BACKGROUND: Cardiac rehabilitation (CR) improves functional capacity (FC), quality of life (QoL), psychosocial well-being, and reduces cardiovascular risk factors using lifestyle management strategies. Despite well known benefits, little is known about the long-term effects of CR on risk factor management and changes in FC following discharge. Therefore, the purpose of this retrospective cross-sectional investigation was to examine changes in 6-minute walk distance (6MWD) 11-15 months following CR. **METHODS:** Patients referred to the UAB Cardiac Rehabilitation Program from 2016-2019 who completed 24-36 sessions and 6-minute walk tests (6MWT) at intake, discharge, and post-discharge were included in this pilot investigation. Twenty-two patients were included with the following CVD diagnoses: myocardial infarction, angina, PCI, CABG, or valve replacement. Repeated measures analysis of variance (ANOVA) was used to examine differences over time for 6MWD with least significance difference (LSD) post-hoc testing (SPSS, v25). **RESULTS:** 6MWD increased by 30% from intake to discharge (388 ± 96 m to 504 ± 123 m, $P < 0.0001$). Post-discharge walking distance (519 ± 118 m) remained higher than intake ($P < 0.0001$) but was similar to discharge ($P = 0.091$). Body weight, waist circumference, systolic blood pressure (SBP), and diastolic blood pressure (DBP) all returned to baseline intake values post-discharge. **CONCLUSIONS:** The results of this study suggest that CR may produce lifestyle and behavioral changes that promote long-term maintenance of FC. While an extensive examination of other risk factors was not performed, increases in body weight and blood pressure observed 11-15 months post-discharge are discouraging. A thorough examination of the long-term consequences of these findings with preserved FC will be needed to explore the interaction between FC and other risk factors as it relates to secondary prevention of CVD.

Comparative Effects Of Interval Warm-up Exercise And Bronchodilator On Exercise-induced Bronchoconstriction In Children With Mild Asthma

Michael W.H. Wong¹, Nicholas A. Ross¹, Ani L. Kechkarian¹, Donna J. Gould¹, Craig Nakamura², Dharini M. Bhammar¹.

¹University of Nevada, Las Vegas, Las Vegas, NV. ²Children's Lung Specialists, Las Vegas, NV.

(No relevant relationships reported)

Purpose: Bronchodilators and interval warm-up exercise are both recommended for preventing exercise-induced bronchoconstriction (EIB). Whether interval warm-up exercise can prevent EIB to the same extent as bronchodilators is unknown but clinically very important. The purpose of this study was to compare the effects of bronchodilator and interval warm-up exercise on EIB in children with mild asthma.

Methods: Eight children (6 boys, 10 ± 1 yr) completed exercise challenge tests (target ventilation 40–60% of predicted maximal voluntary ventilation) following three conditions on separate days: control; 180µg of albuterol; and interval warm-up exercise (eight 30s cycling intervals at 80–90% of HRmax with 45s recovery between intervals). Spirometry and impulse oscillometry (IOS) were completed before; 10min after condition; and after the exercise challenge test at minutes 2, 5, 10, 15, 20, 25, and 30.

Results: Baseline spirometry and IOS were not different between the three conditions. FEV₁ was higher for bronchodilator (2.4 ± 0.4L) compared with interval warm-up (2.2 ± 0.3L) and control (2.2 ± 0.4L; $P = 0.005$). Respiratory resistance at 5 Hz (R5) was lower for bronchodilator (4.78 ± 1.03 cmH₂O/L/s) compared with interval warm-up (5.86 ± 0.96 cmH₂O/L/s) and control (5.93 ± 1.06 cmH₂O/L/s; $P < 0.001$). Only one child was diagnosed with EIB (≥15% reduction in FEV₁) after the exercise challenge test (control), one child was diagnosed with a borderline response (10-14.9% reduction in FEV₁), and five children experienced bronchodilation (Range for FEV₁ %change: 5–18%).

Conclusions: EIB was not common in this limited sample. Pre-treatment with bronchodilator was associated with more favorable changes in lung function when compared with interval warm-up exercise.

(No relevant relationships reported)

Obstructive sleep apnea (OSA) causes systemic inflammation which may contribute to the progression of cardiovascular pathology. Exercise training reduces chronic inflammation in obese individuals and is recommended as a behavioral treatment of OSA. Calprotectin is a useful marker of inflammation that has been associated with OSA severity. Yet, the extent to which OSA predicts a change in systemic inflammation with exercise training is not clear. **PURPOSE:** Examine the effect of 6 weeks of exercise training on plasma calprotectin in obese adults with and without OSA. **METHODS:** At baseline, participants underwent overnight polysomnography to determine the presence and severity of OSA, as defined by apnea hypopnea index (AHI). Body fat was analyzed using dual energy X-ray absorptiometry. Blood specimens were collected and plasma calprotectin levels were determined using a commercial enzyme-linked immunosorbent assay (ELISA) kit. Body fat and blood collections were repeated upon completion of a 6 week (3 sessions/wk; 1 hr/session) moderate intensity aerobic exercise training program. **RESULTS:** Seventeen (age: 52 ± 7 years; BMI: 34.0 ± 4.1 kg/m²; 9 men: 8 women) adults completed the study. By design, the AHI of adults with moderate to severe OSA (n=7) was higher compared to those without or with mild OSA (n=10) (37 ± 13 events/hour vs. 8 ± 4 events/hour; $p < 0.001$), yet no differences in BMI, total body fat percentage or calprotectin levels were observed between the groups at baseline. While no significant change in calprotectin levels (Baseline: 74 ± 16 ng/ml vs. 6 weeks: 76 ± 19 ng/ml; $p = 0.540$) were observed following the exercise intervention, total body fat percentage was significantly reduced (Baseline: 44 ± 7%, vs. 6 weeks: 43 ± 7%; $p = 0.003$). Baseline

AHI was not associated with the change in plasma calprotectin [beta coefficient = -0.11, (95% CI -0.61 - 0.39), p=0.646] or total body fat percentage [beta coefficient = 0.00017, (95% CI -0.00005 - 0.00038), p=0.120]. **CONCLUSIONS:** Contrary to previous findings, we found no association between OSA severity and levels of plasma calprotectin at baseline. Furthermore, a six week moderate intensity aerobic exercise intervention failed to alter calprotectin levels despite decreasing total body fat. Research funded by R15HL133884

Aerobic Exercise Training And Ventilation-cardiac Output Ratio In Interstitial Lung Disease And Pulmonary Hypertension

Lobna S. Elsarafy¹, Lisa MK Chin², Anam Ahmad², Leighton Chan², Randall E. Keyser, FACSM¹. ¹George Mason University, Fairfax, VA. ²National Institutes of Health Clinical Center, Bethesda, MD. (Sponsor: Randall E. Keyser, FACSM)
Email: lelsaraf@gmu.edu
(No relevant relationships reported)

Aerobic exercise training has been shown to elicit physiological changes in cardiorespiratory capacity in people with advanced lung disease such as pulmonary hypertension (PH) and interstitial lung disease (ILD), despite impaired pulmonary ventilation (V_E) and perfusion. **PURPOSE:** To examine whether aerobic exercise training alters the V_E/Q_c ratio in subjects with PH or ILD. **METHODS:** Twelve people with ILD (5 men and 8 women; age 56.83 ± 8.26 years; BMI 28.83 ± 5.01) and 17 females with PH (age 55 ± 8.88 years; BMI 29.97 ± 7.89 kg/m²) participated in the study. All subjects were enrolled in the National Institutes of Health Exercise Therapy for Advanced Lung Disease Trial [ClinicalTrials.gov identifier NCT00678821]. All subjects underwent cardiopulmonary exercise testing (CPET) with bioelectrical impedance measure of cardiac output (Q_c) before and after 10 weeks of supervised vigorous treadmill walking, 30-45 minutes per session, 3 times per week (24-30 sessions). **RESULTS:** V_E , Q_c , and V_E/Q_c increased with CPET work stage before and after training. There was a significant increase in peak work rate after training in both groups (PH before 106 ± 48.36 watts, after 133 ± 64.12 watts p=0.002; ILD before 135 ± 57.04 watts, after 180 ± 77.35 watts p=0.001). There were no significant differences in peak V_E , peak Q_c , and peak V_E/Q_c before and after training in either group. Similarly, significant differences were not observed at rest or at the anaerobic threshold.

	Pre V_E Peak	Post V_E Peak	Pre Q_c Peak	Post Q_c Peak	Pre V_E/Q_c Peak	Post V_E/Q_c Peak
ILD	58.45±15.75 L/min	58.04±16.68 L/min	10.27±2.27 L/min	15.02±3.64 L/min	3.89±1.00	3.92±1.01
PH	43.55±10.76 L/min	44.00±11.35 L/min	13.84±3.89 L/min	13.48±3.89 L/min	3.23±0.78	3.19±0.78

CONCLUSION: Aerobic exercise training does not appear to have an effect on the ventilation-cardiac output ratio in these subjects with PH or ILD.

The Impact A 6 Week Respiratory Training Program Has On Lung Function In Cystic Fibrosis

Taylor E. Lewis. Pulmonary Performance Institute, San Rafael, CA.
Email: taylor@pulmonary-performance.com
(No relevant relationships reported)

Purpose: To evaluate the effects that a 6-week respiratory training program had on lung function and exercise capacity in an adult with cystic fibrosis (CF). **Methods:** This case study consisted of a 6-week respiratory training program for a 33-year-old female with cystic fibrosis who had a lung function of 33%. In individuals with CF, O₂ conduction and respiratory exchange are impeded due to mucus plugging that leads to chronic infections and inflammation, airway obstructions, and decreased lung function. Forced Expiratory Volume (FEV₁), Forced Vital Capacity (FVC), and Peak Expiratory Flow (PEF) are Pulmonary Function Tests (PFTs) that are used to determine lung function in CF patients. The 3-minute Step Test (3MST) is a standardized exercise test used to predict exercise capacity and is used to evaluate pulmonary deterioration in CF. PFTs, oxygen saturation tests, and a modified version of the 3MST were conducted 48 hours pre and post the 6-week program. Training consisted of two, one hour supervised respiratory training sessions and one, unsupervised respiratory training session (18 total; 3/week). A supervised respiratory training session consisted of a 10 minutes of soft tissue work, 10-minute dynamic warm up, three 10-minute respiratory training circuits that focused on respiratory-muscle strength and endurance, and a 10-minute cool down involving diaphragmatic breathing and soft tissue massage and stretching. Outcomes were measured by FEV₁/FVC ratio (decreased FEV₁/FVC ratio have been correlated to decreased lung function and exercise capacity in CF patients), PEF, O₂ saturations, and the modified 3MST. **Results:** Following completion of the 6-week

respiratory training program, the participant showed an increase in the modified 3MST (+10 steps), an increase in oxygen saturation (+5%), an increase in FEV₁/FVC ratio (+6%), and an increase for PEF (+.9L/min). In addition, the participant's lung function increased to 37%. **Conclusions:** This case study showed that a respiratory training program is feasible for an individual with CF, and can result in improved lung function and exercise endurance. Further research is necessary to validate these results using a larger cohort, nonetheless, these results suggest that individuals with CF could benefit from a respiratory training program.

Work Of Breathing Changes After Aerobic Exercise Training In Pulmonary Hypertension Or Interstitial Lung Disease

Xiaorong Hu¹, Anam Ahmad², Lisa M.K. Chin², Monira Aldhahi³, Leighton Chan², Randall E. Keyser, FACSM⁴. ¹The First Affiliated Hospital of Nanjing Medical University, Nanjing, China. ²National Institutes of Health Clinical Center, Bethesda, MD. ³Princess Nourah Bint Abdulrahman University, Riyadh, Saudi Arabia. ⁴George Mason University, Fairfax, VA. (Sponsor: Randall E. Keyser, FACSM)
Email: monicahu198723@outlook.com
(No relevant relationships reported)

People with pulmonary hypertension (PH) or interstitial lung disease (ILD) typically display blunted ventilatory function that include gas-exchange abnormalities, restrictive lung disorders and decreased lung compliance. With the common experience of dyspnea, exercise capacity is often severely limited in people with either PH or ILD, which may lead to physical activity avoidance and progressive deconditioning. This further exacerbates their functional capacity and decreases their health-related quality of life (HRQoL). **PURPOSE:** To determine the effect of aerobic exercise training on the work of breathing (Wb) in subjects with either PH or ILD.

METHODS: Twenty-two subjects with PH (54.5±11 yrs., 22 females) and 14 subjects with ILD (57±9 yrs., 9 females and 5 males) enrolled in this study. All were participants in the National Institutes of Health Exercise Therapy for Advanced Lung Disease Trials [ClinicalTrials.gov identifier NCT00678821]. Subjects completed 10-weeks of supervised vigorous aerobic exercise training (AET) with the target intensity of 70-80% of heart rate reserve, which consisted of walking on the treadmill for 30 to 45 minutes per session, 3 times per week. All subjects also performed a cardiopulmonary exercise test (CPET) on the treadmill, before and after the AET program. Wb was calculated by established algorithms [Men: $Wb = 2.007 \times 10^2 \times V_E^2$; Women: $Wb = 2.007 \times 10^2 \times V_E + 5.355 \times 10^{-5} \times V_E^3$] using ventilatory parameters obtained during the CPET, and compared before and after AET using paired t-tests (2-tailed). Significance was determined using p<0.05.

RESULTS: After AET, peak workload and test duration (time to exhaustion) increased significantly in both groups (PH: p=0.0013, p=0.0003, respectively; ILD: p=0.0014, p<0.0001, respectively). Wb also declined after AET in both the PH (before 417.2 ± 274.5 J/min vs after 322.0 ± 179.4 J/min, p=0.016) and ILD groups (before 675.7 ± 350.9 J/min vs after 476.8 ± 266.4 J/min, p<0.001) during the last completed stage of the pre-AET CPET. A significant difference in the pre- to post-AET change in Wb was not observed between PH and ILD groups.

CONCLUSIONS: This study suggests that decrease Wb may be one of the mechanisms underlying improved exercise and physical activity tolerance following aerobic exercise training in these subjects with either PH or ILD.

Exhaled-breath Temperature And Spirometer Airflow Dynamics Following Cold-water Ingestion In Healthy Subjects

Nicholas B. Tiller, III¹, Louise A. Turner², John Hart². ¹The Lundquist Institute for Biomedical Innovation at Harbor-UCLA Medical Center, Torrance, CA. ²Sheffield Hallam University, Sheffield, United Kingdom. (Sponsor: Harry Rossiter, FACSM)
Email: nicholas.tiller@lundquist.org
(No relevant relationships reported)

PURPOSE. Ingesting cold-water evokes decreases in spirometric indices of pulmonary function. However, given that most commercial spirometers assume an exhaled-breath temperature (EBT) of 37 °C, a cold-water-induced decrease in EBT may influence the accuracy of flow-volume measurements. Accordingly, the aims of this study were: i) to assess whether cold-water ingestion was sufficient to reduce EBT in healthy subjects; and ii) to model the influence of EBT on pneumotachograph airflow dynamics. **METHODS.** Ten healthy, recreationally-active adults (5 male, 5 female), with normal pulmonary function, volunteered to participate (age=36±7 y; mass=87.4±31.8 kg; stature=1.74±0.8 m). In a randomized crossover design, subjects consumed either 1000 mL of refrigerated water (2.1±0.64 °C) or water at room temperature (19.4±0.5 °C), with exhaled-breath temperature assessed (via the

tidal breathing method) at baseline and at 5, 10, 15, and 30 min post-ingestion. The influence of exhaled-breath temperature on the measurement characteristics of a non-heated pneumotachograph, was modelled using computational fluid dynamics (CFD). **RESULTS:** Baseline EBT was not different between the two conditions (33.8 ± 0.4 vs. 33.7 ± 0.5 °C; $p=0.269$, $d=0.25$). Following the ingestion of cold-water, EBT fell below baseline and remained so until the final measure at 30 min ($p<0.01$). When compared to water at room temperature, EBT was significantly lower following the ingestion of cold-water at 5 min (31.7 ± 1.1 vs. 33.0 ± 0.9 °C; $p<0.001$, $d=1.34$), 10 min (32.6 ± 0.6 vs. 33.2 ± 0.6 °C; $p<0.001$, $d=1.06$), and 15 min post-ingestion (32.5 ± 0.6 vs. 33.3 ± 0.5 °C; $p<0.001$, $d=1.46$). A mean decrease in EBT of 2.1 °C (as observed acutely following cold-water ingestion) was modelled to under-predict flow by 0.84% and volume by 0.78%. **CONCLUSIONS:** Cold-water reduces exhaled-breath temperature for at least 30 min post-ingestion, and to a greater extent than water at room-temperature. The mean decrease in EBT resulted in a negligible effect on calculated flow-volume variables. Accordingly, a measured change in lung function that follows cold-water ingestion likely has a physiological explanation which warrants further study. These data may also have implications for the clinical assessment of EBT in monitoring pathological processes of the airway.

Referral Patterns And Barriers To Physical Rehabilitation For Children And Adolescents With Cancer Across Canada

Paula A. Ospina¹, Lesley E. Wiart¹, David D. Eisenstat², Margaret L. McNeely². ¹University of Alberta, Edmonton, AB, Canada. ²University of Alberta, Cross Cancer Institute, Edmonton, AB, Canada.

Email: pospina@ualberta.ca

(No relevant relationships reported)

Two thirds of children who have been diagnosed with cancer will develop at least one chronic or long-term adverse effect of cancer treatment, many of which are amenable to physical rehabilitation (PR). PR may help reduce the burden of cancer side effects; however, research suggests few childhood cancer survivors access PR services. **PURPOSE:** To explore PR referral patterns and barriers to service provision for children and adolescents with cancer across Canada. **METHODS:** A cross-sectional web-based survey in English and French languages was conducted. Participants identified were Canadian healthcare professionals (HCPs) who provide and/or refer children and adolescents with cancer to PR services. The survey gathered data on numbers of childhood cancers either seen or referred to PR, reasons that prompted referral to PR, and existing barriers and facilitators to PR programs. **RESULTS:** A total of 54 responses were received including physical therapists ($n=27$), nurse and nurse practitioners ($n=10$), pediatric oncologists and oncology residents ($n=9$), occupational therapists ($n=6$), a speech-language pathologist ($n=1$), and an exercise professional ($n=1$). Data indicate that approximately 25% of children with cancer are being referred to PR, suggesting less than optimal referral rates. While 70% of HCPs report referring children and adolescents to PR services; the primary reason for referral is when the child presents with, or is at risk of functional disability. Chemotherapy-induced peripheral neuropathy (CIPN) was the second most common reason for referral to PR services (63%), and was identified by survey respondents as a rehabilitation research priority. The existence of a multidisciplinary team (52%), as well as the availability of PR space and equipment (33%) were the most commonly reported facilitators by the oncology medical team; while barriers to service provision included a lack of staffing (24%) and specialized PR services (17%). **CONCLUSIONS:** The survey results demonstrate that gaps in the health system such as limited resources and specialized services exist, that impact the implementation of PR programs. Results from this survey have informed the design of upcoming research investigating the feasibility and effects of an early PR program in children at risk of developing CIPN. No funding was received.

Feasibility And Validity Of Actiheart In Hospitalized Children With Cancer Coadmitted With Classmates

Peter Schmidt-Andersen¹, Tom Moeller², Pernille R. Mogensen¹, Kjeld Schmiegelow¹, Hanne B. Larsen¹, Martin K. F. Nielsen¹.

¹University Hospital (Rigshospitalet) Copenhagen, Copenhagen, Denmark. ²University Hospitals Centre for Health Research, Copenhagen, Denmark.

Email: peter.schmidt-andersen@regionh.dk

(No relevant relationships reported)

The combination of cancer treatment, lack of physical activity, and subsequent reduced energy expenditure causes reduced physical fitness in children with cancer. Valid measures of children's day-to-day activity levels are therefore warranted. **PURPOSE:** We investigated the feasibility of the Actiheart-monitor to determine total daily energy expenditure (TDEE) and the validity of the Actiheart-step-test as an accurate estimate of peak oxygen uptake. **METHODS:** VO₂peak was estimated with The Actiheart-step-test and compared with a cardiopulmonary-exercise-test. TDEE was measured using the Actiheart-monitor on days with and without classmate co-admission. **RESULTS:** Of 26 eligible measurement periods (15 children), 89% participated, 91% could participate safely, however, 35% fulfilled demands for valid monitoring. The percentage of children not completing the monitoring period was 10% (attrition) and adherence to classmate-visits was 84%. Forty eight percent of the measurement periods provided data, and only 27% was calibrated data. Actiheart-step-test significantly overestimated VO₂peak (95% CI 8.2 to 19.7 mL/kg/min, $p<0.001$) compared with CPET. **CONCLUSIONS:** Measuring TDEE using Actiheart is not feasible nor implementable in children with cancer. Further, the-Actiheart-step-test is not a valid test to estimate VO₂peak in children with cancer.

³University of Quebec in Montreal, Montreal, QC, Canada.

Email: maxime.caru@umontreal.ca

(No relevant relationships reported)

PURPOSE: About 65% of childhood survivors who were exposed to chemotherapeutic agents during treatment suffer from multiple late adverse effects. Even though both males and females were treated with chemotherapy during their cancer, the distinction between them is not always taken into consideration in an exercise oncology context. This study aims to assess cardiorespiratory fitness and moderate to vigorous physical activity (MVPA) of survivors in comparison to healthy participants. Genetic associations with cardiorespiratory fitness levels were reported to provide a better understanding of how physiological parameters differ in both males and females, and to find out whether gender and genetic parameters have an impact on their cardiorespiratory fitness.

METHODS: Germline variants in a selected set of genes were analyzed for an association with cardiorespiratory fitness. Whole-exome sequencing in survivors ($N=239$) was performed. Cardiorespiratory fitness and MVPA data were compared between childhood ALL survivors ($N=221$) and healthy participants ($N=825$). Additional analyses were performed to study the physiological differences between males and females.

RESULTS: We found that female survivors (27.7 ± 6.7 mL·kg⁻¹·min⁻¹) were more affected than males (36.8 ± 7.1 mL·kg⁻¹·min⁻¹) by low cardiorespiratory fitness. For a clinically equivalent level of MVPA, cardiorespiratory fitness was significantly lower in female survivors (27.7 ± 6.7 mL·kg⁻¹·min⁻¹), compared to healthy females (37.0 ± 7.6 mL·kg⁻¹·min⁻¹). Female survivors' physical deconditioning seems to increase with age. Female survivors have significant genetic associations between their cardiorespiratory fitness and their trainability genes (*LEPR*, *IGFBP1* and *ENO3* genes) that play an important role in the functioning of their skeletal and cardiac muscles. **CONCLUSIONS:** Female survivors are at higher risk than males to have an impairment in their cardiorespiratory fitness and represent at-risk patients in regard to their genetic dispositions. The promotion of physical activity needs to be encouraged through the care system with the involvement of health care professionals in pediatric oncology. An evidence-based medicine approach is essential to help females to improve their cardiorespiratory fitness through physical activity.

Benefits On Cancer-related Fatigue In Children After Exercise Training: Results From The Randomized, Controlled Mucki-trial

Sandra Stössel¹, Marie A. Neu¹, Arthur Wingerter¹, Wilhelm Bloch², Philipp Zimmer³, Claudia Paret¹, Freerk T. Baumann⁴, Nicole Henninger¹, Alexandra Russo¹, Nadine Lehmann¹, Henrike Otto¹, Joerg Faber¹. ¹Childhood Cancer Center, Mainz, Germany. ²German Sport University Cologne, Köln, Germany. ³German Sport University Cologne and German Cancer Research Center, Köln and Heidelberg, Germany. ⁴University Hospital of Cologne, Köln, Germany.
Email: stoessel@uni-mainz.de
(No relevant relationships reported)

PURPOSE: Cancer-related fatigue (CRF) is recognized as one of the most distressing side effects in children suffering from cancer. In adult cancer patients, specific exercise training has revealed positive effects on muscular and aerobic capacity, which has been associated with benefits on CRF and health-related quality of life. However, in children with cancer, the evidence level of beneficial exercise programs is sparse. Within the “Effects of Combined Resistance and Endurance Training in Pediatric Cancer Patients During Intensive Treatment Phase (Mucki)-trial” training effects on CRF were evaluated.

METHODS: In this randomized, controlled trial, childhood cancer patients aged between 4 and 18 years were enrolled during intensive cancer treatment phase. Individuals within the exercise group (EG) participated in supervised exercise training. Training was focused on child adapted playful, moderate intense resistance and endurance exercises and took place 3 to 5 times weekly over a period of 6 to 8 weeks. Individuals of the control group (CG) received usual care. Children’s pre- and post-interventional CRF levels were evaluated by the children themselves and separately by their parents using the „PedsQLTM 3.0 Multidimensional Fatigue Scale”.

RESULTS: In total 14 patients were included in the EG (mean age 10.8 ± 4.2y) and 15 in the CG (mean age 11.5 ± 5.2y). Children in the EG reported less fatigue post- than pre-intervention ($p = 0.026$; $d = 1.11$). In the CG were no pre-post differences ($p = 0.969$). Group-time-interaction of children’s reported fatigue level was not significant ($F(1,10) = 1.061$; $p = 0.327$). Parents reported favoring effects for their children’s fatigue level in the EG in the group-time-interaction ($F(1,13) = 8.353$; $p = 0.013$; $\eta_p^2 = 0.391$).

CONCLUSIONS: The present results show benefits on CRF in the EG. It is known, that the majority of childhood cancer patients report to suffer from CRF. Mental, physical and social wellbeing might be affected by CRF. So far, there is no gold-standard treatment against CRF. Adapted exercise programs have been getting attention only since recently in pediatric cancer. The present findings support further elaboration and implementation of adapted exercise offers in pediatric oncology.

Safety Of Exercise Testing In Long Term Survivors Of Pediatric Cancer Exposed To Anthracyclines

Michelle Kristin Slawinski, Kan Hor, May Ling Mah.
Nationwide Childrens Hospital, Columbus, OH.
Email: michelle.slawinski@nationwidechildrens.org
(No relevant relationships reported)

Survivors of pediatric cancers are at risk for long-term cardiac complications, often due to a history of treatment with anthracyclines. Current recommendations for these survivors include significant exercise restriction, despite a lack of data on exercise safety. **PURPOSE:** Determine the burden of arrhythmia and/or evidence of ischemia provoked by standardized exercise stress testing in long-term survivors of pediatric cancer treated with anthracyclines. **METHODS:** Cardiopulmonary exercise testing (CPET) was performed in 20 subjects (mean age 23.0 ± 9 yrs; mean BMI 26.3 ± 7; 55% male). The 12-lead exercise EKG was evaluated for arrhythmia and ischemia at baseline, exercise, and recovery segments of the CPET. Anthracyclines mean dose was 266 ± 119 mg/m² with last dose of chemotherapy occurring 5 years ago or later. **RESULTS:** Subjects had normal left ventricular function determined by cardiac MRI (mean ejection fraction 56% ± 8). Mean VO₂ was 32.6 ± 9 mL/Kg/min. No sustained atrial or ventricular arrhythmias or ischemic changes were observed in this sample. Isolated premature atrial contractions (PACs) and premature ventricular contractions (PVCs) existed in 8 of the 20 subjects with 1 demonstrating PVCs at baseline, 6 with PVCs or PACs late in exercise, and 4 with PVCs or PACs in recovery. **CONCLUSION:** CPET revealed safe in a small sample of long-term survivors of pediatric cancer exposed to high-dose anthracyclines with normal heart function. A greater sample size with consistent results could help providers promote physical activity in this population.

Associations Between Fitness And Cardiovascular Disease In Childhood Cancer Survivors: A St. Jude Lifetime Cohort Study

Matthew D. Wogksch, Kirsten K. Ness. *St. Jude Children’s Research Hospital, Memphis, TN.*
Email: Matthew.Wogksch@stjude.org
(No relevant relationships reported)

Progress in biology and therapy for pediatric malignancies has resulted in dramatic improvement in survival in children with cancer. Unfortunately, childhood cancer survivors are at an increased risk for late mortality and morbidity. Physical fitness may mitigate the risk of chronic disease within childhood cancer survivors. **PURPOSE:** To evaluate the associations between baseline physical fitness and the onset of chronic cardiovascular disease in childhood cancer survivors. **METHODS:** Survivors of childhood cancer ($n=501$, mean ± SD age: 35.5 ± 8.2 years, 47.3% male) underwent a baseline, self-limited graded exercise test to assess peak maximal oxygen consumption (VO_{2peak}). Quartiles of fitness were calculated from the percentage of age and sex predicted VO_{2peak}. Moderate to severe chronic cardiovascular disease (grade 2-4) was assessed at baseline and during a follow-up period (3.6 ± 1.0 years) using the Common Terminology Criteria for Adverse Events (CTCAE) v. 4.03. A multivariable Cox-proportional hazard regression was used to examine the risk of developing cardiovascular disease. **RESULTS:** Survivors within the lowest quartile of fitness (< 60% of predicted) were at a significantly increased risk of developing cardiovascular disease compared to the survivors in the three higher quartiles of fitness (Hazard Ratio: 1.54; 95% Confidence Interval: 1.01, 2.36), adjusting for age, sex, and prevalent cardiovascular disease. Interaction between prevalent disease and VO₂ was not significant. **CONCLUSION:** Low fitness is associated with new-onset of moderate to severe cardiovascular disease regardless of previous cardiovascular disease. Importantly, survivors with the lowest fitness may benefit from increasing their cardiopulmonary fitness the most. Interventions specifically targeting cardiopulmonary fitness could help reduce future cardiovascular illness in childhood cancer survivors.

Evaluation Of An Exercise Referral Programme For Young Adult Cancer Survivors In The United Kingdom

Gemma Pugh¹, Natalie Below², Abigail Fisher³, Jemima Reynolds⁴, Sophie Epstone¹. ¹Queen Mary University of London, London, United Kingdom. ²Queen Mary, University of London, London, United Kingdom. ³University College London, London, United Kingdom. ⁴Trekstock, London, United Kingdom.
Email: g.pugh@qmul.ac.uk

Reported Relationships: **G. Pugh:** Consulting Fee; GP has received independent consultancy fees from Trekstock..

PURPOSE: Exercise referral programmes delivered by charity organizations have the potential to facilitate cancer survivors to be active. The purpose of this work was evaluate the uptake and effect of RENEW, a twelve-week exercise referral programme for young adult cancer survivors aged 18 to 39 delivered by Trekstock, a cancer charity based in the UK.

METHODS: The RENEW programme provides one-to-one individually tailored support from a Level 4 Cancer Rehabilitation qualified gym instructor, free gym membership and access to information resources online. Objective and self-report data on cardiorespiratory function, flexibility, fat mass, muscle mass, fatigue, sleep quality and general health-related quality of life (HRQoL) was collected from participants before the programme (week 0), immediately after (week 12) and one month later (week 16).

RESULTS: Ninety-eight RENEW referrals were made between August 2018 and May 2019, 76 young adults with cancer initiated the programme with 48 young adults (83% female; mean age 29 yrs; 73% off active treatment) consenting to participate within the evaluation. The predominant cause of programme drop-out was illness or treatment complications. Physical activity (PA) levels significantly increased following the programme and remained raised at follow-up. Improvements in physical function were significant: peak expiratory flow (mean change: 30.96, $p=0.003$), sit-and-reach test (mean change: 6.55±4.54, $p<0.0001$), and six-minute-walk-test (mean change 0.12±0.04, $p<0.0001$). Significant improvements in fatigue, sleep and HRQoL were observed across the programme and at follow-up (mean change W0-W16; 8.04±1.49; 1.05±0.49; and -0.9±0.46 respectively, $p<0.05$). Changes in self-efficacy to exercise and motivations to exercise were not observed at 12 weeks or at follow-up.

CONCLUSIONS: Results suggest that the RENEW exercise referral programme has a positive effect upon young adult cancer survivors’ physical function, PA levels, HRQoL and well-being. Health professionals and charitable bodies specialising in the care of young adults with cancer should look to address factors (including gender and treatment status) which prevent engagement and uptake of ‘real-world’ PA interventions such as the RENEW programme.

2904 Board #365 May 29 9:30 AM - 11:00 AM Long-Term Favorable Effects Of Physical Exercise On Burdensome Symptoms In The Optitrain Breast Cancer Trial

Sara Mijwel, Fleur Wigenraad, Kate Bolam, Renske Altena, Yvonne Wengström. *Karolinska Institutet, Stockholm, Sweden.*
Email: saramijwel@gmail.com

(No relevant relationships reported)

PURPOSE: Patients with breast cancer report multiple burdensome physical and psychological symptoms during and after adjuvant chemotherapy treatment which can be grouped into symptom clusters. Little is known about the impact of physical exercise on symptom clusters; therefore, we aimed to evaluate the effects of exercise in patients with breast cancer during chemotherapy on longitudinal changes in symptom clusters and core burdensome symptoms. **METHODS:** In the Optitrain trial, 240 patients treated with chemotherapy with stage I-IIIa breast cancer were randomized to 16 weeks of supervised resistance exercise and high-intensity aerobic interval training (RT-HIIT), moderate-intensity aerobic and high-intensity aerobic interval training (AT-HIIT), or usual care (UC). Symptom clusters were composed from self-reported symptoms using the Memorial Symptom Assessment Scale (MSAS), assessed at baseline, 16 weeks (post intervention) and at 12 months after baseline. Principal component analysis was used to form three symptom clusters. Core burdensome symptoms were defined as individual symptoms present in the respective symptom clusters at 16 weeks and 12 months in all groups. **RESULTS:** Three symptom clusters were identified: 'emotional', 'treatment-related toxicity' and 'physical', with core burdensome symptoms that remained stable over time. At 16 weeks post-baseline, the reported burdens of 'feeling sad' (RT-HIIT vs UC: Effect Size [ES] = -0.69 AT-HIIT vs UC : ES = -0.56) and 'feeling irritable' (ES = -0.41 RT-HIIT, ES = -0.31 AT-HIIT) were significantly lower in both intervention groups compared to usual care. At 12 months post-baseline, the AT-HIIT group continued to have significantly lower scores for the core burdensome symptoms 'feeling sad' (ES = -0.44), 'feeling irritable' (ES = -0.44) and 'changes in the way food tastes' (ES = -0.53) compared to UC. No between group differences were found for physical symptoms. **CONCLUSIONS:** These findings indicate a preserved and persistent beneficial effect of physical exercise on self-reported emotional well-being in patients with breast cancer treated with chemotherapy.

2905 Board #366 May 29 9:30 AM - 11:00 AM Exercise Effects On A Symptom Cluster In Breast Cancer Survivors

Linda B. Piacentine, Lauren E. Opielinski, Mauricio Garnier-Villarreal, Judy A. Tjoe, Alexander V. Ng, FACSM. *Marquette University, Milwaukee, WI.*

(No relevant relationships reported)

Breast Cancer Survivors (BCS) have clusters of related symptoms. One proposed treatment related symptom cluster includes fatigue, cognitive changes, depression, pain, and sleep disturbances. The continuation of this cluster and effects of exercise after treatment has not been thoroughly studied. Understanding how exercise impacts this symptom cluster will expand our knowledge of BCS and may lead to improved quality of life. Team triathlon training is a unique and effective type of exercise for this population. PURPOSE: To examine the effects of triathlon training on a treatment related symptom cluster in BCS to determine the relationships in the cluster. **METHODS:** Female BCS (n = 207) participated in one of 7 seasons of a 14-week sprint triathlon training program. Training consisted of 2 supervised and 3 unsupervised sessions per week. Baseline and Post-training measures over the years included fatigue (FACIT-F), and PROMIS questionnaires for cognition (Applied Cognition-General Concerns-Short Form), depression (Emotional Distress-Depression), pain (Pain Interference-SF), and sleep (Sleep Disturbance-SF). Except FACIT-F, higher questionnaire scores represent worse function. T-tests, including Cohen's d for effect sizes, were calculated on pre- and post-training data. **RESULTS:** Data are mean (SD). Fatigue, (pre= 38.9 (10.2), post= 46.5 (5.2), p< 0.01, d=-0.79), cognition (pre= 16.6 (7.8), post= 13.7 (6.4), p< 0.01, d= 0.42), depression, (pre= 12.0 (5.4), post= 9.9 (3.7), p< 0.01, d=0.38), and pain (pre=11.2 (4.6), post= 10.0 (4.1), p< 0.05, d=0.30) presented such that is unlikely that these means are equal over time. In contrast, it is not unlikely for sleep that the mean is equal over time (pre= 14.5 (5), post= 13.8 (3.4), p=0.25, d=0.22). **CONCLUSIONS:** Triathlon training for BCS improved all symptoms in a cluster, we only failed to reject the null for the smallest effect size presented in sleep. The effect size was medium for fatigue and small for

cognition, depression and pain. The symptoms in this cluster of fatigue, cognitive changes, depression, and pain all were present and improved, except sleep disturbances which did not improve in this group of post-treatment female cancer survivors.

2906 Board #367 May 29 9:30 AM - 11:00 AM Effect Of A 12-week Supervised Exercise Program On Anxiety And Depression In Cancer Survivors

Bethany Marie Kanski, Kelsey N. Colaric, Alex J. Sipolino. *Saint Francis University, Loretto, PA.*

(No relevant relationships reported)

A life-altering diagnosis, such as cancer, and its coinciding treatments, can lead to a number of adverse side-effects in patients. Along with physiological changes, cancer-related anxiety, depression, and fatigue are common side effects of patients with cancer. The cause of such psychological side-effects can be multifactorial and difficult to treat. Exercise under the supervision of an exercise professional has been shown to reduce levels of anxiety, depression, and fatigue in patients with cancer, commonly measured using The Hospital Anxiety and Depression Scale (HADS) and the Functional Assessment of Chronic Illness- Fatigue (FACIT-F). **PURPOSE:** To determine the impact of a 12-week, supervised exercise program on levels of anxiety, depression, and fatigue in a rural population of cancer survivors. **METHODS:** Seven male (4) and female (5) cancer survivors age (59.7 ± 9.50), BMI (33.13 ± 7.88), with a variety of cancer diagnosis and treatment, participated in twelve weeks of an individualized exercise program. The exercise program included balance, resistance, aerobic and flexibility on two or three days of the week. Anxiety and depression scores were analyzed using the HADS and FACIT-F. Scores and measures were assessed by running a paired-sample t test through the Statistical Package for Social Science statistical software (SPSS) version 25. **RESULTS:** A significant change was seen in anxiety, t (8) = 3.00, p = 0.017, with anxiety being lower with exercise (M = 3.00, SD = 2.91) after 12-weeks of intervention. No significant changes were seen in depression scores, t (8) = .71, p = 0.50, or levels of fatigue, t (8) = -.14, p = 0.90. **CONCLUSION:** A 12-week supervised exercise program may help the rural cancer survivor feel less anxiety during and after treatment and help them continue their activities of daily living with more normalcy. Depression scores and fatigue levels were trending toward significance suggesting that an exercise program can help maintain these scores throughout and after cancer treatment.

2907 Board #368 May 29 9:30 AM - 11:00 AM Exploring Body Image In Breast Cancer

Corrie Effa, Christopher Sellar, Nicole Culos-Reed, Margaret McNeely. *University of Alberta, Edmonton, AB, Canada.*
Email: ceffa@ualberta.ca

(No relevant relationships reported)

Treatments for breast cancer are invasive, causing visible changes such as loss of the breast, weight gain, and hair loss. These changes in conjunction with the societal pressure for women to conform to feminine beauty ideals may lead to body image disturbance in breast cancer survivors (BCS). Exercise is a positive health strategy that has shown promise in improving body image perception in both general and cancer populations. **PURPOSE:** To determine the prevalence of body image and body weight concerns in BCS participating in an exercise program and to see if a program focussing on fitness and cancer related symptoms results in improvements in self-reported body image and body weight. **METHODS:** The study took place at Wellspring Edmonton; a nonprofit centre that offers supportive programs to meet the psychological, emotional and educational needs of individuals and families living with cancer in Canada. Participants were BCS taking part in the Alberta Cancer Exercise (ACE) Program at the Wellspring site, twice weekly for 12 weeks. Patient-reported outcomes, including questions related to body appearance and weight concerns were collected before and after the intervention. Data were analyzed to compare the proportion of women reporting issues at baseline and post-intervention. Data collection began January 2017 and ended June 2019. **RESULTS:** Eighty-six BCS enrolled and completed the ACE program (100%), with an exercise attendance rate of 84%. Twenty-five (29%) BCS reported body appearance disturbance and 42 (49%) reported issues with body weight. Significant reductions were seen post-intervention in the proportion of BCS reporting issues with both body appearance (n = 14; p<0.05) and body weight (n=31; p<0.05), representing reductions of 44% and 26% respectively. Similar to findings of previous research, no significant changes (p >0.05) were observed in BMI or body weight. **CONCLUSION:** Issues with body appearance and weight are common among BCS at our Wellspring site. Although benefit was seen in some BCS from exercise alone; given that body image can affect BCS physically, psychologically and socially, research involving a multi-disciplinary approach is warranted. Wellspring provides an ideal setting for future research involving multimodal interventions. Supported by the University of Alberta

Post-exertional Malaise In People With Chronic Cancer-related Fatigue

Rosemary Twomey¹, Samuel T. Yeung¹, James G. Wrightson¹, Guillaume Y. Millet², S. Nicole Culos-Reed¹. ¹University of Calgary, Calgary, AB, Canada. ²Univ Lyon, UJM-Saint-Etienne, Saint-Etienne, France.
 Email: Rosemary.Twomey@ucalgary.ca
 (No relevant relationships reported)

PURPOSE: Cancer-related fatigue (CRF) is a distressing and persistent sense of tiredness or exhaustion that interferes with usual functioning. Chronic CRF continues long after the completion of curative cancer treatment. Post-exertional malaise (PEM) is the worsening of symptoms after even minor physical, mental or emotional exertion. PEM has been inadequately investigated in people with chronic CRF. The purpose of this study was to identify and describe self-reported incidences of PEM in a group of people with chronic CRF.

METHODS: Participants ($n=18$) were eligible if they scored ≤ 34 on the Functional Assessment of Chronic Illness Therapy - Fatigue scale, had a cancer-related onset of fatigue and ≥ 3 months since completion of curative cancer treatment. Participants completed a brief questionnaire to assess PEM over a 6-month time frame (the DePaul Symptom Questionnaire - Post-Exertional Malaise; DSQ-PEM). In addition, a maximal exercise test was used to investigate self-reported symptoms (via an open-ended questionnaire) after strenuous physical exertion.

RESULTS: We found preliminary evidence that a minority of people (5/18 in this sample) with chronic CRF may experience PEM. According to the DSQ-PEM, 4 participants indicated that they experienced all symptoms of a frequency (ranging from "at least half of the time" to "all the time") and severity (ranging from "moderate" to "very severe") that were indicative of PEM. Although the majority of people experienced some worsening of fatigue after maximal exercise (12/18), content analysis identified 5 people who experienced prolonged adverse consequences, including the need to reduce daily activities to account for increased fatigue, flu-like symptoms, mood disturbances and/or issues with memory/concentration.

CONCLUSION: While only a minority of people with chronic CRF may experience PEM, exercise specialists and health care professionals working with people with chronic CRF must be aware that PEM may be an issue. Symptom exacerbation after exercise should be monitored, and exercise should be prescribed to limit the potential for harm.

Supported by Canadian Cancer Society grant #704208-1.

2909 Board #370 May 29 9:30 AM - 11:00 AM
Quality Of Life Of Prostate Cancer Men Undergoing Pre-surgical Exercise Prior To Prostatectomy.

Favil Singh¹, Robert U. Newton¹, Dennis R. Taaffe¹, Jeff Thavaseelan², Matthew Brown², Elayne Ooi³, Daniel Galvao, FACSM¹. ¹Edith Cowan University, Perth, Australia. ²Perth Urology Clinic, Perth, Australia. ³Swan Urology, Perth, Australia. (Sponsor: Daniel Galvao, FACSM)
 Email: f.singh@ecu.edu.au
 (No relevant relationships reported)

Exercise interventions in prostatectomy patients have generally focused on the post-surgical period and enhancement of pelvic floor musculature to reduce incontinence. However, quality of life (QOL) and psychological distress are also impacted in the pre- and post-surgical period in this patient group. **PURPOSE:** To evaluate the efficacy of exercise undertaken before surgery to enhance pre- and post-surgical QOL and psychological distress in men scheduled for prostatectomy. **METHODS:** Twenty-three men with localised prostate cancer (50-73 years) scheduled for surgery were randomised to exercise (EX = 13) or usual care (UC = 10). EX underwent 6 weeks of pre-surgical exercise (resistance and aerobic) thrice weekly. Self-reported QOL was assessed using the EORTC QLQ-C30 and psychological distress using the Brief Symptom Inventory-18 (BSI-18) which includes anxiety, somatization, depression, and the global severity index (GSI). Measures were undertaken at baseline, pre-surgery, within 2 weeks post-surgery and 6 weeks post-surgery. Data were assessed for normality and analysed using two-way repeated-measures ANOVA. **RESULTS:** There were no differences between groups at baseline. Following exercise, there was a significant interaction ($p < 0.05$) for somatization with somatization increasing in EX 2 weeks post-surgery and returning to pre-training values 6 weeks post-surgery, with no change in anxiety, depression or the GSI. There was a significant time effect ($p < 0.05$) for global health, physical, role, cognitive and social function, as well as for fatigue, pain, insomnia, appetite loss and diarrhoea, with QOL generally improving over the study period. **CONCLUSION:** A pre-surgical exercise program improves components of quality of life prior to surgery, however, EX patients group had higher symptoms after surgery but then did return to pre-training level at 6 weeks post-surgery. Pre-surgery exercise may have a role in managing quality of life and psychological distress in this patient cohort.

Development Of A Reference Chart For Monitoring Fatigue In Cancer Survivors In An Exercise Program

Ryan J. Marker, Andrew J. Kittelson, John C. Peters, W Thomas Purcell. University of Colorado Anschutz Medical Campus, Aurora, CO.
 Email: ryan.marker@cuanschutz.edu
 (No relevant relationships reported)

Cancer-related fatigue (CRF) is one of the most commonly reported and functionally limiting symptoms reported by cancer survivors. It is present in survivors of all cancer types, during cancer treatment, and potentially years later. Exercise is effective at reducing CRF, though currently it is not possible to predict the magnitude and time course of improvement for an individual survivor participating in an exercise program. This ability would allow providers to set meaningful, realistic goals, and track progress towards those goals, informing appropriate exercise modification.

PURPOSE: To develop a reference chart of CRF improvement for cancer survivors participating in a 3-month exercise program.

METHODS: CRF was assessed every two weeks (using the FACIT - Fatigue scale, range: 0 - 52 with lower scores indicating greater fatigue) in 173 cancer survivors participating in the BfitBwell Cancer Exercise Program, an individualized 3-month program (741 observations). No cancer types were excluded and survivors were either undergoing chemotherapy and/or radiation, or within 6 months of completing treatment. Using Generalized Additive Models for Location Scale and Shape, a reference chart for CRF was developed from the first 127 survivors and preliminarily tested for performance in the remaining 46 survivors.

RESULTS: Each survivor had an average of 4 CRF observations over the course of the program. In the test data, the reference chart demonstrated accurate coverage at each estimated centile. The 10th percentile showed steady improvement from 19 to 32 over the course of the program, while the 90th percentile improved from 46 to 51, with the majority of improvement occurring in the first month of the program.

CONCLUSIONS: This reference chart provides a novel method of monitoring CRF improvement for cancer survivors in an exercise program. Future research can investigate improvements in clinical outcomes through the implementation of the reference chart.

2911 Board #372 May 29 9:30 AM - 11:00 AM
Clinically-Measured Muscular Strength Predicts Quality Of Life And Symptom Burden In Patients With Cancer Cachexia

Kelcey A. Bland¹, Eva M. Zopf¹, Meg Harrison², Matthew Ely², Anna Dowd², Prue Cormie¹, Peter Martin². ¹Australian Catholic University, Melbourne, Australia. ²Barwon Health, Geelong, Australia.
 Email: kelcey.bland@myacu.edu.au
 (No relevant relationships reported)

Cancer cachexia is a multifaceted syndrome defined as weight loss $>5\%$ in the past six months. Weight loss is associated with decreased quality of life (QoL), increased symptom burden and a worse prognosis following a cancer diagnosis. However, evaluating muscle strength, in addition to weight loss, may help identify patients most at need for supportive care interventions in a cancer cachexia setting. **PURPOSE:** To explore the relationship between muscle strength, QoL and symptoms in patients with cancer cachexia. **METHODS:** Adults with cancer who met the criteria for cachexia and attended a cachexia clinic in Geelong, Australia were included in a retrospective analysis. Muscle strength was evaluated via maximal handgrip strength (HGS)

and 30s chair rise testing. QoL and symptoms were evaluated using the European Organization for Research and Treatment of Cancer Quality of life Questionnaire Core 15 Palliative (score: 0-100). Nutritional status was assessed using the Patient-Generated Subjective Global Assessment (PG-SGA) (score: 0-35). Data are presented as mean±SD. **RESULTS:** Overall, 187 patients (male: n=109, 58%, female: n=78, 42%) were included (BMI: 22.4±4.7 kg/m², weight loss: 12.7±7.5%). Most patients had upper gastrointestinal (n=55, 29%) or lung cancer (n=45, 24%) and metastatic disease (n=134, 72%). Weight loss did not predict overall QoL or symptoms. Chair rise repetitions and HGS predicted higher overall QoL (β : 1.36±0.32, $p<0.01$ and β : 0.45±0.19, $p=0.02$, respectively) and reduced appetite symptoms (β : -1.01±0.48, $p=0.04$ and β : -0.61±0.27, $p=0.03$, respectively). Chair rise repetitions also predicted reduced fatigue (β : -1.43±0.36, $p<0.01$), dyspnea (β : -1.53±0.42, $p<0.01$) and a lower PG-SGA score for malnutrition (β : -0.31±0.08, $p<0.01$). Further, the inability to complete a single unassisted chair rise resulted in lower overall QoL (mean difference (MD): 8.8±4.2, $p=0.04$), increased fatigue (MD: 12.0±4.7, $p=0.01$), dyspnea (MD: 11.0±5.5, $p<0.05$) and insomnia (MD: 13.7±5.8, $p=0.02$), as well as a higher PG-SGA score (MD: 3.0±1.1, $p=0.01$). **CONCLUSIONS:** Clinical measures of muscle strength may be useful screening tools in a cancer cachexia setting. Our findings support the rationale to target muscle strength, alongside weight loss, to manage QoL and symptoms in patients with cancer cachexia.

Effect Of Strength Training And Antioxidant Supplementation On Perceived And Performance Fatigability In Cancer Survivors

Martim Bottaro¹, Filipe Dinato de Lima², Sandro Nobre Chaves¹, Lucas Ugliara¹, Jonathan Sarandy¹, Claudio L. Battaglini, FACSM³. ¹University of Brasilia, Brasilia, Brazil. ²University Center of Brasilia, Brasilia, Brazil. ³University of North Carolina at Chapel Hill, Chapel Hill, NC.
 Email: martim.bottaro@gmail.com
 (No relevant relationships reported)

Oxidative stress is a well-described consequence of cancer and its treatment. Oxidative stress has also been associate with late and persistent side effects, such as metabolic impairments and cancer-related fatigue. Strength training and antioxidant supplementation attenuate oxidative stress and may improve performance fatigability. However, chronic interventions analyzing the effect of ST combined with antioxidant vitamins on perceived and performance fatigability in breast cancer survivors (BCS) are scarce.

PURPOSE: To investigate the effect of strength training combined with vitamin C and E supplementation on perceived and performance fatigability in BCS.

METHODS: Twenty-five breast cancer survivors were enrolled in this double-blinded placebo-controlled study. BCS were randomly assigned to one of two groups: Antioxidant (AG; n = 12; 51 ± 9 years; 68.08 ± 10.57kg; 1.61 ± 0.07m); or Placebo (PG; n = 13; 48 ± 8 years; 70.45 ± 9.92kg; 1.58 ± 0.05m) groups. Both groups participated in a 10-week strength training protocol, twice a week, containing six exercises. AG was supplemented with vitamins C (500mg/day) and E (400UI/day) and PG with polydextrose (1g/day). At the beginning and at the end of training period, perceived fatigue was assessed using two dimensions of MFI-20 (general fatigue - GF; and physical fatigue - PF). Also, performance fatigability was assessed using one set of 30 maximal isokinetic knee extension at 120°/s-1. A two-way mixed model ANOVA was used for the analyses.

RESULTS: After the 10-week strength training protocol, GF reduced significantly in both AG (10.58 ± 3.78 to 7.58 ± 3.63; $p = 0.004$) and PG (12.23 ± 2.52 to 9.77 ± 3.47; $p = 0.011$). Also, PF reduced significantly in both AG (9.33 ± 4.51 to 6.33 ± 2.74; $p = 0.011$) and PG (12.00 ± 2.42 to 8.15 ± 2.58; $p = 0.001$). FI reduced significantly in both AG (52.72 ± 9.32% to 48.41 ± 7.25%; $p = 0.026$) and PG (54.22 ± 9.81 to 47.11 ± 7.20; $p < 0.001$).

CONCLUSIONS: Antioxidant supplementation does not appear to add a positive synergistic effect of the strength training on decreases of cancer-related fatigue or muscle fatigability in breast cancer survivors when compared to the placebo group. Further research is need to confirm or refute the results of this initial study.

2913 Board #374 May 29 9:30 AM - 11:00 AM
Increases In Muscular Strength Do Not Correlate With Improvements In Fatigue Severity In Cancer Survivors

Nicholas B. Kelly¹, Danielle M. Halsey², NiCole R. Keith, FACSM¹, Tammy J. Sajdyk², Tarah J. Ballinger³, Jamie L. Renbarger², Mark Urtel¹, Riggs Klika, FACSM⁴. ¹Indiana University Purdue University Indianapolis, Indianapolis, IN. ²Indiana University School of Medicine, Indianapolis, IN. ³Indiana University Health, Indianapolis, IN. ⁴University of Indianapolis, Indianapolis, IN.
 (No relevant relationships reported)

For millions of cancer survivors, cancer related fatigue (CRF) is a severe, disruptive, and lingering aftereffect of cancer treatment. Clinical practice guidelines recommend exercise training including muscle strengthening exercises as a non-pharmacologic treatment for CRF. Yet, the relationship between improved muscle strength and CRF decline is unclear.

PURPOSE: To examine the relationship between strength gains and CRF decline in cancer survivors.

METHODS: 6 cancer survivors aged 40-73 (mean 59.5) participated in three, 60-minute, guided exercise sessions each week for 12 weeks. Sessions involved 20 minutes of cardiorespiratory training, 30 minutes of resistance training, and 10 minutes of neuromotor/balance/stretching. Participants completed baseline and follow up assessments including the Facit-F fatigue scale and estimated one rep max testing (e1rm) using the brzycki equation for chest press, latissimus pull down, and leg press. **RESULTS:** Fatigue scores increased from baseline to follow up (average=7.39%, range=1.3-13.4%). Average e1rm scores also improved following the intervention (chest press average=28.9%, range=-1.7-76.2%, latissimus pulldown average=6.4%, range=-12.2-18.3%, and leg press average=6.2%, range=-13.1-43.4%). Individual comparisons showed much variation when comparing CRF to e1m improvements, and no correlation or relationship was observed. R squared values for each strength measure compared to CRF were: chest ($r^2=0.234$), latissimus pulldown ($r^2=0.120$), and leg press ($r^2=0.017$).

CONCLUSIONS: While exercise has been shown to improve outcomes in CRF and muscular strength, early evaluation did not demonstrate a correlation between these variables in this small feasibility study. We will continue to recruit participants to further explore this relationship.

2914 Board #375 May 29 9:30 AM - 11:00 AM
Impact Of One On One 12 Week Individualized Exercise Program On Cancer Related Fatigue And Functional Capacity

Danielle M. Halsey¹, Nicholas B. Kelly², NiCole R. Keith, FACSM², Jamie L. Renbarger¹, Tarah J. Ballinger¹, Mark Urtel², Riggs J. Klika, FACSM³. ¹Indiana School of Medicine, Indianapolis, IN. ²Indiana University- Purdue University- Indianapolis, Indianapolis, IN. ³University of Indianapolis, Indianapolis, IN. (Sponsor: NiCole R. Keith, FACSM)
 (No relevant relationships reported)

Cancer related fatigue (CRF) is the most commonly reported side effect during and after cancer treatment. This level of fatigue can have disruptive effects on individuals' daily lives, continuing on up to 5 years post treatment. CRF is defined as a persistent feeling of fatigue that is not brought on by cognitive or physical exertion, and is not relieved by sleep or rest. Aerobic exercise is suggested to alleviate symptoms of CRF.

PURPOSE: This feasibility study examined the relationship between functional capacity and CRF. **METHODS:** Six cancer survivors (59.5 ± 11.8 yrs.) enrolled in a one on one individualized 12 week exercise program. The 6 Minute Walk Test (6MWT) and the Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) were used to assess subjects' functional capacity and self-reported fatigue before and after the exercise intervention. Exercise sessions were completed 3 times a week for an hour. Sessions included 20 minutes of cardiorespiratory training, 30 minutes of total body strength training and 10 minutes of balance and flexibility training. 6MWT and FACIT-F were assessed at baseline (week 0) and at the final assessment (week 12). **RESULTS:** Functional capacity as measured by distance walked during the 6MWT showed a significant ($p = 0.007$) increase after exercise intervention. FACIT-F Total scores also showed a significant ($p = 0.013$) increase. **CONCLUSION:** Exercise intervention has a significant impact not only of the functional capacity of cancer survivors but their self-reported CRF.

(No relevant relationships reported)

Prostate cancer patients are subject to psychological distress which may be exacerbated for those undertaking androgen deprivation therapy (ADT) due to treatment-related adverse effects. Exercise is one strategy to counter a range of treatment toxicities in men with prostate cancer and to improve overall physical function and quality of life.

PURPOSE: To assess the effect of up to 12 months of exercise on psychological distress in men with prostate cancer on ADT.

METHODS: Of 163 men (43-90 years) with prostate cancer on ADT and undertaking a 12-month RCT of various exercise modes, 135 had psychological distress assessed using the Brief Symptom Inventory-18 (BSI-18). Patients were randomized to twice weekly impact loading and resistance training (ILRT, n=49), aerobic and resistance training (ART, n=50), and usual care/delayed aerobic exercise (DEL, n=36). ILRT was supervised for 12 months, ART was supervised for 6 months and home-based for 6 months, and DEL underwent supervised aerobic exercise in the second 6 months. The BSI-18 provides three subscales for anxiety, depression, and somatisation, as well as the global severity index (GSI) where higher scores indicate higher distress. Intention-to-treat was utilised for the analyses which included group x time repeated measures ANOVA using log transformed (ln) data.

RESULTS: There were no differences among groups at baseline. Somatisation did not change over the study period, however, there were significant interactions ($p < 0.01$) for depression, anxiety, and the GSI. In ILRT, depression was reduced at 12 months compared to baseline and 6 months (0.78 ± 1.39 vs. 1.88 ± 3.24 and 1.48 ± 2.65 , respectively), as was the GSI (3.67 ± 4.34 vs. 5.94 ± 7.46 and 4.64 ± 4.73 , respectively) with anxiety reduced compared to baseline (1.08 ± 1.54 vs. 1.98 ± 2.56). Depression and the GSI decreased in ART at 6 months but increased by 12 months, while in DEL the GSI was reduced following exercise at 12 months (3.78 ± 3.94 vs. 5.25 ± 4.22 at 6 months).

CONCLUSION: Various exercise modes (when supervised) are effective in reducing psychological distress in men with prostate cancer on ADT. As a result, supervised exercise should be prescribed to not only improve physical but also psychological health in this patient group.

F-06 Thematic Poster - Cardiovascular Health in Firefighters

Firefighting is strenuous and dangerous work. Sudden cardiac death accounts for approximately 50% of firefighter line of duty deaths. **PURPOSE:** To determine the vascular and hemodynamic responses firefighting work across different positional assignments. **METHODS:** 40 experienced male firefighters completed a coordinated fire attack in a wood frame residential structure. Responding personnel were classified based upon four separate positions (assignments), including: Outside Command, Outside Vent, Inside fire suppression and search and rescue, Overhaul. Subjects were equipped with an automated blood pressure and pulse wave analysis device for measurement of cardiovascular variables (Mean Arterial Pressure, Total Vascular Resistance, Cardiac Output, Stroke Volume, Pulse-Wave Velocity). Measurements were made before, immediately after, and 30 minutes after fire suppression activities in a single-story residential structure. **RESULTS:** Increased mean arterial pressure (MAP) measured prior to the exercise indicates an anticipatory rise in sympathetic activation across all positions (Table 1). Those performing Inside suppression/search and rescue exhibited the greatest increase in MAP across all groups, with MAP remaining elevated immediately following the training exercise and a return to baseline conditions occurring 30 minutes post training (Table 1). This group also exhibited the greatest excursion in systolic blood pressure in response to training (Pre: 130.7 ± 12.7, Post: 134.6 ± 17.3). **CONCLUSIONS:** The vascular changes evidenced during acute firefighting may play a mechanistic role in the increased risk of sudden cardiac death with firefighting. Additional research is needed to better understand how these changes are related to myocardial blood flow.

Table 1, Data are expressed as Average (SD)

	Outside Command/Pump	Outside Vent	Inside	Overhaul
Age (years)	47.0 (3.9)	33.1 (6.8)	34.0 (6.8)	37.9 (8.6)
BMI (kg/m ²)	28.5 (3.2)	27.3 (3.4)	26.9 (3.7)	27.1 (2.9)
MAP (mmHg) Pre	107.6 (10.7)	103.6 (5.7)	103.8 (9.3)	103.1 (8.5)
MAP (mmHg) Post	105.3 (10.6)	102.0 (7.9)	105.9 (9.8)	98.6 (9.5)
MAP (mmHg) 30min Post	105.1 (8.2)	99.3 (3.9)	102.3 (9.2)	97.4 (7.8)

Firefighters With More Service Have Smaller Blood Pressure Surge When The Pager Sounds

Megan A. Carty¹, Rachel L. Dickinson², Emily H. Reeve³, Emily N. Blaszkow¹, Julia Gilpin¹, Brian Varani¹, Meghan Lashley¹, Paige E. DeAlba¹, Deborah L. Fearheller⁴. ¹*Ursinus College, Collegeville, PA.* ²*Pennsylvania Dermatology Group, Huntingdon Valley, PA.* ³*University of Oregon, Eugene, OR.* ⁴*University of New Hampshire, Durham, NH.* (Sponsor: Deborah Fearheller, FACS)
(No relevant relationships reported)

Cardiac incidents cause over 50% of LODD in firefighters (FF) and may be related to their BP responses. Also, years of service may affect FF stress and depression levels and impair overall health. Using ambulatory BP (ABP) monitoring to quantify the BP surge with alarm is a novel way to assess risk, and preliminary data showed that newer FF have higher BP surge. **PURPOSE:** To compare changes in health between FF with <10yr service (FF-10) and FF with >10yr service (FF+10) after a 6-wk Mediterranean diet & circuit training program. **METHODS:** We included 21 FF who completed a 6-wk intervention. Pre- and post-intervention testing included ABP monitoring with pager activation, a fasted clinical appt, and fitness testing. Participants wore the ABP cuff for 12-hrs, during which they were paged by a pager app (OnPage) or by emergency service dispatch. When the pager sounded, they were instructed to force an ABP reading to assess the BP surge. Average BP levels and surges were determined. Fasted visit included BP, body fat, lipid panel, and vascular health measures. Fitness test included a treadmill VO_{2peak} and a battery of other fitness tests. Participants also completed a health history form and the DASS-21 questionnaire assessing stress, anxiety, and depression. **RESULTS:** FF+10 (N=12, 45.7 ± 3yrs) had worse health and lower BP surges, but larger improvements with intervention compared to FF-10 (N=9, 36.8 ± 6.2yrs), P<0.05 for differences. FF+10 had lower HDL levels (38.3 ± 2.2 vs 57.9 ± 9.7 mg/dl), were heavier (213.1 ± 8.6 vs 205.1 ± 8.6 lbs), had higher average SBP (136.6 ± 4.8 vs 126.9 ± 3.6 mmHg) and DBP (83.2 ± 2.8 vs 75.7 ± 2.8 mmHg) levels, higher pre-alarm and post-alarm BP, but had a smaller surge in SBP (11.6 ± 3.2 vs 15.0 ± 3.3 mmHg) and DBP (4.1 ± 2.7 vs 7.3 ± 1.7 mmHg) when the pager sounded. FF+10 also had worse overall psychometric scores: higher DASS-21 (11.2 ± 5.3 vs 7.6 ± 1.3; depression 3.4 ± 1.3 vs 1.4 ± 0.3; and stress 5.4 ± 1.7 vs 3.3 ± 0.5; but similar anxiety scores 2.4 ± 1.0 vs 3.0 ± 0.9. With intervention, in FF+10 we found that BP lowered, fitness improved, and psychosocial constructs improved. **CONCLUSION:** With this subset of baseline data, we show that FF+10 have smaller BP surge, worse CV health, stress, and depression levels, but larger improvements with intervention compared to FF-10. Data confirms the importance of wellness programs for FF.

