemakers ($\chi^2 = 4.70$, $p = 0.030$), diabetes ($\chi^2 = 3.98$, $p = 0.046$), and osteoarthritis ($\chi^2 = 5.08$, $p = 0.024$) than rural women. Urban men reported more chronic low back pain ($\chi^2 = 5.65$, $p = 0.017$) and depression ($\chi^2 = 3.90$, $p = 0.048$) than rural men. A higher diastolic blood pressure was observed in urban compared to rural older adults (Urban = $76.2 \pm 0.9 \text{ mmHg}$ kg vs. Rural = $70.2 \pm 1.3 \text{ mmHg}$; $p \leq 0.001$). Urban older adults showed better balance time than rural older adults (Urban

= $22.8 \pm 0.8 \text{ s}$ vs. Rural = $18.4 \pm 1.2 \text{ s}$; $p = 0.003$). Performance was similar between urban and rural older adults on the 6-MWT, 30-s Chair to-Stand, 30-s Arm Curl, TUG, and HGS tests ($p > 0.05$). **CONCLUSION:** In spite of having similar physical fitness performance, Costa Rican urban men and women showed an overall negative health profile compared to rural older adults. Balance was the only functional variable positively observed in urban older adults.

A Comparison of Back Squat & Safety Squat Bar on Measures of Strength, Speed, and Power in NCAA Division I Baseball Players

Richard Meldrum, Mark DeBeliso, FACSM. *Southern Utah University, Cedar City, UT.* (Sponsor: Mark DeBeliso, FACSM)
 Email: r.meldrum00@gmail.com
 (No relevant relationships reported)

Squat exercise variations are considered a cornerstone of resistance training (RT) programs. Understanding the effectiveness of differing squat exercise variations is important for coaches and athletes in order to optimizing the effectiveness of a RT program. **PURPOSE:** The current investigation examined a comparison of the standard Olympic barbell loaded back squat (BS) with a squat performed with the safety squat bar (SSB). **METHODS:** Twenty eight Division I male baseball players (19.2 ± 1.1 years, $182.5 \pm 5.6 \text{ cm}$, $87.6 \pm 5.1 \text{ kg}$) participated in a RT program comprised of two workout sessions a week for nine weeks, performing either a BS or SSB utilizing an autoregulatory progressive resistance periodization protocol, concurrent with their existing, season-specific, RT program. Pitchers ($n=14$) utilized the SSB bar with the goal of minimizing stress on the shoulder and elbow joints during the execution of the squat. The non-pitchers ($n=14$) performed the Olympic barbell BS. Lower body strength (estimated 1RM squat: kgs), sprint speed (54.86 m sprint: secs), and vertical jump (VJ: cms) were assessed prior to and following the RT training period. **RESULTS:** The VJ had a significant positive improvement from pre to post RT for both the BS (pre: 74.6 ± 8.1 , post: 76.5 ± 8.0) and SSB (pre: 72.4 ± 7.6 , post: 75.3 ± 8.3) groups ($p < 0.05$). The estimated squat 1RMs had a significant positive improvement from pre to post RT for both the BS (pre: 136.2 ± 11.0 , post: 166.1 ± 23.7) and SSB groups (pre: 112.3 ± 14.9 , post: 152.6 ± 22.0) ($p < 0.05$). The 54.86 m sprint did not improve significantly from pre to post RT for either the BS (pre: 7.12 ± 0.33 , post: 7.05 ± 0.26) or SSB groups (pre: 7.27 ± 0.17 , post: 7.19 ± 0.20) ($p > 0.05$). When comparing gain scores between each group there were no significant difference between the BS and SSB groups for either 54.86 m sprint or VJ ($p > 0.05$). However, the estimated squat 1RM gain score for the SSB was significantly greater than the BS group ($p < 0.05$) noting that the effect size of change from pre to post RT was 2.69 and 2.71 standard deviations for the BS and SSB groups respectively. **CONCLUSION:** Given that both squat modalities yielded approximately equal improvements in VJ and lower body strength, coaches and athletes can consider the SSB variation of the squat as a viable option for developing lower body strength and power.

Comparison of Glenohumeral Posterior Capsule Tightness between Golfers and Non-Golfers
Abstract

The primary movement of the golf swing is habitually unidirectional. Consistently the leading side, (left side of a right handed golfer) and the trail side, (right side of a right handed golfer) are asked to perform remarkably different tasks with an overall shoulder injury prevalence of between 8-16%.

Purpose. The current study examined glenohumeral posterior capsule mobility of the leading shoulder compared to the trail shoulder in recreational golfers and non-golfers. **Methods.** Participants were twenty-two recreational golfers (15 males, 7 females) mean age 38.8 years ($SD = 18.85$) with at least two years of prior experience golfing and thirteen non-golfers (7 males, 6 females) with a mean age of 33.1 years ($SD = 12.35$). All participants had bilateral glenohumeral posterior capsule mobility measured as medial epicondyle distance from exam table in inches via side lying horizontal adduction of the non weight bearing upper extremity with scapula manually stabilized. **Results.** Golfers exhibited a statistically significant ($P < .001$) asymmetry of glenohumeral posterior capsule mobility in their leading shoulder compared to the trail shoulder. The non-golfing participants demonstrated no statistically significant difference in right to left glenohumeral posterior capsule mobility exhibiting relatively equal measurements bilaterally. **Conclusions.** The sample of golfers demonstrated an asymmetry in glenohumeral posterior capsule mobility in leading to trail shoulders

that was not seen in the non-golfing population. Clinical consideration should be given to this asymmetry in training and care of the golfing athlete especially as it relates to limitations in shoulder mobility and motion.

Adjusted Muscle Strength Evaluation Using Directional and Continuous Jump Motion Test by 3D Motion Analysis

Tamotsu Kitabayashi¹, Kosho Kasuga². ¹Tokyo University of Science, Tokyo, Japan. ²Gifu university, Gifu, Japan. (Sponsor: Kiyoji Tanaka, FACSM)
 (No relevant relationships reported)

PURPOSE: To study adjusted muscle strength evaluation methods using directional and continuous jump motion tests (vertical, forward, backward), this study compares basketball players with general students and examines differences between the groups and directional differences.

METHODS: Subjects were two groups ; General Students (14 male students) and Basketball Students (10 male students). Vertical, forward and backward jumps were each measured twice for maximum exertion (100%) and adjusted exertion (50%). The first vertical jump with full strength and then immediately after landing, adjusted exertion in each direction (50% exertion) (vertical, forward, backward) were measured using 3D motion analysis (Kinect2 (Microsoft)). Difference in average value in single jump measurement (50%) and continuous measurement (50%) using absolute values (cm) was verified and two factor ANOVA was conducted for differences between the groups (basketball vs. general) using relative values (%) and for differences among each direction (vertical, forward, backward). For the multiple comparison test, the Bonferroni method was used. The level of significance was set at 5%.

RESULTS: In single jump and continuous measurements, the general student group showed close to 50% exertion in the order of forward, vertical, and backward jumps. The basketball group showed 50% exertion in the order of forward, backward, and vertical jumps. The order of superiority tended to be different between the two groups. Additionally, compared to the single jump measurement, continuous measurement showed that both the general student and basketball groups demonstrated close to 50% exertion and particularly in the continuous measurement, differences between the two groups tended to become more noticeable in the backward jump.

CONCLUSIONS: For two groups, there are different directions in which adjusted exertion are likely to occur. By continuous jump measurement with initial movement maximum exertion, it is possible to evaluate accurate adjustment abilities and competitive qualities.

Comparison Of RPE Rating Scales For Session RPE

Blaine E. Arney, Reese Glover, Andrea Fusco, Cristina Cortis, Jos J. de Koning, FACSM, Teun van Erp, Salvador Jaime, Richard P. Mikat, FACSM, John P. Porcari, FACSM, Carl Foster, FACSM. University of Wisconsin-La Crosse, La Crosse, WI.
 Email: arney.blaine@uwlax.edu
 (No relevant relationships reported)

Purpose: The Session RPE (sRPE) is an accepted method of monitoring training in athletes in many different sports. It is based on the Category-Ratio (0-10) RPE scale (BORG-CR10) developed by Borg. There is no evidence how substitution of the Borg 6-20 RPE scale (BORG-RPE) might influence the sRPE. **Methods:** Systematically training, recreational level athletes from different sport disciplines performed six, randomly ordered, 30-minute interval training sessions, at intensities based on peak power output (PPO), designed to be easy (50%PPO), moderate (75%PPO) or hard (85%PPO). sRPE was obtained 30-min post-exercise using the BORG-CR10 or BORG-RPE and compared for matched conditions. **Results:** The average percent of heart rate reserve (%HRR) was well-correlated with sRPE from both BORG-CR10 (r = 0.76) and BORG-RPE (r = 0.69). The sRPE from BORG-CR10 and BORG-RPE were very strongly correlated (r = .90) at matched times. **Conclusions:** Although producing different absolute numbers, sRPE derived from either BORG-CR10 or BORG-RPE provide substitutable estimates of perceived exercise training intensity.

3366 Board #54 June 1 9:30 AM - 11:00 AM
Reliability and Validity of Hip Rotation Strength Tests: Systematic Error Due to Tester Hand Dominance

Connor Fedge¹, Tim Tyler². ¹PRO Sports Physical Therapy of Westchester, Scarsdale, NY. ²Nicholas Institute of Sports Medicine and Athletic Trauma, Lenox Hill Hospital, New York, NY. (Sponsor: Malachy P McHugh, FACSM)
 Email: connorfedge@gmail.com
 (No relevant relationships reported)

PURPOSE: Manual muscle testing using hand held dynamometry (HHD) is commonly utilized and for a more objective measure. Deficits in hip rotation strength have been linked to lower extremity pathology, but measurement reliability is unknown. The purpose of this study was to assess the reliability and validity of hip internal (IR) and external (ER) rotation strength in three positions. **METHODS:** Right and Left Hip IR and ER strength was measured using HHD in 20 patients, (30 ± 12 years, 9 women, 11 men), using 3 tests (seated, supine, side-lying), at two different time points (Test 1, Test 2), by two different testers (A and B). Strength was reported as torque (Nm/kg). Intratester and intertester relative reliability were assessed using intraclass correlation coefficients (ICC). Absolute reliability was assessed using 95% limits of agreement (LOA). **RESULTS:** Torque was highest for the seated tests, followed by the supine (13% lower than seated), and side-lying (25% lower than seated). There was a systematic difference between left and right legs for the seated and side-lying tests: the left side was stronger than right side for IR (Seated: 7% p=0.044, Side-lying: 9% p=0.04); right side 7% stronger than left side side-lying ER (p=0.008). Inter- and intratester ICCs are reported in Table 1. **CONCLUSIONS:** Hip ER and IR strength testing had poor intra- and intertester reliability. The right/left difference in seated and side-lying tests, suggest indicate tester hand dominance may be a confounding factor. These data highlight the need for more reliable hip rotation strength testing.

Table 1.

| Intertester ICC | | | | | | | | |
|-----------------|--------|--------|--------|--------|------------|--------|--------|------|
| Supine | | Seated | | | Side-Lying | | | |
| Test 1 | Test 2 | Test 1 | Test 2 | Test 1 | Test 2 | Test 1 | Test 2 | |
| IR R | 0.67 | 0.47 | IR R | 0.88 | 0.67 | IR R | 0.50 | 0.53 |
| IR L | 0.48 | 0.30 | IR L | 0.71 | 0.41 | IR L | 0.70 | 0.69 |

3367 Abstract Withdrawn

3368 Board #56 June 1 9:30 AM - 11:00 AM
Handgrip Fatigue and Forearm Girth in Intermediate Sport Rock Climbers

Grace MacDonald¹, Jacob W. Manning², Szu-Ping Lee¹, Charli Aguilar¹, Nathaniel G. Bodell¹, Jack Young¹, Brian Schilling¹, James W. Navalta, FACSM¹. ¹University of Nevada Las Vegas, Las Vegas, NV. ²Southern Utah University, Cedar City, UT. (Sponsor: Dr. James Navalta, FACSM)
Email: grace.macdonald@duke.edu
(No relevant relationships reported)

Rock climbing has been increasing in popularity both recreationally and competitively. Indoor sport rock climbing is a type of climbing where the climber ascends a wall using artificial rocks (hand and foot holds) and is attached to a safety rope. Despite this increase in popularity of the sport, the physiological responses to sport climbing as an exercise to specific muscle groups are not well defined in literature. **PURPOSE:** The purpose of this study was to quantify the change in handgrip strength over a 30-minute bout of continuous climbing, specifically in intermediate sport climbers. An additional aim of this study was to quantify any change in forearm girth over a bout of climbing and compare it to the change in strength and to identify if there is a relationship between the two. **METHODS:** Ten intermediate rock climbers [Age: 26.7±6.7 years; Height: 174.5±6.12 cm; Mass: 68.14±8.21 kg; Body Fat %: 15.75±.63 %; Years Climbing: 7.3±4.69 years;] consented to participate and completed baseline handgrip strength (via handgrip dynamometer) and forearm girth (via tape measure). A climbing questionnaire indicated each participant's rock climbing ability and defined them as intermediate climbers. Each participant ascended one of two 5.9 YDS (Yosemite Decimal System) routes as many times as possible within 30 minutes. After each ascent, heart rate, handgrip strength and forearm girth was measured. Data were analyzed using repeated measures ANOVA and correlation with significance accepted at the p≤0.05 level. **RESULTS:** Dominant handgrip strength decreased by 22% (p=0.009) and non-dominant handgrip strength decreased by 23% (p=0.002) compared to pre-climb. Dominant and non-dominant forearm girth increased by 4.4% (p=0.001, p=0.001). The average heart rate while climbing was 71±4.2 % of age-predicted HRmax. The rest times in between ascents were 1:22±33 sec. **CONCLUSIONS:** These results show that over a 30 minute bout of climbing, intermediate climbers' handgrip strength decreases and forearm girth increases. It is possible that with longer rest times, handgrip strength would not decrease as substantially. These results contribute to the existing literature and increase understanding of the physiological demands of indoor sport rock climbing.

3369 Board #57 June 1 9:30 AM - 11:00 AM
Biomechanical Comparison of Court Shoes for Indoor Sports Performance

Jolene Lim¹, Govindasamy Balasekaran, FACSM¹, Dianna Thor¹, Anthony Bert², Davy Lim², Jia Bin Fang². ¹Nanyang Technological University, Singapore, Singapore. ²Institute for Sports Research, Singapore, Singapore.
(No relevant relationships reported)

PURPOSE: To compare biomechanical factors between court shoes for indoor sports performance. **METHODS:** The Mizuno Wave Lightning Z (M_{WL}), ASICS Blade 5 (A_{B5}), Rocket 7 (A_{R7}), and Blast 6 (A_{B6}) court shoes were compared. 12 male Singapore handball players (age: 23.7 ± 5.8 years; height: 1.78 ± 0.056 m; weight: 69.6 ± 9.5 kg; shoe size 10.1 ± 1.0) participated in the randomized, counter-balanced study. Participants performed the vertical jump and Illinois Agility Run Test during each session, for four test sessions. Rate of perceived exertion (RPE), comfort, and fit variables were measured before and after both physical tests. **RESULTS:** No significant differences were found in maximum jump height (M_{WL} : 46.083 ± 3.059 cm, A_{B5} : 46.333 ± 2.774 cm, A_{R7} : 45.083 ± 3.777 cm, A_{B6} : 46.083 ± 3.965 cm; p = 0.341), maximum jump force (M_{WL} : 1.304 ± 0.116 N, A_{B5} : 1.283 ± 0.074 N, A_{R7} : 1.300 ± 0.088 N, A_{B6} : 1.304 ± 0.066 N; p = 0.831), and maximum landing jump force (M_{WL} : 3.212 ± 1.312 N, A_{B5} : 2.836 ± 0.850 N, A_{R7} : 2.986 ± 0.979 N, A_{B6} : 3.164 ± 1.628 N; p = 0.730) during the vertical jump. Significant differences were found between all shoes in the total time taken during the agility run (p = 0.020). A_{B5} resulted in better total time (A_{B5} : 17.493 ± 0.453 s, M_{WL} : 18.052 ± 0.432 s; p = 0.002), Straight run 4th quarter (A_{B5} : 1.575 ± 0.065 s, A_{B6} : 1.619 ± 0.062 s; p = 0.043), and Weave run 1st half (A_{B5} : 1.819 ± 0.096 s, A_{R7} : 1.873 ± 0.039 s; p = 0.019) timings. No significant difference was found in RPE values after vertical jump (M_{WL} : 1.917 ± 1.782, A_{B5} : 1.917 ± 1.443, A_{R7} : 1.833 ± 1.642, A_{B6} : 1.667 ± 1.435; p = 0.769) and agility run (M_{WL} : 6.250 ± 1.658, A_{B5} : 5.917 ± 1.929, A_{R7} : 6.000 ± 1.595, A_{B6} : 6.333 ± 1.826; p = 0.727). No significant differences were found in comfort and fit variables, even though A_{B6} had the highest overall comfort (A_{B6} : 11.867 ± 2.225, M_{WL} : 10.233 ± 2.814, A_{B5} : 11.850 ± 2.650, A_{R7} : 10.525 ± 2.650; p = 0.050) and most consistent fit variables (Shoe length: 4.08 ± 0.5, Heel region: 4.08 ± 0.515, Forefoot width: 3.75 ± 0.753, Collar: 4.08 ± 0.669; p = 0.341). **CONCLUSION:** Participants performed fastest during the agility run when

wearing ASICS Blade 5, although participants found that the ASICS Blast 6 was more comfortable and had the most consistent fit. Future research should focus on improving both shoes to enhance comfort and at the same time improve capacity in sports performance.

3370 Board #58 June 1 9:30 AM - 11:00 AM
Characterization Of The Fitness In The Military Personnel Of The Colombian Army Training Schools.

Daniel F. Aparicio Gomez, Rodrigo Cubides Amezcuita, Laura E. Castro Jimenez, Angelica M. Puentes, Ana I. Garcia Muñoz, Camilo Lozada Gutierrez, Paula Melo Buitrago, Ivan D. Chavarro Castañeda. *Escuela Militar de Cadetes - Ejercito Nacional de Colombia, Bogotá, Colombia.*
Email: danapago@gmail.com
(No relevant relationships reported)

Military personnel must assume demanding physical activities during both tactical and physical training in military installations or theaters of operations. In military operations, high levels of aerobic capacity and muscular strength are required, that is why adequate fitness (aerobic endurance, muscular endurance, strength, flexibility, body composition) is an important factor in the performance and survival. **PURPOSE:** To determine the fitness of the military personnel in training of the different schools of the Colombian Army. **METHODOLOGY:** Cross-sectional study with an analytical component, where morphological and physiological variables were measured in 120 senior Military students in the three military training schools (ESMIC-Officers, EMSUB-NCOs and ESPRO-soldiers). The body composition was evaluated by electrical bioimpedance after checking the pre-test protocol conditions. The explosive strength of the upper and lower limbs was assessed in a jump platform, with the Push-Up and Squat Jump tests without load. The flexibility was assessed by the "Sit and Reach" test, the maximum consumption of VO₂ with the "Léger" test and the prehensile force was evaluated by dynamometry. The comparisons were made using one-way analysis of variances (ANOVA) and post hoc tests. **RESULTS:** The comparison between the fitness of the students of the schools, showed differences in the consumption of VO₂ (49.8 vs 48.3 vs 53.5 ml / min / kg, p = 0.001), flexibility (4.5 vs. 3.2 vs 10 cm, p = 0.001), prehensile strength (44.4 vs 37.1 vs 48.3 kilograms, p = 0.001), flight time in the Squat Jump test (481.6 vs 451.1 vs 482.4 milliseconds, p = 0.001), flight time in the Push Up test (404.6 vs 316.7 vs 375.5 milliseconds, p = 0.001), body mass index (23.5 vs 23.7 vs 22.4 weight / height², p = 0.027) and an absolute value of fat-free mass (56.4 vs 52 vs 56 kg, p = 0.009). **CONCLUSIONS:** Although the training plan of the Colombian Army is standardized, it was found that there are differences in the fitness of personnel in military training, which could be due to the differences in intensity, volume, duration, density and frequency of training. Supported by internal Grant 001-2017 / Technological Support Command, Ejército de Colombia.

3371 Board #59 June 1 9:30 AM - 11:00 AM
A Comparison Of Physiological And Anthropometric Characteristics Among Senior And Young Elite Endurance Athletes

Ferenc Ihász¹, Eliza Tóth¹, Lili Kósa¹, Krisztina Szabó². ¹Eötvös Lóránd University, Budapest, Hungary. ²University of Pécs, Pécs, Hungary. (Sponsor: Kevin J. Finn, FACSM)
(No relevant relationships reported)

Aging is a multi-factorial process. The relative contributions of decreases in maximal heart rate, stroke volume, and oxygen extraction rates as well as changes in body weight and composition to the age-related decline in maximal oxygen uptake (VO₂max) are unclear. **PURPOSE:** The purpose of this study is to compare the differences in body size and cardiorespiratory fitness among young and senior elite endurance athletes. **METHODS:** This study measured anthropometric and physiological data on 29 elite endurance athletes (mountain and road bikers, cross-country runners) made up of 12 young athletes (YA), ages 24±5.9 yrs, and 17 senior athletes (SA) ages 52±3.6 yrs. The Research Ethics Committee of ELTE University approved the study. Laboratory measurement of metabolic parameters was performed using a 2-min progressive treadmill protocol of 8 km×h⁻¹ at 3% grade, 8 km×h⁻¹ at 6% grade, 9 km×h⁻¹ at 6% grade, 10 km×h⁻¹ at 8% grade, 10 km×h⁻¹ at 10% grade, 11 km×h⁻¹ at 12% grade with additional 3% increase in grade per 2-min stage until volitional exhaustion. Anaerobic threshold (AT) was determined using ventilatory equivalents from the Vmax C29 Sensesmics (Yorba Linda, CA, USA) software. **RESULTS:** No significant differences were found between the groups' mean height (YA 178.7 ± 7.3 vs SA 174.5 ± 6.2 cm) and body mass (YA 72.8 ± 7.5 vs SA 75.8 ± 7.7 kg). Young athletes (YA) spent nearly twice as much time on the treadmill (YATST: 895 ± 114 sec.) as their senior counterparts (SATST: 529 ± 170 sec.) and their mean VO₂max was significantly higher (57.62±7.55 vs. 40.46±8.59 mL x kg⁻¹ x min⁻¹). However, only 11% of the YA total power was spent under anaerobic conditions, as compared to 43% for the SA group. The ratio of time spent in the aerobic zone during complete load calculated from the means of the values of ventilation (VE), breathing

rate (BF) and absolute aerobic capacity (VO_{2max}) at the AT and peak load (PE) was 80% for senior athletes (SA) and reached a value of 90% ($p < 0.05$) in the young athletes (YA). **CONCLUSIONS:** The difference between the performances of the two groups is not surprising. However, remarkable is the asymmetry of the metabolic performance of the senior athletes (SA), which may carry other pathological hazards. It is therefore important to pay great attention to the physiological characteristics of the age related performance sport.

3372 Board #60 June 1 9:30 AM - 11:00 AM

A Longitudinal Study of Muscular Fitness in Korean National Firefighters

Hyunjoo Kang¹, Kyoungmin Noh², Wook Song², Chungkun Lee², Seiyong Park², Jungjun Park³, Hanjoon Lee⁴, Dongil Seo⁵, Yeonsoon Ahn⁶. ¹*Soonchunhyang University, Asan, Korea, Republic of.* ²*Seoul National University, Seoul, Korea, Republic of.* ³*Pusan National University, Pusan, Korea, Republic of.* ⁴*Ulsan University, Ulsan, Korea, Republic of.* ⁵*Dongkuk University, Gyeongju, Korea, Republic of.* ⁶*Yonsei University, Wonju, Korea, Republic of.*
Email: violethjk@naver.com
(No relevant relationships reported)

Firefighting is a physically demanding profession that requires optimal muscular fitness levels. Until now, there have been no studies investigating longitudinal changes and characteristics of the muscular fitness of firefighters. **PURPOSE:** To investigate the changes in the results of Korean firefighters' muscular fitness test over 6 years for each gender. **METHODS:** Muscular fitness test data was received from the National Fire Service Academy and represented firefighters working in Seoul from 2011 to 2016. We analyzed the muscular fitness from a total of 30,933 people over a 6-year period. The data was made using ANOVA and multiple regression analysis.

RESULTS: Grip strength shows statistically significant differences between genders (Fmale = 256.808, Ffemale = 10.856, both $p < .001$) every year. Records show that grip strength decreased as age increased ($B = -.345$); records also show that grip strength improved in later years ($B = .717$). The results show that males' grip strength was higher than that of females ($B = 22.295$). Back strength increased each year showing statistically significant improvement for each gender (Fmale = 1061.565, Ffemale = 44.921, both $p < .001$). Records show that back strength decreased as age increased ($B = -1.173$); records also show improvements from year to year ($B = 6.114$). As the years went on, male firefighters saw a bigger improvement than female firefighters ($B = 80.276$). Sit-up records each year show statistically significant differences between genders (Fmale = 515.581, Ffemale = 23.336, both $p < .001$). Sit-up results decreased as firefighters aged ($B = -.395$); sit-ups increased each year ($B = 1.252$). Results among males were higher than among females ($B = 10.948$).

CONCLUSIONS: This study provided basic data on firefighter muscular fitness tests and practical information that can be used to training programs. The characteristics of firefighter's tasks show that female firefighters need to perform their duties under the same conditions as male firefighters. However, results show that female firefighters are not testing as well in those three categories. Female firefighters should be required to carry out some tasks in emergency situations. Supported by the Field-oriented Support of Fire Fighting Technology Research and Development Program funded by NFA (MPSS- Fire safety-2017-87)

3373 Board #61 June 1 9:30 AM - 11:00 AM

Convergent Validity and Relative Reliability of Hexoskin during a Maximal Field Test

Monoem Haddad, Feryel Dalansi, Mariam Kharbach, Azam Mohamed, Zlatan Aganovic. *Qatar University, Doha, Qatar.*
Email: mhaddad@qu.edu.qa
(No relevant relationships reported)

PURPOSE: The aim of the study was to determine the convergent validity and relative reliability of a wearable metric Hexoskin "the smart shirt" during a maximal field test in measuring Heart Rate (HR) variables: resting HR and peak HR.

METHODS: Variables were recorded simultaneously by the Hexoskin and Polar Team Pro 3. Fourteen professional male Handball players (age 21.8 ± 2.4 years) participated in the study voluntarily completed two trials of 400 m shuttle run test (10 shuttles), separated by 48h to 72h.

RESULTS: Nearly perfect ($r=0.93$) and trivial ($r=0.009$) correlations have been shown in resting HR and peak HR, respectively, between Hexoskin and Polar Team Pro 3 results. Good ($ICC=0.715$) and low ($ICC=0.081$) intraclass correlation coefficient measured by Hexoskin.

CONCLUSIONS: The findings indicate that Hexoskin has high validity and relatively good reliability in measuring resting heart rate and it can be used in slow activities/ motions. However, it seems that quick movements affect the cardiac sensor and leads to an abnormal recording using Hexoskin.

3374 Board #62 June 1 9:30 AM - 11:00 AM

Cardiovascular Fitness In Recreational Athletes Prior To And After Anterior Cruciate Ligament Reconstruction

Dean M. Cordingley¹, Sheila McRae¹, Jeff Leiter¹, Greg Stranges², Peter MacDonald². ¹*Pan Am Clinic Foundation, Winnipeg, MB, Canada.* ²*Pan Am Clinic, Winnipeg, MB, Canada.*

(No relevant relationships reported)

Emphasis of most rehabilitation programs following anterior cruciate ligament reconstruction surgery (ACLR) is on range of motion and strength, with little, if any, focus on the recovery of cardiovascular fitness. **PURPOSE:** To evaluate cardiovascular fitness of recreational athletes from injury to 12-months post ACLR. **METHODS:** This was a prospective case series. Patients were recruited from a sports medicine clinic with an ACL rupture confirmed on MRI. Participants must have been involved in aerobic sport at least twice a week based on self-report. Study time points were baseline (as soon after injury as possible; T1), 6 (T2)- and 12-months (T3) post-ACLR. The primary outcome measure was relative VO_{2peak} as measured during a graded aerobic exercise test (GXT) on a bike ergometer (Monark, Ergonomic 894E) using a metabolic measurement system (Oxycon Mobile, Carefusion). Secondary outcomes were absolute VO_{2peak} , Tegner activity score, and ACL-Quality of Life. Repeated measures ANOVA was performed to compare within groups between time points. **RESULTS:** Nineteen patients (13 male /6 female) consented at mean age of 22.9 ± 4.8 years. Baseline testing and surgery were performed 78 ± 48 and 152 ± 81 days post injury, respectively. Preoperative relative VO_{2peak} was 33.7 ± 6.3 mL·kg⁻¹·min⁻¹, at T2 was 32.7 ± 8.9 mL·kg⁻¹·min⁻¹ and at T3 was 32.7 ± 9.3 mL·kg⁻¹·min⁻¹ ($p > 0.05$). Based on ACSM cardiorespiratory fitness classifications by age and gender, there was no change in distribution from T1 to T3 ($p=0.88$). Tegner scores decreased from pre-injury to T1 (7.6 ± 1.5 vs. 3.2 ± 1.9 ; $p < 0.001$), and improved by T3 (5.1 ± 2.1 ; $p=0.003$), but did not recover to pre-injury levels ($p < 0.001$). ACL-QOL increased from T1 (32.9 ± 15.5) to T2 (53.5 ± 13.4 ; $p < 0.001$) and to T3 (70.3 ± 18.7 ; $p=0.008$). Relative VO_{2peak} and Tegner score were not correlated at T1 but were at T3 ($r=0.735$, $p=0.001$). **Conclusion:** Recreational athletes were aerobically deconditioned at two months post-ACLR rupture and did not improve with 12-months of rehabilitation following ACLR. Pre-injury aerobic fitness level could not be determined, but participants may have become deconditioned waiting for surgery. Without a conscious effort to promote aerobic fitness, recreational athletes may return to play at a suboptimal performance level with increased risk of injury.

3375 Board #63 June 1 9:30 AM - 11:00 AM

Effects of a Psyching Up Technique on Maximum Deadlift Ability: A Pilot Study

Barbara N. Sanchez¹, Matthew K. Beeler¹, Carl M. Maresh, FACSM¹, William J. Kraemer, FACSM¹, Brett A. Comstock². ¹*Ohio State University, Columbus, OH.* ²*Bloomsburg University, Bloomsburg, PA.*
Email: sanchez.1094@osu.edu

(No relevant relationships reported)

PURPOSE: Psyching-up techniques for maximal lifting efforts are common practice among recreational and professional athletes. The use of psyching-up techniques have shown positive effects on bench press and handgrip performance, and on more complex actions such as the standing broad jump and sprinting. This has not been examined on the deadlift. The purpose of this study was to investigate the influence of a self-selected psyching up technique on maximum performance deadlift.

METHODS: Five resistance trained men (mean \pm SD: 22.60 ± 1.67 year, 98.76 ± 6.94 kg, 4.7 ± 1.64 years training experience, 2.15 ± 0.42 deadlift strength to weight ratio) consented to participate in the study. The men had a self-reported one repetition maximum deadlift of at least one and a half times their body weight and had training experience using power lifts (power clean, deadlift, squat, or other main power lifts). Subjects were familiarized with the deadlift test protocol and observed for proper form. A cross-over study design was used in which each participant was randomly assigned to either a distraction technique or a self-selected psyching up technique prior to a maximum deadlift effort. The two trials were separated by a minimum of 72 hours. The distraction technique involved the participant having to count backwards from 100 for 100 seconds prior to exerting a maximal deadlift effort. The psyching up technique involved the participant using the self-selected psyching-up technique that they routinely used during their training for 100 seconds prior to exerting a maximal deadlift effort. A dependent t-test was used to analyze the psyching up technique on maximal weight deadlifted.

RESULTS: There was no significant difference ($t(4) = -.512$, $p > .05$) between the self-selected psych-up technique (204.93 ± 48.75 kg) and the distraction technique (205.75 ± 48.92 kg) on maximal deadlift performance.

CONCLUSION: Within the limitations of this study, a self-selected psyching up technique provided no significant advantage on maximal weight lifted in the deadlift exercise compared to a distraction technique in experienced male lifters. Further investigation is recommended using a large sample size.

3376 Board #64 June 1 9:30 AM - 11:00 AM
Effect of Treadmill Protocol on Attainment of VO_{2max} Criteria in Collegiate Women Athletes

Lauren M. Biscardi, Margaret T. Jones, FACSM, Jennifer B. Fields, Justin J. Merrigan, Jason B. White. *George Mason University, Fairfax, VA.* (Sponsor: Margaret T. Jones, FACSM)
 Email: lbiscard@gmu.edu
 (No relevant relationships reported)

When performing the same test protocol, athletes from sports of differing metabolic demands may vary in the achievement of physiological criteria that are indicative of attaining maximal oxygen consumption (VO_{2max}).

PURPOSE: To examine whether the attainment of VO_{2max} criteria differs in two sports with differing metabolic demands as a result of the graded exercise treadmill test (GXT) protocol used.

METHODS: Twenty-nine National Collegiate Athletic Association Division 1 women athletes (basketball (WBB): n=11; lacrosse (WLAX): n=18) completed a continuous GXT to volitional fatigue. Speed increased following each 1-minute stage with a 1% constant grade. VO_{2peak} indicated the highest VO_2 value reached during a single test, while VO_{2max} indicated the subject's functional limit was reached. The criteria to attain VO_{2max} were: VO_2 plateau of <0.15 L/min with an increase in the last two workloads; maximum heart rate (HR_{max}) within 10 bpm of age-predicted heart rate max; respiratory exchange ratio ($RER \geq 1.10$); rating of perceived exertion (RPE, 1-10 scale) >8 ; blood lactate (LAC) collected 5-min post-test ≥ 8 mmol/L. The attainment ≥ 3 of 5 criteria was required for VO_{2max} . Independent t-tests were used for comparison of values between teams, and chi-squared test was used for comparison of criteria attainment. Alpha level was set at $p < 0.05$.

RESULTS: Relative VO_{2peak} values did not differ between teams (WBB: 55.3 ± 8.1 ; WLAX: 53.8 ± 5.4 mL·kg⁻¹·min⁻¹). The percent of athletes that met each of the five criteria were: plateau (WBB: 55%, WLAX: 56%), HR_{max} (WBB: 27%, WLAX: 39%), RER (WBB: 0%, WLAX: 17%), RPE (WBB: 55%, WLAX: 44%), LAC (WBB: 100%, WLAX: 83%). More WLAX attained VO_{2peak} than VO_{2max} (55% vs. 45%). WBB was evenly distributed between VO_{2peak} (50%) and VO_{2max} (50%). There was no statistical difference between WBB and WLAX in VO_{2max} or the number of athletes from each team who met each individual criterion. Significant differences between teams were observed for LAC (WBB 13.3 ± 1.7 , WLAX 10.3 ± 2.3 mmol/L; $p=0.001$) and RER (WBB 0.96 ± 0.05 , WLAX 1.04 ± 0.09 ; $p=0.002$).

CONCLUSION: These findings suggest physiological responses to a fixed VO_{2max} protocol may vary between sport teams of different metabolic demands. Consideration should be given to such variations when selecting test protocols and interpreting results.

3377 Board #65 June 1 9:30 AM - 11:00 AM
Evolution Of Exercise-related Dyspnea In Response To Anxiety-provoking Or Relaxing Situations In Healthy Subjects

Elise Piroux, Sarah Rouas, Jennifer Camel-Toueg, Gilles Caty, Grégory Reyckler. *Institut de Recherche Expérimentale et Clinique, Brussels, Belgium.*
 (No relevant relationships reported)

Exertional dyspnea, characterized as a symptom of discomfort or difficulty in breathing, is a common complaint in healthy individuals and in many pathologies. Previous studies have shown that emotions including anxiety and stress influenced the perceived unpleasantness of dyspnea. **PURPOSE:** The aim of this study was to investigate the effects of relaxing and anxiety-provoking situations on exercise-related dyspnea, heart and respiratory rates, blood pressure, mood state, anxiety and depression in healthy subjects. **METHODS:** Twenty-two healthy adults were included in this randomized cross-over study. Each participant performed three submaximal cycling exercise for 30 minutes on three separate days in a randomized order: a neutral condition (NC) with no particular effect, a relaxing condition (RC) where each subject listened to relaxing music and an anxiety-provoking condition (APC) where a horror movie was broadcast. Heart and respiratory rates, blood pressure, dyspnea using the Multidimensional Dyspnea Profile (MDP) and modified Borg scales, mood state using the Profile of Mood States (POMS), anxiety and depression using the Hospital Anxiety and Depression scale (HADS) were evaluated before and 5 minutes after each intervention. In addition, heart and dyspnea rates were measured throughout the intervention. **RESULTS:** Dyspnea and heart rates increased more with APC than NC (1.68 ± 0.15 vs 1.32 ± 0.12 RPE, $p < 0.01$ and 138 ± 2 vs 119 ± 1 bpm, $p < 0.001$). In addition, submaximal exercise with APC showed a higher increase than NC in the subscales "breathing discomfort" (2.50 ± 0.18 vs 1.86 ± 0.11 , $p = 0.02$) and "emotional response domain" (6.82 ± 1.55 vs 0.95 ± 0.34 , $p < 0.001$) of MDP, global POMS score (11.73 ± 3.58

vs -4.64 ± 2.3 , $p < 0.001$) and HADS-Anxiety subscale (8.59 ± 1.27 vs 3.27 ± 0.61 , $p < 0.001$) and the dyspnea rates (0.64 ± 0.12 vs 0.14 ± 0.07 RPE, $p < 0.001$). No significant difference were observed between NC and RC. **CONCLUSION:** Exercise-related dyspnea and anxiety increased with APC in healthy subjects. In contrast, results did not show difference in any parameters with RC. Many activities and daily life situations can lead the patient with a chronic disease to experience dyspnea. Future studies should investigate strategies to reduce dyspnea in chronic diseases and in fine, improve quality of life of these patients.

Oro-nasal Mask Versus Two-way Non-rebreathing Valves For Maximal Aerobic Capacity Testing In Astronauts

Roxanne E. Buxton¹, Meghan Downs², Richard Scheuring³, Staci Latham², James Crowell⁴, Elizabeth Goetichius¹, Andrew FJ Abercromby³. ¹University of Houston, Houston, TX. ²KBRWyle, Houston, TX. ³National Aeronautics Space Administration, Houston, TX. ⁴MEI Technologies, Houston, TX.
 Email: roxanne.e.buxton@nasa.gov
 (No relevant relationships reported)

INTRODUCTION: Astronauts complete maximal aerobic capacity (VO_{2pk}) testing as part of their annual fitness assessment (AFA) as well as several times once assigned to an International Space Station mission. Historically, the 2-Way T-Shape Non-Rebreathing valve with a mouthpiece and nose clip (mouthpiece) has been used in these tests. The testing procedure was updated to use the oro-nasal mask (mask) for the AFA starting in June 2017. Astronauts who used the mask during their AFA requested it be certified to be used for all mission associated tests. Considering the criticality of the data and the schedule constraints of astronauts, it is imperative that the requested hardware change provide data with equivalent reliability and repeatability as provided by the mouthpiece. **PURPOSE:** To assess the reliability of mask vs. mouthpiece by comparing submaximal and VO_{2pk} data within subjects (approximately 1 year apart). **METHODS:** Each of 17 active astronauts completed a VO_{2pk} test with the mouthpiece (first) and the mask (second) for their AFA. The VO_{2pk} test was conducted on a cycle ergometer with a metabolic cart. The nominal protocol started with a 3 minute warm-up at 50 Watts (W) and increased 25W every minute until volitional fatigue (Light: 45W start; 15W increase). The VO_{2pk} were compared between tests and the expected day-to-day variation ($\pm 5\%$) was used as the threshold for determining agreement between tests. Submaximal values were plotted and evaluated visually for deviations between mask and mouthpiece. **RESULTS:** VO_{2pk} values were more than 5% different, despite similar test times, between mouthpiece and mask in 6 of 17 comparisons, 3 of which were higher with the mask ($9.0 \pm 5.9\%$) while 3 were lower ($-10.8 \pm 2.0\%$) with the mask. The submaximal data did not indicate a leak in either apparatus during these tests. An Astronaut Strength & Conditioning Rehabilitation specialist confirmed that the measured differences in VO_{2pk} of these 6 astronauts was consistent with observed changes in exercise habits during the year that separated the two tests. **CONCLUSION:** After being presented with the results of this data mining effort the mask was accepted for use in all tests, accepting that, if a leak is detected without resolve, the test will be repeated (if schedule allows) and remaining tests will be completed with the mouthpiece.

What Type Of Exercise Is Appropriate For An Optimistic Affective Mind-set?

Yusuke ITAYA¹, Sinji SATO², Cgang Hsiao Yun¹, Shingo OTUKI². ¹Nozaki Tokushukai Hospital, Daito, Japan. ²Osaka Sangyo University, Daito, Japan.
 Email: itaya515@outlook.com
 (No relevant relationships reported)

PURPOSE "Affective mind-set" is a mental frame or lens that selectively organizes. Previous reports proved that activation of the left anterior brain region is linked with the optimistic affective mind-set. Aerobic exercise such as moderate-intensity interval training (MIT) and moderate continuous training (MCT) activates the frontal area of the left hemisphere, which gives euphoric feelings. However, whether interval training is appropriate for stimulating an optimistic affective mind-set is unknown. We hypothesized that interval, rather than continuous, training activates the left brain. This study aimed to evaluate which exercise can activate the left brain more by using three different kinds of bicycle exercise. **METHODS** The participants were six healthy male volunteers. The three bicycle exercises used were MCT, MIT, and high-intensity interval training (HIT). Exercise intensity was considered in the assessment of the peak heart rate (PHR) induced by the cardiopulmonary exercise test. A 70% PHR was defined as moderate intensity; and 90% PHR, as high intensity. The MCT protocol included 3 min of warm-up (WU) and 40 min of moderate-intensity (70% PHR) continuous exercise, 3 min of cooldown (CD), and 10 min of rest. The MIT protocol was composed of a 3-minute WU, 4 term of moderate-intensity (70% PHR) exercise, active rest (45% PHR), 5-min CD, and 10-min rest. The HIT protocol was composed of

a 3-min WU, 4 term of high-intensity (90% PHR) exercise with active rest (70% PHR), 3-min CD, and 10-min rest. Brain activity was measured using electroencephalography (EEG; NegPos, Neuro Sky). EEG was performed during each session. Data were the mean values obtained at WU, CD, and 5-min rest. Δ CD-WU and Δ Rest 5-min WU were calculated. The three groups were compared via one-way analysis of variance, with the Bonferroni test for post hoc comparison. **RESULTS** A slight difference was observed among the three groups in Δ Rest 5-min WU (MIT: 42.0 ± 42.6 , HIT: -19.5 ± 48.6 , MCT: -3.8 ± 14.8 , $p < 0.057$). Δ CD-WU was not significantly different among the groups (MCT: -2.7 ± 15.8 , MIT: 39.1 ± 43.7 , HIT: -16.2 ± 51.1 , $p < 0.11$). WU and CD showed no significance differences among the three groups (WU: $p < 0.25$, CD: $p < 0.51$). **CONCLUSION** MIT is the most appropriate exercise for an optimistic affective mind-set. I have no financial relationships to disclose.

Test-retest Reliability Of An Isokinetic Fatigue Test

Giovanna C. Ramos¹, Tyler J. Neltner¹, Emily E. Grammer¹, Cameron J. Addie¹, Marisa K. Straughn¹, Jordan M. Glenn¹, Michelle Gray¹, Nicole E. Moyer¹, Jennifer L. Vincenzo¹, Kylie K. Harmon², Lee E. Brown, FACSM¹. ¹University of West Florida, Pensacola, FL. ²University of Central Florida, Orlando, FL.

(No relevant relationships reported)

By performing muscular testing, such as an isokinetic fatigue test, it is possible to assess anaerobic capacity and measure how muscles perform when isolated. This might also identify weak points and which movements might be related to compensation. However, test-retest reliability is key to obtaining consistent results of muscular function. **PURPOSE:** To establish isokinetic fatigue test-retest reliability when testing without familiarization. **METHODS:** 22 masters (53±5 years), competitive female cyclists completed 2 separate 50-repetition knee extension tests (T1 and T2) on a Biodex isokinetic dynamometer, separated by one-week with no familiarization. **RESULTS:** Test-retest reliability (intra-class correlation coefficients; ICC), were calculated between T1&T2 scores for fatigue index (T1 38.8±9.5%; T2 43.7±6.9%), time to peak torque (T1 280.5±59.8ms; T2 284.1±69ms) average power (T1 99.0±19.4W; T2 100.5±20.6W), and average peak torque (T1 36.6±6.3N·m; T2 37.5±7.1N·m). ICCs between trials exhibited excellent reliability (.93-.97) for all variables except time to peak torque (ICC=.35) and fatigue index (ICC=.65). **CONCLUSION:** There was strong test-retest reliability for strength and power measurements in masters female cyclists during an isokinetic knee extension fatigue test. However, the test was unreliable for its purpose in determining rate of fatigue. Practitioners should seek other forms of knee extension fatigue measurement.

Forearm Circumference as a Sarcopenic Indicator in Older Mexican Population. A Preliminary Study

Ermilo Canton-Martínez¹, Juan R. Gallegos-Ramírez¹, Iván Rentería¹, Patricia C. García-Suárez¹, José Moncada-Jiménez², Alberto Jiménez-Maldonado¹. ¹Universidad Autónoma de Baja California, Campus Ensenada, Mexico. ²University of Costa Rica, San José, Costa Rica.

Email: jose.moncada@ucr.ac.cr

(No relevant relationships reported)

The 10.5% of the total Mexican population is 60 years and older, and it is expected that by the year 2050, the older adult population reaches 28.7 million inhabitants. The "fragility phenotype in the older adult", characterized by sarcopenia or loss of skeletal muscle mass and dynapenia or loss of muscle strength, affect functional capacity by impairing neuromuscular functions. **PURPOSE:** To determine the association between handgrip muscle strength and anthropometric variables associated with muscle mass in a sample of female Mexican older adults. **METHODS:** Volunteers were 40 healthy women (Age = 61.15 ± 6.1 yr.; Body Mass Index [BMI] = 27.9 ± 7.4 kg/m²) residing in Ensenada, Baja California, Mexico. A hand dynamometer (BioRadio, Great Lakes NeuroTechnologies, Cleveland, OH), was used to measure handgrip strength on the dominant hand. The maximal circumference of the dominant forearm was measured following the protocol by the International Society for the Advancement of Kinanthropometry. Bioelectrical impedance analysis (InBody 770; Cerritos, CA) was used to measure body composition. Appendicular skeletal muscle (ASM) relative to BMI and skeletal muscle index (SMI) relative to height (m²) were analyzed as anthropometric sarcopenic indicators. **RESULTS:** The older adult's mean handgrip strength and forearm circumference were 17.0 ± 3.3 kg and 25.5 ± 2.3 cm, respectively. The ASM relative to BMI was 0.6 ± 0.1 and the SMI relative to height was 6.7 ± 0.8. Handgrip strength was related to arm circumference ($r = 0.56$, $p = 0.0001$, 95% CI = 0.31, 0.75, $R^2 = 0.32$), and SMI relative to height ($r = 0.37$, $p = 0.01$, 95% CI = 0.08, 0.62, $R^2 = 0.14$). The ASM relative to height was unrelated to handgrip strength ($r = 0.12$, $p = 0.45$, 95% CI = -0.20, -0.42, $R^2 = 0.01$). **CONCLUSIONS:** Reduced handgrip strength and SMI were observed in the female participants

compared to international norms. Forearm circumference and SMI relative to height might be considered appropriate assessment measures to explore sarcopenic condition in female Mexican older adults.

3382 Board #70 June 1 9:30 AM - 11:00 AM

Aerobic Fitness And Body Composition Of Individuals With Anterior Cruciate Ligament Reconstruction

Ashley N. Triplett, Christopher M. Kuenze. Michigan State University, East Lansing, MI. (Sponsor: James M. Pivarnik, FACSM)

Email: Triple18@msu.edu

(No relevant relationships reported)

Anterior cruciate ligament reconstruction (ACLR) requires 6 to 9 months of rehabilitation, often resulting in long periods of sedentary behavior. Following rehabilitation, only 45% of patients fully return to pre-injury level of sport participation, placing them at elevated risk of developing a physically inactive lifestyle. It is unknown whether ACLR negatively impacts aerobic fitness and body composition in the months following surgery. **PURPOSE:** To compare body composition and aerobic fitness between women with ACLR and healthy controls. **METHODS:** Nine women with ACLR (<5 yrs post-ACLR, age=21.2±3.9 yrs) and seven healthy women (age=22.4±3.7 yrs) with no injury history completed the Tegner Activity Scale to assess current physical activity level. Body fat percentage (%BF) was estimated using air displacement plethysmography. A graded exercise test using a cycle ergometer was performed by all participants to evaluate aerobic fitness (VO_{2peak}), defined as the highest 20 sec VO_2 attained during the test. Maximal heart rate (HR_{max}) and time to exhaustion (mins) were measured. Variables were compared between groups using Mann-Whitney U tests due to limited sample size. **RESULTS:** Individuals with a history of ACLR had significantly higher %BF than controls (ACLR=33.5±6.5%, healthy=24.4±5.2%) ($p=0.008$) and significantly lower relative VO_{2peak} (ACLR=32.1±5.0 ml/kg/min, healthy=40.6±4.4 ml/kg/min) ($p=0.008$). No differences were observed in absolute VO_{2peak} (ACLR=2.4±0.3 L/min, healthy=2.5±0.3 L/min) ($p=0.61$) or time to exhaustion (ACLR=13.0±1.8 mins, healthy=14.2±2.3 mins) ($p=0.25$) on the cycle. **CONCLUSION:** Women with a history of ACLR may have greater %BF than women who have not experienced a significant lower extremity injury. No significant difference was found in aerobic fitness between the groups as absolute VO_{2peak} is typically evaluated in cycle protocols. Although individuals with ACLR displayed lower relative VO_{2peak} , this was most likely due to differences in body weight between groups rather than fitness. Excessive %BF and low aerobic fitness are risk factors for chronic disease and premature mortality; therefore, it is concerning that these young women returning to activity post-ACLR have poorer body composition profiles than healthy women in this pilot study.

Achievement of Healthy Fitness Zone by Academic Major in College Students from Puerto Rico

Lucia del R. Martínez-Colón¹, Maniliz Segarra¹, Mairym Villalobos¹, Israel Almodovar-Rivera², Maritza J. Ruiz-Nieves¹, Farah A. Ramirez-Marrero, FACSM¹. ¹University of Puerto Rico, Rio Piedras Campus, San Juan, PR. ²University of Puerto Rico, Medical Sciences Campus, San Juan, PR.

Email: lucia.martinez1@upr.edu

(No relevant relationships reported)

Healthy fitness components such as body composition, cardiorespiratory endurance, and muscle strength are associated with disease risk and premature mortality. Factors influencing health related fitness in college-aged students are unclear, and academic major has not been yet considered. **PURPOSE:** To assess and compare the achievement of healthy fitness zone (HFZ) by academic major in college students from Puerto Rico. **METHODS:** College students (331 females, 258 males, 18-25 years of age) enrolled in elective courses at the Physical Education Department of the University of Puerto Rico (PR), completed the Fitnessgram® assessment protocol. Achievement of HFZ was determined for each component: strength-endurance fitness (SEF) with push-up, curl-up, and trunk lift; flexibility fitness (FLF) with back-saver sit and reach, and shoulder stretch; body composition fitness (BCF) with BMI, and %fat; and cardiorespiratory fitness (CRF) with the 20-m PACER test. Students were also classified according to their academic major: teacher education (TE), physical education (PE), natural sciences (NS), business administration (BA), and others (OP) including social sciences, humanities, communication, and general studies. Frequencies and percentages of students achieving the HFZ in each component were determined, and Chi-squares used to detect differences by academic major and sex. **RESULTS:** HFZ for the SEF component was achieved by 68% of participants, FLF by 52%, BCF by 61%, and CRF by 26%. More males than females were in the HFZ for SEF (75 vs. 57%, $P=0.001$), and CRF (41 vs. 12%, $P<0.001$); while more females than males were in the HFZ for BCF (65 vs. 52%, $P=0.001$). More PE majors were in the HFZ in SEF (82% vs 68, 59, 66 and 54% for TE, NS, BA and OP majors, respectively; $P<0.01$) and CRF (48% vs 27, 14, 34 and 19% for TE, NS, BA and OP

major, respectively, $P < 0.001$). No differences were observed by academic major for FLF and BCF. **CONCLUSION:** Although a relatively high proportion of students achieved HFZ criterion in SEF, BCF and FLF; the low proportions achieving CRF, particularly females, is of concern. Results also suggest that academic major must be considered when developing strategies to promote the achievement of HFZ in critical health components such as CRF and SEF among college students in PR. Supported by FIPI/DEGI/UPRRP.

Fitness Fights Fires: Examining the Relationship between Physical Fitness and Firefighting Ability

Annmarie Chizewski¹, Richard Kesler², Allyson G. Box¹, Steven J. Petruzzello, FACSM¹. ¹University of Illinois Urbana-Champaign, Urbana, IL. ²Illinois Fire Service Institute, Champaign, IL. (Sponsor: Steven J. Petruzzello, FACSM)

(No relevant relationships reported)

The physical demands of firefighting are evident, and a high level of physical fitness is required to perform the job safely. Despite the clear need for adequate physical fitness, the majority of firefighters (FF) remain unfit for duty. Regular exercise is an effective strategy to prevent/attenuate multiple health risks, as well as improve health and job performance. **PURPOSE:** To investigate the relationship between physical fitness (i.e., cardiovascular endurance and muscular endurance) and performance on the Academy FF Challenge (AFC). **METHODS:** During the first (week 1) and last (week 7) weeks of the FF academy, FF recruits ($n=54$; 26.76 ± 4.16 yrs; 100% male) physical fitness and FF ability were assessed. Physical fitness was assessed via cardiovascular endurance (estimated $\dot{V}O_{2max}$ via 1.5-mile run time) and muscular endurance (60-second sit-ups and push-ups and Young Men's Christian Association (YMCA) bench press), while FF ability was assessed via total completion time on the AFC (Keiser Sled, Self-Contained Breathing Apparatus maze, victim drag, hose advance, equipment carry, and ladder set-up). **RESULTS:** Physical fitness predicted significant variance in FF ability at Week 1 ($R^2=0.48$; $P < 0.001$) and Week 7 ($R^2=0.47$; $P < 0.001$) after accounting for age and BMI. Specifically, cardiovascular endurance accounted for 28.9% ($FA(3, 50) = 22.83$) and 36.4% ($FA(3, 50) = 28.70$) unique variance, while muscular endurance accounted for 11.4% ($FA(6, 47) = 3.45$) and 10.2% ($FA(6, 47) = 3.02$) unique variance on FF ability at week 1 and 7, respectively. **CONCLUSIONS:** Firefighting is a challenging occupation that requires these individuals to be in peak physical condition. Targeting FFs early in their careers and highlighting the importance of fitness is extremely vital to developing healthy, safe, and efficient FFs. By better understanding the relationship between physical fitness and firefighting ability, exercise specialists, researchers, and physicians may be able to better prescribe exercise in this population.

Developing Criterion-Referenced Standards for Cardiorespiratory Fitness Among Canadian Adults Aged 18-69 Years

Justin J. Lang¹, Emily Wolfe Phillips¹, Heather Orpana¹, Deepa Rao¹, Leonard A. Kaminsky, FACSM², Robert Ross, FACSM³, Grant R. Tomkinson⁴. ¹Public Health Agency of Canada, Ottawa, ON, Canada. ²Ball State University, Muncie, IN. ³Queen's University, Kingston, ON, Canada. ⁴University of North Dakota, Grand Forks, ND. (Sponsor: Dr. Robert Ross, FACSM)

Email: justin.lang@canada.ca

(No relevant relationships reported)

PURPOSE: Cardiorespiratory fitness levels among adults are an important indication of general health. The aim of this project was to develop criterion-referenced standards for estimates of cardiorespiratory fitness in Canadian adults aged 18-69 years using a nationally representative sample, and body mass index (BMI) as the criterion measure. **METHODS:** Cross-sectional data were obtained from cycles 1 (2007-09) and 2 (2009-11) of the Canadian Health Measures Survey. The modified Canadian Aerobic Fitness Test (mCAFT) was used to predict cardiorespiratory fitness (as $\dot{V}O_{2max}$). Measured height and weight were used to calculate BMI. Obesity was classified as having a BMI greater than $30 \text{ kg} \cdot \text{m}^{-2}$. Receiver operating characteristic curves were used to identify cardiorespiratory fitness standards that optimized both sensitivity and 1-specificity (Youden's J) for males and females, separately, across five age groups (i.e., 18-29, 30-39, 40-49, 50-59, and 60-69 years).

RESULTS: A total of 4,967 participants (53% female, $M_{age} = 41.0 \pm 13.8$ years) were retained for the present analyses. The area under the curve ranged from 0.79-0.86 in males, and 0.85-0.92 in females. The optimal standards for cardiorespiratory fitness using BMI as the criterion measure ranged from $13.1\text{-}31.7 \text{ mL} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$ for males, and $16.9\text{-}32.6 \text{ mL} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$ for females. The cardiorespiratory fitness standards were slightly higher for females in comparison with males when matched for age.

CONCLUSIONS: These cardiorespiratory fitness standards may be useful in public health settings, particularly in Canada. Future research should further investigate other criterion measures, and research should validate these cut-points to see if they adequately discriminate individuals with chronic diseases.

Relationship Between Maximal Respiratory Muscle Pressure and Strength and Anthropometric Variables in Healthy Young Adults

Andrea P. González, Francisco J. Pizarro, Oscar Achiardi. Pontificia Universidad Católica de Valparaíso, Valparaíso, Chile.

Email: andreaucm@gmail.com

(No relevant relationships reported)

Traditionally, evaluation and training of respiratory muscle strength (RMSt) have been planned and performed independently of gender. RMSt, measured as maximal inspiratory and expiratory pressures (MIP and MEP, respectively), has been related to musculoskeletal characteristics, such as muscle mass and strength, which might be aspects that influence RMSt development. These musculoskeletal features usually differ among genders, and therefore, it seems plausible that their relationships with RMSt would be different as well, for women and men. This might be an important issue, as assessment and training of RMSt maybe should be planned in accordance of the patient's gender.

PURPOSE: to determine the correlations between RMSt and musculoskeletal characteristics, for women and men.

METHODS: After obtaining informed consent from each participant, 71 young adults (41 men, 30 women, age 21.6 ± 3.5 and 21.7 ± 1.4 years, respectively) with normal BMI, were assessed in RMSt with MIP and MEP, general muscle strength (GMSt) with a back and leg dynamometer, and chest, arm, thigh and leg corrected perimeters (CP), according to the ISAK protocol. Normal distribution of data was confirmed with D'Agostino and Pearson test and Pearson's r coefficient was used to determine correlations between RMSt and GMSt and anthropometric variables. A p value < 0.05 was considered of statistical significance.

RESULTS: In women, the only correlation found was a direct and moderate correlation between PEM and GMSt ($r = -0.46$; $p = 0.01$). As for men, PIM had direct and moderate correlations with GMSt ($r = 0.53$; $p < 0.01$), arm CP ($r = 0.44$; $p < 0.01$), thigh CP ($r = 0.40$; $p < 0.01$) and chest CP ($r = 0.47$; $p < 0.01$), and a direct and weak correlation with leg CP ($r = 0.36$; $p < 0.05$); PEM had a direct and moderate correlation with GMSt ($r = 0.40$; $p < 0.01$).

CONCLUSIONS: According to these findings, gender would be an important aspect to be considered when planning RMSt assessment and training, as musculoskeletal mass and strength in women and men would be related to RMSt in a different manner, and therefore, having different implications in RMSt development.

Health Related Fitness Comparison between 1st Year and 4th-6th Year College Students in Puerto Rico

Emmanuel Hernández-Torres¹, Maniliz Segarra¹, Mairym Villalobos¹, Israel Almodovar-Rivera², Farah A. Ramirez-Marrero, FACSM¹, Lucía del R. Martínez¹. ¹University of Puerto Rico, Rio Piedras Campus, San Juan, Puerto Rico. ²University of Puerto Rico, Medical Sciences Campus, San Juan, Puerto Rico.

Email: emmanuel.hernandez3@upr.edu

(No relevant relationships reported)

First year of college is a critical transition period when young adults begin to make lifestyle choices influencing long-term behaviors and health. Cardiorespiratory fitness (CRF) and body fat (BF) are two health-related fitness (HRF) components known to increase disease risk and premature mortality. These components are also known to negatively change during 1st year in college; however, little is known about changes in all health-related fitness components through college years. **PURPOSE:** To evaluate and compare HRF between 1st year and 4th-6th year college students in Puerto Rico.

METHODS: College students taking elective courses at the Physical Education Department of the University of Puerto Rico, were divided in two groups based on academic year: 1st year (28 females, 48 males; 18.5 ± 1.1 years of age) and 4th-6th year (184 females, 114 males; 21.8 ± 1.0 years of age). HRF was assessed using the Fitnessgram® protocol including measures of height, weight, skinfolds (triceps, calf, and abdomen), push-ups, curl-ups, trunk lift, back saver sit and reach, shoulder stretch, and PACER. Non-parametric Wilcoxon-Rank tests were used to detect differences between groups and between sex, and Chi-square analysis to detect differences by healthy fitness zone (HFZ) classification. **RESULTS:** Compared with 1st year, 4th-6th year students had higher BF (19.6 ± 6.6 vs. $23.5 \pm 6.8\%$, $P < 0.001$), and lower number of curl-ups (45.3 ± 22.8 vs. 32.4 ± 20.9 , $P < 0.001$), push-ups (21.8 ± 11.8 vs. 15.8 ± 12.3 , $P < 0.001$), and $\dot{V}O_{2max}$ estimated from PACER (42.4 ± 8.6 vs. $32.3 \pm 7.5 \text{ mL} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$, $P < 0.001$). No group differences were observed for BMI, trunk lift, and flexibility. A higher proportion of 1st year students classified in the HFZ compared to 4th-6th year in curl-ups (90 vs. 71%, $P = 0.002$) and PACER (49 vs. 16%, $P < 0.001$). A higher proportion of males classified in the HFZ compared with females in push-ups (79 vs. 64%, $P = 0.003$), sit and reach (91 vs. 71%, $P < 0.001$), and PACER (40 vs. 10%, $P < 0.001$); while more females classified in the HFZ in shoulder stretch (84 vs. 65%, $P < 0.001$) and BMI (69 vs. 57%, $P = 0.03$). **CONCLUSION:** Important declines in HRF

components associated with cardiorespiratory and muscle health between 1st and 4th-6th year college students highlights a critical need for interventions promoting healthier lifestyles in this young age group.

3388 Board #76 June 1 9:30 AM - 11:00 AM

Acute Effect of Ischemic Preconditioning on Special Judo Fitness Test

Jefferson Vianna¹, Aline Aparecida de Souza Ribeiro², Jefferson Da Silva Novaes³, Daniel Godoy Martinez¹, Luiz Guilherme Da Silva Telles³, Mateus Camaroti Laterza¹, Leandro Raider², Patrícia Panza¹, Victor Machado Reis⁴. ¹Universidade Federal de Juiz de Fora, Juiz de Fora, Brazil. ²Center of Higher Education of Valença / Dom André Arcoverde Educational Foundation, Brazil, Valença, Brazil. ³Rio de Janeiro Federal University, Brazil, Rio de Janeiro, Brazil. ⁴University of Trás-os-Montes and Alto Douro, Portugal, Portugal.
Email: jefferson.vianna@ufjf.edu.br
(No relevant relationships reported)

Ischemic preconditioning improves the physical fitness of athletes of different sports modalities. However, until now, there is no evidence of the effect of ischemic preconditioning (IPC) on the performance of judo athletes.

PURPOSE: Verify the acute effect of IPC on the Special Judo Fitness Test (SJFT) performed by judo athletes. **METHODS:** The study involved 17 judo athletes (age=21.35 ± 3.46 years, practice experience=8.94 ± 3.88 years, height = 1.73 ± 0.9m, body mass=69.34 ± 10.94kg). In the first session, they answered the questionnaires, underwent the anthropometric evaluation and the familiarization of the SJFT. The SJFT was used to evaluate the athletes' physical fitness. In the second and third sessions, two experimental protocols were performed in a randomized and counterbalanced manner: a) IPC (3 cycles x 5 min ischemia at 220 mmHg / 5 min reperfusion at 0 mmHg) + SJFT and b) SHAM (3 cycles x 5 min ischemia at 20 mmHg / 5 min reperfusion at 0 mmHg) + SJFT. A 30 minute interval between the experimental protocols and the SJFT and 72 hours between the 2nd and 3rd sessions was observed. Statistical tests of variance homogeneity and Student's t test were performed to verify possible differences between the IPC and SHAM groups in the following measures: number of throws in the SJFT per series, total number of throw in the SJFT and SJFT index. The magnitude of the difference between IPC and SHAM conditions was assessed using the effect size (d=Cohen's). **RESULTS:** The IPC performed a larger number of throws in the SJFT per series (p=0.004, d=0.50, moderate effect) compared to SHAM. When we analyzed the total number of throws we found a significant difference between the IPC and SHAM groups (p=0.001, d=0.37, small effect). The SJFT index showed a significant difference between IPC and SHAM (p=0.001, d=0.50, moderate effect). **CONCLUSION:** IPC improves the physical fitness of judo athletes.

Does Dynamic Stretching Warm-up Influence Hockey Players' Anaerobic Performance During A Wingate Anaerobic Test?

Rodrigo Villar¹, Alexander Schleper², Robert Anzalone².
¹University of Manitoba, Winnipeg, MB, Canada. ²Franklin Pierce University, Rindge, NH.
Email: rodrigo.villar@umanitoba.ca
(No relevant relationships reported)

PURPOSE: The aim of this study is to determine whether dynamic stretching warm-up prior the Standard National Hockey League Wingate Anaerobic Test (DSW+SNHL) would improve anaerobic performance compared with the Standard National Hockey League Wingate Anaerobic Test (SNHL) of hockey players. **METHODS:** Twenty volunteer ice hockey players (ten males and ten females) visited the laboratory twice to perform the DSW+SNHL and SNHL in a randomized and counterbalanced order. If participants performed the DSW+SNHL on the first day of testing, then they performed the SNHL on the second day of testing and vice versa. The dynamic stretching warm-up consisted of ten different dynamic movements that lasted ~six minutes and targeted the prime movers and the main joints involved in the skating technique. The Wingate Anaerobic Test was comprised of a thirty-second maximal effort sprint performed on a mechanical cycle ergometer with workload representing 7.5% of the participant's body mass. Peak power output (PPO), relative peak power (RPP), anaerobic capacity (AC), and anaerobic fatigue index (AFI) were calculated and compared between conditions (DSW+SNHL and SNHL). **RESULTS:** Paired T-test or Wilcoxon Signed Rank Test analyses showed that for PPO, there were no statistically significant differences between DSW+SNHL (855.3±168.7 W) and SNHL (831.9±159.1 W) (p=0.105). For RPP and AFI, statistical analyses showed that were marginal trends (p=0.055 and p=0.062, respectively) between DSW+SNHL (RPP=11.8 ± 1.5; AFI=48.9±8.7%) and SNHL (RPP=11.5±1.4; AFI=51.0±9.4%). AC showed statistically significant differences between DSW+SNHL (618.7±117.5 W) and SNHL (585.5±110.0 W) (p=0.0008). **CONCLUSION:** The dynamic stretching warm-up did not improve peak power output, but relative peak power and anaerobic fatigue

index may benefit from dynamic stretching warm-up. However, anaerobic capacity performance improved when dynamic stretching warm-up was performed prior to the standard National Hockey League Wingate Anaerobic Test. **Research supported by New Hampshire-INBRE through an Institutional Development Award (IDeA), P20GM103506, from the National Institute of General Medical Sciences of the NIH".**

Validation of an 8-minute Self-Paced Graded Exercise Testing Protocol to Elicit Maximal Responses

Nicholas M. Beltz, Bo Orton, Nicole Fraser, Dawnell Franklin, Jake Johnson. University of Wisconsin-Eau Claire, Eau Claire, WI.
Email: beltznm@uwec.edu
(No relevant relationships reported)

Recent examinations have turned to the development and validation of a 10-min self-paced graded exercise testing protocol. The 10-min duration was chosen because it represents the mean value of the recommended 8-12min ideal protocol duration; however, literature exists suggesting that an 8min duration may be more appropriate to elicit maximal exercise responses. Furthermore, a gender effect may exist to explain the finding. **PURPOSE:** We sought to examine maximal exercise responses during an 8-min self-paced (8SPV), 10-min self-paced (10SPV) and standardized graded exercise testing (GXT) treadmill protocols. **METHODS:** Sixteen recreationally active males (n=8) and females (n=8) completed three separate tests in a randomized order: a) 8SPV consisting of eight 1-min stages of increasing speed clamped by the Borg RPE₆₋₂₀ scale, b) 10SPV consisting of five 2-min stages clamped of increasing speed clamped by the Borg RPE₆₋₂₀ scale, c) traditional Bruce protocol as the GXT. 8SPV and 10SPV maintained a 3% grade. A two-way (gender x protocol) ANOVA with repeated measures was employed to examine differences in maximal responses between protocols. Paired samples t-tests were used to examine the difference in maximal velocity between 8SPV and 10SPV. **RESULTS:** No gender effects were revealed. Maximal values for 8SPV, 10SPV and GXT were similar (p > 0.05) for oxygen consumption (48.0±5.6; 51.8±10.5; 51.4±7.5 mL•kg⁻¹•min⁻¹), heart rate (193±11; 195±9; 194±13 beats•min⁻¹), respiratory exchange ratio (1.11±0.07; 1.12±0.06; 1.13±0.05), ventilation (103.2±22.4; 113.0±30.3; 112.3±33.0 L•min⁻¹), respectively. Maximal velocity for 8SPV and 10SPV were also similar (15.1±3.1 vs. 14.6±2.7 km•hr⁻¹, p > 0.05). **CONCLUSION:** Given no differences between protocols, 8SPV may serve as a valid and time efficient option to elicit maximal responses during self-paced exercise in recreationally trained college-aged men and women.

Thirty Years Aerobic Power Secular Trend in an Epidemiological Transition Community

Victor K. Matsudo¹, Wesley Dornelas¹, Timoteo L. Araujo¹, José da Silva Guedes², João da Silva Junior¹. ¹CELAFISCS, São Paulo, Brazil. ²Santa Casa, São Paulo, Brazil.
(No relevant relationships reported)

PURPOSE: To analyze the aerobic power in male students in a region with typical epidemiological shift (city of Ilhabela).

METHODS: The study is part of the Mixed-Longitudinal Study on Growth and Development from Ilhabela, organized by CELAFISCS since 1978. Sample consisted of 197 boys, aged from 12 to 14 years-old, divided in 4 groups: 1978 (n=41), 1988 (n=43), 1998 (n=61), and 2008 (n=52). Aerobic power was predicted through a cycle-ergometer submaximal test, that provided VO₂max in absolute and relative values. An ANOVA one way, with a post-hoc Scheffé, was taken to analyze the values. A p < .01 was taken as a significant one.

RESULTS: VO₂max in l/min and ml/kg/min values were, respectively, in 1978: 2.4 l/min and 61.7 ml/kg/min; in 1988: 2.0 l/min and 51.4 ml/kg/min; in 1998: 1.9 l/min and 44.5 ml/kg/min; and in 2008: 1.6 l/min and 33.6 ml/kg/min. It represented a VO₂ max decline of 41% in l/min and of 58.6% in ml/kg/min when 1978 data were compared to 2008. As another sign of aerobic deterioration, an increase of 10 bpm was observed in rest heart rate. In the same period it was observed an increase of 11.4 kg in body weight, and an increase of BMI from 17.1 to 18.1.

CONCLUSIONS: It was observed a marked decline in the aerobic power in absolute and relative values, between 1978 and 2008, suggesting a deterioration in physical activity level in that community.

Physical Activity Characteristics of Recreational Doubles Pickleball
 Benjamin D. Boudreaux, Michael D. Schmidt. *University of Georgia, Athens, GA.* (Sponsor: Robert R. Kraemer, FACSM)
(No relevant relationships reported)

Pickleball is the fastest growing racquet sport in the United States and is particularly popular among older adults. Because the typical frequency, intensity, and duration of play is undefined, the extent to which Pickleball participation can contribute to meeting physical activity guidelines is unknown. **PURPOSE:** To estimate the typical frequency, intensity, and duration of physical activity during recreational pickleball play. **METHODS:** A convenience sample of 25 players (59.0±15.8yrs) wore an Actigraph GT3X+ on their waist and rated their perceived exertion (RPE) for 2 to 5 games of recreational doubles play. Data were collected in 5-sec epochs and the Sasaki (2011) cutpoints were used to calculate the percent of game play spent in light, moderate and vigorous intensity activity. Players also reported their typical pickleball participation (frequency, duration, and subjective exertion level) during the past 3 months via an online survey. **RESULTS:** Players reported playing pickleball 96-240 minutes per session for 2-6 days per week (537.5±381.3 mins/week). On average, 63.5±14.3% of game play was at moderate or higher intensities (47.1±10.3% at moderate) based on Actigraph estimates. This was in general agreement with self-reported intensity levels (11.8±1.3 on RPE scale). Assuming only 50% of reported weekly pickleball participation is spent in actual game play, it is estimated that players typically engage in an average of 162.5 ±140.8mins/week (range: 53.8- 526.2 mins/week) moderate and vigorous intensity activity during play. **CONCLUSIONS:** For most recreational pickleball players, over half of the duration of doubles play is spent at a moderate or higher intensity. This suggests that participation in recreational pickleball may be a viable strategy for increasing health enhancing physical activity in adults. However, the physical activity characteristics of pickleball play should be examined using alternative measures of intensity and in larger, more diverse, samples of players.

Relationship Between Bone Mineral Density & Grip Strength in Collegiate Athletes
 Connor J. Collum, Ron L. Snarr, Greg A. Ryan, Emily L. Langford, Michelle L. Eisenman. *Georgia Southern University, Statesboro, GA.*
(No relevant relationships reported)

Increases in bone mineral density (BMD) and hand-grip strength (HG) are important indicators of repetitive loading and resistance training. While the assessment of BMD is not always feasible, HG may provide an indicator of overall bone health. However, this relationship has yet to be determined in elite athletes. **PURPOSE:** The purpose of this study was to determine the relationship between HG and BMD in male and female NCAA collegiate athletes. **METHODS:** Sixty-nine male and forty-eight female athletes from various sports (e.g., basketball, football, tennis, soccer) agreed to participate in this study. For each athlete, BMD was measured via dual energy x-ray absorptiometry; while HG was assessed with a hand-grip dynamometer. Each participant completed three HG trials for each hand with the elbows flexed at a 90-degree angle. Pearson's product correlations were used to determine the significance of the relationship between BMD and HG measurements. **RESULTS:** Pearson's product correlations demonstrated a moderate-to-strong significant association between BMD and HG for both the dominant ($r=0.75$, $p<0.01$) and non-dominant hand ($r=0.72$, $p<0.01$) in the entire group. For males, BMD displayed a significantly low-to-moderate correlation with both dominant ($r=0.49$, $p<0.01$) and non-dominant ($r=0.46$; $p<0.01$) HG. For females, BMD exhibited a significant moderate correlation between HG in the dominant ($r=0.55$; $p<0.01$) and non-dominant ($r=0.49$; $p<0.01$) hand. **CONCLUSIONS:** Results suggests that repetitive loading, along with increased resistance training, particularly in collegiate athletes may reflect this association between BMD and HG strength. While only HG strength was measured, stronger relationships may exist between BMD and lower body strength, as the athletes tested in the current study engaged in primarily lower-body dominant sports.

Correlation Between Activity-type Heart Rate Estimated Energy Expenditure and Indirect Calorimetry
 Tony P. Nuñez¹, Nicholas M. Beltz², Benjamin C. Thompson, FACSM¹. ¹*Metropolitan State University of Denver, Denver, CO.* ²*University of Wisconsin--Eau Claire, Eau Claire, WI.* (Sponsor: Benjamin C. Thompson, FACSM)
 Email: tnunez1@msudenver.edu
(No relevant relationships reported)

Estimating energy expenditure (EE) during exercise is important for tracking energy balance as well as maintaining EE as an individual becomes more accustomed to exercise. Technological advances have led to the purported ability of heart rate (HR) monitors to accurately estimate EE based on user indicated activity (e.g., resistance training, interval training, etc.). However, the accuracy of these devices using "multi-sport" has yet to be established. **PURPOSE:** To determine the accuracy of user indicated activity HR chest strap monitors for estimating EE. **METHODS:** Fourteen males (n=14) ages 20-36 yrs completed two circuit weight training protocols with integrated high-intensity interval training. Both trials were equated for total volume-load and lasted exactly 43.25 min. Following the exercise portion, each participant completed a 20-min excess post-exercise oxygen consumption measurement. Prior to each exercise protocol the HR monitor watch was set using individual subject anthropometric data and age. Heart rate was continuously monitored during the trials by watch device and portable metabolic analyzer. Comparisons of EE (kcal) were performed between estimations by HR monitor and via indirect calorimetry. Device comparisons for EE were made using paired t-tests, Pearson correlation and Bland-Altman analysis (SPSS v22; $p \leq .05$). **RESULTS:** Estimated EE was significantly higher with the user indicated activity HR monitor chest strap compared to indirect calorimetry (596.9 ±121.2 kcal vs. 484.2 ±44.9 kcal, $p<.001$). Correlational analysis determined there was a significant moderate-strong positive relationship between HR monitor and indirect calorimetry ($r=0.56$, $p=.002$) Average HR during the protocol was 149.7 ±14.3 bpm and percent-maximum HR was 78.5 ±5.9%. **CONCLUSION:** Despite accounting for activity type in the EE estimation software, HR derived estimations of EE appear to be far higher than those estimated by indirect calorimetry during high-intensity activity. Specifically, this is true for vigorous intensity exercise as indicated by %HRmax.

