(No relevant relationships reported)

While data have demonstrated that resistance exercise without blood flow restriction (BFR) decreases vagal tone up to 30 minutes, the effects of upper- versus lower-body resistance exercise with BFR on autonomic modulation are unknown. **PURPOSE:** To evaluate autonomic modulation in response to upper- and lower-body resistance exercise with BFR. **METHODS:** Autonomic modulation was assessed in twenty resistance-trained individuals at rest, 30 (R30), and 60 (R60) minutes after either upper- or lower-body resistance exercise with or without BFR. The upper- and lower-body resistance exercise consisted of the lat pulldown and chest press, and knee extension and knee flexion, respectively. The BFR (40% of arterial occlusion pressure) and without BFR conditions consisted of 4 sets of 30, 15, 15, and 15 repetitions at 30% 1-repetition maximum (1RM), and 4 sets of 8 repetitions at 70% 1RM, respectively. Autonomic modulation was expressed as natural logarithm (Ln), and included total power (LnTP), high frequency power (LnHF), and sympathovagal balance (LnLF/LnHF ratio). An ANOVA was used to evaluate groups (upper- or lower-body) across conditions (BFR or without BFR) across time (Rest, R30, and R60) on autonomic modulation. **RESULTS:** There were no significant 3-way interactions for any variables. There were no changes for LnTP. There were significant main effects of time for LnHF (Upper-body with BFR (UBFR): Rest: 7.3±1.6ms², R30: 6.3±1.6ms², R60: 6.7±1.5ms²; Upper-body without BFR (UW): Rest: 7.1±1.4ms², R30: 6.1±1.5ms², R60: 6.5±1.3ms²; Lower-body with BFR (LBFR): Rest: 6.9±1.3ms², R30: 6.2±1.6ms², R60: 7.1±1.4ms²; Lower-body without BFR (LW): Rest: 7.3±1.5ms², R30: 6.3±1.8ms², R60: 7.1±1.4ms²) and the LnLF/LnHF ratio (UBFR: Rest: 3.9±0.9ms², R30: 5.1±10.9ms², R60: 4.8±1.0ms²; UW: Rest: 3.7±1.0ms², R30: 4.9±0.8ms², R60: 4.8±0.7ms²; LBFR: Rest: 4.0±1.0ms², R30: 4.8±1.1ms², R60: 4.5±1.0ms²; LW: Rest: 3.9±1.0ms², R30: 5.0±0.9ms², R60: 4.65±0.84ms²) such that LnHF and LnLF/HF ratio were significantly reduced, and augmented, after upper- and lower-body resistance exercise with and without BFR. **CONCLUSIONS:** These data suggest that either upper- or lower-body resistance exercise with or without BFR significantly alters autonomic modulation up to 60 minutes after an acute bout of resistance exercise.

(No relevant relationships reported)

Purpose: The aim of this study was to evaluate the influence of CVD on cerebrovascular regulation at rest and during exercise. A secondary aim was to explore the relationship between cerebrovascular regulation and 1) the presence of white matter lesions and 2) cognitive function. **Methods:** We recruited individuals who were cognitively normal older adults. CVD risk was assessed by the Pooled Cohort atherosclerotic cardiovascular disease (ASCVD) risk score. Transcranial Doppler ultrasound measured middle cerebral artery at rest and during a bout of moderate intensity exercise. We quantified white matter lesions from MRI and cognitive function outcomes included executive function, language, processing speed, and attention. **Summary of Results:** Seventy-two participants 70.1 ± 4.7 years of age completed the study protocol. ASCVD risk score was significantly associated with both resting and exercise

cerebral blood flow velocity (p<0.01). Cerebrovascular regulation parameters were not associated with white matter lesions (p>0.468). We observed a significant association between cerebrovascular regulation parameters and language processing (p=0.010) but not other cognitive domains. **Conclusion:** In cognitively normal older adults, higher ASCVD risk score was associated with blunted cerebrovascular regulation and with lower language processing performance. These results highlight the need for CVD risk management to maintain optimal brain health.

(No relevant relationships reported)

PURPOSE: Observing little-to-no increase in arterial-venous oxygen difference (a-vo₂diff) following endurance training, some previous investigations have attributed little importance to factors peripheral to the heart, such as maximal mitochondrial oxygen consumption (V_{mito}VO₂max) and convective (Q_mO₂) and diffusive (D_mO₂) muscle oxygen delivery in the training-induced increase in VO₂max. As lack of change in a-vo₂diff does not necessarily indicate a lack of change in peripheral function, the purpose of this study was to determine the combined influences of adaptations peripheral to the heart in the endurance-training-associated increase in VO₂max. **METHODS:** Arterial-venous blood draws and Doppler ultrasound during maximal single leg knee extension (KE) exercise were used to quantify Q_mO₂, D_mO₂, a-vo₂diff and KE VO₂max when free of upstream limitations from the heart in 10 untrained and 10 trained young males. Mitochondrial respiration of muscle biopsied from the vastus lateralis was used to quantify V_{mito}VO₂max when free from upstream oxygen supply limitations. **RESULTS:** In agreement with previous investigations, Q_mO₂ and KE VO₂max were 20-35% greater in the trained (P<0.05), while a-vo₂diff was not markedly different (P>0.05, See Figures A-C). Nevertheless, training was associated with a 50-100%

WEDNESDAY, MAY 29, 2019

increases in $D_m O_2$ and $\dot{V}O_{2max}$, ($P < 0.05$). When plotted as a Wagner diagram (Figure D), it becomes clear that the greater $\dot{V}O_{2max}$ in the trained is the result of 3 synergistic adaptations (1. increased $\dot{V}O_{2max}$, 2. increased $Q_m O_2$ and 3. enhanced $D_m O_2$), which, together, raise $\dot{V}O_{2max}$ more than each adaptation would alone.

CONCLUSIONS: Despite minimal changes in $a-v O_2$ diff, the training-associated increase in $\dot{V}O_{2max}$ is dependent upon specific peripheral factors within the muscle exhibiting a greater capacity, including mitochondrial respiratory capacity, as well as convective and diffusive muscle oxygen delivery.

Autonomic Modulation After High-Intensity Heavy Rope Exercise in Resistance-trained Individuals

Erica M. Marshall, Jason C. Parks, Tyler J. Singer, Stacie M. Humm, J. Derek Kingsley, FACSM. *Kent State University, Kent, OH.* (Sponsor: J. Derek Kingsley, FACSM)

(No relevant relationships reported)

The changes in autonomic modulation after high-intensity heavy rope exercise (HI-HRE) are unknown. **PURPOSE:** To examine the effects of HI-HRE on autonomic modulation in resistance-trained (RT) individuals. **METHODS:** Twenty-two young, RT individuals (mean±SD: age 23±3yrs; height 1.7±0.1m; weight: 74.3±14.9kg) had their heart rate (HR), mean arterial pressure (MAP), and measures of autonomic modulation collected at rest, and 15 (Rec1), 30 (Rec2) and 60 (Rec3) minutes following HI-HRE. Heart rate variability measurements included the root mean square of successive differences between normal heartbeats (RMSSD) in the time domain, high-frequency power (lnHF) and the ratio of low-frequency to high-frequency power (lnLF/lnHF ratio) in the frequency domain. RMSSD and lnHF are indicative of vagal modulation while the lnLF/lnHF ratio is a measure of sympathovagal balance. The HI-HRE consisted of six, 15-second exercise bouts, using a double wave pattern, separated by 30-seconds of passive recovery; the pace of the exercise was set at 180bpm. A one-way repeated measures analysis of variance was used to analyze the effects of HI-HRE across time (rest, Rec1, Rec2, and Rec3). Significant main effects were analyzed using pairwise comparisons with a Bonferroni correction. **RESULTS:** There was a significant main effect of time ($p \leq 0.001$) for HR (rest: 63±10bpm; Rec1: 84±10bpm; Rec2: 76±9bpm; Rec3: 70±8bpm), such that it was augmented during all recoveries compared to rest. There was a significant main effect of time ($p = 0.04$) for MAP (rest: 82.3±4.5mmHg; Rec1: 81.2±4.9mmHg; Rec2: 83.1±114.5mmHg; Rec3: 70±7mmHg), such that it was attenuated during all recoveries compared to rest. There were significant main effects of time ($p \leq 0.001$) for the RMSSD (rest: 4.2±0.69ms; Rec1: 2.8±0.6ms; Rec2: 3.1±0.63ms; Rec3: 3.6±0.5ms) and the lnHF (rest: 7.4±1ms²; Rec1: 4.7±1.2ms²; Rec2: 5.5±1.1ms²; Rec3: 6.3±0.91ms²), such that they were decreased during all recoveries compared to rest. There was a significant ($p \leq 0.001$) main effect of time for the lnLF/lnHF ratio (rest: 0.9±0.1; Rec1: 1.2±0.2; Rec2: 1.1±0.2; Rec3: 1±0.1), such that it was augmented during all recoveries compared to rest. **CONCLUSION:** These data demonstrate that high-intensity heavy rope exerciseresults in significant decreases in vagal modulation for at least 60 minutes.

Effects Of Matched Intermittent Versus Continuous Exercises On The Changes Of Cardiac Biomarkers

Feifei LI¹, Will Hopkins², Nie Jinlei³, Longyan Yi⁴. ¹Hebei Normal University, Shijiazhuang, China. ²Victoria University, Melbourne, Australia. ³Macao Polytechnic Institute, Macao, China. ⁴Beijing Sport University, Beijing, China.

Email: lifeifei.daisy@hotmail.com

(No relevant relationships reported)

PURPOSE: Endurance runners training with high-intensity intermittent exercise might experience damage to cardiac muscle. We have therefore compared the changes of cardiac biomarkers after workload-matched intermittent and continuous exercise in such runners.

METHODS: Twelve endurance runners (11 males, 1 female; age, 23.5±5.5 y; $\dot{V}O_{2max}$, 62.4±5.4 ml.kg⁻¹.min⁻¹; velocity of $\dot{V}O_{2max}$ [$v\dot{V}O_{2max}$], 17.1±1.4 km.h⁻¹; training volume, 44 ± 25 km.wk⁻¹) completed intermittent and continuous exercise trials in random order. Intermittent exercise consisted of hard running at 90% $v\dot{V}O_{2max}$ for 2 min followed by easy running at 50% $v\dot{V}O_{2max}$ for 2 min, repeated for 92 min in total. The continuous run was performed at 70% $v\dot{V}O_{2max}$ for 92 min. Blood samples were drawn before exercise and at 0, 2, 4, 24 and 48 h after the completion of exercise for assay of various cardiac biomarkers. Changes in concentration of each biomarker were averaged over 0-24 h for comparison of intermittent with continuous exercise after adjustment for baseline concentration and exercise intensity expressed as percent of heart-rate reserve (%HRR).

RESULTS: There were trivial differences between the changes in concentration adjusted to the mean intensity of 78%HRR for all biomarkers investigated, but at 85%HRR high-sensitivity cardiac troponin-I and high-sensitivity cardiac troponin-T were moderately higher following intermittent exercise (factor mean change \times/\pm 90% confidence limits: 3.4 \times/\pm 1.9 and 2.1 \times/\pm 1.8 respectively). Changes in other cardiac biomarkers at 85%HRR were trivial.

CONCLUSIONS: Prolonged intermittent exercise is potentially more damaging to heart muscle than continuous exercise of the same average running speed at higher average heart rates.

Exercise Tolerance: New Insights From Single-leg Cycling Exercise

Danilo Iannetta, Ahmad Qahtani, Louis Passfield, Martin MacInnis, Juan M. Murias. *University of Calgary, Calgary, AB, Canada.*

Email: danilo.iannetta@ucalgary.ca

(No relevant relationships reported)

The biological factors determining the maximal exercise capacity are typically assessed during whole-body exercise (e.g. double-leg cycling), implicitly assuming that limbs contribute homogeneously to exercise tolerance. However, given the presence of limb dominance, it is possible that the dominant leg may achieve greater peak O_2 uptake ($\dot{V}O_{2peak}$) and be able to sustain greater power outputs during prolonged dynamic exercise compared to the non-dominant leg.

PURPOSE: To investigate peak power output (PPO), $\dot{V}O_{2peak}$, and maximal lactate steady-state (MLSS) during double-leg as well as during dominant and non-dominant and counter-weighted single-leg cycling exercise performed with the dominant and non-dominant legs. **METHODS:** Twelve men (30 ± 5 yrs) during 12 to 14 lab visits performed: (i) a ramp-incremental test to determine PPO, $\dot{V}O_{2peak}$, and maximal O_2 extraction; and (ii) 30-min constant-load tests to determine MLSS. These tests were performed using both legs (DBL), the dominant leg only (SLd), and the non-dominant leg only (SLnd). Gas exchange variables were measured with a metabolic cart; local de-oxygenation ([HHb]) of the vastus lateralis (VL) was measured using a frequency-domain NIRS; capillary blood samples were analysed for lactate concentration ([Lac]). **RESULTS:** PPO for DBL, SLd, and SLnd was different in each condition: 329 ± 38, 181 ± 30, 168 ± 27 W, respectively ($p < 0.05$). $\dot{V}O_{2peak}$ for DBL, SLd, and SLnd was different in each condition: 3.43 ± 0.34, 2.92 ± 0.42, 2.74 ± 0.38 L.min⁻¹, respectively ($p < 0.05$). The [HHb] amplitude of the VL was greater in the dominant compared to the non-dominant leg during both DBL (18.6 ± 8.5 vs 15.4 ± 9.5 mMol) and SL (15.4 ± 9.5 vs 11.6 ± 7.7 mMol) ramp-exercise ($p < 0.05$). These amplitudes were highly correlated with the $\dot{V}O_{2peak}$ values observed during DBL dominant and non-dominant ($r = 0.86$ and $r = 0.91$, respectively), SLd ($r = 0.79$), and SLnd ($r = 0.71$) RI tests ($p < 0.05$). The PO at MLSS for DBL, SLd, and SLnd was different in each condition: 183 ± 32, 119 ± 25, and 111 ± 24 W, respectively ($p < 0.05$). The $\dot{V}O_{2}$, [Lac], and RPE values during SLnd and SLd were similar ($p > 0.05$) despite this lower PO. **CONCLUSIONS:** These data indicate a heterogeneous exercise capacity of the exercising limbs that should be considered when evaluating exercise tolerance during double-leg exercise.

67 Board #7 May 29 9:30 AM - 11:30 AM

Despite Menstrual Phase Differences in Respiration, Blood Lactate, and Muscle Deoxygenation, Exercise Performance is UnchangedJordyn Smith, Glen R. Belfry. *Western University, London, ON, Canada.*

Email: jsmit577@uwo.ca

(No relevant relationships reported)

PURPOSE: Fluctuations of ovarian hormones over the menstrual cycle result in changes in cardiorespiratory and metabolic responses that may affect exercise performance. The purpose of this study is to evaluate respiration, muscle deoxygenation ($\Delta\%[\text{HHb}]$) and arterialised blood lactate $[\text{La}^-]$ throughout incremental (RAMP) and constant load exercise performance (EP) during follicular (FOL) and luteal (LUT) phases.

METHODS: Ten eumenorrheic females (22 yrs \pm 1.4; 167 \pm 7 cm; 64 \pm 8 kg) completed RAMP (20 W/min) and EP (@ 101% $\text{VO}_{2\text{max}}$) to limit of tolerance during both FOL and LUT phases. Breath-by-breath measures of gas exchange and vastus lateralis muscle deoxygenation were recorded throughout.

RESULTS: RAMP: FOL and LUT maximal oxygen uptake ($\text{VO}_{2\text{max}}$) (FOL: 2.36 \pm 0.4 $\text{L}\cdot\text{min}^{-1}$; LUT: 2.36 \pm 0.4 $\text{L}\cdot\text{min}^{-1}$), ventilation (V_E) (FOL: 53.2 \pm 25 $\text{L}\cdot\text{min}^{-1}$; LUT: 55.1 \pm 25 $\text{L}\cdot\text{min}^{-1}$), and $\Delta\%[\text{HHb}]$ (FOL: 60 \pm 3%; LUT: 57 \pm 3%) were unchanged ($p > 0.05$).

However, $\Delta\%[\text{HHb}]/\Delta\text{VO}_2$ was 65% lower in LUT compared to FOL below lactate threshold (GET) ($p < 0.05$). $\text{P}_{\text{ET}}\text{CO}_2$ values were lower in LUT compared to FOL (FOL: 37 \pm 2 mmHg; LUT: 36 \pm 3 mmHg) ($p < 0.01$), whereas $\text{P}_{\text{ET}}\text{O}_2$ values remained unchanged (FOL: 105 \pm 6 mmHg; LUT: 107 \pm 6 mmHg) ($p > 0.05$). **EP:** V_E (FOL: 83 \pm 19 $\text{L}\cdot\text{min}^{-1}$; LUT: 89 \pm 17 $\text{L}\cdot\text{min}^{-1}$) and $\text{P}_{\text{ET}}\text{O}_2$ (FOL: 115 \pm 4 mmHg; LUT: 118 \pm 4 mmHg) were greater in LUT compared to FOL ($p < 0.05$), without changes in breathing frequency (FOL: 32 \pm 4 $\text{L}\cdot\text{min}^{-1}$; LUT: 35 \pm 5 $\text{L}\cdot\text{min}^{-1}$) ($p > 0.05$). No differences in $\%[\text{HHb}]$ were observed between LUT and FOL (FOL: 83 \pm 21%; LUT: 85 \pm 21%); however, $\Delta\%[\text{HHb}]/\Delta\text{VO}_2$ was 18% lower during the kinetic phase of the EP in LUT compared to FOL ($p < 0.05$). Post-EP $[\text{La}^-]$ were lower in LUT compared to FOL (FOL: 12.9 \pm 2.5 $\text{mmol}\cdot\text{L}^{-1}$; LUT: 11.7 \pm 1.7 $\text{mmol}\cdot\text{L}^{-1}$) ($p < 0.05$). No performance differences were

observed between FOL and LUT for RAMP peak power (FOL: 218 \pm 35 W; LUT: 221 \pm 29 W) or EP endurance (FOL: 99 \pm 20 s; LUT: 96 \pm 15 s) ($p > 0.05$).

CONCLUSION: During RAMP exercise, there was a greater reliance on muscle deoxygenation at sub-GET work rates in FOL compared to LUT. During EP, the LUT phase showed higher V_E , lower Post-EP $[\text{La}^-]$, and lower muscle deoxygenation during the kinetic portion of the step exercise, suggesting increased ventilatory buffering compared to FOL. Despite the different physiological responses between menstrual phases, short duration exercise performance is preserved.

68 Board #8 May 29 9:30 AM - 11:30 AM

Effect Of Ultra-endurance Exercise On Alveolar-Capillary Recruitment And Lung DiffusionGlenn Stewart¹, Caitlin Jorgenson¹, Courtney Wheatley¹, Paul Robach², Alice Gavel², Briana Ziegler¹, Jesse Schwartz¹, Bryan Taylor³, Loïc Chabridon², Pierre Bouzat⁴, Bruce Johnson¹. ¹Mayo Clinic, Rochester, MN. ²Ecole Nationale de Sports de Montagne, Chamonix, France. ³University of Leeds, Leeds, United Kingdom. ⁴Grenoble University Hospital, Grenoble, France.

Email: stewart.glenn@mayo.edu

(No relevant relationships reported)

Purpose—Prolonged vigorous exercise increases cardiac output and pulmonary arterial and capillary pressures to levels that may exceed a tolerable right ventricular and alveolar-capillary load. Accordingly, this study examined the effect of an ultramarathon on resting and exertional measures of alveolar-capillary recruitment & lung diffusion. **Methods**—Cardiac and lung function were examined at rest & during 3 stages of low-intensity exercise in 44 runners (Age: 41 \pm 9 yr BMI: 23 \pm 2 kg/m^2) before, and 1-4-h and 24-h after the Hong Kong 100 and Ultra Trail Mont Blanc ultramarathons. Cardiac biomarkers (cTnI, BNP) were assessed from whole blood (I-stat), while stroke volume (SV) & cardiac output (Q) were quantified via echocardiography. Lung diffusing capacity for carbon monoxide and nitric oxide (DLco & DLno) and its components, alveolar membrane conductance (Dm) and capillary blood volume (Vc), were determined via a single-breath DLco/DLno method.

Results—Participants finished the ultramarathons in 22 \pm 11 h with an average heart rate of 130 \pm 14 bpm. Cardiac biomarkers increased after the race (cTnI: 0.03 \pm 0.01 vs 0.09 \pm 0.02 ng/ml; BNP: 18 \pm 2 vs 129 \pm 14 pg/ml, p 's < 0.01). Stroke volume decreased post-race at rest (86 \pm 2 vs 74 \pm 2 ml, $p < 0.01$) & during exercise (Stage3: 99 \pm 2 vs 92 \pm 3 ml, $p < 0.01$), while cardiac output was similar pre and post-race (Rest: 4.6 \pm 0.1 vs 4.9 \pm 0.2, $p = 0.20$; Stage3: 8.7 \pm 0.3 vs 8.8 \pm 0.3, $p = 0.61$). Resting DLco, DLno & Vc decreased post-race, while Dm was unchanged. On the contrary, DLco, DLno and Dm were reduced during low intensity exercise post-race, while Vc normalized to pre-race values. When corrected for Q, DLco was lower at rest (DLco/Q: 7.1 \pm 0.2

vs 5.7 \pm 0.2, $p < 0.01$), but normalized to pre-race values during exertion (stage3 DLco/Q: 4.0 \pm 0.1 vs 3.8 \pm 0.2, $p = 0.31$). All values returned to baseline after 24-h of recovery. **Conclusions**—The data suggests a transient decrease in lung diffusion at rest following ultra-endurance exercise is related to a reduced capillary blood volume and potential pulmonary de-recruitment; however, pulmonary capillary recruitment during low-intensity exercise remains mostly preserved. On the contrary, alveolar membrane conductance was preserved at rest but reduced during light exercise and may contribute to the exertional decrease in lung diffusion after an ultramarathon.

Effects Of A 16-week Aerobic And Resistance Exercise Intervention On Leptin/adiponectin Ratio In Overweight And Obese Breast Cancer SurvivorsKaylie Zapanta, Kyuwan Lee, Nathalie Sami, Christina M. Dieli-Conwright, FACSM. *University of Southern California, Los Angeles, CA.*

Email: kzapanta@usc.edu

(No relevant relationships reported)

INTRODUCTION: Overweight and obese breast cancer survivors (BCS) are at greater risk of developing type II diabetes (T2D) than non-cancer populations due, in part, from adipose tissue-induced modulations to the adipokines, leptin and adiponectin. Leptin upregulates inflammatory cytokines associated with insulin resistance (IR) while adiponectin inhibits inflammation and regulates glucose uptake. The Leptin/Adiponectin Ratio (LAR) has been used as an indicator for the diagnosis of T2D, due to its ability to measure both inflammatory and glucose abnormalities. In overweight and obese BCS, an elevated LAR induces IR, which contributes to the development of T2D. Exercise may be an effective strategy to reduce the LAR to target the risk of T2D in BCS. **OBJECTIVES:** The purpose of this study was to determine whether a 16-week aerobic and resistance exercise intervention reduces the LAR in overweight and obese BCS. **METHODS:** Sedentary, overweight/obese (BMI \geq 25 kg/m^2) BCS (Stage I-III) were randomized to the Exercise (EX; n=50) or Control (CON; n=50) groups. The EX group underwent supervised moderate-vigorous intensity aerobic and resistance exercise sessions 3 times per week for 16 weeks. Leptin and adiponectin were measured from fasting blood samples using enzyme-linked immunoabsorbant assays. Paired t-tests and mixed-model repeated measures ANOVA were used to examine the within and between group differences in mean changes in LAR. **RESULTS:** On average, women were 53.5 \pm 10.4 years old, postmenopausal (60%), Hispanic (55%) with a BMI 33.5 \pm 5.5 kg/m^2 . Post-intervention, leptin was significantly reduced (-8.0 ng/mL \pm 0.3) in the EX group compared to CON group (+4.8 ng/mL \pm 0.5; $p = 0.001$). Adiponectin was significantly increased (+7.5 $\mu\text{g}/\text{dL} \pm 1.0$) in EX group compared to CON group (-1 ng/mL \pm 0.3; $p = 0.001$). Post-intervention, LAR was significantly reduced (-1.23 \pm 0.21) in the EX group compared to CON (0.66 \pm 0.11; $p < 0.01$). There was a significant increase in LAR in the CON group ($P < 0.01$). **CONCLUSION:** A 16-week aerobic and resistance exercise intervention is an effective approach to reduce the LAR in overweight and obese BCS. This finding supports the utilization of exercise to reduce the risk of T2D following the completion of cancer treatment in overweight and obese BCS.

 Email: kelcey.bland@acu.edu.au
 (No relevant relationships reported)

Chemotherapy for breast cancer may result in fatigue and reduced quality of life (QOL). While exercise can attenuate adverse chemotherapy effects, improvements relative to baseline may be more likely with exercise performed post-treatment. **PURPOSE:** To compare the effect of exercise during versus after taxane chemotherapy for breast cancer on fatigue and QOL. **METHODS:** Women were randomized to supervised aerobic and resistance exercise 3x/wk for 8-12 wk starting pre-chemotherapy (Immediate Exercise=IE) or 2-3 wk post-chemotherapy (Delayed Exercise=DE). Fatigue and overall QOL/functional subscales were evaluated using the Piper Fatigue Scale (0=none, 10=severe) and European Organization for Research and Treatment of Cancer Quality of Life Questionnaire (scored: 0-100), respectively, at: 1) baseline; 2) 2-3 wk post-chemotherapy (post-chemo); and 3) 10-15 wk post-chemotherapy (follow-up). **RESULTS:** Overall, n=27 women enrolled and n=26 (IE n=12, DE n=14) completed the intervention (attended >1 session). Attendance was 79±23% for IE and 81±20% for DE. Fatigue did not differ between groups across time, so change within groups was assessed individually. Fatigue increased in DE from baseline to post-chemo (mean diff: +1.7±0.47, p=0.01) and did not decrease with exercise between post-chemo and follow-up (mean diff: -1.1±0.65, p=0.13). Fatigue did not change over time in IE. Overall QOL differed between groups over time (p<0.01), where it was higher in IE versus DE post-chemo (mean diff: +6.2±3.0, p<0.05). No other group differences were found for QOL/functional subscales. The overall deterioration in QOL in DE during chemotherapy was a result of reductions in physical function (mean diff: -16.4±5.6, p<0.01), role function (mean diff: -20.0±6.3, p<0.05), cognitive function (mean diff: -16.0±5.8, p=0.01) and social function (mean diff: -17.4±7.4, p=0.04). Relative to post-chemo, the DE intervention significantly improved QOL by follow-up (mean diff: +20.2±5.4, p<0.01), such that DE and IE QOL did not differ at follow-up (mean diff: 4.6±3.7, p=0.22). **CONCLUSIONS:** Exercise during taxane chemotherapy may mitigate treatment-related fatigue and reductions in QOL in women with breast cancer. While exercise after chemotherapy increased overall QOL, fatigue experienced during chemotherapy persisted.

 (No relevant relationships reported)

It is unclear whether women at risk of breast cancer-related lymphoedema can safely participate in heavy-load resistance exercise.

PURPOSE

To evaluate the effect of heavy-load resistance exercise on lymphedema outcomes in pre-diagnosis physically inactive women at risk of breast cancer-related lymphedema during adjuvant chemotherapy.

METHODS

Physically inactive women receiving anthracycline and taxane-based chemotherapy for breast cancer (n=153) were randomized to a HIGH (supervised multimodal exercise including heavy-load resistance exercise: 85-90% 1 repetition maximum [RM], three sets of 5-8 repetitions) versus LOW (walking supported by pedometer and one-on-one consultations) 12-week exercise intervention.

Outcomes (assessed at baseline, 12- and 39-weeks follow-up) included lymphedema status (extracellular fluid [L-Dex, bioimpedance spectroscopy] and inter-arm volume % difference [dual energy X-ray absorptiometry]), lymphedema symptoms [numeric rating scale 0-10]), upper-extremity strength (1 RM), and quality of life domains (EORTC breast cancer specific questionnaire). Linear mixed models were used

to evaluate equivalence between groups for lymphedema outcomes (equivalence margins for L-Dex, % difference and symptoms scale: ±5, ±3% and ±1, respectively). Superiority analysis was conducted for muscle strength and quality of life domains.

RESULTS
 Post-intervention equivalence between groups was found for extracellular fluid (0.4; 90% CI -2.5 to 3.2) and symptoms of heaviness (-0.2; -0.6 to 0.2), tightness (-0.1; -0.8 to 0.6) and swelling (0.2; -0.4 to 0.8). Non-equivalence was found for inter-arm volume % difference (-3.5%; -17.3 to 10.3) and pain (-0.7; -1.3 to 0), favoring the HIGH group. Strength gains were superior in the HIGH versus LOW group (3 kg; 1 to 5, p<0.05). Further, clinically relevant reductions in breast (-11; -15 to -7) and arm (-6; -10 to -1) symptoms were found in the HIGH group.

CONCLUSION
 Findings suggest that pre-diagnosis physically inactive women can benefit from supervised heavy-load resistance exercise during adjuvant chemotherapy for breast cancer without increasing lymphedema risk.

A Randomised Clinical Trial Of 'Prehabilitation' High Intensity Interval Training (HIIT) Before Urological Cancer Surgery
 James EM Blackwell, Matthew S. Brook, Brett Doleman, Alistair Morton, John P. Williams, Jonathan N. Lund, Bethan E. Phillips. University of Nottingham, Nottingham, United Kingdom. (Sponsor: Professor Craig Sale, FACSM)
 Email: james.blackwell@nhs.net
 (No relevant relationships reported)

PURPOSE: Operations for urological malignancy are increasing in number and complexity due to the advancing age of patients with multiple comorbidities. Low pre-operative cardiorespiratory fitness (CRF) and muscle mass, are both associated with increased peri-operative morbidity and mortality, as well as poorer post-operative outcomes and delayed return normal activities. High intensity interval training (HIIT) may represent an efficacious training modality to rapidly improve CRF and body composition in the short clinically-dictated time-frame between diagnosis and surgery.

METHODS: Forty patients (mean: 71 years, 98% male) were recruited at diagnosis of urological cancer. Patients providing written informed consent were to randomisation to either HIIT prehabilitation ((HIIT): 12 sessions of 5 x 1-min exertions, 3 sessions/week) or usual care (control (CON)). Patients underwent cardiopulmonary exercise testing (CPET), dual-energy X-ray absorptiometry (DXA) scans and muscle architecture assessments using B-mode ultrasonography before and after a 28-day intervention period. *Vastus lateralis* (VL) muscle biopsies were also taken at both time-points. Statistical analysis, using ANCOVA, compared the effects of HIIT versus CON.

RESULTS: HIIT elicited a clinically significant improvement in CPET-derived measures of anaerobic threshold (2.16 ml/kg/min (95% CI: 0.24 to 4.08), VO_{2PEAK} (2.26 ml/kg/min (95% CI: 1.25 to 3.26) and wattage at failure (12.86 W (95% CI: 5.52 to 20.19) vs. CON. Resting blood pressure (BP) decreased (vs. CON) with HIIT (systolic: -8.2 mmHg (95% CI -16.1 to -0.3), diastolic: -6.5 mmHg (95% CI -12 to -0.4)). There were no differences in whole-body composition changes between the groups, despite HIIT eliciting preferential gains in VL muscle thickness 0.22 mm (95% CI 0.02 to 0.41) and pennation angle 2.49 degrees (95% CI 0.42 to 4.55). HIIT was well-tolerated and safely delivered within this cohort.

CONCLUSIONS: CRF, BP and muscle architecture parameters can be significantly improved with 4 weeks low-volume HIIT in urological cancer patients awaiting surgery. Mass-spectrometry analysis of muscle biopsies from this patient cohort will help elucidate the relative contribution of changes in mitochondrial and/or myofibrillar muscle protein metabolism in achieving these gains.

Exercise is a potential mechanism for mitigating some side effects caused by androgen deprivation therapy (ADT) for metastatic castration-resistant prostate cancer (mCRPC)

and home-based interventions may help eliminate barriers to physical activity.

PURPOSE: To assess feasibility, adherence, and physiological changes following a home-based exercise intervention in men with mCRPC receiving ADT and androgen receptor targeting agents. **METHODS:** Men with mCRPC (age=71y ± 10, BMI=29.64 kg/m² ± 3.4) completed body composition (DXA), muscular strength, physical function, and cardiopulmonary exercise testing (CPET) before and after a 12-week home-based exercise intervention (with weekly phone contact) using resistance band and wearable technology for tracking walking. Patient reported outcomes were used for the assessment of fatigue (FACIT-Fatigue), quality of life (FACT-P) and depression (Hospital Anxiety and Depression Scale). Feasibility (target: 67%) was determined as the % of patients who completed the intervention. Adherence (target: 75%) to the overall program and specific activities was determined as the number completed relative to prescribed. Physiological changes were assessed using paired samples t-tests and adherence rates with a single sample t-test. **RESULTS:** Fourteen men completed baseline testing and eight completed the intervention (57%), which was lower than the target value. Adherence was reached but did not statistically exceed the target value of 75% for overall (82.7% ± 9.5; p=0.076), walking (80.7% ± 14.2; p=0.326), or resistance training (85.3% ± 12.5; p=0.072). Core focused exercises had significantly lower adherence (58% ± 35.7; p<0.001). Training significantly increased leg press maximal strength (10.7% ± 6.7, p=0.023) and peak oxygen consumption (9.7% ± 22.4%, p=0.013). No significant difference occurred in any other variable tested. **CONCLUSIONS:** Feasibility estimates were lower than expected but the high adherence promoted improvements in strength and cardiorespiratory function during mCRPC treatment but did not translate into functional improvements. These preliminary findings suggest home-based interventions are promising, but limited supervision or advanced disease may limit completion of training protocol.

(No relevant relationships reported)

Traditionally, exercise interventions to improve recovery in prostate cancer patients following prostatectomy were limited to the post-surgical period with exercise protocols focusing on the pelvic floor muscles. However, emerging evidence indicates that a more opportune time to intervene to reduce the adverse effects of surgery and length of hospitalisation is the pre-operative period. **PURPOSE:** To evaluate the efficacy of exercise undertaken before surgery to enhance pre-surgical physical function and body composition, and improve recovery from surgery. **METHODS:** Twenty-two men with localised prostate cancer aged 50-73 years scheduled for surgery were randomised to exercise (EX = 12) or usual care (UC = 10). EX underwent a supervised 6-week progressive resistance and aerobic exercise program 3 times per week prior to surgery. Outcome measures included muscle strength and endurance, physical performance by a battery of tests, body composition by dual x-ray absorptiometry, and urinary incontinence. Measures were undertaken at baseline, pre-surgery, and 6 weeks post-surgery, with incontinence assessed following catheter removal and 6 weeks post-surgery. Data were checked for normality and analysed using two-way repeated-measures ANOVA. **RESULTS:** There were no differences between groups at baseline. Following exercise, there was a significant interaction (p < 0.05) for chest press, leg press and leg extension strength with strength increasing in EX prior to surgery and returning to pre-training values post-surgery. There was a significant time effect (p < 0.05) for 6 m fast walk, 6 m backwards walk, and 400 m walk with performance generally improving over the study period. Following surgery, lean mass was reduced (time, p < 0.001) by ~1.9 kg and ~1.4 kg in EX and UC, respectively. Urinary incontinence was significantly reduced at 6 weeks post-surgery in EX and UC (time, p < 0.001). There was no difference in length of hospital stay (3±1 days for EX and UC) and there were no exercise-related adverse effects. **CONCLUSIONS:** A pre-surgical exercise program improves components of physical function prior to surgery which may enhance the patient's fitness for surgery. Given the loss of lean mass following surgery, a longer period of anabolic exercise prior to surgery may prove useful in buffering post-surgical loss.

In the management of prostate cancer androgen deprivation therapy (ADT) is effective in delaying disease progression and enhancing survival, although it is associated with an array of adverse effects including reduced muscle mass, strength and physical function, and an increase in body fat. Exercise is one strategy to counter these musculoskeletal treatment-related toxicities resulting from ADT. However, to recommend and prescribe exercise, clinicians need to know the likelihood of a positive response. **PURPOSE:** To assess the prevalence of exercise responsiveness in men with prostate cancer undergoing ADT on body composition, muscle strength, and physical function. **METHODS:** Prospective analyses were undertaken in 152 men (43-90 years) with prostate cancer on ADT undertaking resistance exercise combined with aerobic and/or impact training for 3-6 months. Whole body lean mass (LM) and fat mass (FM), trunk fat mass, and appendicular skeletal muscle (ASM) were assessed by dual x-ray absorptiometry, upper and lower body muscle strength by 1-RM, and physical function by a battery of tests (6-m usual, fast, and backwards walk, 400-m walk, repeated chair rise, stair climb). **RESULTS:** There were significant improvements (P<0.01) in LM (0.4±1.4 kg, range -2.8 to +4.1 kg) and ASM (0.2±0.8, range -1.9 to +1.9 kg), and all measures of muscle strength (chest press: 2.9±5.8 kg, range -12.5 to +37.5 kg; leg press: 29.2±27.6 kg, range -50.0 to +140.0 kg) and physical function (from -0.1±0.5 s, range +1.3 to -2.1 s for the 6-m usual walk, to -8.6±15.2 s, range +25.2 to -69.7 s for the 400-m walk). In addition, FM (0.6±1.8 kg, range -3.6 to +7.3 kg) increased (P<0.01). Twenty one men did not have a favourable response in at least one body composition component, 10 did not improve muscle strength, and 2 men did not improve physical function. However, all patients responded in at least one of the areas and 120 (79%) favourably responded in all three areas. For all 12 outcome measures, improvement was observed in 8±2 (range 2 to 12) measures. **CONCLUSION:** There were no non-responders to resistance-based multimodal exercise in men with prostate cancer undergoing ADT, and this form of exercise can be confidently prescribed to derive beneficial effects during active treatment.

A-19 Thematic Poster - UCL Injuries in Overhead Athletes

Is Shoulder Joint Rom Or Ucl Thickness A Predictor Of Medial Elbow Joint Space?

Shawn D. Felton¹, Arie J. van Duijn², Jacqueline van Duijn³, Mitchell L. Cordova, FACSM³. ¹Florida International University, Miami, FL. ²Florida Gulf Coast University, Fort Myers, FL. ³Florida Gulf Coast University, Ft. Myers, FL. (Sponsor: Mitchell L. Cordova, FACSM)

Email: sfelton@fiu.edu

(No relevant relationships reported)

UCL injuries among baseball athletes are an extremely common pathology. It is well documented that baseball athletes typically exhibit an increase in shoulder external rotation range of motion (ERRM) and a decrease in internal rotation range of motion (IRRM) while maintaining total rotational range of motion (TROM). Loss of TROM and ERRM may be associated with increased risk for UCL injury. Ultrasound imaging allows clinicians to evaluate UCL thickness and medial joint space (MJS) opening non-invasively. **PURPOSE:** To examine if shoulder joint motion (ERRM, IRRM, TROM), or the thickness of the UCL at the mid substance and apex of trochlea predicts medial elbow joint space (MJS) in asymptomatic collegiate baseball pitchers. **METHODS:** Twenty-nine NCAA Division I pitchers participated in this follow-up study. Ultrasound images were obtained of the MJS and UCL on the participant's

throwing arm using a GE LOGIQ e ultrasound unit. Participants were placed supine with a wedge placed underneath their pitching hand to maintain elbow position at 30 degrees. A 3 kg valgus force, as measured by a hand-held dynamometer, was applied 20 cm distal to the medial epicondyle. Ligament thickness measurements were performed at the mid-substance of UCL and at the apex of the trochlea. Imaging measurements to evaluate MJS opening were performed from the apex of the trochlea to the apex of the ulna. Standard goniometric procedures were performed with the athlete in a supine position to obtain ERRM, IRRM, and TROM values. Three stepwise linear multiple regression analyses were performed to determine if shoulder ROM or UCL thickness measures of the mid-substance and apex of the trochlea could predict MJS. **RESULTS:** Shoulder joint range of motion were not able to significantly predict MJS [$R^2 = .05$, $F(2,25) = 0.58$, $p = 0.56$]. UCL thickness at the mid-substance [$R^2 = .04$, $F(1,25) = 0.10$, $p = 0.76$], and at apex of the trochlea [$R^2 = .00$, $F(1,25) = 0.03$, $p = 0.95$] were not able to significantly predict MJS. **CONCLUSIONS:** Results further supported prior research that shoulder ROM did not predict MJS, and new to this study, UCL thickness measured at two points were unable to predict MJS in asymptomatic baseball pitchers. Further research is recommended to perform multiple imaging sessions throughout the competitive season to further determine predictors of UCL injuries.

Do Outcomes or Subsequent Injuries Differ Following Ulnar Collateral Ligament Reconstruction Using Palmaris vs. Hamstring Autograft?

Joshua Dines¹, Brandon Erickson², Peter Chalmers³, John D'Angelo⁴, Kevin Ma⁴, Anthony Romeo². ¹HSS, New York, NY. ²Rothman Orthopaedic Institute, Tarrytown, NY. ³University of Utah, Salt Lake City, UT. ⁴MLB, New York, NY.
 Email: Brandon.Erickson@rothmanortho.com
 (No relevant relationships reported)

Purpose: Ulnar collateral ligament reconstruction (UCLR) is a successful procedure in professional baseball players. It is unclear if results differ based on graft choice. The purpose was to determine the performance and return to sport (RTS) rate in professional baseball players following UCLR and compare performance and RTS rate, as well as injury rates, between players who underwent UCLR with hamstring vs. palmaris autograft. The authors hypothesize that there is a high RTS rate in professional baseball players following UCLR with no significant difference in injury rates, RTS rate, or performance, specifically related to primary outcome performance variables: WHIP ((walks +hits)/innings pitched), fielding independent pitching (FIP), and wins above replacement (WAR)) between those who had UCLR with a palmaris vs. hamstring autograft. **Methods:** All professional baseball players between 2010-2015 who underwent UCLR using hamstring autograft were included. Surgical details of their procedure were recorded using operative reports. Players with a hamstring UCLR were compared to a matched control group of players who underwent UCLR with palmaris autograft. **Results:** Overall, 191 players underwent UCLR using hamstring autograft. No differences in RTS rates or timing to RTS existed between the hamstring vs. palmaris groups. Significantly more subsequent lower extremity injuries were seen in the hamstring group ($p = 0.040$). More subsequent upper extremity injuries existed in the palmaris group, although this difference was not significant ($p = 0.052$). No consistent differences in performance metrics upon RTS existed between hamstring and palmaris groups, although both groups significantly declined in many performance metrics following surgery. Both groups showed a decline in post-operatively in WAR and WHIP; FIP did not decline. No significant difference in WAR, WHIP, or FIP existed between groups post-operatively. **Conclusion:** Baseball players who undergo UCLR with hamstring autograft are more likely to sustain a subsequent lower extremity injury while those who undergo UCLR with a palmaris are more likely to sustain an upper extremity injury. No difference in performance or RTS rates existed between groups. Both groups significantly declined in WAR and WHIP after UCLR.

Quantity Time: Identifying The Benefit Of Ulnar Collateral Ligament Reconstruction In Major League Baseball

J.P. Wong, William E. Herrin, Courtney D. Jensen. University of the Pacific, Stockton, CA.
 (No relevant relationships reported)

Reconstruction of the ulnar collateral ligament (UCL), known colloquially as Tommy John surgery, was first performed in 1974. Today, approximately 30 Major League Baseball (MLB) players undergo this procedure annually; however, 57% of recipients are youth, age 15-19. Despite the abundance of subjects and accessibility of statistics, few investigations have studied its long-term effects on performance. **PURPOSE:** To evaluate changes in pitching performance following UCL reconstruction. **METHODS:** We compared 3 samples of MLB pitchers: 1) Underwent UCL reconstruction (REC), 2) Sustained an injury without surgical care (INJ), and 3) Never injured (NON). The REC sample was selected at random from a list of players who had pitched at least 2

seasons prior to the operation and at least 2 seasons post-surgery. Matched samples of INJ and NON were created; there were 50 subjects in each group. Mixed ANOVA with repeated measures compared first season statistics to final season statistics, and means of the first 2 seasons to the last 2. Linear regressions tested the effect of UCL reconstruction on changes in performance across those periods, holding all potential confounders constant. **RESULTS:** Among all 150 pitchers, during the first 2 seasons, they won 53.6% of games, struck out 0.88 ± 0.23 batters per inning, and had an earned run average (ERA) of 4.01 ± 1.14 . Between the first 2 and last 2 seasons, REC subjects experienced a 5.7% decrease in win percentage ($p = 0.063$) but struck out 4.7% more batters per inning ($p = 0.015$). Linear regression, evaluating the change from first to last season, found UCL reconstruction to improve winning percentage by 14.4 percentage points ($p = 0.026$); there was no effect on strikeouts per inning ($p = 0.339$) or ERA ($p = 0.892$). UCL reconstruction failed to elicit significance on the change in performance between the first 2 and last 2 seasons in any variable. The ANOVA models found no group effect between first and last season with win percentage ($p = 0.190$), strikeouts per inning ($p = 0.428$), or ERA ($p = 0.600$). Similarly, there was no group effect between the first 2 and last 2 seasons in win percentage ($p = 0.454$), strikeouts per inning ($p = 0.961$), or ERA ($p = 0.496$). **CONCLUSION:** UCL reconstruction does not appear to compromise the quality of pitching performance, but does prolong the quantity of pitches in a player's career.

Open Reduction Internal Fixation of Medial Epicondyle Fractures After Ulnar Collateral Ligament Reconstruction in Professional Baseball Pitchers

Brandon Erickson¹, Peter Chalmers², John D'Angelo³, Kevin Ma³, Anthony Romeo¹. ¹Rothman Orthopaedic Institute, Tarrytown, NY. ²University of Utah, Salt Lake City, UT. ³MLB, New York, NY.
 Email: Brandon.Erickson@rothmanortho.com
 (No relevant relationships reported)

Purpose: Determine the rate of return to sport (RTS) and performance upon RTS in professional baseball pitchers following ORIF of the medial epicondyle, and see if there is a difference in RTS rate and performance between players who underwent ORIF and matched controls. The authors hypothesize that there is a high rate of RTS in professional baseball pitchers following medial epicondyle ORIF with no significant difference in rate of RTS or performance, specifically related to the primary outcome performance variables of win-loss percentage (W-L%), WHIP ((walks +hits)/innings pitched), fielding independent pitching (FIP), and wins above replacement (WAR)) between cases and controls.

Methods: All professional baseball pitchers who underwent medial epicondyle ORIF between 2010-2016 were included. Demographic and performance data (pre and post surgery) for each player was recorded. Performance metrics were then compared between cases and matched controls (no history of UCLR or ORIF). **Results:** Overall, 15 pitchers (80% starters, 73.3% right-handed) underwent ORIF of a medial epicondyle fracture. All underwent a prior UCLR using either the American Sports Medicine Institute (n=9, 60%) or docking (n=6, 40%) technique. ORIF techniques included fixation with one screw (n=13, 86.7%) and fixation with suture anchors (n=2, 13.3%). Eleven (73.3%) pitchers were able to RTS (which did not differ from controls $p = 0.537$). No significant differences existed in the primary performance outcome variables when comparing pre-operative to post-operative performance. No significant differences in the primary performance outcome measures were seen between cases and controls following surgery although cases pitched fewer innings than controls following surgery ($p = 0.003$). **Conclusion:** Following medial epicondyle ORIF of professional pitchers with a history of UCLR, 73.3% were able to RTS without a significant decline in most performance variables when compared to their pre-operative performance levels, or when compared to matched controls. Number of innings pitched declined following surgery.

Performance and Return to Sport Following Ulnar Nerve Decompression/Transposition in Professional Baseball Players

John D'Angelo¹, Brandon Erickson², Peter Chalmers³, Kevin Ma¹, Anthony Romeo². ¹MLB, New York, NY. ²Rothman Orthopaedic Institute, Tarrytown, NY. ³University of Utah, Salt Lake City, UT.
 Email: Brandon.Erickson@rothmanortho.com
 (No relevant relationships reported)

Purpose: Determine performance and return to sport (RTS) rate in professional baseball players following isolated ulnar nerve decompression/transposition, including those who required an ulnar nerve transposition/decompression following ulnar collateral ligament reconstruction (UCLR), and compare outcomes between cases and matched controls.

Methods: All professional baseball players who underwent isolated ulnar nerve decompression/transposition between 2010-2016 were included. Demographic and performance data (pre and post surgery) for each player was recorded. Performance metrics were then compared between cases and a group of matched controls. **Results:** Overall 52 players, 83% pitchers (14 underwent prior UCLR) were included. Most surgeries (92%) were anterior subcutaneous transpositions. Overall, 62% of players were able to successfully RTS and 56% returned to the same or a higher level. There was no significant difference between cases and controls in the majority of performance metrics pre-operative or post-operatively, specifically ERA, WHIP, WAR, and OPS. When players who had a UCLR prior to their ulnar nerve transposition/decompression were compared to controls with a history of a UCLR but who did not go on to have an ulnar nerve transposition/decompression, the only performance difference of all the recorded metrics was cases allowed more walks per 9 innings (4.4 vs. 2.8; $p=0.011$). **Conclusion:** Anterior subcutaneous transposition is the most common surgery in professional baseball players to address ulnar neuropathy at the elbow. Players have a 62% rate of RTS, which is lower than expected for this non-reconstruction or repair procedure. For players who successfully RTS, performance compared to matched controls remained the same in most performance metrics. Post-operatively, pitchers with a UCLR prior to ulnar nerve transposition/decompression that had a successful RTS performed the same as matched controls with prior UCLR.

Land leg vs. Drive Leg Hamstring Graft Harvest Side Does Not Affect Performance or RTS Rates and Does Not Increase Risk for Future Hamstring Injuries Following UCLR in Professional Baseball Pitchers
 Peter Chalmers¹, Brandon Erickson², John D'Angelo³, Kevin Ma³, Christopher Ahmad⁴, Joshua Dines⁵, Anthony Romeo².
¹University of Utah, Salt Lake City, UT. ²Rothman Orthopaedic Institute, Tarrytown, NY. ³MLB, New York, NY. ⁴Columbia, New York, NY. ⁵HSS, New York, NY.
 Email: Brandon.Erickson@rothmanortho.com
 (No relevant relationships reported)

Purpose: To compare, performance, return to sport (RTS) rate, and injury rates between professional baseball players with a history of UCLR using an ipsilateral (drive leg) hamstring autograft to those with UCLR using contralateral (landing leg) hamstring autograft.

Methods: All players between 2010-2015 who underwent UCLR using hamstring autograft were included. Surgical details of their procedure were recorded using operative reports. Players with a hamstring UCLR were compared within group to compare grafts taken from the drive leg vs. landing leg. **Results:** Overall, 191 players underwent UCLR using hamstring autograft (58 [30%] landing/contralateral and 133 [70%] ipsilateral/drive leg). The docking technique was more common in the contralateral/landing leg group while the figure-of-8 technique was more common in the ipsilateral/drive leg group ($p>0.001$). More patients in the ipsilateral/drive leg group underwent concomitant treatment of the ulnar nerve than the contralateral/landing leg group ($p<0.001$). No difference existed in return to sport (RTS) rates, or timing of RTS between groups. No differences in subsequent ipsilateral or contralateral hamstring injuries between players who underwent UCLR using hamstring from the ipsilateral/drive leg or contralateral/landing leg was seen ($p=1.000$; $p=0.460$ respectively). No difference in overall upper or lower extremity injury rates existed between groups. **Conclusion:** No difference in RTS rate, performance upon RTS, or subsequent hamstring, lower extremity, or upper extremity injury rates existed between players who underwent UCLR using hamstring autograft from the ipsilateral/drive or contralateral/landing leg.

A-20 Thematic Poster - Walking Biomechanics

Pelvis and Trunk Motion Comparisons Between Male and Female Soldiers While Walking With Heavy Loads

Joseph F. Seay, Victoria G. Bode, Peter N. Frykman, Nathaniel I. Smith, Rebecca E. Fellin. U.S. Army Research Institute of Environmental Medicine, Natick, MA.
 Email: joseph.f.seay.civ@mail.mil
 (No relevant relationships reported)

With the recent decision permitting female soldiers to enter Combat Arms roles, knowledge of sex differences in military load carriage is more operationally relevant. Limited work comparing the effect of heavy carried loads (> 30 kg) in men and women has attributed differences in gait mechanics to sex without matching for anthropometrics that may contribute to differences. **PURPOSE:** To examine the effect of carrying light to heavy loads on pelvis and trunk range of motion (ROM) between anthropometrically matched male and female soldiers. **METHODS:** Four male and 4 female Soldiers were matched on height and body weight (differences < 2.54 cm and 4.54 kg). All participants walked unloaded (BW), and with vest-borne loads of 15, 35 and 55 kg. Each load was carried for 10 min while walking on a level treadmill at 1.3 $m \cdot s^{-1}$, with pelvis and trunk segmental angles collected after 5 min. Four mixed model ANOVAs (sex x load) compared trunk and pelvis frontal and transverse plane ROM. **RESULTS:** There were sex x load interactions for trunk transverse and frontal plane motion (Table 1). Specifically, as load increased: (A) trunk axial rotation decreased more in females than males ($p=0.037$), and (B) trunk frontal plane motion increased for males and remained relatively constant for females ($p=0.034$). Pelvis frontal plane ROM also increased at 55 kg in both sexes relative to carrying no additional load. **CONCLUSIONS:** Despite anthropometric matching, preliminary results suggest sex-related differences in trunk frontal plane motion while carrying loads ≥ 35 kg and no sex-related differences in pelvis motion. **DISCLAIMER:** The views expressed in this abstract are those of the authors and do not reflect the official policy of the Department of Army, Department of Defense, or the U.S. Government.

Table 1. Pelvis and Trunk Frontal (Y) and Transverse (Z) plane ranges of motion for different loads among male and female Soldiers.

| | | Sex | BW | 15 kg | 35 kg | 55 kg |
|--------|------------|-----|------------|-----------|------------|---------------|

Logistic Regression Analyses Regarding Patient Dissatisfaction with Total Knee Replacement Outcomes

Kevin Valenzuela¹, Songning Zhang, FACSM². ¹CSULB, Long Beach, CA. ²University of Tennessee Knoxville, Knoxville, TN.
 (Sponsor: Songning Zhang, FACSM)
 Email: kevin.valenzuela@csulb.edu
 (No relevant relationships reported)

Current research on patient satisfaction after a total knee replacement (TKR) lacks an examination of objective assessments with respect to gait biomechanics, strength, and balance abilities.

PURPOSE: To examine associations between patient satisfaction and the gait biomechanics, strength, balance, functional capacities, and survey data.

METHODS: Twenty four TKR patients participated in overground walking, stair ascent and descent, isokinetic strength, static and dynamic balance, and functional tests. Nine patients were in the dissatisfied group and fifteen in the satisfied group. Four models of logistic regression analyses were performed to predict patient satisfaction: one for walking, stair ascent, stair descent, and functional/strength/survey data. If high correlations ($r \geq 0.7$) existed, variables were selected based on biomechanical and functional importance identified through review of literature concerning TKR patients. Selected kinematic, kinetic, strength, and balance variables along with functional test and survey data scores were input into a logistic regression analysis using SAS (Version 9.4, Cary, NC, USA). Models were evaluated using Akaike's Information Criterion.

RESULTS: The walking model included 1st and 2nd peak vertical ground reaction force (VGRF), knee extension moment, and forgotten joint score ($R^2=0.69$, $AIC=22.73$, $p=0.0026$). The stair ascent model included 2nd peak VGRF, knee extension moment, preferred gait speed, and peak isokinetic knee extension torque ($R^2=0.72$, $AIC=23.85$, $p=0.0013$). The stair descent model included knee extension moment, preferred gait speed, peak isokinetic knee extension torque, and forgotten joint score ($R^2=0.80$, $AIC=20.47$, $p=0.0003$). The functional model was inclusive of WOMAC total scores, stair ascent and chair rise times, and peak isokinetic knee extension torque ($R^2=0.87$, $AIC=19.51$, $p=0.0002$).

CONCLUSIONS: The biomechanical models included both VGRF and knee extension moments, indicating their relevance to patient satisfaction. Additionally, preferred gait speed was significant to both stair ascent and descent models. Pain was not included in any models due to a complete separation of data points.

Quadriceps Strength and Knee Mechanics in Adults with Prader-Willi Syndrome

Skylar C. Holmes¹, Brett K. Post¹, Steven A. Garcia², Eric J. Shumski¹, Derrick Escano¹, Daniela A. Rubin, FACSM¹, Derek N. Pamukoff¹. ¹California State University Fullerton, Fullerton, CA. ²University of Michigan, Ann Arbor, MI.
Email: skylar.c.holmes@gmail.com
(No relevant relationships reported)

Prader-Willi syndrome (PWS) is a form of congenital obesity that occurs 1 in 25,000 births. Progressive obesity and reduced lean mass contribute to muscle weakness, which may alter knee mechanics during gait. **PURPOSE:** To compare quadriceps strength between individuals with and without PWS, and to examine the relationship between quadriceps strength and knee mechanics during gait in adults with PWS. **METHODS:** 10 individuals with PWS participated in this study (1.70 ± 0.09 m, 71.9 ± 16.1 kg), and were matched on sex to 10 obese controls (1.74 ± 0.08 m, 108.0 ± 13.2 kg) and 10 lean controls (1.67 ± 0.06 m, 65.3 ± 7.16 kg). Participants completed three maximal isometric knee extensor contractions using a dynamometer set at 60° of knee flexion. Early (0-100 ms) and late (100-200 ms) rate of torque development (RTD₁₀₀, RTD₂₀₀), and peak torque were extracted. Gait biomechanics were collected as participants completed 5 walking trials over 2 force plates on a 10-m runway at self-selected speed. Peak knee flexion angle (KFA), excursion (KFE), and knee flexion moment (KFM) were extracted from the first 50% of stance. Strength and joint moments were normalized to lean mass and a product of body weight and height, respectively. One-way MANOVA was used to compare strength variables between groups. Partial correlation controlling for gait speed was used to determine the relationship between strength and gait variables. **RESULTS:** There were group differences in peak torque ($p=.001$), RTD₁₀₀ ($p=.010$), and RTD₂₀₀ ($p=.002$). Post hoc analyses showed that individuals with PWS had lower peak torque ($p=.006$, $p=.001$), RTD₁₀₀ ($p=.038$, $p=.015$), and RTD₂₀₀ ($p=.003$, $p=.016$) than obese and lean controls. There were no significant correlations in control groups ($p>.05$). Greater KFE was related to greater peak torque ($r=-0.71$, $p=.016$), greater RTD₁₀₀ ($r=-0.59$, $p=.049$) KFA ($r=0.69$, $p=.019$). **CONCLUSIONS:** Strength variables were associated with knee mechanics in the PWS group, indicating that aberrant gait in PWS may relate to muscle weakness. Adults with knee osteoarthritis (KOA) have a quadriceps avoidance gait pattern indicated by lower KFE. Individuals with PWS had lower quadriceps strength compared to controls, which was associated with lower KFE. Lower quadriceps strength and altered knee mechanics in individuals with PWS may contribute to KOA.

Recovery of Joint Function During Sit to Walk Following Periacetabular Osteotomy: A Case Study

Cailyn Schroeder¹, Linnea Zavala¹, Laura Opstedal², James Becker¹. ¹Montana State University, Bozeman, MT. ²Build Physio and Performance, PLLC, Bozeman, MT.
(No relevant relationships reported)

To date, biomechanical analyses of outcomes after periacetabular osteotomy (PAO) have not evaluated short term recovery or assessed activities other than walking or running. **PURPOSE:** Evaluate changes in joint moments and moment distributions during a sit to walk (STW) task before (PRE) and 6 weeks (6WK), 12 weeks (12WK), and 6 months (6MO) following PAO surgery. **METHODS:** A 22 year old female who underwent PAO due to a history of failed hip surgeries participated. She was non-weight bearing for 6 weeks following PAO, with physical therapy initiated in the first week. At each time point STW trials were performed under motion capture while ground reaction forces were recorded using force plates. Peak extensor moments at the hip (HEM), knee, and ankle, peak support moment (Ms), and distribution of peak Ms among joints were calculated. Differences between nonsurgical (NS) and surgical (S) limbs and times were evaluated using single subject analysis techniques. **RESULTS:** At PRE, peak Ms and HEM were higher on the NS side (both $p<.01$). However, the distribution of peak Ms among joints was not different between limbs (all $p>.05$). By 6WK after surgery peak Ms and HEM on the NS limb increased by 35.6% ($p<.01$) and 40% ($p<.01$), while decreasing by 49.6% ($p<.01$) and 67% ($p<.01$) on the S limb. Additionally, within the S limb there was a redistribution of load bearing, with the hip carrying a smaller percentage of peak Ms and the knee a larger percent (both $p<.01$). While deficits were still present at 12WK, the magnitude of differences decreased (all $p<.01$). By 6MO Ms, HEM, and distribution of Ms across joints had returned to pre-surgery values (all $p<.01$). However, moments were still larger on the NS limb compared to S limb (all $p<.01$). **CONCLUSION:** During recovery from PAO there is a shift in loading from the S limb to the NS limb and a redistribution of load carriage within the S limb which gradually dissipates over 6 months. Rehabilitation programs should include methods cope with this altered loading.

Figure 1. Peak support moment (Ms), hip (H), knee (K), and ankle (A) extensor moments at instance of peak support moment (A), and distributions of the support moment across the hip, knee, and ankle joints (B). Black bars are the nonsurgical limb and grey bars are the surgical limb. * and # indicate statistically significant differences between limbs and time points, respectively. All differences are at the $p < .01$ level.

Recovery of Hip Biomechanics During Walking After Periacetabular Osteotomy

Linnea J. Zavala¹, Cailyn Schroeder¹, James Becker¹, Laura Opstedal². ¹Montana State University, Bozeman, MT. ²Build Physio & Performance, PLLC, Bozeman, MT.
Email: linnea.zavala@gmail.com
(No relevant relationships reported)

To date, studies on biomechanical outcomes following periacetabular osteotomy (PAO) have focused on gait adaptations 6 months or 1 year post-surgery. There are no reports in the literature on how biomechanics recover during the initial months following surgery. **PURPOSE:** To assess changes in hip angles and moments during walking between pre-PAO-surgery (PRE), and 6 weeks (6WK), 12 weeks (12WK), and 6 months (6MO) post-operation. **METHODS:** One female collegiate athlete (age: 22 yrs; mass: 85 kg; height: 181 cm) with a history of failed hip surgeries participated. At each time point hip kinematics and kinetics in the surgical limb were assessed during walking using motion capture and force plates. Variables of interest included peak hip extension (HE), adduction (HAD), and internal rotation (HIR) angles, hip extensor moment (HEM) at the initial vertical ground reaction force peak, and peak hip abductor (HABM) and internal rotator (HIRM) moments. Differences between time points were evaluated using ANCOVA with walking velocity as a covariate. **RESULTS:** Compared to PRE, HE was reduced at 6WK ($p<.0001$). While HE increased back towards PRE values at each time point ($p<.0001$), it was still reduced at 6MO. By 12W, HEM increased from B ($p<.0001$), which was still true at 6M ($p=.012$). HAD decreased after 12W post-surgery ($p<.0001$). The same pattern was seen for HABM ($p<.0001$). HIR decreased from B to 6M ($p<.0001$) and HIRM decreased after surgery ($p=.031$) but at 6M was not different than B. **CONCLUSIONS:** Overall, hip angles and moments during walking decreased in the involved limb immediately following PAO but began to return towards baseline by 12WK to 6MO. Increased HEM beyond

baseline was also observed, indicating more use of the surgical leg to move the body through stance than prior to surgery. Understanding these initial recovery patterns may help improve PAO-specific rehabilitation programs.

Figure 1 Average hip angles and hip moments for involved leg. Error bars are standard error. The asterisks indicate differences from baseline for p-value < 0.05.

Increased Dynamic Knee Joint Load at the Non-Modified Limb during Medial Knee Thrust Gait Modification

Oladipo Eddo, Bryndan Lindsey, Matthew Prebble, Shane V. Caswell, Nelson Cortes. *George Mason University, Manassas, VA.*
 Email: ncortes@gmu.edu
 (No relevant relationships reported)

Medial contact force (MCF) is a measure of the internal loads contributing to knee cartilage loss. Including both knee adductor moment (KAM) and knee flexor moment (KFM) peaks in regression equations significantly improves the prediction of MCF. The objective of gait modification is to reduce KAM by lateralizing the resultant vector of the ground reaction force of the targeted limb. Yet, scant research currently exists investigating consequential changes in MCF of the non-modified limb. **PURPOSE:** To compare changes in MCF of the non-modified limb as a result of implementing medial knee thrust (MKT) strategy. **METHODS:** 19 healthy participants (age 26.74.8 years; height 1.690.17 m; mass 72.311.8 kg) volunteered for this study. All analyses were completed on the non-modified limb. Participants completed 10 trials each walking with normal gait and MKT. The prescribed change in knee angle during the MKT trials was participant specific, using the mean and standard deviation (SD) from baseline trials. During MKT trials, visual real-time feedback was provided to ensure joint angles fell within 1-3 SD (1st 5 trials) and 3-5 SD (last 5 trials) from baseline average. KAM and KFM were computed on Visual 3D. To assess MCF, a linear regression equation was used. Coefficient values (c1, c2, and c3) were attained from prior studies that quantified MCF using instrumented knee implants. Changes in MCF during the 1st and 2nd half of stance were assessed using an ANOVA (P<0.05). **RESULTS:** MCF of the non-modified limb for the 1st half of stance was significantly greater during the MKT trials (F_{2,36} = 6.747, P=0.003). Participants had greater MCF during the 1-3 SD (d=0.36) and the 3-5 SD (d=0.44) compared to the baseline trials. No other statistically significant difference was found (P<0.05). **CONCLUSION:** Increased MCF in the non-modified knee is possibly explained by the lateralization of the force vector from the modified limb. As a result of the repetitive nature of gait, small increases in MCF over each step may instigate significant ramifications over time. Our results suggest that for individuals with bilateral knee osteoarthritis MKT may be contraindicated. Future studies implementing gait retraining within pathological populations should consider investigating biomechanical changes in the non-modified knee.

Diabetes is Associated with Slow Walking Speed in People with Knee Osteoarthritis

Aqeel M. Alenazi¹, Mohammed M. Alshehri², Shaima Alothman², Corey Gray², Abdalghani A. Yahya², Jason Rucker², Bader A. Alqahtani³, Saad M. Bindawas⁴, Patricia M. Kluding². ¹University of Kansas Medical Center and Prince Sattam Bin Abdulaziz University, Kansas City, KS. ²University of Kansas Medical Center, Kansas City, KS. ³Prince Sattam Bin Abdulaziz University, Alkharj, Saudi Arabia. ⁴King Saud University, Riyadh, Saudi Arabia.
 Email: aalenazi@kumc.edu
 (No relevant relationships reported)

Walking speed is often considered a sixth vital sign and an important predictor for disability and mortality in older adults. Previous research has shown that a decline in

walking speed is associated with diabetes (DM) or osteoarthritis (OA), independently. Slow walking speed may interfere with daily living and basic mobility needs.

Purpose: The aim of this study was to investigate the impact of diabetes on walking speed in people with knee OA. **Methods:** A cross sectional analysis of Osteoarthritis Initiative (OAI) data at 96 months follow up was performed for 2122 individuals aged between 53-87 years with knee pain over 30 days. Participants were grouped into knee OA+diabetes or knee OA only. Walking speed was measured using the average speed of two trials of 20 meter walk test. Diabetes and knee pain over 30 days were assessed via a self-reported questionnaire. Walking speed was categorized as either slow walking speed (<1.0 m/s) or normal walking speed (≥1.0 m/s). Knee pain while walking was assessed immediately after each walk test using a numeric rating scale from 0 to 10. Knee pain while walking was categorized as follows: no pain (0), mild pain (1-3), moderate pain (4-6) and severe pain (7-10). Logistic regression analyses were performed at 0.05 alpha level. **Results:** A total of 1848 participants had knee OA only and 274 had knee OA+diabetes. A total of 245 individuals had a walking speed < 1.0 m/s with 26.5% of these individuals having diabetes. A total of 1877 participants had a walking speed ≥1.0 m/s with 11.1% of these individuals having diabetes. Logistic regression analyses showed that diabetes was significantly associated with slow walking speed (<1.0 m/s), (odds ratio 1.62; 95% confidence interval [1.11, 2.36], p=0.013) after controlling for age, sex, race, body mass index, depression and pain while walking. **Conclusion:** This study found an association between diabetes and slow walking speed in people with knee OA, independent of knee pain. People with diabetes and knee OA are about 1.6 times more likely to have a slow walking speed (<1.0 m/s) than those with OA alone. Previous research has linked slow walking speed to adverse health outcomes. Further research should explore the complex relationships between walking speed, functional ability, and health outcomes in this population.

Obesity Moderates the Association Between Knee Adduction During Gait and Femoral Cartilage Thickness

Derek N. Pamukoff¹, Michael N. Vakula², Eric J. Shumski¹, Skylar C. Holmes¹, Brett K. Post¹, Steven A. Garcia³. ¹California State University, Fullerton, Fullerton, CA. ²Utah State University, Logan, UT. ³University of Michigan, Ann Arbor, MI.
 (Sponsor: Daniela Rubin, FACSM)
 Email: dpamukoff@fullerton.edu
 (No relevant relationships reported)

Mechanical stimuli are necessary for the maintenance of articular cartilage. Individuals with obesity have large joint loads during gait yet are at high risk for knee osteoarthritis. As such, the association between joint loading and cartilage thickness in individuals with obesity is unclear. **PURPOSE:** To examine the moderating effect of obesity on the association between knee adduction characteristics during gait and femoral cartilage thickness.

METHODS: 48 young adults with and 48 without obesity matched on age and sex completed assessments of gait biomechanics and ultrasound imaging. Ultrasound imaging was completed in 140° of knee flexion, and outcome variables included cartilage thickness of the medial and lateral femoral condyles, and the medial to lateral (M:L) thickness ratio. 3-dimensional gait analyses were conducted over 5 trials on a 10m runway at a self-selected speed. Biomechanical outcomes included the peak knee adduction angle (KAA), first (KAM₁) and second (KAM₂) peaks of the knee adduction moment, and the knee adduction angular impulse (KAI). Kinetics were normalized to a product of height and weight. Multiple linear regression was used to examine the association between biomechanical and cartilage outcomes after accounting for sex, gait speed, and step width. The moderating effect of body mass index (BMI) on the association between biomechanical and cartilage outcomes was assessed via the addition of the interaction term (BMI x biomechanical variable). Significant interactions were assessed via post hoc probing of the conditional slopes at each level of BMI group (α=0.05). **RESULTS:** There was a significant interaction between BMI group and KAA (β=-0.029, p=0.03), KAM₁ (β=-15.70, p<0.01), and KAI (β=-34.50, p=0.04) on the M:L ratio. Post hoc probing indicated that KAA (Effect=0.02, p=0.05), KAM₁ (Effect=12.63, p<0.01), and KAI (Effect=29.40, p=0.02) were only associated with M:L ratio in individuals without obesity. No associations were found between biomechanical outcomes and medial or lateral femoral condyle cartilage thickness. **CONCLUSIONS:** Results suggest that obesity influences the ability of cartilage to positively adapt to ambulatory joint loads. Obesity is associated with proinflammatory cytokines, which may impair cartilage remodeling in response to mechanical stimuli.

A-21 Free Communication/Slide - Factors Influencing Work Capacity in the Heat

94 May 29 9:30 AM - 9:45 AM Relationship Between Muscle Oxygenation and Oxygen Uptake During Exercise in the Heat

Margaret C. Morrissey, Luke N. Belval, Gabrielle E. W. Giersch, Rachel K. Katch, Brad D. Endres, Taylor A. Duhart, Douglas J. Casa, FACSM. *Korey Stringer Institute, University of Connecticut, Storrs, CT.* (Sponsor: Douglas Casa, FACSM)
Email: MARGARET.MORRISSEY@UCONN.EDU

(No relevant relationships reported)

Exercising in the warm environments increases thermoregulatory demand for skin blood flow, influencing oxygen delivery and oxygen consumption (VO_2) systemically and to active muscle. Near infrared spectroscopy (NIRS) is a non-invasive technique that indirectly assesses local tissue oxygen delivery and VO_2 and accounts for systemic oxygen uptake. Limited evidence exists on the relationship between muscle oxygenation and systemic oxygen uptake during combined heat stress and exercise. **PURPOSE:** To examine the relationship between muscle oxygenation and VO_2 at different exercise intensities in the heat. **METHODS:** Six participants (4 males, 2 females, age: 21 ± 1.0 years, height: 173.41 ± 15.84 cm, weight: 73.14 ± 17.28 kg, $\text{VO}_{2\text{max}}$: 46.41 ± 3.53 ml·kg⁻¹·min⁻¹) performed a treadmill exercise protocol (30°C, 60% relative humidity) with 10 minutes each at 30%, 40%, 60%, 70%, and 80% of velocity at $\text{VO}_{2\text{max}}$. NIRS (Moxo, Fortiori Design LLC, Minnesota, USA) was used to assess muscle oxygen saturation (SmO_2) of the vastus lateralis muscle and systemic VO_2 was measured using expiratory gas analysis. Pearson correlations coefficients were calculated to evaluate the relationship between average SmO_2 , relative changes from baseline (Δ) in SmO_2 , mean VO_2 at percent of peak velocity, and percent of $\text{VO}_{2\text{max}}$. **RESULTS:** There was a positive correlation between ΔSmO_2 and VO_2 at 80% of peak velocity ($r=0.857$, $p=0.029$). There were no significant correlations between ΔSmO_2 and VO_2 at 30%, 40%, 60%, or 70% of peak velocity (30%: $r=0.483$, $p=0.332$; 40%: $r=0.554$, $p=0.254$; 60%: $r=0.653$, $p=0.160$; 70%: $r=0.620$, $p=0.189$). There were no significant correlations between mean SmO_2 , VO_2 at percent of peak velocity, or percent $\text{VO}_{2\text{max}}$. **CONCLUSION:** At 80% of peak velocity, ΔSmO_2 and VO_2 are positively correlated and may suggest this relationship exists while running at high intensities. Therefore, the relationship between NIRS measured SmO_2 and oxygen uptake during exercise in the heat must be further explored in order to use NIRS as an assessment for energy efficiency and substrate utilization.

95 May 29 9:45 AM - 10:00 AM

Application of the Thermal-Circulatory Ratio to Individuals Without History of Exertional Heat Illness

Brad D. Endres, Luke N. Belval, Gabrielle E. W. Giersch, Rachel K. Katch, Margaret C. Morrissey, Rebecca L. Stearns, Douglas J. Casa, FACSM. *Korey Stringer Institute, Storrs, CT.* (Sponsor: Douglas J Casa, FACSM)

Email: brad.endres@uconn.edu

(No relevant relationships reported)

The thermal-circulatory ratio (TCR) is a supportive measure for the assessment of heat tolerance (HT) that was developed for use in military-age males with a history of exertional heat illness (EHI). Examining the heat tolerance test (HTT) and the TCR in a healthy population would give evidence for the application of these as functional measures of heat tolerance in this population. **PURPOSE:** To assess the sensitivity and specificity of the TCR threshold value during a HTT in a subset of individuals without a history of EHI. **METHODS:** 12 participants (8 males, 4 females; age: 20 ± 2 years; height: 171 ± 11 cm; weight: 68.7 ± 12.97 kg; $\text{VO}_{2\text{max}}$: 46.83 ± 4.59 ml·kg⁻¹·min⁻¹) completed a HTT composed of two hours of treadmill walking at a speed of $5 \text{ km} \cdot \text{hour}^{-1}$ at a 2% grade in 40°C and 40% relative humidity. Rectal temperature (T_{re}) was assessed and heart rate (HR) was assessed. The Israeli Defense Force (IDF) criteria for heat intolerance was utilized and determined when T_{re} exceeded 38.5°C, HR exceeded 150 bpm, or when either did not reach a plateau. The TCR was calculated by dividing T_{re} by HR. The TCR threshold value to determine heat tolerance at the end of the HTT (TCR_{th}) was $0.279^\circ\text{C}/\text{bpm}$. Independent t-tests were performed to compare ending T_{re} and HR between HT and heat intolerant (HI) groups. Data are presented as mean \pm SD and significance level ($p < 0.05$) was set a priori. Diagnostic accuracy of the

TCR criterion in comparison to IDF HTT criterion was assessed using sensitivity and specificity. **RESULTS:** The mean T_{re} , HR, and TCR_{th} were $38.02 \pm 0.79^\circ\text{C}$, 119 ± 19 bpm, and $0.327 \pm 0.04^\circ\text{C}/\text{bpm}$, respectively. There were no differences in T_{re} at the end of the HTT between HT and HI, though HR was observed to be lower in HT versus HI ($p=0.006$). Sensitivity and specificity of the TCR in healthy individuals was 50% and 100%, respectively. The positive likelihood ratio was unable to be calculated due to a lack of false positives. The negative likelihood ratio (-LR) was 0.5. **CONCLUSIONS:** The specificity of the TCR in this study is similar to findings in previous research. The TCR threshold identified all healthy participants who were HT ($n=8$) based on IDF criteria but lacked the ability to determine HI participants. Further research is needed to determine the application of the TCR to varying groups of individuals and if it may be a potential predictor for future EHI risk.

96 May 29 10:00 AM - 10:15 AM Sex Differences in Internal Temperature Responses to Prolonged Exercise in the Heat

Gabrielle E. W. Giersch, Luke N. Belval, Margaret C. Morrissey, Rachel K. Katch, Brad D. Endres, Douglas J. Casa, FACSM. *University of Connecticut, Storrs, CT.* (Sponsor: Douglas Casa, FACSM)

Email: gabrielle.giersch@uconn.edu

(No relevant relationships reported)

Given the increased female presence in military populations and the extreme environmental stress of many military operations, it is important to fully elucidate possible differences in response to environmental stresses between the sexes. **PURPOSE:** To investigate the sex differences in temperature responses to prolonged, dynamic exercise in the heat. **METHODS:** Six individuals (3 males, 3 females, age: 20 ± 2 y height: 166 ± 9.5 cm weight: 69.58 ± 13.6 kg $\text{VO}_{2\text{max}}$: 43.2 ± 2.1 ml/min/kg) completed nine-hour trials with three 80-minute blocks of exercise that consisted of bouts of walking at 30% and 40% $\text{VO}_{2\text{max}}$ and running at 70% and 80% of velocity at $\text{VO}_{2\text{max}}$, followed by 50 minutes of rest. Exercise was completed in two hot environmental conditions (dry: 35°C, 30% relative humidity (RH); and humid 30°C, 60% RH) and two clothing conditions (t-shirt and shorts, and Army Combat Uniform). Internal temperature (T_{int}) was assessed continuously via rectal probe. Independent samples t-tests were utilized to assess differences between the sexes. Data are presented as mean \pm SD, significance was set a priori at $p < 0.05$. **RESULTS:** The only differences in this data set were present in the maximum T_{int} in the third block of exercise (male: $39.23 \pm .40$, female: $38.82 \pm .15^\circ\text{C}$, $p=0.028$). Environmental and clothing condition data was pooled for this preliminary analysis. No differences were observed in mean temperatures for any blocks of exercise (Block 1 – male: $38.06 \pm 0.30^\circ\text{C}$, female: $38.08 \pm 0.39^\circ\text{C}$, $p=0.542$; Block 2 – male: $38.46 \pm 0.31^\circ\text{C}$, female: $38.19 \pm 0.31^\circ\text{C}$, $p=0.941$; Block 3 – male: $38.66 \pm 0.35^\circ\text{C}$, female: $38.27 \pm 0.19^\circ\text{C}$, $p=0.157$). Additionally, there were no differences in sweat rate between sexes any blocks of exercise throughout the trials (Block 1 – male: $1.20 \pm 0.39\text{L} \cdot \text{hr}^{-1}$, female: $0.58 \pm 0.33\text{L} \cdot \text{hr}^{-1}$, $p=0.693$; Block 2 – male: $1.05 \pm 0.20\text{L} \cdot \text{hr}^{-1}$, female: $0.88 \pm 0.31\text{L} \cdot \text{hr}^{-1}$, $p=0.337$; Block 3 – male: $1.14 \pm 0.47\text{L} \cdot \text{hr}^{-1}$, female: $0.65 \pm 0.35\text{L} \cdot \text{hr}^{-1}$, $p=0.410$). **CONCLUSION:** While these preliminary data show only maximum temperature difference in the final block of exercise, additional data is needed to fully elucidate the impact of prolonged exercise heat exposure on both males and females. This investigation aims to help to answer any questions about special military considerations for males and females during prolonged missions or training in the heat.

Effects of Solar Radiation Exposure on Self-regulated Exercise Intensity and Thermoregulation in the Heat Outdoors

Hidegori Otani¹, Mitsuharu Kaya², Akira Tamaki², Heita Goto³, Ronald J. Maughan, FACSM⁴. ¹Himeji Dokkyo University, Himeji, Japan. ²Hyogo University of Health Sciences, Kobe, Japan. ³Kyushu Kyoritsu University, Kitakyushu, Japan.

(No relevant relationships reported)

High radiant heat load reduces endurance exercise performance in the heat indoors, but this remains unconfirmed in outdoor exercise. **PURPOSE:** The present study examined the effects of variations in solar radiation exposure on self-regulated exercise intensity and thermoregulatory responses in the heat outdoors at a fixed rating of perceived exertion (RPE). **METHODS:** Ten male participants completed 45-min cycling exercise in hot outdoor environments (about 31°C) at a freely chosen resistance and pedal cadence at an RPE of 13 (somewhat hard). Participants were blinded to resistance, pedal cadence, distance and elapsed time and exercised at three sunlight exposure conditions: clear sky (mean \pm SD: $1072 \pm 91 \text{ W} \cdot \text{m}^{-2}$; HIGH); thin cloud ($592 \pm 32 \text{ W} \cdot \text{m}^{-2}$; MID); and thick cloud ($306 \pm 52 \text{ W} \cdot \text{m}^{-2}$; LOW). Rectal and skin (chest, upper arm, thigh and calf) temperatures, heart rate, skin blood flow and blood pressure were recorded at rest and during exercise. **RESULTS:** Power output (HIGH $96 \pm 22 \text{ W}$;

MID 103±20 W; LOW 108±20 W) and resistance (HIGH 1.3±0.3 kp; MID 1.4±0.2 kp; LOW 1.5±0.3 kp) were lower in HIGH than MID and LOW (Power output $p<0.001$; Resistance $p<0.01$). Pedal cadence was lower as solar radiation increases (HIGH 64.5±5.1 rpm; MID 65.9±4.2 rpm; LOW 67.7±3.9 rpm) and was different between all trials (all $p<0.001$). The core-to-skin temperature gradient was narrower, body heat gain from the sun (SHG) was greater and thermal sensation was higher with increasing solar radiation and all variables were different between all trials (all $p<0.01$). Mean skin temperature was higher in HIGH than MID and LOW ($p<0.01$), but rectal temperature was similar between trials ($p=0.485$). **CONCLUSIONS:** We conclude that self-regulated exercise intensity in the heat outdoors at a fixed RPE of somewhat hard is reduced with increasing solar radiation because of greater thermoregulatory strain, perceived thermal stress and SHG. Moreover, solar radiation below about 600 $W\cdot m^{-2}$ might be of benefit to maintain endurance physical performance in the heat.

 (No relevant relationships reported)

Heat stress reduces physical work capacity (PWC), which can incur major economic deficits. In the context of climate change, an accurate prediction model for PWC as a function of heat stress severity is urgently required, allowing accurate forecasting of its expected future economic impacts. **PURPOSE:** Evidence shows that physical work at self-selected intensities is characterised by a largely stable working heart rate (HR) indicating a constant cardiovascular strain. Given that both heat stress and work load affect HR, we developed a constant cardiovascular strain methodology to quantify heat-induced reductions in PWC at a workload between moderate and heavy based on WHO definitions. **METHOD:** Sixteen young adult male participants (heterogenous in fitness and body characteristics) performed ten experimental trials each consisting of 1-hour of treadmill walking exercise at a HR clamped at 125 $b\cdot min^{-1}$. The first experimental trial was conducted in a reference environment with no heat stress (15°C, 50% rh). The remaining nine trials were conducted at the same fixed target HR in WBGT ranges of 21 to 41°C (variations in both temperature and humidity). The total kilojoules of energy above resting, generated during treadmill work in each heat-stress experimental trial was expressed as a percentage of that achieved in the reference condition, enabling quantification of the change in PWC (%). **RESULTS:** Clamping the heart rate during physical work in the heat produced individualised predictions of PWC which were sensitive to WBGT and aerobic fitness. Reductions in PWC (12 ± 10 %) were noted at a WBGT of 20°C (i.e. 30°C, 20% rh). In this condition, no losses in PWC were reported in those with high aerobic fitness (≥ 60 ml/kg/min), whereas PWC fell by 20-25% for individuals with a VO_{2max} of 35 to 40 ml/kg/min. At a WBGT of 41°C, PWC fell by 75 ± 11%, indicating that some work was still possible even during extreme heat exposure. **CONCLUSION:** Reductions in PWC were sensitive to WBGT and fitness, allowing for computation of a new formula to predict PWC changes and associated losses in GDP as a result of climate change. Funding was provided by 'Heat-Shield', European Union's Horizon 2020 research and innovation programme under the Grant agreement no. 668786.

Impact of Fan Use on Physical Work Capacity in Extreme Heat

James W. Smallcombe¹, Josh Foster¹, Simon Hodder¹, Ollie Jay, FACSM², Andreas D. Flouris³, Katy Griggs¹, Lucy Dorman¹, George Havenith, FACSM¹. ¹Loughborough University, Loughborough, United Kingdom. ²The University of Sydney, Sydney, Australia. ³University of Thessaly, Thessaly, Greece.
 Email: j.w.smallcombe@lboro.ac.uk
 (No relevant relationships reported)

Emerging evidence suggests that electric fan use can reduce thermoregulatory and cardiovascular strain at air temperatures as high as 42°C during rest. However, there is a dearth of empirical evidence relating to the safety limits for fan use at various combinations of air temperatures and humidity, and how their use impacts physical work capacity (PWC). **PURPOSE:** The aim of the current study is to provide new threshold limit values for electric fan use during physical work. **METHODS:** Sixteen young adult males (heterogenous in fitness and anthropological characteristics) performed ~20 trials, consisting of 1 hour of treadmill walking at a fixed heart rate of 130 $beats\cdot min^{-1}$. The first experimental trial was conducted in a reference environment with no heat-stress (15°C, 50% rh). The remaining trials were conducted at the same fixed heart rate for a maximum of 1 hour at 30-50°C at various humidities.

Each experimental trial was conducted with and without electric fans. The PWC in each heat-stress trial was defined as the total energy expended during 1 hour of treadmill walking and was expressed relative (%) to that expended during the reference condition. The study cohort was split into two subgroups with one group performing trials in minimal clothing (shorts only) whilst the second group undertook trials wearing protective clothing covering the legs, torso and arms (e.g. coveralls). **RESULTS:** Based on individual responses to fan exposure during moderate to heavy work undertaken wearing minimal clothing, forced convection was always beneficial at air temperatures $\leq 34^\circ C$. Between 34 and 43°C, a consistent fan benefit was only observed between 40 and 60% relative humidity, with lowered PWC above and below. In contrast, when protective clothing was worn, the beneficial impact of fans between 34 and 43°C was eroded with negligible effects on PWC observed. PWC was consistently impaired by fan use at air temperatures $>43^\circ C$. **CONCLUSION:** These empirical data will facilitate the formulation of comprehensive threshold limit values for fan use during physical work based on biophysical parameters. Funding was provided by 'Heat-Shield', European Union's Horizon 2020 research and innovation programme under the Grant agreement no. 668786.

Mechanical Unloading of the Respiratory System during 5km Cycling Time Trials in Hypoxia

Daniel P. Wilhite¹, Robert F. Chapman, FACSM², Joel M. Stager, FACSM², Timothy J. Fulton², Hunter L. Paris³, Timothy D. Mickleborough². ¹Institute for Exercise and Environmental Medicine, Dallas, TX. ²Indiana University, Bloomington, IN. ³Pepperdine University, Malibu, CA.
 Email: DanielWilhite@texashealth.org
 (No relevant relationships reported)

In trained endurance athletes, the ability to defend arterial oxy-hemoglobin saturation (SaO_2) during high intensity constant-workload exercise in moderate hypoxia depends in part on the ability to increase minute ventilation (\dot{V}_E). Previous data have shown, however, that despite the existence of a substantial amount of ventilatory reserve ($\dot{V}_{E,Res}$) in some cyclists, \dot{V}_E surprisingly does not increase during 5km time trials (5kTT) in hypoxia, despite a significant decrease in both SaO_2 and mean power output (P_{TT}) from normoxia. **PURPOSE:** To determine the effect of reducing the work of breathing (W_b) on \dot{V}_E , breathlessness (RPB), and P_{TT} during a 5kTT in hypoxia in highly trained cyclists. We hypothesized no change in RPB, while \dot{V}_E would increase with an attenuated decrement in SaO_2 and P_{TT} from normoxia.

METHODS: Fourteen trained male cyclists ($VO_{2max} = 58.7 \pm 4.7$ $ml\cdot kg^{-1}\cdot min^{-1}$) performed a 5kTT under 3 conditions at sea level: 'CON' ($FiO_2 = 0.21$), 'HYP' ($FiO_2 = 0.16$), and 'HYP+He' ($FiO_2 = 0.16$, with balance helium). Esophageal balloons were used to assess W_b in each condition. Inspiratory capacity maneuvers were performed at each km, and flow-volume loop analyses were used to assess the %EFL and $\dot{V}_{E,Res}$. The modified Borg scale (0-10) was used to assess RPB at each km.

RESULTS: W_b decreased from HYP to HYP+He by 30 ± 18% ($p < 0.01$). Despite a substantial $\dot{V}_{E,Res}$ throughout CON (52 ± 44 $L\cdot min^{-1}$), \dot{V}_E was not different between CON (117.4 ± 17.9 $L\cdot min^{-1}$) and HYP (124.8 ± 17.9 $L\cdot min^{-1}$) but increased during HYP+He (139.5 ± 22.0 $L\cdot min^{-1}$; $p < 0.05$). While SaO_2 decreased from CON to HYP by 10 ± 1% ($p < 0.01$), SaO_2 increased by 4 ± 1% from HYP to HYP+He ($p < 0.01$). P_{TT} decreased from CON to HYP (-14.2%; $p < 0.01$) and increased from HYP to HYP+He (+5.5%; $p < 0.01$). When comparing HYP to HYP+He, a significant correlation was observed between ΔSaO_2 and ΔP_{TT} ($r = 0.69$; $p < 0.05$). RPB increased from CON (6.0 ± 2.0) to HYP (7.0 ± 2.0 ; $p < 0.05$) and was unchanged from HYP to HYP+He (6.6 ± 2.0).

CONCLUSIONS: In moderate hypoxia, a low ventilatory reserve does not limit 5km time trial performance, where by design, individuals are free to adjust power output. The ability to utilize ventilatory reserve while remaining below a critical threshold of perceived breathlessness appears conducive to maintaining aerobic exercise performance in moderate hypoxia.

Dysanapsis Ratio as a Predictor of Expiratory Flow Limitation in Endurance Trained Athletes

Joel T. Greenshields¹, Benjamin C. Skutnik¹, Daniel P. Wilhite², Robert F. Chapman, FACSM¹, Joel M. Stager, FACSM¹. ¹Indiana University, Bloomington, IN. ²Texas Health Presbyterian Hospital, Dallas, TX. (Sponsor: Joel M. Stager, FACSM)

Email: jtgreens@indiana.edu

(No relevant relationships reported)

PURPOSE: To investigate whether the dysanapsis ratio (DR) predicts expiratory flow limitation in highly trained athletes, as has been shown in healthy, active men and women. **METHODS:** Data from 124 highly trained men (age 21.9 ± 3.6 yrs) who performed maximal incremental tests to exhaustion were analyzed. The maximum expiratory flow-volume curve, along with inspiratory capacity maneuvers, were used to determine lung volumes, determine expiratory flows, and to quantify flow limitation. The subjects were partitioned into 'flow-limited' (EFL) and 'non flow-limited' (NEFL) groups, where tidal vs. maximal flow-volume overlap >5% qualifies as EFL. Group differences were evaluated using independent T-tests, while logistic regression was used to assess the predictive ability of DR, forced vital capacity (FVC), and $\dot{V}O_{2max}$ on EFL. **RESULTS:** 63% of subjects ($n = 78$) displayed EFL with an average severity of 43.3 ± 21.0%. EFL showed significantly lower FEV_1 (4.5 ± 0.6 vs. 4.9 ± 0.6 L, $p < .001$), FEV_1/FVC (86.3 ± 7.8 vs. 91.3 ± 5.7%, $p < .001$), and FEF_{50} (6.1 ± 2.0 vs. 7.6 ± 1.4 L·s⁻¹, $p < .001$). However, no significant differences were found in FVC (5.2 ± 0.7 vs. 5.3 ± 0.8 L, $p = .191$) between groups. EFL showed a significantly smaller DR (0.2 ± 0.1 vs. 0.3 ± 0.1, $p = .001$) compared to NEFL. There were no differences between EFL and NEFL at peak exercise with respect to $\dot{V}O_{2max}$ (67.1 ± 8.1 vs. 65.4 ± 4.5 ml·min⁻¹·kg⁻¹, $p = .246$), VE (155.9 ± 26.0 vs. 158.6 ± 26.6 L·min⁻¹, $p = .59$), or frequency of breathing (56.8 ± 8.6 vs. 55.4 ± 10.3 br·min⁻¹, $p = .42$). A significant predictive relationship was observed between DR on EFL (Odds Ratio (OR): 0.55, 95% CI 0.36 to 0.81, $p < .01$). A multivariate analysis indicated that DR (OR 0.35, 95% CI 0.21 to 0.58, $p < .001$), FVC (OR 0.49, 95% CI 0.31 to 0.78, $p = .003$), and $\dot{V}O_{2max}$ (OR 1.63, 95% CI 1.05 to 2.53, $p = .028$) were significant predictors of EFL. **CONCLUSIONS:** Consistent with previous findings in active subjects, an increase in DR or FVC significantly decreases the likelihood of EFL in highly trained athletes. However, results from this analysis show that when controlling for DR and FVC, an increase in $\dot{V}O_{2max}$ significantly increases the likelihood of EFL. This relationship was previously found to be non-significant in healthy active individuals and may highlight potential differences that exist within endurance trained populations.

No Sex Differences In Diaphragmatic Fatigue When Matched For Absolute Force During Inspiratory Pressure-threshold Loading

Caitlin M. Geary, Joseph F. Welch, Malcolm R. McDonald, Carl M. Peters, Paige A. Reinhard, Michael G. Leahy, A William Sheel, FACSM. University of British Columbia, Vancouver, BC, Canada. (Sponsor: A. William Sheel, FACSM)

Email: caitlin.geary@alumni.ubc.ca

(No relevant relationships reported)

It has recently been demonstrated that women experience an attenuated cardiovascular response to inspiratory pressure-threshold loading (PTL). Furthermore, due to a significantly longer time to task failure, the rate of development of diaphragmatic fatigue (DF) is slower in women compared to men. It is unclear if the abovementioned differences are due to discrepancies in absolute diaphragm force output. **PURPOSE:** To examine sex differences in DF when matched for absolute diaphragmatic pressure during inspiratory PTL. **METHODS:** Fourteen healthy men ($n = 6$) and women ($n = 8$) performed a single bout of PTL for five minutes. Subjects were required to breathe in a square-wave fashion whilst targeting a transdiaphragmatic pressure (P_{di}) of 92 cm H₂O. Fatigue of the diaphragm was assessed via twitch P_{di} ($P_{di,tw}$) using cervical magnetic stimulation. Cardiovascular responses, including heart rate (HR) and mean arterial blood pressure (MAP) were monitored beat-by-beat throughout PTL. **RESULTS:** Following inspiratory PTL, the total work done by the diaphragm (~13,500 cm H₂O·s, $p = 0.50$) and the reduction in $P_{di,tw}$ was not different between sexes ($M = 26 ± 8\%$, $W = 25 ± 9\%$; $p = 0.82$). When scaled to body mass, women produced more diaphragmatic pressure ($M = 38 ± 7$ cm H₂O·s·min⁻¹·kg⁻¹, $W = 45 ± 8$ cm H₂O·s·min⁻¹·kg⁻¹; $p = 0.01$). There was no effect of sex on Δ HR ($M = +14 ± 12$ bpm, $W = +15 ± 9$ bpm; $p = 0.50$) during PTL; however, Δ MAP was lower in women compared to men ($M = +31 ± 16$ mmHg, $W = +21 ± 13$ mmHg; $p = 0.03$). **CONCLUSION:** Inspiratory PTL matched for absolute diaphragmatic work results in a similar degree of DF between sexes. Despite performing the same level of absolute diaphragmatic work and developing the same degree of DF, women demonstrate an attenuated inspiratory muscle metaboreflex. Effects of Acute Intermittent Hypoxia on Maximal Respiratory Ability after Spinal Cord Injury

Tommy W. Sutor¹, Kathryn Cavka², Shakeel Ahmed¹, David D. Fuller¹, Gordon S. Mitchell¹, Emily J. Fox¹. ¹University of Florida, Gainesville, FL. ²Brooks Rehabilitation, Jacksonville, FL.

Email: tsutor@ufl.edu

(No relevant relationships reported)

After spinal cord injury (SCI), respiratory complications are a leading cause of morbidity and mortality. A novel technique, acute intermittent hypoxia (AIH) triggers spinal motor plasticity, and can increase tidal volume at rest in humans with SCI. Only sparse, inconclusive literature exists about the effects of AIH on maximal effort respiratory maneuvers after SCI. **Purpose:** this pilot study seeks to investigate the effects of AIH on maximal effort respiratory ability in adults with SCI. **Methods:** 4 community-dwelling, adult males with SCI completed a single AIH or sham treatment in randomized order, 7+ days apart. AIH consisted of 15, 1 minute periods breathing a hypoxic gas mixture (9-13% oxygen), interspersed with 1.5 minute periods breathing room air. Sham treatments replicated AIH, but used air (21% oxygen) versus hypoxic episodes. Blood oxygen saturation was monitored. Maximal inspiratory pressure (MIP) and maximal expiratory pressure (MEP) were recorded prior to and 30 minutes after AIH and sham. Pre and post scores for each condition were compared using non-parametric Friedman's two-way ANOVA by ranks. **Results:** Baseline blood oxygen saturation averaged 97 ± 2%. During AIH, saturation decreased to an average of 82 ± 3%, then returned to baseline. Blood oxygen saturation remained stable during sham treatments. MIP did not differ at any point on either day (pre-AIH, 90.4 cmH₂O +/- 34.33; post-AIH, 99.35 cmH₂O +/- 17.6; pre-sham, 98.8 cmH₂O +/- 21.3; post-sham, 85.2 cmH₂O +/- 17.3; $X^2 = 6.231$, $p = .101$). MEP did not differ at any point on either day (pre-AIH, 91.2 cmH₂O +/- 23.1; post-AIH 93.4 cmH₂O +/- 26.8; pre-sham 80 cmH₂O +/- 25.6; post-sham 85.4 +/- 21.1; $X^2 = 2.4$, $p = .494$) Individually, 3 participants increased MIP after AIH, but decreased after sham; the fourth participant increased MEP after AIH, but decreased after sham. **Conclusion:** These pilot study results suggest AIH may affect maximal effort respiratory ability in adults with SCI. Although group means did not differ, individual outcomes varied with AIH improving one outcome in each participant versus sham. Further research is warranted to examine response variations and to determine the therapeutic potential of AIH after SCI. **Support:** Brooks-PHHP Research Collaboration; Center for Respiratory Research and Rehabilitation at the University of Florida.

Combined Influences of Inspiratory Loading and Subsystolic Circulatory Occlusion on Blood Pressure Responses

Joshua R. Smith, Eric J. Bruhn, Jessica D. Berg, Thomas P. Olson, FACSM. Mayo Clinic, Rochester, MN. (Sponsor: Thomas Olson, FACSM)

Email: smith.joshua1@mayo.edu

(No relevant relationships reported)

Group III/IV muscle afferent feedback from the respiratory and locomotor muscles influence the blood pressure response during exercise. Stimulation of these respiratory and locomotor muscle afferents (via inspiratory loading (IL) or subsystolic circulatory occlusion (CUFF), respectively) augments the blood pressure response during exercise. However, it is unknown if the combination of IL and CUFF (IL+CUFF) results in a greater blood pressure response than observed with IL or CUFF. **PURPOSE:** To compare the blood pressure responses with IL, CUFF and IL+CUFF during exercise in healthy adults. **METHODS:** Nine adults (6M/3W; 29±6 yrs; BMI: 27±4 kg/m²) were recruited. Participants performed four 10 min cycling exercise bouts at 40% peak oxygen uptake. For each exercise bout, the first 5 min consisted of spontaneous breathing (SB). The second 5 min consisted of voluntary hyperventilation (i.e. breathing frequency of 40 breaths per min with 50% duty cycle) with IL (30% maximum inspiratory pressure), CUFF (80 mmHg), IL+CUFF or no intervention (CTL) in randomized order. Systolic and diastolic blood pressure (SBP and DBP, respectively) were measured using manual sphygmomanometry. MAP was calculated as (SBP-DBP)/3+DBP. **RESULTS:** Compared to SB, MAP and SBP were greater with CTL, IL, CUFF and IL+CUFF (all, $p < 0.01$). Compared to SB, DBP was greater with IL, CUFF, and IL+CUFF (all, $p < 0.01$). During the second 5 min of exercise, there were differences across all conditions in MAP (CTL: 93±11; IL: 100±10; CUFF: 107±10; IL+CUFF: 113±11 mmHg) (all, $p < 0.01$). During the second 5 min of exercise, there were significant differences across all conditions in SBP (all, $p < 0.01$) except IL was not different than CUFF ($p = 0.09$) (CTL: 134±20; IL: 144±20; CUFF: 150±22; IL+CUFF: 159±23 mmHg). During the second 5 min of exercise, there were significant differences across all conditions in DBP (all, $p < 0.01$) except no differences existed between CUFF and IL+CUFF ($p = 0.15$) (CTL: 73±8; IL: 79±8; CUFF: 86±6; IL+CUFF: 89±7 mmHg). **CONCLUSIONS:** These data demonstrate that combined stimulation of respiratory

and locomotor muscle afferent feedback results in a greater blood pressure response than either alone. These findings have important implications for populations that exhibit exaggerated locomotor and respiratory muscle reflexes (e.g., heart failure).

106 May 29 10:45 AM - 11:00 AM

Roles Of ROS and Akt In Reoxygenated Respiratory Muscle from PO₂ Cycling-Treated Smoking Mice

Li Zuo, FACSM. *University of Maine, Presque Isle, ME.*
Email: zuo.4@osu.edu

(No relevant relationships reported)

PURPOSE: To test the hypothesis that reactive oxygen species (ROS) and protein kinase B (AKT) are signaling molecules involved in the protective effect of PO₂ cycling during reoxygenation in smoking-induced COPD mice. **METHODS:** To develop COPD symptoms, male C57BL6 mice were exposed to cigarette smoking for two hr per day, five days a week for three consecutive months. The smoking mice were then sacrificed, and their diaphragm was dissected out for muscle function analysis. Each muscle strip was mounted in a contractile chamber treated either with 5 cycles of PO₂ cycling or with the respective inhibitors for ROS (Tiron, 1 mM; N-acetyl cysteine, NAC, 1 mM; n = 7) or AKT (MK-2206, 50 μM; n = 5) for 30 min before PO₂ cycling. Muscle was then switched to hypoxia for 30 min, followed by 15 min of reoxygenation. In the middle of reoxygenation (5-10 min), each muscle strip was electrically stimulated for five min using square-wave electrical pulses (70 Hz, 250-ms train duration, at 30 V) at 37 °C. Muscle force was recorded and end contractile force during the 5-min contraction was normalized by the maximal baseline force to represent muscle function. Control muscles followed the same protocol but in the absence of PO₂ cycling or inhibitor treatment. Data were expressed as mean ± SE and statistically compared using one-way ANOVA. **RESULTS:** Our data indicate that PO₂ cycling significantly improved diaphragm function during reoxygenation in smoking mice (18 ± 1.3% for PO₂ cycling vs. 8 ± 1.5% for control, p < 0.05). However, inhibition of either ROS or AKT abolished such protective effects on diaphragm (11 ± 2.5% for Tiron + NAC + PO₂ cycling; 6 ± 2.1% for AKT inhibitor + PO₂ cycling; 18 ± 1.3% for PO₂ cycling, p < 0.05). **CONCLUSIONS:** In smoking-induced COPD mice, we suggest that PO₂ cycling can improve the diaphragmatic function during reoxygenation potentially through the intracellular signaling of ROS and AKT.

107 May 29 11:00 AM - 11:15 AM

Does Acute Preprandial Exercise Attenuate Postprandial Airway Inflammation In Active Younger And Older Adults?

William S. Wiseman¹, Elizabeth S. Edwards¹, Hannah Frick¹, Morgan Medeiros¹, Camden Sutton¹, Michael White¹, Steve Malin, FACSM², Dave Edwards², Stephanie P. Kurti¹. ¹James Madison University, Harrisonburg, VA. ²University of Virginia, Charlottesville, VA. (Sponsor: Steven Kenneth Malin, FACSM)
(No relevant relationships reported)

Even a single high-fat meal (HFM) is associated with increased airway inflammation. While exercise may modify postprandial airway inflammation, the protective effect may be diminished by age. **Purpose:** To determine whether an acute bout of preprandial exercise attenuates postprandial airway inflammation in active younger and older adults. **Methods:** 8 younger active (YA: 23.5±4.5 y/o) and 5 older active (OA: 64.8±2.6 y/o) that habitually exceed physical activity (PA) guidelines completed two HFM sessions in a randomized order. In exercise + HFM (EX+HFM), subjects performed exercise at a heart rate of 65% VO_{2peak} to expend 75% of the caloric content of the HFM. In both sessions, subjects refrained from exercise for 48 hours prior to the HFM challenge (except for the exercise session in EX+HFM), and visited the lab after a 12-hour fast to consume the HFM (12 kcal/kg BW: 57% fat, 39% CHO, 4% protein). Triglycerides (TG) and exhaled nitric oxide (eNO) were measured at baseline, 2- and 4-hours post-HFM. **Results:** The mean eNO at baseline for the YA and OA was not significantly different (p=0.17). The increase in eNO from baseline to 2 hours in the HFM condition was 13.1±26.9% and during the EX+HFM was 2.5±11.6% in the YA adults, and was -1.2±11.3% in the HFM alone and 10.8±15.0% in the EX+HFM. However when analyzing all subjects together, the airway inflammatory response was not significantly different across time (p=0.08), by age (p=0.23), or by condition (p=0.80). There was a significantly greater TG response in the HFM condition compared to the EX+HFM condition in OA (p<0.05), which was also lower in the YA (p<0.05). **Conclusions:** With these preliminary analyses, airway inflammation does not appear to be altered by age or preprandial exercise, however the triglyceride response is modified by acute exercise and age.

Unusual Wrist Injury Presentation in a Football Player

Hamad Saleemi, Jill Sadoski. *UHS Sports Medicine, Vestal, NY.*
(Sponsor: James Dunlap, FACSM)
Email: hamadsaleemi@gmail.com

(No relevant relationships reported)

HISTORY: 17-year-old high school football player presented for sideline evaluation with right wrist pain. The injury occurred when he was tackled and had his wrist twisted and caught under another player. His coach kept him in the game and after one more play, his teammates called out for medical attention. He had diffuse swelling and pain along the ulnar aspect of the distal forearm and wrist. He was placed in a volar splint and sent to the emergency department where x-ray imaging of the wrist was read by radiologist as normal. The athlete followed up in clinic four days later. He continued to have pain, restricted range of motion, and decreased strength. Review of systems was otherwise normal. Past medical history was unremarkable. **PHYSICAL EXAMINATION:** Wrist examination showed moderate diffuse swelling but no ecchymosis or deformity. He had tenderness along the ulnar aspect of the distal wrist. There was no tenderness at the anatomic snuff box or scaphoid tubercle. Range of motion was limited in all directions, especially in supination. Strength was 4+/5 in all motions except for supination, which was 3+/5. Special tests including triangular-fibrocartilage complex grind, Watson's, and Finkelstein's were equivocal. Sensation to light touch was intact. Radial pulses were equally palpable bilaterally. **DIFFERENTIAL DIAGNOSIS:** 1) Ulnar styloid or hook of hamate fracture. 2) Distal radioulnar joint injury. 3) TFCC injury. 4) Scapholunate or lunotriquetral dissociation. **TESTS AND RESULTS:** Initial x-rays at ED were read as normal. Repeat x-rays were concerning for volar ulna dislocation. MRI without contrast showed volar dislocation of the ulna. **FINAL/WORKING DIAGNOSIS:** Radioulnar joint dislocation with volar displacement of ulna. **TREATMENT AND OUTCOMES:** 1. Orthopedic hand surgery referral. Given the length of time since initial injury, closed reduction was performed under general anesthesia. 2. Long arm cast with the forearm in supination position for 4 weeks. Repeat x-rays demonstrated maintenance of reduction. After cast removal, the patient returned to football with a removal wrist splint.

112 May 29 9:50 AM - 10:10 AM

Forearm Pain in a High School Weightlifter

Matthew Severson, Karen Newcomer, FACSM, David Soma. *Mayo Clinic, Rochester, MN.*
Email: mattseverson@gmail.com

(No relevant relationships reported)

HISTORY: A 17 year-old left-handed high school senior baseball player with a history of Langerhans cell histiocytosis presented to the outpatient clinic with pain on the ulnar aspect of his proximal right forearm. The pain had developed over the course of 2 months after he had increased the intensity of his offseason weight training regimen. He first noticed the pain while performing a high volume of upper body lifting, specifically bicep curls; pain was most severe during weightlifting but now occurred even during non-lifting activities. The patient denied any constitutional or neurologic symptoms. **PHYSICAL EXAMINATION:** Inspection was unremarkable. Examination revealed moderate tenderness approximately at the junction of the proximal to mid one-third of the right ulna. There was very mild tenderness over the proximal extensor tendons and muscle bellies on the right forearm. He had subtle pain over the ulna with resisted elbow flexion but otherwise normal, pain free range of motion and full strength in the right upper limb. Reflexes and sensation were normal. **DIFFERENTIAL DIAGNOSIS:** 1. Muscle strain

2. Extensor tendinopathy
3. Bone tumor
4. Posterior interosseous nerve entrapment
5. Ulnar fracture
6. Exertional compartment syndrome

TEST AND RESULTS:

Right forearm AP and lateral x-rays: negative for fracture or bony abnormality
MRI right forearm without contrast: Incomplete intracortical stress fracture of the mid ulnar diaphysis

FINAL WORKING DIAGNOSIS:

Ulnar stress fracture

TREATMENT AND OUTCOMES:

1. Rest and avoidance of weightlifting or loading of the right upper extremity until follow up
 2. Due to patient reluctance to rest, right wrist/forearm brace while awake to remind him to rest the limb
 3. At 4-5 week follow-up, pain was completely resolved
 4. At that time he was instructed to gradually re-introduce weight-bearing exercises of the right upper limb as tolerated, beginning with isometric wrist strengthening followed by low intensity flexion/extension exercise before progressing to heavier lifts involving larger muscles groups and multi-joint movements
- Patient was able to return to all activities and declined physical therapy.

113 May 29 10:10 AM - 10:30 AM

Elbow Pain in an Adolescent Pitcher

Nicholas C. Canzanello, Brittany J. Moore, Karen L. Newcomer, FACSM. *Mayo Clinic, Rochester, MN.* (Sponsor: Dr. Karen Newcomer, FACSM)

Email: canzanello.nicholas@mayo.edu

(No relevant relationships reported)

HPI

Patient is a 16 year old right-hand dominant male baseball pitcher with past medical history of partial tear of the right UCL and OCD of the right lateral trochlea managed with casting 9 months prior. He presented to our clinic with insidious onset right posterolateral elbow and arm pain 2 months after returning to pitching in summer baseball in May.

He described sharp pain in the right lateral elbow with radiation into the posterolateral arm exacerbated with push-ups and bench press. He noticed a painless popping sensation with elbow extension, but denied weakness or sensory changes. The pain was not specifically associated with baseball or pitching and was different from his previous pain.

PHYSICAL EXAM

Mild tenderness at right common extensor tendon origin worsened with 5 push-ups and improved with rest. Mild tenderness at right posterolateral triceps border. Slight weakness of the right triceps with pain. Varus and valgus stress caused no pain, but there was asymmetry with minimally increased laxity during valgus stress on the right. Negative extensor wad stress tests including Cozens, middle finger extension and Mills. No pain with flexor-pronator stretching. No pain with resisted pronation or supination.

DIFFERENTIAL DIAGNOSIS

1. Triceps tendinitis
2. Lateral epicondylitis
3. Radial nerve irritation
4. OCD radiocapitellar joint
5. Intraarticular loose body
6. Stress reaction/stress fracture distal humerus
7. Bony tumor/infection

TEST AND RESULTS

Right elbow non-contrast MRI- Bone marrow edema within the olecranon and distal humerus medially as a result of stress reaction from excessive valgus stress. Thickening of the UCL. Healed osteochondral lesion of the right elbow trochlea.

FINAL DIAGNOSIS

Valgus overload stress injury to distal humerus

TREATMENT AND OUTCOMES

3 months of rest from pitching followed by throwing progression via a pitching rehabilitation program. The program consists of focused strength training (RTC, scapular stabilizers) followed by normalizing throwing mechanics with gradual return to pain free baseball. We discussed with the patient the harmful effects on single sports athletes, particularly pitchers. We recommended he watch his pitch counts closely in the future (he admitted he hadn't been doing that) and take at least 2 months off of baseball during the year.

114 May 29 10:30 AM - 10:50 AM

Medial Elbow Pain - Recreational Athlete

Arie J. van Duijn¹, Shawn D. Felton². ¹*Florida Gulf Coast University, Fort Myers, FL.* ²*Florida International University, Miami, FL.* (Sponsor: Mitchell L Cordova, FACSM)

Email: avanduij@fgcu.edu

(No relevant relationships reported)

HISTORY: 22-year female recreational athlete with history of left elbow pain following a fall on outstretched arm during a running/cutting activity. She noted immediate local pain of 7/10 on VAS and swelling of the medial elbow and forearm. She was unable to fully extend the elbow. **PHYSICAL EXAMINATION:** Edema was noted at the medial elbow, extending into the medial forearm. Palpation of soft tissues, tendon and bony structures revealed significant point tenderness at the medial joint space and at the medial epicondyle. Limited active ROM with extension was noted due to pain. Valgus stress test was positive, with significant discomfort upon moderate loading. Due to significant pain complaints, further physical examination was suspended and clinician progressed to point-of-care ultrasound imaging of the medial elbow complex. **DIFFERENTIAL DIAGNOSIS:** 1. Medical Collateral ligament sprain 2. Medial Collateral ligament disruption 3. Common Flexor Tendon Pathology 4. Pronator Teres Strain 5. Medial epicondyle avulsion fracture 6. Biceps tendon pathology. **TESTS AND RESULTS:** Bilateral ultrasound imaging of the medial elbow complex revealed disruption of the ligamentous fibers of the UCL anterior band at the joint line. A large hypoechoic gap in the UCL is present, denoting the presence of significant fluid. Gravity valgus stress loading revealed a joint gap of 0.76cm compared to 0.38cm of the uninvolved side. **FINAL WORKING DIAGNOSIS:** Full thickness tear of the anterior bundle of the medial collateral ligament. **TREATMENT AND OUTCOMES:** Since the athlete did not participate in overhead throwing activities, conservative management approach was selected. ROM was limited 0-100 degrees initially to full ROM at 4 weeks post injury. Strengthening was initiated with initial emphasis on core and shoulder musculature, progressed to elbow and forearm musculature, including the flexor/pronator group as an active stabilizer against valgus forces. Patient was symptom-free at 4 months following injury, and ultrasound imaging revealed reduced valgus joint gapping. This case presentation illustrates the utility of ultrasound imaging in diagnosing MCL pathology, especially when physical examination is limited due to patient discomfort, and further illustrates the successful conservative management of a full thickness MCL tear.

115 May 29 10:50 AM - 11:10 AM

Acute Bilateral Elbow Pain In a College Volleyball Player

Jonathan Smith, Dennis Khalili-Borna, FACSM. *Kaiser Permanente Fontana Medical Center, Fontana, CA.*

Email: jonathan.x.smith@kp.org

(No relevant relationships reported)

History: A 19 year old college volleyball player presents to the athletic training room with chief complaint of bilateral elbow stiffness and swelling for one day. Her evaluation in the training room revealed mild decrease in elbow extension bilaterally with pain at terminal elbow extension. She was observed and treated conservatively with NSAIDs, compression wraps, over a two day period. Elbow swelling improved initially then began to track down the forearm. After day 2 of observation she continued to have muscle soreness and swelling. She denied abdominal pain, changes in urine color or decreased urine output. She was sent the Urgent Care for further evaluation of her symptoms.

Physical Exam: Vitals were normal during training room visits. Initial exam revealed tenderness to palpation over the flexor and extensor masses of the elbow as well as mild swelling. She had a slight decrease in active and passive elbow extension bilaterally and she exhibited pain at terminal elbow extension bilaterally. Flexion was preserved.

Differential Diagnosis: 1) Delayed Onset Muscle Soreness 2) Epicondylitis 3) Valgus Extension Overload 4) Olecranon Stress Fracture 5) Rhabdomyolysis 6) Exertional Compartment Syndrome 7) Olecranon Fossitis

Tests: CBC was within normal limits. Electrolytes were within normal limits. Creatinine showed mild elevation. CPK was significantly elevated at 40,000 U/L

Final Working Diagnosis: Rhabdomyolysis

Treatment and Outcomes: The patient was admitted the hospital for a 4 day period for IV fluids and observation. Over the course of her hospitalization her CK levels were trended and she was released after CK levels were below 5,000 U/L. Her PCP continued to trend Creatinine levels after she was discharged and they continued to trend downwards. Two weeks after discharge she started on a 3 week gradual return protocol and she remained symptom-free. Follow up labs were drawn prior to her first match and showed only mildly elevated CK (230 U/L) with normal creatinine and GFR. She has been participating in matches at full capacity and remains asymptomatic.

116 May 29 11:10 AM - 11:30 AM
Management of a 58-Year Old Crossfit Athlete with Elbow Pain by Treating the Contralateral Hip Region
 Megan L. Pfeffer, DACBSP, DC, ATC. *Voodoo Chiropractic, Nashville, TN.*
 Email: drmegan13@gmail.com
 (No relevant relationships reported)

MANAGEMENT OF A 58-YEAR OLD CROSSFIT ATHLETE WITH ELBOW PAIN USING MYERS FASCIAL LINES

M. L. Pfeffer, DC, CCSP, ATC, *Voodoo Chiropractic, Nashville, TN*

ABSTRACT

HISTORY: 58 y/o male recreational CrossFit athlete presented with insidious left lateral elbow pain, progressing over several weeks and exacerbated by pull-ups and overhead barbell movements.

CLINICAL EXAMINATION: Patient had mild tenderness over the left lateral epicondyle, as well as moderate tenderness and increased tone in extensor group muscles. Gripping increased left elbow pain. No strength or neurological deficits were noted. Mill's Test was negative. Cozen's Test was positive for pain over the lateral epicondyle. **DIFFERENTIAL DIAGNOSES:** 1. Lateral Epicondylitis 2. Radial Tunnel Syndrome **TREATMENT & RESULTS:** Manual therapy to the forearm extensor group decreased local muscle tension, but had little to no effect on elbow pain following three visits. Stretching, contrast, and rest did not positively impact pain. Referencing the Myers Functional and Arm Lines, treatment of the thoracolumbar junction and right hip region by cupping, dry needling, and spinal adjustment were performed with noticeable improvement noted after the fourth visit. Following another similar treatment, the patient's condition resolved. **FINAL DIAGNOSIS:** Elbow pain secondary to fascial restriction along Myers Functional & Arm Lines **DISCUSSION:** Little has been published regarding the role of fascial lines in diagnosis or treatment of orthopedic injuries. Since local treatment appeared ineffective, looking elsewhere in the biomechanical chain was necessary. Both provocative movements increase lumbar extension if done improperly, creating compensatory dysfunction. Therefore, shoulder & thoracic mobility and core stability were also addressed to prevent future injury. While other factors may have contributed, it appears releasing seemingly unrelated fascial restrictions noticeably impacted the results.

injury that he can recall. He experiences some tightness when running. He denies feeling weak in the hip or knee. He denies any bruising. He can feel a hard mass in the location of his symptoms.
PHYSICAL EXAMINATION: He has a normal gait without limp. There is no visible swelling, bruising or deformities of the left thigh. Approximately over the mid to superior quadriceps there is an area of approximately 4 cm x 3 cm that is slightly indurated, non-tender but the patient reports it is uncomfortable to palpate. There is no fluctuance. There is no limitation or pain with active and passive range of motion at the knee or hip. Hip flexion and knee extension strength are a 4/5 without pain with resistance. The remainder of the physical examination is non-contributory.

DIFFERENTIAL DIAGNOSIS:

1. Quadriceps strain
2. Myositis ossificans
3. Quadriceps hematoma
4. Lipoma
5. Occult tumor

TEST AND RESULTS:

Initial imaging included plain radiographs, which did not show any acute or chronic osseous abnormalities. The soft tissues appear normal. Musculoskeletal ultrasound demonstrated a large hypoechoic defect within the rectus femoris muscle. An MRI showed a full-thickness tear of the indirect muscle of the rectus femoris, with a 1.5 cm craniocaudad gap/retraction of the indirect muscle at the myotendinous unit.

FINAL/WORKING DIAGNOSIS:

Full-thickness tear of the indirect head of the left rectus femoris tendon with retraction of the myotendinous unit

TREATMENT AND OUTCOMES:

Due to the fact that the patient was not very symptomatic, we recommended a trial of non-operative management. This included rest from sports and physical therapy to work on strengthening. Displeased with this plan, the family sought a second opinion from the team physician for a local Division I college volleyball team. In a telephone follow up conversation with the patient's mother, the team physician also recommended non-operative management.

 Email: aloiya.earl@gmail.com
 (No relevant relationships reported)

HISTORY: A healthy 10-year-old male multi-sport athlete experienced insidious onset of right thigh pain associated with limp for about one week prior to office presentation. The pain started during his school day and had progressively worsened over the week, which caused him to be unable to complete his baseball practices. The pain was worse with running and jumping. He did not have nocturnal pain, weight loss, or night sweats. Of note, he had an identical presentation about 8 months prior in his contralateral thigh which was diagnosed as a compression-sided stress fracture of his left femoral neck and treated conservatively. **EXAM:** Afebrile. Well-appearing. Limping gait. Lumbar spine exam WNL. Bilateral knee exam WNL. Left hip exam WNL. On exam of his right hip, he had tenderness diffusely in his proximal anterior and lateral thigh and over his AHS. He had full hip ROM but with pain at the extremes of flexion, IR, and ER. Strength of LLE WNL. Strength of RLE limited to 4/5 with hip abduction and hip flexion due to pain. Seated and supine log roll positive for pain. Unable to perform a single-leg hop on his right side. He had pain with bowing of his femur. Neurovascular examination of bilateral LE WNL. **DDX:** Acute synovitis, stress fracture, Legg-Calve-Perthes disease, SCFE, pathologic fracture **RESULTS:** XR pelvis 10/10/18: No apparent osseous abnormality. MRI right hip 10/11/18: Edema within the medial femoral neck, most likely stress-related. 10/15/18 CMP, PTH, TSH, Vit D: WNL. **FINAL/WORKING DIAGNOSIS:** Compression-sided stress reaction of the right femoral neck, which was his second stress injury within 8 months, the first being in his left femoral neck **TREATMENT/OUTCOME:** The patient was treated for his second stress injury with conservative management again. He was instructed to be NWB with crutches for 6 weeks, after which he would have a follow up visit and if doing well clinically and radiographically, would progress to partial protected weight bearing and formal PT to transition back to sport. Given his normal lab workup, he was also referred to an orthopedic hip specialist to evaluate for possible biomechanical contributions to abnormal stress through the femoral neck or connective tissue disorders. His sports schedule was reviewed. Multi-sport participation was encouraged, but with a 3-month consecutive break during the year.

Insidious Onset of Thigh Swelling After Trauma in a Triathlete

Alexander Jason Bressler¹, Hanh Larson², Robert Sallis, FACSM¹. ¹Kaiser Permanente, Fontana, CA. ²Pomona Valley Hospital Medical Center, Pomona, CA. (Sponsor: Robert Sallis, FACSM)

Email: ajbressler@hotmail.com

(No relevant relationships reported)

HISTORY A 78-year-old female triathlete presented to clinic to follow-up on injuries sustained during a cycling accident. Evaluation in the ED on the day of injury showed facial bone fractures and small peripheral parenchymal hematomas in the right frontal and temporal lobes for which she had follow-up scheduled. In clinic two days later, she complained of pain and bruising over her right hip. She was diagnosed with an abrasion and contusion of the right hip and treated with ice and NSAIDs. She returned four weeks later with worsening right hip pain, described as constant, throbbing, non-radiating, and worse with weight-bearing. It was associated with swelling and a tender mass that had developed gradually over the right hip. She denied fevers or chills.

PHYSICAL EXAMINATION Vitals were normal at both visits. Initial exam of the right hip showed a large abrasion, mild ecchymosis, and tenderness. She had full range of motion without pain or edema. She also had normal balance and gait. Four weeks later, the right hip had a 15 x 17 cm, warm, tender mass over the lateral aspect of the thigh, without erythema. FABER and FADIR were negative, and muscle strength, pulses, and sensation were normal. The abrasion was well-healed. **DIFFERENTIAL DIAGNOSIS** 1. Hematoma 2. Contusion 3. Bursitis 4. Abscess 5. Neoplasm **TESTS AND RESULTS** CBC was normal. Radiographs of right hip were negative for fracture or soft tissue abnormalities. MRI of the right lower extremity showed a heterogeneous fluid collection measuring 22 x 4 x 6 cm (H x W x D, 528 cc) overlying the right hip with small internal foci of hemorrhage/debris, and peripheral rim enhancement without any areas of internal enhancement. **FINAL WORKING DIAGNOSIS** Morel-Lavallée lesion **TREATMENT AND OUTCOMES** The patient underwent aspiration, doxycycline sclerotherapy, and percutaneous drainage. Post-procedure US was negative for any significant fluid collection. Repeat MRI three weeks after the procedure showed incomplete resolution/recurrence of the lesion measuring 20 x 1.5 x 2.8 cm (84 cc). The patient had follow-up with orthopedics and elected for conservative treatment with compression dressings. She returned to triathlon training and has subsequently completed a 100-km bike race at 6 months post injury.

123 May 29 10:30 AM - 10:50 AM

Hamstring Pain - Biker

Kathleen Shaughnessy, Sean M. Harris. *Memorial Hermann, Houston, TX.*

(No relevant relationships reported)

HISTORY: A 53-year-old male reports to physical therapy with L posterolateral thigh pain. Three years prior, pt's spring ligament popped and required surgical reconstruction. During the patient's surgery, he had a nerve block to the lateral hamstring. Patient completed necessary therapy and attempted to return to exercise. Following attempts at exercising, patient reported sporadic symptoms of leg weakness. Patient has had two normal nerve conduction tests as well as a normal MRI of the back, knee, and hip. At initial evaluation, patient is unable to bike or run, and describes symptoms of localized weakness and achiness post-exercise.

PHYSICAL EXAMINATION:

Posture normal, no apparent gait deviations. Pain localized to the distal lateral hamstring. Full, pain-free lumbar spine, hip, and knee AROM and overpressure. Gross LE strength testing within normal limits except for L hamstring (3+/5). Dynamometer reading R: 38lbs, L 25lbs. Contraction did not reproduce patient's pain. Symptoms present with elongation of L hamstring muscle. Deep squat limited by "tightness" in L calf.

DIFFERENTIAL DIAGNOSIS:

1. Distal Peripheral Nerve Entrapment
2. Hamstring Tendinopathy
3. Mechanical Dysfunction

TESTS AND RESULTS:**Near Tissue Testing:**

- Positive slump test
- Painful arc of motion: Patient had symptoms at 40 degrees short of vertical that dissipate once patient's leg was lifted to 35 degrees
- Positive straight leg testing
- Reflexes were within functional limits

FINAL/WORKING DIAGNOSIS:

Distal peripheral nerve entrapment of mechanical nature.

TREATMENT AND OUTCOMES:

- 5 physical therapy sessions over 5 weeks
- Ergonomic desk set up
- Sciatic nerve sliders from slump position
- Progressive hamstring strengthening

- Aerobic circuit training

- Dry needling

- Two needles were inserted into the short head of the biceps and laterally to where the nerve runs.

- Improved LEFS from 60 to 80 in 5 weeks

- Neural symptoms normalized at 3 weeks

- Hamstring strength improved to 37lbs at 4 weeks (per dynamometer)

- Return to running/biking activities at 5 weeks

124 May 29 10:50 AM - 11:10 AM

Thigh Pain in a Baseball Player

Valerie Rygiel, Hallie Labrador. *NorthShore/University of Chicago, Chicago, IL.* (Sponsor: Carrie A. Jaworski, FACSM)

(No relevant relationships reported)

HISTORY:

Patient is a 14 year old male who presented to sports medicine clinic for evaluation of three weeks of right quadriceps pain that began while running during baseball practice. He was initially prescribed physical therapy for a presumed right quadriceps strain but on follow up two months later he continued to have pain with activities as well as a deformity in his right thigh that was growing in size.

PHYSICAL EXAMINATION:

On exam patient was well appearing, his right quad had no erythema or ecchymosis. He had a palpable mobile mass in the mid-thigh that was nontender to palpation but protruded with resisted knee extension. The remainder of the quadriceps muscle belly was nontender. His lower extremity strength and sensation were preserved.

DIFFERENTIAL DIAGNOSIS:

1. Quadriceps tear with retraction
2. Normal anatomic variant
3. Fascial herniation
4. Soft tissue mass

TEST AND RESULTS:

XRAY Right Femur: No acute fracture

MRI Right Femur w/wo Contrast: Grade 1 strain of rectus femoris muscle at the myotendinous junction, suggesting intramuscular degloving mechanism.

FINAL WORKING DIAGNOSIS:

Rectus Femoris intramuscular degloving injury

TREATMENT AND OUTCOMES:

The patient continued to work with physical therapy and was able to slowly reintroduce sport specific activities over the next month without recurrence of pain. His deformity has reduced significantly in size.

125 May 29 11:10 AM - 11:30 AM

Thigh Injury- Lacrosse

Timothy O. Boone, Jr. *University Of Maryland, Baltimore, MD.*

(No relevant relationships reported)

HISTORY: 20 year old sophomore lacrosse player sustained an acute injury to his right thigh while playing football during his senior year of high school. At that time, patient had reported immediate swelling of the thigh but had a delay in presentation to an outside sports medicine physician for about 3 months. Patient completed medical therapies outside of the recommendation of the sports medicine physician which allowed patient to play lacrosse during his senior year and throughout his freshman season of college. When completing off season workouts during his sophomore year, he complained of focal pain at his right thigh with his right knee giving out.

PHYSICAL EXAMINATION: His initial examination revealed a palpable mass over the right thigh with mild tenderness. When presenting 2 years later, his exam revealed no abnormality on inspection but there was a deep, immobile, non-tender palpable growth over anterior right femur with full range of motion of the right knee, hip and back.

DIFFERENTIAL DIAGNOSIS: 1. Heterotopic Ossification 2. Parosteal osteosarcoma

TEST AND RESULTS:

1. Right Femur X-ray (1/9/2017): 15.8 x 4.8 cm soft tissue calcification overlying the proximal femoral diaphysis with a 1.6 x 0.6 cm bone island in the distal femur.
2. Right Femur X-ray (9/18/2018): 13.9 x 1.8 cm matured soft tissue calcification over the anterior lateral aspect of the femur with 1.3 cm oval sclerotic density in the distal femoral metaphysis
3. MRI right thigh (10/2/2018): Mature heterotopic ossification that is contiguous with the anterolateral femoral diaphysis. Heterotopic ossification extends within the vastus intermedius muscle and measures 1.5cm x 6cm x 13cm.

FINAL/WORKING DIAGNOSIS: Mature heterotopic ossification of the right thigh

TREATMENT AND OUTCOMES:

1. Referred for surgical resection of the mass from right thigh due to symptoms, which was completed 1 month after secondary presentation
2. Immediately after surgical intervention, patient was allowed partial eight bearing x 1-weeks with knee locked in full extension and will continue Indomethacin for a total of 6 weeks

3. Patient about 7 days after from surgical intervention, patient advised by surgeon to begin work with physical therapy to wean off crutches and out of brace to work on knee ROM and quadriceps activation
4. Pathology results pending at this time

A-25 Clinical Case Slide - Knee I

Knee Pain - Baseball

Scott Goldberg, John H. Stevenson, Lee Mancini. *University Of Massachusetts, Worcester, MA.*

(No relevant relationships reported)

HISTORY: A 16 year old high school hockey player and baseball pitcher noticed lateral knee pain and intermittent swelling for about 2 months prior to presentation. He does not recall any trauma or injury. He did have a viral URI and episode of strep pharyngitis several weeks before this started. He denies radiation of the pain. He does note some catching and locking sensation of the knee. He feels that his knee flexion is limited. He treated the knee with ice, ibuprofen, and acetaminophen through the season and was able to complete his baseball season prior to presenting to his PCP for evaluation. Because no definite etiology was identified in this visit, MRI was ordered, which showed complex loculated effusion, enlarged popliteal lymph nodes, and synovial thickening. There were no structural injuries appreciated.

PHYSICAL EXAMINATION: Initial exam in the sports medicine clinic revealed tenderness at the lateral joint line and 1+ knee effusion. There was no erythema or warmth at the joint. He had full active and passive range of motion and full strength. Ligamentous testing was normal.

DIFFERENTIAL DIAGNOSIS:

- PVNS
- Rheumatologic condition
- Lymphoma/Leukemia
- Lyme disease
- Traumatic hemarthrosis

TEST AND RESULTS:

Repeat MRI with additional views: Complex loculated effusion; Synovitis/synovial proliferation; No hemosiderin staining with blooming artifact

Joint aspiration: 20 cc cloudy yellow synovial fluid; TNC 37,270, Neutrophils 73%

Cytology: No malignant cells

ANA: 1:80 homogeneous

Rheumatoid Factor: Negative

Lyme: Negative

ESR: 9

CRP: 21.8

CBC: WBC 5.9, Hgb 15.5, Hct 45.4, Plt 287

FINAL WORKING DIAGNOSIS: Juvenile idiopathic arthritis (JIA)

TREATMENT AND OUTCOMES:

- Referred to pediatric rheumatologist
- Bilateral knee aspiration and corticosteroid injection
- Prednisone taper
- Methotrexate therapy
- Check anti-CCP antibodies
- Referred to ophthalmology to rule out uveitis

130 May 29 9:50 AM - 10:10 AM

Knee Pain- Football

Megan Liberty¹, Jason Read². ¹*University of Florida College of Medicine- Jacksonville, Jacksonville, FL.* ²*Nemours Children's Specialty Care, Jacksonville, FL.*

(No relevant relationships reported)

HISTORY: A 14-year-old male football player presented to our sports medicine clinic complaining of left knee pain and swelling. Onset of knee pain was 2 months prior and he began to complain of intermittent swelling over the last 3-4 weeks prior to this initial visit. There was no reported history of trauma or injury. Pain worsened with activity and was localized to his anterior knee and medial joint line. NSAIDs and a knee brace did not alleviate his symptoms. He denied any associated knee instability, popping, locking or patellar instability. Neurological signs and symptoms were absent. Review of systems was otherwise negative. **PHYSICAL EXAMINATION:** Examination revealed a moderate sized left knee effusion with tenderness to palpation around the patella and medial joint line. There was no ecchymosis or erythema. Strength exam was normal. Knee range of motion was decreased in both flexion and extension secondary to swelling. There was pain on patellofemoral grind test with a negative patellar apprehension test. He had a negative Lachman and McMurray test. Anterior and posterior drawer tests were also negative. No ligament laxity was appreciated with varus or valgus stress testing. Examination of the contralateral knee was normal. He was otherwise well appearing with a normal gait. **DIFFERENTIAL DIAGNOSIS** 1. ACL tear 2. Meniscus tear 3. Fracture 4. Juvenile idiopathic arthritis 5. Osteochondritis dissecans **TESTS AND RESULTS** 3 view x-rays of left knee were obtained and normal. MRI revealed distal femoral osteomyelitis with associated intraosseous and subperiosteal abscess with deep posterior knee soft tissue abscess. CBC showed WBC 11.7, Hgb 10.5, Hct 32.2, Platelets 576. CRP 9.45mg/dL, ESR 57mm/hr. **FINAL/WORKING DIAGNOSIS** Osteomyelitis of the left distal femur with intraosseous and subperiosteal abscess **TREATMENT AND OUTCOMES** 1. Taken to the OR for incision and drainage 2. Cultures returned positive for oxacillin sensitive staphylococcus aureus. Pediatric infectious disease was consulted. A PICC line was placed and he completed a 6-week course of IV clindamycin. 3. Follow up x-rays taken 1-month post-op were normal 4. A full return to sports is expected.

131 May 29 10:10 AM - 10:30 AM

Knee Injury - Trampoline

Sabrina P. Sawlani, Brian McCall, Brian J. Donohue. *Presence Resurrection Medical Center, Chicago, IL.* (Sponsor: Poonam Thaker, FACSM)

(No relevant relationships reported)

HISTORY: 21-year-old male presents to ER for left knee injury after mis-landing a flip while jumping on a trampoline. He hyperextended his left leg, felt a pop and severe pain with numbness of left foot. Notable deformity which self-reduced.

PHYSICAL EXAMINATION: LLE: Ecchymoses and edema of distal thigh, knee and proximal leg. ROM- active and passive knee flexion and extension limited due to pain. DP/PT pulses nonpalpable, capillary refill mildly delayed, and cooler to touch distally. Diminished sensation of dorsomedial foot and lateral leg. Unable to extend toes or dorsiflex ankle. Exam under anesthesia with positive Lachman, anterior drawer, posterior drawer and varus stress tests.

DIFFERENTIAL DIAGNOSIS:

1. Knee dislocation with vascular compromise and peroneal nerve injury
2. Anterior cruciate ligament tear
3. Posterior cruciate ligament tear and posterolateral corner injury
4. Lateral collateral ligament rupture
5. Meniscus tear
6. Tibial plateau fracture
7. Distal femur fracture

TEST AND RESULTS:

-XR L Knee 4+ Views: Medial tibial condyle possible fracture.

-CT Angiogram LLE: Popliteal artery severe stenosis at level of tibial plateau.

Comminuted medial tibial plateau fracture.

-Diagnostic angiogram: Cut-off of popliteal artery at level of knee, unable to cross with stent.

FINAL WORKING DIAGNOSIS: Left knee dislocation with popliteal artery rupture and left medial tibial plateau fracture

TREATMENT AND OUTCOMES:

1. Emergent vascular surgery with ligation of L popliteal artery and repair of transected L popliteal artery with reverse saphenous vein interposition graft.
2. Orthopaedic Surgery external fixator placement and fasciotomies with skin closure to prevent possible reperfusion injury/compartement syndrome.
3. 2 weeks post-injury, ORIF medial tibial plateau and replaced ex-fix. Delayed ligament reconstructions unnecessary due to ligaments remain stable.
4. 6 weeks post-injury, removal of L leg external fixator. Nonweightbearing and in physical therapy.
5. 3 months post-injury, EMG for persistent foot drop with severe L peroneal neuropathy at knee.

6. 4 months post-injury, ambulating.
 7. 8 months post-injury, referred to peripheral nerve surgery specialist for decompression of L common peroneal nerve at fibular head, and excision of posterior and anterior crural intermuscular septae.

132 May 29 10:30 AM - 10:50 AM

Postoperative Knee Complication - Soccer

Kathleen Maguire, Lyle Micheli, FACSM. *Boston Children's Hospital, Boston, MA.* (Sponsor: Lyle Micheli, FACSM)

(No relevant relationships reported)

History:

17 year old female status post left ACL reconstruction with hamstring autograft presents one week after surgery with pain and swelling over posteromedial knee. A blood blister was noted and drained. She started on Keflex to prevent superficial wound infection. The following day she returned in exquisite pain with skin discoloration and formation of a collection over the posteromedial knee. This was presumed to be an infected hematoma and she was taken to the operating room for a postsurgical knee washout.

Physical Examination:

Examination noted an abscess at the popliteal fossa medially with surrounding erythema. The area over this collection was warm and tender to touch. The patient had no calf pain or swelling.

Differential Diagnosis:

1. Hematoma
2. Knee infection, bacterial or fungal
3. DVT
4. Contact dermatitis
5. Hemophagocytic lymphohistiocytosis (HLH)
6. Still's disease
7. Pyoderma gangrenosum
8. Behcet's

Tests and Results:

1. Single OR tissue culture positive for *s. hominis* and *p. acnes* early in hospital course, subsequent OR cultures negative for growth
2. Multiple blood cultures negative for growth
3. OR tissue biopsy shows marked neutrophilic infiltrate and abscess formation, clinically consistent with pyoderma gangrenosum (PG)

Final Working Diagnosis: Pyoderma gangrenosum

Treatment and Outcomes:

1. Surgery: 19 combined orthopedic and plastic surgery procedures including irrigation and debridement, wound VAC changes, and skin grafting of left knee
2. Infectious Disease (ID): Multiple courses of antibiotics for presumed left knee postoperative infection. Antibiotics discontinued once PG diagnosis was established
3. Hematology: PICC related DVT treated with anticoagulation, anemia managed with transfusions
4. Rheumatology/Dermatology: Due to the patient's highly elevated inflammatory markers, coagulopathy, anemia, and repeated procedures without significant detectable pathogenic organism, there was concern for an immune-mediated systemic inflammatory response. OR tissue biopsy supported this diagnosis. The patient was started on prednisone and Anakinra and the antibiotics were discontinued
5. She completed her course of anticoagulation, weaned off steroids and immunosuppressive medication and has had no recurrent symptoms

133 May 29 10:50 AM - 11:10 AM

Unexpected Knee Pain in a Young Field Hockey Player

Terrence Tsui, John Herbert Stevenson. *University of Massachusetts, Worcester, MA.* (Sponsor: Pierre Rouzier, FACSM)

(No relevant relationships reported)

HISTORY: A healthy 12-year-old-female field hockey player presented with 2 weeks of left knee pain that began while she was running in a straight line going into a game. She denied trauma to her knee and did not previously have knee pain. She suddenly felt a severe sharp pain localized to her proximal tibia and had trouble ambulating due to pain. She took ibuprofen, iced, and rested for a few days and was able to ambulate with minimal pain afterwards. She tried returning to practice but still had significant pain with running and stairs so was referred to sports medicine clinic by her PMD for further evaluation. Denied knee swelling, buckling, and locking. Denied numbness and tingling in her leg.

PHYSICAL EXAMINATION:

Left knee exam: Full ROM, 5/5 strength in knee flexion and extension, negative effusion, TTP immediately medial to the tibial tuberosity and over the medial tibial plateau, negative varus/valgus stress test, negative anterior and posterior drawer test, negative Lachman's test, negative McMurry's test, negative patella facet tenderness, negative grind test.

DIFFERENTIAL DIAGNOSIS:

Osgood-Schlatter disease
 Pes anserine bursitis
 Salter-Harris fracture
 Tibial plateau stress fracture
 Proximal tibial fracture
 Bone contusion

TESTS AND RESULTS:

Labs: Vit. D 25-OH level low, normal PTH and TSH levels
 Left knee XR: No acute fracture or other osseous abnormality detected.
 Left tibia/fibula: No acute fracture or other osseous abnormality detected.
 Left knee MRI: Transverse undisplaced fracture of the proximal tibial metaphysis.
 DEXA scan: WNL

FINAL WORKING DIAGNOSIS:

Left knee pain secondary to a transverse undisplaced fracture of the proximal tibial metaphysis.

TREATMENT AND OUTCOMES:

Non-weightbearing with crutches for 6 weeks, PT
 Ice and acetaminophen for pain
 Vit. D supplementation
 Improvement in pain at 3 week FUV and complete resolution of pain at 6 week FUV
 Started weight-bearing after 6 week FUV with gradual increase in weight-bearing activities and eventually back to field hockey

A-26 Rapid Fire Platform - Biomarkers in Sport, Performance and Health

Wednesday, May 29, 2019, 9:30 AM - 10:50 AM

Relationship Between Hepcidin, Interleukin-6, And Ferritin In Division-I Cross-country Runners Over A Competitive Season

Jesse A. Goodrich¹, Sewan Kim¹, Dillon J. Frisco¹, Kimberly Detwiler¹, Miguel Rueda¹, Sourav Poddar², William C. Byrnes, FACSM¹. ¹*University of Colorado Boulder, Boulder, CO.* ²*University of Colorado Denver, Denver, CO.* (Sponsor: William C Byrnes, FACSM)

Email: jesse.goodrich@colorado.edu

(No relevant relationships reported)

Iron deficiency, which can be assessed by the iron storage protein ferritin (fer) can negatively affect athletic performance. We have previously observed that Division I cross country (XC) runners have fer levels that are at the low end of normal ranges despite being iron supplemented. The hormone hepcidin and the cytokine/myokine interleukin-6 (IL6) can both influence iron regulation but have not been evaluated in this population.

Purpose: The purpose of this study was to determine how hepcidin and IL6 change over a season in DI XC runners and determine whether changes in these parameters were related to changes in fer, hemoglobin concentration (Hb) or hematocrit (Hct). **Methods:** 45 athletes (25 female, 20 male) were recruited from the University of Colorado DI XC team in the fall of 2017. Fasted blood samples were collected in October (before NCAA XC championships), January, and March (during the outdoor track season). Blood samples were analyzed for Hb, Hct, fer, IL6 and hepcidin. All runners were provided with oral iron supplements from a certified nutritionist during this period.

Results: All biomarkers remained stable across the season except Hb, which was significantly higher in March. In males vs. females, there were no differences in hepcidin (24 ± 11 vs. 21 ± 11 ng/mL; $p > 0.05$) or IL6 (16 ± 21 vs. 12 ± 24 pg/mL; $p > 0.05$). When compared to females, males had higher fer (64 ± 33 vs. 47 ± 24 ng/mL; $p < 0.05$), Hct (48 ± 2 vs. 44 ± 3 %; $p < 0.001$), and Hb (16.3 ± 0.7 vs. 14.8 ± 0.8 g/dl; $p < 0.01$). After controlling for sex, there was a positive relationship between hepcidin and fer ($r = 0.47$, $p < 0.01$); 20% of the variability in fer was explained by hepcidin and 51% was explained by individual variability. There were no relationships between IL6 and hepcidin or IL6 and fer.

Conclusion: Despite a consistent iron supplementation regime, hepcidin, IL6 and fer do not seem to systematically change across a season in collegiate runners. As expected, hepcidin and fer were positively related, but there were no relationships between IL6 and other measured parameters. Although fer was at the low end of

normal for both men and women, all other parameters were normal at all time points, suggesting that the normal range of fer for endurance athletes may be lower than the general population.

136 May 29 9:40 AM - 9:50 AM

Patterns Of Change In Proteomic Markers Of Overreaching In Collegiate Swimmers

Amy M. Knab¹, David C. Neiman, FACSM², Arnold J. Groen³, Artyom Pugachev³, Alexander Rakitko⁴, Ariel E. Blount¹, McKenzie Stevens¹, Lola Bulatova¹. ¹Queens University of Charlotte, Charlotte, NC. ²Appalachian State University, Boone, NC. ³ProteIQ Biosciences, Berlin, Germany. ⁴Lomonosov Moscow State University, Moscow, Russian Federation.
Email: knaba@queens.edu

(No relevant relationships reported)

Using global proteomic analysis, a previous study identified a panel of proteins that were linked to FOR and were associated with the acute phase response and innate immune system activation in athletes. **PURPOSE:** The purpose of this study was to track changes in this panel of proteins in 35 swimmers during the course of their normal training cycles during the 2017-2018 competitive season, and then identify relationships between protein expression data, external markers of overreaching (such as training distress scale (TDS)) and academic stress and performance. **METHODS:** Thirty-five NCAA Division II swimmers were recruited to the study (male n=19, female n=16; Age 19.1±1.6 y). Every Monday prior to morning practice, athletes provided a blood sample (via fingerpick) using the Volumetric Absorptive Micro-sampling (VAMS) technology. Athletes also reported TDS, illness, and RPE. **RESULTS:** Thirty-five swimmers completed the protocol (body fat, males = 12.6±5.1%, females 22.6±4.5%; VO_{2max} males = 55.8±5.10, females = 48.1±6.7 ml/kg/min). 1) GLMM on each protein taking week numbers as factor showed that protein levels after Bonferroni correction and tukey test were significant (p-values < 0.05) in selected weeks. 2) In the next step, the weeks were labelled based on objective events or no-events (exams, competitions, exams+competitions, baseline, no-events). LDA analysis including TDS, RPE and illness data was performed, and this analysis separated the baseline week significantly (p-value 0.000972) from exam weeks and weeks with both exams and competitions. 3) Adding protein expression data enhanced this separation between these groups of weeks (p-value 2.237e-05). 4) Protein expression data without metadata gave clear separation between these groups of weeks (p-value 1.435e-07). We were also able to use protein expression data to predict the week groups with an accuracy of 69-73%. **CONCLUSIONS:** Protein expression data shows a separation of baseline, exams and exams + competition time frames indicating a distinct physiologic response to external academic and performance stress. Use of protein expression data, albeit so far to a modest extent, to predict stress levels of the swimmers under these circumstances deserves further study.

137 May 29 9:50 AM - 10:00 AM

The Association Between Sonographic Metrics of Shoulder Injury and Serum Biomarker Profile in Response to a Hand-Cycling Task

Prakash Jayabalan¹, Dhruval Amin², Hyungtaek Kim¹, Julia Fram³, Yen-Sheng Lin¹, Jennifer Soo Hoo⁴. ¹Shirley Ryan AbilityLab, Chicago, IL. ²Rosalind Franklin University, Chicago, IL. ³Northwestern Feinberg School of Medicine, Chicago, IL. ⁴Weill Cornell Medicine, New York, NY.

Email: pjayabalan@sralab.org

(No relevant relationships reported)

PURPOSE:

Providing the physician the means of screening for 'at risk' individuals for shoulder pathology would be of benefit in the development of treatment strategies and counseling manual wheelchair users (MWC), who have a high incidence of shoulder pain. The objective of this study is to compare the sonographic and biomarker changes at baseline and following a shoulder related functional task in individuals who are able bodied (AB) versus manual wheelchair MWC. **METHODS:** MWC users (with prior spinal cord injury, n=6) and age-matched AB individuals (n=7) performed a 30-minute hand-cycling task on a stationary, recumbent hand-cycle with standardized increasing resistance during this time-period. Pre- and post hand-cycling, subjects reported their shoulder pain using the visual analog scale, and underwent a physical examination. They also had a standardized sonographic assessment, including assessment of the acromioclavicular distance (AHD), reduction in which is associated with pathology and tendon cross sectional area, and blood/serum measurement of specific biomarkers of cartilage turnover (COMP), inflammation (TNF- α , IL-1 β), cartilage degradation (MMP-1) and collagen type-1 (CTX-1) breakdown.

RESULTS: There was no significant difference in physical examination and pain related metrics post hand-cycling. However, there was a significant reduction in the AHD in the neutral positions (p=0.045) and 60 degrees of passive abduction (0.047) in the dominant arm compared to baseline in both groups. MWC users had significantly

higher baseline concentrations of IL-1 β (p=0.047) compared to AB. Irrespective of group, following 30 minutes of hand-cycling, there was also a significant increase in MMP-1 (p=0.013). Across time-points there was a positive correlation between the CTX-1 concentration in the serum and the AHD in the subject's dominant arm (r=0.7, p=0.03).

CONCLUSIONS:

Ultrasound metrics and certain biological markers are potentially sensitive to anatomic and physiologic changes that may occur in response to a functional shoulder task more so than patient report of symptoms or physical examination. Further delineation of the changes seen in this study could aid in the development of a shoulder evaluation protocol that highlights 'at risk' individuals for shoulder pathology.

138 May 29 10:00 AM - 10:10 AM

Are Molecular Deficits Relevant to Concussion Present in Collegiate Football Players Entering the NFL Draft?

Laura J. Kunces¹, John Keenan², Amanda Carlson-Phillips², Michael A. Schmidt³, Caleb M. Schmidt³, Zung V. Tran⁴.

¹Thorne, Scottsdale, AZ. ²EXOS, Phoenix, AZ. ³Advanced Pattern Analysis & Countermeasures Group, Boulder, CO. ⁴MedAware Systems, Inc., Broomfield, CO.

Email: LKunces@thorne.com

(No relevant relationships reported)

PURPOSE: Factors that influence individual susceptibility to brain acceleration forces or poor outcomes in brain injury are not well understood. Characterization of molecular variants in athletes entering a highly competitive contact environment may provide additional insight into factors that influence the longitudinal followhoney-up of concussion incidence and its trajectory. We examined the metabolic phenotype of collegiate football players entering the 2016 National Football League (NFL) draft. The principal aims were to observe and characterize the molecular status of individual athletes and to quantify the prevalence of athletes with multiple concurrent molecular deficits. These will serve as baseline measures, as concussion incidence and trajectory of this cohort of athletes is followed in their NFL careers. **METHODS:** Blood samples were taken from 30 elite American collegiate football players seven weeks before the NFL scouting combine, and 15 weeks before entering the NFL draft. **RESULTS:** Of 74 analytes, results revealed me a undesirable values in Omega-3 Index (4.66%), AA:EPA fatty acid ratio (29.13), homocysteine (11.4 μ mol/L), vitamin D (30 ng/mL), and magnesium (4.1 mg/dL). Using reference ranges optimized for athletic performance, no athlete had 0, 1 or 2 abnormalities in blood values; 10% had 3, 40% had 4, and 50% of athletes had 5 undesirable values. **CONCLUSIONS:** Molecular deficits in this cohort entering the NFL draft appear to be common. Historical evidence exists showing that the molecular deficits observed in this study have mechanistic correlations with concussion trajectory and outcome. A more thorough examination of molecular features that contribute to poor outcomes in concussion may open the door to precision nutrition and clinical countermeasures, not only in football, but in any sport in which acceleration forces to the brain may be present.

Associations Between Circulating Basal BDNF, IGF-1 and Physical Fitness

Heikki Kyröläinen, FACSM¹, Matti Santtila², Kai Pihlainen³, Jani Vaara². ¹University of Jyväskylä, Jyväskylä, Finland.

²National Defence University, Helsinki, Finland. ³Finnish Defence Forces, Helsinki, Finland.

(No relevant relationships reported)

Exercise-induced increase in circulating insulin-like growth factor 1 (IGF-1) levels might stimulate brain-derived neurotrophic factor (BDNF) expression. Thus, circulating IGF-1 can travel from the periphery to the brain and there stimulate the expression of BDNF and facilitate long-lasting changes in neural activity. It has been shown that chronic training leads to upregulation of basal levels of both BDNF and IGF-1. Several longitudinal studies have also shown that aerobic exercise acutely elevates circulating BDNF levels in humans. **PURPOSE:** To investigate associations of peripheral BDNF and IGF-1 with several physical fitness components at rest. **METHODS:** 792 adults (26±6 yr) men participated. BDNF and IGF-1 concentrations were analyzed from venous blood samples using an ELISA Assay (Human BDNF ELISA kit, ScienCell Research laboratories, San Diego, California) and Dynex DS 2 ELISA processing system (Dynex Technologies, Chantilly, Virginia). Cardiorespiratory fitness (VO_{2max}) was determined using an indirect graded cycle ergometer test until exhaustion. Bilateral maximal isometric leg (MVCleg) and arm extension forces (MVCarm) were measured using dynamometers. Muscular endurance tests consisted of repeated 1-min push-ups and sit-ups, while standing long jump assessed muscular power. **RESULTS:** The mean±SD BDNF and IGF-1 concentrations were 15.20±3.96 ng/ml, 25.0±6.9nmol/l, respectively, while VO_{2max} was 41.1±8.8ml/kg/min, MVCleg 3394±933N, MVCarm 871±216N, push-ups 28±14reps/min, sit-ups 35±12reps/min, standing long jump 227±26cm. BDNF and IGF-1 correlated weakly with each

other ($r=-0.146$, $p=0.003$). Linear regression analysis (adjusted for age, smoking and education) revealed that associations between BDNF and physical fitness were weak for VO_{2max} ($\beta=-0.077$, $p=0.006$) and muscle fitness ($\beta=-0.077$, $p=0.895$). This was also the case for IGF-1. **CONCLUSIONS:** The associations between peripheral BDNF, IGF-1 and physical fitness components were weak or non-existent at rest in the present cross-sectional design. Thus, it seems that only exercise-induced elevated values of BDNF and IGF-1 may associate with each other and physical fitness components. Therefore, their interactions should be investigated in future studies during acute and / or chronic exercises.

140 May 29 10:20 AM - 10:30 AM

Effects Of An Intensified Training Period On Resting Metabolic Rate, Energy Availability, Blood-biomarkers And Performance

Monica K. Torstveit¹, Thomas B. Stenqvist¹, Anna K. Melin².
¹University of Agder, Kristiansand, Norway. ²University of Copenhagen, Copenhagen, Denmark. (Sponsor: Jorunn Sundgot-Borgen, FACSM)

Email: monica.k.torstveit@uia.no

(No relevant relationships reported)

Cyclists often block periodize their training in micro and meso periods with high training volumes to prepare for competition. The effect of such periods on surrogate markers for Relative Energy Deficiency in Sport (RED-S) have not yet been properly investigated. **PURPOSE:** To determine how a mesocycle of four weeks of interval training affects RED-S associated surrogate markers and performance variables in well-trained male cyclists. **METHODS:** Twenty-two participants (age: 33.5 ± 6.6 years, height: 181.4 ± 5.2 cm, weight: 76.5 ± 7.4 kg, VO_{2peak} : 63.5 ± 6.6 mL·kg⁻¹·min⁻¹) were recruited for a four-week interval training protocol, consisting of three high-intensity interval training sessions per week with an accumulated work duration of 32 minutes per session. Unlimited low intensity training was permitted. Protocol included pre- and post-intervention assessment of resting metabolic rate (RMR) (ventilated hood), body composition by dual x-ray absorptiometry, blood samples, energy intake and exercise energy expenditure to calculate energy availability (EA), and aerobic- and anaerobic performance. **RESULTS:** Four weeks of interval training increased aerobic performance (mean \pm SD of difference); peak power output [18.5 ± 12.4 W, ($p < 0.001$)], VO_{2peak} [1.5 ± 2.1 mL·kg⁻¹·min⁻¹, ($p = 0.005$)], and functional threshold power [17.0 ± 11.8 W, ($p < 0.001$)] as well as testosterone levels [1.35 ± 2.13 nmol·L⁻¹, ($p = 0.011$)]. However, triiodothyronine (T_3) [-0.12 ± 0.18 nmol·L⁻¹, ($p = 0.008$)], absolute RMR [-52.2 ± 81.4 kcal per day⁻¹, ($p=0.01$)], relative RMR [-0.8 ± 1.2 kcal per kg FFM⁻¹, ($p=0.01$)], and RMR_{ratio} [-0.03 ± 0.04 , ($p = 0.01$)] decreased, and cortisol levels increased (49.3 ± 87.3 nmol·L⁻¹, $p = 0.02$) indicating energy deficiency, while no changes were observed in body weight or -composition, EA, or insulin and insulin-like growth factor 1 (IGF-1). **CONCLUSION:** A successive four weeks of intensified training increased performance and testosterone levels in this group of well-trained male endurance athletes, although surrogate markers of RED-S such as decreased RMR, T_3 and increased cortisol levels were observed. These results indicate the complexity, and the methodological challenges of assessing and evaluating RED-S in male athletes.

141 May 29 10:30 AM - 10:40 AM

Salivary Biomarkers in College Female Basketball Players during the Late Competition Season

Kevin J. Finn, FACSM¹, Jack Ransone, FACSM², Michaela Martinecz¹.
¹University of Central Missouri, Warrensburg, MO. ²College of William and Mary, Williamsburg, VA.

Email: kfinn@ucmo.edu

(No relevant relationships reported)

The college basketball season involves multiple competitions and strenuous practice that have been linked to signs of overtraining. During the late competition period, evaluation of stress and recovery can assist coaches in determining player loads to ensure optimal performance. **Purpose:** To assess factors that reflect on stress and recovery through the study of salivary biomarkers. **Methods:** Fifteen members of the college women's basketball team volunteered to participate. Saliva samples (0.75mL) was collected 24 hours before (pre) and 24 hours after (post) a competition during the last three weeks of the regular season. Salivary samples were stored frozen and then sent to a laboratory for analyses at the end of the study period. Biomarker concentrations were determined using indirect ELISA for testosterone, cortisol and secretory immunoglobulin A. In addition, at the time of the saliva collection, subjects were asked to report their perception of overall health, level of anxiety, and mood. ANOVA were used to test for significance (95 level of confidence) for pre-post measures and weekly variance. Correlations between perceptions of health, anxiety, mood, and salivary biomarkers were conducted. **Results:** The means (SD) of the biomarkers and subjective measures are reported below.

| Week | | Testosterone (pmM) | Cortisol (nmM) | SigA | Health Score | Anxiety | Mood |
|------|------|--------------------|----------------|----------------|--------------|-------------|-------------|
| 1 | Pre | 247.35 (131.34) | 4.49 (1.33) | NA | 7.67 (1.30) | 2.23 (0.83) | 3.08 (0.90) |
| | Post | 229.26 (153.70) | 5.02 (3.07) | 111.84 (88.89) | 7.20 (1.70) | 2.20 (0.94) | 3.21 (0.80) |
| 2 | Pre | 202.34 (129.75) | 7.41 (8.48) | NA | 8.00 (1.62) | 2.07 (0.92) | 3.29 (0.83) |
| | Post | 230.44 (151.49) | 6.05 (4.04) | 92.31 (54.18) | 7.83 (1.34) | 1.75 (0.62) | 3.45 (0.82) |
| 3 | Pre | 222.37 (165.02) | 5.18 (3.68) | NA | 7.73 (1.67) | 1.87 (0.74) | 3.36 (0.63) |
| | Post | 257.36 (126.07) | 4.43 (1.95) | 81.55 (29.45) | 8.27 (1.27) | 1.55 (0.69) | 3.00 (0.45) |

None of the salivary biomarkers were significantly different in pre-post comparisons nor across the three weeks. Changes in health scores, anxiety, or mood were not significantly different. Overall the testosterone showed significant correlations with cortisol ($r=0.51$), sigA ($p=0.46$), and health score ($p=-.31$). In addition, cortisol was significantly related to health score ($p=-0.24$). Health score showed a negative relationship with anxiety ranking ($r=-.30$) while no other relationships were evident. **Conclusion:** The lack of significance between these variables might indicate that these players did not show indication of stress or lack of recovery during this period of competition.

142 May 29 10:40 AM - 10:50 AM

Salivary IgA as a Predictor of Upper Respiratory Tract Infections in Elite Rugby Union Players

Caoimhe Tiernan¹, Tom Comyns¹, Mark Lyons¹, Alan M. Nevill², Giles Warrington, FACSM¹.
¹University of Limerick, Limerick, Ireland. ²University of Wolverhampton, Wolverhampton, United Kingdom.

Email: caoimhe.tiernan@ul.ie

(No relevant relationships reported)

For athletes to optimise their performance, minimising the risk of injuries and illness is essential to reduce the number of training days missed. Upper Respiratory Tract Infections (URTI) are amongst the most common illnesses reported in athletes. An URTI can result in missed training days, which in turn may lead to performance decrements.

PURPOSE: The purpose of this study was to investigate if salivary Immunoglobulin A (sIgA) is a predictor of URTI in elite Rugby Union players.

METHODS: Nineteen male elite Rugby Union players provided morning saliva swabs and completed an illness log documenting symptoms of URTI, bi-weekly (Monday and Friday), over a 10-week training period. Test re-test reliability of sIgA was completed under controlled conditions prior to the study. Multi-level logistic regression was used to analyse the relationship between sIgA and the binary outcome of presence or absence of an URTI.

RESULTS: The results found that a significant decrease in sIgA (-0.00537 (0.00268) ug.ml $p=0.046$) (beta (SE)), increased the odds of a player contracting an URTI. A player was at a greater risk of contracting an URTI, within the subsequent 2-week period, if sIgA decreased by 65% or more.

CONCLUSION: The results show that sIgA is a useful predictor for determining the likelihood of players contracting an URTI. These results provide coaches with an objective monitoring marker, to help reduce the risk of players contracting an URTI and missed training days, which may lead to performance decrements. These results may assist the coaches and support staff in making evidenced based decisions, where sIgA decreases by 65% or more, by adjusting individual player training load and implementing appropriate recovery strategies to ensure optimisation of training.

PURPOSE: Previous studies investigating the effects of blood donation (BD) on power output (PO) concerning all out sprints appear elusive, thus this study determines the effects of BD (~ 470ml) over a period of up to 96 hours on power output during four repeated 15s sprints. **METHODS:** Following local institutional ethical approval 11 participants, 8 males (age 30.3 ± 13.1 years, mass 85.6 ± 10.5 Kg, height 177.8 ± 6.9 cm) and 3 females (age 34.7 ± 10.3 yrs, mass 69.1 ± 11.6 Kg, height 171.2 ± 9.1 cm) volunteered to participate. Testing was conducted in the morning over a two week block with a rest week between testing phases. Week one (W1) was pre-BD and week two (W2) was post BD. Visit one on W1 established haematological levels and VO_{2max}. Subsequent visits during W1 were for Sprint Interval Testing (SIT), with a resistance of 0.07kg·kg⁻¹ of body mass, with 90s of unloaded pedalling prior to each efforting a Lode Excalibur Sport cycle ergometer. W2 was identical except the participant donated blood on visit 1 post haematological testing only. Additionally throughout testing VO₂, cardiac output, stroke volume and heart rate using thoracic impedance cardiography, while Near Infrared Spectroscopy measured O₂ delivery at the muscle. **RESULTS:** Pre-BD (Hb=14.61 ± 0.72g·dL⁻¹, Hct=42.91 ± 2.12%) compared to post BD of day 1 (Hb=13.57 ± 0.97g·dL⁻¹, Hct=39.91 ± 3.02%) reduced by 7.09%. Hb percentage decreases continued over days 1-2 (2.68%) and days 2-3 (2.55%), a percentage increase (1.98%) occurred between days 3-4, values yielded significance in all cases (P< 0.0001). ΔPPO (W) pre-BD on day 1 (46.2 ± 180.3), 2 (45.5 ± 150.7), 3 (18.7 ± 74.7) and 4 (31.9 ± 99.4) compared to post BD on day 1 (170 ± 153.0), 2 (156.6 ± 125.4), 3 (88.7 ± 106.6) with the exception of day 4 (84.9 ± 72.7) all revealed significance (P= 0.006, P= 0.005 and P= 0.04 respectively). There was no interaction for time for either pre or post BD periods for either ΔPPO or mean PO (P>0.05). **CONCLUSIONS:** The data suggests that BD has significant effects on Hb and Hct up to 96 hours post BD. ΔPPO was also significantly influenced up to 72hours post BD, this is potentially attributed to a down regulation of the resynthesis of PCr between sprints from decreased O₂ availability. These findings have significant implications for individuals wishing to undertake sprint interval-based exercise post BD.

(No relevant relationships reported)

PURPOSE: To determine whether heart rate variability (HRV) is a suitable method for monitoring the effect of a training session (TS) in elite synchronized swimmers **METHODS:** We recorded resting HRV (Rest) in 12 elite swimmers (mean age: 21.5±3.5 yrs) for 3 days over one week, interspersed by 48 h, prior to the 2015 World Swimming Championships. During the last TS, we continuously monitored heart rate (HR) and obtained salivary cortisol (SC) samples before and after the session. We measured capillary blood lactate (La_{peak}) 2, 4, and 8 min after the TS and monitored recovery HRV (Rec), which was averaged for the following 5-min periods after the TS: Rec₂₀₋₂₅, Rec₂₅₋₃₀ and Rec₃₀₋₃₅. We assessed rate of perceived exertion (RPE) and tested the association between La_{peak}, SC, and RPE and the relative changes (Δ%) of the natural logarithm (Ln) of the HRV-derived indices [standard deviations of the distance of rate to rate (SD_r and SD_d), the root mean square successive difference of intervals (RMSSD), and the high- and low-frequency domain parameters (HF and LF, respectively)]. We calculated the individual coefficient of variation (CV) of LnRMSSD for each recovery period. **RESULTS:** LnLF (ms²) was lower in Rec₂₅₋₃₀ (5.72±1.05) than in Rec₂₀₋₂₅ and Rec₃₀₋₃₅ (6.68±0.97, 6.26±1.29; P<0.05). On average, CV=10.7%. La_{peak} was correlated positively with Δ%LnRMSSD, Δ%LnLF, Δ%LnSD_r, and Δ%SC. **CONCLUSIONS:** Isolated HRV data from synchronized swimmers may less accurate than other physiological markers for assessing the effect of TSs as a result of exercise bouts performed in apnea.

Synchronization Of Foot Strike And Cardiac Cycle During Treadmill Running In Non-endurance Trained Individuals

Clarence M. Lee, Sean M. Jones, Rachel Wong, Augustus Nordstrom, Marialice Kern, FACSM. *San Francisco State University, San Francisco, CA.* (Sponsor: Marialice Kern, FACSM)
Email: cmlee@sfsu.edu
(No relevant relationships reported)

Synchronizing cardiac diastole with foot strike during running may maximize the efficiency with which skeletal muscle promotes venous return of blood to the heart. Recent research has found that diastolic stepping results in a lower heart rate (HR) compared to systolic stepping in elite endurance runners. **PURPOSE:** To assess HR, metabolic responses, and perceived exertion to running when foot strike occurs during either cardiac systole (CS) or cardiac diastole (CD) in non-endurance trained individuals. **METHODS:** Eight non-endurance trained participants (7 males; Age: 25.3 ± 8 yr; BMI: 23.6 ± 3.2 kg/m²) performed 2, 5-min bouts of treadmill running at a comfortable pace (5.4 ± 0.5 mph) with foot strike occurring during either CD or CS. Participants wore a chest strap that transmitted accelerometer and HR data to a tablet computer with proprietary software. The software generated an auditory beep that was synced with either 45% (CD) or 100% (CS) of each cardiac cycle. Participants were instructed to match their steps to the beeps during both conditions (CD or CS) which were randomized between trials and blinded to the participants. HR, oxygen consumption (VO₂), O₂-pulse, minute ventilation (VE), and respiratory exchange ratio (RER) were recorded continuously and averaged over the last 3 minutes of each condition. Rating of perceived Exertion (RPE) was recorded during the final minute of each condition. Paired T-tests were used to compare the dependent variables between conditions and all tests were considered significant at the 0.05 level. **RESULTS:** HR was significantly lower when foot strike occurred during CD compared with CS (163.0±5 vs. 170.1±4 bpm; P < 0.05). Furthermore, there was a trend for O₂-pulse to be greater during CD (16.3±1.5 vs. 15.7±1.4 ml/beat; P = 0.07). VE (73.3±5 vs. 74.4±4 l/min), VO₂ (35.0±1.3 vs. 35.3±1.2 ml/kg/min), and RPE (10.5±0.7 vs. 10.3±0.8) were not significantly different between CD and CS, respectively. **CONCLUSION:** During relatively short, steady-state running conditions, synchronization of foot strike with CD results in a significantly lower HR when compared to CS. This may lead to enhanced cardiac filling, which may be beneficial to running performance in non-endurance trained individuals.

HEART RATE RESPONSE DURING A COLLEGIATE ESPORTS TOURNAMENT

S. Valladao, T.L. Andre, D. Cox. The University of Mississippi, Oxford, MS
During the last decade, electronic sports (esports), or competitive video gaming, has rapidly increased, generating nearly \$1 billion per year and is now composed of millions of gamers around the globe (online and live). However, the physiological effects of these gaming competitions have not been thoroughly examined yet. A myriad of literature focuses on heart rate (HR) and traditional athletic competition but very little research has addressed the heart rate responses of individuals playing competitive esports and none to date have examined heart rate during collegiate esports tournament in collegiate club sport competitors. **METHODS:** Male members of the University of Mississippi esports team (n=14; age = 19.8±1.0 years; BMI = 24.1±5.5; esports mean hours per week = 18.9±11.6) participated in the study during the Egg Bowl esports tournament. A 5-minute ambient (seated) heart rate was collected using a Polar H10 HR monitor prior to esports competition. Upon sitting on stage, recordings for HR began immediately prior and ended immediately post to their esports matches while remaining seated. For the statistical analyses, Paired-samples t-tests were utilized. Results were considered significant at ≤ 0.05. **RESULTS:** Mean HR during was significantly elevated compared to pre (131.4 ± 19.0 bpm vs. 97.1 ± 19.9 bpm; p = 0.000) and peak HR during was significantly elevated compared to pre (188.1 ± 32.9 bpm vs. 119.6 ± 20.1 bpm; p = 0.000). **CONCLUSION:** Given the elevated HR observed in the study, further understanding of the physiological response to competitive esports in the tournament setting is critical for developing interventions to potentially mitigate the physiological stress experienced by esports athletes.

Abstract

Esports popularity has rapidly grown both in online play and viewing. Little research has addressed the heart rate responses of individuals playing esports and none in the platform of the Esport: Fornite over a longer duration. **Purpose:** Determine the heart rate response during a 3-hour seated session of the Esport: Fortnite. **Methods:** Individuals (n=23; age = 20.7 ** 2.1 years; BMI = 25.8 ** 3.5) who play at least 6 hours of esports per week were recruited to participate in the study from around the University of Mississippi. On two separate occasions a 15-minute seated HR was collected using a Polar H10 heart rate monitor to measure mean resting HR. Participants wore the Polar heart rate monitor during their regular Esport: Fortnite session time for 3-hours. Paired sample t-tests were utilized to compare mean resting and peak heart rates to mean and peak esport HR. Results were considered significant at $p < 0.05$. **Results:** There was a significant increase in mean esport session HR compared to resting HR (75.6 ** 9.6bpm vs. 69.8 ** 10.5bpm; $p = 0.003$) and peak seated esport session HR (119.8 ** 16.3bpm vs. 80.1 ** 10.8bpm; $p < 0.001$). **Conclusions:** Further understanding of the physiological stress induced with chronic playing of esports is warranted given this initial studies results given the increases in individuals seated heart rate.

Association Between Supine Versus Standing Heart Rate Variability, Aerobic Fitness and Exercise Responses in Women
 Brenee K. Rockholt, Andrew A. Flatt. Georgia Southern University, Savannah, GA.
 Email: breneekrockholt@gmail.com
 (No relevant relationships reported)

Heart rate variability (HRV) is used to guide endurance training prescription but the optimal body position for daily recordings is unclear. **PURPOSE:** To assess supine and standing HRV associations with aerobic fitness and submaximal exercise heart rate (HRex) responses to an aerobic interval session. **METHODS:** Healthy women (n = 8, age = 23 ± 3 years) performed a graded treadmill test for the determination of maximal oxygen consumption (VO₂max). Over the subsequent 5 days, post-waking measures of supine and standing natural logarithm of the root mean square of successive RR intervals (LnRMSSD) were averaged to establish baseline. Subjects then performed an interval training session consisting of 7 x 3 min of treadmill running at 90% of the velocity attained at VO₂max (vVO₂max), with two minutes of walking at 4 km·h⁻¹ between sets. Immediately before and 24 h post-interval session, a submaximal test consisting of 3 min of running at 60, 70, 80, and 90% of vVO₂max was performed with HRex recorded at the end of each stage. HRV measures were recorded the morning after the interval session for comparison to baseline and changes in HRex. **RESULTS:** VO₂max ranged from 32.5 - 54.4 ml·kg⁻¹·min⁻¹. Baseline supine LnRMSSD was significantly associated with VO₂max ($r = 0.77$, $p = 0.03$). No differences in supine (4.26 ± 0.57 vs. 4.30 ± 0.70, $p = 0.81$) or standing (3.26 ± 0.67 vs. 3.26 ± 0.87, $p = 0.98$) LnRMSSD were observed between baseline and 1 day post-interval session. However, individual changes in standing LnRMSSD were significantly associated with their changes in HRex at 60% vVO₂ ($r = -0.71$, $p < 0.05$) where those with a decrease in LnRMSSD relative to baseline demonstrated increases in HRex and vice versa. Additionally, we observed a large, non-significant relationship between VO₂max and changes in standing LnRMSSD ($r = 0.69$, $p = 0.056$) where those with reduced standing LnRMSSD relative to baseline at 24 h post-interval session tended to have lower VO₂max and vice versa. **CONCLUSIONS:** These results indicate that standing HRV may provide a better indication of individual exercise responses whereas supine HRV provides a better indication of aerobic fitness level among healthy women.

Relationship Between Heart Rate Variability Threshold and 5-km Outdoor Running Performance in Non-athletes
 Carlos J. Cruz¹, Luiz Grossi Porto¹, Gledson Alves Costa Jr², Guilherme Eckhardt Molina¹. ¹University of Brasília, Brasília-DF, Brazil. ²Centro Universitário Euro Americano-UNIEURO, Brasília-DF, Brazil.
 Email: janssengomes@gmail.com
 (No relevant relationships reported)

The analyses of heart rate variability threshold (HRV_T) under a controlled treadmill incremental exercise test (IET) is considered a practical strategy for cardiac parasympathetic depression and anaerobic threshold assessment. However, the prognostic value of HRV_T for outdoor running performance is unknown. **Purpose:** To correlate the exercise intensity at the HRV_T assessed during a treadmill incremental test and the 5-km outdoor running time in young men. **Methods:** 14 beginner runners (23.5±4.4 yrs, BMI: 23.2±2.7 kg/m²) underwent a treadmill IET. The R-R intervals were collected continuously during exercise test using a heart rate monitor (Polar® v800) and heart rate variability was analyzed by the SD1 index of Poincaré Scatterplot map. HRV_T was considered the load (km/h) corresponding to the point of stabilization at which there was no further significant decline in the values of the SD1 index even with increasing intensity. After a 48h period, the participants individually performed a 5-km running trial on an outdoor 250-m track. The participants were encouraged to conclude the 5-km running test as quickly as possible. Due to non-normality of the data and the sample size, we used the Spearman's correlation test with p-value set at 5%. **Results:** The exercise intensity at HRV_T was 7 (7-8) km/h and the time to complete the 5-km trial was 25.2 (23.2-28.5) minutes. A strong correlation was observed between the treadmill speed at the HRV_T and the time expended to cover the 5-km running test (Figure 1). **Conclusion:** HRV_T evaluated during an IET under controlled conditions was negatively correlated with the outdoor 5-km running performance in young non-athlete men. Our results may open a new application to the HRVt as a practical tool for the prognostic evaluation of a 5-km running performance.

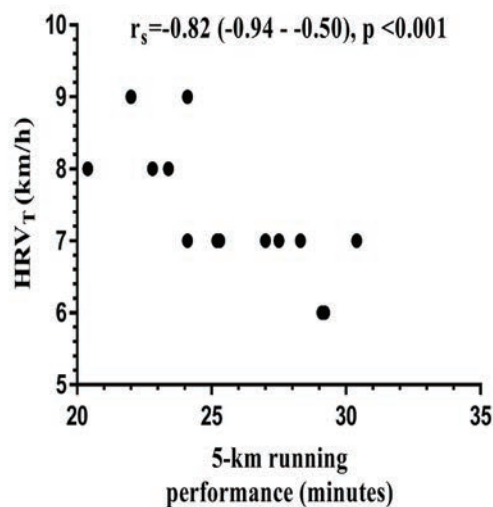

Figure 1- Relationship between HRV_T and 5-km time trial.

Effects of Hemodynamic Responses and Vascular Endothelial Function to Blood Flow Restriction Exercise Training
 Yan Zhao¹, Aicui Lin², Andong Chen¹, Beibei Lu¹. ¹Nanjing Sport Institute, Nanjing, China. ²Nanjing First Hospital, Nanjing, China.
 Email: zynj77@163.com
 (No relevant relationships reported)

PURPOSE: The study aimed to compare hemodynamic responses and vascular endothelial function after 8 weeks resistance exercise with different blood flow

restriction (BFR) in healthy adults. **METHODS:** Twenty-four participants (men 20.63 ± 0.88 yr) were randomly assigned to three groups: resistance exercise without occlusion cuff (CON), resistance exercise with occlusion cuff pressure set at 65% resting systolic blood pressure (BFR-L) and resistance exercise with occlusion cuff pressure set at 130% resting systolic blood pressure (BFR-H). Each subject underwent five bouts of 1-minute 30%1RM resistance exercise with 2-min interval, 5 times a week for 8 weeks. Left ventricular fractional shortening (FS), left ventricular ejection fraction (LVEF), velocity, stroke volume (SV) resistance index (RI), Vascular endothelial growth factor (VEGF), vascular endothelial growth factor receptor (VEGF-R) and interleukin-6 (IL-6) were measured. **RESULTS:** 1. After 8 weeks, compared with AC in BFR-H group (94.42 ± 20.99), AC in the CON group (106.13 ± 18.86) and BFR-L group (108.08 ± 19.22) significantly increased ($p < 0.05$). 2. After 8 weeks, SBP was increased in the BFR-L group (3.37 ± 0.674 mmHg), BFR-H group (4.50 ± 1.21 mmHg) and in the CON group (-6.37 ± -1.02 mmHg). Exercise immediately after 8 weeks, DBP decreased in the BFR-H group (6.44 ± 0.305 mmHg) and the CON group (4.25 ± 0.281 mmHg), and the difference was statistically significant ($p < 0.05$). 3. After 8-week training, compared with the expression of VEGF-R and IL-6 in CON group (641.23 ± 12.68 pg/ml, 7.00 ± 0.76 pg/ml), their expression in the BFR-L group (711.12 ± 16.88 pg/ml, 7.39 ± 0.51 pg/ml) and BFR-H group (703.63 ± 15.49 pg/ml, 11.16 ± 0.82 pg/ml) significantly increased ($p < 0.05$). **CONCLUSIONS:** BFR-L is beneficial to the improvement of aortic compliance. BFR-L and BFR-H all can cause reduction of DBP after exercise, which can be related to increased secretion of local VEGF and VEGF-R, causing angiogenesis and reducing peripheral resistance.

Comparing Total Hemoglobin Mass Between Selected NCAA Division I Athletes And Recreationally Active Students

Sewan Kim, Jesse A. Goodrich, William C. Byrnes, FACSM.
University Colorado Boulder, Boulder, CO. (Sponsor: William C. Byrnes, FACSM)

(No relevant relationships reported)

Total hemoglobin mass (tHb) is linearly related to total body mass, however, whether this relationship is altered by lean tissue mass, training or sex remains controversial. **PURPOSE:** To investigate if lean mass is a more appropriate determinant of tHb compared to body mass across NCAA DI athletes and controls. We will also determine if this relationship is altered by sex and/or training status.

METHODS: Nordic (6F & 6M) and alpine (5M) skiers, football players (7M) and recreationally active student controls (9F & 10M) from the University of Colorado Boulder participated. The optimized carbon monoxide rebreathing procedure was used to determine tHb. Body composition was determined via DXA. Since female athletes were not present in all groups, statistical analyses were performed for males across all groups and a separate comparison was made between female nordic skiers and control groups.

RESULTS: The overall correlations of tHb with body mass or lean tissue mass were significant ($R^2 = 0.73$ & $R^2 = 0.88$), but the positive relationship was stronger when using lean mass ($p < 0.001$).

For males, body mass and lean tissue mass were greater in football with no significant differences between any other group. Football had a greater tHb compared to control and alpine (1168.7 ± 126.9 vs. 925.9 ± 123.0 & 936.8 ± 151.9 g), but was not different than nordic (1052.5 ± 166.7 g). Nordic tHb was greater than control, but not different from alpine. When tHb was normalized using body mass and lean mass, nordic (14.5 ± 1.5 & 16.5 ± 1.2 g/kg) was greater than football (10.4 ± 0.9 & 14.4 ± 1.5 g/kg), alpine (11.6 ± 1.1 & 14.2 ± 0.6 g/kg) and control (11.8 ± 0.6 & 14.6 ± 0.8 g/kg) groups while no differences between any other groups were found.

For females, body mass, lean tissue mass and tHb (656.4 ± 72.9 vs. 566.1 ± 66.0 g) were not different between nordic and control. When tHb was normalized using body mass, nordic (11.3 ± 0.7 g/kg) was greater than control (9.5 ± 1.0 g/kg), but when tHb was normalized using lean mass there was no difference (14.5 ± 1.1 vs. 13.8 ± 1.4 g/kg).

CONCLUSION: Lean tissue mass explains a greater amount of variability in tHb compared to total body mass. In males, to examine the effect of endurance training on tHb, it is more appropriate to normalize by lean mass. Additional research is needed when comparing the effects of endurance training between female groups.

(No relevant relationships reported)

OBSERVATION OF HEART RATE VARIABILITY RESPONSE TO COLLEGIATE ESPORTS TOURNAMENT

G.B. Rhoden, S. Valladao, T.L. Andre, D. Cox. The University of Mississippi, Oxford, MS'

Heart rate variability (HrV) derives from the intricate relationship of sympathetic and parasympathetic autonomic regulation of heart rate. HrV has been utilized as a marker of stress and recovery in traditional sports, however, to date no investigations examined the HrV response to esports. **PURPOSE:** To determine the HrV response during a competitive live esports tournament in collegiate club esports competitors.

METHODS: Male members of the Ole Miss esports team ($n=14$; age = 19.8 ± 1.0 years; BMI = 24.1 ± 5.5 ; esports mean hours per week = 18.9 ± 11.6) participated in the study during a live esports tournament. A pre-HrV and post-HrV (5-minutes each) measures were collected using a Polar H10 HR monitor with the Elite HrV mobile app while seated. Participants were seated for 5 minutes before obtaining pre- and post-HrV measures. For during competition HrV measure, recordings for HrV began immediately prior to their esports matches and ended immediately post while remaining seated. For the statistical analyses, One-Way Analysis of Variance (ANOVA) was used for RMSSD, ln(RMSSD), and R-R intervals. Tukey's post hoc test were used when necessary. Paired-samples t-test were utilized for LF:HF ratio and HF. Results were considered significant at $p \leq 0.05$. Results are reported as mean \pm standard deviation. **RESULTS:** R-R intervals during were significantly lower than pre- and post- (pre: 643.64 ms \pm 138.54 ms; during: 465.71 ms \pm 68.99 ms; post: 616.07 ms \pm 109.98 ms, $p = 0.002$). HF post competition was significantly decreased compared to pre (325.83 ms² \pm 341.81 ms² vs. 494.55 ms² \pm 526.84 ms²; $p = 0.046$). No significant differences were found for RMSSD (pre: 25.67 ms \pm 17.48 ms; during: 15.50 ms \pm 12.34 ms; post: 23.72 ms \pm 18.07 ms; $p = 0.223$), ln(RMSSD) (pre: 3.00 ms \pm 0.77 ms; during: 2.51 ms \pm 0.69 ms; post: 2.86 ms \pm 0.90 ms; $p = 0.249$), or pre and post LF:HF ratio (pre: 4.47 ± 2.96 vs. post: 5.54 ± 3.62 ; $p = 0.260$).

CONCLUSION: This is the first investigation to observe the HrV response to a live esports competition. Future investigations should examine differences between esports games and time durations.

One-Year Changes in Cardiovascular Risk Markers in Police Officers

Steven E. Martin, Danielle Kravits, Kory Sealy, Karina Wilson, Jason R. Lytle, Sean T. Stanelle, John S. Green, FACSM, Stephen F. Crouse, FACSM. *Texas A&M University, College Station, TX.* (Sponsor: Stephen F. Crouse, FACSM)

(No relevant relationships reported)

PURPOSE: The present study retrospectively examined one-year changes in certain traditional and non-traditional cardiovascular disease (CVD) risk markers in police officers ($n = 84$). Subjects were full time police officers employed by a moderate-to-large municipality. **METHODS:** As a part of their annual physical exam, police officers underwent evaluation of several CVD risk markers including body weight, a graded exercise test (GXT; Bruce protocol), pushups completed in 1 minute, situps completed in 1 minute, handgrip strength, body composition (through DEXA), and fasting bloodwork. Maximal oxygen uptake (VO_{2max}) was estimated using the Foster equation. Resting systolic blood pressure (RSBP) and resting diastolic blood pressure (RDBP) were measured before the start of the GXT protocol. Blood analysis was performed by a College of American Pathologists-accredited laboratory. All blood samples were analyzed for total cholesterol (TC), triglycerides (TG), high-density lipoprotein (HDL) cholesterol (HDL-C), low-density lipoprotein (LDL) cholesterol (LDL-C), glucose (GLU), LDL particle number (LDLnum), LDL size (LDLsz), small LDL particle number (sLDLnum), HDL particle number (HDLnum), and HDL size (HDLsz). All data were analyzed using paired t-tests ($p < 0.05$). **RESULTS:** With respect to the fitness testing variables measured, significant increases were noted in pushups performed (4 pushups) and handgrip strength (4.45 kg) while RDBP was significantly reduced (4 mm/Hg). Within the traditional fasting blood panel, GLU was significantly increased (5.5 mg/dL) while LDL-C was significantly reduced (8.4 mg/dL). Non-traditional CVD risk markers were also significantly altered. Increases were noted in LDLnum (309 nmol/L), sLDLnum (347 nmol/L), and HDLnum (6.6 umol/L) while reductions in LDLsz (0.53 nm) and HDLsz (0.5 nm) researched statistical significance. **CONCLUSIONS:** While beneficial changes were noted in several traditional CVD risk markers, unfavorable alterations occurred in the majority of the non-traditional CVD risk markers measured. In addition, these findings support the need for required health and fitness programs for law enforcement personnel.

The Impact of Isometric Exercise Muscle Mass on Post-Exercise Blood Pressure

Lindsay A. Lew, Morgan D. Silvester, Kaitlyn Liu, Sarah Bailey, Kyra E. Pyke. *Queen's University, Kingston, ON, Canada.*

Email: 131a12@queensu.ca

(No relevant relationships reported)

A single bout of aerobic or resistance exercise can lead to a temporary drop in blood pressure (BP) following exercise; a phenomenon referred to as post-exercise hypotension (PEH). Like aerobic and resistance exercise, isometric exercise training can reduce resting BP however, considerably less is known regarding the ability of this type of exercise to elicit PEH. PEH may be more robustly stimulated with a larger

active muscle mass, therefore, isometric leg exercise (ILX) (large muscle mass) may have greater potential than isometric handgrip exercise (IHGX) (small muscle mass) to evoke PEH. **PURPOSE:** To determine the impact of a bout of large (ILX) and small (IHGX) muscle mass isometric exercise on post-exercise blood pressure. **METHODS:** Twelve healthy males (23.7 ± 3.5 yrs) completed 3 experimental visits (1 IHGX, 1 ILX, 1 control (rest no exercise)). Blood pressure (systolic and diastolic; SBP and DBP) was assessed at baseline and at 15, 30, 45 and 60 min post-exercise or control with an automated sphygmomanometer. Isometric exercise consisted of 4 alternating 2 min isometric contractions (quadriceps (ILX) or handgrip (IHGX)) at 30% maximum voluntary contraction. Contractions were separated by 1 min of rest. Participants completed each condition on a separate day (order counterbalanced). **RESULTS:** SBP was lower than baseline at 15 and 45 min post ($p=0.013$ and $p=0.014$ respectively); but this did not differ between the control, IHGX and ILX conditions ($p=0.256$). Control: baseline 110 ± 7.3 mmHg, average post 106.7 ± 8.6 mmHg; IHGX: baseline 110 ± 10.3 mmHg, average post 107.4 ± 8.3 mmHg; ILX: baseline 113.25 ± 11.7 mmHg, average post 111.8 ± 11.2 mmHg. DBP did not differ from baseline (Baseline DBP: control 69.17 ± 7.4 mmHg, IHGX 68.6 ± 7.9 mmHg, ILX 72.3 ± 7.4 mmHg) at any time point in any condition ($P>0.05$). However, DBP 15 min post was higher in the ILX (73.4 ± 8.9 mmHg) vs. the IHGX (68.3 ± 7.9 mmHg) and Control (68.3 ± 8.6 mmHg) conditions. **CONCLUSION:** PEH did not occur following a single session of either IHGX or ILX suggesting that this type of exercise may not be a potent stimulus for PEH in this population, even when engaging the larger quadriceps muscle mass. Further research is required to identify the importance of the duration and intensity of isometric exercise on post-exercise blood pressure. Funded by NSERC

The Effects Of Long-term Functional Training On VO_{2max}
 Adrian Aron, Heather Cumbea, Emily Hiatt, Ross Copeland, Amanda Slaughter. *Radford University, Radford, VA.* (Sponsor: Trent Hargens, FACSM)
 Email: aaron@radford.edu
 (No relevant relationships reported)

High intensity functional training (HIFT) programs have been gaining popularity as an alternative to enhance many fitness domains in a more efficient time period. These programs are characterized by alternation of short periods of intense multimodal exercises with low paced activities or rest. Recent analysis demonstrated inconclusive evidence for beneficial adaptations following short term HIFT participation (Claudio et al., 2018). Aerobic capacity showed disparity results following 5-12 weeks of training, highlighting the limited research for longitudinal aerobic adaptations of HIFT participants. **PURPOSE:** The aim of this study was to investigate the VO_{2max} changes of long-term participation in HIFT on subjects with previous training experience. **METHODS:** The subjects were 11 male, 34.7 years ± 8.3 , with at least five months of HIFT training prior to enrolling in this study. While frequently participating in HIFT, they underwent two VO_{2max} graded exercise maximal exertion tests using a modified treadmill protocol separated by at least 1 year. Subjects warmed up for 3 minutes at 8 km/h and 0% grade, then started running at 9 km/h with 0.5 km/h increase every 30 seconds until exhaustion. Exhaustion was defined as two of the four criteria: plateau of VO₂ for at least two consecutive readings, RPE of at least 18, RER ≥ 1.1 and peak heart rate (HR) of at least 90% of age-predicted maximal HR. **RESULTS:** There was no statistically significant changes between pre and post VO_{2max} (-2.02 ± 3.99 ml/kg/min). Similarly, weight (91.06 ± 13.41 vs 91.97 ± 14.07) and RER (1.05 ± 0.04 vs 1.05 ± 0.08) did not change. Subjects did experience a statistically significant decrease in peak HR from pre-testing (184.18 ± 7.65 bpm) to post-testing (176.45 ± 9.71 bpm), $p = 0.009$. **CONCLUSIONS:** These results suggest that long-term HIFT training provides no improvement in VO_{2max} in participants that already have experience with HIFT, as aerobic adaptations seem to be better evidenced during the early stage of the training period. The decreased peak HR denotes a positive cardiovascular response induced by HIFT and its effects on the increased stroke volume, diminished sympathetic drive, increased blood volume and oxidative adaptations in type II muscle fibers.

Prime: Hemodynamic/vascular Changes Following Peripheral Focused Low-mass, High-repetition Training In Older Adults
 Joaquin Ortiz de Zevallos¹, Michael A. Welsch, FACSM², Mary N. Woessner³, Neil M. Johannsen⁴, Daniel P. Credeur⁵, Conrad P. Earnest, FACSM⁶, William E. Kraus, FACSM⁷, Jason D. Allen, FACSM¹. ¹University of Virginia, Charlottesville, VA. ²University of Mississippi Medical Center, Jackson, MS, USA, Jackson, MS. ³Victoria University, Melbourne, Australia. ⁴Louisiana State University, Baton Rouge, LA. ⁵University of Southern Mississippi, Hattiesburg, MS. ⁶Texas A&M University, College Station, TX. ⁷Duke University School of Medicine, Durham, NC. (Sponsor: Professor Jason D. Allen, FACSM)
 (No relevant relationships reported)

Advancing age is associated with changes in arterial structure and function that contribute to increased blood pressure, pulse pressure and cardiovascular disease risk. Exercise training beneficially moderates these risks. Peripheral Remodeling through Intermittent Muscular Exercise (PRIME) is a novel training approach, involving peripheral focused low-mass high-repetition exercises that imposes a low cardiorespiratory strain. Initiation of structured exercise with PRIME, rather than aerobic training (AT) yields superior benefits in functional ability/capacity, in elderly subjects.

PURPOSE: To determine if PRIME, improves hemodynamic and vascular profiles in subjects >70 y who are at risk for losing functional independence. **METHODS:** Seventy-five subjects (52 F, Age: 76 ± 5 y) were tested at baseline and after 4 wk (Phase I) of either PRIME or AT. All subjects were then enrolled in an 8-wk of combined AT and resistance training (RT) (Phase II). The change scores for (1) Blood Pressure (Brachial-B and Aortic-A), (2) Vascular Stiffness (Pulse Wave Reflection-PWR, and velocity-PWV and Augmentation Index AIX) and (3) Vascular function (Brachial artery flow-mediated dilation - BAFMD), were analyzed. **RESULTS:** At the end of Phase II, there was a significant time effect for B and A blood pressures (bSBP = -4.37 ± 11.95 , bMAP = -2.77 ± 8.69 , bDBP = -2.64 ± 8.66 , aSBP = -4.13 ± 11.31 , aMAP = -2.42 ± 8.31 , and aDBP = -1.97 ± 7.40 mmHg, all $p < 0.05$). Additionally, there was a significant effect for time for BAFMD from baseline ($4.35 \pm 2.90\%$) for both interventions after Phase I and Phase II (5.25 ± 3.12 and $6.68 \pm 2.76\%$ respectively, $p < 0.01$). There was a group effect in favor of PRIME at Phase I for bMAP (-4.66 ± 10.08 vs -0.35 ± 9.11 mmHg), bDBP (-4.08 ± 8.27 vs -0.49 ± 7.56 mmHg), aMAP (-4.70 ± 10.08 vs -0.76 ± 8.60 mmHg), and aDBP (-4.32 ± 7.93 vs -0.89 ± 6.86 mmHg) (all $p < 0.05$). No significant changes were noted in PWR, PWV or AIX. **CONCLUSIONS:** These findings confirm that exercise training improves hemodynamic profile and vascular reactivity in individuals >70 y. Interestingly, individuals who followed PRIME showed greater hemodynamic benefits at 4 wks. PRIME may represent a novel approach to achieve hemodynamics benefits in individuals with limited cardiovascular function.

Effects of Domestic and International Tournaments on Heart Rate Variability in Elite Rugby Sevens Players
 Andrew A. Flatt¹, Daniel Howells², Sean Williams³. ¹Georgia Southern University, Savannah, GA. ²Rugby Football Union, Twickenham, United Kingdom. ³University of Bath, Bath, United Kingdom.
 Email: aflatt@georgiasouthern.edu
 (No relevant relationships reported)

Rugby sevens tournaments involve up to six matches within two days, are often held over consecutive weekends and frequently involve travel to and from international venues. The intense physical demands of competition, short recovery time between tournaments and the added stress of international travel warrant further investigation into recovery status monitoring among elite players. **PURPOSE:** To retrospectively evaluate heart rate variability and athlete self-report measures of recovery status (ASRM) in response to consecutive domestic and international tournaments among an elite rugby sevens team. **METHODS:** Olympic-level players ($n = 10$ males) recorded post-waking natural logarithm (Ln) of the root mean square of successive R-R interval differences (RMSSD) and ASRM (subjective ratings of Sleep, Energy, Soreness, Recovery and Mood) throughout a 1-week period prior to the domestic tournament to serve as baseline and daily thereafter until 2-days post-international tournament. Daily LnRMSSD and ASRM parameters were compared with baseline values. Total distance (TD), high speed distance (>18 km \cdot h⁻¹, HS) and session rating of perceived exertion (sRPE) were compared between tournaments. The team advanced to the finals on both occasions. **RESULTS:** Relative to baseline (4.53 ± 0.40), large and moderate effect size reductions in LnRMSSD ($p = 0.02 - 0.07$) were observed on day-two of the international tournament (4.05 ± 0.36) and one day post-international tournament (4.06 ± 0.59), respectively. Travel to the international tournament (1650 km) involved an early departure time, missed flight connection and 3 a.m. hotel arrival,

which negatively affected ratings of LnSleep (2.09 ± 0.06 vs. 1.82 ± 0.35 , $p < 0.05$) and LnEnergy (2.04 ± 0.08 vs. 1.73 ± 0.23 , $p < 0.05$). No differences in TD (3662 ± 967 vs. 4018 ± 973 m), HS (641 ± 251 vs. 611 ± 191 m) or sRPE (602 ± 241 vs. 658 ± 277 au) were observed between tournaments ($p > 0.05$). **CONCLUSIONS:** Decrements in LnRMSSD were observed in response to the international, but not domestic tournament, despite no differences in match-physical demands. Thus, factors separate from competition alone (e.g., travel-related stress) may impact players' physiological response to a tournament.

The Effects of an Intensive Endurance Training Period on Nocturnal HRV and Endurance Performance

Piia Kaikkonen¹, Juha Ahtainen². ¹Tampere Research Center of Sports Medicine, Tampere, Finland. ²Neuromuscular Research Center, Faculty of Sport and Health Sciences, University of Jyväskylä, Jyväskylä, Finland.
 (No relevant relationships reported)

PURPOSE: The optimal balance between training load and recovery is essential for the development of physical performance. In the athletic population, relatively good knowledge usually exists of individual tolerance for training. In recreationally training individuals with less training background, the optimal balance may be more difficult to estimate. The main aim of this study was to find out whether a ten-day intensive endurance training period of the non-athletic population is overreaching, and whether the changes in endurance performance can be detected in nocturnal HRV.

METHODS: 13 recreationally endurance trained healthy men (25 ± 3 y, 179 ± 6 cm, 79 ± 14 kg, $VO_{2max} 43 \pm 6$ ml/kg/min) participated in two-week baseline training period with two exercises in a week (PRE, 30 min at 70% of P_{max}) and a 10-day intensive training period with nine exercises (INT, 30 min at 70% of P_{max}). All the exercises on were performed on a bicycle ergometer. Each exercise included a 5-minute warm-up and cool-down (50% P_{max}). Maximal aerobic performance test on a bicycle was carried out before and at the end of both training periods. Nocturnal RR-intervals were measured during three consequent nights at the end of PRE and INT. A mean of all three nights was used in the analysis.

RESULTS: Endurance performance improved during the INT (from 294 ± 41 W to 306 ± 41 W, $P = 0.006$). No change occurred in VO_{2max} (PRE 45 ± 6 , INT 46 ± 4 ml/kg/min). Nocturnal HR (PRE 71 ± 9 bpm, INT 69 ± 9 bpm) or RMSSD (PRE 50 ± 14 ms², INT 54 ± 21 ms²) did not change. Participants were retrospectively divided to higher (Resp_H) and lower responders (Resp_L) according to the change (%) in P_{max} during the INT. Resp_H had lower RMSSD at PRE (38 ± 4 ms² vs. 51 ± 9 ms², $P=0.019$) and INT (40 ± 4 ms² vs. 53 ± 11 ms², $P=0.043$) when compared to Resp_L. No difference in nocturnal HR or P_{max} at PRE was detected between groups.

CONCLUSIONS: A ten-day intensive training period was not overreaching for the recreationally trained young men, as the improvement in endurance performance indicates. Despite the rather high training intensity, no change in nocturnal cardiac autonomic function was detected. The results of the present study suggest that in order to improve endurance performance of recreationally trained individuals, relatively high training intensities may be well tolerated.

Validity And Reliability Of Heart Rate Devices Compared Second-by-second Versus Minute-by-minute

James W. Navalta, FACSM, Gabriela Guzman, Crystal Maxwell, Jeffrey Montes. *University of Nevada, Las Vegas, Las Vegas, NV.*
 Email: james.navalta@unlv.edu
 (No relevant relationships reported)

The Consumer Technology Association (CTA) has guidelines for heart rate that wearable devices should be evaluated second-by-second. However, many investigations in the literature have reported minute-by-minute evaluations.

PURPOSE: To determine whether the interpretation of validity and reliability of three heart rate sensing bras during exercise would be similar if data were evaluated second-by-second versus minute-by-minute. **METHODS:** Nine females completed 14-min protocols while wearing the Sensoria Fitness biometric sports bra, the Adidas Smart sports bra, or the Berlei sports bra concurrently with the Polar H7 heart rate monitor (criterion measure). The protocol involved 1-min standing rest on the treadmill, 3-min walking warm up, 5-min run, 5-min walk. Participants rested between bouts until heart rate was within 10 bpm of resting. Validity was determined through three methods: Mean Absolute Percent Error (MAPE), Bland-Altman bias and Limits of Agreement (LOA), and Intraclass Correlations (ICC). Reliability was determined through ICC

analysis, and significance was accepted at $p < 0.05$. **RESULTS:** MAPE, bias and LOA, and ICC for second-by-second and minute-by-minute evaluations are shown in table 1. The reliability ICC values are shown in table 2.

| Device | MAPE (Sec) | MAPE (Min) | Bias (Sec) | Bias (Min) | LOA (Sec) | LOA (Min) | ICC (Sec) | ICC (Min) |
|----------|------------|------------|------------|------------|-----------------|-----------------|-----------|-----------|
| Sensoria | 1.08 | 0.98 | 0.17 | -0.07 | 4.78 to -4.43 | 3.19 to -3.33 | 0.996 | 0.998 |
| Adidas | 3.11 | 3.04 | 0.44 | -0.10 | 22.63 to -21.76 | 25.66 to -25.85 | 0.902 | 0.955 |
| Berlei | 1.08 | 4.81 | -0.34 | 0.40 | 6.93 to -7.62 | 21.44 to -20.64 | 0.989 | 0.911 |

| Device | Reliability ICC (Sec) | Reliability ICC (Min) |
|----------|-----------------------|-----------------------|
| Sensoria | 0.965 | 0.956 |
| Adidas | 0.864 | 0.842 |
| Berlei | 0.961 | 0.955 |

CONCLUSIONS: The validity measures of MAPE, Bland-Altman bias and LOA, and ICC appear to be minimally influenced by sampling rate. Reliability measures are consistent regardless of rate. While further investigation is necessary, this data provides evidence that CTA guidelines for heart rate sampling are minimally influenced if taken at longer periods.

Validity In Step Counting Of Wearable Devices During Uphill Trail Running

Robert W. Salatto¹, James W. Navalta, FACSM¹, Jeffrey Montes¹, Nathaniel G. Bodell¹, Jacob W. Manning², Mark DeBeliso, FACSM². ¹University of Nevada, Las Vegas, Las Vegas, NV. ²Southern Utah University, Cedar City, UT. (Sponsor: James W Navalta, FACSM)
 (No relevant relationships reported)

In today's technological society, there are many options for wearable exercise tracking technology. With a growing emphasis for outdoor recreation, there is a need to validate these devices in a natural setting. **Purpose:** The purpose of this study was to examine the reliability of wearable step tracking devices during uphill trail running. **Methods:** Participants (n=12) completed a self-paced one-mile uphill run, wearing step tracking devices including: Stryd Power Meter (criterion) Garmin Fenix 5 watch (wrist), Suunto Sport watch (wrist), Motiv ring (finger), Fitbit Surge 2 (ankle), Polar A360 (ankle), Garmin Vivosmart (ankle), and Samsung Gear 2 (ankle). Validity was determined via Bland-Altman analysis (limits of agreement; LoA), a mean absolute percentage error (MAPE) lower than 10%, and Intraclass Correlation (ICC) greater than 0.70. Significance was accepted at the $p < .05$ level. **Results:** The wrist and finger-worn devices were all valid compared to the criterion measure (see table 1). Of the devices secured around the ankle, only the Polar A360 was considered valid for step count (see table 1).

| Number | Device | MAPE (%) | ICC, p-value | Bias, LoA |
|--------|------------------|----------|---------------|-------------------------|
| 1 | Garmin Fenix* | 5.1 | 0.962, <0.001 | -59±87, -229 to 112 |
| 2 | Suunto Sport* | 8.5 | 0.971, <0.001 | -145±82, -306 to 15 |
| 3 | Motiv Ring* | 5.1 | 0.907, <0.001 | -29±144, -252 to 311 |
| 4 | Fitbit Surge 2 | 16.1 | 0.741, =0.001 | -245±274, -293 to 783 |
| 5 | Polar A360* | 9.1 | 0.774, =0.001 | -70±293, -644 to 505 |
| 6 | Garmin Vivosmart | 11.0 | 0.506, =0.033 | -240±654, -1522 to 1041 |
| 7 | Samsung Gear 2 | 12.5 | 0.785, =0.001 | -149±240, -321 to 618 |

Conclusion: Several devices (1, 2, 3, 5) demonstrated reliable step counting during uphill trail running. The devices that were not valid (4, 6, 7) were attached around the ankle. Results indicate that several valid devices are available for tracking steps in a trail running situation, however caution should be used for choice of wearable and where it is positioned on the body.

Changes In Lower Body Strength Among 5676 Free-living Persons Using An App-based Program
 Joey Eisenmann, James Moreland, Jace Derwin, Trevor Watkins, Dan Giuliani. *Volt Athletics, Seattle, WA.* (Sponsor: Shawn Arent, FACSM)
Reported Relationships: J. Eisenmann: Consulting Fee; Volt Athletics.

The myriad of beneficial effects of strength training are well-known in humans. However, most previous studies have relatively small sample sizes ($n < 50$) and a brief duration of training (< 3 months). Furthermore, they lack ecological validity. **PURPOSE:** In this study, we leverage the widespread usage of smartphones and a mobile app-based strength training program to investigate the development of muscular strength in 5676 free-living humans from 4 months to 4 years. **METHODS:** We studied a dataset consisting of 5676 people with 24,471 total observations over a period of 4 months to 4 years (mean duration 463 ± 271 days). Lower body muscular strength was taken as the estimated 1-repetition maximum (1RM) using the Epley equation for the barbell back squat exercise. Participants must have had more than one estimated 1RM to be included in the analysis during the period in which they participated in a progressive, periodized strength training program consisting mainly of compound exercises 1-3 times per week. A multi-level growth model with random effects was used to describe strength gains. Variables of baseline strength, gender, training experience, training frequency, volume and intensity were also included in the modeling. **RESULTS:** Lower body strength increased significantly over time (L-Ratio = 91985, $p < .0001$). The mean \pm SE baseline 1RM squat was 98.2 ± 1.12 kg and the largest gains occurred within the first 6 months of initiating the training program (e.g. 3.9 ± 0.12 kg/month from baseline to 6 months; 24% increase) with improvements continuing through 1 year (1.9 ± 0.15 kg/month from 6-12 months; 36% increase from baseline), 2 years (0.9 ± 0.08 kg/month from year 1 to 2; 46% increase from baseline), 3 years (0.5 ± 0.19 kg/month between years 2-3), and 4 years (0.3 ± 0.65 kg/month in years 3-4). **CONCLUSIONS:** This study showed that an app-based strength training program results in substantial and continual increase in lower body strength in a large free-living sample up to 4 years. Subsequent analyses will examine the influence of several demographic and acute training variables and their interactions to confirm and expand upon existing meta-analyses. This study has implications for the application of mobile technology, Big Data, and the Living Lab concept to the field of exercise science.

Validity of the Adidas Smart Bra in Measuring Heart Rate during Exercise Transitions
 Gabriela Guzman, Crystal Maxwell, James W. Navalta PhD., FACSM. *University of Nevada, Las Vegas, Las Vegas, NV.* (Sponsor: James W. Navalta, FACSM)
 Email: gabby10rmz@gmail.com
(No relevant relationships reported)

Wearable technology is becoming very popular; offering a variety of applications for it. **PURPOSE:** The current investigation was designed to evaluate the validity of a heart rate sensing bra during transitions from rest to self-paced running and walking. **METHODS:** Nine females completed a 14-min protocol while simultaneously wearing the Adidas Heart Rate Monitoring Smart Bra and Polar H7 heart rate monitor (criterion measure). The protocol involved 1-min standing rest on the treadmill (to determine resting heart rate), 3-min walking warm up, 5-min run, and 5-min walk. The validity of the sports bra was determined by three methods: mean absolute percent error (MAPE), Bland-Altman bias and limits of agreement (LOA), and intraclass correlations (ICC) with a value greater than 0.7 and significance < 0.05 . Those three methods were used to compare second to second data. **RESULTS:** When all conditions were considered (7569 datapoints), MAPE = 3.11%, bias = 0.44 ± 11.34 and LOA range = -21.75 to 22.63, and ICC = 0.902 ($p < 0.001$). For the resting condition (549 datapoints), MAPE = 2.07%, bias = 0.08 ± 3.46 and LOA range = -6.69 to 6.86, and ICC = 0.977 ($p < 0.001$). The transition from rest to a walking warm up (1621 datapoints) yielded MAPE = 0.047%, bias = 94.38 ± 13.88 and LOA range = 67.16 to 121.59, and ICC = 0.923 ($p < 0.001$). With respect to the transition from warm up to running (2700 datapoints) MAPE = 5.60%, bias = 0.47 ± 18.38 and LOA range = -35.55 to 36.49, and ICC = 0.768 ($p < 0.001$). When the transition from running to walking was considered (2700 datapoints) MAPE = 1.09%, bias = 0.11 ± 1.97 and LOA range = -3.74 to 3.96, and ICC = 0.995 ($p < 0.001$). **CONCLUSION:** These pilot results indicate that the Adidas Heart Rate Monitoring Smart Bra is valid for most conditions (rest, warm-up, walking). Progressing from active warm-up to run should be viewed with caution, as heart rate measurements were not all valid in this condition.

- 183** Board #21 May 29 9:30 AM - 11:00 AM
Impact Identification With Machine Learning From Low Frequency Wearable Sensor Data Among National Ice-hockey Players
 Aaron M. Pilotti-Riley¹, Davor Stojanov¹, Muhammad Sohaib Arif¹, Erik M. Bollt², Stephen J. McGregor¹. ¹Eastern Michigan University, Ypsilanti, MI. ²Clarkson University, Potsdam, NY. (Sponsor: Dr. Andrew R. Coggan, FACSM)
(No relevant relationships reported)

Purpose

To determine if machine learning approaches could be used to improve impact identification from low frequency data collected from wearable sensors (WS) among national ice-hockey team members.

Methods

23 members of the U.S. National (NTDP) U18 team consented to procedures approved by EMU Human Subjects Committee. Using previously validated impact events identified from data collected at 100 Hz (Impact Processor, Zephyr MD), we used two neural network approaches, autoencoder (AE), neural network that can reconstruct inputs of large data sets and multi-layer perceptron (MLP), a neural network that uses non-linear activation of multiple layers of interconnecting nodes as well as support vector machine (SVM) to attempt to improve the identification of impacts from summary data recorded at 1 Hz. A dataset, selected from 8 players with the highest ice time in one game, was comprised of 86 impacts and 88602 samples were used to train the AE. Variables from 1 Hz data used to train the AE included Activity and Peak resultant acceleration as well as Peak and Min accelerations in the Vertical, Lateral and Sagittal planes. The trained AE was then applied to the validated test set from 8 players for 3 games consisting of 409 impacts and 462138 datapoints. Accuracy was determined by F1 score ($F1 = 2 * (\text{precision} * \text{recall}) / (\text{precision} + \text{recall})$), where precision = true positives / (true positives + false positives) and recall = true positives / (true positives + false negatives).

Results

Using only trained AE, 187 true positives, 3299 false positives and 222 false negatives were identified with an F1 score of 0.096. To improve accuracy, AE was used as filter with MLP for classification, which identified 184 true positives, 225 false negatives and only 26 false negatives resulting in an F1 score of 0.594. Finally, using AE filter and the SVM classifier with class weights produced the best results with 272 true positives, 137 false negatives and only 50 false positives and an F1 score of 0.744.

Conclusion

These data show that using autoencoder programming with additional classification (MLP or SVM) impacts can be identified at 1 Hz with relatively high F1 scores in ice hockey using trunk-worn wearable sensors. Finally, using sensor fusion techniques, it is likely impact identification in ice-hockey could be entirely automated.

Monitoring External Training Loads and Neuromuscular Performance For Division I Basketball Players Over the Pre-Season
 Aaron Heishman, Ryan M. Miller, Eduardo D.S. Freitas, Brady S. Brown, Bryce D. Daub, Michael G. Bembem, FACSM. *University of Oklahoma, Norman, OK.* (Sponsor: Michael G. Bembem, FACSM)
 Email: aaronheishman@ou.edu
(No relevant relationships reported)

External training load (TL_E) is used to quantify the biomechanical load accrued during training. The countermovement (CMJ) jump is used to evaluate neuromuscular fatigue and recovery in response to TL_E . However, limited research has coupled TL_E parameters with changes in neuromuscular performance variables from the CMJ. **PURPOSE:** The purpose of this investigation was twofold: 1) to characterize TL_E across the pre-season and 2) examine the differences in TL_E per session and CMJ performance across the 5 weeks of pre-season training in NCAA D1 basketball athletes. Additional analyses examined the influence of position and scholarship standings. **METHODS:** TL_E was monitored in 14 male athletes during 22 basketball practice sessions over the course of the pre-season. In addition, weekly CMJs were used as an indicator of neuromuscular fatigue and performance. A 3-way (2 X 2 X 5) Repeated Measures Analysis of Variance with Bonferroni post hoc analysis was used to examine differences in the average TL_E per session each week and differences in the CMJ variables of Flight Time: Contraction Time (FT:CT) and Jump Height (JH) across time and between position (Guard vs. Forward/Center) and academics (Scholarship vs. Walk-on). Statistical significance was set at $p \leq 0.05$. **RESULTS:** Player load per minute (PL; PL/min) was significantly higher during Week 1 and Week 2 compared to Week 3 ($p < 0.05$). No significant differences were observed for average PL, high inertial movement analysis (IMA), or Total Jumps per session across the 5 weeks of pre-season ($p > 0.05$). A significant group X time interaction indicated Scholarship athletes had greater PL, PL/min, 2 Dimensional PL, High IMA, and Total Jumps compared to the Walk-on athletes. Player position did not influence TL_E . No significant

differences were observed in FT:CT or JH over the 5 weeks of preseason ($p > 0.05$) or between groups ($p > 0.05$). **CONCLUSION:** The present study characterizes the TL_E demands in collegiate basketball during the pre-season. The average TL_E per week did not vary across 5 weeks of training, while differences in intensity (PL/min) were evident. While no differences were observed between position groups, there was a significant difference in TL_E between scholarship and walk-on athletes.

PURPOSE: Two wrist-worn monitors (FBS and GVF) and an armband (SWA) were evaluated in measuring energy expenditure (EE) and heart rate (HR) during a gym-based routine. **METHODS:** Men ($n = 21$) and women ($n = 16$) completed a gym-based routine comprised of 15-min stationary cycling (SC), 15-min treadmill running (TR), and 35-min resistance training (RTR) at self-selected intensities while wearing the monitors. All monitors were compared to a portable metabolic analyzer (OM) for EE. The FBS and GVF were compared to a chest HR monitor (PM) for maximal HR (HR_{max}) and average HR (HR_{avg}). **RESULTS:** Compared to the OM, the FBS and GVF produced higher EE estimates while the SWA overestimated EE during TR and underestimated EE for the rest (Table 1). Equivalency testing determined that no monitor was equivalent to the OM, although the SWA yielded the most favorable agreement for whole session as the 90% CI (410.9-500.1 kcal) overlapped the higher end of the equivalency zone (423.6-517.7 kcal) by only 12.7 kcal. Acceptable measurement error ($\leq 20\%$) for whole session was produced by the SWA and for TR by the SWA and GVF, while for RTR the GVF had the highest measurement error (Table 1). Significant bias was observed for the FBS and GVF during SC (10.1 ± 39.2 kcal and 18.6 ± 33.7 kcal), RTR (47.4 ± 52.7 kcal and 82.0 ± 79.2 kcal), and whole session (83.2 ± 93.7 kcal and 104.4 ± 131.9 kcal). In regards to HR_{avg} and HR_{max} , both monitors' 90% CIs fell in the equivalency zones with the exception of HR_{avg} measured by the FBS for RTR. The GVF had an improved accuracy over the FBS as indicated by lower error rates for HR_{avg} (SC: 2.0% vs 5.9%; TR: 2.4% vs 3.1%; and RTR: 2.4% vs 9.5%) and HR_{max} (SC: 0.8% vs 1.4%; TR: 0.9% vs 1.5%; and RTR: 0.9% vs 7.0%). **CONCLUSION:** The study protocol simulated real-world conditions to facilitate naturalistic application of the findings. No monitor accurately estimated EE, however, the SWA had the most favorable estimates. The FBS and GVF demonstrated comparable performance for both EE and HR estimates.

Innovations in Heart Rate Monitoring Devices and Smart Applications: Physical Configuration Matters!

Calixte Aholu, Nicole J. Smith, Catherine G.R. Jackson, FACSM, David A. Kinnunen. CSU Fresno, Fresno, CA. (Sponsor: Catherine G.R. Jackson, FACSM)

(No relevant relationships reported)

Bluetooth/ANT+ heart rate monitors and smart device applications have the potential to advance heart rate monitoring in non-clinical settings. New innovative applications allow for heart rate monitoring of multiple users simultaneously; however, preliminary attempts to use a particular commercially available model in a typical university gymnasium setting revealed persistent issues with signal interruption; thus, the trustworthiness of the data was limited.

PURPOSE: To reduce the prevalence of signal interruption by determining the best physical configuration of components.

METHODS: A quasi-experimental repeated measures design was utilized to determine the best configuration of the system components. Cluster and ANOVA analyses determined good, better, and best configurations. The dependent variable was signal interruption and the unit of analyses was the number of signal interruptions per two-minute session. The independent variables were height (1.8m, 3.6m, and 5.4m), angle (60°, 75°, and 90°), and location (left corner, middle, right corner) of the transmitter component. University students, male and female adults ages 19-25 with no apparent health problems, were recruited to participate during undergraduate physical education teacher education lab classes. Participants were monitored while participating in physical activities during normal class sessions. Classes were conducted in a typical indoor gymnasium slightly larger than a single standard collegiate-sized basketball court.

RESULTS: Inspection of the graphs and ANOVA analyses revealed that the best configuration of the system was transmitter device placement at a height of 1.8m² F(2,

1,052) = 54.86, $p < .001$, partial $\eta^2 = .09$, at a 60° angle F(2, 1,052) = 12.50, $p < .001$, partial $\eta^2 = .02$, and in the left corner location F(2, 1,052) = 24.28, $p < .001$, partial $\eta^2 = .04$.

CONCLUSIONS: The height, angle, and location of the transmitter component all played a significant role in reducing the prevalence of signal interruption. It was determined that the best results were found with the lowest height and smallest angle chosen. Therefore, random placement of transmitter height, angle and location will not yield the best heart rate monitoring results.

Absolute Validity And Test-retest Reliability Of Step Counts For Fitbit Flex 2 In Pram Walking

Yuling Yuan, Paul Kelly. The University of Edinburgh, Edinburgh, United Kingdom.

Email: ncyuan@126.com

(No relevant relationships reported)

PURPOSE: To test the absolute validity and test-retest reliability in two kinds of pram walking settings and help researchers and postnatal women to choose suitable tools for monitoring physical activity levels. **METHODS:** 12 participants who were adult women (23.2 ± 0.7 years old) wore Fitbit Flex 2 on both wrists to perform the outdoor protocol: Two rounds of state distance pram walking of two settings (one round for each setting): (1) Both hands pushing setting; (2) One hand pushing setting. The step counts from Fitbit Flex 2 were compared to video recording to assess the absolute validity and test-retest reliability. **RESULTS:** The average Mean Absolute Percentage Error(MAPE) of step counts for left and right wrists in both hands pushing setting were -43.1% and -49.1%. In one hand pushing setting, the average MAPE of step counts for wrist of dominant hand was -52.6%, and -5.1% for wrist of non-dominant hand. In both hands pushing setting, the Fitbit Flex 2 had a low correlation ($ICC=0.40$) for wrist of dominant hands while the correlation of wrist of non-dominant hand was good ($ICC=0.85$). In one hand pushing setting, the correlations are excellent ($ICC=0.99$) for wrist of non-dominant hand and moderate for wrist of dominant hand ($ICC=0.68$). **CONCLUSIONS:** The absolute validity of step counts for Fitbit Flex 2 was poor when device applied on the wrists of both hands in both hands pushing setting and dominant hand in one hand pushing setting while the absolute validity was high when the device applied on the wrist of non-dominant hand in one hand pushing setting. The test-retest reliability is excellent to good when the device wore on the wrist of non-dominant hand and moderate to poor on the wrist of dominant hand.

Comparisons of Portable Metabolic Sensors During Outdoor Cycling

Katherine Costello, Darrel Woods, Alexander Toulouse, Patrick R. Davis. Sam Houston State University, Huntsville, TX.

(No relevant relationships reported)

Wearable technology has increased in prevalence and in the ability to monitor health related data. Additionally, the ability to record training data through various sensors has become essential in developing highly personalized training programs. Metabolic measurements have typically been confined to laboratory settings, but portable metabolic carts make the collection of these metrics in real world conditions possible.

Purpose. The purpose of this study was to compare measurements of VO_2 from two different portable metabolic carts, a new consumer focused cart (A) and a research grade cart (B), in outdoor cycling under steady state conditions.

Methods: A total of 10 participants were included in the study. All participants were recreationally trained cyclists who had track racing experience. Participants completed a ramped VO_{2max} test with lactate sampling from capillary blood at one minute intervals. Lactate threshold (LT) was estimated as the first stage prior to an increase of >1 mmol in lactate concentration. Participants later completed six 10-minute intervals in a pairwise manner at 50, 70, and 85% of their power at LT on an outdoor velodrome. Expired gasses during these intervals were analyzed by two different portable metabolic carts (A&B). Data from approximately 6-9 min of each interval were averaged. Comparisons between the two devices were made using paired t-tests.

Results: Average age of participants was 44.3 ± 3.01 years and VO_{2max} was 51.56 ± 2.74 ml/kg/min. Cart A was unable to capture enough data when cycling at 50% of LT and therefore no comparisons were possible. There were significant differences ($p < 0.001$) in absolute VO_2 (1890.0 ± 245.1 mL/min vs. 2627.3 ± 262.0 mL/min) between carts A&B respectively when cycling at 70% of LT. Additionally, there were significant differences ($p < 0.001$) in absolute VO_2 (2269.9 mL/min \pm 362.3 vs. 3069.3 ± 317.5 mL/min) between carts A&B respectively when cycling at 85% of power at LT.

Conclusions: Measurements of VO_2 while cycling in an outdoor environment may not be consistent across devices.

Accuracy of an Armband Heart Rate Monitor

Daniel Hagan, John Wygand, FACSM, John Petruzzo, Robert Otto, FACSM. *Adelphi University, Garden City, NY.* (Sponsor: Robert M. Otto, FACSM)
Email: danielhagan@mail.adelphi.edu
(No relevant relationships reported)

Activity monitors have demonstrated success at facilitating positive physical activity behavior changes in diverse populations by providing self-monitoring, motivation, and timely feedback, yet questions loom due to a paucity of data on the accuracy of armband heart rate monitors (ABM). **Purpose:** The purpose of this investigation was to assess the accuracy of the ABM under aerobic exercise conditions. **Methods:** 15 male and 5 female college-aged subjects (age 20.9 ± 1.7 , ht. 177.0 ± 9.1 cm, body mass 72.8 ± 13.4 kg) engaged in steady state aerobic exercise on a treadmill while wearing the ABM and a hard wire electrocardiograph (ECG). PAR-Q+ and a brief medical screening preceded participation. Resting measures were obtained pre (sitting & standing) and post (sitting) aerobic exercise. The treadmill protocol included 3 minute stages at 1% grade with speeds of 53.6 meters/min, 80.4 meters/min, 107.2 meters/min, 160.8 meters/min, 187.6 meters/min, 214.4 meters/min, and a cool-down at 53.6 meters/min. **Results:** Statistical analysis by paired t-tests revealed NSD between HR of 74 ± 14 & 74 ± 14 , 98 ± 14 & 98 ± 14 , 120 ± 16 & 121 ± 19 , 156 ± 17 & 156 ± 19 , 175 ± 17 & 176 ± 17 , and 187 ± 16 & 187 ± 16 b/min at speeds of 80.4, 107.2, 160.8, 187.6, and 214.4 m/min, for ABM & EKG, respectively. Only the 53.6 speed revealed a significant difference in HR of 90 ± 13 vs 92 ± 13 for ABM and EKG, respectively. In addition, there was a high correlation and low standard error between the ABM and ECG measures ($r = .998$, $SE = .2$). At speeds of 80.4 ($r = .981$, $SE = .59$), 107.2 ($r = .952$, $SE = 1.31$), 160.8 ($r = .99$, $SE = .7$), 187.6 ($r = .98$, $SE = .77$), and 214.4 meters/min ($r = .995$, $SE = .38$) there was also a high correlation and low standard error. Contrary to all other trials, the 53.6 meters/min trial ($r = .992$, $SE = .38$) showed a significant difference at the $p < .01$ level (.004). **Conclusion:** At all workloads in excess of 53.6 m/min, the ABM provides accurate HR measures, however for the novice exercise enthusiast or the slow paced walker, ABM may be insufficient for accurate HR monitoring.