2943 Board #3 May 29 1:00 PM - 3:00 PM

Perturbations In Heart Rate And Heart Rate Variability Of Volunteer Firefighters Responding To Nighttime Calls

Cory J. Coehoon¹, Thomas W. Service², Jodie R. Gawryluk², Lynne A. Stuart-Hill². ¹*Louisiana State University Shreveport, Shreveport, LA.* ²*University of Victoria, Victoria, BC, Canada.*
(No relevant relationships reported)

Firefighters (FFs) can increase their risk of cardiovascular (CV) events >100-fold during emergency response. FF research has tended to analyze career FFs or a career-volunteer blend, while neglecting to provide specific results for the volunteer population. This leaves a gap in literature that seeks to understand the magnitude and duration of call-related perturbations. Autonomic tone (AT), measured by heart rate variability (HRV) is a non-invasive measure providing insight into CV risk and resiliency, and stress response. **PURPOSE:** To identify the magnitude and duration of changes in volunteer FFs' autonomic CV control during night time emergency response. **METHODS:** Eight male FFs (36.9 ± 12.1 years) wore monitors to track heart rate (HR) and R-R intervals from 1900-0700 on nights with, and without call response for a total of 12 calls. Data filtering preceded HRV analysis in both time and frequency domain. Data was organized into 15-minute epochs, focusing on: 15-0 (PRE) pre-dispatch, 0-15 (PC1) and 75-90 (PC2) post-dispatch, and 0-15 (WAKE) when waking without a call. **RESULTS:** Compared to PRE, increases in the LF/HF ratio were observed at both PC1 (1.784 ± 1.345, p=.014), and PC2 (1.265 ± 1.238, p=.046) η²=.505 in the call condition. PRE-PC1 comparisons showed increases in HRMEAN (43 ± 13 bpm, p<.0005, η²=.837) and HRMAX (60 ± 22 bpm, p<.0005, η²=.923) at PC1, though only HRMEAN remained elevated from PRE values at PC2 (12 ± 8 bpm, p=.005). RMSSD and HF Power (HFp) decreased at PC1 (RMSSD:16.868 ± 8.100 ms, p=.001, η²=.781; HFp: 552.057 ± 311.930 ms², p=.002, η²=.758), returning within PRE ranges by PC2. Comparisons of PC1 to normal WAKE revealed decreased HFp (234.726 ± 163.721 ms², p=.002, η²=.577) and increases in both LF/HF (6.920 ± 5.044, p=.013, η²=.556) and HRMEAN (18 ± 13 bpm, p=.012, η²=.564). **CONCLUSION:** Results from the current study show sympathetic activation and parasympathetic withdrawal at PC1 and PC2 compared to

PRE. This facilitated a rapid spike in HR to 85% of age-adjusted HRMAX. Compared to waking normally, waking for call response evokes a distinctly different response where perturbations at AT tend to persist 90-minutes. This persistent ANS imbalance may indicate physiological perturbations that could explain increased atherosclerosis and CVD risk for FFs.

2944 Board #4 May 29 1:00 PM - 3:00 PM
Prevalence Of Coronary Heart Disease Risk Factors In A Large Sample Of Southern Californian Firefighters

Terri Wann, Kris Ross, Jennifer Meloni, Ralph Rozenek. *Santa Ana College, Santa Ana, CA.*
 Email: wann_terri@sac.edu
 (No relevant relationships reported)

Firefighters (FF) are exposed to a variety of work-related stressors that can lead to increased risk of disability and premature death. Heart attack is the primary "on-duty" cause of death in these individuals. Few studies have investigated the prevalence of the various coronary heart disease (CHD) risk factors (RF) in FF and how they are affected by age in this specific group. **PURPOSE:** 1) To determine the prevalence of CHD RF and; 2) to examine the relationship between the CHD RF and age in a large group of FF. **METHODS:** Data from 1949 male (n= 1924) and female (n = 25) FF (mean age \pm s.d. = 39.8 \pm 8.8 yr.) representing 27 departments in Southern California were used for analyses in this cross-sectional study. Apart from age, the RF selected represented those that were independent of gender. Standard statistical techniques were applied to determine CHD RF frequencies and percentages. Chi-Square Analyses with Cramer's V were used to assess the relationship between age-group and RF prevalence and to estimate effect size. **RESULTS:** Overall 70.0% of FF had exceeded at least one CHD RF threshold. High blood pressure (HBP) was the most prevalent RF (26.9%) in the 20-29 yr. age-group followed by elevated body mass index (BMI) (11.2%) and low-density lipoprotein cholesterol concentrations (LDL-C) (11.2%). By contrast, 64.4% of FF in the 50+ yr. age-group had HBP with 31.9% having elevated BMI and 30.7% with elevated LDL-C. While the percentage of FF in the 20-29 yr. age-group with ≥ 2 RF was only 9.9%, it rose to 80.5% in the 50+ yr. age-group. Other than blood glucose, moderate effect sizes were observed for relationships among age-group and the individual RF.

Percentage of FF with CHD risk factor by age group.

Risk Factor	Age Group (years)				p value	Cramer's V
	20-29	30-39	40-49	50+		
HBP $S \geq 130/D \geq 80$ mm Hg	26.9%	38.7%	47.7%	64.4%	<0.001	0.219
BMI ≥ 30 kg x m ²	11.2%	18.4%	30.8%	31.9%	<0.001	0.179
Blood Glucose ≥ 126 mg x dL ⁻¹	0.0%	0.0%	0.8%	0.3%	0.05	0.063
LDL-C ≥ 130 mg x dL ⁻¹	11.2%	22.9%	36.7%	30.7%	<0.001	0.189
METs < 8	0.0%	0.7%	2.7%	8.0%	<0.001	0.172

CONCLUSION: A sizable number of FF had multiple CHD RF. Advancing age increased the percentage of FF with multiple RF. Continued efforts must be made to reduce the number of CHD RF in this specific population who serve a vital function protecting our communities.

2945 Board #5 May 29 1:00 PM - 3:00 PM
Seasonal Changes In Cardiovascular Function, Risk Factors, And Oxidative Stress Of Wildland Firefighters

Cassie Williamson-Reisdorph, Katie S. Christison, Shae C. Gurney, Kathryn G.S. Tiemessen, Joseph A. Sol, Tiffany S. Quindry, Charles G. Palmer, Matthew W. Bundle, Charles L. Dumke, FACSM, John C. Quindry, FACSM. *University of Montana, Missoula, MT.* (Sponsor: John C. Quindry, FACSM)
 (No relevant relationships reported)

Wildland firefighters (WLFF) experience extreme physiological strain throughout a typical season due to intense occupational demands and consistent woodsmoke exposure. There is a rationale to indicate that accumulated physiological strain, and oxidative stress, throughout a WLFF season has the potential to negatively alter cardiovascular function and risk factors. **PURPOSE:** The purpose of the study was to examine the effects of a season on cardiovascular function, risk factors, and markers of oxidative stress in WLFF. **METHODS:** Fourteen members of a Type I interagency hotshot crew participated in the study (males: n=13, females: n=1, age: 30.1 years \pm 4.8). Pre- and post-seasonal resting measurements (May, October) were obtained for heart rate variability (lnRMSSD, lnHF, lnHF, LF:HF), pulse wave velocity (PWV), blood lipid panels (TC, TG, LDL, HDL), metabolic biomarkers (blood glucose, HbA1c), blood pressure (SBP, DBP) and blood oxidative stress (3-nitrotyrosine, 8-isoprostane). Paired samples t-tests were used to identify differences among pre-

and post- seasonal values. **RESULTS:** There were no seasonal effects observed on resting heart rate variability, PWV, 3-nitrotyrosine, 8-isoprostane, TC, TG, LDL, blood glucose, SBP, or DBP ($p > 0.05$). A significant reduction occurred in HDL (Pre: 53 mg/dL \pm 14, Post: 45 mg/dL \pm 18, $p = 0.043$) and HbA1c increased (Pre: 5.2% \pm 0.2, Post: 5.3% \pm 0.2, $p = 0.034$) from pre- to post-season. **CONCLUSION:** These data suggest a WLFF season did not impact resting markers of heart rate variability, pulse wave velocity, and oxidative stress. Alterations in metabolic biomarkers of cardiovascular risk factors (HDL and HbA1c) demonstrate unfavorable seasonal changes, suggesting that the WLFF season may increase cardiovascular risk.

2946 Board #6 May 29 1:00 PM - 3:00 PM
Metabolic And Cardiovascular Alterations During Critical Training In Wildland Firefighters

Shae C. Gurney, Katie S. Christison, Cassie M. Williamson-Reisdorph, Kathryn G.S. Tiemessen, Joseph A. Sol, Tiffany S. Quindry, Matthew W. Bundle, Charles G. Palmer, John C. Quindry, FACSM, Charles L. Dumke, FACSM. *University of Montana, Missoula, MT.*
 (No relevant relationships reported)

Introduction: Wildland firefighters (WLFF) are confronted with numerous physical and mental stressors. Pre-fire season includes an intense two-week critical training period; a preparatory phase that sometimes results in injuries, illness, and rhabdomyolysis. **Purpose:** To identify physiologic changes to oxidative stress and other metabolic biomarkers that occur during 2 weeks of critical training in WLFF. **Methods:** Eighteen male (29.4 \pm 1.1 yr, 182.1 \pm 1.6 cm) and three female (26.7 \pm 2.6 yr, 169.5 \pm 4.2 cm) participants were recruited from a Type I interagency hotshot fire crew and monitored for the duration of their two-week critical training. Subjects were asked to arrive fasted and uncaffeinated for blood draws on days 1, 4, 8, and 11. Plasma was analyzed for changes in the metabolic profile and oxidative stress markers 3-Nitrotyrosine (3-NT) and 8-Isoprostane (8-ISO). A one-way repeated measures ANOVA was used to analyze 8-ISO and 3-NT. Paired samples t-tests were used to compare metabolic biomarkers. Data presented as mean \pm SEM. **Results:** Critical training elicited a decrease in total cholesterol (173.6 \pm 12.1 to 153.4 \pm 8.6 mg \cdot dL⁻¹, $p = 0.01$), hemoglobin A1c (5.2 \pm 0.1 to 5.1 \pm 0.1 %, $p = 0.003$), hemoglobin (15.5 \pm 0.4 to 14.3 \pm 0.3 g \cdot dL⁻¹, $p = 0.003$), and estimated plasma volume (53.8 \pm 0.7 to 50.7 \pm 1.4 %, $p = 0.005$) from day 1 to 11. No difference was observed in high-density lipoprotein cholesterol. A main effect for time was observed in 8-ISO ($p < 0.001$) and 3-NT ($p = 0.033$). A significant decrease was observed in 8-ISO at day 4 and 8 when compared to day 1 (day 1: 15.5 \pm 1.3, day 4: 11.8 \pm 1.0, day 8: 12.9 \pm 1.1 pg \cdot mL⁻¹). 3-NT was significantly elevated from day 4 to day 8 (day 4: 2.4 \pm 0.6, day 8: 2.9 \pm 0.6 μ g \cdot mL⁻¹). **Conclusion:** These data suggest that the exertion required of WLFF during critical training results in positive alterations to the metabolic profile. The unexpected decreases in oxidative stress markers may reflect adaptation to the stressors of critical training, although this cannot be confirmed. Additional markers should be examined across other WLFF crews to confirm and provide further information on alterations during this two-week period.

2947 Board #7 May 29 1:00 PM - 3:00 PM
Nutrition, Physical Activity And Cardiovascular Disease Risk Of Career Firefighters In A Low-income Area

Brandy Ellen Phipps, Kathy Carter, FACSM. *Central State University, Wilberforce, OH.* (Sponsor: Kathy Carter, FACSM)
 Email: bphipp@centralstate.edu
 (No relevant relationships reported)

The majority of on-duty firefighter (FF) deaths result from cardiovascular incidents, and FF wellness is related to job effectiveness and safety. Departments in low-income communities are often unable to provide wellness programming, allowing opportunities for local universities to fill the need.

PURPOSE: To determine health and cardiovascular disease (CVD) risk of local career FF in a low-income community for use in developing ongoing wellness interventions. **METHODS:** Nutrition behavior, physical activity information, anthropometric measurements [body fat percentage (%BF), mass of body fat (MBF); waist circumference (WC); height; weight], and blood lipid levels [total cholesterol (TC); low-density lipoprotein (LDL); high-density lipoprotein (HDL); and triglycerides (TG)] were collected from a cohort of FF and analyzed. **RESULTS:** Thirty-three percent (42/127) of department members participated in the study, with even representation across unit, age, and years worked. Eighty-three percent of FF were overweight/obese, as determined by bioelectrical impedance. Similarly, 83% were at-risk or at-significant-risk for CVD by waist-to-height ratio (WTHR, 0.5-0.6 and >0.6, respectively). Segmental trunk mass of body fat (SMBF_{trunk}) was correlated with waist circumference ($r = 0.915$), and also with TC ($r = 0.167$), LDL ($r = 0.189$) and TG ($r = 0.484$), while inversely correlated with HDL ($r = -0.133$). BMI and %BF were positively correlated ($r = 0.81$). Fifty percent of FF had TC, 38% had LDL, and 45%

had TG levels which placed them at-risk for CVD. Only 33% of participants reported exercising the recommended amount (3-5 times) per week, and 36% and 14% of FF reported intake of the recommended amount of fruits and vegetables, respectively, per day. **CONCLUSION:** In a cohort of career FF in a low-income area, the majority were classified as at-risk for CVD, across multiple indices, including BMI, %BF, WC, WTHR, SMBF_{trunk}, and lipid profiles. In addition, the cohort reported unhealthy levels of fruit and vegetable intake, as well as less-than-recommended levels of physical activity. These results suggest that local FF are an at-risk population for CVD, and that there is a need for nutrition and exercise interventions to help lower the risk and increase job effectiveness in our regional first responders.

2948 Board #8 May 29 1:00 PM - 3:00 PM
Changes In Obesity And Cardiovascular Disease Risk Among Older And Younger Firefighters
 Brittany S. Hollerbach¹, Kevin C. Mathias¹, Yuchen Wu¹, Donald F. Stewart², Denise L. Smith, FACSM¹. ¹Skidmore College, Saratoga Springs, NY. ²Public Safety Occupational Health Center, Fairfax, VA.
 Email: bhollerb@gmail.com
 (No relevant relationships reported)

Over 80% of the US fire service is overweight (BMI: 25-29.9 kg/m²) or obese (BMI≥30 kg/m²), increasing the risk for cardiovascular disease (CVD). Although age is an important CVD risk factor, it is not often examined among firefighters (FFs). Risk scores are a common tool used by medical professionals. However, no investigations have examined calculated risk scores and changes over time among FFs. **PURPOSE:** To describe changes in weight, BMI and CVD risk scores among a large cohort of younger (<45 years) and older (≥45 years) FFs over a 5-year period. **METHODS:** Age, body weight, body mass index (BMI), and calculated CVD risk scores of 672 FFs (<45: n=522; 35±6 yr; ≥45: n=150; 48±3 yr) in a large northeastern fire department were assessed during an occupational medical exam in 2009-2011 and 5 years later. CVD risk scores were calculated using the Framingham Risk Score (FRS) calculation. Descriptive statistics summarized data, logistic or linear regression models compared proportions or means, and paired t-tests were used for within subject comparisons to test for significance. **RESULTS:** At baseline, younger FFs weighed 88.5 kg with a BMI 27.9 kg/m² and FRS of 3.4. Older FFs weighed 89.9 kg with a BMI of 28.5 kg/m² and FRS of 12.1. Over the 5 years, FFs <45 yr gained (+3.0 kg) significantly more weight than those ≥45 yr (+0.8 kg; p<0.001). BMI for both groups increased significantly, +0.9±0.1 and +0.4±0.2 respectively for <45 and ≥45 yr. Significantly more (55%) FFs <45 yr gained weight compared to 38% of FFs ≥45 yr (p<0.01). However, older FFs had significantly higher (p<0.001) CVD risk scores at baseline and follow up (9.3; 12.1) than younger FFs (3.4; 4.9). Although the majority of FFs ≥45 lost/maintained body weight (62%), overall their CVD risk increased (+2.8±0.4; p<0.001). **CONCLUSION:** Although FFs cannot avoid aging, they can aggressively manage other risk factors that affect their CVD risk score including preventing weight gain. Research indicates health care providers are more likely to counsel older FFs regarding weight loss. Our findings suggest younger FFs are more at risk of gaining weight and could benefit from guidance on this important risk factor. Further efforts are needed to encourage physicians and fire departments to direct FFs to establish healthy habits early in their career.

Changes In Peak Accelerations And Shock Attenuation Over The Course Of A Marathon
 Marit A. Zandbergen¹, Jaap H. Bourke¹, Peter H. Veltink², Jasper Reenalda¹. ¹Roessingh Research & Development, University of Twente, Enschede, Netherlands. ²University of Twente, Enschede, Netherlands. (Sponsor: Brian W. Noehren, FACSM)
 Email: m.zandbergen@rrd.nl
 (No relevant relationships reported)

Peak tibial and peak sacral accelerations have been shown to increase during a fatiguing run. Peak accelerations are often used as a surrogate for impacts on the body during running. High tibial impacts have been linked to development of tibial stress fractures. To understand how impacts are related to injury development, we need more insight in how shocks propagate through the body, especially under the influence of fatigue.

Purpose
 To investigate bilateral peak accelerations and shock attenuation over the course of a Marathon.

Methods
 5 trained athletes (2M 3F, 33.8±11.8 years, 182.3±5.8 cm, 73.9±9.1 kg years) ran a Marathon during competition. Inertial measurement units (240Hz) were placed on the sternum, pelvis, and bilaterally on the tibia and foot. Mean peak accelerations around initial contact and shock attenuation (% decrease of peak acceleration) were calculated over 25 strides during the 2nd and 42nd km of the Marathon. Paired sample t-tests were used to test for statistical differences between the 2nd and 42nd km and between the dominant and non-dominant side.

Results
 See Table 1. Mean finish time was 4:07:40±0:19:07.

Conclusion
 Impacts and shock attenuation changed asymmetrically during a Marathon. Both side dominance and fatigue significantly influenced shock attenuation. However, on sternum level, only fatigue influenced impacts and shock attenuation, implying some sort of protective mechanism to keep proximal impacts low. The non-dominant side showed larger impacts during the whole Marathon, possibly because this side is less strong and therefore less able to actively (i.e. muscle contractions) absorb shocks. Overall, impacts increased and shock attenuation decreased towards the end of the Marathon, possibly increasing the risk of overuse injuries.

Table 1. Bilateral peak accelerations and shock attenuations for the 2nd and 42nd km of a Marathon. An asterisk (*) indicates a significant difference (p<0.05) between the 2nd and 42nd km. A superscript s (!) indicates a significant difference (p<0.05) between the non-dominant and dominant side at either the 2nd or 42nd km.

Low Accelerometer Sampling Rates Attenuate Tibial Impact Acceleration Peaks During Running
 Clare E. Milner, FACSM, Kevin G. Aubol. *Drexel University, Philadelphia, PA.*
 Email: milner@drexel.edu
(No relevant relationships reported)

High tibial acceleration peaks have been associated with tibial stress fracture in runners. Field-testing with wearable wireless accelerometers is now commonplace, but some devices have a lower sampling frequency than in laboratory testing. PURPOSE To determine the influence of sampling rate on peak axial tibial acceleration and peak resultant tibial acceleration magnitude during running. METHODS As part of a larger study, 19 healthy adults were recruited (10 women; 31±6 years; 1.70±0.08 m; 68.6±11.6 kg) and provided informed consent to participate. A precision accelerometer sampling at 1000Hz was attached to the distal anteromedial aspect of the right tibia. Participants ran at 3.0m/s in the laboratory for five good trials making contact with a force plate sampling at 1000Hz. Raw data were down-sampled to 500Hz and 100Hz, common sampling rates for wearable wireless accelerometers. All data were low-pass filtered at 70Hz. Stance phase was identified by foot contact on the force plate. Peak positive axial acceleration and peak resultant acceleration were determined for each trial and averaged. One factor repeated measures analysis of variance with least significant difference post-hoc tests determined whether peaks differed among sampling rates. Effect sizes were calculated to aid interpretation of the data. RESULTS Both peak axial and peak resultant acceleration were significantly reduced when tibial acceleration was sampled at 100Hz compared to 500Hz or 1000Hz (p = 0.041). Reductions were 0.7g or about 10% of the peak magnitude at 1000Hz, a small effect. Values were stable between the 500Hz and 1000Hz sampling rates. CONCLUSION We recommend that tibial acceleration data are sampled at rates of 500Hz or greater to avoid attenuation of peaks producing erroneously low values for both peak axial and peak resultant acceleration.

Table: Mean and standard deviation of peak axial and peak resultant tibial acceleration during running when sampling data at different rates

Accelerometer Sampling Rate (Hz)	Peak Axial Acceleration			Peak Resultant Acceleration		
	Mean (SD) g	p value	Effect Size	Mean (SD) g	p value	Effect Size
100	5.4 (1.8)	< 0.01	0.36	7.4 (2.9)	0.025	0.22
500	6.0 (2.1)	0.89	0.05	8.1 (3.4)	0.93	0.00
1000	6.1 (2.1)	-	-	8.1 (3.4)	-	-

Changes In Running Mechanics During A Typical Interval Training On The Track Measured With IMUs
 Jasper Reenalda¹, Emily J.C. Zoetbrood¹, Marit A. Zandbergen¹, Jaap H. Buurke¹, Brian W. Noehren, FACSM². ¹*Roessingh Research and Development, University of Twente, Enschede, Netherlands.* ²*University of Kentucky, Lexington, KY.* (Sponsor: Brian W. Noehren, FACSM)

(No relevant relationships reported)

An 8 x 400 meter interval training is often performed with the aim of improving aerobic fitness. Besides being physiological and physically challenging this type of training is also mechanically demanding. As such it could have potential negative effects on running mechanics. Inertial magnetic measurement units (IMUs) allow for continuous measurement of running mechanics during this type of training. PURPOSE: To investigate changes in running mechanics during an 8 x 400 meter interval training on the athletic track using IMUs. METHODS: 5 trained athletes (4M 1F, 25.4±7.9 years, 185.6±8.3 cm, 69.2±12.7 kg) ran 8 x 400 meters on the athletic track. They were paced to run each 400 meter at 5 km race pace with half of the time run as rest. Eight IMUs (240 Hz) were placed at the feet, tibia, upper legs, sacrum and sternum. Accelerometer data and sensor orientation were used to calculate the following parameters using custom code after calibration trials: Hip, knee and ankle angle at Initial Contact (IC), knee angle at Midstance (MST) and Midswing (MSW), peak tibial and sacral acceleration (PTA, PSA), and centre of mass (COM) displacement. Parameters were calculated for both straights of the 2nd, 4th, 6th and 8th 400 meters. Borg scale (0-10) was asked after every bout for perceived exertion. Paired sample t-tests were used to test for statistical differences between the 2nd and 8th bout. RESULTS: Table 1 CONCLUSIONS: Running mechanics (mainly ankle and knee mechanics and tibial impact) changed over the course of a typical interval training, putting runners at higher risk with increasing bouts. This indicates that this type of training is not only

physiological and physically demanding but puts increasing mechanical stress on the body. These results suggest caution should be used among athletes returning from an overuse injury.

Table 1: Results of the 8 x 400 meters interval training on the athletic track. Mean values (± SD) are presented for the selected parameters during the 2st, 4th, 6th and 8th run. P value is given for the significance between the 2nd and 8th bout.

Bout	#2	#4	#6	#8	#2 vs #8
	Mean±SD	Mean	Mean	Mean	P value

Automated Gait Variability Assessment In Real-World Running Using Wearable Accelerometry
 John J. Davis, IV¹, Marcin Strączkiewicz², James McDonnell¹, Jaroslaw Harezlak¹, Max R. Paquette³, John S. Raglin, FACSM¹, Allison H. Gruber¹. ¹*Indiana University, Bloomington, IN.* ²*Harvard T.H. Chan School of Public Health, Boston, MA.* ³*Memphis University, Memphis, TN.* (Sponsor: John S Raglin, FACSM)
 Email: jjd1@iu.edu
(No relevant relationships reported)

Using wearable sensors to assess running gait variability may be a valuable tool to identify deterioration in performance or health in competitive and recreational runners. PURPOSE: To measure associations between gait variability and training intensity, mood state, and perceived fatigue in collegiate runners (CR) and novice/recreational runners (NR). METHODS: 30 CR wore a waist-mounted ActiGraph GT3X+ accelerometer for all non-interval and non-competition training sessions for a full season. 16 NR wore a waist-mounted GT3X+ and an on-shoe activity monitor (MilestonePod) during 13 weeks of progressive training. Subjects completed written (CR) or email (NR) daily surveys. Recently developed running and step recognition algorithms were applied to isolate running gait cycles from raw sub-second level accelerometer data. Gait variability was assessed using amplitude deviation of resultant acceleration. Associations between variability and training intensity, mood state, and fatigue were assessed with generalized additive mixed models. RESULTS: 1069 runs and 7.64 million steps were analyzed. Variability was greater in CR than NR (0.301 vs 0.262g, p=0.019). Within individual runs, variability was stable from 10-60 minutes in both CR and NR (Fig. 1). In CR, mood state was not significantly associated with variability (p=0.70). In NR, variability increased nonlinearly with average running speed (p<0.001), and a 1-point increase in fatigue on a 0-10 scale was associated with a 0.003g decrease in variability (p=0.051). CONCLUSION: A runner's gait variability may be more strongly influenced by skill level and running speed than by acute changes in perceived fatigue or mood state. Unmeasured variables, such as training surface, may also affect gait variability. Figure 1. Gait variability in CR and NR across different individual runs (top left, black dots), across different levels of fatigue (top right), and within any given run (bottom left and right, thin lines).

(No relevant relationships reported)

With wearable technology becoming more popular, more companies are creating sensors to assess biomechanical parameters including peak tibial acceleration (PTA) during running. However, validity of data from wearable technology relative to "gold-standard" research-grade instruments is highly important. PURPOSE: Assess the difference in PTA obtained from wearable inertial measurement units (IMU) and a research-grade accelerometer at different running speeds. METHODS: Six participants completed 1-2min treadmill running bouts at 3.0 m/s and 4.0 m/s while

wearing standardized footwear (1080, New Balance). A research-grade tri-axial accelerometer (ACC; 1200Hz, model 356A26, PCB Piezotronics) and a 9-axis IMU (1000Hz, Blue Trident, IMeasureU) were secured to the distal tibia to capture PTA during running. The testing at both speeds was completed with the ACC below and above the IMU to account for possible position effects. Data were collected for the final 15 seconds of each running bout and the average of both positions for 10-15 peaks of axial tibial acceleration were used for analyses. Paired t-tests and Cohen's *d* effect sizes were calculated to compare instrument PTA means at different speeds. **RESULTS:** At 3.0 m/s, mean PTA was not different between ACC (5.2±1.9 G) and IMU (5.9±2.2 G; *p* = 0.33; *d* = 0.34). At 4.0 m/s, mean PTA was not different between ACC (8.5±3.7 G) and IMU (9.8±4.2 G; *p* = 0.33; *d* = 0.33). Figure 1 demonstrates the individual variability in the difference in PTA obtained from the ACC and IMU at different speeds (A) and different positions (B). **CONCLUSION:** Despite the statistically similar PTA means obtained from both instruments, the difference in PTA between ACC and IMU appears to be highly variable among individuals. This variability in PTA may be due to differences between devices, device placement, attachment method, or individual running style. This highlights the difficulty in controlling sources of variability during testing.

Figure 1. A) Individual and average (bold) difference of PTA between the ACC and IMU at 3.0 m/s and 4.0 m/s with sensor position pooled. B) Individual and average difference of PTA between the ACC and IMU for both positions with pooled speeds.

Fig. 1: (Left) Hazard ratios (error bars representing 95% CI) of the runners' average complexity across the season and the change in complexity each week across runners. (Right) Mean complexity for each week recorded during the season of exemplar injured (blue shades) and uninjured (red shades) runners.

Risk Of Running-related Injury Associated With Center Of Mass Acceleration Complexity
 James McDonnell¹, John J. Davis, IV¹, Jaroslaw Harezlak¹, Max R. Paquette², Allison H. Gruber¹. ¹Indiana University, Bloomington, IN. ²University of Memphis, Memphis, TN.
 (No relevant relationships reported)

Dynamical systems theory suggests that examining the complexity of biological signals may be more sensitive in differentiating between groups of varying health status, including predicting who may develop a running-related overuse injury (RROI). This theory has yet to be tested in prospective running studies. **PURPOSE:** To evaluate if changes in complexity, quantified by mean control entropy, of center of mass (COM) resultant acceleration during running is associated with RROI development. **METHODS:** 30 collegiate runners wore an ActiGraph GTX3+ during 'easy' training runs throughout a cross-country season. Clinician-diagnosed RROI were reported via an online survey. Complexity was calculated on the resultant acceleration time series from each run. Cox proportional hazards analysis assessed injury risk as a function of the mean complexity for each runner across the season and the change in complexity per week. **RESULTS:** Seven runners sustained an injury. Across all 30 participants over the season, the mean ± 1SD complexity was 0.623 ± 0.086 units. The mean change in complexity over the course of the cross country season was -0.0014 ± 0.0043 units per week. Although not statistically significant, each 0.1-unit increase in complexity was associated with a 1.65-fold increase in injury rate (95% CI 0.70-3.89, *p*=0.30) and a 0.01-unit increase in complexity per week was associated with a 1.50-fold increase in injury rate (95% CI 0.06-35.5, *p* = 0.80). **CONCLUSION:** These preliminary findings suggest that COM complexity could at least contribute to RROI detection strategies in cross-country runners. Given these preliminary results, additional prospective studies with larger sample sizes are necessary to further assess relationships between baseline complexity and changes in complexity during running training that can be monitored with wearable technology.

Relationship Between Wearable Sensor Foot Strike Outcomes And Ankle Sagittal Plane Kinematics During Treadmill Running
 Alexandra F. DeJong, Jay Hertel, FACSM. University of Virginia, Charlottesville, VA. (Sponsor: Jay Hertel, FACSM)
 Email: afd4au@virginia.edu
 (No relevant relationships reported)

PURPOSE: Wearable sensors are capable of measuring biomechanical running outcomes. Traditional gait analyses have determined a strong relationship between ankle angle at initial contact and foot strike. However, there is currently no information available on how sensor-derived metrics of foot strike type relate to ankle sagittal motion during running as a means of validation. Therefore, the purpose of this study was to validate the sensor-derived foot strike type outcome by determining the relationship between foot strike type and ankle sagittal plane kinematics during a treadmill running analysis. We hypothesized that a rearfoot strike (RFS) would highly correlate to increased ankle dorsiflexion, while a forefoot strike (FFS) would highly correlate to increased ankle plantarflexion. **METHODS:** Twenty collegiate cross-country athletes (12 females) ran on an instrumented treadmill with 3-D motion capture at standard (2.68 m/s) and fast (3.60 m/s) speeds. Foot strike outcomes were obtained bilaterally using running wearable sensors, and sagittal plane ankle kinematics were simultaneously recorded. Pearson's *r* correlation coefficients were used to determine the relationship between sensor-derived foot strike categories (1 to 16), and ankle angles at initial contact. Dorsiflexion was defined as in the positive axis. Alpha was set a priori to .05 for all analyses. **RESULTS:** Eight hundred total steps were included for analysis. Foot strike type and ankle angles at initial contact had a strong, inverse correlation, such that a higher foot strike value was strongly related to increased ankle plantarflexion angles (*r* = -0.85, *p*<.001, Figure). **CONCLUSIONS:** Sensor-derived foot strike metrics were highly correlated to sagittal plane ankle measures, thus confirming our initial hypotheses. These outcomes support that the running wearable sensors are a valid means to assess foot strike patterns during distance running.

Mixed-effects Location Scale Modeling For The Analysis Of Accelerometry Data

Whitney A. Welch¹, Donald Hedeker², Bonnie Spring¹, Juned Siddique¹. ¹*Northwestern University Feinberg School of Medicine, Chicago, IL.* ²*University of Chicago, Chicago, IL.*
(Sponsor: Ann Swartz, FACSM)
Email: whitney.welch@northwestern.edu
(No relevant relationships reported)

Purpose: To introduce a statistical technique, the mixed-effects location scale model, for analysis of longitudinal accelerometer-based physical activity (PA) data. This approach jointly models both the mean (location) and within-subject variability (scale) of participants' PA over time as a function of covariates, since within-person variability may be an important construct to explore in PA interventions. Random effects are included in both models to allow for subject-specific deviations beyond the effect of covariates. These random effects can be correlated. **Methods:** Participants (N=204, 77% female, age=33±11y, BMI=28.2±7.1 kg/m²) in the Make Better Choices Study were randomized to one of two activity-related intervention arms: 1) increase moderate-to-vigorous PA (MVPA) (PA group) or 2) decrease sedentary active control (SB group). Physical activity was measured by accelerometer for 5 weeks: a 2 week baseline assessment phase and a 3 week intervention follow-up phase: week 1 (rx1) and weeks 2 and 3 (rx23). The outcome MVPA min/d was analyzed using the mixed-effects location scale model in the MIXREGLS software program in STATA. **Results:** The mean model shows a significant group by time interaction (MVPA group by rx1: B=6.32 (95%CI: 3.93, 8.7) MVPA group by rx23: B=9.85 (95% CI: 7.59, 12.10)) indicating that those in the PA group had significantly greater MVPA min/d at rx1 and rx23 compared to the SB group. The PA group by rx23 interaction was significant in the within-subject variance model, suggesting that those in the PA group had significantly more variability in MVPA min/d during follow-up phase rx23 compared to the SB group. The random-location effect is positively associated with the within subject variance, participants with higher mean min/d MVPA tend to have higher min/d MVPA variability ($\tau_1=0.70$ (95% CI: 0.60, 0.80)). The scale standard deviation is significant indicating that some participant's MVPA min/d are significantly more dispersed than other participants even after adjusting for group and time effects ($\sigma_w=0.60$ (95% CI: 0.55, 0.64)). **Conclusions:** The location-scale mixed model provides a new approach for examining the mean and variability of min/d of MVPA in longitudinal data. To demonstrate, we applied this model to a randomized controlled trial to increase PA in inactive adults.

A Functional Data Analysis Framework For Modeling Physical Activity Intensity Continuously Using Accelerometer Data

Chongzhi Di¹, Xu Wang², Charles Kooperberg¹, Ross Prentice¹, Andrea LaCroix³, David Buchner, FACSM⁴. ¹*Fred Hutchinson Cancer Research Center, Seattle, WA.* ²*University of Washington, Seattle, WA.* ³*University of California, San Diego, CA.* ⁴*University of Illinois at Urbana-Champaign, Champaign, IL.*
Email: cdi@fredhutch.org
(No relevant relationships reported)

PURPOSE: Cutpoints approaches are often used to define physical activity (PA) intensity categories for accelerometry. We proposed methods to characterize the full continuum of PA intensity, free of cutpoints, and to quantify associations between PA accumulated at varying intensity levels and health outcomes. **METHODS:** During 2012-2014, 6,379 women aged 63-99 wore accelerometers on their waist for 7 consecutive days. Accelerometer counts data were analyzed in 15-second epochs. Complementary cumulative distribution functions (CCDF) were used to characterize how each subject distributes PA across all intensity levels. Functional linear regression models were used to estimate flexible dose-response relationships between PA intensity and health outcomes, including body mass index (BMI) and fasting glucose levels. **RESULTS:** The CCDFs of PA intensity showed that age-related decline in PA occurred at all intensity levels. The dose-response relationships between PA intensity and BMI and glucose were shown in Figure 1. Neither effects were constant, indicating

that intensity mattered after controlling for volume (count-min or MET-min). The relationship between BMI and intensity was complicated, while PA accumulated at higher intensity was found to be associated with lower fasting glucose levels, after controlling for volume. **CONCLUSION:** We provided a cutpoint-free analytic framework to model PA intensity continuously. The effect of PA on BMI and fasting glucose varied across intensity levels, even when fixing PA volume. The proposed methods are applicable not only to counts data, but also to other acceleration-based metrics calculated using raw data. **Figure 1.** Association of PA intensity (counts/15-sec or equivalent METs) with BMI and fasting glucose. The adjusted analysis included age, race-ethnicity and education for BMI, and for glucose additionally adjusted for BMI. Corresponding METs were calculated based on an internal calibration study.

Machine Learning Activity Classification Models For Preschool-aged Children: The Need For Free-living Training Data.

Matthew N. Ahmadi, Alok K. Chowdhury, Denise K. Brookes, Stewart G. Trost. *Queensland University of Technology, Brisbane, Australia.* (Sponsor: Stewart G. Trost, FACSM)
Email: matthewnguyen.ahmadi@hdr.qut.edu.au
(No relevant relationships reported)

Machine learning (ML) classification models trained on laboratory activity trials exhibit poor performance when evaluated under free-living conditions. Training models on free living data, including temporal features such as lead and lag windows, and using shorter sliding windows may improve recognition accuracy under free-living conditions.

Purpose:

To evaluate the accuracy of free-living hip and wrist Random Forest activity classifiers for pre-schoolers trained on features extracted from windows of 1s, 5s, 10s, and 15s. Performance was benchmarked against classifiers trained on laboratory-based data using a 15s window.

Methods:

31 preschool-aged children (4.0 ± 0.9 y) were video recorded during a 20-minute unstructured active play session. Participants wore an accelerometer on their right hip and non-dominant wrist. A bespoke two-stage direct observation system was used to code ground truth activity class and specific activity types occurring within each class. Data from 21 of the children were randomly selected to train the classifiers. Models were trained with and without temporal features and cross-validated in a hold sample of the remaining 10 children with overall and class-level accuracy.

Results:

Accuracy improved as window size increased from 1 sec (73.5%-77.7%) to 10 sec (82.4%-86.0%); with only minimal improvements observed for 15s windows. Inclusion of lag and lead features increased accuracy by 1.6% to 6.6%, with the largest improvements observed for shorter duration windows (≤10s). Comparatively, the accuracy of the laboratory trained model was 56.9% and 67.5% for wrist and hip, respectively. For a 10s window, training models on free-living data and including temporal features increased recognition of sedentary from 70.6% - 74.4% to 83.3% - 90.4%; light activities and games from 57.5% - 76.9% to 88.6% - 88.8%; walking from 7.5% - 17.5% to 64.1% - 75.0%; and running from 50.0% - 77.8% to 71.4% - 85.7%. There was no improvement in recognition of mod-vig activities and games (56.3% - 62.5%).

Conclusions:

Unlike models trained on laboratory activity trials, ML activity classification models for pre-schoolers trained on free-living accelerometer data perform well when evaluated under true free-living conditions.

Novel Application Of Accelerometry Data To Enhance Detection Of Falls Risk In Older Adults

Jennifer A. Schrack¹, Jacek K. Urbanek², Amal A. Wanigatunga¹, Erin D. Michos², David L. Roth², Lawrence J. Appel². ¹*Johns Hopkins University, Baltimore, MD.* ²*Johns Hopkins School of Medicine, Baltimore, MD.*

Email: jschrac1@jhu.edu

(No relevant relationships reported)

Purpose: The association between physical activity (PA) and falls is complex and bi-directional, with more active persons often demonstrating greater falls risk. The role of PA in preventing or aggravating falls risk may be illuminated by novel, more sensitive measures of PA. We examined the longitudinal association between accelerometer derived PA metrics and falls in control group participants of STURDY (Study to Understand Fall Reduction and Vitamin D in You), a randomized trial of vitamin D supplementation to prevent falls in older adults.

Methods: PA was assessed at baseline, 12-, and 24-months using the Actigraph Link accelerometer, worn 24-hours per day for 7 days on the non-dominant wrist. Falls were reported using a monthly calendar. Minute level activity counts were examined to derive diurnal patterns of PA and number of active minutes/day in 319 participants (mean age 77 (SD=5.4) years, 43% female). Multiple logistic regression models adjusted for age, sex, and gait speed examined the: i) risk of falls by tertiles of daily PA and ii) risk of falls by demographic and functional characteristics, comparing measures of falls per unit time (year) and falls per unit of activity (active minute).

Results: In adjusted models, those in the high and low PA tertiles had 78% and 7% greater odds of falling over the next 12 months compared to those in the moderate PA tertile, respectively (p<.05). Moreover, peak daily PA declined 12% between baseline and 24-month follow-up among fallers vs. 8% among non-fallers (p<.05). Differences in daily PA between fallers and non-fallers tended to be greatest between 8am-12pm. Models comparing risk of falls over 24 months of follow-up demonstrated stronger trends in falls risk at higher ages (80 vs >80), among men, and for those with slower gait speeds (<0.8 m/s vs 0.8m/s) when analyzed per unit of activity (falls/active minute) vs. unit of time (falls/year).

Conclusion: These results demonstrate a J-shaped association between PA and falls, with stronger differences in PA between fallers and non-fallers during the morning hours. Furthermore, the trend towards more robust results for falls/active minute vs. falls/year highlight the complex nature of the association between PA and falls and suggest that novel PA metrics may serve as more sensitive indicators for discerning falls risk.

Predicting Poor Functional Status In Adults With Knee Osteoarthritis Using Real-life Accelerometry Data

Ruopeng Sun¹, Anne Kuwabara¹, Christy Tomkins-Lane², Matthew Smuck¹. ¹*Stanford University, Redwood City, CA.* ²*Mount Royal University, Calgary, AB, Canada.*

(No relevant relationships reported)

PURPOSE: Investigate the risk factors associated with longitudinal functional decline in people with knee OA using free-living accelerometry data.

METHODS: Longitudinal data from the Osteoarthritis Initiative (OAI) accelerometer study was extracted from 1229 participants tested at baseline and 2 years, including 35 features of functional capacity (gait speed, sit-to-stand time, etc), demographic characteristics, patient-reported outcome measures (WOMAC, etc.), and accelerometry-based physical activity. Poor functional status was defined as declining into or remaining in the worst function quintile compared to baseline status for two outcome measures (WOMAC score and gait speed). A Random Forest classifier was trained to predict individuals' functional status. To explore the feature importance in model prediction, the model prediction was further interpreted using a Shapley additive explanation algorithm.

RESULTS: For poor functional status in gait speed (Fig.1A), the top predictor is baseline low minutes in the performance moderate/vigorous activity range (CPM 2500+) followed by prolonged baseline sit-to-stand performance. Other significant contributing factors include high WOMAC score, low minutes in the performance light activity range (CPM 800-2499). The overall prediction accuracy is 82%. For poor WOMAC status prediction (Fig.1B), the top predictors are impaired baseline sit-to-stand and gait speed, as well as accelerated decline in gait speed. The overall prediction accuracy is 79%.

CONCLUSIONS: Accelerometry-based measures of physical activity were identified as key indicators for the decline in gait speed over time. Whereas only functional

capacity measures (gait speed and sit-to-stand performance) were identified as key indicators for the longitudinal decline in the WOMAC score. These findings may enable early detection and intervention for functional decline prevention in knee OA patients.

Is A Smartphone App A Valid And Reliable Method To Measure Bicycling Behavior?

Anna K. Porter¹, Reegan Ford¹, Kelly R. Evenson, FACSM². ¹*The University of Southern Mississippi, Hattiesburg, MS.* ²*The University of North Carolina at Chapel Hill, Chapel Hill, NC.*

(Sponsor: Kelly Evenson, FACSM)

Email: anna.k.porter@usm.edu

(No relevant relationships reported)

PURPOSE: To determine the criterion validity and test-retest reliability of a smartphone app in measuring bicycling behavior.

METHODS: A GPS device was used as the gold standard for comparison to the smartphone app. Courses ~2 miles in length at two locations were tested; 1) urban college campus and 2) rural bicycle path. Adult bicyclists (N=50; 21 urban, 29 rural) carried a Global Positioning System (GPS) device and their smartphone while riding a bicycle on a course loop twice (5 minute break in between); both the GPS device and smartphone app recorded location data. Movement time was recorded for the GPS device and the smartphone app, and MET*min were calculated for bicycling assuming 6 METs/min. Using a geographic information system (GIS), a 36-foot buffer was created around the road network for each course. Location data from the GPS and smartphone devices were mapped over the course buffers in GIS, and the percent of location data within the buffers was calculated for each. Validity and reliability of the percent within buffer and validity of MET*min for each device were examined using paired sample t-tests.

RESULTS: GPS device data fell within the urban course buffer 69% of the time and within the rural course 37% of the time, while data from the smartphone app was within the urban course buffer 78% of the time and within the rural course 51% of the time. For the GPS device, maximum distance of a single GPS point away from the road buffer averaged 14 meters (range 0-290), while maximum distance of a single GPS point from the smartphone app averaged 15 meters (range 0-92). Mean difference between the GPS and smartphone devices was 9% in favor of the smartphone app on the urban course (n=40, p<0.05), and 13% in favor of the smartphone app on the rural course (n=54, p<0.01). For reliability of the GPS device, mean difference between the two repeated rides was 4% on the urban course (n=20, p>0.05), and 9% on the rural course (n=28, p<0.01). For reliability of the smartphone app, mean difference between the two repeated rides was 3% on the urban course (n=21, p>0.05), and 0.6% on the rural course (n=28, p>0.05). MET*min from the GPS device was 1.22 versus 1.21 from the smartphone app (n=94, p>0.05).

CONCLUSIONS: The smartphone app tested is a reasonable alternative to GPS devices in assessing bicycling behavior in urban and rural environments.

2964 Board #7 May 29 1:00 PM - 3:00 PM
Dynamic Segmentation Of Youth Accelerometer Data By Sojourn And Change Point Detection Methods
 Paul R. Hibbing, Scott E. Crouter, FACSM. *University of Tennessee, Knoxville, TN.*
(No relevant relationships reported)

Dynamic segmentation algorithms are used to find activity transitions in accelerometer data. Youth Sojourn models use a crude algorithm, which may be improved by instead using a change point detection (CPD) algorithm. Pruned exact linear time (PELT) is a CPD algorithm that finds transitions by minimizing a cost function while iterating over the data and pruning out inviable transition points. **PURPOSE:** To compare the performance of youth Sojourn and PELT. **METHODS:** Raw acceleration data (hip-worn ActiGraph GT9X) from 86 youth (age 6-18 yrs; 48% male; 16% overweight/obese) were processed using Sojourn and PELT. Participants performed two semi-structured activity routines on separate days, with each visit lasting approximately 2-2.5 h. A total of 16 activities (eight each day) were performed, twice each, and the study protocol was designed to promote variability in the ordering and duration of activities. Throughout each trial, direct observation was performed using focal sampling, which served as a criterion measure of when activity transitions occurred. Sojourn and PELT were compared to the criterion using the transition pairing method, with a maximum of 5-s lag time allowed for a prediction to be considered a true positive. Performance metrics were recall, precision, and root mean squared error (RMSE). The metrics were calculated for each participant (both visits combined), after which paired t-tests were used to compare Sojourn-vs-PELT means for each metric. **RESULTS:** Values are mean \pm SD. Recall was similar for Sojourn (49.6% \pm 9.0%) and PELT (51.5% \pm 9.2%, $p = 0.15$), and the same was true for RMSE (2.9 \pm 0.3 s for Sojourn, versus 3.1 \pm 0.4 s for PELT, $p < 0.001$). However, precision for Sojourn (21.7% \pm 4.9%) was substantially lower than for PELT (38.7% \pm 11.0%, $p < 0.001$). **CONCLUSION:** Youth Sojourn models may benefit from replacing their current segmentation algorithms with CPD algorithms like PELT. Thus, CPD warrants further investigation. Supported by NIH R01HD083431

2965 Board #8 May 29 1:00 PM - 3:00 PM
Re-examining The Energy Expenditure Of Driving
 Rachel Barnett, Karen Yagi, Sarah Keadle. *California Polytechnic State University, San Luis Obispo, CA.* (Sponsor: Todd A. Hagobian, FACSM)
Reported Relationships: R. Barnett: Industry contracted research; National Cancer Institute.

PURPOSE: Sedentary behaviors are commonly defined as having an energy expenditure < 1.5 metabolic equivalents (METs), while in a sitting, reclining or lying posture. However, the Compendium of Physical Activities (Compendium), a widely used resource, assigns a MET value of 2.5 for driving, which would not meet the consensus definition of sedentary. This MET value is based on outdated automobile and metabolic technology, thus the purpose of this study is to re-examine the MET value of driving and compare driving to other sedentary behaviors and light-intensity walking (Compendium = 2.8 METs).

METHODS: Participants ($n=17$, average age = 32 y, 11 females) wore a portable metabolic system (Cosmed K5), during five different conditions that include sitting quietly, watching TV, sitting while working on a computer, driving, and walking at 2.0 mph. We compared mean measured MET values to the corresponding value from the Compendium using one-sampled t-test. We also ran a repeated measures ANOVA to determine whether there was any significant difference in MET values across conditions.

RESULTS: The mean MET value for driving was 1.5, which is significantly lower than the Compendium value of 2.5 ($p < 0.0001$). Driving yielded significantly higher MET values than quiet sitting (1.1 METs $p < 0.0001$) and watching TV (1.1 METs $p < 0.0002$) but was similar to sitting while working. Although driving and walking at 2.0 mph have similar Compendium MET values, driving produced significantly lower measured MET values (1.46 vs 3.08 $p < 0.0001$).

CONCLUSIONS: The existing Compendium MET value may not accurately quantify the energy expenditure of driving. Measured MET values for driving more closely correspond to sedentary behaviors than light-intensity walking. Since the average American spends 46 min/day in the car, there is a need to update the Compendium to reflect these findings.

F-09 Thematic Poster - Novel Strategies to Increase Physical Activity and Fitness

Effect Of Adapting Sedentary Video Games To Facilitate Physical Activity On Exercise Intensity
 Christen J. Mendonca, Susan S. Smith, Stella L. Volpe, FACSM, Glenn N. Williams, Sinclair A. Smith. *Drexel University, PHILADELPHIA, PA.* (Sponsor: Dr. Stella L. Volpe, FACSM)
(No relevant relationships reported)

PURPOSE: To determine if adapting a sedentary video game's controls to involve total body movements can elicit an exercise intensity consistent with moderate-to-vigorous physical activity. **METHODS:** Thirty adults, 19 to 55 years of age, visited our exercise lab twice. During each visit, the participants played a sedentary video game in three randomized conditions: 1) sitting, using a hand-held controller (Controller), 2) standing, reaching and jumping in front of a motion sensor (Sensor), and 3) standing, moving and reaching for buttons with their hands and feet (Button). Oxygen consumption (VO_2), heart rate, and ratings of perceived exertion (RPE) using the Borg 6 to 20 scale were assessed throughout each condition. We hypothesized that mean relative VO_2 would be 3 to 6 metabolic equivalents (METs), mean heart rate would be 50% to 80% of age-predicted maximum heart rate (%HRmax), and RPE would be 12 (somewhat hard) to 15 (very hard) in the Sensor and Button conditions. Further, METs, %HRmax, and RPE would be lower in the Controller condition than in Sensor and Button conditions. A two-way repeated-measures analysis of variance with Bonferroni post-hoc analysis was used to compare within-participant differences in METs, %HRmax, and RPE across the two visits and three conditions. Chi-square analysis was used to determine if a significant proportion of participants achieved moderate-to-vigorous physical activity during the Sensor and Button conditions. **RESULTS:** All measures were less during the Controller condition (0.99 \pm 0.09 METs, 39 \pm 6%HRmax, 7 \pm 1 RPE) compared to the Sensor (3.52 \pm 0.58 METs, 59 \pm 10%HRmax, 13 \pm 2 RPE, $p < 0.01$) and Button (4.02 \pm 0.61 METs, 62 \pm 12%HRmax, 14 \pm 2 RPE, $p < 0.01$) conditions. There was no difference between visits ($p > 0.32$). For the 30 participants, 83% and 100%, respectively, sustained MET levels of 3 to 6 during the Sensor and Button conditions ($p < 0.01$). Similar results were found for %HRmax and RPE ($p < 0.01$). **CONCLUSION:** Sustained moderate-to-vigorous physical activity was achieved by adapting sedentary video game controls to require total body movements. Future studies should consider adapting video game controls to increase exercise enjoyment, adherence and intensity.

Testing The Feasibility Of Referred At-risk Patients Participating At A Hospital-based Healthy-lifestyle Management Program
 Navin Kaushal¹, Ryan Bojrab², Brian Krohn¹, Daniel O. Clark¹, NiCole R. Keith, FACSM¹. ¹*Indiana University, Indianapolis, IN.* ²*Eskenazi Health, Indianapolis, IN.* (Sponsor: NiCole R. Keith, FACSM)
 Email: nkaushal@iu.edu
(No relevant relationships reported)

PURPOSE: Facilitating health promotion programs within healthcare is supported by the Institute of Medicine, which is establishing a systematic implementation approach that incorporates eight social and behavioral vital signs including exercise in the electronic health record (EHR). Though limited time during clinic visits is a challenge for implementation. Using an established healthy-lifestyle management program (HLMP) to support this approach could reduce burden on clinical practitioner. The purpose was to test the feasibility of implementing fitness measures in an HLMP. **METHODS:** Healthy Me is a free HLMP offered to patients in a public, Midwest health system. Patients are enrolled through physician referral via EHR. Eligible patient have a BMI > 25 , cardiovascular disease, pre /type II diabetes, and/or depression. Low-risk patients who meet eligibility criteria can enter Healthy Me through an EHR automated bulk referral process. Healthy Me is delivered by health coaches trained in motivational interviewing, group fitness, health promotion, and chronic disease management. Patients performed chair stand, arm curl and two-minute step tests.

RESULTS: The sample included 1254 patients (80.1% women), who were 48.9 + 15.46 years of age, with a BMI of 37.4 + 10.46 and reported fair/good (74.9%), poor (16%) or very good/excellent (9.1%) health. Eighty-three patients (6.7%) completed multiple fitness tests and 654 (52.2%) completed one test. Only females completed multiple fitness tests. Chi-square test found those who completed one test had higher perceived health ratings ($\chi^2 = 15.6, p = .048$). Bivariate correlations found BMI was associated positively with waist measures ($r = .88, p < .001$), and negatively with chair the stand score ($r = -.21, p = .015$), march score ($r = -.32, p = .029$), general health rating ($r = -.53, p < .001$), general physical ($r = .11, p = .054$) and mental ($r = .33, p = .043$) health.

CONCLUSIONS: Results revealed differential characteristics between patients who only visited Healthy Me and those who completed the health/fitness tests. Future directions include using tailored approaches to encourage fitness test completion. Multiple correlations with BMI and health/fitness parameters align with previous work and emphasize the importance of promoting healthy behaviors in HLMPs, such as exercise.

2969 Board #3 May 29 1:00 PM - 3:00 PM
Determining Intervention Components For A Physical Activity Program Designed For Former Division I College Athletes

Paula-Marie M. Ferrara¹, Rebecca A. Zakrajsek¹, Morgan R. Eckenrod², Cory T. Beuamont¹, Kelley Strohacker, FACSM¹.
¹The University of Tennessee, Knoxville, TN. ²The University of Southern Mississippi, Hattiesburg, MS.
 Email: pferrarl@vols.utk.edu
 (No relevant relationships reported)

Emerging research shows retired college athletes experience detrimental physical and mental health declines following retirement from sport. Such effects include worsening body composition, health-related quality of life, and physical function, as well as increased prevalence of depression, alcohol dependence, and eating disorders. Despite sports training, former college athletes exhibit substantial decreases in physical activity (PA) levels following retirement, which may contribute to these health declines.

PURPOSE: Explore what intervention components would be attractive, effective, and feasible for a PA program designed for former NCAA Division I (DI) college athletes.

METHODS: Semi-structured, bracketed interviews were conducted with former NCAA DI athletes retired ≤ 10 years from college sport and inactive based on the PA Guidelines for Americans (PAGA; assessed via the Paffenbarger PA Questionnaire). Qualitative analysis was conducted using the Consensual Qualitative Research Method to determine domains, categories, and core ideas from participant responses.

RESULTS: Participants (N=17, 7 men, 26±3 y, 91% Caucasian) retired 3 months to 10 years (4±3 y) and representing 9 sports across 13 athletic conferences underwent individual interviews. Based on the PAGA, 18% did not meet the muscle strengthening guidelines, 29% did not meet the aerobic guidelines, and 53% did not meet both thresholds. Emergent domains include: 1) The Recreated Team, 2) Program Needs, 3) Preventive Factors, 4) Timing. **CONCLUSIONS:** Participants highly advocated for the creation of a PA program for their population. Based on domains, effective program factors include recreating the camaraderie and accountability of a sports team, fitness testing, goal setting, and electronic communication. Potential barriers include high cost, inconvenient scheduling, lack of individual attention, and an intimidating atmosphere. Further, following a break after their last competition, participants stated they would have been ready to begin a PA program tailored for them within one year of retirement. Future directions include testing optimal combinations of intervention components to maximize their effectiveness in a future PA program. Funding provided by the Association for Applied Sport Psychology 2019 Research Grant.

Commercial App Use Linked With Sustained Physical Activity In Two Canadian Provinces: A 12-month Quasi-experimental Study

Marc Mitchell¹, Erica Lau², Lauren White³, Guy Faulkner².
¹Western University, London, ON, Canada. ²University of British Columbia, Vancouver, BC, Canada. ³Carrot Insights Inc, Toronto, ON, Canada.
 Email: marc.mitchell@uwo.ca
 Reported Relationships: **M. Mitchell:** Ownership/interest/stock; Stock options, but co. went out of business June 2019.

BACKGROUND: Top tier commercial physical activity apps rarely undergo peer-reviewed evaluation. Even fewer are assessed beyond six months, the theoretical threshold for behaviour maintenance.

PURPOSE: The purpose of this study was to examine whether a commercial app rewarding users with digital incentives for walking was associated with an increase in physical activity over one year.

METHODS: This 12-month quasi-experimental study was conducted in two Canadian provinces (n=39113 participants). Following a two-week baseline period, participants

earned digital incentives (\$0.04 CAD/day) every day they reached a personalized daily step goal. Mixed-effects models estimated changes in weekly mean daily step count between the baseline period and the last two recorded weeks. Models were fit for several engagement groups and separately by baseline physical activity status within engagement groups.

RESULTS: Nearly half of participants (43%) were categorized as physically inactive at baseline (fewer than 5000 daily steps), and 60% engaged with the app for at least six months [‘Regular’ (24-51 weeks of step data) or ‘Committed’ sub-groups (52 weeks)]. Weekly mean daily step count increased for physically inactive users regardless of engagement status ($P < .0001$). The increase was largest for ‘Regular’ and ‘Committed’ participants—1215 and 1821 steps/day, respectively. For physically active participants, step count increases were only observed in the ‘Committed’ sub-group ($P < .0001$). Effect sizes were modest-to-medium depending on the sub-group analyzed.

CONCLUSIONS: A commercial app providing small but immediate digital incentives for individualized goals was associated with an increased weekly mean daily step count on a population-scale over one year. This effect was more evident for physically inactive and more engaged participants.

2971 Board #5 May 29 1:00 PM - 3:00 PM
Enjoyability And Acceptability Of Bone Targeted Exercise For Young Adult Women: The OPTIMA-Ex Trial

Benjamin K. Weeks, Belinda R. Beck, FACSM, Amy T. Harding, Steven L. Watson, Conor Lambert. *Griffith University, Gold Coast, Queensland, Australia.* (Sponsor: Prof Belinda Beck, FACSM)
 Email: B.Weeks@griffith.edu.au
 (No relevant relationships reported)

PURPOSE: While physical activity participation is recognized as an effective modifiable risk factor for osteoporosis, adherence and compliance present significant challenges. We aimed to explore the experiences related to a bone-targeted exercise intervention, determine enjoyment and acceptability of each exercise mode, and identify barriers and facilitators to osteogenic exercise for young adult women with low bone mass. **METHODS:** A mixed-methods study was conducted within the OPTIMA-Ex trial, a three-arm RCT comparing musculoskeletal outcomes from high-intensity impact training (IT), high-intensity resistance training (RT), and a home-based low-intensity exercise control (CON). All 32 participants (IT=10, RT=12, CON=10) who finished the trial completed questionnaires on physical activity enjoyment (PACES-8, Kruskal-Wallis and Friedman’s test), quality of life (AQoL-6D, repeated measures ANOVA), and semi-structured interviews to facilitate qualitative analysis (Leximancer v4.50) of participant experiences. **RESULTS:** At follow-up, RT had the highest total score for PACES-8 (48.6±4.7), while only the IT group experienced an increase in total score over the 10 months (34.8±4.1 to 41.4±6.9, $p < .05$). Only CON experienced an improvement in total AQoL-6D score. For the sub-domains, all groups experienced clinically significant improvements (> 0.06 points) for ‘mental health’, while IT improved for ‘senses’ and CON improved for ‘coping’ ($p < .05$). The qualitative analysis revealed that overall trial exercises were viewed positively by all groups, yet the two high-intensity groups had the ‘richest’ exercise experiences, developing a more positive attitude to exercise. Barriers to exercise related to time, convenience, accessibility, and cost. Both IT and CON groups experienced a 41% drop out compared to 29% in the RT group. Compliance did not differ between CON (78.8±4.1%), IT (61.4±15.1%), or RT (66.4±11.2%) ($p = 0.085$). **CONCLUSIONS:** While IT and RT provide enjoyable bone-targeted exercise experiences for young adult women, on balance RT appears most favorable. It seems prudent, that bone-targeted exercise interventions for this demographic address perceptions of time demands and environmental barriers to participation in order to maximize compliance and adherence.

Positive Lifestyle Enhancement In At-risk Youth After A 16-wk Mountain Bike Program

Scott N. Drum, FACSM¹, Dana L. Bolduc¹, Connor Ryan¹, Erich Petushek². ¹Northern Michigan University, Marquette, MI. ²Michigan Technological University, Houghton, MI.
 Email: sdrum@nmu.edu
 (No relevant relationships reported)

Weekly, physical activity should be a primary component in long term, healthy lifestyles to enhance aerobic capacity and potentially decrease risk of cardiovascular disease (CVD). Start The Cycle (STC) is a non-profit, community-based program dedicated to building confidence and self-esteem in at-risk youth (e.g., helping them achieve healthy, life goals) through weekly mountain bike rides and adult mentorship.

PURPOSE: To quantify physiological change and probability of CVD in at-risk youth during a 16-wk, mentored mountain biking program. **METHODS:** Participants included (mean ± SD) new members (NM, n = 15, age = 13.6 ± 1.8 yrs), returning members (RM, n = 15, age = 15.9 ± 2.3 yrs), and combined (NM + RM) members (CM, n = 30, age = 14.7 ± 2.4 yrs). Free mountain bikes were provided to participants

by STC with a promise of ownership if the full program was completed. The program met 16-wks, 1 x week, and 2-hrs·day⁻¹ starting late spring and into late summer. Indoor physical conditioning and bike maintenance + skills classes were implemented the initial 4-wks with mentored, group rides occurring the last 12-wks. Maximal oxygen uptake (i.e., via the progressive aerobic cardiovascular endurance run or PACER test) and CVD risk (via a prediction equation from prior, unpublished research) were assessed pre- and post-intervention following the indoor training sessions (i.e., after 4-wks) and immediately prior to a final, 28-mile organized bike race. Data were analyzed using paired t-tests between pre- and post-intervention within NM, RM and CM groups with significance set at $p < 0.05$. Effect size is reported as Cohn's d with $d = .2, .5, \text{ and } .8 = \text{small, medium, and large effect sizes, respectively. RESULTS:}$ Significance from pre- to post-test (mean \pm SD), respectively, is as follows for $\text{VO}_{2\text{max}}$ in $\text{ml}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$ (NM, 37.1 ± 2.5 vs 41.8 ± 5.4 , $p = 0.004$, $d = 0.98$; RM, 40.7 ± 6.9 vs 46.2 ± 10.9 , $p = 0.037$, $d = 0.19$; and CM, 38.7 ± 5.1 vs 43.8 ± 8.3 , $p = 0.000$, $d = -0.04$) and CVD risk with lower score = decreased risk (NM, 5.2 ± 2.8 vs 3.8 ± 2.8 , $p = 0.018$, $d = -0.38$; RM, 6.2 ± 6.2 vs 3.9 ± 8.0 , $p = 0.027$, $d = 0.19$; and CM, 5.7 ± 4.7 vs 3.8 ± 5.8 , $p = 0.001$, $d = -0.07$). Body mass index (BMI) did not change across any group. **CONCLUSION:** A community-based, adult-mentored, youth mountain bike program is a practical means to improve aerobic capacity and reduce CVD risk in at-risk minors.