Comparison of Student Administered vs Computerized Test Results in the Wingate Anaerobic Test
 Nathan Hammon¹, Adam Keath¹, Jacob Cooper¹, Jennifer Bossi². ¹*Anderson University, Anderson, SC.* ²*Winthrop University, Rock Hill, SC.* (Sponsor: Janet Wojcik, FACSM)
 Email: nhammon@andersonuniversity.edu
(No relevant relationships reported)

PURPOSE: The Wingate test (WAnT) is an exercise test designed to measure anaerobic capacity and peak power output. WAnT procedures are conducted through observation of the number of revolutions on a stationary bike. The number of counted revolutions is then used to calculate power output at five-second increments for 30 seconds. It is suspected that student counts can introduce error and lack precision particularly in partial revolutions. The purpose of this study was to examine the deviation between student's calculations and computerized measurement. **METHODS:** Undergraduate exercise physiology students (N=28) were selected to conduct the WAnT procedure. Student observations were collected using the Monark 894E ergometer so that computerized power ratings could be collected simultaneously to student counts. Student results were then directly compared to scores from the Monark software. **RESULTS:** A paired samples t-test revealed that student estimates of peak power were significantly lower (M = 676.72 W, SD = 260.09) than computerized testing results (M = 714.78 W, SD =286.04), with a statistically significant mean underestimate of 38.05 W, 95% CI [4.96, 71.14], $t(27) = 2.36$, $p = .026$, $d = .446$. Additionally student fatigue index calculations (M= 43.9%, SD = 9.7%) underestimated power drop compared to the computerized results (M= 53.3%, SD = 14.8%), with a statistically significant mean underestimation of 9.4%, 95% CI [5.38%, 13.42%], $t(27) = 4.80$, $p < .01$, $d = .907$. **CONCLUSIONS:** The WAnT procedure can be an effective tool for measuring anaerobic capacity for both sports performance and research purposes, however, this study found that there were significantly different values between computer derived testing results and human counting. Therefore when a high level of precision is required, it is recommended that WAnTs are conducted using the computerized software to maximize accuracy, especially when being administered by students. In the classroom, exercise physiology instructors should emphasize practice of WAnT administration to ensure more accurate measurements.

Physiological Responses of Arena Polo Players during Simulated Game Play

Abby Pritchard, Samuel Barthel, David Ferguson. *Michigan State University, East Lansing, MI.*
 (No relevant relationships reported)

Arena polo is surging in popularity as compared to outdoor polo due to the reduced space and horse requirement. Limited information exists on the physiological demands of polo with no information for arena players. **PURPOSE:** To document the oxygen consumption (VO₂), ventilation (VE), and respiratory exchange ratio (RER) in conjunction with heart rate (HR) involved in arena polo to better inform players of the physical requirements of participation. **METHODS:** VO₂, VE, RER, and HR were measured in triplicate with random assignment of horses using a portable telemetric oxygen analyzer coupled with a heart rate monitor on a convenient sample of five female arena polo players (Age: 27 ± 6 yr; Weight: 73 ± 13 kg; Height: 177 ± 3 cm). Data were recorded on each player during designated riding sessions which included a prescribed and free choice warmup, mock gameplay (chukker), and five-minute recovery. Descriptive statistics for each variable (Mean ± SE) were calculated for each time period. A one-way ANOVA was performed to determine differences between time periods within a session, and a linear regression was used to determine if horses affected the physiological responses. **RESULTS:** Descriptive statistics are presented in Table 1 showing an increase in VO₂, VE, and HR for free choice and chukker. Horse had no effect (*P* > 0.05) on HR (*r*² = 0.04), VE (*r*² = 0.03), VO₂ (*r*² = 0.06), or RER (*r*² = 0.13). **CONCLUSION:** Arena polo constitutes intense exercise with gameplay that mimics increased physiological demands comparable to traditional sports above warmup and recovery. Horse does not influence physiological responses, indicating that competition intensity is the primary driver of metabolic demand.

Table 1. Mean ± SE of heart rate (HR), ventilation (VE), oxygen consumption (VO₂), and respiratory exchange ratio (RER) of arena polo players during each time period.
^{a,b,c}Values within a column lacking a superscript differ (*P* < 0.001).

| | HR (bpm) | VE (L/min) | VO ₂ (mL/min/kg) | RER |
|--------------------|----------------------|---------------------|-----------------------------|-------------|
| Warmup | 139 ± 1 ^b | 37 ± 1 ^b | 17.4 ± 0.3 ^b | 0.97 ± 0.01 |
| Free Choice | 164 ± 2 ^a | 61 ± 2 ^a | 23.3 ± 0.6 ^a | 0.97 ± 0.02 |
| Chukker | 169 ± 1 ^a | 57 ± 1 ^a | 24.9 ± 0.4 ^a | 0.96 ± 0.01 |
| Recovery | 136 ± 2 ^b | 26 ± 1 ^c | 10.8 ± 0.5 ^c | 0.98 ± 0.01 |

Exploring Upper Quarter Y-Balance Test Biomechanical Strategies in Active College Students

Kevin Masson, Tal Amasay, Alissa Bello, Parry Meredith, Jessica Aquino. *Barry University, Miami, FL.*
 (No relevant relationships reported)

The Upper-Quarter Y-Balance test (UQYBT) is frequently used to assess shoulder function and stability, and core stability. UQYBT consists three reaching tests in push-up position, Superior-Lateral Reach (SR), Inferior-Lateral Reach (IR), and Medial Reach (MR). Several studies identified differences between genders, sports, and pathologies. However, mechanical strategies during the UQYBT were not explored between the reaching tests.

PURPOSE: To identify vertical ground reaction force (Fz) and center of pressure area (CPa) patterns globally between the three reaching tests and moderated by gender, and handedness. **METHODS:** Twenty college students participated, eight females (25±5 yrs; 65±11 kg; 164±5 cm) and 12 males (23±4 yrs; 83±17 kg; 179±7 cm). After 10 min warm up on an arm ergometer, participants performed three trials of UQYBT on a force plate. The highest scores for each test for each arm were collected and further analyzed. The average of the three reach scores, composite score (COMP), were calculated for each arm. All scores were normalized to the right arm's length. Fz was normalized to body weight in push-up position and CPa was calculated for each test. ANOVAs tests were used. **RESULTS:** No differences in force were observed between %MRFz, %IRFz, %SRFz (80±22%, 81±16%, 90±23%, *p*=0.06) and in area between IRCPa, MRCPa, SRCPa (126±159 mm², 123±119 mm², 127±124 mm², *p*>0.05). Females carried less body weight in the plank position (66±3% vs. 71±5%, *p*<0.01) and had a higher score in the UQYBT %IR (89±15% vs. 78±9%, *p*<0.01). No differences were observed in %SR (75±15% vs. 70±12%, *p*>0.05), %MR (97±8% vs. 97±8%, *p*>0.05), and %COMP (87±11% vs. 82±8%, *p*=0.07). The non-dominant arm portrayed higher forces in %MRFz (89±19% vs. 70±21%, *p*<0.01), %IRFz (86±14% vs. 75±17%, *p*<0.05), %SRFz (98±19 vs. 81±24%, *p*<0.05). However, no differences were observed in UQYBT, %IR (82±13% vs. 82±13%, *p*>0.05), %SR (73±13% vs. 71±14%, *p*>0.05), %MR (99±9% vs. 96±8%, *p*>0.05), and %COMP (85±10% vs. 83±9%, *p*>0.05). **CONCLUSION:** Globally, no differences in Fz and CPa patterns were identified in UQYBT. Similar results were found between genders. In contrast,

differences in Fz were identified in the handedness condition, while no differences found in the UQYBT scores, which may be related to compensation mechanism in the non-dominant arm.

3398 Board #86 June 1 9:30 AM - 11:00 AM
The Role of Asymmetrical Strength Deficit on Balance and Fall Risk in a Mature Population.

Glen Reid, John Wygand, FACSM, Robert M. Otto, FACSM, John Petrizzo. *Adelphi University, Garden City, NY.* (Sponsor: Robert M. Otto, FACSM)
 Email: glenreid@mail.adelphi.edu
 (No relevant relationships reported)

The bilateral deficit (BLD) refers to the phenomenon where the sum of force from each leg is individually greater than the force produced of both legs simultaneously. Muscular strength is often measured in one limb and this tends to be stronger in the dominant leg, and the average or sum of strength in both legs is used for analysis. In many individuals, especially older populations, there can be a difference in muscular strength between each leg, which is termed the asymmetrical difference. There is a paucity of information regarding the asymmetrical difference on fall risk. **Purpose:** The purpose was to evaluate single leg strength and asymmetrical deficits relative to balance performance and fall risk in an active elderly population. **Methods:** 7 male and 5 female (Age: 72.3 ± 5.8 yr, Height: 169.7 ± 11.2 cm, Body Mass: 77.2 ± 15.8 kg) volunteered to participate. Subjects were healthy, asymptomatic, ≥ 65 years and participated in exercise an average of twice per week (including resistance and cardiovascular exercise). Leg strength was assessed with a unilateral (UL) 12-RM single-leg (left & right) and a bilateral leg protocol (BL) on a variable resistance leg press machine and balance was assessed with both the Bilateral Comparison Test (BCT) and the Fall-Risk Screening Test (FRST) on the Biodex Balance System. Familiarization trials preceded testing by a minimum of 72 hrs. with balance tests performed first followed by strength tests. **Results:** 5 participants displayed an asymmetrical difference (1.32 ± 1.8 kg), Pearson correlation statistical analysis revealed no significant relationship with overall balance performance (8.26±2.27 composite score, *r* = -0.151, *p* < 0.05) and no significant difference between right UL (1.24±0.36 overall sway, *r* = -0.174, *p* < 0.05) and left UL (1.34±0.60 overall sway, *r* = 0.405, *p* < 0.05). **Conclusion:** This small sample of active seniors failed to provide a significant correlation between an asymmetrical deficit and balance performance. An asymmetrical deficit does not appear to increase the chance of falls in older adults in this cohort. A larger sample size and a comparison to a sedentary population may provide additional insight.

Alpha And Beta Wave Eeg Activity During A Self-paced Vo₂Max Test In Middle-aged Adults

Nicholas J. Hanson¹, Rachel Dykstra¹, Collin Garner¹, Timothy Michael, FACSM¹, Michael Miller¹, Cory Sheadler². ¹Western Michigan University, Kalamazoo, MI. ²Northern Kentucky University, Highland Heights, KY.
 Email: njhanson@gmail.com
 (No relevant relationships reported)

Electroencephalography (EEG) is a non-invasive method of assessing electrical activity of the brain, and can be used during exercise. Previous studies using younger adults have shown a decrease in relative power spectral density (PSD) toward the end of a maximal exercise test, suggesting an inhibitory role of the prefrontal cortex at high intensities. However, this response is not consistent between studies, and unknown in middle-aged individuals. **PURPOSE:** To determine how brain activity changes throughout a self-paced incremental maximal exercise test in middle-aged adults. **METHODS:** This study included ten middle-aged (49.1±3.2 years) recreationally active individuals (3 men, 7 women). A self-paced VO₂max (SPV) test was performed on a cycle ergometer, while subjects wore a wireless EEG electrode strip. This test consisted of five 2-min. stages using prescribed rating of perceived exertion (RPE) levels of 11, 13, 15, 17 and 20 (in that order). A ParvoMedics metabolic cart was used to analyze expired gases. Alpha (8-13 Hz) and beta (13-30 Hz) wave activity in the prefrontal and motor cortices (PFC and MC) were determined via PSD using Welch periodograms. Values were compared to an eyes open resting condition taken prior to exercise. Repeated-measures ANOVAs were used to determine the effect of test stage on EEG activity. **RESULTS:** The mean VO₂max was 37.6±7.2 ml·kg⁻¹·min⁻¹. Relative PSD in both the alpha and beta frequency bands increased with corresponding increases in exercise intensity. In the PFC, there was a significant main effect of test stage in both the alpha and beta frequencies (*p*=.013 and .034) respectively. In the MC, the main effect of time was significant in the alpha (*p*=.033), but not the beta (*p*=.080) frequency. Large increases in relative PSD were seen in the transition from RPE17 to RPE20 (e.g. 7.6±2.0 μV²·Hz⁻¹ to 16.1±4.6 in the MC beta wave analysis). **CONCLUSIONS:** This study suggests that for middle-aged individuals, there is no decline in EEG activity in either the prefrontal or motor cortices during a maximal

exercise test. As a result of increasing RPE levels, there was a concomitant increase in relative PSD. These results also corroborate previous studies showing RPE17 as an important threshold for determining optimal cognitive function during exercise.

3400 Board #88 June 1 9:30 AM - 11:00 AM
Bilateral Weight Distribution Asymmetry in the Functional Movement Screen Deep Squat

Mary C. Hemmer, Louis R. Castro, Eric P. Scibek, Matthew F. Moran. *Sacred Heart University, Fairfield, CT.*

(No relevant relationships reported)

The functional movement screen (FMS) deep squat (DS) is used to identify movement deficiencies and potentially predict injury. While evidence does not support the predictive validity of FMS scores, useful information can still be obtained. Weight shifts are often observed in the FMS DS, but current literature lacks information about asymmetrical weight distribution. **PURPOSE:** To determine the amount of weight distribution asymmetry in physically active young adults during the FMS DS. **METHODS:** Nineteen physically active participants (11 F, 8 M, 20.2 ± 1.0 yo) were recruited and granted informed consent. Participants performed three trials of the FMS DS with feet flat (FF) followed by three trials with elevated heels (EH) elevated on a 2x6 board. Trials were completed on two embedded force plates (1200Hz). Vertical ground reaction force (vGRF) data were used to determine asymmetry in bilateral weight distribution. Six reflective markers placed bilaterally on the greater trochanter, lateral femoral epicondyle and lateral malleolus were tracked with a 10-camera motion analysis system (120Hz). A Matlab script processed the data and computed knee flexion angle and vGRF asymmetry at squat initiation and full squat. Paired samples t-tests with a significance level of 0.05 were used. **RESULTS:** A significant increase ($p < 0.01$) in knee flexion occurred in the EH squat condition (Left 105.9 ± 20.2°, Right 105.8 ± 20.5°) compared to FF (Left 100.8 ± 22.5°, Right 101.0 ± 23.1°). On average, participants experienced >5% asymmetry (0% being perfectly symmetric) for the starting position and full squat position during both FF and EH. There were no significant differences in weight distribution symmetry in the starting position ($p = 0.31$) between squat conditions. The EH condition did not significantly change weight distribution symmetry ($p = 0.69$) in the full squat position. Within squat condition, there was no significant differences between weight distribution symmetry from the starting position to the full squat position (FF: $p = 0.76$, EH: $p = 0.43$). **CONCLUSION:** Bilateral weight distribution asymmetry was present in the FMS DS both with flat and elevated heels in physically active participants. Coaches and trainers should consider implementing training programs to optimize biomechanical function during the FMS DS.

Effect of a Suspension Training Certification Curriculum on Health Related Fitness and Functional Movement

Emily G. Hilliard¹, Megan Jackson¹, Alexander McDaniel¹, Ann T. Shields¹, Rachel E. Williams¹, Ryan Swiezy¹, Courtney K. Milleson¹, Adrian Gonzalez¹, Andrew Ortiz¹, Brad Hollingsworth¹, Sarah Noland¹, Raechel Santee¹, Phillip Morie¹, Lauren Ackerman¹, Emma Schmid¹, Kelsey Bryan¹, Frances M. Livingston¹, Tiago Barreira², Wayland Tsch¹. ¹University of North Carolina Wilmington, Wilmington, NC. ²Syracuse University, Syracuse, NY. (Sponsor: Dr. Robert Boyce, FACSM)

(No relevant relationships reported)

INTRODUCTION: There is limited research on the fitness benefits of certification courses offered in higher education. **PURPOSE:** To identify the fitness and functional movement effects from a 14-week, didactic, active learning suspension training certification course. **METHODS:** Forty-two participants (30 females; 12 males; Age = 25.6 ± 10.0 yrs; Height = 169.4 ± 9.8 cm; Body Mass = 69.7 ± 15.4 kg) in a suspension training curricular course completed 28 applied-learning sessions over a 14-week period. Initial 9 weeks were instructor-led educational lectures, workouts, and critique of techniques, whereas, the latter 5 weeks were student-led exercise programming and workouts for curricular evaluation. Throughout each 40-minute exercise session, six body positions were utilized across push, pull, rotational, squat, and lunge movements. Pre- and post-fitness assessments included body composition, muscular endurance, muscular strength, flexibility, and a functional movement screen (FMS). Dependent t-tests were used to determine if there were mean changes in fitness-related and functional movement status. Due to multiple comparisons, Bonferroni correction was used, therefore, alpha level was set at .007. **RESULTS:** There were no significant changes in mean body mass, fat mass, and lean mass. There were, however, significant positive changes in mean percent body fat (24.0% ± 9.8% to 22.9% ± 10.5%), sit-and-reach (41.5 ± 9.2 to 44.0 ± 7.9 cm), quantity of push-ups (25.9 ± 11.5 to 32.0 ± 13.5), handgrip dynamometer (83.1 ± 29.5 to 90.6 ± 30.5 kg), and FMS (14.9 ± 2.4 to 16.5 ± 2.2) values. **CONCLUSIONS:** Students participating within the 28-session suspension

training curriculum experienced significant decrements in percent body fat and gains in flexibility, upper body muscular endurance, upper body muscular strength, and functional movement screening scores.

Physiological Differences Between Motorized and Non-Motorized Treadmill Running

Mary Stenson. *College of St. Benedict/St. John's University, St. Joseph, MN.*

Email: mcstenson@csbsju.edu

(No relevant relationships reported)

Non-motorized treadmills (NMT) are designed to replicate overground exercise and are used in fitness testing, simulation of team sport exercise, and sprint training. Limited research describes differences in physiological responses between running on a curved NMT and motorized treadmill (MT) at the same speed. **PURPOSE:** Examine physiological differences between running on a NMT and a MT at the same speed and identify at which MT grade the physiological response to running on a MT is similar to a NMT at the same speed. **METHODS:** Ten active females ran at three speeds (2.68, 3.13, and 3.58 m/s) on a curved NMT and a standard MT. Five participants also ran at 3.13 m/s and 4%, 6%, and 8% grades on the MT. $\dot{V}O_2$, blood lactate, heart rate, and rating of perceived exertion were compared between treadmills at each speed and grade using ANOVAs and paired samples *t* tests. **RESULTS:** NMT $\dot{V}O_2$ was significantly greater at 2.68 m/s (40.89 ± 2.13 vs. 35.73 ± 1.92 ml/kg/min; $p < 0.01$) and 3.13 m/s (47.7 ± 4.06 vs. 42.29 ± 2.14 ml/kg/min; $p = 0.004$), but not significantly different from MT at 3.58 m/s (50.30 ± 5.76 vs. 47.64 ± 2.73 ml/kg/min; $p = 0.085$). NMT blood lactate concentration was significantly greater at 3.13 m/s (8.83 ± 2.55 vs. 6.02 ± 2.75 mmol/L; $p < 0.01$) and 3.58 m/s (11.63 ± 2.25 vs. 8.10 ± 2.74 mmol/L; $p < 0.01$). At 3.13 m/s and a MT grade of 8%, $\dot{V}O_2$ ($r = -1.46$, $p = 0.22$) and blood lactate ($r = -2.64$, $p = 0.06$) were not significantly different from NMT at 3.13 m/s. **CONCLUSIONS:** The physiological response to running on a NMT was significantly greater than a MT at submaximal speeds. A greater non-oxidative contribution to running at 3.58 m/s on the NMT is likely due to runner position on the curved belt. Running on a MT at an 8% grade produces similar $\dot{V}O_2$ and blood lactate responses to running on a NMT at the same speed. Practitioners prescribing NMT exercise should consider exercise intensity and effect of the NMT incline.

3403 Board #91 June 1 9:30 AM - 11:00 AM
Functional Assessment of the Upper Limb: Support for Isotonic Measurement Devices

Mercedes K. Steidley, Emily L. Roessel, J. Mark VanNess, Natalie R. Schlenker, William P. Lydon, Sarah R. McDowell, Courtney D. Jensen. *University of the Pacific, Stockton, CA.*

(No relevant relationships reported)

Accurate evaluation of arm strength and function is important to prevent injury, aid rehabilitation, and enhance training. Traditional assessments involve isokinetic devices (e.g., Cybex) to determine post-injury abilities. However, this method is confined to a linear motion and fails to mimic normal isotonic movement patterns. Instruments that measure isotonic motions in three-dimensional space may be more appropriate. **PURPOSE:** Compare upper limb isokinetic force characteristics to those produced in isotonic actions. **METHODS:** 35 healthy college students (12 women, 23 men) performed biceps curls and triceps extensions of the dominant arm on one of two machines: Cybex HUMAC NORM isokinetic dynamometer (N=17) or Proteus (N=18), which measures upper limb motion in three-dimensional space using magnetically-mediated resistance. Subjects performed practice trials to minimize learning effects. After completing testing, we used independent and paired-samples t-tests to compare peak force ratios of biceps and triceps generated by the different testing devices. **RESULTS:** Peak biceps torque on the Cybex was 25.9 ± 8.5 ft-lb; peak triceps torque was 24.3 ± 6.3 ft-lb. On average, it took the biceps approximately 62% longer to reach peak torque than it did the triceps ($p < 0.001$). The isokinetic biceps-triceps strength ratio was 1.07:1 ± 0.22:1. This ratio was different between men and women ($p < 0.001$). Among men, it was 1.28:1 ± 0.16:1. Among women, it was 0.99:1 ± 0.20:1. This ratio was also different when compared to peak power calculated by Proteus ($p = 0.033$). In our sample, isotonic, free-motion testing associated with a higher and more variable biceps-triceps strength ratio: 1.38:1 ± 0.99:1. **CONCLUSION:** Performance prediction models and return-to-play testing batteries have traditionally captured functional profiles through isokinetic testing. Restricting movement to a limited range of isokinetic motion results in an inaccurate depiction of what a patient or an athlete does outside of the clinic. Isotonic resistance permitting three-dimensional assessment may be able to provide a more optimal analysis of upper limb function, which translates more directly to athletic and therapeutic contexts. More research is needed to understand how these values may help personalize training and rehabilitation programs.

Special Fitness Judo Index Test to Evaluate Sports Performance According to the Training Stage In Athletes

Luis Del Valle, Calvin Illescas, FACSM. *Confederacion Deportiva Autonoma De Guatemala, Guatemala, Ciudad, Guatemala.* (Sponsor: Dr. Calvin Illescas, FACSM)
 Email: calvinimd@gmail.com

(No relevant relationships reported)

Through precise training for the athlete we can improve their specific physical condition for each sport discipline, in the same way the tests we perform to see the metabolic changes according to the corresponding pathways to the sport activity must try to be as specific as possible and simulate sports techniques. **PURPOSE:** To analyze with specific judo fitness test, the sports performance according to the training stage in athletes. **METHODS:** Descriptive study, n = 18, 11 males, 7 females of the Judo Senior Team, age 20.4 ± 3.9 years, with a range of 15 to 29 y. The same test was performed three times, every 4 months. The test is performed to assess the sports training in judo. The first and second tests, 11 athletes were evaluated, and in the 3rd test, 16 athletes participated. The fitness index tests are specific, analyze the performance with Judo technique ("Ippon-sevi-nage"), the Index consists of the measurement of the maximum heart rate of effort (MHRE) plus the heart rate at the minute of recovery at the end of the test, in beats per minute, divided by the number of techniques, made from the 1st 15 seconds (s), 10 s recovery, 2nd 30 s, 10 s recovery and 3rd 30 s work, and the heart rate at the minute of recovery. It started at 0900 hrs, with an ambient temperature 20°C, monitoring the heart rate, during rest, warm-up, maximum effort and at one minute of recovery using PolarV800 heart rate monitors. Additional instruments used were writing board, sheets of bond paper, pencil, whistle and a chronometer. The information was tabulated in Microsoft Excel 2016. **RESULTS:** in the 1st test, 11 athletes, men (7), the results were, 4, 36.4% good, 1, 9% very good, 2, 18.2% excellent; women (4), 1, 9% bad and 3, 27.3% regular, in the 2nd test, 11, men (8), 1, 9% bad, 1, 9% regular, 3, 27.3% good and 3, 27.3% excellent; women (3), 1, 9% regular and 2, 18.2% good and in the 3rd, (16), men 10, 2, 12.5% regular, 6, 37.5% good and 2, 12.5% excellent; women 6, very bad 1, 6.3%, 2, 12.5% regular and 3, 18.7% good. **CONCLUSION:** With the special fitness Judo Index test we can track the sports preparation of judo athletes and evaluate their performance specifically with Judo technique ("Ippon-sevi-nage").

Physiological Demands of Hard Shoe and Soft Shoe Irish Dancing: A Pilot Study

Madison P. Trebour, Jo P. Morrison, Laura Q. Jimenez, Tim G. Coffey, Madison M. Cutten. *Longwood University, Farmville, VA.*

Email: madison.trebour@live.longwood.edu

(No relevant relationships reported)

MP. Trebour, MM. Cutten, TG. Coffey, LQ. Jimenez, JP. Morrison. Longwood University, Farmville, VA 23909

Purpose: Irish Step Dance is a form of dance characterized by maintaining an upright posture and primarily moving the lower extremities with two different shoe styles. Soft shoe (SS) dance requires light and delicate movements, while hard shoe (HS) dance requires forceful and powerful movements. Irish dance competition pieces can last 30-60 seconds and performance pieces can last 10 minutes. The purpose of this study was to characterize the cardiorespiratory demands of female recreational Irish dancers. **Methods:** Seven female dancers (35.8 ± 9.6 y; 166.6 ± 7.5 cm; 79.1 ± 13.1 kg) volunteered for HR monitoring during three separate 45 min classes (n=16 measurements). Classes consisted of a mixture of HS and SS dancing. Three female dancers (28.0 ± 13.9 y; 168.7 ± 1.2 cm; 76.5 ± 15.2 kg) volunteered for $\dot{V}O_2$ testing. Dancers completed a three minute reel and treble reel dances while wearing soft and hard shoes. Steady-state data were analyzed from the last 30 sec of the three minute dance test. The order of testing was randomized and the same piece of music was used for all dances. **Results:** The mean HR for a class session was 128 ± 14 bpm (69.7 ± 9.3 %HR_{max}). The mean maximal HR achieved in class was 184 ± 10 bpm (93.9 ± 8.7 %HR_{max}). There was no significant (p<0.05) difference in $\dot{V}O_2$ (HS 23.33 ± 7.51 ml/kg/min; SS 23.57 ± 6.17 ml/kg/min), R-value (HS 1.31 ± 0.05 ; SS 1.31 ± 0.12), HR (HS 184.7 ± 8.7 bpm; SS 185.0 ± 2.0 bpm), or %HR_{max} (HS 96.3 ± 3.2 %HR_{max}; SS 94.5 ± 3.7 %HR_{max}) for HS and SS dance.

Conclusions: The class data suggest that Irish dance classes are a moderate intensity activity with vigorous intensity intervals. Hard shoe and soft shoe Irish dance are physiologically demanding aerobic activities with anaerobic contribution. Despite differences in dance style these data suggest that there is no difference between the metabolic demands of HS and SS Irish dancing.

Elite Orienteering Athletes In Standardized Time-trial And Distance-trial Tests Own Better Physiological And Psychological Indicators On Treadmill

Chia-Chih Lin¹, Guan-Yu Lin². ¹*National Dong Hwa University, Hualien, Taiwan.* ²*National Taiwan Normal University, Taipei, Taiwan.*

Email: cclin@gms.ndhu.edu.tw

(No relevant relationships reported)

Orienteering founded in north Europe is now gradually popular worldwide. However, how to train focus on event specificity has not been established well. **PURPOSE:** The goal of this preliminary study is to explore physiological and psychological characteristics of elite orienteering players. **METHODS:** Ten elite orienteering athletes (OA) (age: 25.4 ± 8.9 yrs; BMI: 20.2 ± 1.7 ; training: 9.2 ± 2.8 hrs/wk; 5 males and 5 females; $\dot{V}O_{2max}$: 48.8 mL/kg/min) and ten elite running athlete (RA) (age: 21.0 ± 1.5 yrs; BMI: 20.8 ± 1.1 ; training: 12.8 ± 2.7 hrs/wk; 5 males and 5 females; $\dot{V}O_{2max}$: 52.7 mL/kg/min) were recruited to attend a time-trial and a distance-trial treadmill tests in counterbalanced order. Athletic performance of participants were at least national level. Both tests were interspersed by 4 segments of mental games (named Peak in Apple Store) representing the capacity of problem solving, memory, concentration, and thinking agility in sequence. While playing mental games, participants kept on running with their effort. Performance indicators and ECG/EEG signals /game scores were analyzed using independent t test and mixed design of repeated measures respectively. Statistical significance was set at $p < .05$.

RESULTS: Better performance of time/distance trials (1084 min vs. 1100 min; 3338 m vs. 3211 m) in OA and most all indicators of OA were better than those of RA in main effect. Results indicated that attention index (55.6 vs. 44.3), game score (10929 vs. 8817) and %HRR (77.3 % vs. 67.6 %) of OA were significantly higher than those of RA during mental games in time-trial test ($p < .05$) in main effect.

CONCLUSIONS: We conclude that elite orienteering athletes own stronger power for mental management while keeping on higher intensity of running. Introducing mental challenges on running may enhance training effect of orienteering.

Accuracy Of The Equations For $\dot{V}O_{2max}$ In Aerobically Trained Women.

Sergio A. García Corzo, Moises Arturo Cabrera Hernandez, Luis Javier Tafur Tascon, Yecid Mina Paz, Carmen Ximena Tejada Rojas, Hugo Hurtado Gutierrez. *Institucion Universitaria Escuela Nacional del Deporte, Cali, Colombia.*

(No relevant relationships reported)

PURPOSE: Evaluate the accuracy of the $\dot{V}O_{2max}$ equations for aerobically trained Colombian women. **METHODS:** Estimated values of $\dot{V}O_{2max}$ of the equations were compared with those of $\dot{V}O_{2max}$ measured in a maximum cycloergometer test (MCT). When examining the constant error (CE), standard error of estimation (SEE), total error (TE), the comparison of means (Student's t-test), the Bonferroni correction was used to adjust the level of significance, Pearson correlation coefficient (r) and Lin's concordance correlation coefficient (CCC). A total of nine female cyclists and three female triathletes were volunteers for this study. **RESULTS:** The athletes were aged 23.7 ± 5.8 years, with weight 54.2 ± 4.8 kg and height 161.1 ± 3.6 cm. They reached a maximum workload power of 262.5 ± 29.8 W and a $\dot{V}O_{2max}$ of 55.5 ± 7.3 mL.kg⁻¹.min⁻¹ (2992.1 ± 327.3 mL.min⁻¹). Table 4 depicts the results of the comparison analyzes for absolute and relative values. Only equations 1 and 5 show CE values significantly different from zero, both for absolute and relative values. There were significant positive correlations between the CE and $\dot{V}O_{2max}$ through the MCT values for equations 2, 5 and 6 in the relative values, and only for equation 5 in the absolute values. CCC rated all the equations with poor concordance.

Table 4. Comparison of absolute and relative values of VO₂max predicted from the equations.

| Equation | VO ₂ max ml.min ⁻¹ (mean ± ED) | CE (media ± DE) | p value | r | SEE (ml. min ⁻¹) | TE (ml. min ⁻¹) |
|----------|--|-----------------------|------------|-------|------------------------------------|-----------------------------------|
| 1 | 3271.3 ± 336.7 | -279.2 (202.1) | .001 | 0.87* | 161.3 | 339.7 |
| 2 | 2879.5 ± 282.6 | 112.7 (203.2) | .081 | 0.85* | 172.4 | 224.8 |
| 3 | 2840.5 ± 305.1 | 151.6 (191.4) | .019 | 0.87* | 161.3 | 237.9 |
| 4 | 2985.1 ± 321.5 | 7.0 (195.1) | .903 | 0.87* | 161.3 | 187.0 |
| 5 | 2125.9 ± 132.0 | 866.2 (368.3) | .000 | 0.27 | 315.1 | 935.3 |
| 6 | 2957.3 ± 301.1 | 34.8 (193.4) | .546 | 0.87* | 161.3 | 188.4 |
| 7 | 3131.4 ± 320.8 | -139.2 (197.5) | .033 | 0.87* | 161.3 | 234.8 |
| | ml.kg ⁻¹ .min ⁻¹ (mean ± ED) | | | | | |
| 1 | 60.6 ± 6.7 | -5.1 (3.6) | .001 | 0.81* | 4.3 | 6.2 |
| 2 | 53.4 ± 5.7 | 2.2 (3.8) | .078 | 0.78* | 4.6 | 4.3 |
| 3 | 52.6 ± 6.1 | 2.9 (3.6) | .019 | 0.81* | 4.3 | 4.5 |
| 4 | 55.3 ± 6.5 | 0.2 (3.6) | .852 | 0.81* | 4.3 | 3.5 |
| 5 | 39.4 ± 2.9 | 16.1 (7.1) | .000 | -0.12 | 7.3 | 17.5 |
| 6 | 54.8 ± 5.9 | 0.7 (3.6) | .500 | 0.81* | 4.3 | 3.6 |
| 7 | 58.0 ± 6.4 | -2.5 (3.6) | .036 | 0.81* | 4.3 | 4.3 |

* = p value < 0.05

CONCLUSION: Equations 3, 4 and 7 meet all the statistical criteria used to evaluate the accuracy of the prediction in this study; however, none of the equations was rated as good concordance, when using the CCC method.

3408 Board #96 June 1 8:00 AM - 9:30 AM The Development and Validation of a Functional Capacity Test for Dancers

Allison M. Seifert¹, Vincent J. Paolone², Elizabeth M. Mullin², Sarah Zehnder². ¹American International College, Springfield, MA. ²Springfield College, Springfield, MA.

(No relevant relationships reported)

A peak functional capacity test that is incremental in nature, varying in intensity, and includes movements familiar to dancers is a necessary and important addition to the dance specific fitness tests in the current literature. **PURPOSE:** To design and validate a peak functional capacity test that is appropriate in time, intensity, and movement specificity to the dancer. **METHODS:** The Seifert Assessment of Functional Capacity for Dancers (SAFD) was developed using previous valid and reliable functional capacity protocols, published research in dance specific fitness tests, and consult with content experts. Final test parameters included 3 min. stages of increasing intensity utilizing both speed and difficulty of movements, continued until exhaustion. Following pilot testing, a survey of content experts supported the validity of the SAFD. Female dancers (N = 13) completed a total of four separate sessions, a familiarization trial of the SAFD, SAFD trial 1, a peak treadmill test, and SAFD trial 2. Each test measured time to exhaustion, peak oxygen consumption (VO₂peak), respiratory exchange ratio (RER), heart rate (HR), blood lactate (BLA-), and rate of perceived exertion (RPE). Tests were terminated upon volitional exhaustion or a total of three cues regarding poor movement quality or inability to keep pace with the metronome. Interclass Correlation Coefficients were used to assess reliability, while validity was analyzed using Pearson Product Moment Correlations. **RESULTS:** Strong correlations (≥.7) were found between time to exhaustion, VO₂peak, HR and RPE between SAFD trials. No significant (p > .05) differences existed in any of the physiological variables between the SAFD trials. Significant (p < .05) relationships were found between time to exhaustion, VO₂peak, HR, BLA-, and RPE between the SAFD and the treadmill test. **CONCLUSION:** The strength of key physiological correlations of time to exhaustion, VO₂peak, HR, and RPE provide strong evidence for the SAFD being both reliable and valid. Although the threshold value for correlation was not met in neither RER nor BLA-, results do present a particularly meaningful set of values to the physiology practitioner and thus, further support the conclusion that the SAFD is both a reliable and valid method of assessing peak functional capacity in the dance population.

3409 Board #97 June 1 8:00 AM - 9:30 AM

Examining the Learning Effect On An Isokinetic Fatigue Test Protocol

Tyler J. Neltner¹, Giovanna C. Ramos¹, Emily E. Grammer¹, Cameron D. Addie¹, Marisa K. Straughn¹, Jordan M. Glenn¹, Michelle Gray¹, Nicole E. Moyer¹, Jennifer L. Vincenzo¹, Kylie K. Harmon², Lee E. Brown, FACSM¹. ¹University of West Florida, Pensacola, FL. ²University of Central Florida, Orlando, FL.

(No relevant relationships reported)

When performing repeated repetitions of a task, the body becomes familiar with the task and can become more efficient. This is known as the learning effect and can alter performance. **PURPOSE:** To examine the learning effect when fatigue testing without familiarization. **METHODS:** 22 masters-aged [53±5 years], competitive female cyclists completed 3 separate 50-repetition knee flexion/extension tests on a Biodex isokinetic dynamometer, separated by one-week with no familiarization. **RESULTS:** No significant differences [Wilks Λ>.05] existed between trials, indicating no learning effect was associated with the tests for any variable: a) peak torque (T1 50.7±10.4 N·m; T2 53.0±11.5 N·m; T3 56.6±11.0 N·m), b) relative peak torque (T1 36.2 ± 6.7 N·m/kg; T2 37.9 ± 7.5 N·m/kg; T3 39.2 ± 7.3 N·m/kg), c) torque generated at 30° (T1 27.1 ± 10.0 N·m; T2 26.4 ± 10.2 N·m; T3 26.6 ± 9.4 N·m), d) torque generated at 0.18 s (T1 45.7 ± 9.0 N·m; T2 47.4 ± 10.1 N·m; T3 50.1 ± 9.0 N·m), e) relative work completed (T1 50.2 ± 9.7 J/kg; T2 50.5 ± 9.0 J/kg; T3 51.5 ± 10.9 J/kg), or f) total work completed (T1 2548.4 ± 524.4 J; T2 2544.8 ± 516.0 J; T3 2615.3 ± 579.3 J). **CONCLUSION:** No learning effect was seen with the isokinetic knee extension/flexion fatigue protocol in masters-aged, female cyclists. Therefore, these findings would suggest that previous experience in isokinetic muscular fatigue testing does not alter subsequent performance.

3410 Board #98 June 1 8:00 AM - 9:30 AM

A Novel Assessment of Baseball Throwing Mechanics

Mason Jiang¹, William P. Lydon¹, Mark J. Vaness¹, Alexis C. King², Courtney D. Jensen¹. ¹University of the Pacific, Stockton, CA. ²University of Illinois Urbana-Champaign, Champaign, IL. Email: m_jiang1@u.pacific.edu

(No relevant relationships reported)

To remain competitive, collegiate athletes constantly seek novel methods of performance enhancement. As technological advancements permit more sophisticated assessments, it is important to appraise their utility. **PURPOSE:** To establish a mechanical profile of baseball throwing and to test which kinematic domains associate with on-field performance. **METHODS:** 18 collegiate baseball players (11 fielders, 7 pitchers) were tested using Proteus (Boston Biomotion, USA), which analyzes isotonic force production concurrently in all 3 planes. Players performed 5 consecutive throw motions against 3lb of magnetic resistance. Proteus software calculated power, velocity, explosiveness (rate of force development), endurance (maintenance of force characteristics), consistency (repeatability of movement), and range of motion (ROM). Across the total sample, these values were used to generate throwing profiles; among the subsample of pitchers, the values were used in linear regressions to predict in-season performance. **RESULTS:** Across all players, power was 118.4 ± 80.0, explosiveness was 82.9 ± 29.4, velocity was 6.0 ± 1.2, endurance was 97.2 ± 5.9, consistency was 86.5 ± 9.1, and ROM was 4.0 ± 0.6. Consistency was inversely related to power (R = -0.639; p = 0.004). Explosiveness was inversely related to endurance (R = -0.879; p < 0.001). Pitchers exhibited patterns for higher power, velocity, and explosiveness, but none reached significance (p > 0.10). ROM differed between groups: the pitchers' ball path traveled 20.6% farther in 3D space (p = 0.007). Controlling for height, it remained 18.5% farther (p = 0.012). Among pitchers, in-season earned run average (ERA) increased with power (R = 0.933; p=0.002) and velocity (R = 0.931; p = 0.002) and decreased with consistency (R = -0.956; p = 0.001). Each additional point of power predicted an increase of 0.2 strikeouts per nine innings (p = 0.025) and a 0.2-point increase in ERA (p = 0.002). Each additional point of consistency, predicted 0.2 fewer strikeouts per nine innings (p = 0.047) and a 0.2-point decrease in ERA (p = 0.001). **CONCLUSIONS:** Novel instruments to assess pitching mechanics enable the generation of new normative data. Preliminary analyses suggest power and explosiveness are inverse to consistency and endurance, and they predict different performances on the field.

3411 Board #99 June 1 8:00 AM - 9:30 AM
Acute Effects of Neuromuscular Electrical Stimulation on Vertical Jump

Yusuf K. Kaire, Andrew Harveson, Dominick Sturz, Levi Garrett. *California Baptist University, Riverside, CA.*
 Email: ykaire@gmail.com
 (No relevant relationships reported)

Yusuf K. Kaire, Andrew Harveson, Dominick Sturz, Levi Garrett
 California Baptist University, CA

Multiple studies have indicated improvements in muscular strength, power, and performance can be made over time using neuromuscular electrical stimulation (NMES). Yet no previous studies have conducted research into the effects of NMES on vertical jump immediately after isometric stimulation to the quadriceps group.

PURPOSE: To determine the acute effects of NMES on vertical jump. **METHODS:** A group of 24 participants were randomly divided into an experimental and a control group. All participants were pretested in the countermovement jump (CMJ) to determine maximum jumping height. Participants in the treatment group were treated with NMES to the quadriceps. Participants in the control group received sham treatment in identical testing conditions. All participants then engaged in a post treatment CMJ test. The difference between pretest and posttest jump scores was computed to determine the effects of treatment.

RESULTS: A paired samples *t*-test showed a statistically significant increase in experimental CMJ scores from pre-test ($M = 28.69$, $SD = 6.87$) to posttest ($M = 30.14$, $SD = 7.42$), $t(11) = 1.796$, $p < .05$. (Figure 1). A statistically significant decrease in control CMJ scores occurred from pre-test ($M = 30.72$, $SD = 6.51$) to posttest ($M = 29.18$, $SD = 6.24$), $t(11) = 1.796$, $p < .05$. The mean increase in experimental CMJ scores was 1.45 with a 95% confidence interval ranging from 26.61 to 33.67. The mean decrease in control CMJ scores was 1.54 with a 95% confidence interval ranging from 26.21 to 32.15. Cohen's *d* (.24) indicated a small effect size. **CONCLUSION:** The acute application of NMES to the quadriceps group lead to significant improvements in vertical performance.

Correlation Analysis Of The Skulpt® And Bodpod®

Alyne L. Williams, Melissa Renee Cook, Ciro Moraes Costa De Castro, Annabell Kennell, Victoria Haller, Alex Seabeck, Alex Springer. *Indiana Wesleyan University, Marion, IN.*
 Email: aly.williams@indwes.edu
 (No relevant relationships reported)

The BodPod® (BP) is a standard, reliable tool for measuring body composition. A new body composition measurement tool called the Skulpt® (SK) was created recently. The SK is a form of bioelectrical impedance analysis that measures at three different sites, tricep, abdomen, and thigh, but little to no research exists examining the validity of this form of measurement. For this reason, this study sought to determine the accuracy of the SK compared to the BP. If the SK is determined to be accurate, the low cost and convenience of the SK would make measuring body composition more accessible and available to the general population. **PURPOSE:** The purpose of this study was to test the accuracy of the SK against the BP when measuring body composition. **METHODS:** This was accomplished by measuring body fat percentage using the BP first and then the SK on 91 participants. Subjects for this study included: female (50) and male (41) subjects. Demographic data of each subject was taken before the assessment as well as height (cm) and weight (kg). The body fat percentage results were analyzed using SPSS software. **RESULTS:** A Spearman's R correlation coefficient was calculated for the relationship between the body fat % measured from the SK and BP. A strong positive correlation was found $R = 0.904$ ($p < 0.000$), indicating a significant direct relationship between the two variables. This suggests that a subject measuring a high % body fat on the BP also measures high on the SK. A paired-samples *t* test was calculated to compare the mean body fat % from the SK to the mean body fat % of the BP. The results conclude there was a statistical significant difference between the BP and SK of $p < 0.000$. An average of 5.55% difference was found between the results of the two measurement tools. The mean body fat % on the BP was 21.824 ($sd = 10.05$). The mean body fat % on the SK was 27.371 ($sd = 8.67$). **CONCLUSION:** Since there was significant difference found between BP and SK, the SK is not a recommended body fat measurement tool in research settings, but is acceptable to use in general population settings. However, the positive correlation shows the SK can differentiate between individuals with high versus low body fat. These findings suggest an individual could use the SK to track changes in body composition, an important factor in a person's overall health and wellness.

Positional Difference in Linear Momentum During Vertical Jump in Division II College Football Players

Marquez R. Norford, Meghan K. Magee, Justine E. Fox, Scott E. Williams, Jonathan M. Kollars, Allison N. McCracken, Brett A. Comstock, Joseph L. Andreacci, FACSM, Kyle S. Beyer. *Bloomsburg University, Bloomsburg, PA.* (Sponsor: Joseph L. Andreacci, FACSM)
 Email: mmm16031@huskies.bloomu.edu
 (No relevant relationships reported)

Linear momentum, the product of body mass and velocity, is the key determinant of the outcome of collisions. In collision-based sports, such as American football, players with the greatest momentum tend to achieve more favorable outcomes during on-field collision, or tackles. Therefore, today's players are constantly seeking to increase mass without sacrificing velocity. However, no study has quantified linear momentum in American football players.

PURPOSE: To examine the positional differences in linear momentum during a vertical jump in Division II college football players.

METHODS: 56 male Division II college football players were assessed for height, body mass, and vertical jump. All players were categorized according to playing position into defensive back (DB), defensive line (DL), running/full back (RB), linebacker (LB), offensive line (OL), tight end (TE), and wide receiver (WR) groups; all other positions were excluded due to insufficient sample. Height and body mass were assessed using a stadiometer and digital scale, respectively. A vertical jump test was performed to determine jump height, which was then used to calculate vertical jump velocity. Vertical jump momentum (VJM) was calculated as the product of body mass and vertical jump velocity. Positional comparisons in VJM were made using one-way ANOVA with LSD post hoc comparisons. Alpha level was set *a priori* to $p \leq 0.05$.

RESULTS: A significant main effect of position was observed for VJM ($p < 0.001$). Post hoc tests revealed that OL (439.6±44.7 Ns) had significantly higher VJM than DB ($p < 0.001$; 317.3±34.4 Ns), RB ($p = 0.001$; 371.7±24.7 Ns), LB ($p = 0.006$; 376±32 Ns), TE ($p = 0.013$; 377.4±51.9 Ns), and WR ($p < 0.001$; 338.6±25.0 Ns), while trending to be greater than DL ($p = 0.089$; 406.9±59.6 Ns). Also, DL had significantly greater VJM than DB ($p < 0.001$) and WR ($p = 0.001$), and trended to be greater than RB ($p = 0.068$). LB ($p = 0.009$), TE ($p = 0.013$), and RB ($p = 0.004$) had significantly greater VJM than DB, but only RB trended to be greater than WR ($p = 0.086$).

CONCLUSIONS: While positional differences in VJM exist in collegiate American football, positions that regularly engage during game play (OL vs DL, WR vs DB, and LB vs RB vs TE) have no statistically significant differences. Therefore, these positions are most likely evenly matched when colliding on the field.

Validity And Reliability Of The Ymca Submaximal Cycle Test Using An Electrically-braked Ergometer

Justin Kidd, Nicholas D. Luden, Michael J. Saunders, FACSM, Christopher J. Womack, FACSM. *James Madison University, Harrisonburg, VA.* (Sponsor: Christopher Womack, FACSM)
 Email: kiddjm@dukes.jmu.edu
 (No relevant relationships reported)

PURPOSE: Electrically-braked ergometers allow a consistent power output regardless of variances in pedaling cadence. The present study sought to test the effect of using an electrically braked ergometer on the validity and reliability of the YMCA submaximal cycle test.

METHODS: 22 male and 13 female subjects (19 - 31 y) completed one maximal treadmill test and four submaximal cycle tests (using the YMCA protocol) to measure and estimate VO_{2max} , respectively. The submaximal trials consisted of two tests performed using a friction-braked ergometer (Monark) and two using an electrically-braked ergometer (Viasprint). All measured and estimated VO_{2max} values were compared using repeated measures ANOVA and post-hoc tests using paired *t*-tests. Paired *t*-tests were also used to determine potential differences between repeated submaximal trials using the same ergometer. Pearson correlation coefficients were used to determine validity and reliability coefficients.

RESULTS: The treadmill VO_{2max} protocol yielded markedly higher ($P < 0.05$) values (50.3 ± 7.7 mL/kg/min) than the YMCA submax protocol using the friction-braked (40.8 ± 5.5 mL/kg/min) and electrically-braked ergometer (38.8 ± 4.5 mL/kg/min). Furthermore, estimated VO_{2max} using the friction-braked ergometer was higher ($P < 0.05$) than that observed using the electrically-braked ergometer. There were similar reliability coefficients for the friction-braked ($R = 0.63$) and electrically-braked ($R = 0.52$) ergometers. Lastly, a moderately strong ($R = 0.74$) relationship was observed between actual VO_{2max} and prediction error ($VO_{2max} - \text{estimated } VO_{2max}$).

CONCLUSIONS: Both Monark and Viasprint ergometers underestimated VO_{2max} in a sample of fit, young individuals. The magnitude of underestimation was greater in individuals with higher VO_{2max} values. Using an electrically-braked ergometer did not improve either validity or reliability of VO_{2max} estimates from the YMCA protocol.

3415 Board #103 June 1 8:00 AM - 9:30 AM

A New Functional Screening Tool For Lower Limb Injury Risk: A Retrospective Cohort Study

Liping Jiang¹, Shimeng Shi², Xiaojian Shi², Zonghan Yang², Gordon Waddington³, Jeremy Witchalls³, Roger Adams⁴, Doa El-Ansary⁵, Jia Han². ¹Tongji University, Shanghai, China. ²Shanghai University of Sport, Shanghai, China. ³University of Canberra, Canberra, Australia. ⁴University of Sydney, Sydney, Australia. ⁵Swinburne University of Technology, Melbourne, Australia.

(No relevant relationships reported)

PURPOSE: The aim of the current study was to develop a new screening instrument for lower limb functional assessment. **METHODS:** Fifty-three athletes (33M,20F; mean age: 19.4 ± 2.5years old) volunteered for the study. Athlete injury history and sport performance level (international, national, regional, recreational) were recorded. A lower limb functional screening tool was developed (the LoLiFST), based on 5 lower limb movements in different modes, planes, directions and at varying intensities. Both legs were assessed in a random order and each athlete was given a technique and a symptom score. Reliability was evaluated. Spearman's correlation was employed to examine the relationship between the measures and the incidence of injury. Receiver operating characteristic (ROC) analysis was employed to assess the instrument's capacity to classify injury status. **RESULTS:** (1) The test-retest reliability was 0.74. The inter-rater reliability was 0.95. (2) Twenty-five of the athletes had a history of low back or lower limb injuries in the past 12 months. (3) Both the technique and symptom scores from the LoLiFST were significantly correlated with the injuries ($\rho=-0.290$, $P=0.035$; $\rho=-0.390$, $P=0.004$), and the two scores were significantly inter-correlated ($\rho=-0.354$, $P=0.009$). (4) When technique or symptom scores alone were included to differentiate between athletes with or without injury, the area under the ROC curve (AUC) scores were 0.668 ($P=0.036$, 95% CI: 0.520-0.815) and 0.722 ($P=0.006$, 95% CI: 0.582-0.862), respectively. With technique and symptom scores combined, the AUC discrimination score was 0.762 ($P=0.001$, 95% CI: 0.634-0.890). When sport performance level was added into the variable set, the AUC discrimination score was 0.834 ($P=0.00$, 95% CI: 0.728-0.939), meaning that 83.4% of cases can be correctly classified as low back or lower limb injured/non-injured using the decision point obtained from applying Youden's index to the ROC curve. **CONCLUSION:** The findings support the use of a functional movement screening tool that includes both technique and reported symptoms, that can be used in combination with sporting performance level to enhance capacity for identifying injuries. Future longitudinal studies are warranted to explore the validity of the LoLiFST in determining low back and lower limb injury risk.

Comparison of Functional Tests of Leg Power in Collegiate Athletes

Spencer Sullivan, Niles Fleet, Peter Brubaker, FACSM.
Wake Forest University, Winston-Salem, NC. (Sponsor: Peter Brubaker, FACSM)

(No relevant relationships reported)

In the field of sports medicine, functional tests, such as the single leg hop for distance (SLHD) and single leg vertical jump (SLVJ), are often used to determine an athlete's return to competition. Many sports medicine facilities, including Wake Forest University (WFU), have invested in pneumatic resistance machines, such as the Keiser Air420 Leg Press, that precisely measure single leg power in Watts. However, little is known regarding the agreement of the data obtained from the functional tests and the Keiser Air420.

PURPOSE: To compare the results of the Keiser leg press to those of the SLHD and SLVJ in WFU athletes. **METHODS:** Data were obtained from 79 (40 males and 39 females) healthy student-athletes at WFU. After a warmup, each subject performed the SLHD and SLVJ (cm) and the Keiser leg press (W/kg) in random order with a 5-minute rest period between each test. The relationship between tests was examined with Pearson Correlation Coefficients. **RESULTS:** The means for the Keiser, SLHD, and SLVJ tests (listed right and left, respectively) were 15.4±3.7 W/kg and 14.9±3.6 W/kg, 170.6±27.8 cm and 172.9±28.0 cm, 36.2±7.4 cm and 36.2±7.8 cm, respectively. The correlations of leg power were statistically significant at an alpha level of 0.01. The SLVJ and Keiser scores (right leg $r=0.82$, left leg $r=0.83$) had a slightly higher correlation than the SLHD and Keiser scores (right leg $r=0.65$, left leg $r=0.70$).

CONCLUSIONS: As suggested by the observed relationships, both the SLHD and SLVJ data correlate significantly with leg peak power results obtained from the Keiser Air420 in healthy, collegiate athletes. Thus, this study suggests low-tech/low-cost functional tests like the SLHD and SLVJ appear to be appropriate for evaluating leg power and return to competition in this population.

Investigation of Optimal Depth Jump Box Height for Reactive Strength Index

Marisa K. Straughn¹, Cameron D. Addie¹, Giovanna C. Ramos¹, Tyler J. Neltner¹, Emily E. Grammer¹, Jeffrey D. Simpson¹, Ludmila Cosio Lima¹, Eric K. Greska², Lee E. Brown, FACSM¹.
¹University of West Florida, Pensacola, FL. ²University of Delaware, Newark, DE.

(No relevant relationships reported)

Reactive strength index (RSI) is used to assess athleticism through use of the stretch-shortening cycle for power and is determined by jump height over ground contact time. RSI is typically assessed utilizing an incremental drop jump test and while it is well-established that plyometric training positively impacts power production, the optimal depth jump box height for RSI remains unknown. **PURPOSE:** To measure RSI between different depth jump starting heights. **METHODS:** 20 college students were recruited for this study (M=13, F=7; age: 22.8±2.7y, height: 175.65±11.81cm, mass: 78.32±13.50kg) and were prepped using reflective markers on their ASIS and PSIS, bilaterally, which allowed for vertical jump height measurements. After a specific warm-up, subjects were instructed to perform three maximal DJs onto a force plate from five different heights: 30cm (DJ30), 45cm (DJ45), 60cm (DJ60), 76cm (DJ76), and 91cm (DJ91). A repeated measures ANOVA revealed no effect of sex but significant differences in RSI between starting heights (DJ30=1.36±0.11; DJ45=1.42±0.12; DJ60=1.35±0.12; DJ76=1.28±0.12; DJ91=1.16±0.11), with DJ45 and DJ60 being greater than DJ30, DJ76, and DJ91. **CONCLUSION:** A parabolic relationship was observed between depth jump box height and RSI, with the optimal depth jump starting heights being 45 and 60 cm. A potential avenue for future research would be to investigate training effects on RSI from various depth jump box starting heights.

The Effects Of Different Local Muscular Endurance Training Protocols In Muscle Activity And Fatigue

CHRISTOS PAIZIS, CAROLE COMETTI, THOMAS DANIC, NICOLAS BABAU, INSERM U1093-CAPS; Centre d'Expertise de la Performance, DIJON, France.

Email: Christos.paizis@u-bourgogne.fr

(No relevant relationships reported)

The present study assessed fatigue and neuromuscular changes after fatiguing submaximal horizontal chest press exercise between different strength trainings of concentric contractions intensities.

PURPOSE: The purpose of this study was to evaluate the effect of strength trainings with higher intensity contractions in EMG activity and fatigue. **METHODS:** Fifteen trained males (24.1±2.9 years old, 181.8±5.8cm, 83.6±9.6kg) performed four different strength trainings protocols in horizontal chest press (HCP) with different intensities of a load % one repetition maximum (RM) with a similar total impulse and similar rest. Strength trainings protocols consisted of: **A)** 3 blocks x (1 repetition (reps) of 95% RM - 1 rep of 90% RM - 3 reps of 80% RM - 5 reps of 70% RM - 8 reps of 60% RM - 8 reps of 50% RM - 12 reps of 45% RM - 15 reps of 30% RM - 12 reps of 20% RM) rest 5 sec between sets et 3 min between blocks; **B)** 2 blocks x (6 x 15 of 50% RM) rest 30 sec between sets et 3 min between blocks; **C)** 3 sets x (3 reps of 90% RM) rest 30 sec between sets and 1 min rest after block and 4 X (15 of 50% RM) rest 20 sec between sets and 1'40" rest after block and 3 X (15 of 50%) rest 20 sec between sets; **D)** 3 blocks x (6 x 10 reps of 50% RM) rest 10 sec between sets and 2'30" after bloc. The maximal voluntary isometric contraction torque (MVIC) was assessed in the HCP exercise before and after exercise. Electromyography (EMG) of the pectoralis major (P), anterior deltoid (AD), and the long head of the triceps brachii (TB) were assessed during the different exercises. **RESULTS:** Similar reductions of the MVIC (1227.5±184 vs 992±196 N; $P<0.01$) were observed after the four strength training protocols. EMG DA activity was greater in protocol C compared to the other protocols (0.956±0.336 vs 0.878±0.347 mV; $P=0.01$). EMG TB activity was greater in protocol C compared to the other protocols (0.534±0.194 vs 0.473±0.249 mV; $P=0.01$). EMG P activity was greater in protocol B and D compared to the A and C (0.343±0.115 vs 0.329±0.170 mV; $P=0.01$). **CONCLUSIONS:** The effect of strength endurance trainings with higher load % RM contractions compared to the others with a lower, affect similarly the loss of performance in the HCP exercise but with greater activity of DA and T muscles.

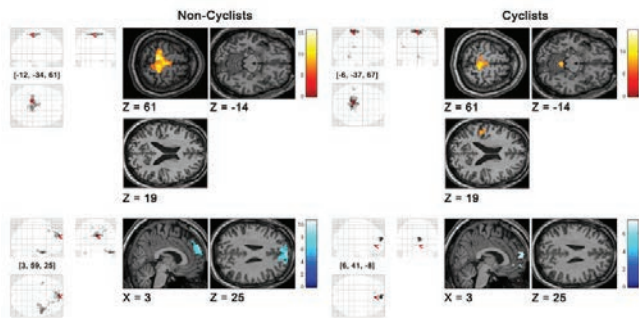

3419 Board #107 June 1 8:00 AM - 9:30 AM

Cyclists' Brain Cycling: An fMRI Study

Eduardo B. Fontes¹, Kell G. Costa¹, Henrique Bortolotti¹, Daniel A. Cabral¹, Andres Vivas¹, Erika Hussey², Nathan Ward², Brunno M. Campos³, Timothy D. Noakes⁴, Li M. Li³. ¹Federal University of Rio Grande do Norte, Natal, Brazil. ²Tufts University, Boston, MA. ³University of Campinas, Campinas, Brazil. ⁴University of Cape Town, Cape Town, South Africa. Email: eduardfontes@gmail.com

(No relevant relationships reported)

Functional and structural changes in the brain have been associated with regular aerobic exercise and expertise in several sports. A variety of neuroimaging techniques have revealed changes in brain activation with increased exercise intensity; however, how expertise modulates neural activation is still unclear for some sports, like cycling. **PURPOSE:** Using an adapted cycling MRI ergometer, we compared the neural patterns of cycling experts and non-cyclists during cycling periods of different intensities. **METHODS:** 22 participants were divided into two groups: 12 healthy adults who performed physical activity 4-6 h/week and 10 trained cyclists (>2 yrs of training and competitive experience, cycling 4-6 days/week for ~60 min). The participants performed an incremental test on an adapted cycling MRI ergometer while whole-brain activity was recorded with functional MRI. Using a one-sample t-test (p<0.05 family-wise error corrected for multiple comparisons), we identified the positive (activation) and negative (inhibition) blood-oxygenation-level-dependent responses associated with all cycling intensities in each group. **RESULTS:** The analysis revealed that both cycling experts and novices activated the precentral gyrus, postcentral gyrus, paracentral lobule and medial frontal gyrus (ts>11.1), while the cerebellum and insular cortex were activated only in cyclists (ts>6.83). In addition, both groups had inhibition of prefrontal cortical areas (ts>7.44) during cycling, but the non-cyclists had larger areas of the prefrontal cortex inhibited (ts>7.52). **CONCLUSION:** Cycling expertise impacts the modulation of subcortical and prefrontal brain areas during cycling. We believe that these findings suggest that regular practice of cycling may enhance the neural regulation of cognitive, motor and homeostatic resources during exercise at different intensities, which may explain the higher performance of cycling athletes.

Comparison of Maximal Aerobic Capacity Between the Treadmill and a Skiing Ergometer

Hannah Nelson, Andy Bosak, Madeline Phillips, Russell Lowell, Branden Ziebell, Moroni de Moors, Anna Blackley, Adriel Lau, Abraham Frech, Abby McCarty. *Liberty University, Lynchburg, VA.* (Sponsor: Dr. James Schoffstall, FACSM)

(No relevant relationships reported)

Cross-country skiing is known to be an extremely aerobically demanding sport. Therefore, the use of a skiing ergometer (ie. SkiErg) to replicate similar aerobic training is increasing in use in lab and fitness settings. The SkiErg is widely used in gyms, research laboratories, and rehabilitation centers, and provides a low impact and total body cardiovascular and muscular endurance workout. Technique for training on the SkiErg can be quickly learned and adapted for immediate use by most individuals. Because of its lower cost and minimal required floor space, this piece of fitness equipment can be used at almost any location for exercise and training. Due to the benefits, convenience, and accessibility, the SkiErg may be a viable alternative max or peak graded exercise test (GXT) mode. To the best of the researchers' knowledge, a comparison of aerobic capacity between a SkiErg and treadmill has not been assessed. **PURPOSE:** To compare treadmill (TM) VO₂max values vs. those elicited from a SkiErg (SE) GXT. **METHODS:** Descriptive data (HT = 176.1 ± 8.2 cm, WT = 80.5 ± 10.1 kg, BF% = 15.1 ± 5.8%, age = 22.7 ± 2.4 yrs) was measured for 21 averagely fit college-age males. In a counterbalanced order and separated by 72 hours

of rest, each subject completed 2 GXT protocols to the point of volitional exhaustion on a TM and SE. Max or peak values for VO₂, HR, VE, and RER were compared between TM and SE using a Paired-Samples t-Test with an alpha level at p ≤ 0.05. Peak RPE was compared using a Wilcoxon Signed Rank Test. **RESULTS:** TM was significantly greater than SE in regard to mean VO₂max (51.1 ± 5.0 vs 44.5 ± 3.8 ml/kg/min, p < 0.01), HR (191 ± 11 vs 186 ± 10 bpm, p < 0.01), and RPE (19.6 ± 2.2 vs 18.3 ± 1.6, p = 0.039). TM was not significantly greater than SE regarding RER (1.2 ± 0.0 vs 1.2 ± 0.1, p = 0.862) or VE (146.2 ± 16.5 vs 144.3 ± 21.5 L/min, p = 0.614). **CONCLUSIONS:** The TM appears to yield higher max values for VO₂, HR, RER, VE, and RPE values compared to SE in college-age males. Although TM elicited higher values than SE, SE VO₂peak was only 15% lower than values measured from TM. This percent difference is comparable to other currently accepted alternative forms of aerobic capacity testing such as leg and arm cycle ergometers. Future studies should assess how gender, protocol variations, SE technique, or various athletic populations may impact VO₂ values during a peak SE GXT.

Short-Term Back Squat Protocol Effect on 5km Run Performance

Matthew Barenie¹, Jordan Domenick², George Schweitzer³, Jason Bennett⁴, Paulina Shetty⁵, Edward Weiss². ¹Indiana University, Bloomington, IN. ²Saint Louis University, St. Louis, MO. ³Washington University, St. Louis, MO. ⁴Carroll University, Waukesha, WI. ⁵Johnson County Community College, Overland Park, KS.

Email: matbaren@iu.edu

(No relevant relationships reported)

Purpose: Previous research indicates conflicting data on concurrent training. For instance, high intensity strength training, an uncommon training method for runners, has the potential to be beneficial as studies show it allows for enhanced fatigue resistance during high intensity endurance performance. Conversely, some evidence suggests high intensity strength training is harmful for endurance running performance and may alter fuel substrate utilization. Therefore, this study sought to determine the effects of a short-term, high repetition back squat training protocol on 5km run performance as well as on carbohydrate and fat oxidation rates. **Methods:** Fifteen runners [4 men, 11 women; 150+ minutes of endurance exercise per week; age = 22 ± 5.1y; 20.4 ± 5.2 body mass index] completed two weeks of a high repetition back squat training protocol consisting of three sets of 15-24 repetitions at 60% of one-repetition max (1RM), three times per week. Pre- and post-tests included a 5km timed run on an outdoor track, respiratory exchange ratio (RER) through indirect calorimetry during two different intensities of steady-state treadmill exercise (60% and 70% heart rate max (HRmax)), and 1RM for back squats. **Results:** Back squat 1RM significantly increased by 15% with training (48.0±27.9 to 56.7±30 kg, P = <0.001). However, no statistically significant differences were found in 5km times adjusted for heat-stress of outdoor conditions (Pre: 21.6±8.3 vs. Post: 21.1±8.0 minutes, P = 0.20), which potentially had a significant confounding effect on post-training outcomes. RER at 60% HRmax (Pre: 0.81±0.04 vs. Post: 0.79±0.05, P = 0.45) and 70% HRmax (Pre: 0.84±0.04 vs. 0.85±0.04, P = 0.85) was unchanged. **Conclusions:** Performing a high repetition back squat protocol for two weeks does not appear to impact 5km running time or alter the body's fuel utilization during exercise but is an effective way to improve lower body strength. Further studies are necessary in a temperature-regulated testing environment to determine whether high repetition strength training alters 5km running performance and fuel utilization.

Proximity To Failure And Repetitions Per Set Effect Rpe Accuracy In The Squat, Bench Press, And Deadlift

Nicholas M. Sautter¹, Colby A. Sousa¹, Daniel J. Belcher¹, Joseph P. Carzoli¹, Trevor K. Johnson¹, Rebecca M. Cerminaro¹, Eric R. Helms², Chun-Jung Huang, FACSM¹, Michael Whitehurst, FACSM¹, Michael C. Zourdos¹. ¹Florida Atlantic University, Boca Raton, FL. ²Auckland University of Technology, Auckland, New Zealand.

Email: mzourdos@fau.edu

(No relevant relationships reported)

The repetitions in reserve (RIR)-based rating of perceived exertion (RPE) scale has gained significant popularity. Previous data has shown that intra-set RIR predictions become more accurate closer to failure. However, research has yet to examine this concept in the deadlift. **PURPOSE:** This investigation examined proximity to failure and total repetitions per set on intra-set RPE accuracy. **METHODS:** Ten males (age: 25.0±4.0yrs, body mass: 84.1±14.3kg, training age: 6.9±4.0yrs) performed 4 sets to failure at 80% of one-repetition maximum (1RM) on the squat, bench press, and deadlift in successive weeks; in a counterbalanced order. During all sets, subjects indicated when they believed to be at a 6 and 9RPE (i.e. 4 and 1RIR). The RIR difference (RIRDIFF) was calculated by subtracting the predicted number of

repetitions from the actual number of repetitions performed. Thus, if 10 repetitions were performed, but a 9RPE was called after 7 repetitions (predicting 8 repetitions), then the RIRDIFF would have equaled 2 (i.e. $RIRDIFF = 10 - 8$). The RIRDIFF at the called 6 and 9RPE was analyzed with a paired t-test and Pearson's correlations were used to assess the relationship between repetitions per set and RIRDIFF; significance was set at $p \leq 0.05$. **RESULTS:** The RIRDIFF across all sets of all exercises and within each individual exercise was significantly lower ($p < 0.01$) at the called 9 vs. 6RPE. Across all squat sets the RIRDIFF at 6RPE was 1.00 ± 1.13 vs. 0.67 ± 0.69 at the called 9RPE ($p = 0.04$, effect size- $ES = 0.35$). Bench press RIRDIFF across all sets was 0.84 ± 0.81 at the called 6 vs. 0.51 ± 0.58 at the called 9RPE ($p < 0.01$, $ES = 0.46$). Additionally, deadlift had an RIRDIFF of 1.12 ± 1.05 at the called 6RPE vs. an RIRDIFF of 0.56 ± 0.70 at the called 9RPE ($p < 0.01$, $ES = 0.62$). Total repetitions performed per set were significantly related to a higher RIRDIFF (i.e. more inaccurate RPE ratings) on squat at 6RPE ($r = 0.47$, $p < 0.01$), and bench at 6RPE ($r = 0.50$, $p < 0.01$) and bench at 9RPE ($r = 0.60$, $p < 0.01$). There was no relationship between repetitions performed and RIRDIFF at the squat called 9RPE or either called RPE on the deadlift ($p > 0.05$). **CONCLUSIONS:** These results suggest that intra-set RPE ratings are more accurate closer to failure on all three exercises and that more repetitions per set may lead to more inaccurate RIR predictions on the squat and bench press.

Standardization of the Technique for a Medicine Ball Throw Test

Mark G. Cullum, Kenneth R. Turley, FACSM. *Harding University, Searcy, AR.* (Sponsor: Kenneth R. Turley, FACSM)
 Email: mcullum@harding.edu
 (No relevant relationships reported)

Muscular power is an essential component of numerous activities. Maximal throws are sometimes used to assess upper body power, but the angle of the throw, which could make an impact on the distance achieved, is typically either controlled with complicated methods or not controlled at all in the existing literature

PURPOSE: Establish consistent and simple procedures to control the effort of a medicine ball throw protocol and establish the reliability and norms for the test. **METHODS:** 124 males and 96 females sat on the floor with their back against a wall, knees bent, and feet flat on the ground. On the adjoining wall a sheet of paper displayed lines at a 45 degree angle. After a technician aligned the subject's outstretched arms with the lines on the sheet, subjects were told to find a point of reference that they were pointing at with their hands. They then held a 6-pound medicine ball at their sternum and were instructed to launch the ball directly at the spot selected. Hand chalk was applied to the ball to indicate the landing spot. After three light practice throws subjects performed a maximal effort three times, with the distance from the wall to the nearest point of the landing spot determined. On a separate occasion 38 subjects completed the protocol a second time to establish test-retest reliability.

RESULTS: Subjects found the process for launching the ball at the proper angle simple to follow. Paired T-test revealed no significant difference between the best throw and the average of the two best throws ($p < 0.01$). Interclass correlation revealed a high test-retest reliability for the procedure ($r = 0.98$). Maximal throw distance showed moderate to good correlation with both height ($r = 0.72$) and weight ($r = 0.63$). The median distance for males was 223.4 inches, with 25th and 75th percentile values of 199.6 and 245.4 inches, respectively. The median distance for females was 143.1 inches, with 25th and 75th percentile values of 128.4 and 154.6 inches, respectively. Relative to height and weight, males and females had median values of 3.22 and 2.21 inches per inch of height, respectively, and median values of 1.27 and 0.99 inches per pound, respectively.

CONCLUSIONS: The protocol demonstrates high reliability and provides a simple mechanism to assist subjects in achieving the desired angle of launch.

Effects of an Acute Strength and Conditioning Training Session on Dual Energy X-ray Absorptiometry Results

Sean T. Stanelle, Jason R. Lytle, Steven E. Martin, John S. Green, FACSM, Stephen F. Crouse, FACSM. *Texas A&M University, College Station, TX.* (Sponsor: Stephen F. Crouse, FACSM)

(No relevant relationships reported)

In the use of dual x-ray absorptiometry (DXA) scans to obtain reliable measures of body composition, athletic staff must be aware of acute factors that may alter scan estimates, such as hydration status. **PURPOSE:** The purpose of this study was to determine if a strength and conditioning (S&C) training session, based upon what athletes regularly engage in, will alter body composition estimates (lean mass, fat mass, and bone mineral content) of a DXA scan. **METHODS:** The S&C session lasted ~ 90 minutes and consisted of upper and lower body resistance exercises and interval running. Twenty-two strength-trained subjects (15 men, 7 women, age 24 ± 2 yrs, height 174.2 ± 8.5 cm, weight 83.5 ± 15.0 kg) volunteered to participate in the study.

Each subject completed two standard DXA scans on the same day, before and after the S&C session. Following the consumption of a free-living meal prior to the first scan, subjects avoided all food intake until completing the second scan. Throughout the S&C session, subjects were encouraged to drink water ad libitum. **RESULTS:** The results of this study were analyzed via correlated t-test ($p < 0.05$ considered significant) and significant values are listed in Table 1 below. **CONCLUSION:** The acute physiological effects of a S&C session alter body composition measures obtained by DXA scan. Thus, athletic staff should consider the timing of DXA scans in relation to S&C sessions.

TABLE 1.

| | Total mass (kg) | Arms tissue mass (% fat) | Arms total mass (kg) | Arms lean mass (kg) | Legs tissue mass (% fat) | Legs lean mass (kg) | Trunk lean mass (kg) |

Effects Of A Short-term Core Stability Exercise On Functional Movement And Balance

Jiyeon Kim, Joungbo Ko, Jongil Lim, Hyejung Choi, Kyoungho Seo, Sukho Lee. *TEXAS A&M- San Antonio, San Antonio, TX.*
 (No relevant relationships reported)

Recently, the importance of maintaining the alignment of the human muscles and managing the left and right symmetry has been widely recognized in fields that study pain medicine, physical therapy and exercise rehabilitation. As a result, core stability exercise has been spotlighting. **PURPOSE:** To investigate the effects of a short-term core stability exercise on functional movement and balance in subjects with mild lower-limb discomfort. **METHODS:** Twenty people with mild lower-limb discomfort were randomly assigned to a non-training control (CG, $n = 10$) and core stability exercise training group (EG, $n = 10$). While CG maintained their daily routine, EG completed twenty 30-min training sessions consisted of 10 modified mat pilates program exercises aimed at increasing core stability. Functional movement, dynamic balance, and discomfort level were assessed before and after twenty sessions of core stability training using functional movement test, balance test and visual analog scale (VAS), respectively. Two-way (group by time) repeated measures ANOVA's were performed for all dependent variables, and the significance for all statistical tests was set at $p < .05$. **RESULTS:** EG demonstrated a significant increase in functional movement indicated by increased hurdle step (CG; -4.7 vs. EG; 25%, $p = 0.024$, group \times time effect) and shoulder mobility (CG; -13.04 vs. EG; 5%, $p = 0.037$, group \times time effect). The dynamic balance score was significantly improved only in EG for both limbs (right: EG = 7.7%, $p = 0.007$; left: EG = 8.10%, $p = 0.011$, time effect). A significant reduction of VAS score in ankle was exhibited in EG (EG; -74.76%, $p = 0.024$, time effect). **CONCLUSION:** This study highlights that twenty sessions of short-term core stability exercise can positively affect the lower limb's functional movement and balance ability in people with mild lower-limb discomfort.

3426 Board #114 June 1 8:00 AM - 9:30 AM
Validity And Reliability Of The Computrainer® During 40 km And 100 km Time-trials

David Jeker, Eric DB Goulet, Jonathan Gosselin, Jean M. Drouet, Jeff Béliveau. *University of Sherbrooke, Sherbrooke, QC, Canada.*

Email: david.jeker@usherbrooke.ca

(No relevant relationships reported)

The ecological validity of findings can substantially be improved when laboratory-based research studies use experimental designs attempting to emulate real-world exercise conditions. The exercise science literature contains ample of research that looked at the impact of various interventions using running and cycling time-trial (TT) protocols. Regarding cycling TT performances, the Computrainer® (CT), an electromagnetically brake bike trainer applying resistance to the rear wheel of a standard bike, has been extensively used for over a decade. Yet, it is unknown whether the CT provides valid and reliable power output data under TT conditions. **PURPOSE:** Determine the validity and reliability of two CTs during 40 km and 100 km TTs. **METHODS:** Power output data of two CT Lab® were compared against those of a calibration rig (Drouet, J.M. et al. Sports Eng. 2008. 15-22.) connected to left side of the crank axle of a road bike with a driving shaft, allowing direct measurement of the true workloads generated by both CTs. The measurement process consisted of comparing the power delivered by the calibration rig to the power displayed by the CTs. Power uncertainty delivered by the calibration rig is $\pm 0.9\%$. Each TT was performed under standardized conditions on two occasions with both CTs®. TTs were completed on a flat course and designed upon previously published results in elite/highly-trained cyclists. **RESULTS:** Mean power outputs generated by the two CTs for the 40 km and 100 km TTs were respectively of 359 ± 38 and 282 ± 56 watts. Mean biases between the CT 1 and the rig for the 40 km TTs varied from -0.8 to -0.7%, and between the CT 2 and the rig for the same distance from -2.7 to 3.6%. For the 100 km TTs, biases between the CT 1 and the rig ranged from -1.4 to -0.4%, whereas for the

CT 2 from -5.9 to -3.4%. For repeated trials, biases within 40 and 100 km TTs for CT 1 were < 1% whereas, for CT 2, bias was also < 1% for the 40 km TTs, but reached 2.5% for the 100 km TTs. **CONCLUSIONS:** Our results indicate that accuracy differs between CTs during 40 and 100 km TTs, suggesting that CTs should not be used interchangeably. Both CTs were shown to provide repeatable data for the 40 km TTs. Whereas for one CT this was also the case for the 100 km TT, for the other CT it was observed that the rig had to produce less torque on one of the two trials to keep the power output generated by CT constant.