Validation of Garmin Fitness Tracker Biomechanics

Bryson Carrier, Tim Holmes, Lauren Williams, Siri Dahl, Libby Weber, Andrew Creer, Tyler Standifird. *Utah Valley University, Orem, UT.*
(No relevant relationships reported)

Purpose: As fitness trackers become more available, the need for independent validation has become more important to drive accuracy in training decisions and physiologic research. Therefore, the purpose of this study was to find the reliability and accuracy of the data collected from the Garmin fenix 3 HR fitness tracker. **Methods:** 17 healthy, recreational runners (9 male, 8 female, 28.11 ± 7.38 yrs, 70.26 ± 10.76 kg, 173.77 ± 5.96 cm) performed three running conditions (flat, incline (5%), and decline (-5%)) on an instrumented treadmill used to collect ground reaction force data. Infrared markers were placed on the foot and trunk and tracked with a 16 camera motion capture system. The data was processed using Visual 3D software (5.0, C-Motion, Inc., Germantown, MD, USA) and variables extracted were compared to data collected by the Garmin fenix 3 HR (Garmin Ltd., Olathe KS). **Results:** Statistical analysis was done via a 2-tailed paired t-test comparing the data taken from the motion capture system and instrumented treadmill to the data collected by the Garmin watch. There were no differences between the Garmin and the treadmill for flat stride length, declined stride length, inclined run cadence, declined run cadence, and inclined ground contact time. Differences ($p < 0.05$) were observed in inclined stride length, flat run cadence, flat vertical oscillation, inclined vertical oscillation, declined vertical oscillation, flat ground contact time, and declined ground contact time. **Conclusion:** Overall the Garmin fenix 3 HR fitness tracker was found to be reasonably reliable for certain variables, such as stride length and run cadence, but not reliable for vertical oscillation and ground contact time. Certain considerations should be taken as to the accuracy of the variables when using this data to drive training adaptations.

Validation of Garmin Fitness Tracker Metabolic Data (VO_{2max})

Brayden Jolley, Bryson Carrier, Tyler Standifird, Andrew Creer. *Utah Valley University, Orem, UT.*
(No relevant relationships reported)

Purpose: As fitness trackers become more available, the need for independent validation has become more important to drive accuracy in training decisions and physiologic research. Therefore, the purpose of this study was to determine the accuracy of predicted maximal aerobic fitness assessment (VO_{2max}) from the Garmin

fenix 3 HR fitness tracker when compared to a lab based VO_{2max} test. **Methods:** 6 healthy recreational runners (4 male, 2 female, 25.4 ± 2.5 yrs, 69.0 ± 6.0 kg, 174 ± 5.7 inches, 35.4 ± 29.9 km/wk) participated in two testing sessions; a graded exercise test to exhaustion (GXT) on a treadmill and a 15-minute submaximal outdoor track session. During the treadmill GXT expired gases were collected and analyzed using a metabolic cart, with the highest value being considered VO_{2max} . Heart rate was measured continuously via telemetry, with the highest value recorded as the maximal heart rate (HR_{max}). Participants then completed a submaximal outdoor run on a track between 48 hrs and 7 days after the lab test. The outdoor run involved maintaining at least 70% of HR_{max} for 15 minutes while wearing a Garmin fenix 3 HR watch and Garmin HR monitor chest strap. The watch was reset to default settings prior to inserting participant data into the watch for each test. Statistical analysis was done via a 2-tailed paired t-test, comparing the lab and field measures. **Results:** There was no difference between the treadmill GXT (51.8 ± 7.8 ml/kg/min) and the Garmin estimated value from the outdoor run (53.2 ± 4.1 ml/kg/min) for VO_{2max} . **Conclusion:** Overall the Garmin fenix 3 HR fitness tracker was found to provide an accurate estimate of VO_{2max} when compared to an actual GXT. Based on these data it would appear that the Garmin fenix 3 HR watch with chest strap may provide individuals an accurate assessment of their aerobic capacity for simple self-monitoring.

Sports Performance Wearable Technology, sEMG, and Manual Muscle Testing: Practical Methods for Measuring Maximal Voluntary Contractions

Katherine Balfany¹, Ming-Sheng (Matthew) Chan², Robert G. Lockie¹, Scott K. Lynn¹. ¹*California State University, Fullerton, Fullerton, CA.* ²*Athos, Mad Apparel Inc, Redwood City, CA.*
(Sponsor: Daniela A. Rubin, FACSM)

(No relevant relationships reported)

PURPOSE: The development in sports performance wearable technology has allowed for the monitoring of an athletes' internal load via surface electromyography (sEMG) - based garments. These garments have been shown to be a valid tool for measuring sEMG in sports settings. However, to conduct valid comparisons of sEMG, current methods often involve referencing data from a particular movement to a maximal voluntary contraction (MVC). MVCs are typically measured using an isokinetic dynamometer (ISO); however, with the application of sEMG in a sports environment utilizing an ISO can be impractical. An alternative is the use of manual muscle testing (MMT), in which manual resistance is applied by a trained practitioner to invoke a MVC. The purpose of this study was to compare sEMG-based garment measurement of MVCs elicited using ISO versus MMT in lower extremity muscles. **METHODS:** Twelve healthy, physically active participants (7 males, 5 females) were recruited for this study. Participants were fitted with a sEMG-based compression short or legging embedded with sEMG sensors. Following a dynamic warm-up, participants performed, in a randomized order, either ISO or MMT normalization protocols to measure the MVC of the vastus medialis (VM), vastus lateralis (VL), bicep femoris (BF) and gluteus maximus (GM). Data were sampled at 1KHz and band pass filtered, with the peak amplitude of the MVC used for analysis. Paired samples t-tests ($p < .05$) were used to compare the mean peak amplitudes from each muscle between ISO and MMT protocols. Pearson's correlations ($p < .05$) were conducted to evaluate the degree of the relationship of peak amplitudes obtained by the two protocols for each muscle. **RESULTS:** No significant differences ($p = .47-.88$) were found between any of the muscles when comparing mean peak amplitudes for the ISO and MMT protocols. Significant correlations indicated a positive association between peak amplitudes obtained through ISO and MMT for the VM, RF, and BF ($r > 0.80$, $p < .001$ for all) and for the GM ($r = .63$, $p = .022$). **CONCLUSIONS:** The present data demonstrated that similar sEMG MVC data for the VM, VL, BF, and GM were recorded for the ISO and MMT. This suggests that the use of MMT, when administered by a trained member of staff, could be a practical method for normalizing each of the measured muscles to the MVC in a field environment.

NICA Injury Surveillance System: Concussion Risk Factors

Christopher C. Nkoy, Stuart Willick, Daniel Kushner, Masa Teramoto. *University of Utah Orthopedic Center, Salt Lake City, UT.*

(No relevant relationships reported)

Scientific Abstract

Clinical experience highlights the dangers of the sport of mountain biking, with a high volume of contusions, laceration, fractures and concussions. Scientific literature to date has been sparse with regards to injuries in this population. While participation in this sport can transform the lives of the racers with its emphasis on fitness and fun, injuries can significantly limit the student-athlete's ability to exercise. However, this project has strong potential to make high school mountain bike racing a safer sport.

PURPOSE: To determine the most common injury occurring in mountain biking athletes and identifying specific risk factors in the most common injury—concussions. **METHODS:** An incident survey was developed using redcap software to give coaches the capacity to report trauma and all circumstances contributing to their athletes' injuries. The Spring 2018 league presented 4,671 students, and the end of the Fall 2018 league added 13,343 more student athletes. In total, this presented a total of 18,014 student athletes from 2018 to look at. Demographics were recorded: age, year in school, division, sex, league, and state. The incline and trail conditions were also accounted for as variables. Weather was marked on the survey, and circumstances for crashes were accounted for—practice, race, passing, familiarity with trail, etc. Statistical and machine learning methods were then used to recognize the most commonly occurring injury and decipher risk factors. **RESULTS:** It is still too early in the project for firm conclusions, but early analysis of the NICA database has shown concussions to account for up to 23% of all injuries recorded in the injury surveillance system in 2018. Team practice accounts for 56.3% of injuries. Downhill racing accounts for 72% of concussions, as well as a distinct gender bias with males. **CONCLUSION:** Concussions account for the most injuries with regard to competitive mountain biking. The varsity league accounts for the least amount of concussions, which suggests injury prevention needs to be taught early on to less experienced riders. Safety strategies on courses, with equipment, and with skills training should be implemented to lower the amount of concussions (and total injuries) for athletes in the coming years.

194 Board #32 May 29 9:30 AM - 11:00 AM EEG Measurement In Elderly People During Stepping Exercise With Visual Perception Tasks

Takahide Kato¹, Taichi Hayasaka¹, Tsukasa Sanuki¹, Takashi Kawagoe², Stanley M. Yamashiro³. ¹National Institute of Technology, Toyota College, Toyota, Japan. ²Aichi Medical University, Nagakute, Japan. ³University of Southern California, Los Angeles, CA.
(No relevant relationships reported)

The increased risk of falling with aging leads to a recurrent problem in elderly in need of long-term care and may become a major social problem. A reduction in muscular strength and a decline in perceptual function are listed as causes of falls. As a countermeasure to fall risk the effect of various types of exercise training and visual perception tasks (VPT) were tried. Recently, previous studies measured electroencephalograms (EEG) during exercise with wireless electroencephalograph. The evaluation of EEG in elderly during exercise with VPT and comparing results in young may provide a novel insight on prevention of falls. **PURPOSE:** The aim of this study was to examine whether the EEG signals during stepping exercise could be amplified by VPT and aging. We measured EEG during stepping exercise with or without VPT for subjects of ages: 70s, 40s, and 20s. **METHODS:** 11 males in 70s (73±5 yrs), 10 males in 40s (44±3 yrs), and 10 males in 20s (20±1 yrs) carried out stepping exercise for 5 min with or without VPT. EEG during stepping exercise was measured using a wireless electroencephalograph (EMOTIV EEG headset). We analyzed the averaged power spectral density (PSD) for all electrodes with time frequency analysis, and a phase locking index (PLI) with phase synchronization quantification. Statistical comparisons were made using two-way ANOVA. **RESULTS:** PSD without VPT in age 70s (1692±77 dBμ) was larger than in 40s (1374±78 dBμ) and 20s (828±78 dBμ) (p<0.05). Moreover, PSD magnitude increased with VPT in all ages (70s: 1795±73, 40s: 1645±79, 20s: 1075±79 dBμ, p<0.05). PLI of θ wave with VPT in age 70s (0.086±0.0019) was smaller than 40s (0.101±0.0021) and 20s (0.110±0.0021) (p<0.05). PLI of α wave with VPT in age 70s was less than without VPT (0.087±0.0011 vs. 0.091±0.0012, p<0.05), whereas PLI of β wave with VPT in 70s was larger than without VPT (0.094±0.0006 vs. 0.091±0.0007, p<0.05). **CONCLUSIONS:** EEG signals in elderly during stepping exercise is larger than in middle age and young, and is enhanced by VPT. Additionally, the phase pattern may help explain the differences of cognitive functions for VPT between age groups. Supported by The Naito Research Grant.

195 Board #33 May 29 9:30 AM - 11:00 AM Does Squat Depth and Width Influence Quadriceps Muscle Activation?

Matt Denning¹, Brad Gardiner², Tyler Standifird³, Lauren Williams³. ¹Brigham Young University - Idaho, Rexburg, ID. ²Weber State University, Ogden, UT. ³Utah Valley University, Orem, UT. (Sponsor: Doug Powell, FACSM)
(No relevant relationships reported)

Squats are a popular closed-chain exercise that benefit strength, power, and balance. Squats are often performed with varying depths and widths. Squat variation may elicit different demands on the neuromuscular system. **PURPOSE:** This study investigated muscle activation of the vastus lateralis (VL) and vastus medialis (VM) during 9 different squat variations. **METHODS:** 13 healthy, college-aged adults (6 female, 7 male, mass = 73.5 ± 15.0 kg; height = 1.7 ± 0.09 m) performed body-weight squats at 3 widths (standard (shoulder width), wide (150% of shoulder width), and widest (200% of shoulder width)) and 3 squat depths (shallow (55 degree knee flexion), parallel (90 degree knee flexion), and deep (125 degree knee flexion)). Electromyography (EMG) and marker data were used to determine peak EMG amplitudes during the eccentric and concentric phases of the squat. 2x3 ANOVAs were used to evaluate the simultaneous effect of squat depth and width on peak EMG amplitude. EMG data were filtered using a root mean square approach and normalized to a 30-degree squat reference position. **RESULTS:** Generally, muscle activation increased with greater squat depth, but did not change with greater squat width. Specifically, VL amplitude during the concentric phase was 61% and 119% greater during the parallel (232.7 ± 81.5% reference value; p < 0.01) and deep squat (315.2 ± 133.3% reference value; p < 0.01) when compared to the shallow squat (144.2 ± 52.4% reference value). Similarly, VM amplitude during the concentric phase was 70% and 88% greater during the parallel (262.9 ± 207.6% reference value; p = 0.03) and deep squat (292.2 ± 171.4% reference value; p < 0.01) when compared to the shallow squat (155.6 ± 99.8% reference value). Surprisingly, there was no statistical difference in EMG amplitude during the eccentric phase or for the depth by width interactions (p > 0.05). **CONCLUSIONS:** These data support the idea that deep squats can be used to generate increased muscle activity of the lower-extremities. Our data also indicate that increased squat width does not increase muscle activity, although our study only examined muscles primarily used for sagittal-plane movement. Further research is needed to investigate the intertwined relationship between squat depth and width on muscle activation for additional lower-extremity muscles.

196 Board #34 May 29 9:30 AM - 11:00 AM Contractile Parameters Of The Knee Extensors In Young, Middle-aged, And Older Males

Phuong L. Ha, Alex A. Olmos, Matthew T. Stratton, Alyssa R. Bailly, Micah J. Poisal, Joshua A. Jones, Benjamin E. Dalton, Amber N. Haire, Trisha A. VanDusseldorp, Yuri Feito, FACSM, Garrett M. Hester. *Kennesaw State University, Kennesaw, GA.* (Sponsor: Dr. Yuri Feito, FACSM)
(No relevant relationships reported)

Peak power (PP) is decreased in older adults; however, less is clear regarding the determinants of PP, contractile torque and velocity. Furthermore, it is unknown if these measures are affected differently in middle and old age. **PURPOSE:** To compare PP and its determinants for the knee extensors in young, middle-aged, and older males. **METHODS:** As part of a larger ongoing investigation, contractile properties of the knee extensors were assessed in healthy, untrained young (YM: n = 8, age = 20.5 ± 1.6 yrs), middle-aged (MM: n = 6, age = 46.0 ± 2.9 yrs) and older (OM: n = 6, age = 69.0 ± 3.10 yrs) males using a Biodex System 4 dynamometer. Upon completing a familiarization visit, a testing visit involving three maximal voluntary isotonic knee extensions, performed at 40% of isometric peak torque, was completed. Participants were instructed to "kick out as hard and fast as possible" prior to each contraction. Power was calculated as the product of torque and velocity for the isotonic contractions using custom written software and PP was recorded. In addition, velocity (VEL) and torque (TQ), at the moment in time PP occurred, were recorded. One-way analyses of variance and Games-Howell post hoc tests were used to compare groups. **RESULTS:** PP was lower in OM compared to YM (50%; p = 0.021), but was similar in MM compared to YM and OM (p > 0.05). VEL was decreased in OM compared to YM (36%; p = 0.007) and MM (24%; p = 0.044), however, no difference was noted between MM and YM. TQ was similar between groups (p = 0.147). **CONCLUSION:** Our preliminary data indicate that reductions in VEL for the knee extensors occur between middle and old age prior to a decrease in PP, while TQ is maintained in old age. Thus, VEL appears to be more dramatically affected by age, and the age-related decrease in PP may be primarily mediated by impaired velocity capacity.

Effect Of Knee Joint Angle On Neuromuscular Activation Of The Quadriceps Femoris During Fatiguing Contractions

Hiroshi Akima¹, Aya Tomita², Ryosuke Ando³. ¹Research Center of Health, Physical Fitness & Sports, Nagoya University, Nagoya, Aichi, Japan. ²Chukyo University, Nagoya, Aichi, Japan. ³Japan Institute of Sports Sciences, Kita-ku, Tokyo, Japan. (Sponsor: Katsumi Asano, FACSM)

Email: akima@nagoya-u.jp

(No relevant relationships reported)

In muscle fatigue studies, repetitive muscle contractions at a submaximal force level (e.g., 50% of maximum voluntary contraction [MVC]) are frequently used as a fatiguing task such as isometric knee extensions. Contrary to submaximal fatiguing contractions, when MVC is used to induce muscle fatigue, muscle force will decrease despite maximal effort and amplitude and/or frequency of electromyographic (EMG) signals will also change with the development of muscle fatigue. However, it is unclear the effect angle of knee joint on the neuromuscular activation of individual muscles of quadriceps femoris during repetitive knee extension tasks. **PURPOSE:** We sought of this study was to assess the effect of knee joint angle on the neuromuscular activation pattern of the four individual muscles in the quadriceps femoris during repetitive fatiguing MVCs. **METHODS:** Fifteen healthy men and women (age, 25 ± 3 years; height, 165 ± 11 cm; weight, 57 ± 10 kg) performed two fatiguing tasks consisting of 40 MVCs at knee joint angles of 80° (flexed) and 140° (extended). Neuromuscular activation of the vastus intermedius (VI), vastus lateralis (VL), vastus medialis (VM) and rectus femoris (RF) was recorded using surface electrodes, and median frequency (MF) and root mean square (RMS) of EMG signals (normalized by pre-test MVCs) were calculated. **RESULTS:** MVCs significantly decreased from the 10th to the 40th repetition at both knee joint angles. The MFs of VI and VM in the flexed knee joint angle and that of RF at the flexed and extended knee joint angles were significantly decreased after the 10th repetition. There were no significant changes in normalized EMG amplitude in any muscles specific to knee angle. Stepwise regression analysis revealed predictive synergistic action may take place in RF, VM, and VI in the flexed joint angle and between RF and VM at the extended joint angle. **CONCLUSION:** These results suggest that neuromuscular activation of RF and VM is independent, but activation of VI and VL is dependent, upon knee joint angle, which may, in part, explain joint angle-specific muscle fatigue.

Joint Flexibility is Affected by Muscle Size in Human Planter Flexors

Keigo Tomoo, Tadashi Suga, Hiromasa Ueno, Masafumi Terada, Akinori Nagano, Tadao Isaka. *Ritsumeikan University, Kusatsu, Japan.*

Email: sh0202f@ed.ritsumei.ac.jp

(No relevant relationships reported)

PURPOSE: Only one study has reported that a larger muscle thickness may relate to a lower joint flexibility in the planter flexors (Kubo et al. *Eur J Appl Physiol* 85, 2001). Muscle volume (MV), compared to muscle thickness, is known to be more appropriate for evaluating muscle size. To further clarify the findings of the previous study, in this study, we examined the relationship between joint flexibility and MV in the planter flexors. **METHODS:** In study 1, we recruited 96 healthy young males (age: 21.6 ± 1.4 years). The planter flexor muscle thickness was measured using ultrasonography (US). The planter flexor MV was estimated using lower leg length and muscle thickness based on a multiple regression equation, which was reported in previous study (Miyatani et al. *Eur J Appl Physiol* 91, 2004). In study 2, we recruited 38 healthy young males (age: 21.5 ± 2.2 years). The planter flexor MV was calculated by multiplying the sum of successive cross-sectional areas measured using magnetic resonance imaging (MRI), and included MVs of the soleus (SOL), gastrocnemius medialis (GM), and gastrocnemius lateralis (GL). In both studies, to evaluate planter flexor flexibility, dorsiflexor active range of motion (ROM) and planter flexor passive stiffness were measured using a dynamometer system. The dorsiflexor ROM was defined as dorsiflexion angle (i.e., end-ROM) which was reached by maximal effort during active dorsiflexion. The planter flexor stiffness was calculated from the liner slope of the torque-angle curve between 10° and 20° dorsiflexor angles during passive dorsiflexion. **RESULTS:** In study 1, US-estimated planter flexor MV was significantly correlated with dorsiflexor ROM ($r = -0.431, P < 0.001$) and planter flexor stiffness ($r = 0.474, P < 0.001$). In study 2, MRI-measured planter flexor MV was significantly correlated with dorsiflexor ROM ($r = -0.484, P = 0.002$) and planter flexor stiffness ($r = 0.592, P < 0.001$). Furthermore, all three MVs among planter flexors were significantly correlated with dorsiflexor ROM ($r = -0.481, P = 0.002$ for SOL; $r = -0.360, P = 0.027$ for GM; $r = -0.432, P = 0.007$ for GL) and planter flexor stiffness ($r = 0.559, P < 0.001$ for SOL; $r = 0.502, P = 0.001$ for GM; $r = 0.510, P = 0.001$ for GL). **CONCLUSION:** The present findings suggest that joint flexibility of planter flexors is affected by their MVs in healthy young males.

Lower Extremity Joint Power and Muscle Activation in High and Low Lactate Threshold Cyclists

Brian K. Leary. *The University of Texas, Austin, TX.*

(No relevant relationships reported)

When comparing cycling and inclined treadmill running in well-trained cyclists, two groups have emerged in prior research: 1) cyclists with equally high LT_{VO_2} while cycling and running uphill (HLT) and 2) cyclists with low cycling LT_{VO_2} (LLT) but high running LT_{VO_2} (closely matching those of the HLT cyclists). The physiological and biomechanical differences between HLT and LLT cyclists have yet to be completely described.

PURPOSE: To determine differences in absolute/relative joint powers and knee extensor muscle activation between HLT and LLT cyclists. **METHODS:** Sixteen well-trained endurance athletes completed cycling and running VO_{2max} and cycling and running lactate threshold (LT_{VO_2}) testing, and were separated into two groups based on cycling LT_{VO_2} (HLT: n=8) and (LLT: n=8). Hip, knee, and ankle absolute and relative joint powers (the percent contribution to total joint powers) and electromyography (EMG) assessed muscle activation of the knee extensors (vastus lateralis (VL), vastus medialis (VM), and rectus femoris (RF)) were compared between groups during submaximal cycling (60-90% VO_{2max}). **RESULTS:** VO_{2max} was similar in the two groups when cycling (HLT: 4.57 ± 0.17 vs LLT: 4.42 ± 0.15 L/min) and running (HLT: 4.47 ± 0.13 vs LLT: 4.49 ± 0.16 L/min). HLT cyclists had higher LT_{VO_2} while cycling compared with the LLT group (HLT: 3.68 ± 0.21 vs LLT: 3.10 ± 0.15 L/min); however, no differences in running LT_{VO_2} were found (HLT: 3.73 ± 0.18 vs LLT: 3.71 ± 0.13 L/min) ($p > 0.05$). Blood lactate concentration increased with work rate and was lower in the HLT group at 80 and 90% of VO_{2max} compared with the LLT group ($p < 0.05$). There were no differences between groups in absolute joint specific power across work rates ($p > 0.05$). However, relative hip contribution was significantly greater in the HLT group at 90% VO_{2max} compared to the LLT group ($p < 0.05$). Furthermore, VM EMG activity was higher in the LLT group at 60 and 70% VO_{2max} ($p < 0.05$); yet there were no between group differences in VL or RF activation ($p > 0.05$). **CONCLUSION:** HLT cyclists have a greater relative hip contribution during submaximal cycling power and reduced stress on a knee extensor muscle (i.e. lower VM activation) compared to LLT cyclists.

Can Transcranial Direct Current Stimulation Improve Counter-movement Jump Performance ?

Yu Liu, Xiuling Bian, Lingyan Huang. *Shanghai University of Sport, Shanghai, China.*

Email: yuliu@sus.edu.cn

(No relevant relationships reported)

Transcranial direct current stimulation (tDCS) is a non-invasive brain stimulation technique and has been known to reliably alter motor cortical excitability. Anodal stimulation increases cortical excitability and cathodal stimulation inhibits cortical excitability. However, the effects of tDCS on counter-movement jump (CMJ) is currently unknown. **PURPOSE:** The aim of this study was to investigate the effects of tDCS on CMJ performance in healthy men. **METHODS:** A double-blinded crossover design was used. Fourteen male subjects (age: 22 ± 2 yrs, height: 174.43 ± 5.74 cm, weight: 68.66 ± 9.47 kg) received three time stimulations, each time an anodal tDCS (a-tDCS) or cathodal tDCS (c-tDCS) or sham tDCS randomly. The electrodes are placed over primary motor cortex (M1) bilaterally and the opposite electrodes pair over the ipsilateral shoulders. Each stimulation lasted 20 min, 48-72 hours apart and current was set at 2mA. Participants were required to get anthropometric measurements and familiar with CMJ in advance. Then, completed five CMJ tests before and after each stimulation, with one minute recovery interval between each test. The best three of the five CMJ in each moment was selected for analysis. Two-way (condition × time) ANOVA with repeated measures were used for CMJ height, flight time, and initial velocity. **summary of RESULTS:** There was a significant interaction between condition and time for CMJ height ($F_{(2,39)} = 7.948, p < 0.001$), flight time ($F_{(2,39)} = 8.228, p < 0.001$), and initial velocity ($F_{(2,39)} = 8.375, p < 0.001$). There were no significant main effects for condition or moment for any of the outcome measures ($p > 0.05$). Post-hoc analysis showed that there were no significant differences between conditions both on pre- and post-stimulation moments ($p > 0.05$). However, post a-tDCS performance was significantly superior to pre a-tDCS for CMJ height, flight time and initial velocity ($p < 0.001$ for all). There were no significant pre-post changes in both c-tDCS and sham-tDCS conditions ($p > 0.05$ for all). **CONCLUSION:** Our findings demonstrate that anodal tDCS may be a valuable tool to enhance vertical jumping ability, which is very important for huamn sport performance.

Relationship between Muscle Damage Magnitude and Sense of Knee Position

Ana C C Pereira, Elisângela Silva, Daniela G M Bueno, Denis B. da Silva, Stefani A M dos Reis, Wagner Z. de Freitas. *FEDERAL INSTITUTE OF EDUCATION, SCIENCE AND TECHNOLOGY SOUTH OF MINES, MUZAMBINHO, Brazil.*

Email: carolina_gpe_11@hotmail.com

(No relevant relationships reported)

It has been proposed in the literature that muscle damage may temporarily and negatively affect proprioceptive capacity, which can be tested through the ability to replicate angles, while muscle damage can be verified by quantifying creatine kinase (CK) in the bloodstream.

PURPOSE: to verify the relationship between muscle damage and sense of position in the isokinetic dynamometer, in knee extensors, after an eccentric exercise protocol.

METHODS: ten male college students (age: 20.6 ± 1.8 years, body mass: 75.0 ± 11.7 kg, height: 177.4 ± 6.9 cm), with no prior experience with resistance exercises, were submitted to an eccentric exercise protocol, in the isokinetic dynamometer, for induction of muscle damage composed of two phases: 1st phase: 10 sets of 10 repetitions with 30 seconds of rest (100 eccentric contractions) - Speed = $30^\circ/s$. There was a 5 minute break between the phases. 2nd phase: 11 sets of 10 repetitions and 30 seconds of rest (110 eccentric contractions) - Speed = $180^\circ/s$. To evaluate the muscle damage was used the values of CK peak found in the post-tests shortly after exercise, 24h, 48h, 72h and 96h. To verify the sense of position, the subjects, blindfolded, should find the angle of 60° in the right knee on the isokinetic dynamometer. Was used a subtraction of the target value (60°) by the angle performed by the subjects on the day of CK peak. The normality of the sample data was verified using the Shapiro-wilk test and Pearson's correlation was applied between peak CK and significance level of 5%.

RESULTS: There was a significant correlation ($p = 0.014$) between CK and knee position sense, with $r = 0.742$ classified as strong (Devore, 2006).

CONCLUSIONS: the induction of muscle damage caused by eccentric exercise significantly influences the subjects' proprioception, since the higher the CK values, the greater the angular discrepancies between the expected value and the one performed by the subjects.

Muscle Activity While Swimming in Triathlon Wetsuits

Boram Lim, Cordero Roche, Andy Do. *University of Nevada, Las Vegas, Las Vegas, NV.* (Sponsor: John A. Mercer, FACSM)

Email: boram.lim@unlv.edu

(No relevant relationships reported)

In a triathlon event, people use various strategies and equipment for enhancing their triathlon performance in each exercise mode (i.e., swim, bike, run). During the swimming portion of a race, triathletes will typically wear a wetsuit that is categorized as either full sleeve or sleeveless. Anecdotally, triathletes may select a sleeveless wetsuit because the full sleeve may increase shoulder movement resistance. **Purpose:** The purpose of this study was to investigate shoulder muscle activity influenced by wetsuit design. **Methods:** Seven subjects (5 male and 2 female, age: 45.7 ± 8.0 yrs, height: 174.8 ± 10.5 cm, mass: 70.1 ± 9.4 kg) participated in the experiment. Muscle activity of the Anterior Deltoid (AD) and Posterior Deltoid (PD) was measured (2000 Hz) using a water proofed electromyography (EMG) system (MiniWave, Cometa, Italy). After a self-directed warm-up, participants were asked to swim 50m at a 'somewhat hard' pace that they could maintain the pace for a sprint triathlon distance (750m) for each condition: No wetsuit (NWS), sleeveless wetsuit (SLW), and full sleeve (FSW). PD EMG data were smoothed using a 4th order Butterworth filter (cutoff frequency = 4 Hz). The smoothed data were used to identify the beginning and ending points of a stroke cycle. Five consecutive stroke cycles were then extracted for analysis as well as the time to complete the five cycles. Data analysis was performed using the raw unfiltered EMG data which were reduced by removing any zero offset, full wave rectifying the signal, and calculating the average EMG across the 5 stroke cycles (PDavg, ADavg). Time and average data were compared between conditions using a 1 x 3 (wetsuit condition) repeated measures ANOVA. **Results:** Muscle activity of both AD and PD were not different among all wetsuit conditions ($p > 0.05$). However, time was different among conditions ($p < 0.05$) with FSW being shorter than NWS ($p < 0.05$), but between the two wetsuits (FSW and SLW) were not different ($p > 0.05$). **Conclusion:** While swimming at a somewhat hard intensity, wetsuit design did not influence muscle activity of the shoulder muscle. However, stroke time was influenced by wearing a wetsuit regardless of design. Triathletes might get a benefit to reduce their swimming race time by wearing a wetsuit regardless of full-sleeve or sleeveless.

Sex Differences in Correlations Between Muscle Architecture and Impulse in a Heterogenous Group of Athletes

Jacob R. Goodin¹, Caleb D. Bazylar². ¹Point Loma Nazarene University, San Diego, CA. ²East Tennessee State University, Johnson City, TN.

Email: jgoodin@pointloma.edu

(No relevant relationships reported)

BACKGROUND: Previous investigations have identified moderate to strong relationships between skeletal muscle architecture (SMA) and performance measures in athletes, however differences between males and females in this regard are not well known. A better understanding of relationships between task-specific impulse windows and SMA in males and females may allow coaches to direct training stimuli toward improving specific morphological underpinnings of sport performance for the athletes under their care. **PURPOSE:** The purpose of this analysis was to determine relationships between components of SMA and isometric impulse in male and female athletes. **METHODS:** Pennation angle (PA), fascicle length (FL), and anatomical cross-sectional area (ACSA) were determined for the vastus lateralis muscle via β -mode ultrasonography in a group of male ($n = 94$) and female ($n = 61$) collegiate, club, and international athletes. Net isometric impulse at 50, 90, 200, and 250 ms was measured during an isometric mid-thigh pull (IMTP) test administered pre-season as part of an ongoing athlete monitoring program. **RESULTS:** Pearson product-moment correlation revealed weak correlations between FL and impulse in males ($r = 0.33$ to 0.36 , $p < 0.05$) but not in females, weak correlations between CSA and impulse in males ($r = 0.39$ to 0.48 , $p < 0.05$), and weak to moderate correlations between CSA and impulse in females ($r = 0.55$ to 0.62 , $p < 0.05$). **CONCLUSIONS:** These results indicate that there may be sex-based differences in the physiological underpinnings of impulse generation in trained athletes, particularly in relation to both muscle size and fascicle length of the vastus lateralis. Further research should investigate changes in these relationships over time and consider contributions from neuromuscular components.

Comparison in Peak Torque Rotations Between Dominant and Non-Dominant Arms in Powerlifters

Erick G. P. de Lucena, Luz A. A. Castaño, Guilherme H. J. Silva, Cassiano A. Massafra, Adonias O. F. de Souza, Luis F. M. Teixeira, Marco C. Uchida. *School of Physical Education, University of Campinas, Campinas, Brazil.*

Email: e166969@g.unicamp.br

(No relevant relationships reported)

The shoulder joint is naturally unstable because of anatomic structure, and depends of passive and active elements, ligaments and muscle, respectively, for proper stability. The bench press, upper body exercise, is one of three exercises of Powerlifting (PL), based on maximum strength. The strength balance between dominant (D) and non-dominant (ND) upper limbs is fundamental to develop a good lift and joint safety. Therefore, not only major muscles are important as pectoral major, but also stability muscles as rotator cuff for shoulder external rotation.

PURPOSE: To compare, in recreational powerlifters, relative peak torque between dominant and non-dominant arms, in external and internal rotation at $60^\circ/s$ and $180^\circ/s$ concentric action velocity for external (ER) and internal rotation (IR) in shoulder joint. **METHODS:** Participants, nine powerlifters (height: 1.73 ± 0.06 cm; weight: 84.1 ± 13.0 kg; bench press 1 repetition maximum: 116.4 ± 19.1 kg; PL minimal experience: 2 years). The muscle group strength for ER and IR were assessed bilaterally by Biodex System 4Pro isokinetic dynamometer. The participants were in a seated position, 45° shoulder abduction, $60^\circ/s$ and $180^\circ/s$ concentric mode was adopted for lever velocity for ER and IR in shoulder joint. Dominant and non-dominant sides peak torque normalized to body weight (PT/BW; $Nm \cdot kg^{-1}$) were compared with paired student's t-test. **RESULTS:** Significant difference ($p = 0.02$) was found at the PT/BW for the ER movements between the dominant (47.8 ± 5.8 $Nm \cdot kg^{-1}$) and non-dominant (44.3 ± 6.1 $Nm \cdot kg^{-1}$) sides at the velocity of $60^\circ/s$, but there was no significant difference between sides in IR ($p = 0.15$; $D = 71.7 \pm 16.3$ $Nm \cdot kg^{-1}$, $ND = 66.1 \pm 12$ $Nm \cdot kg^{-1}$); and at $180^\circ/s$ for ER ($p = 0.24$; $D = 48 \pm 5.3$ $Nm \cdot kg^{-1}$, $ND = 45.7 \pm 8.6$ $Nm \cdot kg^{-1}$) and IR ($p = 0.24$; $D = 68.7 \pm 15.5$ $Nm \cdot kg^{-1}$, $ND = 64.6 \pm 8.6$ $Nm \cdot kg^{-1}$). **CONCLUSION:** For recreational powerlifters, there is only difference between dominant and non-dominant arms in ER movement at $60^\circ/s$, which suggests a necessity of unilateral exercises for a better balance between sides.

Age-related Differences in Vertical Jump Power and Muscle Size and Quality of the Vastus Lateralis

Ahalee C. Cathey¹, Chinonye C. Agu-Udemba¹, Eric J. Sobolewski², Brennan J. Thompson³, Ty B. Palmer¹. ¹Texas Tech University, Lubbock, TX. ²Furman University, Greenville, SC. ³Utah State University, Logan, UT.

(No relevant relationships reported)

Previous studies have reported that decreases in muscle size and quality of the vastus lateralis (VL) may contribute to the lower vertical jump power observed in old compared to young males. However, we are aware of no previous studies that have examined the contribution of VL muscle size and quality to age-related power differences in females, nor have there been any studies that examined these differences between young, middle, and older age groups. **PURPOSE:** To determine the effects of age on vertical jump power and muscle size (cross-sectional area [CSA]) and quality (echo intensity [EI]) of the VL in young, middle-aged, and old females. **METHODS:** Twenty-six young (age = 22 ± 2 yr; height = 163 ± 7 cm; mass = 61 ± 8 kg), 30 middle-aged (36 ± 5 yr; 164 ± 7 cm; 62 ± 11 kg), and 23 old (71 ± 5 yr; 161 ± 5 cm; 59 ± 10 kg) females underwent two diagnostic ultrasound assessments followed by three countermovement vertical jumps (CMJs). Peak power output (Pmax; W) was measured during the CMJs using a portable force plate. VL CSA (cm²) and EI (AU) were measured on the right leg using a portable B-mode ultrasound imaging device and linear-array probe. One-way ANOVAs and post-hoc analyses were used to compare Pmax, CSA, and EI between age groups. Pearson product-moment correlation coefficients (*r*) were used to examine the relationships between Pmax and CSA and EI. **RESULTS:** Higher Pmax and CSA values were observed for the young (Pmax = 2257.40 ± 438.42 W; CSA = 20.59 ± 4.23 cm²) compared to the old (Pmax = 1098.55 ± 242.10 W; CSA = 10.69 ± 2.47 cm²) and middle-aged (Pmax = 1958.20 ± 341.87 W; CSA = 18.05 ± 4.24 cm²) and the middle-aged compared to the old (*P* ≤ 0.001-0.039). EI values for the young (104.29 ± 16.86 AU) and middle-aged (107.71 ± 17.30 AU) were lower than the old (128.35 ± 14.99 AU) (*P* < 0.001), but they were not different from each other (*P* = 0.720). There was a significant positive relationship between Pmax and CSA (*r* = 0.830; *P* < 0.001) and a significant negative relationship between Pmax and EI (*r* = -0.442; *P* < 0.001). **CONCLUSION:** These findings demonstrated that vertical jump power and muscle size and quality decrease with age. The significant relationships observed between Pmax and CSA and EI perhaps suggest that these age-related declines in VL muscle size and quality may play an important role in the lower vertical jump power observed in middle-aged and older adults.

Rate Of Velocity, Torque, And Power Development In Middle-Aged And Older Males

Matthew T. Stratton, Alex A. Almos, Phuong L. Ha, Alyssa R. Bailly, Micah J. Poisal, Joshua A. Jones, Benjamin E. Dalton, Amber N. Haire, Trisha A. VanDusseldorp, Yuri Feito, FACSM, Garrett M. Hester. *Kennesaw State University, Kennesaw, GA.* (Sponsor: Yuri Feito, FACSM)

(No relevant relationships reported)

Rapid contractile measures such as rate of velocity (RVD), torque (RTD) and power (RPD) development dramatically decrease with age, but have rarely been concurrently investigated. Further, few studies have examined the relationship between these parameters and functional performance. **PURPOSE:** To compare rapid contractile parameters of the knee extensors in middle-aged and older males, and examine correlates of 5-chair rise (5CR) performance. **METHODS:** As part of a larger ongoing investigation, twelve healthy untrained, middle-aged (n = 6, age = 46 ± 2.90 yrs) and older (n = 6, age = 69 ± 3.10 yrs) males completed a familiarization visit followed by one testing visit. Using a Biodex System 4 dynamometer, participants performed three maximal voluntary isometric contractions of the right knee extensors followed by three maximal isotonic contractions at 40% of isometric peak torque. Participants were instructed to "kick out as hard and fast as possible" prior to each contraction. The torque and velocity signals were acquired and the power curve was derived from multiplying torque and velocity. RVD and RPD were obtained from isotonic contractions, as the linear slope of the velocity- and power-time curve, respectively. RTD was calculated for the first 50 ms of the isometric torque-time curve. In addition, 5CR, the time to rise 5 times from a chair as quickly as possible was recorded. Groups were compared with independent samples t-tests, while Pearson correlation coefficients were used to examine relationships between age, RVD, RPD, RTD, and 5CR. **RESULTS:** RVD (32.15%; *p* = 0.004) and RPD (53.27%; *p* = 0.03) were decreased in older males, but not RTD (*p* = 0.497). In addition, only RVD was correlated with 5CR (*r* = -0.588; *p* = 0.044). **CONCLUSIONS:** While preliminary, these data suggest that dynamic, rapid contractile measures are preferentially affected by age as compared to RTD, and only RVD was related to 5CR performance.

The Effects Of Muscular Fatigue And Gender On Lower Extremity Biomechanics During The Forward Lunge

Ania Lipat, Amanda Stone, Hillary Holmes, Chris Hass, FACSM. *University of Florida, Gainesville, FL.* (Sponsor: Chris J Hass, FACSM)

Email: ania.lipat@ufl.edu

(No relevant relationships reported)

Purpose. The forward lunge is a common exercise used in strength training and rehabilitation to improve lower extremity strength¹. In other lower extremity exercises, fatigue from high repetitions has been shown to alter biomechanics and increase injury risk^{1,2}. Moreover, fatigue responses appear to be gender specific^{1,2}. Therefore, the purpose of this study was to determine the effects of fatigue and gender on lower extremity biomechanics during the forward lunge. **Methods.** 29 young adults (13 males) participated in the study. Subjects repeatedly completed a set of 7 walking lunges across a ~8 m walkway and 4 stationary lunges on force plates until fatigued. A fatigued state was identified as two consecutive sets that scored a 9 on a modified Borg RPE scale, or a single set that scored a 10. A Vicon motion capture system (Vicon Motion Systems, Oxford, UK) was used to collect the data. Average peak lower limb angles and internal moments of the forward limb were calculated for the baseline set of stationary lunges and the last set (i.e. fatigued set) of stationary lunges. Main effects of gender and fatigue and their interaction were evaluated using a repeated-measures MANOVA. **Results.** Neither a significant fatigue × gender interaction nor gender main effect at the multivariate level were found. A significant multivariate omnibus main effect of fatigue, however, was detected. Variables that changed with fatigue are outlined in Table 1. **Conclusion.** The increase in hip adduction angle, knee adduction angle, and knee adduction moment with fatigue may stress internal stabilizers of the knee^{2,4}. As such, individuals should exercise caution when performing the forward lunge to fatigue.

PURPOSE: to evaluate whether a heavy back squat protocol combining free weight plus elastic band (CR) could promote a post-activation potentiation (PAP) during a countermovement jump (CMJ) test and to determine the optimal recovery time to elicit it.

METHODS: : Nine male elite Brazilian handball athletes [21.4 ± 2.1 years; 90.3 ± 10 kg; 187.5 ± 5 cm; 10.5 ± 4.2 body fat; 9.7 ± 1.8 years of training experience; 1.81 ± 0.23 of Relative 1RM back squat (kg·kg⁻¹); 15 hours of weekly training volume] were recruited into the study. The experimental sessions were performed seven days apart in a counterbalanced order. The athletes were required to complete either a CR protocol or a control protocol (CMJs only). Athletes completed a standardized warm-up consisting of 5 min of light-intensity cycling, static stretching exercises, and three consecutive CMJs. After a 3 min rest period, athletes performed baseline CMJs test. The CR protocol was consisted of three sets of 5 repetitions at 85% of 1RM with 3 minutes of rest between sets. Back squat was loaded with 85% of 1RM combining 55% of 1RM using weight-plate and 29.7 ± 2.04% of the athlete's 1RM in fully erect position (starting position) with elastic band resistance. During control session, the same warm-up routine was included so that the only difference between the PAP and control protocol was the absence of a potentiating stimulus.

RESULTS: One-way repeated measures ANOVA indicated a significant effect of time in CMJ performance within CR condition ($p < 0.01$, $n_p^2 = 0.39$). The vertical jump height was significantly greater (6.5%, $ES = 0.85$) at 2-min as compared to baseline. No significant differences in jump height were detected when compared with baseline at 4-, 6-, and 8-minute recovery. Two-way repeated-measures ANOVA revealed an interaction effect ($p < 0.05$, $n_p^2 = 0.40$) in PAP response. At 2-min, PAP response was significantly larger (4.9%, $ES = 1.38$) in CR condition than control ($p < 0.05$).

CONCLUSIONS: The combination of free weight and elastic bands during heavy squat exercise seems to be effective to create a post-activation potentiation effect to enhance acute neuromuscular performance at 2-min after preconditioning stimulus.

Knee Extensor Torque Is Increased By Far-Infrared Emitting Fabric

Manoel Silva¹, Antonio C. Moraes¹, João Barbieri¹, Renato Barroso¹, Gabriel Figueiredo¹, Leonardo Motta¹, Rômulo Bertuzzi², Arthur Gáspari¹. ¹University of Campinas, Campinas, Brazil. ²University of São Paulo, São Paulo, Brazil.
 (No relevant relationships reported)

Far-infrared (FIR) emitting materials can increase the availability of nitric oxide and calcium in cell culture, and delay fatigue during ex-vivo skeletal muscle contractions. However, FIR effects on humans' neuromuscular performance remains unknown.

Purpose: To verify the effects of FIR emitting fabric on knee extensors torque and electromyography activity. **Methods:** Fourteen healthy strength trained men (24.3 ± 4 years; 82.8 ± 11.3 kg; 176.3 ± 4.2 cm, 7.3 ± 2.9 years of training experience) participated in one familiarization and two experimental sessions. Experimental sessions occurred two weeks apart and after 96 hours of continuous FIR or Placebo fabric usage, in a randomized, crossover, double-blind, placebo-controlled design study. Isometric and dynamic torques were assessed using isokinetic dynamometer. The best result out of 3 maximum ballistic knee extension contractions (MBC) was recorded pre- and post-dynamic test. Dynamic test was composed by 30 maximum repetitions of knee flexion and extension at 180°/s. Peak torque (PT) of each repetition, total work (TW) and fatigue index (FI) of knee extensors were recorded. The mean RMS was calculated from electromyography activity records of superficial quadriceps muscles. Mean quadriceps temperature was assessed pre-protocol with a thermal camera. **Results:** See table. FIR fabric increased pre and post MBC and trend to increase TW. RMS at isometric and dynamic tests, FI, and quadriceps temperature did not change. Additionally, FIR fabric demonstrated higher values of PT at 8th, 12th to 14th and 17th repetitions (all $p < 0.05$). **Conclusion:** FIR emitting fabric is effective to increase isometric and dynamic neuromuscular performance. Further, the absence of changes in electromyography activity and increased performance in single MBC, lead us to suggest that FIR effects are related to muscle contractile machinery improvements.

| | FIR | | Placebo | | p |
|-------------------|--------|---------|---------|---------|------|
| pre-MBC (Nm) | 318.5 | ± 68.7 | 299.3 | ± 68.2 | 0.01 |
| post-MBC (Nm) | 284.1 | ± 58.2 | 268.8 | ± 55.4 | 0.04 |
| pre-MBC RMS (mV) | 0.139 | ± 0.062 | 0.142 | ± 0.082 | 0.70 |
| post-MBC RMS (mV) | 0.143 | ± 0.059 | 0.128 | ± 0.066 | 0.24 |
| TW (J) | 4142.2 | ± 699.8 | 4009.3 | ± 743 | 0.06 |
| FI (%) | 41.7 | ± 6.6 | 40.3 | ± 8.3 | 0.01 |
| Temperature (°C) | 32.48 | ± 0.77 | 32.42 | ± 0.62 | 0.62 |

Data are mean ± standard deviation. p-values are paired T-test ($p \leq 0.05$).

The Acute Effects of a Resistive Exercise on Sprint Times in High School Track Athletes

Kayla Starker, Abigail Larson, Mark DeBeliso, FACSM.
 Southern Utah University, Cedar City, UT.
 (No relevant relationships reported)

The ability to achieve high velocities in a short period of time is a requisite for success in many sporting activities. Post activation potentiation (PAP) can be defined as an increase in neuromuscular activity that occurs immediately after a high intensity exercise or conditioning activity. PAP may improve subsequent exercise performance that requires high muscular power output. **PURPOSE:** This study attempted to determine the acute effects of incorporating a resistive sprint exercise as a PAP conditioning activity on subsequent sprint time in high school track athletes.

METHODS: A randomized repeated measures crossover study design was used to test fifteen high school track athletes (9 male: 16.8 ± 0.7 years, 183.7 ± 9.7 cm, 77.2 ± 5.8 kg, 6 female: 16.0 ± 1.1 years, 156.2 ± 3.5 cm, 52.2 ± 1.2 kg). Each participant completed two testing sessions: a dynamic WU prior to a 36.6 meter sprint and a dynamic WU followed by a resisted sprint sled pull as a PAP conditioning activity (10-15% of body mass) prior to a 36.6 meter sprint. Testing sessions occurred on two different days with at least 48 hours between each session. A paired T-test was used to determine if there were significant differences in sprint times between the WU strategies. **RESULTS:** The 36.6 meter sprint times following a dynamic WU combined with a resisted sprint sled pull as a PAP conditioning activity were significantly lower (5.54 ± 0.52 seconds) than the 36.6 meter sprint times following the dynamic WU alone (5.64 ± 0.51 seconds) ($p < 0.01$). **CONCLUSION:** Within the parameters of this study it can be concluded that a dynamic WU including a resisted sprint sled pull as a PAP conditioning activity is successful at improving short distance sprint times when compared to sprint times following a dynamic WU alone.

The Effects of Five Weeks of Bench Press Training on Salivary Biomarkers of Inflammation in Recreationally-trained College-age Males

Brent M. Peterson, PhD, MS, MPH, Jacob K. Gardner, PhD, Kelsey L. Miller, MS, Justin Chia, BS, Juan Santacruz, BSc, Austin Cattaneo, BSc. Biola University, La Mirada, CA.
 Email: brent.peterson@biola.edu
 (No relevant relationships reported)

INTRODUCTION: Improvements in immunosenescence have been reported to be associated with regular exercise and physical activity. Multiple investigations have elucidated the effectiveness of aerobic exercise on the attenuation of biological markers of systemic inflammation. However, few studies have evaluated the impacts of resistance training on inflammation, and even fewer have examined the effects of resistance training on salivary biomarkers of inflammation. **PURPOSE:** To evaluate the impacts of 5 weeks of bench press-only training on salivary biomarkers of inflammation in trained college-age males ($N = 23$). Pre and post analyses of salivary biomarkers (IL-1 β , IL-6, IL-8, TNF α , CRP, and Testosterone) were conducted. Five weeks of either standard bench press ($n = 12$) or leg drive focused bench press ($n = 11$) was completed. **RESULTS:** No significant ($p > 0.05$) main effects between groups were observed. Within groups measures did reveal that testosterone significantly decreased by 17.0% in the standard bench press group from pre to post ($p = 0.02$). **CONCLUSIONS:** Five weeks of bench press training did not alter pre-training levels of inflammation measured in saliva. Subjects were required to be currently training and have completed a minimum of 6 months of resistance training (including bench press) prior to starting this study. Since the bench press was the only training exercise, the intensity of training administered may not have been sufficient to elicit notable alterations in overall inflammatory status in this sample.

Evidence Of A Ceiling Effect For Training Volume In Muscle Hypertrophy And Strength In Trained Men

Matheus Barbalho¹, Victor Silveira Coswig², James Steele³, James P. Fisher³, Jurgen Giessing⁴, Paulo Gentil¹. ¹Federal University of Goiás, Goiânia, Brazil. ²Federal University of Pará, Castanhal, Brazil. ³Southampton Solent University, Southampton, United Kingdom. ⁴University of Koblenz-Landau, Landau, Germany.

(No relevant relationships reported)

Purpose: To compare the effects of different resistance training (RT) volumes on muscle performance and hypertrophy in trained men.

Methods: The study included 37 volunteers that performed RT for 24 weeks and were divided into groups that performed five (G5), 10 (G10), 15 (G15) and 20 (G20) sets per muscle group per week. Ten repetition maximum (10RM) tests were performed for the bench press, lat pull down, 45° leg press, and stiff legged deadlift. Muscle thickness (MT) was measured using ultrasound on biceps brachii, triceps brachii, pectoralis major, quadriceps femoris and gluteus maximus. All measurements were performed at the beginning (pre) and after 12 (mid) and 24 weeks (post) of training.

Results: All groups showed significant increases in all 10RM tests and MT measures after 12 and 24 weeks of TR ($p < 0.05$). There were no differences in any 10RM test between G5 and G10 ($p > 0.05$) after 12 and 24 weeks. G5 and G10 showed significantly greater increases of 10RM than G15 and G20 for bench press, lat pulldown, leg press and stiff legged deadlift, both at 12 and 24 weeks. There were no group by time interaction for any MT measure

Conclusions: Five to 10 sets per week might be sufficient for bringing about optimal gains in muscle size and strength in trained men over a 24-week period. There appears to be a deleterious effect for higher volumes (≥ 15 sets per week), especially after 12 weeks of training. These results bring evidence of an inverted "U shaped" curve for the dose response curve for muscle strength, with a possible deleterious effect after exceeding a certain training volume. Whilst the same trend was noted for muscle hypertrophy, the results did not reach significance. Therefore, using low volume RT programs might be an interesting alternative for personal trainers, strength coaches and medical practitioners to increase muscle size and strength in trained men.

213 Board #51 May 29 11:00 AM - 12:30 PM

Effects Of An 8-week Mixed-methods Strength Training On Maximal Strength Of Weightlifting Athletes.

Gianpiero Greco, Francesco Camporeale, Francesco Fischetti. University of Study of Bari, Bari, Italy. Email: gianpigreco@hotmail.it

(No relevant relationships reported)

The maximal strength training implies the greatest possible activation of the central nervous system, improving inter and intramuscular coordination and causing considerable benefits recognized by the international scientific community. It is well known that the pyramidal training can give powerful performance results thanks to a progressive increase in the load. However, there are different traditional methods to strength training and all have already been successfully tested. **PURPOSE:** This randomized controlled trial study design with experimenter blinding aimed to compare the effects of an 8-week training period of a Mixed-Methods Strength Training (MST) or Pyramidal Training (PT) on maximal strength performance in weightlifting athletes. **METHODS:** Study participants (20 men, age: 23.9 ± 2.05 years, body mass: 75.6 ± 9.45 kg, height: 1.77 ± 0.05 m, body mass index: 24.09 ± 2.46 kg·m⁻²) were assigned to the MST group ($n = 10$) performed strength training with maximal loads (80-95% of 1RM, 3-min rest) for two sessions per week interspersed with a pyramidal training session (90-sec rest), and PT group ($n = 10$) performed pyramidal training alone (90-sec rest) for three sessions per week. Both groups trained for 8 weeks using a 3:1 loading structure. Measures pre-intervention and post-intervention included one-repetition maximum [1-RM] bench press, barbell deadlifts, lat pull-down, and standing barbell military press. Repeated-measures ANOVA and a paired t-test were used to assess differences in outcome variables across conditions ($p < 0.05$). **RESULTS:** The MST group showed significantly greater improvements than PT in bench press (13.1 ± 0.91 vs. 3.7 ± 0.47 kg, $p < 0.0001$), barbell deadlifts (19.3 ± 1.27 vs. 5.3 ± 0.97 kg, $p < 0.0001$), lat pull-down (17.2 ± 1.72 vs. 2.8 ± 0.79 kg, $p < 0.0001$), and standing barbell military press (13.1 ± 1.54 vs. 1.9 ± 0.59 kg, $p < 0.0001$). **CONCLUSIONS:** These findings suggest that a Mixed-Methods Strength Training characterized by two sessions with maximal loads interspersed with a pyramidal training session may be more effective than the pyramidal training alone for enhancing the maximal strength in weightlifting athletes. It could therefore be considered a valid and motivating alternative to the traditional strength training methods.

Temporary Increasing in Muscle Thickness and Upper Arm Circumference Immediately After Resistance Exercise

Masahiro Goto, Yoshihiro Yamashina, Yousuke Yamato, Hiroto Honda, Hiroshi Sakai, Shigeru Terada, and Takafumi Hamaoka

Aino University, Osaka Japan, Tokyo Medical University, Tokyo Japan

Temporary muscle thickness and limb circumference increased immediately after resistance exercise are strongly affected by reactive hyperemia, which is different from muscle hypertrophy induced by resistance exercise. This study is necessary for determining condition of measuring muscle cross sectional area as a muscle hypertrophic effect induced by resistance exercise. Furthermore, this is useful for bodybuilding and physique contests where muscle volume affects results.

PURPOSE: The purpose of this study was to investigate the duration of temporary increasing in muscle thickness and upper arm circumference induced by resistance exercise in the triceps brachii for resistance-trained and untrained subjects.

METHODS: Four kinds of resistance exercises were performed on 28 healthy adult males (26 ± 3 yrs), resistance-trained ($n = 14$) and untrained ($n = 14$). The extracellular water content, muscle thickness, upper arm circumference, oxygenated hemoglobin (oxy-Hb) were examined before exercise, within 5-minute, 30-minute, and 60-minute after exercise. Two-way analysis of variance was used to confirm acute effects.

RESULTS: The extracellular water content of upper arm ($+0.22$ L), triceps brachii muscle thickness ($+3$ mm), upper arm circumference ($+2$ cm) increased only in the resistance-trained subjects 5-minute after exercise compared with before exercise. However, there was no difference between before exercise and 30-minute after exercise values. The oxy-Hb increased immediately after exercise in both resistance-trained ($+42\%$) and untrained subjects ($+39\%$), but no significant difference was observed between resistance-trained and untrained subjects. **CONCLUSION:** Temporary increasing in muscle thickness and upper arm circumference within 5 minute after resistance exercise was a response occurred only in the resistance-trained subjects, and it was confirmed that the response disappeared within 30-minute.

The Effect Of Strength Training On Physical Performance In Adolescent Female Soccer Players

ELENA PARDOS MAINER, LUCIA SAGARRA ROMERO, OLIVER GONZALO SKOK. Universidad San Jorge, Zaragoza, Spain, Villanueva de Gállego, Zaragoza, Spain.

Email: emainer13@gmail.com

(No relevant relationships reported)

Strength training (ST) is amongst the most frequently used strategies to improve soccer performance and it has been used to obtain significant increases in the levels of maximum strength and muscle hypertrophy. Therefore, using appropriate ST programs could enhance several explosive actions that are crucial to the outcome of the game. ST is a method that has shown to be effective in male soccer players but the scarce studies of ST on female soccer players must also be pointed out. **PURPOSE:** To examine the effects of ST on physical performance after a 12-week training period in adolescent female soccer players. **METHODS:** 37 adolescent female soccer players from Spanish soccer team (age: 16.1 ± 1.1 years; height: 159.7 ± 7.1 cm; body mass: 55 ± 7.1 kg) were randomly assigned to an experimental (EG; $n = 19$) or a control group (CG; $n = 18$). All players underwent a regular soccer training 3 times per week. Participants in the EG received ST program (12 weeks, 2 times per week, 20 min per session). The ST program included lower limb strength and core muscle. The players were tested at the beginning and the end of the intervention on bilateral countermovement jump (CMJ) test, unilateral CMJ test, 40m sprint, 180° COD test and V-cut test. Paired t-test was conducted to detect significant differences between the pre and post-tests in both groups. Statistical significant was inferred from $p < 0.05$. **RESULTS:** EG made significantly greater improvement than CG did on CMJ (GE pre 23.5 ± 3.30 cm vs post 25.6 ± 3.65 cm, $p < 0.01$; GC pre 23.3 ± 3.73 cm vs post 23.9 ± 4.35 cm), right CMJ (GE pre 12.9 ± 1.95 cm vs post 14.3 ± 2.44 cm, $p < 0.05$; GC pre 12.1 ± 2.77 cm vs post 13.1 ± 2.65 cm), 40m sprint (GE pre 6.51 ± 0.26 s vs post 6.24 ± 0.25 s, $p < 0.01$; GC pre 6.24 ± 0.21 s vs post 6.29 ± 0.25 s), left 180° COD (GE pre 2.96 ± 0.16 s vs post 2.89 ± 0.18 s, $p < 0.05$; GC pre 2.93 ± 0.15 s vs post 2.91 ± 0.11 s) and V-cut (GE pre 8.05 ± 0.38 s vs post 7.81 ± 0.27 s, $p < 0.01$; GC pre 7.98 ± 0.38 s vs post 7.97 ± 0.39 s). **CONCLUSIONS:** Twelve weeks ST could improve bilateral and unilateral muscular power, speed and

COD ability performance in adolescent female soccer players. The results indicate that safe, effective, and alternative ST can be useful to coaches, especially in competition season where less time is available to training.

216 Board #54 May 29 11:00 AM - 12:30 PM
Effect of a 2-Week Strength Training Learning Intervention on Self-selected Weight Training Intensity

Sabrina Ahmad, Steve Glass, FACSM, Taylor Gabler. *Grand Valley State University, Allendale, MI.* (Sponsor: Jeff Potteiger, FACSM)

(No relevant relationships reported)

PURPOSE: Research has found that novice clients, fail to self-select weight that is heavy enough to promote strength gain. The purpose of this study was to determine the effectiveness of a 2-week strength training learning intervention on self-selected resistance training intensity. **METHODS:** Subjects between 18-40 y were placed in a control (CON n=7) or experimental (EXP n=8) group. Each subject was provided practice training on 5 resistance training machines (chest press, leg press, triceps extension, bicep curl, shoulder press). On 6 different training days, separated by at least 48h, subjects completed 2 sets on each machine while blinded to the load. CON were instructed to self-select a load to build strength without feedback. Load, repetitions and ratings of perceived exertion (RPE) were recorded. Starting with a self-selected load, EXP were encouraged to lift to fatigue. If EXP exceeded 12 repetitions, the load was increased (Goal- attain 70%IRM). RPE was assessed each set. Post training days, CON and EXP completed self-selection trials for all lifts, plus 3 novel lifts (pec fly, leg extension, shoulder raise). One repetition maximum (1RM) was assessed last. All loads were converted to % 1RM. Comparisons between groups were made using 2Way ANOVA. **RESULTS:** For % 1RM there were significant main effects for both condition and day (Day 1 EXP=57.2±12.0%; CON=47.2±13.7%; Day 6 EXP=74.7±10.8%; CON=66.2±13.4%). For repetitions there were significant effects across days (Day 1 EXP=10.8± 4.8; CON=12.3± 4.0; Day 6 EXP=9.3±3.6; CON=10.0±3.0) with significant interaction effects indicating CON did not change repetition number as load increased. There were significant main effects across days for RPE (Day 1=15.4±2.0; Day 6=16.5±1.9). All loads selected exceeded 60% 1RM indicating that both EXP and CON treatment achieved adequate training loads. However, among the novel lifts only the pec fly was greater than 60% 1RM (pec fly 63.0±11.0%; leg extension 39.8±12.5%; shoulder raise 53.1±12.8%). **CONCLUSION:** Two weeks of supervised resistance training resulted in EXP and CON self-selecting loads greater than 60% 1RM. Repeated training exposure resulted in higher self-selected training loads suggesting that repeated exposure to resistance training sessions is an important factor to attain loads that promote strength gain.

Acute Resistance Training Does Not Impair Cognitive Function in Costa Rican Older Adults

Rebeca Hernández-Gamboa, José Moncada-Jiménez. *University of Costa Rica, San José, Costa Rica.*
 Email: jose.moncada@ucr.ac.cr

(No relevant relationships reported)

Aging imposes a gradual deterioration of brain function and cognitive abilities, which hinder older adult's daily activities and limit their independence and safety. There is a lack of evidence on the acute effects of resistance training (RT) on cognitions in older adults. **PURPOSE:** To determine the acute effect of RT on cognitive performance in healthy Hispanic older adults. **METHODS:** Volunteers were 45 cognitively intact older adults (Mean age = 65.3 ± 3.7 yr.) recruited from a University extension program. Participants were randomly assigned to one of three possible groups (n = 15 in each group): a) High-intensity RT: 3 sets, 8 repetitions at 70% 1-RM, 2-min rest between sets (G1), b) Low-intensity RT: 4 sets, 14 repetitions at 30% 1-RM, 2-min rest between sets (G2), or c) Inactive control (G3). Before and following the experimental intervention, participants completed a comprehensive battery of cognitive tests assessing processing speed, visuospatial processing, executive function and cognitive control, working memory and immediate memory. Following a familiarization phase to RT exercises, participants in G1 and G2 performed 1-RM needed to define the exercise intensity. The intervention session consisted of the cognitive battery tests and five-minute warm-up on a stationary bicycle, followed by the exercise training protocol (knee extension, chest press, knee flexion, seated row, leg press, biceps curl). Immediately after finishing, the cognitive post-test was applied. The control group remained seated on a chair for 30-min and then performed the post-test. A two-way (group x measurement) ANCOVA was carried out using education level as a covariate. **RESULTS:** Significant improvements were found on visuospatial processing in G1 (Pre = 61.6 ± 2.1 vs. Post = 69.7 ± 2.4 pts.; CI95% = 4.8, 11.4; p ≤ 0.001) and G2 (Pre = 62.4 ± 2.2 vs. Post = 67.0 ± 2.5 pts.; CI95% = 1.2, 8.1; p = 0.009). Processing speed, executive function and cognitive control, working memory and immediate memory were unchanged by acute exercise or rest. **CONCLUSION:** Acute RT enhanced or maintained cognitive performance in older adults. Repetitive acute bouts of RT might chronically improve or retard the aging effects on cognitions in older adults.

Does the Physiological Tremor Identify the Intensity of Resistance Exercise?

Wonil Park¹, Gyuseog Hong², Jaeseong Lee¹, Hun-young Park³, Jonghoon Park¹. ¹*Korea University, Seoul, Korea, Republic of.* ²*Convergence Center, LG Electronics, Seoul, Korea, Republic of.* ³*Kunkuk University, Seoul, Korea, Republic of.*
 Email: voguse0403@gmail.com
 (No relevant relationships reported)

Although the various methods are commonly used to predict the intensity of aerobic exercise, there is a lack of information on resistance exercise intensity. **PURPOSE:** Accordingly, the primary purpose of this study was to determine whether the physiological tremor assessed by accelerometer could recognize the intensity of resistance exercise. **METHODS:** Twenty healthy young men (23.8 ± 0.7 years; mean ± SEM) who have not experienced resistance exercises, were recruited for this study. A variety of intensity (resting, 30%, 50%, and 70% of their predetermined one-repetition maximum (1-RM)) of arm-curl exercise was used to reveal physiological tremor. Total work was held equally by varying the number of repetitions with 5 sets during each of the intensities. The session of intensities was performed in random order with at least a week of wash-out period. The physiological tremor responses were recorded during exercise using accelerometers (3-axis) attached at the dominated wrist and left ear. Also, electromyography (EMG) data were collected from the biceps brachii muscle during the exercise. Physiological tremor and EMG data were shown as average root mean square index. **RESULTS:** As we expected, EMG amplitude increased significantly (0.01 ± 0.001 mV, 0.40 ± 0.02 mV, 0.70 ± 0.04 mV, and 1.03 ± 0.05 mV in resting, 30%, 50%, and 70% of RM, respectively, P<0.01) as the intensity of exercise increased. Physiological tremor amplitude significantly increased as the intensity of exercise increased (wrist; 0.008 ± 0.001 m×s⁻², 0.08 ± 0.002 m×s⁻², 0.09 ± 0.002 m×s⁻², and 0.09 ± 0.004 m×s⁻² in resting, 30%, 50%, and 70% of RM, respectively, P<0.01, ear; 0.01 ± 0.001 m×s⁻², 0.03 ± 0.01 m×s⁻², 0.05 ± 0.002 m×s⁻², and 0.07 ± 0.004 m×s⁻² in resting, 30%, 50%, and 70% of RM, respectively, P<0.01). EMG amplitude was significantly related to physiological tremor (r=.632 and r=.649 in wrist and ear, respectively, P<0.01). **CONCLUSION:** To our knowledge, this is the first study to suggest the physiological tremor could be an index of the intensity of resistance exercise.

The Comparison of Velocity between Front Squat, Back Squat, Sumo and Conventional Deadlift

Jovana Kasovic, Benjamin Martin, Christopher A. Fahs. *Lindenwood University, Belleville, IL.*
 (No relevant relationships reported)

Average concentric velocity (ACV) during barbell exercises varies inversely as a function of load and can be used for determining training loads. It is unclear if ACV differs between variations of similar lifts such as the conventional deadlift (CD) and sumo deadlift (SD) or between the front squat (FS) and back squat (BS). **PURPOSE:** To compare ACV, peak concentric velocity (PCV), and range of motion (ROM) between the FS and BS and between the CD and SD. **METHODS:** In a randomized order, nine participants (N=9; age: 22±4) underwent one-repetition maximum (1RM) testing for the FS, BS, CD, and SD. The open barbell system was used to measure ACV PCV, and ROM during the 1RM protocol. During the first testing session, height, body mass, femur and humerus length were measured; training age, frequency of training, and estimated 1RM were obtained via questionnaire. Paired samples t-tests were used to determine differences in ACV, PCV, and ROM between the between the FS and BS and between the CD and SD. **RESULTS:** Paired samples t-tests indicated no differences between the 1RM FS and BS for: ACV (0.24±0.06 vs 0.25±0.06 m/s; p=0.930), PCV (0.66±0.11 vs 0.66±0.16 m/s; p=0.969), or ROM (0.49±0.06 vs 0.51±0.11 m; p=0.819). For the SD and CD there were no differences in AVC (0.27±0.11 vs 0.26±0.08 m/s; p=0.691) or PCV (0.55±0.19 vs 0.51±0.13 m/s; p=0.445) but significant differences were observed in ROM (0.48±0.06 vs 0.53±0.05 m; p=0.015). **CONCLUSIONS:** Despite a lower ROM for the SD compared to the CD, bar velocity is similar at maximal loads (e.g. 1RM). If using velocity to determine training loads, these data suggest that the same velocity ranges for regulating training loads could be used for the SD and CD as well as for the FS and BS.

The Effects of Eccentric Duration on Squat and Bench Press Concentric Performance

Matthew Juber¹, Joseph P. Carzoli¹, Colby A. Sousa¹, Daniel J. Belcher¹, Eric R. Helms², Andy V. Khamoui¹, Michael Whitehurst, FACSM¹, Michael C. Zourdos¹. ¹Florida Atlantic University, Boca Raton, FL. ²Auckland University of Technology, Auckland, New Zealand.
 Email: mzourdos@fau.edu
 (No relevant relationships reported)

Many resistance training exercises incorporate both eccentric and concentric phases of muscle contraction. Through the stretch shortening cycle, the velocity and magnitude in which the eccentric phase is completed directly affects performance during the concentric phase. **PURPOSE:** Therefore, the purpose of this research was to investigate the effects of eccentric phase duration on concentric outcomes at 60% and 80% of one-repetition maximum (1RM) in the back squat and bench press. **METHODS:** Sixteen resistance-trained males (Age: 23.25±2.57yrs, Height: 171.82±7.48cm, Body Mass: 81.96±12.16kg) completed four laboratory visits as follows: Day 1- 1RM testing; Day 2- establishment of normative eccentric durations; Days 3 and 4- randomized fast (0.75 times) or slow (2.0 times) eccentric duration conditions, which were controlled by visual and auditory metronomes. Outcome measures assessed during the concentric phase were: average concentric velocity (ACV), peak concentric velocity (PCV), rating of perceived exertion (RPE), range of motion (ROM), and barbell path. A one-way ANOVA and Pearson's Product Moment correlations were used for analysis with significance set at $p \leq 0.05$. **RESULTS:** Eccentric duration was significantly and inversely correlated with average concentric velocity (ACV) at 60% ($r = -0.408$) and 80% ($r = -0.477$) of 1RM squat and at 100% ($r = -0.604$) of 1RM bench press. At 60% of 1RM squat, both fast and slow eccentric conditions produced greater ($p < 0.001$) peak concentric velocity (PCV) than normative duration with fast also producing greater PCV than slow ($p = 0.044$). Eccentric duration had no impact on RPE, ROM, or barbell path. **CONCLUSIONS:** Therefore, our results show that well-trained athletes performing a deliberately faster eccentric phase may enhance squat and bench press performance. However, caution should be used when interpreting these results as athletes who already perform a fast eccentric duration may not benefit from deliberately increasing eccentric velocity.

221 Board #59 May 29 11:00 AM - 12:30 PM
Workout-Life Balance: How Psychological Stress Affects Force Production in Competitive Powerlifters and Healthy Controls

Keenan J. Dung, J. Mark VanNess, Nathaniel J. Holmgren, Courtney D. Jensen. *University of the Pacific, Stockton, CA.*
 Email: k_dung2@u.pacific.edu
 (No relevant relationships reported)

Powerlifters often focus more on physiological stresses of programming and performance than psychological stress. However, total allostatic load could influence the capacity to generate force. Understanding this relationship can give coaches and athletes tools to optimize workout-life balance. **PURPOSE:** To determine the effect of psychological stress on force production in distinct populations. **METHODS:** Competitive powerlifters (PL) and recreationally active college students (RA) were tested. The RA group consisted of 10 men and 13 who performed knee extension and flexion at 2 time points using a Cybex dynamometer. Once during an academic respite and once during exams. Psychological stress was assessed with a 10-Point Cohen Perceived Stress Scale Questionnaire. Linear regression measured the effect of psychological stress on peak force. The PL group consisted of 26 men and 8 women competing in the 2018 USAPL Raw Nationals. The day before the competition, all athletes were interviewed; peak and expected performances and 10-point stress were recorded. Linear regression tested the effect of stress on the difference between expected and achieved performances. **RESULTS:** In the RA group, between the 2 time points, men produced 257.5 ± 68.9 ft-lbs of torque for flexors and extensors summed; women produced 213.5 ± 26.6 ft-lbs ($p = 0.082$). Holding bodyweight constant, stress did not affect peak torque at time point 1 ($p = 0.217$) or 2 ($p = 0.506$), and change in stress did not affect change in force output ($p = 0.640$). Sex was insignificant in all analyses and no relationships emerged when evaluating flexors or extensors separately. In the PL group, the summation of bench press, squat, and deadlift was 625.4 ± 74.4 kg in men and 377.8 ± 79.5 kg in women ($p < 0.001$). In the regression analysis ($R^2 = 0.325$; $p = 0.003$), holding weight class constant, the deficit precipitated by psychological stress was 3.4 kg per point ($p = 0.006$; 95% CI: -5.69 to -1.06). Results were stronger for women ($R^2 = 0.824$; $p = 0.013$); holding weight class ($p = 0.032$) constant, each additional point of stress predicted a 4.8 kg reduction in performance ($p = 0.005$; 95% CI: -7.43 to -2.27). **CONCLUSION:** Psychological stress does not impair strength performance among untrained individuals. However, stress management may be critical for strength athletes, particularly women.

A Three-Dimensional Assessment of Push-Pull Power Ratios Across Various Loads

Gianna D. Maragliano¹, J. Mark VanNess¹, Maggie E. Bristow¹, Nathaniel J. Holmgren¹, Joseph Arballo², Courtney D. Jensen¹. ¹University of the Pacific, Stockton, CA. ²CSU Chico, Chico, CA.
 Email: g_maragliano@u.pacific.edu
 (No relevant relationships reported)

Capturing a true assessment of power in upper body motions is problematic owing to difficulty reproducing a testing environment that matches kinematic profiles performed in sport. New technology permits more accurate reflections of three-dimensional power in isotonic environments. **PURPOSE:** To quantify power ratios of single-arm press and pull exercises across various loads. **METHODS:** 64 subjects performed a total of 1,145 sets on Proteus (Boston Biomechanics, Inc.): 570 sets of single-arm horizontal presses and 575 sets of single-arm horizontal rows. All subjects performed both exercises. Three-dimensional magnetic resistance was applied at 5, 10, 15, 20 and 25lb. ANOVA tested the subjects' kinematic profile across loads. **RESULTS:** On average, across all sets, maximum power per set was 175.2 ± 103.0 for presses and 183.6 ± 108.5 for pulls. For mean power throughout a set, subjects achieved 159.5 ± 96.3 for presses and 168.2 ± 102.5 for pulls. The different loads had significant differences for maximum ($p < 0.001$) and mean ($p < 0.001$) power; the higher the load, the higher the value in each measurement. At a 5lb load, maximum power (presses and pulls combined) was 31.7 ± 10.8; at a 25lb load, it was 366.4 ± 96.0. Similarly, for mean power, at 5lb, subjects achieved 26.8 ± 10.2 while at 25lb, it was 335.1 ± 92.0. Dominant and non-dominant arms were similar in maximum ($p = 0.497$) and mean power ($p = 0.530$) although overall, pulling was stronger than pushing. Across all sets and loads, push-to-pull ratio was 0.95:1 for both maximum and mean power. This ratio changes at different loads. For peak power, at 5lb, the push-to-pull ratio was 1.22:1. At 10lb, it was 0.99:1. At 15lb, it was 0.98:1. At 20lb, it was 0.95:1. At 25lb, it was 0.94:1. For mean power, the same pattern, though slightly more extreme, was found. **CONCLUSIONS:** Numerous investigations have quantified ideal force ratios of the knee while similar assessments of the upper limbs have received relatively little attention. New technology provides a systematic approach to measure strength ratios of the shoulder and elbow in three-dimensional space. In this context, strength ratios change with load; push power exceeds pull power at low loads whereas the inverse is true at higher loads. These strength ratios may be considered for sport application and recognition of risk for upper limb injury.

223 Board #61 May 29 11:00 AM - 12:30 PM
Correlations Between Resistance Exercise Repetitions Achieved At 60% And 80% 1rm Load In Female Subjects

Jeff T. Wight¹, Caleb Williams², Mike Anton³, Peter M. Magyari, FACSM⁴. ¹Jacksonville University, Jacksonville, FL. ²LaGrange College, LaGrange, GA. ³Airrosti Rehab Centers LLC, San Antonio, TX. ⁴University of North Florida, Jacksonville, FL.

 Email: jwight@ju.edu
 (No relevant relationships reported)

To determine the appropriate load for resistance training (RT), exercise professionals (EPs) commonly have clients complete one repetition maximum testing (1RM). Then, submaximal loads can be easily calculated for RT sessions. A higher load (approximately 80% 1RM) is chosen if lower repetitions (reps) are desired (~ 10 reps) and a lower load (approximately 60% 1RM) is chosen if higher reps are desired (~ 20 reps). However, the number of reps generated (at both low and high loads) varies quite dramatically in standard populations. It is important to determine if there are strong relationships between the number of reps generated at lower and higher loads. The hypothesis is that individuals tend to perform similarly at different loads (i.e. generate above average reps at both loads or below average reps at both loads). However, this topic has not been thoroughly studied. **PURPOSE:** Determine correlations between RT reps achieved at 60% 1RM load and 80% 1RM load. This will help us understand if the number of reps generated at lower loads predicts the number or reps generated at higher loads. **METHODS:** Participants were 19 college-aged (25 ± 4.3 years) females with a minimum of 2 months RT experience. Three exercise sessions were completed under the supervision of certified EPs. For session one, 1RM testing was completed. For sessions two and three, participants completed as many reps as possible for 60% 1RM or 80% 1RM (load and order was randomized) for 8 cam-mediated variable resistance training exercises. For all 8 exercises, Pearson correlation was used to assess the strength of the relationship between the two loads. **RESULTS:** The reps generated at 60% 1RM and 80% 1RM and correlations between the two were determined for the following 8 exercises: bench press (8.2±3.4 reps to 18.3±4.2 reps; $r = 0.51$), leg press (17.9±5.0 reps to 37.3±15.9 reps; $r = 0.63$), shoulder press (7.8±2.5 reps to 13.6±3.5 reps; $r = 0.59$), pull-down (10.3±2.1 reps to 24.1±8.3 reps; $r = 0.05$), knee extension (11.4±4.7 reps to 17.3±5.8 reps; $r = 0.71$), knee flexion (12.4±4.5 reps to 23.4±6.7 reps; $r = 0.74$), elbow extension (12.5±5.0 reps to 23.0±10.3 reps; $r = 0.63$), and

elbow flexion (9.9±5.4 reps to 17.3±6.4 reps; $r = 0.86$). **CONCLUSIONS:** EPs should understand that correlations between repetitions achieved at different loads tend to be moderate.

224 Board #62 May 29 11:00 AM - 12:30 PM
Prioritization of Resistance Training In NCAA Division I Track and Field Athletes

Matthew K. Beeler¹, D H. Dombrowski², Emily M. Post¹, Lydia K. Caldwell¹, William H. DuPont¹, Carl M. Maresh, FACSM¹, Craig R. Denegar², M F. Joseph², William J. Kraemer, FACSM¹.
¹The Ohio State University, Columbus, OH. ²University of Connecticut, Storrs, CT. (Sponsor: William J Kraemer, FACSM)
(No relevant relationships reported)

PURPOSE: Resistance training is a powerful systemic stimulus known to improve a multitude of physiological variables. These include but are not limited to musculoskeletal strength, power, muscle mass, bone mass, and connective tissue. The sport of track and field is composed of many different events that focus on strength, power, and muscular endurance. Therefore resistance training is typically a vital part of athletic preparation for track and field athletes. The purpose of this study was to investigate specific manipulations of the acute program variables within the off-season resistance training program. **METHODS:** 34 NCAA Division I track and field student-athletes men participated in 12 week mesocycle of a non-linear periodized training program between the months of September and December. Groups were separated by needs of their athletic event and thus, performance primary goals (Group 1 (*Power*): $n=12$, age: 20.1±1.10, body mass: 87.8±13.3 kg; Group 2 (*Local Muscular Endurance*): $n=12$, age: 21.1±1.10, body mass: 82.9±10.4 kg; Group 3 (*General Strength*): $n=10$, age: 18.9±0.8, body mass: 80.4±8.1 kg). The training groups prioritized resistance loads and volume for development of power, local muscular endurance, and general strength, respectively. Performance variables were assessed at the beginning and end of this training program and consisted of counter movement vertical jump with arm swing, 1-repetition-maximum in the barbell bench press, and barbell back squat. **RESULTS:** The primary findings of this investigation are Group 1 saw significant ($p \leq 0.05$) statistical increases in vertical jump (4.4±1.1 cm), and back squat maximum (13.1±3.6 kg). Group 2 saw significant ($p \leq 0.05$) statistical increases in bench press maximum (14.2±0.5 kg), and back squat maximum (15.0±0.6 kg). Group 3 saw significant ($p \leq 0.05$) statistical increases in vertical jump (4.7±0.7 cm) and maximum back squat (20.0±5.0 kg). **CONCLUSIONS:** Our data indicate that the prioritization of strength within a 12 week mesocycle in the off-season training program had the best effect on the performance variables that were needed by each group. It appears that multiple stressors of the academic school year and athletic preparation are better mediated with a type of non-linear flexible program for competitive NCAA Division I track and field athletes.

Optimal Load Based on Body Mass: A Pilot Study with The Hang Power Clean

Marcel Lopes dos Santos¹, Ricardo Berton², Adam Jagodinsky¹, Michael Torry¹, Kristen Lagally, FACSM¹.
¹Illinois State University, Normal, IL. ²University of Sao Paulo, Sao Paulo, Brazil.
Email: mlopes@ilstu.edu
(No relevant relationships reported)

A key factor for success in sports is the athletes' capacity of producing mechanical power output. Implementation of weightlifting derivatives such as the hang power clean (HPC) in training programs have been utilized and substantial increases in muscle power are reached when the athletes train at the load in which they produce the peak power output, also defined as the optimal load. The optimal load is commonly determined as a relative percentage of the maximum weight one can lift a single time during a specific exercise, defined as the 1-repetition maximum (1RM) for that exercise. Given the disadvantages of 1RM tests utilization such as risk of injuries and excessive amount of time required for those assessments, it has become apparent the need for alternative strategies for the optimal load identification. **PURPOSE:** To estimate the optimal load of the HPC from body mass (BM) percentages. **METHODS:** Nine healthy young men (age: 21.3 ± 1.8, height: 174.6 ± 6.8 cm, weight: 80.6 ± 6.2 kg, 1RM HPC: 90.8 ± 9.6 kg, 1RM to weight ratio: 1.13 ± 0.07) participated in this study. Subjects performed a 1RM in the HPC in the first session and during the second session the peak power was calculated across loads of 30, 40, 50, 60, 70, 80, and 90% of their BM in the HPC in a randomized order. **RESULTS:** Our results showed significant differences among the power output and the percentages of the BM. Briefly, power output at 30% of the BM was similar in relation to 40% and 50% of the BM, whilst significantly lower than 60%, 70%, 80% and 90% of the BM. For 40% of the BM, it was observed similar result in relation to 50% of the BM, whilst results significantly lower than 60%, 70%, 80% and 90% of the BM. For 50% of the BM, similar result it was observed only 60% of the BM, while lower power output it was observed in comparison to 70%, 80% and 90% of the BM. For 60% of the BM, lower

power output was observed when compared to 70%, 80% and 90% of the BM. Finally, no significant differences were observed between 70% and 80% and 90% of the BM, as well as 80% and 90% of the BM. **CONCLUSION:** Our results indicate that the optimal load based on BM for HPC exercise occurs at 70%, 80% and 90% of the BM.

Comparing Relative Attempt Progressions Of Elite Male And Female Raw Powerlifters

Spencer K. Travis¹, Caleb D. Bazzyler¹, Michael C. Zourdos².
¹East Tennessee State University, Johnson City, TN. ²Florida Atlantic University, Boca Raton, FL.
(No relevant relationships reported)

PURPOSE: In powerlifting, each lifter is given 3 attempts to contest the back squat (BS), bench press (BP), and deadlift (DL). The summation of the best valid attempt for each discipline constitutes a powerlifting total (PT). However, little information is available regarding attempt selection strategies to maximize PT. Therefore, the purpose of this study was to determine and compare the magnitude of load progression from one attempt to the next for each lift between elite raw male and female powerlifters. **METHODS:** Data used in this study was retrieved from the International Powerlifting Federation (IPF) online database for all Classic World Championships from 2012-2018. Males ($n=65$) and females ($n=41$) from all weight classes who completed 9 out of 9 lifts successfully were included in the analysis. A Welch's t -test was used to compare relative attempt progressions (percent increase from attempt 1 to 2 and 2 to 3) between males and females for all lifts with alpha level set at $p \leq 0.05$. **RESULTS:** Relative attempt progression was similar between females (6.08±2.11%) and males (5.59±1.80%) from attempt 1 and 2 on BS and from attempt 2 to 3 on DL (females: 4.33±2.01%; males: 3.75±1.84%). However, relative attempt progression was greater for females compared to males between attempt 1 and 2 on BP (6.50±2.10% vs 5.35±2.18%, $p=0.008$) and DL (6.76±4.19% vs 5.40±2.28%, $p=0.03$), and between attempt 2 and 3 on BP (4.28±1.74% vs 2.85±1.24%, $p<0.001$) and BS (4.04±1.89% vs 3.31±1.43%, $p=0.03$), respectively. **CONCLUSIONS:** These data indicate that successful elite male powerlifters are on average more conservative with their attempt progressions for each lift than females. This may be due to differences in opening attempt selection or perceived effort during subsequent attempts between males and females. Importantly, these findings provide general attempt progression guidelines for coaches working with elite raw (i.e., classic) male and female powerlifters.

Validity of the Two-Point Method for Estimating Squat and Bench Press One Repetition Maximums

Brandon W. Snyder, Dylan S. Zangakis, Gavin L. Moir, Shawn N. Munford, Shala E. Davis, FACSM. East Stroudsburg University, East Stroudsburg, PA. (Sponsor: Shala Davis, FACSM)
(No relevant relationships reported)

PURPOSE: To assess the validity of the two-point method for estimating one repetition maximums (1RM) in the squat and bench press exercises with varied pairs of loads. **METHODS:** Thirteen resistance-trained men (age: 21.7±0.4 years; height 1.74±0.07 m; mass: 82.9±9.5 kg; 1-repetition maximum (1RM) back squat: 149.9±20.7 kg; 1RM bench press: 114.8±18.5 kg) performed three trials of squat and bench press using the following percentages of 1RM: 20, 30, 40, 50, 60, 70, 80%. The order of the loads was counterbalanced across the participants. The mean vertical velocity of the barbell during the concentric phase of each repetition was recorded using a 3-D motion analysis system (Vicon; 200 Hz). Varied loading pairs (20% & 80%, 30% & 70%, 40% & 50%, 40% & 70%) were selected and regressions were created to estimate 1RMs. Analysis of variance was used to compare differences between the measured and estimated 1RMs for the squat and bench press. **RESULTS:** No significant differences were found ($p>0.05$) between estimated and measured 1RMs despite large range of mean differences in the squat (MD: 6.45 kg-27.47kg) and bench press (MD: 1.09 kg-4.32kg). **CONCLUSION:** The two-point method represents a useful means of estimating 1RM during the back squat and bench press exercises without inducing the fatigue associated with directly measuring 1RM. However, individualized force-velocity characteristics should be considered when utilizing the two-point method for estimating a 1RM.

The Influence of Trunk and Tibia Orientation on the Hip/Knee Extensor Moment Ratio During Squatting
 Adam J. Barrack, Rachel Straub, Jordan Cannon, Christopher M. Powers, FACSM. *University of Southern California, Los Angeles, CA.* (Sponsor: Christopher M Powers, FACSM)
(No relevant relationships reported)

The squat is a common and versatile exercise in both the rehabilitation and sports performance settings. Sagittal plane trunk and shank orientations have been theorized to modulate extensor moments at the hip and knee during squatting. For example, increasing trunk inclination is thought to increase the extensor moment at the hip and decrease the extensor moment at the knee, while increasing shank inclination has been theorized to increase the knee extensor moment and decrease the hip extensor moment. Although the influence of sagittal plane tibia and trunk orientations on hip and knee extensor moments have been established in computational models, experimental validation in human subjects is lacking. **Purpose:** To determine the influence of sagittal plane trunk and shank orientations on hip and knee extensor moments during the lowering phase of a barbell back squat. **Methods:** Kinematic and kinetic data were obtained from 8 male and 8 female participants during the execution of 8 different squat conditions in which the tibia and trunk orientations were manipulated. Foot position, bar position, bar load, and stance width were controlled across subjects. Inverse dynamics equations were used to calculate the hip/knee extensor moment ratio at 60, 90, and 120 degrees of knee flexion. Linear regression was used to evaluate the association between the difference in the sagittal plane trunk and tibia angles and the hip/knee extensor moment ratio at each knee flexion angle of interest. **Results:** The difference between trunk and shank inclination explained 67%, 71%, and 67% of the variance in the hip/knee extensor moment ratio at 60 degrees ($p < 0.001$), 90 degrees ($p < 0.001$), and 120 degrees ($p < 0.001$) of knee flexion, respectively. Across all of the examined depths, the squat was deemed to be hip extensor biased (hip/knee extensor moment ratio > 1.0) when the sagittal plane trunk angle exceeded the sagittal plane shank angle. **Conclusion:** The relationship between sagittal plane trunk and shank orientation can function as an acceptable inference as to whether a particular squat technique is hip extensor biased or knee extensor biased.

Differences In Maximal Force Production Of The Squat And Knee Extension With Different Verbal Commands
 Micheal J. Luera, Jesus Hernandez-Sarabia, Carlos Estrada, Tyler Muddle, Jason DeFreitas. *Oklahoma State University, Stillwater, OK.*
 Email: mike.luera@okstate.edu
(No relevant relationships reported)

It is suggested that verbal commands influence the ability to produce peak force during maximal voluntary isometric contractions (MVC). When determining peak force capabilities during MVC it is recommended to use the verbal command, as "hard" as possible. Additionally, when instructing conditions to achieve maximal rate of force development (RFD), using the verbal command as "fast" as possible. **PURPOSE:** To examine the influence of two different verbal commands on peak force production during MVC's performed during the squat (SQ) and knee extension (KE) exercises. **METHODS:** Twenty-five lower-body resistance trained males ($n = 16$, mean \pm SD; 24 ± 3 yrs; 88.08 ± 11.09 kg; 175 ± 7 cm) and females ($n = 9$, 23 ± 4 yrs; 62.53 ± 6.84 kg; 164 ± 7 cm) performed two separate MVC during both SQ and KE exercises. Knee joint angles were set at 110° during both exercise conditions, and hip angle was $\sim 110^\circ$ during SQ and $\sim 105^\circ$ during KE. During both exercise conditions, peak force (N) was measured using an S-beam load cell. Throughout both exercise conditions, subjects performed MVCs under two different verbal command to; 1.) determine maximal force capabilities, subject were verbal instructed to push as "hard" as possible, and 2.) determine maximal RFD capabilities, subjects were instructed to push as "quick" as possible. **RESULTS:** One-way repeated measures analysis of variance indicated that, when instructed to push as "quick" as possible compared to as "hard" as possible, peak force was significantly higher during both the SQ (mean \pm SE; 2258.11 ± 131.01 N vs 2094.33 ± 123.58 N) and KE (785.90 ± 49.03 N vs 757.45 ± 47.04 N) conditions ($P < 0.05$). **CONCLUSION:** Contrary to previous recommendations, these findings indicate that during isometric SQ and KE exercises, performed at the same knee joint angle, peak force is greater when specifically instructed to produce maximal force MVCs as "quick" as possible vs as "hard" as possible.

Validity of Barbell Velocities Recorded from the GymAware Device during Squat and Bench Press Exercises
 Dylan S. Zangakis, Gavin Moir, Brandon Snyder, Shawn Munford. *East Stroudsburg University of Pennsylvania, East Stroudsburg, PA.* (Sponsor: Dr. Shala Davis, FACSM)
(No relevant relationships reported)

Purpose: To assess the validity of the GymAware linear position transducer (LTP) during the squat and bench press exercises. **Methods:** Thirteen resistance-trained men (age: 21.7 ± 0.4 years; height 1.74 ± 0.07 m; mass: 82.9 ± 9.5 kg; squat 1RM: 149.85 ± 20.68 kg; bench 1RM: 114.77 ± 18.47 kg.) performed three trials of squat and bench press using the following percentages of a one repetition maximum (1RM): 20, 30, 40, 50, 60, 70, 80%. The order of the loads was counterbalanced across the participants. The mean vertical velocity of the barbell during the concentric phase of each repetition was recorded using a 3-D motion analysis system (Vicon; 200 Hz) and the GymAware LTP. Analysis of variance was used to assess the differences in the vertical velocities across the seven load conditions for each of the two exercises. **Results:** Mean velocities were significantly different between devices for both the squat and bench press exercises ($p < 0.05$). Specifically the GymAware LTP provided significantly greater velocities under the 20% 1RM and 40% 1RM load conditions in the squat exercise (mean differences: 0.05 ± 0.03 m/s; 0.02 ± 0.02 m/s; $p < 0.05$) in addition to the 30% 1RM load for the bench press exercise (mean difference: 0.04 ± 0.02 m/s; $p < 0.05$). **Conclusion:** The GymAware LTP had a tendency to overestimate barbell velocities during the squat and bench press exercises when compared to the Vicon 3-D motion analysis system, particularly at the lighter loads. Such differences may bring into question the validity of the force-velocity characteristics derived from the LTP device during these resistance exercises.

The search of non-invasive and easy-to-monitor variables is essential to improve the athlete performance. The assessment of neuromuscular characteristics, such as velocity, with a linear position transducer (LPT), allows training optimization and just like heart rate variability (HRV) guarantees an adequate athlete monitoring. The autonomic nervous system (ANS) and Sympathetic nervous system (SNS) exert an important influence on skeletal muscle functions. However, there are no studies that correlate the activity of SNS with current technologies such as LPT to calculate several neuromuscular performance variables. Otherwise, the results of HRV assessment could be related to a TLP strength test performance.

PURPOSE: The aim of this study is to find correlations between HRV variables and TLC variables during a half squat movement in young female soccer players. **METHODS:** Thirteen professional female soccer players were tested (Age 20.7 years ± 2.62 , Weight 60.9 kg ± 4.4), we analyzed HRV during standing, we also evaluated the velocity of a half squat movement with a LPT, during a maximal strength test, statistical analyses were performed to determine associations. **RESULTS:** Associations were found between Stress index during standing position and Mean acceleration to Maximal velocity (m/s) (R^2 0.3115 P 0.0381), Mean velocity (R^2 0.3284 P 0.0322), Propulsive mean velocity (R^2 0.3189 P 0.0354). **CONCLUSIONS:** Stress Index (SI) is a variable that reflects sympathetic activation and suggest autonomic reactivity to stress situations indicating an adequate response to confront the demands presented by the sport. Thus, an abnormal sympathetic predominance could result in chronic fatigue which would evince a SI higher elevation, giving the index greater value. According to our findings the SI during standing position correlated with velocity and acceleration variables during half squat, this suggests that adequate sympathetic reactivity could contribute to the improvement of neuromuscular variables. We hypothesized that SI could be a simple non-invasive way to measure sympathetic reactivity in sports, being part in assessment and monitoring of performance. We also suggest that interventions aimed to improve sympathetic reactivity could improve neuromuscular performance.

Reliability of Barbell Velocities Recorded from the GymAware Device during Squat and Bench Press ExercisesShawn N. Munford, Dylan S. Zangakis, Gavin L. Moir, Brandon W. Snyder, Shala E. Davis, FACSM. *East Stroudsburg University, East Stroudsburg, PA.* (Sponsor: Shala E Davis, FACSM)*(No relevant relationships reported)*

PURPOSE: To assess the reliability of velocities recorded with the GymAware linear position transducer (LTP) during the squat and bench press exercises. **METHODS:** Thirteen resistance-trained men (age: 21.7±0.4 years; height 1.74±0.07 m; mass: 82.9±9.5 kg; 1-repetition maximum (1RM) back squat: 149.9±20.7 kg; bench 1RM: 114.8±18.5 kg.) performed three trials of squat and bench press using the following percentages of 1RM: 20, 30, 40, 50, 60, 70, 80%. The order of the loads was counterbalanced across the participants. The mean vertical velocity of the barbell during the concentric phase of each repetition was recorded using a 3-D motion analysis system (Vicon; 200 Hz) and the GymAware LTP. Reliability of the GymAware was determined using intraclass correlations (ICC) and coefficients of variance (CV%). **RESULTS:** The GymAware showed high intersession reliability for both exercises with ICCs ranging from good to excellent (squat: 0.71-0.91; bench press: 0.83-0.91). CV% showed precision in the recorded velocities during both exercises (squat: 3.6%-5.8%; bench press: 4.9%-7.4%). **CONCLUSION:** The GymAware LTP shows high intersession reliability for recorded velocities during the squat and bench press exercises.

233 Board #71 May 29 11:00 AM - 12:30 PM

Comparison of Pre-stretch and Reactive Strength Between Men and Women During Bench PressStephan Corcho, Andrew Flatt, George Davies, Bryan Riemann. *Georgia Southern University, Savannah, GA.* Email: sc24486@georgiasouthern.edu*(No relevant relationships reported)*

Pre-stretch augmentation (PAI) and reactive strength (RSI) indices have been used to assess the stretch-shortening cycle (SSC) contribution to vertical jumping. SSC activation is also a part of many upper extremity (UE) activities, however quantification of SSC contribution to UE function largely remains unknown. Furthermore, based on differences in UE muscle-tendon properties, the SSC effect is likely different between men and women

PURPOSE: To compare UE PAI and RSI indices between men and women. **METHODS:** 20 men (26±2.4 yrs) and 17 women (21.4±2.6 yrs) with >6 months of UE resistance training completed 3 bench press trials using 2 styles, pure concentric (PC) and rebound (RB) (no pause between eccentric the concentric phases), using 75% of their one repetition maximum. Participants were instructed to complete the concentric phase as quickly as possible. Concentric phase vertical average force (AF) and power (AP) were computed from barbell kinematic data and used to calculate PAI [(RB-PC)/PC*100] and RSI (RB-PC). Independent t tests, adjusted for unequal variances, were conducted to compare indexes between sexes **RESULTS:** Except for one man and one woman, participants demonstrated greater AF and AP during the RB bench press compared to PC bench press. Men (.49±.38) had significantly higher (P=.004, d=.75) AF PAI than the women (.27±.17). There was no significant (P=.068, d=.64) sex difference for AP PAI. Men (AF:3.9±2.9, AP:129.0±56.7) demonstrated significantly higher RSI for both AF (P<.001, d=1.5) and AP (P<.001, d=2.3) than women (AF: .76±.54, AP: 29.6±18.1). **CONCLUSIONS:** Except for two participants, as expected, preceding the concentric phase with SSC resulted in greater average force and power production. With the exception of AP PAI, SSC augmentation was greater for the men. Consistent with the RSI reflecting the AP/AF difference between RB and PC bench press styles, the sex comparison effects sizes were larger for the RSI than the PAI, which expresses the difference relative to the PC. Further research is needed to determine the extent to which UE muscle-tendon properties explain the sex differences identified.

234 Board #72 May 29 11:00 AM - 12:30 PM

FEM Analysis of LumboSacral Joints on the Lift Barbell Preparation PhaseYawei Song, Ke Rong, Xiyuan Zhang. *Nanjing Sport Institute, Nanjing, China.* Email: SywO008@163.com*(No relevant relationships reported)*

PURPOSE: The aim of this study was to analyze the stress characteristics of the lumboSacral segments of the preparation phase of barbell lifting using finite element method and to provide scientific and objective mechanical factors of lumboSacral joint injury in weightlifters for prevention and treatment of lumbar weightlifting injuries.

METHODS: The three-dimensional lumboSacral finite element model was established by reverse engineering method based on DICOM data (L5-S5 segments included). The Von Mises stress trends of lumboSacral bone, soft tissue such as intervertebral disc, ligament were analyzed between normal physiological activities during flexion, extension, left bend, right bend and preparation phase of barbell lifting.

RESULTS: The von Mises stress (mpa) of lifting weight condition respectively are 81.223,199.099,321.646,99.058,152.357,156.882,461.294,699.506,0,0,104.414,8.66,74.9,9.89.15 on posterior longitudinal ligament, left transverse process ligament, right lateral intercostal ligament, yellow ligament, interspinous ligament, spine on the ligament, left joint capsule ligament, right capsular ligament, left joint capsule contact stress, right joint capsule contact stress, end plate, nucleus, lumbar, sacrum.

CONCLUSIONS: The vertebral body is the main stress-bearing part during lifting and the intervertebral disc plays a major role in transmitting the load. Long-term repeated high-stress stimulation could cause slight fractures of cancellous bone and end-plate of vertebrae. Interspinous ligament bears more loads and is more likely to get injured compared to other ligaments. The imbalance of the left and right ligament force also reveals that minimizing spinal flexion and torsion compound action could reduce the possibility of ligament injury.

Muscle Excitation During A Weighted And Unweighted Supine Bridge (a Pilot Study)Kelsey Lewis¹, Wenhui Mao², Sydni Wilhoite¹, Li Li, FACSM¹. ¹Georgia Southern University, Statesboro, GA. ²Nanjing Normal University, Nanjing, China. (Sponsor: Li Li, FACSM)

Email: kl06040@georgiasouthern.edu

(No relevant relationships reported)

Previous studies have examined the relationship between muscle activities during a single leg bridge (SLB) without including the gluteus maximus muscle (Gmax). Similarly, few studies have evaluated the influence of additional loading during a SLB. **PURPOSE:** To examine muscle activation levels of the Gmax, semitendinosus (ST), and the biceps femoris long-head (BFL) during SLB, and weighted single leg bridge (wSLB). **METHODS:** Two recreationally active college students (1 male; 1 female) were recruited for the study and were free of any muscle or orthopedic injuries. Surface electromyography (sEMG) were used to collect muscle activities. Maximal voluntary contractions (MVC) were collected for each muscle group prior to testing. Each participant performed three repetitions of both SLB and wSLB, following a pattern of 60 beats per minute (~2 beats up, ~3 beat hold, and ~2 beats down) which was verified using an electronic metronome. Data was collected and analyzed using a commercially available sEMG package. MVCs of each muscle were used to normalize the observed peak sEMG during the exercise. Peak root mean square (RMS) was obtained for each muscle and the peak RMS in SLB was set to 100% to provide a means of comparison. Burst threshold was defined as 10% of the observed peak value. This value determined the onset and offset of the muscle excitation. **RESULTS:** There was a 37.0 +/- 1.7 average difference in magnitude between the two exercises. The duration of activity of the Gmax, BFL, and ST during the unweighted trials were 4.0 +/- 1.25 seconds, 3.5 +/- 0.75s and 4.2 +/- 0.45s, respectively. Muscle activity duration remained unchanged in the wSLB in the Gmax and STN. However, there was an increase in BFL activity during the wSLB trials (4.0 +/- 0.7s). **CONCLUSION:** In the male participant, it was concluded that the main muscle activated during the original single leg bridge and the weighted single leg bridge was BFL. However, for the female participant, the main muscle was the STN. Muscle activation of the hamstring muscles increased as a whole from the unweighted exercises to the weighted exercise. As well as the duration of BFL activity. This study is preliminary and will be conducted at a larger scale in the future to enhance credibility and reliability.

The Influence of Menthol on Joint Range of MotionWilliam Staffiere, Jason Gillis, Michelle Varnell, Joseph Gallo, Kevin Silva, Jacob Moriarty. *Salem State University, Salem, MA.* Email: staffiere.w@husky.neu.edu*(No relevant relationships reported)*

PURPOSE: To use the known topical analgesic menthol to explore the influence of one's perception of muscle tension on joint range of motion (ROM). **METHODS:** This study received approval from the Salem State University Institutional Review Board. In a familiarization session, 15 participants first completed weight-bearing lunge (WBLT) and active ankle dorsiflexion (AADF) tests (Pre-test) to assess ROM in the soleus-gastrocnemius complex. Participants were always instructed to stretch to a 'maximal tolerable stretch'. They immediately then completed a 6x60s static stretching routine for the ankle plantarflexors, and again completed the WBLT and AADF tests (Post-test). These testing conditions established a control (CONTROL). On two separate occasions participants returned to complete the aforementioned pre-tests, immediately after which they had 5mL of a 4% menthol gel (M) applied to their soleus-gastrocnemius complex on one visit, and on the other visit they had 5mL of a Placebo gel (P) spread over the same area. Participants then

underwent the stretching routine and post-tests as previously described. The following measures were made during each test: ROM, thermal sensation (TS), thermal comfort (TC), electromyography (EMG), and the Hoffman reflex (HR). A two-way RM ANOVA detected differences between time (Pre vs. Post), condition (CONTROL vs. M vs. P), and any interaction, with post-hoc testing used to indicate directionality ($\alpha=0.05$).

RESULTS: Menthol significantly improved AADF ROM by 2.67 degrees compared to P ($p<0.001$), coinciding with significantly cooler sensations ($p<0.01$) and a loss of thermal comfort ($p<0.05$) with menthol. Similarly, menthol improved WBLT ROM by 2.98 degrees compared to P ($p<0.01$), coinciding with a significant loss of thermal comfort ($p<0.05$) with menthol.

CONCLUSION: Menthol appears to improve active joint range of motion during stretches that are held to a maximal tolerable tension. This suggests that one's perception of tension per se, rather than actual muscle tension, may be more important in determining maximal active joint ROM. It is not clear whether menthol achieves this by specifically reducing one's perception of muscle tension during a maximal stretch, or whether other sensory inputs arising from menthol i.e. TS, TC, divert attention from it.

Effect Of Chamois Design on Rider Comfort And Saddle Pressure During Sub-Maximal Cycling

Ross D. Wilkinson¹, Mason Marcus², Jason Williams², Todd Carver². ¹The University of Queensland, St Lucia, Queensland, Australia. ²Specialized Bicycle Components Inc., Morgan Hill, CA.

Email: r.wilkinson@uq.edu.au

(No relevant relationships reported)

Previous research on the link between saddle pressure, rider comfort and urological disorders have focused predominantly on saddle design, bicycle setup and workload. Yet, the effect of chamois design on saddle pressure and perceived comfort during cycling in both men and women remains unresolved.

PURPOSE: In this study we investigated the effects of chamois design on perceived comfort and peak saddle pressure during seated sub-maximal cycling in men and women. **METHODS:** Eighteen subjects (9 M; 9 F) participated in two separate protocols, one laboratory- and one field-based. The laboratory protocol required subjects to ride at 2.5 W.kg⁻¹ for 5 minutes using either a new (A) or old (B) chamois design. Saddle pressure was captured for 30 seconds during each trial. At the conclusion of each trial, subjects were asked to rate the chamois on seven different comfort categories (Overall Comfort, Genital Sensation, Genital Comfort, Sit Bone Comfort, Buttocks Comfort, Stability on the Saddle, Off Saddle Comfort). The field protocol required subjects to complete one week of regular cycling training in each chamois design and were asked to complete the same comfort questionnaire at the end of each week. A repeated measures, two-way ANOVA was performed to test for main and interaction effects (Chamois x Sex) on saddle pressure and each comfort category in both the laboratory and field study.

RESULTS: The laboratory protocol resulted in a significant main effect of chamois design on 'Overall Comfort' (A>B, $p<0.05$). The field protocol also resulted in a significant main effect of chamois design on 'Overall Comfort' (A>B, $p<0.05$) as well as 'Buttocks Comfort' (A>B, $p<0.05$). Peak saddle pressures were significantly higher in Chamois B than Chamois A (B=24.5±3.54 psi vs. A=23.06±3.53 psi, $p<0.05$). There was a significant main effect of Sex on Genital Sensation and Genital Comfort (Males>Females, $p<0.05$) under both laboratory and field conditions.

CONCLUSIONS: Chamois design is an important factor that affects both peak saddle pressure and perceived comfort for males and females during cycling. Innovation of future chamois designs should focus on providing individualized comfort for males and females. Further research is needed to investigate the possible link between chamois design and the development of urological disorders.

Effects of Bicycle Crank Length on Gross Efficiency, Power, and Joint Kinematics During Cycling Ergometry

Christiane R. O'Hara, Robert D. Clark, Kelly Bodwin, Cameron Swick, Natalie Grohmann, Austin Bohn, Ashley Shen. *California Polytechnic State University, San Luis Obispo, CA.* (Sponsor: Todd Hagobian, FACSOM)

Email: crohara@calpoly.edu

(No relevant relationships reported)

PURPOSE: To determine the effects of six different crank lengths (150, 165, 170, 172.5, 175, and 180 mm) on gross efficiency, maximum power, optimal pedaling rate (cadence at maximum power), and joint kinematics of the hip and knee.

METHODS: Elite level cyclists (n = 18) participated in two visits to the Cal Poly Cycling Lab. The purpose of the first lab session was to measure VO₂ peak (60.6 ± 7.6 mL·min⁻¹·kg⁻¹), participant characteristics (28.2 ± 5.3 yrs; 175.6 ± 7.4 cm; 70.5 ± 5.3 kg; 255 ± 105 km/week), and complete familiarization trials with four different crank lengths. These practice trials consisted of 4 second seated maximal sprints on the participant's original crank length (170, 172.5, or 175 mm) and three other crank lengths (150, 165, and 180 mm). The second test session was a single-blind randomized crossover design with the six different crank lengths. After a 5 minute warm up, participants performed a 3 minute steady state effort at 65% VO₂ peak and 90 rpm. This was followed by two maximum effort 4 second seated sprints with 90 seconds rest prior to each sprint. Participants rested for 5 minutes before the next crank length trial. **RESULTS:** During steady state cycling, shorter cranks had a higher gross efficiency (150 mm: 22.1%) compared to longer cranks (180 mm: 21.6%), ($p < 0.001$). No significant differences were found between crank lengths for maximum power output during the 4 second sprints. There was an increase in optimal pedaling rate between 150 mm cranks (130 rpm) and all other lengths (180 mm: 120 rpm) ($p < 0.001$). 150 mm cranks have a significantly smaller hip (45°) and knee (67°) range of motion than all other cranks measured (180 mm: hip 51°, knee 75°) ($p < 0.001$). **CONCLUSIONS:** Shorter cranks resulted in a significantly higher gross efficiency, smaller knee and hip range of motion, and a higher optimal pedaling rate.

Analysis of Kinematics And Electromyography of Cyclists In The Length of Handling

Pablo Rodriguez¹, Rodrigo Argotho², Jenner Cubides³, Sergio Cruz-Leon⁴. ¹Rosario University, Bogota D.C., Colombia. ²Biomechanics Laboratory - Sports Science Center, Bogota D.C., Colombia. ³Militar school of cadets "General José María Córdova, Bogota D.C., Colombia. ⁴Max Planck Institute of Biophysics, Frankfurt, Germany.

(No relevant relationships reported)

PURPOSE: The cyclist's accommodation on the bicycle is essential to avoid injuries and improve performance. The adjustment of the handlebar range of the bicycle can have similar or contrary effects to the horizontal adjustment of the saddle. The backward position generates pelvic anteversion, decreased hip angle, greater activation of the hamstring muscles, plantar flexors and greater tibio-femoral shearing force. On the other hand, the forward position of the saddle generates retroversion of the hip, increase in the angle of the knee, decrease in the activation of the hamstrings and increase of the strength in the quadriceps and can generate patello-femoral pain.

PROPOSITION: Evaluate the variations in muscular activity and joint ranges of the lower extremities in the cycle of pedaling, by changing the length of the handlebar reach in amateur cyclists

METHODS: Eight male cyclists (Age: 41.75 ± 10.08 years; Weight: 72.56 ± 5.53 Kg) of right predominance were measured. The hip, knee and ankle joint angles (three-dimensional kinematics) and muscle activity of the Biceps Femoral, Lateral Gastrocnemius, Lateral and Medial muscles (surface electromyography) and the adjustment of their bicycles in three handlebar lengths were recorded: a) preferred, b) advanced (preferred + 3 centimeters) and c) delayed (preferred - 3 centimeters). It was carried out two stress tests one of incremental load of maximum power and another of constant load to 57% of the maximum power at 90 rpm

RESULTS: A variance analysis (ANOVA) finding differences in the activation units of the left lateral gastrocnemius muscle in the preferred position vs. back (0.34 vs. 0.18, $p = 0.042$) and between the position of the left hip at 150 ° between the forward vs. back position (96.64 vs. 101.20, $P = 0.05$).

CONCLUSIONS: The modification of the handlebar ranges of the bicycle from the preferred position to the backward one, produces an increase in the angle of the hip generating pelvic anteversion. This variation is presented at 150 degrees of the cycle of pedaling in the transition from maximum power to that of the bottom dead center, with the decrease in the activation of the left lateral gastrocnemius muscle.

240 Board #78 May 29 11:00 AM - 12:30 PM
Effects of Saddle Height and Workrate on Frontal Plane Knee Joint Biomechanics

Erik Hummer, Tanner Thorsen, Songning Zhang, FACSM.
 University of Tennessee, Knoxville, TN. (Sponsor: Songning Zhang, FACSM)
 Email: ehummer@vols.utk.edu
 (No relevant relationships reported)

Cycling is one of the most popular exercises for knee osteoarthritis (OA) or total knee replacement (TKR) rehabilitation. It is known for reduced loading to lower extremity joints compared to walking. One way to fit a bicycle to an individual is adjusting saddle height. There have been limited studies on effects of saddle height on frontal-plane knee joint loading.

PURPOSE: To determine the effects of saddle height and workrate on the knee joint biomechanics. **METHODS:** Fourteen experienced cyclists (age 50-70 years) were recruited from bicycle shops and clubs. Subjects participated in a single testing session that included six test conditions of three saddle heights at two workrates. Saddle heights were set at 20°, 30°, and 40° of knee flexion while the crank was at the bottom position. Workrate was electronically controlled at 80 and 120 watts. Three-dimensional kinematic (240 Hz, Vicon) and pedal reaction force (1200 Hz, Customized instrumented pedal) data were recorded for five successful cycles in each condition. Joint kinematics and kinetics were calculated and compared using a 3x2 ANOVA and paired t-tests with a Bonferroni correction. **RESULTS:** There were no significant interactions or saddle height main effect for peak knee abduction moment. There was a significant effect of saddle height on knee extension ROM, peak knee extension moment, and peak knee flexion moment (all $p < 0.012$). The post hoc comparisons showed that the knee extension ROM was different from one another between 20°, 30°, and 40° saddle heights (80.1° vs. 73.7° vs. 67.6°, respectively). The peak knee extension moment for 20° saddle height (19.9 Nm) was different from 30° and 40° saddle heights (22.6 Nm and 23.6 Nm, respectively). Additionally, the peak knee flexion moment was different between all three saddle heights (-33.4 Nm vs. -23.4 Nm vs. -18.9 Nm). There was a significant workrate main effect on knee extension ROM, peak knee extension moment, and peak knee abduction moment (all $p < 0.008$). **CONCLUSIONS:** Although decreased saddle height increased the knee extension moment, the knee abduction moment was not affected. These results suggest that saddle height adjustment could be a potential and safe method to modulate knee joint loading without concern of impacting frontal-plane knee loading in rehabilitation for patients with knee OA or TKR.

241 Board #79 May 29 11:00 AM - 12:30 PM
Determining If A Bike-mounted Aerodynamic Sensor Can Detect Changes In Wheel Rolling Resistance During Cycling With Different Tire Pressures Outdoors

Tedd Girouard¹, Boram Lim¹, Cesar Nava¹, Chris Morton², John A. Mercer, FACSM¹. ¹University of Nevada, Las Vegas, Las Vegas, NV. ²University of Calgary, Calgary, AB, Canada. (Sponsor: John Mercer, FACSM)
 Email: tedd.girouard@unlv.edu
 (No relevant relationships reported)

Rolling resistance represents a key resistance force to overcome during cycling. This resistance force is calculated as the product of the coefficient of rolling resistance (Crr) and rider+bike system weight. Crr is influenced by a number of factors including tire pressure. Typically, Crr is measured in a laboratory situation but more recently, bike-mounted instruments have been developed that are mounted on a bike to measure Crr in the field. **Purpose** To determine if a bike-mounted aerodynamic sensor is able to measure changes in Crr with changes in tire pressure while cycling outdoors. **Methods** A cyclist rode a road bike (combined mass 80.45 kg) equipped with an aerodynamic sensor to measure Crr (Aerolab). The bike-mounted sensor measures a number of parameters such as wind speed, global position system (GPS) data, cycling power, and air temperature, for example. Processing algorithms are used to generate Crr. For this experiment, tire pressure was manipulated in a manner that changes in Crr were expected. Specifically, three tire pressures were tested: 100, 70, and 40 PSI. Tire pressure was measured using a custom made valve system connected to a digital pressure gauge (Ashcroft Digital Gauge, 0.05% terminal point accuracy, 0-200 PSI range). The rider completed 2 trials per pressure condition with each trial consisting of a coast-down test. The rider reached a target velocity and then stopped pedaling. Data were recorded for at least 60 seconds for each trial. The rider maintained the same ride position for each trial. Data were processed using custom software to yield Crr per trial using an iterative algorithm that calculates Crr multiple times using different sections of data with corrections for air temperature. The research team member processing data was not aware of the conditions. Crr values were normalized such that the Crr during the 100 psi condition was set to 100%. **Results** Relative Crr values were 100±2.7% at 100 psi, 95.7±1.8% at 70 psi, and 119.6±2.7% at 40 psi. **Conclusions** Using a bike-mounted aerodynamic sensor, changes in rolling resistance were detected when

tire pressure was manipulated. However, confounding factors that could influence the calculation of Crr include the influence of subtle changes in rider position, yaw angle, and tire temperature, for example.

A Comparison of Forehand Swing Biomechanics between Male and Female Tennis Players

Fahad Syed, Karen Myrick, Juan Garbalosa, Richard Feinn.
 Quinnipiac University, North Haven, CT.
 (No relevant relationships reported)

The forehand is a central component in modern tennis, being the most frequently used swing. However, in comparison to the serve, it has not been analyzed to the same degree under the focus of kinematics. Our study is the first to compare joint angular displacement between male and female athletes during the forehand swing. We selected the shoulder and knee joint as the areas of interest. **PURPOSE:** To compare shoulder and knee joint angular position of the forehand between male and female tennis players. **METHODS:** 7 male and 11 female NCAA tennis athletes participated. Subjects had retroreflective markers placed over bony landmarks. Data collection trials were recorded using an 8-camera motion analysis system. The first set of trials consisted of 7 topspin forehands struck at submaximal (sM) ball velocities, and the second set of trials consisted of 7 topspin forehands struck at maximal (M) ball velocities. A custom-made software was used to obtain the angular position of the shoulder and knee joint at the following 5 time points: 1) end of back swing; 2) lowest point; 3) ball contact; 4) midpoint of follow-through; 5) end swing. The four outcomes measured at each time point are: a) shoulder elevation; b) shoulder abduction; c) shoulder internal rotation (SIR); d) knee flexion (KF). A multilevel multivariate model was used and included fixed effects for the between-subjects factor sex, and the interaction between sex and velocity.

RESULTS: No significant effects for sex were found. For outcomes regarding interaction between sex and velocity: 1) during the end of back swing phase, men showed a greater change in KF from sM to M compared to women (-49.5 vs -59.5 vs -47.1 to -51.2 degrees, $p < 0.05$); 2) during ball contact phase, females showed greater change in SIR from sM to M (-56.3 to -66.9 vs -85.9 to -87.5 degrees, $p < 0.01$); 3) during ball contact phase, males showed less change in KF from sM to M (-26.5 to -26.7 vs -35.4 to -42.7 degrees, $p < 0.01$); 4) during midpoint of follow-through phase, men showed less change in KF from sM to M (17.7 to -20.0 vs -25.1 to -39.2 degrees, $p < 0.01$).

CONCLUSION: At similar velocities, shoulder and knee angular position do not vary significantly between male and female athletes. When transitioning from low to high velocity swings, significant change is found between sex during knee flexion and shoulder internal rotation.

Evaluation Of Shoulder Muscle Activity Patterns While Swimming In Triathlon Wetsuits

John Mercer, FACSM, Boram Lim, Cordero Roche, Andy Do.
 University of Nevada, Las Vegas, Las Vegas, NV.
 Email: john.mercer@unlv.edu
 (No relevant relationships reported)

During the swimming portion of a triathlon, athletes can use a wetsuit if water temperature is below a threshold value. There are two general categories of wetsuits: Full sleeve (FSW) and sleeveless (SLW). It is not known if the type of wetsuit worn influences muscle activity patterns. **Purpose** Compare shoulder muscle activity patterns while wearing different wetsuit designs. **Methods** Subjects (n=7; 45.7±8.0 yrs, 174.8±10.5 cm, 70.1±9.4 kg) completed three swim conditions on the same day: no wetsuit (NWS), FSW, or SLW. Rest was provided between conditions as needed. Muscle activity (posterior deltoid (PD), anterior deltoid (AD)) was measured (2000 Hz) using a water proofed electromyography (EMG) system (Cometa). After a self-directed warm-up, subjects swam a length of the pool at a 'somewhat hard' pace (25 m or 50 m depending on pool set up). EMG data were processed by removing any zero offset, calculating the absolute value, and smoothing (low-pass, cutoff frequency = 4 Hz). PD smoothed data were used to identify the beginning and ending points of five consecutive stroke cycles with extracted data time normalized. Pearson correlation coefficients (r) were calculated between NWS-FSW, NWS-SLW, and FSW-SLW for each extracted pattern data set per muscle with each r transformed to a Z-score. Z-scores and r were each compared between conditions using a 1 x 3 (wetsuit condition) repeated measures ANOVA ($\alpha = 0.05$). **Results** Neither r nor Z-score

for either muscle was influenced by wetsuit condition ($p>0.05$). PD EMG patterns were moderately correlated between conditions (NWS-FSW NWS-SLW FSW-SLW: $r=0.66\pm0.16$, 0.65 ± 0.16 , 0.62 ± 0.20) whereas strength of AD correlations were weak ($r=0.37\pm0.33$, 0.42 ± 0.19 , 0.39 ± 0.21). **Conclusion** Muscle activity patterns of PD were more strongly similar than AD between swimming without a wetsuit then with a wetsuit as well as between wetsuit conditions. The weaker AD correlations between conditions may be influenced by horizontal position due to buoyancy force and/or possible resistance to shoulder movements of the wetsuit.

Comparison Of Torques And Positions Of The Half And Full Golf Swing - A Pilot Study

Audrey L. Millar, FACSME, Chris Wendt, Dexter Perkins, Dustin Sellers. *Winston-Salem State University, Winston-Salem, NC.*
 Email: millaral@wssu.edu

(No relevant relationships reported)

PURPOSE: A concern for healthcare workers is how to advise individuals wishing to return to golf following lower extremity (LE) injury or surgery. A common recommendation is to use a half swing, however, it is not known whether this truly reduces the motion or muscular torque for the LE. The purpose of this study was to examine the peak torques and positions of the hip during a half swing versus a full golf. **METHODS:** Five recreational golfers with handicaps ≤ 20 , both male and female participated. Participants completed 10 full swings and 10 half swings. A 10-camera motion analysis system, with force plates, was used to record swing data. Data was reduced using a 3-D modeling program and standard inverse dynamics were used to determine internal net joint torques. Peak torques are presented as Nm/%BW*Ht and peak position in degrees. Differences were considered significant at the .05 level of probability. **RESULTS:** Subjects average age was 33 ± 17 SD years. The highest torques for the full swing were produced for extension of the trail leg (10.32 ± 1.48), while the half swing trail hip extension torques averaged 8.62 ± 1.84 . This was followed by lead hip abduction, with means of 9.9 ± 2.81 and 7.55 ± 2.45 for the full vs half swing respectively. Significant differences for torques between the full and half swing included trail hip extension, internal rotation, and flexion, along with lead hip extension and abduction. The greatest peak positions were in trail and lead hip flexion, with values of $44.2 \pm 17.8^\circ$ and $40.4 \pm 17.3^\circ$ for trail hip flexion, and $47.8 \pm 20.3^\circ$ and $44.6 \pm 18.8^\circ$ for lead hip flexion. There were significant differences for the positions of trail hip flexion, internal rotation, extension, abduction.

CONCLUSIONS: The preliminary data show that using a half swing does reduce the amount of internal torque around the hip, as compared to a full swing. Interestingly, the changes in peak position of the hip joint and the torques do not appear to be consistent. Our findings showed a great deal of variability in the amount of movement at the joint both for the full and half swing, thus this may be a source of concern for clinicians. In addition, while some of the hip joint torques were reduced with the half swing, some of the torques were still much higher than previously reported torques for walking and activities of daily living.

Comparison of Single-Leg Hopping Parameters Across Different Artificial Turf Systems and Natural Turfgrass

Brandi E. Decoux, Christopher M. Wilburn, Nicholas H. Moore, Wendi H. Weimar. *Auburn University, Auburn, AL.*
 Email: bed0012@auburn.edu

(No relevant relationships reported)

During locomotion, leg spring parameters are adjusted to maximize efficiency and reduce injury risk based on the stiffness of the surface. **PURPOSE:** This study compared leg spring parameters during single-leg hopping on different modern sports turfs, including three artificial turf systems with different structural components and a natural turfgrass surface. **METHODS:** Seven participants (ages 19-30 yrs; height = 1.79 ± 0.08 m; mass = 75.9 ± 10.1 kg) were recruited for this study. Each participant performed three trials of single-leg hopping in place on each of the four surfaces at a self-selected pace. Kinematics were collected using the Xsens MVN Awinia inertial motion capture system. Data were then imported into Visual3D where estimated ground reaction force and subsequent leg spring parameters were computed. For each participant, vertical stiffness and hopping frequency data from three trials for each of the four surface conditions were included in the statistical analysis. **RESULTS:** A repeated-measures MANOVA indicated significant differences present between surface conditions for vertical stiffness ($F(6,15) = 3.48$, $p=.023$, $\eta^2 = .582$), with pairwise comparisons revealing vertical stiffness on turf 3 (18.3 ± 6.3 kN/m) to be significantly less than on turf 2 (20.6 ± 6.2 kN/m; $p=.023$) and natural turfgrass (21.6 ± 6.2 kN/m; $p < .01$). Hopping frequency was not significantly different between surface conditions. **CONCLUSIONS:** Modern artificial turf system innovations continue to utilize various structural components in an effort to reduce the overall stiffness of synthetic surface. However, it appears that individuals still interpret some artificial turfs to be stiffer than alternatives and therefore lessen the vertical stiffness of their leg spring while maintaining their preferred self-selected hopping frequency.

Injuries In Lower Legs Related To The Unipodal Dynamic Stabilization

Alba Lopez¹, Rodrigo Argothy², Jenner Cubides³, Daniel Cohen¹.
¹Rosario University, Bogota D.C., Colombia. ²Biomechanics Laboratory - Sports Science Center - Coldeportes, Bogota D.C., Colombia. ³Militar school of cadets "General José María Córdova, Bogota D.C., Colombia.
 (No relevant relationships reported)

PURPOSE: The instability of the knee and ankle joints are the main risk factors for injuries of the musculoskeletal system and soft tissues when they are subjected to high training loads, as is the case of the military in initial training. The lower train is subjected to accelerations, decelerations, changes of direction and jumps that involve high loads that must support the most distal and intermediate joints in order to absorb the impacts. The measurement of stability is routinely used to measure the risk factors of injury to the ankles and knee, being the most frequent in military training. **PURPOSE:** To determine the risk of lower train injury in Colombian military personnel by analyzing the dynamic stability

METHODS: cross-sectional study in a cohort of 124 cadets. Of the participants in the study 87 (70.2%) were men and 37 women (29.8%), with an average weight of 62 ± 9.2 kg, age 18 ± 1 years, height of 1.70 ± 0.08 meters, which was admitted in the military school in 2017. The measurement of the unipodal dynamic stability was made by using uniaxial force platform. The variables were measured as a percentage of asymmetry of the dynamic stabilization time (26.24 ± 18.86 %) and percentage of asymmetry of the force peak in the landing (28.59 ± 17.62 %).

RESULTS: Of the total number of subjects, 41 presented lesions in the lower limbs during follow-up, corresponding to 33.1%. The logistic regression model developed to determine the risk factors associated with injuries in lower limbs, presented a significance of the model of $P = 0.017$, with a probability of success of 70%. The variables: Body mass index (OR 1.001, 95% CI 0.843 - 1.181), gender (OR 2.709, 95% CI 1.15 - 6.37), the difference of the right-left stabilization time (OR 6.66, 95% CI 1.33 - 32.14), the percentage of asymmetry of the stabilization time (OR 1.021, 95% CI 0.999 - 1.043), the percentage of asymmetry of the peak force (OR 1.015, 95% CI 0.977 - 1.055), are those that best predict the model.

CONCLUSIONS: The stabilization time is a strong predictor of risk factors for lower train injuries. Likewise, gender and dominance of the lower limb are determining factors in the development of injuries under military training. Based on the results, it is considered a tool that can help to measure the risk factors in the military population in training and the controls throughout their training.

Changes In Complexity At Maximal Speeds May Not Influence Functional Performance Immediately After: Pilot Study

Jacqueline Morgan¹, Alexis Nelson², Megan Briley², Max Paquette², Douglas Powell, FACSME². ¹Virginia Commonwealth University, Richmond, VA. ²University of Memphis, Memphis, TN.
 (No relevant relationships reported)

Regulatory statistics have been previously used to quantify nonlinear characteristics of gait and infer changes in central regulation of movement. Evaluating changes in movement complexity under varying running conditions is essential as alterations in central regulation may influence performance. However, few studies have characterized movement complexity during functional performance tests. **PURPOSE:** To quantify changes in complexity during an incremental running test to max speed, and during a single leg hop (SLH) test performed immediately before and after.

METHODS: Seven healthy runners (25.8 ± 4.9 yrs) performed a 30s SLH test before and after an incremental running test on a motorized treadmill using 4-minute stages (preferred, 10, 12, 14, 16, 18km/h) until volitional exhaustion. Three-dimensional accelerations of the pelvis were recorded using a triaxial accelerometer (100Hz, G-Walk, BTS Bioengineering, Milan, IT) fixed to the pelvis. The last 30s of each running speed and SLH were analyzed using multiscale entropy (MSE) across 5 time scales. Sample entropy estimates ($m=2$, $r=.2$) for each scaled time series were summed across all scales to compute complexity index (CI). Paired t-test were employed to compare CI measured from SLH tests and repeated measures ANOVAs with a Bonferroni correction were employed to compare differences in CI between stages for each participant. If significant, Dunnett's test was employed to compare fastest and slowest stages with preferred. Vertical accelerations are reported. **RESULTS:** Testing was completed by runners as follows: stage 4 N=7, stage 5 N=5, stage 6 N=3. Mean differences in CI were significant for 4 of 7 runners ($p<0.007$). Post hoc analyses revealed greater CI in the final stage versus preferred ($\Delta 0.62 \pm 0.1$; $\Delta 1.11 \pm 0.01$; $\Delta 0.35 \pm 0.03$; $\Delta 0.49 \pm 0.07$, $p<0.01$) while no differences were observed in the slowest stage. No change in SLH CI was found between pre- vs post-run tests ($p=0.33$,

2.25±0.9 vs 2.14±0.7). **CONCLUSION:** At maximal speeds, an increase in system adaptability was observed compared to preferred running, however, this increase was not transferred to functional performance immediately after. An increase in complexity during perturbed running and not hopping may be due to dissimilarities in task difficulty and constraint type experienced by the runners.

Muscle Activity Magnitude and Patterns During Plyometric Exercise on Land and in Shallow Water
 Cordero D. Roche. *University of Nevada, Las Vegas, Las Vegas, NV.* (Sponsor: John Mercer, FACSM)
 Email: cdroche89@gmail.com
 (No relevant relationships reported)

PURPOSE: The aim of this study was to compare muscle magnitude and patterns of key lower extremity muscles while performing plyometrics on land and in shallow water. **METHODS:** 10 Subjects (7 males; age:28.6±6.3 yrs, height:69.4±2.9 in, mass:82.1±8.4 kg, 3 females; age:45.7±6.8 yrs, ht:69.6±3.2 in, mass:84.2±8.3 kg) performed two plyometric exercises (countermovement jump (CMJ), drop jump (DJ)) while in two different environments (on land, in shallow water). A water proof electromyography (EMG) system (Cometa Miniwave Infinity, 2000 Hz) was used to record the signals of the muscle activity. Each sensor measured EMG as well as accelerations (3 dimensions). Four muscles (rectus femoris (RF), bicep femoris (BF), gastrocnemius (GA) and tibialis anterior (TA)) were used to capture EMG data. DJ trials were initiated from a 30.5 cm platform and order of conditions was always land followed by water. Depth of water was set to go no higher than xiphoid process level and no lower than the navel while standing. **DATA ANALYSIS:** Resultant acceleration was calculated for each sensor with a composite score calculated as the sum of the resultant acceleration for all sensors. This signal contained a peak upon initiating movement and a peak upon landing to end the movement. These peaks were identified, and EMG data were extracted 0.25 s before and after these discrete events to represent beginning and ending of analysis. Average (AVG), root mean square (RMS) and movement time were each calculated between the two extraction points. AVG, RMS, and movement time were each analyzed using a 2 (jump type) x 2 (environment) repeated measures ANOVA ($\alpha=0.05$). **RESULTS:** EMG (AVG or RMS) was not influenced by the interaction of environment and jump type ($p>0.05$); nor was there a main effect for jump type or environment for any muscle that was measured ($p>0.05$). However, BF_{AVG} was different for jumps regardless of environment ($p>0.05$). **CONCLUSION:** Muscle activity magnitudes appears to not be influenced between environments for CMJ and DJ for any of the four muscles measured.

Influence of Testing Position on Hip Torque and Relationships with Frontal Plane Kinematics in Females
 Neal R. Glaviano, David M. Bazett-Jones. *University of Toledo, Toledo, OH.* (Sponsor: Christopher Ingersoll, FACSM)
 Email: neal.glaviano@utoledo.edu
 (No relevant relationships reported)

The relationship between hip extension, abduction, and external rotation torque has been correlated to frontal plane biomechanics during functional tasks like the single leg squat. Altering testing position has been identified to influence torque output for hip extension, abduction, and external rotation. However, comparing the relationship between hip torque at different testing positions and frontal plane hip and knee squatting kinematics has yet to be evaluated.

Purpose: To assess the influence of testing position on hip extension, abduction, and external rotation torque in females and relationships to frontal plane squatting kinematics. **Methods:** Isometric hip torque was assessed in 19 college aged females at varying degrees of hip flexion. Torque was assessed with hand-held dynamometry for hip extension (0, 45, and 90 degrees of hip flexion); hip abduction (-5, 0, and 45 degrees of hip flexion); and hip external rotation (0, 45 and 90 degrees of hip flexion). Five single leg squats were also completed for 2-dimensional analysis of frontal plane hip and knee kinematics. Repeated measures ANOVAs were used to evaluate differences in hip torque across testing positions. Relationships between hip torque and frontal plane hip and knee kinematics during a single leg squat were explored with correlations. Significance was set at $p<0.05$. **Result:** Greater torque was seen during hip extension at 90 degrees of hip flexion ($0.74\pm0.25\text{Nm/kg}\cdot\text{m}$) compared to both 0 ($0.43\pm0.14\text{Nm/kg}\cdot\text{m}$) and 45 ($0.50\pm0.19\text{Nm/kg}\cdot\text{m}$) degrees of flexion ($p<0.001$). A significant decrease in hip abduction torque was seen at 45 degrees of hip flexion ($0.44\pm0.15\text{Nm/kg}\cdot\text{m}$) compared to both -5 ($0.58\pm0.21\text{Nm/kg}\cdot\text{m}$) and 0 ($0.63\pm0.24\text{Nm/kg}\cdot\text{m}$) degree testing position ($p<0.001$). No differences in torque were seen for hip external rotation. Significant, positive, and moderate correlations were seen with hip extension torque and hip adduction kinematics at 90 degrees of hip flexion ($r=.544$, $p=.016$) compared to 0 ($r=.490$, $p=.033$) and 45 ($r=.477$, $p=.039$) degrees of hip flexion. No significant correlations were seen between squatting kinematics and hip

abduction or external rotation torque. **Conclusion:** Testing position alters hip torque in healthy aged females but does not influence the relationship between torque and lower extremity kinematics of a single leg squat.

Descriptive Kinetics on Unique Skills Performed by a Professional Acrobatic Artist
 Alina P. Swafford, Cordero D. Roche. *University of Nevada, Las Vegas, Las Vegas, NV.* (Sponsor: John A. Mercer, FACSM)
 (No relevant relationships reported)

Acrobatic performers are in essence professional athletes who are employed in the entertainment industry for a vast amount of time. However, there is limited research examining skills through a biomechanical lens. Challenges with analyzing these skills include that the movements can be quite unique to an artist and/or highly complex movement patterns. There may be some insight gained by examining certain basic components of a skill (e.g., landing) that may give some relevance to overall performance. However, there is limited research describing the entirety of a specific movement skill. **PURPOSE:** To describe peak forces during certain acrobatic skills performed by a professional artist. **METHODS:** A professionally trained male subject (age: 24 yo; mass: 65.8 kg) participated in this study. The subject visited the laboratory on one occasion where he performed eight different acrobatic skills. Data collection consisted of the subject performing the movements on top of two force platforms (Kistler) and recording full body kinematics using a 3D motion capture system (Vicon). Each movement was performed twice with some movements including multiple repetitions of a skill (e.g., one-hand hops). In movements that included at least four repetitions, peak forces were identified and averaged. In movements where only two repetitions were recorded, maximum peak force of the repetitions was described. Kinematic data were used to identify which body part was in contact with the ground that corresponded to a particular force peak. **RESULTS:** Average peak forces were: one hand hop hand 3.60 ± 0.10 BW, air chair (hand) 1.92 ± 0.13 BW, air chair (head) 3.64 ± 0.57 BW, and flare 2.54 ± 0.43 BW. Peak forces for jump/land tasks for jump and landing phases: maximum vertical jump 3.08 BW (jump), 5.80 BW (land), front flip 2.22 BW (jump), 10.97 BW (land), back flip 2.88 BW (jump) 11.94 BW (land), single leg jump right leg 2.29 BW (jump) 4.07 BW (land), and single leg jump left leg 2.27 BW (jump) 4.20 BW (land). **CONCLUSION:** Interestingly, peak forces during movements where the hand or head were in contact with the ground were similar in magnitude with landing on the feet from a vertical jump. The collection of these data could be helpful for these types of athletes for injury prevention, enhance performance of these skills or overall performance.

The Analysis Of The Neuromuscular Performance Of The Colombian Military Leap
 John E. Rincon¹, Rodrigo Argothy², Jenner Cubides³, Daniel Cohen¹. ¹Rosario University, Bogota D.C., Colombia. ²Biomechanics Laboratory - Sports Science Center - Coldeportes, Bogota D.C., Colombia. ³Militar school of cadets "General José María Córdova, Bogota D.C., Colombia."
 (No relevant relationships reported)

PURPOSE: Musculoskeletal system injuries associated with military training are one of the major problems that military institutions must confront, due to the high costs. The training programs that are carried out during the initiation of the military, prove the increase in injuries that occur in the first six (6) months of admission. In which the risk factors that provoke it, are not yet clear. As a matter of fact, asymmetries are one of the main risk factors that alter the mechanics of the neuromuscular system. These changes affect the performance and favor the appearance of musculoskeletal injuries that can be acquired by training, or that could have been present in the military before incorporation. Aim, to determine the relationship between the asymmetries and the countermovement jump test with the performance of the lower train. **METHODS:** First, a cross-sectional study in a cohort of 124 cadets (94 men and 32 women) with an average weight of 61.6 ± 10.1 kg, through ages 18 ± 1 years all of whom entered the military school in year 2017. Second, a measurement of the countermovement jump test was performed using uniaxial force platforms. Specifically, variables including peak power (43.74 ± 7.8 watts), jump height (28.29 ± 6 cm), asymmetry of the landing peak ($17.9 \pm 14\%$), percentage of the asymmetry of the concentric average force ($7.1 \pm 5.3\%$) and finally, the asymmetry of the Rate of Force Development (RFD) in the eccentric deceleration ($15.9 \pm 11.5\%$).

RESULTS: Over a comparison of genders, differences in weight 64 vs 54 kg, $p = 0.05$ and jump height (30.7 vs 21.07 cm, $p = 0.001$) were found. By segmenting the database into terciles in the percentage of asymmetry of the Rate of Force Development (RFD) of the eccentric deceleration, differences were found in the personnel. Explicitly, asymmetries bigger than 21% ($\chi^2 p = 0.05$), among the subjects that presented injuries in legs.

CONCLUSIONS: An association was found between the performance variables of the countermovement jump that determine the baseline status of the incoming soldiers,

leading to the findings of reference values of the asymmetries in the Colombian military population. Particularly, the eccentric deceleration TDF was used as a reference marker to evaluate injury risk factors and neuromuscular performance in Colombian military.

Gender Differences Between Muscle Activation during Star Excursion Balance Test on Stable Versus Unstable Surfaces

Navpreet Kaur, Kunal Bhanot, Germaine Ferreira. *University of Saint Augustine for Health Sciences, AUSTIN, TX.* (Sponsor: Dr. John Mercer, FACSM)
 Email: nkaur@usa.edu
 (No relevant relationships reported)

Anterior (A), posteromedial (PM), and posterolateral (PL) directions of Star Excursion Balance Test (SEBT) are used for rehabilitation. Adding unstable surface to the task has been reported to change electromyographic (EMG) activity. Studies have also reported differences in EMG between males and females. **PURPOSE:** To compare EMG of lower extremity (LE) muscles between males and females during SEBT on stable and unstable surfaces. **METHODS:** Surface EMG was collected on 10 male and 10 female healthy adults for gluteus maximus, gluteus medius (GMED), medial hamstrings, biceps femoris (BF), vastus medialis (VM), rectus femoris (RF), vastus lateralis (VL), anterior tibialis (AT), and medial gastrocnemius (MG) on the stance leg during SEBT. Unstable surface was introduced using Theraband™ stability trainer. Independent t test assessed differences in EMG between males and females for each direction and each muscle during SEBT for both stable and unstable. Paired t tests were run separately for males and females to determine difference in each direction for each muscle between stable and unstable surface with α at 0.05. EMG were reported as the percentage of the maximal voluntary isometric contraction (%MVIC). **RESULTS:** Females showed significantly higher EMG than males for AT in PL direction (63 ± 14 vs 47 ± 12 %MVIC; $P=0.01$) on stable surface and A (63 ± 14 vs 47 ± 12 %MVIC; $P=0.01$) and PL (64 ± 15 vs 47 ± 14 %MVIC; $P=0.02$) directions on the unstable surface and MG in PM (44 ± 17 vs 25 ± 17 %MVIC; $P=0.02$) direction on stable surface and A (62 ± 23 vs 37 ± 20 %MVIC; $P=0.02$), PL (76 ± 29 vs 45 ± 25 %MVIC; $P=0.02$), and PM (58 ± 26 vs 36 ± 20 %MVIC; $P=0.04$) directions on unstable surface. EMG was higher for unstable surface in females for VM, RF, and VL in the A direction ($p \leq 0.05$) and MG in all three directions ($p \leq 0.05$) and in males for GMED, VM, RF, VL in the A direction ($p \leq 0.05$) and BF and MG in the PM direction ($p \leq 0.05$). **CONCLUSION:** Females produced higher muscle activation than males for ankle muscles. Adding unstable surface increased LE muscle activation during SEBT. Due to gender differences and surface variability in EMG during SEBT clinicians could consider incorporating both stable and unstable surfaces during rehabilitation especially for women to reduce ankle injuries.

Influence of Turf Surface on Change of Direction Parameters

Wendi Weimar, Brandi Decoux, Nicholas Moore, Christopher Wilburn. *Auburn University, Auburn, AL.*
 Email: weimawh@auburn.edu
 (No relevant relationships reported)

The surface over which people complete sports tasks can influence body posture and performance outcomes. **PURPOSE:** This study compared time to complete a change of direction agility drill and stopping strategies during this drill on different modern sports turfs, including three different artificial turf systems (AS1, AS2, AS3) and a natural grass surface (NS). **METHODS:** Six participants (ages 19-30 yrs; height = 1.79 ± 0.08 m; mass = 75.9 ± 10.1 kg) were recruited and provided voluntary consent. Each participant performed three trials of a 5-10-5 agility drill on each of the four surfaces, as quickly as possible. A Fitlight® timing tool was used to collect the performance measure of time to complete the task. The segment positions were collected using the Xsens MVN Awinda inertial motion capture system and the variable of angle between sacrum, heel and ground (SHAng) was determined through Visual3D for the plant leg. **RESULTS:** The data from three trials for each participant, for each surface, was included in the statistical analysis. The repeated measures ANOVA for each variable yielded significant differences between surfaces. Pairwise comparisons indicated that change of direction time on AS1 (4.70 ± 0.14 s) was significantly less than on AS3 (4.83 ± 0.28 s; $p=0.007$) and NS (4.83 ± 0.30 s; $p=0.014$). In addition, SHAng 5 on NS (39.0 ± 4.7 deg) was significantly larger than on all artificial surfaces (AS1: 35.1 ± 3.8 deg, $p=0.014$; AS2: 34.9 ± 2.5 deg, $p=0.002$; AS3: 35.4 ± 3.6 deg, $p=0.019$). Last, SHAng 10 on NS (38.5 ± 4.5 deg) was significantly larger than on all artificial surfaces (AS1: 35.7 ± 2.9 deg, $p=0.024$; AS2: 35.7 ± 2.4 deg, $p=0.022$; AS3: 36.1 ± 2.5 deg, $p=0.028$). **CONCLUSION:** This project indicates that these participants adopted a different stopping strategy on the natural surface than the artificial surfaces. To mitigate the lower resistance to shear forces offered by natural grass, the participants adopted a more upright body position, presumably increasing the normal force as well

as the friction utilized at the foot-to-ground interface. Assuming adequate friction is maintained, a smaller SHAng and thus lower body position will provide for an increase in propulsive forces resulting in a faster change in direction and better performance outcome.

Kinetic Strategies during Single-Leg Hopping in Individuals With and Without Chronic Ankle Instability

Hiroshi Sagawa¹, Adam E. Jagodinsky¹, Mohammed Zaman¹, Christopher Wilburn², Wendi H. Weimar². ¹*Illinois State University, Normal, IL.* ²*Auburn University, Auburn, AL.*
 (Sponsor: David Thomas, FACSM)
 (No relevant relationships reported)

Adaptability of the motor system indicates successful management of chronic ankle instability (CAI). Research shows that individuals who do not exhibit residual symptoms following an ankle sprain (i.e. copers) exhibit greater adaptability during walking compared to individuals with CAI. However, questions remain surrounding systemic differences exhibited by coper groups, particularly when higher movement demands are imposed on the system. Analysis of load acceptance patterns during single-leg hopping could provide an indication of the systemic movement adaptations between the groups during higher demands of movement tasks.

PURPOSE: Examine percent contribution (%C) to support moment (MS) during single-leg hopping in healthy, coper, and CAI groups.

METHODS: 48 individuals (16 per group) participated in the study. Participants performed 15 trials of single-leg hopping. Position data were collected using a motion capture system, and reaction forces were obtained from force platforms. Joint kinetics were calculated using inverse dynamics, and the MS was calculated as the sum of the ankle (A), knee (K), and (H) moments in the sagittal plane. The %C of the A, K, and H moment to MS was calculated at 15 percent of stance phase. A one-way ANOVA was conducted to assess group effects for each dependent measure.

RESULTS: No significant differences in %C to MS were found between the healthy (A 81.87±18.37%, K 23.81±16.96%, H 2.22±27.19%), coper (A 73.78±23.33%, K 28.28±21.05%, H -6.51±33.17%), and CAI groups (A 83.76±17.91%, K 16.48±12.58%, H 0.78±19.71%) during the initial loading phase of single-leg hopping.

CONCLUSIONS: Copers did not exhibit distinct kinetic patterns during single-leg hopping. This finding suggests that adaptation of movement is less likely to occur with higher demands of movement tasks following ankle injury. It is also possible that low amplitude COM displacement associated with the hopping task may not have placed adequate constraint on the subjects to elicit adaptive strategies. More research is needed to explore how individual joint kinetic adaptations contribute to dynamic tasks across groups.

Biomechanics of Pitching: Horizontal Abduction Predicts Power; Power Predicts Strikeouts and Wins

William P. Lydon, J. Mark Van Ness, Courtney D. Jensen.
University of the Pacific, Stockton, CA.
 (No relevant relationships reported)

Traditional strength training for pitchers focuses on compound lifts, predominantly of the lower extremity, to increase pitching power. Though widely employed, this approach has not been sufficiently validated. **PURPOSE:** To evaluate both predictors and consequences of increased mechanical power in collegiate pitching. **METHODS:** 10 pitchers from a D1 baseball program underwent 4 days of assessment separated by at least 3 days of rest: 1) Squat max was performed and recorded. 2) Sparta force plate (Sparta Science, USA) captured load, explode, and drive. 3) Proteus (Boston Biomotion, USA) measured power and endurance in 10 movements: Left and right core rotation, internal and external rotation, shoulder flexion and extension, elbow flexion and extension, and horizontal adduction and abduction. 4) Proteus recorded throwing mechanics via 5 sets of pitches (4 reps per set) at varying loads of magnetic resistance, ranging from 1-5lbs. For all movements, Proteus calculated and exported power and endurance in 3D space. Linear regressions identified predictors of pitching power and the effect of power on pitching performance. Owing to the small sample and novel technology, trends ($p < 0.08$) were considered. **RESULTS:** Mean pitching endurance did not significantly predict strikeouts or wins. Mean pitching power predicted greater win percentage ($R=0.734$; $p=0.024$), total strikeouts ($R=0.662$; $p=0.052$), and strikeouts per game ($R=0.656$; $p=0.055$). No associations were found between Sparta data or squat max and win percentage or strikeouts. Pitching power had no relationship with Sparta data, squat max, height, weight, class year, or arm length. The strongest predictors of pitching power were horizontal abduction endurance in the dominant arm ($R=0.941$; $p=0.002$) and non-dominant arm ($R=0.934$; $p=0.002$). Strikeouts per game was related to win percentage ($R=0.680$; $p=0.044$).

CONCLUSION: Power was the most important predictor of on-field pitching performance. It was unrelated to anthropometric variables and showed no association with minor differences in maturation (e.g., freshman to sophomore). There was also

no association with force plate and squat performance. These preliminary data suggest training horizontal shoulder abduction may correspond to power; in turn, power appears to increase strikeouts and win percentage.

The Landing Error Scoring System (LESS) is a protocol designed to assess ACL injury risk, and the LESS-RMC (Rocky Mountain Consortium) is a modified version of the LESS designed to be a more objective approach to scoring, and an easier tool to implement for the rater. **PURPOSE:** The purpose of this study was to determine the relationship between the LESS and LESS-RMC and develop an injury risk stratification for the LESS-RMC. **METHODS:** One hundred seventy-eight elite female soccer athletes (14.1 ± 1.5 y, 77.3 ± 33.2 in, 107.6 ± 27.2 lbs), performed three drop-jumps from a height of 30 cm. Front and side views of the landing were recorded with digital video cameras. Movement quality was rated by one researcher evaluating 17 components of the landing with the LESS and a modified, 11 component version of the LESS (LESS-RMC). Each system had a maximum of 17 landing errors and the rater was considered an expert after training with the LESS and LESS-RMC protocols. To accomplish the objectification of the LESS items, cut off points were defined more explicitly for line items: symmetry in feet, joint displacement, and overall impression. These changes, combined with a differentiating score of knee valgus severity/medial knee position (MKP) and its contribution to a new line item, overall asymmetry, added a new component to the LESS's approach to scoring movement quality and assessing injury risk. A one-way ANOVA was used to contrast the number of landing errors determined from the LESS and LESS-RMC. A linear regression was used to determine the relationship between the two scoring system and a LESS value of 5 was used as input to calculate a predicted risk stratification for the LESS-RMC. The alpha level was set at p=.05. **RESULTS:** The number of identified landing errors captured with the LESS-RMC (6.9 ± 2.2) was statistically greater than the LESS (5.6 ± 2.1) (p<.001). A significant linear relationship was found between the LESS and LESS-RMC (R=0.811, Adj R²=.656, SEE=1.59, p<.001). A LESS-RMC cut-off score for the stratification of low and high knee injury risk was calculated to be 6.79. **CONCLUSIONS:** The bi-lateral assessment of MKP and overall asymmetry were significant variables that contributed to higher risk stratification scores with the LESS-RMC.

Association Between Lower Extremity Functional Tests and Injury in Division I Female Collegiate Athletes
 Peter J. Lisman, Bethany Essalhi, Daniel C. MacLea, Nathan Wilder. Towson University, Towson, MD.
 Email: plisman@towson.edu
 (No relevant relationships reported)

The Landing Error Scoring System (LESS) and Single Leg Squat (SLS) are two clinical tools that have been used for screening of injury risk in athletic populations. Prior scoring of these tests was time intensive and required subjective judgement whereas new technology has allowed for automatic scoring and additional objective data. To date, we are unaware of any studies that have examined the association between LESS and SLS performance, as measured with a markerless motion-capture system, and future injury risk in athletes. **PURPOSE:** To examine the association between LESS and SLS performance and risk of lower extremity musculoskeletal injury (LE-MSKI) in female collegiate athletes. **METHODS:** Fifty-six collegiate female athletes (n=31 lacrosse; n=25 field hockey; 19.5 ± 1.4y; 165.6±8.1cm; 67.1±9.6kg) underwent LESS and SLS testing before the start of their 2017-18 competitive seasons. Incidence of LE-MSKI was tracked throughout the season. Participants completed 3 jump landing tasks followed by 3 consecutive SLSs on each leg. A Microsoft Kinect sensor using Athletic Movement Assessment software (PhysiMax®) was used to automatically score the LESS and SLS. The LESS consisted of 22 items while the SLS was comprised of 14 items. The highest scores possible for the LESS and SLS were 22 and 10, respectively. Independent t-tests were used to compare LESS and SLS total scores between injured and non-injured participants. Chi-square statistics were used to examine the association between injury risk and presence of medial knee displacement (MKD R/L side errors) during performance of the SLS and LESS. **RESULTS:** No differences were found between injured and non-injured participants in total LESS (5.1±2.2 vs. 5.2±2.1; p=0.900) and right-legged (4.0±2.1 vs. 3.4±1.2; p=0.273) or left-legged (3.4±1.2 vs. 3.9±0.9; p=0.107) SLS scores. Participants displaying an error for MKD during a right-legged SLS were roughly twice as likely to suffer a LE-MSKI as those with no error ($\chi^2=1.27$; p=0.260, OR=1.9,

95%CI=0.62-5.83). Similar results were found for participants who displayed MKD on their right leg during performance of the LESS compared to those with no error ($\chi^2=0.58$; p=0.444, OR=1.8, 95%CI=0.39-8.51). **CONCLUSION:** SLS and LESS performance was not associated with incidence of LE-MSKI in this cohort of female collegiate athletes.

Predicting Scapular Dynamic Alignment During Throwing From The Scapular Dynamic Alignment During Shoulder Abduction
 Hajime Toda, Yuki Nomura, Masaki Katayose. Sapporo medical university, Sapporo, Japan.
 Email: toda.h@sapmed.ac.jp
 (No relevant relationships reported)

Observing the resting and dynamic scapular alignments during basic shoulder motion is a common clinical evaluation for a throwing athlete. However, how much of the dynamic scapular alignment during throwing motion can be predicted from resting and dynamic scapular alignments during basic shoulder motion is unknown. **Purpose:** To investigate the relationship between dynamic scapular alignment during throwing motion and shoulder abduction and resting alignment. **Methods:** Ten baseball players without a history of shoulder pathology participated in this study. Scapular alignment was measured with a three-dimensional motion-capture system (VICON System) under three conditions: static standing position, abduction, and throwing motion. Scapular Cluster attached to the acromion was used to track the movement of the scapula. Multiple linear regression analysis was used to investigate the relationship between dynamic scapular alignment during throwing motion and shoulder abduction and resting alignment. **Results:** There was no relationship between dynamic scapular alignment during throwing motion and resting alignment. However, there was a relationship between several inclination variables of dynamic scapular alignment during throwing motion and shoulder abduction. The scapular posterior tilting angle at maximum external rotation (MER) of the shoulder during throwing motion decreased significantly with an increase in the scapular internal rotation angle during shoulder abduction (R² = 0.426; p = .034). In the same manner, the scapular internal rotation angle at MER and ball release during throwing motion increased significantly with an increase in the scapular internal rotation angle during shoulder abduction (R² = 0.4; p = 0.04, R² = 0.415; p = 0.036, respectively). **Conclusions:** Our results indicate that approximately 40% of the dynamic scapular alignment during throwing motion can be predicted by the dynamic scapular alignment during shoulder abduction. The dynamic scapular alignment during shoulder abduction should be given greater consideration when assessing a throwing athlete.

 (No relevant relationships reported)

PURPOSE: The purpose of this study was to determine the prevalence and effects of knee valgus asymmetry on the LESS score in young female soccer athletes. **METHODS:** A total of 178 elite youth female soccer athletes (14.1 ± 1.5 y, 77.3 ± 33.2 in, 107.6 ± 27.2 lbs) performed three drop-jump maneuvers from a height of 30 cm. Digital video cameras recorded (60 Hz) front and side views of the landing task. An expert rater evaluated 17 components of each recorded landing according to the LESS protocol. In addition, maximum medial knee position (MKP) was evaluated for each leg based on a straight line projection from the center of the patella to the ground. The MKP was scored as none (0), small (1) or large (2) if the line was lateral to the midfoot, between the mid-foot and great toe, and medial to the great toe, respectively. The LESS was calculated for dominant (DOM) and non-dominant (NON) legs for each landing trial. The DOM leg was defined as the leg used to kick a ball for greatest distance. Side-to-side MKP symmetry for each trial was calculated as the difference between the MKP category of the DOM versus the NON legs (dMKP). Negative dMKP values indicated larger MKP on the NON leg and were classified as small (dMKP= -1; -dMKP_s) and large (dMKP= -2; -dMKP_l), whereas positive dMKP values indicated larger MKP on the DOM leg and were classified as small (dMKP= +1; +dMKP_s) and large (dMKP= +2; +dMKP_l). The LESS scores for DOM and NON legs were grouped according to each non-zero dMKP category (-2, -1, +1, +2) and contrasted using independent t-tests with a Bonferroni adjustment (p=.0125). **RESULTS:** Asymmetrical MKP was found in 50.9% of the trials but the LESS scores were on average not different between legs (DOM, 5.6 ± 2.6; NON, 5.5 ± 2.7, p=.73). However, the LESS scores for the DOM leg were on average 1.3 ± 0.5 (-dMKP small: DOM, 4.9 ± 2.2; NON, 6.2 ± 2.0, p<.001) and 2.7 ± 0.5 (-dMKP_l: DOM, 3.4 ± 2.2;

WEDNESDAY, MAY 29, 2019

NON, 6.2 ± 1.9 , $p < .001$) landing errors lower when MKP was lower for the DOM leg; whereas landing errors were 1.2 ± 0.6 (+dMKP_s: DOM, 6.0 ± 2.1 ; NON, 4.8 ± 2.5 , $p < .001$) and 2.9 ± 0.3 . (+dMKP_l: DOM, 6.0 ± 1.9 ; NON, 3.1 ± 2.1 , $p < .001$) higher when MKP was higher.

CONCLUSIONS: The asymmetry in MKP influenced the LESS scores by 1 to 3 landing errors and has the potential to miss-classify an athlete's injury risk stratification.

 (No relevant relationships reported)

PURPOSE: Judo is one of the popular combat sports, which is played worldwide and organized even in the Olympic Games. Serious neck injuries, however, have been occasionally noted in judo trainings and/or competitions. Since the pattern and severity of neck injuries largely depend on the kinematic motion of the thrown player, it is essential to investigate the mechanisms of neck injury from biomechanical view point in various different throwing techniques. Thus, the aim of this study was to evaluate a predictive indicator of cervical spine injury, neck injury criterion (Nij) with direct head impact by Judo throwing techniques using an anthropomorphic test device (ATD).

METHODS: Two male judo experts (thrower) repeatedly threw the ATD for 5 times by *Seoi-nage* (*Seoi*), *Osoto-gari* (*Osoto*) and *Ouchi-gari* (*Ouchi*) techniques to make ATD's head hit directly to the mat. A 6-axis load cell (force transducer), mounted in the ATD's cervical spine, assessed neck axial force and bending moment in each trial. To evaluate the the ATD's neck load quantitatively, we calculated the Nij value from the neck axial force and bending moment. Kinematic data of the ATD's whole body were also recorded during trials, using high-speed digital video cameras.

RESULTS: In all trials, the largest neck loads were observed at the phase of the head contact to the mat. The peak Nij values of ATD ranged from 0.63 to 1.60 (*Seoi*), 0.54 to 0.58 (*Osoto*) and 0.19 to 0.29 (*Ouchi*). The average Nij value in *Seoi* (1.03 ± 0.19 , mean \pm S.E.) trials was significantly higher than those in *Osoto* (0.56 ± 0.01) and *Ouchi* (0.24 ± 0.02) trials ($p < 0.05$, respectively). In three out of five tests, Nij value in *Seoi* trial exceeded 1.0 implying the real human tolerance limit for neck loading. However, in other two trials (*Osoto* and *Ouchi*), Nij values were less than 1.0.

CONCLUSIONS: When thrown forward, the judo player might be accompanied with a direct contact of parietal and/or frontal regions of the head to the mat and suffered from neck injuries. Judo throwing technique, *Seoi*, has higher risk of serious neck injuries than the other techniques thrown backward including *Osoto* and *Ouchi*.

Comparison of Maximal Forces Produced During Different Chokehold Techniques

Andrew Craig-Jones¹, Damon McCune¹, Duncan French², Kyle Larimer², David Chuang¹, John Mercer, FACSM¹. ¹UNLV, Las Vegas, NV. ²UFC Performance Institute, Las Vegas, NV.
 (No relevant relationships reported)

Mixed martial arts (MMA) has become increasing popular in recent years, with some Pay-Per-View events gaining more than 1.6mil viewers (mmafighting.com). However, with its ever-growing popularity, little is known about kinetics involved with certain movements. **PURPOSE:** The purpose of this study was to compare maximal force production during three different types of MMA chokeholds. We hypothesized that each technique will have a different maximal force associated with it. **METHODS:** Elite MMA fighters ($n=8$; 1.77 ± 0.12 m; 83.70 ± 15.73 kg; 31.22 ± 4.21 yr) completed three chokehold technique conditions: Rear-Naked Choke (RNC), Armbar (AB), and Guillotine (G). Subjects completed 5 repetitions per technique and held each hold for at least 5 s. Each choke was performed on a grappling dummy commonly used in MMA training. A 30 s rest period was required between each repetition, and a 5 minute recovery period was required between conditions. The order of conditions was randomized. Force data were measured at the neck level of the dummy and were collected for the entire application of the choke. Force was measured using a 10cm x 10cm instrument (Loadpad, Novel Electronics USA, St.Paul, MN) secured to the neck portion of the training dummy using elastic bandages. The greatest 1 s average for each repetition was used for analysis. Within each condition, the 5 repetitions were averaged per subject. A repeated-measures ANOVA was used to compare force between conditions ($\alpha=0.05$). Planned comparisons were performed to assess which conditions were significantly different from the others. **RESULTS:** Maximal force was different between chokehold techniques ($F=6.20$, $p=0.012$). Maximal force was different between the RNC ($avg=457.37 \pm 220.51$ N) which produced a higher maximal force than AB chokehold ($avg=192.73 \pm 80.05$ N) ($p < 0.015$). No other

significant differences were found between these chokehold techniques and the G chokehold ($avg=265.37 \pm 164.25$ N) ($p > 0.05$). **CONCLUSIONS:** It is apparent that different chokehold techniques involve different force application. MMA fighters may need to train specific technique to increase force production or to resist forces when experiencing these chokeholds.

262 Board #100 May 29 9:30 AM - 11:00 AM
A Kinematic, Kinetic, and Electromyographic Comparison of "New" And "Dead" Pointe Shoes in Professional Ballet Dancers

Tal Amasay¹, Jessica Aquino¹, Jatin Ambegaonkar², Sue Shapiro¹, Yi-Tzu Kuo¹. ¹Barry University, Miami Shores, FL. ²George Mason University, Manassas, VA.
 (No relevant relationships reported)

Ballet dancers wear pointe shoes. As these pointe shoes gain more wear, the shoes may lose structural integrity, potentially altering the normal biomechanics of dancers while performing ballet movements. These alterations may negatively affect the ballet dancer, possibly resulting in harmful compensations and overall decreasing dancers' performance and increasing dancers' injury risks. Even so, little research exists examining pointe shoes.

PURPOSE: To compare lower body biomechanics and muscle activity between "new" and "dead" pointe shoes in professional female ballet dancers. **METHODS:** Nine professional female ballet dancers (age: 22 ± 2 yrs; height: 163 ± 6 cm; weight: 51 ± 7 kg), with at least 10 years of pointe shoe training and no limiting pain or injuries, performed three complete relevé and arabesques in "New" (3-36 training hours) pointe shoes and "Dead" (108-144 training hours) pointe shoes. Data were collected using force plate and 3D cameras. Separate ANOVAs compared (1) sway area during quiet stance, (2) peak net ankle joint moments, and (3) the average root mean square (RMS) muscle activity (%MVC) of the gastrocnemius and the tibialis anterior muscles between the shoe conditions. **RESULTS:** Dancers showed significantly higher sway area in the "dead" pointe shoes during both relevé (146 ± 115 mm² vs. 94 ± 58 mm², $p < 0.05$) and arabesque (191 ± 159 mm² vs. 112 ± 48 mm², $p < 0.05$). Dancers showed significantly higher tibialis anterior activation during arabesque in "dead" pointe shoes ($39 \pm 13\%$ vs. $33 \pm 7\%$, $p < 0.05$). No significant differences were observed in muscle activation for tibialis anterior during relevé and for gastrocnemius during relevé and arabesque ($p > 0.05$). No significant differences were observed in plantarflexion and dorsiflexion moments during relevé and arabesque ($p > 0.05$). **CONCLUSION:** Overall, we found that the biomechanical profiles presented by the dancers when wearing "dead" pointe shoes have been previously linked to increased risk for ankle instability, lateral ankle sprains, and earlier onset of muscle fatigue. Understanding how pointe shoe biomechanics changes over time may inform dancers, educator, researchers, clinicians, and pointe shoe designers how extended training in "dead" pointe shoes may potentially harm dancers' health.

Evaluating Segmental Contribution To Whole-body Center Of Mass Movement In Sub-maximal Overhand Throwing.

Jake Rosburg, Talin Louder. The University of South Dakota, Vermillion, SD.
 Email: jake.rosburg@gmail.com
 (No relevant relationships reported)

Recent advancements in wearable technology have allowed kinematic data collection in field-based settings, improving the ecological validity of research investigations. The wrench notation and quaternion algebra inverse dynamics technique does not require the integration of force platform data, therefore may allow field-based computation of joint kinetics for various sport movements, including overhand throwing. In order to apply this technique efficiently, it is important to understand segmental contributions to whole-body center of mass (CoM) movement. **PURPOSE:** Evaluate segmental contribution to the estimation of whole-body CoM movement both proximal and distal to the throwing elbow. **METHODS:** Three right-handed, male club baseball players performed forty trials of sub-maximal overhand throwing. Position data for each trial were acquired using a 3-d optical motion capture system and infrared reflective markers placed according to standard body segment parameter recommendations. From position data, segmental and whole-body CoM were computed for body mass positioned proximal and distal to the throwing elbow. Root Mean Squared Error (RMSE) values were computed using time-series position data between each segment CoM and whole-body CoM. Two one-way ANOVAs were performed on RMSE values in the x (direction of throw), y (perpendicular to the throw), and z (vertical) directions. To evaluate the movement of mass proximal to the throwing elbow, twelve body segments were included as levels within a single segment factor. To evaluate the movement of mass distal to the throwing elbow, two segments were included as levels within a single segment factor. **RESULTS:** Main effects of segment were observed for RMSE in the x, y, and z directions ($p < 0.001 - 0.001$). Trunk RMSE in the x, y, and z directions ($x: 40.5 \pm 7.4$ mm, $y: 28.9 \pm 5.2$ mm, $z: 9.5 \pm 4.0$ mm) was significantly

lower versus all other segments proximal to the throwing elbow ($p < 0.001 - 0.028$). Right forearm RMSE in the x, y, and z directions (x: 28.9 ± 3.3 mm, y: 22.6 ± 2.3 mm, z: 31.7 ± 1.0 mm) was significantly lower versus the right hand ($p < 0.001 - 0.001$). **CONCLUSION:** During an overhand throwing task, the results suggest that CoM movement of the trunk and throwing forearm pattern closely with the movement of whole-body CoM located proximal and distal to the throwing elbow.

Ankle Bracing Effects on Contributions to the Support Moment during Hopping

Carlos Santillan, *Illinois State University, Bloomington, IL*. (Sponsor: Dale Brown, FACSM)
 Email: Cksantil@gmail.com
 (No relevant relationships reported)

Ankle Bracing Effects on Contributions to the Support Moment during Hopping
 Carlos Santillan, Adam E. Jagodinsky, Mohammed Zaman, Christopher Wilburn, Wendi H. Weimar
 Illinois State University, Normal, IL, Auburn University, Auburn, AL
INTRODUCTION: Ankle bracing is commonly implemented to prevent ankle sprain injuries. However, research shows ankle bracing can alter joint kinetics during a variety of dynamic tasks. Analysis of the support moment (Ms) characteristics in response to bracing could provide insight into possible global motor strategies adopted when an ankle brace is applied. **PURPOSE:** Examine bracing effects on lower extremity contributions to the Ms during hopping. **METHODS:** 16 healthy individuals participated in the study. Participants performed 15 trials of single-leg hopping during no brace (NB) and brace (B) conditions. Position data were collected using a motion capture system, and reaction forces were obtained from force platforms. Joint kinetics were calculated using inverse dynamics, and the MS was calculated as the sum of ankle, knee, and hip moments in the sagittal plane. Data from the stance phase of hopping was extracted and time normalized to 0-100% of stance phase. The percentage contribution (%C) of ankle (A), knee (K), and hip (H) moment to Ms was calculated at 15, 30, 45, 60, and 75 percent of stance phase. Comparisons of percentage contribution between conditions were made at each time point using paired-samples t-tests. **RESULTS:** Analysis revealed that for K, %C was significantly lower during B ($19.5 \pm 4.06\%$) compared to NB ($21.76 \pm 4.42\%$) ($t = 2.228, p = .041$). Additionally, for K, %C was significantly lower during B (34.025 ± 9.14) compared to NB (35.26 ± 10.23) ($t = 2.306, p = .035$). No other significant differences for the study were observed. **CONCLUSION:** Bracing significantly decreased the contribution of the knee to the MS during single-leg hopping. Changes in the knee contribution to the Ms suggests that ankle bracing invokes adaptations to motor control strategies during the landing phase of single-leg hopping.

Support Moment Dynamics Are Similar In Individuals With and Without Chronic Ankle Instability During Hopping

Umaiyaa Vasudevaraja¹, Adam E. Jagodinsky¹, Mohammed Zaman¹, Christopher Wilburn², Wendi H. Weimar². *Illinois State University, Normal, IL. ²Auburn University, Auburn, AL.* (Sponsor: Dr.Dale Brown, FACSM)
 (No relevant relationships reported)

It has been proposed that the development of chronic ankle instability (CAI) is related to a maladaptive cascade stemming from mechanical and/or neuromotor impairments following an initial ankle sprain injury. Contrarily, individuals who do not exhibit recurring instability following initial ankle injury (copers) may benefit from adaptive movement strategies that allow for healthy functioning, yet the mechanisms surrounding this theory remain in question. Previous investigations have found that copers exhibit significantly greater variability in the support moment (Ms) and lower extremity joint moments compared to individuals with CAI during walking, which could indicate a mechanism by which copers adapt to both mechanical and/or neuromotor constraints relating to initial injury. However, these measures have not been explored in tasks that place greater demand on the previously injured limb. **PURPOSE:** The purpose of this study was to compare the Ms variability characteristics between healthy, coper and CAI individuals during a single-leg hopping task. **METHODS:** 48 individuals (16 per group) participated in the study. Participants performed 15 trials of continuous single-leg hopping. Position data were collected using a motion capture system, and reaction forces were obtained from force platforms. Joint kinetics were calculated using inverse dynamics, and the MS was calculated as the sum of ankle, knee, and hip moments in the sagittal plane. Variability of the MS was expressed as the percent coefficient of variation (%CV) across stance phase. A one-way ANOVA was conducted to compare %CV across groups. **RESULTS:** No differences in %CV were found between healthy ($13.27 \pm 6.014\%$), Coper ($16.14 \pm 10.6145\%$) and CAI ($14 \pm 10.61\%$) groups. **DISCUSSION:** Individuals had no change in %CV compared with the previous study of walking. The contrast in findings may be attributed to the nature of task demands placed on subjects. Specifically, the

rapid and cyclic transition of loading-propulsion-loading, and low amplitude COM displacement associated with the hopping task performed in this study may not have placed an adequate constraint on the subjects to elicit adaptive strategies. Future studies investigating Ms variability characteristic should consider implementing tasks that will stress motor system adaptability.

Test-Retest Reliability of Performance Scores Using a Markerless Motion Capture System

Eric M. Mosier¹, Andrew C. Fry², Justin X. Nicoll³, Dimitrije Cabarkapa², Stephanie A. Sontag². *¹Northwest Missouri State University, Maryville, MO. ²the University of Kansas, Lawrence, KS. ³California State University, Northridge, CA.*
 Email: emosier@nwmissouri.edu
 (No relevant relationships reported)

PURPOSES: This investigation examined the test-retest reliability of a markerless motion capture system (MCS) for six performance (PERF) scoring scales using a performance motion analysis protocol (PMA) across multiple visits. **METHODS:** Healthy, recreationally active men ($n=11$; \pm SD; age= 23.0 ± 2.6 yrs, height= 180.3 ± 4.8 cm, weight= 80.4 ± 7.3 kg) and women ($n=11$; age= 20.8 ± 1.1 yrs, height= 172.2 ± 7.4 cm, weight= 68.0 ± 7.3 kg) were screened once a week for 4 weeks using the PMA protocol, consisting of 19 motions. These include shoulder ranges of motions, trunk rotation, five types of squatting motions, single leg balances, and six types of vertical jumps and depth jumps. A three-dimensional markerless MCS using the DARI Motion Software (Scientific Analytics, Lincoln, NE) was used to analyze the kinetic and kinematic data, from which 192 variables were calculated to determine the PERF scores. The PERF scores evaluated included Composite, Power, Functional Strength, Dysfunction, Vulnerability, and Exercise Readiness. One-way repeated measures ANOVAs (performance scores x visit) ($p \leq 0.05$), and intraclass correlation coefficients (ICCs) were determined to compare performance scores. **RESULTS:** Results are shown in the table. Excellent test-retest reliability was observed for composite, power, functional strength, and exercise readiness scores (ICCs > 0.8) across all 4 visits. The vulnerability scores displayed fair test-retest reliability, while the dysfunction score exhibited poor reliability. No significant differences were observed for any performance scores on any visits. **CONCLUSION:** These results indicated excellent reliability for all PERF scores except vulnerability and dysfunction scores. It is possible that the vulnerability and dysfunction scales require several visits to establish a consistent baseline and may require 1-2 familiarization visits. Further study is needed to determine the magnitude of change for any score that is meaningful.

Table 1.

| Visit | Composite | Power | Functional Strength | Dysfunction | Vulnerability | Exercise Readiness |
|-----------------|----------------|---------------|---------------------|--------------|---------------|--------------------|
| 1 | 1611.8 ± 307.3 | 836.4 ± 216.9 | 907.3 ± 114.9 | 132.8 ± 56.6 | 42.2 ± 12.3 | 18.7 ± 3.9 |
| 2 | 1611.8 ± 271.4 | 836.4 ± 196.5 | 900.8 ± 106.8 | 125.5 ± 45.4 | 40.5 ± 7.7 | 18.8 ± 3.6 |
| 3 | 1602.7 ± 270.9 | 825.7 ± 197.9 | 885.6 ± 117.9 | 108.6 ± 42.8 | 39.3 ± 9.4 | 18.6 ± 3.6 |
| 4 | 1601.6 ± 270.5 | 833.6 ± 207.6 | 879.0 ± 100.5 | 111.7 ± 46.6 | 39.0 ± 9.3 | 18.7 ± 3.4 |

Identification of Risk Factors Associated with Groin Injury in an Upright Standing Position

Maria C. Herrera¹, Tal Amasay¹, Zacharias Papadakis¹, Ana Castillo¹, Samantha Day¹, Noah Padgett². *¹Barry University, Miami, FL. ²Baylor University, Waco, TX.*
 Email: maria.herrera5@mymail.barry.edu
 (No relevant relationships reported)

Groin injury is a common injury in sports such as soccer. This type of injury is associated with quick change of direction or acceleration, and kicking. Several studies have identified decrease in hip internal (Int) and external (Ext) rotations or decrease in hip adduction (Add) and abduction (Abd) torques ratio as risk factors for groin injury. However, it is still unclear what relationship exists between these variables, specifically performed in upright position which is more functional. **PURPOSE:** To explore the relation between low hip Add and Abd torque ratio and hip Int and Ext rotations, performed in upright position, in college students. **METHODS:** Fourteen college students participated in the study, Eight males (21 ± 1 yrs, 81 ± 11 kg, 176 ± 6 cm) and Six females (22 ± 2 yrs, 62 ± 5 kg, 163 ± 6 cm). Data were collected in two different sessions. Hip isokinetic maximal Add and Abd torques were captured using isokinetic dynamometer at two speeds, $30^\circ/s$ and $60^\circ/s$. Participants performed five trials of continuous Add and Abd at each speed and the averages of the highest

three peaks and their corresponding angles were calculated. Add and Abd torques ratio were calculated and the data were categorized as high risk (HR), if ratio was <1, or low risk (LR), if ratio was >1. Hip 3D Int and Ext rotations were captured using 3D cameras at 240 Hz. Participants performed three separate trials of maximal Int and Ext rotations using sliding disk and highest lower leg Int and Ext rotations were analyzed. T-tests assuming unequal variance were performed. **RESULTS:** Mean Add and Abd torque ratios were 0.72 ± 0.13 in HR group and 1.30 ± 0.19 in LR group. Lower peak Add torque was observed in the HR group (48 ± 15 Nm vs. 86 ± 27 Nm, $p < 0.01$). No significant difference was observed in peak Abd torque between the groups (67 ± 19 Nm vs. 66 ± 18 Nm, $p > 0.05$). Hip Ext rotations were lower in the HR group, however not significant ($17 \pm 7^\circ$ vs. $20 \pm 9^\circ$, $p = 0.07$), same was observed for hip Int rotations ($13 \pm 5^\circ$ vs. $15 \pm 4^\circ$, $p = 0.08$). The total hip Int and Ext rotations range of motion was significantly lower in the HR group ($30 \pm 9^\circ$ vs. $34 \pm 10^\circ$, $p < 0.05$). **CONCLUSION:** Decrease in hip Int and Ext range of motion was related to lower hip Add and Abd peak torque ratio. Future research should further investigate the association between these variables in athletes to better predict and prevent groin injuries.

Effects Of Stroboscopic Vision On Reactive Strength Index Scores In Female Ncaa Division I Volleyball Players.
Talin Louder, Melissa Kroll, Jordan Preuss, Jake Rosburg, Lara Boman. *The University of South Dakota, Vermillion, SD.*
Email: talin.louder@usd.edu
(No relevant relationships reported)

It is believed that ACL injury risk is multifaceted and includes structural, biomechanical, and cognitive factors. Recently, it is observed that overreliance on exteroception (visual stimuli) following ACL rehabilitation may increase the risk of re-rupture. There may be utility in using stroboscopic vision as an enhancement to plyometric movements and neuromuscular ACL-prevention programs. **PURPOSE:** To evaluate the effects of stroboscopic vision on Reactive Strength Index (RSI) scores in female NCAA Division I volleyball players. **METHODS:** Thirteen female NCAA Division I volleyball players performed three trials of depth jumping across five conditions: (1) 0.38 m - no visual restriction, (2) 0.53 m - no visual restriction, (3) 0.69 m - no visual restriction, (4) 0.38 m - high-frequency stroboscopic vision (H-f), and (5) 0.38 m - low-frequency stroboscopic vision (L-f). For all trials, the RSI, rebound jump height (RJH; m), and ground contact time (GCT; s) were computed from vertical ground reaction force data acquired via a tri-axial force platform. To evaluate the statistical significance of results, a Multivariate General Linear Model Analysis of Variance (GLM ANOVA) was performed using RSI, RJH (m), and GCT (s) as dependent measures. The five depth jump conditions were included as levels within a single condition factor. Statistical significance was set at an alpha level of 0.05. **RESULTS:** Main effects of depth jump condition were observed for RSI and GCT (s) ($p = 0.001$), but not for RJH (m) ($p = 0.101$). Post-hoc comparisons revealed that RSI scores were lower for stroboscopic conditions (H-f: 0.75 ± 0.16 ; L-f: 0.72 ± 0.16) versus no visual restriction (0.38 m: 0.80 ± 0.17 ; 0.53 m: 0.79 ± 0.17 ; 0.69 m: 0.79 ± 0.16). Post-hoc comparisons revealed that GCT (s) was greater for stroboscopic conditions (H-f: 0.47 ± 0.07 s; L-f: 0.49 ± 0.07 s) versus no visual restriction (0.38 m: 0.46 ± 0.07 s; 0.53 m: 0.45 ± 0.07 s; 0.69 m: 0.45 ± 0.07 s). **CONCLUSION:** Integrating stroboscopic vision into the depth jump movement reduced RSI scores in a sample of female NCAA Division I volleyball players, which was attributable to longer GCTs (s). The results suggest that adding stroboscopic vision to plyometric movements may increase the difficulty of the task from either a cognitive or biophysical perspective.

Women's Collegiate Volleyball Players Exhibit Kinetic Asymmetries during Sport-Specific Tasks
Jenna D. Smith, Kevin R. Ford, FACSM, Audrey E. Westbrook, Rachel A. Kordonow, Jeffrey B. Taylor. *High Point University, High Point, NC.* (Sponsor: Kevin R. Ford, FACSM)
Email: jsmith8@highpoint.edu
(No relevant relationships reported)

Women's volleyball demands frequent lateral movements and vertical jumps. Repetitive lateral movements in the same direction could lead to biomechanical asymmetries and a potential increased risk of lower extremity injury. **PURPOSE:** To identify and analyze biomechanical asymmetries in collegiate women's volleyball players during sport-specific lateral and vertical jumping tasks.

METHODS: Nineteen female collegiate volleyball players were analyzed using standard 3D motion capture techniques during a drop vertical jump (DVJ) from a 30-cm box and a reactive jump (REACT) task. For the REACT, participants began in an athletic stance awaiting a directional cue on a screen placed in front of them. Once directed, participants were instructed to jump laterally and then vertically as high and fast as possible to mimic a volleyball block. Repeated measures MANOVA models were used to identify asymmetries in kinematic and kinetic measures in the DVJ and REACT task ($\alpha = 0.05$). Paired t-tests identified asymmetries in reaction time during the REACT task. Limb symmetry indices (LSI) were calculated for significant findings. **RESULTS:** Significant kinetic asymmetries were identified for both the DVJ ($p = 0.01$) and REACT ($p = 0.003$) tasks, but no kinematic asymmetries were found in either task ($p > 0.05$). During the DVJ, participants exhibited asymmetrical knee abduction (LSI=81%, $p = 0.03$), ankle dorsiflexion (LSI=94%, $p = 0.03$), and ankle inversion (LSI=30%, $p = 0.001$) external joint moments and vertical ground reaction forces (LSI=93%, $p = 0.04$). During the REACT task, participants exhibited asymmetrical ankle dorsiflexion (LSI=85%, $p = 0.03$), and ankle inversion (LSI=73%, $p = 0.001$) external joint moments. There were no differences in reaction times between the two limbs ($p > 0.05$).

CONCLUSIONS: Collegiate women's volleyball players exhibit significant asymmetry in the knee and ankle during jumping and landing tasks. Interestingly, asymmetries were identified in kinetic variables but not kinematic variables. These findings indicate that screening, injury prevention and rehabilitation practices cannot solely rely on visual observation to identify lower extremity asymmetry in this athletic population.

270 Board #108 May 29 9:30 AM - 11:00 AM
Differences in Lower-Extremity Kinematics Among Female Collegiate Soccer and Volleyball Players
Anjali Gairola, Dustin Malandra, Marisa J. Christensen. *Cabrini University, Radnor, PA.*
(No relevant relationships reported)

Joint angles and leg stiffness play a role in an athlete's Reactive Strength Index (RSI). RSI is a variable that can quantify the elasticity and stiffness capacity of muscle during rapid changes from eccentric to concentric contraction. **PURPOSE:** To evaluate the differences in RSI, joint absorption strategies for knee joint displacement (KD), and ankle joint displacement (AD) among soccer and volleyball female athletes during a landing task. **METHODS:** A total of 30 (Soccer=21, Volleyball=9) healthy, NCAA Division III female athletes (19.76 ± 1.24 years) volunteered for this study. The subjects jumped over a hurdle with subsequent maximal vertical jump measured on EZE jump mat (swift performance). The maximal vertical jump landing was video recorded and joint angle displacements (KD and AD) analyzed using Hudl technique application on iPhone. Of three jump trials, highest (RSI_H) and lowest RSI (RSI_L) were recorded. A one-way ANOVA was used to determine differences among soccer and volleyball athletes for RSI_H . Further, two-way ANOVA with replication was used to examine the differences between joint angular displacements (KD and AD) at RSI_H and RSI_L . **RESULTS:** There was no significant difference ($p = 0.178$) between soccer (1.9 ± 0.44) and volleyball (1.67 ± 0.39) athletes for RSI_H . There was a statistically significant interaction ($p = 0.043$) between the effects of levels of RSI on joint angular displacements.

| n=30 | RSI_H (mean \pm SD) | RSI_L (mean \pm SD) |
|------|-------------------------|-------------------------|
| KD | 32.9 ± 11.3^0 | 35.2 ± 11.5^0 |
| AD | 36.5 ± 10.4^0 | 33.9 ± 8.6^0 |

CONCLUSION: The power production and dynamic stability of leg during jump landing involves the coordination between the hip, knee, and ankle joints. In current study, RSI_H was associated with knee stiffness and elasticity of ankle joint. It was observed that there was no observable difference in ground force attenuation strategies by sport. Future studies should explore lower-extremity absorption strategies using bigger sample size, NCAA Division I or II athletes, and comparing genders during sport-specific tasks.

(No relevant relationships reported)

INTRODUCTION: Anterior Crucial Ligament (ACL) injuries are common in female soccer players and can have serious, even lifelong consequences. The Landing Error Scoring System (LESS) and a modification of the LESS, the LESS-RMC, have been useful tools in screening athletes and identifying individuals at "high-risk" so appropriate interventions could be provided. However, it is unclear

how knee confidence and age influences these screening tools in female soccer athletes. **PURPOSE:** The aim of this study was to investigate the effects of age and knee confidence on ACL injury risk classification in female youth soccer players. **METHODS:** 178 healthy female youth soccer players (ht: 1.63 ± 0.07 m, mass: 48.8 ± 4.9 kg, age: 14.1 ± 1.5 yrs) participated in this study. Participants were asked to jump from a 30cm box a distance 50% of their height where they immediately performed a maximum vertical jump and landing upon initial ground contact. Two HD cameras were used to record (60 Hz) this motion in the frontal and sagittal planes. The video of the task was then used to assess the participant's ACL injury risk by evaluating these landings using the LESS and LESS-RMC procedures. Knee confidence was evaluated by using a 5-point Likert scale in response to an item asking "How much do you trust your knee" from the knee-related quality of life subscale in the KOOS knee questionnaire. The participants were classified as confident if they answered "completely" and not confident for all other responses. Two-way ANOVAs were used to investigate the effects of age group (11-12, 13-14, 15-16 and 17-18 y) and knee confidence on the LESS and LESS-RMC scores. **RESULTS:** There was a statistically significant main effect of age on the LESS score, [F (3, 167) = 2.667, $p = 0.049$]. Post-hoc tests revealed that the age group of 11-12 years displayed significantly higher LESS scores (6.43 ± 2.14) than the 17-18 group (4.49 ± 2.11) ($p = 0.029$). There was no significant main effect for knee confidence ($p = 0.501$). **CONCLUSION:** The results reveal that female soccer players in the 11-12 age range are at a greater risk of ACL injury than the 17-18 age range. Further research should be conducted to examine the mechanical contribution to this risk and methods to reduce injury risk across age ranges.

Lower Extremity Force Production And Postural Stability Changes With Age In Young Male Soccer Players

Frantisek Zahalka¹, Tomas Maly¹, Kevin R. Ford, FACSM², Dai Sugimoto³, Lucia Mala¹, Tomas Gryc¹, Veronika Mikesova¹.
¹Charles University, FPES, Prague, Czech Republic. ²High Point University, High Point, NC. ³Harvard Medical School, Boston, MA. (Sponsor: Kevin R. Ford, FACSM)
Email: zahalka@ftvs.cuni.cz
(No relevant relationships reported)

Optimizing lower extremity force production is key for elite soccer players (SP). Additionally, improved postural stability (PS) is generally associated with a decreased risk of injury. However, it is not well understood, in elite youth SP, how force production during explosive movements and PS during quiet stance differ among typical age categories.

PURPOSE: To compare lower extremity force production and PS performance in four different age categories in youth SP.

METHODS: A total of 73 elite youth SP from four age categories (U12: $n = 18$, U13: $n = 20$, U14: $n = 16$, U15: $n = 19$) were tested using a force platform (KISTLER AG, Switzerland) during different types of jumps (countermovement jump free arms (CMJFA), countermovement jump (CMJ), squat (SJ) and depth jump (DJ)). PS was assessed on a pressure platform (RS SCAN, Belgium) during narrow standing, with (NSW) and without (NSN) visual control, and single limb stance on preferred (SLSP) and non-preferred leg (SLSN). We calculated: jump height (JH), maximum force, force asymmetry between legs (FA), absolute (FI) and relative force impulses and total center of pressure distance. Statistical analyses ($p < 0.05$) consisted of MANOVA, Bonferroni post-hoc test and partial eta square (η_p^2).

RESULTS: A significant age effect was found on JH in all jump tests (CMJFA: $F_{3,69} = 13.92$, $p = 0.00$, CMJ: $F_{3,69} = 14.44$, $p = 0.00$, SJ: $F_{3,69} = 19.82$, $p = 0.00$, DJ: $F_{3,69} = 19.04$, $p = 0.00$,) and PS performance (NSN: $F_{3,69} = 3.93$, $p = 0.01$, FLP: $F_{3,69} = 7.88$, $p = 0.00$, FLN: $F_{3,69} = 3.22$, $p = 0.03$,). Older players (U15) had a higher performance in CMJFA (JH = 37.59 ± 5.32 cm) and force impulse (FI = 166.26 ± 32.42 N.s) compared to younger (U12: JH = 30.36 ± 2.63 cm, FI = 111.89 ± 25.14 N.s, U13: JH = 30.15 ± 3.31 cm, FI = 126.35 ± 20.01 N.s). Age had non-significant effects on FA ($p > 0.05$). Decreased postural control (NSN) was found in U15 players (204.58 ± 64.83 mm) compared to U13 (140.25 ± 35.01 mm). Younger players (U12) had lower performance in SLSP (1956.06 ± 822.70 mm) compared to older players (U13 = 1437.30 ± 370.13 mm, U14 = 1157.94 ± 316.85 mm, U15 = 1304.05 ± 404.12 mm). **CONCLUSIONS:** Explosiveness and PS are different by ages in youth elite SP. The results indicate that CMJFA and CMJ had different neuromuscular strategies compare to SJ and DJ. Findings of this study are beneficial to develop age specific training program in youth SP.

Evaluation Of A Novel Acl Injury Prevention Technique:can Martial Arts Fall Training (break-falling And Rolling) Alter The Lower Extremity At-risk Biomechanics In Soccer Athletes?

Karen M. Myrick¹, Zobian John Edward Franklin¹, Conor Kasabo¹, Thomas Martin¹, Michael Golden², Darin Reisler³, Richard Feinn¹, Juan Garbalosa¹.
¹Quinnipiac University, Hamden, CT. ²Custom Neruo Solutions, West Hartford, CT. ³Plus One Defense Systems, West Hartford, CT.
Email: karen.myrick@quinnipiac.edu
(No relevant relationships reported)

Purpose We propose that by introducing martial arts fall training (specifically break-falling and rolling), the neuropathways in these athletes will be trained to recognize and avoid at risk postures by having an alternative response. Given the absence of research utilizing martial arts falling techniques in other sports, this study aims to compare lower extremity biomechanics and risk factors in soccer athletes with fall training compared to those without. **Methods:** 5 youth premier soccer athletes between the ages of 9 and 16 were recruited for participation. Subjects were randomly divided into a control group and an intervention group. All subjects continued their usual soccer training. The intervention group completed a twice weekly 10-week training program in addition to their usual training, taught by a karate and aikido expert at the level of 3rdrd degree black belt. At baseline and after the 10 week program was completed, all subjects underwent a biomechanical evaluation that measured hip and knee movement/position in frontal, transverse, and sagittal planes at 4 different time points during a drop fall. A mixed factorial ANOVA model was used to determine the effects of the intervention training on the kinematic variables of interest. The between subjects' factor was treatment group (intervention and control) and the within subjects factor was time point (pre-intervention and post-intervention). The test of the interaction between group and time point was used to determine if the intervention produced change in the variables of interest. The alpha level of significance for this study is set at the 0.05 level. **Summary of Results:** There was a significant decrease in knee flexion in the sagittal plane at initial contact when comparing pre and post-intervention (-4.802 degrees, $P < 0.001$). There was also a significant decrease in knee flexion in the sagittal plane at heel strike 33ms (-7.384 degrees, $P < 0.001$). There was no significant change in any of the other motion points examined. **Conclusion:** There was a statistically significant change in body mechanics when comparing pre and post-break falling intervention. Prior research has shown that neuromuscular programs decrease ACL injury rates when they are started at an early age and continued with strong compliance.

Isokinetic Strength and Strength Asymmetries of Lower Extremities in Professional Soccer Players

Tomas Maly¹, Frantisek Zahalka¹, Kevin R. Ford, FACSM², Dai Sugimoto³, Lucia Mala¹, David Bujnovsky¹, Mikulas Hank¹, Egon Kunzmann¹.
¹Charles University, FPES, Prague, Czech Republic. ²High Point University, High Point, NC. ³Harvard Medical School, Boston, MA. (Sponsor: Kevin R. Ford, FACSM)
Email: maly@ftvs.cuni.cz
(No relevant relationships reported)

Muscle strength (MS) is an important component of physical fitness in soccer players (SP). Side-to-side differences may be developed due to the unilateral nature of certain soccer skills and movement patterns. Constant loading on one side of the body over time may lead to strength asymmetry and imbalances in tissue adaptation.

PURPOSE: To investigate isokinetic strength asymmetry (SA) and magnitude in professional male SP.

METHODS: Professional male SP from the first division of Czech Republic ($n = 148$, age 25.1 ± 4.8 years) volunteered to participate in the study. SP performed isokinetic strength testing (Humac Norm, CYBEX, USA) concentrically at angular velocities of 60, 180 and 300°·s⁻¹. The peak muscle torque of knee extensors (PT_e) and flexors (PT_f) in both legs, hamstrings and quadriceps strength ratio of muscle torque for both preferred and non-preferred extremities (H:Qp and H:Qn respectively), bilateral ratio between the exerted strength of knee extensors (Q:Q) and flexors (H:H) were calculated. Mixed-design RM ANOVA, Bonferroni's post hoc tests and partial eta square (η_p^2) were used for statistical assessment.

RESULTS: Knee flexors showed significantly higher SA (H:H = $9.77 \pm 0.40\%$) compared to the extensors (Q:Q = $7.24 \pm 0.40\%$) ($F_{1,294} = 20.49$, $p = 0.00$, $\eta^2 = 0.07$). Greater hamstrings and quadriceps strength ratio was found in preferred leg (H:Qp = 59.89%) compare to non-preferred (H:Qn = $58.10 \pm 0.63\%$) ($F_{2,588} = 4.01$, $p = 0.04$, $\eta^2 = 0.01$). Contraction velocity speed did not have a significant difference on SA ($p > 0.05$). MS of knee extensors reached the highest value at the lowest velocity for both legs (PT_{e60} = 2.94 ± 0.36 N·m·kg⁻¹). Exerted MS significantly decreased with}

increasing velocity in both: extensors ($F_{2,588}=4218.92$, $p=0.00$, $\eta^2=0.94$) and flexors ($F_{2,588}=2932.69$, $p=0.00$, $\eta^2=0.91$). At the highest velocity ($300^\circ\cdot s^{-1}$), MS achieved ~55% (PT₂) respectively ~53% (PTF) of MS exerted at the lowest velocity ($300^\circ\cdot s^{-1}$). **CONCLUSIONS:** Greater SA was found in knee flexion (H:H) rather than knee extension (Q:Q) in a group of professional male SP. Also, greater hamstrings and quadriceps strength ratio was found in preferred leg (H:Qp) compared to non-preferred leg (H:Qn). The findings of this study will be useful in the design of injury prevention and performance enhancement programs.

Effect of Previous Groin Pain on Sagittal Plane Joint Moments During Soccer Instep Kicks

Anna C. Severin¹, Daniel B. Mellifont², Mark GL Sayers².
¹University of Arkansas for Medical Sciences, Little Rock, AR.
²University of the Sunshine Coast, Sippy Downs, Australia.
 Email: aseverin@uams.edu
 (No relevant relationships reported)

Previous groin pain is common in male soccer players, often results in re-injury,^{1,2} has been linked to maximal instep kicks.^{3,4} Research has shown aberrant kinematics during the instep kick in players with previous groin pain.⁵

PURPOSE: To quantify differences in sagittal plane joint moments during maximal instep kicks between players with and without previous groin pain.

METHODS: Data were collected from 12 experienced male soccer players who reported nonspecific groin pain in the last 12 months, and 11 controls who each performed six maximal instep kicks. A 10-camera Qualisys motion capture system (500 Hz) and two Bertec force platforms (2000Hz.) collected data that were then processed using standard software (Visual 3D). Bilateral normalized joint moments of the hip, knee, and ankle were quantified at stance limb plant (PL), swing limb peak knee flexion (PKF) and at ball contact (BC). The foot speed of the swing limb at impact was considered an indication of kicking performance. The two-tailed alpha level was set to 0.05 and Cohen's *d* was used to quantify the magnitude of differences between groups.

RESULTS: A moderate difference in foot velocity existed between the groups (C: 15.5 m·s⁻¹, PGP 14.8 m·s⁻¹, $p=0.087$, $D=0.77$). Differences in stance limb joint moments were evident throughout the kick, while the swing limb only displayed differences at BC (Figure 1).

CONCLUSION: The PGP group often utilized lower sagittal plane joint moments about the hip, knee, and ankle of the stance limb but without evidence of a matching decrease in foot velocity at BC. This suggests that compensations occurred elsewhere in the kinetic chain to make up for the reduced joint moments. The stance hip flexion moment in the PGP group at PL is atypical and further supports the presence of aberrant motor patterns.

¹Walden, M. *BJSM*, ²Werner, J. *BJSM*, ³Rahnama, N. *BJSM*, ⁴Esteve, E. *BJSM*, ⁵Severin, AC. *SMF*.

Figure 1. Graphs of joint moments of the limbs during the phases of the kick for C (black) and PGP (grey) groups. * indicates $P<0.05$, ** indicate $D>0.8$, † indicate $0.5<D<0.8$, and ‡ indicate $D>0.5$.

Using Isokinetic Strength Assessment to Predict Performance and Prevent Injuries in Indian Cricket Fast Bowlers

Sai A. Krishna, Thiagarajan K. Alwar, Rajendran Ramasamy, Sakthi Vinayagam, Arumugam Sivaraman. *Centre for Sports Science, Chennai, India.*
 (No relevant relationships reported)

Cricket is the most commonly played & followed sport in India. It demands a high level of performance from the fast bowler. The fast bowling action involves a run up, leap and landing onto the lower limbs, followed by ball release. The large ground reaction forces generated during landing put fast bowlers at high risk of lower limb and lumbar spine injury. Precise dynamic coordination of lower body segments is needed to absorb these forces and transfer the energy via the core to the upper limb

to propel the ball at faster speeds. Thus, knowledge of lower quadrant strength can be very useful for injury prevention and better performance in fast bowlers. Dynamic Knee Strength in the front limb is critical during the leap phase of bowling for optimal performance. There is a lack of literature in this subject in Indian fast bowlers despite the popularity of the sport.

PURPOSE: To evaluate the Isokinetic knee strength, determine the relevant asymmetries and strength imbalances & their relationship with performance and injury risk in Cricket Fast Bowlers. **METHODS:** 42 male Indian State Level fast bowlers underwent Isokinetic knee strength testing. Quadriceps concentric (Qconc), Quadriceps eccentric (Qecc), Hamstring concentric (Hconc) & Hamstring eccentric (Hecc) Peak Torques normalized to body weight (PT/BW) were obtained. Bilateral Strength Asymmetries (BSA) and Dynamic Control Ratios (Hamstring DCR= Hecc/Qconc & Quadriceps DCR=Qecc/Hconc) were evaluated. Vertical Jump Height (VJ) & Standing Broad Jump (SBJ) distance were used as indicators of jump performance. Descriptive statistical analysis of data & Pearson correlation was done to obtain relationship between Isokinetic parameters & jump performance. **RESULTS:** A significant correlation was found between Qconc Strength and VJ ($r=0.67$, $p=0.04$) & SBJ ($r=0.39$, $p=0.04$). 67% of bowlers had significant Qecc strength asymmetry. 40% had poor Hamstrings DCR & 19% had poor Quadriceps DCR on the front limb. **CONCLUSION:** A significant proportion of fast bowlers have unfavorable strength asymmetry & DCR and thus are at risk of injury. Improving Dynamic Knee Strength through plyometric training could help optimize performance and reduce injury risk.

Biceps and Triceps Contribute to Pitching Performance in College Baseball

Marie R. Acosta¹, J. Mark Van Ness¹, William P. Lydon¹, Brian G. Graham¹, Alexis C. King², Courtney D. Jensen¹. ¹University of The Pacific, Stockton, CA. ²University of Illinois at Urbana-Champaign, Champaign, IL.
 (No relevant relationships reported)

Training for pitching traditionally focuses on core and leg work, but there may be justification for isolated arm muscle training to enhance performance. **PURPOSE:** To evaluate the influence of biceps and triceps function during pitching. **METHODS:** Pitchers ($n=10$) from a Division-1 collegiate team were recruited. Throwing mechanics and isolated arm movements were assessed using Proteus technology (Boston Biomechanics Inc). A single set of biceps and triceps movements (with 12 and 10 lbs respective resistance) and biomechanical assessment of a throwing movement were collected. All movements completed on Proteus result in seven variables: power, explosiveness, braking, consistency, endurance, velocity, and range of motion (ROM). Pearson correlation coefficients were employed to analyze relationships between the Proteus variables for biceps curls and triceps extensions, throw mechanics, and statistics from in-game performances from the 2017 season. **RESULTS:** The strongest relationship among all comparisons was biceps curl endurance and ERA ($r=-0.959$; $p=0.001$). The biceps curl ROM was also weakly related to throw power ($r=0.429$; $p=0.076$). Throw endurance corresponded with positive trends for biceps curl power ($r=0.419$; $p=0.089$), explosiveness ($r=0.452$; $p=0.060$), velocity ($r=0.417$; $p=0.085$), and ROM ($r=0.429$; $p=0.075$). A strong positive relationship was observed between throw endurance and biceps curl braking ($r=0.535$; $p=0.022$) and a positive trend between biceps curl ROM and throw velocity ($r=0.429$; $p=0.075$). Triceps extensions corresponded closely with throwing mechanics and in-game statistics; trends were found between triceps explosiveness and strikeouts per nine innings ($r=0.728$; $p=0.064$) and Proteus throw velocity ($r=0.462$; $p=0.053$). Throw endurance was related to triceps extension braking ($r=0.496$; $p=0.037$) and it displayed a trend with triceps extension endurance ($r=0.435$; $p=0.071$). **CONCLUSIONS:** New technology permits advanced biomechanical analysis of baseball pitching. Preliminary testing reveals the importance of arm conditioning for a pitcher's ability to maintain power output. As more players are tested, we may further our understanding of the role of biceps and triceps function in throwing mechanics.

Biomechanical Predictors of Fastball Velocity in Collegiate Pitching

Samson J. Abernathy¹, William P. Lydon¹, J. Mark VanNess¹, J.P. Wong¹, Alexis C. King², Courtney D. Jensen¹. ¹University of the Pacific, Stockton, CA. ²University of Illinois at Urbana-Champaign, Champaign, IL.
 (No relevant relationships reported)

Recent pitching analyses indicate development programs should emphasize ball speed to optimize performance on the mound. Proper training is likely to increase velocity, but pitch delivery involves complex motions in all cardinal planes. Until recently, accurate analyses were encumbered by technological limitations. For example, isokinetic torque assessment measures fundamentally different phenomena from isotonic pitch delivery. New technology permits more accurate analysis. **PURPOSE:** To evaluate kinematic predictors of fastball velocity in collegiate

pitchers. **METHODS:** We tested all pitchers (n=10) from a private D1 baseball team in the West Coast Conference. Velocity was recorded as the mean speed of the three fastest in-game pitches. We used Proteus (Boston Biomotion, USA) to conduct three-dimensional isotonic assessments of pitching form, dominant and non-dominant core rotation, dominant arm internal and external shoulder rotation, and anterior flexion and extension of the dominant shoulder. Proteus software calculated power, explosiveness, velocity, and endurance. Non-mechanical predictors of fastball velocity were class year, height, weight, and limb lengths. Simple linear regressions quantified mechanical predictors of fastball velocity and the effect of fastball velocity on in-game pitching performance. **RESULTS:** Pitchers with a higher fastball speed had more appearances (r=0.763; p=0.028), pitched more innings (r=0.715; p=0.046), had more wins per appearance (r=0.524; p=0.183), and more total strikeouts in the season (r=0.829; p=0.011) but not per appearance (r=0.566; p=0.143) or per inning (r=0.074; p=0.861). Anthropometric variables were unrelated to fastball velocity. Internal rotation explosiveness (p=0.031) and endurance (p=0.030) of the dominant arm predicted fastball velocity. For each additional point of endurance, fastball speed increased 0.7 mph (p=0.030); for each additional 10 points of explosiveness, fastball velocity increased 0.4 mph (p=0.031). There was a positive relationship associated with explosiveness in straight-arm anterior shoulder raises (r=0.898; p=0.015); trends were found in the non-dominant arm. **CONCLUSION:** Increased fastball velocity may be facilitated by training internal shoulder rotation and shoulder flexion.

Match Acceleration and Deceleration Patterns in Female Collegiate Soccer Players

Jessica L. Trapp, Matthew F. Moran, Julie K. Nolan, Alicja B. Stannard. *Sacred Heart University, Fairfield, CT.*
 Email: jessica.trapp15@gmail.com
 (No relevant relationships reported)

Non-contact anterior cruciate ligament (ACL) sprains are becoming increasingly problematic for athletes, especially females. Running performance factors like acceleration and deceleration are often underestimated when examining fatigue in soccer players, but may be useful for prophylactic training to counter dysfunctional lower body mechanics under fatigued conditions. Currently no study exists that characterizes these factors in match play in female collegiate soccer players. **PURPOSE:** To describe match acceleration and deceleration patterns in female collegiate soccer players and compare positional influence. **METHODS:** 24 female NCAA Division I soccer players (11 defenders, 5 midfielders, 8 strikers) underwent global positioning system (GPS, 10Hz) monitoring throughout a 16-game competitive season. A custom written Matlab script processed GPS data and computed the amount of low (<1 m/s², <-1m/s²) and high (>2 m/s², <-2 m/s²) acceleration-efforts (AE) and deceleration-efforts (DE), distance covered per effort, and starting speed of efforts. A Kruskal-Wallis H test and two separate paired t-tests were used to compare variables by position and by halves of matches, respectively. A significance level of p<.05 was used for all analyses. **RESULTS:** Strikers performed significantly more high-intensity AE (1st half: 0.97 efforts/min; 2nd half: 1.07 efforts/min) and DE (1st half: 1.15 efforts/min; 2nd half: 1.24 efforts/min) when compared to defenders (AE: 0.76 efforts/min; 0.75 efforts/min; DE: 0.90 efforts/min; 0.87 efforts/min) (p = 0.00, p = 0.00, p = 0.00, p = 0.00) and midfielders (AE: 0.73 efforts/min; 0.86 efforts/min; DE: 0.91 efforts/min; 0.80 efforts/min) (p = 0.00, p = 0.00, p = 0.00, p = 0.00). Significant decreases occurred in the second half across all matches in distance covered in low-intensity AE (1.9 ± 0.2 m, p = .01) and low-intensity DE (0.9 ± 0.1 m, p = .01), and starting speed in low-intensity AE (6.9 ± 0.3 m/s, p = .01) and DE (3.9 ± 0.2 m/s, p = 0.00). **CONCLUSION:** Strikers performed more high-intensity AE and DE than other positions, and may be at greater risk of lower body injury. Transient decreases in AE and DE occurred between halves of match play, and may relate to an increased risk of lower body injury in female soccer players.

The Kick Motion Analysis Of Adolescent Male Soccer Player With Osgood-schlatter Disease

Seira Takei¹, Michio Tojima², Shuji Taketomi¹, Suguru Torii³.
¹Graduate School of Medicine, The University of Tokyo, Tokyo, Japan. ²Tokyo International University, Saitama, Japan. ³Waseda University, Saitama, Japan.
 Email: saranaga0330@hotmail.com
 (No relevant relationships reported)

Osgood-Schlatter disease(OSD) is an epiphyseal disease of tibial tubercle by repeated traction of patellar tendon, especially on epiphyseal or apophyseal stage. OSD is associated with sports that involve kicking, and running, but none have analyzed the kick motion of adolescent soccer players who experienced the OSD.

PURPOSE: The purpose of this study was to compare the kick motion in adolescent soccer players with and without OSD using three-dimensional motion analysis system. **METHODS:** We recruited 112 adolescent soccer players (13 ± 1 years old) All players went through the medical examination including the ultrasonography of tibial tubercle, and the muscle tightness test of lower limbs. We included only those tibial tubercle stage was epiphyseal or apophyseal stage for this study and made two groups: presence of OSD on kicking leg (OSD group; n = 10) and absence of OSD or any other injuries (NP group; n = 30).

We measured real-time kick motion using a three-dimensional motion analysis system (Qualisys track manager, Qualisys AB., Sweden). We placed 65 spherical markers on each anatomical landmark and calculated the angle of the lumbar spine, pelvis, hips, knees and ankles. We collected data for the following six events of kicking leg: foot contact (FC), toe off (TO), max hip extension (HE), max knee flexion (KF), ball impact (BI), and max hip flexion (HF). We used unpaired t-test to compare all the factors we measured between OSD group and NP group.

RESULTS: The anthropometric index, muscle tightness, ball speed of OSD group were not different from NP group. In HE, the supporting leg's ankle flexion angle in OSD group was smaller in OSD group(14.9±3.7 vs. 18.9±5.0 °, p=0.024). In KF, the hip abduction angle of the kicking leg was smaller(24.5±5.9 vs. 28.6±5.1 °, p=0.041) in OSD group. In HF, the lateral bending angle of pelvis toward the supporting side was significantly smaller in OSD group (-2.6±16.4 vs. 7.4±11.3 °, p=0.037) In HF, supporting leg's ankle was more dorsal flexion(0.4±14.9 vs. -14.1±14.5 °, p=0.010), more valgus(26.3±12.4 vs. 11.5±11.1 °, p=0.001)compared to NP group.

CONCLUSION: OSD group had smaller dorsal flexion angle of supporting leg before and after BI. They also had smaller hip abduction angle of kicking leg before BI, and lateral bending angle of pelvis toward the supporting leg side was smaller after BI.

 (No relevant relationships reported)

Lower extremity injuries in youth soccer players continue to rise and have been related to poor landing mechanics. Identifying modifiable factors that influence at-risk landing mechanics is crucial toward the development of effective injury prevention programs. Dynamic core stability is needed to control lower extremity motion and decrease the risk of lower extremity injury. However, there is limited research that has examined the relationship between core stability and landing mechanics in youth athletes. Furthermore, understanding this relationship using screening methods that are readily accessible to clinicians is necessary as participation and injuries in youth soccer programs continue to increase. **PURPOSE:** To investigate the relationship between core endurance and the Landing Error Scoring System (LESS). **METHODS:** One hundred and ninety-two youth soccer players (M 108, F 84, 11.9±1.0yrs, 153.2±11.1cm, 43.2±8.8kg) participated. Core endurance was assessed using a validated sport-specific endurance plank test. Two-dimensional kinematics were collected during three trials of a 30cm drop-jump landing task and scored using an automated LESS scoring system (PhysiMax Technologies Ltd. Tel Aviv, Israel). Separate Pearson correlations (r) examined the relationship between time to exhaustion during the plank test and total LESS scores for males and females. **RESULTS:** In males, core endurance time to exhaustion (73.6±15.1s) was negatively correlated (r=-0.210, P=0.030) to total LESS scores (5.6±1.8). In females, core endurance time to exhaustion (72.5±15.3s) was not correlated (r=-0.061, P=0.578) to total LESS scores (6.4±1.9). **DISCUSSION:** Decreased core endurance was related to increased landing errors in male, but not female, youth athletes. These data suggest that prevention programs should incorporate core endurance exercises to improve at-risk landing patterns known to increase the risk of lower extremity injuries in youth male soccer players. More work is needed to identify the modifiable factors that increase the risk of injury in youth female soccer players.

Using Functional Movement Screento Predict Injuries in Soccer Players

Rodrigo Pandelo, Domingos R. Pandelo, Jr. *Centro de Alta Performance, Santos, Brazil.*
 Email: rodrigo.pandelo@hotmail.com
 (No relevant relationships reported)

Purpose: The aim of this study was to evaluate the predictive capacity of the Functional Movement Screen (FMS) to predict injuries in under 17 soccer players. In this study we tested the model in its original form, which will be called T7, with

an alternative model, proposed here, based on only 4 of the 7 evaluated in its original form. The choice of the four items considered the fact that they are movements that more directly evaluate balance and lower limb movement pattern, which are more related to musculoskeletal injuries in soccer.

Methods: The sample was selected from 33 under 17 players of a Brazilian soccer team. The evaluation of the functional movement pattern was performed by 2 evaluators and when there was conflict in the athletes' score, a third evaluator was called for the final decision. The evaluations were all made in the preseason. As predicted by the method, each one of the 7 analyzed items were rated with 1 (worst), 2 or 3 (best). The items evaluated were: deep squat (1), hurdle step (2), in-line lunge (3), active straight-leg raise (4), shoulder mobility stability (7). The complete index (T7) is what is normally used in this type of work. What we have suggested is T4, in which evaluations 1, 2, 3 and 4 come in.

Summary of Results: In 31 athletes selected, 7 had some type of skeletal muscle injury throughout the season (22.58% of the total). Through the analysis of effect size (Hedge's g) it can be verified that when the injured athletes are compared with the complete index T7 in relation to the proposed T4, the effect size is 0.854, which can be considered a significant difference, in a clinical way. Regarding those who were not injured, the power of explanation is even greater, with an ES of -1.104. The most relevant finding of the present study was when comparing the predictive power of T7 and T4 to predict injuries. While the T7 ES stood at 0.276, the T4 ES stood at 2.698.

| Effect Size (ES) | ES (hedges g) | IC 95% | |
|---------------------------------|---------------|---------------|---------------|
| ES T7Injury x ES T4Injury | 0,854 | 0,757 | 0,950 |
| ES T7Notinjury x ES T4Notinjury | -1,104 | -1,150 | -1,059 |
| ES T7Injury x ES T7Notinjury | 0,276 | 0,214 | 0,338 |
| ES T4Injury X ES T4Notinjury | 2,698 | 2,632 | 2,764 |

Conclusion: The present study showed that FMS can be used for the prediction of musculoskeletal injuries in soccer players.

(No relevant relationships reported)

PURPOSE: To investigate the efficacy and safety of different exercise regimens in the rehabilitation of patients with stable coronary heart disease.

METHODS: This study was a randomized controlled trial to screen 112 patients with stable coronary heart disease who were admitted to General Administration of Sport of China Sports Medical Science Institute from March 2017 to June 2018. They were randomly divided into aerobic resistance training group for 12 weeks (ART group, 36 cases) and traditional Chinese medicine training group 12 weeks (TCMT group 2, 37 cases) and control group (CON group, 39 cases). We analyzed the baseline parameters of all participants and the 12-week exercise plate test parameters and related physical and body parameters.

RESULTS: After 12 weeks of intervention, VO₂, VO₂/Kg, METS, VO₂/HR, SV, peaked grip strength and flexibility parameters of ART group and TCMT group were significantly higher than those of the control group (P<0.05). Resting heart rate (RHR) of TCMT Group was significantly lower than CON group, but there was no significant difference between groups ART and CON (P>0.05). VE/VO₂ of TCMT group was significantly higher than that of CON group. Body mass index (BMI) of ART group was significantly lower than that of TCMT group and CON group, and BMF of TCMT group was significantly smaller than that of ART group, but there was no difference between TCMT group and CON group for BMI and Body fat mass (BFM).

CONCLUSIONS: Both ART and TCMT can improve the cardiopulmonary aerobic exercise capacity and physical fitness of patients with stable coronary heart disease. Although the degree of improvement is different, they all have certain curative effect on the rehabilitation of patients with stable coronary heart disease and the application is safe.

284 Board #122 May 29 11:00 AM - 12:30 PM Effect of Walking Exercise on Metabolic and Pulmonary Health in Non-ambulatory Stroke Survivors, Pilot Data

Abdulfattah S. Alqahtani, Ramzi Alajam, Sarah Eickmeyer, Wen Liu. *University of Kansas Medical Center, Kansas City, KS.*
Email: aalqahtani@kumc.edu
(No relevant relationships reported)

PURPOSE: Most of rehabilitation interventions in stroke rehabilitation have focused on improving the impaired sensorimotor function. However, up to 75% of stroke survivors are prone to have cardiovascular disease, which is the main cause of death in people after stroke. Diabetes mellitus is one of the major risk factors for developing cardiovascular diseases. Stroke survivors are prone to have diabetes mellitus due to increased fat tissue in their affected limbs. In addition, lung function is compromised in stroke survivors, which may cause fatigue and exercise intolerance. Furthermore, past studies of aerobic exercise have involved only stroke survivors who could walk independently. Stroke survivors who were unable to walk were not included in previous research investigating changes in risk factors of cardiovascular diseases and lung function from walking exercise interventions. In this project, we examined the effect of aerobic walking exercise on blood glycemic control and lung function in non-ambulatory stroke survivors using a treadmill, body weight support system, and a gait training device.

METHODS: In this on-going project, we have completed a low intensity walking exercise program (30 minutes/session; three sessions/week for eight weeks) in 5 ischemic stroke survivors (4 males, mean age 63.8±14.8 years). Before and after the intervention, a glycated hemoglobin (HbA1c) was measured using A1CNow+™ Systems, and vital capacity (VC) and forced vital capacity (FVC) were measured using a spirometer according to the guideline from American Thoracic Society/European Respiratory Society.

RESULTS: HbA1c decreased from 5.7±0.2% to 5.4±0.2% from before to after the intervention. Pre- and post-intervention VC increased from 2.69±1.01 L to 2.85±0.82 L; FVC increased from 2.65±1.08 L to 2.72±0.97 L, respectively.

CONCLUSIONS: The results are promising and suggest that the low intensity aerobic walking exercise may improve blood glycemic control by decreasing HbA1c in non-ambulatory stroke survivors. Also, the results suggest that the low intensity aerobic walking exercise may improve lung function by increasing VC and FVC. This is an ongoing study; we anticipate recruiting 20 study participants for the study.

285 Board #123 May 29 11:00 AM - 12:30 PM Effects Of Intra-dialytic Exercises On Physical Fitness And Health Related Quality Of Life (HRQOL).

Aashish Contractor, Jaini Patel. *Sir H.N. Reliance Foundation Hospital, Mumbai, India.*
Email: aashish.contractor@rfhospital.org
(No relevant relationships reported)

PURPOSE: Patients undergoing dialysis have low levels of physical activity compared to their age matched healthy sedentary adults (*Kidney International, Vol. 57 (2000), 2564-2570*). It is observed that there is continuous decline in physical function and associated increased mortality and morbidity, in these patients. In 2016, the *American College of Sports Medicine* stated that intradialytic exercise is medicine for haemodialysis patients. Exercise during haemodialysis has been shown to benefit muscle strength and bone demineralization, reducing cardiovascular risk dialysis related symptoms and improving physical fitness and HRQOL. Exercise during haemodialysis has higher adherence compared to out-patient exercise in a rehab center. Therefore, this study was conducted to see the effects of intra-dialytic exercises on fitness and quality of life. **METHODS:** Before enrolling the patients (N=50), a general history was taken. Physical fitness was assessed by 6-minute walk test with telemetry ECG monitoring and health-related quality of life assessment was done using DSI Scale (Dialysis symptom index). Patients were given breathing exercises, active movements of extremities, strengthening and specific therapies for other issues during each dialysis session (2-3 days/week). After completion of the dialysis, patients performed aerobic exercise on a stationary bicycle. At the end of 12 sessions, the 6-minute walk test (N=17) and DSI questionnaire (N=25) were repeated. **RESULTS:** There was an average 40 meters (13.88%) improvement in 6-minute walk test distance after 12 sessions of rehabilitation (p<0.0001, t=5.935). The number of symptoms patients suffered related to dialysis went down by 2.44 points (21.40%) after rehabilitation (p=0.0015, t=3.584). The Dialysis symptom Index score improved by 10 points (27.80%) (p<0.0001, t=4.798). **CONCLUSIONS:** An intradialytic aerobic and strengthening exercise program showed significant health benefits by reducing dialysis related symptoms, improved physical fitness and improved health related quality of life.

 (No relevant relationships reported)

Diabetes is a high prevalent comorbid condition in patients with peripheral arterial disease (PAD). Previous studies showed that diabetes impair physical function in PAD patients. However, whether cardiovascular function is also affected by diabetes is unknown.

PURPOSE: To compare walking capacity and cardiovascular function in PAD patients with and without diabetes. A total of 80 patients (n=41 non-diabetic and n=39 diabetic) with PAD were recruited. Six-minute walk test (total walking capacity), 4-meter test, walking impairment questionnaire (WIQ) and the walking estimated-limitation calculated by history (WELCH) were used to assess walking capacity. Cardiovascular function was assessed by blood pressure, arterial stiffness, heart rate variability and flow-mediated dilation. Mann-Whitney U test were performed, and data are presented in median and interquartile range. **RESULTS:** Diabetic PAD patients presented lower total walking capacity (308 ± 120 m vs. 370 ± 125m, p=0.025), WIQ distance score (10 ± 23 vs. 30 ± 46, p=0.002), WIQ speed score (17 ± 21 vs. 28 ± 27, p=0.001), WIQ stairs score (21 ± 42 vs. 42 ± 42, p=0.024), WELCH total score (20 ± 26 vs. 40 ± 42, p=0.006) compared to non-diabetic PAD patients. In addition, diabetic PAD patients had lower SDNN (22 ± 21 vs. 29 ± 36, p=0.030), and a trend to have lower RMSSD (13 ± 19 vs. 19 ± 32, p=0.061), and PNN50 (0.4 ± 3.7 vs. 1.6 ± 21.0, p=0.072). The remaining variables were similar between PAD patients with and without diabetes. **CONCLUSION:** Diabetes impairs walking capacity and cardiac autonomic modulation in patients with PAD. Therefore, interventions to improve these parameters should be emphasized in diabetic PAD patients. Supported by FAPESP (# 2016/16425-9) and CNPq (#310508/2017-7)

High Intensity Interval Versus Moderate Intensity Training In Heart Failure Patients: Systematic Review And Meta-analysis
 José Trejos-Montoya¹, Felipe Araya-Ramirez¹, Braulio Sánchez-Ureña¹, George A. Kelley, FACSM². ¹Universidad Nacional, Heredia, Costa Rica. ²West Virginia University, West Virginia, WV. (Sponsor: George A. Kelley, FACSM)
 Email: jtrejos@una.cr
 (No relevant relationships reported)

Studies examining high intensity interval training (HIIT) and moderate intensity continuous training (MICT) have yielded conflicting findings regarding changes in left ventricular ejection fraction (LVEF) in heart failure (HF) patients with reduced ejection fraction (EF). **Purpose:** Use the meta-analytic approach to compare the effects of HIIT versus MICT on LVEF in HF patients with reduced EF. **Methods:** A search for studies published up to July 2018 was conducted using four electronic databases: PubMed, Academic Search Complete, SportDiscus and ScienceDirect. Studies were included if they met the following criteria: (1) clinical trials, (2) studies that reported means and standard deviations for LVEF, (3) adult men and women 18 years of age and older with a previous diagnosis of HF and an ejection fraction <55%, and (4) studies published in English or Spanish. Change outcome effect sizes (ES) using the original metric were calculated from each study. Results were pooled using random-effects models. A two-tailed alpha value <0.05 was considered statistically significant. Heterogeneity was assessed using the Q statistic and inconsistency using I². Small-study effects was examined using funnel plots and influence analysis was conducted with each study deleted once. **Results:** Of the 235 studies screened, 12 trials representing 418 HF patients met the criteria for inclusion. The number of sessions ranged from 24-48 and duration from 28-47 minutes per session. Overall, HIIT significantly increased LVEF (ES = 6.4%, 95% CI = 3.7% to 9.1%; p < 0.001). No statistically significant changes were found for either MICT (ES = 3.1%, 95% CI = -0.4% to 6.7%; p = 0.08) or Controls (ES = -0.8%, 95% CI = -1.8% to 0.2%; p = 0.11). Statistically significant heterogeneity and a moderate amount of inconsistency was found for HIIT (Q = 18.4, p=0.02; I² = 56.5%), statistically significant heterogeneity and a large amount of inconsistency for MICT (Q = 42.9, p < .001; I² = 79.0%), but no statistically significant heterogeneity or inconsistency for Controls (Q = 0.42, p = 0.81; I² = 0%). Small-study effects were observed for both HIIT and MICT but not Controls. With each study deleted from the models once, changes ranged from 5.5% to 7.9% for HIIT, 1.9% to 3.6% for MICT, and -3.0% to 0.4% for Controls. **Conclusion:** HIIT increases LVEF in HF patients with reduced EF.