A Randomized Controlled Trial Comparing Two Different Approaches To Prescribe Exercise

Melody A. Kramarz, Beth A. Taylor, FACSM, Rachel Berkowsky, Ming-Hui Chen, Elyssa Eror, Linda S. Pescatello, FACSM. *University of Connecticut, Storrs Mansfield, CT.*
 Email: melody.kramarz@uconn.edu
 (No relevant relationships reported)

The Physical Activity Guidelines for Americans (PAG) recommend 150min/wk of moderate intensity aerobic physical activity (PA) plus 2days of muscle strengthening PA for health. Yet, 26% of Americans and 36% of college students perform no leisure time PA, stressing the need to increase PA in these populations. **PURPOSE:** We conducted a randomized controlled trial (RCT) comparing two different exercise prescription (ExR_x) approaches to increase PA among college students. The purpose of this interim analysis was to assess differences in the Transtheoretical Model stage of change (SOC) and drop-out (DO) rates at the 6wk mid-point (6W) of the RCT compared to baseline (BL) between the two ExR_x approaches. **METHODS:** 60 sedentary, healthy college students >18yr were randomized to two groups: ExR_x #1 emphasized meeting the PAG via the Frequency, Intensity, Time, and Type or FITT principle of ExR_x ; and ExR_x #2 emphasized that all PA counts. Both ExR_x approaches progressed students from being sedentary to meeting weekly PA goals over the 12wk PA intervention. The primary RCT outcome was the change in PA volume at 12wk, assessed via accelerometer and the Paffenbarger PA Questionnaire. At BL and 6W students completed the SOC to measure PA action transitions over time. Height (cm) and weight (kg) were measured to calculate the body mass index (BMI) at BL. DO was calculated as those who ceased participation at 6W divided by the total randomized sample $\times 100$. RMANOVA tested if SOC differed over time by group and Chi-Square tested if DO differed between groups. **RESULTS:** Subjects ($n=32$) were sedentary, overweight ($\text{BMI}=26.0\pm 4.2 \text{ m}^2/\text{kg}$), healthy college students ($24.7\pm 5.2\text{yo}$) with no differences in BL characteristics between ExR_x groups or DO and completers (>0.05). At 6W DO was 28.1% for the total sample with no differences between ExR_x groups ($p>0.05$). At 6W SOC increased from BL in both ExR_x groups ($p<0.001$), but to a greater level in ExR_x #1 of 3.6 ± 1.2 indicating progression from the contemplation to action stage than ExR_x #2 of 2.7 ± 1.0 indicating progression from the contemplation to preparation stage ($p=.045$). **DISCUSSION:** Improvements in SOC suggest PA increased with both ExR_x approaches at 6W. Whether these SOC improvements persist at 12wk and translate into greater increases in PA and lower DO remains to be determined.

Is There A Cross Over Effect In Post Activation Potentiation?

Vickie Wong, Yujiro Yamada, Zachary W. Bell, Robert W. Spitz, Ricardo B. Viana, Raksha N. Chatakondi, Takashi Abe, Jeremy P. Loenneke, FACSM. *The University of Mississippi, University, MS.* (Sponsor: Jeremy P. Loenneke, FACSM)
 Email: vwong@go.olemiss.edu
 (No relevant relationships reported)

Post activation potentiation (PAP) is a phenomenon whereby strength is acutely increased following a conditioning contraction. This effect is purported to be small and specific to the contraction history of the muscle (local), however, a potential cross-over effect in PAP has not been ruled out. **PURPOSE:** To determine if PAP is specific to the muscle being conditioned or if it is also observed within the homologous muscles of the contralateral limb. **METHODS:** 56 men and women participated in a four-visit study. Visit 1 included baseline measurements and familiarization of the unilateral biceps contractions (isometric and isokinetic for each arm). Visits 2-4 included the completion of one of the three experimental conditions: 1) control, 2) same side PAP, and 3) cross over PAP in a randomized order. Each visit included a warm up followed by three maximal isokinetic contractions at 210°/second (baseline). The control condition then rested eight minutes prior to completing three more maximal isokinetic contractions (post). The other two conditions completed the pretest followed five minutes later by a six-second maximal isometric contraction on the same side as the baseline isokinetic test (same side PAP) or on the opposite side (cross over PAP) followed by three additional maximal isokinetic contractions (post) three minutes after conditioning stimulus. The variable of interest was the change from baseline in isokinetic strength. Three hypotheses were compared using Bayesian Informative Hypothesis Evaluation (BAIN). The hypotheses were as follows: H1) same > cross = control; H2) same > cross > control; H3) same = cross = control. **RESULTS:** Torque produced during the potentiating stimulus was similar between PAP conditions (same: 47 Nm vs. cross: 45 Nm). The change [mean (95% credible interval)] in isokinetic strength for each condition was: control = -0.41 (-0.91, 0.07) Nm; same side PAP = 0.48 (-0.20, 1.16) Nm, and cross PAP = -0.03 (-0.67, 0.60) Nm. The posterior probabilities were 0.45, 0.28, 0.19, and 0.06 for H1, H2, H3, and the unconstrained model, respectively. H1 was 1.5 and 2.2 times more likely than H2 and H3, respectively. **CONCLUSIONS:** The current evidence indicates that if a PAP effect exists, it is small and may be specific to the muscle being conditioned. There does not seem to be a substantial cross over effect in PAP.

2976 Board #2 May 29 1:00 PM - 3:00 PM
Muscle Thickness Changes Do Not Mediate Changes In Muscle Strength

Matthew B. Jessee¹, Scott J. Dankel², John P. Bentley¹, Jeremy P. Loenneke, FACSM¹. ¹*The University of Mississippi, University, MS.* ²*Rowan University, Glassboro, NJ.* (Sponsor: Jeremy P. Loenneke, FACSM)
 (No relevant relationships reported)

The position that hypertrophy mechanically increases muscle strength is currently debated among scientists.

Purpose: To determine indirect (via hypertrophy) and direct (not hypertrophy) effects of training on muscle strength.

Methods: 151 participants were randomized into control, one-repetition maximum training, or traditional training. For 6 weeks control avoided resistance exercise; training groups performed elbow flexion 3x/week (dominant arm). One-repetition maximum participants had 5 attempts to lift the greatest load possible. Traditional participants performed 4 sets to task failure (load adjusted for ~8-12 repetitions). Attempts/sets were separated by 90 s. Anterior muscle thickness (B-mode ultrasound) at 50, 60, and 70% upper arm length, and strength (one-repetition maximum) were assessed pre- and post-training. Change-score mediation models (adjusted for sex, pre-muscle thickness, and pre-strength) were constructed for each muscle thickness site. Effects of each training were evaluated relative to control. Data presented as coefficient (95% CI).

Results: Relative direct effects on strength were greater for one-repetition maximum [50% = 1.89 (1.20, 2.58); 60% = 1.88 (1.19, 2.58); 70% = 1.81 (1.12, 2.50) kg] and

traditional training [50% = 2.04 (1.28, 2.79); 60% = 1.98 (1.21, 2.74); 70% = 1.79 (1.04, 2.53) kg]. The relative effect of one-repetition maximum on muscle thickness was different in 60% [0.09 (0.01, 0.17) cm] and 70% [0.09 (0.00, 0.17) cm] models [50% = 0.67 (-0.01, 0.14) cm] while traditional was greater in all three: [50% = 0.24 (0.15, 0.32); 60% = 0.24 (0.16, 0.33); 70% = 0.22 (0.14, 0.31) cm]. The effect of muscle thickness on strength was not significant for 50% [-0.44 (-1.72, 0.84) kg], 60% [-0.15 (-1.48, 1.17) kg], or 70% [0.73 (-0.48, 1.96) kg] models. The relative indirect effect on strength was not significant for one-repetition maximum [50% = -0.02 (-0.16, 0.09); 60% = -0.01 (-0.17, 0.16); 70% = 0.06 (-0.09, 0.27), or traditional training [50% = -0.10 (-0.48, 0.29); 60% = -0.03 (-0.42, 0.40); 70% = 0.16 (-0.22, 0.58)].

Conclusions: One-repetition maximum and traditional training increase strength, however, there was no evidence that the increase in strength was mediated by hypertrophy, providing experimental and analytical evidence for the disconnect between variables.

 (No relevant relationships reported)

Purpose: To compare the effects of high-volume (HV) versus high-intensity (HI) resistance training on vastus lateralis muscle morphology. **Methods:** Resistance trained, college-aged males (n=15) participated in 6 weeks of resistance training in which their legs were randomized to undertake HV and in the contralateral leg HI. Resistance training was undertaken 3 days per week. All participants went through 10 days of deload following the 6 weeks of training. Muscle ultrasound of both vastus lateralis muscles was conducted prior to week 1 of training (T1), 72 hours following the last training bout of week 6 (T2), and 10 days following the last training bout (T3) for muscle thickness, pennation angle, and fascicle length assessments. **Results:** There was a significant condition by time effect ($p=0.039$) for muscle thickness. Post hoc analysis revealed that muscle thickness significantly increased from T1 to T2 (2.7±0.4 cm to 2.9±0.4 cm, $p=0.023$) in the HV leg, but not in the HI leg. However, there was no difference between conditions at any time point. Furthermore, there were no significant interactions or main effects for pennation angle or fascicle length. **Conclusion:** HI versus HV training elicits differential effects in vastus lateralis muscle thickness over a 6-week period, albeit neither training modality altered pennation angle or fascicle length.

 (No relevant relationships reported)

PURPOSE: Our laboratory has recently shown high-volume resistance training (RT) can elicit increases in skeletal muscle sarcoplasmic protein concentrations, while also causing a dilution of contractile protein concentrations (i.e., sarcoplasmic hypertrophy). The purpose of this study was to evaluate effects of 6 weeks of high-load (HL) and high-volume (HV) training on skeletal muscle sarcoplasmic and contractile protein concentrations. **METHODS:** Trained college-aged males (n = 15; training age = 7 ± 3 yrs; mean 1RM squat relative to bodyweight = 1.9 ± 0.4 kg) performed 6 weeks of unilateral lower-body RT, with one leg performing HV training and the contralateral leg performing HL training using leg press and leg extension. Participants underwent a period of passive recovery lasting 10 days following the training intervention. Vastus lateralis biopsies were obtained from both legs prior to the start of training (PRE), 72 hours following the last training day (POST), and 1 week following POST testing (POSTPR). Sarcoplasmic protein content was determined following differential centrifugation using bichononic assays, and actin and myosin

concentrations were quantified using SDS-PAGE and Coomassie staining. **RESULTS:** Significant main effects of time ($p = 0.022$) and condition ($p=0.002$) were observed and condition by time approached significance for sarcoplasmic protein concentrations ($p = 0.088$). There were no significant interactions or main effects for actin or myosin concentrations. **CONCLUSIONS:** Contrary to our prior data, sarcoplasmic, actin and myosin concentrations remained unaffected with HV training. However, interesting trends were observed for sarcoplasmic protein concentrations and these will be further interrogated.

Acute Signaling Responses To Resistance Exercise In Previously Trained And Untrained Skeletal Muscle

Sebastian Edman, Marcus Moberg, Niklas Psilander. Åstrand Laboratory, Swedish School of Sport and Health Sciences, Stockholm, Sweden.
 Email: sebastian.edman@gih.se
 (No relevant relationships reported)

It has been indicated that human skeletal muscle has a heightened sensitivity to exercise stimulus when it has been previously trained i.e. possess a "muscle memory". While previous studies have been directed to the aspects of myonuclear content and epigenetic modifications, no previous study have explored the potential of a muscle memory concerning signaling responses related to acute resistance exercise.

PURPOSE: The aim here was to study whether basal and acute resistance exercise induced cell signaling is influenced by previous strength training history in human skeletal muscle.

METHODS: 19 training naïve women and men completed 10 weeks of hypertrophy inducing unilateral strength training followed by 20 weeks of detraining. Subsequently, an acute resistance exercise session involving leg press and knee extensions was performed alternated with both legs. *Vastus lateralis* biopsies taken at rest and 1 h post exercise in both the Control- and Memory-leg. Immunoblotting was used to assess total content and phosphorylation status of proteins in the mTORC1- and related pathways.

RESULTS: Following detraining leg muscle hypertrophy had been reversed, but the Memory-leg was on average 19% stronger than the Control-leg. There were no differences between legs with regard to total protein content of all the signaling proteins analyzed. The phosphorylation of AMPK^{Thr172} and eEF2^{Thr56} was 16%, respectively 21%, higher in the Memory-leg compared to the Control-leg at both time points. The effect on AMPK^{Thr172} was attributed to changes in the women only, whereas the effect on eEF2^{Thr56} was present in both sexes. Exercise induced an increased phosphorylation of mTOR^{Ser2448} (26-36%), S6K1^{Thr389} (6- to 7-fold) and S6^{Ser235/236} (13- to 18-fold), that did not differ between the Control- and Memory-leg. In contrast, post exercise phosphorylation of 4E-BP1^{Thr46} and 4E-BP1^{Ser65} was 18%, respectively 31%, higher in the Memory-leg compared to the Control-leg. For 4E-BP1^{Ser65} the effects were attributed to changes in the male subjects only.

CONCLUSION: In summary, we illustrate that both basal- and exercise induced cell signaling important for muscle adaptations to strength training can be altered by previous training history, and that some of the changes seem to be sex dependent.

Effect Of Muscle Contraction Number On Muscle Protein Synthesis And Hypertrophy In Rat

Tatsuro Maekawa, Karina Kouzaki, Yuki Tamura, Takaya Kotani, Naoki Kikuchi, Koichi Nakazato. Nippon Sport Science University, Tokyo, Japan.
 Email: ta0514na@icloud.com
 (No relevant relationships reported)

PURPOSE: When a high number of lifts are performed in resistance exercise (RE), the power (load × lifting speed) gradually decreases. In particular, the physiological meaning of repeated lifting at low power in the latter half of the session is unclear. In this study, we investigated the effect of different numbers of REs on the anabolic response of skeletal muscle using the RE model of Sprague Dawley (SD) rats.

METHODS: Eleven weeks old male SD rats (n=17) were randomly assigned into low repetitions group (n=8, 5 repetitions x 5 sets) and the high repetitions group (n=9, 10 repetitions x 5 sets). Unilateral electrical stimulation of rat right gastrocnemius as a resistance exercise (isometric contraction, 100V, 100 Hz, 3 sec stimulation-7 sec rest). Left hindlimb was served as the internal control. Six hours after exercise session, we injected puromycin 15 minutes prior to dissection. Medial gastrocnemius muscles were used for biochemical analysis. Puromycin-labeled newly synthesized proteins and a mammalian target of rapamycin complex 1 signal proteins were measured by western blot. In addition, 4-weeks training (3 sessions per week) was conducted. 48 hours after training, the medial gastrocnemius muscles were excised to perform further analysis. **RESULTS:** We found significant elevations muscle of protein synthesis rate and phosphorylated ribosomal protein small 6 (rpS6) at ser240/244 in both groups. However, there was no difference between groups. Both of chronic training similarly increased muscle wet weights. Muscle protein synthesis increased

at 30% in the high contraction frequency group and 50% in the low contraction frequency group. Phosphorylated rpS6 (Ser240/244) significantly increased 70% in both groups ($P < 0.05$). After the chronic training sessions, muscle wet weight increased significantly on the exercise side by 10.7% in the high contraction group and 6.8% in the low contraction group ($P < 0.05$) without significant difference between the two groups. **CONCLUSIONS:** Even though exercise volume was different (5 repetitions \times 5 sets vs 10 repetitions \times 5 sets), anabolic responses and muscle hypertrophy rate were equivalent. We speculate that repetitions with high power output are enough for inducing muscle protein synthesis and muscle hypertrophy.

Does Muscle Glycogen Content Account For The Contralateral Force Deficit During Unilateral Fatigue?
 JoCarol E. Shields, Jesus A. Hernandez-Sarabia, Alejandra Barrera-Curiel, Micheal J. Luera, Jason M. DeFreitas. *Oklahoma State University, Stillwater, OK.*
(No relevant relationships reported)

Performing unilateral contractions to exhaustion has been shown to lead to force deficits of both the exercised and unexercised limbs. It has been proposed that the contralateral force deficits are of neural origin, and not due to peripheral mechanisms of fatigue (e.g. glycogen depletion). While this proposed model appears likely, it remains speculative as the absence of peripheral factors to contralateral force deficits have not been verified. **PURPOSE:** Therefore, the purpose of the study was to quantify the changes in muscle glycogen content and maximal force of both limbs in response to unilateral fatigue. **METHODS:** Nineteen healthy subjects performed two maximal voluntary isometric (MVC) knee extensions of each leg before (PRE) and after (POST) a fatiguing protocol of the right leg. The fatiguing protocol consisted of repeated 56 second long ramp contractions of the right leg at 30% MVC until failure. During the plateau phase of each contraction, ultrasound images were taken at the midpoint of the rectus femoris (RF). The echo intensity, which has been shown to be sensitive to acute changes in muscle glycogen content, was analyzed from each image of the RF muscle. **RESULTS:** A two way repeated measures ANOVA showed a significant time \times limb interaction ($p < 0.001$) for MVCs. Follow-up paired sample t-tests indicated that both limbs showed significant force loss. However, the right leg (-33%, from 773.36 \pm 191.79 to 517.13 \pm 136.72, $p < 0.001$) demonstrated a much larger force deficit than the left leg (-9.7%, from 803.07 \pm 215.32 to 725.04 \pm 198.44, $p = 0.002$). For echo intensity, the right leg demonstrated a significant change (8.8%, from 48.64 \pm 7.70 to 52.58 \pm 8.68, $p = 0.009$) from PRE to POST. However, the left leg did not change (1.34%, from 53.93 \pm 7.65 to 54.65 \pm 7.72, $p = 0.621$). It is worth noting the increase in echo intensity, such as seen with the right leg, represents a decrease in tissue density (e.g. decreased muscle glycogen content). **CONCLUSION:** Our findings suggest peripheral fatigue mechanisms, such as muscle glycogen content, were not responsible for the decreased force in the contralateral limb. This absence of peripheral, intracellular changes supports the original proposal that the contralateral force deficit is of a central, neural origin.

Does Skeletal Muscle Growth Contribute To Strength Adaptation In Resistance Trained Individuals?
 Ryo Kataoka, Ecaterina Vasenina, Noam Yitzchaki, Wenyuan G. Zhu, Tayla E. Kuehne, Samuel L. Buckner. *University of South Florida, Tampa, FL.*
(No relevant relationships reported)

Performing a one-repetition maximum (1RM) strength test twice a week has been shown to produce similar strength adaptations as traditional resistance exercise. Of note, the increase in muscle size with traditional training has no additive effect on strength adaptation in non-resistance trained individuals. The training status is often pointed out as a limitation to understanding the "potential" of muscle growth to contribute to strength. Specifically, it is thought that growth would be of increased importance for resistance trained individuals. **PURPOSE:** To examine the changes in biceps muscle thickness (MT), and 1RM strength following 8 weeks of 1RM practice or traditional training. **METHODS:** 19 individuals completed the study. Participants visited the lab for 18 visits. During visit 1, MT and strength were measured. MT was measured at 50, 60 and 70% the distance between the acromion process and lateral epicondyle. Participants then performed biceps curls twice a week for 8 weeks. One arm performed 4 sets of as many repetitions as possible with approximately 70% of their 1RM, and the other arm performed a single maximal repetition. Post measurements of MT and strength were taken. Results are displayed as means (SD). **RESULTS:** For MT at the 50% site there was an interaction ($p = 0.004$). MT increased from pre [2.60 (.6) cm] to post [2.71(.5) cm, $p = 0.02$] intervention in the hypertrophy condition, with no change in the strength condition ($p = 0.57$). For MT at the 60% site there was an interaction ($p = 0.03$). MT increased from pre [2.86 (.6) cm] to post [3.02 (.5) cm, $p = 0.004$] intervention in the hypertrophy condition, with no change in the strength condition ($p = 0.52$). For MT at the 70% site there was an interaction ($p < 0.001$). MT increased from pre [3.26 (.5) cm] to post [3.48 (.5) cm, $p < 0.001$]

intervention in the hypertrophy condition, with no change in the strength condition ($p = 0.26$). For 1RM strength there was no condition \times time interaction ($p = 0.29$). However, there was a main effect for time ($p < 0.001$). 1RM strength increased from pre [16.7 (4.2) kg] to post [18.9 (4.2) kg] intervention, with no difference observed between conditions. **CONCLUSIONS:** In resistance trained individuals, bi-weekly 1RM training produces similar increases in 1RM strength as a more traditional resistance training approach without inducing muscle growth.

Relationship Between Lung Diffusion And Exercise Capacity In Heart Failure With Preserved Ejection Fraction
 Caitlin C. Fermoye, Glenn M. Stewart, Barry A. Borlaug, Bruce D. Johnson. *Mayo Clinic, Rochester, MN.*
 Email: fermoye.caitlin@mayo.edu
(No relevant relationships reported)

Purpose: Patients with heart failure with preserved ejection fraction (HFpEF) have impaired lung diffusion (DL) at rest and during exercise which may contribute to a reduced exercise capacity. However, it is unclear whether these impairments are solely due to alterations in pulmonary hemodynamics or related to other cardiopulmonary factors which may impair oxygen uptake such as the inability to recruit lung surface area. Therefore this study examined simultaneous measurements of DL for carbon monoxide (DLCO) and nitric oxide (DLNO), which allows for partitioning of DL into its alveolar-capillary membrane (Dm) and pulmonary capillary blood volume (Vc) components, to better understand the relationship between exertional changes in lung diffusion and exercise capacity.

Methods: HFpEF patients (N=17, age=62 \pm 9y, BMI=36 \pm 8kg/m²) undergoing exercise right heart catheterization performed simultaneous rebreath DLCO/NO tests at rest and during each stage of incremental supine cycling exercise, and membrane conductance (Dm) and pulmonary capillary blood volume (Vc) were calculated. Breath-by-breath pulmonary gas exchange was recorded throughout rest and exercise. **Results:** All patients were hemodynamically diagnosed with HFpEF (pulmonary capillary wedge pressure >15 at rest and/or >25 mmHg during exercise). Overall lung and alveolar-capillary membrane diffusion increased from rest to peak exercise (DLCO: 11.8 \pm 4.0 to 16.2 \pm 7.4 ml/min/mmHg, DLNO: 33.1 \pm 11.5 to 48.4 \pm 21.9 ml/min/mmHg, Dm: 18.9 \pm 7.2 to 28.3 \pm 13.1 ml/min/mmHg; p 's <0.01). The change in DL was related to exercise capacity (change in DLCO vs. peak $\dot{V}O_2$: R=0.69, $p < 0.01$, change in DLNO vs. peak $\dot{V}O_2$: R=0.65, $p < 0.01$) and this was primarily driven by changes in Dm (change in Dm vs. peak $\dot{V}O_2$: R=0.63, $p < 0.01$) but not Vc (change in Vc vs. peak $\dot{V}O_2$: R=0.15, $p = 0.582$).

Conclusions: These data highlight that a limited increase in lung diffusion and alveolar-capillary membrane conductance during exercise are associated with a lower $\dot{V}O_2$ peak in HFpEF patients. In addition to hemodynamic constraints previously reported in HFpEF, an inability to recruit lung surface area during exercise may also contribute to the reduced exercise capacity in these patients.

The Effect Of Exercise Intensity On The Development Of Diaphragm And Expiratory Abdominal Muscle Fatigue

Tim A. Hardy, Matt R. Chadwick, Carrie Ferguson, Bryan J. Taylor. *University of Leeds, Leeds, United Kingdom.* (Sponsor: Dr Thomas P Olson, FACSM)
 Email: bsth@leeds.ac.uk
(No relevant relationships reported)

Exhaustive high-intensity exercise (85-95% of $\dot{V}O_{2peak}$) elicits respiratory muscle fatigue, likely due to a high work of breathing (WoB) combined with a competition for available cardiac output (Q). However, the WoB associated with submaximal heavy-intensity exercise ($\leq 75\% \dot{V}O_{2peak}$) makes insufficient demands for $\dot{V}O_2$ and Q to engender a substantial competition for available blood flow. Whether the respiratory muscles fatigue in response to exhaustive heavy-intensity exercise remains unclear.

PURPOSE: To investigate the effect of exercise intensity on the presence and severity of exercise-induced diaphragm and expiratory muscle fatigue in healthy humans. **METHODS:** Ten healthy adults (25 ± 3 y, 3 females) performed a 'ramp sprint' test to determine critical power (CP), peak ramp power (P_{peak}) and $\dot{V}O_{2peak}$ (54 ± 9 ml/kg/min). The subjects then performed two constant-power cycling tests to exhaustion: 1) 5% < CP (173 ± 50 W, *heavy intensity*); 2) ~25% of the difference between CP and P_{peak} (215 ± 53 W, *severe intensity*). Diaphragm and expiratory muscle fatigue were quantified as the pre- to post-exercise reduction in the transdiaphragmatic (Pdi_{tw}) and gastric (Pga_{tw}) twitch pressure response to magnetic stimulation of the cervical and thoracic nerves, respectively. **RESULTS:** Exercise time was longer for heavy vs. severe exercise (36 ± 6 vs. 10 ± 3 min, $P < 0.05$). Final min $\dot{V}O_2$ was lower during heavy (3.12 ± 0.74 L/min; $82 \pm 5\%$ of $\dot{V}O_{2peak}$) vs. severe exercise (3.60 ± 0.83 L/min; $95 \pm 4\%$ of $\dot{V}O_{2peak}$) ($P < 0.05$). Both heavy and severe exercise elicited a significant reduction in Pdi_{tw} ($-13 \pm 11\%$ and $-19 \pm 13\%$) and Pga_{tw} ($-23 \pm 20\%$ vs. $-24 \pm 17\%$) (both $P < 0.05$); however, the magnitude of exercise-induced respiratory muscle fatigue was not different between trials ($P > 0.05$). The cumulative diaphragm and gastric pressure-time products were greater for heavy vs. severe exercise (PTP_{di} : 16790 ± 6727 vs. 5945 ± 1956 cmH₂O/s; PTP_{ga} : 7818 ± 3368 vs. 2595 ± 1233 cmH₂O/s; both $P < 0.05$). **CONCLUSION:** The diaphragm and expiratory muscles fatigue in response to exhaustive heavy- and severe-intensity exercise in healthy humans. The magnitude of exercise-induced respiratory muscle fatigue between trials was not different despite a substantially greater cumulative PTP_{di} and PTP_{ga} for heavy- vs. severe-intensity exercise.

Reduction In Pulmonary Arterial Pressure At Rest And During Exercise Following Percutaneous Closure Of Patent Foramen Ovale
 Tyler Kelly, University of Oregon, Eugene, OR.
 Email: tkelly5@uoregon.edu
 (No relevant relationships reported)

Purpose: The PFO is a source of intracardiac right-to-left shunt and is present in ~1/3rd of the adult population. Deficits in pulmonary gas exchange efficiency associated with PFO have been well-documented (Lovering *et al*, J Appl Physiol 2016). However, changes in pulmonary artery pressure and total pulmonary resistance (TPR) following closure have not previously been reported. **Methods:** Four candidates (3F, 1M) for closure of PFO were identified by local cardiologists and referred to our laboratory as subjects. 3 subjects (3F) received physician clearance to participate in the exercise trials. 1 subject (1M) was not cleared for exercise so only resting measures were taken. Presence and size of PFO was confirmed utilizing transthoracic saline contrast echocardiography (TTSCE). Subjects exercised at 4 sub-maximal workloads (25%, 50%, 75% and 90% of pre-closure VO_{2Max}). Transthoracic ultrasound measures of cardiac output (QT) and pulmonary arterial systolic pressure (PASP) were taken prior to exercise and during the final minute of each workload. TPR was calculated as $PASP / QT$. All measures were repeated in the laboratory 3-6 months after closure of PFO following confirmation of endothelialization of the closure device with TTSCE. **Results:** Data were analyzed by a 2-way (Closure x Workload) RMANOVA. There was a main effect of closure on PASP $F(1, 11) = 21.05$, $p = 0.0008$, and a main effect of closure on TPR $F(1, 11) = 9.899$, $p = 0.0093$, with reductions in both following closure. There was a main effect of workload, but not closure, on cardiac output $F(4, 11) = 60.18$, $p < 0.0001$. **Conclusion:** Improvements in pulmonary gas exchange efficiency are expected with removal of the intracardiac right-to-left shunt. However, our results demonstrating a significantly reduced pulmonary artery pressure, due to a significantly reduced TPR, are intriguing and deserve more attention to better understand the contributing factors of a PFO to exercise-induced pulmonary hypertension.

Effect Of Active Muscle Mass On Work Of Breathing And Oxygen Cost Of Ventilation
 Saad A. Alhammad¹, Monira I. Aldhahi², Andrew A. Guccione¹, Randall E. Keyser, FACSM¹. ¹George Mason University, Fairfax, VA. ²Princess Nourah Bint Abdulrhaman University, Riyadh, Saudi Arabia. (Sponsor: Randall E. Keyser, FACSM)
 Email: salhamma@masonlive.gmu.edu
 (No relevant relationships reported)

PURPOSE: To compare estimates of work of breathing (Wb) and O₂ cost of ventilation in the respiratory muscles (V_{RMO2}) among three types of exercise, representing smaller and large active muscle masses. **METHODS:** Twenty healthy adults (25±4.9 yrs, BMI: 23.9 ±2.6 kg/m²) completed three randomized peak cardiopulmonary exercise tests (CPET) on separate days: 2-leg (large muscle mass) and 1-leg (medium mass) tests and 1-arm (small mass). Estimates of Wb and V_{RMO2} were compared at power outputs corresponding to 25%, 50%, 75%, and 100% of the peak power output on the tests and at Isomax, defined as the power output identical to peak exercise on the 1-arm CPET. Wb was estimated using an established algorithm: $Wb = V_{RMO2} \times P_{aw}$ and $V_{RMO2} = \frac{Wb}{P_{aw}}$. **RESULTS:** Peak power output was 32 ± 11.96 watts for the 1-arm, 97.8 ± 30.48 watts for the 1-leg, and 186.25 ± 44.03 watts for the 2-leg CPETs. At 50% of peak WR, significant differences in Wb and V_{RMO2} between 1-arm and 2-leg (Wb $p=0.001$; V_{RMO2} $p=0.001$). At 100%, there were differences in Wb and V_{RMO2} between 1-arm and 2-leg (Wb $p<0.01$; V_{RMO2} $p<0.01$) and between 1-leg and 2-leg CPETs (Wb $p=0.02$; V_{RMO2} $p=0.02$)

	1-arm		1-leg			2-leg		
	50%	100%	50%	100%	Isomax	50%	100%	Isomax
Wb kg.m.min ⁻¹	1.3±0.9	5.91±4.7	2.2±1.2	9.5±6.5	1.2±0.8	2.8±1.3	15.8±9.7	0.3±0.3
VRMO ₂ mL.min ⁻¹	44.9±7.4	79±35.4	51.2±9.2	105.9±48.2	43.8±5.9	55.5±9.7	152.7±72.1	37.4±2.4

At Isomax, significant increases were found in Wb and V_{RMO2} between the 1-arm and 1-leg ($p<0.001$) CPETs and between the 1-arm and 2-leg ($p<0.001$) CPETs. **CONCLUSION:** The findings suggest that breathing economy is diminished with respect to exercising that requires progressively smaller active muscle masses. This study suggests that CPETs requiring smaller active muscle masses may not be sufficient for examining maximal Wb or V_{RMO2} capacity

2988 May 29 2:00 PM - 2:15 PM

External Dead Space Explains Sex-differences In The Exercise Ventilatory Response In Obese And Nonobese Children

Bryce N. Balmain¹, Daniel P. Wilhite¹, Dharini M. Bhammar², Ashley Peck¹, Marcus Payne¹, Tanya Martinez-Fernandez³, Tony G. Babb, FACSM¹. ¹Institute for Exercise and Environmental Medicine, Dallas, TX. ²University of Nevada Las Vegas, Las Vegas, NV. ³UT Southwestern Medical Center, Dallas, TX. (Sponsor: Dr Tony Babb, FACSM)
Email: brycebalmain@texashealth.org
(No relevant relationships reported)

PURPOSE: Increases in external dead space augment the exercise ventilatory response independent of the potential respiratory effects of sex and obesity. Therefore, the dead space imposed by the mouthpiece and breathing valve (V_{DM}) should be accounted for when comparing the exercise ventilatory response, particularly in prepubescent children who have smaller lungs. We evaluated the impact of V_{DM} on the exercise ventilatory response, defined as the slope of the relation between minute ventilation (\dot{V}_E) and carbon dioxide ($\dot{V}CO_2$), in obese and nonobese prepubescent boys and girls. **METHODS:** 27 nonobese (age: 10 ± 1 y; height: 146 ± 8 cm; weight: 39 ± 7 kg; BMI percentile: 57.2 ± 21.3) and 46 obese (age: 10 ± 1 y; height: 147 ± 8 cm; weight: 62 ± 16 kg; BMI percentile: 98.0 ± 1.3) children were studied. Subjects were divided into groups by sex (nonobese: 13 girls and 14 boys; obese: 17 girls and 29 boys). All subjects performed a 6-minute constant load cycling test at a fixed intensity (40W). To correct the $\dot{V}_E/\dot{V}CO_2$ slope for the effects of V_{DM} , we subtracted V_{DM} (0.225 L) from \dot{V}_E to derive a slope that was absent from the effects of V_{DM} . A two-way group (obese vs nonobese) by sex (girls vs boys) analysis of variance was conducted. **RESULTS:** When \dot{V}_E was not corrected for V_{DM} , there was no group by sex interaction in the $\dot{V}_E/\dot{V}CO_2$ slope ($p = 0.76$). $\dot{V}_E/\dot{V}CO_2$ slope was not different ($p = 0.48$) between obese (32.7 ± 4.3) and nonobese children (32.2 ± 6.1) however, there was a main effect for sex ($p = 0.03$) where the $\dot{V}_E/\dot{V}CO_2$ slope was higher in girls (35.4 ± 5.6) compared with boys (32.6 ± 4.9). When \dot{V}_E was corrected for V_{DM} , the $\dot{V}_E/\dot{V}CO_2$ slope remained similar ($p = 0.31$) between obese and nonobese children; however, the main effect for sex was eliminated ($p = 0.12$). There was no main effect for group (obese vs nonobese) or sex (girls vs boys) in the end-tidal partial pressure of carbon dioxide at rest ($p > 0.05$) or during exercise ($p > 0.05$). **CONCLUSIONS:** Accounting for the external dead space imposed by the valve and mouthpiece eliminates the difference in the exercise ventilatory response detected between pre-pubescent boys and girls. Considering that the breathing apparatus comprises a large portion of both resting and exercise tidal volume in children, it should be accounted for before evaluating the $\dot{V}_E/\dot{V}CO_2$ slope, especially in prepubescent children.

Bronchodilation Increases Estimated Ventilatory Capacity In Children With Mild Asthma

Nicholas A. Ross¹, Michael W.H. Wong¹, Ani L. Kechkarian¹, Donna J. Gould¹, Craig Nakamura², Dharini M. Bhammar¹. ¹University of Nevada, Las Vegas, Las Vegas, NV. ²Childrens Lung Specialists, Las Vegas, NV. (Sponsor: Tony G. Babb, FACSM)
(No relevant relationships reported)

Purpose: Children with asthma experience reduced maximal expiratory flows, which can decrease ventilatory capacity and increase ventilatory limitations during exercise; however, the effects of mid-flow bronchodilation on these variables are underappreciated. The purpose of this study was to examine the effect of bronchodilation on ventilatory capacity and ventilatory limitations during a maximal exercise test.

Methods: Nine children with mild asthma (7 boys, 10 ± 1 yr, BMI percentile: 66 ± 30 , forced expiratory volume in 1s, FEV₁; 106 ± 24 %predicted, Range 78-144) completed spirometry before and after 360µg of albuterol. On a separate visit, they completed an incremental exercise test to exhaustion. Estimated ventilatory capacity was calculated using the volume time curve from estimated maximal tidal volume (FVC/2) and estimated maximal total respiratory cycle time ($2 \times FET_{25-75\%}$) both before and after bronchodilator. Ventilatory limitation was defined as $<10\%$ of breathing reserve (Estimated ventilatory capacity - maximum minute ventilation).

Results: Estimated ventilatory capacity increased by 16% after bronchodilator (60 ± 23 vs. 69 ± 27 L/min; $p = 0.013$). Measured maximal tidal volume was lower than estimated (1.12 ± 0.32 vs. 1.33 ± 0.25 , $p = 0.002$) but measured maximal total respiratory cycle time (T_{tot}) was not different from estimated (1.41 ± 0.36 vs. 1.47 ± 0.46 , $p = 0.792$). In a subset of seven children who received 180µg albuterol before the incremental test, five would have been ventilatory limited (i.e., $<10\%$ breathing reserve) at maximal exercise using "before bronchodilator" estimated ventilatory capacity (breathing reserve range: -61 to +9%). However, only one child was ventilatory limited at maximal exercise using "after bronchodilator" estimated ventilatory capacity.

Conclusions: Bronchodilator administration prior to maximal exercise testing may be necessary to increase estimated ventilatory capacity and reduce ventilatory limitations even in children with mild asthma.

Exercise Training In Chronic Obstructive Pulmonary Disease: Examining The Plasticity Of Oxygen Transport Limitations To $\dot{V}O_{2peak}$

Ryan M. Broxterman¹, Jan Hoff², Peter D. Wagner³, Russell S. Richardson¹. ¹University of Utah, Salt Lake City, UT. ²University of Science and Technology, Trondheim, Norway. ³University of California, San Diego, La Jolla, CA.
Email: ryan.broxterman@utah.edu
(No relevant relationships reported)

In patients with chronic obstructive pulmonary disease (COPD), exercise training-induced improvements in peak O₂ uptake ($\dot{V}O_{2peak}$) are reliant on adaptations beyond the lungs, particularly in skeletal muscle. Muscle $\dot{V}O_{2peak}$ is determined by the integration of convective and diffusive O₂ transport, which are markedly diminished in COPD. It remains to be determined how these components of O₂ transport respond to exercise training and if their adaptation is compromised in COPD. **PURPOSE:** To test the hypothesis that exercise training improvements in muscle convective and diffusive O₂ transport, and therefore $\dot{V}O_{2peak}$, would not be attenuated in patients with COPD compared to matched controls. **METHODS:** Metabolic and vascular adaptations to single leg knee extensor exercise (KE) training (1 h, 3 times a week for 8 weeks) were compared between 8 patients with severe COPD (FEV₁±SE=0.9±0.1 L, 30% of predicted) and 8 controls matched for age and physical activity. Femoral arterial and venous blood samples, in conjunction with thermodilution, were used to determine muscle O₂ transport and utilization at peak KE. **RESULTS:** Training increased muscle convective O₂ transport in the controls (0.69 ± 0.07 vs. 0.80 ± 0.10 l/min, $p < 0.05$), but not in the patients with COPD (0.44 ± 0.06 vs. 0.49 ± 0.08 l/min, $p > 0.05$). Muscle diffusive O₂ transport was increased with training in both the patients (6.6 ± 0.8 vs. 9.1 ± 0.12 ml/min/mmHg) and controls (10.4 ± 0.9 vs. 13.3 ± 0.9 ml/min/mmHg) (each $p < 0.05$), which equated to an 86% training response in the patients relative to the controls. Training increased $\dot{V}O_{2peak}$ in the patients with COPD (0.27 ± 0.04 vs. 0.34 ± 0.05 l/min) and controls (0.42 ± 0.05 vs. 0.58 ± 0.07 l/min) and peak work rate in the patients (12 ± 2 vs. 16 ± 2 W) and controls (24 ± 4 vs. 36 ± 4 W) (each $p < 0.05$), which equated to a 44% ($\dot{V}O_{2peak}$) and 33% (peak work rate) training response in the patients relative to the controls. **CONCLUSION:** These findings document limited plasticity in convective O₂ transport to the muscle, but relatively conserved plasticity in muscle diffusive O₂ transport with exercise training in COPD. Thus, despite a near restoration of muscle diffusive O₂ transport, the improvements in muscle $\dot{V}O_{2peak}$ and peak work rate in patients with COPD were constrained by the limited plasticity in convective O₂ transport.

DOES TRAINING ALTER BIOMARKERS OF IRON HOMEOSTASIS IN FEMALE COLLEGIATE ATHLETES RESIDING AT MODERATE ALTITUDE?

Dillon J. Frisco¹, Jesse A. Goodrich¹, Sewan Kim¹, Sourav Poddar², Miguel Rueda¹, William C. Byrnes, FACSM¹. ¹University of Colorado, Boulder, CO. ²University of Colorado School of Medicine, Denver, CO. (Sponsor: William C Byrnes, FACSM)
Email: Dillon.Frisco@colorado.edu
(No relevant relationships reported)

Iron deficiency is reported to be more prevalent in female athletes compared to the general population, which can negatively affect athletic performance. Hepcidin (HEP) and erythropoietin (ERY) play a significant role in the homeostatic control of iron, but erythropoietic activity, inflammation, and red cell turnover also influence iron homeostasis. It is unknown whether these factors are altered in female athletes while

training at altitude. **Purpose:** To determine how markers of iron homeostasis, including ferritin (fer), hemoglobin concentration (Hb), reticulocytes, HEP, ERY, interleukin 6 (IL6), and tumor necrosis factor alpha (TNFa), lactate dehydrogenase (LDH) and creatine phosphokinase (CPK) change during training in female endurance and team sport athletes residing at moderate altitude. **Methods:** We recruited 94 female athletes from the University of Colorado DI cross country (XC; n = 28), nordic (n = 6) and alpine (n = 8) skiing, lacrosse (LAX; n = 35) and soccer teams (n = 17). In addition, 12 full time female college students were recruited as controls. Between 2 to 7 fasted blood samples were collected over a minimum of 3 months. All athletes were provided with oral iron supplements from a certified nutritionist during this period. **Results:** Average fer and Hb were higher in endurance athletes (fer: 53 ± 30 ng/dL; Hg: 14.6 ± 0.8) compared to team sport athletes (31 ± 19 ; 13.8 ± 0.8) and controls (18 ± 9 ; 13.9 ± 1.1). Fer remained stable over time for all groups except LAX, who decreased by 20 ng/dL post season. HEP was higher in endurance (36.6 ± 60.3 ng/dL) compared to team sport athletes (18.0 ± 12.0), but there were no differences between groups for ERY (overall average: 10.1 ± 50.8 ng/dL); neither HEP or ERY changed significantly over time. In LAX, soccer, and nordic, IL6 and TNFa were lower than XC and remained stable over time; however, IL6 and TNFa started higher in XC and decreased over time. All teams except nordic showed fluctuations in LDH and CPK over the training cycle, but there were no differences between groups for these parameters or percent reticulocytes for any groups. **Conclusion:** Endurance athletes had higher Hb, fer, and HEP. While IL6 and TNFa were higher in XC athletes, other biomarkers of iron homeostasis tended to not be different between groups, although some parameters fluctuated over time.

Markers Of Training Stress Associated With Functional Overreaching In Middle Distance Runners

Phillip Michael Bellinger, Chris Irwin, Clare Minahan, Surendran Sabapathy, Jonathan Craven, Evan Pennell, Amanda Cox, Ben Desbrow. *Griffith University, Southport, Australia.*
Email: p.bellinger@griffith.edu.au
(No relevant relationships reported)

PURPOSE: The present study aimed to identify markers of training stress that were related to the incidence of overreaching in response to overload training in middle distance runners. **METHODS:** Twenty-four middle distance runners ($n=16$ M, $\dot{V}O_{2peak}$: 73.3 ± 4.3 mL·kg⁻¹·min⁻¹; $n=8$ F, $\dot{V}O_{2peak}$: 63.2 ± 3.4 mL·kg⁻¹·min⁻¹) completed 3 wk of normal training, followed by 3 wk of high-volume training (HVTr; 10% increase in volume each successive week), and a 1-wk taper (TapTr; 55% exponential reduction in training volume from HVTr wk 3). Before, and immediately after each training phase, an incremental treadmill test was performed to measure time to exhaustion (TTE), peak heart rate (HR_{peak}), HR recovery, peak blood lactate concentration ([La]_{bpeak}) and $\dot{V}O_{2peak}$. In addition, resting metabolic rate (RMR), body composition, energy intake and resting blood biomarkers of training stress were measured. Runners who had a decreased TTE (>CV) after HVTr were classified as being functionally overreached (FOR), others as acutely fatigued (AF; no decrease performance). Differences between AF and FOR were analysed using mixed-model ANOVAs with pairwise comparisons. **RESULTS:** Following HVTr, there were significant between group differences in the responses to exhaustive running, whereby FOR ($n=12$) had a decrease in TTE (-49 ± 14 s), HR_{peak} (-4 ± 3 BPM; $p = 0.02$), [La]_{bpeak} (-4.30 ± 1.80 mmol·L⁻¹; $p = 0.01$) and $\dot{V}O_{2peak}$ (-2.33 ± 2.0 mL·kg⁻¹·min⁻¹) and a faster HR recovery (-5 ± 4 BPM; $p = 0.03$) compared to AF ($n=12$). There were no between group differences in these variables during submaximal running, nor were there changes in absolute or relative RMR, while only the FOR group increased energy intake during the HVTr. There was no statistically significant change in body composition in either group throughout the study nor were there changes in resting blood biomarkers that reflected inflammation (IL-6, GDF-15 and CRP), metabolism (thyroid hormones), catabolism and anabolism (DHEA, urea, total protein, testosterone, cortisol and GH) or iron regulation (iron, ferritin, and UIBC). **CONCLUSIONS:** Middle distance runners who were classified as FOR following an overload training period did not have alterations in RMR, resting blood biomarkers or submaximal exercise responses compared to runners who did not have impaired performance.

Molecular Mechanisms Underpinning The Regulation Of Peak Fat Oxidation Rates During Exercise

Oliver Chrzanowski-Smith, Robert Edinburgh, Eleanor Smith, Mark Thomas, Jean-Philippe Wahlin, Francoise Koumanov, Sean Williams, James Betts, FACSM, Javier Gonzalez. *University of Bath, Bath, United Kingdom.* (Sponsor: Professor James Betts, FACSM)
Email: o.j.chrzanowski-smith@bath.ac.uk
(No relevant relationships reported)

PURPOSE: The molecular regulation of peak fat oxidation (PFO) during exercise remains poorly characterized. The aim of this study was to examine the relationship between the content of key proteins involved in adipose tissue and skeletal muscle fat metabolism with PFO.

METHODS: Thirty-six healthy men and women adults [15 females; mean (SD) age 40 (11) years; $\dot{V}O_{2peak}$ 42.5 (9.5) mL·kg⁻¹·min⁻¹; body fat %: 21.8 (8.2) %] completed two incremental exercise tests (separated by 7-28 days) to determine PFO via indirect calorimetry. A DEXA scan and adipose tissue and/or skeletal muscle biopsies were obtained 2-7 days after the second exercise test to determine the protein content of PLIN1, CGI-58, ATGL, HSL, ACSL1, and oestrogen receptor α (ER α) in adipose tissue, and FABPpm, ATGL, ACSL1, CTP1b and ER α in skeletal muscle. Sex comparisons were performed on sub-groups of males and females matched for aerobic capacity relative to fat free mass and classifications of the physical activity level index and fat mass index ($n = 14$ and 12 for adipose tissue and skeletal muscle comparison sub-groups, respectively).

RESULTS: Moderate strength correlations were found between PFO (mg·kg⁻¹·min⁻¹) and the protein content of ATGL [$r = 0.41$ (0.05 - 0.68), $p < 0.05$] and CPT1b [$r = 0.41$ (0.05 - 0.68), $p < 0.05$] in skeletal muscle. No other statistically significant bivariate correlations were found between PFO and the content of proteins in adipose tissue or skeletal muscle. Females had a greater PFO compared to males when expressed relative to fat-free mass [mean (SD): 7.1 (1.9) and 7.3 (1.7) vs 4.5 (1.3) and 4.8 (1.2) mg·kg⁻¹·min⁻¹ in the adipose tissue and skeletal muscle-sub-groups, respectively, $p < 0.05$]. No statistically significant sex differences were found in the content of any of the measured proteins involved in lipid metabolism in adipose tissue or skeletal muscle.

CONCLUSIONS: The molecular regulation of PFO may primarily lie within skeletal muscle rather than adipose tissue, involving processes relating to intramyocellular triglyceride hydrolysis (ATGL) and mitochondrial fatty acid transport (CPT1b). Future studies should explore alternative molecular mechanisms that may account for sexual dimorphism in exercise fuel metabolism.

2995 May 29 1:45 PM - 2:00 PM

The Effect Of Ischemic Preconditioning And Hypoxia On Neuromuscular Function During Intense Exercise

Samuel Halley, Paul Marshall, Jason Siegler, FACSM. *Western Sydney University, Sydney, Australia.* (Sponsor: Dr Jason Siegler, FACSM)
(No relevant relationships reported)

Ischemic preconditioning (IPC) has been proposed to preserve neural drive during fatiguing exercise, however the underlying mechanism of this response remains unclear. Previous research has shown exercises impairing local tissue oxygenation to be more favourable in eliciting the humoral effects of IPC. **PURPOSE:** To determine whether IPC mediated effects on neuromuscular function are dependent on tissue oxygenation. **METHODS:** Eleven resistance-trained males completed four exercise trials (6 sets of 11 repetitions of maximal effort dynamic single-leg extensions) in either normoxic (fraction of inspired oxygen (FiO₂): 21%) or hypoxic (FiO₂: 14%) conditions, preceded by treatments of either IPC (3 x 5 min bilateral leg occlusions at 220 mmHg) or sham (3 x 5 min at 20 mmHg). Femoral nerve stimulation was utilized to assess voluntary activation and potentiated twitch characteristics during maximal voluntary contractions (MVCs) performed at baseline, prior to the exercise task and after each set of the exercise task. Tissue oxygenation (via near-infrared spectroscopy), blood oxygenation (via pulse oximetry) and surface electromyography activity was measured throughout the exercise task. **RESULTS:** MVC and twitch torque declined 62% and 54%, respectively (MVC: 96 ± 24 Nm, 95% CI = 73 to 119 Nm, Cohen's $d = 2.9$, $p < 0.001$; twitch torque: 37 ± 11 Nm, 95% CI = 26 to 48 Nm, $d = 1.6$, $p < 0.001$), between pre- and post-exercise measurements without reductions in voluntary activation (mean decrease $0.2 \pm 6.2\%$, 95% CI = -5.7 to 6.1%, $d = 0.05$, $p > 0.21$); there were no differences between conditions. Hypoxia reduced both blood and tissue oxygenation by 5% and 6%, respectively, compared to normoxic conditions (blood oxygenation: $4.8 \pm 0.3\%$, 95% CI = 4.7 to 5.0%, $d = 1.9$, $p < 0.001$; tissue oxygenation: $3.5 \pm 1.5\%$, 95% CI 2.6 to 4.4%, $d = 2.4$, $p < 0.001$), with a further 3% reduction in tissue saturation evident in the hypoxic IPC compared to hypoxic sham trial (mean decrease $1.8 \pm 0.7\%$, 95% CI = 0.5 to 3.5%, $d = 1.0$, $p < 0.05$).

CONCLUSION: IPC did not affect any measure of neuromuscular function regardless of tissue oxygenation. A reduction in FiO_2 did invoke a humoral response and improved muscle O_2 extraction during exercise, however it did not manifest into any performance benefit.

Blood Lactate Steady State Is Maintained During Moderate Intensity Interval Training Depending Rest Time Duration

Juan C. Mazza, FACSM¹, Raul R. Festa¹, Sandra L. Prieto², Gustavo D'Andrea³, Maria B. Pasquali⁴, Alvaro N. Gurovich, FACSM⁵. ¹Biosystem Institute Sports Sciences, Rosario, Argentina. ²National University of Colombia, Bogota D.C., Colombia. ³Echesortu Swimming Club, Rosario, Argentina. ⁴National University of Rosario, Rosario, Argentina. ⁵The University of Texas at El Paso, El Paso, TX.
Email: juanmazza@arnet.com.ar
(No relevant relationships reported)

Interval training (IT) is a method commonly used by coaches. The rest between stimuli is a variable that can be manipulated in IT. Rest time influences the specificity of workload. Considering that Blood Lactate (BLA) represents the balance of metabolic intracellular production-removal-oxidation, is very important to determine different levels of Lactate Steady-State (La SS) with variation in rest time, which are able to sustain La SS for longer periods, using IT workouts. **PURPOSE:** To analyze BLA during 90s of passive rest (pr) in steady-state moderate intensity IT (mIT). In previous work, we have shown that La SS was maintained for 60s of pr (Mazza et al., 2018), without significant differences (SD). **METHODS:** Eleven trained swimmers (19.4±3.8 y) performed a mIT (BLA 4 to 6 mMol/l). The bout was 10x100m freestyle with 90s pr. BLA and heart rate (HR) were measured at 10s, 50s and 80s at same time, during pr, every 2 reps. We applied Shapiro-Wilk test to analyze distribution's data. We compared BLA-10s vs. BLA-50s vs. BLA-80s applying One-way ANOVA ($p < 0.05$) in reps 2-4-6-8 and 10; also, we determine Pearson correlation coefficient (r) between BLA-10s, BLA-50s, BLA-80s vs. HR-10s, HR-50s, HR-80s, respectively. **RESULTS:** BLA data show normal distribution ($p > 0.05$). The mean BLA max./min. values were 6.25/5.08 mMol/l, respectively, at 1.49±0.07 m/s. Statistical analyses are shown in the following table: & SD BLA-10s vs. BLA-50s; * SD BLA-50s vs. BLA-80s; # SD BLA-10s vs. BLA-80s. We found a low r between BLA and HR ($r = 0.25-0.30$). **CONCLUSION:** This work shows that La SS in mIT depends of pr duration to generate sustained metabolic stress during whole exercise - rest workout. BLA-10s vs. BLA-50s does not register SD (except rep. 6). However, BLA-50s vs. BLA-80s are SD, showing a tendency to lower BLA level. La SS is maintained within BLA 4 to 6 mMol/l range with only 1.17 mMol/l differences between max./min. mean values. Also, we found that HR is not valid variable to control metabolic stress in mIT.

2997 May 29 2:15 PM - 2:30 PM

Training Alterations In Total Hemoglobin Mass And Plasma Volume In Collegiate Athletes Residing At Altitude

Sewan Kim¹, Jesse A. Goodrich¹, Dillon J. Frisco¹, Miguel Rueda¹, Sourav Poddar², William C. Byrnes, FACSM¹. ¹University Colorado Boulder, Boulder, CO. ²University Colorado School of Medicine, Denver, CO. (Sponsor: William C. Byrnes, FACSM)
Email: sewan.kim@colorado.edu
(No relevant relationships reported)

Total hemoglobin mass (THM) is directly related to maximal oxygen consumption and can be used to determine blood volume, red cell volume and plasma volume (PV). The effect of training on THM and PV for male and female intercollegiate athletes across sports residing at altitude has received limited attention. **Purpose:** To examine if training alters THM and PV in NCAA DI athletes residing at altitude. In addition, the effects of sex and/or sport were investigated. **Methods:** We recruited 88 NCAA DI athletes from the University of Colorado Boulder alpine ski, (8M & 7F), nordic ski (NSKI; 6M & 6F), football (FB; 9M), lacrosse (LAX; 35F) and soccer (17F) teams. THM and PV were measured over 3 or more months at selected time points where coaches indicated a change in training stimulus. Recreationally active students (14M & 12F) served as baseline controls. The optimized carbon monoxide rebreathing procedure was used to measure THM and determine PV. Values were reported as means and standard errors while significance was set at $p < 0.05$. **Results:** **Females:** Initial THM for controls, alpine, LAX, NSKI and soccer (577 ± 27, 622 ± 39, 614 ± 11.2, 658 ± 29, 628 ± 23 g, respectively) were not different between groups and did not change with training for any teams. Initial PV for controls, alpine, LAX, NSKI and soccer (2981 ± 190, 3079 ± 128, 3118 ± 56, 3160 ± 194, 3341 ± 107 mL, respectively) were not different between groups. PV decreased with training for alpine, LAX and soccer by 304 ± 116, 112 ± 51 and 268 ± 84 mL, respectively. **Males:** Initial THM

for alpine, FB and NSKI (996 ± 43, 1169 ± 35 & 1089 ± 64 g, respectively) were not different and did not change with training. Initial THM for controls (894 ± 38.1) was lower than FB and NSKI. Initial PV values for controls, alpine, FB and NSKI were 3763 ± 158, 3901 ± 268, 4855 ± 121 and 4597 ± 260 mL, respectively. Initial PV for controls were lower than FB and NSKI, while alpine was lower than FB. NSKI had a decrease in PV (-477 ± 157 mL), which then returned to initial values. **Conclusion:** THM remained constant during training, regardless of sport or sex, indicating that the training stimuli experienced by the athletes may not alter THM. During the course of training certain teams exhibited a decrease in PV, which could be a result of the nature of training stimuli and/or hydration status.

Brain-Heart Dynamics Are Associated With Cardiorespiratory Fitness & Cognitive Control

Derek C. Monroe¹, Matthew P. Herring, FACSM², James W. Hicks¹, Julian F. Thayer¹, Steven L. Small³. ¹University of California, Irvine, Irvine, CA. ²University of Limerick, Limerick, Ireland. ³University of Texas at Dallas, Richardson, TX.
Email: dcmunroe@uci.edu
(No relevant relationships reported)

An association between cardiovagal activity and cognitive control may represent overlapping roles of the prefrontal cortex for autonomic and cognitive functions. Greater vagal tone is associated with greater cardiorespiratory fitness and may partially explain the well-established benefits of exercise for cognitive control.

PURPOSE: The aim of this study was to relate cardiorespiratory fitness ($\text{VO}_{2\text{max}}$) and cognitive control to dynamic brain-heart connectivity.

METHODS: Twenty-three, recreationally active young adults (14 women; 18-35 years old) completed a treadmill $\text{VO}_{2\text{max}}$ test, assessment of cognitive control, and resting measures of electroencephalography (EEG) and electrocardiography (EKG). Cognitive control was defined by performance on the Flanker Test ('inhibitory control') and Dimensional Change Card Sort Test ('cognitive flexibility'). A multi-taper method (1-50 Hz; 1 Hz steps) was used to compute dynamic power from from six frontal electrodes and six posterior electrodes as controls. A point-process model, based on an inverse Gaussian distribution fit between R-peaks, was used to produce an instantaneous estimate of heart rate. The maximal information coefficient (MIC), a non-parametric statistic capable of identifying linear and non-linear associations, was computed between the heart rate model and time-varying power at each electrode and frequency to represent dynamic brain-heart connectivity. A partial least squares analysis characterized the brain-heart connections that significantly and reliably contributed to a relationship between MIC and $\text{VO}_{2\text{max}}$ and cognitive control.

RESULTS: One latent variable ($p = .036$) represented independent, negative correlations between MIC and $\text{VO}_{2\text{max}}$, inhibitory control, and cognitive flexibility. High $\text{VO}_{2\text{max}}$ and cognitive control were positively associated with right-lateralized MICs (boot-strap ratios ≤ 1.96) in the delta band (1-3 Hz) and negatively associated with left-lateralized MICs (boot-strap ratios ≥ 1.96) in the delta and theta bands (1-7 Hz). There was no relationship between MIC measured with control (posterior) electrodes and the dependent variables ($p > .236$).

CONCLUSION: The benefits of exercise for cognitive control may be associated with right-lateralized communication between the prefrontal cortex and heart.

Aerobic Exercise Regulates Synaptic Homeostasis In The Hippocampal CA1 Region Of APP/PS1/tau Mice

Laikang Yu, Li Zhao. Beijing Sport University, Beijing, China.
(No relevant relationships reported)

PURPOSE: Physical exercise is an important lifestyle behavior that may reduce the risk of Alzheimer's disease (AD) and delay the onset and progression of AD. Most of the mechanisms underlying these effects are based on molecular biology and little reports are involved in cellular function. In this study, we were to explore the changes

of synaptic homeostasis in the early pathology (6 months) of APP/PS1/Tau transgenic (3xTg) mice, and the possible mechanism of aerobic exercise improving synaptic plasticity.

METHODS: 3xTg mice (2 months old) were randomly divided into exercise groups and sedentary groups (AS, AE), and C57BL/6J mice as cohort control (CS, CE). The exercise groups would run on the treadmill for 16 weeks. Brain slice patch clamp were used to detect the changes of I-O curve, PPF, LTP, LTD, miniature EPSCs (mEPSCs), miniature IPSCs (mIPSCs) and E/I ratio of pyramidal neurons in hippocampal area CA1.

RESULTS: In hippocampal area CA1 of AS, the I-O curve (0.31 ± 0.02) was reduced compared with the CS (0.60 ± 0.02 , $p<0.01$), also in LTP (151.29 ± 7.63 vs $183.55\pm 13.71\%$, $p<0.01$), the mEPSCs frequency (0.25 ± 0.02 vs 0.39 ± 0.03 Hz, $p<0.01$), the amplitude of mIPSCs (23.48 ± 0.44 vs 26.11 ± 0.55 pA, $p<0.05$) and E/I ratio (0.51 ± 0.02 vs 0.81 ± 0.02 , $p<0.01$) of pyramidal neurons. At the interval time of 20 ms, the PPF (1.78 ± 0.08 vs 1.55 ± 0.04 , $p<0.01$) was increased, as were LTD (62.61 ± 3.25 vs $76.14\pm 2.88\%$, $p<0.01$), the amplitude of mEPSCs (14.51 ± 0.34 vs 12.83 ± 0.35 pA, $p<0.01$) and the frequency of mIPSCs (2.46 ± 0.19 vs 1.99 ± 0.10 Hz, $p<0.05$) of pyramidal neurons. Aerobic exercise apparently reversed the changes above of AS in I-O curve (0.74 ± 0.03), LTP ($170.97\pm 5.42\%$), the frequency of mEPSCs (0.51 ± 0.04 Hz), the amplitude of mIPSCs (41.20 ± 1.13 pA) and E/I ratio (0.71 ± 0.03), and decreased PPF (1.42 ± 0.07), LTD ($79.01\pm 4.99\%$), the amplitude of mEPSCs (11.52 ± 0.29 pA) and the frequency of mIPSCs (1.72 ± 0.12 Hz). Meanwhile, those electrophysiology signals were also increased in the CE group.

CONCLUSIONS: Aerobic exercise could regulate synaptic homeostasis plasticity by increasing mEPSCs frequency and mIPSCs amplitude, and decreasing mEPSCs amplitude and mIPSCs frequency. Then it would improve basic synaptic transmission and LTP, weaken LTD in hippocampal area CA1 of the early pathology in 3xTg mice to enhance synaptic plasticity.

Is Aerobic Fitness Associated With The Dopaminergic System? Evidence From Spontaneous Eye Blink Rate

Ryuta Kuwamizu, Kazuya Suwabe, Takemune Fukuie, Genta Ochi, Taichi Hiraga, Hideaki Soya. *Faculty of Health and Sport Sciences, University of Tsukuba, Tsukuba, Ibaraki, Japan.*
(No relevant relationships reported)

Many studies, including ours, have revealed that aerobic fitness, as a physiological indicator of physical activity, is associated with cognitive performance based on the prefrontal cortex and the hippocampus (Hyodo, Soya *et al.*, *NeuroImage*, 2016; Suwabe, Soya *et al.*, *Sci Rep*, 2017). As a potential neurobiological basis for this, the brain dopaminergic system is postulated by animal and a few human studies. Current studies hypothesize that higher physical activity levels may prevent elderly people from declining cognitive function probably via a protective effect against reduced dopamine D2/3-receptor availability (Köhnecke *et al.*, *NeuroImage*, 2018; Jonasson *et al.*, *NeuroImage*, 2019). It remains uncertain, however, whether this association could generally be observed in a healthy population without cognitive decline. To this end, we measured spontaneous eye blink rate (EBR), a potential non-invasive marker for activity in the dopaminergic system related to D2/3-receptors (Groman *et al.*, *J Neurosci*, 2014). **PURPOSE:** We examined the association between aerobic fitness, physical activity and EBR as an indicator of the dopaminergic system in healthy young adults. **METHODS:** Thirty-six 18- to 24-yr-old healthy young men completed an aerobic fitness assessment ($V\cdot O_{2peak}$) using a graded exercise test with a recumbent ergometer, self-reported on their leisure-time physical activity (the Japanese language version of the International Physical Activities Questionnaire), and had their EBR measured while staring at a fixation cross while at rest. **RESULTS:** Greater aerobic fitness ($V\cdot O_{2peak}$) was correlated with both higher leisure-time physical activity ($r=0.51$, $p<0.01$) and higher EBR ($r=0.40$, $p<0.05$) after controlling for age. In addition, Leisure-time physical activity was also positively correlated with EBR ($r=0.37$, $p<0.05$). **CONCLUSION:** These results show that aerobic fitness is associated with EBR in healthy young adults, supporting the hypothesis above that aerobic fitness is an indicator of physical activity associated with cognitive function via the dopaminergic system related to D2/3-receptors.

Forced Running Exercise Modulates Amyloid-beta Protein Clearance Anddegradation Pathways In Prevention Of Alzheimer'S Disease

Li ZHAO¹, Yangyang TONG¹, Ziqi Zhao². ¹Beijing Sport University, Beijing, China. ²Chinese Academy of Sciences, Beijing, China.
Email: zhaolispring@126.com
(No relevant relationships reported)

PURPOSE: Most of studies demonstrate positive effects of exercise on A β levels in Alzheimer's Disease (AD) model, while a small subset of investigations reports no change. Nearly all studies using the APP/PS1 mouse showed reduced A β levels after

a forced exercise, but studies using the 3xTg-AD mouse did not after a voluntary exercise. Discrepancies in the data may be due to the wide range of transgenic animal strains, starting age, intervention type, and length of intervention used in these studies. Here, we used 12-week protocol starting with different age of 3xTg mouse to investigate forced running effect on A β levels.

METHODS: 6, 9 and 12 months 3xTg mice were randomly divided into exercise and sedentary groups, 2-month 3xTg mice as the control group. The exercise groups would run on the treadmill for 12 wks. Immunofluorescence and Dot blot were used to detect A β plaque and soluble A β respectively. Western blot was used to detect β -site APP cleaving enzyme (BACE1) and A β degradation or clearance enzyme Neprilysin (NEP) in the cerebral cortex and hippocampus and Insulin-degrading enzyme (IDE) in liver.