3427 Board #115 June 1 8:00 AM - 9:30 AM
Exercise and Non-Exercise Methods for Determining
Cardiorespiratory Fitness

Kelley Phillips, Elizabeth Yost, Amelia Wagenknecht, Sarah Heesacker. *University of Minnesota Duluth, Duluth, MN.*
 (Sponsor: Charles Fountaine, FACSM)
 (No relevant relationships reported)

Cardiorespiratory fitness (CRF) is a criterion measure expressed as maximal volume of oxygen consumption per unit of time (VO_{2max}). The criterion measure is closely related to functional capacity of the heart. Functional capacity of the heart has direct ties to risks associated with cardiovascular disease and cardiac mortality. CRF is traditionally measured using exercise protocols. Exercise protocols can be contraindicated for clinical high-risk populations. Instances where exercise tests are contraindicated, prediction equations have been useful to estimate CRF. **PURPOSE:** The purpose of this study was to determine the validity between a treadmill exercise test and a prediction equation to determine CRF level.

METHODS: Participants (N=25) were collegiate level students who were recreationally active and met physical activity standards. CRF was assessed using two methods, a Bruce treadmill test (BTT) and the World Fitness Level (WFL) prediction equation. The prediction equation used to estimate VO_{2max} uses age, body mass index (BMI), resting heart rate (RHR), physical activity index (PA-I) and is specific to gender. Women: $70.77 - (0.244 \cdot \text{age}) - (0.749 \cdot \text{BMI}) - (0.107 \cdot \text{RHR}) + (0.213 \cdot \text{PAI})$
 Men: $92.05 - (0.327 \cdot \text{age}) - (0.933 \cdot \text{BMI}) - (0.167 \cdot \text{RHR}) + (0.257 \cdot \text{PA-I})$. Participants completed the BTT on a separate day as the WFL questionnaire. Participants were asked to complete the BTT to volitional fatigue. Heart rate, blood pressure, and VO_{2max} were recorded. Pearson product-moment correlations, mean average percentage error (MAPE), and 95% limits of agreement were performed to assess validity.

RESULTS: The correlation between the treadmill test and questionnaire was moderate ($r = 0.75$, $r^2 = 0.56$), whereas the observed MAPE values were large (18%). The 95% limits of agreement for the mean difference between the treadmill test and questionnaire were poor (-18.94 mL · kg⁻¹ · min⁻¹ to 10.99 mL · kg⁻¹ · min⁻¹).

CONCLUSIONS: The results would suggest the WFL prediction equation is not a valid predictor for CRF. It is important to consider that the PA-I is subjective and may not accurately represent the true physical activity levels of the participants in this study.

The Relative Intensity of Split Squat Exercise
Performed on Stable vs Unstable Surfaces

Abigail LeBlanc, John Wygand, FACSM, John Petrizzo, Michele Aquino, Abigail LeBlanc. *Adelphi University, Garden City, NY.*
 (Sponsor: Robert M. Otto, FACSM)
 Email: abigailleblanc@mail.adelphi.edu
 (No relevant relationships reported)

The intensity of exercise may vary relative to the stability of the surface the exercise is performed on. There is limited data in regards to suspension training and whether it can modify the intensity of a resistance training session. Motor unit activation can be inferred through surface electromyography, therefore the recorded activity can translate to the relative intensity of a specific exercise. **Purpose:** The purpose of this study is to determine the magnitude of motor unit activation while performing a split squat on a stable surface (SS), and on an unstable surface (US) (suspension cables). **Methods:** 18 subjects (age 19 ± 3.7 y/o, height 166.7 ± 20.1 cm, weight 71.4 ± 11.0 kg, 9 ♀) volunteered to participate in a randomized cross over study. EMG electrodes were placed on four primary muscles (bicep femoris [BF], gluteus maximus [GM], rectus abdominis [RA], rectus femoris [RF]) involved in the split squat. Each participant was familiarized with the correct biomechanical movement of the split squat. All trials required the rear foot elevated 40.6 cm above the floor. Both SS and US trials were conducted with no external load present and required the subject to perform 5 correct repetitions at a 3-1-3 cadence. **Results:** EMG peak millivolts for the RF was 1.41 ± 0.27 & 1.45 ± 0.53, BF was 0.77 ± 0.52 & 0.22 ± 0.35, GM was 0.75 ± 0.28 & 0.96 ± 0.48, and RA was 0.19 ± 0.21 & 0.22 ± 0.11 for SS and US, respectively. Paired T test revealed a significant difference (p<.05) only for the GM trials. **Conclusion:** Although suspension training may create a new challenge while exercising, increased motor unit activation on the unstable surface may be limited to select muscles. Unstable surface training does not appear to increase the overall muscle activation for this given activity.

Reliability of Single Limb Squat and Lateral Step Down
Assessment in Novice and Expert Clinicians

Esther Kim¹, Richard A. Brindle², Clare E. Milner, FACSM¹.
¹Drexel University, Philadelphia, PA. ²High Point University, High Point, NC. (Sponsor: Clare Milner, FACSM)
 (No relevant relationships reported)

The single limb squat (SLS) and lateral step down (LSD) are common lower extremity tests used to assess gross lower extremity strength and motor control. **PURPOSE:** To compare intra-rater reliability of lower extremity tests between novice and expert clinicians between sessions. **METHODS:** Six licensed physical therapists (3 "novice" and 3 "expert") rated 20 frontal plane video recordings of healthy adults who participated in a previous study performing the SLS and LSD. The sample size required to find a kappa of at least 0.50 with a 95% confidence interval of ±0.40 was estimated to be 18. Novice physical therapists were operationally defined as those within 3 years of initial licensure. Expert physical therapists were licensed for at least 10 years and held a board certification in either orthopedics or sports. Prior to data collection, clinicians practiced rating the SLS and LSD on a separate set of recordings. Kappa statistics were calculated based on previous reported formula and interpreted using a standard index. If bias or prevalence indices were above 0.5, the prevalence-adjusted bias-adjusted kappa (PABAK) was calculated. **RESULTS:** For the SLS, intra-rater reliability of all raters, except one, had moderate reliability or better. For the LSD, most raters had substantial reliability except for two raters, one novice and one expert, who had fair and moderate reliability, respectively. **CONCLUSIONS:** Our findings suggest using the SLS to assess lower limb strength and control given its higher reliability in novice and experts. The SLS rating was based on knee movement, while LSD was based on trunk, arm, pelvis, knee, and foot. The higher reliability on SLS than LSD may be due to evaluating only one component rather than several simultaneously.

Table 1: Intra-rater reliability of single leg squat and lateral step down test performance by novice and expert raters; kappa (95% confidence interval)

| | Novice Clinicians | | | Expert Clinicians | | |
|---------------------------|----------------------|-------------------------|-------------------------|----------------------|-------------------------|--------------------------|
| | 1 | 2 | 3 | 4 | 5 | 6 |
| Single Leg Squat (κ) | 0.71 (0.40 -1) | 0.79 (0.52 -1) | 0.60 (0.25- 0.95) | 0.89 (0.69 -1) | 0.49 (0.10- 0.88) | 0.90 (0.71 -1) |
| Lateral Step Down (PABAK) | 0.70 (0.39 -1) | 0.50 (0.12- 0.88) | 0.70 (0.39 -1) | 0.70 (0.39 -1) | 0.70 (0.39 -1) | 0.30 (-0.12- 0.72) |

κ = unadjusted kappa; PABAK = prevalence-adjusted bias-adjusted kappa

3430 Board #118 June 1 8:00 AM - 9:30 AM
Correlation Of Functional Movement Screen (FMS) And
Mobility, Activation, Posture, And Symmetry (MAPS)
Among Older Adults

Christina M. Pierle¹, Nathan Futrell², Ann T. Shields¹, Haley O. Norris¹, Bailey E. Hester¹, Tiago V. Barreira³, Wayland Tseh¹.
¹University of North Carolina Wilmington, Wilmington, NC.
²Liberty Senior Living Management Services, Wilmington, NC.
³Syracuse University, Syracuse, NY. (Sponsor: Dr. Robert Boyce, FACSM)
 (No relevant relationships reported)

PURPOSES: 1) To determine the relationship between Functional Movement Screen (FMS) and Mobility, Activation, Posture, Symmetry (MAPS) within an older adult population, 2) to identify the number of "declined attempts" among the 7 FMS tests, and 3) to determine if there was a relationship between the FMS Deep Squat test scores and MAPS scores. **METHODS:** Informed consent was received from 97 volunteers between the ages of 69-95 years of age (65 females; 32 males; Age = 81.9 ± 5.8 yrs; Height = 165.9 ± 10.4 cm; Body Mass = 74.2 ± 15.0 kg) who were asked to complete the FMS and MAPS. Spearman correlation was run to determine the relationship between FMS and MAPS. The frequency of "declined attempts" was quantified for each of the 7 FMS tests. One-Way ANOVA was used to investigate the relationship between FMS Deep Squat and MAPS scores due to the categorical nature of the Deep Squat scores. **RESULTS:** Data revealed a significant but low-to-moderate correlation between FMS and MAPS (r=0.46). On average, there were 7 "declined attempts" per FMS test. Hurdle Step and Active Straight Leg Raise had the lowest "declined attempts" with 0, whereas Trunk Stability Push Up had the highest "declined attempts" with 17. One-Way ANOVA results showed a significant difference between groups (p < .001). Participants that scored a 2 on the Deep Squat had higher average MAPS scores compared to participants that scored 0 or 1 (p < .001). Participants that scored 1 on the Deep Squat had higher average MAPS scores than participants who scored 0 (p = .011). **CONCLUSIONS:** Of the 97 participants, as many as 18% declined

to attempt at least one of the 7 FMS tests, whereas all participants completed the MAPS assessment. A higher score on the FMS Deep Squat was related to a higher score on MAPS; however, given the 21% common variance, FMS and MAPS are not interchangeable. From a practical perspective, one cannot replace the other when assessing movement in older adults.

3431 Board #119 June 1 8:00 AM - 9:30 AM
Impact of Short Cranks on 3-Min All-Out Cycling Test and Critical Power Metrics

Boe M. Burrus¹, Jessie Armendariz², Brian M. Moscicki³.
¹Gonzaga University, Spokane, WA. ²Humboldt State University, Arcata, CA. ³Indiana University, Bloomington, IN. (Sponsor: Dr. Vincent Paolone, FACSM)
 Email: burrus@gonzaga.edu
 (No relevant relationships reported)

The 3-minute all-out cycling test (3MT) is a valid, practical, and time effective method for determining Critical Power (CP) and intensities used in training and competition for cyclists. Changing the crank length (CL) on a bicycle may affect an individual's ability to produce and/or maintain power output while cycling. A change in CP due to CL differences would lead to a change in the ability of the cyclist to maintain power output. **PURPOSE:** To determine the impact of short crank arms on the metrics of the 3MT. **METHODS:** A total of 9 recreationally trained male cyclists (27.6 ± 7.5 yrs.) participated in the study. Subjects completed an incremental cycle test to determine $\dot{V}O_{2peak}$ (57.4 ± 6.4 ml/kg/min; 366 ± 47 W) and gas exchange threshold (276 ± 59 W) to calculate the resistance for the 3MT. Session two consisted of a familiarization trial of the 3MT. For sessions three and four, subjects completed the 3MT using CLs of 145 (short crank, SC) and 175mm (normal crank, NC). CL was determined in a randomized counterbalanced format. T-tests were utilized to determine differences between outcome variables of the 3MT. **RESULTS:** Peak power and peak cadence were significantly higher in the SC trial compared to the NC trial (SC 531 ± 116 vs NC 496 ± 113 W, $p = 0.00$; SC 168.9 ± 9.2 vs NC 157.6 ± 8.9 RPM, $p = 0.00$). The mean cadence over the last 30 sec of the 3MT did not differ between CLs (SC 93.4 ± 13.9 vs NC 93.0 ± 13.0 RPM, $p = 0.79$), but the average pedal speed over the same 30 sec was significantly slower in the SC trial compared to the NC trial (SC 1.41 ± 0.21 vs NC 1.70 ± 0.23 m/s, $p = 0.00$). CP (SC 287 ± 41 vs NC 287 ± 46 W, $p = 0.97$) and work above end power (WEP) (SC 12.2 ± 4.0 vs NC 11.4 ± 3.4 kJ, $p = 0.08$) were not significantly different between CL trials. **CONCLUSION:** CP was not different in the current study and demonstrated that changing CL by as much 30mm may not be a major factor in maintaining submaximal power output when position on the bike is maintained between CLs. However, individual differences among the subjects reveal changing CL could affect CP by up to 20 watts; some individuals performed better with 175mm while others performed better with 145mm. Cyclists should begin testing CLs to determine if a CL outside of the typically prescribed norms of within 2.5mm of 172.5mm could possibly benefit their performance and comfort while cycling.

3432 Board #120 June 1 8:00 AM - 9:30 AM
Correlation Of Functional Movement Screen (FMS) And Mobility, Activation, Posture, Symmetry (MAPS) Among College Students

Annie G. Shirk, Michel J.H. Heijnen, Ann T. Shields, Minda Harvey, Cody Leviner, Sarah Noland, Jeremy Grissett, Brad Hollingsworth, Cameron Fitch, Brianna Auer, Emma Baer, Cassandra Berger, Victoria Grande, Laurel K. Koontz, Cassidy J. Smith, Morgan Sanderson, Brittni Moskus, Rebecca Edwards, Jeffrey Welch, Kennedie Pate, Sierra McCoy, Sarah Cox, Michaela Tran, Claire Campbell, Wayland Tseh. *University of North Carolina Wilmington, Wilmington, NC.* (Sponsor: Dr. Robert Boyce, FACSM)
 (No relevant relationships reported)

INTRODUCTION: Despite the growing popularity of functional assessment and corrective exercise prescription, there is limited research evaluating the correlation between two functional movement assessments: the Functional Movement Screen (FMS) and the Movement, Activation, Posture and Symmetry (MAPS). FMS is a commonly-used tool that takes approximately 20-25 minutes for a trained technician to subjectively score participants on 7 movements. MAPS is a novel assessment tool that takes about 45-60 seconds for a computer-based system to objectively score participants completing 1 movement. **PURPOSE:** To evaluate the relationship between FMS and MAPS among an apparently healthy, young adult population. **METHODS:** Two hundred and nineteen participants (140 Females; 79 Males; Age = 19.5 ± 1.7 yrs; Height = 169.4 ± 10.1 cm; Body Mass = 68.5 ± 15.5 kg) completed FMS and MAPS within a single testing session. Pearson's correlation coefficients were used to determine the relationship between FMS and MAPS, as well as FMS and the four individual MAPS components. **RESULTS:** A weak correlation was observed between FMS and MAPS ($r = 0.25$, $p < 0.001$). Furthermore, all individual MAPS components demonstrated a negligible to weak relationship with FMS ($r = 0.29$,

0.11, 0.12, and 0.06 for Mobility, Activation, Posture, and Symmetry, respectively). **CONCLUSION:** These findings suggest that FMS and MAPS are relatively independent of one another. From an applied perspective, one cannot replace the other in terms of evaluation. Future research will have to examine the value of MAPS as a tool to monitor improvements during exercise interventions.

Agreement And Reliability Between Powertap™ Power Measurement Pedals And Velotron™ Load Generator Ergometer

Frank Plonka, Brandon Bastianelli, Andrea Workman, Stephen McGregor. *Eastern Michigan University, Ypsilanti, MI.*
 (No relevant relationships reported)

Title: Agreement and reliability between PowerTap™ power measurement pedals and Velotron™ load generator ergometer
Author Block: Frank Plonka, Brandon Bastianelli, Andrea Workman, Stephen McGregor. Eastern Michigan University, Ypsilanti, MI.
Abstract: The PowerTap P1 pedal based power meter allows for measurement of power at the pedal/rider interface independent of crank or hub. This allows for the use of the measurement of power at the pedal to examine putative effects of changes in components such as the crank. The Velotron cycle ergometer is an extensively used ergometer for laboratory testing.
Purpose: To test the agreement between a portable pedal power measurement system (PowerTap; PT, Saris, WI) and Velotron (VCE, Racermate, WA) stationary ergometer. Additionally, to determine the test-retest reliability of PT relative to VCE.
Methods: 16 trained cyclists and/or triathletes consented to procedures approved by the EMU-HSRC, which consisted of three visits. For visit 1, subjects completed an incremental trial on VCE and using indirect calorimetry (Parvomeds, CO) to determine power and ventilatory threshold (pVT) and $\dot{V}O_{2MAX}$. During visits 2 and 3, subjects warmed-up on VCE and then completed twelve, six-minute stages which consisted of pedaling at a given cadence while maintaining a power output equivalent to 70, 80, or 90 percent of pVT. The six min stages were randomized, power was measured at the pedal (PT), and the load applied by VCE. Linear regressions to determine agreement across power and intraclass correlations to determine reliability were performed using SPSS 24.0 (IBM, IL) with an alpha = 0.05.
Results: Across all absolute VCE power (125-305 watts), linear regression showed strong agreement ($r^2 = 0.94$; $p < 0.001$) between VCE and PT. Intraclass correlations showed strong agreement between tests ($r = 0.983$; $p < 0.001$). Overall, the ratio of PT/VCE was 0.98 and 0.97 and coefficients of variation were 5.6% and 4.1% for visits 2 and 3, respectively.
Conclusion: These results indicate that the PowerTap P1 power measurement pedal agrees strongly with the Velotron cycle ergometer and is reliable from a test-retest perspective. Therefore, a PowerTap pedal system can be used to evaluate the effects of component changes with the use of a Velotron ergometer.

Novel Crank with Elastomer Spring Improves Effective Power in Trained Cyclists and Triathletes

Brandon M. Bastianelli, Andrea Workman, Stephen McGregor. *Eastern Michigan University, Ypsilanti, MI.* (Sponsor: Dr. Mark Peterson, FACSM)
 Email: bbastian@emich.edu
 (No relevant relationships reported)

Purpose Test claims a novel cycling crank (IMPACT, Huron Cycling, LLC) may increase effective cycling power. The crank incorporates an elastomer spring and is purported to return energy during the "dead spot" of the pedal revolution, thus improving the net transfer of external power.
Methods 15 trained cyclists/triathletes (38 ± 7 y, 74.5 ± 9.9 kg, 174.7 ± 6.6 cm) consented to procedures approved by the EMU-HSRC. The study consisted of three visits. During V1, subjects performed a graded exercise protocol on a Velotron (Racermate, WA) cycle ergometer (VCE) to determine ventilatory threshold (VT) (Parvomeds, CO) and power at VT (pVT). During V2 and V3, subjects warmed-up on VCE then completed twelve, six-minute stages which consisted of pedaling at a 85 rpm while maintaining a power output equivalent to 70, 80, or 90 % of pVT. Additionally, a cadence effect was tested at 80% pVT at 75, 85 or 95 rpm. The six stages were randomized, and each stage was completed twice; i) with a pin in the crank (CON),

and ii) without the pin (EXP). The pin eliminated the spring effect of the elastomer, thus making a traditional rigid crank. There was a minute rest between each stage, except when changing from EXP to CON (3 minutes) to change the pin and allow subject to drink. The VCE was used as the external load generator and power was also measured at the pedals (PowerTap P1, WI; PT) to determine if any difference in power between external load and power necessary to turn the cranks against the load was present. MANOVA statistical tests compared %pVT between PT and VCE and VO₂ in both EXP and CON ($\alpha=.05$).

Results

Across all conditions, there was a Large effect for EXP power being 1.3 % lower than CON ($p=.008$; $\eta^2=.028$). Although not significant, there were small effects for cadence at 80% pVT, where EXP was lower than CON, but to a greater extent at 85 and 95 than 75 rpm (77.7± 2.8, 77.1±3.6 and 78.5±4.2 %, respectively, $\eta^2=.019$). There was no significant difference between VO₂ at each workload when expressed as a percentage of VT between EXP and CON. There were no significant differences by trial for any variables tested.

Conclusion

Lower power, but similar VO₂ during EXP compared to CON supports the notion that the IMPACT crank improves effective power during cycling. Although small in magnitude, the effect was large and could be of interest to competitive cyclists or triathletes.

A New Equation to Estimate VO_{2max} for a Racquet Sport Modality**

Jesus Barrera-Exposito¹, Elvis Alvarez Carnero². ¹Virgen de la Victoria-Martiricos Institute, Málaga, Spain. ²Florida Hospital. Translational Research Institute, Orlando, FL.
Email: jesusbarreraexposito@gmail.com
(No relevant relationships reported)

The 'padel' is a relatively new racquet modality (less than 30-year-old in USA) played in a 20x10 meters enclosed court. There is little information about its metabolic characteristics, and a lack of tests to estimate physiological performance on the field. The goal of this study was to describe body composition and aerobic capacity of amateur padel players; additionally, we aimed to develop an equation to estimate aerobic capacity (VO_{2max}) on padel players. **Methods:** Thirty-three male padel players with a valid direct VO_{2max} test were included in this analysis (36.4±5.9 years; BMI, 24.5±2.1 kg/m²; % fat mass (%FM), 20.5±5.7%). Body composition (lean mass and %FM) was measured by DXA; appendicular lean tissue was used to derive skeletal muscle mass (SMM). A specific progressive shuttle-run test was created to measure VO_{2max} inside the padel court; briefly, each player needed to run from one wall to the other wall of the court grasping his racquet, pace feedback was provided by a digital audio system, starting at 8.5 km/h the speed increased 0.5 km/h. VO_{2max}, anaerobic threshold (AT) and heart rate (HR) was directly measured by a portable indirect calorimeter over the all-out test. Stepwise multiple regression analysis was utilized to derive an equation to estimate VO_{2max}. The concordance coefficient correlation (ρ_c) was used to assess the accuracy of the equation. **Results:** Body composition and metabolic exercise variables are shown in table 1.

Table 1. Physiological characteristics of amateur padel players.

| Variables | | Mean | SD |
|--------------------|------------------------------|-------|---------|
| Age | (years) | 36.4 | ± 5.9 |
| Lean | (kg) | 61.5 | ± 5.7 |
| SMM | (kg) | 33.0 | ± 3.4 |
| HR _{max} | (beats/min) | 179 | ± 9 |
| VO _{2max} | (l/min) | 3.822 | ± 0.611 |
| VO _{2max} | (ml/kg/min) | 48.8 | ± 6.4 |
| VO _{2max} | (ml/kg _{lean} /min) | 62.7 | ± 6.3 |
| AT | (ml/kg/min) | 33.2 | ± 6.2 |
| %AT | (%) | 68.3 | ± 11.0 |
| HR _{AT} | (beats/min) | 134 | ± 21.8 |

SD, standard deviation; AT, %AT and HR_{AT} indicate oxygen uptake, % of VO_{2max} and HR at anaerobic threshold, respectively.

SMM and number of stages were the main predictors of absolute VO_{2max} ($R^2 = 0.72$, $P<0.001$); the equation was $VO_{2max} (L/min) = -0.00195 + 0.148 \times SMM (kg) - Stage (number)$. The ρ_c between measured and estimated VO_{2max} was moderately high ($\rho_c=0.807$). **Conclusions:** We have provided references for body composition and maximal aerobic capacity variables in amateur padel players and a new equation to estimated aerobic capacity from a specific test for the sport of padel. Larger and more heterogeneous datasets are necessary to validate these results.

**3436 Board #124 June 1 8:00 AM - 9:30 AM
Dual Stress Warm-Up Protocol Does Not Significantly Improve Anaerobic Performance**

Matthew P. Sacco¹, Margaret M. Glick¹, Eric C. Bredahl¹, Michael T. Lane², Jacob A. Siedlik¹. ¹Creighton University, Omaha, NE. ²Eastern Kentucky University, Richmond, KY.
(Sponsor: Joan Eckerson, FACSMS)
(No relevant relationships reported)

Dual stress challenges (e.g. paired physical and psychological challenges) have been shown to increase sympathetic activity above that of exercise alone. Although the rise in sympathetic activity represents a maladaptive increase in physiological load, there is a possibility that a dual stress challenge in a warm-up setting may optimize sympathetic activation while minimizing peripheral fatigue. **PURPOSE:** To determine whether a dual stress warm-up protocol improves performance on the 30 s Wingate Anaerobic Test (WAnT). **METHODS:** Thirteen college-aged subjects (Mean ± SD; age = 21 ± 3 yr; Height = 177 ± 9 cm; Weight = 81.8 ± 11.8 kg) volunteered to participate and completed a familiarization WAnT on a Monark cycle ergometer using a resistance of 7.5% bodyweight prior to testing. On two separate visits, separated by at least 3 d but no more than 1 wk, subjects randomly completed a WAnT preceded by either a 5 min warm-up at a resistance of 1.5% BW at a pedal rate of 70-80 rpm (CTRL) or the same warm-up while also completing the Paced Auditory Serial Test, which is a mental arithmetic challenge (EXPT). Zephyr Bioharnesses were used to record heart rate (HR) during the testing sessions. Difference in HR during the warm-up, and WAnT peak power, average power, and power drop were investigated using paired samples *t*-tests. **RESULTS:** There were no significant differences in performance or HR response during the warm-up between the CTRL and EXPT. **CONCLUSION:** These finding suggest that the addition of a mental task during a warm-up on a cycle ergometer has no effect on sympathetic activity or performance during a 30 s WAnT. The lack of significant findings may be due to the small sample size. Future work should focus on more challenging psychological stressors in conjunction with warm-up protocols to determine whether dual stress challenges can be utilized to optimize performance.

**3437 Board #125 June 1 8:00 AM - 9:30 AM
Vertical Jump Versus Kinematic Sequencing: Advanced Technology Doesn't Always Enhance Appraisal**

Margaret E. Bristow, Nathaniel J. Holmgren, J. Mark VanNess, Brian G. Graham, Joey Rossi, Courtney D. Jensen. University of the Pacific, Stockton, CA.
Email: m_bristow@u.pacific.edu
(No relevant relationships reported)

In an age when science informs sport, new technology for athlete appraisal is often adopted before it is tested. Sparta kinematic sequencing (Sparta Science Corp.) is an instrument for player assessment that's employment has outpaced its examination. **PURPOSE:** To evaluate the effectiveness of Sparta data in predicting basketball performance. **METHODS:** We analyzed 37 basketball players from a D1 collegiate basketball program over a 4-year period (2013-2014 through 2016-2017). Each player's vertical jump (VJ) was measured and tested on a Sparta force plate, which provides 3 proprietary outputs: Load, Explode, and Drive. On average, each player was tested 24.9 ± 20.3 times; there were 922 total observations evenly distributed over the 4 years and over year in school. The Sparta outputs were used to predict on-court performance of each athlete during each season that the values were collected via multiple linear regression analyses. The dependent variables were in-game statistics per 40 minutes of court time: points, rebounds, assists, blocks, and turnovers. **RESULTS:** Athletes played 19.3 ± 12.7 games per year. On average, they scored 12.8 ± 4.4 points, had 6.6 ± 2.7 rebounds, and turned the ball over 2.4 ± 1.0 times. Regression analyses found no significance with Load, Explode, or Drive in points per game, field goals per game, or assists per game. In each analysis all 3 Sparta outputs had negative associations that didn't reach significance while VJ had a positive association that failed to reach significance. Load predicted rebounds per game ($\beta=0.18$; $p<0.001$) and blocked shots per game ($\beta=0.03$; $p=0.021$). Explode and Drive had non-significant negative relationships and VJ had a non-significant positive relationship. Explode ($\beta=0.31$; $p=0.017$) and Drive ($\beta=0.304$; $p=0.011$) predicted more turnovers per game, VJ predicted fewer ($\beta=-0.982$; $p=0.020$), and Load had a non-significant positive association. Without controlling for the full Sparta profile, Explode associated with fewer rebounds ($p<0.001$) and more turnovers ($p=0.020$); it had no association with improvements in performance. **CONCLUSION:** Athletic programs are often quick to incorporate new technology believing that it equates to improved player assessment. More analyses are required before simple jumping analyses can be displaced by sophisticated equipment.

Differences In Performance Traits In Intermittent Versus Continuous Exercise Testing Of Handball Players and Triathletes

Björn Sterzing, Tobias Ehlert, Sarah Breitbach, Perikles Simon. *Johannes Gutenberg University, Mainz, Germany.*
 Email: sterzing@uni-mainz.de
 (No relevant relationships reported)

External validity of endurance performance diagnostics may depend on type of sports. In order to reflect different load quality for the muscle specific endurance testing regimes have been developed for intermittent sports. Here we examined the influence of an intermittent versus a typical continuous step-wise progressive treadmill protocol on metabolic and cardiorespiratory parameters. **PURPOSE:** To determine if handball players (HB) in comparison to triathletes (T) show differences in typical submaximal lactate thresholds (LT and LT + 1.5 mmol), or in VO₂max depending on either continuous or intermittent type of a step-wise progressive exercise testing. **METHODS:** 13 HB and 13 T; mean (SD) age 24.7 (3.1 yrs) height 184.2 (7.2 cm), weight 82.7 (10.8 kg) with a training load of 6.8 (3.1) h/wk in HB versus 8.8 (3.3) h/wk in T. Each subject performed two treadmill protocols within one week. First a typical step-wise incremental treadmill test (CTT) starting at 6 km/h increasing every 3 min by 2 km/h until exhaustion. Second a step-wise incremental intermittent test (IMT) with steps split into 6x15s load phase interlaced with 6x15s active recovery. Load phase started at 8km/h and was increased every 3 min by 2 km/h, while active recovery remained at 6 km/h throughout all steps until exhaustion. VO₂max, velocity at LT, velocity at LT + 1.5 mmol/l lactate (LAT). **RESULTS:** VO₂max in ml/min/kg was not significantly different between sports and testing protocols (all 4 groups) with CTT for HB 50.5 (4.7) and T 53.2 (3.5), or with IMT 50.1 (3.7) in HB and 51.2 (4.2) for T. Velocity in km/h at LAT was not significantly different between all groups with CTT for HB 11.9 (0.8) and 12.4 (1.3) for T, or with IMT 11.2 (0.4) for HB and 11.5 (0.7) for T. For the LT in km/h we revealed in an analysis of co-variance a slightly significantly higher velocity of $\Delta V = 0.74$ km/h (95% CI = 0.03-1.45, $p < 0.04$) in T than in HB in CTT. **CONCLUSIONS:** We recruited a collective of HB and T with an almost comparable weekly training load. HB and T showed comparable typical performance trait characteristics for the higher work-load demand (VO₂max and LAT), which was even independent of type of test. The slightly better performance of T in specifically the continuous test setting principally reflects higher load and potentially a better adaptation to this type of working demand.

A Comparison of Techniques for Estimating and Detecting Changes in Skeletal Muscle Cross-Sectional Area

Johnathon H. Moore¹, Cody T. Haun², Emily L. Grandprey³, Katelyn P. Joubert³, Christopher G. Vann¹, Paul A. Roberson¹, Petey W. Mumford¹, Matthew A. Romero¹, Shelby C. Osburn¹, C Brooks Mobely¹, Jordan R. Moon⁴, Michael D. Roberts⁵, Kaelin C. Young⁵. ¹Auburn University, Auburn, AL. ²LaGrange College, LaGrange, GA. ³Edward Via College of Osteopathic Medicine-Auburn Campus, Auburn, AL. ⁴ImpediMed, Inc., Carlsbad, CA. ⁵Auburn University, Edward Via College of Osteopathic Medicine-Auburn Campus, Auburn, AL.
 (No relevant relationships reported)

Muscle biopsy and subsequent histological analysis of muscle fibers is a criterion technique for determining hypertrophy of skeletal muscle in resistance- and endurance-trained individuals. However, due to the training necessary to complete the biopsy, and the invasive nature of the biopsy itself, alternative methods for depicting muscle fiber hypertrophy offer increased ability to gather data discerning skeletal muscle hypertrophy. Furthermore, such procedures require less training and are noninvasive. **PURPOSE:** This project sought to determine if estimated mid-thigh whole muscle cross-sectional area (CSA) is related to muscle fiber CSA from muscle biopsies. **METHODS:** Twenty-nine resistance-trained men (age: 21 ± 2 yrs, weight: 83.6 ± 11.0 kg, height: 178.7 ± 8.1 cm) underwent six weeks of total-body resistance training. Muscle biopsies were taken from the Vastus lateralis prior to and following training. Mid-thigh circumference and skinfold measurements (anterior, posterior, medial, and lateral) were used to estimate whole muscle mid-thigh cross-sectional area using the methods of Moritani and deVries. **RESULTS:** Whole-muscle CSA did not significantly increase from pre- (272.737 ± 37.401 cm) to post-training (277.286 ± 29.474 cm; $p = 0.201$). Muscle fiber CSA did not significantly increase from pre- (4068 ± 865 μm) to post-training (4221 ± 704 μm; $p = 0.368$). Additionally, pre muscle fiber CSA did not correlate to pre whole-muscle CSA ($r = 0.029$, $p = 0.882$). Also, Muscle fiber CSA percent change did not correlate with whole-muscle CSA percent change ($r = -0.064$, $p = 0.741$). **CONCLUSION:** Estimated whole-muscle CSA and muscle fiber CSA do not appear to correlate well. A lack of a relationship between the changes in these measurements following hypertrophy are puzzling and warrant further study.

Is Core Temperature Influenced by Triathlon Wetsuit Models When Swimming in Warm Water?

Melissa J. Aure, Gabriela Guzman, Boram Lim, Cordero Roche, John A. Mercer, FACSM. *University of Nevada, Las Vegas, Las Vegas, NV.*
 Email: aurem1@unlv.nevada.edu
 (No relevant relationships reported)

Swim-related fatalities have raised safety concerns in the sport of triathlon. As a majority of deaths occur during the swim, there are strict guidelines related to water temperatures and the use of wetsuits in triathlon events governed by USA Triathlon (USAT). Due to the varying water temperatures, athletes can select from a wide variety of wetsuit models. Two main categories of wetsuit models are sleeveless and full sleeve. The use of a wetsuit in warm water may increase body heat storage and may result in an increase in core temperature. However, there are no data investigating the influence of triathlon wetsuit design on core temperature when swimming in warm water. **PURPOSE:** The purpose of this study was to examine the influence of wetsuit design on core temperature responses during swimming in warm water (25.5 °C). **METHODS:** Three experienced triathletes (mean ± standard deviation (SD), age 48 ± 4.93 years, height 1.73 ± 0.09 m, weight 71.62 ± 8.54 kg) participated in the study. At least 8 hours prior to attending the test session, participants swallowed an ingestible core temperature pill. Before beginning the test session, core temperature (T_c) data were transferred to the monitor and sample rate was set to 0.1 Hz (1 sample every 10 s). Testing consisted of a self-directed warm-up followed by a 500-m swim in an indoor pool (set to either 25-m or 50-m in length) for each condition: no wetsuit (NW), sleeveless wetsuit (SL), and full sleeve wetsuit (FS). Participants swam at a self-selected pace at a somewhat hard intensity (Borg Rating of Perceived Exertion = 13). Participants were required to rest until core temperature was within 0.5 °C of baseline before beginning the next condition. Core temperature data were transferred to the monitor after each swim. Average T_c during the first and last minute of each swim was computed for analysis. A 2 (time) x 3 (wetsuit condition) repeated measures ANOVA was used ($\alpha = 0.05$). **RESULTS:** T_c was not influenced by the interaction of time and wetsuit ($p > 0.05$) and there was no main effect for time ($p > 0.05$) nor wetsuit condition ($p > 0.05$). Mean values for T_c between NW, SL, and FS were 37.82 ± 0.44 °C, 37.64 ± 0.68 °C, and 37.64 ± 0.42 °C, respectively. **CONCLUSIONS:** These pilot results indicate that wetsuit design does not significantly influence thermoregulatory responses.

Synchronous Music Does Not Appear to Change YMCA Bench Press Results

Rhiannon M. Seneli, Samantha R. Lang, Abigail C. Hammer, Alyssa M. Tompkins, Sandra Tecklenburg-Lund. *St. Ambrose University, Davenport, IA.*
 (No relevant relationships reported)

Listening to music while exercising is thought to enhance physical performance by enhancing focus, elevating mood, increasing motivation, and decreasing perceived effort. Research, however, has debated the actual effects of music on performance, as results of the ergogenic effect vary with different music types, modes of exercise, intensities, and training status. One of the variations observed both in and outside the laboratory is exercise which is synchronized with the rhythm of the music. It is unclear how synchronous music affects maximal exercise testing when a cadence is required as part of the protocol, such as during the YMCA bench press test. **PURPOSE:** The purpose of this study was to investigate the effect of synchronous music on the YMCA bench press test. **METHODS:** Sixteen subjects (6 males, 10 females, 22.1 ± 4.1 years) self reported being active or non-active according to ACSM physical fitness guidelines. Each performed a YMCA bench press test at a cadence of 60 repetitions per minute under two conditions: (1) using a metronome set at 60 bpm and (2) with pre-determined synchronous music with a beat of 120 bpm. With the metronome, each bench press repetition was completed with each beat, while the music trial required subjects to complete each repetition every other beat. The number of successful repetitions completed was recorded and means from each condition were compared using a dependent t-test ($\alpha = .05$). Individual differences between the conditions were also identified and the difference between conditions for active subjects ($n = 11$) was compared to non-active subjects ($n = 5$) using an independent t-test. **RESULTS:** There was no significant difference in the number of repetitions completed during the metronome condition (39.1 ± 22.3 repetitions) and the synchronous music condition (39.1 ± 23.1 repetitions, $p = .99$). There was also no significant difference in change of repetitions completed between active (0.5 ± 6.3 repetitions) and non-active subjects (-1.0 ± 8.3 repetitions, $p = .74$). **CONCLUSION:** Synchronous music did not have an effect on the YMCA bench performance. Because the test requires maximal effort, it may be that the beneficial distraction often caused by music was muted by the high intensity required for the exercise.

Validity of a New Portable Metabolic Gas Exchange System
 Holly L. McClung¹, Leila A. Walker¹, David P. Looney¹, William J. Tharion¹, Alexander P. Welles¹, Heather M. Hansen¹, Adam W. Potter¹, Maxwell N. Rome², Christopher R. Chalmers², Reed W. Hoyt¹. ¹US Army Research Institute of Environmental Medicine, Natick, MA. ²Oak Ridge Institute for Science and Education, Oak Ridge, TN. (Sponsor: Scott Montain, FACSM)
 Email: holly.l.mcclung.civ@mail.mil
 (No relevant relationships reported)

Valid and reliable methods to measure oxygen consumption ($\dot{V}O_2$) and carbon dioxide production ($\dot{V}CO_2$) are required in the assessment of exercise capacity and energy expenditure. However, research is often restricted by financial and portability issues with existing open circuit spirometry, metabolic cart or portable devices. **PURPOSE:** Evaluate a new, light-weight and scalable metabolic system (CO₂/O₂ Breath & Respiration Analyzer, COBRA) against a criterion metabolic cart system (Parvomedics TrueOne 2400®, PARVO). **Methods:** Fourteen volunteers (13 male, 1 female; 24 ± 6 y (mean ± SD), 76 ± 13 kg BW, $\dot{V}O_{2peak}$ 3.8 ± 0.7 L·min⁻¹) performed four identical trials over two laboratory test days. The COBRA and PARVO were used to monitor four steady-state work rates: sitting rest, walk (23-36% $\dot{V}O_{2peak}$), jog (49-67% $\dot{V}O_{2peak}$), and run (60-76% $\dot{V}O_{2peak}$) on a treadmill in a laboratory (20 ± 0.5 °C; 45 ± 22 % RH). Simultaneous gas samples were averaged over 3-4 minute steady-state periods for each work intensity. Coefficient of determination and Concordance Correlation Coefficients (CCC) were used to evaluate the agreement between the systems when measuring $\dot{V}O_2$, $\dot{V}CO_2$, and minute ventilation (V_E). Systematic bias was examined to assess the accuracy of the COBRA. **Results:** The COBRA and PARVO produced highly correlated measures of $\dot{V}O_2$ ($R^2=0.98$), $\dot{V}CO_2$ ($R^2=0.98$) and V_E ($R^2=0.99$). The COBRA had very low bias compared to the PARVO for $\dot{V}O_2$ (0.01 ± 0.13 L·min⁻¹), $\dot{V}CO_2$ (0.06 ± 0.13 L·min⁻¹), and V_E (2.12 ± 2.75 L·min⁻¹). COBRA was in high agreement (CCC=0.99) with the PARVO across each measure of $\dot{V}O_2$, $\dot{V}CO_2$ and V_E . **Conclusion:** The COBRA device is an accurate mobile metabolic system for measuring respiratory variables across a range of work intensities.

Relationship of OMNI Scale of Perceived Exertion to Heart Rate and RER During Incremental Exercise
 Christopher R. Chalmers¹, David P. Looney², Reed W. Hoyt², Alex P. Welles², William J. Tharion², Heather M. Hansen², Leila A. Walker², Maxwell N. Rome¹, Holly L. McClung². ¹Oak Ridge Associate Universities, Natick, MA. ²United States Army Research Institute of Environmental Medicine, Natick, MA. (Sponsor: Dr. Scott Montain, FACSM)
 Email: cchalmers@worcester.edu
 (No relevant relationships reported)

The OMNI rating of perceived exertion (RPE) scale is a subjective indicator of physiological strain experienced during aerobic exercise. Unlike its predecessor the Borg RPE scale, relatively few studies have examined the relationship between OMNI Scale reported and the measured heart rate (HR) and respiratory exchange ratio (RER) during exercise. **PURPOSE:** To analyze the strength of the relationship between RPE scores from the OMNI scale and HR and RER during incremental exercise. **METHODS:** Twelve active military personnel (11 male, 1 female; 24 ± 5 yr; height, 175 ± 9 cm; body mass, 79 ± 14 kg) completed two trials over one test day. Each trial consisted of three exercise intensities (walk, jog, run) based on percentages of their maximal oxygen uptake (% $\dot{V}O_{2max}$) performed at baseline separated by a 20-30 minute rest between trials. Measures of RER were collected using a metabolic cart (ParvoMedics TrueOne® 2400), HR with a commercial chest belt monitoring system (Polar T31 Heart Rate Sensor), and RPE with the OMNI-walk/run scale (Adult OMNI Scale of Perceived Exertion 2004). **RESULTS:** The calculated Pearson's correlation of coefficients for RPE was moderately correlated with HR ($r=0.83$) but weakly correlated with RER ($r=0.47$). The average RPE for walk (RPE, 2 ± 1), Jog (RPE, 4 ± 1), and Run (RPE, 6 ± 1) increased with each higher work rate. **CONCLUSION:** The OMNI RPE Scale is positively related to heart rate responses elicited by exercise, but is less correlated to changes in RER and therefore less indicative of the transition to greater reliance on glycolytic energy pathways.

DISCLAIMER: The views expressed in this paper are those of the authors and do not reflect the official policy of the Department of Army, Department of Defense, or the US Government. This research was supported in part by appointments to the Postgraduate Research Participation Program at the US Army Research Institute of Environmental Medicine administered by the Oak Ridge Institute for Science and Education through an interagency agreement between the US Department of Energy and USAMRMC.

A Comparison of Waist-to-Height Circumference Ratios to Standardized Measures of Overweight and Obesity
 David Q. Thomas, FACSM, Marin McElroy, Ayunna Moore, Jennifer Spring. *Illinois State University, Normal, IL.*
 (No relevant relationships reported)

Several methods have been used to screen people for overweight and obesity. Recently, waist-to-height circumference ratios have been gaining in popularity due to their ease of measure and focus on central adiposity. However, research on this method is lacking. **PURPOSE:** To determine the relationship between waist-to-height circumference ratios (WTHR) and more traditional methods (body mass index, waist-to-hip ratio, sum of skinfolds, and percent fat) of screening for overweight and obesity. **METHODS:** Thirty-one volunteers (17 females and 14 males) ages 18-24 (20.8 ± 0.98 yrs.) participated in the study. After completing informed consent, each participant had height, mass, waist and hip circumferences, skinfolds (tricep, bicep, mid-axillary, abdominal, supra-iliac, anterior thigh, medial calf, and pectoral {men only}) and percent fat (via air-displacement plethysmography - ADP) measured. **RESULTS:** Height (1.71 ± 0.10 m), mass (69.98 ± 14.20 kg), waist circumference (76.7 ± 8.61 cm), and hip circumference (98.94 ± 7.71 cm) were determined following standard procedures. Body mass index (BMI) was calculated by dividing mass in kg by height in meters squared (23.68 ± 3.27). Skinfolds (SF) were summed (111.20 ± 42.17 mm). Waist-to-hip (WTH) ratio (0.77 ± 0.06) and WTHR (44.77 ± 4.40) were calculated by dividing waist circumference by hip circumference (WTH) and by height (WTHR). Percent fat (21.06 ± 9.33) was measured by ADP. Pearson product-moment correlations for WTHR and BMI ($r=0.83$), WTH ($r=0.63$), SF ($r=0.57$), and percent fat ($r=0.55$) were calculated. **CONCLUSIONS:** Waist-to-height circumference ratios had a strong positive relationship with BMI and moderate positive relationships with WTH, SF, and percent fat. It appears that WTHR may be an acceptable alternative to screening for overweight and obesity. Since WTHR only involves the measure of height and waist circumference, this method has a high degree of feasibility. Its focus on central adiposity is an additional benefit. Further research is necessary to determine if these relationships hold true for other populations varying in age and body composition.

Can the Talk Test Be Used to Predict Training Induced Changes in Ventilatory Threshold?
 Carl Foster, FACSM, Kristen M. Deal, John P. Porcari, FACSM, Richard P. Mikat, FACSM, Cristina Cortis, Andrea Fusco. *University of Wisconsin-La Crosse, La Crosse, WI.*
 (No relevant relationships reported)

PURPOSE: To test the reliability of the talk test (TT) for tracking changes in ventilatory threshold (VT). **METHODS:** Thirteen healthy college-age students (mean±SD; age, 20.5±1.91 years; BMI, 25±2.8 kg/m²; Females=6) completed a TT and graded exercise test (GXT) before and after six weeks of increased training or detraining. The TT was used to predict VT by assessing the ability to talk comfortably during 3-minute exercise stages. The criterion measure of VT was respiratory gas exchange during the GXT using the v-slope method. Training and detraining were self-directed. Subjects recorded their exercise minutes and average rating of perceived exertion during the training session (sRPE) using the CR10 scale, which was used to calculate training LOAD. A two-way repeated measures analysis of variance (ANOVA) with Tukey's post-hoc analysis was used to detect differences between the change in power output (PO) during the TT and at VT ($p<.05$). **RESULTS:** No significant differences were found between the PO at equivocal stage (EQ) of the TT (135±29.8 W) and $\dot{V}O_2$ at VT (134±32.4 W) ($p>.05$). There was no significant change between exercise baseline minutes (160±7.6 minutes) and experimental minutes (213±46.6 minutes) ($p>.05$). However, there was a significant change between sRPE and LOAD at baseline (4.5±0.17 and 715±204.7, respectively) and experimental (5.9±0.23 and 1302±228.5, respectively; $p<.05$). Baseline training loads were considerably more than the 150 min/week at moderate intensity (RPE=3) recommended by ACSM (2017) for basic fitness with 68% of subjects exceeding the recommendations. **CONCLUSION:** The TT was shown to be reliable in tracking changes in VT over time. The results suggest that tracking training induced changes in exercise capacity can be done using the simpler method of the TT.

U.S. Navy Physical Readiness Test Modality Pilot Study
 Rebecca S. Weller¹, Douglas M. Jones¹, Katherine M. Wilson¹, Andrew J. Ordille¹, Dale A. Hirsch¹, John J. Fraser¹, Trevor B. Viboch¹, Aaron J. Wolf¹, Valerie M. Costantini¹, Heath Clifford², Jay H. Heaney¹, Melissa D. Laird¹. ¹Naval Health Research Center, San Diego, CA. ²21st Century Sailor, Millington, TN. Email: rweller223@gmail.com
 (No relevant relationships reported)

The U.S. Navy is transitioning from a culture of fitness testing to a more pervasive culture of functional fitness. The objective is to shift away from the current Physical Fitness Assessment, which evaluates general physical fitness levels and disease risk, toward more operationally relevant metrics of performance fitness and mission readiness. **PURPOSE:** To assess and down-select from 11 fitness tasks to 3-5 modalities for potential inclusion in an alternative Physical Readiness Test (PRT). **METHODS:** Forty-one active duty sailors (30 males; 11 females) completed traditional strength tests and 11 performance fitness modalities consisting of upper/lower body strength and power events, total body strength events, timed sprints/runs, and a core strength task. Modality down-selection was based on scalability, physical space and equipment requirements, safety, time and cost to administer, and correlations of sailors' individual performance on the new modalities to both their performance on traditional strength tests and most recent PRT (curl-ups, push-ups, 1.5 mile run). **RESULTS:** Seated medicine ball throw (SMBT)—the only modality that measured upper body strength and power—had a strong correlation with the 1 repetition maximum (1RM) bench press ($r=0.79$). Standing long jump (SLJ) evaluated lower body strength and power and had a moderate correlation with 1RM seated leg press ($r=0.50$) and 1.5 mile run ($r=0.59$). The repeated 300-yd shuttle run (300SR) assessed agility and aerobic/anaerobic capacity and was highly correlated ($r=0.82$) with participants' 1.5 mile run times on their most recent PRT. Forearm plank (FP) did not show significant correlations to traditional strength tests or previous fitness test scores (PRT), with the exception of a moderate correlation to PRT push-up scores ($r=0.51$). **CONCLUSION:** SMBT, SLJ, 300SR, and FP were the modalities recommended for inclusion in an alternative PRT. These new modalities evaluate more operationally relevant measures of performance fitness, thereby providing advanced knowledge of a sailor's physical capabilities and/or limitations. Future considerations should include a follow-on, large scale validation study to develop the appropriate norms and performance standards across gender/age brackets.

Trauma Exposure Predicts Functional Movement Characteristics of Male Tactical Athletes
 Stephanie Coffin. Leidos/NHRC, San Diego, CA. Email: stephaniecoffin95@gmail.com
 (No relevant relationships reported)

Accumulating data have demonstrated a link between psychological distress and musculoskeletal injury (MSKI) prevalence. High levels of physical stress are commonly experienced during the career of a military tactical athlete, which can result in injury and subsequently affect functional movement (FM) outcomes. It is also plausible that trauma exposure (TE), a psychologically salient factor, may influence FM characteristics. It is vital to understand psychological predictors of FM in tactical athletes to optimize performance and to help attenuate MSKI incidents. **PURPOSE:** The primary objective was to determine the associations of combat exposure (CE) and TE with FM characteristics in tactical athletes. Secondary objectives were to explore the confounding influences of age and physical injury history as well as the mediating role of bodily pain. **METHODS:** Eighty-two male, active duty U.S. Navy Explosive Ordnance Disposal personnel (mean age \pm SD = 34.0 \pm 6.7 years) self-reported CE, TE, physical injury history, and bodily pain. FM characteristics (i.e., Functional Movement Screen [FMS], Y-Balance Test) were assessed by trained researchers, from which a composite functional status (CFS) measure was derived. Hypotheses were tested using correlational and multiple regression (causal steps) models. **RESULTS:** In unadjusted models, TE was inversely associated with FMS ($r = -0.32, p = .005$) and CFS ($r = -0.30, p = .009$). In adjusted models, these relationships were robust to the confounding influences of age and physical injury history. In causal steps models, TE and bodily pain were substantive, independent predictors of FMS ($R^2_{adj} = .20, p = .02$) and CFS ($R^2_{adj} = .18, p = .02$), implying additive, rather than mediated, effects. CE did not predict FM characteristics. **CONCLUSIONS:** To our knowledge, this is unprecedented evidence of the influence of TE on FM characteristics of male tactical athletes that is independent of age, physical injury, and bodily pain. The shared variance of TE and FM characteristics implies that the addition of TE, and other psychologically relevant constructs in association with FM, may advance FM theories. Including TE into physical assessments may not only optimize performance in the tactical environment, but also advance MSKI prevention and treatment.

A New and Simple Prediction Equation For Health-Related Fitness: Use of Honest Assessment Predictive Modeling
 Peter D. Hart. Montana State University - Northern, Havre, MT. Email: peter.hart@msun.edu
 (No relevant relationships reported)

PURPOSE: Health-related fitness is a set of attributes that relate to the ability to perform physical tasks and also relate to health outcomes. To assess an individual on all health-related fitness attributes can be time consuming. Thus, it would be useful to fitness specialists if a simpler and valid assessment was available to measure overall health-related fitness. The purpose of this study was to employ honest assessment predictive modeling to find a parsimonious set of variables that can predict overall health-related fitness. **METHODS:** Data used for this study came from college students who completed a fitness test battery. An overall health-related fitness score (T-score) was constructed using maximal oxygen consumption (VO₂, ml/kg/min), 1RM bench press (BP, lb), maximal push-up repetition (PU, #), and percent body fat (PBF, %). The set of possible predictor variables consisted of participant age (yr), sex (male/female), body mass index (BMI, kg/m²), waist circumference (WC, cm), 1RM leg press (LP, lb), countermovement vertical jump (VJ, in), flexed arm hang (FAH, sec), physical activity rating (PAR, 0 thru 10), and sit-and-reach (SNR, cm). The honest assessment predictive modeling procedure included three steps: 1) development of competing models using a TRAINING dataset, 2) selection of an optimal model using a separate VALIDATION dataset, and 3) assessment of fitness score construct validity using a final SCORING dataset. **RESULTS:** Stepwise model selection with Schwarz Bayesian criterion (SBC) on the TRAINING data resulted in five possible models including sex, VJ, PAR, and WC. Results on the VALIDATION data indicated a three-variable model had the lowest average squared error (ASE) and consisted of sex, VJ, and PAR ($F=107.8, p<.001, R^2=.82, SEE=3.09$). Finally, predicted values from the SCORING data showed that athletes ($Mean=54.9, SD=5.1$) had a significantly ($p<.001$) greater mean fitness score than non-athletes ($Mean=39.8, SD=4.8$). **CONCLUSION:** This study presents a valid equation that can simply predict overall health-related fitness in college students.

3449 Board #137 June 1 9:30 AM - 11:00 AM
Ability to Predict Impending Volitional Exhaustion Based on Aerobic Capacity
 Dustin W. Davis, Jenna L. Carducci, Matthew J. Garver, Whitley J. Stone, Meera Penumetcha, Nicolas M. Philipp, Josie H. Hair, Jordan R. Elledge, Haley R. Williams, Matthew T. Oliphant, Zachariah S. Hopkins. University of Central Missouri, Warrensburg, MO. Email: dwdavis@ucmo.edu
 (No relevant relationships reported)

Maximal relative oxygen consumption (VO_{2max}), assessed via a treadmill test to volitional exhaustion, is the foremost measure of aerobic capacity in healthy, recreationally active young adults. Habitual exercise may improve the ability to perceive exercise difficulty and predict impending exhaustion. **PURPOSE:** The primary aim of this investigation was to determine if a correlation existed between VO_{2max} and time to test termination after participants indicated they were 30 s from volitional exhaustion. A secondary aim was to ascertain if participants more accurately predicted impending exhaustion during a repeated trial. **METHODS:** Participants completed a familiarization trial to minimize learning effects and determine treadmill speed for maximal testing. During the familiarization trial, participants self-selected a zero-grade jogging speed associated with a value of 12-13 on Borg's 6-20 RPE scale when steady-stated. This speed was used during two maximal tests separated by 36-72 h. During maximal testing, grade was increased 2% every two minutes until volitional exhaustion. VO_{2max} was measured as a 15-breath moving average via a metabolic cart. Participants were instructed before and during testing to tap on the treadmill when they perceived themselves to be 30 s from volitional exhaustion. **RESULTS:** Thirteen (Females: 8, Males: 5) recreationally active individuals (20.7 \pm 1.4 yrs., 72.4 \pm 12.3 kg) completed the protocol. Mean VO_{2max} during session 1 (10.00 \pm 2.46 min) was 47.0 \pm 7.4 ml·kg⁻¹·min⁻¹, and time to test termination after the tap was 36.2 \pm 7.4 s. Mean VO_{2max} during session 2 (10.08 \pm 2.38 min) was 47.5 \pm 7.7 ml·kg⁻¹·min⁻¹, and time to test termination after the tap was 40.0 \pm 18.5 s. No significant correlation was detected between VO_{2max} and time to test termination after the tap in session 1 ($r = -.032, p = .917$) or session 2 ($r = .315, p = .295$). A dependent t-test ($t(12) = -.800, p = .439$) did not reveal significant differences in time to test termination after the tap between session 1 and session 2. **CONCLUSIONS:** Aerobic capacity did not affect the ability of healthy, recreationally active young adults to predict impending volitional exhaustion during maximal treadmill running. Time to test termination after the tap did not significantly change during a repeated trial.

3450 Board #138 June 1 9:30 AM - 11:00 AM
Bilateral And Split Stance Isometric Midhigh Pulls Can Equally Predict Change Of Direction Ability

Brandon J. Richards, Mark Gifford, James K. Morrison, Ken Seaman. *University of New Brunswick, Fredericton, NB, Canada.*

Email: brandon.richards@unb.ca

(No relevant relationships reported)

The isometric midhigh pull (IMTP) has been shown to be able to predict change of direction (COD) ability. This is of interest for sports that require COD movements, as it could potentially be used to identify standout athletes in their respective sports. However, no literature to our knowledge has assessed split stance isometric midhigh pull (SSIMTP) as a predictor of COD ability compared to the IMTP. **Purpose:** The purpose of this study was to determine whether SSIMTP is a better predictor of COD ability than the IMTP. **Methods:** Seventeen (12M and 5F) university aged adults participated in the following study. Mean height, weight, and age were 176 ± 8.6 cm, 172 ± 24.2 kg, and 22 ± 3 years, respectively. Participants completed two sessions randomized in order that were two to five days apart; four trials of the SSIMTP (two trials per lead leg) and the other session involved two trials of the IMTP. Each day also consisted of four trials of the 505-agility test. Two trials involved pivoting off of the left foot and two trials pivoting off of the right foot, which was randomized in order. **Results:** All results are Pearson Correlation Coefficients presented with their respective p-value. The combined peak force (PF) of the IMTP and the best 505-agility time for the left and right foot had r values of -0.648 ($p < 0.09$) and -0.464 ($p < 0.08$), respectively. The r values during the SSIMTP condition were -0.722 ($p = 0.02$) and -0.462 ($p = 0.07$) when the left leg is the lead leg and COD to the left and when the right leg is the lead leg and COD to the right, respectively. **Conclusion:** The main finding of this study is that the combined PF produced during the IMTP and the PF produced by the lead leg during the SSIMTP can both uniformly predict COD. For the SSIMTP condition, a significant strong inverse correlation exists between left COD ability and left leg when it is forward and a moderate inverse correlation between right COD ability and the right leg when it is forward. For the IMTP condition, there is a strong inverse correlation between the combined PF and COD ability to the left and moderate inverse correlation between the combined PF and COD to the right. Previous literature has found correlations between IMTP and COD ability anywhere between -0.47 to -0.89.

Use Of A Clinic-Based ACL Prediction Algorithm In Division III Female Soccer And Basketball Players

Charles Ruot, Rachel Holick, Lindsay Edwards. *Hardin-Simmons University, Abilene, TX.* (Sponsor: Dr. Dennis O'Connell, FACSM)

Email: cruot@hsutx.edu

(No relevant relationships reported)

During landing and pivoting movements female athletes have an increased lower extremity valgus alignment and knee abduction moment (KAM) making them four to six times more likely than males to sustain a sports-related, non-contact anterior cruciate ligament (ACL) injury. **Purpose:** To utilize a clinic-based ACL prediction algorithm developed by Myer, Ford and Hewett (2011) that determines the probability of high knee abduction moment (KAM) in Division III female soccer and basketball players. **Methods:** Twenty female athletes were recruited ($n = 10$ basketball, $n = 10$ soccer). Five measures were obtained and utilized in the prediction algorithm, namely tibial length, body mass, knee valgus, knee flexion range of motion, and quadriceps-to-hamstring isokinetic strength ratio. A prediction nomogram was applied to award a point value for each variable, which when summed generated a probability of high knee abduction moment (KAM). High KAM is associated with a higher risk of ACL injury. In each group a dependent t-test was used to compare KAM in the left and right leg. Significance was tested at $p < 0.05$. **Results:** The probability of high KAM in basketball and soccer players was higher in the left leg compared to the right leg. In soccer players, this difference in KAM between the left and right leg was significant (basketball: $t_l = 0.76 \pm 0.27$, $t_r = 0.71 \pm 0.24$, $t(9) = 0.82$, $p = 0.43$; soccer: $t_l = 0.64 \pm 0.31$, $t_r = 0.49 \pm 0.31$, $t(9) = 2.65$, $p = 0.03$). **Conclusion:** The higher KAM scores for the basketball players suggest that they may be at a greater risk for ACL injury compared to the soccer players. The significant difference in bilateral KAM scores in the legs of the soccer players suggests a greater risk of ACL injury in the left leg compared to the right leg. This difference may be attributed to leg dominance, although leg dominance was not measured in this study. The current study supports the use of a clinic-based ACL prediction algorithm to evaluate ACL injury risk of athletes when advanced biomechanical equipment is unavailable. Identification of risk of ACL injury allows for potential implementation of injury prevention training.

Can a Field Based Neuromuscular Test Determine Readiness to Train in Female Team Sport Athletes?

Joel Prowting, Nick Hodgson, Rebecca Larson, Christopher Black, FACSM, Jason Campbell. *University of Oklahoma, Norman, OK.* (Sponsor: Christopher Black, FACSM)

Email: joel.prowting@ou.edu

(No relevant relationships reported)

Purpose: To determine if a field-based neuromuscular test (Counter Movement Jump (CMJ)) could accurately detect EIMD-related performance decrements incurred by repeated sprinting in female team sport athletes. **Methods:** 10 female athletes (Age: 21.7 ± 2.5 y) performed an eccentrically-biased, repeated sprint protocol consisting of 5 sets of 8 maximal sprint (MS) trials (20m in length, 5m deceleration zones). Participants then immediately performed three CMJs on a force plate (FD4000, NMP ForceDecks Ltd, UK) to assess fatigue before beginning the next set of 8 sprints. Blood lactate and RPE were assessed following the completion of the sprint protocol. After 24-48h, participants returned to complete soreness ratings, 3 CMJs and 3 MSs. This process was completed 4 times (each "Trial" = 1 repeated sprint protocol visit + 1 24-28h follow up visit). **Results:** A number of CMJ metrics were significantly lower ($p < 0.05$) when measured during the 24-48h follow up visits, however the only one that was consistently lower across all 4 trials was concentric RFD (N/s/kg) (Pre v 24-48h post: Trial 1 = 36.03 ± 16.81 v 20.64 ± 13.49 ; Trial 2 = 49.37 ± 32.29 v 29.44 ± 21.87 ; Trial 3 = 50.45 ± 40.86 v 27.59 ± 24.43 ; Trial 4 = 43.87 ± 32.37 v 31.01 ± 29.41). No significant differences ($p > 0.05$) were found for peak or average velocity during the MSs across any trial. Lower body soreness was significantly greater ($p < 0.05$) during the 24-48h follow up visits as assessed via a 0-10 visual analogue scale. The sprint protocol induced a high internal physiological load, evidenced by significantly elevated post-exercise blood lactate levels (pre: 1.51 ± 0.50 vs post: 5.6 ± 2.53). **Conclusion:** Concentric RFD determined using a CMJ was the best metric for detecting performance impairments, as it consistently declined 24-48h after completing a repeated sprint protocol. The other CMJ metrics, as well as MS performance did not decrease across all trials. A CMJ test that assesses concentric RFD may be a useful tool for coaches to determine readiness to train in female athletes. Future research should seek to replicate this protocol using higher sprinting volumes, to determine whether concentric RFD declines in a predictable dose-response manner. Limitations of this study were the small sample size and the lack of control for external damaging activity (i.e. rugby training).

Predict Failure: Muscle Oxygen Dynamics In Elite Climbers During Finger Hang Tests

Andri Feldmann, Daniel Erlacher, Sandro Pfister. *University of Bern, Bern, Switzerland.*

Email: andri.feldmann@ispw.unibe.ch

Reported Relationships: A. Feldmann: Salary; Part-Time employment in development. Industry contracted research; private industry contribution. Ownership/interest/stock; own stocks.

Introduction: Failure in elite sport climbing is associated with an inability to maintain isometric muscle contraction. The ability to supply and utilise oxygen is the primary bioenergetic contributor to muscle contraction and can be examined locally using near-infrared spectroscopy (NIRS). Examining changes in NIRS derived muscle oxygenation (SmO_2) have shown to be related to changes in performance output during gripping exercises. Purpose: The aim of this study is to measure SmO_2 dynamics in a climbing specific test until task failure in varying conditions. Our prediction is that SmO_2 should be a good marker to predict task failure. Methods: Eight elite level climbers performed a finger-hang test with four different intensities maintaining grip until voluntary exhaustion. During each trial SmO_2 and time to failure (TTF) were measured. TTF was then compared to the minimally attainable value of SmO_2 (SmO_{2min}) and time to SmO_{2min} (TTmin). Results: Two-one-sided tests (TOST) resulted in SmO_{2min} equivalence for the high intensity conditions ($M_1 = 21.9\%$ $SD_1 = 5.0\%$; $M_2 = 25.4\%$; $SD_2 = 6.5\%$; $M_3 = 24.1\%$; $SD_3 = 5.9\%$), $t(7) = 2.72$, $p = 0.015$; $t(7) = 3.85$, $p = 0.003$, but failed to show equality for the fourth and lowest intensity condition ($M_4 = 32.4\%$, $SD_4 = 8.8\%$), $t(7) = -1.01$, $p = 0.173$. Equivalence was also found between TTF and TTmin for the high intensity conditions. Conclusion: The duration with which oxygen is extracted and utilised changes, while the attainable SmO_{2min} remains constant at high intensity conditions and is related to the ability to maintain task performance.

Prediction Of 1rm Bench Press From Repetitions To Fatigue In Untrained, Trained, And Athletic Men
 Jerry L. Mayhew¹, William F. Brechue, FACSM², Richard M. Schumacher¹, Monica L. Hunter¹, Jana L. Arabas¹, Bryan Mann³.
¹Truman State University, Kirksville, MO. ²A. T. Still University, Kirksville, MO. ³Miami University, Miami, FL.
 Email: jmayhew@truman.edu
 (No relevant relationships reported)

Numerous prediction equations have been developed to estimate one-repetition maximum (1RM) bench press in various subject populations. While many of these equations have been validated on various groups, rarely have groups of various levels of training been combined to evaluate the accuracy of separate and combined equations developed on participants of differing strength levels and training backgrounds.

PURPOSE: To produce and evaluate 1RM bench press prediction equations developed on untrained, trained, and athletic men. **METHODS:** Untrained college men (UT, n = 166), resistance-trained college men (RT, n = 170), and college athletes (ATH, n = 179) were measured for 1-RM bench press and repetitions-to-fatigue (RTF) on separate days. RT men had trained 3 days/wk for 12 wks using a linear periodization program. ATH had trained for several years using either linear periodization or autoregulatory progressive resistance training. Linear regression equations were generated on validation samples of each group (UT = 119, TR = 120, ATH = 131) using a weight (RepWt) that produced between 2 and 10 RTF. **RESULTS:** All 3 groups differed significantly in 1RM (UT = 74.1 ± 15.5 kg, RT = 88.8 ± 21.7 kg, ATH = 136.2 ± 21.8 kg) but not in % 1RM used for RTF (UT = 83.4% ± 7.4%, RT = 83.0% ± 5.5%, ATH = 83.4% ± 6.0%). Despite the nonsignificant difference in %1RM, ATH (6.7 ± 2.4) produced significantly more RTF than UT and RT men (6.1 ± 2.2 and 6.0 ± 2.1, respectively). Multiple correlations and standard errors of estimate (SEE) for group equations were similar for UT (R = 0.94, SEE = 5.7 kg), RT (R = 0.97, SEE = 5.3 kg), and ATH (R = 0.96, SEE = 6.1 kg). A global equation compiling all 3 groups had comparable results [1RM (kg) = 1.16 RepWt (kg) + 2.07 RTF - 9.4, R = 0.98, SEE = 6.2 kg]. Cross-validation of each equation on 25% randomly selected subsamples accurately predicted 89%-96% of each group within ±10% of actual 1RM. The global equation predicted slightly better in RT (94%) and ATH (96%) than in UT (87%). **CONCLUSIONS:** A newly developed global prediction equation appears to have acceptable accuracy for estimate 1RM bench press in men with varying resistance training backgrounds.

Lower Limb Kinematic Assessment to Predict Water Polo Performance
 Cameron A. Williams, J. Mark VanNess, Joey Rossi, John Mayberry, Courtney D. Jensen. *University of the Pacific, Stockton, CA.*
 Email: c_williams29@u.pacific.edu
 (No relevant relationships reported)

Water polo requires leg muscle biosequencing that is different from weight bearing sports. The kinematics and forcefulness for each player could be optimized for different positions and help predict player success. Comparing vertical jump with kinematic biosequencing, and comparing each with athletic performance, may enhance training assessments. **PURPOSE:** To test the effect of vertical jump and Sparta Science force plate technology outputs on in-season performance of women's water polo players. **METHODS:** 14 Division 1 women's water polo players were evaluated during two consecutive seasons: 2015-2016 and 2016-2017. Statistics tabulated for each season were: Games played, shots, goals, shooting percentage, assists, steals, exclusions (EX), and exclusions drawn (DEX). All players were tested for vertical jump once a week during conditioning prior to resistance training using Sparta force plate and proprietary outputs, which calculated "Load" (rate of eccentric force), "Explode" (power generation during concentric force output), and "Drive" (neural impulse on timing and range of motion). Linear regression tested Sparta data on in-season performance outcomes. **RESULTS:** Athletes weighed 70.2 ± 8.6 kg, had a vertical jump of 30.7 ± 4.3 cm and Sparta Load of 45.4 ± 6.2, Explode of 34.8 ± 4.1, and Drive of 65.3 ± 10.0. On average, throughout each season, the athletes played 29.5 ± 6.3 games, took 92.7 ± 61.5 shots, scored 31.3 ± 8.1% of shots taken, had 24.3 ± 12.5 steals, and 16.4 ± 14.4 assists. Vertical jump predicted a higher shooting percentage ($\beta=0.010$; $p<0.001$), more steals ($\beta=0.820$; $p=0.043$), fewer assists ($\beta=-1.324$; $p=0.005$), and fewer EX ($\beta=-1.466$; $p<0.001$). Load predicted a lower shooting percentage ($\beta=-0.003$; $p=0.001$) and more EX ($\beta=0.284$; $p<0.001$) and DEX ($\beta=0.219$; $p=0.002$). Explode predicted a higher shooting percentage ($\beta=0.003$; $p=0.009$), more steals ($\beta=0.642$; $p<0.001$), and lower EX ($\beta=-0.454$; $p<0.001$). Drive predicted a higher shooting percentage ($\beta=0.002$; $p<0.001$), fewer assists ($\beta=-0.221$; $p=0.007$), lower EX ($\beta=-0.099$; $p=0.017$), and higher DEX ($\beta=0.107$; $p=0.017$). **CONCLUSION:** These findings indicate that both vertical jump and force plate biosequencing data may be useful predictors of water polo performance and could be employed to identify athletic capacities that need improvement.

Use of Traditional and Modified Functional Movement Screening to Predict Balance with Military Load

Eric M. Scudamore¹, Sandra L. Stevens², Dana K. Fuller², John M. Coons², Don W. Morgan², FACSM

¹Arkansas State University, Jonesboro, AR; ²Middle Tennessee State University, Murfreesboro, TN

PURPOSE: To determine if Functional Movement Screen (FMS) or modified Functional Movement Screen (mFMS) item scores predict dynamic balance scores of potential military recruits who wore a 24.2 kg military load. **METHODS:** Thirty physically-active males and females who displayed anthropometric and physical fitness characteristics typical of military recruits entering basic training completed FMS and mFMS. Torso-loaded balance was assessed as loaded composite reach distance (LCR) and loaded overall stability indices (LOSI) measured using the Y Balance test and Biodex Balance System, respectively. **RESULTS:** FMS composite scores exhibited the strongest relationship with LCR and participants with higher FMS composite scores (≥ 15) displayed higher LCR values compared to those with lower FMS composite scores (≤ 14). Analysis of FMS subscores using penalized regression indicated that an in-line lunge score of 1 predicted a shorter LCR (Coef for score of 2 = 6.86 (95% CI = 2.88, 10.93)); Coef for score of 3 = 8.36 (95% CI = 3.96, 13.70)) and a shoulder mobility score of 3 predicted better LOSI (Coef = -2.38 (95% CI = -3.56, -0.57)). Loaded shoulder mobility (Coef = -2.11 (95% CI = -4.12, -0.26)) and trunk stability push-up (95% CI = Coef = 1.61 (0.08, 3.13) scores of 3 also predicted better and worse LOSI, respectively. **CONCLUSION:** The in-line lunge item score from the FMS may be the best predictor of torso-loaded balance and the FMS may be more appropriate than items from a torso-loaded FMS battery in predicting torso-loaded balance in military recruits. Use of the FMS by clinicians may aid in mitigating musculoskeletal injuries in service members, thus minimizing losses that contribute to decreased military readiness.

A Fitness Field Test to Predict VO₂max in Female Collegiate Field Hockey Players
 Jennifer Morton, Ian Klein. *Ohio University, Athens, OH.*
 (No relevant relationships reported)

Field hockey is a competitive sport requiring aerobic fitness. The gold standard method for determining aerobic fitness is a maximal oxygen consumption (VO₂max) test performed in a laboratory on a motorized treadmill (LAB) by a trained professional. The 30-15-intermittent fitness test (FIELD) is a new maximal effort running test designed to predict VO₂max on the field relative to a traditional treadmill graded exercise test (GXT).

PURPOSE: To compare the predicted VO₂max using the 30-15-intermittent FIELD test to the measured VO₂max LAB test in collegiate female field hockey players. **METHODS:** Nine (N=9) experienced female collegiate field hockey players (mean age=19.78±1.56 y, field hockey experience=8.80±2.49 y) were classified as healthy via a health assessment consisting of height, weight, and body fat (BF%). Each participant completed a LAB GXT test in a temperature-controlled laboratory using a metabolic cart and motorized treadmill, followed by the FIELD test a month later on a standardized turf field as a group under the same conditions. The FIELD test consists of a series of 30 second shuttle runs with 15 second intermittent walking breaks with an increase in speed every shuttle run of 0.5 km/h. The FIELD test uses an equation to predict VO₂max. Both tests were completed to exhaustion. All results are reported as mean±SD. Statistical significance was accepted at $\alpha=0.05$. Paired *t*-tests ($\alpha=0.05$) were utilized to compare means between groups. **RESULTS:** There was no significant difference between predicted VO₂max (FIELD 46.15±3.22 mL/kg/min) and measured VO₂max (LAB 48.68±6.94 mL/kg/min) ($p=0.102$). The percent difference between the LAB test and FIELD test averages was -4.25±8.37. There was a significantly greater percentage difference between the most fit participants (n=4) (-11.23±5.84) compared to the least fit participants (n=4) (+2.46±5.21) ($p=0.011$). **CONCLUSION:** The predicted VO₂max values using the FIELD test were similar as compared to the measured LAB test. However, greater percentage differences were seen in higher fit athletes. Coaches and athletes should consider the 30-15 intermittent field test as a potentially inexpensive and time efficient test for predicting VO₂max in a large group.

Prediction of Lower Extremity Injuries from Vertical Jump Kinetic Data in Collegiate Athletes
 Marisa Pontillo, Brian Sennett. *University of Pennsylvania Health System, Philadelphia, PA.*
 Email: marisa.pontillo@uphs.upenn.edu
 (No relevant relationships reported)

Purpose: The vertical jump provides critical kinetic information regarding athletic performance, and can be quantified by the force-time (F-T curve) with defined phases of movement. Alterations in the efficiency of mechanisms used for force production could potentially lead to abnormal force dissipation and resultant injury. The purpose of this study was to identify which force plate variables from a vertical jump task could identify collegiate athletes who sustained a lower extremity injury. **Methods:** Vertical jump testing using a force plate with dedicated software (SpartaTrac system) was performed by all healthy varsity collegiate athletes at several intervals throughout the athletic year over 3 academic years. The testing procedure consisted of each subject performing a series of 6 consecutive vertical jumps. Injuries were documented by the team athletic trainers and verified with the health care organization's electronic medical documentation system. Injuries were defined as occurring no more than 60 days after a jump and defined as lower extremity by SICCS 10 code. 234 lower extremity injuries were identified. Subjects were matched by age, sex and sport. Vertical jump variables used were load, explode and drive, operationally defined as the average eccentric rate of force development, average concentric force, and concentric impulse, respectively. Logistic regression was used to determine if the battery of variables could predict whether or not an athlete would sustain a lower extremity injury. Additionally, athletes who sustained an ACL injury were identified, matched, and analyzed correspondingly. **Results:** Load, explode, and drive, when entered into the regression equation, showed the ability to predict lower extremity injury, $\chi^2=14.6$, $df=4$, $P<0.01$; with explode independently showing significant prediction at $P=0.02$. Load, explode, and drive also showed the ability to predict ACL injury, $\chi^2=13.92$, $df=3$, $P<0.01$, with load and explode independently showing significant prediction at $P<0.05$. **Conclusion:** The force plate variables collected from vertical jumps were able to identify athletes who sustained a lower extremity injury. Additionally, these variables were able to identify athletes who sustained an ACL injury.

Validation Of A Cycle Ergometer Protocol In The Prediction Of $\dot{V}O_2$
 Alyssa A. Feher, Ashley L. Heffelfinger, Cassidy A. Barrett, Emily A. DeDonna, Alissa Rusbarsky. *Cedar Crest College, Allentown, PA.* (Sponsor: Michael D. Brown, FACSM)
 (No relevant relationships reported)

Protocols for the prediction of maximal oxygen uptake ($\dot{V}O_{2max}$) on a cycle ergometer have been criticized for either being too long or aggressive for individuals of variable fitness and/or disease status. Current protocols typically increase workload by adding resistance to the flywheel at a fixed RPM. Increases in RPM rather than resistance later in the test may provide increased physiological efficiency, yielding a more valid prediction of $\dot{V}O_{2max}$. **Purpose:** The purpose of this study was to design and validate a novel $\dot{V}O_{2max}$ cycle ergometer protocol using workload increments based on the subject's predicted heart rate reserve (HRR) in order to individualize the test protocol while adhering to well-documented $\dot{V}O_{2max}$ testing principles. **Methods:** Subjects included 12 females (20-27 y/o) who performed a $\dot{V}O_{2max}$ test using the new cycle ergometer protocol. Prior to testing, seat height on a Monark cycle ergometer was standardized with a 5-10 degree knee bend in the pedal-down position with the sole of the foot parallel to the floor. $\dot{V}O_2$, blood pressure, rating of perceived exertion (RPE), and heart rate using ECG were measured at rest and throughout the cycle ergometer exercise test, as well as the assessment of signs and symptoms. Workload increases were based on pre-determined Incremental Target Heart Rates (ITHR) using HRR. Stages commenced at a workload of 150 kgm/min (0.5 kg; 50 RPM) and were increased every 2 minutes by adding 0.5 kg or 1.0 kg resistance based on achievement of ITHR for each stage. When an ITHR representing $\geq 60\%$ HRR was achieved, workloads were increased by 10 RPM for each subsequent stage. Exercise tests were terminated when the subject could not maintain RPM or reached volitional exhaustion. Correlation between predicted (ACSM cycle equation) and measured $\dot{V}O_{2max}$ at peak workload was examined using Pearson's r . **Results:** The range for measured $\dot{V}O_{2max}$ was 20.7 - 37.4 mL/kg/min and 23.29 - 37.57 mL/kg/min for predicted $\dot{V}O_{2max}$. There was a statistically significant correlation between predicted and measured $\dot{V}O_{2max}$ ($r=0.894$; $p<0.001$). **Conclusion:** This novel cycle ergometer protocol was demonstrated to be a valid predictor of $\dot{V}O_{2max}$ for the population tested. Further testing on other diverse populations is warranted.