 (No relevant relationships reported)

The transition from hospital-based (phase II) to community-based (phase III) cardiac rehabilitation (CR) is an important step in the long-term maintenance of positive health behaviour change.

PURPOSE: To evaluate the effect of participation in a phase III, community-based CR (CBCR) programme on selected fitness indices in comparison to a control group that received usual care advice and to explore participant experiences and perceived benefits in transitioning from hospital-based phase II CR to CBCR. **METHODS:** Following completion of phase-II CR, 95 individuals were referred to a 10-week CBCR exercise programme (intervention). A total of 22 (73% male) participants were unable to attend CBCR classes and were assigned to the control group. The remaining 73 (67% male) were assigned to the CBCR exercise program. Aerobic fitness (6MWT), functional upper (hand grip) and lower (timed sit to stand) limb strength, flexibility (sit and reach test) and body composition (waist & hip girth and BMI) were measured pre and post the intervention. All participants from the intervention group were invited to attend a focus group on completion and a thematic analysis was conducted. **RESULTS:** A total of 51 participants (69% male) completed the 10-week program (70% compliance). There was a significant improvement (p<0.05) in the timed sit to stand (26.5±7.21 v 21.4±5.65sec), 6MWT (505±66.6 v 534±71.9m,) and waist circumference (100.9±13.09 v 98.5±13.37cm) in the intervention group. There was no significant change in any of the fitness indices in the control group. The focus groups were attended by 20 participants (60% male). The main themes identified included the strong sense of need for CBCR programmes and the reassurance provided by the link between the hospital and community provider. Physical, psychological and social benefits were described including moving from fear to confidence in their ability to exercise. **CONCLUSION:** Participation in a 10-week CBCR programme resulted in improved lower limb strength, aerobic fitness and waist circumference with maintenance of all other measured fitness components. Participants self-reported an increased ability and motivation to undertake exercise. This study provides an important insight into the experience and benefits, both perceived and actual, in the early transition to CBCR.

PURPOSE: The advances in the clinical and surgical management of patients with univentricular physiology after Fontan operation have allowed many patients to reach adulthood with a good quality of life. Nevertheless, most of these patients show a lower functional capacity compared to their healthy peers. Controlled data on supervised physical training in the Fontan patients are lacking, thus further studies are needed. The aim of this study was to evaluate the effect supervised exercise training on functional capacity (FC) in Fontan patients (FP).

METHODS: Randomized controlled trial with fifteen FP divided in two groups: supervised exercise training (ET) and no exercise training (NET). The ET group was submitted an incremental cardiopulmonary exercise test (CPX) before and after the intervention. The NET group was submitted to the CPX at baseline condition and after four months, maintaining their habitual activities. The training protocol consisted of three 60-minute exercise sessions per week for 4 months. The session was 40 minutes of aerobic exercise, 15 minutes of local strengthening exercises. The exercise intensity was monitored by heart rate between the anaerobic threshold and respiratory compensation point, obtained by a progressive maximal CPX.

RESULTS: There were no significant differences in baseline data between groups (age, gender, weight, medications, variables of CPX). There was an improvement in the FC as demonstrated by peak VO2 L/min, VO2 ml/kg/min and % predicted peak VO2 ml/kg/min in ETG [1,35 (1,27-1,95) vs 1,50 (1,40-2,55) L/min p=0,044; 26,9 (22,5-30,5) vs 30,6 (25,5-37,0) ml/kg/min p=0,021 and 69 (57-80) vs 79 (69-89) % p=0,018] respectively. In the NETG there was a mild decrease in FC and no significant. [1,57 (1,30-2,20) vs 1,55 (1,24-2,27) L/min p=0,753; 30,3 (25,9-38,6) vs 28,5 (23,8-

41.2) ml/kg/min, $p=0.600$; 79 (61-89) vs 69 (61-91) % $p=0.599$]. We also observed an improvement in peak ventilation and oxygen uptake efficiency slope (OUES) in ETG [54.7 (42.6-68.3) vs 67.6 (57.6-100.8) L/min $p=0.028$; 1.80 (1.52-2.63) vs 2.11(1.65-2.88) $p=0.028$] respectively.

CONCLUSIONS: Our results demonstrate that the supervised exercise training based on CPX was able to improve FC in patients with univentricular physiology after Fontan operation

Inertial Flywheel Resistance Exercise in Veterans with Chronic Kidney Disease Predialysis: A Case Series

Jared M. Gollie, Michael O. Harris-Love, Samir S. Patel, Marc R. Blackman. *Veterans Affairs Medical Center; The George Washington University, Washington, DC.* (Sponsor: Peter F. Kokkinos, FACSM)

(No relevant relationships reported)

Chronic kidney disease (CKD) is associated with skeletal muscle loss and neuromuscular dysfunction, resulting in reduced physical performance. Inertial flywheel resistance exercise (RE) has been shown to be an effective training option for improving neuromuscular outcomes in healthy adults. However, evidence supporting its application in patients with CKD is limited. **PURPOSE:** To determine the effects of inertial flywheel RE on neuromuscular measures and physical function in Veterans with CKD predialysis. **METHODS:** Two adult men with stage 3 or 4 CKD (age: 70±7.1 yrs; eGFR: 41.5±19.5 mL/min/1.73 m²; weight: 111.3±16 kg; height: 178.2±9.7 cm) were enrolled to perform 12-weeks of inertial flywheel RE for the squat movement (3 sets x 12 repetitions). RE emphasized maximizing power output and was progressed by manipulating inertial load and contraction velocity. Knee extensor peak isometric and isokinetic torque (180°/s) and rate of torque development (RTD) were assessed using dynamometry. Muscle thickness (MT) and echo intensity (EI) of the rectus femoris and vastus lateralis muscles were determined via B-mode diagnostic ultrasound. Physical function was assessed as time to complete five chair stands (STS-5). **RESULTS:** Both subjects improved similarly after RE, thus data are presented as Mean ± SD. Peak isometric and isokinetic torque increased from 106.7±8.5 to 122.4±9.7 ft-lbs (+14.7%) and 67.5±3.2 to 80.9±8.4 ft-lbs (+19.9%). RTD at time intervals of 50, 100, 200, and 300 ms increased after RE from 0.14±0.13 to 0.49±0.46 ft-lbs/s (+255.4%), 0.19±0.17 to 0.41±0.34 ft-lbs/s (+119.7%), 0.19±0.13 to 0.27±0.27 ft-lbs/s (+44.3%), and 0.18±0.09 to 0.24±0.06 ft-lbs/s (+32.3%), respectively. STS-5 was reduced from 16.2±3.3 to 13.5±2.8 s (-16.4%). No changes were observed in MT or EI. **CONCLUSIONS:** Our initial findings support the notion that inertial flywheel RE was safe and feasible in these Veterans with CKD predialysis. Improvements were observed in peak isometric and isokinetic knee extensor torque, RTD, and STS-5. Lack of change in MT and EI suggest increases in torque generation may have, in part, been due to neurological adaptations. Larger-scale studies are required to determine the potential efficacy of inertial flywheel RE for enhancing neuromuscular health and physical function in persons with CKD.

Cardiovascular Rehabilitation: New Indications For Old Entities.

DIEGO IGLESIAS, JORGE FRANCHELLA, FACSM, IGNACIO DAVOLOS. *UNIVERSITY OF BUENOS AIRES, BUENOS AIRES, Argentina.*
Email: franchellaj@gmail.com

(No relevant relationships reported)

Introduction: The first Argentine Consensus of Cardiovascular rehabilitation (CR) is on the eve of publication. This adds new populations not included in other consensus, on pathologies that the Argentine Society of Cardiology (ASC) has updated through others published in recent years. **Purpose:** To highlight the interest to include pathologies that are increasingly underestimated and require greater focus. Although there are individual experiences that have not been published in Argentina so far. **Methods:** The consensus director, working together with two coordinators, and 35 editors, completed the task force of medical doctors with relevant experience in CR. In addition, had also participated an external evaluation committee comprised of four members, two of them international. The new candidate populations for CR programs are hypertrophic cardiomyopathy (HCM), pulmonary hypertension (PH) and chronic atrial fibrillation (CAF). **Results:** Individuals with these entities tend to over-demand what could trigger undesirable interferences. We focus on brief recommendations on each of them. Table. Synthesis of protocols in the considered pathologies

| | PH | HCM | CAF |
|--------------------|--|--|---|
| Inclusion criteria | Stable patient and with optimal pharmacological treatment. | Asymptomatic (finding). | 1) isolated, or only episode 2) chronic stable. |
| Exclusion criteria | | Symptomatic (intolerance to effort) or with demonstrable associated pathology. | paroxysmal, or repeated |
| Patient training | + | + | + |
| Elongation | yes | yes | Yes |
| Balance | yes | yes | Yes |
| Coordination | Yes | Yes | yes |
| Aerobic power | yes | no | Yes |
| Aerobic resistance | yes | yes | Yes |
| Strength | Yes | no | yes |
| Cool down | yes | yes | yes |
| Nutrition | + | + | + |
| Psychology | + | + | + |

Conclusion: 1) The valuable contribution that will constitute the consensus on CR next to be published by the ASC stands out. 2) It focuses on the value it will have on three pathologies previously not sufficiently considered. 3) It also inferred the value it will generate when inducing the registry during its implementation, since there is not data enough in Argentina in this regard. 4) It proposes the integration and interaction of the different regions of the country in the same, which will stimulate the valuable integral contribution of the community of specialists in cardiology of Argentina. 5) It should be noted that at the last meeting of the ASC, in October 2018, 10,000 attendees were registered.

Low-health Literate Patients With Heart Failure Are At An Increased Risk Of Readmission

James Kostra II¹, Kelly Allsup², Amanda Delligatti¹, Gavid Hickey², John Jakicic, FACSM³, Daniel E. Forman². ¹University of Pittsburgh, Pittsburgh, PA. ²VA Pittsburgh, Pittsburgh, PA. ³Healthy Lifestyle Institute, University of Pittsburgh, Pittsburgh, PA. (Sponsor: John Jakicic, FACSM)
Email: jkk83@pitt.edu

(No relevant relationships reported)

PURPOSE: Health literacy (HL) is the degree to which individuals can obtain, process, and understand basic health information and services needed to make proper health decisions. Low-HL is associated with reduced adherence to exercise, medications, healthy nutrition, and low utilization of preventive health services. Cardiac Rehabilitation (CR) is a secondary prevention program that targets risk factor education and reduction, to associated improvements in health status. Heart failure (HF) has recently been added as an eligible diagnosis for CR, and it is associated with particularly high rates of readmission. We hypothesized that that low-HL may contribute to high hospital readmission among HF patients. To evaluate differences in hospital readmission rates for HF patients who did and did not attend CR. To compare rehospitalization in relation to low- versus (vs) high-HL in the HF patients who attended CR. **METHODS:** Retrospective quality improvement analysis. Comparison of matched HF patients who did versus did not attend CR. We then assessed HL in those who attended CR to compare 30-day and 90-day readmissions in patients with low-HL (less than 9th grade reading level) vs high-HL (greater than 9th grade reading level). HL was evaluated using the REALM-SF. **RESULTS:** Readmissions in 104 HF patients who attended CR were significantly lower than in the HF patients who did not attend CR (17.44% vs 21% at 30 days, and 22.62 vs. 39.3% at 90 days). Among the 104 HF patients who attended CR, 67 who categorized as high-HL had significantly lower readmission than the 37 who categorized as low-HL at both 30 (8.96% vs 29.73, $p=0.0061$) and 90 days (22.39% vs. 40.54%, $p=0.05$). **CONCLUSIONS:** CR enrollment was associated with reduced readmission in HF patients. Among HF patients who attend CR, low-HL was associated with relatively greater risks of rehospitalization compared to patients with high-HL, suggesting that refinements to address low-HL might improve the efficacy of CR.

| Readmission rates in HF patients who participated in VA Pittsburgh Cardiac Rehab (N=109) | | | | | | | |
|--|---|---------|--|---------|-------|--------------|---------|
| | Low health literacy <9 th grade (N=37) | | High Health literacy ≥9 th grade (N=67) | | | | |
| | Frequency (n) | Percent | Frequency (n) | Percent | OR | 95% CL | P-value |
| ≥1 hospital readmission within 30 days | 11 | 29.73 | 6 | 8.96 | 4.30 | (1.44, 2.86) | 0.0061 |
| ≥1 hospital readmission within 90 days | 15 | 40.54 | 15 | 15 | 22.39 | (0.98, 5.65) | .05 |

Feasibility Of Overground High-intensity Interval Training (hit) In Persons With Chronic Stroke

Daniel L. Carl, Victoria Scholl, Sarah Doren, Emily Staggs, Dustyn Whitesel, Kari Dunning, Hamza Sultan, Pierce Boyne. *University of Cincinnati, Cincinnati, OH.*
Email: daniel.carl@uc.edu

(No relevant relationships reported)

Evidence suggests that treadmill (TM) HIT can be safe and effective as a rehabilitation tool in persons with stroke. However, translation to overground walking can be limited and no studies have tested overground (OG) HIT. **PURPOSE:** To compare training speeds and HR responses for TM HIT and OG HIT in persons with chronic stroke. **METHODS:** Ten subjects (mean ± SD) 59.8 ± 6.8 years old and 2.4 ± 1.7 years post stroke with comfortable gait speed of 0.41 ± 0.35 m/s and fast gait speed of 0.56 ± 0.56 m/s participated and passed a symptom-limited GXT. Subjects performed 12 sessions of HIT over 4 weeks, alternating short and long interval HIT sessions. Both HIT protocols included 10 minutes of overground HIT (OG1), then 20 minutes of treadmill HIT, followed by another 10 minutes of overground HIT (OG2). Short interval HIT involved 30s bursts at maximum safe speed and 30-60s rest periods. Long interval HIT involved 4-min bursts at ~90% of peak heart rate (HR_{peak}) from the GXT and 3-min recovery periods at ~70% HR_{peak}. Variables recorded included gait training speeds and mean and max heart rate. OG1 and OG2 data were combined to control for warm up and cardiovascular drift effects. Mixed effects models were used to compare TM and OG exercise responses, while accounting for repeated measures from the same participant.

RESULTS: All participants completed 12 sessions and no serious adverse events occurred. With the short interval protocol, OG HIT elicited significantly slower gait training speeds than TM HIT (0.75 vs. 0.90 m/s, p<0.0001), with lower mean HR (78.4 vs 82.9 %HR_{peak}, p<0.0001) and max HR (89.2 vs. 97.0 %HR_{peak}, p<0.0001). With the long interval protocol, OG HIT elicited significantly faster gait training speeds than TM HIT (0.66 vs. 0.51 m/s, p<0.0001) with similar mean HR (81.2 vs 81.9 %HR_{peak}, p=0.10) and lower max HR (92.7 vs. 95.8 %HR_{peak}, p<0.0001).

CONCLUSIONS: OG HIT appears to be reasonably feasible and safe in chronic stroke. Mean OG HIT speeds were 34% and 18% faster than baseline fastest gait speed for short and long interval HIT, respectively. For short interval HIT, it may be optimal to combine the task specificity of overground training with the higher speeds and intensity of treadmill training. For long interval HIT, treadmill training does not appear to provide the same intensity benefit and overground training alone may be superior.

Cardiorespiratory Differences Between Knee Scooter and Crutch Use for Mobility.

Charles RC Marks, Caitlyn Heath. *Oakland University, Rochester, MI.* (Sponsor: Tamara Hew-Buttler, FACSM)
Email: marks@oakland.edu

(No relevant relationships reported)

PURPOSE: In recent years, use of knee scooters (KS) has increased as a modality for moving around with a foot or ankle injury. There is a paucity of research examining the physiological demands of the knee scooter. Therefore, the purpose of this study was to compare moving on a knee scooter with moving using crutches (C). **METHODS:** Nineteen (13 females, 6 males) apparently healthy young adults were recruited. The participants had one day of practice then another day of testing. Participants completed a figure eight hallway route (196 m) under three conditions: first with walking, then (order randomized) using C and KS. The speed was self-paced with six minutes of sitting rest between conditions. Heart rate and oxygen consumption were monitored

with a mobile metabolic system. With alphas = 0.05, One-Way Repeated Measures ANOVA with paired t-Testing (Bonferroni with Holm’s sequential adjustment) for *post hoc* testing were done. **RESULTS:** The average VO₂ (1223 ± 321 mL/min) of C was significantly 27% higher than the average VO₂ (992 ± 221 mL/min) for the KS. In addition, the average heart rate (164 ± 17 bpm) for the C was significantly 12% higher than the average heart rate (146 ± 24 bpm) for C. Crutch use speed was on average non-significantly 4.2% (2.9 m/min) slower than the KS speed. **CONCLUSIONS:** The KS caused less cardiorespiratory stress than the C. This indicates that the KS be recommended over C especially for those with poor fitness levels. Supported in part by an Oakland University Honors College Grant.

295 Board #133 May 29 11:00 AM - 12:30 PM

Feasibility of Stroke Volume Measurement during Treadmill Exercise in Adults with Down syndrome.

Brooks A. Hibner, Thessa I.M. Hilgenkamp, Elizabeth C. Schroeder, Bo Fernhall, FACSM. *University of Illinois at Chicago, Chicago, IL.*
Email: bhibne2@uic.edu

(No relevant relationships reported)

Individuals with Down syndrome (DS) exhibit reduced peak aerobic capacity (VO_{2peak}) compared to those without DS. Lower VO_{2peak} is partly due to impaired autonomic function, resulting in lower peak heart rate, thus altering cardiac output (CO). Autonomic dysfunction may also impact stroke volume (SV), further affecting CO. SV can be determined during exercise by measuring blood flow velocity in the ascending aorta with continuous wave (CW) Doppler echocardiography. It is unknown whether individuals with DS will tolerate the method or if it is feasible due to their specific physical features and gait abnormalities. **PURPOSE:** To determine the feasibility of SV measurement during exercise using CW Doppler in adults with and without DS. **METHODS:** Adults with DS (n= 6, 25 ± 2 yrs, 31.7 ± 4.6 kg/m², 24.2 ± 4.2 ml/kg/min) and without DS (n= 5, 26 ± 4 yrs, 24.9 ± 4.8 kg/m², 32.5 ± 6.4 ml/kg/min) performed a maximal incremental treadmill test to assess VO_{2peak}. Images were obtained at rest and every 2 min, until 8 min, of the treadmill test. Success rate of CW Doppler was expressed as a percent of acquired images vs total potential images. The method was feasible if success rate was ≥80%, and if obtained values for SV indexed to body surface area (SVI) were physiologically plausible. **RESULTS:** Resting measures were equally feasible with both groups at 100% success rate. As exercise progressed, the ability to obtain clear images was compromised, however, feasibility remained ≥ 80% in both groups. Further, percent change of SVI from rest to 8 min was within expected range (DS: 24.4%, Control: 22.7%). **CONCLUSIONS:** This pilot data indicates that SV measures during exercise with CW Doppler are feasible in adults with DS similar to that in controls, even with the DS-specific physical characteristics and gait pattern. Future research with more subjects should compare the SVI and CO with increasing exercise intensity between groups to better understand what limits exercise capacity in persons with DS.

| | | DS (n=6) | Control (n=5) |
|--|--------------|-------------|---------------|
| Seated Rest | Success rate | 100% (6) | 100% (4) |
| | SVI | 42.5 ± 6.5 | 34.3 ± 10.7 |
| Standing Rest | Success rate | 100% (6) | 100% (4) |
| | SVI | 36.9 ± 11.0 | 32.4 ± 12.8 |
| 2 minutes exercise | Success rate | 83% (6) | 100% (4) |
| | SVI | 54.0 ± 8.8 | 43.6 ± 14.2 |
| 4 minutes exercise | Success rate | 83% (6) | 100% (5) |
| | SVI | 56.2 ± 16.0 | 46.9 ± 16.4 |
| 6 minutes exercise | Success rate | 100% (6) | 80% (5) |
| | SVI | 54.2 ± 18.4 | 45.8 ± 17.2 |
| 8 minutes exercise | Success rate | 100% (6) | 80% (5) |

Exercise Preconditioning Reduces Brain Damage and Accelerates Physical Rehabilitation in Rats with Cerebral Ischemia

Wenqian Deng, Ke Chen, Duanhao Wang, Haihao Ma, Yanan Zhao, Xiang Zhou. *Chengdu Sport Institute, Chengdu, China.*
 (Sponsor: Tongjian You, FACSM)
 Email: deng_wen_qian@163.com
 (No relevant relationships reported)

Stroke has become one of the major causes of disability and mortality worldwide. There is increasing evidence that exercise training is associated with reduced risk of stroke. However, the effects of exercise training on protection of brain damage and subsequent motor and vestibular functions have not been fully understood.

PURPOSE: To determine the effects of exercise training prior to brain ischemia on protection against brain damage and subsequent motor and vestibular functions following transient cerebral ischemia/reperfusion injury in rats.

METHODS: Male Sprague-Dawley rats were either endurance exercise trained (N=10, ET, treadmill running at 16 m/min, 0° incline, 60 mins/day, 5 day/week, 4 weeks), resistance exercise trained (N=10, RT, climbing vertical ladder start load at 75% bodyweight with an additional 15% bodyweight added every 2 sets of climb until exhaustion, 10 sets/day, 5 day/week, 4 weeks) or remained sedentary (N=20) for 4 weeks. Brain ischemia induced by transient middle cerebral artery occlusion (MCAO) or sham surgery (sham) were then performed on these rats, which results in four groups: sham, MCAO, ET+MCAO, and RT+MCAO. 24 hours after the induction of brain ischemia, motor and vestibular functions were evaluated by various scoring methods. Ischemic infarct volume was measured by triphenyltetrazolium chloride (TTC) staining. One-way ANOVA followed by post-hoc Bonferroni test were used for data analysis.

RESULTS: Rats in both ET+MCAO and RT+MCAO group had significantly lower cerebral infarct volumes when compared to those in MCAO group (31.97±8.65% vs. 37.85±10.45% and 33.13±7.82% vs. 37.85±10.45%, respectively $p < 0.05$). Consistently, the coordinated locomotor function and vestibular function were also significantly improved in ET+MCAO (2.33±0.52 vs. 3.40±0.89, 1.77±0.97 vs. 2.56±1.23) and RT+MCAO (2.40±0.55 vs. 3.40±0.89; 1.78±1.09 vs. 2.56±1.23) in comparison to MCAO group ($p < 0.05$), while the rats in the sham group did not exhibit any cerebral injury and functional impairment. There were no difference between the two exercise training groups.

CONCLUSIONS: Exercise preconditioning prior to brain ischemia induction effectively reduced cerebral infarct volumes and protected against the decline in motor and vestibular functions in a rat model of brain ischemia.

The Effect of Physical Activity on Hemodynamic Response to Angiotensin Converting Enzyme Inhibition in Hypertension

Stephen A. Maris, Jonathan S. Williams. *Brigham and Women's Hospital & Harvard Medical School, Boston, MA.*
 Email: stephen.a.maris@gmail.com
 (No relevant relationships reported)

PURPOSE: Physical activity (PA) can reduce blood pressure (BP) in hypertensive populations. Although underlying mechanisms remain unclear, an interaction with the renin-angiotensin-aldosterone system (RAAS) is a logical focus of exploration. We conducted a nested cohort analysis to determine if reported level of PA was associated with vascular responsiveness to acute angiotensin converting enzyme inhibition (ACEi).

METHODS: Data were extracted from the HyperPATH dataset, which is an ongoing program to identify genetic mechanisms underlying cardiometabolic risk. Individuals with hypertension who completed a physical activity self-assessment and who had completed hormonal assessment (serum aldosterone [ALDO] and plasma renin activity [PRA]) and vascular response (BP) to a single dose of an ACEi (captopril 25mg) were included for analysis. All participants (n=144) were studied in a clinical research center after overnight, supine, fasting status and on a sodium, potassium, and calcium controlled diet for 7 days. PA was reported as 1) no additional PA, 2) little, 3) moderate, or 4) high amounts of exercise. The response to ACEi was evaluated by ANOVA or multivariate regression when appropriate, with all analyses adjusted for age, sex, race, and BMI.

RESULTS: As expected, both acute ACEi and increased PA levels were significantly associated with reduced systolic BP ($p < 0.05$). However, individuals who reported

high amounts of exercise displayed a greater BP lowering effect from ACEi compared to those who reported moderate (-14.8 ± 8.1 mmHg vs -8.4 ± 9.9 mmHg, $p < 0.01$) or no additional PA (-14.8 ± 8.1 mmHg vs -2.6 ± 9.9 mmHg, $p < 0.001$). Exploratory analyses indicated high amounts of PA were associated with: a reduced heart rate when compared to no PA (54.2 ± 7.7 bpm vs 66.4 ± 9.8 bpm, $p < 0.001$), reductions in PRA (0.42 ± 0.48 ng/ml/hr vs 0.59 ± 0.52 ng/ml/hr, $p < 0.05$), and reductions in ALDO ($\beta = -0.44$, CI=0.19-0.70, $p = 0.001$).

CONCLUSIONS: Higher levels of self-reported PA are associated with decreased BP, and acute ACEi resulted in an augmented BP lowering effect in hypertensive subjects. PA is inversely correlated with RAAS activity. These data shed light on how physical activity interacts with vascular function in RAAS activity and suggest that PA and ACEi medications may act synergistically.

Previous Aerobic Exercise Increase Vo2 Peak And Improves Renal Protective Effects In Chronic Kidney Disease

Wesley H. Silva, Rafael S. Luiz, Alexandre Saul, Natália R. Vaccas, Luciana Jorge, Samuel Trindade, Rodolfo Rampaso, Nestor Schor (in memoriam). *Universidade Federal de São Paulo, São Paulo - SP, Brazil.*
 Email: wesleyhenrique@gmail.com
 (No relevant relationships reported)

INTRODUCTION: Patients with chronic kidney disease (CKD) have lower physical and when compared to the general population. It is common for patients with chronic diseases to be physically inactive, therefore patients with CKD in their different stages, present reduced physical capacity around 60% to 70% of the level expected for the age. **OBJECTIVE:** Evaluate the effects of previous aerobic exercise on oxygen consumption (peak VO₂), renal function and glomerulus sclerosis index in rats with CKD due to nephrectomy 5/6 (Nx5/6). **METHODS:** Adult Wistar rats were divided into groups (n = 8): Sedentary+Nx5/6+Sedentary (Sed), Sedentary + Nx5/6 + Exercise (Sed-Exe), Exercise + Nx5/6 + Sedentary (Exe-Sed) and Exercise + Nx5/6 + Exercise (Exe). The exercise was performed on treadmill, the intensity of 40 to 60% of the maximum load test, 60 minutes a day and 5 times a week, during the total period of 8 weeks of training. Nx5/6 was performed in the 4th week of the training protocol. Blood pressure (BP), oxygen consumption (Vo₂ peak), proteinuria, nitrogen urea base (BUN) and glomerulus sclerosis index were evaluated in the hematoxylin-Eosin staining.

RESULTS: There was an increase in the Sed-Exe and Exe groups in relation to the Sed group (34.2 ± 2.1; and 37.9 ± 1.7 vs. 24.8 ± 0.6, $p < 0.05$, respectively). The Exe group presented a significant reduction in proteinuria when compared to the Sed-Exe group (176.6 ± 39.2 vs 61.1 ± 20.9, $p < 0.05$, respectively). The BUN of the Exe-Sed group was inferior to Sed group (31.7 ± 2.3 vs 65.6 ± 7.8, $p < 0.05$, respectively). There was a decrease in BP in the Sed-Exe and Exe groups when compared with the Sed group (215 ± 1 and 219 ± 2 vs 251 ± 2, $p < 0.05$, respectively), but the BP values still remained high. The glomerulus sclerosis index was classified as follows: the Exe group presented the mild degree index (25%), the Sed-Exe and Exe-Sed groups moderate degree (50%), and the sedentary group presented degree high (over 75% injury).

CONCLUSION: The exercise minimizes the impact of Nx5/6, attenuating proteinuria, important analysis of progressive loss of renal function. Increasing physical capacity and VO₂. Finally, previous exercise indicates protection for CKD, especially under this experimental protocol. Thus, it is reasonable to suggest that exercise may be an additional strategy to be employed in CKD.

 (No relevant relationships reported)

Efficacy of exercise to improve renal function remains understudied in adults with mid-spectrum chronic kidney disease (CKD). In addition, a comparison of steady-state exercise (SSE) and high-intensity interval exercise (HIIE) may contribute clinically-relevant information for exercise-related augmentation of renal function in mid-spectrum CKD. **PURPOSE:** To determine the influence of SSE and a comparable amount of HIIE on indicators of post-exercise renal function in patients diagnosed

with secondary Stage 3 or 4 CKD. **METHODS:** Twenty participants (n = 6 men; n = 14 women; age 62.0 ± 9.9 yr; weight 80.9 ± 16.2 kg; body fat $37.3 \pm 8.5\%$ of weight; VO_{2max} 19.4 ± 4.7 ml/kg/min) completed 30 min of SSE at 65% $VO_{2reserve}$ or HIIE by treadmill walking (90% and 20% of $VO_{2reserve}$ in 3:2 min ratio) in a randomized crossover design. Both exercise conditions averaged ~ 65% $VO_{2reserve}$. Blood and urine samples were obtained by the same technician under standardized conditions just before, 1hr and 24hrs after exercise. Serum creatinine (sCR), urine epidermal growth factor ratio (uEGFr), cystatin C and estimates of glomerular filtration rate - modification of diet in renal disease (MDRD) and the CKD-EPI - responses were analyzed using 2 (condition) by 3 (sample point) repeated measures ANOVAs. **RESULTS:** sCR decreased from 1.45 ± 0.05 pre-exercise to 1.26 ± 0.05 mg/dl (-13%) 1hr after exercise and returned to pre-exercise levels by 24hr ($p = 0.009$). Both MDRD and CKD-EPI estimates of glomerular filtration rate were 16 to 19% higher at 1hr, returning to pre-exercise values by 24hrs after exercise. The MDRD estimate increased from 43.1 ± 1.9 pre-exercise to 50.3 ± 2.1 ml/min/1.73m² 1hr after exercise ($p = 0.007$) and CKD-EPI from 45.2 ± 2.1 to 53.8 ± 2.4 ml/min/1.73m² at 1hr post-exercise ($p = 0.009$). Relative to pre-exercise measures, uEGFr remained stable with SSE but was 5.4% greater 24hr after HIIE ($p = 0.052$). Cystatin C remained stable in the hours after exercise ($p > 0.05$). **CONCLUSION:** By clinical estimates, renal function was not normalized but transiently improved with SSE and HIIE in mid-spectrum CKD.

With aging, there is a decline in both skeletal muscle size and quality. This occurrence is known as sarcopenia and the implications due to this decline can be debilitating. Previous research has elucidated genes that are associated with muscle sarcopenia and how a change in expression can affect both muscle protein synthesis and degradation, which can affect skeletal muscle size and quality. **PURPOSE:** To investigate the expression of genes relating to skeletal muscle growth, collagen synthesis, and inflammation across the lifespan of rats. **METHODS:** Sedentary male Fischer 344 rats were fed ad libitum and were aged to 3 and 24 months (mo) (n=8 per age group) and then sacrificed. Body and gastrocnemius (gastroc) weights were collected and muscle was processed for RNA isolation and sent out for RNA sequencing. The following genes relating to muscle growth, collagen synthesis and inflammation were analyzed: Myostatin (MSTN), Insulin-like Growth Factor 1 (IGF-1), Insulin-like Growth Factor 2 (IGF-2), phosphorylated Mechanistic Target of Rapamycin (mTOR), Collagen Type I Alpha 1 Chain (COL1a1), Collagen Type I Alpha 2 Chain (COL1a2), Collagen Type IV Alpha 1 Chain (COL4a1), Lysyl Oxidase (LOX), Nuclear Factor Kappa B Subunit 1 (NFkB1), Tumor Necrosis Factor (TNF), Interleukin 6 (IL-6), and Interleukin 1 Beta (IL-1B). **RESULTS:** MSTN expression was significantly higher in 3 vs. 24 mo rats ($p = 0.018$), and was positively correlated to relative gastroc weights ($R = 0.663$, $p = 0.005$). All genes related to collagen synthesis were significantly higher in 3 vs. 24 mo rats (COL1a1, $p < 0.001$; COL1a2, $p = 0.007$; COL4a1, $p = 0.030$; LOX, $p = 0.046$). Furthermore, COL1a1 and COL1a2 were positively correlated to relative gastroc weight ($R = 0.649$, $p = 0.007$; $R = 0.730$, $p = 0.001$, respectively). However, no genes related to inflammation were significantly different between age groups, but there was a negative correlation between IL-6 gene expression and relative gastroc weights ($R = -0.546$, $p = 0.028$). **CONCLUSION:** We suspect 24-month old rodents may be too young to capture the sarcopenia symptoms that occur with aging. However, the relationship between inflammation and relative gastrocnemius muscle weight may warrant further investigations in rodents older than 24 months.

301 Board #139 May 29 11:00 AM - 12:30 PM Skeletal Muscle Phosphodiester Content is Related to Muscle Mass and Strength in Older Sarcopenic Adults

J. Matthew Hinkley, Heather H. Cornell, Robert A. Standley, Rick B. Vega, Bret H. Goodpaster, Paul M. Coen. *Translational Research Institute for Metabolism and Diabetes, Orlando, FL.*
(No relevant relationships reported)

Age-associated loss of skeletal muscle mass and strength (sarcopenia) is a critical healthcare issue for older adults. Effective therapeutic options are limited in part because the underlying etiology is not well-defined. Studies utilizing magnetic resonance spectroscopy (MRS) revealed that resting phosphorus metabolites and maximal ATP production (ATP_{max}) are altered in muscle from older adults. However, it is unclear whether resting phosphorus metabolites and ATP_{max} are related to muscle characteristics that define the sarcopenic phenotype. **PURPOSE:** To determine whether *in vivo* resting phosphorus metabolites and ATP_{max} are associated with skeletal muscle mass, strength, and function in older adults. **METHODS:** *In vivo* metabolites and ATP_{max} were measured by phosphorus-MRS during rest and following a brief bout of isometric leg contractions in 74 sedentary older adults (68.6 ± 0.5 years; 23M/51F). Skeletal muscle mass was evaluated by DEXA and mid-thigh MRI. Quadriceps contractile function was assessed by Biodex. These variables were further explored in participants that were classified as sarcopenic (n=6) or non-sarcopenic (n=15). Muscle biopsies of the vastus lateralis were obtained to determine fiber type proportion and cross-sectional area by immunohistochemistry. **RESULTS:** Several resting phosphorus metabolites were related with muscle size and function in older adults. In particular, a phosphodiester peak (PDE2), considered a marker of membrane integrity, was negatively associated with skeletal muscle mass index ($r = -0.38$, $p < 0.01$), muscle volume ($r = -0.37$, $p < 0.01$), and peak power ($r = -0.38$, $p < 0.01$). PDE2 was elevated in sarcopenic patients in comparison to non-sarcopenic controls (2.48 ± 0.11 mM vs. 1.92 ± 0.08 mM, $p < 0.01$). ATP_{max} was not different between sarcopenic and non-sarcopenic individuals. At the cellular level, PDE2 was negatively correlated to myofiber area ($r = -0.51$, $p = 0.03$) but not fiber type proportion. **CONCLUSION:** Elevated resting PDE2 levels in muscle were associated with lower muscle mass and strength in older sarcopenic adults. While ATP_{max} was not related to the sarcopenic phenotype, our results reveal that resting *in vivo* phosphorus metabolite profiles may be a viable cellular marker of muscle quality in older adults. Supported by NIH Grants K01 AG04437 and R01 AG021961

302 Board #140 May 29 11:00 AM - 12:30 PM Amount and Variability of Adipose Tissue Content in Human Quadriceps Muscles of Older Adults

INTRODUCTION: Obesity is a significant health problem that can compound health-related morbidities in aging adults. While substantial research has elucidated many of the metabolic consequences of obesity, much less is known about the effects of adipose tissue (fat) deposition on skeletal muscle function. Some evidence exists to suggest that obesity may interfere with muscle force production, but this is an understudied area of research. **PURPOSE:** To quantify *in vivo* the amount and distribution of fat and lean muscle tissue in the quadriceps muscles of healthy older adults. **METHODS:** The dominant legs of 8 healthy, sedentary adults (71 ± 4 yrs, mean \pm SD; 4 men; BMI: 25.1 ± 3.3 kg·m⁻²) were evaluated using a 6-point Dixon imaging technique in a 3 tesla magnetic resonance system. Axial slices (5 mm thick) were acquired for the entire thigh, and each image in which all 4 quadriceps muscles were visible was analyzed to determine fat and muscle volumes (cm³), and fat fractions (fat/total*100; %). The location (% muscle length) of peak muscle volume and fat fraction, as well as the deviation from the line of best fit (2nd order polynomial) of these variables were calculated as measures of tissue distribution and heterogeneity. Differences in means were evaluated by paired t-tests. **RESULTS:** Fat-free muscle volume, fat volume, and fat fraction were 821 ± 287 cm³, 75 ± 26 cm³ and $8.6 \pm 1.1\%$, respectively. Peak muscle volume and fat fraction occurred in different locations (70.7 ± 7.7 vs. $19.3 \pm 23.2\%$ length, $p=0.001$), with a 3-fold greater coefficient of variation for fat fraction than muscle volume. Likewise, slice-to-slice variability of fat fraction was greater than for muscle volume (4.7 ± 1.5 vs. $1.2 \pm 0.3\%$, $p<0.001$). **CONCLUSIONS:** These data show greater spatial variability of fat deposition in comparison to lean tissue in the quadriceps muscles of older adults. Combining these measures with traditional indices of muscle function may provide additional insight about the mechanical impact of intramuscular adipose tissue deposition *in vivo*.

Age-related Changes In The Passive Properties Of The Plantarflexor Muscles

Hayden K. Giuliani, Gena R. Gerstner, Jacob A. Mota, Eric D. Ryan. *University of North Carolina at Chapel Hill, Chapel Hill, NC.* (Sponsor: Abbie E. Smith-Ryan, FACSM)
 (No relevant relationships reported)

Limited data exists examining age-related changes in the passive mechanical properties of the musculotendon unit. **PURPOSE:** To examine the influence of age on maximum range of motion (MROM), peak passive torque (PT_{pass}), and the dissipative coefficient (DC). **METHODS:** Twenty-one young (20.3 ± 2.4 yrs) and 14 older (69 ± 3.1 yrs) men completed MROM and isometric strength (for EMG normalization) assessments of the plantarflexors, following ultrasonography of the gastrocnemii. Muscle cross-sectional area (CSA) and subcutaneous fat corrected echo intensity (EI) of the gastrocnemii were determined as the sum and average of both muscles, respectively. Participants were seated in a calibrated dynamometer, with their leg fully extended and ankle and foot held in a custom steel foot plate. MROM assessments were performed by dorsiflexing the ankle at $5^\circ s^{-1}$ from 10° of plantarflexion to the participants maximally tolerated ROM. PT_{pass} , loading, unloading, and the DC were calculated during the initial 80% of MROM. Independent samples *t*-tests were used to examine group differences. A Pearson's correlation coefficient was used to determine the relationship between PT_{pass} and MROM. Analyses of covariance (ANCOVAs) were used to determine age-related differences in loading and unloading, while controlling for MROM. Additional ANCOVAs were used to determine the age-related difference in DC, while controlling for CSA and EI, respectively. An alpha level of 0.05 was used to determine statistical significance. **RESULTS:** The PT_{pass} , MROM, loading, and unloading ($P \leq 0.046$) were greater in the younger men, whereas the DC and EI ($P \leq 0.024$) were greater in the older men. When accounting for MROM, unloading ($P = 0.044$) remained significantly different between groups, while there was no difference between groups for loading ($P = 0.223$). When accounting for CSA, differences between groups for the DC remained ($P = 0.028$), while there were no longer differences between groups when accounting for EI ($P = 0.120$). PT_{pass} was also strongly related to MROM ($r = 0.755$, $P < 0.001$). Mean EMG amplitude values across muscles was 1.61% MVC. **CONCLUSIONS:** Older men exhibited lower MROM and greater DC, which may be explained by an altered stretch tolerance and qualitative changes (i.e. non-contractile tissue accumulation) in aged skeletal muscle, respectively.

Longevity and Physical Vitality during Aging Altered by Adipose-derived Mesenchymal Stem Cell-Lysate Injection

Chia-Hua Kuo, FACSM. *University of Taipei, Taipei, Taiwan.*
 Email: kuochiahua@gmail.com
 (No relevant relationships reported)

Background: Adipose-derived mesenchymal stem cell (MSC)-lysate injection effectively decreases body weight and improves glucose tolerance in mice on a high-fat diet. **Purpose:** To determine whether lifelong injection of MSC can minimize age-dependent decline in physical vitality and increase longevity in naturally aging rats. **Methods:** Rats were sex-balanced and randomly assigned into the vehicle-injected group ($N = 46$) and the MSC lysate injected group ($N = 46$). We measured body composition by dual energy X-ray absorptiometry (DEXA), spontaneous locomotor activity, and longevity in rats maintained on a normal diet and received an intermittent treatment of human adipose-derived MSC lysate (3 times a week, 11 times a month given every second month), starting at 12 months of age until natural death. Although our data agreed with previous observation on fat loss and marginally improved insulin resistance index subservient to long-term MSC lysate treatments, there was a shortened average lifespan, a longer inactive time, and a greater bone loss with a relative increase in lean mass compared with the vehicle-injected counterparts. **Conclusion:** Tissue renewal in multicellular systems requires regeneration after destruction. The results of the study implicate that simply enhancing regenerative signals from MSC does not beneficial and appear to be harmful for physical vitality and longevity.

 (No relevant relationships reported)

Sufficient intracellular NAD⁺ is required for mitochondrial function and skeletal muscle health during aging. Sirtuins (SIRT), the major NAD⁺-consuming enzymes, regulate mitochondrial function via deacetylating transcription factors and enzymes such as PGC-1 α and GCN5, whereas Poly [ADP-ribose] polymerase 1 (PARP-1), the competing enzyme with SIRT for consuming NAD⁺, is activated by DNA damages during aging, leading to depletion of cellular NAD⁺. Lowered NAD⁺ may dysregulate SIRT and induce hyperacetylation of its target proteins. Thus, it is important to know how aging impacts on NAD⁺ pool and its consuming enzyme levels in the skeletal muscle. **PURPOSE:** To investigate the effect of aging on NAD⁺ and protein levels of SIRT, PARP-1, GCN5, and PGC-1 α as well as protein acetylation (AC) in mouse muscles. **METHODS:** C57BL/6J mice at the age of 6 mo (young, Y; N=8), 12 mo (middle, M; N=8), and 24 mo (old, O; N=8) were used. Quadriceps (Q), gastrocnemius (G), and heart (H) muscles were collected for colorimetric assay and Western blotting to quantify NAD⁺ and proteins levels of various enzymes. **RESULTS:** Aging decreased nuclear NAD⁺ by 60 and 50% ($p < .05$) in the G, and by 60 and 70% ($p < .05$) in the Q of M and O, respectively. SIRT1 in G and Q increased by 3.1-fold ($p < .01$) and 1.4-fold ($p < .05$) with aging, whereas aging had no effect on SIRT1 in H. SIRT3 increased 1.3 ($p < .05$), 2.2 ($p < .01$), and 1.5-fold ($p < .05$), respectively, in G, Q and H of O. SIRT5 was increased by ~4.8-fold ($p < .01$) in G and Q of both M and O, but not in H. Aging increased SIRT6 by ~2.4-fold ($p < .01$) in G and Q, whereas the level was decreased by 50% in H. PGC-1 α was increased in G of M (1.7-fold, $p < .01$) and H of O (2.2-fold, $p < .01$) vs. Y. GCN5 decreased 30% in the Q of O ($p < .01$), but increased by 2.6 and 2.9-fold ($p < .01$) in the H of M and O, respectively. Aging increased PARP-1 by 80% in G of M ($p < .01$), and by 40 and 90% in H of M and O ($p < .01$), respectively, but decreased by 40% in Q of O vs. Y. Cleaved-PARP-1 and AC were increased in all muscles with aging ($p < .01$). **CONCLUSION:** Aging decreased NAD⁺ pool, whereas SIRT, GCN5, PARP-1, and AC were increased with aging. Decreased level of NAD⁺ and increased levels of NAD⁺-consuming enzymes in aged muscles may intensify the competition among enzymes for utilizing NAD⁺, which can contribute to age-associated mitochondrial dysfunction and muscle atrophy.

 (No relevant relationships reported)

Current literature indicates that positive results were obtained on strength, hypertrophy, power, and cognitive performance when strength training protocols were chronically applied in the elderly. Twelve weeks appears to be enough to improve strength and cognitive performance. On the other hand, the age range was large, starting with 60 years through 90 years old in the same study. **PURPOSE:** The purpose of this study was to examine if elderly individuals aged 60 years old to less than 70 years old presented different responses in strength and cognitive performance after 12 weeks of a strength training program. **METHODS:** Thirty elderly women were separated into a control group (CG) ($n=7$), 60 years old group (G60) ($n=14$) and 70 years old group (G70) ($n=9$). The participants had body mass, height, upper lean limbs (ULL), lower lean limbs (LLL), and cognitive performance measured after answered the Montreal Cognitive Assessment (MoCA). The data was analyzed via a one-way ANOVA with $p \leq 0.05$. **RESULTS:** The CG indicated a difference between the G60 and G70 ($p=0.05$) for ULS, LLS, and MoCA, while G60 and G70 had no significant differences in strength capacity and cognitive performance. **CONCLUSIONS:** After 12 weeks of a strength training program all groups improved strength capacity and cognitive performance compared to CG, however no differences were observed between G60 and G70.

 Email: nserrano1991@gmail.com
 (No relevant relationships reported)

PURPOSE: A reduction in satellite cells has been reported to contribute to muscle loss with aging. Exercise presents a powerful strategy to stimulate satellite cells, however, to what extent various forms of exercise stimulate skeletal muscle satellite cells in older adults is less understood. The purposes of this study were to 1) examine relationships of satellite cell density, capillary density, and VO₂peak in older adults, and 2) identify changes in satellite cell density following two different intensities of aerobic exercise.
METHODS: In a counter-balanced, cross-over design, six older adults (4M, 2F; 67±2yr; BMI: 26.6±2.0 kg·m⁻²) completed an acute bout of high-intensity interval (HIIE; ten, 1-min intervals, 85-95% heart rate max, 1-min rest between intervals) and moderate intensity continuous cycling (MOD; 30-min, 60-65% VO_{2peak}), separated by ~1 week. Muscle biopsies (*vastus lateralis*) were obtained before exercise and 24h after each exercise bout. Immunofluorescence was used to identify myosin heavy chain (MHC), satellite cells, and capillaries. **RESULTS:** A significant relationship between capillary density and satellite cell density (P=0.018; R²=0.789) was observed. Significant correlations were also found between satellite cell density and VO₂peak (P<0.001; R²=0.99), capillary density and VO₂peak (P=0.019; R²=0.785), satellite cells/MHC I fiber and VO₂peak (P=0.026; R²=0.750), and satellite cells/MHC II fiber and VO₂peak (P=0.002; R²=0.93) at baseline. Total satellite cells/fiber and fiber type-specific satellite cells/fiber were unchanged in response to acute MOD or HIIE (P>0.05) and no differences were observed between exercise trials (P>0.05). **CONCLUSIONS:** These data reveal positive relationships between capillaries and satellite cell density in skeletal muscle of older adults. Further, while no changes in satellite cell density were observed 24h following acute MOD or HIIE, our preliminary findings suggest an association between satellite cell density and VO₂peak in older adults. Thus, future research is needed to examine whether these exercise strategies differentially impact changes in proliferation or differentiation of satellite cells in older adults, and to what extent capillary density may be related to chronic adaptations in satellite cell density and VO₂peak.

Predicting Prevalence and Mortality in Female Mice Using The Mouse Frailty Phenotype
 Dongmin Kwak¹, Cory W. Baumann², LaDora V. Thompson¹.
¹Boston University, Boston, MA. ²University of Minnesota, Minneapolis, MN.
 Email: skk0831@gmail.com
 (No relevant relationships reported)

Frailty is a clinical syndrome associated with adverse health outcomes. Preclinical studies are important in the identification of the underlying mechanisms contributing to frailty. Interestingly, previous preclinical studies focused on male rodents with minimal attention to female rodents.
PURPOSE: The two purposes of this study were to identify the prevalence of frailty across the lifespan in female mice, and to determine if frailty status at a younger age predicts mortality. **METHODS:** Female C57BL/6J (n=29) were used. Starting at 17 months of age, mice were assessed using a frailty phenotype that consisted of 5 criteria, including body weight, walking speed (Rotarod), strength (grip strength), endurance (treadmill) and physical activity (voluntary wheel running). Mice were tested every three months across their lifespan using the frailty phenotype. The designated cut-off points for each frailty criterion, using 20 months of age characteristics, were set using the top 20% for body weight and bottom 20% for the other 4 criteria. Mice with 3 or more positive frailty markers were identified as frail, mice with 2 markers were identified as pre-frail and mice with 1 or no positive marker were identified as non-frail. **RESULTS:** The mean survival age was 28.1 months, with the first and last mouse dying at 21.1 and 34.3 months, respectively. Prevalence of frailty increased across the lifespan. At 17 months of age, there is evidence of pre-frail and frail mice. Frail mice steadily increased up to 66.7% at 32 months. Non-frail mice steadily decreased to 18.2% at 29 months. Beyond 29 months, no mouse was identified as non-frail. The percentage of pre-frail mice increased and peaked at 26 months (36.8%). Following 29 months this percentage declined, with 18.2 and 33.3% of mice being identified as pre-frail at 29 and 32 months. Frail/pre-frail and non-frail mice had mean survival ages of 26.9 months and 29.0 months, respectively. Frailty status predicted mortality with the non-frail mice living longer than the frail/pre-frail mice (P=0.037). **CONCLUSIONS:** Using a mouse frailty phenotype, we are able to identify

that the prevalence of frailty in female mice increases across the lifespan. In addition to predicting mortality, this frailty phenotype has potential to yield information about underlying mechanisms contributing to frailty.

Bone Health of Patients Diagnosed With Rheumatoid Arthritis
 Sebastien Beaugard, Adriana De la Parra-Sólomon, Nathan Chiarlitti, Alexe Sirois, Susan Bartlett, Ross Andersen, FACSM.
 McGill University, montreal, QC, Canada.
 (No relevant relationships reported)

Rheumatoid arthritis (RA) is the most common type of chronic inflammatory disease in adults and often is associated with bone health problems. It is estimated that poor bone health may occur in 50% of patients. **PURPOSE:** First, to explore bone health among sedentary patients diagnosed with RA. Secondly, to explore the relationship among regional bone mineral density (BMD) with age, weight, and height. **METHOD:** Twenty-one sedentary participants with diagnosed RA whose mean age was 39.43± 18.3yrs, height was 162.56± 7.452 cm, and weight averaged 66.67± 9.07 kg. Dual energy x-ray absorptiometry (DXA) was used to measure bone health. Linear regression was used to explore relationships among age, height, weight, and BMD in RA patients. **RESULTS:** BMD of the FN and L1-L4 averaged 0.12± 1.29 SD and 0.38±1.57 SD, respectively. Mean Z-scores were 0.72± 1.43 for TB, 0.38± 1.57 for LV, and 0.12± 1.29 for the FN. In the FN region 25% of patients had Z-scores below -1 SD and 5% were below -2 SD. In the LS 20% has Z-scores below -1 SD and 45% were below 0 SD. Additionally, no significant relationships were observed among BMD, age, weight, and height. **CONCLUSION:** These findings suggest that a great range of variability in bone health exists in RA patients. Furthermore, healthcare professionals should monitor bone health in the RA population and future interventions should explore the effects of tailored exercise programming to simultaneously improve bone health and well-being.

Cells progenitors potential in Cartilage: Changes from moderate to severe OA
PURPOSE: Recent data suggests that osteoarthritic (OA) cartilage contains mesenchymal progenitor cells (MPC) with multi-differentiation potential. Yet, there is limited information concerning how their prevalence changes with disease stages. Herein, we explore presence, prevalence and differentiation potential of MPC cells isolated from different OA grades. **METHODS:** Human osteoarthritic tibial plateaus were obtained from 25 patients undergoing total knee replacement. Each sample was classified as mild, moderate or severe OA according to OARSI scoring. The mRNA expression levels of CD105, CD166, Notch 1, Sox9, Acan, Col II A1 and Col I A1 were measured at day 0, day 14 (2 weeks in vitro) and day 35 (after chondrogenesis). At D35, the pellets matrix composition was tested on formation of proteoglycan, collagen II and I by HES and Immunofluorescence. **RESULTS:** Cells from all OA grades significantly increased MPC markers mRNA in vitro expression. Proliferated cells expressed MPC specific antigens: CD105, CD166, CD73, CD90, Notch-1 and Nucleostemin. The chondrogenesis induced decrease in CD105, Notch 1 and Sox9 mRNA only in mild and moderate OA. Yet, only moderate OA-derived pellets revealed significantly high levels of proteoglycans and hyaline cartilage marker - collagen II and low expression of fibrocartilage marker - Collagen I at both mRNA and protein level. **CONCLUSION:** A novel finding emerges from our data confirms differences in MPC potential between OA grades. Only moderate OA-derived cells were able to form hyaline-like matrix.

Correlation between Generalized Joint Hypermobility and Chronic Musculoskeletal Pain in College Students
 Kaylee R. Fichthorn, Peter R. Reuter. *Florida Gulf Coast University, Fort Myers, FL*
 Email: krfichthorn9132@eagle.fgcu.edu
 (No relevant relationships reported)

The main complaint of patients with benign joint hypermobility syndrome (BJHS) is chronic musculoskeletal pain (MSP) that may affect their daily activities, leading to a decreased quality of life. While some studies support an association between generalized joint hypermobility (GJH) and MSP in children and adolescents, there is no published study yet looking into a correlation of GJH and MSP in a college-aged population in the US. **PURPOSE:** To determine whether young adults with generalized joint hypermobility are more likely to suffer from chronic musculoskeletal pain. **METHODS:** Undergraduate students studied the general structure of joints and range of motion, including joint hypermobility, before completing a survey that included questions about chronic musculoskeletal pain and the severity of pain. They worked in groups to evaluate each other's joints for hypermobility under supervision by the research team. **RESULTS:** Overall, 20.8% of 654 participants showed GJH based on a cutoff Beighton score of ≥ 4 . Women had statistically significant higher rates of GJH (23.9%) than men (12.2%) (Wald Test, $DF = 1$, Chi-square = 10.049, $P = 0.0015$; odds ratio female to male: 0.44). Ninety four of 650 participants (14.4%) recalled chronic joint pain. The most commonly named joints were knee ($n = 59$), shoulder ($n = 17$), hip ($n = 14$), ankle ($n = 9$), and elbow ($n = 7$). Male and female participants with GJH reported higher rates of chronic joint pain than participants without GJH. There was, however, no significant difference (Pearson Chi-square Test, Chi-square = 1.386, $p = 0.5001$, $n = 650$). The prevalence of chronic neck/back pain in our study was 20.8%. Participants with GJH reported higher rates of chronic back/neck pain, yet, the difference was not statistically significant (Pearson Chi-square Test, Chi-square = 3.850, $p = 0.1459$, $n = 650$). The average pain intensity on a scale from 0 to 10 was more or less the same for both types of chronic pain (4.5 for chronic joint pain, 4.2 for chronic neck/back pain) and for respondents with and without GJH. The ranges for the reported pain intensity as well as the standard deviations for all averages were also very similar. **CONCLUSION:** Young adults with GJH are not reporting higher rates of chronic pain in joints, the neck or the back nor do they suffer from more severe pain than their peers without GJH.

Association between Muscle Carnosine Content and Changes in Muscle Cytokines following Lower-Body Resistance Exercise
 David D. Church¹, Adam R. Jajtner², Jeremy R. Townsend³, Kyle S. Beyer⁴, Michael B. La Monica⁵, Leonardo P. Oliveira⁶, Jay R. Hoffman, FACSM⁷. ¹University of Arkansas for Medical Sciences, Little Rock, AR. ²Kent State University, Kent, OH. ³Lipscomb University, Nashville, TN. ⁴Bloomsburg University, Bloomsburg, PA. ⁵Missouri State University, Springfield, MO. ⁶The University of Chicago, Chicago, IL. ⁷University of Central Florida, Orlando, FL. (Sponsor: Jay R. Hoffman, FACSM)
 (No relevant relationships reported)

PURPOSE: Carnosine has a pluripotent role in skeletal muscle (SkM) physiology, enhancing intracellular buffering and acting as an antioxidant, antiglycating and ion-chelating agent. Carnosine also acts as a diffusible Ca²⁺/H⁺ exchanger. Cytokines mediate the inflammatory response to exercise-induced muscle damage. Carnosine's role as a physiochemical buffer and antioxidant may affect SkM cytokine production. Therefore, the purpose of this study was to assess the association between SkM carnosine content and cytokine production following a lower body resistance exercise session.

METHODS: Ten recreationally active men completed a lower body resistance exercise protocol consisting of the squat, leg press, and leg extension exercises. SkM biopsies were obtained from the vastus lateralis at baseline (BL), one hour (1H), and five hours (5H) post-resistance exercise. SkM Carnosine content was assessed via high performance liquid chromatography. Multiplex signaling assay kits were used to quantify SkM cytokines (GCSF, GMCSF, IL-1ra, IL-6, IL-8, MCP-1, TNF- α), and fold changes from BL were calculated. Associations were assessed with Pearson bivariate correlations, with significance set at $\alpha \leq 0.05$.

RESULTS: Carnosine content was not significantly associated with 1H and 5H changes of GCSF ($r = 0.257$, $p = 0.473$; $r = 0.254$, $p = 0.479$, respectively), GMCSF ($r = -0.285$, $p = 0.426$; $r = -0.431$, $p = 0.214$, respectively), IL-1ra ($r = -0.019$, $p = 0.962$; $r = 0.126$, $p = 0.747$, respectively), IL-6 ($r = -0.192$, $p = 0.596$; $r = -0.011$, $p = 0.977$, respectively), MCP-1 ($r = -0.491$, $p = 0.150$; $r = 0.147$, $p = 0.685$, respectively), or TNF- α ($r = -0.050$, $p = 0.899$; $r = -0.239$, $p = 0.537$, respectively). However, a trend for a significant positive correlation was noted for IL-8 at 5H ($r = 0.705$, $p = 0.051$), but not at 1H ($r = 0.044$, $p = 0.918$).

CONCLUSIONS: SkM Carnosine content was not associated with the change in GCSF, GMCSF, IL-1ra, IL-6, MCP-1, or TNF- α following resistance exercise. However, a trend for a significant positive association was observed for IL-8 at 5H and carnosine content. IL-8 and carnosine are involved in the histamine response to stress and intracellular Ca²⁺ handling, which may explain the observed relationship. Further research is required to discern the observed correlation.

Redefining Physiologic Predictors of Endurance Performance with Measures of Skeletal Muscle Oxygenation: E pluribus unum

Philip M. Batterson, Michael R. Norton, Sarah E. Hetz, Sachi Rohilla, Keston Lindsay, Andrew W. Subudhi, FACSM, Robert A. Jacobs. *University of Colorado Colorado Springs, Colorado Springs, CO.* (Sponsor: Andrew W. Subudhi, FACSM)
 Email: pbatters@uccs.edu

Reported Relationships: P.M. Batterson: Consulting Fee; Moxy Monitor, Fortiori Design, LLC.

PURPOSE: To scrutinize the ability of classic measures of endurance performance vs. NIRS-derived measures of skeletal muscle oxygenation to predict 25 km cycling time trial performance. **METHODS:** 14 participants (4 f / 10 m) underwent 3 sequential exercise bouts on a cycle ergometer while fitted with NIRS devices over each vastus lateralis: 1) A warmup consisting of 2 sequential 7.5-min bouts of 50 and 100 W at 80 rpm to determine gross efficiency (GE), exercise economy (EC), and delta efficiency (DE) across the same absolute workloads followed by an incremental max test to volitional fatigue (VF) used to discern 3 separate measures of ventilatory threshold (VT), maximal rates of whole-body oxygen consumption (VO_{2max}) and maximal aerobic power (W_{max}); 2) A warmup consisting of 2 sequential 7.5-min bouts at 80 rpm corresponding to 15% and 30% W_{max} for GE, EC, and DE across the same relative workloads followed by a 60 sec ramp to a sustained 110% W_{max} until VF to verify VO_{2max} ; and 3) A 25 km TT. Ventilatory measures were sampled throughout bouts 1 and 2. **RESULTS:** Stepwise and multiple linear regression analyses revealed that from the classic variables only mean VT_{VO2} (2.59 ± 0.53 l O₂·min⁻¹, $p = 0.019$) and EC at 15% W_{max} (47 ± 10 W, $p = 0.030$) explained (adj R² = 0.463; $p = 0.013$) 25 km TT performance ($46:40 \pm 04:36$ min:sec) variance whereas the change in skeletal muscle oxygenation (ΔSmO_2 ; $-6.9 \pm 6.1\%$; $p = 0.001$) from 50 to 100 W and the deoxygenated hemoglobin and myoglobin index (HHb) at W_{max} (9.57 ± 1.56 ; $p = 0.044$) were the best NIRS-derived variables to describe TT performance (adj R² = 0.751; $p < 0.001$). When combining all variables, skeletal muscle measures provided a superior physiologic explanation of 25 km TT performance versus those classically used to describe endurance performance (VT_{VO2} , EC @ 15% W_{max} , HHb_{max}, and ΔSmO_2 at $p = 0.083$, 0.056, 0.008, and 0.005, respectively). **CONCLUSION:** These results demonstrate that measures reflecting the balance of skeletal muscle O₂ delivery and utilization during exercise are superior to classic measures of whole-body aerobic capacity, ventilatory threshold, and/or the efficiency of exercise at predicting 25 km time trial (TT) cycling performance.

Western Diet-Induced Obesity Does Not Cause Diaphragm Muscle Abnormalities

Rachel C. Kelley, Dongwoo Hahn, Derek R. Muscato, Leonardo F. Ferreira. *University of Florida, Gainesville, FL.* (Sponsor: Dr. Michael Reid, FACSM)
 Email: kelleyrc@ufl.edu

(No relevant relationships reported)

Purpose: Obese individuals demonstrate ventilatory abnormalities at rest and during exercise, which may reflect inspiratory (diaphragm) muscle weakness. Several studies have shown diaphragm abnormalities in genetically obese animal models. However, the effects of an obesogenic diet on the diaphragm are not well defined. The purpose of this study was to determine if a Western diet (high-saturated fat, high-sugar: HFHS) causes diaphragm muscle pathology, perhaps related to oxidative stress.

Methods: Adult male Wistar rats were randomly allocated to one of two ad libitum diets for 24 weeks: healthy control ($n=8$) or HFHS diet ($n=8$). Diaphragm muscle then underwent i) in vitro contractile function assessment, ii) histology and immunohistochemistry for determination of fibrosis and fiber cross-sectional area (CSA) and iii) analysis of mitochondrial reactive oxygen species (ROS) emission. Data are mean \pm SE.

Results: We previously reported that HFHS diet did not impair diaphragm maximal specific force or peak power. Alongside this maintenance of contractile function, HFHS-fed rats did not differ in diaphragm muscle interstitial fibrosis (in %: lean 3.4 ± 0.8 , HFHS 2.7 ± 1.7), type I fiber CSA (in μm^2 : lean 1954 ± 121 , HFHS 2174 ± 103), type IIa fiber CSA (in μm^2 : lean 2062 ± 329 , HFHS 2412 ± 155), or type IIb/x fiber CSA (in μm^2 : lean 4165 ± 1232 , HFHS 4523 ± 526). Additionally, no shifts in fiber type occurred. Interestingly, HFHS diaphragm demonstrated a trend toward a lower succinate-induced increase in ROS emission (in pmol/min: lean 1.313 ± 0.2 , HFHS 0.73 ± 0.2 , $p = 0.09$). Analyses of glutathione and antioxidant enzymes are ongoing. **Conclusion:** A high-saturated fat, high-sugar diet did not induce diaphragm muscle dysfunction or morphological changes. These results, combined with our previous findings of normal contractile function, suggest that intrinsic diaphragm muscle abnormalities do not contribute to breathing difficulties in obesity.

Anabolic Signaling Phosphorylation Does Not Explain Differential Muscle Protein Synthesis with Intra-Set Rest Manipulation

Colleen F. McKenna¹, Amadeo F. Salvador¹, Andrew T. Askow², Sarah S. Burke¹, Scott A. Paluska, FACSM¹, Jonathan M. Oliver², Nicholas A. Burd¹. ¹University of Illinois Urbana-Champaign, Urbana, IL. ²Texas Christian University, Fort Worth, TX. (Sponsor: Scott A. Paluska, FACSM)
 (No relevant relationships reported)

Power development is imperative for dynamic sport athletes. Cluster sets (CLU) are an effective method to allay the progressive decrement in power output normally observed in a traditional (TRD) resistance exercise strategy. CLU configurations incorporate a brief intra-set rest period to preserve velocity and power. Despite favorable performance, we previously established that TRD configurations elicit higher myofibrillar protein synthesis (MPS) rates when compared to CLU. However, it remains unclear if hallmark readouts related to mTORC1-signaling underlie this observation.

PURPOSE: To elucidate anabolic signaling mechanisms driving differential MPS rates observed between CLU and TRD paradigms of the barbell back squat in trained men and women.

METHODS: In randomized crossover design, 8 resistance-trained adults (7M, 1F; 23 ± 4 y; LBM, 63 ± 9 kg; back squat 1RM, 150 ± 26 kg) performed an acute bout of either CLU (4 sets \times (2 \times 5) repetitions, 30s intra-set rest, 90s inter-set rest) or TRD (4 sets \times 10 repetitions, 120s inter-set rest) barbell back squats at $\sim 70\%$ 1RM. Volume load and total rest were matched between bouts. Participants ingested 20g of whey protein immediately before and after exercise. Muscle biopsies were collected at rest and at 0, 2, and 5 h post-exercise during primed-continuous L-[ring-¹³C]₆phenylalanine infusions. Total and phosphorylated states of targeted proteins were assessed through immunoblotting. Data was normalized to an internal loading control.

RESULTS: The phosphorylation of focal adhesion kinase (FAK) was doubled with TRD, but not significantly different, from CLU (TRD 2.1 ± 0.9 -fold increase from baseline; CLU 1.3 ± 0.9 -fold; $p > 0.05$). Downstream targets of mTORC1 also showed no differences in phosphorylation between paradigms (4E-BP1: TRD 1.6 ± 0.3 -fold, CLU 0.4 ± 0.2 -fold; p70S6K: TRD 1.5 ± 0.4 -fold, CLU 0.9 ± 0.4 -fold). Similarly, there was no difference in AMPK phosphorylation between conditions (TRD 1.3 ± 0.9 -fold; CLU 0.9 ± 0.7 -fold).

CONCLUSION: Our data demonstrated that changes in protein phosphorylation as noted by various readouts within the mTORC1 pathway do not underpin the greater post-exercise muscle protein synthetic response with TRD versus CLU-style in resistance trained men and women.

Resistance Exercise-Induced Hormonal Response Promotes Satellite Cell Proliferation in Untrained Men

Hui-Ying Luk¹, Danielle E. Levitt², James Boyett², Sharon Rojas², Shawn M. Flader², Brian K. McFarlin, FACSM², Jakob L. Vingren, FACSM². ¹Texas Tech University, Lubbock, TX. ²University of North Texas, Denton, TX. (Sponsor: Jakob L. Vingren, FACSM)
 (No relevant relationships reported)

Evidence suggests that resistance exercise (RE)-induced transient release of anabolic hormones can be beneficial for muscle adaptation (e.g. muscle size, strength); however, no prior research appears to have investigated the effect of the RE-induced hormonal response on satellite cell (SC) proliferation and differentiation, an important step in any such muscle adaptations. **Purpose:** To determine the effect of transient resistance exercise (RE)-induced hormonal changes on satellite cell myogenic state following eccentric exercise. **Methods:** Untrained men ($n=10$, 22 ± 3 y) and women ($n=9$, 21 ± 4 y) completed 2 sessions of 80 unilateral maximal eccentric knee extensions followed by either an upper body RE protocol (EXE) or a 20-min rest (CON). Muscle samples were collected and analyzed for protein content of Pax7, MyoD, myogenin, cyclin D1, and

p21 before exercise (PRE), and 12 hours (+12h) and 24 hours after the session (+24h). Serum testosterone, growth hormone, cortisol, and myoglobin concentrations were measured at PRE, immediately after eccentric knee extension (IMD), immediately after (IP), 15, 30, and 60 min after the session. **Results:** Testosterone was significantly ($p < 0.05$) higher immediately after the session in EXE (6.34 ± 0.48 ng·ml⁻¹) than CON (4.87 ± 0.26 ng·ml⁻¹) for men. A significant time \times gender \times condition interaction was found for MyoD with 20.1 ± 10.8 -fold increase for EXE in men and 21.9 ± 7.6 -fold increase for CON in women at +12h compared to PRE. A significant time \times condition interaction was found for Pax7 with 0.8 ± 0.1 -fold decrease for EXE and 1.6 ± 0.3 -fold increase for CON at +24h compared to PRE. A significant time effect was found for myogenin, p21, and cyclin D1. Myogenin (+12h: 5.9 ± 1.5 -fold; +24h: 5.0 ± 1.1 -fold) and p21 (+12h: 25.4 ± 4.5 -fold; +24h: 12.4 ± 1.9 -fold) were increased at +12h and +24h and Cyclin D1 was 6.6 ± 1.9 -fold increased at +12h compared to PRE. **Conclusion:** These results suggest that the RE-induced hormonal response can be important to promote SC proliferation for men but not women. In addition, markers of SC differentiation appeared to be unaffected by the hormonal response but were increased in response to the knee eccentric exercise protocol. Supported in part by a grant from the National Strength and Conditioning Association Foundation

Contralateral Repeated Bout Effect of Elbow Flexors Not Observed in Young Women

Bailey A. Brown, Xin Ye, Ling Xin. University of Mississippi, Oxford, MS.
 (No relevant relationships reported)

Previous studies have reported that a prior bout of damaging exercise with one limb attenuated the magnitude of muscle damage in the subsequent damaging exercise with the contralateral limb, a phenomenon called contralateral repeated bout effect (CL-RBE). To our knowledge, these studies involved either exclusively men or a mixture of both sexes.

PURPOSE: To determine whether contralateral repeated bout effect of elbow flexors exists in women. **METHODS:** Twelve healthy women (20.9 ± 2.5 yrs) performed two bouts of 45 maximal eccentric contractions (ECC) of elbow flexors separated by 14 days. The isokinetic muscle strength (60°/sec) was measured pre-exercise, immediately post-exercise, and at 24 and 48 h post-exercise. Limb girth, range of motion (ROM), and muscle soreness were measured pre-exercise, and at 24 and 48 h post-exercise. Surface Electromyography (EMG) was recorded during both exercise bouts from the biceps brachii muscle. Data of all variables were analyzed using two-way repeated measures ANOVA (Bout \times Time) except that of median frequency of EMG which was analyzed via paired t-test.

RESULTS: The isokinetic strength was significantly reduced after the eccentric exercise for both bout 1 ($-19.3 \pm 17.4\%$, $P < 0.01$) and bout 2 ($-15.3 \pm 15.2\%$, $P < 0.01$). Significant main effects of time were also observed for muscle soreness and ROM. Limb girth did not change significantly after either exercise bout. There were no significant differences between bouts for all the measured variables.

CONCLUSION: The CL-RBE of elbow flexors was not evident in healthy young women, which is probably because the magnitude of the muscle damage induced by the first exercise bout was not sufficient to induce protective adaptation for the contralateral arm in the second bout.

Tissue Hemodynamics of Skeletal Muscle and Prefrontal Cortex is Related to Rowing Time Trial Performance

Mauricio Martinez, Matthew Dove, Leilani Madrigal, Joshua Cotter. California State University of Long Beach, Long Beach, CA.
 Email: mauricio.martinez01@student.cslub.edu
 (No relevant relationships reported)

Near-infrared spectroscopy (NIRS) is a non-invasive method for measuring tissue concentrations of oxy- (HbO₂) and deoxyhemoglobin (Hb) providing information about local metabolism, tissue-specific oxygen availability, and blood flow. Time-resolved NIRS can quantitatively measure absolute hemoglobin concentrations in tissue. Its ability to separate light absorption from scattering makes it an ideal tool for measuring tissue hemoglobin levels where there may be large changes in blood volume such as with exercise. Furthermore, it has been hypothesized that blood flow and oxygenation to the prefrontal cortex (PFC) may be related to fatigue. **PURPOSE:** To quantify tissue oxy- and deoxyhemoglobin (Hb) concentrations in the vastus lateralis (VL) and (PFC) during a 2,000 m ergometer time trial test with collegiate rowers. **METHODS:** Eighteen collegiate club rowers (11 males and 7 females, 20.33 ± 1.65 years, VO_2max 42.77 ± 7.62 ml/kg/min.) performed a maximum 2,000 m test on a Concept 2 ergometer. A two-channel time-resolved NIRS instrument (TRS-21, Hamamatsu) was used to assess tissue HbO₂, Hb, and total hemoglobin (tHb) of the right VL and PFC. **RESULTS:** Average time to complete the 2,000 m time trial was 475.4 ± 44.37 seconds. A significant correlation was observed for

the 2,000 m ergometer test and VO₂max (Pearson $r = -0.523$; $p = 0.045$). Exercise reduced HbO₂ ($p = 0.0063$) and increased Hb ($p = 0.0038$) compared to baseline in the VL with tHb remaining unchanged ($p = 0.0677$). No changes were observed during exercise in the PFC except for an increase in tHb ($p < 0.0001$). The magnitude of change in VL tissue oxygenation (HbO₂) was correlated with the time to complete the time trial with a faster time relating to a greater reduction in VL HbO₂. Similarly, the magnitude of change in VL deoxygenated hemoglobin (Hb) trended towards a greater increase in concentration with a faster time trial (Pearson $r = -0.4422$, $p = 0.0661$). **CONCLUSION:** Exercise during a 2,000 m rowing time trial test resulted in decreased HbO₂ and increased Hb levels in the VL compared to baseline which was correlated with performance on the time trial. Total hemoglobin was found to increase in the PFC which may represent increased fatigue that occurs due to the maximal nature of the time trial.

Calf Muscle Endurance and Gait Variability among Older Adults

ADEOLA A. SANNI, Kevin McCully, FACSM. UNIVERSITY OF GEORGIA, Athens, GA. (Sponsor: Kevin McCully, FACSM) Email: aas56767@uga.edu

(No relevant relationships reported)

Declines in skeletal muscle functions are associated with aging which affects daily activities and quality of life. Fall risk and fall-related injuries are related to muscle fatigability among older adults. **Purpose:** Measure calf muscle endurance and gait function in older adults. We hypothesize that gait abnormalities will be associated with reduced calf muscle endurance. **Methods:** Ten participants ages 55-80 years volunteered for the study. Skeletal muscle endurance was measured on the calf muscle of the participant's right leg at 2Hz, 4Hz and 6Hz using previously established protocol. Selected gait measurements (stride length, left/right ratio step length, %CV of step length, stride width) were recorded on three trials at self-selected speed on a 20foot gait mat (Protokinetics Zeno walkway). Pearson's r was used to test the relationship between the selected gait variables and endurance index at 6Hz. ANOVA Levene's test of covariance was used to test the difference in the variance in step length of both legs. Significance was accepted at 0.05 alpha level **Results:** Muscle endurance at 6Hz ($0.75 \pm 0.21\%$) varied from 0.3% to 1.0%. Stride length ($145\text{cm} \pm 11\text{cm}$) varied from 127.4cm to 168.5cm and step length ($1.0\text{cm} \pm 0.06\text{cm}$) varied from 64.6cm to 82.7cm. There was a positive correlation between endurance index and stride length ($r = 0.68$, $p = 0.02$), and the right/left ratio step length ($r = 0.72$, $p = 0.01$) but there was no significant relationship between endurance index and step width ($r = -0.43$, $p = 0.11$). A Levene's test verified equality of variances in step length %CV of both legs ($p = 0.84$). **Conclusions:** Muscle endurance in the calf was associated with some selected gait parameters which have been shown to predict increase fall risk among older adults.

320 Board #158 May 29 11:00 AM - 12:30 PM

Effects Of Rate Of Force Production On Vastus Lateralis Pennation Angle During Isometric Squats And Knee Extensions

Cody L. Diehl, Micheal J. Luera, Jesus A. Hernandez-Sarabia, Carlos A. Estrada, Tyler W.D. Muddle, Jason M. Defreitas. Oklahoma State University, Stillwater, OK. Email: cody.diehl@okstate.edu

(No relevant relationships reported)

Previous literature has shown that force exerted by muscle is closely related to its size, length (i.e. joint angle) and pennation angle (PA). For a mono-articular muscle such as the vastus lateralis (VL), its ability to produce maximal force is dependent on the joint angle of the knee. However, since the VL shares a joint action with a bi-articular muscle, the rectus femoris (RF), it's possible that its performance may also be affected by the angle of the hip (i.e. the RF contribution to knee extension is hip angle dependent, which may influence VL performance as well). It is unknown how the pennation angle of the VL during contraction differs between maximal multi- and single-joint exercises, such as the isometric squat (SQ) and knee extension (KE), and whether those changes are dependent on the rate of the force production. **PURPOSE:** To examine the pennation angle of the VL during slow and rapid maximal force production of the isometric SQ and KE exercises. **METHODS:** Fifteen lower-body resistance trained males (mean \pm SD age = 24 ± 3 yrs) performed two separate maximal voluntary contractions (MVC) for both SQ and KE exercises. The first MVC (MVC1) cue was used to elicit peak force, with no instructions on the rate, while the 2nd (MVCR) was used to elicit rapid force production. Knee joint angles were set at 110° during both exercises, while hip angle was $\sim 110^\circ$ and $\sim 105^\circ$ during the SQ and KE, respectively. During all MVCs, ultrasonography was used to measure pennation angle of the VL muscle at peak force production. **RESULTS:** A two-way [MVC speed (slow vs. rapid) \times exercise (SQ vs. KE)] repeated measures ANOVA indicated no significant differences in pennation angle of the VL between slow vs. rapid MVCs of the squat (mean MVC1 = $16.19 \pm 3.18^\circ$, MVCR = $16.13 \pm 3.26^\circ$) and knee extension

exercises (mean MVC1 = 16.21 ± 2.23 , MVCR = 16.08 ± 2.34), nor were there any differences between the exercises ($p > 0.05$ for all analyses). **CONCLUSION:** When knee angle is controlled for, the pennation angle of the VL during isometric squats and knee extensions do not differ. Furthermore, neither the rate of force, nor the slightly different hip angles had an effect.

321 Board #159 May 29 11:00 AM - 12:30 PM
Electrical Pulse Stimulation Induced Increase In Lipid And Mitochondria Depends On Donor's Physical Activity Level

Mario Garcia¹, Christopher Figueroa¹, Jeffrey D. Convington², Steven R. Smith³, Sudip Bajpeyi¹. ¹University of Texas at El Paso, El Paso, TX. ²The University of Vermont Medical Center, Burlington, VT. ³Sanford Burnham Prebys Medical Discovery Institute, Orlando, FL.

(No relevant relationships reported)

We have previously shown that human primary myotubes retain *in vivo* characteristics of their donors. Electrical pulse stimulation (EPS) has recently been used as an exercise mimetic in a cell culture model, and could be beneficial to understanding underlying molecular mechanisms of exercise.

Purpose: To determine if EPS induced adaptations on mitochondria and lipid content is dependent on the donor population and the duration of EPS applied.

Methods: Human primary skeletal muscle myotubes were cultured from four endurance trained athletes (23 ± 1 yrs and BMI 24.4 ± 0.9 kg/m²) and five lean healthy Caucasian donors (23 ± 1.9 yrs and BMI 24.2 ± 0.6 kg/m²). EPS was applied to pooled cells from athlete and lean donor groups for either 24 hours or 48 hours (single bipolar pulses of 1 Hz for 2 ms; 30V) and were harvested after stimulation. Control cells were maintained simultaneously and harvested alongside EPS treated cells. Lipid and Mitochondrial content were measured by fluorescent histochemical techniques, and quantified using Image J software.

Results: Myotubes cultured from athletes had a significantly greater lipid (35.68 ± 5.78 vs 0.51 ± 0.08 AU; $p < 0.0001$) and mitochondrial (108.3 ± 18.9 vs 6.9 ± 0.87 AU; $p = 0.03$) content compared to lean donors at baseline. Lipid and mitochondrial content were significantly greater in lean after 24 hours (both $p < 0.05$), but not after 48 hours (both $p > 0.05$) of EPS compared to control of EPS (Lipid: control 0.51 ± 0.08 AU, 24hr. 10.15 ± 0.79 AU, 48 hr. 6.06 ± 1.1 AU; Mitochondria: Control 6.9 ± 0.87 , 24hr. 116.9 ± 14.4 , 48 hr. 89.57 ± 12.4 AU). Lipid content did not change in myotubes cultured from athletes with EPS after 24 hours ($p = 0.8$) or 48 hours ($p = 0.4$) (Control 35.68 ± 0.51 AU, 24 hr. 35.43 ± 5.12 AU, 48 hr. 25.9 ± 2.6 AU) whereas mitochondria content was significantly greater after 24 hours EPS ($p = 0.0004$) but not after 48 hours ($p = 0.8$) of EPS (control 108.3 ± 18.9 AU, 24 hr. 239.1 ± 25 AU, 48 hr. 125.1 ± 15.3 AU).

Conclusion: Primary human skeletal muscle cells cultured from athlete donors have a higher lipid and mitochondrial content compared to lean, healthy donors. EPS induced increases in lipid and mitochondrial content depends on the physical fitness of the population being studied. 24 hours of EPS stimulation seems to result in greater mitochondrial content compared to 48 hours of stimulation.

(No relevant relationships reported)

Contusions are a common sports injury, often resulting in acute skeletal muscle contractile dysfunction. Whole-body heat shock is reported to attenuate skeletal muscle atrophy in animal models. **PURPOSE:** The purpose of this study was to test the hypothesis that whole-body heat shock attenuates contusion induced-skeletal muscle contractile dysfunction. **METHODS:** Male mice (14.4 ± 1.4 mo) were randomized to either the heat shock contusion group (HSC $n = 5$), the normal body temperature contusion group (NTC $n = 4$), or sham ($n = 3$). Under anesthesia, the *in vivo* torque-frequency relationship (1hz-300hz) of the anterior crural muscle group was measured in all mice. Body temperature was then raised to 41°C (HSC) or maintained at 37°C (NTC and sham) for 30 min and then all mice were allowed to recover consciousness. Twenty-four hours later all mice were anesthetized again and a single contusion (HSC and NTC) was delivered via the instrumented mass-drop technique (14.1 g steel ball was dropped through a tube from 115 cm onto an impactor directly striking the tibialis anterior) or no contusion (sham); all mice were then allowed to recover. Following 5 days of normal cage activity (5-d recovery), *in vivo* torque-frequency relationships were measured in all mice. Data were analyzed using a factorial ANOVA with an *a priori* level of significance of 0.05. Fisher's LSD pair-wise comparisons were made *post hoc*. **RESULTS:** There was a significant group-time-frequency interaction ($F = 1.791$, $p = 0.034$). Within group pairwise comparison pre to 5-d recovery revealed sham did not differ ($p = 0.529$), HSC fully recovered ($p = 0.899$), and NTC did not recover ($p = 0.001$) muscle contractile function. Within group comparison pre to 5-d

at 40hz (submaximal stimulation) and 250hz (maximal stimulation) found sham did not differ ($p=0.765$; $p=0.912$, respectively), HSC recovered ($p=0.786$; $p=0.602$, respectively), and NTC did not recover at either frequency ($p=0.001$; $p=0.006$, respectively). **CONCLUSION:** Whole body heat shock treatment prior to a single blunt trauma contusion accelerates the rate of recovery of *in-vivo* skeletal muscle contractile function within the 5-d recovery period. Funding: This work was partially supported by an Appalachian State University GRAM award.

The Effect of 10%O₂ Microenvironment and Electric Pulse Stimulation on Glucose and Lipid Metabolism

Li Songbo¹, Sun Jingquan², Wang Yang¹, Yan Lu¹, Wang Yi¹.
¹Beijing Sport University, Beijing, China. ²Sichuan University, Sichuan, China.
Email: 95lsb@163.com

(No relevant relationships reported)

PURPOSE: There is currently no successful cell contraction model *in vitro*. Electrical pulse stimulation (EPS) can induce muscle cell contraction. 10%O₂ microenvironment is closer to the human skeletal muscle environment. In this study, EPS was applied to myotubes to test the changes of the metabolism of glucose and lipid, and to establish successful cell contraction model in a 10%O₂ microenvironment *in vitro*.

METHODS: After seven days of differentiation in 5% CO₂(20%O₂) incubator, the mouse myoblast cell line C2C12 were transferred into the 10%O₂ incubator. After adaptation to the hypoxia for 12h, the myotubes were subjected to EPS. The EPS stimulation was performed for 120min each, total 4 consecutive days. And cell extracts obtained from each were prepared 3h after EPS. The content of PGC-1 α , MyHC I, MyHCIIa, MyHCIIb and MyHCIIx were determined by ELISA. And RT-PCR analysis was applied to determine mRNA expression of PGC-1 α , MCAD, Cpt1B, GLUT1, GLUT4, PDH, LDH and GAPDH.

RESULTS: Both 10%O₂ microenvironment and EPS significantly increased the protein level of PGC-1 α , and the synergistic effect of hypoxia and EPS was more significantly. 10%O₂ microenvironment significantly decreased the content of MyHC I, MyHCIIx and MyHCIIa in myotubes. EPS significantly decreased the content of MyHC I and MyHCIIx but significantly increased the content of MyHCIIa in myotubes. 10%O₂ microenvironment significant decreased the mRNA level of GLTT1 and GLTU4. However, in stimulated myotubes, the mRNA level of GLUT1 was significantly elevated, but the RNA level of GLUT4 was decreased. Meanwhile, 10%O₂ microenvironment significantly decreases the mRNA level of MCAD, CPT1B and PDH, and EPS increased the mRNA level of MCAD.

CONCLUSIONS: 4 days of 10%O₂ microenvironment combined with EPS successfully established myotubes cell contraction model. 10%O₂ microenvironment inhibited the proliferation and glycolipid metabolism in myotubes. The usage energy of EPS-induced contraction is based on aerobic oxidation of glucose and fatty. The pulse frequency increases from 1 Hz to 2 Hz in the EPS protocol, were association with substrate from fat to glucose.

Assessment Of Quadricep Femoris Pennation Angle And Force Production Asymmetry In College-Aged Males

Ashley N. Fox, Daniel J. Blackwood, Daniel J. Larson, Christopher D. Black, FACSM, Rebecca D. Larson. *University of Oklahoma, Norman, OK.*
Email: ashnfox@ou.edu

(No relevant relationships reported)

Muscular architecture is a valuable tool for quantifying muscle function. The arrangement of muscle fibers, commonly referred to as pennation angle (PA), influences the amount of force that a muscle can produce. Levels of leg asymmetry (PA, strength, ROM, etc.) is a growing topic of interest due to its link to functional disorders, injuries, and fall risk. Hence, a better understanding of the amount of asymmetry present can serve as a guide for future researchers and practitioners when examining lower limb function and performance. **PURPOSE:** The current study examined asymmetry in pennation angle (PA) and force production (FP) in the quadriceps femoris (QF) muscle group in college aged males. **METHODS:** Thirty-eight college-aged males (22.97 \pm 2.58 yrs., 180.22 \pm 6.90 cm, 88.62 \pm 14.88 kg) were recruited to participate in this study. All measurements were taken in random order on both legs. PA's were measured using B-mode ultrasound. Three images were captured and analyzed for each muscle of the QF: the vastus medialis (VM), vastus lateralis (VL), rectus femoris (RF) and vastus intermedius (VI). QF FP was measured on two separate visits by performing 3 knee extension maximal voluntary isometric contractions (MVICs). The mean MVIC was used in data analysis. **RESULTS:** FP was significantly different between legs (31.64 \pm 103.43N, $p<0.05$) which equated to one leg being 7% stronger than the other leg. However, there was no difference in PA in any of the muscles between legs (VM, VL, RF, and VI, $p>0.05$). **CONCLUSION:** The current study revealed a significant strength asymmetry in the absence of differences in PA for

the QF muscles. These data suggest that the strength asymmetry was not due to muscle architecture differences as measured by PA. However, further research is needed in other musculature of the legs as it relates to PA and FP differences.

Comparison Of Effects Of Different Exercise Modes On Gastrocnemius Of Obese Rats

Xiujuan liu, Nianyun zhang, Lei Sheng. *Nanjing Sports Institute, Nanjing, China.*

Email: 59684540@qq.com

(No relevant relationships reported)

Purpose: To explore the effects of different exercise patterns on gastrocnemius in obese rats.

Methods: Forty-eight SD rats were randomly divided into 4 groups, 12 in each group, which were quiet control group(Con), continuous exercise group (CE), high-intensity intermittent exercise group (HIIT) and ladder exercise group (LE). After 8 weeks of exercise training, each exercise group was anesthetized including quiet control group and samples were collected for testing. The body weight and gastrocnemius weight of each group were recorded. The cross-sectional area of gastrocnemius muscle was observed by HE staining. The levels of MSTN and insulin in serum were detected by ELISA. The expressions of MSTN, IGF1 and p70S6K in rat gastrocnemius muscle were detected by Western blot.

RESULTS: Compared with the group Con, the body weights of group CE, HIIT, LE were reduced by 13.8%,14%,10%, and the weight of the gastrocnemius muscles in group HIIT was decreased by 22%. Compared with the group Con, the gastrocnemius mass index of group CE and group LE was increased by 10.7%. Morphological observation of the gastrocnemius showed that compared with the group Con, the gastrocnemius muscle cross-section of the group LE was increased by 17%. The serum GDF8 level in the group CE was reduced by 32% than that in the group Con, and the serum insulin level in the group CE and group HIIT was decreased by 42% and 35%. Compared with the group Con, the expression of GDF8 and P70S6K protein in the gastrocnemius muscle of the group CE and group HIIT was reduced by 31%, 26%,13% and 21% respectively, while the expression of IGF1 protein in the three exercise groups was increased by 6%,40% and 190% respectively.

Conclusion: Although the three exercise modes may significantly reduce the body weight of rats, only continuous exercise and ladder exercise improve the gastrocnemius muscle mass index. Continuous exercise and high-intensity intermittent exercise had similar effects on serum GDF8, insulin, and similar effects on the proteins of MSTN, IGF1 and P70S6K in the gastrocnemius muscle, but the effects of three exercise modes on serum GDF8 and insulin and gastrocnemius MSTN, IGF1 and P70S6K proteins, laddering exercise is different from sustained exercise and High intensity intermittent exercise.

Pennation Angle of the Quadricep Femoris Muscles in Resistance Trained Males vs. Non-Resistance Trained Males

Braylon Warrior, Daniel J. Blackwood, Daniel J. Larson, Christopher D. Black, FACSM, Rebecca D. Larson. *University of Oklahoma, Norman, OK.*

(No relevant relationships reported)

Pennation angle (PA) is the orientation at which muscle fibers attach to the deep aponeurosis within a muscle. PA is measured using *in-vivo* methods (ultrasound) which allows researchers to observe any angle discrepancies throughout different locations in the muscle. The quadriceps femoris (QF) is a muscle group used on a daily basis. Understanding the architecture of the QF is helpful for understanding and improving performance in sports or activities which relies on running, jumping, or explosive movements. Another reason to pursue our understanding of muscle architecture is examining potential for injury. Furthermore, asymmetrical strength of the quadriceps can lead to increased risk of injuries. However, limited research has looked at muscle architecture asymmetry as it relates to injury and function. **PURPOSE:** The aim of this study was to determine the magnitude of bilateral asymmetry for PA in the QF in resistance trained (RT) and non-resistance trained (NRT) males. **METHODS:** Thirty-eight males (22.97 \pm 2.58 yrs., 180.22 \pm 6.90cm, and 88.62 \pm 14.88 kg) were recruited to participate in this study (25 were lower body RT and 13 were NRT). The first visit consisted of protocol explanation and familiarization. The following visit consisted of PA assessment of the QF muscles using B-mode ultrasound. All PA measurements were taken in random order on both legs. Three images were taken and analyzed from the vastus medialis (VM), vastus lateralis (VL), rectus femoris (RF) and vastus intermedius (VI). **RESULTS:** There was no significant group x leg effect for PA of the QF, [VM ($p = 0.470$), VL ($p = 0.795$), RF ($p = 0.431$), VI ($p = 0.563$)]. Collapsing across groups revealed a non-significant effect on asymmetry as well (all $p > 0.05$). The between leg percent differences were; VM 6.08% \pm 3.65%, VL 4.84% \pm 4.1%, RF 3.87% \pm 4.0% and VI 3.53% \pm 5.87%. **CONCLUSION:** This study revealed that PA angle in the QF muscles was not significantly different between RT and NRT in males.

Field-based Simplified Methods For Predicting Skeletal Muscle Index In Japanese University Women

Tomohiro Yasuda. *Seirei Christopher University, Shizuoka, Japan.*
 Email: tomohiro-y@seirei.ac.jp
 (No relevant relationships reported)

PURPOSE: A recent study reported that the rate of 'presarcopenia' (low SMI without impact on muscle strength or physical capability) was over 30% for healthy young women in Japan. This means that the SMI assessment is particularly attentive for the healthy young women in early prevention of mobility problems and frailty. Thus, we examined if the field-based simplified methods for predicting skeletal muscle index (SMI) in Japanese university women.

METHODS: A total of 193 Japanese university freshmen women (ages 18-25 years) volunteered to participate in this study. A stepwise multiple-regression analysis (method of increasing and decreasing the variables, criterion was set at $p < 0.05$) was performed to SMI and 17 variable factors (body mass index, % body fat, waist-hip ratio, girth (mid-thigh and lower-leg), muscle thickness (anterior and posterior mid-thigh and posterior lower-leg), handgrip, knee extension, standing long jump, vertical jump, sit-to-stand test, side step test, multi-stage 20-m shuttle run test, two-step test, sit and reach).

RESULTS: Twelve of 17 variables was correlated ($P < 0.05$) with SMI. There was excellent relationship between mid-thigh girth and SMI ($r = 0.81$, $P < 0.001$). The prediction equations were highly correlated with SMI ($R^2 = 0.64$ for step 1 [$SMI = 0.11 \times \text{thigh girth (cm)} + 0.71$] and $R^2 = 0.90$ for step 7 [$SMI = 0.02 \times \text{thigh girth (cm)} - 0.07 \times \text{body fat (\%)} + 0.22 \times \text{BMI (kg/m}^2) + 0.02 \times \text{handgrip (kg)} + 0.04 \times \text{lower leg girth} + 0.01 \times \text{side step} + 0.14$], $P < 0.05$).

CONCLUSIONS: Our results indicated that the SMI could be evaluated by the field-based simplified methods, especially for the mid-thigh girth measurement, which may be a major determinant to maintain an active life for healthy young women.

Muscular Activation Differences during Daily Activities in a Unilateral Trans-Femoral Amputee

Ronald L. Snarr¹, Cindy Ouellet². ¹Georgia Southern University, Statesboro, GA. ²University of Southern California, Los Angeles, CA.
 Email: rsnarr@georgiasouthern.edu
 (No relevant relationships reported)

Lower-limb amputees often exhibit an increased atrophy of remaining skeletal musculature as compared to the non-amputated side. This difference in lean mass may present variations in the contribution of physical effort between the affected and unaffected musculature. While most literature has focused mainly on microprocessor-controlled prosthetics, few investigations have examined mechanical (i.e., un-powered) prosthetics during daily activity tasks. **PURPOSE:** The purpose was to examine the electromyographical activity of the lower limb musculature of the amputated versus non-amputated side in a unilateral trans-femoral amputee. **METHODS:** The participant ($n=1$, age=26) performed four activities of daily living (i.e., sit-to-stand, 10-meter walk, and stair ascent and descent without support) with an above-knee mechanical prosthetic. The participant completed each task three times with 1-minute rest in between each trial. EMG was recorded, on both sides of the body, at the following sites and compared to a percentage of maximal voluntary contraction (%MVC): gluteus maximus (GM), gluteus medius (GMed), rectus femoris (RF), and biceps femoris (BF). Ratios (affected:unaffected) and percent differences between the affected and unaffected sides of the body were calculated. **RESULTS:** Results demonstrated large mean muscular activation differences of 34% for RF and 20% for GMed throughout overall movement patterns. Small mean activation differences were seen within the GM (2%) and BF (1%). The largest observed imbalance ratios for the sit-to-stand trials were in the RF (1:1.8) and GM (4:1). For the 10-meter walk, the largest differences were seen in the GM (3:1) and GMed (4.5:1). During the stair ascent without support, only the RF and GMed showed large imbalances between limbs (i.e., 1:3.5 and 3:1, respectively). Lastly, for the stair descent, the GM (4:1) and GMed (2:1) demonstrated a large imbalance; while BF and RF exhibited small differences. **CONCLUSIONS:** Results indicate that performing daily tasks for amputees may provide large imbalances in muscular effort between limbs. While some imbalances (increased motor unit recruitment) favored the unaffected limb, the affected limb did display increased recruitment in the gluteal musculature during walking, stair climbing, and sit-to-stand tasks.

Skeletal Muscle Mass And Bone Mineral Density Of Japanese alpinist Mr. Yuichiro Miura.

Eiji Fujita¹, Takuya Akamine¹, Yohei Takai¹, Masashi Kawanishi², Dennis R. Taaffe³, Yu Yaginuma¹, Masayoshi Yamamoto¹. ¹National Institute of Fitness and Sports in Kanoya, Kagoshima, Japan. ²Hokusho University, Ebetsu, Japan. ³Edith Cowan University, Joondalup, Australia.
 Email: fujita@nifs-k.ac.jp
 (No relevant relationships reported)

Purpose: In this study, we report on the skeletal muscle mass and bone mineral density of Japanese alpinist Mr. Yuichiro Miura who is the oldest person to climb to the summit of Mount Everest (8,848m) at the age of 80 years compared with Japanese community-dwelling middle-aged and older men. **Method:** The appendicular skeletal muscle mass index (SMI), total bone mineral density (tBMD), whole body fat free mass index (FFMI) and fat mass index (FMI) in Mr. Miura (84.6 yr) and 209 community-dwelling middle-aged and older men (50-79 yr, mean age: 68.1 yr) were obtained by dual X-ray absorptiometry. **Results:** The SMI, tBMD, FFMI and FMI in Mr. Miura were 8.79 kg/m², 1.075 g/cm², 22.3 kg/m² and 9.8 kg/m², respectively, and in the community-dwelling middle-aged and older men 7.46 ± 0.81 kg/m², 1.020 ± 0.100 g/cm², 18.1 ± 1.9 kg/m² and 5.5 ± 1.7 kg/m², respectively. The values were higher in Mr. Miura than the community-dwelling middle-aged and older men, with z-scores for the SMI and tBMD of 1.63 and 0.55, respectively. **Conclusion:** Mr. Miura maintained total body bone mineral density and skeletal muscle mass at a high level even at the age of 84 years which may in part be due to his long-term training for mountain climbing.

Motor Nerve Conduction Velocity with Eccentric Contractions of Flexor Pollicis Brevis Muscle

Eisuke Ochi¹, Hisashi Ueda², Yosuke Tsuchiya³, Karina Kozaki⁴, Koichi Nakazato⁴. ¹Hosei University, Tokyo, Japan. ²Teikyo Heisei University, Chiba, Japan. ³Teikyo Heisei University, Tokyo, Japan. ⁴Nippon Sport Science University, Tokyo, Japan.
 Email: ochi@hosei.ac.jp
 (No relevant relationships reported)

Eccentric contractions (ECCs) cause muscle damage indicated by loss of muscle strength, limited range of motion (ROM), and development of delayed-onset muscle soreness (DOMS). Previously, we showed that ECCs induce nerve dysfunction and damage in rats and humans. In a human study, the M-wave latency of the biceps brachii increased by 12-24% at 1-2 days after eccentric exercise of the elbow flexors in women. However, whether ECCs cause a decrease in motor nerve conduction velocity (MCV) is unknown. **PURPOSE:** In the present study, we aimed to establish a new ECC model for the flexor pollicis brevis muscle (FPBM) and evaluate MCV. **METHODS:** Twelve men (age, 19.8 ± 1.7 y; height, 172.4 ± 7.0 cm; weight, 64.0 ± 8.6 kg) performed 100 maximal ECCs at 60 deg/sec with the FPBM of the non-dominant arm (ECC) with a custom-made torque dynamometer. The dominant arms were the controls (CON). Maximal voluntary contraction (MVC), ROM, DOMS, and MCV were assessed before, immediately after, and 1, 2, and 5 days after the ECCs. MCV was calculated as the distance by stimulation divided by the latencies of the waveforms generated. Values were statistically analyzed, and the significance level was set at p values of < 0.05 . **RESULTS:** MVC, ROM, and DOMS of the ECCs significantly increased as compared with their values before the ECCs (MVC: post, 67.1%; day 1, 73.8%; ROM: post, 83.4%; day 1, 92.1%; DOMS: day 1, 178.8%; day 2, 181.0%; $p < 0.05$) and as compared with those of the CON (MVC: post, 67.1%; day 1, 73.8%; ROM: post, 83.4%; day 1, 92.1%; DOMS: day 1, 178.8%; day 2, 181.0%; $p < 0.05$). The MCV of the ECCs decreased significantly immediately after exercise (63.6%, $p < 0.05$) and as compared with that of time-matched CON. The M-wave latency of the ECCs delayed significantly immediately after exercise (127.3%, $p < 0.05$) and as compared with before exercise. **CONCLUSIONS:** Our new ECC model leads to muscle damage similar to those reported in previous studies that used other muscles and motor nerve dysfunction.

Combined Exercise and Leucine Supplementation Promotes Skeletal Muscle Protein Deposition in Tumor Bearing Mice
 Hua-yu SHANG, Junzhi Sun, Haili Ding, Zhifei Ke, Jing Zhao.
Chengdu Sport Institute, Chengdu, China. (Sponsor: Tong-jian You, FACSM)
 Email: santanashy@hotmail.com
 (No relevant relationships reported)

PURPOSE: To investigate the effect of concurrent exercise training and leucine supplementation on skeletal muscle protein deposition in Colon 26 tumor bearing mice.

METHODS: Male BALB/c mice were divided into a control group (C, n=8), a C26 tumor bearing group (T, n=8) and a tumor bearing plus exercise and leucine supplementation group (TEL, n=8). Mice in the C and T groups were fed with normal chow diet, while mice in the TEL group were fed with formulated diet contained 5% leucine and received 30-min swimming training 3 days per week (Monday, Wednesday and Friday) and resistance training 3 days per week (Tuesday, Thursday and Saturday) for 2 weeks. At 24 hours after the last training session, blood and gastrocnemius muscle samples were collected under full anesthesia. The contents of TNF- α and IL-6 in gastrocnemius muscle and serum were determined by ELISA. Maximal grip strength was measured with a commercial grip strength meter. Two-way ANOVAs and post-hoc tests were used for data analysis.

RESULTS: After tumor bearing, cumulative food intake appeared to decrease, whereas body weight (20.7 g vs. 26.1 g), wet gastrocnemius muscle weight (97.3 mg vs. 128.9 mg), total protein content (35.7 mg/g vs. 51.2 mg/g), sarcoplasmic protein content (26.5 mg/g vs. 38.3 mg/g), myofibrillar protein content (28.6 mg/g vs. 43.3 mg/g) and muscle strength (82.7 g vs. 156.5 g) were significantly lower in the T group than in the C group (all $p < 0.01$). TNF- α and IL-6 contents in serum and gastrocnemius were obviously higher in the T group than in the C group ($p < 0.01$). After exercise and leucine supplementation, cumulative food intake and the TNF- α and IL-6 content were significantly lower in the TEL group than in the T group ($p < 0.05$), while body weight (21.8 g), wet gastrocnemius muscle weight (111.1 mg), total protein content (40.3 mg/g), sarcoplasmic protein content (30.7 mg/g), myofibrillar protein content (34.0 mg/g) and muscle strength (112.2 g) were significantly higher in the TEL group than in the T group ($p < 0.05$ to $p < 0.01$).

CONCLUSIONS: Combined exercise and leucine supplementation significantly ameliorated skeletal muscular protein deposition in C26 tumor bearing mice, which may be through down-regulating the inflammatory response. (Supported by Research Foundation of Sichuan Provincial Department of Education grant #18ZB0106).

Environmental Enrichment Increases Spontaneous Locomotor Activity In Rats
 Mizuki SUDO¹, Soichi ANDO². ¹Meiji Yasuda Life Foundation of Health and Welfare, Hachioji, Tokyo, Japan. ²University of Electro-Communications, Chofu, Tokyo, Japan.
 (No relevant relationships reported)

[Purpose] Environmental enrichment (EE) involves housing conditions that facilitate enhanced sensory, cognitive and motor stimulation. EE is beneficial to brain functions, probably due to increases in spontaneous locomotor activity. However, actual spontaneous locomotor activity has not been directly measured because of the technical difficulties involved in housing rats in groups. The purpose of this study was to assess spontaneous locomotor activity in the EE using a recently developed three-axis accelerometer. We also examined whether wheel running is the key to increase spontaneous locomotor activity housed in the EE. [Methods] Thirty-two Wistar rats were divided into four different housing groups (standard environment: SE; only running wheel group: W; EE without running wheel group: EE-S and EE). The present EE contained running wheel, slope, three tunnels, and small hut. Locomotor activity of each was continuously recorded using a three-axis accelerometer, which was embedded in the back. After exposure to each environment for 6 weeks, the tibialis anterior (TA), extensor digitorum longus (EDL) and soleus (Sol) muscles were removed and immediately weighted. [Results] Locomotor activity was higher during the dark period in the W (23,182 \pm 9,730, frequency/day) and EE (28,260 \pm 12,705) groups compared with EE-S (15,703 \pm 6,510) and SE (19,757 \pm 9,964) groups ($p < 0.05$, respectively). In contrast, locomotor activity during the light period was not different between groups. All hindlimb muscles except for EDL muscle were greater in the W (TA: 1.60 \pm 0.23, Sol: 0.42 \pm 0.49 mg/g) and EE (TA: 1.60 \pm 0.24, Sol: 0.41 \pm 0.51) groups compared with EE-S (TA: 1.52 \pm 0.23, Sol: 0.39 \pm 0.50) and SE (TA: 1.49 \pm 0.21, Sol: 0.37 \pm 0.52) groups ($P < 0.05$, respectively). [Conclusions] The present study suggests that environmental enrichment increase spontaneous locomotor activity housed in groups, which was accompanied by muscle hypertrophy. Wheel running appears to play a key role in increased spontaneous locomotor activity in the EE.

Investigating The Repeated-bout Effect To Eccentric Contractions For Females And Males
 Christina D. Bruce, Luca Ruggiero, Gabriel U. Dix, Paul D. Cotton, Chris J. McNeil. *The University of British Columbia, Kelowna, BC, Canada.* (Sponsor: Charles L. Rice, FACSM)
 (No relevant relationships reported)

Performing unaccustomed eccentric (ECC) exercise leads to temporary muscle damage, initiating a prophylactic response to minimize injury from a subsequent bout (i.e., the repeated-bout effect; RBE). Few studies have investigated sex-related differences to ECC maximal voluntary contractions (MVCs). There is indirect evidence to suggest females may have greater muscle damage following ECC MVCs. If true, this could induce a larger RBE for females than males; however, the RBE has not been compared between the sexes. **PURPOSE:** To compare the magnitude of the RBE for females and males. **METHODS:** To date, data from two bouts of ECC MVCs have been collected from 15 healthy young participants (22.7 \pm 2.8y; 6 females). The fatigue/damage protocol involved 200 ECC MVCs of the dorsiflexors (60°/s from a neutral ankle position to 30° of plantar flexion; 4 sets of 50 reps; 2s rest between reps and 1min rest between sets). Isometric (ISO) MVC torque and the ratio of ISO torque responses to low vs. high frequencies of electrical stimulation (10:100Hz) were compared before and after (2, 3, and 5min, as well as 2, 4, and 7d) the fatigue/damage protocol. The fatigue/damage protocol and recovery visits were repeated four weeks later. **RESULTS:** After bout 1, ISO MVC torque decreased 27.2 \pm 10.9% (females) and 25.1 \pm 14% (males) at 2min post-fatigue. At 2d, ISO MVC torque was 91.0 \pm 8.3% and 90.0 \pm 11.9% control for females and males, respectively. The 10:100Hz ratio decreased markedly in acute recovery (5min: 53.5 \pm 13.6% and 40.4 \pm 10.4% for females and males, respectively) but returned to 94.7 \pm 16.3% and 88.8 \pm 10.6% control at 2d. After bout 2, ISO MVC torque was impaired by 19.4 \pm 13.3% (females) and 23.1 \pm 13.7% (males) at 2min post-fatigue, and restored to 91.3 \pm 8.1% and 96.3 \pm 6.0% control (females and males, respectively) at 2d. The decrease in the 10:100Hz ratio at 5min post-fatigue was 41.8 \pm 15.0% and 35.7 \pm 12.3% for females and males, respectively. At 2d, the ratio was 92.1 \pm 12.5% (females) and 94.7 \pm 8.8% (males) of control. **CONCLUSIONS:** Our preliminary results suggest that an initial bout of ECC MVCs may cause greater fatigue or transient damage for females than males. After bout 2, acute decreases in ISO MVC torque and 10:100Hz ratio appear to be attenuated more for females than males, which may suggest a greater RBE for females. Supported by NSERC, CFI, and BCKDF

Effect of Red Spinach Extract Supplementation on Cycle Time Trial Performance in Recreationally Active Individuals

Adam M. Gonzalez¹, Matthew R. Accetta¹, Robert W. Spitz¹, Gerald T. Mangine², Jamie J. Ghigiarelli¹, Katie M. Sell¹.
¹Hofstra University, Hempstead, NY. ²Kennesaw State University, Kennesaw, GA.
 Email: adam.gonzalez@hofstra.edu
 (No relevant relationships reported)

Red spinach extract (RSE) offers a rich source of dietary nitrates and evidence suggests that it may positively impact exercise performance. **PURPOSE:** The purpose of this investigation was to examine the effects of short-term red RSE supplementation on cycling time trial performance. **METHODS:** Seventeen recreationally active men (n=9, 22.2 \pm 3.8 y) and women (n=8, 22.8 \pm 3.5 y) underwent two testing sessions administered in a randomized, counterbalanced, double-blind fashion. Participants were assigned to supplement daily with 1 gram of RSE or placebo (PL) for seven days prior to each testing session. During each testing session, an additional serving was provided 1 hour prior to completing a 4-km cycling time trial test. Performance variables (time-to-completion, average power, relative power, cadence, and average speed) and subjective measures (perceived exertion and muscle fatigue) were assessed during each testing session. Heart rate, systolic blood pressure, and diastolic blood pressure (DBP) were also assessed around exercise. **RESULTS:** Compared to PL, RSE supplementation significantly improved ($p < 0.05$, $\eta_p^2 = 0.24$) 4-km completion time (404.6 \pm 24.6 vs. 410.6 \pm 31.3 s), relative power (2.53 \pm 0.44 vs. 2.46 \pm 0.40 W \cdot kg⁻¹), and average speed (35.7 \pm 2.2 vs. 35.3 \pm 2.5 km \cdot hr⁻¹). Additionally, a trial \times time interaction was observed for DBP ($F = 4.5$, $p = 0.020$, $\eta_p^2 = 0.22$) where DBP was lower following the RSE trial compared to the PL trial (66.1 \pm 6.1 vs. 70.1 \pm 5.0 mmHg). No other differences were observed between trials. **CONCLUSION:** In conclusion, RSE

supplementation significantly reduced time-to-completion and increased measures of power and speed during a 4-km cycling time trial. RSE also appeared to lower DBP following the cycling time trial, without altering participants' perceived exertion or subjective measures of muscle fatigue. The Probiotic *Streptococcus Salivarius* M18 Increases Plasma Nitrite But Does Not Alter Blood Pressure

Mia C. Burleigh. *University of the West of Scotland, West Kilbride, United Kingdom.* (Sponsor: Jason David Allen, FACSM)
 Email: mia.burleigh@uws.ac.uk
 (No relevant relationships reported)

The probiotic *Streptococcus salivarius* M18 increases plasma nitrite but does not alter blood pressure

Mia C Burleigh¹, Nicholas Sculthorpe¹, Fiona Henriquez¹, John Butcher², Chris Easton¹

¹University of the West of Scotland, Blantyre, Scotland

²Glasgow Caledonian University, Glasgow, Scotland.

Some species of bacteria in the mouth can reduce nitrate (NO₃⁻) from the diet to nitrite (NO₂⁻) which can be later converted to nitric oxide (NO). Increased levels of NO can reduce blood pressure (BP) and improve exercise performance. The bacteriocin-producing probiotic *Streptococcus salivarius* M18 (*S.salivarius* M18) can inhibit pathogenic oral bacteria but it is unclear whether an alteration to the oral microbiome will influence circulating levels of NO metabolites and BP. **Purpose:** To determine the effects of *S.salivarius* M18 supplementation on BP, plasma and saliva [NO₂⁻], and [NO₃⁻]. **Methods:** Eight healthy males (age 32 ± 8 y, body mass 80 ± 11 kg) completed 2 x 14 day supplementation phases in a randomized order at least 14 days apart. In one phase, participants consumed *S.salivarius* M18 probiotic lozenges (2.5 billion colony-forming units/dose) once per day and in the other they ingested water (placebo). Samples of unstimulated saliva and venous blood were collected, and BP was measured before and after each phase. Samples of saliva were later analysed for [NO₂⁻] and [NO₃⁻] using chemiluminescence. The change (Δ) in each outcome from pre- to post-supplementation was compared between phases using paired t-tests.

Results: Plasma NO₂⁻ increased from baseline (173 ± 38 nM) following probiotic supplementation (Δ50.24 ± 51.23 nM, P = 0.04) in comparison to the placebo phase (Δ8.77 ± 61.51 nM). There were no significant changes in systolic BP (probiotic Δ0 ± 3 mmHg; placebo Δ1 ± 4 mmHg, P = 0.51). Diastolic BP and salivary NO metabolites were also unaffected (all P > 0.05). **Conclusions:** Supplementation with *S.salivarius* M18 increased plasma NO₂⁻, a key marker of NO availability, potentially by altering the abundance or activity of NO₃⁻-reducing bacteria in the mouth. Despite this, *S.salivarius* M18 did not lower BP in healthy participants. Further research is therefore required to determine the therapeutic and ergogenic potential of probiotic supplementation.

Effect of Beetroot Juice Supplementation on Thermoregulation and Running in a Hot Environment

Elizabeth H. Kasperek, Jason C. Dorman, Thayne A. Munce, FACSM. *Sanford Sports Science Institute, Sioux Falls, SD.* (Sponsor: Thayne A. Munce, FACSM)
 Email: elizabeth.kasperek@sanfordhealth.org
 (No relevant relationships reported)

Beetroot juice (BRJ) is a rich source of dietary nitrate (NO₃⁻), and has become increasingly popular as a dietary supplement due to its positive effects on exercise performance. However, the effect of BRJ supplementation on thermoregulation and/or exercise performance in the heat is uncertain.

PURPOSE: To examine the effects of BRJ supplementation on thermoregulation and running performance and physiology in a hot/humid environment. **METHODS:** Using a double-blind, placebo-controlled, crossover design, 13 male runners (age, 35.8 years ± 6.1 yr; V_{O_{2max}}, 57.4 ± 6.5 mL·kg⁻¹·min⁻¹) were randomly selected to receive either nitrate-rich BRJ or a nitrate-depleted placebo (PLA) (2 x 70 mL) for 6 days, separated by a washout period of at least 10 days. On Day 6 of BRJ or PLA supplementation, subjects performed a 10 km time trial in an environmental chamber (26.6 °C, 50 % RH) after consuming their last supplement dosage. The first 8 km of each trial were run on a motorized treadmill (fixed speed for each subject), while the final 2 km were run on a non-motorized treadmill, allowing subjects to select their own pace. We examined core body temperature (T_{re}), heart rate (HR), ratings of perceived exertion (RPE) and thermal stress ratings (TSR) during each trial (every 2 min), as well as time trial performance (every 500 m). **RESULTS:** Only 4 out of 13 participants completed a full 10 km trial in both (BRJ and PLA) conditions. Participants who did not finish both trials had their session(s) terminated when their T_{re} reached 39.5°C (safety precautions), and one trial ended early due to the participant not feeling well. A time to event

analysis revealed that a higher proportion of runners from the PLA group remained in the trial compared to the BRJ group for any given distance, although these differences were not statistically significant (P = 0.221). For the first 5.5 km (a distance every participant completed in both conditions), there were no significant differences in T_{re} (P = 0.092), HR (P = 0.437), or RPE (P = 0.5013) between trials. TSR was significantly greater in PLA vs. BRJ (P < 0.001) during the first 5.5 km. **CONCLUSION:** There is weak evidence that BRJ supplementation may be associated with elevated T_{re} when running in the heat, even though thermal perceptions of heat stress are lower. It is unclear if these differences have health or performance implications.

Ergogenic Effect of Citrulline Malate Supplementation on Total Training Load and Muscle Thickness in Trained Women.

Tatiane G. Pinto, Sidney Diyoo Tamura, Luis Felipe Milano Teixeira. *NEPECE - HOSBOS/UNISO, Sorocaba, Brazil.*
 Email: luis.teixeira@prof.uniso.br
 (No relevant relationships reported)

Practitioners of physical activity, to improve performance in training sessions, commonly use pre-workout supplements. Recently, Citrulline Malate (CM) has attracted attention for its potential to improve performance in resistance training (RT). However, there is still a need to understand the ergogenic effect of CM in some populations with different levels of training. **PURPOSE:** To evaluate the acute effects of CM supplementation on the total training load and muscle thickness (MT) in recreationally resistance-trained women. **METHODS:** Six women (27.8±3.5 y; 67.8±6.6 kg; 164.5±3.1 cm) experienced in RT (36.1±19.5 months) underwent three RT sessions (RTS) in a randomized, double blind fashion. Participants were submitted to the maximum strength test (1RM) for the Arm Curl (AC) and Leg Extension (LE) exercises 120h before experimental trials (ET). Then, each participant performed a RTS in three randomized ET with 96h of interval among them: i) Control (CON): without consumption of any supplement; ii) Placebo (PLA): with 8g of synthetic magnesium silicate and; iii) Supplemented (SUP): with 8g of CM. PLA and SUP consumed their supplements 60min before the RTS that consisted in 3 sets until concentric muscle failure with 80%1RM and 90sec interval-rest among sets in AC and LE exercises. The total number of repetitions and the total training load was recorded for each series and the muscle thickness of the extensor muscles of the thigh and arm flexor muscles was obtained, immediately, before and after each exercise (Bodymetrix PRO-BX2000®). One-way ANOVA with Tukey's post-hoc was utilized to compare differences among ET, Wilcoxon test was utilized to within groups analyzes and effect size (ES) was calculated by using Cohen d. **RESULTS:** There were no significant differences in total training load among the ET (CON: 4714±1269kg; PLA: 4758±922.4kg; SUP:4826±940.7kg). Significant differences were observed in MT pre and post RTS in all ET in the arm flexors (CON: p=0.01, ES:1.2; PLA: p=0.007, ES:1.8; SUP: p=0.005, ES:1.4) and in the thigh extensors (CON: p=0.048, ES:0.6; PLA: p=0.01, ES:1.2; SUP: p=0.01, ES:1.4), however, no significant differences were observed when compared to the ET. **CONCLUSION:** The supplementation with 8g of CM 60min before a RTS has no ergogenic effect on total training load or MT in resistance-trained women.

Oral Creatine Supplementation On Physically Active Elderly Women Cognition Improvement

Marco Machado¹, Elvis Q. Borges¹, Lacy F. Machado¹, Alexander J. Koch², Dailson Paulucio¹. *¹Universidade Iguacu Campus v at Itaperuna, Itaperuna, Brazil. ²Lenoir-Rhyne University, Hickory, NC.*
 Email: marcomachado1@gmail.com
 (No relevant relationships reported)

PURPOSE: The aim of this study was to verify if creatine supplementation in conjunction with a community-based exercise program improved cognition in elderly women.

METHODS: Twenty elderly women were randomized into 2 groups: creatine (CRE, n=10, age = 71± 6 y; body mass = 67.4± 6.0 kg; height = 166±2 cm) or control (CON, n=10, age = 73±6 y; body mass = 67.4±5.7 kg; height = 164±4 cm). All subjects were active and did not use CM or pro-cognitive drugs before the experiment. CRE group received 2.0 g.kg body mass⁻¹.d⁻¹ of CM for 28 days. CON group received 2.0 g.kg body mass⁻¹.day⁻¹ of dextrosol. Community-based exercises (walking, dancing, calisthenics, stretching) were performed 3x a week with 1 h per session. Cognition was assessed using a battery of five tests: a Visual Reaction Time (VRT) test, a visual GO/NO GO reaction time (GNG) test; a Differentiation task test (DTT), an Eriksen flanker test (EFT), and a Corsi block test (CBT). Subjects completed a familiarization, taking the testing battery on two sessions over nonconsecutive days the week prior to the experiment. The week after familiarization, subjects completed the test battery and initiated supplementation (CRE or CON). After 28 days, they repeated the test battery.

Chi-square tests were used to compare groups and sessions for DTT, EFT, and CBT. Repeated measures ANOVA were used to compare VRT and GNG. Significance level was set $p \leq 0.05$.

RESULTS: Significant ($p \leq 0.05$) pre-post performance increases in GNG, EFT, and CBT were observed in CRE vs. CON (table 1). We did not find difference between moments or groups in VRT ($p > 0.05$) nor DTT ($p > 0.05$).

Table 1 - Cognitive tests results * $p \leq 0.05$ difference from other means according to ANOVA. Differing superscripts (^{a,b}) indicate $p \leq 0.05$ difference according to Chi-Square

| Test (units) | Group | Pre | Post | p-value |
|--------------|-------|-----------------|-----------------|---------|
| GNG (ms) | CRE | 1140.2 ± 520.7 | 590.3 ± 134.1* | 0.0235 |
| | COM | 967.6 ± 386.6 | 997.9 ± 517.7 | |
| EFT (%) | CRE | 76 ^a | 94 ^b | 0.0104 |
| | COM | 74 ^a | 76 ^a | |
| CBT (%) | CRE | 56 ^a | 84 ^b | 0.0298 |
| | COM | 62 ^a | 70 ^a | |
| VRT (ms) | CRE | 952.1 ± 442.5 | 578.2 ± 219.9 | 0.0915 |
| | COM | 543.4 ± 448.7 | 611.4 ± 418.3 | |
| DTT (%) | CRE | 66 | 68 | 0.6304 |
| | COM | 62 | 74 | |

CONCLUSIONS: We conclude that $2g \cdot kg^{-1} \cdot day^{-1}$ during 28 days of oral CM supplementation improved results in some cognitions tasks in elderly woman.

METHODS: 12 male, physically active participants were randomized in a double-blind fashion to placebo (PL) (n=6, 23±2 yrs) or creatine (CM) (n=6, 21±2 yrs) groups. Subjects received 0.3 g/kg/day creatine monohydrate or placebo in gelatin capsules for 7 days. Ultrasonography of the carotid artery, applanation tonometry, submaximal exercise tests (10 minute treadmill activity at 3.7 mph and 9% incline), and lower leg pain (analog visual scale and pain test algometer) assessments were conducted at baseline and on day 7 of the study period. **RESULTS:** There were no significant differences between PL and CM in carotid-femoral pulse wave velocity (CF PWV) (4.60 ± 10.42 vs. -2.71 ± 21.20 % change), β -stiffness index (5.81 ± 26.3 vs. 1.65 ± 41.35 % change), central pulse pressure (CPP) (-17.38 ± 16.31 vs. 6.05 ± 24.61 % change), and arterial compliance (AC) (19.79 ± 37.50 vs. 12.48 ± 53.89 % change) (all $P > 0.05$). There were no significant changes in SmO_2 (-7.95 ± 10.24 vs. 29.94 ± 36.13 % change) and peak pain (-6.55 ± 29.87 vs. -12.5 ± 30.62) between PL and CM, respectively (all $P > 0.05$). Finally, there were also no significant differences in body weight (0.53 ± 0.79 vs. 0.20 ± 0.87 % change), fat mass (-3.40 ± 3.49 vs. -0.23 ± 8.17 % change), and fat free mass (1.12 ± 0.98 vs. 0.23 ± 0.80 % change) between PL and CM, respectively (all $P > 0.05$). **CONCLUSIONS:** Using a randomly controlled, double-blind trial with validated measurements of AS and SmO_2 , acute creatine supplementation does not appear to impact vascular compliance or oxygen saturation in skeletal muscle in young, otherwise healthy males.

339 Board #177 May 29 9:30 AM - 11:00 AM
Creatine Supplementation And Repeated Sprint Ability - A Systematic Review And Meta-analysis

Mark Glaister, FACSM. *St Mary's University, Twickenham, United Kingdom.*
 Email: mark.glaister@stmarys.ac.uk
 (No relevant relationships reported)

PURPOSE: The aim of this study was to conduct a systematic review and meta-analysis of the effects of creatine supplementation on repeated sprint ability. **METHODS:** Sixteen studies met the inclusion criteria of adopting double-blind randomized placebo-controlled designs (crossover or between-subject) in which adult participants (age ≥ 18 years) completed a repeated sprint test (number of sprints: $4 < n \leq 20$; sprint duration: ≤ 10 s; recovery duration: ≤ 90 s) before and after supplementing with creatine or placebo for ≥ 3 days in a dose of ~ 20 g per day. No exclusion restrictions were placed on the mode of exercise. Meta-analyses were completed using random-effects models, with effects on measures of peak sprint performance (peak power or fastest sprint) and fatigue during each repeated sprint test presented as standardized mean difference (δ) and with effects on body mass and post-test blood lactate concentration presented as raw mean difference (D). Analyses were completed using pre-post supplementation differences, with standard deviations imputed, where necessary. 95% confidence limits (CL_{95}) were calculated for all estimates. **RESULTS:** Relative to placebo, creatine supplementation resulted in a significant increase in body mass ($D = 0.67$ kg; CL_{95} [0.47, 0.88]; $p < 0.00001$). However, there was no corresponding effect of creatine supplementation on measures of peak sprint performance ($\delta = 0.25$; CL_{95} [-0.19, 0.69]; $p = 0.27$), fatigue ($\delta = 0.19$; CL_{95} [-0.14, 0.53]; $p = 0.26$), or post-test blood lactate concentration ($D = 0.36$ mmol·L⁻¹; CL_{95} [-0.13, 0.85]; $p = 0.15$). **CONCLUSION:** Although the increase in body mass following creatine supplementation supports an increase in creatine retention; the results of this meta-analysis show that there is no corresponding effect on measures of repeated sprint ability.

340 Board #178 May 29 9:30 AM - 11:00 AM
The Effect of Creatine Supplementation on Muscle Oxygen Saturation and Arterial Stiffness

Tim Werner. *Salisbury University, Salisbury, MD.*
 Email: tjwerner@salisbury.edu
 (No relevant relationships reported)

There is a void in our knowledge on the impact of exercise, in particular creatine monohydrate supplementation, on arterial stiffness (AS) in the major elastic arteries. This study also examined the effects of creatine supplementation on skeletal muscle oxygen saturation (SmO_2) in the lower leg. Data have indicated that creatine supplementation can result in an increase in lower leg anterior compartment pressure at rest and post exercise. Although the increased pressures seen during these studies were not pathological, this and additional factors associated with creatine supplementation could possibly effect SmO_2 during exercise and recovery. **PURPOSE:** To determine the effects of acute creatine monohydrate supplementation on AS and SmO_2 .

341 Board #179 May 29 9:30 AM - 11:00 AM
Exhaustive Resistance Exercise Alters Serum Creatine and Guanidinoacetic Acid in Active Men

Zoran S. Milosevic¹, Patrik Drisd¹, Saad Al Fazazi², Valdemar Stajer¹, Nebojsa Maksimovic¹, Sergej M. Ostojic¹. ¹University of Novi Sad, Novi Sad, Serbia. ²University of Granada, Granada, Spain.
 (No relevant relationships reported)

Exhaustive exercise adversely affects biomarkers of creatine metabolism yet it remains unknown when the values back toward pre-disturbance conditions. **PURPOSE:** To evaluate a 24-hour post-exercise response in serum guanidinoacetic acid (GAA), creatine and creatinine in young active men subjected to a single session of exhaustive resistance exercise and matched it with exercise-induced changes in serum cortisol, interleukin 6 (IL-6), creatine kinase (CK), and lactate dehydrogenase (LDH). **METHODS:** Twelve healthy active men (age 22.7 ± 0.8 years; weight 79.8 ± 7.3 kg; height 182.4 ± 4.9 cm; weekly exercise 5.1 ± 1.6 hours) were subjected to a single session of bench press exercise until volitional exhaustion, with venous blood sampled before, immediately after exercise (~ 2 min), and after 15 min, 60 min and 24 h after the end of exercise. **RESULTS:** Baseline values for serum GAA, creatine and creatinine were 2.2 ± 0.5 μ mol/L, 18.9 ± 3.6 μ mol/L, and 72.4 ± 6.0 μ mol/L, respectively. Serum GAA significantly dropped for $9.6 \pm 7.3\%$ immediately after bench press exercise (95% CI, 5.0 to 14.2; $P < 0.001$), while both creatine and creatinine increased immediately after the test for $5.0 \pm 2.5\%$ (95% CI, 3.4 to 6.6; $P < 0.001$) and $11.9 \pm 4.3\%$ (95% CI, 9.2 to 14.6; $P < 0.001$), respectively. GAA and creatine levels recovered to the baseline values after 24 hours post-exercise, yet creatinine remained significantly higher at 24-hour period as compared to the baseline values for $2.5 \pm 2.3\%$ (95% CI, 1.0 to 4.0; $P = 0.002$). **CONCLUSIONS:** A single session of exhaustive resistance exercise induces transient alterations in biomarkers of creatine metabolism, with serum creatinine outlined as a most persistent marker of exhaustion. Exercise-induced changes in creatine metabolism poorly corresponded to perturbations in inflammation and muscle fatigue biomarkers following exercise. This project was partly supported by the Serbian Ministry of Education, Science and Technological Development (175037 and 179011), the Provincial Secretariat for Higher Education and Scientific Research (142-451-2473 and 114-451-710) and the Faculty of Sport and Physical Education, University of Novi Sad (2018 Annual Award).

Fish Oil Intake and Exercise Improve Physical Function and Resting Metabolic Rate in Older Adults

Sang-Rok Lee, Rebecca P. Mehlin, Gilbert Sigala, Joshua K. Krause, Lexie P. Fitch, Josi R. Gabaldon, Neva L. Williams. *New Mexico State University, Las Cruces, NM.* (Sponsor: Jeong-Su Kim, FACSM)
 Email: srlee@nmsu.edu
 (No relevant relationships reported)

Omega-3 polyunsaturated fatty acids (n-3) have received great attention due to their health-enhancing benefits; however, effects of chronic n-3 administration combined with resistance training (RT) in physical function and resting metabolic rate (RMR) in older adults are not well established. **PURPOSE:** To investigate the effects of 12-wk n-3 administration with programmed RT on muscular strength, physical function, and RMR in older adults. **METHODS:** Healthy older adults (62 - 77 years) were randomly assigned to the fish oil plus RT group (FRT; n=8) or control group (CON; n=5). The FRT group consumed fish oil supplements enriched with n-3 polyunsaturated fatty acids [3 capsules per day - 2100 mg of eicosapentaenoic acid (EPA) and 720 mg of

docosahexaenoic acid (DHA)] and performed progressive RT including lat pull-down, seated row, biceps curl, leg press, and calf raise (2 sets of 10 repetitions; 2x/week for 12 weeks). Muscular strength, physical function, and RMR were evaluated pre- and post-intervention. Data were analyzed using 2×2 (group \times time) repeated-measures ANOVA. **RESULTS:** There were significant group \times time interactions for muscular strength ($p < 0.01$), physical function ($p < 0.05$), and RMR ($p < 0.01$). There were significant increases in muscular strength; lat pull-down (+22%), seated row (+45%), biceps curl (+36%), leg press (+54%), and calf raise (+43%) ($p < 0.01$) in FRT with no detectable changes in CON. In addition, there were great improvements in physical function; five-stand chair (+22%) and 30-sec chair stand (+22%) in FRT ($p < 0.05$) with no changes observed in CON. RMR significantly increased in FRT (+6%, $p < 0.05$), while remarkably decreased in CON (-6%, $p < 0.05$). **CONCLUSION:** Twelve-weeks of n-3 administration with progressive RT greatly improved muscular strength and physical function as well as appears to reverse the aging-induced decline in RMR in healthy older adults.

Effects Of A Single Dose Multi-ingredient Pre-workout Supplement On Aerobic And Anaerobic Performance In Men

Meghan K. Magee¹, Justine E. Fox¹, Marquez R. Norford¹, Scott E. Williams¹, Brett A. Comstock¹, Rudy M. Inaba², Joseph L. Andreacci, FACSM¹, Kyle S. Beyer¹. ¹Bloomsburg University of Pennsylvania, Bloomsburg, PA. ²Cenegenics, Las Vegas, NV. (Sponsor: Joseph L. Andreacci, FACSM)

(No relevant relationships reported)

PURPOSE: To assess the effects of a single dose of a multi-ingredient pre-workout supplement (MIPS) on aerobic and repeated anaerobic performance tests. **METHODS:** Eight college-aged men were recruited to participate in a randomized, double-blind, placebo-controlled, crossover study. All participants were tested within the same week separated by 48 hours and were provided either the placebo (PLA) or the MIPS on each day. As per the manufacturer's instructions, the participants waited 25 minutes to begin the tests, following consumption of the drink. Aerobic exercise performance was assessed using the Modified Astrand Treadmill Protocol, during which maximal oxygen consumption (VO_{2max}) and maximal aerobic exercise time were determined. Following this test, participants were provided a 20-minute seated rest period. After the rest period, participants completed a short warm-up which consisted of 2 minutes of cycling at 50 RPMs against a light resistance, followed by 3, 10-second sprints, to determine the max RPMs. After the warm-up, participants completed the repeated anaerobic power test, which consisted of 10, 6-second sprints, with 45 seconds of active rest in between each sprint. For each sprint, a resistance of 7.5% of the participant's body mass was applied at 90% of their max RPM. Peak power (PP) was determined for each sprint and the percent decline in PP from the first to the last sprint was calculated. VO_{2max}, exercise time and the percent decline in PP for the sprints were analyzed using a dependent t-test. The peak power of the 10 sprints were analyzed using 2x10 ANOVA. The alpha level was set a priori to $p < 0.05$. **RESULTS:** There was no significant difference between the PLA and MIPS for VO_{2max}. However, there was a significant difference in treadmill time ($p = 0.005$) with MIPS (10.4 ± 1.6 min) performing better than PLA (10.0 ± 1.6 min). There were no significant differences between the PLA and MIPS when analyzing peak power during the 10 sprints or percent decline in PP. **CONCLUSIONS:** A single dose of this MIPS improved maximal aerobic exercise time despite no changes in VO_{2max}. However, this MIPS did not improve performance during a repeated anaerobic power test. Study supported by Cenegenics®

Antioxidants Supplementation Hamper Muscle Growth after 10 Weeks Strength Training

Sávio Alex¹, Maurílio Dutra², Alysson Silva¹, André Martorelli³, Flávia Espírito Santo¹, Lee E. Brown, FACSM⁴, Martim Bottaro¹. ¹University of Brasilia, Brasilia, Brazil. ²Federal Institute of Brasilia, Brasilia, Brazil. ³Federal Institute of Goiás, Valparaíso, Brazil. ⁴University of West Florida, Pensacola, FL. (Sponsor: Lee Brown, FACSM)
 Email: savioalex@outlook.com
 (No relevant relationships reported)

Strength Training (ST) is recommended for increased muscular mass. It has been suggested that reactive oxygen species (ROS) produced by a ST session may play a positive role in the hypertrophic process. However, there is some evidence that chronic antioxidant supplementation may indeed reduce ROS and play a negative role in protein synthesis. Few studies have investigated the effects of ST combined with antioxidant supplementation on muscle hypertrophy. However, results are still controversial. **PURPOSE:** To investigate the effects of ST combined with Vitamin C and E supplementation on muscle thickness (MT). **METHODS:** Thirty-three untrained

women (22.9 ± 2.5 years, 57.7 ± 8.4 kg, 1.6 ± 0.6 m) were allocated into three groups: Vitamins (VG, n=12), Placebo (PG, n=11) and Control (CG, n=10). Participants of VG and PG underwent lower-body (lunge and deadlift exercises) periodized ST, two-times a week, for 10 weeks. VG group was supplemented with vitamins C (1g/day) and E (400IU/day) during the training period, PG ingested placebo pills and CG did not perform training or supplementation. Muscle thickness (MT) of the quadriceps femoris of the dominant limb was analyzed by ultrasonography. **RESULTS:** Both VG (+11.6%; $P < .05$) and PG groups (+17.1%; $P < .05$) presented increased values of MT after 10 weeks of ST. However, there was no difference between the VG and PG groups, only the PG presented a significant gain of MT when compared to CG (17.1% vs 2.0%; $p < .05$). **CONCLUSIONS:** The results of this investigation suggest that chronic antioxidants supplementation may mitigate improvements in muscle hypertrophy, after 10 weeks of ST in untrained young women.

Combination Polyphenol and MSM Supplementation Alters Post Half Marathon Systemic Inflammatory Response

Melody A. Gary, Elizabeth A. Tanner, Asheal A. Davis, Brian K. McFarlin, FACSM. University of North Texas Applied Physiology Lab, Denton, TX. (Sponsor: Brian McFarlin, FACSM)

Email: melody.gary@unt.edu

(No relevant relationships reported)

Individuals participating in prolonged endurance performances and associated training experience regular inflammation and muscle soreness. Natural products with known anti-inflammatory and/or oxidative stress blocking effects represent attractive options to traditional NSAID treatments. **PURPOSE:** To investigate the effect of combined curcumin (500-1000 mg/d; Longvida), pomegranate extract (500-1000 mg/d; Pomella), and methylsulfmethane (500-1000 mg/d; OptiMSM) supplementation for 30-days on inflammation-associated RNA, protein inflammatory biomarkers, and biomarkers of oxidative stress. **METHODS:** All protocols were approved by the University IRB committee and participants gave written informed consent. Subjects supplemented with the combination supplement (N=5) or placebo (N=5) for 30-d prior to the half marathon race. Venous blood samples were collected for RNA (PAXgene tube) or serum (evacuated serum separator tube) 24-h pre-race, 4-h, and 24-h after a half marathon race. PAXgene treated blood was analyzed in duplicate using a custom, bead-based RNA assay (Quantigene; ThermoFisher). Serum samples were analyzed in duplicate using separate bead-based protein assays to measure cytokines, soluble cytokine receptors, and myokines (Milliplex; Millipore-Sigma). Bead-based analysis was conducted using an automated analyzer (Luminex FM3D). Oxidative stress (TAC, AGE) was measured using enzymatic assays (Cell Biolabs, Aviva Systems Biology). Fold change from pre was calculated for the various outcome variables to allow for better comparison and model creation. **RESULTS:** Fold changes in RNA and proteins exhibited a trend toward reduced inflammation while showcasing an increased ability of soluble cytokine receptors to tolerate inflammation with supplementation post-race. Reduced oxidative stress (via TAC and AGE) was observed post-race with the supplement compared to placebo. **CONCLUSIONS:** These data support the notion that the combined use of curcumin, pomegranate and MSM prior to and after a half marathon race may result in reduced systemic inflammation and oxidative stress. More research is needed in order to understand how to use these effects to improve the effectiveness of a long-term training program.

Acute Fermented Soy Supplementation Improves 20-km Time Trial Performance through Improvements in Power and Speed

ChiHo A. Cheung, Afton D. Seeley, Natasha Cruz, Jesse S. Brenman, Kevin A. Jacobs, FACSM, Joseph F. Signorile. University of Miami, Miami, FL. (Sponsor: Kevin Jacobs, FACSM)

(No relevant relationships reported)

INTRODUCTION: Isoflavones, a chemical class of phytoestrogens, are found in soybeans and soy products and may have biological functions similar to estradiol. After binding with ER_β or perhaps independently of estrogen receptors, isoflavones may augment vascular endothelial relaxation, contributing to improved skeletal muscle blood flow. **PURPOSE:** To determine if acute fermented soy extract supplementation influences 20-km time trial cycling performance and cardiac hemodynamics compared to a placebo. **METHODS:** Subjects included twenty-five recreationally trained cyclists and triathletes (31 ± 8 y, 177.3 ± 5.9 cm, 78.3 ± 8.5 kg, VO_{2peak}: 55.1 ± 8.4 mL·kg⁻¹·min⁻¹ (4.3 ± 0.7 L·min⁻¹) at 315 ± 42 W). Each subject completed a VO_{2peak} assessment, familiarization, and two 20-km time trials in randomized order following ingestion of a fermented soy extract supplement or placebo. The fermented soy extract consisted of 30 g powdered supplement in 16 fl. ounces of water. The placebo consisted of the same quantities of organic cocoa powder and water. Each trial

consisted of 60 min of rest, 30 min of steady-state exercise at 55% W_{peak} , and a self-paced 20-km time trial. Heart rate, stroke volume, and cardiac output were measured continuously using impedance cardiography. Ergometer software continuously recorded power output, speed, cadence, and time to completion. **RESULTS:** Soy supplementation elicited a faster time to completion (-0.22 ± 0.10 min; -37 s), lower average heart rate (-5 ± 1 bpm), and significantly greater power (6.8 ± 2.5 W) and speed (0.42 ± 0.16 km·hr⁻¹) during the last 5 km of the time trial compared to placebo. Analysis of the results by relative fitness level (< 60 vs. ≥ 60 mL·kg⁻¹·min⁻¹) indicated that soy supplementation resulted in lower values of cardiac output (-1.6 ± 0.8 L·min⁻¹), stroke volume (-5.4 ± 3.1 ml·beat⁻¹), and heart rate (-5 ± 3 bpm) in those with higher levels of fitness. **CONCLUSIONS:** Ingestion of a fermented soy extract supplement improved sprint-distance performance through improvements in both power and speed. For those with great aerobic fitness, soy supplementation may help to decrease cardiac demand alongside performance improvement.

Effects of Short-Term Spirulina Supplementation on Oxidative Stress Markers in Mountaineers at High Altitude

Majid S. Koozehchian¹, Khadijeh Taheri Kazaj², Amir Sarshin², Abbasali Gaeni³, Alireza Naderi⁴, Stephen R. Stannard⁵, Maryam Kaveh⁶, T. Jeff Chandler, FACSM¹. ¹Jacksonville State University, Jacksonville, AL. ²Karaj Branch, Islamic Azad University, Karaj, Iran, Islamic Republic of. ³University of Tehran, Tehran, Iran, Islamic Republic of. ⁴Boroujerd Branch, Islamic Azad University, Boroujerd, Iran, Islamic Republic of. ⁵Massey University, Wellington, New Zealand. ⁶Karnataka College of Pharmacy, Bangalore, India. (Sponsor: Jeff Chandler, FACSM)
 Email: mkoozehchian@jсу.edu
 (No relevant relationships reported)

PURPOSE: To investigate effects of 14 days of spirulina supplementation on oxidative stress responses of climbers at high altitude. Spirulina is a source of antioxidants, which can protect against oxidative damage.

METHODS: Eighteen apparently healthy men and women mountaineers (age 24.87±5yr, height 170.7±15.34cm, weight 75.92±17.21kg) volunteered to participate in a one group pretest-posttest study design. All participants completed two winter ascents to the summit (4,000meters) a week before as well as 14 days after spirulina supplementation (3g/day). Blood samples (4cc) were collected at pre-climbing and summit prior to and following supplementation under the same conditions. Participants were instructed to maintain their diet and avoid using antioxidant-containing products throughout the study. Blood samples were analyzed to measure oxidative stress markers such as malondialdehyde (MDA), superoxide dismutase (SOD), catalase (CAT), glutathione peroxidase (GPx), and total antioxidant capacity (TAC). All data were expressed as the mean ± SEM. Statistical comparisons were performed using t-test (*p* values < 0.05 were considered to be statistically significant).

RESULTS: Results indicated that resting MDA at pre-climb were significantly reduced following supplementation ($3.37 \pm 0.017U$ vs. $2.89 \pm 0.14U$; $p=0.036$); however, significant increases occurred in SOD resting values ($132.8 \pm 6.39U$ vs. $147.8 \pm 3.37U$; $p=0.042$) and TAC ($10.52 \pm 0.32U$ vs. $12.98 \pm 0.48U$; $p=0.001$) after supplementation. The TAC values were significantly higher at the summit compared to pre-climb values in pre-supplementation ($10.87 \pm 0.30U$ vs. $10.52 \pm 0.32U$); conversely, TAC values were significantly lower at the summit compared to pre-climb values after the supplementation ($12.09 \pm 0.36U$ vs. $12.98 \pm 0.48U$) ($p=0.047$). Spirulina Supplementation did not significantly change resting GPx and CAT levels as well as the responses of MDA, SOD, GPx and CAT in high altitude ($p>0.05$).

CONCLUSION: Spirulina supplementation for a 14-day period reduced the oxidative stress in participants during pre-climbing phase and increased the total antioxidant capacity. However, there were no significant changes in the variables at high altitude. It appears that 3g/day of spirulina cannot completely cope with oxidative stress in hypoxic condition.

348 Board #186 May 29 9:30 AM - 11:00 AM
Effect of Huperzine A on Cognitive Function and Perception of Effort During Exercise

Chadsley M. Wessinger¹, Cynthia Inman², Jeremiah Weinstock¹, Edward P. Weiss¹. ¹Saint Louis University, St. Louis, MO. ²Southern Illinois University Edwardsville, Edwardsville, IL.
 Email: chadwessinger@gmail.com
 (No relevant relationships reported)

PURPOSE: Huperzine-A has shown the ability to acutely improve cognitive function in certain populations, and therefore is commonly added to pre-workout supplements.

However, its effects have not been studied in exercise-trained individuals. We hypothesized that acute consumption of huperzine-A would improve cognitive function during exercise, which may be beneficial for exercise performance.

METHODS: From January to April, 2018, 15 exercise-trained individuals (women and men, BMI 23.5±1.4 kg/m², age 30.4±3.6 years) were studied in a double blind randomized-sequence cross-over study, in which they underwent tests for cognitive function (digit span, verbal/word fluency, and Stroop), neuromuscular performance (sharpened Romberg and dart throwing), and exercise performance (estimated aerobic capacity, hand-grip strength, vertical jump, and push-up) after acute ingestion of huperzine-A (200 mcg) or placebo. A 7- to 10-day washout period separated the subsequent trials.

RESULTS: No measures of cognitive function differed between placebo or huperzine-A trials (all $p \geq 0.296$). Heart rates (157 ± 4 vs. 158 ± 4 bpm; $p=0.518$) and ratings of perceived exertion (13.7 ± 0.56 vs. 13.9 ± 0.61 ; $p=0.582$) did not differ between placebo and huperzine-A trials, respectively. Ratings of subjective difficulty post-exercise (0-10 scale) were significantly higher (5.7 ± 0.38 vs. 6.8 ± 0.38 ; $p=0.002$) in the huperzine A trial than the placebo trial. No differences were observed for neuromuscular or exercise performance measures between both groups (all $p \geq 0.497$). **CONCLUSION:** Huperzine-A does not enhance cognitive function during exercise despite it being marketed as a cognitive enhancer. Because of its inability to enhance cognitive function, its inclusion in pre-workout supplements warrants reconsideration. Other more practical and effective strategies should be considered.

349 Board #187 May 29 9:30 AM - 11:00 AM
No Recovery Differences with Acute vs. Pre-load Montmorency Tart Cherry Juice Supplementation Following Strenuous Exercise

Jerusalem Tesfaye¹, Kelly Pritchett¹, Robert Pritchett¹, Tom Clifford², Mitchell Fisher¹, Devin Drummer¹. ¹Central Washington University, Ellensburg, WA. ²Newcastle University, Newcastle upon Tyne, United Kingdom.
 (No relevant relationships reported)

Montmorency tart cherry juice (MC) has been shown to enhance exercise recovery following high intensity exercise by decreasing inflammation and oxidative stress.

Methodologies for previous studies involving MC consumption as a recovery aid utilize a pre-load dosage strategy involving a 3-7 day loading phase prior to strenuous exercise. No consistent rationale has been provided for dosage strategies, therefore a pre-load strategy may be unnecessary for proposed benefits. **PURPOSE:**

To investigate whether acute consumption of MC following a bout of strenuous exercise is equally as effective as consuming MC pre and post exercise on markers of recovery. **METHODS:** Healthy resistance-trained males ($n=10$, age, height, mass: 25.30 ± 8.08 years, 179.81 ± 10.84 cm, 90.95 ± 18.04 kg) and females ($n=8$, age, height, mass: 25.63 ± 3.85 years, 165.89 ± 3.46 cm, 70.98 ± 8.54 kg) were randomized into two groups that consumed 30 mL of MC twice per day for three days following exercise (no-preload; NPL) or six consecutive days beginning three days prior to strenuous exercise (pre-load; PL). Participants completed a squatting exercise protocol designed to induce muscle damage and reported to the lab immediately post-exercise, 24, 48 and 72-h later to assess recovery indices including: serum creatine kinase (CK), the Adapted Brief Assessment of Mood (BAM+) survey, pressure-pain threshold (PPT), countermovement jump height (CMJ) and the Wingate anaerobic test (WANt).

RESULTS: Serum CK peaked at 24-h in the NPL and PL group as compared to baseline (410.56 ± 253.90 , 778.17 ± 780.95 U/L, respectively) ($p < 0.05$). Perceived recovery (BAM+) was lowest at 48-h in the NPL and PL group (45.16 ± 25.59 , 35.96 ± 29.67 mm, respectively) ($p < 0.05$). PPT of the vastus medialis muscle was lowest at 48-h in the NPL and PL group (5.99 ± 1.34 , 5.36 ± 0.84 kg-force, respectively) ($p < 0.05$). CMJ performance was lowest at 24-h in the NPL and PL group as compared to baseline (94.28 ± 5.29 , $88.94 \pm 11.74\%$, respectively) ($p < 0.05$). No differences were found between the NPL and PL groups for all recovery indices. **CONCLUSIONS:** These results suggest no additional benefits of a pre-load strategy when using MC as a post-exercise recovery aid following high-intensity, muscle-damaging exercise. These findings could have implications for dosage strategies currently used by athletes.

Performance Enhancing Effects Of Ecdysterone- A Human Intervention Study

Patrick Diel¹, Eduard Isenmann¹, Gabriella Ambrosio², Jan Felix Joseph², Xavier de la Torre³, Philipp Zimmer¹, Rymantas Kazlauskas⁴, Catrin Goebel¹, Francesco M Botre³, Maria Kristina Parr². ¹Geman Sports University Cologne, Cologne, Germany. ²Freie Universitaet Berlin, Berlin, Germany, Berlin, Germany. ³Laboratorio Antidoping FMSI, Rome, Italy., Rome, Italy. ⁴Australian Sports Drug Testing Laboratory, National Measurement Institute, Australia, North Ryde, Australia.
Email: diel@dshs-koeln.de

(No relevant relationships reported)

PURPOSE: Recent studies suggest that the anabolic effect of ecdysterone (a naturally occurring steroid hormone present in some supplements claimed to enhance physical performance) is mediated by estrogen receptor (ER) binding. In comparison to the prohibited anabolic agents (e.g. metandienone and others) ecdysterone revealed to be even more effective in a recent study performed in rats. However, scientific studies in humans are very rarely accessible. Thus, our project aimed at investigating the effects of ecdysterone containing products on human athletic performance

METHODS: A ten weeks intervention study in young man has been conducted including regular resistance training for all volunteers. Different doses of ecdysterone containing supplements have been administered during the study to evaluate the performance enhancing effect. Analysis of blood and urine samples for ecdysterone and potential biomarkers of performance enhancement have been conducted. To ensure the specificity of the measured effects a comprehensive screening for prohibited compounds was also performed. Furthermore, the administered supplements have been tested for the absence of anabolic steroid contaminations prior to administration.

RESULTS: Used ecdysterone supplements displayed anabolic activity in C2C12 cells. Dose dependent administration of Ecdysterone supplements to human volunteers results in detectable ecdysterone concentrations in serum. Effects on endocrine parameters were detectable. Serum IGF1 concentrations increased in comparison to the control group while thyroxin (T4) concentrations decreased. Significantly higher increases in muscle mass were observed in those volunteers that were dosed with the ecdysterone supplements. Even more relevant with respect to sports performance, also significantly more pronounced increases in one-repetition bench press performance were observed.

CONCLUSIONS: These data underline the effectivity of an ecdysterone supplementation with respect to sports performance. Our results strongly suggest to include ecdysterone in the list of prohibited substances and methods, in the class S1.2 "other anabolic agents".

PURPOSE: Citrus active substances can extend aerobic exercise time in mice. The objective of this study was to determine whether citrus bioactive substances could improve aerobic exercise and resilience of athletes.

METHODS: Weightlifters (male = 6; female = 5) Took citrus bioactive substance (200mg/d) orally for 5 weeks, blood sampling before intervention, and then collected once every 6 days, and the fasting sampling was proceeding from 7:00 to 8:00 am. Athlete-related biochemical indicators were detected and analyzed.

RESULTS: Citrus active substances could maintain the number of athletes leucocytes. After 5 weeks, the testosterone contents of male and female athletes decreased and then increased during intervention time, increasing the testosterone content (more than 1.5 times) of male athletes with low initial testosterone levels. The cortisol concentrations of all athletes significantly lower than that before non intervention. Serum ferritin content rose during intervention time. The erythrocytes number of male athletes decreased and the amount of increased compared the initial state, while hemoglobin/red blood cells showed an increasing trend. In terms of fatigue index, the

male athlete's blood urea level fell, while that of the female athlete escalated; male athletes' uric acid content decreased, female athletes increased gently in the early stage.

CONCLUSION: Our findings showed that the citrus bioactive substance diminished serum cortisol levels and increased the testosterone/cortisol ratio, thus helping the recovery of the athlete's body. The increase in the amount of hemoglobin carried by athletes in red blood cells increases the rate of oxygen transport. In general, athletes can use citrus

bioactive substances as a supplement to enhance physical recovery and exercise capacity.

7-Day Hydrogen Inhalation Affects Exercise Performance and Hormonal Profiles in Young Volunteers

Sergej M. Ostojic, Dejan Javorac, Valdemar Stajer. *University of Novi Sad, Novi Sad, Serbia.*

(No relevant relationships reported)

The use of medical gasses has been recently displayed as an emerging exotic strategy in exercise physiology and sports medicine community, with few unconventional medical gasses put forward as performance-enhancing agents. Among others, molecular hydrogen (H₂) pops up as an innovative compound that might be applicable among athletes. **PURPOSE:** To examine the effects of 7-day H₂ inhalation on exercise performance outcomes and serum hormonal and inflammation profiles in a cohort of young men and women. **METHODS:** Twenty healthy volunteers (10 men and 10 women; age 22.9 ± 1.5 years; body mass index 23.4 ± 2.5 kg/m²) participated in this randomized, double-blind, placebo-controlled, crossover pilot trial. All participants were allocated to receive either gaseous hydrogen (4%) or placebo (room air) by 20-min once-per-day inhalation for 7 days, with wash-out period of 7 days to prevent the residual effects of interventions across study periods. Gaseous hydrogen was provided by biological gas supplying apparatus (MIZ Company Ltd, Kanagawa, Japan), with day-to-day H₂ inhalation supervised by study investigators throughout the trial. The primary treatment outcome was the change in running time-to-exhaustion from baseline to day 7. Secondary outcomes included change from baseline to end of treatment in other exercise performance endpoints and clinical chemistry biomarkers.

RESULTS: Breathing H₂ was superior to placebo to increase peak running velocity during a maximal incremental running test (for up to 4.2%; $P \leq 0.05$), also to attenuate a drop in maximal voluntary isometric strength at 7-day follow-up ($P = 0.04$). Hydrogen inhalation resulted in a notable drop in serum IGF-1 for 48.2 ng/mL at follow-up, while IGF-1 levels were elevated by 59.3 ng/mL after placebo intervention ($P = 0.04$). Baseline CRP levels were decreased by 1.0 mg/L and 0.7 mg/L after H₂ and placebo inhalation at 7-day follow up, respectively. **CONCLUSION:** Inhalational hydrogen appears to show ergogenic properties in young volunteers. Gaseous H₂ should be further evaluated for its efficacy and safety in athletic environment. Supported by the Serbian Ministry of Education, Science and Technological Development (175037), the Provincial Secretariat for Higher Education and Scientific Research (114-451-710) and the Faculty of Sport and Physical Education.

Using Combined Curcumin and Boswellia Serrata Supplementation to Alter Inflammatory Response to Consecutive Exercise Days

Asheal A. Davis, John H. Curtis, Meolody A. Gary, Elizabeth A. Tanner, Jakob L. Vingren, FACSM, Brian K. McFarlin, FACSM. *University of North Texas, Denton, TX.* (Sponsor: Brian McFarlin, FACSM)

Email: asheal.davis@unt.edu

(No relevant relationships reported)

Repetitive exercise on consecutive days is a key component of many long-term training plans. This type of training results in muscle inflammation and soreness that limits the capacity to sustain exercise at a high intensity. Several dietary polyphenols have the capacity to manage inflammation and thus supplementation may be an effective component of a long-term training plan. **PURPOSE:** The purpose of this study was to investigate the effect of combined oral supplementation with curcumin and boswellia serrata prior to and following three consecutive days of intense interval exercise. **METHODS:** All protocols were approved by the University IRB committee and participants gave written informed consent. Participants were supplemented with either combined active (N=10; 95% full spectrum curcumin=400 mg/d and 90% boswellia serrata extract standardized for AKBA=100 mg/d) or placebo (rice flour; N=7) for 7-d prior to and immediately following each exercise session. Each exercise day consisted of 45-min of interval exercise (ladder climbing, cycling, and downhill running). Subjective muscle soreness and muscle strength were evaluated using a visual analog scale and isokinetic dynamometer respectively. Venous blood samples were collected for serum prior to and 1-h after each of the three exercise days and 24-h after the final exercise day. Samples were analyzed in duplicate using separate bead-

based assays to measure cytokines and myokines (Milliplex; Millipore-Sigma). Sample analysis was performed on a multiplex analyzer (Luminex LX200). **RESULTS:** Active resulted in trends toward reduced muscle soreness and improved muscle strength compared to placebo. Active was also associated with transient reductions in serum creatine kinase, MIP-1 β , and IL-6. **CONCLUSIONS:** These data support the notion that combined supplementation with curcumin and boswellia serrata may represent an effective means to manage systemic inflammation during consecutive days of training. More research is needed to understand how curcumin and boswellia serrata may be able to manage inflammation in other exercise models.

Curcumin Supplementation Alters Inflammatory Cytokines Following Exercise

Brian K. McFarlin, FACSM, Elizabeth A. Tanner, Melody A. Gary, Asheal A. Davis, John H. Curtis, Jakob L. Vingren, FACSM. *University of North Texas, Denton, TX.*
Email: brian.mcfarlin@unt.edu

Reported Relationships: B.K. McFarlin: Industry contracted research; Research Grant to UNT.

Nutritional supplementation is often misused as a component of a holistic approach to muscle recovery following exercise. Supplementation that reduces post exercise inflammation or muscle soreness might improve recovery time. **Purpose:** The phase 1 purpose was to evaluate different doses of a curcumin supplement following a bout of eccentric leg press. The phase 2 purpose was to determine if the effective curcumin dose from phase 1, could alter inflammation in an open-label, field-based model. **Methods:** We consented self-reported healthy men and women to participate in the two phases of the study. In phase one, we tested a dose response for curcumin (Longvida) by comparing three doses (200, 400, & 1000 mg/d) to a placebo. In phase two, we evaluated a single dose of curcumin (1000 mg/d) combined with another polyphenol (pomegranate extract; Pomella; 1000 mg/d) endurance exercise model (half-marathon performance). Venous blood samples and analyzed for inflammatory cytokines (IL-1 β , IL-6, IL-8, and TNF- α) using a bead-based multiplex assay and an automated analyzer. Creatine kinase was analyzed using an enzymatic assay on a biochemistry analyzer (ChemWell T). **Results:** The 400 and 1000 mg doses were associated with a reduction in inflammatory cytokines and CK at 24 & 48-h after injury. Only the 1000 mg dose was associated with a reduction in subjective muscle soreness. The 200 mg dose responded in a similar manner as placebo (i.e. no reduction in muscle soreness or inflammation). When curcumin (1000 mg) was combined with pomegranate (1000 mg) in half-marathon runners, we found a significant reduction in inflammatory cytokines at 24-h post-race compared to pre-race. **Conclusions:** The key findings of this study suggest that the effectiveness of an oral curcumin supplement is dose-dependent and also activity-dependent. The combination of curcumin with pomegranate extract appeared to be more effective than curcumin alone at altering inflammation. More research is needed to identify how to incorporate curcumin and pomegranate supplementation into long-term exercise program.

355 Board #193 May 29 9:30 AM - 11:00 AM

Effect Of New Zealand Blackcurrant Extract On Recovery From Exercise Induced Muscle Damage Following Half Marathon Running

Rianne Costello¹, Stephen D. Myers¹, Mark E.T. Willems¹, Fiona Myers², Nathan A. Lewis³, Sam D. Blacker¹. ¹University of Chichester, Chichester, United Kingdom. ²University of Portsmouth, Portsmouth, United Kingdom. ³English Institute of Sport, Bath, United Kingdom.

(No relevant relationships reported)

New Zealand blackcurrant (NZBC) is a rich source of polyphenols, namely anthocyanins, which improve blood flow and display anti-inflammatory and anti-oxidant properties that may improve recovery from exercise-induced muscle damage (EIMD). Limited evidence is available as to whether a polyphenol supplement can aid recovery in the days following a half-marathon event. **Purpose:** To examine whether NZBC extract would accelerate recovery after a half-marathon race. **Methods:** Following a double blind, independent groups design, 20 (8 women) recreational runners (mean \pm SD: age 30 \pm 6 years, height 1.73 \pm 0.74 m, body mass 68.5 \pm 7.8 kg, previous half-marathons 7 \pm 2, finishing time 1:56:33 \pm 0:18:08 h:min:s) ingested either 2 x 300 mg day⁻¹ capsules of a NZBC supplement (CurraNZ™; each containing 105 mg anthocyanin) or a visually matched placebo (PLA) 7-days prior to and 2-days following a half-marathon. Force plates sampling at 1000 Hz recorded countermovement jumps (CMJ) performance variables: jump height (JH), time to take off (TTT) and reactive strength index modified (RSImod) and visual analogue scales for perceived muscle soreness and fatigue were measured pre-, immediately post-, and at 24 h and 48 h after the half-marathon. The CMJ performance variables, muscle soreness and fatigue were analysed using a mixed model ANOVA. **Results:** CMJ variables were reduced immediately after the half marathon ($P < 0.05$) (NZBC; JH 0.19 \pm 0.06 and PLA 0.18 \pm 0.05 m, NZBC; TTT 0.98 \pm 0.16 and PLA 1.03 \pm 0.20

s, NZBC; RSImod 0.20 \pm 0.08 and PLA 0.18 \pm 0.06 ratio) and had returned to baseline by 48 h, with no difference between NZBC and PLA for any variables ($P > 0.05$). Perceived muscle soreness was increased immediately post (NZBC; 6 \pm 2 and PLA; 6 \pm 2) and had returned to baseline by 48 h, with no difference between NZBC and PLA ($P = 0.404$). Perceived muscle fatigue was increased immediately post (NZBC; 7 \pm 2 vs. PLA; 6 \pm 2) and had returned to baseline by 48 h, with no difference between NZBC and PLA ($P = 0.170$). **Conclusion:** NZBC extract did not accelerate recovery of CMJ variables or perceptions of muscle soreness or fatigue following a half-marathon in recreational runners, possibly because the event only induced modest changes in the indices of EIMD in the days after the event. **Acknowledgement:** We thank Health Currency Ltd (UK) and CurraNZ (NZ) for supplements.

New Zealand Blackcurrant Extract Increases Circulating Hsp32 And Hsp90 α But Doesn'T Affect Circulating Hsp72

Ben J. Lee¹, Tessa R. Flood¹, Ania M. Hiles¹, Ella F. Walker¹, Lucy Wheeler¹, Kimberly M. Ashdown¹, Mark ET Willems¹, Matthew R. Kuennen². ¹University of Chichester, Chichester, United Kingdom. ²High Point University, High Point, NC.
Email: b.lee@chi.ac.uk

(No relevant relationships reported)

Extracellular heat shock protein 72 (eHSP72) acts as an inflammatory molecule, inducing cytokine production in immune cells, whereas HSP90 α is implicit in recovery and adaptation to cellular stress. Heme oxygenase-1 (eHSP32) protects the vasculature and suppresses inflammation. Each are elevated following exertional heat stress. Polyphenols are proposed to have anti-inflammatory properties, so may affect eHSP responses to exercise. **Purpose:** To determine the effects of 7-days supplementation with New Zealand blackcurrant (NZBC) extract on eHSP72, eHSP90 α , and eHSP32 before and after exertional heat stress. **Methods:** In a randomized double-blind design, 12 men (Age: 28 \pm 6 years, stature: 1.81 \pm 0.07 m, mass: 80.5 \pm 9.8 kg, VO_{2max} : 55.6 \pm 6.0 mL \cdot kg⁻¹ \cdot min⁻¹) completed 2 trials. Participants ingested 2x300 mg day⁻¹ capsules of CurraNZ™ (each containing 105 mg anthocyanin) or a visually matched placebo for 7 days (washout 14 days). On day 7, participants ran 60 minutes at 65% VO_{2max} in hot ambient conditions (34°C and 40% relative humidity). eHSP72, eHSP90 α , and eHSP32 were measured in EDTA plasma at rest and 20 and 60 minutes after exercise. **Results:** Post exercise eHSP72 concentrations were elevated after the placebo [by 1.98 ng mL⁻¹ (95% CI: 0.65 - 3.33 ng mL⁻¹)] and NZBC trials [by 1.59 ng mL⁻¹ (95% CI: 0.03 - 3.15 ng mL⁻¹)] and remained elevated 60 minutes after exercise [Placebo: by 0.68 ng mL⁻¹ (95% CI: -0.07 - 1.46 ng mL⁻¹); NZBC by 0.51 ng mL⁻¹ (95% CI: -0.37 - 1.40 ng mL⁻¹)]. Basal eHSP90 α concentration was increased following NZBC supplementation [by 5.60 ng mL⁻¹ (1.85 - 9.51 ng mL⁻¹), trial x time interaction, $F = 3.57$, $p = 0.046$, $np2 = 0.25$], and were elevated at 20 and 60 minutes post exercise in both conditions. Similarly, basal eHSP32 was elevated after NZBC supplementation [by 3.9 ng mL⁻¹ (95% CI: 0.37 - 7.42 ng mL⁻¹), trial x time interaction $F = 5.62$, $p = 0.01$, $np2 = 0.34$], but were not altered at 20 or 60 minutes after heat stress in either condition. **Conclusion:** We present moderate evidence to support that 7 days of NZBC extract supplementation increases basal eHSP32 and eHSP90 α , with no effect on eHSP72 before or after exercise. Further research is required to determine the functional relevance of these increases. **Acknowledgement:** We thank Health Currency Ltd (UK) and CurraNZ (NZ) for supplements.

Does Supplementation With Pedicoccus Acidilactici Probiotics Alter Inflammatory Response To Exercise On Consecutive Days?

John H. Curtis, Asheal A. Davis, Elizabeth A. Tanner, Melody A. Gary, Jakob L. Vingren, FACSM, Brian K. McFarlin, FACSM. *University of North Texas, Denton, TX.* (Sponsor: Brian McFarlin, FACSM)

Email: john.curtis@unt.edu

(No relevant relationships reported)

Oral supplementation with probiotics has been reported to treat a variety of common gastrointestinal conditions (i.e. IBS, IBD, etc.); however, probiotics have not been studied for potential sport nutrition applications. Management of post-exercise inflammation, particularly on consecutive days poses a unique challenge to the body and effects future training and performance. **Purpose:** The purpose of this study was to investigate if a novel plant based, non-spore forming high temperature (up to 85°C) and acid resistant probiotic strain (*Pedicoccus acidilactici*; NRRL B-50517, 8 billion cfu per day; N=6) or placebo condition (maltodextrin; N=5) for 14-d prior to two consecutive days of 45-min of intense, interval exercise (intervals of ladder climbing, cycling, and downhill running). Subjective muscle soreness and muscle strength were

evaluated using a visual analog scale and isokinetic dynamometer respectively. Venous blood samples were collected prior to exercise and 48-h after the final exercise day. Samples were analyzed in duplicate using separate bead-based assays to measure cytokines and myokines (Milliplex®; Millipore-Sigma). Sample preps were analyzed using a multiplex analyzer (Luminex LX200). **RESULTS:** There were trends toward reduced MIP-1 α , MIP-1 β , and IL-8 in probiotic compared to placebo during recovery from exercise. There were no obvious trends in any additional outcome measures. **CONCLUSIONS:** These data support the concept that probiotics may be useful for managing the trafficking of monocytes and other phagocytes during exercise-induced inflammatory responses. More research is needed to determine if a more extensive exercise model may be capable of eliciting probiotic associated improvements in post-exercise inflammation.

Combined Dietary Polyphenol Supplementation Reduces Inflammation Associated Gene Expression Following a Half Marathon Race

Elizabeth A. Tanner, Melody A. Gary, Asheal A. Davis, Brian K. McFarlin, FACSM. *University of North Texas, Denton, TX.* (Sponsor: Brian McFarlin, FACSM)
 Email: elizabeth.tanner@unt.edu
 (No relevant relationships reported)

Prolonged endurance exercise provides a unique model for investigating skeletal muscle damage through the combined effects of oxidative stress and eccentric muscle contraction on differential gene expression with nutritional interventions known to blunt inflammation. Dietary polyphenols (i.e. curcumin, pomegranate, etc.) have been shown to reduce exercise-induced inflammation associated mRNA and protein expression with fewer side effects than NSAIDs. **PURPOSE:** To investigate the effect of a combined curcumin (500-1000 mg/d; Longvida) and pomegranate extract (500-1000 mg/d; Pomella) supplement for 30-days on mRNA expression following a half marathon race. **METHODS:** All protocols were approved by the University IRB committee and participants gave written informed consent. Participants supplemented for 30-days prior to running a half marathon race with either the active (N=6) or no supplement (N=6). Venous blood samples were collected in PAXgene RNA tubes 24-h before (PRE) and 4-h after completing a half marathon. After collection, tubes were stored frozen at -80°C until RNA isolation. PAXgene whole blood was thawed and isolated using a PAXgene Blood miRNA sample processing system (PreAnalytiX) along with a QIAcube automation system (Qiagen). Isolated RNA was analyzed using a 594-plex Human Immunology Panel on a NanoString nCounter platform. Data were normalized to housekeeper genes and reported as log₂ fold change. Detailed pathway and interaction analysis was conducted using Nanostring nSolver software to identify RNA that were significantly affected by the supplement. **RESULTS:** Analysis revealed significant down regulation of nine pro-inflammatory associated mRNA at 4-h post-race with supplementation compared to control. **CONCLUSIONS:** Combined curcumin and pomegranate extract supplementation altered expression of inflammation associated mRNA prior to and following a half marathon race. Based on these findings, it appears that curcumin and pomegranate extract supplementation may positively affect short-term inflammatory response and recovery in endurance athletes and recreationally active individuals participating in half marathon races. More research is needed to determine how to best use these dietary polyphenols as part of a long-term training plan.

Mood: There Are Some Connection Between Probiotics Supplementation On Marathon Runners? A Double Blind Study

Geovana SF Leite¹, Valdir de Aquino Lemos², Helena A P Batatinha¹, Edgar Tavares², Ayane S. Resende¹, Ricardo A. Fock¹, José C R Neto¹, Ronaldo V T dos Santos², Antonio H. Lancha Junior¹. ¹University of São Paulo, São Paulo, Brazil. ²Federal University of São Paulo, São Paulo, Brazil.
 Email: geovana.leite@usp.br
 (No relevant relationships reported)

Prolonged exercise may cause Gastrointestinal Symptoms (GIS) as well as rise some negative affects, which may be mitigated by probiotics according to evidences. **PURPOSE:** Investigate the probiotic effect on mood and GIS after a marathon race. **METHODS:** Twenty seven marathoners were double-blind randomly assigned to either a probiotic group (PR) (35.96 ± 5.81 years, 79.30 ± 10.99 Kg) or placebo (PL) (PL=13 40.46 ± 7.79 years, 72.67 ± 10.20 Kg). PR consumed during 30 days a sachet containing *Lactobacillus Acidophilus* and *Bifidobacterium Lactis* (10x10⁹UFC + maltodextrin 5g/day) while PL received a sachet with maltodextrin (5g/day). GIS were evaluated before the supplementation period (B) and one day before the race (1D) by questionnaires. Brunel Mood Scale (BRUMS) was applied at the B, immediately after the race (AR) and one hour after the race (1H). The data were analyzed in SPSS version25® using ANOVA two way with repeated measures, "group" and "time"

as factors, and Tukey's post-hoc test ($p < 0.05$). Results were expressed as means ± standard deviation (SD). **RESULTS:** GIS were not different after the supplementation period or between groups. According to BRUMS, PL group showed significant increase of depression (B: 0.23 ± 0.43; AR: 1.30 ± 2.01; 1H: 1 ± 0), anger (B: 0 ± 0; AR: 6.61 ± 1.51; 1H: 5.53 ± 1.33), fatigue (B: 0.69 ± 1.54; AR: 12.15 ± 0.98; 1H: 7.30 ± 0.75), tension (B: 1.46 ± 2.06; AR: 6.38 ± 0.65; 1H: 3.84 ± 0.37) and mental confusion (B: 0.53 ± 0.77; AR: 4.46 ± 0.51; 1H: 2.92 ± 0.27) and decrease of vigor (B: 10.30 ± 2.25; AR: 2 ± 0.91; 1H: 6.76 ± 1.30) when compared with B, AR and 1H. Probiotic group shown significant increase of anger (B: 0.21 ± 0.42; AR: 1.21 ± 0.89; H: 0.14 ± 0.36), fatigue (B: 1 ± 0.87; AR: 4.28 ± 1.43; 1H: 0.71 ± 0.72), tension (B: 0.92 ± 1.20; AR: 1.42 ± 0.64; 1H: 0.71 ± 1.13) and mental confusion (B: 0.28 ± 0.46; AR: 0.42 ± 0.51; 1H: 0.42 ± 0.64) when compared B, AR and 1H. Between groups, for all mood parameters, PR showed significant increase at AR and 1H compared to PR ($p < 0.05$). **CONCLUSION:** *Lactobacillus Acidophilus* and *Bifidobacterium Lactis* (10x10⁹UFC/day) consumption did not seem to have effect on GIS, but it plays a positive role on mood affects in order to attenuating the increase of negative affects and maintaining the vigor state which may influence sport performance. **Financial Support:** CNPq, CAPES/PROEX.

No Acute Effects of Placebo or Open-Label Placebo Supplementation on Strength and Neuromuscular Fatigue

Dennis P. Kwon, Alina P. Swafford, David H. Fukuda, Jeffrey R. Stout, Matt S. Stock. *University of Central Florida, Orlando, FL.*
 Email: dkwongolf@knights.ucf.edu
 (No relevant relationships reported)

PURPOSE: We utilized a repeated measures design to examine the acute effects of placebo, open-label placebo, and control treatments on muscle strength and voluntary activation (Experiment #1), as well as neuromuscular fatigue (Experiment #2). **METHODS:** Following a familiarization session, 21 untrained males ($n = 11$) and females ($n = 10$) visited the laboratory on three occasions to receive placebo, open-label placebo, and control treatments in a randomized, counter-balanced manner. All visits involved a pretest, 15-minute intervention period, and posttest. All visits were at the same time of day. The time between sessions was ≥ 48 hours but < 1 week. Laboratory conditions were constant throughout the study, and participants were asked to keep their physical activity levels, dietary habits, and caffeine consumption consistent. In Experiment #1, knee extensor maximal voluntary isometric contraction (MVIC) peak torque and percent voluntary activation were evaluated. In Experiment #2, participants performed 20, six-second MVICs while surface electromyographic signals were detected from the vastus lateralis. Subjective assessments of energy and perceived exertion were also examined. **RESULTS:** In Experiment #1, there were no differences among interventions for peak torque or voluntary activation, but a main effect revealed that energy levels increased following all treatments ($p = .016$, $\eta^2 = .257$). Experiment #2 demonstrated that placebo and open-label placebo treatments had no influence on neuromuscular fatigue, but there were main effects for declines in absolute ($p = .001$, $\eta^2 = .675$) and normalized peak torque ($p = .001$, $\eta^2 = .765$), normalized electromyographic mean frequency ($p = .001$, $\eta^2 = .565$), neuromuscular efficiency ($p = .001$, $\eta^2 = .585$), and energy levels ($p = .006$, $\eta^2 = .317$). **CONCLUSIONS:** Compared to a control condition, placebo and open-label placebo treatments had minimal influence on muscle strength, voluntary activation, and fatigue resistance in untrained participants.

361 Board #199 May 29 9:30 AM - 11:00 AM
Evaluation of the Placebo Effect in Elite and Amateur Athletes

Andressa F. de Abreu, Domingos R. Pandelo, Jr. *Centro de Alta Performance, Santos, Brazil.*
 Email: andressaabreu_82@hotmail.com
 (No relevant relationships reported)

Purpose: The aim of the present study was to test the placebo effect effect. This was made possible by the research design. In this way the impact of the placebo effect could be effectively measured. **Methods:** 22 athletes were selected for the experiment. Out of this total 16 recreational and 6 elite. The test was performed on a cycle ergometer. The tests were performed in 2 days, with a 72-hour interval between one and the other. All tests were performed at the same time of the day. The load of the test was adjusted by the weight of the athlete to work with the same load relative to the weight (watt / kg). The load was kept fixed throughout the test and the test ended after exhaustion and voluntary request of the athlete. During the evaluation, the heart rate was continuously measured and the subjective perception of effort (Borg scale) was measured minute by minute. On the first day the athletes received 30 minutes before the test a supplement. This supplement was placebo. There was no ergogenic feature in the capsule, but they received the information that it was a new, very powerful supplement.

In the second encounter, the athlete did the test without any capsule. He was informed that the goal was to compare how much the supplement, offered in the first encounter, would lead to a better performance.

Summary of Results: Overall, in the supplement test (which was placebo) there was an average increase of 9.66% in performance, measured by a longer time to exhaustion. This result was obtained with all 22 athletes. In the case of elite athletes, the result was lower, showing an increase of 4.39%, on average. In the case of amateur athletes, the increase was 22.87%.

The fact that the increased impact of the placebo effect was greater in amateur athletes seems quite reasonable and may be explained by their greater susceptibility to placebo. In the case of elite athletes, the impact of the placebo effect was smaller, but can be considered as important from a practical point of view, since a performance increase of 4.39% a professional athlete, seems to be something fantastic.

Conclusion: The present study showed that the placebo effect is important to be considered even in the case of elite athletes. The way the study was designed allowed a more reliable measurement of the real dimension of the placebo effect.

Effects of Nutritional Supplementation on Body Composition and Bio-markers during Army Initial Entry Training

Jeremy McAdam¹, Kaitlin McGinnis¹, Darren Beck², Andrew Frugé¹, Michael Roberts¹, JoEllen Sefton¹. ¹Auburn University, Auburn, AL. ²Edward Via College of Osteopathic Medicine- Auburn Campus, Auburn, AL.
 Email: jsm0039@auburn.edu
 (No relevant relationships reported)

Purpose: Previous research has reported that military training can result in reductions in fat free mass (FFM) and serum testosterone while increasing cortisol and interleukin-6 (IL-6). This can be due to inadequate nutrition combined with rigorous training. The purpose of this study was to investigate whether once daily whey protein (WP) or carbohydrate (CHO) supplementation positively impacts the physiologic response to Initial Entry Training (IET).

Methods: Eighty-one male soldiers (WP: n = 39, Ht. = 173 ± 8 cm, Wt. = 76.8 ± 12.8 kg, Age = 21 ± 3yrs; CHO: n = 42, Ht. = 175 ± 8 cm, Wt. = 77.8 ± 15.3 kg, Age = 23 ± 4yrs) participating in Army IET were supplemented with one 38.6 g protein (from WP hydrolysate; WP, n = 45) or one energy, fat and taste matched CHO (n = 51) serving per day, for seven weeks. Physical performance, body composition and serum markers were collected during weeks one and eight of training. Testosterone, cortisol and IL-6 were measured using enzyme-linked immunosorbent assays. All measures were collected in the morning after an overnight fast, in a hydrated state, and prior to physical activity. Repeated measures ANOVA with one within subjects' factor (time) and one between subjects factor (group) were used to evaluate biomarker response to training. Regression analysis was used to determine if change in biomarkers were related to changes in FFM.

Results: There was a significant increases in testosterone (F = 14.06, p < 0.01) and the testosterone to cortisol ratio (F = 10.08, p = p < 0.01) and a significant decrease in IL-6 across military training (F = 7.63, p = 0.01). There was no significant change in cortisol (F = 3.64, p = 0.06). There were no group by time interactions for testosterone, cortisol or testosterone to cortisol ratio or IL-6. Change in Testosterone to cortisol ratio was a significant predictor of change in FFM (P = 0.04). FFM increased 1.2 kg (95% CI: 0.4, 2.0 kg) in the WP group; whereas FFM increased only 0.1 kg (95% CI: -0.9, 1) in the CHO group during IET.

Conclusion: We found no differential effects of once daily supplementation with WP or CHO on testosterone, cortisol or IL-6. However, our results in light of previous research in military training, suggests that supplementation in general may benefit the physiologic response to training. Additionally, there may be a clinical benefit of WP on FFM during Army IET.

 (No relevant relationships reported)

Sea, Air, and Land (SEAL) Qualification Training (SQT) students must successfully complete several months of advanced tactical training in order to become a NAVY SEAL Operator. During SQT training students are discouraged from consuming any dietary supplements (DSs). **PURPOSE:** Evaluate the DS habits of SQT Students. **METHODS:** 282 male Students (Age 24 ± 2.7 y) completed a detailed DS questionnaire. **RESULTS:** Ninety percent of SQT students reported consuming at least one DS on a consistent basis during the previous 12 months. Of these, 59% consumed

whey protein supplements (WP), 47% multivitamin and mineral supplements (MVM) and 31% energy drinks (EDs) (Table 1). Table 1: Common dietary supplements, purpose for use, perceived benefits and adverse reactions among SQT students (top 3 responses reported as % Students)

| Supplement Category | Purpose of Use* | Adverse Reactions | Perceived Benefits* | Impact* |
|-----------------------------------|--|--|--|--|
| Whey | Increase muscle mass, strength, recovery 88% Supplement diet Improve health 23% Improve performance 23% | None 98% Bloating, gas, lactose intolerance 2% | No benefit 40% Improved recovery 41% Increase muscle mass/strength 34% | Beneficial 85% Neither harmful or beneficial 15% |
| Multivitamin & Mineral Supplement | Supplement diet/ Improve Health 97% Improve performance 15% Increase muscle mass, strength, recovery 6% | None 99% Upset stomach 1% | No benefit 74% Stayed healthy/ Improved immunity 14% Better energy/ feel better 8% | Beneficial 63% Neither harmful or beneficial 36% N/A 1% |
| Energy Drinks | Improve cognitive function 50% Improve performance 35% Tastes Good 8% | None 85% Jittery/ Shaky 7% Increased heart rate 3% | Awake/Alert 48% More energy 31% No benefit 23% | Beneficial 62% Neither Harmful/ Beneficial 19% Harmful 17% |

*Subjects were allowed to select more than 1 response. **CONCLUSION:** SQT students reported taking WP was beneficial (75%) in increasing muscle mass/strength and improving recovery. MVM supplements had the lowest reported adverse reactions and was beneficial in maintaining/improving health. EDs had the highest response for adverse reactions including jitters, shakiness and increased heart rate, with 17% of Students indicating taking EDs was harmful. Whey protein and MVM are safe and effective DSs that aid in muscle hypertrophy/strength (WP) and supplementing the diet (MVM). **Supported by ONR N00014-11-1-0929.**

Dark Chocolate Supplementation Elevates Resting Energy Expenditure In Exercise Trained Females

Michael J. Webster, FACSM, Katie M. Presler, Derya Keskin. Valdosta State University, Valdosta, GA.
 Email: MJWebster@Valdosta.edu
 (No relevant relationships reported)

PURPOSE: To investigate the influence of dark chocolate supplementation on resting and exercise metabolism.

METHODS: Using a randomized, double-blind design 18 exercise trained female subjects were assigned to a 30 day supplementation with either 20-g per day of 70% dark chocolate (DC) (n=9) or a calorically matched white chocolate (WC) (n=9). Prior to supplementation (PRE), subjects underwent indirect calorimetry assessment for resting energy expenditure (REE) followed by an assessment of exercise energy expenditure consisting of cycling for 20 min, 10 min at 50 watts (EEE-50) and 10 min at 100 watts (EEE-100). Upon completion of the 30 day supplementation, subjects repeated the assessment for REE, EEE-50, and EEE-100. All data are presented as mean (SE).

RESULTS: Pre supplementation REE (DC 1454 (51), WC 1565 (48) kcal per day), EEE-50 (DC 4.86 (0.11), WC 4.61 (0.18) kcal/min), and EEE-100 (DC 7.07 (0.15), WC 6.77 (0.18) kcal/min) were not significantly different between groups (p > 0.05). Post supplementation REE was significantly increased by 9.4% in the DC group (DC 138 (39), WC -29 (18) kcal per day, p=0.001). Neither EEE-50 (DC 4.49 (0.19), WC 4.48 (0.11) kcal/min), nor EEE-100 (DC 6.50 (0.20), WC 6.65 (0.14) kcal/min) were significantly different between groups (p > 0.05).

CONCLUSIONS: These results indicate that in athletic female subjects, DC supplementation significantly increases REE by 9.4%, but doesn't significantly influence exercise energy expenditure.

Amelioration Of Capillary Regression Of Skeletal Muscle Under Disuse Condition By Enterococcus Faecium Strain R30 Supplementation

Hidemi Fujino¹, Hiroyo Kondo², Takuya Ikeji¹, Yusuke Hirayama³, Airo Takegaki³, Akihiko Ishihara³. ¹Kobe University Graduate School of Health Sciences, Kobe, Japan. ²Nagoya Women's University, Nagoya, Japan. ³Kaneka Corporation, Takasago, Japan. ⁴Kyoto University, Kyoto, Japan.
Email: fujino@phoenix.kobe-u.ac.jp

(No relevant relationships reported)

PURPOSE: Disuse condition results in impaired capillary network of skeletal muscle. Capillary regression appears to be an adaptation to a reduction in blood flow to the skeletal muscles caused by a decrease in oxidative demand. Increased blood flow leads angiogenesis via increases in angiogenic factors in skeletal muscles. A probiotic strain of lactobacillus affects autonomic nerve activity has been reported. The purpose of the present study was to investigate the amelioration of enterococcus faecium strain R30 (R30) supplementation on the capillary regression and fatigue of skeletal muscle under disuse condition. **METHODS:** Thirty-six male Sprague-Dawley rats were assigned randomly either to a control, control with R30 supplementation, hindlimb unloaded or hindlimb unloaded with R30 supplementation group for 14 days. The three-dimensional capillary network of soleus muscle was visualized using a confocal laser scanning technique, and the capillary volume and diameter were measured. The angiogenic factors, VEGF and eNOS, were also determined. Furthermore, the tensions during muscle isometric contraction in plantar muscles was generated by successive electrical stimulations were measure in vivo. **RESULTS:** The capillary volume and diameter in disuse muscle were lower than those in control. R30 supplementation attenuated the decrease of capillary volume and diameter in disuse muscle. In addition, the decreased expression levels of VEGF and eNOS in R30 supplemented muscle were attenuated. In addition, the resistance to fatigue (isometric tension expressed relative to the initial value) was significantly higher in the R30 supplementation group than the hindlimb unloaded group **CONCLUSION:** These data suggest that R30 supplementation may be an effective treatment to counter the detrimental effects of a chronic decrease in muscle activities on the microcirculation and endurance in skeletal muscle.

Circulating Levels of Select Micro-RNA Are Not Impacted by Manipulating Nutrient Intake Following High-Intensity Cycling

Jeremy Via¹, Ryan Sapp², Daniel Shill², Michael Saunders, FACSM¹, Christopher Womack, FACSM¹, James Hagberg, FACSM², Nicholas Luden¹. ¹James Madison University, Harrisonburg, VA. ²University of Maryland, College Park, MD.
(Sponsor: Michael Saunders, FACSM)

(No relevant relationships reported)

Circulating microRNAs (ci-miRNA) may facilitate intercellular communication as well as fine-tune phenotype adaptations to exercise through post-transcriptional regulation. Ci-miRNA levels are sensitive to acute aerobic exercise, yet much less is known about the influence of high-intensity interval type exercise. Further, almost nothing is known about the impact of post-exercise nutrition (carbohydrate and/or protein) on ci-miRNA levels. **Purpose:** To examine the effects of high-intensity interval cycling and different post-exercise nutrition treatments on select ci-miRNA levels. **Methods:** Eight recreationally active males (age 22 ± 2 yrs; VO_{2max} 50 ± 4 mL/kg/min) completed 3 trials, each consisting of 4 sets of 3-min intervals (90% W_{max}) flanked by 30-sec Wingate intervals. Placebo (PLA; water), carbohydrate (CHO; 65 g), and carbohydrate (65 g) + protein (20 g) (PRO) beverages (600 mL) were consumed immediately following exercise. Serum levels of 9 miRNA (miR-1, -21, -126, -146a, -150, -210, -221, -222, and -486) were measured pre-exercise (Pre), immediately post (Post-0), Post-1hr, and Post-4hr. miRNA levels were expressed as fold changes relative to baseline and analyzed with repeated measures ANOVAs. **Results:** With the exception of a 1.3-fold increase (p<0.05) in ci-miRNA-486 there was no main effect of time for any of the target ci-miRNA from Pre to Post-0 (i.e. prior to any nutritional intervention). There was a main effect of time for Ci-miRNA-150 from Pre to Post-1hr (0.6 fold-change, p<0.05) and from Pre to Post-4hr (0.7 fold-change, p<0.05), but there were no detectable nutritional effects. Further, ci-miRNA-1 increased from Pre to Post-4hr (3.1-fold-change, p<0.05) but again with no nutrition effect. No other differences, across time or between treatments, were detected. **Conclusion:** In general, high-intensity cycling had a subtle impact on serum levels of miRNA. However, miRNA associated with skeletal muscle (miRNA-1 and -486) and cardiac physiology (miRNA-1 and -150) were affected by exercise. Post-exercise nutrition had no consequences on any of the targets of interest. However, the extent to which ci-miRNA reflects intracellular miRNA activity is poorly understood and future work should investigate how nutrition may influence intracellular mi-RNA levels.

Can a Dynamic Warm-up Reduce the Magnitude of Immune Perturbation Following Vigorous Aerobic Exercise?

Mahmoud T. Elzayat, Emily Claire-pyle LaVoy. University of Houston, Houston, TX.
Email: mtelzayat@uh.edu

(No relevant relationships reported)

Exercise transiently increases several leukocyte populations in peripheral blood in an intensity-dependent manner, with numbers returning to baseline or lower during recovery. This mobilization of immune cells is explained in part by sympathetic activity and the release of stress hormones (catecholamines and cortisol). The literature examining immune responses to exercise has by and large failed to control for the presence of a warm-up prior to the experimental bout. Gradually increasing exercise intensity over a period of minutes may reduce the stress of the exercise bout and thus may influence the immune response to a given exercise protocol.

PURPOSE: To compare the mobilization of leukocyte subpopulations following a bout of high intensity aerobic exercise with and without a dynamic pre-exercise warm-up.

METHODS: 8 physically active adults (4 women, 27±4 years) cycled 30 minutes at 80% heart rate maximum with and without warm-up in a randomized, counter-balanced order. Warm-up was provided immediately prior to the exercise, and involved increasing wattage by 10% each minute for 10 minutes starting at 10% of desired exercise intensity. Blood collected pre-, post- and 1-hour post-exercise was analyzed by flow cytometry to characterize cell populations. Differences in cell concentrations across time points and conditions were assessed by maximum likelihood linear mixed models.

RESULTS: Exercise transiently increased lymphocyte concentration in blood, and the number and proportion of late differentiated CD8 T cells (main effects of time; p<0.001). Inclusion of warm-up diminished these post-exercise increases in lymphocytes (pre- to post- change with warm-up: 45±19 cells/microliter, representing a 17% increase; change with no warm-up: 93± 11 cells/microliter, a 42% increase; p<0.05) and in late differentiated CD8 T cells (pre- to post- change with warm-up: 1±5 cells/microliter representing a 2% increase; change with no warm-up: 10±4 cells/microliter, a 46% increase; p<0.05).

CONCLUSIONS: Inclusion of a dynamic warm-up prior to vigorous aerobic exercise lessens the exercise-induced mobilization of lymphocytes and late differentiated T cells. Athletes should include a dynamic warm-up to reduce immune perturbations during high intensity exercise.

Natural killer (NK) cells are the most responsive lymphocytes during acute exercise, with increased concentrations. After exercise, NK cell levels drop below their resting level if the exercise intensity was high, but values usually recover within 1-3 hours. NK cells may be divided into CD56^{dim} and CD56^{bright} subsets. The CD56^{dim} subset is the major population, representing about 80% of NK cells. Smaller subpopulations were recently studied for cell developments and diseases. We previously reported that exercise decreased the expression of Fcγ-receptor III (CD16); however, it is not yet understood how exercise affects these small subsets.

PURPOSE: To clarify the effect of acute exercise on the mobilization and expression of CD16 on the six different NK cell subsets.

METHODS: Healthy male students (n=6, 22.8±0.8 years old) exercised on a cycle ergometer for 30 min at intensities corresponding to the individual's onset of blood lactate accumulation (70-85% maximum oxygen consumption). Venous blood samples were collected at rest (PRE), just before the end of exercise (END), 30 (POST 30), 60 (POST 60), 120 (POST 120), and 180 (POST 180) min after exercise. Cell counts and proportions of total lymphocytes expressing CD16^{CD56^{bright}} (R1), CD16^{CD56^{bright}} (R2), CD16^{CD56^{dim}} (R3), CD16^{dim}CD56^{dim} (R4), CD16^{bright}CD56^{dim} (R5) and CD16^{bright}CD56^{dim} (R6) subsets were determined. CD16 expressions of these subsets were also examined by flow cytometry. ANOVA was used for statistical analyses.

RESULTS: Exercise induced changes in NK cell concentration in CD56^{dim} (R3, $p=0.04$; R4, $p<0.01$; R5, $p<0.01$) and CD56^{bright} (R6, $p<0.01$) subsets. However significant changes between time points were only found in R5. In this subset, NK cell counts increased from PRE (356 ± 151 cells/ μ L) to END (1182 ± 159 cells/ μ L, $p<0.01$) and decreased under the PRE-level at POST 30 (108 ± 27 cells/ μ L, $p<0.01$) and POST 60 (106 ± 70 cells/ μ L, $p<0.01$). There were no changes in CD56^{bright} (R1, R2) subsets. These cell mobilizations were reflected in proportions to the total lymphocyte count. Expressions of CD16 were down-regulated at END in R5 (-502 ± 135 , $p<0.01$) and R6 (-416 ± 99 , $p<0.01$) then recovered at POST 30.

CONCLUSIONS: These results suggest that the influence of acute exercise on NK cell mobilization and CD16 expression are clear in subset R5, but not in R1 and R2.

Tumor Necrosis Factor-alpha, TNFR, And STNFR Relationships to Body Temperature

Elliott Arroyo¹, Brittany N. Followay², Jeremiah A. Vaughan³, Joseph A. Laudato¹, Brandon M. Gibson¹, Ellen L. Glickman, FACSM¹, Adam R. Jajtner¹, ¹Kent State University, Kent, OH, ²Ripon College, Ripon, WI, ³Bemidji State University, Bemidji, MN. (Sponsor: Ellen L. Glickman, FACSM)
 (No relevant relationships reported)

PURPOSE: To examine the TNF- α , TNFR, and STNFR relationships to body temperature in response to the heat. **METHODS:** 12 recreationally active men (24.4 ± 3.1 yrs; 181.0 ± 6.8 cm; 81.5 ± 8.0 kg; 47.2 ± 4.8 ml \cdot kg⁻¹ \cdot min⁻¹) completed an exercise protocol under four conditions: 23°C/45%RH; 23°C/70%RH; 35°C/20%; and 35°C/45% RH. The protocol consisted of a 60-minute cycling trial at 60% VO₂max, a 15-minute rest, and a time-to-exhaustion trial at 90% VO₂max (TTE). Blood was collected before (T1) and after (T2) the 60-minute trial, and immediately after TTE (T3). Plasma concentrations of TNF- α , STNFR1, and STNFR2 were measured via ELISA. Surface expression of TNFR1 and TNFR2 on human classical (CD14⁺CD16⁻) monocytes was measured via flow cytometry (n=8). Participant's rectal (T_{re}) and skin temperatures at 5 locations: Chest, Triceps, Forearm, Thigh and Calf were monitored continuously. Total skin temperature (T_{sk}) and whole body temperature (T_{wb}) were calculated using weighted averages. The Area Under the Curve with respect to increase (AUCi) was then calculated for T_{re}, T_{sk} and T_{wb}. Data were analyzed as Pearson Product Moment Correlations between AUCi for T_{re}, T_{sk} and T_{wb} with TNF- α , TNFR, and STNFR. The time spent above specific critical temperatures for T_{re} (37.5, 38.0, 38.5 and 39.0°C) and T_{wb} (35.0, 36.0, 37.0 and 38.0°C) were related to TNF- α , TNFR, and STNFR using stepwise linear regression. **RESULTS:** T_{re} was correlated with the change in STNFR1 from T1 to T3 ($r=0.307$; $p=0.048$) and with the change in STNFR2 from T1 to T3 ($r=0.340$; $p=0.028$). T_{sk} was correlated with both the change in STNFR1 from T1 to T2 ($r=0.321$; $p=0.038$) and from T1 to T3 ($r=0.320$; $p=0.039$); with the change in STNFR2 from T1 to T3 ($r=0.430$; $p=0.004$); and with the change in TNF- α from T1 to T2 ($r=0.357$; $p=0.020$). Time spent with a T_{re} above 38.5°C was related to the change in STNFR1 from both T1 to T2 ($r=0.837$; $p<0.001$) and from T1 to T3 ($r=0.773$; $p<0.001$); and to the change in TNF- α from T1 to T2 ($r=0.426$; $p=0.005$) and from T1 to T3 ($r=0.415$; $p=0.006$). **CONCLUSION:** Changes in circulating levels of TNF- α , STNFR1, and STNFR2 are influenced by rectal and whole body temperature. Classical monocyte expression of TNFR1 and TNFR2 do not appear to be influenced by rectal or whole body temperature.

This investigation was partially funded by Kent State University Research Council.

Monocyte Adhesion Molecule Expression Following an Acute Bout of Moderate Intensity Cycling

Natalie J. Bohmke, Lindsay M. LaFratta, Lauren N. Pedersen, Anson M. Blanks, Virginia L. Mihalick, Morgan B. Senter, R. Lee Franco. Virginia Commonwealth University, Richmond, VA.
 (No relevant relationships reported)

Monocyte adhesion to the endothelium is a key step in the development of atherosclerosis. It is well established that higher CV fitness is associated with a reduced risk for CV disease. **PURPOSE:** To investigate the impact of fitness on monocyte surface receptor expression of CD11c and VLA4 following an acute bout of exercise. **METHODS:** 9 fit (VO₂ peak; males: ≥ 45 mL \cdot O₂/kg/min, females: ≥ 35 mL \cdot O₂/kg/min) and 13 unfit (VO₂ peak; males: < 40 mL \cdot O₂/kg/min, females: < 30 mL \cdot O₂/kg/min) subjects performed 30 min of moderate intensity (60% VO₂ peak) cycling. Blood samples were obtained pre-exercise, immediately, and 1 h post-exercise. Monocytes were stained with antibodies against CD14, CD16, VLA4, and CD11c and were analyzed via flow cytometry. A mixed between-within repeated measures ANOVA was used to determine the impact of fitness on VLA4 and CD11c following a submaximal bout of exercise. **RESULTS:** There were no significant between-subjects main effect for groups in either of the monocyte subsets ($p>0.083$). A main effect for time was significant in VLA4 ($p=0.004$) and CD11c ($p=0.014$) expression in non-classical and classical monocytes, respectively. A profile plot suggested that VLA4 was increased 1 h post-exercise and CD11c was reduced immediately post-exercise. **CONCLUSIONS:**

Monocyte receptor expression does not appear to be impacted by physical fitness in young, apparently healthy adults. Nevertheless, an acute bout of cycling altered the expression level of monocyte adhesion molecules to varying degrees depending on the specific monocyte subset.

Aerobic Capacity And LPS-induced iNOS mRNA Expression In Leukocytes Of Healthy College-aged Males

Tiffany M. Zuniga¹, Aaron L. Slusher², Ryan S. Garten³, Edmund O. Acevedo, FACSM³. ¹The University of Arizona, Tucson, AZ. ²University of Michigan, Ann Arbor, MI. ³Virginia Commonwealth University, Richmond, VA. (Sponsor: Dr. Edmund O. Acevedo, FACSM)
 (No relevant relationships reported)

PURPOSE: Inducible nitric oxide synthase (iNOS) is an enzyme expressed in leukocytes that supports innate immune function. While iNOS expression is low-to-undetectable in leukocytes under normal resting conditions, LPS-stimulated overexpression of iNOS increases indices of pro-inflammation, oxidative stress, and apoptosis. Aerobic exercise is a known anti-inflammatory mechanism shown to regulate iNOS expression. Therefore, this study examined the relationship between LPS-induced iNOS mRNA expression and indices of pro-inflammation, oxidative stress, and apoptosis in isolated leukocytes of aerobically fit (AF) and unfit (UF) males. **METHODS:** iNOS mRNA expression and TNF- α , MDA, and p53 concentrations were quantified from 3-hour LPS stimulated and unstimulated whole blood. **RESULTS:** iNOS mRNA expression remained unaltered following LPS stimulation in AF and UF subjects ($p=0.146$). However, LPS stimulation significantly lowered MDA concentrations to a greater extent in UF compared to AF subjects ($p=0.001$), whereas LPS stimulation increased TNF- α and lowered p53 to a similar extent in both groups ($p=0.002$, $p=0.022$, respectively). Interestingly, change in relative iNOS mRNA expression was not associated with the percent change (control vs. LPS stimulation) in the concentrations of MDA, TNF- α , and p53. **CONCLUSIONS:** Findings suggest that although aerobic fitness did not alter iNOS mRNA expression following LPS stimulation and may not directly impact indices of pro-inflammation or the pro-apoptotic marker p53 in healthy, young males, fitness may impact LPS-induced oxidative stress.

372 Board #210 May 29 9:30 AM - 11:00 AM
Monocyte Chemoattractant Protein-1 and C-C Chemokine Receptor Type 2 Expression related to Body Temperature Changes

Joseph A. Laudato. Kent State University, Kent, OH. (Sponsor: Dr. Ellen Glickman, FACSM)
 (No relevant relationships reported)

Purpose: To examine the relationship between Monocyte Chemoattractant Protein-1 (MCP-1) and its receptor C-C Chemokine Receptor Type 2 (CCR2) and the time spent above critical body temperatures while cycling. **Methods:** 12 recreationally active men (24.4 ± 3.1 yrs; 1.81 ± 0.07 m; 81.5 ± 8.0 kg; 47.2 ± 4.8 ml/kg/min) completed five experimental visits: a VO₂ max test and cycling trials in 23°C/45%RH, 23°C/70%RH, 34°C/20%RH and 34°C/45%RH. Within each trial, participants completed a 60-minute bout of cycling at 60% VO₂max, 15min rest, and a time to exhaustion (TTE) at 90% VO₂max. Blood samples were taken prior to cycling (PRE), immediately after (60), and after TTE. Rectal temperature (T_{re}) and skin temperatures (chest, triceps, forearm, thigh and calf) were monitored continuously during trials. Total skin (T_{sk}) and whole body (T_{wb}) temperatures were calculated using weighted averages. The Area Under the Curve with respect to increase from baseline (AUCi) was then calculated for T_{re}, T_{sk} and T_{wb} at 60 and TTE. Data were analyzed as Pearson Product Moment Correlations between AUCi for T_{re}, T_{sk} and T_{wb} with changes in MCP-1 and CCR2 from PRE to 60 (p₆₀) and PRE to TTE (p_{TTE}). Additionally, the time spent above critical temperatures for T_{re} (37.5, 38.0, 38.5, 39.0°C) and T_{wb} (34.5, 35.5, 36.5, 37.5°C) were related to MCP-1 and CCR2. **Results:** No significant correlations were observed between MCP-1_{p60} or MCP-1_{pTTE} and AUCi of T_{re} and T_{wb} ($p \geq 0.260$). There were no significant correlations observed between CCR2_{p60} or CCR2_{pTTE} and AUCi of T_{re} and T_{wb} ($p \geq 0.156$). MCP-1_{p60} was significantly correlated to time spent with a T_{wb} above 35.5°C ($r=0.292$; $p=0.047$), however no correlations were observed between MCP-1_{p60} or MCP-1_{pTTE} and any other critical T_{re} and T_{wb} ($p \geq 0.112$). CCR2_{p60} and CCR2_{pTTE} were not significantly correlated to time spent above critical T_{re} and T_{wb}. Of note was a non-significant negative correlation ($r=-0.312$) observed between CCR2_{pTTE} and T_{re} above 37.5°C ($p=0.053$). **Conclusion:** These data suggest that the duration of time spent at T_{wb} above 35.5°C influences MCP-1_{p60} concentrations, while not being affected by time spent above other critical T_{re} and T_{wb}. CCR2 expression was not influenced by time spent above critical T_{re} and T_{wb}.

Changes In Salivary Antimicrobial Protein Concentrations In Response To Maximal Exercise In Collegiate Swimmers

Bailey Theall¹, Connor Kuremsky¹, Eunhan Cho¹, Haoyan Wang¹, Katelyn Hardin¹, Jack Marucci¹, Shelly Mullenix¹, Brian Harrell², Brian Irving, FACSM¹, Neil Johannsen¹, Guillaume Spielmann¹. ¹Louisiana State University, Baton Rouge, LA. ²Baton Rouge General Sports Medicine, Baton Rouge, LA. (Sponsor: Brian Irving, FACSM)
 Email: btheall1@lsu.edu
 (No relevant relationships reported)

Salivary Antimicrobial Proteins (sAMPs) play a central role in innate immune responses by exerting their antibacterial and antiviral properties. Acute psychological and physiological stressors reduce sAMPs concentrations, and increase the risk of upper respiratory tract infections (URTI). However, the impact of sustained stressors on sAMPs and their relation to URTI symptoms is unknown. **Purpose:** To characterize the impact of acute bouts of exercise on sAMPs and symptoms of URTI in collegiate swimmers over a 6-month period. **Methods:** Salivary samples were collected from sixteen NCAA D1 swimmers (8 M, 8 F: 19.8 ± 0.7 yrs) before and after exhaustive in-pool swims at 2 timepoints (V₁: immediately post-season 1 and V₂: early season 2). An additional V₃ mid-off season 1 timepoint was collected in a subset of 10 swimmers. Azurocidin and secretory leukocyte protease inhibitor (SLPI) sAMPs were measured by ELISA, and self-reported measures of stress were collected to assess sleep quality (PSQI) and symptoms of URTI (WURRS-21). Linear mixed models were used to determine the effects of exercise, season timepoint, and their interaction on sAMP concentrations and secretion rates ($\alpha=0.05$). Pearson's correlation coefficients were used to determine linear correlations between resting sAMP concentrations and secretion rates with stress measures. **Results:** Post-exercise SLPI levels were elevated 8 fold at V₂ and 3 fold at V₃ when compared to resting values ($p<0.05$); however, resting SLPI concentrations and secretion rates remained unchanged during the season ($p>0.05$). Acute exercise was associated with increased Azurocidin concentrations, with the greatest post-exercise increase seen at V₂ ($p=0.03$). Resting salivary Azurocidin concentrations and secretion rates were positively associated with sleep quality ($r=0.42$, $p=0.04$ and $r=0.49$, $p=0.02$ respectively), while salivary SLPI concentrations were not. Furthermore, resting Azurocidin concentrations were associated with self-reported symptoms of URTI ($r=0.52$, $p=0.03$) during all 3 visits. **Conclusion:** Oral innate immunity in collegiate swimmers is differently impacted by acute maximal exercise over a season. Greater sleep quality appears to promote salivary Azurocidin concentration and oral innate immune health, which could in turn protect athletes against URTIs.

Acute And Chronic Anti-inflammatory Responses During A Season Training in Young Swimmers

Dimitra Nafpaktitoud¹, Anastassios Philippou¹, Nikos Vagiakakos¹, George Vagiakakos², Markos Mantaloufas¹, George Chrousos³, Michael Koutsilieris¹, Theodoros Platanou¹. ¹National And Kapodistrian University Of Athens, Athens, Greece. ²National Technical University Of Athens, Athens, Greece. ³National And Kapodistrian University Of Athens, Biomedical Research Foundation Of The Academy Of Athens, Athens, Greece.
 Email: nafpaktitoud@cosmotemail.gr
 (No relevant relationships reported)

It is well established that prolonged intense exercise training suppresses aspects of immune function and a perturbation in balance between pro- and anti-inflammatory cytokines may induce chronic, low-level systemic inflammation. Although swimming exercise training is demanding, however it is not clear whether it can promote changes in inflammatory responses. **Purpose:** This study investigated the acute and chronic effects of a full season swimming training on serum interleukin (IL)-4 and IL-1 receptor antagonist (IL-1ra), both at rest and after a maximal exercise bout. **Methods:** Twelve well-trained male swimmers (14.08±1.0 yrs) were recruited. Measurements were carried out at the beginning of the training season (T1) and pre- and post the taper of each of the two competitive periods (i.e., T2, T3 for the first macrocycle, and T4, T5 for the second macrocycle, respectively). At each of the above time points, blood samples were collected pre- and 1 hour post a maximal, 400m swimming testing. Serum IL-1ra and IL-4 levels were measured by ELISA. Adjustment for exercise-induced plasma volume changes was performed before all data analyses. Two-way ANOVA with repeated measures was used for statistics. **Results:** Significant pre-post testing differences for IL-1ra ($p=0.000$), but not for IL-4 ($p>0.05$), were found throughout the experimental period. Pre-post testing difference was greater at T5 for IL-1ra and at T1 for IL-4 (165.95±36.16 pg/ml and 0.06±0.04 pg/ml, respectively). Both IL-1ra and IL-4 had similar, no significant ($p>0.05$) pre-testing responses, exhibiting an increase from T1 to T2 (IL-1ra:

200.04±14.73 vs 250.76±73.56 pg/ml and IL-4: 0.08±0.02 vs. 0.11±0.03 pg/ml) and from T3 to T5 (IL-1ra: 171.15±11.85 vs 187.66±19.89 pg/ml, IL-4: 0.08±0.03 vs 0.9±0.3 pg/ml) and a decrease from T2 to T3 (IL-1ra: 250.76±73.56 vs 171.15±11.85 pg/ml, IL-4: 0.11±0.03 vs 0.08±0.03 pg/ml). Post-testing, IL-4 response exhibited a 59% decline from T1 to T4 (0.14±0.05 vs 0.08±0.03 pg/ml) and a 157% increase from T4 to T5 (0.08±0.03 vs 0.13±0.03 pg/ml), however those responses failed to reach statistical significance throughout the experimental period ($p>0.05$). **CONCLUSION:** These findings indicate that long-term swimming training can affect the resting and acute (pre-post testing) anti-inflammatory profile in young swimmers.

375 Board #213 May 29 9:30 AM - 11:00 AM
Fitness-related Differences In The Polarization Of Lipid-exposed Macrophages Following Acute Exercise

Lauren Pedersen, Lindsay Lafratta, Natalie Bohmke, Anton Blanks, Virginia Mihalick, Morgan Senter, Robert Lee Franco. Virginia Commonwealth University, Richmond, VA.
 (No relevant relationships reported)

Compared to anti-inflammatory M2 (CD206⁺) macrophages, pro-inflammatory M1 (CD86⁺) macrophages are considered to be highly atherogenic. Increased cardiovascular fitness is linked to attenuated atherosclerotic plaque formation as well as anti-inflammatory alterations in the immune cells that mediate this process. Therefore, macrophage polarization in unfit individuals may differ from that of fit individuals following exposure to physical stress and elevated lipids. **Purpose:** To determine fitness-related differences in the polarization of lipid-exposed macrophages following acute, moderate-intensity exercise. **Methods:** 8 fit (VO₂ peak; M: ≥ 45 mL O₂/kg/min, F: ≥ 35 mL O₂/kg/min) and 12 unfit (VO₂ peak; M: < 40 mL O₂/kg/min, F: < 30 mL O₂/kg/min) male and female subjects performed 30 minutes of moderate-intensity (60% VO₂ peak) cycling. Blood samples were collected pre-exercise (PRE) and immediately- (POST), 1 hour- (1HR), and 2-hours (2HR) post-exercise. Peripheral blood mononuclear cells (PBMCs) were isolated by density gradient centrifugation, and adherent monocytes were cultured with LDL (150 mg/dL) and palmitate (10ug/mL) for 4 hours. Cells were washed and cultured with 20% autologous serum for 7 days. The resulting macrophages were subsequently stained with antibodies against CD86 and CD206 for flow cytometric analysis. A mixed between-within ANOVA was performed to determine differences in receptor expression between groups (fitness) and within subjects (time). **Results:** A mixed between-within ANOVA found no significant between-subjects main effects for CD86 ($p=0.667$) and CD206 ($p=0.675$) macrophage expression. A main effect of time was significant for the expression of CD206 ($p=0.033$). A profile plot suggests that CD206 expression was different between fitness groups PRE, POST, and 1HR. **Conclusion:** Macrophage expression of CD206 was observed to be different between fit and unfit individuals immediately before and following an acute bout of moderate-intensity exercise and lipid exposure. Alterations in "M2" macrophage polarization may contribute to cardiovascular risk in unfit individuals.

 (No relevant relationships reported)

Previous research has shown that the Family Nutrition and Physical Activity (FNPA) Screening Tool is related to obesity risk in children. However, there is limited research on the utility of the FNPA among adolescent populations and its association with health behaviors. **Purpose:** To examine the association of the FNPA Screening Tool with physical activity, dietary quality, screen time behaviors, and obesity risk in ninth grade students. **Methods:** Data were collected from ninth grade students ($n=175$, 51% boys, 72% Caucasian) from a Midwestern high school. Physical activity, dietary quality, and screen time behavior were measured using the Physical Activity Questionnaire (PAQ-A; 8 items, scored 1-5), Healthy Eating Index-2010 (HEI-2010; scored 0-100), and self-reported total screen time (television, video game, and computer usage), respectively. Trained research assistants measured height and weight to calculate body mass index (BMI). Percent body fat (BF) was measured using a foot-to-foot bioelectrical impedance scale. The FNPA Screening Tool was mailed

home to parents of the students to be completed. Upon completion, parents returned the FNPA to researchers, and it was scored (range 20-80). Multiple linear regression, with and without controlling for age, sex, and race (Caucasian or non-Caucasian), was used to examine associations between the FNPA and PAQ-A, HEI-2010, and total screen time. Logistic regression was used to determine differences in FNPA score by weight categories. **RESULTS:** Mean BMI ($22.3 \pm 4.6 \text{ kg/m}^2$) approximated the 65th percentile, with 18.3% of the sample being overweight and 11.4% being obese. No significant relationships were found in the linear regression analyses between the FNPA, PAQ-A, HEI-2010, or total screen time ($F=0.49$, $p=0.83$, Adjusted $R^2 = 0.018$). When controlling for age, sex, and race, these relationships remained non-significant. Logistic regression analyses showed no significant associations between the FNPA and weight status (OR = 1.21, CI = 0.62-2.36) or overfatness (OR = 1.91, CI = 0.92-3.95). **CONCLUSION:** This study highlights that the FNPA Screening Tool may not be associated with health behaviors or obesity risk in an adolescent population. Further research is needed to explore the utility of the FNPA Screening Tool in adolescents.

Factors Associated to Mechanical Efficiency among Adolescent Boys Performing a Graded Maximal Exercise

Georges Jabbour¹, Lina Majed¹
¹Qatar University, Doha, Qatar.

PURPOSE: To determine the mechanical efficiency (ME) and associated factors among adolescent boys at different stages of graded maximal exercise. **METHODS:** 45 sedentary adolescent boys were separated into three groups according to their percentage of fat mass as follows: 15 normal-weight (NW) (body fat: $16.0 \pm 1.9\%$), 15 overweight (OW) (body fat: $24.0 \pm 1.6\%$) and 15 obese (OB) (body fat: $31.0 \pm 3.0\%$). Each of them completed a maximal graded test in which energy consumption in watt (E), ME (expressed as a %), plasma epinephrine, and norepinephrine concentrations were determined consecutively through three stages corresponding to ~50% and 75% of each participant's maximal heart rate (50%HRmax and 75%HRmax) and at peak oxygen consumption ($\text{VO}_{2\text{peak}}$) level. **RESULTS:** During the maximal graded test, plasma epinephrine, and norepinephrine as well as ME determined at 50%HRmax, 75%HRmax and at $\text{VO}_{2\text{peak}}$ stages were significantly lower in OB compared to NW and OW individuals ($ps < 0.01$). ME correlated negatively to body weight ($r = -0.80$; $p < 0.01$) at 50%HRmax level. However, at 75%HRmax and at $\text{VO}_{2\text{peak}}$ stages, ME correlated significantly to power output ($r = 0.88$ and $r = 0.91$, $ps < 0.01$) as well as with epinephrine ($r = 0.82$, $p < 0.01$) and norepinephrine concentrations ($r = 0.88$, $p < 0.01$) for entire group. **CONCLUSION:** These findings suggest that the body's weight excess exerts a negative effect on ME values at a low intensity, while at higher intensities (75%HRmax and $\text{VO}_{2\text{peak}}$) the lower ME could be better explained by the reduced catecholamine responses as observed in obese adolescent boys.

Weight Trajectories Are Associated With Exercise Capacity Among Children With Complex Congenital Heart Defects
 Tyler Kung¹, Kenneth Tang¹, Warsame Yusuf¹, Jane Lougheed², Patricia E. Longmuir¹. ¹Children's Hospital of Eastern Ontario Research Institute, Ottawa, ON, Canada. ²Children's Hospital of Eastern Ontario, Ottawa, ON, Canada.
 Email: tkung@cheo.on.ca
 (No relevant relationships reported)

Children with complex congenital heart defects (CHD) are often short/lightweight relative to peers, and may require supplementary feeding to meet energy demands. It was hypothesized that CHD patients with limited growth would also have decreased energy for exercise. **PURPOSE:** To investigate the impact of chronic energy deficit, as evidenced by negative growth trajectory, on submaximal exercise capacity. **METHODS:** Retrospective chart review of Bruce treadmill exercise test results, weight/height at each visit for 5 years prior to the exercise test, age at exercise test, sex and CHD diagnosis among CHD patients 8 to 14 years of age. Submaximal energy consumption (VO_{2150} = estimated ml O₂/kg/min at heart rate of 150 bpm) and growth trajectory (slope of the body weight z-score over 5 years) were calculated per child. A linear regression model examined energy consumption by growth trajectory, adjusting for age, sex, CHD severity and initial body weight z-score. **RESULTS:** Participants were 90 children with CHD (34 females (38%)), mean age 10.5 (SD=2.3) years. CHD diagnoses were simple (n=19, 21.1%), moderate (n=33, 36.7%) or complex (n=38, 42.4%). Mean VO_{2150} was 28.7 (SD=7.4). Initial height (median 0.36, IQR: -0.65, 1.04) and weight (median 0.21, IQR: -0.69, 1.12) z-scores indicated most participants were taller/heavier than expected for age.

Submaximal energy consumption was significantly higher (model $R^2 = 0.29$) with lower initial weight z-score ($b = -1.4$ [0.2, 2.5] per 1 unit increase, $p = .02$), a decreasing slope of the weight z-score ($b = 7.9$ [1.8, 14.0], $p = .01$), male sex ($b = 3.8$ [1.2, 6.3], $p = .004$) and severe CHD ($b = 4.0$ [0.7, 7.4], $p = .02$), but not by age ($b = 0.4$, $p = 0.15$). **CONCLUSIONS:** Children with CHD who were underweight or had a negative growth trajectory had significantly higher energy consumption during submaximal exercise. The relationship between a negative growth trajectory and daily physical activity should be examined to assess whether the higher energy demands for submaximal exercise are also associated with an inactive lifestyle, and therefore the known increase in risk for sedentary lifestyle morbidities. Prospective studies are required to understand the mechanisms linking growth limitations to reduced exercise capacity.

Boys with Obesity have Attenuated Cardiorespiratory Fitness Independent of Fat Mass
 Julianna J. Kilpatrick¹, Kyleigh Allie¹, Oscar E. Suman, FACSM², Eric Rivas¹. ¹Texas Tech University, Lubbock, TX. ²University of Texas Medical Branch, Galveston, TX. (Sponsor: Oscar E. Suman, FACSM)
 Email: j.kilpatrick@ttu.edu
 (No relevant relationships reported)

Purpose: The assessment of cardiorespiratory fitness using ratio scaling to total body mass (TBM) is confounded by fat mass in obese populations because fat tissue does not contribute to oxygen utilization during exercise. Our objective was to isolate the independent effects of obesity on fitness when normalized to total lean body mass (TLM) and leg lean mass (LLM). We tested the hypothesis that boys with obesity would have attenuated cardiorespiratory fitness compared to age-matched non-obese boys. **Methods:** Values are expressed as means \pm SD with significance set at $P < 0.05$. Seventeen non-obese boys (10.6 ± 0.9 y, 141.8 ± 6.5 cm, 35.5 ± 7.0 kg, $24 \pm 5\%$ body fat) and thirteen age-matched obese boys (10.6 ± 1.4 y, 146.3 ± 10.6 cm, 60.25 ± 13.0 kg, $44 \pm 2\%$ body fat) completed a cardiorespiratory fitness test ($\text{VO}_{2\text{peak}}$) and body composition scan (DXA). **Results:** Utilizing a 2-tailed independent T-test, both groups had comparable $\text{VO}_{2\text{peak}}$ test times (9.1 ± 1.4 min; $P = 0.80$), and peak heart rates (187 ± 12 bpm; $P = 0.50$). Boys with obesity had a reduction in $\text{VO}_{2\text{peak}}$ when normalized to TBM (54% of age-matched boys without obesity); however, this effect was reduced less when compared to LBM (76%) and LLM (68%). Further, simple linear regression found that total body fat accounted for 69% variance for mL/kgTBM/min, 49% variance for mL/kgLBM/min, and 40% variance for mL/kgLLM/min. **Conclusions:** These data indicate that obesity in young boys impairs cardiovascular fitness which supports the concept that obesity in pediatrics reduces aerobic capacity, which may have later life consequences in regards to cardiorespiratory fitness and all-cause mortality. Lastly, we show that the normalization of VO_{2} to LBM and LLM can provide an independent measure of fitness.

Social Media-Based Physical Activity Promotion by Craft Brewing Establishments Located in Knoxville, Tennessee
 Paula-Marie M. Ferrara, Eugene C. Fitzhugh, Cory T. Beaumont, Kelley Strohacker, FACSM. *University of Tennessee, Knoxville, TN.*
 Email: pferrarl@vols.utk.edu
 (No relevant relationships reported)

Researchers have consistently observed a positive relationship between physical activity (PA) and alcohol consumption (AC). Anecdotally, craft breweries (CBs) appear to capitalize on this relationship by marketing to active populations (e.g. sponsorship of athletic associations, post-competition product donation, hosting of PA-related events). To date, empirical analysis of PA promotion by CBs has not been conducted. **PURPOSE:** Preliminarily assess PA promotion by CBs located in a single community. **METHODS:** Facebook posts by 15 CBs located in Knoxville, TN were screened between November 2016-October 2017, with PA-related posts coded by activity type. Non-parametric correlations assessed associations between CBs' total PA posts and built environment factors via Geographic Information System (e.g. walk score, transit score, culture score). Chi-square tests were also used to assess the distribution of PA-posts across each season (Winter, Spring, Summer, Fall).

RESULTS: Of 3845 Facebook posts, 147 (3.82%) referred to PA. PA posts made by individual CBs ranged from 0-47 (median=4.50; IQR=9; mean=10±13) over one year, and pertained to fitness classes (29.25%), biking (24.49%), running, (21.77%), outdoor activities (12.24%), sports (4.08%), and miscellaneous PA (8.16%). PA posts were not equally distributed across seasons ($\chi^2(2, N=3)=14.68, p=0.002$); Summer contained the highest percentage of posts (34.51%), followed by Spring (28.87%), Fall (23.94%), and Winter (12.68%). PA posts were significantly and inversely correlated with scores regarding culture ($r=-0.67, p=0.01$) and shopping ($r=-0.62, p=0.01$). Moderate, but statistically insignificant correlations were observed between PA posts and scores for walkability ($r=-0.36, p=0.18$), dining and drinking ($r=-0.46, p=0.08$), and errands ($r=-0.38, p=0.16$). **CONCLUSIONS:** Although PA posts represent a minimal portion of social media advertising in this local sample of CBs, a wide variety of activities is promoted. Additionally, promotion volume fluctuates seasonally, and CBs that promote PA more frequently tend to be located in areas that are less walkable, with fewer desired amenities.

Pre- and Post-Season Electroencephalography Measures of Brain Vital Signs in Youth Football Players

Thayne A. Munce, FACSM¹, Shaun D. Fickling², Daniel N. Poel¹, Jason D. Dorman¹, Ryan C.N. D'Arcy². ¹Sanford Sports Science Institute, Sioux Falls, SD. ²Simon Fraser University, Metro Vancouver, BC, Canada.
 Email: thayne.munce@sanfordhealth.org
 (No relevant relationships reported)

Amid growing concern of potential brain trauma caused by repetitive head impacts (RHI) in youth football, there is an emerging need to develop objective, physiologic assessments of brain function that can identify sub-concussive impairment. Electroencephalography (EEG) may be a viable tool to evaluate neurologic dysfunction associated with RHI. **PURPOSE:** To evaluate the neurophysiologic activity of youth football players in association with RHI. **METHODS:** EEG data were captured from nine middle school football players (13.1 ± 0.5 yr) before (PRE) and after (POST) one season using a portable 8-channel EEG cap with three electrodes (Fz, Cz and Pz) while subjects listened to an auditory stimulus sequence (~5 min). Amplitudes (A) and latencies (L) of event-related potentials (ERP) corresponding to auditory sensation (N100A, N100L), basic attention (P300A, P300L), and cognitive processing (N400A, N400L) were converted to normalized brain vital signs scores (0-100 scale). Larger ERP amplitudes equate to higher scores and delayed latencies equate to lower scores. RHI were measured during the season via accelerometry (Head Impact Telemetry System). EEG data from three subjects were of insufficient quality for analysis; thus, results were limited to the six remaining subjects. **RESULTS:** Scores for N400L decreased significantly ($P = 0.031$) from PRE (63.9 ± 7.6) to POST (38.2 ± 16.8). There were no significant changes in N100A ($P = 0.971$), N100L ($P = 0.308$), P300A ($P = 0.562$), P300L ($P = 0.183$), or N400A ($P = 0.685$) scores. On average, players sustained 134 ± 66 head impacts during the season. Head impact frequency was not significantly associated with any brain vital signs score ($P = 0.169-0.783$). **CONCLUSION:** In this small sample of youth football players, cognitive processing was delayed following a single season as measured by the significant reduction in N400 latency scores. However, this change was not associated with RHI incurred by the players. While these data should be interpreted with caution, they provide preliminary evidence for the potential value of using the brain vital signs framework to evaluate brain function and sub-concussive impairment in collision-sport athletes.