RESULTS: The hippocampal and cortical tissue showed soluble A β increased with age. Obvious A β plaque accumulation was showed at 9 and 12-month-old. With AD-pathology the BACE1 levels were increased ($p<0.05$) while NEP expression decreased ($p<0.05$) in hippocampus and cortex, and IDE content decreased ($p<0.05$) in liver. Disturbances went more severe with aging. Exercise treatment ameliorated soluble A β aggregation and A β plaque, BACE1 (0.70 ± 0.13 , 0.78 ± 0.13 , $0.81\pm 0.08/1.06\pm 0.12$, 0.78 ± 0.08 , 0.69 ± 0.10 , $p<0.05$), NEP (1.50 ± 0.24 , 1.19 ± 0.12 , $1.20\pm 0.12/1.16\pm 0.04$, 1.22 ± 0.26 , 1.31 ± 0.12 , $p<0.05$) and IDE (1.07 ± 0.13 , 1.19 ± 0.20 , 1.24 ± 0.12 , $p<0.05$) changes were partially protected by exercise.

CONCLUSIONS: In the 3xTg-AD mice at different age of 6, 9 and 12 months, 12 wks forcing treadmill exercise can obviously reduce the levels of A β with lower BACE1, higher NEP expression in the brain and IDE of the liver. Although it is not definite that forced exercise interventions are better for reducing A β levels, the benefits of exercise interventions still support the value of this healthy life-style against neurodegeneration.

Effects Of Aerobic Exercise On The Nicotine Addiction Induced Inhibitory Synaptic Plasticity In The Vta

Yan Li, Jie Zhang, Li Zhao. *Beijing Sport University, Beijing, China.*
(No relevant relationships reported)

PURPOSE: Disinhibition of the ventral tegmental area (VTA) dopamine neurons has been implicated in nicotine addiction. This study aimed to investigate the effect of aerobic exercise on the nicotine addiction behavior in mice, and the effect on GABAergic transmission and dopaminergic activity in the VTA.

METHODS: 2 months old male C57BL/6J mice were randomly divided into sedentary + saline group (SS), sedentary + nicotine group (SN), exercise + saline group (ES) and exercise + nicotine group (EN) respectively. The ES and EN groups were made to run on the treadmill for 1 hour per one day, five times a week, for 12 weeks. The exercise workload consisted of running at a speed of 12 m/min for the first 10 min, 15 m/min for the last 50 min, with 0% grade of inclination. The conditioned place preference (CPP) assay was used to evaluate nicotine addiction related behavior. In the CPP assay, SN and EN mice were given an intraperitoneal (i.p.) injection of nicotine (0.5 mg/kg) while SS and ES mice were given an injection of saline. Patch clamp was used to investigate the dopamine neuron excitability and GABAergic transmission in the VTA. Immunofluorescence was used to detect the expression of tyrosine hydroxylase (TH) in the VTA.

RESULTS: 8 weeks of treadmill exercise decreased nicotine exposure induced CPP expression (CPP score, SS, -33.69 ± 16.57 ; SN, 121.51 ± 14.53 ; ES, -21.72 ± 15.12 ; EN, 66.34 ± 15.12 ; SS vs. SN, $p<0.001$; EN vs. SN, $p<0.05$, two-way ANOVA). Exercise decreased nicotine CPP induced dopamine neuron hyperexcitability (SS, 3.36 ± 0.45 ; SN, 6.63 ± 0.56 ; ES, 3.22 ± 0.48 ; EN, 4.60 ± 0.18 ; SS vs. SN, $p<0.001$; EN vs. SN, $p<0.01$, two-way ANOVA). Exercise decreased nicotine CPP induced increase of TH expression in the VTA (relative fluorescence intensity, SS 1.00; SN, 2.03 ± 0.15 ; ES, 1.38 ± 0.06 ; EN, 1.04 ± 0.07 ; SS vs. SN, $p<0.001$; EN vs. SN, $p<0.001$, two-way ANOVA). Exercise restored nicotine CPP induced impairment of GABA transmission in the VTA (sIPSCs frequency, % as baseline, SS, $154.62\pm 6.86\%$; SN, 102.19 ± 6.20 ; ES, 141.36 ± 5.84 ; EN, 121.82 ± 4.41 ; SS vs. SN, $p<0.001$; EN vs. SN, $p<0.05$, two-way ANOVA).

CONCLUSIONS: Aerobic exercise restores nicotine addiction induced VTA dopamine neuron hyperexcitability by enhancing the inhibitory transmission. Supported by the China Postdoctoral Science Foundation (2018M641260, 2019T120067).

Pupillary Responses Indicate Working Memory Processing Differences: Implications For Healthy And Clinical Populations

Christina B. Vander Vegt¹, Lawrence Gregory Appelbaum², Jason P. Mihalik, FACSM¹, Kevin M. Guskiewicz, FACSM¹, Johna K. Register-Mihalik¹. ¹The University of North Carolina at Chapel Hill, Chapel Hill, NC. ²Duke University, Durham, NC. Email: cbv33@email.unc.edu
(No relevant relationships reported)

Task-evoked pupillary responses (PR) are established psychophysiological measures for neural resource allocation. During working memory tasks, pupils dilate proportional to increasing cognitive demands and constrict when demands exceed resource availability. PRs have demonstrated greater sensitivity to load-dependent processing differences in clinical populations, beyond performance accuracy, under high cognitive demands. Few studies have examined concussion history, sex, and performance accuracy effects on PRs across varying cognitive load levels.

PURPOSE: To examine effects of concussion history, sex, and performance accuracy on PR in healthy individuals during a digit-span task. **METHODS:** Participants self-reported sex (female vs. male) and concussion history (yes vs. no), and completed a backwards digit-span task in a single testing session. A virtual reality headset with 60Hz infrared eye tracking displayed the task and recorded pupil size fluctuations. Pupil size (diameter in mm) was recorded before each trial (baseline=3sec) and following randomly presented digit sequences between 4 and 14 digits long (retention=2sec). PR was calculated as the mean size during retention, normalized to mean baseline. Accuracy was calculated as the proportion of correctly recalled digits by serial position. A mixed effects model examined concussion history, sex, and accuracy effects on PR across sequence-lengths (*a priori* $\alpha=0.05$). **RESULTS:** 40 participants were included [age=21.9±2.1years; males=50%; 17 (43%) with concussion history]. There were significant effects of sex ($F_{1,36}=15.66, p<0.001$) and accuracy ($F_{1,2588}=4.70, p<0.03$) on overall relative PR controlling for all other model predictors and interactions. Specifically, females exhibited smaller mean PRs compared to males. Smaller mean PRs were also associated with higher average task accuracy. **CONCLUSION:** In our study, females exhibited smaller overall pupillary responses during a digit-span working memory task compared to males, indicating potential sex-dependent processing differences. The association between better task accuracy and smaller PRs may further support PR measure to better inform neurocognitive processing differences in healthy and clinical populations, when demands exceed cognitive resource availability.

Behavioral-induced Prefrontal Cortex Activation And Episodic Memory Function

Lindsay Crawford, Paul D. Loprinzi, Grace Burnett, Morgan Chism, Gina Robinson, Jeremiah Blough. University of Mississippi, Oxford, MS.
(No relevant relationships reported)

PURPOSE Here we evaluated the effects of several behaviors (e.g., acute exercise, fist clenching, and saccades) on episodic memory, and whether prefrontal cortex oxygenation mediated these relationships. Six experiments were conducted to evaluate these direct and indirect effects. **METHODS & RESULTS** Experiment 1 was a four-visit, within-subject, counterbalanced randomized controlled experiment. The visits included 1) exercise and saccadic eye movements, 2) exercise only, 3) saccadic eye movements only, and 4) no exercise and no saccadic eye movements (control). A word-list based episodic memory assessment was employed, including a long-term memory evaluation. The RM ANOVA was statistically significant ($P=0.01, \eta_p^2=0.15$), as the number of words recalled at the delay period were, respectively, 7.8 (2.7), 8.1 (2.7), 8.1 (2.3), and 6.6 (2.8). In our second experiment, we evaluated the effects of saccadic eye movements on prefrontal cortex oxygenation (PFC O_2Hb), a proxy for neuronal activity. We found a main effect for time over a three-minute period, ($P<0.001, \eta_p^2=0.31$), representing higher oxygenation levels during saccadic eye movement. In our third experiment, we evaluated the effects of acute exercise on PFC O_2Hb , which also demonstrated an increase in PFC O_2Hb across time, ($P=0.04, \eta_p^2=0.09$). Experiment 4 replicated Experiment 1, but instead of saccadic eye movements, used a fist clenching protocol. The RM ANOVA was statistically significant ($P<0.001, \eta_p^2=0.46$), with memory being significantly better for the exercise only, fist only, and exercise + exercise visit compared to control. Experiment 5 evaluated the effects of fist clenching on PFC O_2Hb . Results demonstrated a significant main effect for time, with oxygenation increasing during fist clenching, ($P<0.001, \eta_p^2=0.35$). Experiment 6 demonstrated that PFC oxygenation was statistically significantly positively associated with episodic memory function, in that, for every 1 μM increase in oxygenation during memory encoding, there was a 0.27 increase in the number of words (out of 8) recalled ($b=0.27; 95\% CI: 0.02, 0.52; p = .03$). **CONCLUSION** These six experiments suggest that several behaviors may improve memory function and may, potentially, do so via increases in PFC O_2Hb .

Relationships Between Muscular Strength, Cognitive Control, And Hippocampal Dependent Relational Memory Function

Jeongwoon Kim¹, Colleen F. McKenna¹, Amadeo F. Salvador¹, Susannah E. Scaroni¹, Jonathan Cerna¹, Corinne N. Cannavale¹, Scott A. Paluska, FACSM¹, Michael De Lisio², Nicholas A. Burd¹, Naiman A. Khan¹. ¹University of Illinois, Urbana-Champaign, IL. ²University of Ottawa, Ottawa, ON, Canada. (Sponsor: Scott A. Paluska, FACSM)
Email: jk51@illinois.edu
(No relevant relationships reported)

PURPOSE: An increasing number of studies have shown a positive correlation between aerobic fitness and cognitive control, and hippocampal memory performance. However, the relationship between muscular strength and specific domains of cognitive function has not yet been well elucidated. The aim of this study was to examine cross-sectional relationships between muscular strength and cognitive control (i.e., attention and inhibitory control), as well as hippocampal-dependent relational memory. **METHODS:** Adults (N=35) between 45 and 64 years underwent strength assessments measured by leg extension one-repetition maximum (1RM), maximal voluntary isometric contraction (MVC), and isokinetic knee extension. Selective attention, inhibitory control, and hippocampal-dependent relational memory was assessed using the Flanker, Go/NoGo, and a Spatial Reconstruction task, respectively. Lean mass was measured via dual X-ray absorptiometry (DXA). **RESULTS:** Following adjustment for covariates (i.e., age, sex, and lean mass), greater MVC ($r=-0.37, P=0.04$) and isokinetic peak knee extension torques measured at $60^\circ \cdot s^{-1}$ ($r=-0.47, P=0.008$), $120^\circ \cdot s^{-1}$ ($r=-0.37, P=0.04$), and $180^\circ \cdot s^{-1}$ ($r=-0.39, P=0.03$) were related to faster incongruent reaction time during the Flanker task. Misplacement error during spatial reconstruction task was inversely related to peak knee extension torques measured at $120^\circ \cdot s^{-1}$ at the trend level ($r=-0.36, P=0.05$). No significant associations were observed for Go/NoGo accuracy (all $r's \leq -0.34$, all $P's \geq 0.6$). **CONCLUSION:** Individuals with greater muscular strength exhibit greater cognitive function. These findings provide insights into the potential for domain-specific interrelationships between muscular strength attentional abilities over memory performance and inhibitory control. This work was funded by The Beef Checkoff.

F-14 Free Communication/Slide - Older Adults: Methods, Interventions, and Outcomes

Friday, May 29, 2020, 1:00 PM - 3:00 PM
Room: CC-2022

Effect Of Type And Intensity Of Community-based Exercise Interventions In Older Women

Emmanuel Gomes Ciolac¹, Gabriel Souza Zanini¹, Vanessa Teixeira Amaral¹, Gabriel Falcão¹, Bianca Fernandes¹, Isabela Roque Marçal¹, Awassi Yophiwa Ngoman¹, Guilherme Veiga Guimarães². ¹São Paulo State University - UNESP, Bauru, Brazil. ²University of São Paulo - USP, São Paulo, Brazil. Email: emmanuel.ciolac@unesp.br
(No relevant relationships reported)

PURPOSE: To assess the effect of different community-based exercise interventions on hemodynamic and functional variables in older women. **METHODS:** 33 sedentary or insufficiently active older women (69 ± 5 ys) were randomly assigned to perform a twice-weekly community-based moderate-intensity continuous aerobic training plus resistance training (MICT+RT), high-intensity interval training plus resistance training (HIT+RT) or resistance training (RT) programs. Anthropometric (weight, height and BMI), hemodynamic (resting blood pressure and carotid-femoral pulse wave velocity) and functional variables (seat-and-reach, handgrip, five times sit-to-stand (FTSS), timed up-and-go (TUG), and 6-minute walking (6MW) tests) were assessed before and after 9 months of follow-up.

RESULTS: There were no significant difference between groups in any variable at baseline. Anthropometric and hemodynamic variables, as well as seat-and-reach and handgrip did not change during follow-up in any group. However, FTSS, TUG and 6MW improved ($P < 0.05$) similarly between groups during follow-up. (Table 1).

CONCLUSION: The present preliminary results suggest that twice-weekly community-based exercise programs of different types and intensity are effective to improve functional capacity, but not anthropometric and hemodynamic variables, in older women.

Table 1. Anthropometric, hemodynamic and functional variables before and after 9 month follow-up

Variable	MICT_RT		HIIT+RT		RT	
	Before	After	Before	After	Before	After

Associations Between Accelerometer-derived Daily Physical Activity Patterns And Frailty Among Older Adults At Elevated Risk For Falls

Amal A. Wanigatunga¹, Jacek K. Urbanek², David L. Roth², Erin D. Michos², Qian-Li Xue², Karen Bandeen-Roche¹, Jeremy D. Walston², Lawrence J. Appel², Jennifer A. Schrack¹. ¹Johns Hopkins Bloomberg School of Public Health, Baltimore, MD. ²Johns Hopkins School of Medicine, Baltimore, MD. (Sponsor: Todd M. Manini, FACSM)
 Email: awaniga1@jhu.edu
 (No relevant relationships reported)

BACKGROUND: With aging, the degradation of free-living physical activity patterns may indicate phenotypic frailty.

PURPOSE: To determine the baseline, cross-sectional association between accelerometer-derived physical activity patterns and frailty in participants of Study to Understand Fall Reduction and Vitamin D in You (STURDY) trial

METHODS: Baseline wrist-worn accelerometer and frailty data were collected from 505 STURDY participants (mean age 77 (SD=5.5) years; 43% women). Accelerometer data collected over 24-hour, 7-day periods were used to derive continuous physical activity metrics, including mean activity minutes/day and activity fragmentation (reciprocal of the average length of activity bouts). Robust, pre-frail and frail statuses were identified using a modified version of the physical frailty phenotype defined as having 0, 1, or ≥2 (of 4) phenotypes, respectively: weight loss, exhaustion, slowness, and weakness. Using multiple logistic regression models, the interaction between age and each accelerometer metric was examined to estimate an odds ratio between frailty and pre-frailty/robustness.

RESULTS: Robust (30%) and pre-frail participants (48%) had similar physical activity patterns, spending approximately 6.5 hours/day in activity with a 25% level of activity fragmentation, while frail participants (28%) appeared to accumulate less activity in a more fragmented manner (5.8 hours/day and 29% activity fragmentation). The odds of frailty (versus pre-frailty/robustness) was lower by a factor of 3% with each higher year of age by higher hour of activity (OR:0.97, 95% CI:0.94-0.99, age x activity interaction $p=0.01$). The interaction between age and fragmentation was not significant ($p=0.39$) but higher fragmentation was associated with a higher likelihood of frailty (OR:1.04, 95% CI:1.01-1.07, $p=0.02$).

CONCLUSION: Our results show an inverse relationship between objectively-measured physical activity and frailty that becomes stronger with age among at-risk older adults. More daily activity breaks (activity fragmentation) was associated with

higher frailty odds; an association that remained stable across age. Our findings warrant further investigation into whether longitudinal declines in objectively-measured physical activity patterns precede frailty onset.

Effects Of Community-based Exercise Training And Detraining On Hemodynamic Variables In Older Women: Role Of Intensity And Modality

Vanessa Teixeira Amaral, Gabriel Souza Zaninni, Guilherme Falcão, Isabela Roque Marçal, Bianca Fernandes, Awassi Yophiwa Ngomane, Emmanuel Gomes Ciolac. São Paulo State University - UNESP, Bauru, Brazil.
 Email: amaral.vtm@gmail.com
 (No relevant relationships reported)

Regular exercise is associated with a reduced risk of developing chronic diseases and improved physical capacity. However, to our knowledge, the effects of modality, intensity and consequences of detraining have not yet been investigated in the elderly population. We sought to evaluate and compare the effect of modality and intensity (moderate intensity continuous aerobic training - MICT, high intensity interval aerobic training - HIIT, resistance training - RT, or combined - MICT + RT and HIIT + RT) of a training program, on the behavior of hemodynamic and functional variables of elderly women after 12 weeks of training and 16 weeks after their interruption.

PURPOSE: To verify the effect of exercise modality and intensity on the hemodynamic variables of the elderly.

METHODS: 69 elderly women (69.19 ± 7.89 years) were randomized into MICT (n = 29), RT (n = 15), MICT + RT (n = 12), and HIIT + RT (n = 13). Participants performed physical exercises twice a week during 60 minutes. The variables investigated were blood pressure (BP), heart rate (HR), abdominal circumference (AC) at pre, after 12 weeks of intervention, and after 16 weeks of training interruption (detraining).

RESULTS: Diastolic blood pressure decreased in HIIT + RT between pre and untrained ($p < 0.01$) and in RT between post and untrained ($p < 0.02$). There was a significant increase in HR between post and detraining MICT ($p < 0.02$) and a decrease in MICT + RT between pre and post training ($p < 0.000$), with no significant difference in detraining. AC decreased in HIIT + RT between pre and post ($p < 0.01$), in RT between pre and detraining ($p < 0.009$) and post and detraining ($p < 0.00$). There was an increase in post and detraining WC for MICT ($p < 0.05$) and MICT + RT ($p < 0.03$).

CONCLUSION: Isolated or combined aerobic training can be effective in reducing blood pressure levels. Resistance training was also effective for reducing abdominal fat levels.

Table 1. Blood pressure, heart rate and abdominal circumference during follow-up

 (No relevant relationships reported)

PURPOSE: Aerobic exercise is recommended to improve glycemic control; however, the optimal intensity of exercise for older adults with prediabetes is unknown. The objective of this pilot study was to compare the effects of moderate vs. vigorous intensity aerobic exercise on glycemic control and non-exercise physical activity (NEPA). **METHODS:** 19 older adults (14F; 68.1 ± 5.8 yrs) with prediabetes (HbA1c 5.7-6.4% or fasting glucose 100-125 mg/dl) were randomized to 12-weeks of supervised aerobic exercise (45-min sessions 4 days/wk) at either moderate (MOD: 60-65% HR_{max}) or vigorous (VIG: 80-85% HR_{max}) intensity. Free-living glycemic control (24h mean; percent of day ≥140 mg/dL) was measured using continuous glucose monitors (CGM, Dexcom). NEPA (>1.5 METs, excluding exercise sessions) was assessed using a thigh worn accelerometer (ActivPAL v4). A 3h Oral glucose tolerance test (OGTT, 75g) was performed at baseline and following the exercise intervention (72-96h following the last exercise bout) to compare to free-living CGM and as measure of insulin sensitivity (Matsuda Index). Data are presented as mean±SE. **RESULTS:** Adherence rates to the exercise interventions were 85±9% and 89±3% in MOD and VIG with mean heart rates during exercise of 99±1 bpm (65% HR_{max}) and 123±4 bpm (79% HR_{max}), respectively. Mean 24h glucose (-8.4±6.4 vs. -2.2±6.7 mg/dl) and percent of day >140 mg/dL (-9.7±11.0% vs. 0.7±4.6%) did not significantly change in MOD or VIG, respectively. However, there was a significant group by time interaction (p=0.05) for change in insulin sensitivity in MOD (+2.4±1.1) and VIG (-0.6±0.8). There were no differences between groups for change in NEPA, fasting glucose, or 2h glucose. Changes in free-living CGM were not significantly correlated with changes in OGTT outcomes. **CONCLUSION:** In older men and women with prediabetes, both MOD and VIG had minimal effects on free-living glycemic control, but MOD induced greater improvements in insulin sensitivity. These preliminary results suggest that a more comprehensive lifestyle intervention combining dietary intervention and exercise may be needed to improve glycemic control in this population.

The Stay Strong, Stay Healthy Program's Effect On Fall Risk In Older Adults

Kelsey J. Weitzel, Breanne S. Baker, Lisa A. Royse, Stephen D. Ball, Dana L. Duren. University of Missouri, Columbia, MO.
 (Sponsor: Dr. Jill Kanaley, FACSM)
 Email: kelsweitzel@gmail.com
 (No relevant relationships reported)

Falling and fear of falls among older adults can have significant impacts on daily life such as restricted activity, functional decline, and social isolation. Exercise interventions need to target modifiable risk factors to have the greatest impact. **PURPOSE:** The first aim was to determine the effectiveness of an eight-week Stay Strong, Stay Healthy (SSSH) exercise intervention on older adults' fear of falling and risk of falls. The second aim was to determine the strongest predictors of reported number of falls among older adults. **METHODS:** 60 adults over the age of 60 yrs, were randomized into SSSH, active control (WALK), or sedentary control (CON) groups. 46 participants (SSSH n=15, WALK n=17, CON n=14) completed pre/post intervention questionnaires on physical activity (PA), fear of falling, and sleep quality using the Pittsburgh Sleep Quality Index Survey (PSQI). Participants also completed the 8 ft timed up and go (TUG) and 30 s sit to stand (30STS), dynamic balance tasks and grip strength testing. Repeated measures ANOVAs were used to determine group (SSSH, WALK, CON) × time (pre, post) interaction effects for TUG, 30STS, and grip strength; one-way ANOVAs were used to analyze percent changes (%Δ); and simple linear regression was used to predict the number of falls in the last 12 months; alpha was set at 0.05. **RESULTS:** SSSH and WALK significantly improved 30STS performance by 2.4 repetitions and 1.1 repetitions, respectively, while CON did not improve. PSQI scores significantly increased (worsened) in CON (p=0.040), did not change in WALK, and decreased (improved) by 1.3 points in SSSH (p=0.009). Reported PA did not change for WALK or CON; however, SSSH increased by 60+ min/wk (p=0.049). A significant time effect was observed as TUG times decreased and grip strength did not change for all groups. CON and WALK increased their overall fear of falling scores by 7.7% and 3.9% respectively, while SSSH decreased by 2.3%. The strongest predictive model for the number of falls reported in the past 12 months included PSQI scores, PA, and grip strength (R²=0.282; p=0.003). **CONCLUSIONS:** These data suggest participation in eight weeks of the SSSH significantly improves important modifiable risk factors (e.g., sleep and PA), and reduced fear of falling scores which is consistent with our prediction model for the number of falls sustained.

The Stay Strong, Stay Healthy Program Improves Physical Function And Fall Risk In Older Adults

Breanne S. Baker, Kelsey J. Weitzel, Lisa A. Royse, Stephen D. Ball, Dana L. Duren. University of Missouri, Columbia, MO.
 (Sponsor: Dr. Jill Kanaley, FACSM)
 Email: bakerbre@health.missouri.edu
 (No relevant relationships reported)

The aging process, even in the absence of chronic disease, is marked by a decline in the mass, quality, and function of skeletal muscle, increasing the risk of falls. **PURPOSE:** The purpose was to determine effectiveness of an 8-week Stay Strong, Stay Healthy (SSSH) exercise intervention on improving older adults' muscle strength, dynamic balance, and fall risk compared to controls. **METHODS:** 60 adults aged ≥60 yrs, were randomized into SSSH, active control (WALK), or sedentary control (CON) groups. 46 participants (SSSH n=15, WALK n=17, CON n=14) completed pre and post intervention general health and physical activity (PA) questionnaires, the Pittsburgh Sleep Quality Index Survey (PSQI), and total body DXA. Participants also completed the 10 m walk test (10MWT), 8 ft timed up and go (TUG), 30 s sit to stand (30STS), back scratch (BS), sit and reach flexibility tests, and the CDC four phase balance task. Repeated measures ANOVAs were used to determine group (SSSH, WALK, CON) × time (pre, post) interaction effects and percent changes (%Δ) were analyzed using one-way ANOVAs, alpha was set at 0.05. **RESULTS:** SSSH and WALK participants significantly improved 30STS performance by 2.4 repetitions (p < 0.001) and 1.1 repetitions (p = 0.008), respectively, while CON did not improve. PSQI scores significantly increased (worsened) in CON (p = 0.040), did not change in WALK, and decreased (improved) by 1.3 points in SSSH (p = 0.009). Average BS distance for WALK or CON did not change, but SSSH participants improved (+ 4.3 cm, p = 0.040). Reported auxiliary PA did not change for WALK or CON; however, SSSH increased by more than 60 min/wk (p = 0.049). **CONCLUSIONS:** Participation in the 8-week SSSH resistance training program significantly improves lower body strength/coordination, dynamic balance, sleep quality, and engagement in auxiliary PA over sedentary and exercise volume matched walking groups.

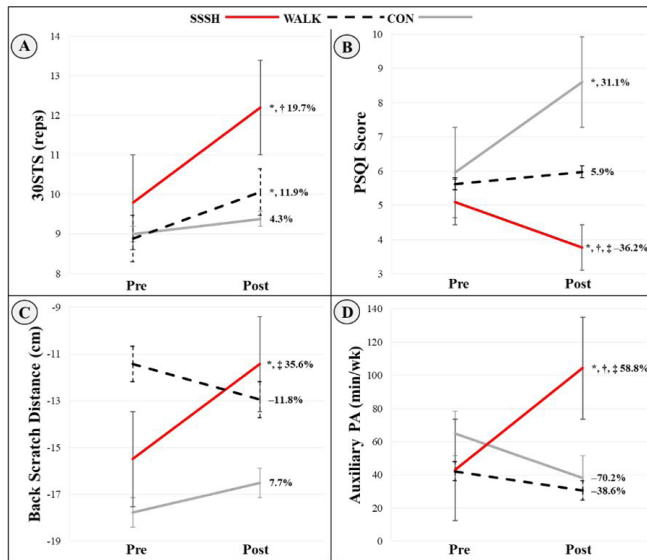

Figure 1. Significant interactions for 30STS, PSQI, back scratch flexibility, and auxiliary physical activity. * denotes a significant within group difference from pre ($p < 0.05$). † and ‡ denote significant magnitudes of change greater than CON or WALK respectively ($p < 0.05$).

Influence Of Exercise And Gardening Activity On Successful Aging: A Six-year Cohort Study

Yuxin Yang, Xu Wen. *Zhejiang University, Hangzhou, China.*
Email: yangyx20@163.com

(No relevant relationships reported)

Purpose: Population aging has become a prominent social problem in China. This study aimed to examine the influence of exercise and gardening activity on successful aging (SA).

Methods: This study was based on the 2008-2014 data set of Chinese Longitudinal Healthy Longevity Survey (CLHLS). A total of 5245 elderly people aged 65 and older were included in this study. SA was defined as no major illness, being free of disability, normal cognitive function, engaging in social or productive activity, and satisfaction on life. Correlates of SA included demographics (gender and age) and socio-economic feature (education). With activities being measured in 2008 and 2011, SA being assessed both in 2008, 2011 and 2014. Binary logistic regression analysis was used to determine whether these two activities have positive effects on SA.

Results: According to the activity data of 2008 and SA situation in 2014, the regression analyses indicated that regular exercise (OR=1.223, 95%CI: 1.001-1.495) and gardening (OR=1.640, 95%CI: 1.272-2.115) were significant predictors to better SA ($P < 0.05$). From the combination activity data of 2008 and 2011, compared with the sedentary elderly, the elderly participated exercise (OR=1.661, 95%CI: 1.286-2.145, $P < 0.05$) or gardening (OR=1.807, 95%CI: 1.331-2.453, $P < 0.05$) continuously were found to have higher odds to be successful agers in 2014. Moreover, the results showed that the elderly just participated from 2011 have higher probability to be successful agers in 2014 than the sedentary elderly, the odds ratios of exercise and gardening were 1.396 and 1.441 respectively.

Conclusion: These findings suggest that exercise and gardening activity may have positive effects on SA, and continuous participation has better effects.

F-32 Thematic Poster - Blood Flow Restriction

Exercise With Blood Flow Restriction To Improve Muscular And Physical Function After Total Knee Arthroplasty

Alexander Kuck¹, Benjamin Cockfield², Alicia DenHerder¹, Lydia Lytle³, Isaac Wedig⁴, Steven Elmer². ¹Central Michigan University, Mt Pleasant, MI. ²Michigan Technological University, Houghton, MI. ³Aspirus Keweenaw Outpatient Therapies, Laurium, MI. ⁴Michigan Technological University, Houghton, MI.

Email: bacockfi@mtu.edu

(No relevant relationships reported)

After a total knee arthroplasty (TKA), quadriceps strength and physical function can be impaired for several years. Blood flow restriction (BFR) exercise is an effective method to improve muscular and physical function in clinical populations with knee joint pathologies. To date, there are two case studies documenting application of BFR after TKA. A next step is to determine the feasibility of BFR in a larger TKA cohort. **PURPOSE:** To evaluate the effectiveness of a 10wk home-based BFR exercise program to improve muscular and physical function after TKA. **METHODS:** Six adults (age: 59±9yrs, BMI: 33±5) with a unilateral TKA (2.7±1.7yrs post-surgery) performed body weight half squats, isolated knee extension using a resistance band, and walking exercises with BFR 3x/wk for 10wk. During exercise, blood flow in the affected limb was restricted using a 15cm wide thigh cuff inflated to 50% of limb occlusion pressure which was identified using Doppler ultrasound. Outcome measures of vastus lateralis thickness, maximal knee extensor isometric torque, and physical function (repetitions performed during 30s chair stand test, distance covered during 6min walk test) were assessed at baseline and post-training. **RESULTS:** Participants completed 98% of the home-based BFR training sessions and tolerated the exercise program well as joint pain (0.6±0.1cm) and muscle soreness (0.5±0.1cm) were very low (0-10cm visual analogue scale). Vastus lateralis thickness and knee extensor strength in the affected leg increased by 18±11% and 17±13%, respectively (both $P < 0.05$). After training, number of repetitions during the 30s chair stand test increased (11±2 vs. 18±4 repetitions, $p < 0.01$) and this change (6 repetitions) exceeded the minimally important clinical difference. There was a significant increase in distance covered during the 6min walk test (51±28 vs. 556±36m, 9±7%, $p = 0.03$) but this improvement (46m) did not exceed the clinical threshold. **CONCLUSION:** Results from this pilot study are promising and suggest that home-based BFR exercise can be feasible, safe, and effective for improving muscular and physical function after TKA. Further research is needed to confirm these initial findings in a larger randomized TKA control trial.

Acute Physiological Responses To Low-intensity Exercise With Different Levels Of Blood Flow Restriction

Jia Wei¹, Zhengqiu Gu¹, Yongdi Zou¹, Xiaolu Wang¹, George Nassis², Yongming Li¹. ¹Shanghai University of Sport, Shanghai, China. ²City Unity College, Athens, Greece.

Email: weijia_gavin0807@163.com

(No relevant relationships reported)

PURPOSE: External pressure is a key factor in blood flow restriction (BFR) training. Previous studies have used a limited range of occlusion pressures to compare the acute physiological and perceptual responses during leg exercise. The aim of this study was twofold: i) to compare the physiological and perceptual responses of low-intensity exercise (LI) with different levels of BFR, and ii) to compare LI with BFR on the bike with high-intensity (HI) exercise without BFR.

METHODS: Twenty-one healthy, moderately-trained male (age: 24.6±2.4 yrs; VO_{2peak} : 47.2±7.0 ml/kg/min, mean±sd) volunteered to perform one maximal graded exercise test on the bike and seven 5-min constant intensity exercise bouts on separate days and in a counterbalanced order. Six bouts were at 40% peak power (P_{peak} ; LI); one without BFR and five with different levels of BFR (40%, 50%, 60%, 70%, 80% of arterial occlusion pressure, LI-BFR_{40/50/60/70/80}). Finally, they performed one HI bout (70%

P_{peak}) without BFR. Oxygen uptake (VO_2), heart rate (HR), blood lactate (BLa), rating of perceived exertion (RPE), and tissue oxygen saturation (TSI) with near-infrared spectroscopy were recorded.

RESULTS: Regardless of pressure, HR, BLA and RPE during LI-BFR were higher compared to LI ($p<0.05$), and TSI reduction was greater in LI-BFR (LI-BFR_{40/50/60/70/80}: $-10.6\pm 3.1\%$, $-10.2\pm 4.0\%$, $-10.1\pm 5.1\%$, $-10.0\pm 4.2\%$, $-11.3\pm 4.9\%$, respectively) than LI ($-6.0\pm 4.2\%$, $p<0.05$). The responses of VO_2 , HR, BLA, RPE and TSI induced by the different levels of BFR applied in LI-BFR were similar. Regardless of pressure, the responses of VO_2 , HR, BLA and RPE induced by LI-BFR was lower than HI ($p<0.05$), except for TSI. TSI change was similar between LI-BFR_{40/50/60/70/80} and HI (LI-BFR_{40/50/60/70/80} range: $-10.0\pm 4.2\%$ to $-11.3\pm 4.9\%$, HI: $-11.5\pm 4.5\%$).

CONCLUSION: It appears that BFR equal to 40% of arterial occlusion pressure is sufficient to reduce TSI. This BFR level seems to stress the physiological mechanisms adequately and there is no need for higher external pressure application. This level of BFR can also produce local hypoxia similar to that during HI. Therefore, low-intensity exercise with BFR could be an alternative exercise mode for individuals who are unable to perform high-intensity exercise.

3073 Board #3 May 29 3:15 PM - 5:15 PM
Central And Systemic Haematological Responses Are Similar Between Continuous And Intermittent Blood Flow Restricted Resistance Exercise

Llion A. Roberts¹, Charlie Davids², Jeff Coombes, FACSM², Jonathan Peake³, Truls Raastad⁴. ¹Griffith University, Southport, Australia. ²University of Queensland, Brisbane, Australia. ³Queensland University of Technology, Brisbane, Australia. ⁴Norwegian School of Sport Science, Oslo, Norway. (Sponsor: Jeff Coombes, FACSM)
 Email: llion.roberts@griffith.edu.au
 (No relevant relationships reported)

Resistance training (RT) with blood flow restriction (BFR) induces similar adaptations to traditional RT but uses markedly lower training loads. However, information about the acute exercise pressor, hemodynamic, and local metabolic cost of this training approach is sparse. These data are needed to understand the acute safety implications of this training approach and help identify an optimal BFR protocol. **PURPOSE:** To compare the acute central and systemic cardiovascular, and local metabolic responses to resistance exercise performed with continuous (BFR-C) and intermittent (BFR-I) BFR.

METHODS: 12 resistance-trained males (mean \pm SD) aged 22.3 ± 3.2 yrs, 1.82 ± 0.06 m, and 84.1 ± 9.0 kg performed 4 separate acute resistance training sessions in a random order, each separated by 7 days. Training sessions involved four sets of squat-based RT at 30% of individuals' 1 repetition maximum with 1) no BFR (CON), 2) BFR-C, 3) BFR-I, and 4) traditional high load training at 70% of 1 repetition maximum with no BFR (HL). Systemic blood pressure and derivatives of cardiac output, central aortic blood pressure pulse wave characteristics, and local blood volume and metabolism were assessed periodically during, and after each training session. Data were assessed by two-way ANOVA with Bonferroni-corrected post-hoc comparisons.

RESULTS: All sessions similarly increase average metabolic demand, seen by a decreased tissue saturation index (-15% , 95% CI 13.3 to 17.4, $p<0.0001$) with no difference between conditions ($p>0.05$). Whilst changes in haemoglobin-derived Vastus Lateralis blood volumes were similar between conditions, they were higher with BFR-C than CON ($6.97 \mu\text{mol/L}$, 95% CI 0.2 to 13.6, $p=0.04$) and HL ($7.9 \mu\text{mol/L}$, 95% CI 1.2 to 14.8, $p=0.01$). Training equally increased mean systemic mean arterial pressure (MAP) ($+70.5$ to 76.6 mmHg, $p<0.001$) and cardiac output ($+0.74$ to 0.96 L, $p<0.001$) above baseline, with no difference between conditions. Training also equally increased mean aortic MAP ($+14.8$ to 24.2 mmHg, $p<0.001$) above baseline across conditions.

CONCLUSIONS: BFR-C and BFR-I cause similar exercise pressor responses comparable with both traditional resistance training, and training without BFR. Adding BFR to resistance training didn't exacerbate the magnitude or duration of the associated cardiovascular stress.

3074 Board #4 May 29 3:15 PM - 5:15 PM
The Effect Of Blood Flow Restriction Resistance Training On Exercise-induced Hypoalgesia

Stephen David Patterson, Luke Hughes. St Marys University, Twickenham, United Kingdom.
 Email: Stephen.patterson@stmarys.ac.uk
 (No relevant relationships reported)

PURPOSE: Exercise-induced hypoalgesia (EIH) describes a reduction in pain sensitivity following exercise, characterised by an elevation in pain threshold or decrease pain intensity ratings following exercise. Recent research suggests that performing light-load resistance exercise with blood flow restriction (BFR-RE) may have a pain-modulation effect. Therefore, the aim of this study was to compare

the magnitude of EIH with BFR-RE to resistance exercise at both low and high intensities. **METHODS:** Twelve recreationally active individuals were recruited to participate. In a randomised crossover design, participants completed 4 experimental trials of resistance exercise ((1) light load resistance exercise (LLRE); (2) BFR-RE with low pressure (BFR40); (3) BFR-RE with high pressure (BFR80) and (4) heavy load resistance exercise (HLRE)). Pressure pain threshold (PPT) was then assessed at multiple body sites (dominant and non-dominant quadriceps and non-dominant trapezius muscle) pre, 5 min, 10 min and 24 hr post exercise. **RESULTS:** There was a two-way interaction effect for the dominant quadriceps site. Post-hoc analysis showed that, compared to LLRE, PPT was higher following BFR40, BFR80 and HLRE. PPT was higher following BFR80 compared to BFR40 and HLRE. At 24h post-exercise, PPTs were $14.5 \pm 6.7\%$ and $23.9 \pm 8.2\%$ higher than pre-exercise values in the BFR40 and BFR80 trials, respectively, whereas PPTs had returned to baseline in the LLRE and HLRE trials. Compared to LLRE, the increase in PPT was greater following BFR40 (0.28 ± 0.13 AU), BFR80 (0.64 ± 0.42 AU) and HLRE (0.34 ± 0.20 AU) in the non-dominant quadriceps. At 24h PPTs had returned to baseline. Compared to LLRE, the increase in PPT was greater following BFR40 (0.31 ± 0.27 AU), BFR80 (0.30 ± 0.17 AU), and HLRE (0.26 ± 0.13 AU) for the trapezius. At 24h PPTs had returned to baseline. **CONCLUSIONS:** In conclusion BFR with higher pressure leads to EIH in both dominant and non-dominant limbs suggesting both central and peripheral mechanisms of action.

Resistance Exercise With Blood Flow Restriction Under Different Occlusion Pressure On Muscular Performance

Jieming Lu, Zhiqiang Lian, Peng Sun, Wulan Li, Shanyun Liu, Dongqing Xu. Tianjin University of Sport, Tianjin, China.
 (No relevant relationships reported)

PURPOSE: The study compared the effect of low intensity resistance exercise with blood flow restriction (BFR) in the proximal thigh under different occlusion pressure on muscle morphology and function.

METHODS: Twenty-seven healthy college students who had no training experience were randomly divided into three groups by different occlusion pressure: 0 mmHg (CON), 120 mmHg (LBFR) and 180 mmHg (HBFR). Before and after 12 weeks training with an inflatable cuff (20% 1RM, half squat, 4 sets, 75 repetitions in total, 3 days a week) in three groups, the muscle thickness (MT) of rectus femoris and medius femoris were assessed by ultrasound for all subjects. The maximal isokinetic torque (IT_{max}), relative maximal isokinetic torque (R-IT_{max}) and maximal power (P_{max}) were measured at angular velocities of 60°/sec by ISOMED 2000 System in dominant low limb of all subjects.

RESULTS: The MT of rectus femoris and medius femoris in LBFR increased after training compared with pre-training (2.12 ± 0.22 vs. 1.99 ± 0.16 cm and 2.01 ± 0.09 vs. 1.82 ± 0.15 cm, $p<0.05$), as well as in HBFR (2.15 ± 0.16 vs. 1.95 ± 0.19 cm and 2.02 ± 0.19 vs. 1.86 ± 0.14 cm, $p<0.01$). The IT_{max} after training were higher than pre-training not only in LBFR (213.00 ± 26.04 vs. 204.56 ± 29.16 Nm, $p<0.01$), but also in HBFR (217.00 ± 20.13 vs. 190.33 ± 15.71 Nm, $p<0.01$). A significant increase in R-IT_{max} was noted in LBFR than pre-training (2.87 ± 0.35 vs. 2.74 ± 0.38 Nm/kg, $p<0.01$), and also in HBFR (2.94 ± 0.26 vs. 2.57 ± 0.20 Nm/kg, $p<0.01$). However, there was no significant increase in P_{max} after training in LBFR (124.78 ± 18.93 vs. 119.89 ± 13.32 W, $p>0.05$) or HBFR (122.56 ± 16.44 vs. 120.26 ± 17.43 W, $p>0.05$). There was no significant change in MT, IT_{max}, R-IT_{max} and P_{max} before and after training in CON ($p>0.05$). Besides, the MT, IT_{max} and R-IT_{max} in LBFR and HBFR had a significant change compared with CON respectively after training ($p<0.05$). There was no any significant difference in the MT, IT_{max}, R-IT_{max}, P_{max} between LBFR and HBFR after training ($p>0.05$).

CONCLUSION: BFR training protocols under 120mmHg or 180mmHg pressure are effective in improving muscular morphology and function. But the higher occlusion pressure may not have more benefit in improving muscular performance than the lower occlusion pressure.

Blood Flow Restriction Training During A Dynamic Warm-Up And Its Effects On Various Sprint Times

Alexandra Howard¹, Justin Goins¹, Matthew Steurys², Amy Fraley Hand¹, Jay Patel². ¹University of South Carolina, Columbia, SC. ²Primis Health, Columbia, SC.
 Email: ah56@email.sc.edu
 (No relevant relationships reported)

PURPOSE: To examine the effects of blood flow restriction (BFR) during a dynamic warm-up on a 25, 50, and 100-meter run time, rating of perceived exertion (RPE), and heart rate (HR) in recreational athletes. **METHODS:** Fourteen participants (22.3 ± 1.8 years) volunteered to participate in this cross-over study. Participants were randomly assigned to either the BFR or control group during their first trial, then completed the other trial seven days (± 1 day) later. During the BFR training intervention, the cuffs

were placed on the proximal thigh at the level of the gluteal fold and were inflated to 80% of the participants' limb occlusion pressure (LOP), which was assessed prior to participation. Participants completed a five-minute dynamic warm-up wearing the blood flow restriction cuffs, and the same dynamic warm-up was completed during the control intervention without the use of the cuffs. After each warm-up, a three-minute revascularization period was provided before participants ran a 100-meter sprint at maximal effort, in which 25, 50, and 100-meter times were recorded. Heart rate was measured throughout the entirety of the study, and RPE was measured immediately after the sprint for both trials. Time measures, RPE scores, and heart rate were compared using a paired samples t-test ($\alpha < .05$). **RESULTS:** There were no significant differences between control and BFR sprint times, post warm-up HR, or post run HR. There was a significant difference between the control and BFR RPE scores ($3.14 \pm .66$ vs. 4.79 ± 1.42 , $p < .001$). **CONCLUSION:** There is currently minimal evidence investigating the acute effects of BFR. Based on our results, there were no significant differences in sprint times between the control and BFR trials. RPE scores during the BFR trial were significantly higher than the control, indicating that participants felt the intensity of the BFR trial was more difficult although the times did not vary. Although not statistically different, average heart rates in the BFR trial were lowered by up to nine beats per minute compared with the control. This may be attributed to the perceived difficulty of the BFR trial as participants possibly could not exert themselves as much as when completing the control trial. These results do not support acute use of BFR to increase short-term performance, but more research should be performed.

Physiological Responses To Acute Arm Cranking With Blood Flow Restriction

Benjamin Cockfield, Isaac Wedig, Jana Hendrickson, Steven Elmer. *Michigan Technological University, Houghton, MI.*
 Email: sjelmer@mtu.edu

(No relevant relationships reported)

Aerobic exercise with blood flow restriction (BFR) is emerging as an effective method to improve both aerobic capacity and muscular function. Using an inflatable cuff, blood flow is usually restricted during walking and cycling. The extent to which BFR can be applied during upper-body aerobic exercise such as arm cranking is not well documented. Arm cranking with BFR might offer an exercise option for clinical populations that need to exercise upper-body muscles (e.g., wheelchair users, individuals with shoulder injuries). **PURPOSE:** To evaluate physiological and perceptual responses to acute submaximal arm cranking with BFR. **METHODS:** Five active adults (age: 23 ± 3 yrs, arm cranking VO_{2peak} : 33 ± 8 ml/kg/min) performed 4 intermittent arm cranking protocols (6x2 min, 1min recovery): 1) low-load arm cranking (LL, 40% VO_{2peak}), 2) low-load arm cranking with BFR (BFR, 40% VO_{2peak}), and 3) high-load arm cranking (HL, 80% VO_{2peak}). For BFR, blood flow was restricted using 5cm cuffs inflated to 70% of limb occlusion pressure as identified using Doppler ultrasound. Cardiorespiratory and perceptual responses (VO_2 , HR, perceived effort) and tissue perfusion (tissue saturation, deoxyhemoglobin concentrations) were measured using a metabolic cart and near-infrared spectroscopy, respectively. **RESULTS:** Oxygen consumption during BFR (1.15 ± 0.32 ml/kg/min) did not differ from LL (1.04 ± 0.26 ml/kg/min, $P=0.31$) and was less than HL (2.28 ± 0.60 ml/kg/min, $P<0.01$). Compared to LL (104 ± 6 b/min), heart rate during BFR increased (115 ± 13 b/min, $P=0.04$) but was less than HL (166 ± 19 b/min, $P<0.01$). BFR required greater perceived effort in the arms (12 ± 3) compared to LL (9 ± 2 , $P=0.03$) but less effort than HL (16 ± 2 , $P=0.01$). In general, BFR decreased tissue saturation and increased deoxyhemoglobin concentrations compared to arm cranking without BFR (all $P<0.05$). **CONCLUSION:** These results suggest that arm cranking with BFR has potential to increase metabolic stress without excessive cardiorespiratory strain. This exercise mode may provide a useful alternative to HL for populations that need to exercise upper-body muscles for rehabilitation. These findings provide guidance for future acute and chronic studies examining the feasibility and efficacy of arm cranking with BFR.

Combining Blood Flow Restriction Training With Heat To Maximize Hypertrophy And Strength In Rugby Players

Franck Brocherie¹, Leo Morelet¹, Olivier Girard², Brendan R. Scott². ¹French Institute of Sport, Paris, France. ²Murdoch University, Perth, Australia.

Email: franck.brocherie@insep.fr
 (No relevant relationships reported)

PURPOSE: We assessed whether blood flow restriction (BFR) training with the addition of heat stress (BFRH) improves hypertrophy, muscle strength and sport-specific physical performance in rugby union players, compared to BFR training alone. **METHODS:** Nineteen elite U23 rugby union male players were randomly assigned to BFRH ($n = 7$), BFR ($n = 6$) or traditional high-load resistance training (CON, $n = 6$) groups. BFRH and BFR groups trained twice weekly for 3 weeks using BFR exercise (half squat, 4 sets of 30-15-15-15 repetitions at 30% 1 maximum repetition (1RM)

with 30 s of passive recovery; 50% of resting arterial occlusion pressure) in hot (37°C) and cool (22°C) conditions, respectively. Before and after the intervention, thigh circumference, half squat 1RM, squat jump force-velocity profile, and performance in vertical jump, sprint and repeated-sprint ability (RSA) tasks were measured. Muscle damage marker (creatin kinase) was measured before and after (0.1-24 h) the first and last training session. **RESULTS:** Thigh circumference significantly increased ($P<0.001$) from pre- to post-training in both BFRH (+6%, $P<0.001$) and BFR (+4%, $P<0.05$). Significant time \times group interaction revealed improvement in half squat 1RM (+12% and +19%, $P<0.01$) and maximal force component (+102% and +116%, $P<0.001$) of the force-velocity profile for BFRH and BFR. Vertical jump performance did not change. 10-m sprint (-5% and -3%, $P<0.001$) and RSA best and total times (both -2%, both $P\leq 0.001$) improved similarly in BFRH and BFR. Although not significant, muscle damage was lowered after the last session in BFRH only. No pre- to post-training changes occurred in CON.

CONCLUSIONS: Combining BFR training with heat stress can potentially induce hypertrophy and improve rugby union-specific physical performance while also inducing lower muscle damage than BFR training alone. Such gains could be of benefit during competitive period or rehabilitative setting.

F-33 Thematic Poster - Carbohydrate and Time Restricted Feeding

(No relevant relationships reported)

The effects a particular kind of short term fasting called time restricted feeding (TRF) have been recently investigated on resistance training athletes; no data are available, instead, on endurance athletes. **PURPOSE:** We sought to investigate the effects of 4 weeks of 16/8 TRF (with windows of 16 hours of fasting and 8 hours of feeding) on elite cyclists. **METHODS:** 16 elite under-23 cyclists were randomly assigned to a TRF group or to a control group (CTRL) with a traditional meal pattern. The TRF group consumed 100% of its estimated daily energy needs in an 8-hour time window: from 10:00 AM to 6:00 PM whilst the CTRL group consumed 100% of its estimated daily energy needs in 3 meals between 7:00 AM and 9:00 PM. During the experimental period, training loads were similar in the two groups. Athletes were tested before and after 4 weeks of the intervention. Fat and lean body mass were measured by bioelectrical impedance analysis, VO_{2max} and basal metabolism were measured by indirect gas analyzer. In addition, blood counts, free testosterone, SHBG, IGF-1, IL-6, TNF alpha, VES, PCR, total cholesterol, triglycerides, TSH, free T3, insulin, adiponectin, and cortisol were measured. **RESULTS:** After 4 weeks, there was a significant decrease of body weight (TRF: $-1.26 \text{ kg} \pm 1.57$ vs. CTRL: $+0.22 \pm 0.96 \text{ kg}$, $p=0.038$) and fat mass in the TRF group ($p=0.0093$) compared to CTRL group with no differences in lean body mass. Performance tests showed no significant differences between groups even though there was a significant increase in the peak power output/body weight ratio ($p=0.024$) in the TRF group due to weight loss. Free testosterone and IGF-1 decreased significantly ($p=0.004$ and $p=0.048$ respectively) in the TRF group; leukocyte count decreased more in the CTRL group ($p = 0.039$). Lymphocyte count increased in TRF group ($p<0.001$) whilst neutrophils decreased in both groups ($p<0.001$), thus the neutrophils to lymphocytes ratio (NLR) decreased significantly ($p=0.003$) in TRF group. No significant changes in other blood chemistry values were observed. **CONCLUSIONS:** Our results suggest that a TRF program with an 8-hour feeding window causes fat loss, maintains lean mass and performance indexes and improves peak power output/body weight ratio. The changes of white blood cells parameters worth further investigation.

3081 Board #2 May 29 3:15 PM - 5:15 PM

The Effects Of The 16/8 Diet On Cardio-metabolic Outcomes In Competitive Male Runners

Christine E. Richardson¹, Ashley P. Tovar¹, Gretchen A. Casazza², Brian Davis, FACSM³, Nancy Keim¹. ¹University of California, Davis, Davis, CA. ²Sacramento State, Sacramento, CA. ³University of California at Davis Medical Center, Sacramento, CA. (Sponsor: Dr. Brian Davis, FACSM)
Email: Cerrichardson@ucdavis.edu

(No relevant relationships reported)

Purpose: The objective of the present study was to investigate the effects of the 16/8 diet on cardio-metabolic risk factors in competitive male runners. **Methods:** This ongoing study is a randomized cross-over intervention that consists of two 4-week arms: a "normal diet" arm (ND: 12 hours fasted and 12 hours fed) and a "16/8" (TRF: 16 hours fasted and 8 hours fed) arm along with a 2-week washout. Sixteen subjects will complete the study and will participate in 4 test days (12 hour fasted), one at the beginning and end of each arm, where they will undergo a DXA scan, resting energy expenditure measurement and a fasting blood draw for biomarker quantification. Overall calories, macronutrient intake and exercise training will be held constant over the 2 interventions. **Preliminary Results:** Data on 9 subjects shows no significant differences between groups in changes in body mass (+0.41 ND vs. -0.72 kg TRF, p=0.25), fat mass (-0.29 ND vs. -0.63 kg TRF, p=0.65), fat free mass (+0.56 ND vs. -0.25 kg TRF, p=0.18) and body fat (-0.42 ND vs. -0.61 % TRF, p=0.72) with the 4 week intervention. Changes in resting energy expenditure (+152.3 ND vs. +11.3 kcal TRF, p=0.18), resting respiratory exchange ratio (-0.003 ND vs. -0.04 TRF, p=0.36), blood glucose (-3.9 ND vs. -1.9 mg/dl TRF, p=0.61), total cholesterol (+1.0 ND vs. -3.0 mg/dl TRF, p=0.68), HDL cholesterol (-1.7 ND vs. 0.0 mg/dl TRF, p=0.71), LDL cholesterol (0.0 ND vs. -3.8 mg/dl TRF, p=0.41), and triglycerides (+17.9 ND vs. *4.3 mg/dl TRF, p=0.46) also did not differ between interventions. **Conclusion:** So far, with limited power, there does not appear to be any physiological health benefits in male runners adhering to a 16/8 diet when compared to a normative eating timeframe.

3082 Board #3 May 29 3:15 PM - 5:15 PM

The Effect Of Continuous Energy Restriction Vs Intermittent Fasting, With Resistance Training, On Lean Mass

Stephen Keenan¹, Matthew Cooke², Sam Wu¹, Ebrahim Bani Hassan³, Denny Meyer¹, Won Sun Chen¹, Josef Sullivan¹, Gustavo Duque³, Regina Belski¹. ¹Swinburne University of Technology, Melbourne, Australia. ²Swinburne University of Technology, Victoria University, Australian Institute for Musculoskeletal Science (AIMSS), Department of Medicine-Western Health, Melbourne Medical School, The University of Melbourne, Melbourne, Australia. ³Australian Institute for Musculoskeletal Science (AIMSS), Department of Medicine-Western Health, Melbourne Medical School, The University of Melbourne, Melbourne, Australia.

(No relevant relationships reported)

PURPOSE: To determine if two energy restricted diets (continuous energy restriction (CER) and 5:2 intermittent fasting (IF)) combined with resistance training (RT) results in lean body mass (LBM) retention while reducing bodyweight.

METHODS: Thirty-four young, untrained males and females were randomised to undertake the following diets for 12 weeks: CER (consume 80% of estimated energy requirements (EER) every day), or IF (consume approximately 30% of EER twice per week on fast days and 100% of EER every other day). Fast days included meals of protein shakes, a soup and vegetables. Both groups aimed to be isocaloric with an average energy restriction of 20% EER, and isonitrogenous consuming an average protein intake of 1.5 grams per kilogram of bodyweight per day. Both groups completed 2 supervised RT sessions and 1 unsupervised workout per week. The IF group completed their exercise on non-fast days. Body composition was assessed by dual x-ray absorptiometry. Data was analysed using an intention-to-treat linear mixed model, assuming AR(1) dependence across time. In addition, a change analysis was conducted for participants who completed both the baseline and 12 week assessments. **RESULTS:** For females, bodyweight was significantly reduced (mean decrease 3.1%, p=0.009), and LBM significantly increased (mean increase 5.8%, p<0.001), with no difference observed between diets. Similarly for men, there was no significant diet effect on bodyweight; both groups experienced an overall reduction of 6.3% (p<0.001). Combined, men in both diet groups experienced a significant increase in LBM (mean increase 1.4%, p=0.021), however there was a trend towards a greater increase in LBM in the IF compared to the CER group (mean increase CER = 0.7%, IF = 2.0%).

CONCLUSIONS: Across both diet groups, males and females experienced a significant reduction in bodyweight while, on average, increasing LBM. Neither diet was more effective for bodyweight reduction, however there was a trend towards greater LBM accrual in IF compared to CER males. Gender specific responses to

the intervention were evident, with a greater increase in LBM for females. Moderate energy restriction with high protein intake and RT can lead to concomitant weight loss and LBM accrual.

Impact Of Time-Restricted Feeding On Cardiometabolic Health And Performance Among Firefighters

Andrew E. Gonzalez¹, Mark G. Abel², Matthew J. McAllister¹. ¹Texas State University, San Marcos, TX. ²University of Kentucky, Lexington, KY.

Email: aeg96@txstate.edu

(No relevant relationships reported)

PURPOSE: Firefighters (FF) have an elevated risk for heart disease and sudden cardiac death (SCD) due to physiological and psychological stressors such as low cardiovascular fitness levels, disturbed sleep patterns, frequent snacking, smoke exposure, and intense physical exertion. Research suggests time-restricted feeding (TRF) may improve cardiometabolic health markers and performance variables. Therefore, the purpose of this study was to examine the effects of an 8-week TRF intervention on cardiometabolic health markers and performance variables.

METHODS: Twenty apparently healthy male professional structural FF completed a battery of health and fitness assessments prior to and following an 8-week TRF dietary intervention while performing a standardized resistance training program. The FF were assigned to either the normal diet (n=4) or TRF group (n=16) based on their preference. The TRF group followed a daily 14 hr fast vs. 10 hr feeding protocol.

RESULTS: Despite no interaction effect, there were significant improvements for both groups for push-ups completed (41.7 and 37.1 reps; p = 0.007) and ventilatory threshold in absolute (2.47L/min to 2.58L/min; p = 0.01) and relative (65.8%VO_{2peak} to 69.7%VO_{2peak}; p = 0.001) terms. The control group had significantly lower mean body fat percentage compared to the TRF group (14.27 and 20.5%, respectively; p < .0001). The TRF group had significantly higher VO_{2peak} values compared to the control group (3.80 L/min and 3.65 L/min, respectively; p = 0.016).

CONCLUSIONS: While TRF did not directly improve health or performance variables, the diet did not hinder health or performance outcomes. The standardized resistance training program resulted in improvements for muscular endurance and ventilatory threshold. The improved performance variables may result in reduced risk for heart disease and SCD while optimizing markers of performance.

The Effect Of Fasted Cycling Exercise At Different Times Of The Day In Overweight Individuals

Victoria J. McIver¹, Lewis R. Mattin², Gethin H. Evans², Adora M.W. Yau². ¹Northumbria University, Newcastle upon Tyne, United Kingdom. ²Manchester Metropolitan University, Manchester, United Kingdom. (Sponsor: Glyn Howatson, FACSM)

Email: victoria.mciver@northumbria.ac.uk

(No relevant relationships reported)

Intermittent fasting has become an increasingly popular intervention for metabolic health. Combining intermittent fasting with exercise may lead to benefits for weight management. **PURPOSE** To investigate the effect of fasted exercise at different times of the day on metabolic responses and appetite regulation in overweight males.

METHODS Twelve healthy males (Mean ± SD; age 26 ± 4 y; body fat 23 ± 2%) completed four, 60 min cycle ergometry trials at 60% VO_{2peak} in a randomised order; in the morning fasted (AMFAST), evening fasted (PMFAST) and after consuming a breakfast meal in the morning (AMFED) and evening (PMFED). Circulating levels of ghrelin, glucagon-like peptide-1 (GLP-1), pancreatic polypeptide (PP), peptide tyrosine tyrosine (PYY), insulin, triglycerides, non-esterified fatty acid (NEFA), glucose, and cholesterol were measured at baseline, post-breakfast, pre-exercise, post-exercise, pre-soup ingestion, then every 30 min post soup-ingestion for 2 h. Appetite was assessed at 15 min intervals throughout. Substrate utilisation was measured every 30 min and continuously throughout exercise. **RESULTS** Area under the curve (AUC) values for NEFA were greater in PMFAST compared to all trials (186.5 ± 46.3 vs. AMFAST 120.5 ± 42.6, AMFED 80.8 ± 23.8, PMFED 91.1 ± 36.4 mmol/L 4.75 h; P<0.05). AMFAST NEFA was also greater than AMFED (P=0.029). AUC values were greater for GLP-1 in AMFED trial compared to PMFAST (8660.2 ± 12232.5 vs 5967.0 ± 12027.5 mmol/L 4.75 h, P<0.05), and PP values for PMFED greater compared to all trials (155411.9 ± 86064.1 vs. AMFAST 90165.4 ± 90145.6, AMFED 107162.5 ± 72846.2, PMFAST 105364.0 ± 81320.2 mmol/L 4.75 h, P<0.05). A time of day effect was seen for cholesterol with PM greater than AM (P<0.05). Fat oxidation was greater during AMFAST and PMFAST exercise compared to FED trials (P<0.05). Ratings of appetite did not change between trials once all participants consumed the lunch meal post exercise (P>0.05). No differences were seen in AUC between trials for ghrelin, PYY, glucose or insulin. **CONCLUSION** Fasted exercise elicited greater NEFA responses, and some appetite hormones appear to respond differently to varying

exercise conditions and time of day in overweight males. Regardless of the time of day, fasted exercise favours fat metabolism and may induce a short-term negative energy balance.

3085 Board #6 May 29 3:15 PM - 5:15 PM
Changes In Fat And Carbohydrate Oxidation From Rest To Exercise After Different Fasting Lengths

Emma Ryan Thompson, James Brown, Kelly E. Johnson, Jakob D. Lauver, Justin P. Guilkey. *Coastal Carolina University, Conway, SC.*

Email: erthomp1@coastal.edu
 (No relevant relationships reported)

An overnight fast (10-12 hours) is a popular pre-exercise trial control in fuel use studies, but can lead to premature fatigue during exercise in participants. Measuring substrate oxidation at rest could be an alternative, but it is unclear how length of fasting effects fuel use responses from rest to during exercise. **PURPOSE:** The purpose was to examine the changes in fat (fatox) and carbohydrate (carbox) oxidation rates during rest and exercise after various fasting lengths. **METHODS:** Participants (24.5 ± 5.1 yrs) randomly performed 3 experimental trials. Trials were preceded by a standard meal (19.4 ± 1.8% of daily energy expenditure) followed by a fast for 12 hours (hrs), 3 hrs or 1 hr. Each trial consisted of 30 min of rest and 30 min of exercise at 55% of peak oxygen uptake (VO_{2peak}). VO_2 and carbon dioxide production (VCO_2) were averaged over the final 10 minutes of rest and exercise. The equations fatox = $1.695 * VO_2 - 1.70 * VCO_2$, and carbox = $4.585 * VCO_2 - 3.226 * VO_2$ were used to calculate oxidation rates ($g \cdot min^{-1}$). Two-way repeated measures (RM) ANOVAs and one-way RM ANOVAs analyzed differences. Significance was established if $p < 0.05$. **RESULTS:** Participants exercised at a similar VO_2 and % of VO_{2peak} in the 12hr (1.58 ± 0.28 L · min⁻¹; 56.8 ± 2.4 % of VO_{2peak}), 3hr (1.60 ± 0.30 L · min⁻¹; 57.7 ± 4.6 % of VO_{2peak}), and 1hr (1.64 ± 0.30 L · min⁻¹; 59.1 ± 1.7 % of VO_{2peak}). There was no significant interactions for fatox and carbox, but there were significant main effects of time. Fatox increased from rest to exercise in the 12hr (0.30 ± 0.04 $g \cdot min^{-1}$ vs. 7.34 ± 3.00 $g \cdot min^{-1}$), 3hr (0.30 ± 0.10 $g \cdot min^{-1}$ vs. 7.56 ± 3.53 $g \cdot min^{-1}$) and 1hr (0.34 ± 0.10 $g \cdot min^{-1}$ vs. 8.43 ± 4.00 $g \cdot min^{-1}$) trials. Additionally, carbox increased from rest (12 hr = 0.30 ± 0.07 $g \cdot min^{-1}$; 3hr = 0.27 ± 0.09 $g \cdot min^{-1}$; 1hr = 0.34 ± 0.10 $g \cdot min^{-1}$) to exercise (12hr = 1.92 ± 0.55 $g \cdot min^{-1}$; 3hr = 1.90 ± 0.64 $g \cdot min^{-1}$; 1hr = 2.18 ± 0.81 $g \cdot min^{-1}$). Relative percent changes from rest to during exercise were not different between 1hr, 3 hrs and 12 hrs for fatox (2489.1 ± 1008.9 % vs. 2257.5 ± 853.3 % vs. 2200.8 ± 901.7 %) or carbox (660.2 ± 294.8 % vs. 579.6 ± 231.2 % vs. 492.5 ± 241.9 %). **CONCLUSIONS:** Fatox and carbox responses from rest to exercise were similar between trials. This suggests that a standard meal and resting oxidation rates could control for differences in substrate use during exercise, regardless of fasting length.