Can A Simple Transfer Task Predict Lower-extremity Physical Function As Measured By Standardized Clinical Measures?
 Rachel Salyer¹, Ginny Frederick¹, Rachele Reed¹, Alison Berg¹, Chad Straight², Anne Brady³, Lauren Higgins³, Ellen Evans, FACSM¹. ¹The University of Georgia, Athens, GA. ²University of Massachusetts, Amherst, MA. ³University of North Carolina Greensboro, Greensboro, NC. (Sponsor: Ellen Evans, FACSM)
 Email: res69159@uga.edu
 (No relevant relationships reported)

PURPOSE: Lower-extremity physical function (LEPF) is associated with health outcomes such as risk for falling, physical disability, and mortality in older adults. Due to increasing evidence of disability onset occurring earlier in the lifespan, expanding assessment of functional status in middle-age adults is of growing importance. Furthermore, administering many of the current standardized objective tests (i.e. 6-Minute Walk Test, Timed Up and Go, and 30-second Chair Stand tests) in clinical settings is not feasible due to limited time, space, and equipment. Identifying simple, cost-effective assessments to evaluate LEPF status is paramount due to the potential for clinical application. Thus, this study aimed to evaluate if a simple transfer task could predict LEPF in middle-age and older adults. **METHODS:** Middle-age and older adults ($n=230$, 17% male; 52-89 yo; 29.1 ± 5.8 kg/m²) completed a transfer task (TRANSFER). This required them to start in a standing position, and without the use of assistive devices, sit on the floor, and return to a standing position as quickly as possible. LEPF was calculated using a composite Z-score based on scores from conventional and standardized 6-Minute Walk Test, Timed Up and Go, and 30-second Chair Stand tests. **RESULTS:** Bivariate correlations revealed that TRANSFER was associated with age ($r=0.27$, $p<0.01$), comorbidities ($r=0.33$, $p<0.01$), and BMI ($r=0.28$, $p<0.01$). Using linear regression analyses, TRANSFER was a significant predictor of LEPF Z-score (standardized $\beta=-0.73$, $p<0.01$) independently accounting for 39.6% of the variance after adjustment for covariates. **CONCLUSION:** Our results suggest that the ability to lower oneself to the ground and return to a standing position is a significant indicator of LEPF in middle-age and older adults. Further study is warranted to determine the clinical relevance of this simplified evaluation of LEPF and its ability to predict falls, physical disability, and mortality.

The Association Between Step Frequency Test, Sprint And Agility Performance
 Terje Dalen, Truls V. Roaas, Håvard Lorås, Morten A. Aune, Tore K. Aune. *Nord University, Levanger, Norway.*
 Email: terje.dalen@nord.no
 (No relevant relationships reported)

A variety of training methods have been described in the literature to improve speed and agility. Step frequency, which is the rate at which steps can be reproduced, is one of the traditional step kinematic measure used to describe running technique. Previous research has illustrated the importance for faster acceleration (Murphy, Lockie, & Coutts, 2003). This has led athletes to investigate time in different step frequency training (i.e. ladder training) in order to gain increase in sprint or acceleration performance. **PURPOSE:** The purpose of this study was to investigate the association between two different step frequency test, sprinting and agility performance in sport science students. In addition, we aimed to investigate any gender differences in the association between variables. **METHODS:** The present study used a correlational research design in order to investigate the association between step frequency test (anterior-posterior and medial-lateral), agility test (5+5 meter) and 20-meter sprinting performance. Twenty-one male (height 181.1 cm, mass 79.6 kg) and seventeen female students (height 169.9 cm, mass 68.9 kg) sport science were included as subjects in the study. All subjects performed two different step frequency tests (anterior-posterior and medial-lateral), one agility test and a 20-meter sprint test. Pearson's correlation analysis were used in order to investigate the association between step frequency and sprint and agility performance. **RESULTS:** Overall, modest correlations between step frequency (anterior-posterior and medial-lateral) and sprint performance ($r=0.36$ and $r=0.42$, respectively ($p<0.05$)). In addition, this study found correlation between agility test and sprint test ($r=0.53$, ($p<0.001$)). No correlation were found between either of the step frequency tests and the agility test (5+5 meter). **CONCLUSIONS:** This study found modest association between step frequency tests and 20-meter sprint performance in sport science students. The fact that no association was found between step frequency tests and the agility test makes it difficult to conclude any relationship between step frequency test performance and acceleration performance.

Do Physical Activity Behaviors Predict Fitness Gains To An Aerobic Exercise Trial?

Ryan J. Dougherty¹, Elizabeth A. Boots², Ozioma C. Okonkwo¹, Dane B. Cook, FACSM¹. ¹University of Wisconsin - Madison, Madison, WI. ²University of Illinois at Chicago, Chicago, IL. (Sponsor: Dane B. Cook, FACSM)

(No relevant relationships reported)

PURPOSE: Investigate whether baseline physical activity behaviors predict aerobic fitness adaptations following an individualized structured exercise intervention in an older adult population.

METHODS: Twenty-four cognitively healthy adults (age=64.8±4.6 years) from the Wisconsin Registry for Alzheimer's Prevention participated in this study. Subjects were randomized to an individualized 6-month treadmill training program (3x week; 70-80% heart rate reserve) or a control group. Baseline and post-intervention measurements included a maximal exercise test and 7 days of physical activity monitoring via accelerometry. Aerobic fitness was defined as the highest oxygen consumption (VO_{2peak} , ml/kg/min) value recorded during the exercise test and physical activity was defined as total minutes spent in moderate-vigorous physical activity. A repeated measure ANOVA design, adjusted for age, gender, APOE status, and BMI was used to examine changes in fitness. Bivariate Pearson correlations were used to investigate 1) the relationship between baseline physical activity and baseline fitness across the entire group (n=24) and 2) baseline physical activity and changes in fitness ($\% VO_{2peak}$) within participants randomized to the exercise intervention (n=12).

RESULTS: For the entire sample, baseline physical activity was significantly and positively associated with baseline fitness ($r = .452$; $p = .026$). Demonstrating the effectiveness of our trial we observed a significant group by time interaction for fitness ($p = .018$; $\eta^2_p = .260$), participants randomized to aerobic exercise displayed on average, a 17.5% increase in their fitness level. This observed fitness adaptation was weakly associated to baseline physical activity behaviors ($r = .25$).

CONCLUSIONS: Six-months of aerobic exercise training significantly improved fitness levels in our older adult population. As expected, baseline physical activity and fitness were positively associated. However, baseline physical activity did not predict aerobic fitness gains to a structured exercise training program. Future exercise trials with larger sample sizes are needed to determine whether it is necessary to recruit inactive participants.

Body Composition Assessment Does Not Improve Prediction of VO_{2max} Using a Yo-Yo Intermittent Shuttle Test

Sherry Barkley, FACSM, Brooke Bleeker. Augustana University, Sioux Falls, SD.

Email: sherry.barkley@augie.edu

(No relevant relationships reported)

The gold standard for determining aerobic fitness is VO_{2max} testing, a time-consuming test which requires expensive equipment. The Yo-Yo Intermittent shuttle test is a field test purported to provide a more soccer-specific estimate of aerobic fitness, but its validity varies with the population being tested.

PURPOSE: To determine whether the addition of anthropometric measures and body composition data would strengthen the predictability of the Original Yo-Yo (YYO) test for estimating VO_{2max} for collegiate women soccer players.

METHODS: Division II female soccer players who completed fitness assessments as part of their normal pre-season evaluation were invited to participate. Thirty-one women (18-23 yrs) consented and 29 completed assessments. Fitness assessments were conducted during fall camp on a rest day. Measures of height, weight, waist circumference, and sum of 7 skinfolds were collected by a trained investigator; body fat percentage was estimated with the Bod Pod; VO_{2max} was measured on a motor driven treadmill with gas analysis using a ParvoMedics TrueOne metabolic system. The Yo-Yo test was performed as a group two days later. Regression analysis was used to determine which variables impacted the prediction equation, and correlation analysis was used to compare the original (YYO) and revised (YYR) Yo-Yo formulas against measured VO_{2max} .

RESULTS: Analysis showed that the Yo-Yo distance ($p = .00075$) but not anthropometrics and body composition ($p > 0.05$) significantly impacted the VO_{2max} prediction resulting in the following YYR formula: $VO_{2max} = (0.00574 \times \text{Yo-Yo distance (m)}) + 30.952$. Measured VO_{2max} (45.2 ± 1.1 ml/kg/min) was correlated with predicted VO_{2max} from YYR ($45.4 \pm .67$ ml/kg/min, $r = .58$) and YYO ($57.6 \pm .98$ ml/kg/min, $r = .58$).

CONCLUSION: The addition of body composition variables did not strengthen the ability of the Yo-Yo Intermittent shuttle test to accurately predict VO_{2max} in women soccer players.

Ability Of Oddvar-holton Diagram To Predict Repetitions Achieved At 60% And 80% Loads In Females.

Peter M. Magyari, FACSM¹, Caleb Williams², Jeff T. Wight³, Mike Anton⁴. ¹University of North Florida, Jacksonville, FL. ²LaGrange College, LaGrange, GA. ³Jacksonville University, Jacksonville, FL. ⁴Airrostri Rehab Centers, San Antonio, TX.

(No relevant relationships reported)

To determine the appropriate load for resistance training (RT), exercise professionals (EPs) commonly have clients complete one repetition maximum (1RM) testing. Then, submaximal loads can be easily estimated for RT sessions and expected repetitions can be determined utilizing published prediction tables. **PURPOSE:** To determine the ability of Oddvar Holton (OH) diagram to accurately predict repetitions achieved at 60% and 80% loads in female lifters. **METHODS:** Participants were 19 college-aged (25 ± 4.3 years) females with a minimum of 2 months RT experience (average experience 76 ± 42 months). Three exercise sessions were completed under the supervision of certified EPs. For session one, 1RM testing was completed. For sessions two and three, participants completed as many reps as possible for 60% 1RM or 80% 1RM (load and order was randomized) for 8 cam-mediated variable resistance training exercises (bench press, leg press, shoulder press, pull-down, knee extension, knee flexion, elbow extension, and elbow flexion). First, for all 8 exercises, an error-score was calculated (for each individual) by comparing the actual number of repetitions completed to the OH 1RM prediction diagram. The OH predicted values for 80% 1RM and 60% 1RM were 11 reps and 30 reps, respectively. Then, for each exercise, the overall error score was calculated (mean error for all 19 subjects). A t-test was utilized to determine differences in mean error score between loads. **RESULTS:** For most exercises, the repetitions achieved deviated substantially from the expected repetitions (14 of 16 exercises deviated by 3+ repetitions). These findings were most extreme at lower loads: 60% load error scores (11.9 ± 2.7 reps) were significantly greater ($p < 0.01$) than 80% loads error scores (3.9 ± 1.4 reps). **Conclusion:** Considerable variability exists among females in the repetitions achieved versus the repetitions predicted by OH. In all exercises, greater deviations from expected values occurred at lower loads.

Maximal Oxygen Consumption Prediction Equation For Athletes Undergoing Cardiopulmonary Exercise Testing On A Treadmill Ramp Protocol

Rodrigo P. Silva¹, Camila Duarte², Cássia Campi², Alan Barbosa¹, Bárbara Gonze¹, Evandro Sperandio¹, Marcello Romiti³, Antônio Gagliardi³, Rodolfo Arantes³, Victor Dourado¹. ¹Federal University of São Paulo (UNIFESP), Santos, Brazil. ²Metropolitan University of Santos (UNIMES), Santos, Brazil. ³Angiocorpore Institute of Cardiovascular Medicine, Santos, Brazil.

(No relevant relationships reported)

PURPOSE: To develop an equation for predicting VO_{2max} in athletes submitted to cardiopulmonary exercise test (CPT) using a treadmill ramp protocol. Secondly, we evaluated the influence of the use of supplements on VO_{2max} .

METHODS: 77 athletes were evaluated in a cross-sectional design. 65 percent of them were men (34.7 ± 7.9 years, BMI 24.7 ± 3.3) and 35 percent were women (36.8 ± 11.1 years, BMI 22.7 ± 2.5). The sample consisted of 66 percent of athletes practicing endurance sports, of which 55 percent were runners or triathletes. After participants answered an inquiry about the use of dietary supplements, time of practice and the weekly training volume, they underwent anthropometric evaluation, spirometry and CPT. CPT was performed on a treadmill using ramp protocol, where increments in speed and incline were empirically individualized. At least 14 mL/min/kg were added to the VO_{2max} estimate of active performers so that the test lasted 10 minutes on average. Following univariate analysis, we evaluated the predictors of VO_{2max} using stepwise multiple linear regression analysis.

RESULTS: BCAA (39 percent), creatine (13 percent) and whey protein (43 percent) were the most frequent responses in the survey about the use of supplements. VO_{2max} was 51.8 ± 9.2 and 44.1 ± 7.5 mL/min/kg for men and women respectively. In the univariate analysis significant correlations were found ($p < 0.05$) between VO_{2max} and age, sex, BMI, practice time, endurance sport modality, running practice, use of BCAA, use of creatine and use of supplements in general. In the multivariate model, running practice, age, BMI, sex, weekly training volume and supplement use in general together accounted for 68.4 percent of total VO_{2max} variability. The equation was: $VO_{2max} \text{ (ml/min/kg)} = 84.78 + (5.53 \times \text{running}) - (0.39 \times \text{age}) - (1.42 \times \text{BMI}) + (8.05 \times \text{sex}) + (0.21 \times \text{training volume}) + (2.95 \times \text{use of supplements})$.

CONCLUSIONS: The developed equation allows for individualized assessment of athletes using ramp warm-up protocol, as well as exploring dynamic physiological variables that are not properly evaluated in traditional staggered protocols.

3466 Board #154 June 1 9:30 AM - 11:00 AM

Predicting Metabolic Costs Of Heavy BackpackingDavid P. Looney, Peter N. Frykman, Laurie A. Blanchard, Christopher R. Chalmers, Eric O. Hansen, Everett A. Harman, Holly L. McClung, Scott J. Montain, FACSM, Adam W. Potter, William R. Santee. *USARIEM, Natick, MA.* (Sponsor: Dr. Scott J. Montain, FACSM)*(No relevant relationships reported)*

The US Army Load Carriage Decision Aid (LCDA) is a planning tool composed of biomedical models that predict Warfighter physiological responses during dismantled operations. The LCDA's metabolic model requires new equations to accurately predict the added metabolic cost of carrying varying types and amounts of military equipment. **Purpose:** Develop an equation for the LCDA metabolic model that better predicts the metabolic costs of carrying backpack loads.

Methods: Thirteen studies in which volunteers walked while carrying heavy pack loads were obtained for analysis. Treadmill speeds ranged between 1.1 - 1.8 m·s⁻¹ with maximum pack loads exceeding 55% body mass. We used k-fold cross-validation to test how well the new model generalized to new data. Equivalence of predicted and measured metabolic rates was tested using the two one-sided t-test (TOST). We compared the new backpacking equation's accuracy against the LCDA graded walking equation using the Concordance Correlation Coefficient (CCC).

Results: Predictions from the LCDA metabolic model were statistically equivalent to metabolic rates measurements during each step of the k-fold cross-validation ($p < 0.05$). Predictions from the new backpacking equation had a much higher correlation with measured energy expenditures (CCC, 0.93) than the existing LCDA graded walking equation (CCC, 0.44). The median absolute error was considerably lower for the backpacking equation (0.46 ± 0.36 W·kg⁻¹) versus the existing LCDA graded walking equation (1.61 ± 1.32 W·kg⁻¹).

Conclusions: The LCDA metabolic model accurately predicts the metabolic costs of backpacking. Military mission planners, backpackers, and trail walker can rely on improved guidance from the LCDA metabolic model for training, nutritional intake, and heat injury prevention.

The views expressed in this abstract are those of the authors and do not reflect the official policy of the Department of Army, Department of Defense, or the U.S. Government.

Accuracy Of Indirect Calorimetry And Predictive Equations For The Measurement Of Resting Metabolic RateJason D. Waggoner. *Southeast Missouri State University, Cape Girardeau, MO.* (Sponsor: Thomas J. Pujol, FACSM)
Email: jwaggoner@semo.edu*(No relevant relationships reported)*

Indirect calorimetry is used to measure oxygen consumption for estimating resting metabolic rate (RMR). Laboratory devices are available for the measurement of RMR, such as the BodyGem[®] indirect calorimeter and the Vacumed VO₂ Lab metabolic measuring system. Established prediction equations, such as the Mifflin-St. Jeor (MSJ), Harris-Benedict (HB), and Fleisch, can also be used to provide an estimate of RMR.

PURPOSE: The purpose of this study was to compare the RMR of college-aged participants measured using a BodyGem[®] indirect calorimeter, a Vacumed VO₂ Lab metabolic cart, and established prediction equations. **METHODS:** Each participant (male = 15; female = 15; age = 22.7 ± 3.3 yrs; wt = 77.5 ± 14.5 kg; ht = 173.5 ± 9.6 cm) completed a thirty-minute supine resting session in a quiet environment. Five minutes of resting data were then collected using the Vacumed while in the supine position. Immediately thereafter, five minutes of resting data was collected using the BodyGem[®] indirect calorimeter while in the seated position. The RMR values for the HB and Fleisch prediction equations were calculated using the proprietary software utilized by the Vacumed metabolic system, while the MSJ estimate of RMR was hand-calculated. **RESULTS:** A repeated measures ANOVA showed a significant difference among the measurement methods (BodyGem[®] = 1995.0 ± 540.5 kcal; Vacumed = 1520.9 ± 452.5 kcal; MSJ = 1669.3 ± 242.9 kcal; HB = 1749.0 ± 275.1 kcal; Fleisch = 1690.3 ± 220.7 kcal) ($p < 0.001$). A Post hoc paired samples t-test indicated RMR measured using the BodyGem[®] was significantly higher than the Vacumed, HB, Fleisch, and MSJ ($p < 0.01$). The HB estimation of RMR was greater than that of the Vacumed measurement ($p < 0.025$). For the equations, the RMR estimate of the Fleisch was higher than the MSJ ($p < 0.025$), while the HB was greater than both the Fleisch and the MSJ ($p < 0.01$). **CONCLUSION:** The Vacumed VO₂ Lab metabolic cart measured RMR closer to the prediction equation estimates compared to the BodyGem[®] indirect calorimeter. Further research needs to be conducted comparing laboratory instruments to established prediction equations, on various populations, before those methods can be deemed accurate for measuring RMR.

Effects Of A Pre-season Intervention On Hydration In Female Collegiate Volleyball AthletesAlyssa M. Pollard-McGrandy¹, Brian C. Rider², Adam M. Coughlin¹. ¹*Saginaw Valley State University, University Center, MI.* ²*Hope College, Holland, MI.* (Sponsor: Tamara Hew-Butler, FACSM)*(No relevant relationships reported)*

Urine specific gravity (USG) is commonly utilized to assess hydration status. Athletic performance has been shown to be affected by hydration status. In addition to nutritional and hydration practices, environmental conditions can also influence hydration status. Therefore, healthcare professionals should also consider environment, both indoor and outdoor, when assessing hydration. **PURPOSE:** To compare base-line USG to season-long urine collections following a one-time, pre-season hydration intervention. **METHODS:** Fourteen NCAA Division II female collegiate volleyball athletes participated in this study. Urine was collected in sterile cups in the hours preceding either a game or practice. Collections were roughly two weeks apart, starting August 25th and ending November 4th, 2017, resulting in eight total collections. The hydration intervention consisted of information and guidelines presented to the team and coaching staff. The intervention was administered verbally immediately following base-line urine collection. Written guidelines were left with athletes and coaching staff. Urinalysis was conducted via reagent strips. Data was analyzed via SPSS v.22 with an a priori level of 0.05. Subsequent urinalyses were compared to the baseline urinalysis. **RESULTS:** USG statistically decreased from base-line to the second collection and did not statistically differ again until the final three collections (base-line = 1.021±0.008, 1.007±0.003*, 1.015±0.008, 1.013±0.006, 1.020±0.016, 1.014±0.005*, 1.011±0.008*, and 1.013±0.003*, * $p < 0.05$ compared to baseline). **DISCUSSION:** The hydration intervention illustrated a short-term effect on USG. A correlation between USG and environmental temperatures was evaluated post hoc for the final six urine collections, arguably when the effects of the intervention had subsided. The coefficient of determination (r^2) revealed that 35.7% of the difference in USG was due to the environmental temperature, which was statistically significant ($r = 0.597$, $p < 0.05$). **CONCLUSION:** The intervention appeared to have a limited impact on USG. Differences in USG were evident again later in the season (late October to early November). Further analysis demonstrated a statistical influence of cooler temperatures on lower USG near the end of season.

The Effects of Back Squats and Front Squats on Sprint Speed and Vertical Jump within Active IndividualsAfton Staheli Balderree, Mark DeBeliso, FACSM. *Southern Utah University, Cedar City, UT.**(No relevant relationships reported)*

The back squat (BSQ) is among the most popular resistance training (RT) modalities for the purpose of increasing muscular strength and power output. Front squats (FSQ), while not as popular as the BSQ, are arguably another squat modality that may improve muscular strength/power. **PURPOSE:** This study compared the effects of performing the BSQ and FSQ on squat strength, sprint speed, and vertical jump (VJ). **METHODS:** Active individuals both male (n=9, age: 30.6±7.6 yrs, height: 179.1±3.8 cms, mass: 87.8±7.8 kgs) and female (n=16, age: 29.4±6.5 yrs, height: 165.3±5.9 cms, mass: 68.5±10.7 kgs) were separated into two groups via a randomized matched pair design based on initial one repetition maximum (1-RM) squat strength. Both experimental groups employed linear periodization RT protocols differing only in that one group executed the BSQ and the other group performed the FSQ as the lower body exercise. No additional lower body auxiliary movements were performed in the study. The dependent variables (DV's) of VJ, 36.6 m sprint speed, and 1-RM squat strength were collected prior to and following the 6-week RT period. Dependent t-tests were used to compare the DV's from pre to post RT intervention within experimental groups. Independent t-test were used to compare the gain scores for each of the DV's between experimental groups. **RESULTS:** The VJ had a significant improvement from pre to post RT for both the BSQ (pre: 52.9±10.1, post: 56.0±10.9 cm) and FSQ (pre: 47.4±10.9, post: 49.9±12.1 cm) groups ($p < 0.05$). The 36.6 m sprint improved significantly from pre to post RT for both the BSQ (pre: 5.9±0.7, post: 5.6±0.5 sec) and FSQ (pre: 6.3±0.7, post: 5.8±0.6 sec) groups ($p < 0.05$). The squat 1-RMs also improved significantly from pre to post RT for both the BSQ (pre: 100.5±34.2, post: 110.3±36.6 kgs) and FSQ (pre: 77.8±31.0, post: 87.5±29.1 kgs) groups ($p < 0.05$). When comparing gain scores between each group there were no significant differences between the BSQ and FSQ groups for any of the DV's ($p > 0.05$). **CONCLUSION:** Within the parameters of this study, both FSQ and BSQ RT programs improved muscular strength, power and

sprint speed in active individuals. Coaches and active individuals may consider the FSQ and BSQ as interchangeable squat modalities providing squat modality variability within RT protocols.

Impact Forces When Exercising On The Freebouncer™

John Porcari, FACSM, Megan Thiel, Nagmeh Gheidi, Susan Bramwell, Abigail Ryskey, Carl Foster, FACSM. *University of Wisconsin-La Crosse, La Crosse, WI.*
 (No relevant relationships reported)

The Freebouncer™ Fitness and Rehab Machine consists of a spring-loaded platform attached to a metal frame and has characteristics similar to those of a mini-trampoline. The Freebouncer™ purportedly reduced the impact forces on the lower body during an aerobic workout. **PURPOSE:** This study was designed to compare the ground reaction forces (GRF) and loading rate (LR) when subjects exercised on the Freebouncer™ compared to walking and running on a treadmill and double leg-bouncing on a mini-trampoline. **METHODS:** Eighteen volunteers (9 M and 9 F) between 19-28 years of age completed 4 conditions, in random order: walking at 3.0 mph on a motorized treadmill, running at 6.0 mph on a motorized treadmill, double-leg bouncing on a mini-trampoline at 80 jumps/min, and double-leg bouncing on the Freebouncer™ at 60 bounces/min. During all testing plantar forces were collected using Loadsol in-shoe sensors. Data were recorded during the last 10 seconds of each trial, with 5 representative strides being analyzed for GRF and LR. **RESULTS:** The GRF (Freebouncer™ = 564 ± 126.2 , walking = 918 ± 232.5 , mini-trampoline = 1415 ± 353.2 , running = 1668 ± 395.4) and LR (Freebouncer™ = 518 ± 260.2 , walking = 5315 ± 1094.1 , mini-trampoline = 7454 ± 1898.1 , running = 14555 ± 3895.7) when exercising on the Freebouncer™ were significantly lower ($p < .05$) when compared to walking and running on a treadmill and double-leg bouncing on a mini-trampoline. **CONCLUSION:** These findings suggest that the Freebouncer™ is an excellent low-impact option for individuals looking for an alternative aerobic exercise modality compared to more traditional modes of exercise.

Effects of Whole Body Vibration Training on Muscular Strength and Balance Ability of Elderly Men

Li Peng, Jie Zeng, Li Huang. *South-West University, Chongqing, China.* (Sponsor: Weimo Zhu, FACSM)
 (No relevant relationships reported)

PURPOSE: As we age, various functional functions of our body such as muscular strength and balance ability will gradually decline. The decline of muscular strength associated with aging is a major cause of decreased balance ability and gait instability. The purpose of this study was to examine the effects of whole-body vibration training (WBVT) on muscular strength and balance ability of elderly men. **METHODS:** 30 elderly men aged 60-79 years, who met the inclusion criteria, were recruited and randomly assigned into training and control groups. Training group carried out 12-wk WBVT at the same amplitude (3mm) and frequencies (25-30Hz) on the Power-Plate vibration platform, while control group had no any training. Muscular strength of back and knee, static and dynamic balance ability were measured respectively by portable digital muscle strength tester (microFET3, American) and dynamic balance assessment training system (Biodex-950-440, American) before and after the experiment. **RESULTS:** The core and lower extremity muscular strength of the subjects in training group were significantly enhanced after 12-wk WBVT, with the average increase of dorsal extensor muscular strength by 15.3% and extensor knee muscular strength by 7.42%; with the eyes open, the overall (1.93 ± 0.49 vs. 1.70 ± 0.27), left-and-right (1.71 ± 0.42 vs. 1.57 ± 0.51) static balance index decreased significantly and the overall (4.86 ± 0.21 vs. 3.41 ± 0.29), fore-and-aft (4.51 ± 0.30 vs. 2.53 ± 0.14), left-and-right (4.21 ± 0.26 vs. 2.95 ± 0.18) static balance index with the eyes closed also decreased significantly; the dynamic balance scores in the front (36.63 ± 12.41 vs. 38.72 ± 16.27), left (43.95 ± 16.42 vs. 47.52 ± 16.51) and right (44.34 ± 14.92 vs. 47.39 ± 18.91) enhanced significantly. Meanwhile, there was no obvious change in muscular strength and balance ability in the control group at the end of experiment. **CONCLUSIONS:** It was concluded that the core and lower extremity muscular strength as well as static and dynamic balance of elderly men could be improved with a 12-wk WBVT.

3472 Board #160 June 1 8:00 AM - 9:30 AM
Energy Contributions of Short-distance Running with Change of Direction in Tennis Baseline Practice

Bo Li, Xiaotian Li, Lu Jin, Yuchao Cao, Xinxin Wang, Lv Miao, Wei Yang, Yongming Li. *Shanghai University of Sport, Shanghai, China.* (Sponsor: Carl Foster, FACSM)
 Email: 412001625@qq.com
 (No relevant relationships reported)

Short-distance running with change of direction (SR-COD) is one of the baseline practice regularly performed in tennis training, but the energy contributions of this practice is relatively lacking.

Purpose: To investigate the energy contributions of tennis SR-COD, with the emphasis on the duration, distance, and frequency.

Methods: 16 collegiate male tennis players (22.2 ± 1.7 yrs, 175 ± 5 cm, 69.2 ± 6.1 kg) volunteered to this study. Two duration (1 and 2 min), two distance (1 and 2 min) and two frequency (20 and 30 stroke/min) were utilized, i.e. 1min-2m-20stroke/min, 2min-2m-20stroke/min, 1min-4m-20stroke/min and 1min-2m-30stroke/min. A portable spirometric system (K4b², Cosmed, Italy) was utilized to measure the ventilatory activities. Capillary blood from earlobe was collected and analyzed with blood lactate analyzer (Biosen C-line, EKF, Germany) prior to and post the test. The aerobic (Aer), anaerobic lactic (Anl), anaerobic alactic (Anal) energy contributions were calculated with the method based on the accumulated oxygen uptake and blood lactate during the practice, as well as the fast part of the oxygen uptake kinetics during the recovery. The relative energy contributions from the corresponding three pathways were also calculated as Aer%, Anl%, and Anal%.

Result: The energy contributions of SR-COD was Anal 37.4~40.1kJ (32.1~41.7%), Anl 15.1~33.5kJ (14.8~30.4%) and Aer 37.8~100.8kJ (33.9~61.9%), respectively. With the increase of duration, distance and frequency, there was no significant change in Anl, there was significant increase in Anal and Aer ($P < 0.05$, except Aer when increasing frequency). Further, %Anal decreased with the increase of duration, distance, and frequency ($P < 0.05$). %Anl enhanced significantly with the increased distance and frequency ($P < 0.05$), but declined insignificantly with increased duration ($P < 0.05$). %Aer increased significantly with longer duration ($P < 0.05$), but reduced with longer distance and higher frequency ($P < 0.05$).

Conclusion: Longer duration of SR-COD mainly increases the stimulation on Aers system, while longer distance and higher frequency of SR-COD mainly increases the stimulation on Anl energy. These findings should be taken into account when designing the SR-COD training program in tennis.

3473 Board #161 June 1 8:00 AM - 9:30 AM
The Effects Of Leg-drive On Bench Press Performance: Results Of A 5-week Training Study

Jacob K. Gardner¹, Kelsey L. Miller¹, Justin T. Chia², Brent Peterson¹. ¹*Biola University, La Mirada, CA.* ²*Western Washington University, Bellingham, WA.*
 Email: jake.gardner@biola.edu
 (No relevant relationships reported)

Among common resistance training methods, the bench press is often implemented to train upper body strength. Recently, curiosity regarding the potential impact of lower extremity involvement on overall bench press performance has gained in popularity. While the effectiveness of bench press training on strength has been shown in the literature, many suggestions as to the importance of leg-drive have been offered. Yet, to our knowledge, no studies have evaluated the impacts of leg-drive technique on bench press performance. **PURPOSE:** To determine if bench press training with leg-drive elicits similar strength characteristics to a standard bench press in strength and body fat measures after 5 weeks of bench press only training. **METHODS:** 23 apparently healthy, college-age men were randomized into two groups: standard bench press (STD) ($n = 12$, age 22.2 ± 2.3 yrs, height 173.2 ± 6.8 cm, mass 75.1 ± 7.5 kg), and leg-drive (LD) ($n = 11$, age 22.5 ± 1.9 yrs., height 176.8 ± 5.0 cm, mass 82.0 ± 10.4 kg). Pre and post analyses of bench press 1-repetition maximum (1RM), and changes in body fat percentage were conducted. Average bench-press volume was determined on a weekly basis. The training consisted of two sessions per week for five weeks of either standard bench press or bench press using leg-drive. For each session, participants completed four sets of bench press to volitional fatigue at 80% of his 1RM. During week three of training, a new 1RM was conducted to determine whether to move the participant up in weight. A 2 x 2 repeated measures ANOVA (RMANOVA) was conducted for 1 RM and body fat, and a 2 x 5 RMANOVA was conducted for average weekly lifting volume. **RESULTS:** Significant condition main effects were found with both groups experiencing an approximate 5% increase in 1RM strength (p -values < 0.001), and an approximate 0.5% reduction in body fat percentage ($p = 0.040$). A condition main effect was found for average lifting volume ($p = 0.041$) and post-hoc analysis revealed that week three was significantly higher than all other weeks. No significant group main effects were observed for any of the variables (all p -values $>$

0.05). **CONCLUSIONS:** Five weeks of bench press training did result in favorable strength outcomes for both groups, but leg-drive focused training did not produce noticeable changes in performance compared to the standard bench press.

Effect of Vibration Intervention on Balance, Core Stability and Muscle Strength in Martial Arts Athletes
 kun wang, junzhi sun. *Chengdu Sport Institute, Chengdu, China.*
 Email: 464535162@qq.com
 (No relevant relationships reported)

Objective: To compare the effects of vibration training(V)and control training(C)on balance, core stability and muscle strength in young martial arts athletes. **Methods:** Fourteen athletes were recruited and randomly assigned to two groups:vibration group(V, n=7)and control group(C, n=7). Before and after the 12 weeks training, The SMART Balance Master system was used to measure scores in the limits of stability(LS): reaction time(RT), movement velocity(MVL), end point excursion(EPE), maximum excursion(MXE), and directional control(DCL). The core stability is evaluated by the performance of grade 8 abdominal bridge. Core muscle strength are indirectly evaluated by integrating electromyography (iEMG). Student t-tests were used for data analysis. **Results :** MVL(1.37 deg/sec, $P < 0.01$),EPE(10.86%, $P < 0.01$),MXE(7.00%, $P < 0.05$),DCL(2.86%, $P < 0.05$)in group V were significantly higher after the Vibration Intervention . EPE (8.86%, $P < 0.01$),MXE(4.43%, $P < 0.01$)in group C were higher after the control training . The percentage range was higher in group V(8.29%)than C(4.50%). No significant differences were found in LS between the groups at 12 weeks of follow up. The full score of grade 8 abdominal bridge was obtained in the vibration group, and the overall Range was higher in group C than group V($P < 0.01$). The scoring of core stability also revealed no differences between the groups. In group V left rectus abdominis iEMG value(nearly 100% mV·s, $P < 0.01$), left rectus femoris(0.71 mV·s, $P < 0.05$) , left tibialis anterior (0.39 mV·s, $P < 0.05$)were higher after 12 weeks training .In group C left rectus femoris (0.42 mV·s, $P < 0.01$), left tibialis anterior (0.12 mV·s, $P < 0.05$) were higher after 12 weeks training . After 12 weeks training, the iEMG value of left tibialis anterior(0.63 mV·s, $P < 0.01$),right rectus abdominis (0.34 mV·s, $P < 0.05$) in group V were higher than C. There were no significant differences in the right erector spinae, left Rectus abdominis, left rectus femoris, left erector spinae and left gluteus maximus between group V and C. **Conclusion:** Vibration training improved balance, core stability and muscle strength of movements in young martial arts athletes.

Quantifying Training Loads During High-Intensity Functional Training: Session-RPE Method
 Justin DeBlauw. *Kansas State University, Manhattan, KS.*
 Email: jdeblauw@ksu.edu
 (No relevant relationships reported)

High intensity functional training (HIIFT), due to its constant variance and multi-modal approach presents a unique challenge in quantifying external loads. The session rate of perceived exertion (sRPE) method has been shown valid in determining training loads (TL) in a variety of sports. However, sRPE has yet to be psychometrically evaluated within HIIFT. **PURPOSE:** To estimate the psychometric properties of the sRPE method within HIIFT. **METHODS:** Twenty-five healthy, recreationally active men (n=13; age = 22.6 ± 3.5 years; body mass = 86.1 ± 13.9 kg; height = 182.8 ± 8.1 cm) and women (n=12; age = 21.0 ± 1.5 years; body mass = 70.5 ± 11.3 kg; height = 165.6 ± 5.7 cm) participated in six weeks (5 d·week⁻¹) of HIIFT. Heart rate was continuously monitored throughout each training session and rate of perceived exertion was recorded immediately following daily workouts completion. Daily TL was quantified using sRPE and compared to two heart rate-based criterion methods (i.e., Edwards' TL and Banister's TRIMP). **RESULTS:** In training block 1 (i.e., weeks 1-3), sRPE significantly predicted both Edwards' TL (n = 271, $r = 0.81$, $p < 0.001$; $R^2 = 0.67$, 95% CI = 0.60–0.73) and TRIMP (n = 260, $r = 0.43$, $p < 0.001$; $R^2 = 0.18$, 95% CI = 0.10–0.27). In training block 2 (weeks 4-6), these associations remained significant but also improved in their predictive capability for both Edwards' TL (n = 268, $r = 0.88$, $p < 0.001$; $R^2 = 0.78$, 95% CI = 0.73–0.82) and TRIMP (n = 258, $r = 0.57$, $p < 0.001$; $R^2 = 0.33$, 95% CI = 0.23–0.42). However, reliability estimates (n = 554, ICC = 0.58, 95% CI = 0.52–0.63, $p < 0.001$; CoA = 52%) between perceived exertion and HR were generally poor. **CONCLUSION:** We observed the sRPE method was a valid tool across individual, group, and sex levels when compared to criterion heart rate-based measures. However, the utility of this strategy within HIIFT is limited due to poor reliability in participants' abilities to correctly match their perceived exertion with the relative level of physiological effort (i.e., percentile of maximum heart rate). Over time, however, these participants demonstrated the ability to improve agreement between perceived and actual effort. Future investigations should continue to explore the potential utility of this monitoring strategy with HIIFT interventions.

3476 Board #164 June 1 8:00 AM - 9:30 AM
Training Intensity Distribution In A Chinese Top-level Women's Single Sculls Rower Preparing For 2008 Olympic Games Season
 Hongjun Yu¹, Xiaoping Chen², Wei Zi³. ¹*Tsinghua University, Beijing, China.* ²*China Institute of Sport Science, Beijing, China.* ³*He Nan University, Kai Feng, China.* (Sponsor: Carl Foster, FACSM)
 Email: yuhj12@mail.tsinghua.edu.cn
 (No relevant relationships reported)

Purpose: This study was to report seasonal training intensity distribution characteristics in a Chinese top-level Women's Single rower during 2007-2008, while season preparing for 2008 Olympic Games. **Methods:** A Chinese top-level (33 y, height 177 cm, weight 71 kg) World Rowing Cup champion Women's Single Sculls rower participated in this case study. The season's training load included overall duration (calculated in hours and km), frequency (calculated by overall sessions), and training intensity (measured by blood lactate and estimated by heart rate). Her performances at World Cup and Olympic competitions during the seasons, and 2000m ergometer test were also collected and analyzed. **Results:** A training program of 46 weeks (33 weeks of pre-season and 13 weeks of in-season) was analyzed. 193 training days was performed during the season. Total training hours were 737 hours. Total training time consisted of 48.9% on-water rowing (362 hours), 9.18% ergometer rowing (68 hours), 15.2% condition training (112 hours), and 18.4% warm-up and recovery programs (136 hours). All training sessions were quantified using continuous heart rate monitoring, a subset of 117 training sessions was quantified using blood lactate measurements. Intensity distribution across rowing and ergometer training hours (n=489 hours) based on heart rate analysis and blood lactate analysis was 91.12% in zone 1 (74.5% ≤2.0 mM blood lactate, 16.8% between 2.1 and 3.5 mM blood lactate), and 4.13% in zone 2 (>3.5 and 5 mM blood lactate) and 4.75% in zone 3 (over 5mM blood lactate). 2000m ergometer trials performed in weeks 2, 12 and 24 was in times 6 minutes 57 seconds, 6 minutes 55 seconds and 6 minutes 46 seconds, respectively. Maximal power test was 309 W, 313 W and 334 W, respectively. Rowing performance improved 1.29% and 6.27% during the period. She finished the season in 3rd place in the World Cup and fourth place in the 2008 Olympic Games. **Conclusion:** Training-intensity distribution with an emphasis on low-intensity polarized training model led to the success in top Chinese top-level Women's Single Sculls rower in the 2007-08 season. Possible mechanisms underlying the association between intensity distribution and performance success require further investigation.

3477 Board #165 June 1 8:00 AM - 9:30 AM
Impact of Workload on Time-Loss Incidence Rates in Elite Rugby Union Players.
 Ben E.W. Cousins¹, John G. Morris¹, Caroline Sunderland¹, Mary E. Nevill¹, Anthony M. Bennett², Simon B. Cooper¹.
¹*Nottingham Trent University, Nottingham, United Kingdom.*
²*Swansea University, Swansea, United Kingdom.*
 (No relevant relationships reported)

Rugby Union has one of the highest reported time-loss incidence rates of all professional team sports. However, the relationship between workload and time-loss incidence rate has not been well studied. **PURPOSE:** To investigate the impact of workload on time-loss incidence rates in elite Rugby Union players and compare different methods of workload quantification. **METHODS:** Sixty elite Rugby Union players were followed over one season (46 weeks) of competition. Workload was measured for all training and matches using subjective (RPE load; RPE x session duration) and objective (GPS; total distance and high-speed running (HSR) distance) methods and quantified using both the acute:chronic workload ratio (ACWR) and exponentially weighted moving average (EWMA). Chi-square analysis was used to examine the influence of workload on time-loss incidence rate. **RESULTS:** Of the 240 time-loss incidences that occurred across the season, 125 were contact injuries (106 during matches and 19 during training), 76 were non-contact injuries (25 during matches and 51 during training) and 39 were illnesses. Chi-square analysis showed that time-loss incidence rates were affected by ACWR RPE load ($X^2_{(5)} = 12.3$, $p = 0.031$), EWMA RPE load ($X^2_{(5)} = 30.8$, $p < 0.01$), EWMA total distance ($X^2_{(5)} = 23.9$, $p < 0.01$) and EWMA HSR distance ($X^2_{(7)} = 18.0$, $p = 0.012$), yet were unaffected by ACWR total distance ($p = 0.067$) and ACWR HSR distance ($p = 0.894$). EWMA RPE load and EWMA total distance exhibited an optimum range of 0.8-1.2 where actual time-loss incidence rate was lower than expected. Whereas for EWMA HSR distance values <1.0 led to a lower than expected time-loss incidence rate. ACWR RPE load had an optimum range of 0.6-1.2, whilst ACWR total distance and ACWR HSR distance did not affect time-loss incidence rates. **CONCLUSION:** This is the first study to compare different methods of workload quantification in elite Rugby Union and demonstrate that the EWMA method is better at explaining the variance in time-loss incidence risk compared to the ACWR method. When using the EWMA approach, an optimum range of 0.8-1.2 for RPE load and total distance and <1.0 for HSR distance demonstrated

a reduced time-loss incidence rate. These findings suggest that the EWMA of each individual player should be monitored to minimise time-loss incidence risk in elite Rugby Union.

The Influence Of Combine Preparation Training Duration On NFL Combine Or Pro Day Performance
 Megan D. Jones¹, Jeremy Townsend¹, Jordan Luallen², William Vantrease¹, Ian Hunter¹, Ann Toy¹, Kent Johnson, FACSM¹.
¹Lipscomb University, Nashville, TN. ²Ignition Athletic Performance Group, Nashville, TN. (Sponsor: Dr. Kent Johnson, FACSM)
 Email: mdjones1@mail.lipscomb.edu
 (No relevant relationships reported)

For collegiate football players, an outstanding performance at the NFL scouting combine or an athlete's college pro-day may increase the likelihood of being drafted or signed to an NFL team. In recent years, it has become common for players to decline playing in bowl games to allow for additional preparation for combine and pro-day performance. **PURPOSE:** To determine if the duration of combine preparation training influences NFL Combine or Pro Day performance. **METHODS:** 23 college football players (22.6±0.51 y, 108.8±18.2 kg 1.88±0.07 m) completed a preparation training program leading up to the 2018 NFL combine and college pro-days. Prior to training, all players were assessed in the 40yd dash, 225 bench press test, 3-cone drill, pro-agility test, broad jump and vertical jump. Post-training values were obtained from the players combine or pro-day performances and athlete data were then allocated to two groups: (1) athletes who completed 9-10 weeks of training (n=11) and (2) athletes who completed 6-8 weeks of the same training program (n=12). Combine training consisted of 4 resistance training sessions per week with position and test specific training occurring 6 days a week for the duration of the program. An analysis of variance with repeated measures was used to assess differences in training outcomes for each variable. **RESULTS:** Significant ($p < 0.05$) main effects for time were observed for improvements in 40-yard dash times ($p = 0.046$), 3-cone drill time ($p = 0.002$), along with 225 bench press repetitions, vertical jump height, broad jump distance, and pro-agility drill time ($p < 0.001$). There were no significant group by time interactions for any of the physical performance tests. Out of the 23 participants, 3 players were drafted and were on active rosters for the 2018 NFL season, one participant was drafted and signed a practice squad contract, while 5 other participants signed undrafted free agent contracts with various NFL teams. **CONCLUSION:** It appears that length of combine preparation did not produce significant differences in pro day performance between the two groups. Therefore, NFL hopefuls can improve their combine performance even with a short duration combine training program.

- 3479** Board #167 June 1 8:00 AM - 9:30 AM
Table Tennis Training Results with Robot: Spin Rate and Hitting Speed in Forehand Loop-Drives
 Istvan Kovacs, Austin McClinton, Catherine Rauenzahn, Wenhao Liu, FACSM. Slippery Rock University, Slippery Rock, PA. (Sponsor: Wenhao Liu, FACSM)
 Email: istvan.kovacs@sru.edu
 (No relevant relationships reported)

PURPOSE: Limited studies have addressed spin rate (SR) and hitting speed (HS) in forehand loop-drive (FLD) among recreational table tennis players. This study examined how the use of a table tennis robot would improve SR and HS of the FLD among recreational table tennis players during a self-regulated training program. **METHODS:** Thirteen middle-aged (46.2 ± 18.3 yr., 8 males) players with 4.8 ± 4.1 yr. of recreational table tennis experience participated in an eight-week table tennis program that met twice a week with the purpose of increasing SR and HS in FLD. A pretest and posttest were conducted to assess average SR and HS from five consecutive FLDs performed by each participant against consistent backspin balls served by a table tennis robot. SR was assessed with high-speed video recordings at 480fs⁻¹, and HS was assessed at 60 fs⁻¹. Each training session included a 20-min practice of FLD against balls served by the robot. The ball, after its bounce on the table, arrived to the participants at the speed of approximately 2.9 ms⁻¹ with a SR of approximately 21 rs⁻¹, the same condition as that in the pretest/posttest. In training sessions, participants also studied written and visual instructional materials, and utilized self-regulated feedback (feedback from coaches was available only when requested). In addition, progress results of SR and HS were assessed and provided to each participant every two weeks. Differences in SR and HS between pretest and posttest were examined with paired-samples t test. **RESULTS:** Participants showed significant improvements during the training program in both SR and HS measurements ($p < .05$). SR demonstrated an 45.9% improvement from 41.6 ± 30.5 rs⁻¹ to 60.7 ± 31.6 rs⁻¹, and HS resulted in a 13.3% improvement from 8.57 ± 0.98 ms⁻¹ to 9.71 ± 1.22 ms⁻¹. **CONCLUSION:** The eight-week training with a robot significantly improved SR and HS in FLD for recreational table tennis players. The use of the robot and the biomechanical feedback for self-regulated training seem to be successful tools in developing SR and HS in

recreational table tennis setting, where working with a personal coach is often limited. The effective use of technology helps the middle-aged population to meet ACSM's recommendation for neuromotor exercise training.

The Effects of Suspension Training in Lower Body Strength and Balance in Sedentary
 aksel celik¹, murat tutar². ¹indiana university bloomington, bloomington, IN. ²nisantasi university, istanbul, Turkey.
 Email: aksel.celik@deu.edu.tr
 (No relevant relationships reported)

ABSTRACT

Purpose: The aim of the study was to investigate the effects of suspension training in lower body muscle strength and balance in sedentary.

Methods: A total of 60 healthy, sedentary volunteer aged 30-45 years participated in this study. Participants were randomly divided into two groups that were suspension strength group (40,67±3 yrs) (SSG), and traditional strength group (TSG) (39,10±3,3 yrs). In SSG were applied suspension exercises 8 weeks, twice in a week, 40-45 min. In TSG were applied traditional strength exercises 8 weeks, twice in a week, 40-45 min. In both groups volunteers' anthropometric, hand grip strength, push-up, static squat, crunch, plank and balance performances were measured before and after 8 weeks training programs.

Results: As a result of the findings in this research which was made to determine the effects of suspension exercises on muscle strength development in sedentary individuals, suspension strength training studies differ from traditional strength training. At the end of eight-week strength training; all parameters in the suspension strength group and only squat (54,27±22,67 vs. 61,60±22,39, $p < 0.05$), crunches (21,00±4,01 vs. 24,23±6,05 $p < 0.05$), plank (54,73±19,47 vs. 58,53±23,76 $p < 0.05$), flexibility (25,10±9,38 vs. 27,33±9,11 $p < 0.05$) and balance (5,13±1,90 vs. 3,33±1,44 $p < 0.05$) parameters were found significantly in traditional strength group.

Conclusion: As a result, strength training (push-up, squat, crunches and plank) applied on unstable surfaces showed more improvement than traditional strength training. It is also thought that the suspension strength exercise method may be an alternative to force exercises and may be more useful for strength development.

Key words: Traditional Strength, Fitness, TRX

 (No relevant relationships reported)

Unstable surfaces have been used to enhance the muscle activity (MA) in different strength and conditioning exercises. Some evidence supports that the unstable surface increases the motor unit recruitment and improves the neuromuscular coordination in order to maintain balance. Thus, an emerging trend is the utilization of suspension devices to increase the amount of instability.

Purpose: To examine the MA of the lower limb when perform a Bulgarian squat, suspended lunge and suspended lunge-Bosu.

Methods: Seventeen physically active university students (age = 24±3.31y, height = 1.78±0.06 m, weight= 74.99±9.39 kg) were recruited to perform a Bulgarian squat, suspended lunge and a suspended lunge-Bosu. The MA was assessed using sEMG on the front leg (FL) to measure the rectus femoris_FL (RF_FL), biceps femoris (BF), gluteus medius (Gmed), vastus medialis (VM), vastus lateralis (VL) and the RF of the rear leg (RF_RL). The activity of all analyzed muscle was expressed as percentage of maximum voluntary isometric contraction (% MVIC). A one-way repeated-measures ANOVA was carried out to determine the effect of exercise condition on MA.

Results: A main effect was found for exercise condition on muscle activation for RF_FL [$F_{(2,32)} = 7.678$ $p = 0.002$], BF [$F_{(2,32)} = 4.076$ $p = 0.026$], Gmed [$F_{(2,32)} = 33.878$ $p = 0.000$], VL [$F_{(2,32)} = 3.508$ $p = 0.042$] and RF_RL [$F_{(2,32)} = 5.704$ $p = 0.008$], except for VM [$F_{(2,32)} = 2.346$ $p = 0.112$]. The suspended lunge-Bosu showed a higher activation for RF_FL, Gmed, and VL (44.25%±4.78; 66.56%±4.84; 75.58%±4.48, respectively) respect Bulgarian squat (RF_FL: 33.13%±3.87 $p = 0.024$; Gmed: 47.97%±4.41 $p = 0.000$) and suspended lunge (RF_FL: 33.86%±3.82 $p = 0.006$; Gmed: 47.89%±3.21 $p = 0.000$; VL: 63.87%±4.69 $p = 0.041$). However, the suspended lunge-Bosu reached a lower activity for RF_RL (25.98%±2.60) in comparison with Bulgarian squat (RF_RL: 35.69%±4.19 $p = 0.025$).

Conclusions: These findings suggested that leaning the RL on the suspension device did not provoke the sufficient stimuli to increase the muscle demands of the FL, but adding the unstable device on the FL in a suspended lunge could be a challenge to

increase the MA. Funding for this project was provided by Secretaria d'Universitats i Recerca del Departament d'Empresa i Coneixement de la Generalitat de Catalunya i als Fons Socials Europeus.

Developing Muscular Power vs. Muscular Endurance: Results from Two Different Push-ups Training Programs

Austin McClinton, Istvan Kovacs, Wenhao Liu, FACSM.
Slippery Rock University, Slippery Rock, PA. (Sponsor: Wenhao Liu, FACSM)
 (No relevant relationships reported)

PURPOSE: While development of muscular power (MP) vs. muscular strength (MS) requires the use of different repetitions, weights, and movement velocity, push-ups involve overcoming constant resistance (body) weight and might be able to develop both MP and ME, especially among beginning trainees. This study examined whether two different push-ups training programs, one focusing on MP and the other on ME, would influence the development of MP and ME of the upper body differently among novice trainees.

METHODS: A six-week push-ups training with three sessions each week was administered to 46 college students (mean age: 21.36±1.67). Participants had limited experience in resistance training, and were randomly assigned to the MP group (MPG) or the ME group (MEG), with each group having 14 males and 9 females. In each training session, the MPG performed six sets of ballistic plyometric push-ups with low (4-6 for females, 4-8 for males) repetitions at maximum velocity, and the MEG did six sets of regular push-ups with high (10-20 for females, 15-25 for males) repetitions. Two push-ups tests were administered before (pretest) and after (posttest) the six-week training: (a) four consecutive ballistic push-ups for average flight height (T1), calculated from the flight time provided by a contact mat, and (b) regular push-ups for maximum repetitions (T2). The test results were compared within and between groups. **RESULTS:** Paired-samples t-tests indicated significant within-group improvements in both push-ups tests ($p < 0.05$) in both groups. The MPG improved in T1 from 6.53±1.76 to 7.59±1.74 in., and in T2 from 26.63±13.31 to 30.08±8.93 reps. The MEG improved in T1 from 6.64±3.63 to 7.33±2.86 in. and in T2 from 23.4±13.31 to 26.9±11.10 reps. As for between-group comparisons, MANCOVA showed no significant differences ($p > 0.05$) in adjusted means in either push-ups test after controlling for pre-test differences: MP 7.48±1.74 vs. ME 7.06 in±2.86 in. (T1), and 29.01±8.93 vs. 27.39±11.10 reps. (T2).

CONCLUSION: While the two push-ups training programs each has a different focus (MP or ME), they have roughly the same results in developing both MP and ME. This may be related to the constant resistance (bodyweight) in push-ups, as well as the transfer effect between MP and ME in early stage of resistance training among novice trainees.

Actinin 3 Genotypes and Altitude Training

Orville Byfield, Rachael Irving. *University of the West Indies, Kingston, Jamaica.* (Sponsor: Melanie Poudevigne, FACSM)
 Email: oabyfield@gmail.com
 (No relevant relationships reported)

Certain genotypes determine adaptation to certain exercise and can be used to monitor adaptability to training. **PURPOSE:** To gauge cardiovascular response by using oxygen saturation and heart rate change to determine adaptation to altitude training in athletes with 577RR/577RX and the 577XX genotypes. **METHODS:** Athletes who were previously genotyped for the actinin 3 genes were recruited for the study. Forty athletes consented to participate and were divided in two groups. One group participated primarily in running events of distance > 1000m (group M, n=5) and the other participated in running events ≤ 400m (Group S, n=35). Each group was subjected to running up a steep slope of 5000M twice weekly for 12 weeks. Oxygen saturation was recorded using a pulse oximeter for each participant before the start of 12 weeks and each four weeks up to 12 weeks. Blood pressure and heart rate were recorded before the start of the 12 week trail and each 4 weeks up to 12 weeks. **RESULTS:** Thirty five athletes had the 577RR or the weaker 577RX variant of the actinin 3 gene. Five had the 577XX genotype. Those with the 577RR and 577RX genotypes had no significant increase in their SpO₂ values over 12 weeks (P=0.1). Their heart rate and blood pressure did not significantly decrease over 12 weeks (p>0.5). Group M athletes had significant increase in SpO₂ values, heart rate and pulse rate also significantly decreased over 12 weeks (p<0.001). **CONCLUSION:** Those with the 577XX genotype adapted better to altitude training than those with the 577RR and 577RX genotypes

Effect of Progressive Unilateral Eccentric versus Concentric Training on Muscle Damage of the Contralateral Limb

Trevor C. Chen¹, Jian-Han Lai¹, Kuo-Wei Tseng², Wei-Chin Tseng², Tai-Ying Chou¹, Kazunori Nosaka³. ¹National Taiwan Normal University, Taipei City, Taiwan. ²University of Taipei, Taipei City, Taiwan. ³Edith Cowan University, Joondalup, Australia.
 Email: tcchen@ntnu.edu.tw
 (No relevant relationships reported)

Muscle damage of the elbow flexors (EF) induced by maximal eccentric exercise (100%EC) is significantly less following the second bout of the same exercise performed at 1-28 days after the first bout by not only the ipsilateral EF but also the contralateral EF (contralateral repeated bout effect: CL-RBE; Chen et al. *MSSE* 2016). However, it is not known whether the magnitude of the CL-RBE of the opposite limb would be differently conferred if one limb received progressive unilateral eccentric training (PET) compared with progressive unilateral concentric training (PCT). **PURPOSE:** This study tested the hypothesis that a greater CL-RBE would be conferred upon the EF by PET than by PCT. **METHODS:** Untrained young men were placed into PET, PCT and control (CON) groups (n=8/group). Both the PET and PCT groups performed 5 sets of 6 contractions of the EF of one arm once a week for 5 weeks, in which the load was increased from 10 to 30, 50, 80 and 100% of maximal voluntary isometric contraction (MVC), followed 1 week later by 5 sets of 6 100%EC of the opposite EF. The CON group performed 100%EC with one EF, and repeated the 100%EC with the opposite EF 1 week later. MVC, range of motion, upper arm circumference, muscle soreness (SOR) and plasma creatine kinase activity were measured before to 3 days after each PET and PCT, as well as before and for 5 days after 100%EC. Changes in these variables after 100%EC were compared between groups by a mixed-design two-way ANOVA. **RESULTS:** The magnitude of increases in MVC for the trained (22%) and untrained arms (10%) after PET was greater (P<0.05) than after PCT (11%, 5%). Changes in all variables after 100%EC were smaller (P<0.05) for the PET group (e.g. MVC: -9% at 4 days post) compared with 100%EC for the PCT group (-23%) and the first 100%EC of the CON group (-27%), without significant difference between the PCT and CON groups. Changes for the PET group (e.g. peak SOR: 12 mm) were smaller (P<0.05) than those after 100%EC for the PCT group (34 mm) and after the second 100%EC for the CON group (25 mm), and changes in all variables after the second 100%EC for the CON group were smaller (P<0.05) than for the PCT group. **CONCLUSIONS:** These results supported the hypothesis and showed that the CL-RBE conferred after PET would be greater than that conferred after PCT. Supported by MOST, TAIWAN (MOST105-2410-H-003-052-MY3).

Comparison of Eccentric Utilization Ratio and Reactive Strength Index between Football Linemen and Backs

Taylor J. Manes¹, Eric G. Yackle¹, Jacob D. Morris¹, Jerry L. Mayhew¹, Bryan Mann². ¹Truman State University, Kirksville, MO. ²Miami University, Miami, FL.
 Email: jmayhew@truman.edu
 (No relevant relationships reported)

Explosive generation of force is a fundamental component of many sports. Various jumping indices have become major indicators of player potential or for judging training improvement. However, there is limited information concerning these indices for college football players. **PURPOSE:** To compare two forms of reactive strength index (RSI) between college football linemen and backs. **METHODS:** Linemen (n = 12) and backs (n = 16) were tested for static jump (SJ) and drop vertical jump (DVJ) on a force plate to determine flight time (Ft), ground contact time (GCT), and peak takeoff force (PTF). Peak landing force (PLF) was determined during DVJ. Each player performed 2 trials of each jump with a 1-min rest between. RSI was calculated as a ratio of DVJ to GCT (RSI-1) and Ft/GCT (RSI-2). A modified elastic utilization ratio (EURmod) was calculated as DVJ/SJ. **RESULTS:** Linemen were significantly heavier (127.9 ± 7.8 kg) than backs (92.0 ± 7.8 cm) but the two were not statistically different in age (20.2 ± 1.3 vs 19.8 ± 1.6 yrs, respectively) or height (186.5 ± 6.0 vs 183.6 ± 6.0 cm, respectively). Reliabilities for GCT (ICC = 0.870), SJ Ft (ICC = 0.952), DVJ Ft (ICC = 0.959), DVJ (ICC = 0.958), and SJ (ICC = 0.949) were high. GCT was not significantly different between backs (0.275 ± 0.055 s) and Linemen (0.288 ± 0.039 s). RSI-1 and RSI-2 were greater in backs (1.26 ± 0.37 and 1.95 ± 0.42, respectively) than in linemen (0.77 ± 0.18 and 1.47 ± 0.23, respectively) with large effect sizes (ES = 2.78 and 2.11, respectively). RSI-1 (1.05 ± 0.38) was statically greater than RSI-2 (1.74 ± 0.42), although they were highly correlated (r = 0.95). EURmod was significantly higher in backs (0.91 ± 0.13) than in linemen (0.75 ± 0.14) with a large ES = 1.69). PLF/kg was not significantly different between linemen (47.2 ± 7.5 N/kg) and backs (49.5 ± 8.3 N/kg) but PTF/kg was significantly greater in backs

(40.8 ± 6.4 N/kg) than in linemen (34.7 ± 3.5 N/kg). Discriminant analysis indicated that JH/kg could correctly classify 94% of backs and 100% of linemen to the correct position.

CONCLUSIONS: Various ratios indicating the ability of players to handle their body weight during explosive movements may be useful in classifying playing position and evaluating training improvement.

(No relevant relationships reported)

MINIMALIST STYLE MILITARY BOOT DOES NOT IMPROVE WALKING ECONOMY UNDER LOAD IN TRAINED MALES

D.W. Sharp¹, M.T. Pace¹, J.C. Swain¹, R.T. Albino¹, J.M. Green¹, L.G. Killen¹, H. Chander², J.D. Simpson³, E.K. O'Neal¹. University of North Alabama, Florence, AL¹, Mississippi State University, Mississippi State, MS², University of West Florida, Pensacola, FL³.

Footwear may be a simple external factor to improve rucking economy (RE) for soldiers that must carry heavy external loads, but it is also possible that with no flight phase, RE may not be enhanced by footwear style. This study compared RE with an ~500 g minimalist style boot (MIN) versus an ~800 g traditional style boot (TRD) while wearing a 16 kg external load consisting of a 7.5 kg weighted compression vest and ruck sack with 8.5 kg of weight. Male participants (n = 14) completed two testing sessions for this study. In session 1 participants completed a VO₂ peak test (46.6 ± 7.3 ml/kg/min) under load while wearing their normal athletic shoes. The second session consisted of two 5-min walking treadmill sessions under load. Treadmill speed was based on the highest speed stage that allowed the participant to walk for the full stage during the VO₂ peak test. RE was evaluated using indirect calorimetry (TrueOne2400, Parvo Medics Inc. Provo, Utah) and calculated by averaging the 60-s average values of minutes 3-4 and 4-5. Steady state was confirmed by a difference < 0.1 L/min between minutes 4 and 5. MIN and TRD were worn in a counter-balanced crossover order. There was a 10-min rest period between rucking bouts. RER did not differ between treatments (MIN = 0.86 ± 0.48; TRD = 0.86 ± 0.51; p = 0.96). A two-tailed t-test with an was ran for all data (α = 0.05). Although MIN (1.79 ± 0.23 L/min) tended (p = 0.13) to improve RE versus TRD (1.85 ± 0.30 L/min), breathing RPE was the only measure that reached significance (p = 0.045) between MIN (2.0 ± 0.9) versus TRD (2.4 ± 1.2). Altering boot type does not improve RE.

3487 Board #175 June 1 8:00 AM - 9:30 AM
Cortisol and Testosterone Awakening Response During Training in Elite Military Men

Jake R. Bernards, Andrew E. Jensen, Laura J. Arrington, Brenda A. Niederberger, Jason T. Jameson, Karen R. Kelly. *Naval Health Research Center, San Diego, CA.*

(No relevant relationships reported)

Elite military training is highly stressful on the body and challenges the individual operator to maintain allostasis (i.e., the ability to adapt and recover from repetitive stressors). It is well understood that increased allostatic load, above that of allostasis, may lead to hormonal imbalances in the hypothalamic-pituitary adrenal (HPA) and gonadal (HPG) axes. However, it is not well understood if elite military training elevates allostatic load enough to disrupt the HPA and HPG axes. **PURPOSE:** To determine the cortisol awakening response (CAR)—an outcome metric of the HPA axis—and the testosterone awakening response (TAR)—an outcome metric of the HPG axis—over the course of a 9-month unit level training (ULT) cycle. **METHODS:** Active duty, elite, male operators (n = 37; age: 28.6 ± 3.8 yrs; height: 178.0 ± 5.3 cm; weight: 87.0 ± 8.6 kg) participated in this study. Operators were stratified into 3 groups based on age (20-26, 27-29, and 30-41 yrs). Daily self-administered saliva samples were completed by each operator at the time of Wake, Wake + 30 min, and Wake + 60 min, pre- and post-ULT cycle. All CAR and TAR data were calculated as area under the curve from the ground (AUC_G). Differences and interactions between age groups and days were examined using a 3 (age) × 2 (day) mixed effects model. **RESULTS:** There was a significant interaction between age groups and days for CAR (p < .0001) and TAR (p < .0001) AUC_G. Simple effects comparing differences in the CAR AUC_G from operators aged 27-29 yrs exhibited a 22.8% decrease in CAR following ULT (AUC_G: = 17.5 ± 8.3 vs. 13.6 ± 7.5, p = .01). Examination of the individual main effects revealed significant differences comparing age groups in TAR (p = .006). Adjusted contrast analysis revealed operators aged 20-26 yrs had a heightened TAR during both pre- and post-ULT time points when compared with those aged 27-29

yrs (AUC_G: pre = 12059.8 ± 3819.0 vs. 8439.4 ± 3801.5; post = 11834.1 ± 5588.5 vs. 7754.2 ± 2606.3, p < .0001) and 30-41 yrs (AUC_G: pre = 12059.8 ± 3819.0 vs. 8298.1 ± 3440.0; post = 11834.1 ± 5588.4 vs. 8640.4 ± 5087.7, p < .0001). **CONCLUSION:** Results indicate the middle-aged group (27-29 yrs) has a decrease in CAR over the 9-month ULT cycle compared with the younger and older age groups. Additionally, the youngest operators, aged 20-26 yrs, have the highest TAR, regardless of time point.

The Effectiveness Of Neuromuscular Training Versus Traditional Training On Dynamic Balance In Athletes: A Meta-analysis

Meiqi Zhang, John LIU. *Springfield College, Springfield, MA.*
 Email: mzhang2@springfieldcollege.edu

(No relevant relationships reported)

Neuromuscular training has been viewed as an effective approach to improving dynamic balance through enhancement of unconscious motor responses in athletes. However, it is still unclear whether neuromuscular training is better than traditional training to improve the dynamic balance ability. **Purpose** The primary purpose of the present paper was to determine whether or not neuromuscular training is better than traditional training in improving dynamic balance through a systematic review and meta-analysis of the available research articles. **Methods** The meta-analysis was conducted and reported according to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA). Relevant articles were searched independently by two researchers through PubMed, web of science, Google scholar, CNKI, which was completed before September 2018. The randomized controlled trials involving the effects of neuromuscular training and traditional training on athletes' dynamic balance were included. **Results** 6 RCT studies with 162 athletes met inclusion criteria for this review and were included. On average sessions went for 45 ± 20mins; 3 ± 2 times a week for 6 ± 2 weeks. Compared with traditional training, there was a significantly improve in Star excursion balance test (SEBT), the anterior (MD = 6.92 cm, 95%CI: 3.22 to 10.63), anteromedial (MD = 3.64 cm, 95%CI: 0.86 to 6.43), lateral (MD = 6.3 cm, 95%CI: 3.21 to 9.48), posterior (MD = 10.19 cm, 95%CI: 7.29 to 13.10, posteromedial (MD = 9.69 cm, 95%CI: 7.2 to 12.19) and posterolateral (MD = 5.75 cm, 95%CI: 1.81 to 9.69) scores of SEBT, respectively. No significantly differences in anterolateral (MD = 11.68, 95%CI: -0.03 to 23.38), medial (MD = -0.51 cm, 95%CI: -7.20 to 6.17) of SEBT between neuromuscular training and traditional training were found in the available research articles. **Conclusions** Neuromuscular training could be an effective training method for improving the dynamic balance of athletes in different sports and could be applied to athletes' training programs. More attention is needed in future research on validating the effectiveness of neuromuscular training between different sports programs through large randomized controlled trials and exploring the underlying physiological mechanisms.

The Impact of Isometric Handgrip Training on Cardiovascular Stress Reactivity: Does Baseline Psychological Stress Matter?

Ellen C. McGarity-Shiple, Morgan Silvester, Kaitlyn Liu, Sarah Bailey, Kyra E. Pyke. *Queen's University, Kingston, ON, Canada.*

Email: 0sem3@queensu.ca

(No relevant relationships reported)

Cardiovascular stress reactivity (CSR) is associated with cardiovascular risk factors such as hypertension and carotid intima media thickness. It may also be influenced by baseline perceived psychological stress. Isometric handgrip training (IHGT) has been shown to reduce CSR in hypertensive adults, however, the impact of IHGT on CSR in normotensive adults is unknown.

PURPOSE: To examine the effect of IHGT on CSR in young, healthy males and to assess the potential influence of variability in baseline perceived stress across the intervention.

METHODS: Young, healthy male subjects were randomly assigned to a control (n=11, 22±4 yrs) or IHGT group (n=11, 23±4 yrs). The Perceived Stress Scale (PSS) was administered and mean arterial pressure (MAP) was assessed during the Trier Social Stress Task. CSR was calculated as the difference in MAP from baseline to peak during stress. A single training session consisted of 4 alternating right and left 2 min isometric handgrip contractions (30% maximal voluntary contraction) and this was performed 5 days/week for 5 weeks. All measurements were performed before and after the intervention.

RESULTS: There was a significant reduction in CSR post-intervention (19±10 vs. 23±11 mmHg, p<0.02) however, this was not significantly different between groups (p=0.45). PSS score did not change with the intervention (14±7 vs. 13±6 p=0.56) or differ between groups (p=0.7). Overall, CSR did not correlate with PSS scores (r²= -0.03, p>0.2) and addition of the PSS score to CSR analysis did not alter the findings. However, there was a significant negative correlation between CSR and PSS scores of

less than 15 ($r^2 = -0.3, p < 0.001$). Addition of PSS score to CSR analysis in only these participants did not show a training reduction of CSR compared to the control group (28 ± 3 vs. 19 ± 3 mmHg; 20 ± 3 vs. 18 ± 3 mmHg, $p = 0.172$).

CONCLUSION: In contrast to some findings with aerobic training, IHGT did not lower CSR in young, healthy males. Lower responses overall post intervention suggest that some habituation to the TSST occurred. Although considering PSS score did not alter current findings, CSR decreased with increasing reported stress up to a moderate reported stress level (PSS score of 15). This suggests that considering baseline levels of stress may be helpful in interpreting CSR changes with exercise interventions.

Pushing A Sled: Assessing Its Impact On Gait Temporospatial Parameters In Young Healthy Adults

Martin G. Rosario¹, Aneesah Hyder², Monica Mathis¹, Stephanie Timon¹, Heather Taylor¹, Chad Swank¹. ¹Texas Woman's University, Dallas, TX. ²Texas Woman's University, Denton, TX. (Sponsor: Alexis Ortiz, FACSM)
Email: mrosario1@twu.edu
(No relevant relationships reported)

Resistance exercise (RE) has been demonstrated as a superior modality for increasing muscle strength, muscle endurance, power, and motor performance. The sled used in this study is a novel device that provides a proportional increase in resistance with increased speed.

PURPOSE: To examine the impact of resistance on gait temporospatial parameters using a sled in healthy young adults while walking and running.

METHODS: Fifteen young adults (ages 21-35) were recruited to participate in this study. Mobility Lab sensors (accelerometers and gyroscopes) were placed on each subject at the chest, waist, and both wrists and ankles. Each participant performed three trials of 40 feet for the following conditions: self-paced walking (W), self-paced walking while pushing the sled (WP), and maximal speed running while pushing the sled (RP).

RESULTS: A repeated measures MANOVA was conducted to compare gait temporospatial parameters across conditions. Results indicate significant differences ($p < 0.005$) between all conditions for stride length, cadence, double support time, swing %, and stance %. Stride length decreased across all three conditions: W (85 ± 3.0), WP (68 ± 4.1), and RP (56 ± 7.0). Cadence decreased while WP (92 ± 10.1), yet increased during RP (169 ± 14.9), compared to W (109 ± 6.7). During resistance conditions (WP and RP) participants demonstrated greater gait cycle percentage in stance phase [(WP, stance phase: 66 ± 1.6 , swing phase: 34 ± 1.6) and (RP, stance phase: 57 ± 2.7 , swing phase: 42 ± 2.7)] when compared to W (stance phase: 37 ± 2.1 , swing phase: 37 ± 2.2).

CONCLUSIONS: Longer stance phase with a proportional increase in resistance could be utilized as a combined resistance and gait training tool as supposed to only gait training. This resistance as an intervention might be a viable option to improve the push off of patients with limitations such as neurological disorders. Future studies should focus on neuromuscular activation of the lower extremity, specifically the muscles involved in the gait cycle stance phase when walking or running with resistance.

3491 Board #179 June 1 8:00 AM - 9:30 AM

The Specificity of Muscular Coordination between Front Crawl Swimming and Dry-land Resistance Training Exercises.

Emmet Crowley. University of Limerick, Limerick, Ireland. (Sponsor: Dr Giles Warrington, FACSM)
Email: emmet.crowley@ul.ie
(No relevant relationships reported)

PURPOSE

Specificity is an integral component in understanding the mechanism of transfer of dry-land resistance training exercises (RT) to front crawl swimming (FC). The specificity of intra and inter muscular coordination is deemed to be important, with neuromuscular adaptations at the forefront namely motor unit recruitment, synchronisation and co-contraction. Limited research has investigated the muscular coordination between FC and RT. Therefore, the aim of this investigation is to explore the muscular coordination between RT and FC.

METHODS

Fourteen male international and national level swimmers were recruited. EMG and 2D kinematic data were collected whilst FC, bench press (BP) and pull-up (PU) were performed. A standardised warm up was conducted followed by 3 x 35 m FC bouts, 1 x 70 % and 2 x 100 % of maximal exertion, with 5 minutes' recovery between bouts. The BP and PU were performed using the same protocol, with participants performing 3 x 5 RM. EMG data were filtered using a 4th order Butterworth filter and normalised to peak EMG. The EMG data were presented using a 50 % threshold of peak EMG and

demonstrated temporal overlaps (TO) for each muscle. 2D data were collected during the propulsive (PRO) phase of FC and eccentric (ECC) and concentric (CONC) phase of BP and PU.

RESULTS

The individual results show little TO between FC and BP and FC and PU. Furthermore, FC and BP had significantly ($P < 0.05$) greater TO compared to FC and PU. The ratio of the ECC and CONC phase during the 5RM, BP and PU, show significant ($P < 0.001$) differences compared to the recovery (REC) and PRO phase of FC. Additionally, duration of time under tension during the CONC phase, of BP ($P < 0.01$) and PU ($P < 0.001$), was significantly higher than during the PRO phase of FC.

CONCLUSION

The EMG data shows different individual responses and little specificity between FC and BP and FC and PU. The targeted prime movers show little TO between FC and RT. These findings may question the validity of this method for assessing specificity, as it does not account for their dynamic nature. The lack of specificity between RT and FC shows further differences as the ratio and duration of time under tension of the RT compared to FC show significant differences. Velocity based training may be a viable method to target specific movement velocities and increase specificity.

Effects Of Lower-leg Kinesio Taping On Ankle Strength, Foot Pressure And Balance

Young-Bae Eum¹, Ah-Ram Kim², Jong-Hak Lee¹, Ho-Seong Lee¹. ¹Dankook University, Cheonan-si, Korea, Republic of. ²Yonsei University, Cheonan-si, Korea, Republic of.
Email: hoseh28@dankook.ac.kr
(No relevant relationships reported)

The use of kinesio tape among health care professional has grown recently in efforts to efficiently prevent and treat joint injuries. However, limited evidence exists regarding the efficacy of this technique in enhancing joint stability and neuromuscular control.

PURPOSE: To compare of the effect of lower-leg kinesio taping and traditional taping method on ankle strength, foot pressure and static and dynamic balance.

METHODS: In a double-blinded, randomized, crossover trial, and twenty healthy adults were applied lower-leg kinesio taping and traditional taping method for 1-week. The two taping methods were separated by a 2-week. All subjects were evaluated for isokinetic strength (plantar flexion, dorsiflexion, inversion and eversion of 30°/sec and 60°/sec), foot pressure during gait and static and dynamic balance.

RESULTS: Results showed that backward, leftward and rightward of dynamic balance were significantly increased in lower-leg kinesio-taping compared to CON ($p < 0.05$, respectively). Leftward and rightward of dynamic balance were significantly increased in traditional taping compared to CON ($p < 0.05$, respectively). However, no significant difference in the ankle strength, foot pressure and static balance were observed between the taping methods.

CONCLUSIONS: Both taping methods applications are recommended for increasing dynamic balance ability. Further research might investigate how this affects participants with a history of injury.

Effects Of Whole-body Electrostimulation On Concurrent Training Related To Explosive Strength, Anaerobic Power And VO₂max.

Ismael Martínez Guardado¹, Manuel Del Viejo Gragera¹, Jeffrey M. Mjaanes, FACSM², Aldo Vásquez Bonilla¹, Rafael Timón Andradá¹, Guillermo Olcina Camacho¹. ¹Sport Sciences Faculty, University of Extremadura, Cáceres, Spain. ²Northwestern University, Evanston, IL. (Sponsor: Jeffrey M. Mjaanes, FACSM)
Email: imartinezg@unex.es
(No relevant relationships reported)

Training programs typically involve the concurrent use of strength and endurance training sessions. Moreover, whole-body electrostimulation has also been used by athletes in the context of training programs to develop strength and physical performance. We postulate that the addition of whole-body electrostimulation (WB-ES) to concurrent training may improve explosive strength, anaerobic power and aerobic performance.