Aerobic Exercise Regulates Gamma Oscillation in Hippocampal CA1 of APP/PS1/Tau Mice

Yan Li¹, Cui Li¹, Lianwei Mu¹, Ziqi Zhao², Li Zhao¹. ¹Beijing Sport University, Beijing, China. ²Institute of Genetics and Developmental Biology, Chinese Academy of Sciences, Beijing, China.
 (No relevant relationships reported)

PURPOSE: Changes in gamma oscillations have been observed in multiple brain regions in mouse models of Alzheimer's disease. This study aimed to investigate the effect of aerobic exercise on gamma activity in hippocampal CA1 of APP/PS1/Tau transgenic (3×Tg) mice during awake state when theta oscillation occurs, and the effect on slow gamma activity in CA1 during sleep state when SWRs occur.

METHODS: 3×Tg mice (6 months old) and C57BL/6J mice were randomly divided into exercise groups and sedentary groups respectively. The exercise groups were made to run on the treadmill for 1 hour per one day, five times a week, for 12 weeks. The exercise workload consisted of running at a speed of 12 m/min for the first 10 min, 15 m/min for the last 50 min, with 0% grade of inclination. Radial arm maze was used to evaluate the memory function of the mice. Multichannel recording technology was

used to record electrical activity of hippocampal CA1 in vivo. Theta oscillation and sharp waves and ripples (SWRs) were detected by MATLAB programs, and spectral analysis was computed using multi-taper methods. Immunofluorescence was used to detect the Aβ deposits in CA1.

RESULTS: 12 weeks of treadmill exercise ameliorated working memory (2.00±0.35 vs. 1.20±0.38, $p<0.05$) and reference memory (5.47±0.36 vs. 3.70±0.45, $p<0.05$) deterioration of 3×Tg mice. The 9-month-old 3×Tg mice exhibited a reduction of both gamma power (0.33±0.05 vs. 0.51±0.02, $p<0.01$) during the theta rhythms awaking and slow gamma power (0.50±0.03 vs. 0.55±0.04, $p<0.01$) during SWRs sleeping in the hippocampal CA1 compared to control mice, respectively. 12 weeks of treadmill exercise could increase gamma power either being awake (0.50±0.06, $p<0.01$) or being asleep (0.54±0.03, $p<0.05$) in 3×Tg mice. Furthermore, these disturbances were observed to be consistent with Aβ pathological deposits (AS, 1.42±0.21, $p<0.01$ vs. CS; AE, 0.53±0.09, $p<0.01$ vs. AS).

CONCLUSIONS: Consistencies between these alteration in gamma power and Aβ deposits suggest that disturbances in rhythmic organization of theta and gamma may contribute to spatial memory deficits in 9-month-old 3×Tg mice. Given these data, aerobic exercise could improve spatial performance by regulating gamma power when theta oscillations or SWR occur.

Aerobic Exercise Differential Alters Intrinsic Neuronal Properties In The 3xtg Mouse Model Of Alzheimer's Disease

Li Zhao¹, Fei Chen¹, Cui Li¹, Ziqi Zhao², Forrest Fabian Jesse³. ¹Beijing Sport University, Beijing, China. ²Chinese Academy of Sciences, Beijing, China. ³Beijing Jiao Tong University, Beijing, China.
 Email: zhaolispring@126.com
 (No relevant relationships reported)

PURPOSE: Alterations in network activities in Alzheimer's disease (AD) are accompanied by an early imbalance of excitation and inhibition that related to cognitive function. Although that aerobic exercise could enhance synaptic plasticity from various AD mouse models have been found, the properties of neurons firing in specific conditions remain poorly understood. This study was to investigate the neurophysiological signals underlying the effects of aerobic exercise on the brains of APP/PS1/Tau transgenic (3×Tg) mice and 129 mice as wild type (Wt) control at 9 months of age.

METHODS: 3×Tg mice (6 months old) were randomly divided into exercise groups and sedentary groups (AS, AE), and Wt mice as cohort control. The exercise groups would run on the treadmill for 12 weeks. Multichannel recording technology was used to record population spikes in cortical and hippocampal region at 9 months of age in vivo during awake or sleep state. Spike sorting was performed using offline sorter software. Pyramidal cells (PNs) were distinguished from putative interneurons (INs) on the basis of average firing rate, bursting properties, and spike width.

RESULTS: Recordings took place across 5-7 consecutive days while mice were awake exploring or asleep, and the number of spikes was calculated every 10 sec as a session. During awake, in three AS, AE and Wt mice, we recorded 15 PNs, 48 PNs and 10 PNs, while 9, 23 and 11 INs in cortex (with a total of 192 place fields); 36 PNs, 77 PNs and 35 PNs, while 10, 37 and 15 INs in hippocampus (with a total of 330 place fields). During sleep state, with a total of 138 place fields, we recorded 22 PNs, 19 PNs and 13 PNs, while 7, 15 and 14 INs in cortex; 29 PNs, 58 PNs and 21 PNs, while 9, 24 and 11 INs in hippocampus (with a total of 270 place fields). In both awake and sleep state, IN firing rates were differential changed in AS compared to the control, and the ratio of IN/PN was lower in both cortex (0.6±0.02, 0.31±0.00) and hippocampus (0.28±0.00, 0.31±0.01) of AS compared to Wt mice (1.1±0.02, 0.43±0.01/ 1.08±0.02, 0.52±0.01, $P<0.01$). Exercise attenuated the phenomena (0.48±0.01, 0.48±0.01/0.79±0.02, 0.41±0.02, $p<0.01$).

CONCLUSIONS: Aerobic exercise could regulate aberrant cellular neurophysiology related to cognitive impairments dependent network function.

Aerobic Exercise Regulates GSK3β Activity to Attenuate the Neuropathology In APP/PS1 Transgenic Mice

Peng HAN, Boya GU, Li ZHAO. Beijing Sport University, Beijing, China.
 (No relevant relationships reported)

PURPOSE: Glycogen synthase kinase 3 beta (GSK3β) is involved in hyperphosphorylated Tau, one of the hallmarks of Alzheimer's disease (AD). This study was to evaluate the possible effect of aerobic exercise on GSK3β and the phosphorylating Tau protein in APP/PS1 transgenic mice. **METHODS:** C57BL/6J (6-month-old) and APP/PS1 transgenic mice (6-month-old) were randomly divided into exercise group (CE/AE) and sedentary group (CS/AS) respectively. Animals

were subjected to treadmill exercise for 12 weeks. The changes of behavior were detected by eight arm maze. The phosphorylation levels of AKT, GSK3 β and Tau were measured by using Western Blotting. **RESULTS:** The eight arm maze showed that working and reference memory errors and time to complete testing in AE decreased significantly compared with the mice of AS (3.67 \pm 0.41 vs 4.83 \pm 0.24, $p < 0.05$; 6 \pm 0.73 vs 8.40 \pm 0.59, $p < 0.01$; 109 \pm 35 vs 256 \pm 45.26, $p < 0.05$), indicating that aerobic exercise improved behavioral and cognitive response ability. The levels of pTau ser262 and pTau ser396 were severely increase at hippocampus in AS compared with those of control cohorts (CS) (0.98 \pm 0.09 vs 0.82 \pm 0.09, $p < 0.05$; 0.89 \pm 0.06 vs 0.73 \pm 0.11, $p < 0.05$). Aerobic exercise could decrease pTau ser262 and pTau ser396 (0.69 \pm 0.08 vs 0.98 \pm 0.09, $p < 0.01$; 0.67 \pm 0.02 vs 0.89 \pm 0.06, $p < 0.05$). As in case of GSK3 β , the levels of pGSK3 β ser9 were significantly decreased, while pGSK3 β tyr216 were significantly increased in hippocampus of AS compared with those of CS (0.51 \pm 0.08 vs 0.69 \pm 0.08, $p < 0.05$; 0.90 \pm 0.07 vs 0.67 \pm 0.02, $p < 0.01$). The levels of pGSK3 β ser9 were increased (0.79 \pm 0.09 vs 0.51 \pm 0.08, $p < 0.01$), and the levels of GSK3 β tyr216 were decreased after aerobic exercise training in the hippocampus (0.69 \pm 0.06 vs 0.90 \pm 0.07, $p < 0.05$). The levels of pAKT (GSK3 upstream regulator) ser473 were significantly decreased in hippocampus of AS compared with those of CS (0.49 \pm 0.07 vs 0.73 \pm 0.13, $p < 0.05$). Aerobic exercise induced to increase the activity of pAKT ser473 (0.74 \pm 0.13 vs 0.49 \pm 0.07, $p < 0.05$). **CONCLUSION:** Aerobic exercise regulates GSK3 β activity to attenuate the neuropathology of hyperphosphorylated Tau in APP/PS1 transgenic mice. Supported by the National Natural Science Foundation of China (NSFC) (No. 31571229)

Aerobic Exercise Attenuates The A β Oligomer-induced Mitochondrial Permeability Transition Pore Opening In App/ps1 Transgenic Mice
 Lianwei MU, Cui Li, Boya Gu, Yuanyuan LV, Li Zhao. *Beijing Sport University, Beijing, China.*
 (No relevant relationships reported)

PURPOSE: The mitochondrial permeability transition pore (mPTP) plays a role in the onset and the progression of Alzheimer's disease (AD). This study was to analyze the effects of 12 weeks aerobic exercises on mPTP activation in AD models mice.

METHODS: 6-month-old of APP/PS1 transgenic mice and C57BL/6J mice were randomly divided into exercise group (CE, AE) and sedentary group (AS, CS) respectively. The exercised mice were subjected to a treadmill exercise for 12 weeks, then the experimental age was at 9-month-old. The behavioral changes were detected by eight arm maze. Immunofluorescence, histochemistry and Dot blot were to analyze mPTP opening, the level of amyloid- β (A β) and soluble oligomers (oA β). ELISA and Western Blotting were used to detect the activity of COXIV, ABAD, and the levels of COXIV, ABAD, Cyp-D, ANTI1, ANTI2, VDAC-1. **RESULTS:** Both working memory errors and reference memory errors were significantly increased in AS compared with those in the CS (40 \pm 4 vs. 30 \pm 4%; 71 \pm 2 vs. 54 \pm 1%, $p < 0.01$). The AE performed better than AS (22 \pm 1 vs. 39 \pm 3%; 55 \pm 3 vs. 71 \pm 2%, $p < 0.05$). A β was aggregated at hippocampus in AS, accompanied with an increase of oA β (1 vs. 1.1 \pm 0.1, $p < 0.05$). A decline was detected in A β plaque and oA β content in AE than AS (0.6 \pm 0.1 vs. 1.5 \pm 0.1; 0.9 \pm 0.1 vs. 1.1 \pm 0.1, $p < 0.05$). There was an increase in AS compared with CS in the mPTP opening (0.07 \pm 0.002 vs. 0.08 \pm 0.002, $p < 0.01$), and which was decreased after aerobic exercise (0.07 \pm 0.002 vs. 0.08 \pm 0.003, $p < 0.01$). AS displayed an increase in Cyp-D, ANTI1, VDAC-1, ABAD of the hippocampus compared with the CS (1.1 \pm 0.1 vs. 1, $p < 0.05$), but a decrease in ANTI2, COXIV protein (0.9 \pm 0.1 vs. 1, $p < 0.01$). Aerobic exercise decreased the expression of Cyp-D, ANTI1, VDAC-1, ABAD in AS (1.1 \pm 0.1 vs. 1 \pm 0.1, $p < 0.05$) and increased ANTI2, COXIV (0.9 \pm 0.1 vs. 1 \pm 0.1, $p < 0.05$). The activity of COXIV and ABAD in the hippocampus of AS were decreased compared with those of the CS (3.3 \pm 0.1 vs. 3.7 \pm 0.2; 0.5 \pm 0.1 vs. 1 \pm 0.2, $p < 0.01$), and aerobic exercise caused an increase of their activities (3.3 \pm 0.1 vs. 5.6 \pm 0.2; 0.5 \pm 0.1 vs. 0.8 \pm 0.1, $p < 0.01$). **CONCLUSIONS:** Aerobic exercise attenuates the oA β deposition and the opening of mPTP, then regulates the mitochondrial oxidative phosphorylation for energy production in AD models. Supported by the National Natural Science Foundation of China (NSFC) (No. 31571229)

Effects Of Aerobic Exercise On Learning And Memory Ability And Hippocampal Tgf-1 In Depressed Rats
 Xue Li, Lu Wang, Yu Jin, Xiang Hu, Qi Ye. *Chengdu Sport Institute, Chengdu, China.*
 Email: 361128550@qq.com
 (No relevant relationships reported)

OBJECTIVE: To investigate the effects of different periods of aerobic exercise intervention on hippocampal TGF- β 1 expression and spatial learning and memory ability in depressive model rats.

METHODS: 36 male SPF grade Sprague Dawley (SD) rats were randomly allocated into 4 groups (n=9): Control group (C group), Pre-model exercise group (EC group), Model group (M group), Motion group (ce group). Except for group C, all other groups

used CUMS stress stimulation to establish an animal model. Morris water maze test was used to detect spatial learning and memory ability of rats. Nissl staining was used to observe the morphology of rat hippocampal neurons. Real-time PCR, Western Blotting were used to detect the expression of TGF- β 1.

RESULTS: There was no significant difference in time-consumption of escaping the incubation period between the 1st and the 2nd day in each group ($P > 0.05$). On the fourth day, the escape latency of M group was significantly longer than that of rats in the C and ce groups ($P < 0.05$). On the 5th day, the escape latency in M group was significantly longer than that in C and ce groups ($P < 0.05$), and EC group was significantly longer than that in C group ($P < 0.05$). Results of the number of crossing platforms: The number of crossing in the M and EC groups were significantly lower than those in the C and ce groups ($P < 0.01$). Compared with EC and M group, the morphological structure of neurons in ce group was better. The expression of TGF- β 1 mRNA in hippocampus of EC and ce group was significantly lower than that of C and M groups ($P < 0.01$). The expression levels of TGF- β 1 protein in C and M groups were significantly higher than those in ce group ($P < 0.01$). The expression of TGF- β 1 protein in M rats was significantly higher than that in EC and ce groups ($P < 0.01$). **CONCLUSION:** Aerobic exercise intervention can improve the morphological structure of hippocampal CA3 neurons, and decrease the expression of TGF- β 1. It indicated that aerobic exercise can improve the depression.

Aerobic Exercise Inhibits Tau Hyperphosphorylation Through Activation Of The P13k/akt Pathway In The Hippocampus Of App/ps1 Mice
 Guoliang Fang. *China Institute of Sport Science, Beijing, China.*
 Email: fangguoliang@ciss.cn
 (No relevant relationships reported)

PURPOSE:

Many studies suggest that regular physical exercise can reduce the risk of Alzheimer's disease and slow its onset and progression. However, the exact mechanism is still unclear. Clinically, Alzheimer's disease is characterized by the presence of extracellular amyloid plaques and intraneuronal neurofibrillary tangles, which are associated with amyloid- β and tau hyperphosphorylation respectively. The PI3K/Akt signaling pathway regulates tau phosphorylation and plays a pivotal role in the development of pathology in Alzheimer's disease. Therefore, we try to investigate the effects of aerobic exercise on tau phosphorylation and examined whether these effects were mediated by the PI3K/Akt pathway in the hippocampus of APP/PS1 and C57BL/6J mice.

METHODS: 40 male APP/PS1 mice and 40 male C57BL/6J mice were randomly divided into four groups respectively: sedentary group, exercise group, sedentary with GNE-317 treatment group and exercise with GNE-317 treatment group. The mice in the exercise group and exercise with GNE-317 treatment group were given exercise training on a treadmill for 8 weeks. After 8 weeks of treadmill exercise, the morris water maze, immunohistochemistry and western blot analysis were performed.

RESULTS: We found out that 8 weeks of aerobic exercise enhanced PI3K expression and increased phosphorylation of Akt at Thr308 and Ser473 and of GSK3 β at Ser9. Furthermore, 8 weeks of aerobic exercise reduced tau phosphorylation at multiple sites including Ser202, Thr231 and Ser396. In the morris water maze test, the exercise group showed a reduced escape time and distance compared with those of the sedentary group, suggesting that aerobic exercise improved the cognitive ability in mouse. While the above-mentioned results were attenuated in the PI3K/Akt inhibitor GNE-317 treatment groups.

CONCLUSIONS:

Our study demonstrated that 8 weeks of aerobic exercise could inhibit tau hyperphosphorylation and improve cognitive function through activation of the PI3K/Akt pathway in the hippocampus of APP/PS1 and C57BL/6J mice.

Cutaneous Sensitivity Increases During an Ultra-Marathon
 Domenica A. Rivera, Sharon C. Thompson, Amina Rahmoune, Steven B. Hammer, James W. Agnew. *Indian River State College, Fort Pierce, FL.*
 Email: riverada2@mail.irsc.edu
 (No relevant relationships reported)

Very little data is available on variation in cutaneous sensation that occurs during an ultra-marathon competition. Decreased sensory activity may be a factor in gait deterioration that may lead to injury during ultra-endurance activities. **PURPOSE:** We hypothesized that cutaneous sensation, assessed with two-point discrimination tests (2PD), may be altered by running in an ultra-marathon. **METHODS:** Twenty-one male and female ultra-marathoners who completed the Keys-100 ultra-marathon on a flat course in hot, humid conditions, gave informed consent and volunteered for this study that was previously approved by Indian River State College Institute Review Board. To measure 2PD calipers were set at 5mm, 10mm, 15mm, 20mm,

and 25mm apart. Calipers were placed on the calcaneal plantar surface of the foot before the ultra-marathon and again immediately after the runners completed their ultra-marathon distance. The different width calipers were placed randomly either in a horizontal or vertical position. Subjects were in a prone position and were unable to observe caliper placement. Subjects were asked to indicate caliper placement position. Technicians used hand signals to indicate to the recorder: 1. caliper position and 2. the subject's response either correct or incorrect. This was repeated 5 times randomly for each caliper setting and their respective answers were recorded as: correct=1 and incorrect=0. Two-Way ANOVA was used to analyze the overall Pre vs. Post accuracy difference ($p < .05$). Pre vs. post accuracy differences between each specific caliper distance were analyzed with a paired t-test ($p < .05$). **RESULTS:** A significant increase in 2PD was observed after completing the ultra-marathon across all caliper distances ($p < .05$). While the 2PD across all caliper distances increased in accuracy only the two widest caliper settings 20mm and 25mm were significantly more accurate ($p < .05$). **CONCLUSION:** The increased 2PD suggests an increase in cutaneous sensitivity after an ultra-marathon. We have previously found increased sensitivity in pain threshold after an ultra-marathon. There, and in this present study, it is likely that the inflammatory response from ultra-endurance activity has a sensitizing effect on nociceptors and cutaneous receptors, respectively, thus increasing pain and cutaneous sensitivity.

Postexercise Intracranial Hypotension

Lonnie G. Petersen, Evan Grace, Alan Hargens, FACSM, Johan Petersen. *University of California, San Diego, San Diego, CA.* (Sponsor: Alan Hargens, FACSM)
Email: lgpetersen@ucsd.edu

(No relevant relationships reported)

Arterial hypotension, minutes to hours after exercise, is a well described phenomenon. The drop in mean arterial blood pressure (MAP) likely results from a combination of sustained vasodilation of the previously active muscles, centrally mediated reduction in sympathetic nervous activity and resetting of thermo-, chemo-, and baroreceptors. Despite decreased MAP, cerebral blood flow is generally well maintained. **PURPOSE:** To characterize effects of moderate aerobic exercise on intracranial pressure (ICP) as a mechanism for maintaining cerebral perfusion pressure during and following exercise. **METHODS:** Sixteen healthy volunteers completed 30-min exercise at 70% estimated VO_2 -max on an upright ergonomic bicycle followed by a one-hour recovery phase in supine position. MAP, heart rate, stroke volume, and total peripheral resistance (TPR) were recorded continuously (Nexfin). In 15 subjects (8 female, 20 ± 2 years, height 169 ± 10 cm, weight 64 ± 12 kg) ICP was estimated non-invasively by evoked tympanic membrane displacement (Cerebral Cochlea Fluid Pressure device). Invasive parenchymal ICP recordings were performed in one, cerebrally intact, former patient (male, 74 years, 176 cm, 80 kg) via a permanently implanted tip-transducer telemetric ICP-sensor (Neurovent-P-tele). **RESULTS:** 30 min moderate exercise did not increase ICP (-6.1 mmHg during seated rest vs -6.8 mmHg during exercise). Invasive ($N=1$) and non-invasive ($N=15$) ICP recordings followed the same trend, demonstrating a $52.8 \pm 22.9\%$ ($P < 0.005$) decrease immediately postexercise and gradually returned to baseline (fig). ICP was correlated to MAP ($r^2=0.8$, $P < 0.05$) and TPR ($r^2=0.9$, $P < 0.005$) **DISCUSSION:** Postexercise decrease in ICP is a potential factor for maintaining cerebral perfusion pressure during arterial hypotension. Future analysis and ongoing trials are stratifying these responses according to responsiveness, gender and age. Supported by Novo Nordic Foundation (NNF150C0019196)

Concussion History Does Not Predict Pupillary Light Reflex or Visual Sensory Performance in Young Adults

Cassie B. Ford, Christina B. Vander Vegt, Nikki Barczak, Patricia R. Combs, Jamie DeCicco, Lillian Vandermark, Kou Yang, Erik A. Wikstrom, FACSM, Jason P. Mihalik. *University of North Carolina at Chapel Hill, Chapel Hill, NC.* (Sponsor: Erik A. Wikstrom, FACSM)
Email: cbford@unc.edu

(No relevant relationships reported)

Visual sensory performance (VSP) tasks may dynamically assess deficits following concussion, as these tasks reflect visual and cognitive function and motor response. The pupillary light reflex (PLR) represents autonomic nervous system activity, and is inexpensive and noninvasive to assess. This activity may be compromised following concussion; however, deficits in young adults are currently unknown. The relationships among PLR and VSP outcomes are interesting given these metrics may reflect different but overlapping visual domains.

PURPOSE: To investigate the effects of concussion history on the relationships between PLR and VSP outcomes in young adults. **METHODS:** Participants [$n = 89$, age = 21.0 ± 1.5 years, concussion history = 19 (21.3%)] completed a test battery including PLR and VSP. Seven PLR parameters included initial and final pupil diameters, constriction and dilation velocities, constriction latency, time to 75% initial diameter recovery (T75), and average maximum constriction velocity. VSP tasks included visual clarity, contrast sensitivity, depth perception, near-far quickness, perception span, multiple object tracking, reaction time, target capture, eye-hand coordination, and go/no-go. Regression models tested concussion history effects on PLR controlling for age; and whether history moderated relationships between

PLR and VSP outcomes. **RESULTS:** The PLR and VSP outcomes did not differ by concussion history ($P > 0.05$). We found a negative relationship between reaction time and T75 ($r_{88} = -0.30$, $p = 0.005$) which was not moderated by concussion history ($t = -0.97$, $p = 0.33$), indicating that people with faster PLR recovery times also had faster reaction times. No other significant relationships were observed ($P > 0.01$). **CONCLUSION:** Our PLR and VSP measures did not differ by concussion history. These measures may be insensitive to long-term physiological and behavioral deficits due to prior concussion injury, or no such long-term deficits exist in young adults. It is worth further studying the inverse relationship between reaction time and time to diameter recovery, providing a possible link between an involuntary process supporting vision with visual-sensory task performance.

Working Memory Differences Between Fallers and Non Fallers

Michelle (Yee) S. Wong, Lindsay S. Nagamatsu. *Western University, London, ON, Canada.*
Email: ywong252@uwo.ca
(No relevant relationships reported)

Falls are a major concern for older adults and their quality of life. Cognitive impairment is associated with falls in older adults; however, the electrophysiology while performing a working memory task has not been investigated. Working memory is a necessity for everyday function (walking, postural control, conversing), and the processing of a stimulus to elicit the appropriate response might lead to important insights into potential causes for falls and help us identify older adults at risk or develop future intervention strategies. **PURPOSE:** To examine differences between Non-Fallers and Fallers in performance on a working memory task and corresponding electrophysiology. **METHODS:** Older adults ($n=38$, female= 23) aged 60 - 80 years ($m=68.8$, $SD=4.7$) completed two separate sessions on two separate days. The first session incorporated general demographic questionnaires and mobility and neuropsychological assessments. Participants were classified as Non-Fallers or Fallers based on their self-reported falls history over the past 12 months. In the second session we assessed working memory using the n-back (0-, 1-, 2-), while behavioural and electroencephalograms (EEG) results were recorded. **RESULTS:** In the 2-Back test, the EEG results showed that Fallers were more impaired in processing the stimuli, with earlier latencies for the N2 ($p<0.001$) and P3 ($p<0.001$) components in comparison to Non-Fallers. As well, delayed peak latencies in the N2 ($r=0.507$, $p=0.01$) and P3 ($r=0.451$, $p=0.024$) components were associated with increased accuracy in the working memory task. **CONCLUSIONS:** Fallers show processing impairments in working memory compared to Non-Fallers. Future studies should consider incorporating working memory as a component of falls risk screening for older adults.

Effects Of Different Load Forced Swimming On The Expression Of Psd-95 And Ncam In Hippocampus Of Rats

Yuan Qiong-jia¹, Fu Yan², Zhang Ye-ting¹. ¹Chengdu Sport Institute, Chengdu, China. ²Southwest Minzu University, Chengdu, China.
Email: zzyjlt@163.com
(No relevant relationships reported)

OBJECTIVE:To investigate effects of different load forced swimming exercise on the spatial learning and memory ability of rats and to detect the expression of hippocampus PSD-95 and NCAM. **METHODS:**Thirty male 2-monthes old Sprague-Dawley rats were divided randomly into three groups: Control group (C), moderate load exercise group (M), overloading exercise group (O), 10 in each group. Group C rats were fed naturally for 8 weeks, and Group M rats were involved in 8 weeks of moderate load swimming intervention, and Group O rats were involved in 8 weeks of overload swimming intervention. Then, the Morris Water Maze (MWM) test was performed to estimate rats' learning and memory abilities and the Western Blot and Real-time PCR were used to determine the expression levels of PSD-95 mRNA, NCAM mRNA, PSD-95 and NCAM in the hippocampus. **RESULTS:**(1)In the process of navigation training, all animals' escape latencies gradually shortened. On the third day, the average escape latency of Group M was significantly lower than that of Group C and Group O ($p < 0.05$), there were no significant difference in other days; in the navigation experiment, for the time of through the area of the original platform, Group M was significantly higher than Group C and Group O ($p < 0.05$, $p < 0.01$). (2)The expression of PSD-95 mRNA and PSD-95 protein in Group M was significantly higher than that in Group C ($P < 0.05$), as well as the expression of PSD-95 mRNA in Group O was significantly lower than that in Group C and Group M ($P < 0.05$); the expression of NCAM mRNA and NCAM protein in Group M was significantly higher than Group C ($P < 0.05$), as well as the expression of NCAM protein in group O was significantly lower than Group M ($P < 0.05$), but there was no significant difference with Group C ($p > 0.05$). **CONCLUSION:**Moderate load swimming can improve the expression of

PSD-95 and NCAM in the rat hippocampus, as well as improve the spatial learning and memory ability of rats; overload swimming has little influence on PSD-95 and NCAM expression.

Protective Effects Of Treadmill Exercise On $\alpha\beta_{1-42}$ -induced Inflammation And Cognitive Impairment In Rat

Hu Xiaoyong, Fu Yan, Luo Xiao. *Southwest Minzu University, Chengdu, China.*
(No relevant relationships reported)

Many studies suggest that regular exercise could reduce memory impairment, the main symptoms of Alzheimer's disease (AD), but the underlying mechanisms has not been elucidated. Inflammation induced by β -amyloid ($A\beta$) deposition has been shown to play an critical role in AD pathogenesis. Increasing evidence show that aerobic exercise has anti-inflammatory and neuroprotective effects. We hypothesized that aerobic exercise could attenuates memory deficits by regulating inflammatory status. **PURPOSE:** To investigate whether regular aerobic exercise regulate inflammation and attenuate memory deficits induced by $A\beta_{1-42}$ in rat. **METHODS:** Sprague-Dawley rats were divided into 3 groups: control group (C), $A\beta_{1-42}$ infusion group (A), $A\beta_{1-42}$ infusion with exercise group (E). Rats in group A and E were injected 10 μ g $A\beta_{1-42}$ oligomer (1 μ g/ μ l saline) into their hippocampus, and rats from group C were injected with an same volume of saline. The rats in group E underwent aerobic exercise training on a leveled motorized treadmill at a moderate speed for consecutive 5 weeks (once a day, 6 days/week) starting at the 2nd day after $A\beta_{1-42}$ injection. The memory ability was evaluated by Morris Water Maze (MWM) and the inflammatory status was analyzed by expressions levels of proinflammatory cytokines (TNF- α , IL-1 β) and anti-inflammatory cytokine (TGF- β , IL-10) in hippocampus using Western Blot. **RESULTS:** MWM test showed that memory functions of rats were impaired by $A\beta_{1-42}$ infusion, but this impairment was ameliorated by aerobic treadmill exercise. Compared with group C, both pro-inflammatory and anti-inflammatory cytokines in group A increased by different degrees (TNF- α : 306.9%, IL-1 β : 255.6%, TGF- β : 78.3%, IL-10: 80.0%). Compared with group A, the expression of TNF- α and IL-1 β in group AE decreased by 31.4% and 25.0%, whereas TGF- β and IL-10 increased by 68.5% and 39.0% respectively. **CONCLUSIONS:** The findings demonstrated that treadmill exercise could adjust inflammation status in hippocampus and attenuate the cognitive impairment of rats induced by $A\beta_{1-42}$. Supported by the Fundamental Research Funds for the Central Universities, Southwest University for Nationalities (2018NQ19) and the Sichuan Science and Technology University (18YYJC1355).

Treadmill Exercise Alters Microglia Phenotype via Inhibiting NF- κ B Signaling in Rats Hippocampally Injected With $A\beta_{1-42}$

Fu Yan¹, Zhang Ye-ting², Hu Xiao-yong¹. ¹Southwest Minzu University, Chengdu, China. ²Chengdu University, Chengdu, China.
Email: 349095131@qq.com
(No relevant relationships reported)

Microglia has been shown to play a pivotal role in the pathogenesis and prognosis of Alzheimer's disease (AD) for its' distinct activation phenotype, including pro-inflammatory, neurotoxic M1 and anti-inflammatory, neuroprotective M2. Previous studies have showed that regular exercise has anti-inflammatory effect and can reduce the memory deficit of AD rats induced by β -amyloid ($A\beta$), but whether exercise modulates microglial phenotype remain unclear.

PURPOSE: To evaluate the impact of a moderate treadmill exercise program on activation of microglial M1/M2 phenotype in the hippocampus of rats injected with $A\beta_{1-42}$ and to probe the underlying molecular mechanism. **METHODS:** Health Sprague-Dawley rats were randomly separated into sham (S), $A\beta_{1-42}$ (A) and $A\beta_{1-42}$ /exercise (AE) groups. Rats in group A and AE were bilateral hippocampally injected with 10 μ l $A\beta_{1-42}$ solution (1 μ g/ μ l), and rats in group S were injected with 10 μ l saline. Rats in group AE performed running on a treadmill for 5 weeks (6 days/week, once a day, 8-10 min for 10-20 min at a time in the first week, 15 min for 30 min at a time in the next 4 weeks) starting 1 day after $A\beta_{1-42}$ injection. The microglial M1/M2 phenotype in the hippocampus were determined by flow cytometry (FC) and immunofluorescence (IF). The expression of nuclear factor-kappa B (NF- κ B/p65), which has been shown to be involved in the regulation of microglial phenotype, was measured using western blotting (WB) and quantitative real-time PCR (qRT-PCR). **RESULTS:** Both FC and IF showed that the number of M1 microglia (CD11b+CD86+ cell, Iba-1+iNOS+ cell) increased markedly in comparison with group C ($P < 0.01$), but no significant change was observed in M2 microglia (CD11b+CD206+ cell, Iba-1+Arg-1+ cell), and that the number of M1 microglia in group AE was significantly lower than group A ($P < 0.01$), whereas that of M2 microglia was increased ($P < 0.01$). WB and qRT-PCR analysis suggested that the expression of NF- κ B/p65 in the hippocampus was significantly increased after $A\beta_{1-42}$ injection ($P < 0.01$), which was

down-regulated by exercise ($P < 0.05$). **CONCLUSIONS:** These results indicated that the treadmill exercise could suppress the M1 phenotype activation of microglia following A β 1-42 insult and effectively promote microglia toward M2 polarization, which may relate with inhibition of NF- κ B pathway.

Brain Modulation For Perceived Exertion Processing After Different Cycling Exercise Intensities: An fMRI Study

Henrique Bortolotti¹, Eduardo Bodnariuc Fontes¹, Kell Grandjean Costa¹, Bruno Campos², Timothy Noakes³, Maria Augusta Peduti Dal Molin Kiss⁴, Li Li Min⁵. ¹Federal University of Rio Grande do Norte, Natal, Brazil. ²University of Campinas, Natal, Brazil. ³University of Cape Town, Cape Town, South Africa. ⁴University of São Paulo, São Paulo, Brazil. Email: henriquebortolotti@gmail.com
 (No relevant relationships reported)

Ratings of perceived exertion (RPE) during exercise is processed in the brain, however, the modulation of the associated areas at different intensities levels remains unclear. **PURPOSE:** To verify the brain modulation while RPE processing immediately after cycling exercise performed at different intensities.

METHODS: 24 healthy adults (77.6 \pm 9.4 kg; 176 \pm 7.2 cm; 25.9 \pm 5.9 years old) performed an incremental load test on an adapted cycling ergometer attached to a MRI scanner. The workload started at 25 W and increased 25W after every four blocks of 30 s of cycling and 30 s rest. At the end of each block, participants had four seconds to report their RPE based on the 6-20 Borg scale presented on a screen. The RPE processing periods for RPE responses from 6 to 12 were labeled as LOW intensity while those from 13 to 18 were considered as HIGH intensity. To identify the common areas associated to RPE processing, the one sample t-test was used for each condition (all RPE, LOW and HIGH intensities). The statistical threshold established was family-wise error corrected (FWE $<$ 0.05).

RESULTS: When grouping all RPE responses throughout exercise intensities, we found an activation of several areas related to motor control (primary motor cortex, primary somatosensory cortex and cerebellum), homeostatic regulation (insular cortex) and cognition for executive functions (dorsolateral and anterior prefrontal cortex), spatial cognition (superior parietal lobule), reflective self-awareness (precuneus), and others (T=5.33; FWE $<$ 0.05). For the inhibited areas, we observed brain structures located in occipital lobe, prefrontal cortex, and thalamus, angular gyrus, Wernicke's area, associative visual cortex, premotor cortex and supplementary motor cortex (T=5.44; FWE $<$ 0.05). At LOW, the somatosensory cortex and cerebellum (T=6.46; FWE $<$ 0.05) were activated and at HIGH, only the cingulate gyrus was activated (T=6.53; FWE $<$ 0.05). **CONCLUSIONS:** By using a gold standard technique to analyze brain activity, we described here the modulation of brain areas to the RPE processing immediately after exercise cessation performed at different intensities. The integration of motor control, homeostatic regulation and cognitive related areas seems to, together, process the RPE responses after exercise.

Different Characteristics Of Brain Function Between Endurance And Sprinting Athletes: A Resting State fMRI Study

Keying Zhang¹, Chunmei Cao¹, Weimo Zhu, FACSM². ¹Tsinghua University, Beijing, China, China. ²University of Illinois at Urbana-Champaign, Urbana, IL, Urbana, IL. (Sponsor: Weimo Zhu, FACSM) Email: bsuzky0812@163.com
 (No relevant relationships reported)

Long-term motor training has been shown to create adaptations in regional brain plasticity, including brain structure and function, and this has been demonstrated by a number of studies. However, different influences on brain characteristics caused by different specific physical ability like endurance or sprinting still remain unknown. **PURPOSE:** To investigate spontaneous brain activity characteristics of national level endurance and sprinting athletes, as well as different pattern of brain functional connectivity between these two groups.

METHODS: Fifty-seven Chinese national level athletes were recruited and assigned to the endurance group (n=29) and the sprinting group (n=28) according to their physical fitness. Their resting functional magnetic resonance imaging data were acquired by Philips Achieva 3.0T Trio scanner with a standard 32 channel head coil for all subjects. Amplitude of low frequency fluctuation (ALFF) was used to evaluate the intensity of regional spontaneous brain activity. Based on the ALFF results and previous studies, six region of interests (ROIs) were defined, including the cingulate gyrus (6, -21, 27) and right SMA (4, -12, 74). Then whole-brain seed based-functional connectivity analysis was conducted to examine characteristics of brain activation

pattern. SPM8 was used for preprocessing and statistical analysis of the images, and DPARSF was used to acquire the ALFF and FC maps for each individual. Two-sample t-tests were used to analyze differences between the groups.

RESULTS: 1. Compared to the sprinting group, the endurance group demonstrated higher ALFF in the right cingulate gyrus (peak t= 4.20) and lower ALFF (peak t= 4.5) in the left precuneus ($p < 0.001$, cluster size $>$ 6). 2. The sprinting group showed higher functional connectivity between right cingulate gyrus and left Temporal Lobe (peak t=3.83), as well as right SMA and lateral prefrontal cortex (peak t= 4.06) ($p < 0.001$, cluster size $>$ 25).

CONCLUSIONS: Long time specialized training seems associated with the changes in athletes' regional spontaneous brain activity and patterns of brain functional connectivity.

Changes in Inhibitory Markers of Neuronal Plasticity Following Exercise and Intermittent Hypoxia

Natalie E. Doody, Graham N. Askew, Jessica C.F. Kwok, Ronaldo M. Ichiyama. University of Leeds, Leeds, United Kingdom. Email: bsned@leeds.ac.uk
 (No relevant relationships reported)

Studies exploring the effects of exercise in the brain mainly focus on exercise induced modulation of growth factors, whereas research regarding inhibitory factors of plasticity in the brain such as Nogo-A and chondroitin sulfate proteoglycans (CSPGs) is limited. **PURPOSE:** To determine the expression of CSPGs and Nogo-A in selected brain areas after treadmill exercise training or intermittent hypoxia.

METHODS: Male Wistar rats (228g \pm 12.63) underwent six weeks of moderate intensity continuous training (MICT), high intensity interval training (HIIT), intermittent hypoxia (IH), IH and HIIT simultaneously (IH+HIIT), or remained sedentary (CON). MICT animals trained for 3 minutes at 25 cm.s⁻¹ followed by 30 minutes at 32 cm.s⁻¹. HIIT animals trained for 3 minutes at 25 cm.s⁻¹ followed by five cycles of 3 minutes at 50 cm.s⁻¹ and 3 minutes at 15 cm.s⁻¹. MICT and HIIT protocols were matched for duration and distance. IH animals were exposed to five cycles of 3 minutes of hypoxia (FiO₂ 15%) and 3 minutes of normoxia (FiO₂ 20.95%). The IH+HIIT animals were exposed to the IH and HIIT protocols simultaneously, training at the higher speeds during the hypoxic intervals. Hindlimb muscles were snap frozen and citrate synthase activity was measured. Brains were harvested following transcardial perfusions and fixation in 4% paraformaldehyde. 25 μ m coronal brain sections were immunohistochemically stained for Nogo-A and CSPGs. **RESULTS:** Preliminary results show that MICT reduced the average staining intensity of Nogo-A in the dentate gyrus (DG) (99%), CA1 (51%) and CA3 (98%) regions of the hippocampus compared to the CON group. HIIT reduced the intensity of Nogo-A to a larger extent than MICT in the CA1 region (62%). However, HIIT only slightly reduced the intensity of Nogo-A in the DG (22%) and CA3 (9%) regions. MICT increased the expression of CSPGs in the CA1 (300%) and CA3 (27%) regions and reduced the expression of CSPGs in the DG (77%) compared to CON. HIIT reduced the intensity of CSPGs in the DG (73%), CA1 (62%) and CA3 (61%) regions compared to the CON group. **CONCLUSIONS:**

These results show that MICT and HIIT have the capacity to reduce inhibitory molecules within the brain which may contribute to enhancing plasticity.

Age-Related Variation of Pressure Pain Threshold and Condition Pain Modulation During an Ultra-Marathon

Alexandre L. Roy, Zachary L. Roy, Steven B. Hammer, James W. Agnew. Indian River State College, Fort Pierce, FL. Email: alexandrero1011@yahoo.com
 (No relevant relationships reported)

There is insufficient data available on age related variation in pain mechanisms during ultra-marathon competitions.

PURPOSE: We examine pressure pain threshold (PPT) and condition pain modulation (CPM) in older versus younger age groups during an ultra-marathon. **METHODS:** Informed consent was obtained from all subjects prior to their participation. Age groups were formed from the mean age of 41 years-old in our subject population: n=21 for <40 years and n=23 for >40 years. PPT was measured using a Baseline© Dolorimeter. The dolorimeter was placed equidistant to the radial and the ulna styloid processes. A trained technician applied consistent, gradual pressure until the subject indicated that they felt a change from pressure to pain. This was repeated three times and the mean score was used for statistical analysis. CPM was measured with the same technique while subjects placed the opposite hand in cold water (20°C). During this process neither the technician nor the subjects were able to see the dolorimeter. Another technician recorded the results to maintain double blinding of data collection. To investigate any differences between the pre versus post changes during the ultra-marathon "Delta" PPT and CPM values were calculated by subtracting the Post PPT

and CPM from the Pre PPT and CPM, respectively. Independent sample t-tests were used to assess differences in Delta values for PPT and CPM between the two age groups. **RESULTS:** The Post PPT and CPM were significantly decreased ($p < 0.05$) for both age groups, indicating greater pain sensitivity. The age group analysis (< 40 versus > 40) showed a decrease in Delta PPT in the older age group: (Mean Delta < 40 years = 149.40 kPa, Mean Delta > 40 years = 48.38 kPa $t(42) = 2.69$; $p < .05$. A similar decrease was found in Delta CPM: (Mean Delta < 40 years = 31.75 kPa, Mean Delta > 40 years = 11.69 kPa $t(42) = 2.03$; $p < .05$. **CONCLUSION:** Previous research from our group has shown a decreased PPT and CPM, indicating greater pain sensitivity, across all ages during an ultra-marathon. In this present study we have seen similar decreases in PPT and CPM but clearly a difference between age groups in the degree of these changes. Further research is required to determine how factors of immunosenescence, directly or indirectly, may affect the age group variations in pain during an ultra-marathon.

399 Board #237 May 29 9:30 AM - 11:00 AM
Impact of a Carbohydrate Mouth Rinse on Corticomotor Excitability after Mental Fatigue.

Tracy A. Llewellyn¹, Kaitlin K. Lewis¹, Stephen E. Folger¹, G. Keith Harris², Stephen P. Bailey, FACSM¹. ¹Elon University, Elon, NC. ²North Carolina State University, Raleigh, NC.
 Email: tllewellyn@elon.edu
 (No relevant relationships reported)

Mental Fatigue (MF) has been associated with reduced physical performance. Carbohydrate (CHO) mouth rinse (MR) has been shown to be effective at increasing corticomotor excitability. **PURPOSE:** The purpose of this study was to determine if CHO MR positively impacts corticomotor excitability and cognitive function after MF. **METHODS:** Nine subjects (6 females, 3 males; Age = 23 ± 1 years; Height = 170 ± 3 cm; Weight = 68 ± 4 kg) completed 2 experimental sessions under different MR conditions (Placebo (PLAC), 6.4% glucose (CHO)) each separated by at least 48 hours and applied in a random fashion. Motor-evoked potential (MEP) of the left first dorsal interosseus (FDI) was determined at rest by transcranial magnetic stimulation (TMS) before and immediately after completion of a task designed to cause MF. The MF task required the subjects to complete six blocks (448 trials each) of the Stroop Color Word Test (SCWT). MR was applied between each SCWT block and held in the mouth for 20 sec. Perceived MF was recorded before and after the MF task using a 100 mm VAS. **RESULTS:** Perceived MF increased from pre (PLAC = 16 ± 6 mm; CHO = 19 ± 7 mm) to post (PLAC = 41 ± 5 mm; CHO = 46 ± 4 mm) in both conditions ($p < 0.001$) but no differences were seen between the groups. Overall reaction time during SCWT was better ($p = 0.03$) in CHO (698 ± 10 ms) compared to PLAC (738 ± 16 ms), but correct response rate was not different between the groups (PLAC = 97.5 ± 0.4 ; CHO = 98.1 ± 0.2). MEP improved ($33 \pm 9\%$) ($p = 0.03$) after the MF task in CHO (Pre = 2241 ± 633 μ V; Post = 2704 ± 606 μ V) and declined ($-28 \pm 6\%$) ($p = 0.02$) after the MF task in PLAC (Pre = 1810 ± 389 μ V; Post = 1208 ± 244 μ V). **CONCLUSIONS:** CHO MR was successful at preventing a reduction in corticomotor excitability subsequent to MF. CHO MR also had a positive impact on some measures of cognitive performance during the MF task. CHO MR did not impact perceived MF. These results suggest that CHO MR may be a valuable tool at combating the negative consequences of MF.

The Influence Of Transcranial Direct Current Stimulation On Skill Acquisition In A Complex Motor Task.

Milan Pantovic¹, Austin Pomerantz¹, Sierra Kreamer-Hope¹, Lidio L. Albuquerque¹, Matt C. Pettit², Michael Zurowski¹, Mark A. Guadagnoli¹, Zachary A. Riley³, Brach Poston¹. ¹University of Nevada, Las Vegas, Las Vegas, NV. ²Brigham Young University, Provo Utah, Provo, UT. ³Indiana University-Purdue University Indianapolis, Indianapolis, IN.
 (No relevant relationships reported)

INTRODUCTION: A single application of transcranial direct current stimulation (tDCS) delivered to motor cortex improves skill acquisition in relatively simple motor tasks performed unilaterally with the hand and arm. **PURPOSE:** The purpose of this study was to examine the acute effects of tDCS on skill acquisition in a complex, multi-joint arm movement in healthy young adults. **METHODS:** The study employed a double-blind, SHAM-controlled, between-subjects experimental design. Twenty-two right-handed adults were randomly assigned to either a tDCS or a SHAM group. Subjects participated in one experimental session that involved overhead throws to a target in a baseline-test block, 5 practice blocks, and a post-test block (10 trials per block). After the baseline-test block, transcranial magnetic stimulation (TMS) was used to locate the first dorsal interosseus muscle (FDI) motor representation area (motor hot spot) of the left hemisphere. Subsequently, motor evoked potentials (MEP) were obtained in the resting FDI muscle prior to and after 5 minutes of tDCS (current: 1 mA). After a 20 minute rest period, tDCS was applied again for 20 minutes to the FDI hot spot while subjects performed the 5 practice blocks of overhead throws. Finally, subjects performed a post-test block of overhead throws

5 minutes after the tDCS/practice session ended. Motor performance was quantified as the endpoint error, whereas MEP amplitude was used to quantify cortical excitability. Percent change in endpoint error between the baseline-test block and the post-test block for the two groups was compared with an unpaired t-test. Similarly, percent change in MEP amplitude before and after the 5 minutes of tDCS for the two groups was compared with an unpaired t-test.

RESULTS: The percent change in endpoint error (decrease) was greater for the tDCS group compared to the SHAM group, but this difference just failed statistical significance (-16.9 vs. -5.2% ; $P = 0.127$), whereas the percent change in MEP amplitude was significantly greater for the tDCS group compared to the SHAM group (49.7 vs. -13.5% ; $P = 0.012$).

CONCLUSION: These findings indicate that a single-session of tDCS enhances cortical excitability and appears to improve motor skill, although there was high inter-individual response variability to tDCS for this difficult motor task.

Impact of Acute Aerobic Exercise on Cue Reactivity in Heavy Episodic Drinkers

Emily Phillips, Caitlin Osborn, Sarah Hynes, Stephen Folger, Stephen Bailey, FACSM. *Elon University, Elon, NC.* (Sponsor: Stephen Bailey, FACSM)
 (No relevant relationships reported)

Physical exercise has been shown to reduce craving for alcohol in alcoholics. There is a high prevalence of heavy episodic drinking in college-aged adults (18-29 years of age). This can be predictive of an alcohol or other substance use disorder developing later in life. **PURPOSE:** The purpose of this investigation is to examine the impact of acute aerobic exercise on cue reactivity to alcohol in heavy episodic drinkers. **METHODS:** Seven participants (6 females, 1 male) (Age = 20 ± 0.44 years, BMI = 22.6 ± 0.59 , $VO_{2Max} = 32.014 \pm 2.14$ ml \cdot kg $^{-1}$ ·min $^{-1}$) completed 2 experimental sessions. Heavy episodic drinking was identified using an adapted version of the CAGE questionnaire. During one session subjects rested for 30 minutes and during the other session subjects exercised for 30 minutes at a moderate exercise intensity ($77 \pm 1\%$ of Peak HR). Sessions were randomized for each participant. Prior to and immediately following each session, EEG data were collected using a 64-channel system while subjects were exposed to 180 images (90 alcoholic drinks (ALC), 90 non-alcoholic drinks (NON)). Images were presented in a random order and proceeded by a fixation stimulus using a variable time span (0.5 to 1.5 sec). Mean amplitude and peak latency was calculated for P300 (300-380 ms post stimulus) in parietal-occipital electrodes. **RESULTS:** Before exercise, subjects had a greater response ($p = 0.002$) to ALC (1.85 ± 0.20 μ V) as compared to NON (1.47 ± 0.21 μ V). After exercise the response to ALC (1.62 ± 0.37 μ V) was similar to that seen for NON (1.72 ± 0.31 μ V). Before exercise the peak latency was shorter ($p = 0.025$) for ALC (325 ± 32 ms) compared to NON (366 ± 25 ms). After exercise, the peak latency was similar for ALC (313 ± 26 ms) and NON (323 ± 27 ms). **CONCLUSION:** These findings suggest that acute aerobic exercise of moderate intensity attenuates cue reactivity to images of alcoholic beverages in heavy episodic drinkers.

Effect of High Intensity Aerobic Training on Fitness and Health in Individuals with Parkinson's Disease

David Edwards. *University of Virginia, Charlottesville, VA.* (Sponsor: Arthur Weltman, FACSM)
 Email: dae7c@virginia.edu
 (No relevant relationships reported)

Parkinson's disease (PD) is a neurodegenerative disorder characterized by motor dysfunction. Impaired mitochondrial capacity, as well as glucose and lipid toxicity, have been linked to neuronal dysfunction and apoptosis. Although aerobic exercise impacts these outcomes, few data exist in PD. **PURPOSE:** We tested the hypothesis that high intensity aerobic exercise (AEX) would improve aerobic fitness and metabolic outcomes. **METHODS:** Nineteen subjects (11 female, age: 67.5 ± 1.4 yrs) with idiopathic PD (Hoehn and Yahr stage 2 or 3) were enrolled in a 16-week supervised aerobic exercise program. Subjects exercised 3d/wk at a rating of perceived exertion (RPE) of 15-17 for 30 min. They also performed 30 min. of unsupervised exercise 2d/wk at an RPE of 10-12. Paired sample t-tests were used to assess maximal oxygen consumption, 6 min. walk, body weight (kg), body fat % (BIA), respiratory exchange ratio (RER; indirect calorimetry), blood pressure (BP), heart rate (HR), as well as fasting glucose and free fatty acids (FFA) pre/post intervention. **RESULTS:** AEX increased VO_{2peak} (PRE: 22.6 ± 1.6 vs. POST: 25.1 ± 1.4 ml/kg/min., $p = 0.004$) and distance covered during the 6 min. walk (PRE: 470 ± 19.3 vs. POST: 539.7 ± 24.3 m, $p = 0.0001$). AEX also reduced systolic BP (PRE: 119 ± 3.1 vs. POST: 106.7 ± 2.6 mmHg, $p = 0.007$) and fasting FFA (PRE: 0.40 ± 0.07 vs. POST: 0.3 ± 0.07 , $p = 0.03$). There were no statistical change in body weight, body fat %, diastolic BP, HR, RER or fasting glucose. **CONCLUSIONS:** An AEX intervention improves fitness and

metabolic health independent of weight loss in PD. Whether AEX improves metabolic health and PD related clinical outcomes more than other exercise prescriptions awaits further investigation. Supported by a grant provided by The Manning Foundation.

Dopaminergic Receptor and Transporter Densities in Nucleus Accumbens Are Not Altered by a Western Diet

Brianne M. Breidenbach, Ayland C. Letsinger, Jorge Z. Granados, Tatiana N. Castro Padavoni, Heather L. Vellers, J. Timothy Lightfoot, FACSM. *Texas A&M University, College Station, TX.* (Sponsor: J. Timothy Lightfoot, FACSM)
 (No relevant relationships reported)

Multiple studies have indicated that physical activity regulation may be largely controlled by central neural factors, such as dopamine (DA) signaling in the nucleus accumbens (NAc). DA signaling has been shown to be altered by nutritional interventions. The key identified proteins involved with DA signaling are DA receptors one and two (DRD1, DRD2), tyrosine hydroxylase (TH), vesicular monoamine transporter (VMAT), and DA transporter (DAT).

PURPOSE: To determine if a high fat/high sugar (HFHS) diet alters DA signaling in the NAc of male and female C57Bl/6J mice. **METHODS:** Mice were randomly assigned to either a HFHS diet or a standard CHOW diet (C) at three weeks of age for a total of nine weeks. The C diet consisted of 4% fat, 25.2% protein, 39.5% carbohydrate, and 23.2% fiber, while the HFHS diet consisted of 45% fat, 20% protein, and 35% carbohydrate along with a 20% fructose solution replacing drinking water. Physical activity was measured using a running wheel for three days during the last week. Mice were sacrificed at 12 weeks, the NAc was dissected on ice, and flash frozen in liquid nitrogen. Immunoblotting was performed using NAc lysate probed with the following antibodies; DRD1, DRD2, TH, VMAT, DAT. Bands were analyzed after normalization using Welch's t-tests to compare target protein densitometries between the HFHS and C diet conditions. **RESULTS:** There were no significant differences in protein densitometries in male mice for DRD1, TH, VMAT, DAT, or DRD2 ($p = 0.85; 0.46; 0.38; 0.38; 0.36$ respectively) or in female mice ($p = 0.16; 0.39; 0.31; 0.33; 0.83$ respectively). **CONCLUSION:** A HFHS diet did not alter dopaminergic receptor or transporter densities in the NAc. Previous analyses revealed the HFHS group had greater kcal consumption and decreased physical activity while the C diet group had lower kcal consumption and higher physical activity. Thus, we conclude that each group mediated DA activity via separate mechanisms; the HFHS through diet and the C through physical activity.

404 Board #242 May 29 9:30 AM - 11:00 AM
Changes in Cue Reactivity to Fatty Foods After Exercise

Stephen Bailey, FACSM, Lauren Cooper, Kahli Castagnera, Brianna Hurt, Stephen F. Folger. *Elon University, Elon, NC.*
 Email: baileys@elon.edu
 (No relevant relationships reported)

Acute aerobic exercise has been shown to reduce craving for various addictive substances like cigarettes and alcohol. A similar effect has been seen in children when examining brain fMRI responses to fatty foods. **PURPOSE:** The purpose of this investigation is to examine the impact of acute aerobic exercise on cue reactivity to fatty and healthy foods in college-aged women. **METHODS:** Sixteen women (Age=21±1 years, BMI=22.1±0.5, $VO_{2peak}=39.1\pm 1.5$ ml·kg⁻¹·min⁻¹) completed 2 experimental sessions. During one session subjects rested for 30 minutes and during the other session subjects exercised for 30 minutes at a moderate exercise intensity (77±2% of Peak HR). Treatments were applied in a counter-balanced fashion and subjects fasted for 4 hours prior to each session. Prior to and immediately following each session, EEG was collected using a 64-channel system while subjects were exposed to 280 images (40 Distractor (DIS), 120 Fatty Foods (FAT), 120 Healthy Foods (HEALTHY)). Images were presented in a random order and proceeded by a fixation stimulus using a variable time span (0.5 to 1.5 sec). Adaptive mean and peak latency for N100 (100-130 ms post stimulus) and P300 (240-300 ms post stimulus) were determined in parietal-occipital electrodes. **RESULTS:** Before exercise, subjects had a greater P300 response ($p=0.001$) to FAT (5.68±0.46 μV) as compared to HEALTHY (5.23±0.48 μV). After exercise the response to FAT (4.92±0.45 μV) was similar to that seen for HEALTHY (4.94±0.54 μV). The N100 response to FAT (Pre=3.48±0.24 μV; Post=2.96±0.28 μV) was greater than the response to HEALTHY (Pre=3.20±0.22 μV; Post=1.96±0.42 μV) before ($p=0.001$) and after ($p=0.005$) exercise. No differences in peak latency were seen for N100 or P300 at either time point. **CONCLUSION:** These findings suggest that acute aerobic exercise of moderate intensity can influence cue reactivity to images of fatty and healthy foods in college-aged women.

405 Board #243 May 29 9:30 AM - 11:00 AM
Changes in Analgesia, Hyperphagia and Depression are Mediated by Endogenous Opioids Following Forced Swimming Exercise

Harlee B. York, Bryce J. Muth, Kelly A. Dougherty, John J. Guers. *Stockton University, Galloway, NJ.*
 Email: yorkh@go.stockton.edu
 (No relevant relationships reported)

Exercise is specifically linked to at least three phenomena that are likely to involve opioid release; the 'athlete's high', increased pain tolerance, and addiction to exercise. Exercise studies that have examined the effects of the opiate receptor blocker naltrexone, found that its administration prior to exercise alter these before mentioned phenomena. **PURPOSE:** The purpose of this study was twofold: 1) to establish an exercise modality that is sufficient to stimulate the release of endogenous opioids and 2) to examine the role endogenous opioids play in post-exercise pain tolerance and depression. **METHODS:** Following a week of familiarization, mice underwent a 50-minute (min) bout of forced swimming (FS). Mice were injected with either saline (S; 0.9%) or the opioid blocker naltrexone (NTX; 4g/kg) 15 mins prior to exercise. Following exercise mice were challenged with a tail suspension test (TST), pain tolerance test or monitored for post exercise food consumption for 2 hours. **RESULTS:** NXT injection decreased total FS time (46 ± 1.2 mins. vs. 35 ± 1.6 mins; $p<0.05$). Forced swimming increased food consumption by 88% ± 11 ($p<0.05$) two hours following exercise but was abolished by NXT ($p<0.05$), verifying an increase in opioid mediated hyperphagia. An increase in hot water tail immersion time following exercise ($S = 2.72 \pm 0.13$ vs. $FS = 4.28 \pm 0.19$; $p<0.05$) demonstrated an improvement in pain tolerance. Pain tolerance decreased by 20% ± 0.05 with the addition of NXT ($P<0.05$). Finally, a TST demonstrated that following a bout of exercise, mice spent 49 ± 3.1% less time immobile ($p<0.05$), signifying lower depression levels. This effect was reversed with the opioid blockade ($p<0.05$). **CONCLUSIONS:** Fifty minutes of forced swimming is an effective stimulus for the release of endogenous opioids and modulates behavioral changes specific to the release endogenous opioids in mice.

Endurance Exercise-induced Autophagy Coincides With Anabolic Activation And Neurogenesis In The Hippocampus Of The Mouse Brain

Yongchul Jang, insu Kwon, Wankeun Song, Ludmila Cosio-Lima, Jeffrey Simpson, Youngil Lee. *University of West Florida, Pensacola, FL.* (Sponsor: John Quindry, FACSM)
 Email: yjang@uwf.edu
 (No relevant relationships reported)

PURPOSE: Autophagy and neurogenesis play a pivotal role in maintaining cellular homeostasis of neurons in the brain. Endurance exercise (EXE) serves as a potent activator of both autophagy and neurogenesis in the hippocampus of the brain; however, the molecular mechanisms of the dual activation remains unclear. We investigated EXE-induced molecular signaling nexus of autophagy and neurogenesis pathways in the hippocampus.

METHODS: C57BL/6 mice (8 weeks old, male, n=24) were randomly divided into two groups: control (CON, n=12) and endurance exercise (EXE, n=12). Animals performed treadmill running exercise at 13 m/min (65-70% VO_{2max}) for 60 min/day for 6 weeks. 24 hours after the last session of EXE, whole brains were excised, and the hippocampi were isolated for Western blot analysis. For immunofluorescence microscopy, the excised whole brains were frozen. A student t-test was used for statistical analysis ($p<0.05$).

RESULTS: EXE significantly increased autophagy evidenced by an increase in LC3II, ATG7, BECLIN1, and phosphorylation of BCL-X_L by JNK activation along with an increase in lysosomal proteins (LAMP2, CATHEPSIN L and TEEB, $p<0.05$). Intriguingly, EXE-induced autophagy coincided with activation of anabolic signaling cascades (AKT-mTOR-p70s6k, $p<0.05$), known to interfere in autophagy. This autophagy promotion was associated with activation of endoplasmic reticulum stress adaptors (p-PERK, ATF6, and p-IRE1, $p<0.05$). Interestingly, EXE-mediated neurogenesis was induced, despite the downregulation of canonical neurotrophic factors (BDNF, GDNF, and NGF, $p<0.05$). Instead, EXE promoted neuroglia-mediated neurotrophic signaling (p-ERK, p-RSK, and p-CREB, $p<0.05$).

CONCLUSIONS: EXE-induced coactivation of autophagy and anabolism suggest that enhanced recycling of damaged molecules along with increased anabolism in the hippocampus may confer neuroprotective phenotypes of the brain. Furthermore, EXE-mediated improvement in neurogenesis devoid of canonical neurotrophic factors suggests that there exists a potential modulatory mechanism regulating the optimal levels of neurogenesis, which prevents undesired excessive chronic neurogenesis. Our results suggest that coactivation of autophagy and neurogenesis via EXE is critical for maintaining optimal neuronal homeostasis.

407 Board #245 May 29 11:00 AM - 12:30 PM Suicidality, Physical Activity and Sport Participation in US Middle and High School Students

Sarah R. Marchisio, Madelaine Mitchell-Ward, Sydney Swindell, Rachel Zajchowski, Jeremy Sibold, Erika Edwards. *The University of Vermont, Burlington, VT.*
Email: sarah.marchisio@gmail.com
(No relevant relationships reported)

PURPOSE: Exercise is inversely related to both sadness and suicidality in developing adolescents. To date, the literature has addressed neither the contextual factors nor the dynamic fluctuations of these relationships in middle and high school children over time. The purpose of this study is to examine the temporal changes in the relationship between physical activity, sport participation, sadness, and suicidality in students in grades 6-12 in the U.S.

METHODS: Using the 2015 National Youth Risk Behavior Survey (N=199,194), regression models adjusted for age, sex, and race estimated the odds ratios between sadness, suicidal ideation, and suicidal attempts, stratified by exercise and sports participation.

RESULTS: Overall, 19.7% of students in grades 6-12 reported suicidal ideation or attempt. Only 68.4% of students reported ≥60 minutes of physical activity on four or more days of the week, and 55.2% reported sport team participation. Physical activity on four or more days per week was associated with a 27% reduction in the odds of suicidality, and sport team participation was associated with 17% reduction in suicidality.

CONCLUSIONS: Exercise and sport team participation are inversely related to sadness and suicidality in adolescents and this relationship persists throughout adolescence. Future research should examine the influence of exercise and sport participation on a longitudinal basis and identify other biopsychosocial factors that may be contributing to these results in developing adolescents.

408 Board #246 May 29 11:00 AM - 12:30 PM Device-based Sedentary Time And Executive Function Among African-american Children With Behavior Disorders

Maria Enid Santiago-Rodriguez, Jared Donald Ramer, Eduardo Esteban Bustamante, FACSM. *University of Illinois at Chicago, Chicago, IL.*
Email: msanti24@uic.edu
(No relevant relationships reported)

Screen time in children with ADHD can exacerbate symptoms and affect self-regulation and attention. **PURPOSE:** To test relationships between device-based ST and children's executive function (EF) with behavior disorders. **METHODS:** Eleven African-American girls and 12 boys (mean age = 9.3 ± 1.9-years) wore a triaxial accelerometer for 5-consecutive-days at the beginning of an intervention trial. Evenson (2008) cut-points were used to determine ST (min/day), sedentary breaks (min/day), and ST% (% per day) during weekdays and a filter to remove intervention time and non-wear time during the night was applied. Data was included if a participants wore the accelerometer ≥ 3 weekdays for ≥ 8 hrs/day. EF was assessed through parental-report of behavioral manifestation of EF (BRIEF-GEC score) and children underwent neuropsychological tests of verbal and visuospatial working memory (AWMA verbal and AWMA visuospatial scores). ST (min/day) was reciprocal by 100 transformed to achieve normality. Bivariate correlations and multiple regression analyses tested relationships between EF and ST, controlling for wear-time and moderate-to-vigorous physical activity. **RESULTS:** On average, children spent 295.60±67.17 min/day in ST, 417.60±120.78 min/day in sedentary breaks, and 49.31±7.11% of the day in ST. Children obtained an average score of 59.21±10.42 points in BRIEF-GEC, 32.70±25.68 points in AWMA verbal score, and 38.05±23.31 points in AWMA visuospatial score. BRIEF-GEC, AWMA verbal, and AWMA visuospatial scores were low. In this case, BRIEF-GEC scores indicate a better EF, while AWMA verbal and visuospatial scores represent a less fewer difficulties in working memory and a less problematic behavior in the classroom. In bivariate correlations, a significant relationship was observed between ST% and AWMA visuospatial score ($r(17)=-0.49, p=0.04$). None of the regression analyses, controlling for wear-time and moderate-to-vigorous physical activity, showed significant results, though there was a trend for all ST variables to explain ≥ 15% of the variance in AWMA visuospatial scores after controlling for wear-time. **CONCLUSIONS:** Few significant relationships were evident between objectively-measured ST and assessments of African-American children's EF with behavior disorders.

409 Board #247 May 29 11:00 AM - 12:30 PM Exercise Group In a Geriatric Psychiatry Clinic - Improving Physical Strength and Mental Health

Sivan Klil-Drori¹, Sophia Escobar¹, Allana Goodman², Marylin Segal², Karl Looper¹, Soham Rej¹. *¹McGill University, Montreal, QC, Canada. ²Jewish General Hospital, Montreal, QC, Canada.*
(No relevant relationships reported)

Introduction: Exercise has wide range of health benefits, more than any other single intervention. It improves depression and anxiety symptoms, attention and other cognitive functions. Exercise is recommended for common chronic diseases, such as diabetes, hypertension, coronary heart disease, osteoporosis, insomnia and more. Benefits to exercise include low cost, social interactions, no drug interactions or drug metabolism, improved physical health, and positive stigma.

Methods: We designed an exercise group for patients followed at our geriatric-psychiatry clinic. We recruited older adults age ≥ 60 with any type of major mental disorder, followed at the tertiary-care geriatric psychiatry clinic, Jewish General Hospital, Montreal.

Intervention of Exercise Group: Aerobic and anaerobic exercise, for 50 minutes, twice a week, total of 12 weeks, at medium intensity which gradually increased. Groups included 6-12 participants every 3 months and led by an exercise instructor. We ran four groups during 2017-2018.

Results: We had 24 individual participants in 4 groups, among them we had 9 patients who joined the group during the first 4 weeks of the 12-week session, completed at least 75% of the exercise sessions, and completed both pre- and post questionnaire (PHQ-9) were included in the final analysis.

Quantitative results:

We used the PHQ-9 to examine depressive symptoms, analysis by Wilcoxon signed rank test.

Pre and post intervention analysis showed improvement in depressive symptoms with a significant P=0.03

Qualitative results:

We conducted a focus group at the end of the fourth group. Repeated themes were: feeling more confident, stronger, more energetic, and more calm. Most patients described the exercise environment as positive, non-judgmental, and supportive. Quality of sleep during the night was not improved, though most patients mentioned feeling much less sleepy during the daytime.

Conclusions: Exercise could potentially help number of outcomes for older adults with mental illness. It has been shown to significantly improve depressive symptoms, and qualitative results show improvement in general well-being. Our results and future research in this field will help establish an evidence base to tailor this promising intervention to this vulnerable population of older adults with mental illness.

410 Board #248 May 29 11:00 AM - 12:30 PM Functional Capacity, Cognition And Spatial Navigation In Older Adults With Mild Cognitive Impairment

Jessica Plácido, José Vinicius Ferreira, Felipe Oliveira, Paula Santana, Renato Sobral Monteiro-Junior, Jerson Laks, Andrea C. Deslandes. *UFRJ, rio de janeiro, Brazil.*
Email: jessica.placido10@hotmail.com
(No relevant relationships reported)

Spatial navigation is a complex and fundamental cognitive ability that allows an individual to maintain independence and, combined with episodic memory, emerges as one of the first deficits in patients with Alzheimer's disease (AD). A successful spatial navigation depends on an interaction between physical (mobility, balance and aerobic capacity) and cognitive ability (memory and executive function). However, although Mild Cognitive Impairment (MCI) typically precedes AD, the mechanisms of spatial navigation in real environment in this population are still not well understood, especially the influence of physical variables.

Purpose: To compare spatial navigation performance through use of the Floor Maze test (FMT) - an easy-to-apply two-dimensional maze - on healthy elderly individuals and those with MCI. A secondary objective we examined which cognitive and functional functions were associated with performance in this task.

Methods: We evaluated 62 older adults (> 60 years) (healthy=39; MCI=23). Spatial navigation was evaluated through the FMT (Planning (PMT), Immediate (IMT) and Delayed Maze Time (DMT)). Functional capacity was evaluated through the Sit to Stand, 8 Foot up and go and STEP (Senior Fitness Test battery). Cognitive functions were evaluated through MMSE, clock-drawing test, Verbal Fluency, RAVLT, Digit Span and Trail Test (A and B). The relationship and possible association between FMT performance and independent variables were analyzed using multiple and logistic regression models.

Results: The group with MCI was significantly slower in all stages of the FMT. PMT performance was associated with clock drawing test ($R^2=0.26, p<0.001$). Performance in the IMT was associated with STEP ($R^2=0.15, p=0.02$), while DMT was influenced by the STEP and clock drawing test ($R^2=0.33, p<0.001$). Logistic regression analysis

showed that older adults with low aerobic capacity are 18 times more likely to have a worse performance in the DMT ($O.R=18.76$ $p=0.04$).
 Conclusion: Older adults with MCI presented significant spatial navigation deficits. Their performance on the FMT is mainly influenced by spatial orientation and aerobic capacity. Elderly people should be encouraged to practice physical exercises, aiming to maintain cardiorespiratory levels and spatial navigation.

411 Board #249 May 29 11:00 AM - 12:30 PM
Do Aerobic Exercise And Mindfulness Act Synergistically To Mitigate Psychological Distress In High-stress College Students?

Gabriel H. Zieff, Lee Stoner, FACSM, Barnett Frank, Susan Gaylord, Sarah Battle, Anthony C. Hackney, FACSM. *University of North Carolina Chapel Hill, Chapel Hill, NC.* (Sponsor: Dr. Anthony C. Hackney, FACSM)
 Email: gzieff@live.unc.edu
 (No relevant relationships reported)

Mindfulness meditation (MM) and aerobic exercise (AE) decrease stress, but the combined effects are unknown. **Purpose:** Assess effects of AE plus MM, compared to effects of MM alone, on stress in young adults. **Methods:** High-stress, sedentary ($N=32$, 27 F, 20.5 ± 2.7 years, 23.9 ± 5.0 kg/m²) individuals were randomized to a 4-week MM, AE+MM, or control group. MM and AE+MM groups participated in 200 minutes/week of guided MM or AE+MM. MM consisted of present moment, non-judgmental awareness. AE consisted of moderate-intensity (40-60% heart rate reserve) exercise. Stress (PSS) and anxiety/depression symptoms (DASS) were measured at baseline, and after weeks 1 and 4. An analysis of variance assessed effects of group and time on PSS and DASS. **Results:** There were no group x time interactions for PSS ($p = 0.12$) or DASS ($p = 0.21$). There were main effects of time in which PSS and DASS were significantly lower after week 1 (PSS: $p = 0.04$; DASS: $p = 0.01$) and at post-intervention (PSS: $p < 0.001$; DASS: $p = 0.004$) compared to baseline. There were large effect size (ES; Cohen's d) changes in the pre to post PSS and DASS scores for the MM (PSS: -1.33; DASS: -1.03) and AE+MM (PSS: -1.24; DASS: -0.97) groups, and small ES changes in the PSS and DASS scores for the control group (PSS: -0.45; DASS: -0.13). **Conclusion:** MM may be as effective as AE+MM in combatting psychological distress in high-stress young adults. Further research should compare AE-only to AE+MM.

412 Board #250 May 29 11:00 AM - 12:30 PM
The Feasibility Of Pilates To Improve Mental Health Outcomes Among People With Multiple Sclerosis: An 8-week Randomized Controlled Pilot Trial

Karl M. Fleming¹, Susan Coote², Blathin Casey², Matthew P. Herring². ¹*Physical Education and Sport Sciences, Limerick, Ireland.* ²*University of Limerick, Limerick, Ireland.*
 (No relevant relationships reported)

Evidence supports positive effects of exercise on mental health outcomes among people with Multiple Sclerosis (PwMS). However, non-traditional exercise modes like yoga, tai chi, and Pilates remain understudied. **Purpose:** Thus, this 8-week feasibility trial examined the effects of supervised or home-based Pilates compared to a wait-list control on mental health outcomes among PwMS. **Methods:** Nineteen PwMS were recruited; one refused randomization and the one male was omitted from analyses. Seventeen females (49.8±8.4 y) were randomised to two weekly sessions of supervised Pilates ($n=5$), two weekly home-based Pilates sessions guided by a DVD ($n=6$), or wait-list control ($n=6$). Pilates sessions involved 60min sessions of 14 mat-based beginners' level exercises; repetitions progressed from 4-10 for each exercise across eight weeks. Feasibility was assessed relative to recruitment, retention, compliance with the Pilates intervention, and the presence/absence of adverse events. Well-validated questionnaires assessed symptoms of anxiety, depression, and fatigue, and mood states at baseline and weeks two, four, six, and eight. Differences in outcome change were examined with 3 group X 4 time ANCOVAs adjusted for baseline. Significant interactions were decomposed with simple effects analysis. Hedges' d effect sizes quantified magnitude of change. **Results:** Attrition was high for supervised Pilates ($n=2$ of 5; 40%); no home-based or wait-list participant withdrew. Compliance was high across groups (>80%). No adverse events were reported. Group X time interactions were significant for feelings of depressed mood ($F_{(6,33)}=2.80$, $p<0.03$), physical symptoms of fatigue ($F_{(6,33)}=4.92$, $p<0.001$), and total fatigue ($F_{(6,33)}=3.76$, $p<0.006$). Compared to wait-list, scores for home-based Pilates were significantly lower (all $p<0.02$) for feelings of depressed mood at weeks 4 ($d=1.25$), 6 ($d=0.47$), and 8 ($d=0.90$), physical symptoms of fatigue at weeks 4 ($d=0.84$) and 8 ($d=0.82$), and total fatigue at weeks 4 ($d=0.60$) and 8 ($d=0.57$). **Conclusions:** Findings support the feasibility of home-based Pilates to improve mental health outcomes among women with MS. These results support development of larger randomized controlled trials to better understand Pilates' clinical effectiveness and plausible mechanisms of action.

413 Board #251 May 29 11:00 AM - 12:30 PM
Physical Activity and Sedentary Behaviors Influence Executive Function and Psychological Well-being in Chinese University Students

Tao Huang, Kun Wang, Xiang Fan, Zuosong Chen. *Shanghai Jiao Tong University, Shanghai, China.*
 Email: taohuang@sjtu.edu.cn
 (No relevant relationships reported)

PURPOSE: To investigate the associations of physical activity and sedentary behaviors with executive function and psychological well-being in Chinese university students.

METHODS: Participants were 214 college students (aged 19.0 ± 1.1 yrs, 46.3% women) recruited from Shanghai, China. Executive function was assessed using a task switching paradigm. The outcomes of the task were global switch costs and local switch costs. The self-rating anxiety scale (SAS) and the self-rating depression scale (SDS) were used to measure anxiety and depressive status, respectively. Sleep quality was assessed by the Pittsburgh sleep quality index (PSQI). Physical activity was objectively measured using hip-mounted accelerometry monitors (Actigraph wGT3X-BT, Pensacola, FL, USA). Time spent on TV viewing, computer use, and smartphone use was used as indicators of sedentary behaviors, which were surveyed by a questionnaire. Linear regression modelling was conducted to assess the associations of physical activity and sedentary behavior with executive function and psychological variables.

RESULTS: Female students accumulated more time spent on light physical activity (LPA) (157.2 ± 37.7 vs. 131.1 ± 48.0 min, $P < 0.01$) and moderate-to-vigorous physical activity (MVPA, 49.6 ± 22.3 vs. 38.6 ± 17.0 min, $P < 0.01$), and had higher total PA (326.9 ± 119.6 vs. 271.7 ± 114.8 CPM, $P < 0.01$) than males. After adjustment for wear time of accelerometers, age and gender, MVPA ($\beta = -0.19$, 95% CI, -0.35 to -0.03, $P = 0.02$) and LPA ($\beta = -0.17$, 95% CI, -0.34 to -0.01, $P = 0.04$) were associated with smaller global switch costs, which indicated that higher levels on MVPA and LPA were associated with better task switching performance. Longer time spent on smartphone use was associated with worse scores on depression ($\beta = 0.31$, 95% CI, 0.15 to 0.47, $P < 0.001$), anxiety ($\beta = 0.29$, 95% CI, 0.13 to 0.45, $P < 0.001$) and sleep quality ($\beta = 0.29$, 95% CI, 0.14 to 0.44, $P < 0.001$). No other significant associations were observed.

CONCLUSIONS: Participation in physical activity was associated with better performance on a test of executive function. Longer time on smartphone use was associated with worse scores on depression, anxiety and sleep quality. Therefore, interventions targeting college students should be developed to increase physical activity and reduce smartphone use.

High Intensity Interval Training Is Associated With Decreased Negative Affect In Individuals With Anxiety Disorders

Vincenzo Lauriola¹, Kathleen M. McIntyre¹, Yael Stovezky², Tse-Hwei J. Choo², Abby Fyer², Rene Hen², Blair Simpson², Richard P. Sloan¹. ¹*Columbia University, New York, NY.* ²*New York State Psychiatric Institute, New York, NY.*
 Email: vl2286@cumc.columbia.edu
 (No relevant relationships reported)

INTRODUCTION: Exercise has been shown to reduce negative affect (NA) in people with anxiety.

PURPOSE: To investigate associations between 2 heart rate (HR)-derived indices of exercise volume and change scores on NA measures using a novel high intensity interval training (HIIT) protocol administered at home with remote coaching in people with anxiety disorders.

METHODS: In a pilot study, eleven insufficiently active people (Chester Step Test estimated baseline $VO_{2peak} 33.18 \pm 5.89$ ml·kg⁻¹·min⁻¹) diagnosed with an anxiety disorder and State-Trait Anxiety Inventory (STAI) score > 44 performed a 6-week, 4 days/week HIIT program using a stepper machine. Each session included 8 to 12-minutes of HIIT (20/40 sec ratio - target HR 85% of estimated maximal HR) and data were uploaded to a cloud server. Questionnaires were collected at baseline, 3, and 6 wks. Continuous HR was recorded, producing an HR curve. Amount of exercise was computed as the sum (AUC_s) and average (AUC_a) area under these HR curves above the baseline resting HR. For each combination of the 6 clinical outcomes (STAI, Depression, Anxiety, and Stress Scales and Quality of Life Questionnaires) and 2 AUC measures, nonparametric correlations were calculated and adjusted by Bonferroni correction for multiple comparisons (significant if $p < .0014$). Correlations were calculated for change scores from baseline to wk 6, baseline to wk 3, and wk 3 to 6.

RESULTS: 2 males and 9 females aged 25.05 ± 2.82 years, BMI 23.95 ± 4.27 completed the study. Adherence was 88%. AUC_s and AUC_a in the first 3 wks were negatively associated with wk 3-baseline change in state anxiety ($r = -.95$, $p < .0001$ and $r = -.84$, $p < .0014$ respectively), indicating that patients with greater volume of exercise experienced greater state anxiety reductions over the same period. AUC_s and AUC_a

variance explained 90.25% and 70.56% of the variance in state anxiety change over the same period, respectively. Correlations between AUC indices and other NA measures also were negative but nonsignificant, possibly due to small sample size.

CONCLUSIONS: AUC indices were significantly and inversely associated with changes in state anxiety from baseline to wk 3 and the remaining outcomes showed nonsignificant associations in the predicted directions. HIIT could be a promising intervention to reduce NA in anxiety disorders.

Examination of Eating Disorder Risk among Female College Athletes and Performers

Allison B. Smith¹, Toni M. Torres-McGehee¹, Samantha R. Weber¹, Dawn M. Emerson², Kelly Pritchett³. ¹University of South Carolina, Columbia, SC. ²University of Kansas, Lawrence, KS. ³Central Washington University, Ellensburg, WA.
 (No relevant relationships reported)

The demands of being a female college athlete/performer may create mental and physical stress that may increase the likelihood of eating disorders and disordered eating. **PURPOSE:** The overall purpose was to examine the prevalence of Eating Disorder (ED) risk among female college athletes/performers across academic status and sport type (equestrian, volleyball, beach volleyball, women's soccer, softball, and ballet). **METHODS:** Data from a larger cross sectional was used. A convenience sample of NCAA Division I female athletes/performers (n=127; age: 19.8±2.0 years; weight: 63.6±9.2 kg, height: 163.9±28.8 cm) from a University in the southeastern region of the United States participated in the study. Participants completed a basic demographic survey, the Eating Disorder Inventory-3 (EDI-3), and the EDI-3 Symptoms Checklist (SC). Basic descriptive stats were used for demographic information. Cross-tabulations were used to examine the proportion of participants classified as "at risk for EDI-3 and EDI-3 SC" across sport and academic status. **RESULTS:** Significant differences [X²(15, N=127) = 25.2, P=0.04] were found between the distribution of ED risk and sport with 18.9% (n=24) at risk for EDI-3; 29.9% (N=38) EDI-3 SC, and 31.5% (n=40) were at risk for both EDI-3 and EDI-3 SC. Overall, pathogenic behaviors revealed: 52.8% (n=66) dieting, 13.6% (n=17) exercise 50-100% of the time to lose weight, 20% (n=25) binge eating, 13.6% (n=17) purging, 4.0% (n=5) laxatives, 7.2% (n=9) diet pill use, and 1.6% (n=2) use diuretics. A significant difference between dieting and sport [X²(5, N=125) = 12.2, P=0.03] was found with the highest prevalence within equestrian (16%, n=20/28) and ballet (13.6%, n=17/29). Sport type and exercise to control weight more than 50-100% of the time was significantly different [X²(20, N=125) = 54.1, P<0.01] with the highest prevalence within equestrian (10.4%, n=13/29). **CONCLUSIONS:** Athletes in the college setting are at risk for eating disorders. Medical professionals such as athletic trainers who work within this setting need to be educated on the potential risk factors that can lead to EDs. There should be a referral process in place for those athletes who are at risk. Those involved in the screening, prevention, and treatment of at-risk athletes should understand the sensitive nature of the topic.

The Relationship Between Physical Activity, Sleep Quality, and Subjective Well-being in College Students

Zhanjia Zhang¹, Zhonghui He², Weiyun Chen¹. ¹University of Michigan, Ann Arbor, MI. ²Peking University, Beijing, China.
 (No relevant relationships reported)

While previous studies have well documented the beneficial effects of physical activity (PA) and sleep quality on mental disorders (e.g., depression and anxiety), relatively few have explored their relationship with subjective well-being (SWB), which is a core construct in positive psychology and is linked with various health outcomes. **Purpose:** To examine the associations between the PA, sleep quality, and SWB in college students while controlling for gender and age. **Methods:** 726 college students (41.1% female, mean age = 19.28 years) voluntarily completed a set of questionnaires assessing the life satisfaction (Satisfaction with Life Scale), happiness (Subjective Happiness Scale), positive affect and negative affect (Scale of Positive and Negative Experience), walking, moderate-intensity PA (MPA), and vigorous-intensity PA (VPA; International Physical Activity Questionnaires), and sleep quality (Pittsburgh Sleep Quality Index). Four multiple regression models were performed with happiness, life satisfaction, positive affect, and negative affect as the outcome variables, respectively. Walking, MPA, VPA, and sleep quality were predictor variables for each model. Age and gender were controlled in each model as covariates. **Results:** The regression models indicated that the predictors significantly explained the variance for each outcome with R² being 15.68% for life satisfaction, 19.43% for happiness, 22.32% for positive affect, and 24.81% for negative affect (p's < 0.001). Higher levels of VPA were associated with higher levels of life satisfaction (β = 0.09, p = 0.008), happiness (β = 0.26, p < 0.001), and positive affect (β = 0.13, p < 0.001), and lower levels of negative affect (β = -0.10, p = 0.003). However, MPA and walking were associated with none of the outcome variables (p's > 0.05). This emphasized the importance of the intensity of physical activity in advancing SWB. Better sleep quality

was associated with higher levels of life satisfaction (β = 0.37, p < 0.001), happiness (β = 0.36, p < 0.001), and positive affect (β = 0.43, p < 0.001), and lower levels of negative affect (β = -0.47, p < 0.001).

Conclusion: For college students, better sleep quality and regular participation in VPA are beneficial for SWB while increased levels of walking and MPA might not be helpful in improving SWB.

Patterns of Physical Activity and Mental State Among College-Aged Men and Women

David Bellar¹, Ben Kern¹, Lawrence W. Judge², Gregory R. Davis¹. ¹University of Louisiana at Lafayette, Lafayette, LA. ²Ball State University, Muncie, IN.
 Email: dbellar@louisiana.edu
 (No relevant relationships reported)

PURPOSE: Increasingly, mental health is a concern among young adults. It is known that physical activity can improve mental health. The present investigation sought to examine the associations of physical activity on mental health by sex. **METHODS:** Eighty-one young adults (20.5±1.5 years) took part in the investigation. The participants underwent body fat percentage assessment and completed the Depression, Stress and Anxiety Scale (DASS 21) and the Leisure and Physical Activity Survey (LPA). Data were analyzed for associations between sex, physical/sedentary activities, body composition and mental health via multiple linear regression analysis. **RESULTS:** Female participants (n=49) reported less weightlifting exercise (p<0.001, 55% 0-2 days, 41% 3-5 days, 4% 6-7 days) compared to males (23% 0-2 days, 61% 3-5 days, 16% 6-7 days); however, no significant sex differences were noted for aerobic exercise. Physical activity by sex was regressed against scores from the DASS 21. Significant interactions were noted between sex and min/day of aerobic exercise (F=6.26, p=0.003) and days/week engaged in weightlifting exercise (F=5.46, p=0.006) for anxiety. In contrast to males, females engaged in higher numbers of weight training sessions and reported increased anxiety (0-2 days: 5.33±4.28; 3-5 days: 5.65±5.51; 6-7 days: 7.50±9.19). Whereas increasing time of aerobic exercise among females was associated with lower anxiety (0-15 min per session: 12.5±5.0; 16-30 min per session: 4.65±4.74; >30 minutes per session: 4.47±2.87), male students who engaged in more days per week of weight lifting exercise reported lower levels of anxiety (0-2 days: 10.00±5.88; 3-5 days: 4.52±2.98; 6-7 days: 3.6±3.21). **CONCLUSIONS:** For college-aged females, a focus on time engaged in aerobic exercise may produce not only cardiovascular benefits, but also psychological, and encouraging resistance exercise among college males may have similar results. University and college communities should encourage different patterns of exercise for male and female students to reduce anxiety.

Moderate and Intense Exercise not Modify Anxiety Scores but Promote Different Affective Answers in Adults

Cyro G. Borges, Marcos Mônico-Neto, Sergio Tufik, Hanna K. M. Antunes. Universidade Federal de São Paulo, UNIFESP, Santos, Brazil.
 Email: cyroborges@hotmail.com
 (No relevant relationships reported)

It is well known that moderate exercise can positively modulate mood states; however, few studies have shown the effects of intense exercise. **PURPOSE:** Compare the impact of moderate and intense exercise on anxiety, affective and positive subjective experience answers in healthy adults. **METHODS:** Ten healthy male subjects (28.70±6.25yrs; 72.51±10.68kg; 175±4.38cm; 23.60±2.66kg/m²; 16.56±6.38%Fat mass), were submitted to two intensities based on maximal treadmill test separated by 7 days: 1) 60%; 2) 85%. For these conditions, the subjects answered a Subjective Exercise Experiences Scale (SEES) and IDATE-State scale in the following time-courses: baseline (B), immediately after (IA) and 30 minutes after (R) finishing of the exercise. The Feeling Scale (FS) was recorded at 1, 5, 10 and last minutes of exercise. The situations were compared by two-way ANOVA with post-hoc Duncan test, with significance p<0.05. The protocol was approved by Unifesp Ethics Committed (#2.381.537). **RESULTS:** We didn't observe differences in anxiety comparing groups or time-courses, however, SEES Positive well-being subscale show lower scores at IA during 85% when compared with 60% (19.90±2.23vs17.40±2.95; p=0.02). The increase of fatigue was observed at B when compared IA in 60% (6± 3.83vs11.10±7.64; p=0.01). Similar data was observed in 85%, with increase in B when compared to IA (8.80±6.39vs14.40±7.41; p=0.006) and remain higher at R (p=0.03). The FS on 60% show a significant decrease at last minute compared to 1 (p=0.0002), 5(p=0.002) and 10(p=0.009) minutes; on 85%, similar data was observed. The last minute was lower when compared to 1 (P<0.001), 5 (p<0.001), 10 (p<0.001); but the 10 minute was

WEDNESDAY, MAY 29, 2019

lower compared to 1 ($p < 0.001$) and 5 ($p < 0.001$). When comparing intensities 60% showed higher scores at the FS at the 10 ($p < 0.001$) and the last minute ($p < 0.001$) compared to 85%.

CONCLUSIONS: The comparison between the exercise intensities show that, there was no difference between anxiety scores, on the other hand, moderate exercise presented better IA well-being response, faster fatigue recovery and maintained affectivity with positive values indicating pleasure from the beginning to the end of the test.

Impact of Wearing Graduated Compression Stockings on Psychological and Physiological Responses during Prolonged Sitting

Yukari Horiuchi¹, Yoko Handa Kirihara², Masahiro Horiuchi².
¹Kyushu Sangyo University, Fukuoka, Japan. ²Mt. Fuji Research Institute, Fuji-yoshida, Japan.
 Email: yhuriuti@ip.kyusan-u.ac.jp
 (No relevant relationships reported)

PURPOSE: Links between a prolonged sitting and increased risk of cardiovascular diseases or poor mental health have been found. A usage of compression garment may have some potential psychological and physiological benefits during prolonged sitting.

METHODS: We investigated the impact of with or without wearing graduated compression stockings on psychological and physiological responses in 18 healthy young people (12 men and six women) during 3 h prolonged sitting. Heart rate (HR) was measured throughout the sitting time, and heart rate variability (HRV) was analyzed to evaluate sympathetic and para-sympathetic nerve activity at pre, 1h, 2h, and 3h during the sitting for 5-min each. To assess psychological stress-related variables, Profile of Mood States (POMS) and saliva cortisol were evaluated before and after 3 h sitting. Visual analogue (VAS) scale was also assessed for whole body and lower limbs uncomfortable feelings.

RESULTS: POMS scores did not show marked differences between with and without stockings. A 3 h sitting significantly decreased saliva cortisol in both conditions ($P < 0.05$) with no differences between conditions (0.263 ± 0.108 mg dl⁻¹ vs. 0.189 ± 0.075 mg dl⁻¹ without stockings at pre vs. post; 0.267 ± 0.100 mg dl⁻¹ vs. 0.186 ± 0.081 mg dl⁻¹ with stockings at pre vs. post). Wearing stockings suppressed a subjective uncomfortable sensation (e.g., pain; swelling) in the lower limbs assessed by VAS (58.2 ± 23.3 mm without vs. 39.3 ± 24.4 mm with stockings, $P < 0.001$). HR at 1 h and 3 h was significantly greater without than with stockings (77 ± 8 bpm without vs. 74 ± 6 bpm with stockings at 1h, and 80 ± 9 bpm without vs. 75 ± 6 bpm with stockings at 3h, $P < 0.05$, respectively). High-frequency oscillations (0.15-0.4 Hz) showed higher values with than without stockings throughout the 3 h sitting period, and it was significantly higher at 1 h (229 ± 169 m sec without vs. 324 ± 251 m sec with stockings, $P < 0.05$). When data for both conditions were pooled, pre-to-post changes in saliva cortisol were positively associated with higher VAS in the lower limbs and negatively associated with changes in the Vigor subscale of POMS ($P < 0.05$, respectively).

CONCLUSIONS: These findings suggest that wearing graduated compression stockings may benefit from subjective comfort and increased parasympathetic nerve activity.

420 Board #258 May 29 11:00 AM - 12:30 PM
Psychosocial Mechanism of Adolescents' Physical and Mental Health: A Self-Determination Health Behavior Perspective

Tao Zhang¹, Xiangli Gu², Scott Martin, FACSM¹. ¹University of North Texas, Denton, TX. ²University of Texas at Arlington, Arlington, TX.
 Email: TAO.ZHANG@UNT.EDU
 (No relevant relationships reported)

PURPOSE: Research indicates that adolescents' health can be promoted by satisfying their basic psychological needs through a supportive social environment in school physical education (PE; Ryan & Deci, 2017). Guided by the Self-Determination Health Behavior Model (SDHBM; Ryan et al., 2008), this study aimed to examine the relations among perceived need support (i.e., autonomy support, competence support, and relatedness support), need satisfaction (i.e., autonomy, competence, and relatedness), physical health (i.e., physical fitness [PF]), and mental health (i.e., health-related quality of life [HRQOL]) among adolescents. The mediation models were conducted to specify relations among psychosocial processes toward PE, adolescents' PF and HRQOL, respectively. **METHODS:** A prospective correlational design was used across one academic school year. Participants were 198 adolescents (58.6% female; $M_{age} = 12.63$) recruited from three schools in the south region of the U.S. At the beginning of school year, participants completed previously validated questionnaires assessing their perceived need support and need satisfaction toward PE. At the end of school year, they self-reported their HRQOL using the PedsQL™ inventory, which included measures of physical, emotional, school, and social functioning. Finally, FitnessGram® test battery was used to measure their PF including body composition,

aerobic fitness, and muscular fitness. **RESULTS:** Correlation analysis revealed positive associations among the study variables (r s ranged from .19 to .83). Using structural equation modelling (AMOS 22.0), the hypothesized model resulted with a good fit to the data ($\chi^2/df = 130.46/61$; IFI = .93; RMSEA = .076; 90% CI [.058, .094]). The need support had a direct influence on need satisfaction ($\beta = .79$, $p < .01$), and need satisfaction had a direct contribution on PF ($\beta = .23$, $p < .05$). The psychosocial process from need support to need satisfaction had no direct influence on HRQOL, but had an indirect influence through PF ($\beta = .34$, $p < .01$). **CONCLUSION:** The findings supported the theoretical tenets of SDHBM in adolescents, particular on their physical health. Creating a need-supportive environment in PE is critical in order to enhance adolescents' need satisfaction, which ultimately indirectly influence their HRQOL.

421 Board #259 May 29 11:00 AM - 12:30 PM
Differences in Depressive Symptoms across Physical Activity Levels Based on Comorbid Anxiety and Depression Status

Chloe Forte, Cillian P. McDowell, Ciaran MacDonnacha, Matthew P. Herring. University of Limerick, Limerick, Ireland.
 (No relevant relationships reported)

Research supports inverse associations between physical activity (PA) and depressive symptoms and status among adolescents. However, the degree to which comorbid anxiety and depression status may influence relations of PA with depressive symptoms is unknown. **PURPOSE:** This study investigated differences in depressive symptoms across low, moderate, and high PA frequencies among adolescents with no anxiety or depression, anxiety-only, depression-only, and comorbid anxiety and depression. **METHODS:** Adolescents (N=481; 200 female) aged 15.1±1.7y self-reported PA frequency (modified PACE+); low, moderate, and high PA were classified as engaging in ≥ 60 mins of PA 0-2, 3-4, and ≥ 5 /wk, respectively. Depressive symptoms were assessed with the Quick Inventory of Depressive Symptomatology (≥ 6 indicated depression status). The Trait subscale of the State-Trait Anxiety Inventory assessed trait anxiety (≥ 50 indicated high trait anxious status). Two-way ANCOVA examined variation in depressive symptoms according to the interaction of PA and comorbid anxiety and depression status. Covariates were age, sex, rural or urban residence, and school sex-type (i.e., female only, male only, or mixed sex). Bonferroni-adjusted simple effects analysis decomposed significant interaction. **RESULTS:** The two-way interaction between PA and comorbid status was statistically significant ($F_{(6,385)} = 4.69$, $p < 0.001$, $\eta_p^2 = 0.07$). Depressive symptoms were significantly lower among those with comorbid anxiety and depression with moderate PA compared to low PA (mean difference = -2.29, $p \leq 0.007$) and high PA (mean difference = -2.65, $p \leq 0.003$). Depressive symptoms were significantly higher for comorbid anxiety and depression compared to depression-only for those engaged in low PA (mean difference = 3.73, $p < 0.001$) and high PA (mean difference = 3.40, $p < 0.001$), and non-significantly higher among those engaged in moderate PA (mean difference = 1.26, $p > 0.30$). This finding may be due partly to the smaller number of comorbid anxiety and depression participants with moderate PA (22 vs. 48). **CONCLUSIONS:** Depressive symptoms differed across PA levels based on comorbid anxiety status. Though the exact role of comorbid anxiety is not clear, it may be important to consider relative to relations of PA with depressive symptoms among adolescents.

Improving Acute Exercise Prescription In Depression: Predictors Of Optimal Intensity For Improving Depressive Mood

Gabriel Cruz-Maldonado¹, Maria Perez¹, Jeni E. Lansing¹, Laura D. Ellingson, FACSM¹, Dane Cook, FACSM², Jacob D. Meyer¹.
¹Iowa State University, Ames, IA. ²University of Wisconsin-Madison, Madison, WI.
 Email: gacruz@iastate.edu
 (No relevant relationships reported)

Overall mood improves following acute exercise for people with major depressive disorder (MDD), yet it is unclear how to maximize this effect. Determining factors that predict what the most beneficial intensity of exercise is for an individual could lead to prescriptions that maximize the positive effects of each session potentially leading to increased exercise participation. **PURPOSE:** To explore potential factors influencing the most effective exercise intensity for improving mood in individuals with MDD. **METHODS:** Women with MDD (n=24) were prescribed 20-minute sessions of light (L), moderate (M), and hard (H) intensity exercise (rating of perceived exertion: 11, 13, 15, respectively) in a counterbalanced, within-subject design. The most effective session was defined as the one resulting in the greatest reduction in depressive mood (measured via depression subscale of Profile of Mood States) from pre- to post-exercise for each participant [L (n=10), M (n=9), and H (n=5)]. Potential individual factors related to these effects were age, body mass index (BMI), objectively measured minutes of total daily moderate to vigorous physical activity as well as weekly physical activity in bouts ≥ 10 min, and total sedentary time and prolonged sedentary time

(PSED; time in bouts ≥ 30 min). Kruskal-Wallis tests compared all groups for each predictor, with the Dunn test and effect sizes (Cohen's *d*) comparing each group pair (L:M, M:H, L:H). **RESULTS:** Potential predictive factors did not differ significantly based on group (all $p > 0.05$). However, effect sizes showed large differences for L:H comparisons in: PSED (pairwise $p = 0.021$; $d = -1.23$), age ($d = 1.08$), and BMI ($d = 0.81$). While effect sizes comparing L or H to M were smaller, PSED, age and BMI generally followed a linear pattern L-M-H. **CONCLUSIONS:** While there were no overall differences across groups, effect sizes indicated that light intensity led to the greatest improvement for people who were younger, had lower BMI, or spent more hours in PSED, while hard exercise was most beneficial for the reverse (i.e. older, high BMI, low PSED). The large effect sizes in the present sample suffering from MDD suggest personal characteristics may influence the affective response to acute exercise, yet more research is required to determine the reliability and magnitude of these effects.

423 Board #261 May 29 11:00 AM - 12:30 PM
Impact of a Simulated Workday of Sit-stand Desk Use on Sleep Among Adults Screened as High Risk for Sleep Apnea

Christopher E. Kline¹, Robert J. Kowalsky², Sophy J. Perdomo³, Patrick J. Strollo¹, Bethany Barone Gibbs¹. ¹University of Pittsburgh, Pittsburgh, PA. ²Texas A & M University-Kingsville, Kingsville, TX. ³University of Kansas Medical Center, Kansas City, KS.
 Email: chriskline@pitt.edu
 (No relevant relationships reported)

Exercise improves sleep and reduces apnea severity in adults with obstructive sleep apnea (OSA). However, whether reducing sedentary behavior impacts sleep and apnea severity is unknown. **Purpose:** To examine whether reducing prolonged sitting during a simulated workday by use of a sit-stand desk leads to changes in sleep compared to a sedentary workday in a sample of adults at high risk for OSA. **Methods:** Eight inactive adults (5 males, 53.8 \pm 8.5 yr, body mass index: 29.8 \pm 5.5 kg/m²) who were classified as 'high risk' for OSA based upon the STOP-BANG screening algorithm participated in a randomized crossover trial consisting of two simulated 8-h workdays: (1) continuous sitting (SIT); and (2) alternating periods of sitting and standing every 30 min (SIT-STAND). Sleep and apnea were assessed on the night following each simulated workday by wrist-worn actigraphy and a portable OSA testing device, respectively. Actigraphic measures of total sleep time (TST) and wake after sleep onset (WASO) served as the primary sleep variables, while the apnea-hypopnea index (AHI) assessed OSA severity from the OSA testing device by a blinded assessor. Natural logarithm transformation of AHI was performed due to non-normality. Effect sizes (Hedges' *g*) and Pearson correlations evaluated differences in sleep following each condition and associations between changes in sleep measures, respectively. **Results:** In the full sample, trivial improvements in WASO ($g=0.16$) and TST ($g=0.03$) were observed following SIT-STAND compared to SIT. In contrast, a small increase in AHI (i.e., worsening of OSA) was observed following SIT-STAND compared to SIT ($g=0.31$). The change in AHI was associated with the change in actigraphic WASO ($r=.63$, $P=.09$). Four of the 8 adults had clinically significant OSA (i.e., mean AHI ≥ 10 across conditions). Among those with clinically significant OSA, large increases in WASO and AHI were seen following SIT-STAND relative to SIT ($g=1.16$ and 0.89, respectively). In those without significant OSA, small- to moderate-sized reductions in WASO and AHI were observed following SIT-STAND compared to SIT ($g=0.68$ and 0.30, respectively). **Conclusion:** Following sedentary behavior reduction during a simulated workday, changes in sleep and apnea seemed to differ based upon the presence of clinically significant OSA.

 (No relevant relationships reported)

Effectiveness of Short-Term Yoga Interventions for Stress of College Students: A Meta-analysis

Liwen Ju, Weimo Zhu (FACSM), Hai Yan, Zhenglun Wang
Purpose:

To determine the effectiveness of yoga interventions for the stress management of college students using a meta-analysis.

Methods:

Key words, such as "yoga," "stress," "college students", etc. were searched in a number of databases such as PubMed/Medline, Scopus, Cochrane Library, PsycINFO, Webscience and Google through Dec., 2018. Only randomized controlled trials of yoga

based stress interventions for college student were included for the meta-analysis. Risk of bias the studies were independently assessed by two of the authors using the Risk of Bias Tool by the Cochrane Back Review Group. Effectiveness of Yoga intervention was determined by computing standardized mean differences (SMD), in which the difference in the means of pre- and post-test difference between groups was divided by the pooled standard deviations.

Results:

12 studies (Total college students = 763, Male%=16.64, Intervention length = 8.79 \pm 3.96 wk.) were included in the final analysis. Main outcomes included self-reported anxiety, depression, stress, as well as objective measures of heart rate and blood pressure. The yoga interventions were found effective in reducing anxiety, depression, stress and heart rate:

| | Anxiety | Depression | Stress | Heart Rate |
|--------|-----------------|-----------------|-----------------|-----------------|
| SMD | -0.995, | -1.708 | -0.953 | -1.623 |
| 95% CI | [-1.762 -0.227] | [-2.005 -1.412] | [-1.707 -0.199] | [-2.911 -0.334] |
| P | 0.011 | 0 | 0.013 | 0.01 |

Due to the paucity and heterogeneity of the researches, the long-term effects could not be examined.

Conclusion:

Short-term yoga intervention has been found effective in helping the stress management of college students. Studies with longer intervention, with a comparison with other exercise mode, are needed

Key Words: stress, yoga, college students, meta-analysis, review

 (No relevant relationships reported)

Several aspects could influence mental and physical components of subjective quality of life perceptions. In particular, healthy diet and physically active lifestyles could play a crucial role for successful aging and sustainable quality of life in advancing years. **PURPOSE:** To determine the mediating effects of energy expenditure (EE) and intake (EI), body composition (BC) and dissatisfaction (BD) on the relation between age and health and quality of life perception. **METHODS:** 42 senior athletes, 55 physically active, and 61 sedentary adults (aged 55-85 years) were submitted to anthropometric (body mass, height - Body Mass Index [BMI]), weekly energy expenditure (EE), and dietary intake (EI) evaluations, and administered Body Image Dimensional Assessment (BDI), Short Form Health Survey - Physical (PCS) and Mental Component Summary (MCS) questionnaires. Two serial multiple model mediation analyses were applied to assess whether mechanisms involving diet-related and physical activity-related personal characteristics and behaviors (4 mediators: EE, EI, BMI, BDI) mediated the relation between age and PCS or MCS health-related quality of life perception. **RESULTS:** Only for MCS the mediation analysis showed: a) a direct effect of age on MSC ($c'=0.31$, $p=0.002$; CI(95%)=0.12; 0.50); b) a mediation path by EE, EI, BMI, and BDI (-0.0027, Bootstrap CI(95%)=-0.0105; -0.0002); and c) a positive total effect ($c=0.22$, $p=0.02$; CI(95%)=0.04; 0.39). **CONCLUSIONS:** The combination of positive and negative effects throughout the mediation path of mental health perception of older individuals underlined that the maintenance of adequate level of physical activity could influence the body image and, in turn, positively impact mental health with advancing age. Supported by MIUR Grant 2010KL2Y73

Cardiorespiratory Fitness Moderates the Relation Between Years of Drug Use and Stress in Drug Abusers

Daniel A. Cabral, Vagner Deuel Tavares, Kell Grandjean Da Costa, Eduardo Bodnariuc Fontes. Federal University of Rio Grande do Norte, Natal, Brazil.
 Email: daniel_aranha13@hotmail.com
 (No relevant relationships reported)

Substance use disorders (SUD) have increased worldwide and is currently a major global issue. In SUD, stress is linked to drug-seeking behaviors and greater rates of relapse. Physical activity has been related with increased self-esteem, mood and reduced stress levels in SUD. However, it remains unclear whether the relation between the time of drug use over the years and stress might be under influence

of cardiorespiratory capacity. **PURPOSE:** This study investigated whether cardiorespiratory fitness has a moderate function over the relation between years of drug use and stress levels. **METHODS:** Sixth-two male SUD individuals (34.17 ± 8.82 years; 24.62 ± 2.91 m/kg²) have participated in the study. We took a collection of measures in one visit including: (1) anthropometric measures of height and weight to compute BMI; (2) self-reported demographics and drug use history, including years of drug use, days of abstinence, and number of hospitalizations; (3) a questionnaire to measure negative emotional states; and (4) a shuttle run test to estimate the maximum consumption of oxygen (VO_{2max}). For this study, we tested a moderation analysis using the Macro PROCESS plugin for SPSS (Model 1), in which the independent variable was the years of drug use, the dependent variable was stress levels and the moderator was VO_{2max}. The moderation analysis was adjusted for age, days in abstinence, BMI and number of hospitalizations. **RESULTS:** It was found that VO_{2max} moderates the relation between years of drug use and stress levels ($\beta = -0.82$, $p = 0.03$, 95% confidence interval (-0.15 to -0.007)). The conditional effect at each level of the moderator (one SD below the mean, at the mean and one SD above the mean) showed that for those individuals with lower VO_{2max} the negative relation between years of drug use and stress was not significant ($\beta = -0.23$, $p > 0.05$), for those with an average VO_{2max} it was significant ($\beta = -0.81$, $p = 0.04$) and for those with higher VO_{2max} the relation was even more significant ($\beta = -2.03$, $p < 0.01$). **CONCLUSION:** For those SUD individuals with an average and higher VO_{2max}, the negative relation between years of drug use and stress is more pronounced. Therefore, fitness level seems to have a protective effect over stress in SUD individuals, which may minimize the chances of relapse and enhance the rehabilitation process.

Identifying Mental Health Risks through Screening among Collegiate Ethnic-Minority Athletes
 Samantha R. Weber, Toni M. Torres-McGehee, Allison Smith.
University of South Carolina, Columbia, SC.
 (No relevant relationships reported)

Ethnic minority student-athletes are under immense amounts of pressure to perform, meet academic requirements for scholarships, and maintain relationships with peers, coaches, and parents. A change in stressors can cause physiological disturbances and mental health disorders such as depression (DEP), eating disorders (ED), low self-esteem (LSE) and body image dissatisfaction (BID). **PURPOSE:** To examine the prevalence of DEP, ED, LSE, and BID in ethnic minority student-athletes. A secondary purpose examined mental health risks across sex, academic status, and sport type. **METHODS:** Student-athletes ($n = 274$) were recruited from multiple Ethnic Minority Universities to participate in an online study. Demographic information, Center for Epidemiologic Studies Depression Scale. Eating Attitudes Test. Rosenberg Self-Esteem Scale, and Standard Figural Stimuli were completed. **RESULTS:** Overall prevalence was 31.8% for DEP, 18.1% for ED, and 8.4% for LSE. Chi-square analysis revealed no significant differences between mental health risks and sex, academic status and sport type. A 2 sex (female, male) x 2 clothing type (daily clothing, competitive uniform) x 2 perceptions (perceived, desired) repeated measures ANOVA indicated a main effect ($P \leq 0.01$) with significant interactions for perceptions ($F_{1,208} = 4.586$, $P < .033$, $n_2 = .022$) and perceptions by gender interactions ($F_{1,208} = 7.384$, $P < .007$, $n_2 = .034$). Body image results revealed female athletes desired to be smaller than their perceived image in both daily clothing and uniforms, whereas males desired to be larger. A 2-sex x 3 meta-perceptions (peers, parents, coaches) x 2-perceptions repeated measures ANOVA indicated a main effect ($P \leq 0.01$) with significant interactions between perceptions by gender ($F_{1,208} = 5.896$, $P < .016$, $n_2 = .028$), meta-perceptions by perceptions ($F_{1,208} = 2.382$, $P < .001$, $n_2 = .037$), and perceptions by meta-perceptions and gender ($F_{1,416} = 4.923$, $P < .009$, $n_2 = .023$). **CONCLUSIONS:** Although no significant associations were found for gender, academic status or sport type, both male and female athletes demonstrated a high risk of DEP, ED, BID, and a lower risk for LSE. Future research is necessary to further examine mental health risks, screening, prevention strategies, and intervention in ethnic minority student-athletes.

428 Board #266 May 29 11:00 AM - 12:30 PM
Prevalence of Low Self-esteem and Weight Pressures among Collegiate Male Athletes
 Nicole C. Pruchnik, Toni M. Torres-McGehee, Allison B. Smith, Samantha R. Weber, Eva Monsma. *University of South Carolina, Columbia, SC.*
 (No relevant relationships reported)

Previous studies have examined mental health disorders in female athletes, but very few have examined the prevalence of signs and symptoms of sub-clinical mental health conditions (i.e., low self-esteem [LSE], and weight pressures [WP]) in male athletes. Understanding these sub-clinical mental health conditions may aid in preventing mental health disorders.

Purpose: Examine the prevalence of low self-esteem (LSE) across academic status and the effects LSE on weight pressures (WP) in sport among male collegiate athletes.

Methods: As part of a larger study, collegiate male athletes ($n = 238$; age: 19.7 ± 1.3 years; males: $n = 234$, height: 184.3 ± 7.5 cm, weight: 91.5 ± 19.4 kg) were recruited over a 3-year period from a NCAA Division I Institution. Demographic information (e.g., age, self-reported height, self-reported weight, ideal weight, mental weight, sex, academic status, and sport type), the Rosenberg's Self-Esteem scale, and the Weight Pressures in Sports-Males surveys were collected via SurveyMonkey. Cross tabulations and chi square analyses examined the relationship and distribution of general weight pressures, LSE and WP risk and academic status. One way ANOVA examined LSE risk and WP Total score and subscales.

Results: A total of 95 athletes (39.9%) reported feeling pressure to change their weight and/or eating habits for their sport and 18.5% ($n = 44$) revealed they felt pressured to meet a target weight with routine weigh ins. More specifically, athletes wanted to weigh 2.4 ± 4.1 kg more than their current weight. Overall, Prevalence of LSE for all male athletes was 9.4% ($n = 22$). No differences were found between academic status and prevalence of LSE, WP total score, Coach/Teammate Pressure subscale and Appearance Pressure subscale. Significant differences were found between Coach/Teammate Pressure subscale and LSE prevalence (LSE risk: 2.4 ± 1.1 vs. Not at Risk: 2.6 ± 0.86 ; $P = 0.019$).

Conclusion: Although there was a relatively low number of male athletes at risk for LSE, male athletes still displayed weight pressures for their sport. Healthcare professionals working with male athletes need to be aware of these sub-clinical mental health concerns to ensure that prevention and treatment can occur before the onset of issues such as eating disorders and depression.

 (No relevant relationships reported)

There are a multitude of factors that contribute to cardiovascular (CV) health. Psychosocial factors contribute to CV risk, and anxiety is one of the psychological disorders diagnosed in CV patients. It is unclear whether there is a potential relationship between inflammation and anxiety.

PURPOSE: 1) To compare CV health between Caucasian (C) and Mixed-Race (MR) adults, and 2) to explore the relationship between anxiety levels and CV health measures across these populations. This pilot study is the first step in our clinical trial to investigate the relationship between anxiety measures and CV risk factors across racial differences. **METHODS:** Thirty-two young adults (C: $N = 16$, 22.94 ± 7.4 ; MR: $N = 16$, 22.813 ± 7.51 yrs) underwent 2 test visits. First, CV health was assessed by fasting glucose, lipids, blood pressure (BP), carotid artery intima media thickness (IMT), body fat (BF) measured by bioelectrical impedance, and flow-mediated dilation (FMD). At the second visit, ECG, clinic BP and VO_{2max} were measured. Anxiety measurements using the DASS-21 scale are ongoing. **RESULTS:** Pilot data on physiological outcomes show no differences between groups. Compared to C adults, the adults in MR group show a small trend towards having worse CV profiles. In the MR group, we found higher levels of cholesterol (156.4 ± 27.2 vs. 144.2 ± 36.6 mg/dL), BF (31.1 ± 9.7 vs. 28 ± 9.2 %), and lower levels of FMD (7.1 ± 4.3 vs. 8.7 ± 4 %) and VO_{2max} (42.95 ± 8.8 vs. 38.65 ± 10.6 ml/kg-min). Within groups, we found significant ($p < 0.05$) race-related relationships between several variables. In C, we found an inverse relationship between IMT and HDL ($R = -0.654$). In MR, we found an inverse relationship between BF and FMD ($R = -0.832$), BF and HDL ($R = -0.836$), and BF and VO_{2max} ($R = -0.741$). Also, we found direct relationships between BF and glucose ($R = 0.834$) and BF and DBP ($R = 0.751$). Data from DASS-21 is being analyzed between groups. **CONCLUSION:** We found relationships with BF in the MR group that did not exist in the C group. Considering that literature suggests that young adults of color tend to have higher levels of anxiety, we hypothesize that we will find relationships between anxiety and CV measures in the MR group that are different than that in the C group.

Effect Of Aerobic Exercise On Depression In Rats: Role Of Mitophagy

Lu Wang, Yingying Lv, Wenqian Deng, Xue Li, Yu Jin. *Chengdu Sports Institute, Chengdu, China.* (Sponsor: Tongjian You, FACSM)

(No relevant relationships reported)

Abstract:

Depression is a common health problem and a major cause of agrypnia and disability. Recent evidence supports an anti-depressive effect of aerobic exercise on unpredictable chronic mild stress (UCMS)-induced depression in rats; however, the biological mechanism remains to be investigated.

Purpose: To investigate whether aerobic exercise could improve UCMS-induced depression and alter mitophagy in depressive rats.

Method: Thirty-six male Sprague-Dawley rats were randomly divided into three groups: a control group (Con, n=12), a UCMS-induced depression group (UCMS, n=12), and a UCMS-induced depression plus aerobic exercise group (UCMS+E, n=12). After 4 weeks of UCMS stimulation, rats in the UCMS+E group carried out 3 weeks (60 min/day) of swimming exercise. A sucrose preference test (SPT) was performed, and the content of 5-hydroxytryptamine (5-HT) was measured to verify whether the depression model was successful. A Morris water maze (MWM) test was used to evaluate spatial learning and memory ability. The expression levels of mitophagy-related proteins (Beclin1, LC3-I, LC3-II and P62) were determined by Western blot. Statistically significant group differences were assessed by using one-way ANOVAs and post-hoc tests.

Results: Based on the change of sucrose consumption and the expression level of 5-HT following UCMS treatment, the depression model was successfully established in the rats. Spatial learning and memory ability were lower in the UCMS group than the Con group (both $p < 0.05$), but improved in the UCMS+E group (both $p < 0.05$). According to the Western blot results, the expression levels of Beclin1 (Con: 0.37 ± 0.02 , UCMS: 0.26 ± 0.04 , UCMS+E: 0.43 ± 0.07) and P62 (Con: 0.34 ± 0.03 , UCMS: 0.20 ± 0.02 , UCMS+E: 0.31 ± 0.05), as well as the LC3-II/LC3-I ratio (Con: 0.36 ± 0.05 , UCMS: 0.19 ± 0.04 , UCMS+E: 0.33 ± 0.04) were significantly lower in the UCMS group than the Con group (all $p < 0.05$), but were significantly higher in the UCMS+E group than the UCMS group (all $p < 0.05$).

Conclusion: This study suggests that rats with UCMS-induced depression presented alterations in mitophagy. Three weeks of aerobic exercise significantly up-regulated mitophagy in depressive rats. Therefore, mitophagy may play an important role in the biological mechanism underlying the anti-depressive effect of aerobic exercise.

Exercise And Physical Activity Promotion Improves Cardiorespiratory Fitness, Symptoms Of Disease And Well-being In Patients With Schizophrenia

Mirko Brandes¹, Sirka Ginsel², Christian Figge³, Alexandra Philipsen⁴. ¹Leibniz Institute for Prevention Research and Epidemiology, Bremen, Germany. ²Oldenburg University, Oldenburg, Germany. ³University Hospital for Psychiatry and Psychotherapy, Oldenburg, Germany. ⁴University Hospital for Psychiatry and Psychotherapy, Bonn, Germany.

Email: brandes@leibniz-bips.de

(No relevant relationships reported)

Patients suffering from Schizophrenia (SZ) show low fitness, a sedentary lifestyle and comorbidities like diabetes and cardiovascular diseases, resulting in 20 years less of life expectancy.

Purpose: To evaluate the impact of an intervention combining exercise and physical activity promotion (PAP) on cardiorespiratory fitness (CRF), severity of SZ, symptoms of disease and well-being.

Methods: 35 patients were randomized into an intervention (n=19, aged 39.0 ± 13.6 years, BMI 28.3 ± 7.3) or control group (n=16, aged 36.0 ± 9.3 years, BMI 25.7 ± 5.2), directly after inpatient treatment for SZ. Intervention included two sessions of high intensity indoor cycling (IC; each 45min), and one session of PAP (60min) per week for three months. In months 4-6, the intervention was reduced to one session IC and one session PAP per week. The control group received a physiologically ineffective control intervention. Measurements were conducted at baseline (t0), after three (t1)

and 6 months (t2) of intervention, and after 12 months (six-month follow up, t3). Measurements included CRF (bicycle ergometry), severity of SZ (PANSS-Score), well-being (SF-36), and psychological distress (SCL-90).

Results: The intervention improved significantly severity of SZ (t0: 55.4 ± 16.3 , t2: 34.8 ± 3.3 , $p < .05$), well-being (t0: 50.4 ± 10.1 , t2: 60.5 ± 7.1 , $p < .05$) and psychological distress (t0: 159 ± 47.4 , t2: 119.8 ± 34.3 , $p < .05$). For CRF, patients were able to improve their physical capacity, expressed as W/kg (t0: 1.85 ± 0.6 , t2: 2.13 ± 0.6 , $p < .05$), but did not significantly improve their peak oxygen uptake, expressed as ml/min/kg (29.0 ± 7.0 , t2: 30.5 ± 8.7 , n.s.). Six month after the intervention, only improvements in severity of SZ, well-being and psychological distress remained statistically significant (PANSS: 38.0 ± 9.0 , SF-36: 59.2 ± 8.0 , SCL-90: 119.2 ± 36.6 , all $p < .05$).

Conclusion: Exercise and PAP significantly improves CRF, severity of SZ, well-being and psychological distress in SZ patients. Effects on CRF are declining shortly after the end of the intervention. We recommend the implementation of exercise and PAP into the post-acute care of SZ patients. Moreover, it is necessary to further strengthen the sustainability of effects with respect to CRF, in order to prevent fall-backs and health detriments caused by low physical fitness.

432 Board #270 May 29 11:00 AM - 12:30 PM
Fitness, Fatness And Survival In Older Adults With Intellectual Disabilities. Which One Is Key?

Alyt Oppewal¹, Thessa Hilgenkamp². ¹Erasmus MC, University Medical Center Rotterdam, Rotterdam, Netherlands. ²University of Illinois, Chicago, IL.

Email: a.oppewal@erasmusmc.nl

(No relevant relationships reported)

Older adults with intellectual disabilities have very poor physical fitness levels. Additionally, overweight and obesity are highly prevalent in this population, even more prevalent than in the general population. Both fitness and fatness have been found to be related to survival in the general population. To improve healthy ageing and survival of older adults with intellectual disabilities we need to know which problem requires our main focus. **PURPOSE:** To determine whether fitness or fatness is more important for survival in older adults with intellectual disabilities. **METHODS:** As part of the Healthy Ageing and Intellectual Disabilities (HA-ID) study, fitness (comfortable gait speed) and fatness (Body Mass Index) of 874 older adults with intellectual disabilities (≥ 50 years; 61.4 ± 7.8 years) was measured at baseline. All-cause mortality was collected over a 5-year follow-up period. The relationship between fitness, fatness, and survival was analysed with Kaplan-Meier curves and Cox proportional hazard models. **RESULTS:** Fitness was significantly related to survival (HR = 0.21, 95% CI = 0.09 - 0.48, $p < 0.001$), while fatness was not related to survival. People who were unfit and fat were 4.6 (95% CI = 2.0 - 10.7) times more likely to die, and people who were unfit and not fat were 3.6 (95% CI = 1.7 - 7.5) times more likely to die within the follow-up period, than people who were fit, regardless of their fatness. **CONCLUSIONS:** Being fit is key for survival in older adults with intellectual disabilities. Our results therefore do not support the emphasis seen in research and practice on reducing weight. The focus should primarily be on improving the fitness of older adults with intellectual disabilities to improve healthy ageing and survival.

433 Board #271 May 29 11:00 AM - 12:30 PM
The Effect Of Moderate-intensity Physical Activity On Biopsychosocial Factors Among Veterans With Symptoms Of Ptsd

Michelle Bateman¹, Jamie C. Clark². ¹Oklahoma State University, Stillwater, OK. ²University of Central Oklahoma, Edmond, OK.

(No relevant relationships reported)

Physical activity has been shown to have a positive impact on biopsychosocial variables among individuals who may be experiencing symptoms related to PTSD.

PURPOSE: The purpose of this study was to evaluate the impact of a moderate-intensity physical activity regimen on aerobic endurance, barriers to accessing health care, and symptom severity of PTSD among military veterans. **METHODS:** Participants of this study (n=4) engaged in a 4-week physical activity regimen that met two times per week. The dependent variables were aerobic endurance, measured with the Cooper 12 Minute Walk test, barriers to accessing health care, measured with the BACE, and symptoms of PTSD, measured with the PCL-5. **RESULTS:** Descriptive statistics and a paired samples *t*-test were utilized to analyze data. There were statistically significant differences for all dependent variables at the post-assessment level, indicating statistically significant improvements in the PCL-total score ($p = .032$), BACE-total score ($p = .043$), BACE-stigma score ($p = .032$), VO_{2max} ($p = .014$), and METS ($p = .014$). **CONCLUSION:** Researchers concluded that a moderate-intensity physical activity regimen may be effective at improving aerobic endurance, perceived barriers to accessing health care, and symptom severity of PTSD among military veterans. Future studies should aim to increase sample size and utilize a laboratory grade assessment for capturing changes in VO_{2max} and METS. Additionally, future

research should aim to investigate the dose-response effect on dependent variables based on varying physical activity intensity levels, duration of intervention, and the duration of acute bouts of physical activity.

Exercise Is Medicine And Could Improve Your Gpa

Bia R. Pandelo, Domingos R. Pandelo, Jr. *Centro de Alta Performance, Santos, Brazil.*

Email: biaroch@gmail.com

(No relevant relationships reported)

Purpose: The aim of this study is to evaluate the impact of physical activity (PA) on academic performance. Several studies have already confirmed the importance of physical activity for the life quality and health. Several health problems can be avoided with the regular practice of PA, which is why it can be said that "exercise is medicine". The question in this work is to seek key points in order to evaluate whether PA positively impacts academic activity. Will the practice of PA bring a positive impact on academic performance, will it entail a higher grade point average (GPA)? The final objective will be to present a framework with potentially impacting variables, within an physiological elements.

Methods: An initial research was done on academic bases to raise academic articles on the subject. The base consulted was PubMed. Keywords used were physical activity and academic performance. There was no concern in evaluating studies relating PA and health, because we assumed such a relationship as true in this review.

Summary of Results: From a physiological standpoint there are some important studies showing the impacts on cognitive and motor functions coming from the practice of PA. Through a dynamic interaction, regular PA can lead to a cerebral capillary growth, with the increase in blood flow and oxygenation. The growth of nerve cells in the hippocampus, that have a great function as a center of memory and learning, is another important effect of PA. The production of neurotrophins and the development of new connections, with the increase of density of neural network could have a positive impact in attention, cognition and academic performance.

Conclusion: There are good reasons to be physically active. Including reducing developing heart disease and diabetes, for example. So, it's possible to say: Exercise is medicine. It's a good point you can be health, lose weight, lower your blood pressure. But, maybe we have another one great reason to be physical active. Some studies show us that physical activity can improve academic performance and it's great. You can be health, fell better and improve your GPA.

Effects of Alternative Treatments on Behavioral Outcomes In Patients with Mild Cognitive Impairment, Alzheimer's Disease and Dementia: A Comprehensive Summary of Evidence and Meta-analysis

Kate Yzquierdo, Anna Ivashchenko, Zung V. Tran. *MedAware Systems, Inc., Broomfield, CO.*

Email: kjendersee@medawareystems.com

(No relevant relationships reported)

Purpose: Mild cognitive impairment, Alzheimer's disease (AD) and dementia are associated with onset behavioral disturbances such as depression, psychosis, and anxiety. These ailments affect overall outcomes, decrease quality of life, and are primarily treated with antidepressants. However, there are additional therapies available to alleviate and mitigate these onset disturbances. Based on published clinical data, this comprehensive review and meta-analysis evaluates the effects of alternative therapies and treatments on behavioral outcomes in patients with mild cognitive impairment (MCI), mild or moderate AD, and dementia. **Methods:** We applied novel clinical data extraction and aggregation technologies developed by MedAware Systems, Inc. It is a patent-pending process where two scientists, blinded to each other, extract data from the same study. Intelligent software compares each data field for matches (or mismatches). A senior scientist reconciles data mismatches. Where pre- and post-treatment outcomes are available, a standardized mean difference is calculated as the MedAware Standardized Index of treatment effect (MSI-E). This methodology was used to examine differences in efficacy and behavioral outcomes among the alternative treatments (supplements, therapy and counseling, exercise, education and training, and rehabilitation) to identify efficacious treatments for behavioral outcomes.

Results: A total of 89 studies reporting anxiety and depression outcomes in patients with MCI, AD or dementia were located. There were no significant differences in MSI-E among treatments. Cognitive and behavioral showed the most efficacy (MSI-E = 0.023 ± 0.002). Among alternative treatment categories, there were no significant differences, with rehabilitation showing the most efficacy (MSI-E = +0.254 ± 0.063), and exercise showing the least (MSI-E = -0.105 ± 0.013). **Conclusions:** Using the MedAware Systems, Inc. literature database and meta-analytic methodology, we found that rehabilitation therapy may decrease anxiety and depression, while exercise has almost no effect. Overall results for alternative therapies were not significant. Because the number of studies within each therapy is small, additional research on alternative therapies is warranted.

Supported by MedAware Systems, Inc.

Mental Health in First Responders and Military Personnel: Is Physical Activity A Viable Option?

Allyson G. Box, Steven J. Petruzzello, FACSM. *University of Illinois Urbana-Champaign, Urbana, IL.* (Sponsor: Steven J. Petruzzello, FACSM)

(No relevant relationships reported)

Mental Health (MH) is a growing concern among first responders and military personnel, with a relatively large percentage presenting with disorders. However, many avoid or remove themselves from treatment, which may be related, in part, to treatment stigmas. **PURPOSE:** Compare physical health (PH) and MH stigmas, and explore whether physical activity is a viable option for treatment. **METHODS:** The Perceived Stigma and Barriers to Care for Psychological Problems and Self Stigma of Seeking Help questionnaires were provided through an online survey, along with researcher developed questions regarding physical activity behavior. Separate paired-samples *t*-tests were used to compare PH versus MH treatment stigmas, and descriptive statistics were used to denote interest in physical activity for mental health treatment. **RESULTS:** First responders and/or military personnel ($N = 35$; 36.2 ± 11.6 yrs; 80% male) currently residing in the United States completed the survey. When comparing PH and MH, differences ($P < 0.001$) were observed between perceived (PH=1.99; MH=2.56) and self-stigmas (PH=2.17; MH=2.52). The majority (91.4%) of participants indicated interest in using physical activity for MH improvement. Additionally, 29 participants (82.9%) indicated they would be more willing to undergo physical activity as a treatment mechanism for MH than traditional methods (e.g., medication, psychotherapy). **CONCLUSIONS:** This study expands upon previous stigma literature by emphasizing the discrepancies between physical and mental health stigmas. Additionally, these findings suggest physical activity as a viable option to circumnavigate MH stigmas in first responders and military personnel.

(No relevant relationships reported)

Purpose: Global cognitive function is associated with increased physical activity, physical frailty is associated with increased risk of Alzheimer's disease (AD), and can predict future cognitive decline in adults. We performed an exhaustive literature review and meta-analysis of the effects of physical activity on cognitive functions in adults with AD and dementia, based on the published clinical data. **Methods:** We applied novel clinical data extraction and aggregation technologies developed by MedAware Systems, Inc. It is a patent-pending process where two scientists, blinded to each other, extract data from the same study. Intelligent software compares each data field for matches (or mismatches). A senior scientist reconciles data mismatches. Where pre- and post-treatment outcome data are available, standardized mean differences are calculated as the MedAware Standardized Index of treatment effect (MSI-E). This methodology is used to capture the published literature, with physical activity as the intervention, reporting cognitive functions as outcomes, in AD patients. **Results:** A total of 2,201 studies were screened for possible inclusion. 34 studies reported the use of some form of physical activity interventions, such as aerobic exercise (9 studies), other types of physical activity (23 studies), and strength training (5 studies) in AD and dementia patients, and were included in the meta-analysis. Instruments such as the ADAS-cog and the MoCA measured cognitive outcomes. Overall, there appears to be little to no cognitive decline over time (MSI-E = 0 indicates no change) in the aerobic exercise group (MSI-E = -0.08 ± 0.003), other physical activity group (MSI-E = -0.015 ± 0.001), and a slight improvement in the strength training group (MSI-E = +0.016 ± 0.005). **Conclusions:** Using the MedAware Systems, Inc. literature database and meta-analytic methodology, we found that physical activity appears to mitigate cognitive declines in AD and dementia patients, with strength training having a small beneficial effect. Although these findings are based on a small number of studies in each physical activity category, results of this meta-analysis should provide investigators with evidence to further explore the use of physical training in AD and dementia patients.

Supported by MedAware Systems, Inc.

Depression and Fitness Level in College Students Attending a Diverse University
 Sharon Jalene, Jennifer Pharr, Brach Poston. *University of Nevada Las Vegas, Las Vegas, NV.*
 Email: sharon.jalene@unlv.edu
 (No relevant relationships reported)

PURPOSE: The purpose of the study was to determine the association between estimated cardiorespiratory fitness (eCRF) and moderate to severe depression (MS_DEP) in college students. The relationships between MS_DEP and age, sex, race, sexual/gender orientation, and grade point average (GPA) were examined.

METHODS: This cross-sectional study occurred at a public university via electronic survey. Participants (n=438) reported their age, height, weight, race, sex, sexual orientation, GPA, resting heart rate, exercise habits (frequency, intensity, and duration), and completed the Patient Health Questionnaire (PHQ-9), a standard depression survey. A validated regression model (Nes et al., 2011) was used to calculate eCRF (ml/min/kg). The difference between eCRF and age-predicted CRF was used for analyses. Chi square and independent t-tests determined differences in demographic characteristics between students who reported MS_DEP and students who reported no depression. For odds ratio analyses, MS_DEP was dichotomized (yes/no) and fitness was categorized as FIT (reference), LOW-FIT, and HIGH-FIT. The reference (FIT) represented those with eCRF within +/- 1, LOW-FIT was <1, and HIGH-FIT >1 of their age-estimated CRF.

RESULTS: Chi square analyses indicated fit individuals (=> age-predicted CRF) were less likely than unfit (< age-predicted CRF) to have MS_DEP (36.4% vs. 63.6% respectively) (P = 0.02). Belonging to a sexual gender minority (SGM) (P <0.01) or to the Hispanic race (P=0.04) were also significant for MS_DEP. T-tests revealed that individuals who reported depression were more likely to be younger (P=0.04) or have a lower GPA (P<0.01) than those who reported no depression. Odds ratio analyses found that those with LOW-FIT were 2.39 times more likely to report MS_DEP when compared with the reference (95% CI=1.17-4.87). HIGH-FIT compared with FIT was not significant.

CONCLUSION: Students with low fitness are at a higher risk for depression. However, fitness above age-predicted CRF did not decrease susceptibility indicating that an age-appropriate level of fitness is sufficient to reduce depression risk. Also, Hispanic, SGM, and younger students may be more vulnerable. Those with depression have a lower GPA. Estimated CRF could provide a simple method to identify students at-risk for depression.

Comparison Between Pilates And Home-exercises On Health-related Outcomes In Individuals With Chronic Low Back Pain
 Caroline Ribeiro Tottoli, Yara Marques, Katharina Mascarenhas, Lais Medeiros, Isabela Costa, Elaine Oliveira, Everton Nunes, Wagner Martins, Rodrigo Luiz Carregaro. *Universidade de Brasilia (UnB), Brasilia, Brazil.*
 (No relevant relationships reported)

Chronic non-specific low back pain (CNLBP) is a major cause of disability and absenteeism. Pilates is commonly adopted in the treatment of CNLBP, though the evidence is controversial. Low-cost interventions such as home-exercises are prominent and considered effective to improve disability. **Purpose:** To compare the efficacy of Pilates and home-exercises on disability and utility (health states). **Method:** Randomized controlled trial with blind assessor. Thirty-one participants with CNLBP for at least 12 weeks were randomly assigned to the Pilates (PT; n=16) or Home-Exercise (HE; n=15) groups. Allocation was concealed. The intervention lasted 6 weeks (two times/week), and 4-months follow-up. The PT was composed by fifty-minutes sessions (seven to ten exercises; two sets of 8 to 12 repetitions). The HE was composed by prescribed postural, muscle stretching and strengthening exercises (booklet, instructions to perform 2 times/week, weekly monitored by text message). Disability was measured by the Quebec Back Pain Questionnaire. The score ranges from no disability (0) to worst disability (100). Health states were measured by the EQ-5D-3L (mobility, self-care, usual activities, pain/discomfort, anxiety/depression; final utility score ranging from 0 to 1). A linear mixed-model was used to analyze the global effect over time and separate effects at baseline, post-intervention and follow-up. Significance was set at 5%. **Results:** No significant differences were found between PT vs HE (global effects). Both groups showed a significant improvement only for disability (post-intervention and follow-up, compared to baseline). **Conclusion:** Both PT and HE were effective and improved the disability of individuals with CNLBP. However, the utility was not influenced by the interventions.

Table. Effects of PT (Pilates) and HE (Home Exercises)

| Disability | PT | HE | Effects | |
|-------------------|-------------|-------------|---------------------|---------|
| | Mean (ste) | Mean (ste) | B (CI95%) | P-value |
| Baseline | 26.6 (2.9) | 28.0 (2.9) | - | - |
| Post-intervention | 11.9 (3.2) | 13.3 (3.0) | -14.7 (-20.8; -2.0) | <0.02 |
| Follow-up | 15.2 (4.3) | 16.6 (4.6) | -11.4 (-21.4; -7.9) | <0.01 |
| Global Effect | n.a | n.a | -3.3 (-10.0; 3.2) | 0.3 |
| Utility | | | | |
| Baseline | 0.60 (0.04) | 0.61 (0.04) | - | - |
| Post-intervention | 0.67 (0.05) | 0.68 (0.04) | 0.06 (-0.003; 0.13) | 0.06 |
| Follow-up | 0.62 (0.05) | 0.63 (0.06) | 0.02 (-0.08; 0.13) | 0.6 |
| Global Effect | n.a | n.a | -0.01 (-0.13; 0.11) | 0.8 |

Do Pilates And Home-exercises Improve Balance And Kinesiophobia Of Individuals With Low Back Pain?
 Rodrigo Luiz Carregaro, Caroline Tottoli, Yara Marques, Katharina Mascarenhas, Lais Medeiros, Isabela Costa, Elaine Oliveira, Wagner R. Martins, Everton Nunes. *Universidade de Brasilia (UnB), Brasilia, Brazil.*
 Email: rodrigocarregaro@unb.br
 (No relevant relationships reported)

Chronic non-specific low back pain (CNLBP) is the main cause of years lived with disability, and can be associated with strength deficits and postural instability. Pilates exercises are deemed to be useful in the management of CNLBP and improvement of outcomes such as flexibility and postural control, though evidence is controversial. **Purpose:** To compare the efficacy of Pilates and home-exercises on kinesiophobia and postural balance. **Method:** Randomized controlled trial with blind assessor and concealed allocation. Thirty-one participants of both sexes, with CNLBP for at least 12 weeks were randomly assigned to Pilates (PT; n=16) or Home-Exercise (HE; n=15) groups. PT group was composed by sessions of fifty-minutes (seven to ten exercises; two sets of 8 to 12 repetitions). The HE was prescribed to the participants (characterized by general exercises - postural, muscle stretching and strengthening) within a booklet, and they were instructed to exercise 2 times/week, weekly monitored by text messaging. The intervention lasted 6 weeks (two times/week). Outcomes were assessed on baseline, post-intervention and after 4-months follow-up. Kinesiophobia was measured by the Tampa Scale. The score ranges from 17 to 68 (higher scores meaning a worse fear of moving). Balance was measured by the limits of stability (challenge to move and control the center of gravity within the base of support). A linear mixed-model was used to analyze the global effect over time and separate effects at baseline, post-intervention and follow-up. Significance was set at 5%. Dropouts were included by multiple imputation. **Results:** No significant differences were found between PT vs HE (global effects). Likewise, no separate effects were found for balance and kinesiophobia. **Conclusion:** An intervention of Pilates and home-exercises did not improve the balance and kinesiophobia.

Table. Effects of PT (Pilates) and HE (Home Exercises)

| Kinesiophobia | PT | HE | Effects | |
|-------------------|------------|------------|-------------------|---------|
| | Mean (ste) | Mean (ste) | B (CI95%) | P-value |
| Baseline | 42.7 (1.9) | 42.2 (2.0) | - | - |
| Post-intervention | 38.7 (2.3) | 38.2 (2.3) | -3.9 (-8.1; 0.2) | 0.06 |
| Follow-up | 38.8 (3.0) | 38.3 (3.1) | -3.8 (-10.6; 2.9) | 0.2 |
| Global Effect | n.a | n.a | 0.51 (-4.3; 5.3) | 0.8 |
| Balance | | | | |
| Baseline | 52.4 (4.2) | 55.9 (4.3) | - | - |
| Post-intervention | 57.3 (4.6) | 60.8 (4.6) | 4.9 (-3.3; 13.1) | 0.2 |
| Follow-up | 56.0 (5.7) | 59.4 (5.8) | 3.5 (-8.8; 15.9) | 0.5 |
| Global Effect | n.a | n.a | -3.4 (-13.5; 6.6) | 0.5 |

Effect Of Core Strength Training On Dysfunction And Rehabilitation Of Patients With LBP
 Yushi Hu. *ChengDu Sport Institute, ChengDu, China.*
 Email: 603457104@qq.com
 (No relevant relationships reported)

PURPOSE: To observe the effect of core strength training on dysfunction and rehabilitation of patients with chronic low back pain.

METHODS: 120 patients diagnosed as LBP in the affiliated sports hospital of Chengdu Sport Institute are divided into core strength training group, regular gymnastics group and general treatment group (40 in each) by using randomized, controlled, single-blind experimental methods. The patients in the first group (group A) use basic treatment (acupuncture, massage, TDP irradiation) and core strength training. Basic treatment and gymnastics training are applied for the patients in the second group (group B), while basic treatment is used for the third group (group C). All the trainings continue 8 weeks. Spss 19.0 is used for statistics analyses. Efficiency, VAS score, JOA score are tested before treatment, 3 and 8 weeks after treatment. The overall scores before and after treatment are measured, the efficiency is calculated by Redit analysis.

RESULTS: 106 patients participate the whole process and the baseline data before intervention are basically the same. After intervention, all the indicators have changed as follows: 1.Efficiency: The total effective rate is 94.1% in group A, 88.6% in group B, 86.5% in group C. There is a significant difference between group A,B and C by Redit analysis($P<0.01$). There is no difference between group B and C ($p>0.05$). 2.VAS score: There is no significant difference before intervention. After intervention, the VAS scores are reduced significantly. The score of group A decreased by 4.68 points, 3.77 points in group B and 3.81 points in group C. There is a significant difference in three groups ($p<0.01$), while there is no significant difference between group B and C($p>0.05$). The difference indicates that the improvement of this index in group A is better than others. 3.JOA score: There is no significant difference before intervention. The average of group A decreased by 6.74 points, 4.34 points in group B, 4.16 points in group C. After 8 weeks, there is a significant difference between group A and B and C ($p<0.01$). There is no significant difference between group B and C($p>0.05$).

CONCLUSIONS: After 8 weeks intervention, basic treatment and core strength training can significantly improve the dysfunction and rehabilitation of patients with pain and activity limitation.

442 Board #280 May 29 11:00 AM - 12:30 PM
Dose-related Effects of Moderate Intensity Walking Exercise on Sensitivity to Pain in Healthy Humans
 Anna M. Polaski, Amy L. Phelps, Matthew C. Kostek, FACSM, Kimberly A. Szucs, Benedict J. Kolber. *Duquesne University, Pittsburgh, PA.*
 (No relevant relationships reported)

Increasing evidence implicates exercise as a front-line adjuvant therapy for the treatment of nearly all forms of chronic pain. Knowledge of efficacious dosing respective to exercise type and pain condition is extremely limited in the literature. This leaves both clinicians and patients less informed with regard to the best practice.

PURPOSE: To determine the optimal dose of moderate intensity treadmill walking necessary to reduce acute pain in healthy human participants. **METHODS:** After screening, 40 female participants (21.6±0.4 yrs) were pseudo-randomized into 1 of 4 groups: control (no exercise), low dose exercise (3x/wk), moderate dose exercise (5x/wk) and high dose exercise (10x/wk). Over a 7-day period, participants performed moderate intensity walking on a treadmill during assigned exercise days (days 1-5). Quantitative measures of pain were measured at baseline (day 0), 5- and 30-min post intervention on days 1, 3, and 5 and 24 hrs post-final intervention session (day 6) via sensitivity thresholds to painful thermal stimulation and painful pressure stimulation. Subjects also rated the intensity and unpleasantness of both thermal and pressure stimuli qualitatively on a visual analog scale (VAS). **RESULTS:** One-way ANOVA revealed a significant analgesic effect of treatment for constant pressure pain intensity ($F_{3,36}=6.2, p<0.01$) and constant pressure pain unpleasantness rating ($F_{3,36}=6.4, p<0.01$) as measured by VAS. Tukey post-hoc tests showed significant differences between the control and moderate dose groups (157.6±20.8 vs. 49.6±6.9%baseline, $p<0.01$) and control and high dose groups (157.6±20.8 vs. 67.3±25.8%baseline, $p<0.01$) for constant pressure pain intensity rating and significant differences between control and moderate dose groups (127.9±19.3 vs. 46.6±9.4%baseline, $p<0.01$) and control and high dose groups (127.9±19.3 vs. 46.6±14.6%baseline, $p<0.01$) for constant pressure pain unpleasantness rating. **CONCLUSION:** In healthy adults, we have identified a dose response of exercise-induced analgesia. Our study suggests that a low dose of exercise is insufficient to induce analgesia. The moderate dose of exercise may be an appropriate starting dose for exercise-based adjuvant pain therapy. Future studies include applying these results and techniques in chronic pain groups.

The Efficacy of Qigong on the Main Symptoms of Fibromyalgia. A Randomized Clinical Trial
 Caio Vinicius M. Sarmento, Taylor Pfeifer, Sanghee Moon, Mehrdad Maz, Sue Min Lai, Yvonne Colgrove, Irina V. Smirnova, Wen Liu. *The University of Kansas Medical Center, Kansas City, KS.*
 Email: cmessiassarmiento@kumc.edu
 (No relevant relationships reported)

Some of the most debilitating symptoms of fibromyalgia (FM) include widespread chronic pain (WCP), sleep disturbances (SD) and chronic fatigue (CF) all that negatively impact health status (HS) in individuals with FM. Yet, there's a lack of effective self-management exercise interventions capable of alleviating FM symptoms.

PURPOSE: To examine the efficacy of a 10-week daily practice qigong program on WCP, SD, CF, and HS in individuals with FM. **METHODS:** 20 individuals with FM were randomly assigned to one of two groups with participants blinded to the intervention allocation. The experimental group learned, and practiced mild body movements synchronized with deep diaphragmatic breathing and meditation. The control group learned and practiced only the mild body movements (same movements as the experimental group). Both groups were asked to practice the interventions for 10-week, two times per day at home plus one weekly group practice with a qigong instructor. Clinical assessments collected at baseline and upon completion of the intervention were: Short-Form McGill Pain Questionnaire, a visual analog scale for pain graded from 0 (no pain) to 10 (worst possible pain), Pressure Pain Threshold measured by a dolorimeter, the Pittsburgh Sleep Quality Index and the Revised Fibromyalgia Impact Questionnaire. WCP score comparisons were made using MANOVA. SD, CF and HS were compared with *t*-tests. **RESULTS:** The experimental group experienced greater clinical improvements when compared to the control group with the mean scores differences of WCP, SD, CF, and HS all being statistically significant at $p<.05$. Within group analysis revealed that the experimental group improved WCP by 35% ($p<.01$), SD by 34% ($p<.01$), CF by 30% ($p<.05$) and HS by 31% ($p<.01$). The control group only presented significant improvement in HS by 21% ($p<.05$). **CONCLUSION:** Daily practice of Qigong might have a positive impact on the main FM symptoms that is beyond group interaction and solely mild exercise.

Effect Of Core Strength Training On Efficiency, Core Strength Of Patients With LBP
 Siqi Song¹, Yushi Hu², Xiaorui Zhang². ¹*ChengDu Sport Institute, Chengdu, China.* ²*ChengDu Sport Institute, ChengDu, China.*
 Email: 840426078@qq.com
 (No relevant relationships reported)

PURPOSE: To observe the effect of core strength training on rehabilitation and core strength of patients with chronic low back pain.

METHODS: 120 patients diagnosed as LBP in the affiliated sports hospital of Chengdu Sport Institute are divided into three groups by using randomized, controlled, single-blind experimental methods. The patients in the first group (group A) use basic treatment (acupuncture, massage, TDP irradiation) and core strength training. Basic treatment and gymnastics training are applied for the patients in the second group (group B), while basic treatment is used for the third group (group C). All the trainings continue 8 weeks. Spss19.0 is used for statistics analyses. Efficiency analysis, VAS score and core strength are tested before treatment, after 3 and 8 weeks of treatment. The efficiency is calculated by Redit analysis.

RESULTS: 106 patients participate the whole process and the baseline data before intervention are basically same, and there is no difference in three groups. After 8 weeks training, all the test indicators have changed as follows: 1.Efficiency: The total effective rate is 94.1% in group A, 88.6% in group B, 86.5% in group C. There is a significant difference between group A,B and C by Redit analysis($P<0.01$). There is no difference between group B and C ($p>0.05$). 2.VAS score: There is no significant difference before intervention. After intervention, the score of group A decreased by 4.68 points, 3.77 points in group B and 3.81 points in group C. There is a significant difference in three groups ($p<0.01$), while there is no significant difference between group B and C($p>0.05$). 3.core strength: the strength of group A has a significant improvement between three groups($p<0.01$). There is no significant difference in the ratio of extension/flexion strength, left/right flexural force($p>0.05$). After 8 weeks, The ratio of extension/flexion strength changes significantly in group A ($p<0.01$); the ratio of muscle strength in left/right curve shows that group A and B has significant differences ($p<0.05$) while highly significant difference C ($p<0.01$).

CONCLUSIONS: After 8 weeks intervention, basic treatment and core strength training can significantly improve the rehabilitation and the core strength, reduce pain and optimize the efficiency of LBP patients.

The Mapping Knowledge Analysis of Exercise Intervention for Drug Dependence Research at Home and Abroad
 Yuehui Zhou. *School of Sport Science, Qufu Normal University, Jining, China.*
 Email: mszyzh2006@126.com
 (No relevant relationships reported)

Based on the 542 articles with the theme of “exercise intervention and drug dependence” from 1991 to 2018 included in WOS core collection database, this study analyzed the annual output quantity, country/region, high-yield authors, subject distribution, high-frequency keywords, keywords time zone view, high-frequency classical literature, etc. by using CiteSpace, as a mean of visualization. The purposes of this study were to analyze structural characteristics, quantitative relation, research hotspots and evolution in the field of exercise intervention and drug dependence. Results: The number of publications on exercise intervention and drug dependence was on the rise. The United States, the United Kingdom and Canada were in the world leading position in the exercise intervention and drug dependence, and Shanghai University of Sport occupied the dominating position in China. Universities and hospitals were the important positions. The research involved several interdisciplinary subjects, such as neuroscience, drug abuse, public environment and occupational health, pharmacology and sports science, etc. The research hotspots focused on tobacco and alcohol-dependent population, mainly taking exercise intervention or physical activity as the independent variable, withdrawal symptoms, behavioral cognition, craving degree, health risk and other indicators as the dependent variable, with little research on drug dependence population, especially the optimal form and neural mechanism of exercise intervention were still unclear.

Title: Exercise as an adjuvant to Post- Acute Withdrawal Syndrome in Substance Use Disorder

The role of exercise to prevent SUD, and as a component of conventional treatment for SUD has been described before by others.

Purpose: Our study purpose was to explore the relationship between exercise and Post-Acute Withdrawal Syndrome symptomatology.

Study Design: 26 clients with documented history of SUD involving methamphetamine, heroin or both were enrolled in the study at a regional licensed behavioral healthcare facility outpatient recovery program. 17 male and 9 female clients ranging in age from 17-41 were enrolled. 13 were enrolled in traditional recovery plans (Counseling, recovery coaching, and 12 Step meetings), and 13 were enrolled in the exercise arm of the study which included structured resistance training, aerobic exercise along with the traditional recovery plan modalities. Study duration was 6 weeks.

The study specifically measured symptoms of Post-Acute Withdrawal at weeks 1-6 utilizing the Addiction Severity Index (ASI) and Post-Acute Withdrawal Symptom Index (PAWSI). The researchers utilized the indices by self-report surveys conducted at enrollment and at the end of weeks 1-6.

Results: By Week 6 symptom reduction (see table)

Discussion: Post-Acute Withdrawal syndrome is well described in early recovery from SUD and has been shown to be a significant factor in relapse. The role of dopamine depletion has been well described as the neurophysiologic correlate of Post-Acute Withdrawal Syndrome. The use of a structured exercise program including resistance training coupled with aerobic exercise can be a useful adjuvant to potentiate early recovery, reduce symptoms of Post-Acute Withdrawal Syndrome and to mitigate early relapse.

| Symptom Reduction By Week 6 | | | | | | |
|-----------------------------|--------------|-------|--------|------|---------------|-----------------------|
| PAWS Symptom | Restless Leg | Sleep | Energy | Mood | Concentration | Engagement in therapy |
| Conventional Arm | 30% | 17% | 22% | 26% | 15% | 25% |
| Exercise Arm | 55% | 43% | 76% | 71% | 46% | 80% |

Conclusion: Exercise significantly reduces the symptoms of Acute Post-Withdrawal Syndrome in clients with SUD, and is should be considered an important adjunct to treatment.

Physical Activity, Physical Function And Quality Of Life In Patients With Single And Multiple Chronic Diseases
 Fiona Skelly¹, Niall Moyna¹, Noel McCaffrey¹, Lisa Loughney¹, Kieran Dowd², Andrew McCarron¹, Mairead Cantwell², Brona Furlong¹. ¹Dublin City University, Dublin, Ireland. ²Athlone Institute of Technology, Westmeath, Ireland.
 Email: fiona.skelly2@mail.dcu.ie
 (No relevant relationships reported)

PURPOSE: An estimated 50 million people in the Europe live with multi-morbidity (MM). Research has found that those with MM have a greater risk of physical function (PF) decline and poorer quality of life (QoL) than those with a single chronic disease (SCD). The aim of this study was to compare the physical activity (PA) levels and sedentary behavior (SB) in patients with MM and SCD and to investigate the association between PA and PF and QoL. **METHODS:** Subjects (n=229, 54.4% female, age (mean±SD) 62.2±11.1 yr) were recruited at induction to a community-based exercise program for chronic disease. Medical history was obtained from a referral letter provided by a healthcare professional. Subjects with a single diagnosis of a chronic disease, primarily including cardiovascular, respiratory disease, cancer, diabetes, were classified as SCD. Participants with ≥2 of these diagnoses were classified as MM. BMI and waist to hip ratio (WHR) were measured and calculated using standard procedures. Upper and lower body strength, flexibility and cardiorespiratory fitness were assessed using a hand-grip test, sit-to-stand test (STS), sit and reach test (SRT), and 6-min time trial (6MTT), respectively. PA and SB were recorded using an activPAL³ micro accelerometer. QoL was assessed using the EQ5D VAS. Independent sample T tests were used to compare MCD with SCD on measures of PA, SB, PF and QoL. General linear models were used to investigate the association between PA and SB and PF and QoL.

RESULTS: 102 (44.5%) participants were defined as MM. Participants with MM had higher waking SB (9.3 ± 1.8 vs 9.9 ± 1.9 hrs/d, p=.013), lower MVPA (0.3 ± 0.2 vs 0.4 ± 0.2 hrs/d, p=.001) and daily step count (6185 ± 3016 vs 7270 ± 3196 steps/d, p=.009) compared with SCD. MM had higher BMI (31.6 ± 7.3 vs 28.0 ± 5.3 kg/m²), (p=.000 for all). MM achieved significantly poorer results for the STS (23.8 ± 9.6 vs 21.2 ± 7.3 s, p=.021) and 6MTT (453.3 ± 118.9 vs 514.4 ± 113.2 m, p=0.00). There were no differences between groups for WHR, SRT and QoL. MVPA was significantly related to weight, BMI, 6MTT, daily step count was related to STS, 6MTT and QoL and waking SB was related to WHR. **CONCLUSIONS:** Individuals with MM had greater SB and less PA than those with SCD. PF was poorer for individuals with MM. There were significant associations between PA with physical function and QoL in a CD population.

448 Board #286 May 29 11:00 AM - 12:30 PM
Physical Activity and Quality of Life: Using Exercise as Treatment in Primary Care
 Stefanie M. Meyer, Mary Larson, Joe Deutsch. *North Dakota State University, Fargo, ND.* (Sponsor: Donna J. Terbizan, FACS M)
 Email: stefanie.meyer@ndsu.edu
 (No relevant relationships reported)

Physical inactivity is linked to a reduced quality of life (QOL) and is more pronounced in those living with chronic health conditions. The use of exercise referral as a therapeutic treatment by healthcare providers may be an important clinical tool in improving QOL in the chronic disease population. **PURPOSE:** To explore differences in QOL and physical activity (PA) of patients who were medically referred to an exercise-as-treatment (EAT) program. Secondly, to explore factors that contribute to QOL.

METHODS: A Midwest healthcare system referred 213 chronic disease patients to an on-site EAT program. A total of 59 patients (64y ± 12; 64.4% female) responded to a follow-up survey that included the eight-scale RAND-36 item health questionnaire to assess QOL and the Physical Activity Vital Sign questions to determine average PA level in minutes per day. Respondents were categorized into 1) did not engage in the exercise program 2) engaged in up to two sessions 3) engaged in three or more sessions. ANOVA was conducted to test for between-group differences, Pearson correlations between QOL and exercise visits, independent samples t-test for influence of PA behavior on general health QOL, and forward selection to explore a model to best inform general health QOL.

RESULTS: No significant differences were found between exercise visit categories, QOL scales, and PA. Number of exercise visits was found significantly negatively correlated with emotional well-being QOL (r = -.350, p<.01) and with pain QOL (r = -.326, p<.01). A significant difference was found (SF-36 score) in general health QOL for patients who met the PA guideline of 150 minutes per week (M=68.81, SD=22.299) versus those who did not meet the guideline (M=53.71, SD=17.382); t(54)=2.827, p=.007. Forward selection chose social functioning, energy, minimal role limitations due to physical health, and PA minutes as contributors to patient general health QOL with adjusted R²=.714 (p=.004).

WEDNESDAY, MAY 29, 2019

CONCLUSIONS: Results support the positive influence of exercise behavior on QOL. Using the healthcare system to assess PA behavior, such as including exercise as a vital sign, is a strategy that will enable providers to refer and deliver an EAT approach. Future research should include comparison of PA behavior as well as exercise program visits with specific chronic diseases and QOL.

Effects Of Cooled Compression Exercise Technology On Health, Sleep, And Quality Of Life In Veterans.

Chloe Wernecke¹, Pat Marques², Grove Higgins², Sara Webb², Lindsay Haughton², Liz Grimm², Mary Wilson², Aaron Black², Cristian Torres¹. ¹Vaspar Systems, Moffett Field, CA. ²Colorado Springs Center for Human Performance and Rehabilitation, Colorado Springs, CO. (Sponsor: 7960, FACSM)
 (No relevant relationships reported)

Veterans are disproportionately affected by physical and emotional functional disorders compared to their civilian counterparts, a discrepancy that is deepened by delay to care within the Veterans Health Administration. Research has supported use of compression exercise in physically limited populations and demonstrated physiological responses at lower intensities (10-20% one repetition maximum vs 70% for hypertrophy in resistance exercise). Combination of low-pressure compression exercise and cooling has shown elevated growth hormone and testosterone and depressed nighttime cortisol, indicating this may be beneficial for addressing emotional and sleep dysfunctions.

PURPOSE: To determine the safety and efficacy of an accessible cooled compression exercise system on markers of physical and emotional function in veterans.

METHODS: 14 veterans completed 24 sessions in 12 weeks. Baseline and endpoint questionnaires validated for clinical significance were administered to determine sleep quality (Pittsburg Sleep Quality Index), quality of life (RAND Short Form 36), and respiratory dysfunction related to stress and anxiety (Nijmegen Questionnaire).

RESULTS: Two-tailed T-tests were performed on the data. Sleep quality improved in 71% of subjects (9.15±6.87 vs 5.57±3.74, $p = 0.0232$), 57% improved quality of life (73.45±17.17 vs 84.46±9.27, $p = 0.0316$), and 71% decreased adverse respiratory symptoms (11.29±8.38 vs 7.86±6.26, $p = 0.0594$) compared to baseline. Increases were seen in all 8 sub-scores of quality of life, with statistically significant improvements in social functioning (75±28.17 vs 94.64±11.62, $p = 0.0058$), energy and fatigue (48.93±25.21 vs 65.63±19.26, $p = 0.0426$), emotional wellbeing (66±24.29 vs 85.14±14.16, $p = 0.0054$), and general health (72.14±15.78 vs 79.64±12.78, $p = 0.0497$). For sleep quality, those subjects with baseline scores defined as clinically disturbed sleep ($n=8$, 58%) all (100%) experienced sleep improvements (9.14±6.87 vs 5.57±3.74, $p = 0.00301$), with 25% resolving below clinical delineation.

CONCLUSION: These findings suggest that the combination of cooling and compression exercise may be an effective intervention method to address symptoms in veterans and other individuals living with insomnia, post-traumatic stress, chronic fatigue, and depression.

 (No relevant relationships reported)

PURPOSE: The aim of this study was to undertake secondary data analysis from a three-arm feasibility trial of high intensity interval training (HIIT), moderate intensity continuous training (MICT), and usual care, in Crohn's disease (CD) patients ($n=36$), with a primary focus on exploring affective and enjoyment responses to the two types of exercise training. **METHODS:** Twenty-five participants with quiescent or mildly-active CD were randomised to one of the two active groups: HIIT ($n=13$) and MICT ($n=12$). Both groups were offered three exercise sessions per week for 12 weeks. MICT consisted of cycling for 30 minutes at 35% peak power (Wpeak), whereas HIIT involved ten 1-minute bouts at 90% Wpeak, interspersed with 1-minute bouts at 15% Wpeak. Peak power was determined prior to the intervention and reassessed at weeks 4 and 8 to adjust training load. Heart rate (HR) and differentiated ratings of perceived exertion (RPE) for legs (RPE-L) and central (i.e. ventilatory and circulatory; RPE-C), along with feeling state (Feeling Scale; FS) were measured at regular time intervals during each exercise session. In addition, enjoyment was measured at the end of the training programmes using the Physical Activity Enjoyment Scale (PACES). Post-hoc exploratory analysis involved a mixed-model two-way ANOVA to compare HR, RPE-C, RPE-L and FS at weeks 1, 6 and 12 between groups. An independent t-test was used to assess between-group differences in PACES scores. **RESULTS:** HR was greater ($p < 0.01$) during HIIT (168 ± 20 bpm) compared with MICT (124 ± 18 bpm). Similarly, RPE-L and RPE-C responses were greater ($p = 0.03$ and $p = 0.03$, respectively) during HIIT (5.5 ± 1.6 and 5.1 ± 1.7 i.e. 'hard', respectively) compared to MICT (3.3 ± 1.5 and 2.9 ± 1.5 i.e. 'moderate', respectively). Overall, FS recorded was 2.2 ± 1.8 (i.e. 'fairly good') for HIIT and 2.1 ± 1.3 (i.e. 'fairly good') for MICT with no effect of condition ($P=0.25$) or time ($P=0.94$). There was also no statistically significant difference in PACES scores between HIIT (99.4 ± 12.9) and MICT (101.3 ± 17.4; $p = 0.78$). **CONCLUSION:** Despite the differences in HR and RPE responses, the findings suggest that the HIIT and MICT protocols elicited similar enjoyment and affective responses in adults with quiescent or mildly-active CD.

High-intensity Interval Training And Moderate-intensity Continuous Training In Adults With Crohn'S Disease: A Pilot Trial

Garry A. Tew¹, Dean Leighton², Roger Carpenter³, Simon Anderson⁴, Louise Langmead⁵, John Ramage⁶, James Faulkner⁷, Elizabeth Coleman⁸, Caroline Fairhurst⁸, Michael Seed³, Lindsay Bottoms⁹. ¹Northumbria University, Newcastle-upon-Tyne, United Kingdom. ²Queen Mary University of London, London, United Kingdom. ³University of East London, London, United Kingdom. ⁴Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom. ⁵Barts and the London NHS Trust, London, United Kingdom. ⁶Hampshire Hospitals NHS Foundation Trust, Basingstoke, United Kingdom. ⁷University of Winchester, Winchester, United Kingdom. ⁸University of York, York, United Kingdom. ⁹University of Hertfordshire, Hatfield, United Kingdom. (Sponsor: Prof Glyn Howatson, FACSM) Email: garry.tew@northumbria.ac.uk
 (No relevant relationships reported)

PURPOSE: To assess the feasibility and acceptability of two common types of exercise training—high-intensity interval training (HIIT) and moderate-intensity continuous training (MICT)—in adults with Crohn's disease (CD).
METHODS: In this mixed-methods pilot trial, participants with quiescent or mildly-active CD were randomly assigned 1:1:1 to HIIT, MICT or control (usual care). The HIIT and MICT groups were offered three exercise sessions per week for the first 12 weeks and followed up for 6 months. Feasibility outcomes included rates of recruitment, retention, outcome completion, and exercise attendance. Data were collected on cardiorespiratory fitness (e.g., peak oxygen uptake), disease activity, fatigue, quality of life, adverse events, and intervention acceptability (via interviews).
RESULTS: Over 17 months, 53 patients were assessed for eligibility and 36 (68%) were randomised (47% male; mean age 36.9 [SD 11.2] years); 13 to HIIT, 12 to MICT, and 11 to control. The overall exercise session attendance rate was 68% (608/891), and 64% (16/25) of participants completed at least 24 of 36 sessions. One participant was lost to follow-up. Outcome completion rates ranged from 89 to 97%. The mean increase in peak oxygen uptake, relative to control, was greater following HIIT than MICT (2.4 vs. 0.7 mL/kg/min). There were three non-serious exercise-related adverse events, and two exercise participants experienced disease relapse during follow-up.
CONCLUSIONS: The findings support the feasibility and acceptability of the exercise programmes and trial procedures. A definitive trial is warranted. Physical exercise remains a potentially useful adjunct therapy in CD. Support by CCUK Grant SP2015/1.

452 Board #290 May 29 11:00 AM - 12:30 PM
Metabolic Profile And Myocardial Performance Of Renal Transplant Recipients Adherent To Unsupervised Exercise As Prescription Program.

Beatrice Leone¹, Luciano Moscarelli², Elena Zappelli¹, Chiara Ingletto³, Marco Mandoli³, Giorgio Galanti⁴, Pietro Amedeo Modesti¹, Laura Stefani⁴. ¹Sports Medicine Center -University of Florence, Florence, Italy. ²Nephrology Unit-University of Florence -Italy, Florence, Italy. ³Sports Medicine, Florence, Italy. ⁴Sports Medicine-FIMS(Italian Federation of Sport Medicine), Florence, Italy.
 (No relevant relationships reported)

Purpose : Renal transplant recipients (RTR) are at elevated cardiovascular mortality in comparison with the general population especially after surgical treatment. Literature supports the role of the supervised exercise intervention, however few data are available about the potential impact of the unsupervised exercise . We investigated whether a home-based program of exercise could reduce CV risk in RTR by evaluating the changes in renal and cardiometabolic parameters and myocardial performance measured by echocardiography. **Methods:** From a large cohort of 60 RTR, 30 RTR (12 females and 18 males, aged 47.9 ± 12.3 y) participated in individualized and unsupervised exercise programs for 6 months, at moderate intensity. Cardiometabolic risk factors, anthropometrics parameters, lipid and glucose blood sample profile were studied as well the myocardial performance by the 2D echo examination at T₀, T₆, months. **Results:** lipid profile maintained in the range of a low risk level, despite without significant improvement. the myocardial performance, especially EF was significantly (p<0.05) ameliorated (EF^{RTR}: 60.2±5¹⁰ vs 62.0±3.7¹⁶ ; EF^{HC}: 63.6±3.8¹⁰ vs 62.4±3.3¹⁶). **Conclusions:** an home based exercise program has a positive impact on myocardial function and maintains low cardiovascular risk profile since 6 months of exercise. The trend support the importance to highlight the role of a correct reconditioning of the lifestyle in RTR, by the unsupervised exercise program at moderate intensity, where well tolerated. **Table 1: Characteristics of renal transplant recipient (RTR) and healthy controls (HC)**

| RTR (n =30) | RTR T ₀ | RTR T ₆ | P value |
|--------------------------|--------------------|--------------------|---------|
| Weight (kg) | 70.6±15.6 | 70.7±15.3 | 0.830 |
| BMI (kg/m ²) | 24.3±3.8 | 24.9±4.4 | 0.631 |
| Creatinine (mg/dL) | 1.5±0.5 | 1.5±0.7 | 0.808 |
| Urea (mg/dL) | 66±0.26 | 71±0.43 | 0.787 |
| Cholesterol (mg/dL) | 187.0±55.7 | 194.7±47.8 | 0.688 |
| HDL (mg/dL) | 54.9±22.4 | 54.1±16.0 | 0.218 |
| LDL (mg/dL) | 130.6±95.0 | 134.5±93.0 | 0.655 |

The Effect Of Traditional Chinese Exercise On early Diabetic Nephropathy

Jing Li¹, Tongtong Gao¹, Mian Jia², YiYun Jiang³. ¹Dongzhimen Hospital of Beijing University of Chinese Medicine, Beijing, China. ²World Federation of Chinese Medicine Societies, Beijing, China. ³Beijing Pinggu Hospital of Traditional Chinese Medicine, Beijing, China.
 Email: NatashaLee@163.com
 (No relevant relationships reported)

PURPOSE: It was reported that early diabetic nephropathy (DN) is associated with sedentary lifestyle, and proper exercise can improve its symptoms and prognosis. However, limited data evaluated the effects and safety of traditional Chinese exercise in patients with early DN. This study was aimed at observing the effects and safety of traditional Chinese exercise on early DN.
METHODS: Participants (n=21) were divided into the traditional Chinese exercise group (A group, n=12) and the control group (B group, n=9) for 12 weeks. On the basis of foundation treatment, group A was given the exercise 30 minutes per day, 4 times a week while no exercise intervention was given in group B. Fasting blood glucose, glycated hemoglobin (HbA1c), serum creatinine, urea, and the MUNSH scale were taken at baseline and 12 weeks later.
RESULTS: 1) Significant differences were found in group A in HbA1c (6.90±0.92 vs 6.43±0.78, P<0.05), BMI (26.30±3.49 vs 25.83±3.06, P<0.05) and VO2peak (15.43±1.49 vs 16.14±1.89, P<0.05) compared with group B (Ps>0.05). The differences of MUNSH scale were significantly greater: positive emotion (6.75±3.14 vs 7.92±2.97, P<0.01), positive experience (8.08±4.03 vs 10.00±3.77, P<0.05), total score (32.67±11.28 vs 38.33±12.27, P<0.01). 2) No adverse reactions were observed during the trail. Few changes were found in renal function and urinary protein in two groups (P>0.05).
CONCLUSIONS: Traditional Chinese exercise therapy was safe and effective in treating early DN patients. It also has effects on improving the physical and mental health. Supported by JDZX2015136

Overall Fitness Benefits In Individuals With HIV Participating In A Community- Based Exercise Program

ELizabeth Orozco¹, Gabriel Gines², Christian Wade¹, Martin G. Rosario¹. ¹Texas Woman's University, Dallas, TX. ²Ponce Health Science University, Ponce, PR.
 Email: eorozco1@twu.edu
 (No relevant relationships reported)

Exercise has been shown to improve the health of persons living with HIV. **PURPOSE:** Identify the effects of a community-based exercise program on the immunity (CD4 cell count) and overall fitness (cardiovascular and strength) in individuals living with HIV in San Juan, Puerto Rico.
METHODS: Twenty-five adults with HIV age 59.2± 1.7 years participated in this study. Individuals were recruited by word of mouth to a Community Based Exercise Program (La Perla de Gran Precio). A Certified Personal Trainer performed all the exercise testing. Cardiovascular fitness was assessed using a submaximal treadmill test (Ross). Strength was assessed by determining the 1 repetition maximum (1RM) for bench press and leg press and the maximum number of push-ups and sit-ups that could be completed in 1 minute. Flexibility was tested using the Sit and Reach Test. Participants were asked to bring in the most recent lab for the CD4 data. This same evaluation was administered three times to track each participant's progress over a year.
RESULTS: A repeated measures ANOVA was used to determine whether there was a statistically significant mean difference in CD4 count, cardiovascular fitness (time

WEDNESDAY, MAY 29, 2019

completed and cardiac frequency), 1RM bench press and leg press, the maximum number of push-ups and sit-ups that could be performed in 1 minute, and flexibility between evaluations. There was a statistically significant difference ($p < 0.05$) between CD4 count from evaluation 1 (695 ± 318.58) to evaluation 4 (945.57 ± 433.12) and the most significant mean difference was noted between evaluation 1 (695 ± 318.58) to evaluation 3 (932.85 ± 408.42). The data showed the steady improvement in strength (bench press, leg press, push-ups, and sit-ups) occurred between evaluation 1 and evaluation 3; however, the gains were not statically significant ($p > 0.05$). Time completed during the submaximal test improved most between evaluation 1 and evaluation 2 but did not demonstrate the statistically significant mean difference ($p > 0.05$).

CONCLUSION: Participation in a community-based exercise program can help significantly improve immunity (increase CD4 count) in people with HIV. Therefore, clinicians should encourage individuals with HIV to participate in regular exercise and introduce them to community/recreational programs.

Web-based Individualized Exercise Intervention Improves Physical Performance and Hepatic Inflammation in Patients with NAFLD

Perikles Simon¹, Yvonne Huber², Daniel Pfirrmann¹, Beate K. Straub³, Jörn M. Schattenberg². ¹Institute for Sports Science, Johannes Gutenberg-University Mainz, Mainz, Germany. ²University Medical Centre, Johannes Gutenberg-University Mainz, Mainz, Germany. ³Institute of Pathology, Johannes Gutenberg-University Mainz, Mainz, Germany.
Email: simonpe@uni-mainz.de
(No relevant relationships reported)

Non-alcoholic fatty liver disease (NAFLD) is the most frequent cause of liver disease with Non-alcoholic steatohepatitis (NASH) as a subtype showing lobular inflammation and ballooning as characteristic liver cell damage.

PURPOSE: Here we studied the impact of regular physical activity promoted and controlled by a novel Web-based approach on physical performance, liver inflammation, and histology. **METHODS:** We enrolled 44 Patients with NAFLD in a prospective, 8-week interventional single arm study with a 12-week follow-up period (NCT02526732). Peak oxygen uptake (VO₂peak) was measured by spiroergometry from baseline (T0) to post intervention (T1) and laboratory parameters for liver function (AST, ALT) and inflammation (CRP and Ferritin) as well as liver fibrosis non-invasively by Vibration Controlled Transient Elastography (VCTE) were also measured after follow-up (T2). Training consisted out of combined endurance and strength exercise 3-5 times a week under qualified instruction. Via an online support platform, weekly bidirectional feedback was provided. Differences between groups were calculated by Mann-Whitney-U-rank test.

RESULTS: A total of 44 patients with NAFLD were assigned and 41 patients, including 29 patients with NASH, completed the study protocol. Median VO₂peak increased significantly 6.6% from 27.0 ml/kg/min at T0 to 30.3 ml/kg/min ($p < 0.001$) at T1. All laboratory values decreased significantly from T0 to T1 and T0 to T2. Median pressure measured by VCTE improved significantly from 7.4 kPa at T0 to T1 by 1.0 kPa ($p < 0.05$) and also from T0 to T2 by 1.9 kPa ($p < 0.05$). Interestingly, the subgroup of patients with NASH achieved better improvements of effect sizes for all measured parameters at all points in time. **CONCLUSIONS:** The current study demonstrates the feasibility and effectiveness of a Web-based individualized exercise program in patients with NAFLD. More severe liver inflammation and damage (NASH) does not compromise treatment effects. Sustained improvement in liver function tests and fibrosis marker support the concept of fibrosis resolution through decreasing hepatic inflammation during and following exercise intervention in this patient population.

Exercise is Medicine®: Physical Activity Prescriptions and Behavior During Pregnancy

Ariel A.B. Cruz¹, Kara Whitaker², Jennifer West³, Mark Stoutenberg⁴, Emily A. Weible¹, Christopher P. Connolly¹. ¹Washington State University, Pullman, WA. ²The University of Iowa, Iowa City, IA. ³Cabarrus Health, Kannapolis, NC. ⁴University of Tennessee Chattanooga, Chattanooga, TN.
(No relevant relationships reported)

Physical activity (PA) is beneficial to the health of both pregnant mother and unborn child, particularly when current PA guidelines are met (e.g., 150 min/week of moderate-intensity PA). The impact of PA prescriptions given by prenatal physicians, following the Exercise is Medicine® program, is currently unclear. **PURPOSE:** This study examined the relationship between healthcare provider PA prescriptions given at two prenatal healthcare visits and subsequent PA behavior of pregnant women. **METHODS:** Prenatal healthcare providers in Cabarrus County, North Carolina assessed physical activity days/week and minutes/day among all prenatal patients (N=965) at two prenatal visits (V1: 20 weeks gestation; V2: 28 weeks gestation).

Minutes/week of physical activity were calculated, and providers were trained to provide physical activity prescriptions if the patient was not meeting current guidelines. Wilcoxon-Mann-Whitney tests were used to determine the association between healthcare provider PA prescription and self-reported physical activity from V1 to V2. **RESULTS:** The frequency of PA assessment at visits decreased as pregnancy progressed (V1=82.1%; V2=45.9%). Median PA minutes reported increased from V1 (25.0 min/wk) to V2 (60.0 min/wk). Likewise, the percentage of pregnant women receiving a PA prescription decreased from visit to visit (V1=68.6%; V2=56.3%). Women who received a PA prescription reported a greater increase in PA from V1 to V2 (117 min/wk) compared to women who did not receive a PA prescription (72 min/wk) ($p < 0.001$). However, only 18.1% of PA prescriptions were consistent with current PA guidelines at prenatal visits. **CONCLUSIONS:** PA among pregnant women appears positively influenced by PA prescriptions provided by healthcare providers. Further training of healthcare providers is needed to increase the prevalence of prenatal exercise prescriptions consistent with PA guidelines.

457 Board #295 May 29 11:00 AM - 12:30 PM
Provider Advice on Weight Gain, Physical Activity, and Healthy Eating in Twin Pregnancies

Kara M. Whitaker¹, Meghan Baruth², Rebecca A. Schlaff², Christopher P. Connolly³, Jihong Liu⁴, Sara Wilcox, FACSM⁴. ¹University of Iowa, Iowa City, IA. ²Saginaw Valley State University, University Center, MI. ³Washington State University, Pullman, WA. ⁴University of South Carolina, Columbia, SC.
(Sponsor: Sara Wilcox, FACSM)
Email: kara-whitaker@uiowa.edu
(No relevant relationships reported)

PURPOSE: To examine provider advice on gestational weight gain (GWG), physical activity (PA), and healthy eating (HE) during twin pregnancies, and to determine if advice on GWG is associated with women's GWG.

METHODS: Data are from 301 women, aged 21-43 years, who delivered twins in the prior 24 months and completed an online survey in 2018. The 2009 Institute of Medicine (IOM) provisional weight gain guidelines for twin pregnancies defined whether provider advice on GWG and women's GWG were below, within, or above guidelines. Content analysis described provider advice on PA and HE. Multinomial logistic regression examined the associations of provider advice on GWG with women's GWG, after adjustment for potential confounders.

RESULTS: Approximately 66% of women reported provider advice on GWG, 73% on PA, and 59% on HE during their twin pregnancy. Of those who reported GWG advice, 30% described advice below, 60% within, and 10% above the IOM guidelines. Women who were not on bedrest (15%) reported recommendations to engage in light- or moderate-intensity activities like walking or swimming, but cautioned to avoid overexertion. Advice on HE included recommendations to increase consumption of protein, fruits, vegetables and vitamins/minerals, with emphasis on increasing caloric intake. As seen in **Table 1**, compared to women who reported GWG advice within IOM guidelines, women who reported advice below guidelines or who reported no advice were 7.23 and 2.76 times more likely to gain less than recommended, respectively. Women who reported provider advice above guidelines were 5.05 times more likely to exceed guidelines (all $p < 0.05$).

CONCLUSION: Forty percent of women reported GWG advice outside IOM guidelines, and inaccurate or no advice was strongly associated with inadequate or excessive GWG. There is a clear need for intervention strategies to educate providers about IOM guidelines, including how to counsel women on GWG, PA, and HE to optimize outcomes in twin pregnancies.

Table 1: Association Between Provider Advice on Gestational Weight Gain (GWG) and Compliance with the Institute of Medicine (IOM) Guidelines*

| Provider Advised GWG | GWG Below IOM Guidelines | | GWG Above IOM Guidelines | |
|-----------------------|--------------------------|--------------------|--------------------------|--------------------|
| | Adjusted OR† | 95% CI | Adjusted OR† | 95% CI |
| Below IOM guidelines | 7.23 | 3.20, 16.33 | 1.86 | 0.75, 4.61 |
| Above IOM guidelines | 0.64 | 0.07, 5.81 | 5.05 | 1.61, 15.85 |
| Within IOM guidelines | Reference | Reference | Reference | Reference |
| Did not discuss | 2.76 | 1.32, 5.78 | 1.88 | 0.92, 3.85 |

*Due to differences in gestational age at delivery, a GWG ratio was calculated by dividing the lower and upper bounds of the IOM guidelines by 37 (guidelines created for women undergoing delivery ≥ 37 weeks gestation), to estimate GWG/week. The GWG ratios consistent with IOM guidelines for normal weight, overweight, and obese women were calculated as 1.00-1.46, 0.84-1.35, and 0.68-1.14 pounds per week, respectively.
 †Model adjusted for maternal age at delivery, education, parity, twin type (dichorionic/diamniotic vs. dichorionic/monoamniotic or monochorionic/monoamniotic), assisted reproductive technologies (yes/no), and pre-pregnancy BMI category. Bolded values are statistically significant (p<0.05).

Lifestyle and Exercise Interventions for Lumbopelvic Pain and Pelvic Floor Dysfunction: A New Protocol
 Marc P. Bonis, Jenn Lormand, Christina Walsh. *University of New Orleans, New Orleans, LA.* (Sponsor: Mark Loftin, FACSM)
 Email: mbonis@uno.edu
(No relevant relationships reported)

PURPOSE: The purpose of this study was to evaluate whether a protocol that included the implementation of lifestyle modifications and a specialized exercise program would improve the symptoms of pelvic floor dysfunction and mild pelvic organ prolapse in women.

METHODS: The five-week IRB-approved study included 23 female subjects aged 43.0 ± 9.0 years (Mean ± S.D.) who exhibited symptoms of pelvic floor dysfunction as defined by 3 assessments (the Pelvic Floor Distress Inventory [PFQI-7], the Oswestry Low Back Pain Disability, and the Pelvic Floor Impact [PFDI-SF20] questionnaires). The study also included InBody570 body composition measurements, pelvic alignment assessments, diastasis recti assessments, and manual external pelvic floor muscle activation assessments. Participants were instructed in specific lifestyle modifications and participated in an exercise program over the course of seven live group sessions, 45 minutes each, led by one or both of the investigator clinicians. They were also taught to perform a home exercise program at least 5 days per week and completed compliance forms that were returned at the next live group session. The clinicians were a licensed physical therapist and a clinical exercise physiologist.

RESULTS: IBM SPSS version 24 statistical programming was utilized and non-parametric Wilcoxon “related-items” analyses were employed. A 0.05 level of significance was applied. The study results of the pre- and post- values indicated significant improvements of lower back pain (Oswestry, z(23) = -3.67, p < .05), significant improvements of the quality of life subjective emotional gauge (PFDI -20, z(23) = -4.11, p < .05), and significant improvements of bladder, bowel, and prolapse symptoms (PFQI - 7, z(23) = -3.74, p < .05).

CONCLUSIONS: The study was highly labor- and time-intensive, and the sample was not large enough to eliminate statistical bias. However, the successful results warranted a continuation of the study to include 40 female volunteers with no modifications to the study’s protocol using the same clinicians. Researchers are currently recruiting volunteers to complete the study.

Association Between Cognitive Function And Funcional Capacity Of Patients With Peripheral Artery Disease

Juliana Ferreira de Carvalho¹, Marilia de Almeida Correia², Paulo Longano³, Francielli Monteiro¹, Nelson Wolosker¹, Gabriel Grizzo Cucato¹, Raphael Ritti-Dias². ¹Hospital Israelita Albert Einstein, São Paulo, Brazil. ²Universidade Nove de Julho, São Paulo, Brazil. ³Hospital Israelita Albert Einstein, São Paulo, Brazil.

(No relevant relationships reported)

Introduction: Patients with peripheral arterial disease (PAD) and symptoms of intermittent claudication present reduced mobility and decreased ability to exercise activities of daily living due to atherosclerotic plaques in the lower limbs that limit blood flow to the muscles. Because it is a systemic disease, PAD has been associated with cognitive decline, however, as far as functional impairment is related to cognitive impairment is still uncertain. **Purpose:** To analyze the association of cognitive function with the overall functional capacity and fragmented in three factors: (walking speed, muscle strength and balance) of patients with PAD. **Methods:** Two hundred and nineteen patients with PAD and symptoms of intermittent claudication were submitted to the MoCA test to evaluate cognitive function. Functional ability was assessed by the Short Physical Performance Battery consisting of balance tests, sit-up and stand-up tests, and 4-meter walk test. For analysis of the associations, the binary logistic analysis was used, using the sex and age adjustment of the patients. **Results:** There was no association between MoCA and sit-up (OR = -0.099, P = 0.780) as well as the test and balance (OR = -0.084, P = 0.832). The MoCA score was associated with performance on the test regardless of gender and age (OR = 1.186, P = 0.007). Despite the non-association in the first two tests, we found that cognitive function is associated with walking capacity. **Conclusion:** The cognitive function is associated with the ability to mobility in patients with PAD, based on these results we can assume that individuals physically active, yet affected by the disease, can slow cognitive decline.

(No relevant relationships reported)

PURPOSE: To determine which patient demographics and patient reported outcomes (PROs) are associated with the average daily volume (ENMO) of accelerometer measured physical activity (PA) in people with heart failure (HF). **METHODS:** Baseline data was pooled from two studies which measured PA levels of people with both HF with reduced ejection fraction (HFrEF) and preserved ejection fraction (HFpEF) using 7-day wrist-worn accelerometry. Associations between PA volume, demographics and PROs were assessed using univariate linear regression. Variables with significant or close to significant associations (p<0.15) with PA were subsequently entered into multivariable stepwise regression models: (1) a demographic model, (2) a PRO model, (3) an overall model consisting of all closely associated variables (p<0.15), and (4) a final model consisting of all variables with p<0.05 identified in the demographic and PRO multivariable models. **RESULTS:** 245 participants were included in the analysis and had a mean daily PA volume of 17.8±6.6 mg, with no difference between HFrEF and HFpEF patients (t(242)=0.60, p=0.55). Univariate analysis showed age, body mass index (BMI), New York Heart Association (NYHA) class, ischaemic HF, NT-proBNP, living alone, chronic renal impairment, number of comorbidities, number of cardiorespiratory-metabolic comorbidities, incremental shuttle walk test (ISWT) distance, HEART QoL global and physical scores, EQ-5D-3L, MLHFQ overall, physical and emotional scores, and HADs depression scores were significantly associated with PA volume (p<0.05). The overall multivariable analysis (3) showed that age, BMI, being employed, currently smoking, NT-proBNP and ISWT peak distance had the strongest association with PA volume (R²=0.42, p<0.001). **CONCLUSION:** Multivariable analysis identified factors which may be important for clinicians and researchers to consider when tailoring PA interventions. However, our results should be treated with a degree of caution due to a relatively small sample size in relation to the number of exploratory variables included. That >50% of the variance in PA volume remained unexplained indicates the need for further investigation in this area, with bigger data sets required to make firm conclusions.

Lifestyle and Exercise Intervention Reduces Blood Pressure: A Multiethnic Control TrialGuillermo Hernando Rodríguez Vélez¹, Elvis Alvarez Carnero², Elisero Iglesias-Soler³, Manuel Avelino Giráldez García³.¹Facultad de Ciencias Naturales, Exactas y de la Educación, University of Cauca, Popayan, Colombia. ²Florida Hospital, Translational Research Institute, Orlando, FL. ³Facultad de Ciencias del Deporte y la Educación Física, University of A Coruna, A Coruna, Spain.

Email: ghrv1958@gmail.com

(No relevant relationships reported)

The effect of ethnicity and medication on blood pressure (BP) have been widely described; however, less is known about the interaction between ethnicity, BP medication and regular exercise on hypertensive patients. **PURPOSE:** This study was aimed to determine the effectiveness of an exercise training and healthy lifestyle education program to reduce BP levels and improve adherence to pharmacological therapy on a multiethnic group of hypertensive patients.

METHODS: An 8-month quasi-experimental longitudinal intervention with an exercise group (EG) and control group (CG) was designed. Five hundred and sixty-eight hypertensive patients (67.4±8.8 years; BMI, 26.4±3.1 kg/m²; systolic BP (SBP), 146±9 mmHg and diastolic BP (DBP), 95±7 mmHg; 18% Indigenous, 23% Colombian-African and 59% Hispanic) finalized the study (EG, n= 307 and CG, n= 261). EG participated in 3 weekly exercise training sessions (30 to 60 minutes of concurrent training), which were complemented by medication and lifestyle education. The average of three repeated measures of BP performed with an electronic sphygmomanometer was utilized as primary outcome. Health status, medication adherence, salt consumption, tobacco and alcoholic habits were recorded by questionnaires during clinic history assessment. Non-parametric tests were carried out to compare differences between EG and CG. Several logistic regression models were used to find independent variables predicting two levels (-3 or -5 mmHg) of reduction in systolic (SBP) or diastolic blood pressures (DBP).

RESULTS: We found significant reductions both SBP and DBP in EG (-5.92 mmHg and -5.0 mmHg, respectively, $P<0.001$ for both) but not in the CG. Also, prevalence of medication adherence was significantly improved in 28.7% ($P<0.001$) in the EG. In the logistic regression, all models confirmed the EG as the main explanatory variable of a 3 or 5 mmHg BP reduction, independently of other lifestyle risk factors and medication adherence. **CONCLUSIONS:** In accordance with other studies patients in EG showed more diminution in SBP and DBP than CG, which was independent of other risks factors. However, the main findings were that either ethnic or medication adherence did not influence statistically the reduction in BP associated with our exercise/lifestyle intervention.

Tai Chi as Antihypertensive Lifestyle Therapy: A Systematic Review and Meta-AnalysisYin Wu¹, Blair T. Johnson¹, Shiqi Chen², Yiyang Chen³, Jill Livingston¹, Linda S. Pescatello, FACSM¹. ¹University of Connecticut, Storrs, CT. ²University of Michigan, Ann Arbor, MI. ³Shanghai University of Sport, Shanghai, China. (Sponsor: Linda S. Pescatello, FACSM)

Email: yin.2.wu@uconn.edu

(No relevant relationships reported)

Due to limited evidence professional health organizations are reluctant to recommend Tai Chi to treat hypertension. **PURPOSE:** We conducted a systematic review and meta-analysis to examine the efficacy of Tai Chi as antihypertensive lifestyle therapy. **METHODS:** Tai Chi interventions published in English and Chinese were included when they involved healthy adults, reported pre-and post-intervention blood pressure (BP), and had a non-exercise/non-diet control group. We systematically searched 11 electronic databases through August 1, 2018, yielding 31 qualifying controlled trials. We: 1) evaluated the risk of bias and methodological study quality; 2) performed meta-regression analysis following random-effects assumptions; and 3) generated additive models representing the largest possible clinically relevant BP reductions. **RESULTS:** On average, participants ($N=3,223$) were middle-aged (56.6±15.1 years) adults with prehypertension (systolic BP [SBP] 136.9±15.2/diastolic BP [DBP] 83.4±8.7 mmHg). Tai Chi was practiced 4.0±1.4 sessions/week for 54.0±10.6 minutes/session for 22.3±20.2 weeks. Overall, Tai Chi elicited moderate to large reductions in SBP ($d=-0.75$, 95%*CI*s: -0.97, -0.53; -8.7 mmHg) and DBP ($d=-0.53$, 95%*CI*s: 0.71, 0.34; 4.7 mmHg) compared to control ($P<.001$). Controlling for publication bias among samples with hypertension, Tai Chi interventions published in English elicited SBP reductions of 10 mmHg and DBP of 4 mmHg, half the magnitude of trials published in Chinese with SBP reductions of 19 mmHg and DBP reductions of 9 mmHg. **CONCLUSION:** Our results indicate that Tai Chi is viable antihypertensive lifestyle therapy that produces BP reductions that rival or exceed the antihypertensive

effects of aerobic exercise of 5-8 mmHg in both the English and Chinese literature. Further investigation is needed to explain the discrepancy in the magnitude of the antihypertensive effects between Tai Chi trials published in English and Chinese. Supported by a sub-contract from U.S. PHS grant 5U24AG052175, and University of Connecticut Center for Excellence in Teaching and Learning

Physical Activity Patterns Vary by BMI and Asthma Control in Patients with AsthmaMolly B. Conroy, FACSM¹, Bonny J. Rockette-Wagner², Juan Wisnivesky³, Fernando Holguin⁴, Shiqi Chen³, Emily Federmann³, Vongphone Smith⁴, Alex Federman³. ¹University of Utah, Salt Lake City, UT. ²University of Pittsburgh, Pittsburgh, PA. ³Icahn School of Medicine at Mt. Sinai, New York, NY.⁴University of Colorado, Aurora, CO.

Email: Molly.Conroy@hsc.utah.edu

(No relevant relationships reported)

PURPOSE: Persons with chronic medical conditions, such as obesity and asthma, may be at higher risk for physical inactivity. In this analysis, we evaluated objectively-measured physical activity (PA) in a population of patients with asthma to determine whether physical activity varied by body mass index (BMI) or asthma control.

METHODS: We used data from a prospective cohort of English and Spanish speaking adults ≥21 years of age with physician diagnosis of asthma recruited from the outpatient practices of two health care systems located in New York, NY and Denver, CO. Exclusion criteria included history of other chronic pulmonary conditions or smoking >15 pack-years. Physical activity was objectively measured using Actigraph wGT3X-BT accelerometers. BMI (kg/m²) was measured by trained research staff and the Asthma Control Questionnaire (ACQ) was used to assess asthma control. We used Kruskal-Wallis tests to compare physical activity measures among obese (≥30 kg/m²), overweight (<30-25 kg/m²) and normal or underweight (<25 kg/m² and <18.5 kg/m²) individuals, as well as among subgroups by asthma control: good (ACQ ≤ 0.75), poor (ACQ > 0.75, but <1.5) and very poor (ACQ ≥ 1.5). **RESULTS:** Of the 125 participants, 103 (82%) were female. 56 (45%) were white; 52%, 30% and 18% were obese, overweight and normal/underweight, respectively. Half reported very poor asthma control. Mean (SD) sedentary time/day was 406.5 (114.1) minutes/day and did not vary by BMI or ACQ. Mean light activity was 397.4 (95.4) minutes/day and moderate-vigorous activity (MVA) was 38.9 (28.5) minutes/day. Patients with obese or overweight BMI had somewhat lower MVA than those with normal BMI (35.7, 39.9, 46.2 minutes/day; $p=0.09$) and significantly lower daily steps (5670, 7105, 7727; $p=0.004$). Similarly, patients with very poor asthma control had non-significantly lower MVA than those with poor or good control (34.1, 39.4, 49.0 minutes/day; $p=0.08$) and significantly lower daily steps (5690, 6742, 7910; $p=0.003$). **CONCLUSIONS:** Overall, activity levels in these patients with asthma were not lower than the general adult population. However, those with higher BMI and worse asthma control were less active (respectively), suggesting that interventions to increase PA in patients with asthma should consider addressing body weight and asthma control.

Less Evening Exercise is Associated with Progressive Visual Field Defect in POAG PatientsYuanbo Liang¹, Xiafei Pan¹, Kai Xu², Xin Wang¹, Guofu Cheng¹, Huanhuan Cheng¹, Jie Cheng¹, Alice Jia Liu¹. ¹The Eye Hospital, School of Ophthalmology and Optometry, Wenzhou Medical University, Wenzhou, Zhejiang, China, Wenzhou, China. ²Nanjing Sport Institute, No.8 Linggusi Road, Nanjing, Jiangsu, China, Nanjing, China.

Email: yuanboliang@126.com

(No relevant relationships reported)

PURPOSE: To investigate the exercise habits of those with primary open angle glaucoma (POAG) and its associations with the progression of glaucomatous visual field (VF) loss. **METHODS:** Daily PA was monitored by an accelerometer (ActiGraph wGT3x-BT), which patients wore for 24-hours on their waist (right) for 1 week. main outcome measures are daily PA, such as calories (kcal), light PA time, moderate PA time, vigorous PA time, moderate to vigorous physical activity (MVPA) and step counts. Progressive VF loss is defined as the same three or more points in pattern deviation change probability maps in at least two consecutive visits detected by Glaucoma Progression Analysis. **RESULTS:** No significant difference was found for daily PA between the 76 non-progressive and 22 progressive patients who wore the device for more than 10 hours per day ($P>0.05$ for all). Better eye VF mean deviation (MD) averaged -3.1 dB in non-progressive group and -4.1 dB in progressive group. 88 (89.8%) participants who had worn an accelerometer for an entire day were analyzed for their 24-hour exercise habits. Patients with POAG preferred to exercise more during 07:00-09:00 am, 15:00-17:00 pm, and 18:00-20:00 pm. Additionally, MVPA time in the non-progressive group is significantly higher than the progressive group at 18:00-20:00 pm (25.0(34.3) min VS 18.9(17.6) min, $P=0.002$). Binary logistic

regression analysis indicated that MVPA (18:00-20:00 pm) and other parameters, such as mean retinal nerve fiber layer (mRNFL), MD, mean arterial pressure (MAP), mean intra-ocular pressure (miOP), age and gender were significantly correlated with POAG patients' progressive VF damage. Multivariate analysis showed that MVPA (odds ratio, OR (95% confidence intervals, CI) =0.96(0.94, 0.99), $P=0.002$), mRNFL (OR (95%CI) =0.97(0.94, 1.00), $P=0.02$), MAP (OR (95%CI) =0.88(0.83, 0.92), $P<0.001$), age (OR (95%CI) =1.10(1.06, 1.15), $P<0.001$) and gender (OR (95%CI) =0.44(0.22, 0.91), $P=0.001$) were still related to progressive VF loss after adjusting the other risk factors. **CONCLUSIONS:** Patients with POAG prefer to exercise more during 07:00-09:00 am, 15:00-17:00 pm and 18:00-20:00 pm. Less evening exercise is associated with glaucomatous progressive VF damage, with an increasing of one minute of MVPA time decreasing the progression of POAG about 4%.

Increased Functional Capacity For Adaptive Athletes Through High Intensity Functional Training (HIFT)

Victor Andrews¹, Katie M. Heinrich¹, Derek A. Crawford², Theresa Larson³, Max Conserva⁴. ¹Kansas State University, Manhattan, KS. ²Pittsburg State University, Pittsburg, KS. ³Movement Rx Integrated Health, San Diego, CA. ⁴Adaptive Athletic, San Francisco, CA.
 Email: victorandrews1@k-state.edu
 (No relevant relationships reported)

BACKGROUND: Individuals with adaptive needs (e.g., spinal cord injuries, cerebral palsy, amputations) encounter various barriers that limit their physical activity (PA). High intensity functional training (HIFT) programs have been developed to help those with adaptive needs improve their functional capacity. Adaptive HIFT programs allow for the preservation of a workout stimulus with exercise modifications or substitutions made for current physical conditions. However, research is lacking for adaptive HIFT programs.

PURPOSE: To compare ratings for difficulty and confidence of functional movements before and after an adaptive HIFT intervention.

METHODS: Participants included 13 adults (age = 38 ± 11 years, 75% male), and required the use of wheelchairs, limb braces, prosthesis, and crutches. The study consisted of an 8-week adaptive HIFT intervention with 2-3 60-minute supervised sessions per week. Participants completed a survey before and after the intervention that included the Outpatient Physical Therapy Improvement in Movement Assessment Log (OPTIMAL), which measured difficulty and confidence in performing 22 movements necessary to perform various functional activities (e.g., rolling over, squatting), on a 5-point scale (1 high, 5 low). All 13 participants completed the intervention. Due to differential survey completion (i.e., baseline $n = 8$, posttest $n = 5$; only 2 of those completed it at each time point), data were treated as cross-sectional and independent samples t-tests were performed via SPSS 25 to compare ratings for each time point.

RESULTS: Difficulty ratings approached significance for lying flat, $\Delta M = 1.1 [-0.1, 2.3]$, ($N = 8, 5$), $t(7) = 2.3$, $p = .051$, $SE = .4$; squatting, $\Delta M = 1.7 [-1.1, .9]$, ($N = 7, 5$), $t(10) = 2.1$, $p = .06$, $SE = .8$; and walking long distances, $\Delta M = 1.7 [-1.4, 3.7]$, ($N = 7, 5$), $t(10) = 2.2$, $p = .06$, $SE = .8$. Confidence ratings were significant for grasping, $\Delta M = .6 [0.03, 1.2]$, ($N = 8, 5$), $t(7) = 2.4$, $p = .05$, $SE = .3$. No difficulty or confidence ratings had significantly lower scores at posttest.

CONCLUSION: Adaptive HIFT programs show promise for addressing functional movement limitations for adaptive adults. This would allow for increased PA participation. Future studies should increase sample sizes and compare outcomes from HIFT programs to other types of PA for the adaptive population.

466 Board #304 May 29 11:00 AM - 12:30 PM
The Effects of Endurance Stair Climbing on Individual Health

Ryan Doyel, Joseph Dadabo, Courtney Stefanski, Prakash Jayabalan. Northwestern University Feinberg School of Medicine / Shirley Ryan AbilityLab, Chicago, IL.
 (No relevant relationships reported)

Purpose

To assess cardiovascular intensity in athletes participating in an endurance stair climbing event.

Methods

This was an observational pilot study in which participants wore fitness tracking watches during an endurance stair climb of 103 floors. The devices provided continuous heart rate data throughout the climb. Participants completed the Borg Rating of Perceived Exertion upon completion of the event. The sample included 11 stair-climb event participants, including eight novices and three elites (i.e., Tower Running World Association members). The primary outcome was proportion of time spent with heart rate $>50\%$ of estimated maximum (moderate-to-vigorous intensity) and $>70\%$ of estimated maximum (vigorous intensity). Perceived level of exertion (Borg score) was a secondary outcome.

Results

The sample ($N=11$) comprised eight women and three men, with mean age of 34 years ($SD=11.5$) and BMI 23.2 ($SD=2.8$). All participants spent at least 90% of the climb with heart rate $>50\%$ of estimated maximum, and 64% of participants spent at least 50% of the climb with heart rate $>70\%$ of estimated maximum. Elite participants spent a greater proportion of time in vigorous intensity activity than did novices (68% vs 55%), though this finding was not statistically significant ($p>.05$). Participants did not differ in time taken to reach $>70\%$ of estimated maximum heart rate ($M=6.5$ minutes, $SD=5.7$). On average, participants perceived their level of exertion as "very hard" (Borg score $M=16.7$, $SD=2.4$).

Conclusion

This pilot study provides evidence that endurance stair climbing represents an alternative form of moderate-to-vigorous intensity exercise, as characterized by percent of estimated maximum heart rate and perceived level of exertion. Elite athletes achieved vigorous intensity activity levels for a greater duration than did novices, although a larger scale study is needed to confirm this trend. Next steps include assessing the health benefits of sustained daily stair climbing across the continuum of age and baseline activity level.

467 Board #305 May 29 11:00 AM - 12:30 PM
Ankylosing Spondylitis: How Important is Exercise as Part of Management

Christa Janse van Rensburg, FACSM, Audrey Jansen van Rensburg, Catharina C. Grant, Dimakatso A. Ramagole. Sports Medicine, University of Pretoria, Pretoria, South Africa.
 Email: christa.jansevanrensburg@up.ac.za
 (No relevant relationships reported)

INTRODUCTION: Ankylosing Spondylitis (AS) is an autoimmune disease characterised by chronic inflammation of the sacroiliac joints and axial spine. The body's immune response to chronic inflammation initiates calcification and excessive bone formation causing structural joint damage and spinal fusion subsequently restricting mobility. AS has a 3:1 male-to-female ratio and symptoms typically appear at 15 - 45 years of age. Current treatment involves both pharmacological and non-pharmacological therapy. **PURPOSE:** To identify the role of exercise as part of the treatment plan in AS patient. **METHODS:** Investigate and summarise current knowledge on recommended practice points, frequency, intensity, time and type of exercise as well as progression of an exercise program, in AS patients. **RESULTS:** Current literature indicates the importance of exercise as part of treatment with pharmacological agents is aimed to delay progression of disease, relieve pain, minimise inflammation, maintain function and improve quality of life. Recommended practice points include a professional team with: knowledge of continual patient assessment and monitoring, realisation of complications, understanding complex exercise and pathology interactions, and a practical approach to the exercise setting that will encourage and motivate patients. The main long-term therapeutic goals should be: posture, mobility and respiratory function. Four key elements of the FITTPro Principle (frequency, intensity, time, type and progression) is recommended in exercise prescription. An AS exercise program of 5 days/week, for 30 minutes/day is advised. It generally consists of daily range of motion (ROM), aerobic-, breathing- and strengthening exercises 1-3 times/week. The type of exercises should fit the patient's profile e.g. hydrotherapy is beneficial, but contact sports should be avoided. **CONCLUSIONS:** Individualised continual assessment and exercise prescription with the emphasis on spinal mobility, ROM, muscle strengthening and cardiorespiratory fitness to improve balance, coordination and fitness are an important part of the management plan. Continuous disease modifying treatment including anti-TNF α therapy combined with regular exercise prescription confers additional benefit to pharmacological therapy alone.

A-57 Exercise is Medicine®/Poster - EIM On Campus, Children, Adolescents, EIM and Physicians

Exercise Is Medicine On Campus: A Survey Of Opinions And Attitudes

Melissa A. Reed¹, Annie O'Brien¹, Umit Tokac², Katelyn Koser¹, Scott Heinerichs¹, Selen Razon¹. ¹West Chester University, West Chester, PA. ²University of Missouri, St. Louis, MO.

Email: mreed3@wcupa.edu

(No relevant relationships reported)

Exercise is Medicine (EIM) is a global joint initiative between the American Medical Association (AMA) and the American College of Sports Medicine (ACSM). West Chester University (WCU) is recognized by the ACSM as an EIM-On Campus which indicates that WCU is a campus that is actively trying to engage the campus community in physical activity. **PURPOSE:** The purpose of this study was to gauge opinions and attitudes related to EIM Day at WCU—a first-time event launched at the campus. This event was hosted by the College of Health Sciences (CHS) at WCU and included participation from all six departments in the CHS, faculty and staff across campus, alumni, and community stakeholders.

METHODS: Forty participants (11 male, 29 female) ($M_{age} = 27.5$, $SD=12.16$) who visited the event responded to an exit program evaluation survey. **RESULTS:** Descriptive results from Likert scale data (1=not at all - 5=very much) indicated that participants reported high levels of enjoyment related to the event ($M_{enjoyment} = 4.6$, $SD=0.78$). They also reported that they found the event largely beneficial for improving their physical activity and nutritional habits ($M_{helpfulPA} = 4.4$, $SD=0.97$; $M_{helpfulNutrition} = 4.3$, $SD=0.99$). Participants also expressed strong intentions to revisit the event in the future ($M_{futurevisit} = 4.7$, $SD=0.75$). Additional Bayesian analysis also suggested that in comparison to their male counterparts ($M = 3.75$, $SD=1.28$), female participants ($M=4.67$, $SD=0.51$) found the event significantly ($p < .05$) more helpful for improving their nutritional habits. Of the motives for participation, 87.5% of the participants reported that they participated because they expected the event to be fun. Finally, with regards to participants' recommendations two themes emerged from the qualitative content analysis: (1) additional activities to include in the event and, (2) greater variety of food and beverage options to offer throughout the event. **CONCLUSIONS:** These results suggest that individuals that participated in this first-time event evaluated it highly favorably and found it beneficial for improving important health behaviors. Future research needs to explore the effectiveness of these initiatives and advance recommendations to further increase their impact.

Exercise Is Medicine On Campus Program Comparisons: A Descriptive Study

Kristen Lagally, FACSM¹, Jacquelyn Sherman¹, Anthony J. Amorose¹, Anna Rinaldi-Miles¹, Carena S. Winters, FACSM². ¹Illinois State University, Normal, IL. ²Jacksonville University, Jacksonville, FL.

Email: kmlagal@ilstu.edu

(No relevant relationships reported)

PURPOSE: The purpose of this study was to describe the client experience and program characteristics of existing Exercise is Medicine® on Campus (EIM-OC) programs. **METHODS:** A 49-question survey was emailed to all campuses with registered EIM-OC teams. Participants were identified via ACSM Exercise is Medicine® on Campus advisor email list. Permission to send the survey was obtained from the EIM-OC Committee Chair and EIM-OC Program Manager. Frequencies were used to describe EIM-OC program characteristics.

RESULTS: Twenty-eight campuses responded to the survey. Approximately 80% of the responding campuses offer outreach activities and special events as part of EIM-OC programs. Other EIM-OC program options included peer-led programming (50%), referral program (38%), individualized programming (36%), and motivational interviewing (17%). Campuses with funded EIM-OC programs indicated that funding came from a Kinesiology-related department, Campus Recreation, Health Promotion/Wellness, Student Health Services, grants, student government associations and/or student clubs. Seven campuses (25%) indicated no funding source. Twelve of the 28 campuses are referring clients (~80% from student health or student counseling services) or directing clients (30% by campus recreation or an EIM-OC administrator) to a fitness setting (campus recreation in 75% of cases). In all cases, referred or directed clients include students, for whom EIM-OC programs are free. Some campuses also include faculty/staff or community members among referred/directed

clients. "Not meeting physical activity guidelines" was a reason for referral in all cases, with many campuses also reporting existing physical or mental conditions and obesity as reasons for referral. Referred or directed EIM-OC clients are offered some form of individualized programming (one-on-one, small or large group training) in 75% of cases, with the remaining 25% offering reduced gym or training fees or free fitness assessments. Twenty-one respondents (88%) indicated that EIM-OC programs provide new opportunities for students.

CONCLUSIONS: The results provide evidence of a variety of structures and activities involved in current EIM-OC programs, with anecdotal evidence of the benefits for student clients and leaders.

Implementation of Exercise is Medicine On Campus at the University of North Carolina - Chapel Hill

Kathryn Burnet, Elizabeth Kelsch, Theyv Chai, Lee Stoner, FACSM. University of North Carolina at Chapel Hill, Chapel Hill, NC. (Sponsor: Dr. Lee Stoner, FACSM)

Email: katieburnet@gmail.com

(No relevant relationships reported)

PURPOSE: The University of North Carolina at Chapel Hill was recently registered as an Exercise is Medicine (EIM) campus. To enable effective and sustainable implementation of EIM within Campus Health, the purpose of the current study was to anonymously survey students and determine: current exercise behavior, barriers and motives, interest in receiving exercise advice and by whom, and appropriate methods of communication. **METHODS:** 500 surveys were distributed in Campus Health services between January-April 2018. **RESULTS:** The 407 responders were evenly distributed among college status (20% Freshman, 21% Sophomore, 16% Junior, 17% Senior, 23% Graduate Student, 3% Post-Doc). Time was the biggest barrier to exercise (57%). More than half wanted to receive guidance about exercise (48% Agree, 10% Strongly Agree), and agreed they would be more likely to exercise if they were given advice about exercise (46% Agree, 11% Strongly Agree). Students wanted a referral to an exercise professional (41%), and to receive initial advice and communicate through email (56%). **CONCLUSIONS:** Students attending Campus Health are interested in receiving exercise guidance and, following a referral, this advice should be delivered by trained exercise professionals, e.g., the Exercise and Sport Science Department. Findings from this study will be used to implement a full trial in Counseling and Psychological Services.

Exercise Is Medicine On Campus In The Curriculum

Kelly D. Helm, Gladys Reyes, Maricruz Hernandez, Billie Bal. Valparaiso University, Valparaiso, IN.

Email: kelly.helm@valpo.edu

(No relevant relationships reported)

All universities should promote physical activity (PA) on campus to make PA a part of campus culture. Kinesiology departments can promote PA for cardiorespiratory health by offering a simple walking class. Studies indicate that even a low-volume walking program can yield cardiovascular benefits. **PURPOSE:** To determine the impact of a seven week walking course on cardiovascular health in college students. **METHODS:** Six college students (1=M; 5=F) enrolled in a walking class offered in Fall 2018. Five students completed the course. The 50 minute class met twice per week for seven weeks and students walked a minimum of 40 minutes each class period. An estimated VO_{2max} was determined for each student during the first class meeting using the Rockport 1-Mile walk test. Following the seven week course, students completed another Rockport 1-Mile walk for VO_{2max} estimation. Pre-test and post-test estimated VO_{2max} results were compared. **RESULTS:** All students showed improvements in estimated VO_{2max} . Mean estimated VO_{2max} for all students pre-intervention was 47.11 ($ml/kg/min^{-1} \pm 8.44$) with a post-intervention mean of 42.06 ($ml/kg/min^{-1} \pm 10.13$). Paired t -tests identified significant improvement in estimated VO_{2max} ($\mu = 3.89 ml/kg/min^{-1} \pm 1.76$, $p = 0.008$). Female mean estimated VO_{2max} improved significantly by 3.23 ($ml/kg/min^{-1}$, $p = 0.10$). **CONCLUSION:** Introducing PA courses as simple as walking to the campus course curriculum may yield improved cardiovascular health in college students. Kinesiology departments are encouraged to offer PA courses promoting Exercise is Medicine On Campus.

Exercise is Medicine on Campus 2018 Expanding EIMOC Programming Across a Branch Campus Network
 Zack Papalia, Melissa Bopp, FACSM, Christopher Bopp, Thomas Kramer. *Pennsylvania State University, University Park, PA.* (Sponsor: Melissa Bopp, FACSM)
 Email: zvp5003@psu.edu
 (No relevant relationships reported)

PURPOSE: Pennsylvania State University has been promoting Exercise is Medicine on Campus (EIMOC) since 2010 and has expanded the year-round program to include events, student and employee-focused initiatives, numerous on- and off-campus partnerships, and more. A recent focus of the EIMOC program has been expansion to other Penn State campus locations. As a University, Penn State operates 24 campuses throughout the state, with over 84,000 undergraduates enrolled. The wide array of locations, sizes, and educational foci present opportunities and challenges as EIMOC at Penn State attempts to expand beyond its founding campus. **METHODS:** The central EIMOC program conducts year-round activities the main campus, while providing assistance and guidance to commonwealth campuses when appropriate. Several times per year the EIMOC team travels to commonwealth campuses to assist on-site in the development and execution of EIMOC commonwealth programs, in partnership with local EIMOC committees at each campus. Program components are adjusted based on campus location, setting, size, partners, and available funding. Counts are conducted at each event for participation and engagement, lessons learned are reviewed to ensure the successful progression and expansion of future initiatives. Reviews are shared with other campuses to inform program development. **RESULTS:** EIMOC at Penn State has expanded to six commonwealth campuses, with four locations earning official EIMOC recognition. In 2017, Penn State University Park, the largest undergraduate campus earned Gold, Penn State Berks and Harrisburg both earned Silver, and Penn State Hershey School of Medicine earned Bronze. Three other campuses are currently pursuing official EIMOC status. Larger campuses benefited from higher levels of available resources and partnerships, though struggled spreading awareness. Smaller institutions had greater success with awareness and engagement, though had smaller scopes. Additional differences were noticed between rural and urban settings. **CONCLUSIONS:** The current study offered insights on the challenges and successes in leveraging a large university network to expand EIMOC programming across a diverse array of campuses. EIMOC programming has proven successful across a broad range of campus settings and sizes.

Exercise And Adiposity In Overweight And Obese Children And Adolescents: A Network Meta-analysis
 George A. Kelley, FACSM¹, Kristi Sharpe Kelley¹, Russell R. Pate, FACSM². ¹*West Virginia University, Morgantown, WV.* ²*University of South Carolina, Columbia, SC.*
 Email: gkelley@hsc.wvu.edu
 (No relevant relationships reported)

Overweight and obesity are major public health problems among children and adolescents. However, the effects of different types of exercise on adiposity are not well established. **PURPOSE:** Use the network meta-analytic approach to determine the effects of different types of exercise (aerobic, strength training, or both) on adiposity in overweight and obese children and adolescents. **METHODS:** Direct and indirect randomized exercise intervention trials ≥ 4 weeks that were published in any language up to June 16, 2018 and assessed body mass index (BMI) in kilogram-meters-squared, fat mass (kg), or percent body fat in overweight and obese children 2-18 years of age were eligible. Studies were retrieved by searching seven electronic databases, cross-referencing, and expert review. Dual selection and data abstraction were conducted. Results were pooled using random-effects, restricted maximum likelihood models. Surface under the cumulative ranking curves (SUCRA) were used to establish a hierarchy of exercise interventions (aerobic, strength, both). A two-tailed alpha value ≤ 0.05 and non-overlapping 95% confidence intervals were considered statistically significant. **RESULTS:** Fifty-seven studies representing 127 groups (73 exercise, 54 control) and up to 2,792 participants (1,667 exercise, 1,125 control) met the criteria for inclusion. Statistically significant reductions in BMI, fat mass, and percent body fat were observed in aerobic vs. control comparisons (BMI, mean, 95% CI, -1.0, -1.4 to -0.6; fat mass, -2.1, -3.3 to -1.0 kg; percent fat, -1.5, -2.2 to -0.9%) and combined aerobic and strength vs. control comparisons (BMI, -0.7, -1.4 to -0.1; fat mass, -2.5, -4.1 to -1.0 kg; percent fat, -2.2, -3.2 to -1.2%). A statistically significant reduction in percent fat was also found for strength vs. control comparisons (-1.3, -2.5 to -0.1%). Based on SUCRA results, combined aerobic and strength training was ranked first for improving both fat mass (kg) and percent body fat while aerobic exercise was ranked first for improving BMI. **CONCLUSIONS:** Combined aerobic and strength training is optimal for improving adiposity-specific outcomes in overweight and obese children and adolescents. Supported by AHA Grant 17GRNT33630158

Freshmen Physical Activity Habits And Senior Fitness Levels: Examining A Healthy Transition To College
 Melissa Bopp, FACSM, Oliver W.A. Wilson, Zack Papalia, Christopher Bopp. *Pennsylvania State University, University Park, PA.*
 Email: mjb73@psu.edu
 (No relevant relationships reported)

The years in post-secondary education are important for building healthy lifestyle habits to transfer into adulthood. Previous research has indicated that physical activity (PA) declines during the years of college, and Exercise is Medicine on Campus (EIMOC) programs are poised to help address this.

PURPOSE: To examine how freshmen exercise patterns and perceptions were related to fitness and physical activity in senior year of college at a large Northeastern university.

METHODS: A volunteer sample of university seniors (n=439) completed a fitness assessment (YMCA bicycle test) and an online survey which addressed their PA participation, freshman exercise perceptions and engagement in on-campus exercise opportunities. Pearson correlations examined the relationship between fitness and PA with freshman variables. T-tests examined differences in fitness and PA by freshman variables.

RESULTS: The sample was predominately male (n=254, 59.3%) and Non-Hispanic White (n=343, 78.4%). Many (n=232, 53%) reported being more active currently than in freshman year. Most (n=178, 52.7%) reported that they were well informed of campus exercise options, 28.5% (n=125) reported doing intramural sports and 10% (n=44) did club sports as freshmen. Current VPA was associated with being better informed of options for exercise on campus as a freshman ($r=.11$, $p=.04$), campus fitness center membership as a freshman ($p=.004$), and freshman club sport participation ($p=.004$). VO₂max was associated with club sport participation as a freshman ($p<.001$). Challenges with time management (n=305, 85.4%) and lack of motivation (n=226, 63.6%) were frequent barriers to exercise as freshmen. Motivation challenges as a freshman was negatively associated with current VPA ($r=-.21$, $p<.001$) and VO₂max ($r=-.19$, $p=.001$). Students indicated that programs partnering with an exercise buddy (n=255, 74.1%) or events around outdoor exercise/outings (n=179, 52%) would have been the most useful to motivate them as freshmen.

CONCLUSIONS: This study examined how exercise patterns and perceptions as a freshman were related to PA participation and fitness as a senior. Findings indicate the importance of developing EIMOC programs and strategies to specifically help freshmen transition to college campuses and engage in healthy behaviors.

Physical Play with Children Predicts Better Hematological Health; Hematological Health Predicts Cognitive and Behavioral Development
 Kendall D. Bietsch¹, Cynthia Villalobos¹, William E. Herrin¹, Jessica Avalos¹, Norah Madaya², Courtney D. Jensen¹.
¹*University of the Pacific, Stockton, CA.* ²*Uganda Bureau of Statistics, Kampala, Uganda.*
 Email: k_bietsch@u.pacific.edu
 (No relevant relationships reported)

More than half of all Ugandan children under the age of 5 are anemic. The consequences of anemia are amplified during this period as it is critical to cognitive and physical development. Adequate physical play may bolster hematological health, and in turn cognitive and behavioral development, but this has not been previously explored. **PURPOSE:** Examine the effect of play on serum hemoglobin (Hb) among children under the age of 5 in Uganda, and to test the effect of Hb on cognitive and behavioral development. **METHODS:** We analyzed the 2016 Demographic Health Surveys of Uganda, Children's Records dataset. Anemia testing was performed on children age 6-59 months whose parents or guardians consented (N=3,944). Hb levels were collected to determine the incidence and severity of anemia. Children with Hb ≥ 11 g/dL were not considered anemic. Multiple linear regression was used to identify the effect of physical play with parents on Hb. Logistic regression analyses were used to test the effect of Hb on the odds that children were developing literacy and appropriate behaviors. **RESULTS:** On average, children were 31.3 ± 15.6 months old and had 10.9 ± 1.61 g/dL of Hb; 54.6% were anemic. Holding constant the mothers' height and weight, the child's age, height, and weight, and the region (controlling for differences in culture, geography, and altitude), if the mother or father played with their children, the children's Hb was elevated by 0.14 g/dL ($p=0.019$); if the mother smoked, the children's Hb decreased by 0.3 g/dL ($p=0.036$). Holding constant the child's age, height, and weight, increased Hb associated with increased odds of behaving appropriately around other children ($\beta=0.38$; $p=0.001$), being capable of performing tasks independently ($\beta=0.13$; $p=0.036$), being able to read and count to 10 ($\beta=0.19$; $p=0.002$), being able to read at least 4 words ($\beta=0.31$; $p<0.001$), and being able to identify at least 10 letters ($\beta=0.32$; $p<0.001$). **CONCLUSIONS:** In a sample of children from Equatorial Africa, physical play with parents predicted elevations in Hb.

In turn, elevated Hb predicted more advanced cognitive and behavioral development. Implementing physical activity in parent-child interactions may have value as a primary prevention for anemia and it may also help advance the child's growth and maturation.

476 Board #314 May 29 11:00 AM - 12:30 PM
Health/Fitness Assessments of Resident Physicians by Exercise Science Interns - Exercise Prescriptions and Follow-Up Measures

Rachel R. Swinford, Stephen M. Fallowfield, Brain D. Krohn, NiCole R. Keith, FACSM. *IUPUI, Indianapolis, IN.* (Sponsor: NiCole Keith, FACSM)
 Email: rswinfor@iupui.edu
 (No relevant relationships reported)

Resident physicians' postgraduate training and fitness status are important predictors of their decision to provide physical activity (PA) counseling to their patients. Providing instruction about these topics within medical education may improve residents' health/fitness outcomes and increase the likelihood of residents providing PA counseling to their patients. **Purpose:** To assess the health/fitness status of resident physicians during a healthy lifestyle rotation. **Methods:** We measured 187 resident physicians' health/fitness status for one required assessment and two optional follow-up assessments that were on average, 9.5 months apart. Residents learned their results, received an exercise prescription, and were supported by an Exercise Science Student Trainer during one PA session. Residents could then exercise independently at an employee only fitness facility, elsewhere, or not at all. **Results:** The mean age of the sample was 28.07 ± 1.99 yrs. All baseline measures indicated residents were in a healthy (good to above average) range for males (n = 110) and females (N = 77). T-tests were used to evaluate the waist circumference of residents who completed assessments 1 and 2 (n=55). Waist circumference increased from 78.7 ± 32.1 cm to 84.3 ± 33.7 cm (p<.05). No other measures (BMI, body fat, VO₂max, RHR, SBP, DBP, push-up, plank, and sit and reach) were significantly different. ANOVA was used to evaluate those who completed three assessments (n=18). This group experienced an increased BMI (23.9 ± 3.51 kg/m², 24.27 ± 4.11 kg/m², 24.56 ± 3.71 kg/m²; p<0.05) and body weight (73.14 ± 15.74 kg, 74.05 ± 18.1kg, 76.90 ± 17.23 kg; p<0.05). No other measures were significantly different. **Conclusion:** Few residents participated in more than the mandatory assessment. Those who volunteered for follow-up demonstrated increases in weight-related measures and no improvement in health/fitness outcomes. Additional supports for residents to participate in PA, achieve or maintain a healthy weight, and maintain or improve health/fitness outcomes is needed to positively influence these factors and increase the likelihood of resident physicians promoting PA to their patients.

477 Board #315 May 29 11:00 AM - 12:30 PM
Examining the Effects of Exercise Referral Schemes on Changes in Physical Activity Levels.

Nikita Z. Rowley¹, James Steele², Steve Mann³, Gary Liguori, FACSM⁴, Alfonso Jimenez¹, Elizabeth Horton¹. ¹Coventry University, Coventry, United Kingdom. ²uactive, London, United Kingdom. ³Places for People, London, United Kingdom. ⁴University of Rhode Island, Kingston, RI.
 Email: nikitarowley@outlook.com
 (No relevant relationships reported)

Exercise referral within the United Kingdom (UK) offers individuals an opportunity to take part in physical activities in a non-clinical environment, yet gain clinical health benefits. Referral schemes focus on improving health outcomes, including increased physical activity (PA), of medically referred individuals. However, inconsistencies have been found within the literature reviewing impact of exercise referral on improving PA levels. **PURPOSE:** To determine if exercise referral schemes (ERS) influence change in PA levels amongst individuals across the UK. **METHOD:** Data were obtained from 5246 participants (53 ± 15 years; 68% = female) who attended 12 different ERSs. Participants self-reported IPAQ scores pre- and post- scheme completion to determine if exercise referral had any impact on PA levels. Schemes were 12 weeks in length and situated in leisure environments including gyms, leisure centres and community halls, throughout the UK. Exercise prescriptions consisted of both aerobic and resistance training. Two-stage individual patient data meta-analysis was performed separately on the pre-ERS, and on the change scores (post- minus pre-ERS scores), for metabolic equivalent (MET)-minutes per week; analysis was chosen due to data being hierarchical and accounting for clustering at scheme level. **RESULTS:** Analyses were conducted on the continuous data collected through the IPAQ. For pre-ERS MET-minutes the estimate from random effects model was 1183 MET-minutes per week [911 to 1457], p< 0.0001. For ERS change, the estimate from random effects model for was 666 MET-minutes per week [385 to 948], p< 0.0001. Significant heterogeneity was evident among the schemes (Q₍₁₁₎ = 162.22, p< 0.001; I² = 97.71%). Considering the estimate for pre-ERS MET-minutes (1183 MET-minutes), the estimate for change in MET-minutes could be considered meaningful, as it would result in participants moving from the 'moderate' to 'high' category for PA. **CONCLUSION:**

This change in PA represents greater reductions of risks of specific physical inactivity-related conditions, such as obesity and type 2 diabetes. The results showed meaningful change in MET-minutes, which resulted in participants moving from 'moderate' to 'high' on the IPAQ, suggesting that a scheme length of 12 weeks is sufficient for changing PA levels.