Low Carbohydrate Availability, Not Energy Availability, Alters The Immune Response To Exercise In Elite Race-walkers

Alannah K.A McKay¹, Peter Peeling¹, David B. Pyne, FACSM², Nicolin Tee³, Ida A. Heikura³, Louise M. Burke, FACSM³.

¹University of Western Australia, Perth, Australia. ²University of Canberra, Canberra, Australia. ³Australian Institute of Sport, Canberra, Australia.

Email: alannah.mckay@ausport.gov.au
 (No relevant relationships reported)

PURPOSE: To compare the effects of a ketogenic low carbohydrate (CHO) high fat (LCHF) diet, and a low energy availability (LEA) diet, on innate immune response during a short-term training intervention in endurance athletes. **METHODS:** Twenty elite male race walkers completed one of three 5-7 day diet/training phases in a parallel groups design. During the initial 5 day Harmonization phase, all athletes consumed a high energy availability (HEA) diet equating to 40 kcal kg^{-1} fat free mass (FFM) day^{-1} . Athletes were then assigned to either a HEA (n=6), LCHF (<50 g CHO day^{-1} and isocaloric to HEA, n=7) or a LEA diet (15 kcal kg^{-1} FFM day^{-1} , n=7) for the 7 day Intervention phase. Subsequently, all athletes were placed back on a HEA diet for a further 5 days (Re-feed phase). On day 5 of each phase, athletes completed a 25 km hybrid laboratory-field race walk protocol at ~75% VO_{2max} . Venous blood samples were collected pre-, post-, and 1 h post-exercise and analyzed for serum ferritin, white blood cell counts, cortisol and blood glucose concentration. **RESULTS:** Serum ferritin decreased from Harmonization to Re-feed in all 3 groups (HEA: 30%, 20-40% (mean change, 95% CI); LCHF: 38%, 22-54%; LEA: 40%, 17-63%, $p < 0.01$), however, the magnitude of decrease was similar between groups. During the Intervention phase, the LCHF had a larger post-exercise increase in total white blood cells (67%, 61-72%), neutrophils (77%, 71-82%), monocytes (49%, 32-65%) and lymphocytes (41%, 31-51%) than both HEA ($p < 0.001$) and LEA ($p < 0.001$). Similarly, a small increase in cortisol (14%, -10-39%) and a decrease in blood glucose levels (46%, 18-74%) were evident during the post-exercise period during LCHF,

which was significantly different to, and occurred in the opposite direction to changes seen in HEA and LEA. No differences in any marker measured occurred between HEA and LEA, or between the Harmonization and Re-feed phases.

CONCLUSIONS: Adherence to a ketogenic LCHF diet for 5 days resulted in transient perturbations to the immune response to exercise, however, the LEA intervention did not influence immune markers. It appears that the acute restriction of CHO, rather than energy intake, has a more detrimental impact on the immune response to exercise in elite endurance athletes.

3087 Board #8 May 29 3:15 PM - 5:15 PM
The Effect Of Acute Carbohydrate Restriction On Squat Performance And Serum Energy Substrate Levels

Amber Normann, Abbey Brown, Kurt Escobar, Joshua Cotter, FACSM, Evan Schick. *California State University, Long Beach, Long Beach, CA.* (Sponsor: Dr. Joshua Cotter, FACSM)

(No relevant relationships reported)

Carbohydrate restrictive diets have become increasingly prevalent among recreational and professional athletes as a means of losing weight and improving body composition. Currently, few data indicate a clear relationship between carbohydrate restriction (CR) and performance in resistance exercise (RE). **Purpose:** To investigate the acute effects of CR on squat performance and serum energy substrate levels in recreationally trained individuals. **Methods:** Seven healthy recreationally trained males (22.6 ± 3.47 yrs., 80.74 ± 8.40 kg, 178.05 ± 5.00 cm) completed RE under two conditions in randomized order: 1) control (CON) and 2) a (CR) condition, which included a carbohydrate depletion exercise trial (CDEX). In CR, subjects first performed the CDEX, which consisted of 60 minutes of cycling at >75% of participants' heart rate (HR) max followed by four 1-minute bouts at >95% HR max with two minute rest in between sets. CDEX was then followed by 48 hours of reduced carbohydrate (CHO) intake (<5% daily caloric intake). RE in both CON and CR consisted of squats, loaded via inertial resistance using a Yo-Yo™ flywheel squat device. Fasting blood glucose and triglyceride (TG) levels were measured pre-exercise in both conditions as well as throughout the CDEX. **Results:** Total caloric intake was significantly ($p < 0.001$) lower during CR (mean ± SD: 1661.24 ± 691.6 kcal) compared to the CON (2433.85 ± 527.4 kcal). No differences were found in total grams of protein (PRO) or fat intake between conditions. Percent total daily caloric intake from CHO ($p < 0.001$) was significantly lower in the CR condition (7.40 ± 3.32% CHO), while percent total daily caloric intake from PRO and fat were significantly higher in the CR (32.90 ± 8.54% PRO, 58.17 ± 11.96% fat) compared to CON (37.81 ± 9.26% CHO, 20.03 ± 5.53% PRO, 37.47 ± 11.80% fat). Fasting blood glucose levels ($p = 0.017$) were significantly lower in the CR (84.57 ± 4.79 mg/dL) compared to the CON (93.28 ± 6.90 mg/dL) yet there was no difference in blood TG levels ($p = 0.177$; 64.43 ± 15.13 mg/dL vs. 59.29 ± 14.16 mg/dL). Total average power output ($p = 0.05$) and total peak power output ($p = 0.047$) were significantly lower in the CR. **Conclusion:** While CDEX combined with CR may acutely reduce fasting blood glucose, this may be at the sacrifice of RE performance, especially during the initial phase of CR adaptation.

Cognitive Reappraisal Enhances Affective Valence During Exercise At The Ventilatory Threshold
 Kell Grandjean da Costa¹, Heather L. Urry¹, Eduardo Bodnariuc Fontes², Grace Elliott¹, Grace E. Giles³. ¹Tufts University, Medford, MA. ²Federal University of Rio Grande do Norte, Natal, Brazil. ³U.S. Army CDC-Soldier Center, Natick, MA.
 Email: kellgrandjean@gmail.com
(No relevant relationships reported)

Affective valence during exercise is thought to switch between positive and negative at the ventilatory threshold (VT), the upper boundary of “moderate” intensity exercise. Cognitive strategies may shift the exercise intensity at which affective responses are positive and negative. The emotion regulation strategy cognitive reappraisal (CR) involves reevaluating emotional stimuli to reduce negative and increase positive emotional experience. **PURPOSE:** Here we investigated if cognitive reappraisal would increase emotional valence, demonstrated by higher scores on the feeling scale (FS), and reduce felt arousal scale (FAS) scores and ratings of perceived exertion (RPE) during 60-min of exercise performed at the VT. **METHODS:** 26 young recreational runners (n = 13 women, Age 25.4 ± 4.3 years old; BMI 21.3 ± 2.3 kg/m²; maximal oxygen consumption (VO₂max) = 55.02 ± 7.31 ml/kg/min) performed three sessions each separated by one week. During the first session, runners performed a maximal exertion test on a treadmill to assess their VO₂max and VT. During the next two sessions, runners were trained in CR or UR (unregulated) instructions, in counterbalanced order. They then ran at their VT for 60 minutes, during which they were reminded of the emotion regulation instructions and were instructed to provide RPE, FS, and FAS during the last 30 seconds of every 10-minute period. FS, FAS, RPE were analyzed for main effects of time and condition with non-parametric repeated measures (Friedman test) with post-hoc pairwise comparisons of Durbin-Conover test. **RESULTS:** Runners ran at VT velocity of 6.92 ± 0.46 mph corresponding to 46.8 ± 5.2 % of the VO₂ max. Similar levels of RPE were reported during the CR, 11.74 ± 1.64, and UR, 11.82 ± 1.88, sessions. However, they reported marginally higher FAS during CR, 2.9 ± 0.98, than UR, 2.6 ± 0.95, X²=20.3; df=11, p=0.042. They also reported higher FS during CR, 2.54 ± 1.47, than UR, 2.1 ± 1.52, X²=65.2; df=15, p<0.001. Post-hoc analysis showed that FS was higher during CR than UR (p<0.01) only at time points 30 (CR: 2.57 ± 1.4 vs UR 1.84 ± 1.65), 40 (CR: 2.53 ± 1.54 vs UR 1.76 ± 1.57) and 50 (CR: 2.57 ± 1.52 vs UR 1.88 ± 1.73) minutes of exercise. **CONCLUSION:** Cognitive reappraisal can be used as a strategy to increase emotional valence after 30 min of exercise at light to moderate intensity in recreational runners.

Strong evidence shows that physical activity (PA) affects the structure of the nervous system and can improve cognitive function (CF) in older adults. Additionally, recent studies have shown that a healthy diet may protect against aging-related impairments in hippocampal structure or function. **PURPOSE:** To investigate the influence of PA and adherence to dietary guidelines on CF in a sample of healthy older adults. **METHODS:** Demographics, habitual PA (Baecke’s Questionnaire Sport score), and cognitive function (Montreal Cognitive Assessment; MoCA) were collected at consent in a sample of 359 healthy adults (50-75 years) in a memory function study. Dietary

guidelines adherence (Alternate Healthy Eating Index 2010; aHEI), and two indices of cognitive function (Modified Benton Recognition Task (ModBent) and Modified Rey Auditory Verbal Learning Test (ModRey) were collected in the randomized subsample of these participants (N=211).

The relationship between lifestyle factors and three outcomes (MoCA, ModBent, ModRey) were assessed using Pearson correlations in the full sample and subsample. Linear models were fit for MoCA on the full sample, and for each of the three outcomes on the randomized subsample. Each series of models included age, gender, and education. PA and aHEI scores were then added to each model and their standardized regression coefficients (change in R²) were assessed to determine whether they contributed additional predictive value towards CF.

RESULTS: In the full sample, the correlation between MoCA total score and PA was weak (r = .111). In the subsample, correlations between aHEI and MoCA and between aHEI and ModRey were also weak (r = .175 and r = .141, respectively). Correlations between PA and aHEI and between age and ModRey were weak (r = .222 and r = -.219, respectively). Adding PA or aHEI did not significantly explain a greater proportion of variance in cognitive task scores beyond demographic factors alone. **CONCLUSIONS:** In an older adult population, there is a weak direct relationship between performance on CF tasks and lifestyle factors. Reviewing the individual standardized regression coefficients finds that education and age were the most sensitive to changes in CF task scores, and adherence to dietary guidelines was more sensitive than a measure of habitual PA.

Does An Acute Bout Of Aerobic Exercise Bolster Reactivity To A Sad Mood Induction In Clinically Depressed Individuals? A Study Of Responders And Non-responders
 Anthony J. Bocchine¹, CJ Brush², Andrew A. Ude¹, Gregory H. Pappas¹, Kelsey L. Piersol¹, Brandon L. Alderman¹.

 Email: ajb376@scarletmail.rutgers.edu
(No relevant relationships reported)

Major depressive disorder (MDD) is a debilitating mental health condition that presents a major public health burden. Respiratory sinus arrhythmia (RSA) reactivity has been proposed as an index of impaired emotion and self-regulation in depression. Acute exercise has consistently been shown to improve affect, but it is unknown whether exercise affects RSA reactivity to emotional challenge. In addition, previous studies have not addressed nonresponse to sad emotion inductions, which limits understanding of important individual differences in affective processing. **PURPOSE:** To determine the effects of a single bout of moderate-intensity aerobic exercise on RSA and affective responses to a sad mood induction. Additionally, to characterize responders and non-responders to the sad mood paradigm and whether acute exercise impacts emotional responding to the emotion induction paradigm. **METHODS:** Using a within-subjects design, young adults diagnosed with MDD completed a 30-min exercise and sedentary control session in counterbalanced order on two separate days. Following a recovery period, RSA reactivity was assessed using electrocardiography (ECG) during a 3-min sad mood induction. The Positive and Negative Affect Scale (PANAS) was used to assess affective responses throughout each session and sadness to the mood induction was assessed on a 9-point Likert scale. **RESULTS:** Individuals with depression demonstrated dampened RSA withdrawal during the sedentary control day. Following exercise, RSA withdrawal increased, p < .05, although post-exercise changes in NA and PA were not related to neurocardiac reactivity to the sadness induction. There were significantly more responders than non-responders to the mood induction following the exercise condition, p < .05. **CONCLUSIONS:** These findings indicate that acute aerobic exercise may be an effective approach to increase emotional regulation and behavioral flexibility in clinically depressed individuals. Future research should continue to examine individual differences in emotional responding as well as investigating who will successfully respond to exercise treatment.

(No relevant relationships reported)

PURPOSE: To investigate the correlation between individual parameters (age, body composition, and inflammation) and cognitive performance. **METHOD:** Fifty-six healthy women (age range: 20–60 yrs) were recruited and completed four cognitive tests, including attention, speedup test, Stroop tests (word, square, congruent,

incongruent, and neutral conditions), and memory span test. All cognition tests were conducted in a counter-balanced order. Blood samples were collected to determine the ratio of neutrophil and lymphocyte (NLR) and the ratio of platelet and lymphocyte (PLR) which were considered as indicators of inflammation. The body composition was measured by using Dual Energy X-ray Absorptiometry. The correlation between age, body composition, inflammatory factors, and cognitive variables was analyzed by Pearson's correlation coefficient (r). $P < 0.05$ was considered statistically significant. **RESULTS:** There were negative correlation between age and attention test ($r = -0.47$, $p < 0.005$), Stroop tests (word: $r = -0.65$, $p < 0.001$; square: $r = -0.69$, $p < 0.001$; congruent: $r = -0.61$, $p < 0.001$; incongruent: $r = -0.70$, $p < 0.001$; neutral: $r = -0.70$, $p < 0.001$). The results also showed that the higher the body fat % (BF%), the worse the cognitive test performance (attention test, $r = 0.46$, $p < 0.005$; Stroop's word tests, $r = 0.49$, $p < 0.005$; Stroop's square test, $r = 0.61$, $p < 0.001$; Stroop's congruent test, $r = 0.44$, $p < 0.01$; Stroop's incongruent, $r = 0.56$, $p < 0.001$; Stroop's neutral test, $r = 0.59$, $p < 0.001$). Similarly, the higher the body lean mass (BLM%), the better the cognitive test performance. There was positive correlation between age, NLR and PLR, but there was no significant correlation between inflammatory markers and cognitive performance. Furthermore, after controlled age, although the above net correlation was eliminated, the correlation between Stroop's square test and BF% ($r = -0.343$, $p = 0.035$), square and BLM% ($r = -0.334$, $p = 0.040$), neutral test and BLM% ($r = 0.32$, $p = 0.050$) still exists. Besides, after controlled BF%, the age-related correlation effects are unchanged, and only the correlation between BLM% and the speed of answering represent significant ($r = 0.393$, $p < 0.015$). **CONCLUSION:** In addition to age, body fat is an important factor affecting cognitive performance. Exercise-Based Cardiac Rehabilitation Improves Cognitive Function Among CVD Patients

Terence Moriarty¹, Kelsey Bourbeau², Christine Mermier², Len Kravitz², Ann Gibson, FACSM², Nicholas Beltz³, Omar Negrete², Micah Zuhl⁴. ¹University of Northern Iowa, Cedar Falls, IA. ²University of New Mexico, Albuquerque, NM. ³University of Wisconsin-Eau Claire, Eau Claire, WI. ⁴Central Michigan University, Mount Pleasant, MI.
Email: terence.moriarty@uni.edu
(No relevant relationships reported)

PURPOSE: To investigate the effects of cardiac rehabilitation (CR) exercise training on cognitive performance and if the changes are associated with alterations in prefrontal cortex (PFC) oxygenation among patients with cardiovascular disease (CVD). **METHODS:** Twenty (M=15, F=5; 64.8±11.6 yrs) participants from an outpatient CR program were enrolled in the study. Each participant completed a cognitive performance test battery (the NIH Fluid Cognition test battery which measured 5 cognitive constructs) and a submaximal graded treadmill evaluation (a measure of cardiorespiratory capacity) on separate occasions at pre and again upon completion of 18 individualized CR sessions (approximately 6 weeks later). A functional near-infrared spectroscopy (fNIRS) device was used to measure left- and right- PFC (LPFC and RPPFC) oxygenation parameters (O₂Hb = oxyhemoglobin, HHb = deoxyhemoglobin, tHb = total hemoglobin, Hbdiff = oxyhemoglobin difference) during the NIH Fluid Cognition evaluation. **RESULTS:** Patients showed improvements in cardiorespiratory capacity (increased by 1.4 METs) and various cognitive constructs (processing speed, attention, executive function, and working memory scores). A significant increase in PFC oxygenation, primarily in the LPFC region, occurred at post-CR test (in four of the five cognitive tests). Correlation analyses revealed negative associations between changes in cognition (executive function (LPFC O₂Hb: $r = -0.445$, $p = 0.049$; LPFC tHb: $r = -0.487$, $p = .030$) and fluid composite score (RPPFC Hbdiff: $r = -0.467$, $p = 0.038$; LPFC Hbdiff: $r = -0.447$, $p = .048$)) and PFC changes. The change in cardiorespiratory capacity was positively associated with the change in working memory score ($r = 0.546$, $p = 0.016$). **CONCLUSION:** CVD patients enrolled in CR showed significant improvements in multiple cognitive domains along with increased cortical activation. The negative associations between cognitive functioning and PFC oxygenation suggest an improved neural efficiency, which is identified as higher cognitive performance for a given (or reduced) amount of cortical activation.

IMPACT OF AUTONOMY ON ENJOYMENT AND AFFECTIVE VALENCE DURING HIGH-INTENSITY INTERVAL TRAINING

Marcus W. Kilpatrick, FACSM¹, Gianna F. Mastrofini¹, Lauren A. Hudson¹, Alanis P. Rosado¹, Chelsea M. Aggor¹, Ralph C. Tauran¹, Abby R. Fleming². ¹University of South Florida, Tampa, FL. ²University of Alabama, Tuscaloosa, AL.
Email: mkilpatrick@usf.edu
(No relevant relationships reported)

High-intensity interval training (HIIT) is a popular modality for conducting intense aerobic exercise. Research indicates that HIIT is generally well-tolerated and produces relatively positive affective valence and enjoyment responses, especially when compared to intense continuous exercise. Recent research has started considering how autonomy and choice might impact psychological responses to HIIT. **PURPOSE:** The purpose of this study was to determine the impact of autonomy and variation on enjoyment and affective valence during HIIT exercise. **METHODS:** Twenty-one physically active participants (12 male, 9 female; mean BMI = 27 ± 3 ; mean age = 28 ± 6) completed three, 20-minute HIIT trials after completion of maximal testing. Work and recovery were conducted at 90% and 10% of peak work, respectively. All trials included a total of 10 minutes of work and 10 minutes of recovery. Trials included: a standard interval bout with repeating 60-sec work and recovery segments (Traditional), an interval bout with a mix of predetermined 30-, 60-, 90-, & 120-second segments (Varied), and a bout with a self-selected number of 30-, 60-, 90-, & 120-second segments (Autonomous). In-task affective valence and enjoyment were measured four times during work and recovery. Data was analyzed using ANOVA. **RESULTS:** Affective valence declined during the Traditional and Varied trials (-0.75 units; $P < 0.05$) but not during the Autonomous trial ($P > 0.05$). There was also a trend for the Autonomous trial to produce greater pleasure than the Traditional or Varied trials (-0.5 units; $P = 0.06$). Enjoyment increased during the trials (-0.5 units; $P < 0.05$) and enjoyment was higher in the Autonomous trial than the Varied trial (-0.5 units; $P < 0.05$). **CONCLUSIONS:** Findings indicate that all HIIT trials produced at least moderate levels of pleasure and enjoyment, with Autonomous HIIT resulting in the most desirable responses, especially when compared to Varied HIIT. These findings suggest that HIIT sessions that include self-selected interval durations can produce more positive responses, which provides the basis for recommending autonomy for exercisers participating in HIIT exercise sessions.

The Sustained Effects Of Acute Aerobic Exercise On Inhibitory Control In Children With ADHD

Shu-Shih Hsieh¹, Chien-Lin Yu², Ting-Yu Chueh², Yu-Jung Tsai², Charles H. Hillman¹, Tsung-Min Hung². ¹Northeastern University, Boston, MA. ²National Taiwan Normal University, Taipei, Taiwan.
(No relevant relationships reported)

Despite mounting evidence supporting the beneficial effects of acute aerobic exercise on cognitive control in children with attention-deficit/hyperactivity disorder (ADHD), little is known regarding the sustained effect of acute aerobic exercise. **PURPOSE:** To examine the sustained effects of a single bout of aerobic exercise on inhibitory control in children with ADHD. **METHODS:** Twenty-four children diagnosed with ADHD (mean age = 9.8 ± 1.3 years; 23 boys) underwent a moderate-intensity (60% of heart rate reserve) aerobic exercise session and a video-watching session in counterbalanced order. Following the exercise/video-watching session, each participant was administered congruent and incongruent trials from a modified flanker task under electroencephalography (EEG) at 30 minutes and 60 minutes following intervention. Response accuracy, reaction times (RT), and standard deviation of RT (SDRT) were reported as behavioral outcomes, and the P3 component of an event-related brain potential (P3-ERP) was collected as a measure of brain function. A 3-way repeated-measure ANOVAs was used to analyze behavioral and P3-ERP data. **RESULTS:** Higher response accuracy was observed following exercise relative to video-watching across both time points and trial types (Exercise: $90.5 \pm 6.2\%$ vs. Video: $84.1 \pm 11.1\%$, $p = .002$). SDRT, an index of response variability, was smaller during congruent trials following exercise compared to video-watching at the 30-minute time point (Exercise: 129.8 ± 27.4 ms vs. Video: 142.2 ± 32.9 ms, $p = .04$). Further, P3-ERP latency at the parietal site (Pz) was shorter following exercise relative to video-watching across trial types at the 30-minute time point (Exercise: 426.9 ± 71.5 ms vs. Video: 517.9 ± 62.5 ms, $p < .001$). **CONCLUSION:** The data suggest that the beneficial effects of acute, moderate-intensity exercise are only sustained for about 30-40 minutes following exercise cessation in children with ADHD. Such a finding differs from typically developing children, who demonstrate acute exercise benefits to brain and

cognition for approximately 60-70 minutes. Future research should provide a more direct comparison to better understand the sustained effects of acute exercise across different populations of children.

(No relevant relationships reported)

PURPOSE: People with Parkinson's disease (PD) have impaired balance during walking that contributes to reduced physical activity and lower quality of life.

Overground locomotor training (OLT) is one method to improve dynamic balance for people with PD during walking. The purpose of this study is to examine the effect of an OLT program on dynamic balance during overground walking in people with PD.

METHODS: Five participants with PD (age: 68.9±6.7 yrs) were enrolled in a 12-week OLT program with an emphasis on power, stepping and stability within all planes of movement. Participants completed a 10-minute walk test (10MWT) overground wearing portable tri-axial motion sensors at baseline (PRE) and after (POST) intervention. Temporospatial data were collected pre- and post-intervention to obtain time in double limb support (TDLS) and calculate gait stability ratio (GSR) during the 10MWT. TDLS represents one's strategy for maintaining dynamic balance during gait. GSR is the ratio between number steps per minute and gait velocity. For both TDLS and GSR, lower values following intervention represent improved dynamic balance during walking. Gait characteristics were analyzed separately for each limb using paired Student's *t* tests.

RESULTS: Average TDLS was reduced for both limbs after intervention (PRE (L: 18.88±3.03; R: 18.89±3.04%); POST (L: 15.10±2.66; R: 15.11±2.68), *p*<.001). GSR improved following intervention (PRE (L: 82.83±9.58; R: 82.61±8.83); POST (L: 79.41±6.52; R: 78.88±6.54) *p*<.05).

CONCLUSION: Individuals with PD demonstrated improved dynamic balance during walking following the 12-week intervention. Decreased TDLS and GSR are gait characteristics that provide an opportunity to increase physical activity and improve quality of life. Incorporating OLT with multiplanar movements and stepping strategies should be considered as a treatment strategy to address impaired dynamic balance in people with PD.

Do Individualized Physical Therapy Interventions Improve Balance And Gait Initiation In Persons With Parkinson'S Disease?

Krista Nunn¹, Natalie Atwood¹, Hemang Shah², Crystal Ramsey¹, Srikant Vallabhajosula¹. ¹*Elon University, Elon, NC.* ²*Duke University, Durham, NC.* (Sponsor: Dr. Stephen Bailey, FACSM)
Email: knunn2@elon.edu

(No relevant relationships reported)

Resting tremor, bradykinesia, rigidity, and loss of postural reflexes are the cardinal signs of Parkinson's disease (PD). Persons with PD frequently have balance impairments and postural instability which correlates with the increase in fractures and soft tissue injuries when compared to age-matched peers without PD. Persons with PD also frequently present with increased postural sway during quiet stance in addition to impaired weight shifting when transitioning between states of static and dynamic equilibrium such as during gait initiation and termination. Previous intervention studies lasting at least 12 weeks implemented a variety of methodologies such as strength training, aerobic training, tai chi, and dance therapy and produced

long-term benefits. Previous studies are inconclusive whether a multi-faceted approach for physical therapy intervention based on preferences of the participants will affect balance and gait initiation in those persons with PD. **PURPOSE:** To investigate if 12 weeks of individualized and supervised physical therapy intervention improves balance and gait initiation in persons with PD. **METHODS:** Six adults diagnosed with mild to moderate PD (mean age= 68.8 years±10.3 years), Hoehn and Yahr Levels I-III (Level I, n=2) (Level II, n=3) (Level III, n=1) participated in a 12-week program. The interventions were tailored to address functional deficits and participants' goals. Pre- (PRE) and post-testing (POST) included the Mini-BESTest, which measures 4 balance control systems. Gait initiation assessments were also performed as the participants voluntarily initiated gait from a quiet stance position on force plates. A paired sample *t*-test was used to compare PRE and POST. **RESULTS:** Four participants met or exceeded the minimal clinically important difference for the Mini-BESTest. The Mini-BESTest scores improved significantly (PRE, 18.5±5.8; POST, 24.7±3.5; *p*=0.021). There was no significant change in gait initiation parameters related to center of pressure movement. **CONCLUSION:** The 12-week individualized and supervised physical therapy program improved dynamic and static balance, but not gait initiation. The intervention was individualized towards the functional deficits and goals that were obtained in pre-testing. A limitation for this study was the small sample size.

Improved Coordination And Coordination Variability In Response To Deep Brain Stimulation In Individuals With Parkinson's Disease

Alexis K. Nelson¹, Hailey B. Fong¹, Clinton J. Wutzke², Alexandra Schaller³, David O'Reilly⁴, Douglas W. Powell, FACSM¹. ¹*University of Memphis, Memphis, TN.* ²*Department of Rehabilitation Science, Fairfax, VA.* ³*University of Tennessee Health Science Center, Memphis, TN.* ⁴*Central Remedial Clinic, Dublin, Ireland.* (Sponsor: Douglas Powell, FACSM)

(No relevant relationships reported)

Parkinson's disease (PD) is a progressive neurodegenerative disease associated with motor impairments. Deep brain stimulation (DBS) is associated with vast improvements in the motor symptoms of PD. Recent evidence has identified improvements in movement complexity during treadmill walking in response to DBS [1]. However, the effects of DBS on gait coordination have not been well elucidated. **PURPOSE:** to evaluate the effects of DBS on ankle and knee joint coordination and coordination variability during a treadmill walking task. **METHODS:** Five individuals with PD performed a four-minute treadmill walking task while 3D kinematics were collected over two 30-s periods. Participants completed testing in the DBS-ON followed by DBS-OFF conditions to avoid the confounding factor of fatigue. Kinematics were recorded simultaneously using an 9-camera motion capture system (120 Hz, Qualisys Inc., Goteburg, Sweden). Visual 3D was used to calculate segmental angles and velocities. Custom software (MATLAB, MathWorks) calculated continuous relative phase angles. Mean absolute relative phase (MARP) and deviation phase (DP) were used to quantify joint coordination (MARP) and coordination variability (DP). A paired samples *t*-test was used to determine the effects of DBS on MARP and DP. **RESULTS:** At the ankle, DBS was associated with greater MARP values (*p*=0.016; DBS-ON: 3.2±1.5; DBS-OFF: 2.1±0.9) and DP values (*p*=0.047; DBS-ON: 2.2±1.0; DBS-OFF: 1.4±0.4). At the knee, DBS was associated with greater MARP (*p*=0.021; DBS-ON: 6.8±2.8; DBS-OFF: 5.1±2.8) and DP values (*p*=0.045; DBS-ON: 2.9±1.5; DBS-OFF: 2.0±0.6). **CONCLUSIONS:** DBS allows individuals with PD to perform walking tasks with greater freedom of coordination and coordination variability. Increased availability of coordinative patterns may represent a greater number of successful strategies available to the system to optimize mechanical and metabolic efficiency during walking.

Effects Of Motor Timing Training On Golf Swing Motion In Parkinson's Disease.

Jin hyun Kim, Zach Lemke, Younguk Kim, Angela Ridgel, FACSM. *Kent State University, Kent, OH.* (Sponsor: Angela Ridgel, FACSM)
Email: jkim74@kent.edu

(No relevant relationships reported)

Individuals with Parkinson's disease often show deficits in motor timing, specifically during tasks that require rhythmic motor patterns such as gait and finger tapping. However, it is not clear if rehabilitation training that focuses on improving motor timing can improve rhythmicity during coordinated movements. In this study, we utilized a computer-based rehabilitation tool, called Motor Timing training (MT), which trains individuals to improve motor timing by reacting to an auditory or visual reference cue. Changes in motor timing and coordination were measured using a golf swing motion. **PURPOSE:** The purpose of this study was to examine if MT training with golf swing motion improves motor timing in Parkinson's disease.

METHODS: Participants completed 12 MT sessions, three times weekly training for 4 weeks. The aim of each session was to perform the golf swing motion to match the audible beat. Visual feedback was given to the participants to encourage them to hit the 'target zone' (± 15 ms) during the golf swing. Motor timing was assessed using the Long Form Assessment (LFA) which evaluated timing and accuracy during fourteen movement tasks of the hands and feet. A wireless kinematic sensor system was utilized to measure pelvic acceleration in 3 axes (X, Y, Z) during the backswing and down swing. To determine variation of pelvic movement, the coefficient of variation (CV) were applied for analyzing the data. Paired t-test were used to compare pre- and post-intervention measures. **RESULTS:** There was a significant difference between pre-post training in the pelvis of X-axis on the back swing [$t=2.783$, $p=.039$] and there was a significant difference between pre-post training in the pelvis of Y-axis on the down swing [$t=3.873$, $p=.012$]. Motor timing also showed significant improvements as measured with LFA [$t=3.102$, $p=.027$]. **CONCLUSIONS:** These results suggest that MT training can improve motor timing and reduce the variation of pelvis movement during the golf swing in Parkinson's disease. In light of these findings, future studies will also examine if MT training promotes improved motor timing and golf swing mechanics in individuals who show impaired range of motion.

Effects Of Motor Timing Training On The Golf Performance In Parkinson'S Disease

Younguk Kim, Jin Hyun Kim, Zachary Lemke, Angela L. Ridgel, FACSM. *Kent State University, Kent, OH.* (Sponsor: Angela L. Ridgel, FACSM)
Email: ykim38@kent.edu
(No relevant relationships reported)

BACKGROUND: Motor timing is essential for improving motor skills and it is a critical factor to determine the success in a golf swing. However, individuals with Parkinson's disease have deficits in motor timing due to bradykinesia, tremor, and rigidity. Rehabilitative training that employs a metronome beat to set a rhythm (Interactive Metronome) could provide rehabilitative training to improvement in motor timing and variability in golf performance. **PURPOSE:** The purpose of this study is to investigate the effects of 10 sessions of Interactive Metronome training on motor timing and variability in the golf performance of older adults with Parkinson's disease. **METHODS:** The participants with Parkinson's disease completed 10 sessions, 35-40 minutes per session, three times a week for 4 weeks. The speed and tempo of the golf swing with a seven iron were measured. Motor timing was analyzed by using Long Form Assessment (LFA) which evaluates timing and accuracy when performing movement tasks of the hands and feet. The speed and tempo data were obtained using a golf simulator. Paired sample t-test was used to compare the pre and post measure outcomes. **RESULTS:** After 10 sessions, there was a significant improvement in motor timing between pre-post testing (pre: 158.16 ± 75.05 , post: 94.66 ± 67.76 , $t=3.102$, $p=0.027$). However, tempo variability (pre: 22.81 ± 14.00 , post: 11.05 ± 7.16 , $t=1.739$, $p=0.143$) and speed variability (pre: 5.99 ± 3.58 , post: 4.49 ± 1.81 , $t=-.721$, $p=0.503$) were not significantly different. **CONCLUSION:** These findings indicate that Interactive metronome training can promote improvements in motor timing and golf performance in older adults with Parkinson's disease. In addition, motor timing training could be widely utilized along with the exercise to reduce the symptoms of Parkinson's disease.

Sample Entropy Analysis Of Dance Interventions In People With Parkinson's Disease And Older Adults

Zachary C. Lemke¹, Peter Gates¹, Jin Hyun Kim¹, Fred Disenozo², Angela L. Ridgel, FACSM¹. ¹*Kent State University, Kent, OH.* ²*Retired, Brecksville, OH.* (Sponsor: Angela L. Ridgel, FACSM)
Email: zlemke@kent.edu
(No relevant relationships reported)

Dance comprises a broad range of techniques and styles, which have been utilized in classes specifically designed for individuals with Parkinson's disease (PD) and healthy older adults (OA). Previous studies have shown that a series of dance sessions can improve balance, posture, and gait for people diagnosed with PD and healthy older adults. However, these studies have not analyzed the features of body limb movement during dance. Sample Entropy (SamEn) analysis can be used to examine the complexity of movements in order to provide direction in the development of optimal dance interventions for these populations. **PURPOSE:** To identify dance movement patterns resulting in the greatest improvement in tests of gait, balance and upper extremity function using partnered and non-partnered dance to music in PD and OA. We hypothesize that entropy-driven variation in movement will enhance improvements in motor performance and that PD participants will show greater sample entropy during dance than OA participants. **METHODS:** Participants with and without PD participating in structured group dance classes were recruited for this study. Motion capture was used to examine movement patterns and sample entropy analysis was used to calculate the complexity of movements during dance. **RESULTS:** Participants with

PD had a greater spread of SamEn in left hip abduction during tango movements than right hip abduction ($p < 0.0001$). A greater SamEn in right hip rotation during tango movements than left hip rotation ($p < 0.0001$) was seen during tango but no significant difference during fox trot. Furthermore, PD group had no significant difference in left/right knee flexion SamEn during tango but left knee flexion SamEn was higher during fox trot than right knee flexion SamEn ($p = 0.006$). OA participants saw a much smaller, but still significant, spread in SamEn in left hip abduction during Tango than right hip abduction ($p = 0.002$), with no significant difference in hip rotation SamEn. **CONCLUSION:** We interpret our entropy results as showing a decrease in PD left hip abduction control compared to the right hip during tango. Our PD participants reported that the left side was more affected. These types of data could be used to optimize dance interventions in regards to dance type, music beat/rhythm in order to improve limb control.

Relationship Between Lower Extremity Muscle Function And Gait Variability In Individuals With PD

Jared W. Skinner¹, Chris J. Hass, FACSM². ¹*Appalachian State University, Boone, NC.* ²*University of Florida, Gainesville, FL.* (Sponsor: Scott Collier, FACSM)
Email: skinnerjw@appstate.edu
(No relevant relationships reported)

PURPOSE: Increased variability in motor function can significantly impair performing activities of daily living. The difficulty in performing daily motor tasks is increased in pathological populations, e.g., Parkinson's disease (PD). The muscular capabilities, e.g., torque production and force control, in PD, are reduced compared to older adults. It is unclear if the reduced muscular capabilities in PD are related to increased difficulty performing regular movements, i.e., gait. This study examined the relationship between muscular capabilities of the lower extremity and gait variability in persons with PD.

METHODS: 12 PD and 11 age-matched controls underwent gait and lower extremity muscle testing. Gait was evaluated by having the subjects perform ten over-ground walking trials over a 9-m walkway at a self-selected speed using an 8-camera motion capture system. Linear measures of gait, including stride length, stride time, step width, and velocity, were calculated. Gait variability and force variability were examined using the coefficient of variation ($CV = \text{standard deviation}/\text{mean} \times 100\%$). Lower extremity testing consisted of 1) maximal isometric torque production and 2) submaximal force control using a tracing paradigm at 5, 10, and 20% of their maximal torque production in multiple directions at the hip and ankle. Pearson's correlations were applied to analyze associations between gait variability and force variability. **RESULTS:** In the PD group, stride time was positively correlated with 20% of ankle dorsiflexion CV ($r(21)=.62$, $p<.05$) and velocity was positively correlated with 10 and 20% of ankle plantarflexion CV ($r(21)=.59$, $p<.05$) and 20% of hip extension CV ($r(21)=.63$, $p<.05$). Maximal torque production of the dorsiflexors ($r(21)=.75$, $p<.05$) and plantar flexors ($r(21)=.67$, $p<.05$) were positively correlated stride time variability in the PD group.

CONCLUSION: The results highlight an association between lower-extremity muscle function and gait function in PD. Interestingly, in those with PD, both maximal strength and control of muscle strength were found to be related to the temporal parameters of gait variability. These results suggest that gait dysfunction could be the result of specific pathological impairments and provide unique opportunities for specialized interventions.

F-36 Thematic Poster - Sex Differences During Exercise Hyperthermia and Stress

Sex Differences In Physical Performance Under Simulated Military Operational Stress

Phil J. Agostinelli. *University of Pittsburgh, Pittsburgh, PA.* (Sponsor: Bradley C. Nindl, FACSM)
(No relevant relationships reported)

PURPOSE: Military personnel are in a constant effort to maintain operationally specific physical performance under high levels of stress. Physical exertion, cognitive

overload, sleep deprivation, and caloric restriction are all factors of operational stress in the military. This study aims to investigate how Simulated Military Operational Stress (SMOS) effects performance on the operationally relevant tasks both in men and women. **METHODS:** As part of an ongoing study; Forty male soldiers (26±5yrs, 176±8cm, 85±15kg, 20±7%BF) and eleven female soldiers (25±5yrs, 167±12 cm, 63±6kg, 26±7%BF) completed a SMOS protocol lasting 5 days (D) and nights (N). Days 3 & 4 (D3, D4), subjects consumed 50% of caloric demands. N1, 2, & 5 (D1, D2, and D5) subjects slept from 2300-0700. N3-4, subjects slept from 0100-0300 and 0500-0700. Familiarization was completed D1. During D2 & 5 participants underwent a Tactical Mobility Test (TMT), consisting of the following: 2-min water can carry (WCC) (20 kg each hand), fire & movement course, 20-m casualty drag (CD) (91kg), 300-m shuttle run unloaded (SRU) and loaded (SRL) (16 kg), 2-mi paced, and 2-mi best effort timed ruck march (RM) (15 kg). Two-way mixed ANOVAs with Bonferroni Post Hoc ($p < 0.05$) were used to identify if the difference in TMT performance form D2-5 was different between men and women. **RESULTS:** Regardless of sex a main effect for SRU across days was found. SRU increased by 6% from D2 to D4 and D5 (D2: 97.2±20, D4:103.3±22.8, $p=0.047$; D5: 103.5±18.8, $p=0.011$); additionally, D5 increased by 4% from D3 (D5: 103.5±18.8, D3: 99.3±20.2; $p=0.047$). **CONCLUSION:** Short-term exposure to military operational stress leads to a decline in anaerobic capacity; regardless of sex. Operational tasks involving muscular strength, endurance, and aerobic endurance such as the WCC, CD, and RM were well maintained over 5-days of during SMOS equally between men and women. The preliminary findings of this study suggest simulated military operational stress effects women and men equally. Future investigation with a larger sample size is needed. This study was funded by the Department of Defense (Award # W81XWH-17-2-0070). The results and opinions herein are those of the authors and do not necessarily constitute endorsement of the Department of Defense.

Females Have An Increased Sensitivity To Thermal Stress During Matched Exercise Metabolic Heat Production
Lauren Schoech, Kyleigh Allie, Paolo Salvador, Mauricio Martinez, Eric Rivas. *Texas Tech University, Lubbock, TX.* (Sponsor: Oscar Suman, FACSM)
Email: lauren.schoech@ttu.edu
(No relevant relationships reported)

PURPOSE: Females report greater sensitivity in cold compared to hot conditions. However, it is unclear how thermal sensitivity is affected when the change for internal temperature (ΔT_{in}) and metabolic heat production (MHprod) are matched. This project tested the hypothesis that females have enhanced sensitivity to thermal stress during exercise hyperthermia when ΔT_{in} and MHprod is matched. **METHODS:** Twenty-two healthy active (7 day activity: 8620±3008 steps/day; VO_{2max} : 49±10 mL/kg/min) adults (11M/11F, 22.4±4.9y, 169±7.6cm, 68.3±13kg) exercised at similar MHprod (M: 7.1±1.5 W/kg, F: 6.9±1.4 W/kg; $P=0.32$) for 60 min (cycle ergometer) in cool (24.0±0.0°C; 14.4±3.6%Rh) and hot (42.3±0.2°C; 27.9±5.5%Rh) conditions in random order separated by at least 7 days. The ΔT_{in} , heart rate (ΔHR), and thermal stress indices for comfort (TC, -4 very cold to +4 very hot), sensation (TS, -4 very cold to +4 very hot), perception (TP, 1 so cold I am helpless to 13 so hot I am sick), feeling (TF, +5 very good to -5 very bad), and focus (F, 0 internal focus [bodily sensations] to 100 external focus [external environment]) were measured every 10 minutes. A 2-way repeated-measures analysis of variance on area under the curve was used to examine Interaction (I) and Main Effect (ME) for condition × sex. Values are expressed as means ±SD with significance set at $P < 0.05$.

RESULTS: Males and females had similar increase in hot compared to cool for ΔT_{in} (Cool: $\Delta 0.5 \pm 0.1^\circ C$, Hot: $\Delta 1.5 \pm 0.6^\circ C$; ME: condition; $P < 0.0001$) and ΔHR (Cool: 58±15 b/min, Hot: 71±15 b/min; ME: condition; $P < 0.01$). Females reported that TC and TS felt hotter in both conditions (ME: sex; $P < 0.0001$) and both groups increased in hot compared to cool (ME: condition; $P \leq 0.04$). Females reported that TS was elevated compared to males in cool compared to hot (I: condition × sex; $P < 0.005$). TP felt hotter in the cool but similar increase in hot for females compared to males (I: condition × sex; $P < 0.02$). Females reported TF was more positive compared to males in hot (I: condition × sex; $P < 0.0001$). Females reported greater external focus in cool compared to males (ME: sex; $P < 0.0002$). **CONCLUSIONS:** These data indicate that sex differences exist for thermal stress. Females perceive thermal stress in hot and cool conditions to a greater extent than males exercising at similar metabolic heat production.

Recovery Of Heart Rate Variability And Hemodynamics After Heated Exercise In Active Females

Hannah A. Zabriskie¹, Chad M. Kerksick, FACSM², Andrew R. Jagim³. ¹Towson University, Towson, MD. ²Lindenwood University, St. Charles, MO. ³Mayo Clinic Health Systems, Onalaska, WI. (Sponsor: Chad Kerksick, FACSM)
(No relevant relationships reported)

Previous research has demonstrated that men who exercise in heat have challenged autonomic recovery, though little research has been conducted in females. **PURPOSE:** The purpose of this study was to assess the recovery of autonomic function in women who performed moderate-intensity exercise in heat. **METHODS:** Seven women (31.7±7.6 years, 67.3±4.1 kg, 25.7±5.6 % Fat, 43.9±5.1 mL/kg/min) completed two identical bouts of graded treadmill walking (~60% VO_{2peak}). One bout was hot (35-40°C, > 40% relative humidity (RH)), and the other served as a control (18-22°C, < 40% RH). For 24 h before and after each bout, participants had heart rate variability (HRV), specifically RMSSD, monitored. After each exercise bout, HR and BP were monitored during 30 min of supine recovery and 10 min of orthostatic tolerance assessment. **RESULTS:** RMSSD was more suppressed following exercise in the heat and remained lower than in the control condition for one hour ($p < 0.05$). During supine recovery, heat exposure led to higher HR ($p = 0.002$) and lower DBP ($p = 0.016$). SBP ($p = 0.037$) and DBP ($p = 0.008$) were both lower after 10 min of supine recovery following hot exercise than after control temperature. Average response did not reveal orthostatic hypotension despite heat causing a higher HR ($p = 0.011$) and lower SBP ($p = 0.026$) after 10 min of orthostatic exposure. **CONCLUSIONS:** Exercise in heat causes greater disruptions in cardiovascular autonomic functioning for at least one hour after exercise. Women who exercise in heat should be wary of an exacerbated HR response following exercise in the heat and low recovery blood pressures with associated symptoms.

3111 Board #5 May 29 3:15 PM - 5:15 PM
Sex Difference In Cerebral Blood Flow During Exercise Hyperthermia

Eric Rivas, Kyleigh Allie, Paolo Salvador, Lauren Schoech, Mauricio Martinez. *Texas Tech University, Lubbock, TX.* (Sponsor: Oscar Suman, FACSM)
Email: eric.rivas@ttu.edu
(No relevant relationships reported)

PURPOSE: Young healthy females are more prevalent to orthostatic hypotension compared to males. It is unknown if females show similar cerebral blood flow hemodynamics (middle cerebral artery, $MCA_{V^{mean}}$) compared to males during exercise hyperthermia. We tested the hypothesis that females have an attenuated $MCA_{V^{mean}}$ response to exercising in hyperthermic conditions.

METHODS: Twenty-two healthy active adults (7 day activity: 8620±3008 steps/day; VO_{2max} : 49±10 mL/kg/min) adults (11M/11F, 22.4±4.9y, 169±7.6cm, 68.3±13kg) exercised at similar metabolic heat production (M: 7.1±1.5 W/kg and F: 6.9±1.4 W/kg; $P=0.32$) for 60 min (cycle ergometer) in cool (24.0±0.0°C; 14.4±3.6%Rh) and hot (42.3±0.2°C; 27.9±5.5%Rh) conditions in random order with 7 days washout. $MCA_{V^{mean}}$ absolute and percent change from rest, $MCA_{V^{mean}}$ conductance ($MCA_{V^{mean}}CVC$), cardiac output index (COi) and systemic vascular resistance index (SVRi), and the difference between conditions (hot minus cool) were examined by a mixed model 2-way repeated-measures analysis of variance for Interaction (I) and Main Effect (ME) for time and sex. Significance was set at $P < 0.05$.

RESULTS: Thermal (ΔT_{in} , Cool: $\Delta 0.5 \pm 0.1^\circ C$, Hot: $\Delta 1.5 \pm 0.6^\circ C$; ME: condition; $P < 0.0001$) and cardiovascular strain (ΔHR Cool: 58±15 b/min, Hot: 71±15 b/min; ME: condition; $P < 0.01$) were similar between sex and increased in hot compared to cool condition. During the cool condition, absolute $MCA_{V^{mean}}$ and $MCA_{V^{mean}}CVC$ were higher in females compared to males (ME: sex $P < 0.005$). In contrast, $MCA_{V^{mean}}$ and $MCA_{V^{mean}}CVC$ increased then decreased over time in hot compared to the cool condition (ME: time; $P < 0.0001$). COi increased in hot compared to cool condition (ME: condition; $P < 0.008$). Females had greater SVRi compared to males in both conditions (ME: sex; $P < 0.008$). However, the %change and the difference between conditions, females compared to males had an attenuated $MCA_{V^{mean}}$ (ME: sex; $P < 0.03$) and $MCA_{V^{mean}}CVC$ (I: time × sex; $P < 0.01$).

CONCLUSIONS: These data indicate that sex differences exist for exercise cerebral blood flow. Females have higher $MCA_{V^{mean}}$ in cool and have an attenuated $MCA_{V^{mean}}$ response during exercise hyperthermia compared to males. This sex difference may be due to differences in blood pressure and systemic vascular resistance.

Post-Exercise Hyperthermia Cerebral Blood Flow Hemodynamics Are Similar Between Males And Females

Mauricio Martinez, Kyleigh Allie, Paolo Salvador, Lauren Schoech, Eric Rivas. *Texas Tech University, Lubbock, TX.* (Sponsor: Oscar Suman, FACSM)
 Email: mauricio.martinez@ttu.edu
 (No relevant relationships reported)

PURPOSE: Females have greater orthostatic intolerance and increased adrenergic sensitivity to passive heat stress compared to males. It is unknown how cerebral blood flow is affected during post-exercise heat stress. We tested the hypothesis that females would have lower middle cerebral artery blood flow velocity (MCAV^{mean}) during post-exercise hyperthermia. **METHODS:** Twenty-two healthy active adult (7 day activity: 8620±3008 steps/day; VO₂max: 49±10 mL/kg/min) subjects (11M/11F, 22.4±4.9y, 169±7.55cm, 68.3±13kg) exercised at a similar metabolic heat production (M: 7.1±1.5 W/kg and F: 6.9±1.4 W/kg; P=0.32) for 60 minutes (cycle ergometer) in cool (24±0.0°C; 14.4±3.6%Rh) and hot (42.3±0.2°C; 27.9±5.5%Rh) conditions in random order with a 7 day washout. During 1-hour post-exercise recovery, Transcranial Doppler examined MCAV^{mean}, pulsatility index (PI) and intracranial pressure (ICP). Systemic vascular responses for mean arterial pressure (MAP), augmentation index (AIx), pulse wave velocity (PWV), systemic vascular resistance (SVR), and change in intestinal temperature (ΔTin) and heart rate (ΔHR) and were measured during 1-hour recovery. Area under the curve (AUC) variables were analyzed using a mixed model 2-way repeated-measures analysis of variance for interaction (I) and main effects (ME) for Condition x Sex. Alpha priori was set at P<0.05. **RESULTS:** Exercise thermal (ΔTin, Cool: Δ0.5±0.1°C, Hot: Δ1.5±0.6°C; ME: Condition; P<0.0001) and cardiovascular strain (ΔHR Cool: 58±15 b/min, Hot: 71±15 b/min; ME: Condition; P<0.01) was similar between groups that increased in hot compared to cool condition. During recovery both sexes had a similar AUC MCAV^{mean}, however, MCAV^{mean} was lower in hot compared to cool (ME: Condition; P<0.03). Females also showed reduced stiffness (AUC PWV and AIx) compared to males (ME: Condition; P<0.0001; ME: Sex, P<0.0008). Females had greater AUC SVR compared to males in both conditions (ME: sex; P<0.01). There were no differences for MAP, PI, or ICP between the Condition or Sex. **CONCLUSIONS:** These data suggest that no sex difference exists for MCAV^{mean} during recovery. Both sexes have lower MCAV^{mean} in hot compared to cool conditions. However, the peripheral vascular mechanisms for this attenuation may differ as females have lower arterial stiffness and higher SVR.

F-37 Free Communication/Slide - Cardiometabolic Disease

Friday, May 29, 2020, 3:15 PM - 5:15 PM
 Room: CC-3014

Effect Of Pre-Operative Aerobic Exercise On Surgical Outcomes And Cardiometabolic Health In Bariatric Surgery Patients

Nicole M. Gilbertson¹, Natalie ZM Eichner², Elizabeth A. Rexrode², Sibylle Kranz², Arthur Weltman, FACSM², Peter T. Hallowell², Steven K. Malin, FACSM². ¹*Pennsylvania State University, Altoona, PA.* ²*University of Virginia, Charlottesville, VA.* (Sponsor: Steven K. Malin, FACSM)
 Email: nmg46@psu.edu
 (No relevant relationships reported)

PURPOSE: Examine if adding pre-operative aerobic exercise to standard medical care (EX+SC) improves surgical outcomes and enhances cardiometabolic health 30 d after surgery compared to SC only in bariatric surgery candidates. **METHODS:** Patients receiving bariatric surgery were match-paired to pre-operative SC (n=7 (6F), age 39.0±5.3 y, BMI 46.4±3.0 kg/m²) or EX+SC (n = 7 (7F); age 43.9±4.2 y, BMI 45.1±2.5 kg/m²; walking 30min/d, 5d/wk, 65-85% HR_{peak}) for 30 d. Fitness (VO₂peak), body composition (waist circumference and BodPod), lipids/lipoproteins, systemic inflammation (C-reactive protein (CRP)), and arterial stiffness (augmentation index (AIx); 120min mixed meal tolerance test) were assessed pre-intervention, post-intervention (~2 d prior to surgery), and 30 d post-operation. **RESULTS:** SC and

EX+SC reduced body weight (SC -8.4±0.8% vs. EX+SC -9.3±0.8%), fat mass (SC -9.6±1.1% vs. EX+SC -12.0±1.7%), and waist circumference (SC -5.6±1.4% vs. EX+SC -2.1±2.8%) similarly (all P<0.04). Treatment had no effect on CRP (P=0.58) but lowered fasted systolic blood pressure (SC -4.5±3.1% vs. EX+SC -7.9±3.0%), low-density lipoprotein (SC -20.1±4.5% vs. EX+SC -26.2±4.9%), and total cholesterol (SC -19.7±3.8% vs. EX+SC -21.6±4.6%) as well as AIx total area under the curve (SC -40.7±14.0% vs. EX+SC -19.7±11.2%) similarly for both groups (all P<0.02) pre-intervention to 30 d post-surgery. EX+SC had a shorter length of hospital stay than SC (41.3±4.4 vs. 56.7±5.7 hrs; P=0.05). Although VO₂peak (SC -5.8±5.0% vs. EX+SC 1.7±5.2% pre- to post-intervention) and lean mass (SC -2.4±0.8% vs. EX+SC -0.4±1.4% pre- to post-intervention) were not significantly different between groups after the interventions, increased VO₂peak prior to surgery correlated to a shorter length of stay (r=-0.58, P=0.03). Increased VO₂peak (r=-0.78, P=0.001) and lean mass (r=-0.56, P=0.04) pre- to post-intervention was also associated with decreased CRP 30 days post-operation. **CONCLUSIONS:** EX+SC did not enhance the effect of SC on cardiometabolic risk factors. However, adding aerobic exercise to SC appears to benefit the bariatric patient as increased pre-operative VO₂peak related to a shorter length of stay and increased VO₂peak and lean mass prior to surgery correlated to decreased systemic inflammation 30 d post-surgery.

3115 May 29 3:30 PM - 3:45 PM
High Intensity Exercise Training In Patients With Hypertrophic Cardiomyopathy

Mitchel Samels¹, Katrin A. Dias², Christopher M. Hearon, Jr², James P. MacNamara², Michinari Hieda², Aslan T. Turer³, Mark S. Link³, Satyam Sarma², Benjamin D. Levine, FACSM². ¹*Institute for Exercise and Environmental Medicine, Texas Health Presbyterian Dallas, Dallas, TX.* ²*Institute for Exercise and Environmental Medicine, Texas Health Presbyterian Dallas & University of Texas Southwestern Medical Center, Dallas, TX.* ³*University of Texas Southwestern Medical Center, Dallas, TX.*
 (No relevant relationships reported)

Patients with hypertrophic cardiomyopathy (HCM) are excluded from high intensity activities due to perceived fear of sudden cardiac death though data from athletes with HCM suggest competitive sport may be safe for some. Low cardiorespiratory fitness in sedentary HCM patients may confer a greater lifetime cardiovascular event risk than exercise *per se*. While moderate intensity exercise training in patients with HCM modestly increases fitness, high intensity exercise may be superior. **PURPOSE:** To compare the efficacy of five months of moderate intensity exercise and high intensity exercise training to improve cardiorespiratory fitness (VO₂max) in patients with HCM. **METHODS:** Eight patients with HCM (50 ± 7 years, 3 female) were assessed for maximal oxygen uptake (VO₂max, Douglas Bag method), cardiac output (Q_t, acetylene rebreathing), and peripheral oxygen extraction (av-O₂ diff, Fick equation) before randomization and after 5 months of moderate or high intensity exercise training. Patients completed 3-4 sessions of moderate intensity exercise each week, while the high intensity group also incorporated a weekly interval training session. **RESULTS:** Five months of moderate intensity exercise increased absolute VO₂max by 3% and relative VO₂max by 4%, while high intensity exercise consistently increased absolute VO₂max by 6% and relative VO₂max by 5% (Figure). Maximal Q_t did not change after moderate intensity exercise (+0.0L [95% CI -2.0 to 1.7]) but increased in all three patients after high intensity exercise (+1.2L [95% CI -1.4 to 3.9]), while maximal av-O₂ diff remained stable in both groups (moderate intensity: +0.8mL/100mL [95% CI -1.0 to 2.6]; high intensity: -0.5mL/100mL [95% CI -3.6 to 2.7]). **CONCLUSION:** Preliminary findings show similar increases in cardiorespiratory fitness following five months of moderate and high intensity exercise training in patients with HCM, although improvements were more consistent after high intensity exercise.

Figure. Similar increases in absolute (A) and relative (B) cardiorespiratory fitness following five months of moderate intensity exercise (MIE) and high intensity exercise (HIE). The increase in VO₂max was consistent in all three patients who completed high intensity exercise training whereas the training response to moderate intensity exercise was more variable.

Adding Resistance Training To Endurance Training Improves Glucose Metabolism In Individuals With Metabolic Syndrome

Alfonso Moreno-Cabañas, Juan Fernando Ortega, Felix Morales-Palomo, Miguel Ramirez-Jimenez, Laura Alvarez-Jimenez, Ricardo Mora-Rodriguez. *University of Castilla-La Mancha, Toledo, Spain.*
Email: alfonso.moreno@uclm.es
(No relevant relationships reported)

Elevated fasting blood glucose is one of the five components of metabolic syndrome (MetS) which is a cluster of anthropometric, metabolic and cardiovascular derangements. Insulin resistance (IR) has been identified as an important risk factor to develop diabetes (i.e. T2D) and MetS. Both, aerobic (AT) and resistance training (RT) prevent the development of T2D although it is unclear which is most effective. It has been suggested that mechanisms to improve IR are different between AT and RT. Thus, we hypothesized that the combination of both modes of training could provide additive effects to treat IR.

Purpose: To determine whether the addition of resistance training (RT) to high-intensity interval training (HIIT) was able to improve glucose metabolism in patients with metabolic syndrome (MetS). **Methods:** One hundred MetS patients (age, 56±8 years; weight, 92±17 kg; and Mets factors, 3.8±0.8 components) were randomized to undergo one of the following 16-wk program: (a) 4 x 4-min high-intensity interval training at 90% of HR_{max} plus 3 sets of 8-12 rep at 60-85% 1RM of 3 legs free-weight exercises (HIIT+RT group; n=35), (b) 5 x 4-min high-intensity interval training at 90% of HR_{max} (HIIT group; n=43) or (c) no exercise control group (CONT group; n=22). We measured the evolution of all five MetS components (i.e. Z-score), CRF (i.e. VO_{2max}), legs strength and power (i.e. leg press 1RM and countermovement jump (CMJ)) and fasting glucose (FG) and insulin (FI) to calculate HOMA-IR before and after intervention. Pre-intervention FG was similar among groups (110±23; 115±21; 121±30, mg·dL⁻¹ for HIIT, HIIT+RT and CON, respectively). **Results:** After 16 weeks of training, HIIT+RT improved CMJ and 1RM leg press above HIIT and CON (P<0.010). After 16 weeks of training FG (4%; p=0.046) and HOMA-IR (18%; p=0.032), decreased only in HIIT+RT. However, both training groups improved similarly their VO_{2max} (HIIT+RT, 7%, p=0.001; HIIT, 11%, p<0.001) and Z-score (HIIT+RT, 43%, P=0.022; HIIT, 63%, P=0.004). **Conclusion:** Our findings suggest that in initially sedentary individuals with MetS, RT combined with HIIT further improves the insulin-sensitizing effects of exercise reducing glucose concentrations.

Exercise Training Volume And The Fitness-fatness Index (FFI) In Adults With Metabolic Syndrome

Joyce S. Ramos¹, Lance C. Dalleck², Claire Drummond³, Matthew P. Wallen⁴, Robert G. Fassett⁵, Jeff S. Coombes, FACSM⁵. ¹Flinders University and University of Queensland, Adelaide and Brisbane, Australia. ²Western Colorado University, Gunnison, CO. ³Flinders University, Brisbane, Australia. ⁴Federation University, Victoria, Australia. ⁵University of Queensland, Brisbane, Australia. (Sponsor: Professor Jeff Coombes, FACSM)
Email: joyce.ramos@flinders.edu.au
(No relevant relationships reported)

Cardiorespiratory fitness and fatness (central obesity) are purported to be mediating factors of metabolic syndrome (MetS), and consequent cardiovascular disease (CVD)/mortality risk. The recently developed fitness-fatness index (FFI) combines these and has been reported to be a better indicator of CVD and all-cause mortality risk, beyond the capacity of either fitness or fatness alone. **PURPOSE:** To investigate the effects of different exercise volumes on FFI in adults with MetS. **METHODS:** Ninety-nine adults diagnosed with MetS according to the International Diabetes Federation criteria were randomized to one of the following 16-week exercise intervention: i) moderate-intensity continuous training (MICT) at 60-70% HR_{peak} for 30 min/session (n=34, 150 min/week); ii) 4 x 4 min bouts of high-intensity interval training (4HIIT) at 85-95% HR_{peak}, interspersed with 3-min active recovery at 50-70% HR_{peak} (n=34, 38min/session, 114 mins/week); and iii) 1 x 4 min bout of HIIT at 85-95% HR_{peak} (n=31, 17 min/session, 51 min/week). Fitness (VO_{2peak}) was determined via indirect calorimetry during maximal exercise testing and fatness was the ratio of waist circumference-to-height (WHtR). FFI was calculated as VO_{2peak} in METs divided by WHtR. A positive response to the exercise intervention was determined as a 1FFI increase. **RESULTS:** Seventy-seven participants completed pre and post testing to determine FFI. There was a greater proportion of participants who responded positively to a change in FFI following 4HIIT (56%, 14/25) compared to MICT (31%, 8/26)

and 1HIIT (42%, 11/26), but with no significant between-group difference (p=0.19). After excluding 21 participants who had <85% adherence rate to the training sessions, a total of 56 were included in the analysis (4HIIT, n=15; MICT, n=20; 1HIIT, n=21). A similar trend in FFI responders was found (4HIIT, 60%; MICT, 30%; 1HIIT, 38%; between-group difference, p=0.19). **CONCLUSION:** This study suggests that there may be a threshold of exercise volume (intensity and duration) that must be obtained to improve FFI, and thus CVD and all-cause mortality risk in adults with MetS.

3119 May 29 4:30 PM - 4:45 PM
Water-based Exercise Training For Coronary Heart Disease

Anna Sarah Scheer¹, Amit Shah², Beatriz I.R. de Oliveira¹, Daniel J. Green³, Andrew J. Maiorana¹. ¹Curtin University, Bentley, Perth, Australia. ²Fiona Stanley Hospital, Murdoch, Perth, Australia. ³University of Western Australia, Crawley, Perth, Australia.
(No relevant relationships reported)

Exercise training is an important component of coronary heart disease (CHD) management, however engagement in gym-based exercise (GEX) remains sub-optimal. Water-based exercise (WEX) may provide an alternative, especially for patients with obesity or arthritis due to the buoyancy effect of water.

PURPOSE: To examine the effectiveness of WEX for people with CHD.

METHODS: Participants were randomised to 12 weeks of WEX, GEX, or control. Training groups undertook three, one-hour sessions of circuit training per week.

Aerobic capacity (VO_{2peak}), muscular strength (one repetition maximum; 1RM), body fat (DXA) and endothelial function (flow mediated dilation; FMD) were assessed at baseline and 12 weeks. Data were analysed using STATA 16 with mixed effects linear regression.

RESULTS: Forty-five participants completed the study; WEX (n= 15), GEX (n=18), control (n=12). Data reported are estimated mean and 95% confidence interval.

Outcome	Week 0	Week 12	p
VO _{2peak} (mL.kg ⁻¹ .min ⁻¹) WEX	25.9 (23.5-28.7)	27.4 (24.7-30.8)	0.03
VO _{2peak} (mL.kg ⁻¹ .min ⁻¹) GEX	25.2 (23.1-27.7)	26.8 (24.4-29.7)	0.004
Hamstrings (kg) WEX	49.3 (43.3-55.7)	54.0 (47.3-61.2)	0.01
Hamstrings (kg) GEX	50.7 (44.8-57.2)	57.5 (51.0-64.2)	<0.001
Biceps (kg) WEX	10.4 (8.7-12.0)	10.3 (8.6-12.0)	0.80
Biceps (kg) GEX	10.5 (8.9-12.1)	11.5 (9.8-13.1)	0.003
Body fat (kg) WEX	28.7 (24.9-32.5)	27.8 (24.1-31.6)	0.02
Body fat (kg) GEX	28.4 (24.7-32.2)	27.4 (23.7-31.2)	0.003
FMD (% change from baseline) WEX	3.9 (2.8-5.0)	5.0 (3.8-5.8)	0.02
FMD (% change from baseline) GEX	4.8 (3.7-5.9)	5.2 (4.1-6.3)	0.39

No changes were evident in controls.

CONCLUSION: WEX and GEX improved aerobic fitness, leg strength and fat mass similarly, while WEX alone improved endothelial function. These findings support WEX as an alternative to GEX in patients with CHD.