PURPOSE: To identify which of two concurrent training protocols-consecutive (weightlifting + HIIT) or simultaneous (WB-ES + HIIT)-is more effective in enhancing explosive strength, anaerobic power and aerobic performance in recreationally trained subjects. **METHODS:** Twenty-two recreationally trained subjects (Age 20.08 ± 2.08 yr, Weight 72.49 ± 5.20 kg, BMI 22.23 ± 2.47 kg/m²) were randomized into 3 groups: Concurrent Consecutive (CC), Concurrent Simultaneous (CS) or Control Group (CG), who carried out 5 weeks of training, 2 days per week. The CC group performed a circuit strength training of 4 exercises (bench press, front pull down, back squat and femoral curl); 4 x 8 reps 60-65% 1RM, followed by HIIT (4 x 4 min 90-95% maximal aerobic power with 3 min of recovery) on a cycle ergometer. Conversely, the CS group

completed the same HIIT training combined with a strength program with WB-ES (WiemsPro, USA). Participants were evaluated in three moments; PRE, POST, and after a detraining (DET). Testing included Wingate test for anaerobic power, CMJ for explosive strength and an incremental maximal test for $\dot{V}O_{2\max}$. Analysis was performed using two-way ANOVA with repeated measures. **RESULTS:** CS and CG increased mean power in Wingate test between all measurements (CC 471 ± 87 W vs 562 ± 77 W vs 553 ± 70 W; CS 457 ± 74 W vs 566 ± 112 W vs 563 ± 105 W $p < 0.01$). CMJ increased in CC in POST (29.75 ± 3.87 cm vs 33.42 ± 4.11 cm $p < 0.001$) and DES (29.75 ± 3.87 cm vs 33.68 ± 4.48 cm $p < 0.05$). However, CS group only improve CMJ after DET with respect to PRE measurement (28.40 ± 3.78 cm vs 30.94 ± 3.82 cm $p < 0.05$). No differences were found in $\dot{V}O_{2\max}$. **CONCLUSIONS:** Concurrent consecutive training is more effective at improving lower-limb explosive strength, however both concurrent training protocols are effective at improving anaerobic power even though concurrent simultaneous protocols take half the time to complete. 3494 Board #182 June 1 8:00 AM - 9:30 AM
Improving Shoulder Internal Rotation Motion of In-season Throwing Athletes: A Randomized Controlled Trial

David Roskin¹, Kimberly Keyser¹, Christina Alperi², Heather Myers¹. ¹Duke University Health System, Durham, NC. ²North Carolina School of Science and Mathematics, Durham, NC.
 (No relevant relationships reported)

PURPOSE: Throwing athletes commonly experience loss of shoulder internal rotation (IR). This adaptation, when combined with compromised resting posture, has the potential to increase risk of rotator cuff and biceps tendinopathy, labral tears, and elbow injuries. This study investigated the effectiveness of two methods prescribed to restore IR: the Sleeper Stretch (SS), which aims to stretch the capsule, and the Ballroom Blow (BB) which aims to optimize breathing, posture, and scapular stability. Because the BB is less stressful to the shoulder joint, it may be a superior alternative. We hypothesized that when using the BB, IR would be increased either as effectively, or more so, than the SS.

METHODS: Healthy in-season baseball and softball players were randomly assigned an intervention (BB or SS) to the dominant arm 2x/day for 5 consecutive days. After a 2-week period of no intervention, both groups crossed over and performed the alternate intervention. IR was passively measured in supine at baseline, immediately after a throwing session on day 1, after intervention on day 1, and prior to practice on days 2-5. On the last day of the study, each subject was asked if he/she had a preference for either exercise. Statistical analysis for comparisons of differences in IR among intervention type (SS and BB) were performed using an analysis of covariance (ANCOVA) for the 6 instances as listed above. Statistical significance was set *a priori* at $\alpha \leq 0.05$.

RESULTS: 13 softball players (17.49 ± 0.63 yrs.; BMI 28.4 ± 5.6) and 10 baseball players (17.07 ± 0.56 yrs.; BMI 24.6 ± 4.7) participated in the study. Both interventions increased IR over the course of the 5 days, but there was no significant difference ($p = 0.66$) between SS and BB. When performing SS, the mean IR was 45.7 ± 11.38 degrees immediately after the throwing session and incrementally improved to 53.06 ± 10.95 degrees on day 5. When performing BB, the similar incremental increase was from 47.39 ± 12.15 degrees to 53.56 ± 8.61 degrees. There was no statistically significant difference in preference between the SS (51.1%) and the BB (48.9%).

CONCLUSIONS: The BB and the SS were both observed to be effective at increasing IR ROM in healthy in-season baseball and softball players over 5 days, yet neither proved to be superior with regard to degree of improvement nor speed of attaining increased IR.

The Influence Of Previous Training Intensity On The Rating Of Perceived Exertion

Jos J. de Koning, FACSM¹, Jos de Haan¹, Carl Foster, FACSM². ¹Vrije Universiteit, Amsterdam, Netherlands. ²University of Wisconsin - La Crosse, La Crosse, WI.
 Email: j.j.de.koning@vu.nl
 (No relevant relationships reported)

A discrepancy between coach' intended session-intensity, and the intensity as experienced by the athlete has been found in many sport settings. To avoid deconditioning as well as non-functional overreaching, it is important that athletes execute and perceive the training as prescribed by the coach. **PURPOSE:** The aim of this study is to find an explanation for the difference between intended and perceived RPE (dRPE). **METHOD:** Thirteen athletes completed 1392 training sessions. Athletes and coach rated each session on BORG-CR10 scale (RPE). dRPE was calculated as athlete's RPE minus coach' RPE. Linear regression was used to analyze the relation between dRPE and the average RPE from, respectively, the previous 1, 2, 3, and 7 days. **RESULTS:** A weak correlation was found between the coach intended RPE and athlete executed RPE ($r = 0.302$; $P < 0.01$). Mean dRPE was 0.51 (sd = 2.07). Easy

sessions (RPE < 4.8) were underestimated by the coach, and harder sessions (RPE > 4.8) were overestimated by the coach. A significant linear regression was found between dRPE and all 4 predictor variables. **CONCLUSION:** This study demonstrates evidence for dRPE to be influenced by the intensity of training sessions during the previous days. Intended intensity has shown to be overestimated when previous days were of low intensity and underestimated when previous days had a severe intensity. This information might help the coach to adjust the program and avoid these problems in advance.

The effects of 12-week yoga practice on flexibility and dynamic balance of female college students

INTRODUCTION: In recent years the practice of yoga has gained popularity as a means to improve health, sports performance and psychological wellbeing.

PURPOSE: The aim of this study was to evaluate the effects of a 12-week yoga intervention on flexibility and dynamic balance of female college students.

METHODS: A one-group pretest-posttest design was employed. Seventy females (20.8 ± 1.9 years; 1.62 ± 0.15 m; 54.2 ± 9.64 kg; BMI 21.2 ± 3.18 kg·m⁻²) attended yoga practice for a total of 12 weeks, consisting of one 90-min session per week. All participants have no previous experience on the Star Excursion Balance Test (SEBT) and yoga practice. Lumbar and hamstring flexibility and dynamic balance were assessed using the sit and reach test and SEBT before and after 12-week intervention. Participants performed the anterior (ANT), posterolateral (PL), and posteromedial (PM) reach directions of both legs in the SEBT.

RESULTS: A statistically significant increase in post-intervention normalized reach distances from 4.5% to 9.9% was seen in all directions of both legs. Results of paired sample t-test also displayed a significant normalized reach distance difference before and after the intervention. Left leg: (ANT: $76.8 \pm 9.5\%$ versus $67.0 \pm 13.1\%$; $t(69)=5.78$, $P < 0.01$; PL: $88.0 \pm 11.8\%$ versus $81.4 \pm 17.3\%$; $t(69)=3.29$, $P < 0.05$; PM: $91.2 \pm 10.9\%$ versus $86.7 \pm 17.0\%$ $t(69)=2.23$, $P < 0.01$); Right leg: (ANT: $75.2 \pm 10.8\%$ versus $68.0 \pm 16.6\%$; $t(69)=3.25$, $P < 0.01$; PL: $88.6 \pm 10.5\%$ versus $83.7 \pm 17.4\%$; $t(69)=3.17$, $P < 0.01$; PM: $92.3 \pm 11.1\%$ versus $85.9 \pm 17.2\%$; $t(69)=2.54$, $P < 0.05$). The increase in flexibility was observed after the intervention (39.3 ± 5.8 cm versus 37.8 ± 6.5 cm; $t(69)=4.64$, $P < 0.01$).

CONCLUSIONS: The dynamic balance ability and flexibility of the female college students were significantly enhanced after 12-week yoga intervention.

Abstract

Dance is an art form in which it is necessary to develop various physical abilities because for a ballet dancer to achieve high performance it is necessary to acquire technical, athletic and aesthetic capacities so that the movements flow in a controlled way and without apparent effort. To generate positive effects on the performance, it is necessary to complement the training program with a method that maintains the technical ballet characteristics and principles. One type of training is the Mat Pilates method.

PURPOSE: To verify the effect of a training periodization with the original Mat Pilates on the performance of muscle strength and flexibility in a ballerina.

METHODS: A female ballet dancer (age: 19 yrs; height: 1.54 m; body mass: 56 kg; BMI: 23.6 kg/m²), without lesions, were submitted to the Mat Pilates method during 8 weeks, with a duration of 1 hour per training session, performed 2 times a week with a 48-hour interval between the sessions. The pre- and post-intervention tests were: strength and resistance abdominal test, isometric test of the column extensor, sit and reach, My Jump, and hip flexion with extended knee.

RESULTS: The highest post-intervention response value was for the abdominal resistance test, possibly because the exercises of the Mat Pilates contemplate this musculature. However, the jump test showed a negative post-intervention response (Table 1).

Table 1. Results of the pre- and post-intervention tests.

| | Pré-test | Post-test | % Post-test | Result (%) | Absolute Difference |
|-----------------------|----------|-----------|-------------|------------|---------------------|
| Seat and Reach | 30 | 40 | 133.3 | 33.3 | 10 |
| Abdominal | 20 | 30 | 150.0 | 50.0 | 10 |
| Lumbar hyperextension | 4 | 5 | 125.0 | 25.0 | 1 |
| hip flexion (right) | 90 | 110 | 122.2 | 22.2 | 20 |
| hip flexion (left) | 100 | 130 | 130.0 | 30.0 | 30 |
| Jump height (cm) | 17.12 | 19.0 | 110.9 | 10.9 | 1.9 |
| Flight time (ms) | 351.33 | 393.0 | 111.9 | 11.9 | 41.7 |
| Velocity (m/s) | 0.86 | 1.0 | 111.6 | 11.6 | 0.1 |
| Force (N) | 1527.30 | 1345.4 | 88.1 | -11.9 | -181.93 |
| Power (W) | 1322.60 | 1298.7 | 98.2 | -1.8 | -23.86 |

CONCLUSIONS: The original Mat Pilates Method applied in the present study potentiated the increase in the flexibility, abdominal and lumbar resistance and strength levels, but did not influence the performance of the vertical jump. New studies are suggested with a greater number of participants, with Pilates exercises in machines, in both sexes, in different age groups and with subjects of other sports and artistic modalities.

Relationship Between Cumulative Training Loads and Treatments of Division II Swimmers

Cristopher Lara, Candace Juhala, James Mouat, IV, Jose Alvarez, Bianca Lagamon, Angel Quintero, Adam Murphy, Cameron LeBato, Shruti Bali, Vivy Hua, Derrick Gardner, Nicole Kuhar, Arianna Mazzarini, Marcela Fernandes-Alvez, Vanessa Yingling, FACSM. *CSU East Bay, Hayward, CA.* (Sponsor: Vanessa Yingling, FACSM)
 Email: clara27@horizon.csueastbay.edu
(No relevant relationships reported)

Coaches are responsible for designing training sessions to optimize athlete progression while decreasing the incidence of treatments and fatigue by monitoring training loads. Training loads (TL) consist of the external load (work done by the athlete) and internal load (athlete's perceived intensity of that work). Multiple methods are used to monitor both external and internal TL's such as the utilization of heart rate, lactate concentration, rate of perceived exertion (RPE) and session duration (Gabbett et al, 2004). Among NCAA Division II athletics, monitoring team training loads necessitates a cost-effective method, like that of RPE and session duration. Purpose: To determine the relationship between cumulative training load, and number of visits to the Athletic Trainer for treatments, in a Division II women's swimming team. Methods: For one season, twenty-four collegiate female swimmers (mean ± SD, age 20.2 ± 1.23 years; height 169.03 ± 6.18 cm; mass 68.7 ± 8.87 kg) were surveyed after each practice and competition, and asked to report the date, the duration of training in minutes and the RPE for that session. TL was calculated as the product of the RPE and training session duration and reported as arbitrary units (au). All treatments (visits to the athletic trainer) were recorded by the athletic trainer, ranging from a cosmetic treatment (ice pack) to a soft tissue injury. TL's were averaged daily across the whole team, and a weekly cumulative TL was compared to total treatments for that week. The relationship between TL's and number of treatments was examined using a Pearson correlation. Results: On average the athletes recorded weekly a cumulative TL < 4000 au. A weak negative correlation was found between TL's and treatments, possibly contributing to TL's decreasing as athletes underwent more treatments (r = -.229). Over the course of 14 weeks the swimmers had a total of 152 treatments, 91 of which occurred following a 3 week period where TL's were consistently high (>4000 au). A 72.5% increase in number of treatments occurred after a 3 week period of high TL's. Conclusion: A latent increase in treatments after consecutive high TL's (>4000 au) is expected based on the cumulative load theory and may explain the negative correlation between TL and treatments over the entire season.

The Effect Of Core Strength Training On Dynamic Balance And Agility In Collegiate Korfball Players

Lei Yao¹, Hao Guo², Lingjie Zheng³, Jindong Chang⁴.
¹Southwest University, Chongqing, China. ²Chongqing College of Humanities, Science & Technology, Chongqing, China. ³High School Affiliated to Southwest University, Chongqing, China. ⁴The Branch of the Collaborative Innovation Center of Assessment toward Basic Education Quality at Southwest University, Chongqing, China.
 Email: yaoleisouthwest@163.com
(No relevant relationships reported)

PURPOSE: The purpose of this study was to investigate the effect of core strength training (CST) on core endurance, dynamic balance and agility in collegiate korfball players.

METHODS: Twenty-two college students (age = 20.9 ± 1.4 years; height = 179.8 ± 8.9 cm, weight = 72.4 ± 12.2 kg) korfball players were randomly divided into two groups as training group (TG, N=11) and control group (CG, N=11). The TG completed CST twice a week, for 8 weeks. The CG trained according to the original plan. Star Excursion Balance Test (SEBT), Illinois Agility Test, and the core endurance tests were used to evaluate all subjects. Paired sample T-test and factor analysis were used as data analysis.

RESULTS: There were significant increases in core endurance tests (t=-7.5, p<0.05) and directions of SEBT (t=-3.1, p<0.05) after the experiment in the TG. However, no significant change was observed for agility (t=0.9, p>0.05). In addition, there were significant increases in core endurance tests (t=-4.7, p<0.05), no changes in the directions of SEBT (t=0.8, p>0.05) and agility (t=1.3, p>0.05)

CONCLUSIONS: The core strength training could improve core endurance and directions of the SEBT in collegiate korfball players, but not in agility. Consequently, if the goal of training is to enhance agility, then CST has limited. (This study was supported by Fundamental Research Funds for the Central Universities at SWU Grant 1309232)

Studies On The Effect Of Single Scull Training On The Skill Improvement In Sweep Rowers

Chunmei Cao¹, Congming Chen¹, Keying Zhang¹, Yu Liu¹, Weimo Zhu, FACSM. ¹Division of Sports Science and Physical Education, Beijing, China. ²University of Illinois at Urbana-Champaign, Urbana, IL. (Sponsor: Weimo Zhu, FACSM)
 Email: caocm@tsinghua.edu.cn
(No relevant relationships reported)

In recent years some sweep rowers use single scull boat to train their rowing skill, especially during winter times. However, there is no report about the scull training efficiency in improving the sweep skill. **PURPOSE:** To evaluate the effect of single scull training on the skill training efficiency of sweep rowers.

METHODS: Thirty-five national level male sweep rowers (22.31±2.42 yr., height: 196.33±3.76 cm, mass: 96.05±4.77 kg) volunteered attending the test, who were randomly divided into experimental group (n = 18) and control group (n = 17). All subjects performed rowing skill training 5 times a week, 90 minutes each, for 4 weeks.

Two groups trained same except that the subjects in experimental group used single scull boat and the subjects in control group used sweep boat. The key parameters of rowing skill were measured before and after 4 weeks training by bio-row system including catch, release, total angle, catch slip, release slip, maximal fore, average force, leg speed and power. Separate two-way ANOVA with repeated measures was performed to compare groups (experimental, control) and times (before, after) for each of the parameters. Tukey's HSD tests were conducted for post-hoc comparisons. The alpha level was set at <0.05.

RESULTS: 1. There were significant group by time interactions for release (F_(1,32) = 6.23, p<.05), catch slip (F_(1,32) = 33.18, p<.001) and leg speed (F_(1,32) = 7.95, p<.005). 2. The main effect for time was significant for catch slip (F_(1,33) = 53.86, p<.001), average force (F_(1,33) = 37.64, p<.001), leg speed (F_(1,33) = 22.63, p<.001) and power (F_(1,33) = 9.25, p<.01). The main effect for group was significant for catch (F_(1,33) = 3.50, p<.05), release (F_(1,33) = 4.61, p<.05), release slip (F_(1,33) = 8.15, p<.01). 3. The release of experimental group significantly increased larger than that of control group (8.25 ± 2.06 vs. 1.28 ± 2.10), so that with release slip (7.88 ± 2.51 vs. 1.39 ± 2.67).

CONCLUSIONS: Single scull training dose have effect in improving release and release slip skill for sweep rowers.

Results of a Six Week Training Protocol for Dancers to Achieve Pointe (Toe Shoe) Readiness

Marijeanne Liederbach¹, Kristen Stevens¹, Emily Sandow¹, Karl Orishimo², Ian J. Kremenc², ¹*NYU Langone Orthopedic Hospital, New York, NY.* ²*Lenox Hill Hospital, New York, NY.*
 (Sponsor: Malachy P. McHugh, PhD, FACSM)
 Email: marijeanne.liederbach@nyumc.org
 (No relevant relationships reported)

PURPOSE: It is estimated that 2 million children study dance each year in USA public schools alone, and that more than 35% of all adolescent girls participate in some form of dance training. Their most common injury is ankle sprain, with recurrence as high as 80%. This study aimed to test the efficacy of a six-week, pre-pointe (toe shoe) progressive training program that, if effective, would subsequently be put into a 3-year prospective epidemiologic study examining the intervention's effect on ankle sprain rate. **METHODS:** 16 pre-pointe students, (average age 11 yrs), at a professional ballet school assented, (along with parent/guardian consent), to participate. Three motor control-based concepts were incorporated into a 50 minute progressive exercise class taught twice per week for 6-weeks. The motor control principles underlying all of the exercises were: 1.) identification and maintenance of trunk-pelvic neutral; 2.) appropriate weigh shift; 3.) dissociation of the limbs from the trunk. Tests of lower extremity and trunk strength were assessed using hand-held dynamometry and Kendall methods. Four functional tasks, (single leg eyes-closed balance; topple; airplane and sauté tests), were assessed along with one IMU-based jump task. Jump height and GRF were estimated using an inertial sensor (BTS G-Sensor 2, Brooklyn, NY). The sensor, worn in a pouch on a velcro belt wrapped around the dancer's trunk at umbilicus level, contained a triaxial accelerometer, gyroscope and magnetometer and connected wirelessly via Bluetooth® to a computer. Based on the accelerations measured by the sensor and the weight of the subject, several parameters were estimated. **RESULTS:** Paired t-tests revealed changes from the pretest to posttest assessment day: hip abduction ($p=0.009$) and trunk strength ($p=0.045$), balance ($p<0.001$), topple ($p=0.006$), airplane ($p=0.005$), all improved significantly; sauté showed a trend to improve ($p=0.084$). No G-Sensor jump parameters showed improvement. **CONCLUSIONS:** Significant improvements in strength, balance, and alignment were demonstrated by this cohort. Jump performance did not show improvement, but was an unfamiliar task to the subjects at the beginning of the training; it will be monitored intermittently as training continues.

3502 Board #190 June 1 8:00 AM - 9:30 AM
Effect Of 3d Multiple Object Tracking Training On Collegiate Ice Hockey And Lacrosse Game Performance

Erin Manning, Jesse Hall, John Rosene. *University of New England, Biddeford, ME.*
 Email: emanning1@une.edu
 (No relevant relationships reported)

3D multiple object tracking (3D MOT) aids in improving working memory and spatial awareness by stressing foveal and peripheral vision while demanding multi-faceted attentional focus. 3D MOT also improves cognitive processing which may improve the ability to rapidly extract data from the environment thereby enhancing decision making capabilities. These attributes have the potential to enhance sports performance. **PURPOSE:** The purpose of this study was to determine if 3D MOT training increases in-game performance during a competitive season. **METHODS:** 79 athletes from four NCAA DIII collegiate athletic teams (ice hockey $n=34$; lacrosse $n=45$) participated. Athletes were assigned to either a 3D MOT ($n=38$) training intervention or control (C) group ($n=41$). Athletes completed 24 sessions of 3D MOT training, 2-4 times per week over 12 weeks during the respective competitive seasons. At the conclusion of the seasons, independent samples t-tests were used to compare performance measures (game statistics) between 3D MOT and C groups for ice hockey (men's and women's combined), men's lacrosse, and women's lacrosse. **RESULTS:** There were no significant differences in performance measures between 3D MOT and C groups for ice hockey ($p>0.05$). For men's lacrosse, faceoff winning percentage was significantly different ($p=0.000$) with the C group having a greater faceoff winning percentage versus the 3D MOT group (30% vs. 0%). For all other performance measures there were no significant differences ($p>0.05$) between groups. For women's lacrosse, there were significant differences for assists ($p=0.045$), points ($p=0.034$), shots ($p=0.035$), and free-position shots ($p=0.014$) with the 3D MOT group having lower values versus C. **CONCLUSIONS:** Athletic performance is multifactorial in uncontrolled environments such as competitive ice hockey and lacrosse, which may suggest that performance benefits of 3D MOT training may be overshadowed by the complexities of game play. The significant differences found between groups may be due to player skill differences versus a 3D MOT effect. Further research is warranted to determine the effectiveness of 3D MOT training and its impact on sport performance.

Pelvic and Core Strength Training Improves Pelvic Posture, Hamstrings-to-Quadriceps Ratio, and Vertical Jump Performance

Chee-Hoi Leong, Cassandra York, Zachary Bohling. *Central Connecticut State University, New Britain, CT.*
 Email: c.leong@ccsu.edu
 (No relevant relationships reported)

Poor pelvic posture demonstrated through anterior pelvic tilt have been known to produce musculoskeletal imbalances involving muscular weakness of the abdominal and pelvic regions. While stretching and massage techniques have been reported to be effective in alleviating anterior pelvic tilt, it remains unclear if similar improvements can be elicited by pelvic and core strength training. **PURPOSE:** To examine the effect of an 8-week pelvic and core strengthening program on anterior pelvic tilt (APT), hamstrings-to-quadriceps (H:Q) strength ratio, and vertical jump performance in healthy individuals. **METHODS:** Nine healthy males (age=27.11±12.15 years; mass=82.78±8.84 kg; height=178.76±8.07 cm) performed resistance training (2x/week; 30-40 min) involving a combination of abdominal and hip extensors strengthening exercises for 8 weeks. APT (°), vertical jump height (m), vertical jump power (W), and H:Q ratio at 60, 180, and 300 °/s were assessed prior to and following the 8-week pelvic and core strengthening program. Paired samples t-tests were used to evaluate pre- to post-training changes in APT, vertical jump height and power, and H:Q ratio. Effect sizes (*ES*) were calculated for all analyses and *ES* magnitudes of < 0.50, 0.50-1.0, and > 1.0, were interpreted as small, medium, and large effects, respectively. **RESULTS:** APT was significantly decreased, and vertical jump height and the H:Q ratio at the angular velocity of 300 °/s were significantly increased, following 8 weeks of pelvic and core strength training (all $p < 0.05$, Table 1). **CONCLUSION:** Resistance training emphasizing pelvic and core strengthening was effective in reducing APT, improve vertical jump performance and H:Q ratio. Our findings have potential implications for clinicians prescribing resistance exercises to improve pelvic posture in patient populations with musculoskeletal imbalances, and for injury prevention and maintenance of postural equilibrium in healthy individuals.

Table 1. Pre- versus post-training responses (mean±SD) following pelvic and core strength training.

| | Pre-training | Post-training | %Δ | <i>P</i> | <i>ES</i> |
|--------------------------|--------------|---------------|----|----------|-----------|
| APT (°) | 14.9±3.2 | 8.6±3.5* | 42 | 0.0005 | 1.95 |
| Vertical jump power (kW) | 4.45±8.76 | 4.56±1.02 | 2 | 0.18 | 0.12 |
| Vertical jump height (m) | 0.457±0.099 | 0.493±0.090* | 8 | 0.004 | 0.36 |
| H:Q ratio @ 60 °/s | 0.49±0.07 | 0.56±0.12 | 14 | 0.06 | 0.92 |
| H:Q ratio @ 180 °/s | 0.50±0.15 | 0.57±0.12 | 15 | 0.06 | 0.49 |
| H:Q ratio @ 300 °/s | 0.51±0.13 | 0.60±0.13* | 18 | 0.04 | 0.70 |

*Significantly different compared to pre-training ($P<0.05$).

Impact of 4-week Brain Endurance Training (BET) on Cognitive and Physical Performance in Professional Football Players

Walter Staiano¹, Michele Merlini², Chiara Gattoni², Samuele Marcora³. ¹*University of Valencia, Valencia, Spain.* ²*University of Kent, Chatham Maritime, United Kingdom.* ³*University of Bologna, Bologna, Italy.*
 (No relevant relationships reported)

PURPOSE: It has been hypothesized that acute negative effect of mental fatigue (MF) could potentially become a training stimulus for the brain (Brain endurance training [BET]) to adapt and improve its ability to better sustain or attenuate MF states during sport competitions. The aim of this study was to test the efficacy of BET to reduce fatigue during a battery of cognitive and physical tests in players from a professional football team. We hypothesized that combination of BET and standard physical training during a 4-week period would increase cognitive capacity and physical football performance by increasing resilience to fatigue, more than standard football training alone. **METHODS:** 24 professional football players were randomly assigned to 2 different training groups: BET and Control. Both groups completed 20 supervised physical training sessions. Immediately after each session BET group completed on average 400 min (20 min/session) of cognitive training. Control group, instead, was asked to listen to neutral music for the same amount of time. Endurance performance (30-15 Intermittent Fitness Test), Sprint and Decision Making (RSA Random Test), Reactive Agility alongside with cognitive performance (STROOP Task) were measured at baseline (pre-test) and after 4 weeks of training (post-test). Data were

analysed using mixed model ANOVAs. **RESULTS:** STROOP task showed reaction time in both groups decreased at post-test. However, BET decreased significantly more compared to control group ($p < 0.02$) despite no significant differences in accuracy. BET group completed the reactive agility test significantly faster than the control group ($p < 0.05$) and with lesser fouls ($p < 0.03$). During the RSA Random Test no significant differences were found between the groups for linear acceleration phase (first 10 m). However, BET group completed significantly faster ($p < 0.05$) the decisional phase (second 10 m). Distance covered during the 30-15 test showed there was no difference in the performance of the BET group. However, control group showed a significant decrease ($p < 0.05$) in performance. **CONCLUSION:** The results of this study provide evidence that the combination of BET and standard football training is more effective than standard training alone in boosting cognitive and physical performance in elite football players.

Effect of Wheelchair Tai Chi Ball Exercise on Physical & Mental Health among Elderly

Jingle Xu¹, Shiqi Yu¹, Chung-Hyun Goh¹, Ting Liao², Xuanliang Neil Dong¹, Gloria Duke¹, Danita Alfred¹, Yong Tai Wang, FACSM¹. ¹The University of Texas at Tyler, Tyler, TX. ²Wuhan Sports University, Wuhan, China. (Sponsor: Yong Tai Wang, FACSM)
Email: JXu3@patriots.uttler.edu
(No relevant relationships reported)

Mind-body exercise and strength training are crucial for elderly with disability. In this project, we developed an innovative exercise of Wheelchair Tai Chi Ball 12 forms (WTCB12), which combines mind-body exercise with strength training for elderly with disability. **PURPOSE:** To examine the effect of a 3-month WTCB12 intervention on physical and mental health and functional abilities among elderly.

METHODS: Twenty-six participants from a local senior living facility participated in the WTCB12 intervention with 13 in each group. Nine completed the study in WTCB group (age: 86.55±3.39 yrs; height: 1.69±0.17 m; mass: 75.54±20.28) and ten completed in the control group (age: 81.78±14.39yrs; height: 1.64±0.07m; mass: 68.31±15.17kg). The weights of the WTCB ranged from 1 pound to 2 pounds selected by the participants based on their physical conditions. The WTCB group practiced WTCB12 twice a week, one hour each time. The control group did their daily routine without WTCB intervention. The following variables were measured: Pain Self-Efficacy Questionnaire (PSEQ), heart rate (HR), blood pressures, range of motion (ROM) and muscle strengths of the dominant arm at the shoulder, elbow and wrist joints, and SF-36v2 for physical and mental health. The Independent t test and paired t test were employed to examine the differences between and within the two groups in the pretest and posttest.

RESULTS: The results indicated that the PSEQ was significantly improved in WTCB group after WTCB intervention (Pre-test: 41.44±13.89 vs Posttest: 50.11±8.94, $p < .05$), but no significant improvement in the control group. The HR, blood pressures, ROM and SF-36v2 physical and mental health were not significantly different between two groups, however, the WTCB group had significant greater muscle strengths at the shoulder extension, abduction and adduction, elbow flexion and extension and wrist flexion and extension in the posttest than the control had since the WTCB group's joint muscle strengths maintained and the control group's muscle strengths at these joints decreased.

CONCLUSIONS: WTCB12 exercise may help with pain management, maintain upper extremity muscle strength and is a feasible exercise for elderly with disability. Supported by Paralyzed Veterans of America Education Foundation Grant #819

Health And Fitness Benefits Using A Heart Rate Intensity-based Commercial Fitness Exercise Regimen

John C. Quindry, FACSM, Cassie Williamson. University of Montana, Missoula, MT.
Email: John.quindry@mso.umt.edu
(No relevant relationships reported)

PURPOSE: Inactivity leads to morbidity and mortality, while engaging fitness approaches improve health outcomes.

METHODS: The current study examined an 8-week commercial group exercise regimen for comprehensive health and fitness indices. Study duration gauged the time frame by which high intensity interval training (HIIT) elicits improved health and fitness. Aerobic fitness, body composition, resting metabolic rate, blood cholesterol and glucose, in addition to resting blood pressure were quantified. Exercise training utilized multimodal HIIT-based exercises and work intensity was gauged by real-time heart rate feedback.

RESULTS: Program adherence was 100% with 23 participants. Pre-Post analyses indicate aerobic fitness (O_{2max} +4 ml·kg⁻¹·min⁻¹), body composition (%fat -1.1%), resting metabolic rate (+107 Kcal), resting blood pressure (-8.1mmHg systolic, -2.5mmHg diastolic), and circulating triglycerides (-21%) were altered.

CONCLUSIONS: This study is the first study to quantify comprehensive improvements in aerobic fitness, body composition, resting metabolic rate, resting blood pressure, and triglycerides after a brief 8-week HIIT regimen. The implications of franchised group exercise with wearable technology serves as an unexplored scientific approach to understand novel exercise prescriptions on health-fitness outcomes. Future research should investigate sociological aspects of program adherence, while biological applications should be examine the adaptive stimuli of HIIT training on health and fitness improvements.

Comparison of Two Training Programs for Improvement of Muscular Strength Quantified via Pull-Ups

Ciara-Lyn Lee¹, Eric C. Bredahl¹, Michael T. Lane², Jacob A. Siedlik¹. ¹Creighton University, Omaha, NE. ²Eastern Kentucky University, Richmond, KY. (Sponsor: Joan Eckerson, FACSM)
(No relevant relationships reported)

The requirement to integrate women into combat-arms military occupational specialties represents an opportunity to refocus training protocols for optimized performance in specific components of military physical and combat fitness tests. The United States Marine Corps will incorporate new standards in 2019 which include requiring more pull-ups for female Marines. The pull-up requirement is often difficult for Marine recruits to achieve and the overabundance of training protocols potentially confuses recruits and minimizes potential gains in event specific muscular strength.

PURPOSE: To quantify changes in completed pull-ups between two training protocols to determine an optimal program for improved performance in college-aged females.

METHODS: Twenty-nine female subjects volunteered to participate and were randomized to either a control group or one of two training programs (Control [n = 3]; Free Weights [n = 14]; Machines [n = 12]). The two training programs consisted of pre-programmed workouts 3 d·wk⁻¹ focused on upper body and core exercises. There was at least 1 d of recovery between workouts. Subjects were monitored for the first 2 wk of training to ensure compliance and proper technique. Maximum number of pull-ups were assessed at baseline, 3 wk, and 6 wk. Data were analyzed using a 3x3 repeated measures ANOVA. **RESULTS:** There were no significant differences in age, height, or weight between the groups (Mean ± SD; age = 20 ± 1 yr; Height = 164 ± 6 cm; Weight = 64.2 ± 9.9 kg). Over the 6 wk period a total of 5 subjects withdrew from the study (Control [n = 3]; Free Weights [n = 11]; Machines [n = 10]). No significant interaction effect was observed between programs ($p = .7$); and there was no main effect for time ($p = .1$). **CONCLUSION:** Overall the training protocols improved pull-up performance with 4 of the free weight participants and 3 of the machine-based participants improving from zero to one or more pull-ups. Results are limited due to the dropout rate of ~17% over the training period which is not unexpected given the duration of this study. Future research should focus on improved adherence, and subject monitoring, to optimize performance in the pull-up event.

3508 Board #196 June 1 8:00 AM - 9:30 AM

Effect Of Suspension Training On Functional Movement Screen (FMS) and Mobility, Activation, Posture, and Symmetry (MAPS)

Megan Jackson¹, Emily Hilliard¹, Ann T. Shields¹, Alex McDaniel¹, Ryan Swiezy¹, Rachel Willilams¹, Courtney K. Milleson¹, Andrew Ortiz¹, Brad Hollingsworth¹, Sarah Noland¹, Raechel Santee¹, Phillip Morie¹, Lauren Ackerman¹, Emma Schmid¹, Kelsey D. Bryan¹, Frances M. Livingston¹, Tiago Barreira², Wayland Tseh¹. ¹University of North Carolina Wilmington, Wilmington, NC. ²Syracuse University, Syracuse, NY. (Sponsor: Dr. Robert Boyce, FACSM)
(No relevant relationships reported)

INTRODUCTION: Although suspension training is used in various exercise routines, there has been insufficient research to determine the effect of suspension training on functional movement. **PURPOSE:** 1) to examine the effect of suspension training on functional movement, assessed via the FMS and MAPS and 2) to identify the correlation between the FMS and MAPS. **METHODS:** Twenty-seven participants (19 females; 8 males; Age = 26.0 ± 11.1 yrs; Height = 167.9 ± 9.1 cm; Body Mass = 69.6 ± 14.1 kg) completed 28 exercise sessions over a 14-week course. Throughout each 40-minute exercise session, six body positions were utilized on the suspension training straps which included push, pull, rotational, squat, and lunge movements; participants also engaged in functional training utilizing stability balls and resistance bands. Pre- and post-fitness assessments included the FMS, MAPS, body composition, muscular endurance, muscular strength, and flexibility. Dependent t-tests were used to determine if there were mean changes in functional movement status. Due to multiple comparisons, Bonferroni correction was used, therefore, alpha level was set at .007.

RESULTS: There were significant positive changes in FMS (14.6 ± 2.7 to 15.9 ± 2.1, $p < 0.001$) and MAPS (52.9 ± 10.3 to 56.3 ± 9.7, $p < 0.001$) values, as well as mean quantity of push-ups (24.9 ± 11.5 to 29.4 ± 13.9, $p = 0.004$) and handgrip dynamometer (78.0 ± 21.7 kg to 85.6 ± 24.0 kg, $p = 0.006$). There were no significant changes in

mean body mass, fat mass, lean mass, percent body fat, and sit-and-reach values. Pearson correlation was used to determine the relationship between FMS and MAPS both at pre- and post-testing. At both time points, pre- and post-testing, the correlations were significant ($r = .52$ and $.43$, respectively). **CONCLUSIONS:** Participation in suspension training produced significant improvements in overall functional movement, muscular strength, and endurance. Although there were significant positive changes in both FMS and MAPS from pre- to post-assessment, a weak correlation existed between the FMS and MAPS assessments.

Biomechanical Analysis of Collegiate Baseball: Training Implications for Enhancement of Pitching Endurance

Andria C. Moitoza¹, William P. Lydon¹, J. Mark VanNess¹, Alexis C. King², Courtney D. Jensen¹. ¹University of the Pacific, Stockton, CA. ²University of Illinois at Urbana-Champaign, Champaign, IL.

(No relevant relationships reported)

Endurance is critical to a starting pitcher's success. However, the repetition of pitching stress can decrease performance and increase risk of injury in later innings. Improving arm endurance likely enhances late-game performance. **PURPOSE:** To evaluate predictors of mechanical endurance in collegiate pitchers. **METHODS:** 10 Division-1 pitchers were tested using Proteus technology (Boston Biomotion, Inc.). They completed 6 sets of 5 pitches; each set changed in resistance, ranging from ½ to 5 lbs. Endurance was a calculation of the ability to preserve power in each set on a continuous scale of 0.00 (0% preservation) to 1.00 (100% preservation). Mean endurance was the mean value of all 6 sets. Proteus also assessed biceps curls, triceps extensions, internal and external rotation, and horizontal adduction and abduction. Pitchers were tested during the 2017 season and data were compared to in-game performances. Linear regressions tested the relationships between endurance, performance on other tests, and in-game statistics. **RESULTS:** Pitchers were 72.0 ± 2.7 inches in height, had a mean fastball velocity of 84.6 ± 3.9 mph, a mean earned run average (ERA) of 5.8 ± 2.8 , and a mean endurance of $97.7 \pm 1.9\%$. Endurance was unrelated to class year ($p=0.857$) and was not related to anthropometric measurements, including height ($p=0.460$), weight ($p=0.188$), arm length ($p=0.350$), and leg length ($p=0.464$). Maximum squat strength ($p=0.917$), fastball velocity ($p=0.832$), and three-dimensional measurement of pitch range of motion ($p=0.730$) were also unrelated to pitch endurance. Biceps curl endurance ($p=0.035$) and triceps extension explosiveness ($p=0.089$) of the dominant arm correlated with pitching endurance. These relationships lost significance on non-dominant arm for curls ($p=0.241$) and extensions ($p=0.187$). Given a larger sample, other associations may be found; of interest, there may be relationships between endurance and innings per appearance ($\beta = 0.353$, $R^2=0.196$; $p=0.232$) and ERA ($\beta = -0.559$, $R^2=0.149$; $p=0.305$). Post-hoc power analyses revealed samples of 30 and 38 respectively to reach significance (power=0.80; $p=0.05$). **CONCLUSIONS:** Fatigue results from repetitive overhead throwing, elevating risk of overuse injuries. Use of Proteus may provide modes of exercise unrecognized by traditional baseball training.

Automated Impact Corroboration From Game Video In Ice-hockey Using Computer Vision Approaches

Muhammad Sohaib Arif¹, Aaron Pilotti-Riley¹, Erik Bollt², Stephen J. McGregor¹, Davor Stojanov¹. ¹Eastern Michigan University, Ypsilanti, MI. ²Clarkson University, Postdam, NY. (Sponsor: Mark Peterson, FACSM)

Email: marif@emich.edu

(No relevant relationships reported)

Purpose

Video corroboration of on ice impacts identified by wearable sensors (WS) is a time-consuming task. To automate this, we attempted a computer vision approach to recorded game video to corroborate impacts identified using WS among national ice-hockey team members.

Methods

23 U.S. National U18 Hockey team members consented to procedures approved by EMU HSRC. Impacts were previously validated from data collected at 100 Hz (Impact Processor, Zephyr MD) from 8 players with the top activity levels determined by WS in 4 games. Game video was manually synchronized, and timestamps were used to extract frames from the video that allowed for visually identifying and labeling impacts. A convolutional neural network (YOLO) was used to detect impacts in video and generate a training dataset from 1060 images from 3 game videos that included 86 impacts.

Video and timestamps were used for training instead of still frames. Denoising filters were used to account for time shift errors due to manual labeling and anomalous detections appearing and disappearing in up to half a second of video. Thus, we

removed any impacts detected by video for less than 30 or 60 continuous frames (0.5 or 1.0 second, respectively). An smaller version of the model (YOLO-tiny) was also tested on a Note 8 (Samsung) smart phone to determine applicability to real-time game setting.

Results

The trained YOLO network was applied to the 4th game video that had 32 validated sensor identified impacts. The model successfully detected all 32 impacts but generated 1000 false positives. With a 60 frame filter, the model detected 20 of the 32 events, but false positives were reduced to 211. With a 30 frame filter, the model detected all 32 impacts but false positives increased to 391. Interestingly, the mobile model and 30 frame filter detected all 32 impacts with 222 false positives, of which, 99 were classified as "Pass Bys" or players that occluded each other on the video but did not make physical contact.

Conclusion

These results demonstrate that computer vision techniques can be used to identify validated impacts with high success, but with many false positives. The high false positive rate presents a challenge, but since a large proportion of false positives were simple pass-bys, using a real-time sensor fusion approach with WS, the false positives may be reduced substantially.

Relationship Between the Perceived Training Loads of Division II Swimmers and Coaches

Bianca Lagamon, Angel Quintero, Derrick Gardner, Vanessa Yingling, FACSM, James Mouat IV. California State University, East Bay, Hayward, CA. (Sponsor: Vanessa Yingling, FACSM)

(No relevant relationships reported)

Monitoring training loads provides coaches the opportunity to create effective programs for their athletes to prepare for competition and make adjustments to manage fatigue, reduce the risk of soft-tissue injuries and non-functional overreaching. An athlete's training load is a combination of the external load (work completed by the athlete) and internal load (physiological or psychological stress from that work). The individuality of perceived training loads is an important consideration for a coach as the athlete's perception may be different from the intended demands from the coach. The difference in perceived training loads between the coach and athlete can increase the risk of undertraining or overtraining. **PURPOSE:** To compare the perceived training loads between a coach and athletes on a Division II women's swimming team. **METHODS:** Twenty-four athletes participated (age 20.2 ± 1.2 years; height 169.03 ± 6.2 cm; mass 68.7 ± 8.9 kg). The expected training loads of the coach and perceived training loads of the athletes were monitored for one season. A survey link was sent to the coach and players to report the date, the duration of training in minutes and the rate of perceived exertion (RPE) for each practice and competition. Training load (TL) was calculated as the product of the RPE and training session duration in minutes and labeled arbitrary unit (AU). The relationship between the coach's expected training loads and the athletes' perceived training loads were examined using paired t-test and Pearson correlation. **RESULTS:** The swimmers average TL over the 54 sessions was 554.5 ± 237.1 au which showed no significant difference from the coach's average perceived TL, 555.6 ± 246.5 au ($p=0.85$). A strong correlation was found between the TL of the coach and the average TL of the 24 athletes ($r=0.87$, $CI=0.79-0.92$, $p<0.0001$). **CONCLUSION:** On average, the athletes perceived the training sessions to be harder than what the coach expected. Differences in training expectations and perception could be due to fitness levels among athletes, sleep (quantity and quality), academic stress or illness. However, the differences in TL expectation and perception could result in fatigue, injury and/or suboptimal training adaptation. Monitoring planned and perceived training load is critical to optimize performance and reduce injury.

3512 Board #200 June 1 8:00 AM - 9:30 AM
Relationships Between Isometric and Dynamic Strength in Recreationally Active Women

Stephen J. McGuire, Sam D. Blacker, Jason Lake, Stephen D. Myers. University of Chichester, Chichester, United Kingdom.

(No relevant relationships reported)

Women entering training for physically demanding occupations typically perform strength orientated tasks less well than their male counterparts. However, they are not often strength-trained and appropriate training may reduce these differences. Force-time assessment of the isometric mid-thigh pull (IMTP) has been used to monitor strength adaptations in athletes as they relate to dynamic task performance. The ratio between peak countermovement jump (CMJ) concentric force and IMTP peak force (Dynamic Strength Index [DSI]) has also been used to guide prescription of maximal or ballistic strength training. **PURPOSE:** To examine the efficacy of IMTP and DSI to monitor and prescribe strength training in untrained women. **METHOD:** Following familiarization, 26 civilian women volunteers (mean \pm SD, age: 24 ± 3 y, height: 1.64 ± 0.05 m, body mass: 65.4 ± 11.8 kg) completed five tests in this order: bench press one-repetition maximum (1RM); CMJ; IMTP; seated medicine ball throw (MBT); dominant handgrip strength. Force plates sampling at 1000 Hz recorded IMTP and

CMJ performance, and IRMs were predicted from submaximal load-velocity profiles. Relationships were assessed between IMTP and dynamic tests (Pearson's *r*), and performance compared between Low (<0.60, n = 8) and High (>0.80, n = 10) DSI participants (Bonferroni adjusted independent t-tests or Mann-Whitney U test), with effect sizes calculated (Hedges *g*). **RESULTS:** Absolute peak IMTP force (minus body weight) correlated moderately with handgrip strength (*r* = 0.66), MBT (*r* = 0.70) and IRM (*r* = 0.57), and relative IMTP peak force (per kg body mass) with CMJ height (*r* = 0.48). The IRM (Low vs High DSI: 45.0 ± 11.0 vs 31.5 ± 6.5 kg, *g* 1.6), absolute IMTP (1386 ± 276 vs 709 ± 166 N, *g* 2.9), relative IMTP (20.7 ± 2.8 vs 11.0 ± 1.9 N·kg⁻¹, *g* 4.9), MBT (3.3 ± 0.3 vs 2.7 ± 0.3 m, *g* 2.4) and handgrip (34.5 ± 1.8 vs 26.2 ± 3.9 kg, *g* 3.1) were greater in Low DSI participants (*p* < 0.01), with no difference in CMJ height (0.23 ± 0.03 vs 0.19 ± 0.05 m, *g* 0.51). **CONCLUSION:** Moderate relationships between IMTP force and dynamic performance are consistent with current athletic literature, thus absolute and relative force are both recommended to monitor strength training adaptations in untrained women. Similar ballistic (CMJ) performance between Low and High DSI individuals support its use to prescribe training modality.

G-39 Free Communication/Poster - Anterior Cruciate Ligament

Quadriceps Oxygen Consumption During Exercise in Patients with ACL-Reconstruction**

Abbis Jaffri, Maggie Lynch, Susan Saliba, Joe Hart, FACSM.
University of Virginia, Charlottesville, VA.
Email: ahj8uw@virginia.edu
(No relevant relationships reported)

PURPOSE: Patients with ACL reconstructed knees (ACLR) commonly experience persistent muscle weakness. Altered oxygen consumption (OC) during voluntary rehabilitation exercises of the quadriceps may be a contributing factor. The purpose was to compare quadriceps muscle OC during knee extension exercises in patients with ACLR versus healthy controls. **METHODS:** 10 patients with primary, unilateral ACLR (7M/3F, 22.9±3.5y, 170.81 ± 7.93cm, 73.7 ± 15.1kg) and 10 matched controls (7M/3F, 22.9±3.5y, 170.4 ± 10.7cm, 68.86 ± 9.51kg) participated. Each participant completed a single data collection session consisting of 5-second isometric contractions at 25, 50 & 75% of the volitional maximum followed by a 30s maximal isometric knee extension contraction. We continuously recorded measures of oxygenated hemoglobin (O2Hb) on the reconstructed thigh (versus the non-dominant thigh of healthy controls) using three wearable, wireless near-infrared spectroscopy units placed superficial to the vastus medialis, lateralis and rectus femoris muscles. Relative changes in OC were ensemble averaged and plotted for each contraction intensity with associated 90% confidence intervals. Statistically significant differences were defined as portions of the exercise trials where confidence intervals of the O2Hb graph did not overlap. Effect sizes were calculated for statistically significance. **RESULTS:** We observed significantly lower relative change in O2Hb for ACLR compared to healthy controls in the rectus femoris at 25% (2.1[1.5-2.7]), 50% (2.8[2.6-2.9]), 75% 2.0[1.9-2.2] and for the vastus medialis at 75% (1.5[1.4-1.5]) and 100% (2.6[2.5-2.7]) (Figure 1). No other statistically significant differences were observed. **CONCLUSION:** Differences exist in quadriceps muscle OC between patients with ACLR during the same exercises versus healthy controls. However, not all portions of the quadriceps are affected uniformly across contraction intensities.

Figure 1: O2Hb in ACLR thighs compared to a healthy matched thighs at different exercise intensities for rectus femoris (RF) and vastus medialis (VM). Blue solid lines represent ACLR, green lines represent Healthy and dotted lines represent 90% confidence intervals over the course of knee extension isometric contraction trials. Data presented as changes relative to the start of the trial.

Comparison of Knee Functional Outcomes after Anterior Cruciate Ligament Reconstruction between Older and Younger Patients**

do kyung kim, Geon Park, WonHah Park. *Samsung Medical Center, seoul, Korea, Republic of.*
Email: hrmax1@naver.com
(No relevant relationships reported)

Anterior cruciate ligament (ACL) reconstruction is frequently performed to restore knee stability and function following ACL injury. Traditionally, ACL injury people older than 40 years received non-operative treatments because of not performing high demanding activities and possible inferior surgical outcomes. According to increasing sports activities, there are more chance to injury and surgical reconstruction in patients older than 50 years. However, a few numerous research with knee function and stability outcomes had been reported following ACL reconstruction in age over 50 years old.

PURPOSE: The aim of this study was to evaluate muscle strength, ligament stability, and functional outcomes in comparing older (>50 years) and younger (<40 years) patients at 1 year after ACL surgery. **METHODS:** A retrospective analysis of prospectively collected data was performed in 40 younger (29.0±5.1yr) and older (52.5±2.1yr) ACL reconstruction patients each. All patients were evaluated for isokinetic extensor and flexor muscle strength, laxity, and functional scores at 1 year after operation. The highest peak torque at each velocity was compared with the uninjured side by isokinetic device. The knee laxity was assessed by the KT-2000 arthrometer. The comparing injured and uninjured knee side-to-side difference was measured at anterior maximum manual tension. Knee functional score were evaluated using the validated International Knee Documentation Committee (IKDC) and Lysholm scores. **RESULTS:** There was no statistically significant difference in extensor strength deficits between older and younger groups at 60°/s and 180°/s (*p* = 0.495, *p* = 0.419, respectively). In addition, there was no differences in knee flexor strength deficits between the groups (*p* = 0.417, *p* = 0.449, respectively). There was also no statistically significant difference in ligamentous laxity (*p* = 0.06) and Lysholm scores (*p* = 0.126). However, IKDC scores in the younger group showed significantly greater improvement than those in the older group (*p* = 0.009). **CONCLUSION:** Older patients with ACL reconstruction surgery would have similar results for knee strength and ligament laxity. This study showed that ACL reconstruction is more effectiveness and safety for restoration of knee strength and stability in older than 50 years patient group.

3515 Board #203 June 1 9:30 AM - 11:00 AM
Associations Between Muscle Morphology Measured with Ultrasonography and Self-Reported Function Following Anterior Cruciate Ligament Reconstruction

Steven A. Garcia, Michael T. Curran, Riann Palmieri-Smith.
University of Michigan, Ann Arbor, MI.
 Email: stevenag@umich.edu
 (No relevant relationships reported)

Deficits in quadriceps function are common in patients who sustain an anterior cruciate ligament (ACL) injury and undergo subsequent ACL reconstruction (ACLR). Quadriceps atrophy is among the notable changes in muscle tissue after ACLR. The relationship between muscle morphology and self-reported function should be established so treatment options can be targeted to improve function after ACLR. **PURPOSE:** (1) To evaluate rectus femoris (RF) cross-sectional area (CSA) and intramuscular fat percent (PF) in the injured and uninjured limb from 9 weeks post ACLR to return to activity (RTA) and (2) identify associations between injured limb quadriceps CSA, PF and self-reported function. **METHODS:** 28 individuals with primary unilateral ACLR (Age=16.6±2.7; Weight=71.8±17.7; 64% female; 18 bone-patellar tendon-bone; 2 quadriceps tendon; 5 hamstring tendon) were recruited for this study. RF was imaged at 15cm proximal of superior border of the patella. Quadriceps CSA and PF of the injured and uninjured limb were used for analysis. Self-reported function was evaluated using the International Knee Documentation Committee score (IKDC). Paired-samples t-tests were used to compare inter-limb differences in CSA and PF and changes from 9 weeks to RTA. Partial correlations adjusting for sex were used to analyze the relationship between RF morphology and IKDC scores. **RESULTS:** Injured limbs had smaller RF CSA at each time point (4.5±1.6cm² vs 5.2±1.9cm², p<.01 and 5.2±1.9cm² vs 5.6±2.1 cm², respectively) compared to the uninjured limb. Injured limb CSA increased at RTA (4.5±1.6cm² vs 5.2±1.9cm², p<.01) while the uninjured limb did not (p=0.12). No differences in PF were found between limbs (p=0.18, and p=0.43, respectively) or time point (p=0.67, and p=0.92, respectively). After adjusting for sex, larger injured limb CSA was associated with higher IKDC scores at 9 weeks and trended toward significance at RTA (r=0.32, p=0.05, and r=0.26, p=0.09, respectively). Injured limb PF was negatively associated with IKDC scores at both time points (r=-0.55, p<.01, and r=-0.39, p=0.02, respectively). **CONCLUSIONS:** Inter-limb differences in RF muscle CSA are not ameliorated at RTA. RF CSA and PF are associated with self-reported function in individuals with ACLR and should be treatment targets to improve patient function following injury.

Evaluating Collagen Matrix Degradation after ACL Reconstruction using Quantitative MRI

Logan K. Faux-Dugan. *Delaware State University, Dover, DE.*
 (Sponsor: Thomas Buchanan, FACSM)
 Email: lkfauxdugan15@students.desu.edu
 (No relevant relationships reported)

Logan K. Faux-Dugan¹, Jack R. Williams², Kelsey Neal², Ashutosh Khandha², PhD, Thomas S. Buchanan², PhD, FACSM. ¹Delaware State University, Dover, DE, ²University of Delaware, Newark, DE
 Forty percent of individuals who undergo anterior cruciate ligament (ACL) reconstruction develop knee osteoarthritis (OA) within eight years of the procedure. T2 magnetic resonance imaging (MRI) can be used to assess the cartilage's collagen matrix health. Higher T2 times, when compared to healthy cartilage, are indicative of cartilage matrix degradation. When the ACL is injured, a bruise develops on the central and posterior regions of the tibial plateau. It is not known if this bruising has a long-term effect on the cartilage health in this region. **PURPOSE:** To determine if T2 values at the site of initial ACL injury (central and posterior regions of tibial cartilage) are higher in the involved vs. uninvolved limb, three months post ACL reconstruction. **METHODS:** Ten participants (8 men/2 women, age = 22 ± 5 years) underwent T2 MRI testing and analysis. Menisci boundaries were used to establish regions of interest (ROI). These ROI were further divided into deep and superficial sub-layers. The average T2 value for each ROI was calculated and each was compared in the involved vs. uninvolved limb using a paired t-test ($\alpha = 0.05$). **RESULTS:** For the tibial central deep region, the inter-limb difference (involved vs. uninvolved) approached significance (36±4 SD vs. 33±6 SD; p = 0.06, (Cohen's d = .59)), with higher T2 values in the involved limb cartilage. No statistically significant results were found for the other ROI. **CONCLUSION:** While not statistically significant, higher T2 values within the involved limb's central tibial cartilage indicate that bone bruising may result in collagen matrix degradation three months post ACL reconstruction. Future studies should include follow-up time points and a larger sample size. Supported by NIH R25-NS095371 and NIH R01-HD087459.

Skeletal Muscle Mass and Circumference Discrepancies Between Injured and Un-Injured Limbs Post-ACL Reconstruction

Kassi J. Meacham, A. Page Glave, Mary L. Williams. *Sam Houston State University, Huntsville, TX.*
 (No relevant relationships reported)

Lower extremity injuries are common in sport. Anterior cruciate ligament (ACL) injuries often result in muscle atrophy in the thigh and calf muscles of the injured leg. Evaluating muscle atrophy via circumferences to document asymmetry has been recommended and is often used clinically (1). Previous studies have shown a small loss of skeletal muscle mass (SMM) may cause a greater loss in muscular strength (1), thus investigating muscle mass and girth may be beneficial in evaluating return to play post-ACL injury.

PURPOSE: The purpose of this study was to examine SMM and circumference discrepancies between injured and uninjured limbs post- ACL reconstruction. **METHODS:** Participants (n = 7, 4 F, 3 M; 21.9 ± 4.3 y; 5.24 ± 4.74 y post injury) were tested using bioelectrical impedance analysis (BIA). Fat mass, fat-free mass, body fat percentage, and SMM (kg) for extremities and torso were obtained. Circumference measurements were taken on the injured (I) and un-injured (NI) limbs at the mid-patella, and superiorly and inferiorly of the patellar poles at 10, 15, and 20 centimeters, using a standard, non-elastic tape measure. **RESULTS:** There was no significant difference between SMM (I :14.54 ± 3.80 kg; NI:14.48 ± 3.48 kg; t(6) = 0.46, p = .660). Roughly half of participants had greater SMM in the injured leg versus un-injured leg. There were no significant differences in circumference measurements between the limbs. **CONCLUSIONS:** There was evidence of decreased SMM in some participants following ACL injury. It is possible that continued study with more participants may find difference in muscle mass following injury. SMM and circumferences provide useful information concerning muscular atrophy and discrepancies between limbs. SMM obtained via BIA may be utilized as a cost-effective measure indicative of knee stability and limb strength for return to play protocol (1). Future research should include measurements made pre and post injury/surgery to understand muscle mass progression following injury. 1-Ross, C. M., & Worrell, T. W. (1998). Thigh and calf girth following knee injury and surgery. *Journal of Orthopaedic & Sports Physical Therapy*, 27(1), 9-15.

Patient Reported Outcomes after Anterior Cruciate Ligament Reconstruction Predict Isometric Quadriceps Torque

Alexa K. Johnson¹, Nicholas R. Heebner¹, Nicholas P. Baumann¹, Emily R. Hunt¹, Caitlin E-W Conley¹, Cale A. Jacobs¹, Darren L. Johnson¹, Mary L. Ireland, FACSM¹, Christian Lattermann², John P. Abt, FACSM¹. ¹University of Kentucky, Lexington, KY. ²Harvard Medical School, Boston, MA.
 (Sponsor: John Abt, FACSM)
 Email: johnson.alex@uky.edu
 (No relevant relationships reported)

Individuals who have undergone anterior cruciate ligament reconstruction (ACLR) have reduced muscle function that has been shown to persist for many years post-surgery. The ability to predict future levels of neuromuscular function with the use of early-on inflammatory markers may assist clinicians to better target common muscle function deficits seen after ACLR. **PURPOSE:** The purpose of this study is to determine if levels of inflammation and patient reported outcomes one month post-surgery predict muscle function at six months post-surgery. **METHODS:** Nineteen patients who underwent ACLR (82.8±20.3kgs, 1.7±0.1m, 18.4±2.8yrs, 8M, 11F) completed this study. One month post-surgery (1.1±0.3 months) individuals completed the Knee Osteoarthritis Outcomes Score (KOOS), and visual analog scale (VAS) for pain. Patients were also aspirated one month post-ACLR and commercially available ELISA kits were used to determine concentrations of interleukin-1 β (IL-1 β) in the synovial fluid. At six months (6.1±0.3months) patients completed maximal isometric contractions of the involved limb at 60 degrees of knee flexion. Rate of torque development (RTD) was calculated as the slope of the time-torque curve taken from onset of torque to peak torque. Multiple linear regressions were run to determine if levels of IL-1 β , KOOS scores, and VAS scores, while controlling for height and weight, one month post-ACLR would better predict peak torque or RTD six months post-ACLR. Models were compared and the highest adjusted R² was identified as the best model. An alpha value of 0.05 was used. **RESULTS:** Levels of IL-1 β , and patient reported outcomes one month post-surgery did not significantly contribute to the variance of RTD (86.8±68.0Nm/kg) six months post-surgery in the involved limb. Height, mass, KOOS-pain (73.3±19.2), KOOS-sport (41.9±40.2), and VAS (30.6±28.8) were included in the final model predicting 50.6% of the variance of peak isometric torque (151.3±49.1Nm; p=0.038). IL-1 β (-4.75±1.3pg/mL) did not significantly contribute to predicting the variance of peak torque. **CONCLUSION:** Although levels

of inflammation one month after surgery may not explain muscle function six months after surgery, patient reported outcomes for pain and sport performance can, suggesting early clinical use to help drive targeted rehabilitation.

Differences in T1 ρ Relaxation Time in the Vastus Lateralis after an Anterior Cruciate Ligament Tear

Madalyn G. Romines, Lauren N. Erickson, Kylie A. Davis, Peter A. Hardy, Anders H. Andersen, Cale J. Jacobs, Brian Noehren, FACSM. *University of Kentucky, Lexington, KY.*

(No relevant relationships reported)

Anterior cruciate ligament (ACL) injury results in quadriceps atrophy and fibrotic changes in the extracellular matrix of the muscle that may not resolve. To date, assessments have used a muscle biopsy; however, this is an invasive procedure and impractical on a wide scale. Magnetic resonance imaging (MRI) techniques, such as T1 ρ , hold promise to measure fibrotic changes. This technique has been used to study cartilage degeneration and liver fibrosis, but has not been widely applied to muscle. Whether T1 ρ relaxation time is different between the quadriceps of the injured and non-injured limbs, as well as its relationship to quadriceps strength, is not established.

PURPOSE: To investigate the variance in T1 ρ relaxation times in the vastus lateralis (VL) between the injured and non-injured limb following an ACL tear and possible correspondence to quadriceps strength.

METHODS: 17 ACL deficient patients (8M, 9F, 21 \pm 4.52 y, BMI 25.95 \pm 3.83, days since injury 26 \pm 17.26) underwent an MRI. T1 ρ acquisition included a single 6 mm thick slice at the location of the largest cross-sectional area of the VL with 8 echoes collected within spin lock times of 0-70 ms (spin lock amplitude 300Hz, matrix 256x256, 2 excitations with 4 shots per slice). Data was fitted to a mono exponential decay curve using custom MATLAB code. Quadriceps strength was assessed via maximal voluntary isometric contractions on a dynamometer. Paired t-tests and Pearson product moment correlation coefficients were used to analyze the data.

RESULTS: T1 ρ times were significantly longer in the involved limb compared to the non-involved limb (involved: 0.0296 \pm 0.0032 s; non-involved: 0.0280 \pm 0.0031 s; 5.7% difference; p=0.04). Peak isometric torque was significantly less in the involved limb as to the non-involved limb (involved: 1.91 \pm 0.71 Nm/kg; non-involved: 2.65 \pm 0.52 Nm/kg; 27.7% difference; p<0.001); however, was not significantly correlated with longer T1 ρ time (r=0.07; p=0.70).

CONCLUSION: T1 ρ was significantly longer soon after injury, indicating that this tool is sensitive to measure early changes in muscle organization. Contrary to our hypothesis, a relationship to quadriceps strength was not found. Potentially, T1 ρ measures a different factor than peak strength and additional variables of muscle function should be evaluated.

Acute Muscular Responses to Practical vs. Traditional Blood Flow Restriction Resistance Exercise

Robert Thiebaud¹, Takashi Abe², Jeremy Loenneke², Tyler Garcia¹, Yohan Shirazi¹, Javier Fiol¹, Ross McArthur¹. ¹Texas Wesleyan University, Fort Worth, TX. ²The University of Mississippi, University, MS.

Email: rthiebaud@txwes.edu

(No relevant relationships reported)

PURPOSE: To compare the impact of blood flow restriction (BFR) resistance exercise on changes in muscular force output (MVC), muscle thickness (MTH) and total exercise volume (TEV) when using elastic knee wraps (practical) or nylon cuffs (traditional) inflated to 40 and 80% of arterial occlusion pressure (AOP).

METHODS: Participants (male=7, female=2) were 22 (4) years and had a body mass index of 25.4 (1.5) kg/m². A randomized cross-over study design used unilateral knee extension exercise (4 sets to failure) with six different conditions at three separate visits. Low-load (LL, 30% 1-RM) exercise was performed with four conditions: elastic knee wraps (Valeo®) stretched two inches from resting length (K2) and to a value that was 85% of thigh circumference (K85), and nylon cuffs inflated to 40% (BFR40) and 80% (BFR80) of AOP. LL (30% of 1-RM) and high-load (HL, 70% of 1-RM) exercise

without restriction were also performed. MVC and MTH were measured pre and post exercise. TEV was also calculated for each condition. Two-way [Condition x Time] repeated measures ANOVA and one-way repeated measures ANOVA were used to analyze the data. Data reported as mean (standard deviation). Statistical significance was set at p<0.05.

RESULTS: MVC decreased from pre to post-exercise for all conditions [Δ HL: -90 (81) N, Δ LL: -126 (57) N, Δ BFR40: -168 (89) N, Δ BFR80: -240 (134) N, Δ K2: -178 (91) N, Δ K85: -197 (57) N, p<0.05]. The changes in MVC were significantly different in K85 vs. HL (p<0.001) and K85 vs. LL (p=0.013). HL and BFR80 MVC at 15 minutes post-exercise were not different from pre-values (Δ HL: -53 (68) N, p=0.095; Δ BFR80: -67 (77) N, p=0.138) but LL, BFR40, K2 and K85 were still significantly below pre-values (p<0.05). MTH changes were similar from pre to post-exercise [Δ HL: 0.22 (0.22) cm, Δ LL: 0.26 (0.1) cm, Δ BFR40: 0.26 (0.14) cm, Δ BFR80: 0.28 (0.19) cm, Δ K2: 0.26 (0.21) cm, Δ K85: 0.25 (0.13) cm, p=0.892]. HL TEV was higher [889.6 (227.7) kg] compared to all the other conditions (p<0.05) while the LL [686.1 (173.1) kg] was higher than the BFR40 [576.8 (160.7) p=0.026], BFR80 [434.9 (142.3) kg, p<0.001] and K85 [520.2 (139.2) kg, p=0.023] conditions.

CONCLUSIONS: Exercising to fatigue with elastic knee wraps could be used to produce similar acute changes in MVC, MTH and TEV compared to known BFR pressures.

(No relevant relationships reported)

Low load [30% of one repetition maximum (1RM)] exercise performed to volitional failure appears to result in similar skeletal muscle adaptations as low load exercise with the addition of blood flow restriction (BFR). However, there may be a point where the training load becomes too low (<20% 1RM) to stimulate an anabolic response without the addition of BFR. **PURPOSE:** To examine the skeletal muscle adaptations to very low load exercise with and without BFR in the upper body. **METHODS:** Changes in muscle thickness (MT), one repetition maximum strength (1RM), isometric strength, isokinetic strength and endurance were examined following 8-weeks of training with a traditional high load [70% 1RM,(70/0)], low load (15% 1RM), low load with moderate BFR (15% 1RM+40%BFR), or low load with greater BFR (15% 1RM+80%BFR). Results are displayed as mean (95% CI). **RESULTS:** 40 untrained men and women completed the study. For 1RM strength, there was a condition x time interaction (p = 0.003). 1RM strength changes were greater in the 70/0 condition [2.09 (95% CI=1.35-2.83) kg] compared to all low load conditions. For isometric and isokinetic strength, there were no changes. For endurance, there was a main effect for time [mean pre to post change = 7.9 (4.3, 11.6) repetitions, p < 0.001]. At the 50% MT site there was a condition x time interaction (p = 0.004). The mean change in MT in the 70/0 condition [0.16 (0.10-0.22) cm] was greater than all low load conditions. For the 60% MT site there was a condition x time interaction (p = 0.014). The mean change in MT for the 70/0 condition [0.15 (0.08-0.22) cm] was greater than all low load conditions. For the 70% MT site there was a main effect of time (p=0.001). Muscle thickness increased from pre-testing to the midpoint [mean change = 0.06 (0.01- 0.10) cm] and remained elevated above baseline at post-testing [mean change = 0.09 (0.5 - 0.14) cm]. **CONCLUSIONS:** All groups increased muscle size; however, this response was lower in all very low training conditions compared to high load training. 1RM strength increased in the 70/0 condition only, with no other changes in strength observed. These results suggest that loads as low as 15% 1RM do not provide adaptations comparable to high load resistance training. Further, BFR cannot be used to compensate for an insufficient external load regarding muscle size and strength adaptations.

3522 Board #210 June 1 9:30 AM - 11:00 AM
Nitric Oxide-dependent Myogenic Satellite Cell Activation In Human Skeletal Muscle Following Blood-flow Restricted Exercise

Jakob L. Nielsen¹, Charlotte Suetta², Ulrik Frandsen¹, Lene Rørdam³, Jens Bülow⁴, Robert Boushel⁵, Per Aagaard¹.

¹University of Southern Denmark, Odense, Denmark.

²Bispebjerg-Frederiksberg & Herlev-Genotofte Hospitals, Copenhagen, Denmark. ³Bispebjerg Hospital, Copenhagen, Denmark. ⁴Bispebjerg Hospital & Copenhagen University, Copenhagen, Denmark. ⁵University of British Columbia, Vancouver, BC, Canada.

(No relevant relationships reported)

PURPOSE: Skeletal muscle contractions performed under concurrent blood-flow restriction (BFR) have been shown to elicit myogenic satellite cell (MSC) proliferation and differentiation, however, the upstream signaling events governing MSC activation with BFR exercise remains unknown. A potential important upstream regulator of MSC activation initiated by BFR exercise may be nitric oxide (NO). Thus, the aim of the present study was to investigate the effect of endogenous nitric oxide (NO) synthesis on MSC activation in human skeletal muscle in response to BFR exercise.

METHODS: Eight male subjects (20.9 ± 2.7 (SD) years) performed five sets of low-load knee extensor exercise (20% 1RM) with concurrent BFR applied with a pressure cuff (100 mmHg) positioned at the proximal thigh. Concurrently, local arterial infusion of the NO synthase (NOS) inhibitor, NG-monomethyl-L-arginine (L-NMMA) or Placebo was applied in a within-subject cross-over design. Arterio-venous blood samples were obtained before and after exercise (30min) for assessment of leg blood-flow and oxygen extraction. Muscle biopsies were obtained at Baseline as well as 1, 3, 24 and 48h post exercise (Post1-48) for assessment of myogenic satellite cell (Pax7⁺) content using immuno-fluorescence techniques. **RESULTS:** Resting leg blood-flow decreased 37% (0.57 ± 0.14 L/min to 0.36 ± 0.12 L/min) and oxygen extraction increased 98% (26.8 ± 9.2 to 53.1 ± 7.9%) with NOS inhibition (P<0.001), while remaining unchanged in the Placebo condition. MSC counts increased (47-94%) with Placebo infusion from baseline (9.7 ± 3.3 MSC per 100 myofiber) to Post1 (15.0 ± 4.1), Post3 (15.3 ± 4.2) and Post24 (18.8 ± 7.0) and Post48 (14.2 ± 5.3) (P<0.05-0.001), while remaining unchanged with NOS inhibition.

CONCLUSIONS: This study is the first to show that inhibition of endogenous NO synthesis leads to blunted MSC activation in response to muscle contractions performed during conditions of partial blood-flow restriction in human skeletal muscle. In conclusion, the present data suggest that NO is a key signaling molecule activating MSC in human skeletal muscle in vivo.

Endurance is Augmented By Greater Blood Flow Restriction Pressures: Muscle Size and Strength Are Not

Matthew B. Jessee¹, Samuel Buckner², Grant Mouser³, Kevin Mattocks⁴, Scott Dankel⁵, Takashi Abe⁵, Zachary Bell⁵, John Bentley⁵, Jeremy Loenneke⁵. ¹University of Southern Mississippi, Hattiesburg, MS. ²University of South Florida, Tampa, FL. ³Troy University, Troy, AL. ⁴Lindenwood University - Belleville, Belleville, IL. ⁵University of Mississippi, University, MS.

Email: Matthew.Jessee@usm.edu

(No relevant relationships reported)

Purpose: The importance of training to failure, especially when using low-loads (i.e., 30% 1RM) is well established. However, it remains unknown if lifting 15% 1RM can disrupt muscular blood flow enough to induce failure and stimulate adaptation. This study was designed to compare muscular adaptations between training with 15% 1RM and 70% 1RM, to determine if blood flow restriction (BFR) could augment the response to 15% 1RM, and if the effect of BFR is pressure dependent [40% versus 80% arterial occlusion pressure (AOP)].

Methods: 40 untrained participants performed 4 sets of unilateral knee extension 2x/week for 8 weeks, with two conditions, one per leg. Conditions (label) were: 15% 1RM 0% AOP (15/0), 15% 1RM 40% AOP (15/40), 15% 1RM 80% AOP (15/80), 70% 1RM 0% AOP (70/0). Sets were stopped at 90 repetitions or volitional failure, as determined by an inability to maintain metronome cadence (2 s/contraction) or full repetitions. Inter-set rest was 30 s for 15/0, 15/40, 15/80 and 90 s for 70/0. A 10 cm wide nylon cuff was used for BFR.

Results: Data presented as [mean change (95% CI)]. There were condition x time interactions for 1RM (p<0.001) and endurance (p=.028). 70/0 increased 1RM [3.15 (2.04, 4.25) kg]; 15/0 [-0.06 (-1.13, 1.01), 15/40 [0.066 (-1.06, 1.20), and 15/80 [0.68 (-0.41, 1.79) did not. Increased endurance was greatest for 15/80 [6.2 (4.3, 8.0)] compared to 15/0 [4.2 (2.4, 6.0)], 15/40 [4.7 (2.8, 6.5)], and 70/0 [4.0 (2.2, 5.9)]. There were main effects of time for isometric MVC [10.51 (3.87, 17.16) Nm, p=.002] and

isokinetic MVC at 180°/s [change = 8.61 (5.54, 11.68) Nm, p<.001]. Isokinetic MVC at 60°/s did not change [2.45 (-1.84, 6.74) Nm, p=.261]. There were no condition x time interactions for muscle thickness sites (all p≥.313), which increased over time (all p<.001). There were main effects of condition for each site (70/0 was greater, all p<.001) except 30% lateral (p=.059).

Conclusion: Most muscle strength and size changes appear similar despite large discrepancies in training load and restriction pressure. While the change in 1RM with high-load may be due to motor learning or practicing, the greater endurance adaptation favoring high restriction pressures should be explored further regarding underlying mechanisms. These results are relevant to mechanistic exploration, therapeutic purposes, and program design.

The Acute Muscle Swelling Response: The Influence Of Sex And Cuff Size

Vickie Wong, Raksha N. Chatakondi, Takashi Abe, Zachary W. Bell, Robert W. Spitz, Scott J. Dankel, Jeremy P. Loenneke. *The University of Mississippi, University, MS.*

(No relevant relationships reported)

Muscle cell swelling is a purported mechanism for the muscle hypertrophy following blood flow restriction (BFR) training. There are numerous cuff widths used in literature in BFR. It is presently unknown if cuff width impacts the swelling response and whether this differs between sexes. **PURPOSE:** To examine whether the acute muscle swelling response differs based on cuff size and sex. **METHODS:** Forty-nine (25 men, 24 women) participants completed two conditions in a random order (one each arm). Participants completed four sets of unilateral elbow flexion exercise to failure using 30% of their one repetition maximum with BFR applied with either a narrow (5cm) or a wide (12 cm) cuff inflated to 40% of the arterial occlusion pressure. Muscle thickness and echo intensity were measured before and after each exercise bout in the supine position. A repeated measures analysis with a between subject factor of sex was used to assess changes between conditions. Default priors were used for fixed effects (r=0.5) and random effects (r=1). Bayes Factors (BF10) were used to quantify evidence for the null and alternative hypothesis. Data are presented as mean (SD) unless otherwise stated. **RESULTS:** For muscle swelling, there was evidence for an interaction. Men had greater swelling than women [Men: 0.57 (0.18) vs. Women: 0.39 (0.15) cm] with the narrow cuff [median δ (95% credible interval) .903 (.324, 1.52); BF10: 38.57]; but there was no evidence of a difference within the wide cuff [median δ (95% credible interval) .348 (-.170, .902); BF10: .690]. There was some evidence that men had greater swelling with the narrow [0.57 (0.18) cm] cuff compared to the wide [0.49 (0.14) cm] cuff [median δ (95% credible interval) .602 (.071, 1.174); BF10: 2.61]. However, there was no evidence (BF10: .439) for this in women [Narrow: 0.39 (.15) vs. Wide: 0.43 (.12) cm]. For changes in echo intensity, there was no evidence for an interaction or an effect of cuff [Narrow: 1.2 (8) vs. Wide: -.5 (7) AU, BF10: .41]. There was evidence for the null with sex (BF10: .322). **CONCLUSIONS:** Acute muscle swelling occurs in both men and women, even when using a wide cuff. There is evidence, however, that the change in swelling is greater in men, particularly with the narrow cuff. Whether these acute changes translate to differences in chronic adaptations is currently unknown.