Low Usage of Physical Activity Related Diagnostic Codes Among Indiana Medical Providers

NiCole R. Keith, FACSM¹, Lauren R. Lembke², Erik A. Imel³. ¹Indiana University Purdue University, Indianapolis, Indianapolis, IN. ²Regenstrief Institute, Incorporated, Indianapolis, IN. ³Indiana University School of Medicine, Indianapolis, IN.
 Email: nkeith@iupui.edu
 (No relevant relationships reported)

The National Academy of Medicine and "Exercise Is Medicine®" recommend physicians routinely advise patients about physical activity (PA) and, when needed, refer to PA support to improve patient and population health. Uptake of these recommendations has been slow. Knowledge of diagnostic codes for billing may influence provider behavior. The Indiana Health Information Exchange (IHIE) connects more than 100 healthcare entities and 40,000 providers for >18 million patients, with >10 billion clinical data elements. **Purpose:** To document ICD-9 and ICD-10 PA-related billing code use for "Lack of Physical Exercise" and "Physician Exercise Counseling". **Methods:** We searched IHIE for PA-related ICD-9 and ICD-10 codes and comorbidity codes from 01/01/94 through 04/24/18. **Results:** PA-related ICD codes were used for 54,543 patients, but <10% (5,221) were used for adults. Fewer occurrences were in adult patients with common chronic diseases that could be improved through PA (Table 1).

| Table 1 | Total Patient Count | "Lack of Physical Exercise" | | "Exercise Counseling" | |
|--|---------------------|-----------------------------|--------------|-----------------------|---------------|
| | | ICD-9 V69.0 | ICD-10 Z72.3 | ICD-9 V65.41 | ICD-10 Z71.82 |
| All Patients | 54,543 | 993 | 357 | 52,317 | 1,104 |
| Adults Only | 5,221 | 607 | 329 | 3,970 | 382 |
| Comorbidities of 5,221 Adults – ICD Code Use within 1 Year of PA-Related Code | | | | | |
| | Adults | "Lack of Physical Exercise" | | "Exercise Counseling" | |
| Condition | | ICD-9 V69.0 | ICD-10 Z72.3 | ICD-9 V65.41 | ICD-10 Z71.82 |
| Type 2 Diabetes | 821 | 160 | 97 | 515 | 60 |
| Hypertension | 1,577 | 299 | 73 | 1,217 | <10 |
| Insomnia | 392 | 58 | 38 | 275 | 21 |
| Osteoarthritis | 611 | 134 | 77 | 380 | 27 |
| Osteoporosis | 116 | 38 | 22 | 53 | <10 |
| BMI 25.0-29.9 | 104 | <10 | 24 | 54 | 28 |
| BMI 30.0-34.9 | 284 | <10 | 19 | 167 | 109 |
| BMI 35.0-35.9 | 352 | 12 | 22 | 177 | 155 |
| BMI 40-49.9 | 425 | 20 | 19 | 219 | 173 |
| BMI > 50 | 163 | 12 | <10 | 87 | 57 |

Discussion: Low use of PA-related ICD codes may be due to a lack of awareness of existing codes. Physician education regarding PA-related ICD codes may increase physician counseling, code usage and possibly referral to PA resources.

Making Strides Towards Health: Expanding Physician-led Walking Groups In The Community
 Alexa Namba, Adeola Awodele, Cherie Conley, Sarah McMahon, Jaehan Yi, Amy Zhao, Janet Bettger. *Duke University, Durham, NC.*
 Email: alexa.namba@duke.edu
 (No relevant relationships reported)

While healthy lifestyle modification is often the first line recommendation to treat and prevent chronic disease, physicians inconsistently provide patients with guidance and resources to ensure appropriate physical activity participation. **PURPOSE:** To increase physical activity among patients, this project aimed to expand a physician-led walking program from a single clinic to a community-based partnership for broader reach. **METHODS:** The originally developed Walk with a Doc (WwaD) program was established in a family medicine clinic. Patients were referred to attend the monthly program during clinical encounters. The four phases of the IHI Scale-up Framework were applied to (1) examine the existing program (provider buy-in for walking prescriptions, rate of referral, and patient participation and satisfaction); (2) define a scalable program; (3) test the new context for scale-up (validate feasibility, utility and acceptability); and (4) plan to go to full scale. **RESULTS:** The WwaD program had 82 unique patients participating over 36 months of implementation with 15 providers making referrals to the walking program and 100% participant satisfaction. A landscape assessment of available parks and trails was completed and locations were geospatially mapped to examine distance from outpatient clinics. In partnership with the city's Parks and Recreation department, new walking program sites were identified to leverage "healthy mile" trails in local neighborhoods with existing clinics. Site surveys confirmed clinic patients' and providers' interest, and trail safety and accessibility. The scalable program was defined to include a walking prescription and referral to the program, program reminders for the patient, and use of the city's designated healthy mile trails. Pre-health students were incorporated to improve the ratio of program leads to patients, improve participant satisfaction, and to build student volunteers' understanding of exercise as medicine and interdisciplinary competencies for future health professions careers. **CONCLUSION:** Leveraging the commitment to shared goals for increased physical activity, we developed a scalable walking program with integrated clinical, academic and community resources in a mutually beneficial partnership to improve patients' health and well-being.

Translating Physical Activity Evidence into Exercise Medicine the Moving Medicine Project, UK
 Kush Joshi¹, Natasha Jones², Hamish Reid², Ralph Smith², Rebecca Robinson³. ¹Homerton University Hospital, London, United Kingdom. ²Oxford University Hospitals, Oxford, United Kingdom. ³Sheffield University Hospitals, Sheffield, United Kingdom. (Sponsor: Kathryn Schmitz, FACSM)
 (No relevant relationships reported)

Moving medicine is a novel interactive information resource in UK healthcare. This initiative from the Faculty of Sport and Exercise Medicine was developed in partnership with Public Health England and Sport England. **PURPOSE** The UK's pandemic levels of physical inactivity are associated with high mortality and morbidity. Despite overwhelming evidence supporting the role of physical activity (PA) in management of non-communicable chronic disease, knowledge, skills, time and healthcare professionals (HCP) confidence limit PA promotion across healthcare environments. This integrative digital resource was developed to empower HCPs to give PA advice. The resource provides an evidence-based approach to facilitate interaction and behaviour change. **METHODS** Using a knowledge into action framework this interactive tool was developed in a 2-step process. 1. Knowledge creation Literature reviews defined the evidence and expert working groups were recruited across 9 NCD streams, undertaking narrative reviews, refining evidence in clinical context. 2. Action cycle Delphi study and behavioural change framework analysis underpinned an iterative development process to create action cycles in a time based framework. **RESULTS** Moving Medicine was launched successfully in October 2018 by the UK Secretary of State for Health, headlining this flagship set of resources that champion physical activity as a powerful tool to change behaviour and improve the trajectory of chronic disease. Formal evaluation will follow the initial launch and delivery phase. **CONCLUSION** High levels of professional engagement and early positive feedback indicate Moving Medicine is an acceptable, adaptable novel tool supporting HCPs to engage patients with meaningful conversations about PA. Formal analysis will add to this knowledge and inform transferability across healthcare environments. Further steps for development are projected to include online modules on prescribing movement, educational resources and an active hospital toolkit. Moving Medicine welcomes international collaboration and is open access and free to use at www.movingmedicine.ac.uk.

Tennis Players Enjoy Better General, Physical, Social and Mental Health: A Survey of 10,380 United States Tennis Association Leagues Players Using Norm-Based SF-36 Scores
 Jared C. Tishelman, Daniel Bu, James Gladstone, Alexis Colvin. *Icahn School of Medicine at Mount Sinai, New York, NY.*
 (No relevant relationships reported)

PURPOSE: The purpose of this study is to characterize the general, physical, social and mental health of USTA members using validated SF-36 outcomes domains in reference to the general population.

METHODS: A modified SF-36 version 1.0 was administered to USTA members via online form. The following patient variables were included: Age group (18-29, 30-39, 40-49, 50-59, 60-69, 70-79, 80+), days of tennis per week, self-reported ability, National Tennis Rating Program (NTRP) score, smoking status, BMI and sex. The following SF-36 outcomes domains were included for analysis: Physical Functioning (PF), Role Physical (RP), Bodily Pain (BP), General Health (GH), Vitality (VT), Social Functioning (SF), Role Emotional (RE), Mental Health (MH). Physical Component Summary (PCS) and Mental Component Summary (MCS) scores were calculated. Norm-Based Scores (NBS) were computed for these domains using an algorithm provided by Optum Health (Eden Prairie, MN); general population mean of 50; standard deviation of 10.

RESULTS: 10,380 USTA leagues members responded and completed the modified SF-36 questionnaire. 63% of respondents were female, the average BMI of the cohort was 24.88±4.17 and 97.7% reported that playing tennis helps them manage their health. For all Norm-based SF-36 domains, USTA athletes scored higher than the general population (mean = 50). Multivariate comparisons revealed higher SF-36 outcomes scores for younger athletes (all SF-36 domains, p<0.001), and more frequent players (all domains, p<0.001). Elite tennis players (NTRP>4) scored higher for the PF domain than those with less advanced tennis skills. Female tennis players reported higher BP, GH, PCS scores and lower BMI (All p<0.002). Elderly tennis players (age > 70) scored worse for PF, RP, GH, VT, SF, RE, and MH domains for the SF-36 (p<0.001). Additionally, patients who reported playing more than 3 days per week scored higher in all categories (all p<0.003).

CONCLUSIONS: USTA members enjoy above average general, physical, social and mental health scores. Patients with a higher level of skill have higher physical functioning. Younger tennis players and athletes who competed more than 3 occasions per week scored higher in all SF-36 domains than those who were older and played less, respectively.

B-07 Thematic Poster - Blood Flow

Imaging Transcranial Doppler: A Novel Approach to Assess Cerebral Blood Flow

Catherine L. Jarrett¹, Katherine L. Shields¹, Ryan M. Broxterman¹, Soung Hun Park¹, Jayson R. Gifford², Russell S. Richardson¹. ¹University to Utah, Salt Lake City, UT. ²Brigham Young University, Provo, UT.

Email: catherine.jarrett@utah.edu

(No relevant relationships reported)

Cerebral blood flow is commonly assessed in the middle cerebral artery (MCA) as blood velocity, using non-imaging transcranial Doppler ultrasound (TCD). However, to accurately determine blood flow, both blood velocity and vessel diameter are critical components, and there is mounting evidence that the MCA is vasoactive. **PURPOSE:** Therefore, the purpose of this study was to employ imaging TCD (ITCD), utilizing color flow and pulse wave velocity, as a novel approach to measure both MCA blood velocity and diameter to quantify cerebral blood flow. **METHODS:** ITCD was performed at rest in 9 healthy participants (7M/2F; 29±5 yrs) with sublingual nitroglycerin (NTG, 0.8mg) and without (CON). Measurements were taken for 2 minutes prior, and for 5 minutes following NTG or sham delivery (CON). **RESULTS:** There was a 6-fold fall in MCA blood velocity in response to NTG ($\Delta -4.8\pm 4.2$ cm/s) compared to negligible fluctuations in CON ($\Delta -0.81\pm 2.5$ cm/s). MCA diameter increased much more in response to NTG ($\Delta 0.17\pm 0.02$ cm) compared to the basal variation in CON ($\Delta 0.01\pm 0.04$ cm). Interestingly, the product of this NTG-induced fall in MCA blood velocity and increase in MCA diameter was a significant increase in blood flow following NTG ($\Delta 159\pm 59$ ml/min) compared to CON ($\Delta 24\pm 46$ ml/min). **CONCLUSIONS:** These juxtaposed data highlight the importance of measuring both MCA blood velocity and diameter when assessing cerebral blood flow and document ITCD as a novel approach to achieve this goal. Supported by the Veterans Administration Rehabilitation Research and Development Service (E6910-R, E1697-R, E1433-P, E9275-L and E1572-P).

519 Board #2 May 29 1:00 PM - 3:00 PM
Arm Circumference As A Method To Standardize The Practical Blood Flow Restriction Pressure

Scott J. Dankel¹, J Grant Mouser², Takashi Abe¹, Zachary W. Bell¹, Samuel L. Buckner³, Kevin T. Mattocks⁴, Matthew B. Jessee⁵, Jeremy P. Loenneke¹. ¹The University of Mississippi, University, MS. ²Troy University, Troy, AL. ³The University of South Florida, Tampa, FL. ⁴Lindenwood University-Belleville, Belleville, IL. ⁵University of Southern Mississippi, Hattiesburg, MS.

(No relevant relationships reported)

Practical blood flow restriction training using elastic cuffs is gaining popularity. A criticism of this method is that the pressure applied and the amount of blood flow restriction induced is difficult to quantify. **PURPOSE:** To quantify blood flow following the application of an elastic-cuff and compare that to what is observed using a more traditional pressurized nylon-cuff. **Methods:** 35 participants visited the laboratory once for testing. In a randomized order (one condition per arm), an elastic-cuff (5cm wide) was applied to one arm and blood flow was measured following the cuff being pulled to two distinct lengths; 110% (low pressure) and 120% (high pressure) of the individuals resting arm circumference. The other arm followed a similar protocol but used a pressurized nylon-cuff (5cm wide) inflated to 40% (low pressure) and 80% (high pressure) of the individuals resting arterial occlusion pressure. **RESULTS:** There was a main effect of pressure ($p<0.001$) with blood flow decreasing from resting in a pressure dependent manner as follows: low pressure: -27.3 (95% CI: -39.5, 15.1) mL/min and high pressure: -47.2 (95% CI: -64.5, -29.9) mL/min. The mean difference (95% CI) in blood flow between cuffs at a given pressure was -5.9 (-18.9, 7.0) % for the lower pressure and -4.0 (-13.2, 5.1) % for the higher pressure. When the relative changes for each cuff were separated by sex, there were no differences in the changes from Pre. The relative difference (95% CI) between sexes were as follows: -5.3 (-23.5, 12.9) % for the nylon cuff inflated to a low pressure, -1.6 (-20.1, 16.8) % for nylon cuff inflated to a high pressure, 6.5 (-13.3, 26.3) % for the elastic pulled to a low pressure, and -4.5 (-24.2, 15.1) % for the elastic cuff pulled to

a high pressure. **CONCLUSIONS:** Our results indicate that an elastic cuff pulled to 110% and 120% of resting arm circumference decreases brachial artery blood flow in a pressure dependent manner. These pressure dependent decreases in blood flow were similar to that observed when a pressurized nylon cuff was inflated to 40 and 80% of the individuals resting arterial occlusion pressure. The application of a pressure relative to the initial cuff length, which is largely dependent upon arm circumference, appears to provide one method to standardize the practical blood flow restriction pressure for future research.

Understanding the middle cerebral artery dynamic response during different exercise intensities is vital for understanding brain health and designing and evaluating exercise strategies for maximizing therapeutic potential. However, whether there is an interaction between exercise intensity and cerebrovascular kinetics is unknown. **PURPOSE:** To characterize mean middle cerebral artery blood flow velocity (MCAv) kinetics associated with two exercise work rates: low and moderate. We tested the hypotheses that increasing work rate would increase the MCAv amplitude and that age and estimated maximal oxygen uptake ($\dot{V}O_{2max}$) would be related to the MCAv amplitude. **METHODS:** Baseline values were collected for 90-seconds followed by a 6-minute exercise bout on a recumbent stepper. Heart rate, end tidal CO_2 ($P_{ET}CO_2$), beat-to-beat blood pressure, and MCAv were recorded at rest and during exercise. The MCAv kinetics response for participants from baseline (BL) was described by the response amplitude (Amp), time delay (TD), and time constant (τ). **RESULTS:** Sixty-four adults completed the low and moderate intensity exercise transitions. MCAv Amp increased from rest as a function of work rate, low and moderate intensity, respectively, (11.8 and 14.7 cm/s; $p<0.001$) while no difference between work rates were observed in either TD (43.5 and 45.8 s; $p=0.65$) or τ (35.2 and 31.4 s; $p=0.47$). Age showed a moderate, negative association with MCAv Amp ($r=-0.40$ and $r=-0.42$; $p<0.01$). Higher estimated $\dot{V}O_{2max}$ demonstrated a moderate, positive correlation with MCAv Amp ($r=0.41$ and $r=0.50$; $p<0.01$). **CONCLUSION:** Moderate intensity exercise induced a greater MCAv response amplitude compared to low intensity exercise. The amplitude of the initial MCAv response for both exercise intensities increased systematically with work rate whereas the TD and τ kinetics parameters were invariant. Therefore, the possibility exists that the cerebrovascular system may have protective mechanisms in place to avoid the more rapid responses as seen in skeletal muscle, however more work is needed to address this hypothesis. Finally, although the MCAv Amp declines with age, maintaining higher cardiorespiratory fitness may benefit the cerebrovascular response to exercise.

The Influence of a High Sodium Meal on Cerebrovascular Reactivity

Kamila U. Migdal¹, Austin T. Robinson¹, Joseph C. Watson¹, Matthew C. Babcock¹, Jorge M. Serrador², William B. Farquhar, FACSM¹. ¹University of Delaware, Newark, DE. ²Rutgers University, Newark, NJ.

(No relevant relationships reported)

Single high sodium (Na^+) meals transiently reduce peripheral blood vessel function in humans. Rodent models demonstrate that high dietary Na^+ intake reduces middle cerebral artery (MCA) function. Cerebrovascular reactivity (CVR) to carbon dioxide (CO_2) is a validated method for assessing the cerebrovasculature in humans. However, the effects of a single high dietary Na^+ meal on CVR in humans is unknown. **PURPOSE:** We tested the hypothesis that a single high- vs low- Na^+ meal impairs CVR in young adults. **METHODS:** Nineteen healthy, normotensive adults (9M/10F; age: 26±4 yrs; BMI: 23.6±5.1 kg/m²; BP: 105±9/58±6 mmHg, mean±SD) participated in this crossover design study. We provided participants with high- (HS: 1,495 mg) and low- (LS: 138 mg) Na^+ meals in randomized order. Visits were separated by one week for males. We tested females in the early follicular phase of their menstrual cycle. Transcranial doppler of the right MCA was assessed while participants lay supine. Serum Na^+ and CVR (% Δ MCA velocity/ Δ CO₂) to high CO₂ (hypercapnia) and low CO₂ (hypocapnia) were measured prior to-, 30 minutes post- and 60 minutes post-meal. Data were analyzed using two-way repeated measures ANOVA (meal x time). Tukey post hoc comparisons were used when appropriate. **RESULTS:** Serum Na^+ was elevated on the high- Na^+ meal at 30- (HS=141.2±0.3 vs LS=140.0±0.5 mmol/L, $p<0.01$) and 60-minutes post meal (HS=141.7±0.8 vs LS=140.2±0.6 mmol/L, $p<0.001$). Hypercapnia increased MCA velocity from baseline at 30- (HS=29±1 vs

LS=28±1%) and 60- (HS=27±1 vs LS=29±1%) minutes post meal without an effect of the meal ($p>0.05$). Hypocapnia decreased MCA velocity from baseline at 30- (HS=43±4 vs LS=45±4%) and 60- (HS=47±3 and LS=45±4%) minutes post meal without an effect of the meal ($p>0.05$). Despite elevated serum Na⁺, the HS meal did not alter CVR to hypercapnia (30min: HS=Δ-0.03±0.21 vs LS=Δ-0.19±0.22 %/mmHg; 60min: HS=Δ-0.08±0.20 vs LS=Δ-0.16±0.21 %/mmHg, $p>0.05$). Additionally, CVR to hypocapnia was not different between the two meals (30min: HS=Δ0.15±0.08 vs LS=Δ0.08±0.12 %/mmHg; 60min: HS=Δ0.17±0.07 vs LS=Δ-0.001±0.09 %/mmHg, $p>0.05$). **CONCLUSION:** These preliminary data suggest that a high sodium meal does not acutely alter cerebrovascular reactivity in healthy young adults. Supported by: ACSM 17-00577 (KUM) and NIH Grant R01HL128288 (WBF)

The Effects of Prolonged Sitting on Cerebral Perfusion and Executive Function

Jade Blackwell¹, Quentin Willey¹, Bill Evans², Katie Burnet¹, Erik Hanson¹, Daniel Credeur³, Lee Stoner, FACSM¹. ¹University of North Carolina, Chapel Hill, NC. ²University of Maryland, College Park, MD. ³University of Southern Mississippi, Hattiesburg, MS. (Sponsor: Lee Stoner, FACSM) (No relevant relationships reported)

Purpose: Little is known about the effects of prolonged sitting on cerebrovascular function. We hypothesized intermittent calf raises (every 10min) would: (i) prevent venous pooling in the lower extremities; (ii) maintain cerebral perfusion; (iii) maintain executive function. **Methods:** 20 healthy, yet sedentary subjects (19-35 years old) were recruited to participate in two 3 hr sitting conditions: control (CON) and experimental heel-raise (HEEL) study. Cerebral perfusion (total haemoglobin, tHb) and tissue oxygenation (tissue saturation index, TSI) were measured using near-infrared spectroscopy (NIRS) and the Stroop-color test evaluated executive function. Measurements were made at 10, 90 and 170min. **Results:** There were non-significant time effects for cerebral tHb ($p=0.287$) and TSI ($p=0.923$); however, calf raises decreased tHb ($p<0.001$, $d=0.633$) but had no effect on TSI ($p=0.761$). There was a non-significant time ($p=0.641$) and condition ($p=0.083$) effect for the Stroop-color test. **Conclusion:** Intermittent calf raises prevent venous pooling in the lower extremities in healthy, yet sedentary young subjects, but do not improve cerebral perfusion or executive function.

Using Continuous And Interval Exercise To Manipulate Shear Rate Patterns In The Common Femoral Artery

Abigail L. Cook, Gemma K. Lyall, Karen M. Birch, FACSM. University of Leeds, Leeds, United Kingdom. (Sponsor: Karen M. Birch, FACSM) Email: bsaco@leeds.ac.uk (No relevant relationships reported)

Vascular shear rate (SR) assessed via ultrasound represents frictional force of blood flowing over the endothelium. Low and oscillatory shear confers a pro-inflammatory phenotype, whereas greater shear has an anti-inflammatory phenotype decreasing CVD risk. Exercise increases SR, however the impact of continuous (CON) and interval (INT) exercise upon the balance of antegrade (ANT) and retrograde (RET) SR and thus the oscillatory shear index (OSI) is unknown. **PURPOSE:** To examine the impact of acute CON and INT (no active recovery) exercise on SR patterns and OSI in the common femoral artery (CFA) during exercise. **METHODS:** 10 healthy individuals (25±3 years, n=5 male) underwent two work-matched exercise sessions (CON and INT) on a supine cycle ergometer at 125% lactate threshold. In each protocol repetitive ultrasound scans were taken of the CFA during a brief cessation in exercise to determine in-exercise shears. Flow mediated dilatation (FMD) was measured before and after exercise to assess acute changes in endothelial function. **RESULTS:** FMD did not differ after exercise in either protocol (CON: 9.9±8.1% vs 8.4±6.2%; INT: 9.1±5.9% vs 6.6±3.4%; $P>0.05$). ANT and RET SR reached a plateau in each protocol. Total ANT SR was lower in CON than INT (CON: 861540±291534 vs INT: 1955615±674594 s⁻¹; $P<0.05$), however total RET SR did not differ between protocols (CON: 76625±89390 vs INT: 78126±78697 s⁻¹; $P>0.05$). Peak and mean SR were similar in CON and INT, respectively (peak ANT: 1258±403 vs 1480±510 s⁻¹; RET: 107±123 vs 108±75 s⁻¹; $P>0.05$; mean ANT: 1171±372 vs 1358±469 s⁻¹; RET: 61±81 vs 54±55 s⁻¹; $P>0.05$). Mean and peak OSI were also similar in both types of exercise (peak CON: 0.07±0.08 vs INT: 0.08±0.06 AU; mean CON: 0.05±0.06 vs INT: 0.04±0.04 AU; $P>0.05$). No time was spent in pure oscillatory shear (>0.5 AU). **CONCLUSION:** During exercise matched for intensity and the duration of muscular work, using an INT approach ensured a similar OSI but a greater total ANT SR compared to CON. This would suggest that in the exercising limb INT exercise does not confer a negative oscillatory profile. GRANT FUNDING: Medical Research Council

Impact of a Brief Period of Uninterrupted Sitting on Cerebrovascular Hemodynamics

Raymond Jones¹, Dominique McArthur¹, Stephanie M. McCoy¹, Lee Stoner, FACSM², Daniel P. Credeur¹. ¹University of Southern Mississippi, Hattiesburg, MS. ²University of North Carolina, Chapel Hill, NC. (Sponsor: Lee Stoner, FACSM) Email: raymondjones@usm.edu (No relevant relationships reported)

Prolonged periods of uninterrupted sitting (1-6 hours) have been shown to reduce lower limb blood flow, impair vascular endothelial function of leg arteries, and increase central arterial stiffness. It is unclear whether sitting can have a similar negative impact on cerebrovascular hemodynamics. **PURPOSE:** To determine the impact of a brief period (1 hour) of uninterrupted sitting on total brain blood flow (BBF). **METHODS:** Eleven participants (25±1 years, BMI=26±1 kg/m², Female=5) completed a 1-hour bout of sitting. Assessments of central (heart rate and mean arterial pressure) and cerebrovascular hemodynamics (carotid artery blood flow, assessed via Doppler-ultrasound) were performed pre-post 1-hour of sitting (supine), as well as during the sitting intervention (10- and 60-minutes). In a subset (N=7), blood flow through the internal carotid (ICA) and vertebral arteries (VA) was examined to estimate total BBF [(ICA+VA)*2]. **RESULTS:** When measured supine, HR and MAP were similar pre-post sitting. However, there was a significant increase in HR when measured while seated (i.e., 10-mins=67±3 vs. 60-mins=70±4 bpm; $p=0.02$). CCA blood flow was comparable pre-post sitting ($p=0.25$), but decreased 10-60 minutes while seated (10-mins=1049±64 vs. 60-mins=921±63 mL/min; $p=0.006$). Conversely, estimated total BBF significantly decreased pre-post sitting (pre=1039±135 vs. post=843±82 mL/min; $p=0.01$), but was comparable between the 10- and 60-minute time points (10-mins=799±148 vs. 60-mins=802±125 mL/min; $p=0.95$). **CONCLUSIONS:** These preliminary findings suggests that cerebrovascular hemodynamics are significantly affected by a 1-hour bout of uninterrupted sitting, largely due to a reduction in estimated total BBF.

An Examination of Group and Individual Response Rates to Ischemic Preconditioning for Sport Performance

Joshua Slysz, Heather Petrick, Jamie Burr, FACSM. University of Guelph, Guelph, ON, Canada. (Sponsor: Jamie Burr, FACSM) Email: jslysz@uoguelph.ca (No relevant relationships reported)

PURPOSE: Ischemic Preconditioning (IPC) has been shown to improve exercise performance; yet large variability in response exists between individuals and the mean changes reported between studies. It has been suggested that there are responders and non-responders to IPC and this is a common explanation for the observed variability. At present, existing studies that demonstrate individual responses to IPC lack an appropriate assessment of the within-subject variability of the exercise task, thereby preventing proper evaluation of response versus non-response to the stimulus. Thus, the purpose of this study was to use repeated control trials to measure within-subject variability to assess the existence of true responders to IPC. **METHODS:** In a randomized, crossover design, twelve recreational cyclists (7m/5f, 30yrs, 72kg, 175cm, 55ml·min⁻¹·kg⁻¹) completed six, 5km cycling time trials, each separated by one week. Three separate trials were performed with and without IPC to characterize the expected individual variability in performance with and without treatment. For each IPC trial, IPC was completed 15 minutes prior to exercise and consisted of 3x5-min cycles of bilateral occlusion and reperfusion to the upper thighs. **RESULTS:** Comparing baseline control to IPC, mean time to completion did not reach significance (5±8s or 1.0±1.8%, $p=0.08$), despite a 1% change commonly being recognized as the benchmark for a meaningful alteration in performance. Examination of individual participant data revealed 8 of 12 (68%) participants improved mean 5km TT performance following IPC (2.1±1.3%). If the individual's mean IPC response is considered only as an improvement that exceeded one's own percent coefficient of variation from the repeated controls (0.4±0.8%) then 7 (58%) and 5 (42%) would be classed as legitimate responders and non-responders. When the individual response or non-response to IPC was examined over the three repeated IPC trials, 81% and 87% of trials confirmed the effect, respectively. **CONCLUSIONS:** We present evidence that individual performance is affected at a magnitude that exceeds normal variability. This suggests the existence of participants who consistently respond to IPC exposure at a magnitude that exceeds chance.

B-08 Thematic Poster - Cooling Interventions, Physiological Responses, and Performance in the Heat

527 Board #1 May 29 1:00 PM - 3:00 PM Extra- And Intra- Renal Vascular Responses To Sympathetic Activation Are Not Modified Following Cooling Recovery

Christopher L. Chapman, Julia M. Benati, Nicole T. Vargas, Blair D. Johnson, Penelope C. Lema, Zachary J. Schlader, FACSM. *University at Buffalo, Buffalo, NY.* (Sponsor: Zachary J Schlader, FACSM)
(No relevant relationships reported)

Elevated renal vascular resistance (RVR) during heat stress may provoke localized ischemia, especially when exposed to multiple sympathetic stressors. Whole-body cooling reduces risks associated with heat stress. However, this cooling raises RVR and could therefore exacerbate increases in RVR caused by prior heat stress, particularly during sympathetic activation. **PURPOSE:** To test hypotheses that increases in both extra- and intra- RVR to the cold pressor test (a sympathoexcitatory stimulus, CPT) are exacerbated by whole-body cooling following heat stress. **METHODS:** Nineteen healthy adults (22 ± 2 y) underwent passive heat stress sufficient to raise core temperature 1.2°C above normothermic baseline (NT), after which they underwent passive cooling recovery (CR) to within 0.2°C of NT. Participants completed a 2 min CPT at NT and at the end of CR. Changes in body weight provided an indication of dehydration. Heart rate (HR), mean arterial pressure (MAP), and renal blood velocity (RBV) were measured pre-CPT (Pre) and at the end of the CPT (End). RBV was measured using the coronal approach with Doppler ultrasound at the distal segment of the right renal artery (Extra-, n=11) or in the same segmental artery within participants in the right kidney (Intra-, n=8). RVR was calculated as MAP/RBV. Data are presented as mean ± SD. **RESULTS:** The change in body weight was -1.2 ± 0.5%. In Extra- at Pre, MAP was elevated in CR compared to NT (95 ± 9 vs. 85 ± 7 mmHg, P<0.01) with no differences in HR (58 ± 7 vs 56 ± 9 bpm, P=0.24). MAP and HR in Intra- at Pre did not differ from Extra- (P≥0.72). In Extra- at Pre, RBV (33 ± 4 vs 36 ± 5 cm/s, P=0.01) and RVR (0.35 ± 0.06 vs 0.43 ± 0.08 mmHg/cm/s, P<0.01) were lower in CR compared to NT. RBV was lower and RVR was higher in Intra- compared to Extra- (P≤0.02) at Pre. At End, increases in HR (12 ± 9 vs 14 ± 7 bpm, P=0.50) and MAP (24 ± 16 vs 24 ± 16 mmHg, P>0.99) were not different between CR and NT in Extra-. Changes in RBV (-3 ± 5 vs -2 ± 7 cm/s, P=0.59) and increases in RVR (1.24 ± 0.97 vs 0.95 ± 0.99 mmHg/cm/s, P=0.29) did not differ between CR and NT in Extra- at End. There were no differences in the HR, MAP, RBV, or RVR response to CPT in Intra- compared to Extra- (P≥0.10). **CONCLUSION:** Whole-body cooling following passive heat stress does not affect the extra- or intra- renal vascular responses to sympathetic activation.

528 Board #2 May 29 1:00 PM - 3:00 PM Cooling Treatment Induces Changes in Aquaporins Expression as a Protective Mechanism for Exertional Heat Stroke

Abstract: Cooling treatment is important to ensure the survival of patients with Exertional Heat Stroke (EHS); however, the protective mechanism of aquaporins in the cooling treatment of EHS is not very clear. Cooling treatment induces changes in renal aquaporins and regulates homeostasis of water metabolism, which mechanism involves aquaporin gene expression. **PURPOSE:** To determine the role of AQP2 mRNA expression and AQP2 protein expression in kidney in the homeostasis of water metabolism when EHS rats were treated with cooling. **METHODS:** In this study, there

were 4 groups of male SD rats, including normal control group (NC, n=8), EHS onset group (EHSO, n=9), EHS rest group (EHSR, n=9) and EHS cooling group (EHSC, n=8). We established the rat model of EHS by exercising to exhaustion in the environment of 36°C temperature and 75% humidity until rectal temperature reaching about 42°C. The cooling treatment for EHS was to immerse in cold water for 5 minutes at 19°C. Blood and kidney were taken. Hct in serum was measured by automatic blood cell analyzer. PCR and WB were used to detect AQP2 mRNA expression and AQP2 protein expression respectively. Data were analyzed with Mann-Whitney U in nonparametric test. **RESULTS:** When EHS occurs, Hct increased significantly (EHSO: 0.43±0.29 vs. 0.40±0.04/L, p<0.05). To fit for water metabolism, AQP2 mRNA expression and AQP2 protein expression were up-regulated significantly (EHSO vs. NC) (mRNA: 3.45±0.95 vs. 1.19±0.37, p<0.01; Protein: 2.76±1.01 vs. 1.00±0.00g/L, p<0.01). After cold water immersion, No significant change of Hct was found, AQP2 mRNA expression and AQP2 protein expression were significantly down-regulated (EHSC vs. EHSO) (mRNA: 1.66±0.33 vs. 3.45±0.95, p<0.01; Protein: 1.52±0.85 vs. 2.76±1.01g/L, p<0.05). **CONCLUSIONS:** Hct, AQP2 mRNA expression and AQP2 protein expression are pathophysiological biomarkers of EHS. Cooling treatment restrain water reabsorption by down-regulating the expression of AQP2 mRNA and AQP2 protein in kidney.

529 Board #3 May 29 1:00 PM - 3:00 PM The Central Mechanism Underlying Arginine Vasopressin Changes During Cooling Therapy For Exertional Heat Stroke Rats

(No relevant relationships reported)

Bing Zhang¹, Xiuzhen Liu¹, Yuanlong Liu², Liye Zou³.

¹*Tsinghua University, Beijing, China.* ²*Western Michigan University, Michigan, MI.* ³*The Chinese University of Hong Kong, Hong Kong, China.* (Sponsor: Yuanlong Liu, FACSM)

Abstract:

Cooling therapy is very effective for improving the survival of patients with Exertional Heat Stroke (EHS); however, the central activation mechanism of Arginine Vasopressin in cooling therapy for EHS is not very clear. The central mechanism of cooling therapy induces changes of AVP to adjust water metabolism, which involves that the synthesis and release of AVP in hypothalamus. **PURPOSE:** To determine the central activation of AVP mRNA expression and AVP protein expression in hypothalamus in improving water metabolism when EHS rats were treated with cooling. **METHODS:** Male Sprague Dawley rats were randomly divided into normal control group (NC n=8) and EHS group. EHS group was further divided into the onset group (EHSO n=9), the rest group (EHSR n=9) and the cooling group (EHSC n=8). The rat model of EHS was induced by exercising to exhaustion and raising rectal temperature to about 42°C in the environment of 36°C temperature and 75% humidity. Cold water immersion for 5 min at 19°C was used as cooling treatment. Blood and hypothalamus were taken for testing. AVP in serum was measured by ELISA method. AVP mRNA expression and AVP protein expression were detected by PCR and WB respectively. We analyzed data with Mann-Whitney U of nonparametric test. **RESULTS:** Onset of EHS, to regulate water metabolism, AVP, AVP mRNA expression and AVP protein expression of EHSO group rats were upregulated significantly than that of NC group (AVP: 66.02±24.55 vs. 33.52±11.13, p<0.01; mRNA: 5.06±4.10 vs. 1.21±0.49, p<0.01; Protein: 2.90±1.26 vs. 1.00±0.00g/L, p<0.01). After cold water immersion, AVP mRNA expression and AVP protein expression were significantly downregulated, AVP changed little (EHSC vs. EHSO) (mRNA: 1.22±0.50 vs. 5.06±4.10, p<0.01; Protein: 1.48±0.89 vs. 2.90±1.26g/L, p<0.05). **CONCLUSIONS:** AVP, AVP mRNA expression and AVP protein expression can be used as pathophysiological biomarkers of EHS. Cold water immersion inhibits anti-dehydration reaction by downregulating the expression of AVP mRNA and AVP protein in hypothalamus.

530 Board #4 May 29 1:00 PM - 3:00 PM Continuous Forearm Cooling Attenuates Increase in Core Body Temperature of Elite Cyclists under Heat Stress

Eric T. Hedge¹, Kathryn A. Zuj¹, Alexander G. Stothart¹, Erica H. Gavel², Len S. Goodman³, Sean D. Peterson¹. ¹*University of Waterloo, Waterloo, ON, Canada.* ²*University of Toronto, Toronto, ON, Canada.* ³*Defence Research and Development Canada - Toronto Research Centre, Toronto, ON, Canada.*
Email: ethedge@uwaterloo.ca
(No relevant relationships reported)

Physical activity results in the generation of heat which is dissipated through thermoregulatory processes, such as the production of sweat. Environmental conditions

can inhibit thermoregulation resulting in heat accumulation with eventual impairment in performance. **PURPOSE:** To determine if continuous inner forearm cooling helps to maintain body core temperature and athletic performance during cycling in a hot and humid environment. **METHODS:** Preliminary results report on data collected from three competitive triathletes [two male, one female; age: 31 ± 2 years; mean \pm standard deviation]. Each performed two cycling sessions at $70 \pm 4\%$ of their functional threshold power for up to 45 minutes in an environmentally controlled chamber (temperature: 30°C , humidity: 70%). One trial included continuous inner forearm cooling (FC), while the other was a control trial (NFC). Heart rate (HR) was monitored throughout the test and body core temperature (T_{core}) was measured using an ingestible radio capsule. Ratings of perceived exertion and thermal comfort were assessed every 10 minutes throughout exercise. **RESULTS:** Preliminary data suggest that forearm cooling attenuated the increase in T_{core} during exercise (FC: $2.32 \pm 0.36^\circ\text{C}\cdot\text{hr}^{-1}$ vs. NFC: $2.85 \pm 0.33^\circ\text{C}\cdot\text{hr}^{-1}$), as 89.6 ± 11.7 kJ of heat were removed from the body during the cooling trials. Furthermore, two of the three participants were unable to complete the non-cooling trial due to reaching the temperature threshold for test termination (39.3°C). Similarly, HR appeared to be lower in the FC condition compared to the NFC condition. Participants' ratings of perceived exertion were similar between conditions; however, participants' thermal comfort was improved with inner forearm cooling. **CONCLUSION:** Preliminary data analysis suggests that during cycling in the heat, continuous cooling of the forearms may improve athlete comfort by attenuating the exercise induced increase in core body temperature.

531 Board #5 May 29 1:00 PM - 3:00 PM

Influence of Face and Head Cooling on Thermoregulation and Perception During Simulated American Football

Daniel A. Judelson, FACSM¹, Mitchell Naughton², Christopher J. Tyler². ¹Nike, Inc., Beaverton, OR. ²University of Roehampton, London, United Kingdom.
Email: dan.judelson@nike.com
(No relevant relationships reported)

The skin of the human face and head is uniquely sensitive to cold stimuli, influencing whole body thermal perception more than most other skin surfaces. This sensitivity might be particularly relevant for American football, where padding and equipment cover much of the body but athletes regularly experience large thermal stress. **PURPOSE:** To assess how face and head cooling impact thermoregulation and perception during simulated American football. **METHODS:** Ten male American football or rugby athletes (age = 27 ± 5 y, height = 184.1 ± 5.9 cm, mass = 96.7 ± 18.2 kg; mean \pm SD) completed two 165 min intermittent exercise protocols. Each protocol was divided into four quarters (Q1 - Q4) and consisted of maximal sprints and plyometric push-ups separated by breaks regularly occurring during an American football game (e.g. breaks between quarters, time outs, and offense-defense transitions). Sessions occurred in 36°C and 50% RH and participants wore full American football uniforms throughout. During one session (COOL), each participant removed his helmet and donned a cooling hood during breaks longer than two minutes; the cooling hood covered the cheeks, forehead, head, and neck and was activated by soaking in an ice slurry mixture. During the other session (CON), each participant only removed his helmet during breaks longer than two minutes. Thermoregulatory and perceptual variables were measured throughout. **RESULTS:** No significant differences existed between COOL and CON for gastrointestinal temperature (COOL = $38.0 \pm 0.5^\circ\text{C}$, CON = $38.1 \pm 0.5^\circ\text{C}$), mean weighted skin temperature (COOL = $35.5 \pm 0.7^\circ\text{C}$, CON = $35.6 \pm 0.7^\circ\text{C}$), or heart rate (COOL = 124 ± 26 bpm, CON = 125 ± 26 bpm). COOL significantly improved whole body thermal sensation compared to CON (COOL: Q1 = 4 [4-5], Q2 = 5 [4-5], Q3 = 5 [4-5], Q4 = 5 [4-5]; CON: Q1 = 6 [6-6], Q2 = 6 [5-6], Q3 = 6 [5-6], Q4 = 7 [6-7]; median [interquartile range]). COOL similarly benefitted thermal comfort. **CONCLUSIONS:** These data confirm the sensitivity of the face and head to cooling stimuli and reinforce their influence over whole body thermal sensation and comfort during exercise in the heat. Moreover, these data indicate a cooling hood covering the cheeks, forehead, head, and neck can significantly improve thermal perception during exercise in the heat without influencing classic thermoregulatory measures.

Precooling's Effects on American Football Skills

Libby Bradley, Kevin Miller, Brian Weise, Jason Novak. Central Michigan University, Mount Pleasant, MI.
Email: bradl1j@cmich.edu
(No relevant relationships reported)

Precooling (i.e., cooling before exercise, PC) with cold-water immersion (CWI) may help reduce the risk of exertional heatstroke (EHS) in American football athletes. However, implementation of PC would likely be low if it impaired American football performance. **PURPOSE:** We investigated PC effect on eight American football skills. **METHODS:** Twelve physically-active men (24 ± 2 y, mass = 85.5 ± 6.3 kg, height = 181.8 ± 8.1 cm) completed this randomized, crossover, counterbalanced study.

Participants practiced each skill until proficient and then completed two testing days outdoors (wet bulb globe temperature = $19.3 \pm 4.1^\circ\text{C}$). On testing days, participants were precooled for 15 minutes using CWI ($10.1 \pm 0.3^\circ\text{C}$) or not. They donned an American football uniform and completed multiple bouts of 40-yard dash, vertical jump, broad jump, agility test, dynamic (i.e., catching while running) and stationary catching, throwing distance, and throwing accuracy. Rectal temperature (T_{rec}) was measured before, during, and after precooling and every 5 minutes during skill testing. MANOVA and dependent t-tests identified differences between conditions for football skill data. Repeated measures ANOVA and Tukey-Kramer post-hoc tests identified differences in T_{rec} between conditions over time. **RESULTS:** Data are means and standard deviations. Cohen's effect sizes (ES) were calculated when significant differences occurred. PC did not affect vertical jump, broad jump, agility, dynamic or stationary catching, or throwing distance ($P \geq 0.13$). PC impaired 40-yard dash time (PC = 5.72 ± 0.53 s, Control = 5.31 ± 0.34 s; $P = 0.03$, ES = 1.2) and throwing accuracy (PC = 0.9 ± 0.2 points, Control = 1.3 ± 0.3 points; $P = 0.001$, ES = 1.4). On average, T_{rec} was $0.58 \pm 0.35^\circ\text{C}$ lower during skills testing following PC and statistically differed from control from minute 10 to the end of testing (~ 35 minutes; $P < 0.05$, ES ≥ 1.2). **CONCLUSION:** PC may be a useful strategy to prevent EHS in American football players since it lowered T_{rec} without affecting most American football skills. By lowering T_{rec} , PC would prolong the time it would take for an athlete's body core temperature to become dangerous (i.e., $>40.5^\circ\text{C}$). If PC is implemented, coaches should alter practice so throwing accuracy and speed drills occur after an athlete's body core temperature returns to normal.

533 Board #7 May 29 1:00 PM - 3:00 PM

An Ice Vest Limits the Rise in Core Temperature During a Rugby Sevens Warm-up

Lee Taylor, FACSM¹, Christopher J. Stevens², Heidi R. Thornton³, Nick Poulos⁴, Bryna CR Christmas⁵. ¹Aspetar – Orthopaedic and Sports Medicine Hospital, Doha, Qatar. ²Southern Cross University, Coffs Harbour, Australia. ³Newcastle Knights Rugby League Club, Newcastle, Australia. ⁴Australian Rugby Union (ARU), Sydney, Australia. ⁵Qatar University, Doha, Qatar.

(No relevant relationships reported)

Purpose: Determine how a cooling vest worn during a warm-up could influence selected performance [counter movement jump (CMJ)], physical (GPS metrics) and psycho-physiological (body temperature and perceptual) variables. **Methods:** In a randomized crossover design, twelve elite male World Rugby Sevens Series athletes completed an outdoor (WBGT: $23\text{-}27^\circ\text{C}$) match-specific externally-valid 30 min warm-up wearing a phase change cooling vest (VEST; also worn for 70 min prior-to warm-up) and without (CONTROL), on separate occasions 7 days apart. CMJ was assessed before and after the warm-up, with GPS indices and heart rate monitored during the warm-ups, whilst core temperature (T_c ; ingestible telemetric pill; $n = 6$) was recorded throughout the experimental period. Measures of thermal sensation (TS) and comfort (TC) were obtained pre- and post-warm-ups, with rating of perceived exertion (RPE) taken post-warm-ups. **Results:** Athletes in VEST had a lower ΔT_c from pre-warm-up to post-warm-up [effect size (ES) $\pm 90\%$ confidence limit; $-1.54; \pm 0.62$] and T_c peak (-0.7°C lower on average) at the end of the warm-up ($-1.59; \pm 0.64$) compared to CONTROL. Athletes demonstrated a decrease in ΔTS ($-1.59; \pm 0.72$) and ΔTC ($-1.63; \pm 0.73$) in VEST compared to CONTROL, pre- to post-warm-up. Furthermore, athletes in VEST had a lower post-warm-up RPE compared to CONTROL ($-1.01; \pm 0.46$). Changes in CMJ and GPS indices were *trivial* between conditions (ES < 0.2). **Conclusions:** Wearing the vest prior-to and during a warm-up can elicit favorable alterations in physiological (T_c) and perceptual (TS, TC and RPE) warm-up responses, without compromising the utilized warm-up characteristics or physical performance measures. Supported by Aspire Zone Foundation (AZF; Doha, Qatar) funding.

B-09 Thematic Poster - Ergogenic Aids

(No relevant relationships reported)

PURPOSE: The effect of 30 days of β -alanine (BA) supplementation (100 mg·kg⁻¹) on behavioral response, expression of brain-derived neurotrophic factor (BDNF), neuropeptide Y (NPY) and markers of inflammation was examined in both young (4 months) and older (14 months) rats.

METHODS: Animals were assigned to either a control group in which young (YC) or older (OC) rats were fed regular food and water or a β -alanine group, in which rats were fed regular food and provided β -alanine in their water (YBA or OBA, respectively). Behavior measures were conducted following the 30-day supplementation period, which included spatial learning, memory and an anxiety index. Hippocampal expressions of BDNF, NPY, glial fibrillary acidic protein, NF- κ B p50 and p65 subunits, TNF α and cyclooxygenase-2 were also analyzed.

RESULTS: Learning ability was reduced ($p=0.001$) and anxiety index higher ($p=0.001$) in older compared to young rats. Similarly, BDNF and NPY expressions were reduced, and all inflammatory markers were elevated ($p's < 0.05$) in the older animals. β -alanine increased BDNF expressions in the CA1 ($p=0.003$) and CA3 ($p < 0.001$) subregions of the hippocampus. BDNF expression for YBA was also significantly greater than YC in CA3. Learning for young animals fed β -alanine was significantly better than all other groups. Significant reductions in anxiety were noted in both older and younger rats fed β -alanine compared to age-matched controls.

CONCLUSIONS: Results indicated that β -alanine ingestion in both young and older rats was effective in attenuating anxiety and augmenting BDNF expression in the hippocampus.

The Effects of Two Multi-Ingredient Pre-Workout Supplements on Endurance Capacity and Anaerobic Cycling Performance

Meaghan E. Beckner¹, Brian J. Martin¹, Alexis A. Pihoker¹, Matthew E. Darnell¹, Alicia L. Kjellsen¹, Paul J. Arciero, FACSM², Mita T. Lovalekar¹, Kim Beals¹, Shawn D. Flanagan¹, Bradley C. Nindl, FACSM¹. ¹University of Pittsburgh, Pittsburgh, PA. ²Skidmore College, Saratoga, NY.
Email: meb115@pitt.edu
Reported Relationships: M.E. Beckner: Industry contracted research; Isagenix International LLC..

Multi-ingredient pre-workout supplements (MIPS) have become an increasingly popular ergogenic aid among fitness enthusiasts. Previous research has primarily focused on the effectiveness of individual ingredients, rather than the combination. **PURPOSE:** To examine the effectiveness of two MIPS, one with beta-alanine and caffeine (BAC) and one without (NBAC), vs. placebo (PLA) on anaerobic performance and endurance capacity. **METHODS:** Twenty-eight exercise-trained individuals (15 men, 13 women, 24.3 \pm 4.9 years, 173.6 \pm 9.2 cm, 74.7 \pm 15.5 kg) participated in a randomized, counterbalanced, double-blind, placebo controlled cross-over study to assess anaerobic power and capacity via Wingate (WAnT_{AP} and WAnT_{AC}), and aerobic endurance via cycle VO_{2peak}. On three separate occasions (7 days between trials) subjects completed vertical jump (VJ), 30-second Wingate test and VO_{2peak} test 30 minutes after ingestion of BAC, NBAC, or PLA. WAnT_{AP} and WAnT_{AC} were calculated as the peak and average power relative to body mass, respectively. Following a 10 minute walking recovery, subjects completed the cycle VO_{2peak} test. Blood lactate was collected within 5 minutes post WAnT (BLA_{WAnT}), and VO_{2peak} (BLA_{VO2}). Following tests for normality, outcome variables were compared between supplements using one-way repeated measures ANOVA or Friedman test ($\alpha=0.05$) and Bonferroni adjusted pairwise comparisons as appropriate. **RESULTS:** There was a significant

effect of treatment on WAnT_{AP} ($p=0.016$). WAnT_{AP} was higher in BAC (10.9 \pm 1.4 W/kg) and NBAC (10.8 \pm 1.2 W/kg) compared to PLA (10.5 \pm 1.2 W/kg) ($p = 0.018$ and $p = 0.014$, respectively). WAnT_{AC} was significantly different across supplements ($p=.043$), but post hoc pairwise comparisons were not significant. BLA_{WAnT} was higher with BAC (17.7 \pm 3.5 mmol) and NBAC (17.4 \pm 3.2 mmol) compared to PLA (15.3 \pm 3.3 mmol) ($p = 0.028$ and $p = 0.033$, respectively). BLA_{VO2} was higher with BAC (12.7 \pm 5.9 mmol) compared to NBAC (9.9 \pm 2.4 mmol, $p < 0.001$) and PLA (9.7 \pm 2.8 mmol, $p < 0.001$). No significant differences were observed in VO_{2peak} or VJ. **CONCLUSION:** MIPS demonstrate the potential to augment production of anaerobic power during a Wingate cycle test, accompanied by higher blood lactate accumulation. Improvements may be less apparent in vertical jump type movements or prolonged endurance exercise.

537 Board #3 May 29 1:00 PM - 3:00 PM
Acute Capsaicin Supplementation Improves 400 and 3000 Meters Running Time-trial Performance in a Distance-dependent Way

Valéria L G Panissa¹, Lázaro F A Da Costa², Alcione De Sá², Marcelo C. De Freitas³, Fabrício E. Rossi². ¹University of São Paulo, São Paulo, Brazil. ²Federal University of Piauí, Teresina, Brazil. ³University of Western of São Paulo, Presidente Prudente, Brazil.

(No relevant relationships reported)

Ergogenic effect of capsaicin has been shown in middle-distance time trial (1500 meters) but not in repeated maximal sprints indicating the need of explore exercises with different metabolic demands. **PURPOSE:** The purpose of this study was to investigate the acute effect of capsaicin supplementation on short (400 m) and middle distance (3000 m) running time-trial performance, maximum heart rate and rate of perceived exertion in physically active adults. **METHODS:** Twelve physically active men (age = 28.6 \pm 5.4 y) completed four randomized, double-blind trials: Capsaicin condition (12 mg) or a placebo condition. Forty-five minutes after supplement consumption, the participants performed a randomized 400- or 3000-meters running time trial. Time (in seconds) was recorded. Heart rate was analyzed at rest and immediately post-exercise, and the rate of perceived exertion (RPE) was collected immediately after exercise. The effect of capsaicin on time-trial performance, maximum heart rate and rate of perceived exertion during short (400 m) and middle distance (3000 m) running were analyzed via a Paired t test. In addition, the effect size (ES, 90% confidence interval [CI]) and magnitude-based inference statistics in the selected variables were calculated. **RESULTS:** For 400 m time-trial (Capsaicin = 66.4 \pm 4.2 sec vs Placebo = 67.1 \pm 4.8 sec, $t = 2.250$, $p = 0.046$) and 3000 m time-trial (Capsaicin = 876.2 \pm 76.1 sec vs Placebo = 905.1 \pm 73.3 sec, $t = 2.848$, $p = 0.016$) the time in seconds was significantly lesser in the capsaicin compared to placebo. Capsaicin showed a *likely* small improvement of performance in the 3000 m ($d = 0.40$, IC 90% = -0.60 to -0.14) and *likely* trivial in the 400 m ($d = 0.13$, IC 90% = -0.24 to -0.03). There was no statistically significant difference for the maximum heart rate (400m: $p = 0.114$; 3000m: $p = 0.319$) and RPE (400m: $p = 0.615$; 3000m: $p = 0.438$). **CONCLUSION:** In summary, acute capsaicin supplementation improved 400 m and 3000 m running time-trial performance in a distance-dependent way without modifying RPE and maximum heart rate in physically active adults. Furthermore, the present study showed a meaningful improvement in the performance during 3000 m running time-trial.

538 Board #4 May 29 1:00 PM - 3:00 PM
Acute Supplementation with Caffeine Improves Strength and Increases Metabolic Stress After a Maximal Strength Test

Luis H. Boiko Ferreira¹, Andre C. Smolarek¹, Steven R. McNulty², Brad J. Schoenfeld³, Alan A. Aragon⁴, Alan C. Utter, FACSM⁵, Táciio P. Souza-Junior¹. ¹Universidade Federal do Paraná, Irati, Brazil. ²Appalachian State University, Boone, NC. ³CUNY Lehman College, Bronx, NY. ⁴California State University, Northridge, CA. ⁵Texas Woman's University, Denton, TX.

(No relevant relationships reported)

BACKGROUND: Caffeine has dose-dependent benefits on endurance, but the effect of different doses of caffeine on strength are inconclusive. **PURPOSE:** We aimed to analyze the acute effect of different doses of caffeine on strength and metabolic stress in recreationally trained men. **METHODS:** The effect of different doses of caffeine on strength, creatine phosphokinase (CPK), lactate dehydrogenase (LDH), and uric acid (AU) were assessed in 17 recreationally active young adults (19.2 \pm 2.5 yrs of age), who performed three tests, separated by 14 days between trials. Day one involved collection of baseline data and brief explanation of the strength test protocol.

The protocol used to analyze the effect of different doses of caffeine on strength was examined by three different exercises (bench press (BP); deadlift (DL); and squats (SQ) following a 10 RM test protocol. Blood samples were collected immediately upon arrival to the laboratory, followed by consumption of a standardized isocaloric shake along with capsules containing different doses of caffeine: 6mg • kg⁻¹ (CF1), 8mg • kg⁻¹ (CF2), or placebo (CG). Another blood sample was collected 45 minutes after caffeine/placebo consumption and immediately after the execution of each exercise. The supplementation followed a double-blind, randomized model. **RESULTS:** The strength on BP, DL and SQ statistically improved between CG and CF2 (BP 98.5 ± 3.2 to 106.7 ± 2.7; DL 123.2 ± 6.5 to 138.3 ± 9.1; SQ 116.4 ± 7.9 to 135.1 ± 5.7 p=0.01); no other statistical differences were observed for strength outcomes. CPK statistically improved in CF2 in comparison to CF1 and CG one hour after strength tests (198.1 ± 10.1 U/L to 171.8 ± 7.4 U/L and 198.1 ± 10.1 U/L to 169.4 ± 11.2 U/L with p=0.001). The LDH levels were significantly higher in CF2 after the third exercise compared to CG and CF1 (229.1 ± 8.3 U/L to 179.3 ± 11.4 U/L and 229.1 ± 8.3 U/L to 229.1 ± 13.2 U/L with p=0.001). AU levels were significant higher in CF2 at 60 minutes posttest compared to GC (7.1 ± 0.8 mg/dL to 5.5 ± 0.6 mg/dL with p=0.01). **CONCLUSION:** An 8 mg • kg⁻¹ dosage of caffeine seems to be more effective than 6 mg • kg⁻¹ and placebo for improving strength levels on BP, DL and SQ. In addition, higher doses of caffeine increased LDH and uric acid concentrations compared to other treatments, which may imply a higher oxidative stress condition.

Omega-3 Supplementation Does Not Impair Torque and Power Improvements Following 8 Weeks Eccentric Quadriceps Training

Lynsey S. James, David J. Hunter, Beth Hussey, Glenda Anderson, Sarabjit S. Mastana, Martin R. Lindley.
Loughborough University, Loughborough, United Kingdom.
 Email: l.wilson2@lboro.ac.uk
 (No relevant relationships reported)

Individuals who are unaccustomed to resistance exercise experience greater levels of exercise-induced muscle soreness, this can deter individuals from completing an exercise programme and improving strength and power. To alleviate the symptoms, they may consume Non-steroidal anti-inflammatory drugs (NSAIDs). Evidence suggests NSAIDs blunt muscle protein synthesis (Trappe *et al.*, 2002) and attenuate strength and muscle hypertrophic adaptations from resistance training (Lilja *et al.*, 2018), negating the effects of the exercise. Omega-3 supplementation has been suggested as an alternative to NSAIDs but the impact of Omega-3 on resistance training is inconclusive. **PURPOSE:** To determine the effects of omega-3 supplementation on eccentric training-induced increases in torque and power. **METHODS:** Nine physically active but non-resistance trained males (29 ± 9 years) were pair matched for isometric and eccentric quadriceps strength and randomly assigned, in a double-blind manner, to either omega-3 (5.1g/d) or olive oil (6.0g/d) supplementation for 3 weeks prior to and for 8 weeks during eccentric training. Performance measures of peak torque (isometric, concentric, eccentric) and jump height were conducted before and after 8 weeks of training. Supervised training consisted of maximal eccentric quadriceps contractions on an isokinetic dynamometer at 60°s⁻¹ through 80° range of motion. Two training sessions were conducted per week, with a minimum of 48 hours recovery between sessions. Number of repetitions and sets were increased over the 8 weeks. **RESULTS:** Following 8 weeks of eccentric training, peak eccentric torque significantly increased by 40 ± 56 Nm in omega-3 group and 51 ± 52 Nm in olive oil group, with no differences between groups (p > 0.05). Both groups also significantly increased their maximal isometric torque (p = 0.02); omega-3 group increased by 21 ± 10 Nm and olive oil group increased by 23 ± 30 Nm, with no differences between groups (p > 0.05). There was no main effect of training on peak concentric torque (p > 0.05). Jump height increased by 1.0 ± 1.9 cm in the omega-3 group and decreased by 0.03 ± 1.33 cm in the olive oil group, with no difference between groups (p > 0.05). **CONCLUSIONS:** Omega-3 supplementation does not impair or augment eccentric training-induced increases in torque or power in young males.

The Effect of Beetroot Supplementation on High Intensity Functional Training Performance
 Sean Collins, Danielle Kearns. *University of Lynchburg, Lynchburg, VA.*
 Email: collins.s@lynchburg.edu
 (No relevant relationships reported)

Nitrate supplementation has been shown to improve athletic performance for short-duration, vigorous activity, as well as long-duration, aerobic activity. As an antioxidant, nitrates have the ability to reduce oxidative stress on exercising muscles, which is thought to help maintain energy metabolism, therefore, decreasing fatigue. **PURPOSE:** The purpose of this research was to explore the effects of beetroot nitrate supplementation on performance during a baseline CrossFit® workout. **METHODS:**

Twenty current CrossFit® participants (25±6.5 years, 175.17±8.1cm, 84.94±12.09kg), who attended CrossFit® classes at least 3 days per week for the past 3 months, performed a benchmark performance test, "Nancy" (5 rounds of 15 overhead squats with a 95lb (for males)/65lb (for females) barbell followed by a 400m run). In a randomized order, 72 hrs apart, participants were tested under a control session and once after consuming 2.4oz beetroot nitrate supplement, Beet It®, 2 hours prior to beginning the assigned workout. For both workouts, time to completion, pre- and post-exercise blood lactate levels, RPE, and pre-, during, and post-exercising heart rates were measured. **RESULTS:** No significant difference (p<0.05) between the control (15.50±3.21 min) and supplement (15.88±3.43 min) performance on time to completion. Post-exercise blood lactate (11.14±2.84 mmol/dL) was not significantly different (p< 0.05) than the control (12.00±2.53 mmol/dL). Additionally, mean RPE for BR supplement (14.78±2.50) was not significantly different (p < 0.05) than the control (14.92±2.12). **CONCLUSIONS:** The findings show no improvement in performance following nitrate supplementation. These findings may have been caused by the duration and intensity of the benchmark workout which included both anaerobic and aerobic components, unlike previous research that found relationships between beetroot nitrates and performance of aerobic and anaerobic exercises alone.

541 Board #7 May 29 1:00 PM - 3:00 PM
Potato Ingestion as an Effective Race Fuel to Improve Cycling Performance in Trained Cyclists

Amadeo F. Salvador¹, Colleen F. McKenna¹, Susannah Scaroni¹, Rafael A. Alamilla¹, Isabel G. Martinez¹, Ryan Cloud¹, Adriana Miltko¹, Alex Keeble¹, Alexander V. Ulanov¹, Scott Paluska, FACSM¹, Elizabeth Broad², Nicholas A. Burd¹. ¹University of Illinois at Urbana-Champaign, Urbana, IL. ²US Olympic Committee, Chula Vista, CA. (Sponsor: Scott A. Paluska, FACSM)
 Email: amadeos2@illinois.edu
 (No relevant relationships reported)

Carbohydrate (CHO) ingestion is an established strategy to improve endurance performance. Race fuels should not only sustain performance, but also be readily digested and absorbed and replenish electrolytes. Potatoes are a cost-effective option that fulfills these criteria; however, their impact on endurance performance remains unexamined. **PURPOSE:** Compare the effects of potato purée (POT) ingestion during endurance cycling on subsequent performance versus commercial CHO gel (GEL) or a control (water, CTL). **METHODS:** Ten trained cyclists (28.2±5.6y; 70.1±7.4kg; 1.7±0.1m; 62.7±9.3mL/kg/min) consumed a standardized breakfast then performed a 2h cycling challenge (60-85%VO_{2max}) followed by a time trial (6kJ/kg body mass) while consuming POT, GEL, or CTL in a randomized-crossover design. POT, GEL and CTL were administered with U-[¹³C]₆glucose for an indirect estimate of gastric emptying rate. Repeated blood samples were collected. **RESULTS:** Time trial performance significantly improved (p<0.01) with POT (32.2±1.9min) and GEL (32.4±1.9min) versus CTL (38.6±1.9min); no difference between POT and GEL was observed (p=1.00). Post challenge blood glucose concentrations were lower (p<0.01) with CTL (77.9±4.2mg/dL) versus POT (95.5±4.4mg/dL) and GEL (95.6±4.4mg/dL). Similar results (p<0.001) were observed post time trial for blood glucose concentrations (CTL, 68.5±4.2 mg/dL; GEL, 97.5±4.2mg/dL; POT, 92.0±4.2mg/dL). No difference (p=0.88) in blood glucose concentrations were observed between GEL or POT conditions at both time points. Post challenge, blood lactate concentrations were higher (p=0.005) with GEL (5.1±0.4mmol/L) versus POT (3.4±0.4mmol/L). Blood U-[¹³C]₆glucose enrichments were not different between GEL or POT (p>0.05). **CONCLUSION:** Potatoes serve as a viable alternative to commercial gels by sustaining performance and blood glucose concentrations during endurance cycling events in trained cyclists.

Post-exercise And Pre-sleep Protein-polyphenol Supplementation Improves Recovery Following Muscle-damaging Eccentric Exercise: Preliminary Findings.

Tom S. O Jameson¹, George F. Pavis¹, Marlou L. Dirks¹, Benjamin T. Wall¹, Catherine Mikus², Nima Alamdari², Francis B. Stephens¹. ¹University of Exeter, Exeter, United Kingdom. ²Beachbody LLC, Santa Monica, CA.
 Email: t.jameson@exeter.ac.uk
 (No relevant relationships reported)

Purpose Eccentric contraction (EC) induced muscle damage is characterised by weakened force production, increased soreness and elevated plasma creatine kinase (CK). Recovery rate is likely to be dependent on muscle remodelling, which may be influenced by dietary protein and polyphenol availability. We investigated if consuming protein-polyphenol drinks post-exercise and before bed improved recovery of knee extensor function and reduced soreness following a bout of EC.

Methods In a randomised, parallel groups, placebo controlled double blind design, 18 healthy males and females (22 ± 1 y; BMI: 24.0 ± 0.9 kg·m⁻² (\pm SEM)) consumed a controlled isocaloric diet (1.2 g·kg⁻¹ protein) for 7 days before and after a single bout of 300 maximal unilateral quadriceps EC, in combination with either post-exercise (20 g whey, casein and pea protein blend and 650 mg pomegranate extract) and pre-bed (20 g casein protein and 480 mg tart cherry extract) drinks (Beachbody LLC) (PRO; $n = 9$; 4 females), or isocaloric maltodextrin placebos (PLA; $n = 9$; 3 females). Total isokinetic work over 30 maximal knee extensions (TW), peak isometric torque (PT) and muscle soreness (visual analogue scale (VAS) and pressure pain threshold (PPT)) were measured relative to the contralateral control limb (%con) before and every 24 h for 7 d following EC, as was CK. Data were analysed using two-way ANOVAs.

Results EC caused a maximum decline in TW in PLA after 48 h to 68 ± 6 %con ($P < 0.001$) which remained below baseline until 120 h ($P < 0.05$). Conversely, TW in PRO was reduced at 24 h only (to 89 ± 5 %con; $P < 0.05$) and was restored thereafter. PT decreased following EC ($P < 0.001$) and was significantly lower in PLA compared with PRO at 48 h (69 ± 5 vs 107 ± 13 %con, respectively) and 96 h (76 ± 7 vs 110 ± 14 %con, respectively). Muscle soreness in both groups peaked within 72 h of EC ($P < 0.05$), but *vastus medialis* PPT was attenuated at 72 h in PRO compared to PLA (102 ± 3 vs 88 ± 3 %con, respectively; $P < 0.05$). Plasma CK rose > 30-fold from 96 to 120 h ($P < 0.01$), and was similar between groups ($P > 0.05$).

Conclusion Consumption of commercially available post-exercise and before bed protein-polyphenol beverages accelerated recovery of skeletal muscle function following EC-induced muscle damage, potentially due to improved protein turnover and remodelling.

Supported by a Beachbody LLC (USA) grant.

Post Meal Hypoglycemia With and Without Exercise in Non-Obese and Obese Individuals.

Jay W. Porter¹, Ryan Pettit-Mee¹, Sean Ready¹, Nathan C. Winn PhD¹, Anand Chockalingam MD², Guido Lastra Gonzalez MD², Jill A. Kanaley PhD, FACSM¹. ¹University of Missouri, Columbia, MO. ²University of Missouri School of Medicine, Columbia, MO. (Sponsor: Jill A Kanaley, FACSM)
Email: jwpp64@mail.missouri.edu

(No relevant relationships reported)

PURPOSE: Hypoglycemia (<70 mg/dL) during exercise has been observed in some individuals when exercise is preceded by carbohydrate ingestion. Counterregulatory responses normally maintain plasma glucose concentrations to prevent hypoglycemic events in healthy adults. The degree to which hypoglycemia is observed across health statuses in response to an evening meal plus moderate intensity exercise is unknown. The purpose of this study was to examine glucose variability when a dinner meal was followed by moderate exercise in lean and obese individuals, and to establish if transient hypoglycemia occurs during exercise at a time of day when glucose tolerance is poorer. **METHODS:** Obese (OB) and non-OB adults completed 2 study conditions: dinner meal only (NOEX) and meal + exercise (EX) 2 h post meal. Blood samples were collected prior to the meal and for 5 h post meal for blood glucose (BG). The meal contained 10 kcal/kg (40% CHO, 35% FAT, 25% PRO). EX was 45 minutes of 55% of VO₂ peak. RM ANOVA was utilized for analyses. **RESULTS:** 21 adults (5 Male, 16 Female) completed both conditions. Groups consisted of 8 Non-OB and 13 OB. Peak BG conc. was similar between groups and conditions (Non-OB: NOEX 168.6 ± 9.8 , EX 153.9 ± 10.2 mg/dL; OB: NOEX 158.3 ± 7.7 , EX 166.2 ± 8.0 mg/dL). BG nadir was different by group ($p = 0.015$) and condition ($p < 0.001$) (Non-OB: NOEX 58.0 ± 3.7 , EX 44.3 ± 3.0 mg/dL; OB: NOEX 67.1 ± 2.9 , EX 55.9 ± 2.3 mg/dL). Delta (peak-nadir) was similar between groups and conditions (Non-OB: NOEX 110.6 ± 10.6 , EX 109.5 ± 9.1 mg/dL; OB: NOEX 92.4 ± 8.3 , EX 110.3 ± 7.1 mg/dL). Seven Non-OB and 8 OB experienced hypoglycemia during NOEX, while 8 Non-OB and 12 OB experienced hypoglycemia with EX. Non-OB subjects experienced hypoglycemia during NOEX from time 165-225 min. EX shifted this hypoglycemic period earlier by 30 min. OB experienced hypoglycemia during EX from time 150-165 min post meal consumption, overlapping with the exercise session. **CONCLUSIONS:** Very low BG levels are seen following a modest carbohydrate dinner meal in healthy and obese participants, suggesting a previously unappreciated response to exercise. All subjects

remained asymptomatic throughout hypoglycemic periods, alluding that many adults may unknowingly experience low BG values even when exercise begins 2 h post meal. **SUPPORT:** NIH RO1DK101-43-01A1 <!--EndFragment-->

Population And Sex Differences In The Associations Between Igf-1, Protein Consumption, And Lean Mass

Lee Weidauer, Tianna Beare, Teresa Binkley, Maggie Minett, Bonny Specker. *South Dakota State University, Brookings, SD.*

(Sponsor: Dr. Matthew Vukovich, FACSM)

Email: lee.weidauer@sdsstate.edu

(No relevant relationships reported)

Purpose: Protein intake and IGF1 concentrations are two factors that have been implicated as having a positive effect on lean mass (LM); however, the relationship of both protein intake and circulating IGF1 on LM is not well understood. The purpose of this study was to determine the contributions of IGF1 and protein intake on LM and to determine if these associations are similar in Hutterites (H) (self-sufficient, farming, Anabaptist group) and non-Hutterites (NH), as well as in males and females.

Methods: 307 adults (118 H and 54 NH females, 75 H and 60 NH males) aged 20-66 years had body composition measured using DXA, serum (fasted) IGF1 concentrations and protein intake (by FFQ). Correlations were used for bivariate analyses and multivariate modeling was used to determine whether relationships between LM and IGF1 and LM and protein intake were similar in both sexes and populations (sex-by-IGF1, and sex-by-protein, population-by-IGF1, population-by-protein interactions) controlling for age, height, and fat mass.

Results: IGF1 correlated with protein intake in NH ($r = 0.27$, $p = 0.004$), but not in H ($r = -0.01$, $p = 0.9$); there was no correlation between circulating IGF1 and protein consumption in females ($r = 0.12$, $p = 0.1$) or males ($r = 0.01$, $p = 0.1$). LM was not correlated with IGF1 in NH ($r = 0.09$, $p = 0.3$) or H ($r = -0.11$, $p = 0.1$); LM was correlated with IGF1 in males ($r = 0.21$, $p = 0.02$) but not females ($r = 0.02$, $p = 0.8$). LM was positively correlated with protein intake in NH ($r = 0.44$, $p < 0.01$) and H ($r = 0.44$, $p < 0.01$), and in males ($r = 0.33$, $p < 0.01$) but not females ($r = 0.02$, $p = 0.8$). Greater LM was not associated with age ($\beta = -0.04$, $p = 0.09$), but was associated with greater fat mass ($\beta = 0.51$, $p < 0.001$), being taller ($\beta = 0.49$, $p < 0.001$), being male ($\beta = 15.4$, $p < 0.001$), and consuming more protein ($\beta = 0.02$, $p = 0.02$). None of the interactions were significant indicating that the relationships between LM and IGF1 and protein intake are similar for both populations and sexes.

Conclusions: Results from this study indicate that protein intake is an important factor in maintaining LM and is independent of IGF1 concentrations. These data support previous studies indicating that manipulating IGF1 concentrations to improve LM may be ineffective and that individuals attempting to gain LM should focus on ensuring that adequate protein is being consumed.

Changes in Metabolic Hormones and Their Associations With Cancer-Related Fatigue in Cancer Survivors

Po-Ju Lin¹, Michelle C. Janelins¹, Eva Culakova¹, Julia E. Inglis¹, Ian R. Kleckner¹, Luke J. Peppone¹, Charles E. Heckler¹, Laura J. P. Feldman², Joan Long³, Jeremy Deutsch⁴, Karen M. Mustian¹. ¹University of Rochester Medical Center, Rochester, NY. ²Metro Minnesota Community Oncology Research Consortium, St. Louis Park, MN. ³Cancer Research Consortium of West Michigan NCORP, Grand Rapids, MI. ⁴Wichita NCORP, Wichita, KS.

Email: po-ju_lin@urmc.rochester.edu

(No relevant relationships reported)

Cancer-related fatigue (CRF) is the most common toxicity experienced by patients with cancer, particularly in patients with metabolic syndrome. Metabolic syndrome is associated with dysregulated metabolic hormones such as decreased ghrelin and increased insulin levels. Whether changes in serum metabolic hormones are associated with changes in CRF is unknown.

PURPOSE: To assess changes in serum metabolic hormones and their associations with CRF in cancer survivors after 4 weeks of behavioral interventions.

METHODS: We selected 36 cancer survivors (age 56.4 ± 1.87 years) based on changes in CRF, regardless of intervention assignments, from an ongoing randomized controlled trial. Twenty-four survivors reported having no change/improved CRF (IMPV) and 12 survivors reported having worsened CRF (DECL). CRF and serum metabolic hormones (ghrelin, insulin, glucagon, leptin, PP) were assessed by Multidimensional Fatigue Symptom Inventory (MFSI) and a Luminex Multiplex Immunoassay, respectively, at pre- and post- intervention. T-tests and ANCOVAs were used to evaluate within- and between-group differences, respectively. Spearman's rank correlation was used to examine the associations of metabolic hormones with MFSI.

RESULTS: Changes in ghrelin were significantly different between groups ($p = 0.02$): serum ghrelin level was increased in the IMPV group (11.8 ± 2.19 pg/mL) but it was

decreased in the DECL group (-8.0 ± 5.93 pg/mL) from pre- to post-intervention. Changes in MFSI were negatively correlated with changes in serum ghrelin levels ($r = -0.32$, $p = 0.06$), indicating that increased serum ghrelin level is associated with improvements in CRF. No within- or between-group differences in other tested metabolic hormones nor their associations of CRF were found.

CONCLUSIONS: These exploratory findings suggest a potential association between increases in serum ghrelin and improvements in CRF among cancer survivors. Studies with larger sample sizes are needed to further establish the associations of metabolic hormones and CRF.

Improved Immune Profile Accompanying Increased Fitness Following an Exercise Intervention Among Overweight Older Women

Emily C. LaVoy¹, Mahmoud T. Elzayat¹, Maria Cardenas², Michael M. Levitt³, Carmen A. Cook³, Melody D. Phillips, FACSM³. ¹University of Houston, Houston, TX. ²Emory University, Atlanta, GA. ³Texas Christian University, Fort Worth, TX.

Email: eclavoy@uh.edu

(No relevant relationships reported)

Aging is associated with a decrease in naïve T cells and an increase in late differentiated T cells, an immune profile associated with increased inflammation and decreased protection against illness. Physical fitness appears to delay the appearance of the aging immune profile, but this has only been examined cross-sectionally.

PURPOSE: To assess longitudinally whether increasing fitness can increase naïve T cells and decrease late differentiated T cells in older overweight women. **METHODS:** 16 women (63±5 years) completed 36 exercise training sessions over 14 weeks.

Training occurred 3 days a week and consisted of supervised strength training and walking. 9 women (66±5 years) participating in a health education class meeting 24 times over the same period served as controls. Blood was sampled before and after the interventions and analyzed by flow cytometry. Changes in fitness and lymphocyte subpopulations were assessed by maximum likelihood linear mixed models.

RESULTS: The training group decreased gynoid fat (pre: $51 \pm 0.8\%$, post: $49.2 \pm 0.8\%$; $p < 0.05$) and increased strength (8RM leg press pre: 145.6 ± 11 lbs, post: 200 ± 12 lbs, $p < 0.001$; 8 RM chest press pre: 60 ± 3 lbs, post: 84.4 ± 3.7 lbs, $p < 0.001$); there was a trend for increased VO₂max (pre: $21.6 \pm .97$ ml/kg/min, post: 24.1 ± 1.3 ml/kg/min; $p = 0.62$). No differences in body composition or performance were observed in controls (all $p > 0.05$). The training group increased the proportion of naïve (CD45RA+CD62L+) CD8 T cells (pre: $23.9 \pm 2.9\%$, post: $27.8 \pm 3.2\%$, $p < 0.05$) and T memory stem cells (pre: $3.3 \pm 0.7\%$, post: $4.4 \pm 0.7\%$, $p < 0.05$). No changes were observed in high differentiated T cell subsets, or in any immune phenotype of controls (all $p > 0.05$).

CONCLUSIONS: Improvements in fitness following a supervised 14 week resistance and aerobic exercise intervention amongst overweight older women is accompanied by an increase in naïve and memory stem CD8 T cells. This suggests the immune system is modifiable with fitness, even at older age.

Obesity, Physical Activity, And Sedentary Behavior, Not Diet, Predict Low Testosterone Status in Men

Trevor J. Dufner¹, John S. Fitzgerald¹, James N. Roemmich, FACSM², Patrick B. Wilson³. ¹University of North Dakota, Grand Forks, ND. ²Grand Forks Human Nutrition Research Center, USDA, Grand Forks, ND. ³Old Dominion University, Norfolk, VA. (Sponsor: James N Roemmich, FACSM)

Email: trevor.j.dufner@und.edu

(No relevant relationships reported)

Hypogonadism (serum testosterone concentration < 300 ng·dL⁻¹) has been associated with poor health in men. The current treatment for hypogonadism—testosterone replacement therapy—is expensive, may produce adverse effects and its long-term safety is unknown.

Purpose: To identify nutritional and physical activity predictors of low serum testosterone status in men using the National Health and Nutrition Examination Survey (NHANES), a nationally representative sample of the United States.

Methods: A secondary analysis of cross-sectional data from 2011-2012 NHANES was carried out to examine the associations between weight status, dietary intakes, physical activity and serum testosterone concentrations; 1,933 adult men were included in the study after exclusion for missing and unreliable data. Nutrient intakes from foods and supplements were assessed using 24-hour recall via the 5-step Automated Multiple Pass Method. Participants self-reported typical weekly physical activity and daily sitting time. Body mass index (BMI), age, race, relationship status, education, and smoking behavior and serum testosterone concentration were assessed during

mobile exam center visits. Logistic regression was used to identify predictors of low testosterone status (lowest quartile; 204 ± 4 ng·dL⁻¹). Sampling weights were utilized in the analyses to account for the complex sampling design.

Results: Overweight and obese men had greater odds (2.10, 95% CI 1.17-3.78; 5.23, 95% CI 3.12-8.76) of low testosterone. Men reporting any vigorous physical activity, either recreational or work-related, had lower odds (0.42, 95% CI 0.28-0.64; 0.56, 95% CI 0.33-0.98) of low testosterone, whereas sitting time was associated with greater odds (1.05, 95% CI 1.02-1.08). None of the dietary variables were statistically significant predictors of low testosterone status in the logistic regression model (all $p > 0.153$).

Conclusion: BMI, vigorous physical activity and sitting time were independently associated with low testosterone status and appear to be candidates for lifestyle interventions. Future research should examine the effectiveness of weight loss interventions employing dietary, sedentary behavior, and physical activity modification to increase testosterone in overweight/obese men with low testosterone status.

549 Board #6 May 29 1:00 PM - 3:00 PM
Energy Availability is Predictive of LH Pulse Frequency Across a 3-month Diet and Exercise Trial

Kristen J. Koltun, Mary Jane De Souza, FACSM, Nancy I. Williams, FACSM. Penn State University, University Park, PA.

(No relevant relationships reported)

Exercising women are at risk for low energy availability (EA). Restricting EA to 20 kcal/kgLBM/d for 5 days reduces LH pulse frequency, but it's unclear how low EA over a longer duration affects LH. Slowed LH pulse frequency reflects reproductive axis suppression and is linked to menstrual disturbances. We showed that daily EA over a 3 month diet and exercise intervention predicted the frequency of menstrual disturbances, but the relation between low EA and upstream LH pulse dynamics is unclear. **PURPOSE:** To determine if reductions in EA due to diet and exercise over a prolonged period are related to LH pulse frequency in premenopausal, previously sedentary women. **METHODS:** This was a randomized controlled trial consisting of a 3 month controlled diet and supervised exercise program (5d/wk) leading to moderate weight loss. EA was calculated by measured energy intake (kcal) and recorded exercise energy expenditure (kcal) normalized to fat free mass (kgFFM). EA was measured daily and averaged during baseline and each of 3 intervention menstrual cycles. Blood samples were obtained via intravenous catheter every 10 min for 24hr in the early follicular phase prior to the intervention ($n=16$) and after 3 months of diet and exercise ($n=14$). Samples were assayed for LH via Immulite. LH pulse dynamics were assessed by Cluster. Paired t-tests compared Pre-Post differences. A linear mixed model was used to determine if EA predicts LH pulse frequency in the same or subsequent menstrual cycle.

RESULTS: Subjects were 20 ± 1 yrs old, 165 ± 1 cm tall, and weighed 58.4 ± 1.1 kg. Average weight loss was 3.1 ± 0.6 kg ($p < 0.001$). LH pulse frequency was 0.81 ± 0.06 pulses/hr prior to the intervention and 0.63 ± 0.08 pulses/hr after ($p = 0.047$). Average EA in the Pre cycle was 38.6 ± 1.8 kcal/kgFFM/d and 27.9 ± 2.1 kcal/kgFFM/d during Post ($p < 0.001$). EA measured within a menstrual cycle was a significant positive predictor ($p = 0.011$) of LH pulse frequency in the same or subsequent cycle. Specifically, for every 1 kcal/kgFFM/d increase in EA, LH pulse frequency increases by 0.014 pulses/hr. **CONCLUSIONS:** EA is a positive predictor of LH pulse frequency within the same or subsequent menstrual cycle. To prevent suppression of the reproductive axis, EA should be maintained at optimal levels, as a reduction in EA from 38 to 28 kcal/kgFFM/d suppresses LH pulse frequency by 19%.

551 May 29 1:00 PM - 1:15 PM Ground Reaction Force Characteristics In Power Cleans With And Without The Double Knee Bend Technique

Alexander M. Carnall, Jake A. Melaro, Douglas W. Powell, FACSM. *University of Memphis, Memphis, TN.* (Sponsor: Douglas W Powell, FACSM)

(No relevant relationships reported)

INTRODUCTION: Muscular power (i.e. muscular force x shortening velocity) is arguably the most important physical quality an athlete can possess. Many athletes use power cleans to improve muscular power but are not taught to use a double knee bend (DKB). The DKB is used by competitive weightlifters to increase muscular power produced in the second pull of the power clean exercise. Thus, athletes using power cleans to improve muscular power without using the DKB may not experience optimal benefit from the exercise. **PURPOSE:** To determine differences in ground reaction force characteristics between a power clean from the floor both with, and without, the use of a DKB in athletes with weightlifting experience. **METHODS:** Six participants with weightlifting experience each performed three power cleans with and without a DKB at 80% of their self-reported one-repetition maximum. Ground reaction forces (GRFs) were captured using two force platforms (1200Hz). Commercially available biomechanical analysis software was used to calculate concentric impulse (IMP_{CON}), peak vertical ground reaction force ($VGRF_{PEAK}$), and rate of force development (RFD) in the second pull for each trial. Paired samples t-tests were used to compare dependent variables in each condition: DKB and NO DKB. Cohen's *d* estimates of effects size were used to determine meaningful differences. **RESULTS:** RFD was greater in the second pull of the power clean when a DKB was used ($p < .001$, $d = 2.25$; DKB: 6922 ± 1664 ; NO DKB: 4710 ± 277 N/s). IMP_{CON} was lower in the DKB condition ($p < .001$, $d = 1.09$; DKB: 146 ± 28.8 N*s; NO DKB: 174 ± 36.6 N*s), and no differences were observed in $VGRF_{PEAK}$ ($p = 0.375$, $d = 0.15$; DKB: 1607 ± 221 N; NO DKB: 1582 ± 169 N). **CONCLUSIONS:** Although no differences were observed in $VGRF_{PEAK}$ and IMP_{CON} was reduced, RFD was significantly greater in the second pull with the DKB. These data suggest that DKB may enhance the training stimulus by enabling the athlete to produce comparable peak forces in shorter time periods by increasing muscular shortening velocity. This may be due to a positional optimization of muscular length-tension properties in the hip, knee, and ankle extensor musculature uniquely offered by utilizing a DKB technique.

552 May 29 1:15 PM - 1:30 PM Modulation Of Corticospinal Excitability and Short Intracortical Inhibition During Different Levels Of Voluntary Contraction In Untrained And Chronically Resistance Trained Individuals.

Behzad Lahouti. *Memorial University of Newfoundland, St. John's, NL, Canada.*

Email: blahouti@mun.ca

(No relevant relationships reported)

PURPOSE: To investigate central nervous system (CNS) excitability modulation in chronic resistance trained and untrained participants by assessing 1) short intracortical inhibition (SICI) and 2) motor evoked potential (MEP) of the biceps brachii, during different voluntary contraction intensities.

METHODS: 12 participants, 6 untrained (30 ± 1.4 years) and 6 chronic resistance trained (29.6 ± 7.5 years), completed one experimental session during which three blocks of contractions were performed. Each block included 10 brief (7s) elbow flexors isometric contractions at the intensity of 15, 25 or 40 % of maximum voluntary contraction (MVC). Prior to the contractions: 1) elbow flexors MVC, 2) maximal compound muscle action potential (Mmax) in the biceps brachii during a 5% MVC elbow flexion contraction and 3) active motor threshold at the three different contraction intensities were recorded. A total of 60 MEPs, evoked by transcranial magnetic stimulation (TMS), were assessed from biceps brachii muscle of the dominant arm during the three different contraction intensities.

RESULTS: 1) MVC force of the chronic resistance trained group was 33 % higher ($p \leq -0.001$) than the untrained group. 2) The chronic resistance trained group had lower AMTs at all contraction intensities ($p \leq -0.03$, $p \leq -0.01$, $p \leq -0.08$ for the 15 %, 25 % and 40 % of MVC, respectively) compared to the untrained group. 3) MEP amplitude (normalized to Mmax) did not differ between the two groups. 4) During 25 % of MVC, the untrained group exhibited decreased SICI in comparison to the chronic resistance trained group (SICI: $78 \pm 13\%$ vs. $97 \pm 9\%$ of test pulse; $p \leq -0.01$, respectively). During 40 % of MVC, the untrained group also exhibited decreased SICI in comparison to the chronic resistance trained group (SICI: $86 \pm 14\%$ vs. $102 \pm 11\%$ of the test pulse; $p \leq -0.03$, respectively). SICI did not differ between groups at 15 % MVC ($p \leq -0.30$).

CONCLUSION: Based on the results, chronic resistance training significantly reduces SICI at stronger contraction intensities compared to no training. The significant reduction in inhibitory outputs suggest the presence of an adaptive process of facilitatory network activation, which can cancel out the SICI, to increase corticomotor drive to the exercised muscle following a long period of resistance training.

553 May 29 1:30 PM - 1:45 PM Patellofemoral Joint Loading While Squatting To Different Depths Using High and Low Bar Positions

William Goodman, Christopher Casillas, James Becker. *Montana State University, Bozeman, MT.*

(No relevant relationships reported)

In high bar (HB) squats, the bar is placed just inferior to C7 while in low bar (LB) squats the bar is placed across the inferior scapular spine. These different positions change the moment arm of the weight relative to the knee joint, and thus potentially alter knee extensor moments and patellofemoral (PF) joint loading. **PURPOSE:** Examine how knee extensor moments (pKEM) and PF joint reaction forces (PFJRF) and stresses (PFJS) change when squatting to above parallel (AP), parallel (P), and below parallel (BP) depths using HB and LB positions. **METHODS:** 20 individuals (sex: 10M/10F; age: 23.0 ± 2.8 years) participated in this study. On day one, a one repetition maximum (1RM) was measured. On day 2 participants performed squats using 70% 1RM to AP, P, and BP depths using both HB and LB. Motion capture and two force plates were used to record whole body kinematics and ground reaction forces, respectively. pKEMs were calculated using inverse dynamics while PFJRF and PFJS were calculated using a model incorporating knee angles, extensor moments, and estimates of PF contact area. Effects of depth and bar position were evaluated using 3x2 repeated measures ANOVAs. **RESULTS:** For pKEMs, there was a main effect of depth ($p = .047$), with pKEMs being lower at P than either AP ($p = .044$) or BP ($p = .030$) depths. For PFJRF there was a significant depth by load interaction ($p = .024$). For both HB and LB positions, PFJRF was lower at BP compared to the AP ($p = .001$) depths. However, when using LB position PFJRF was also lower at P than AP ($p < .001$) depth. There were no differences in PFJS between depths ($p = .675$) or bar positions ($p = .191$). **CONCLUSION:** Individuals can squat to parallel or deep depths with their preference of bar position without increasing PFJS or PFJRF. However, squatting to parallel may be preferred as pKEM are lowest at this depth.

Table 1: Peak Knee Extensor Moments (pKEM), Peak Patellofemoral Joint Reaction Force (PFJRF), Peak Patellofemoral Joint Stress

| | pKEM (Nm) | | PFJRF (BW) | | PFJS (MPa) | |
|----|---------------|---------------|-------------|-------------|------------|-----------|
| | HB | LB | HB | LB | HB | LB |
| AP | 100.9 ± 40.5* | 102.8 ± 41.9* | 17.9 ± 4.2* | 18.9 ± 4.4* | 7.9 ± 5.5 | 8.4 ± 5.6 |
| P | 96.6 ± 38.3* | 96.5 ± 37.9* | 17.1 ± 4.7 | 16.5 ± 4.2 | 10.1 ± 9.9 | 7.9 ± 9.6 |
| BP | 101.8 ± 41.8* | 103.3 ± 45.5* | 16.4 ± 4.3 | 15.9 ± 4.1* | 8.8 ± 10.0 | 7.0 ± 5.9 |

*Indicates that pKEMs were significantly different, indicates that PFJRF were significantly different, indicates that LB PFJRF were significantly different, indicates that at AP bar positions were significantly different. All significance levels were $p < .05$.

554 May 29 1:45 PM - 2:00 PM Strength Training Effects on Force Production and Drive Distance in Female Golfers: A Pilot Study

Lana Prokop, Elizabeth Larson, Kaitlyn Alvarez. *St. Catherine University, St. Paul, MN.* (Sponsor: Mark Blegen, FACSM)

Email: lprokop@stkate.edu

(No relevant relationships reported)

Strength training (ST) by golfers is a relatively recent phenomena, gaining popularity only over the last two decades. Thus, little quantitative research exists on its benefits. Previous research provides support for golf performance gains, primarily club head speed, following ST. It has also been reported that vertical jump height is positively correlated to vertical thrust during a golf swing with a driver, which positively impacts carry distance of the golf ball. However, there is a paucity of research describing the vertical ground reaction force (vGRF) generated during a golf swing and the relationship of said force to the carry distance of the golf ball.

Purpose: 1) To evaluate if there is a relationship between vGRF produced and drive distance (DD) of the golf ball during a swing with a driver. 2) To determine if an

8-week ST program geared toward increasing vertical jump height affects vGRF and DD. 3) To evaluate the methodology for feasibility with a larger, more diverse population in future studies.

Methods: Participants were six female athletes (n=6) from a NCAA Division III varsity golf team (19.3 ± 1.4 years). Data was collected before and after an 8-week ST program focused on increasing vertical jump height. Participants completed two 45-minute ST sessions/week under the supervision of a certified strength and conditioning coach. Exercises included squats, broad jumps, box jumps, lunges with and without rotations, and sprints. vGRF was measured on force plates during the downswing phase of the golf swing with a driver and DD was measured with a golf launch monitor. Vertical jump height and measures of lower extremity and core strength were also collected.

Results: The correlation between vGRF and DD was weak ($r = -0.03$, $p = 0.74$). There were no significant differences between pre and post vGRF (25.3 N ± 32.8 N, $p = 0.12$) nor DD (-3.7 m ± 11.6 m, $p = 0.47$) within subjects.

Conclusion: The golf swing is an intricate maneuver with numerous factors impacting ball flight and distance. It is likely that other factors such as club head speed and angle of attack have a greater influence on DD than vGRF. Further research with larger and more diverse populations may determine whether or not significant relationships exist between ST, vGRF production, and golf swing performance. The methodology has been deemed feasible for future studies.

555 May 29 2:00 PM - 2:15 PM

Poor Pelvic Control During A Knee Lift Test Is Associated With Increased Risk Of Knee Injuries

Mari Leppänen¹, Marko Rossi¹, Jari Parkkari¹, Ari Heinonen², Sami Äyrämö², Tommi Vasankari², Pekka Kannus³, Kati Pasanen⁴. ¹Tampere Research Center of Sports Medicine, Tampere, Finland. ²University of Jyväskylä, Jyväskylä, Finland. ³UKK Institute, Tampere, Finland. ⁴University of Calgary, Calgary, AB, Canada.

Email: mari.leppanen@uta.fi

(No relevant relationships reported)

PURPOSE: To investigate whether deficits in stance leg, hip and pelvic stability during a standing knee lift test are associated with increased risk of non-contact knee and ankle injuries in youth team sports.

METHODS: At baseline, 263 basketball and floorball players (age range 12–21 y.) participated in a standing knee lift test using 3-dimensional motion analysis. The test was a modified version of the Trendelenburg test to assess stance leg and hip stability. Two trials per leg were recorded from each participant and mean value was used in the analysis. The biomechanical variables calculated were peak anterior pelvic tilt angle (APT) and peak lateral pelvic drop angle (LPD). The APT and LPD were categorized into two groups using the median of the cohort: low group (values less than median value) and high group (values larger than median). All new non-contact knee and ankle injuries, as well as match and training exposure, were then recorded for 12 months. Cox regression models were used to calculate hazard ratios (HRs) and 95% CIs.

RESULTS: A total of 16 new non-contact knee injuries (of which eight were ACL ruptures, all affecting female players) and 36 new non-contact ankle injuries were registered during the study period. Athletes displaying high lateral pelvic drop angles were at increased risk of knee injuries (adjusted HR for high versus low group 4.22; 95% CI 1.34–13.3). A borderline significant ($p=0.05$) association was found between high lateral pelvic drop angles and ACL injury risk in female athletes (adjusted HR for high versus low group 8.14; 95% CI 0.97–68.6). No potential ankle injury risk factors were found. A receiver operating characteristic curve analysis for the LPD and knee injuries showed an area under the curve of 0.60, which indicates poor combined sensitivity and specificity of the test.

CONCLUSIONS: Poor pelvic control, with increased lateral pelvic drop, is associated with increased risk of non-contact knee injuries among young team sport players. However, the knee lift test cannot predict non-contact knee injuries in youth team sports.

Effects of Foot Instability Variations on Muscle Activation during Front Plank Exercise

Saori Hanaki, Kimberly J. Evans, Tim Ruden. Weber State University, Ogden, UT.

Email: saorihanaki@weber.edu

(No relevant relationships reported)

Adding instability is a common method of increasing the difficulty of an exercise. Front plank exercise is often performed with various instability types and levels; however, how induced instability influences muscle activation during front plank is not well-understood.

PURPOSE: To examine how 4 different foot stability variations of front plank influence activation of 5 different muscles.

METHODS: 19 physically active, healthy individuals (8 males, 11 females; age 39±16.0 years; height 1.68±0.1 m; mass 75±17.51 kg) performed each of 4 plank variations in a randomized order. The foot stability was modified by placing the feet: 1) on a level, stable floor (FLOOR); 2) on an elevated stable step (STEP); 3) in elevated suspension straps (SUSPEND); 4) on a rubber dome (DOME). STEP, SUSPEND and DOME were height-matched for foot placement. Electromyography of 5 muscles, rectus abdominis (RA), external oblique abdominis (EO), rectus femoris (RF), serratus anterior (SA) and erector spinae (ES) during front plank with 4 different foot stability conditions was examined and normalized as % maximal voluntary isometric contraction (%MVIC). Foot stability variation effect on normalized average muscle contraction of 5-second static plank trials was assessed using one-way repeated measure ANOVA and Friedman test for normally and non-normally distributed data respectively.

RESULTS: SUSPEND was associated with greater muscle activation than DOME in RF (43.2±25.8 vs. 32.9±25.9 %MVIC), $p<0.05$) and in RA (39.5±18.2 vs. 30.3±18.5 %MVIC, $p<0.05$). Compared to FLOOR, SUSPEND was associated with higher activation of SA (57.2±27.5 vs. 48.2±23.1 %MVIC, $p<0.05$) and ES (8.9±4.3 vs. 7.5±3.4 %MVIC, $p<0.05$).

CONCLUSIONS: Plank with suspended feet increased average activation of muscles used in the front plank. The use of RF and RA increased primarily due to foot instability induced by suspension, and the activation of SA and ES increased with combination of instability and increased weight distribution to the upper body.

Gender Comparisons of Muscle Activation Patterns Across Handle Types During Seated Row Exercise

Swapan Mookerjee¹, Sam W. Meske¹, Kyle S. Beyer¹, Daniel G. Drury, FACSM². ¹Bloomsburg University, Bloomsburg, PA. ²Gettysburg College, Gettysburg, PA. (Sponsor: Daniel G. Drury, FACSM)

Email: smookerj@bloomu.edu

(No relevant relationships reported)

Muscular responses and performance during resistance exercise can be affected by handle design and wrist/forearm positioning. **PURPOSE:** To compare the electromyographic (EMG) responses during seated row exercise in the Biceps Brachii (BB), Latissimus Dorsi (LD), and Flexor Carpi Radialis (FCR), using a neutral forearm positioning (NF) handle versus a Wrist flexed positioning (WF) handle. **METHODS:** The protocol was performed on a cable machine by 10 males (21.6 ± 1.2 yrs) and 10 females (21.7 ± 2 yrs) with prior resistance training experience (5.0 ± 2.5 yrs). Participants completed a one-repetition maximal lift (1-RM) followed by one set at 85% 1-RM until failure, using both handle types in randomized order. Root mean square EMG (EMG_{RMS}) from the BB, LD, and FCR were normalized to the 1-RM values. Two-way repeated measures ANOVA was used to analyze EMG differences for each muscle group between genders and handle types. **RESULTS:** The 1-RM lifts were significantly greater ($p < 0.05$) with the WF handle (90.2 ± 30.6 kg) versus the NF handle (87.8 ± 30.4 kg). There were significant differences ($p<0.05$) between genders for the 1-RM lifts across both handle types. However, there were no significant differences between handles for the total number of repetitions completed (NF 11.9 ± 3.6; WF 11.2 ± 2.4). Although there was a trend ($p<0.07$) for BB EMG activity between the genders, there was no significant difference in the EMG amplitudes between the LD and FCR for either gender or handle type.

CONCLUSION: These findings showed significantly higher maximal lifts with the WF handle type, but non-significant EMG differences in the BB, LD and FCR between genders and across handle types. This indicates similar muscle activation patterns. The possible mechanisms for the 1RM differences may be related to actin and myosin overlap of the forearm flexors, ergonomic factors such as grip comfort and differences in handle contact surface area.

Modified Supine Bridge Alters Muscle Coordination Patterns

Wenhui Mao¹, Li Li, FACSM², Kelsey Lewis², Yi Jia³, Sydni Wilhoite². ¹Nanjing Normal University, Nanjing, China. ²Georgia Southern Uni., Statesboro, GA. ³North University of China, Taiyuan, China.

Email: wmao@georgiasouthern.edu

(No relevant relationships reported)

Contributions of mono- and bi-articular hip extensor muscles while performing single leg supine bridge (SLB) and modified single supine bridge (mSLB) is not quite clear. To identify hip extensor muscles activation patterns among different unilateral-bridges, could be a key point for hip extensor strength and rehabilitation trainings. **PURPOSE:** To compare hip extensor muscles activation patterns during performing SLB and mSLB.

METHODS: We have recruited healthy collegiate students for the project. Participants signed an informed consent form before data collection. They have performed SLB and mSLB at a constant pace (~2s up and ~2s down). mSLB was performed unilaterally with the exercise leg placed up on a box of 40 cm in height. Surface electromyography (sEMG) of the right gluteus maximus (Gmax), biceps long head (BFL), and semitendinosus (STN) muscles was recorded using a wireless surface electromyography system. Peak RMS sEMG of each muscle during SLB define as 100% and used as the base of comparison with that of mSLB. On- and off-set of sEMG bursts threshold were defined as 10% of the peak value. One-tailed paired-test was used for statistic examination. Alpha value was set at 0.05.

RESULTS: The peak RMS of Gmax, BFL and STN sEMG while performing mSLB were 82.1±21.4, 141.5±36.4, and 155.0±2.5, respectively. The peak magnitude of the hamstring muscle activations were greater, although peak Gmax activity was lower ($p<0.05$), while performing mSLB than that of SLB ($p<0.05$). Muscle activation burst duration of BFL was 1.6±0.7s longer while performing mSLB than that of SLB ($p<0.05$). Muscle activation burst durations of STN (3.82±0.58s) and Gmax (3.53±1.72s) were (0.42±0.50s) and Gmax (0.47±0.44s) shorter than that of mSLB ($p<0.05$).

CONCLUSIONS: Comparing to SLB, mSLB increased bi-articular hip extensor (BFL and ST) muscle activation level while reduced mono-hip extensor (Gmax) activation level accompanied by prolonged BFL activities and shortened Gmax/St activation durations.

560 May 29 1:00 PM - 1:15 PM Sites of Disruption in Dystrophic Muscle Following Eccentric Contractions

Cory W. Baumann¹, Gordon L. Warren, FACSM², Dawn A. Lowe, FACSM¹. ¹University of Minnesota, Minneapolis, MN. ²Georgia State University, Atlanta, GA.
Email: cbaumann@umn.edu

(No relevant relationships reported)

PURPOSE: Dystrophin is responsible for maintaining plasmalemmal integrity and cellular homeostasis. A key feature of skeletal muscle that lacks dystrophin, as in the mdx mouse model for Duchenne muscular dystrophy (DMD), is a heightened sensitivity to eccentric (ECC) contraction-induced strength loss. However, the mechanisms responsible for the exaggerated loss of strength in dystrophic muscle have yet to be fully established. The purpose of this study was to determine possible sites within mdx muscle that are disrupted following ECC contractions. **METHODS:** Male wildtype and mdx mice (n = 8 per group) were chronically implanted with stimulating electrodes on the left common peroneal nerve and EMG electrodes on the left tibialis anterior (TA) muscle. The left anterior crural muscles (TA and extensor digitorum longus; EDL) of anesthetized mice performed 50 maximal ECC contractions. In vivo peak dorsiflexion torque and M-wave root mean square (RMS) were measured prior to and immediately after the ECC contractions. Following the in vivo assessment, the EDL was removed and ex vivo peak isometric force and caffeine-induced force were analyzed. **RESULTS:** Peak torque and force in wildtype mice were reduced 36 ± 4 and 28 ± 4% ($p \leq 0.001$) following the ECC contractions, while no changes were observed in M-wave RMS (10 ± 2%; $p = 0.49$) or caffeine-induced force (10 ± 4%; $p = 0.20$). To the contrary, both M-wave RMS and caffeine-induced force were reduced in mdx muscle (60 ± 4 and 58 ± 5; $p \leq 0.001$), and corresponded to reductions of 60 ± 2 and 67 ± 8% ($p \leq 0.001$) in peak torque and force. **CONCLUSIONS:** On the basis of the disproportional reductions in strength measured in vivo and ex vivo (36 and 28%, respectively) compared with that of in vivo M-wave RMS (10%) and ex vivo caffeine-induced force (10%), we confirm that ECC contractions uncouple the plasmalemma from the ryanodine receptors (RyRs) in wildtype muscle. However, in mdx muscle, in vivo peak torque and M-wave RMS in addition to ex vivo force and caffeine-induced force were all reduced to a similar degree (58-67%), indicating that various sites were disrupted immediately following the injury. These data indicate strength loss in wildtype and mdx mice differ, in that plasmalemmal function and sites at or distal to the RyRs may all be impaired in dystrophic muscle following ECC contractions.

The Effects of High Intensity Interval Training on Autophagy in Soleus Muscle of Rats

Xinwen Cui¹, Yiming Zhang², Zan Wang², Jingjing Yu².
¹China Institute of Sport Science, Beijing, China. ²Beijing Sport University, Beijing, China.
Email: cuixinwensu@qq.com
(No relevant relationships reported)

PURPOSE: The aim of this study was to investigate the impacts of the high intensity interval training (HIIT) on basal autophagy in soleus muscle of rats. **METHODS:** Nine months old, male Wistar rats were randomly divided in 3 groups: control group (C group, n = 18, sedentary), traditional moderate-intensity continuous training (MICT) group (M group, n = 19, 50-min moderate intensity continuous running at 60% VO₂max) and high intensity interval training (HIIT) group (H group, n = 19, 6 bouts × 3 min running at 80% VO₂max interspersed with 6 bouts × 3min active recovery at 40% VO₂max with a 7-min warm-up and cool down at 60% VO₂max). Before the intervention, a total of 8 rats were killed as the baseline. At the 4th and 8th week, 8 rats of each group were killed 24 h after the last exercise. The test of VO₂max, the observation of autophagosome by transmission electron microscope (TEM) and the expression of autophagy-related proteins by western blot were assayed at three time points: baseline, 4th and 8th week after the intervention. Statistical significance was tested by two-way ANOVA. **RESULTS:** In the 4th week of intervention, compared to the C group, only H group resulted a 30% increase in VO₂max (2732.85±135.43 vs. 2103.53±135.43, $P<0.01$), a 82% increase in the number of autophagosomes (0.50±0.04 vs. 0.28±0.04, $P<0.05$), a 25% increase in the expression of LC3II (1.62±0.10 vs. 1.29±0.10, $P<0.05$), no change in the LC3II/LC3I; M group and H group resulted a 38% and 18% decrease respectively in the expression of P62 (0.75±0.05 vs. 0.99±0.05 vs. 1.21±0.05, $P<0.001$, $P<0.01$). In the 8th week, compared to the C group, only H group resulted a 30% increase in VO₂max (2830.46±135.43 vs. 2182.30±135.43, $P<0.05$), a 62% increase in the number of autophagosomes (0.53±0.04 vs. 0.33±0.04, $P<0.05$), a 25% increase in the expression of LC3II (1.79±0.10 vs. 1.43±0.10, $P<0.05$); a 31% increase in the LC3II/LC3I (2.33±0.12 vs. 1.77±0.12, $P<0.01$); M group and H group resulted a 26% and 30% decrease respectively in the expression of P62 (0.89±0.05 vs. 0.84±0.05 vs. 1.20±0.05, $P<0.001$, $P<0.001$ respectively). There was no significant change in the expression of ULK1^{Ser757} and Beclin-1 in all groups across the training period. **CONCLUSION:** An engagement in HIIT might promote the basal autophagy activity and autophagy flux, with prominent effects for HIIT than MICT.

Bovine Milk Exosome Depletion Affects Skeletal Muscle and Liver in Young Growing Rats

Hailey A. Parry¹, C. Brooks Mobley¹, Petey W. Mumford¹, Matthew A. Romero¹, Yufeng Zhang¹, Janos Zempleni², John J. McCarthy, FACSM³, Kaelin C. Young⁴, Michael D. Roberts¹, Andreas N. Kavazis, FACSM¹. ¹Auburn University, Auburn, AL. ²University of Nebraska-Lincoln, Lincoln, NE. ³University of Kentucky College of Medicine, Lexington, KY. ⁴Edward Via College of Osteopathic Medicine-Auburn Campus, Auburn, AL. (Sponsor: Andreas N Kavazis, FACSM)
Email: hap0017@auburn.edu
(No relevant relationships reported)

Exosomes are extracellular vesicles that carry 'cargo', such as microRNA, which may interact with different tissues and regulate cellular signaling pathways. **PURPOSE:** To determine the effects of exogenous bovine exosomes on the liver and skeletal muscle in young, growing rats. **METHODS:** Twenty-eight-day Fisher 344 rats were provided a milk-based diet that either contained exosomes (EXO+, n=12) or was exosome depleted via sonication (EXO-, n=12) for four weeks. Following the intervention, the liver and gastrocnemius were removed and measurements of respiratory control ratio (RCR), reactive oxygen species emission (ROS), antioxidant levels, cross sectional area (CSA), total RNA, and transcriptomics were performed. Except for transcriptomic data, independent samples t-tests were performed between diet groups and statistical significance was set at $p<0.05$. For transcriptomic data, all annotated transcripts with FPKM scores >1.0 were analyzed between groups and any score exceeding a fold-change cut-off >1.5 fold ($p<0.01$) were considered meaningful. **RESULTS:** There was no significant change in mitochondrial volume in either the liver ($p=0.707$) or gastrocnemius ($p=0.724$), however the liver had increased state 3 and state 4 in the EXO- treated group ($p=0.040$ and $p=0.009$) with complex I substrates. No significant differences were detected in liver antioxidant protein levels or oxidative damage markers ($p>0.050$). There was an increase in GPX protein levels in gastrocnemius in the EXO- rats ($p=0.020$), which may explain the significant decrease in ROS emission ($p=0.016$). No significant change was observed in gastrocnemius mitochondria respiration ($p>0.050$). Interestingly, gastrocnemius CSA and total RNA significantly increased in EXO- group ($p=0.018$ and $p=0.001$). Further analysis of the diet verified sonication decreased exosomes, however RNA was enriched per particle by >7.5

fold. **CONCLUSION:** An exosome depleted diet affects liver and skeletal muscle parameters and resulted in increased muscle hypertrophy. These changes may be due to the enhanced mRNA nature of the EXO- diet. Resolvin E1 Attenuates Inflammatory Induced Muscle Atrophy In Human Derived Muscle Cells

Martin R. Lindley¹, Luke Baker², Neil Martin¹, Gareth Pritchard¹, Marc Kimber¹, Jiani Qian¹, Mark P. Lewis¹.
¹Loughborough, Loughborough, United Kingdom. ²University of Leicester, Leicester, United Kingdom.
Email: m.r.lindley@lboro.ac.uk
(No relevant relationships reported)

Purpose Loss in skeletal muscle size and function is a common debilitating comorbidity in an array of chronic disease states as well as during the ageing process. This can lead to a loss of physical activity and ability to perform everyday tasks, leading those affected into a downward spiral of muscle loss and inactivity which has been strongly linked to increased rates of morbidity and mortality. Many factors have been linked to induce such processes, one of which is inflammation, with therapeutic research looking for ways to resolve chronic inflammation to subsequently alleviate related muscle atrophy. Resolvin E1 (RvE1) is a specialised pro-resolving lipid mediator, derived from the metabolism of the omega-3 fatty acid EPA, which has shown to have beneficial pro-resolving properties in an array of cell types, including our previous work in immortalised skeletal muscle cell lines. **Method** This set of experiments cultured human derived skeletal muscle cells from healthy control participants (n = 6). Once differentiated, myotubes were exposed to Lipopolysaccharide (LPS) in the presence or absence of RvE1 (100ng/ml) and compared with a control condition. Post exposure, myotubes were harvested for gene expression and intracellular protein analysis. From the same experiment, wells were also fixed and stained for immunocytochemistry analysis of myotube size and number. **Results** Our work indicates beneficial pro-resolving properties of RvE1 in human skeletal muscle cells. RvE1 was seen to attenuate LPS induced inflammatory related gene expression of both IL-6 (LPS 7.82 ± 0.52 vs. RvE1 3.93 ± 0.32, p = 0.015) and MCP-1 (LPS 21.45 ± 0.92 vs. RvE1 17.31 ± 0.52, p = 0.023) leading to an alleviation in downstream endotoxin induced myotube atrophy (µm) (LPS 20.29 ± 1.36 vs. RvE1 28.76 ± 1.13, p = 0.003). **Conclusion** Preliminary evidence suggests that RvE1 may induce its effects through the inhibition of classical canonical inflammatory signalling. Our novel findings provide initial rationale for further investigation of RvE1 as a naturally occurring nutritional therapeutic in chronic conditions characterised with a degree of inflammatory induced skeletal muscle atrophy.

Concurrent Exercise of the Arm Extensors Modulates Anabolic Signaling and Gene Expression for Ribosome Biogenesis

Tommy R. Lundberg¹, Björn Hansson¹, Luke A. Olsen², Ferdinand von Walden¹, Rodrigo Fernandez-Gonzalo¹.
¹Karolinska Institutet, Stockholm, Sweden. ²University of Kansas Medical Center, Kansas City, KS.
Email: tommy.lundberg@ki.se
(No relevant relationships reported)

PURPOSE: As most concurrent exercise studies to date have focused on lower-limb muscles, this study explored the acute molecular response to concurrent exercise of the arm extensors. Specifically, the effects of a preceding bout of aerobic exercise (AE) on subsequent anabolic signaling and ribosome biogenesis response to resistance exercise (RE) were explored. **METHODS:** Eleven moderately trained men (28 ± 5 years, 181 cm ± 6 cm, 81 ± 8 kg) performed a unilateral bout of arm extensor aerobic exercise (~45 min) in a seated isokinetic dynamometer. Subsequently, unilateral resistance exercise (4 sets of 7 reps) was performed for both arms using flywheel technology. Thus, one arm was subjected to RE alone, while the other arm performed consecutive bouts of AE and RE interspersed by 15 min recovery. Peak power (merged across concentric and eccentric actions) was assessed during the resistance exercise bout. Muscle biopsies were taken from the m. triceps brachii of each arm immediately before, 15 minutes and 3 h after the RE bout. Muscle samples were assessed for gene (q-PCR) and protein (immunoblotting) expression of markers involved in the regulation of muscle hypertrophy and ribosome biogenesis. **RESULTS:** The AE bout resulted in reduced (~24%) power performance during the subsequent RE bout (P < 0.05). Gene expression of MuRF-1, atrogin-1, and PGC-1α were significantly greater in AE+RE compared to RE (arm x time interactions P < 0.05). Myostatin expression decreased in both AE+RE and RE (main effect of time P < 0.05). Phosphorylation of AMPK increased (2.5-fold), and 4E-BP1 decreased (0.5-fold), after the AE bout (arm x time interactions, P < 0.05). Phosphorylation of P70S6K remained unaltered.

Gene expression of c-Myc and 45S pre-rRNA (ITS) increased with exercise and was greater in AE+RE compared with RE alone (main effect of time and arm P < 0.05). Polr1b expression increased in both AE+RE and RE (main effect of time P < 0.05). **CONCLUSION:** The results suggest that post-exercise translational signaling could be compromised by prior aerobic exercise. In contrast, concurrent exercise of the arm extensors accentuates the expression of key regulators of ribosome biogenesis and promotes rDNA transcription.

The Skeletal Muscle Transcriptome Signature of 84-day Bed Rest and its Reversal by Resistance Exercise

Rodrigo Fernandez-Gonzalo, Per A. Tesch, Tommy R. Lundberg, Eric Rullman, Thomas Gustafsson. Karolinska Institutet, Stockholm, Sweden.
Email: rodrigo.gonzalo@ki.se
(No relevant relationships reported)

PURPOSE: Given the poor understanding of the molecular mechanisms regulating skeletal muscle alterations to long-term unloading/microgravity, this study assessed the transcriptomic changes to 84 days of bed rest, and the potential of high-intensity, low-volume resistance exercise (RE) to counteract the bed rest signature. **METHODS:** Healthy men (age range 26-41 yr) were randomized to perform 84-d bed rest with (BRE; n=9) or without (BR; n=12) concurrent RE targeting the knee extensors (i.e. supine squat; 4 sets of 7 maximal concentric-eccentric repetitions every third day) employing Yo-Yo iso-inertial flywheel technology offering eccentric overload. Biopsies from m. vastus lateralis were obtained from all subjects before and after bed rest. The muscle specimens were used to conduct a DNA microarray analysis. **RESULTS:** Three hundred thirty-five probesets were down- and 315 were upregulated after bed rest at a false discovery rate of 0.01. Amongst the downregulated genes, ontologies related to muscle structural and contractile components, and acetylcholine receptors, were highly enriched. Yet, the ontology most substantially affected by bed rest, with 109 genes downregulated, was the mitochondrion. Although RE normalized a large portion of the transcripts affected by bed rest, genes that were upregulated after bed rest were less likely to become normalized by BRE. The greatest counteracting effect of RE was noted in genes belonging to the mitochondrion. This ontology was even slightly elevated by exercise compared with the baseline signature in BRE (Pre-Post within BRE; P<0.05, interaction BR-BRE; P=2e-78). A group of upregulated transcripts were not affected by RE. These genes are involved in transcriptional regulation, and DNA and chromatin stability. **CONCLUSIONS:** Long-term bed rest has a profound effect on muscle mass and function. Our data indicate that such changes are driven by alterations in molecular pathways regulating muscle structure, contractile properties, neuromuscular junction, and importantly, the mitochondrion. This particular RE regimen appears to counteract, and even reverse, selected transcriptomic modifications induced by long-term bed rest. Yet, some genes modulated by bed rest were resistant to RE and thus represent the residual signature of bed rest induced muscle atrophy.

566 May 29 2:30 PM - 2:45 PM

Lifelong Deficiency in Ulk1-Mediated Autophagy Precipitates Skeletal Muscle Aging

Anna S. Nischenko¹, William Michael Southern², Grant Mercer¹, Sarah M. Greising², Jarrod A. Call¹. ¹University of Georgia, Athens, GA. ²University of Minnesota, Minneapolis, MN.
(No relevant relationships reported)

Autophagy is a cellular recycling mechanism critical for maintaining cellular homeostasis because it degrades dysfunctional organelles and proteins. Insufficient autophagy is implicated in the pathophysiology of a plethora of diseases (i.e. Type 2 diabetes, obesity, and sarcopenia) and in the process of aging across many cell types. Ulk1 is an autophagy-related protein kinase that initiates autophagy and may be particularly critical for maintaining skeletal muscle cellular homeostasis throughout life. **PURPOSE:** To investigate muscle health and function in an aging mouse model with a lifelong deficiency of Ulk-1-mediated autophagy. **METHODS:** Longitudinal measurements of *in vivo* ankle dorsiflexion torque of muscle-specific Ulk1 knockout mice (Ulk1 KO) and their littermate controls (LM) were performed beginning at 12 months of age. At age 22 months, mice were administered a glucose tolerance test (GTT), followed by *in vitro* force testing of the extensor digitorum longus (EDL) and soleus (SOL) muscles. Mice were then sacrificed and mitochondrial function was measured via oxygen consumption rates of permeabilized muscle fibers from the gastrocnemius muscle. **RESULTS:** Body mass did not change throughout the longitudinal force measurements (p=0.58). Ulk1 KO mice experienced a greater reduction in *in vivo* ankle dorsiflexion torque from age 12 months to age 22 months compared to LM mice (-50% vs. -36%, p=0.026). *In vitro* peak-isometric force of isolated EDL muscles was less in Ulk1 KO mice (p=0.035) compared to LM mice, but there was no difference in isolated SOL muscle force between genotypes suggesting an accelerated aging phenotype in predominantly fast-twitch muscle fibers. There was no difference in the GTT between genotypes (p=0.1). Interestingly, mitochondrial respiration was greater in the Ulk1 KO mice when normalized to muscle fiber mass

($p=0.001$). This may reflect an accumulation of mitochondria due to Ulk1-mediated autophagy insufficiency, or an undetermined compensatory adaptation affecting mitochondrial function. **CONCLUSIONS:** A lifetime of insufficient Ulk-1-mediated autophagy exacerbates age-related skeletal muscle contractile dysfunction and may alter mitochondrial quality and/or quantity.

A Crtc2/Creb1-mediated Molecular Mechanism for the Beneficial Effects of Exercise on Weight Loss

Nelson E. Bruno. *The Scripps Research Institute, Jupiter, FL.*
Email: nbruno@scripps.edu

(No relevant relationships reported)

Exercise is one of the few behavior modifications that enable long-term weight loss through unknown mechanisms. High-intensity exercise (HIE) induces norepinephrine and calcium signaling, which together, stimulate the Crtc2 coactivator to activate the Creb1-mediated transcriptional program in skeletal muscle. We previously demonstrated that Crtc2 activation drives an adaptive anabolic transcriptional response that includes hypertrophy and enhanced exercise performance (Bruno et al. EMBO J. 2014). **PURPOSE:** Here, we examined the role of skeletal muscle-selective Crtc2/Creb1 signaling in the metabolic response to weight loss. **METHODS:** Crtc2 was selectively overexpressed in skeletal muscle using a doxycycline-inducible transgene. 18-week old, naturally obese control or Crtc2 transgenic (Tg) mice were treated with doxycycline for 2 weeks and then subjected to 8 cycles of alternate day fasting (ADF). **RESULTS:** Compared to control Tg mice, which lost lean body mass ($p = 0.02$), Crtc2 Tg mice lost more weight over time (Crtc2, $p = 0.013$; Crtc2 x Time, $p = 0.00015$) through a selective loss of fat body mass ($p = 0.004$). This effect was due to higher energy expenditure during fasting (1 kcal/hr, $p < 10^{-15}$), and was associated with improved glucose tolerance (Crtc2, $p = 0.037$; Crtc2 x Time, $p = 0.0023$) and insulin sensitivity ($p = 0.012$), increased fatty acid oxidation ($p = 0.05$) and mitochondrial DNA content, and upregulation of Pgc-1 α and cytochrome C expression. **CONCLUSION:** This work reveals Crtc2/Creb1 signaling as a key driver of both anabolic and metabolic adaptations in skeletal muscle and explains how HIE facilitates successful weight loss by preventing the lowering of sympathetic tone, which reduces metabolic rate during fasting. During ADF-induced weight loss, the Crtc2/Creb1-mediated transcriptional program in skeletal muscle upregulates mitochondrial biogenesis to provide the excess energetic capacity required to maintain a higher metabolic rate and selectively burn fat.

Accuracy of the Cosmed K5 Portable Metabolic System

Scott E. Crouter, FACSM¹, Samuel R. LaMunio¹, Paul R. Hibbing¹, Andrew S. Kaplan², Michael E. Quarantillo¹, David R. Bassett, Jr, FACSM¹. ¹The University of Tennessee Knoxville, Knoxville, TN. ²University of Wisconsin-Milwaukee, Milwaukee, WI.

Email: scrouter@utk.edu

(No relevant relationships reported)

The Cosmed K5 is the latest generation of Cosmed portable metabolic systems. Similar to previous generations of the Cosmed devices, the K5 measures oxygen consumption (VO_2) and carbon dioxide production (VCO_2) on a breath-by-breath (BxB) basis. New to the K5 is the ability to measure VO_2 and VCO_2 using a dynamic mixing chamber (MC) mode that uses micro-proportional sampling. **PURPOSE:** The purpose of this study was to assess the accuracy of the Cosmed K5 MC and BxB modes against the criterion Douglas bag (DB) method. **METHODS:** Eleven healthy males (mean age \pm SD, 33.5 \pm 6.3 yrs) had their metabolic variables measured at rest (17 min) and during cycling at 50, 100, 150, 200, and 250 W (13 min at each work rate). Within each stage, steady-state metabolic variables were measured using three systems (DB, BxB, MC), with the order varied to account for possible order effect. During each stage the participant was connected to the first system for the first four minutes to reach steady state, followed by collection periods of 5-min (DB) or 3-min (MC and BxB) for

the resting condition, or 2-min each for all cycling intensities. The collection periods for the second and third systems were preceded by a washout of 1-3 min. Repeated measures ANOVAs were used to compare metabolic variables measured by each system for rest and each cycling work rate. **RESULTS:** For ventilation (V_E) and VO_2 , the K5 MC and BxB modes were not significantly different from the DB V_E and VO_2 at rest or any cycling work rate ($p \geq 0.05$). Across all stages, the VO_2 from the K5 MC and BxB modes were within 0.09 L/min of the DB VO_2 . Compared to DB values, VCO_2 was significantly underestimated by the K5 MC mode at 150W (mean difference, -0.17 L/min) and by the K5 BxB mode at 200W (-0.17 L/min) and 250 W (-0.40 L/min, all $p < 0.05$). K5 MC and BxB respiratory exchange ratio (RER) values were significantly lower than DB RER across most work rates by 0.04 to 0.09 ($p < 0.05$). When comparing the K5 MC and BxB modes to each other, V_E , VO_2 , VCO_2 , and RER were similar at rest and across all cycling intensities. **CONCLUSION:** These findings suggest that the Cosmed K5 portable metabolic system MC and BxB modes are acceptable for measuring VO_2 during rest and across a wide range of exercise intensities.

570 May 29 1:15 PM - 1:30 PM

Agreement between Deuterium Oxide and Bioimpedance Spectroscopy Measures of Total Body Water

Zackary Cicone¹, Clifton Holmes¹, Bjoern Hornikel¹, Todd Freeborn¹, Jordan Moon², Michael Fedewa¹, Michael Esco, FACSM¹. ¹University of Alabama, Tuscaloosa, AL. ²Impedimed, Inc, Carlsbad, CA. (Sponsor: Michael R. Esco, FACSM)
Email: zcicone@crimson.ua.edu

Reported Relationships: **Z. Cicone:** Industry contracted research; ImpediMed, Inc..

The inclusion of total body water (TBW) into body composition analyses improves the accuracy of measures. However, the criterion method using deuterium oxide dilution (D_2O) is impractical for clinical settings.

PURPOSE: The purpose of this study was to compare TBW estimates from two commercial bioimpedance spectroscopy (BIS) devices against D_2O .

METHODS: 89 subjects (64% female; age: 18 to 82 years; body mass index [BMI]: 18.0 to 39.5 kg/m²) had TBW determined via D_2O and whole-body BIS using two devices: a standard supine BIS device (BIS_{sup}), and a new commercial standing BIS device (BIS_{new}). Agreement between TBW from D_2O and the two BIS devices was determined using the Bland-Altman method.

RESULTS: Mean differences between D_2O and BIS devices were significantly greater than zero ($ps < 0.05$), however the magnitudes of the differences were small (Cohen's $ds < -0.20$) and both devices were highly correlated with D_2O (Pearson's $rs > 0.90$, $ps < 0.01$). Bias and limits of agreement (bias \pm 1.96*SD) for BIS_{sup} (-1.5 \pm 5.7) and BIS_{new} (-0.7 \pm 5.8) were small and relatively tight. The BIS devices were strongly correlated with each other ($r=0.99$).

CONCLUSIONS: The results of this study demonstrate that both the standard and new BIS devices measured TBW with minimal bias and tight limits of agreement compared to D_2O . These findings support the use of both the standard and new BIS device as a surrogate of D_2O for the assessment of TBW in adults across a wide range of both age and BMI.

Exercise Testing Protocol Matters: Sub-maximal and Maximal Measures Before and After Marathon Training

Christopher J. Lundstrom, Emma J. Lee. *University of Minnesota, Minneapolis, MN.* (Sponsor: Dr. Eric Snyder, FACSM)

Email: lund0982@umn.edu

(No relevant relationships reported)

Maximal and sub-maximal physiological testing can assess aerobic variables important in running performance. We compared two protocols to demonstrate the impact of protocol on measures of maximal (VO_{2MAX}) and submaximal aerobic variables: energy cost of running (ECR), oxygen cost of running (OCR), and substrate utilization, assessed with respiratory exchange ratio (RER). **PURPOSE:** To compare two physiological testing protocols before and after marathon training. **METHODS:** Recreational runners ($n=111$; 72% female; ages 21.2 \pm 1.6) enrolled in a marathon training class participated in the study. Subjects ran a 2-mile time trial (2MI) on a 200m indoor track, followed by laboratory testing 1-2 weeks later, both prior to and after 18 weeks of training for a marathon race. Testing included a sub-maximal 6-minute treadmill run at 75% of 2-mile velocity followed by a graded exercise test to assess VO_{2MAX} . The final 5 minutes of the 6-minute run were averaged for analysis of ECR, OCR, and RER. For post-testing one cohort ($n=54$) had the treadmill velocities adjusted to their current 2MI ability (ADJ) while another cohort ($n=57$) repeated the pre-test velocities (REP). Repeated measures ANOVA was used to assess the effect of testing protocol on ECR, OCR, RER, and VO_{2MAX} . **RESULTS:** Subjects improved in 2MI with training (16.3 \pm 2.0, 15.0 \pm 2.0 min; $p < 0.001$), with no group-by-time interaction. RER decreased with training ($p=0.02$). There was an effect of protocol

on RER ($p=0.02$): ADJ did not change but REP decreased (0.90 ± 0.05 , 0.86 ± 0.05 ; $p\leq 0.001$). There were no changes in ECR, but there was a trend towards an effect of protocol ($p=0.085$) with an increase in ECR for ADJ and a decrease for REP. There was an effect of protocol on OCR ($p\leq 0.001$): REP did not change whereas ADJ increased (32.3 ± 4.6 , 35.7 ± 4.5 mL \cdot kg $^{-1}\cdot$ min $^{-1}$). There was a trend toward an increase in VO_{2MAX} with training ($p=0.064$), and an effect of protocol ($p\leq 0.001$), with ADJ increasing in VO_{2MAX} (49.2 ± 6.8 , 52.2 ± 6.6 mL \cdot kg $^{-1}\cdot$ min $^{-1}$) and no change in REP. **CONCLUSIONS:** Marathon training decreases RER during moderate exercise at the same absolute but not relative velocity. Changing the speed of the exercise testing protocol to reflect current running ability helps detect changes in aerobic capacity (VO_{2MAX}), but may mask changes in sub-maximal running variables such as ECR, OCR, and RER.

572 May 29 1:45 PM - 2:00 PM

The Exercise Response In Blood Flow Restriction Training Varies As A Function Of Cuff Type

Johanna Vogel, Jan Wilke, Lutz Vogt, Winfried Banzer, FACSM. *Institute of Sports Sciences, Frankfurt, Germany.* (Sponsor: Winfried Banzer, FACSM)

Email: johvogel@em.uni-frankfurt.de

(No relevant relationships reported)

PURPOSE: Blood flow restriction (BFR) training is a popular method to induce muscle hypertrophy. Both conventional blood pressure cuffs and devices specifically developed for BFR are used to achieve vascular occlusion/BFR. However, it is unknown if the training response differs depending on the cuff type. This study elucidated the acute effects and the safety of exercising with a medical blood pressure cuff (MC) and a BFR cuff (BFR-C). **METHODS:** Ten healthy individuals (30 ± 8 years, 5 ♀) completed three sessions of unilateral low-intensity resistance exercise (30% 1RM) of the knee extensors. In the first session, wearing a BFR-C, the participants performed three sets until maximal exhaustion. In the two other conditions (order selected randomly), the same workload (sets & repetitions) was used for a training session with a MC and without any BFR. Pre and post-intervention, blood lactate, thigh circumference, pressure pain threshold, tissue stiffness and elasticity were measured. During exercise, heart rate, subjective discomfort and fatigue were documented. Twenty-four, 48 and 72 hours after training, muscle soreness was assessed. To judge safety, the pressure [mmHg] needed to provoke full occlusion at rest was determined with Doppler sonography. Differences between conditions were detected by means of Friedman tests including adjusted post hoc Conover comparisons. **RESULTS:** Both, BFR-C (+49%, $p=.03$) and MC (+29%, $p=.03$) induced greater lactate concentrations than the no-BFR control. Compared to the other conditions, BFR-C resulted in higher values for exercise heart rate (+3% vs MC, $p=.015$, +3% vs. no-BFR, $p=.015$) as well as muscle soreness after 24 hours (+81% vs MC, $p=.012$, +150% vs. no-BFR, $p=.004$). 72 hours post training, soreness was still increased in BFR-C (+3.5 pts on NRS vs. no-BFR, $p=.045$). Similarly, BFR-C elicited stronger fatigue sensations (+36%, vs. no-BFR, $p=.005$). Ultrasound examinations revealed that MC could generate a full occlusion while BFR-C did not entirely obstruct blood flow as long as the normal scale was not exceeded. **CONCLUSIONS:** Although BFR-C seems to provide a stronger exercise stimulus than MC, it may be a better choice regarding exercise safety. This finding may particularly be of value if applying the method in elderly/untrained persons or individuals with chronic disorders.

573 May 29 2:00 PM - 2:15 PM

Influence of Testing Sequence on an Adult's Ability to Achieve Maximal Aerobic and Anaerobic Power

Luke Stong, Luke Haile, Kyle Beyer, Jonathan Kollars, Cristina Alvine, Roslyn Pulcini, Joseph Andreacci, FACSM. *Bloomsburg University, Bloomsburg, PA.* (Sponsor: Joseph Andreacci, FACSM)

(No relevant relationships reported)

PURPOSE: To examine how testing sequence affects an adult's ability to achieve maximal aerobic and anaerobic power during a single assessment visit. **METHODS:** Fifty-three adults (31 women, 22 men; 21.9 ± 1.6 years) participated in this investigation. All subjects were tested on three separate occasions. Participants completed two baseline visits (Visits 1 and 2) consisting of either a VO_{2max} or WAnT in a randomized counterbalanced order. Participants then completed an experimental visit (Visit 3) which consisted of both a VO_{2max} and WAnT in randomized order (Group A: WAnT/ VO_{2max} ; Group B: VO_{2max} /WAnT) with 20 minutes of rest between tests. Mixed model ANOVAs with Bonferroni post hoc analyses compared baseline (Visits 1 or 2) and experimental (Visit 3) exercise test performance between and within groups for both relative VO_{2max} and absolute peak power. **RESULTS:** No significant main or interaction effects were observed for relative VO_{2max} at baseline and experimental visits when comparing Group A (42.9 ± 7.2 ml/kg/min and 42.0 ± 8.0 ml/kg/min, respectively) and Group B (40.9 ± 8.6 ml/kg/min and 41.2 ± 8.2 ml/kg/min, respectively). Similarly, no significant main or interaction effects were observed for absolute peak power at baseline and experimental visits when

comparing Group A (747.7 ± 229.4 W and 742.7 ± 221.3 W, respectively) and Group B (747.7 ± 229.4 W and 742.7 ± 221.3 W, respectively) (681.7 ± 209.0 W and 690.2 ± 197.6 W, respectively).

CONCLUSIONS: Our findings indicate that testing sequence had no effect on achievement of maximal aerobic and anaerobic power. Researchers and clinicians can include VO_{2max} testing and a WAnT during the same visit with 20 minutes of rest without compromising maximal performance.

574 May 29 2:15 PM - 2:30 PM

Effects Of Honest And Dishonest Pre-exercise Placebo Ingestion On VO_{2} Peak And Isometric Handgrip Performance

Jessica Moon¹, Christian Espitia², Landon Hiebert², Christopher A. Fahs², Lindy M. Rossow². ¹Lindenwood University, St. Charles, MO. ²Lindenwood University Belleville, Belleville, IL.

(No relevant relationships reported)

Pre-exercise consumption of placebo has been shown to improve resistance and endurance exercise performance. However, the effects of placebo ingestion on graded exercise test performance have not been widely reported in the literature. **PURPOSE:** The purpose of this study was to examine the effects of honest (subjects were told they were consuming placebo) or dishonest (subjects were told they were consuming a pre-workout supplement) placebo ingestion on VO_{2peak} values determined during a maximal treadmill graded exercise test. A secondary purpose of this study was to examine the effects of placebo consumption on isometric handgrip performance. We hypothesized that pre-exercise ingestion of both placebo conditions would result in increased VO_{2peak} and handgrip performance compared to control. **METHODS:** 28 males (178.4 ± 6.94 cm, 83.3 ± 14.8 kg, 22.6 ± 2.3 yrs.) and 13 females (166.4 ± 8.49 cm, 73.6 ± 20 kg, 26.4 ± 11 yrs.) participated in this study. In a randomized, cross-over design, subjects performed treadmill VO_{2peak} and isometric handgrip testing after consumption of honest placebo (HP) or dishonest placebo (DP). In addition, a third baseline trial (CON) was performed to establish performance values that were unaffected by a perceived placebo effect due to supplementation. All outcomes were assessed for normality using the Shapiro-Wilks test. When assumptions of normality were violated, log transformations were computed. However, transformations did not improve model assumptions. Therefore, non-transformed data is reported. One-way ANOVAs were used to analyze VO_{2peak} and handgrip strength data across conditions. Alpha was set at 0.05 prior to all analyses. **RESULTS:** Significant between-groups differences ($p < 0.05$) were not detected for relative VO_{2peak} (CON = 46.2 ± 9.3 mL/kg/min; HP = 46.7 ± 10 mL/kg/min; DP = 46.6 ± 9.6 mL/kg/min) or for maximal handgrip strength (CON = 43 ± 9.6 kg; HP = 44.1 ± 12.4 kg; DP = 43.4 ± 12.1 kg). **CONCLUSION:** Administration of honest or dishonest placebo immediately prior to VO_{2peak} and handgrip testing had no effect on performance compared to control. The VO_{2peak} and isometric handgrip tests were found to be robust exercise tests not significantly influenced by perceived pre-workout supplement consumption.

575 May 29 2:30 PM - 2:45 PM

Using a Stretch Sensor to Evaluate Muscle Contraction Timing During a Neuromuscular Control Screening Activity

Shannon E. Linderman¹, Donna Moxley Scarborough¹, William Day², Daniel Wrafter³, Eric M. Berkson¹. ¹Massachusetts General Hospital, Boston, MA. ²figur8, Inc, Boston, MA. ³Massachusetts Institute of Technology, Cambridge, MA.

Email: slinderman@mgh.harvard.edu

Reported Relationships: S.E. Linderman: Salary; figur8, Inc.

PURPOSE: Stretch sensors are wearable devices that when applied over a muscle group, can measure the physical output of muscle deformation resulting from a muscle contraction. Electromyography (EMG) is the clinical standard for assessing the electrical signal identifying muscle activation. The well-established challenges in EMG data collection and analysis methods limit utility for wearable wide-spread neuromuscular control screening. The purpose of this study was to investigate the ability of stretch sensors to detect timing patterns of muscle contraction and compare time events to those collected through traditional clinical EMG.

METHODS: 4 healthy subjects (mean age: 23.29 ± 3.45 y) completed 5 repetitions of a unilateral partial squat with a stretch sensor and an EMG unit simultaneously applied to the dominant leg quadriceps muscle. Paired T-test and linear regression analyses assessed differences in key muscle contraction time events (Figure 1) for the stretch sensor (SS) and EMG.

RESULTS: Relative times of peak contraction ($r^2=0.99$, mean relative error (RE)=0.04), activation ($r^2=0.98$, RE=0.14), and deactivation ($r^2=0.92$, RE=0.35) displayed excellent correlation between the EMG and SS. Duration of ascent ($p=0.103$, EMG: 1.14 ± 0.46 s, SS: 1.36 ± 0.27 s) and descent ($p=0.079$, EMG: 1.38 ± 0.49 s, SS: 1.14 ± 0.37 s) squat phases and total contraction time ($p=0.95$, EMG: 2.55 ± 0.83 s, SS:

2.49 ± 0.30 s) did not differ significantly between EMG and SS. Average within-subject variation was not significantly different for EMG timing of ascent ($p = 0.56$) and descent ($p = 0.15$) phases, and total contraction ($p = 0.08$).

CONCLUSIONS: Our findings reveal similarities in time signatures between SS and EMG for assessing quadriceps activation during a standard neuromuscular screening activity. This suggests the potential for utility of SS evaluation of muscle activation timing.

This study was supported in part by figur8 Inc

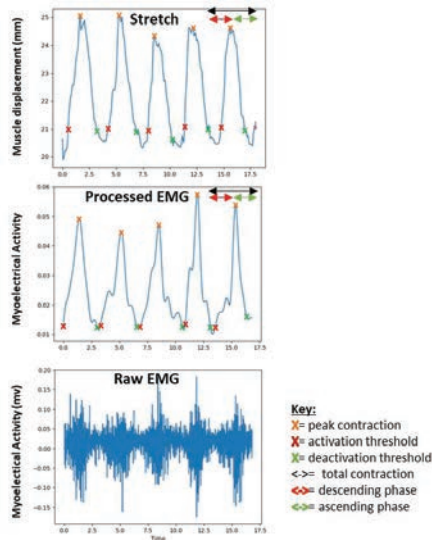

Figure 1: Example of relative muscle contraction timing for stretch sensor and EMG signals during a repeated partial squat task.

A 6th order low-pass Butterworth filter (3 Hz) and rectified TKEO function were applied to raw EMG data. Threshold of activation/deactivation was defined as 3 standard deviations of a resting calibration trial.

576 May 29 2:45 PM - 3:00 PM

Estimation of Running and Cycling VO_2 max Using the Heart Rate Ratio Method

Pat R. Vehrs, FACSM, Sabrina Adams, Kaylee Massey, Nicole Tafuna'i, Brady Hanson. *Brigham Young University, Provo, UT.*

(No relevant relationships reported)

Although the direct measurement of VO_2 max during an exercise test provides the most accurate assessment of cardiorespiratory fitness, estimates of VO_2 max are often more practical. Prior research suggests that VO_2 max obtained during a treadmill maximal graded exercise test can be accurately estimated in men using the Heart Rate Ratio Method. This method estimates VO_2 max using the following equation: VO_2 max (mL/kg/min) = (HRmax / HRrest) x 15. The validity of this equation to estimate VO_2 max has not been established in women or in other modes of exercise, such as cycling.

PURPOSE: This study compared VO_2 max values measured during running and cycling to estimates of VO_2 max using the Heart Rate Ratio Method in 42 men and women. **METHODS:** Resting metabolic rate (RMR) and VO_2 max on the treadmill and cycle ergometer were measured on 21 men and 21 women between 19-39 years of age. Each subject's running and cycling VO_2 max was estimated using the Heart Rate Ratio Method and their resting HR measured during the RMR test and their actual maximal HR achieved during the maximal exercise tests. **RESULTS:** The average running and cycling VO_2 max values for males (54.2 ± 7.1 ; 50.0 ± 8.9 mL/kg/min) were higher ($p < 0.0001$) than in females (43.4 ± 5.8 ; 39.8 ± 7.4 mL/kg/min), respectively. Resting HR values for males (55 ± 7 bpm) and females (57 ± 6 bpm) were similar as were the maximal HR values during running (186 ± 12 ; 190 ± 12 bpm) and cycling (181 ± 11 ; 184 ± 13 bpm), respectively. The estimates of running and cycling VO_2 max under-predicted actual values in males (-2.9 ± 8.0 ; -0.26 ± 7.8 mL/kg/min) and overestimated actual values in females (7.3 ± 7.9 ; 9.3 ± 8.2 mL/kg/min), respectively. There was a significant gender effect in the prediction of VO_2 max using the Heart Rate Ratio Method. Regression and Bland Altman analysis for treadmill running yielded an $R^2 = 0.076$, an SEE = 8.19, and a 95% limits of agreement (LOA) of ± 18.46 mL/kg/min. Likewise, regression and Bland Altman analysis for cycling yielded an $R^2 = 0.18$, an SEE = 8.85, and a 95% LOA = ± 18.24 mL/kg/min. **CONCLUSION:** The high SEE and LOA precludes this method for predicting running and cycling VO_2 max. Gender differences in maximal HR and VO_2 max are not accounted for in predictions of VO_2 max using the Heart Rate Ratio Method.

B-14 Clinical Case Slide - Oncology

Wednesday, May 29, 2019, 1:00 PM - 3:00 PM

Decreased Movement Of Right Arm In A Non-verbal Child

Eric M. Bankert, Scott Annett, Vicki R. Nelson. *Steadman Hawkins Clinic of the Carolinas, Greenville Health System, Greenville, SC.* (Sponsor: Kyle J. Cassas, FACSM)

Email: EBankert@ghs.org

(No relevant relationships reported)

HISTORY:

A 4 y/o non-verbal male with Rubinstein-Taybi syndrome presented for poor motion of his right arm. The patient was noted to become fussy when his parents put his shirt on that morning and when they tried to move his right arm. There were no known injuries, trauma, fever, or recent illness. Birth history was unremarkable. He had a tethered cord release in his first year of life. At baseline he uses all extremities and can crawl but not walk.

PHYSICAL EXAMINATION:

T 97.9F BP 104/80 HR 115

Well appearing, nonverbal and wheelchair-dependent male. No ecchymosis or significant erythema to the right arm. Limited active and full passive ROM of right shoulder, elbow and wrist with fussiness noted on manipulation. No focal tenderness noted. 2/4 MSR in bilateral upper and lower extremities.

DIFFERENTIAL DIAGNOSIS:

1. Radial Head Subluxation
2. Non-accidental Trauma - fracture or dislocation
3. Osteomyelitis
4. Septic Arthritis
5. Tumor/Malignancy

TESTS AND RESULTS:

R Shoulder and Elbow XRs: No fracture or soft tissue abnormality seen

CRP 41.7 mg/L, ESR 44 mm/hr, Blood culture No growth

MRI of Right Humerus: Effusion with surrounding enhancement in the right shoulder; subtle changes in the metaphysis of the right humerus with periosteal edema and enhancement

FINAL WORKING DIAGNOSIS:

Pre-B cell Acute Lymphoblastic Leukemia

TREATMENT AND OUTCOMES

1. The patient underwent manual reduction of possible radial head subluxation, which was felt to be successful with improved ROM of the elbow. However, symptoms returned within a day.
2. Labs and imaging were concerning for infection and he was admitted for surgical wash-out of right shoulder and sent home on prolonged IV antibiotics.
3. He developed contralateral shoulder symptoms with prolonged fever and left shoulder MRI showed similar findings.
4. After multiple wash outs and rounds of IV antibiotics, Flow Cytometry was noted to be positive for Pre-B cell acute lymphoblastic leukemia, so patient was started on appropriate chemotherapy regimen and is currently in the maintenance phase.
5. This case demonstrates the difficulty in pediatrics of identifying the cause of medical issues in patients who are non-verbal, as well as the vast differential diagnoses possible in children with musculoskeletal complaints. It also highlights the need for close follow up to resolution of symptoms.

581 May 29 1:20 PM - 1:40 PM

The Use Of Individualized Exercise Prescription To Target Oxidative Metabolism In A Stage Iv Colorectal, Metastatic Cancer PatientInigo San-Millan. *University of Colorado School of Medicine, Aurora, CO.*

Email: isanmillan@gmail.com

(No relevant relationships reported)

HISTORY: A 42 year-old male was diagnosed with stage IV colorectal, metastatic cancer. In 2017 (2 years post-diagnosis) he came to our laboratory seeking exercise advice. He had received 56 rounds of chemotherapy without signs of remission. He also exercised on the bike 4-5 days/week with a duration of 1-3h/session. **PHYSICAL EXAMINATION:** He performed an incremental cardiopulmonary cycling exercise test. O₂ consumption, blood lactate (BLa) as well as fat and carbohydrate oxidation rates (FATox/CHOox) were measured to assess cardiopulmonary and mitochondrial function. Both his FATox and lactate clearance capacity were poor, suggesting poor mitochondrial function despite exercising 4-5 days/week. He was given an individualized exercise prescription program for 3 months with the same amount of days and hours/week but with specific exercise intensities based on his individual metabolic parameters with the aim to improve oxidative metabolism to try to target the glycolytic phenotype of cancer (Warburg Effect). During the course of this exercise program he continued with chemotherapy. **TESTS AND RESULTS:** 3 months after the individualized exercise program he returned to the lab for re-evaluation. Significant increases in oxidative metabolic capacity at different exercise intensities were observed: -At 115, 150 and 190 Watts his FATox significantly increased (0.11g·min⁻¹ vs 0.29g·min⁻¹; 0.06g·min⁻¹ vs 0.25g·min⁻¹ and 0.0g·min⁻¹ vs 0.25g·min⁻¹ respectively). - Significant decreases in (BLa) were observed at 115, 150, 190 and 235 Watts (2.0 mmol·L⁻¹ vs 1.0 mmol·L⁻¹; 2.6mmol·L⁻¹ vs 1.4 mmol·L⁻¹; 4.4 mmol·L⁻¹ vs 2.2 mmol·L⁻¹ and 9.7 mmol·L⁻¹ vs 4.6 mmol·L⁻¹ respectively) **FINAL/WORKING DIAGNOSIS:** The patient's cardiovascular and oxidative capacity significantly improved after 3 months of individualized exercise program. **TREATMENT AND OUTCOMES:** One month later, he performed a new PET scan showing remission and no evidence of cancer. **CONCLUSIONS:** This case shows a novel approach to individualize exercise prescription in cancer patients to try to elicit improvements in oxidative metabolism to counteract the glycolytic phenotype of many cancers. The mechanisms for this metabolic reprogramming could be a possible crosstalk between skeletal muscle and cancer cells via exosomes could be a possible explanation.

582 May 29 1:40 PM - 2:00 PM

Hand Mass in an Active Military PersonnelBenjamin Tan, Daniel Montero. *Mayo Clinic Hospital, Jacksonville, FL.* (Sponsor: George Pujalte, FACSM)

(No relevant relationships reported)

History:

A previously healthy 21 year-old male, right-hand dominant, presented into sports medicine clinic with a right thumb mass that had been present for approximately a year and a half. Over this period, the mass had grown slowly but had since stabilized. He denied any associated sensitive pain or dysfunction. He presented due to concern regarding the size of the mass, and because it was interfering with tasks related to his physical training and duties in the Air National Guard.

Physical Exam:

Generally healthy-appearing, muscular but thin-built, gentleman in no acute distress. Evaluation of the hand showed an obvious mass on the dorsal aspect of the right first interphalangeal (DIP) joint that was elevated by approximately 3mm and measured 17 mm x 5 mm. It was non-tender to palpation. It did not affect flexion or extension of the right DIP joint. However, it did not transilluminate by penlight. It felt firm on exam.

Differential Diagnoses:

Ganglion cyst of distal interphalangeal joint

Epidermoid cyst

Giant cell tumor

Tests and Results:

Ultrasound briefly performed showed echogenicity and no obvious free fluid within or surrounding the mass. X-rays revealed rounded a soft tissue density overlying the dorsum of the thumb's interphalangeal joint. No radiopaque foreign object was present. No adjacent periosteal reaction or osseous destructive changes were noted. Magnetic resonance imaging (MRI) revealed an enhancing, soft tissue mass measuring 13 mm x 9 mm x 6 mm, along the dorsal aspect of the right thumb at the interphalangeal joint, most compatible with a giant cell tumor, associated with the extensor pollicis longus tendon sheath.

Final Working Diagnosis:

Giant cell tumor, rarely seen on the thumb (2% of cases occur within the hand)

Treatment and Outcomes:

Patient shortly underwent a surgical excision of the giant cell tumor which revealed intraarticular extension into the interphalangeal joint of the right thumb. Pathology confirmed the diagnosis.

Patient was doing well as of this writing, with no pain or range of motion restriction after surgery

Given reports of recurrence of giant cell tumors, follow-up was recommended in the event that the mass recurred or was noted in other locations.

583 May 29 2:00 PM - 2:20 PM

A Pheochromocytoma in an Elite Collegiate AthletePierre L. Viviers, FACSM¹, Craig Thompson¹, Glen Hageman², Wayne Derman¹. ¹Stellenbosch University, Stellenbosch, South Africa. ²Sharks Medical, Durban, South Africa.

Email: plviviers@sun.ac.za

(No relevant relationships reported)

HISTORY: A 22-Year-old rugby union player presented to the Sports Medicine clinic complaining of a sore throat and skin rash over his back and upper arms for the past week. Further symptoms included rhinorrhoea and dry cough for the previous week, feeling "hot" (especially at night) and constant fatigue. The occurrence of these symptoms coincided with a regional measles outbreak. The clinical symptomatology persisted at subsequent visits over a period of 12 months and ranged from diarrhoea, skin rash, dry cough, headaches, anxiety, night sweats, rapid heart rate and exercise intolerance. Despite follow-up visits when he was asymptomatic, constant weight loss occurred over the period since he first presented. Except for weight loss and a single blood pressure reading of 135/90mmHg previously his medical history was uncompromised. He had a history of various sport related musculoskeletal injuries and there was no family history of note. **PHYSICAL EXAMINATION:** At initial physical examination athlete was afebrile, HR 100 b/min with a blood pressure reading of 110/60mmHg. Palpable tender occipital lymph nodes were present. Except for the non-purulent pharyngitis and maculopapular rash over the back and upper arms, the remainder of systemic physical examination was normal. Although normal or low BP measurements were recorded occasionally, he remained tachycardic and BP mildly elevated (135/90 mmHg) with the skin rash located over the trunk at most visits. **DIFFERENTIAL DIAGNOSIS:** Viral infection (measles, rubella, coxaci, EBV), Viral infection unspecified, Hyperthyroidism, Pulmonary tuberculosis, Vasomotor response to immune activation, Essential Hypertension, Pheochromocytoma. **TEST AND RESULTS:** FBC's-normal, ESR-normal, CRP-normal, Rubella/Measles IGM (-), s-Urea(7.7mmol/L), s-Creatinine(108µmol/L), S-ALKP(136µmol/L), s-GGT(140µmol/L), S-ALT(101µmol/L), Coxaci-B AB (+), EBV(+), U-VMA-24hrs (50112 nmol/L), MIBG Scan negative(left) indicated a left adrenal gland mass, CT Abd (Triphasic)-well defined mass left adrenal gland **FINAL WORKING DIAGNOSIS:** Benign pheochromocytoma-left adrenal gland **TREATMENT AND OUTCOMES:** Laparoscopic adrenalectomy (left), Uncomplicated post operative recovery, Full return to sport

584 May 29 2:20 PM - 2:40 PM

Anaplastic Oligodendroglioma: Impacts Of Aerobic And Flexibility Training On Physiological, Psychosocial, And Cognitive FunctionBrent M. Peterson¹, Alyse P. Brennecke², Daniel Y.K. Shackelford³, Jessica M. Brown³, Reid Hayward⁴. ¹Biola University, La Mirada, CA. ²University of Colorado Denver Anschutz Medical Campus, Aurora, CO. ³Carroll University, Waukesha, WI. ⁴University of Northern Colorado, Greeley, CO. Email: brent.peterson@biola.edu

(No relevant relationships reported)

HISTORY: A 44-year old female diagnosed with class III anaplastic oligodendroglioma with 1p19q genetic co-deletion who underwent a left-frontal craniotomy, chemotherapy, and radiation prior to starting an exercise-based cancer rehabilitation program. During initial assessments, she qualified and was enrolled in an ongoing research study examining the impacts of aerobic and flexibility training on cognitive function. **CLINICAL EXAMINATION:** Comprehensive physical, psychosocial, and cognitive assessments were completed pre and post training (36-session intervention). **DIFFERENTIAL DIAGNOSIS:** 1. Brain Metastases 2. Seizure Disorders 3. Glioblastoma Multiforme **TESTS AND RESULTS:** Sought medical assistance following grand mal seizures. Magnetic resonance images (01/15/2013) revealed infiltrative lesions on the anterolateral aspect of the left frontal lobe which measured at approximately 4.6cm x 3.3cm in the axial plane - involved cortex and subcortical white matter Patient underwent craniotomy (01/24/2013) Pathology confirmed grade III anaplastic oligodendroglioma - positive: 1p36 and 19q13 sequence deletions - negative: epidermal growth factor receptor sequences, tumor suppressor gene phosphatase - negative for the loss of the tumor suppressor gene phosphatase and tensin homolog sequences Follow-up (02/12/2013) the patient was awake, alert, and oriented, but physically fatigued New presentations: - blurred visual acuity (left eye), ambulation and postural difficulty, lower right extremity weakness, continual word aphasia with speech interruption **FINAL/WORKING DIAGNOSIS:** Class III anaplastic oligodendroglioma with 1p19q genetic co-deletion; referred to the University of Northern Colorado Cancer Rehabilitation Institute

and recommended participation in study **TREATMENT AND OUTCOMES:** 1. Procarbazine, Lomustine, and Vincristine Sulfate (PCV) chemotherapeutic (6x) with ionized radiation (46Gy followed by 14Gy boost to resection site and G2/FLAIR regions) - temozolomide added as adjuvant to radiation 2. Patient completed 36 sessions of aerobic and flexibility training 3. Improvements observed in physiological, psychosocial, and cognitive variables 4. Patient then made a positive transfer into a standard exercise-based cancer rehabilitation program

(No relevant relationships reported)

HISTORY: A 53-year-old female patient (Body mass = 71.30 kg; Height, 1.58 m; BMI = 28.74 kg / m²) from the Mato Grosso Cancer Hospital in Cuiabá, Brazil, with stomach cancer, reported stomach pain for at least 12 months, with no improvement in the use of proton pump inhibitors (omeprazole) and/or antacids (sodium bicarbonate). She reported vomiting and increasing pain after consuming beer and using tobacco. The patient denied having decreased body weight over the last six months. Abdominal distension was reported.

PHYSICAL EXAMINATION: Clear awareness, without edema, afebrile, normal blood pressure SARC-F questionnaire: score = 4 (tendency for sarcopenia).

DIFFERENTIAL DIAGNOSIS:

1. Reported muscle strength loss
2. Needed help to walk and lift chair
3. Could not climb stairs

TEST AND RESULTS:

Tomography of the whole abdomen:
— wall thickening of the gastric antrum
Pathological stage:

— T₃ N₂ M₁

Functional evaluation:

— Handgrip test: mean of 30 kg.f in both hands (good); 30-second elbow flexion test: 13 repetitions (good); 30-second chair stand test: 11 repetitions (adequate); Timed Up and Go test: 9 seconds (low risk of falls); Walking speed test: 1m / sec (adequate); 2-minute walk test: 109 knee elevations (good functional capacity)

FINAL/WORKING DIAGNOSIS:

Locomotor difficulties were diagnosed through the physical/clinical examination and there was a tendency for sarcopenia; on the other hand, the physical tests did not corroborate this information and did not independently confirm physical incapacity prior to the total gastrectomy

TREATMENT AND OUTCOMES:

1. Total gastrectomy.
2. Need to develop physical/functional tests to be applied, specifically, in cancer patients, regardless of tumor type.
3. Currently available physical tests were developed for an elderly population, which may compromise the interpretation of the results obtained (low specificity and sensitivity).
4. Prescription of physical exercises (as a non-pharmacological treatment) for patients with stomach cancer should begin before surgery, because the current patient presented, in advance, with locomotor difficulties.
5. The SARC-F questionnaire seems to be a good tool to detect sarcopenia in a patient with stomach cancer, although it also requires future adaptations for this purpose.

Severe Shoulder Pain in a Healthy Adolescent Child

Ashkan Alkhamisi, M.D., J. Parker Chapman, M.D., Laurel Blakemore, M.D., Jason Zaremski, M.D., FACSM. *University of Florida, Gainesville, FL.*

Email: ashkan.alkhamisi@ufl.edu

(No relevant relationships reported)

HISTORY:

A 12-year-old child presented to sports medicine clinic with his grandfather for evaluation of 4 days of diffuse left shoulder and upper arm pain. Pain developed hours after holding onto a rope while tubing in a lake. He denies being thrown off the tube or shoulder pain while riding. Pain was 4/10 pain at rest and 9/10 pain with movement. Pain gradually worsened over previous past 4 days. He denied any previous injury to the left arm or shoulder. He denied any numbness, or tingling of the left arm. He denied any changes in vision, headaches, chest pain, shortness of breath, or rashes. Of note, he went to the ED two days prior due to subjective fevers and diagnosed with a viral upper respiratory infection.

Physical Exam:

Vitals signs were normal. He was distressed and tearful. He had no tenderness and full range of motion (ROM) of his cervical spine. There was diffuse left sided tenderness over the sternum, ribs, mid-humerus, biceps, upper trapezius, and rhomboids. Pain with active and passive ROM of the elbow and shoulder. Shoulder strength was limited due to pain. Sensation was intact throughout the left upper extremity. No skin discoloration, breaks, or increased warmth of the left arm or shoulder.

Differential Diagnoses:

1. Rotator cuff tendinopathy
2. Shoulder dislocation and/or glenoid labral tear
3. Occult Humerus fracture
4. Infection

Initial Test and results:

Left shoulder and humerus radiographs were normal. Due to the disposition of the patient, the patient and his family were advised to go to the pediatric ER. A work-up revealed a normal WBC count, and an elevated CK and CRP. Urine and blood cultures were positive for MSSA. MRI of the shoulder and elbow revealed osteomyelitis of left scapular body with left periscapular abscess. Pediatric Orthopedic Surgery was then consulted and performed an incision and drainage (I&D) of the left supraspinatus, infraspinatus, and subscapularis abscesses.

Final Diagnosis:

Acute MSSA osteomyelitis of left scapula with left periscapular abscess

Treatments and Outcomes:

After surgical I&D, the patient clinically improved over a two-week hospital course and discharged after 4 weeks of IV antibiotics. He was then transitioned to oral antibiotics for an additional 8 weeks. At the 8-week clinical follow-up there was a complete resolution of shoulder and upper extremity pain.

590 May 29 1:20 PM - 1:40 PM

Treatment of Neurogenic Thoracic Outlet Syndrome in a Professional Baseball Pitcher with Soft Tissue TechniqueJean-Paul Lucke. *Rothman Orthopaedic Institute, Philadelphia, PA.*

Email: Jean-Paul.Lucke@rothmaninstitute.com

(No relevant relationships reported)

HISTORY: A 28-year-old male, left hand dominant professional baseball pitcher, with a several year history of persistent left upper extremity numbness presented with increased pain and numbness of the elbow and forearm after throwing a pitch.

PHYSICAL EXAMINATION: On physical examination, the patient had decreased cervical range of motion with hypertonicity and tenderness of the supraclavicular fossa. Spurling's maneuver was negative and his shoulder and elbow had full range of motion and strength. There was no significant laxity or pain with valgus stress of the elbow and his wrist and intrinsic hand muscle strength was intact. Skin was intact without discoloration or edema. Tinel's was negative at the cubital and carpal tunnel, however, his sensation was slightly diminished throughout the ulnar nerve distribution. Roos and Adson tests were positive. **DIFFERENTIAL DIAGNOSIS:** UCL tear, Flexor pronator strain, ulnar neuritis, cervical radiculitis, thoracic outlet syndrome

TEST AND RESULTS: Radiographic evaluation included views of the left elbow and cervical spine which were unremarkable. An MR arthrogram of the elbow was negative for any significant pathology.

FINAL WORKING DIAGNOSIS: Acute on Chronic Neurogenic Thoracic Outlet Syndrome

TREATMENT AND OUTCOMES: Access to formal physical therapy was limited. The patient's pain and numbness persisted despite oral medications and daily treatment by the athletic trainer so he was referred to the team chiropractor. During the initial chiropractic treatment, which consisted of trigger point release and stretching applied to the anterior scalene musculature and cervical distraction manipulation, the patient experienced a sudden and complete resolution of his pain and numbness. He remained symptom free for the rest of the season.

591 May 29 1:40 PM - 2:00 PM

Abnormal Anatomical Etiology and the Resultant Bilateral Thoracic Outlet Syndrome: An Exploration Case ReportJennifer Rizzo¹, Brent M. Peterson². ¹*Concordia University Irvine, Irvine, CA.* ²*Biola University, La Mirada, CA.*

Email: jennifer.rizzo@cu.edu

(No relevant relationships reported)

HISTORY: 32-year-old healthy female presented to the vascular surgeon for right arm pain (pn) and a hand tremor. She was a mesomorph with forward head posture and was a volleyball athlete and triathlete.

PHYSICAL EXAMINATION:

Patient reported years of pn and dysfunction with no mechanism of injury. Symptoms began as stabbing pn 8/10 along right ulnar and radial nerves. Pn increased when the arms were unsupported. Right hand tremor increased with ADLs, and arm above 100 degrees. Feeling of heaviness and tingling in the arms impaired sleep and decreased effective grasping of objects causing patient to often drop things. Left arm pn 6/10 in trapezius, radiated to the forearm. Trapezius felt as if it needed to be stretched, but stretching increased pn 7/10. Pn was felt in the jaw and teeth 5/10 and the ear had a "cloudy" sensation. Patient had three root canals yet the facial pn persisted.

DIFFERENTIAL DIAGNOSIS:

Paget-Schroetter syndrome

Rotator Cuff injury

Multiple Sclerosis

TEST AND RESULTS:

MRA right shoulder:

-Labrum tear, infraspinatus atrophy, rotator cuff tear. Suprascapular nerve laceration with maximal involvement of infraspinatus

MRI c-spine:

-Minor arthrosis, slightly desiccated discs with no bulging at C5-C6

X-ray c-spine:

-No cervical ribs or narrow facets

MRI brain:

-No multiple sclerosis

Electromyography:

-Infraspinatus atrophy

Special Tests - Adson, Allen, Military Brace:

-Absent bilateral pulse

DASH score:

-Significant ADL impairment

Lidocaine muscle block, scalenes and right pec minor:

-Patient reported 50% decrease in pn

MRI bilateral brachial plexus:

-Post-surgical edema, asymmetrically large right jugular vein, pec minor and subclavian muscle atrophy with scarring at SC joint. Brachial plexus matted in scalene compartment; left side normal

FINAL/WORKING DIAGNOSIS:

Bilateral TOS with right pec minor impingement

TREATMENT AND OUTCOMES:

1.

Sx 1: Subtotal resection of subclavius, scalenes, resection of scalene minimus, division of pec minor, brachial plexus neurolysis, and subclavian artery lysis

2.

Sx 2: Subtotal resection of subclavius, scalenes, brachial plexus neurolysis, and subclavian artery lysis

3.

Sx 3: Scaleneotomy of right scalenes and scar tissue removal

4.

Paralyzed right diaphragm from surgery complication

5.

Patient reports 75% improvement on right, 90% improvement on left.

592 May 29 2:00 PM - 2:20 PM

Shoulder Injury - WeightliftingAndrew G. Cheung. *John Muir Health, Walnut Creek, CA.*

(Sponsor: Mark Lavallee, MD, FACSM)

Email: andrewcheungdo@gmail.com

(No relevant relationships reported)

History: 27-year-old male weightlifter with history of left UCL sprain and chronic bilateral partial-thickness supraspinatus tears was training for the 2017 FISU Summer World University Games in Taipei, Taiwan at the end of August 2017.

He was finishing his training session with pull-ups, when he felt a tearing sensation in his left anterior shoulder during the eccentric portion of the pull-up, with pain with flexion of that shoulder and tenderness to the area. Two days later, he felt a pop in his left anterolateral arm when he caught an 88 kg snatch slightly forward. He did not have any pain at that time and stopped his training session that day.

Physical Examination:

Left arm: Neurovascularly intact. Mild tenderness to palpation over bicipital groove.

"Popeye" deformity of proximal lateral biceps without ecchymosis or significant tenderness, accentuated by active flexion of the forearm.

Differential Diagnosis:

1. Rupture of the left biceps brachii long head proximal tendon

2. Partial thickness tear of the left biceps brachii distal tendon

3. SLAP tear of the left shoulder

4. Exacerbation of left elbow UCL injury

Tests and Results: Patient was sent 2 days later for ultrasound, which showed disordered muscle fibers and fluid collection over the area of the left proximal biceps deformity. Proximal biceps long head tendon not directly visualized in the bicipital groove on ultrasound.

Final Working Diagnosis: Rupture of the left biceps brachii long head proximal tendon

Treatment and Outcomes: Over the following month, the patient was seen by a physical therapist twice a week for manual therapy, including ice, compression, e-stim, and therapeutic ultrasound to the area in an effort to prevent potential myositis ossificans. Throughout this period, the patient continued to have intermittent left anterior arm pain while training, worse with snatches and other barbell exercises involving a wide grip; he continued to train at lighter weights, avoiding snatching more than 60% of his maximum in this period. Given the time proximity to competition, the patient decided against surgical evaluation. In competition, he snatched 99 kg (just 2 kg under his best), clean and jerked 125 kg (also 2 kg under his best), and had no significant discomfort or pain.

593 May 29 2:20 PM - 2:40 PM

Scapular Winging II - A New ApproachKevin M. Mullins, Brian A. Davis, FACSM. *University of California, Davis, Sacramento, CA.* (Sponsor: Brian A. Davis, FACSM)

(No relevant relationships reported)

HISTORY: A 62-year-old woman sustained a right shoulder injury after falling onto an outstretched arm. Initial workup with essentially normal cervical x-rays, MRI, and shoulder x-rays. On shoulder MRI mild increased T2 signals at insertion sites of supraspinatus and long head biceps. NCS for median/ulnar nerves and EMG of deltoid, infraspinatus, serratus anterior and rhomboid major were normal. She was treated with a subacromial corticosteroid injection and therapy without improvement.

EXAM: On inspection decreased bulk in right trapezius, rhomboids and supraspinatus. No palpation tenderness. Full passive ROM. Right scapular hike with abduction greater than 90 degrees and loss of adduction control of scapula into anterior/superior supraclavicular region. Active shoulder abduction pain limited to 54 degrees when

standing, but full 170 degrees when supine. Right trapezius strength 4/5, remaining muscles 5/5 with scapula stabilized. Sensation intact and impingement maneuvers negative.

DIFFERENTIAL: 1. Spinal accessory nerve lesion. 2. Long thoracic nerve lesion. 3. Supraspinatus tendinopathy. 4. Long head biceps tendinopathy. 5. Adhesive capsulitis.

RESULTS: NCS: Normal left spinal accessory nerve CMAP to trapezius, abnormal right spinal accessory nerve with decreased amplitude and onset latency compared. EMG: Normal right deltoid, infraspinatus, serratus anterior, rhomboid major but abnormal right upper/middle trapezius findings with increased insertional activity, fibrillation potentials, positive sharp waves, polyphasic MUAPs and reduced recruitment.

DIAGNOSIS: Right incomplete spinal accessory neuropathy

OUTCOME: Custom anterior-wrapped to posterior shell scapular stabilization brace fabricated. Once donned, improvement in abduction/flexion ROM quantified utilizing the Microsoft Kinect Motion Analysis. However, there was decrease in cross body adduction, and poor compliance long term due to weight and bulk. An updated lighter weight orthosis was fabricated, including a primary dynamic force strap for anteriorly directed pressure with a scapula plate shield intended to provide a superiorly directed force. The newer materials and design have provided significant improvement in function and compliance, indicating future treatment options for spinal accessory neuropathy.

594 May 29 2:40 PM - 3:00 PM

Shoulder Injury - Rower

Rahul Khapekar. *Advocate Lutheran General Hospital, Park Ridge, IL.* (Sponsor: Mark Hutchinson, FACSM)

Email: rahul.khapekar@gmail.com

(No relevant relationships reported)

HISTORY: A 64-year-old expert male rower presented with persistent overhead weakness for 27 months of his right shoulder. He initially felt pain when lowering his arm after placing his canoe on top of his car. Patient denied any acute popping, tearing or swelling. After failed alternative treatments, patient completed MRI shoulder showing full thickness supraspinatus tear and subsequently underwent arthroscopic repair. Despite adherence to physical therapy, patient reported persistent weakness with overhead activity. After an MR arthrogram showed massive supraspinatus re-tear without labral pathology, patient obtained a second opinion at which time he was instructed that he has an "unrepairable torn rotator cuff".

PHYSICAL EXAMINATION: On inspection of his right shoulder, there is marked atrophy superior and inferior to spine of scapula. Patient has excellent functional ROM actively with significantly limited ROM when shoulder is stabilized - he is able to abduct to 100° and forward flex to 110°. Empty can, drop arm, lift off and belly press test are positive. Labral testing is negative and there is full ROM of neck. There is adequate deltoid musculature with equal sensation bilaterally. Patient has significant winging of scapula in all planes of motion. **DIFFERENTIAL DIAGNOSIS:** 1. Massive rotator cuff tear 2. Acromioclavicular joint arthritis 3. Glenohumeral joint arthritis

TEST AND RESULTS: EMG: no deltoid denervation with carpal tunnel findings XR: glenohumeral and AC joint arthritic changes MRI right shoulder w/o contrast: massive rotator cuff (supraspinatus and subscapularis) tear

FINAL WORKING DIAGNOSIS: Chronic right massive rotator cuff tear without deltoid denervation

TREATMENT AND OUTCOMES: 1. Physical therapy 2. No reverse total shoulder arthroplasty indicated given no pain 3. Resume all activities as tolerated, may resume kayaking and canoeing

B-16 Rapid Fire Platform - Physical Activity and Health in 2019: An Expansive Snapshot

10-year Trends in Americans Sedentary Behavior (Sitting).

Tiago V. Barreira¹, Deirdre M. Harrington², Ted W. Zderic³, John M. Schuna Jr.⁴. ¹Syracuse University, Syracuse, NY. ²University of Leicester, Leicester, United Kingdom. ³University of Houston, Houston, TX. ⁴Oregon State University, Corvallis, OR.

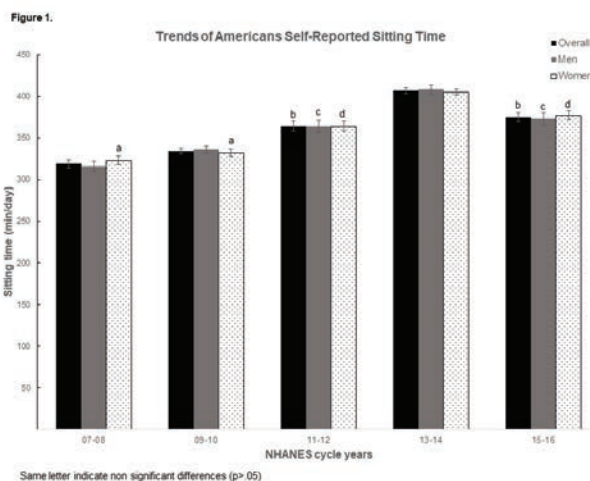

Email: tvbarrei@syr.edu

(No relevant relationships reported)

Sedentary behavior is recognized as a detrimental behavior to one's health.

PURPOSE: To describe 10-year trends in Americans sitting time. **METHODS:** Data from 5 cycles (2007-2016) of the National Health and Nutrition Examination Survey (NHANES) were used in this analysis. During the 07-08 NHANES cycle, participants were asked: "How much time do you usually spend sitting or reclining on a typical day?" For the following NHANES cycles (09-16), participants were asked: "How much time do you usually spend sitting on a typical day?" Mean sitting time for the overall sample and for each sex separately were quantified. Regression analyses accounting for the complex, multi-stage design of NHANES were conducted to examine for linear trends and mean differences in sitting time between cycles.

RESULTS: 26,771 participants (51.5% females, 20 years of age or older) provided sitting time data for all cycles. Data are presented in Figure 1. Significant positive linear trends across cycles were observed for the overall sample and for each sex separately (all $p < .001$). For the overall sample and men, mean sitting time was significantly higher at each successive cycle between 07-08 to 13-14. During 15-16 cycle, mean sitting time was significantly lower than 13-14 but not different from 11-12 for the overall sample ($p = .16$) and men ($p = .34$). For women, sitting time trends were similar to those observed among the overall sample and men with the exception that the 07-08 and 09-10 cycles were not significantly different from each other ($p = .30$). **CONCLUSIONS:** Americans' average self-reported sitting time increased between 2007 and 2014. 2016 data showed lower sitting time compared to 2014. Future NHANES waves will help determine whether Americans sitting time has reached a peak or if 2016 data were an exception.

597 May 29 1:10 PM - 1:20 PM

Effects of an Acute Physical Activity Intervention on Classroom Behavior in Off-Task PreschoolersSarah Burkart, Christine W. St. Laurent, Sofiya Alhassan, FACSM. *University of Massachusetts Amherst, Amherst, MA.*
Email: sburkart13@gmail.com*(No relevant relationships reported)*

Evidence suggests that physical activity (PA) may improve classroom behavior in elementary school children. Further, studies have shown that the most off-task children may exhibit greater benefit from acute bouts of PA. However, limited data exists in preschoolers. **PURPOSE:** To examine baseline relationships between PA and classroom behavior, and to identify if the most off-task preschoolers responded differently to PA compared to those least off-task. **METHODS:** Participants (n=31, age=3.8±0.8 years, 61% male) attended a university-based preschool. In week one of this two-week pilot study, children engaged in their typical curriculum. Week two included daily short bouts of PA that were integrated into early learning standards. PA was assessed with accelerometers worn on the lower back during preschool attendance. Trained researchers conducted weekly 10-minute classroom observations to quantify children's classroom behavior [active engaged time, (AET); passive engaged time, (PET); off-task motor, (OFT-M); off-task verbal, (OFT-V); off-task passive, (OFT-P)] using the Behavioral Observation of Students in Schools (BOSS) tool. Spearman correlations were used to examine baseline relationships between PA and classroom behavior variables. To test if children with high off-task behavior (HIGH) responded differently to PA compared to children with low off-task behavior (LOW), participants were categorized into tertiles based on baseline off-task behavior and groups were compared using *t*-tests. **RESULTS:** A negative correlation was observed between light intensity activity (min/day) and AET at baseline ($r=-0.44, p=0.02$). No other significant relationships were observed. However, when classroom behavior following PA in the most off-task children was examined, improvements were observed in OFT-M (HIGH=-36.5±5.4%, LOW=10.5±5.7%; $p=0.0001$), OFT-V (HIGH=-16.7±2.8%, LOW=5.7±3.3%; $p=0.0004$), and OFT-P behaviors (HIGH=-19.6±7.6%, LOW=12.0±7.1%; $p=0.01$). **CONCLUSION:** Initial evidence for PA to improve classroom behavior among children who exhibited greater off-task behavior was observed and is consistent with previous findings. Future work should build on this acute study and examine chronic PA to limit classroom off-task behaviors. Supported by: NASPEM Marco Cabrera Student Research Award

598 May 29 1:20 PM - 1:30 PM

Improving Research Dissemination and Reach: Impact of a Daily Twitter Campaign in Exercise OncologySarah Weller¹, Kirstin Lane², Logan Meyers¹, Kristin L. Campbell, FACSM¹. ¹*University of British Columbia, Vancouver, BC, Canada.* ²*University of Victoria, Victoria, BC, Canada.*

(Sponsor: Kristin L Campbell, FACSM)

Email: sarah.weller@ubc.ca

(No relevant relationships reported)

Approaches to communicating health research has changed with the widespread adoption of digital and social media platforms. Knowledge exchange and research dissemination can now occur at exponential rates compared to traditional methods, providing an opportunity for improved research understanding, impact and implementation. However, it is unclear how effective scientists have been at using digital platforms for knowledge translation. The use of Twitter as a dissemination tool may prove to be an effective strategy to enhance the reach and impact of research and assist with implementation of exercise into healthcare.

PURPOSE: To understand the engagement and reach of a daily academic-delivered twitter campaign focused on disseminating scientific publications specific to exercise oncology.

METHODS: The Clinical Exercise Physiology Lab at the University of British Columbia (@CEPL_UBC) delivered a #365papers Twitter campaign that posted one academic paper daily specific to exercise oncology. The first 9-months of this digital campaign were analyzed in 3-months periods (first, middle, last) to understand the project reach, using Twitter metrics (engagements and impressions) and Altmetric attention scores.

RESULTS: Overall, 499,899 impressions and 16,741 engagements occurred from 1 January 2018 to 30 September 2018 from 273 exercise oncology article posts. Average engagement rate increased by 35% from the first period compared to the last period (3.1 to 4.2%, $p<0.001$). Link clicks per daily article averaged 23.1 ±25.9 and ranged from 0 to 227 clicks. Followers increased by 296% from 229 to 677 users ($p<0.01$) and were predominantly female (64%) from 39 countries including United States (24%), Canada (23%), United Kingdom (23%) and Australia (10%). Altmetric attention scores indicate 76% of articles had engagement scores in the top 25% of all research outputs and high attention scores compared to outputs of the same age (85% ±12.4) and source (84% ±13.2).

CONCLUSIONS: A daily exercise oncology twitter campaign was able to engage a broad international audience and provide high levels of reach, indicating that this may be an effective strategy for communication and dissemination of exercise research.

599 May 29 1:30 PM - 1:40 PM

Increasing Non-Exercise Physical Activity With Training Reduces Chance Of Non-Response To ExerciseJoshua E. McGee¹, Damon L. Swift¹, Nicole R. Gniewek¹, Patricia M. Brophy¹, Chelsey A. Solar¹, Joseph A. Houmard, FACSM¹, Leslie D. Lutes². ¹*East Carolina University, Greenville, NC.* ²*University of British Columbia, Kelowna, BC, Canada.* (Sponsor: Joseph A. Houmard, FACSM)

Email: mcgee16@students.ecu.edu

(No relevant relationships reported)

Evidence of cardiorespiratory fitness (CRF) non-response is growing in both clinical and exercise training studies. Along with aerobic training, an increase in non-exercise physical activity may reduce CRF non-response contingency. **PURPOSE:** To determine if increases in non-exercise physical activity mitigates CRF non-response to exercise training among sedentary, overweight/obese adults. **METHODS:** Thirty-six adults (age: 54.19±7.14 years; BMI: 35.83±4.66 kg/m²; 77.8% female) were assessed from a previous exercise study (>70% adherence to 4 weekly sessions across 24 weeks). Participants were randomized to an aerobic training group or an aerobic training and increasing non-exercise physical activity group (increase 1,000 to 3,000 steps per day from baseline). Both groups performed the same supervised aerobic training (50-75% VO₂ max) for 24 weeks at a dose of 12 kcals per kg per week. CRF non-response was determined via calculated delta (Δ) values (follow-up minus baseline values) for absolute VO₂ max (L/min) and participants were categorized as non-responders via technical error (TE) ($\Delta<0.71$ L/min) and classical measures ($\Delta<0$ L/min). Pearson Chi-square test of independence was conducted for categorical variables (i.e. responders vs. non-responders) in TE and classical non-responders, separately. A binary multivariable logistic regression was used to estimate odds of CRF non-response based on baseline demographic factors (age, race, BMI, fitness, waist circumference). **RESULTS:** Participants increasing non-exercise physical activity with aerobic training were significantly more likely to increase CRF based on TE analysis, $X^2(2, N=36)=10.99, p=.004$, compared to aerobic training alone. Whereas, classic non-response did not show a significant relationship $X^2(2, N=36)=2.77, p=.251$. Baseline age ($p<.05$) was a significant predictor of TE response, while baseline BMI ($p<.05$) was a significant predictor for classic response. **CONCLUSION:** Increasing non-exercise physical activity concurrent with aerobic training may improve likelihood of increasing CRF and, thus, reduce risk of cardiovascular disease and mortality. Supported by a grant from the American Heart Association (13SDG17140091).

600 May 29 1:40 PM - 1:50 PM

Trainability Genes Provide Answers To The Cardiorespiratory Fitness Deficit In Childhood Acute Lymphoblastic Leukemia Survivors.Maxime Caru¹, Kateryna Petrykey¹, Mariia Samoilenko¹, Simon Drouin¹, Valérie Lemay¹, Laurence Kern², Lucia Romo², Patrick Beaulieu¹, Pascal St-Onge¹, Laurence Bertout¹, Geneviève Lafleur³, Caroline Levertiere¹, Gregor Andelfinger¹, Maja Krajnovic¹, Daniel Sinnett¹, Daniel Curnier¹. ¹*Sainte-Justine University Hospital, Montreal, QC, Canada.* ²*University of Paris Nanterre, Nanterre, France.* ³*University of Quebec in Montreal, Montreal, QC, Canada.*

Email: maxime.caru@umontreal.ca

(No relevant relationships reported)

PURPOSE: As the survival rate of acute lymphoblastic leukemia continues to improve, it has been shown that survivors' exposure to chemotherapeutic agents leads to multiple long-term side effects. Thus, the decrease in the cardiorespiratory fitness of childhood acute lymphoblastic leukemia (ALL) survivors may be due to their cardiovascular response to the chemotherapeutic agents. The first aim of this study was to determine whether cardiorespiratory fitness and physical activity levels were lower among survivors than control subjects, while the second aim was to reported associations between genetic variants and cardiorespiratory fitness in survivors. **METHODS:** Cardiorespiratory fitness (VO₂peak) and moderate to vigorous physical activity (MVPA) were compared between childhood ALL survivors (N=221) and control subjects (N=825). We performed whole-exome sequencing in survivors (N=239). Germline variants (both common and rare) in a selected set of genes (N=238) were analyzed for an association with cardiorespiratory fitness. **RESULTS:** A difference of 9.2mL·kg⁻¹·min⁻¹ for VO₂peak between survivors and control subjects was observed. For an identical level of MVPA, the increase in VO₂peak was different between the both studied cohorts. Also, the VO₂peak decreased more rapidly with age among survivors, especially in females. Genetic association analyses showed that the common variant in the TTN gene was significantly associated with a

low cardiorespiratory fitness level, while the LEPR, IGF1 and ENO3 genes were significantly associated with a low cardiorespiratory fitness level in female survivors. Positive associations between the cardiorespiratory fitness level and trainability genes were mainly observed in females.

CONCLUSIONS: For an identical level of MVPA in both survivors and control subjects, the cardiorespiratory fitness was significantly lower in survivors, which can be associated with variants in genes related to subjects' trainability. These findings could allow better follow-ups tailored to survivors' genetic profile and cardiorespiratory fitness. This study has important implications for survivors, physicians and researchers, which could help reduce at least some of the burden of long-term adverse effects of treatments.

601 May 29 1:50 PM - 2:00 PM

Physical Activities in Northern Song Dynasty (906-1127), China: A Painting Analysis

Weimo Zhu, FACSM¹, Shantian Wen², Hai Yan¹. ¹University of Illinois at Urbana-Champaign, Urbana, IL. ²Huzhou University, Huzhou, China.

Email: weimozhu@uiuc.edu

(No relevant relationships reported)

“Qingming Shanghe Tu, 清明上河图” (Painting of “Along the River during the Qingming Festival”) is a historical Chinese painting collected in Palace Museum, Beijing, China. Painted around 1101-1108 by artist Zeduan Zhang (1085-1145), this 24.8 cm x 528 cm painting captures the daily life of people and the landscape of the capital Bianjing of North Song Dynasty. Together, a total of 814 persons were included in the painting revealing the lifestyle and activities of all levels of the society then. Thus, it provides a golden opportunity to study physical activity (PA) pattern of people in China about 900 years ago.

PURPOSE: To examine people's PA pattern in North Song Dynasty, China through analyzing a historical painting.

METHOD: After each person in the painting was numbered, they were coded by their age category, sex, activity engaged (using 2011 Compendium PA codes when apply), activity context, if labor-saving means was used, etc. The coded information was then analyzed using descriptive statistics.

RESULTS: Except for very few female adults and young children and two older adults, most of persons in the painting are male adults, reflecting the male-centered culture then. Most of PA, due to likely the painting was used to record activities related to a major festival, are recreation (miscellaneous) - standing; only one person is running; a few fast walking; many sitting either on chairs or on the ground; and none was doing traditional Chinese exercise. Some labor-saving efforts were already made then, e.g., using donkeys or cows to pull carriage, horses for riding and one case camels for carrying goods. Meanwhile, human power was still the most important source of mechanical energy then, e.g., rowing or pulling boats, carry persons using sedan chair, pushing wheelbarrow for transportations etc. Most noticeable and frequent human power activities are carrying heavy goods on men's shoulders directly or through a carry pole.

CONCLUSION: It was noticed that labor-saving efforts were already made in a well-developed civilization society about 900 years ago in China although human power was the major source of mechanical energy then. Painting analysis of ancient paintings and graphics provides a unique and useful means to understand the evolution of human PA.

(No relevant relationships reported)

PURPOSE: Our objectives were to: (1) examine the effects of combined strength and aerobic training program on stretch-shortening cycle potentiation (SSCP) and net $\dot{V}O_2$ (inverse of walking economy) among older women and; (2) determine the relationship between SSCP and relative exercise intensity on walking economy. **METHODS:**

Participants were 93 postmenopausal women (60-74 years), 67 of which completed 16 weeks of supervised strength and aerobic training. Participants were randomized into one of three groups: 1 d-wk⁻¹ of resistance training and 1 d-wk⁻¹ of aerobic training; 2 d-wk⁻¹ of resistance training and 2 d-wk⁻¹ of aerobic training or; 3 d-wk⁻¹ of resistance training and 3 d-wk⁻¹ of aerobic training. Body composition (DXA), peak $\dot{V}O_2$ uptake on a cycle ergometer, concentric velocity during a counter-movement leg press throw (CM: 100% of body weight), concentric velocity during a static leg press throw (CO: 100% body weight), SSCP (difference between CO and CM), and net $\dot{V}O_2$ while

walking at 2 mph were measured before and after the training. Net $\dot{V}O_2$ was calculated by subtracting resting $\dot{V}O_2$ from steady-state $\dot{V}O_2$ during flat ground walking at 2 mph. A paired samples *t*-test was used to determine differences in measures before and after exercise training. Multiple linear regression of baseline measures was used to determine associations of walking economy adjusted for SSCP and relative exercise intensity (% peak $\dot{V}O_2$) during the walking task. **RESULTS:** Among all participants, body weight did not significantly change (-0.4 kg, $p = .067$), however, percent body fat decreased (-1.3%, $p < .001$). All groups increased peak $\dot{V}O_2$ (+1.2 mL·kg⁻¹·min⁻¹, $p = .002$). In the 2 d-wk⁻¹ group ($n = 24$) mean CM velocity increased ($p = .004$), but mean CO velocity did not change ($p = .711$). Mean SSCP increased ($p = .048$), while net $\dot{V}O_2$ during the walk task decreased ($p = .002$). Linear regression analysis showed SSCP and relative exercise intensity were independently related to net $\dot{V}O_2$ while walking at 2 mph ($r = 0.54$, $p < .001$; $r = -0.21$, $p = .047$; respectively). **CONCLUSION:** These results reveal exercise training in older women, not only increases walking economy, but increases SSCP. Multiple regression reveals SSCP is associated with walking economy independent of relative exercise intensity among older women.

Differences in Sleep Quality and Adherence to Energy Intake and Physical Activity Recommendations during an 18-Month Behavioral Weight Loss Intervention

Seth A. Creasy, Danielle M. Ostendorf, Jill L. Kaar, Jaron Arbet, Laura Grau, Zhaoxing Pan, Holly R. Wyatt, Daniel H. Bessesen, Edward L. Melanson, FACSM, Victoria A. Catenacci. University of Colorado Denver, Aurora, CO. (Sponsor: Edward L. Melanson, FACSM)

Email: seth.creasy@ucdenver.edu

(No relevant relationships reported)

PURPOSE: Long-term adherence to EI and PA recommendations during a behavioral weight loss interventions is difficult. It is possible that short sleep duration and/or poor sleep quality makes adherence to these recommendations challenging. In this analysis, we explored the association between sleep duration and sleep quality and adherence to EI and PA recommendations during an 18-month behavioral weight loss intervention.

METHODS: Adults ($n=104$, age: 18-55 years, BMI: 27-42 kg·m⁻²) were enrolled in a behavioral weight loss program. Participants were prescribed a calorie-restricted diet (1200-1900 kcals/day) and were instructed to complete ≥ 300 min of moderate to vigorous physical activity (MVPA) per week. In this post-hoc analysis, participants were grouped based on adherence to EI (measured using 3-day food records) and PA (measured using the SenseWear armband) recommendations at 18-months. Adherence to the EI recommendation was defined as eating \leq individually prescribed calories determined using a validated prediction equation at 18 months. Adherence to the PA recommendation was defined as accumulating ≥ 300 min/week of MVPA in bouts of ≥ 10 min at 18 months. Sleep duration, sleep onset latency (SOL), wake after sleep onset (WASO), and sleep efficiency were calculated at baseline and 18 months using the armband.

RESULTS: Individuals who were adherent to both the EI and PA recommendations had significantly lower WASO at baseline (65.7 \pm 11.2 min) compared to non-adherent individuals (82.9 \pm 49.1 min; $p < 0.05$). Individuals who were adherent to only the EI recommendation had significantly lower WASO (61.0 \pm 30.7 min) at baseline compared to those who did not meet the EI recommendation (81.5 \pm 44.0 min; $p < 0.05$). Individuals who were adherent to only the PA recommendation had significantly lower SOL (37.0 \pm 21.1 min) at baseline compared to individuals who did not meet the PA recommendation (44.2 \pm 28.4 min; $p < 0.05$). There were no differences in sleep duration or sleep efficiency between any of the groups.

CONCLUSIONS: Sleep quality at the beginning of an 18-month weight loss intervention may influence adherence to EI and PA recommendations during the behavioral intervention. Future behavioral weight loss interventions may be improved by focusing on improving sleep quality in addition to EI and PA.

B-36 Thematic Poster - Acute and Predicted Physiological Responses to Altitude

Resting Heart Rate Variability at Sea Level does not Predict Arterial Desaturation or Ventilatory Responses to Acute Hypoxia Exposure

Grace K. Becker, T. Hunter Embry, Kelsey J. Short, Kenneth W. Kambis, M. Brennan Harris. *William & Mary, Williamsburg, VA.* (Sponsor: Joseph W. Starnes, FACSM)
(No relevant relationships reported)

Acute exposure to hypoxia results in a stress response categorized by sympathetic dominance, resulting in increased ventilation to prevent arterial desaturation. Heart rate variability (HRV) can be used as an estimation of overall stress and provides understanding of the balance between sympathetic and parasympathetic autonomic regulation. **PURPOSE:** The purpose of this study was to determine whether resting heart rate variability at sea level is correlated with arterial desaturation and respiratory responses to acute normobaric hypoxia exposure equivalent to an altitude of 3500 meters. **METHODS:** Resting HRV, %SpO₂, and respiratory rate was measured in 24 male and female subjects at sea level for 15 minutes. HRV was measured using Firstbeat Bodyguard2 and included RMSSD, High Frequency (HF), and Low Frequency (LF) components. Subjects then returned for a subsequent visit and resting HRV, SpO₂ and respiratory rate were measured at rest in a normobaric hypoxic chamber (Colorado Altitude Training) set at either 3500 meters or sea level for control subjects. Correlation analysis using RStudio was performed. **RESULTS:** No significant correlation was observed between HRV in the time domain (RMSSD) and %SpO₂ at rest ($r=0.26$, $p=0.39$), %SpO₂ during exercise ($r=-0.15$, $p=0.62$), or respiratory rate during rest ($r=0.42$, $p=0.15$) when exposed to hypoxia. No significant correlation was observed between HRV in the frequency domain (LFHF Ratio) and %SpO₂ at rest ($r=-0.10$, $p=0.74$), %SpO₂ during exercise ($r=-0.18$, $p=0.53$), or respiratory rate during rest ($r=-0.39$, $p=0.19$) when exposed to hypoxia. **CONCLUSION:** Although exposure to acute hypoxia exerts a physiologic stress response, HRV as a measure of overall stress and the balance of sympathetic and parasympathetic balance does not seem to be predictive of the change in %SpO₂ or respiratory rate.

Biological Variation of Resting Ventilation and its Diagnostic Accuracy for Acute Mountain Sickness at Altitude

Kirsten E. Coffman, Samuel N. Cheuvront, FACSM, Robert W. Kenefick, FACSM. *U.S. Army Research Institute of Environmental Medicine (USARIEM), Natick, MA.* (Sponsor: Robert W Kenefick, FACSM)
(No relevant relationships reported)

Individuals who develop acute mountain sickness (AMS) upon exposure to high altitude (HA) exhibit differential responses in resting measures of minute ventilation (V_E) and end-tidal partial pressure of carbon dioxide ($P_{ET}CO_2$). **PURPOSE:** To determine the biological variation and diagnostic potential of ventilatory parameters in association with AMS. **METHODS:** We performed a retrospective analysis via the Mountain Medicine Database of 22 studies completed by the U.S. Army Research Institute of Environmental Medicine ($N = 424$). First, we determined the biological variation of resting measures of ventilation and defined the accompanying static and dynamic thresholds that indicate a significant deviation from normal at sea level (SL). Second, the diagnostic accuracy of ventilatory measures for AMS development was assessed at HA (4300 m). **RESULTS:** Resting measures of ventilation demonstrated substantial variability within (range 0.4 - 7.7%) and between (range 1.0 - 24.5%) subjects. Based on the index of individuality (II), end-tidal partial pressure of oxygen ($P_{ET}O_2$) and respiratory exchange ratio (RER) may be useful in the static assessment of physiological deviations from normal ($II = 0.57$ and 0.60 , respectively) at HA. Based on the index of heterogeneity (IH), $P_{ET}O_2$ and peripheral oxygen saturation (SpO_2) may be useful in the dynamic assessment of deviations from normal ($IH = 1.91$ and 0.41 , respectively) at HA. RER and SpO_2 showed significant diagnostic accuracy in

the static assessment of AMS (sensitivity/specificity = 53/86 and 24/96, respectively). Ventilatory efficiency for oxygen (V_E/VO_2), RER, and SpO_2 showed significant diagnostic accuracy in the dynamic assessment of AMS (sensitivity/specificity = 72/54, 53/74, and 25/98, respectively). Among all measures, RER showed the greatest Youden's Index, a value indicative of the combined sensitivity and specificity of a given predictor (static: 39, dynamic: 28). **CONCLUSION:** Many resting ventilation measures do not demonstrate potential for AMS prediction. However, the few measures identified as potential predictors of AMS following SL biological variation analysis also demonstrated the greatest diagnostic power for AMS at HA. RER shows particular promise as a potential AMS prediction tool. **DISCLAIMER:** Author views not official US Army or DOD policy.

676 Board #3 May 29 3:15 PM - 5:15 PM
Arterial Desaturation during Moderate Aerobic Exercise in Hypoxia is Positively Correlated to VO2 Peak at Sea Level in Men and Women

Thomas H. Embry, Grace K. Becker, Kelsey J. Short, Kenneth W. Kambis, M. Brennan Harris. *William & Mary, Williamsburg, VA.*
(No relevant relationships reported)

Predicting responses to acute hypoxia based on physiologic measures at sea level may be valuable in anticipating adverse responses to acute hypoxia. **PURPOSE:** The purpose of this study was to determine the arterial saturation response in men and women (18-33 years old) of varying fitness levels, at a normobaric altitude of 3500 meters. **METHODS:** 91 subjects (54 women, 37 men) completed a VO₂ peak test on a stationary exercise bike at sea level; to determine aerobic fitness (range 27.7-72.2 ml/kg/min). Each subject then performed an 8-10-minute bout of cycling in normobaric hypoxia corresponding to 3500 meters at 65% of their maximal heart rate at VO₂peak (sea level). **RESULTS:** VO₂peak was positively correlated with decreased oxygen saturation during exercise at normobaric hypoxia corresponding to 3500 meters. For women ($n=54$), a greater predictive response was observed with a linear model depicting a strong positive correlation between VO₂ peak and oxygen desaturation in hypoxia ($r = 0.1643$, $p = 0.001028$). For men ($n=37$), a predictive response was also observed with a linear model that was slightly less significant compared to women subjects ($r = 0.1139$, $p = 0.04412$). Furthermore, a relationship between average oxygen saturation difference (resting SpO₂ minus exercise SpO₂) at normobaric altitude, and VO₂ peak at sea level in women subjects ($r=0.1855$, $p=0.01719$) was observed. **CONCLUSION:** These results demonstrate that increased VO₂ peaks in individuals at sea level, is predictive of higher arterial oxygen desaturation during exercise, in normobaric altitude (3500m), especially in women which may make them more susceptible to adverse responses to acute altitude exposure. Supported by The Doug Morton/Marilyn Brown Endowment for Biomedical Research, The Foundation for Aging Studies and Exercise Science Research, and The Borgenicht Program.

Variability in Human Plasma Volume Responses during High-Altitude Sojourn

Andrew J. Young, FACSM, Claire E. Berryman, Scott J. Montain, FACSM, Beth A. Beidleman, Stefan M. Pasiakos, FACSM, J. Phillip Karl. *US Army Research Institute of Environmental Medicine, Natick, MA.*
(No relevant relationships reported)

Hematocrit (Hct) and hemoglobin concentrations (Hb) rapidly increase when sea-level (SL) residents ascend to high altitude (HA) due to a decrease in plasma volume (PV), generally but not universally, attributed to changes in oncotic pressure. The ΔPV at HA varies, depending on exposure duration and elevation, and sojourner age, sex and SL red cell mass. A quantitative model for predicting individual PV changes (% ΔPV) over the first 7d at HA was recently published (Beidleman et al., 2016). That model, developed from measurements of those parameters and the measured % ΔPV in 393 HA sojourners, was internally cross-validated using boot-strap resampling, but has not been validated against an independent sample of sojourners, or for sojourns >7d in real world conditions, e.g. energy deficit (ED). **PURPOSE:** To compare measured % ΔPV with % ΔPV predicted by the model in 17 young, healthy, male, SL natives sojourning 21 d at HA and consuming a diet designed to elicit 40% ED. **METHODS:** Hct, Hb and total circulating protein (TCP) measured in blood of fasting participants at SL and after living 2, 7, 13 and 19 d (HA2, HA7, HA13 & HA19, respectively) at 4300m were used to calculate % ΔTCP and % ΔPV from SL. Correlations between % ΔPV and % ΔTCP were calculated, and means and individual values of measured % ΔPV were compared to predicted % ΔPV . **RESULTS:** Body mass loss was 8 kg by d21 at HA, but body mass loss was not associated with % ΔPV or % ΔTCP on HA2, 7, 13 or 19. Mean [95%CI] measured % ΔPV on HA2, 7, 13 and 19 were -2.5 [-8.2, 3.1], -11.0 [-16.6, -5.5], -11.7 [-15.9, -7.4], and -16.8 [-22.2, -11.3], respectively. % ΔPV and % ΔTCP were positively correlated ($P < 0.001$) at HA2, 7, 13 & 19 ($r^2 = 0.77$, 0.88, 0.78, 0.89, respectively). The model over-predicted mean [95% CI] decrease

WEDNESDAY, MAY 29, 2019

in %ΔPV on HA2 (-12.5 [-13.9, -11.1]) and HA7 (-21.5 [-23.9, -19.1]), accurately predicted the mean decrease on HA13 (-14.3, [-20.0, -8.7]), and predicted a mean increase in %ΔPV on HA19 (12.4 [-5.0, 29.8]). On HA2, 7, 13 and 19 only 2, 2, 6 and 1, respectively, of 17 individual measures of %ΔPV were within 95% CI for predicted %ΔPV. **CONCLUSION:** These observations indicate that human PV responses to HA exposure are oncologically mediated, vary considerably among individuals, and available quantitative models require further refinement to reliably predict %ΔPV exhibited by individual HA sojourners.

Resting and Submaximal Exercise Hemodynamic Changes When Sea Level Individuals Are Exposed to Altitude (11,237ft)

Holley Sirois¹, Gabriel Tilton¹, Thomas Bresnahan¹, Jordan Stebbins¹, Parker Nally¹, Juleah Heath¹, Lee Spahr¹, Spencer Bourassa¹, Corey Young¹, Melissa Benton², Andrew Subudhi², Paul Visich¹. ¹University of New England, Biddeford, ME. ²University of Colorado, Aurora, CO.
 Email: hsirois@une.edu
 (No relevant relationships reported)

Hypertension is a major risk factor for cardiovascular disease, and is present in 46% of the US adult population. An increase in one's blood pressure (BP) (~10mmHg) has been observed when individuals are exposed to altitude for 10-12 months. Less is known of the acute effect on BP in young healthy individuals when exposed to altitude. **PURPOSE:** The purpose of this study was to observe BP changes during rest and submaximal exercise in normotensive sea level (SL) individuals after 24 and 96 hours of altitude exposure (11,237ft). **METHODS:** Nine college students were asked to participate in five trials. Trials 1&2 determined their VO₂max and 60% HRR workload (WL) at SL, respectively. Trials 3-5 assessed BP, O₂ saturation, heart rate and double product (DP = ((SBP*HR)/100)) during rest and submaximal exercise. Trial 3 was completed at SL and trials 4&5 were completed at 11,237ft after 24 and 96 hours of altitude exposure. **RESULTS:** 5 males and 4 females; age=21.9±1.4 y; weight=72.3±14.3 kg; height=174.2±6.1 cm; VO₂max=43.6±8.3 ml/kg/min, completed the study. Oxygen saturation decreased (p=0.00) during rest and exercise at 24h (89±1.68, 82±2.5%) and 96h (90.3±0.75, 83.6±0.21%) vs SL (97.7±0.45, 95.8±0.82%), respectively. Heart rate increased at rest (p=0.00) and exercise (p<0.05) at 24h (77.2±7.9, 160.5±3.6 bpm) and 96h (73.5±10, 155.5±2.2 bpm) vs SL (65.9±8.5, 139±1.8 bpm), respectively. Resting SBP increased (p<0.05) at 24h (119.5±9.5 mmHg) and 96h (122.2±11.6 mmHg) vs SL (115.9±10.9 mmHg). Resting DBP increased (p<0.05) at 24h (78.5±8.5 mmHg) and 96h (80.5±8.9 mmHg) vs SL (71.3±9.6 mmHg). Exercise SBP increased (p<0.05) at 96h vs SL (160.6±15.6 to 153.4±16.5 mmHg), respectively. Double product increased during rest (p=0.00) and exercise (p<0.05) at 24h (91.4±9.6, 254.2±8.2) and 96h (91±12.5, 249.6±10) vs SL (77±10, 214.4±10), respectively. **CONCLUSION:** These results demonstrate that when sea level individuals are acutely exposed to altitude (11,237ft), there is a significant decrease in O₂ saturation, and a significant increase in HR, BP and DP after 24h and up to 96h. These hemodynamic changes are tolerable in young healthy individuals, but could be concerning in individuals with documented or latent CVD.

679 Board #6 May 29 3:15 PM - 5:15 PM
Hypoxic Cerebrovascular Reactivity Does Not Predict Cognitive Function in Mt. Everest Basecamp Trekkers

Jacob P. DeBlois¹, Wesley K. Lefferts², Taylor S. Harman¹, Kevin S. Heffernan¹, Trevor A. Day³, Tom D. Brutsaert¹. ¹Syracuse University, Syracuse, NY. ²University of Illinois, Chicago, IL. ³Mount Royal University, Calgary, AB, Canada.
 (No relevant relationships reported)

Cognitive function may be negatively impacted at high-altitude, which has important implications for decision making in such environments. The ability to predict changes in cognitive function at high-altitude may safeguard against potential adverse events in both novice and experienced high-altitude trekkers. Hypoxia results in compensatory increases in cerebral blood flow to maintain oxygen delivery. An inability to increase blood flow in this setting may contribute to cognitive performance at high-altitude. Cerebral reactivity to hypoxia at low-altitude may thus be a useful predictor of cognitive performance at high-altitude. **PURPOSE:** Determine if hypoxic reactivity of middle cerebral artery (MCA) mean blood velocity (V_m) at low-altitude predicts changes in cognitive function on a trek to Mt. Everest Basecamp. **METHODS:** 17 Mt. Everest Basecamp trekkers (n = 8 females; age = 26 ± 13 yrs; body fat = 19.5 ± 6.5%) underwent a 10-day trek from Kathmandu, Nepal to Gorak Shep, Nepal. Cerebral reactivity testing occurred at low-altitude (116 m). V_m of the left MCA was determined via transcranial Doppler under normobaric normoxia (NN, ~21% FiO₂) and hypoxia (NH, ~10% FiO₂). Each condition lasted 4 min. V_m was measured between 2.5 and 3.5 min and the average V_m over the 1-min period was used for analysis. Change in V_m was calculated as ΔV_m = V_mNH - V_mNN. Cognitive function was assessed as accuracy and reaction time (RT) on a working memory task (2-back number matching task)

performed at NN (116 m) and hypobaric hypoxia (HH; Gorak Shep, Nepal 5,160 m). Changes in cognitive function were calculated as the change in accuracy and RT from NN to HH. **RESULTS:** Accuracy was reduced at HH compared with NN (9.8 ± 10.0% reduction; p = 0.001) while RT was faster (0.06 ± 0.08 s faster; p = 0.007). Univariate regression analysis showed that ΔV_m did not predict changes in accuracy (β = -0.064, p = 0.807) or RT (β = 0.341, p = 0.181) at HH. **CONCLUSIONS:** Cognitive function was reduced at high-altitude hypoxia, as is consistent with previous work. Changes in MCA V_m during a hypoxic reactivity test at low-altitude did not relate to changes in cognitive function with ascent to high-altitude. Hypoxic cerebral reactivity tests at low-altitude may not be suitable for predicting high-altitude cognitive function.

Effects of High-Altitude Hypoxia on Neurovascular Coupling During Cognitive Activity

Wesley K. Lefferts¹, Jacob P. DeBlois², Trevor A. Day³, Jan E. Soriano⁴, Leah Mann³, Zahrah Rampuri⁴, Brittany Herrington³, Scott Thrall³, Jordan Bird³, Kevin S. Heffernan², Tom D. Brutsaert². ¹University of Illinois at Chicago, Chicago, IL. ²Syracuse University, Syracuse, NY. ³Mt Royal University, Calgary, AB, Canada. ⁴University of Calgary, Calgary, AB, Canada. (Sponsor: Bo Fernhall, FACSM)
 Email: wleffert@uic.edu
 (No relevant relationships reported)

Neurovascular coupling (NVC) describes the ability to deliver continuous, non-pulsatile blood flow to working regions of the brain. NVC during visual stimulation appears maintained in posterior cerebral blood vessels under high-altitude hypoxic conditions. It is unknown, however, if high-altitude hypoxia impairs NVC in frontal regions of the brain undergoing cognitive activation. **PURPOSE:** Examine the effect of high-altitude hypoxia on NVC by measuring anterior (ACA) and middle cerebral artery (MCA) hemodynamic responses to sustained cognitive activity (Stroop task). **METHODS:** Nine adults (23 ± 7 yr, 23.5 ± 2.4 kg/m², 4 female) underwent simultaneous, continuous, bilateral measurement of ACA and MCA mean velocity and pulsatility index (PI) via transcranial Doppler during a 3-min Stroop task at 1400m, 3440m, and 4240m. Mean arterial pressure and arterial oxygen saturation were assessed via oscillometric cuff and pulse oximetry at rest and during the Stroop task. **RESULTS:** Blood pressure increased, MCA and ACA PI, and arterial oxygen saturation decreased with high-altitude hypoxia (p<0.05). Cognitive activity resulted in similar increases in MCA and ACA mean velocity and arterial oxygen saturation, and decreases in MCA PI (p<0.05) at all altitudes. No significant high-altitude hypoxia by Stroop interactions were detected, indicating NVC was similar with increasing high-altitude hypoxia. **CONCLUSION:** Our data suggest high-altitude hypoxia does not disturb compensatory increases in mean velocity and reductions in pulsatility in vessels feeding the frontal regions of the brain during cognitive activity. These data agree with a growing body of evidence that NVC is maintained in hypoxic environmental conditions.

Table 1: Cerebrovascular hemodynamics at rest and during activation (mean ± SD).

The Effects of Hypoxia on Cerebral Blood Flow Velocity and Hemodynamics during Ergometer Bicycle Exercise
 Seongdae Kim¹, Hee-Hyeok Lee¹, Sangho Kim², Moon-Hyun Hwang³, Ilgyu Jeong¹. ¹Hannam University, Daejeon, Korea, Republic of. ²Korea University, Sejong, Korea, Republic of. ³Incheon National University, Incheon, Korea, Republic of.
 (No relevant relationships reported)

The cerebral blood flow velocity (CBFV) response to acute hypoxia during exercise has been known to increase. But, how hemodynamics might respond to exercise in hypoxic condition and be associated with the change of CBFV remains unclear. **PURPOSE:** To determine the effects of hypoxia on CBFV and hemodynamics during bicycle ergometer exercise. **METHODS:** In a randomized, double-blind, crossover study, Twelve healthy volunteers (22.1±0.6yrs) were asked to perform the bicycle ergometer exercise three times in two hypoxic (3150m and 1900m altitudes) and control (sea level) condition with a week interval, respectively. Exercise intensity was set initially at 50W and increased by 25W every 2 minutes to 125W. Acute normobaric hypoxic condition corresponding to the altitudes of 3150m and 1900m was maintained using low oxygen gas mixture for the whole procedure of 40 minutes. CBFV in middle cerebral artery (MCA) were measured at rest 15 minutes, 5 and 10 minutes during exercise, 10 minutes recovery using transcranial-Doppler sonography. Non-invasive electrical cardiometry was used to obtain cardiac output (CO), thoracic fluid content (TFC) and flow time corrected (FTC). All data were analyzed using two-way ANOVA with repeated measures and Pearson's correlation. **RESULTS:** CBFV in MCA in 3150m and 1900m was significantly higher than in control condition at 10 minutes during exercise (110±28 and 99±25 vs. 75±18 cm/s, p<.05). Heart rate (HR) in 3150m was significantly higher than in 1900m and control condition at 10 minutes during exercise (163±10 vs. 154±6 and 152±8 bpm, p<.05). TFC in 3150m and 1900m was significantly lower than in control condition at 10 minutes during exercise (27±1 and 26±1 vs. 30±2, p<.05). FTC in 3150m and 1900m was significantly lower than in control condition at 10 minutes during exercise (240±20 and 254±16 vs. 265±18 ms, p<.05). However, CO and stroke volume (SV) were not significant different between three conditions. **CONCLUSIONS:** These results suggest that exercise in normobaric hypoxic condition might increase CBFV, which might be independent of hemodynamic changes.

Free-Living Accelerometer Calibration: A Novel Direct Observation System
 Melanna F. Cox, Greg J. Petrucci, Robert T. Marcotte, Brittany R. Masteller, John Staudenmayer, Patty S. Freedson, FACSM, John R. Sirard, FACSM. *University of Massachusetts, Amherst, MA.* (Sponsor: John R. Sirard, FACSM)
 (No relevant relationships reported)

PURPOSE: To develop a direct observation (DO) system to serve as a criterion measure for model calibration using free-living (FL) accelerometer data. **METHODS:** Ten participants (19.4±0.8 yrs) were video-recorded during four, 1-hr FL sessions in different settings: school, home, community and physical activity (PA). For each setting, 10-min clips from three, randomly selected sessions were extracted and coded by a criterion coder and assistant coders (ACs) using the Observer XT software (Noldus, Wageningen, the Netherlands). Coders identified the movement/body position and four modifiers: locomotion (yes or no), activity type (e.g. reading), MET value, and intensity category. For intra-rater agreement, the criterion coder coded all 12 videos twice, separated by at least one week. For inter-rater agreement, all 12 videos coded by each AC were compared to the criterion coder. Intraclass correlation coefficients (ICCs) were calculated to assess agreement of intensity category for intra- and inter-rater comparisons. **RESULTS:** Intra-rater agreement ranged from 91% to 100% across all variables in all four settings. Inter-rater agreement between the criterion coder and the ACs ranged from 88±3.5% to 100±0% across all variables in all four settings. As shown below, ICCs for intensity category ranged from 0.74-1.00

and 0.81-1.00 for intra- and inter-rater comparisons, respectively. **CONCLUSION:** The DO system is reliable and feasible to serve as a criterion measure of FL physical activity in young adults. The DO system can serve as a standardized instrument to develop accelerometer models for estimating PA and sedentary behavior in FL settings. Supported by: NIH NIDDK 1R01DK110148-01

Reliability Analysis of the COSMED K5 Portable Metabolic System
 Lindsey E. White, Jacob P. DeBlois, Tiago V. Barreira. *Syracuse University, Syracuse, NY.*
 (No relevant relationships reported)

Increased energy expenditure via physical activity has been shown to improve health outcomes. It is difficult to measure energy expenditure and physical activity outside the laboratory. **PURPOSE:** To determine the reliability of the COSMED K5 portable metabolic system. **METHODS:** 27 (n = 14 females) healthy adults (27 ± 5 yrs; 21.0 ± 8.2% body fat) completed a treadmill walking protocol. Participants completed 3 identical trials of 5-min stages that included standing and 6 walking speeds from 1.5 to 4.0 mph in 0.5 mph increments, with a 2-min rest between stages for a total of 47 minutes. Visit 1 consisted of wearing the K5 system. During visit 2 (1-7 days later), participants wore the K4 and K5 systems in a randomized, counter-balanced order. Oxygen consumption (VO₂, ml·min⁻¹), carbon dioxide production (VCO₂, ml·min⁻¹), ventilation (V_e, L·min⁻¹), metabolic equivalents (METs), respiratory exchange ratio (RER), and energy expenditure (EE, kcal·min⁻¹) were recorded breath-by-breath and averaged from minutes 2.5 to 4.5 from each stage for analysis. Reliability of the K5 was determined using an intraclass correlation coefficient (ICC) and coefficient of variation (CV). **RESULTS:** As shown in Table 1, the ICC for standing ranged from 0.26-0.75 and CV ranged from 4.0-11.0%. During walking, ICC ranged from 0.41-0.88 and CV from 3.0-8.0%.

Table 1. Reliability of COSMED K5 in standing and at various walking speeds

| Variable | | Standing | 1.5 mph | 2.0 mph | 2.5 mph | 3.0 mph | 3.5 mph | 4.0 mph |
|------------------|--------|------------|-----------|-----------|-----------|-----------|-----------|-----------|
| VO ₂ | ICC | 0.47 | 0.64 | 0.72 | 0.76 | 0.76 | 0.78 | 0.85 |
| | CV (%) | 11.0 ± 9.0 | 8.0 ± 5.0 | 6.0 ± 6.0 | 7.0 ± 5.0 | 7.0 ± 5.0 | 6.0 ± 4.0 | 5.0 ± 4.0 |
| VCO ₂ | ICC | 0.53 | 0.50 | 0.64 | 0.67 | 0.73 | 0.75 | 0.80 |
| | CV (%) | 11.0 ± 9.0 | 8.0 ± 6.0 | 7.0 ± 7.0 | 7.0 ± 6.0 | 6.0 ± 5.0 | 7.0 ± 5.0 | 7.0 ± 5.0 |
| V _e | ICC | 0.75 | 0.74 | 0.80 | 0.77 | 0.79 | 0.83 | 0.88 |
| | CV (%) | 10.0 ± 7.0 | 6.0 ± 5.0 | 6.0 ± 6.0 | 6.0 ± 5.0 | 5.0 ± 4.0 | 4.0 ± 3.0 | 4.0 ± 3.0 |
| METs | ICC | 0.65 | 0.54 | 0.56 | 0.65 | 0.66 | 0.74 | 0.82 |
| | CV (%) | 11.0 ± 8.0 | 8.0 ± 5.0 | 6.0 ± 6.0 | 7.0 ± 5.0 | 6.0 ± 5.0 | 6.0 ± 4.0 | 5.0 ± 4.0 |
| RER | ICC | 0.26 | 0.41 | 0.55 | 0.49 | 0.44 | 0.62 | 0.80 |
| | CV (%) | 4.0 ± 3.0 | 4.0 ± 3.0 | 3.0 ± 2.0 | 4.0 ± 3.0 | 4.0 ± 3.0 | 5.0 ± 3.0 | 6.0 ± 4.0 |
| EE | ICC | 0.50 | 0.62 | 0.71 | 0.74 | 0.75 | 0.78 | 0.84 |
| | CV (%) | 11.0 ± 9.0 | 8.0 ± 5.0 | 6.0 ± 6.0 | 6.0 ± 5.0 | 6.0 ± 5.0 | 6.0 ± 4.0 | 5.0 ± 4.0 |

CONCLUSIONS: The K5 provided reliable measures of $\dot{V}O_2$, $\dot{V}CO_2$, \dot{V}_e , METs, RER, and EE across a variety of walking speeds, with higher reliability noted at 3.0-4.0 mph. Future studies should examine the reliability of the K5 during running and other activities.

685 Board #3 May 29 3:15 PM - 5:15 PM
Free-living Evaluation Of Laboratory-based Machine Learning Algorithms For Activity Classification In Preschool Children

Matthew N. Ahmadi¹, Alok K. Chowdhury¹, Dylan Cliff², Toby Pavey¹, Markus Hagenbuchner², Stewart G. Trost¹. ¹Queensland University of Technology, Brisbane, Australia. ²University of Wollongong, Wollongong, Australia.
 Email: matthew.ahmadi@qut.edu.au
 (No relevant relationships reported)

Machine learning (ML) classification models for accelerometer data are a potentially more accurate method to measure physical activity in young children than conventional cut-point methods. However, existing algorithms have been trained on laboratory-based activity trials. To our knowledge, no studies have evaluated the performance of classification algorithms trained on structured activity trials for preschool-aged children under free-living conditions, and none have used fine-grained video-based direct observation to evaluate algorithm performance.

Purpose:

To evaluate the performance of hip and wrist Random Forest (RF) and Support Vector Machine (SVM) activity classification algorithms for preschool-aged children (Trost et al. 2018) under free-living conditions.

Methods:

31 children (4.0 ± 0.9 yrs) were video recorded using a GoPro during a 30-minute unstructured active play session in a park while wearing an ActiGraph GT3X+ accelerometer on their right hip and non-dominant wrist. Direct observation was used to continuously code ground truth activity type and activity class using the Noldus Observer XT. Algorithm performance was assessed using overall accuracy and confusion matrices were generated to summarize class-level classification accuracy.

Results:

Accuracy for the hip and wrist RF algorithms was 69.4 (95% CI:67.4 – 71.2), and 59.1 (95% CI:57.1-61.1), respectively. Accuracy for hip and wrist SVM algorithms was 66.4 (95% CI:64.4 – 68.3), and 59.3 (95% CI:57.3 – 61.3), respectively. Classification was moderate for sedentary (71-77%), poor-moderate for light activity and games (58-79%), and moderate-good for moderate to vigorous activity and games (71-84%) and running (66-75%). Classification for walking (9-15%) was poor. When 15-sec windows with multiple activities were excluded from analysis, overall accuracy was improved by 8-10%. Prediction of walking improved by 19-34%.

Conclusion:

The accuracy of laboratory-based activity classification algorithms for preschool-aged children was attenuated when tested on new data collected under free living conditions. Future studies should develop and evaluate the performance of activity classification algorithms trained on accelerometer data collected under true free-living conditions.

Insights On Free-living Sedentary Behavior Estimates Using A Hip- Or Wrist-worn Accelerometer

Robert T. Marcotte, Greg J. Petrucci, Jr, Melanna F. Cox, Patty S. Freedson, FACSM, John W. Staudenmayer, John R. Sirard, FACSM. *University of Massachusetts Amherst, Amherst, MA.* (Sponsor: John R. Sirard, PhD, FACSM)
 Email: rmarcotte@umass.edu
 (No relevant relationships reported)

PURPOSE: The primary purpose was to validate existing methods to estimate sedentary behavior (SB) under free-living conditions using ActiGraph GT3X+ accelerometers (AG). The secondary purpose was to identify method-specific systematic errors that result in the misclassification of SB. **METHODS:** Forty-eight participants (age:20.4±1.3 years, 45.8% male) were video-recorded during four 1-hour sessions in different settings (home, community, school, environment) while wearing an AG on the right hip and non-dominant wrist. Videos were coded for postural orientation and activity type (e.g. walking). Observed time in sitting and lying postures were classified as SB (criterion measure). Twelve methods were applied to hip and wrist accelerometer data to estimate time spent in SB (see Figure 1). Repeated measures linear mixed models were used to estimate method bias (estimate - criterion SB) and a 95%CI around the bias. **RESULTS:** On average, participants spent 34.1 of the 57.2 minutes/session in SB. Four of the hip methods were unbiased (Soj1x, Soj3x, CPM100, CPM150), however SB was underestimated using CPM200vm (-5.5 minutes, 95%CI: -7.1, -3.8) and overestimated using ENMO47.4 (12.2 minutes, 95%CI: 9.9, 14.5). For the wrist, Sed Sphere was the only unbiased method. SB was overestimated using ENMO44.8 (3.7 minutes, 95%CI: 1.8, 5.5) and underestimated using Wrist RF, CP15s376vm, Wrist TR, and CPM1853vm, ranging from -9.5 to

-5.7 minutes. The majority of misclassified SB occurred during standing or sitting behaviors (67.0-96.7%). **CONCLUSION:** Accurate estimates of SB from a hip-worn AG can be achieved using either simpler count-based approaches (CPM100, CPM150) or machine learning models (Soj1x, Soj3x). Only the Sedentary Sphere may be suitable to estimate SB from the non-dominant wrist. Future work to distinguish standing from SB may lead to improvements in estimating SB. Supported by NIH NIDDK 1R01DK110148

Using A Thigh Worn Accelerometer To Identify Periods Of Seated Car Travel

Kate Lyden¹, Craig Speirs¹, David Loudon¹, Cami Christopher², Rachel Barnett², Julian Martinez², Mami Takeda², Sarah Keadle². ¹PAL Technologies, Glasgow, United Kingdom. ²California Polytechnic State University, San Luis Obispo, CA.
 Reported Relationships: K. Lyden: Consulting Fee; PAL Technologies.

Thigh inclination has been shown to be a highly specific discriminator between upright and seated activities. During periods of sitting, the background noise in the acceleration signal can provide important contextual information about the seated behaviour.

PURPOSE The purpose of this study was to develop and validate a simple algorithm to distinguish periods of seated car travel. The algorithm is based on the premise that during seated car travel, 1) body-worn accelerometers register a background level of external dynamic acceleration due to forces generated by the road surface and car engine and 2) leg movements are restricted due to the spatial constraints of the car. **METHODS** Participants (n=26, mean age=30.5yrs, 16 female, 20 male) were directly observed in their free-living environment on two separate occasions, for two hours each. Raw accelerometer data were summarized in 15-second epochs and synced with direct observation video. Using knowledge based on *a priori* observations of car travel, four features of the accelerometer signal were extracted from periods of sitting and tested 1) median vector magnitude (VM), 2) lower VM decile, 3) maximum VM and 4) range of inclination angles. Parameter constants were chosen based on grid search methods with the objective of maximizing positive and negative predictive value (PPV, NPV). **RESULTS** Threshold constants identified included 1) median VM < 500, 2) lower VM decile > 5, 3) maximum VM < 5000 and 4) inclination angle range < 40. 100% of car travel events were correctly identified, with a single false positive (1%). PPV and NPV were 95.5% and 100%, respectively. **CONCLUSION** Using a thigh worn accelerometer, seated behaviours can be identified as car travel or not. Importantly, acceleration features pertaining to both the inclination angle and vector magnitude were needed to optimize classification accuracy.

 (No relevant relationships reported)

Quantifying gait parameters and ambulatory monitoring of changes in these parameters has become increasingly important for epidemiological and clinical studies. Wearable accelerometers provide objective high-density measurements of human gait dynamics through recording of acceleration. Many studies use accelerometry to objectively measure physical activity using the activity counts, vector magnitude, or number of steps. These measures use just a fraction of the information in the raw accelerometry data as they are typically summarized at the minute level. To address this problem, we focus on raw, sub-second level accelerometry data and define a set of gait characteristics based on these data. Additionally, to overcome the analytical challenges of these complex and voluminous data we develop automatic and unsupervised methodology for precise segmentation of stride patterns. **PURPOSE:** We propose Adaptive Empirical Pattern Transformation (ADEPT) and maximization-tuning procedure for automatic identification of individual walking strides from raw accelerometry data that uses data-derived baseline patterns, representing a population-specific strides. **METHODS:** Data were collected as a part of the study on Identification of Walking, Stair Climbing, and Driving Using Wearable Accelerometers, funded by the Indiana University CTSI grant and conducted at the Department of Biostatistics, RM Fairbanks School of Public Health at Indiana University. The study enrolled 32 healthy participants between 23 and 52 years of age. Participants wore accelerometers on a wrist, hip and both ankles during a 450-meter outdoor walk. **RESULTS:** ADEPT yields results that are in most cases visually indistinguishable from manual segmentation and reduces strides segmentation time radically. The average absolute deviation of estimated stride duration across study participants was 4.74, 1.42, 1.28 and 1.31 percent, for wrist, hip and both ankles respectively. **CONCLUSIONS:** Our results indicate that the errors are small relative to the signal for all body locations suggesting that ADEPT is a robust and universal tool for segmentation of strides in accelerometry data.