Supported by the Spinnaker Foundation, The Heart Foundation (Australia), and the Australian Government Research Training Programme.

3120 May 29 4:45 PM - 5:00 PM
Aerobic Exercise Training Enhances The Blood Pressure-lowering Effect Of Antihypertensive Medication.

MIGUEL RAMIREZ-JIMENEZ, FELIX MORALES-PALOMO, ALFONSO MORENO-CABAÑAS, JUAN FERNANDO ORTEGA, LAURA ALVAREZ-JIMENEZ, RICARDO MORA-RODRIGUEZ. *UNIVERSIDAD DE CASTILLA-LA MANCHA, TOLEDO, Spain.*
Email: miguel.ramirez@uclm.es
(No relevant relationships reported)

Hypertension is an important risk factor for suffering cardiovascular diseases and many hypertensive individuals are under pharmacological treatment (antihypertensive

medication; AHM). Aerobic exercise training in hypertensive individuals has been shown to reduce their blood pressure. However, information is scarce on the effects of aerobic training and AHM on the control of hypertension. **PURPOSE:** To analyze the effects of AHM on 21-h ambulatory blood pressure (ABP) before and after an aerobic exercise training program in hypertensive individuals. **METHODS:** Twenty-seven participants chronically medicated with angiotensin receptor blockers or angiotensin-converting enzyme inhibitors antihypertensive medicine (AHM) underwent high-intensity interval training (HIIT; 3 sessions per week, 4x4' at 90 HR_{MAX}/3' at 70% HR_{MAX}) during 4-months. Before and after training, 21-h ABP was monitored under 2 conditions in a double-blind, placebo randomized design: a) PLAC trial substituting for 3 consecutive days antihypertensive medicine by placebo, and b) AHM trial, taking their prescribed antihypertensive medicine. Cardiorespiratory fitness (CRF), body weight and aldosterone to plasma renin activity ratio (ARR) were measured as secondary outcomes. Differences among the 4 trials (i.e., PLAC_{PRE}, AHM_{PRE}, PLAC_{POST}, AHM_{POST}) were analyzed by one-way repeated-measures ANOVA. **RESULTS:** CRF increased significantly from 2.45±0.02 to 2.58±0.02 L·min⁻¹ (P=0.025), body weight decreased from 95.6±2.5 to 93.6±2.4 kg (P=0.007), whilst ARR only decreased significantly after training (-10.8±2.6 a.u., P=0.002). At baseline, AHM reduced daytime ambulatory mean arterial pressure by 4.5±1.1 mmHg, being that reduction enhanced to 7.4±1.1 mmHg after 4-months of training (P=0.047). However, at nighttime this difference faded out and the reductions of AHM before (6.1±1.5 mmHg) and after training (4.7±1.2 mmHg) remained similar (P=0.437). **CONCLUSIONS:** The present data show that 4 months of HIIT enhances the effects of antihypertensive medication on blood pressure during daytime. This effect fades out during the night, a time where BP naturally falls. These results demonstrate that aerobic training could be used as a strategy to improve pharmacological treatment in hypertensive individuals.

3121 May 29 5:00 PM - 5:15 PM

Effects Of Statins Therapy And Exercise On Postprandial Triglycerides In Overweight Individuals With Hypercholesterolemia.

Ricardo Mora-Rodriguez, Juan F. Ortega, Felix Morales-Palomo, Miguel Ramirez-Jimenez, Alfonso Moreno-Cabañas, Laura Alvarez-Jimenez. *University of Castilla La Mancha, Toledo, Spain.*

Email: Ricardo.Mora@uclm.es

(No relevant relationships reported)

PURPOSE: To determine the effects of statins on postprandial lipemia (PPL) and to study if exercise could enhance statin actions.

METHODS: Ten hypercholesterolemic (blood cholesterol 204±36 mg·dL⁻¹; LDL-c 129±32 36 mg·dL⁻¹) overweight (BMI 30±4 kg·m⁻²), metabolic syndrome (MetS) individuals chronically medicated with statins (> 6 months) underwent 5-hr PPL tests in four occasions in a randomized order; a) substituting their habitual statin medication by placebo medicine during 96 hours (PLAC trial), b) taking their habitual statin medicine (STA trial), c) placebo medicine combined with a bout of intense aerobic exercise (EXER+PLAC trial) and d) combining exercise and statin medicine (EXER+STA trial).

RESULTS: Before the fat meal, statin withdrawal (i.e., PLAC and EXER+PLAC) increased blood triglycerides (TG; 29%), LDL-c (37%) and total cholesterol (23%; all P<0.05) evidencing treatment compliance. After the meal, statin withdrawal increased 5-h postprandial TG (PPTG) compared to its matched trials (94% higher PLAC vs STA and 45% higher EXER+PLAC vs EXER+STA; P<0.05). EXER+PLAC trial did not lower PPTG below the PLAC trial (i.e., incremental AUC of 609±152 vs 826±190 mg·dL⁻¹·5 h; P=0.09). Neither adding exercise to statin resulted in larger reductions in PPTG (i.e., EXER+STA vs STA iAUC of 421±87 vs 421±84 mg·dL⁻¹·5 h; P=0.99).

CONCLUSIONS: In hypercholesterolemic MetS individuals, chronic statin therapy blunts the elevations in TG after a fat meal (i.e., iAUC of PPTG) reducing the cardiovascular risk associated to their atherogenic dyslipidemia. However, a single bout of intense aerobic exercise before the high fat meal does not reduce PPTG but neither interferes with the effects of statin treatment.

F-38 Clinical Case Slide - Cardiovascular and Gastrointestinal

Friday, May 29, 2020, 3:15 PM - 4:55 PM

Room: CC-2005

3125 May 29 3:15 PM - 3:35 PM

Cardiac-Football

Brady Fleshman. *University of Kentucky, Lexington, KY.*

(Sponsor: Robert Hosey, FACS)

(No relevant relationships reported)

HISTORY: A 20 year-old male Division I football player with no significant past medical history presented with syncope and collapse one hour ago. Patient was doing cone drills and was feeling short of breath with mid-sternal chest tightness. The trainers had him sit out the rest of the drill. Five minutes after resting he asked the trainer if he could go back in and they said no. Ten seconds later, he passed out from a standing position. Upon awakening a few seconds later, he was asymptomatic. He was immediately escorted from practice to the clinic. Patient states over the last week he had not been keeping up with his peers in practice.

PHYSICAL EXAMINATION: No acute distress. Moist oral mucosa. Heart rate 100, regular rhythm, no murmurs with Valsalva, sitting, standing, squatting or grip squeeze. Lungs are clear and no labored or auscultation bilaterally without wheezing.

DIFFERENTIAL DIAGNOSIS: Vasovagal syncope, hypoglycemia, seizure, arrhythmia, hyponatremia **TEST AND RESULTS:** Labs showed normal CMP and TSH. CBC showed normocytic anemia (Hgb 13.1). Serum protein electrophoresis was normal. Coxsackie B virus antibody testing showed a 1:320 titer of Coxsackie type B-3. Additional history revealed that four weeks prior to collapse he had upper respiratory symptoms. Cardiac testing: EKG was normal. Echocardiogram showed borderline reduced LVEF 51% and mild hypokinesia of the left ventricle. A Holter monitor showed rare premature atrial and ventricular contractions and patient was asymptomatic while wearing. Stress echocardiogram showed supraventricular tachycardia at nine minutes of exercise, concerning for atrial flutter. The arrhythmia lasted for 10-15 minutes and then resolved spontaneously. Patient wore a Zio patch (heart rhythm monitor) for one week and it showed paroxysmal atrial flutter.

FINAL WORKING DIAGNOSIS: Paroxysmal atrial flutter **TREATMENT AND OUTCOMES:** It is thought that patient had viral myocarditis syndrome from Coxsackie virus causing patients symptomatic atrial flutter. He was started on Flecainide 50mg twice-daily oral tablet. Patient is allowed to continue with full contact football without restrictions while on medication. Cardiology will consider Zio patch monitor and possibility of ablation post-season but will need to briefly be on anticoagulation.

3126 May 29 3:35 PM - 3:55 PM

Abdominal Bloating - Cross Country

Christine Linh Vuong. *Kaiser Permanente, Fontana, CA.*

(Sponsor: Robert Sallis, FACS, FACS)

(No relevant relationships reported)

HISTORY: A 17-year-old college cross country runner presents with 4 years of abdominal distension and bloating, most symptomatic after a run. Symptoms have been worsening, but do not interfere with her ability to run. She denies abdominal pain, but states that it is uncomfortable after running. She denies constipation or diarrhea, but notes that she usually has a bowel movement after running. There is no improvement of her symptoms after a bowel movement. She has had rare occasions of mucus and blood in her stools. She denies nausea or vomiting. She admits to frequent urination, but does drink a lot of water and denies dysuria or hematuria. She denies change in symptoms with her menses, which are regular.

KUBs in 2016 and 2017 showed stool in the colon and nonspecific bowel gas pattern. LFTs, H.pylori, ESR, CRP were normal in 2017. She was diagnosed with constipation and irritable bowel syndrome. She tried a daily probiotic, the low FODMAP diet, and gave up dairy for months without improvement of her symptoms.

PHYSICAL EXAM: The abdomen appears distended. Decreased bowel sounds in all quadrants. Dull to percussion. The abdomen is firm, but no guarding or rebound. Prior to a run, abdominal girth measured at 90cm at the umbilicus. After a run, no change.

DIFFERENTIAL DIAGNOSES: Exercise induced bowel ischemia, Inflammatory Bowel Disease, ascites, organomegaly, abdominal mass, pregnancy, diastasis recti.

TEST AND RESULTS:

Stool calprotectin negative. WBC 11.6, hemoglobin 13.4, platelets 303. LFTs within normal limits. Serum HCG negative. Creatinine 0.81

CT abdomen and pelvis with contrast: Large cystic lesion in the abdomen and pelvis measuring 28 x 19 x 38 cm. The origin of this lesion is unclear. Secondary moderate to severe right and mild to moderate left hydronephrosis.

FINAL WORKING DIAGNOSIS:

Large cystic abdominal mass, originating from the pelvis

TREATMENT AND OUTCOMES:

1. Emergent laparotomy showing large left ovarian cyst. 10L of fluid drained. Left salpingo-oophorectomy performed.
2. Pathology consistent with serous cystadenoma. Fallopian tube without significant abnormality. No malignant cells in the pelvic washing.
3. After surgery, abdominal girth measured 75cm at the umbilicus.
4. Gradual return to running 2 weeks post-op.

3127 May 29 3:55 PM - 4:15 PM

Diarrhea (Infectious Disease)-Swimming And Diving

Jordan P. Hilgefert, Christina Murphy, Amy Miller, Keri Denay, FACSM. *University of Michigan, Ann Arbor, MI.* (Sponsor: Keri Denay, FACSM)

Email: jordanhilgefert@gmail.com

(No relevant relationships reported)

History: 19-year-old men's collegiate swimming athlete with PMH of anxiety & major depressive disorder presented with 3-days of nausea, vomiting & diarrhea. He reported several teammates with similar symptoms. He returned for reassessment 1 week following initial evaluation endorsing 2 days of symptom improvement followed by return of several episodes of emesis, diarrhea & fatigue.

Physical Examination:

General: Well-developed, Well-nourished, NAD

HEENT:

-Head: NC, AT

-Eyes: conjunctiva clear, EOMI, PERRL, no discharge

-Ears: hearing normal on gross assessment, TMs normal

-Nose: nares clear, no deformity

-Throat: MMM, no erythema or exudate

NECK: normal ROM, no lymphadenopathy

PULM/CHEST: CTAB, no wheezes, rales or rhonchi

CV: RRR, no MRG. CR < 2 sec

ABD: BS+, soft, non-tender, non-distended, no organomegaly

SKIN: no visualized rashes or skin lesions, skin is warm and dry

PSYCH: appropriate mood and affect

Differential Diagnosis:

- 1) Viral gastroenteritis
- 2) Bacterial gastroenteritis
- 3) Parasitic infection
- 4) Irritable bowel syndrome
- 5) Anxiety

Tests and Results: Initial CBC, BMP and TSH were remarkable only for mild thrombocytosis (447 K/mm³) and hypoglycemia (63 mg/dL). After incomplete resolution of symptoms, GI PCR panel was obtained and found to be positive for cryptosporidium.

Final Diagnosis: Cryptosporidiosis

Treatment and Outcomes:

- 1) He was treated with Nitazoxanide 500 mg PO BID x 3 days and held out of the pool for 2 weeks.
- 2) Athletes with exposure to university pools presenting with diarrhea were tested for cryptosporidium via PCR. 6 were positive and all were held out of the pool for 2 weeks.
- 3) The public health department and environmental health experts were consulted to assist with management.
- 4) Administrators from every university and local swimming clubs who shared a common pool with our athletes were notified of potential exposure to cryptosporidium. One head-to-head swimming meet was cancelled in an effort to limit potential exposure.
- 5) University pools were shut down and treated twice with a high-concentration chlorine.

6) Water samples were collected serially before and after treatment cycles to ensure eradication prior to re-opening the pools.

3128 May 29 4:15 PM - 4:35 PM

Emesis- Football

Lauren E. Cianci, Tesa E. Johns, Peter H. Seidenberg, FACSM. *Penn State University, University Park, PA.* (Sponsor: Peter H. Seidenberg, FACSM)

Email: laurencianci@gmail.com

(No relevant relationships reported)

HISTORY: An 18-year-old NCAA D-I football athlete developed emesis during exercise. During his freshman season, he had recurrent URIs and emesis during practice. The vomiting appeared to be post-tussive during intense exercise. The athlete has not experienced this before but has a history of asthma and allergies. Symptoms improved temporarily with a non-sedating antihistamines and a H2 blocker. But, after one week, the vomiting returned. A PPI, fluticasone nasal spray and albuterol were then added, which appeared to help. Symptoms returned in the spring and montelukast was added to his regimen. He continued to complain of mucus accumulating in his throat that would cause him to gag which would occur with intense exercise and then even while trying to sleep. An EGD was performed which was normal. The athlete was then referred for allergy testing and immunotherapy.

PHYSICAL EXAMINATION: Afebrile. Pulse ox 98% on room air. NAD, A&O. Nasal mucosa is pale, boggy and swollen with clear d/c; TM clear bilaterally; OP with posterior cobble stoning; no tonsillar exudate or erythema. No cervical LAN. CV: RRR. Lungs CTAB. Abdomen ND, BS (+), mild epigastric TTP, and no rebound or mass.

DIFFERENTIAL DIAGNOSIS:

1. Sinusitis
2. Allergic rhinitis
3. GERD
4. Gastritis
5. asthma

TESTS AND RESULTS:

Chest radiograph: normal

Spirometry Testing:

- normal FVC
- FEF max was decreased
- Increased RV/TLC
- diffusion 68% of predicted

EGD: normal

Allergy testing: (+) ragweed pollen, several weed pollens, tree pollens, several grasses, dust mites, cockroach, animal dander

FINAL/WORKING DIAGNOSIS:

Allergic rhinitis accompanied by emesis due to hypersensitive gag reflex stimulated by postnasal drip

TREATMENT AND OUTCOMES:

1. Continue antihistamines and fluticasone nasal spray
2. Weekly immunotherapy injections
2. Dust mite bed covers to reduce exposure
3. Medication compliance

With the above measures, the athlete's symptoms were controlled and he continues to play football without difficulty.

3129 May 29 4:35 PM - 4:55 PM

General Medicine / Gastroenterology-Cycling

Laura Beth Anderson, Amie Kim. *Icahn School of Medicine at Mount Sinai Medical Center, New York, NY.*

Email: amie.kim@gmail.com

(No relevant relationships reported)

HISTORY: 31 year old male presents with left (L) groin pain. While cycling, he twisted rightward with sharp pull and "fullness" to L lateral abdomen and groin. This developed into new GI symptoms including constipation and acid reflux. In 4 months, his BMI decreased from 23 to 17 due to inability to tolerate food bolus. Additional urologic symptoms developed including perineal numbness and pain, incomplete void, and soreness with sexual activity.

PHYSICAL EXAMINATION: Positive affect, marked cachexia. Long torso relative to lower extremity length. Abdomen soft, no hernia. Marked tenderness to palpation at L perineum, inguinum, radiating to L lateral abdomen and obliques. Resisted sit-up with pain reproduced, 5/5 strength. L hip extension, 50 degrees L, 70 degrees right. No inguinal lymph nodes. Normal scrotal exam. L4-S1 motor 5/5, sensory intact to light touch. Gluteal squeeze intact **DIFFERENTIAL DIAGNOSIS:** athletic pubalgia, labral tear, iliopsoas tendonitis, osteitis pubis, small bowel dysmotility

TEST AND RESULTS: Hip ultrasound-rectus femoris transversalis fascia with invagination, herniating 0.2 cm at area of tenderness. Joint fluid at L anterior femoral recess. Iliopsoas bursa at L pelvic crest asymmetrically increased. Pubic symphysis

osteitis. No snapping iliopsoas tendon. **MRI pelvis with IV contrast**-trace pelvic ascites. No small bowel obstruction or mass. No abdominal hernia with Valsalva. No musculotendinous injury at pubic symphysis. **Scrotal ultrasound**-L epididymal cyst. **Endoscopy/colonoscopy**-no findings, with biopsies. **Mayo Clinic-nuclear medicine gastric emptying test**-significantly delayed 6 hour small and large bowel transit 9% (mean 58%). **Anorectal manometry**-markedly increased anal resting pressures with normal function. **Nuclear medicine gastric accommodation**-no findings. **FINAL WORKING DIAGNOSIS:** Athletic pubalgia with secondary small bowel dysmotility **TREATMENT AND OUTCOMES:** Marked improvements in musculoskeletal, neurologic, and gastrointestinal symptoms with dedicated pelvic floor PT. Has transitioned to plyometrics and high resistance activities. Acupuncture with athletic pubalgia protocol. Continues supportive boxer briefs, probiotic supplements, daily laxative. Stool transplant evaluation pending. Sports hernia surgical evaluation pending

F-39 Clinical Case Slide - Medical Issues II

Friday, May 29, 2020, 3:15 PM - 4:55 PM

Chest And Neck Pain In A Tennis Player
 Kathryn Elizabeth McLellan, Jeffrey Kovan, Nathan Fitton, Jill Moschelli. *Michigan State University, East Lansing, MI.*
 (Sponsor: James Dunlap, FACSM)
(No relevant relationships reported)

History: An 18-year old male D-1 tennis player presented to the office with new onset pain in his chest and neck. It started the night prior to presentation in the center of his chest. He fell asleep without pain, but the next day noted pain in his upper chest and neck. He described it as a stiffness and as a weight pressing down on his chest. The pain was constant and worse with swallowing, speaking, neck extension, and head rotation. He also reported feeling more out of breath than usual. Two days prior to symptom presentation, he performed baseline strength testing. He denied fever, pain with neck flexion, radiation to either arm, syncope, wheezing, sore throat, N/V/D or headache. He had no personal or family history of asthma, pneumothorax, or cardiac disease. He denied current or prior smoking, drug use, and vaping.

Physical Exam: Vitals: Ht 182 cm, Wt 77.1 kg, BP 119/74, HR 74 bpm, Temp 36.6 C (oral), BMI 23.2

Gen: NAD, nontoxic

ENT: no pharyngeal erythema or tonsillar swelling

Neck: no lymphadenopathy. Supple, full ROM but pain in full extension. No TTP of spine or soft tissues.

CV: RRR, no M/R/G

Resp: CTA bilaterally, good air entry, no wheeze, no accessory muscle use

Chest: No TTP of ribs, sternum, costo-sternal joint, or intercostal spaces. No palpable subcutaneous crepitus to the chest or neck.

Skin: no erythema of the skin of neck or chest

Differential diagnosis:

Acute coronary syndrome

Pneumomediastinum

Strain

Infection

Asthma

Testing:

X-ray of Chest/Neck: Lucency seen along paravertebral regions of upper thorax raising concern for pneumomediastinum. No pneumothorax.

Final Diagnosis: Spontaneous pneumomediastinum

Treatment/Outcome:

Patient was held from activity until follow-up weekly X-rays demonstrated resolution of free air in the neck.

Symptoms and X-ray findings resolved within two weeks.

He was cleared at 2 weeks with a gradual progression of activity and avoidance of full exertion or weight lifting.

One week later, he was cleared to return to full activity with no restrictions. He was advised to avoid breath-holding with activity. He has had no recurrence of symptoms.

3134 May 29 3:35 PM - 3:55 PM
Severe Bleeding In A Collegiate Water Polo Athlete

Casey N. Maxwell. *Princeton University, Princeton, NJ.*

(Sponsor: Margot Putukian, FACS)

Email: cmaxwell@princeton.edu

(No relevant relationships reported)

HISTORY: 18 y/o male presents during review of incoming student-athlete health history documents with history of "severe hemophilia A", self-treated with Factor VIII infusions every other day & "extra doses" as needed. Letter from pediatric hematologist clearing him to participate: "there is no medical reason he cannot participate in competitive water polo." PMH: Two hospitalizations due to blood infection (2003 & 2005), ADHD diagnosis (2009), Type 2 SLAP lesion right shoulder (2016), Wisdom Teeth Extraction (3/2017).

PHYSICAL EXAMINATION: Visible keloid scarring present at two sites on the right and left side of patient's chest consistent with port removals. BP: 129/92mmHG. Pulse: 64bpm. Height 77in. Weight 225.2lbs. PE otherwise benign.

DIFFERENTIAL DIAGNOSIS:

Hemophilia A

Von Willebrand Disease

TEST AND RESULTS:

VWF profile: Normal

Random Factor VIII level: 12% (~30hours after infusion)

Post-infusion Factor VIII level: 147% down to 77% at 6 hours.

Hepatitis A/B/C Immune Status, HIV Antibody: negative

Normal PT. Prolonged PTT which corrects with normal plasma mixing.

Unremarkable CBC, CMP

FINAL WORKING DIAGNOSIS: Severe Hemophilia A.

TREATMENT AND OUTCOMES: Prophylactic Treatment of Advate 5000units daily, during water polo season, just prior to participation in practice or game. If practice/games extend post-infusion 8 hours or beyond, patient to self-infuse additional 5000units. Self-infusion every other day when not participating in water polo. In case of an emergency/life-threatening bleeding, patient to infuse first and then, if stable, seek care at RWJ-Rutgers ER (or other regional Hemophilia Treatment Center while traveling). If clinically warranted, patient to seek care at closest ER and bring factor with him. Annual re-evaluations to be performed at Hemophilia Treatment Center Rutgers-RWJ. Patient has been fortunate to participate in competitive collegiate water polo for 2+ seasons with no adverse sequelae.

3135 May 29 3:55 PM - 4:15 PM

Calf Pain-Brazilian Jujitsu Fighter

Alyssa Neph, Kevin Burnham. *University of California, Davis,*

Sacramento, CA. (Sponsor: Brian Davis, MD, FACSM)

Email: aneph@ucdavis.edu

(No relevant relationships reported)

HISTORY: 29 yo male Brazilian jujitsu fighter with a history of Henoch-Schonlein purpura and eczema presents to clinic for 6 months of right anterolateral calf pain without a clear injury. He reports constant, dull, aching pain, worse with dorsiflexion and resisted plantar flexion. He notes associated pitting edema, dry leathery skin, hypopigmentation, and hyperesthesia that began 3-4 months ago. He has stopped jujitsu due to symptoms. Tib-fib xrays and venous duplex were negative. He tried acetaminophen, ibuprofen, physical therapy, topical clobetasol, and oral prednisone with short-term improvement. **PHYSICAL EXAMINATION:** Skin of the anterolateral calf is indurated with hair loss, a leathery appearance, and areas of depigmentation. The distal lateral calf is warm and erythematous, with swelling posterior to the lateral malleolus. Tinel's sign is negative at the fibular head. Pulses are normal bilaterally with ankle plantar and dorsiflexion. Ankle ROM is full. Light touch sensation is intact in L2-S2 dermatomes and strength is 5/5 in lower extremities.

DIFFERENTIAL DIAGNOSIS: Complex regional pain syndrome, Cellulitis, Scleroderma, Eosinophilic fasciitis, Chronic exertional compartment syndrome, Vascular insufficiency **TEST AND RESULTS:** Lab work: inflammatory markers and rheumatologic labs negative except for elevated CK (356) of unknown significance. EMG/NCS: low amplitude right vs left sural sensory nerve suggesting sural neuropathy although within normal limits; no fibular neuropathy or radiculopathy. MRI right leg: nonspecific skin thickening of anterolateral shin with fascial edema and mild fibularis longus myositis. Skin biopsy: linear morphea versus eosinophilic fasciitis **FINAL WORKING DIAGNOSIS:** Segmental Linear Morphea (localized scleroderma)

TREATMENT AND OUTCOMES: Dermatology referral led to biopsy; subsequently, treatment with PO methotrexate (MTX), high dose IV methylprednisolone for three cycles, and topical clobetasol ointment BID. UVA1 phototherapy was also started due to extensive disease and ankle and knee joint involvement. Subjective improvement in ROM, skin stiffness, and strength per patient after 2 cycles of methylprednisolone. Switched to SQ MTX for better absorption and lower cost. Patient continues to improve as he remains on the above treatment protocol.

3136 May 29 4:15 PM - 4:35 PM

An Unexpected Curveball Causing Fatigue In A Softball Player

Om Sam¹, Stanley Hunter², Nina Millet¹. ¹UHS, Johnson City, NY. ²UHS, Binghamton, NY.
Email: omsam3288@gmail.com

(No relevant relationships reported)

HISTORY: 19 year old caucasian female softball player with no past medical history presented to the office for fatigue and reduced exercise tolerance for a month. She also complained of muscle cramps in her calves, decreased appetite, intermittent headaches, nausea and one episode of non-bloody, non-bilious emesis. Her athletic performance had decreased despite no changes in her training regimen. She measured her glucose via a glucometer with readings in the 70s. She maintained proper fluids, electrolyte and nutrient intake. She denies any changes in her weight, menstrual cycle, depression and recent illness.

10 point ROS was negative. Social history is unremarkable except for occasional alcohol intake. Regular menstrual cycle.

PHYSICAL EXAMINATION: Vital signs within normal limits. No signs of acute distress. Normal mentation and affect. No jaundice or pallor. Regular rhythm and rate. No murmurs appreciated. Lungs clear to auscultation. Abdomen is soft, non-tender, with normal bowel sounds, no masses appreciated. 5/5 strength and sensation to light touch intact in all extremities. Biceps and knee jerk reflex 2+.

DIFFERENTIAL DIAGNOSIS: Iron-deficiency anemia. Thalassemia.

Hypothyroidism.

TEST AND RESULTS: CBC: RBC 5.58, H&H 11.6/37.8, MCV 67.7, MCHC 30.7, MCH 20.8 - Microcytic anemia. Peripheral blood smear reveals anisocytes. CMP: Na 133-hyponatremia. Iron panel: Ferritin 20,1, Transferrin saturation 36, Total FE binding 376, Serum iron 137 - Normal iron panel TSH 1.120 - normal. Vit D 47 - normal. Haptoglobin 23 (low), LDH 606 (N), Total bilirubin 0.9 (N) - No signs of hemolysis. Hgb electrophoresis: Hgb A 95 (low), Hgb A2 4.7 (high), Hgb F, 0.3 (N), Hgb variant 0- Beta thalassemia trait. EKG: normal

FINAL WORKING DIAGNOSIS: Beta-thalassemia trait

TREATMENT AND OUTCOMES: Initial treatment with iron supplementation for 3 weeks showed no improvement. Although it may take 6-8 weeks for Hgb levels to return to normal. Repeat Hgb after 3 weeks should have revealed a mild improvement. Iron panel was ordered to confirm diagnosis, which was normal. Further family history revealed thalassemia, which was then confirmed with Hgb electrophoresis. Folic acid 2 mg daily started, iron supplementation discontinued. Cessation of activity for 4 weeks to promote recovery, then gradual return to full activity. Follow-up in 2 months.

3137 May 29 4:35 PM - 4:55 PM

Almost Vaping Your Way To Medical Disqualification

Eric Emmanuel Coris, William Anderson, Yuri Chulskiy, Sanders Chae, Byron Moran. *The University of South Florida, Tampa, FL.*

Email: ecoris@usf.edu

(No relevant relationships reported)

HISTORY:

18 year old male freshman Division I football athlete with a history of abnormal pre-participation EKG. Initial EKG was significant for left axis deviation, incomplete right bundle branch block, prominent p wave, t wave inversion in V1 and V2. He had no symptoms, and denied significant past medical history. Echocardiogram revealed significantly enlarged right atrium, pulmonary hypertension.

PHYSICAL EXAMINATION:

Normal, except CV: RRR without M/G/R; nl S1, prominent S2 in pulmonic area, Intermittent fixed split S2, normal PMI.

DIFFERENTIAL DIAGNOSIS:

Pulmonary hypertension/Anomalous pulmonary return/Arrhythmogenic right ventricular dysplasia/Interstitial lung disease/Sarcoid/Intracardiac shunt/Atrial septal defect/Ventricular septal defect/Obstructive sleep apnea/Obstructive lung disease/HIV/Granulomatous lung disease/Hypersensitivity Pneumonitis

TEST AND RESULTS:

CT angiogram of the chest revealed mild enlargement of the right atrium. Ill-defined opacities bilaterally with tiny focal lucencies which may represent focal developing cavitation. Mixed solid and ground-glass opacities with focal internal lucencies mainly located peripherally. Small lucent central regions are suggested within these regions.

Further significant history of two months prior to initial EKG, and the day after initial EKG two vaping episodes. No tobacco, no THC reportedly contained but some type of flavoring was present. Believes he split one e cigarette with another person. Prior to that episode he vaped every other weekend, for a few weekends, two months prior to the initial EKG. No symptoms ever noted after vaping that he was aware of. Did have rhinorrhea and sneezing for several months this summer, he felt related to seasonal allergic rhinitis.

FINAL WORKING DIAGNOSIS:

Vaping induced hypersensitivity pneumonitis

TREATMENT AND OUTCOMES:

Athlete refrained from further vaping. Held from competitive activity until completion of workup, athlete was gradually progressed through increasing cardiopulmonary exercise to return to play. Returned to full play over a 2 week progressive period with no symptoms. Follow up CT of the chest and pulmonary function tests returned to normal.

F-40 Clinical Case Slide - Spine

"Tingling In The Scrum": Paresthesias And Neck Pain - Rugby

Jonathan Smits¹, Pierre Rouzier, FACSM², John Herbert Stevenson¹. ¹University of Massachusetts Medical School, Worcester, MA. ²University of Massachusetts, Amherst, MA.

(No relevant relationships reported)

HISTORY: A 19 year old female college student "new to club rugby" presented to the campus health clinic for evaluation of neck stiffness and extremity tingling following last week's practice. She was unable to recall a specific injury. However, she reported later feeling neck stiffness with associated soreness. She also reported paresthesias involving both hands, left worse than right, and her left foot. Her symptoms were improving but she had not resumed practice.

She reported being a multi-sport high school athlete with participation in varsity field hockey and lacrosse without prior concussion, head or neck pain, or extremity abnormalities. She had also been in an auto accident years prior without subsequent injury. History was notable for resolved low back pain, and a family history of back pain.

PHYSICAL EXAMINATION: Spine exam demonstrated FROM with no C/T/L spinous process tenderness. Spurling maneuver was negative. Tightness was appreciated in left trapezius muscle compared to right. Shoulders demonstrated FROM with normal rotator cuff strength. Upper and lower extremities with equal sensation, reflexes, and pulses. Grip strength normal. Straight leg raise and slump tests were negative.

DIFFERENTIAL DIAGNOSIS:

1. Cervical strain
2. Herniated cervical disc
3. Cervical spondylolysis
4. Vertebral fracture
5. Spinal stenosis
6. Spinal infection
7. Autoimmune disease

TESTS AND RESULTS:

1. Cervical spine x-rays: straightening without bony pathology
2. MRI brain & cervical spine:
 - Mild disc narrowing at C5-6
 - Chiari I malformation with pointed tonsils herniated 1.1 cm from foramen magnum
 - Syrinx spanning C5-T4 with max diameter 3 mm in upper thoracic cord

FINAL WORKING DIAGNOSIS:

Chiari I malformation with C5-T4 syringomyelia

TREATMENT AND OUTCOMES: The athlete was initially restricted from rugby activities until follow-up evaluation. She noted interval improvement and wished to pursue strength training at season end. Her symptoms then recurred with overhead lifting, and later with chiropractic treatments. Upon return to campus, brain and cervical MRI were ordered as recommended by a neurologist. Due to the above MRI findings, she stopped recreational activity and was referred for urgent neurosurgical evaluation. She will undergo decompression surgery.

3142 May 29 3:35 PM - 3:55 PM

Neck Injury - Football

Paiyuam Asnaashari, Robert E. Sallis, FACSM. *Kaiser Fontana, Fontana, CA.* (Sponsor: Dr Bob Sallis, FACSM)

Email: paiyuam.x.asnaashari@kp.org

(No relevant relationships reported)

HISTORY: 21-year-old senior high school football offensive line men sustained a neck injury while tackling. During the third quarter of a midseason game, he tackled an opponent player, and they both landed on the ground. The patient was facing down with opposing player just underneath his anterior torso. Shortly after the play, given he was near the ball, a pile up of players landed on his upper back. He sustained a hyperextension injury of his cervical neck since his head was laying on the player he tackled. Patient described an immediate “pop” sensation in his neck and had “complete weakness & numbness” of his R upper & lower extremities.

PHYSICAL EXAMINATION: After safely placing patient in supine position on spine board, examination demonstrated he as alert and orientated x 4, had spinous process tenderness from C4-C7. Sensory testing along both extremities revealed significantly decreased and almost absent sensation in R upper & lower extremity. He was unable to raise / move his R arm or leg. His distal pulses and breathing were within normal ranges.

DIFFERENTIAL DIAGNOSIS: Cervical Cord Compression, Cervical Fracture, Cervical Disc Herniation, Cervical Facet Radiculopathy,

TESTS AND RESULTS:

Cervical X-RAYS: No osseous abnormality.

Cervical CT Scan: L neural foramina stenosis at C3/C4, R neural foramina stenosis at C6/7. Mild to moderate spinal canal stenosis at C6/7 and C7/T1.

Thoracic CT Scan: Normal CT chest, abdomen, pelvic, and thoracic spine.

MRI Cervical Spine: C6-7 where a right paracentral / foramina disc protrusion. Mild central canal stenosis at T1-2 level due to diffuse disc bulge.

FINAL WORKING DIAGNOSIS: C6-7 cervical disc herniation with mild to moderate cervical cord stenosis at C6/7 and T1-2.

TREATMENT AND OUTCOMES: R-sided weakness resolved after 4 weeks of supportive care, watchful waiting and physical therapy.

3143 May 29 3:55 PM - 4:15 PM

Trampoline Training Trauma: A Diver's Injury

Luting Eckensweiler¹, Anne Doran², Poonam Thaker, FACSM¹.

¹Resurrection Medical Center, Chicago, IL. ²Lutheran General Hospital, Park Ridge, IL. (Sponsor: Poonam Thaker, FACSM)

(No relevant relationships reported)

Trampoline Training Trauma: A Diver's Injury

History:

A 15 year old male presented to the emergency department with back pain after sustaining an injury while practicing a diving routine on the trampoline. He was in forward rotation when he landed awkwardly on his chin and upper chest, sending his back into hyperextension with his legs landing above his head. He felt immediate low back pain and complete loss of sensory and motor function of his legs for about 30 seconds. All sensory and motor function subsequently returned and he was able to ambulate from the trampoline into the home. He denied ongoing sensory or motor deficits in his legs, loss of consciousness, neck pain, urinary or bowel incontinence, or upper extremity weakness.

Physical examination:

Examination revealed a well appearing male who was able to ambulate slowly but independently with normal gait. He had midline tenderness in the upper lumbar vertebrae. There was normal alignment of the spine without step offs. His strength was 5/5 and reflexes were 2+ in lower extremities. He did not have deficits to touch sensation and did not have saddle anesthesia.

Differential diagnoses:

1. Spinal cord contusion
2. Lumbar vertebral fracture
3. Lumbar sprain
4. Acute spondylolysis or spondylolisthesis
5. Lumbosacral neurapraxia

Tests and results:

Xray of cervical spine, chest, and pelvis: unremarkable

CT cervical spine: unremarkable

MRI cervical-thoracic-lumbar:

- traumatic injury of the lumbar spine with disruption of the interspinous ligament at the L1-L2 level
- small ventral extradural hematoma contained by the posterior longitudinal ligament at L2-L4

MRI lumbar spine, hospital day #2:

- decrease in size and cradiocaudal extent of the ventral extradural collection
- edema within psoas and paraspinal muscles at L2-L4

Final diagnosis:

Extradural hematoma of lumbar spine at L2-L4

Tear of interspinous ligament at L1-L2

Treatment and outcomes:

1. Admission to PICU for close neurologic monitoring with neurosurgery and trauma on consult. He did not report further numbness or tingling in lower extremities
2. Physical therapy
3. Stepped down to general pediatric floor on hospital day #2
4. Discharged on hospital day #3 with lumbar sacral orthosis brace
5. Experienced ongoing headaches for several weeks
6. Back to activity as tolerated, continue to monitor recovery

3144 May 29 4:15 PM - 4:35 PM

Neck Injury-Motor Vehicle Accident

Briana N. Fedorko¹, Brent F. Fedorko². ¹Pivot Physical Therapy, Cambridge, MD. ²Salisbury University, Salisbury, MD.

(No relevant relationships reported)

HISTORY: A 57-year-old male was involved in a motorcycle accident, landing on his right side. Injuries included a flaccid right arm and hand, laceration of his right thigh, and a fracture of the 3rd metatarsal of his right foot. Patient's chief complaint was pain in right shoulder and neck and an inability to complete ADLs.

PHYSICAL EXAMINATION: Patient demonstrated flaccid right upper extremity with very little finger movement. Patient was able to achieve some finger flexion of all 5 digits and thumb opposition to index finger, although could not achieve pad to pad contact. All PROM of joints was preserved. Sensation was grossly intact. Patient tolerated initial examination well with mild discomfort during objective measures. No red flags arose during medical screening/systems review.

DIFFERENTIAL DIAGNOSIS: 1. Cerebrovascular accident 2. Brachial plexus stretch injury 3. Brachial plexus avulsion injury

TESTS AND RESULTS: MRI of cervical spine without contrast – small disc herniation, MRI of brachial plexus with and without contrast - edema involving right scalene and adjacent fascial planes extending into brachial plexus as well as into right C6/C7 and C7/T1 neural foramen to confirm nerve root sleeve tears, CTA of neck – negative for artery involvement, EMG study showed that the brachial plexus was not avulsed, but not currently sending EMG signals to hand.

FINAL WORKING DIAGNOSIS: Brachial plexus stretch injury

TREATMENT AND OUTCOMES: 1. Therapeutic exercises (ROM, strength, endurance, stability), 2. Therapeutic activity (work specific, ADL specific), 3. Neuromuscular rehabilitation (muscle re-education, sequencing, coordination, neurodynamics), 4. Patient education (home exercise program, home safety).

Patient has been responding well to a treatment plan combining aspects of the above mentioned interventions. Has been showing greater activation of right hand and forearm muscles with ability to complete weak grip at this stage. Right upper extremity remains supported in sling.

3145 May 29 4:35 PM - 4:55 PM

Abstract Withdrawn

3146 May 29 4:55 PM - 5:15 PM

Bilateral Forearm And Elbow Pain - Tennis

Christina Giacomazzi, Vivian Shih. *Stanford, Redwood City, CA.*

Email: mazzichristina@gmail.com

(No relevant relationships reported)

HISTORY: A 75 year-old female tennis player was referred for bilateral elbow pain with suspected lateral epicondylitis. She noted 3 months of pain in her left more than right ventral forearms with radiation into her lateral elbows as well as posterior

bilateral shoulder pains. The forearm pain was constant and worsened by single backhand with tennis, lifting weights. She reported reduced grip strength and her racquet falling out of her hands.

PHYSICAL EXAMINATION:

Cervical range of motion was within functional limits. Elbow examination showed full active and passive range of motion, minimal tenderness along lateral epicondyle and just distal at tendinous origin, and no pain with resisted wrist extension and middle finger extension. She had finger extension weakness without pain bilaterally 3/5 and otherwise motor testing was 5/5 C5-T1 myotomes. Sensation was intact in C5-T1 dermatomes bilaterally. Reflexes were 2+ and symmetric of biceps and brachioradialis and 3+ at the triceps bilaterally.

DIFFERENTIAL DIAGNOSIS:

1. Bilateral lateral epicondylitis
2. Cervical spine stenosis with myelopathy
3. Posterior interosseous neuropathy

TEST AND RESULTS:

Cervical Spine anterior-posterior and lateral radiographs:

- Grade 2 anterolisthesis of C7 on T1 is seen with bilateral pars fracture of C7.

Moderate multilevel degenerative disc disease.

MRI of the Cervical Spine without Contrast:

- Advanced facet arthropathy at C7-T1. Anterolisthesis of C7 on T1 causing moderate/severe spinal stenosis with mild cord deformity. Severe bilateral foraminal stenosis at this level.

FINAL/WORKING DIAGNOSIS:

Cervical central spine stenosis with myelopathy

TREATMENT AND OUTCOMES:

1. Neurosurgery referral recommended urgent C7-T1 anterior cervical discectomy and fusion followed by C5-T2 posterior spinal fusion
2. She was placed in hard cervical collar at all times and surgery was performed 1 week after neurosurgery evaluation
3. At 1 week postoperative, patient felt 80% improvement in pain in forearms and elbows along with subjectively improved grip strength
4. She continued the hard cervical collar until repeat radiographs at 6 weeks post surgery.
5. Patient was instructed to avoid playing tennis. She was also informed to avoid bending, twisting of her neck or lifting greater than 5 pounds until further evaluation in 6 week visit.

F-53 Free Communication/Poster - Body Composition

Friday, May 29, 2020, 1:30 PM - 4:00 PM

Room: CC-Exhibit Hall

3180 Board #1 May 29 1:30 PM - 3:00 PM Comparison Of DXA And Ultrasound For Measurement Of Body Composition In Physically Active College Students

Jeremy T. Barnes¹, Jason D. Wagganer¹, Jeremy P. Loenneke, FACSM², Monica L. Kearney¹, William M. Miller³, Majid M. Syed-Abdul⁴. ¹*Southeast Missouri State University, Cape Girardeau, MO.* ²*The University of Mississippi, University, MS.* ³*The University of Mississippi, Cape Girardeau, MS.* ⁴*The University of Missouri, Columbia, MO.*

(No relevant relationships reported)

Body composition is a frequently assessed component of health-related fitness. Recently, a portable computer based A-mode ultrasound system has become commercially available for estimating percent body fat (%fat). If a single-site estimate of %fat is valid against the dual-energy X-ray absorptiometry, this would have immediate implications for assessing body composition in field based settings. However, little is known how these estimates compare with each other. **PURPOSE:** The aim of this study was to determine the accuracy of the A-mode ultrasound device as a way to estimate %fat. **METHODS:** Participants %fat was estimated using an A-mode ultrasound device biceps measurement and DXA, which served as the criterion estimate. Participants (75 males, 87 females) were physically active college students [age 21 (SD 3) yrs, height 1.73 (SD 0.10) m, body mass 76.09 (SD 15.74) kg and BMI 25.4 (SD 4.1) kg/m²]. Methods were compared using a Bland-Altman plot with DXA serving as the criterion method. The coefficient of determination and standard error of the estimate were assessed using linear regression. Total error was calculated to determine the average deviation of individual scores from the line of identity. **RESULTS:** DXA estimate %fat was 25.9 (SD 11.5%) and the A-mode ultrasound estimate was 22.6 (SD 10.9%). The A-mode ultrasound device underestimated %fat by -3.3 (SD 8.0) % (p<0.00001). With a standard deviation of 8, the calculated 95% limits of agreement (SD x 1.96 ± mean difference) were -12.3 to 19.04% fat. The coefficient of determination was 0.55 with a standard error

of the estimate of 7.6 %fat. The average deviation of individual scores from the line of identity was 8.6% (total error). **CONCLUSIONS:** The development of time efficient methods for estimating %fat are important for better screening large samples; particularly in field settings. Although a single site estimate of %fat is efficient, it did not provide valid estimates when compared to DXA in this population. The limits of agreement were wide, indicating poor agreement between the two assessments of %fat. Future studies may want to consider investigating multiple measures using sites A-mode ultrasound as this may better estimate overall %fat.

3181 Board #2 May 29 1:30 PM - 3:00 PM The Accuracy And Reliability Of Body Composition Measurement Techniques: Using The Right Instruments In Research And Practice

Grace L. Atkinson. *The University of Queensland, St Lucia, Australia.*

Email: grace.atkinson@uq.edu.au

(No relevant relationships reported)

PURPOSE:

Isolated body composition measurement techniques are regularly used as time- and cost-effective alternatives to the gold standard four compartment (4C) model in clinical, sports and research settings. However, isolated measurements of body composition are subject to error. This large, population-representative validation study is the first to assess the accuracy and between-day reliability of common body composition measurement techniques, in reference to the 4C model.

METHODS:

Participants (n=45, age = 52±21, body mass index=26.8±3.7 kg/m²) completed two consecutive days of body composition testing under controlled conditions (fasted, nil exercise). Body composition assessment methods bio-electrical impedance spectroscopy (BIS), dual-energy x-ray absorptiometry (DXA) and air-displacement plethysmography (BODPOD) were compared to the 4C model (combined measurement of total body water, bone mineral mass, body density and body mass). A priori cut points for accurate and reliable isolated measurement techniques were an intra-class correlation co-efficient (ICC) ≥0.95 and co-efficient of variation (CV) of ≤3%.

RESULTS:

Compared to the 4C model, DXA was the only accurate isolated measurement technique (ICC=0.968); as all other measurements were below the limits of agreement (ICC=0.763-0.886). For measurement of reliability, DXA had the lowest between-day error (CV=2.8%) compared to the 4C model, however the confidence intervals (CI) exceeded the acceptable limits of measurement error (1.7%-3.9%). When BIS and DXA were combined, measurement error was within acceptable limits [CV=2.1(1.2-3.0% CI)]. All other isolated body composition techniques had an average between-day CV of 3.4-5.1%.

CONCLUSION:

Unlike BIS and BODPOD, DXA is an accurate body composition measurement technique compared to the 4C model. The between-day reliability of DXA is meaningfully enhanced when combined with BIS. It is recommended that researchers and health and sports practitioners implement DXA and BIS assessment techniques where possible, for accurate and reliable measurement of body composition.

3182 Board #3 May 29 1:30 PM - 3:00 PM Training Effects Of Alternated And Pulsed Currents On Body Mass Of Competitive Athletes

Pedro F A Oliveira¹, Karenina A G Modesto², Bottaro Martim², João L Q Durigan², Nicolas Babault³. ¹*Federal Institute of Brasilia - IFB, Brasilia, Brazil.* ²*University of Brasilia - UnB, Brasilia, Brazil.* ³*Université de Bourgogne - UB, Dijon, France.*

Email: pedro.oliveira@ifb.edu.br

(No relevant relationships reported)

Neuromuscular electrical stimulation (NMES) is widely used for strength training in healthy individuals and athletes. Previous studies have shown that alternated mid-frequency currents (MF) and low-frequency pulsed currents (PC) have similar effects on quadriceps evoked strength and level of discomfort in this population. However, little is known about the effects and best parameters of NMES to induce body mass loss.

Purpose: To evaluate the effects of 6 weeks of training with 2 different NMES currents - medium alternated and low frequency pulsed current - on body mass of competitive athletes. **Methods:** A double-blind controlled and randomized experimental study was carried out with 33 athletes (22.2 ± 2.6 yrs, 74.7 ± 9.8 kg, 176.8 ± 6.0 cm), divided into 3 groups: mid-frequency current (MF, n=12), pulsed current (PC, n=11) and control group (CG, n=10). Body mass was assessed before and after the intervention through a body mass scale (BC-418, Tanita Corporation of America Inc., Illinois, USA). NMES training was performed 3 times per week and consisted of 18 sessions, 15 min/session (36 involuntary isometric quadriceps contractions per session), 6s duration in each contraction interspersed with 18s rest. Data were expressed as means ± standard

deviation (SD) and normality was checked using the Shapiro-Wilk test. A two-way analysis of variance (ANOVA) with repeated-measures and Tukey post-hoc test were used to analyze data (group and time effects). Statistical significance was accepted with $p < 0.05$. **Results:** After the training period, body mass did not change in any group (PRE: PC = 76.1 ± 8.1 kg, MF = 74.7 ± 9.8 kg, CG = 73.5 ± 21.5 kg; POST: PC = 76.7 ± 8.9 kg, MF = 74.7 ± 9.4 kg, CG = 74.0 ± 11.3 kg; $p > 0.05$). All currents produced similar evoked torque and levels of discomfort ($p > 0.05$). **Conclusion:** Quadriceps NMES training applied through alternated or pulsed currents produced similar effects and did not change body mass in competitive athletes.

3183 Board #4 May 29 1:30 PM - 3:00 PM
**Changes In Body Composition Following A
 Competitive Season In Division I Collegiate Female
 Gymnastics Athletes**

Monica L. Kearney, Jeremy T. Barnes, Jason D. Waggener,
 Seth M. Sievers, Patryk R. Piekarczyk, Michelle L. McIntosh.
Southeast Missouri State University, Cape Girardeau, MO.
 Email: mlkearney@semo.edu
 (No relevant relationships reported)

A large muscle mass to total body mass ratio benefits power athletes such as gymnasts. While collegiate gymnastics athletes train strength and power in the pre-season but reduce training during the competitive season, the degree to which body composition changes during the competitive season is not known. **PURPOSE:** This study examined changes in body composition in a team of female Division I collegiate gymnastics athletes before and after their competition season. It was hypothesized that percent body fat (%BF), total fat mass (TFM), and bone mineral content (BMC) would remain unchanged from pre- to post-season. **METHODS:** Fifteen female collegiate gymnasts (age = 19 ± 1 year, ht = 1.62 ± 0.05 m, wt = 62.7 ± 7.2 kg) volunteered to undergo measures of body composition assessment before and after their spring competitive season. During pre-season (PRE), participants were instructed to arrive to the laboratory in a euhydrated state. Following written informed consent, participants provided a mid-stream urine sample which was used to screen for pregnancy and to determine urine specific gravity (USG) using a handheld digital refractometer. Participants then performed a dual-energy x-ray absorptiometry (DXA) scan to determine TFM, %BF, and BMC. Immediately after the competitive season, participants returned to the laboratory and repeated all procedures (POST). Data were analyzed using paired-samples t-tests with significance set at $p < 0.05$. **RESULTS:** BMC significantly increased across the season (6.422 ± 0.206 g PRE vs. 6.485 ± 0.203 g POST; $p < 0.05$). While there was a downward trend in both TFM (34.158 ± 2.211 kg PRE vs. 32.905 ± 2.335 kg POST; $p < 0.1$) and %BF (25.68 ± 1.16 % PRE vs. 24.99 ± 1.23 % POST; $p < 0.1$), these were not significantly different at the a priori $p < 0.05$ level. There was no change in body weight. **CONCLUSION:** The significant increase in BMC, combined with the downward trend in TFM and %BF, with no change in body weight, suggests athletes maintained body composition in a favorable manner during the competitive season. The increase in BMC further suggests that stimuli during the competitive season were strong enough to elicit favorable changes in bone remodeling during in-season competition.

3184 Board #5 May 29 1:30 PM - 3:00 PM
**Correlation Between Visceral Fat Measured By
 Bioelectrical Impedance And Dual Energy X-ray
 Absorptiometry In Males**

Saori Braun, Morgan Goldammer, Tucker Goesch, Alexa Hayes,
 Garrett Stadler, Steven Fleck, FACSM. *University of Wisconsin-
 Eau Claire, Eau Claire, WI.*
 Email: braunsi@uwec.edu
 (No relevant relationships reported)

Measurement of abdominal adiposity/visceral adipose tissue is clinically relevant in determining individuals' risks of developing cardiometabolic conditions. Bioelectrical impedance (BIA) can be utilized to estimate visceral adipose tissue as an indicator for cardiometabolic dysregulation. **PURPOSE:** To determine the correlation between multi-frequency BIA-derived areal visceral fat (cm^2) and dual energy x-ray absorptiometry (DXA)-derived volumetric visceral fat (cm^3) in normal weight college-aged males. **METHODS:** Visceral fat was measured three times in the following order: 1) BIA, 2) DXA and 3) BIA in college aged males during the early morning. The mean of the two BIA measurements was used for statistical analyses. All three measures were completed in the same session lasting no longer than 30 minutes. To ensure participants were normally hydrated [urine specific gravity (USG) range: 1.022-1.028], USG was determined immediately prior to the testing session. Correlations between BIA areal visceral fat and DXA volumetric visceral fat and a correlation between BIA visceral fat level and DXA android/gynoid (A/G) percent fat ratio Pearson r correlation coefficients were calculated. **RESULTS:** Assessments were done on 102 males (mean age = 20.35 ± 1.38 years; mean body mass index = 25.40 ± 3.36 $\text{kg} \cdot \text{m}^{-2}$). Correlation analysis indicated a moderately high direct correlation between BIA areal visceral fat ($47.54 \pm 32.78 \text{cm}^2$) and DXA volumetric visceral fat (172.20

$\pm 274.36 \text{cm}^3$), $r = .678$, $p < .001$. There was a moderately direct correction between BIA visceral fat levels (4.26 ± 3.24) and DXA A/G percent fat ratio (0.83 ± 0.20), $r = .570$, $p < .001$. **CONCLUSIONS:** In normal weight adults, visceral adiposity and A/G percent fat ratio have much stronger associations with cardiometabolic dysregulation than android and gynoid percent fat. The results of this investigation indicate areal visceral fat and visceral fat level derived from BIA may be a set of useful and meaningful indicators of cardiometabolic disease risk when access to DXA is not available. Future research should explore the predictability of BIA-derived areal visceral fat and visceral fat levels, while controlling for factors such as sex, age, and BMI, on cardiometabolic risk.

3185 Board #6 May 29 1:30 PM - 3:00 PM
**Effects Of Compression Apparel On Body Composition
 Measurements By Air Displacement Plethysmography
 In College Males**

Scott Murr, Alexandra Hultstrom. *Furman University,
 Greenville, SC.* (Sponsor: Anthony Caterisano, FACSM)
 Email: scott.murr@furman.edu
 (No relevant relationships reported)

Body composition measured by air displacement plethysmography (ADP) accounts for the effects of trapped isothermal air in hair by having the subject wear a swim cap to compress the hair on the head. It is recommended that even subjects with very little hair wear a swim cap. Currently, there are no recommendations that account for the effects of trapped isothermal air in body hair. **PURPOSE:** The purpose of this study was to investigate the impact of exposed body hair and the effect of wearing limb length single layer compression apparel on body composition measurements using ADP in college males. **METHODS:** Forty male college students (age 20.0 ± 1.2 yrs; BMI 24.1 ± 3.1 kg/m^2) volunteered to participate in the study. Percentage of body fat was evaluated by ADP. To assess the impact of body hair on body composition measurements, ADP measures were performed in two conditions: wearing single layer compression shorts (CS) apparel with a swim cap (as recommended) and wearing limb length single layer compression (LC) apparel with the same swim cap. The order of apparel was conducted in random order to avoid any potential order effects. **RESULTS:** Wearing limb length single layer compression apparel to compress body hair increased body mass by an average of 0.3 kg (± 0.02); however, there was no significant difference in body density between the CS condition (1.0580 ± 0.014 g/cm^3) and the LC condition (1.0629 ± 0.015 g/cm^3 , $p < 0.001$). The mean percentage of body fat in the LC condition ($15.9 \pm 6.5\%$) was significantly lower than the mean percentage of body fat in the CS condition ($18.0 \pm 6.2\%$, $p < 0.001$). **CONCLUSIONS:** The effect of trapped isothermal air in body hair impacts body composition measurements by ADP. Covering exposed body hair in males when assessing body composition via ADP results in a significantly lower percentage of body fat compared to the minimal clothing recommendation. Attention should be paid to minimizing exposed body hair on males when assessing body composition by air displacement plethysmography. The present results suggest that this minimization may be achieved with males by wearing limb length single layer compression apparel.

3186 Board #7 May 29 1:30 PM - 3:00 PM
**Athlete-specific Prediction Equations For Appendicular
 Upper And Lower Body Lean Soft Tissue With BIA**

Megan Hetherington-Rauth, João P. Magalhães, Pedro B. Júdice,

 (No relevant relationships reported)

Given sport specific physiological demands, knowing the distribution of lean soft tissue among the body segments is of relevance for optimizing athletic performance, monitoring response to specific training regimens, as well as for evaluating potential injury risk. Bioelectrical impedance (BIA) is a widely used portable, low cost, and easy technique to assess body composition. However, most equations used by BIA to predict lean tissue are not specific for the athlete population. **Purpose:** The aim of this investigation was to develop and cross-validate prediction equations to estimate dual-energy X-ray absorptiometry (DXA)-derived appendicular lean soft tissue (LST) of the arms and legs based on whole body BIA in a population of athletes. **Methods:** Two-hundred sixty-five athletes (age 22.2 ± 4.6 yrs) from a variety of sports had LST of the arms and legs assessed by DXA and whole-body reactance (Xc) and resistance (R) measured by BIA. Using measures of height, the resistance index ($\text{RI} = \text{height}^2/\text{R}$) was calculated. Prediction equations were established using a cross validation method where 177 athletes (2/3 of the sample) were used for equation development and the remaining 88 athletes (1/3 of the sample) were used for equation validation. **Results:** The developed prediction equations were as follows: arm LST = $0.940 \cdot \text{sex}$ (0=male; 1=female) + $0.042 \cdot \text{total body weight (kg)} + 0.080 \cdot \text{RI} + 0.024 \cdot \text{Xc} - 3.927$; leg LST = $1.983 \cdot \text{sex}$ (0=male; 1=female) + $0.154 \cdot \text{total body weight (kg)} + 0.127 \cdot \text{RI} -$

1.147. Both equations cross-validated very well for the arms (mean difference=0.11 kg, $R^2=0.89$, $SEE=0.61$) and for the legs (mean difference=0.05 kg, $R^2=0.81$, $SEE=1.95$ kg). There were no differences ($p > 0.05$) in the mean values for both arm and leg LST equations and LST assessed with DXA.

Conclusion: The developed BIA-based prediction equations seem to provide a valid estimation of upper and lower body LST in athletes.

Test-retest Reliability Of Various Methods For Body Composition Assessments

Julia C. Blumkaitis¹, Riley Stefan², Patrick S. Harty³, Petey W. Mumford¹, Alicia Barry¹, Jessica M. Moon¹, Kayla M. Ratliff¹, Richard A. Stecker¹, Kyle L. Sunderland¹, Scott Richmond¹, Chad M. Kerksick, FACSM¹. ¹Lindenwood, St. Charles, MO. ²Northern Illinois University, DeKalb, IL. ³Texas Tech University, Lubbock, TX. (Sponsor: Chad Kerksick, FACSM)
(No relevant relationships reported)

Multi-compartment body composition assessment techniques are common in research and for assessing intervention success. Establishing the validity and reliability of assessment techniques help to ensure appropriate outcomes. **PURPOSE:** To identify the intra (same day) and inter (between-day) test-retest reliability of BIA, BIS, and DEXA composition assessments conducted on two consecutive days in a healthy population. **METHODS:** 40 healthy, collegiate-aged participants (male: $n=20$; 24.6 ± 4.1 yr, 177.5 ± 6.7 cm, 88.1 ± 13.3 kg; female: $n=20$; 22.8 ± 4.5 yr, 163.6 ± 6.5 cm, 64.6 ± 14.3 kg) completed two study visits with 24 hours. All participants arrived fasted (10 h) and after abstaining from exercise (24 h). Each visit consisted of two consecutive rounds (four total measurements) of assessments including body weight, BIA (InBody 570), DEXA scan, and BIS. Pearson correlations, intraclass correlation coefficient (ICC), coefficient of variation (CV), and standard error of the mean (SEM) were computed to assess relationship and reliability between measurement techniques. A p -value of 0.05 was used to assess all statistical outcomes. **RESULTS:** Intra-test and inter-test ICC, CV, and SEM values for all three measurement techniques are provided in table 1. Strong, positive correlations between BIA vs DEXA FM ($r = 0.95$), DEXA vs BIS FM ($r = 0.89$), BIA vs DEXA FFM ($r = 0.99$), and DEXA vs BIS FFM ($r = 0.96$) were observed. **CONCLUSION:** All three methods yielded high intra- and inter-test retest reliability with strong correlations between measurements and excellent CV and ICC values suggesting good repeatability with the largest variation being observed for BIS FM and FFM.

Table 1: ICC, CV, and SEM values for BIA, DXA, and BIS analysis				
		ICC	CV (%)	SEM (grams)
BIA Fat Mass	Intra	1.00	1.20	52.13
	Inter	1.00	2.36	94.33
DXA Fat Mass	Intra	0.99	1.92	138.97
	Inter	0.99	1.26	127.83
BIS Fat Mass	Intra	0.99	4.22	179.51
	Inter	0.98	5.86	280.90
BIA Fat-Free Mass	Intra	1.00	0.36	59.03
	Inter	0.99	0.68	110.04
DXA Fat-Free Mass	Intra	1.00	0.38	56.34
	Inter	0.99	0.75	110.90
BIS Fat-Free Mass	Intra	0.99	0.97	118.21
	Inter	0.99	1.72	285.12

The Impact Of Residual Lung Volume Method On Multi-compartment Model Body Composition Assessment

Zackary S. Cicone, Bjoern Hornikel, Clifton J. Holmes, Michael V. Fedewa, Michael R. Esco, FACSM. University of Alabama, Tuscaloosa, AL. (Sponsor: Michael R. Esco, FACSM)
(No relevant relationships reported)

PURPOSE: Researchers use both direct and indirect nitrogen analysis to determine residual lung volume (RLV) for body composition assessment. However, the agreement between direct and indirect methods, and thus the impact on percent fat (%fat), has yet to be examined. The purpose of this study was to compare multi-compartment %fat using direct and indirect measures of RLV.

METHODS: Thirty-four healthy adults (53% female; 37.7 ± 15.5 y; 27.6 ± 7.0 kg·m⁻²) participated in this study. RLV was measured via oxygen dilution using direct (DIR)

and indirect (IND) nitrogen analysis. Participants also completed hydrostatic weighing, dual energy X-ray absorptiometry, and bioimpedance spectroscopy for body density, bone content, and total body water. Two, three, and four-compartment (2C, 3C, and 4C) model %fat was calculated using RLV from both DIR and IND nitrogen analysis. Agreement for each model was assessed using paired t tests and Bland-Altman analysis. Significance was accepted at $p < 0.05$.

RESULTS: Strong correlations (ICCs > 0.98) were observed for all %fat models between RLV methods. Measures of %fat using IND were larger than DIR (mean differences, 0.7 to 1.6%fat, all $p < 0.001$). However, the magnitudes of the differences were small (Cohen's d , 0.08 to 0.17). Additionally, the range of individual differences between IND and DIR was less than 4.0%, with 3C and 4C producing especially narrow limits of agreement ($\pm 1.4\%$ fat and 1.9% fat) compared to 2C ($\pm 3.4\%$ fat).

CONCLUSIONS: Multi-compartment models using DIR and IND nitrogen analysis to determine RLV demonstrated strong agreement. The more complex models (3C and 4C) were less affected by RLV method than the 2C model and produced limits of agreement less than $\pm 2.0\%$ fat. The results presented here indicate that DIR and IND nitrogen analysis may be used interchangeably for the assessment of body composition when using 3C and 4C models.

Body Composition And Anaerobic Fitness Testing During A Complete NCAA III Men's Hockey Season

Adam M. Coughlin¹, Brian C. Rider², Stephen J. McGregor³, Andrea Workman³. ¹Saginaw Valley State University, University Center, MI. ²Hope College, Holland, MI. ³Eastern Michigan University, Ypsilanti, MI. (Sponsor: Rebecca A. Schlaff, FACSM)

Email: amcoughl@svsu.edu

(No relevant relationships reported)

PURPOSE: Determine the effects of a competitive Division III men's hockey season on anthropometric and anaerobic fitness markers.

METHODS: Seven Division III men's hockey players participated in this season-long study. Athletes reported at four time-points: pre-season (Oct), mid-season 1 (Dec), mid-season 2 (Feb), and post-season (Apr). Each time-point included athletes' height, weight, body composition via air plethysmography, and anaerobic capacity via 30-s Wingate cycle test (WCT). During this season the team appeared in the Frozen Four of the Division III National Tournament, ultimately losing in the championship game. A repeated measured ANOVA was utilized to determine differences in fitness outcomes over the course of the season.

RESULTS: Data for the seven athletes is presented as mean and standard deviation for Oct, Dec, Feb, and Apr time-points. Neither weight (87.9 ± 6.6 , 87.6 ± 7.2 , 88.5 ± 6.7 , 88.2 ± 8.3 kg) nor percent fat (14.4 ± 4.2 , 13.1 ± 3.6 , 14.2 ± 3.0 , $14.3 \pm 3.8\%$) differed significantly throughout the season. Additionally, fat mass (FM) nor fat-free mass (FFM) differed significantly over the course of the season. Peak power (958 ± 96 , 902 ± 144 , 947 ± 139 , 908 ± 145 W, $p = 0.01$) and peak power per kilogram of body weight (10.9 ± 1.0 , 10.3 ± 1.2 , 10.6 ± 0.9 , 10.3 ± 0.9 W/kg, $p = 0.04$) only differed significantly from Feb to Apr. There was also a significant decrease in mean power from Feb to Apr (734 ± 67 , 705 ± 88 , 729 ± 97 , 713 ± 100 W, $p = 0.04$). The only significant difference in mean power per kilogram of body weight occurred from Oct to Dec (8.4 ± 0.5 , 8.0 ± 0.5 , 8.2 ± 0.6 , 8.1 ± 0.6 W/kg, $p = 0.04$). Lastly, fatigue index also decreased significantly from Feb to Apr (51.4 ± 4.3 , 52.2 ± 8.2 , 50.8 ± 3.6 , $46.4 \pm 5.7\%$, $p = 0.03$).