3525 Board #213 June 1 9:30 AM - 11:00 AM
Time Course of Blood Flow Restricted Resistance Training Adaptations in Older Adults

Summer B. Cook, FACSM, Christopher J. Cleary. *University of New Hampshire, Durham, NH.*

Email: summer.cook@unh.edu

(No relevant relationships reported)

Blood flow restricted (BFR) resistance training leads to increased muscle mass and strength but the time course of adaptations may be different as they are often to a lesser magnitude than high-load (HL) training. **PURPOSE:** To evaluate the impact of resistance training loads and repetitions on older adults' muscle mass and strength following BFR or HL training. **METHODS:** Twenty-one older adults (67-90 years) were randomly assigned to HL (n=11) or BFR (n=10) training on the knee extensors and flexors twice per week for 12 weeks. Muscle strength was measured with 10-repetition maximum (10-RM) and muscle mass was assessed via magnetic resonance imaging and quantified as cross-sectional area (CSA). The measurements were performed before and after 12 weeks of training. **RESULTS:** After 12 weeks of resistance training, the HL and BFR interventions increased 10-RM knee flexion strength by 36.9±25.4% and 18.9±25.5%, respectively, but there was not a significant time x group interaction (P=.16). CSA of the knee flexors increased an average of 4.8±5.9% among the HL and BFR training interventions (time main effect P<.01) but was not different between the training groups (time x group interaction P=.89). There were similar rates of progression of knee flexion training load and repetitions (time x group interactions of each variable P>.05) as the groups combined averaged an increase of .28±.1 kg·session⁻¹ and .97±.8 repetitions·session⁻¹ of training (time main effects P<.05). Participants in the HL training group experienced greater improvements

in knee extension 10-RM strength than the BFR group (60.7±36.0% vs 35.3±25.5%; P=.03). The growth in quadriceps CSA was significant (time main effect P<.01) and to similar magnitudes (time x group interaction P=.62) following HL training (6.5±3.1%) and BFR training (7.8±8.2%). The HL group experienced a faster progression of load when compared to BFR training (.46±.30 kg·session⁻¹ vs .15±.10 kg·session⁻¹; P=.006). The BFR training group progressed at a rate of 1.8±.63 repetitions·session⁻¹ while the HL group progressed at 1.1±.21 repetitions·session⁻¹ (P=.003).

CONCLUSIONS: HL resistance training may result in better strength gains than BFR resistance training because of distinctive rates of progressive overload. Supported by NIH grant 1R15 A6040700-01A1

(No relevant relationships reported)

Low volume blood flow restricted (BFR) training has been proposed to induce comparable adaptations to traditional resistance training, however the underlying mechanisms remain unknown. Despite the absence of direct support, a suggested mechanism of BFR is an increase in reactive oxygen species (ROS). **PURPOSE:** We aimed to determine if the rate of mitochondrial ROS emission was altered following an acute bout of occluded (BFR) or non-occluded resistance training (RT), and to mechanistically investigate the role of skeletal muscle O₂ partial pressure (pO₂) in this response.

METHODS: Ten males (25±1yrs) performed 3 sets of single leg squats to failure at 30% 1RM, with either BFR (60-70% occlusion), or without occlusion (RT), while skeletal muscle tissue oxygenation was estimated using near-infrared spectroscopy. Muscle biopsies were obtained at rest and 2-hours post-exercise to determine mitochondrial respiration and ROS emission in permeabilized muscle fibers. In a separate cohort, muscle biopsies were obtained from six males (25±2yrs) to examine the effects of pO₂ on *in vitro* mitochondrial bioenergetics.

RESULTS: Resistance exercise, with or without BFR, did not alter maximal respiratory capacity or mitochondrial sensitivity to ADP. While maximal mitochondrial ROS emission was unchanged following RT, BFR decreased this response compared to rest (66.6 vs. 86.2 pmol min⁻¹ mg dry wt⁻¹, p<0.05). Skeletal muscle oxygenation was lower in the BFR compared to RT leg, both during (41.4% vs. 46.1% saturation respectively, p<0.01) and between (50.3% vs. 61.1% saturation respectively, p<0.01) exercise sets. Further evaluation of mitochondrial bioenergetics *in vitro* revealed that mild O₂ restriction (50µM) dramatically attenuated maximal mitochondrial ROS emission (~4-fold), and fraction electron leak to ROS (~3-fold) compared to room air (200µM). This effect was especially evident in the presence of non-saturating ADP, as submaximal ROS emission was almost completely suppressed during O₂ restriction, without a reduction in submaximal respiration.

CONCLUSIONS: These data indicate that a reduction in skeletal muscle pO₂ attenuates the propensity of mitochondria to produce ROS, a mechanism which may contribute to the acute responses to BFR training. This research is supported by NSERC funding.

(No relevant relationships reported)

Blood flow restriction (BFR) therapy has been observed to improve post-operative recovery in the limbs when combined with low intensity resistance exercise (LIX). Little data exists regarding use of BFR for proximal benefit of the upper limbs (shoulders). **PURPOSE:** (1) Determine if rotator cuff (RC) exercises combined with BFR (BFR-Rx) promote greater increases in strength, muscular endurance, and lean mass compared to exercise alone (NoBFR-Rx); (2) Determine if BFR applied to the arm during acute LIX increases activation of RC muscles. **METHODS:** Eighteen healthy adults (♂11, 32±5yr, 92.3±15.2kg | ♀7, 34±7yr, 81.9±6.3kg) were recruited and randomized into 2 groups (BFR-Rx, NoBFR-Rx). Each performed 8wks of LIX

(2/wk) using 4 RC exercises: cable external rotation (ER), cable internal rotation (IR), dumbbell scaption, and side-lying dumbbell ER; 20% 1RM; 1set/30reps followed by 3sets/15reps (30s rest between sets, 2min rest between exercises, ^1lb resistance each week all repetitions achieved). For the BFR-Rx group, BFR was applied to using an tourniquet system (Delfi®) that maintained 50% limb occlusion pressure during each exercise with pressure released between exercises. A group x time ANCOVA (co-varied on baseline) followed by a tukey's post hoc test was used to detect absolute & relative changes in strength (pre/post training), lean mass (pre/post training; DEXA, GE®), and achieved weekly exercise volume (sets x reps x resistance). A two-tailed paired samples t-test was used to detect differences in RC muscle activation (EMG, Delsys®) recorded during acute ER and IR fatigue tests in all subjects. Type I error was set at α=0.05.

CONCLUSIONS: Combined BFR-Rx using RC exercises may yield greater increases in shoulder/arm lean mass, strength, and muscular endurance compared to exercise alone. These findings may be partially due to a greater activation of shoulder musculature while using BFR. Data collection is ongoing and will be completed prior to conference.

The Perceived Tightness Scale Does Not Provide Reliable Estimates Of Blood Flow Restriction Pressure

Zachary W. Bell, Scott J. Dankel, Robert W. Spitz, Raksha N. Chatakondi, Takashi Abe, Jeremy P. Loenneke. *The University of Mississippi, University, MS.*

(No relevant relationships reported)

When completing blood flow restriction, use of a perceived tightness scale is recommended as a method for setting sub-occlusive pressures. However, whether or not participants can consistently rate a similar pressure using this scale is unknown.

PURPOSE: To determine the reliability of a perceived pressure when asking participants to rate a 7 out of 10, considered a moderate pressure with no pain, during blood flow restriction. **METHODS:** Participants (12 men, 12 women) were tested over 3 visits, involving measurements for arterial occlusion and the relative pressure at which participants deemed a 7 out of 10. Participants arrived to the lab and proceeded to lie supine for a 10-minute rest period. Measurements were completed in one limb for the upper and lower body. A repeated measures analysis with a between subject factor of sex was used to compare relative arterial occlusion pressures across days and sex with a default prior of 0.5 for the fixed effects and 1 for the random effects. An independent samples t-test was used to determine if there were sex differences in %CV with a default prior of 0.707. A Bayes factor (BF₁₀) of 3 and 0.33 was considered evidence for the alternative and null hypotheses, respectively. **RESULTS:** The %CV for the measurement in the upper body was 12%, with no effect of sex (men: 12.3% vs. women 12.2%; BF₁₀: .403; median δ (95% credible interval): .016 (-.741, .752)). The %CV for relative arterial occlusion pressure in the lower body also did not differ between sexes (men: 13.7% vs. women 10.3%; BF₁₀: .509; median δ (95% credible interval): .266 (-.396, .999)). Participants' rated a 7/10 pressure above the arterial occlusion pressure for the upper body and below for the lower body. At the group level, participants rated a 7 out of 10 at a higher relative pressure on day 1 compared to days 2 (BF10: 4.482, median δ (95% credible interval): -.694 (-1.307, -.130)) and 3

(BF₁₀: 10.2, median δ (95% credible interval): -.838 (-1.468, -.189)) for the lower body but no differences in the upper body. There was no effect of sex. **CONCLUSIONS:** The use of a perceived tightness scale does not appear to provide a reliable method for the prescription of blood flow restriction pressure. Future work should consider alternative methods or modifications to the scale for improving reliability when setting sub-occlusive pressures.

3529 Board #217 June 1 9:30 AM - 11:00 AM The effect of Metabolic Syndrome on Exercise Performance in American Football Players From a Mexican University

Dulce E. Morales Elizondo, FACSM, Pedro G. Morales-Corral, FACSM, Rosalinda Sepulveda, Hector E. Pérez, Elfega Sámano-Pérez, Francisco J. Barrera-Flores, Emanuel Rizo-Belloso. *UANL, San Nicolás de los Garza, Mexico.*
Email: dulcemorales@gmail.com
(No relevant relationships reported)

PURPOSE: To demonstrate the effect that the presence of the metabolic syndrome (MetSyn) has on the physical performance on American Football Players of a college team in México

METHODS: Seventy six players were included in the study, thirteen had MetSyn (21.7±1.5 yrs) and sixty three were not diagnosed with MetSyn (21.8±1.5 yrs). In order to establish a statistical significance between the physical performance and MetSyn, the data was analyzed in two different ways: With MetSyn (WMS) or absence of MetSyn (AMS) and by groups of similarity of Body Mass and type of execution in the field **Group 1** Offensive and Linemen (OL and DL) and Tight ends (TE). **Group 2** Running Backs (RB), Linebackers (LB) and Quarterbacks (QB). **Group 3** Wide Receivers (WR), Kickers (K), Strong Safeties (SS) and Cornerbacks (CB). The physical performance tests that were measured were: Maximum strength, explosive strength, Isometric hand strength, muscular resistance, power of upper and lower body, lumbar flexibility, agility, speed and cardiovascular resistance

RESULTS: The physical performance tests between WMS revealed better performance in maximum upper body strength 293.46(56.54) against the ABS group 246(36.45), explosive strength with Snatch 165(135-205) against 155(105-205) and Jerk 228.08(31.46) against 204.29(34.70) tests, as well as muscular resistance test 9.5(1-25) against 3(0-26) repetitions. Lower athletic performance was shown in the WMS group in the speed 5.6(5.23-7.12) sec against 5.21(4.75-8.22), agility 8.84(7.1-9.79) seconds against 5.21(4.75-8.22) and cardiovascular resistance 13.32(10-18) against 11.16(9.06-17.11) min.

CONCLUSIONS: The weight and BMI and the body fat percentage were variables that presented significance difference in the WMS group, coinciding with the authors who affirm that the weight and the percentage of fat have an influence on the physical performance. The physical performance tests in the WMS group revealed better performance in maximum chest force, explosive strength with Snatch and Jerk tests, as well as muscular resistance suggesting a possible favorable relationship to presence MetSyn. We observed a lower athletic performance in the tests of speed, agility and cardiovascular resistance in the players with the presence of MetSyn negatively relating the MetSyn with these motor skills.

3530 Board #218 June 1 9:30 AM - 11:00 AM Inhibition Of miR-16 In Vitro Decreases Glucose Uptake And Insulin Signaling

Seongkyun Lim, David E. Lee, Megan E. Rosa-Caldwell, Jacob L. Brown, Tyrone A. Washington, Nicholas P. Greene. *University of Arkansas, Fayetteville, AR.* (Sponsor: Matthew S. Ganio, FACSM)

(No relevant relationships reported)

Type 2 Diabetes Mellitus (T2DM) is a fast-growing epidemic and skeletal muscle insulin resistance may be the onset point in the development of T2DM. Recent data have suggested that microRNAs (miR) may play an important role in T2DM glucose intolerance. Specifically, reduced miR-16 content in muscle has been noted in human and rodent models of T2DM. However, regulation of miR-16 and its relation to muscle insulin resistance is largely unexplored. **PURPOSE:** To investigate how miR-16 content affects insulin resistance and glucose regulation in myotubes during insulin resistant states. **METHODS:** This study was performed in three experiments. Experiment (Ex) 1: To test if miR-16 is necessary for muscle insulin sensitivity, C2C12

myoblasts were cultured to become myotubes. Cells were transfected with a plasmid to inhibit function of miR-16. Ex 2: To test if miR-16 is sufficient to improve insulin resistance, myotubes were treated with a 1-oleoyl-2-acetyl-sn-glycerol (OAG), to simulate lipid overload-induced insulin resistance, cells were transfected with plasmid to overexpress functional miR-16. Ex 3: To test if Primary-miR16 (Pri-miR16) is differently expressed in insulin resistance state, Pri-miR16 level was measured by RT-PCR in both in vivo and in vitro models of insulin resistance. In experiment 1 and 2, glucose uptake and insulin signaling were measured by uptake of 2-NBDG (a fluorescent analog of glucose), and immunoblot of phosphorylation of AKT and IRS1. Data were analyzed by ANOVA or t-test as appropriate, significance was denoted at $p < 0.05$. **RESULTS:** Ex 1: Insulin-stimulated glucose uptake was ~25% lower in myotubes following miR16 inhibition ($p=0.01$). Insulin signaling was lower in myotubes with miR16 inhibition (31%, $p=0.002$). Ex 2: OAG-induced insulin resistant myotubes exhibited lower glucose uptake ($p=0.01$; 12%). However, overexpression of miR16 did not improve OAG-induced insulin resistance ($p > 0.05$). Ex 3: Pri-miR16 level was not different between control and OAG. **CONCLUSION:** Reduction of miR-16 content seems to be necessary for glucose handling, however, miR-16 overload is not sufficient to rescue glucose regulation and synthesis of pri-miR16 was not a culprit for reduced miR16 during insulin resistance, therefore it may be due to either degradation or export of miR16 during the miRNA process.

3531 Board #219 June 1 9:30 AM - 11:00 AM Amelioration Of Diabetes-associated Muscle Atrophy By Transcutaneous Carbon Dioxide Exposure

Hiroyo Kondo¹, Hidemi Fujino², Tomohiro Matsumoto², Akihiko Ishihara, FACSM³. ¹Nagoya Womens University, Nagoya, Japan. ²Kobe University, Kobe, Japan. ³Kyoto University, Kyoto, Japan.
(No relevant relationships reported)

PURPOSE: Diabetes has been known to result in attenuated growth and atrophy in skeletal muscle. Recently, it has been reported the Carbon dioxide (CO₂) exposure leads to an increase of muscle mass in normal rats. Therefore, the aim of the present study was to investigate the effects of transcutaneous CO₂ exposure with the hydrogel (eCO₂GEL) on diabetic-associated muscle atrophy.

METHODS: Male Goto-Kakizaki (GK) rats were divided into control (GK) and CO₂ exposure (CO₂) groups and male Wistar rats used as a non-diabetic control. The hair on the lower limbs was shaved and the hydrogel (eCO₂GEL), which can increase the absorption of CO₂ from skin, was applied. The CO₂ adaptor was attached to the limbs and sealed, and CO₂ gas was administered into the adaptor for 30 min. The CO₂ exposure was performed everyday for 8 weeks.

RESULTS: The muscle weights of soleus and tibialis anterior in the GK group decreased compared with those of the control group. CO₂ exposure attenuated decreased muscle weights in diabetes-associated muscles ($P < 0.05$). In addition, the blood flow in skeletal muscle was increased by CO₂ exposure compared with non-CO₂ exposure condition ($P < 0.05$). Furthermore, the level of fasting blood glucose in the CO₂ exposure group was significantly decreased compared with the GK group ($P < 0.05$).

CONCLUSIONS: These results indicate that the transcutaneous CO₂ exposure may have a therapeutic potential for diabetic-associated muscle atrophy. This amelioration may associate with increased blood flow in skeletal muscle.

3532 Board #220 June 1 9:30 AM - 11:00 AM Exercise and High-Fat Diets Upregulate Endoplasmic Reticulum Membrane Protein Sensors and Muc2 in Female Mice

Paul J. Wisniewski, Natasha Malonza, Lauren A. Hall, Robert A. Dowden, Sara C. Campbell, PhD, FACSM. *Rutgers University, New Brunswick, NJ.* (Sponsor: Sara C. Campbell, PhD, FACSM, FACSM)
Email: pjwisniewski86@gmail.com

Reported Relationships: P.J. Wisniewski: Other (please describe); Supported by a Student Research Fellowship Award: Crohn's & Colitis Foundation (Ref. # 535042).

A dense dual layered mucus barrier, comprised of the muc2 mucin glycoprotein, protects the colon epithelium from luminal microbes and the external environment. The complexity and high secretory output of muc2 makes it prone to misfolding which activates the unfolded protein response (UPR) contributing to endoplasmic reticulum (ER) stress if unresolved. Interestingly, high fat diets have shown to induce colonic epithelial stress and inflammation which may be attenuated by exercise. **PURPOSE:** We aimed to examine impact of a high-fat diet (HFD) and exercise on the gene expression of factors involved in the UPR and ER stress in male and female mice colon. **METHODS:** 56 (n=7/group) 6-week old C57BL/6N^{Tac} male and female mice were weighed and randomly assigned to one of 4 groups: (1) control-diet sedentary (CDS, 10% fat diet, Research Diets); (2) very high-fat diet sedentary (VHFS, 60% fat, Research Diets); (3) control-diet exercise (CDX); and (4) very high-fat diet exercise (VHFX) for 12 weeks. Mice had *ad libitum* access to food and water. Exercised mice

had free access to a running wheel in their cages. Food intake was monitored every other day and body weights once per week. After 12 weeks animals were sacrificed. Total RNA was extracted from colon tissue fixed in RNAlater and converted into cDNA using the RNeasy Mini and First Strand kits. qRT-PCR was performed using a custom RT2-profiler PCR array (Qiagen). Ct values were normalized to GAPDH and a one-way ANOVA with LSD post-tests was used to analyze group means of Δ Ct values for each sex. A difference of mean with a p value of ≤ 0.05 was considered statistically significant. mRNA expression was expressed relative to CDS groups using the $\Delta\Delta$ Ct method. **RESULTS:** For females, Atf6 and Ire1 β expression was increased in VHF mice (0.9 and 1.1-fold times) compared to VHFS (0.6-fold times; $p = 0.001$ and $p = .008$). Muc2 expression was significantly increased in CDX mice (2.3-fold times) compared to VHFS (0.7-fold times; $p = 0.02$). In males, no significant differences in the expression of any factor was observed. **CONCLUSION:** High-fat diets coupled with exercise increase the expression of endoplasmic reticulum membrane protein sensors involved in the unfolded protein response in females. Exercise increases muc2 expression in females.

3533 Board #221 June 1 9:30 AM - 11:00 AM
Hypocaloric High Fat and High Carbohydrate Diets on Visceral Adipose Tissue and Body Composition
 Jarrett Walbolt, Yunsuk Koh. *Baylor University, Waco, TX.*
(No relevant relationships reported)

Introduction: Excess visceral adipose tissue (VAT) is strongly associated with increased cardiometabolic risks. High-fat (HF) diets are a popular method for improving body composition. **Purpose:** To determine the role of HF diets in body composition and VAT. **Methods:** In a randomized, cross-over design, 12 healthy, sedentary individuals were assigned either to a HF or HC diet trial with a 20% reduction in total caloric intake from their typical diet. Participants maintained their 1st assigned diet for 2 weeks followed by a 1-week washout period where they consumed their typical diet. After the 1-week washout period, participants began the opposite diet trial (either HF or HC) for 2 weeks. The HF diet consisted of 70% fat and 30% carbohydrate and protein, with a limit of 50 grams of carbohydrate. The HC diet consisted of 70% carbohydrate and 30% fat and protein. Body composition including VAT in mass and volume were determined using dual-energy x-ray absorptiometry. **Results:** Total body mass decreased up to 1.5 kg from the pre-intervention (78.07 \pm 17.36 kg) following either the HF (76.63 \pm 15.99 kg) or HC (76.24 \pm 15.71 kg) trial, yet it was not statistically significant. VAT in mass and volume decreased following either the HF or HC diet from the pre-intervention (429.57 \pm 225.43g and 464.42 \pm 244.02cm³). However, the magnitude of change in VATmass and VATvolume was greater in the HF diet (374 \pm 159.59g and 404.14 \pm 172.54cm³) than the HC diet (388.71 \pm 184.73g and 420.42 \pm 199.93cm³) although it was not statistically significant. Notably, percent body fat decreased only following the HF diet (pre-intervention: 29.70 \pm 9.75, HF: 27.65 \pm 10.55, and HC: 29.15 \pm 11.43%). **Conclusion:** Although a short-term hypocaloric diet with either HF or HC did not yield a significant change in body composition, there was a strong trend showing that hypocaloric diets, whether HF or HC, can lower total body weight. HF diets though may be more effective than HC at decreasing body fat percentage and VAT. Our study only looked at changes after two-week dietary interventions in healthy sedentary individuals. Thus, future studies examining long term effects of HF diets in a variety of subject populations, including obese people, may provide more accurate information regarding a role of HF diets in body composition and visceral adipose tissue.

Exploring The Utility Of Muac In Classifying Adult Metabolic Syndrome Risk Using Nhanes 2015-2016
 Hayley G. Boucher, Brian Miller, Laura Richardson, Judith A. Juvancic-Heltzel. *The University of Akron, Akron, OH.* (Sponsor: Dr. Ronald Otterstetter, FACSM)
 Email: hgb6@zips.uakron.edu
(No relevant relationships reported)

Metabolic syndrome (MetS) is a constellation of cardiometabolic risk factors (visceral adiposity, dyslipidemia, hyperglycemia, and hypertension) that, when presented in tandem, exponentially increases the risk of heart disease and insulin resistance. Finding a simple and validated screening method is critical to proactively intervene and attenuate the development of these cardiometabolic diseases, thereby improving healthcare outcomes such as quality of life and associated costs. The utility of mid-upper arm circumference as a metric of MetS risk has not been widely investigated. There is paucity in the literature exploring the relation between mid-upper arm circumference (MUAC) and MetS.

PURPOSE: This study defined and attempted to validate a risk criterion for MetS using MUAC as a valid alternative criterion for MetS classification risk. **METHODS:** The target sample was derived from National Health & Nutrition Examination Survey (NHANES) 2015-2016 data that included adults over the age of 18 ($N = 9,971$). MetS was defined using the NCEP ATP III 2005 MetS diagnosis criteria. A recursive partitioning methodology (RPM), using the Classification & Regression Tree

Algorithm, was employed to create binary MUAC criterion by sex, using 75% of the total sample. Validation of the criteria was performed with the remaining 25% of the total sample, selected at random.

RESULTS: Seventeen percent (17%) of the total sample presented with the MetS. The RPM resulted in sex specific MetS criteria with the MUAC criterion being >32 cm ($p = 0.024$) and >29 cm ($p = 0.024$) for males and females, respectively. Specifically, those presenting with the risk criteria were 9.84, for males, and 9.23, for females, times more likely to present with MetS than without the MUAC criterion. The overall classification accuracy for both the training and validation models were 83% with no statistical difference between models ($p = 0.983$). **CONCLUSIONS:** MUAC shows promise in being an effective screening method for MetS in guiding further diagnostic tests to prevent associated cardiometabolic morbidity and mortality.

3535 Board #223 June 1 9:30 AM - 11:00 AM
Patterns of Interrupting Prolonged Sitting and Postprandial Triglycerides in East-Asian Young Men with Central Obesity
 Waris Wongpipit, Jane J. Yu, Stephen H.S. Wong, FACSM. *The Chinese University of Hong Kong, Hong Kong, Hong Kong.*
 Email: waris.w@link.cuhk.edu.hk
(No relevant relationships reported)

Prolonged sitting is related to an increased risk of morbidity and mortality. In the literature, frequent interruptions to prolonged sitting, e.g., every 30 min of sitting, have been found to be beneficial for cardiometabolic health. Interrupting prolonged sitting less frequently, however, may be preferred due to practical issues.

PURPOSE: To examine the acute effect of different frequency of interrupting prolonged sitting on postprandial triglycerides (TG) in young men with central obesity compared with prolonged sitting.

METHODS: Twenty-one East-Asian men with central obesity (mean age: 23.24 \pm 3.65 years; body mass index: 29.78 \pm 3.17 kg·m⁻²; waist circumference: 98.71 \pm 7.08 cm) completed three randomized 7-h laboratory-based trials including 1) a prolonged sitting trial (SIT), 2) 3-min walking every 30 min (3-min) at 3.2 km·h⁻¹, and 3) 6-min walking every 60 min (6-min) at 3.2 km·h⁻¹ separated by 7-14 days washout period. Standardized mixed meals (50% carbohydrate, 30% Fat, and 15% Protein) were provided at 0 and 3 h. Blood samples were collected at -1, 0, 0.5, 1, 2, 3, 3.5, 4, 5, and 6 h. TG concentrations were changed to total area under the curve (tAUC) using the Trapezoidal method. One-way (trial) and two-way (trial \times time) ANOVAs with repeated measures were used to compare tAUC value and TG concentrations, respectively.

RESULTS: Regarding the tAUC, the main effect of trial ($F_{2,40} = 4.210$, $P = 0.022$, $\eta^2 = 0.174$) was significant with 6-min trial (10.58 \pm 3.62 mmol·L⁻¹ per 7 h; $P = 0.020$) being lower than SIT trial (11.83 \pm 3.52 mmol·L⁻¹ per 7 h). There were no differences on the 7-h tAUC for TG concentrations between 3-min (11.52 \pm 3.47 mmol·L⁻¹ per 7 h; $P > 0.05$) and SIT trials as well as between 3-min and 6-min trials (both P s > 0.05). Regarding TG concentrations, the main effect of trial ($F_{2,40} = 4.448$, $P = 0.018$, $\eta^2 = 0.182$) was significant with 6-min trial being lower than SIT trial ($P = 0.013$). The main effect of time was also significant ($F_{9,180} = 66.589$, $P < 0.001$, $\eta^2 = 0.769$) with the TG concentrations significantly increased from 1 h to 6 h (all P s < 0.05) compared with the baseline (the average of TG concentrations between -1 and 0 h).

CONCLUSIONS: Interrupting prolonged sitting with 6-min trial elicits a superior benefit on reducing postprandial TG than SIT trial in East-Asian young men with central obesity.

The Relationship Between a High Sugar-Low Fiber Dietary Food Intake and Obesity in a Clinical Setting
 Emma R. Lucas, Nicholas V. Neuwald, Arlette C. Perry, FACSM, Wesley N. Smith. *University of Miami, Coral Gables, FL.* (Sponsor: Arlette Perry, FACSM)
 Email: ex1192@miami.edu
(No relevant relationships reported)

Diets high in simple sugars and processed foods, and low in whole, fibrous plant foods have been linked to insulin resistance and weight gain. To prevent obesity and cardiometabolic disease, it is recommended that Americans limit intake of sugary beverages, fruit juices, added sugars, and processed carbohydrates, in favor of more fibrous foods such as whole fruits and vegetables, nuts, beans, whole grains, and seeds.

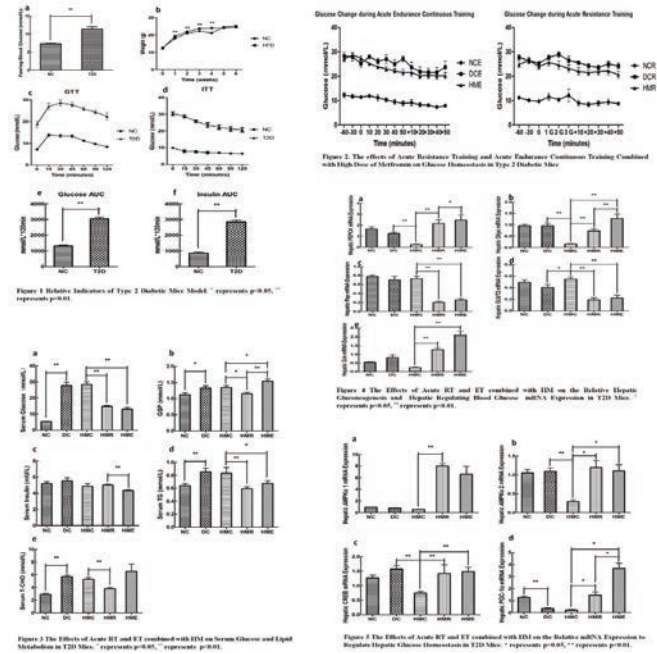

PURPOSE: To examine the relationship between frequency of foods consumed high in sugar and low in fiber (HSLF) with BMI. We hypothesized that a HSLF diet would be significantly higher among obese individuals (BMI ≥ 30) than non-obese (BMI < 30). **METHODS:** A total of 2,703 adults (1,521 females and 1,182 males) from a HealthSnap wellness assessment used in physicians' offices across the country were evaluated for anthropometric measurements and nutritional behaviors. HSLF consumption was evaluated from patients' self-reported intake of soda, juices, energy drinks, and other high sugar foods versus selection of whole grains, whole plant foods, nuts, beans, and seeds. To identify the association between HSLF and obesity, a

Chi-squared analysis (χ^2) was performed using quintiles of HSLF for obese and non-obese subjects. A relative risk (RR) was evaluated across data quintiles. **RESULTS:** A significant association between obesity and HSLF was observed (χ^2 [12, n = 2703] = 178.73, $p < 0.001$). Patients with HSLF in the highest 20%, Q5, had a 242% higher RR of obesity than those in the lowest 20%. Q1 (RR: 2.42, 95% CI: 1.95-3.03, $p < 0.001$). **CONCLUSION:** A diet encompassing foods high in sugar and low in fiber is associated with obesity. This supports the promotion of whole foods, high in fiber while limiting intake of foods high in sugar, as a simple recommendation to protect against obesity in a clinical setting.

Acute Exercise Intervention Combined with Metformin's Influences on Glucose Homeostasis in T2D Mice

Wenqing Shen, Yi Zhang, Qiang Zhang, Zhengtang Qi, Yi Sun, Shuzhe Ding, East China Normal University, Shanghai, China.
 Email: GraceShen07@163.com
 (No relevant relationships reported)

Purpose: The aim of our investigation was to determine the effects of different ways of acute exercise intervention combined with high dose of metformin on glucose homeostasis and its relative molecular mechanisms in type 2 diabetic mice.
Methods: 4-week high fat diet (HFD) and one-time Streptozocin (100mg/kg) intraperitoneal injection were used for building T2D mice. 24 mice were divided into normal control (NC), normal acute resistance training (NCR) and normal acute endurance training (NCE) group, all n=8, fed in normal chow. Finally 48 mice were developing T2D and divided into diabetic control (DC), diabetic acute resistance training (DCR), diabetic acute endurance training (DCE), high dose of metformin (200mg/kg) control (HMC), metformin combined with acute resistance training (HMR) and metformin combined with acute endurance continuous training (HME) group, all n=8.
Results: The two ways also enhanced blood glucose and lipid metabolism in T2D mice. Compared to HMC group, hepatic G6Pase mRNA expression in HMR and HME group was significantly escalated and hepatic FBP1 mRNA expression of both groups were significantly declined. Compared to HMC group, hepatic GLUT2 and Gck mRNA expression in HMR and HME group showed opposite trends, one was down and the other was up. Compared to HMC group, hepatic PEPCK mRNA expression in HMR group mice was notably raised and hepatic AMPK α , PGC-1 α and CREB mRNA expression in HMR and HME group mice were notably increased and only hepatic AMPK α mRNA expression in HMR group was significantly increased.
Conclusions: Acute resistance training (ART) and acute endurance training (AET) combined with metformin can effectively improve glucose homeostasis in T2D mice. And the two ways can improve blood glucose and lipid metabolism in T2D mice. ART combined with metformin was better to improve glucose homeostasis and inhibit hepatic gluconeogenesis relative mRNA expression in T2D mice probably via the signaling pathway of AMPK α -PGC-1 α -CREB.

 (No relevant relationships reported)

PURPOSE: Aerobic exercise is accepted as therapy for control of glucose levels and body fat in type 2 diabetes (T2D). High-intensity interval training (HIIT) is new aerobic training method with benefits for T2D patients. There are few documented studies of traditional exercise plus HIIT effect on resting energy expenditure (REE) in T2D. The purpose was to compare the effect of traditional training (aerobic constant intensity+resistance) with new training (HITT + aerobic constant intensity + resistance) on REE and metabolic control in patients with T2D.
METHODS: Forty two sedentary people (Age = 50.7 \pm 6.1 years) with T2D were randomized to one of three groups for 16-week training program with dietary recommendation: new training (NT; n = 14) (85-100% HRmax 10 intervals of 1 minute; resistance: 12 repetition maximum (12RM); dietary recommendation), traditional (TT; n = 14) (65% -75% HRmax, resistance: 12RM, dietary recommendation) and control (C; n = 14 dietary recommendation). Body composition was measured by bio-electrical impedance (INBODY S10), REE was evaluated by indirect calorimetry (COSMED, FITMATE model). Maximum oxygen uptake (VO₂max), HRmax and Power (Watts/Kg body weight) were recorded during incremental exercise test (Monark 828 e). Glycosylated hemoglobin (HbA1c) and lipid profile were measures in fasting blood (12 hrs). Measurements were evaluated at baseline and 16 weeks.
RESULTS: The decrease in HbA1c was greater in NT compared to C (-23.1% \pm 10.2 vs -8.6% \pm 10.2; $p = 0.005$). BMI decreased in the NT compared to C group (-3.1% \pm 2.4 vs -0.1 \pm 3.0; $p = 0.03$) and power increased in NT compared to C (27.9% \pm 25.3 vs 6.3% \pm 20.5; $p = 0.05$). VO₂peak was increased in NT compared to C (19.8% \pm 18.1 vs 2.8% \pm 13.3; $p = 0.02$).
CONCLUSIONS: Our results indicate that NT improves aerobic fitness, BMI, and glucose control in patients with T2D compared to C, despite no changes in the REE among groups.

3539 Board #227 June 1 9:30 AM - 11:00 AM
Lactate Response During Graded Exercise Test In Individuals With Prediabetes After Aerobic Exercise Training

Salvador Saenz-Herrera¹, Victoriano Pérez-Vazquez¹, Maciste H. Macías-Cervantes¹, Arturo Figueroa, FACSM², Inigo SanMillan³, Rodolfo Guardado-Mendoza¹, Talitha G. Vallejo¹, Katya Vargas-Ortiz¹. ¹Universidad de Guanajuato, León, Mexico. ²Texas Tech University, Texas, TX. ³Colorado University, Denver, CO. (Sponsor: Arturo Figueroa, FACSM)
 Email: darksalvador_1988@hotmail.com
 (No relevant relationships reported)

PURPOSE: Prediabetes (PD) is a metabolic disorder that precedes type 2 diabetes. The lactate concentration at rest, the response of lactate during graded exercise test, and the effect of aerobic training (AT) on lactate adaptation in subjects with prediabetes is little know. **The aim** of this study was to measure the lactate response adaptation to AT in individuals with prediabetes.
METHODS: Twenty-one subjects participated (age 39 \pm 6 y; BMI 29 \pm 5.4 kg/m²); after a glucose tolerance test, they were classified as normoglycemic (NG, n=11) and PD (n=10) group according to the criteria of the American Diabetes Association. All participants performed a graded exercise test in cycloergometer (MONARK 828), capillary lactate was measured every 5 min as well as the power output at a lactate concentration of 4mmol/l. The maximal heart rate (HR max) and peak oxygen consumption (VO₂peak) were also determined. Blood biomarkers, anthropometric measurements, and physical capacity were evaluated before and after AT.
RESULTS: Participants in both groups showed no change in blood glucose and lipid profile. VO₂peak increased similarly ($p < 0.01$) in both groups (NG: 33.5 \pm 5.3 vs 37.9 \pm 6.5 ml/kg/min; PD: 33.5 \pm 4.1 vs 36.8 \pm 3.8 ml/kg/min). The lactate at rest was similar in both groups before intervention and did not change significantly after AT (NG: 1.39 \pm 0.5 vs 1.17 \pm 0.4 mmol/L; PD: 1.76 \pm 1.8 vs 1.59 \pm 0.8 mmol/L). However, after AT, it was observed that the workload needed to reach the lactate threshold (4 mmol/L) increased significantly in each group (NG: 89.9 \pm 16 vs 120 \pm 22 W, $p < 0.05$; PD: 87.6 \pm 16 vs 101 \pm 15 W, $p < 0.01$), without a difference between groups.

CONCLUSIONS: Nine weeks of AT resulted in increased exercise capacity in both NG and PD, which indicates that patients with PD manage to respond and adapt to an exercise program and increase their aerobic capacity.

Effect Of Exercise Intervention On Expression And Translocation Of FAT/CD36 In Aging Mice

Jingyu Sun, Yajuan Su, Lili Qin, Yunhe Zhou, Jingmei Dong, Jingmei Dong. *Tongji University, Shanghai, China.*

Email: jysun@tongji.edu.cn

(No relevant relationships reported)

The international trend of rehabilitation medicine is leaning towards the prevention of metabolic disease these years. Especially in the prevention of insulin resistance, exercise therapy has become an effective means of rehabilitation. In view of the close association of fatty acid metabolism with insulin resistance, the potential role of Fatty Acids Translocase/CD36 (FAT/CD36) in treatment of aging-induced insulin resistance has been attracted more attentions. However, the regulative role of FAT/CD36 in exercise improving insulin sensitivity remains unclear. **PURPOSE:** To determine the regulative role of FAT/CD36 in exercise improving aging-induced muscle insulin resistance.

METHODS: Male C57BL/6J mice (8-week old) were randomly divided into two groups: (1) control group (CON; n = 6) and (2) endurance exercise group (EX; n = 6). The treatment was administered for one year. The mRNA levels of FAT/CD36 and other fatty acid transporters were determined by semi-quantitative reverse-transcription polymerase chain reaction (RT-PCR). The protein levels of FAT/CD36 and insulin signaling pathway related molecules were examined by western blot analysis. The localization of FAT/CD36 were detected by immunofluorescence. The differences in means were analyzed by t test. **RESULTS:** Compared with the aging CON group, the mRNA levels of FAT/CD36 (1.000 ± 0.156 vs. 0.543 ± 0.051 , $P < 0.05$) and CPT-1 β (1.033 ± 0.167 vs. 0.528 ± 0.055 , $P < 0.05$) in the EX group were significantly decreased, while other fatty acid transporters were not significantly changed (FATP4: 1.000 ± 0.153 vs. 0.832 ± 0.036 , $P > 0.05$) and (FABPpm: 1.000 ± 0.048 vs. 0.718 ± 0.095 , $P > 0.05$). When compared to the aging CON group, the protein levels of FAT/CD36 were also significantly decreased in the EX group (0.415 ± 0.053 vs. 0.337 ± 0.021 , $P < 0.05$), as well as the phosphorylation levels of AKT (0.177 ± 0.012 vs. 0.290 ± 0.034 , $P < 0.05$) and ERK (0.098 ± 0.014 vs. 0.322 ± 0.088 , $P < 0.05$) were significantly increased. The immunofluorescent pictures showed that FAT/CD36 were localized to the caveolae of plasma membrane, but not the mitochondrial membrane.

CONCLUSIONS: Exercise intervention protects against aging-induced insulin resistance by regulating FAT/CD36 expression and translocation.

Supported by the National Natural Science Foundation of China (No. 31600966).

An Attempt To Reverse Diabetic Cardiomyopathy By Aerobic Interval Training In High-fat Diet And Streptozotocin Induced Type 2 Diabetes Rat Models

Huan Cai, Yuxiu He, Xun Li. *Hebei Normal University, Shijiazhuang, China.*

Email: sherrycaiuk@126.com

(No relevant relationships reported)

Purpose: Diabetes mellitus (DM) is an important risk factors of cardiovascular disease. Long-term hyperglycemia, hyperlipemia and insulin resistance may lead to diabetic cardiomyopathy (DCM). No rodent models fully captured the whole process of cardiac morphology and function changes during the course of DCM. Aerobic interval training (AIT) has been advised as a non-pharmacological strategy against DM patients. However, little is known whether impose AIT intervention at the onset of DM will reverse the process of DCM. In this study, we sought to evaluate the cardiac function during the development of DCM and explore whether AIT will reverse the process of DCM. **Methods:** 60 Wistar male rats were randomly divided into control group (CON), DCM group (DCM) and AIT intervention group (AIT). Rats in DCM group and AIT group used high fat diet and STZ to induce diabetes models. Rats in AIT group were subjected to 8 weeks AIT intervention Fasting blood glucose (FBG), lipid profiles, insulin resistance (IR) and GLP-1 levels was measured. HE staining and echocardiography were used to identify cardiac morphology and function. α -MHC and β -MHC gene expression were detected by RT-PCR. GLP-1 and GLP-1R expression were detected by western blotting.

Results: Compared with CON, the heart function of DCM gradually changes from impaired diastolic function to impaired systolic function, with heart developed hypertrophy at onset and gradually cardiac walls became thinner with large LV volume. The FBG, TG and LDL-c levels in AIT was 16.8%, 45.6% and 74.7% lower than that in DCM ($P < 0.01$). AIT increased HDL-c level up to 60% than DCM ($P < 0.01$). AIT significantly decreased IR for 37.3% ($P < 0.01$). Histological analysis and echocardiography results revealed that AIT prevent the thinners of cardiac wall and improve systolic and diastolic function. There is a 81% increase of α -MHC mRNA expression and a 67% decrease of β -MHC mRNA expression in AIT group than in

DCM ($P < 0.01$), which represented that AIT prevent the heart transformation to embryo type. AIT protect DCM heart through improving serum GLP-1 level (80%, $P < 0.05$), heart GLP-1 expression (144%, $P < 0.01$) and GLP-1R expression (219%, $P < 0.01$).

Conclusions: AIT intervention may reverse the process of DCM by activating of GLP-1/GLP-1R signaling.

Predictors of Clinical Measures of Insulin Resistance

Vincent M. Smith, Gabrielle A. Volk, Elizabeth A. Sohns, Callan R. Conroy, Rebecca E. Bartram, Casey R. Heindl, Kyle T. Timmerman, FACSM. *Miami University, Oxford, OH.*

(No relevant relationships reported)

Approximately 30.3 million adults in the United States have diabetes. Diabetic complications include stroke, myocardial infarction, nerve damage, and renal failure, among others. In addition to being the seventh leading cause of death in the country, the medical costs due to diabetes is over \$325 billion annually. Clinical evaluation for type II diabetes can be assessed in a variety of ways: fasting blood glucose (FBG), hemoglobin A1c (HbA1c) percentage, and the homeostatic model assessment of insulin resistance (HOMA-IR). The **PURPOSE** of this study was to evaluate the relationships between these clinical indicators and body composition, physical activity level, and glucose response to mixed nutrient challenge in older adults. **METHODS:** In 38 subjects (7 m /31 f) body composition (bioelectrical impedance); blood glucose (glucometer); insulin (enzyme-linked immunosorbent assay); and HbA1c (HbA1c Analyzer) were assessed. In a subset of 30 subjects, physical activity was assessed via accelerometry (Actical). Further, in a subset of 16 subjects, glucose area under the curve (gAUC) was calculated following mixed nutrient challenge (0.5 g dextrose/kg lean mass + 0.3 g protein/kg lean mass). Partial correlations (controlling for age and sex) were utilized to examine associations. Significance was set as $p < 0.05$. **RESULTS:** Subject characteristics included: age= 67.9 ± 6.6 y, BMI= 29.3 ± 7.5 kg/m², FBG= 104.0 ± 19.0 mg/dL, HOMA-IR= 2.61 ± 1.95 , and HbA1c= 5.42 ± 0.25 %. FBG was significantly correlated with body mass ($r = 0.62$), body fat percentage ($r = 0.33$); and gAUC ($r = 0.59$). HOMA-IR was significantly correlated with body mass ($r = 0.64$) and body fat percentage ($r = 0.51$). HbA1c was significantly correlated with gAUC ($r = 0.83$). There was a trend for a correlation between HbA1c and habitual, daily moderate-to-vigorous intensity physical activity ($r = -0.36$, $p = 0.06$). **CONCLUSION:** These preliminary data support previous findings that clinical indices of insulin sensitivity are associated with body composition. Interestingly, our data show blood glucose response to mixed nutrient intake, but not FBG, is predictive of HbA1c.

A Family History Of Type 2 Diabetes Does Not Limit Exercise Induced Improvement In Aerobic Fitness And Mitochondrial Function In Normoglycemic Sedentary Men

Jasmin Jenkins¹, Conrad P. Earnest, FACSM², Kevin Conley³, Steven R. Smith⁴, Sudip Bajpeyi¹. ¹University of Texas at El Paso, El Paso, TX. ²Texas A&M University, College Station, TX. ³University of Washington Medical Center, Seattle, WA. ⁴Sanford Burnham Presbys Medical Discovery Institute, Orlando, FL.

(No relevant relationships reported)

A family history of type 2 diabetes (FH+) is considered a risk factor for the development of type 2 diabetes (T2D). However, it is unclear whether exercise induced improvements in insulin sensitivity (IS), maximal aerobic fitness (VO_{2max}), and mitochondrial maximum ATP synthesis rate (ATP_{max}), are impacted by a FH+.

PURPOSE: The purpose of this study was to 1) determine if normoglycemic, sedentary healthy individuals with FH+ have a lower IS, VO_{2max} , and ATP_{max} compared to those without a family history of T2D (FH-) and 2) if exercise induced changes in IS, VO_{2max} , and ATP_{max} is impeded in those with a FH+.

METHODS: Fourteen normoglycemic sedentary males with (n=6; age= 27.33 ± 2.65 years; BMI= 26.48 ± 1.25 kg/m²) or without (n=8; age= 26.63 ± 1.44 years, BMI= 26.46 ± 0.57 kg/m²) FH were trained on a stationary bicycle for 30-55 minutes/session on alternate days of continuous and interval training for 13 days over 3 weeks. Non-exercising control (n=8; age= 25.75 ± 1.85 years; BMI= 24.38 ± 1.31 kg/m²) without a FH completed the same testing procedures at baseline and after 3 weeks. IS was assessed by hyperinsulinemic euglycemic clamp. ATP_{max} was measured by magnetic resonance spectroscopy, and VO_{2max} was measured by a standardized graded exercise test.

RESULTS: There were no differences in IS, ATP_{max} and VO_{2max} between groups at baseline (one-way ANOVA all $p > 0.05$). Three weeks of exercise increased VO_{2max} only in FH- (Mean \pm SEM; Control 33.25 ± 1.68 to 32.66 ± 1.92 mL/kg/min, $p = 0.73$; FH- 33.47 ± 1.85 to 35.24 ± 1.60 mL/kg/min, $p = 0.03$; FH+ 29.96 ± 2.09 to 31.49 ± 2.07 mL/kg/min, $p = 0.14$), increased ATP_{max} only in FH+ (Control 0.68 ± 0.04 to 0.69 ± 0.04 mM ATP/s, $p = 0.98$; FH- 0.70 ± 0.05 to 0.73 ± 0.03 mM ATP/s, $p = 0.81$; FH+ 0.61

± 0.04 to 0.74 ± 0.05 mM ATP/s, $p=0.02$) but did not change IS in any group (Control 8.24 ± 0.93 to 7.00 ± 0.92 mg/kg/min, $p=0.38$; FH- 7.84 ± 0.82 to 8.42 ± 1.11 mg/kg/min, $p=0.87$; FH+ 5.39 ± 0.48 to 6.62 ± 0.83 mg/kg/min, $p=0.51$).

CONCLUSION: Three weeks of combined endurance and interval exercise training improved ATP_{max} and VO_{2max}, overall, but did not change IS in normoglycemic sedentary individuals. FH+ does not seem to be a limiting factor for achieving exercise stimulated improvement in whole body aerobic fitness and mitochondrial function in a normoglycemic healthy sedentary population.

 (No relevant relationships reported)

Previous study reported that hyperbaric treatment with 36% oxygen decreases glucose and insulin level in type 2 diabetes rats, and the improvement could be due to increased oxygen saturation and blood flow during hyperbaric treatment. However, the effects of simple hyperbaric treatment without high oxygen remain unknown. **PURPOSE:** To investigate the effects of hyperbaric treatment with normal air on hyperglycemia in type 2 diabetes, focusing on skeletal muscle hemodynamics.

METHODS: 24-week-old male Otsuka Long-Evans Tokushima fatty (OLETF) rats and Long-Evans Tokushima Otsuka (LETO) rats were used as diabetes model and non-diabetes model, respectively. All rats were assigned to hyperbaric treatment or non-treatment groups. The rats in the hyperbaric treatment group were exposed to hyperbaric chamber at 1.3 ATA with normal air for 8 hours a day for 16 weeks. The oxygen saturation and total-hemoglobin (Hb) changes in the calf muscle during hyperbaric treatment was measured by near-infrared spectroscopy. Oral glucose tolerance test was performed at 40-week-old.

RESULTS: Oxygen saturation and total-Hb were significantly increased during hyperbaric treatment from 73.3 to 76.7% and 25.0 to $26.3 \times 10^9/\text{mm}^3$ in OLETF rats, 71.1 to 74.8% and 20.1 to $22.5 \times 10^9/\text{mm}^3$ in LETO rats ($p < 0.05$). The glucose and insulin levels were significantly higher in OLETF rats than LETO rats at both fasting and after glucose administration ($p < 0.05$). Among OLETF rats, the glucose levels at 30, 60, 120 min after glucose administration were significantly lower in the hyperbaric treatment group than the non-treatment group (30 min: 325 ± 71 vs. 385 ± 48 , 60 min: 332 ± 67 vs. 421 ± 111 , 120 min: 216 ± 45 vs. 230 ± 20 mg/dL, $p < 0.05$). Additionally, the fasting insulin level and the levels at 120 min after glucose administration were significantly lower in the hyperbaric treatment group than the non-treatment group (Fasting: 3.6 ± 1.1 vs. 4.3 ± 2.7 , 120 min: 4.4 ± 1.6 vs. 5.2 ± 3.9 ng/mL, $p < 0.05$).

CONCLUSIONS: The present study demonstrated that hyperbaric treatment with normal air also prevents the progression of hyperglycemia in OLETF rats, and the treatment without high oxygen increases oxygen saturation and blood flow in the skeletal muscle.

 (No relevant relationships reported)

PURPOSE: To verify the effect of HIT on cardiorespiratory performance and substrate oxidation in obese adolescents with and without insulin resistance. **METHODS:** Clinical trial with 25 obese adolescents, allocated to two groups: with insulin resistance (IR, $n=12$, HOMA ≥ 3.16) and no insulin resistance (nIR, $n=13$), submitted before and after six sessions of HIT to cardiopulmonary test for determination of oxygen consumption (VO₂), heart rate (HR), and velocity (V) at peak intensities and the first ventilatory anaerobic threshold (LAV1), more indirect calorimetry protocol for determination of lipid oxidation rate (LIPox) and carbohydrate oxidation rate (CHOox). The training protocol included six HIT sessions with 48h intervals, consisting of six series at 100% of Vpeak and active recovery at 50% of Vpeak. Data were treated by Student t or Mann-Whitney tests (comparisons between groups) and Student t or Wilcoxon tests (pre and post-training comparisons); the influence of HIT was tested by Cohen's d. The level of significance was 5%. **RESULTS:** Significant increases in Vpeak, VO₂, V and HR at LAV1 were observed in post-training in both

groups ($p < 0.05$; $d < 0.02$). As a consequence, the groups presented alterations in oxidation substrates patterns, with increases of 56.13% and 20.21% of CHOox for nIR ($p=0.03$) and IR ($p=0.06$), respectively. **CONCLUSION:** Six HIT sessions were sufficient to alter parameters of cardiorespiratory and CHOox performance in obese adolescents resistant or not to insulin, suggesting its use in potential implications for the regulation of physical fitness and glycemia in these populations.

Weight Loss Combined with Increased Water Consumption Improves Cognitive Performance in Overweight Older Adults

Kayla J. Airaghi, Brenda M. Davy, FACSM, Elaina L. Marinik, Kevin P. Davy, FACSM, Tina Savla, Benjamin Katz. Virginia Tech, Blacksburg, VA.
 Email: kairaghi@vt.edu
 (No relevant relationships reported)

Existing research has established links between cognition and hydration in athletes and young adults, and a higher BMI has been linked to deficits in inhibitory control and attention. We recently reported that hydration status was associated with cognitive performance in overweight older adults. However, there is little work exploring the influence of weight loss interventions that also increase water intake on cognition. **PURPOSE:** This study investigated the impact of a short-term weight loss intervention with and without increasing water intake on attention and inhibition in older overweight adults. **METHODS:** Older adults aged 50-69 ($n=23$, 67% female, BMI = 32 ± 4) were randomly assigned to one of two groups for 4 weeks: 1) hypocaloric diet + 16 fl. oz. of pre-meal water 3 times/d ($n=13$; "water"), 2) hypocaloric diet with no additional water ($n=10$; "nonwater"). Assessments at baseline and week 4 included weight, hydration (urinary specific gravity; USG), and the AX-Continuous Performance Task (CPT), a measure of inhibitory control and attention. Univariate ANCOVAs with experimental condition as a fixed factor, pre-test as a covariate, and post-test performance as the dependent variable were used to examine the outcome of the intervention on cognition.

RESULTS: Weight loss was 4.7% (± 0.7) and 4.3% (± 0.2) of baseline bodyweight for water and non-water groups, respectively, with no group difference. Intervention compliance evaluated at week two demonstrated lower USG in the water group (1.009 ± 0.002) than the nonwater group (1.015 ± 0.002), ($p=0.067$). Furthermore, at week 4, the nonwater group was 7% faster ($p=0.046$) and 4% less accurate ($p=0.076$) than the water group on the final block of the CPT after controlling for baseline performance. These results suggest a speed-accuracy tradeoff, such that individuals who were randomized to drink additional water while consuming a hypocaloric diet performed more slowly but more accurately on the later stages of the attention task. **CONCLUSIONS:** Among older, overweight adults undergoing weight loss, increasing water consumption may reduce cognitive fatigue during an attention task such that more hydrated individuals may favor accuracy over speed, relative to less hydrated individuals.

Effectiveness Of 12-week Exercise Training On Body Composition And Lipid Metabolism Of Non-alcoholic Fatty Liver Disease

Zhu Lin¹, Jing-xin Liu².
¹Guangzhou Sport University, Guangzhou, China. ²Shanghai University of Sport, Shanghai, China.
 Email: 40848567@qq.com
 (No relevant relationships reported)

Exercise training is often prescribed to treat non-alcoholic fatty liver disease (NAFLD). However, body-weight training, as a simple and convenient exercise method, the effectiveness on NAFLD is still unclear.

PURPOSE: To determine the effects of 12-week individualized body-weight training combined with aerobic training on body composition, blood lipid and liver function of NAFLD. **METHODS:** Thirty participants (male: 10, female: 10, age 45.82 ± 7.55 years) who were clinically diagnosed as NAFLD were randomized allocated to the experimental group (EG) with a trained program that 3 times per week over 12 weeks (30 min body-weight training, 30 min walking exercise at 40 - 60% heart rate reserve) or a control group (CG) with health education. Body composition, blood lipid and liver function were measured at baseline and after intervention.

RESULTS: At 12th weeks there were significant changes within group in body weight (-4.61 ± 1.87 kg, $p < 0.01$), body mass index (-1.57 ± 0.78 kg/cm², $p < 0.01$), waist circumference (-5.20 ± 2.81 cm, $p < 0.01$), hip circumference (-5.07 ± 2.28 cm, $p < 0.01$), body fat percent ($-1.86 \pm 1.62\%$, $p < 0.01$), body fat mass (-1.69 ± 0.87 kg, $p < 0.01$) and visceral fat (-1 ± 0.78 kg, $p < 0.01$) in EG. There was no significant change in body composition of CG ($p > 0.05$), all these changes were significant different between EG and CG ($p < 0.05$). EG resulted in a significant increase in triglyceride (-0.56 ± 0.91 mmol/L, $p < 0.05$), low-density lipoprotein cholesterol (-0.33 ± 0.53

mmol/L, $p < 0.05$), while total cholesterol and high-density lipoprotein cholesterol did not change significantly after exercise. Exercise training decreased Alanine aminotransferase (43.87 ± 31.34 to 23.53 ± 12.78 u/L, $p < 0.0001$) and Aspartate aminotransferase (33.87 ± 15.67 to 22.40 ± 6.32 u/L, $p < 0.0001$), which were significantly different from CG. **CONCLUSIONS:** Participates in regular combination exercise of body-weight exercise and aerobic exercise have marked beneficial effects on body composition, blood lipid and liver function on NAFLD.

Post-Meal Walking Vs. Pre-Meal Vinegar Ingestion: Strategies to Reduce Postprandial Hyperglycemia

Brady J. Holmer¹, Sarah J. Taylor², Cory M. Scheadler³, Matthew J. Garver⁴. ¹University of Florida, Gainesville, FL. ²Abilene Christian University, Abilene, TX. ³Northern Kentucky University, Highland Heights, KY. ⁴University of Central Missouri, Warrensburg, MO.
Email: holmerb1@ufl.edu

(No relevant relationships reported)

Postprandial hyperglycemia is a risk factor for future CVD events. Lifestyle interventions to blunt postprandial glucose are needed to reduce diabetic and CVD risk. Apple cider vinegar, a "functional food", has been shown to attenuate the rise in glucose following a meal. Aerobic exercise may also reduce blood glucose (BG) levels when performed before or following a high-glycemic meal. **Purpose:** This study aimed to compare the effectiveness of post-meal vinegar ingestion and pre-meal walking in reducing postprandial hyperglycemia in elderly individuals. We also investigated whether this population will self-select walking speeds sufficient to reduce postprandial glucose spikes. **Methods:** Participants ($n=12$) reported for testing following a 3 hour fast. Baseline BG was measured upon arrival, after which participants completed one of three conditions in a randomized, crossover order: (1) Consumption of standard meal followed by 2 hours of sitting, (2) Consumption of standard meal with apple cider vinegar (.3g/kg BW) or (3) Consumption of a standard meal followed by 15 minutes of self-paced walking. BG was measured by finger stick at 30, 60, 90, and 120 minutes following meal consumption. The meal was designed to be high glycemic-index (GI) and included a bagel, butter, and orange juice. Total energy content of the meal was 470kcal (79g CHO [28g sugar], 12g FAT, 1g PRO). **Results:** The control trial confirmed BG rose significantly following the meal at 30 (167.8 ± 6.1 mg/dl vs. 91.8 ± 2.4 mg/dl; $p < .005$) and 60 minutes (172.8 ± 11.8 mg/dl vs. 91.8 ± 2.4 mg/dl; $p = .024$). There was no difference in BG area under the curve (AUC) at any time point following vinegar or walking interventions vs. control. However, following vinegar and walking, the absolute increase in BG at 30 minutes following the meal was significantly reduced vs. control ($\Delta 30BG$ in control 76.1 ± 7.0 mg/dl vs. vinegar 46.8 ± 9.2 mg/dl vs. walking 44.3 ± 7.5 mg/dl; $p < .05$). Speed was found to be correlated with BG AUC, such that an increase in walking speed was associated with a greater reduction in 2-hour glucose AUC ($R = .590$). **Conclusions:** Lifestyle interventions such as walking and vinegar ingestion may effectively lower postprandial glucose spikes. For elderly individuals these represent alternative therapies to aid in glucose management and improve metabolic health.

Effects Of Different Exercise On Autophagy & Inflammation In Visceral Adipose Tissue Of Obese

Yongjun Zhao¹, Yuxiu He². ¹Ly liang University, Ivliang, China. ²Hebei Normal University, Shijiazhuang, Hebei, China, China.
Email: zhaoyun@126.com

(No relevant relationships reported)

PURPOSE: to examine the impact of exercise on autophagy and inflammation response in visceral adipose tissue in obesity in order to explore the relationship between them in adipose tissue after exercise. **METHODS:** 42 obese mice were randomly divided into four groups as follows: high fat diet (HC, $n=9$), normal diet (NC, $n=9$), normal diet combined with endurance exercise intervention (NE, $n=12$), and normal diet combined with resistance exercise intervention (NR, $n=12$). NE and NR conducted treadmill and ladder climbing exercise respectively for 8 weeks. Then to detect the gene and protein expression of autophagy, inflammation, ER stress and antioxidant markers using RT-PCR and WB, in addition, TEM and IHC were used to observe the autophagosome in visceral adipose tissue.

RESULTS: BW, Lee's index and BFI were significantly decreased in all three intervention groups, and there is a great decreasing in the two exercise group, but no difference between them. Atg5, Becn1 expression and LC3II/I were decreased significantly in NE and NR group compared with HC, meanwhile p62 expression were significantly increased. When compared with NC group, p62 expression were significantly increased in NE and not happened in NR group. Becn1 mRNA expression increased and p62 protein expression decreased significantly in NR group when compared with NE group. IL-1 β was decreased significantly in NC, NE and NR group compared with HC. In addition, IL-6 and IL-10 protein expression increased significantly both in NE and NR group. When compared with NC group, IL-6 and

IL-10 protein expression increased and IL-1 β was decreased significantly both in NE and NR group except IL-6 protein expression in NR group. IL-6 increased and IL-10 decreased significantly in NR group when compared with NE group. Finally we found that IL-10 showed a negative correlation with almost every autophagy markers used in this study.

CONCLUSIONS: The effectiveness of 8wks different exercise intervention had no difference in fat reduction. The autophagic activity of visceral adipose tissue was inhibited after exercise, especially after aerobic exercise. Autophagy and inflammation enjoy the same trend before and after exercise in visceral adipose tissue in obesity, and the IL-10 is the most sensitive factor in reflecting the relationship between autophagy and inflammation.

"Living High-training Low" Improves Hepatic Steatosis In Obese Mice

Wang Ru. Shanghai University of Sport, Shanghai, China.
Email: wangru0612@163.com

(No relevant relationships reported)

"Living high-training low" (LHTL) is effective for weight loss in nutritional obese individuals. But whether the LHTL improves hepatic steatosis is unknown.

PURPOSE: To explore the effect of LHTL on serum lipids and hepatic steatosis in obese mice.

METHODS: High-fat diet induced obese mice (male C57BL/6J) were randomly divided into obesity (OB, $n=9$) and "Living high-training low" group (LHTL, $n=9$), both of which were fed a high-fat diet that fat provides 60% calories (Research Diets). Mice in OB group were kept quiet, while mice in LHTL group conducted hypoxia exposure (Mixing nitrogen and air, PO₂ 14.7%, from 08:30 to 16:30, 8 h/d, 6 d/w) and exercise training (starting at 20:00, treadmill slope is zero, 14 m/min, 840 m/d, 6 d/w) intervention for 4 weeks. Animals were euthanized after the intervention. Body weight (BW), fat mass (FM), body fat percentage (BFP), liver index, serum High/low density lipoprotein cholesterol (HDL/LDL-C), Triglyceride (TG), Alanine aminotransferase (ALT), Free fatty acids (FFA), liver FFA and Histological staining (HE & Oil red O) were measured.

RESULTS: LHTL 1) reduced BW (38.41 ± 0.74 vs. 44.21 ± 0.74 g, $p < 0.01$), FM (2.06 ± 0.09 vs. 2.45 ± 0.14 g, $p < 0.05$) significantly, while BFP (5.76 ± 0.30 vs. $6.49 \pm 0.29\%$, $p > 0.05$), serum HDL-C (0.72 ± 0.01 vs. 0.72 ± 0.01 $\mu\text{g}/\mu\text{l}$, $p > 0.05$), LDL-C (0.66 ± 0.02 vs. 0.68 ± 0.01 $\mu\text{g}/\mu\text{l}$, $p > 0.05$), TG (0.20 ± 0.02 vs. 0.20 ± 0.03 pmol/L, $p > 0.05$) and FFA (722.59 ± 40.74 vs. 606.06 ± 15.97 $\mu\text{mol}/\text{L}$, $p > 0.05$) levels showed no significant difference between the two groups; 2) reduced liver index (3.58 ± 0.12 vs. $4.45 \pm 0.19\%$, $p < 0.01$), serum ALT (5.06 ± 0.12 vs. 6.28 ± 0.31 U/L, $p < 0.01$) and liver fat content significantly while liver FFA (0.11 ± 0.01 vs. 0.13 ± 0.01 $\mu\text{mol}/\text{L}$, $p = 0.131$) only showed a downward trend.

CONCLUSIONS: "Living high-training low" is effective for weight loss and improves hepatic steatosis without attenuating circulating dyslipidemia.

Effects Of Nutritional Status On Arterial Stiffness In The Subjects With Pre-sarcopenia

Keqin Huang, Shizue Itano, Kanako Hamaguchi, Toshiyuki Kurihara, Natsuki Hasegawa, Motoyuki Iemitsu, Kiyoshi Sanada. Ritsumeikan University, Shiga, Japan.

Email: gr0361xx@ed.ritsumei.ac.jp

(No relevant relationships reported)

Sarcopenia associated with arterial stiffness and poor nutrition intake. However, it is unclear whether the effects of nutritional status on arterial stiffness in the subjects with pre-sarcopenia. **PURPOSE:** The purpose of this study was to investigate whether the effects of nutritional status on arterial stiffness in the subjects with pre-sarcopenia in Japanese men and women. **METHODS:** The participants included 56 Japanese adults (44-77 years). Men ($n=15$) and women ($n=41$) in whom skeletal muscle index (SMI; appendicular muscle mass/height²) was measured by dual-energy X-ray absorptiometry. Pre-sarcopenia was defined as the cut-off value of SMI based on Asian Working Group for Sarcopenia. We assessed nutritional status by Brief-type self-administered Diet History Questionnaire, and the subjects divided into high- and low- nutritional status based on the mean values of this study independent of gender.

RESULTS: Two-way ANCOVA with adjustment for age, gender and physical activity as a covariate indicated that total energy intake and sarcopenia interacted to produce a significant effect on the brachial-ankle pulse wave velocity (baPWV) in Japanese adults ($P < 0.05$). The baPWV was significantly higher in the subject with coexisting sarcopenia and low-energy intake than that with non-sarcopenia regardless of total energy intake. **CONCLUSION:** Low-energy intake effects on arterial stiffness in the subjects with pre-sarcopenia even adjustment of age and physical activity involved. Future prospective studies are needed to assess the effects of nutritional status on

arterial stiffness in sarcopenia. Supported by Grant-in-Aid for Scientific Research from the Ministry of Education, Culture, Sports, Science and Technology of Japan (#24300239).

Effects of Novel Compression Exercise Technology on Glycohemoglobin Levels and Weight in Type II Diabetics

Cristian Torres¹, Richard Henderson², Chloe Wernecke¹. ¹*Vaspar Systems, Moffett Field, CA.* ²*Covenant Medical, Lubbock, TX.*
Reported Relationships: C. Torres: Salary; Vaspar Systems.

The most potent lifestyle intervention for treatment of Type II Diabetes (T2D) is consistent exercise. However, for many patients with the condition, other comorbidities such as osteoarthritis, hypertension, and high body mass indexes prevent them from being able to exercise intensively and consistently enough to experience optimal metabolic benefits. Recent research has supported the use of compression exercise in physically limited populations and demonstrated physiologic responses at lower intensities (10-20% one repetition maximum vs. 70% for hypertrophic response in conventional resistance exercise). The combination of compression technology with core cooling further lowers the exertional requirements and has been used in cardiopulmonary rehabilitation populations to provide a safe and reliable exercise intervention. Compression exercise has also been shown to significantly increase muscle hypertrophy, with a greater growth in type II fibers (higher expressers of GLUT4). Therefore, this technology could directly address basal metabolism through increasing muscle protein turnover, increasing glucose storage in skeletal muscle mass, and improving glycemic control. This capacity to attenuate the insulin response combined with the accessibility of the platform suggests a clinical implication for diabetes management.

PURPOSE: To establish safe use of cooled compressive exercise in Type II Diabetics and to examine the effect of 6 months of training on biometabolic markers, especially Glycohemoglobin levels and weight.

METHODS: Thirty Type II Diabetics agreed to 3 training sessions a week for 6 months. Biometabolic markers via blood draw were analyzed at 0, 3, and 6 months.

RESULTS: Midpoint data from 16 participants at 0 and 3 months were analyzed with a two-tailed T-test, revealing significant differences in Glycohemoglobin and weight. There was an 8% average decrease in Glycohemoglobin levels (8.5±2.2 vs. 7.8±1.8 mg/dl, $p = 0.002$) and an average weight loss of 3.6 lbs (211±50 vs. 208±48 lbs, $p = 0.032$).

CONCLUSION: The preliminary results of this study suggest exercise with compression and cooling contributes to a reduction in biometabolic markers of diabetes. This intervention has promise in contributing to effective management of T2D with a low physical burden.

High-fat Diet-induced Obesity Induces Peripheral Neuropathy During Impaired Cutaneous Wound Healing

Emma C. Moore, Adam Johnston. *University of Prince Edward Island, Charlottetown, PE, Canada.*
 Email: ecmoore@upeu.ca
(No relevant relationships reported)

Type-II diabetes is a societal epidemic that is associated with obesity and metabolic disease often resulting from poor diet and reduced physical activity. Two major complications associated with type-II diabetes are peripheral neuropathy which leads to a loss of sensation and chronic pain as well as poor wound healing, which can progress to ulceration and ultimately amputation. Since clinical trials for the treatment of these chronic conditions have only fostered limited success we examined the possibility that the nervous system and wound repair are linked. The **PURPOSE** of this study was to investigate the potential that the peripheral nervous system is a necessary regulator for normal wound repair and that diabetes-induced neuropathy is in part, causative of impaired wound healing. **METHODS:** We administered a 6 mm skin punch biopsy wound to high-fat diet (HFD, 10 weeks of feeding with 60% of energy from fat content, $n=9$) and control (10% of energy via fat content, $n=9$) fed mice. **RESULTS:** A diabetic phenotype was confirmed in HFD mice as evidenced by elevated body weight (Control mean weight=32.4g, HFD mean weight=40.7g) and impaired glucose tolerance ($p < 0.05$) in response to an intraperitoneal glucose tolerance test. Following skin injury, HFD mice demonstrated an impaired wound healing rate as evidenced by a larger wound diameter and area ($p < 0.05$) at days 2-9 while hematoxylin, and eosin staining of tissue-cross sections revealed larger wound widths and a poorly formed dermis in HFD mice in comparison to controls at day 9. Immunohistochemical analysis demonstrated that poor wound healing was coincident with a reduction of S100β+ cutaneous Schwann cells within and around the healing dermis. Ongoing analysis includes the examination of additional markers of cutaneous neuropathy using immunohistochemistry to quantify total nerve axons (UCHL-1+ cells), growing/regenerating axons (Gap43+ cells) and markers of activated/

dedifferentiated Schwann cells (p75NTR+Sox2+ cells) as well as testing the efficacy of Schwann cell transplantation to rescue HDF-induced neuropathy and wound healing deficits. **CONCLUSION:** Collectively, these experiments will give insight into the mechanisms underpinning two major complications associated with type-II diabetes that could be further explored to develop novel therapeutics.

Home Cooked Meals With Whole, Plant Foods and the Protection Against Central Adiposity

Nicholas V. Neuwald, Arlette C. Perry, FACSM, Wesley N. Smith. *University of Miami, Coral Gables, FL.* (Sponsor: Arlette Perry, FACSM)
 Email: nneuwald@gmail.com
(No relevant relationships reported)

It is well-established that central adiposity (CA) is associated with the risk of chronic disease. Diets high in processed foods and low in whole, fibrous plant foods, are often cited as risk factors for the development of CA and its adverse metabolic sequelae. Much of the processed foods consumed consist of pre-prepared foods and foods eaten outside of the home.

PURPOSE: To examine whether the consumption of processed, ready-to-eat (PRE) or restaurant meals that lack whole, plant-based foods was positively associated with CA in male and female adults. **METHODS:** A total of 2,703 adults (1,521 females and 1,182 males), from a HealthSnap wellness assessment platform used in physicians' offices across the country, self-reported their frequency of consuming PRE foods or restaurant meals versus whole, plant foods. CA was based upon a waist-to-hip ratio of ≥ 0.95 and ≥ 0.85 for males and females, respectively. To identify the association between PRE and CA, a chi-squared analysis (χ^2) was performed across quintiles of PRE by CA, and a relative risk (RR) was calculated. **RESULTS:** A significant association between PRE and CA ($\chi^2 [4, n = 2703] = 48.27, p < 0.001$) was observed. These associations remained significant regardless of gender. The RR for CA among patients in the top 20%, *Q5*, was compared to the lowest 20%, *Q1*, for PRE. The RR of a patient having CA in *Q5* for PRE was 225% greater than *Q1* (RR: 2.25, 95% CI: 1.69-2.99, $p < 0.001$). **CONCLUSION:** A strong positive association exists between dietary consumption of PRE and CA. This supports the consumption of more home-cooked meals with whole, plant foods over PRE in the clinical setting to protect against CA and its adverse health consequences.

3555 Board #243 June 1 9:30 AM - 11:00 AM
Role Of Aerobic Exercise On Cardiac Autonomic Modulation And Adipokines In Polycystic Ovary Syndrome

Stella V. Philbois, Tábara P. Facioli, Hugo C. Souza. *University Of Sao Paulo, Ribeirão Preto, Brazil.*
 Email: hugocds@fmrp.usp.br
(No relevant relationships reported)

Women with Polycystic Ovary Syndrome (PCOS) present substantial weight gain that may increase the risk of developing cardiovascular diseases. Hormonal, metabolic and cardiac autonomic changes also occur and increase the risk of these diseases. However, despite advances, the effects of aerobic exercises on the different aspects of this syndrome are still unknown, especially when the body fat percentage is considered. **PURPOSE:** To investigate the effects of aerobic exercise on hormonal and metabolic aspects and cardiac autonomic modulation in women with PCOS with different percentages of body fat. **METHODS:** Women with PCOS ($N=60$) and without PCOS (control, $N=60$), between the ages of 18 and 39 years, were divided into three groups, according to their body fat percentage (22-27%, 27-32% and 32-37%). The participants were submitted to assessment of the following parameters before and after the aerobic physical training (16 weeks); body composition, fasting glucose and insulin, androgens, leptin, adiponectin, tumor necrosis factor- α (TNF- α), interleukin-6 (IL-6), and the analysis of heart rate variability (HRV). **RESULTS:** Women with PCOS had increased serum levels of androgens, insulin (insulin resistance), leptin, TNF- α and IL-6 associated with reduced serum levels of adiponectin. Autonomic assessment revealed that these women also exhibited an impaired autonomic modulation characterized by reduced HRV, but mainly in high-frequency oscillations (HF=0.2-0.5Hz), corresponding to vagal modulation. These findings were directly associated with the body fat percentage; however, according to some parameters evaluated (insulin, TNF- α , IL-6 and HRV), PCOS seems to play a key role. In turn, the aerobic physical training was effective in improving almost all the parameters evaluated, except the serum levels of androgens and TNF- α . **CONCLUSIONS:** The results showed that PCOS has been found to be associated with significant endocrine/metabolic disturbances and cardiovascular autonomic dysfunction, which are exacerbated by overweight. Aerobic physical training proved to be an effective treatment for most parameters evaluated and should be prescribed as an adjunct treatment for PCOS, the same way it has been used to treat chronic degenerative diseases.

Aerobic Exercise Reduced Body Weight through Midbrain-striatal Dopaminergic Plasticity in Obese MiceWei Chen, Juan Li, Yuxiu He, Yakai Niu. *Hebei Normal University, Shijiazhuang, China.**(No relevant relationships reported)*

PURPOSE: Previous research indicates that midbrain-striatal dopaminergic disruption is associated with obesity and involved in feeding behavior and voluntary physical activity. Since the action of exercise on midbrain-striatal dopamine, it may be an effective strategy to improve physical inactivity and overeating induced by food reward dysfunction in obesity. We therefore explored the mechanisms.

METHODS: Male C57BL/6 mice were randomly divided into control group (C, n=12), exercise group (CE, n=12) fed a normal diet (13% fat), and an additional group (H, n=40) fed a high fat diet (51% fat). Obese mice in H were further divided into obesity group (O, n=12) and obesity + exercise group (OE, n=12). The CE and OE mice underwent treadmill exercise (5-13 m/min, about 58%-75% VO₂max, 50 min/d, 5 d/wk for 8 wks). The food preference test and open-field test were used to assess food reward, and voluntary physical activity. Tyrosine hydroxylase (TH)⁺ neurons were detected by immunohistochemistry, and the expression of TH protein in midbrain-striatum were measured by western blot.

RESULTS: Body weight of OE was 15.2% lower than that of O ($P < 0.01$). Sucrose preference, physical activity level and time were decreased by 25.8%, 46.77% and 37.56% in O compare to C ($P < 0.05$, $P < 0.01$, $P < 0.01$), but were 18.2%, 37.28% and 26.35% higher, respectively, in OE than O ($P < 0.05$). TH⁺ cells in substantia nigra pars compacta (SNc) and ventral tegmental area (VTA) decreased by 15.41% and 18.45%, respectively, in O compare to C ($P < 0.05$), but increased by 12.62% and 15.53% in OE compare to O ($P < 0.05$). TH⁺ fibers in dorsal striatum nucleus accumbens were 16.36% and 17.48% lower in O than C ($P < 0.05$), but was 12.54% and 14.13% higher in OE vs. O ($P < 0.05$). In addition, the expression of TH protein in midbrain and striatum decreased by 18.46% ($P < 0.05$) and 16.35% ($P < 0.05$) in O compared with C, but increased by 12.23% and 11.58% in OE compare to O ($P < 0.05$).

CONCLUSIONS: The aerobic exercise inhibits body weight gain, improves food reward and voluntary physical activity in obese mice. The exercise-induced midbrain-striatal dopaminergic plasticity may be one of the important mechanisms for this adaptation.

Email: theusfernandes10@hotmail.com

(No relevant relationships reported)

PURPOSE: The overweight/obesity affects brain function from cellular to structural levels, and due to the mitochondria importance, several studies have focused upon its involvement in the obesity and brain function. On rodents, previous data have already identified impairments of the prefrontal cortex triggered by obesity and its association with the oxidative stress. As the effect of moderate exercise training in the amelioration of the oxidative balance on prefrontal cortex was not examined in leptin-deficient ob/ob mice, this study assesses the effect of moderate physical exercise on oxidative stress parameters in the prefrontal cortex of leptin-deficient ob/ob mice. **METHODS:** Male ob/ob mice (Jackson Laboratories, Bar Harbor, ME, USA) with nine-weeks-old (32 g) were assigned into groups sedentary (S) and trained (T), housed in temperature and humidity controlled rooms, and kept on a 12 h light/dark cycle with food and water ad libitum. The physical training was performed at 60% of the maximal running capacity, 5 times/week, for 8 weeks. Forty-eight hours after last training, the animals were sacrificed and the prefrontal cortex quickly collected for oxidative balance analysis.