Development And Testing Of An Integrated Score For Physical Behaviors

Sarah Keadle¹, Eli Kravitz², Charles E. Matthews, FACSM³, Marilyn Tseng¹, Raymond J. Carroll⁴. ¹California Polytechnic State University, San Luis Obispo, CA. ²Texas A&M University, College Station, TX. ³National Cancer Institute, Bethesda, MD. ⁴Texas A&M, College Station, TX. (Sponsor: Charles Matthews, FACSM)
 Email: skeadle@calpoly.edu
 (No relevant relationships reported)

There is expanding interest in the 24-hr activity cycle in relation to health outcomes, creating a need for new statistical approaches to analyze the joint effects of distinct but inter-related physical behaviors (e.g., exercise, sitting time, sleep). **PURPOSE:** To develop and test an integrated physical behavior score (PBS) in relation to all-cause and cause specific mortality. **METHODS:** NIH-AARP Diet and Health Study participants (N=163,016) completed a questionnaire (2004-2006) asking about time spent in five exercise and non-exercise physical activities, two sedentary behaviors (television and non-television), and sleep. In half of the sample, we used shape constrained additive regression to model the relationship between each behavior and survival. Maximum logit scores from each of the eight behavior-survival functions were summed to produce a PBS that was proportionally rescaled to range from 0-100. We examined predictive validity of the PBS in the other half-sample using Cox Proportional Hazards models after adjustment for covariates for all-cause and cause-specific mortality. **RESULTS:** In the testing sample, over an average of 6.6y of follow-up, 8,732 deaths occurred. We found a strong graded decline in risk of all-cause mortality across quintiles of PBS (Q5 vs Q1 hazard ratio [95%CI] = 0.53 [0.49, 0.57]). Risk estimates for the PBS were higher than any of the components in isolation. Results were similar but stronger for cardiovascular disease (Q5 vs Q1 = 0.42 [0.39, 0.48]) and other mortality (Q5 vs Q1 = 0.42 [0.36, 0.48]). The relationship between PBS and mortality was observed in stratified analyses by median age, sex, BMI and health status. **CONCLUSIONS:** Although widespread in other areas of epidemiology, this is one of the first attempts to characterize integrate multiple distinct physical behaviors into

a single composite score. In a large sample of US adults, we showed this score has strong predictive validity for both men and women. Future research is needed to test this approach in an independent sample. Supported by the National Institutes of Health U01-CA057030 and the Intramural Research Program.

 (No relevant relationships reported)

PURPOSE: Determine the accuracy of wrist-worn ActiGraph GT3X+ accelerometer (AG) data processing models and examine relationships among model features and type of MVPA. **METHODS:** Forty-eight participants (20.4 ± 1.3 years, 45.8% male) wore an AG on their non-dominant wrist during four, 1-hour sessions in free-living settings. Sessions were video-recorded and coded using a direct observation (DO) system that provided criterion measures for minutes and type of MVPA. Four previously developed AG processing models were applied to estimate MVPA minutes: raw acceleration and arm angle cut-point (sed-sphere), Euclidean norm corrected for gravity cut-point (ENMO), random forest (RF) and decision tree (DT) models. Mixed models were used to assess the difference between model estimated and DO measured MVPA minutes. Principle components analysis (PCA) was used to examine features of the AG data that were associated with MVPA. **RESULTS:** DO identified 12.8 minutes of MVPA/session. Sed-sphere was the only model to accurately estimate MVPA minutes (bias [95% confidence interval] = 1.0 [-0.4, 2.5] minutes). MVPA was overestimated using RF and DT (5.9 [3.3, 8.5] and 4.0 [2.4, 5.6] minutes, respectively) and ENMO significantly underestimated MVPA minutes (-10.7 [-12.9, -8.4] minutes). PCA showed that two principle components account for 89.4% of the variance in MVPA type (64.4% and 25.0%, respectively; Figure 1). The first principle component placed equal weight on three features (mean, standard deviation of acceleration vector magnitude and standard deviation of arm angle) while the second loaded on mean arm angle. **CONCLUSIONS:** Sed-sphere was the only model to accurately estimate minutes of MVPA. PCA indicates that arm angle estimates aspects of MVPA beyond acceleration vector magnitude, and future research should use that feature. Supported by NIH NIDDK R01DK110148

(No relevant relationships reported)

ACSM Scientific Abstract Submission 2019

PURPOSE: Fit 5 is a resource published by Special Olympics that provides instruction for making healthy choices including exercise, diet, and hydration. The purpose of this study was to examine the effectiveness of the Fit 5 program at improving the health of persons with developmental disabilities when promoted through a community day program. **METHODS:** Individuals with developmental disabilities were invited to participate in a weekly fitness program that utilized the Fit 5 resources at their community day program. Participants were given a Fit 5 booklet that provided instruction on making healthy choices. Participants attended one 45-minute group exercise session per week for a total of six weeks. Exercise sessions included Level 1 and Level 2 exercises from the Fit 5 resource and targeted aerobic endurance, muscular fitness, flexibility, and balance. At each group exercise session, participants submitted a weekly record of their exercise, diet, and hydration and were prompted to continue healthy behaviors. A pre-test/post-test design was used. Exactly one week before (pre-test) and one week after (post-test) the 6-week intervention, waist circumference, total modified push-ups performed, and total modified curl-ups performed were recorded for each participant. Repeated measures MANOVA was used to test the effect of time (pre-test, post-test) on the measures of waist circumference, total push-ups, and total curl-ups in order to evaluate the effectiveness of the intervention for improving body composition and muscular fitness. **RESULTS:** 18 individuals (Mean age: 43 ± 19; 11 females) have participated in the intervention to date. Pillai's trace repeated measures MANOVA revealed a significant difference between measures of fitness on the pre-test and post-test ($F_{(df=3,13)} = .582$; $p < .01$, $\eta^2 = .58$). The total curl-ups ($p < .001$) performed increased between the pre-test (15+11) and post-test (23+13). Neither total push-ups performed nor waist circumference was significantly changed by the intervention ($p > .05$). **CONCLUSIONS:** A 6-week intervention using the Fit5 resources was effective at improving muscular fitness for persons with developmental disabilities within a local community day program.

Feasibility of a 6-week Handcycling High Intensity Interval Training Program for Spinal Cord Injury

Alicia Koontz, Sarah Bass, Anas Dighiri, Theresa Crytzer.
University of Pittsburgh, Pittsburgh, PA.
Email: akoontz@pitt.edu
(No relevant relationships reported)

PURPOSE: Spinal cord injury (SCI) can be debilitating to one's health, functional capacity, and quality of life. Specifically, SCI contributes to an elevated risk of preventable cardiometabolic and hypokinetic diseases. Many individuals with SCI have low levels of fitness due to barriers including lack of time, accessible equipment and awareness of exercises that are safe and effective. Using an indoor stationary handcycle to perform a high-intensity exercise program (HIIT) could be a time-efficient and accessible means of improving fitness. The primary aim of this study was to determine adherence, acceptance and fitness outcomes of a 6-week HIIT program for non-ambulatory persons with SCI.

METHODS: Three men with SCI have completed the study to date (Table). At baseline, S2 did not participate in regular physical activity (PA). S1 and S3 participated in 1-3 hours of PA 2 times/week. Participants completed a baseline and post graded exercise test. The HIIT program consisted of 2, 25 min supervised at-home sessions (2-3 min warm-up, 10, 1:1 min work/recovery phases at 90% peak power output (PPO) and 0-20% PPO and 2-3 min cool-down). Real-time power, heart rate (HR), cadence and velocities were recorded via sensors and an app (Garmin Connect). **RESULTS:** Subjects completed all 12 sessions and 10 bouts with the exception of S2 (7/10 and 8/10 bouts for sessions 1 and 4). S2 performed 3 unsupervised sessions

verified via the app. Fitness outcomes were not apparent for S2 and S3 while S1 showed increases in VO₂ (16.0 to 17.1 ml/kg), minute ventilation (37.9 to 42.0 ml/kg), and tidal volume (1.2 to 1.5 L) peaks after training.

Table: Baseline and training data averaged over the 12 sessions (work phases)

| Subject | Age, SCI level, Years Post Injury | Baseline HR | Baseline PPO | HR Beats/min | Power Watts | Cadence Rev/min |
|---------|-----------------------------------|-------------|--------------|--------------|-------------|-----------------|
| S1 | 58, L5/S1, 24 | 89 | 50 | 85 (3) | 51.8 (6.0) | 57 (5) |
| S2 | 17, C5, 2 | 133 | 50 | 100 (3) | 41.4 (4.5) | 51 (13) |
| S3 | 30, C5/C6, 15 | 100 | 40 | 102 (3) | 29.0 (2.8) | 59 (5) |

CONCLUSION: Feasibility was demonstrated by excellent adherence and remote monitoring of compliance with HIIT intensities. A greater number of weekly sessions and/or a longer training period are likely to lead to improvements in fitness parameters.

Physical Activity, Sleep, And Stereotypic Behaviors In Youth With Autism Spectrum Disorder

Justine M. Renziehausen, Paola M. Rivera, Baker M. Kayla, Nicholas A. Leahy, Jeanette M. Garcia. *University of Central Florida, Orlando, FL.*
(No relevant relationships reported)

PURPOSE: The purpose of this study was to compare the associations between moderate-to vigorous physical activity (MVPA), sedentary behavior (SB), sleep quality, and stereotypic behaviors in children with Autism Spectrum Disorder (ASD). **METHODS:** Activity levels and sleep quality were measured in 16 children with ASD (ages 8-17) using Actigraph GT9X Accelerometers. All participants wore the device on their non-dominant wrist for a period of seven days and nights. Parents completed the Aberrant Behavior Checklist (ABC) which examined child irritability, stereotypic behaviors, hyperactivity, inappropriate speech, and lethargy. Spearman correlations were used to examine associations between minutes of MVPA, sleep duration, and adverse behaviors.

RESULTS: Greater levels of MVPA were correlated with less stereotypic behaviors ($r = -.62$, $p = .02$). Although they did not quite reach statistical significance, trends were seen for the associations between 1) longer sleep duration and lower ratings of hyperactivity ($r = -.43$, $p < .1$); and 2) greater amounts of SB and higher ratings of lethargy ($r = .4$, $p < .1$).

CONCLUSIONS: Adequate duration of sleep and participation in MVPA may be linked with fewer adverse behaviors in children with ASD. Future studies should examine larger samples of children with ASD over a longer duration to better determine causal mechanisms that may explain these associations between MVPA, sleep habits and ASD-related behaviors.

Comparison of Energy Expenditure in Wheelchair Users During Active Video Gaming with Adapted Game Controllers

Laurie A. Malone, FACS, Sangeetha Padalabalanarayanan, Mohanraj Thirumalai. *UAB/Lakeshore Research Collaborative, Birmingham, AL.*
Email: lmalone@uab.edu
(No relevant relationships reported)

Active video gaming (AVG) options are limited for individuals with mobility impairments due to inaccessibility of the gaming controllers. Two gaming controllers (Wii Fit balance board and gaming mat) were recently adapted for individuals with physical disabilities (www.rectech.org), thereby providing increased opportunities for AVG play. **PURPOSE:** To compare energy expenditure in persons with mobility impairment during seated AVG play using an adapted Wii Fit balance board (WFBB) and adapted gaming mat. **METHODS:** During the first lab visit, demographic data were collected, and participants completed a game play familiarization period. During the next two lab visits, metabolic data (COSMED) were collected during a 20-minute baseline, followed by two 10-minute bouts of game play. During one visit, participants played select Wii Fit Plus games on the adapted WFBB and during the other visit Active Life Explorer and Outdoor Challenge games were played on the adapted gaming mat. For all AVGs participants played seated. The adapted WFBB was designed so that the player could wheel onto the platform. For play using the adapted gaming mat, the mat was placed on a height-adjustable table. A paired sample t-test was computed to compare mean energy expenditure during game play on the adapted WFBB and gaming mat. **RESULTS:** Sample included 26 participants, 16 men, mean age 37.50 ± 12.77 yrs. All participants utilized a wheelchair for mobility and daily activities. Mean energy expenditure (METs) during game play was significantly greater

($p < .05$) on the adapted WFBB (2.24 ± 0.68 kcal/kg/hr) as compared to the gaming mat (1.99 ± 0.68). **CONCLUSION:** The adapted WFBB and gaming mat provided an opportunity for persons with mobility impairments, specifically wheelchair users, to engage in AVG. Although mean MET values achieved during AVG represented light intensity exercise, several participants ($n = 12$) achieved moderate intensity (3-4 METs) on at least one game set. Factors not accounted for that may have influenced exercise intensity include game selection, limited familiarization, and discomfort wearing the COSMED system. Adapted controllers for AVG play provide a viable option for increasing leisure-time physical activity in persons with mobility impairments. Supported by NIDILRR grant 90RE5009-01-00.

Prediction of Energy Expenditure from Accelerometers during Physical Activity in Adults with Down Syndrome: The Effect of Accelerometer Placement

Anthony T. Allred, Poram Choi, Stamatis Agiovlaitis, FACSM. *Mississippi State University, Mississippi State, MS.* (Sponsor: Stamatis Agiovlaitis, FACSM)
 Email: ata54@msstate.edu

(No relevant relationships reported)

INTRODUCTION: For accurate physical activity assessment with accelerometers in adults with Down syndrome (DS), there is a need to examine if the relationship between the rate of oxygen uptake ($\dot{V}O_2$) and output from hip- and wrist-worn accelerometers across different activities and sedentary behaviors is different between adults with and without DS. In this study, we examined this question and we also evaluated the accuracy of hip- and wrist-worn accelerometers in estimating the $\dot{V}O_2$. **METHODS:** The sample included 16 adults with DS (10 men; age 31 ± 15 years) and 19 adults without DS (10 men; age 24 ± 6 years). We measured $\dot{V}O_2$ with a portable spirometer (K4b², Cosmed) and accelerometer output (Vector Magnitude [VM]) with a hip- and a wrist-worn accelerometer (wGTX-BT, Actigraph). We used multi-level regression to predict $\dot{V}O_2$ from VM and group. Additional predictors included body mass index (BMI), age, height, weight, and sex. We evaluated the accuracy of the prediction with the absolute percent error and Bland-Altman plots.

RESULTS: For both the hip and the wrist accelerometer, VM and group were significant predictors of $\dot{V}O_2$ ($p \leq 0.021$). However, when BMI was added to the models, BMI was a significant predictor and DS was no longer significant for both accelerometer models. The final models included Vector Magnitude and BMI ($p \leq 0.001$; $R^2 = 0.78$ and 0.57 , for hip and wrist accelerometer model, respectively). For the hip accelerometer, absolute percent error across all tasks and for both groups combined was $22.5 \pm 27.4\%$, whereas, for the wrist accelerometer, error was $37.8 \pm 38.0\%$. Absolute percent error across tasks combined and for each task separately did not differ between groups. The Bland-Altman plots indicated nearly zero mean error for both groups. However, error had somewhat greater 95% confidence intervals for the wrist- than the hip-accelerometer models.

CONCLUSION: Adults with DS have different $\dot{V}O_2$ to VM responses, but this is due to their higher BMI. Predictability of $\dot{V}O_2$ from accelerometer output is better for a hip- than a wrist-worn accelerometer. These results may help advance physical activity assessment for adults with DS.

Comparing Gross Efficiency Between Rigid And Hydraulic Prosthetic Ankles During Graded Treadmill Walking

Isaac B. Yoder, Alexander J. Koch. *Lenoir-Rhyne University, Hickory, NC.*

Email: isaac.yoder@my.lr.edu

(No relevant relationships reported)

Recent advancements have led to the development of prosthetic ankles that actively plantar and dorsiflex using hydraulics during walking. In theory, hydraulic ankles allow for more efficient locomotion due to the increased ROM, but these ankles are often heavier than rigid ankles. It is unclear if the increased ROM leads to decreased oxygen consumption during graded walking. **PURPOSE:** To determine which type of ankle prosthesis, a rigid ankle (RA) or a hydraulic ankle (HA) is most efficient when walking uphill. **METHODS:** A female transfemoral amputee (age = 56 y, height = 173 cm, body mass = 77.8kg) walked on a treadmill set at $4.02 \text{ km} \cdot \text{h}^{-1}$, 5% grade, for six min using two types of ankles. A total of four trials were completed in a counterbalanced fashion, with a 15 min recovery between trials. The subject was accustomed to wearing a rigid prosthetic, so a one week acclimation period to walking in the HA was allowed before testing. Expired gases were collected using open-circuit spirometry and gas analysis was completed using a metabolic measurement system. Gross efficiency (GE) was calculated in $\text{ml} \cdot \text{km}^{-1} \cdot \text{min}^{-1}$, and averaged over the two trials. Percent differences were compared between prostheses and trials. **RESULTS:** The HA weighed 0.4kg more than the RA. Compared to RA (average GE = $184 \text{ ml} \cdot \text{km}^{-1} \cdot \text{min}^{-1}$), GE was 7.2% (+6.4% trial 1, +8.2% trial 2) less when using a HA (average GE = $197 \text{ ml} \cdot \text{km}^{-1} \cdot \text{min}^{-1}$). **CONCLUSIONS:** Walking uphill using a HA incurs a greater O₂ cost than does

walking with a RA. The greater mass of the HA may explain the lower GE observed during graded treadmill walking. Longer familiarization with HA may improve GE during walking.

Feasibility and Effectiveness of Community-Based Virtual Reality Group Exercise Training in Persons with Spinal Cord Injury

Ryan R. Porter¹, Kevin W. Kopera², Jennifer L. Trilk, FACSM¹.

¹University of South Carolina School of Medicine Greenville, Greenville, SC. ²Roger C. Peace Rehabilitation Hospital, GHS, Greenville, SC. (Sponsor: Jennifer L. Trilk, FACSM)

(No relevant relationships reported)

Persons with spinal cord injury (SCI) are at an increased risk of physiological morbidity compared to their ambulatory counterparts in whom well-established, beneficial correlations exist between exercise, cardiorespiratory health and body composition. Furthermore, SCI who participate in sport may have reduced risk of physiological morbidity than SCI who are sedentary. **PURPOSE:** This pilot study was two-fold: 1) to determine whether differences exist in cardiorespiratory health and body composition between SCI athletes (ATHL) and sedentary SCI (SED), and 2) to determine whether an 8-week handcycling exercise training program is feasible in an SED SCI population, and if improvements in cardiorespiratory fitness and body composition occur. **METHODS:** Twenty-seven SED and six ATHL were recruited to participate in the study. All SCI completed a graded hand cycling maximal exercise test for cardiorespiratory fitness ($\dot{V}O_{2\text{max}}$) and body composition testing (iDEXA). SED participants were then randomized into a virtual reality intervention (VR) or waitlist (WL) group (e.g. offered VR after 8 weeks of WL). The intervention consisted of an 8-week community-based VR group hand cycling exercise training with a USA level 1 coach two days/week. Pre-post outcomes were measured in each group. **RESULTS:** Thirty-three SCI were recruited to participate (SED $n=27$; ATHL $n=6$). All ATHL and 17 SED participants (VR=9, WL=8) completed study protocol, with 10 (VR=1 and WL=9) lost to follow up. One participant was dropped from analysis due to not giving a full effort during testing as determined by investigators. ATHL had 23 physiological and anthropometric variables that were significantly different ($p \leq 0.01$) compared to SED including higher $\dot{V}O_{2\text{max}}$ (19.1 ml/kg/min), lower BMI (-4.6 kg/m^2), and lower total body fat percentage (-10.4%). $\dot{V}O_{2\text{max}}$ increased 16% in VR and 9% in WL, which was not statistically different. **CONCLUSION:** This study demonstrates the feasibility of a hand cycling program in SCI. ATHL had better outcomes associated with long term health compared to their SED counterparts. Though no significant changes were noted in VR compared to WL, changes in $\dot{V}O_{2\text{max}}$ may be clinically relevant. A larger sample size or longer training period may be needed to observe significant differences in physiological health in an SED SCI population.

699 Board #8 May 29 3:15 PM - 5:15 PM
Effects Of Virtual Reality On Pain And Fatigue In Individuals With SCI

Daniel Azurdia, Angelica Alberto, Travis Watkins, Isabel Lorimer, Mercedes Fernandez, Mai Jara, Danica Tolentino, Ovande Furtado, Taeyoung Jung. *California State University, Northridge, Northridge, CA.*

(No relevant relationships reported)

Background: Pain and fatigue are among the most commonly reported barriers to exercise for individuals with spinal cord injury (SCI). Previous studies have documented virtual reality's (VR) pain and fatigue reducing properties. However, no study has investigated the benefits of using VR for reducing pain and fatigue during exercise in individuals with SCI. **Purpose:** To investigate the effects of using VR during exercise on perceptions of pain and fatigue in individuals with SCI. **Methods:** A total of 18 individuals with traumatic SCI (aged 43.29 ± 17.5 years) participated in this repeated measure comparative study. Three visits were required from each participant. Baseline data was collected during the first visit. The following two visits consisted of a 6-minute exercise test using arm ergometry. Participants were randomly assigned to an exercise condition, either VR or non-VR. Participants rated their pain and fatigue using visual analogue scales and qualitative data was collected following the completion of the exercise test. Dependent variables included pain and fatigue. **Results:** Repeated measures ANOVA showed statistically significant improvements in pain and fatigue scores. VR sessions decreased pain and fatigue by 34% and 36% respectively, as compared to the non-VR exercise sessions. All p values were $p < .05$. In addition, three higher order themes emerged from qualitative analysis, positive psychological impact, positive physiological impact, and virtual reality enhancing exercise experience. **Conclusion:** Our results indicate that exercise in combination with VR can be effective in reducing pain and fatigue in individuals with SCI.

B-39 Free Communication/Slide - Adolescent and Young Adult Female Athlete

Assessment of Sport Specialization and Menstrual Dysfunction in High School Athletes During Pre-season Screening

Darryl A. Bates¹, Charles A. Camarata¹, Michael K. Stein¹, Joe E. Bailey¹, Kelsey M. Cooper², Lily A. Seynaeve², Kelly L. Prescher², Michael D. Rosenthal², Mitchell J. Rauh, FACSM². ¹Southwest Sports Wellness Foundation, Chula Vista, CA. ²San Diego State University, San Diego, CA. (Sponsor: Mitchell J. Rauh, FACSM)

Email: skintobonehelp@gmail.com

(No relevant relationships reported)

Sport specialization and menstrual dysfunction (MD) are of concern for high school athletes as they may contribute to sports injury. Limited evidence exists on the extent of sport specialization and prevalence of MD assessed at pre-season screening.

PURPOSE: The objectives of this study were to 1) determine the prevalence of sport specialization and MD, and 2) determine if sport specialization and MD are higher in team/ball sports than individual sports. **METHODS:** Seven hundred ninety-two (250 females, 542 males) athletes from 14 San Diego high schools participated in a pre-season screening clinic. The athletes completed a questionnaire regarding sport specialization, sport type (individual vs. team/ball sport), menstrual health. Sport specialization was determined by the athletes' responses to 1) declared a primary sport, 2) quit other sports to focus on primary sport, and 3) trained >8 months/year in primary sport in the past year. Scores of 0-1 were considered low specialization, and scores of 2 and 3 indicated moderate and high sport specialization, respectively. MD was defined as ≤ 9 menstrual periods reported in the past year. **RESULTS:** Overall, 54.8% of the athletes were classified as low sport specialists, 38.4% as moderate sport specialists, and 6.8% as high sport specialists. Golf (42.9%), swimming/diving (18.8%), and tennis (15.8%) had the greatest percent of high sport specialization. High sport specialization was almost two times (OR=1.81, 95% CI: 0.9-3.4; $p=0.07$) greater among those whose primary sport was an individual sport (10.0%) than athletes participating in a team/ball sport (6.0%). Females (9.2%) were twice as likely (OR=1.94, 95% CI: 1.1-3.5; $p=0.02$) to highly sport specialize than males (5.7%). Twenty-four (9.7%) female athletes reported MD. Tennis (33.3%), cross-country (15.8%), and swimming (14.3%) had the highest percent of MD. Although a non-significant trend, females who reported MD were twice as likely (OR=2.01, 95% CI: 0.9-4.9; $p=0.10$) to participate in an individual sport (14.5%) as their primary sport than those whose primary sport was a ball/team sport (7.6%). **CONCLUSIONS:** Females were more likely to sport specialize than males. High sport specialization was most common among individual-type sports.

Association Between Sport Specialization and Low BMD Among Female High School Distance Runners

Mitchell J. Rauh, FACSM¹, Michelle T. Barrack², Adam S. Tenforde³, Michael D. Rosenthal¹, Jeanne F. Nichols, FACSM⁴. ¹San Diego State University, San Diego, CA. ²California State University Long Beach, Long Beach, CA. ³Spaulding Rehabilitation Hospital/Harvard Medical School, Charlestown, MA. ⁴University of California San Diego, La Jolla, CA.

Email: mrauh@sdsu.edu

(No relevant relationships reported)

Sport specialization has become increasingly common and has been related to sports injury and menstrual dysfunction among female high school distance runners. The association between sport specialization and low bone mineral density (BMD) is poorly described in this population. **PURPOSE:** To determine the association between sports specialization and low BMD in female high school distance runners. **METHODS:** Participants consisted of 64 female runners (age 15.6 ± 1.4 y), not currently on birth control medication, who competed in interscholastic cross-country and distance track events in southern California. Each runner completed a survey on sport participation and menstrual function, and had her height and weight measured.

Each runner's spine and hip BMD were assessed using DXA, standardized to BMD Z-score by age and sex normative values. Sport specialization classifications were: low specialization (distance running sport(s) for ≤ 8 months/year and participation in ≥ 1 other non-running high school sports); moderate specialization (only distance running sport(s) for ≤ 8 months/year, or participation in distance running sport(s) ≥ 9 months/year and ≥ 1 other non-running sports); and high specialization (participation in distance running sport(s) for ≥ 9 months/year and no other sports. Multivariable logistic regression was performed to determine the adjusted odds ratio (OR) and 95% confidence interval (CI), adjusting for BMI and gynecological age. **RESULTS:** Overall, 21.9% of the runners were high sport specialists, and 37.5% and 40.6% were moderate and low sport specialists, respectively. Twenty-three (35.9%) runners had low BMD (Z-score < -1.0). After adjusting for gynecological age and BMI, high sport specialists were five times more likely (OR=5.4, 95% CI: 1.3-23.3; $p=0.02$) to have low BMD than low sport specialists. **CONCLUSIONS:** Our findings indicated that high sport specialization was associated with low BMD among female high school distance runners. Further investigation of this association is warranted as low BMD has been related to increased risk of stress fracture.

703 May 29 3:45 PM - 4:00 PM

The Relationship between Bone Mineral Accrual and Changes of Body Composition in Competitive Girl Runners

Norimitsu Kinoshita¹, Eriko Uchiyama¹, Kenta Okuyama².

¹Hosei University, Tokyo, Japan. ²Shimane University, Shimane, Japan.

Email: sportsmed.kinoshita@hosei.ac.jp

(No relevant relationships reported)

Low bone density is a complication of a long-term strict weight control during adolescence in women.

PURPOSE: To assess whether decrease in percent body fat (%BF) is associated with an impaired bone mineral accrual in girl runners.

METHODS: Consecutive 22 freshmen girl runners (15y/o, 158cm, 45kg) during 7 years in competitive high school teams were evaluated over 2 years of training. DXA was performed at the preparatory phase (baseline) and repeated after 23 ± 2 months (follow-up). The runners were divided into 2 groups; negative (DEC, $n=11$) or positive (GAIN, $n=11$) changes of %BF ($\Delta\%$ BF) during the period. The effect of the period and the group on the changes in bone mineral content (BMC) and density (BMD) of total body less head and z-score were analyzed by 2-way repeated measures ANOVA. As for lean soft tissue mass (LSM) and fat mass (FM), paired t-test was used to compare between baseline and follow-up. Bivariate correlation analysis was used to examine the relationship between bone mineral accrual (Δ BMC and Δ BMD) and $\Delta\%$ BF as well as the changes of FM (Δ FM) and LSM (Δ LSM). Written informed consent was obtained from the runners and their parents. $P < 0.05$ was considered as statistically significant. **RESULTS:** %BF changed from 17.4 to 14.3 (DEC) and 15.0 to 18.4 % (GAIN). The period had significant effects on BMC, BMD, and z-score without interactions. Contrast showed significant increases in those variables, while the group of $\Delta\%$ BF had no significant effect, indicating the values of DEC and GAIN were similarly increased; 1.57 to 1.64 and 1.66 to 1.77 kg, 0.98 to 1.00 and 1.00 to 1.03 g/cm², and -0.25 to -0.20 and 0.04 to 0.22, respectively. The DEC runners gained LSM (34.2 to 36.1 kg) and reduced FM (7.7 to 6.4 kg) significantly, while the GAIN runners significantly increased FM (6.9 to 9.0 kg) without LSM change (36.6 to 37.0 kg). Neither $\Delta\%$ BF nor Δ FM, but Δ LSM was significantly correlated with Δ BMC ($r=0.45$) and Δ BMD ($r=0.55$).

CONCLUSIONS: Bone mineral was equally accrued among the runners of which %BF increased or decreased, where the accretion was associated with LSM gain. Competitive distance runners would develop leanness by not only losing FM but also gaining LSM (i.e., skeletal muscle) along with long-term exercise training. This would ameliorate an impairment of bone mineral acquisition by strict weight control.

Examination of Energy Availability and Injury Prevalence in Collegiate Dancers

Kenya Moore¹, Toni M. Torres-McGehee¹, Erin M. Moore², Elena Burrus¹, Kelly Pritchett³, Susan Anderson¹. ¹University of South Carolina, Columbia, SC. ²University of South Florida, Tampa, FL. ³Central Washington University, Ellensburg, WA.

(No relevant relationships reported)

Performing arts is an emerging population in the realm of sports medicine. Health care professionals must first understand the types of demands placed on dancers including risks associated with the Female Athlete Triad (Triad; low energy availability [LEA], reproductive hormonal disruption, and compromised bone mineral density [BMD]). **Purpose:** Examine the relationship between energy availability (EA) & musculoskeletal injuries, nutritional behaviors (carbohydrates [CHO] and protein [PRO]), and fat, and prevalence of eating disorders/disordered eating (ED/DE) amongst female collegiate dancers.

Methods: A cross-sectional design of 26 female college ballet & contemporary dancers (age: 20.5 ± 3.6 , weight: 56.4 ± 7.0 kg, height: 165.2 ± 6.9 cm) was conducted at a local university. Dancers completed 1 week of dance classes/rehearsals and data collection included: anthropometric data, questionnaires (e.g., demographics, health history, Eating Disorder Inventory-3, RMR, a 7-day food log to measure dietary energy intake (EI) and wore a SenseWear armband to calculate exercise energy expenditure (EEE).

Results: Overall, 69.2% (n=18) were at risk for LEA (< 30 kcal/kg/FFM) and none were at risk for low BMD. Energy needs assessments measured: RMR (1155 ± 206.54 kcals), EI (1473.9 ± 321.5 kcals), and EEE (884.7 ± 324.8 kcals). Macronutrient profile included: 100% (n=26) below the recommended CHO and 73.1% (n=19) were below PRO, and fat was within limits. There were 88.5% (n=23) dancers with elevated ED/DE risks. Retrospective injuries demonstrated: 96.2% (n=25) dancers self-reported a previous dance related injury, 15.4% (n=4) were previously diagnosed and treated for a stress fracture, and during their current dance season 61.5% (n=16) of dancers were diagnosed with an injury. Of those diagnosed within the current season, 34.6% (n=9) presented with LEA and 19.2% (n=5) had ED risk.

Conclusion: Overall, there were high occurrences of LEA & injuries among dancers. LEA and Triad symptoms diminish musculoskeletal integrity, thus negatively affecting overall health. Primarily, dancers' LEA was due to diet restriction (low CHO and PRO). Understanding more about the effects LEA and the Triad have on dancers will aid clinicians in treating injuries, maintaining nutritional balance, and improving the health of performers.

705 May 29 4:15 PM - 4:30 PM

How are Adolescent Ballet Dancers' Eating Attitudes Related to Social Media Viewing Habits?

Toni-Ann M. Triolo¹, Catherine A. Schaeffer¹, Robin L. Collen², Alan M. Levine¹. ¹Marywood University, Scranton, PA. ²SUNY Potsdam, Potsdam, NY.

Email: tmtriolo@m.marywood.edu

(No relevant relationships reported)

Social media has a great impact on adolescent's behavior. Since many young ballet dancers spend many hours on dance websites, they may adopt unhealthy eating attitudes and behaviors that are depicted on-line. **Objective:** The purpose of this descriptive study was to evaluate dancers aged 10-16 years in Northeastern Pennsylvania (NEPA) to determine if there was a relationship between social media exposure and disordered eating attitudes. **Methods:** Participants included 39 white adolescent female dancers (13.7 \pm 1.8 years) from five dance studios in Northeastern Pennsylvania who completed the Children's Eating Attitude Test (ChEAT-26) and the Questionnaire of Exposure and Reinforcement Through Facebook (QERF) to assess eating attitudes and social media viewing practices. Data were analyzed using descriptive statistics and Pearson correlations. **Results:** Mean time spent dancing each week was 6.2 ± 2.0 hours. Mean ChEAT-26 score was 20.8 ± 15 . Over one-third (36%) of the dancers scored 20 or above indicating disordered eating attitudes and/or behaviors. Mean QERF score was 26.5 ± 5.7 . 87.5% of the dancers scored 23 or greater out of a possible 45, exposure to social media. Mean time spent on Facebook was 4.7 ± 2.8 hours per week, while mean time spent on Facebook looking at dance websites was 1.3 ± 1.2 hours per week. Although we did not observe a significant relationship between ChEAT and QERF, there was a trend ($r=.27$, $p=.10$); as social media exposure increased, disordered eating attitudes and behaviors also increased. **Conclusions:** Adolescent dancers are at risk of developing unhealthy eating attitudes and behaviors. Their substantial exposure to social media, especially on dance websites, may play a role in accelerating problematic eating patterns. Since limiting young dancers' social media exposure may well be problematic, parents, dance teachers, nutritionists and other health professionals must become aware of these issues and should consider interventions that model positive eating attitudes and behaviors.

706 May 29 4:30 PM - 4:45 PM

Surgical Outcomes of Os Trigonum Syndrome in Dancers

Keifer P. Walsh. *Alabama College of Osteopathic Medicine, Birmingham, AL.*

Email: walshkp@acom.edu

(No relevant relationships reported)

PURPOSE: Management of ankle pain in dancers can be challenging due to the complex demands placed on their ankles and feet. Despite the prevalence of ankle pain or injuries in this population, literature on the outcomes of surgical approach is limited. The hypothesis of this study was that dancers return to their previous level of activity following open excision of a symptomatic os trigonum syndrome. **METHODS:** We followed 54 ankles (44 patients, 91% female, mean age 18.2 years) in patients who underwent surgery for posterior impingement. Dance style varied across patients but was largely ballet and included many professionals. All patients completed a specific rehabilitation protocol prior to surgical discussions and eventual excision of the os trigonum was done through an open approach. All patients then

committed to a specific rehabilitation program and gradually returned to dance. Outcomes were evaluated with the Veterans Rand 12 Item Health Survey (VR-12) Mental and Physical Scores, Foot Function Index-Revised (FFI-R), Visual Analog Scale (VAS) scoring, and patient satisfaction preoperatively and postoperatively. This study was conducted in compliance and approved with a local Institutional Review Board (IRB). **RESULTS:** Most recent follow-up was a mean 32.3 months with data collected across a range of 6 weeks to 8 years post-operative. Between pre-operative and most recent postoperative follow-up, there was no significant difference in VR-12 Mental Scores (mean scores of 55.4 and 53.9), however Physical Scores increased 37.8 to 51.2, respectively. Significant improvement was also seen in both the FFI-R cumulative score (63.2 to 42.4) and VAS (54% to 17%). Major complications included transient sural nerve paresthesia and scar tissue buildup that resolved over time. Overall, patients were extremely satisfied with their result (82.7% post-operative satisfaction). **CONCLUSIONS:** An open os trigonum excision is fairly simple, has a low complication rate, and proves to have a high success rate in returning athletes back to their sport of choice. In this study, dancers of varying level and primary style improved significantly according to various clinical measures and maintained thriving postoperative careers. Successful return to dancing relied greatly on well-structured physical rehabilitation therapy.

707 May 29 4:45 PM - 5:00 PM

Comparison of Total Body Composition and Bone Mineral Density Measures in Female Collegiate Athletes

Kyle Leppert, Peter Lisman, Nicolas D. Knuth, Nathan Wilder, Devon Dobrosielski. *Towson University, Towson, MD.*

Email: kleppert@towson.edu

(No relevant relationships reported)

Body composition and bone mineral density (BMD) are important factors in sport performance and the overall short and long-term health of athletes. Despite this function, few investigations to date have documented total body composition in female collegiate athletes. Further, we are unaware of any studies examining both total body composition and BMD in this population. **PURPOSE:** To generate descriptive data for total body composition and BMD in a large sample of female collegiate athletes using dual X-ray absorptiometry (DXA) and examine differences between 10 competitive sports. **METHODS:** A total of 211 female collegiate athletes (19 \pm 1 yrs; 167.8 \pm 8.9 cm; 45.9 \pm 6.1 kg; 2.4% Asian, 15.2% Black, 1.4% Hispanic, 80.6% White, 0.5% Other) underwent DXA: basketball (BB; n=22), cross country (CC; n=11), field hockey (FH; n=25), gymnastics (GYM; n=23), lacrosse (LAX; n=42), soccer (SOC; n=27), swimming (SW; n=27), tennis (TN; n=11), track (field only); (TR; n=7), and volleyball; (VB; n=16). Descriptive statistics were calculated for total body fat percentage (BF%), and BMD. Differences in total BF% and BMD between sports were examined using a one-way Welch's ANOVA test. Post-hoc testing was completed using the Games-Howell test. **RESULTS:** The mean total BF% was 27.8 ± 5.1 (range: 23.0 - 37.5%) while BMD was 1.30 ± 0.11 g/cm² (range: 1.17 - 1.45 g/cm²); TR had the highest BF% (37.5 \pm 5.5%), followed by TN (31.1 \pm 4.0%) and LAX (29.3 \pm 3.8%), CC (23.0 \pm 6.0%) and GYM (23.5 \pm 2.9%) had the lowest. For BMD, TR had the highest (1.45 ± 0.07 g/cm²), followed by BB (1.40 ± 0.12 g/cm²) and VB (1.36 ± 0.10 g/cm²); CC (1.17 ± 0.07 g/cm²) and SW (1.22 ± 0.06 g/cm²) had the lowest. Group mean differences in BF% ($p < 0.001$; $\omega^2 = 0.26$) and BMD ($p < 0.001$; $\omega^2 = 0.35$) were observed between teams. Specifically, GYM had lower BF% than BB, FH, LAX, SOC, SW, TN, and TR (mean difference range: -4.0 to -13.9%, all $p < 0.05$). CC had lower BMD than BB, FH, GYM, LAX, SOC, TR, and FH (mean difference range: -0.11 to -0.28 g/cm², all $p < 0.01$). **CONCLUSION:** Total body composition and BMD measures varied across female collegiate sports. These findings may assist sports medicine and strength and conditioning practitioners with identifying appropriate goal values for BF% and BMD in female collegiate athletes across various sports.

708 May 29 5:00 PM - 5:15 PM

Awareness of the Female Athlete Triad in NCAA Cross Country Coaches

Anna G. Warner¹, Katherine H. Rizzone², Scott Davis³, Timothy Harvey¹, Robert D. Chetlin¹. ¹Mercyhurst University, Erie, PA. ²University of Rochester Medical Center, Rochester, NY. ³Marshall University, Huntington, WV. (Sponsor: Paul M Gordon, FACSM)

Email: awarne53@lakers.mercyhurst.edu

(No relevant relationships reported)

The Female Athlete Triad is a pervasive, multifactorial morbidity amongst collegiate female athletes, particularly those participating in endurance sports. Cross country coaches' awareness of the Triad within all NCAA divisions is unknown. **PURPOSE:** To assess National Collegiate Athletic Association (NCAA) cross country coaches' awareness of the Triad components. **METHODS:** Ninety-nine Division I-III NCAA compliance officers were sent an email containing a request to disseminate a web-based survey to cross country coaches in their respective conferences. The web-

linked instrument included: a study synopsis; an informed consent statement, and; the IRB-approved survey tool. Reminder emails were sent approximately two months after the original participation request. Statistical analysis, using JMP software, included frequency distributions and chi-square tests for categorical association. Significance level was set at $p < 0.05$. **RESULTS:** Coaches ($n = 143$; mean age = 40.7 ± 11.9 years; mean coaching experience = 14.1 ± 10.3 years) from 45 conferences participated; 74% of respondents were male. All NCAA Divisions were equitably represented (I = 29.7%, II = 35.5%, III = 34.8%). While respondent majorities: coached male and female athletes (82.1%); reported they were familiar with the Triad (73.4%), and; felt comfortable/very comfortable discussing diet (87.6%) and menstruation (65.6%) with female athletes, only 54% correctly identified all three Triad components (re: low energy availability, amenorrhea, low bone mineral density). Female coaches, however, were more comfortable than male coaches discussing menstrual issues ($X^2 = 94.7$, $p < 0.001$). When compared to the other divisions, Division I coaches were more likely to: have Triad awareness ($X^2 = 10.1$, $p < 0.05$), and; have athletes with access to registered dietitians ($X^2 = 16.5$, $p < 0.01$) and sports psychologists ($X^2 = 18.0$, $p < 0.01$). **CONCLUSION:** A slim majority of NCAA cross country coaches demonstrated comprehensive understanding of Triad components, but; resource disparities to effectively address the Triad exist between the NCAA divisions. Future research should examine how to increase coaches' Triad awareness and education, and; optimize resources across NCAA divisions to reduce the negative outcomes associated with this common morbidity.

B-40 Free Communication/Slide - Behavioral Approaches to Increasing Physical Activity

Wednesday, May 29, 2019, 3:15 PM - 5:15 PM

A Comparison Between Physician and Patient Perceptions Regarding Barriers to Exercise

john gunel¹, Jessica Lucas², Elizabeth Rothe¹. ¹Maine Dartmouth Sports Medicine Fellowship, Augusta, ME. ²Central Maine Medical Center, Lewiston, ME.

(No relevant relationships reported)

PURPOSE: To compare physician vs patient perceptions regarding barriers to exercise, preferred physical activities, and amount of time spent exercising. **METHODS:** A survey was given to patients and their physicians at a family medicine residency clinic. The survey consisted of a Likert scale of barriers to exercise, a checklist of preferred exercise activities, and the amount of exercise their patients engaged in. Barriers to exercise were categorized as motivational, physical, or external barriers. **RESULTS:** Physicians consistently overestimated the importance of external barriers to exercise ($t = -2.38$, $df = 19.473$, $p\text{-value} = .0275$) when compared to their patients (e.g. "There are no facilities in my area.", "It's too dangerous in my area"). Residents also consistently overestimated the importance of internal motivational barriers ($t = -2.2355$, $df = 18.77$, $p = 0.03774$). ("I hate to fail, so I will not start.", "Exercise is boring"). There was an 80% correlation between the activities physicians predicted their patients enjoyed and what patients actually endorsed enjoying. Physicians predicted 54% less exercise than that endorsed by their patients. **CONCLUSIONS:** Our data show that physicians overestimate their patients' external and motivational barriers to exercise. This suggests an opportunity for physicians to enhance motivational interviewing by reducing their focus on external and motivational barriers. Physicians were excellent predictors of the exercise modalities preferred by their patients but significantly underestimated the amount of exercise endorsed by their patients, suggesting a missed opportunity to acknowledge patient efforts towards a healthy lifestyle. **SIGNIFICANCE:** Exercise prescriptions and motivational interviewing are the two most effective tools physicians have to increase physical activity in their patients. Our study and survey can be a template to facilitate and enhance this discussion.

711 May 29 3:30 PM - 3:45 PM

Physical Activity Promotion: Content Analysis of Nationally Representative Elementary School Websites

Thomas L. McKenzie, FACSM, David Kahan. *San Diego State University, San Diego, CA.*

Email: tmckenzie@sdsu.edu

(No relevant relationships reported)

School choice legislation has increased the number of public charter schools and about 7000 were licensed in DC and 44 states in 2018. Health authorities advocate that schools provide diverse physical activity (PA) programs to enable students accrue at least 50% of their daily recommended 60 min of moderate-to-vigorous physical activity (MVPA). School websites have great potential to provide information about PA and be a catalyst for students participating in school PA programs. Investigations of websites relative to PA are rare, and no studies assessing the PA content of charter school websites have been published. **PURPOSE:** To complete a quantitative content analysis of PA-related information on the websites of U.S. charter elementary schools. **METHODS:** During spring 2018 we conducted a content analysis of a stratified random sample of U.S. charter elementary schools ($n=759$) for information specific to PA. **RESULTS:** Nearly all schools (97%) had a functioning website, but these rarely mentioned PA program opportunities: PE (34.1%), PA clubs (13.7%), interscholastic sports (9.1%), recess (7.9%), and intramurals (5.5%). No website identified all 5 program types and 52.0% did not mention their school provided a PA program at all. Information on PE was scarce. Only 7.1% of sites mentioned a PE curriculum and only 2.8% and 2.0%, respectively, mentioned its sequence or content. A PE teacher was mentioned on 37.4% of websites, but only 6.1% indicated he/she had specialist PE training. Only 4.6% of sites identified PE frequency and only 2.7% mentioned lesson length. Similarly, only 7.9% of websites mentioned recess. There were no significant associations between school age, size, or type (i.e., elementary vs. elementary/middle combination) with websites mentioning PE, having a PE teacher, or offering one or more PA programs. **CONCLUSIONS:** This is the first study to complete a quantitative content analysis of information about PA programs on the websites of a nationally representative sample of elementary charter schools. Results show that PE and PA is essentially ignored on elementary charter school websites across the country. As they are public "windows" designed to convey important information to constituents, we recommend all schools assess their websites to ensure they provide comprehensive messaging about PA.

712 May 29 3:45 PM - 4:00 PM

Generating and Applying a Physical Activity Model for an Underserved Community: A Mixed Methods Approach

Kori Hahn, Kara Hamilton, Shewanee Howard-Baptiste, Melissa Powell, Mia Faragalli, Gregory Heath, FACSM. *The University of Tennessee Chattanooga, Chattanooga, TN.* (Sponsor: Gregory Heath, FACSM)

Email: zrn252@mocs.utc.edu

(No relevant relationships reported)

Physical activity (PA) determinants differ depending on the population being studied. **PURPOSE:** A PA predictive model for an underserved community was generated and further insight of the results were gained by conducting focus groups with parents and school staff. **METHODS:** Previous literature was used to identify PA predictors and to form constructs of a survey. The survey was given to 35 families at a school-based event. Cronbach's alpha was used to assess construct reliability, and a stepwise regression was run to determine predictors. Significant predictors were presented and discussed with community focus groups. **RESULTS:** Parental PA support ($a=.9$), parental perceived barriers ($a=.8$), parental dietary intake ($a=.8$), PA beliefs ($a=.6$), screen time ($a=.6$), and gender were included in a forward stepwise regression. The overall model was significant ($p=.001$), where parental support of PA ($B=.567$, $p=.024$), gender ($B=.462$, $p=.010$), and PA beliefs ($B=.579$, $p=.016$) were significant predictors of PA. **CONCLUSION:** This innovative approach enabled community participants to prioritize their actions more efficiently in addressing the most pressing determinants contributing to low levels of physical activity among their children. These results will contribute significantly to the design of a subsequent physical activity intervention among community children and their families.

713 May 29 4:00 PM - 4:15 PM

Variations in Preschoolers' Physical Activity Across the School YearConnie L. Tompkins, Erin K. Shoulberg, Lori E. Meyer, Caroline Martin, Allison Krasner, Marissa Dennis, Betsy Hoza. *University of Vermont, Burlington, VT.*

Email: Connie.Tompkins@med.uvm.edu

(No relevant relationships reported)

PURPOSE: To examine variations and sex differences in preschoolers' physical activity (PA) across the school year, with and without a PA intervention

METHODS: The *Kiddie CATs on the Move* PA curriculum was implemented in preschools over 22-weeks, 2-3 times per week by classroom teachers and college students enrolled in a service-learning course. Accelerometry was used to measure PA during the school day at 5 time points across the year [2 Baseline (Fall, Winter), 3 Intervention (Fall, Winter, Spring)]. A total of 68 children ($M_{age} = 4.15 \pm 0.6$, 33 males, 35 females) with ≥ 2 days of valid data at each time point were included in analyses. Minutes per hour of moderate-to-vigorous (MVPA) and total PA (light + MVPA) were calculated. Paired-samples *t*-tests were used to compare sex differences at each time point. A series of 5 (time) x 2 (sex) mixed model ANOVAs were used to examine PA across assessments and whether or not patterns of change in PA varied by sex.

RESULTS: Boys engaged in significantly more total PA than girls only during the Winter Baseline assessment (17.3 ± 4.0 vs 15.0 ± 4.8 min/hr, $p < 0.04$). Boys engaged in significantly more MVPA (min/hr) than girls during the Fall Baseline (9.6 ± 2.4 vs 8.3 ± 2.7 , $p < 0.04$), Fall Intervention (10.2 ± 3.1 vs 8.7 ± 2.8 , $p < 0.04$) and Winter Baseline (9.2 ± 2.5 vs 7.4 ± 2.9 , $p < 0.01$). For the combined sample, total PA, $F(4, 264) = 6.81$, $p < 0.001$, and MVPA, $F(4, 264) = 9.43$, $p < 0.001$, varied across the time points. Total PA (min/hr) was significantly higher at all intervention time points compared to winter baseline (17.2 , 17.4 , 17.9 vs 16.1 , $ps < 0.01$) and spring intervention also significantly higher than fall baseline (17.9 vs 16.9 , $ps < 0.01$). MVPA (min/hr) was significantly higher at all intervention time points compared to winter baseline (9.4 , 9.1 , 9.8 vs 8.3 , $p < 0.05$) and spring intervention was significantly higher than fall baseline MVPA (9.8 vs 8.9 , $p < 0.01$). The pattern of change in PA across assessments did not vary based on child sex.

CONCLUSIONS: Findings highlight the importance of structured programs to promote preschoolers' PA, especially during winter months when PA appears to decline. Although there were no sex differences in the pattern of PA change for boys and girls, girls consistently engaged in less PA than boys during the year and future work should examine factors related to this sex difference.

714 May 29 4:15 PM - 4:30 PM

Supporting Physical Health Of Black Male Faculty Through A Wellness-integrated Professional Development Program: FIT LeadersEmily R. Martini¹, Turhan Carol¹, Carl M. Maresh, FACSM¹, Joshua J. Joseph², David A. Delaine¹. ¹The Ohio State University, Columbus, OH. ²The Ohio State University Wexner Medical Center, Columbus, OH. (Sponsor: Carl M. Maresh, FACSM) Email: martini.36@osu.edu

(No relevant relationships reported)

Purpose: An intervention strategy examining the integration of professional development and wellness for black male faculty at an R1 university was conducted. The intervention was directed at supporting the retention and academic promotion of black male faculty through minimizing the impact of culturally relevant physical (i.e., hypertension, obesity) and cognitive (i.e. John-Henryism, social isolation, discrimination, etc.) challenges. The implications on the physical health of the participants are presented here. **Method:** A 24-week intervention brought together black male faculty of differing ranks at a university fitness center twice per week. Each session included a 45 min trainer lead exercise session followed by a 30 min semi-guided discussion on culturally relevant professional development topics. A series of assessments implemented in a pre-/post-structure around the intervention included cardiovascular measures including central aortic pressure, brachial blood pressure (BP) and carotid-femoral pulse wave velocity (cf-pwv) measured via the Sphygmocor Xcel Device, body composition via BodPod, strength and cardiorespiratory fitness via graded exercise treadmill test. Pre-post analyses using paired T-tests were performed using STATA 13.4. **Results:** Among 9 participants the mean age was 40.4 ± 4.1 years. Cardiovascular measures improved including Aortic Systolic Pressure 123 ± 11 vs 117 ± 12 mmHg, $p=0.007$; Brachial systolic BP 136 ± 10 vs 128 ± 12 mmHg, $p=0.002$; Brachial diastolic BP 87 ± 10 vs 84 ± 10 , $p=0.057$; and Cf-pwv 8.3 ± 1.4 vs 6.9 ± 0.6 m/s ($n=6$, $p=0.007$). Adiposity measures improved including body mass index 29.6 ± 5.0 vs 29.0 ± 4.9 kg/m², $p=0.014$; waist circumference 96.6 ± 11.8 vs 93.4 ± 12 cm, $p < 0.001$; and body fat percentage 26.9 ± 7.7 vs 23.4 ± 7.6 %, $p=0.005$. Max chest press improved from 174.4 ± 52.1 vs 191.4 ± 45.9 lbs, $p=0.008$. There were no improvements in cardiorespiratory fitness, highest VO₂max 37.1 ± 7.4 vs

37.5 ± 6.9 ml/kg/min ($n=7$), $p=0.801$. **Conclusion:** Changes in the physical health of participants indicate that this intervention shows promise for supporting the physical wellness of black male faculty in parallel with culturally relevant leadership support.

715 May 29 4:30 PM - 4:45 PM

Effects Of A National School Intervention Programme On The Levels Of Physical ActivityFernando Rodríguez-Rodríguez¹, Carlos Cristi-Montero¹, José Castro-Piñero². ¹PONTIFICIA UNIVERSIDAD CATÓLICA DE VALPARAÍSO, VIÑA DEL MAR, Chile. ²UNIVERSIDAD DE CÁDIZ, CÁDIZ, Spain. (Sponsor: Alvaro Gurovich, FACSM) Email: fernando.rodriguez@pucv.cl

(No relevant relationships reported)

Since the school context greatly influences children and youth and can ensure that a large number of school children participate in activities and maintain active behaviors during the school day.

PURPOSE: The aim of this study was to compare the level of physical activity during the school day of a group of children participating in the school intervention program in comparison to a control group.

METHODS: A randomized sample of 154 school children (7-11 y) was obtained out of the Integral Sports Schools of the National Sports Institute of Chile, (70 intervention group; 84 control group), all belonging to socioeconomic vulnerable public schools. The program is structured as a comprehensive sports practice workshop with a duration of 90 min/session and performed three times/week. Each session develops activities to strengthen the skills for life and healthy lifestyles, and children experience a wide range of pre-sports and sports activities. Physical activity levels were recorded continuously with triaxial accelerometers during the school day, recess, physical activity session (PA) or physical education session (PE), and lunch. A value of $p < 0.05$ was defined as statistically significant in Student's *t*-test.

RESULTS: Fifty per cent of the children in the intervention group complied with the recommendations of moderate-to-vigorous physical activity (MVPA), vs. 22.7% of the control group. During the first recess, the MVPA time of the control group was double that of the intervention group ($p < 0.001$), where the recommendations of MVPA were not met, but at lunch it was possible to add important minutes of physical activity. None of the groups complied with the recommendations for steps in the PA or PE. During the PA, sedentary time was less and MVPA was greater in the intervention group (Table 1).

CONCLUSIONS: It was concluded that although the MVPA in recesses and lunchtime was greater in the control group, the activity in the PA of intervention group was greater and contributed more MVPA to the school day. This highlights the role of physical education classes in meeting MVPA's daily recommendations.

716 May 29 4:45 PM - 5:00 PM

Acceptability of a Walking Intervention Among Inactive Adults Using a Smartphone-Based Gaming ApplicationJason R. Bentley¹, Zakkoyya H. Lewis-Trammell², Maria C. Swartz¹, Elizabeth J. Lyons¹. ¹University of Texas Medical Branch, Galveston, TX. ²Loyola Marymount University, Los Angeles, CA.

(No relevant relationships reported)

Routine physical activity and maintenance of a normal body mass are critical for cardiovascular health. However, most adults do not meet the ACSM recommendations for physical activity. Previous research has shown that adding video games to traditional exercise programs may increase adherence. In recent years, smartphones allow much of the population to utilize games while engaging in exercise, particularly walking, and have a great potential for public health impact. **PURPOSE:** This study tested the acceptability of a 12-week walking intervention that used an active game delivered on a smartphone among community-dwelling adults. **METHODS:** Forty adults were randomized to receive the intervention or a wait list control. The 20 randomized to the intervention (18 females, age 46.9 ± 13.4 years, BMI 33.1 ± 9.37 kg/m², 70% Caucasian) chose an activity goal starting at ≥ 60 mins/week, increasing it over the 12-week duration to ≥ 150 mins/week. They were instructed to use the smartphone game "Zombies, Run!" while walking due to its popularity and low-cost, and received weekly brief phone counseling to assist with adjusting goals, problem solving, and relapse prevention. Acceptability of the intervention was determined using satisfaction scales that evaluated the smartphone interface, game application, and technical issues; a Likert-scale rating of > 4 (from 1 to 5) was the threshold for acceptability. **RESULTS:** Satisfaction of the smartphone hardware was 4.25 ± 0.63 , with 2 participants indicating that the device was overly complicated; satisfaction of the gaming application was 4.37 ± 0.75 , although 2 participants found the zombie game disinteresting; and, avoidance of technical issues was 4.11 ± 0.74 , with 2 participants reporting problems with either the game or device. **CONCLUSION:** Among our target population, a smartphone-based gaming intervention was acceptable over a 12-week walking program. This intervention has the potential to be a valuable

tool in promoting routine physical activity among a large population of individuals who desperately need a lifestyle modification, although adding alternate game choices may be beneficial in future studies. Supported by American Heart Association grant #13BGIA17110021.

717 May 29 5:00 PM - 5:15 PM

Use of Wearable Technology and Social Media to Improve Physical Activity and Dietary Behaviors among College Students: A 12-week Randomized Pilot Study

Zachary C. Pope, Daheia J. Barr-Anderson, FACSM, Beth A. Lewis, Mark A. Pereira, Zan Gao, FACSM. *University of Minnesota, Minneapolis, MN.* (Sponsor: Zan Gao, FACSM) Email: popex157@umn.edu

(No relevant relationships reported)

PURPOSE: Evaluated efficacy of combining smartwatch use and a theoretically-based, social media-delivered health education intervention on improving college students' (CS) health behaviors/outcomes relative to a comparison arm. Intervention use/acceptability were also assessed.

METHODS: Thirty-eight CS (28 female; $M_{age} = 21.5 \pm 3.4$ years) participated in this two-arm randomized 12-week pilot trial. After screening, participants were randomized into two groups: (a) experimental: consisted of Polar M400 use and a twice-weekly theory-based Facebook-delivered health education intervention; or (b) comparison: enrolled in separate, but content-identical, Facebook group. ActiGraph Link accelerometers and the National Cancer Institute's ASA24 food recall measured PA and dietary behaviors, respectively. Health-related Social Cognitive Theory and Self-Determination Theory psychosocial constructs were measured using psychometrically-validated questionnaires while the YMCA 3-Minute step test and bioelectrical impedance assessed cardiorespiratory fitness and body fat percentage, respectively.

RESULTS: Only whole grain consumption differed between groups at baseline, $t = 2.3, p = 0.03$. For PA, a trend toward a significant main effect for time was observed for moderate-to-vigorous PA, $F(2, 72) = 2.6, p = 0.08$; partial eta-squared = 0.07, with experimental and comparison groups demonstrating 4.2- and 1.6-minute/day increases, respectively, at 6 weeks. For secondary outcomes, both groups demonstrated non-significantly decreased weight from baseline to 12 weeks (experimental: -0.6 kg; comparison: -0.5 kg). Further, significant main effects for time were observed for self-efficacy, social support, and intrinsic motivation (all $p < 0.01$; partial eta-squared: 0.18-0.38) as both groups improved over time. Finally, both groups demonstrated lower daily caloric consumption over time (experimental: -41.0 calories; comparison: -143.3 calories). Intervention adherence was high (~86%), with participants implementing health education tips at least once weekly.

CONCLUSIONS: While both arms demonstrated initial efficacy in improving CS health outcomes, observations did not indicate the experimental intervention as more efficacious than comparison. Future research warranted.

B-41 Free Communication/Slide - Exercise and Cardiovascular Risk Factors

Wednesday, May 29, 2019, 3:15 PM - 5:15 PM

Ambulatory Central Blood Pressure Over 24 Hours Following Intermittent Vs. Continuous Moderate Intensity Exercise

McKenzie A. Williams, Erika Silva, Nicholas Carlini, Brandon Kistler, Bradley Fleenor, Matthew Harber, FACSM. *Ball State University, Muncie, IN.* (Sponsor: Matthew Harber, FACSM)

(No relevant relationships reported)

Ambulatory blood pressure (BP) derived from the large central arteries has been shown to be a better predictor of cardiovascular events and mortality compared with peripheral ambulatory brachial blood pressure. Currently, however, it is unknown if exercise, either intermittent or continuous bouts, influence ambulatory central BP.

PURPOSE: To examine the ambulatory central blood pressure response over 24 hours following a moderate intensity intermittent (MII) bout of aerobic exercise compared to a moderate intensity continuous (MIC) bout. **METHODS:** Eight, non-hypertensive males (61.5 ± 2.4 yrs) performed three trials in a randomized order: control, MII (3X10

minutes at 50-60% heart rate reserve (HRR) with 5 minutes of seated rest), and MIC (30 minutes continuous at 50-60% HRR). Total work performed during the exercise trials was matched. Ambulatory brachial and central hemodynamics (Suntech Oscar 2 with SphygmoCor) were averaged over 24 hours, and divided by time of day (Morning, Afternoon, Evening, and Nighttime) and compared among each trial.

RESULTS: No differences ($P > 0.05$) between CON, MII, and MIC were observed for any variable. Brachial and central hemodynamic variables were lower ($P < 0.05$) during Nighttime (Nt) compared to other times of day, independent of trial. Brachial SBP was lower ($P < 0.05$) during Nt (120.5 ± 4.5 mmHg) compared to morning (Mn, 131.6 ± 5.6 mmHg); afternoon (An, 132.3 ± 5.2 mmHg) and evening (Evn, 134.4 ± 5.3 mmHg). Central SBP was lower during Nt (112.7 ± 4.4 mmHg) compared to morning (Mn, 120.8 ± 4.9 mmHg); afternoon (An, 119.3 ± 4.5 mmHg) and evening (Evn, 123.0 ± 4.5 mmHg). **CONCLUSION:** An acute bout of moderate intensity exercise in accordance with the physical activity guidelines, independent of delivery mode (continuous or intermittent), did not influence 24 hour ambulatory brachial or central hemodynamics in middle-aged and older men. Moreover, we show that reductions in central hemodynamics during night time hours (i.e., dipping) is not compromised after exercise. Future work should explore different exercise parameters to better understand the influence of acute exercise on ambulatory central hemodynamics.

720 May 29 3:30 PM - 3:45 PM

Maximal Exercise Blood Pressure and Glycemic Responses: Association with Resting Parameters in Healthy Young Adults.

Manuela Zanoletti-Mannello, Juan C. Cárdenas-Arciniegas, Sebastián C. Cortés-Rosero, Julio C. Bermúdez-Muñoz, Maritsabel Ruiz-Molina, Manuel A. Cárdenas-Romero. *Pontificia Universidad Javeriana, Bogotá, Colombia.*

Email: manuzanoletti@gmail.com

(No relevant relationships reported)

Hypertension and hyperglycemia are known components of the metabolic syndrome. Massive adrenergic stimulation during high-intensity exercise has been associated to high blood pressure (BP) and blood glucose concentration. The predictive value of exercise-induced hypertension is an area of active research. An exaggerated and persistent hyperglycemia induced by intense exercise has been described in type-1 diabetics. For healthy subjects is not clear if BP and glycemic responses during maximal exercise are correlated with resting BP and glycemic values within the span of normal range.

PURPOSE: To find the association between resting and maximal exercise BP and glycemic responses in healthy young adults.

METHODS: An exploratory analysis was conducted on 145 young adults (63 female) aged 18-25 deemed healthy by medical and anthropometric evaluation (body mass index 18.4 - 24.9) as well as laboratory tests, including a complete metabolic profile. All subject had normal resting BP, glycated hemoglobin A1c (HbA1c) and fasting glucose concentration (FG) values. On a separate day subjects performed a maximal ramp cardiopulmonary exercise test (CPET) on a cycle ergometer; capillary blood glucose concentration (cBG) and BP were measured every 2.5 minutes. Pearson product-moment correlations between resting and exercise parameters were assessed with a significance level < 0.05 . Separate analysis were made for males and females.

RESULTS: The analysis for the female group is presented: at maximal workload, cBG was correlated with HbA1c ($r = 0.29, p = 0.016$) while diastolic BP was correlated with resting diastolic BP ($r = 0.26, p = 0.034$). Overall, maximal cBG was correlated with HbA1c ($r = 0.27, p = 0.025$) and FG ($r = 0.27, p = 0.026$) and maximal systolic BP was correlated with resting systolic BP ($r = 0.27, p = 0.0009$).

CONCLUSIONS: For healthy young females BP and glycemic parameters at rest were positively associated with cBG and BP responses at or near maximal workloads during CPET. In otherwise healthy adults with resting BP and BG values in the upper limit of normal, acute intense exercise could play a role unmasking early subclinical cBG and BP changes in the metabolic syndrome continuum. The predictive and prognostic role of these findings remains to be determined.

Ambulatory Blood Pressure Reduction In Response To Supramaximal Interval Exercise; Interactions With Antihypertensive Medication.

Miguel Ramirez-Jimenez, Felix Morales-Palomo, Juan F Ortega, Ricardo Mora-Rodriguez. *UNIVERSIDAD DE CASTILLA-LA MANCHA, Toledo, Spain.*

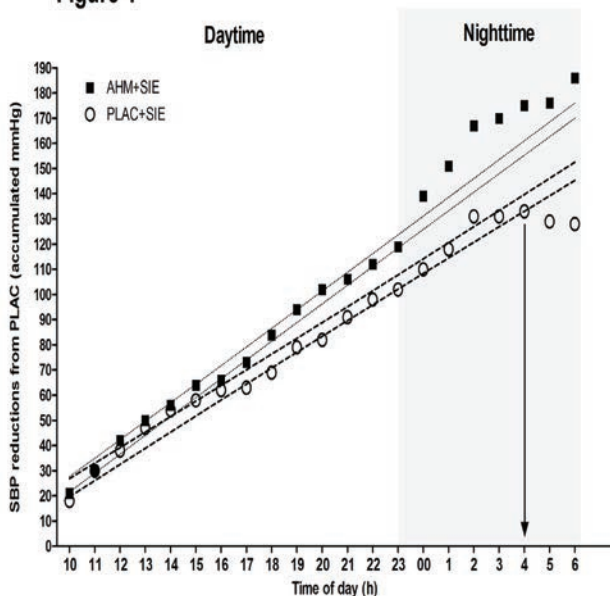

Email: miguel.ramirez@uclm.es

(No relevant relationships reported)

Metabolic Syndrome (MetS) increases the risk of cardiovascular and all-cause mortality. High blood pressure is the most frequent factor of MetS. General guidelines for hypertension recommend both pharmacological and exercise treatment while their combined effects on blood pressure have not been thoroughly explored yet. **Purpose:**

To compare the blood pressure (BP) response to a bout of supramaximal aerobic interval exercise (SIE) alone or in combination with antihypertensive medication in MetS hypertensive patients. **Methods:** Twelve patients chronically medicated with angiotensin II receptor 1 blockade antihypertensive medicine (AHM), underwent 3 trials separated by 1 week in a randomized order: *a*) control trial without exercise and substituting their AHM by a placebo (PLAC); *b*) placebo medicine and a morning bout of SIE (PLAC+SIE) and *c*) combining AHM and exercise (AHM+SIE). Acute and ambulatory blood pressure responses were measured for 21-h after treatments. Repeated-measures crossover, double-blind, placebo randomized design was used. **Results:** Acutely (i.e., 20 min after treatments), systolic blood pressure (SBP) were reduced similarly after PLAC+SIE (-9.7 ± 6.0 mmHg, $P < 0.001$) and AHM+SIE (-10.4 ± 7.9 mmHg, $P = 0.001$). Chronically, (21-h following treatments) SBP remained reduced after PLAC+SIE (125 ± 12 mmHg, $P = 0.022$) and AHM+SIE (122 ± 12 mmHg, $P = 0.013$) in comparison to PLAC (132 ± 16 mmHg). The BP reduction in PLAC+SIE faded out at 4 a.m., whilst in AHM+SIE continued over the complete measurement period (Figure 1). At nighttime BP reduction was larger in AHM+SIE than PLAC+SIE (-5.6 ± 4.0 mmHg, $P = 0.006$). **Conclusion:** Our data show that a bout of supramaximal aerobic interval exercise in combination with antihypertensive medication in the morning elicits a sustained blood pressure reduction that lasts at least 21-h. Exercise potentiates the effects of antihypertensive medicine reducing blood pressure longer and at a larger magnitude than exercise alone.

Cardiorespiratory Fitness & Healthy Vascular Aging
 Nicholas A. Carlini, Matthew P. Harber, FACSM, Bradley S. Fleener. *Ball State University, Muncie, IN.*
 (No relevant relationships reported)

Healthy Vascular Aging (HVA), defined as carotid femoral pulse wave velocity (cfPWV; arterial stiffness) < 7.6 m/s and absence of hypertension in adults ≥ 50 years of age, is associated with lower incidence of cardiovascular disease (CVD). Higher cardiorespiratory fitness (CRF) is associated with lower CVD mortality; however, the relation between HVA and CRF has not been examined. **PURPOSE:** To determine the relation between HVA and CRF in an apparently healthy adult population. **METHODS:** One hundred and one individuals (54M/47F) with a mean age of 63.5 ± 0.8 years and body mass index (BMI) of 28.3 ± 0.5 kg/m² underwent measures of vascular hemodynamics (cfPWV; resting blood pressure, BP), CRF (VO_{2max}), and traditional CVD risk factors. Participants were divided into either the HVA or no-HVA groups based on the resting cfPWV and BP values and medication status. Data were analyzed with unpaired t-tests and Pearson correlations. **RESULTS:** HVA was present in 25% (n=25) of the subjects, while 75% (n=76) had no-HVA. Compared to no-HVA, HVA were younger (59.7 ± 1.8 vs. 64.7 ± 0.9 years, $p < 0.05$), had lower cfPWV (6.7 ± 0.1 vs. 8.5 ± 0.1 m/s, $p < 0.05$) and systolic BP (111.2 ± 2.5 vs. 117.6 ± 1.5 mmHg, $p < 0.05$). CRF was not different between groups (27.2 ± 1.4 vs. 25.2 ± 0.8 ml/kg/min, $p > 0.05$), but age and sex adjusted CRF percentiles according to the Fitness Registry and Importance of Exercise National Database (FRIEND) demonstrated greater CRF in HVA vs. no-HVA ($62\% \pm 5.7$ vs. $47\% \pm 3.0$, $p < 0.05$). HVA compared with no-HVA had lower ($p < 0.05$) BMI (26.3 ± 1.1 vs. 29.0 ± 0.6 kg/m², $p < 0.05$), waist circumference (88.9 ± 2.8 vs. 98.5 ± 1.6 cm, $p < 0.05$), and blood glucose (91.8 ± 2.1 vs. $103.4 \pm$

2.6 mg/dL, $p < 0.05$). cfPWV ($r = -0.3406$) and bSBP ($r = -0.3202$) were both inversely correlated with the FRIEND percentiles ($p < 0.05$, both). **CONCLUSIONS:** Our findings indicate HVA is associated with greater CRF. These data support the notion for lower CVD-related mortality with higher levels of CRF may be attributable, in part, to HVA.

723 May 29 4:15 PM - 4:30 PM
The Differential Effects Of Amount, Intensity, And Mode Of Exercise Training On A Novel Lipoprotein Multimarker Of Insulin Resistance
 Leanna M. Ross¹, Cris A. Slentz¹, Irina Shalaurova², Margery A. Connelly², James D. Otvos², Connie W. Bales¹, Joseph A. Houmard, FACSM³, William E. Kraus, FACSM¹. ¹Duke University Medical Center, Durham, NC. ²Laboratory Corporation of America Holdings (LabCorp), Morrisville, NC. ³East Carolina University, Greenville, NC.
 (No relevant relationships reported)

Purpose To examine the effects of amount, intensity, and mode of exercise training on Lipoprotein Insulin Resistance Index (LP-IR; a relatively new spectroscopic multimarker of insulin resistance) across 10 exercise interventions from the STRRIDE studies. **Methods** A total of 531 men and women with dyslipidemia [STRRIDE I (n=222) and STRRIDE AT/RT (n=142)] or prediabetes [STRRIDE-PD (n=167)] were randomized to either control group or one of 10 exercise interventions, which ranged from doses of 8-22 kcal/kg/week (KKW); intensities of 50-75% $\dot{V}O_{2peak}$; and durations of 6-9 months. Two groups included resistance training and one group included dietary intervention (weight loss goal of 7%). Fasting blood samples were obtained at both baseline and 16-24 hr after the final exercise bout. NMR spectroscopy was performed at LabCorp to determine LP-IR score, which is comprised of six lipoprotein subclass and size parameters. LP-IR score ranges from 0 (most insulin sensitive) to 100 (most insulin resistant). Paired t-tests determined post- minus pre-intervention change score significance within groups ($p < 0.05$). Study-specific ANCOVA determined differences between groups. **Results** The inactive control group did not significantly change LP-IR. After training, seven of the 10 exercise groups significantly improved LP-IR, ranging from -4.0 ± 7.6 to -12.5 ± 14.2 . The figure displays change scores across all groups. The Aerobic plus Resistance group resulted in significantly greater change than the Resistance only group in STRRIDE AT/RT. The Moderate plus Diet group had significantly greater LP-IR change than all other groups in STRRIDE-PD. **Conclusion** On average, STRRIDE interventions improved LP-IR. Our results provide compelling evidence that adding resistance to aerobic training elicits a synergistic training effect on LP-IR. In individuals with prediabetes, incorporating dietary intervention with aerobic training results in the most robust LP-IR improvement.

724 May 29 4:30 PM - 4:45 PM
Effect of Aerobic Exercise on Blood Glucose and CVD Risk in Glucose Metabolism Disorders People
 Yan Wang, Shousheng Xu, Xuemei Li, Juan Wang, Zhengzhen Wang, FACSM. *Beijing Sport University, Beijing, China.*
 (Sponsor: Zhengzhen Wang, FACSM)
 (No relevant relationships reported)

It's essential for glucose metabolism disorders people to monitor the change of blood glucose, heart rate (HR), systolic blood pressure (SBP) during and after exercise in order to prevent hypoglycemia and CVD risks. **PURPOSE:** To determine blood glucose after aerobic exercise in glucose metabolism disorders people, and to monitor recovery of HR and SBP. **METHODS:** By PAR-Q and OGTT, 58 subjects were divided

into : normal glucose metabolism group (N,n=18), impaired fasting glucose (IFG) group (PD,n=20), and diabetes group (D,n=20). Everyone completed 30-minute cycle ergometer at 45%-55%HR. According to assessment standard of HR recovery and abnormal standard of SBP increasing during exercise, the CVD risk was judged. All subjects were provided the same amount diet, and exercise began just after one hour of the meal. All wrote consent, and the study was approved by the ethical committee of BSU. **RESULTS:** (1) Compared with blood glucose at the beginning of the exercise, the decreased amount of PD and D were bigger than N's (At the moment of finishing exercise, blood glucose of N, PD and D decreased respectively 2.19 ± 1.25 mmol/L, 3.59 ± 1.47 , 3.19 ± 2.02 ; at 1h-point after exercise, 1.31 ± 1.25 , 2.29 ± 2.63 , 2.66 ± 2.57 ; at 2h, 2.11 ± 1.31 , 3.72 ± 1.77 , 4.66 ± 2.47 , $P < 0.05$.) (2) The fluctuation of blood glucose in PD and D were much sharper than N's when the data of seven time-point samples were calculated (1.62 ± 0.53 , 1.96 ± 0.73 , 1.11 ± 0.44 , $P < 0.05$ and $P < 0.01$), and the seven time-points followed as fasting glucose, 1h after meal, the moment just finishing exercise, 15min, 30min, 1h, 2h in turn. (3) As to N, PD, D's HR, the incidences of abnormal recovery at the 1st minute after exercise were 6.7%, 13.3%, 13.3% respectively, and the incidences of SBP abnormal increase during exercise were 20%, 33.3%, 60%. **CONCLUSIONS:** (1) The study found blood glucose of healthy or glucose metabolism disorders people after aerobic exercise changed regularly: decreased remarkably at the end of exercise, and then increased gradually with its peak at 30min, recovering almost entirely at 2h-point. (2) IFG subjects benefited more in blood glucose from 30min aerobic exercise than diabetes. (3) The CVD risk of exercise for diabetes patients was higher than that for IGR people and healthy ones. Supported by Research on Prevention and Control of Major CNCD (2016YFC1300202).

725 May 29 4:45 PM - 5:00 PM

Differences in Daytime vs. Night-time Travel Stress and Recovery as Measured by Heart Rate Variability

Christa Janse van Rensburg, FACSM, Catharina C. Grant, Audrey Jansen van Rensburg, Dimakatso A. Ramagole, Gehart Kalmeier. *Sports Medicine, University of Pretoria, Pretoria, South Africa.*

Email: christa.jansevanrensburg@up.ac.za

(No relevant relationships reported)

Purpose: Air travel over several time zones causes disruption of circadian rhythms resulting in disorientation, nausea, gastrointestinal distress and difficulty concentrating. This may compromise health and decrease performance in travelling athletes. Heart rate variability (HRV) used to assess autonomic cardiac control may be an indicator of jetlag. This case study investigated trans-meridian travelling effects on the autonomic nervous system (ANS) by measuring time domain (RMSSD), high frequency domain (HF) and autonomic balance (LF/HF) indicators. **Methods:** A recreational athlete was monitored on tour from South Africa (SA) to New Zealand (NZ) for 28 days. HRV measurements were averaged over 3 days/nights and reported as means (SD): a) after a 18 hour flight from SA, b) after 1 week in NZ, c) after 2 weeks in NZ, d) upon return to SA. **Results:** Active daytime vagal cardiac influence showed a return to normal/higher values measured after 2 weeks of arrival in Auckland, with a marked decline directly upon return to SA; RMSSD (ms): a) 45.63 (23.88), b) 62.90 (32.20), c) 67.00 (40.06) and upon return to SA d) 43.50 (25.75); HF (ms^2): a) 613.33 (366.11), b) 1164.00 (632.90), c) 1324.50 (795.30) and upon return to SA d) 834.33 (849.58). However, night time measurements indicated a decrease of the vagal control set point. RMSSD (ms): a) 52.37 (26.93), b) 50.55 (29.29), c) 46.80 (27.02) and upon return to SA d) 36.07 (18.12); HF (ms^2): a) 829.33 (471.39), b) 772.50 (451.86), c) 530.00 (309.22) and upon return to SA d) 336.00 (179.77). Daytime autonomic balance (LF/HF) followed the same pattern, returning to lower/normal values after 2 weeks in NZ, and upon homecoming values reversed, signalling a new stress response due to the return flight: a) 3.66 (1.97), b) 2.83 (1.66), c) 2.71 (1.59) and finally d) 7.64 (4.50). Night time LF/HF values had small increases during the first 2 weeks with a stress response upon return to SA: a) 2.81 (1.62), b) 2.83 (1.66), c) 3.25 (1.88) and d) 6.40 (3.39). **Conclusion:** Reduced daytime vagal control improved with time (i.e. ANS adaptation) following international travel, illustrating the potential for HRV quantification as a jetlag marker. A novel finding is that during periods of travel it appears if autonomic cardiac control, as measured by HRV during daytime, differs to the nocturnal response.

726 May 29 5:00 PM - 5:15 PM

Autonomic Modulation Adjustments In Two Different Ergometric Tests In Young Adults

Giovanna Lima de Oliveira, Vanessa Ferrari da Fonseca, Beatriz Pozzolo, Amanda Archeleiga Guedes, Adriana Hernandez Marques, Taís Capucho Santos, Fernanda Panacioni, Aurezo Mocelin, Renata Labronici Bertin, Anderson Zampier Ulbrich. *UFPR, Curitiba, Brazil.*

Email: gilima0914@gmail.com

(No relevant relationships reported)

An inadequate position while performing an ergometric test (ET), specifically by grasping tightly the front or side rails, can lead to a misinterpretation of a person's physical capacity and hemodynamic responses. **PURPOSE:** This study has compared heart rate variability (HRV) kinetics throughout an ET executed in two different positions. Wherefore, was tested the hypothesis of an overestimated autonomic dynamic in ET while performed in an incorrect position. **METHODS:** Thirty-five undergraduates (21.08 ± 2.98 years old) of both sexes, volunteered to undertake two treadmill ET on *Ellestad* protocol, in non-consecutive days. The first test (T1) was performed in an inadequate position and, after seven days, the second test (T2) without holding the front or side rails of the treadmill. Autonomic function was measured by HRV during both tests and resting. Repeated comparisons of HRV variables on each stage of *Ellestad* protocol on ET were performed with *two way ANOVA* and multivariate linear regression, considering *P* values of < 0.05 . **RESULTS:** Estimated value of peak oxygen uptake (VO_2) was 22.4% higher in T1 ($P < 0.0001$) when compared to T2. Overall, parasympathetic pathway was deactivated earlier in T2 than in T1, showed by NNxx ($P < 0.005$) and HF ($P < 0.05$). In stage two, mean values of HF in T2 corresponded to 32% of values in T1 ($P < 0.048$). Stage three presented a difference of 60% ($P < 0.014$) in LF between means reached in T1 and T2. An association of LF and VO_2 was verified in early stages of both ET's. Each increase of one ms^2 in LF added up 0,013ml.kg.min in VO_2 mean. **CONCLUSION:** When performed on the right positioning, the duration of the test is closer to real effort undertaken. Parasympathetic component stays activated for a longer period when the person grasps the rails of the treadmill because maximum effort is reached later.

Figure 1. HRV frequency domain components dynamic during both ETs. Graphic analysis in each stage of T1 and T2 for: (A) high frequency component (HF), (B) low frequency component, (C) LF/HF and (D) very low frequency component (VLF). Values are expressed in means in each stage for both tests. CPX is cardiopulmonary exercise, without recovery, REC is recovery time of 3 minutes; S1: stage one; S2: stage two; S3: stage three; S4: stage four; S5: stage five; S6: stage six; S7: stage seven. * $P < 0.05$

Buttock Pain - Cross Country Skier

Jake H. Reisner, Elena J. Jelsing. *Mayo Clinic, Rochester, MN.*
Email: reisner.jacob@mayo.edu

(No relevant relationships reported)

HISTORY: A 32 year old male cross country skier presented with a multi-year history of right posterior “deep” buttock pain. He endorsed associated radiation down his posterior right thigh, leg and into the plantar foot. He described “burning” and “tingling” that increased with prolonged sitting and standing. Surgical history was significant for bilateral hip arthroscopic surgeries for femoral acetabular impingement. He denied any significant weakness or change in bowel/bladder function.

PHYSICAL EXAMINATION: Exam revealed right toe flexor weakness. Straight leg raise reproduced his right lower limb and buttock pain. Reflexes were physiologic and symmetric. Hip range of motion was full and pain free. Intraarticular provocative maneuvers were negative. He had tenderness to palpation of his deep hip external rotators. FABER’s test and passive piriformis stretch reproduced his right buttock and lower limb symptoms.

DIFFERENTIAL DIAGNOSIS:

- S1 Radiculopathy
- Sacroiliac Joint Dysfunction
- Piriformis Syndrome
- Hip Osteoarthritis
- Proximal Hamstrings Tendinopathy
- Ischiofemoral Impingement Syndrome

TEST AND RESULTS: Lumbar spine x-rays showed anterolisthesis of L5 on S1 with associated disc space narrowing and MRI showed paracentral disc protrusion at L5-S1 effacing the right S1 nerve root. Electromyogram showed evidence of a chronic, inactive right S1 radiculopathy. Ultrasound of the right hip identified a small nerve fascicle, separate from the sciatic nerve, appearing to pierce the piriformis muscle. MRI of the pelvis with lumbosacral plexus protocol demonstrated the sciatic nerve coursing deep to the right piriformis muscle and identified the right S2 nerve root coursing through the piriformis muscle.

FINAL WORKING DIAGNOSIS:

Piriformis syndrome resulting in active, compressive, right S2 neuritis
Superimposed, chronic, inactive right S1 radiculopathy

TREATMENT AND OUTCOMES:

Extensive PT with plateau in improvement.
No relief with right S1 selective nerve root block.
Ultrasound guided piriformis corticosteroid injection provided temporary relief of buttock pain.
Ultrasound guided sciatic nerve hydrodissection coupled with neural flossing provided several months of relief and allowed the patient to return to cross country skiing.
Surgical referral for consideration of piriformis release.

731 May 29 3:35 PM - 3:55 PM

A Simple Leg Injury? - World Champion Super-Heavyweight Weightlifter

David Cole¹, Ryan Rompolo², Mark E. Lavallee, FACSM¹. ¹York Hospital - WellSpan Health, York, PA. ²Franciscan Health Sports Medicine, Lafayette, IN. (Sponsor: Mark E. Lavallee, FACSM)
(No relevant relationships reported)

HISTORY: A 41-year-old male Bulgarian was lifting in a Masters Championship in Barcelona in the 105+kg weight class. The first series was the snatch with his first attempt at 115 kg (254 lbs) going well and without pain. On his second attempt at 121 kg (267 lbs) he experienced some anterior left thigh pain. He attempted the third at 126 kg (278 lbs) unsuccessfully. After a short break he attempted the clean and jerk series first at 145 kg (320 lbs) and had a good lift. He attempted his second clean and jerk at 150 kg (331 lbs) at which point his pain increased and he forfeited the last attempt. Overnight at his hotel his pain intensified, and he sought care at a local ER. He was subsequently discharged with no imaging, intervention, or treatment plan. The following morning, he presented to the event medical tent with worsening pain, swelling and difficulty with bearing weight on his left lower extremity. **PHYSICAL EXAMINATION:** Appreciable difference in thigh size, no erythema with mild lacey bruising over left knee and distal to the knee joint. Right thigh measuring 65cm and left thigh measuring 72cm. Marked tenderness to palpation over the superior quad tendon and over the bodies of the rectus femoris and vastus lateralis. Limited hip and knee flexion, with endorsed pain in anterior thigh and superior aspect of patella. Sensation intact, Palpable femoral, DP, PT pulses. **DIFFERENTIAL DIAGNOSIS:** 1. Quadriceps hematoma 2. Superior patella avulsion fracture 3. Quadriceps tendon tear 4. Morel-Lavallee Lesion 5. Evolving thigh compartment syndrome **TEST AND RESULTS:** Plain film showed superior pole avulsion fracture of the left patella and soft tissue swelling suggestive of hematoma. MRI obtained 4 days following evaluation indicated significant diffuse edematous changes of muscle and fascia with interstitial hematoma and evidence of muscle body rupture of the vastus lateralis **FINAL/WORKING DIAGNOSIS:** Left vastus lateralis rupture with avulsion fracture of the superior pole of the patella **TREATMENT/OUTCOMES:** Sent back to ER, radiograph obtained, placement in a long leg splint and LMWH given. Inability to obtain better imaging in Spain due to cost. Orthopedic evaluation upon return to Bulgaria within 4 days of injury with subsequent MRI. Patient treated conservatively with rehab and no surgical intervention.

732 May 29 3:55 PM - 4:15 PM

Left Anterior Hip and Groin Pain-Rowing

Jeffrey Smith, Kentaro Onishi. *UPMC, Pittsburgh, PA.* (Sponsor: Brian Davis, FACSM)
Email: smithjd7@upmc.edu
(No relevant relationships reported)

HISTORY

21 year old female division I rower with history of left L5 radiculopathy s/p L5-S1 microdiscectomy and foraminotomy presented with a 3 month history of dull, deep, aching anterior hip pain radiating into the groin, provoked by hip flexion, prolonged sitting, and rowing. Her symptoms started after a 15 mile row. She complained of quadriceps weakness worsening over the past month. She tried NSAIDs, heat, ice, and stretching without success. A separate provider ordered EMG/NCS for radiculopathy workup, which showed an L5 radiculopathy, but did not investigate the rectus femoris, medial femoral cutaneous nerve or saphenous nerve.

PHYSICAL EXAMINATION

Atrophy of the quad musculature. No gait abnormalities. She was nontender to palpation at the greater trochanter, ischial tuberosity, piriformis, and quadratus femoris. Active and passive ROM of hip was full and not painful. Strength was 5/5 except knee extension was 4/5. Sensation intact in all dermatomes of lower extremity. Negative log roll test. Positive Stinchfield, femoral nerve stretch and Tinel’s over anterior hip reproducing pain. Straight leg raise produced posterior leg and back pain. FABER and FADIR produced anterior hip pain.

DIFFERENTIAL DIAGNOSIS

1. Acetabular labral injury
2. Femoral neuropathy
3. High lumbar spinal stenosis
4. High lumbar disc herniation
5. External Iliac artery fibrosis

TEST AND RESULTS

Lumbar MRI: no abnormalities at L1-L4, scar tissue at L5-S1 causing mild flattening of the S1 nerve root and a shallow disc bulge at L4-L5 with no canal or foraminal stenosis

Pelvic MRI: no compressive lesions in the lumbosacral plexus and no labral injury
Diagnostic ultrasound of the anterior hip: negative based on a complete ultrasound following AIUM protocol

FINAL/WORKING DIAGNOSIS

Labral injury vs femoral neuropathy, chronic L5 radiculopathy
TREATMENT AND OUTCOME

Initial treatment was a diagnostic ultrasound guided (USG) intraarticular hip injection with local anesthetic with no response. This was followed by an USG femoral nerve diagnostic hydrodissection with lidocaine that provided short term relief. 1 week later, she received an USG femoral nerve hydrodissection with 15cc of D5W and sent for femoral nerve focused therapy. At 3 month follow up she had relief of her symptoms. She is now assistant coach for the rowing team with no symptoms.

733 May 29 4:15 PM - 4:35 PM

Acute Proximal Posterior Thigh Pain in a Division 1 Women's Soccer Player

Alyssa Neph, Steven Schaaf, Kentaro Onishi. *UPMC, Pittsburgh, PA.* (Sponsor: Brian Davis, FACSM)
Email: nepham@upmc.edu

(No relevant relationships reported)

HISTORY: A 22-year-old female soccer player for a Division 1 College team with a previous history of contralateral hamstring injury a year ago presents to the training room with acute onset left posterior thigh pain. She was seen in the training room 5 days prior with an ache in the posterior thigh. Sideline ultrasound was unremarkable for any abnormality at that time. Pain worsened while performing a drill during practice so she presents for re-evaluation. **PHYSICAL EXAMINATION:** No obvious gait abnormalities. No ecchymosis over posterior thigh. Tender to palpation at left proximal semitendinosus muscle belly but no palpable defect noted. Resisted knee flexion/hamstring activation and reverse plank reproduced pain. Strength was full and symmetric and sensation intact in bilateral lower extremities. **DIFFERENTIAL DIAGNOSIS:** 1. Acute medial hamstring strain/tear 2. Proximal medial hamstring tendinitis 3. Ischial bursitis 4. Adductor strain **TEST AND RESULTS:** Limited training room ultrasound reveals separation in the layers of investing fascia of semitendinosus/biceps femoris interval with sonopalpation tenderness reproducing her concordant symptom at the proximal hamstring region. There were no signs of muscular injuries on ultrasound. **FINAL WORKING DIAGNOSIS:** Acute left proximal semitendinosus/biceps femoris fascia tear without sonographic evidence of muscle strain in a senior soccer player with 3 games left of her career. **TREATMENT AND OUTCOMES:** Using sonographic guidance, 4 cc of autologous conditioned plasma (ACP/PRP) was injected at the site of fascial abnormality. Patient remained prone for 5 minutes following the injection followed by application of ACE wrap for the next 2 hours and use of thigh compression until she was pain free. She was instructed to rest completely for 24 hours with a progressive rehabilitation program to return to play. At 6 days post procedure, she progressed to jogging and warm up exercises with minimal residual pain but was advised to continue to refrain from soccer. At 1-week post procedure she was completely pain free and was cleared to return to play in the game the following day. She then returned as a starter in the last game of the season, 11 days post injection, and even assisted a goal that led to her team's win. She is now 22 days post injury and remains pain free.

734 May 29 4:35 PM - 4:55 PM

Right Lateral Hip Injury - Squash

Jacqueline M. Spangenberg, Monica E. Rho. *Shirley Ryan AbilityLab, Chicago, IL.*
Email: jspangembe@sralab.org

(No relevant relationships reported)

HISTORY

55 year old elite male squash player felt a sudden onset of hip pain mid match. As he lunged to his left to return a ball, his left leg was in the stance phase and his right leg was in the swing phase, crossing over his body towards his left side. While mid-swing of the right leg, he heard a pop in his right hip and could not bear weight on his right leg. The next day, he began to ambulate with a hiking stick for assistance. He reported to the outpatient sports medicine clinic 10 days after the injury presenting with lateral hip pain described as focal, dull and rated 1/10.

PHYSICAL EXAMINATION

5/5 strength in hip flexors, knee flexors and extensors. Tenderness to palpation of the anterior rim of the right iliac crest. No tenderness to palpation of the right PSIS, buttock, or greater trochanter. No pain with passive hip flexion, internal or external rotation. Pain with hip abduction in the side-lying position on the right, worse with the hip extended and with clamshells. Pain with single leg hop on the right. No sign of an antalgic gait.

DIFFERENTIAL DIAGNOSIS

Hip osteoarthritis
Iliopsoas tendonitis
Trochanter bursitis
Tear of gluteus medius muscle
Lumbar paraspinal muscle sprain

TESTS AND RESULTS

Right hip radiographs: No acute fracture, mal-alignment or osseous findings. Mild degenerative disease of the visualized lower lumbar space.

Ultrasound focused on the right lateral hip at the iliac crest: Appeared to be a 2 cm x 2 cm partial tear of the right gluteus medius muscle off of the iliac crest.

FINAL WORKING DIAGNOSIS

Right gluteus medius partial muscle tear at the attachment to the iliac crest

TREATMENT AND OUTCOMES

A non-load bearing mechanism of injury is unusual in this case, which could mean the patient had underlying degenerative changes to the gluteus medius prior to the injury. Physical Therapy (weeks 1-2 after evaluation) - progressive strengthening of hip girdle muscles with no direct gluteus medius muscle activation.

Repeat focused ultrasound at week 4 showed healing of the partial gluteus medius muscle tear.

Physical Therapy (weeks 4-8) - progressive strengthening exercises focusing on dynamic movements of the lower musculoskeletal extremity with a low-intensity return to squash program.

Return to squash matches starting at week 8 and painless hip abduction, extension and dynamic movements required for competitive squash.

735 May 29 4:55 PM - 5:15 PM

A Typically Female Hip Issue in a Male Basketball Coach

Keri L. Denay, FACSM. *University of Michigan, Ann Arbor, MI.*
Email: kschwide@med.umich.edu

(No relevant relationships reported)

HISTORY: 34 year-old male basketball player/coach with left hip pain. Pain anteriolateral for the last month with hip rotation and lying on left. No preceding injury or trauma. No pain at rest. Improves with sitting. No fever, chills, numbness, tingling, radiation, other joint involvement, swelling, erythema, catching, locking. No pertinent medical, surgical, or family history. No medications other than ibuprofen above. Works as a teacher and basketball coach, recreational basketball player. Denies tobacco, alcohol, or drugs.

PHYSICAL EXAMINATION: BMI 27. Trendelenburg gait, uncompensated and positive trendelenburg test on left leg standing. Internal rotation of the hip of 15 degrees with mild pain. External rotation of the hip unremarkable. Neurovascularly intact. Mild pain with passive, bent knee internal rotation. No pain with passive, bent knee external rotation. 5/5 strength with resisted straight knee hip flexion with + pain. 5/5 strength with resisted bent knee hip flexion, adduction, and abduction without pain. Negative FABER test for pain but decreased ROM, slightly worse than contralateral. Positive FADIR. Tender only at ASIS and along IT band. Positive Ober's test.

DIFFERENTIAL DIAGNOSIS: Osteoarthritis, Inflammatory arthritis, femoroacetabular impingement/labral pathology, fracture, lateral hip pain/gluteus medius tendinopathy and weakness, IT band syndrome, lumbar radiculopathy, infiltrative process/mass.

TEST AND RESULTS: X-ray: Decreased bone density within the left femoral head without fracture or mass. This could recommend transient osteoporosis of the hip. MR arthrogram: Subchondral insufficiency fracture in the superior aspect of the left femoral head with significant bone marrow edema in the left femoral head and neck. Small left anterior superior labral tear.

FINAL WORKING DIAGNOSIS: Transient osteoporosis of the left femoral head with subchondral insufficiency fracture and anterior, superior labral tear.

TREATMENT AND OUTCOMES: Crutches for pain-free guided weight-bearing and pain-free water exercise. 6 weeks after diagnosis, doing pain-free ADLs without difficulty. Physical therapy started. 6 months after diagnosis: x-ray with no fracture seen and improved bone density. Cleared for all activity without restrictions.

Bilateral Upper Extremity Weakness in a Wrestler

Kimberly S. Casten, Adam Lewno. *University of Michigan, Ann Arbor, MI.* (Sponsor: Robert Kinningham, FACSM)

(No relevant relationships reported)

HISTORY: A 19-year-old male college Wrestler with a history of right labral repair presented with 4-month insidious 10/10 neck pain and band-like pain over his shoulders. In the last month he developed bilateral dorsal hand paresthesias with shoulder fatigue while wrestling. After a month off, symptoms would emerge after 2-5 minutes of wrestling and progressively longer. No illness, increase in activity, color changes, temperature differences, loss of dexterity.

PHYSICAL EXAMINATION:

General: Well-developed male

Skin: No rashes or lesions

Vascular: Normal pulse and capillary refill

Neuromuscular: Normal muscle bulk and tone. Normal range of motion, strength, deep tendon reflexes, and sensation to light touch and pinprick in the bilateral upper extremities. Positive Tromner reflex bilaterally, otherwise negative special testing of the cervical spine, shoulder, scapula, and neurovascular bundle.

DIFFERENTIAL DIAGNOSIS:

1. Cervical Radiculopathy
2. Transient quadriplegia
3. Suprascapular or Axillary Mononeuropathy
4. Brachial Plexopathy
5. Thoracic Outlet Syndrome
6. Myopathy
7. Quadrilateral Space Syndrome
8. Spinal cord injury
9. Cervical facet pathology

TEST AND RESULTS:

Cervical MRI identified absent right C5 pedicle with no spinal cord signal abnormality.

C5 and C6 spinal nerve roots were separate with no dural extension

Cervical CT showed no fracture of the right C5 pedicle; likely congenital absence.

Anterior and posterior columns were normal

Cervical radiographs revealed no dynamic instability

Bilateral upper extremity electrodiagnostics were normal with no axillary or suprascapular mononeuropathy, upper trunk plexopathy, or radiculopathy.

FINAL WORKING DIAGNOSIS: Congenital absent right C5 pedicle with C6 subluxation

TREATMENT AND OUTCOMES:

1. Neurosurgical consultation which confirmed spinal stability with no restriction on sporting activities
2. Progressed from limited sporting activities including aerobic activities without upper body utilization and non-Olympic lower body weight lifting without barbell utilization, to stabilization exercises aimed at cervical musculature, trapezius, deltoids, and rhomboids.
3. Return to sport in process, focusing on Folk style wrestling given less submission and upper extremity rapid force transmission.

Back Injury - Crossfit

Kevin Bonfield. *University of Kentucky, Lexington, KY.*

Email: kevin.bonfield@uky.edu

(No relevant relationships reported)

HISTORY: A 31 year old female with obesity s/p gastric sleeve presents with left shoulder pain after an injury sustained performing a power clean during a crossfit session 2 months prior. At the top of the lift she felt a tearing pain between her scapula and spine that radiated all the way down her left arm and felt like numbness and tingling in her small three fingers. She has tried ibuprofen, ice, heat, and cyclobenzaprine which have only mildly improved her pain over the past 2 months. **PHYSICAL EXAMINATION:** Examination revealed a normal appearance to the left shoulder. Palpation noted for tenderness over the left rhomboid, trapezius. Tenderness over spinous process with tenderness at C6-C7 spinous processes. ROM of left shoulder intact with pain elicited on extension, abduction and external rotation. Strength 3/5 with forward flexion, abduction and external rotation. Positive Lift Off test.

DIFFERENTIAL DIAGNOSIS: 1. Cervical Radiculopathy 2. Rotator Cuff tear 3. Brachial plexopathy

TEST AND RESULTS: Left Shoulder x-ray- No acute findings. Spinal Survey AP/ Lat- Small ossific fragment along posterior aspect of C6 spinous process. Large ossific fragment between the C7 and T1 spinous processes. MRI Thoracic Spine w/ out Contrast- Old 50% compression deformity of T4. Syrinx in the lower thoracic spinal cord centered at T9 level measuring 4cm craniocaudally and 5mm in maximal transverse dimension. NM Bone Scan SPECT- Increased bone uptake at the spinous process of C7 extending between C7 and T1. 15mm well corticated fragment most compatible with healing fracture. C7 spinous process excisional biopsy pathology- Bone and dense peri-osseous soft tissue without significant histological abnormality.

FINAL WORKING DIAGNOSIS: C7 vertebral fracture with C7 spinous process ossicle

TREATMENT AND OUTCOMES: 1. Surgical Excision of the ossicle complicated by wound dehiscence and surgical site infection necessitating debridement and antibiotic therapy. 2. Cervical collar for 2 weeks weaned out of over the third week. 3. Lifting restriction of less than 10 pounds for 6 weeks. 4. Neck extension exercises out of the collar and isometric exercises. 5. Returned to activities as tolerated 3 months post op from original excision surgery with improvement in strength, range of motion and numbness symptoms.

Perplexing Presentation- Preserving Function

Germaine Herman. *Eskenazi Health System, Indianapolis, IN.*

Email: germaine.herman@eskenazihealth.edu

(No relevant relationships reported)

History:

A 60-year-old female with uncontrolled DM II, HTN, hyperthyroidism, tobacco abuse and depression arrived to physical therapy for evaluation of chronic left leg pain and weakness of sudden onset eight months prior. She reported constant pain including unremitting night pain, changes in bowel habits and a twenty five pound weight loss within the last six months. She denied urinary incontinence, night sweats, chills and fevers. She reported left knee buckling, falls, difficulty working as a bartender and completing daily activities. She endorsed non-adherence with medications and marijuana and non-prescription opiate use.

Physical Examination:

Examination revealed gross atrophy of the left thigh and left foot drop during gait. Sensation was decreased to light touch and deep pressure along L2-4 dermatomes in the left leg and was normal on the right. Reflexes were absent in L4/5 and S1 bilaterally; she had a negative Hoffman and Babinski bilaterally. Myotomes were 2-/5 proximal and 3+/5 distal to the knee on the left and 4/5 throughout on the right. There was flaccidity throughout the left leg. All other tests of the hip and spine including slump and straight leg raise tests were unremarkable.

Differential Diagnosis:

* Lower motor lesion with systemic etiology

* Malignancy

Tests and Results:

The physical therapist referred the patient back to the primary care physician (PCP) who ordered an abdominal CT and a spinal MRI. The patient was referred back to physical therapy. At re-evaluation one month later the patient presented with progressive motor loss scoring 3-/5 grossly on the right and 2-/5 grossly on the left leg. Sensory deficits extended to both lower extremities. Falls increased to thrice a week forcing patient to discontinue work. The patient was referred back to the PCP who admitted the patient to hospital for further workup. A brain MRI, myositis panel, aldolase, ANA and inflammatory markers were all unremarkable. EMG results revealed lumbosacral polyradiculopathy without evidence of myopathy.

Final/Working Diagnosis:

Diabetic Lumbosacral radiculoplexus neuropathy

Treatment and Outcomes:

* Glycemic and pain control were achieved and, after three weeks at an inpatient rehab facility, patient walked with a walker without falls. She returned to work without the walker despite an increase in falls.

742 May 29 4:15 PM - 4:35 PM

Osteomyelitis After Deadlifting Injury- A Rare Case Of A Burst Abscess

Edmund M. Qiao, Kenneth Vitale. *UCSD School of Medicine, La Jolla, CA.*

Email: emqiao@ucsd.edu

(No relevant relationships reported)

HISTORY: 68-yr old male weightlifter presented with 1 mo. L buttock pain, acute onset of popping mid-lift during a deadlift, with radiating vague pain in L buttock. He continued to exercise through pain and 1 wk later pain progressed to severe deep buttock pain and difficulty ambulating. Denied low back pain, radiating thigh/leg symptoms, numbness/tingling, weakness, or bowel/bladder changes. Past hx positive for melanoma (treated in remote past), social hx negative for smoking, drug/alcohol abuse. He initially went to outside facility (only lumbar x-rays taken) without improvement, came in for another opinion with progressive symptoms.

PHYSICAL EXAMINATION: Skin normal without warmth, erythema. Vague tenderness in region of L buttock and SI joint. Full lumbar spine and hip ROM. Negative SLR. Mild nonspecific back discomfort with FABER. Normal lower limb neurovascular exam.

DIFFERENTIAL DIAGNOSIS: 1. SI Joint Dysfunction 2. Lumbar Radiculopathy 3. Piriformis Syndrome 4. Lumbar or Sacral Compression Fracture 5. Metastatic Cancer 6. Sacroiliitis

TEST AND RESULTS: Outside lumbar x-rays negative for fracture, showed minimal degenerative disc changes. We obtained hip/pelvis radiographs showing significant erosions and destructive changes of L SI joint. An urgent MRI showed fluid-filled and widened SI joint, severe inflammatory sacroiliitis with extensive erosions and bone marrow edema, widespread reactive muscle edema (iliacus showing fluid collection/early abscess at SI joint); SI joint aspirate was obtained.

FINAL WORKING DIAGNOSIS: septic sacroiliac arthritis with iliacus abscess and secondary osteomyelitis; aspirate grew staphylococcus aureus (MSSA).

TREATMENT AND OUTCOMES: The patient had a unique etiology of osteomyelitis not commonly reported. Orthopedics and ID determined he had pre-existing asymptomatic abscess that ruptured. Under the extreme abdominal pressures of deadlifting, they felt abscess burst leading to local spread and secondary osteomyelitis. This case highlights the rapidity and widespread destruction of infectious arthritis and need for awareness and prompt workup. Patient was treated with 6 wks of oxacillin and responded well. He returned to baseline physical activity at follow up; repeat x-rays showed SI joint sclerosis and patient was counseled on SI joint arthritis.

B-44 Rapid Fire Platform - Distance Running

Changes in Shock Absorption and Kinematics during a Half Marathon as Measured with Inertial Sensors

Marit A. Zandbergen, Michel Klaassen, Jaap Buurke, Jasper Reenalda. *Roessingh Research and Development, University of Twente, Enschede, Netherlands.* (Sponsor: Brian W. Noehren, FACSM)

Email: m.zandbergen@rrd.nl

(No relevant relationships reported)

The repetitive impacts of the foot with the ground are hypothesized to be related to overuse injuries in running. Shocks caused by these impacts can be absorbed actively (i.e. muscle contractions) or passively (i.e. bones, tendons and ligaments). When fatigued, shock absorption is expected to shift from active to passive structures, increasing the risk of overuse injuries. Inertial sensors were used previously to quantify running mechanics in a real-world setting.

PURPOSE: To investigate shock absorption mechanisms between the tibia and sacrum in trained athletes during different phases of a Half Marathon, using inertial magnetic measurement units (IMUs).

METHODS: 8 trained athletes (5M 3F, 32.1±9.2 years, 177.4±8.1 cm, 67.8±7.5 kg) performed a Half Marathon during competition. A total of 8 IMU's (240 Hz) were placed at the feet, tibia, upper legs, sacrum and sternum. Parameters of interest included two indicators of impact; peak tibial acceleration (PTA) and peak sacral acceleration (PSA), and the knee angle at midstance (MS). Mean values over 100 strides were calculated bilaterally during three periods in the Half Marathon (1st km, halfway and 20th km). Paired sample t-tests were used to test for statistical differences in the parameters between the three periods.

RESULTS:

Both PTA and PSA increased significantly during a Half Marathon, despite a unilateral increase in knee angle at MS.

CONCLUSIONS:

In the first part of the Half Marathon, an increase in PTA did not increase PSA, probably due to an increase in shock absorption by active structures (i.e. unilateral increase in knee angle at MS). During the last part of the Half Marathon shock absorption decreased, resulting in an increased PSA. We speculate that fatigue caused the shock absorption mechanism to shift from active to more passive structures during the last part of the Half Marathon. Future research should determine if shock absorption by passive structures is sufficient to prevent overuse injuries.

Table 1. Mean values ± standard deviation for the selected outcome parameters during different phases of a Half Marathon during competition. PTA = peak tibial acceleration; PSA = peak sacral acceleration; MS = midstance.

Differences in Lower Extremity Kinematic Variability between Healthy Runners Classified as Low or High Mileage

Amanda Estep¹, Steven Morrison², Shane Caswell³, Nelson Cortes³. ¹Austin Peay State University, Clarksville, TN. ²Old Dominion University, Norfolk, VA. ³George Mason University, Manassas, VA.

(No relevant relationships reported)

Evidence suggests that running mechanics may differ between runners based on their weekly mileage; greater weekly mileage (WM) may act as a protective mechanism against injury. While the interaction between coordination patterns and WM has been investigated, interaction between lower extremity (LE) kinematic variability and WM has not. **PURPOSE:** To compare changes in LE kinematic variability between low (LM) and high mileage (HM) healthy runners after a prolonged run. **METHODS:** 23 healthy participants (27.4±7.7 yrs., 1.70±0.11 m, 67.9±15.4 kg, 16.3±5.6 km/week) were included in the LM group, while 12 participants (25.1±6.3 years, 1.71±0.1 m, 65.8±9.4 kg, 46.9±14.5 km/week) were included in the HM group. Participants ran on a treadmill for 30 minutes at a self-selected training pace. 3D kinematic data were collected after 5 minutes of running and again at the end of run at 200Hz using reflective markers placed on the lower body with 6 infrared cameras. Variables of interest included ankle, knee and hip sagittal and frontal plane angles. Standard deviation (SD) and coefficient of variation (CV) were calculated for each dependent variable (DV) at the beginning and end of the run. Approximate entropy (ApEn) was also calculated for each DV at both time intervals. Two repeated measures ANOVAs with time and joint as the within-subject factors and group as the between-subject factor, were used to compare kinematic variability. Post-hoc analyses were conducted for significant interactions. Alpha level was set at 0.05. **RESULTS:** Average running speed for the LM and HM group were 2.5±.3 m/s and 2.9±.4 m/s, respectively. In the sagittal plane, a significant interaction was found between joint and group ($F_{2,62}=5.5$, $p=.006$). Specifically, the HM group demonstrated greater amounts of variability (SD) than the LM group (LM=25.7±3.0; HM=29.5±3.7). No other statistically significant differences were attained.

CONCLUSIONS: Kinematic variability differed between the LM and HM groups, but only for the knee in the sagittal plane. Ankle and hip sagittal plane movement was comparable between the LM and HM groups. This may suggest that movement of the ankle and the hip do not differ in response to having to control variability at the knee. When assessing kinematic variability, it is important to consider the weekly mileage of each runner.

Are Joint Kinetics Proximally Redistributed Following A Long Run In Well-trained Runners?

Max R. Paquette, Victoria A. White, Jake A. Melaro, Douglas W. Powell, FACSM. *University of Memphis, Memphis, TN.* (Sponsor: Douglas Powell, FACSM) Email: mrpquette@memphis.edu
(No relevant relationships reported)

Proximal redistribution of joint work to the hip occurs following intensive running in novice runners [1] and might explain the reduced running economy following prolonged running [2]. These findings in novice might be different in well-trained runners due to their training status. **PURPOSE:** The purpose of this study was to assess if proximal redistribution of joint kinetics following a running bout is observed in well-trained runners. **METHODS:** 14 well-trained male runners with habitual rearfoot strike patterns (76±22km/week) completed 5 running trials at a speed equivalent to ±5% of their long run pace while 3D kinematic and ground reaction force data were collected before and after a treadmill run equal to 25% of weekly mileage (19±6km). Joint powers and work were calculated from these data using Visual3D. Percent contribution of each joint work relative to total lower limb joint work was computed. Paired samples t-tests were used to compare joint kinetics before and after the run ($p < 0.05$). Cohen's *d* effect sizes were computed to assess mean difference magnitudes. **RESULTS:** Peak ankle negative power (Table 1) and hip negative relative work contribution (pre: 14.3±3.6%, post: 15.6±4.5%, $p=0.041$; $d=0.33$) showed significant pre- to post-run effects. Positive ankle (pre: 50.6±6.8%, post: 49.5±7.3%, $p=0.35$; $d=0.16$) and hip relative work (pre: 26.2±10.1%, post: 27.1±8.8%, $p=0.53$; $d=0.10$) were unaffected by the long run in these well-trained male runners. **CONCLUSIONS:** These findings suggest that previously reported distal-to-proximal shift in positive joint work in novice runners following a running bout [1] is not observed in well-trained male runners. This might be the result of chronic training exposure in these trained runners and suggest a preservation of mechanical joint output despite prolonged running exposure. Differences in run type (intense vs steady prolonged run), foot strike, and gender might also be responsible for these differences between studies.

Table 1. Peak negative and positive joint powers ($W \cdot kg^{-1}$) before and after the prolonged run (mean±SD).

| Joint Kinetic Variables | Pre-Run | Post-Run | p-value | d |
|-------------------------|-----------|-----------|---------|------|
| Ankle negative power | -8.4±2.0 | -7.8±2.1 | 0.005 | 0.33 |
| Ankle positive power | 10.2±2.8 | 9.7±2.8 | 0.12 | 0.34 |
| Knee negative power | -13.5±2.6 | -12.8±2.3 | 0.16 | 0.39 |
| Knee positive power | 4.4±1.2 | 4.4±1.1 | 0.99 | 0.00 |
| Hip negative power | -3.3±1.9 | -3.4±2.1 | 0.73 | 0.05 |
| Hip positive power | 4.3±1.9 | 4.5±2.3 | 0.57 | 0.10 |

Notes: %: percent of total lower limb joint negative or positive work.

747 May 29 3:45 PM - 3:55 PM

Pelvic Motion Differences in Three Different Techniques of Jogging Stroller Propulsion

Tyler W. Standifird, Williams Lauren, Steven McCuch, Johnny Crimm, Caitlyn Stainbrook, Kirk Wyckoff. *Utah Valley University, Orem, UT.* (Sponsor: Douglas Powell, FACSM) Email: tyler.standifird@uvu.edu
(No relevant relationships reported)

Running with a jogging stroller has become a viable option for exercise in individuals serving as caregivers. Previous research has shown that stroller running leads to altered kinematics, but for many studies, running velocity was not constant between conditions. Some studies have reported altered trunk and pelvic motion during two-handed stroller running. **PURPOSE:** This study compared pelvic motion in all three planes of motion using various methods of pushing a stroller while running. **METHODS:** 13 recreational runners ran behind a Thule Urban Glide 2 jogging stroller suspended over an instrumented treadmill (Bertec, Inc, Columbus, OH). The study measured running in four different conditions: one with the participant's right hand on the handlebar (RH), another with left hand on the handlebar (LH), one with both hands on handlebar (BH), and running without the stroller (CON). The first three conditions were randomized between participants, but the final condition was always performed without the stroller. Biomechanical data were collected with Vicon Nexus 2.3 (Vicon, Inc., Oxford, UK) and processed through Visual 3D (5.0, C-Motion, Inc., Germantown, MD, USA). A repeated measures ANOVA was utilized to compare peak angles of the pelvis in all three planes of motion. **RESULTS:** The pelvis was more anteriorly tilted in the BH condition (25 ± 1.9°) compared to CON (23 ± 1.7°, $p=0.01$), RH (22 ± 2.0°, $p<0.01$) and the LH conditions (24 ± 1.9°, $p=0.04$). In the transverse plane only the LH (5.2 ± 0.75) and CON (5.6 ± 0.83°) conditions were similar. There was more right to left rotation of the pelvis in the BH condition (7.8 ± 0.7°) compared to the CON ($p=0.02$), RH (3.1 ± 0.88°, $p<0.01$) and the LH conditions ($p=0.02$). The RH was different from all other conditions for left to right rotation ($p<0.01$). There were no difference between conditions for pelvic obliquity, motion in the frontal plane, for any

of the four conditions. **CONCLUSIONS:** Running while behind a stroller alters some aspects of pelvic motion when compared with regular running. This is true for both one and two-handed stroller running. Pelvic motion plays a role in many aspects of running and altered mechanics in this region may lead to increased risk for injuries of the low back or lower extremity.

748 May 29 3:55 PM - 4:05 PM

Immediate Effects of a Textured Insole on Running Biomechanics in Rearfoot Strikers

Ann-Uriel H. Knausenberger¹, Matthew F. Moran¹, Justin C. Wager². ¹Sacred Heart University, Fairfield, CT. ²New Balance Sports Research Laboratory, Lawrence, MA.
(No relevant relationships reported)

Running biomechanics are influenced by footwear and insole properties. The sensorimotor system, specifically subcutaneous plantar receptors, play a role in initiating adaptive gait mechanics. Designed to increase afferent signaling via plantar surface deformation, an insole inlaid with a textured heel-plate (TI) is proposed to precipitate gait changes during running. **PURPOSE:** To compare biomechanical patterns during over-ground running between the TI and a non-textured insole (NI). **METHODS:** Nineteen rearfoot strike runners (24.9 ± 5.7 yo; 6 M, 13 F) performed twenty, 35-meter running trials under TI and NI conditions. Insole conditions were counter-balanced, and velocity was controlled (±5%). Plantar sensation was assessed using a 3.61g monofilament applied to seven standardized sites. Thirty-six reflective markers (dia.=16-20 cm), affixed bilaterally to lower extremity bony landmarks, were tracked via a 10-camera motion analysis system (120 Hz), and ground reaction forces were collected (1200 Hz). Visual3D and a custom Matlab script were used to determine lower extremity kinematics and kinetic variables. Perceived insole comfort was scored with a visual analogue scale. Dependent variables were analyzed using paired-samples t-tests; for data that violated assumptions, a Wilcoxon signed-rank test was utilized. **RESULTS:** Kinetic measures did not differ significantly between insole conditions; impact peak (NI=1.46±0.58 BW, TI=1.50±0.44 BW, $p=.74$), active peak (NI=2.37±0.16 BW, TI=2.35±0.15 BW, $p=.28$), loading rate (NI=35.9±12.2 BW/s, TI=34.0±13.2 BW/s, $p=.26$), peak braking (NI=-.31±.03 BW, TI=-.32±.06 BW, $p=.69$) and peak propulsion (NI=.27±.05 BW, TI=.27±.04 BW, $p=.28$). A significant increase in ankle internal rotation angle at initial contact was observed in the TI versus NI (NI=5.9 ± 5.9°; TI=7.3 ± 5.9°; $p=.01$, $d=.24$), however, no other significant kinematic differences were detected. NI (mdn=9.0) was rated as significantly more comfortable than TI (mdn=8.0) ($\tau=-2.026$ $p=.04$). **CONCLUSION:** Because kinematic and kinetic variables did not vary significantly between the TI and NI, the efficacy of the TI as a method of immediately altering running mechanics in a population of rear foot strikers should be further investigated. Comparison of Running Gait Kinematics Among College Students With and Without ASD

Brian Rios¹, Michael Salazar¹, Teri Todd¹, Melissa Mache², Danielle N. Jarvis¹. ¹California State University Northridge, Northridge, CA. ²California State University Chico, Chico, CA. Email: brian.rios.613@my.csun.edu
(No relevant relationships reported)

BACKGROUND: Autism Spectrum Disorder (ASD) is a developmental disability associated with difficulties in social communication and the presence of repetitive behaviors. Along with social impairments, motor deficits can be identified as another characteristic associated with ASD. Although gait deviations have been looked at in children with ASD, not much is known about how gait deviations may persist in college students with ASD. **PURPOSE:** To compare running gait deviations between college students with and without ASD. **METHODS:** Ten college students participated in this study. Five participants had a diagnosis of ASD (age 21.5±2.9 years) and 5 participants did not have an ASD diagnosis and comprised a healthy control (CON) group (age 24±3.5 years). Each participant performed 3 running trials over a 7.62 meter distance. Kinematic data were collected using a 12-camera 3D motion capture system. Stance and swing phase time, and hip, knee, and ankle angles at initial contact and at toe off were extracted for further analysis. Variables were compared between groups using independent t-tests. As this is a preliminary analysis with a small sample size, significance was set at $\alpha<0.10$. **RESULTS:** Individuals with and without ASD had similar lower extremity joint angles at initial contact (hip 60.21±13.13° ASD, 53.60±16.07° CON, $p=0.53$; knee 37.10±12.40° ASD, 43.48±3.30° CON, $p=0.36$; ankle 17.66±4.89° ASD, 18.18±6.47° CON, $p=0.90$). The two groups also demonstrated similar knee and ankle angles at toe off (knee 24.51±3.86° ASD, 19.36±4.28° CON, $p=0.11$; ankle -15.74± 6.45° ASD, -13.22±10.32° CON, $p=0.69$), but the ASD group demonstrated less hip extension at toe off (2.97±1.07° ASD, -2.02±4.60° CON, $p=0.07$). The ASD group also demonstrated longer stance phases (0.29±0.03s ASD, 0.23±0.02s CON, $p=0.02$) and shorter swing phases (0.40±0.05s ASD, 0.47±0.05s CON, $p=0.10$) compared to the control group. **CONCLUSION:** The

control group demonstrated more hip extension at toe off, which could suggest greater forward propulsion of the body. Greater propulsion is also associated with shorter ground contact times, and requires greater stability. The ASD group exhibited greater time in stance phase, and less time in swing phase, which could suggest potential balance deficits and less effective running patterns in college students with ASD.

Stride Frequency Manipulation: Physiological And Perceptual Responses During Backward Running With Body Weight Support

Kenji Masumoto¹, Daniel Denton², Andrew Craig-Jones², John A. Mercer, FACSM². ¹*Kyushu University, Fukuoka, Japan.* ²*University of Nevada, Las Vegas, NV.* (Sponsor: Professor John A. Mercer, FACSM)

(No relevant relationships reported)

Manipulation of stride frequency (SF) influences gait mechanics of forward running, regardless of body weight support (BWS). Nevertheless, no research has investigated the influence of a change in SF on physiological and perceptual responses during backward running with BWS.

PURPOSE: To investigate influence of a change in SF on physiological and perceptual responses during backward running at different levels of BWS. **METHODS:** Nine participants (33.2 ± 12.1 years) ran forward and backward at 0%BWS, 20%BWS, and 50%BWS conditions on a lower body positive pressure treadmill. The SF conditions consisted of forward and backward running at preferred stride frequency (PSF), PSF+10%, and PSF-10%. Oxygen uptake (VO_2), heart rate (HR), rating of perceived exertion (RPE), and muscle activity from the rectus femoris, biceps femoris, tibialis anterior, and gastrocnemius were measured. VO_2 , HR, RPE, and muscle activity from lower extremity were analyzed using a 2 (running direction) x 3 (BWS) x 3 (SF) repeated measures analysis of variance ($\alpha = 0.05$). **RESULTS:** VO_2 , HR, RPE, and muscle activity from the rectus femoris, tibialis anterior, and gastrocnemius were not influenced by the interaction of running direction, BWS, and SF ($P > 0.05$). VO_2 , HR, and muscle activity from the rectus femoris were significantly different between SF conditions ($P < 0.05$). For example, VO_2 and HR during running at PSF+10% were significantly higher than when running at PSF, regardless of running direction and BWS (e.g., 27.4 ± 5.7 ml/kg/min and 24.9 ± 4.3 ml/kg/min in VO_2 for PSF+10% and PSF during forward running at 50%BWS, respectively; $P < 0.05$). However, RPE was not different between SF conditions ($P > 0.05$). **CONCLUSION:** These observations suggest that manipulation of SF (i.e., a 10% change in SF from the PSF) during running may have greater impact on physiological responses than on perceptual responses, regardless of running direction and BWS. Supported by JSPS Grant Number 16K01663.

Non-Linear Relationship between Footstrike Angle and Vertical Loading Rate during Running

Mikel R. Stiffler-Joachim, Christa M. Wille, Bryan C. Heiderscheidt. *UW-Madison, Madison, WI.*
Email: joachim@ortho.wisc.edu

(No relevant relationships reported)

Footstrike is considered a primary determinant of lower limb mechanics during running. Indeed, vertical loading rates, often a focus of investigations into running-related injuries, are typically found to be lower in forefoot compared to rearfoot strikers fostering the belief that forefoot strike is desirable. However, prior work has shown that foot angle relative to the ground (foot inclination angle (FIA)) is a poor predictor of vertical loading rate when using a linear model, suggesting a more complex relationship is present. **PURPOSE:** To determine if a non-linear model improves the ability to estimate average vertical loading rate (AVLR) from FIA compared to a linear model.

METHODS: Whole body kinematics and vertical ground reaction forces (VGRF) were collected for 169 NCAA Division I athletes (96 males) during treadmill running at 2.68, 3.35, and 4.47 m/s. Athletes were healthy at testing, had no history of lower limb surgery, and no bone stress injury within 3 months prior to testing. FIA and AVLR were calculated for 15 strides and averaged across strides for each limb. FIA at initial contact was calculated, with positive and negative FIA indicating a more rearfoot and forefoot position, respectively. AVLR was the VGRF slope over 20-80% of the force from initial contact to impact peak or, when an impact peak was absent, to the force at 30.79% of time to peak VGRF. The relationship between FIA and AVLR was evaluated using linear and non-linear models at each speed.

RESULTS: AVLRs were lowest at the extremes of FIA (i.e., -15° , 20°), while greater AVLRs were observed between $5-10^\circ$. The non-linear model to estimate AVLR from FIA resulted in an approximate increase in R^2 values of 0.30 above the linear model at all speeds (linear: 0.13, 0.14, 0.12; non-linear: 0.46, 0.39, 0.44, for 2.68, 3.35, and 4.47 m/s, respectively). Model error was reduced in the non-linear models by 30-60 N/kg/s (linear: 165.2, 202.6, 293.4 N/kg/s; non-linear: 130.7, 170.9, 234.9 N/kg/s for 2.68, 3.35, 4.47 m/s, respectively).

CONCLUSIONS: AVLR among FIA reflective of forefoot strike was low, but AVLR varied considerably among FIA associated with rearfoot striking, indicating a distinct non-linear relationship. This supports that dichotomous treatment of FIA does not appropriately estimate AVLR and may bias models utilizing AVLR to assess injury risk.

B-53 Free Communication/Poster - High Intensity Training

Effects Of High-intensity Interval Training Vs Sprint Interval Training On Body Composition And Aerobic Power In Healthy Young Women

Paulo Gentil¹, João Pedro Naves¹, Ricardo Viana¹, Ana Cristina Rebelo¹, Claudio Andre de Lira¹, Gustavo Pimentel¹, Patricia Cristina Lobo¹, Jordana Oliveira¹, Rodrigo Ramirez-Campillo². ¹*Federal University of Goiás, Goiânia, Brazil.* ²*Universidad de Los Lagos, Osorno, Chile.*

(No relevant relationships reported)

PURPOSE: To compare the effects of two types of interval training, High-Intensity Interval Training (HIIT) and Sprint Interval Training (SIT), on anthropometric measures and cardiorespiratory fitness in healthy young women.

METHODS: A randomized clinical trial in which 49 young active women (age, 30.4 ± 6.1 years; body mass index, 24.8 ± 3.1 kg.m⁻²; peak oxygen consumption (VO_2peak), 34.9 ± 7.5 mL.kg⁻¹.min⁻¹) were randomly allocated into a SIT or HIIT group. The SIT group performed four bouts of 30 s all-out cycling efforts interspersed with four minutes of recovery (passive or light cycling with no load). The HIIT group performed four bouts of four-minute efforts at 90-95% of peak heart rate (HR_{peak}) interspersed with three minutes of active recovery at 50-60% of HR_{peak}. The protocols were performed three times per week (Monday, Wednesday, and Friday) for eight weeks. At baseline and after eight weeks of intervention, waist circumference, skinfolds (triceps, subscapular, suprailiac, abdominal and thigh), body mass and BMI were measured by standard procedures and cardiorespiratory fitness was assessed by cardiorespiratory graded exertion test on an electromagnetically braked cycle ergometer. **RESULTS:** The HIIT and SIT groups improved, respectively, $14.5 \pm 22.9\%$ ($P < 0.001$) and $16.9 \pm 23.4\%$ ($P < 0.001$) in VO_2peak after intervention, with no significant difference between groups. Sum of skinfolds reduced $15.8 \pm 7.9\%$ and $22.2 \pm 6.4\%$ from baseline ($P < 0.001$) for HIIT and SIT groups, respectively, with greater reduction for SIT compared to HIIT ($P < 0.05$). There were statistically significant decreases in waist circumference ($P < 0.001$) for the HIIT ($-3.1 \pm 1.1\%$) and SIT ($-3.3 \pm 1.8\%$) groups, with no significant difference between groups. Only SIT showed significant reductions in body weight and BMI ($p < 0.05$). No significant difference ($P > 0.05$) was found in dietary intake between the HIIT and SIT groups at baseline and after eight weeks of training.

CONCLUSIONS: Eight weeks of HIIT and SIT resulted in improvements in anthropometric measures and cardiorespiratory fitness, even in the absence of changes in dietary intake. In addition, the SIT protocol induced greater reductions than the HIIT protocol in the sum of skinfolds.

Application of High-intensity Interval Training Program of Increased Intensity and Decreased Volume: A Pre-competition Case

Guoqiang MA. *Shanghai Research Institute of Sports Science, Shanghai, China.*

Email: maguoqiang1978@163.com

(No relevant relationships reported)

The training effect of track-sprinted cycling largely depends on the completed riding intensity on track or ergometers. Especially before the big events, coaches normally arrange a training plan of gradually decreased volume. Meanwhile, the training intensity should be kept or increased, which is difficult to be achieved.

PURPOSE: To investigate the effect of seven high-intensity interval training (HIT) sessions with increased intensity for an elite female track-sprinted cyclist before the Hong Kong track cycling world cup in January 2015. **METHODS:** Seven sessions of HIT on Wattbike Pro cycle ergometer (UK) were completed in continuous three weeks (2 or 3 days interval). Each session included four groups' HIT of 20 s riding and 10 s active recovery with the different group times. The pedalling cadence of 20 s should be kept around 120 rpm, and there were 30 min rest between four groups. The total training volume of sessions declined gradually through the decreased riding

times (40, 32, 32, 32, 28, 24, 24). But the total gear meters of sessions were set to be increased gradually (26m, 27.2m, 27.2m, 27.2m, 27.8m, 28.4m, 28.4m) by adjusting the air brake gear of Wattbike. The power, work and HR were recorded with the sampling rate of 200 Hz. Blood lactate was tested at one and three minutes after each group. **RESULTS:** Except the average cadence (Cavg) of the first session was closed to 120 rpm, other six sessions' Cavg were only around 117 rpm. Although the total work of HIIT sessions were decreased from 266.8 kJ of the first session to the last session's 201.0 kJ. But the average power of each session were increased gradually by 341.2±10.2 W, 369.0±9.2 W, 383.0±18.8 W, 377.1±9.8 W, 408.4±26.9 W, 416.3±9.3 W and 418.1±9.5 W respectively. The average HR only decreased by 6.1% in the second session than the first, and rised to the same level in the next five sessions. Although the post-group BLA increased obviously from the third session, the degree of BLA recovery between 3 min and 1 min increased significantly in the sixth and seventh session. **CONCLUSIONS:** A specific pre-competition training phase with obviously increased intensity should improve the lactate buffer and transportation capacity of blood significantly. The achieved intensity in HIT should be the decisive factor for the improvement of anaerobic exercise capacity.

769 Board #3 May 29 2:00 PM - 3:30 PM
Effects Of High-intensity Interval Training On Aerobic Capacity And Sleep Quality In Middle-aged Women

Ting Y. Wang. *Tzu Chi University of Science and Technology, Hualien County, Taiwan.*
 Email: tingyao.wang@gmail.com
 (No relevant relationships reported)

Middle-aged women often have a tendency to gain weight due to decreased basal metabolic rate and physical activity. In order to make women's elderly life more quality, women's physical fitness in middle age is an issue that needs attention. **PURPOSE:** To investigate the effects of different percentages of critical velocity (CV) training on cardio-pulmonary fitness, body composition, and sleep quality in middle-aged women. **METHODS:** Twenty-four middle-aged women (age: 45.0±7.2 yrs, height: 160.3±5.0 cm, weight: 61.6±7.1 kg, body fat percentage: 38.3±7.1%) participated in the study who were paired by CV to perform high-intensity interval training (HIIT, 130% CV, running 2 minutes with 1 minute recovery, repeated 7 times) or moderate-intensity continuous training (MICT, 90% CV, running 20 minutes) 3 times a week for 12 weeks. Participants were asked to wear the Mi band II 3 weeks before and during the intervention period to record the number of steps and sleep status. **RESULTS:** The body fat percentage (HIIT group: 39.7±4.5% to 38.5±4.7%, MICT group: 36.9±3.2% to 35.7±3.3) and maximal oxygen uptake (HIIT group: 30.7±5.3 to 33.8±5.3 ml/min/kg, MICT group: 30.8±3.5 to 33.3±5.0 ml/min/kg) were significantly improved in both groups ($p < .05$), and there was no difference between the groups ($p > .05$). However, the HIIT group significantly improved the ventilation threshold (26.3±5.6 to 29.5±4.2 ml/min/kg) and increased the proportion of deep sleep (31.1±8.0% to 33.2±9.2%) ($p < .05$). **CONCLUSIONS:** When training time was the same, both HIIT and MICT have significant improvement on body composition and cardio-respiratory fitness, but HIIT can also improve high-intensity exercise ability and sleep quality.

Examining Work-to-Rest Ratios to Optimize Upper Body Sprint Interval Training

Michael B. La Monica¹, David H. Fukuda², Tristan M. Starling-Smith², Nicolas W. Clark², Jose Morales³, Jay R. Hoffman, FACSM², Jeffrey R. Stout². ¹Missouri State University, Springfield, MO. ²University of Central Florida, Orlando, FL. ³Universitat Ramon Llull, Barcelona, Spain.
 Email: michaelamonica@missouristate.edu
 (No relevant relationships reported)

PURPOSE: The primary purpose of this study was to evaluate the effectiveness of upper body sprint interval training (SIT) protocols with varying work-to-rest ratios on both aerobic and anaerobic performance. The secondary purpose was to investigate the changes in metabolic and neuromuscular fatigue thresholds from two weeks of SIT in recreationally active men. **METHODS:** Forty-two recreationally trained men were randomized into one of three training groups [10s work bouts with two minutes of rest (10:2) or four minutes of rest (10:4), or 30s work bouts with four minutes of rest (30:4)] or a control group (CON). Participants underwent six training sessions over two weeks with four to six 'all-out' sprints. During pre- and post-intervention visits, participants underwent a graded exercise test to determine maximal oxygen consumption ($\dot{V}O_{2peak}$) and peak power output (PPO), four constant-work rate trials to determine critical power (CP), anaerobic working capacity (W'), and electromyographic fatigue threshold (EMGFT), and an upper body Wingate test to determine peak power (PP), mean power (MP), and total work (TW). An analysis of covariance was performed on all testing measurements collected at post with the associated pre-values used as covariates.

RESULTS: There were significant between group differences in post-test absolute $\dot{V}O_{2peak}$, with an adjusted pre-test mean of 2.44L·min⁻¹, and PPO, with an adjusted pre-test mean of 130.9W. Absolute $\dot{V}O_{2peak}$ was greater in 30:4 (2.36±0.26L·min⁻¹, $p = .007$) and 10:2 (2.53±0.38L·min⁻¹, $p = .036$) than CON (2.17±0.34L·min⁻¹), and PPO was greater in 30:4 than CON (136±14 vs. 127±22W, $p = .007$, respectively). No differences were observed between groups in CP ($p = .530$), W' ($p = .900$), EMGFT ($p = .692$), PP ($p = .692$), MP ($p = .290$), or TW ($p = .291$).

CONCLUSION: SIT protocols with larger work-to-rest ratios appear to have enhanced $\dot{V}O_{2peak}$ in the upper body over a short-term two-week intervention.

Four Weeks of Low Volume High-Intensity Interval Training Has No Effect On VO_{2max}

Dan A. Gordon¹, Patrick Swain¹, Don Keiller¹, Viviane Merzbach¹, Diane Johnson¹, Luciano Prado², Andre Maia-Lima², Henry Chung¹. ¹Anglia Ruskin University, Cambridge, United Kingdom. ²Universidade Federal de Minas Gerais, Belo Horizonte, Brazil.
 Email: dan.gordon@anglia.ac.uk
 (No relevant relationships reported)

Previous works assessing the impact of high intensity interval training on VO_{2max} have offered varying results

PURPOSE: To determine the meaningful effects of a short-term high-intensity interval training (HIIT) or continuous training (CET) intervention on VO_{2max} and the anaerobic capacity through quantification of both the respiratory and haemodynamic responses. **METHOD:** Following local institutional ethical approval, 37 physically active participants undertook 4-weeks of either cycling-based HIIT (age, 17.0 ± 0.5 yrs; height, 173.1 ± 9.2 cm; mass, 62.4 ± 6.9 kg), (8 x 20 s at 170% pO_{2max} with 10 s recovery) or CET (age, 17.0 ± 0 yrs; height, 173.6 ± 8.7 cm; mass, 69.3 ± 17.0 kg) (30 min at 70% O_{2max}) 3 times per week. VO_{2max} , anaerobic capacity as determined through the maximally accumulated oxygen deficit (MAOD), blood-based markers and haemodynamic responses were assessed pre and post the intervention period. VO_{2max} and MAOD were evaluated using breath-by-breath open circuit spirometry while haemodynamic responses were monitored using thoracic impedance cardiography. Analysis conducted using both inferential analysis as well as magnitude-based inferences (MBI) and effects sizes (ES). **RESULTS:** VO_{2max} exhibited a non-significant 4.1% increase ($P > 0.05$) (ES = 0.24) for HIIT with 7.0% $p = 0.007$ (ES = 0.40, MBI = likely trivial) increase for CET. Haemodynamic responses (Q_{max} , SV_{max}) displayed non-significant responses for CET and HIIT ($P > 0.05$) while a- $vO_{2dif-max}$ increased from 15.8 ± 4.8 to 18.3 ± 2.9 ml·100 ml⁻¹) ($p = 0.02$) (ES = 0.63, MBI = possibly beneficial) following HIIT. MAOD increased by 7.3 ml·kg⁻¹ for HIIT ($p = 0.001$) (ES = 0.72, MBI = likely beneficial), with CET showing no change ($p > 0.05$). **CONCLUSIONS:** VO_{2max} is a function of Q_{max} and a- $vO_{2dif-max}$, so for a meaningful change to occur in cardiorespiratory fitness there must be a concomitant increase in O_2 delivery. This study demonstrates that a short-term HIIT intervention evokes peripherally mediated responses (a- vO_{2dif}) and anaerobic substrate utilisation rather than O_2 delivery components. The increase in VO_{2max} for CET in the absence of haemodynamic responses lends further support to the need for valid quantification of VO_{2max} .

High-intensity Interval Training In The Heat: A "hotter" Alternative For Promoting Cardiovascular Health And Performance?

Isabelle F. Albin, Leah Glickman, Alexs A. Matias, Peter A. Califano, Justin M. Faller, Stephen J. Ives. Skidmore College, Saratoga Springs, NY.
 Email: ialbin@alumni.skidmore.edu
 (No relevant relationships reported)

Chronic heat exposure during exercise, exercise heat acclimation (EHA), and high-intensity interval training (HIIT) both promote positive physiological and performance adaptations; however, it remains unknown if HIIT acts synergistically with EHA compounding the performance benefit of HIIT. **PURPOSE:** To investigate the effects of HIIT and EHA (HIIT+Heat) on cardiovascular function (CV), endurance running performance, and muscle function vs. HIIT alone. **METHODS:** Using a randomized controlled parallel-design, 10 young healthy males and females completed 6 sessions of HIIT (8 x 30s on, 90s off) performed either in the heat (HIIT+Heat, 30°C, 50% RH) or thermoneutral (HIIT, ~20°C, 15% RH) condition. Measures of cardiovascular and muscle function, running performance and economy were measured prior to, and >72hr post, training in a thermoneutral environment. A 5 km time-trial and graded treadmill protocol were conducted to assess for running performance and economy, while power and velocity during maximal vertical jump were used to assess muscle function. CV function was assessed via, heart rate (HR), HR variability (HRV; root mean square of successive differences; RMSSD, and standard deviation of N-N intervals; SDNN), central (cBP), peripheral blood pressure (pBP), and pulse wave velocity (PWV). **RESULTS:** No baseline differences were observed between groups.

No differences in performance improvement (-4 ± 2 vs. $-4 \pm 4\%$ in 5km time) or running economy were observed between groups ($p > 0.05$). Resting HR (-2 ± 3 vs. $-2 \pm 2\%$) and HRV (SDNN 5 ± 2 vs. $11 \pm 4\%$) were improved in both groups but were not different between conditions (HIIT vs. HIIT+Heat, $p > 0.05$). However, cSBP (1 ± 2 vs. $-7 \pm 3\%$), pSBP (-2 ± 2 vs. $-8 \pm 2\%$), and PWV (0 ± 1 vs. $-6 \pm 3\%$) only decreased in the HIIT+Heat (HIIT vs. HIIT+heat, respectively, all $p < 0.05$). Improvements in jump velocity (-3 ± 5 vs. $8 \pm 5\%$) and power (-2 ± 5 vs. $9 \pm 6\%$) tended to be greater in HIIT+heat ($p = 0.08-0.10$). **CONCLUSION:** Short term HIIT combined with heat stress did not improve running performance or economy more than HIIT alone, but did significantly improve blood pressure, vascular stiffness, and tended to improve muscle function in thermoneutral conditions. Further work exploring longer training and/or greater heat stress in larger populations, or those with vascular dysfunction, is warranted.

773 Board #7 May 29 2:00 PM - 3:30 PM
Effectiveness Of HIIT And MICT On Body Weight And Fat% Of Overweight Adults: A Meta-analysis

Xiaofei Wang, Chenggang Zhang, Bing Zhang, *Tsinghua University, Beijing, China.* (Sponsor: Weimo Zhu, FACSM)
 Email: 15652662676@163.com
 (No relevant relationships reported)

PURPOSE: To determine the effectiveness of high-intensity interval training (HIIT) and medium-intensity continuous training (MICT) on body weight and fat% of overweight adults.

METHODS: A comprehensive bibliographic search was conducted on the intervention studies of HIIT and MICT on body weight and fat% published in peer-reviewed journals between January 1, 2013 and January 1, 2017. Databases searched included Pubmed, WebScience, Embase and CNKI (Chinese database). Identified studies were analyzed using a meta-analysis so that the effect size of HIIT and MICT interventions can be determined. Risk bias evaluation was used to evaluate the quality of each included study and STATA 13.1 software was used for the analysis.

RESULTS: A total of 10 studies involving 233 subjects (100 males, age = 32.3 ± 5.9 yr.) were included in the final analysis. Intervention durations averaged 10.3 ± 2.7 weeks with a mean sample size of 23.3 ± 6.5 . The reduction of body weight by HIIT and MICT was 1.56% and 1.53%, respectively and the reduction of fat% was 4.05% and 4.06%, respectively. Thus HIIT had no better effect in reducing weight (effect size = -0.18 , 95% CI: $-1.03 \sim 0.66$, $P = 0.67$) or fat% (effect size = -0.38 , 95% CI: $-1.02 \sim 0.27$, $P = 0.25$) than MICT. The further subgroup analysis showed that, the more times of HIIT, the larger of the training effect; e.g., the subgroup had "greater than or equal to 48 times" training led a significant difference in reducing body weight (effect size = -1.51 , 95% CI: $-2.73 \sim -0.29$, $P = 0.016$). For fat%, it was found that the longer training period, the more significant effect of HIIT, e.g., in the period of "12 weeks" subgroup, there was a significant marginal significance (effect size = -0.73 , 95% CI: $-1.49 \sim 0.03$, $P = 0.061$).

CONCLUSION: While both HIIT and MICT led reduction in body weight and fat%, but there was no significant difference between them. Longer and higher frequency HIIT may be needed to lead a more significant weight and fat% reduction.

774 Board #8 May 29 2:00 PM - 3:30 PM
Inter-Individual Adaptive Responses to Sprint Interval Training in Recreationally Active Males

Tom P. Aird, Brian P. Carson. *University of Limerick, Limerick, Ireland.*
 Email: tom.aird@ul.ie
 (No relevant relationships reported)

Sprint interval training (SIT) has emerged as a time efficient alternative to conventional endurance exercise, inducing similar physiological adaptations in both athletic and non-athletic populations. These include both anaerobic adaptations such as those observed during a 30 s Wingate test, and aerobic adaptations such as improved time trial performance. However, the magnitude of such adaptations can vary considerably on an individual level. **PURPOSE:** To investigate the inter-individual variation in response to a 3 week SIT intervention in healthy males.

METHODS: Healthy recreationally active ($\text{VO}_2 \text{ max} < 50 \text{ ml.kg.min}^{-1}$) males ($n=25$) participated in a 3 week SIT intervention, comprising 9 exercise sessions. Each SIT session consisted of 4-6 30 s "all out" cycle sprints at a resistance of 7.5 % body mass, interspersed with 4 min active recovery. Participants completed a 30 s Wingate and a 20 min cycle performance test at baseline and 72-96 h following the final SIT session. (Non-)Responders were identified using twice the typical error (TE) of measurement for Wingate peak power (PP; $2 \times \text{TE} = 1.58 \text{ W.kg}^{-1}$), minimum power (MP; $2 \times \text{TE} = 0.81 \text{ W.kg}^{-1}$) and average power (AP; $2 \times \text{TE} = 0.39 \text{ W.kg}^{-1}$), and for mean power during the cycle performance test (CP; $2 \times \text{TE} = 10.07 \text{ W}$).

RESULTS: Group level (mean \pm SD) increases in PP ($0.9 \pm 1.1 \text{ W.kg}^{-1}$), MP ($0.3 \pm 0.6 \text{ W.kg}^{-1}$), AP ($0.4 \pm 0.4 \text{ W.kg}^{-1}$) and CP ($16.8 \pm 15.6 \text{ W}$) were observed (all $p < 0.05$). Non-responders in PP (17/25, 68 %), MP (19/25, 76 %), AP (9/25, 36 %), and CP (10/25, 40 %) were all identified. Adverse responses in AP and MP (1/25, 4 %) were also observed. Global non-responders to SIT were identified (4/25, 16 %), who did not improve any performance measure. All other participants improved at least one performance measure. Of participants that improved CP a large subset (10/15, 67 %) also improved AP, this is the most common response. Interestingly, $n=4$ participants improved CP in response to SIT without improving any anaerobic variable.

CONCLUSIONS: This study's findings indicate significant heterogeneity in the individual adaptations to SIT in measures of anaerobic and aerobic performance. Subsets of responders to multiple performance variables, as well as those who improved aerobic, but not anaerobic performance, were identified, demonstrating the wide range of adaptive responses to SIT.

Six Hit Treadmill Training Sessions Improves Lipid Oxidation and Ventilatory Thresholds Intensities

Marcelo L. Marquezi¹, Juliana M. Lino¹, Antonio H. Lancha Jr.², *¹Universidade Cidade de São Paulo, São Paulo, Brazil. ²Universidade de São Paulo, São Paulo, Brazil.*
 Email: mlmqzz@gmail.com
 (No relevant relationships reported)

The high-intensity interval training (HIT) has been used as alternative to cardiorespiratory training performed continuously with submaximal intensity and prolong time. **PURPOSE:** The aims of this study were to propose a treadmill HIT protocol and verify the influence of six HIT sessions on intensities of ventilatory anaerobic thresholds (VATs) and substrate oxidation rates during submaximal continuous exercise (SCE). **METHODS:** Fifteen irregularly active men performed incremental treadmill exercise testing followed by submaximal work-rate running for 45min to determine VATs, $\text{VO}_{2\text{peak}}$, peak velocity (V_{peak}), and substrate oxidation rates, before and after training period. The training period consisted of six HIT sessions, composed each one of eight sets of 60s running at $100\%V_{\text{peak}}$ interspersed by 75s recovery, every 48h. **RESULTS:** Our results showed increases in VATs intensities of 4.4% for VAT1 and 8.8% for VAT2, reduction of 12.8% for carbohydrate oxidation (CHOox) and increase of 23.7% for lipid oxidation (LIPox); as a result, the relative energy derived from LIPox was 20.3% higher after the training period. V_{peak} was $\sim 15 \text{ km/h}$, which produces the relative intensities of $\sim 84\%V_{\text{O}_{2\text{peak}}}$ e $\sim 91\%FC_{\text{peak}}$ during the training period. **CONCLUSION:** The proposed protocol promoted similar adaptations and intensities which were described by the literature; but unlike others, it can be applied in irregularly active individuals.

Effects Of High-intensity Strength Training On Muscle Strength Gain And Muscle Hypertrophy In Males And Females: A Meta-analysis

Yukina Mochizuki, Naoki Kikuchi, Noriko Kaji, Takashi Okada, Kentaro Terada, Yoshiaki Haakaku, Nobuyasu Tomabechi, Toshiaki Soga, Tomoya Era, Naoyuki Kobatake, Tetsunari Nishiyama. *Nippon sport science University, Tokyo, Japan.*
 Email: my.ca0813@gmail.com
 (No relevant relationships reported)

High-intensity strength training is known to induce muscle strength gain and muscle hypertrophy. However, there are only few reports on the effects of high-intensity strength training on strength gain and muscle hypertrophy in females. **PURPOSE:** To conduct a systematic review of a meta-analysis to compare changes in strength gain and muscle hypertrophy between males and females after high intensity resistance training.

METHODS: To carry out present review, English-language literature searches on PubMed and SPORTDiscus databases were conducted from all time points up until June 2018. Combinations of the following keywords were used as search terms: "training intensity," "strength training," "resistance training," "strength," "muscle hypertrophy." **RESULTS:** Thirty-five articles were included in the meta-analysis. The standardized mean differences for muscle strength gain were 1.27 (95% confidence interval [CI], 0.99-1.55) and 1.16 (95% CI, 0.45-1.87), in males and females, respectively. The standardized mean differences for muscle hypertrophy were 0.73 (95% CI, 0.41-1.05) and 0.33 (95% CI, 0.07-0.60) in males and females, respectively. **CONCLUSIONS:** Our results suggested that high-intensity strength training induces muscle strength gain and increases muscle hypertrophy in both males and females. However, in the case of muscle hypertrophy, females tend to have lower standardized mean difference than males after high-intensity strength training.

Influence Of Combining Aerobic And High Intensity Interval Training on 400m Performance And Post-exercise Responses.

Panagiotis Doukas¹, Amvrosios Chatziapostolou², Costas Chryssanthopoulos¹, Giorgios Paradisis¹, Maria Maridaki¹, Michael Koutsilieris¹, Anastassios Philippou¹. ¹National and Kapodistrian University of Athens, Athens, Greece. ²Educons University, Novi Sad, Serbia.
 Email: P.doukas@gmail.com

(No relevant relationships reported)

PURPOSE: To examine the possible influence of combining aerobic and high intensity interval training (HIIT) on post-exercise responses in 400m in young sprinters. **METHODS:** Fourteen male sprinters (100-200 m) (18.4 ± 0.3 years old; mean ± SE) performed 400m at maximal effort (400mMax), 400m at 90% (400m-90%), and the Cunningham-Faulkner treadmill test (C-F) (12.8 km·h⁻¹, 20% inclination to fatigue). Afterwards, participants were divided in 2 equivalent groups of 7 persons each and underwent 6 weeks of either HIIT training two times per week (HIIT), or HIIT and supplementary aerobic training two times per week (Comb). After training, 400mMax was repeated, whereas the 400m-90% was performed at pre-training intensity. Saliva samples for the determination of testosterone (TESTO) and Cortisol (CO) were collected before and 30min after the 400mMax and 400m-90%. Pre and post exercise differences between trials were analyzed using 2-way ANOVA and responses over time by 3-way ANOVA. **RESULTS:** Performance improvement with training in 400mMax (HIIT: 2.6 ± 0.4% vs. Comb: 1.9 ± 0.4%, *p*=0.23) and C-F (HIIT: 15.7 ± 1.3% vs. Comb: 13.9 ± 3.9%, *p*=0.66) was similar between groups. In 400m-90% the TESTO/CO ratio increased after training only in Comb (Pre-Training: 7.0 ± 2.2 vs. Post-Training: 13.4 ± 2.2, *p*=0.045), while CO was higher (*p*=0.016) after training in HIIT (13.6 ± 1.5 ng ml⁻¹) compared to Comb (8.4 ± 1.5 ng ml⁻¹). Higher hormonal increases (*p*<0.05) with exercise were observed in 400mMax compared to 400m-90% irrespective of training (pre/post training) and type of group (HIIT/Comb). No other hormonal differences were detected between groups. The increase of lactate concentration (post-pre exercise difference) 3 min after 400mMax (Comb: 9.6 ± 0.6 mmol l⁻¹ vs. HIIT: 12.2 ± 0.6 mmol l⁻¹; *p*=0.04) and C-F (Comb: 12.1 ± 0.4 mmol l⁻¹ vs. HIIT: 15.4 ± 0.5 mmol l⁻¹; *p*=0.012) was lower after training in Comb compared to HIIT. During the 3-min recovery, mean percentage heart rate was lower (*p*<0.001) in Comb (75 ± 1%) compared to HIIT (80 ± 1%) in 400mMax. **CONCLUSIONS:** Comb training possibly attenuated CO response 30min post-exercise in 400m-90%. Also, the Comb training did not further improve performance in 400mMax and C-F compared to HIIT but probably induced adaptations that facilitated the faster blood lactate and heart rate recovery.

The Effect Of Varying High-intensity Interval Training Style Warm-ups On Hemodynamic, Power, And Flexibility Responses

Nelson Wise, Orlando Cepeda, Klarissa Ybarra, Brenda Palma, Brianna Lopez, Manuel Nunez, Ezra Meza, Alexandria Hinojosa, Amanda Hankins, Murat Karabulut, FACSM. *The University of Texas Rio Grande Valley, Brownsville, TX.*
 Email: nelson.wise01@utrgv.edu

(No relevant relationships reported)

PURPOSE: The purpose of this study was to examine the effectiveness of high-intensity interval training (HIIT) style warm-up on hemodynamic, power, and flexibility responses.

METHODS: Twelve male subjects (age: 24.15 ± 3.1 yr. & weight: 78.78 ± 16.83 kg) completed the study. On the first day, initial screening, anthropometric measures, and familiarization with testing procedures were completed. There was a total of 6 randomized testing sessions (separated by at least 48 hours.). The testing sessions were as follows: 3-min warm-up session with 20 sec work followed by 10 sec (C1), 3-min warm-up session with 30 sec work followed by 10 sec (C2), 5-min warm-up session with 20 sec work followed by 10 sec (C3), 5-min warm-up session with 30 sec work followed by 10 sec (C4), 8-min warm-up session with 20 sec work followed by 10 sec (C5), and 8-min warm-up session with 30 sec work followed by 10 sec (C6). The warm-up sessions included timed interval body weight squats. Hemodynamics (heart rate (HR) and systolic (SBP) and diastolic (DBP) blood pressure), a countermovement jump, and flexibility values were recorded before and after warm-up protocols.

RESULTS: There was a significant duration*time interaction for flexibility (*p*<0.01) and vertical jump (*p*=0.02). Flexibility increased from pre to post for 3-min and 5-min warm-up conditions, however, decreased for 8-min warm-up conditions. Vertical jump increased for 3-min conditions and decreased for 5-min and 8-min conditions. There were significant duration main effects for HR (*p*<0.03); time main effects for HR (*p*<0.01), SBP (*p*<0.01), and DBP (*p*<0.01); duration*time interaction for HR (*p*<0.01) and intensity*time interaction for SBP (*p*<0.04).

CONCLUSIONS: The findings of the study indicate that a 3-min duration of HIIT style warm-up may be enough to physically prepare individuals to improve flexibility and vertical jump. In addition, the data also suggests that the required/recommended duration for a warm-up protocol to prepare the body may be shortened with HIIT style warm-up. Future studies should compare and contrast the efficacy of varying work to rest ratio of HIIT style warm-up with other warm-up protocols to determine the most effective warm-up protocol.

Performance Recovery In Army Reserve Officer Training Corps Cadets Following A Bout Of High-Intensity Exercise

Jay A. Campbell, Rebecca D. Larson, Christopher D. Black, FACSM, Kellea N. McGuire. *University of Oklahoma, Norman, OK.*

Email: jcampbell21@ou.edu

(No relevant relationships reported)

PURPOSE: The aims of this study were to determine the time-course for recovery in Army ROTC cadets following a bout of high-intensity exercise, if sex differences for recovery exist, & examine the use of a countermovement jump (CMJ) as a measure of fatigue & muscle damage.

METHODS: 10 male (M) & 9 female (F) ROTC cadets performed high-intensity interval resistance (HIIR) exercise using their 10RM for 3 sets of 8 resistance exercises (Chest press, leg press, lat pull, etc.) w/60s work:60s rest. Soreness ratings (100mm VAS) & perceived recovery status (PRS) were recorded prior to performing 5 countermovement jumps (CMJ). RPE (CR10 scale) was taken after each round. Immediately post-exercise, subjects performed 5 more CMJs. Thirty-minutes post exercise, subjects provided session RPE (sRPE). This protocol was used at baseline (BL), 24, 48 & 72 hrs post BL.

RESULTS: For M & F subjects, exercise performance was similar w/24, 48, & 72 hrs of recovery & all were > than BL (385.3-419.8 vs. 331.9 reps). CMJ relative peak power was > in M vs. F at all time points (47.2 vs. 33.7 W/kg, respectively) & decreased from pre-to-post at BL only for both M & F cadets (1.1% vs. 1.8%, respectively). Percent change in CMJ performance from pre-to-post did not differ between genders at any time point. Soreness ratings were > at 24H (27.2) versus BL (7.5) and 72H (12.3). Upper body soreness ratings were > than lower body soreness for BL (7.5 c 6.2), 24H (24.3 v 15.1) & 48H (16.8 v 10.1). M & F did not differ in soreness ratings. PRS was moderately correlated (*r* = 0.484, 0.682, 0.503, 0.528)) with soreness ratings for BL, 24H, 48H, & 72H; sRPE did not differ between time points for all subjects (overall \bar{x} = 8.3±0.7). RPE increased from set 1 to set 3 (7.5 v 8.8, respectively). M & F did not differ in RPE for all sets.

CONCLUSIONS: ROTC cadets could recover 24H following a bout of HIIR exercise with no differences between M & F cadets. CMJ performance did not match the change in exercise performance. Soreness patterns were similar for M & F cadets for high-intensity exercise. PRS matched the pattern of soreness indicating it is associated with soreness rather than performance. More work is needed to understand the utility of CMJ for recovery monitoring in this population. Lastly, this type of resistance exercise protocol may be useful for improving muscle fitness in entry-level ROTC cadets.

Comparing Strength Outcomes Of An 8 Week Hift Interventon Vs 8 Week Traditional Weight Training.

Jason Sartor. *Kansas State University, Manhattan, KS.*

(No relevant relationships reported)

Jason Sartor¹, Justin A. DeBlauw¹, Brittany S. Hollerbach¹ and Katie M. Heinrich¹
¹Kansas State University, Manhattan, KS

High-intensity functional training (HIFT) temporally combines aerobic and resistance exercise at relative high intensity levels. Functional workouts include varied exercises that simulate movements of daily living to improve overall fitness. Traditional weight training (TWT) focuses on progressive sets and repetitions of resistance exercise performed both with free weights and machines. Training includes both multi joint (squat) and single joint (arm curls) exercises to improve strength. With comparison Data of these interventions' individuals can obtain a better understanding of expected fitness outcomes for HIFT and TWT.

PURPOSE: To compare effects of HIFT and TWT on power, strength and muscular endurance in college students.

METHODS: Participants (n = 95) were enrolled in 8-week TWT or HIFT fitness classes. Baseline and posttest measures were completed by 83 participants (87.4%); TWT: N = 35, age = 22.6 ± 4.11 years, body mass = 78.3 ± 21.4kg; HIFT: N = 48, age = 21.2 ± 3.1 years; body mass = 77.2 ± 14.6kg). After completing a standardized warm-up, participants completed measures testing lower body muscular power (vertical jump), strength (handgrip dynamometer), and muscular endurance (2-minute timed push-ups and 1-minute body weight squats). Within (paired) and between (independent with change scores) samples t-tests were conducted using SPSS 25.

RESULTS: Significant improvements were seen for squats in both groups (HIIT +3.9 ± 5.5 reps, $t = 4.86$, $p < .001$; TWT +3.8 ± 5.3 reps, $t = 4.29$, $p < .001$) and push-ups in TWT (+4.3 ± 4.5 reps, $t = 5.67$, $p < .001$). No significant changes were found for power or strength. Independent samples t-tests revealed no significant differences between groups.

CONCLUSIONS: After 8-weeks of either HIIT or TWT participants significantly improved muscular endurance, with no significant differences between groups. More direct measures of strength (e.g., 1 rep max testing) should be examined in future research along with longitudinal changes in fitness comparing different training modalities.

Effect Of Ethnicity On Change In Vo2max And Substrate Oxidation In Response To HIIT

Jamie DeRevere¹, Todd A. Astorino¹, Sean Walsh, FACSM².

¹California State University San Marcos, San Marcos, CA.

²Central Connecticut State University, New Britain, CT.

(No relevant relationships reported)

Introduction: About 20% of adults meet the 2008 Physical Activity Guidelines and this lack of physical activity increases individuals' risk of heart disease, stroke, type-2 diabetes, and certain cancers which increases morbidity and all-cause mortality. Typically, moderate intensity continuous training (MICT) is prescribed to clients to improve overall fitness and health status, although a primary barrier to regular physical activity among sedentary individuals is lack of time. An alternative to MICT is high intensity interval training (HIIT) which significantly increases VO₂max and fat oxidation, in turn improving exercise capacity and reducing health risks. One widely ignored aspect of individual response to exercise training is ethnicity, as there are minimal data examining the effect of ethnicity on responses to exercise training. **Purpose:** To determine if ethnicity alters adaptation to low volume HIIT in sedentary women. **Methods:** Inactive, non-obese women (age and VO₂max = 24.3 ± 4.1 yr and 29.1 ± 2.1 mL/kg/min) participated in 9 sessions over a 3-week period of cycling-based HIIT (8-10 1-minute bouts at 85% PPO interspersed with 75-sec recovery at 10% PPO). Participants were Caucasian (C) (n=6) or Hispanic (H) (n=4). To assess VO₂max, the initial work rate began at 30 or 40 W for 2-min followed by a 15 or 20 W/min increase in power output until volitional exhaustion. To assess substrate oxidation, a 6-min warm up began at 10% PPO and subsequently work rate increased by 10% PPO every 5-min during 4 remaining stages. These variables were measured pre- and post-training. **Results:** Training elicited a HR equal to 88-94% HR_{max}. Data showed an increase ($p=0.016$) in VO₂max in C (30.5 ± 1.3 vs 32.6 ± 3.9 mL/kg/min, +7%) and H (27.7 ± 2.8 vs 31.7 ± 2.6 mL/kg/min, +14%) with no significant group×time interaction ($p=0.35$). There was a significant training×bout×group interaction for fat oxidation ($p=0.005$), carbohydrate oxidation ($p=0.009$), and RER ($p=0.000$). Data showed an increase in the rate of fat oxidation and a reduction in carbohydrate oxidation in response to training which differed based on ethnicity. **Conclusion:** These data show HIIT induces significant increases in VO₂max which are slightly higher in H vs C. In addition, ethnicity seems to mediate changes in substrate metabolism after interval-based exercise.

High-Intensity Interval Training Does Not Induce Anti-Inflammatory Changes in Healthy Men

Paul Nagelkirk, James Sackett, Dan Farrell. Ball State University, Muncie, IN.

Email: prnagelkirk@bsu.edu

(No relevant relationships reported)

Low-grade inflammation is associated with the risk of various chronic diseases, and the protective effects of a physically active lifestyle may be partially ascribed to the anti-inflammatory effects of exercise. The impact of moderate intensity exercise training on circulating pro-inflammatory molecules has received much attention in recent years. However, there are very few well designed and adequately powered studies on the influence of high-intensity interval training (HIIT) on circulating markers of inflammation. **Purpose:** The purpose of this study was to examine potential changes in plasma concentrations of C-reactive protein (CRP), interleukin-6 (IL6), and soluble interleukin-6 receptor (sIL6r) following four (4w) and eight weeks (8w) of HIIT in healthy men. **Methods:** Healthy, sedentary men participated in a HIIT program three days/week for eight weeks. Training bouts were modeled after the traditional Wingate test, consisting of repeated, 30-second bouts of maximal intensity cycling separated by 4.5 minute rest intervals. Training began with three bouts per day and an additional bout/day was added to the regimen every two weeks, progressing up to six bouts per day in the final two weeks. Plasma concentrations of CRP, IL6, and sIL6r were assessed by ELISA at baseline, 4w, and 8w. Statistical comparisons across the three time points were done using repeated measures ANOVA. Variables that deviated from normality were log transformed prior to analysis. Significance was set to $p < 0.05$. **Results:** 21 men (age: 25 ± 5 yrs, BMI: 26.7 ± 6.2 kg/m²) completed the study. No significant changes were observed for CRP during training (baseline: 1.5 ± 2.3, 4w:

1.0 ± 1.4, 8w: 2.2 ± 3.0 mg/L, $p > 0.05$). Likewise, IL6 (baseline: 1.4 ± 1.6, 4w: 1.6 ± 1.7, 8w: 1.2 ± 2.2 pg/ml) and sIL6r (baseline: 36.2 ± 23.9, 4w: 27.8 ± 22.0, 8w: 32.6 ± 22.2 ng/ml) did not change with training (all $p > 0.05$). **Conclusion:** Though it has been suggested that HIIT may reduce inflammation, results of the present study do not indicate HIIT influences specific inflammatory mediators in healthy young men. Future research should explore the potential anti-inflammatory benefits of HIIT in different populations and disease states.

(No relevant relationships reported)

Acute moderate intensity continuous training (MICT) and high-intensity interval training (HIIT) result in increased mitochondrial transcriptional activity. The mitochondrial open reading frame of the 12S rRNA-c (MOTS-C) is a peptide encoded from mitochondrial DNA. This mitochondrial derived peptide can regulate skeletal muscle glucose uptake and fatty acid beta-oxidation. However, it is not known if MOTs-C concentrations are altered following an acute bout of MICT or HIIT. **PURPOSE:** The present study investigated the effects of acute MICT and HIIT on MOTs-C levels in plasma pre- and 3 hours post-exercise. **METHODS:** Ten recreationally active (> 150 min moderate-vigorous intensity aerobic activity per week ≥ 1 year) males (n=5; age 25.2 ± 1.1, VO₂max 48.0 ± 4.9 mL/kg/min) and females (n=5; age 21.6 ± 3.6, VO₂max 39.4 ± 7.7 mL/kg/min) were conveniently recruited for an initial study conducted at the UNM Exercise Physiology Laboratories. The original study, and the current expanded exploration were approved by the institution's Institutional Review Board (IRB). Participants completed a health history, and physical activity history questionnaire. Based on criteria from the American College of Sports Medicine, all participants were considered low-risk. Utilizing a crossover design subjects performed an acute bout of MICT and HIIT exercise on a treadmill. The MICT bout consisted of 60 minutes at 55% of maximum velocity (V_{max}) achieved during the VO₂max test and the HIIT trial required two sets of 6 x 1-min bouts at 100% V_{max}, with 5 minutes recovery at 3 MPH between sets. Trials were conducted at least 72 hours apart in randomized order and in a fasted state. Plasma samples were collected during a previously conducted study and frozen for future analysis. MOTs-C was measured from the previously collected samples obtained pre- and 3 hours post-exercise using an enzyme-linked immunosorbent assay. **RESULTS:** There were no significant changes in plasma MOTs-C ($p = 0.21$) from pre to post-exercise for MICT (220.4 ± 62.9 vs 248.4 ± 45.2 ng/ml, respectively) or HIIT ($p = 0.38$) (227.9 ± 62.4 vs 246.9 ± 75.9 ng/ml, respectively). **CONCLUSION:** Our findings show plasma MOTs-C does not increase in response to a single session of MICT or HIIT.

Effects of Heart Rate Variability Modulation on High Intensity Functional Training Strength Outcomes

Brady K. Kurtz¹, Nicholas B. Drake², Justin A. Deblauw¹, Derek A. Crawford², Katie M. Heinrich¹. ¹Kansas State University, Manhattan, KS. ²Pittsburg State University, Pittsburg, KS. (Sponsor: Craig Harms, FACSM)

Email: bkkurtz@ksu.edu

(No relevant relationships reported)

PURPOSE: High Intensity Functional Training (HIFT) involves completing concurrent aerobic and resistance training functional movements at high intensity with the goal of increased fitness. We examined the effectiveness of using daily heart rate variability (HRV) status to modulate training intensity and increase performance outcomes. We hypothesized that HRV modulation for HIFT would facilitate strength improvements. **METHODS:** Participants (N = 55) were healthy, untrained or recreationally trained adults not participating in a structured exercise program. Participants were randomly assigned to either HIFT (n = 29, age = 24.1 ± 4.1 years, 41.4% male) or HIFT-HRV (n = 26, age = 23.7 ± 4.5 years, 53.8% male) groups. Both groups underwent an 11-week training protocol which included: 2-weeks baseline HRV collection, baseline, midpoint, and post-intervention anthropometric and fitness assessments, and 6 weeks of HIFT, 5 days/week. All participants recorded their HRV daily via validated mobile app throughout the study. HIFT-HRV participants' exercise was modulated by reducing rate of perceived exertion based on their daily HRV statuses. Maximal strength was tested using the squat, overhead press, and deadlift in kg at baseline, midpoint, and post-intervention. **RESULTS:** There were no differences in intervention fidelity between groups, which included adherence to HIFT ($p = .21$) and providing daily HRV data ($p = .75$). The HIFT-HRV group had their training modified 17.12 ± 6.75 days. Additionally, one-way RM-ANOVAs indicated significant increases in the squat (HIFT = +14.10 ± 1.63 kg, $F = 55.38$, $p < .001$; HIFT-HRV =

+13.25 ± 1.77, $F = 50.87$, $p < .001$), overhead press (HIFT = +3.75 ± .93, $F = 11.82$, $p < .001$; HIFT-HRV = +4.37 ± .87, $F = 10.72$, $p < .001$), and deadlift (HIFT = +15.40 ± 2.51, $F = 28.7$, $p < .001$; HIFT-HRV = +15.62 ± 2.75, $F = 27.7$, $p < .001$) within each group. Independent samples t -tests showed no differences in strength ($p = .41-.99$) between groups. **CONCLUSIONS:** Results suggest that HIFT-HRV produced equal increases in strength while having reduced training intensity for over half of the training days. HRV appears to be an effective means of modulating HIFT to increase strength outcomes.

785 Board #19 May 29 2:00 PM - 3:30 PM
Differences in Physiological Demands Between Common High-Intensity Interval Training Protocols

David Elmer, Elise Barron, Juan Chavez. *Berry College, Mount Berry, GA.*
Email: delmer@berry.edu
(No relevant relationships reported)

PURPOSE: The definition of high-intensity interval training (HIIT) is broad, with no accepted procedure for classifying HIIT protocols with different workloads and work and recovery interval times. Additionally, little is known about the differences in training load and recovery between common HIIT protocols. The purpose of this study was to evaluate the differences in acute physiological demands and perceived difficulty between three common HIIT protocols.

METHODS: Eight participants completed the following training sessions on a cycle ergometer in a randomized order, with at least one week between sessions: 4 x [30-sec all-out, 4-min active recovery], 12 x [1-min 100% $\dot{V}O_{2max}$, 1-min 50% $\dot{V}O_{2max}$], and 4 x [4-min 90% $\dot{V}O_{2max}$, 3-min 60% $\dot{V}O_{2max}$]. Metabolic variables and HR were measured throughout exercise and 30-min of recovery. Training impulse and session-RPE were also determined.

RESULTS: There were significant differences during exercise in total O_2 consumption between the 30-sec and 1-min ($ES = -3.4$, $p < 0.001$), and 30-sec and 4-min ($ES = -3.4$, $p < 0.001$) protocols, average $\dot{V}O_2$ between 30-sec and 1-min ($ES = -2.6$, $p < 0.001$) and 30-sec vs. 4-min ($ES = -1.9$, $p < 0.001$) protocols, average HR between 30-sec and 1-min ($ES = -1.3$, $p = 0.007$) and 30-sec and 4-min ($ES = -1.3$, $p = 0.02$) protocols, and blood lactate between 30-sec and 1-min ($ES = 0.9$, $p < 0.001$) and 30-sec and 4-min ($ES = 1.0$, $p < 0.001$) protocols. There was a difference in training impulse between 30-sec and 4-min protocols ($ES = 1.5$, $p = 0.009$). There were no significant differences in peak $\dot{V}O_2$ or peak HR attained during the protocols, or in session-RPE reported after the protocols. There were no differences in $\dot{V}O_2$ or HR after 5-min or 30-min of recovery. Blood lactate was only significantly higher after 30-min of recovery from the 30-sec compared to the 4-min ($ES = 1.3$, $p = 0.001$) protocol.

CONCLUSIONS: These findings show several differences, but also some similarities, in the acute physiological demands from HIIT protocols. However, differences in total metabolic work, average intensity, and training load did not result in differences in $\dot{V}O_2$ or HR during recovery or in the perceived difficulty of these protocols. These factors should be accounted for when planning training sessions or research studies, or when interpreting past research.

Relationship Between Running Bio-mechanics, Hip Mobility, And Knee Injury Risk In Division III Runners.

Zachery P. Juarez, Ana B. Freire Ribeiro. *Augsburg University, Minneapolis, MN.* (Sponsor: Mark Blegen, FACSM)
Email: juarez@augsbu.edu
(No relevant relationships reported)

Introduction: Hip mechanics influence foot strike patterns while running (Valenzuela et al., 2015) **Objective:** To observe the relationship between foot strike and sagittal plane passive hip range of motion in runners, as a surrogate for their risk for patellofemoral pain (PFP). **Methods:** Ten participants (20.5 ± 1.75 years) completed FMS testing and were rated by one certified tester. Participants' passive hip flexion and extension ranges of motion (ROM) were measured via goniometry. Then, reflective markers were placed at the lateral knee, lateral malleolus of fibula, and 5th metatarsal to define relative ankle angles. Participants ran at 3 different speeds and were filmed from the sagittal plane on both sides. Angles were analyzed on Dartfish software. **Results:** Hip flexion ($p = 0.08$, $r = 0.57$) and extension ($p = 0.17$, $r = 0.47$) were not significant predictors of dorsiflexion angles. Runners with pain/tightness experienced reduced hip extension ROM by 10.5% and had increased hip flexion ROM by 13.6% than runners without pain/tightness. The deep squat (DS) significantly predicted right hip flexion ($p = 0.02$, $r = -0.71$), but not left ($p = 0.12$, $r = -0.51$). Runners with pain/

tightness scored 1.75 on the DS, which was 12.5% lower than normative values.

Discussion: As passive hip sagittal plane ROM increased, the ankle angles increased, indicating a trend towards a more mid-forefoot strike, decreasing stress on the knee. Anterior hip tightness showed to decrease extension ROM, but not flexion ROM. The DS is sensitive to self-reported pain/tightness. **Conclusion:** For DIII runners, passive hip flexion and extension ROM were not significant predictors of foot strike type, runners with pain/tightness had presented changes in hip ROM and lower scores on the FMS DS.

Lower Extremity Stiffness in Collegiate Distance Runners Pre- and Post-Competition

Jake P. Tavernite, Matthew F. Moran. *Sacred Heart University, Fairfield, CT.*
Email: tavernitej@mail.sacredheart.edu
(No relevant relationships reported)

During running, the lower extremities are compared to a spring due to their ability to store and release energy. Recent evidence suggests a relationship between increased lower extremity stiffness and enhanced athletic performance, specifically in distance running. Current literature lacks information on the influence of fatigue on leg stiffness across multiple days in response to competition. **PURPOSE:** To determine how leg stiffness in runners was influenced in the 24- and 48-hour period following a cross country race. **METHODS** Twenty-two collegiate cross-country runners (13 M, 9 F, 19.5 ± 1.4 y) were recruited and participated. Leg stiffness was assessed 24h before a race and 24h and 48h post-race. Participants performed three static jumps (SJ) and three countermovement jumps (CMJ) on two force plates (AMTI Optima OPT464508; Watertown, MA; 1000 Hz). During each jump, participants held a dowel across the shoulders to prevent arm swing. Participants then performed a hop test (HT) where they completed 10-s of straight leg maximal hopping in sync with a metronome (2.2Hz). Leg stiffness was calculated, in agreement with previously reported methods, from the vertical ground reaction force of the 5th-7th hop of the HT. Repeated measures ANOVA and post-hoc analysis were used to assess significance ($p \leq 0.05$).

RESULTS: A significant main effect was found for SJ height, CMJ height and leg stiffness. Leg stiffness was significantly reduced 24h post-race (pre-race 36.84 ± 4.96 $kN \cdot m^{-1}$, 24h post 33.11 ± 8.05 $kN \cdot m^{-1}$, $p = 0.05$) and then increased significantly from 24h post-race to 48h post-race (36.84 ± 6.88 $kN \cdot m^{-1}$, $p = 0.015$). No significant differences were found in post-hoc analysis for CMJ height (pre-race 30.81 ± 5.79 cm, 24h post-race 29.89 ± 6.06 cm, 48h post-race 31.44 ± 6.47 cm, $p > 0.05$) and eccentric utilization ratio (pre-race 1.24 ± 0.10, 24h post-race 1.20 ± 0.10, 48h post-race 1.22 ± 0.10, $p > 0.05$). SJ height increased significantly from 24h to 48h post-race (24h post-race 25.99 ± 5.65 cm, 48h post-race 27.19 ± 5.63 cm, $p > 0.05$). **CONCLUSION:** Following a cross country race leg stiffness significantly declined in a group of collegiate runners 24 hours post-race but returned to baseline 48 hours post-race. Sport scientists and coaches may be able to monitor leg stiffness as a metric to properly prescribe training regimens.

Physiological Correlates With 300 And 1000 M Performance In U14 Athletes

PROKOPIOS CHATZAKIS. *NATIONAL AND KAPODISTRIAN UNIVERSITY OF ATHENS, ATHENS, Greece.*
(No relevant relationships reported)

Physiological correlates with 300 and 1000 m performance in U14 athletes.
Prokopios Chatzakis, Eirini Zanni, Giorgos Paradisis, Polyxeni Argeitaki, Elias Zacharogiannis
National and Kapodistrian University of Athens, Athens, Greece

Abstract

PURPOSE: To determine the contribution of selected field tests physiological parameters with running performance in U14 track athletes.

METHODS: Fifteen trained U14 young track and field athletes (12 girls and 3 boys, 12-13 years old) participated in the study. During the first and second visit after anthropometry the athletes performed a 20 m Shuttle Run Test, a RAST (Running Anaerobic Speed Test), a vertical squad jump and a 40 m maximal effort to determine aerobic, anaerobic capabilities and leg explosive strength. The 300 and 1000 m time trial followed. All maximal tests were performed at least three days apart. Pearson's r and Stepwise Multiple Linear Regression were used for the correlation between maximal O_2 uptake ($\dot{V}O_{2max}$), velocity at $\dot{V}O_{2max}$ ($v\dot{V}O_{2max}$), maximal heart rate (HR_{max}), minimal, maximal and mean relative power output values ($P_{min_{RT}}$, $P_{max_{RT}}$ and $P_{mean_{RT}}$, respectively), squat jump (SJ), maximal running speed (V_{max}), body mass (BM), body height (BH), %body fat (%BF) and the time trials 300 (t300m) and 1000 m (t1000m).

RESULTS: Univariate relationships showed significant correlations between t1000m and $\dot{V}O_{2max}$ (-0.866, $p < 0.01$), $v\dot{V}O_{2max}$ (-0.899, $p < 0.01$), $P_{min_{RT}}$ (-0.519, $p < 0.05$), $P_{mean_{RT}}$ (-0.568, $p < 0.05$), SJ (-0.606, $p < 0.05$), BM (0.770, $p < 0.01$) and %BF (0.698, $p < 0.01$). Furthermore, t300m significantly correlated with $P_{max_{RT}}$ (-0.553,

$p < 0.05$), $P_{min_{RT}}$ (-0.579 , $p < 0.05$) and $P_{mean_{RT}}$ (-0.670 , $p < 0.01$). Stepwise Multiple Linear Regression showed that the best predictor variables for t_{1000m} in U14 were vVO_{2max} , $P_{mean_{RT}}$, BM and $P_{max_{RT}}$ ($t_{1000m} = 444.229 - 15.857 * vVO_{2max} - 37.105 * P_{mean_{RT}} + 1.270 * BM + 23.042 * P_{max_{RT}}$, Adjusted $R^2 = 0.948$, $P < 0.001$, $SEE = 6.86$ s), while the single predictor variable for t_{300m} was $P_{mean_{RT}}$ ($t_{300m} = 81.805 - 5.276 * P_{mean_{RT}}$, Adjusted $R^2 = 0.406$, $P = 0.006$, $SEE = 3.97$ s).

CONCLUSIONS: The moderate to high correlations shown in the present study between t_{1000m} and t_{300m} and the selected parameters can predict with acceptable accuracy 1000 m and 300 m in young runners and can be used to estimate performance.

789 Board #23 May 29 2:00 PM - 3:30 PM
Effects of Pulsed Electromagnetic Field Application on Aerobic Performance in Runners During Short-Term Altitude Training

Tanuj Wadhi¹, Nauris Tamulevicius¹, Guillermo R. Oviedo², Ashmeet S. Anand¹, Dror Vaknin¹, Fraser Houston¹. ¹The University of Tampa, Tampa, FL. ²Universitat Ramon Llull, Barcelona, Spain.

(No relevant relationships reported)

Pulsed Electromagnetic Field (PEMF) application increases microcirculation throughout the body and has been shown to be beneficial in clinical populations. In athletic populations, PEMF is used to improve recovery. Altitude training has long been used by endurance athletes to improve sea-level performance. **PURPOSE:** To determine if recovery with PEMF during altitude performance leads to greater improvements in VO_{2peak} and ventilatory threshold (VT) in cross-country runners. **METHODS:** Fourteen male NCAA cross-country runners (age: 19.07 ± 0.92 y.o.) with initial VO_{2peak} of 73.13 ± 5.65 ml/kg/min participated in the study. Subjects were randomly assigned either to the PEMF intervention (INT) ($n=8$) or to a control group (CON) ($n=6$). VO_{2peak} and VT were evaluated using a metabolic cart at sea-level, pre- and post-training. Runners from sea level traveled to high altitude where they lived at 1322m above sea-level for 6 days. Six training sessions were performed at altitudes ranging from 881.25 ± 148.87 m to 1047.70 ± 237.29 m above sea-level with training sessions averaging a duration of 75.25 ± 7.04 mins, speed of 13.02 ± 1.60 kmph and distance of 16.42 ± 2.95 km. Subjects in INT received PEMF application prior to and after training, while subjects in CON did not. **RESULTS:** There was no significant difference in either absolute or relative VO_{2peak} . A main-effect of time was found for absolute VT ($p < 0.01$), which changed from 3.35 ± 0.52 L/min to 3.89 ± 0.55 L/min, and VT relative to VO_{2peak} ($p < 0.01$), which changed from $73.10 \pm 1.60\%$ of VO_{2peak} to $87.08 \pm 1.82\%$ of VO_{2peak} . There was no significant difference between groups for absolute VT ($p = 0.24$) however, the INT group displayed a positive-trend for VT relative to VO_{2peak} (INT: 18.28%, CON: 9.68%; group*time $p = 0.07$). Consequently, there was a main effect of time for heart-rate at VT ($p = 0.02$), which changed from 168.10 ± 3.25 bpm to 175.34 ± 3.49 bpm, with no difference between groups (group*time $p = 0.11$). **CONCLUSION:** While altitude training showed some positive adaptations in cross-country runners, the addition of PEMF did not improve these adaptations significantly. This can be attributed to the short duration of application, since a positive-trend was found for VT relative to VO_{2peak} . PEMF could have beneficial effects when combined with a longer duration of altitude training.

The Effects of Hip Tightness on Running Mechanics and the FMS Deep Squat in DIII Track & Field Runners

Samuel D. Rosario, Ana B. Freire Ribeiro. Augsburg University, Minneapolis, MN. (Sponsor: Dr. Mark Blegen, FACSM)

Email: rosarios@augsborg.edu
 (No relevant relationships reported)

Introduction: Running requires rapid hip movements. Increasing running speeds place increased loads on hip flexor and extensor muscles (Schache et al., 2011). It is unclear whether Division III track and field athletes with self-reported hip tightness would present altered sagittal plane hip mechanics while running and functional limitations when performing the Functional Movement Screen (FMS) deep squat. **Objective:** To investigate the relationship between hip tightness, as measured by the Functional Movement Screen (FMS) deep squat (DS), and running mechanics, as measured by the peak flexion and extension angles in Division III Track & Field athletes. **Methods:** Ten subjects completed the FMS DS and were filmed from both sides while running on a treadmill at 3 different speeds. Reflective markers were placed on the greater trochanter and lateral epicondyle of the femur. Absolute peak flexion and extension angles were obtained using Dartfish software. **Results:** DS was not a significant predictor of running mechanics. There were moderate positive correlations between peak hip flexion angles and DS. DS scores of 1 were associated with increased hip flexion ROM and decreased extension, especially on the left side. Runners who reported hip tightness had higher

average DS scores. **Conclusion:** Self-reported hip tightness group showed earlier toe-off and increased flexion ROM during swing phase. Differences between groups are greater in hip extension.

Findings also suggest asymmetries in the non-affected side for the tightness group. Future studies could investigate these changes in running mechanics in different planes of motion and injury prevalence in runners with self-reported hip tightness.

Prevalence And Spectrum Of Electrocardiogram Abnormalities In Amateur Marathon Runners

xu wen. Zhejiang University, Hangzhou, China. (Sponsor: Stanley Sai-chuen HUI, FACSM)

Email: wenxu@zju.edu.cn

(No relevant relationships reported)

PURPOSE: The purpose of this study was to assess the prevalence and the spectrum of electrocardiogram (ECG) abnormalities in amateur marathon runners.

METHODS: The participants of this study were contestants who participated in Hangzhou marathon (full marathon or half marathon) in 2015 and 2016. 12-lead ECG data of 24,210 amateur marathon runners aged 18-70 were included for analysis. The prevalence of ECG abnormalities were calculated and Chi square test was applied to compare the prevalence between different gender, age, weight status and sports performance groups. Logistic regression was utilized to determine the odds ratios of having certain ECG abnormalities in runners with good performance as compared with the runners with poor performance.

RESULTS: Sinus bradycardia and sinus arrhythmia were found in approximate 15% and 5% of participants. Prevalence of left ventricular high voltage, T wave change and right axis deviation are also higher than 1%. Runners with better performance had higher odds ratios to have sinus bradycardia, left ventricular high voltage, right ventricular high voltage and atrioventricular block (AVB).

CONCLUSIONS: Sinus bradycardia, sinus arrhythmia and left ventricular high voltage are the most common ECG abnormalities in amateur marathon runners. Sinus bradycardia and ventricular high voltage could be physiological adaptation after long-term marathon training, but ST-T change and axis deviation are not training-related ECG abnormalities.

Running Economy of Highly-Trained Distance Runners in Marathon Racing Shoes compared to Track Spikes

Kyle R. Barnes¹, Jordan Juzwiak². ¹Grand Valley State University, Wyoming, MI. ²Grand Valley State University, Allendale, MI. (Sponsor: Stephen Glass, FACSM)

(No relevant relationships reported)

Running economy represents a complex interplay of physiological and biomechanical factors that are able to adapt chronically through training or acutely through other interventions such as changes in footwear. The Nike Vaporfly (NVF) shoe was designed for marathon running on the roads and has been shown to improve running economy by ~4% compared to other marathon shoes, however, during track racing distance runners traditionally wear a much lighter shoe with an embedded spike plate around the forefoot. **PURPOSE:** To determine if, and to what extent, the NVF shoes improve running economy compared with established track spikes (SPIKE) and marathon racing shoes (MAR). **METHODS:** 24 highly-trained runners (12 male, 12 female) ran 4x5 min trials on a treadmill while wearing each of the four shoe conditions: NVF, SPIKE, MAR, and the NVF matched in weight to the MAR shoe (NVF+), during three separate visits: (Visit 1) familiarization; (Visit 2) 14 and 18 km·h⁻¹ run for men, 14 and 16 km·h⁻¹ for women; (Visit 3) 16 km·h⁻¹ run for men, 15 km·h⁻¹ for women plus a VO_{2max} test for both genders. We measured rates of oxygen uptake (VO_2), carbon dioxide production (VCO_2) and biomechanical measures (stride rate, contact time, stride length, flight time) were made at each run velocity and shoe condition. Differences in running economy while running in the four shoe conditions over three velocities was assessed using a two-way ANOVA with repeated measures. Multiple regression analyses were used to evaluate potential relationships between changes in biomechanical measures and running economy. **RESULTS:** The NVF shoe improved running economy by $2.6 \pm 1.3\%$ compared to SPIKE, $4.2 \pm 1.2\%$ compared to MAR, and $2.9 \pm 1.3\%$ when matched in weight of the MAR shoe. Among the 24 subjects, the difference in running economy over the four velocities between the NVF and SPIKE shoes ranged from +0.50 to -5.34% and from -1.72 to -7.15% for NVF versus MAR. Correlations between changes in running economy and changes in biomechanical variables were either trivial or small ($r < 0.27$) but unclear. **CONCLUSION:** The NVF enhanced running economy compared to track spikes and marathon shoes and should be considered a viable shoe option for track and road racing.

Influence of Body Weight, FMS, & Summer Training on Mile Run Performance in Endurance Runners

Nathan Goslin-Klemme, Preston Kauder, Jake Till, Elaina Biechler. *Loras College, Dubuque, IA.* (Sponsor: Vincent Paolone, FACSM)
 Email: ngoslin10@gmail.com

(No relevant relationships reported)

PURPOSE: Anthropometrics, summer training volume, and functional movement including unilateral strength, flexibility and coordination have all previously been linked to athletic performance. The purpose of the current investigation was to determine the best predictor of mile time trial performance in division III cross country runners across the variables of body weight, functional movement screen (FSM), and total volume of miles run in the 14 weeks leading up to the start of the cross country season. **METHODS:** 31 subjects (M=22, F=9) aged (20 +/- 2 yrs) on a division III collegiate cross country team were asked to record and report summer mileage each week for the 14 weeks preceding the start of the season. Additionally, FMS tests were conducted on all subjects, as well as body weight measurement within the first week of the season. All subjects also completed a mile time trial run concomitantly. A multiple regression analysis was utilized to determine if FMS score, pre-season mileage, and/or body weight were significant predictors of mile time trial performance. **RESULTS:** The overall regression analysis revealed that FMS, body weight, and summer mileage were significant predictors of mile time trial performance ($r = .41$; $p < .05$). When covaried out, body weight was not significantly ($p > .05$) correlated with mile time trial performance for males or females ($r = .35$, $r = .27$, respectively). Summer mileage was statistically significant ($p < .05$) to mile time trial results. Lastly, FMS testing was deemed not significant ($p > .05$) towards mile time trial performance. **CONCLUSIONS:** Summer running volume, as recorded in the 14 week period leading up to the cross country season is the best predictor of performance when compared to anthropometric data as well as functional movement screening. Cross country athletes should focus on utilizing the progressive overload principle to gradually increase running volume over the summer months in order to maximize in season performance.

The Effect of Plyometric versus Muscular Endurance Training on Cross Country Time Trial Results

Zack B. Murphy, Mikaela D. Lengwin, Elaina S. Biechler. *Loras College, Dubuque, IA.* (Sponsor: Vincent Paolone, FACSM)
 Email: zackary.murphy@loras.edu

(No relevant relationships reported)

PURPOSE: Traditionally, endurance runners have supplemented aerobic training with muscular endurance training. Recent research has suggested that plyometric training improves running efficiency and endurance performance, and hence may be a more effective option in comparison to muscular endurance training. The purpose of the current investigation was to compare the effect of a plyometric and power intervention to a muscular endurance intervention on running performance in division III male and female cross country runners. **METHODS:** Both plyometric and muscular endurance training groups were assigned using stratified selection based on 2-mile time trial results completed during the first week of cross country practice. Subjects (N=46; M=29, F=17) participated in a 9 week intervention in conjunction with the cross country season. The muscular endurance group participated in exercises with a high repetition, low intensity scheme, while the plyometric/ power group participated in explosive exercises with a low repetition, high intensity scheme. To ensure equal training time, proper technique, and safety, researchers coached both groups during each training session. An unpaired t-test was utilized to determine if significant differences existed in cross country race finish time based on group assignment. **RESULTS:** The unpaired t-test revealed there was no significant difference ($T = 1.68$, $p > .05$) in race time to completion for the plyometric group compared to the muscular endurance group (27:12 +/- 3:08 vs 27:32 +/- 5:40, respectively). **CONCLUSIONS:** The plyometric/ power group was not significantly faster when compared to the muscular endurance group. However, on average the plyometric group was 20 seconds faster when compared to the muscular endurance group. Future interventions may need to be longer than nine weeks in order to elicit significant positive adaptations in endurance running as a result of the supplementation of plyometric training.

Relationship Between Hemoglobin Saturation and Performance in Collegiate Cross Country Runners

Mikaela D. Lengwin, Nathan E. Goslin-Klemme, Elaina S. Biechler. *Loras College, Dubuque, IA.* (Sponsor: Vincent Paolone, FACSM)

Email: mikaela.lengwin@loras.edu

(No relevant relationships reported)

PURPOSE: Hemoglobin is essential for proper transportation of oxygen in the blood to muscles within the body. This is of especial importance and focus within endurance athletics as effects on performance can vary based on the level of hemoglobin saturation. Previous research mainly focused on the significance of higher hemoglobin levels improving performance, while the significance of negative effects from low levels is still of equal importance. The purpose of this study was to investigate the relationship between hemoglobin saturation and running performance in collegiate division III cross country runners.

METHODS: Hemoglobin saturation level was measured by capillary puncture and analyzed with a hemoglobin meter and test cartridges of 34 collegiate cross country runners (11 females, 23 males). Endurance performance was measured by two-mile time trial in minutes. A linear regression analysis was utilized to show the relationship between levels of hemoglobin saturation and time trial performance. Further, a one sample t-test was utilized to compare the averages of males classified with low levels of hemoglobin saturation and those in the normal range.

RESULTS: There was no significant correlation between hemoglobin saturation and two-mile time trial performance for both males ($R = .268$; $p > .05$) and females ($R = .282$; $p > .05$). Subjects were also classified as low hemoglobin if values were < 12.0 mg/dL for females, and < 13.0 mg/dL for males. Male subjects classified within the standard levels (mean=10:4870 ± .817599 min) had significantly faster ($t(15) = -3.126$; $p = .007$) two-mile times in comparison to subjects who were below this standard (mean=11:12586 min) with a mean difference of .638860 min.

CONCLUSIONS: Hemoglobin saturation levels are important in cross country athletes. The relationship, however, is more important and significant when saturation levels go below the normal range compared to those within the range. Runners categorized as low in hemoglobin saturation see significant decreases in performance for two-mile time trials compared to those in the normal range.

Functional Movement Screen Scores of Division III Cross-Country and Track and Field Runners

Ana B. Freire Ribeiro, Samuel D. Rosario, Zachery Juare. *Augsburg University, Minneapolis, MN.* (Sponsor: Mark Blegen, FACSM)

Email: ribeiro@augsbu.edu

(No relevant relationships reported)

The functional movement screen (FMS) is a battery of seven fundamental movement patterns that include the Deep squat (DS), hurdle step (HS), in line lunge (ILL), shoulder mobility (SM), active straight leg raise (ASLR), trunk stability push up (TSPU), and rotary stability (RS) (Cook et al., 2006). FMS tests are scored on a 0 to 3 scale, for a composite score of up to 21 points. **PURPOSE:** To describe the FMS scores of DIII cross-country and track and field athletes and compare them to normative values for experienced distance runners, as reported by Agresta (2014).

METHODS: Ten NCAA Division III cross-country and track and field athletes (6 sprinters and 4 distance runners) were screened by one level 1 FMS certified tester. **RESULTS:** Mean DS was 1.9 (SD=0.57), mean HS was 1.7 (SD=0.48), mean ILL was 2.1 (SD=0.57), mean SM was 2.4 (SD = 1.07), mean ASLR was 2.4 (SD=0.84), mean TSPU was 2.6 (SD=0.7), and mean RS was 1.9 (SD =0.32). The mean composite score was 15 (SD = 1.76). When compared to the normative values established by Agresta (2014), DIII runners scored higher on SM by 25%, ASLR by 12.5%, TSPU by 24.2%, RS by 21.1%, and total FMS score by 12.7%. Results were the same for DS and ILL and lower on the HS by 5.9%. **DISCUSSION:** Despite having higher mean scores than the norm, three individuals had composite scores below the suggested threshold of 14 (Kiesel, 2007, Chorba, 2010, Hotta, 2015) and eight participants had scores of one and zero in individual tests, suggesting that the composite score alone is not sensitive enough to capture these asymmetries/imbbalances. Overall scores were higher than the normative values by Agresta (2014), but similar to mean composite values of 16.4 for young adult runners reported by Loudon et al. (2014). **CONCLUSIONS:** The mean composite score for DIII Cross-country and track and field runners was 12.7% higher than the scores for experienced runners in Agresta (2014). Future studies should continue to establish normative values for NCAA DIII cross-country and track and field runners.

Can High Intensity Interval Training Effect Division I College 800/1500m Runner's Performance
 Ffion G. Price, Alana Turner, Benjamin Krings, Hunter Waldman, Harish Chander, Adam Knight, JohnEric Smith, Matthew McAllister. *Mississippi state university, Starkville, MS.*
 Email: fgp13@msstate.edu
 (No relevant relationships reported)

HITT is a common training method incorporated for all fitness levels and been shown to improve athlete performance. However, these results were shown in sedentary and recreationally active populations and little research has been done with the Division I collegiate athlete population. **PURPOSE:** This study questioned whether HIIT could increase performance within this level of athletes, specifically middle distance runners (800/1500 m).

METHODS: A total of six Division I Collegiate level (800/1500 m) runners completed the study (three males, three female). The participant completed four weeks of HIIT, consisting on two HIIT workouts per week. The HIIT consisted of four 20-s Wingate tests with 4-min recovery between each. Both pre- and post- performance tests were completed, consisting of a run to volitional exhaustion, RPE, HR, which were collected on a treadmill. Stride length and stride frequency, were also measure during a 1500 m time trial on the track.

RESULTS: Significant differences were not found for performance pre- and post-training intervention, with respect to time to completion of the 1500 m time trial (pre-intervention: 5.0 ± 0.7 min; post-intervention: 4.8 ± 0.5 min; $p = 0.23$), and time to volitional exhaustion (pre-intervention: 20.1 ± 1.2 min; post-intervention: 19.7 ± 1.3 min; $p = 0.14$). RPE ($p = 0.64$), HR ($p = 0.09$), stride length ($p = 0.09$), and stride frequency ($p = 0.78$), showed no significant changes pre- and post-intervention.

CONCLUSIONS: HIIT did not impact 800/1500 m middle distance runner's performance, suggesting it can maintain performance, providing alternative training methods.

Telomere Length, Lipid Profile and Body Composition of Master Sprinters and Endurance Runners
 Larissa A. Maciel¹, Lysleine A. Deus², Samuel S. Aguiar¹, Caio V. Sousa¹, Herbert G. Simões¹. ¹*Universidade Católica de Brasília, Brasília, Brazil.* ²*Universidade Católica de Brasília, Taguatinga, Brazil.*
 Email: larimaciel@live.com
 (No relevant relationships reported)

BACKGROUND: Previous studies have shown that middle-aged Master Athletes have better body composition and lipid profile, as well as longer leukocyte telomeres compared to untrained peers. However, no comparisons were made with markers of biological aging, body composition, and metabolic health among athletes who performed different training regimens through life (ie, sprint / strength vs. resistance training).

PURPOSE: The telomere length, lipid profile and body composition were compared in sprinters and endurance runners from Master category.

METHODS: Middle-aged master athletes (n=23) with a minimal of 20 yrs of lifelong training in Track and Field were allocated according to their training specificity, being Sprinters (n=12; 49.41 ± 9.10 yr-old) and Endurance Runners (n=11; 55.45 ± 7.84 yr-old). Blood samples were collected after 8-hour fasting. Relative leukocyte telomere length was determined with qPCR analyses (T/S). The serum lipid profile was analyzed using commercial kits and body composition was predicted through skinfold measures.

RESULTS: Unpaired T-test revealed no differences between Sprinters vs Endurance athletes regarding to Leucocyte Telomere Length (T/S) [1.26 ± 1.01 vs. 1.11 ± 1.13 ($p=0.732$)], Body Fat (%) [12.32 ± 4.51 vs. 13.29 ± 4.49 ($p=0.612$)], Free Fat Mass (kg) [87.68 ± 4.51 vs. 86.70 ± 4.49 ($p=0.612$)], and lipid profile (mg.dL⁻¹) through Triglycerides [79.04 ± 51.28 vs. 120.20 ± 75.81 ($p=0.139$)], HDL [93.21 ± 28.66 vs. 70.41 ± 38.06 ($p=0.116$)], LDL [83.53 ± 76.34 vs. 125.59 ± 58.18 ($p=0.155$)] and Total Cholesterol [192.56 ± 72.85 vs. 220.04 ± 29.02 ($p=0.256$)].

CONCLUSION: For master athletes, regarding of whether they were trained lifelong in sprints or endurance, both training models revealed to be similar for the leukocyte telomere length and equally beneficial for lipids profile and body composition.

Can Your Face Affect Your Pace? The Impact of Facial Expression on Running Economy
 Brian C. Rider, Grace L. Ditzenberger, Thomas J. Sprys-Tellner, Brooke T. Hedglen. *Hope College, Holland, MI.* (Sponsor: Tamara Hew-Butler, FACSM)
 Email: rider@hope.edu
 (No relevant relationships reported)

Running economy (RE) is an important performance metric for runners. It is determined by comparing the oxygen cost of steady state exercise at given running speeds across individuals. A recent study examined the physiological impact that facial expressions (smiling and frowning) had on RE compared to more traditional cognitive relaxation techniques. Smiling while running resulted in a 2.8% improvement in RE among a group of recreational adult runners. **PURPOSE:** The purpose of this study was to determine whether facial expression would impact RE in a group of aerobically trained collegiate athletes. **METHODS:** Twenty-four Division III collegiate athletes (females n=14) completed four 6-minute running blocks at 70% of $\dot{V}O_{2max}$. The order of bouts was determined using a balanced Latin square design with each participant serving as his/her own control. Participants completed running blocks while smiling (Smile), frowning (Frown), relaxing their hands and upper bodies (Relax), and running as they "normally" would (Control). Cardiorespiratory responses were recorded continuously and participants reported perceived effort (RPE), affective valence (FS), and arousal (FAS) after each condition. Blood lactate was measured at the end of each block. Repeated measures analysis of variance was run on all primary variables with a significance level set a priori at 0.05.

RESULTS: There were no significant differences in RE between conditions (Smile 33.72 ± 4.4 , Frown 34.15 ± 4.08 , Relax 34.17 ± 4.12 , Control 34.16 ± 3.91 ml/kg/min, $p > 0.05$). Additionally, unlike previous research, there were no significant differences in RPE during smiling and frowning conditions (11.71 ± 2.56 vs. 11.82 ± 1.97 , $p = 0.71$). There were also no significant differences in affective valence, arousal, or blood lactate between all conditions. **CONCLUSIONS:** Among a group of aerobically trained collegiate athletes running at 70% $\dot{V}O_{2max}$, smiling does not improve RE. However, future research should be conducted in order to discern what meaningful effect, if any, facial expression could have on psycho-physiological markers associated with running performance across a more diverse population.

800 Board #34 May 29 2:00 PM - 3:30 PM
The Changing Relationship Between Performance and Aging as the Duration of an Ultramarathon Increases
 Kyle Brandenberger. *Georgia State University, Atlanta, GA.*
 Email: kyle@fitness-ministry.com
 (No relevant relationships reported)

PURPOSE: It is often said that increasing the distance of a race eliminates or reduces the age decline in performance. After, the age of 25 maximal oxygen consumption typically declines by 1% per year. If aging is not associated with impaired performance, it would suggest factors other than aerobic fitness become more important for racing extreme distances. **METHODS:** Data on finishing times, and age of participants was collected from Western States 161 km run (WSER) from 1974 through 2018. Age and mileage completed were collect from Across the Years 6 day race (ATY) from 2011 - 2017. **RESULTS:** From 1974 - 2018, 9310 individual finishes were recorded for the WESR. Mean age was 42.01 ± 8.65 yr with finish times of 25.57 ± 3.44 h. Regression analysis revealed age to be positively associated with finishing times (Finishing Time = $0.134 * \text{Age} + 19.937$), with a significant, weak correlation ($p < 0.001$, $r = 0.337$). From 2011 - 2017 there were 305 performances recorded for the ATY 6 day race. Mean age was 50.44 ± 16.36 yr, and mean distance completed was 332.90 ± 197.12 km. A regression analysis revealed that age was positively associated with distance completed (Distance Completed = $3.03 * \text{Age} + 179.85$), with a significant, but weak correlation ($p < 0.001$, $r = 0.252$). **CONCLUSIONS:** Aging tended to impair performance at the WSER. With every one year increase in age, finishing time tended to increase by 8 min, but it should be noted this association was weak. In contrast, aging was weakly associated with increased performance at ATY 6 day race. For every year increase in age, runners at ATY tended to run an additional 3 miles. This suggests that as the distance or time frame of the race increases beyond some point that age becomes less of a factor in performance. This suggests that that aerobic fitness may play less of a role compared to other factors for performance in a 6 day race, but remains important for a 161 km race.

The Isokinetic Muscular Strength Characteristics Of Ultra-endurance Runners

Viviane Merzbach¹, Danny Longman², Alison Macintosh², Rebecca Roberts², Jay Stock², Jorge Marques Pinto¹, Michael Ferrandino¹, Dan Gordon¹. ¹Anglia Ruskin University, Cambridge, United Kingdom. ²University of Cambridge, Cambridge, United Kingdom.

Email: viviane.merzbach@anglia.ac.uk

(No relevant relationships reported)

Descriptive information on strength characteristics of ultra-marathon runners is currently limited.

PURPOSE: To determine the isokinetic (ISO) strength of quadriceps and hamstring muscles for eccentric (ECC) and concentric (CON) muscle actions in ultra-marathon runners in conjunction with the physiological assessment of running economy, fractional utilisation and VO_{2max} .

METHODS: Following local institutional ethical approval, 46 ultra-endurance runners (27 males, 19 females) gave their written informed consent to volunteer in this study (age, 41 ± 8 yrs; height, 174.3 ± 9.1 cm; mass, 75.8 ± 13.3 kg). Each participant took part in at least one of four multi-stage ultra-marathon events: Rovaniemi150 (Finland), Jungle Ultra (Peru), Al Andalus Ultimate Trail (Spain) and Everest Trail Race (Nepal). ISO knee extension (EXT) and flexion (FLEX) peak torques were measured across three angular speeds ($60^\circ \cdot s^{-1}$, $180^\circ \cdot s^{-1}$, $240^\circ \cdot s^{-1}$) during ECC and CON loading for the left (L) and the right (R) leg. Furthermore, running economy, blood lactate responses and VO_{2max} were assessed during an incremental treadmill test.

RESULTS: There were non-significant differences in peak torque for EXT between the L and R leg across all angular speeds for both ECC and CON muscle actions ($p > 0.05$). However, the ECC peak torque was significantly greater in the R FLEX compared to the L for both $240^\circ \cdot s^{-1}$ (114.0 ± 34.1 vs. 105.7 ± 33.5 Nm) and $180^\circ \cdot s^{-1}$ (114.6 ± 37.9 vs. 103.2 ± 37.5 Nm), $t(43) = -2.11$, $p = 0.041$ ($ES = 0.12$) and $t(43) = -2.71$, $p = 0.01$ ($ES = 0.15$), respectively. No other significant differences were observed for peak torque for FLEX. The average ECC peak torques (Nm) across the speeds were R EXT ECC 203.7 ± 54.7 , L EXT ECC 204.7 ± 55.4 , R FLEX ECC 115.0 ± 36.6 , L FLEX ECC 106.7 ± 36.8 . The average CON peak torques (Nm) for both legs at 60, 180 and $240^\circ \cdot s^{-1}$ were R/L EXT CON-60 171.6 ± 43.9 , R/L EXT CON-180 121.7 ± 34.0 , R/L EXT CON-240 101.6 ± 29.4 , R/L FLEX CON-60 88.7 ± 28.6 , R/L FLEX CON-180 60.2 ± 19.3 , R/L FLEX CON-240 50.1 ± 18.3 , respectively.

CONCLUSION: This study provides normative ISO strength data for endurance trained athletes who participate in ultra-marathons offering insight into the balance between EXT and FLEX of the knee. These findings will be of interest to ultra-marathon runners, coaches and exercise physiologists supporting these athletes.

802 Board #36 May 29 2:00 PM - 3:30 PM
Relationship Among Physiological, Perceptual, And Biomechanical Variables During Exercise On A Non-motorized Treadmill In D2 Cross-country Athletes

Sean Bonilla, Anne Roquet, Elizabeth Corella, Steven Deverell, Miranda J. Reid, Jason Ng, Nicole Dabbs. *California State University, San Bernardino, San Bernardino, CA.* (Sponsor: Bryan Haddock, FACSM)

(No relevant relationships reported)

PURPOSE: The purpose of this study was to examine the relationship between physiological, perceptual, and biomechanical variables during exercise on a non-motorized treadmill (NMT) in cross-country athletes.

METHODS: Thirteen female cross-country Division II athletes (age, 20.77 ± 3.27 yrs; height, 161.92 ± 5.48 cm; weight, 55.54 ± 6.45 kg) participated in separate familiarization and testing sessions. On day one (familiarization), participants performed a treadmill protocol that consisted of a 5-min warm-up walk, 5-min walk, 5-min run, and 5-min cool-down on the NMT. Participants' velocity was recorded every minute to determine average self-selected pace for walking and running. Day two (testing day) consisted of performing the treadmill protocol with the previously determined velocities. Heart rate (HR), rating of perceived exertion (RPE), oxygen uptake (VO_2), vertical GRF (GRFv), horizontal GRF (GRFh), power, and velocity was recorded and steady-state minutes were averaged and used for analysis. Separate Pearson's r correlation analyses were used to determine the relationship among HR, RPE, VO_2 , GRFv, GRFh, power, and velocity.

RESULTS: There was a significant strong positive correlation in walking between in HR and velocity ($r = 0.75$; $p = 0.003$), horizontal force ($r = 0.73$; $p = 0.004$), and power ($r = 0.76$; $p = 0.002$). There was a significant positive strong correlation in running between HR and velocity ($r = 0.76$; $p = 0.002$), power ($r = 0.76$; $p = 0.002$). There was a significant positive strong correlation in running between VO_2 and running velocity ($r = 0.71$; $p = 0.006$), GRFh ($r = 0.69$; $p = 0.008$), and power ($r = 0.72$; $p = 0.005$). There was no significant ($p > 0.05$) correlation for all other variables in walking and running conditions.

CONCLUSIONS: The results indicate that VO_2 has strong correlations with running velocity, force, and power, and that HR has strong correlations with running velocity and power. VO_2 and HR are indicators of exertion in running conditions. Since the runners were in a steady-state condition, these results suggest that an increase in exertion—indicated by cardiovascular and metabolic responses—also requires an increase in kinetic measures. Because the NMT requires users to self-propel, the results suggest mechanics of running on a curved-NMT may influence physiological responses.

Evaluation of Running Performance in Recreationally Active Individuals at Submaximal Speeds: Shod vs. Barefoot Conditions

Matthew Miltenberger, Nicholas Roughan, Gavin Moir, Shala Davis, FACSM. *East Stroudsburg University, East Stroudsburg, PA.* (Sponsor: Dr. Shala Davis, FACSM)

Email: mmiltenber@esu.edu

(No relevant relationships reported)

The concept of barefoot running (BFR) is to purposely change foot strike patterns to promote metabolic efficiency, however exposing normally shod runners to BFR may have detrimental effects on overall running performance. **PURPOSE:** The purpose of this study was to evaluate the differences in physiological variables in running performance when individuals were acutely exposed to BFR. **METHODS:** This study consisted of 9 college aged males, (22.67 ± 1.0 y/o, 83.68 ± 9.01 kg, 178.36 ± 4.54 cm, and $14.60 \pm 5.27\%$ body fat), who engaged in aerobic exercise at least twice a week with no prior BFR experience. Subjects were blindly asked during each condition to self-select running speeds that they could maintain for 10 min. Variables collected included speed, VO_2 , HR, RER, VE, LRPE, SRPE, and foot pain. **RESULTS:** Data analysis revealed no statistically significant differences in physiological variables between conditions. However significant differences were seen between selected running speed and foot pain. Results indicated that subjects decreased their running speed by .98mph ($p = 0.004$) and experienced greater amount of foot pain ($+2.11$, $p = 0.02$) when in the BFR condition. **CONCLUSIONS:** The findings of this study suggest that acute exposure to BFR may decrease overall running speed during a workout and subjects may also experience a greater amount of foot pain compared to shod running. Caution should be used when introducing the concept of BFR to athletes or recreational runners.

Relationship Between Training Load and Intensity and Next Day Resting Heart Rate in Running.

Julio Morales, Keith Fallon. *Lamar University, Beaumont, TX.*

Email: jmorales@lamar.edu

(No relevant relationships reported)

Resting heart rate (RHR) is a commonly used indicator used to monitor adaptations in aerobic conditioning. In long distance training, measures such as heart rate and distance covered are used as indicators of intensity and workload to affect changes in aerobic conditioning. However, there appears to be a need for more information on possible interactions between measures of intensity and workload and their effect on RHR as an indicator of adaptation. **PURPOSE:** To examine the relationship between training load (LOAD) and training intensity (INT) on next day RHR. **METHODS:** Seven middle-long distance runners, members of a Division I varsity team participated in the study during a cross country season in the fall. Variables were morning RHR, INT measured using Borg's Ratings of Perceived Exertion 16-point scale and LOAD expressed as miles ran. Variables were recorded by each participant on each training day and were aggregated for a total of 224 data points among the seven participants. Correlation and Multiple Regression analyses were used to examine the relationship between the variables. **RESULTS:** Significant correlations were found between LOAD and INT (.392) and between INT and next day RHR (.200). Multiple Regression found INT contributed significantly to the prediction of RHR yielding the following formula: $RHR = 47183 + 0.483 * (INT)$, $R^2 = 0.055$, $SEE = 4.722$.

CONCLUSIONS: Although a relationship was found between LOAD and INT it seems that each may have a unique contribution to next day's RHR.

Number Of Sprints Performed By Players Of Different Playing Positions During A Soccer Match

Mario Norberto Sevilio de Oliveira Junior, Alyson Felipe da Costa Sena, Jefferson Fernando Coelho Rodrigues Júnior, Christian Emmanuel Torres Cabido, Emerson Silami Garcia, Christiano Eduardo Veneroso. *Federal University of Maranhão, São Luís, Brazil.*
Email: msevilio@hotmail.com
(No relevant relationships reported)

Soccer is a sport characterized by intermittent efforts and by a variation of intensity between the first and the second half-times of the match. The sprints, actions performed at high speeds and which demand a high energy expenditure, are among the several parameters which can be used to evaluate the performance capacity of the players along a match.

PURPOSE: To compare the sprints performed by professional players of different playing positions along Soccer matches. **METHODS:** Twenty-two professional Soccer players (weight = 76.4 ± 5.2 kg; height = 179.9 ± 6.2 cm; BMI = 23.7 ± 1.7 kg/m²) participated in the study. The Polar Team Pro® GPS system was used to measure distances and speed of the subjects during the games. The number of sprints at speed above 25 km/h were registered in the first and in the second halves of the matches. Only players who participated during 75% of the total time of each of 10 matches were included in the study. Data normality was tested using the Shapiro-Wilk (p = .714). The Friedman test followed by the post-hoc Tukey were used to analyse the sprints (p < .05). **RESULTS:** The average number of sprints (> 25 km/h) was 13.3 ± 6.4 sprints per game. There was a difference amongst playing positions (Expected P = .039 and Calculated P = .042) and there was a difference between the second half and the total match time. The number of sprints of mid-fielders and forwards, but not of full-backs and half-backs, was reduced in the second half-time. **CONCLUSIONS:** There was a difference in the number of sprints between players of different positions and also a difference between the first and the second half-times. This information may be used by coaches in conducting training sessions and in matches.

Average number of sprints in the 10 matches

| Player Position | 1st half | 2nd half | Total |
|-----------------|----------|----------|-------|
| Full-backs | 7 | 7 | 14 |
| Half-backs | 7 | 7 | 14 |
| Midfielders | 8 | 6 | 14 |
| Forwards | 8 | 7 | 15 |

Structured Physical Training Program Reduces Injury Risk Factors Unrelated to Performance Improvements in Soccer Players

Meleesa Wohleber, Jason Metz. *West Liberty University, West Liberty, WV.*
Email: meleesa.wohleber@westliberty.edu
(No relevant relationships reported)

Physical training programs are designed to improve sport performance. To augment these programs, specific injury prevention protocols can be included. However, structured physical training programs alone could reduce injury risk.

Purpose: To determine the effects of a structured offseason training program on physical performance and modifiable LE injury risk factors.

Methods: Twenty-three male collegiate soccer players were enrolled (20 ± 1.54 yrs.). Body fat percentage (BF%), aerobic capacity (VO₂max), vertical jump, anaerobic power (Wingate), bench press (1RM), Y-balance (YB) bilaterally and weight bearing lunge ankle dorsiflexion (WBDF) bilaterally were measured pre and post a 12-week physical training program.

Results: Performance measures of BF%, VO₂max, vertical jump, and Wingate were not significantly different after the 12-week program. Bench press 1RM (177.22 ± 31.44 lb.) was the only statistically significant performance measure (n=9, p=0.02). Right(R) (691.13 ± 81.27 mm) and Left(L) (684.54 ± 85.49 mm) side absolute YB in the anterior-posterior direction (p=0.03) and LWBDF (26.5 ± 8.47°, p=0.05) were statistically different pre to post assessment (n=10). All other YB directions (posterior-medial, posterior-lateral) and RWBDF were not statistically significant. Composite

scores for YB normalized to leg length pre (RYB=82.84± 9.64%, LYB=80.63 ± 12.64%) and post (RYB=78.76± 26.88%, LYB= 80.53 ± 19.36%) resulted in no significant change.

Conclusion: Participants improved some modifiable injury risk factors at the LE (YB, WBDF) and increased upper extremity strength. However, no other performance measures significantly changed. These results indicate structured physical training programs could positively affect injury risk factors, absent of specific injury prevention programming and unrelated to physical performance improvements. Specific physical training programming and its relationship to reduction of injury risk factors requires further research.

Effects of Soccer Kicking Training Using Virtual Reality on Kicking Performance in Boy Soccer Players

Somi Yun¹, Min Gi Jung¹, Jaemyung Kim¹, Yunbin Lee¹, Dae Taek Lee¹, Seung Chan Lim². ¹*Kookmin University, Seoul, Korea, Republic of.* ²*Airpass, Seoul, Korea, Republic of.*
Email: ysmysm7@naver.com
(No relevant relationships reported)

Purpose: Adoption of virtual reality (VR) into sports, games, and educational settings has become popular in recent years, but no evidence regarding VR's effects on athlete's performance has been elucidated. This study evaluated an efficacy of VR soccer kicking training system for kicking performance in young soccer players. **Methods:** A total of 24 experienced boy soccer players enrolling in a elementary school soccer team was recruited for the 6 months study, and divided into two groups; VR training group (VR-G; n=13, 11.8±1.0 yrs, 148±7.5 cm, 39.0±7.9 kg) and outdoor training group (OT-G; n=11, 11.4±3.4 yrs, 152±9.7 cm, 45.2±10.2 kg). Before (M0) and after (M6) the study, they were tested. For the test, they kicked a ball, in which a sensor was installed, to a curtain screen on which targets were marked by a beam. The VR room was sized 12×8 meter. Using the data of ball speed and target hitting accuracy, a scoring point was calculated for kicking accuracy (Ka) and speed (Ks). They were also tested on a soccer field for measurement of kicking accuracy (Kfa). For the test, they practiced twice and kicked 5 times for measurement. During the study, they were trained for two phases; regular and extra training. For the regular training, the team was trained 4 times/week in a soccer field for 120 min/session. For a total of 15 sessions of extra training, OT-G practiced only kicking on the field, while VR-G did in a VR room. **Results:** For VR-G, Ka, Ks, and Kfa increased from 53.6±9.5, 26.1±11.8, and 18.6±14.9 at M0 to 62.9±10.0 (t=-6.138, p<.001), 38.0±13.2 (t=-2.396, p<0.05), and 31.9±16.0 unit (t=-2.442, p<0.05), respectively. For OT-G, Ka, Ks, and Kfa were not changed from 58.8±8.9, 35.9±15.5, and 19.6±13.6 at M0 to 63.1±5.7, 29.1±10.0, 22.2±12.8 unit, respectively. No differences were found in 3 kicking variables at M0 and M6 between two groups. **Conclusion:** The regular soccer training and the extra kicking training improved the kicking speed and accuracy in VR-G, while OT-G maintained their performance. VR soccer kicking training program could be a potential substitutional and additional training model for young soccer players. (This research project was supported by the Sports Promotion Fund of Seoul Olympic Sports Promotion Foundation from Ministry of Culture, Sports and Tourism, project # s072016122016)

Initial Profiling of Division II Soccer Athletes Revealed Minimal Body Composition Changes Throughout Competitive Season

Sara L. Terrell, Diana I. Griessler, Charles R. Allen, Zachary Wallace, James M. Lynch. *Florida Southern College, Lakeland, FL.*
Email: sterrell@flsouthern.edu
(No relevant relationships reported)

Body composition (BC) assessment is a metric utilized in sport performance, yet there is a paucity of BC data profiling NCAA Division II female athletes.

PURPOSE: To measure and compare BC data of Division II female soccer athletes during a competitive season thereby developing an initial profile relative to this sport and division. **METHODS:** Subjects (Age: 19.09 ± 1.15 yrs.) consisted of Division II women's soccer athletes (n=22). Body fat percentage (BF%) utilizing air plethysmography [BODPOD, Cosmed] was measured during pre-season and within the penultimate week of the competitive season. Descriptive statistics and dependent t-tests (SPSS version 25.0) were used to analyze data. **RESULTS:** Pre-season data indicated the following team anthropometrics: Height: 165.38 ± 9.05 cm; Weight: 60.02 ± 5.2kg; BMI: 21.64 ± 1.39. Team BF% was 19.99 ± 4.39% with freshman (n=10) BF% recorded at 18.73 ± 5.07% and returners (n=12) at 21.0 ± 3.62%. Latter season weight of 59.80 kg ± 5.09 and BMI of 21.47 ± 1.25 was down slightly. Team BF% increased to 20.27 ± 4.09% with freshman BF% increasing to 20.55% ± 4.90 % while returners decreased to 20.02 ± 3.47%. There were no statistically significant differences in team, freshman, or returners BF% or BMI for both time points assessed. **CONCLUSION:** Team BF% was lower at both assessment points than recently

published data on Division I female soccer athletes (Field et al., 2018). Freshman demonstrated lower BF% than returners initially but returners BF% trended downward at the latter part of the season. Future research should continue to explore physical profile changes over time while expanding sport performance testing metrics to obtain a more comprehensive snapshot of the Division II female soccer athlete. Reference: Field, J. et al. (2018). Comparison of body composition variables across a larger sample of national collegiate athletic association women athletes from 6 competitive sports. *Journal of Strength and Conditioning Research*, 32(9), 2452-2457.

Use Of Muscle Saturation Oxygen As A New Marker Of Fatigue In Female Soccer Players

Aldo A. Vasquez-Bonilla¹, Ismael Martinez-Guardado², Jeffrey M. Mjaanes M. Mjaanes, FACSM³, Samantha Guerrero-Flores², Rafael Timón², Guillermo Olcina². ¹National Pedagogical University Francisco Morazán, San Pedro Sula, Honduras. ²University of Extremadura, Cáceres, Spain. ³Northwestern University, Evanston, IL. (Sponsor: Jeffrey M. Mjaanes, FACSM)
 Email: alvasquez@alumnos.unex.es
 (No relevant relationships reported)

According to UEFA, a paucity of relevant studies has led to a significant increased interest in women's soccer research. Additionally, early detection of muscle fatigue could have profound impact on injury prevention and recovery in many sports including soccer. Measurement of muscle oxygen saturation (SmO₂%) with non-invasive near infrared spectroscopy (NIRS) technology has been investigated as a possible indicator of fatigue, however no clear protocol exists regarding interpretation of NIRS data or its application for training assessment or fatigue detection. **PURPOSE:** To evaluate SmO₂% kinetics and relate it to markers of fatigue induced by an official match. **METHODS:** 12 female soccer players (age 19 ± 3 years, weight 59.1 ± 5.7 kg, height 1.61 ± 0.05 m, Fat 18.5 ± 3.5%). They were evaluated pre-match (PRE) and 24 hours after an official match (POST). Blood plasma parameters were measured including Blood Urea Nitrogen (BUN), Glutamate-Pyruvate Transaminase (GOT) Lactate Dehydrogenase (LDH), Creatine phosphokinase (CPK), and total hemoglobin (THb). Additional outcomes were assessed including rate of perceived exertion (CR-10 Borg scale), Visual Analog Scale (VAS-pain 1-10), and "Repeated Ability Sprint Test" (RAST) using a portable "Muscle Oxygen Monitor" (MOXY) placed in the gastrocnemius muscle of the dominant leg to measure SmO₂%. Deoxygenation rate (De-Oxy) and Reoxygenation Rate (Re-Oxy) were calculated. For statistical analysis, T-test, Pearson correlation and mechanical inferential statistics were applied to measure the magnitudes of change. **RESULTS:** Average SmO₂% during test RAST increased after match ((23 ± 8 vs. 29 ± 8 p < 0.05); Δ% = 19.1%), as well minimum SmO₂% values (12 ± 8 vs. 21 ± 8 p < 0.05) and maximum values (31 ± 8 vs. 36 ± 8 p < 0.05). Other fatigue markers increased too after match, LDH (282 ± 45 vs. 341 ± 79 IU/L p < 0.05) and VSA pain (3.2 ± 1.7 vs. 5.1 ± 1.7 p < 0.01). It was also found that a higher Re-Oxy correlated with increases in LDH (r = 0.88 p < 0.01), VSA pain (r = 0.61 p < 0.05) and BUN (r = 0.84 p < 0.01). Taken together, the decrease in SmO₂% was considered as the best performance in the RAST test (r = -0.79 p < 0.01). **CONCLUSIONS:** MOXY monitor can be used as a novel, non-invasive method to identify post-match fatigue in female soccer players through measurement of SmO₂% kinetics and the rate of reoxygenation.