CONCLUSIONS: Anthropometric measurements did not change significantly over the course of the season. Other than an improvement in fatigue index at the end of the season, anaerobic measurements from the WCT either didn't change or worsened over the course of the season. These findings illustrate that championship caliber teams do not necessarily need to improve lab-based anaerobic performance markers (as measured by a 30s Wingate cycle test) nor anthropometric measurements (body weight, FM, FFM, or percent fat) to have successful regular and post-seasons.

3190 Board #11 May 29 1:30 PM - 3:00 PM
Total And Regional Body Composition Of Ncaa Division I Female Soccer Athletes Through Competitive Seasons

Erica Roelofs¹, April Bockin¹, Tyler A. Bosch¹, Christopher W. Bach², Jonathan M. Oliver³, Aaron Carbuhr⁴, Philip R. Stanforth⁵, Donald R. Dengel, FACSM¹. ¹University of Minnesota, Minneapolis, MN. ²University of Nebraska, Lincoln, NE. ³Texas Christian University, Fort Worth, TX. ⁴University of Kansas, Lawrence, KS. ⁵University of Texas at Austin, Austin, TX. (Sponsor: Dr. Donald Dengel, FACSM)

Email: roelo044@umn.edu

(No relevant relationships reported)

Analyzing body composition and tracking changes over seasons is critical to have comprehensive insight to player performance and health as body composition is

strongly related to soccer performance. **PURPOSE:** To examine body composition of NCAA Division I female soccer players by position and season. **METHODS:** One hundred seventy-five female collegiate soccer players from 4 NCAA Division I Universities participated in this study. Athletes were categorized by positions of forward (n=47), midfielder (n=51), defender (n=57), and goalkeeper (n=20). Seasons were defined as pre-season (Aug), in-season (Sep - Oct), post-season (Nov - Dec), winter off-season (Jan), spring season (Feb - Apr), and summer off-season (May - Jul). A whole body dual X-ray absorptiometry scan assessed percent body fat (%BF), total lean muscle mass (LM), total fat mass (FM), arm and leg LM and FM, and visceral adipose tissue (VAT). Separate ANOVAs with linear mixed-effects models to account for repeated measures assessed differences across positions and seasons. **RESULTS:** Goalkeepers had significantly higher height, body mass, FM, and arm and leg LM and FM compared to all other positions ($p < 0.05$). Goalkeepers ($28.1 \pm 4.3\%$) had significantly higher %BF than defenders ($24.4 \pm 3.4\%$) and forwards ($24.5 \pm 4.0\%$; $p < 0.01$), and midfielders ($26.0 \pm 3.9\%$) had significantly higher %BF than defenders ($p < 0.01$) and forwards ($p = 0.04$). Goalkeepers had significantly greater LM (50.5 ± 4.3 kg) than all other positions, and defenders (46.2 ± 4.7 kg) had greater LM than forwards (44.2 ± 3.7 kg) and midfielders (44.3 ± 4.0 kg; $p < 0.01$). For all positions, %BF was significantly higher in winter off-season (26.7%) compared to summer off-season (25.7%) and pre-season (25.8% ; $p < 0.01$). For all positions, total LM and leg LM was significantly lower in winter off-season compared to all other seasons, and total LM was significantly higher in summer off-season than pre-season ($p < 0.01$). **CONCLUSIONS:** Goalkeepers had higher body mass and FM but also had more LM compared to the other positions. In winter off-season, %BF increased and LM decreased indicating potential undesired changes in training and/or nutrition over the holiday break. In summer off-season, LM was the highest reflecting the emphasis on resistance training and increased volume of training.

3191 Board #12 May 29 1:30 PM - 3:00 PM
Combined Anthropometry And Bioelectrical Impedance To Predicted Body Fat In Female Athletes
 Craig Horswill¹, Doug Foote², Max Berkelhammer¹. ¹University of Illinois at Chicago, Chicago, IL. ²University of Eugene, Eugene, OR.
 Email: horswill@uic.edu
 (No relevant relationships reported)

PURPOSE: To determine whether combining anthropometry (skinfolds, SF) and bioelectrical impedance analysis (BIA), an indicator of hydration status, would accurately approximate the expected percentage body fat (%Fat) value and reliably predict %Fat. Accurate and reliable estimation of body composition in female athletes can be challenging since the methodological assumptions are easily violated. For example, hydration status can vary due to menstrual cycle phase, dehydration, and training, and thereby distort %Fat. We hypothesized that compared to outcomes for SF or BIA alone, %Fat using SF+BIA would not differ from our criterion method, and SF+BIA would account for a greater percent of the variance (r^2) in predicting %Fat. **METHODS:** Eighteen female athletes (D1 NCAA competitors) were recruited from the swim team and gymnastic team and measured for body density (air displacement plethysmography), total body water (D_2O dilution), and bone mineral mass (DEXA). Assessments were applied to a four-component model (4C) to determine the criterion %Fat. Skinfolds (Slaughter 2-site equation; Lange caliper), and BIA (Chumlea TBW equation; Quantum VI, RJL) were measured as the predictors. SF was used to determine body volume and BIA was used to determine TBW; these values were then applied to Siri's 3-component equation to predict %Fat (SF+BIA). One-way ANOVA with repeated measures was used to compare mean %Fat values determined for SF, BIA, and SF+BIA and 4C %Fat. Bonferroni multiple comparisons were used as the post hoc test ($p < 0.05$). Regression was used to determine r^2 SF, BIA, and SF+BIA vs 4C criterion.

RESULTS: A significant one-way ANOVA led to post hoc detection of differences in %Fat for BIA (26.6 ± 7.5) and SF+BIA (25.5 ± 7.2) vs. the 4C (22.3 ± 7.5) ($p < 0.05$). The SF estimate (24.0 ± 7.8) did not differ from the 4C value. Regression revealed the highest adjusted variance accounted for in 4C was SF+BIA ($r^2 = 0.87$) followed by BIA ($r^2 = 0.80$) and SF ($r^2 = 0.76$), all of which were statistically significant.

CONCLUSIONS: Skinfolds alone were more accurate at predicting the mean %Fat in these female athletes but combining SF and BIA might provide greater reliability for predicting percent body fat in female athletes.

3192 Board #13 May 29 1:30 PM - 3:00 PM
Increased Body Fat Negatively Impacts Aerobic Capacity Of Elite American Football Players Regardless Of Position
 Matthew E. Darnell¹, Laura E. Kleiber¹, Julian R. Chismar¹, Paul N. Whitehead². ¹University of Pittsburgh, Pittsburgh, PA. ²University of Alabama Huntsville, Huntsville, AL. (Sponsor: Elizabeth Nagle, FACSM)
 (No relevant relationships reported)

Aerobic capacity and body composition play an important role in athletic performance and health. Previous research demonstrates an association between lower body fat percentage (BF%) and enhanced aerobic as well as anaerobic capacity, while higher BF% is linked to an increased risk of chronic diseases related to obesity. The amount of research on aerobic performance in elite football players is limited, and even less research has compared maximal oxygen uptake (VO_2 peak) with body composition by position. **Purpose:** To determine the relationship between BF% and VO_2 peak in elite football players by position group. **Methods:** Elite American football players ($n = 112$, age: 25.03 ± 2.89 yrs, ht: 187.06 ± 7.62 cm, and wt: 110.89 ± 22.71 kg) were split by position into three groups. Small skill (SS) ($n=50$): running back, cornerback, safety, and wide receiver; big skill (BS) ($n=27$): tight end, linebacker, and quarterback; and linemen (LM) ($n=35$): tackle, guard, center, and defensive end. BF% was calculated using air displacement plethysmography. VO_2 peak was measured via indirect calorimetry during a treadmill test using three protocols based on position group. SS and BS ran at 7.5 or 6.5 mph (respectively) with a 2% increase of elevation every 2 minutes, and LM performed a Bruce protocol. Subjects ran until volitional fatigue. A Kruskal-Wallis test with Bonferroni post hoc was used to compare BF% and VO_2 peak values between position groups. A Spearman's rank-order correlation was used to determine the relationship between BF% and VO_2 peak. **Results:** LM (39.58 ± 5.07 ml·kg⁻¹·min⁻¹) VO_2 peak was significantly different from BS (47.75 ± 5.47 ml·kg⁻¹·min⁻¹) and SS (49.93 ± 4.31 ml·kg⁻¹·min⁻¹) ($p < .001$). There was no difference in VO_2 peak between BS and SS ($p > 0.05$). BF% was significantly different ($p \leq .002$) between all groups (SS: $12.23 \pm 4.83\%$, BS: $17.81 \pm 4.32\%$ and LM: $26.26 \pm 5.23\%$). A statistically significant ($p < 0.01$) moderate negative correlation was found between BF% and VO_2 peak overall ($r_s = -0.772$) and for each position group (SS $r_s = -0.49$, BS $r_s = -0.54$, and LM $r_s = -0.62$). **Conclusions:** Body composition differs between position groups. Lower BF% was associated with higher VO_2 peak in elite football players regardless of position group. Future research should explore the impact of these variables on player performance and risk of injury.

Bioimpedance Phase Angle Reliability In Mexican College Students
 Jorge Aburto-Corona¹, Alan D. Torres-Hernández¹, Luis M. Gómez-Miranda¹, Yamileth Chacón-Araya², José Moncada-Jiménez². ¹Autonomous University of Baja California, Tijuana, Mexico. ²University of Costa Rica, San José, Costa Rica.
 Email: jorge.aburto@uabc.edu.mx
 (No relevant relationships reported)

Bioimpedance (BIA) phase angle (PA) is a body composition measure related to cell structure, integrity and body cell mass. Although PA has been positively correlated to clinical outcomes, there is scarce information on ethnic differences in PA and its overall reliability. **PURPOSE:** To determine phase angle reliability in Mexican college students. **METHODS:** College students from the city of Tijuana, México, were recruited for this study. Volunteers were 26 males (Age = 22.7 ± 3.1 yr., Height = 172.8 ± 5.6 cm, Weight = 70.9 ± 11.7 kg) and 26 females (Age = 21.1 ± 2.2 yr., Height = 159.0 ± 7.1 cm, Weight = 60.8 ± 8.6 kg). Participants arrived euhydrated to the testing session (Urine specific gravity = 1.005 ± 0.003) and were measured on a multi-frequency InBody 770 BIA device in two occasions separated by five minutes of seated resting. Body weight, %fat mass, muscle mass (kg) and PA were recorded and analyzed by repeated measures 2 (gender) x 2 (measures) ANCOVA, using hydration status and age as covariates. Intraclass correlation coefficient (ICC) and 95% confidence interval were used to determine reliability between measures. **RESULTS:** Gender differences were found on PA (Males = 6.8 ± 0.1 vs. Females = 5.9 ± 0.1 , $p \leq 0.0001$), and muscle mass (Males = 31.9 ± 0.7 vs. Females = 23.2 ± 0.7 kg, $p \leq 0.0001$). Significant ($p \leq 0.0001$ for all) ICC reliability coefficients were found between pre- to post-measures of PA ($r = 0.998$, 95%CI = 0.996 to 0.999), %fat ($r = 0.999$, 95%CI = 0.998 to 1.00) and muscle mass ($r = 1.00$, 95%CI = 1.00 to 1.00). **CONCLUSION:** Young college students showed reliable BIA PA, muscle mass and %fat values following five minutes of seated resting. Mexican males showed higher muscle mass and PA than women after controlling for the influence of hydration and age.

3194 Board #15 May 29 1:30 PM - 3:00 PM

Sex Affects The Difference In Body Fat Estimation Between Body Composition Devices

Christopher A. Fahs¹, Maddison Beck², Jonathan Boring³, Lindsay LeVault², William Varner². ¹Logan University, Chesterfield, MO. ²Lindenwood University Belleville, Belleville, IL. ³Lindenwood University, St. Charles, MO. (Sponsor: Michael Bembem, FACSM)

Email: christopher.fahs@logan.edu

(No relevant relationships reported)

Commercially available upper-body (UB) and lower-body (LB) bioelectrical impedance analyzers (BIA) are commonly used to measure body fat percentage (%BF) and classify body composition status. Some evidence suggests that LB BIA underestimate %BF specifically in women. It is not clear if UB BIA devices also underestimate %BF in women or if LB and UB BIA devices underestimate %BF in men. **PURPOSE:** To compare %BF from air displacement plethysmography (ADP), UB BIA, LB BIA, and whole-body (WB) BIA and to determine if the %BF differences between devices are affected by sex. **METHODS:** 53 women (21±5 yrs) and 42 men (23±5 yrs) had their %BF measured via ADP, a hand-held UB BIA, a digital scale LB BIA, and a validated eight-electrode multifrequency WB BIA device following each device's recommended procedures. Paired samples t-tests were used to compare %BF between devices within each sex. Independent samples t-tests were used to compare the %BF difference between devices for each sex. **RESULTS:** In women, UB (23.8±4.3%) and LB (20.4±5.8%) BIA yielded significantly ($p<0.001$) lower %BF than ADP (28.3±7.4%) and WB BIA (28.9±5.0%). In men, UB (15.6±5.3%) and LB BIA (15.0±4.0%) also yielded significantly lower %BF values than ADP (17.6±7.7%; $p=0.012$ vs. UB BIA; $p=0.008$ vs. LB BIA) and WB BIA (19.1±6.7%; $p<0.001$ vs. UB and LB BIA). The differences in %BF between devices were greater in women compared to men: WB - UB BIA difference 5.0±2.6 vs. 3.6±3.3%, $p=0.021$ (women vs. men); WB - LB BIA difference 8.5±4.1 vs. 4.2±5.1%, $p<0.001$; ADP - UB BIA difference 4.5±5.9 vs. 2.0±5.0%, $p=0.028$; ADP - LB BIA difference 7.9±6.3 vs. 2.7±6.2%, $p<0.001$; UB - LB BIA difference 3.4±3.5 vs. 0.7±3.2%, $p<0.001$. **CONCLUSIONS:** These results suggest that commercially available UB and LB BIA devices systematically underestimate %BF in both men and women compared to a validated multifrequency WB BIA and ADP. The degree of underestimation in %BF for commercially available BIA devices is greater in women compared to men. Use of these commercially available BIA devices may cause misclassification of body composition status, especially in women.

An Equation To Estimate Head Volume For Hydrostatic Weighing In Partially Immersed Subjects

Panayiotis Papadopoulos¹, Forrest A. Dolgener¹, David M. Reineke², Jeff C. Tesch³. ¹University of Northern Iowa, Cedar Falls, IA. ²University of Wisconsin-La Crosse, La Crosse, WI. ³EXERTECH, Dresbach, MN. (Sponsor: Kevin J. Finn, FACSM)

Email: panayiotis.papadopoulos@uni.edu

Reported Relationships: P. Papadopoulos: Other (please describe); One of the authors (Jeff C. Tesch) is the vendor of the equipment used in the study.

PURPOSE: The purpose of the study was to derive prediction equations for head volume (HV) from head girths and diameters and to use the equations for hydrostatic weighing (HW).

METHODS: HW was performed with and without head submersion of subjects using a computerized, 4 load cell weighing system. Forty-four males and 46 females comprised the experimental groups from which equations were derived to predict HV by water displacement. HW was then performed on 46 additional subjects (21 males and 25 females) to compare body density (BD) and body fat percent (BF%) for head below water (HBW) and head above water (HAW) immersion using the HV prediction equations. Subjects exhaled to residual volume and maintained the same lung volume during the HAW phase and the HBW phase of each immersion trial.

RESULTS: Head girths showed higher correlations and smaller SEEs than head diameters for the prediction of HV. Regression analysis indicated that the equations with the highest R^2 and the lowest SEE were from head girth (HG), face girth (FG) and body mass in air (MA). The equation for males was $HV = 0.1294 \cdot HG + 0.0299 \cdot FG + 0.0055 \cdot MA - 5.7506$ ($R^2 = 0.57$, $SEE = 0.26$ L). The equation for females was $HV = 0.1314 \cdot HG + 0.0504 \cdot FG + 0.0094 \cdot MA - 8.9008$ ($R^2 = 0.73$, $SEE = 0.21$ L). The validation groups showed no significant differences ($p < 0.05$) in BD between HAW immersion and HBW immersion for either males ($R^2 = 0.98$, $SEE = 0.0028$ g·ml⁻¹) or females ($R^2 = 0.90$, $SEE = 0.0054$ g·ml⁻¹). There were no significant differences ($p < 0.05$) in BF% between HAW immersion and HBW immersion for either males ($R^2 = 0.98$, $SEE = 1.16\%$) or females ($R^2 = 0.90$, $SEE = 2.24\%$). Fluctuations in weight scale readings were significantly lower ($p < 0.05$) for HAW immersion than for HBW immersion in both males ($SD_{HAW} = 0.31$ kg, $SD_{HBW} = 0.40$ kg) and females ($SD_{HAW} = 0.22$ kg, $SD_{HBW} = 0.30$ kg).

CONCLUSIONS: Weight readings are more stable and BD and BF% are not significantly different when HW is performed without head submersion using predicted HV.

Test-retest Reliability Of Total Body Volume Derived From A Single 2-dimensional Digital Image

Michael Vernon Fedewa, Katherine Sullivan, Clifton J. Holmes, Bjoern Hornikel, Shengting Cao, Yu Gan, Michael R. Esco, FACSM. University of Alabama, Tuscaloosa, AL. (Sponsor: Michael R. Esco, FACSM)

Email: mvfedewa@ua.edu

Reported Relationships: M.V. Fedewa: Receipt of Intellectual Property Rights/Patent Holder; Provisional Patent Submitted. Dr. Fedewa developed the Intellectual Property related to this abstract as part of his research at the University of Alabama.

Simple, accurate, and cost-effective methods to estimate body composition in field settings are valuable to practitioners and clinicians. An automated smartphone- or tablet-based method of determining body composition from a single 2-dimensional (2D) digital image has recently been developed. However, the test-retest reliability has yet to be determined. **PURPOSE:** The purpose of this study was to evaluate the test-retest reliability of total body volume (BV) estimated from a single 2D digital image. **METHODS:** A convenience sample was recruited for this study ($n=30$, 21.0±3.1 yrs., 86.7% female, 24.8±3.0 kg/m²). Body mass was measured (to the nearest 0.1 kg) with a calibrated digital scale (Tanita BWB-800, Tanita Corporation, Tokyo, Japan). Standing height was measured (to the nearest 0.1 cm) with a stadiometer (SECA 213, Seca Ltd., Hamburg, Germany). Two digital images of each participant were taken from the rear/posterior view using a 12.9 inch, 64g iPad Pro. A paired sample T-test was used to examine differences between BV obtained from the images (BV₁, BV₂). An Intraclass Correlations Coefficient (ICC) assessed the strength of the association between BV₁ and BV₂. **RESULTS:** No differences were observed between BV₁ and BV₂ (71.2±12.0 L versus 71.1±11.7 L, respectively, $p=0.51$), with excellent agreement between the two measures (ICC=0.99).

CONCLUSIONS: This novel method of acquiring BV produced near-perfect reliability within our small sample. Given the excellent reliability, future research should examine the validity of acquiring body composition from a single 2D digital image using an automated smartphone- or tablet-based application.

Acute Exercise And Resulting Dehydration Does Not Alter Body Composition Measures Using Fit3D

Emily A. Freund, Jennae M. Fenton, Nick J. Rein, Courtney D. Jensen, J. Mark VanNess. University of the Pacific, Stockton, CA.

Email: e_freund@u.pacific.edu

(No relevant relationships reported)

Fit3D is a novel, camera-based system to assess anthropometric measurements and determine body composition. Little data exist on how the values generated by this system may be influenced by acute exercise and associated dehydration and fluid shifts. **PURPOSE:** To determine the effect of a prolonged bout of acute exercise on the body composition measures generated by the Fit3D. **METHODS:** 17 subjects (7 female, 10 male) underwent body composition analysis using the Fit3D before and after one hour of acute exercise. The exercise protocol consisted of a maximal treadmill exercise test to volitional fatigue followed by 40 min of continuous exercise at the estimated anaerobic threshold calculated by taking 65% of each subject's ventilatory threshold. Each subject had their vitals (heart rate, blood pressure, and scale weight) taken, provided a urine sample to measure specific gravity, and performed a Fit3D scan before and after the exercise bout. **RESULTS:** Subjects lost 2.5±1.8 lbs during exercise. This loss of body water was associated with an increase in urine specific gravity of .007±.004. These changes did not influence any of the circumference measures and only slightly influenced percent body fat measured on the Fit3D. Pre-to-post measures of body fat (24.5±6.9% vs 24.8±6.7%), trunk-to-leg volume ratio (1.45±0.59 vs 1.49±0.56), fat mass (73.4±15.7 vs 72.5±15.6kg), lean mass (54.9±9.9 vs 54.1±10.2 kg), and basal metabolic rate (1637±242 vs 1630±242 cal/day) were not statistically different ($p=0.894$, 0.876, 0.999, 0.822 and 0.930 respectively). **CONCLUSION:** Our results provide preliminary evidence that the Fit3D instrument is a consistent tool for assessment of body composition even after a bout of acute exercise resulting in the loss of body water.

Body Composition And Aerobic Fitness Levels In College Freshmen
 Nicole Varone, Vipa Bernhardt. *Texas A&M University Commerce, Commerce, TX.* (Sponsor: Tony G. Babb, FACSM)
(No relevant relationships reported)

Nicole Varone & Vipa Bernhardt
Texas A&M University Commerce

Background: Research has shown that college students exhibit gains in fat mass that are up to 5.5 times greater than their peers of the same age who do not attend college (Mihalopoulos et al, 2008). Because of concerns over increasing rates of obesity, college campuses nationwide are engaging in campaigns designed to target college youth and educate them about the benefits of healthy lifestyle behaviors. In order to implement effective intervention strategies, a clear picture of current student fitness must be acquired.

Purpose: The purpose of this study was to examine objective measures of body composition and aerobic fitness levels in current first year students of a rural university.

Methods: 24 participants (17F/7M, 18±1yr, 167.5±72.0 cm, 67.9±17.1kg, 24.5±5.2kg/m² BMI) underwent dual energy x-ray absorptiometry for body fat determination and performed the Astrand submaximal bicycle ergometer test with metabolic measurements (e.g., VO₂), from which estimated VO₂max was extrapolated. The International Physical Activity Questionnaire (IPAQ) was administered to gather subjective self-evaluation of weekly exercise volume.

Results: The majority of students (13F/4M) fell into the "very poor" category for body fat percentage as defined by ACSM (34±7% in females and 24±10 in males). Five(5F/0M) were classified as "poor", 1 (0F/1M) as "fair", and 3 (1F/2M) as "good". 13 participants were classified as "good" or better on VO₂ max and 11as "fair" or worse (female: 42.5±11.2 ml/kg/min and male: 39.0±15.7 ml/kg/min). The majority (8F/7M) of participants claimed to engage in a "high" volume of physical activity per week as measured by the IPAQ, while 7 (7F/0M) scored "moderate" and 2 (2F/0M) "low" levels.

Conclusion: Although BMI average was normal, the majority of students failed to meet body fat standards. It is also interesting that all 7 males in the study scored themselves as "high" on the IPAQ, yet 6 of the 7 scored "poor" or "very poor" in the objective determination of VO₂max. Follow-up studies will investigate how these variables change within their first semester and over their entire college life.

Validity Of A 3-Compartment Body Composition Model Derived From A Single 2-Dimensional Digital Image
 Katherine Sullivan, Clifton J. Holmes, Bjoern Hornikel, Shengting Cao, Yu Gan, Michael R. Esco, Michael V. Fedewa.
University of Alabama, Tuscaloosa, AL.
Reported Relationships: K. Sullivan: Receipt of Intellectual Property Rights/Patent Holder; Michael Fedewa.

Laboratory-based methods for assessing body composition often require specialized equipment, trained administrators, and relatively complex, time-consuming protocols. Simple, accurate, and cost-effective methods to assess body composition in field settings are limited. **PURPOSE:** The purpose of this study was to evaluate the validity of a digital image derived 3-compartment model estimate of body composition (IMAGE-3C) when compared to a 3-compartment skinfold estimate of body composition (SKF-3C). **METHODS:** A convenience sample of female participants was recruited for this study (n=24, 20.4±1.0 yrs., 73.1±10.3 kg). Body mass was measured (to the nearest 0.1 kg) with a calibrated digital scale (Tanita BWB-800, Tanita Corporation, Tokyo, Japan), and a standing height was measured (to the nearest 0.1 cm) with a stadiometer (SECA 213, Seca Ltd., Hamburg, Germany). Double measurements (within 2 mm of each other), of skinfold thickness were taken using calibrated skinfold calipers (Lange Skinfold Caliper, Seko, USA) across 7 standard sites on the body. A digital image of each participant was taken from the rear/posterior view using a 12.9 inch, 64g iPad Pro. A paired sample T-test was used to examine potential differences between body composition when measured via IMAGE-3C and SKF-3C. Intraclass Correlations Coefficient (ICC) was used to determine the strength of the association between the two methods. **RESULTS:** No differences in body composition were observed between IMAGE-3C and SKF-3C (17.9±5.1 versus 18.7±5.6, respectively, p=.08), with excellent agreement between methods (ICC=.96). **CONCLUSIONS:** The IMAGE-3C model appears to be a valid method of estimating body composition. The ability to evaluate body composition from a single digital image provides an accurate and efficient alternative to laboratory methods, which can be utilized by the general public. Data collection is ongoing. A larger and more diverse sample is needed to confirm these findings.

3200 Board #21 May 29 1:30 PM - 3:00 PM
COMPARISON OF BODY COMPOSITION METHODOLOGIES BETWEEN SKINFOLD AND ULTRASOUND IN ELITE CROSSFIT ATHLETES: A PILOT STUDY.

Maraline Santos Sena¹, Matheus Lima Caetano¹, Adriana Pereira Sampaio¹, Marília Cabral Mendes¹, Eder Evangelista Costa², Marcio Leandro Ribeiro de Souza³, Valden Luis Matos Capistrano Junior¹. ¹*VClínica de Nutrição, Fortaleza, Brazil.* ²*Gurkha Crossfit, Fortaleza, Brazil.* ³*Faculdade de Minas FAMINAS BH, Fortaleza, Brazil.*
(No relevant relationships reported)

PURPOSE: The aim of the present work was to compare body composition methodologies between skinfold and ultrasound in elite CrossFit athletes.

METHODS: The sample consisted of 8 male CrossFit athletes with practice time (mean ± standard deviation) 58.66 ± 11.13 months, age 25.33 ± 4.38 years, height 181.11 ± 6.09 cm, weight 93.8 ± 8.41 kg and participating in national competitions, and international. The athletes were evaluated through skinfold (ST) (Cescorf plicometer) and ultrasound (BodyMetrix - BX 2000) in triceps, subscapularis, biceps, middle axillary, iliac, supraspinatus, abdominal, mid thigh and middle calf. The circumferences were measured with a flexible and inelastic anthropometric tape measure. ISAK standardization was used to measure skin folds. Descriptive statistics data are expressed as mean and ± standard deviation (SD) of absolute values of skinfold thickness measured by plicometer and ultrasound. A t-test for paired measurements was used, the Shapiro-Wilk normality test. Wilcoxon for nonparametric data). The confidence interval (CI) is 95% and Cohen's d was calculated for effect size. The existence of correlation was analyzed by Pearson's test (Spearman for non-normal data).

RESULTS: The difference between the means generated by ultrasound and plicometer was statistically significant for: -1.67mm ST triceps; - 4.15mm ST Subscapular; - 1.65mm ST Axillary; - 0.21mm ST Iliac; - 3.48mm ST Thigh; - 1.61mm ST Calf. Comparing each skinfold and ultrasound result it was possible to perform a proportion, and it was noted that the triceps ST was 1.56 times higher, subscapular ST 1.95, axillary ST 1.49, iliac ST 1.67, abdominal ST 1.39, and thigh DC 1. calf 1.53, comparing plicometer with ultrasound, respectively. In addition, the variables with small correlation (r = 0 - 0.25) were: triceps (r = 0.177); subscapular (r = 0.109); axillary (r = 0.005); iliac (r = 0.222); thigh (r = 0.044); calf (r = 0.097); variables with weak correlation (r = 0.26 - 0.5) were: abdominal (r = 0.343).

CONCLUSIONS: We conclude that there is a significant reduction in the thickness of the anatomical point collected by ultrasound and the skinfold thickness collected by the plicometer. Thus, we suggest that these differences at each anatomical point be taken into account when using a predictive equation to estimate body fat.

3201 Board #22 May 29 1:30 PM - 3:00 PM
Comparison Of Waist And Hip Circumference Measures From 3-dimensional Technology And Manual Measurements

Gabrielle J. Brewer, Malia N.M Blue, Katie R. Hirsch, Alyson G. Nelson, Abbie E. Smith-Ryan, FACSM. *University of North Carolina - Chapel Hill, Chapel Hill, NC.* (Sponsor: Abbie Smith-Ryan, FACSM)
(No relevant relationships reported)

Three-dimensional (3D) scanning technology is becoming increasingly popular to obtain quick anthropometric and body composition measurements and may be a practical alternative to manual assessment methods. **PURPOSE:** To compare waist and hip circumferences measured from a 3D scan to manual measurements in healthy adults. **METHODS:** Data was collected on 66 healthy male (n=22) and female (n=44) young adults (Mean ± SD: Age: 20.6 ± 1.1 yrs, BMI: 22.6 ± 2.0 kg/m²). Manual measurement of the waist was assessed at the narrowest part of the trunk; hip circumference was measured at the widest region of the buttocks. Circumferences were measured twice by the same researcher and averaged. Measurements corresponding to the same waist and hip regions assessed manually were automatically determined by the 3D scanner software. Paired-samples t-tests were utilized to determine differences between methods for the total sample and each sex. Manual measurements were used as the criterion to evaluate prediction error (standard error of the estimate [SEE]). **RESULTS:** For the total sample, the 3D scan significantly underestimated waist (Mean difference (3D - manual) [MD]: MD: 6.3 ± 2.2 cm; p<0.001) and hip (MD: 2.8 ± 2.3 cm; p<0.001) circumferences compared to manual assessments. For the men, the 3D scanner significantly underestimated waist (MD: 6.6 ± 2.1 cm; p<0.001) and hip (MD: 2.2 ± 1.9 cm; p<0.001) circumferences. The same trend was seen for women for the waist (MD: 6.1 ± 2.2 cm; p<0.001) and hips (MD: 3.0 ± 2.5 cm; p<0.001). Prediction error of hip circumference was greater for women (SEE=2.42 cm) compared to men (SEE=1.94 cm); waist circumference error was similar for women (SEE=2.14 cm) and men (SEE =2.05 cm). **CONCLUSIONS:** 3D technology may underestimate

waist and hip circumference estimates compared to manual techniques in normal weight adults. However, 3D technology may be useful to provide quick anthropometric measurements.

Reliability Of Seca® Medical Body Composition Analyzer (mbca) In Healthy Young Adults

Chloe Y. Marr, Chandler Cornett, Kirsten Villanueva, Kent A. Lorenz, MiSook Kim, James R. Bagley. *San Francisco State University, San Francisco State University, CA.*
 Email: cymarr@mail.sfsu.edu
 (No relevant relationships reported)

PURPOSE: Bioelectrical impedance analysis (BIA) is an emerging method to measure body composition. The purpose of this study was to determine 1) baseline values of fat mass (FM), fat-free mass (FFM), skeletal muscle mass (SMM), total body water (TBW) extracellular water to total body water ratio (ECW/TBW), phase angle (PA), bioelectrical vector analysis (BIVA), and visceral adipose tissue (VAT), 2) any gender differences among measures, and 3) test-retest reliability on a newly obtained SECA® BIA device. **METHODS:** 37 young adults [22 males and 15 females; mean±SD, age 24.4±3.5; BMI 25.6±4.1 kg/m²] were measured in a single trial on the SECA® BIA machine having fasted overnight and abstaining from exercise for 12 hours. Multivariate analysis of variance was used to determine effects of gender on measures. To determine test-retest reliability, a subset of participants (26 healthy young adults) were measured 48 hours after the initial visit under the same conditions. Interclass correlation coefficients (ICC) were used to determine reliability of measures. **RESULTS:** Results: Males had higher (p<0.05) FFM, SMM, TBM, and VAT, whereas females had higher (p<0.05) FM, and ECW/TBW ratio. Correlation analysis revealed that all variables except ECW/TBW and BIVA were highly correlated between visit 1 and visit 2 (ICC>0.9) indicating reliability of measurements. **CONCLUSIONS:** Conclusion: SECA® scale measurements have high test-retest reliability. Future investigations should determine the validity of the SECA® compared to standard methods.

Body Composition And Somatotype By Sex In Candidates That Apply To Dance And Theater University Degrees.

Sergio Alejandro Copado-Aguila, Sayra Nataly Muñoz-Rodriguez, Alejandro Gaytan-Gonzalez, Zulema Getsemami Alfaro-Fregoso, Luis Abraham Zuñiga-Ramirez, Xochitl Citlalli Olivares-Ochoa, Juan Ricardo Lopez-Taylor. *Universidad de Guadalajara, Guadalajara, Mexico.*
 (No relevant relationships reported)

PURPOSE: To determine and to compare the body composition and somatotype profiles with anthropometric methods by sex in Mexican candidates that apply to dance and theater university degrees at the University of Guadalajara. **METHODS:** 264 (95 males, 169 females) Mexican candidates that applied to dance and theater university degrees were evaluated anthropometrically by certified staff by the International Society for the Advancement of Kinanthropometry (ISAK). A complete profile anthropometric evaluation according to ISAK methodology was performed for each subject. We estimated body composition by four compartments according to Kerr equations (adipose, muscle, bone, and visceral tissues), and Somatotype was determined by the Heath and Carter method (decimal equations). The sample was divided by sex. Body composition values (adipose tissue, muscle, bone) and the somatotype components were expressed as mean, standard deviation, minimum and maximum. T-test for independent samples was performed to compare variables by sex. **RESULTS:** Subject's age, weight, height, and body mass index were: 19 ± 3 and 19 ± 2 years, 67 ± 13 and 57 ± 12 kg; 172 ± 8 and 160 ± 6 cm; and 22 ± 4 and 22 ± 4 kg/m², for males and females, respectively. There were significant differences in all three compartments between males and females (percentage and mass). In the case of somatotype, we found that values of Endomorphy were lower and values of Ectomorphy were higher in males than females. Values of Mesomorphy were similar among sex. The mean value for males was Central (4-4-3), while in females was Mesomorphic Endomorph (5-4-2). **CONCLUSIONS:** In this study, we found that body composition, as well as somatotype, differs by sex. However, the sample was not divided by performing art (dance and theater), being able to find either similarities or differences with the existing literature.

Table 1. Body composition and somatotype profile of the evaluated subjects

Variable	Total (n=264)	Males (n=95)	Females (n=169)	p-value
Adipose tissue (%)	27 ± 7.4 (8-40)	20 ± 5.7 (8-32)	31 ± 4.4 (19-40)	<0.001
Adipose tissue (kg)	16 ± 6.2 (3-36)	14 ± 6.2 (3-32)	18 ± 5.7 (7-36)	<0.001
Muscle mass (%)	35 ± 5.1 (25-50)	40 ± 4.6 (29-50)	33 ± 3.4 (25-41)	<0.001
Muscle mass (kg)	21 ± 5.4 (13-43)	26 ± 4.5 (16-43)	18 ± 3.5 (13-40)	<0.001
Bone mass (%)	16 ± 2.1 (10-23)	17 ± 2.3 (10-23)	15 ± 1.8 (10-20)	<0.001
Bone mass (kg)	9 ± 1.7 (7-15)	11 ± 1.5 (7-15)	9 ± 1.1 (7-12)	<0.001
Endomorphy	4 ± 1.6 (1-8)	4 ± 1.5 (1-8)	5 ± 1.4 (2-8)	<0.001
Mesomorphy	4 ± 1.4 (1-11)	4 ± 1.3 (1-9)	4 ± 1.4 (1-11)	1.000
Ectomorphy	2 ± 1.4 (0-8)	3 ± 1.5 (0-8)	2 ± 1.4 (0-6)	<0.001

Data expressed as mean ± standard deviation (min-max)

3204 Board #25 May 29 1:30 PM - 3:00 PM
Cross-calibration Of Two Dual-energy X-ray Absorptiometry Systems For Body Composition Measurements In Young Adults

Ana Mejia, Johnny Huatran, Erick Ramirez, Guillermo Escalante, Bryan Haddock, Zhaojing Chen. *California State University, San Bernardino, San Bernardino, CA.* (Sponsor: Bryan Haddock, FACSM)
 (No relevant relationships reported)

Dual-energy X-ray absorptiometry (DXA) is one of the most accurate methods to measure body composition, and it has been widely used in both clinical and research settings such as the Appendicular Lean Mass (ALM) in sarcopenia. The body composition results on the same client may vary depending on the manufacture, model and software version of the DXA. Therefore, it is important to compare the measurements between different systems in longitudinal research studies and clinical practice. **PURPOSE:** To properly cross calibrate the body composition measurements between the Prodigy and iDXA in young adults. **METHODS:** Thirty healthy college students, including ten males (23.7 ± 1.9 years; 171.9 ± 6.7 cm; 81.8 ± 11.4 kg) and twenty females (23.1 ± 1.9 years; 161.8 ± 6.1 cm; 64.9 ± 15.3 kg) participated in the study. Body composition was measured using two DXA systems: Prodigy and iDXA, and analyzed by enCORE version 13 and 17, respectively by the same licensed DXA technician on the same day. Paired sample t-tests and regression analyses were performed to compare the body composition variables between the two systems. **RESULTS:** No significant differences were found in total body and leg percent fat (%fat), total and leg Fat Mass (FM), and total Bone Free Lean Mass (BFLM) (p > 0.05). However, there were statistically significant differences in total body and leg Bone Mineral Content (BMC) (p = 0.000), arm %fat (p = 0.012), arm FM (p = 0.000), arm and leg BFLM (ALM, p = 0.000) between the two systems (**Table 1**). **Conclusion:** Our results suggest that calibration equations are needed for the appendicular lean mass when comparing body composition between the Prodigy and iDXA in young adults. Further study in older adults is needed for the comparison of sarcopenia assessment using the two models of DXA.

Table 1. Comparison of Regional Body Composition Between iDXA and Prodigy

Body Composition	iDXA	Prodigy	%Diff	P
Arm BFLM (lbs)	12.3 ± 5.6	12.6 ± 5.8	-2.37	0.012
Arm FM (lbs)	5.3 ± 2.3	4.3 ± 2.3	22.68	0.000
Leg BFLM (lbs)	35.6 ± 9.4	34.8 ± 9.4	2.23	0.000
Leg FM (lbs)	17.5 ± 7.9	17.6 ± 9.1	-0.34	0.83

BFLM: Bone Free Lean Mass; FM: Fat Mass

The Effects Of Training Method And Experience Level On Measurement Error For Skinfold Thicknesses

Laurie A. Milliken, FACSM¹, Timothy G. Lohman². ¹University of Massachusetts Boston, Boston, MA. ²University of Arizona, Tucson, AZ.
 Email: laurie.milliken@umb.edu
 (No relevant relationships reported)

Accurate estimation of fatness from skinfolds is highly dependent on using the appropriate skinfold protocol, the methods of training and experience of the trainee. Purpose: To determine the effects of the type of training method and experience level on the accuracy of performing skinfold thickness measures at the triceps, subscapular and calf skinfold sites.

Methods: This study was designed to test the experience of the trainee using three different methods of training in a 2x3 factorial plan with a manual (M), audiovisual (AV) and in person (IP) training approach. Half of the trainees had no experience and half had some or considerable experience as judged by the number of subjects they had measured previously assessed by self report. Thirty subjects were randomly assigned to each of three methods in instruction (n=10/method). Half of the trainees were inexperienced in each training method. Three skinfolds (triceps, subscapular and calf) were measured using standardized procedures. To be trained on the skinfold measurement method, the M method group read a description of the skinfold method, the AV method group watched a training video, and the IP method group attended an IP workshop. All trainees measured the skinfolds of from 15 participants and were compared to an expert. An ANOVA was used to determine whether expert versus trainee systematic errors were different due to the method of training, experience level, or their interaction were significant.

Results: The mean systematic errors for the tricep were 1.0±0.9, 1.4±1.0, 1.0±0.6 for the M, AV and IP groups, respectively. For the calf, the mean errors were 1.4±0.7, 1.6±1.1, 0.7±0.3 for the M, AV and IP groups, respectively. For the subscapular, the mean errors were 1.1±1.0, 1.2±0.7, 0.8±0.7 for the M, AV and IP groups, respectively. There was no effect (p>0.05) of experience level or training method for all skinfolds except for the training method in the calf with the IP group trending toward the lowest error (p<0.10). The interaction between type of training and experience level was also not significant (p>0.05).

Conclusion: The systematic errors in measuring skinfolds were not influenced by experience level of the trainee or the training method however, outliers were found in every treatment group which contributed to the variability in the measures.

3206 Board #27 May 29 1:30 PM - 3:00 PM
Waist To Height Ratio: The Up To Date Method Of Predicting Chronic Disease Risk

Sadie Engelken, Natalie Romenesko, Sydney Breitenbach, Bradley Koch, Rodney Pintang, Jessica M. Brown. Carroll University, Waukesha, WI.
 (No relevant relationships reported)

Approximately 60-70% of the adult population is classified as overweight or obese, and it is estimated by 2030 adulthood obesity will increase by 33%. As obesity rates increase, there are associated increases of comorbidities such as cardiovascular disease, cancer, and type-2 diabetes. This increasing pandemic stresses the importance for healthcare professionals to efficiently and accurately measure body composition (BC), and most importantly determine chronic disease risk (CDR). Quantifiable values are important for exercise testing; however, CDR classifications may be more understandable to patients. There are many validated ways of obtaining BC and anthropometric measures (AM). Direct-segmental bioelectrical impedance analysis (DSM-BIA) directly measures both body and visceral fat (VF). AM aims to yield CDR by estimating fat, mainly in the splanchnic region. Although commonly used, inexpensive, and easy to perform, AM accuracy has been questioned. **PURPOSE:** The purpose of this study is to compare CDR between BC and AM techniques against DSM-BIA VF. **METHODS:** Males and females, 18 years and older, were recruited for a sample of 133. BC and AM were analyzed using body mass index (BMI), two waist circumference measurements: narrowest (nWC) and umbilicus (uWC), two waist-to-hip ratios: narrowest (nWHR) and umbilicus (uWHR), narrowest waist-to-height ratio (nWHtR), body fat percent (BF%) from three-site skinfold novice (nSK) and expert (eSK) trained clinicians, handheld bioelectrical impedance analysis (BIA), and DSM-BIA against DSM-BIA VF. Using consistent, numerical CDR stratification, the BC and AM values were assigned a classification. Paired sample t-tests were used to compare the CDR classifications between all measurements and DSM-BIA VF. **RESULTS:** When compared to DSM-BIA VF (1.30 ± 0.59), there was no statistical difference in CDR for nWHtR (1.37 ± 0.58), eSK (1.23 ± 0.54), and DSM-BIA BF% (1.37 ± 0.67) (p > 0.05). All other BC and AM were statistically different (p < 0.05) when compared to the DSM-BIA VF. **CONCLUSION:** VF is a key indicator of increased CDR and all-cause mortality. The DSM-BIA should be considered by clinicians due to

its accuracy in measuring both BF and VF. Our data suggests that out of all commonly used BC and AM, nWHtR, eSK, and DSM-BIA BF% predict CDR with equivalency to DSM-BIA VF.

Association Between Television Viewing, Physical Fitness Markers, And Body Composition In College-Aged Adults

Rachel N. Tauber, James R. Peterson, Rachel A. Kowal, Emerson Sebastião, Clayton L. Camic, Zachary Wahl-Alexander, Peter J. Chomentowski, III. Northern Illinois University, DeKalb, IL.
 (No relevant relationships reported)

Obesity and sedentary behavior are major concerns in the United States. It has been observed that Americans who watch more television are at greater risk of becoming obese and have lower health-related fitness markers. Most literature, however, has not focused on college-aged adults. **PURPOSE:** The purpose of this study was to examine the association between daily screen time viewing (proxy of sedentary behavior) and health-related fitness markers in college-aged adults. **METHODS:** A total of one hundred and forty one college-aged subjects (mean age ± SD= 22.9 ± 2.6 years; percent body fat= 22.9 ± 10.3%) were separated into four groups in accordance to reported screen time (very low viewing time, low viewing time, moderate viewing time, and high viewing time) and participated in two data collection (screening & exercise) sessions. In the screening session, subjects completed an informed consent form, inclusion criteria form, screen time survey, and body composition assessment through a bioelectrical impedance analysis device. Seven days later, participants returned to complete a countermovement jump assessment of lower body anaerobic power and an aerobic capacity PACER test to assess cardiorespiratory fitness. **RESULTS:** Spearman rank-order correlation coefficient tests showed a significant positive correlation (p = 0.032, r = 0.352) between daily time spent watching television and vertical jump displacement for the very low viewing time group. A significant positive correlation (p = 0.022, r=0.402) between daily time spent watching television and PACER laps was found in the very low viewing time group as well as a significant negative correlation (p = 0.49, r = -0.340) in the high viewing group. However, there were no statistically significant associations between daily time spent watching television and percent body fat. A one-way ANOVA showed a statistically significant difference (p < 0.05) for viewing time groups. A Tukey post hoc analysis showed statistically significant differences (p < 0.001) between all viewing time groups. **CONCLUSION:** Lower amounts of daily television viewing in college-aged adults was associated with greater lower body power production and greater cardiorespiratory fitness. Higher amounts of daily television viewing were associated with decreased cardiorespiratory fitness.

Three Methods Of Assessing Percent Body Fat In Healthy Older Adults

Rolando T. Lazaro. California State University Sacramento, Sacramento, CA. (Sponsor: Rafael Escamilla, FACSM)
 Email: rolando.lazaro@csus.edu
 (No relevant relationships reported)

PURPOSE: We compared body fat using three different body fat percent methods that can be performed in 60 seconds or less. One hundred healthy older adults between 60 and 88 years old (mean: 72.28) served as subjects. **METHODS:** The three methods used to assess body fat were the following: skinfold calipers using regressive equations developed from seven skinfold sites; tape measure using regression equations developed from waist, abdominal, and hip circumference measurements and age, height, and weight; and body mass index (BMI), using regression equations developed from BMI, age, and gender. **RESULTS:** Significant differences were found in the calculation of percent body fat between the three methods (F = 143.30825, p<.01). **CONCLUSION:** While excessive body fat is correlated with several diseases in older adults such as cardiovascular disease, diabetes, and stroke and is an important aspect of all health/wellness programs, assessing body fat can be very expensive and time consuming. The three quick and inexpensive methods of calculating percentage body fat however produced significantly varied calculations of percentage body fat. More research is needed to compare these three methods to the gold standard of measuring percent body fat such as hydrostatic weighing and Dual-Energy X-Ray Absorptiometry (DEXA).

SOMATOTYPING IN COLLEGE TRACK & FIELD ATHLETES: EVALUATING CHANGE ACROSS A COMPETITIVE SEASON

Whitley J. Stone¹, Amanda J. Wakeman², Matthew J. Garver², Josie N. Hair², Dustin W. Davis³, Eric J. Nehlsen², Drake A. Grinde², Shayne J. Allan². ¹Western Kentucky University, Bowling Green, KY. ²University of Central Missouri, Warrensburg, MO. ³University of Nevada-Las Vegas, Las Vegas, NV. (Sponsor: T. Scott Lyons, FACSM)

(No relevant relationships reported)

Coaches may find value in following track and field athletes' anthropometrics as the extended competitive season requires a unique balance of peak and maintained preparation. Somatotyping may offer a more holistic metric compared with BMI, mass, or body fat percentage alone when tracking changes across competition mesocycles. **PURPOSE:** The purpose of this study was to record track and field athletes' somatotype scores to elucidate potential changes across the competitive season according to sex and/or age. **METHODS:** Division II track and field athletes ($n=47$) were tested at the start and end of the outdoor season. Somatotype data were collected according to the Heath-Carter manual (skinfolds, girths, breadths, stature & mass). Raw data were converted to mesomorph, endomorph, and ectomorph scores. One-way RM ANOVAs with between subject variables (sex & age) were used to evaluate change in endomorphy, mesomorphy, and ectomorphy scores across the season. **RESULTS:** Scores for endomorphy ($F(1,45)=117.9, p<.001, \eta^2=.072$, males (M)= +3.2%, females (F)= -0.1%) and mesomorphy ($F(1,45)=10.1, p=.003, \eta^2=.018$, M = -3.4%, F = +4.6%) differed across time by sex, but not ectomorphy ($F(1,52)=0.03, p=.86, \eta^2=.001, M$ = -6.2%, F = -6.3%). Age did not influence somatotype scores across the season. **CONCLUSIONS:** The rigors of a competitive season may influence only certain sex-somatotype combinations. Influencing factors for the divergent changes in somatotype presently found should be identified to optimize training approaches.

3210 Board #31 May 29 1:30 PM - 3:00 PM

Relationships Between Sport Nutrition Knowledge, Body Composition And Body Weight Goal In Female Soccer Players.

Andrew Jagim¹, Alexis Shafer², Jordan Paisley², Andrew Askow³, Joel Luedke², Charles Nolte¹, Jacob Erickson¹. ¹Mayo Clinic Health System, Onalaska, WI. ²University of Wisconsin - La Crosse, La Crosse, WI. ³University of Illinois - Urbana-Champaign, Champaign, IL. Email: andrew.jagim@gmail.com

(No relevant relationships reported)

Sport nutrition knowledge may impact the quality of an athlete's dietary intake. It is currently unknown how sport nutrition knowledge (SNK) influences body composition and what factors may contribute to an athlete's body weight goal.

PURPOSE: To examine relationships between SNK and body composition and identify predictors of body weight goal in female collegiate soccer players.

METHODS: Twenty-six Division III female soccer athletes (height: 1.61 ± 0.30 m; body mass: 66.7 ± 7.5 kg; fat-free mass: 50.3 ± 6.5 kg; body fat %: 25.6 ± 5.1 %) participated in the current study. All players had body composition assessed using air displacement plethysmography and completed a validated questionnaire designed to assess sport nutrition knowledge. Athletes were also asked questions about perceived dietary requirements and body weight goal. Pearson correlation coefficients were assessed to examine relationships between SNK and body fat percentage (BF %), fat-free mass, fat-mass, body mass (BM), body mass index (BMI), and perceived dietary requirements. Multinomial logistic regression was used to identify predictors of body weight goal. Paired sample t -tests were used to compare differences between calculated and perceived dietary needs.

RESULTS: The mean number of questions answered correctly on the SNK questionnaire was 44.5 ± 11.2 %. An inverse relationship was observed between BF % and SNK ($r = -0.391; p=0.044$). Body mass, BMI and BF % were all significant predictors of body weight goal ($p<0.05$). For every 1% increase in BF % and 1 kg increase in BM, athletes were 1.3 times more likely to want to lose weight. For every 1 unit increase in BMI, athletes were 2.7 times more likely to want to lose weight. All players significantly underestimated daily energy (-578 ± 104.9 kcal/d, $p<0.001$) and carbohydrate (-283.7 ± 141.8 g/d, $p<0.001$) requirements when compared to their calculated required daily intakes.

CONCLUSIONS: Division III female collegiate soccer players have a low sport nutrition knowledge base which was associated with a higher BF %. Players who had a higher BM, BF % and BMI were more likely to have weight loss as a body weight goal. Players also significantly underestimated their energy and carbohydrate requirements based on the demands of their sport. Players could likely benefit from a sport nutrition education intervention.

3211 Board #32 May 29 1:30 PM - 3:00 PM

Body Composition Values Of Division 1 Men's Lacrosse Players Derived From Dual Energy X-ray Absorptiometry

Kyle M. Leppert, Hannah A. Zabriskie, Nicolas D. Knuth, Devon A. Dobrosielski, FACSM, Peter Lisman. Towson University, Towson, MD.

(No relevant relationships reported)

Total and regional body compositions are key components of sport performance. Dual energy X-ray absorptiometry (DXA) allows for precise measurements of body composition parameters between athletes who experience different competitive demands. Yet, accurate interpretation of DXA data is dependent on the availability of reference values. Despite the widespread use of DXA to measure body composition in collegiate athletes, positional reference values for men's lacrosse do not exist.

PURPOSE: To generate descriptive data for total and regional body composition in men's collegiate lacrosse players using DXA, and examine differences between positions. **METHODS:** Members of an NCAA Division 1 Men's Lacrosse team underwent DXA scanning and were categorized according to position. Descriptive statistics were calculated for total and regional body composition measures and differences between positions were examined using a one-way ANOVA or a Kruskal-Wallis test. **RESULTS:** A total of 98 players (age: 19.2 ± 1.0 yrs; height: 181.1 ± 7.0 cm; total mass: 82.4 ± 9.2 kg) completed the study (Attack; $n=24$, Midfield; $n=44$, Defense; $n=25$, Goalkeeper; $n=6$). The mean total body fat percentage (BF%) was 18.9 ± 3.4 % (range: 11.0 - 27.6). No differences in BF% between positions were identified (Attack= 18.9 ± 3.9 %, Midfield= 18.8 ± 4.2 %, Defense= 18.9 ± 3.7 %, GK= 20.5 ± 2.9 %; $p=0.79$). For the android region, no differences between positions were identified for fat mass (Attack= 1.0 ± 0.5 kg, Midfield= 1.0 ± 0.5 kg, Defense= 0.9 ± 0.4 kg, GK= 1.1 ± 0.5 kg; $p=0.9$), or lean mass (Attack= 4.3 ± 0.5 kg, Midfield= 4.3 ± 0.4 kg, Defense= 4.4 ± 0.3 kg, GK= 4.4 ± 0.8 kg; $p=0.7$). For the gynoid region, no differences between positions were noted for fat mass (Attack= 2.6 ± 0.8 kg, Midfield= 2.5 ± 0.9 kg, Defense= 2.7 ± 0.8 kg, GK= 0.3 ± 1.1 kg; $p=0.48$), or lean mass (Attack= 10.3 ± 1.6 kg, Midfield= 10.4 ± 1.0 kg, Defense= 10.5 ± 0.7 kg, GK= 10.4 ± 1.4 kg; $p=0.79$). **CONCLUSION:** Total and regional body composition measures did not vary across positions in a group of men's collegiate lacrosse players. These data suggest that the athletic demands across positions of men's collegiate lacrosse are not related to differences in body composition. Therefore, training programs tailored to specific positions may not be needed in order to achieve athletic success.

3212 Board #33 May 29 1:30 PM - 3:00 PM

Somatotype Of Female And Male Field Athletes: Comparing Between Sexes And Among Select Events

Matthew J. Garver¹, Whitley J. Stone², Amanda J. Wakeman¹, Josie N. Hair¹, Dustin W. Davis³, Drake A. Grinde¹, Shayne J. Allan¹, Eric J. Nehlsen¹. ¹University of Central Missouri, Warrensburg, MO. ²Western Kentucky University, Bowling Green, KY. ³University of Nevada, Las Vegas, Las Vegas, NV. Email: Garver@ucmo.edu

(No relevant relationships reported)

Anthropometrics (e.g. BMI, mass, limb lengths) have their place in the discussion of sports performance, but their unidimensional view prevents whole-athlete evaluation. Classical somatotyping categorizes the human build into ectomorph (ECTO), mesomorph (MESO), and endomorph (ENDO) according to stature and mass distribution. Somatotyping may offer clues as to desirable physique when investigating human performance in a diverse athletic group like field athletes. **PURPOSE:** The aim was to compare the somatotype of Division II field athletes between sexes and among select events. **METHODS:** Somatotyping data were collected on competitive female ($n=9$, age: 20.0 ± 0.7 yrs., ht.: 173.4 ± 6.5 cm, body fat: 18.8 ± 5.2 %) and male ($n=16$, age: 19.9 ± 1.1 yrs., ht.: 183.4 ± 3.4 cm, body fat: 9.0 ± 2.8 %) field athletes nearing the conference championship; an assumption was made that athletes were in peak form. Raw data included stature (cm), mass (kg), skinfolds (mm), girths (cm), and breadths (cm) and were converted into ECTO, MESO, and ENDO scores. Independent t -tests were used to test significance. Data are represented as means and standard deviations. **RESULTS:** Data for female athletes were: ECTO= 2.76 ± 1.30 , MESO= 3.32 ± 1.64 , and ENDO= 8.02 ± 1.04 and for males were: ECTO= 2.78 ± 0.74 , MESO= 4.48 ± 0.75 , and ENDO= 5.00 ± 0.96 . Between the sexes, there was a difference for ECTO ($t(23)=7.33, p<.000$), but not MESO ($t(23)=-.05, p=.958$) or ENDO (equal variance not assumed; $t(9.91)=-2.01, p=.073$) scores. Among the multi-field athletes (female heptathletes= 3 and male decathletes= 5) there were not any differences for ECTO (2.99 ± 1.56 vs. $3.08 \pm 0.54, p=.907$) or MESO (2.91 ± 1.43 vs. $4.13 \pm 0.73, p=.153$) scores, but there was a difference for ENDO (7.81 ± 1.10 vs. $4.79 \pm 0.71, p=.003$) scores. The jumpers (long, high, and triple; females= 3 and males= 7) were not different on ECTO (3.27 ± 0.65 vs. $2.81 \pm 0.76, p=.396$), but they differed on both MESO (2.77 ± 0.94 vs. $4.54 \pm 0.72, p=.011$) and ENDO (7.00 ± 0.42 vs. $5.28 \pm 0.96, p=.020$) scores. **CONCLUSIONS:** Evidence regarding somatotype among competitive athletes is interesting but

ambiguous. Investigating scores between multi-field athletes and uni-field athletes and aligning somatotype with performance data to ascertain potential predictive relationships are the next steps in this inquiry.

3213 Board #34 May 29 1:30 PM - 3:00 PM
Somatotyping Male And Female Sprinters And Endurance Sprinters

Josie N. Hair¹, Matthew J. Garver¹, Whitley J. Stone², Amanda J. Wakeman¹, Dustin W. Davis³, Drake A. Grinde¹, Shayne J. Allan¹, Eric J. Nehlsen¹. ¹University of Central Missouri, Warrensburg, MO. ²Western Kentucky University, Bowling Green, KY. ³University of Nevada, Las Vegas, Las Vegas, NV. Email: jnh78100@ucmo.edu
(No relevant relationships reported)

Coaches and athletes plan for peak physical condition to occur at specified times during the competitive season (e.g. conference championship). Depending upon the event, athletes may or may not have similar somatotypes (endomorph=Endo, ectomorph=Ecto, and mesomorph=Meso). It is currently unclear whether competitive, Division II sprinters and endurance sprinters differ in somatotype. **PURPOSE:** The aim was to calculate somatotype of male and female collegiate sprinters and endurance sprinters preceding their outdoor conference championship. **METHODS:** Athletes ($n=18$) were tested near the end of their outdoor season. Somatotype data were calculated, for sprinters ($n=10$; 100m and 200m) and endurance sprinters ($n=8$; 400m), according to the Heath-Carter manual [breadths (cm), girths (cm), stature (cm), mass (kg), and skinfolds (mm)]. Comparisons were made by independent t-tests. Means and standard deviations are presented. **RESULTS:** Male sprinters ($n=5$, age: $19.8 \pm .5$ yrs., ht.: 180.3 ± 10.5 cm, wt.: 73.2 ± 10.2 kg, body fat: $6.1 \pm .9\%$) displayed as Endo= $4.74 \pm .69$, Ecto= $3.09 \pm .92$, and Meso= 3.71 ± 1.03 and endurance sprinters ($n=4$, age: $19.5 \pm .6$ yrs., ht.: 181.9 ± 3.9 cm, wt.: 73.2 ± 4.2 kg, body fat: $6.2 \pm 1.6\%$) displayed as Endo= $4.40 \pm .46$, Ecto= $3.31 \pm .26$, and Meso= $3.84 \pm .70$. Male sprinters and endurance sprinters were not significantly different on Endo ($t(7)=.85$, $p=.424$), Ecto (equal variance not assumed; $t(4.79)=-.52$, $p=.628$), or Meso ($t(7)=-.22$, $p=.830$) scores. Female sprinters ($n=5$, age: 19.2 ± 1.3 yrs., ht.: 166.4 ± 5.4 cm, wt.: 60.8 ± 4.6 kg, body fat: $15.5 \pm 5.3\%$) displayed as Endo= 7.45 ± 1.21 , Ecto= $2.50 \pm .75$, and Meso= $3.21 \pm .94$ and endurance sprinters ($n=4$, age: 19.8 ± 1.7 yrs., ht.: 167.9 ± 5.0 cm, wt.: 58.6 ± 2.7 kg, body fat: $15.8 \pm 5.5\%$) displayed as Endo= 7.39 ± 1.37 , Ecto= $3.13 \pm .74$, and Meso= $2.70 \pm .67$. Female sprinters and endurance sprinters were not significantly different on Endo ($t(7)=.08$, $p=.942$), Ecto ($t(7)=-1.27$, $p=.245$), or Meso ($t(7)=.91$, $p=.393$) scores. **CONCLUSIONS:** There was no difference in the somatotype of male and female sprinters and endurance sprinters. Further research should be conducted to analyze the relationships between early season somatotype, late season somatotype, and performance season long.

3214 Board #35 May 29 1:30 PM - 3:00 PM
The Relation Of Body Composition Methodologies Between Sports In Division 1 Collegiate Athletes.

Cullen Vincelle. Louisiana State University, Baton Rouge, LA. (Sponsor: Brian Irving, FACSM)
Email: cvinc19@lsu.edu
(No relevant relationships reported)

Body composition has a significant impact on athletic performance, as well as overall health and wellbeing. Athletes and coaches often attempt to optimize performance by changing body composition without sport specific guidelines. Several techniques for measuring body composition exist, but the validity compared to the DXA has not been fully elucidated in athletic populations in various sports. **PURPOSE:** The aim of this study is to examine the relationship of surrogate body composition methodologies in Division 1 NCAA men's and women's sports. **METHODS:** Student athletes from men's (baseball, swim and dive, track, and tennis) and women's (softball, soccer, basketball, swim and dive, track and, tennis) sports volunteered to participate in 3 measures of body composition including Dual Energy X-ray Absorptiometry (DEXA), Bioimpedance Analysis (BIA), and 3D body imaging (FIT-3D). **RESULTS:** 106 assessments were completed (age 19.7 ± 1.4 y, mean \pm SD) with 84 athletes (61 Female, 17 African American athletes). The average weight, lean mass (LM), and % body fat (%BF) by DXA for men were 79.8 ± 9.0 kg, 67.7 ± 8.1 kg, and $15.9 \pm 1.5\%$ and women were 69.6 ± 9.5 kg, 54.5 ± 7.3 kg; and $25.5 \pm 3.9\%$, resp. Matched pairs analysis showed that compared to DXA, BIA underestimated LM and overestimated %BF in women ($-1.9 \pm .3$ kg; $P<0.0001$; $0.8 \pm .4\%$; $P=0.04$), but missed statistical significance in men (-1.2 ± 1.1 kg; $P=0.3$; $1.5 \pm .7\%$; $P=<0.07$), resp. Likewise, the FIT-3D over estimated LM and underestimated %BF in women ($0.4 \pm .4$ kg; $P=0.3$; $-2.4 \pm .3\%$; $P<.0001$), but not men (0.8 ± 1.2 kg; $P=0.6$; $-0.8 \pm .5\%$; $P=0.2$), resp. compared to DXA LM and %BF. Linear regression analysis from the Bland-Altman analysis shows a significant bias for male BF% from the FIT-3D to DXA ($r=0.61$; $P=0.009$), as well as BIA to DXA ($r=0.80$; $P<0.0001$). **DISCUSSION:** This is an ongoing longitudinal study of which this cross-sectional data was used to examine the relationship between body composition methodologies. Understanding the sex specific mean differences and bias between

body composition methodologies may assist in the development of algorithms to improve the correlation between the criterion standard measure (DXA) and surrogate measures.