RESULTS: We did not observe differences in the lipid ($p=0.3285$) and protein oxidation ($p=0.3208$) in leptin-deficient ob/ob exercised mice, with concomitant unchanging in the superoxide dismutase activity ($p=0.2366$) and catalase ($p=0.7068$). However, we observed that the physical training significantly increased glutathione-S-transferase activity (S: 0.93 ± 0.3 vs. T: 3.63 ± 0.8 U/mg prot; $p=0.04$). Moreover, the physical training increased the non-enzymatic antioxidant defense (GSH= S: 5.1 ± 0.3 vs. T: 6.4 ± 0.6 μ M/mg prot, $p=0.04$; -SH levels= S: 0.016 ± 0.003 vs T: 0.031 ± 0.001 mM/mg prot, $p=0.02$). Additionally, we evaluated the AMPK and PGC1 α gene expression, and we observed that AMPK wasn't modified after 8 weeks of physical training ($p=0.86$), however, PGC1 α expression increased significantly (S: 1.00 ± 0.2 vs. T: 1.98 ± 0.20 ddCt; $p=0.013$). **CONCLUSIONS:** We suggest that physical

exercise can minimize the detrimental effect of the obesity-induced oxidative stress in prefrontal cortex by activates an important transcription factor and possibly stimulates mitochondrial biogenesis.

(No relevant relationships reported)

Cancer-related fatigue (CRF) is defined as a distressing, persistent, subjective sense of physical, emotional, and/or cognitive tiredness or exhaustion related to cancer or cancer treatment that is not proportional to recent activity and interferes with usual functioning. It has previously been suggested that CRF is associated with cardiorespiratory deconditioning. However, there is a lack of data to support this hypothesis. **PURPOSE:** To investigate: (i) peak oxygen uptake (VO_{2peak}) in fatigued vs. non-fatigued cancer survivors; and (ii) the relationship between VO_{2peak} and CRF severity. **METHODS:** Participants ($n=86$) were recruited via a cancer-registry mail-out and from local cancer centres. Participants were allocated into two groups using the Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) scale and a previously established cut-off (score of ≤ 34 and > 34 for fatigued and non-fatigued, respectively). Participants categorized as fatigued ($n=48$ [25 female]; mean \pm SD age 55 ± 9 years; FACIT-F 27 ± 6) and non-fatigued ($n=38$ [21 female]; age 57 ± 11 years; FACIT-F 44 ± 5) performed an incremental exercise test to volitional exhaustion on a cycle ergometer. Data were compared to reference standards based on sex and age. Differences between groups were compared using an independent samples t -test. The association between FACIT-F score and VO_{2peak} was examined using linear regression. **RESULTS:** In comparison to reference standards, 23% of the fatigued group and 5% of the non-fatigued group were below the 50th percentile for VO_{2peak}. VO_{2peak} was significantly lower in the fatigued vs. non-fatigued group (25.7 ± 6.0 vs. 30.4 ± 5.9 mL.kg⁻¹.min⁻¹; $t_{(84)} = -3.9$; $p < 0.001$; $d = 0.8$). There was a significant association between FACIT-F score and VO_{2peak} ($r = 0.36$; $p = 0.001$). The variance in VO_{2peak} explained 13% of the variance in FACIT-F score. **CONCLUSIONS:** Cardiorespiratory fitness was associated with the severity of CRF. In cancer survivors with CRF of a clinically-relevant severity, VO_{2peak} was lower in comparison to cancer survivors categorised as non-fatigued. Although CRF is complex and multifactorial, an improvement in cardiorespiratory fitness may explain some of the improvement in CRF severity with aerobic exercise interventions.

Comparing Modified Treadmill Protocols for Cancer Survivors: A Pilot StudyDaniel Y.K. Shackelford, Jessica M. Brown, Edwin R. Rodriguez, Richard K. Thomas, Jessica J. Ruffert, Anne E. Smith, Kieran J. DeGroot. *Carroll University, Waukesha, WI.*

Email: dshackel@carrollu.edu

(No relevant relationships reported)

INTRO: The University of Northern Colorado Cancer Rehabilitation Institute (UNCCRI) treadmill protocol has been validated to accurately predict peak oxygen consumption (VO_{2peak}) in the cancer population. It is unknown if the Modified Bruce and Balke-Ware treadmill protocols are an accurate means to assess VO_{2peak} in cancer survivors. **PURPOSE:** Determine whether the Modified Bruce and Balke-Ware treadmill protocols yield similar VO_{2peak} values and are as feasible as the UNCCRI protocol in the cancer population. **METHODS:** Eight cancer survivors participated in the study, one of which dropped out. All participants performed three VO_{2peak} treadmill tests using the following protocols: UNCCRI, Modified Bruce, and Balke-Ware. One protocol was performed per week in a randomized order. VO_{2peak} values were obtained via gas analysis using a research-grade CosMed metabolic cart. A Kruskal-Wallis test was used to determine differences in VO_{2peak} between all three protocols. **RESULTS:** VO_{2peak} values (mL.kg⁻¹.min⁻¹) did not significantly differ between the UNCCRI (27.1 ± 5.8), Modified Bruce (27.3 ± 5.5), or Balke-Ware treadmill protocols (28.8 ± 5.8) ($p = 0.42$). **CONCLUSION:** The findings from this limited data set suggest that the Modified Bruce and Balke-Ware may be suitable in

determining VO₂peak in cancer survivors. However, these are not cancer-specific protocols and may be difficult to perform in patients suffering from severe muscular impairments, cachexia, balance issues, peripheral neuropathy, and/or cancer-related fatigue. The Modified Bruce has large and abrupt single-stage increases in speed and grade and the Balke-Ware has a faster, consistent speed of 3.5 mph. Attempting either of these two protocols with the aforementioned side effects may cause early test termination due to non-cardiovascular reasons, be a barrier to testing, and result in an inaccurate VO₂peak. The UNCCRI protocol accounts for cancer side effects by using a more gradual increase in speed and grade, resulting in validated and accurate values. Nevertheless, valid VO₂peaks may be achieved from the Modified Bruce and Balke-Ware if the participant is not suffering from any severe side effects and is fully able to exert themselves during testing, as occurred in this pilot study. Further data collection is needed to expand upon these findings.

PURPOSE: To determine whether chemotherapy tolerance and side effects differ among women with breast cancer who do and do not participate in an exercise program.

METHODS: Women with early stage breast cancer who were offered supervised exercise programming as supportive care during adjuvant chemotherapy (n=73) were compared to a randomly selected, retrospective, usual care group (n=87). Exercise programming included supervised moderate-intensity aerobic and whole-body resistance training 3x/week plus home-based aerobic training 2x/week. Clinical data were extracted from medical records in a standardized manner for both groups. Weight gain was defined as ≥0.5 kg increase in body weight from chemotherapy records. Complete blood counts were extracted to determine prevalence of anemia and neutropenia.

RESULTS: The groups were matched on age, body mass index, medical history, diagnosis, and treatment characteristics. The relative dose intensity and risk of a dose reduction of any chemotherapy type did not differ between groups. Neuropathy was the most common reason for a dose reduction and the prevalence did not differ between groups. Dose reductions due to neutropenia or fatigue were significantly less common, while dose reductions due to mucositis were more common in the exercise group (all p<0.04). The severity, frequency, and risk of experiencing neutropenia and anemia did not differ between groups. Most (95%) patients experienced anemia, while one-third experienced neutropenia for at least 1 treatment cycle. There were some agent-specific effects of exercise including 1) a relative risk reduction of a doxorubicin dose reduction (relative risk, RR=0.40, 95% CI=0.17-0.94, p=0.04), but not for docetaxel or paclitaxel; and 2) risk reduction of weight gain with receipt of docetaxel and cyclophosphamide (RR=0.61, 95% CI = 0.37-1.00, p=0.05) but not with receipt of doxorubicin and cyclophosphamide.

CONCLUSIONS: Women who participated in a supportive care exercise program did not experience greater overall tolerance for chemotherapy treatment. However, exercise may have some selective effects on tolerance for doxorubicin chemotherapy, weight gain with docetaxel chemotherapy, and dose reductions due to neutropenia and fatigue.

 (No relevant relationships reported)

Exercise throughout cancer treatment can positively affect clinical and patient-reported outcomes. However, adverse side effects (e.g. fatigue) may reduce exercise adherence

during chemotherapy. To potentially further improve patient prognosis, developing strategies to maximize exercise participation across the cancer treatment trajectory is warranted. **Purpose:** To compare adherence and attendance to a supervised multimodal exercise intervention completed during chemotherapy for breast cancer to the same intervention completed after chemotherapy. **Methods:** Women with stage I-III breast cancer were randomized to: 1) immediate exercise during chemotherapy (IE); or 2) delayed exercise after chemotherapy (DE). The exercise intervention matched the length of each participant's chemotherapy regime (8-12 wks) and included 3x/wk supervised aerobic (50-75% HRR, 30-35 min), resistance (1-2 sets, 10-12 reps, 50-65% estimated 1-RM), and balance training. Mean attendance and adherence to aerobic (i.e. intensity/duration) and resistance (i.e. sets/reps) exercise were calculated. Exercise trainers recorded reasons for missed sessions. **Results:** 26 women enrolled and attended ≥1 session (IE: n=12, DE: n=14). Attendance did not differ between groups (IE=79±24%, DE=81±21%, p=0.82). No group differences were found for adherence to aerobic duration (IE=94±12%, DE=98±2%, p=0.28) or intensity (IE=78±30%, DE=82±17%, p=0.64), or resistance training (IE=73±35%, DE=90±9%, p=0.13). Among IE participants, top reasons for missed sessions were treatment-related symptoms (38%) (i.e. fatigue) and non-treatment related illness (17%) (i.e. cold/flu). Missed sessions for the DE group were most often due to non-treatment-related injury (43%) and travel (23%). **Conclusion:** Adherence to an identical supervised exercise intervention did not vary based on whether it was completed during or after chemotherapy. Barriers to attendance differed by group, thus strategies to maximize exercise participation during chemotherapy should be unique to the time of intervention delivery. Although feasibility does not appear to vary by timing relative to treatment, further analysis is required to determine if the timepoint of exercise delivery has differing effects on physical and psychological benefits.

Changes of Total and Tumor Specific Cell Free Dna During an Exhaustive Cycling Exercise Test

Tobias Ehlert, Suzan Botzenhardt, Perikles Simon. Johannes Gutenberg University, Mainz, Germany.
 Email: ehlert@uni-mainz.de
 (No relevant relationships reported)

PURPOSE: Circulating, cell free DNA (cfDNA) is known to directly accumulate in a load-dependent fashion in various aerobic and anaerobic exercise sessions within minutes. Furthermore, increases of cfDNA at baseline have been reported for different patient groups with cancer to depend on malignancy and tumor progression. Typically, such analysis did not differentiate between cfDNA and circulating tumor derived levels of DNA (ctDNA). Here we investigated for the first time, whether exercise to voluntary exhaustion induces increases in cfDNA and ctDNA in patients with advanced stage cancer.

METHODS: In a pilot study, individuals with solid tumors of diverse entities and an age matched control group (n = 5) were subjected to a step-wise incremental cycling spiroergometry until exhaustion. Blood samples were taken before, directly after, and 90 minutes after the end of the test. Total cfDNA was quantified directly from the blood plasma using a qPCR targeting repetitive Line-1 elements and ctDNA was measured following silica-based total DNA purification and enrichment from plasma and subsequent specific quantification using a nested qPCR assay targeting the seven most frequent oncogenic KRAS sequences in comparison to wild-type sequence. Additionally, DNase activity reduction was measured with a commercial ELISA kit.

RESULTS: We quantified total cfDNA in all blood samples and detected and quantified ctDNA concentrations in all three samples of one cancer patient with metastatic colon cancer. Total cfDNA concentrations increased 1.7-fold (95% CI 1.28-2.22-fold; p<0.01) in all tumor patients during exercise, but to a significantly lesser extent (p=0.003) than in the healthy control group (3.7-fold; CI 2.23-6.15-fold, p<0.01). The decrease of cfDNA concentrations during the recovery period was significantly lower in tumor patients than in the healthy control (1.8-fold vs 5.5-fold decrease, p=0.001), independent of the DNase activity. Tumor DNA increased only slightly, causing a relative decrease in the ctDNA during exercise.

CONCLUSIONS: cfDNA kinetics seem to be less dynamic in tumor patients, especially the depletion of cfDNA from the plasma seems to be impaired. This effect does not seem to be a result of circulating DNA originating from the Tumor.

Cardiac Rehabilitation Improves Fitness In Patients With Subclinical Markers Of Cardiotoxicity While Receiving Chemotherapy

Dennis J. Kerrigan, FACSM, Madhulata Reddy, Eleanor Walker, Bernard Cook, Randa Loufif, James McCord, Jodi Baxter, Steven J. Keteyian, FACSM. *Henry Ford Heart and Vascular Institute, Detroit, MI.*

Email: dkerrig1@hfhs.org

(No relevant relationships reported)

Cardiotoxicity is the leading non-cancer related cause of morbidity and mortality in cancer survivors. Cardiac rehabilitation (CR) improves function and reduces morbidity and mortality in patients with heart failure, but little is known about its ability to ameliorate or attenuate the known cardiotoxic effects of chemotherapy agents. **PURPOSE:** Determine if participation in CR improves fitness and quality of life (QOL) in patients undergoing treatment with either Doxorubicin or Trastuzumab who exhibit markers of subclinical cardiotoxicity. **METHODS:** 20 female patients with breast cancer and evidence of subclinical cardiotoxicity (i.e. >10% decrease in global longitudinal strain (GLS) or a cardiac troponin > 20 ng·L⁻¹) were randomized to 10 weeks of CR or usual care (UC). Exercise training was performed at a cardiac rehabilitation facility and included 2-3 days per week of interval training on a treadmill or cycle at 70-90% of heart rate reserve for 40 minutes. **RESULTS:** Cardiorespiratory fitness, as measured by peak oxygen uptake (VO₂), significantly improved with CR and decreased in the UC group (between group change, 0.009; Table). No changes were observed between or within groups with respect to QOL or high sensitivity troponin. GLS, improved overtime in both groups, but no differences were observed between groups. **CONCLUSIONS:** This pilot study suggests the use of CR may be a viable option to attenuate the reduction in fitness that occurs in patients undergoing cardiotoxic chemotherapy. While trends were observed for improvements in both predictors of cardiotoxicity (GLS and troponin) with CR, these changes were not significant when compared to UC. The long-term effects of exercise on these predictors and left ventricular function warrants further investigation.

| | Exercise Baseline | Exercise post test | Control baseline | Control post test | P value |
|--|-------------------|--------------------|------------------|-------------------|---------|
| Peak VO ₂ (mL* kg ⁻¹ * min ⁻¹) | 17.5 ± 4.8 | 19.2 ± 5.9* | 16.7 ± 1.5 | 15.7 ± 1.4 | 0.009 |

Exercise Prescription Based on a Six Minute Walk Test in Childhood Acute Lymphoblastic Leukemia Survivors

Gabrielle E. Duhamel¹, Maxime Caru¹, Valérie Lemay¹, Simon Drouin², Nathalie Alos², Laurence Bertout², Maja Krajcinovic², Caroline Laverdière², Marie-Josée Raboisson², Daniel Sinnett², Gregoir Andelfinger², Daniel Curnier¹. ¹University of Montreal, Montreal, QC, Canada. ²Sainte-Justine University Hospital Research Center, Montreal, QC, Canada.

Email: gabrielle.duhamel@gmail.com

(No relevant relationships reported)

PURPOSE: Advance in cancer treatment induced drastic improvements in survival rate of Acute Lymphoblastic Leukemia (ALL) for pediatric patients. These medical advancements came at the cost of cardiac dysfunction. Regular physical activity (PA) has been known to have a preventive effect on these health issues. Previous studies have shown that survivors are less active than their peers and below the recommended PA guidelines. The aim of this study is to evaluate the intensity measured from the Six Minute Walk Test (6MWT) comparatively to maximal exercise test and verified if it is compatible with standard recommendations.

METHODS: We tested 177 ALL survivors. We used a 6MWT and a cardiopulmonary exercise test (VO_{2max}). Classification of risk level factors was based on treatment dosage, age at diagnosis, sex, prognostic risk group, time from the end of the treatment (Standard Risk (SR) and High Risk (HR)). Participants were divided in two groups according to their median cardiorespiratory fitness level (<84.3% vs ≥84.3)

RESULTS: Mean survivors age was 22.27±6.30. The survivors included had 44.6% SR and 55.4% HR factors. The mean VO_{2max} measured was significantly lower than the one predicted; 85.8%±16.5. The heart rate measured at the end of the walk represents a mean of 75.8% of the maximal predicted. The mean intensity measured at the end of the walk test was 60.4%±17.9 of the VO_{2max}. There is no significant difference between low and high cardiorespiratory fitness level of relative exercise intensity during the 6MWT (p=0.609). We observe a trending difference in relative exercise intensity during the 6MWT depending on risk factors (SR=63.3%±17.0 vs HR=58.1%±18.4; p=0.051).

CONCLUSIONS: Although the physical cardiorespiratory fitness of survivors is lower, our results demonstrate that with a self-pace exercise (i.e. 6MWT) participants reached similar level as those of a healthy population. Their physical fitness level does not impact the relative intensity levels measured during the 6MWT. Criteria link to the disease (ALL risk prognostic: SR and HR) needs to be considered while prescribing PA to this population. Survivors have greater chances of overcoming their disease than in past history, but specific and increased knowledge about physical activity is needed to prevent late-effects related to the treatments.

Comparison of Body Composition Quantification Methods in Prostate Cancer Patients Undergoing Androgen Deprivation Therapy

Zachary L. Chaplow¹, Brian C. Focht, FACSM¹, Alexander R. Lucas², Elizabeth Grainger¹, Christina Simpson¹, Ciaran M. Fairman³, Jennifer M. Thomas-Ahner¹, Jessica Bowman¹, Victoria R. DeScenza¹, Kathryn Dispennette¹, Marcy Haynam¹, Steven K. Clinton¹. ¹The Ohio State University, Columbus, OH. ²Virginia Commonwealth University, Richmond, VA. ³Edith Cowan University, Perth, Australia.

(No relevant relationships reported)

Androgen deprivation therapy (ADT) results in adverse effects on body composition (BC) and places prostate cancer (PCa) patients at increased risk for sarcopenic obesity. Accurate BC assessment across the treatment continuum is an important aspect of integrating successful supportive care strategies. Dual-energy x-ray absorptiometry (DEXA) and air displacement plethysmography (ADP) are valid methods and have exhibited excellent reliability in various populations. Evaluation of the relationship between methods when used to detect BC changes in PCa patients across an active treatment timeline would inform future trials of their respective clinical relevance.

PURPOSE: The purpose of the single-blind, randomized controlled Individualized Diet and Exercise Adherence-Pilot (IDEA-P) trial is to evaluate the preliminary efficacy of an exercise and dietary intervention, implementing a group-mediated cognitive behavioral approach, relative to standard of care treatment among PCa patients undergoing ADT. In the current study, we evaluated the reliability and absolute agreement of estimates of percent body fat (%BF), fat mass (FM) and fat-free mass (FFM) between DEXA and ADP in PCa patients to establish efficacy for detecting change in BC during treatment. **METHODS:** Change in BC estimates (baseline to 3-month) from a total of 30 PCa patients (M age = 66) on ADT were analyzed by DEXA and ADP. Degree of interrater reliability between methods was evaluated using mean-rating (k = 2), absolute-agreement, 2-way mixed-effects model intraclass correlation coefficients (ICC) and 95% confidence intervals. Potential bias between DEXA and ADP was examined using Bland-Altman plot analysis. **RESULTS:** A high degree of reliability and agreement was found for measurements of %BF and FM change between methods with average measure ICC = 0.865 (95% CI = 0.719, 0.936; p < .001) and 0.904 (95% CI = 0.800, 0.954; p < .001), respectively. Bland-Altman plots of change in %BF, FM and FFM revealed no evidence for proportional bias between DEXA and ADP. **CONCLUSIONS:** Findings from this study suggest DEXA and ADP measure change in BC with similar sensitivity across time. These results support the clinical application of DEXA and ADP as valid and reliable methods of BC quantification for PCa patients undergoing ADT. Supported by NIH/NCI R03 CA16296901

Delivering Exercise Medicine To Pancreatic Cancer Patients: Is It Feasible, Safe And Efficacious?

Nicolas H. Hart¹, Dennis R. Taaffe, FACSM¹, Robert U. Newton¹, Nigel A. Spry², Daniel A. Galvão, FACSM¹. ¹Edith Cowan University, Perth, Western Australia, Australia. ²Genesis Care, Perth, Western Australia, Australia. (Sponsor: Dennis Taaffe, FACSM)

Email: n.hart@ecu.edu.au

(No relevant relationships reported)

Pancreatic cancer is an aggressive adenocarcinoma affecting men and women, with very poor patient prognoses. Alarmingly, the 5-year survival rate is only 8.7%, despite the provision of intensive treatment regimens involving surgery, chemotherapy, radiotherapy or combination therapy, all of which significantly impact function and

quality of life. Exercise has been shown to be feasible, safe and effective in other cancer populations to mitigate treatment-related side-effects, improve quality of life and minimise dose limitation. Exercise may therefore have clinical utility within pancreatic cancer.

Purpose: To establish the safety and feasibility of a supervised exercise program for patients with histologically confirmed adenocarcinoma of the pancreas.

Methods: This non-blinded, single cohort feasibility study provided patients with a 3-month supervised exercise program consisting of resistance and aerobic exercise two days per week. Upper and lower-body muscle strength, physical function (6MWT, 400m Walk Test), and body composition (DEXA) were obtained at baseline, 12 and 24 weeks.

Results: Thirty nine patients (M=23, F=16) were referred with approximately 56% of referrals leading to enrolments (n=22; M=11, F=11). Patients who declined to participate reported feeling too unwell (41%), unable to travel easily (23%), not interested (17%), lost to follow-up (17%), and in one case, the patient deceased during the screening period (2%). Twenty two patients aged 60.9 ± 12.8 years attended baseline testing and commenced exercise, however, a 50% withdrawal rate was observed during the intervention consisting of 8 females (73%) and 3 males (27%). Increased appendicular lean mass at baseline was significantly associated with patient completion, using gender and age as covariates ($F = 4.609$; $p = 0.046$). For those who exercised, improvements ($p < 0.05$) were observed at 12 weeks and maintained at 24 weeks for 6MWT, 400m Walk Test, 1RM Seated Row and 1RM Leg Press. Diastolic BP was also significantly reduced following training ($p = 0.012$).

Conclusion: Exercise programs are safe for pancreatic cancer patients. Appendicular skeletal muscle (ASM) appears critical to facilitate program completion. Focusing on increasing ASM could be a priority for this patient population. RCT's are required to confirm these results.

PURPOSE: Older adults with MS have worse physical and cognitive function than older adults without MS and young and middle-aged adults with MS. To date, there is no evidence regarding the associations, or coupling, of cognitive and physical function outcomes in older adults with MS. The purpose of this study was to examine the associations between physical (i.e., walking speed and endurance and functional mobility) and cognitive (i.e., information processing speed and verbal memory) functions in older adults with multiple sclerosis (MS) and healthy controls.

METHODS: 40 older adults with MS and 40 demographically-matched controls undertook measures of physical and cognitive function. Bivariate linear relationships were examined with Pearson correlations in the overall sample and subsamples of older adults with MS and healthy controls. Linear regression analyses were further used to examine the independent associations between demographic characteristics and physical and cognitive function variables in the subsamples.

RESULTS: Cognitive function (i.e., information processing speed) was significantly correlated with all physical function variables in the overall sample, and these correlations were driven by the subsample of older adults with MS. The linear regression analyses further indicated that information processing speed and years of education consistently explained variance in all physical function variables, beyond the influence of demographic variables, in older adults with MS.

CONCLUSIONS: Information processing speed and physical function are strongly correlated in older adults with MS. Future research should examine underlying neurobehavioral mechanisms associated with cognitive and physical function and behavioral strategies for jointly improving these functions in older adults with MS.

Influence of Acute Aerobic Exercise on 24-hour Ambulatory Central Blood Pressure

Malvina Shoukri, Thomas Burke, Brandon Kistler, Bradley Fleenor, Matthew Harber, FACSM. *Ball State University, Muncie, IN.* (Sponsor: Matthew P. Harber, FACSM)
(No relevant relationships reported)

Ambulatory central blood pressure (cABP) assessed for 24-hours is a relatively new measurement that may be predictor of cardiovascular disease (CVD). Acute bouts of exercise lower peripheral blood pressure; however, it is currently unknown if an acute bout of vigorous exercise reduces 24-hour cABP. **PURPOSE:** To examine the response of cABP over 24 hours after an acute bout of aerobic exercise. **Methods:** Apparently healthy adults (N=10; 6 males; age 25.9 ± 1.8 years; body mass index 25.4 ± 0.6 kg/m²; VO_{2max} 46.1 ± 2.7 ml/kg/min) completed two trials in a randomized order. Trials consisted of a progressive maximal treadmill exercise test to assess VO_{2max} or a non-exercise control. During each trial, participants wore an ambulatory BP (ABP) monitor to record brachial and central BP variables over 24 hours. Hemodynamic variables between trials were analyzed as mean for 24 hours and by time of day; Daytime (0800-2200 hours), and Nighttime (2200- 0800 hours). Dependent t-test were used to compare 24-hour averages between control and exercise. A 2-way ANOVA with repeated measures was performed to examine time of day differences between trials. **Results:** Over the course of 24 hours, average brachial systolic BP (bSBP) (119.6 ± 2.2 vs. 122.0 ± 2.5 mmHg) central systolic BP (cSBP) (108.1 ± 2.2 vs. 111.2 ± 2.4 mmHg), and mean arterial pressure (MAP) (86.9 ± 1.5 vs. 89.4 ± 1.9 mmHg) were lower ($p < 0.05$) after exercise compared to control. A main effect for time ($p < 0.05$) indicated that bSBP, bDBP, brachial pulse pressure, MAP, cSBP, and cDBP, were lower during nighttime compared to day time, independent of exercise. **Conclusion:** A single, vigorous bout of aerobic exercise lowers ambulatory central hemodynamics for at least 24 hours. These novel findings provide insight into the regulatory effects of exercise on blood pressure.

Leucocyte Telomere Length, Inflammation and Oxidative Stress in Master Athletes: The Interplay

Herbert G. Simões, Samuel S. Aguiar, Lysleine A. Deus, Caio V. Souza, Rodrigo VP Neves, Lucas P. Barbosa, Patrick A. Santos, Érica C c c Rosa, Rosângela V. Andrade, Thiago S. Rosa. *Catholic University Of Brasilia, Brasília, Brazil.*
Email: hgsimoes@gmail.com
(No relevant relationships reported)

Leucocyte telomere length, chronic inflammation and oxidative stress play a self-feeding loop that may be cause and consequence of several age-related diseases. However, the interplay of markers of biological aging, oxidative stress and inflammation were not investigated in master athletes who follow an anti-aging lifestyle. **PURPOSE:** To analyze the leucocyte telomere length (LTL), inflammatory markers and redox profile of master athletes and compare to young and age-matched untrained controls. **METHODS:** Subjects (n=45) were 23 middle-aged master athletes (MA, 51.95 ± 8.87 yrs.), 11 young controls (YC, 21.81 ± 3.97 yrs.) and 11 middle-aged untrained controls (MU, 45.40 ± 10.33 yrs.). Relative LTL was determined with qPCR analyses (T/S). Markers of inflammatory, oxidative and anti-oxidant status were assessed in plasma using commercial kits. A one-way ANOVA and Pearson's moment correlation enabled for comparisons and correlations. **RESULTS:** The LTL (T/S) of YC (1.26 ± 1.01) differ significantly from MU (0.48 ± 0.52) ($p < 0.05$) but did not differ from MA (0.99 ± 0.67). MA and YC demonstrated a higher CAT, SOD activity, CAT/TBARS and SOD/TBARS ratios than MU, and the % body fat of MA was also lower than MU ($p < 0.05$). The levels of inflammatory cytokines TNF, soluble TNF receptor (sTNF), IL6 and sIL6 were lower in the YC in comparison to MU and MA. Moreover, MA presented lower levels of sTNF, IL6 and sIL6 and higher IL10 and IL10/IL6 ratio compared to MU. Negative associations were found between body fat and antioxidant enzymes (CAT: $r = -0.448$ and SOD: $r = -0.413$) and IL10 ($r = -0.585$) and positively correlated with pro-inflammatory cytokines (TNF: $r = 0.278$; sTNF: $r = 0.709$; IL6: $r = 0.720$; sIL6: $r = 0.430$) ($p < 0.05$). Further, CAT and SOD were negatively associated with inflammatory parameters (sTNF, IL6 and sIL6), while the LTL was negatively associated with inflammatory markers and positively associated with anti-inflammatory variables ($p < 0.05$). **CONCLUSIONS:** Middle-aged master athletes presented lower markers of oxidative stress and inflammation, with improved antioxidant defense and longer LTL. Once inflammatory and oxidative status were negatively associated to adiposity and LTL, the biological aging of MA is attenuated possibly due to a low adiposity, a better redox balance and reduced inflammatory markers.

Short-term Detraining Effects On Cardiorespiratory Fitness And Body Composition In Trained Older Adults

Inês R. Correia, Sofia L. Freitas, Júlia M. Lopes, João P. Magalhães, Diana A. Santos, Luís B. Sardinha. *Faculdade de Motricidade Humana, Universidade de Lisboa, Lisbon, Portugal.*

(No relevant relationships reported)

An interruption in the training routine may have deleterious effects on cardiorespiratory fitness (CRF) and body composition. Particularly the decline that can occur in the phase-angle (PhA), derived from the tangent value of the ratio of reactance versus electric resistance from bio-impedance analysis (BIA), may be of concern, as it is a predictive marker for cellular integrity, sarcopenia, muscular function, and frailty in older adults.

PURPOSE: To determine the effects of 2-week detraining period on CRF and body composition (including PhA) in older trained adults.

METHODS: A total of 11 older adults (4 females) aged ≥ 65 years were assessed at baseline and follow-up for CRF and body composition in the early morning in fasting condition. Fat-free mass (%FFM), fat mass (%FM), android fat mass (%AFM), and gynoid fat mass (%GFM) were estimated with dual-energy X-ray absorptiometry (DXA) and PhA was assessed with BIA. CRF was evaluated with a breath-by-breath gas analyser system (Quark RMR, Cosmed) with a modified Bruce protocol. During the 15-day detraining period, participants were instructed to refrain from structured and supervised exercise sessions. One - way repeated measures ANOVA were performed and all analyses were adjusted for sex.

RESULTS: The interruption of structured and supervised exercise sessions for 15-days resulted in declines in PhA (5.5%; p -value=0.037). No differences were found for weight ($p=0.662$), body mass index ($p=0.631$), %FM ($p=0.953$), %FFM ($p=0.455$), %AFM ($p=0.138$), %GFM ($p=0.300$), and CRF ($p=0.618$).

CONCLUSIONS: A short-term detraining period of 2-weeks resulted in detrimental changes in PhA, suggesting a decline in the integrity of body cells, but no changes in the remaining body composition outcomes or CRF. These results highlight the importance of maintaining structured exercise sessions in older adults in order to preserve body cell integrity.

3571 Board #259 June 1 9:30 AM - 11:00 AM
The Effects of Aerobic Exercise on Heart Rate Variability in People Living with HIV

Norberto Quiles¹, Alex Evangelista², Alexis Ortiz, FACSM³.
¹Queens College, Flushing, NY. ²Borough of Manhattan Community College, New York, NY. ³UT Health San Antonio, San Antonio, TX. (Sponsor: Alexis Or, FACSM)
 Email: bodyworks.pt@gmail.com

(No relevant relationships reported)

People living with HIV (PLWH) often present with lower heart rate variability (HRV) than healthy counterparts. This is problematic because lower HRV has been associated with cardiovascular morbidity and mortality. Aerobic exercise has been shown to improve HRV in the general population and in those with chronic diseases but its effectiveness in PLWH is unknown. **PURPOSE:** To evaluate the effects of 8-week aerobic exercise in PLWH on anti-retroviral therapy. **METHODS:** Twenty-six participants were randomly assigned to either a control group (no exercise) or an aerobic exercise group. Twenty-three participants completed the study. Resting HRV was measured for 5 minutes through an electrocardiogram. Measures included high frequency power (HF), low frequency/high frequency ratio (LF/HF ratio), low frequency power (LF), very low frequency power (VLF), standard deviation of normal-to-normal (NN) intervals (SDNN), and the square root of the mean squared differences of successive intervals (RMSSD). Estimated $\dot{V}O_{2peak}$ was assessed through a 6-minute walk test (6-MWT) on a treadmill. Body fat percentage (BF%) was measured through air displacement plethysmography. The training group performed aerobic exercise 3 times per week (2 lab-based sessions and 1 home-based session per week) at 65%-75% of the heart rate max. Exercise duration was 30 minutes per session during the 1st week increasing to 45 minutes for weeks 2 to 8.

RESULTS: Participants were 48.4 years old with a CD4 T-cell count of 681.9 cells/ μ L. There were no significant differences between groups in any of the HRV indices. However, SDNN (a marker of overall autonomic function) increased significantly in the exercise group (Pre: 46.97 ± 32.70 ms vs Post: 59.49 ± 37.20 ms, $p=0.036$). There was a moderate correlation between SDNN and $\dot{V}O_{2peak}$ ($r=-.53$; $p=0.01$). There were no significant differences in $\dot{V}O_{2peak}$ or BF% between groups. **CONCLUSIONS:** While differences in HRV were not observed between groups, our data suggests that overall autonomic function can improve with aerobic exercise and these changes are associated with higher levels of $\dot{V}O_{2peak}$. These results advocate the importance of improvements in HRV as greater levels of HRV are associated to lower risk of CVD and mortality.

3572 Board #260 June 1 9:30 AM - 11:00 AM
Associations Between Cardiorespiratory Fitness and Brain-derived Neurotrophic Factor In Serum and Platelets-poor Plasma

Anne K. Gejl¹, Lars Bo Andersen², Jakob Tarp³, Natascha Holbæk Pedersen⁴, Niels Wedderkopp¹, Lone Pejts⁵, Anna Bugge¹. ¹University College Copenhagen, Copenhagen, Denmark. ²Western Norway University of Applied Sciences, Sogndal, Norway. ³Norwegian School of Sport Sciences, Oslo, Norway. ⁴University of Southern Denmark, Odense, Denmark. ⁵University Hospital Copenhagen, Copenhagen, Denmark.
 Email: akge@kp.dk

(No relevant relationships reported)

Emerging evidence suggest that brain-derived neurotrophic factor (BDNF) could mediate some of the beneficial effects of physical activity observed in neurodegenerative and metabolic disease. Observational studies report that cardiorespiratory fitness (CRF) is associated with circulating BDNF levels, but the direction of the association is inconsistent among studies. Accordingly, it appears that CRF is mostly positively associated with BDNF in plasma and negatively associated with BDNF in serum. **PURPOSE:** To investigate the associations between CRF and BDNF measured in serum and platelet-poor plasma, respectively.

METHODS: This cross-sectional study was conducted using data from a subgroup of 81 participants (mean age: 14.3 (1.4), 51% males) included in the 2015 follow-up of the population-based CHAMPS Study-DK. Blood samples were drawn in resting horizontal position from the antecubital vein after an overnight fast (≥ 8 hours). BDNF was analyzed in serum and platelets-poor plasma. CRF was assessed using a field-based running test (the Andersen test). Linear regressions adjusted for potential known confounders (age, sex, Tanner stage and BMI) were conducted in the total sample and stratified by sex.

RESULTS: No significant associations were found between CRF and BDNF measured in serum (std. $\beta = -.02$, CI: $-.21$; $.18$) or platelet-poor plasma (std. $\beta = -.09$, CI: $-.28$; $.09$). Likewise, when stratified by sex, no associations were observed between CRF and BDNF in males (serum, std. $\beta = -.17$, CI: $-.42$; $.08$ or plasma std. $\beta = -.10$, CI: $-.35$; $.15$) or females (serum, std. $\beta = .18$, CI: $-.21$; $.57$ or plasma, std. $\beta = -.10$, CI: $-.40$; $.19$).

CONCLUSIONS: Opposite to some studies in the field, results from this study suggest no association between CRF and BDNF measured in either serum or platelet-poor plasma or in males or females. However, the measured level of BDNF may be highly modified by several unmeasured factors such as physical activity prior to blood drawing or pre-analytical handling of the blood samples (e.g. storage time and centrifugation strategy), making it problematic to use BDNF concentrations obtained from a single blood sample as a measure of general circulating levels of BDNF. Funding: The study was funded by the Tryg Foundation (104982).

Effect of Resistance Training Session on Intraocular Pressure in Patients with Primary Open Angle Glaucoma

Luis Felipe Milano Teixeira¹, Sidney Diyoo Tamura², Henrique Malaquias Possebon³, Marcelo Conte⁴. ¹Universidade de Sorocaba, Sorocaba, Brazil. ²NEPECE - HOSBOS, Sorocaba, Brazil. ³HOSBOS, Sorocaba, Brazil. ⁴Escola Superior de Educação Física de Jundiá, Jundiá, Brazil.
 Email: teixeira.luisfelipe@gmail.com

(No relevant relationships reported)

Chronically elevated intraocular pressure (IOP) scores are considered as main risk factor for the development of primary open angle glaucoma (POAG). It is known that aerobic and resistance training (RT) can promote reductions of IOP in individuals without diagnosis of the disease. However, there is still a need to understand the IOP behavior during RT in individuals with POAG. **PURPOSE:** To evaluate the IOP behavior in individuals with POAG during and after a RT session (RTS). **METHODS:** Six sedentary woman (64 ± 8.2 y), with POAG, were submitted to RTS. After two familiarization sessions and seven days prior to RTS, participants were submitted to a maximum strength predictive test (IRM) in each of the exercises that comprised RTS (leg-press; chest press machine; leg curl machine; rower machine; calf machine; abduction machine; adduction machine; seated crunch machine and side lateral raise). Then, they performed the RTS composed of the nine exercises tested, 3 sets until the concentric muscle failure with 60% IRM and rest interval of 60seg among sets. IPO and lactacidemia (LAC) were measured at the pre-RTS (M1), after the fourth exercise (M2), immediately after the last exercise (M3) and after 5min of the RTS end (M4). The LAC was measured by blood lactate analyzer, while the IOP was measured by an ophthalmologist by Perkins tonometer. One-way ANOVA with Bonferroni's post-hoc was utilized to compare differences among the RTS moments; pearson's correlation test was used to verify possible correlations between IOP and LAC and; Effect Size was calculated by using Cohen d. **RESULTS:** There was a significant reduction in IOP at all moments evaluated in relation to M1 (M1: 13 ± 2.1 mmHg; M2: 8.33 ± 2.6

mmHg, ES=1.97; M3: 6.83±1.7 mmHg, ES=3.22; M4: 7.33±3.8 mmHg, ES=1.8, p <0.01). LAC showed a significant increase in all moments evaluated in relation to M1 (M1: 2.60±1.3mmol/dL; M2: 10.88±5.8mmol/dL, ES=1.9; M3: 11.25±5.1mmol/dL, ES=2.3; M4:8.45±4.3 mmol/dL, ES=1.8, p <0.01). Significant negative correlation between LAC and IOP was observed ($r=-0.79$, $p<0.05$). **CONCLUSION:** A single RTS was able to reduce IOP in POAG patients. RT protocols that promote significant increases in lactacidemia are able to promote important reductions in IOP. RT should be understood as a relevant non-pharmacological resource in the control of POAG.

 (No relevant relationships reported)

Hippocampal Growth Factor and Myokine Cathepsin B Response to Aerobic and Resistance Training in 3xTg-AD Mice

Gabriel S. Pena, Hector G. Paez, Trevor K. Johnson, Jessica L. Halle, Joseph P. Carzoli, Nishant P. Visavadiya, Michael C. Zourdos, Michael A. Whitehurst FACSM, Andy V. Khamoui
 Florida Atlantic University, Boca Raton, FL
 Alzheimer's disease (AD) is a progressive neurodegenerative disease and the most prevalent form of dementia among the elderly today. Aerobic training (AT) has been shown to support brain health in AD through mechanisms involving neurotrophins including BDNF and IGF-1. Unlike AT, the role of resistance training (RT) in AD is not well-established, yet RT may modulate brain health through skeletal muscle-derived myokines. **PURPOSE:** This study examined the effects of AT and RT on hippocampal BDNF and IGF-1 signaling, β -amyloid expression, and myokine cathepsin B in the triple transgenic (3xTg-AD) model of AD. **METHODS:** 3xTg-AD mice were assigned to sedentary (Tg), aerobic-trained (Tg+AT, 9 wks treadmill running), or resistance-trained (Tg+RT, 9 wks weighted ladder climbing) (n=10/group). RotaRod latency and grip strength were assessed pre- and post-training. Hippocampus and skeletal muscle were collected after training and analyzed by high-resolution respirometry, ELISA, and immunoblotting. **RESULTS:** Tg+RT showed greater grip strength than Tg and Tg+AT at post-training (+13% vs. both groups, $p<0.01$). Only Tg+AT improved RotaRod peak latency after training (+88%, $p<0.01$). Hippocampal IGF-1 concentration was ~15% greater in Tg+AT and Tg+RT compared to Tg ($p<0.05$), however, downstream signals p-IGF-1R, p-Akt, p-MAPK, and p-GSK3 β were not altered. Myokine cathepsin B, hippocampal p-CREB and BDNF, and hippocampal mitochondrial respiration were not affected by AT or RT. β -amyloid was ~30% lower in Tg+RT compared to Tg ($p<0.05$). **CONCLUSION:** This data suggests that resistance training may ameliorate β -amyloid load in the hippocampus concurrent with increased concentrations of IGF-1. Both types of training offered distinct benefits, either by improvement of whole body physical function, or by modifying signals in the hippocampus. Therefore, inclusion of both training modalities may address central defects, as well as peripheral comorbidities in AD.

Comparison of Work-induced Fatigue Responses Between One Versus Three 12-hour Shifts in Nurses

Brennan J. Thompson. *Utah State University, Logan, UT.*
 Email: brennan.thompson@usu.edu
 (No relevant relationships reported)

Fatigue-related impairments in the nursing workforce contribute to a multitude of health, safety, and economic consequences at the individual, organizational and societal levels. Long and compressed work schedules are commonly worked in the healthcare industry, but more research is needed to understand the cumulative effects of multiple work shifts on performance-based fatigue responses in nurses and aides. **PURPOSE:** To examine the effects of a single nursing work shift compared to three successive (one every 24-hours) 12-hour shifts on performance-based fatigue responses in nurses and aides. **METHODS:** Twenty-six fulltime hospital working nurses and aides (age = 36.1 ± 13.3 years) reported to the lab for testing before, immediately after a single 12 hour shift, and after working three 12-hour shifts in a 72-hour period. Outcome measures included vigilance-based reaction time and muscle function assessments (lower and upper body maximal strength, rate of torque development and vertical jump performance). **RESULTS:** All performance variables except hand grip strength showed a significant ($P < 0.05$) decline following the three work shifts. The psychomotor vigilance reaction time variable significantly declined from the end of shift one to the end of the three shifts (8% more impaired following shift 3 versus shift 1), indicating an accumulation of fatigue with increasing number of shifts worked. Muscle function variables responded early in the shift cycle, showing a significant decline following shift one ($P < 0.05$ for all but hand grip) and remained reduced but did not further decline by the end of the third shift (performance reductions ranged from 6 – 18% from baseline to post shift three). **CONCLUSION:** This study used objective measures to substantiate that

fatigue impairments occur from working a single 12-hour shift and in several instances, increases further with increased number of successive work shifts. Nurse personnel and administrators should view work schedules involving multiple successive shifts with caution. Fatigue management strategies may reduce consequences from fatigue-related mishaps, and this study reports several variables – namely lower body strength and power and psychomotor vigilance reaction time – that appear to be sensitive for identifying and tracking fatigue in a full time working nurse population.

The Effectiveness Of Simulation-based Learning In Preparing Exercise Physiology Students For Emerging Clinical Practice Domains

Nathan E. Reeves. *Griffith University, Griffith University, Australia.*
 Email: n.reeves@griffith.edu.au
 (No relevant relationships reported)

PURPOSE: Given the pivotal role exercise plays in the prevention and management of chronic diseases, developing practice-ready clinical exercise physiology (EP) students to program and prescribe exercise-based interventions across these conditions is critical. In emerging clinical domains, the lack of practicum opportunities makes it challenging to provide students with the vital opportunity to translate theory into practice. This study reports on the impact a simulation-based learning experience (SBLE) had on EP student's confidence and perception of knowledge in the clinical domain of palliative care. **METHODS:** 12 EP students completed a palliative care interprofessional SBLE alongside students from Dietetics (n=50), Pharmacy (n=44) and Social Work (n=7). The SBLE comprised modules on what is palliative care, effective communication for grief, and spiritual and cultural considerations in palliative care. Experienced and accredited practitioners across the range of health disciplines facilitated the SBLE which included pre-reading, briefing, simulation using simulated patients, and debriefing components. Interprofessional simulated patient interactions included initial consultations, education and treatment planning, and a multidisciplinary case conference. A post-simulation questionnaire explored the effectiveness of the SBLE in developing palliative care graduate capabilities. **RESULTS:** 100% of students ranked their confidence in caring for people with a life-limiting illness as moderate or higher (mean 7.6/10), while 91.7% of students ranked their knowledge and preparedness as moderate or higher (mean 7.5). 75% of students reported having one or no experience, in the past twelve months, caring for a person who has died due to a life-limiting illness in either a clinical placement, employment or personal capacity. Qualitative responses supported the quantitative data with students appreciating the opportunity of being exposed to the clinical domain in a safe and supportive environment that bridged the gap between theory and a real world setting. **CONCLUSIONS:** The positive impact on student confidence and perceived knowledge highlights the influence of SBLE in palliative care, suggesting a broader utility for this mode of learning in other emerging clinical domains for EP students.

3577 Board #265 June 1 9:30 AM - 11:00 AM
Relationship Between Changes in Gait Speed & Resistance Training

William Perez, Brian Phipps, Jeffrey Beans, Leslie Katzel, Odessa Addison. *Veterans Affairs Medical Center, Baltimore, MD.*
 (No relevant relationships reported)

Self-selected gait speed (SGS) is an important indicator of current health. Maximal gait speed (MGS) is an important functional outcome to assess how people can function in their environment. With insufficient MGS individuals may lack the ability to adapt to sudden changes or dangerous situations. Muscular strength is related to both self-selected and maximal gait speed, however there is little known about the relationship between changes in lower extremity strength training and changes in both SGS and MGS. **PURPOSE:** To examine the effect of lower body strength training on changes in SGS and MGS. **METHODS:** Eleven individuals (10 male, 72±8 years, BMI 36±7) with dysmobility, (SGS below 1.0 m/s), or use of an assistive device were recruited. SGS and MGS were measured at baseline and after a 12-week multimodal exercise intervention that included walking, balance, and lower extremity resistance training. Strength progressions, defined as the resistance used in the leg press during weekly exercise sessions, were recorded. After 12 weeks participants were categorized as either responders (>100% increase in leg press) or non-responders (<100% increase in leg press). The relationship between strength change, SGS, and MGS was examined with a Pearson product correlation. An independent t-test was used to compare speed changes in responders and non-responders. Significance was set at $p<0.05$. **RESULTS:** Changes in MGS (Pre = 1.10±0.21 m/s, Post = 1.14±0.28 m/s) were significantly positively correlated with leg press change (Pre = 166±51 psi, Post = 313±121 psi, $r = 0.81$, $p < 0.01$). There was no significant relationship between SGS change (Pre = 0.89±0.19 m/s, Post = 0.98±0.15 m/s) and leg press strength change. Responders (n= 5) improved MGS by 16.5% (Pre = 1.06±0.18 m/s, Post = 1.24±0.30 m/s, $p < 0.01$) while non-responders (n = 6) showed reduced MGS by 7.6% (Pre =

1.14±0.24 m/s, Post = 1.05±0.27 m/s). Responsiveness had no effect on the change in SGS. **CONCLUSIONS:** MGS improved in those who made the largest progress in lower extremity strength. Encouraging the use of an aggressively progressed strength program may help a geriatric population to greater improve a functional outcome such as MGS.

3578 Board #266 June 1 9:30 AM - 11:00 AM
Telephone Intervention Is An Effective Follow-up To Stabilize %body Fat and Markers Of Inflammation After Primary Intervention

Kyung-Shin Park¹, Brett S. Nickerson¹, Seongkwan Cho¹, Boung Jin Kang². ¹Texas A&M International University, Laredo, TX. ²Elizabeth City State University, Elizabeth City, NC.
 Email: kpark@tamui.edu
 (No relevant relationships reported)

Reductions in %body fat and markers of obesity-related disorders have been reported following obesity treatments; however, this short-term success is regressed after the termination of treatments. **PURPOSE:** The purpose of this study was to evaluate whether telephone follow-up intervention is effective in preventing long-term regression of %body fat and inflammation after primary intervention in obese children. **METHODS:** 56 obese children (aged 10-14yrs) completed this study (19 PITI: primary intervention and telephone follow-up intervention, 18 PI: primary intervention only, and 19 CON: no intervention). Anthropometric data and blood samples were obtained before (PRE), after 8 weeks of primary intervention (POST), and 10 month telephone follow-up intervention (1YEAR) to measure levels of %body fat, tumor necrosis factor-alpha (TNF- α), C-reactive protein (CRP), and adiponectin. **RESULTS:** 8 weeks of primary intervention in PITI and PI significantly reduced %body fat (PITI: 29.2±1.1%→25.8±1.3, Mean±SE, P=.003; PI: 28.9±1.0→26.1±1.4, P=.008), TNF- α (PITI: 4.18±.40pg/mL→3.24±.62, P=.02; PI: 4.05±.38→3.19±.56, P=.016), and CRP (PITI: 2.95±.33mg/L→2.31±.47, P=.035; PI: 2.87±.36→2.28±.49, P=.031) and elevated levels of adiponectin (PITI: 6.68±.69 μ g/mL→8.55±.85, P=.019; PI: 6.48±.60→8.18±.85, P=.024), while CON showed an increase in %body fat (29.3±1.0%→30.7±1.1, P=.028) with no differences in inflammatory cytokines. Results of 10 month follow-up measurement (1YEAR) were reverted back to PRE for the PI (1YEAR value and P value for PRE vs. 1YEAR; %body fat: 28.3±1.2, P=.89; TNF- α : 4.14±.51, P=.60; CRP: 2.66±.55, P=.75; adiponectin: 6.98±.79, P=.47) whereas those in PITI at 1YEAR remained statistically significant to PRE (1YEAR value and P value for PRE vs. 1YEAR; %body fat: 27.1±1.3, P=.016; TNF- α : 3.68±.52, P=.035; CRP: 2.48±.47, P=.043; adiponectin: 8.03±.80, P=.038). **CONCLUSIONS:** Results of this study confirm that levels of inflammation are correlated to changes in %body fat, indicating that fat loss is effective in preventing and managing obesity-associated disorders. It is suggested that a telephone intervention is an effective follow-up tool for stabilizing reductions in %body fat, and levels of inflammation obtained from an intensive primary intervention in obese children.

Sports Injury Management Program in Pima Community College Offers Study Abroad Opportunities for International Students

Akira Kondo¹, Chiaki Ishioka¹, Nobuko Hongu, FACSM². ¹Pima Community College, Tucson, AZ. ²University of Arizona, Tucson, AZ. (Sponsor: Nobuko Hongu, FACSM)
 Email: akondo@pima.edu
 (No relevant relationships reported)

PURPOSE: Sports injury management program is a growing academic discipline. Pima Community College, Tucson, Arizona offers study abroad sports science program. The program attracts the students who are interested in pursuing athletic training, personal training, exercise sciences, and sports coaching as a career. **METHODS:** Pima Community College Sports Injury Management (SIM) program offers an athletic training student internship. Students interns are expected to fulfill requirements including taking classes at the college and professional development activities in the US. Qualified student applicants were evaluated on the quality of their athletic training experiences, academic performance, and professional attitudes. To be enrolled in the program, the students went through an application process such as writing a letter of interest, resume, and references, then had a face-to-face interview experiencing a formal job-hunting process with SIM staff. **RESULTS:** All selected applicant international students were from Japan (18 years and older). They were assigned to work with SIM staff who provide athletic training services to their 16 intercollegiate athletic teams. The interns took classes on SIM (i.e., learning principles and techniques of preventing, recognizing, treating and rehabilitating sports related injuries, recognition of common sports injury, gaining skills of taping/wrapping technique, and an event preparation and risk managements). They also independently continued their academic development in health, physical education, recreations, coaching, dance, or fitness. Some students completed their prerequisite classes to transfer to four-year college/university and/or to apply for an entry level of master's

degree program for athletic training. **CONCLUSION:** Pima Community College SIM interns were not only preparing to become an athletic trainer (e.g., completion of an accredited athletic trainer degree program, hands-on experiences, etc.), but they also gained cultural awareness and valuable life-changing experiences by receiving opportunities such as volunteer work in a local community.

A Comparison of Attitude Toward Physical Education Class, Physical Activity Level, and Aerobic Fitness between Hong Kong and Shanghai Adolescents

HU Rui, HUI Stanley Sai-Chuen, FACSM. *The Chinese University of Hong Kong, Hong Kong, Hong Kong.*
 Email: hurui@link.cuhk.edu.hk
 (No relationships reported)

Studies revealed that participation in Physical Education (PE) classes could increase the chance to be more physically active and influence aerobic fitness among youth (Chen, 2014; Fairclough & Stratton, 2004). Meanwhile, it is noted that weekly amount of PE classes in Shanghai and Hong Kong is largely different (Shanghai: 5 times per week, 40 mins per session; Hong Kong: 80-120 mins per week). Due to the difference in PE class volume, we hypothesized that attitude toward PE class, physical activity (PA) level and aerobic fitness of adolescents may be different between these two cities. **PURPOSE:** to compare the attitude toward PE class, PA and fitness between adolescents in Hong Kong and Shanghai. **METHODS:** A total of 2,059 adolescents (12-15 yrs old) randomly recruited from middle-schools of Hong Kong and Shanghai completed questionnaire surveys on attitudes toward PE (like, okay, or dislike), self-reported weekly moderate to vigorous PA (MVPA) (IPAQ), and field test on aerobic fitness (15m PACER). **RESULTS:** Chi-square test showed Hong Kong adolescents "like" PE (54.8%) more than that of Shanghai counterparts (39.5%) ($p<0.001$), whereas Hong Kong adolescents "dislike" PE (5.3%) much less than the Shanghai adolescents (21.5%) ($p<0.001$). After adjusting for age and gender, ANCOVA revealed that MVPA of Hong Kong adolescents was considerably higher (369.8±10.8) than that of Shanghai counterparts (302.0±8.4) ($p<0.001$). There was no difference ($p>0.05$) in aerobic fitness between adolescents from the two cities. **CONCLUSIONS:** The present study demonstrated that Shanghai adolescents, though receiving much higher volume of PE classes than Hong Kong adolescents, do not have better attitudes toward PE class nor higher MVPA level than the Hong Kong counterparts. Other factors other than the PE volume, such as PE curriculum and contents, teaching styles or leaderships, may be more important to affect attitude toward PE, PA and fitness levels.

PURPOSE: Understanding the effect that field exercises have on soldier muscular strength is an area of interest for the US Army. Reliably quantifying muscle strength in this context has been limited by availability of portable assessment equipment. The widely used hand-held dynamometer (HHD) presents a challenge when assessing strong muscle groups of healthy soldiers accurately. We devised a portable, field-ready HHD fixation solution to assist researchers in the evaluation of lower body and core isometric maximal muscle contractions. Reliability of the fixation system (patent pending) was assessed prior to implementation at a large-scale data collection during a military field exercise. The purpose of the current investigation was to identify strength changes in select muscle groups prior to and immediately following a loaded road march.

METHODS: 39 soldiers (36M, 3F) performed 4 maximal isometric contraction types, including lumbar extension, lumbar flexion, hip flexion, and knee extension. 3 trials of each contraction type were recorded during a pre-mission baseline, and 2 trials were recorded immediately following a 6-mi road march executed with an average load of 50% body weight. Measurements were recorded using the system developed, which provided repeatable subject stabilization, muscle group isolation, and HHD fixation.

The maximum force recorded from each muscle group during a session was used for analysis. A paired sample t-test was conducted to compare pre and post road march strength measures.

RESULTS: No significant change in lumbar extension strength was identified between the pre and post conditions. Significant decreases in strength performance were observed in the hip flexion (8.3%; $p=0.03$), knee extension (7.8%; $p=0.032$), and lumbar flexion (9.9%; $p=0.009$) measurements between the pre and post conditions.

CONCLUSION: While lumbar extension strength did not change following the road march, the decreases identified for hip flexion, knee extension, and lumbar flexion followed the hypothesized trend. This study provides novel insight into the effects of field activities on soldier muscle strength that were not quantifiable prior to the portable HDD fixation system, and presents a range of new opportunities to understand the impact of military exercises on strength.

Effects of High-Intensity Interval Training on Fitness during Initial Military Training

Author Block John R. Borman¹, Brittany R. Hotaling², Kevin A. Bigelman¹, Dan A. Jaffe¹, Jesse L. Germain¹, Richard B. Westrick², Nicholas H. Gist¹. ¹*United States Military Academy, West Point, NY.* ²*United States Army Research Institute of Environmental Medicine, Natick, MA.* **ABSTRACT**

High-Intensity Interval Training (HIIT) may confer rapid aerobic and anaerobic physiological adaptations. While several studies have compared HIIT and Moderate-Intensity Continuous Training (MICT), none have compared the United States Army's doctrinal interval training work-to-rest ratios to examine its effects on aerobic capacity, anaerobic power and physical performance. We hypothesize that HIIT will improve aerobic and anaerobic fitness as well as MICT.

PURPOSE: To investigate the effects of a 9-week low volume HIIT intervention on selected laboratory and field-based assessments {maximal oxygen uptake (VO_{2max}); Running Anaerobic Sprint Test (RAST) performance} compared to MICT protocol in Initial Military Training Soldiers.

METHODS: 30 college-aged males at the United States Military Academy Preparatory School participated in an 11-week (1 week of pre-testing, 9 weeks of exercise training, 1 week of post-testing) research study examining the effects of HIIT on components of aerobic and anaerobic endurance, anaerobic power and performance time.

RESULTS: After training, HIIT experienced a 4.3% increase in peak power as measured by RAST performance. MICT had a statistically significant decrease in VO_{2max} . Both groups had a non-significant increase in average power.

CONCLUSIONS: Using the United States Army's interval training work-to-rest ratios, the HIIT protocol was more effective for improving peak power and maintaining both anaerobic and aerobic endurance when compared to MICT protocol. The MICT protocol enabled the maintenance of peak power but decreased overall aerobic endurance. **DISCLAIMER:** The views expressed in this abstract are those of the authors and do not reflect the official policy of the Department of Army, Department of Defense, or the U.S. Government. (No relationships reported)

Abstract category: Fitness Assessment, Exercise Training, and Performance of Athletes and Healthy People - 102 Exercise Training Interventions in Healthy People
 Cleiton Augusto Libardi, Vitor Angleri, Carlos Ugrinowitsch. Federal University of São Carlos, SP, Brazil; University of São Paulo, SP, Brazil. To maximize, or to prevent the stagnation of gains in muscle strength and mass, coaches have used resistance training (RT) systems. It has been showed that traditional RT (TRAD) and drop-set systems (DS) result in similar gains in muscle hypertrophy and strength. However, a large variability has been reported for muscle strength and hypertrophy outcomes even when subjects perform RT programs. **PURPOSE:** The aim of this study was to compare the individual muscle mass and strength gains to TRAD vs DS in well trained young men. **METHODS:** We used a within-subjects design in which 14 participants had one leg randomly assigned to TRAD (3-5 sets

of 6-12 repetitions at 75% 1RM) and the other to DS [3-5 sets of ~50-75% 1RM to muscle failure]). Participants had one leg fixed in the TRAD while the contralateral leg performed either DS to allow for total training volume (TTV) equalization. Muscle cross-sectional area (CSA) and one repetition maximum (1RM) were assessed at baseline and after 12-wks of RT. For group analyses, the accumulated TTV and changes in muscle CSA and 1-RM values were compared between TRAD and DS using paired *t*-tests. For individual analyses, if an individual that showed a difference in the response (for CSA or 1RM increases) from TRAD or DS (or vice-versa) within 2 typical errors (CSA typical error [TE] = 2.20%, 1RM TE = 2.62%), no difference in the response between RT schemes was considered. **RESULTS:** No significant differences in TTV ($P > 0.05$) were detected between protocols TRAD and DS. Muscle CSA and 1RM values increased significantly and similarly for TRAD and DS ($P < 0.0001$). This study highlights that some individuals showed greater muscle strength gains following TRAD (35.7% of individuals), and other show similar responses between TRAD and DS (64.3% of individuals). For muscle CSA, individuals showed similar responses to TRAD and DS. **CONCLUSION:** Despite the analysis groups show similar gains in strength and muscle hypertrophy, some individuals show greater strength gains for TRAD compared to the DS.

Wearable Positive End-Expiratory Pressure Valve Increases Aerobic Capacity and Performance

STEPHEN F. CROUSE, FACSM¹, Sean Boutros², William B. Benton³, Michael Moreno¹, Patrick McCulloch⁴, Bradley S. Lambert⁵. ¹*Texas A&M University, College Station, TX.* ²*HOUSTON PLASTIC AND CRANIOFACIAL SURGERY, Houston, TX.* ³*PEEP Performance, LLC, Houston, TX.* ⁴*Houston Methodist Hospital, Houston, TX.* ⁵*Methodist Research Institute, Houston, TX.*

Reported Relationships: S.F. Crouse: Other (please describe); Member, Board of Directors, PEEP Performance LLC.

PURPOSE: We report testing results of wearing a positive end-expiratory pressure (PEEP) valve mouthpiece during exercise on VO_{2max} and cycling time to exhaustion. **METHODS:** 4 women & 5 men (Age 31 ± 2 yrs, Ht 172.2 ± 3.8 cm, WT 72.1 ± 3.7 kg) were assigned at random on two separate occasions (time of day controlled, at least 48 hr between each test) to wear our PEEP mouthpiece or a Battle Oxygen Mouthguard® during cycle ergometer (Corival®) testing to maximal voluntary exhaustion (3 min unloaded warmup, then 150W for 2 min x 30W/2 min stages thereafter until exhaustion); VO_2 was measured continuously (MGC Ultima®), and heart rate (HR, bpm) and blood pressure (BP, mmHg) were recorded at the end of each stage. There followed approximately one week later a timed endurance ride to exhaustion with the assigned mouthpiece at a power (W) equivalent to each subject's ventilatory threshold (VT) measured during the VO_2 test. **RESULTS:** Table (all $p < 0.05$, paired *t*-test). Notably, time to exhaustion at VT was 13% greater with PEEP, but this did not reach statistical significance. Ratings of perceived exertion recorded during exercise did not differ between mouthpiece conditions.

| Variable | VO_{2max} (ml·kg ⁻¹ ·min ⁻¹) | VO_{2max} Test Time to Exhaustion (sec) | Max Systolic Blood Pressure (mmHg) |
|---------------------|---|---|------------------------------------|
| Control | 42.44 ± 2.33 | 495.3 ± 72.8 | 193 ± 6 |
| PEEP | 45.18 ± 2.41 | 521.8 ± 73.4 | 186 ± 5 |
| Change from Control | +6.7% | +5.8% | -3.6% |

CONCLUSION: The wearable PEEP-valve mouthpiece significantly improves cycling maximal aerobic capacity, reduces peak exercise systolic blood pressure, and may improve cycling performance. The PEEP mouthpiece technology appears to confer a benefit to cyclists performing high intensity exercise.

(No relationships reported)

Competitive ice hockey is a high-intensity intermittent sport with an activity pattern characterized by short fast-paced bouts of skating repeated continuously over the course of the game interspersed by passive recovery intervals. However, no previous studies have yet examined the physiological response and degree of fatigue during an elite game. **PURPOSE:** To examine muscle, blood and performance responses to match-play in elite male ice hockey players in relation to physiologically mediated

fatigue. **METHODS:** Thirty players from the Danish U20 national team participated and completed one experimental game. The game was modified so each period consisted of 8 shifts of 1 minute duration per player separated by 2 minutes of recovery resulting in a total playing time of 24 min for each participant. During the game each player was monitored continuously using heart rate monitors and a local positioning system assessing the activity pattern. Muscle biopsies were taken before and after the game ($n=7$) as well as instantly following shifts during the game ($n=6$). Blood sampling was performed before the game and at the end of each period. In addition, players performed a repeated sprint test consisting of three maximal 30 m sprints interspersed by 25 s recovery before the game and following each period. **RESULTS:** Players covered on average 6015 ± 199 m reaching peak speeds of 29 ± 2 km/h including 109 ± 14 intense accelerating or decelerating actions and 2701 ± 251 m high-intensity- and sprint skating resulting in an average and peak heart rate of 143 ± 9 and 182 ± 8 beats pr. min, respectively. Muscle lactate rose from 6.9 ± 3 before the game to 38 ± 20 and 20 ± 12 mmol/kg d.w during the first and third period, while blood lactate increased from 0.8 ± 0.3 at baseline to 4.7 ± 3 and 4.9 ± 3 mM following the first and third period ($p \leq 0.05$). Muscle glycogen decreased from 400 ± 22 to 188 ± 43 mmol/kg d. w. over the course of the game ($p \leq 0.05$). Compared to pre-game values mean sprint time declined following the first ($p \leq 0.05$) and third ($p \leq 0.01$), but not after the second period. **CONCLUSIONS:** Ice hockey is a high-intense team sport with a large anaerobic contribution resulting in significant glycogen utilization and fatigue development especially at the end of the game. The latter finding may at least partly be explained by lowered muscle glycogen levels.

 (No relationships reported)

Many potential benefits of altering bicycle crank length (CL) have been proposed from reducing injury to increasing aerodynamics and consequently, performance. Submaximal cycling bouts are often used to simulate various riding efforts to determine how CL can impact race performance in various cycling disciplines. These studies either used a set wattage for all participants or an intensity relative to VO_{2max} or Ventilatory Threshold (VT) based on a Cardiopulmonary Exercise Test (CPET) performed on one CL. However, it is unknown whether CL impacts VO_{2max} and/or VT, thus altering the prescribed submaximal intensity when CL is changed. This is crucial prior to future work in the area and for interpreting previous studies. **PURPOSE:** The purpose of this study was to determine the influence of crank length on VO_{2max} and VT in trained cyclists and multisport athletes. **METHODS:** After a familiarization session, 10 subjects performed three separate trials using different crank lengths (162.5, 172.5 and 182.5 mm) in randomized, counter-balanced order. The trials consisted of a maximal CPET to determine VO_{2max} and VT, a supra-maximal effort to verify VO_{2max} , and two 10-min submaximal efforts at a low intensity (70% of VT) and a high intensity (95% of VT). Individual repeated measures analysis of variance (ANOVAs) were used to compare differences in VO_{2max} and VT across the three crank lengths. To achieve a power of 80% with a difference of 3 mL/kg/min and a standard deviation of 1.5, nine subjects were required. **RESULTS:** VO_{2max} and VO_2 at VT values were not significantly different across the three crank lengths (162.5, 172.5 and 182.5 mm) 4.35, 4.39 and 4.36 L/min, $p=0.65$ and 3.08, 3.04 and 3.08 L/min, $p=0.64$, respectively. **CONCLUSION:** Mean differences in the VO_{2max} and VT values between crank lengths were not statistically significant; however, several individual differences were of clinical relevance (5/10 subjects for VO_{2max} and 6/10 for VT differed by ~ 3 mL/kg/min or more between at least two CLs). Factors including explosive power capacity, preferred cadence, leg length, body composition, and submaximal cycling economy could influence these individual differences and warrant further evaluation.

The Effects of Experiential Learning on Exercise Physiology Self-Efficacy
 Miriam E. Leary, Lori A. Sherlock. West Virginia University, Morgantown, WV.
 Email: miriam.leary@hsc.wvu.edu
 (No relationships reported)

Purpose: This mixed methods, experiential learning research project incorporated multiple teaching methodologies to assess improvements in knowledge and self-efficacy in exercise physiology (EXPH) human performance testing. **Methods:** Six undergraduate EXPH students completed a pre-intervention quiz which assessed knowledge of blood lactate production and lactate threshold. Participants received

a lecture on lactate production and lactate threshold from an expert in the field of human performance and discussed peer-reviewed research readings. Supervised training and practice were held prior to conducting lactate threshold testing on the varsity women's rowing team. Following, participants met to review physiological concepts, data collection procedures, discuss research readings, and reflect on the service component of the project. At the end of the project, participants completed the same lactate threshold quiz as well as an anonymous, online, 15-question self-efficacy and satisfaction survey with answer choices on a 7-point Likert scale. A focus group discussion moderated by trained researchers captured participants' perceptions of the experiential service learning project. Data were content analyzed to identify common themes using independent data reviewers and a tiebreaker when necessary. **Results:** All participants agreed or strongly agreed that participation in this project would allow them to make a difference in [their] community, enable them to interact with relevant professionals in ways that are meaningful and effective, and apply [their] knowledge in ways that solve real-life problems. All students strongly agreed they would recommend this experience to their friends. Compared with a pre-assessment, participants scored 10% higher on the lactate knowledge quiz at the end of the experiential learning project. Students reported improved self-efficacy, knowledge, communication, and confidence in exercise physiology related content as well as professional skills. **Conclusion:** An experiential learning project incorporating multiple teaching methodologies successfully improved knowledge, self-efficacy, and professional skills in human performance testing.

Left Ventricular Function and Cardiac Biomarker Release -The Influence of Exercise Intensity, Duration and Mode: A Systematic Review and Meta-Analysis
 James A. Donaldson. CANTERBURY CHRIST CHURCH UNIVERSITY, Canterbury, United Kingdom.
 Email: james.donaldson@canterbury.ac.uk
 (No relationships reported)

Prolonged strenuous endurance exercise is associated with altered cardiac physiology that often manifests as both transient cardiac dysfunction and detectable cardiac troponin (cTn) in peripheral circulation. The extent of a possible relationship between cTn release and cardiac function is unclear as many studies do not report significant correlations. The influence of exercise intensity, mode and duration on EICF and cTn release is also unknown due to large methodological variation. **Purpose:** We performed a systematic review, meta-analysis and meta-regression of studies that sought to determine the relationship between cTn and left ventricular (LV) function. The second objective was to determine how study-level and exercise factors influenced the variation in the body of literature.

Methods: A systematic search of Pubmed Central, Science Direct, SPORTDISCUS, and MEDLINE databases for original research articles published between 1997-2018 involving >30mins of continuous exercise, measuring cTn event rates, LV ejection fraction and E/A ratio. Random-effects meta-analyses and meta-regressions with four *a priori* determined covariates (age, exercise heart rate [HR], duration, mass) were performed.

Results: Pooled cTn event rates were evident in 45.6% of participants (95% CI = 33.6 – 58.2%); however, the overall effect was non-significant ($P > 0.05$). There were significant ($P < 0.05$) reductions in E/A ratio: -0.38 (SMD = -1.2 , 95% CI $[-1.4, -1.0]$), and LVEF: 2.02% (SMD = -0.38 , 95% CI $[-0.7, -0.1]$) pre to post-exercise. Exercise HR predicted cTn release and E/A ratio. Participant age was negatively associated with cTn release. There was a significant negative association between E/A ratio and cTn event rate ($P < 0.05$).

Conclusions: High levels of statistical heterogeneity and methodological variability exist in the majority of EICF studies. Exercise intensity and age are the most powerful determinants of cTn release. E/A ratio is influenced by exercise HR and cTn release, implying exercise bouts at high intensities are enough to elicit cTn release and reduce E/A ratio. Future EICF studies should reduce heterogeneity by use of echocardiographic techniques such as myocardial speckle tracking, maintaining participant hydration, serial follow-up measures to assess symptom progression or recovery.

Independent and Combined Effects of Arterial Angulations and Shear Stress on Vascular Function
 Aaron R. Caldwell, Lisa T. Jansen, Megan E. Rosa-Caldwell, Ronna C. Turner, Erin K. Howie, Kaitlin M. Gallagher, Matthew S. Ganio, FACSM. University of Arkansas, Fayetteville, AR.
 Email: ac039@email.uark.edu
 (No relationships reported)

Excessive sedentary time is a significant health risk, independent of daily physical activity or exercise. In particular, long periods of prolonged sitting is associated with an increased risk of cardiovascular disease. Prolonged sitting reduces flow-mediated

dilation (FMD), which is a key indicator of vascular health. Recent evidence suggests that the seated position strains the arteries through angulations that create turbulent blood flow, thereby reducing FMD. However, when blood flow in the arteries is slightly increased (via local heating), vascular function improves even when seated. However, the combined effects of removing arterial angulations (i.e., standing) and increasing shear stress (i.e., local heating) on reducing sitting-induced vascular dysfunction have yet to be investigated. **PURPOSE:** This project aims to determine if arterial angulations (through sitting or standing), shear stress (through local heating), or a combination of these factors affect vascular function. **METHODS:** 13 individuals (n = 4 male; n = 9 female) participated in a randomized crossover design study. Participants completed two experimental trials (one sitting and one standing). At the beginning of each experimental trial, participants laid supine for at least 20-minutes prior to baseline measurements of FMD at the superficial femoral artery (SFA). Participants then moved into a sitting or standing position. One leg was then passively heated through a water-perfused pant leg in order to increase shear rate. Participants maintained this position for 2-h. Participants then returned to a supine position and post measures of FMD were obtained. **RESULTS:** Overall, sitting led to approximately a 1.2% decline in FMD. Standing appeared to confer the greatest benefit independent of heating ($p = .025$). By the end of standing, participants FMD was 2.88% ($p = .037$) greater than after 2-h of sitting. However, there was no significant effect of local heating ($0.75\% \pm 1.90$, $p = .594$) and no interaction between heating and body position ($-0.17\% \pm 2.70$, $p = .879$). **CONCLUSION:** Standing was superior to sitting with regards to FMD while local heating had a non-significant effect. However, future studies need to examine modifiers such as biological sex.

Association Of Mid-pregnancy And Current Exercise With Arterial Stiffness 6 Months-3 Years After Delivery In Women

Abby J. Heinichen, Catherine A. O'Byrne, Paige Wilbanks, Nicole Hoffner, William Tucker, Abbi D. Lane-Cordova.
University of South Carolina, Columbia, SC.
 Email: lanecord@mailbox.sc.edu
 (No relationships reported)

PURPOSE: Regular exercise is associated with lower cardiovascular disease (CVD) risk. Pregnancy influences longer-term CVD risk for women, regardless of their previous prenatal risk level. Our purpose was to assess whether prenatal and/or current physical exercise levels were associated with arterial stiffness in women 6 months-3 years after a singleton delivery.

METHODS: We performed gold-standard measurement of central arterial stiffness (aortic pulse wave velocity; PWV) in 19 women (mean age=34±1 yrs; mean BMI=27.0±2 kg/m²; 15 white/3 black/1 Asian). Participants were asked to recall leisure-time exercise performed during mid-pregnancy, as well as current exercise habits, and reported both using a validated survey (Godin Leisure-time Exercise Questionnaire). We used linear regression to determine associations of mid-pregnancy and current exercise with PWV, adjusted for age.

RESULTS: Average exercise units were 39±6 (mid-pregnancy) and 43±7 (current). Mean systolic and diastolic blood pressures were 111±3 and 70±2 mmHg, respectively; mean PWV was 6.4±0.3 m/s. Mid-pregnancy exercise score ($b = -0.02 \pm 0.01$, $p = 0.051$), but not current exercise score ($b = -0.01 \pm 0.01$, $p = 0.24$), was associated with PWV after adjustment for age.

CONCLUSIONS: Mid-pregnancy exercise levels were significantly associated with PWV 6 months-3 years after delivery. The findings suggest that exercise during pregnancy may be important for influencing longer-term maternal vascular function.

The Impact of Blood Flow Restrictive Exercise on Endothelial Function

Leryn Reynolds, Robbie Pittman, Hannah Twiddy. *Old Dominion University, Norfolk, VA.*
 Email: lreynold@odu.edu
 (No relationships reported)

Research has shown low intensity resistance training done with blood flow restriction (BFR) to be an effective means at increasing skeletal muscle strength. However, research is lacking examining the effects of BFR exercise on brachial artery endothelial function, which is closely linked to coronary artery endothelial function and thus predisposition to developing atherosclerosis. Given the important role of blood flow (i.e., shear stress) on maintaining endothelial function, BFR exercise may have negative consequences on vascular health. **PURPOSE:** The purpose of this study was to examine the effects of blood flow restriction training on endothelial function in healthy men. **METHODS:** Subjects were 9 healthy males, 23.9±1.2 years, 27.7±1.2 kg/m² who regularly participated in resistance training exercises at least 2 times per week. Subjects performed 3 sets of bicep curls at 30% of their 1 repetition maximum to failure with a blood pressure cuff at 80% arterial occlusion pressure. Endothelial function was assessed by percent flow mediated dilation (%FMD) performed before,

immediately after, and one hour post an acute bout of BFR exercise. **RESULTS:** %FMD was unaltered immediately (9.57 ± 2.33) and 1 hr post (9.43 ± 3.05) BFR exercise compared to baseline (9.62 ± 1.63) ($p > 0.05$). **CONCLUSION:** An acute bout of BFR exercise does not alter endothelial function in healthy males. Future studies are aimed at determining if females display a similar response when controlling for the impact of the menstrual cycle on vascular function.

The Effects of Simultaneous Upper and Lower Body Cycling on Cardiorespiratory Responses.