810 Board #44 May 29 2:00 PM - 3:30 PM
Effects of Video Feedback on Kicking Performance and Temporal Patterns in U-10 Soccer Players

Bernat Buscà, Marc Quintana, Joan Aguilera-Castells, Mònica Solana-Tramunt, Jose Morales, Ainhoa Nieto. *FPCEE Blanquerna. Ramon Llull University, Barcelona, Spain.*
 Email: bernatbs@blanquerna.url.edu
 (No relevant relationships reported)

Kicking is a crucial motor skill in soccer. Accuracy and velocity are the two primary factors responsible for kicking performance. Coaches and practitioners design programs with practice sessions in which kicking actions are involved. **PURPOSE:** To examine the effects on kicking performance of different types of extrinsic video feedbacks such as slow-motion video feedback (SMVF) or normal video feedback (NVF), with additional velocity feedback, in comparison with no feedback (NF) was studied in U-10 soccer players. **METHODS:** Thirty male children soccer players (mean age: 8.9 ± 0.8 years) asked to perform series of dynamic soccer kicks. Their kicking performance was measured in terms of accuracy and velocity, and the motor skill pattern variations were assessed in terms of temporal variables of approach time (ATIME), the last step time (LSTIME) and the foot descent time (DTIME). Players performed 4 blocks of 5 kicks with a 30-second rest period and a retention block of 10 kicks 2 days later. **RESULTS:** Results showed significant differences both between the SMVF and NF groups in terms of performance (F_{2,27} = 3.97, p < 0.05; η²_p = 0.227). SMVF group

significantly improved performance during the practice phase but not in retention. Significant differences of the coefficient of variation (CV) were found in the main temporal variables of the action (F_{6,214} = 6.96, p = 0.000; η²_p = 0.44). Univariate analysis showed a significant effect of group on LSTIME (F_{2,108} = 4.07, p = 0.015; η²_p = 0.06) and DTIME (F_{2,108} = 16.99, p = 0.000; η²_p = 0.16) but not on ATIME (F_{2,108} = 1.28, p = 0.30; η²_p = 0.16). **CONCLUSIONS:** The type of multimodal feedback (slow motion video and velocity) significantly affects the acute kicking performance in children and its temporal pattern. The present study suggests possible benefits of using slow-motion video feedback in the learning sessions of children soccer players. The accessibility of such technology using low-cost cameras or mobile phones makes this finding especially relevant. Coaches and practitioners can induce significant changes in kicking performances (and other motor skills) and temporal patterns. This study is inconclusive about the retention of these changes and has not studied the transfer in learning.

Lower and Upper Body Muscle Characteristics among Collegiate Baseball and Soccer Players

Savannah Ange, Pragma Sharma Ghimire, Peter Gaither, Sara Rogers, Leland Nielsen, Martin Carmichael, Amir Bhoohibhoya. *Lander University, Greenwood, SC.*
 Email: psharmaghimire@lander.edu
 (No relevant relationships reported)

Increased muscular strength in athletes has shown a prolific effect in the development of sports skills including jumping, throwing, sprinting, and change of direction abilities. Sports, such as soccer and baseball, differ largely in specific characteristics needed for success. To date, few studies have reported differences in sports specific skills between these two sports to measure and quantify the neuromechanical capacity. **PURPOSE:** To compare both lower and upper body strength among collegiate baseball (BB) and soccer (SC) players. **METHODS:** In this non-randomized cross-sectional study, 19 baseball and 19 soccer players, age ranges from 18-25 years completed the protocols. Lower body strength and power were assessed by a two-leg press maximal strength test (1RM) and vertical jump test (Just Jump Mat, Tendo Sports Machine), respectively. Upper body strength was assessed by a handgrip (HG) test using handgrip dynamometry (Takei, Japan). **RESULTS:** Independent sample t-test showed BB players (88.05 ± 7.1 kg) were significantly heavier than SC players (72.1 ± 7.2 kg) (p < 0.05). However, weight-adjusted upper body strength and leg power were not significantly different between the two groups. BB players had significantly higher jump height (JH), time in air, and 1RM leg strength compared to SC players (p < 0.05). **CONCLUSIONS:** BB players showed significantly higher lower muscle strength compared to SC players, however no differences were observed for peak power. These results provide a quantitative measure of the performance difference between these two sports, reinforcing the need for further research along with large sample size to assess the possible differences in training effectiveness and inherent characteristics between BB and SC players.

Table 1. Athlete Performance Variables (Adjusted Mean ± SE)

| Variables | BB Players (n= 19) | SC Players (n=19) |
|---------------------------|--------------------|-------------------|
| Time in air (s)** | 0.72 ± 0.01 | 0.64 ± 0.01 |
| Jump Height (inches)** | 25.99 ± 0.79 | 20.10 ± 0.79 |
| Velocity (m/s) | 1.42 ± 0.02 | 1.39 ± 0.02 |
| Power (Watts) | 1125.99 ± 25.62 | 1075.14 ± 25.62 |
| Relative Power (Watts/kg) | 13.99 ± 0.31 | 13.31 ± 0.31 |
| 1 RM (Kg)* | 355.54 ± 14.88 | 300.43 ± 14.88 |
| Rt HG (Kg) | 44.91 ± 2.36 | 41.15 ± 2.36 |
| Lt HG (Kg) | 42.51 ± 2.20 | 42.20 ± 2.20 |

Performance Implications of Arousal State in Female Collegiate Soccer Players

Adam Lowe¹, Neil M. Johannsen¹, Brian A. Irving, FACSM¹, Jack Marucci¹, Shelly Mullenix¹, Arnold Nelson, FACSM¹, Guillaume Spielmann¹, Erik Lind². ¹Louisiana State University, Baton Rouge, LA. ²State University of New York-Cortland, Cortland, NY. (Sponsor: Brian A. Irving, FACSM)
 (No relevant relationships reported)

Arousal, defined as a blend of physiological activation and psychological awareness, prior to collegiate soccer matches may have important implications on performance. How various arousal states are related to measures of sport-specific performance and

the hormone cortisol in and around matches in female collegiate soccer players is largely unknown. **PURPOSE:** To investigate the effect of arousal state on passing performance and salivary cortisol in female collegiate soccer players.

METHODS: Eighteen NCAA Division I female soccer athletes (20.2±1.1 y) participated in this study during the spring season. One hour before five competitive matches, the Activation-Deactivation Adjective Checklist (AD-ACL) was administered to assess tension arousal (TA) and energy arousal (EA) using tiredness (Ti), energetic (E), tension (Te), and calmness (C) subscale scores. Salivary samples were collected via synthetic swab placed under the tongue 1 hour before, and 30 minutes after each match. Enzyme-linked immunosorbent assay (ELISA) was used to analyze salivary samples for cortisol. Passing performance was defined as percentage of total attempted passes received by a teammate.

RESULTS: Pre-match subscale scores (out of 4, [mean, ±SD]) for the five competitions were: Ti: 1.9±0.8, 1.7±0.9, 1.6±0.6, 1.6±0.8, 1.4±0.5, respectively; E: 2.9±0.6, 3.1±0.7, 3.2±0.4, 3.0±0.6, 3.0±0.6, resp.; Te: 1.7±0.5, 2.1±0.5, 1.9±0.4, 1.7±0.5, 1.7±0.5, resp.; C: 2.1±0.5, 2.0±0.5, 2.0±0.4, 2.0±0.5, 1.8±0.6, resp. Passing performance for the five competitions was 73.6±14.1%, 81.6±9.6%, 79.1±8.6%, 74.6±8.8%, 76.6±12.1%, resp. ($p > 0.05$). Collapsed across matches, Ti and C scores demonstrated negative associations approaching significance with passing performance (both $p = 0.06$, $r = -0.28$); E score was positively associated with passing performance ($p = 0.04$, $r = 0.30$). Collapsed across matches, post-match cortisol was significantly greater than baseline-predicted-values ($p = 0.03$). Percent change in cortisol pre- to post-match in the first match was associated with E score ($p = 0.04$, $r = 0.72$).

CONCLUSIONS: Higher energy-arousal states were associated with improvements in passing performance. Cortisol response may be mediated by energy arousal. Future investigations should examine mediating factors of pre-match arousal states.

Relative Age Effects In Men's Collegiate Soccer Are Influenced By Nationality, Position, Class, And Success

Kyle S. Beyer, Eoin Hurley, Luke Haile, Brett A. Comstock.
Bloomsburg University, Bloomsburg, PA.
 (No relevant relationships reported)

Relative age effects (RAEs) refer to an unequal birth-date distribution within cohort of individuals, typically due to selection bias. RAEs have been shown to exist in sports, specifically youth soccer and elite professional soccer. However, no study has assessed the prevalence of RAEs at the collegiate level. **PURPOSE:** To evaluate the existence of RAEs in Division I Men's collegiate soccer. Additionally, the study assessed the impact of nationality, position, class, and post-season tournament qualification on the prevalence of RAEs. **METHODS:** Birth-dates from Division I Men's collegiate soccer athletes ($n=4,082$) from the 2017-2018 season were categorized into calendar quarters (CQ1: January-March; CQ2: April-June; CQ3: July-September; and CQ4: October-December) and scholastic quarters (SQ1: September-November; SQ2: December-February; SQ3: March-May; and SQ4: June-August). All athlete birth-date distributions were compared with the expected birth-date distributions for the United States. All data were assessed using χ^2 goodness of fit tests. **RESULTS:** International-born athletes (INT) displayed a significant ($p < 0.001$) difference in birth-date distribution when assessed with calendar quarters, with an over-representation in CQ1 (31.2±2.8%) and an under-representation in CQ4 (20.0±2.4%). However, American-born athletes (USA) showed a significant difference ($p < 0.001$) in birth-date distribution when assessed with scholastic quarters, with over-representation in SQ1 (27.6±1.6%) and an under-representation in SQ4 (23.0±1.5%). Furthermore, INT showed significant ($p \leq 0.001$) RAEs for midfielders and defenders, while USA showed significant RAEs for midfielders ($p=0.009$) and goalkeepers ($p=0.004$). In terms of class, INT had significant ($p \leq 0.045$) RAEs for all classes, while USA had significant RAEs only for freshmen ($p=0.001$) and sophomores ($p=0.007$). All INT had significant ($p \leq 0.003$) RAEs regardless of tournament qualification; however, USA had significant RAEs only for non-tournament teams ($p < 0.001$). **CONCLUSION:** Significant RAEs exist in Division I Men's collegiate soccer; however, the presence of RAEs are influenced by nationality, position, class, and on-field team success. Coaches should be aware of RAEs during the recruitment process to avoid potential selection bias.

814 Board #48 May 29 2:00 PM - 3:30 PM
Influence of Thresholds on GPS Speed Zones and Sprint Determination in Female Collegiate Soccer Players

Matthew F. Moran, Jessica L. Trapp. *Sacred Heart University, Fairfield, CT.*
 Email: moranm@sacredheart.edu
 (No relevant relationships reported)

Use of team sport global positioning system (GPS) to track player movements and determine training load has expanded recently. Following training sessions or games, player velocity is categorized into discrete zones utilizing velocity thresholds (VT).

VT are typically pre-determined by the software provider or modified from previous reports. Currently there is no universally accepted standard for VT in collegiate women's soccer players.

PURPOSE: To determine the influence that VT individualization based on maximum speed testing (MST) has on distance covered in speed zones and sprint determination. **METHODS:** Twelve collegiate female soccer players (19.6 ± 0.9 yo, 61.0 ± 6.5 kg, 1.63 ± 0.05m) were recruited and participated. Maximal velocity (MV) was determined via MST on a 37-meter runway with electronic timing gates. GPS data (10Hz) from five games was processed in a custom written Matlab script to determine distance covered in five velocity zones (Z1-5) and total number of sprints completed. The following two sets of VTs were implemented: (1) manufacturer supplied (MS) (0.83, 1.94, 3.06, 4.17, and 5.28 m/s), (2) player specific (PS) (11.8, 27.7, 43.6, 59.4, 75.2 %MV). Paired samples t-tests were conducted to determine significance ($p \leq 0.05$).

RESULTS: There were no significant differences for distance covered in any of the five velocity zones when using either MS or PS velocity thresholds (Z1: MS 234.1±95.6m, PS 235.0±103.7m, $p=0.88$) (Z2: MS 1509.4±442.8m, PS 1490.2±472.2m, $p=0.18$) (Z3: MS 1572.3±410.9m, PS 1557.7±379.1m, $p=0.56$) (Z4: MS 1373.2±343.6m, PS 1380.0±367.7m, $p=0.58$) (Z5: MS 260.4±141.1m, PS 274.7±156.6m, $p=0.42$). Number of sprints determined from MS (32.2±14.6) was not significantly different from PS (35.05±17.9) ($p=0.18$).

CONCLUSIONS: Distance covered in speed zones and sprint determination from GPS data was not significantly different when using an absolute scale (MS) versus a relative scale (PS) determined from MST. Although aggregate team data did not significantly differ between methods, sport scientists should remain cautious when utilizing an absolute scale. Analysis of individual player differences between methods yielded overestimations >250m for Z5 and an overestimation in the number of sprints completed by >30 for the fastest player when using an absolute scale.

Comparison of Performance Measures Between Starters Vs Non-starters in a Division III Women's Soccer Team

Barry Myers, Dillon Frees, John MacDonald, Ronald W. Mendel. *University of Mount Union, Alliance, OH.* (Sponsor: Ron Otterstetter, FACSM)
 Email: myersbj2019@mountunion.edu
 (No relevant relationships reported)

INTRODUCTION: It is widely known that there are physical and physiological differences between members of a collegiate soccer team but less is known regarding the magnitude of those differences between starters (S) and non-starters (NS). Previous research between S and NS players at the NCAA Division I level did not elucidate any differences (Risso et al., 2017), however this might not be the case at other NCAA competition levels. **PURPOSE:** To compare performance measures of S and NS of a NCAA Division III female soccer team. **METHODS:** Performance measures between S and NS of a Division III female collegiate soccer team ($n=22$) were assessed. Data was collected pre-season and consisted of descriptive physical measures (age, height, weight, body fat percentage, fat mass, lean mass) and performance measures (vertical jump, standing broad jump, triple hop, 30-m sprint). All data were analyzed utilizing independent t-tests with significance set at $p < 0.05$. **RESULTS:** Findings show that there were no statistical differences between S and NS in any of the descriptive physical measures. Performance measures demonstrated statistically significant differences in vertical jump (S 0.38±0.06 m vs NS 0.31±0.05 m ($p=0.01$)); standing broad jump (S 1.78±0.16 m vs NS 1.58±0.17 m ($p=0.00$)); standing broad jump right foot (S 1.46±0.14 m vs NS 1.23±0.17 m ($p=0.00$)); triple hop left foot (S 4.79±0.45 m vs NS 4.37±0.48 m ($p=0.04$)); triple hop right foot (S 4.94±0.48 m vs NS 4.25±0.41 m ($p=0.00$)); and change of direction left foot (S 2.64±0.14 sec vs NS 2.77±0.11 sec ($p=0.04$)). There were no differences observed in the 30-m sprint times or any of the intervals (0-5, 0-10, or 0-30 m). **CONCLUSION:** In the current study, S and NS did display significant differences in a number of performance measures. Due to these differences, substitutions could have a major impact on team performance; therefore, training considerations may be warranted between S and NS.

Correlation between Sprint Tests and Agility 505 Test and Ktest in Elite Young Soccer Players

Lee Cabell¹, Frantisek Zahalka², Tomas Maly², Lucia Mala².
¹Arkansas Tech University, Russellville, AR. ²Charles University, Prague, Czech Republic. (Sponsor: Kevin Ford, FACSM)
 Email: lee.cabell@gmail.com
 (No relevant relationships reported)

Agility, acceleration, change of direction (COD), deceleration, and sprinting are critical technical skills in soccer. The ability to sprint and quickly change direction are determinants of performance in a soccer game. Sprint performance relative to a new Agility K-test and 505 tests were examined. **PURPOSE:** To examine the relationship between the sprint and agility tests in elite young soccer players. **METHODS:** Elite

Czech young male soccer players ($n=29$, $age=19.5\pm 0.4$ yrs) volunteered for this study. The KT consisted of the subjects running at maximum speed between cones positioned in a "K" pattern on a field with non-slip running surface. The subjects started and ended running at the intersection of the "K" pattern with two conditions: touching a photocell with the foot (KT_foot) or a contact switch placed on the top of each cone with the hand (KT_hand). The 505 COD test allowed subjects a "flying start" with a 10 m run-up before crossing the timing gates, a five-meter sprint, turn 180° either right or left and a final five-meter sprint. Linear sprinting was also tested with subjects sprinting 5 m (S5) and 10 m (S10) from a static position. The subjects performed two trials of each test, and the time of test execution was measured in seconds. Pearson correlation coefficient test was used to correlate two dependent variables, and independent t-test was used to test differences between KT_hand and KT_foot. $P<.05$. **RESULTS:** The correlation tests between dependent variables showed weak to moderate correlations. Specifically, 505_R vs $S5=.45$, $p<.05$; 505_R vs $S10=.49$, $p<.01$; 505_L vs $S5=.11$, NS; 505_L vs $S10=.11$, NS; KT_foot vs $S5=.34$, NS; KT_foot vs $S10=.32$, NS; KT_hand vs $S5=.30$, NS; KT_hand vs $S10=.41$, $p<.05$. The association between KT_foot and $KT_hand=.18$, NS. T-test showed the significance, $t(56)=17.48$, $p<.01$. **CONCLUSION:** Specific "movement strategy" may exist in 505 COD tests due to asymmetries that may exist from the one-side dominant nature of the participants. However, due to multiple direction tested, KT-hand coordination "eye-hand" is faster and a more natural motor pattern than KT-foot. The speed variables exhibited significant heterogeneity. Speed and agility are not dependent; therefore, each component of speed must be considered independently when designing training programs for young soccer athletes.

Tensiomyographic And Sprint Assessments Following Different Warmup Protocols In Collegiate Male Soccer Athletes

Chad H. Herring, Michael J. Redd, Tristan M. Starling-Smith, Jeffrey R. Stout, David H. Fukuda. *University of Central Florida, Orlando, FL.*
(No relevant relationships reported)

Tensiomyography (TMG) has been shown to be a non-invasive technique to assess the contractile properties of skeletal muscle which may have application in assessing the effectiveness of warm-up procedures prior to training and athletic competition. **Purpose:** The purpose of this study was to evaluate the effects of three different warm-up protocols on TMG variables and sprint performance in collegiate male soccer athletes. **Methods:** Fifteen collegiate male soccer athletes ($age = 20.1\pm 1.3$ y, $height = 176.6\pm 6.9$ cm, $body\ mass = 78.2\pm 7.8$ kg, $body\ fat\ percentage = 12.9\pm 3.6$) participated in the study. The three testing days consisted of: pre- and post-TMG assessments; warm-up protocol [dynamic (DYN); plyometrics (PLY); and passing patterns (SOC)]; and two 20-m sprints. Pre- and post-TMG assessments were completed for the biceps femoris (BF) and rectus femoris (RF) of both legs for all participants. The DYN warm-up protocol consisted of a six-minute jog followed by nine minutes of dynamic stretching. The PLY warm-up protocol consisted of a six-minute jog followed by nine minutes of plyometric exercises. The PAS consisted of a five-minute jog followed by a passing pattern drill typically used in advanced soccer athletes termed the "Rondo." Repeated measures ANOVAs (condition x leg x time) were used to evaluate muscle displacement (Dm) and contraction time (Tc) in the BF and RF. A repeated measures ANOVA was used to evaluate the fastest of the two 20-m sprint times between conditions. **Results:** Results showed no significant interactions for Dm (BF: 2.851 to 3.508mm; RF: 6.793 to 8.253mm) or Tc (BF: 20.04 to 24.00ms; RF: 26.87 to 29.36ms); however, a main effect for time ($p=0.035$) was found for BF Tc with a significant decrease from pre- (22.24±9.09ms) to post-warmup (20.47±5.01ms). Significant differences ($p<0.05$) between conditions for 20-m sprint performance were also noted (DYN: 2.76±0.27 s; PLY: 2.64±0.13s; SOC: 2.62±0.15s). **Conclusion:** In collegiate male athletes, the warm-up protocols did not appear to have differential effects on specific TMG variables, while differences in sprint performance were seen. The warm-up procedures decreased Tc as evaluated by TMG; however, further research is needed to examine the influence of this change on performance.

Effect Of Excentric Training On Balance And Explosive Strength In Women University Soccer Players

Diana A. Camargo Rojas, John Jarior Rincón Gómez, DANIEL FELIPE URREGO VILLABÓN, LEIDY SOFIA MOLINA RODRIGUEZ, Silvia Lucia Lara Gomez. *Universidad Nacional de Colombia - Bogotá, Bogota, Colombia.*
 Email: dacamargor@unal.edu.co
(No relevant relationships reported)

PURPOSE: Women's football has begun to be considered as a potential sport thanks to the performance of sportswomen. For the prevention of injury, the eccentric training appears as part of sports training programs. However, preventive programs do not recognize the characteristics of women, this being the object of this study. Objective.

Determine the effects of an eccentric training on the balance and explosive strength in female soccer players from two universities in Bogotá, Colombia. **METHODS:** Randomized controlled trial, which evaluated the explosive force with the Sargent test and the balance with the Star Excursion Balance Test (SEBT) with the participation of 19 university athletes. The players were randomly distributed among the control group ($n = 9$) that made the protocol FIFA 11+ and experimental group ($n = 10$) that made the eccentric exercise protocol. Statistical analysis was performed with SPSS, using comparative statistics between groups like the Student's T test for related samples. **RESULTS:** Significant changes are shown for the balance variables ($p \leq 0.05$), in 15 of the 16 directions, and significant changes in the explosive force ($p \leq 0.05$; $p = 0.000$) of athletes who carried out the training eccentric after 4 weeks of intervention. For the FIFA 11+ group only significant changes were observed ($p \leq 0.05$) in 3 of the 16 directions of the SEBT and there were no changes in the Sargent test ($p \geq 0.05$, $p = 0.141$). Therefore, it is verified that the intervention protocol of eccentric training has significant effects on the explosive force, in four weeks of intervention. **CONCLUSIONS:** This study provides evidence on the use of eccentric protocols in amateur soccer players, showing significant changes in the balance and explosive strength, after 4 weeks of training, giving sustenance to introduce eccentric exercises in warm-up programs and injury prevention.

(No relevant relationships reported)

In 2006, new category of motor disorders was established: musculoskeletal ambulation disability symptom complex (MADS). MADS is defined as an increased rise of falls and isolation due to an age-related decline in balance and walking ability. **PURPOSE:** To examine physical, mental and dietary functions of older community-dwellers using balance assessment, physical, and cognitive function tools, and eating habit questionnaire and understand the MADS in older women. **METHODS:** Eighty-six women aged 65 years and over (mean age 71±3 yrs.) participated in this study. The participants completed a demographic questionnaire, one-leg standing time with eyes open (OLS) and timed up-and-go test (TUG). Then, they were divided into two groups according to OLS: G1) longer than 15 sec. ($n=61$,) and G2) less than 15 sec. ($n=25$). Following items were measured: hand-grip strength, chair-stand, functional reach, gait speed as physical function, Mini-Mental State Examination (MMSE) and Trail Making Test-A (TMT-A) as cognitive function, and brief-type self-administered diet history questionnaire (BDHQ) as examining eating habits. **RESULTS:** The average time of OLS was significantly different in G1 and G2 (72.7±58.0 and 7.6± 3.9 sec., $p<0.01$). Age was significantly different in G1 and G2 (70.2±2.5 vs. 73.2± 4.4 yrs., $p<0.05$). The results show that maximal gait speed and TUG was significantly lower in G1 than G2 (1.73±0.24 vs. 1.87±0.28 m/sec., $p<0.01$) and (6.8±1.1 vs. 7.5±1.5 sec., $p<0.01$). BDHQ revealed that the consumption of marine products (34.4±43.3 vs. 5.0±2.5 g, $p<0.01$) and cooked fish (25.7±30.4 vs. 5.6±3.5 g, $p<0.01$) were significantly higher in G1 than G2. Older adults without MADS consumed more marine products and cooked fish. In ANCOVA adjusting for the age, only TMT-A was significantly different in G1 (86.2±25.2 sec) and G2 (98.4±28.5 sec.), $p<0.01$. MADS may affect the TMT-A in the older women living in Japan. **CONCLUSIONS:** These results suggest that decline in physical, dietary and cognitive functions may be associated with MADS in older women.

The Effects Of Exercise Training To Frailty Patient During Post-acute Care HospitalizationYu-Tsai Tu¹, Mu- Jung Kao¹, Chin-Shan Ho². ¹TAIPEI CITY HOSPITAL, TAIPEI, Taiwan. ²National Taiwan Sport University, Taoyuan, Taiwan.

Email: smalldopon@gmail.com

(No relevant relationships reported)

In Taiwan, frailty patient can receive post-acute rehabilitative care in hospital after they leave acute care hospital. The post-acute care program is proposed by the Ministry of Health and Welfare in Taiwan for functional recovery of the frailty patient. The post-acute care program including strengthening, flexibility, cardiopulmonary, and balance exercise. **PURPOSE:** To evaluate the functional recovery of the frailty patient in in Taiwan with a two-weeks of regular exercise training. **METHODS:** Twelve frailty elderly (Age: 83.25±5.5 years of age) just leave acute medical care were included in this study. The patient must have one of the underlying diseases include dementia, chronic kidney disease, parkinsonism, and Chronic Obstructive Pulmonary Disease. The therapeutic interventions were regular exercise training including strengthening, flexibility, cardiopulmonary, and balance exercise for two weeks. Before and after intervention, Functional outcome were evaluated. Data collection from multiple variables was conducted using questionnaire and examination including Barthel index, IADL, Clinical Frailty scale, Confusion Assessment Method, and Mini Nutritional Assessment-Short Form. **RESULTS:** The result shows significant improvement in Barthel index, Clinical Frailty scale, and Mini Nutritional Assessment-Short Form ($p < .05$). Among other tests, there is no significant difference. **CONCLUSION:** Two-week exercise training program can improve functional outcome of frailty patient during post-acute care.

(No relevant relationships reported)

Purpose. The study aimed to elucidate the effects of age and self-reported exercise behaviour on metabolic risks in clinically healthy participants according to age and exercise behaviour groups (Table 1). The participants were from the Exercise for Life Across Asia (ELIXA) cohort. Active participants reported $\geq 3 \times 45$ min of moderate to high intensity exercise weekly and sedentary participants reported $< 1 \times 30$ min of moderate intensity exercise weekly in the last 5 years. **Methods.** The participants performed an oral glucose tolerance test (OGTT), with fasted blood (13 mL) collected at baseline, followed by ingesting 75 g of glucose in a solution, and blood collections at 0.5 h intervals until 2 h. **Results.** Age and exercise behaviour had no significant effects on body mass index, blood pressure, and waist-hip ratio, and fasted blood glucose and lipids (total cholesterol, triglycerides, and high- and low-density lipoproteins), and plasma insulin and non-fasted plasma pro-inflammatory cytokine concentrations. However, the magnitude of increases in plasma insulin and blood glucose concentrations after glucose ingestion were significantly higher in the sedentary than in the active groups over the 2 h OGTT, when all the age groups were combined and in the “Young” group (Table 2). **Conclusion.** In a clinically healthy population, regular exercise can lower metabolic risks, which can increase from young age due to sedentary lifestyle.

Table 1 Sample sizes in age and exercise behaviour groups

| | Young (18 – 39 Yr old) | Middle-aged (40 – 59 Yr Old) | Older-aged (≥ 60 Yr Old) |
|-----------|---------------------------|---------------------------------|-----------------------------------|
| Active | YA, n = 33 | MA, n = 36 | OA, n = 14 |
| Sedentary | YS, n = 28 | MS, n = 25 | OS, n = 11 |

Table 2 Mean (SEM) for blood glucose and plasma insulin concentrations at 2-hour time point of the oral glucose tolerance test

| Groups | Blood Glucose (mmol/L) | Plasma Insulin (mu/L) |
|----------------------|------------------------|-----------------------|
| Combined (Sedentary) | 6.0 (0.2)** | 48.8 (4.6)*** |
| Combined (Active) | 5.3 (0.1) | 26.8 (2.8) |
| YS | 5.7 (0.3)* | 45.6 (5.7)* |
| YA | 4.7 (0.2) | 25.5 (4.1) |
| MS | 6.0 (0.4) | 38.1 (8.8) |
| MA | 5.6 (0.2) | 22.6 (4.0) |
| OS | 7.5 (1.0) | 60.9 (11.6) |
| OA | 5.9 (0.4) | 43.2 (8.0) |

Note: * = $p < 0.05$, ** = $p < 0.01$, and *** = $p < 0.001$ between Active and Sedentary groups

Walking People - Aruku-hito, Community-based Group Exercise Program For Older Adults: Expanding The ReachTatuo Doi¹, Kazuhira Onishi², Shinji Sato³, Atuko Fujii⁴, Nobuko Hongu, FACSM⁵. ¹Dynamic Sport Medicine Research Institute, Osaka, Japan. ²Oval Heart, Japan, Tokyo, Japan. ³Osaka Sangyo University, Daito-shi, Japan. ⁴Izumisano City Office, Izumisano, Japan. ⁵The University of Arizona, Tucson, AZ.

Email: loco-health@nike.eonet.ne.jp

(No relevant relationships reported)

PURPOSE: Regular physical activity helps older adults improve their health and enhances overall quality of life. The aim of this study was to determine how the community-based, group exercise program, “Walking People – Aruku-hito” has offered and continues to expand its reach through training health educators for the program in various cities in Japan. **MEHOTDS:** This presentation highlights “Walking People – Aruku-hito” program that was started helping older adults who were the victims of Tohoku earthquake and tsunami that created over 300,000 refugees in Tohoku/Northeast region, Japan in 2011. The contents and resources for reaching older adults, maintaining and expanding the “Walking People – Aruku-hito” program will be presented. **RESULTS:** The “Walking People – Aruku-hito” program started helping sedentary older adults who had limited social activities in a living temporary apartment complex after the loss of their houses. The program teams visited about 400 community-gathering centers, where people who had deeply affected by the Tohoku earthquake and tsunami met regularly. From April 2012 to April 2018, more than 10,000 older adults (65 to 96 years) participated in a supervised workshop. The workshop emphasized 1) benefits of walking, 2) stress-free walking, 3) basic conditionings (strength training, flexibility, balance) for walking, and 4) benefits of habitual daily walking. This tailored physical activity workshop was developed by the joint efforts of community agencies and academic partners. Because of the popularity of the “Walking People – Aruku-hito” program, the workshops have been offered in several regions of Japan with the support of Japan Medical Association and Ministry of Health, Labor and Welfare. Originally, instructors for the program were either certified exercise instructors, nurse practitioners, or physical therapists. Now, the number of instructors is increasing using the Train-the-Trainer approach; the instructors of the program train well-fit older participants who have been helping other participants in the program. **CONCLUSIONS:** The “Walking People – Aruku-hito” program started a community-based program designed for older adults’ specific needs and challenges. With the new supports and existing community resources, the program will be disseminated widely in Japan.

823 Board #57 May 29 3:30 PM - 5:00 PM

Effects Of Social Network Incentives And Financial Incentives On Physical Activity Among Elderly WomenRyo Yamashita¹, Shinji Sato², Ryoichi Akase³, Tatsuo Doi⁴, Shigeki Tsuzuku⁵, Toyohiko Yokoi², Shingo Otsuki², Eisaku Harada¹. ¹Kumamoto Institute of Total Fitness, Kumamoto, Japan. ²Osaka Sangyo University, Osaka, Japan. ³Kumamoto Kinoh Hospital, Kumamoto, Japan. ⁴Dynamic Sports Medicine Institute, Osaka, Japan. ⁵Kumamoto University, Kumamoto, Japan.

(No relevant relationships reported)

We know that an increase in physical activity improves health. To achieve a behavior change of physical activity, previous studies have used financial incentives. However,

the benefit of the incentive is lost when the intervention ends. Thus, we focused on social network incentives that leveraging the power of peer pressure to regulate behavior.

PURPOSE: The main goal is to ascertain whether combining financial incentives with social network incentives can lead to changes in physical activity (steps/day) during and after the intervention.

METHODS: We conducted a three month, randomized controlled study using pedometers. The effects of incentives on physical activity maintenance were measured six months post-intervention. The subjects were 39 elderly women over 65 years of age, residing in Kumamoto, Japan. The financial incentive (FI) group received a payment ranging from US\$4.40 to US\$6.20 per month depending on the number of steps taken during the intervention. For the other group, we provided a social network incentive (SNI) in addition to the financial incentive. The SNI+FI group walked in three people to use the power of peer pressure.

RESULTS: A two-way ANOVA revealed that in terms of physical activity, there was a statistically significant interaction between group and time ($p=0.017$). The FI group showed no statistically significant improvement in physical activity during the observation period.

CONCLUSIONS: Our results suggest that combining financial incentives and social network incentives is more effective than financial incentives alone. Especially, the effect can continue in post-intervention.

Does High-Cadence Cycling Improve Emotional Recognition in Individuals With Parkinson's Disease?

Bryan Dowdell¹, Sara Harper², Alena Varner¹, Jin Hyun Kim¹, Brandon Pollock³, Angela Ridgel, FACSM¹. ¹Kent State University, Kent, OH. ²The University of Alabama at Birmingham, Birmingham, AL. ³Walsh University, North Canton, OH. (Sponsor: Angela Ridgel, Ph.D, FACSM)

(No relevant relationships reported)

Parkinson's disease (PD) is a progressive neurodegenerative disease that can lead to cognitive dysfunction including deficits in emotional recognition, which is the ability to identify different facial expressions. This deficit has been shown to lead to difficulties in social interaction and communication. High cadence cycling is a unique rehabilitation modality that has been shown to improve motor function in PD, but it is not known how this modality alters cognition. **PURPOSE:** To examine if three bouts of high-cadence cycling improved emotional recognition in individuals with PD. **METHODS:** Individuals with PD (N=20) completed three sessions of high cadence cycling (48 hours apart), on a custom motorized stationary cycle, consisting of a 5-minute warm-up at 50 revolutions per minute (rpm), 30 minutes of high cadence cycling between 75-85 rpm, and a 5-minute cool down. Emotional recognition was assessed using a computerized cognitive assessment battery at baseline and after the three cycling sessions. Individuals with PD in the control group (N=15) did not cycle and just underwent baseline and post testing. The percentage of accurately identified emotions and the average reaction time to correctly select an emotion (emotion bias) was used for the analysis of the overall emotion domain. Z-scores were used for the analysis. Independent samples t-tests were run for the change scores between the intervention and control group. **RESULTS:** Both groups displayed negative z-scores representing an emotional recognition deficit. There was no significant difference between the cycling and control group in the overall emotion domain ($p=0.76$). Cycling resulted in a z-score improvement in the emotion domain by 0.22 while the control group improved 0.14. Cycling did significantly improve "disgust" emotion accuracy compared to the control group ($p=0.03$). **CONCLUSIONS:** Three bouts of high-cadence cycling specifically improved "disgust" emotional recognition compared to the control. However, there was no significant difference between groups in the overall emotion domain. While high-cadence cycling might be a valuable rehabilitation modality for improving motor function in individuals with PD, the efficacy for improving emotional recognition and potentially social interaction is unclear.

Functional Capability, Flexibility, Strength And Quality Of Life In Sedentary Or Trained Elderly Women

OTÁVIO A S MACHADO¹, BRUNA VIEIRA DE SOUZA¹, FÁBIO GIANOLLA¹, LUIZ F. KILLIAN¹, GIOVANNA A C MACHADO¹, WALDECIR P. LIMA², RENATA GORJÃO³. ¹FEFISO, SOROCABA, Brazil. ²IFSP, SAO PAULO, Brazil. ³UNICSUL, SAO PAULO, Brazil. Email: otavioasm@gmail.com

(No relevant relationships reported)

Throughout the last decades the elderly population has been increasing around the world. During the aging process, all physiological systems undergo significant functional changes and sedentary lifestyle has an elevated correlation with this imbalance. The inactivity increases the rate of chronic diseases development. Although any type or amount of physical exercise may discontinue the cellular aging processes,

regular physical exercise can attenuate the decline in physical and functional capabilities observed in elderly. Currently, some of the most encouraged activities in gyms are resistance exercise, weight-bearing training, and hydrogymnastics.

PURPOSE: The main objective of this study was to compare the effects of the above-mentioned exercises regarding muscle strength, flexibility, functional capability and quality of life in elderly women. **METHODS:** We evaluated 36 elderly women (age 70.17±5.18 years) separated in four groups in agreement with their physical activity practice: 9 Sedentary (S); 9 Hydrogymnastics (H); 9 Weight-bearing Training (WB); 9 Resistance Training (RT). This was a transversal study, and all exercise practitioners had at least 3 months with 3 days a week of frequency. **RESULTS:** All exercised groups showed a significant difference ($p<0.05$) in relation to S in all measured variables. Among the exercises groups, the RT had greater strength and better functional capability. **CONCLUSION:** Regular physical exercise is important to reduce the deleterious effects of sedentary lifestyle in muscle strength, flexibility, functional capability and quality of life and among the exercises evaluated, RT showed to be a key component of a training program for elderly women.

Effect Of Acute Specific Exercise And Wuqinxi On Hand Function Of Patients With Parkinson's Disease

Tian Wang, Guiping Xiao, Kunchen Jie, Zhenlan Li, Zhen Wang, Jie Zhuang. Shanghai University of Sport, Shanghai, China. Email: 724793513@qq.com

(No relevant relationships reported)

PURPOSE: The aim of the study was to study the improvement of hand movement speed and flexibility in patients with Parkinson's Disease (PD) by an acute exercise of specific exercise and WuQinXi.

METHODS: This study selected 45 patients with PD (22 males and 23 females) from the PD patients Training Camp of Shanghai University of Sport, and randomly divided 22 patients(11 males and 11 females),age67.17±5.88into Wu Qin Xi intervention group and 23 patients in the specific exercise intervention group(11 males, 12 females),age65.52±5.18. According to the patient's Hoehn-Yahr stage, Wu Qin Xi and specific exercise were divided into three groups: 1-1.5 group, 2-2.5 group, and ≥3 group. Two groups of subjects were given 60 minutes' specific exercise and Wu Qin Xi intervention training. The specific exercise is consisted with several different health-care Qigong, which specifically target at the patients with Parkinson's Disease. The Purdue pegboard test, which has good predictive and concurrent validity. The test data were analyzed by SPSS 24.0. The paired sample t test was used for the pre- test and post-test in the group. p value of <0.05 was adopted.

RESULTS: After the intervention, the specific exercise group had significantly improved the three scores of Dominant hand, the Both hand and the assembly subtest ($P<0.05$), especially for the patients whose Hoehn-Yahr stage from 1-1.5, these three scores were improved. The patients whose Hoehn-Yahr stage from 2-2.5 only improved in the assembly subtest, and the patients whose Hoehn-Yahr stage ≥3 phase did not significantly increase in either four scores ($P>0.05$). After the intervention, the Wu Qin Xi group showed significant improvement in the Dominant hand, Nondominant hand and assembly subtest ($P<0.05$), especially for the patients whose Hoehn-Yahr stage from 1-1.5, these three scores were improved. There was no significant increase in the four scores in patients whose Hoehn-Yahr stage from 2-2.5 and ≥3 ($P>0.05$).

CONCLUSIONS: The acute exercise intervention of specific exercise and Wu Qin Xi can improve the speed and flexibility of hand movement in Parkinson's patients. The effect of specific exercise is more obvious for patients whose Hoehn-Yahr stage from 1-1.5.

The Role of 'Exercise Is Medicine' in Asia: Perspectives for the Older Adult Population

Chae-Hee Park¹, Kiyoji Tanaka, FACSM², JaeHoon Seol², Andiana Schwingel³, Wojtek Chodzko-Zajko, FACSM³. ¹Korea National Sport University, Seoul, Korea, Republic of. ²University of Tsukuba, Tsukuba, Japan. ³University of Illinois at Urbana-Champaign, Urbana-Champaign, IL. (Sponsor: Wojtek Chodzko-Zajko, FACSM) Email: chaepark@knsu.ac.kr

(No relevant relationships reported)

Asia is home to the largest older adult population in the world, and the proportion of people aged 65 and over is projected to rapidly grow in all Asian countries. Many chronic diseases and conditions are prevalent in older adults, and regular exercise and physical activity can help prevent and manage many of these conditions. A significant component of Asian cultures is the promotion of active lifestyles, where many older adults would have the opportunity to practice exercise for free or at low cost. However, if seniors have a chronic condition and no previous experience with exercise, it is not always easy to start an exercise routine without specialized information and appropriate instruction. Exercise is Medicine (EIM) was created to help seniors with

chronic diseases to incorporate exercise into their everyday lives. **PURPOSE:** Due to the initial development of EIM within Western cultures and traditions, the purpose our work was to examine how best to adapt, implement, and disseminate EIM for the older adult population in Asia. **METHODS:** From April, 2017 to September, 2018 numerous discussions were held between researchers and practitioners from Asian countries who had between 15 to 30 years of experience in the area of aging and physical activity. Additionally, research articles, reports, and web-sites related to EIM were reviewed and analyzed. Finally, interviews were conducted among EIM personnel in Asia. **RESULTS:** The results have been divided into three sections. The first section provides a historical overview of EIM development in Asia. The second presents an assessment of the potential role of EIM for older adults in Asia. The final section provides a blueprint for the development of an extended concept of EIM as a stimulus for further conversations and discussions among the medical, exercise, and health related communities. **CONCLUSION:** EIM has the potential to play an important role in the prevention and management of chronic diseases in Asia, and improving quality of life among Asian seniors.

Effect Of Wu Qi Xin Exercise On The Quality Of Life Of Parkinson's Patients

Kuncheng Jie, Guiping Xiao, Zhenlan Li, Tian Wang, Jie Zhuang, Zhen Wang. *Shanghai University of Sport, Shanghai, China.*
 Email: 724793513@qq.com
 (No relevant relationships reported)

PURPOSE: To determine the effect of 12-wk Wu Qin Xi exercise intervention on the quality of life of Parkinson's patients.

METHODS: 23 Parkinson (PD) patients (12 men and 11 women; age in 65.65±4.82 yr.) were recruited to participate in a 12 wk Wu Qin Xi, a traditional Chinese exercise, intervention in the Pai Training Camp of Shanghai University of Sport, China. Patients' clinical status was assessed with Unified Parkinson's Disease Rating Scale (UPDRS) parts I-III, and Quality of Life - Disease Questionnaire (PDQ-39). The assessments were conducted before and after the intervention group, which included 120-minute Wu Qin Xi exercises, twice a week for 12-wk. The paired sample t test was used for the pre- and post-test difference. **RESULTS:** A statistically significant pre- and post-test difference were found after the 12-wk Wu Qin Xi intervention: UPDRS score decreased by 23% (p=0.01); UPDRS part I score decreased by 28% (p=0.003); part II decreased by 20% (p=0.004); part III decreased by 24% (p=0.036) and PDQ-39 score decreased by 30% (p<0.001). **CONCLUSIONS:** Wu Qin Xi exercise could improve the quality of life of PD patients.

Significant Improvement In Dxa Scores Is Observed With Osteoporotic Patients When High Force, Short Duration Stimulus Is Created

Jason M. Conviser, FACSM¹, Jenny Conviser¹, Joe Koehler².
¹Ascend - Consultation in Health Care, Chicago, IL.
²Performance Health Systems, Northbrook, IL.
 Email: j.conviser@onesmallworldusa.com
 (No relevant relationships reported)

PURPOSE: Determine if high intensity short duration forces applied to bone results in improved DXA measures.

The relationship between bone geometry and mechanical influences on bone suggests that when significant forces are applied to bone, the compression will stimulate an adaptive response, commonly known as Wolff's Law. However traditional exercise as a treatment for osteoporosis has generally not been able to create the forces needed to stimulate bone growth in a safe and effective manner. **METHODS:** Twenty-six women X age 63 with diagnosis of osteoporosis participated in a one-year study using a novel exercise device that allows bone to adapt to significant forces. A subset (9 individuals) were followed for one additional year after the study concluded. Three independent clinics had identical equipment and protocol. Subjects completed a minimum of 48 sessions once a week over the year. DEXA scans were conducted at the same testing location for both pre-and post-assessments. Subjects self-reported weight, weekly minutes of exercise, diet and prescription medications. **RESULTS:** Of the 26 subjects, 16 individuals demonstrated a significant reduction p<.05 (improvement in bone) in their mean DEXA score, while 6 had no significant change and 4 individuals showed a further degradation. Forces required to significantly improve bone were 2 - 10x multiples of body weight. Of those who continued for an additional year, 6 demonstrated additional improvements p<.05 while 3 were not significantly different. **CONCLUSIONS:** These data suggest that a non-pharmacologic exercise solution is available to individuals diagnosed with osteoporosis. Further study is required with larger sample sizes and more diverse demographics. Additional research is needed to validate this approach as a viable and safe strategy for bone reformation.

 (No relevant relationships reported)

PURPOSE: The objective of the present study was to analyze what changes the long-term recommendation of regular physical exercises could cause in individuals with knee osteoarthritis (KOA) during 4 years of follow-up.

METHODS: Individuals undergoing care for primary KOA (N = 153; age = 67 ± 2) in the public health system were randomly assigned to either an educational (GI; n = 83) or control group (CG; n = 70). The volunteers were asked to respond to the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC™) for the assessment of pain, function, and quality of life. The short version of the International Physical Activity Questionnaire (IPAQ) (validated in the Brazilian population) was used to assess the level of daily physical activity in all volunteers. Functional capacity was evaluated at baseline (pre), and at 24 and 48 months follow-up, and included the sit-and-reach test, 6-min walk test (6MWT), timed up and down stairs test (TUDST), Timed Up and go test (TUGT), and sit and lift five times test (FTSST).

RESULTS: The Body mass index (BMI) significantly decreased (3.5%) after 24 and 48 months of follow-up in the GI (P <0.05), while a slight increase was observed in the GC. The GI group presented improved (P <0.001) TUGT (27%) and FTSST (36.5%) performance after 48 months of follow-up. The GC did not change during the same period. In the GI, the total WOMAC score fell by 8.0 points, WOMAC pain decreased by 2.5 points, and WOMAC stiffness decreased by 0.5 point, while being higher in the GC (P <0.001). There was also an increase (P <0.001) in the prevalence of "active" (26.6%) and "very active" (30%), as well as a reduction in sedentary prevalence (12.5%) in the GI during follow-up. No significant improvements were observed in the sit-and-reach, TUDST, and TC6' tests in either group.

CONCLUSIONS: The results suggest that a program promoting regular physical exercise could be an effective tool to improve physical fitness, functional capacity, quality of life, and level of daily physical activity in individuals with KOA, even over a long period.

Intergenerational Multicomponent Training Strategy to Improve Cardiovascular Risk Factors and Quality of Life in Elderly

Raquel Silva, Andreia Pizarro, Joana Carvalho. *Faculty of Sport - University of Porto, Porto, Portugal.*
 Email: raquelerlima@hotmail.com
 (No relevant relationships reported)

With the aging process, there are several changes in the body composition, a reduction of the lean mass and a progressive increase of the fat mass (FAT%). The percentage of fat mass (FAT%) and arterial stiffness (cPWV) are shown to be risk factors for the development of cardiovascular diseases, but the association between both is not established, especially during aging. Research shows the main benefits of intergenerational programs in the elderly population reflects a better perception of quality-of-life and prevention of cardiovascular diseases. Purpose: The objective of this study was to analyse the effects of a 6-month intergenerational exercise program on body composition, arterial stiffness and quality of life of elderly users of day-care centers. Methods: This is a randomized clinical study with a sample of 37 individuals (27 intervention group- IG and 10 control group-CG) with a mean age of 76.68±9.96 years attending day centers in Porto. Body composition (FAT%) was evaluated by double-energy bone densitometry (DEXA); Arterial stiffness was measured as carotid-femoral pulse wave velocity (cPWV) using the SphygmoCor device (AtCor Medical, Australia). In brief, sequential and consecutive carotid and femoral pressure waves

were registered with parallel electrocardiogram recording and the quality of life was self-reported in the SF-36 questionnaire, with a scale of 0-100, where a higher score indicates a better quality of life. The pre and post intervention differences were analysed using the Kruskal Wallis test. Results: The %FAT had a decrease of $1.83 \pm 2.33\%$ with in GI (before = $38.70 \pm 7.62\%$; after = $36.87 \pm 6.92\%$) in relation to CG (before = $39.92.68 \pm 7.82$; after $41.48 \pm 5\%$), ($p = 0.952$). The values of cIPWV increased 7.34 ± 3.79 in IG (before = 39.50 ± 13.42 after 46.84 ± 12.74) in relation to GC (before 42.82 ± 12.96 ; after 45.35 ± 11.14), ($p = 0.042$) Regarding the self-reported quality of life, there were no significant differences ($p = 0.176$) between GI (before = 39.50 ± 13.52 after = 46.84 ± 12.74) and the CG (42.82 ± 12.96 after 45.35 ± 11.14). Conclusion: The results show that an integrational exercise program can reduce arterial stiffness in the elderly when compared to older people not involved in an exercise program.

832 Board #66 May 29 3:30 PM - 5:00 PM

Barriers of Being Active: Differences Between Two Generations

Benedetta Tosi, Martina Rosselli, Gabriele Mascherini, Cristian Petri, Giorgio Galanti, Pietro Amedeo Modesti. *University of Florence, Florence, Italy.*

(No relevant relationships reported)

PURPOSE: Physical inactivity and sedentary behaviors are nowadays included among principal risk factors for cardiovascular disease and mortality and have the highest Population Attributable Fraction, especially for women. Regular exercise reduces the risk of cardiovascular events; these evidences led to new guidelines where 150 min/week of moderate physical activity or 75 min/week of intense physical activity (or a combination of both) are recommended. Physical activity is also included in the seven metrics of AHA's definition of Ideal Health. Furthermore, the worldwide prevalence of childhood obesity has increased over the past three decades with a simultaneous decrease of physical activity. The study aimed to investigate the principal perceived barriers to exercise in young and adult populations.

METHODS: "Why Not" was a cross-sectional study conducted in 2018 in a high school (87 students, 19.1 ± 0.4 years old) and in the Rectorate of University of Florence (106 adults, 48.4 ± 12.2 years old). Personal anamnesis and information about the amount of weekly physical activity were collected. Barriers to Being Active Quiz (BBAQ), and Mediterranean Diet Score questionnaires were administered. Weight and height were measured according to standardize protocols.

RESULTS: Sedentary habits were present in the 35% of adults and 24% of all students enrolled. Lack of time for exercise was the most frequently reported barrier for adults, followed by lack of energy and laziness. These barriers were well represented in young population too, especially in girls (48% lack of energy and laziness, 39% lack of time) compared with boys (25% lack of energy, 14% laziness, 23% lack of time). Surprisingly, fear for injuries was reported only by men. Prevalence of overweight (BMI > 25 kg/m²) was 17% and 42% in adults and 4% and 3.9% among students (woman and men respectively). Mean adherence score of Mediterranean diet was 34 ± 3 among adults and 32 ± 5 among students (score range 0-55) without sex differences.

CONCLUSIONS: Sport medicine physicians should be aware of the barriers that patients face during exercise prescription and be able to contrast them with useful individual strategies. Analysis of young people life-style habits can help finding social strategies to promote healthy behaviors.

833 Board #67 May 29 3:30 PM - 5:00 PM

Optimal Loads for Power in Young and Old Men and Women Using Plate-Loaded Resistance Machines

Keri Strand¹, Lucrezia Lucchi¹, Tamara Gonzalez Copo², Nicholas Cherup¹, Joseph F. Signorile¹. ¹University of Miami, Coral Gables, FL. ²San Juan Bautista School of Medicine, Caguas, PR.

Email: kxs353@miami.edu

(No relevant relationships reported)

PURPOSE: Power affects quality of life and sports performance across age. Plate-loaded machines are the most common equipment used by recreational lifters; however, no studies have determined the optimal loads that maximize power outputs using this equipment. **METHODS:** Fourteen older men (69.4 ± 6.7 y), 21 older women (69.8 ± 7.9 y), 24 young men (21.0 ± 2.2 y) and 22 young women (20.7 ± 1.5 y) participated in two sessions of strength and power testing. They performed ten different plate-loaded exercises to determine their maximum dynamic strength (1RM) and peak power output (PP). Power was tested at 40, 50, 60, 70 and 80% 1RM using a linear position transducer. PP was expressed relative to the highest power produced (PP_{REL}). **RESULTS:** Significant sex x load interactions were seen for all upper body lifts ($p < .05$). Post hoc analyses showed that for multi-joint upper body exercises, men reached their highest PP_{REL} at the low end of the loading spectrum (chest press and seated row: 40-60%1RM; shoulder press: 40-70%1RM), while women's highest PP_{REL} was at higher loads (50-70%1RM). For single joint upper body exercises, the biceps curl and triceps extension showed no differences in PP_{REL} across loads for men, while women's optimal loads were at 50-80%1RM for both exercises. For shoulder press and

biceps curl there were also age x load interactions ($p < .05$). Younger persons reached PP_{REL} at 40%1RM and 50-60%1RM, respectively and older persons at 60-70%1RM and 50-80%1RM, respectively. For lower body exercises, leg press, leg curl and hip abduction showed a significant main effect for load ($p < .033$) with optimal load at 60-70%1RM, 50-70%1RM, and 50-60%1RM, respectively. Hip adduction produced significant age x load ($p < .031$) and sex x load ($p < .034$) interactions. 50-70%1RM was optimal for both age groups, but older persons produced significantly higher PP_{REL} at 40%1RM. For load x sex, optimal load was 50-70%1RM for both sexes; however, PP_{REL} occurred at 70%1RM for men and 50%1RM for women. Analysis for the calf raise showed a significant age x load interaction ($p < .001$) where PP_{REL} was 40-70%1RM for young and 50-80%1RM for older participants. **CONCLUSIONS:** Different optimal load ranges are required for individual plate-loaded exercises depending on age and sex. Younger persons and men optimize power at lower loads than older persons and women.

834 Board #68 May 29 3:30 PM - 5:00 PM

Evidence-based Fall Prevention Program. A 5-year Evaluation.

Harry Papadopoulos. *Pacific Lutheran University, Tacoma, WA.* (Sponsor: Eli Lankford, FACSM)

Email: papadoha@plu.edu

(No relevant relationships reported)

Falls among older adults are common, costly, and preventable. Stay Active and Independent for Life (SAIL) is a public-domain evidence-based program that emphasizes on strength and balance to prevent falls in older adults. **PURPOSE:** To evaluate the physical function of older adults participating in the SAIL program over multiple years.

METHODS: Data were collected from multiple locations in Washington State that offer the SAIL program. Physical functioning was assessed using the 8-foot up and go test, the 30-second bicep curl test, and the 30-second chair stand test. A total of one hundred and forty-nine participants completed the baseline assessment. One hundred and forty-three individuals completed the test a year after the baseline assessment, but declined in subsequent years. A paired-sample *t*-test was used to evaluate differences in mobility and strength between baseline and the first year of participation in the SAIL program. A repeated-measures ANOVA was used to evaluate differences in functional assessments among years 1 through 5. Significance was set at $p < 0.05$.

RESULTS: After one year of participation, all functional assessments were significantly different ($p < 0.01$) compared to the baseline measurements. The 8-foot up and go test improved by 8.3% (7.2 ± 2.9 vs. 6.6 ± 2.3), the 30-second bicep curl test increased by 7% (17.1 ± 4.9 vs. 18.3 ± 4.9), and the 30-second chair stand test improved by 12.2% (13.9 ± 5.2 vs. 15.6 ± 5.6). During the five years post baseline, the average time to complete the 8-foot up and go test was less than 7 seconds, but there were no significant ($p > 0.05$) differences among years. The average upper body strength for SAIL participants increased for four years. There was a significant ($p = 0.04$) difference on the number of repetitions completed in 30 seconds between year 3 and year 1 (19.8 ± 5.2 vs. 17.8 ± 4.9). Finally, the average number of chair stands in 30 seconds increased for four years. There was a significantly higher number of repetitions in year 3 compared to year 1 (19.1 ± 7.5 vs. 17.1 ± 6.3 ; $p < 0.01$) and to year 2 (19.1 ± 7.5 vs. 17.6 ± 7.6 ; $p < 0.01$).

CONCLUSIONS: These results indicate that the SAIL program was successful at maintaining mobility and increasing upper and lower body strength of individuals over 5 years. These results suggest a potential decline in the risk of falling for SAIL participants.

835 Board #69 May 29 3:30 PM - 5:00 PM

Effects Of Exercise Classes And Subsequent Independent Exercise Practice On Physical Fitness In Older Adults

Tomoaki Sakai, Takahiro Nakano. *Nagoya Gakuin University, Seto, Aichi, Japan.* (Sponsor: Kiyoji Tanaka, FACSM)

(No relevant relationships reported)

PURPOSE: This study aimed to clarify the effects of instructor-led exercise classes and subsequent independent exercise practice on older adults' physical fitness levels. **METHODS:** The participants were 19 community-dwelling elderly adults (7 males, 12 females, 69.4 ± 3.5 yrs) who took part in exercise classes under the leadership of an expert instructor, held once a week over 10 weeks. They subsequently performed independent exercise practice following the same schedule for 1 year. The exercise program emphasized aerobic exercises such as walking, muscle strength training for the trunk and limbs, and recreational activities. All the participants completed physical fitness assessments before and after the 10-week instructor-led exercise classes and at the 1-year follow-up. This assessment comprised 12 items designed to evaluate physical fitness levels, including hand-grip strength, sit-up, sitting trunk flexion, standing on one leg with the eyes open, 10-m walking time, 10-m obstacle walk, functional reach, the 30-s chair sit to stand test, the timed up and go test, the 5-second stepping test, whole body reaction time, and the 6-minute walk test. The participants

were instructed to wear the accelerometer on their waistline all day. **RESULTS:** The participation rate of exercise classes and exercise practice was $90.0 \pm 11.0\%$ and $76.5 \pm 14.6\%$, respectively. Significant changes were observed in the 10-m walking time (pre: 5.80 ± 1.48 sec and post: 4.93 ± 0.57 sec, $p < .05$), 10-m obstacle walk (pre: 4.56 ± 0.82 sec and post: 3.88 ± 0.66 sec, $p < .05$), and timed up and go test (pre: 4.83 ± 0.59 sec and post: 4.33 ± 0.53 sec, $p < .05$) performance after completion of the 10-week program. Furthermore, these changes were maintained at the 1-year follow-up. Although no significant change was observed in the 6-minute walk test after the 10-week exercise classes, a significant change was apparent at the follow-up (pre: 629.9 ± 51.8 m and follow-up: 677.1 ± 54.7 m, $p < .05$). **CONCLUSIONS:** Our results clearly indicated that even low-frequency, continuous exercise can help improve and maintain physical fitness. However, probably because the independent exercise practice simply continued the activities of the 10-week exercise program, we observed no further effects by the 1-year follow-up.

836 Board #70 May 29 3:30 PM - 5:00 PM
Acceptance And Feasibility Of Using A Seated Elliptical During Sedentary Behaviors In Older Adults

Nicholas L. Lerma¹, Chi C. Cho², Ann M. Swartz, FACSM³, Young Cho⁴, Scott J. Strath, FACSM⁴. ¹Grand Valley State University, Allendale, MI. ²University of Wisconsin-Milwaukee, Milwaukee, WI. ³University of Wisconsin-Milwaukee, Milwaukee, WI. ⁴University of Wisconsin-Milwaukee, Milwaukee, WI. (Sponsor: Scott Strath, FACSM)
 Email: lerman@gvsu.edu
 (No relevant relationships reported)

Older adults aged 60+ years are particularly vulnerable to the exposure and negative health consequences related to sedentary behavior (SB). There is limited evidence for the feasibility and effectiveness of SB interventions in older adults. **PURPOSE:** The purpose of this study is to explore the feasibility and acceptability of using a seated elliptical device (SED) to replace SB with a light-intensity physical activity (LPA) in the homes of older adults. **METHODS:** Twenty older adults (mean \pm SD, 71.9 ± 5.3 years) participated in this feasibility study. Each participant was outfitted with hip-mounted activity monitor and SED in the home for seven days. Participants were randomly assigned to one of four pedaling duration groups (15, 30, 45, and 60 minutes/day) and instructed to accumulate SED pedaling at a self-selected light-intensity during typical SB activities for a minimum of three of the next seven days. A Fisher's exact test was used to test for group differences in pedaling goal adherence and a one-way ANOVA was used to test for linear trends in accumulated pedaling durations across groups. Cohen's *d* was performed to estimate effect sizes for displacing SB with SED-based LPA for each group. **RESULTS:** There was 100% adherence across all four pedaling duration groups with no significant difference in total pedaling days completed ($p = .241$) and a significant linear group trend ($p < .001$) for minutes pedaled per day. The 45 and 60 min group accumulated greater minutes per day of pedaling than the 15 and 30 min groups ($p < .005$) with no significant differences between the 45 and 60 min groups or the 15 and 30 min groups. Across groups there was a 4.3% to 11.3% reduction in daily SB (Cohen's *d*: 0.72 to 1.57) and 8.3% to 23.6% increase in LPA (Cohen's *d*: 0.41 to 1.2) on pedaling days. Participants' perceptions of using the SED were positive. **CONCLUSIONS:** Older adults were successfully able to exceed 60 minutes of daily pedaling without altering or interrupting their typical daily behaviors. The long term impact of these daily changes in LPA on health and function in aging populations are to be determined.

Cadence (steps/min) Thresholds For Relative Intensity Indicators In Older Adults

Zachary R. Gould¹, Scott W. Ducharme¹, Aston K. McCullough¹, Christopher C. Moore¹, Colleen J. Sands¹, Marcos A. Amalbert-Birriel¹, Elroy J. Aguiar¹, John M. Schuna, Jr.², Tiago V. Barreira³, Stuart R. Chipkin¹, Catrine Tudor-Locke, FACSM¹. ¹University of Massachusetts Amherst, Amherst, MA. ²Oregon State University, Corvallis, OR. ³Syracuse University, Syracuse, NY. (Sponsor: Catrine Tudor-Locke, FACSM)
 (No relevant relationships reported)

In young adults, a cadence (steps/min) of 100 steps/min has been associated with absolutely-defined moderate intensity, measured in metabolic equivalents (METs; 1 MET = 3.5 mL/kg/min). However, less is known about how cadence is associated with relative intensity indicators in older adults.

PURPOSE: To investigate cadence thresholds associated with ACSM-defined indicators of moderate relative intensity (40-59% of heart rate reserve [%HRR], 64-76% of maximum heart rate [%HRmax] percentage, and a Borg scale rating of perceived exertion [RPE] of 12-13).

METHODS: Thirty-seven older adults (mean \pm SD; age = 68.5 ± 4.7 years, BMI = 26.3 ± 3.9 kg/m²) completed a progressive treadmill walking protocol that consisted of 5-minute bouts increasing by 0.5 mph from 0.5 to 6.0 mph. The protocol ended following the

bout where the participant naturally selected to jog or run, > 75% HRmax, or reported a Borg scale RPE > 13. Intensity indicators were analyzed using Receiver Operating Characteristic curves. Optimal cadence thresholds associated with moderate intensity were determined using Youden's index.

RESULTS: Four participants did not reach moderate intensity based on %HRR, and three did not reach moderate intensity based on %HRmax. %HRR and %HRmax were both associated with moderate intensity cadence thresholds of 111 steps/min. %HRR had a sensitivity of 76%, a specificity of 87%, and an area under the curve (AUC) of 0.76. %HRmax had a sensitivity of 75%, a specificity of 87% and an AUC of 0.75. Additionally, RPE was associated with a moderate intensity threshold of 104 steps/min, with 78% sensitivity, 80% specificity, and an AUC of 0.83.

CONCLUSION: Cadence thresholds associated with relative indicators of moderate intensity were consistently higher (4-11 steps/min) than the commonly reported heuristic value of 100 steps/min, although still within an obtainable cadence for ambulatory, healthy older adults. Relative indicators provide an opportunity to individualize cadence-based intensity prescription.

Less Is More: A Pilot Study Assessing The Benefit Of Exercise Frequency For Older Adults

Catherine Patrick, Chris Larrauri, Marlee Maloy, Melissa Powers. University of Central Oklahoma, Edmond, OK.
 (No relevant relationships reported)

There are countless benefits of exercising for older adults including a maintenance of bone density, muscle mass, and the preservation of muscular strength and endurance. Although older adults benefit from exercising it may be more convenient, more accessible, and less of a burden to exercise less times per week. **PURPOSE:** The purpose of this pilot study is to quantify if there are any added benefits to exercising three days a week compared to two days a week. **METHODS:** Participants included community dwelling adults ($N = 36$, $M = 74.34 \pm 7.91$ years) who self-selected exercise frequency by joining a multi-component fitness class offered in their local community. Classes were held either two or three days per week depending on the location. The Functional Fitness Test and Short Physical Performance Battery were conducted two times 6 months apart at all locations. Results were analyzed using repeated measures ANOVA. **RESULTS:** A significant group-by-time interaction was observed for hand-grip strength, $F(1, 18) = 7.92$, $p = .01$, with the two days per week group improving by 13% and the three days per week group decreasing by 1.9%. Interactions were not significant for chair stands test, arm curl test, 8 Foot Up-and-Go, or Gait speed, $p > .05$. There was a significant time effect for the chair stand test [$F(1, 15) = 7.54$, $p = .01$], gait speed [$F(1, 19) = 7.91$, $p = .01$], and hand-grip strength [$F(1, 18) = 4.61$, $p = .04$] with all tests indicating improvements from the first to second test. Univariate effect sizes indicate a trend toward greater improvements in the 2 d/wk group when compared to the 3 d/wk group with the exception of the arm curl which favors 3 d/wk. **CONCLUSION:** Although results are preliminary, this study indicates that handgrip strength was enhanced when participants were involved in a multi-component exercise program two days per week (13%). Chair stands test, arm curl test, 8 Foot Up-and-Go, and Gait speed increased regardless of the number of days per week of exercise. Notable limitations to the study are the number of males ($N = 6$) compared to females ($N = 30$) and participant's self-selection of exercise frequency. Also, we did not track outside influences such as physical activity levels, health status, and history of disease. Future studies should confirm these results using an experimental design in a larger, more diverse sample.

The SIENA Study: Sisters Integrating Exercise and Neuro Activity

Yulia Churakova, Jeanne Barcelona, Mariane Fahlan, FACSM. Wayne State University, Detroit, MI.
 (No relevant relationships reported)

PURPOSE: Alzheimer's disease (AD) dementia affects an estimated 4.7 million aging adults and is projected to significantly increase to 13.8 million by the year 2050. The prevalence of AD dementia is higher in women with more than two-thirds of all diagnosed cases exhibited in women. This condition is characterized by memory loss and cognitive decline. Pro-health behaviors including physical activity and meditation have been evidenced as neuroprotective behaviors among aging adults. Therefore, the purpose of this study was to explore health behaviors that may contribute to better cognitive functioning among aging women. **METHODS:** Catholic Sisters $n = 39$; $M_{age} = 78.9$, $SD = 8.2$ completed three cognitive assessments; digit symbols task (DST), controlled oral word association (COWAT) and animal naming (AN) and four functional fitness tasks; sit to stand (STS), get up and go (GNG), arm curl (AC) and six minute walk task (WALK). Demographics and prayerful meditation were measured via self-report. Bivariate correlation analyses between variables and mediation analyses using SEM in stata were conducted to explore direct and indirect effects. **RESULTS:** The DST was associated with three functional fitness tasks; AC ($r = .39$, $p < .05$) GUG

($r=-.49, p<.05$) and WALK ($r=.44, p<.05$). AN was associated with 2 functional fitness tasks; AC ($r=.44, p<.05$), GUG ($r=.37, p<.02$) and COWAT was associated with WALK ($r=.37, p<.03$). A mediation model was explored and explained 24% of the variance. There was a significant indirect effect of functional fitness on Age ($B=-.211358, SE=.49, z=-4.3, p<.001$) and Age on Cognition ($B=-1.32, SE=.41, z=-3.18, p<.001$). Functional fitness had a direct effect on meditative prayer ($B=-.28, SE=1.11, z=-2.55, p>.01$) but not on cognition ($B=-.784, p>.05$). **CONCLUSION:** Given the positive associations between functional fitness and cognition, yet the inverse association between fitness and prayer, future research should explore physically active prayer interventions and their influence on cognition.

Daytime Steps Per Minute Correlate With Functional Fitness In Hispanic Elders In Puerto Rico

Osvaldo J. Hernández-Soto¹, Farah A. Ramírez-Marrero, FACSM², Rubed S. Hernández-González¹, Grimes A. Hernández-Crespo¹, Luis D. Torre-Esteves¹. ¹Inter American University, San Germán, Puerto Rico. ²University of Puerto Rico, Río Piedras, Puerto Rico.
 Email: ojhsui@gmail.com

(No relevant relationships reported)

Walking cadence is a gait parameter associated with reduced risk of mortality, cardiovascular events, and falling among elder adults; but has not been reported among older Hispanics in Puerto Rico (PR). However, poor physical function, and low moderate to vigorous physical activity among older Puerto Rican adults in the USA and PR have been reported. **PURPOSE:** To evaluate the association between functional fitness and daytime walking cadence among Hispanic elders living in PR. **METHODS:** A group of 62 older adults ($F=38, M=24$; age = 76.4 ± 8.4 yr), participants in two HOPE centers in PR, completed a battery of senior fitness tests (and wore an accelerometer for 7-consecutive days. Spearman correlation and linear regression analyses were conducted to test associations between mean daytime walking cadence (steps/min) and functional fitness. **RESULTS:** Mean steps/day = $3,410 \pm 1,910$, and total daytime mean steps/min = 4 ± 2 . Significant correlations were observed between walking cadence and cardiorespiratory fitness (6 min walk) ($\rho = 0.41, P=0.001$), agility (foot up and go) ($\rho = -0.39, P=0.003$), muscle endurance (sit-ups and biceps curl) ($\rho = 0.27, 0.29; P=0.03, 0.02$, respectively), and body composition (waist to height ratio) ($\rho = -0.27, P=0.03$). **CONCLUSION:** Supporting previous studies, walking cadence significantly correlated with most functional fitness parameters in our group of older Hispanic adults in PR; thus, suggesting that those with higher mean steps/min (uncensored mean cadence) have higher cardiorespiratory fitness, agility, muscle endurance, and lower waist to height ratio; all critical health parameters for this population.

841 Board #75 May 29 3:30 PM - 5:00 PM
Physical Activity, Sedentary Time, And Sleep Quality Among Hispanic Women With Rheumatoid Arthritis

Maria C. Pacheco-Pares, Farah A. Ramírez-Marrero, FACSM. University of Puerto Rico-Río Piedras Campus, San Juan, Puerto Rico. (Sponsor: Farah A. Ramírez-Marrero, FACSM)
 Email: maria.pacheco3@upr.edu

(No relevant relationships reported)

Rheumatoid Arthritis (RA) is a chronic inflammatory disease commonly associated with physical inactivity and poor sleep quality (SQ). No previous studies have evaluated these associations among Hispanic women, and none have used objective assessment of physical activity (PA) and sedentary time (ST) in this population. **PURPOSE:** To evaluate associations between PA, ST, and SQ among Hispanic women with RA. **METHODS:** A group of 16 Hispanic women with RA (mean age = 49.4 ± 14.5 yr, and BMI = 26.91 ± 5.3 kg/m²) wore an ActiGraph GT3X+ accelerometer attached to an elastic waist band in the right hip area for 7 consecutive days to determine PA and ST. Participants also completed the Pittsburgh Sleep Quality Index (PSQI). Correlation analyses were used to evaluate associations between PA, ST, and SQ components. **RESULTS:** Mean of total moderate to vigorous PA (MVPA) was 178.6 min/week, and ST was 6.2 hr/day. Considering total MVPA, 50% of study participants were considered active, while 33% were considered sedentary. From the PSQI, 62.5% had poor sleep quality. A significant association was observed between ST and sleep efficiency ($r = 0.61, P = 0.01$); thus, suggesting that ST negatively influence this aspect of sleep quality in our group of Hispanic women with RA. PA and ST did not appear to influence other sleep quality components. **CONCLUSION:** Different from other studies, physical inactivity and ST were not highly prevalent behaviors, but ST was an important determinant of sleep efficiency in our group of Hispanic women with RA. Regardless of PA classification, ST must be considered in any intervention aimed to improve sleep in this population.

The Effect Of A Multicomponent Exercise Program On Sleep Quality In Institutionalized Elderly

Lucía Sagarra Romero, Elena Pardos Mainer, Ignacio Minguez, Alberto Reyes, Jaime Marco. UNIVERSIDAD SAN JORGE, VILLANUEVA GÁLLEGO, ZARAGOZA, Spain.

Email: lsagarra@usj.es

(No relevant relationships reported)

Sleep disorders are one of the most prevalent changes in the elderly and this has been associated with a negative impact on health outcomes. Exercise to be a potential non-pharmacological treatment to improve sleep quality. However, the effects in older has been largely unexplored. **PURPOSE:** To evaluate the effects of exercise on sleep complaints in older adults residing in a nursing home. **METHODS:** A total of thirteen older adults (84.1 ± 6.9 years) were according to the inclusion criteria. Socio-demographic data was collected using a structured questionnaire. Anthropometric measures were obtained using standardized techniques. Sleep quality was collected by self-report through the face to face Oviedo sleep questionnaire. The EQ-D5 was used to assess the health related quality of life. The training program included a multicomponent exercise intervention (9 weeks; 2 times per week) focused on mobility, strength and balance. Student paired t-test was carried out to detect any significant differences between the pre-test and post-test in any variable. The difference between variables was calculated using the effect size (ES) through Cohen's d. The significance level was set at $p < 0.05$. **RESULTS:** The EQ-5D mean scores were similar for the four dimensions (pre-post intervention) including mobility, pain/discomfort, self-care and usual activities; however the dimension related with depression improved 31% at the end of the intervention. The t-student test and Cohen's d showed a medium non-significant effect on sleep satisfaction ($p = 0.26$; ES: 0.32; insomnia ($p = 0.37$; ES: 0.38) and hypersomnia ($p = 0.09$; SE: 0.52). **CONCLUSIONS:** A supervised exercise program has a moderately beneficial effect on sleep quality in terms of insomnia, hypersomnia and depression in older people.

Assessing The Health Needs of Older Adults Living in an Underserved Urban Community

Dustin Durke, Kellie A. Walters, Michael Duxx Natividad. California State University Long Beach, Long Beach, CA.

Email: dustindurke159@gmail.com

(No relevant relationships reported)

Between 2012 and 2050, the population of older adults (>65 years old) is projected to nearly double and the preservation of their capacity to live independently remains a large public health concern. The American Gold Star Manor is a not for profit trust that owns and operates an older adult living community, subsidized by the Housing and Urban Development Division of the United States. Located in an urban subset of northern Long Beach, California, the manor is home to seniors with relations to the United States military and veterans. **PURPOSE:** The purpose of this study was to assess the health needs of a multi-ethnic older adult population in an underserved urban community. The data collected from this study will be used in a future study to inform the development and assessment of a monthly walking program for older adults living at Gold Star Manor. **METHODS:** An information session was held at American Gold Star Manor where an eleven-item survey was used to assess the current health needs of residents living at Gold Star Manor. In total, 29 residents (62+ years) attended the information session and completed the survey. The residents were given a set of topics and instructed to mark all topics they were interested in learning more about. Additionally, they were given space to fill in any topics that were not part of the provided selection. **RESULTS:** Of the 29 individuals surveyed, we found that 55% residents preferred English as their spoken language, 35% residents preferred Korean as their spoken language, and 10 residents preferred Spanish. Of the choices provided, 66% residents selected joint health, 62% selected social health, 48% selected cardiovascular health, 34% selected pedestrian safety, and 34% selected hydration and nutrition. In the open-ended section, residents recorded interest in learning about diabetes management, physical fitness, and cognitive health. **CONCLUSIONS:** Based on the needs assessment, the topics garnering the most interest among the American Gold Star Manor residents include joint health, social health, cardiovascular health, pedestrian safety, hydration, nutrition, diabetes management, physical fitness, and cognitive health.

Handgrip Strength as a Screening Assessment for Functional Limitations
 Nathan W. Saunders, Alyssa K. Braun, Meghan E. Hess, Uriel Ibarra-Moreno, Megan D. Salvatore. *University of Mount Union, Alliance, OH.*
 Email: saundenw@mountunion.edu
 (No relevant relationships reported)

There appears to be an undisputed strong relationship between isometric handgrip strength (HGS) and functional fitness test performance, ability to perform activities of daily living (ADLs), and mortality, but the extreme diversity in how HGS data are interpreted make it difficult to utilize the assessment in a meaningful way. **PURPOSE:** To simplify this interpretation by establishing a single and meaningful universal HGS cutoff that would inform the test administrator whether or not additional functional fitness testing was warranted. It was hypothesized that subjects scoring above the HGS cutoff would exhibit fewer perceived and actual functional limitations. **METHODS:** Male ($n = 24$; Age = 62.3 ± 14.3 years) and female ($n = 59$; Age = 64.7 ± 13.0 years) subjects self-reported their perceived ability to complete the variety of ADLs included in the Composite Physical Function Scale (maximum score of 24 indicating no perceived functional limitations). They additionally completed a battery of functional fitness assessments, which included HGS, 30-s Chair Stand, 8-ft Up-and-Go, 10 lb and 25 lb lift and carry, and 400 m Walk Test. A self-developed cell phone application was utilized to produce more outcomes, such as steady-state gait speed and cadence during the 400 m Walk Test. Independent samples *t*-tests were used to compare the perceived and actual functional fitness outcomes between subjects with grip strength < 30 kg and those with grip strength ≥ 30 kg. Additionally, positive predictive value (PPV), and negative predictive value (NPV) were calculated to investigate the accuracy of a 30 kg HGS cutoff to identify subjects with perceived or actual functional limitations. **RESULTS:** Subjects with a HGS ≥ 30 kg scored significantly higher on the CPF Scale, compared with subjects with a HGS < 30 kg (23.9 ± 3.3 vs. 22.4 ± 3.3 , respectively). Likewise, Subjects with a HGS ≥ 30 kg performed significantly better on every functional fitness test outcome, compared with subjects with a HGS < 30 kg. The NPV (true negative) was excellent ($\geq 90\%$) for all outcomes, while the PPV (true positive) was poor ($\leq 56\%$) for all outcomes. **CONCLUSIONS:** A HGS ≥ 30 kg appears to be an appropriate cutoff to accurately rule out current functional limitations in males and females 40 years of age and older.

Relationship Between Functional Physical Condition And Age In Institutionalized Older Adults In Bogotá-Colombia
 Cindy Lorena Benavides, Jose Alexander Garcia, Jairo Alejandro Fernández Ortega, Diogo Rodrigues Bezerra. *Corporación Universitaria CENDA, Bogotá, Colombia.*
 (No relevant relationships reported)

Purpose

The quantification of functional physical condition (CFF) in the elderly is an important indicator to define the state of health, the level of dependence and the quality of life in functional physical condition this population. The objective of this study was to establish the relationship between age and age in a group of elderly people residing in retirement home in the city of Bogotá.

Methodology

Cross-sectional descriptive observational study, which evaluated the functional physical condition (SFT) in 253 older adults (42.6% men and 57.3% women) institutionalized in the city of Bogotá. The CFF was evaluated through the senior fitness test, in the application the protocols proposed in the validation to Colombia were followed. The measure consisted of 6 physical tests: chair stand (repetitions), arm curl (repetitions), aerobic capacity in 2 minutes (repetitions), flexibility (cm); and 8 foot up and go (ms). A univariate descriptive analysis and a correlation analysis between age and physical condition variables were performed. An appreciative scale of the correlations was established as follows: weak for values > 0.40 ; moderate, between 0.41 and 0.60; strong, between 0.61 and 0.80, and very strong, between 0.81 and 1.0.

Results

In all CFF tests, significant differences were found for all age ranges in both men and women ($p < 0.01$). The following correlations were identified between the CFF variables and age: chair stand ($r^2 = 0.850$), arm curl ($r^2 = 0.928$), trunk flexion ($r^2 = 0.928$), back scratch ($r^2 = 0.862$), 2-minute step ($r^2 = 0.914$), 8 foot up and go ($r^2 = 0.877$) in men. In the case of women, very strong correlations were observed in the aerobic capacity ($r^2 = 0.916$), chair stand ($r^2 = 0.764$), arm curl ($r^2 = 0.682$), back scratch ($r^2 = 0.678$), 8 foot up and go ($r^2 = 0.739$) and moderate in trunk flexion ($r^2 = 0.458$).

Conclusion.

There is a linear relationship between age and performance in CFF tests.

Objectively-determined Physical Activity And Its Association With Mobility Limitations In Older, Chronic Disease Patients
 Victoria R. DeScenza¹, Alexander R. Lucas², Christina Simpson¹, Ciaran M. Fairman³, Jennifer M. Thomas-Ahner¹, Jessica Bowman¹, Zachary L. Chaplow¹, Marcy Haynam¹, Steven K. Clinton¹, Brian C. Focht, FACSM¹. ¹The Ohio State University, Columbus, OH. ²Virginia Commonwealth University, Richmond, VA. ³Edith Cowan University, Perth, Australia. (Sponsor: Brian C. Focht, FACSM)
 (No relevant relationships reported)

Mobility limitations are linked with increased risk of disability and mortality among older adults with chronic disease. Physical activity (PA) has consistently been associated with the preservation of mobility and improvements in physical function in aging populations. Although accelerometry is accepted as the gold standard of objective PA measurement, knowledge of objectively-determined PA in free living conditions and its association with mobility limitations among older adults with chronic disease remains limited. **PURPOSE:** To examine the association of objectively-determined PA in free-living conditions, assessed using the LIFECORDER EX (LC) accelerometer, with select mobility outcomes. **METHODS:** Associations between objectively-determined PA and mobility performance (400 MWalk and Stair Climb tests) and mobility-related self-efficacy (MRSE) were examined from the baseline assessments of 3 prior lifestyle intervention trials in 156 older prostate cancer and knee osteoarthritis patients. Moderate-Vigorous (MVPA) and light (LPA) were measured using LC accelerometry in free-living conditions across 7 consecutive days. **RESULTS:** Results of partial correlation analyses controlling for age revealed that total weekly MVPA was significantly correlated with 400 MWalk ($r = -.36$; $p < .01$), Stair Climb ($r = -.29$; $p < .05$), and MRSE ($r = -.27$; $p < .01$). LPA was also significantly correlated with 400 MWalk ($r = -.49$; $p < .01$), Stair Climb ($r = -.40$; $p < .01$), and MRSE ($r = -.38$; $p < .01$). **CONCLUSIONS:** The present findings demonstrate that objectively-determined PA measured using the LC accelerometer are associated with mobility performance and MRSE in older adults with chronic disease. The results also provide evidence further supporting the validity of accelerometry as a measure of mobility limitations among older prostate cancer and knee osteoarthritis patients. Given the established complexity of objective PA assessment in aging populations, the present findings have implications for PA interventions in the preservation of mobility among older adults with chronic disease.

Cardiovascular Risk Among Non-sedentary Elderly: Circumferences Trend Analysis Over Three Decades
 Carolina Gonzalez Beltran¹, João Pedro da Silva Júnior¹, Rafael Benito Mancini¹, Tatiane Kosimenko Ferrari², Timoteo Leandro Araujo³, Sandra Matsudo⁴, José da Silva Guedes⁵, Victor Keihan Matsudo¹. ¹CELAFISCS, São Paulo, Brazil. ²Universidade de São Paulo- USP, São Paulo, Brazil. ³UNIFMU Faculdades Metropolitanas Unidas, São Paulo, Brazil. ⁴Universidad Mayor, Santiago, Chile. ⁵Santa Casa, São Paulo, Brazil.
 (No relevant relationships reported)

Purpose: To describe and analyze the trend of adiposity-related circumferences of non-sedentary women between 1998 and 2017 **Methods:** The present study is part of the Mixed Longitudinal Project of Physical Fitness and Aging of SCS, developed by CELAFISCS, since 1998, in Brazil - SP. Sample comprised only female subjects, 50 years-old and older, and who were involved in a PA program and participated in at least one evaluations between 1998 and 2017, totalizing a sample of 6367 individuals. The circumference analyzed were waist, hip and waist for hip ratio (WHR). To analyze the trend, the sample was divided into age groups: 50 to 59 years, 60 to 69 years and 70 years and over **Statistical analysis:** Polynomial regression models were estimated. In the modeling process, the mean of each one of the anthropometric variables was considered as dependent variable (Y) and the years of evaluation as independent variable (X). For each variable, the model with the highest statistical significance (p) and the best accuracy measure (r^2) was selected. Was considered significant model $p < 0.05$. **Results:** Waist circumference presented a negative trend in the three age groups analyzed. Hip circum (cm) presented a negative trend in the age groups of 60 to 69 and 70 years and over, while WHR showed a negative trend in the age groups of 50-59 and 70 years and over. In the age group of 50 to 59 years, the mean WHR was 0.88 cm, with a decrease of 0.01 cm every year. In the age group of 60 to 69 years, the mean waist circumference was 87.90 cm, and there was a decrease of 0.05 cm in each year; the mean hip circum was 98.82 cm, with a decrease of 0.02 cm every year. In the age group of 70 years and over, the mean waist circum was 88.62 cm, with a decrease of 0.07 cm every year; the mean WHR was 0.89 cm, with every year decrease of 0.01 cm. **Conclusion:** Over the three decades analyzed, elderly active women of all age groups showed a tendency to decrease CV risk, although it still remained at a high risk, suggesting a positive impact of a PA program on CV risk.

Table. Trend analysis of adiposity-related circumferences of non-sedentary elderly according to age group

| | 50 to 59 years | | | 60 to 69 years | | | 70 years and over | | |
|--------------------|--------------------------------|------|--------|--------------------------------|------|--------|-------------------------------|------|--------|
| | Model | r | p | Model | r | p | Model | r | p |
| Waist Circum. (cm) | y = 89.80 - 0.04 ^a | 0.36 | 0.0060 | y = 87.50 - 0.05 ^b | 0.51 | 0.0000 | y = 88.02 - 0.07 ^c | 0.64 | 0.0001 |

Different Exercise Training On Reaction Time In Older Adults With Mild Cognitive Impairment

Linda Lin¹, Michael S W Lo², Nai-Hsin Yang¹, Guei-Jang Li¹.
¹National Cheng Kung University, Tainan, Taiwan. ²Kun Shan University, Tainan, Taiwan.
 Email: lin22@mail.ncku.edu.tw
 (No relevant relationships reported)

PURPOSE: To examine the effects of reaction ability after 12 weeks of two different types of exercise intervention in community-dwelling elderly with mild cognitive impairment.
METHODS: 72 participants aged over 60 years old were classified as probable mild cognitive impairment (MCI) using the Saint Louis University Mental Status (SLUMS) examination. Participant were assigned to 3 groups (CG, n=22, 74.58±5.78 years; RTG, n=24, 72.00±7.15 years; MEG, n=26, 72.77±5.65 years). Exercise groups performed twice-weekly resistance training or multicomponent exercise training for 1.5 hours led by certified fitness instructors, and the control groups performed twice-weekly tablet personal computers course for 12 weeks. The primary outcome measure were the simple reaction time and simple movement time were measured by Vienna-test system (VTS), the total body reaction time was measured with both their feet on a measuring instrument (HELMAS NH-3000I).
RESULTS: After the training period, of the 72 participants, 53 completed 12-week trial (18 in the MEG group, 18 in RT group, 17 in CG group). The total body reaction time for the MEG (-21.93%), and RTG (-9.04%) had decreased significantly than the CG (+1.13%) (p < .05), and the simple movement time for the MEG (-7.41%), and RTG (-0.81%) had decreased significantly than the CG (+27.58%) (p < .05).
CONCLUSIONS: These findings indicate that participating in the multicomponent exercise and resistance exercise program on building community for health promotion can improve reaction time in elderly with cognitive impairment. These findings suggest that short time twice-weekly MET and RTG are promising and effective strategies in community-based health promotion activities with mild cognitive impairment.

Bone-targeted Exercise For Older Men With Osteopenia And Osteoporosis: LIFTMOR For Men Trial Preliminary Findings

Amy T. Harding¹, Benjamin K. Weeks¹, Lisa J. Weis², Conor Lambert¹, Steven L. Watson¹, Belinda R. Beck, FACSM¹.
¹Griffith University, Gold Coast, Australia. ²The Bone Clinic, Brisbane, Australia.
 Email: amy.harding@griffithuni.edu.au
 (No relevant relationships reported)

PURPOSE: The LIFTMOR (Lifting Intervention For Training Muscle and Osteoporosis Rehabilitation) for Men trial was designed to compare the effects of 2 novel bone-targeted exercise programs on risk factors for falls and fracture in men with low bone mineral density (BMD). **METHODS:** LIFTMOR for Men is a 3-arm, 8-month, semi-randomised, intervention trial. Men ≥50 years of age with low BMD, screened for conditions and medications known to affect bone, were recruited. Eligible participants were randomised to 2/week, supervised high-intensity resistance and impact training (HiRIT) or bioDensity (bD) machine-based isometric exercise. Intervention responses are compared with those of a self-selected, non-randomised control (CON) sample of age-matched men following their habitual lifestyles. Outcomes at baseline and follow-up include: anthropometry; DXA-derived lumbar spine (LS) and femoral neck (FN) BMD; physical function (back extensor strength [BES], lower extremity strength [LES], timed-up-and-go [TUG], and 5-times sit-to-stand [STS]); and safety and compliance. Per-protocol analyses of preliminary outcomes were conducted using repeated measures ANCOVA, controlling for age, calcium consumption, prior physical activity, and initial values for BMD [adjusted mean change ± SE and adjusted p values are presented]. **RESULTS:** 93 men (67.1±7.5yr; 82.1±11.6kg; 175.2±6.7cm) with low BMD (FN T-score -1.6±0.6) were recruited, and designated CON (n=26) or randomly assigned to HiRIT (n=34) or bD (n=33). To date, 67 have completed the study and are included in these preliminary findings (21 CON; 24 HiRIT; 22 bD). Compliance is 75.6±17.9% for HiRIT and 81.1±12.1% for bD (NS). Between-group differences have appeared in several outcome measures but only the improvement in LS BMD (HiRIT 0.049±0.01g/cm² vs CON 0.013±0.01g/cm²; p=0.01) and STS (HiRIT 1.6±0.3s vs bD 0.8±0.3s; p=0.01) have reached significance. Within-group improvements have been observed for LS

and FN BMD in both HiRIT and bD, all functional outcomes for HiRIT (all p<0.05), and in LES, TUG, and STS for bD (all p<0.05). There have been no adverse events. **CONCLUSION:** Although preliminary, findings suggest that both novel bone-targeted exercise programs improved BMD and physical function in older men with osteopenia and osteoporosis. Data collection is ongoing.

Behavioral Responses on a Virtual Reality Induced Cognitive Task Between Young and Older Adults

Brett Baker, Yeonhak Jung, Preeti Chopra, Darla Castelli.
 The University of Texas at Austin, Austin, TX. (Sponsor: John Bartholomew, FACSM)
 (No relevant relationships reported)

Controlling for and measuring explanatory variables can be difficult but virtual reality (VR) is emerging as a viable means for replicating authentic physical activity settings within the lab. **PURPOSE:** Using VR, we determined if young and older adults differ on behavioral responses of reaction time and accuracy during standing, walking and fast walking conditions that require dual-task completion. **METHODS:** Thirty-two young adults (Mean age= 21.03) and thirteen older adults (Mean age= 69.6) participated in this study and were instructed to stand or walk on a Motek instrumented treadmill integrated with a 180° VR projection screen. Participants performed three eight-minute physical activity conditions; standing, walking and fast walking. During the conditions, 60 red and green objects appeared at random on the VR screen to replicate a Go/No Go cognitive task. Using gloves that had kinematic-motion capture markers, participants were instructed to strike the green objects. A motion capture system connected to the treadmill recorded reaction time and accuracy on correct object strikes for all conditions. **RESULTS:** We used paired sample t-tests to verify that the physical activity conditions increase in intensity by comparing heart rate measurements between conditions. There was a significant increase in heart rate (bpm) between the standing and walking conditions (p<0.05) and between the walking and fast walking conditions (p<0.05) for both the young and older adults. T-tests determined that there were no significant differences in accuracy between the young and older adults during any of the three conditions (p>0.05). T-tests determined that young adults had a significantly quicker reaction time than older adults during all three conditions (p<0.05). **CONCLUSIONS:** Surprisingly, older adults performed just as accurately as young adults during dual-task cognitive conditions carried out in a VR environment. VR may be an appropriate intervention to enhance cognitive stimulation to attenuate cognitive decline.

851 Board #85 May 29 3:30 PM - 5:00 PM
Relationship Between Attention And Balance In Older Adults

Congming Chen, Chunmei Cao. Tsinghua University, Beijing, China.
 Email: 1073798249@qq.com
 (No relevant relationships reported)

Several studies found that the reduction of capacity of concentration in older adults contributed to gait and mobility disturbances. The natural walking pattern was disrupted by diverting their attention to a secondary task, and the situation was even more serious among balance-impaired older adults who showed impairments when shifting their attention from task to task. However, there is limited information about the performance of attention and balance in old adults. **Purpose:** To investigate the relationship between attention and balance in community-dwelling older adults. **Method:** Thirty-three elderly (67.9±4.8 years) with no cognitive or neurological deficits (MMSE score: 28.41± 2.33) volunteered attending the test. The balance ability was measured by Y-balance which included three parameters, right front side, right rear inner stride and right rear outer stride. The single and dual tasks were used to measure the attention of the subjects. The single task was face emotion recognition including happy face and sad face. The dual task was face emotion recognition while walking with self-selected speed. Face recognition correct rate and face recognition correct reaction time in single and dual task were gathered. Person correlation coefficient (r) was used to determine the relationship between attention and balance. **Results:** Some low-to-moderate correlations were found between attention and balance, which were summarized in the table below:

| Tasks | | | Balance | | |
|------------|-------------|-----------------------|------------------|-------------------------|-------------------------|
| | | | right front side | right rear inner stride | right rear outer stride |
| Sad face | Dual task | Correct rate | -0.12 | -0.17 | -0.08 |
| | | Correct reaction time | -0.32* | -0.33* | -0.32* |
| | Single task | Correct rate | -0.16 | -0.12 | -0.14 |
| | | Correct reaction time | -0.12 | -0.20 | -0.21 |
| Happy face | Dual task | Correct rate | 0.19 | 0.06 | 0.09 |
| | | Correct reaction time | -0.31* | -0.33* | -0.31* |
| | Single task | Correct rate | -0.08 | -0.10 | -0.18 |
| | | Correct reaction time | -0.16 | -0.27* | -0.25 |

Note: * $p < .05$.

Conclusions: The attention does have low-to-moderate relationship with balance, which means that we may promote one through training another one.

Key words: attention; balance ability; elderly.

The Effects of Modified Parkour Exercise on Arterial Health and Fitness Components in Elderly Individuals
 Moneeb A. Khokhar¹, Alexei Wong¹, Jennifer Tripken¹, Ngoc-Huong Vinnedge¹, Arturo Figueroa, FACSM². ¹Marymount University, Arlington, VA. ²Texas Tech University, Lubbock, TX.
 (Sponsor: Arturo Figueroa, FACSM)
 Email: mak91433@marymount.edu
 (No relevant relationships reported)

Aging is associated with declines in vascular and muscular functions. It is crucial to reduce the negative effects of aging on vascular and muscular health by implementing appropriate lifestyle interventions, such as exercise training. Modified Parkour Exercise (MPK) has been found to increase agility and balance in elderly individuals. However, the possibility of MPK improving vascular and muscular functions in the elderly is currently unknown. **PURPOSE:** The purpose of this study was to examine the effects of a MPK regimen on blood pressure (BP), wave reflection (AIx), muscular strength and flexibility in elderly individuals. **METHODS:** Eighteen elderly individuals [age (69 ± 1 years); BP (126/78 mmHg) and body mass index (28.3 ± 1.6 kg/m²)] were randomized to either MPK (n=9) or no-exercise control group (n=9) for 8 weeks. MPK consisted of modified dynamic and static bodyweight exercises 3 x week. Training volume was progressed by increasing the number of exercises (2 to 5), sets and repetitions for dynamic exercises (3 to 4 sets and 8 to 20 repetitions) and duration for static exercises (30 s to 60 s). Modified Parkour movements were progressed by increasing their complexity. Supine BP, AIx, and heart rate (HR), 30s chair stands (CHAST) and sit and reach (SITNR) scores were measured at baseline and after 8 weeks.

RESULTS: There were significant group-bytime interactions ($P < 0.05$) for BP, AIx, CHAST and SITNR. There were significant decreases ($P < 0.05$) insystolic BP (-4±1 mmHg), diastolic BP (-3±1 mmHg) and AIx (-4±1 %) as well as significant increases ($P < 0.05$) in CHAST (2±1 stands) and SITNR (6±2 cm) following MPK compared with no changes after control. No significant changes were observed in HR for both groups.

CONCLUSIONS: MPK led to reductions in BP, wave reflection in elderly individuals. MPK may be an effective intervention in the prevention of hypertension and cardiovascular events as well as declines in muscular strength and flexibility in the elderly.

Changes in Physical Function and Body Composition among Group Lifestyle Balance Program Participants with Arthritis
 Ferdinand Delgado, Cheryl Der Ananian, Aubry Merkel. Arizona State University, Phoenix, AZ.
 Email: fdelgad5@asu.edu
 (No relevant relationships reported)

Weight loss through diet and physical activity (PA) is recommended for osteoarthritis (OA) management. The Group Lifestyle Balance Program (GLBP) is an evidence-based, behavior change program designed to promote weight loss in individuals with prediabetes or metabolic syndrome through PA and healthy eating. To date, the GLBP has not been evaluated on those with OA specifically.

PURPOSE: To examine the effects of the GLBP on measures of body composition and physical function (PF) in overweight and obese (BMI ≥ 27) individuals with OA (N=15).

METHODS: This study used a single-group, quasi-experimental design with repeated measures. All participants received the GLBP and outcome variables were obtained at baseline, 3, 6, and 12 months. Lean mass (LM), fat mass (FM), and body fat percentage (BF%) were obtained via bioelectric impedance. Total weight (WT), Body Mass Index (BMI), and waist circumference (WC) were also obtained. Measures of PF included the Short Physical Performance Battery (SPPB), grip strength (GS), 30-second chair stand test (CS30), and the Long Distance Corridor Walk (LDCW). The SPPB includes the time to complete 5 repeated chair stands (5CS), balance testing (side-by-side stand, semi-tandem stand, and tandem stand), and an 8-foot walk. The Friedman test was used to examine differences in SPPB scores and one-way repeated measures analysis of variance was used to examine mean differences in scores for all other outcomes.

RESULTS: Participants had a mean age of 70.20 ± 3.95 years and were primarily white (93%), female (80%) and college educated (67%). There was a significant effect of time for WT ($F_{(1,448,20,275)} = 6.591, p = .011$), BMI ($F_{(1,529,21,408)} = 6.474, p = .010$), and WC ($F_{(2,898,40,566)} = 4.826, p = .006$). Bonferroni post hoc analyses indicated WT ($p = .001$), BMI ($p = .002$), and WC ($p = .022$) significantly improved from baseline to 3 months. There was also a significant effect of time for 5CS ($F_{(3,42)} = 3.190, p = .033$) and CS30 ($F_{(3,42)} = 6.956, p = .001$). Post hoc analyses indicated CS30 scores significantly improved from baseline to 3 months and from baseline to 12 months ($p = .007$). There were no significant differences observed for any other outcome measure ($p > 0.05$).

CONCLUSION: The GLBP may be effective at improving weight and physical function measures in people with OA, but more research is warranted.

Role of Physical Exercise on Cognition & Falls Risk Factors in Alzheimer's Disease
 Joana Carvalho, Pedro Caçote, Flávia Machado, Arnaldina Sampaio. Faculty of Sport, University of Porto, Porto, Portugal.
 Email: jcarvalho@fade.up.pt
 (No relevant relationships reported)

PURPOSE: Falls are one of the leading cause of mortality and morbidity in older people and the risk of falling is exacerbated by impaired mental status due to dementia. However, whether persons with dementia benefit from fall prevention exercise training is unclear. This study aimed to evaluate the contribution of an exercise multicomponent training (MT) on cognition, balance, mobility and lower limbs muscle strength in the elderly with dementia as important risk factors for falling. **METHODS:** Sixty-four elders (78.5 ± 8.3 years) clinically diagnosed with dementia, were divided for convenience into two groups: Experimental Group (EG, n= 38) and Control Group (CG, n= 26). The EG participated in a 6-month supervised MT intervention (2 days/week, 60 min/session including aerobic, muscular resistance, flexibility, coordination and postural exercises). Cognitive function (MMSE), functional mobility (Time Up and Go -TUG -Test), balance and gait (POMA, Tinetti Index) and lower muscle strength (30-second Chair Stand) were assessed before and after 6 months of the experimental protocol. **RESULTS:** A two-way ANOVA, with repeated measures, revealed significant group and time interactions on cognitive function, TUG and Tinetti Index, presenting the EG a significantly better performance over the time compared to the CG. However, no statistically significant main effect was founded on the lower muscle strength. **CONCLUSIONS:** Our results suggest that a 6-month exercise multicomponent training can have a positive influence on the gait, balance, mobility and cognition, and therefore, seems to be an important strategy to reduce the risk of falling in dementia older adults. Support from IPDJ and FCT (CIAFEL -UID/DTP/00617/2013; "Body and Brain" -POCI-01-0145-FEDER-031808).

Physical Activity Levels in a Structured Physical Exercise Community Program in ElderlyRenata A. Miyabara, Ovidiu Constantin Baltatu, Luciana Aparecida Campos Baltatu. *Universidade Anhembi Morumbi, São Paulo, Brazil.*

Email: renatamiyabara@gmail.com

(No relevant relationships reported)

PURPOSE: A decline in physical activity levels in older people is related with worsening of quality of life and a lower cardiorespiratory fitness level, which are associated with cardiovascular disease events and mortality from all causes. The aim of this study was to survey the level of self-reported physical activity in elderly people practicing different levels of physical activity program. An urban community of Sao Paulo was investigated. **METHODS:** This was a community-based cross-sectional study of a cohort of 50 individuals aged 60 or over, participating in a 6-month structured physical exercise community program and a control group of 50 sedentary elderly individuals age-matched. The structured physical exercise community program adheres to the Position Stand of the American College of Sports Medicine, as it included combined aerobic exercise, muscle strengthening exercises, and flexibility exercises. Physical activity levels were evaluated using the International Physical Activity Questionnaire (IPAQ).

RESULTS: The group participating in a physical exercise program had significantly higher levels of physical activity in the moderate activity (318.8 ± 561.8 vs. 238.5 ± 831.6 MET-min/wk, $p < 0.001$), vigorous (125.8 ± 245.7 vs. 66.2 ± 228.9 MET-min/wk, $p < 0.002$) and total activity (846.0 ± 951.1 vs. 691.0 ± 1239.1 MET-min/wk, $p < 0.05$). No differences between these groups were observed in walking activity (275.6 ± 289.8 vs. 320.1 ± 498.4 MET-min/wk, $p = 0.6$).

CONCLUSIONS: Our structured physical exercise community program proved effective in order to overcome the decline in physical activity levels in elderly population.

Effects Of Resistance, Power, And Multicomponent Training With Elastic Resistance On Strength In Older WomenNicole L. Rogers¹, Pedro Gargallo², Álvaro Jueas², Eva Tamayo², Sara Torkamanech², J.F. Guzmán², J. Fernández-Garrido², Guillermo Saez², Michael E. Rogers, FACSM¹, Juan C. Colado². ¹Wichita State University, Wichita, KS. ²University of Valencia, Valencia, Spain. (Sponsor: Michael E. Rogers, FACSM)

Email: nicole.rogers@wichita.edu

(No relevant relationships reported)

The associations between strength losses in lower limbs and functional limitations are high for older adults. It is necessary to know the effects of modalities such as power training (PT) and multicomponent training (MT) on muscle strength compared to traditional resistance training (TRT) in this population. **PURPOSE:** To investigate the effects of 20-weeks of PT, MT, and TRT using variable resistance (elastic bands with loops) on isokinetic strength in older women (OW). **METHODS:** 136 sedentary OW (68.09 \pm 4.78 yr) were randomized into PT (n=34), MT (n=34), TRT (n=34), and control groups (CG) (n=34). All exercise groups trained twice weekly for 20 weeks. PT performed 6 exercises, 3-4 sets of 10-12 repetitions, at a 4 rate of perceived exertion (RPE) in the first repetition and no more than 6 in the last. MT performed balance, muscular endurance (2 exercises, 3-4 sets of 15 repetitions at 7-9 RPE), aerobic, flexibility, and coordination exercises. The TRT performed 6 exercises, 3-4 sets of 6 repetitions at 7-9 RPE. Maximum strength of knee extensors (KE) and hip abductors (HA) was measured at 60°/s and 180°/s in the dominant side with an isokinetic dynamometer. Trial (2) by group (4) repeated measures ANOVA was used to determine differences regarding time and groups. **RESULTS:** PT group showed a significant increase in HA (+89.61%) and KE (+22.75%) muscle strength at 180°/s with significant differences ($p < 0.05$) between MT, TRT, and CG groups for HA, and between CG for KE. TRT group showed a significant improvement in HA (+76.74) and KE (+11.29) at 60°/s with significant differences between CG in both. MT showed a significant increase in HA at 60°/s (+13.5%) and 180°/s (+29.85%), and also in KE at 60°/s (+4.62%) with significant differences between CG in HA at 180°/s and KE at 60°/s. No significant changes were observed for the CG. **CONCLUSIONS:** PT is the most effective training modality for increasing muscle strength output at high velocity, while TRT is more effective for improving maximal strength at low velocity, for HA and KE. MT can be an effective alternative as it induces adaptation at high velocity on HA and at low velocity on KE. The use of elastic bands with loops (CLX bands) can facilitate the application of these types of programs.

Multicomponent, Power, And Resistance Training With Elastic Resistance: Effects On Physical Function In Older WomenMichael E. Rogers, FACSM¹, Pedro Gargallo², Álvaro Jueas², Eva Tamayo², Sara Torkamanech², J.F. Guzmán², J. Fernández-Garrido², Guillermo Saez², Nicole L. Rogers¹, Juan C. Colado².¹Wichita State University, Wichita, KS. ²University of Valencia, Valencia, Spain.

Email: michael.rogers@wichita.edu

(No relevant relationships reported)

For older adults, the maintenance of muscle power and balance is a key factor in everyday task performance. Understanding the effects of emerging training modalities such as power training (PT) and multicomponent training (MT) compared to traditional resistance training (TRT) is of benefit to this age group. **PURPOSE:** To investigate the effects of 20-weeks of PT, MT, and TRT using variable resistance (elastic bands with loops) on physical function in older women (OW). **METHODS:** 136 sedentary OW (68.09 \pm 4.78 yr) were randomized into PT (n=34), MT (n=34), TRT (n=34), and control groups (CG) (n=34). All exercise groups trained twice weekly for 20 weeks. PT performed 6 exercises, 3-4 sets of 10-12 repetitions, at a 4 rate of perceived exertion (RPE) in the first repetition and no more than 6 in the last. MT performed balance, muscular endurance (2 exercises, 3-4 sets of 15 repetitions at 7-9 RPE), aerobic, flexibility, and coordination exercises. The TRT performed 6 exercises, 3-4 sets of 6 repetitions at 7-9 RPE. Variables analyzed were static balance (Romberg), agility (Up & Go), gait speed (4m), muscle strength (30-s chair stand), and aerobic capacity (6-minute walk test). Trial (2) by group (4) repeated measures ANOVA was used to determine differences regarding time and groups. **RESULTS:** MT showed significant improvements ($p < 0.05$; +56.8%) in static balance with significant differences between TRT and CG. PT showed significant improvements in all variables except static balance, with significant differences between MT and CG in muscle strength (PT: +29.20%; MT: +21.14%; CG: -2.69%), being the group with greatest improvements in 3 of 5 variables (agility: -14.26%; gait speed: -13.83%; muscle strength: +29.20%). PT, MT, and TRT showed significant improvements over time and between CG in agility, gait speed and aerobic capacity. No significant changes were observed for the CG. **CONCLUSIONS:** The three interventions are effective in improving physical function in OW, although the PT program induces greater adaptations in lower limb muscle strength, gait speed, and agility, while MT had a larger influence on balance. The use of elastic bands with loops (CLX bands) can facilitate the application of these types of programs.

Compositional Associations Of Objectively Measured Activities With Declined Cognitive Function In Older Adults: NEIGE StudyShiho Amagasa¹, Shigeru Inoue¹, Hiroshi Murayama², Takeo Fujiwara³, Hiroyuki Kikuchi¹, Noritoshi Fukushima¹, Masaki Machida¹, Sebastien Chastin⁴, Yugo Shobugawa². ¹Tokyo Medical University, Tokyo, Japan. ²The University of Tokyo, Tokyo, Japan. ³Tokyo Medical and Dental University, Tokyo, Japan. ⁴Glasgow Caledonian University, Glasgow, United Kingdom. ⁵Niigata University, Niigata, Japan.*(No relevant relationships reported)*

There is a growing literature that takes into account the co-dependence of time-use domains. Less is known about the combined effect of time spent in sedentary behavior (SB) and accumulating physical activity (PA) at different intensity and bout length. **PURPOSE:** To investigate a cross-sectional association of objectively-determined activities and cognitive function in community-dwelling older adults.

METHODS: A random sample of older adults (n=512, 47% male, aged 65-84 years) from NEIGE study in Tokamachi city, Niigata, Japan wore a tri-axial accelerometer (HJA-750C, Omron) for seven consecutive days and responded to a questionnaire in the fall of 2017. We assessed SB, light-intensity PA (LPA), short-bout (<10min) moderate-to-vigorous PA (MVPA), and long-bout (≥ 10 min) MVPA. Cognitive function was assessed by interviewers using the Mini-Mental State Examination, regarding a score of ≤ 26 as declined cognitive function. Data were analyzed using the compositional regression approach using isometric log-ratio transformations of the time-use composition, adjusting for age, sex, residential area, living arrangement, working with income, educational attainment, BMI, perceived health, and number of disease.

RESULTS: One third of older adults had declined cognitive function. SB, LPA, short-bout MVPA, and long-bout MVPA accounted for 50.2%, 43.8%, 3.4% and 2.6% of accelerometer wear time, respectively. A significant beneficial association was observed between larger proportion of long-bout MVPA relative to other activities and cognitive function. SB, LPA, and short-bout MVPA were not associated.

CONCLUSIONS: Promoting long-bout MVPA may be important for cognitive health among older adults.

Changes in Fitness and Fatness Levels in Qatari Schoolboys Over the Last Decade

Pitre C. Bourdon¹, Christopher R. Brandner², Andrew R. Douglas², Mohammed Farooq³, Saleh Al Marri², Esa Peltola², Nigel T. Cable⁴. ¹University of South Australia, Adelaide, Australia. ²Aspire Academy, Doha, Qatar. ³Aspetar - Orthopaedic and Sports Medicine Hospital, Doha, Qatar. ⁴University of Birmingham, Birmingham, United Kingdom.
(No relevant relationships reported)

PURPOSE: This study examined changes in anthropometric and cardiorespiratory fitness (CRF) characteristics of 26,325 Grade 6 (G6) schoolboys (11.0-12.99 y) living in the State of Qatar between 2003-2016. **METHODS:** Anthropometric measures included standing height (cm), body mass (kg) and body mass index (BMI, kg/m²). A multistage shuttle run test (MSRT, laps) was used to assess CRF. Comparisons between Qatari and non-Qatari boys were also conducted. **RESULTS:** The results showed a trend for decreasing CRF (less MSRT laps) and increasing fatness (higher BMI) across the study period, irrespective of nationality. Qatari students generally performed worse on the MSRT test and were fatter than their non-Qatari peers. Also, the Qatari students displayed bigger decreases in MSRT (10 vs 4 laps) and their body mass (2.5 vs 0.7 kg) and BMI (1.3 vs 0.6 kg/m²) increased more over the study period than their non-Qatari peers. Furthermore, the percentage of G6 schoolboys classified as overweight or obese increased over the study period for all nationalities, with Qatari boys showing a greater prevalence of overweight or obesity than their non-Qatari peers. For example, the percentage of Qatari boys classified as overweight or obese by Centers for Disease Control and Prevention (CDC) standards increased from an average of 40.1% between 2003-2006 to 49.3% between 2013-2016 while the average for non-Qatari boys increased from 32.6% to 39.9% for the same periods. **CONCLUSIONS:** These data support the need to establish a mechanism for the prevention and treatment of obesity and the development of physical activity strategies in the State of Qatar.

Participation in Physical Activity is Associated with Sexual Activity in Older English Adults

Lee Smith¹, Sarah E. Jackson². ¹Anglia Ruskin University, Cambridge, United Kingdom. ²University College London, London, United Kingdom.
Email: lee.smith@anglia.ac.uk
(No relevant relationships reported)

Purpose: Physical activity (PA) is a potential modifiable correlate of the age-related decline in sexual function, but no studies have explicitly tested associations between PA and sexual activity. This study aimed to examine associations between PA, sedentary behaviour and sexual activity, problems and concerns in older adults. **Methods:** A Cross-sectional observational population study. Data were from the English Longitudinal Study of Ageing, a nationally representative sample of older men and women living in England. A total of 7,038 older men and women aged ≥ 50 years were included. PA and TV viewing time were self-reported. Sexual behaviour and concerns were assessed by validated self-completion questionnaire and analyses were weighted for non-response. Covariates included age, partnership status, socio-economic status, limiting long-standing illness, smoking status, alcohol intake and depressive symptoms. Adjusted logistic regression were used to investigate associations between PA, sedentary behaviour and sexual activity, problems and concerns. **Results:** The odds of reporting any sexual activity were increased among individuals who participated in moderate (OR=1.64, 95%CI:1.24-2.15 in men, OR=1.21, 95%CI:0.97-1.52 in women) or vigorous (OR=2.06, 95%CI:1.50-2.84 in men, OR=1.42, 95%CI:1.09-1.85 in women) PA at least once a week. Erectile difficulties were less common among men who were active (OR=0.58, 95%CI:0.44-0.77 for vigorous PA). Results linking sedentary behaviour with sexual activity and function were less consistent, although women who watched ≥ 6 hours of TV/day had lower odds of thinking about sex frequently (OR=0.69, 95%CI:0.50-0.96) or, if they did not live with a partner, being sexually active (OR=0.40, 95%CI:0.22-0.72). **Conclusions:** Encouraging older adults to be more physically active could help to improve sexual relationships and, as a result, mental health and wellbeing.

Lower Aerobic Reserve is Associated with Poorer Physical Function in Community Dwelling Older Adults

Nicolas D. Knuth¹, Morgan Denny¹, Jennifer A. Schrack². ¹Towson University, Towson, MD. ²Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.
Email: nknuth@towson.edu
(No relevant relationships reported)

Reduced gait speed in older adults is a well-established predictor of disability and mortality. Recent evidence indicates that this decline in gait speed is accompanied by an increase in the energetic cost of walking and a decrease in peak energy expenditure. However, the association between this loss of aerobic reserve (AR) and functional performance has not been explored. **PURPOSE:** To examine the relationship between AR and physical function in older men and women. **METHODS:** AR was calculated as the percentage of the energetic cost of slow walking relative to peak walking energy expenditure in 20 participants of the Longitudinal Aging Study at Towson (65% women, age 70 \pm 8 yrs). Slow walking energy expenditure was assessed as the average rate of oxygen consumption during the final 2 minutes of a 5 minute standardized treadmill walking test at 1.5 mph (0.67m/s) using indirect calorimetry. Peak walking energy expenditure was assessed as the average steady-state rate of oxygen consumption during 400 meters of fast-paced walking over a 20-meter course using a portable indirect calorimeter. Physical function (PF) was assessed using components of the expanded Short Physical Performance Battery (ExSPPB) test consisting of time to complete 5 repeated chair stands, standing balance, and two measures of gait speed over 6 meters (normal walk and narrow walk). The association between AR and functional performance was modeled using linear regression models, adjusted for age and body mass index. **RESULTS:** In fully adjusted models, PF was negatively associated with AR ($\beta = -0.014$, $p = 0.002$), indicating that PF score improved 0.014 for each one-percentage higher AR. In further analyses of the individual components of PF, time to complete 5 chair stands ($\beta = -0.006$ chair stands per second, $p = 0.02$) and normal gait speed ($\beta = -0.009$ m/s, $p < 0.005$) were found to be negatively associated with AR, but there was no association with standing balance. **CONCLUSION:** Greater aerobic reserve was associated with higher physical function, specifically chair stand time and normal gait speed. These results suggest that maintaining AR is critical to preserving lower extremity strength and speed with aging. Interventions to improve mobility in older adults should aim to both increase peak capacity and reduce energetic costs to optimize potential benefits.

Detrimental Links Between Inflammation and Muscle Mass are Moderated by Physical Activity in Older Adults

Andreas Nilsson, Janelle Tarum, Fawzi Kadi. Örebro University, Örebro, Sweden.
Email: andreas.nilsson@oru.se
(No relevant relationships reported)

While age-related elevations in systemic inflammation may contribute to the accelerated loss of skeletal muscle mass, previous findings have been based on a limited number of biomarkers. Moreover, whether links between inflammation and muscle mass are independent of protein intake and habitual physical activity (PA) remain unknown. **PURPOSE:** The aim of the study was to explore links between skeletal muscle mass and inflammatory biomarkers in older women with different metabolic risk status, while accounting for adherence to guidelines on protein intake and PA.

METHODS: Skeletal muscle mass index (SMI) was assessed in 112 women (67 \pm 1.5 years) by bioelectrical impedance together with the equation of Janssen et al. (2002) to obtain muscle mass expressed in relation to body weight. Fasting blood samples were obtained following standardized protocols. Acute-phase proteins C-reactive protein (CRP) and fibrinogen were determined, together with the following inflammatory biomarkers: Adiponectin, Oncostatin-M (OSM), Leukemia inhibitory factor-receptor (LIF-R), Interleukin-6 (IL-6), IL-8, IL-12, and IL-18. Protein intake and PA were determined during 6 days by food record and accelerometry, respectively. Classification of metabolic risk status was based on the metabolic syndrome. Multivariate regression models were used to explore links between SMI and inflammatory biomarkers while adjusting for adherence to PA and protein intake guidelines and metabolic risk status.

RESULTS: Variations in SMI were inversely linked to levels of CRP (β -coefficient: -0.47; $p < 0.05$) and OSM (-0.20 $p < 0.05$), where the OSM link was attenuated after further adjustment for PA. In contrast, positive links between SMI and adiponectin (0.19 $p < 0.05$) and LIF-R (0.24 $p < 0.05$) were observed, which both remained significant in fully adjusted models. Links to other biomarkers were non-significant. **CONCLUSIONS:** Several inflammatory markers are linked to skeletal muscle mass in older adults, where detrimental or beneficial actions are indicated depending on the

biomarker. While adherence to PA guidelines moderates some of these links, others seem unaffected by either PA and protein intake or metabolic risk status. Further research is needed to elucidate mechanisms underlying these observations.

863 Board #97 May 29 2:00 PM - 3:30 PM The Relationship between Physical Activity and Physical Performance and Cognitive Abilities in the Chinese Elderly

Liu Ruidong, Chen Congming, Cao Chunmei. *Tsinghua University, BEIJING, China.*
Email: 763689088@qq.com

(No relevant relationships reported)

PURPOSE: Decreased physical and cognitive ability have become seriously problematic in aging. Studies seldom describe the relationship between physical activity (PA), physical performance and cognitive abilities, most of which by measuring only one or two specific abilities using questionnaires. The study was thus designed to examine the relationship between PA and physical performance and multiple cognitive abilities in the Chinese elderly.

METHODS: The design was a cross-sectional study. 148 people aged 65.15±7.79 were included from Guangxi Province in southern China. PA was measured by the Physical Activity Scale for the Elderly (PASE, Cronbach's $\alpha=0.752$; Test-retest reliability=0.980). Physical performance included coordination and lower limb strength, functional walking ability and the balance ability. Cognitive abilities were measured by computer-based tests, including simple reaction time and executive function (stroop task and shifting task). The association between PA and the outcomes were examined using correlation matrix and linear regression.

RESULTS: 1) The average time spent on physical activity was 1.8h/d; 2) High levels of PA significantly associated with better gait speed ($B=-0.67, p<0.05$), 30-s chair-stand test ($B=0.72, p<0.05$) and reaction abilities ($B=0.89, p<0.05$); 3) The gait speed significantly correlated with the accuracy of stroop task ($r = 0.23, p = .018$) and shifting task ($r = 0.21, p = 0.023$), grip strength significantly correlated with the accuracy and the reaction time of the stroop task ($r = 0.19, p = 0.04$ & $r = 0.19, p = 0.04$). However, other physical performance outcomes had no significant correlation with the cognitive abilities.

CONCLUSIONS: More physically active residents scored higher on physical performance outcomes. Positive associations were found between physical performance, executive function and reaction ability.

864 Board #98 May 29 2:00 PM - 3:30 PM Cardiorespiratory Fitness and Body Mass Index with Gastroesophageal Reflux Disease in Older Adults

Joey M. Saavedra, Angelique Brellenthin, Duck-Chul Lee, FACSM. *Iowa State University, Ames, IA.* (Sponsor: Dr. DC-Lee, FACSM)
Email: joeysav@iastate.edu

(No relevant relationships reported)

Purpose: To examine the associations of cardiorespiratory fitness (CRF) and body mass index (BMI) with prevalence of Gastroesophageal Reflux Disease (GERD) in older adults.

Methods: This cross sectional study included 566 older adults (57% women; 72 years old) who were without heart attack, stroke, or cancer in the past 5 years. CRF was assessed via a 400-meter walk test and the minutes to complete the test were divided into sex-specific quartiles (fourths). Participants were categorized into normal weight (<25 kg/m²), overweight (25-29 kg/m²), and obese (≥ 30 kg/m²) BMI groups. GERD cases were identified via self-report on a medical history questionnaire. Logistic regression was used to calculate the odds ratios (ORs) and 95% confidence intervals (CIs) of GERD among CRF quartiles and BMI groups while adjusting for sex, age, smoking, heavy alcohol consumption, meeting walking guidelines based on $\geq 7,500$ steps/day, and BMI (in CRF analyses) or CRF (in BMI analyses).

Results: Of the 566 adults, there were 123 (22%) GERD cases. Compared with the first quartile of CRF (least fit), the ORs (95% CIs) of having GERD were 0.70 (0.40-1.22), 0.65 (0.37-1.16), and 0.46 (0.25-0.87) among those in the second, third, and fourth (fittest) quartiles of CRF, respectively, after adjusting for all confounders except BMI. However, these associations were not significant after adjusting for BMI. Compared with the normal weight group, the ORs (95% CIs) of having GERD were 2.67 (1.51-4.72) and 4.32 (2.30-8.09) among the overweight and obese groups,

respectively, after adjusting for all confounders including CRF. In a joint analysis, compared with the unfit (first quartile of CRF) and obese, ORs (95% CIs) were 0.13 (0.03-0.48), 0.41 (0.17-0.96), 0.17 (0.08-0.36), 0.44 (0.23-0.83), and 0.53 (0.26-1.07) for the unfit-normal weight, unfit-overweight, fit-normal weight, fit-overweight, and fit-obese, respectively, after adjusting for all confounders.

Conclusions: Although both CRF and BMI appears to be associated with GERD in this sample of older adults, BMI was found to be more strongly associated with GERD independent of CRF. Among obese individuals, having high CRF may be associated with lower odds of GERD, but more research is warranted. Supported by unrestricted research grant by Biospace.

865 Board #99 May 29 2:00 PM - 3:30 PM Longitudinal Stability of Exercise Behavior Across Exercise Domains

Matthijs D. van der Zee, Denise van der Mee, Meike Bartels, Eco J.C. de Geus. *Vrije Universiteit Amsterdam, Amsterdam, Netherlands.*

Email: m.d.vander.zee@vu.nl

(No relevant relationships reported)

PURPOSE: Many previous studies that have assessed the tracking of leisure time exercise behavior focused on various parts of the life span, and have treated exercise behavior as a uniform construct. This study provides novel insight by assessing the longitudinal tracking of exercise in six different domains: (1,2) team-based versus solitary activities, (3,4) competitive versus non-competitive, and (5,6) externally paced versus internally paced activities across the life-span (8-80 years).

METHODS: From the Netherlands Twin Register (NTR) all subjects with longitudinal exercise data were selected ($N = 43,889$) and used to analyse the tracking of exercise behavior over time. With this dataset, we were able to examine tracking as a function of baseline age (8 to 80 years) and tracking duration (2 to 22-year follow-up), taking into account sex differences using generalized estimating equations.

RESULTS: Two-year tracking coefficients for total volume of exercise across age at baseline, ranging from .38 to .77 with a median of .57. Tracking coefficients tend to decrease as the distance to follow-up increases, down to a median of .38 for the 22-year tracking coefficients. The patterns of tracking were largely similar for solitary, competitive, non-competitive, externally and internally paced activities. With the exception of team-based activities, tracking was seen to increase as a function of baseline age.

CONCLUSIONS:

We conclude that exercise is moderate to highly stable across the lifespan, especially in late adulthood the tracking of exercise is high. This stability reinforces the existing evidence that exercise habits may be hard to change, but simultaneously suggests that successful intervention can lead to life-long habits.

866 Board #100 May 29 2:00 PM - 3:30 PM Parasympathetic Nervous Regulation and Prevalence of Lifestyle-related Diseases In Japanese: Waseda's Health Study

Masayuki Konishi¹, Susumu S. Sawada, FACSM¹, Ryoko Kawakami¹, Kumpei Tanisawa², Hiroki Tabata¹, Nobuhiro Nakamura¹, Hyeon-Ki Kim¹, Tomoko Ito¹, Mitsuru Higuchi, FACSM¹, Katsuhiko Suzuki¹, Suguru Torii¹, I-Min Lee, FACSM³, Steven N. Blair, FACSM⁴, Koichiro Oka¹, Shizuo Sakamoto¹. ¹Waseda University, Saitama, Japan. ²National Institutes of Biomedical Innovation, Health and Nutrition, Tokyo, Japan. ³Harvard Medical School, Boston, MA. ⁴University of South Carolina, Columbia, SC.

Email: m.konishi@aoni.waseda.jp

(No relevant relationships reported)

PURPOSE: Limited data are available on the relationship of parasympathetic nervous regulation with the prevalence of lifestyle-related diseases in Japanese men and women. We conducted a cross-sectional study to investigate the relationship between diving reflex (DR) and heart rate recovery after exercise (HRR) - markers of parasympathetic nervous regulation - with the prevalence of hypertension, diabetes, and dyslipidemia among Japanese men and women in WASEDA'S Health Study.

METHODS: WASEDA'S Health Study is a cohort study which was launched in 2014. We used data collected at baseline in this study. Participants were 193 Japanese men [median (IQR) age 57 (48-67) years] and 81 women [median (IQR) age 52 (44-58) years] who completed a medical examination, maximal exercise test, and diving reflex test. The participants were divided into tertiles based on DR indexes and HRR indexes. DR indexes were the peak value of the R-R interval during the test (R-Rmax), the relative difference between the baseline and peak response due to the test (R-Rchange), and the latency of DR (Latency). Also, HRR indexes were defined as the reduction in the heart rate from the rate at peak exercise to the rates 1, 2, and 3 minutes after the cessation of exercise (HRR1, HRR2, and HRR3). Odds ratios and 95% confidence

intervals for the prevalence of lifestyle-related diseases were obtained using logistic regression models while adjusting for sex, age, body mass index, physical activity, family history of lifestyle related diseases, cigarette smoking, and alcohol intake.

RESULTS: 119 participants had hypertension, 17 had diabetes, and 125 had dyslipidemia. Using the lowest DR indexes and HRR indexes as reference, we calculated odds ratios and 95% confidence intervals for the outcomes of interests. We found statistically significant dose-response relationships between R-Rmax and diabetes (P for trend = 0.016) as well as R-Rchange and diabetes (P for trend = 0.010). There was also a statistically significant dose-response relationship between Latency and dyslipidemia (P for trend = 0.013) and HRR3 and hypertension (P for trend = 0.047).

CONCLUSIONS: In cross-sectional analysis, the data suggest diving reflex may be related to the prevalence of lifestyle-related diseases, particularly diabetes.

Impact of Physical Activity Participation on Waist-to-Hip Ratio: A Propensity Score Analysis

Zhigang Yang, Department of Physical Education, FuDan University, China; Weimo Zhu (FACSM), Department of Kinesiology and Community Health, University of Illinois at Urbana-Champaign

PURPOSE: To examine the impact of physical activity (PA) participation on college students' WHR using the propensity score analysis.

METHOD: A total of 1,144 college students (Male = 53.8%) from a major Chinese university were recruited for the study and their waist circumference (WC) and hip circumferences (HC) were measured, and WHR were computed. In addition, their daily time spent on the internet (ITT), their PA participation frequency per week (PAFW), time spent on PA each time (PATE) and time spent on PA per week (PATW) were collected through a survey. Using the propensity score analysis, in which sex, age, ITT, PATE, PAFW and PATW were used as the matching variables so that the impact of PA participation on WHR can be independently examined.

RESULTS: The descriptive statistics of key variables measures are summarized as below:

| Variables | Mean | SD |
|------------|--------|---------|
| Age (yr.) | 20.570 | 3.424 |
| WC (cm) | 74.22 | 0 7.600 |
| HC (cm) | 92.200 | 5.297 |
| WHR | .805 | .066 |
| ITT (hr.) | 6.410 | 2.773 |
| PAFW | 3.780 | 2.312 |
| PATE (hr.) | 1.708 | .794 |
| PATW (hr.) | 7.350 | 5.951 |

Using the ACSM 3-time per week recommendation as a criterion, 439 of 703 college students were extracted as the high frequent PA participation (HFPA) group and the rest as the low frequent PA participation (LFPA) group, and their group difference in WHR was computed and compared:

LFPA (M±SD) 0.834±0.048
 HFPA (M±SD) 0.758±0.056

Mean Difference 0.081

Effect size 0.642

p-value <0.001

t-value 24.347

Coefficients 0.779

Conclusion: After using the propensity-score matching, the impact of the frequency of PA participation became very significant (ES = .64 and p<0.001), which indicates regular PA participation is the key for college students' weight control and management.

868 Board #102 May 29 2:00 PM - 3:30 PM
Stronger Relationships Between Cardiometabolic Risk Factors and Physical Fitness than Objectively Measured Physical Activity

Jani Vaara¹, Tommi Vasankari², Harri Koski³, Heikki Kyröläinen, FACSM⁴. ¹National Defence University, Helsinki, Finland. ²UKK Institute for Health Promotion Research, Tampere, Finland. ³Finnish Defence Forces, Helsinki, Finland. ⁴University of Jyväskylä, Helsinki, Finland.
 Email: jani.vaara@mil.fi
 (No relevant relationships reported)

Previous studies have shown that physical fitness is more strongly associated with cardiometabolic health outcomes than self-reported physical activity (PA). However, objectively measured PA may offer more precision in defining PA than self-report methods. Therefore it is of interest to determine associations of objectively measured PA with cardiometabolic risk factors.

PURPOSE: To assess associations of objectively measured PA, as well as aerobic and muscular fitness, with cardiometabolic risk factors.

METHODS: 415 young healthy adult men (28±6 yrs.) participated in the study. PA was measured with a tri-axial accelerometer (Hookie Am 20, Traxmeet Ltd, Espoo, Finland) to assess light intensity (LIPA, 1.5-2.9 METs) and moderate-vigorous (MVPA, ≥3.0 METs) PA. Physical fitness was measured with 1-min push-ups and sit-ups (reps/min) and standing long jump tests. In addition, maximal isometric force of the leg and arm extensors was measured. All muscular fitness results were converted into a muscular fitness index (z-score). Cardiorespiratory fitness (VO₂max) was determined using an indirect graded cycle ergometer test until exhaustion. In addition, blood pressure was measured and blood samples were drawn after an overnight fast. The analyzed cardiometabolic risk factors consisted of serum lipids (total cholesterol, LDL, HDL, triglycerides) and plasma glucose, insulin and HbA1C.

RESULTS: After adjustments for age and smoking, LIPA was associated with insulin (β=0.14, p<0.005), whereas MVPA was associated with HDL (β=0.13, p<0.05). Aerobic fitness was inversely associated with blood pressure and serum lipids (β=-0.15 - -0.42, p<0.005), excluding HDL, which was positively associated with aerobic fitness (β=0.32, p<0.001). Muscular fitness was inversely associated with diastolic blood pressure, serum lipids and insulin (β=-0.10 - -0.26, p<0.05), and positively with HDL (β=0.20 p<0.001).

CONCLUSIONS: MVPA was positively related only to HDL concentration, whereas physical fitness was related with numerous cardiometabolic risk factors. These findings emphasize the stronger relationship of physical fitness to cardiometabolic risk factors compared to physical activity. MVPA leading to higher fitness levels should be promoted in order to provide cardioprotective effects.

869 Board #103 May 29 2:00 PM - 3:30 PM
Sedentary Behavior in Cardiac Patients

Esmée A. Bakker¹, Bram MA van Bakel¹, Esther P. Meindersma¹, Wim RM Aengevaeren², Maria TE Hopman, FACSM¹, Dick HJ Thijssen¹, Thijs MH Eijssvogels¹. ¹Radboud university medical centre, Nijmegen, Netherlands. ²Rijnstate Hospital, Arnhem, Netherlands. (Sponsor: Maria Hopman, FACSM)
 Email: Esmee.Bakker@radboudumc.nl
 (No relevant relationships reported)

Sedentary Behavior (SB) is associated with increased risks for many adverse outcomes. Evidence is limited about 1) the amount of SB in cardiac patients and whether this changes after cardiac rehabilitation (CR), and 2) which cardiac patients present higher levels of SB. **PURPOSE** To examine 1) the amount of SB in cardiac patients and whether SB changes following completion of a supervised CR program, and 2) characteristics of cardiac patients with high levels (≥ 8 hrs per day) of SB. **METHODS** To investigate aim 1, cardiac patients (n=84) were included upon enrolment of a Dutch CR program with supervised exercise training sessions. SB was objectively assessed during 7 consecutive days using the ActivPal3 micro. Data were collected at baseline, directly after and 2-3 months after completion of the CR program. For aim 2, patients (n=600) who participated in CR were invited to complete an online questionnaire about general and disease-specific characteristics. Sedentary time was assessed using the Sedentary Behavior Questionnaire. **RESULTS Aim 1.** The mean sedentary time in cardiac patients (mean age 65 [SD 33] yrs, 79% male) was 10.2 (SD 1.7) and 10.4 (SD 1.8) hours per week- or weekend day, respectively. Sedentary time did not change after completion of the CR program (mean difference weekdays = 0.26 [95% CI -0.02; 0.54]; weekend day = 0.40 [95% CI -0.06; 0.88] hrs/day), or 2-4 months later (mean difference weekdays = 0.23 [95% CI -0.12; 0.58]; weekend day = 0.35 [95% CI -0.17; 0.88] hrs/day). **Aim 2.** Being employed (prevalence ratio

(PR) 1.46 [95% CI 1.26; 1.70]), being divorced or widow(er) (PR 1.75 [95% CI 1.21; 2.53]), being resuscitated (PR 1.31 [95% CI 1.09; 1.59]), a high level of cardiac anxiety (PR 1.38 [95% CI 1.19; 1.59]), and living in a rural environment (PR 0.80 [95% CI 0.66-0.97]) were independently associated with high levels (≥ 8 hrs per day) of self-reported SB. **CONCLUSION** Cardiac patients present high levels of SB, and SB did not change after CR. Several patient characteristics (i.e. employment, marital status, resuscitation, cardiac anxiety and living environment) were significantly associated with sedentary time, which provides insight in who is the most at risk for SB associated adverse outcomes. Our data suggest that tailored initiatives are needed to target high levels of SB among cardiac patients.

Measured Vs. Self-reported Height, Weight And BMI: Relationships With Anthropometry, Fitness, And Physical Activity
 Oliver W. Wilson, Christopher M. Bopp, Zack Papalia, Melissa Bopp, FACSM. *The Pennsylvania State University, State College, PA.* (Sponsor: Melissa Bopp, FACSM)
 Email: oww2@psu.edu
 (No relevant relationships reported)

Researchers, policy makers, and clinicians commonly use height and weight to determine BMI and classify weight status. Self-report measures are utilized in a considerable portion of the scientific literature and national surveys, but often result in misreporting of height and weight, and consequentially underestimation of BMI and therefore potentially BMI category (weight status) misclassification. **PURPOSE:** To examine differences in self-reported and measured height, weight and BMI values, and whether discordance is associated with other anthropometric measures, fitness levels, and physical activity (PA) and sedentary behaviors (SB). **METHODS:** Data were collected from college students via: (1) a pre-consultation online questionnaire where participants self-reported sex, height, and weight; (2) an objective fitness assessment that assessed height, weight, body fat percentage, abdominal girth, predicted aerobic fitness, and muscular endurance; and, (3) a post-assessment electronic survey that assessed PA and SB. Parametric and non-parametric analyses was used to examine differences between groups. **RESULTS:** Self-report and measured height and weight data were collected from 1,061 participants, 224 of whom also provided PA and SB data. Women significantly under-reported weight ($p = .003$, $\eta^2 = .02$), and both sexes over-reported height ($p < .001$, $\eta^2 \geq .07$), resulting in a significant difference between BMIs calculated using self-reported and measured values ($p < .001$, $\eta^2 \geq .07$) and misclassification of BMI category of ~15% of both sexes. Minimal differences were found in anthropometric, fitness, or PA between those who over and underreported their height, but significant differences were found based on reporting differences for weight ($p \leq .015$) and BMI ($p \leq .015$). **CONCLUSIONS:** Students were found to have a tendency to underreport weight and overreport height, resulting in BMI category misclassification. Findings suggest that those who underreport weight tend to be in poorer health, as indicated by lower aerobic fitness in and higher abdominal girth and body fat percentage in particular. With respect to PA, overreporters tended to report lower PA levels than under and accurate reporters. Further research is required to establish the link between underreporting weight and overreporting PA.

871 Board #105 May 29 2:00 PM - 3:30 PM
Muscle Strength and Bone Strength Assessed with Osteo-sono Assessment Index Among Recreationally Athletic Japanese Women
 Takahisa Ohta¹, Junzo Nagashima², Haruhito Aoki², Takeshi Yoshihisa², Yasunori Imagawa², Nobuyoshi Ono², Wataru Fukuda², Reo Konagi², Susumu S. Sawada, FACSM³, Hiroyuki Sasai¹, Naokata Ishii¹. ¹The University of Tokyo, Tokyo, Japan. ²Yokohama Sports Medical Center, Yokohama, Japan. ³Waseda University, Saitama, Japan.
 (No relevant relationships reported)

Low muscle strength is an independent risk factor for low bone strength, which is a well-established predictor of osteoporotic fracture. However, the association between muscle strength and bone strength remains unclear among recreationally athletic Asian women. **PURPOSE:** To investigate the association between muscle strength and bone strength among recreationally athletic Japanese women. **METHODS:** This cross-sectional study was conducted in 7091 recreationally athletic Japanese women [mean (standard deviation), age 50.3 (15.2) years] who had undergone medical checkup and various exercise tests voluntarily from 1998 to 2016 at a preventive medical center. Participants completed a maximal voluntary knee extension test, quantitative ultrasound (QUS), calcaneal measurements, a medical examination, and questionnaires on lifestyle. Muscle strength, expressed as Nm per body weight in kilogram (Nm/kg), was measured at 60 degrees/s in the knee with an isokinetic dynamometer. The osteo-sono assessment index (OSI) evaluated right calcaneus heel bone strength using a QUS measurement. Multiple linear regression

analysis assessed independent association of muscle strength and OSI ($\times 106$) after adjustment for age, systolic blood pressure, smoking, drinking, prevalence of diabetes, and body mass index. **RESULTS:** Muscle strength had a positive association with OSI score after adjustment for potential confounding factors ($\beta=0.17$, 95% confidence interval; 0.15-0.19, $p < 0.001$). Furthermore, age-stratified (≥ 50 years and under) analyses showed similar patterns of association. **CONCLUSIONS:** Our results suggest a dose-response association between muscle strength and bone strength after adjustment for potential confounding factors. We need to further investigate longitudinal relationship between muscle strength and bone strength in a cohort study.

872 Board #106 May 29 2:00 PM - 3:30 PM
Cardiorespiratory Fitness and Prevalence of Lifestyle-related Diseases In Japanese Men And Women: WASEDA'S Health Study

F. Oberlin University, Tokyo, Japan. ⁴Harvard Medical School, Boston, MA. ⁵University of South Carolina, Columbia, SC.
 Email: yusumi@gmail.com
 (No relevant relationships reported)

Many epidemiological studies report that there is an inverse relationship between cardiorespiratory fitness and the prevalence of lifestyle-related diseases. However, limited data are available on this relationship among Japanese men and women. **PURPOSE:** This cross-sectional study is to investigate the relationship between cardiorespiratory fitness and the prevalence of hypertension, diabetes, and dyslipidemia among Japanese men and women in WASEDA'S Health Study. **METHODS:** WASEDA'S Health Study is a cohort study which was launched in 2014. We used part of the baseline data collected for this study. Participants were 631 Japanese men [median (IQR) age 56 (48-65) years] and 306 women [median (IQR) age 50 (45-57) years] who completed a medical examination, and maximal exercise test at baseline. The participants were then divided into quartiles based on cardiorespiratory fitness. The prevalences of lifestyle-related diseases were based on self-reports from questionnaires, blood pressure, and/or blood test at the medical examination. Odds ratios and 95% confidence intervals for the prevalences of lifestyle-related diseases were obtained using logistic regression models while adjusting for sex, age, body mass index, physical activity, family history of lifestyle-related diseases, cigarette smoking, and alcohol intake. **RESULTS:** 366 participants had hypertension, 55 had diabetes, and 420 had dyslipidemia. Using the 1st quartile of cardiorespiratory fitness as reference, odds ratios and 95% confidence intervals for 2nd, 3rd, and 4th quartiles are shown in the table below. **CONCLUSIONS:** These results suggest that there is an inverse relationship between cardiorespiratory fitness and the prevalence of hypertension and diabetes, but not dyslipidemia, among Japanese men and women. We intend to continue prospective follow-up of participants, to obtain more robust findings with longitudinal analyses.

| | Cases | Q1 (lowest) | Q2 | Q3 | Q ₄ (highest) | P for trend |
|--------------|-------|------------------|------------------|------------------|--------------------------|-------------|

Association of Active Commuting with Sport Time and Outdoor Play Time in Chinese Schoolchildren
 Gang He, Jingcheng Li, Yili Zhu, Gang Ji. *Capital University of Physical Education and Sports, Beijing, China.* (Sponsor: Stephen H. Wong, FACSM)
 Email: hegang@cupes.edu.cn
 (No relevant relationships reported)

PURPOSE: Active commuting has been proved to be related to higher levels of physical activity in children in Western countries. Whether this relationship exists for specific forms of physical activity, e.g., sport participation and outdoor play, remains

WEDNESDAY, MAY 29, 2019

unclear, especially among Chinese children. This study aimed to investigate the association of active commuting with sport time and outdoor play time in Chinese schoolchildren.

METHODS: A total of 441 children (49.7% boys, mean age = 8.3 ± 0.9 years) in grades 1 to 3 from four primary schools in Beijing participated in this study. Information of children's walking trips, daily sport time, and daily outdoor play time was reported by parents using the modified Chinese version of the children's leisure activities study survey. Children were categorized as either active (≥ 6 walking trips per week) or passive commuters (< 6 walking trips per week) based on the parent-reported number of trips walking to and from school. Children reported their own sex, age, and exercise self-efficacy. Children's body weight and height were measured by researchers to calculate body mass index (BMI). Differences of daily sport time and outdoor play time between active vs. passive commuters were examined by the analysis of covariance (ANCOVA) adjusting for children's age, BMI, and exercise self-efficacy. ANCOVA were conducted separately for boys and girls.

RESULTS: 42.7% of boys and 40.3% of girls were classified as active commuters. In boys, no difference was found for daily sport time between active and passive commuters (62.0 ± 46.7 min/d vs. 55.4 ± 41.4 min/d, $P = 0.266$), whereas active commuters had more time of outdoor play than passive commuters (194.8 ± 122.4 min/d vs. 153.7 ± 122.3 min/d, $P = 0.041$). For girls, neither daily sport time (64.1 ± 37.7 min/d vs. 54.1 ± 43.9 min/d, $P = 0.110$) nor daily outdoor play time (146.3 ± 129.6 min/d vs. 178.5 ± 141.4 min/d, $P = 0.156$) differed between active and passive commuters.

CONCLUSIONS: Boys who actively commute to school have higher levels of outdoor play time. Promoting active commuting may increase levels of physical activity in Chinese schoolchildren.

874 Board #108 May 29 2:00 PM - 3:30 PM
A Comparison of Obesity and Other CVD Risk Factors between Boys and Girls in Kuwait

Abdulaziz K. Alfarhan¹, Lorraine J. Weatherspoon¹, Wei Li¹, Karin A. Pfeiffer, FACSM¹, Nabil K. Badawy², Joseph J. Carlson¹. ¹Michigan State University, East Lansing, MI. ²The Public Authority for Applied Education and Training, Kuwait, Kuwait.

(No relevant relationships reported)

The prevalence of childhood obesity in Kuwait, among the highest globally including the US, is higher in boys than girls. Cardiovascular disease (CVD) risk is hence a concern, but data are limited comparing other CVD risk factors between boys and girls. **PURPOSE:** To compare the mean level and prevalence of CVD risk factors between 5th grade boys and girls in Kuwait. **METHODS:** A cross-sectional study of 367, 5th graders at 10.4 ± 0.4 years of age, (53% girls), from 16 schools in 6 Kuwaiti cities. Outcome variables and at-risk cut points included: Body mass index (BMI) to classify overweight (OW) or obese (OB) [WHO 2007], total cholesterol (TC ≥ 170 mg/dL), low-density lipoprotein (LDL ≥ 130 mg/dL), high-density lipoprotein (HDL < 40 mg/dL), TC:HDL-C (≥ 3.5), triglycerides (TG ≥ 100 mg/dL), resting systolic (SBP), and diastolic blood pressure (DBP) (≥ 90 th centile). Trained research assistants took measures with a portable anthropometer, scale, Cardiocheck Plus analyzer, and BP via auscultation with manual cuff. Physical activity (PA) and screen time (ST) were self-reported. Differences were examined with ANOVA or χ^2 (significance $p \leq 0.05$). **RESULTS:** Mean and % at-risk for boys vs girls was: BMI Z score ($1.32 \pm .11$ vs $1.29 \pm .09$; $p < 0.44$), OW (15.5% vs 27.1%, $p < 0.007$), and OB (41.1% vs 37.8%, $p < 0.487$). There were no significant differences in blood lipids except girls had higher TG (108.5 ± 58.6 vs 91 ± 42.7 mg/dL, $p < 0.009$). Girls vs boys had higher (non-significant) % at risk for TC (29% vs 23%; $p < 0.28$), low HDL-C (21% vs 12%; $p < 0.06$), TC:HDL-C (29.5% vs 22%; $p < 0.16$), and TG (38% vs 30%; $p < 0.19$); and lower % at risk for LDL-C (3.2% vs 4.5%; $p < 0.60$). Girls also had significantly higher SBP (107.7 ± 12 vs 102.4 ± 11.5 mmHg; $p < 0.001$) and DBP (70.3 ± 9.6 vs 64.8 ± 8.7 mmHg; $p < 0.0001$), and % at-risk for BP (10% vs 6%; $p < 0.16$), respectively. Boys mean PA (ds/wk ≥ 60 min; 3.37 ± 2.36 vs 2.47 ± 2.24 ; $p < 0.001$) and ST (hrs/d; 4.97 ± 2.56 vs 4.50 ± 2.77 ; $p < 0.119$) were higher than girls. Most girls and boys ($> 80\%$) did not meet PA or ST (≤ 2 hrs/d) recommendations. **CONCLUSION:** Contrary to previous data Kuwaiti boys did not have significantly higher obesity prevalence vs girls. Girls had significantly higher OW % at risk; and mean TG, SBP, DBP, and lower PA levels. Intervention studies on Kuwaiti children are warranted to reduce CVD risk factors including improving PA and ST behaviors.

875 Board #109 May 29 2:00 PM - 3:30 PM
Handgrip Strength and Congestive Heart Failure in Aging Adults: Getting a Grip on Heart Health

Ryan McGrath¹, Duck-Chul Lee, FACSM², William Kraemer, FACSM³, Brenda Vincent⁴, Donna J. Terbizan, FACSM¹. ¹North Dakota State University, Fargo, ND. ²Iowa State University, Ames, IA. ³The Ohio State University, Columbus, OH. ⁴VA Ann Arbor Healthcare System, Ann Arbor, MI.

(No relevant relationships reported)

Handgrip strength is a powerful biomarker of aging that is linked to a variety of health conditions; however, it is not well understood how handgrip weakness factors into certain cardiovascular diseases such as congestive heart failure (CHF). **PURPOSE:** To determine the association between handgrip weakness on time to CHF for aging adults in the United States. **METHODS:** A discrete sample of 12,658 adults aged at least 50 years (age: 68.0 ± 10.2 years at baseline) who participated in at least one wave of the 2006-2014 waves of the Health and Retirement Study were included. Interviews were conducted on participants biennially. Healthcare provider diagnosed CHF was self-reported at each wave. A spring-type hand-held dynamometer assessed maximal handgrip strength. Age- and race-specific maximal handgrip strength cut-points were used for determining weakness (Black men: < 40 -kilograms, Black women: < 31 -kilograms, White men: < 35 -kilograms, White women: < 22 -kilograms). A Cox proportional hazard regression model examined the association between handgrip weakness and time to CHF. Sex, race, age, body mass index, current smoking status, smoking history, self-rated health, diabetes status, and previously reported heart conditions aside from CHF were controlled for in the analyses. **RESULTS:** For those included, 4,141 (32.7%) were weak and 252 (2.0%) developed CHF during the mean follow-up of 5.6 \pm 4.5 years. The covariate-adjusted Cox model revealed that those who were weak had a 35% higher hazard of CHF (hazard ratio: 1.35; 95% confidence interval: 1.02, 1.80), relative to those who were not-weak. **CONCLUSIONS:** Our findings suggest that handgrip weakness was associated with an increased risk of incident CHF for aging adults in the United States. Measures of handgrip strength should become more commonplace in clinical settings for assessing age-related weakness and risk for poor clinically-relevant health outcomes such as CHF. Similarly, interventions aiming to prevent or treat CHF in aging adults should incorporate measures of handgrip strength. Engaging in muscle strengthening activities and behaviors earlier in life may help to preserve strength and lower risk for CHF during aging.

Association Between Grip Strength and Diabetes Prevalence in 45- to 60-Year Old Chinese Men

Juan Wang, Zhengzhen Wang, FACSM, Yan Wang. BEIJING SPORT UNIVERSITY, BEIJING, China. (Sponsor: Zhengzhen Wang, FACSM)

Email: wangjuan2006cn@126.com

(No relevant relationships reported)

Several studies showed that grip strength is related to cardiovascular risk factors, but few on the relationship between grip strength and prevalence of diabetes, especially for Chinese people.

PURPOSE: To explore the associations between grip strength and fasting blood glucose of diabetes and diabetes prevalence in 45- to 60-year old Chinese men. **METHODS:** All the subjected were recruited from three health management centers of hospitals in China, they finished the basic medical examination and grip strength test and VO_{2max} test. Diabetes was assessed by physical diagnosis or fasting blood glucose. Grip strength was tested in dominant hand; and VO_{2max} was measured by YMCA cycle test.

RESULTS: 1) There are 800 men recruited in this study, 82 of them are diabetes, the prevalence of diabetes is 10.25%. 2) The grip strength of diabetes patients is lower than that of other people [(35.50 \pm 6.96) kg vs. (37.26 \pm 7.40) kg, $P < 0.05$], and also the VO_{2max} is lower than that of other people [(35.17 \pm 7.86) mL/kg/min vs. (32.72 \pm 6.06) mL/kg/min, $P < 0.05$]. 3) In all men, the grip strength is negatively correlated with fasting blood glucose ($r = -0.10$, $P < 0.05$). In diabetes men, the grip strength is also negatively correlated with fasting blood glucose ($r = -0.21$, $P < 0.05$), after adjusted the age and BMI, the relationship is still significant ($r = -0.233$, $P < 0.05$). 4) If 5 kg increase in grip strength, the fasting blood glucose of diabetes men can decrease 1.165 mmol/L, and the prevalence of diabetes men will decrease 36.22%.

CONCLUSIONS: 1) The grip strength of diabetes men is related to fasting blood glucose; improving the grip strength can improve the blood glucose level of diabetes men and reduce the prevalence of diabetes. 2) Fasting blood glucose is negatively correlated with grip strength in men, which indicated that grip strength, a simple test index, could be as a predictor of diabetes in men.

Non-Exercise Estimated Cardiorespiratory Fitness Mediates the Relationship Between Comorbidities and Health-Related Quality of Life in Korean Older Adults

Inhwan Lee, Youngyun Jin, Jinkyung Cho, Kiuk Jang, Taehyung Shim, Yujin Lee, Haeryun Hong, Hyun-Sik Kang.
Sungkyunkwan University, Suwon, Korea, Republic of.
 (No relevant relationships reported)

PURPOSE: To investigate whether or not CRF mediates the relationship of comorbidities with health-related quality of life (HRQoL) in a representative sample of Korean older adults.

METHODS: Data from a total of 7,350 Korean older adults aged ≥ 60 years (58% women) who participated in the 2008-2011 Korean National Health and Nutritional Examination Survey were used in this analysis. HRQoL was assessed with the EuroQoL-5 dimensions (EQ-5D) index and EuroQoL visual analogue scale (EQ-VAS). Comorbidity was defined as physician-diagnosed chronic conditions. CRF was estimated with a non-exercise regression equation derived from sex, age, body mass index, and self-reported physical activity. The SPSS macro provided by Preacher and Hayes was used to test whether CRF mediated the relationship between comorbidity and HRQoL at statistical significance of $p=0.05$.

RESULTS: The total effect of the presence of comorbidities on HRQoL was significant (path c; $\beta=-3.091$, $p<0.001$). The presence of comorbidities was negatively related to eCRF in HRQoL model (path a: $\beta=-0.403$, $p<0.001$). As illustrated in Fig. 1, the effect of eCRF as a mediator on HRQoL was also significant (path b: $\beta=1.574$, $p<0.001$). The mediation analysis using the bootstrapping method (5,000 resamples) showed that eCRF mediated the relationship between the presence of comorbidities and HRQoL in Korean older adults (path $a \times b$: $\beta=-0.635$, 95% CI= $-0.746 \sim -0.524$, Sobel test result $Z=-11.029$, $p<0.001$). In addition, a direct effect of the presence of comorbidities on HRQoL was also significant (path c': $\beta=-2.456$, $p<0.001$).

CONCLUSIONS: The current findings suggest that CRF mediates the relationship between comorbidities and HRQoL in Korean older adults. Supported by the National Research Foundation funded by the Korean Government (NRF-2018R1D1A1B07048153 and NRF-2016R1A6A3A11932432).

Longitudinal Associations Between Handgrip Strength and Cardiovascular Biomarkers Among Rural Adults: A Project FRONTIER

Youngdeok Kim¹, Joaquin U. Gonzales¹, Hemachandra Reddy².
¹Texas Tech University, Lubbock, TX. ²Texas Tech University Health Sciences Center, Lubbock, TX.
 Email: youngdeok.kim@ttu.edu
 (No relevant relationships reported)

The decrease in muscular strength is one of the key symptoms of sarcopenia in older adults. A growing body of literature shows inverse associations of maximal isometric handgrip strength, a simple and non-invasive measure of skeletal muscle strength, with risk for cardiovascular disease (CVD)-related morbidity and mortality. However, the evidence is equivocal and there is little research examining the relationship of the concurrent longitudinal change in handgrip strength and CVD biomarkers. **PURPOSE:** This study examined longitudinal relationships between maximal handgrip strength and CVD biomarkers in older adults living in rural areas. **METHODS:** Data for this study came from Project FRONTIER (N=138; 59 \pm 12y, average 2.8 follow-up years), an ongoing epidemiological study monitoring the health of adults in rural northwest Texas, USA. Handgrip strength normalized to body mass index and CVD biomarkers including triglycerides, fasting blood glucose, high-density lipoprotein cholesterol (HDL-C), waist circumference (WC), and blood pressure (BP) were obtained. The association between strength and CVD biomarkers was examined at baseline, with strength as a predictor of the annual change in biomarkers, and in a parallel fashion between the annual change in strength and CVD biomarkers. **RESULTS:** After adjusting for demographic information, results for the total sample showed strength to associate with WC ($b=-13.6$, $P<0.001$) and diastolic BP ($b=6.1$, $P=.025$) at baseline. Strength was not found to predict the annual change in any biomarker.

Rather, the annual change in strength was positively associated with the change in HDL-C ($b=12.7$, $P=.003$). Interestingly, when participants were stratified into low and higher CVD risk groups, low risk adults who did not lose strength had greater annual increases in HDL-C than low risk adults that lost strength (2.3 vs. -1.4 mg/dl/year, $P<0.001$). Adults with higher CVD risk who did not lose strength had greater annual decreases in triglycerides ($P=.054$) and BP ($P\leq 0.05$) than higher risk adults that lost strength. **CONCLUSIONS:** Collectively, the present findings suggest that maintenance of muscle strength with aging is related to positive changes in CVD risk factors.

Reallocating Sedentary Time to Sleep or Physically Active Behaviors: Associations with BMI in College Students

Rachel M. Sanders, Michael V. Fedewa, Hayley V. MacDonald, Mark T. Richardson, John C. Higginbotham. *University of Alabama, Tuscaloosa, AL.*
 Email: rmsanders1@crimson.ua.edu
 (No relevant relationships reported)

Rachel M. Sanders, Michael V. Fedewa, Hayley V. MacDonald, Mark T. Richardson, John C. Higginbotham.
 The University of Alabama, Tuscaloosa, AL.

PURPOSE: More than 160 million US adults aged 20 years and older are overweight or obese. College students represent a subpopulation at a higher risk for excess weight gain, which is often influenced by daily health behaviors, such as time spent in sleep, sedentary time (SED), and physical activity (PA). **METHODS:** This study applied a novel isotemporal substitution model approach to investigate how reallocating time spent in SED activities to sleep and PA influenced body mass index (BMI). College students ($n=1,533$, mean age: 20.1 \pm 1.5 years, mean BMI: 24.4 \pm 4.7 kg/m²) provided self-reported height, weight, and time spent in sleep, SED, and PA data anonymously through an online survey. Sleep was assessed via the Pittsburgh Sleep Quality Index. PA and SED were assessed via the International Physical Activity Questionnaire. **RESULTS:** Sleep ($r=-0.070$) and moderate-to-vigorous intensity PA (MVPA) ($r=-0.068$) were weakly but significantly associated with BMI (all $P<0.05$). SED ($r=0.043$) and light-intensity PA (LPA) ($r=-0.014$) were not associated with BMI (all $P>0.05$). In both the single and partition models, sleep ($B=-0.223$ and $B=-0.238$, respectively) and MVPA ($B=-0.333$ and $B=-0.348$, respectively) were inversely associated with BMI (all $P<0.05$). Among the total sample, reallocating 60-min of SED behavior with sleep ($B=-0.277$, 95% CI: -0.461, -0.093) or MVPA ($B=-0.386$, 95% CI: -0.635, -0.147) was associated with a small but significant decrease in BMI. In a subgroup analysis of overweight and obese participants ($n=543$, mean BMI: 29.2 \pm 4.3 kg/m²), reallocating 60-min of SED behavior with sleep ($B=-0.384$, 95% CI: -0.667, -0.108) or MVPA ($B=-0.796$, 95% CI: -1.15, -0.436) was associated with a decrease in BMI, with the strongest association occurring when MVPA was substituted for SED. **CONCLUSION:** Reallocating 60-min of sedentary time with sleep or MVPA was associated with favorable effects on BMI among college students. Reductions in BMI were greater among overweight and obese individuals, especially when SED was replaced with MVPA.

Co-existence Of Physical Activity And Sedentary Behavior Among Children And Adolescents In Shanghai, China

Yang Liu, Si-Tong Chen, Jin-Tao Hong, Yan Tang, Zhen-Bo Cao, Jie Zhuang, Zheng Zhu, Pei-Jie Chen. *Shanghai University of Sport, Shanghai, China.* (Sponsor: Mark Tremblay, FACSM)
 Email: docliuyang@hotmail.com
 (No relevant relationships reported)

There is limited evidence for the prevalence of the co-existence of meeting physical activity (PA) and sedentary behavior (SED) guidelines, and their correlates among children and adolescents.

PURPOSE: To investigate the prevalence of PA and SED guidelines, and their co-existence, and to examine the associations between PA or SED, or both with gender and age among children and adolescents in Shanghai, China.

METHODS: Using a cross-sectional study design (conducted from September to December 2014), 50,090 children and adolescents (10-18 years old, 50.4% boys) were included in this study. A self-report questionnaire was used to measure participants' socio-demographic characteristics, PA, and SED. Descriptive statistics were used to describe sample characteristics, the prevalence of meeting PA and SED guidelines, and their co-existence. A Generalized Linear Model was conducted to explore the associations between the prevalence of PA and SED, and their co-existence with gender and age separately.

RESULTS: Of the children and adolescents studied, only 18.4% met the guidelines for PA, 25.5% met the guidelines for SED, and 5.7% met the guidelines for both. Boys

were more physically active (aOR = 1.43, 95% CI: 1.36-1.50), and girls were less sedentary (aOR = 1.29, 95%CI: 1.24-1.34). The prevalence of PA, SED, or both all declined as age increased ($p < 0.001$). Stratified analysis by gender revealed greater declining trends of meeting the PA or SED guidelines, or both in girls with increasing age (all $p < 0.005$).

CONCLUSIONS: Very few children and adolescents showed active lifestyles, and this was significantly related to age. Effective interventions aiming to promote PA and concurrently to limit SED among children and adolescents should be implemented as early as possible.

(No relevant relationships reported)

Ideal cardiovascular health (CVH) is a composite metric of seven health factors and behaviors. How cardiorespiratory fitness (CRF) is related to CVH is unclear. **Purpose:** To identify associations of CVH trajectories throughout adulthood with CRF in late-middle age. **Methods:** CVH components were measured in Black and White adults (N=2723, aged 18-30 yrs. at baseline) in the CARDIA Study at seven in-person examinations over 20 years. Graded treadmill tests at years 0 and 20 were used to measure CRF (minutes duration). CVH was determined by assigning each metric a score of 2 (ideal), 1 (intermediate), or 0 (poor) and summing the scores (range 0-14). Latent class modeling was used to identify subgroups of individuals with similar CVH trajectories from young adulthood to middle age. Multivariable logistic Poisson regression was used to assess the association between 20-year CVH trajectories and race- and sex-specific quartiles of CRF at year 20. **Results:** Five distinct CVH trajectories were identified: high (n=485), high-moderate (n=666), moderate (n=805), low-moderate (n=603), and low (n=164). Compared to the high trajectory group, odds ratios for low fitness (bottom quartile) at year 20 were 3.2 (95% CI: 1.9-5.2) for high-moderate, 6.6 (4.1-10.7) for moderate, 9.9 (6.1-16.4) for low-moderate, and 14.0 (8.2-24.0) for the low CVH trajectory groups after adjusting for race, sex, education, center, baseline CVH, and baseline CRF. **Conclusion:** Lower CVH trajectories throughout adulthood are associated with higher odds of low CRF in late-middle age.

Email: r.kawakami@aoni.waseda.jp

(No relevant relationships reported)

There is limited evidence exploring the association between cardiorespiratory fitness and the incidence of glaucoma. However, associations between other components of fitness and incident glaucoma are still unknown.

PURPOSE: To investigate the association between muscular and performance fitness and the incidence of glaucoma among Japanese workers in the Niigata Wellness Study. **METHODS:** Participants included 26,183 workers (18,129 men) [median (interquartile range) age 50 (44-56) years] free of glaucoma who underwent physical fitness tests in 2001. Muscular and performance fitness index was calculated using a summed z-score by sex and age from grip strength, vertical jump, single-leg balance with eyes closed, forward bending, and whole-body reaction time. The participants were divided into quartiles according to the muscular and performance fitness index and each physical fitness test. During 2002-2007, participants were followed for development of glaucoma, which was defined based on physician diagnosis. Hazard ratios (HRs) and 95% confidence intervals (95% CIs) for the incidence of glaucoma

were estimated using Cox proportional hazards models after adjusting for age, sex, body mass index, cigarette smoking, alcohol intake, hypertension, dyslipidemia, and diabetes.

RESULTS: During the follow-up, 292 participants developed glaucoma. The HRs (95% CIs) for developing glaucoma across quartiles of muscular and performance fitness index (lowest to highest) were 1.00 (reference), 0.99 (0.74-1.34), 0.64 (0.46-0.89), and 0.64 (0.46-0.89) (P for trend = 0.001). For vertical jump, the HRs (95% CIs) of developing glaucoma across quartiles (lowest to highest) were 1.00 (reference), 0.73 (0.54-0.99), 0.76 (0.56-1.03), and 0.54 (0.38-0.77) (P for trend < 0.001). For whole-body reaction time, the HRs (95% CIs) across quartiles (slowest to fastest) were 1.00 (reference), 0.77 (0.57-1.04), 0.65 (0.47-0.89), and 0.51 (0.37-0.72) (P for trend < 0.001). There were no associations between the other physical fitness tests and the incidence of glaucoma.

CONCLUSIONS: Muscular and performance physical fitness may be associated with lower risk of incident glaucoma. The precise mechanisms, which may include beneficial changes to intraocular pressure and antioxidant effects, are unknown and should be explored.

Effects of Arterial Stiffness Between Objectively
Measured Physical Activity and Domain-Specific
Cognition in Older Adults

Leidys Gutierrez-Martinez, Angelique Brellenthin, Duck-chul Lee, FACSM. Iowa State University, Ames, IA. (Sponsor: Duck-chul Lee, FACSM)

Email: leidysg@iastate.edu

(No relevant relationships reported)

PURPOSE: To examine the effects of arterial stiffness (AS) on the associations between objectively measured physical activity (PA) and domain specific cognitive functioning in older adults. **METHODS:** This cross-sectional analysis included baseline data from 415 older adults enrolled in the Physical Activity and Aging Study (PAAS). Cognitive functioning was measured by working memory using Digit Span Test and selective attention and processing speed using computerized Stroop Test. PA over 7 days was measured with Omron accelerometer-based pedometers and time engaged in light-, moderate-, and vigorous-intensity PA with FitBit Charge 2 wristbands. AS was derived from carotid-femoral pulse wave velocity (cfPWV; AtCor Sphygmocor XCEL). High AS was defined as cfPWV ≥ 10 m/s, which is an established risk factor of cardiovascular diseases. Multivariable linear regression was used to model the associations between PA, AS, and each cognitive-domain score. **RESULTS:** Participants were a mean age of 72 (± 6) years old and were well educated with 82% having a bachelor's degree or higher. Participants were also cognitively healthy (Mean Score of Mini-Mental State Examination 29.2 [± 1.29] out of 30). Participants with high AS (20.96%, n=87) accumulated fewer total steps per day ($p=0.01$), engaged in less light-intensity PA ($p<0.01$), and had worse precision on the Stroop test ($p < 0.01$) compared to those with low AS. There were no significant group differences for other cognitive test scores. Light-intensity PA was associated with better performance on the digit span forward among those with high AS ($p=0.01$), but not those with low AS, after adjusting for age, sex, education, diabetes, hypertension, and current smoking status ($p=0.01$) from linear regression. However, no significant results were found in other PA variables regardless of AS status. **CONCLUSIONS:** These results suggest a possible association of increased light-intensity PA with better working memory, particularly among older adults with high AS who are at higher risk of developing cardiovascular diseases.

Supported by unrestricted research grant by Biospace

Benefits of Behavior: Exercise Enhances Perception of
Physical Function Independent of Improvement Among
Diabetic Patients

Shabnam A. Behin¹, Cynthia Villalobos¹, Nathaniel J. Holmgren¹, Alexis C. King², J. Mark VanNess¹, Paul D. Vosti³, Courtney D. Jensen¹. ¹University of the Pacific, Stockton, CA. ²University of Illinois at Urbana-Champaign, Champaign, IL. ³St. Joseph's Medical Center, Stockton, CA.

Email: s_behin3@u.pacific.edu

(No relevant relationships reported)

In the U.S., approximately 1.5 million new cases of diabetes arise each year. Although these patients commonly report lower quality of life (QOL) than those without chronic illness, much of the literature remains focused on the physical benefits of weight loss and blood glucose management. To deliver individualized care, practitioners must also evaluate psychological health, including patient perceptions. **PURPOSE:** To determine factors that affect perception of physical function in diabetic patients. **METHODS:** 38 men and women with diabetes completed a 10-week, 20-session exercise program that included both aerobic and resistance training components. At baseline and follow-up, we measured body fat percent (BF%), body mass index (BMI), and performance on

six standard functional tests. Subjects also completed a self-report QOL questionnaire in which perception of physical function was assessed. Linear regressions tested the effect of functional performance (baseline capacity and 10-week change) on perception of function. **RESULTS:** Patients were 67.9±9.1 years of age, mean BMI was 31.5±6.1, and self-reported physical functioning ranged from 5.0 (very poor) to 100.0 (optimal); mean score was 54.7±26.8. At baseline, perception of physical functioning was not related to sex (p=0.751), age (p=0.405), BMI (p=0.610), or BF% (p=0.864). It was related to improved performances in six-minute walk (p<0.001), functional reach (p=0.046), timed up-and-go (p=0.080), chair stand (p=0.006), and sit-and-reach (p=0.024). At follow-up, perceptions of functioning improved by 13.8±24.5 points (25.7%; p=0.002) but there was no association with improvement in any anthropometric or functional tests: BMI (p=0.457), BF% (p=0.526), six-minute walk (p=0.131), functional reach (p=0.293), timed up-and-go (p=0.226), arm curl (p=0.966), chair stand (p=0.592), and sit-and-reach (p=0.970). **CONCLUSION:** 10 weeks of exercise improved perception of physical function by more than 25% in patients with diabetes. Improvement was unrelated to enhancement of any anthropometric or performance domain. Patients with diabetes seem to improve their perceptions via participation rather than progress. Thus, it may be important to incorporate the behavior of exercise into treatments, even if it fails to elicit physical improvement.

Sedentary Behavior and Physical Inactivity among College Students Affect Core Strength, Flexibility, and Posture

Amanda A. Price, Khadija Jackson, Darlene Lane, Kurt W. Kornatz. *Winston-Salem State University, Winston Salem, NC.*
 Email: priceaa@wssu.edu
 (No relevant relationships reported)

Sedentary behavior and physical inactivity have increased with advancements in technology. College students are high utilizers of computers and mobile devices, often for long periods with poor posture, putting them at risk for negative health consequences. **PURPOSE:** To evaluate the effects of sedentary behavior and physical activity participation on core strength, flexibility, and posture in college students. **METHODS:** College students (N=33; n=22 female, n=11 male) completed physical measures and questionnaires of sedentary behavior (SB) and physical activity (PA). Curl-up tests, sit and reach, and plumb line assessments indicated core strength, flexibility, and posture, respectively. Two-way ANOVAs were performed with participants categorized by their posture measures (rounded shoulders; RS, and forward head posture; FHP) on weekday and weekend SB, and PA per week. Associations were determined between SB, PA, core strength, flexibility, and body fat percentage by computing Pearson's correlation coefficients. **RESULTS:** There were no significant differences in SB and PA between postural groups. However, participants with RS and FHP spent an hour more per day being sedentary on average than those with RS alone (RS & FHP: SB weekday, M=3.74 hrs ± 0.79, SB weekend, M= 3.74 hrs ± 0.9; RS only: SB weekday, M= 2.62 hrs ± 0.36, SB weekend, M= 2.77 hrs ± 0.48). SB was associated with decreased flexibility (SB weekday: r=-0.47, p<0.01; SB weekend: r=-0.48, p<0.01), while physical inactivity was associated with higher body fat percentage (r=0.36, p=0.04) and decreased core strength (r=-0.51, p<0.01). Furthermore, college students who were sedentary during the week were also sedentary on the weekend (r=0.82, p<0.01). **CONCLUSIONS:** Sedentary behavior and physical inactivity were associated with negative changes in core strength, flexibility, posture, and body composition. Interventions targeting improvements in these behaviors among college students should include guidance on reducing screen time and limiting improper posture.

Effects Of BMI And VO_{2peak} On Cardiometabolic Health In Inactive, Overweight And Obese Adults

Joshua S. Beaumont, Benjamin E. Hook, Jane C. Hurley, Sonia Vega-Lopez, Marc A. Adams, Siddhartha S. Angadi, FACSM. *Arizona State University, Phoenix, AZ.* (Sponsor: Siddhartha Angadi, FACSM)
 Email: josh.beaumont@asu.edu
 (No relevant relationships reported)

PURPOSE: Body mass index (BMI) and cardiorespiratory fitness (CRF; VO_{2peak}) are significant predictors of cardiovascular health with high CRF being protective in the presence of high BMI. The current analysis aimed to determine relative contribution of overweight (OW) vs obese (OB) BMI while cross-stratifying with higher (HF) and lower (LF) CRF on blood lipids and glycemic markers. We hypothesized that an OW-HF group was more likely to have normal biomarkers compared to the OB-LF CRF group. **METHODS:** Insufficiently-active participants (N=89, male=22, female=67, BMI range=25-50) underwent the following assessments with the following cut-points for normal/abnormal: fasting glucose (GLU, ≤100 mg/dL), insulin (≤10 μU/mL), HOMA-IR (≤2.5), total-cholesterol (TC, ≤200 mg/dL), LDL-cholesterol (LDL-C, ≤130 mg/dL),

HDL-cholesterol (HDL-C, male ≥40 mg/dL, female ≥50 mg/dL), triglycerides (TG, ≤150 mg/dL). BMI was calculated from measured height and weight and VO_{2peak} was estimated using a modified Balke protocol. BMI was stratified by overweight/obese cut-offs; high/low fitness was stratified at ≥6-MET from VO_{2peak}. Groups were: OW-HF (n=28), OW-LF (n=36), OB-HF (n=5), OB-LF (n=20). Odds ratios (OR) for having normal biomarker concentrations were reported using multiple logistic regressions (α = 0.05).

RESULTS: Participants biomarker concentrations were (mean±SD): GLU: 92.0±8.8 mg/dL, insulin: 14.1±8.4 μU/mL, HOMA-IR: 3.3±2.2AU, TC: 173.5±29.5 mg/dL, LDL-C: 119.6±29.0 mg/dL, HDL-C: 48.9±13.6 mg/dL, and TG: 109.1±47.5 mg/dL. Measured height and weight confirmed BMI (33.4 ± 5.9 kg/m²). Estimated VO_{2peak} was 23.5± 3.8 mL/kg/min. Compared to OB-LF, the OW-HF group was more likely to have normal HOMA-IR (OR 1.6; 95%CI = 1.04, 2.4; p = .03) and desirable HDL-C concentrations (OR 1.9; 95%CI = 1.2, 2.8; p < .01). No significant cross-stratified differences for HDL-C or HOMA-IR were observed. There were no significant differences for the other five biomarkers.

CONCLUSIONS: In this sample of insufficiently-active overweight and obese individuals, when cross-stratifying by CRF and BMI, a combination of OW and HF factors were related to normal HOMA-IR and HDL levels.

887 Board #121 May 29 2:00 PM - 3:30 PM
Temporal Trends Of Physical Activity Among High School Students In The United States, 2011-2017

Seungho Ryu, Heontae Kim, Paul Loprinzi, Minsoo Kang, FACSM. *The University of Mississippi, Oxford, MS.* (Sponsor: Minsoo Kang, FACSM)
 (No relevant relationships reported)

BACKGROUND: Physical activity has long been considered an important component of a healthy lifestyle. The habit of physical activity as a childhood affects adults as well. Therefore, it is important to investigate the trend of physical activity among adolescents. **PURPOSE:** The purpose of this study was to evaluate temporal trends in physical activity among US high school students. Physical activity trends were evaluated by the whole group and the various subgroups, including different gender, race-ethnicity, and body mass index (BMI) levels. **METHODS:** Data from a total of 52,288 high school students who participated in the Youth Risk Behavior Survey (YRBS) from 2011 to 2017 were analyzed for this study. Physical activity was measured using a question of YRBS; during the past 7 days, on how many days were you physically active for a total of at least 60 minutes per day? BMI was categorized into four levels: (1) Obese (i.e., BMI ≥ 95th percentile by age and gender); (2) Overweight (i.e., 85th percentile ≤ BMI < 95th percentile by age and gender); (3) Normal weight (i.e., 5th ≤ percentile BMI < 85th percentile by age and gender); (4) Underweight (i.e., BMI < 5th percentile by age and gender). SAS (v 9.3) and Stata (v. 12) were used to examine the temporal trends of physical activity among US high school students. Tests for trend over the years were performed using linear and quadratic-specific orthogonal polynomial coefficients. **RESULTS:** For the overall sample, there were no linear and quadratic trends found in the weighted mean of number of days per week children engaged in at least 60 min/d of physical activity (linear: β = .05, p = .29; quadratic: β = .08, p = .28). Further, for nearly all subgroups, linear and quadratic trends were not observed. However, there was a linear trend observed by BMI; only students who are obese increased their physical activity from 2011 to 2017 (β = .15, p = .03). **CONCLUSIONS:** Despite the increased emphasis on physical activity over recent years, engagement in physical activity did not increase. Continuous monitoring of surveillance data is necessary to provide information on the allocation, development, implementation, and evaluation of community-based physical activity programs for adolescents.

Temporal Associations of Nocturnal Sleep Duration with Physical Activity and Sedentary Time in Preschool Children

Wendy Y. Huang¹, Ka Ho Lai¹, Ruirui Xing¹, Stephen H.S. Wong, FACSM². ¹Hong Kong Baptist University, Hong Kong, China. ²The Chinese University of Hong Kong, Hong Kong, China.
 Email: wendyhuang@hkbu.edu.hk
 (No relevant relationships reported)

PURPOSE: To examine the associations between nocturnal sleep duration and physical activity (PA), sitting time (ST) and sit-to-stand transitions the following days among young children in Hong Kong. **METHODS:** 114 young children (71 boys) aged 3-6 years were recruited from 3 kindergartens. They were instructed to wear an activPAL™ for 24-hour over 7 consecutive days to determine PA, ST, sleep duration, and sit-to-stand transitions. For each participant, 7 pairs of sleep → PA/ST/transitions were generated, representing unique rows of sleep duration the preceding evening (e.g., Monday) and PA/ST/transitions the following day (e.g., Tuesday). To account for total waking hours, the

WEDNESDAY, MAY 29, 2019

outcomes were presented in relative values (e.g., PA/waking hour). Linear mixed models were performed to determine the associations of nighttime sleep duration with PA, ST, and sit-to-stand transitions the following days, adjusting for age, sex, body weight status, parental educational attainment, and number of wear days. The repeated outcomes of sleep duration and activity patterns the following day nested within participants were treated as random effect.

RESULTS: Seventy children provided valid data of PA, ST, and sleep. On average, the children accumulated 2.37 hours of PA a day (SD 0.45) and slept for 9.72 hours per night (SD 0.97). Sleep duration in the preceding night was positively associated with daytime PA ($b = 0.007$; 95% CI, 0.002 to 0.012; $p = 0.011$) and sit-to-stand transitions ($b = 0.573$; 95% CI, 0.336 to 0.810; $p < 0.001$), while was negatively associated with ST ($b = -0.016$; 95% CI, -0.028 to -0.004 ; $p = 0.008$) the following day.

CONCLUSIONS: Longer nocturnal sleep duration was associated with more PA, frequent posture transitions, and less sitting time in the following day for preschool children. More work is needed to investigate how sleep parameters other than duration affect daytime activity behaviors.

This study was supported by Health and Medical Research Fund Research Fellowship Scheme from Food and Health Bureau, the Government of the Hong Kong Special Administrative Region of the PRC (#02160127).

An Extended Twin-pedigree Study Of Voluntary Exercise Behavior In The Netherlands

Eco J.C. de Geus, Quinta Helmer, Dorret Boomsma, Matthijs D. van der Zee. *Vrije Universiteit Amsterdam, Amsterdam, Netherlands.*

(No relevant relationships reported)

PURPOSE: In the current research we investigated the heritability of voluntary regular exercise behavior using extended pedigrees, this allowed us to estimate the contribution of shared household effects in the presence of non-additive genetic effects, in contrast to much of the earlier work based on twin data. In addition, rather than assessing the total volume of exercise behavior as a unitary construct we have separated this across three domains: time spent on (1) any voluntary exercise and sports, (2) solitary exercise and sports, or (3) team-based exercise and sports.

METHODS: For the participants in the Netherlands Twin Register (NTR) we constructed the extended pedigrees which specify all relations among nuclear and larger twin families in the register. A total of 253,015 subjects from 58,645 families were linked to each other, to the degree that we had information on the relations among participants. For 56,161 adolescent and adult NTR participants in 20,897 families data were available on harmonized scores for total weekly MET hours, and the six domains. We analyzed these data in the Mendel software package to estimate the contributions of additive and non-additive genetic factors.

RESULTS: The estimated broad-sense heritability of total weekly MET hours spent on (1) any voluntary exercise and sports was 41% (26% additive genetic effects (A), and 15% non-additive genetic effects (D)). A shared household effect explained 24% and unique environmental factors explained the remaining 35% of the variance. For weekly MET hours spent on team-based exercise non-additive (dominance) genetic factors (28%) were a larger contributor compared to additive genetic factors (19%), while in solitary exercise these results were reversed (12% and 22% respectively).

CONCLUSIONS: In concordance with previous literature, our results suggest that exercise is a heritable trait, however our varying results in the various domains of exercise suggest that, at least in behavioral genetics, splitting exercise over domains rather than treating it as a unitary construct may be preferable.

Diurnal and Circannual Variation in Body Temperature: Implications for Heat Illness Protocols

Nathaniel J. Holmgren¹, J. Mark VanNess¹, Lewis E. Jacobson², Jonathan M. Saxe², Courtney D. Jensen¹. ¹University of the Pacific, Stockton, CA. ²St. Vincent's Hospital, Indianapolis, IN. Email: n_holmgren@u.pacific.edu

(No relevant relationships reported)

As warm-season temperatures continue to rise, the incidence of heat illness is likely to increase. Although preventive protocols currently consider environmental risk factors, there may be reason to emphasize

diurnal and seasonal influences. Data supporting seasonal fluctuation in body temperature are abundant in animals but limited in humans. **PURPOSE:** To examine circannual and diurnal patterns of body temperature in a patient population.

METHODS: We analyzed 2,184 men and women admitted to a major hospital in Indiana over 3 years. Demographic, anthropometric, and cardiometabolic variables were collected along with season, month, and time of admission. The National Centers for Environmental Information's National Climate Report was used to generate month-by-month ambient temperature data; there were clearly defined cold (October through April) and warm (May through September) periods. All patients received oral temperatures. We used t-tests and ANOVAs to detect differences in

body temperature by time conditions; we used linear regression to test the effect of chronological variables on body temperature, holding all measured confounders constant. **RESULTS:** Mean body temperature was $98.16 \pm 0.73^\circ\text{F}$. The warmest period of the day was 6:00 to 10:00pm (98.27°F). The coldest period was 2:00 to 6:00am (98.05°F ; $p < 0.001$). ANOVA revealed differences in body temperature by month ($F = 2.525$; $p = 0.004$) and by season ($F = 3.656$; $p = 0.012$). The strongest comparison was the cold vs. warm period ($T = -3.835$; $p < 0.001$). Patients admitted during the cold period ($N = 1,139$) had a temperature of $98.10 \pm 0.81^\circ\text{F}$ while patients admitted during the warm period ($N = 1,045$) had a temperature of $98.22 \pm 0.63^\circ\text{F}$ ($p < 0.001$). Lower temperatures were also found among patients ≥ 65 years ($p < 0.001$) and those with a positive blood alcohol test ($p = 0.004$). Holding all measured confounders constant, being admitted during the warmer months predicted an elevation in body temperature of 0.13°F ($p < 0.001$). **CONCLUSION:** These findings support diurnal and circannual variations in humans. Coaches and athletic trainers may consider this when designing and monitoring practice conditions. Athletes will likely require closer observation along with updated prevention protocols when practicing outdoors to minimize the risk of a heat-related event.

891 Board #125 May 29 2:00 PM - 3:30 PM

Compliance with Physical Activity Guidelines and Associations with Physical Literacy Among Future Physical Educators

Katherine E. Spring, Megan E. Holmes, Yonjoong Ryuh, Chih Chia Chen. *Mississippi State University, Starkville, MS.*

(No relevant relationships reported)

Purpose: To examine the relationship between pre-professional physical educators meeting the U.S. Physical Activity Guidelines and steps per week and physical literacy.

Methods: Twenty-five physical education teacher education (PETE) undergraduate majors (19 males, 6 females, aged 19-24 years) participated in assessments of Physical Literacy using the Canadian Assessment of Physical Literacy and wore GTX3+ accelerometers on their waist for a week. Freedman 1998 cut-points were used for determining moderate-to-vigorous physical activity (MVPA). Descriptive statistics were calculated for all variables. Correlations were calculated to examine the relationships between measured MVPA, measured steps, Physical Literacy, self-reported PA and sedentary time, and physical competence. **Results:** 16% were compliant with MVPA guidelines, 4% were compliant with both MVPA and 10,000 steps recommendations, 56% met MVPA but were considered low active steps, and 24% did not meet any recommendations. Participants' physical literacy considered below that of a proficient 12-year old. Significant relationships existed between self-reported PA and Physical Competence ($r=0.40$, $p \leq .05$), and MVPA and Physical Literacy ($r=0.42$, $p \leq .05$); however, no other relationships existed. **Conclusions:** These findings suggest that while PETE students may meet the minimum guidelines for physical activity, more work needs to be done to address their Physical Literacy.

892 Board #126 May 29 2:00 PM - 3:30 PM

Association Between Walking and Sunburn: A Potential Trade-Off Between Cancer Prevention and Risk Factors

Calvin P. Tribby, David Berrigan, Frank M. Perna. *National Cancer Institute, Bethesda, MD.*

Email: calvin.tribby@nih.gov

(No relevant relationships reported)

The association between higher physical activity levels and increased sunburn prevalence is a health behavior trade-off between the health benefits of physical activity and potential increased risk of skin cancer. Walking is a common form of physical activity accessible to most people yet has an unknown association with sunburn. This is important because risk of melanoma doubles with five or more sunburns. **PURPOSE:** To examine whether sunburn prevalence varied by walking behavior.

METHODS: This study used the 2015 National Health Interview Survey of adults ($N=26,632$), age ≥ 18 years. We defined four exclusive categories of weekly walking: 1) those who reported no walking or less than ten minutes total; 2) only transportation walking; 3) only leisure walking; and, 4) both categories of walking. It was necessary to disaggregate walking into categories, as there are different behaviors and contexts associated with leisure and transportation walking. We estimated the adjusted prevalence of sunburn (one or more in the past 12 months) by walking category and separately for walking duration; we stratified by gender and sun-sensitivity (any reported skin burn when not protected from the sun for one hour).

RESULTS: The adjusted sunburn prevalence was not different between walking categories for women, but it was for men. Specifically, prevalence was lower for men who reported not walking, 34.1% (95% CI: 32.2%-36.1%) compared to 38.8% (95% CI: 36.5%-41.2%) who walked for both purposes ($P=0.003$). Among sun-sensitive individuals, the adjusted sunburn prevalence was not different by walking category for women ($P=0.28$) or men ($P=0.21$). Regardless of sun-sensitivity status, weekly minutes of transportation or leisure walking was not significantly associated with sunburn prevalence for women or men.

CONCLUSIONS: The results suggest that walking, unlike leisure-time physical activity, may not be generally associated with sunburn, except for the higher sunburn prevalence for men who walked for both leisure and transportation purposes. Research is needed into public health messages that encourage walking for physical activity and advise sun protection, with special attention to men.

893 Board #127 May 29 2:00 PM - 3:30 PM

Relationship between Neighborhood Environment and Physical Activity in Freshmen from Tsinghua University in Beijing, China

Jiali Cheng, Hongjun Yu, Chengang Zhang, *Tsinghua University, Beijing, China.* (Sponsor: James Fleming Sallis, Jr., FACSM)
Email: cjl18@mails.tsinghua.edu.cn
(No relevant relationships reported)

Neighborhood walking environment is an environmental issue affecting human health-related behaviors in China and worldwide. Few studies so far have researched the relationship between neighborhood environment walkability and physical activity among freshmen in China.

PURPOSE: We examined the relationship between neighborhood environment walkability and physical activity. **METHODS:** Neighborhood environment was measured using the Neighborhood Environment Walkability Scale for Youth (NEWS-Y). Physical activity data by the Global Physical Activity Questionnaire (GPAQ) were collected. The data were analyzed by Stata14.0. **RESULTS:** We conducted a cross-sectional questionnaire study on 3,411 freshmen from Tsinghua University in Beijing, China. Of the total sample size, 2,318 were male (67.96%), and 1,093 were female (32.04%). One of seven environmental attributes were significantly related to moderate and vigorous physical activity (MVPA) (MET-minutes/week) in neighborhood aesthetics (168.64 [44.12-293.16]; $p=0.008$). One of seven environmental attributes were significantly related to vigorous physical activity (VPA) (MET-minutes/week): neighborhood aesthetics (151.57 [45.08-258.07]; $p=0.005$). Two of seven environmental attributes were significantly related to moderate physical activity (MPA) (MET-minutes/week): walking facilities (75.56 [5.36-145.76]; $p=0.035$) and neighborhood aesthetics (68.07 [3.51-132.62]; $p=0.039$). One of seven environmental attributes were significantly related to sitting time (minutes/week) in walking facilities (-18.64 [-32.57 - -4.71]; $p<0.001$). **CONCLUSIONS:** A positive correlation between neighborhood environment walkability, especially neighborhood aesthetics and walking facilities, and physical activity was found.

Factors Leading to Discrepancies in Accumulated Physical Activity During School Hours in Elementary School Students

Robert Booker¹, Riley Galloway², Megan E. Holmes¹.
¹Mississippi State University, Mississippi State, MS. ²Missouri State University, Springfield, MO.
(No relevant relationships reported)

Inconsistently implemented state physical activity (PA) mandates lack oversight and regulation. **PURPOSE:** This study quantifies sex and racial differences of in-school PA among fourth grade students. **METHODS:** Students ($N=148$) from eight rural, low socioeconomic schools wore accelerometers during school for one week. Teachers recorded data related to PA setting and duration. **RESULTS:** Of the 148 students, only 12 met the 150 minutes of in-school moderate-to-vigorous physical activity (MVPA) per week, in accordance with the state's mandate. Students spent a significant percentage of the total school day sedentary (75.7±5.7%, mean±SD). Males spent significantly more of daily recess engaged in MVPA than females (24.9% and 18%, respectively). White students spent a higher percentage of recess in MVPA than Non-White students (29.2±13.1% and 21.1±13.1%, respectively). Schools with a certified physical education instructor ($n=2$) participated in significantly more minutes of MVPA during recess (9.1±7.3) and physical education class (3.1±2.0) than other schools (5.2±2.7 and 2.5±1.8, respectively). **CONCLUSIONS:** Very few students achieved the state-mandated 30 minutes of MVPA per day during school hours; however, schools with certified physical educators achieved more MVPA throughout the school day. Recess PA contributed considerably to this discrepancy, highlighting the importance of encouraging active play and other types of PA during breaks in the school day.

Title: Association of Sleep and Physical Activity with Cardiometabolic Risk in Older Women: A Compositional Analysis

Jowon Lee¹, Maura E. Walker¹, Karen A. Matthews², Lewis H. Kuller², Nalini Ranjit³, Kelley P. Gabriel, FACSM³. ¹Boston University, Boston, MA. ²University of Pittsburgh, Pittsburgh, PA. ³University of Texas Health Science Center, Austin, TX.
(Sponsor: Kelley Pettee Gabriel, FACSM)
Email: lee8690@bu.edu
(No relevant relationships reported)

PURPOSE: To investigate the effect of daily (24-hour) activity behaviors (sleep, sedentary, light and moderate physical activity [LPA and MVPA]) on cardiometabolic risk among older women, using a compositional data analysis approach.

METHODS: Participants from the Healthy Women Study 2010-11 follow-up visit ($N=145$, aged 73.3±1.7 years, white=91.5%) wore an ActiGraph GT1M accelerometer (hip) and an Actiwatch-2 (wrist) for 7 consecutive days, to objectively monitor physical activity and sleep. The estimated duration of sleep, sedentary, LPA, and MVPA, were averaged across valid wear days (≥ 4 days of ≥ 10 hours). For each participant a composite cardiometabolic risk score was calculated by transforming metabolic syndrome (MetS) components including waist circumference, blood pressure, fasting triglyceride, fasting high-density lipoprotein (HDL), and fast blood glucose into z-scores and summing z-scores to create a continuous MetS z-score. A 24-hour time composition of activity behaviors was derived and isometric log-ratio multivariable linear regression was used to predict MetS z-score. Additional 24-hour compositions were created where a fixed duration of time was reallocated from one activity behavior to another (e.g., sedentary to LPA), while time spent in the remaining activities was unchanged. Reallocation was defined as 15 minutes for sleep, sedentary and LPA, behaviors; and 5 minutes for MVPA. **RESULTS:** Participants had a mean MetS z-score -0.01 ± 3.22 . Mean daily time (minutes) spent in activity behaviors was 403, 749, 282, and 7; for sleep, sedentary, LPA and MVPA, respectively. The 24-hour composition was a statistically significant correlate of MetS z-score ($P < 0.001$). Reallocation of 5 minutes from MVPA to sleep, sedentary, and LPA, increased the predicted MetS z-score by 1.07, 1.07, and 1.06, respectively. The predicted MetS z-score was reduced by 0.88, 0.91, and 0.85 when 15 minutes of sleep, sedentary, or LPA time was replaced with MVPA. Reallocation 15 min of sedentary time to LPA reduced the predicted MetS z-score by 0.05. **CONCLUSIONS:** This cross-sectional study demonstrates the beneficial effect of MVPA on cardiometabolic risk among older women. The exchange of sedentary time for LPA may also reduce cardiometabolic risk in older women.

Screen and Non-screen Sedentary Time in Older Adults Living in a Retirement Community

Ryan Ziebart, Joshua Pak, Karisa Fuerniss, David Benner Jr., Emerson Sebastião. *Northern Illinois University, DeKalb, IL.*
Email: Z1787586@students.niu.edu
(No relevant relationships reported)

PURPOSE: This study aimed to describe the magnitude and composition of screen (SST) and non-screen sedentary time (NSST) in older adults living in a retirement community (RC); documenting gender, mobility aid, chronic disease and exercise participation in screen and non-screen sedentary time variation. **METHODS:** One hundred subjects (84.7 ± 6.3 years; 70% female) were recruited from a RC located in the Midwest area of United States. Sedentary behavior (SB) was measured using a questionnaire specifically developed for the older adult population. The questionnaire comprises of 10 questions related to time spent in different activities (eight related to NSST and two related to SST). Based on the questionnaire, three metrics were calculated and expressed as hours per day: a) NSST, given by the sum of time spent in the eight out of 10 possible activities; b) SST, given by the sum of time spent in two out of 10 activities and; c) total sedentary time (TST), given by the sum of the time spent in NSST and SST. **RESULTS:** The findings indicated that overall older adults living in a RC spend on average 10 hours per day in sedentary activities; being 6.5 in NSST and 3.5 hours in SST. Older males reported spending significant higher SST compared to their older female counterparts (4.5 vs. 3.1; $P<.05$). Those not making use of a mobility aid reported significant higher TST (10.2 vs. 9.3) and NSST (6.8 vs. 5.6) compared to those using a mobility aid ($P<.05$). Older adults presenting with ≥ 3 chronic diseases reported significant higher TST (10.6 vs. 9.5) and NSST (6.9 vs. 5.5) compared to those with less than 3 chronic diseases ($P<.05$). No differences were observed for TST, NSST and SST between older adults engaged and not engaged in a regular exercise. The findings further indicated that activities such as TV watching and reading comprise nearly 45% of participants' TST and computer use accounted for about 12%. **CONCLUSION:** The findings indicated that older adults living in a RC spend a large number of hours in sedentary activities and that 65% of this time is

spend in NSST and 35% in SST. The findings further suggest that significant gender, mobility aid, and chronic disease variations exist in terms of TST, NSST and SST in this population. Supported by Dean's Research Grant COE-NIU (2017-2018)

 (No relevant relationships reported)

Metabolic syndrome (MetS) risk factors, adiposity and physical activity (PA) levels have a multifactorial aetiology, comprising genetic and non-genetic factors. Notwithstanding the consistent findings about their aetiology, biological and behavioural traits do not explain the total variation and the increase of metabolic disorders and physical inactivity over the past decade. Additionally, links may be identified between built and natural environments, namely PA environments, on adiposity, MetS and PA phenotypes, as well as how they may affect different behaviours, especially within families. **PURPOSE:** The purpose of this study was to estimate the magnitude of genetic and environmental factors on adiposity, MetS risk factors and PA levels, and to investigate the role of PA environments on these traits. **METHODS:** The sample comprised 259 nuclear families (781 individuals) from a rural city of Portugal. All PA facilities' locations and families' home addresses were geocoded and Euclidian distances were calculated. Percentage of total body fat was estimated by bioelectrical impedance. Systolic and diastolic blood pressure, waist circumference, fasting glucose, triglycerides and total cholesterol were measured. PA was estimated by the Baecke questionnaire. Quantitative genetic models were used and computations performed in SOLAR software.

RESULTS: Genetic and shared environmental factors explained 22% and 38% of PA and body fat total variance, respectively. MetS risk factors were moderate-to-highly heritable, ranging from 26% to 73%. Spatially structured data of PA environments had significant effects on MetS risk factors, adiposity and PA phenotypes ($p < 0.05$), except for waist circumference, contributing to low adiposity levels ($p < 0.05$), increases in PA ($p < 0.05$), and being protective against the development of MetS risk factors ($p < 0.05$). **CONCLUSIONS:** Taken together, these results have important implications for the design of intervention programs, which need to consider the familial context and PA environments to promote physically active lifestyles and their positive effects on health.

Objectively-Measured PA and Sedentary Behavior Across The Lifespan Of Individuals With and Without Metabolic Syndrome

Lundon C. Burton, Eduardo Bustamante, FACSM. *University of Illinois at Chicago, Chicago, IL*
 Email: lburto2@uic.edu
 (No relevant relationships reported)

PURPOSE: To investigate whether PA and sedentary behavior (SB) differ across the lifespan of individuals with and without metabolic syndrome (MetS). Few studies investigating lifestyle behaviors in this population have utilized objective measures of PA or included youth. **METHODS:** Participants from NHANES 2003-2006 (ages 6-85) were divided into 5 age categories: Childhood (≤ 12 years) ($N=6,672$), adolescence (13-19 years) ($N=5,938$), early adulthood (20-40 years) ($N=5,537$), middle adulthood (40-64 years) ($N=5,176$), and late adulthood (≥ 65) ($N=3,730$). Classification of MetS was based upon waist circumference (men $> 40''$, women $> 35''$), triglycerides (≥ 150 mg/dl), HDL cholesterol (men < 40 mg/dl, women < 50 mg/dl), plasma glucose (≥ 110 mg/dl or medicated), and blood pressure (≥ 130 mmHg or medicated). Participants ($N=27,053$) wore Actigraph AM-7164 accelerometers on the right hip for 7 days and were included in analyses if they wore the device for ≥ 10 hrs per day for 4 days. Independent samples t-tests were conducted between each group at each stage on counts per min (cpm), sedentary minutes, and minutes of light PA and MVPA. **RESULTS:** In this sample, MetS prevalence was 0% in children, 1% in adolescents, 4% in early adulthood, 13% in middle adulthood, and 17% in late adulthood. Pairwise comparisons of accelerometer values revealed no significant differences between groups in adolescence or early adulthood (all $p > .05$). However, groups diverged sharply in middle adulthood, where adults with MetS evidenced lower cpm ($M=316 \pm 150$ vs. $M=249 \pm 127$), higher minutes of sedentary behavior ($M=481 \pm 120$ vs.

$M=504 \pm 121$), and fewer minutes of light PA ($M=259 \pm 70$ vs. $M=241 \pm 71$) and MVPA ($M=22 \pm 23$ vs. $M=13 \pm 18$) (all $p < .01$). Differences remained in late adulthood for cpm ($t=3.473$, $p=.001$) and minutes of light PA ($t=3.004$, $p=.003$) only. **CONCLUSION:** No differences were identified during the first 40 years of life, suggesting that MetS at these ages may be less behaviorally based. However, beginning in middle adulthood there was a divergence in accelerometer-measured behaviors, which coincided with a spike in prevalence in this age group. Middle adulthood is characterized by increasing responsibility through roles as caregivers and bread winners and may be an appropriate target for PA interventions to prevent chronic disease.

Vitamin D Status And Muscular Strength In Youth: NHANES 2011-2014

Nicholas M. Pilli, Jaime N. Thomas, Jennifer L. Barnes, Kelly R. Laurson. *Illinois State University, Normal, IL*. (Sponsor: Dale Brown, FACSM)
 (No relevant relationships reported)

Vitamin D is a critical component of musculoskeletal health in youth. While several studies have established the importance of vitamin D for bone development, research specific to muscular strength is lacking. **PURPOSE:** To investigate the association between serum 25-hydroxyvitamin D (25OHD) status and muscular strength in a nationally-representative sample of U.S. youth. **METHODS:** The analysis included 1,706 boys and 1,644 girls from the National Health and Nutrition Examination Survey 2011-2014 between 6-18.9 years. Status of 25OHD was defined as: severe/deficient ≤ 37.5 nmol/L, insufficient > 37.5 to < 50 nmol/L, and sufficient ≥ 50 nmol/L. Muscular strength was assessed via handgrip and expressed as age- and sex-specific percentiles of relative strength (kg strength/kg body mass). General linear models were used to quantify differences in strength percentile by 25OHD status. Logistic models were used to compare the odds of low strength ($< 25^{\text{th}}$ percentile) between 25OHD groups. All analyses were stratified by sex while controlling for age, calcium intake, socio-economic status, race/ethnicity, physical activity, body mass index, and season of testing. **RESULTS:** Boys with sufficient 25OHD had a higher mean (SE) relative strength percentile than those in the insufficient or severe/deficient groups, 49.1 (1.8), 43.5 (2.2), and 40.7 (2.9), respectively ($p < 0.05$). Relative strength percentile was also highest for girls with sufficient 25OHD compared to the insufficient or severe/deficient groups, 51.8 (1.9), 45.6 (2.4), and 41.1 (3.3), respectively ($p < 0.05$). Further, boys in the insufficient group had a higher odds of low strength than 25OHD sufficient boys (odds ratio, OR = 1.8, 95%CI 1.1 to 3.0). Both girls in the insufficient and severe/deficient groups were more likely to have low strength compared to those with sufficient 25OHD, OR = 1.8 (1.1 to 2.8) and 3.3 (1.8 to 5.9), respectively. **CONCLUSIONS:** Youth with less than sufficient levels of 25OHD were consistently found to have lower relative handgrip strength and were more likely to have strength values below the 25th percentile. These findings underscore the importance of vitamin D for muscular strength in youth and future prospective studies to elucidate the mechanisms would be of benefit.

Is Seasonal Affective Disorder A Symptom Of A Larger Collection Of Sedentary And Obesity-related Disorders?

Stephanie Ta¹, Nathaniel J. Holmgren¹, J. Mark VanNess¹, Alexis C. King², Lewis E. Jacobson³, Jonathan M. Saxe³, Courtney D. Jensen¹. ¹University of the Pacific, Stockton, CA. ²University of Illinois at Urbana-Champaign, Champaign, IL. ³St. Vincent Hospital, Indianapolis, IN.
 Email: s_ta2@u.pacific.edu
 (No relevant relationships reported)

Seasonal affective disorder (SAD) is a subtype of major depressive disorder (MDD) that occurs during cold and overcast months. Physical activity (PA) is known to counteract depressive symptoms; however, the relationship between seasonal changes in PA and MDD is largely unexplored. Physical inactivity and consequent weight gain may contribute to a host of cardiometabolic and cerebral complications, with SAD being one diagnostic feature. **PURPOSE:** To evaluate seasonal differences in MDD among obese and non-obese patients in conjunction with cardiovascular, metabolic, and cerebral diagnoses. **METHODS:** We analyzed 2,306 consecutively-admitted patients at a Midwestern hospital over 3 years. Mean environmental temperature of the hospital's city during each of the 36 months was computed. Patients were assessed for obesity, MDD, diabetes, hypertension, peripheral vascular disease, congestive heart failure, cerebrovascular accidents, and dementia. Logistic regressions tested the effects of season and temperature on all diagnoses. **RESULTS:** Patients were 52.1 \pm 22.4 years old, 16.3% were obese, 1.1% had MDD, 14.3% had diabetes, 36.8% had hypertension, 0.7% had peripheral vascular disease, 4.4% had congestive heart failure, 3.6% had a cerebrovascular accident, and 4.6% had dementia. Between March 1 and June 30, MDD incidence was 532.8% higher than it was during all other months ($p < 0.001$). These were not the coldest months (mean temperature was 5.9°F higher during this

period; $p < 0.001$), but it was the period of greatest obesity (33.3% higher incidence; $p = 0.003$). Likewise, colder temperature was a poor predictor of MDD ($p = 0.465$), but predicted elevated rates of obesity ($p < 0.001$), diabetes ($p = 0.034$), hypertension ($p < 0.001$), congestive heart failure ($p = 0.013$), peripheral vascular disease ($p = 0.058$), cerebrovascular accidents ($p = 0.003$), and dementia ($p = 0.001$). **CONCLUSION:** MDD diagnosis was highest at the end of the cold season, when obesity was at its peak; in turn, the likelihood of numerous obesity-related diagnoses was increased. This suggests a possibility that seasonal incidence of depression is not exclusively caused by diminished exposure to sunlight. Perhaps a colder environment limits engagement in PA; in turn, SAD is one component of a larger picture, which includes dysfunction of numerous systems.

901 Board #135 May 29 2:00 PM - 3:30 PM
Muscular Strength and Whole-Body Bone Mineral Density in Older Adults With and Without Artificial Joints

Hyunsoo Kim, *Iowa State Univrsity, Ames, IA.* (Sponsor: Duch-chul Lee, FACSMD)
 Email: hskim@iastate.edu

(No relevant relationships reported)

Purpose Artificial joints (AJ) are prevalent in older adults, yet commonly ignored in bone related studies. We examined the effect of AJ on the association between muscular strength (MS) and whole-body bone mineral density (BMD) in older adults. **Methods** This cross-sectional study included 303 older adults (58% women) ≥ 65 years old from the Physical Activity and Aging Study (PAAS). MS (peak torque at 60°/sec) was assessed by leg extension (LE), leg flexion (LF), elbow extension (EE), and elbow flexion (EF) on the dominant limbs using isokinetic dynamometry (Biodex). Whole-body BMD (t-score) was assessed by dual-energy X-ray absorptiometry (DXA). Low BMD was defined as t-score < -1.0 . AJ status was identified via medical history questionnaire. Linear and logistic regression were conducted in stratified samples of AJ status (yes/no) and sex including MS, age, hormone therapy (women only), smoking, cardiorespiratory fitness (400-meter walk test), physical activity, and body mass index (BMI). Odds ratios (ORs) of low BMD by sex-specific tertiles of MS were calculated in each stratum.

Results Forty-five (15%) older adults had AJ. T-scores were higher in individuals with AJ compared with individuals without AJ in both men (-0.6 vs. 1.9) and women (-1.4 vs. 0.6) (both $p < 0.01$) since most materials in AJ (e.g., metals) are considered as bone tissues by DXA. LF, EE, and EF were positively associated with BMD in men without AJ (all $p < 0.05$), but not in men with AJ after adjusting for the possible confounders including BMI. There were no associations between MS variables and BMD in women, regardless of AJ status (all $p > 0.05$). Compared with the lowest (weakest) third of LF, ORs (95% confidence intervals) of low BMD for the middle and upper thirds of LF were 0.40 (0.15-1.08) and 0.27 (0.09-0.85) among men without AJ after adjusting for the possible confounders without BMI. We found similar results in LE. However, no associations were observed after further adjustment for BMI, possibly due to the confounding effects of BMI on both MS and BMD.

Conclusion Higher MS appears to be associated with higher BMD and lower odds of having low BMD in men without AJ, but not in men with AJ. These results indicate that AJ status should be considered in studies of muscular strength and bone health in older men.

Changes in Psychological State Measures After Green versus Suburban Walking Exercise: A Pilot Crossover Study

Junia N. Brito¹, Zachary C. Pope¹, Nathan R. Mitchell¹, Ingrid E. Schneider¹, Teresa H. Horton², Mark A. Pereira¹. ¹University of Minnesota, Minneapolis, MN. ²Northwestern University, Evanston, IL. (Sponsor: Matthew Buman, FACSM)
 Email: nogue013@umn.edu

(No relevant relationships reported)

PURPOSE: Green exercise may have psychological benefits. This study compared changes in anxiety, mood, directed-attention abilities, and stress after walking in green (i.e., nature-based) and suburban environments.

METHODS: Twenty-three adults (4 male; 50±7 yr; BMI 31±8 kg/m²) participated in a crossover study comprised of once-weekly 50-min moderate-intensity walking sessions. Participants walked for three weeks in each of two treatment conditions: green and suburban, separated by a two-week washout period. In the first treatment period, 11 participants were assigned to green walking and 12 to suburban walking. Previously validated psychological questionnaires measured pre- and post-walk values for: 1) Anxiety: assessed by the State-Trait Anxiety Inventory; 2) Mood: evaluated via the Positive and Negative Affect Schedule; 3) Directed-attention: measured with the visual Backwards Digit-Span (BDS) Test; and 4) Stress: assessed by the Perceived

Stress Scale. Linear mixed models for repeated measures assessed pre- to post-walk changes between treatments. Baseline BDS scores were included as a covariate in the BDS outcome model to control for a learned effect.

RESULTS: Pre-walk outcomes were similar between walking conditions. Results indicated that anxiety decreased after green walking and increased after suburban walking (-1.75 vs. +1.13 units, respectively; $p < 0.001$). For mood, positive affect improved after green walking and decreased after suburban walking (+2.16 vs. -0.32 units, respectively; $p < 0.003$), and negative affect decreased marginally after green and suburban walking (-0.59 vs. -0.04 units, respectively; $p = 0.06$). Directed-attention abilities did not improve after green and suburban walking (-0.09 vs. -0.08 units, respectively; $p > 0.9$). Stress levels were slightly but not significantly reduced after green and suburban walking (-0.91 vs. -0.69 units, respectively; $p > 0.5$). There were no sequence effects. Finally, no carryover effects were observed - suggesting adequate washout between treatments.

CONCLUSIONS: Green exercise was effective in reducing anxiety and improving mood in this sample but not in improving stress and directed-attention. Future research should identify the optimal dose of green exercise for maximum psychological health gain.

903 Board #137 May 29 2:00 PM - 3:30 PM
Relationship Of Physical Activity And Quality Of Life During ART Treatment Among People Living With HIV

Xuemei Sui, FACSM¹, Shan Qiao¹, Yuchen Mao¹, Yuejiao Zhou², Xiaoming Li¹. ¹University of South Carolina, Columbia, SC. ²Guangxi CDC, Nanning, China.

Email: MSUI@mailbox.sc.edu
 (No relevant relationships reported)

Physical functional impairments are seen among HIV-infected persons on effective antiretroviral therapy (ART). The impact of physical activity (PA) on health-related quality of life (HRQoL) during ART treatment is currently unknown. **Purpose:** To study the relationship between PA and physical and mental components of HRQoL in people living with HIV (PLWH) in China. **Methods:** This cross-sectional study is based on an HIV disclosure intervention study in Guangxi Zhuang Autonomous Region which initially enrolled 791 PLWH in 2013. The participants completed a total of six follow-up surveys at 6 month intervals. The International Physical Activity Questionnaire (IPAQ) was added only after the 4th follow-up in 2015 in which 718 PLWH participated. After excluding those with missing PA data (n=199), those with PA outlier (n=24), and those not under ART treatment (n=49), we included 446 participants (40.4% women, mean age 39.8 years) in the final analysis. Participants with a MET-minutes/week ≥ 500 were defined as active, and those < 500 as inactive based on the current PA guidelines. The 12-item short-form health survey (SF-12) was used to measure HRQoL that is summarized by physical and mental component scores (PCS and MCS, respectively). Logistic regression was used to compare the odds of having a HRQoL component score above the norm between active and inactive participants. **Results:** The proportion of participants with a mean PCS and MCS 50 or above was 44% and 55%, respectively. More than 70% of participants met the current PA guidelines. Inactive individuals served as the referent group. After adjusting for age, gender, education, marital status, smoking, drinking, substance use, and body mass index, active participants had a 60% higher odds (odds ratio (OR), 1.60; 95% confidence interval (CI), 1.01-2.55) of MCS above the norm comparing with inactive participants. Additional adjusting for HIV duration did not change the association. However, no significant relationship was observed between physical activity and PCS. **Conclusion:** Physically active PLWH from China have greater QoL in mental health domain. PLWH commonly experience long-term psychological sequelae and impaired QoL. Findings from this study highlight the importance of examining the influence of PA on mental health in this high-risk population.

904 Board #138 May 29 2:00 PM - 3:30 PM
Physical Activity, Sedentary Time, And BMI In 1st-4thGrade Hispanic Children In Puerto Rico

José A. Martínez-Rodríguez, Lucía del Rosario Martínez, Carmen Nevárez, Mercedes Rivera, Israel Almodóvar, Farah A. Ramírez-Marrero, FACSM. *University of Puerto Rico, Rio Piedras, Puerto Rico.*

(No relevant relationships reported)

Low physical activity (PA) and high sedentary time (ST) are behaviors associated with poor health among children and adolescents, and are known to increase with age. Evidence of these associations among Hispanic children is sparse. **PURPOSE:** To compare PA and ST among 1st to 4th grade Hispanic children in Puerto Rico, and determine their association with BMI. **METHODS:** Children from 6 to 10 years of age attending 1st (n=44), 2nd (n=124), 3rd (n=90), and 4th (n=70) grade wore an ActiGraph® accelerometer for 7 consecutive days, and measures of height and weight were obtained to determine BMI. Generalized least squares fit model with random effects and post-hoc analyses were performed to detect differences and associations by school year and sex in PA (moderate to vigorous PA [MVPA]), ST, and BMI. **RESULTS:**

Minutes/day of MVPA averaged 287.4±54.5 in 1st, 277.4±55.4 in 2nd, 262.7±53.1 in 3rd, and 219.1±60.3 in 4th grade; with a significantly lower value in 4th grade, and girls being less active than boys (199.4±72.4 vs. 238.7±48.1 min/day, $P<0.05$). Average hours/day of ST was 6.1±1.2 in 1st, 6.4±1.1 in 2nd, 6.6±1.2 in 3rd, and 7.3±1.5 in 4th grade; with higher values observed in 3rd and 4th grade ($P<0.05$), and no differences by sex. BMI percentile for most children was in the normal weight range (girls= 62.5%, boys= 69.0%), and 33.4% were in a percentile representing overweight and obesity (girls= 37.5%, boys= 28.5%, $P= 0.04$). No association was detected between BMI, PA, and ST. **CONCLUSION:** Although mean MVPA indicates compliance with current PA recommendation for children, lower values at 4th grade suggests a potential trend that must be addressed. No consensus yet exists regarding ST among children; however, the increase from 2nd to 3rd grade is another potential pattern to watch. Results also suggest that BMI classification might not affect PA and ST behavior in these young children. Supported by UPRRP/DEGI/FIPI.

Modeling Longitudinal Changes in Physical Activity Levels: Oporto Growth Health and Performance Study

Michele de Souza Ribas¹, Raquel Chaves², Thayse Gomes³, Fernanda Santos⁴, Sara Pereira⁵, José Maia⁶. ¹Federal University of Santa Catarina, Florianópolis, Brazil. ²Federal University of Technology of Paraná, Curitiba, Brazil. ³Federal University of Sergipe, São Cristóvão, Brazil. ⁴Federal University of Viçosa, Viçosa, Brazil. ⁵Faculty of Sport, University of Porto, Porto, Portugal.

Email: souza.michele@ufsc.br
 (No relevant relationships reported)

Adolescence is often viewed as a critical window for the development of healthy behaviors which can prevent the development of metabolic risk factors and related comorbidities. Although there is evidence of the independent associations of physical activity with subject and contextual factors, few studies examined the joint longitudinal links of these factors. **PURPOSE:** We aim to model longitudinal changes in youth total physical activity (TPA) as a function of their biological maturation (BM), weight status, socioeconomic status (SES), physical fitness (PF), sleep habits, fruits and vegetables consumption and built environment. **METHODS:** This is a mixed longitudinal study and the data comprised 7315 adolescents (3621 girls) divided into four age cohorts (10 to 12, 12 to 14, 14 to 16 and 16 to 18 years) measured annually for three consecutive years. TPA was estimated with the Baecke questionnaire; BM was indirectly assessed by the maturity offset; weight status was defined with cut-off points for age and sex defined by the International Obesity Task Force; SES was determined by the Portuguese schools' social support system; PF was assessed with the Fitnessgram test battery; sleep habits, fruits and vegetables consumption and built environment information were obtained by questionnaire. Random effects mixed-models were used and computations done in SuperMix v.1. **RESULTS:** Girls' TPA at baseline (10 years) was 7.27 points (possible range: from 3 to 15), being boys systematically more active ($\beta=0.85$, $p<0.001$); with increasing age, TPA decreases, independently of sex ($\beta=-0.07\pm0.03$, $p=0.022$); and the fittest teenagers were those more active ($\beta=0.29\pm0.039$, $p<0.01$); favorable neighborhood environments to healthy lifestyles were positively linked to TPA over the age (built facilities: $\beta=0.06\pm0.02$, $p<0.01$); sociocultural: $\beta=0.09\pm0.02$, $p<0.01$; and economic/political: $\beta=0.07\pm0.02$, $p<0.01$); although marginally, BM was positively associated with TPA changes ($\beta=0.07\pm0.04$, $p=0.064$). The others predictors did not show any significant association with TPA trajectories either sex. **CONCLUSIONS:** These results showed the decline of TPA during adolescence, emphasize the relevant role of PF, as well as favorable neighborhood environments to provide increments in TPA among adolescents.

Additive And Interactive Effects Of Mvpa And Sitting Time On Metabolic Syndrome Risk Indicators

Jaemyung Kim¹, Hyo Lee², Miyoung Lee¹. ¹Kookmin University, Seoul, Korea, Republic of. ²Sangmyung University, Seoul, Korea, Republic of.

Email: jaemyung3102@gmail.com
 (No relevant relationships reported)

Purpose: This study was purposed to estimate the associations between MVPA and sitting time and metabolic syndrome risk in Korean adults. **Methods:** A total of 8997 non-institutionalized Korean adults (age=19-65) participated in the 2014-2015 KNHANES. Daily physical activity and sitting time during a typical week was measured using GPAQ. Metabolic syndrome risk factors were examined at the mobile examination center. The associations between MVPA + sitting time and metabolic syndrome risk indicators were analyzed using logistic and ordinary logistic regression. **Results:** Sitting time was associated with elevated risk for central obesity (OR=1.04, $p<0.001$), hypertriglyceridemia (OR=1.04, $p=0.001$), low HDL-cholesterol (OR=1.02, $p=0.05$), hypertension (OR=1.04, $p<0.001$). MVPA was significantly associated with

Impaired glucose tolerance (OR=.96, $p=.004$), hypertension (OR=1.02, $p<0.035$). Also, MVPA significantly moderated the association between sitting time and hypertriglyceridemia (OR=.997, $p=.053$) and hypertension (OR=.996, $p=.011$). According to the ordinary logistic model, sitting time was significantly associated with increased chance for having more number of metabolic syndrome risk indicators in the abnormal range (OR=1.04, $p<0.001$). Even though MVPA did not have significant direct effects, it significantly moderated the sitting time-metabolic syndrome association in the same model (OR=.997, $p=.009$). **Discussion:** While sitting time and MVPA are respectively a risk and protective factor for metabolic syndrome, negative effects of sitting time may be attenuated by participating in more MVPA or vice versa. Therefore, lifestyle interventions for the metabolic syndrome prevention should include both increasing MVPA and reducing sedentary behavior strategies. Associations of Cardiorespiratory Fitness and Muscular Strength with Arterial Stiffness in Older Adults

Emma Albin, Angelique Brellenthin, Duck-chul Lee, FACSM. Iowa State University, Ames, IA. (Sponsor: Duck-chul Lee, FACSM)

(No relevant relationships reported)

Purpose: To evaluate the associations of cardiorespiratory fitness (CRF) and muscular strength (MS) with arterial stiffness (AS) in older adults. **Methods:** This cross-sectional study included 390 older adults aged ≥ 65 years (mean age 72). Participants were free of diabetes and cardiovascular disease events that occurred within the past 2 years. CRF was assessed by time (minutes) to complete a 400-m walk test and MS by grip strength (Jamar Plus+ 12-064). Carotid-femoral pulse wave velocity (PWV) was used to assess AS (AtCor, Sphygmocor Xcel). High AS was defined as a PWV of 10 m/s or greater, as it has been established as a threshold for increased cardiovascular risk. Logistic regression was used to calculate odds ratios (ORs) and 95% confidence intervals (95% CIs) of having high AS across sex-specific tertiles of CRF and MS. Further, CRF and MS were dichotomized into either weak or unfit (lower one-third), or strong or fit (upper two-thirds) in a joint analysis of CRF and MS with high AS. All logistic regression models included age, mean arterial pressure, body mass index, physical activity, smoking, heavy alcohol consumption (>14 drinks per week for male, >7 for female), and MS or CRF for each other. **Results:** Sixty-three (16 %) adults were identified as having high AS. Compared to the lowest CRF tertile (lowest 33%), ORs (95% CIs) of having high AS were 0.36 (0.16-0.81) and 0.51 (0.21-1.22), for middle and upper CRF, respectively, after adjusting for the possible confounders including MS. Compared to the lowest MS tertile (lowest 33%), ORs (95% CIs) of having high AS were 0.68 (0.33-1.39) and 0.31 (0.13-0.74), for middle and upper MS, respectively, after adjusting for the possible confounders including CRF. In the joint analysis, compared to the unfit and weak group, ORs (95% CIs) for high AS were 0.47 (0.16-0.81) for unfit and strong, 0.37 (0.13-1.04) for fit and weak, and 0.25 (0.12-0.60) for fit and strong. **Conclusion:** Higher levels of both CRF and MS were independently associated with reduced odds of having high AS in older adults. Future prospective studies could evaluate longitudinal associations of CRF and MS and attenuation of age-related AS, which is an emerging risk factor for cardiovascular diseases. Supported by unrestricted research grant by Biospace.

(No relevant relationships reported)

Fracture is a common source of morbidity and mortality in the elderly, approximately 10% of falls resulting in fractures. **Purpose:** To examine whether physical activity could reduce the risk of falls and fall-related fractures, which based on the epidemiological survey of older Chinese people. **Methods:** Referring to the questionnaire by the Disease Control and Prevention Center of Jurong. The Han nationality elderly over 60 years old (including 60) was involved. 6117 questionnaires were collected and 161 invalid questionnaires were deleted. The MET value was referred to the IPAQ. According to Physical Activity Index, the physical activity level (PAL) was divided into "Low", "Moderate" and "High". Comparisons between different groups were performed through Two-way ANOVA. **Results:** The significant difference was shown in height, weight, BMI and bone density between males and females ($P<0.01$). The height had significant differences between different PAL. Bone density increased significantly with the increase of PAL. (Table1)

Table 1. Characteristics of subjects in baseline

| Characteristics | sex | PAL | | | P |
|-----------------------|-----|--------------|-----------------|---------------|-------|
| | | Low 3,617 | Moderate 911 | High 1,428 | |
| Height(cm) | M | 163.58(6.32) | 164.52(6.44) | 163.47(6.26) | 0.003 |
| | F | 152.71(5.78) | 153.32(5.46) | 153.36(5.31) | |
| Weight(kg) | M | 64.92(10.70) | 66.64(10.83) | 64.31(10.39) | 0.032 |
| | F | 58.83(10.01) | 59.35(8.98) | 59.14(9.27) | |
| BMI | M | 24.24(3.76) | 24.60(3.73) | 24.03(3.45) | 0.238 |
| | F | 25.18(3.76) | 25.22(3.41) | 25.13(3.61) | |
| Bone density(T value) | M | -0.57(0.81) | -0.48(0.75) | -0.40(0.76) | 0.000 |
| | F | -1.28(0.79) | -1.15(0.74) | -1.02(0.76) | |

The RR of falls of “Moderate” decreased significantly compared with “Low” (RR=0.83, 95%CI=0.59-1.16). The RR of fall-related fractures of “Moderate” and “High” decreased significantly compared with “Low” (RR=0.58 and 0.69, 95%CI=0.26-1.28 and 0.37-1.27). (Figure 1)

Conclusions: Physical activity could increase the bone density; and the moderate PAL could decrease the RR of falls and fall-related fractures of the elderly. Though the high PAL could increase the RR of falls which might be explained by the increasing of outdoor activities, it could reduce the incidence of fall-related fractures.

Figure 1. Relationship between PAL and falls and falls and fall-related fractures (The calculation of relative risk: based on the “Low” PAL group)

and 21 were classified as either Stage 1 hypertension (n=13, 9 M, 4 F; SBP: 129±6, DBP: 81±13 mmHg) or Stage 2 hypertension (n=8: 7 M, 1 F; SBP: 144±3, DBP: 83±13 mmHg). **CONCLUSIONS:** Under the recently-revised hypertension guidelines, the prevalence of elevated BP and Stage 1 and 2 hypertension was much higher than expected in this apparently healthy, physically-active college-aged group. It is a matter of debate if this group should be considered an important target for lifestyle modifications beyond physical activity, or if the new guidelines are applicable in this particular group.

(No relevant relationships reported)

Reviews of physical inactivity (PIA) have not consistently identified systematic determinants influencing such behavior. Associations in subjective rather than objective measures may be important to consider when designing effective policy targeting PIA. **PURPOSE:** To analyze predictive variables that could influence PIA and how these factors may inform PIA-reducing policy. **METHODS:** Data from the 2014 Special Eurobarometer 412 (n = 27,919) were analyzed, including 40 separate variables and the International Physical Activity Questionnaire (IPAQ) for determining physical activity (PA) in MET-min per week. Variables included alternatives to car, places, reasons, and barriers to engaging in PA, memberships to clubs, and categorical responses regarding the extent of agreement with statements about the area, provision of activities, and local governance. A logistic regression model with a likelihood ratio statistic and a backward stepwise method was used to identify what variables contributed to PIA, which was defined as a “low” level based on IPAQ score. PIA was used as the dependent variable (0 = PA and 1 = PIA). Beta values (β) and standard errors (SE) are reported and Nagelkerke R² is indicated. A priori alpha level was set at 0.05. **RESULTS:** The model for detecting PIA (χ² = 2,023; p < 0.001; R² of Nagelkerke = 0.153) was able to identify 10.7% of the inactive and 96.9% of the active people (74.5% of the total sample). The variables contributing to the detection of PIA were (p ≤ 0.01): having a disability or an illness (β = 0.521, SE = 0.052), not having friends to do sport with (β = 0.314, SE = 0.089), lacking motivation or interest (β = 0.407, SE = 0.04), and being afraid of the risk of an injury (β = 0.190, SE = 0.073). Additionally, totally agreeing, tend to agree, and tend to disagree regarding the extent of local providers offering enough opportunities to be more active also contributed to the model (β = 0.302-0.433, SE = 1.353-1.542). **CONCLUSIONS:** Overall, the model was effective for detecting PA but not PIA. However, in the proportion where PIA was detected, key subjective factors influencing PIA began to emerge. Greater insight into these subjective mediators will be helpful in drafting effective policy around active living, and therefore better correlates should be included in future public health surveillance efforts.

(No relevant relationships reported)

Despite the robust statistical association between waist circumference (WC) and cardiometabolic risk factors (hypertension, dyslipidemia), and outcomes (type 2 diabetes, cardiovascular disease (CVD)) there is little evidence exploring the addition of WC to risk factors commonly employed in CVD risk prediction models. **PURPOSE:** To assess the influence of adding WC to a CVD mortality risk model. **METHODS:** Data were obtained from the Aerobics Center Longitudinal Study. A total of 34,377 males (mean age 44.9 years; standard deviation (SD), 9.9 years) who completed a baseline medical examination between 1978 and 2002 were included. WC was measured at the level of the umbilicus and expressed as a continuous variable. CVD mortality was the main outcome. Deaths among participants were identified from the National Center for Health Statistic’s National Death Index. Follow-up time of less than 1 year (baseline to December 31, 2003 or CVD mortality) were excluded.

High Prevalence of Hypertension in Apparently Healthy Physically-Active College-Aged Adults Under the New Hypertension Guidelines

Lisa Ferguson-Stegall¹, Brenden J. Shanley¹, Alyssa D. Huch¹, Brandon J. Puterbaugh¹, Lauren Faust¹, Anoulack Phousarith², Hannah Scheel¹, Alicia Williams¹, Meghan Webb¹, Britni A. Delcastillo¹, Owen Sloop¹, Marisa D. Smet¹. ¹Hamline University, Saint Paul, MN. ²University of Minnesota - Duluth, Duluth, MN. (Sponsor: Hirofumi Tanaka, FACSM)

Email: lstegall01@hamline.edu
(No relevant relationships reported)

Hypertension is an important risk factor for cardiovascular disease. Under the previous hypertension guidelines, 29% of adults in the US aged 18-60+ were hypertensive, with the highest prevalence (63%) in the 60+ age group. Prevalence in the 18-39 age group was the lowest at 7.5%. The newly revised American College of Cardiology/ American Heart Association Hypertension Guidelines lowered the threshold for hypertension. Many more individuals are expected to be diagnosed with either elevated blood pressure (EBP, 120-129/<80 mmHg) or hypertension (Stage 1, 130-139/80-89 mmHg; Stage 2, ≥140/90 mmHg) than before. Prevalence of hypertension in the lower end of the young adult group, ages 18-25, is not well characterized, and how the new guidelines apply to this age group has not yet been studied. **PURPOSE:** We aimed to determine the prevalence of hypertension (EBP, Stage 1, and Stage 2) in active college-aged adults. We hypothesized that hypertension would be <30% in this population. **METHODS:** Resting blood pressure (BP) was measured with a sphygmomanometer according to AHA guidelines in 100 participants (21±2 y, 53 females (F), 47 males (M)) after sitting for 10-15 min. Participants avoided caffeine and exercise for 4 h prior to measurement. All were physically active (athletes or recreationally active exercisers), and none were taking medications or supplements that directly affect resting BP. **RESULTS:** Of 100 participants, 54 (17 M, 37 F) had normal (<120/<80 mmHg) blood pressure. 25 (13 M, 12 F) had EBP (SBP: 123±4, DBP: 76±10 mmHg),

RESULTS: A total of 645 CVD deaths occurred over a mean follow-up period of 13.6 years (SD 7.4 years), for a total of 467,213 person-years of follow-up. Mean WC of the cohort was 94 cm (SD 11 cm). In a Cox proportional hazards model, including age, total cholesterol, HDL cholesterol, systolic blood pressure, current smoking status, and diabetes, WC was independently associated with CVD mortality ($p < 0.0001$). The Harrell's C-index without WC in the model was 0.834, and 0.837 upon addition of WC to the model. **CONCLUSION:** In this large population sample of men, WC was significantly associated with cardiovascular disease mortality independent of cardiometabolic risk factors. However, the addition of WC to these variables did not meaningfully improve our cardiovascular disease mortality risk prediction model.

912 Board #146 May 29 2:00 PM - 3:30 PM

The Prevalence of Depression Among Diabetic Patients is Associated with Hemoglobin

Angela A. Colback¹, Cynthia Villalobos², Jonathan M. Saxe³, Lewis E. Jacobson³, J. Mark VanNess², Courtney D. Jensen².
¹University of California, Berkeley, Berkeley, CA. ²University of the Pacific, Stockton, CA. ³Saint Vincent Hospital, Indianapolis, IN.

(No relevant relationships reported)

More than 400 million adults have diabetes. Complications associated with diabetes poorly impact quality of life, including interactions between cardiovascular risk and depression. A diagnosis of diabetes associates with a three-fold increase in depression. The consequences of low Hb values on increased depression among healthy populations are well defined; however, isolating the relationship within a diabetic population requires further investigation. **PURPOSE:** To explore the effect of diabetes on hemoglobin levels (Hb) and depression in a diabetic population. **METHODS:** 2,206 hospital patients, age 15-98 years old were sampled; 14.6% had a diagnosis of diabetes. Independent-samples t-tests characterized the differences between diabetics ($n=1,884$) and non-diabetics ($n=322$). One-way ANOVA examined group differences between categorical Hb values, Chi-Square determined the relationship between diabetes and hemoglobin category, linear regression determined Hb levels among diabetics, and logistic regression analyses predicted depression outcomes based on Hb levels. **RESULTS:** Patients with diabetes were older ($p<0.001$) and had lower hemoglobin ($p<0.001$) and oximetry levels ($p<0.001$). Non-diabetic patients had lower international normalized ratio ($p<0.001$), systolic blood pressure ($p<0.001$), mean arterial pressure ($p=0.015$), and pulse pressure ($p<0.001$). Hb categories differed in age, oximetry, international normalized ratio, pulse, diastolic blood pressure, mean arterial pressure, and pulse pressure ($p<0.001$); groups differed for systolic blood pressure ($p=0.013$). Additionally, chi-squared analysis demonstrated lower hemoglobin levels associated with increased diagnosis of diabetes ($p<0.001$). Linear regression, controlling for age, predicted a decrease in Hb among diabetic patients ($\beta=-0.460$; $p<0.001$). Lastly, logistic regression determined with each additional g/dL of Hb, the odds of experiencing depression decreased by 31% ($p<0.001$). **CONCLUSIONS:** Diabetes diminishes cardiovascular health, particularly Hb levels, and this predicts depression within this population. Physical activity should be a first-line intervention to improve quality of life in patients suffering from diabetes.

Changes In Physiological Factors And Performances In Female Track-and-field Athletes Transitioning To Senior

Yuka Tsukahara¹, Suguru Torii², Fumihiko Yamasawa³, Jun Iwamoto⁴, Takanobu Otsuka⁵, Hideyuki Goto⁶, Torao Kusakabe⁷, Hideo Matsumoto¹, Takao Akama². ¹Keio University, Tokyo, Japan. ²Waseda University, Tokorozawa, Japan. ³Marubeni Clinic, Tokyo, Japan. ⁴Keiyu Orthopaedic Hospital, Tatebayashi, Japan. ⁵Tokai Gakuen University, Nagoya, Japan. ⁶Shigakkan University, Obu, Japan. ⁷Kyoto Daini Red-Cross Hospital, Kyoto, Japan.

Email: yuka.voila@gmail.com

(No relevant relationships reported)

Performance decline in female track-and-field (T&F) athletes transitioning to senior has been indicated but there has not been any solutions of that yet. **PURPOSE** To examine changes of physiological factors in female T&F athletes transitioning to senior and analyze their relationship to performances. **METHOD** Of 142 top-level female T&F athletes recruited, we analyzed the data of 38 subjects who were sprinters and jumpers aged 17-18 in the season of 2016. We measured body composition with whole body mode dual-energy X-ray absorptiometry device in post-season of 2016 (Po-16) and 2017 (Po-17). Athletes' performances were assessed by International Amateur Athletics Federation scoring system. Comparisons were made by a one-way analysis of covariance. **RESULTS** Compared to performances in Po-16, 14 athletes (Group A) were able to maintain or improve in Po-17, while the other 24 (Group B) were not able to and the scores were significantly different between the two groups (991.36 ± 46.50 vs 947.46 ± 64.24 score, $p<0.05$). In Po-16, there were no significant

differences in their body composition between the two groups. In Po-17, however, fat mass (FM) and FM% increased in Group B in all body parts, while they did not in Group A in any, and were significantly different between the two groups (Upper extremities (UE): FM 833.07 ± 182.34 vs 1030.93 ± 260.77 g, $p<0.05$, FM% 15.90 ± 3.28 vs 18.44 ± 3.55 %, $p<0.05$; Trunk: FM 2587.11 ± 699.19 vs 3493.36 ± 856.99 g, $p<0.01$, FM% 11.18 ± 2.60 vs 13.99 ± 2.46 %, $p<0.01$; Lower Extremities (LE): FM 3175.16 ± 649.74 vs 4228.59 ± 830.73 g, $p<0.01$, FM% 16.84 ± 3.02 vs 20.54 ± 2.67 %, $p<0.01$; Total: FM 7467.39 ± 1440.28 vs 9638.89 ± 1821.62 g, $p<0.01$, FM% 14.44 ± 2.36 vs 17.29 ± 2.22 %, $p<0.01$, in Po-17, Group A vs Group B). In addition, lean mass (LM)% was significantly higher in Group A compared to Group B in Po-17 (UE: 79.22 ± 3.12 vs 76.65 ± 3.43 %, $p<0.05$; Trunk: 86.20 ± 2.59 vs 83.42 ± 2.36 %, $p<0.01$; LE: 78.68 ± 3.09 vs 75.17 ± 2.54 %, $p<0.01$; Total: 81.25 ± 2.30 vs 78.51 ± 2.08 %, $p<0.01$) in all body parts although there had been no significant difference in Po-16. **CONCLUSION** While majority of female T&F athletes face performance decline when transitioning to senior, those who maintain or improve high performance levels were shown to have kept their FM and FM% low and LM% high. Supported by Japan Sports Agency, Support for female athletes.

Arterial Compliance is Improved Following a Community-led 12-week Indigenous Wholistic Health and Wellness Program

Erin M. Shellington¹, Shannon S.D. Bredin¹, Kai L. Kaufman¹, Henry Lai¹, Jan Hare¹, Moss Norman¹, Paul Oh², Ryan Rhodes³, Darren E.R. Warburton¹. ¹University of British Columbia, Vancouver, BC, Canada. ²University Health Network, Toronto, ON, Canada. ³University of Victoria, Victoria, BC, Canada.

(No relevant relationships reported)

PURPOSE: Indigenous peoples are at a higher risk for many chronic diseases compared to the general population. Colonization and forced assimilation have led to marked changes in traditional roles and healthy lifestyle behaviors. The purpose of this study was to examine vascular health (arterial compliance) prior to and following an Indigenous led, and community-based 12-week lifestyle program representing Indigenous views of wholistic health and wellness.

METHODS: Indigenous adults were recruited to participate in a healthy lifestyle program through a community walk on National Indigenous Peoples Day (21/06/2018) in an Indigenous community. The program was a once weekly education session on healthy lifestyle behaviours (e.g., traditional diet), including sharing circles and a physical activity component (e.g., walk). Arterial compliance was assessed using applanation tonometry (HDI/PulseWave CR-2000) at pre- and post-intervention.

RESULTS: A total of 11 participants (1 male; Age = 47.3 ± 10.7 yr, Height = 161.1 ± 6.4 cm, and Weight = 82.3 ± 18.3 kg) completed arterial compliance assessments. Large artery elasticity index was significantly improved over the program duration, $t=-2.3$, $p=0.04$ (pre: 10.4 ± 1.9 ; post: 12.0 ± 2.4 mL/mmHg x 10). There were no significant changes in resting systolic or diastolic blood pressure, pulse pressure, pulse rate, estimated cardiac output, cardiac index, systemic or total vascular resistance or small artery elasticity index following the program.

CONCLUSIONS: Arterial compliance, an important predictor of vascular health, is improved in Indigenous adults living in rural British Columbia following a 12-week program based on Indigenous worldviews. This data demonstrates health-related benefit of culturally appropriate programs. This project was funded by the Canadian Institutes of Health Research.

(No relevant relationships reported)

Purpose: Exercise program can improve the side effects of cancer treatment, such as, decreased total fat mass and trunk fat mass, however, it is not known whether these positive outcomes acquired are maintained long-term after program interruption. Thus,

the objective of this study was to verify if the effects of combined training on the body composition persisted over 1 year follow-up after training interruption in older breast cancer survivors undergoing aromatase inhibitor therapy.

Methods: Thirty-six breast cancer survivors (50+ years of age) that participated in a clinical trial during 9 months [Exercise group (EG): n= 18 and Control group (CG): n=18] were assessed for the 1 year follow-up. Body composition (total fat mass, percentage of fat mass, trunk fat and lean body mass) and bone mineral density were evaluated by DXA. The exercise group performed about 40 min of resistance training plus 30 min of aerobic training, three times per week during 9 months. Two-way repeated measure of ANOVA was used to compare groups and a Bonferroni's post hoc test was conducted when a significant interaction was observed.

Results: There were a significant group × time interaction for total fat mass (Pre= 30.7±7.7 vs Post=28.6±7.8 vs Follow-up= 30.3±8.1 kg, $F= 4.864$, $p=0.012$) and percentage of fat mass (Pre= 45.4±5.1 vs Post=43.2±5.8 vs Follow-up= 45.7±5.4 %, $F= 6.808$, $p= 0.002$). The Bonferroni's Post hoc test showed a decreasing for fat mass only in the EG after 9 months of training but there was a regain over 1 year follow-up. There were no statistically significant interaction for lean mass, trunk fat and bone mineral density ($p>0.05$).

Conclusions: This study demonstrated the potential benefits of combined training (resistance plus aerobic) to decreased total and percentage of fat mass in breast cancer survivors undergoing aromatase inhibitor therapy, however, after training interruption there was a regain of body fat. Therefore, our results emphasize that is important to maintain an exercise training program over a prolonged period for this population.

 (No relevant relationships reported)

PURPOSE: To compare muscle performance on breast cancer women (BCW) during the treatment chemotherapy with apparently healthy women (CNT).
METHODS: 19 BCW (52.2 ± 13,11yrs, 1.60 ± 0.07m, 66,8 ± 12.33kg, 27,6 ± 3,8kg/m²) undergoing chemotherapy (between the third and fourth cycle of chemotherapy: AC+T - Doxorubicin + Cyclophosphamide - Paclitaxel) and 18 CNT (55.8 ± 8.37yrs, 1.60 ± 0.06m, 69,0 ± 11.49kg, 28,3 ± 3,1kg/m²) without breast cancer, performed 2 sets of 4 unilateral isokinetic knee extension repetitions at 60°/s (Biodex system III, Inc., Shirley, NY, USA). The rest interval between sets was 2 minutes. All subjects were not involved in exercise programs that included resistance exercise. The normality of the data was performed by the Shapiro-Wilk test and the Student *t* test to compare the groups. Statistical significance was set at $p<0.05$ for all comparisons.
RESULTS: No significant differences were found in the peak torque values between groups ($p = 0.95$). The peak torque was 101.1 ± 26.79 N.m for the BCW group and 101.7 ± 26.98 N.m for the CNT group. Separating the volunteers according to the level of physical activity, no differences were found between the groups for the PT values.
CONCLUSIONS: Women with breast cancer undergoing chemotherapy treatment, between the third and fourth cycle of chemotherapy, did not present differences in measures of muscle performance when compared to apparently healthy women.

 (No relevant relationships reported)

The manifold benefits of exercise during and after breast cancer therapy are well investigated and lead international agencies to recommend exercise for breast cancer patients and survivors (Schmitz, 2010). However, there is still a knowledge gap regarding the efficacy of prehabilitative exercise for patients undergoing breast cancer surgery. **PURPOSE:** Investigate the effects of exercise before surgery (prehabilitation), on the health perception and functional capability of women after surgery. **METHODS:** 33 sedentary breast cancer patients scheduled for breast cancer surgery were randomized to either a partly supervised (SE), a home based (HE) resistance exercise groups or a usual care group (UC), each consisting of 11 patients. The patients were assessed before the intervention, immediately before surgery, before and after adjuvant treatment. The data were analyzed via linear Mixed-Effect-Models, questionnaire scales were standardized to the pooled pretest standard deviation. The reported results are the incremental effects in the intervention groups compared to the UC at the post-surgical follow up. **RESULTS:** The interim results showed superior functional fitness for both exercise groups, with an incremental increase in the 6min walk distance of 123.5 meter (95%-CI= 41.8 - 206.1) in the HE and 113.0 meter (95%-CI= 27.3 - 198.7) in the SE. The gain of grip strength in the dominant hand surpassed the gain in the UC by 7.0kg (95%-CI= 3.6 - 10.4) in the HE and 5.4kg (95%-CI= 3.4 - 7.3) in the SE. In the non-dominant hand the strength gains were lower with 3.2kg (95%-CI= -0.15 - 6.6) in the HE and 3.1kg (95%-CI= -0.5 - 6.7) in the SE. Both exercise groups showed superior improvements in quality of life compared to the UC. With large effects of $\beta= 1.34$ (95%-CI= 0.18 - 2.50) in the HE and $\beta= 2.60$ (95%-CI= 1.31 - 3.89) in the SE in role function, and $\beta= 0.49$ (95%-CI= -0.29 - 1.27) in the HE and $\beta= 1.54$ (95%-CI= 0.66 - 2.42) in the SE, in physical function measures. **CONCLUSION:** These results support the implementation of a brief prehabilitative exercise intervention and display the multidimensional effects of exercise on functional, as well as psychological health parameters.

Preliminary Findings from an eHealth Intervention to Increase Physical Activity Among Young Adult Cancer Survivors.

Leah Meuter¹, Ashlen Kuntz¹, Cami Christopher¹, Suzanne Phelan¹, Siobhan Phillips², Sarah Keadle¹. ¹California Polytechnic State University, San Luis Obispo, CA. ²Northwestern Medical School, Chicago, IL. (Sponsor: Dr. Todd Hagobian, FACSM)
 (No relevant relationships reported)

PURPOSE: This pilot study aims to determine the feasibility and acceptability of a remotely-delivered eHealth intervention that links physical activity and charity-based incentives to motivate young adult cancer survivors to initiate and maintain physical activity (PA). **METHODS:** Inactive cancer survivors (diagnosed between age 18-39y) were recruited through hospital support groups and online forums across the western United States. Screening and informed consent were done online; activity was measured via activPAL for 7-days at baseline and again at 12-weeks. Participants were randomized into either a PA only or Physical Activity+Charity Incentive group. Participants in the PA only group received a Fitbit One, personalized step goals, and weekly behavioral change content via email. PA+Incentive participants received the PA intervention plus donations to a cancer charity of their choice if daily step goals were attained. The primary aim was to evaluate feasibility and acceptability and the primary outcome was 12-week between-group changes in steps per day as measured by the activPAL. **RESULTS:** Seventy-six participants were screened; of those, 54 (71%) were eligible and provided informed consent and 51 (94%) completed the baseline assessments and were randomized. Those randomized were 88% female, 54% with prior breast cancer, 56.9% Non-Hispanic White; and had a mean age of 36.8 years. Of those eligible to date to complete the 12-wk measure (N=47), retention was high for the PA only (22/25) and PA+Charity (23/26) groups. The majority of participants reported they were "satisfied or very satisfied" with the overall intervention experience. There was some evidence that the PA+Incentive group was more satisfied with the overall experience as a study subject compared to the PA only group (45% vs 30% reporting "very satisfied"). This also holds true for the level of contact with staff (27% vs 15%) and content of emails (23% vs 10%). Some participants (23%) wanted more contact with study staff or other participants. **CONCLUSIONS:** These preliminary findings show that a mail-based intervention among young adult cancer survivors is feasible and acceptable to participants. The next step will be to evaluate if there was a significant change in daily steps as a result of the intervention. Support by Frost Fund and Cal Poly RSCA.

Higher Perceived Breast Cancer Risk is Associated with Less Aerobic Physical Activity in Women

Shreya Desai, Keana Asadifar, Umaima Memon, Daphne C. Hernandez, Lorraine R. Reitzel, Rosenda Murillo. *The University of Houston, Houston, TX.*
 Email: sdesai11@uh.edu
 (No relevant relationships reported)

PURPOSE: To examine the association between perceived breast cancer risk and aerobic physical activity among women. **METHODS:** We used cross-sectional data on women aged ≥ 18 years who participated in the 2015 National Health Interview Survey (n=17,967). Participants were asked to self-report whether they perceived themselves at less than average risk (ref), average risk, or higher than average risk for breast cancer. Aerobic physical activity was measured based on self-reported minutes of moderate-to-vigorous aerobic physical activity engaged in per week, then categorized into none (ref), some activity, and meeting the aerobic activity recommendation. Multinomial logistic regression models were fit, accounting for the complex survey design, to estimate associations between perceived risk of breast cancer with aerobic physical activity. Models were adjusted for age, education, race/ethnicity, and insurance. **RESULTS:** In adjusted models, compared with women who perceived themselves at low risk for breast cancer, those perceiving themselves at higher than average risk had 14% lower odds to meet the aerobic activity guideline, relative to no activity (Odds Ratio [OR]: 0.86; 95% Confidence Interval [CI]: 0.76-0.97). Similarly, compared with women who perceived themselves at low risk for breast cancer, those perceiving themselves at average risk for breast cancer had 23% lower odds to meet the aerobic activity guideline (OR 0.77, 95% CI 0.65-0.91). **CONCLUSIONS:** Among women, higher perceived breast cancer risk was associated with a lower likelihood of engaging in aerobic physical activity. Since greater physical activity can reduce the risk of breast cancer, future studies should also use longitudinal designs to determine if increasing physical activity decreases perceived breast cancer risk. Results suggest a possible role for health promotion interventions linking perceived breast cancer risk with physical activity. Supported by NIH P20CA221697-02, P20CA221696-02, and P20CA221697-01S1.

Effects Of Resistance Training On Muscle Strength Of Breast Cancer Survivors

Wanderson Santos¹, Gabriel Siqueira¹, Paulo Gentil¹, Claudio Lira¹, Mário Campos¹, João Mota¹, Raquel Schincaglia¹, Claudio Battaglini, FACSM², Carlos Vieira¹. ¹Federal University of Goiás, Goiânia, Brazil. ²University of North Carolina at Chapel Hill, Chapel Hill, NC.
 Email: wanderson.nilo@gmail.com
 (No relevant relationships reported)

PURPOSE: Examine the effects of highly supervised resistance training (RT) with low weekly frequency on muscle performance in women breast cancer survivors (BCS). **METHODS:** Seven BCS (55.85 \pm 3.62 years old, 68.48 \pm 11.21 kg) undergoing hormonal therapy (HT) (tamoxifen® or anastrozole), with no RT experience participated in the study. The BCS performed a full body RT protocol once a week for 8 weeks, followed by a resting period of 4 weeks and another 8 weeks of RT, totaling twenty weeks of the training protocol. The RT volume consisted of 3 sets of 8 to 12 repetitions until concentric volitional failure, performed on free weight and machines at 2 seconds of eccentric movement and 1 second of concentric movement, with 2 min of rest between sets on the following exercises: leg press (LP), stiff-legged deadlift, bench press (BP), supine lat pull down or seated cable row, and sit-up. Each BCS was individually supervised by trained physical education teachers. Muscle strength (MS) was assessed by the 10RM-test for the BP and LP. The assessments occurred pre-training (pre), post-training initial 8 weeks of training (post8), after 4 weeks of rest on week 12 (post12), and post-training second 8 weeks of training on week 20 (post20). Descriptive analyses are presented as mean and standard deviation. A repeated measurement ANOVA with the Bonferroni post hoc tests was used to examine differences between MS changes. **RESULTS:** MS was improved on the BP from pre to post8 (16.57 \pm 2.22 kg, 21.71 \pm 2.13 kg, p < 0.01), pre to post12 (16.57 \pm 2.22 kg, 20.14 \pm 1.67 kg, p = 0.01), and from pre to post20 (23.71 \pm 2.13 kg, p < 0.0001) and on the LP from pre to post8 (79.28 \pm 27.45 kg, 116.42 \pm 33.87 kg, p < 0.01), pre to post12 (79.28 \pm 27.45 kg, 108.57 \pm 34.24 kg, p = 0.04), and from pre to post20 (79.28 \pm 27.45 kg, 135.00 \pm 37.19 kg, p < 0.01). In addition, there was no significant difference during the rest period for upper and lower body strength (p=0.25 and p=0.99, respectively). **CONCLUSION:** It appears that weekly session of RT with individual supervision promotes gains in MS in women BCS undergoing HT. Furthermore, even with a rest period of 4 weeks from RT, MS in these women was maintained. Therefore, future studies examining the effects of RT on MS in women BCS should explore one day a week of RT protocols to confirm or refute the results of this promising new approach.

Effect of Exercise Therapy During Treatment for Gynecological Cancer: A Systematic Review and Meta-Analysis

Alice Iannaccone¹, Cristina Cortis¹, Elisabeth Edvardsen², Giovanni Capelli¹. ¹University of Cassino and Lazio Meridionale, Cassino, Italy. ²Norwegian School of Sport Sciences, Oslo, Norway. (Sponsor: Carl Foster, FACSM)
 Email: alice.iannaccone@unicas.it
 (No relevant relationships reported)

Side effects of gynecological cancer treatments (GCT), such as cancer related fatigue, physical pain, lower limb lymphedema, induced menopause and sexual dysfunction, negatively affect the patients' Quality of Life (QoL). **PURPOSE:** To evaluate the effect of exercise therapy in randomized controlled trials (RCTs) on QoL in women during GCT. Secondary outcomes were the effects on body composition (BC), training modality, safety and physical activity (PA) behavior. **METHODS:** A systematic search in PubMed, Cochrane, EMBASE and SPORTDiscus was carried out to identify exercise training RCTs during GCT. Primary endpoint was the change in QoL from baseline (PRE) to after (POST) exercise intervention. Exclusion criteria was investigations with participants' mean age <18years, not written in English and not published in peer-review journals. Meta-analysis of Standardized Mean Differences (SMD) and 95% Confidence Interval (95%CI) were performed. **RESULTS:** Seven RCTs were selected, including a total of 112 and 105 participants in the exercise therapy and the control group, respectively. Four studies underwent unsupervised, home-based (HB) exercise; one study received instructions for unsupervised HB training (walking and strength exercises); one study received a comprehensive care program (group education and self-help group support, relaxation and HB aerobic and strength exercises); one study underwent pelvic floor rehabilitation training supervised by a physiotherapist and instructions for HB exercise. After the exercise therapy an increase in PA has been reported for all included studies (SMD=0.56, 95%CI: 0.38, 0.74). Exercise therapy did not show any significant differences in waist circumference (PRE:65.5 \pm 33.1cm; POST:64.9 \pm 33.6cm; SMD=-0.10, 95%CI: -0.78, 0.59), body mass (PRE: 105.6 \pm 7.4kg; POST:102 \pm 7.8kg; SMD=-0.09, 95%CI: -0.67, 0.50) or BMI (PRE:29.5 \pm 8.3kg/m²; POST:30 \pm 8.2 kg/m²; SMD=0.01, 95%CI: -0.67, 0.70),

compared to the control groups. No adverse events were reported during the exercise intervention. **CONCLUSION:** Exercise therapy during GCT showed improvements in PA and QoL. However, exercise therapy seems safe during GCT. Further research is needed to evaluate effect of supervised exercise interventions on cardiorespiratory fitness, type, frequency and training intensity.

Factors Affecting the Change in Quality of Life in Participants of a Cancer Exercise Program

Emanuel Schembri¹, Friederike Rosenberger², Karen Steindorf³, Joachim Wiskemann, FACSM². ¹University Hospital Heidelberg, National Center for Tumor Diseases (NCT) Heidelberg and Heidelberg University, Institute of Sports and Sports Sciences, Heidelberg, Germany. ²University Hospital Heidelberg and National Center for Tumor Diseases (NCT) Heidelberg, Heidelberg, Germany. ³German Cancer Research Center (DKFZ) and National Center for Tumor Diseases (NCT) Heidelberg, Heidelberg, Germany. (Sponsor: Joachim Wiskemann, FACSM)
Email: schembri.emanuel@gmail.com
(No relevant relationships reported)

Purpose: Anti-cancer treatment causes numerous cancer related symptoms (CRS) which may influence quality of life (QOL). The purpose of this analysis was to determine the relationship between having CRS and the magnitude of the change in QOL in cancer patients participating three to four months in various exercise classes at a comprehensive cancer center.

Methods: Data of 779 patients who participated between 2012 and 2017 in exercise classes at the National Center for Tumor Diseases (NCT) Heidelberg, Germany, were examined. Baseline characteristics assessed were anthropometric data, cancer diagnosis, peak power output (PPO) and, maximum peak oxygen uptake (VO_{2peak}) in a cycle ergometer test as well as CRS by a self-developed anamnesis questionnaire. QOL was assessed at the start of the exercise program (t0) and after three to four months (t1) using the European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire (EORTC QLQ-30, subscale global health status/QOL). CRS included fatigue, lymphedema, peripheral neuropathy, weight loss, pain, restricted mobility, and negative emotions (distress, anxiety, and depression). A multiple regression analysis was performed to determine the relationship between CRS and the change of QOL (Δ QOL) from t0 to t1.

Results: Participants' (71% female, 29% male, n=779) mean age was 56±12 years (16-88 years, n=772), and body-mass-index was 25±5 kg/m² (15-57 kg/m², n=755). Most frequent diagnoses were breast cancer (44%), colorectal cancer (7%), and gynaecologic tumor diseases (6%) (n=779). PPO averaged 1,7±0,6 W/kg (0,3-3,5 W/kg, n=273) and VO_{2peak} averaged 25±5 ml/min/kg (6-47 ml/min/kg, n=273). Δ QOL was 1.75±16.02 (-50.0-50.0, n=105). Multiple regression analysis revealed that CRS explained 16% of the variance in Δ QOL ($R^2=.158$, $F(7,97)=2.606$, $p<.05$) ($p=.272$, $n=105$). Restricted mobility ($\beta=.233$, $p<.05$) and weight loss ($\beta=.216$, $p<.05$) significantly affected Δ QOL.

Conclusion: Overall, QOL increased through exercise participation. Results indicated that participants who reported to have restricted mobility and weight loss at baseline tended to benefit more from exercise in terms of QOL. The results of this study can be used to understand how to modify the daily exercise sessions and focus on specific CRS to further improve QOL in cancer patients.

Home Exercise Program with Weekly Phone Calls Impacts Quality of Life in Cancer Survivors

Jill E. Mayer, Kayleigh Plumeau. Ithaca College, Ithaca, NY.
Email: jmayer@ithaca.edu
(No relevant relationships reported)

Studies have proven exercise as an effective intervention for cancer survivors to improve quality of life (QOL). Less research has focused on the impact in a home setting, specifically for those in early phases of recovery. Limited evidence exists on techniques that can improve compliance to carry out home exercise programs (HEP).

PURPOSE: To determine the impact of weekly phone calls on QOL and adherence to an individualized HEP while simultaneously identifying motivators and barriers to completion. **METHODS:** This study was a case control of a heterogeneous sample of 16 participants with various cancer types in active treatment or less than 90 days since treatment. At physical therapy (PT) initial evaluation and following an 8 week program, participants completed the European Organization of Research and Treatment of Cancer QoL Questionnaire-Cancer 30 (EORTC). Participants were allocated based on blocked randomization and provided with an individualized HEP including strength and aerobic exercise. They were instructed to perform at a frequency consistent with the American College of Sports Medicine (ACSM) guidelines and maintain activity logs. The intervention group received weekly phone calls by a student PT. The control group did not receive communication. Wilcoxon signed-rank, Mann-

Whitney U, and thematic analysis were used to analyze data. **RESULTS:** There was no difference between groups for HEP completion and 20% of participants across groups achieved ACSM guidelines. No difference was found between groups for the EORTC QoL ($p=.199$). The intervention group demonstrated significant improvements in the EORTC QoL ($p=.046$) and physical function ($p=0.017$). Motivators found in the treatment group included phone calls, decreased fatigue, feeling better with exercise, self-motivation, caregiver support and confidence. Barriers included fatigue, medical complications, weather, lack of time, pain, social engagements, nausea and psychological well-being. Only one barrier was determined and seen in the control group; pain/injury. **CONCLUSIONS:** Although phone calls did not impact compliance in this small study, they may be an effective strategy to help cancer survivors identify weekly motivators and barriers to completing a HEP and create adequate support to improve QOL.

Personal Training vs. Group-based Exercise Prescription Compliance in Breast Cancer Survivors

Mary C. Hidde¹, Kelli A. LeBreton¹, Kelley R. Covington¹, Catherine M. Jankowski, FACSM², Heather J. Leach¹. ¹Colorado State University, Fort Collins, CO. ²University of Colorado, Aurora, CO. (Sponsor: Catherine Jankowski, FACSM)
(No relevant relationships reported)

PURPOSE: Exercise interventions can improve fitness and quality of life among breast cancer survivors. The magnitude of these effects may be dependent on compliance to the intended exercise prescription (ExRx), but few studies in cancer survivors have reported this information. This study examined breast cancer survivors' ExRx compliance during a personal training (PT) or group-based exercise (GBE) intervention.

METHODS: Women (N=26) with stage I-II breast cancer who had completed chemotherapy and/or radiation treatment within the previous year were randomly assigned to PT or GBE for 8 weeks. All participants received supervised exercise twice per week for 60 minutes a session. Participants were compliant to aerobic ExRx if they completed 20-30 minutes at 50-80% of heart rate reserve. Participants were compliant to upper and lower body resistance ExRx if they completed 2-3 sets of 8 repetitions within 50-80% of 1RM for chest and leg press. Compliance to aerobic, upper, and lower resistance ExRx was coded dichotomously (yes/no) for each session, then summed and divided by the number of sessions attended to calculate percent compliance. Independent t-tests examined differences in ExRx compliance between PT and GBE. Results are reported as mean±SD.

RESULTS: Participants were aged 52±8.5 years, and 13.4±5.1 months post diagnosis. Of the N=24 who completed the intervention, exercise session attendance was 15.8±0.5 (99%) in PT, and 13.4±1.0 (82%) in GBE out of 16 possible sessions ($p=.000$). Compliance for aerobic ExRx was 77.2±0.17% in PT, and 70.1±0.17% in GBE ($p=.41$). Compliance for upper body resistance ExRx was 76.0±0.37% in PT and 82.4±0.20% in GBE ($p=.597$). Compliance for lower body resistance exercise was 80.2±0.23% in PT and 87.9±0.21% in GBE ($p=.40$).

CONCLUSION: Exercise session attendance was higher in PT. Overall ExRx compliance was >70% for aerobic, >80% for resistance, and similar in PT and GBE. With growing support for establishing exercise programs for cancer survivors, it is important to determine sustainable and scalable delivery modalities. GBE may be more resource conscientious than PT, and this study suggests GBE can achieve comparable ExRx compliance to PT. Future exercise intervention studies in breast cancer survivors should examine how ExRx compliance affects health and/or fitness outcomes.

Higher Perceived Colorectal Cancer Risk is Associated with Greater Aerobic Physical Activity in Adults

Rosenda Murillo, Keana Asadifar, Umaima Memon, Shreya Desai, Daphne C. Hernandez, Lorraine R. Reitzel. University of Houston, Houston, TX.
(No relevant relationships reported)

PURPOSE: To examine the association between perceived colorectal cancer risk and aerobic physical activity among US adults.

METHODS: We used cross-sectional 2015 National Health Interview Survey (NHIS) data on participants 18 years of age and older (n=16,711). Perceived colorectal cancer risk was assessed based on measures to which participants responded whether they considered themselves at less than average risk, average risk, or higher than average risk. Aerobic physical activity was measured based on self-reported minutes of moderate-to-vigorous aerobic activity per week, which were categorized into none (0 min/week), some aerobic physical activity (>0 min/week of activity but less than recommendation), and meeting the aerobic activity guideline (≥150 min of moderate-vigorous physical activity or ≥75 min of vigorous physical activity or 150 min of moderate physical activity/week). Multinomial logistic regression models that accounted for NHIS' complex survey design were used to estimate associations

between perceived risk of colorectal cancer (ref= less than average risk) with activity (ref= none). All models were adjusted for age, sex, education, race/ethnicity, and insurance.

RESULTS: After adjusting for covariates, compared with individuals who perceived themselves at less than average risk, those who perceived themselves at higher than average risk for colorectal cancer had 22% higher odds of engaging in some activity and 60% higher odds of meeting the aerobic activity guideline (Odds Ratio [OR]: 1.22, 95% Confidence Interval [CI]: 1.01-1.48; OR 1.60, 95% CI 1.37-1.86, respectively). In addition, those who perceived themselves at average risk for colorectal cancer had 25% higher odds of meeting the guideline (OR 1.25, 95% CI 1.07-1.47).

CONCLUSIONS: These findings suggest that perceived colorectal cancer risk may contribute to aerobic activity levels among adults. Although causal relations could not be established from these data, aerobic activity is known to aid in colorectal cancer prevention; therefore, adults who are aerobically active may be accurately perceiving their risk relative to those who are inactive. Future studies should use longitudinal designs to examine mechanisms that underlie this link.

Supported by NIH P20CA221697-02, P20CA221696-02, and P20CA221697-01S1.

The Effect of Familiarization on the Reliability of Isokinetic Assessment in Breast Cancer Survivors

Filipe Dinato de Lima¹, Sandro Nobre Chaves¹, Lucas Ugliara¹, Andrew Correa Fonseca¹, Jonathan Santana Sarandy¹, Natália Leite Colombelli², Claudio L. Battaglini, FACSM³, Martim Bottaro¹. ¹University of Brasília, Brasília, Brazil. ²University Center of Brasília, Brasília, Brazil. ³University of North Carolina at Chapel Hill, Brasília, Brazil. (Sponsor: Claudio L Battaglini, FACSM)
Email: fdinatolima@gmail.com
(No relevant relationships reported)

Muscle function plays an important role in quality of life of breast cancer survivors (BCS). Hence, several interventions have been proposed to improve muscle function during and after treatment. Thus, the assessment of muscular strength is essential for understanding the performance capacity of a BCS. Isokinetic dynamometer has been considered a gold standard method for assessing muscle strength in different populations. However, many internal and external factors in the isokinetic testing procedures can have an undesirable effect on the test results on BCS. **PURPOSE:** To assess the number of familiarization sessions required to test knee extensors strength and to state isokinetic dynamometer test-retest reliability to assess muscle function in BCS.

METHODS: Eleven breast cancer survivors (48.00 ± 6.25 years, 71.91 ± 11.55kg, 1.61 ± 0.06m) performed three isokinetic knee extension tests, separated by, at least, 72 hours. The isokinetic tests were composed by one warm-up set of 10 submaximal knee extensions at 120°/s, followed by two sets of four maximal knee extensions at 60°/s. All volunteers rested two minutes between sets. Muscle strength was determined as the greatest peak torque (PT) of each session. PT achieved in each session were compared with one-way ANOVA and Bonferroni adjustment. Typical error and intraclass correlation coefficients (ICC3.1) between non-different measures were calculated to determine test-retest reliability. **RESULTS:** Peak torque on the second session (119.18 ± 30.83 N.m) was significantly greater than first session (105.66 ± 30.21 N.m, p = 0.002). However, there was no difference between second and third sessions (121.30 ± 30.21 N.m, p = 0.885). Typical error and ICC_{3.1} between second and third sessions were 3.08 and 0.97, respectively (95% ICC confidence interval: 0.92 to 0.99).

CONCLUSIONS: Isokinetic dynamometer is a reliable device to assess muscle function on BCS. However, to assess knee extensors strength on the isokinetic dynamometer, BCS require one familiarization session.

927 Board #161 May 29 3:30 PM - 5:00 PM

Effects of a Smartphone Based Exercise Intervention on Quality of Life in Breast Cancer Survivors

Margaret F. Bedillion, Emily B. Ansell, Gwendolyn A. Thomas. Syracuse University, Syracuse, NY.
Email: mfbedill@syr.edu
(No relevant relationships reported)

A physically inactive lifestyle in breast cancer survivors elevates risk for recurrence, morbidity, and co-occurring chronic diseases. Exercise interventions, particularly those that combine both aerobic and resistance exercise, can help mitigate these risks and serve as an important pathway for promoting health and quality of life in breast cancer survivors. However, barriers to exercise may prevent adherence to recommended levels of activity. Smartphone based exercise programs may promote improvements in quality of life via a method that is both scalable and widely feasible for breast cancer survivors. **PURPOSE:** To determine the effects of a 6-week smartphone based aerobic and resistance exercise intervention on quality of life in breast cancer survivors.

METHODS: 34 women (age = 57.5 y.o) 6.7 years since diagnosis (YSD) were recruited through Army of Women, a national non-profit breast cancer organization,

to complete a 6-week intervention remotely. They were provided with a Fitbit and a mobile application that provided prompts to complete aerobic and resistance exercise. Additionally, written and video instructions were provided for each resistance exercise workout on the app. Surveys on depression and quality of life (Center for Epidemiologic Studies Depression, Short Form Health Survey, and Functional Assessment of Cancer Therapy - Breast Cancer) were completed pre and post the 6-week intervention. **RESULTS:** Regression analyses examined effects of aerobic and resistance exercise completed during the intervention on quality of life, controlling for YSD, race, stage, and BMI. Only resistance exercise was significantly associated with improvements in depression ($\beta = 0.431$, $t=2.79$, $p = 0.01$), social functioning as measured by the SF-36 ($\beta = -0.378$, $t=-2.25$, $p = 0.03$) and social well-being as measured by the FACT-B ($\beta = -0.361$, $t=-1.95$, $p = 0.06$). **CONCLUSIONS:** These findings demonstrate the unique effects of a brief resistance exercise program delivered via a mobile application in improving quality of life in breast cancer survivors. Mobile application based exercise interventions offer significant scalability and improved feasibility for breast cancer survivors who may have limited access to a supervised exercise program.

The Long-term Effects Of A Physical Activity Behaviour Change Intervention On Cancer Survivors' Levels Of Depression, Fatigue And Mental Well-being

Mairéad Cantwell¹, Bróna Furlong¹, Catherine Woods², Noel McCaffrey¹, Lisa Loughney¹, Fiona Skelly¹, Andrew McCarren¹, Niall Moyna¹. ¹Dublin City University, Dublin, Ireland. ²University of Limerick, Limerick, Ireland. (Sponsor: Dr. Michael Harrison, FACSM)
Email: mairead.cooney4@mail.dcu.ie
(No relevant relationships reported)

PURPOSE: Exercise is known to increase cancer survivors' cardiorespiratory fitness and strength, assist in the management of treatment related side effects and reduce the risk of cancer recurrence and mortality. The aim of this study was to determine the long-term effects of the MedEx IMPACT (IMprove Physical Activity after Cancer Treatment) trial, a patient centred, evidenced-based and theoretically informed physical activity behaviour change intervention, on cancer survivors' long-term levels of depression, fatigue and mental well-being (MWB).

METHODS: Adults with an established diagnosis of cancer, who had completed their adjunctive therapy, were referred to a community-based exercise rehabilitation programme (CBERP) for survivors of cancer known as 'MedEx Move On'. Participants in the control group (CG) and intervention group (IG) attended two 60-min supervised exercise classes each week for 12 weeks. In addition, participants in the IG also received: i) a home-based exercise programme, ii) 4 PA information sessions and iii) a 1:1 exercise consultation. At baseline, programme completion (week 12) and 3-month follow-up, depression, fatigue and MWB were measured using the Patient Health Questionnaire (PHQ-8), Functional Assessment of Chronic Illness Therapy-Fatigue Scale (FACIT-Fatigue) and the short Warwick-Edinburgh mental well-being scale (SWEMWBS), respectively.

RESULTS: One-hundred and ninety-one survivors of cancer were recruited (CG, n=87; IG, n=104; mean age 56 ± 10 yrs, 73% female). Cancer diagnoses were breast (60%), colorectal (16%), prostate (13%) and other (11%). On average, participants attended 66% of the supervised exercise classes (CG=67±22%; IG=65±27%). 97 participants (51%) completed the trial. Depression, fatigue and MWB significantly improved in both groups from baseline to week 12, and 3 month follow-up (p<.001). There were no statistically significant differences between the CG and IG.

CONCLUSIONS: Participation in a 12-week CBERP has a positive long-term effect on cancer survivors' levels of depression, fatigue and MWB. The inclusion of additional behaviour change strategies to the supervised exercise classes did not augment the benefits achieved.

Cancer Survivorship Fitness Program: College and Community Connect

Joseph O'Haire, Jill E. Mayer, Jennifer Hunter, Frank Micala. Ithaca College, Ithaca, NY.
Email: johaire@ithaca.edu
(No relevant relationships reported)

Evidence confirms that exercise has positive effects on physical functioning (PF) and quality of life (QOL) in cancer survivors after treatment. Long term medical complications may impact exercise ability and precautions need to be taken to ensure safety. Exercise scientists (ES) and physical therapists (PT) are ideal providers suited to prescribe exercise in this population. An educational clinic where ES and PT students work together may be a beneficial environment to provide fitness support to cancer survivors.

PURPOSE: To examine the effects of an interdisciplinary 8-week supervised exercise program in post-treatment cancer survivors on a college campus, hypothesizing that participants would improve in QOL and PF.

METHODS: Nine participants with various types of cancer, stages II-III, within 3 years of treatment were included in this pilot-study. QOL was measured using the Short Form-36 (SF-36). PF was measured using grip strength, 30 second sit to stand (30s STS), single limb stance, 6 minute walk test (6MWT), and sit and reach flexibility test. Measurements were taken at baseline and at the end of the 8 week program. Participants worked with ES and PT students at the campus fitness facility on an individualized program created by the pair with faculty oversight. Participants were encouraged to meet American College of Sports Medicine guidelines for cardiorespiratory endurance, muscular fitness, and flexibility. Results were analyzed using descriptive statistics.

RESULTS: Seven participants completed the study. The greatest gains in PF were demonstrated in the 6MWT, flexibility, 30s STS, and grip strength. Overall, 86% of participants improved in the majority of PF tests. QOL improved in 71% of participants for physical function but only in 43% of participants for general health subscales.

CONCLUSIONS: This is the first known study design to combine an interdisciplinary approach (ES and PT) to exercise care for cancer survivors in an academic setting. This supportive and collaborative environment allowed for an individualized program and participant monitoring from both disciplines. Furthermore, it permitted learning opportunities for students and fitness opportunities for cancer survivors to enhance the continuum of care.

(No relevant relationships reported)

Cancer treatments including surgery, chemotherapy, radiation, and hormone suppressant therapy have greatly improved the survival of breast cancer patients. Although these treatments have been successful in reducing breast cancer mortality, they are accompanied by long-term side effects that include accelerated losses in muscle mass and gains in fat mass. These changes lead to losses in strength and physical function. While resistance training programs have been shown to attenuate these negative changes in body composition, strength, and physical function, there is a lack of research examining the effects of resistance training combined with high impact training or a low impact yoga program to maintain or improve these measures. **PURPOSE:** To examine the effects of functional impact training (FIT) and yin yoga (YY) on body composition, strength, and physical function in breast cancer survivors (BCS). **METHODS:** Forty-four BCS (60.3 ± 8.3 yrs) were assigned to a 24-week FIT (resistance+high impact exercises) or YY intervention (stretching+relaxation) 2x/wk. Pre- and post-body composition measurements were assessed via dual energy X-ray absorptiometry. Upper body strength was measured by a one-repetition maximum chest press test. Lower body strength was assessed by Biodex isokinetic knee extension and flexion at 60, 120 and 180°/s. The Continuous Scale-Physical Functional Performance (CS-PFP) test assessed physical function. Data were analyzed using a repeated measures analysis of variance. Significance was accepted at p≤0.05. **RESULTS:** Body composition did not change. FIT improved upper body strength (73 ± 18 to 83 ± 22 kg) compared to YY (60 ± 15 to 59 ± 16 kg). Main time effects occurred for lower body strength with a mean extension and flexion improvement of 13% and 16%, respectively. A main time effect occurred for CS-PFP (68.53 ± 12.87 to 73.66 ± 12.62 U). **CONCLUSION:** Our findings suggest that FIT and YY are beneficial for strength and physical function in BCS. FIT may be a high impact alternative to traditional weight training for BCS while YY may be a viable option for BCS who require a program of lower intensity. Supported by: ACSM Doctoral Student Grant; NSCA Graduate Student Research Grant.

Cross-sectional Correlates of Physical Activity and Sedentary Time among Young Adult Cancer Survivors

Ashlen Kuntz, Leah Meuter, Gabrielle Jee, Cayetano Ramirez, Cami Christopher, Sarah Keade. *California Polytechnic State University, San Luis Obispo, CA.* (Sponsor: Todd Hagobian, FACSM)

(No relevant relationships reported)

Cancer survivors are less active than the general population. Previous research has examined predictors of physical activity among cancer survivors; however, few studies have focused on adolescent and young adult (AYA) survivors.

Purpose: To examine cross-sectional relationships between demographic, psychosocial, disease-related characteristics, and measures of physical activity (steps, MVPA, and sedentary time) among AYA cancer survivors.

Methods: Eligible participants were diagnosed with cancer between 18-39y, >6 months post-treatment, and engaged in <60 min/wk of exercise. Participants wore an activPAL monitor for 7-days to obtain estimates of physical activity and sedentary time. Participants self-reported their health history (e.g., cancer type and treatment), demographics, psychosocial correlates (e.g., self-efficacy), and symptoms (e.g., fatigue). We used Pearson correlations to assess bivariate relationships. For variables with significant correlations, we used linear regression models to assess the relationship between activity variables, demographics, and psychosocial factors.

Results: Fifty-four participants were eligible and provided informed consent; of those, 51 completed the baseline assessments and 48 had valid baseline data. Fatigue was significantly correlated with steps per day (R = -0.39), minutes of MVPA (R = -0.38), and percent of time sedentary (R = 0.40). There were no other significant correlations between psychosocial variables and steps, MVPA, or sedentary time. After adjusting for age and gender, breast cancer survivors had significantly higher steps per day than other cancer types (1,651 steps), more minutes of MVPA (13.7 min/day) and less sedentary time (-8.4%, p<0.05). The relationship between higher levels of fatigue, less physical activity, and more sedentary time remained significant after adjusting for age, gender, and cancer type (p<0.05).

Conclusions: Preliminary results indicate a significant relationship between higher levels of fatigue, more sitting time, and less daily physical activity. Future research is needed to determine if increasing physical activity will reduce fatigue in AYA cancer survivors. Supported by Frost Fund and Cal Poly RSCA Grant.

Social Representations About Physical Activity In A Group Of Women With Breast Cancer In Bogota

Oscar Jose Julián Castañeda Espitia, Sergio Jhoan Delgado Sanchez, Cindy Natalia Agudelo Cárdenas, Bernardo Castiblanco Torres. *Universidad Santo Tomás Colombia, Bogota, Colombia.*

Email: oscarcastaneda@usantotomas.edu.co

(No relevant relationships reported)

Abstract. The social representations are systems with an own logic and language with the function to establish an order both in the material and social world, which give explanations and generate codes to name and signify a lot of the experiences that accompany them. In the case of Physical Activity (PA) representation in patients with cancer, his meaning can be of vital importance for the illness coping. This investigation pretended identify the social representations of the physical activity (understanding P.A. as a mediator of all activity that generate pleasure, integration and identity to a group), in a group of women that live with breast cancer in Bogotá city. From a hermeneutic historical paradigm, a qualitative approach and a narrative design, we inquired 11 women that live with breast cancer about their representations of physical activity, using ATLAS TI as tool. A content analysis was developed, in which 65 codes and 18 emerging categories associated with the concepts of information, attitude and representational field were identified. According to this analysis physical activity is represented as a way to be more conscientious about their health and a mechanism that generates well being, favoring the quality of life. Likewise, it was recognized that physical activity is seen as an aspect that favors family relationships and a tool for strengthening networks generating attitudinal changes, a feeling of overcoming and the desire to help other people who live with the disease. The body and human movement in this disease is a mediator of the daily activities of women that gives a new meaning to cancer and the beliefs about the disease by making possible new alternatives of intervention in addition to the medical ones for management and treatment.

A wealth of evidence suggests exercise as a complementary therapy for breast cancer (BC), by reducing the expression of oncogenes and atrophy genes, inducing antioxidant defense pathways and helping combat chronic inflammation. However, exercise appears not to be adequately incorporated in the therapeutic strategy of cancer. **PURPOSE:** This study assessed the physical activity (PA) levels and quality of life (QoL) of women under different BC treatment strategies and compared them with those of age-matched healthy females.

METHODS: 141 women were recruited, 76 women with BC under chemotherapy or radiotherapy (age: 53.3 yrs, height: 1.61m, mass: 71.3kg, BMI: 26.7 kg/m²) and 65 healthy women who served as control group (age: 49.6 yrs, height: 1.65m, mass: 69.0kg, BMI: 25.3 kg/m²). Levels of PA were self-estimated with the International Physical Activity Questionnaire (IPAQ) and QoL with the SF-36 Health Survey questionnaire.

RESULTS: All BC women refrained from high-intensity PA, while 49.30% of the control group participated in high-intensity PA. However, 50.55% of women under radiotherapy, 44.43% under chemotherapy and 35.70% of women subjected to both therapies participated in moderate-intensity PA. They selected brisk walking as the preferred form of PA by 87.33%, 90% and 83.50%, respectively. In the control group, 50.70% of the individuals participated in moderate-intensity PA and 98.40% of them used to walk. Moreover, BC patients accumulated 8-10.3 h per day of sedentary lifestyle in contrast with the control group that spent 2 h per day sitting. When BC patients estimated their QoL, 15.30% of them assessed it as excellent, 60% as very good, 23.07% as average and 1.50% as poor. Similarly, 10.30%, 55.17%, 29.30% and 3.40% of the control group evaluated their QoL as excellent, very good, average and poor, respectively. **CONCLUSIONS:** Our findings revealed that BC patients didn't engage in high-intensity PA, however they estimated their QoL as very good. PA levels of moderate-intensity were similar in the two groups, indicating that BC patients were willing to exercise but refrained from doing more intense activities, possibly because of their cancer-related fatigue. Moreover, patients subjected to both therapies exhibited lower rates of PA, potentially due to the overall burden of the therapeutic intervention.

934 Board #168 May 29 3:30 PM - 5:00 PM
Effects of a Lifestyle Intervention on Self-Efficacy Outcomes in Prostate Cancer Patients Undergoing Androgen Deprivation

Brian C. Focht, FACSM¹, Alexander R. Lucas², Elizabeth Grainger¹, Christina Simpson¹, Ciaran M. Fairman³, Jennifer M. Thomas-Ahner¹, Jessica Bowman¹, Victoria R. DeScenza¹, Zachary L. Chaplow¹, Kathryn Dispennette¹, Marcy Haynam¹, Steven K. Clinton¹. ¹The Ohio State University, Columbus, OH. ²Virginia Commonwealth University, Richmond, VA. ³Edith Cowan University, Perth, Australia.
 (No relevant relationships reported)

Self-efficacy (SE) beliefs in one's ability to successfully satisfy the demands of planning and engaging in health behaviors are integral to successful exercise and dietary (EX+D) behavior change. Emerging evidence suggests lifestyle EX+D interventions result in improvements in a variety of clinically relevant outcomes in prostate cancer (PCa) patients undergoing androgen deprivation therapy (ADT). However, studies delineating the effects of EX+D interventions upon changes in key SE outcomes remain limited. **PURPOSE:** The purpose of the single-blind, randomized controlled Individualized Diet and Exercise Adherence-Pilot (IDEA-P) trial is to evaluate the preliminary efficacy of a combined exercise and dietary (EX+D) intervention, implementing a group-mediated cognitive behavioral (GMCB) approach, relative to standard of care (SC) treatment among PCa patients undergoing ADT. In the current study, we evaluated the effects of the EX+D intervention on select SCT outcomes at the end of the intensive phase of the intervention. **METHODS:** A total of 32 PCa patients (*M* age = 65 years) on ADT were randomly assigned to the EX+D (*n* = 16) or SC (*n* = 16) interventions. Measures of select SE outcomes were obtained at baseline and 2 and 3-month follow-up assessments. **RESULTS:** Results of intention to treat ANCOVA analysis of residualized change scores yielded a significant treatment main effects for (*p* < 0.05) for multiple SE outcomes. Post hoc analysis revealed that the EX+D intervention resulted in superior improvements in exercise (*d* = .62), coping (*d* = .68), and scheduling (*d* = .68) SE relative to the SC intervention at 3 months. Partial correlation analyses also revealed that scheduling and coping SE were significantly correlated with mobility performance (*p* < 0.01) and exercise participation

(*p* < 0.01) at 3 months. **CONCLUSIONS:** Findings from the IDEA-P trial suggest that the EX+D intervention, implementing a GMCB approach, resulted in superior changes in select SE outcomes relative to SC approach. Additionally, greater SE was related to superior mobility performance and exercise participation across the trial. These results underscore the utility of a GMCB-based EX+D intervention for promoting meaningful improvement in key SE outcomes among PCa patients undergoing ADT.

Relationship Between Perceived Fatigue & Muscular Performance Fatigability in Cancer Survivors

Ritielli Valeriano¹, Carlos A. Vieira², Filipe D. de Lima¹, Claudio L. Battaglini, FACSM³, Martim Bottaro¹. ¹Universidade de Brasilia, Brasilia, Brazil. ²Universidade Federal de Goias, Goiania, Brazil. ³University of North Carolina, Chapel Hill, NC.
 Email: ritielli@gmail.com
 (No relevant relationships reported)

BACKGROUND: Cancer related fatigue (CRF) is the most prevalent treatment-related side-effect in cancer survivors (CS). Few studies have verified the relationship between CRF to biochemical, psychological and behavioral factors. However, to date, the relationship between perceived fatigue (PF) and muscular performance fatigability (MPF) has not been evaluated in CS.

PURPOSE: To evaluate the relationship between PF and muscular performance fatigability in CS, after treatment.

METHODS: Nineteen CS participated on this preliminary/exploratory study. To evaluate MPF, the CS performed an unilateral isokinetic right knee extension, consisting of one set of 30 repetitions either at 90°.s-1 or 120°.s-1. MPF was defined as the decline in force during the 30 reps and was expressed as a percentage of the decline on knee torque. CS performed a warm-up consisting of one set of 10 reps at 120°.s-1 prior to testing. The PF was evaluated by the Multidimensional Fatigue Inventory (MFI-20), that comprises five subscales: general fatigue, physical fatigue, mental fatigue, reduced activity, and reduced motivation, with scores on each subscale ranging from 4 to 20, with higher scores indicating greater fatigue. The relationship between PF and MPF was analyzed using Pearson correlations. A significance level of *p* < 0.05 was used for all analyses.

RESULTS: Nineteen hematological CS, 32.9±2.0 years weight 72 ±11.57 kg, height 1.71±0.08 m participated in the study. CS reported an average general fatigue score of 12.3±3.3, physical fatigue of 10.9±3.8, mental fatigue of 11.4±3.8, reduced activity of 11.0±2.9 and reduced motivation of 8.1±2.8. MPF score was 56.9±8.9. There were significant moderate positive correlations between muscular performance fatigability and physical fatigue (*r*=0.45, *p*<0.04) and mental fatigue (*r*=0.57, *p*<0.01).

CONCLUSIONS: A significant correlation between MPF and the MFI physical fatigue and mental fatigue domains were observed. The results of this preliminary investigation warrants the need for further research necessary for a better understanding of mechanisms associated with physical and mental influences on muscular performance. The understanding of potential mechanisms are paramount for the development of exercise training interventions aimed to maximize muscle performance in CS.

Effects Of Exercise Dose And Type During Breast Cancer Chemotherapy On Longer-term Body Composition Outcomes

Dong-Woo Kang¹, Ki-Yong An¹, Andria R. Morielli¹, Christine M. Friedenreich², Donald C. McKenzie³, Karen Gelmon⁴, John R. Mackey⁵, Robert D. Reid⁶, Kerry S. Courneya¹. ¹University of Alberta, Edmonton, AB, Canada. ²Alberta Health Services, Calgary, AB, Canada. ³University of British Columbia, Vancouver, BC, Canada. ⁴British Columbia Cancer Agency, Vancouver, AB, Canada. ⁵Cross Cancer Institute, Edmonton, AB, Canada. ⁶University of Ottawa Heart Institute, Ottawa, ON, Canada.

(No relevant relationships reported)

PURPOSE: To examine the effects of different doses and types of exercise during breast cancer chemotherapy on body composition outcomes and the associations between self-reported physical activity and body composition outcomes at 1-year follow-up.

METHODS: The Combined Aerobic and Resistance Exercise (CARE) Trial randomized a total of 301 breast cancer patients during chemotherapy either to standard-dose (20-30 min/session) aerobic exercise (STAN; *n*=96), higher-dose (50-60 min/session) aerobic exercise (HIGH; *n*=101), or aerobic and resistance-combined (50-60 min/session) exercise (COMB; *n*=104). Each exercise program consisted of three sessions/week in supervised settings for one year. Body composition including lean body mass, whole body fat, and percent body fat was measured using dual x-ray absorptiometry. Physical activity levels were assessed by self-reported questionnaire

and categorized into meeting physical activity guidelines (aerobic only; strength only; combined; and neither). Assessment was conducted at baseline, post-intervention, and 12-month follow-up.

RESULTS: Of 301 patients, 284 (94.4%) and 263 (87.4%) completed body composition and self-reported physical activity assessment at 12-month follow-up, respectively. There were no significant effects of the randomized interventions on body weight, lean body mass, body fat mass, and percent body fat at 12-month follow-up; and no significant changes within each group. Meeting the combined physical activity guideline at 1-year follow-up was significantly associated with higher lean body mass compared to meeting neither guideline (+0.9 kg; $p = 0.017$). Moreover, meeting the aerobic guideline only was significantly associated with a lower body fat percent compared to meeting the combined guideline (-1.3%; $p = 0.049$) and with a higher lean body mass compared to meeting neither guideline (+0.8 kg; $p = 0.037$).

CONCLUSIONS: Combined or higher dose aerobic exercise during breast cancer chemotherapy was not superior to a standard dose of aerobic exercise for body composition outcomes at 1-year follow-up. Meeting the combined or aerobic guidelines during follow-up, however, was associated with higher lean body mass and lower percent body fat, respectively which can have implications for breast cancer outcomes.

A Modified Participatory Action Research Process To Enhance Utilization Of a Co-located Exercise Oncology Clinic

Mary A. Kennedy¹, Robert U. Newton¹, Sara Bayes¹, Dennis R. Taaffe, FACSM¹, Nigel Spry², Nicolas H. Hart¹, Michael Davis³, Daniel A. Galvão, FACSM¹. ¹Edith Cowan University, Joondalup, Australia. ²GenesisCare, Joondalup, Australia. ³GenesisCare, Wembley, Australia. (Sponsor: Daniel Galvão, FACSM)
 Email: m.kennedy@ecu.edu.au
 (No relevant relationships reported)

Exercise offers great potential as an adjunct therapy to reverse treatment-related side-effects and increase quality and quantity of life in people with cancer. Regardless, most patients do not exercise during treatment and it is often overlooked by clinicians as an important component of cancer care. Innovative implementation strategies are needed to overcome these barriers. A 5+ year partnership between the Exercise Medicine Research Institute at Edith Cowan University (ECU) and GenesisCare has demonstrated that co-locating an exercise clinic within a cancer treatment facility is a feasible solution, yet referrals and program uptake have been suboptimal.

PURPOSE: To investigate the barriers and facilitators to program referral and uptake and provide recommendations to optimize program utilization.

METHODS: A variation of participatory action research methodology was employed to understand the factors impacting exercise program referral and uptake, and to design solutions to improve both. A stakeholder advisory group (SAG) was convened to guide the process. Key stakeholders were identified as SAG members and a comprehensive mixed methods approach was used to gain feedback from all program users. Utilization and financial data were collected via clinic records.

RESULTS: This 6-month process successfully engaged key partner organizations and individuals, and led to the development of an implementation-ready program model. Multiple barriers and facilitators within and across the domains of the social-ecological model were revealed and accounted for in the model's development. Logistics (e.g., finances, hours of operation, referral pathways), programming options, and issues around clear communication within the system were targeted as major areas for improvement. Leadership's commitment to change and strong belief in the value and potential of the program were key to success.

CONCLUSION: The successful operation of a co-located exercise and cancer treatment facility requires leadership buy-in supported by a robust implementation plan that considers all domains of the social-ecological model. Stakeholders should be engaged throughout the process, using their input to create a clear vision that can be effectively communicated to all program users.

Feasibility And Adherence For Exercise During All Chemotherapy: EnACT

Kelsey G. Taylor, Erica A. Schleicher, Melanie Potiaumpai, Jessica Moyer, Natasha Burse, Kathryn Schmitz, FACSM. Penn State Hershey College of Medicine, Hershey, PA. (Sponsor: Kathryn Schmitz, FACSM)
 Email: ktaylor@phs.psu.edu
 (No relevant relationships reported)

Several national and international agencies recommend exercise following a cancer diagnosis. Current research suggests that exercise is safe and effective during adjuvant therapy and has been shown to improve fatigue, pain, physical function, symptom management, quality of life, depression and anxiety. Despite the evidence in favor

of exercising during chemotherapy, the acceptability and feasibility of an exercise intervention among cancer patients receiving chemotherapy remains unknown.

PURPOSE: To determine if an individualized exercise intervention is accepted by cancer patients receiving chemotherapy and is feasible for them to complete.
METHODS: One hundred sixty-eight patients diagnosed with cancer actively receiving chemotherapy were recruited for an out-patient exercise intervention. Participants were prescribed an individualized home-based exercise program that included resistance, aerobic, flexibility and balance exercises. Exercise equipment included resistance bands, and adjustable dumbbells. Participants were in the study either the length of their chemotherapy regimen or for six months, whichever came first. An exercise physiologist followed-up with participants during their regularly scheduled infusions to document the progress of their exercises and make any necessary adjustments to the exercise prescription. **RESULTS:** Seventy four participants (47F, 27M; 58.2 ± 11.9 years) completed the entirety of the exercise intervention. Feasibility was defined as completing one third of prescribed exercises and adherence was defined as the number of completed exercise sessions divided by the number of prescribed sessions. Overall 86.5% of participants reached the feasibility threshold. Patients with non-metastatic cancer had higher feasibility at 89.4% compared to patients with metastatic cancer at 81.5%. The adherence rate for aerobic, balance and flexibility training was 75%, while the resistance training adherence rate was 60%. Adherence rates were higher in the metastatic group, 76%, compared to the non-metastatic group, 70%. **CONCLUSION:** An exercise intervention for cancer patients receiving chemotherapy is feasible and the adherence rates are comparable to and even higher than those seen in previous exercise studies done with cancer patients.

Moving Medicine: Development Of An Exercise Oncology Tool For Clinical Practice

Rebecca Robinson¹, Kush Joshi², Hamish Reid², Natasha Jones², Mike Loosemore², Katy Hornby², Florence Newton¹. ¹Faculty of Sports and Exercise Medicine, Sheffield, United Kingdom. ²Faculty of Sports and Exercise Medicine, London, United Kingdom. (Sponsor: Kathryn Schmitz, FACSM)
 Email: rjrobinson@doctors.org.uk
 (No relevant relationships reported)

The Moving Medicine Cancer resource translates exercise oncology evidence into a tool for everyday practice in healthcare. It was created by the Faculty of Sport and Exercise Medicine in partnership with Public Health England and Sport England.

PURPOSE

Evidence that Physical Activity (PA) can mitigate cancer-related fatigue, deconditioning and late effects, positively impacting physical function, quality of life and survivorship continues to grow. However most people living with cancer do not attain recommended PA levels and under 10% of HCPs provide PA advice. The Moving Medicine digital resource is designed to overcome barriers and integrate PA into every healthcare contact.

METHOD

Created in a knowledge-into-action framework, Moving Medicine Cancer is one of 9 themes promoting PA in non-communicable disease. Development comprised two phases:

1. Knowledge creation

A literature search yielding 34000 papers found 500 relevant for inclusion.

Evidence was graded and divided into pre, during and post treatment. An expert multidisciplinary panel was recruited for consultation. An iterative process refined and prioritized evidence into clinical context.

2. Action cycle

Delphi study and COM-B framework analysis drove action cycle creation. This enabled end-user driven design.

RESULTS

The online tool is a time-based framework with practical information reflecting clinical priorities and accessible embedded evidence. It presents infographics with a conversational guide to support patient-focused consultation using behavioural change techniques. Moving Medicine was developed in collaboration with over 25 medical organisations and charities. Its launch in October 2018 by the UK Health Secretary received positive feedback. Formal evaluation will follow the initial delivery phase.

CONCLUSION

This novel resource harnesses current knowledge to facilitate quality conversations about PA across cancer care. As exercise oncology evolves, the Cancer Moving Medicine tool has capacity to develop precision PA prescription for the growing population of people living with and after cancer. Its developers welcome future collaboration with the international Exercise Oncology community to optimise health and wellbeing for patients. Moving Medicine is open access and free to use at www.movingmedicine.ac.uk.

Exercise During Chemotherapy And Its Effects On Symptom Management: Enact: Exercise In All Chemotherapy

Erica Schleicher, Melanie Potiaumpai, Kelsey Taylor, Jessica Moyer, Natasha Burse, Kathryn Schmitz, FACSM. *Pennsylvania State University, Hershey, PA.* (Sponsor: Kathryn Schmitz, FACSM)
Email: ericaaschleicher@gmail.com
(No relevant relationships reported)

Nearly half of all cancer patients undergo chemotherapy. Many patients experience chemotherapy-related side effects, including decreased quality of life. The American College of Sports Medicine recommends exercise following a cancer diagnosis and current research suggests that exercise is safe during chemotherapy and can be used as a complementary strategy to manage symptoms. **PURPOSE:** To examine whether an individualized exercise program delivered during chemotherapy can improve chemotherapy-related symptoms. **METHODS:** One hundred sixty-eight patients diagnosed with cancer actively receiving chemotherapy were recruited for a home-based exercise intervention. Participants were prescribed an individualized exercise program focusing on resistance, aerobic, flexibility, and balance training. Participants were in the study for the length of their chemotherapy regimen or up to six months, whichever came first. At baseline and completion of the study participants were asked to complete the following questionnaires: Brief Pain Index (BPI), European Organization for Research and Treatment of Cancer- Quality of Life (EORTC QLQ-C30), Patient-Reported Outcomes version of the Common Terminology Criteria for Adverse Events (PRO-CTCAE), and Fatigue Symptom Inventory (FSI). **RESULTS:** An interim analysis included seventy-four participants (47F, 27M; 58.2 ± 11.9 years). A Paired-Sample T-test analysis showed a significant increase in social functioning (MD=8.18, SD=27.38, p=.03) and a significant decrease in fatigue inference in regards to relations with others (MD= -0.38, SD=2.80, p=.01). Additionally, severity of headaches (MD= -0.31, SD= .60, p=.05) and frequency of nausea (MD=-0.47, SD=1.54, p=.02) significantly decreased with exercise. Severity of neuropathy significantly increased (MD=0.47, SD=1.24, p= .005), however, it did not significantly interfere with activities of daily living. Severity of pain and overall fatigue did not significantly change with exercise. **CONCLUSION:** These preliminary findings show that an individualized exercise program can improve some chemotherapy related symptoms and may help manage others.

941 Board #175 May 29 3:30 PM - 5:00 PM

The Effects of Different Intensity Exercise on Lactate Metabolism of DEN-induced Hepatocellular Carcinoma.

Lu Cao, Zhengtang Qi, Shuzhe Ding. *East China Normal University, Shanghai, China.*
Email: 982371586@qq.com
(No relevant relationships reported)

PURPOSE: Lactate is not only a waste product of glycolysis, but also an important signaling molecule regulating tumorigenesis. Lactate also is produced during exercise, but exercise can enhance body function to eliminate lactate. Whether exercise suppress tumorigenesis by regulating lactate metabolism? So the primary purpose of our investigation to compare the anti-tumor effect between different intensity exercise from the perspective of lactate metabolism.

METHODS: From 8 to 26 weeks of age, mice with DEN treatment run on the treadmill at different intensity. NC: injection saline only. DEN: injection DEN only. HIT: treatment DEN, running on the treadmill at 1.5km/h, alternating run 2 minutes and rest 2 minutes for 40 minutes once a day, 5 days a week. ET: treatment DEN, running on the treadmill at 0.8 km/h for 40 minutes once a day, 5 days a week. ELISA, RT-PCR and WB were used to evaluate relative serum, relative mRNA and protein expression. **RESULTS:** We found that tumor incidence was similar between DEN and HIT (66.7% vs. 62.5%); however, it was significantly smaller in ET compared to DEN and HIT (20% vs. 66.7%, 20% vs. 62.5%). The lactate in serum was significantly higher in HIT compared to DEN (25.817±2.696 vs. 18.668±1.086mmol/l, p<0.05.). The pyruvate in serum was also significantly higher in HIT compared to DEN (17.136±1.354 vs 13.545±0.545mmol/l, p<0.05). The lactate in mitochondria was significantly lower in ET compared to NC (0.453±0.047 vs. 0.703±0.066mmol/l, p<0.01), but there was no significant change in cytoplasm lactate dehydrogenase between each groups. Most importantly, we found that endurance exercise significantly increased the mRNA levels of COX1 in ET in liver, compared to NC, DEN and HIT (2.629±0.5 vs. 1.0±0.107, p<0.001, 2.629±0.5 vs. 0.884±0.154, p<0.01, 2.629±0.5 vs. 1.172±0.288, p<0.05). The mRNA levels of CYTb in ET in liver was significantly higher than NC and DEN (1.964±0.452 vs. 1.0±0.122, p<0.05, 1.964±0.452 vs. 0.829±0.140, p<0.05). The mRNA levels of NDI in ET in liver was also significantly higher than NC and DEN (1.894±0.433 vs. 1.0±0.176, p<0.05, 1.894±0.433 vs. 0.654±0.069, p<0.01).

CONCLUSIONS: Long-term endurance exercise decreased the hepatic tumor incidence and improved the mitochondrial function. But high-intensity interval exercise increased the lactate production.

942 Board #176 May 29 3:30 PM - 5:00 PM

Exercise during Chemotherapy Improves Physical Function: Findings from EnACT: Exercise in All Chemotherapy

Melanie Potiaumpai, Erica Schleicher, Kelsey G. Taylor, Jessica Moyer, Natasha Burse, Kathryn Schmitz, FACSM. *Penn State University College of Medicine, Hershey, PA.* (Sponsor: Kathryn Schmitz, FACSM)
(No relevant relationships reported)

Current research shows that exercise during chemotherapy is safe, feasible, and effective at improving physical function and managing symptom severity and interference in a number of different cancer types. Despite the positive findings of exercise during chemotherapy, referral for exercise during treatment has not yet become standard of care. Additionally, there is a lack of information on the effectiveness of an institute-wide exercise program for patients receiving chemotherapy. **Purpose:** To evaluate changes in objectively-measured physical function in patients receiving chemotherapy after receiving a personalized exercise prescription. **Methods:** One hundred sixty eight subjects (65M, 103F; 59.32 ± 11.83 years) actively receiving chemotherapy enrolled in an out-patient exercise intervention. Participants were given home-based exercises that included resistance, aerobic, flexibility, and balance exercises. Exercise equipment included resistance bands and adjustable dumbbells. Physical function (PF), was measured using the 30-second chair stand (30CST), Timed-Up-and-Go (TUG), Hand-Grip Strength (HGS), and the 4-Stage Balance test (BAL). Data collection was performed prior to beginning the exercise program and following completion of their chemotherapy regimen (non-metastatic patients) or 6 months after starting EnACT (metastatic patients). **Results:** Eighty two subjects completed physical function testing. A Paired-Samples T-test analysis showed a significant increase in the 30CST (MD= .74, SE= .34, p= .03) and a significant decrease in TUG (MD= -0.42, SE= .19, p= .03). There were no significant changes in HGS for either right or left hand. While the BAL also showed no significant changes after the exercise intervention, the Instep balance test showed a trend towards significant increases in performance time (MD= 0.31, SE= .17, p= .06). **Conclusion:** These preliminary results indicate that integrating a personalized exercise prescription into standard of care is efficacious in improving physical function despite the rigorous burden of receiving chemotherapy. Improving the physical function of patients during chemotherapy may prevent future treatment-related decrements in functional capacity and the need for rehabilitative measures.

(No relevant relationships reported)

Scientists and healthcare professionals are utilizing social media to amplify their scientific impact, acquire and share information, and communicate research to a broader audience. As such, researchers are looking for ways to engage this medium to promote scientific findings while also providing networking opportunities, particularly when costs associated with conference travel are high. **Purpose:** To examine the use of a Twitter Conference as a means to effectively communicate advances in the field of exercise oncology. **Methods:** The Exercise Oncology Twitter Conference (ExOncTC) occurred in October, 2018. Each presentation consisted of six tweets over 15 minutes, each using the official conference hashtag (#ExOncTC). Attendees were able to interact during a presentation via the conference hashtag. Website registration data was used to descriptively characterize presenters and registered participants while Twitter Analytics (twitter.com) and Union Metrics (unionmetrics.com) were used to aggregate data to determine engagement and reach. **Results:** The ExOncTC featured 68 presenters from 13 countries and 48 unique institutions. Presenters varied in academic background, ranging from undergraduate students (1.5%) to terminal degree holders (46%), and profession (inc. professors/researchers (42.5%) and M.D.s (6%)). Participants, including researchers, physicians, students, patients, and cancer organizations, could officially register via the website (n=231), follow the @ExOncTC Twitter handle (n=805), or search the conference hashtag (#ExOncTC). During the conference, #ExOncTC was tweeted 1,501 times by 483 unique users for 4,943 total engagements (number of times a user interacts with a tweet). Collectively, these tweets reached 453,900 unique users and 145,000 impressions (number of times users saw a tweet) with potential impressions equaling 1.8 million (total number of

views possible). **Conclusions:** Total reach of the ExOneTC demonstrates the potential effectiveness of utilizing a Twitter conference as a platform to communicate the field of exercise oncology. When considering the low financial and environmental costs, as well as the opportunity to increase scientific communication across populations, Twitter conferencing should be explored as a tool for scientific dissemination.

Effects of Taichi-Qigong Exercise On QoL of Nasopharyngeal Carcinoma Survivors

Xiaoyue HU, Stanley Sai-chuen HUI, FACSM. *The Chinese University of Hong Kong, Shatin, Hong Kong.* (Sponsor: Stanley Sai-chuen Hui, FACSM)

Email: mooncahu@link.cuhk.edu.hk

(No relevant relationships reported)

The incidence of nasopharyngeal carcinoma (NPC) in endemic areas is high. The long-term chemotherapy and radiotherapy cause bodily dysfunction and low quality of life (QoL) in NPC survivors. Complementary therapy especially mind-body exercise such as Taichi-Qigong becomes an option for NPC survivors to improve the QoL.

Purpose: To examine the effects of 10 weeks Taichi-Qigong training and health education lectures on QoL of NPC survivors. **Methods:** Thirty eligible participants were recruited and randomly assigned into either intervention or control group. 14 of NPC survivors (n=7 for intervention group; n=7 for control group) completed pre-post assessment of QoL satisfactory. The intervention group practiced the active, low-intensity 18-form internal Taichi-Qigong exercise for at least 3 times a week for 10 weeks plus three health education seminars during the 10-weeks intervention period. The control group engaged in the health education seminars only over the 10-weeks period. QoL was assessed by Functional assessment of cancer therapy - General (FACT-G) which included four subscales: physical well-being (PWB), social well-being (SWB), emotional well-being (EWB) and functional well-being (FWB). **Results:** Significant differences were found on subscales of EWB (p=0.011), and the effects of Taichi-Qigong on SWB is marginally significant (p=0.056). **Conclusion:** The results of this study provide preliminary data to support that Taichi-Qigong exercise, as a complementary therapy, may contribute to positive effects for NPC survivors in terms of improved QoL outcomes.

945 Board #179 May 29 3:30 PM - 5:00 PM

Objectively Assessed Physical Activity And Sedentary Behavior In Patients With Advanced Renal Cell Carcinoma

Philipp Zimmer¹, Kathrin Schlüter², Sybill Hessler², Valerie Perrot³, Heiko Wunderlich⁴. ¹German Sport University Cologne, Cologne, Germany. ²IPSEN Pharma GmbH, Ettlingen, Germany. ³IPSEN SAS, Boulogne-Billancourt, Germany. ⁴St. Georg Hospital Eisenach, Eisenach, Germany.

Reported Relationships: P. Zimmer: Consulting Fee; IPSEN Pharma GmbH. Industry contracted research; IPSEN Pharma GmbH.

PURPOSE: Increased levels of physical activity are associated with decreased cancer risk and mortality in many cancer types. Moreover, physical activity is known to reduce several side effects of cancer and its treatment thereby improving patients' quality of life. So far, most studies have focused on frequently observed types of cancer, such as breast-, prostate-, lung- and colorectal carcinoma. Recent data from epidemiological studies also reported such relationships for renal cell carcinoma (RCC). Observational studies have included heterogeneous populations in view of stage of disease and type of treatment. Further, collected data on physical activity have based on self-reported assessments, representing a major limitation of these trials.

METHODS: Against this backdrop we have initialized the multicenter observational CABOCARE trial in Germany and Austria. Patients with advanced RCC (n=105) are recruited after treatment decision for cabozantinib has been made. Cabozantinib is an inhibitor of receptor tyrosine kinases c-MET, VEGFR and AXL, which has proven to prolong progression free survival (PFS) compared to standard care with sunitinib. Patient characteristics, state of disease, occurrence of adverse events, quality of life (FACT NFKSI-19), self-reported physical activity (newly developed visual analogue scales) as well as objective physical activity, sedentary behaviour and sleep data (Actigraph® GT9X Link device) are recorded at baseline, and each-three months thereafter. **RESULTS/ CONCLUSIONS:** Thereby, CABOCARE (NCT03647878) will be the first observational trial collecting objective physical activity and sleep data and their associations with PFS, adverse events and quality of life in patients with advanced RCC in a longitudinal fashion. The trial has opened in September 2018. Here we would like to present data of the first patients.

Effect of High Intensity Interval Training on Cardiorespiratory Fitness in Breast Cancer Patients Undergoing Anthracycline Chemotherapy

Kyuwan Lee, Citlalin Lopez-Torres, Caia Rice, Christina Dieli-Conwright, FACSM. *U of Southern California, Los Angeles, CA.* (Sponsor: Christina Dieli-Conwright, FACSM)

Email: kyuwanle@usc.edu

(No relevant relationships reported)

PURPOSE: Anthracycline is a cardio-toxic chemotherapy regimen to treat breast cancer, however, breast cancer patients experience significantly impaired cardiorespiratory fitness (CRF) during and after anthracycline chemotherapy. Exercise, particularly, high-intensity interval training (HIIT), appears to be more effective than continuous steady-state exercise training for increasing CRF in patients with heart failure. It remains unclear whether HIIT improves CRF in breast cancer patients undergoing anthracycline chemotherapy. We sought to determine the effects of HIIT on CRF, measured by $\dot{V}O_{2max}$, in breast cancer patients undergoing anthracycline chemotherapy.

METHODS: Thirty breast cancer patients were randomized to either the HIIT (n=15) or delayed (DEL; n=15) groups. CRF was assessed at baseline and post-intervention using a maximal cycling protocol to obtain $\dot{V}O_{2max}$. Peak power output (PPO) was obtained at the last stage of testing to prescribe intensity of HIIT. The HIIT group participated in an 8-week HIIT intervention 3 times per week on a cycle ergometer. Each HIIT session included 7 alternating bouts of 90% PPO followed by 10% PPO. The DEL group was offered the same HIIT intervention after the 8 week study period. Paired t-test and repeated measures ANOVA were performed to assess changes in CRF. **RESULTS:** At baseline, the HIIT and DEL groups did not differ by age (46.9±9.8 yr), BMI (31.0±7.5 kg/m²), and $\dot{V}O_{2max}$ (18.8±5.9 ml/kg/min). At post-intervention, $\dot{V}O_{2max}$ significantly decreased (19.4±3.9 to 16.2±3.1; -16.5±7.9%) in the DEL group (P<.01). $\dot{V}O_{2max}$ did not change post-intervention in the HIIT group (18.2±7.6 to 18.3±7.7 ml/kg/min; 0.5±6.2%; P>.05). There was no group (HIIT vs DEL) x time interaction (Pre vs Post) following the 8-week intervention (P>.05). **CONCLUSIONS:** An 8-week HIIT intervention did not significantly improve CRF in breast cancer patients undergoing anthracycline chemotherapy, however HIIT may be an option to maintain CRF during anthracycline chemotherapy.

Physiological Fitness Efficiency of Breast Cancer Survivors Improves Despite Maintenance of Aerobic Capacity: Preliminary Analysis

Jordan T. Lee¹, Chad W. Wagoner¹, Stephanie A. Sullivan¹, Erik D. Hanson¹, Brian C. Jensen¹, Lee Stoner, FACSM¹, Aaron Piepmeier², Kirsten A. Nyrop¹, Hyman B. Muss¹, Claudio L. Battaglini, FACSM¹. ¹University of North Carolina Chapel Hill, Chapel Hill, NC. ²University of Rhode Island, South Kingstown, RI. (Sponsor: Dr. Claudio Battaglini, FACSM)

Email: jlee25@live.unc.edu

(No relevant relationships reported)

PURPOSE: To evaluate the ranges of physiological fitness responses of breast cancer survivors (BCS) following a 16-week community-based exercise intervention. **METHODS:** Cardiopulmonary exercise testing was used to evaluate aerobic capacity ($\dot{V}O_{2peak}$), time to exhaustion (TTE), Borg rating of perceived exertion (RPE), max power, and peak lactate. Brachial cuff tonometry was used to evaluate augmentation index (AIx@75) and subendocardial viability ratio (SEVR). Assessments were completed pre-post 16-weeks of progressive aerobic and strength training exercise at a community-based center. Specific attention was directed at evaluating the range of changes per outcome. Descriptive statistics were used to characterize the sample, paired t-tests to assess pre-post changes in study outcomes. **RESULTS:** Twenty BCS (mean±SD; 58±9.6yrs, 166±8cm, 75±15kg) participated and were evaluated. Mean changes (min, max; p-value) revealed AIx@75= -3.4(-27, 18.5; p=0.17), SEVR=7(-11, 36; p<0.05), $\dot{V}O_{2peak}$ =0.5(-6.2, 6.8; p=0.5)mL/kg/min, TTE=60(-6, 132; p<0.001) sec, RPE=0(-5, 4; p=0.9), peak power=15(-1, 34; p<0.001)Watts, lactate=1.1(-1.1, 4.7; p<0.01)mmol. **CONCLUSION:** All 20 patients produced the same or significantly more work at post testing despite no change in aerobic capacity, demonstrating greater physiological efficiency. The heterogeneity of responses observed support the notion that tailored training programs are likely necessary to maximally benefit individual patients. Means to significantly improve or prevent declines in $\dot{V}O_{2peak}$ like those observed in some patients within our study, are critical as $\dot{V}O_{2peak}$ relates to

comorbidity and mortality. However, community-based exercise programs can be a powerful tool for improving other physiological outcomes related to cardiovascular health and physical fitness. Supported by funding from Breast Cancer Research Foundation of New York.

948 Board #182 May 29 3:30 PM - 5:00 PM
Acute Effect of Aerobic Exercise on Arterial Stiffness in Breast Cancer Survivors: Preliminary Results

Georgios Grigoriadis¹, Brooks A. Hibner¹, Elizabeth C. Schroeder¹, Alexander J. Rosenberg², Garrett Griffith³, Amanda V. Sardeli⁴, Oana C. Danciu¹, Bo Fernhall, FACSM¹, Tracy Baynard, FACSM¹. ¹University of Illinois at Chicago, Chicago, IL. ²University of North Texas Health Science Center, Fort Worth, TX. ³Northwestern University, Chicago, IL. ⁴University of Campinas, São Paulo, Brazil. (Sponsor: Tracy Baynard, FACSM)

(No relevant relationships reported)

Breast cancer survivors (BCS) who underwent chemotherapy treatment have increased risk of cardiovascular disease (CVD). Chemotherapy contributes to increased arterial stiffness. Acute aerobic exercise has been demonstrated to be effective in improving arterial stiffness in healthy individuals, however, it is unknown if BCS have a similar response to aerobic exercise. **PURPOSE:** To determine if arterial stiffness is different between BCS and healthy controls following acute aerobic exercise. **METHODS:** Seven BCS (48 ± 4 yrs; 26.0 ± 2.8 kg/m²) and seven female controls (43 ± 9 yrs; 22.7 ± 3.5 kg/m²) completed a 30-min bout of aerobic cycling exercise at 65% of their maximal aerobic capacity. Central arterial stiffness was evaluated by pulse wave velocity (PWV) via applanation tonometry at baseline, 5 and 30-min post exercise. Hemodynamic variables [cardiac output (Q), heart rate (HR), and mean arterial blood pressure (MAP)] were acquired with an automated ambulatory blood pressure monitor. Carotid arterial stiffness was determined using ultrasonography [β-stiffness index, pressure-strain elasticity modulus (Ep) and arterial compliance (AC)]. **RESULTS:** See Table. Both groups had similar increases in AC at 30-min compared to 5 min post-exercise ($p < 0.05$). HR increased in both groups post exercise ($p < 0.05$); however, BCS had an overall higher HR compared to the control group ($p < 0.05$). There were no differences in PWV, β-stiffness, Ep and AC responses following exercise between the groups. **CONCLUSIONS:** These results suggest that BCS have similar arterial stiffness responses compared to a healthy control group. Interestingly, PWV decreased (approached significance), while AC decreased following exercise, showing a possible differential response between the aorta and carotid artery, suggesting more investigation in this area.

| | Group | Baseline | 5-min | 30-min |
|----------------------------|---------|-------------|-------------|-------------|
| PWV (m/s) | BCS | 7.0 ± 1.5 | 6.6 ± 0.7 | 6.6 ± 0.9 |

949 Board #183 May 29 3:30 PM - 5:00 PM
Do Taxane Based Chemotherapies Impair Improvements in VO₂ in Female Cancer Survivors

Stephen LoRusso¹, Henry Piascik¹, Karen Wonders, FACSM². ¹Saint Francis University, Loretto, PA. ²Maple Tree Cancer Alliance, Dayton, OH.

Email: slorusso@francis.edu

(No relevant relationships reported)

Purpose: To determine if female cancer patients who underwent taxane-based chemotherapies benefited from exercise as compared to those who received non-taxane based treatments. **Methods:** Retrospectively, 101 females (57.88 ± 11.59), with female cancers (Breast (79), Ovarian (10), Endometrial (4), Uterine (2), and Cervical (1)) enrolled in a cancer rehabilitation program underwent a variety of fitness assessments, but only measures of VO₂ are reported here. Each subject was provided an individualized mixed home (2 days) and facility based (1 day) 12 week exercise intervention. **Results:** A strong positive correlation between VO₂₁-VO₂₂

($r = 0.802$, $p = 0.000$), a low to moderate negative correlation between VO₂₁+age ($r = -0.365$, $p = 0.000$), a low negative correlation between VO₂₂+age ($r = -0.215$, $p = 0.036$) were found. A significant change from VO₂₁ to VO₂₂ ($t = -5.372$, $p = 0.000$) was determined. While there were no differences between Taxane and Non-Taxane measures of VO₂, there was a trend in percent change in VO₂ ($F = 3.306$, $p = 0.073$). There were also no differences in any measure of VO₂ between taxane and non-taxane treatments by cancer type. Regression analysis indicated only age ($t = 2.775$, $p = 0.007$) predicted percent change in VO₂ values and VO₂ 1 values ($t = -3.606$, $p = 0.001$), while age and cancer type predicted VO₂₂ values ($t = -2.117$, $p = 0.037$; $t = -2.217$, $p = 0.029$ respectively). **Conclusion:** The data does not support the hypothesis that taxane based chemotherapies result in lower VO₂ values, as both age and cancer type had greater overall effects on VO₂. Additionally, significant improvements in VO₂ after the 12-week exercise intervention, regardless of treatment type, age, or cancer type supports the effectiveness of exercise-based cancer rehabilitation program to improve VO₂ in a female cancer population.

950 Board #184 May 29 3:30 PM - 5:00 PM
Taxane Based Chemotherapies Impact on Balance and VO₂ in Female Cancer Survivors.

Maura Jegerski¹, Karen Wonders, FACSM², Stephen LoRusso¹.

¹Saint Francis University, Loretto, PA. ²Maple Tree Cancer Alliance, Dayton, OH.

Email: slorusso@francis.edu

(No relevant relationships reported)

Purpose: The purpose of this study was to determine if taxane based chemotherapies have an impact on VO₂ and or balance versus non-taxane based chemotherapies in female cancer survivors. **Methods:** Twenty-six females (Avg. 58.11 years 29-72), enrolled in a cancer rehabilitation program underwent a treadmill assessment of VO₂ and four measures of balance (TUG, 4stage, sittostand, 6MWT). **Results:** No differences were found in measures of balance or VO₂ between those who received taxane based chemotherapies vs. non-taxane based chemotherapies ($p > 0.05$). Significant increases in HR ($t = 10.71$, $p = 0.000$) and Dyspnea ($t = 5.96$, $p = 0.000$) occurred with significant correlations between pre-exercise ($r = 0.605$, $p = 0.001$) and post-exercise ($r = 0.729$, $p = 0.001$) Dyspnea and RPE. Trends in associations between TUG and 6MWT ($p = 0.073$), 4stage and VO₂ ($p = 0.057$), 6MWT and 4stage ($p = 0.08$) were also observed. Significant positive correlation between 6MWT and VO₂ ($r = 0.487$, $p = 0.012$) and a negative correlation between %change in Dyspnea and VO₂ ($r = -0.474$, $p = 0.014$) were found. A negative correlation between pre-exercise HR and 6MWT speed ($r = -0.441$, $p = 0.027$) and strong positive correlation between 6MWT distance and 6MWT Speed ($r = 0.968$, $p = 0.000$). 6MWT distance moderately predicted VO₂ ($r = 0.487$, $F = 7.461$, $p = 0.012$). **Conclusion:** The data does not support the hypothesis that taxane based chemotherapies affect VO₂ values, or measures of balance. However, trends suggest a larger population might detect an association among the balance measures and VO₂ and therefore perhaps detect a difference. Expected changes and associations between RPE and Dyspnea were found, with lower scores likely associated with higher fitness as evidenced by negative correlation between %change in Dyspnea, 6MWT speed and pre-exercise HR and 6MWT speed and distance.

951 Board #185 May 29 3:30 PM - 5:00 PM
The Effect Of Doxorubicin On Myocardial Extracellular Matrix Degradation

Wisam O. Najdawi¹, Eric C. Bredahl¹, Joan Eckerson, FACSM¹, Jacob Siedlik¹, Kristen Drescher². ¹Creighton University, Omaha, NE. ²Creighton School of Medicine, Omaha, NE. (Sponsor: Joan Eckerson, FACSM)

Email: WisamNajdawi@creighton.edu

(No relevant relationships reported)

Doxorubicin (DOX) is an effective anthracycline chemotherapy agent associated with several adverse side effects including cardiotoxicity. Although the mechanism responsible for the cardiotoxic effects of DOX has yet to be fully elucidated, the leading theory is that the generation of reactive oxygen species (ROS) damages cardiomyocytes and leads to cell death. ROS play a role in the expression and activation of matrix metalloproteinases (MMPs), a family of enzymes involved in extracellular matrix (ECM) degradation. Normally, MMP activity is regulated by tissue inhibitors of metalloproteinases (TIMPs). We hypothesized that DOX treatment would lead to overexpression of MMPs or underexpression of TIMPs, which would compromise the integrity of the myocardial ECM and disrupt cardiac function.

PURPOSE: To investigate the effects of DOX on MMP-2, MMP-9, and TIMP-2 expression in rat cardiac tissue. **METHODS:** At 20 weeks of age, Sprague Dawley rats received a bolus injection of DOX (12 mg/kg; n=6) or saline (0.9%; n=8) as a control. Five days post-injection, cardiac tissue was collected from each animal, homogenized, and standardized for protein content. Samples were analyzed for expression of MMP-2, MMP-9, and TIMP-2 using western blotting with enhanced chemiluminescence. All results were normalized to GAPDH. Data were analyzed using a Student's T-Test ($\alpha = 0.05$). **RESULTS:** Results showed significantly lower expression of MMP-9 in

cardiac tissue from animals treated with DOX relative to the control ($p = 0.0068$). There was no significant difference in expression of MMP-2 ($p = 0.8757$) or TIMP-2 ($p = 0.2266$) between groups. **CONCLUSIONS:** These findings suggest that treatment with DOX significantly reduced the expression of MMP-9, contradicting our hypothesis. A potential explanation for these findings is that there is an intermediate factor affecting MMP-9 expression. Future studies should profile all components of MMP/TIMP signaling during DOX treatment.

952 Board #186 May 29 2:00 PM - 3:30 PM Evaluating Physiological Stress Response in Junior LevelTrack and Field Athletes

Eon Campbell, Rachael Irving, Lowell Dilworth, Janel Bailey.
The University of The West Indies, Mona, Kingston 7, Jamaica.
(Sponsor: Melanie Poudevigne, FACSM)
Email: ceon88@yahoo.com
(No relevant relationships reported)

Exercise and competition function as stress factors and may result in dysregulation in the neuroendocrine and cardiovascular systems. **PURPOSE:** The intent of the study was to evaluate neuroendocrine and cardiovascular response using salivary cortisol and heart rate/ blood pressure respectively in junior track and field athletes across a season. **METHOD:** Fifty-One Jamaican junior level track and field athletes (26 females, 25 males) participated in the study. Data was collected throughout the athletic season over two main periods: (1) a preparation period and (2) a competition period which was further subdivided into two stages: development game stage and major game stage. Athletes delivered a saliva sample prior to bedtime (8 pm - 10 pm) during each phase of the season. Resting blood pressure and heart rate were monitored throughout the season. Data collected during the preparation and competition periods were compared using Friedman's test and Wilcoxon signed-rank test. **RESULTS:** There were significant changes in salivary cortisol across the season $p < 0.05$. The concentration of cortisol increased during the development game stage (42%), then further increased in the major game stage (53%). With regard to cardiovascular response, there were significant differences in heart rate across the season $p < 0.05$. However, there was no significant change in blood pressure across the season in the athletes. **CONCLUSION:** Overall, there was an increase in cortisol across the season. This could possibly be due to the accumulation of stress factors over the competitive season which might be due to improper training regimens. Resting heart rate and blood pressure may not be good indicators of stress in athletes.

953 Board #187 May 29 2:00 PM - 3:30 PM The Acute Cardiovascular And Respiratory Responses To Isotonic Versus Isometric Whole Body Resistance Exercises

Andrew Scott, James Daubney, Courtney Green, Barnaby Lyons, George Nicholas, Manisha Patel. *University of Portsmouth, Portsmouth, United Kingdom.*
Email: andrew.scott@port.ac.uk
(No relevant relationships reported)

PURPOSE: Aerobic exercise is recommended for blood pressure control rather than resistance exercise. However, resistance exercise is gaining prominence, particularly isometric exercise. The purpose was to compare the cardiorespiratory responses to whole body isotonic (IT) and isometric (IM) resistance exercises.

METHODS: 8 normotensive males (21 ± 2 years) completed one familiarisation session, then an IM and IT session in a counter-balanced order, each separated by at least 72 hours. 10-repetition maximum (10-RM) for each exercise was determined in the familiarisation session. IM were held in the mid-range for 40 seconds and IT were performed for 10 repetitions with 2 seconds concentric and 2 seconds eccentric. Single sets of dumbbell lunge, barbell bench press, barbell squat, bent-over barbell row, and dumbbell shoulder press were performed, with 150 seconds rest between exercises. Oxygen uptake (VO_2) was collected continuously. Blood pressure (BP) and heart rate (HR) were recorded post-exercise. Rate-pressure product (RPP) was calculated from HR and BP. Energy expenditure (EE) was calculated from VO_2 . Repeated measures analyses were applied to the data.

RESULTS: Mean EE was significantly greater during IT (6.14 ± 0.65 kcal) than IM (4.52 ± 0.73 ; $p=0.024$), with EE greater during IT compared to IM for lunge (6.86 ± 1.55 v 4.98 ± 0.92 kcal; $p=0.033$), squat (8.32 ± 1.80 v 4.54 ± 1.14 kcal; $p=0.002$), and row (6.66 ± 0.82 v 5.36 ± 0.77 kcal; $p=0.001$). Mean systolic BP (137 ± 12 v 134 ± 11 mmHg; $p=0.609$) and diastolic BP (73 ± 13 v 73 ± 4 mmHg; $p=0.923$) were not significantly different between IT and IM for the five exercises. Mean RPP was not

significantly different between IT (18086 ± 2764) and IM (16879 ± 2386 ; $p=0.300$), but was significantly greater during squat in IM (18668 ± 2217) and IT (20080 ± 4017) compared to bench press in IM (15023 ± 2324 ; $p=0.025$) and IT (15858 ± 2379 ; $p=0.003$). Systolic BP was not significantly reduced 60 minutes following IT (-8 ± 9 mmHg; $p=0.053$) and IM (-10 ± 15 mmHg; $p=1.05$) or diastolic BP (-0 ± 9 mmHg; $p=1.000$) following IT, however diastolic BP significantly reduced following IM (-10 ± 11 mmHg; $p=0.028$).

CONCLUSIONS: An IT resistance exercise session induced significantly greater energy expenditure while an IM resistance exercise session induced significantly greater post-exercise diastolic hypotension.

954 Board #188 May 29 2:00 PM - 3:30 PM Effects of Acute Moderate Exercise on Nitric Oxide and Endothelial Microparticles in Patients with Hypertension

Yan Yan, Xuemei Li, Juan Wang, Yan Wang, Zhengzhen Wang, FACSM. *Beijing Sport University, Beijing, China.* (Sponsor: Zhengzhen Wang, FACSM)
(No relevant relationships reported)

PURPOSE: Nitric oxide (NO) is a strong vasodilator released by endothelial cells, and endothelial microparticles (EMP) are membranous vesicles released into the circulation from activated or apoptotic endothelial cells, both of whose level can reflect the endothelial function. But few research explored the effect of exercise on nitric oxide and endothelial microparticles. The purpose of the study was to evaluate the effects of acute moderate exercise with different duration on NO and EMP in young male patients with grade 1 hypertension.

METHODS: Seventeen young male patients with grade 1 essential hypertension (SBP between 140-159 and/or DBP between 90-99 mmHg) who did not take antihypertensive drugs were recruited in this study. They randomly performed twice exercises on a bicycle ergometer at a moderate intensity of 40%-50% of their HR reserve; one was 20 min (E20 group), the other one was 40 min (E40 group); there was one week break between two exercises. The level of NO (nitrate/nitrite reduction) and EMP (flow cytometry) in plasma were detected before and immediately after exercise. CD31⁺/CD42⁻ events were defined as EMP and were expressed as events per ml plasma.

RESULTS: Mean age of patients was 34.8 ± 3.5 yrs, and BMI was 27.6 ± 2.7 kg/m². The plasma NO level of E20 and E40 increased significantly after exercise (65.75 ± 23.97 umol/L vs. 71.37 ± 25.18 umol/L and 64.08 ± 23.13 umol/L vs. 77.94 ± 23.73 umol/L, $P < 0.01$ for both). There was no difference in plasma NO level between the two groups before and after exercise, but the increase of NO level in E40 was greater than that in E20 (24.47% vs. 9.24% , $P < 0.01$). The plasma EMP level of E20 and E40 decreased significantly after exercise (1968.38 ± 399.40 vs. 1814.99 ± 388.25 and 1891.43 ± 334.15 vs. 1604.61 ± 351.61 , $P < 0.01$ for both). There were no difference in plasma EMP level between the two groups before and after exercise, but the decrease of EMP level in E40 was greater than that in E20 (15.66% vs. 8.00% , $P < 0.01$).

CONCLUSION: Both 20-min and 40-min acute moderate exercise can improve endothelial function by increasing nitric oxide and decreasing endothelial microparticles level in patients with hypertension, and the effect of 40-min is better than that of 20-min. Supported by Research on Prevention and Control of Major Chronic Non-communicable Diseases (2016YFC1300202).

PURPOSE: We investigated whether changes in oxygen uptake (VO_2), blood acidosis, or peripheral muscle oxygenation became limiting factors when interval exercise increases above the maximal intensity. **METHODS:** A group of nine active but not specifically trained male volunteer subjects participated in our study (age: 23 ± 3 yrs., body mass: 72 ± 7 kg, height: 177 ± 5 cm and $\text{VO}_{2\text{max}} = 57 \pm 5$ ml.kg⁻¹.min⁻¹). The exercise was conducted on an electronically braked cycle ergometer and consisted of two tests. The first test (T1) consisted of initial warmup, followed by 10×1 min maximal intensity and 1 min recovery intervals to determine if all subjects were able to complete the required 10 intervals. Several days later, subjects conducted a second test (T2) that was identical to the T1 with the exception that the workload was increased by 40 W above the workload conducted in T1. During tests, we determined individual maximal intensities, VO_2 and the resulting $\text{VO}_{2\text{max}}$. The respiratory gas exchange

measures, blood acid-base, muscle oxygenation and heart rate (HR) were determined. Exercise values and recovery intervals from 3rd to final repetition were compared between T1 and T2 intensity using two-way repeated measures ANOVA. **RESULTS:** Subjects reached 9±1 intervals during T1 (350±40 W) compared to 5±2 during T2 (390±40 W) due to fatigue. $\dot{V}O_2$ increased from 3.33±0.34 in T1 to 3.83±0.53 l·min⁻¹ in T2 ($p=0.006$). Pulmonary ventilation (\dot{V}_E) increased from 77±31 in T1 to 117±27 l·min⁻¹ in T2 ($p=0.04$). HR increased from 171±12 beats per minute (bpm) in T1 to 178±9 bpm in T2 ($p=0.03$). Although, blood lactate concentration (LA) increased and blood pH values decreased considerably during T2, they were similar to values at exhaustion in T1 test. None of the muscle oxygenation variables: oxyhemoglobin (HbO₂), deoxyhemoglobin (HHb) and total hemoglobin (Hb_{tot}) changed significantly. **CONCLUSION:** The results of our study revealed that changes in blood acidosis and muscle oxygenation during tests were the limiting factors and not the $\dot{V}O_2$ uptake.

Sodium Induced Volume Loading and the Exercise Pressor Reflex

Evan L. Matthews, John J. Del Vecchio, Peter A. Hosick.
Montclair State University, Montclair, NJ.
 Email: matthewse@montclair.edu
 (No relevant relationships reported)

The average American consumes far more sodium than is recommended. Consuming high amounts of sodium may augment blood pressure (BP) responses to physical stress like exercise. Exaggerated BP responses to exercise are thought to be an early symptom of some cardiovascular diseases like hypertension. **PURPOSE:** This analysis contains two studies. The purpose of study one was to determine at what time point both blood plasma and serum sodium would be consistently elevated following sodium and water consumption. The purpose of study two was to examine if elevated plasma and serum sodium result in an elevated BP response to handgrip (HG) exercise and the cold pressor test (CPT). **METHODS:** Study 1: Eight participants drank 423mL of normal saline (sodium 154mmol/L) and had repeat blood draws every 30min for 3hr. Study 2: Sixteen different participants underwent two randomized data collection visits; an experimental (EXP) visit 90min following normal saline consumption and a control (CON) without saline consumption. At each visit beat-by-beat BP and heart rate were recorded during a 5min rest period followed by 2min of isometric HG at 30% maximal voluntary contraction. Two minutes of post exercise ischemia (PEI) were performed immediately following HG. After a ≥10min rest, participants underwent a 2min CPT. **RESULTS:** Study 1: Both plasma volume (+6.8 ± 1.3 %Δ) and serum sodium (+3.5 ± 1.3 %Δ) were elevated ($p<0.05$) at or before the 90min time point and remained elevated throughout the 3hr follow-up period. Study 2: There were no significant differences in mean arterial pressure (MAP) during HG (EXP: 17.4 ± 2.1 mmHg; CON: 19.1 ± 1.5 mmHg), PEI (EXP: 16.9 ± 2.9 mmHg; CON: 16.9 ± 1.9 mmHg), or the CPT (EXP: 20.3 ± 2.7 mmHg; CON: 20.9 ± 2.9 mmHg) between conditions ($P>0.05$). MAP recovery from the CPT was significantly slower in the saline condition (1min recovery: EXP; 15.7 ± 2.0 mmHg, CON; 12.3 ± 2.2 mmHg, $P<0.05$). **CONCLUSIONS:** The current data found no significant differences in cardiovascular responses during handgrip or the cold pressor test between conditions. However, a modest delay in the recovery of blood pressure was found following the cold pressor test during sodium and volume loading. This suggests acute salt and water consumption increases cardiovascular strain following an intense physical stressor.

Recovery Pattern of Cardiac Autonomic Control Following Aerobic Exercise with Different Volumes in Hypertensive Men

André C. Michalski, Guilherme F. Fonseca, Victor A. B. Costa, Tainá B. Pryor, Paulo C. Junior, Tainah P. Lima, Felipe A. Cunha. *State University of Rio de Janeiro, Rio de Janeiro, Brazil.*
 (No relevant relationships reported)

The recovery pattern of cardiac autonomic control to acute aerobic exercise (AE) is a robust index of individual ability to recruit vagal tone and may provide further evidence of the risks and benefits of a typical AE bout to promote health. However, the extent to which postexercise autonomic control, as assessed by heart rate variability (HRV), depends on exercise volume remains unclear in hypertensive individuals. **PURPOSE:** The present study investigated the effect of cycling bouts with different volumes on HRV markers in hypertensive men. **METHODS:** Ten unmedicated men [age: 39±7 yr; body mass index: 29.3±1.0 kg/m²; maximal oxygen uptake ($\dot{V}O_{2max}$): 26.7±0.8 mL·kg⁻¹·min⁻¹; 24-h ambulatory systolic/diastolic BP (SBP/DBP): 139±8/86±7 mmHg] visited the laboratory four times to undertake the following procedures: a) assessment of resting and maximal $\dot{V}O_2$; b) perform a non-exercise control session (CTL) and two AE expending 150 (AE150) and 300 kcal (AE300) at 50% $\dot{V}O_{2reserve}$ in a randomized, counter-balanced order. The root mean square of successive R-R differences calculated for consecutive 30-s windows (rMSSD 30s) was calculated to assess the vagal reactivation during the first 5 min of recovery in a supine

position via cardiachometer (RS800cx, Polar TM, Finland). Prolonged HRV analysis [i.e. low-frequency band (LF), high-frequency band (HF), and sympatho-vagal balance (LF:HF ratio)] was performed during the subsequent 21-h under ambulatory conditions using a three-channel Holter (CardioLight, Cardios Ltda, Brazil). Marginal models were used to compare HRV changes between trials. **RESULTS:** Significant differences for rMSSD 30s were only detected between CTL vs. AE150 [Δ - 38.8 ms ($P<0.001$)] and CTL vs. AE300 [Δ - 40.0 ($P<0.001$)]. Within the subsequent 21-h of recovery, no significant differences were observed among CTL, AE150 and AE300 for LF, HF and LF:HF ratio.

CONCLUSIONS: These findings suggest that exercise volume is not a major determinant of exercise prescription when considering the recovery pattern of cardiac autonomic control in hypertensive men, at least when AE is performed at moderate-intensity.

Pulse Wave Reflection Responses After Aerobic Exercise with Different Volumes in Normotensive and Hypertensive Men

Guilherme Fonseca, Tainah de Paula, Mario Neves, Felipe Cunha. *State University of Rio de Janeiro, Rio de Janeiro, Brazil.*
 Email: guilhermefonseca08@gmail.com
 (No relevant relationships reported)

Although aerobic exercise (AE) has been established as effective for lowering blood pressure (BP), little is known about the alterations in aortic BP after exercise. **PURPOSE:** To investigate the acute pulse wave reflection responses after moderate AE with different volumes in normotensive (NT) and hypertensive (HT) men. **METHODS:** We included 14 normotensives [age: 40.7±2.8 yr; body mass index (BMI): 25.7±0.9 kg/m²; maximal oxygen uptake ($\dot{V}O_{2max}$): 31.3±1.8 mL·kg⁻¹·min⁻¹; 24-h ambulatory systolic/diastolic BP (SBP/DBP): 120.6±1.6 / 73.9±1.2 mmHg] and 10 hypertensive men [age: 39.2±2.3 yr; BMI: 29.3±1.0 kg/m²; $\dot{V}O_{2max}$: 26.7±0.8 mL·kg⁻¹·min⁻¹; 24-h ambulatory SBP/DBP: 139.3±2.6 / 86.4±2.1 mmHg]. Participants undertook a maximal cardiopulmonary exercise test, a non-exercise control session (CTL), and two cycling bouts at 50% $\dot{V}O_2$ reserve (150 vs. 300 kcal) in a randomized order. Aortic systolic blood pressure (SBPa), aortic pulse pressure (PPa), augmentation pressure, and augmentation index were determined using applanation tonometry 10 min before, and 30- and 70-min after CTL and the two exercise bouts (SphygmoCor v7). **RESULTS:** In NT, AE50%-150kcal decreased SBPa in comparison with CTL, until 30 min of recovery [CTL: [9.2±0.9 mmHg; AE50%-150cal: [-0.5±2.8 mmHg ($p<0.05$)]. However, in HT men, only AE50%-300kcal attenuated the SBPa increase observed in the CTL (CTL: [9.2±0.9 mmHg ($p<0.001$); AE50%-300cal, [4.9±2.3 mmHg ($p=0.07$)). In addition, NT men showed a decrease in PPa after all AE bouts, without differences between conditions. In the HT group, both AE bouts attenuated the PPa increase observed in CTL (CTL: [4.3±0.1 mmHg ($p<0.05$); AE50%-150cal, [1.6±1.4 mmHg ($p=0.41$); AE50%-300cal, [2.6±3.9 mmHg ($p=0.18$)). Lastly, only AE50%-150kcal was able to reduce pulse wave reflection until 30 min of recovery in NT men. **CONCLUSION:** In NT, lower AE volume was able to reduce pulse wave reflection and central BP until 30 min of recovery. However, only the greater AE volume attenuated the increase in central aortic BP and PPa, with no difference in pulse wave reflection after any experimental protocol in the HT group.

Peak Physiological Responses In Cycling And A New Underwater Swimming Test In Highly Trained Artistic Swimmers

Eric Viana¹, David J. Bentley², Adam Pinos¹, Lars MacNaughton³, Heather M. Logan-Sprenger¹. ¹University of Ontario Institute of Technology, Oshawa, ON, Canada. ²Canadian Sport Institute Ontario, Toronto, ON, Canada. ³Edge Hill University, Ormskirk, United Kingdom.
 (No relevant relationships reported)

PURPOSE: The purpose of this study was to compare peak oxygen uptake ($\dot{V}O_{2peak}$) measured in an underwater swim test (UWST) and during a maximal aerobic capacity test on a cycle ergometer (Velotron Pro, Seattle, WA, USA). **METHODS:** Highly trained artistic swimmers (n=14, 14.9 ± 1.9 yrs) completed a synchronised swimming specific test (275m UWST) in a 25m pool an incremental exercise test to volitional fatigue (15 W every 30 sec to exhaustion) on a cycle ergometer to determine $\dot{V}O_{2peak}$. The UWST and maximal aerobic capacity testing occurred on consecutive days. The 275m UWST comprised 50m freestyle followed by 25m underwater breast stroke three times, with an additional 50m freestyle. During the UWST participants wore water-resistant HR monitors (Polar OH1) and had expired gases collected (Cosmed K4 b²) in the 20 sec immediately upon completion of the UWST to determine $\dot{V}O_{2peak}$. During the cycle test, HR (Polar Electro, Kempele,

Finland) and expired gases were collected using a MOXUS metabolic cart (AEI Technologies, Pittsburgh, PA, USA). Peak physical work capacity (PWC) (W) was measured as the highest completed 30 sec stage of the test.

RESULTS: VO_{2peak} achieved after the UWST (44.3 ± 8.0 mL/kg/min) and cycle ergometer (42.3 ± 7.2 mL/kg/min) did not differ significantly from each other ($t=-0.59$, $df=13$, $p=0.563$, $d=0.21$). HR_{peak} was significantly lower during the UWST (162.5 ± 18.4 bpm) ($t=7.812$, $df=12$, $p<0.00$, $d=2.10$) when compared to the cycle test (194.6 ± 11.6 bpm). The UWST time and PWC during the bike test were not significantly correlated to each other ($r=-0.25$, $p=0.393$). There was no significant correlation between the VO_{2peak} achieved during the UWST and the duration of the UWST ($r=-0.39$, $p=0.17$). HR_{peak} during the UWST was significantly correlated with the VO_{2peak} ($r=0.62$, $p=0.03$, CI_{95} [38.93, 46.44]) and HR_{peak} achieved on the cycle ergometer ($r=0.59$, $p=0.04$, CI_{95} [188.79, 200.92]).

CONCLUSIONS: The similarities in VO_2 data during the UWST and VO_{2peak} protocol suggest the UWST is a valid method of determining VO_{2peak} in highly trained artistic swimmers. A goal when selecting a VO_2 protocol is to mimic the demands of the sport. In this population, the UWST is likely better than the cycle ergometer, as the modality of swimming with breath holding more closely matches the demands of an artistic swim routine.

Sex Differences in Autonomic Function Following Aerobic Exercise

Noelle Merchant, Joe Champagne, Huimin Yan. *University of Massachusetts Boston, Boston, MA.*
 Email: noelle.merchant001@umb.edu
 (No relevant relationships reported)

Heart rate variability (HRV), blood pressure variability (BPV) and baroreceptor sensitivity (BRS) provides insight into cardiovascular regulation in different physiological settings. Pre-menopausal females have been shown to exhibit a cardioprotective autonomic profile compared to males following maximal exercise, but it is unknown if there are sex differences in autonomic recovery following submaximal aerobic exercise.

PURPOSE: To determine the effects of sex on autonomic function at rest and following an acute bout of submaximal aerobic exercise.

METHODS: Forty-three (males n=22, age = 22 ± 1 yrs, BMI = 25.9 ± 0.7 kg/m²; females n=21, age = 22 ± 1 yrs, BMI = 23.7 ± 0.5 kg/m²) healthy, normotensive participants completed a 45-min moderate intensity aerobic exercise session. Beat-to-beat BP was recorded using finger plethysmography for 5 min prior to exercise (REST), at 30 min (P30), 60 min (P60) and 90 min (P90) following exercise. Frequency domain measurements of HRV and BRV were calculated. The low frequency power of BPV (BPV_LF) was used as an estimation of sympathetic vasomotor tone and the ratio of low- (LF) and high-frequency (HF) bands in HRV (LF/HF) has been used to quantify the degree of sympathovagal balance. BRS was estimated by the alpha coefficient method (Alpha_LF). Repeated measures analysis of variance (ANOVA) (2 x 4; sex x time-point) was performed.

RESULTS: Data were presented in Table 1 as mean \pm standard error.

CONCLUSION: Forty-five min of submaximal aerobic exercise results in sustained disturbance of cardiovascular homeostasis as manifested by elevated sympathovagal balance and increased cardiovagal baroreceptor sensitivity 90 min after exercise. In addition, young, healthy women exhibited lower sympathetic tone at rest and during recovery from aerobic exercise compared to age-matched males.

| Table 1. Autonomic function variables at rest and 30,60, and 90 mins following aerobic exercise | | | | | | | | |

Augmentation of Oxygen Uptake Response through Inhalation of Molecular Hydrogen during an Incremental Exercise Test

Amane Hori, Hisayoshi Ogata, Masatoshi Ichihara, Takaharu Kondo, Norio Hotta. *Chubu University, Kasugai, Japan.*
 Email: amane199679@gmail.com
 (No relevant relationships reported)

It has recently been shown that molecular hydrogen (H2) ameliorates oxidative stress-induced tissue damage by scavenging reactive oxygen species and modifies mitochondrial function. However, studies on the effects of H2 during exercise in healthy humans are limited. **PURPOSE:** To investigate the effects of H2 gas inhalation on oxygen uptake (VO2) response during an incremental exercise test performed on a cycle ergometer. **METHODS:** This study was designed as a single-blind, randomized, controlled trial. Eight men and a woman (height, 169.4 ± 8.0 cm; age, 22.4 ± 5.54 years; weight, 64.9 ± 9.8 kg [means \pm SD]) volunteered to perform an incremental cycling exercise test while inhaling two kinds of gases: 1% H2 gas (H2 trial) and air (control trial). The workload was gradually increased by 20 W every 1 min until volitional fatigue. Respiratory parameters were measured during the test using a metabolic gas analyzer. The peak VO2 (VO2peak) was defined as a 20-s averaged peak value of VO2 during exercise. Blood samples were collected from the subjects' fingertips before, during, and immediately after exercise to evaluate the systemic redox status by measuring biological antioxidant potential (BAP) and diacron-reactive oxygen metabolites (d-ROMs). **RESULTS:** The result of repeated-measure two-way analysis of variance showed no significant trial-by-work rate interaction in carbon dioxide production ($P = 0.64$), respiratory exchange ratio ($P = 1.00$), minute ventilation ($P = 0.81$), and heart rate ($P = 1.00$) responses to the exercise. However, the H2 trial showed a significantly augmented VO2 response to exercise compared with that observed in the control trial ($P < 0.05$). Furthermore, the H2 trial showed a significantly increased VO2peak compared to the control trial (3705.4 ± 285.9 vs. 3398.7 ± 249.9 mL/min, means \pm SE, $P < 0.01$, paired t-test). BAP/d-ROM responses, indicative of systemic redox status, tended to increase in the H2 trial compared to the response in the control trial ($P = 0.05$), suggesting that the H2 trial reduced oxidative stress or increased antioxidative activity. **CONCLUSIONS:** H2 gas inhalation significantly increased the VO2 response and VO2peak during incremental exercise, suggesting that H2 gas might affect mitochondrial function during exercise.

Heavy Rope Exercise on Cardiovascular Hemodynamics and Arterial Stiffness in Resistance-Trained Individuals
 Jason C. Parks, Erica M. Marshall, Tyler J. Singer, Stacie M. Humm, J. Derek Kingsley, FACSM. *Kent State University, Kent, OH.* (Sponsor: J. Derek Kingsley, FACSM)
 (No relevant relationships reported)

Heavy rope exercise is utilized as a means to increase power, muscle hypertrophy and maximal strength. However, the effects of heavy rope exercise on cardiovascular hemodynamics and arterial stiffness is not known. **PURPOSE:** To evaluate the effects of an acute bout of heavy rope exercise on cardiovascular hemodynamics and arterial stiffness. **METHODS:** Fifteen resistance-trained individuals volunteered to participate. Cardiovascular hemodynamics and arterial stiffness were collected at rest, 15 (Rec1), 30 (Rec2) and 60 (Rec3) minutes after an acute bout of heavy rope exercise. Cardiovascular hemodynamics were determined through the use of photoplethysmography, and included heart rate (HR), mean arterial pressure (MAP), cardiac output (CO), stroke volume (SV), and total peripheral resistance (TPR). Arterial stiffness was measured via carotid-femoral pulse wave velocity (cfPWV). The acute heavy rope exercise consisted of six, 15-second exercise bouts, using a double wave pattern, separated by 30-second passive recovery intervals; the pace of the exercise was set at 180bpm. One-way repeated measures analysis of variance were used to evaluate the main effect of time (rest, Rec1, Rec2, and Rec3) on all variables. Paired t-tests, with a Bonferroni correction, were used for post-hoc comparisons. **RESULTS:** There were no significant main effects of time for MAP or SV. There were significant ($p=0.0001$) main effects of time for HR (rest: 64 ± 11 bpm; Rec1: 86 ± 10 bpm; Rec2: 78 ± 10 bpm; Rec3: 72 ± 9 bpm), CO (rest: 6.8 ± 0.7 L/min; Rec1: 8.3 ± 1.1 L/min; Rec2: 7.9 ± 0.9 L/min; Rec3: 7.5 ± 0.9 L/min) and TPR (rest: 12 ± 1.2 mmHg/mL/min; Rec1: 9.8 ± 1.1 mmHg/mL/min; Rec2: 10.6 ± 1.1 mmHg/mL/min; Rec3: 11.3 ± 1.1 mmHg/mL/min). HR, and CO were elevated at all times post-exercise, and were higher at Rec1 compared to Rec2, and Rec3, and were lower at Rec3 compared to Rec1 and Rec2. TPR was reduced at Rec1, Rec2 and Rec3 compared to rest. There was also a significant main effect of time ($p=0.003$) for cfPWV (rest: 5.6 ± 0.8 m/s; Rec1: 5.9 ± 0.7 m/s; Rec2: 5.7 ± 0.8 m/s; Rec3: 5.5 ± 0.7 m/s) such that it was attenuated at Rec3 compared to Rec1 and Rec2. **CONCLUSIONS:** These data demonstrate that acute heavy rope exercise increases cardiovascular workload for at least 60 minutes, as demonstrated by the augmentation of HR and CO for up to one-hour post-exercise.

Hemodynamic and Pressor Responses to Combination of Yoga and Blood Flow Restriction
 Savannah V. Wooten, Sten Stray-Gundersen, Hirofumi Tanaka, FACSM. *The University of Texas at Austin, Austin, TX.* (Sponsor: Hirofumi Tanaka, FACSM)
 Email: svwooten@utexas.edu
 (No relevant relationships reported)

Blood flow restriction (BFR) training has been increasingly incorporated into a more common activity of daily exercise (e.g., yoga). However, BFR may increase blood pressure and myocardial oxygen demand by augmenting vascular resistance. Yoga is characterized by systemic isometric exercises and accompanied by marked pressor responses. This raises the concern of exaggerated cardiovascular responses when yoga is performed with BFR. **Purpose:** To determine the impact of a combination of yoga and BFR on cardiovascular responses. **Methods:** Twenty young healthy participants ($M=10$, $F=10$) performed 20 yoga poses with and without BFR bands placed on both legs. Beat by beat blood pressure and heart rate were measured using finger plethysmography during the yoga exercise. Blood lactate concentration, flow-mediated dilation (endothelium-dependent vasodilation), and cardioankle vascular index (arterial stiffness) were measured before and after the yoga exercise. **Results:** At baseline, there were no significant differences in any of the variables between the BFR and non-BFR conditions. Systolic and diastolic blood pressure and heart rate increased significantly in response to the various yoga poses ($p<0.01$). However, there were no significant differences between the BFR and non-BFR conditions. In general, hemodynamic responses were more pronounced during more difficult yoga postures (e.g., Crescent Lunge, Half Moon, Chair Pose, and Downward Facing Dog). Rate-pressure products increased significantly during yoga exercises with no differences between the two conditions. Rating of perceived exertion (RPE) was not different between the conditions. Blood lactate concentration was significantly greater after performing yoga with BFR bands ($p=0.007$). Cardioankle vascular index decreased similarly after yoga exercise in both conditions while flow-mediated dilation remained unchanged. **Conclusion:** The use of blood flow restriction bands in combination with systemic isometric exercise like yoga did not result in marked hemodynamic and pressor responses.

Cardiac Autonomic and Blood Pressure Responses to an Acute Session of Battling Ropes Exercise
 Douglas R. Bergen¹, Alexei Wong¹, Michael Nordvall¹, Arturo Figueroa, FACSM². ¹Marymount University, ARLINGTON, VA. ²Texas Tech University, Lubbock, TX. (Sponsor: Arturo Figueroa, FACSM)
 Email: drb96235@marymount.edu
 (No relevant relationships reported)

Increased blood pressure (BP) and autonomic dysfunction are independent risk factors for cardiovascular disease. Heart rate variability (HRV) is used as a measure of cardiac autonomic function in many research settings, including the evaluation of the autonomic control during and after physical activity. A prolonged sympathetic predominance and a slow parasympathetic reactivation contribute to a delayed BP and heart rate (HR) recovery after exercise which is thought to be associated with increased risk of acute cardiac events. Therefore, understanding the impact of various exercise modalities on the post-exercise autonomic modulation of HR and BP would allow for appropriate exercise prescription in susceptible populations. Battling ropes exercise (BRE) has become an extremely popular training modality for improving both anaerobic and aerobic fitness. However, the HRV and BP responses induced by an acute BRE bout are currently unknown. **PURPOSE:** To evaluate the effects of an acute session of BRE on HRV and BP responses in healthy young males. **METHODS:** 8 young healthy males [age (23 ± 1 years)] completed a BRE or a no-exercise control trial in a randomized order. During the BRE trial, participants completed ten-30s sets of battling ropes waves followed by 1 min of rest. Low-frequency power (LF), high-frequency power (HF), the LF to HF ratio (LF/HF), HR, and BP were collected in the supine position at baseline, 3, 10 and 30 min after each trial. LF and HF were normalized to total power resulting in nLF, nHF and nLF/nHF. **RESULTS:** There were significant group-by-time interactions ($P<0.05$) for nLF (sympathetic activity), nHF (vagal tone), nLF/nHF (sympathovagal balance), HR, systolic and diastolic BP. There were significant increases ($P<0.05$) in nLF, nLF/nHF, and HR as well as significant decreases ($P<0.01$) in nHF, systolic (~ 6 mmHg) and diastolic (~ 4 mmHg) BP for 30 min after BRE compared to no changes after control. **CONCLUSIONS:** Our findings indicate that BRE increases sympathovagal balance 30 min post-exercise which is concurrent with a sustained hypotensive effect in young healthy males. Further research is warranted to evaluate the potential clinical application of BRE in populations that might benefit from post-exercise hypotension.

Renal Vascular Responsiveness to Sympathetic Activation is Not Affected by Prior High Intensity Anaerobic Exercise
 Jonathan Larson. *University at Buffalo, Buffalo, NY.* (Sponsor: Zach Schlader, FACSM)
 (No relevant relationships reported)

Purpose: Orthostatic hypotension is common following high intensity anaerobic exercise. The renal vasculature contributes to blood pressure regulation during orthostasis. Renal blood flow decreases during anaerobic exercise and remains depressed for up to 60 min following exercise cessation. The responsiveness of the renal vasculature to sympathetic stimulation, such as during orthostasis, following anaerobic exercise is unknown. We hypothesize that prior high intensity exercise attenuates increases in renal vascular resistance (RVR) during sympathetic activation. **Methods:** Ten healthy adults (23 ± 3 y) completed two 2 min cold pressor tests (CPT). The CPT stimulates the sympathetic nervous system. A CPT was completed before and after a Wingate Anaerobic Test that consisted of 30 s of maximal effort cycling exercise at a resistance equal to 7.5% body mass. In both instances, the CPT was administered following 10 min supine rest. Heart rate (ECG), mean arterial pressure (Penaz method, MAP), and renal blood velocity (RBV) were measured pre-CPT, at 1 min and 2 min of the CPT, and 1 min post-CPT. RBV was measured via the coronal approach at the distal segment of the right renal artery with Doppler ultrasound. RVR was calculated as MAP/RBV. Data are presented as mean \pm SD. **Results:** Pre-CPT, heart rate was elevated after exercise (61 ± 5 vs. 87 ± 13 bpm, $P<0.01$) and RBV was lower (34 ± 7 vs. 32 ± 7 cm/s, $P=0.02$). However, MAP (85 ± 13 vs. 82 ± 13 mmHg, $P=0.50$) and RVR (2.4 ± 0.5 vs. 2.6 ± 0.7 mmHg/cm/s, $P=0.08$) were not different between before and after exercise. Before exercise, heart rate (at 2 min CPT: 66 ± 9 bpm, $P=0.02$) and MAP (at 2 min CPT: 108 ± 21 mmHg, $P=0.05$) increased during the CPT, returning to pre- levels 1 min post-CPT ($P=0.22$). Before exercise, RBV decreased during the CPT (at 2 min: 29 ± 7 cm/s, $P=0.03$), returning to pre- levels 1 min post-CPT ($P=0.61$). RVR increased during the CPT (at 2 min: 4.0 ± 0.7 mmHg/cm/s, $P<0.01$), returning to pre- levels 1 min post-CPT ($P=0.28$). Changes in heart rate, MAP, RBV, and RVR during the CPT did differ between before and after exercise (interaction: all $P\geq 0.74$). **Conclusion:** Increases in RVR invoked by sympathetic activation are not affected by prior high intensity anaerobic exercise. Therefore, the renal vasculature does not likely contribute to post- anaerobic exercise orthostatic hypotension.

 (No relevant relationships reported)

The recording of heart rate variability (HRV) is a strategy for the rapid and non-invasive evaluation of the Autonomic Nervous System (ANS) activity. Previous studies have shown a rapid activation of the parasympathetic nervous system at the end of a physical effort and the association of this with the likelihood of developing cardiovascular disease. **PURPOSE:** Establish the relationship between recovery heart rate (RHR) after exercise and HRV at rest in apparently healthy men and women. **METHODS:** Quantitative, cross-sectional, exploratory research conducted in 50 subjects (25 men and 25 women) of 19 ± 2.34 years. Subjects were monitored by continuous electrocardiographic reading all throughout the different activities. The HRV was evaluated at rest for 5 minutes, using time, frequency and non-linear analyzes, cardiac vagal index (CVI) was calculated using $\text{Log}_{10}(\text{SD1} * \text{SD2})$. Subsequently, a physical test of 6 minutes on the bike was performed between 50 and 60% of the maximum reserve heart rate. In the end, the RHR was evaluated every 10 seconds during the first minute. Subsequently, the relationship between HRV and RHR was analyzed using the Pearson correlation coefficient (r). **RESULTS:** In all population, mean HR at rest and RHR had an inverse effect, finding the following correlations: 10s ($r = -0.35$ $p = 0.01$), 20s ($r = -0.37$ $p = 0.007$), 40s ($r = -0.40$ $p = 0.004$) and 60s ($r = -0.53$ $p = 0.000$). Additionally, in women exist a direct correlation between RHR and CVI been more significant in the following correlations: 40s ($r = 0.41$ $p = 0.044$), 50s ($r = 0.52$ $p = 0.008$) and 60s ($r = 0.59$ $p = 0.002$); however, in men this correlation was not significant. **CONCLUSIONS:** When performing stress tests in apparently healthy people, the decrease of the HR after exercise could be used to evaluate the activity of the ANS, specifically the activation of parasympathetic system demonstrated by the significant correlations between RHR and HR at rest, as well as the correlation between RHR and CVI. Therefore, the activity in the first minute after ceasing the exercise shows that the evaluation of the parasympathetic nervous system could be implemented in the early diagnosis and prognosis of chronic diseases including cardiovascular disease.

Effects of Electronic and Conventional Cigarette Smoking on Post-exercise Autonomic Recovery
 Choun-Sub KIM, Maengkyu KIM, Hye-Young Jung, Min-Ghyu SUN, Yong-Woo KIM. *Kyungpook National University, Daegu, Korea, Republic of.*
 Email: kimmk@knu.ac.kr
 (No relevant relationships reported)

Since nicotine-bearing cigarette smoking can induce acute cardiac autonomic imbalance, it may cause to persist sympathetic excitatory, and delay vagal reactivation during post-exercise recovery. However, the effects of post-exercise cigarette smoking on cardiac autonomic nervous system is still uncertain; especially the difference between *e*-cigarettes and conventional cigarette smoking on cardiac autonomic recovery after exercise is unknown. **PURPOSE:** this study was aimed at investigating the influence of cigarette smoking on heart rate variability, and the difference between *e*-cigarettes and conventional cigarette smoking on autonomic balance after aerobic exercise. **METHODS:** Apparently healthy male smokers ($n=40$, 23.03 ± 3.30 yrs) were participated in a randomized crossover study where three experimental sessions (non-smoking condition, NS; *e*-cigarette smoking, ES; conventional cigarette smoking, CS) were applied after 30 min single bout treadmill running at 60% HR_{max} . Either *e*-cigarette or conventional cigarette smoking was performed for 5 min immediately after exercise. Heart rate variability (HRV) was monitored before, during, and after exercise. **RESULTS:** As results of HRV analysis, parasympathetic activity indices ($r\text{MSSD}$, $p\text{NN50}$, HF and SD1) were significantly decreased in both CS and ES compared to NS ($p < .001$, respectively). In particular, those parasympathetic indices at CS were significantly decreased at CS while smoking and post-exercise recovery ($p < .001$, respectively) whilst there was no significances at ES. In contrast, sympathetic activity index (LF/HF ratio) was significantly increased at both CS and ES compared to NS ($p < .001$). Especially CS had significantly greater LF/HF ratio than ES while smoking and post-exercise recovery ($p < .001$). **CONCLUSIONS:** This study had found that both *e*-cigarette and conventional cigarette smoking induce delayed parasympathetic reactivation and sympathetic withdrawal after aerobic exercise. In particular, conventional cigarette smoking had more sympathetic excitatory persisting responses than *e*-cigarette after aerobic exercise.

Hypotensive Effects of High Intensity Resistance Training to Muscle Failure in Hypertensive Postmenopausal Women
 Juliana Alves Carneiro, Arthur Ferreira Vale, Paulo Gentil, Thiago Veiga Jardim, Weimar Kunz Sebba Barroso Souza, Ana Luiza Lima Sousa, Paulo Cesar Brandão Veiga Jardim. *Universidade Federal de Goiás, Goiânia, Brazil.*
 Email: julianacarneiro77@hotmail.com
 (No relevant relationships reported)

PURPOSE: Moderate-intensity Resistance Training (RT) has been recommended for blood pressure (BP) control by the main guidelines. However hypotensive effects of high intensity RT using higher loads to muscle failure in hypertensive patients is little know. Therefore, the aim of the study was to verify the behavior of BP after the session of high intensity resistance training in hypertensive women. **METHODS:** A randomized crossover design clinical trial was conducted with 10 controlled hypertensive women with age equal to: 58.9 ± 6.8 , body mass index equal to: 27.1 ± 3.8 . The participants performed two experimental protocols: a control session and RT session with 6 repetition maximum (RM) to muscle failure. The order of execution of the sessions was performed randomly by lot. The sessions of 6RM was performed with three exercises (lat pulldown, barbell bench press and 45° leg press) in three sets to momentary concentric failure. During the control session the participants followed of rest in the laboratory. Systolic blood pressure (SBP), diastolic blood pressure (DBP) were collected pre, immediately post, 1 h post, and 24 h post each protocol. Repeated measures ANOVA were used. **RESULTS:** The SPB decrease in 1 h (124.3 ± 10.8) and 24 h (126.2 ± 13.6) after the 6RM session to muscle failure when compared to pre (135.7 ± 14.1), ($p < 0.05$). SBP was higher for 6RM (144.7 ± 16.4) than control (134.2 ± 18.1) immediately after session ($p < 0.05$). There were no differences for DBP among protocols ($p \geq 0.05$). **CONCLUSIONS:** The RT using higher loads to muscle failure promote SPB hypotension 1 h and 24 h after the session. No DPB changes were observed after the RT protocols. The high intensity resistance training can decrease the SPB acutely and help in control of blood pressure in hypertensive women.

Circulating Inflammatory And Oxidative Stress Responses To Steady-state Moderate-intensity And High-intensity Interval Exercise In Mid-spectrum Chronic Kidney Disease
 Matthew N. Peterson¹, Jeffrey S. Forsse¹, Zacharias Papadakis¹, Nicholas Schwedock², Burritt W. Hess², Jackson O. Griggs², D. Crawford Allison³, Ron L. Wilson³, J. Kyle Taylor⁴, Kathryn Dugan⁴, Kathy W. Jones⁴, Kathleen Adair¹, Mitchell C. Cholewinski¹, Peter W. Grandjean, FACSM¹. ¹Baylor University, Waco, TX. ²Family Health Center, Waco, TX. ³Baylor Scott & White Health, Waco, TX. ⁴Auburn University-Montgomery, Montgomery, AL. (Sponsor: Peter W. Grandjean, FACSM)
 (No relevant relationships reported)

Inflammation and oxidative stress can be potent modulators of vascular function. These factors may transiently respond to moderate-intensity steady state exercise (SSE) in a manner that improves post-exercise vascular function in healthy adults. Whether exercise imparts similar effects in adults with Stage 3 or 4 chronic kidney disease (CKD) remains understudied. Moreover, a comparison of SSE and high-intensity interval exercise (HIIE) may add to clinically-relevant findings for improving vascular function in mid-spectrum CKD. **PURPOSE:** To determine the influence of SSE and a comparable amount of HIIE on post-exercise inflammation and oxidative stress in patients diagnosed with secondary Stage 3 or 4 CKD. **METHODS:** Twenty participants ($n = 6$ men; $n = 14$ women; age 62.0 ± 9.9 yr; weight 80.9 ± 16.2 kg; body fat $37.3 \pm 8.5\%$ of weight; $\text{VO}_{2\text{max}}$ 19.4 ± 4.7 ml/kg/min) completed 30 min of SSE at 65% $\text{VO}_{2\text{reserve}}$ or HIIE by treadmill walking (90% and 20% of $\text{VO}_{2\text{reserve}}$ in 3:2 min ratio) in a randomized crossover design. Both exercise conditions averaged ~ 65% $\text{VO}_{2\text{reserve}}$. Blood samples were obtained by the same technician under standardized conditions just before, 1hr and 24hrs after exercise. Total antioxidant capacity (TAC), paraoxonase1 (PON1), asymmetric dimethylarginine (ADMA), ³nitrotyrosine (³NT) and interleukin-6 (IL6) responses were analyzed using 2 (condition) by 3 (sample point) repeated measures ANOVAs. **RESULTS:** Relative to pre-exercise measures: TAC increased by 4.3% 24hr after exercise ($p = 0.012$). PON1 was maintained 1hr and elevated by 6.1% 24hr after SSE, but not HIIE ($p = 0.035$). When corrected for plasma volume shifts, ADMA increased 30 ng/ml at 1hr but was 58 ng/ml lower 24hrs after exercise ($p = 0.0006$). ³NT and IL6 remained stable in the hours after exercise ($p > 0.05$). **CONCLUSION:** Modest inflammatory and oxidative stress marker responses to either SSE and HIIE may contribute to improved vascular function in mid-spectrum CKD.

Arterial Stiffness Response to High Intensity Interval Training in Young Healthy Individuals

Isabela Roque Marcal, Miss¹, Pedro Guilherme de Mattos Falqueiro, Mr¹, Bianca Fernandes, Miss¹, Vanessa Teixeira do Amaral Teixeira do Amaral, Miss¹, Gabriel de Souza Zanini, Mr¹, Awassi Yupiwa Ngomane, Miss¹, Matheus Monge Soares Corrêa, Mr¹, Guilherme Veiga Guimarães, Mr², Emmanuel Gomes Ciolac, Mr¹. ¹São Paulo State University, Bauri, Brazil. ²University of São Paulo, São Paulo, Brazil.
Email: isabelamarcal@gmail.com
(No relevant relationships reported)

PURPOSE: To assess arterial stiffness response to high-intensity interval training (HIIE) controlled by rating of perceived exertion (RPE) and heart rate (HR) in young healthy individuals. **METHODS:** Twelve young (21 ± 2 ys) sedentary or insufficiently active individuals were randomly assigned to perform HIIE prescribed and self-regulates by 6 to 20 RPE (HIIE_{RPE}, 25 min), HIIE prescribed and regulated by HR response to cardiopulmonary exercise testing (HIIE_{HR}, 25 min) and non exercise control (CON) session (25 min of seated resting). Arterial stiffness (carotid-femoral pulse wave velocity - PWV) were measured before (pre), immediately after (post) and 30 min after (recovery) each intervention with participants quietly in supine position. Two-way ANOVA with repeated measures (intervention vs. time) was used to indicate inter- and intra-interventions differences and the Bonferroni *post hoc* analysis was used to identify significant differences were indicated by two-way ANOVA. **RESULTS:** PWV was lower ($P < 0.05$) at post- than pre-intervention during both HIIE_{RPE} (0.28 ± 0.17 m/s) and HIIE_{HR} (0.27 ± 0.11 m/s). However, PWV remained lower at recovery only during HIIE_{RPE} (0.30 ± 0.10 m/s, $P < 0.05$), returning to pre-intervention levels during HIIE_{HR}. PWV did not change significantly during CON. **CONCLUSION:** These results suggests that HIIE promotes positive acute effects in arterial stiffness in young healthy individuals. Both exercise intervention reduced PWV at post-intervention, but only HIIE_{RPE} maintained the reduction at recovery, demonstrating that 6 to 20 RPE scale is an accessible, simple and useful tool for prescribing and self-regulating HIIE and promote cardiovascular benefits in young individuals.

Figure. Pulse wave velocity during interventions. Data are expressed as mean ± SD. HIIE_{RPE}: high-intensity interval exercise prescribed and self-regulated by RPE; HIIE_{HR}: high-intensity interval exercise prescribed and regulated by heart rate response to cardiopulmonary exercise testing. Asterisk denotes significant difference from pre at same group (*: $P < 0.05$).

The Effect of Sodium Supplementation on Postexercise Hypotension Following Acute Submaximal Aerobic Exercise

Matthew C. Babcock¹, Austin T. Robinson¹, Joseph C. Watso¹, Kamila U. Migdal¹, Christopher R. Martens¹, David G. Edwards¹, Linda S. Pescatello, FACSM², William B. Farquhar, FACSM¹. ¹University of Delaware, Newark, DE. ²University of Connecticut, Storrs, CT. (Sponsor: William Farquhar, FACSM)
Email: mcbabco@udel.edu
(No relevant relationships reported)

PURPOSE: Acute submaximal aerobic exercise confers cardiovascular benefits including a prolonged reduction in blood pressure (BP) termed postexercise hypotension (PEH). PEH is thought to contribute to the chronic BP-lowering effects of aerobic training. Chronic sodium (Na⁺) supplementation expands plasma volume (PV) and may attenuate PEH. Therefore, this study tested the hypothesis that Na⁺ supplementation attenuates PEH following acute aerobic exercise. **METHODS:** Healthy young adults (n=11, age 26 ± 4 years; body mass index 23.5 ± 2.4 kg/m²) consumed a recommended Na⁺ diet (2,300 mg Na⁺/d) for 10 days on two occasions;

participants also consumed pills containing a total of either 4,000 mg Na⁺ or a placebo in random order. Participants collected their urine for the final 24 hours of each intervention for quantification of urinary Na⁺ excretion. On day 10 of each intervention, participants completed 50 minutes of dynamic cycling exercise at 60% VO_{2peak}. Brachial BP was recorded via automated oscillometry before and every 10 minutes after exercise for one hour. The change in PV was estimated using hemoglobin and hematocrit following each intervention. BP responses following exercise were compared using a two-way repeated measures ANOVA. Urinary and blood measures and the nadir in BP after exercise were compared using paired t-tests. **RESULTS:** The mean VO_{2peak} of participants was 41.6 ± 8.8 ml/min/kg and mean power at 60% VO_{2peak} was 127 ± 40 W. Urinary Na⁺ excretion was increased following Na⁺ supplementation (277 ± 50 vs. 153 ± 73 mmol/24 hours, $p < 0.001$). Na⁺ supplementation expanded PV approximately 10.2 ± 8.9%. Despite significantly greater Na⁺ excretion, serum [Na⁺] (141.0 ± 1.8 vs. 141.7 ± 3.0 mEq/L, $p = 0.34$) and plasma osmolality (294 ± 4 vs. 295 ± 6 mOsm/kg H₂O, $p = 0.22$) were not different following Na⁺ supplementation compared to placebo. PEH was observed following both conditions (nadir systolic BP: -4.7 ± 3.8 vs. -4.6 ± 2.9 mmHg, $p = 0.91$ and mean BP: -6.1 ± 4.3 vs. -5.0 ± 3.4 mmHg, $p = 0.38$). However, when comparing Na⁺ supplementation to placebo, there was not a significant diet effect regarding reductions in systolic BP ($p = 0.93$) or mean BP ($p = 0.41$) following exercise. **CONCLUSIONS:** These preliminary data suggest that Na⁺ supplementation does not attenuate PEH following acute aerobic exercise despite increased PV.

Blood Chemistry Changes During an Ultra-marathon Competition

Junior E. Cianne¹, Steven B. Hammer¹, James W. Agnew¹, Dana Mathew². ¹Indian River State College, Fort Pierce, FL. ²Brevard Physician Associates, Melbourne, FL.
Email: shammer@irsc.edu
(No relevant relationships reported)

PURPOSE: The purpose for this study is to assess venous electrolyte changes in ultra-marathon athletes. There are few studies on ultra-endurance activities reporting blood parameter changes and their potential effects, and those that are published have conflicting results. We speculate that plasma fluid shifts and the metabolic demands occurring during an ultramarathon will result in significant changes in metabolites, electrolytes, hemoglobin and hematocrit levels that could be of risk to the runner's health. **METHODS:** Consent was obtained from each participant the day before the Saint Sebastian 100, November 2017. The event was conducted over a repeated ten-mile loop in the Saint Sebastian Preserve, Florida. The environmental conditions were moderately warm and humid. Races consisted of 50 kilometers, 50 miles and 100-mile distances. Blood samples were collected from the antecubital vein with 1 cc insulin syringes. Blood was analyzed with an i-STAT Handheld blood analyzer with the CHEM8+ cartridge (© Abbot Point of Care, Princeton, NJ). Paired sample t-tests were used to compare pre and post-race values (mean ± SD), $p \leq 0.05$, number of participants n=12. **RESULTS:** Significant changes pre to post race were found in the following: Potassium (3.97 ± 0.19, 4.27 ± 0.48 (mmol/L), $t(11) = -2.31$; $p = 0.04$); BUN (16.75 ± 8.18, 25.25 ± 7.28 (mg/dl), $t(11) = -4.89$; $p < 0.001$); Creatinine (0.85 ± 0.13, 1.48 ± 0.68 (mg/dl), $t(11) = -3.31$; $p = 0.007$); Hematocrit (44.75 ± 3.41, 47.25 ± 3.67 (%), $t(11) = -4.38$; $p = 0.001$); Hemoglobin (15.217 ± 1.15, 16.07 ± 1.24 (g/dl), $t(11) = -4.35$; $p = 0.001$); Sodium and glucose did not show significant changes pre to post race. Significant changes were not noted between different race distances. **CONCLUSION:** The results from this study show dehydration, muscle catabolism, and increased stress upon kidney function in the ultra-marathon athletes. These results demonstrate that electrolytes are altered post ultramarathon. The severity of these alteration is not known as various studies show opposing results. More research is needed to determine the extent of these changes and why some studies show changes when others do not. These changes could be of clinical significance to the runner's health or possibly through training they have adapted to these stressful alterations.

973 Board #207 May 29 2:00 PM - 3:30 PM

Electrocardiogram T-Wave Morphology and Amplitude Differences during an Ultramarathon Competition

Diamond Nicholas, James Agnew, Steven Hammer. Indian River State College, Fort Pierce, FL.
Email: shammer@irsc.edu
(No relevant relationships reported)

PURPOSE: The goal of this research is to study the effect of ultramarathon competition on T-wave morphology and amplitude changes. T-wave changes can be an indication of a vast number of conditions with many being of critical nature. This makes understanding what changes ultrarunners are undergoing critical for monitoring and understanding physiological changes associated with ultramarathons. **METHODS:** In this study, volunteer subjects Male n=25, Female n=20 signed an informed consent, then completed their ultramarathon distance. 12 lead EKGs were measured pre and post-race. EKGs were recorded and analyzed with ECG

Synchronous V1.3.1 and statistics were performed in SPSS V21. Paired sample t-tests were used to compare pre and post-race T-wave amplitude values (Pre/Post mean \pm SD, $p < 0.05$). **RESULTS:** A total of 405 T-waves were analyzed. There was no change in t-wave morphology pre versus post-race for 83.95% ($n=340$), while 16.05% ($n=65$) changed morphology (upright, inverted, flat, camel hump and biphasic). Major changes observed were inverted to upright ($n=24$), upright to inverted ($n=9$), biphasic to upright ($n=9$) and camel hump to upright ($n=6$), other changes only occurred in 1 or 2 leads. Significant changes in T-wave amplitude (mv) pre- to post-race were found in the following leads: (Pre/Post mean \pm SD, $p < 0.05$): **lead I** (0.168 ± 0.114 , 0.254 ± 0.105 , $t(44) = -4.845$; $p < 0.001$); **lead II** (0.305 ± 0.124 , 0.398 ± 0.137 , $t(44) = -4.081$; $p < 0.001$); **lead aVR** (-0.24 ± 0.11 , -0.29 ± 0.15 , $t(44) = 0.04$); **lead aVF** (0.231 ± 0.0805 , 0.284 ± 0.117 , $t(44) = -3.666$; $p < 0.001$); **lead V1** (0.00333 ± 0.136 , 0.0973 ± 0.161 , $t(44) = -5.144$; $p < 0.001$); **lead V2** (0.358 ± 0.233 , 0.528 ± 0.346 , $t(44) = -5.462$; $p < 0.001$); **lead V3** (0.440 ± 0.215 , 0.590 ± 0.290 , $t(44) = -5.951$; $p < 0.001$); **lead V4** (0.480 ± 0.190 , 0.589 ± 0.254 , $t(44) = -3.899$; $p < 0.001$); **lead V5** (0.168 ± 0.114 , 0.254 ± 0.105 , $t(44) = -4.035$; $p < 0.001$), and **lead V6** (0.329 ± 0.103 , 0.398 ± 0.148 , $t(44) = -3.348$; $p < 0.001$); leads III and aVL showed no change in amplitude. **CONCLUSION:** From this study, the results show evidence that long-distance running can alter T-wave morphology and amplitude pre- to post-race. Possible causes of these changes include hyperkalemia, cardiac strain, long QT syndrome, Tachycardia Induced cardiomyopathy all in response to the ultramarathon.

974 Board #208 May 29 2:00 PM - 3:30 PM
Metabolic and Hemodynamic Efficiency of Identical Workloads Performed with Stable Supine vs Upright Cycle Ergometry

Robert M. Otto, FACSM, Michele Aquino, Jessica Diaz, John Petrizzo, Peter Byrne, Casey Spor, Ryan Mullin, Jacob Virginia, John Wygand, FACSM, Adelphi University, Garden City, NY.
 Email: otto@adelphi.edu
 (No relevant relationships reported)

Although differences among postural positions during cycle ergometry generally display a metabolic response favoring the upright posture, the use of identical workloads regardless of pedal frequency are scarce. Using an electromagnetically braked ergometer with a constant load that accommodates a range of pedal frequency of 155 rpm, provided an identical workload despite positional changes and/or variation in pedal frequency. In addition, a lack of subject stability during supine exercise may contribute to an increased energy cost. **Purpose:** To determine the metabolic efficiency between supine (S) versus upright (U) cycling at identical workloads with stable supine subject positioning. **Methods:** 15 healthy college students (age 20.9 ± 1.3 yr, ht. 172.3 ± 8.5 cm, body mass 76.9 ± 12.6 kg, $8 \frac{1}{2}$) volunteered to participate in two randomly assigned GXT trials preceded by 5 minutes of rest, followed by a progressive increase of 25 watts per 3 min stage, starting at 50 w. Open circuit spirometry measured metabolism and hemodynamics were assessed by cardiac impedance. The seat was located 12° posterior of vertical above the center crank (CC) for the U trial and the subject was supine with the CC elevated 33 cm above the platform for the S trial. **Results:** $\dot{V}O_2$ (L/min) were 1.12 ± 0.17 vs 1.06 ± 0.14 , 1.35 ± 0.18 vs 1.28 ± 0.13 , 1.55 ± 0.17 vs 1.52 ± 0.12 , and 1.76 ± 0.17 vs 1.78 ± 0.15 , and cardiac output [Q](L/min) were 13.6 ± 2.8 vs 12.0 ± 3.5 , 15.1 ± 3.1 vs 14.1 ± 3.5 , 16.4 ± 3.1 vs 16.6 ± 2.0 , and 18.3 ± 3.0 vs 19.1 ± 2.4 , for 50, 75, 100, and 125 watt workloads, for U vs S trials, respectively. NSD was found between $\dot{V}O_2$ or Q at all workloads, except $\dot{V}O_2$ at 75 w. **Conclusion:** Often extraneous subject supine mobility may impact cycling energy cost, however the subjects used a supine cycling platform, thus shoulder support prevented posterior body migration. At low to moderate intensity cycle exercise, with subjects in a stable position, the hemodynamic and metabolic response to supine vs upright cycling is virtually indistinguishable.

975 Board #209 May 29 2:00 PM - 3:30 PM
Acute Effects of a Vinyasa Flow Yoga DVD on Lipid Profile and Fasting Glucose

Adetola Fadeyi, James Shadiow, Alexander Pina, Anabel Chavez, Stacy D. Hunter. Texas State University, San Marcos, TX.
 Email: tobifadeyi@gmail.com
 (No relevant relationships reported)

Short- and long-term interventional trials have demonstrated the efficacy of various styles of hatha yoga in improving both lipid profile and fasting glucose concentrations; however, the acute effects of yoga on these measures are unknown. Vinyasa flow yoga is a style of hatha yoga characterized by continuous movement, smooth transitioning between postures, and a synchronization of breath and posture transitions. **PURPOSE:** The purpose of this study was to evaluate the acute effects of a Vinyasa yoga session on lipid profile and fasting glucose concentrations in yoga practitioners with a minimum of 3 months of yoga practice experience. **METHODS:** Nine yoga practitioners (20 - 75) completed one 60-minute Vinyasa yoga DVD. Whole blood samples were obtained (after 8 hrs of fasting) and analyzed for

total- and HDL-cholesterol, triglyceride, and glucose concentrations via reflectance photometry. Briefly, 35 μ L blood samples were applied to test cassette sampling wells and color changes of the reagent pads were converted to concentration values. LDL-cholesterol was calculated using the Friedewald equation.

RESULTS: After completion of the Vinyasa flow yoga session, a significant decrease in LDL-cholesterol ($p < 0.01$) was observed. Total cholesterol tended to decrease ($p = 0.128$) after the intervention, although not statistically significant. No changes occurred in fasting glucose ($p = 0.769$), HDL-cholesterol ($p = 0.431$), or triglyceride concentrations ($p = 0.328$).

CONCLUSIONS: These results illustrate that a 1-hour session of Vinyasa flow yoga can improve LDL-cholesterol concentrations. These acute changes in lipid measures could lend support for the potential efficacy of yoga, an alternative exercise mode, in inducing positive changes in lipid profile and producing favorable changes in cardiovascular disease risk profile. This study was funded in part by Pure Action, Inc. Austin, TX, USA.

Acute Handgrip Exercise Alters the Inter-arm Systolic Blood Pressure Difference in Young Males and Females

Michael E. Holmstrup, FACSM, Lance S. Neuscheler, Marlea A. Sprandle, Stephanie N. Ace, Rachel K. Borland, Benjamin DH Gordon, Brock T. Jensen. Slippery Rock University, Slippery Rock, PA.
 Email: michael.holmstrup@sru.edu
 (No relevant relationships reported)

A large inter-arm difference (IAD) in systolic blood pressure (BP) is linked to an increased likelihood of cardiovascular and peripheral vascular disease, hypertension, and premature mortality. An acute bout of aerobic exercise can alter IAD both during the activity and into post-exercise recovery. Isometric handgrip exercise (IHE) results in acute alterations in BP that differ from aerobic exercise. Further, sex differences in IHE-mediated BP exist, and cardiovagal modulation is a plausible mechanism. No prior investigations have examined IAD during IHE in males and females. **PURPOSE:** To characterize IAD and heart rate variability (HRV) to IHE in men and women. **METHODS:** On visit one, participants completed three maximal voluntary isometric contractions (MVIC) per arm using a handgrip dynamometer. During visit two, after a five-minute rest, resting HRV was assessed while each participant breathed at a rate of 12 breaths/minute. HRV analysis software was used to determine relative low- and high-frequency power for each participant. Subsequently, a series of three resting bilateral BP measures were collected and averaged (REST) utilizing an automatic oscillatory BP device. Following REST, participants maintained the handgrip dynamometer at 20% MVIC for two minutes (arm randomly assigned), at which time bilateral BP and HRV were again measured (IHE). An independent-samples t-test and repeated measures ANOVA were used to compare and track variables of interest. **RESULTS:** IHE resulted in increased IAD in both males and females. Males demonstrated higher IAD at REST (7 ± 6 vs 3 ± 3 mmHg) and during IHE (12 ± 9 vs 5 ± 4 mmHg) than their female counterparts ($P < 0.05$), with males also expressing a lower high-frequency HRV at rest ($P < 0.05$). **CONCLUSIONS:** Isometric handgrip exercise altered IAD from rest to exercise, with males displaying increased IAD during both conditions. The attenuated exercise pressor response observed in female participants may be due, in part, to a higher observed baseline of cardiovagal modulation. Future studies should address potential responses following repeated bouts of IHE, which may have important implications in those with IAD.

The Acute Effects of Vinyasa Flow Yoga on Arterial Stiffness

Alexander A. Piña, 1st, Adetola Fadeyi, 1st, James Shadiow, Anabel B. Sanchez, Stacy D. Hunter. Texas State University, San Marcos, TX.
 (No relevant relationships reported)

Arterial stiffness (AS) is a marker of subclinical atherosclerotic disease associated with reductions in the buffering capacity of the central, elastic arteries. Previous research has demonstrated reductions in AS with a relatively short-duration, 8-week Bikram (hot) yoga practice. However, the acute effects of yoga on this measure have not been investigated. Vinyasa flow yoga is a style of hatha yoga which involves a higher intensity sequence of postures compared to other yoga styles along with continuous movement. As yoga could potentially be as effective as aerobic exercise in treating co-morbidities associated with CVD, it is pertinent to clarify whether an acute bout of Vinyasa flow yoga could lead to meaningful changes in indices of AS.

PURPOSE: The aim of this study was to investigate the acute impact of one bout of Vinyasa flow yoga on indices of AS in healthy adults. **METHODS:** 11 apparently healthy adults ages 20-75 yrs with at least 3 months of yoga experience completed a one-hour Vinyasa flow yoga DVD. Seated blood pressure measures were obtained pre- and post-intervention. Augmentation index (AIx) and carotid-femoral pulse wave velocity (cfPWV) were measured before and after the yoga

session via Sphygmocor applanation tonometry. Aix recordings included crude Aix, Aix at a heart rate of 75 beats per minute (Aix@75), and peripheral Aix (P2/P1). Mood affect was assessed via PANAS 20-item survey.

RESULTS: After completion of the yoga DVD, significant reductions in Aix and peripheral Aix ($P < 0.05$ for both) were observed. Although not statistically significant, Aix@75 tended to decline ($p = 0.068$) while cPPWV ($P = 0.459$) was unaltered. No significant changes in positive or negative affect were observed although negative affect tended to decline ($P = 0.126$).

CONCLUSIONS: These results highlight the efficacy of a single bout of hatha yoga in improving central and peripheral arterial stiffness measures and provide insight into the potential effects of yoga in mediating CVD risk.

Walking With Leg Blood Flow Restriction: Wide-rigid Cuffs Vs. Narrow-elastic Bands

Sten Stray-Gundersen, Savannah Wooten, Hirofumi Tanaka, FACSM. *University of Texas at Austin, Austin, TX.*

Reported Relationships: S. Stray-Gundersen: Other (please describe); Received BFR bands from company as a gift for research.

Blood flow restriction (BFR) training has become a popular form of exercise. The concept is that light exercise with BFR would elicit similar adaptations achieved with intense exercise. Walking exercise in combination with pressurized wide-rigid (WR) cuffs has been shown to elicit higher cardiac workload and a vascular dysfunction due presumably to reperfusion injury to the endothelium. In contrast, narrow-elastic (NE) BFR bands, similar to the original Kaatsu bands, may elicit different hemodynamic effects, as the limb is able to increase in diameter with increased blood flow accompanying exercise. **Purpose:** To compare two distinct forms of BFR bands during light-intensity exercise on cardiovascular responses. **Methods:** Six young healthy participants ($M = 4, F = 2$) performed 5 bouts of 2-minute walking intervals at 3.2 kph with a 1-minute rest and deflation period between bouts with either WR or NE bands placed on both upper thighs. Cuff pressure was increased to 160 mmHg in WR cuffs and 300 mmHg in NE bands. Beat-by-beat blood pressure and heart rate were measured continuously using finger plethysmography. Blood lactate concentration, rating of perceived exertion (RPE), flow-mediated dilation (index of endothelium-dependent vasodilation), and cardio-ankle vascular index (measure of arterial stiffness) were assessed before and after the walking exercise. **Results:** At baseline, there were no significant differences in any of the variables between the WR and NE conditions. Heart rate increased similarly in both conditions. Increases in systolic and diastolic blood pressure were greater ($p < 0.01$) in the WR than the NE condition ($160 \pm 13 / 92 \pm 11$ mmHg vs. $127 \pm 9 / 71 \pm 16$ mmHg, respectively). Double product, a function of heart rate and systolic blood pressure, increased to a greater extent in the WR than in the NE condition. Increases in RPE and blood lactate concentration from baseline were greater in the WR compared with the NE condition ($p < 0.05$). **Conclusion:** Use of wide-rigid BFR cuffs resulted in a marked increase in pressor responses compared with narrow-elastic BFR bands, suggesting that narrow-elastic bands may present a safer alternative for at-risk populations to perform BFR exercise.

The Hemodynamic and Metabolic Response to Maximal Supine vs Upright Cycle Ergometry

John Wygand, FACSM, Michele Aquino, Jessica Diaz, John Petrizzo, Jacob Virginia, Ryan Mullin, Casey Spor, Peter Byrne, Robert M. Otto, FACSM. *Adelphi University, Garden City, NY.* Email: wygand@adelphi.edu

(No relevant relationships reported)

Performance comparisons between supine (S) and upright (U) cycling have been reported to range from similar responses to as much as 150% greater for U conditions. In part, differences in performance have been attributed to a greater muscle perfusion pressure in the upright position resulting from an enhanced hydrostatic pressure in the lower extremities. **Purpose:** The purpose was to determine the hemodynamic and metabolic response to a maximal workload performed in a supine and an upright cycling position. **Methods:** 15 healthy college students (age 20.9 ± 1.3 yr, ht. 172.3 ± 8.5 cm, body mass 76.9 ± 12.6 kg, 8♂) volunteered to participate in two randomly assigned GXT trials preceded by 5 minutes of rest, and followed by a progressive increase of 25 watts per 3 min stage, starting at 50 w to volitional exhaustion. Open circuit spirometry measured metabolism and hemodynamics were assessed by cardiac impedance. The seat was located 12° posterior of vertical above the center crank (CC) for the U trial and each subject was supine with the CC elevated 33 cm above the platform for the S trial. **Results:** The following variables were measured during the final minute of exercise: workload 216 ± 41 vs 175 ± 39 watts*, $\dot{V}O_2$ 2.68 ± 0.52 vs 2.32 ± 0.60 , (L/min)*, $\dot{V}e$ 95.2 ± 17.8 vs 75.9 ± 19.0 (L/min)*, RER $1.15 \pm .04$ vs $1.12 \pm .05$, $\dot{V}e/\dot{V}O_2$ 42.9 ± 5.8 vs 36.7 ± 6.1 *, RPE 9.9 ± 0.3 vs 9.9 ± 0.6 , HR 193 ± 6.6 vs 177 ± 11 b/min*, cardiac output (Q) 23.6 ± 7.2 vs 22.4 ± 2.7 (L/min), and SV 121 ± 33 vs 126 ± 10 (mL/beat), for U vs S, respectively (* $p < .05$). Workload, $\dot{V}e$, $\dot{V}O_2$, and HR were 23, 27, 15, 11, and 9% higher for U vs S trials, respectively ($P < .05$).

Conclusion: Attainment of a greater workload in the U trial (+23%), may, in part, be attributed to enhanced peripheral perfusion, familiarity with the U testing, and greater sympathetic drive. Despite a theoretical advantage for venous return in the S position, Q and SV did not differ between positions. Energy requirements of 12.4 vs 13.3 mL O_2 /watt for U vs S, respectively, confirms S to be less efficient than U.

Menstrual Phase Differences In The Physiological Resolution Of Periodic Breath-holding During Heavy Intensity Fartlek Exercise

Calaina Brooke¹, Jordyn Smith², Glen R. Belfry². ¹Western University, Toronto, ON, Canada. ²Western University, London, ON, Canada.

(No relevant relationships reported)

PURPOSE: Fluctuations in ovarian hormones have been shown to affect the physiological responses to heavy-intensity exercise. These responses may be exacerbated during backstroke swimming during the underwater push-off phase where swimmers are required to perform breath holds (~5 s) while kicking to the surface. The purpose of this study was to compare the singular and combined effects of repeated cycles of 5 s breath holds (BH) and hi-power output (HPO), every 30 s, during heavy-intensity (HVY) exercise during follicular (FOL) and luteal (LUT) phases.

METHODS: Eight eumenorrheic women (22 ± 1 yr, $\dot{V}O_{2\max}$ 2.36 ± 0.4 L \cdot min⁻¹) performed four 6-min exercise bouts on a cycle ergometer at a power output of 50 % of the difference between ventilatory threshold and $\dot{V}O_{2\max}$ ($\alpha 50\%$) in the FOL and LUT. A continuous HVY (CONT) with free breathing, and 3 intermittent conditions including, repeated cycles of 25 s free breathing and 5 s BH (BH), repeated cycles of 25s at $\alpha 50\%$ and 5s at peak aerobic power (HPO) and combining the BH and HPO (BH-HPO) perturbations were performed. Gas exchange and vastus lateralis deoxygenation (HHb) were recorded during all trials.

RESULTS: Mean Ventilation (\dot{V}_E) and total [hemoglobin] were higher in all conditions during LUT vs FOL (LUT 78.0 ± 10.7 ; FOL 75.1 ± 10.7 L \cdot min⁻¹ and FOL: 2.0 ± 2.2 μ Mol; LUT: 2.9 ± 1.9 μ Mol respectively $p < 0.05$). Carbon dioxide production ($\dot{V}CO_2$) was higher during LUT BH-HPO (LUT: 2.41 ± 0.18 L \cdot min⁻¹; FOL: 2.19 ± 0.24 L \cdot min⁻¹ $p < 0.05$). Whereas % α HHb was greater during the 5s BH vs the 25s free-breathing period in both LUT (25s: $87 \pm 9\%$; 5s: $89 \pm 8\%$ $p < 0.05$) and FOL (25s: $86 \pm 15\%$; 5s: $89 \pm 13\%$ $p < 0.05$) phases. Further, % α HHb/ α $\dot{V}O_2$ was greater during BH (6%) and HPO-BH (7%) during the 5s BH vs the 25s free-breathing in both phases (FOL: $46.0 \pm 18\%$; LUT: $45 \pm 14\%$ and FOL: $44 \pm 18\%$; LUT: $44 \pm 15\%$ respectively $p < 0.05$).

CONCLUSION: Low PO_2 in the area of investigation (i.e. vastus lateralis) during heavy intensity exercise has been shown to increase CO_2 transport by increasing the affinity of CO_2 to Hb (Haldane effect). Moreover, the increased pulmonary diffusion capacity during the LUT phase suggested elsewhere would facilitate the observed increase in $\dot{V}CO_2$ and \dot{V}_E during the BH-HPO protocol of the present study. Finally, females show increased local muscle deoxygenation in both BH conditions during both the FOL and LUT phases.

Integrative Physiological Responses To A 25-day Ultra-endurance Exercise Challenge

Nicholas B. Tiller¹, Scott T. Chiesa², Justin D. Roberts³, Louise A. Turner¹, Siana Jones², Lee M. Romer, FACSM⁴. ¹Sheffield Hallam University, Sheffield, United Kingdom. ²University College London, London, United Kingdom. ³Anglia Ruskin University, Cambridge, United Kingdom. ⁴Brunel University London, London, United Kingdom. (Sponsor: Lee Romer, FACSM)

Email: n.tiller@shu.ac.uk

(No relevant relationships reported)

Purpose. This case-report characterised the respiratory, cardiovascular, and nutritional/gastrointestinal (GI) responses of a trained individual to a novel ultra-endurance exercise challenge. **Methods.** A male athlete (age 45 yr, mass 80.7 kg, stature 1.71 m, $\dot{V}O_{2\max}$ 54.8 mL \cdot kg⁻¹ \cdot min⁻¹) summited 100 mountains on foot (all elevations >600 m) in 25 consecutive days, and cycled between five base-camps throughout the UK. Laboratory measures of pulmonary function (spirometry, whole-body plethysmography, single-breath rebreath), respiratory muscle strength (maximum static mouth-pressures), and cardiovascular structure and function (echocardiography, electrocardiography, large vessel ultrasound, flow-mediated dilatation) were assessed at baseline and at 48 h post-challenge. Dietary intake (4-d food diary), self-reported GI symptoms, and plasma endotoxin concentrations were assessed at baseline, pre/post mid-point (day 13), pre/post penultimate point (day 24), and at 48 h post-challenge. **Results.** The participant completed the challenge with a total exercise time of 142 h (5.3 ± 2.8 h \cdot d⁻¹), distance of 1141 km (42.3 ± 43.9 km \cdot d⁻¹), ascent of 33804 m (1252 ± 807 m \cdot d⁻¹), and energy expenditure of 80460 kcal (2980 ± 1451 kcal \cdot d⁻¹). Relative to

baseline, there were post-challenge decreases in pulmonary volumes and capacities (6 - 32%), expiratory flows (9 - 28%), maximum expiratory mouth-pressure (19%), and maximum voluntary ventilation (29%). Heart rate variability had deteriorated, manifesting in a 48% decrease in the root mean square of successive differences (RMSSD) and a 70% increase in the low-frequency/high-frequency ratio (LF/HF). There were no notable changes in any other index of cardiovascular structure or function. Pre- to post-challenge endotoxin concentrations were elevated by 60%, with a maximum increase of 130% after a given stage, congruent with an increased frequency and severity of GI symptoms. **Conclusions.** This is the first study of the integrative physiological responses to an ultra-endurance exercise challenge. The findings extend our understanding of the limits of physiological function and may inform medical best-practice for personnel supporting ultra-endurance events.

Genetic, Physiologic, And Behavioral Predictors Of Cardiorespiratory Fitness In Specialized Military Men
 Dianna Christine Laver¹, Lisa M. Hernández¹, Matthew R. Schoenherr¹, Jeremiah Stump², Marcus K. Taylor, FACSM³.
¹Leidos/Naval Health Research Center, San Diego, CA.
²Explosive Ordnance Disposal Training and Evaluation Unit One, San Diego, CA. ³Naval Health Research Center, San Diego, CA. (Sponsor: Marcus K. Taylor, FACSM)
 (No relevant relationships reported)

Cardiorespiratory fitness (CRF) is a crucial performance requirement of specialized military occupations. Age and physical activity (PA) are established predictors of CRF, but it is not clear how these predictors combine with each other and/or with genetic predisposition. **PURPOSE:** To derive inclusive explanatory models of CRF in U.S. Navy Explosive Ordnance Disposal (EOD) operators, synthesizing conventional (e.g., age, body composition, and PA) and novel influences (e.g., genetic variance), was performed. **METHODS:** Forty male, active duty EOD operators completed a graded exercise test to assess maximal oxygen consumption and ventilatory threshold (VT) using the Bruce protocol. Aerobic performance was further quantified via time of test termination and time at which VT was achieved. Body composition was determined via dual-energy x-ray absorptiometry, and PA was assessed by self-report. Genetic variants underlying human stress systems (5HTTLPR, BclII, -2C/G, and COMT) were assayed. **RESULTS:** In univariate regression models, age, body composition, PA, and 5HTTLPR consistently predicted CRF and/or aerobic performance (R^2 range .07-.55). Multivariate regression models routinely outperformed the univariate models, explaining 36%-62% of variance. **CONCLUSIONS:** This study signifies a shift toward inclusive explanatory models of CRF and aerobic performance, accounting for combined roles of genetic, physiologic, and behavioral influences. These findings have implications for assessment, selection, and training of specialized military members, and may also impact mission success and survivability.

983 Board #217 May 29 2:00 PM - 3:30 PM
Influence of Menstrual Cycle Phase on Cardiovascular Drift and Maximal Oxygen Uptake During Heat Stress
 Tori M. Stone. *The University of Alabama, Tuscaloosa, AL.*
 (Sponsor: Jonathan E Wingo, FACSM)
 Email: tmstone3@crimson.ua.edu
 (No relevant relationships reported)

Cardiovascular drift (CV drift) is related to reduced maximal oxygen uptake ($\dot{V}O_{2max}$) during heat stress. Whether this relationship is modified by elevated core temperature during the luteal phase (LP) of the menstrual cycle remains unknown. **PURPOSE:** To test the hypothesis that the magnitude of CV drift and accompanying decrement in $\dot{V}O_{2max}$ is greater during the LP of the menstrual cycle vs. the follicular phase (FP). **METHODS:** Seven women (mean±SD; age=24±5 y) completed a graded exercise test in ~22 °C to determine $\dot{V}O_{2max}$, followed by one 15-min and one 45-min trial at 60% $\dot{V}O_{2max}$ in 35 °C—each immediately followed by measurement of $\dot{V}O_{2max}$ —in the FP and LP. CV drift was measured between 15 and 45 min during the 45-min trials. The purpose of the separate 15- and 45-min trials was to measure CV drift and $\dot{V}O_{2max}$ over the same time interval. **RESULTS:** Rectal temperature (T_{re}) at rest and during exercise was higher in the LP ($p<0.05$). Heart rate increased 9% between 15 and 45 min in both phases ($p=0.71$), while stroke volume decreased more in the LP (-18%) compared to the FP (-11%; $p<0.001$). $\dot{V}O_{2max}$ decreased significantly over time ($p=0.002$), but menstrual cycle phases were not different (16% and 13% for LP and FP, respectively, $p=0.28$). **CONCLUSION:** Greater thermal strain in the LP compared to the FP did not modulate the relationship between CV drift and $\dot{V}O_{2max}$ during exercise in the heat.

984 Board #218 May 29 2:00 PM - 3:30 PM
Should $\dot{V}O_2$ Be Normalized By Fat-free Mass In Recreationally Active Adolescent Males And Females?
 Marco Meucci, Hwan Kim, Nicholas David Tocci, Austin Trump Lassiter, Kaitlin Taylor McShea. *Appalachian State University, Boone, NC.* (Sponsor: Scott R Collier, FACSM)
 Email: meuccim@appstate.edu
 (No relevant relationships reported)

PURPOSE: This research aims to observe sex difference in oxygen consumption ($\dot{V}O_2$) expressed in absolute terms and relative to body weight and to fat-free mass in adolescent children while exercising at submaximal and maximal intensity. **METHODS:** Body composition (Bod Pod, COSMED) and cardiorespiratory fitness (K5, COSMED) were assessed on twenty-two recreationally active, healthy adolescents (age 16-17 years; 9 males, fat mas% 16.8 ± 8.0; 13 females, fat mas% 27.4 ± 5.4). A 15 watts/min incremental test to exhaustion was performed on a cycle ergometer to measure $\dot{V}O_2$ at the aerobic threshold (AerT) and at peak exercise ($\dot{V}O_{2peak}$) using breath-by-breath gas analysis. Values were expressed in both absolute terms and normalized by body mass and fat-free mass. The AerT was identified using the V-slope technique and as the lowest respiratory equivalent for oxygen. **RESULTS:** The $\dot{V}O_2$ at the AerT was higher in males than females when expressed in absolute terms (1184 ± 222 vs 942 ± 202 ml/min, $p = 0.015$) and normalized by body weight (16.9 ± 2.2 vs 16.4 ± 3.1 ml/kg/min) but the trend was inverted when $\dot{V}O_2$ was normalized by FFM (20.43 ± 2.92 vs 21.57 ± 2.86 ml/kg/min). The same trend was observed at peak exercise. Males reported higher $\dot{V}O_{2peak}$ than females when expressed in absolute terms (1792 ± 250 ml/min vs 2344 ± 554 ml/min, $p < 0.01$) and normalized by body weight (33.5 ± 6.1 vs 30.6 ± 5.5 ml/kg/min) but lower when normalized by FFM (40.1 ± 5.7 vs 41.4 ± 8.0 ml/kg/min). Male adolescents exerted higher power than females both at the AerT (63 ± 13 vs 57 ± 20 watts) and peak effort (198 ± 40 vs 160 ± 20 watts, $P < 0.01$). **CONCLUSIONS:** This study provides reflection on whether $\dot{V}O_2$ should be normalized by total mass or FFM in adolescent males and females.

Cardiovascular Drift and Maximal Oxygen Uptake in Men Versus Women During Heat Stress
 Anne M. Mulholland, Tori M. Stone, Sarah G. Burnash, Jonathan E. Wingo, FACSM. *The University of Alabama, Tuscaloosa, AL.* (Sponsor: Jonathan E. Wingo, FACSM)
 Email: ammulholland@crimson.ua.edu
 (No relevant relationships reported)

It has been well demonstrated that biophysical factors, such as rate of metabolic heat production (\dot{H}_{prod}) and body size, are of primary importance in explaining variability of thermoregulatory responses during exercise in a compensable environment. It is unknown whether these same factors influence cardiovascular (CV) drift and a concomitant reduction in maximal oxygen uptake ($\dot{V}O_{2max}$) during prolonged exercise in the heat. **PURPOSE:** To test the hypothesis that men experience a greater increase in heart rate (HR) and decrease in stroke volume (SV) accompanied by a greater reduction in $\dot{V}O_{2max}$ during prolonged exercise in a hot environment compared to women at the same relative metabolic intensity. **METHODS:** Seven men [(mean±SD); mass=76.2±8.8 kg, $\dot{V}O_{2max}$ =54.7±5.5 mL/kg/min] and 7 women (mass=58.9±9.4 kg, $\dot{V}O_{2max}$ =42.0±9.2 mL/kg/min) performed a graded exercise test in ~22 °C to determine $\dot{V}O_{2max}$. Then on separate, counterbalanced occasions participants cycled at 60% $\dot{V}O_{2max}$ for either 15 or 45 min in 35 °C, immediately followed by graded exercise to elicit $\dot{V}O_{2max}$. CV drift was measured between 15 and 45 min during the 45-min trials. The separate 15- and 45-min trials were necessary to measure $\dot{V}O_{2max}$ during the same time interval that CV drift occurred. Women were tested during the follicular phase of the menstrual cycle. **RESULTS:** Because of differences in aerobic fitness and body size, \dot{H}_{prod} was higher ($p<0.05$) for men (666 W, 8.8 W/kg) than women (402 W, 7.1 W/kg), but the increase in rectal temperature from 15 to 45 min was not different (men=1.0±0.4 °C; women=0.7±0.2 °C; $p=0.25$). Likewise, CV drift was not different between groups (men: 14% increase in HR and 12% decrease in SV; women: 9% increase in HR and 11% decrease in SV; all $p>0.05$). $\dot{V}O_{2max}$ decreased between 15 and 45 min, but men (-13%) and women (-13%) were not different ($p=0.95$). **CONCLUSION:** Despite exercising at a higher \dot{H}_{prod} , larger, more aerobically fit men did not experience greater CV drift and concomitant reductions in $\dot{V}O_{2max}$ during heat stress compared to smaller, less fit women.

Sedentary Behaviors Modulates Metabolic and Inflammatory Biomarkers in Healthy MalesChen Zheng, Stephen H.S. Wong, FACSM. *The Chinese University of Hong Kong, Hong Kong, Hong Kong.* (Sponsor: Stephen H.S. Wong, FACSM)

Email: zhengchen@link.cuhk.edu.hk

(No relevant relationships reported)

PURPOSE: Sedentary behavior (SB) has emerged rapidly as a serious health problem globally. The purpose of this study was to assess the association between the increased time spent in SBs and metabolic and inflammatory biomarkers in healthy males.

METHODS: Thirty-five healthy male adults participated in this cross-sectional study (age, 21.8 ± 2.8 yr; body height, 171.9 ± 6.4 cm; body weight, 61.7 ± 5.6 kg; % body fat, 15.6 ± 4.3%; body mass index (BMI) 20.9 ± 1.5 kg/m²; waist circumference 75.5 ± 5.2 cm; heart rate (HR) 69.4 ± 7.8 bpm; systolic blood pressure (SBP) 108.7 ± 9.4 mmHg; diastolic blood pressure (DBP) 69.7 ± 8.3 mmHg). Subjects were required to wear the activPAL™ to continuously monitor their 24-hour activities for 7 days without any removal. Based on their SB, subjects were divided into high SB group (HSB, N=18) and low SB group (LSB, N=17). Blood samples were collected in the morning after overnight fast and no exercise was performed over the past 24 hours. Serum inflammatory biomarkers, including tumor necrosis factor alpha (TNF α), interferon- γ (IFN γ), interleukin 1 β (IL-1 β), monocyte chemoattractant protein 1 (MCP1) were measured by Flow Cytometry, while total cholesterol (TC), triglycerides (TRG), high-density lipoprotein (HDL), low-density lipoprotein (LDL) were analysed by xMark™ Microplate Absorbance Spectrophotometer at 500.0nm. Blood glucose (GLU) was measured by Alere Cholestech LDX® Analyzer. Independent-Samples T test and bivariate correlate were applied to analyze the differences between two groups and correlations among various biomarkers using SPSS version 23. **RESULTS:** Sedentary time of subjects in HSB group was higher than LSB group (19.9 ± 0.9 vs 17.3 ± 1.2 hr, p<0.01). No difference was found between two groups in MVPA and anthropometric results. An inverse relationship was observed between IFN- γ and sedentary time (r = -0.342, p<0.05). TNF- α was negatively associated with TC (r = -0.343, p<0.05), whereas IL-1 β was negatively associated with TRG (r = -0.395, p<0.05). In addition, TRG and GLU were higher in the HSB group (p<0.05), while HDL was lower in the LSB group (p<0.01). **CONCLUSIONS:** The results suggest that a close relationship exists between sedentary time and inflammatory and metabolic biomarkers.

Prevalence Of Fluctuated Heart Rate Recovery In Healthy Adults Undergoing Repeated Exercise Stress TestsItai Goldfarb¹, Mickey Scheinowitz, FACSM². ¹Tel-Aviv University, Tel Aviv, Israel. ²Tel-Aviv University, Tel-Aviv, Israel. Email: golditai@gmail.com

(No relevant relationships reported)

Background: Heart rate (HR) at 1 minute during the recovery from an exercise stress test (EST) of less than 18 beats per minute (b/min) is regarded as “pathologic” and is associated with poor prognosis. We previously showed the inconsistency of HR recovery (HRR) in patients referred for diagnostic EST.

Purpose: To investigate the prevalence of HRR in healthy individuals undergoing routine ESTs. In addition, we examined the autonomic function of HR variability measures prospectively in “Normal”, “Pathological” and inconsistency / “Fluctuated” HRR subjects undergoing EST.

Methods: We collected ESTs data from healthy subjects (n=66) undergoing annual checkups at the Institute for Medical Screening, Sheba Medical Center. We also examined the autonomic function prospectively in individuals (n=29) undergoing EST. Autonomic function was calculated using power spectral analysis. Independent T-Test and analysis of variance with repeated measures (ANOVA) were performed and a p-value \leq 0.05 was considered significant.

Results: 40% of individuals demonstrated “fluctuated” HRR, 57% demonstrated “normal” HRR (> 18 b/min), and 3% demonstrated “pathological” HRR (\leq 18 b/min) during 17 years (average of 5.39 ± 1.65 tests). HRV indices showed no significant differences between the 3 groups either at rest, peak exercise or during the recovery period.

Conclusion: Our results demonstrate that HRR is not a constant value, and fluctuate between “normal” to “pathologic” among individuals undergoing routine and repeated ESTs. No differences were found in autonomic function indices. These data may question the clinical significance of HRR post exercise.

Scientific literature suggests that oxygen consumption (VO₂) variability during cardiopulmonary exercise tests results mainly from ventilation (VE) irregularities. Gas sampling intervals (GSI) reduce irregularities to unveil the underlying metabolic rate, however, large GSIs may obscure the true maximal rate. Despite the many used GSIs, few studies have investigated the simultaneous effect of altering GSI on ventilation and VO_{2peak}. **PURPOSE:** The purpose of this study was to determine the degree to which GSIs alter VE variability and the correlation with simultaneous changes in VO_{2peak}. **METHODS:** Recreational to well-trained subjects (12 male, 2 female, 23.9 ± 7.9 years) completed a Bruce treadmill test. Eight GSIs from previous literature were chosen. VE data was taken from the last minute of the last full stage completed by the participant. VE variability was reported as standard deviation (VESD) and normalized standard deviation (VENSD, SD divided by number of values used to determine SD). VO_{2peak} for each GSI was defined as the single highest VO₂ value. One-way, repeated measures ANOVAs were used to determine GSI differences in VE variability and VO_{2peak}. Pearson's correlations were used to determine the strength of relationship between VESD and VENSD with VO_{2peak} for each subject, then averaged for the group. **RESULTS:** ANOVAs showed significant differences for VESD (max: 15-sec block, 5.5 L*min⁻¹; min: 15-breath block, 3.1 L*min⁻¹) between (p < 0.001, η^2 = 0.841) and within subjects (p < 0.005, η^2 = 0.337). ANOVAs showed significant differences for VENSD (max: 30-sec block, 2.3 L*min⁻¹; min: 15-breath moving, 0.1 L*min⁻¹) between (p < 0.001, η^2 = 0.827) and within subjects (p < 0.001, η^2 = 0.644). VO_{2peak} was significantly different between GSIs (max 7-breath median 62.7 ± 10.6 ml*kg⁻¹*min⁻¹, min 30-sec block 58.7 ± 11.7 ml*kg⁻¹*min⁻¹, p < 0.001, η^2 = 0.577). The average individual Pearson's correlations for VO_{2peak} vs VESD and VENSD were 0.083 and -0.484, respectively, with only one individual reaching significance in VESD (p < .05) and three reaching significance in VENSD (p < .05). **CONCLUSIONS:** VE variability appears to be subject dependent. Within-subject VE variability did not correlate well with VO_{2peak}. VE variability does not appear to play a role in the change in VO_{2peak} that occurs with a change in GSI.

(No relevant relationships reported)

Previous studies have reported that slower VO₂ kinetics typically observed in healthy older individuals can be prevented by long-term endurance training interventions. However, the chronic adaptations on the VO₂ kinetics and muscle deoxygenation ([HHb]) kinetics response in trained older adults with coronary artery disease (CAD) remains unknown.

PURPOSE: to compare VO₂ and [HHb] kinetics response in moderate exercise in older adults with CAD and a control group (CG) of healthy active age- and gender-matched individuals. Both groups did at least 6 months the following exercise training (ET) prescription, 3 d.wk⁻¹ x 60-min: 30 min at 60-70% heart rate reserve + 2 x 8-12 repetitions in 6 major muscle groups.

METHODS: thirty-two male participants (age: 63.5 ± 8.3 years; n= 17 CAD and n=15 CG) completed the following assessments: 1) incremental symptom-limited cycling cardiopulmonary exercise test; 2) square-wave transitions from rest to moderate-intensity exercise. Pulmonary VO₂ was collected breath-by-breath and [HHb] data of the vastus lateralis was determined by near-infrared spectroscopy. The parameters of the VO₂ and [HHb] kinetics were determined using a monoexponential model. Differences between groups was assessed with the independent-samples t-test. **RESULTS:** Peak oxygen consumption and peak work load were lower in CAD compared to CG (CAD: 23.2 ± 6.2, CG: 30.4 ± 7.5 ml/kg/min, p<0.05; and CAD: 158 ± 47, CG: 193 ± 50 W, p<0.05). For the square-wave transition, VO₂ amplitude was significantly lower in CAD patients than CG group (10.1 ± 2.9 vs 13.1 ± 3.8 ml/kg/min, p<0.05). In contrast, VO₂ baseline, time constant of the primary phase, gain and mean response time were not significant (p>0.05). The effective deoxy-[HHb+Mb] was not statistically different between groups (p>0.05). **CONCLUSIONS:** Long term ET in CAD participants had lower measured VO_{2peak} and work load compared to age- and gender matched. However, both pulmonary and muscular oxygen kinetics were not slower in older adults with CAD compared to their training-matched counterparts. These findings support the importance on the referral of elderly patients to community-based cardiac rehabilitation ET program to maintain their submaximal pulmonary and muscle [HHb] kinetics to continue their ability to perform daily activities.

Dynamic Adjustment Of Beat-by-beat Cardiac Output And Vo₂ Kinetics During Moderate Intensity Exercise Transitions

Erin Calaine Inglis, Danilo Iannetta, Juan M. Murias. *University of Calgary, Calgary, AB, Canada.*
 Email: ecinglis@ucalgary.ca
 (No relevant relationships reported)

The kinetic adjustment of oxygen utilization (VO₂) to exercise transitions of higher metabolic demands is proposed to be affected by central and peripheral alterations within the O₂ transport system and/or intracellular mechanisms of control. Although limitations in O₂ availability within the microcirculation but not at the conduit artery level have been proposed, knowledge is limited in relation to the contribution of the dynamic adjustment of cardiac output (Q) to the VO₂ kinetics response, and how training status might modify this response. **PURPOSE:** This study aimed to compare the adjustment of muscle VO₂ (i.e., Phase II VO₂) to that of central O₂ delivery as examined by the adjustment of Q during step transitions to moderate intensity exercise. **METHODS:** Sixteen young healthy male participants (35 ± 6 yrs) performed 3 step transitions from 20W to moderate-intensity cycling on a cycle ergometer to determine the breath-by-breath VO₂ and the beat-by-beat Q responses. Participants were separated into two groups: trained (n= 9, VO_{2max} 4.54 ± 0.40 L/min) and untrained (n= 7, VO_{2max} 3.49 ± 0.68 L/min). Phase II VO₂ and Q were modeled with a monoexponential model. Paired and unpaired t-tests and Pearson product moment correlations were used to compare the time constants of VO₂ (τVO₂) and Q (τQ). Statistical significance was set at P<0.05. **RESULTS:** Mean τVO₂ was faster in the trained (13.9 ± 2.7s) compared to untrained (24.4 ± 6.4 s). τQ was slower than τVO₂ in the trained (18.5 ± 6.0 s) but not untrained (20.2 ± 9.2 s). No difference was found between τQ between groups. Overall mean data showed no difference between τVO₂ (18.5 ± 7.1 s) and τQ (19.3 ± 7.3 s). No significant correlations were found between τVO₂ and τQ in trained (r=0.34), untrained (r=0.47), or when considering the two conditions together (r=0.37). **CONCLUSION:** This study demonstrated the dynamic adjustment of Q to exercise transition within the moderate intensity domain does not differ amongst trained and untrained individuals, even in the presence of training induced speeding of the VO₂ kinetics. These data support the notion that mechanisms other than central delivery of O₂, such as improved blood flow redistribution within the active tissues and/or intracellular components are responsible for controlling the rate of adjustment of VO₂.

Case Study of Physiological Measurements during Yoga Asana Practice

Kathryn-Ann B. Conroy¹, Jason Casey¹, William Seffens², Paula Seffens¹. ¹U. of North GA, Oakwood, GA. ²U. of North GA, Dahlonega, GA. (Sponsor: Walter R Thompson, FACSM)
 (No relevant relationships reported)

PURPOSE: To conduct a preliminary case study to evaluate real time physiological changes and responses to mediation, Hatha yoga, inversion (experimental) and standing postures (control) and to determine the feasibility, reliability and validity of oxygen consumption and rate pressure product measured by a wearable metabolic device.

METHODS: A 500-hour registered yoga teacher (RYT) volunteered for this study and informed consent was obtained from the subject. A wearable metabolic device, calibrated to according to manufacturer's specifications, was worn for the duration

of each session. We conducted three sessions for this study. Blood pressure (BP), Heart Rate (HR), Oxygen Consumption (VO₂) and Respiratory Quotient (RQ) were monitored. Each session began with a two minute meditation in a cross leg pose, followed by a warm up consisting of Sun Salutations and ended with a cool down. In addition, the first session included Mountain Pose then Chair Pose held for two minutes each. For the third session, supported shoulder stand and headstand were performed in place of the standing postures, each for two minutes. Heart Rate and VO₂ were recorded every minute. We obtained BP during the last 30 seconds of each posture.

RESULTS: Over the trials, mean VO₂ was 3.1 ± 0.08 mlkg⁻¹min⁻¹ for the meditative pose, while the inverted pose yielded a mean VO₂ of 19.5 ± 1.5 mlkg⁻¹min⁻¹. A t-test between meditation and inversion for VO₂ and HR was significant (p<0.05).

CONCLUSIONS: These results will be put into the broader aspects of yoga and physiological measurements discussed above with further trials and additional subjects. This will assist in the implementation of yoga and other meditative movement technologies to be implemented into exergame software applications that can be hosted on personal computers and smartphones.

| Trial | Meditation | | | Inversions | | |

Limb Stiffness Is Lower In Those Who Rupture Contralateral Non-ACLR Knee Post Primary ACL Surgery

Chris Richter¹, Enda King¹, Katherine Daniels¹, Andy Franklyn Miller¹, Ray Moran¹, Mark Jackson¹, Siobhan Strike². ¹Sports Surgery Clinic, Dublin 9, Ireland. ²University of Roehampton, London, United Kingdom.
 Email: mr.chris.richter@gmail.com
 (No relevant relationships reported)

Purpose

The aim of this study was to identify biomechanical differences during jump and CoD testing 9 months after ACL reconstruction (ACLR) between those that went on to injure their non-ACLR limb and those that did not at 2 year follow up.

Methods

Nine months after ACLR, 105 males athletes who were returning to pre-injury sport participation (55 going on to suffer contralateral ACL injury/60 matched subjects with no second injury at 2 years post op) were prospectively assessed using isokinetic strength testing and 3D biomechanical analysis of double leg drop jump (DLDJ), single leg drop jump (SLDJ) and planned and unplanned 90° change of direction (CoD) as well as an IKDC questionnaire. Differences in IKDC, strength and jump height measures on the non-ACLR side and in limb symmetry index between groups were analysed with statistical parametric mapping (SPM, OD unpaired t-test). Biomechanical differences in the jump and CoD tests on the non-ACLR side and in symmetry between groups was analysed with SPM (1d, unpaired t-test). Effect size was calculated using Cohen's D for all analyses.

Results

There was no difference in IKDC score between groups. There was a small effect size difference in quadriceps strength on the non-ACLR side in the group that went on to injure that limb (ES 0.39) with no difference in LSI or across the hamstring strength and jump height tests. There was no difference in measures of biomechanical symmetry between groups for any of the tests and no difference on the non-ACLR side for the CoD tests. There were large effect size differences on the non-ACLR side in the SLDJ and DLDJ for COM stiffness (ES 0.78 & 0.82), ground contact time (ES 0.73 & 0.85), lowering of COM to ankle and knee (ES 0.7 to 0.81), vertical ground reaction force (ES 0.63 to 0.78) representing less stiffness on the non-ACLR side in the group that went on to injure non-ACLR limb after return to sport.

Conclusion

This study demonstrated clear biomechanical differences on the non-ACLR side in those that went on to injure the ACL in the limb despite little difference in strength and jump measures and measures of symmetry. These results suggest plyometric exercises to improve limb stiffness may be important to reduced injury risk to the non-ACLR limb after primary ACLR.

 (No relevant relationships reported)

Wearable inertial sensors are practical and inexpensive technology that can be used to detect gait asymmetries following anterior cruciate ligament reconstruction (ACLR). Specifically, individuals after ACLR walk with asymmetries in shank angular velocity (SAV) during landing, which may be indicative of abnormal knee joint loading. However, it is unknown whether these asymmetries in SAV detected at early stage of rehabilitation can predict functional performance at 6 months after ACLR. **PURPOSE:** To investigate whether SAV asymmetries during walking at 4 months after surgery can predict return-to-activity criteria at 6 months in individuals with ACLR. **METHODS:** Fourteen individuals (8 females; age= 27.79±7.9 y) with primary unilateral ACLR participated in the study. Participants were instructed to walk at a self-selected speed along a 12-meter straight walkway at 4 months after surgery. SAV peak was calculated bilaterally during landing as the first negative peak value after heel strike in the sagittal plane. The average SAV peak was calculated for each limb. At 6 months after surgery, participants completed return-to-activity criteria testing (isometric quadriceps index, single-legged hop tests, Knee Outcome Survey-Activities of Daily Living Scale (KOS-ADLS), and Global Rating Score (GRS)). Inter-limb symmetry (ACLR limb/uninjured limb*100) was calculated for SAV peak and functional measures. Linear regression models were used to determine whether SAV peak at 4 months would predict functional performance at 6 months following surgery. **RESULTS:** Asymmetry in SAV at 4 months was a significant predictor for asymmetries in the isometric quadriceps strength ($r^2=0.39$, $p=.02$), single hop for distance ($r^2=0.36$, $p=.02$), triple hop for distance ($r^2=0.34$, $p=.03$), and triple-crossover hop for distance ($r^2=0.51$, $p=.001$), but not for the 6-meter timed hop ($r^2=0.17$, $p=.14$) at 6 months. Greater SAV asymmetry was a significant predictor for worse scores on the KOS-ADLS ($r^2=0.49$, $p=.006$) and GRS ($r^2=0.46$, $p=.008$). **CONCLUSIONS:** This pilot study showed that gait asymmetry detected by inertial sensors at early stage of rehabilitation can predict functional performance at 6 months after ACLR. Implementing these sensors in clinical practice may help clinicians to monitor gait on a regular basis during rehabilitation.

Hip, Knee, And Ankle Contributions During Sloped Walking In Individuals With Aclr
 Katie Corona, Hillary H. Holmes, Randall Fawcett, Jaimie A. Roper. *Auburn University, Auburn, AL.* (Sponsor: Mark Tillman, FACSM)
Reported Relationships: K. Corona: Other (please describe); This was sponsored by an undergraduate research fellowship from Auburn University.

PURPOSE: To compare joint moment contributions at the knee, ankle, and hip during flat, incline, and decline walking between limbs in individuals with ACL reconstructed (ACLR). **METHODS:** We analyzed 8 participants with ACLR. Each participant walked flat, uphill, and downhill at 0, 10, and -10 degrees with pre-determined speeds (1.3 m/s, 1.0 m/s, 1.0 m/s). Kinematic and kinetic data were collected during the final 30 seconds of each condition using 17 cameras (Vicon) and an instrumented split-belt treadmill (Bertec). Joint moment contributions at the hip, knee, and ankle were determined by dividing the peak sagittal joint moments by the sum of all three peak moments during stance. A 2x3 (limb x condition) ANOVA was implemented to evaluate interlimb differences across conditions, with post-hoc bonferroni adjustments. **RESULTS:** No significant main effect of limb or limb x condition interaction was found. Hip contributions were 13% greater during incline walking (28% contribution) compared to decline (15% contribution). During decline walking (57% contribution) knee contributions were 42% greater compared to incline (15% contribution) and 41% greater compared to flat walking (16% contribution). During flat walking (54% contributions) ankle contributions were 27% greater compared to decline (27% contributions) and 30% greater during incline walking (57% contributions) compared to decline. **CONCLUSIONS:** These results suggest that individuals with ACLR are capable of maintaining lower extremity joint symmetry with respect to walking at an incline and decline. Future studies will investigate differences in lower extremity joint contributions between individuals with ACLR and a healthy, age-matched control group.

Post-Trial Feedback Alters Single and Dual Task Landing Performance in Healthy and ACL Reconstructed Athletes
 Thomas W. Kernozek, FACSM¹, Brett McCutchin¹, Maria Lee¹, Jackie Cleerman¹, Jessica Onsager¹, Jeremie Schiedermaier¹, Becky Heinert², Drew Rutherford¹. ¹*University of Wisconsin-La Crosse, La Crosse, WI.* ²*Gundersen Health System, La Crosse, WI.*
 Email: kernozek.thom@uwlax.edu
 (No relevant relationships reported)

ACLR reconstructed (ACLR) individuals have unequal lower extremity loading during bilateral landing. Post-trial feedback may be used to alter landing mechanics in both healthy and ACLR populations. **PURPOSE:** Determine how post-trial feedback of vertical ground reaction force (vGRF), loading asymmetry (LA), and frontal-plane video (FPV) of control and ACLR groups can be used to alter these variables during single- and dual-task landing performances using a low-cost custom portable system in female athletes. **METHODS:** 24 female athletes were placed in a control (n=12) or ACLR (n=12) group. Single-task (ST) or dual-task (DT with/without jumping for a ball) drop landing trials were performed from a 50 cm height in blocks of 3 ST and 6 DT (pre-tests), 6 ST and 6 DT with post-trial visual feedback, and 3 ST and 6 DT post-tests. Peak vGRF, LA, and frontal plane knee-to-ankle ratio between task (ST or DT) and over time (pre-test, feedback, post-test) were compared using a three-way repeated measures ANOVA. **RESULTS:** Peak vGRF decreased (4.43±0.81 vs. 3.64±0.44 vs. 3.44±0.48 BW, $p<0.001$) and improved knee-to-ankle ratio (0.94±0.13 vs. 1.01±0.12 vs. 1.05±0.12, $p<0.001$) occurred over time (pre-test, feedback, post-test). ACLR group LA was larger compared to controls (0.16±0.08 vs. 0.09±0.08, $p=0.043$). **CONCLUSION:** Peak vGRF and knee-to-ankle ratio improved over time for both groups. The ACLR group had higher LA compared to controls. Post-trial feedback may produce immediate changes in peak vGRF and knee-to-ankle ratio, however more post-trial feedback in LA may be necessary to produce changes in asymmetry in ACLR populations.

Spatiotemporal Variables During Self-selected And Fastest-comfortable Walking Speeds In Individuals Following Acl Reconstruction
 Jennifer L. Hunnicutt¹, Michelle M. McLeod², Harris S. Slone³, Chris M. Gregory, FACSM³. ¹*Emory University, Atlanta, GA.* ²*College of Charleston, Charleston, SC.* ³*Medical University of South Carolina, Charleston, SC.* (Sponsor: Dr. Chris Gregory, FACSM)
 Email: jlhunni@emory.edu
 (No relevant relationships reported)

PURPOSE: As a first step in translating the wealth of biomechanical gait studies following ACL reconstruction (ACLR), we conducted a study evaluating gait using more clinically applicable tool, the GAITRite portable walking system. Although this system has been used in a number of other populations (i.e., older adults, stroke), it has rarely been used in individuals following ACLR. The purpose was to describe spatiotemporal variables in individuals following ACL reconstruction. We hypothesized that individuals following ACLR would demonstrate between limb differences in spatiotemporal variables. **METHODS:** Participants walked over a portable walking system (GAITRite, CIR Systems, Inc., Franklin, NJ, USA) for three trials at their self-selected walking speed and three trials at their fastest-comfortable speed. They were not permitted to use any assistive devices during trials. Gait speed and spatiotemporal variables were collected and analyzed. Between limb differences in step length and percentage of gait cycle spent in single limb support were analyzed using paired samples t-tests. **RESULTS:** Data from 30 active individuals (23 years; 19 males; 9 mo. post-ACLR; IKDC score=80.5) are presented. Self-selected and fastest comfortable walking speeds were 1.22 and 1.89 m/s. Step length was significantly different between limbs at both self-selected (surgical limb=69.9±8.1; non-surgical limb=70.9±8.5; $p=0.029$) and fastest-comfortable walking speeds (surgical limb=86.7±10.0; non-surgical limb=88.4±10.0; $p<0.001$). There were no significant differences between limbs for percent of gait cycle spent in single limb support during self-selected walking (37.0±1.3 vs 37.3±1.5; $p=0.065$), however, there were significant differences during fastest-comfortable walking speed (40.1±1.6 vs 40.6±1.5; $p=0.003$). **CONCLUSIONS:** Although small, the observed shorter steps may be indicative of off-loading of the surgical limb. Further work is underway to include investigation of earlier time points following ACLR and relationship of spatiotemporal parameters to kinetic data.

Dexterity of the Lower Limb Coordination In ACL Injured Athletes

Issei Ogasawara¹, Yohei Shimokochi², Ken Nakata¹. ¹Osaka University, Toyonaka, Japan. ²Osaka University of Health and Sport Sciences, Sennan-gun, Japan.
 Email: ogasawaraissei@hss.osaka-u.ac.jp
 (No relevant relationships reported)

PURPOSE: Regaining the “dexterity” in lower limb control is important for successful return to sports after ACL injury. The purpose of this pilot study is to evaluate the dexterity of the ACL-injured limb from the viewpoint of the complexity, smoothness, and accuracy of the inter-joint coordination. **METHODS:** Three male volunteers who had histories of ACL rupture participated in this study (One had already reconstructed, and the other had not reconstructed yet at the test day). The motor task was the lower limb target pursuing with the custom-made smart leg press device. As a target, the vertical bar, which sinusoidally up and down with the 0.5 Hz frequency, was presented on the PC screen. The volunteers were asked to control the vertical position of the mouse cursor with the leg press device and follow the target as precise as possible. The ankle, knee, and hip joint angles in the sagittal plane were calculated from 3D motion capture data. To quantify the complexity, the approximated entropies (ApEn) of those joint angles and cursor movement were calculated. The smoothness of the movement was evaluated with the root mean squared jerk (RMSJ), and the accuracy was quantified with the root mean squared error between target and cursor (RMSE). Those three performance variables were presented as the involved/uninvolved ratio. **RESULTS:** The ACL-reconstructed limb showed high complexity, less smooth, and moderately accurate pattern as compared to uninvolved limb. The non-reconstructed limb showed low complexity, less smooth, and not accurate patterns (Fig. 1). **CONCLUSIONS:** The complex and less smooth, but the accurate pattern in the reconstructed limb may suggest that the ACL reconstruction contributed on regaining fine inter-joint coordination which creates precise end-effector control based on the various combination of joint angles. The ACL reconstruction may help not only rebuilding the ligamentous structure but also regaining a dexterity of the movement.

Figure 1. The involved/uninvolved ratio in the approximated entropy (ApEn), root mean squared jerk (Smoothness), and root mean squared error (Accuracy) from three ACL injured athletes

 (No relevant relationships reported)

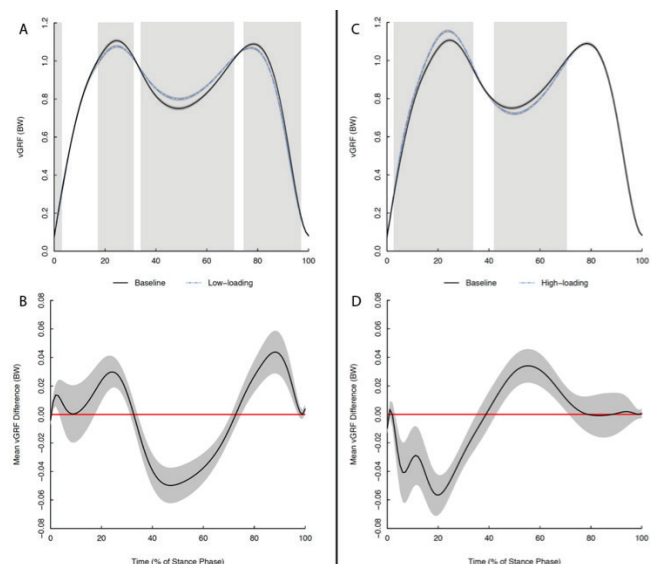

Recent studies have suggested that an anterior cruciate ligament reconstruction (ACLR) causes neuroplastic changes in the brain associated with muscle coordination. However, it remains unclear how an ACLR patients’ brain responds during postural control, which is a good clinical indicator for muscle coordination, when compared to healthy controls. **PURPOSE:** To examine differences in brain activity during a single-legged postural control testing between ACLR patients and healthy controls. **METHODS:** In this preliminary data, four healthy controls (CONT; 21.8±2.2yrs, 84.8±28.3kg, 180.3±5.08cm) and four ACLR patients (ACLR; 28.5±10.7yrs, 83.9±23.3kg, 179.1±10.5cm) volunteered. Frontal theta (Fz, 4-8Hz) and Parietal alpha-2 (Pz, 10-12Hz) electrocortical activations ($\mu V^2/Hz$) were quantified using a mobile electroencephalograph (EEG) during one-legged postural stability testing. Independent t-tests were used to determine electrocortical activation differences between groups. **RESULTS:** The ACLR had a lower Alpha-2 power at Pz compared to the CONT (32.71±3.33, V^2/Hz vs. 38.76±3.24, V^2/Hz , $p=0.041$) during the single-legged postural control. No difference in frontal theta power (Fz) existed between the groups (38.46±1.02, V^2/Hz vs. 41.63±4.34, V^2/Hz , $p=0.205$). **CONCLUSIONS:** Our findings reveal less parietal Alpha-2 power in the ACLR patients compared to the healthy controls, while no different frontal theta power between groups during the postural control. As less Alpha-2 power represents less inhibition of sensory and attention to or movement in space, our findings suggest that ACLR patients may have increased cortical activation in the somatosensory cortex to compensate for altered proprioception following a surgical repair, when compared to healthy controls. During critical decision making, such as high intensity athletics,

this heightened somatosensory cortex activation could disrupt the rapid response mechanisms, and it may explain why some ACLR patients suffer poor muscle coordination and are at higher incidence of re-tear.

Manipulating Initial Peak vGRF During Walking Affects Loading Throughout Stance in Individuals with ACL Reconstruction

Alyssa Evans¹, Brittney A. Luc-Harkey², Hope C. Davis¹, J. Troy Blackburn¹, Matthew K. Seeley³, Jason R. Franz¹, Brian Pietrosimone, FACSM¹. ¹University of North Carolina at Chapel Hill, Chapel Hill, NC. ²Brigham and Women’s Hospital, Boston, MA. ³Brigham Young University, Provo, UT. (Sponsor: Brian Pietrosimone, FACSM)
 Email: alyssa7evans@gmail.com
 (No relevant relationships reported)

Gait alterations may be associated with osteoarthritis development following anterior cruciate ligament reconstruction (ACLR). Novel gait retraining paradigms are being developed to optimize peak vertical limb loading in the first half of stance; yet the effect of changing this single discrete variable on loading characteristics across the entire stance phase remain unknown. **PURPOSE:** Determine the effect of increasing and decreasing the first peak of the vertical ground reaction force (vGRF) by 5% during walking using real-time biofeedback (RTBF) of vGRF throughout stance. **METHODS:** 30 ACLR participants (21 females, 20.4±2.9 yrs, 172.7±10.8 cm, 73.2±16.1 kg, 47.8±4.2 months post-ACLR) completed one 20-minute control condition and two experimental conditions (high- and low-loading). For high- and low-load conditions, participants walked for 20 minutes on a force-measuring treadmill with RTBF displayed on a screen cuing a 5% increase (high) or decrease (low) in the first peak of the vGRF relative to vGRF collected in the control condition. vGRFs were collected at 1000 Hz throughout the 19th minute. Two functional analyses of variance were conducted to evaluate vGRF magnitude throughout stance. **RESULTS:** Figures 1A and 1C depict mean vGRF, normalized to body weight (BW), throughout the stance phase. Figures 1B and 1D depict pairwise comparison functions (solid black lines) and associated 95% confidence intervals (gray bands), indicating mean differences between the two conditions. Significant between-condition differences existed in the high-loading condition between 42 and 74% of stance, and in the low-loading condition (between 38 and 70%, and 76 and 97% of stance). **CONCLUSION:** RTBF, used to cue changes in the first vGRF peak, results in loading alterations throughout stance. Specifically, high loading results in lesser vGRF at midstance but a similar propulsive peak. Conversely, low loading increases vGRF during midstance and decreases vGRF during toe-off.

(No relevant relationships reported)

Injury to the anterior cruciate ligament (ACL) is considered one of the most devastating injuries to the lower extremity. The gold standard treatment for ACL injury is surgical ACL reconstruction (ACLR) followed by 6-12 months of rehabilitation. Kinematic lower limb asymmetries in individuals post-ACLR have been identified during a variety of tasks such as walking, hopping and landing. However, there is limited understanding of whether limb kinematic asymmetries exist during a multi-directional high-risk task such as cutting. **PURPOSE:** To assess kinematic asymmetry between ACLR and non-surgical limbs during a cutting task. **METHODS:** Twelve participants (7 females, 5 males) who had undergone an ACLR and returned to full activity participated in this study. Twenty-one lower extremity markers and six marker clusters were placed on participants who ran down a 7-meter runway, planted their foot, and performed a 45° angle cutting task. Cutting tasks were performed to the right and the left of the runway. For left cutting tasks, the right limb was the planting limb and vice versa. Five successful trials were collected for each limb using an 8-camera 3D motion capture system. Joint kinematics were calculated and variables of interest included peak hip and knee flexion, ankle dorsiflexion, and combined sagittal-plane joint excursion. Differences in kinematics between limbs were calculated using paired *t*-tests with the alpha level set to 0.05. **RESULTS:** Peak hip flexion was greater in the non-surgical limb (non-surgical: 45.11 ± 14.97°, ACLR: 41.68 ± 16.62°, *p* = 0.029), and a trend for greater peak knee flexion was found in the non-surgical limb (non-surgical: 51.9 ± 8.04°, 49.44 ± 8.88°, *p* = 0.068). Combined sagittal-plane joint excursion was greater in the non-surgical limb during the cutting task (non-surgical: 146.28 ± 15.90°, ACLR: 133.66 ± 16.02°, *p* < 0.01). **CONCLUSION:** Subjects post-ACLR exhibited greater utilization of their non-surgical limb in the sagittal plane during a cutting task. This movement pattern suggests an avoidance behavior of their ACLR limb and suggests that further rehabilitation is necessary in these individuals post-ACLR in an effort to reduce their risk of re-injury.

Altered Brain Morphology In Women With History Of ACL Rupture: A Structural MRI Study**

Felix Proessel, Anne Z. Beethe, Adam J. Sterczala, Courtenay Dunn-Lewis, Christopher Connaboy, Bradley C. Nindl, FACSM, Shawn D. Flanagan. *University of Pittsburgh, Pittsburgh, PA.*
(No relevant relationships reported)

Anterior cruciate ligament ruptures (ACLR) are among the most common musculoskeletal injuries in young women. Despite the presence of supraspinal alterations after ACLR, the global and localized morphological underpinnings have yet to be elucidated.

PURPOSE: This study aimed to determine whether brain morphology differs in individuals with a history of ACLR compared to healthy controls with no history of injury.

METHODS: Twenty (10 ACLR, 10 controls) age- and physical activity-matched women (age: 20.9±2.9yr, weight: 65.9±8.8kg, height: 165.2±6.2cm) underwent 3T T1-weighted structural brain magnetic resonance imaging. Mean cortical thickness, grey matter and white matter volume were measured globally and within 70 and 95 anatomically defined regions of interest (ROIs), respectively. A two-way analysis of variance was used to determine differences in global and regional brain structure between ACLR and controls, while correcting for multiple comparisons by controlling the false discovery rate.

RESULTS: Mean duration since the completion of rehabilitation after ACLR was 3.1±1.1yr. Five injured the left leg and all but two participants were right foot dominant. Cortical thickness was significantly greater for controls in the left precentral gyrus (3.62±0.22 vs. 3.19±0.39mm, respectively *P*=0.019) and left paracentral lobule (3.70±0.23 vs. 3.27±0.26mm respectively; *P*=0.025). No differences in gray or white matter volume were seen for any of the ROIs between groups.

CONCLUSION: Three years after ACLR rupture, young women demonstrated persistent alterations in cortical thickness relative to individuals without a history of injury. Together with evidence of other supraspinal and neuromuscular deficits,

this suggests cortical involvement in the ACLR pathological process. Thus, neurophysiological assessments should be considered in addition to traditional musculoskeletal measurements.

Traumatic peripheral injury, like ACL rupture, may alter neurobiological structure and function, with regional reductions in sensorimotor circuit excitability and altered activity patterns in the prefrontal cortex. **PURPOSE:** To examine the long-term neurobiological consequences of ACL rupture on cortical silent periods (CSPs) in the motor cortical (M1) representations of the vastus lateralis (VL). **METHODS:** Nine women with a history of unilateral ACL rupture, repair and rehabilitation (3.3 ± 1.2 years prior) participated in the study. Maximal voluntary isometric contraction force (MVIC) was obtained for each leg during a bilateral, closed kinetic chain movement. Active stimulus response curves were produced at 15% MVIC. Biphasic single pulse transcranial magnetic stimulation (TMS) was delivered to the left or right VL hotspot at 40, 50, 60, 70, 80, and 90% stimulator output (SO). Five pulses were delivered during each 25s contraction, with 30s rest between contractions. SO order and leg were randomized. Contralateral CSPs were measured from TMS stimulus onset to the visual resumption of muscle contractile activity. Responses to each leg-specific SO were averaged for each subject and analyzed via two-way repeated measures ANOVA with Fisher's LSD pairwise comparisons. **RESULTS:** Because CSPs were consistently produced above 70% SO, quantitative analysis was limited to 70, 80, and 90% SO. Significant main effects were observed for SO (*p*=0.001) and Leg (*p*=0.026). CSP duration increased in parallel with SO intensity (80% vs. 70% Δ=32.1ms, *p*=0.002; 90% vs. 70% Δ=54.5ms, *p*=0.002; 90% vs. 80% Δ=22.4ms, *p*=0.015). CSPs were generally longer in the injured leg (Δ=21.6ms, *p*=0.026). At 70 and 80% SO, CSPs were longer in the injured leg (70% SO: 25.8ms Δ, *p*=0.017; 80% SO: 18.3ms Δ, *p*=0.026; 90% SO: 20.6ms Δ, *p*=0.099). A trend of increased CSP duration at 90% SO may reflect ceiling effects in the silent period of the injured leg. **CONCLUSIONS:** Injured-leg M1 representation stimulation increased CSP durations compared to the uninjured leg. These deficits persisted years after rehabilitation, and were reproducibly detected during bilateral closed kinetic chain movements at 15% MVIC and SOs above 70%. Our observations indicate long-term reductions in the strength of the sensorimotor circuits governing the injured leg.

(No relevant relationships reported)

PURPOSE: The mechanism and specific characteristics of differences between sexes are not clear. Using three-dimensional motion capturing system in kinematics and surface electromyography (sEMG) to discuss the changes of hip and knee flexion angle and neuromuscular signals in ACLR.

METHODS: Eight MX-F20 motion-capture cameras were connected with a VICON Vgas CMOS sensor. 10 subjects (5 males and 5 females) were selected after ACLR within 1 year. Making sure model of lower limbs can be caught by cameras. Placing electrodes on subjects' lower limbs of gluteal muscle, vastus medialis, lateral femoral, rectus femoris, and biceps femoris respectively. The electrodes are connected with the NORAXON wireless sEMG signal collector to collect the surface myoelectric signal of 10 muscles during action process. Subjects to stand in a standing position by their feet, on a skip box with the height of 30cm, and landing in the feet. At the same time, collecting landing moments in the course of the operation, gathering flexion angles of hip joint and knee joint, and changing of the 10 muscular sEMG signal. Rate of contributing in these muscles of this motion and hip and knee flexion angles were analyzed. Using a separate T-test comparative analysis of gender was performed by SPSS19.0.

RESULTS: There is a significant difference in hip flexion angle of affected side (unaffected side: Mean = 17.01, SD = 9.28; affected side: Mean = 17.33, SD = 13.53; *t* = 0.467, *p* = 0.034), and knee flexion angle is not significantly different. (unaffected: Mean = 29.0, SD = 15.51; affected: Mean = 27.54, SD = 16.33; *t* = -0.298, *p* = 0.404). There is a significant difference in knee flexion angle of gender (male: Mean

= 376.56, SD = 156.86; female: Mean = 17.52, SD = 9.87; p = 0.049), and there is no significant gender difference in hip flexion angle in affected side. Among the Averaged mean amplitude of all periods, the gluteal muscle play an important role in this action.

CONCLUSIONS:

Changing about range of motion and stability of hip joint with affected side is greater than unaffected. The knee flexion angle is affected by gender in the presence of foot-landing-landing process, and knee flexion angle of female knees is smaller than that in males, but in muscle stimulation rate, women are more dependent on thigh muscle strength rather than gluteal muscle.

Associations Between Knee Kinematics During Gait And Quadriceps Corticomotor Excitability Following Anterior Cruciate Ligament Reconstruction

Sarah Ward¹, Matthew Harkey², Brittney Luc-Harkey³, Derek Pamukoff⁴, Troy Blackburn⁵, Brian Pietrosimone, FACSM⁶.
¹University College Dublin, Dublin, Ireland. ²Tufts Medical Center, Boston, MA. ³Massachusetts General Hospital, Boston, MA. ⁴California State University, Fullerton, Fullerton, CA. ⁵Univeristy of North Carolina at Chapel Hill, Chapel Hill, NC. ⁶University of North Carolina at Chapel Hill, Chapel Hill, NC. (Sponsor: Brian Pietrosimone, FACSM) (No relevant relationships reported)

Impaired quadriceps function is associated with a more extended knee throughout the stance phase of gait in individuals with anterior cruciate ligament reconstruction (ACLR). This stiffened knee strategy may alter tibiofemoral loading and hasten joint breakdown and osteoarthritis development. Altered quadriceps corticomotor excitability may influence knee kinematic during gait; yet it is unknown if quadriceps corticomotor excitability associates with gait kinematics.

PURPOSE: To determine associations between quadriceps corticomotor excitability and sagittal plane knee kinematics during walking for ACLR individuals. **METHODS:** Thirty-three individuals with unilateral ACLR participated in this cross-sectional study (72% female, 22.2 ± 3.5years; 72.5 ± 17.2kg; 1.7 ± 0.1m; 49.9 ± 40.4 months post-ACLR). Quadriceps corticomotor excitability was assessed as active motor threshold (AMT) from the vastus medialis of the ACLR limb using transcranial magnetic stimulation. Three dimensional biomechanics were collected during over ground walking at a self-selected speed and extracted from the first 50% of stance. We evaluated sagittal plane knee kinematics for the current study including (knee flexion angle at heel strike [HS]; peak knee flexion angle; knee flexion excursion [peak angle - HS angle]). Partial Pearson product-moment correlations were used to assess associations between kinematic variables and corticomotor variables in the ACLR limb controlling for gait speed ($\alpha = 0.05$).

RESULTS: AMT was not associated with sagittal plane knee kinematics in the ACLR limb during walking (angle at HS $r = -0.13$ $P = 0.47$; peak knee flexion angle $r = -0.22$ $P = 0.22$; knee flexion excursion $r = -0.19$ $P = 0.29$).

CONCLUSIONS: No associations were found between quadriceps corticomotor excitability and sagittal plane knee kinematics during gait in individuals with ACLR. Central pattern generators, and not cortical excitability, may more strongly influence gait kinematics. Further work is necessary to determine the influence of altered corticomotor excitability on other gait outcomes including kinetics and lower limb muscle activity patterns.

Hyaluronate Injections after Anterior Cruciate Ligament Reconstruction Does Not Improve Running Mechanics

Nicholas P. Baumann¹, Alexa K. Johnson¹, Nicholas R. Heebner¹, Caitlin E-W Conley¹, Cale A. Jacobs¹, Darren L. Johnson¹, Mary L. Ireland, FACSM¹, Christian Lattermann², John P. Abt, FACSM¹. ¹University of Kentucky, Lexington, KY. ²Harvard Medical School, Boston, MA. (Sponsor: John Abt, FACSM) Email: npba222@g.uky.edu (No relevant relationships reported)

Mitigating inflammation early after anterior cruciate ligament reconstruction (ACLR) may help strength and biomechanical outcomes further in rehabilitation. **PURPOSE:** The purpose of this study was to determine if hyaluronate injections (HI) administered early after surgery improves strength and running mechanics six months after ACLR. **METHODS:** Nineteen individuals (Table 1) who suffered an ACL tear during sport participation were enrolled in a randomized double-blind controlled trial to test a post-operative intraarticular HI compared to a placebo one week after surgery (one patient screen failed, and one withdrew after surgery). Six months post-surgery individuals completed isokinetic quadriceps strength (IKQS) at 60°/second and a biomechanical analysis of overground running using 3D motion capture and force plates. Visual 3D was used to calculate bilateral lower extremity biomechanics including knee excursion (KEX) from initial contact to peak knee flexion, and peak vertical ground reaction forces (VGRF). Inverse dynamics were used to calculate internal peak knee abduction

moments (KAM), and peak knee extension moments (KEM). A repeated measures analysis of variance was used to determine differences between groups (injection vs control) and limb (involved and uninvolved). An alpha value of 0.05 was used.

RESULTS: There were no significant differences between the injection group and the control group in peak IKQS or running mechanics, and there was no significant group x limb interaction. In both the injection group and the control group, the involved limb exhibited significantly lower IKQS and KEM, less KEX, and lower peak VGRF (Table 1) compared to the uninvolved limb. **CONCLUSION:** The individuals who received the HI post-surgery did not present with improved strength or running mechanics six months post ACLR compared to control subjects. Future research should investigate further benefits of neuromuscular and physiological factors from a HI.

| Table 1 | Control Mean ± SD | | Hyaluronan Injection Mean±SD | | | | |
|-------------------|----------------------|---------------|------------------------------|---------------|---------------|----------------------|-------------------------------------|
| Sex | Female = 4, Male = 4 | | Female = 6, Male = 3 | | | | |
| Age (yrs) | 18.88± 3.78 | | 18.40± 2.17 | | | | |
| Mass (kg) | 87.41± 17.36 | | 81.45± 24.41 | | | | |