Jessica Royen, Brandi N. Guillotte, Kierstin Marshall, Kimberly Billiot, Robert R. Kraemer, FACSM. *Southeastern Louisiana University, Hammond, LA.*
 (No relationships reported)

Some forms of physical activity require greater amounts of upper body activity combined with lower body activity. Arm ergometry has been shown to elicit larger increases in blood pressure and heart rate when compared to lower body ergometry. Arm ergometry, in workloads up to 125 W, has been shown to illicit greater increases in VO₂ due to extra stabilization of the torso and mechanical efficiency. The effects of a combined lower and upper body ergometry simultaneously, with identical workloads, on the cardiorespiratory system has not yet been studied. Previous studies have evaluated cardiorespiratory responses to elliptical ergometry, which utilizes both upper and lower body extremities. However, an elliptical does not allow for precise regulation and measurement of work performed by both upper and lower body. **PURPOSE:** The aim of this study was to examine the effects graded upper body ergometry, lower body ergometry, and combined upper and lower body ergometry on oxygen consumption, heart rate, minute ventilation, respiratory exchange ratio, and blood pressure. **METHODS:** Eight males, ages 18-28y, participated in three trials over seven days. Subjects were divided into two groups. Session one included one trial of graded leg ergometry and one trial of graded arm ergometry. The two groups completed each of these trials in a counterbalanced fashion with 20min rest between trials. Session two included a trial of graded leg ergometry combined with graded arm ergometry, performed simultaneously, at identical workloads. Each trial began with a warmup at 0kp and maintained a 60rpm cadence. Workload for each trial increased by 0.5kp every 2 min peaking at 95W. **RESULTS:** Combined body ergometry produced significantly ($p < .001$) greater peak oxygen consumption (36.14 ± 4.95 ml/kg/min) compared lower body ergometry (19.41 ± 3.88 ml/kg/min) and upper body ergometry (21.58 ± 7.08 ml/kg/min). Combined elicited a significantly higher peak blood pressure ($p < .005$) and heart rate ($p < .005$), respectively ($180\text{mmHg} \pm 10$) (168 ± 16 BPM), than lower body (156 ± 13 mmHg) (126 ± 12 BPM), but not upper body. **CONCLUSIONS:** These data could be helpful in considering cardiorespiratory stress in healthy and clinical populations from manual tasks involving both upper and lower body extremities.

Bone Density and Cross-Sectional Area are Inversely Related in the Young Adult Distal Tibia

Nathaniel I. Smith¹, Paul M. Bartlett¹, Katelyn I. Guerriere¹, Kathryn M. Taylor¹, Mary L. Bouxsein², Stephen A. Foulis¹, Julie M. Hughes¹. ¹USARIEM, Natick, MA. ²Massachusetts General Hospital; Beth Israel Deaconess Medical Center; Harvard University, Boston, MA.
 Email: nathaniel.i.smith2.ctr@mail.mil
 (No relationships reported)

Bone is posited to develop and adapt to loads by satisfying the competing demands for achieving sufficient stiffness and minimizing mass. This compromise has been demonstrated at the midshaft of the tibia by an inverse relationship between cross-sectional area and thickness of the cortical shell. The requirement for minimizing mass is likely greater at the distal tibia where inertial properties cause bone mass to be more metabolically expensive. Whether there is a similar tradeoff between bone size and the amount of bone tissue at the distal tibia remains to be determined. **PURPOSE:** Determine whether cross-sectional area of bone is inversely related to bone density at the distal tibia. **METHODS:** Six hundred seventy-three (476M, 197F) Army trainees (20.4 ± 3.4 yrs; 1.71 ± 0.09 m; 72.5 ± 13.3 kg) underwent high resolution peripheral quantitative computed tomography (HR-pQCT, XtremeCT2, Scanco Medical AG) scans of their non-dominant distal tibias at 4% of bone length from the distal growth plate, at the start of their initial military training. Generalized linear models adjusted for sex were used to test the significance and directionality of relationships between total cross-sectional area (CSA) normalized to body mass and total volumetric bone mineral density (vBMD). **RESULTS:** Normalized CSA was significantly and inversely related to vBMD ($p < 0.001$) where a one-unit increase in normalized CSA (mm²/kg) resulted in a 5.856 mg HA/cm³ reduction in vBMD. Specifically, the lowest compared to the highest quartile of normalized CSA had 13% higher vBMD, per unit body mass. **CONCLUSION:** These findings support the hypothesis that bone in the distal tibial

metaphysis develops in a manner which balances the need to be adequately stiff against that of minimizing the mass of a metabolically costly tissue through maintaining lower bone density relative to larger bone size.

Dynamic Changes Of Doppler Signal During Tendon Scraping

Andrea Dockry, Michael Baria. *Ohio State University Wexner Medical Center, Columbus, OH.*

Email: andrea.dockry@osumc.edu

(No relationships reported)

Midsubstance Achilles tendinosis and patellar tendinosis are degenerative lesions that impede athletic performance and activities of daily living. Tendon scraping (TS) is a minimally invasive procedure to accelerate pain relief by disrupting neovascularity and reinnervation hypothesized as responsible for pain. The original description uses color Doppler (CD) to identify the region with increased blood flow but does not comment on how CD changes during TS. Others propose that TS is complete when Doppler flow is absent. Our observation is that CD is absent after a small volume injection of local anesthesia, before scraping is begun.

PURPOSE: This case series reports changes in CD during TS to better inform technical understanding of this procedure.

METHODS: Six patients (male=4, female=2) with 5 cases of Achilles and 1 case of patellar tendinosis presented to the Sports Medicine Clinic. Ultrasound identified diseased tendon, and all patients had increased CD prior to the procedure. A 25-gauge 1.5-inch needle was advanced from lateral to medial to the tendon-fat pad interface. Doppler was left on during anesthetic administration. Once local anesthesia was administered, a stab incision was made with an 11 blade scalpel. A 14-gauge 2-inch needle was then advanced under ultrasound guidance in identical fashion. The bevel was turned to make contact with the tendon surface. The fat pad was separated by pulling it away from the tendon in an anterior-posterior direction and then semi-circular, cranial-caudal sweeps were made to complete fat pad separation until the needle moved with unrestricted motion.

RESULTS: In all six patients, CD was absent after injecting 1-3 mL of lidocaine. Though only 1 needle pass was made, CD was completely absent throughout the length of the tendon. No complications occurred.

CONCLUSION: The most important finding of this work is that CD is absent after a small injection of local anesthetic, demonstrating that CD cannot be used to determine TS completion. CD is still a useful pre-procedure guide to identify the tendon region needing treatment, but it cannot be used as a marker of effective scraping / devascularization. A superior marker of procedure completion is freedom of needle motion demonstrating tendon separation from adjacent fat pad.

Mesenchymal Stem Cells Injection As A Therapy In A Rat Model Of Collagenase-induced Tendinopathy

Beatrice Deschenes St-Pierre¹, Mathieu Boudier-Reveret², Shant Der Sarkissian³, Henry Aceros³, Louis Gaboury², Carl-Elie Majdalani², Melanie Borie³, Nicolas Noiseux³, Martin Lamontagne². ¹Laval University, Quebec, QC, Canada.

²University of Montreal, Montreal, QC, Canada. ³Centre Hospitalier Universitaire de Montreal (CHUM) Research Centre, Montreal, QC, Canada.

Email: beatrice.deschenes-st-pierre.1@ulaval.ca

(No relationships reported)

Tendinopathy represents 30 to 50% of sports-related injuries. Yet, a significant proportion of patients do not respond to the first-line conservative management with progressive loading and strengthening exercises program. Recently, Mesenchymal Stem Cells (MSC) have emerged as a potential regenerative treatment in tendinopathy. **Purpose:** The aim of the present study is to determine whether the injection of MSC and/or Celastrol-conditioned MSC promote histopathological healing in a rodent Achilles tendinopathy model.

Methods: Eighteen Sprague-Dawley rats (36 Achilles tendons) were injected with collagenase type 1A (25 international units) in each Achilles tendons under echographic guidance. After one week, rats were randomly and equally assigned to receive a repeat injection, also under echographic guidance, with either: 1) 60 µL of Phosphate-Buffered Saline (PBS: vehicle); 2) 2.4M MSC derived from rat bone marrow aspirate or; 3) 2.4M MSC conditioned with celastrol, a HSP90 inhibitor and antioxidant. The outcome measurements were histopathological changes assessed after Hematoxylin Eosin Saffron, Bleu Alcian and Factor VIII staining of Achilles tendons. Each item of the semi-quantitative modified Bonar score (tenocytes morphology, cellularity, vascularity, abundance of mucin in fundamental substance and collagen organization) was assessed by a blinded experienced pathologist at 4 weeks (4 rats/8 tendons per group) and at 12 weeks (2 rats/4 tendons per group).

Results: There were no statistically significant differences between groups, both at 4 weeks and 12 weeks ($\alpha > 0.05$). However, at 12 weeks, there was a trend towards

more improvement and better Modified Bonar Scores in the tendons treated with MSC (0.48 ± 0.46) and conditioned-MSC (1.51 ± 0.81) compared to tendons injected with vehicle (2.26 ± 1.90).

Conclusion: No difference was found in Modified Bonar Scores in tendon specimens injected with PB-saline compared to MSC and celastrol-conditioned MSC at 4 weeks. The number of rats per group that was observed until 12 weeks for pathologic analysis was insufficient to draw any conclusion. Nevertheless, these results underline that we need to host rats for a longer period for pathologic analysis. We are currently expanding this experiment with a larger number of rats to be assessed at 12 weeks.

Modeling Elbow Valgus Torque From Throwing Distance With 54,701 Collegiate Baseball Throws

Ben Hansen, Brittany Dowling. *Motus Global, Inc., Rockville Centre, NY.*

Email: ben@motusglobal.com

Reported Relationships: B. Hansen: Salary; Motus Global. Receipt of Intellectual Property Rights/Patent Holder; Motus Global.

The scalability and usability of inertial measurement units (IMU's) allows for biomechanical research to be conducted on datasets that are orders of magnitude larger than traditional motion-capture equipment allows for. From a clinical rehabilitation perspective, there is a large need to better understand the effects of throwing distance on elbow valgus torque in a real-world setting.

PURPOSE: To develop a framework for the prediction of elbow valgus torque at specific long-toss distances in college baseball players. **METHODS:** 30 players from a NCAA baseball team were fitted with a motusTHROW sensor and sleeve (Rockville Centre, NY, USA) that measures peak elbow valgus torque. The sensor was worn during all training in 2018, resulting in a total of 238,611 anonymized throws captured. Of this, 54,701 throws were tagged with a long-toss distance (30-300 ft). A 3rd order polynomial regression and one-way ANOVA were performed to test for differences in elbow torque between throwing distances with Tukey post-hoc tests used to for p-value calculation. **RESULTS:** A strong relationship was found between the throwing distance and elbow torque from the 3rd order polynomial (torque = $1.18 \times 10^{-7}x^3 - 8.90 \times 10^{-5}x^2 + 2.41 \times 10^{-2}x + 0.55$, $p < 0.001$). The ANOVA showed all but 7 of 35 distance relationships had statistically significant differences: 80-90 ft, 210-240/270/300 ft, 240-270/300 ft, and 270-300 ft ($p < 0.001$).

CONCLUSION: There was a strong cubic relationship between throwing distance and elbow torque. The cubic regression formula allows for clinicians to estimate peak valgus torque in the throwing arm from distance alone. This relationship can be used to better design return-to-throw programs.

Does Sharing Wearable Physical Activity Monitor Data with Others Lead to Longer User Engagement?

Ciarán P. Friel¹, Keith M. Diaz². ¹Teachers College, Columbia University; ²Columbia University Medical Center, New York, NY.

³Columbia University Medical Center, New York, NY.

Email: cpf2111@cumc.columbia.edu

(No relationships reported)

The use of wearable physical activity (PA) monitors has increased rapidly over recent years and these devices are becoming more widely used in behavior change interventions. However, high rates of disengagement have been reported, with up to 70% stopping device use within 3 months. This trend is concerning, as these devices are unlikely to impact habitual PA behavior if they are not worn for a sustained length of time. Understanding which factors contribute to long-term engagement can support more effective use of this technology. **PURPOSE:** To assess whether the sharing of data from physical activity monitors (PAMs) via social media or directly with others (e.g. doctor, personal trainer/coach, friends/family) are related to sustained device engagement in a longitudinal survey study. **METHODS:** Current PAM users ($n=418$; mean age: 36.3 ± 12.6 ; 78% female) from across the United States were recruited online and completed a baseline web-based survey in 2015/2016. Participants were followed-up again in 2017. How respondents shared their device data (on social media, privately with family/friends, with their doctor, with coach/personal trainer [yes/no response items]) was queried. Sustained PAM engagement was defined as those who continued PAM use at follow-up. **RESULTS:** The median follow-up time was 15.5 (± 3.7) months. Approximately, 11.5%, 55.7%, 9.1%, and 4.3% reported sharing their data via social media, with family/friends, with a doctor, or with a coach/personal trainer, respectively. At follow-up, 72.5% of participants were still using their PAM. Sharing data from the PAM publicly on social media (e.g. Facebook, Twitter) was significantly associated with long-term PAM engagement (OR: 4.45; 95% CI: 1.51-13.15, $p=0.007$). Sharing of PAM data privately with family/friends (OR: 1.21; 95% CI: 0.76-1.92, $p=0.418$), with a doctor (OR: 1.38; 95% CI: 0.57-3.34, $p=0.477$), or with a coach/personal trainer (OR: 0.91; 95% CI: 0.28-3.00, $p=0.881$) were not significantly associated with sustained PAM use. **CONCLUSION:** Sharing PAM data on social media was associated with sustained device use of over median follow-up

of 1.3 years. The extent to which PAM users share their data should be considered when using this technology as a behavior change tool. Encouraging users to share data publicly may lead to longer device engagement.

Does Post-diagnosis Physical Activity Prolong the Duration of Active Surveillance in Men With Prostate Cancer?

Efthymios Papadopoulos¹, Shabbir M.H. Alibhai², George A. Tomlinson¹, Andrew G. Matthew², Michael Nesbitt², Antonio Finelli², John Trachtenberg², Daniel Santa Mina¹. ¹University of Toronto, Toronto, ON, Canada. ²University Health Network, Toronto, ON, Canada.

Email: efthymios.papadopoulos@mail.utoronto.ca

(No relationships reported)

PURPOSE: In this retrospective cohort study, we examined the effect of post-diagnosis physical activity on active surveillance (AS) termination in men with low-risk prostate cancer.

METHODS: 630 participants on AS were included in the analysis. Post-diagnosis physical activity was measured using the Godin Leisure-Time Exercise Questionnaire and expressed in metabolic equivalent-minutes per week (MET-min/wk). Four physical activity categories were created to classify participants throughout the study: inactive (<210 MET-min/wk), insufficiently active (210-500 MET-min/wk), active/meeting physical activity guidelines (500-1000 MET-min/wk), or highly active (>1000 MET-min/wk). Using Cox regression models, we evaluated the relationship between post-diagnosis physical activity and risk of terminating AS, adjusting for age, prostate-specific antigen (PSA) and number of positive cores most proximal to AS initiation. **RESULTS:** Of the 630 participants, 198 underwent active treatment and 432 were censored. The earliest and latest events of AS termination, indicated by active treatment initiation occurred at 5 and 116 months, respectively. In this cohort, post-diagnosis physical activity was not significantly associated with time to AS termination. PSA (HR, 1.11; 95% CI, 1.03 to 1.20) and the number of positive cores (HR, 1.34; 95% CI, 1.12 to 1.61) most proximal to AS initiation were associated with a significantly increased risk of initiating active treatment. **CONCLUSIONS:** The findings of this study suggest that termination of AS and initiation of active treatment is not influenced by post-diagnosis, self-reported physical activity status.

Assessing Safety, Ease of Use, and Productivity While Using Treadmill Desks: A Pilot and Feasibility Study

Lucy N. Berman, Sarah A. Rydell, Nathan R. Mitchell, Mark A. Pereira. University of Minnesota, Minneapolis, MN.

Email: Berma200@umn.edu

(No relationships reported)

BACKGROUND: Sedentary behavior is associated with a variety of health complications. Long bouts of sitting is becoming a recognized risk of workplace environments.

OBJECTIVE: The purpose of this study was to evaluate the safety, ease of use, and productivity associated with using treadmill desks (TD) during the work day.

METHODS: Sedentary office workers (n=14; 86% female, 40±12 yrs) took part in a within-person, 4-week randomized crossover study comparing group usage of a TD to a usual desk condition. During the TD condition, participants were asked to use the treadmill for a minimum of 30 minutes each workday. In-person study visits were conducted at baseline and during the final week of each condition, and electronic surveys were administered via an email link. Treadmill use and physical activity bouts were tracked with logs and the activPAL accelerometer worn on the thigh. **RESULTS:** During the TD period, participants spent an average of 33±25 minutes at an Active Station (Hopkins, Minn.) TD each day; the range of the walking bout durations, when the TD was used, was 15-120 minutes. All participants reported feeling safe while using the TD. 12 people reported it was 'easy' to use, with one person reporting it was 'somewhat easy'. Productivity results were mixed; 4 reported they were somewhat or much more productive, 4 were neutral, and 5 reported they were somewhat less productive. All participants endorsed a desire to continue using the treadmill desks.

CONCLUSIONS: Results suggest that, over the short term, treadmill desks are safe and easy to use and appear to have mixed effects on productivity. Further research should include full-scale long-term efficacy trials of treadmill desks that include measures of productivity, adherence, and cardiometabolic health outcomes.

Dearborn SHINES For Healthy Kids: Understanding Physical Activity Among Arab American Students in Physical Education and the Impact of SPARK

Erin E. Centeo¹, Jeanne Barcelona², Hayley McKown¹, Christine Pedder², Mariane Fahlman, FACSM². ¹University of Hawaii at Manoa, Honolulu, HI. ²Wayne State University, Detroit, MI.

Email: ecenteo@hawaii.edu

(No relationships reported)

Background/Purpose: Arab Americans account for almost 3.7 million people in the United States (Arab American Institute, 2014). However, limited health data is available on youth populations. Additionally, very few interventions have been designed to increase the physical activity levels of Arab American youth. Therefore, the purpose of this study is twofold: evaluate Arab American children's physical activity (PA) levels during physical education (PE) class and understand how the implementation of SPARK can influence the PA of Arab American youth in the PE context.

Methods: System for Observing Fitness Instruction Time (SOFIT) was used to assess activity levels, lesson context, and teacher involvement during PE class. A total of 66 PE classes in one urban, primarily Arab American, district, were observed in grades 3-8, involving 18 PE teachers. Data collection took place over two time points, with one professional development of the SPARK PE curriculum occurring in-between. Data were downloaded from the iSOFIT app and analyzed using SPSS (v25).

Results: MANCOVA's were run to better understand the effect grade level has on physical activity minutes, lesson context, and teacher involvement while controlling for teacher, total lesson minutes, and type of activity. In general results showed that students were not meeting suggested PA guidelines during PE class $M_{MVPA3rdgrade}=18.6$ min, $M_{MVPA4thgrade}=14.1$ min, $M_{MVPA5thgrade}=13.4$ min, $M_{MVPA6thgrade}=12.3$ min, $M_{MVPA7thgrade}=18.7$ min, $M_{MVPA8thgrade}=15.3$ min. Overall, grade did not have a significant effect on level of PA ($p=.08$). MVPA did not increase between T1 and T2 ($p>.05$), but there were significant changes across timepoints in lesson context ($p<.01$) and teacher involvement ($p<.01$).

Conclusions: The results show that youth were not meeting recommended amounts of daily PA during PE class at either timepoint. A one-time SPARK professional development did not significantly change student behavior as measured by MVPA, but did show improvements in teacher knowledge as measured by lesson context and teacher involvement. Implications for using SOFIT data gathered to inform the ongoing SPARK and Dearborn SHINES intervention and importance of prolonged professional development to transition from increases in knowledge to behavior change will be discussed.

Do Activity Monitors Correctly Classify Driving Time as Sedentary?

Rachel Barnett, Matthew Nelson, Cami Christopher, Mami Takeda, Julian Martinez, Sarah K. Keadle. California Polytechnic State University, San Luis Obispo, CA.

(No relationships reported)

PURPOSE: Driving is a common sedentary activity for many individuals. Previous studies suggest that accelerometers may misclassify driving as a more active behavior due to vehicle vibrations not related to human movement. Therefore, the purpose of this study is to examine how accurately accelerometer processing methods classify driving-specific sedentary time.

METHODS: Participants (n=26, mean age=30.5yrs, 16 female, 20 male) wore an ActiGraph wGT3X-BT (AG) on the right hip, an AG on the non-dominant wrist, and an activPAL (AP) accelerometer on the thigh. They were directly observed for two 2-hour sessions using a GoPro Hero 5 to establish the criterion measure of driving time. We used published methods to classify accelerometer data as sedentary, light, and moderate to vigorous physical activity (MVPA). For the AG-hip, we used the Sojourn-3x (S3x), Freedson, Sasaki, and Crouter methods. The AG-wrist was classified using a random forest (RF) and linear model (lm), and the AP used a proprietary algorithm. We isolated the directly observed driving time and determined whether each of the methods categorized the driving time as sedentary, light or MVPA.

RESULTS: Nine of the twenty-six participants drove during the observed time, resulting in 24 separate driving bouts with a mean bout length of 8.5 minutes, totaling 3.4 hours of sedentary driving time. For the AG-hip, the Crouter method produced the lowest classification accuracy with 26.5% correctly classified as sedentary, 68.4% classified as light and 7.0% as MVPA. In contrast, using the Sojourn-3X method, 70.2% of driving time was correctly classified as sedentary, 26.9% was classified as light and 2.9% as MVPA. For the wrist, using a random forest method resulted in 44.5% correct classification, while the accuracy of a linear model was 30.2%. The AP classified 100% of the driving time as sedentary.

CONCLUSIONS: Existing algorithms to estimate sedentary time for hip- and wrist-worn accelerometers do not accurately classify driving time, while the thigh-worn AP

is highly accurate. Since the average American spends 46 min/day in the car, there is a need to develop new methods that correctly classify driving time for hip- and wrist-worn devices.

3602 Board #290 Jun. 1 9:30 AM - 11:00 AM
Comparing Estimates Of Sedentary, Light And Moderate-vigorous Physical Activity Between Activity Monitors

Cami Christopher, Rachel Barnett, Mami Takeda, Julian Martinez, Matt Nelson, Sarah Keadle. *California Polytechnic State University, San Luis Obispo, San Luis Obispo, CA.*
 Email: cchris17@calpoly.edu
 (No relationships reported)

Accelerometers are widely used in research, but studies use different monitors, attachment sites, and/or data processing methods, making it difficult to compare results across studies.

PURPOSE: Therefore, the purpose of our study is to compare data collected at the hip, wrist, and thigh to determine if estimates of sedentary time (ST), light physical activity (LPA) and moderate-vigorous physical activity (MVPA) are comparable over a 7-day wearing period.

METHODS: Participants wore an ActiGraph (AG) on the hip and non-dominant wrist, and activPal on the thigh 24 hours/day for 7-days. Intensity was categorized using the following methods: AG-Hip 3x, Freedson, Sasaki, Matthews, and Crouter; AG-wrist random forest (RF), linear model (LM) and GGIR; and activPal software. Across the different methods, we compared mean estimates and Pearson correlations for ST, LPA and MVPA.

RESULTS: Average ST ranged from 461 min/day (Hip-Crouter) to 610 min/day (Hip-Freedson), the lowest correlation was between Hip-3x and Wrist-GGIR ($R=0.14$) and the highest was between Hip-Freedson and Hip-Sasaki ($R=0.94$). Average LPA ranged from 201 min/day (Hip-Matthews) to 338 min/day (Hip-Sasaki), the lowest correlation was between Hip-3x and Wrist-LM ($R=0.46$) and the highest was between Hip-Freedson and Hip-Matthews ($R=0.94$). Average time in MVPA ranged from 53 min/day (Hip-Freedson) to 186 min/day (Wrist-LM), the lowest correlation was between Wrist-LM and Wrist-GGIR ($R=0.30$) and the highest was between Hip-3x and Hip-Matthews ($R=0.93$).

CONCLUSIONS: Estimates of ST, LPA and MVPA are heterogeneous across different processing methods and attachment sites, particularly when comparing hip and wrist attachment sites. There is a need to identify which procedures will result in equivalent methods to facilitate data pooling and ensure coherent public health translation of prospective cohorts that are using accelerometers.

High-active Mice Have Elevated Clearance Rate Of Bcaas Compared To Low-active Mice

Jorge Z. Granados, Gabriella A. M. Ten Have, Ayland C. Letsinger, John J. Thaden, J. Timothy Lightfoot, FACSM, Nicolaas E. P. Deutz. *Texas A&M University, College Station, TX.*
 Email: jgranados@tamu.edu
 (No relationships reported)

Physical activity (PA) is associated with a diminished prevalence of hypokinetic related diseases and its worldwide economic burden on health care cost. For several decades, branched-chain amino acids (BCAAs; leucine [LEU], isoleucine [ILE], valine [VAL]) have been studied for muscle wasting disorders. However, little is known about the metabolic interactions between BCAAs and regulation of PA levels.

PURPOSE: To assess BCAA metabolism by measuring plasma clearance rates in mice previously classified as either low-active (LA; C3H/HeJ) or high-active (HA; C57L/J). **METHODS:** 12-week-old male LA ($n=23$) mice (body weight: 25.8 ± 1.2 g; lean body mass: 21.0 ± 1.1 g; fat mass: 2.5 ± 0.5 g) and HA ($n=20$) mice (27.5 ± 1.2 ; 22.5 ± 1.3 ; 2.5 ± 0.7) were used. Under anesthesia, a pulse of stable tracers (L-LEU[13C6], L-ILE [1-13C], and L-VAL [13C5]) was administered via the right jugular vein catheter. Subsequently, blood samples were taken (Time: 1, 3, 5, 7, 10, 15, 20, 25, 30, and 40 mins). Plasma enrichments and concentrations of LEU, ILE, and VAL were determined by LC-MS/MS. Whole-body production (WBP) was calculated from fitted area under the curve (AUC) as pulse/AUC, and clearance of stable tracers was calculated as WBP/plasma concentrations. Fitting and statistical analysis (unpaired student t-tests) were performed using GraphPad Prism 8 software. Data are expressed as mean \pm SE.

RESULTS: HA mice had significantly lower plasma concentrations for LEU (125.2 ± 4.8 vs 144.8 ± 6.4 $\mu\text{mol/l}$, $p=0.02$), ILE (48.5 ± 1.9 vs 57.7 ± 2.3 $\mu\text{mol/l}$, $p<0.01$) and VAL (156.8 ± 4.9 vs 187.9 ± 7.1 $\mu\text{mol/l}$, $p<0.01$) and significantly higher WBP values for ILE (11.6 ± 0.6 vs 8.3 ± 1.1 nmol/g lbm/m, $p=0.02$) and VAL (111.4 ± 5.4 vs 92.8 ± 2.8 nmol/g lbm/m, $p<0.01$) compared to LA mice. No significant WBP differences were observed for LEU (75.5 ± 3.3 vs 72.7 ± 3.2 nmol/g lbm/m, $p=0.56$). HA mice demonstrated higher percent clearance for LEU (40%), ILE (76%), and VAL (29%) compared to LA mice. **CONCLUSIONS:** The observed changes in plasma

concentration, WBP, and clearance of BCAAs suggest modified metabolic pathways of LEU, VAL, and ILE in HA mice, compared to LA mice. **FUNDING SOURCES:** Texas A&M Vice President of Research Office, TACSM Student Research Development Award, College of Education & Human Development Student Research Grant, and funds from the Omar Smith Endowment.

Ghrelin and PYY are Differentially Altered Following an Acute Bout of Aerobic vs Resistance Exercise

Tanya M. Halliday¹, Mollie H. White², Davis M. Bitton², Allison K. Hild², Jonathan R. Miller², Edward L. Melanson, FACSM², Marc-Andre Cornier². ¹University of Utah, Salt Lake City, UT. ²University of Colorado Anschutz Medical Campus, Aurora, CO.
 Email: tanya.halliday@utah.edu
 (No relationships reported)

PURPOSE: The purpose of our ongoing trial is to determine if aerobic exercise (AEx) and resistance exercise (REx) differentially influence acute energy intake and appetite regulation.

METHODS: Physically inactive adults with overweight/obesity ($n=19$, 35 ± 1.7 yrs, BMI: 28.7 ± 1.1 kg/m²) completed 2 conditions; 1) AEx (treadmill walking at 65-70% of age-predicted maximum heart rate for 45 minutes) and 2) REx (1-set to failure of 12 resistance exercises). Each condition was initiated in the post-prandial state (35 minutes post breakfast). Appetite (visual analog scale [VAS] for hunger and satiety) and hormones (ghrelin and PYY) were measured every 30 minutes for 3 hours following consumption of the standardized breakfast meal. Post exercise food cravings (following 90 min VAS and blood draw via Food Cravings Inventory [FCI] questionnaire) and ad libitum energy intake at the lunch meal were also measured.

RESULTS: There was no difference in post-exercise *ad libitum* energy intake between conditions (AEx: 932 ± 75 kcal vs. REx: 910 ± 81 kcal). There were also no differences in post exercise food cravings, nor area under the curve (AUC) for hunger, satiety, ghrelin, and PYY. However immediately following exercise (90 minutes post breakfast), ghrelin (AEx: 784 ± 66 pg/mL vs. REx: 642 ± 41 pg/mL, $p=0.08$) and PYY (AEx: 166 ± 12 pg/mL vs. REx: 124 ± 11 pg/mL, $p=0.05$) were both higher in the AEx condition. Across conditions, higher scores on the FCI ($r=0.49$, $p<0.01$), increased hunger AUC ($r=0.62$, $p<0.001$), and decreased satiety AUC ($r=-0.43$, $p=0.013$) were associated with increased *ad libitum* energy intake.

CONCLUSIONS: The data suggest that an acute bout of aerobic exercise appears to transiently increase both ghrelin and PYY, which are orexigenic and anorectic gut peptides, respectively, compared to resistance exercise. However, ad libitum energy intake was not different between conditions. Future work is needed to confirm these findings and uncover mechanisms by which exercise influences appetite indices and energy intake.

3605 Board #293 Jun. 1 9:30 AM - 11:00 AM
Can A Polyphenol Supplement Improve Sports Vision And Reaction Time? A Pilot Investigational Study

Neil E. Wolkodoff¹, Gerald M. Haase², Bethany Braunstein³. ¹Colorado Center for Health & Sport Science, Denver, CO. ²University of Colorado, Aurora, CO. ³Boulder Community Hospital, Boulder, CO.
 Email: neil@cochss.com
 (No relationships reported)

PURPOSE: Polyphenol supplements have emerged as positive influencers in lipid and metabolic regulation related to cardiovascular disease risk. Limited research has assessed their value in neurological function and sports reaction measures. A highly concentrated extract of citrus bergamot polyphenols was tested because of extensive publications demonstrating benefits in oxidative stress and dyslipidemias, and therefore might improve visual components.

METHODS: Nineteen (19) volunteers, aged 50-74 years old, were studied. Fourteen (14) subjects consumed BergaMet Sport, a high concentration polyphenol compound, and five (5) controls consumed a placebo. Subjects were randomly assigned to either the placebo or intervention groups. Weight, body composition, visually directed balance, sports vision reaction time and a seven-test sports vision battery were measured at time 0 and at 30 and 60 days.

RESULTS: The mean age for the control group was 58, + or - 9.42 yrs for the and for the intervention group, 57.1 + or = 6.42 yrs. 52% were female and 48% were male. The subjects who received the intervention improved to statistically significant levels in all sports vision and balance measures compared to the placebo group. The key measures of time to balance task (5.76 second increase Placebo (PL) vs. 15.51 second decrease/improvement Intervention (INT)), reaction time test (73.6 point improvement PL vs. 492.5 point improvement INT) and the sports vision ranking composite of seven measures as a percentile to normative (.654 point improvement in percentile ranking for PL vs. 6.33 point improvement for INT), were all significant ($P<0.05$), using paired student's t-tests.

CONCLUSIONS: In this pilot study, consumption of a high concentration polyphenol produced significant improvements in neurological function specifically related to visual components, balance and reaction time in this older age group in a relatively short time period. Further investigation in other age groups attempting to regain and maintain function in domains related to vision and reaction time is warranted in respect to polyphenol compounds.

 (No relationships reported)

Metabolic Flexibility is Impaired in Response to Acute Exercise in the Young Offspring of Mothers with Type 2 Diabetes.

Cullen Vincelle¹, Timothy Allerton², Brian Irving¹, Guillaume Spielmann¹, and Neil Johannsen¹

¹Louisiana State University, Baton Rouge, LA. ²Pennington Biomedical Research Center, Baton Rouge, LA. Healthy adults with a family history (first degree relative) of T2D demonstrate impairments in metabolic flexibility (MF), which is considered to be a factor in the development of T2D. Insulin sensitivity has been shown to improve in the first 48 hours in response to exercise. Whether, a single bout of high intensity interval exercise (HIIE) improves MF in men and women with a family history of T2D remains to be resolved. **PURPOSE:** The purpose of this study was to assess MF in a group of young, seemingly healthy adults with a positive family history of maternal T2D (FH+) and those without a family history of T2D (FH-) in response to a single bout of HIIE and 1 hour (1H) and 48 hours (48H) after exercise. **METHODS:** Seventeen participants (n=9 FH+ 2M/6F) consumed a liquid mixed meal with 3-hour post-prandial resting metabolic assessments (RMR) taken at baseline (BL, no prior exercise), and at 1H and 48H after a bout of HIIE (10 x 60s @90% watt max). **RESULTS:** ΔRER AUC for FH+ vs. FH- groups differed at BL, but not significantly (p=0.08); however, at the 1H visit the ΔRER AUC for the FH+ group (4.3 ± 1.6) was lower when compared to FH- group (6.5 ± 1.9; p=0.02). The suppression of FatOx (reduction at 60 minutes post-meal) was attenuated during the 1H visit in the FH- participants (-0.018 ± 0.01 g/min), but not in FH+ participants (0.007 ± 0.01 g/min; p=0.03). ΔRER AUC was increased at 48H in FH+ participants. **DISCUSSION:** Our results suggest that young adults with a maternal family history of T2D demonstrate impaired MF in response to a mixed meal tolerance test 1H post-HIIE. However, MF was improved to the level of FH- participants at 48H.

Relationship Of Leptin, Body Composition And Resting Metabolic Rate In Chinese Overweight And Obese Adults

Jingjing Xue¹, Shuo Li², Xiujuan Hao³, Yue Fu³, Rou Wen⁴, Ping Hong⁵. ¹China Institute of Sport Science, Beijing, China. ²Shanghai University of Sport, Shanghai, China. ³Beijing Sport University, Beijing, China. ⁴Beijing Dance Academy, Beijing, China. ⁵Winter sports management center of the general administration of sport of China, Beijing, China.
 Email: xue_jing_jing@126.com
 (No relationships reported)

PURPOSE: Resting metabolic rate (RMR) and substrate utilization are important factors in maintaining energy balance and leptin is postulated to be involved in the regulation of body weight. However, in overweight and obese individuals, excess fat mass has a significant impact on metabolic function both directly through altered metabolic rate and substrate oxidation, and indirectly, through chronic changes in hormonal concentrations. This study determined the relationship of body composition and leptin with RMR and substrate utilization (carbohydrate, fat and protein oxidation rates) in Chinese overweight and obese adults.

METHODS: The subjects were 33 women (age = 44.0±12.1 years; BMI = 27.9±3.2 kg/m²; percent body fat (%fat) = 38.7 ± 4.0%) and 34 men (age = 30.0±9.7 years; BMI = 27.4±1.7 kg/m²; percent body fat (%fat) = 27.5 ± 4.3%). RMR and substrate utilization were measured by indirect calorimetry (Metamax 3B[®] Metabolic Measurement system, German) and body composition by the bioelectrical impedance method. Serum leptin levels were determined by radioimmunoassay.

RESULTS: In men and women, RMR significantly correlated with Skeletal Muscle Mass (Men: R=0.556, p=0.001; Women: R=0.493, p=0.004), but both not significantly correlated with leptin (both p>0.05). In stepwise multiple regression analysis, SMM was the main predictor of RMR, explaining 42.5% and 28.5% of the variance of RMR in men and women respectively. In women, but not men, leptin significantly correlated

with RER (R=-0.581, p=0.029) and carbohydrate, fat, and protein oxidation rates respectively (R=-0.558, 0.689, 0.690; all p<0.01). Furthermore, in stepwise multiple regression analysis, leptin explaining 33.7% of the variance of RER in women.

CONCLUSIONS: Skeletal Muscle Mass is a significant predictor of RMR in Chinese overweight and obese adults, evaluation of body composition may be an effective and efficient way to evaluate metabolic status. Serum leptin concentrations in female subjects showed a negative association with respiratory quotient and carbohydrate oxidation rate and positive association with fat and protein oxidation rates. We suggest that sex-specific evaluations are also necessary. **Acknowledgements:** This work was supported by National science and technology program of China (Grants No.2013FY114700)

Exercise, Estradiol, And Specific Estrogen Receptor Activation For The Prevention Of Type 2 Diabetes

Brittany Gorres-Martens¹, Janelle Shiffler¹, Teresa Binkley². ¹Augustana University, Sioux Falls, SD. ²South Dakota State University, Brookings, SD.
 Email: brittany.gorres-martens@augie.edu
 (No relationships reported)

Postmenopausal women have an increased risk for type 2 diabetes (T2D), and hormone replacement therapy (HRT) decreases this risk. However, HRT increases the risk of breast cancer and stroke, and thus, the US Preventive Services Task Force does not recommend HRT to prevent or manage T2D. Moreover, exercise is an effective means to prevent and treat T2D. **PURPOSE:** To compare exercise treatment with drug-induced estrogen receptor (ER) activation in ovariectomized (OVX) rats fed a high-fat diet (HFD). **METHODS:** OVX female rats were fed a HFD for 10 weeks. One group of rats ran on a treadmill for 25 minutes/day at 40 cm/s for 5 days/week (Ex), while the other rats were treated with estradiol (E₂: 1.4 µg/day), the specific ERα activator PPT (18 µg/day), or the specific ERβ activator DPN (18 µg/day) (n=8/group). Throughout the study, weekly food intake was determined by weighing the amount of food given and the amount of food remaining at the end of the week, and voluntary cage activity was measured using Optmo-M4 cage monitors. At the end of the study dual energy X-ray absorptiometry (DXA) determined the body composition. Normally distributed data were analyzed using a one-way ANOVA and an LSD post-hoc test. Non-normally distributed data were analyzed using Kruskal-Wallis testing. **RESULTS:** At the end of the study, the Ex and E₂ groups gained 125±5 g and 125±9 g of body weight, which was significantly less than the PPT and DPN groups (165±12 g and 160±8 g, respectively; p<0.05). Although the Ex and E₂ groups gained the same amount of total body weight, the Ex group had a significantly lower abdominal fat % compared to the E₂ group (30±1% vs. 37±2%; p<0.001), and the abdominal fat % of the E₂ group was the same as the PPT and DPN groups (39±3% and 38±2%, respectively). Although the food intake (kcal/day) did not differ between the groups, the voluntary cage activity of the E₂ group (498±27 counts/hr) was significantly greater (p<0.05) than the Ex, PPT, and DPN groups (387±34, 397±27, and 370±27 counts/hr, respectively). **CONCLUSION:** The prescribed exercise in the Ex group contributed to a lower body weight and lower % abdominal fat, and the voluntary cage activity in the estradiol group contributed to a lower body weight, but not lower % abdominal fat, which is the greatest risk factor for T2D. Supported by NIH Grant P20GM103443 and NSF Grant IIA-1355423.

The Effect Of Gestational Physical Activity On The Psychological Health Of Their Offspring

Jung eun Byun¹, Da-Ae Kim¹, Yong-Chul Jang², Sung-Hun Park³, Tayler S. Thurston³, Eun-Young Kim⁴, Hyun-Chul Cho⁵, Joon-Yong Cho⁶, Jung-Hoon Koo⁶. ¹Korea Incubator Laboratory of group exercise, Seoul, Korea, Republic of. ²University of West Florida, Pensacola, FL. ³University of Utah, Salt Lake City, UT. ⁴Preventive Medicine, Chungbuk, Korea, Republic of. ⁵Yongin University, Gyeonggi, Korea, Republic of. ⁶Korea National Sport University, Seoul, Korea, Republic of.
 (No relationships reported)

PURPOSE: Gestational physical activity (GPA) has been associated with improved fetal outcomes. The purpose of this study was to examine whether exercise during pregnancy contributes positively to the psychological health of their offspring.

METHODS: A survey was administered to 1509 children (ages 11-13) to identify psychological health factors such as mental stress, depression, and self-esteem using a modified Daily Hassles Questionnaire, Children's Depression Inventory, and Rosenberg's self-esteem, respectively. Mothers of the participants were retrospectively categorized into three groups based on GPA: non-exercisers (CON), low-intensity aerobic exercise (AE), and body-weight strength training (BWT).

RESULTS: After excluding questionnaires due to incomplete data sets, 855 surveys were analyzed. Our results indicated significantly lower levels of depression with concomitant increased self-esteem among children of exercising mothers compared

to CON (AE: $p < 0.05$ and $p < 0.01$; BWT: $p < 0.05$ and $p < 0.01$, respectively). However, there was no effect of exercise on offspring mental stress levels, nor were there any differences observed between AE and BWT for any psychological health factors. Mental stress was significantly correlated with depression ($r = 0.640$, $p < 0.01$) and self-esteem ($r = -0.534$, $p < 0.001$). In addition, depression was negatively correlated with self-esteem ($r = -0.689$, $p < 0.01$).

CONCLUSIONS: GPA had a positive influence on the psychological health of their offspring. Interestingly, there were no differences between types of physical activity, which should be recognized to benefit the mental health of their children regardless of modality. Therefore, implementation of GPA should be accepted as part of the healthy gestational regimen along with prenatal vitamins and a healthy balanced diet.

Investigation of the Association of Depression and Cardiovascular Disease Risk in Retired Professional Football Players
 Eric Kessler, Jocelyn N. Simons, Genevieve E. Smith, Mark M. Cassidy, Gregory W. Stewart, FACSM. *Tulane University School of Medicine, New Orleans, LA.*
 (No relationships reported)

Former professional football players have considerable cardiovascular disease risk. Studies have shown that psychosocial factors and depression are also strongly associated with CVD morbidity and mortality. **PURPOSE:** To better understand the association of cardiovascular disease and psychosocial factors such as depression in a population of retired NFL players. **METHODS:** Blood pressure, anthropometry, and laboratory blood analyses were collected from former NFL athletes ($n = 648$) between October 2016 and February 2018 during cardiovascular screenings held throughout the U.S. Questionnaires were used to collect demographic information, exercise frequency and Patient Health Questionnaire 2 (PHQ-2) scores. Means were analyzed via one-way ANOVA and associations between variables assessed using GLM. Chi-square analysis or t-test was used to assess differences between categorical variables, as appropriate. **RESULTS:** Variables of race ($p = 0.0007$), log of systolic blood pressure (SBP) ($\beta = -0.5258$, $p = 0.0404$), log of waist circumference ($\beta = -16.9366$, $p = 0.0218$), log of hip circumference ($\beta = 17.2927$, $p = 0.0196$) and waist to hip ratio ($\beta = 8.2430$, $p = 0.0171$) were significantly associated with positive screen for depression on the PHQ-2. Variables race ($p = 0.0002$), log of SBP ($\beta = -3.3818$, $p = 0.0009$), diastolic blood pressure (DBP) ($\beta = 0.0168$, $p = 0.0035$), log of waist circumference ($\beta = -46.3330$, $p = 0.0100$), log of hip circumference ($\beta = 46.5107$, $p = 0.0100$), and waist to hip ratio ($\beta = 22.3890$, $p = 0.0078$) were significantly associated with higher score on the little interest in doing things question of the PHQ-2. Variables race ($p = 0.0048$), log of SBP ($\beta = -2.2832$, $p = 0.0122$), and DBP ($\beta = 0.0141$, $p = 0.0059$) were significantly associated with higher score on the feeling depressed question of the PHQ-2. There were significant differences in prevalence between racial groups for positive screen for depression on the PHQ-2 ($p = 0.0006$). **CONCLUSIONS:** Factors reflecting body composition were found to be significantly associated with a positive screen for depression and depressive symptoms. Measures for abdominal obesity may be a better indicator for the association of body composition and depression in retired athletes. Accounting for racial differences in clinical practice may also help improve overall health outcomes.

Influence of Physical Stress on Interpretation of Ambiguous Social Cues
 Julie A. Cantelon¹, F. Caroline Davis², Nate Ward¹, Erika Hussey², Robin B. Kanarek¹, Holly A. Taylor¹. ¹Tufts University, Medford, MA. ²U.S. Army Combat Capabilities Development Command Soldier Center, Natick, MA.
 Email: julie.cantelon@tufts.edu
 (No relationships reported)

Individuals with high stress jobs (e.g. law enforcement or military personnel) are often tasked with quickly interpreting ambiguous information in order to guide appropriate action. For example, certain social cues, such as (surprised) facial expressions, are ambiguous as they do not clearly signal whether an individual feels positive or negative, and could be interpreted as either safe or threatening. Previous work has demonstrated that acute emotional stress, which heightens arousal and negative affect, makes individuals more likely to interpret surprised facial expressions negatively. Likewise, exercise also influences affect and arousal, with the direction depending on exercise intensity. However, the influence of exercise intensity on valence bias, or tendency to interpret ambiguity as positive or negative, remains unexplored. **PURPOSE:** To examine shifts in valence bias of ambiguous social cues under moderate and high intensity exercise. **METHODS:** Forty-two healthy young adults (19 men, 23 women, ages 18-35) who engaged in regular exercise, completed 40 minutes of continuous steady-state cycling at moderate (65% Heart Rate Reserve, HRR) and high (85% HRR) intensities on two separate days. They completed measures of perceived exertion, affect and arousal 30 minutes into exercise, then rated a series of

ambiguous (surprised) faces as positive or negative. **RESULTS:** Heart rate, perceived exertion, negative affect and arousal were significantly higher under the high relative to moderate intensity condition (all p 's $< .05$). However, there was no significant difference in valence bias of surprised faces as a function of exercise intensity ($p > .1$). **CONCLUSIONS:** Understanding factors that influence interpretation of ambiguous social cues is important, as even slight shifts might alter if information is perceived as safe vs. threatening. This could have significant behavioral consequences for individuals operating in high-stakes environments. Results suggest that despite differences in participant's emotional state between moderate and high levels of physical stress, interpretation of ambiguous social cues remains unaffected. Supported by the U.S. Army Combat Capabilities Development Command Soldier Center (CCDC, Natick, Massachusetts, USA) under award number W911QY13C0012.

 (No relationships reported)

PURPOSE: We have observed chronic overfeeding via a high fat/high sugar diet decreases wheel running and substantially alters the microbiome in C57BL/6J mice. In this study, we tested the hypothesis that gut microbiota modulates the effect of nutrient intake on physical activity. **METHODS:** 40 C57BL/6J male mice (5 wks of age) were individually housed, adjusted to a standard "chow" diet (CHOW) for a week, and then divided randomly into four groups: Group 1 (control group) received an *ad libitum* CHOW diet and water while Groups 2, 3, and 4 received an *ad libitum* high fat diet and a 20% fructose drinking water solution (HFHS) for a total of 12 weeks. Each group was given a running wheel for physical activity monitoring after three days on the new diet. After 12 weeks, Groups 2 and 3 were changed to a CHOW diet. Fresh fecal pellets from Group 1 (control group) were collected, homogenized in an anaerobic solution, and then 100 ul was orally gavaged into Groups 2 and 4 one time a week for five weeks. Wheel running and body composition data were analyzed via repeated ANOVAs. The major bacterial phyla were quantified using qPCR. **RESULTS:** By week 12, Groups 2, 3, and 4 (HFHS diet) ran significantly less distance, duration, and speed than Group 1 on a CHOW diet ($p < 0.05$). The HFHS animals ate significantly greater calories and had more body fat ($p < 0.05$) over the 12 weeks. With the diet alteration at week 13, Groups 1-3 (now all on CHOW) ran at a significantly higher speed than Group 4 (HFHS). Group 2 (CHOW plus transplant) had a significantly greater increase in wheel running compared to Group 3 (CHOW diet and a vehicle transplant). *Bacteroidetes* and *Firmicutes* were similar between Groups 1-3 within two weeks after the diet change regardless of the fecal transplant. **CONCLUSIONS:** A HFHS diet increases body fat and decreases wheel running activity compared to a CHOW diet in C57BL/6J male mice. Recovery of wheel running and lowering body fat was accomplished within 2 weeks by switching from a HFHS diet to a CHOW diet. However, switching diets plus receiving a fecal transplant provided quicker results than diet alone. A fecal transplant without changing diet type did not recover activity levels.

The Association Between Player Age and Initial Helmet Contact Amongst American Football Players.
 David Wang¹, Anthony Napoli², Alexander Webb¹, Priyanka Tripuraneni¹, Phillip Nelson¹, Matthew Civilette¹, Eleonor Belilos¹, Brandon Stryder¹, Kevin Berardino¹, Matthew Druckenbrod¹, Harry Tsou¹, Janette Baird². ¹Georgetown University School of Medicine, Washington, DC. ²Warren Alpert Medical School of Brown University, Providence, RI.
 Email: dxw2@georgetown.edu
 (No relationships reported)

Recent research has demonstrated an association between repetitive head trauma and the incidence of chronic traumatic encephalopathy (CTE), particularly among professional American football players. It is believed that younger players are more susceptible to head injury yet the incidence in these younger age groups appears to be lower. We have shown that video review of game film is a reliable tool in quantifying the frequency and characteristics of head impacts in football games. **PURPOSE:** To study the association between player age and dangerous tackling techniques in all age groups of tackle football using video review of game film. **METHODS:** 8 video reviewers were trained in a universal definition of a "hit" and 3 were chosen to individually review each game. Each reviewer classified each "hit" between a ball carrier and defender based on the level of helmet involvement from the two players. Initial Helmet Contact (IHC) hits were defined as hits between a

ball carrier and a defender that were initiated by at least one of the players' helmets. Regional or national championship level game-films from 2016 and later were obtained, from each age division, via open-source locations on the internet or a private subscriptions service for film review (NFHS Network, Indianapolis, IN). This study received IRB waiver of consent, an a priori power analysis was done to detect a 5% difference between age divisions, and data analyzed by assessing relative risk of each division as compared with the NFL and utilizing tests of trends.

RESULTS: A total of 37 games, 2,912 hits, were watched over 7 age groups. Nearly 1 in 6 (16% [95% CI 15-17]) hits involved IHC. 18.9% [95% CI 15.8-22.31] of hits were IHC at the NFL level. Most lower age levels demonstrated significantly lower relative risks of IHC (range 0.55-0.92) as compared with the NFL and there was a trend toward increasing risk of IHC with increasing age division of play ($p=0.09$). IHC was twice as common amongst defensive participants as offensive (RR 2.0, $p<0.01$).

CONCLUSIONS: IHC is relatively frequent amongst all levels of American tackle football. There is a higher rate amongst defensive participants and a trend toward an increased relative risk at higher age divisions. Further study is necessary to identify the relationship with quantitative forces of impact and potential cognitive sequelae.

Taylor, IV, FACSM². ¹Texas Christian University, Fort Worth, TX. ²University of Mary Hardin-Baylor, Belton, TX. ³United States Military Academy, West Point, NY. ⁴Wake Forest School of Medicine, Winston-Salem, NC. ⁵University of North Texas Health Science Center, Fort Worth, TX.

Email: a.kreutzer@tcu.edu

(No relationships reported)

Repetitive subconcussive impacts to the head are commonplace in soccer. The ability to detect the extent of neurological injury due to these impacts over the course of a season is paramount. **PURPOSE:** The purpose of the current study was to examine alterations in blood biomarkers of head injury over the course of a soccer season.

METHODS: Sixteen National Collegiate Athletic Association (NCAA) male soccer athletes (20.1±1.3 years, 178.6±8.3 cm, 77.8±11.3 kg, 15.0±6.0 %BF) participated in weekly blood sampling throughout an 18-week season. Coaches provided player statistics following the season. Headers (HEAD) were defined as any impact of the players' head with the ball. Serum samples were stored at -80°C until analysis for Tau and Neurofilament Light polypeptide (NFL). We used R statistical language and the *lme4* statistical package to perform a linear mixed effects analysis of the relationships of minutes played (MP) and HEAD with Tau and NFL. We included the intercept for subjects as a random effect, and time point (TP), MP, and HEAD (without the interaction term) as fixed effects. P-values for model comparisons were obtained by likelihood ratio tests of the full model with the effect in question against the model without the effect in question. Visual inspection of residual plots did not reveal any obvious heteroscedasticity or deviation from normality. **RESULTS:** NFL was significantly elevated in weeks 5 (7.3±2.8pg/mL; $p<0.001$), 14 (7.0±3.1pg/mL; $p=0.047$), and 15 (7.9±4.0pg/mL; $p<0.001$) compared to baseline (5.2±1.2 pg/mL). Tau did not change significantly over the course of the season. Neither adding MP ($\chi^2(1)=1.85$, $p=0.17$, $\Delta AIC=0.2$) nor adding HEAD ($\chi^2(1)=0.15$, $p=0.69$, $\Delta AIC=1.85$) as fixed effects improved the model fit for Tau, compared to the simpler model with TP. Similarly, the addition of MP did not improve model fit for NFL ($\chi^2(1)=1.50$, $p=0.22$, $\Delta AIC=0.5$). Conversely, including HEAD improved the model for NFL compared to the simpler model with TP ($\chi^2(1)=5.68$, $p=0.02$, $\Delta AIC=-3.7$). However, only a small negative effect of HEAD, -0.09 (95%CI=-0.16, -0.02), was detected. **CONCLUSION:** In our study, neither MP nor HEAD had a significant effect on Tau concentration over the course of an NCAA Men's soccer season. HEAD appeared to have a small negative effect on NFL concentrations across the season.

3615 Board #303 Jun. 1 9:30 AM - 11:00 AM
The Role of Endogenous Opioids in Cerebral Glucose Uptake Following Acute Exercise

Qudratullah Qadiri¹, Candance Longoria², Harlee York¹, Kelly A. Dougherty¹, Bryce J. Muth¹, Sara C. Campbell, FACSM², John J. Guers¹. ¹Stockton University, Galloway, NJ. ²Rutgers University, New Brunswick, NJ.

(No relationships reported)

Exercise has been linked to several opioid mediated phenomena including exercise mediated analgesia, euphoria "runner's high" and addiction. The role of the endogenous opioid system in these events have all been verified using the opioid receptor blocker naltrexone. Despite this, a full understanding on how the endogenous opioid system influences brain activity under acute exercise conditions is lacking. **PURPOSE:** To investigate the role of the endogenous opioid system on brain

glucose uptake following an acute bout of exercise with and without administration of naltrexone. **METHODS:** To assess cerebral glucose uptake mice were fasted overnight and scanned using positron emission tomography (PET) in one of four assigned conditions: control (CON), exercise (EX), naltrexone injection (NTX) or exercise + naltrexone injection (EX+NTX). Mice were delivered a dose of 18F-fluorodeoxyglucose (FDG) 1 hour prior to scanning. Mice that underwent exercise performed 50 minutes of forced swimming (FS) following a week of familiarization, which consisted of 5-25 minutes of FS. NTX was given via intraperitoneal injection (4 mg/kg) 15 minutes prior to exercise or FDG administration. Data was imaged using VivoQuant software and analyzed using PMOD software by a technician blinded to the experimental conditions. Data was calculated as average standardized uptake values (SUV) for 19 regions of interest (ROI) and made relative to the SUV of the whole brain. **RESULTS:** Exercise increased the SUV of glucose in the cerebellum (EX=1.27 ± 0.14; $P<0.05$) relative to mice under CON (0.98 ± 0.07) or NTX (0.85 ± 0.03) conditions. The exercise mediated increase in activity in the cerebellum was abolished ($P<0.05$) with the addition of NTX (0.88 ± 0.10). The combination of EX+NTX increased the SUV of glucose in the hypothalamus region relative to all groups ($P<0.05$). **CONCLUSIONS:** The cerebellum is largely responsible for the regulation of voluntary muscular activity. Exercise appears to have a potent effect on brain activity specific to this region and may be at least partially mediated by endogenous opioids. Further, the endogenous opioid system may play a role in the attenuation of the hypothalamic-pituitary-adrenal system during exercise.

Diminished Cardiovascular Performance That Persists Up To 3 Days After Completion Of Repeated 6-hour Hyperoxic Resting Dives At 1.35 ATA Is Associated With Reduced Oxygen Consumption

Elizabeth R. Bergeron, John P. Florian. Navy Experimental Diving Unit, Panama City Beach, FL.

(No relationships reported)

Previous measures of cardiovascular endurance after repeated dives on air and 100% oxygen at 1.35 atmospheres absolute (ATA) have shown reductions in performance that persist up to 3 days post-dive for the hyperoxic group only. **PURPOSE:** Examine ventilatory parameters associated with changes in treadmill endurance immediately and 3 days after completing repeated air and oxygen resting dives. **METHODS:** 15 and 12 healthy male Navy divers completed 5 consecutive 6-hr dives with 18-hr surface intervals while breathing air and 100% oxygen, respectively, at 1.35 ATA (Air/Oxygen: 30±5/32±7 yrs; VO_2 max: 52±7/53±5 ml/kg/min; mean±SD). Treadmill endurance time at 80-85% of VO_2 max and associated physiological variables were tested a few days prior to the first dive (BL), 2 hours post-dive day 5 (PD) and 3-days post-dive (PD3) on day 8. Breath-by-breath (Innocor) minute ventilation (VE), end-tidal CO_2 ($F_{ET}CO_2$), oxygen consumption (VO_2), and respiratory quotient (R) were collected during the 80-85% VO_2 max run at 10% grade until exhaustion. PD and PD3 were compared to BL (BL-PD and BL-PD3) using data from the first minute, mid-run, and last minute of the run. **RESULTS:** PD cardiovascular endurance significantly decreased for Air and Oxygen phases (Air: -34%; Oxygen: -36%; $p<0.05$), yet only the Oxygen phase remained reduced PD3 (Air: -11.9%; $p>0.05$; Oxygen: -31%; $p<0.05$). VE increased significantly during the run, but was not different between Air and Oxygen phases or across testing days. Although $F_{ET}CO_2$ decreased across run times and testing days for Air and Oxygen, values for the Oxygen group remained lower than Air throughout ($p<0.05$). PD VO_2 showed decline in both groups (Air/Oxygen: PD -7%; $p<0.05$). VO_2 for Air recovered by PD3, whereas Oxygen remained reduced (Air: +1%; Oxygen: -13%; $p<0.05$). PD R increased overall for both groups, yet Air returned to baseline while Oxygen remained elevated by PD3 (Air: PD: +4%; $p<0.05$; Oxygen: PD +7%, PD3 +4%; $p<0.05$). **CONCLUSIONS:** Treadmill endurance is reduced after long-duration diving and persists longer when exposed to hyperoxic diving conditions. Reduced VO_2 and elevated R has been reported in the literature to correlate with increased lactate production and a greater reliance on anaerobic energy systems making them likely causes of this decrease in aerobic performance.

3617 Board #305 Jun. 1 9:30 AM - 11:00 AM
The Combined Impact Of Altitude And Heat On Heat Shock Protein 70 And Hypoxia-inducible Factor-1 Alpha

Roy M. Salgado, Katherine M. Mitchell, Karleigh E. Bradbury, Adam J. Luippold, Charles S. Fulco, Jermaine A. Ward, Robert W. Kenefick, FACSM. US Army Research Institute of Environmental Medicine, Natick, MA.

Email: roy.m.salgado.civ@mail.mil

(No relationships reported)

There are areas in the world where elevated temperatures occur at relatively high altitudes. Exposure to heat or altitude typically induces an increase in intracellular heat shock protein 70 (iHSP70) and hypoxia-inducible factor-1 α (iHIF-1 α), which

have beneficial down-stream physiological effects. However, the responses to the combination of these environments are unclear. **Purpose:** To determine the impact of combined acute exposure to heat and altitude on iHSP70 and iHIF-1 α .

Methods: Using a randomized, cross-over study design, 10 men (mean \pm SD; age: 25 \pm 7 yr; weight: 88 \pm 13 kg; height: 180 \pm 6 cm; sea level (SL) VO_{2peak}: 42 \pm 5 ml \cdot kg⁻¹ \cdot min⁻¹) were exposed to four environmental conditions separated by at least one week: (1) SL thermoneutral (SLTN; 250m, 20°C, 30-50% rh); (2) SL hot (SLH; 250m, 35°C, 30% rh); (3) altitude thermoneutral (ATN; 3000m, 20°C, 30-50% rh); and (4) altitude hot (AH; 3000m, 35°C, 30% rh). Blood samples were collected at SL (baseline, BL) prior to ~1.5 hour environmental equilibration period and again immediately Pre- and Post- 30 minute of steady state (SS) exercise (cycling, 50% of SL VO_{2peak}). iHSP70 and iHIF-1 α were measured from peripheral blood mononuclear cells. The percent change (% Δ) from BL to Pre- and PostSS was analyzed with 2 x 4 (% Δ BL to Pre- and PostSS x environment) RM ANOVA. **Results:** iHSP70: there was an effect of exercise (PreSS: 4.4 \pm 7.6% vs PostSS: 17.5 \pm 9.6%, $p < 0.05$), but no effect of environment ($p > 0.05$) or an exercise x environment interaction ($p > 0.05$). iHIF-1 α : there was no effect for exercise ($p > 0.05$), environment ($p > 0.05$), or an exercise x environment interaction ($p > 0.05$). **Conclusion:** Our results indicate that iHSP70 increased in response to SS exercise while iHIF1 α was unaltered in these testing conditions. The combination of heat and altitude did not result in an even greater protein expression when compared to exercise alone. However, it is plausible that a more severe environmental stress and/or higher exercise intensity (> 50% SL VO_{2peak}) would result in elevated cellular response compared to a single environment. Effects Of Exercise On Stress-induced Attenuation Of Vaccination Responses In Mice

Yi Sun¹, Selena S. Wang², Christy S. Carter¹, Thomas W. Buford, FACSM¹, Jeffrey A. Woods, FACSM². ¹UNIVERSITY OF ALABAMA AT BIRMINGHAM, BIRMINGHAM, AL. ²UNIVERSITY OF ILLINOIS AT URBANA-CHAMPAIGN, URBANA, IL.
 Email: yisun@uabmc.edu
 (No relationships reported)

Vaccination is one of the most successful public health interventions for preventing infectious diseases, although the immunosuppressive effects of chronic stress can reduce a vaccine's efficacy. Exercise improves vaccine responses, but the role in attenuating stress-induced effects is unknown. **Purpose:** We investigated the effects of forced/acute (eccentric exercise; ECC) and voluntary/long-term (wheel running; VWR) exercise on antibody and cell-mediated immune responses to vaccination in chronically stressed mice. **Methods:** Mice were randomized into Control (CON), S (Stress)-ECC, S-VWR, and S-SED (Sedentary) groups. Chronic restraint stress occurred 6-h/day, 5-days/week for three weeks. S-VWR mice were allowed access to a wheel for the entire experiment. One week post-stress, S-ECC mice ran on a treadmill for 17m/min, -20% grade, for 45 minutes and were then injected with 100 μ g of ovalbumin (OVA) and 200 μ g of alum adjuvant (intramuscularly), along with all other groups. Anti-OVA IgM and IgG was measured via ELISA. Three weeks post-stress, mice were injected with OVA into the ear to determine delayed-type hypersensitivity (DTH) response as a measure of cell-mediated immunity. **Results:** As expected, chronic restraint stress significantly reduced body weight and caused adrenal hypertrophy. Over the course of the experiment, S-ECC, and S-VWR groups had significantly elevated anti-OVA IgG compared to S-SED which had significantly lowered levels compared to CON ($p < 0.05$). No differences were observed with anti-OVA IgM nor DTH responses. **Conclusion:** Acute ECC and VWR alleviated chronic stress-induced reductions in anti-OVA IgG vaccination responses while neither type of exercise had an impact on anti-OVA IgM or cell-mediated immune responses. Future experiments need to address the mechanism of the exercise beneficial effects on IgG.

Body Composition Assessment in Athletes with Spinal Cord Injury

Claudia Pérez¹, Juan Tejo², Raul Smith³, Fernando Carrasco⁴. ¹Hospital de Carabineros de Chile, Santiago, Chile. ²Centro de Alto Rendimiento de Chile, Santiago, Chile. ³Instituto Teleton, Santiago, Chile. ⁴Universidad de Chile, Santiago, Chile.
 Email: claudiaperezlmd@gmail.com
 (No relationships reported)

PURPOSE: To determine which anthropometric equation used to estimate body composition in athletes with chronic spinal cord injury (SCI) has better concordance with Dual X-ray absorptiometry. **METHODS:** Seventeen male athletes with chronic SCI AIS A or B, participated from this study. Body composition was estimated using two anthropometric equations (Kerr Ross and Durnin Womersley). The evaluation was performed with the athlete in the supine/prone position and seating in their wheel chair. The same day a DEXA scan was performed. Shapiro Wilk test was used

and results were analyzed with student T test, Pearson correlation test and Bland & Altman method. **RESULTS:** The athletes were 30,9 year old (SD: 7,1), they trained 14,5 (SD 7,7) hours a week and averaged 5,4 years of experience in sports. They had 29,5% Fat Mass (FM) (SD: 7,3) and 48,6 (SD: 5,5) kilograms of Free Fat Mass (FFM) measured with DEXA scan. There was no difference between FM and FFM results determined by DEXA scan and those estimated by Kerr Ross Method ($p < 0,001$). There was a significant difference between DEXA scan results and estimations by Durnin Womersley equation ($p > 0,05$). No difference was found when comparing anthropometric results with the athlete in the supine/prone position and seating in their wheel chair. The correlation between FM and FFM measured with DEXA scan and the estimated By anthropometric equation where superior for Kerr Ross method ($r = 0,75$ and $r = 0,86$ respectively). The average difference between DEXA scan results and Kerr Ross method estimation for FM and FFM was: 0,84% (SD= 5.04) and -0,39 kilograms (SD= 3,49) respectively. **CONCLUSIONS:** When using anthropometric evaluation to estimate body composition in athletes with SCI, Kerr Ross method is superior to Durnin Womersley equation. But this method does not have acceptable agreement with DEXA scan for clinical purposes. Anthropometric evaluations are easily performable in the field and affordable, but more research is needed to determine the best method to estimate body composition in athletes with SCI.

Wearable Technology To Reduce Sedentary Behavior And CVD Risk In Older Adults: A Pilot Trial

Lisa M. Roberts¹, Byron C. Jaeger¹, Liliana C. Baptista¹, Sara A. Harper¹, Elizabeth Jackson¹, Anna K. Gardner², Bhanuprasad Sandesara², Todd M. Manini², Stephen D. Anton², Thomas W. Buford¹. ¹University of Alabama at Birmingham, Birmingham, AL. ²University of Florida, Gainesville, FL.
 (No relationships reported)

Older adults account for the vast majority of healthcare expenditures and deaths attributable to cardiovascular disease (CVD). Physical activity (i.e. exercise) is associated with decreased CVD risk, but recent large-scale trials suggest that exercise alone is insufficient to reduce CVD events in high-risk populations of older adults. **PURPOSE:** This pilot randomized clinical trial evaluated the impact of combining structured exercise with an intervention designed to enhance non-exercise physical activity (EX + NEPA) compared to EX alone. **METHODS:** Participants aged ≥ 60 years ($n = 40$) with moderate to high risk of coronary heart disease (CHD) events were randomly assigned to either the EX + NEPA or EX groups and followed for 20 weeks. Both groups underwent a twice weekly, eight-week center-based exercise intervention with aerobic and resistance exercises. The EX + NEPA group also received a mobile activity tracking device along with behavioral monitoring and feedback throughout the study. Study outcomes evaluated at week 20 were: 1) physical activity patterns (steps/day and sedentary time), 2) blood pressure, and 3) circulating indices of cardiovascular risk (blood glucose and triglyceride levels). Linear mixed models estimating group differences were adjusted for age, sex, group, visit, and baseline level of the outcome. Data are presented as mean differences (EX + NEPA relative to EX) with 95% confidence intervals at week 20. **RESULTS:** Relative to EX, the change in steps/day at week 20 was 2,071 [61.07, 4081] for EX + NEPA. For sedentary time (minutes per day) the difference between groups was -31.21 [-168.18, 105.76]. The differences for systolic and diastolic blood pressure were -9.94 [-19.57, -0.31] and -1.77 [-6.89, 3.34] mm Hg, respectively. The difference was 0.70 [-15.90, 17.31] mg/dL for glucose and -5.53 [-58.63, 47.57] mg/dL for triglycerides. **CONCLUSIONS:** The addition of activity tracking technology appeared to positively influence daily activity patterns and directionally favored blood pressure and triglyceride levels. Wearable technology may impact daily habits of older adults and improve risk factors for CHD - although a fully-powered trial is needed to definitely test this hypothesis. Supported by AHA 16IRG27250237, NIA 2P30AG028740, NCMRR 1P2CHD086851, and the UAB Center for Exercise Medicine

Identifying Specific Elements Necessary for a Pediatric Cardiac Rehabilitation Program: An e-Delphi Study

Tracy Curran¹, Susan Duty², Naomi Gauthier¹, Rachelle Pojednic, FACSM². ¹Boston Children's Hospital, Boston, MA. ²Simmons University, Boston, MA.
 Email: tracy.curran@cardio.chboston.org
 (No relationships reported)

Encouraging children and adolescents with congenital heart disease (CHD) to participate in regular exercise is an essential component in helping them rise toward their full potential physically, socially, and emotionally. Identifying appropriate tools and resources that promote healthy and active lifestyles specifically for this population are currently lacking and must be developed. Cardiac rehabilitation programs are an effective modality with beneficial clinical outcomes for adult patients with coronary heart disease, however these programs are scarce for the CHD pediatric population and not well defined.

Purpose: The purpose of this study was to identify relevant content for the development and structure of a pediatric cardiac rehabilitation curriculum for young patients with CHD using a consensus approach.

Methods: A three-round e-Delphi study among CHD and pediatric exercise physiology (EP) experts was conducted. In the first round, experts provided opinions in a closed- and open-ended electronic questionnaire to identify specific elements necessary for inclusion in a Pediatric Cardiac Rehab Program. In the second round, experts were asked to re-rate the same items after feedback and summary data was provided from round one. In the third round, the same experts were asked to re-rate items that did not reach consensus from round two.

Results: 47 experts were contacted via e-mail to participate on the Delphi panel. 37 consented, 35 completed round one, 29 completed round two and 28 completed the final round. After the third round, consensus was reached in 55 of 60 (92%) questionnaire items. Experts identified specific elements across four domains: exercise training, education, outcome metrics and self-confidence to be included in a Pediatric Cardiac Rehab Curriculum.

Conclusion: This study established consensus toward the ideal program structure, exercise training principles, educational content, patient outcome measures and self-confidence promotion. By identifying the key components within each domain, there is potential to benchmark recommended standards and practice guidelines for the development of a Pediatric Cardiac Rehab curriculum to be used healthcare team members for optimizing the health and wellness of pediatric CHD patients.

(No relationships reported)

Low physical activity (PA) levels are implicated in the aetiology of many non-communicable diseases. However research often fails to specifically focus on the impact of physical inactivity on the health of older adults, despite the fact that PA declines and health worsens with age.

PURPOSE: An umbrella review of the epidemiological evidence for the effects of physical inactivity on physical and mental health in older adults (≥ 60 yrs) for the 2019 Copenhagen Consensus Statement on PA and Ageing.

METHODS: Systematic database search for meta-analyses (MA) of longitudinal observational studies. Titles and abstracts were reviewed independently by two researchers. Duplicates were removed and data from included MAs extracted, including relative risk (RR) for health outcomes, characteristics and risk of bias (AMSTAR Scale) of included reviews.

RESULTS: 4,434 citations identified. 17 full text MA were included. Key findings of high quality reviews ($\geq 8/11$ on AMSTAR scale): **All-cause mortality:** 34% RR reduction with highest vs lowest level of PA (≥ 70 yrs, RR=0.66, 95% CI 0.50-0.88) (Samitz et al., 2011); **Healthy ageing** was significantly associated with PA (n=174,114, ≥ 65 yrs, ES=1.14 95% CI 1.07-1.22) (Daskalopoulou et al., 2017); **Cognitive decline:** Moderate vs lowest level of PA=RR reduction ranged from 26% (OR=0.74, 95% CI 0.60-0.90) (Guure et al., 2017) to 35% (HR=0.65, 95% CI 0.57-0.75) (Sofi et al., 2011); **Dementia:** Highest vs lowest level of PA=14% RR reduction (n=40,384, RR=0.86, 95% CI 0.76-0.97) (Blondell et al., 2014); **Alzheimer's disease:** Highest vs lowest level of PA=35% RR reduction (n=23,345, 70-80 yrs, RR=0.65, 95% CI 0.56-0.74) (Santos-Lozano et al., 2016); **Incident depression:** Highest vs lowest level of PA=17% RR reduction (adjusted OR=0.83, 95% CI 0.79-0.88) (Schuch et al., 2018); **Musculoskeletal health:** RR reduction in hip fracture=6% (n=96,966 women, RR=0.94, 95% CI 0.93-0.96) (Rong et al., 2016) and 29% RR reduction in total fractures for highest vs lowest level of PA (RR=0.71, 95% CI 0.63-0.80) (Qu, et al., 2014). Adverse risks were not reported.

CONCLUSION: PA confers contemporaneous and wide ranging health benefits in later life. These findings make a compelling case for further investment in preventive services that promote PA in older adults.

How Does Circadian Rhythmicity Relate to Neuropsychological and Neuroimaging Markers in Older People at Risk for Dementia?

Shantel Duffy, Jonathon Pye, Jake Palmer, Sharon L. Naismith. University of Sydney, Camperdown, Australia.
(No relationships reported)

Background: Changes in the circadian regulation of the sleep-wake cycle occur with ageing and may be linked to neurodegeneration. It is unclear the extent to which such changes are evident in mild cognitive impairment (MCI), and how they may relate to neuropsychological functioning, the integrity of key temporal lobe structures

and longitudinal decline. **Method:** 334 older individuals (mean age=66.1, sd=8.9) with subjective cognitive impairment (SCI) and MCI (mean MMSE=28.1, sd=1.4) received detailed neuropsychological assessment including Logical Memory, Rey Auditory Verbal Learning Test, Rey Figure and Boston Naming Test. They also received clinical and wrist-worn actigraphic assessment, and a subset of 60 individuals underwent neuroimaging. Circadian rhythm analysis was performed using non-parametric methods to obtain intradaily variability, interdaily stability, and activity during the least and most active 5-hours and 10-hours of the day, respectively. Cosinor methods were also used to derive amplitude, mean, and variability of the rest-activity rhythm. For the neuroimaging subset, cortical thickness of the entorhinal cortex and hippocampal volume were derived using Freesurfer. A subset of 90 individuals had 2-year longitudinal follow-up data from which memory decline scores were computed. **Results:** Compared to SCI, after controlling for age, participants with MCI showed significantly greater intradaily variability as well as lower amplitude of activity across the circadian period, and lower activity during the most active 10-hour period. Across both groups, circadian disruption was associated with poorer performance on tests of verbal memory ($p<0.05$), visuospatial memory ($p<0.001$) and confrontation naming ($p<0.001$). Lower activity amplitude was associated with reduced cortical thickness in the entorhinal cortex. For those with follow-up data, greater activity during the least active 5-hours of the day was associated with memory decline longitudinally ($p<0.05$). **Conclusion:** Disruptions to the rest-activity cycle relate to both memory and language decline cross-sectionally and memory decline longitudinally as well as to degeneration of key temporal brain regions. Alterations in this cycle may represent a preclinical or prognostic marker for dementia and may warrant intervention.

Exercise Intervention Reduces Circadian Clock Suppressor, CRY2, in Adults with Obesity

Melissa L. Erickson¹, Hui Zhang², John P. Kirwan, FACSM¹. ¹Pennington Biomedical Research Center, Baton Rouge, LA. ²Case Western Reserve University, Baton Rouge, LA.
Email: melissa.erickson@pbrc.edu
(No relationships reported)

PURPOSE: Exercise improves skeletal muscle insulin sensitivity, and also resets physiological circadian clocks. CRY2, a circadian clock suppressor, reduces exercise capacity in mouse models. Whether exercise impacts CRY2 in humans is unknown. Thus, we tested the effects of 12 weeks of exercise training on circulating CRY2 concentrations in adults with obesity. Secondly, we assessed whether these changes were related to improvements in insulin sensitivity. **METHODS:** Thirteen adults (Age: 64.4 \pm 13.7, BMI: 35.9 \pm 5.1) participated in 12 weeks of exercise training (5 day/wk, 60 min/session, 85% HRmax) combined with a eucaloric diet. Body composition (abdominal adiposity using computed tomography), insulin sensitivity (glucose disposal rate from euglycemic-hyperinsulinemic clamp), exercise capacity (VO_{2max}), and circulating CRY2 levels measured by ELISA were assessed before and after intervention. **RESULTS:** Body composition (BMI, abdominal adiposity), insulin sensitivity, and exercise capacity all improved (all $P > 0.05$). CRY2 levels decreased after intervention (Pre: 12.2 \pm 2.1; Post: 10.1 \pm 2.3 ng/mL; $P=0.001$). Baseline CRY2 inversely correlated with baseline fat-free mass ($r=-0.56$, $P=0.046$) and baseline insulin sensitivity ($r=-0.61$, $P=0.038$). **CONCLUSION:** We show for the first time that exercise training reduces circulating levels of CRY2, a circadian clock suppressor, in adults with obesity, which was accompanied by increased insulin sensitivity and improved body composition. Direct links between exercise-induced changes in circadian clock function and parallel systemic metabolic improvements are worthy of further investigation.

Email: contato@alexandrelevangelista.com.br
(No relationships reported)

PURPOSE: To investigate the effects of different resistance training (RT) zones with equalized volumes on muscular adaptations. **METHODS:** Thirty-one volunteers underwent 8 weeks of RT and were distributed in two groups: ten sets of three maximal

repetitions (10x3, n=14) and three sets of ten maximal repetitions (3x10, n=17). The biceps curl, squat and elbow extension exercise were performed twice a week. The maximum strength (one repetition maximum test-1RM) was tested before and after the study for these exercises. Muscle thickness (MT) was also measured (pre x post) for biceps braquii (BB), triceps braquii (TB) and vastus lateralis (VL). RESULTS: As showed in Table 1, a significant main effect (p=0.001) on time in 1RMbiceps curl, 1RMsquat and 1RMelbow extension was observed for both groups. There was no significant difference in time x group interaction for 1RMbiceps curl, 1RMsquat and 1RMelbow extension (all p>0.05). A significant main effect (p=0.001) in time was observed in MT for BB, TB and VL. There was no significant difference in time x group interaction for BB, TB and VL (all p>0.05). CONCLUSION: The present study suggests that, regardless of the number of sets and maximum repetition zone, the improvement of maximum strength in squatting, elbow flexion and extension, as well as biceps, triceps and vastus lateralis muscle thickness occurs similarly when volume of repetitions is equalized.

KEY WORDS: Resistance training; Muscular adaptations; Volume of training

Table 1. Muscle strength and muscle thickness measures after 8 weeks of training.