3215 Board #36 May 29 1:30 PM - 3:00 PM
Evaluating Fat Free Mass Index For Sport Specific Performance Goals In Female Collegiate Athletes

Louis-Philip Marc-Antoine Guindon, Patrick Delisle-Houde, Jessica A. Insogna, Adriana P. Sólomon, Ross E. Andersen, FACSM. McGill University, Montreal, QC, Canada.
(No relevant relationships reported)

Fat free mass index (FFMI) in an athletic female population is computed as (bone mineral content + lean mass / height²). It has been associated with performance and training status in their relevant sport, collegiate female athletes need to optimize bone mineral density (BMD), and lean mass as multiple factors impact their levels, including: the type of sport, nutrition, menstrual cycle, training program variation, lifestyle habits, and genetics. **PURPOSE** To compare FFMI and lower body BMD across female collegiate athletes and sedentary control considering their desired sport-specific performance and training. **METHODS** A sample of 68 women (Mean \pm SD; Age: 20.89 ± 1.91 yrs, Height: 1.65 ± 0.07 m, and Weight: 62.25 ± 10.11 kg) including 43 females collegiate athletes ($n=23$ hockey players, $n=20$ synchronize swimmers) and 25 sedentary university students received a scan using dual-energy x-ray absorptiometry (DEXA). ANOVA was used to evaluate differences in: FFMI, and regional BMD in the spine and the femur. **RESULTS** The FFMI of hockey players (18.11 ± 1.33 kg/m²), was significantly ($p<.05$) higher than both the synchronized swimmers (15.43 ± 1.25 kg/m²) and the controls (14.99 ± 1.45 kg/m²). Hockey players, compared to synchronized swimmers and the control group, have a higher BMD of the spine, $F(2, 65) = 13.391$, $p<.05$, FFMI, $F(2, 66) = 37.06$, $p<.05$. BMD of the total femur in the hockey players was great than the controls, $F(2, 65) = 4.06$, $p<.05$. Total lean mass of synchronized swimmers (40.77 ± 3.67 kg.) was greater ($p<.05$) than the control group (36.65 ± 5.30 kg). **CONCLUSION** BMD and FFMI of the control group compared to female athletes show how sports' demands influence bone's health in a female collegiate population. BMD and FFMI of hockey players compared to synchronized swimmers may demonstrate the importance of percussive activities for bone health in female athletes. Differences in FFMI between female hockey players and synchronize swimmers suggest that establishing sport-specific norms in this new measure may help coaches and strength specialists better tailor training programs to optimize performance and bone health in varsity athletes.

3216 Board #37 May 29 1:30 PM - 3:00 PM
Validity Of The Portable Ultrasound Device To Estimate Body Fat Percentage.

Yong Ik Kim¹, Seung Yun Shin², Seoung Ki Kang², Jae Hyung Lee², Byung Kwon Kim², Jin Su Seok², Seong Bong Hong³, Myoung-Won Seo⁴, Jung-Min Lee⁴. ¹Kook Min University, Seoul, Korea, Republic of. ²Yong In University, Yongin, Korea, Republic of. ³Sung Kyun Kwan University, Suwon, Korea, Republic of. ⁴Kyung Hee University, Suwon, Korea, Republic of.
Email: hyyongik@naver.com
(No relevant relationships reported)

Many studies have performed to examine the validity of those tools to measure body composition, including DEXA (Dual-energy X-ray absorptiometry), underwater weighing (UWW), Skin-fold thickness (SFT), and Bioelectrical impedance analysis (BIA). Technological advances now permit the use of the portable ultrasound device for the field measures. But no information is available regarding the validity of the device in collegiate students. **Purpose:** The purpose of the present study was to examine the validity of Body Metrix™ ultrasound device for estimating percent body fat in normal and obese college-aged male participants, compared to DEXA. **Methods:** In total, ninety-eight (73 Normal, 25 Obese, 20.11 ± 2.13 years, 175.15 ± 6.00 cm, 73.63 ± 13.92 kg) male collegiate students volunteered for this study. Height and weight were measured and participants' percent body fat was measured twice; 1) the DEXA (Dual-energy X-ray absorptiometry; GE Lunar, Madison, WI, USA) and 2) the BodyMetrix BX2000 (IntelaMetrix, Livermore, CA, USA) using Pollock three site technique (P3). For data processing, the average and standard deviation of the data were calculated by using SPSS 25.0 program and MedCalc program. Correlation analysis (r) and Bland & Altman were performed to examine the validity of the portable ultrasound device. Mean absolute percentage errors (MAPEs) were calculated as measurement errors. **Results:** There was a strong correlation between DEXA and Body Metrix™ ultrasound device (Normal, $r = 0.84$, $p = 0.001$); Obese, $r = 0.80$, $p = 0.001$). Bland-Altman analysis identified that 95% relative limits of agreement for the portable ultrasound device were again clinically acceptable in participants with BMI <25 and BMI ≥ 25 (-1.90% to 7.70% and 5.20% to 16.58% , respectively). MAPEs were 20.3% and 36.3 for normal BMI and Obese participants, respectively. **Conclusion:** We found that the Body Metrix™ ultrasound device appears to be an

alternative measurement to estimate percent body fat. However, relatively large MAPEs indicated that Body Metrix™ ultrasound device requires careful interpretation to estimate percent body fat in clinically obese collegiate participants.

Effects Of Blood Flow Restriction And Neuromuscular Electrical Stimulation On Muscle And Adipose Tissue Thickness Of The Calves

Yaremi M. Ontiveros, Jonathan Aguilera, Neil Sundberg, Joshua A. Cotter, FACSM. *California State University Long Beach, Long Beach, CA.* (Sponsor: Joshua A. Cotter, FACSM)
 Email: yaremi.ontiveros@student.csulb.edu
 (No relevant relationships reported)

Accelerated muscle atrophy is an important factor to consider in several different environments such as spaceflight, paralysis, immobilization, and aging. Understanding optimal exercise countermeasures in such environments is therefore necessary to examine. **PURPOSE:** To assess muscle and adipose tissue thickness in the calves while using the unconventional training methods of blood flow restriction (BFR) and neuromuscular electrical stimulation (NMES). **METHODS:** Six sedentary participants (4 males and 2 females; 20.5 ± 1.4 yrs, 73.5 ± 13.8 kg) underwent 6 weeks of calf training with each leg randomly assigned to one of three conditions: 1) BFR (n=4), 2) NMES (n=3), and 3) combined BFR+NMES (n=5). A control group of seven sedentary participants (4 males and 3 females; 23.1 ± 4.3 yrs, 75.1 ± 12.2 kg) were also used. Adipose tissue thickness was measured via ultrasound and skinfolds while muscle thickness of the gastrocnemius and soleus was assessed via ultrasound. Comparisons were made using separate two-way ANOVA's for each variable. **RESULTS:** A significant main effect of time was found for ultrasound measurements of the lateral ($p = 0.0021$) and medial ($p = 0.0467$) adipose tissue. A significant interaction effect was found for medial adipose tissue ($p = 0.0282$) with post-hoc comparisons revealing a significant increase in medial adipose tissue thickness with the BFR ($p = 0.0176$). No differences were found in muscle thickness for both the medial and lateral gastrocnemius, however, there was a significant main effect of time ($p = 0.0025$) and interaction ($p = 0.0013$) for soleus muscle thickness. Post-hoc comparisons showed a significant increase in soleus muscle thickness with the BFR+NMES condition ($p = 0.0029$) only. **CONCLUSION:** These results suggest that a combined BFR+NMES training condition may be a feasible method for increasing soleus muscle thickness with 6 weeks of training. Additional research is warranted to elucidate the potential use of BFR and NMES for stimulating positive physiological change in the calves. Supported by National Institute of Health grants UL1GM118979; TL4GM118980; RL5GM118978.

Development And Cross-validation Of A Bmi-based Equation For Percent Fat In Children With Intellectual Disability

Fabio bertapelli¹, Stamatis Agiovlatis¹, FACSM², Robert W. Motl³, Marcos M. de Barros-Filho¹, Gil Guerra-Junior¹.
¹University of Campinas, Campinas, Brazil. ²Mississippi State University, Starkville, MS. ³University of Alabama at Birmingham, Birmingham, AL. (Sponsor: Stamatis Agiovlatis, FACSM)
 Email: fbortapelli@gmail.com
 (No relevant relationships reported)

Children with intellectual disability (ID) have higher rates of obesity than children without ID, and the management of obesity might be facilitated through simple and accurate methods for estimating percent body fat (%BF) in children with ID. **PURPOSE:** To develop and cross-validate an equation for estimating %BF from Body Mass Index (BMI), age, sex and other independent variables in children with ID. **METHODS:** Participants were 107 children (aged 6-15 years) with ID allocated to development (N = 81; 50 boys; age 12 ± 3 years) and cross-validation (N = 26; 13 boys; age 12 ± 3 years) samples. Dual-Energy X-Ray Absorptiometry (DXA) served as the criterion method for %BF determination. Candidate predictor variables for estimation of DXA-determined %BF were BMI, age, sex, disability status, ID level, ethnicity, and presence of diseases. Using the data from the development sample, we derived a %BF prediction equation with hierarchical linear regression. The performance of the equation was assessed in the cross-validation sample by comparing the actual (DXA-determined %BF) and predicted (Equation-determined %BF) values with paired-samples t-test, Pearson's correlation coefficient, mean absolute and root mean square errors, and Bland-Altman plot. **RESULTS:** BMI, age, and sex (0=boy; 1=girl) were significant predictors of %BF ($p < 0.001$; $R^2 = 0.66$; SEE = 5.95% BF). Disability, ID level, ethnicity, and presence of diseases did not significantly contribute to the model ($p > 0.05$). The equation was: $\%BF = 15.269 + (1.412 \times BMI) - (1.350 \times age) + (5.362 \times sex)$. The equation had high accuracy during cross-validation as indicated by: (i) strong correlation between actual and predicted %BF ($r = 0.80$; $p < 0.001$); (ii) non-significant difference between

actual and predicted %BF ($30.2 \pm 7.1\%$ and $28.6 \pm 9.6\%$, respectively; $p > 0.05$); (iii) mean absolute and root mean square error of $4.4 \pm 4.1\%$ and 5.6% , respectively; and (iv) small mean overestimation of DXA-determined %BF but somewhat wide limits of agreement in the Bland-Altman plot (mean error: -1.53% ; 95% CI: 10.2% , -13.3%). **CONCLUSIONS:** BMI, age and sex significantly predicted %BF in children with ID. The developed equation was cross-validated for estimating %BF in children with ID. Supported by FAPESP Grants 2019/07103-6, 2018/02795-4, 2018/02677-1, and 2017/13071-4

Development Of A Dxa-derived Body Volume Equation In Hispanic Adults For Administering In 4-compartment Models

Brett S. Nickerson¹, Kyung-Shin Park¹, Michael V. Fedewa², Cherilyn N. McLester³, John R. McLester, FACSM³, Michael R. Esco, FACSM². ¹Texas A&M International University, Laredo, TX. ²University of Alabama, Tuscaloosa, AL. ³Kennesaw State University, Kennesaw, GA. (Sponsor: John McLester, FACSM)
 Email: brett.nickerson@tamui.edu
 (No relevant relationships reported)

PURPOSE: The purpose of the current study was two-fold: 1) to develop a new dual energy X-ray absorptiometry (DXA)-derived body volume (BV) equation with the GE-Lunar Prodigy while utilizing underwater weighing (UWW) as a criterion and 2) cross-validate 4-compartment(4C) models when utilizing the new DXA-derived BV equation (4C-DXA_{NICKERSON}), Wilson DXA-derived BV equation (4C-DXA_{WILSON}), and air displacement plethysmography (ADP)-derived BV (4C-ADP) in Hispanic adults. **METHODS:** 191 Hispanic adults (18-45yrs) participated in the current study. The development sample consisted of 60 females and 60 males whereas the cross-validation sample comprised of 41 females and 30 males. Criterion body fat percentage (BF%) and fat-free mass (FFM) were determined using a 4C model with UWW as a criterion for BV (4C-UWW). The new DXA-derived BV equation (Nickerson) was developed by linearly regressing UWW-derived BV with DXA fat mass (FM), lean mass (LM), and bone mineral content (BMC). 4C-DXA_{NICKERSON}, 4C-DXA_{WILSON} and 4C-ADP were compared against 4C-UWW in the cross-validation sample. **RESULTS:** The new DXA-derived BV equation (L) was generated in the development sample as follows: $(FM/0.91) + (LM/1.06) + (BMC/16.95) + 0.268$. 4C-DXA_{NICKERSON}, 4C-DXA_{WILSON}, and 4C-ADP all produced similar mean values (BF%=21.04±5.99, 22.23±6.93, and 20.62±6.26%, respectively) when compared to 4C-UWW (21.29±6.14%) in Hispanic males (all $p > 0.05$). 4C-DXA_{NICKERSON} also yielded similar BF% and FFM values as 4C-UWW when evaluating the constant error (CE) in Hispanic females (CE=-0.79% and 0.38kg; $p=0.060$ and 0.174 , respectively). However, 4C-DXA_{WILSON} produced significantly different BF% and FFM values (CE=3.22% and -2.20kg, respectively; both $p < 0.001$). Additionally, 4C-DXA_{WILSON} yielded significant proportional bias when estimating BF% (coefficient=0.226; $p < 0.001$) whereas 4C-ADP produced significant proportional bias for BF% and FFM (coefficient=0.188 and -0.084; both $p < 0.05$) when evaluated in Hispanic females. **CONCLUSIONS:** Current study findings demonstrate that 4C-DXA_{NICKERSON} is a valid measure of BV in Hispanics and is recommended for use in clinics where DXA is the main body composition assessment technique.

Physiological And Anthropometric Predictors Of Discrepancies Between Bioelectrical Impedance Analysis And Dual-energy X-ray Absorptiometry

Patrick S. Harty¹, Matthew T. Stratton¹, Nelson Griffiths¹, M. Lane Moore², Marqui L. Benavides¹, Jacob R. Dellinger¹, Brian T. Adamson³, Grant M. Tinsley¹. ¹Texas Tech University, Lubbock, TX. ²Mayo Clinic Alix School of Medicine, Phoenix, AZ. ³Texas Woman's University, Denton, TX.
 (No relevant relationships reported)

Assessment methods such as dual-energy x-ray absorptiometry (DXA) and bioelectrical impedance analysis (BIA) are commonly used to determine molecular-level body composition estimates in both healthy and clinical populations. Though discrepancies in body composition estimates between BIA and DXA have been previously reported, virtually no investigations have explored potential predictor variables that may explain the disagreement between these methods. **PURPOSE:** To explore the physiological and anthropometric predictors of discrepancies between DXA and BIA total body composition estimates. **METHODS:** During a single visit, 103 female participants (Mean ± SD; 33.4 ± 15.9 years; 65.6 ± 12.1 kg; 165.5 ± 6.3 cm; 32.2 ± 7.4 DXA body fat percentage [BF%]) and 76 male participants (33.8 ± 14.5 years; 83.9 ± 15.1 kg; 178.8 ± 6.6 cm; 22.9 ± 8.0 DXA BF%) underwent body composition assessment via DXA and 8-point single-frequency BIA. Potential predictors of the discrepancies between DXA and BIA body composition estimates were obtained during the same visit using air displacement plethysmography,

bioimpedance spectroscopy, and 3-dimensional optical scanning. Select DXA variables were also utilized as predictors. Ordinary least squares regression was conducted to predict the differences in total fat mass (FM) and total lean soft tissue (LST) between DXA and BIA. Standardized model coefficients (β), p-values for coefficients, and R^2 values were generated. **RESULTS:** For FM estimates, significant predictors ($p \leq 0.01$) of the differences between DXA and BIA were hydration of LST (TBW:LST; $\beta = -0.82$), height ($\beta = -0.78$), percentage of TBW as extracellular fluid (%ECF; $\beta = -0.36$), and the male sex ($\beta = 0.26$). For LST, significant predictors of the errors between DXA and BIA were TBW:LST ($\beta = 0.85$), height ($\beta = 0.77$), %ECF ($\beta = 0.40$), the male sex ($\beta = -0.22$), and racial identification as Black ($\beta = -0.09$). The R^2 values for regression models predicting differences between DXA and BIA were 0.80 to 0.86 for FM and 0.73 to 0.87 for LST. **CONCLUSION:** Hydration variables and height are primary predictors of discrepancies between DXA and BIA total body composition estimates.

Explaining Segmental Lean Soft Tissue Discrepancies Between Bioelectrical Impedance Analysis And Dual-Energy X-Ray Absorptiometry
 Matthew T. Stratton¹, Patrick S. Harty¹, M. Lane Moore², Nelson Griffiths¹, Jacob R. Dellinger¹, Marqui L. Benavides¹, Brian T. Adamson³, Grant M. Tinsley¹. ¹Texas Tech University, Lubbock, TX. ²Mayo Clinic Alix School of Medicine, Phoenix, AZ. ³Texas Woman's University, Denton, TX.
 (No relevant relationships reported)

Interest in evaluating the composition of specific anatomical regions has become commonplace in a variety of settings. Appendicular lean soft tissue (A_{LST}) estimates are considered in the diagnosis of sarcopenia. While dual-energy x-ray absorptiometry (DXA) is viewed as a reference method for regional assessments, its availability is limited. Thus, explaining discrepancies in regional body composition estimates between DXA and the more accessible bioelectrical impedance analysis (BIA) is of utmost importance. **PURPOSE:** To assess the anthropometric and physiological predictors of variations between BIA and DXA segmental lean soft tissue (LST) estimates. **METHODS:** During a single visit, 179 participants (103 females, 76 males; Mean \pm SD: 33.6 \pm 15.3 years; 73.4 \pm 16.2 kg; 171.2 \pm 9.2 cm; 28.2 \pm 8.9% DXA body fat %) underwent body composition assessments via DXA and 8-point single-frequency BIA. Potential predictors of discrepancies between DXA and BIA LST estimates were obtained from these methods and additional laboratory techniques. Specifically, air displacement plethysmography, 3-dimensional optical scanning, and bioimpedance spectroscopy were used to estimate body volume, anthropometrics, and hydration variables, respectively. Significant predictors ($p \leq 0.05$) of the mean difference between DXA and BIA estimates of trunk LST (T_{LST}) and A_{LST} were established using ordinary least squares regression. Standardized model coefficients, p-values for coefficients, and R^2 values were generated. **RESULTS:** For both T_{LST} and A_{LST} , extracellular fluid percentage, LST hydration, height, total LST mass, the male sex, and racial identification as Black significantly predicted discrepancies between DXA and BIA. Additional predictors for T_{LST} discrepancies were DXA total fat mass (FM) to LST ratio and DXA T_{LST} , while additional predictors of A_{LST} discrepancies included DXA A_{LST} , DXA FM to LST ratio of the legs, DXA appendicular FM, and DXA-derived volume of the arms and legs. Regression models including these significant predictor variables produced R^2 values of 0.92 and 0.95 for T_{LST} and A_{LST} , respectively. **CONCLUSIONS:** Hydration variables, the quantity of LST in the region of interest, and height were the most influential predictor variables for discrepancies between DXA and BIA segmental LST estimates.

Effects Of Training With Blood Flow Restriction On Muscular Strength: Meta-analysis
 Kyungun R. Kim¹, Katelyn G. Gear², Kenda Maese², Cindy Thinh², Sukho Lee². ¹University of Central Missouri, Warrensburg, MO. ²Texas A&M-University San Antonio, San Antonio, TX. (Sponsor: Minsoo Kang, FACSM)
 Email: kykim@ucmo.edu
 (No relevant relationships reported)

Blood flow restriction (BFR) training has been a breakthrough in both practice and equipment used in the field of exercise science and rehabilitation. However, previous literature showed inconsistent findings regarding the effects of BFR training on muscle strength. **PURPOSE:** The purpose of this study was to analyze how different types of BFR training influence muscular strength by means of a meta-analysis. **METHODS:** The review was conducted according to the Preferred Reporting Items for Systematic Review and Meta-Analyses guidelines. The following databases were used to conduct the research: Academic Search Complete, Medline, Web of Science, SPORT-Discus, HealthSource: Consumer, and HealthSource: Nursing. Search words used included "blood flow restriction" * AND strength*. The following search limited to full text articles, peer-reviewed academic journals, and published in the English language. Out of 327 articles, 25 were eligible to be included where 47 ESs were calculated. Comprehensive meta-analysis v.3 software was used to examine a random effect model and moderator analysis of the collected data. **RESULTS:** The results showed that BFR training had positive effects on skeletal muscle strength. The overall effect size (Cohen's d) was .558 (95% CI=.385, .731) which yielded a medium effect. The moderator analysis identified a group difference in workload (15-60% (ES=.423, SE=.090), >60% (ES=1.004, SE=.181), Qbetween=9.008, df=2, p=.011. However, gender, intervention length, mode (upper body, lower body) and cuff type/pressure did not affect the muscular strength. **CONCLUSION:** This study confirmed that BFR training has a moderate impact on increase of skeletal muscle strength. Also, the study identified that more than 60% of workloads in exercise result in greater strength gain compared to 15 to 60% workloads. The results of this meta-analysis can help design optimal exercise interventions to maximize increases in muscle strength through BFR training.

Effects Of Blood Flow Restriction And Neuromuscular Electrical Stimulation On Strength Of The Plantar Flexors
 Jonathan A. Aguilera, Yaremi Ontiveros, John Poli, Joshua A. Cotter, FACSM. California State University, Long Beach, Long Beach, CA.
 (No relevant relationships reported)

Exposure to a microgravity environment removes the frequent loading of postural, or antigravity muscles, such as those found in the calf. Due to this reduced stimulation, muscle mass and strength are greatly reduced. Blood flow restriction (BFR) and neuromuscular electrical stimulation (NMES) are unconventional training methods that have been shown to elicit growth in thigh and wrist musculature. However, the effects of these methods on the calves are unknown. **PURPOSE:** The purpose of this study was to explore the effectiveness of BFR and NMES individually and in combination for increasing calf strength. **METHODS:** Thirteen participants (9 males and 4 females; 20.15 \pm 1.72 yr, 69.95 \pm 11.45 kg) were recruited from California State University, Long Beach with each leg being randomized to one of three training conditions: 1) BFR only, 2) NMES only, or 3) BFR and NMES, for six weeks of training. Calf strength was measured using an isokinetic dynamometer to assess peak and average torque during maximal plantar flexion contractions through a range of velocities (0-210 deg/s). Comparisons were made using separate two-way ANOVA's for each variable. **RESULTS:** Average isometric torque during five second maximal plantar flexion contractions increased in the NMES (P=0.019) and BFRNMES groups (P=0.01), while peak isometric torque only increased in the NMES group (P=0.031). Peak torque at 30 deg/sec and 90 deg/sec increased only with BFRNMES (P=0.001 and P=0.008, respectively). A significant main effect for time was found at 60 deg/sec (P=0.014) and 210 deg/sec (P=0.019), with no differences found during post-hoc comparisons. No significant differences were found at the other velocities. **CONCLUSION:** NMES and BFRNMES conditions may have potential for increasing strength of the plantar flexors at slower velocities (≤ 90 deg/sec). This study adds to the literature regarding the feasibility of these methods as alternative exercise countermeasures for promoting favorable adaptations in the calf musculature.

Discomfort And Ratings Of Perceived Exertion To Practical Vs. Traditional Blood Flow Restriction Resistance Exercise

Robert Thiebaud¹, Takashi Abe², Jeremy Loenneke, FACSM², Tyler Garcia³, Yohan Shirazi³. ¹Brigham Young University-Idaho, Rexburg, ID. ²The University of Mississippi, University, MS. ³Texas Wesleyan University, Fort Worth, TX.
 (No relevant relationships reported)

Elastic knee wraps are used to produce blood flow restriction (BFR) but it is unclear how discomfort and perceived exertion may compare to more traditional ways of producing BFR such as nylon cuffs where the pressure is known. **PURPOSE:** To investigate how elastic knee wraps (practical) compare in ratings of perceived exertion (RPE) and discomfort after exercising to failure when compared to nylon cuffs (traditional) or low and high loads without BFR.

METHODS: Nine participants (male=7, female=2) completed this study. The average age and body mass index were 22 (4) years and 25.4 (1.5) kg/m². Each participant completed six conditions, in a randomized order, of unilateral knee extension exercise to failure for four sets. Two conditions (30% one-repetition maximum, 1-RM) included elastic knee wraps that were either stretched by two inches from resting length (Practical-Low) or they were stretched to a new length that was 85% of the thigh circumference (Practical-High). Two more conditions (30%-1RM) used nylon cuffs that were inflated to either 80% (BFR-High) or 40% (BFR-Low) of arterial occlusion pressure. The last two conditions had no restriction stimulus and were 30% 1-RM (LL) or 70% 1-RM (HL). Discomfort (0-10) and RPE (6-20) were measured before exercise and at the end of the four sets. The change scores from before exercise to the end of set 4 were used for analysis. Friedman's test and Conover's post hoc test were used to determine if there was a difference in discomfort and RPE between conditions. Statistical significance was set at p<0.05. **RESULTS:** Practical-High had larger changes in discomfort compared to HL (8 vs 6, p=0.007) and LL (8 vs 6, p=0.018). Practical-Low had a smaller change in discomfort compared to BFR-High (7 vs. 9, p=0.028) but it was not different from BFR-Low (7 vs. 7, p=0.450). No differences were found between Practical-High vs. BFR-High (8 vs. 9, p=0.211) or Practical-High vs. BFR-Low (8 vs 7, p=0.316). Practical-Low had smaller changes in RPE compared to BFR-High (12 vs 11, p=0.024) but there was no difference in RPE between Practical-High and the other conditions (p>0.05).

CONCLUSIONS: When exercising to failure, both discomfort and RPE are impacted by the pressure used and elastic knee wraps can produce changes in discomfort and RPE levels that are comparable to high pressure BFR.

Training-induced Changes In The Control Of Heart Rate Throughout A Competitive Season In Collegiate Female Swimmers.

John L. Dobson, Loren Stroud. Georgia Southern University, Statesboro, GA.
 Email: jdobson@georgiasouthern.edu
 (No relevant relationships reported)

In competitive swimming, overload training is often used to elicit transient states of overreaching in the hopes that subsequent periods of taper will lead to performance supercompensation. However, if the overload stress is too great relative to the level of recovery, fatigue will accumulate and cause both a greater risk of injury and more prolonged decrements in performance. Measures of vagal control of the heart rate (HR) have been shown to reflect the balance between training-induced fatigue and recovery, and so those measures can provide valuable feedback to help guide coaches as they develop and revise training plans. **PURPOSE:** The purpose of the present study was to use three different indicators of vagal control of HR to investigate the impact of overload training and tapering in collegiate female swimmers. Those indicators were the resting logarithm of the root mean square of successive R-R intervals (lnRMSSD_{rest}), HR responses to forced breathing (HR_{diff}), and HR responses to one minute of sustained handgrip exercise (HR_{hg}). **METHODS:** Thirteen female Division-I swimmers performed lnRMSSD_{rest}, HR_{diff}, HR_{hg} assessments three times throughout their competitive season: 1. at the beginning of the season (BL), 2. eleven weeks later during a period of intense overload training (OL), and 3. another eleven weeks later and following a taper (TP). Differences in the cardiovascular variables during BL, OL, and TP were determined using repeated measures ANOVAs. **RESULTS:** Very large decreases in lnRMSSD_{rest} (p<0.01) and increases in HR_{hg} (p<0.05) occurred during OL, but those values then returned to BL levels during TP (p<0.05 and p<0.01, respectively). By contrast, HR_{diff} values fell progressively throughout the season, and there was a large difference between the BL and TP measurements (p<0.05). **CONCLUSION:** Changes in all three variables demonstrated that OL impaired vagal

stimulation of the heart, and the bulk of evidence indicated that vagal stimulation was fully restored during TP. This was one of only a few longitudinal studies that have investigated the control of HR over the course of an entire competitive swim season, and it was the first study to demonstrate that overload training and taper can alter HR responses to both forced breathing and sustained handgrip exercise.

Peripheral Heart Action Training: A Metabolic Profile With Between Sex Comparison

Zachary Aaron Mang, University of New Mexico, Albuquerque, NM.
 Email: zmang@unm.edu
 (No relevant relationships reported)

ABSTRACT

Peripheral heart action (PHA) is a time-efficient and under-researched style of circuit training that alternates upper and lower body exercises with minimal rest between sets. **Purpose:** To compare the metabolic profile of PHA to traditional (TRAD) resistance training (RT) and report sex-specific responses during each. **Methods:** In a repeated measures design, twenty resistance-trained individuals underwent two bouts of volume-matched RT: PHA and TRAD. For PHA, subjects executed 6 consecutive lifts (75% 10-RM, 12-15 repetitions) in circuit fashion with little rest between them. Four rounds were performed, and one minute of rest was allotted between rounds. Volume-load and intensity were matched for the subsequent bout of TRAD, during which straight-sets were performed and 90 seconds of rest was allotted between every set. Oxygen uptake (VO₂), heart rate (HR), blood lactate concentration [La], rating of perceived exertion (RPE), and excess post-exercise oxygen consumption (EPOC) were measured. **Summary of Results:** PHA elicited significantly greater %VO₂Max (45±7.1 vs. 28±4.3%, p<0.0001), %HRmax (80±4.0 vs. 61±9.1% p<0.0001), RPE (16±1.8 vs. 12±2.0, p<0.0001), and EPOC (9.6±2.4 vs. 7.1±1.4 ml/kg/min, p<0.0001) compared to TRAD. PHA was also completed in less time (20±3.2 vs. 46±3.8 min, p<0.0001). Compared to TRAD, [La] was significantly higher at mid-exercise (8.1±1.5 vs. 5.6 ±1.9 mmol/L, p<0.0001), post-exercise (10.5±2.8 vs. 5.2±1.8 mmol/L, p<0.0001), and 5-min post-exercise (10.3±3.0 vs. 4.5±1.9 mmol/L, p<0.0001) during PHA. There were no between sex differences for [La] at any time-point for TRAD. During PHA, [La] was significantly higher for males at mid-exercise (9.6±2.0 vs. 6.6±2.4 mmol/L, p = 0.008), post-exercise (12.1±2.0 vs. 8.9±2.5 mmol/L, p = .006), and 5-min post-exercise (12.2±2.1 vs. 8.4±2.4 mmol/L, p = .002). No between sex differences were detected for HR, VO₂, or RPE for either style of RT. **Conclusion:** PHA is a time-effective and metabolically demanding circuit that may be employed to stimulate musculoskeletal and cardiorespiratory adaptations. Males produced more lactate than females during PHA, and one may speculate this was caused by discrepancies in total-body lean-mass, cross-sectional area per muscle fiber, or Type I fiber distribution.

Neuromuscular Training Intervention Developed To Combat The Effects Of Acute Fatigue In Collegiate Pivoting Athletes

Julianna Harpine, Kevin Robinson, Craig Parker, Paige Koshar, Grace Webb, Glenn Fleenor, Shelby Martin, Dylan Green, Tyler Hoek, Pat Sells. Belmont University, Nashville, TN Email: julianna.harpine@pop.belmont.edu
 (No relevant relationships reported)

Purpose: A large body of evidence has mounted supporting the efficacy of neuromuscular training (NMT) for prevention of anterior cruciate ligament (ACL) injury. Incorporation of NMT with athletes has been shown to improve biomechanics during dynamic pivoting movements. However, there is a lack of literature to date examining the influence of NMT on biomechanical measures during dynamic movements in a state of acute fatigue. This study examined strength, dynamic balance, and lower quarter biomechanics while performing functional movements succeeding a short-term fatigue protocol in collegiate soccer athletes before and after an eight-week NMT intervention. **Methods:** 28 Division II NCAA male and female soccer players ages 18-23 participated in the study. Hip strength was measured with hand dynamometry and single-leg stance modified balance (SLS^M) was measured with eyes shut and in static heel rise. The Noraxon MyoMotion system assessed peak hip and knee excursion in three dimensions during select movement assessments following execution of the functional agility short-term fatigue protocol. Training consisted of 16 NMT sessions, performed over eight weeks, following which the tests were repeated. **Results:** Improvements post-intervention were found in hip abduction strength L (p=0.015), hip extension strength R (p=0.031) and L (p=0.013); SLS^M with eyes-closed on R (p=0.000) and L (p=0.000); SLS^M with heel rise bilaterally (p=0.000); peak ROM for L hip abduction (p=.025), R knee flexion (p=0.002), and L knee flexion (p=0.006) during single-leg squat; peak ROM for R hip flexion (p=0.033) during bilateral squat; peak ROM for L hip flexion (p=0.045) and L knee flexion (p=0.000) during single-leg jump assessment and peak ROM for R knee flexion

($p=0.029$) and L knee flexion ($p=0.045$) during bilateral jump. **Conclusions:** Following the NMT intervention, proximal hip strength, dynamic balance, and functional loading capacity significantly improved, illustrating positive neuromuscular adaptations in the lower quarter and nervous system. Enhanced kinematics during select sport-specific movement assessments were evident by the MyoMotion system following a fatigue protocol, defending the hypothesis that NMT can improve lower extremity biomechanics of collegiate pivoting athletes while acutely fatigued.

The Effects Of Vertical And Horizontal Training On Sprint Ability In Athletes: a Systematic Review And Meta- Analysis

Xiaochen Zhao¹, Weimo Zhu, FACSM², Qing Li¹. ¹Tsinghua university, Beijing, China. ²University of Illinois at Urbana-Champaign, Illinois, China.
Email: 18614222993@163.com
(No relevant relationships reported)

Plyometrics exercises are characterized by rapid stretch- shortening cycle (SSC) muscle actions. While studies have proved the effectiveness of plyometrics training on improving athletes' sprint ability, limited information is available on which specific method is more effective to athletes improve their sprint ability. **PURPOSE:** To examine the effect of vertical training (VT) and horizontal training (HT) on sprint ability in athletes. **METHODS:** Searched databases (MEDLINE, PubMed, websites of science core database) till Oct.1, 2019. Search keywords included: Vertical, horizontal, countermovement jumps (CMJ), sprint, and speed. The screening conditions were as follows: (a) Randomized controlled trials; (b) Participants were athletes, (c) VT or HT were the training method and there are at least 8 training lessons; (d) The study design consisted of an intervention group and a control group, or a vertical group and a horizontal group. (multiple training methods were excluded); (e) Other training courses (e.g. warm-up, technical, tactical, and strength training, volume, intensity); and (f) The final results of the study should include sprint ability test, and CMJ. **RESULTS:** A total of 340 articles were screened out and then removing the papers with duplicate titles and abstracts; as a result, 252 articles remained; additional 35 papers were removed after excluding the reviews and reading the abstracts; thereafter, 26 articles were read in full text according to the screening criteria; finally, 7 articles were included in the meta-analysis. The risk of bias was evaluated using the Cochrane collaboration's tools. Compared with VT, HT is more effective in improving athletes' sprint ability [0.84(95%CI =0.06,1.62), $Z=2.10$ ($P=0.04$)], but there is no difference between VT and HT in improving CMJ [0.45 (95% = -0.05,0.94), $Z=1.78$ ($P=0.08$)]. Through subgroup analysis of 10-M sprint time, the large number of training lessons (≥ 20) had a significant effect; age (under 17 yr. old) and project soccer player (Others include basketball and handball) were no statistically significant. **CONCLUSION:** HT is more helpful to improve the sprint ability, but HT and VT were about the same in improving CMJ.

(No relevant relationships reported)

PURPOSE: To compare the effect of aerobic training using Swiss-ball (SB) and aerobic training using bicycle on postural stability. **METHODS:** Sixteen healthy adults allocated into two group randomly: SB training group performed two-month aerobic training using SB and bicycle training group (Bike group) performed two-month aerobic training using bicycle ergometer. Subjects were asked to do the training for 30minute in a day and three days in a week. In each group, baseline and post intervention postural stability and peak oxygen consumption were measured. Postural stability was measured using stabilometric platform. During the assessment of stability, subjects were asked to close eyes and stay as still as possible for 30 seconds. Fundamental parameters obtained are: position of the body center of gravity, area and shape of sway density curve and velocity variables. **RESULTS:** All results show mean (SD). There was no main effect on peak oxygen consumption and no difference between training group (SB group: 33.1(5.0) ml/kg/min to 32.9(5.4) ml/kg/min, Bike Group: 32.2(7.6) ml/kg/min to 35.5(8.0) ml/kg/min). On the other hand, significantly interaction was found on some postural stability measurement: area in which the center of gravity (SB group: 2.3(0.4) cm² to 3.0(1.3) cm², Bike Group: 1.9(1.0) cm² to 2.4(1.4) cm²: no significantly interaction), total length of center of gravity displacement ((SB group: 55.3(9.9) cm to 46.4(8.4) cm, Bike Group: 39.9(11.6) cm to 43.3(13.1) cm: interaction $p<0.05$), velocity of center

of pressure ((SB group: 1.8(0.3) cm/sec to 1.6(0.3) cm/sec, Bike Group: 1.3(0.4) cm/sec to 1.4(0.4) cm/sec: interaction $p<0.05$). **CONCLUSIONS:** SB training shows no significantly effect on peak oxygen consumption. On the other hand, SB training improved postural stability compared with bicycle ergometer training.

Effects Of A 10-week Physical Activity Intervention Among Seminary Students

Sara Ness¹, Lesley M. Scibora¹, Angela Effertz². ¹University of St. Thomas, St Paul, MN. ²Normandale Community College, Bloomington, MN.
(No relevant relationships reported)

PURPOSE: While the number of overweight and obese Americans increases, fewer people meet recommended physical activity levels. Among Americans, 32 - 56% of Christian clergy have obesity and associated chronic diseases. Seminararians are an optimal group to introduce interventions to decrease the prevalence of obesity, as they have the power to improve both their own health as well as the health of those in their congregation. This study aims to determine whether a physical activity intervention in a seminary population is an effective way to improve physical fitness and body composition, in an effort to decrease obesity and related diseases. **METHODS:** 59 male seminary students (age range 22 - 66 years; mean age 30.12 years) participated in a 10-week physical activity intervention, attending two trainer-led exercise sessions per week for 10 weeks, which including cardiorespiratory and resistance training components. Pre- and post-intervention anthropometric measures included weight, BMI, waist-to-hip ratio, and body fat (%). Physical fitness assessments included the Rockport Walk test, cardiorespiratory endurance, and flexibility. Blood panels included a lipid and glucose panel. **RESULTS:** Results are shown in Table 1 (not all data shown). Body weight, BMI, triglycerides and LDL cholesterol did not change as a result of the intervention. Mean waist circumference decreased 3 cm ($p < 0.001$). Significant improvements were observed in all physical fitness assessments (all $p < 0.05$). Mean total cholesterol increased 8.7 mg/dL, HDL cholesterol increased 5 mg/dL, and blood glucose decreased 10 mg/dL (all $p < 0.05$). **CONCLUSIONS:** The results of this study show that a 10-week physical activity intervention in seminary students was effective in improving body composition, physical fitness and blood cholesterol and glucose measures. Results of this study suggest that seminararians may be an optimal group for future interventions to improve overall health and fitness.

Table 1. Pre- and post-intervention anthropometric, fitness and blood panel outcomes

Variable	n	Pre-Pre-TestMean (±SD)	Post-TestMean (±SD)	p-value
Anthropometrics				
Weight (kg)	51	89.7 (±17.9)	89.2 (±17.8)	0.161
Waist Circumference (cm)	51	94.5(±13.1)	91.5 (±11.3)	0.000
Hip Circumference (cm)	50	106.2 (±8.9)	104.9 (±8.7)	0.041
Physical Fitness Tests				
Push-up Test (n)	51	20.1 (±12.0)	23.9 (±11.1)	0.000
Curl-up Test (n)	51	33.9 (±19.5)	47.1 (±22.6)	0.000
Trunk Flexion (cm)	51	25.4 (±9.9)	28.6 (±10.6)	0.000
Blood Panel				
Glucose (mg/dL)	43	94.7 (±31.1)	84.7 (±13.2)	0.005
Total Cholesterol (mg/dL)	44	175.9 (±32.2)	184.6 (±29.3)	0.018
HDL (mg/dL)	44	48.1 (±13.1)	53.2 (±14.5)	0.000
LDL (mg/dL)	44	105.7 (±25.9)	110.3 (±24.2)	0.109

Acute Response Of Biochemical And Hematological Markers After A Crossfit® Training Session.

Andreia Gomes Naves¹, Lilian Cardoso Vieira¹, Mariane Iori¹, Franz H P Burini², Lazaro Alessandro Soares Nunes³. ¹NutreeX, Sao Paulo, Brazil. ²CeMENutri – UNESP Medical School, Botucatu, Brazil. ³Faculty of Pharmacy, Unimetropcamp Wyden, Campinas, Brazil.

Email: andrea.naves@nutreeX.com.br

(No relevant relationships reported)

Crossfit® is a strength and conditioning program recognized as one of the most popular and practiced types of high-intensity functional training today. The goal of participants is to optimize physical conditions in some fitness domains: strength, flexibility, power, cardiovascular or respiratory endurance, coordination, and agility. The exercises are executed quickly, repetitively in a high intensity with little or no recovery time between sets. **PURPOSE:** This study aimed to verify muscle damage and immune markers parameters in the response of the Crossfit® training session. **METHODS:** Sixteen male recreational Crossfit® practitioners (Mean± SD: 29.4 ± 5.3 years old) performed a single session of AMRAP (means as many rounds as possible) for 12 minutes. This session followed a sequence of 12 box jumps, 6 thrusters and 6 burpees facing bar. After the rest of 3 minutes, participants were instructed to complete a Wingate test on a cycle ergometer in the fastest time possible. Blood samples were collected immediately before the session of AMRAP (PRE) and after Wingate test (POST). Were analyzed white blood cells and platelet count in EDTA samples. Creatine kinase, C-reactive protein and uric acid were quantified in serum samples. The paired t test was applied to verify PRE and POST statistical differences. Values of $P < 0.05$ were considered significant. **RESULTS:** The data are presented as mean and SE. There was significant increases in leukocytes (PRE 7.6 ± 0.4 and POST 15.0 ± 0.8x10⁹/L, $p < 0.001$); neutrophils (PRE 4.3 ± 0.4 and POST 6.2 ± 0.6x10⁹/L, $p < 0.001$); lymphocytes (PRE 2.5 ± 0.1 and POST 6.9 ± 0.4 10⁹/L, $p < 0.001$) and platelets counts (PRE 271 ± 6 and POST 344 ± 12 x10⁹/L, $p < 0.001$); Creatine Kinase (PRE 363 ± 94 and POST 452 ± 114 U/L, $p < 0.001$) and C-reactive Protein (PRE 7.1 ± 0.9 and POST 8.0 ± 1.1 mg/L, $p < 0.001$). Uric acid concentrations were not different (PRE 4.7 ± 0.3 and POS 5.0 ± 0.2 mg/L, $p 0.184$). **CONCLUSION:** In conclusion, these results indicate that the AMRAP session associated with the Wingate test elicits an acute immune response, including neutrophils, lymphocytes, and platelets. Besides, this protocol acutely increase muscle damage and inflammatory markers. These blood parameters could be analyzed in the recovery strategies in Crossfit® practitioners.

A Comparison Of Functional Movement Between CrossFit Trained, Recreationally Trained And Sedentary Individuals

Kelsey Ede, Laurel Hill, Shelby Moreno, Natalia Traverzo, Shelly Weise, Teresa Huckaby. *Angelo State University, San Angelo, TX.*

(No relevant relationships reported)

CrossFit programs focus on performance of aerobic and strengthening exercises which incorporate multi-joint, functional movements. These variables combine to enhance athletic performance and improve an individual's ability to perform daily functional movement. A limited amount of research has compared CrossFit with other training groups regarding aerobic capacity, muscular strength, and body composition. A smaller percentage of research has compared functional movement variables. **PURPOSE:** Current research supports that CrossFit athletes demonstrate high symmetry of functional movement patterns. The primary aim of this study was to determine if CrossFit training was more beneficial to functional movement as compared to a standard exercise regimen. **METHODS:** This investigation was an exploratory cross-sectional study. Sixty (28 males, 32 females) healthy adults (age, 25±5 yr; ht, 170.5±10.3 cm; wt, 79.2±20.0 kg; BIA 23.10±8.44%) participated. Participants were recruited from the community and assigned to three groups based on their reported exercise lifestyle: CrossFit trained (CF), recreationally trained (RT), and sedentary (SD). The 60 participants underwent a series of tests including a functional movement assessment (FMS components), a maximal strength test (Deadlift 1-Rep Max assessment; kg deadlift/kg body wt), and an estimated aerobic capacity assessment (Astrand-Rhyming Cycle Ergometer Test; LO₂/min). Exclusion criteria, anthropometric data and vital signs were assessed in all patients. **RESULTS:** The CF group (6.97±1.13) was significantly higher than the sedentary group (5.73±1.41) in the FMS components score. The CF group deadlift score (1.90±0.40) was significantly higher than both the SD (1.18±0.36) and RT groups (1.47±0.51). For aerobic capacity, both the CF (3.09±1.00) and RT (2.84±0.67) groups were significantly higher than the SD group (1.96±1.17). All testing significance was set at $p \leq 0.05$. **CONCLUSION:** CrossFit training provided improved fitness and functional performance parameters as compared to sedentary counterparts. For muscular strength, CrossFit was associated

with higher scores as compared to recreationally trained individuals. CrossFit and recreationally trained groups scored evenly for aerobic fitness and components of functional movement patterns.

Stretching Training Can Change Shoulder And Neck Function In Middle-aged Women With Upper Crossed Syndrome

chaoming Wu¹, junzhi Sun¹, yanxia Zhao². ¹Chengdu sport university, chengdu, China. ²Chongqing university, chongqing, China.

Email: 834791487@qq.com

(No relevant relationships reported)

PURPOSE: Upper Crossed Syndrome (UCS) is a syndrome of abnormal movement patterns of the upper limbs. To judge the improvement of shoulder and neck function, the changes in shoulder joint function and shoulder cervical spine angle after 8 weeks of stretching training was observed in middle-aged women with.

METHODS:

12 middle-aged women (Table 1) were selected for a detailed assessment of upper crossover syndrome included in Acromion height test, the distance from the medial margin of the inferior angle of scapula to the spine, measurement of range of motion of shoulder joint, cervical the vertebra and stretching training program.

RESULTS:

1. The angles related to the range of motion of the cervical vertebrae were measured and the results were shown in Table 2. It was found that the average range of movement of the cervical spine after training was significantly higher than that before training, and the difference was significant before and after training.
2. The angle related to the range of motion of the shoulder was measured, and the results shown in Table 3. It found that the average amplitudes of shoulder flexion, extension, abduction, adduction, and abduction and horizontal abduction in patients with superior crossover syndrome after training was significantly higher than those before training, and there was a significant difference before and after training ($P < 0.05$).
3. The height of the acromion and the distance between the inferior angle of the scapula and the spine before and after training was compared (Table 4), and the results were shown in Table 3.

CONCLUSION: A long-term sedentary lifestyle may lead to muscle imbalance, weakening the primary motor function of the body, and increasing the risk of soft tissue injury. Stretching training has a significant effect on the shoulder and neck function of patients with UCS. The right joint function sequence can reduce the asymmetry of the body, prevent and reduce bone and joint wear.

Table 1. Subject characteristics

Physiological Adaptations To A Concurrent Exercise Training Program In Physically Inactive Women
 Mynor G. Rodriguez-Hernandez¹, Lorena Huffman², James McDonald², Danielle D. Wadsworth². ¹University of Costa Rica, San Ramon, Costa Rica. ²Auburn University, Auburn, AL.
 (Sponsor: David D Pascoe, FACSM)
 Email: mynor.rodriguez@ucr.ac.cr
 (No relevant relationships reported)

PURPOSE: To assess the effect of a 10-week, high-intensity concurrent exercise training program on body composition, bone density and muscular strength in physically inactive aging women.
METHODS: 53 inactive women (age 40-64) were randomized into two sprint interval training (SIT) programs, 0% incline (age 51.9 ± 6.6) and 6% incline (age 53.4 ± 7.6). SIT was performed to achieve 95% of each participant's age-predicted maximal heart rate for 40 seconds followed by 20 seconds of passive recovery for approximately 15 minutes. Additional, each group performed a resistance training protocol, alternating between two programs: back squat, bent over row, bench press; and squat jumps, weighted lunges, standing press, back extensions. Participants attended 30 workouts over the course of 10 weeks. DXA scans assessed body composition and bone density of the femoral neck. IRM was performed to assess muscular strength changes in bench press and back squat. A repeated measure ANOVA examined group (0% incline and 6% incline) by time interactions.
RESULTS: There was no significant effect of group (p>.05). Significant decreases in fat mass (p = .02), visceral adipose tissue (p = .048) and significant increases in muscular strength for both bench press (p<.0001) and back squat (p<.0001) occurred for both groups. No significant differences were found for lean body mass (p=.872) and bone density of the femoral neck (p=.092).
CONCLUSIONS: A SIT and resistance training program is an effective strategy to improve fat mass and muscular strength in inactive, aging women. Muscular strength improvements resulting from this intervention are particularly important as muscular strength losses are strong predictors of morbidity and mortality.

Comparison Of Upper-Body Strength Changes With Different Training Modalities Among Women Of Different Body Builds

Jana L. Arabas¹, Jerry L. Mayhew¹, William F. Brechue, FACSM², Monica L. Hunter¹, Bryan Mann³. ¹Truman State University, Kirksville, MO. ²A. T. Still University, Kirksville, MO. ³University of Miami, Miami, FL.
 Email: jlarabas@truman.edu
 (No relevant relationships reported)

Previous investigation has noted that neither body build nor initial strength level appear to influence upper-body strength gains resulting from a short-term resistance training (RT) program in young men. Such information is lacking in young women. With increasing interest of women in RT, it would be beneficial to determine if the same outcome as noted in men is operating in women. **PURPOSE:** To determine the influence of body build on changes in upper-body strength resulting from different modes of RT in college women.
METHODS: College women (n = 708, age = 19.0 ± 0.9 yrs, Ht = 165.0 ± 6.0 cm, Wt = 62.6 ± 10.7 kg) self-selected to train with free weights or machine weights during 12 weeks of periodized RT 3 days/week. 1RM press was measured with free weights (FW, n = 170), supine vertical machine weight (SVP, n = 284), and seated horizontal machine weight (n = 232) before and after training. Fat mass (FM) and fat-free mass (FFM) were determined from a gender-specific skinfold %fat equation. Body build was determined by regressing FFM/Ht² on FM/Ht². Body build was partitioned into thirds as slender (SL, n = 231), average (AV, n = 239), and solid (SO, n = 232) groups.
RESULTS: The SVP group had a significantly greater initial 1RM (37.8 ± 8.5 kg) than the FW (35.6 ± 7.8 kg) and SHP (35.6 ± 7.8 kg) groups. SO body type (36.6 ± 8.3 kg) had a greater initial 1RM than SL (35.8 ± 8.0 kg) and AV (35.1 ± 8.4 kg) body types. Mode x body type ANOVA indicated that SVP (9.5 ± 6.2 kg) and SHP (8.8 ± 5.1 kg) made significantly greater 1RM gains than FW (4.9 ± 3.9 kg), while SO (9.3 ± 6.2 kg) and AV (8.8 ± 5.1 kg) body types made significantly greater gains than SL (6.9 ± 5.0 kg), with no significant interaction. Absolute strength gains had low correlations with initial strength in all modes (r = -0.08 to -0.26), accounting for no more than 7% of the common variance. Body type also had low correlations with absolute strength gains (r = 0.11 to 0.25). **CONCLUSIONS:** Young women appear to make slightly better initial strength gains using machine weights compared to FW. Body type does not appear to influence training potential to gain strength in women from RT using either mode. Thus, when beginning RT, young women of any body size or initial strength level can make significant gains using either free weights or machine weights.

3237 Board #58 May 29 1:30 PM - 3:00 PM
Use Of Pool Bottom Mirror In Coaching Front Crawl Stroke Correction

Boram Lee, Somi Yun, Heejin Lee, Yunbin Lee, Ah-Reum Jung, Dae Taek Lee. Kookmin University, Seoul, Korea, Republic of.
 Email: lbr0424@gmail.com
 (No relevant relationships reported)

PURPOSE: The mirror can provide visual information about the learner's body movement instantaneously and allow immediate error detection followed by appropriate correction. This study analyzed whether coaching recreational swimmers using pool bottom mirror for correcting front crawl stroke is effective in achieving an intended stroke. **METHODS:** Thirty adults who enrolled swimming lessons for more than 1 year participated and were randomly divided into two groups; mirror group (MG: 12 men; 32.3±8.2 yrs, 175.0±5.5 cm, 70.9±9.2kg; 3 women; 37.6±13.7 yrs, 160.0±3.4 cm, 55.6±3.5 kg) and control group (CG: 7 men; 28.7±6.1 yrs, 176.2±3.7 cm, 72.4±14.4 kg; 8 women; 38.8±14.6 yrs, 162.1±4.4 cm, 54.1±7.3 kg). They performed front crawl twice in a swimming flume (2.43 × 4.57 × 1.37 meter) at their chosen speed (pace of 87.9±4.2 for men, 102.7±4.7 sec/100 meter for women). Their stroke was video recorded by an underwater camera (xnb-6001, Samsung, Korea) and dry land camera (gnd-6020R, Samsung, Korea). After their first trial and recording, individual stroke was evaluated and verbal feedback was given for correction targeting full arm range stroking. During second trial, MG had a mirror (81 × 151 cm) installed under the bottom of flume so that they could check their stroke. CG did not use mirror during second trial. An image analyzer (Dartfish, Swiss) was used to analyze the distance between reference point (RP: where fingertip was reached over Vastus lateralis during standing till on land) and fingertip as well as stroke time (time between left hand immersion cycle). Stroke frequency was counted cycles of both arms. Two trials were compared. **RESULTS:** The distance between RP and fingertip was 7.7±3.3 and 2.5±3.5 cm in MG in 1st and 2nd trial, respectively (p<0.001) while it was 6.0±4.0 and 5.1±3.8 cm in CG. The stroke frequency was 60.7±7.3 in MG and 57.7±6.8 freq/min in CG at 1st trial. It was decreased to 53.7±5.4 in MG (p<0.001), but not in CG (56.3±6.6 freq/min). The stroke time was increased from 2.1±0.3 to 2.4±0.3 sec in MG (p<0.01), but it was not changed in CG (2.1±0.2 vs. 2.2±0.3 sec). **CONCLUSION:** The results

suggest that a pool bottom mirror is an effective tool in coaching for correction of front crawl stroke. Both verbal and visual instruction is valuable in correcting stroke of recreational swimmers and it can be achieved by the mirror.

3238 Board #59 May 29 1:30 PM - 3:00 PM
Effects Of Unilateral Resistance Training On Muscular Strength, Power, And Measures Of Core Stability In Trained Individuals

Anthony Duong, Andrew J. Carnes, Thomas Wójcicki.
Bellarmine University, Louisville, KY. (Sponsor: Sara E. Mahoney, FACSM)
 Email: aduong01@bellarmine.edu
 (No relevant relationships reported)

PURPOSE: This study examined the effects of unilateral resistance training on lower body muscular strength and power, and measures of core stability in resistance-trained college students.

METHODS: Participants (N=22) underwent either 10 sessions of lower body unilateral (URT) or bilateral (BRT) resistance training on three non-consecutive days per week for three weeks. Training sessions consisted of three sets of five repetitions of 80% 1-RM for each exercise. BRT exercises included the barbell back squat, deadlift, and weighted jump squat. URT exercises included the Bulgarian split squat, single leg of Romanian deadlift, and single leg weighted jump squat. Outcome measures were a one repetition maximum (1-RM) leg press for lower body strength, standing vertical jump (VJ) for lower body power, and double leg lowering (DLL), hip abduction isometric strength (HAIS), and Sorensen (SOR) tests for core stability.

RESULTS: Training elicited a positive main effect of time for all variables ($p < 0.05$). Both groups improved pre to post training in 1-RM (297 ± 95.4 to 373 ± 114 kg), VJ (56.5 ± 15.0 to 62.2 ± 10.8 cm), DLL (33.9 ± 14.9 to 43.6 ± 13.2 deg), HAIS (29.6 ± 8.86 to 32.6 ± 10.1 kg), and SOR (91.4 ± 33.1 to 112 ± 36.7 sec). The magnitude of change was similar between groups for all variables except HAIS, in which the UL group demonstrated significantly ($p=0.0155$) greater improvement (14.3% vs. 5.3%). However, the effect size was larger in UL for all variables except VJ (Cohen's $d = 0.86$ vs. 0.61 for 1-RM, 0.92 vs. 0.55 for DLL, 0.64 vs. 0.19 for HAIS, 0.90 vs. 0.36 for SOR).

CONCLUSIONS: Relative to bilateral training, unilateral resistance training produced similar improvements in measures of lower body strength and power in trained subjects. Additionally, these data suggest that unilateral training may potentially offer the benefit of enhanced core stability.

Effect Of Core Strength Exercise On Colon Transit Time In Female University Students

Yeon Soo Kim¹, Dongsuk Han¹, Angelique G. Brellenthin², Bong Kil Song². ¹*Sports science, Seoul, Korea, Republic of.* ²*Physical activity epidemiology lab, ames, IA.*
 Email: kys0101@snu.ac.kr
 (No relevant relationships reported)

PURPOSE: To evaluate the benefit of core strength exercise (CSE) on colonic transit time (CTT) for female university students. **METHODS:** Eighty women were enrolled and randomly assigned to participate in a 12-week instructor-led group CSE program (exercise group; $n = 40$) or to maintain their ordinary daily activities (control group; $n = 40$). The final groups were composed of 27 participants (age: 22.9 years) in the exercise group and 21 participants (age: 22.9 years) in the control group (CG). The CSE program consisted of 60 minute sessions, two days a week for 12 weeks. Each session included a 10-minute warm-up, 40-minute core strengthening exercises, and 10-minute cool-down. Body composition, Trunk muscle power and endurance, physical fitness and CTT were measured twice before and twice after the exercise program. CTT was measured using a multiple marker technique with a radio-opaque marker. Data were analyzed with a 2-way, repeated measures ANOVA. **RESULTS:** After the 12-wk core exercise intervention, decreased intestinal transit time was observed in segment CTT of the exercise group, including the right CTT (exercise: 9.0 ± 1.8 vs 6.4 ± 1.5 , control: 5.3 ± 1.3 vs 6.5 ± 1.5), left CTT (exercise: 10.9 ± 2.0 vs 6.9 ± 1.8 , control: 10.6 ± 2.3 vs 8.7 ± 1.5), recto-sigmoid CTT (exercise: 17.4 ± 2.9 vs 12.1 ± 2.0 , control: 8.7 ± 2.3 vs 11.9 ± 2.8), and total colonic transit time (TCTT) (exercise: 37.5 ± 4.4 vs 25.5 ± 3.8 , control: 24.7 ± 4.8 vs 27.2 ± 4.8). After the 12-wk core exercise period, LCTT (mean difference, -3.7 h; 95% confidence interval [CI], -6.9 to -0.6 h; $P=0.02$) and TCTT (mean difference, -9.4 h; 95% CI, -16.4 to -2.4 h; $P=0.01$) was significantly shortened within the exercise group in mean changes from baseline to 12wk follow-up. **CONCLUSIONS:** The CTT was reduced due to increased physical activity via a 12-wk CSE program. In addition to eating habits, water intake, and fiber intake, the increased physical activity level as a result of the 12-wk CSE reduced the CTT. Further prospective studies will need to study the effects on CTT according to dose-response, type of exercise, and intensity.

Chronic Influence Of Inspiratory Muscle Training At Different Intensities On The Serum Metabolome

Ettore Signini¹, Camila Sakaguchi¹, Raphael Abreu¹, Claudio Silva¹, Patricia Rehder-Santos¹, Carla Dato², Maria Carosio¹, Roberta Maria¹, David Nieman³, Tiago Venâncio¹, Antônio Ferreira¹, Aparecida Catai¹. ¹*Federal University of São Carlos, São Carlos, Brazil.* ²*Central Paulista University Center, São Carlos, Brazil.* ³*North Carolina Research Campus, Appalachian State University, Kannapolis, NC.*
 (No relevant relationships reported)

PURPOSE: To investigate the chronic effect of inspiratory muscle training (IMT) on the human serum metabolome in healthy male recreational cyclists. **METHODS:** This study employed a randomized, parallel group design. Recreational male cyclists ($n=23$, 20-40 y, BMI < 30 kg/m²) were randomized to three IMT groups: low intensity (6 cm H₂O) (LI, $n=7$); moderate intensity or 60% of maximal inspiratory pressure (MI, $n=10$) and high intensity, the critical inspiratory pressure ($\approx 85-90\%$ of maximal inspiratory pressure) (HI, $n=11$). The IMT was performed for 11 weeks, 3 times per week (3 sets of 15 minutes/session). Another group of participants under the same conditions, who did not perform the IMT but participated in all assessments and procedures, was included as controls (CG, $N=6$). Blood samples were collected one week before and one week after 11 weeks of IMT and analyzed using 1H NMR spectroscopy. Statistical analysis included a 4 (group) x 2 (time) repeated measures ANOVA using the general linear model (GLM), and multivariate Principal Component Analysis (PCA). **RESULTS:** The targeted metabolomics analysis of serum samples identified 23 metabolites, including amino acids, lipids, and tricarboxylic acid cycle intermediates. No significant interaction effects from GLM were found for the 23 metabolites, and this was confirmed by PCA. **CONCLUSION:** These data indicate that IMT at three intensity levels did not alter the serum metabolome relative to the control group. These results are consistent with other exercise training studies showing negligible alterations in the serum metabolome compared to the large but transient perturbations linked to prolonged and intensive exercise.

 Email: angelatsopanidou@hotmail.com
 (No relevant relationships reported)

The recent global rise in obesity appears to be a threat to public health as it is connected with various cardiovascular and metabolic diseases. Surya Namaskar (SN), a component of Vinyasa yoga, consisted of a specific sequence of 12 yoga postures performed with controlled breath, is often used as an alternative of a typical fitness program to improve overall health, including body weight management. However, research data studying high intensity SN (HSN) are limited. **PURPOSE:** The aim of the present study was to assess cardiorespiratory and metabolic demands of HSN performed with 3 s/pose. **METHODS:** Heart rate (HR) response of twenty-four moderately trained subjects (12 males and 12 females; mean \pm sd age: 39 ± 7.33 years, body stature: 167.38 ± 9.32 cm, body mass: 66.60 ± 14.07 kg, % body fat: 23.30 ± 5.86 ; $\dot{V}O_{2peak}$: 45.48 ± 7.12 ml.kg⁻¹.min⁻¹ and HRmax: 183.54 ± 10.13 bpm) was recorded during two-15 min sessions HSN practice 7 days apart. Maximal oxygen uptake ($\dot{V}O_{2peak}$) and maximum HR (HRmax) had been estimated earlier, after an incremental test to exhaustion. $\dot{V}O_2$ during HSN was estimated from individual regression equations using the relationship of $\dot{V}O_2$ and HR values derived from $\dot{V}O_{2peak}$ test, while the metabolic rate (kcal.min⁻¹) was calculated from the relationship of HR and kcal.min⁻¹. Total HSN energy consumption was the average value of the two-15 min sessions. **RESULTS:** Mean \pm sd values of the %HRmax, % $\dot{V}O_{2max}$ and rate of energy expenditure during HSN were $71.7 \pm 7.5\%$, 59.9 ± 10.3 and 8.9 ± 3.3 kcal.min⁻¹ (7.9 ± 2.0 METs) respectively. Total session energy expenditure was 133.04 ± 50.14 kcal. **CONCLUSIONS:** The results of the present study confirm that an HSN session may produce a sufficient training stimulus to promote cardiorespiratory fitness and favor weight loss in moderate trained adults.

**Low Volume Bodyweight Interval Training Improves
 Cardiorespiratory Fitness: A Contemporary Application
 Of The 5BX Approach**

Linda R. Archila¹, William Bostad¹, Michael J. Joyner², Martin J. Gibala¹. ¹McMaster Univ., Hamilton, ON, Canada. ²Mayo Clinic, Rochester, MN. (Sponsor: Stuart Phillips, FACSM)
 (No relevant relationships reported)

Brief vigorous exercise training can improve cardiorespiratory fitness. Few studies, however, have examined the efficacy of basic bodyweight exercises that can be performed in a small space, without the need for specialized equipment. Practical, time-efficient approaches of this sort have been advocated for decades, including the 11-minute "Five Basic Exercises" (5BX) program developed by the Canadian government in the 1960s. **PURPOSE:** We determined the effect of a 5BX-style program on peak oxygen uptake (VO_{2peak}) in inactive but healthy young men and women (20 ± 1 y; body mass index: 20 ± 5 kg/m²; mean \pm SD). **METHODS:** Participants were randomized to a training group that performed 18 sessions over six weeks (n=9), or a non-training control group (n=10). Each session involved a 1-minute warm-up (jumping jacks), followed by 1-minute bouts of five exercises (burpees, high knees, split squat jumps, high knees, squat jumps), each interspersed with 1-minute of active recovery (walking around the room). Participants were instructed to complete as many repetitions per bout as possible, at a self-determined "challenging" pace. All sessions were supervised and compliance was 100%. **RESULTS:** Mean intensity during training was $82 \pm 5\%$ of maximal heart rate. Borg Scale ratings of perceived exertion for the five exercises ranged from 12 ± 2 to 15 ± 3 out of 20. ANCOVA revealed a significant difference between groups after the intervention, such that VO_{2peak} was higher in the training group compared to control (34.2 ± 6.4 vs 30.3 ± 11.1 ml/kg/min; $P=0.03$). Peak power output during the VO_{2peak} test was also higher after training compared to control (211 ± 43 vs 191 ± 50 W, $p=0.004$). There were no changes in leg muscular endurance, handgrip strength or vertical jump height in either group. **CONCLUSIONS:** A simple bodyweight interval training program, requiring 11 minutes per session, increased cardiorespiratory fitness in previously sedentary young adults when performed three times per week for six weeks. Supported by NSERC.

Biomechanics And Energetics Of Curved Treadmills

Dustin Durke, Kellie Walters, Kevin Valenzuela, Jill Crussemeyer. California State University Long Beach, Long Beach, CA.
 Email: dustindurke159@gmail.com
 (No relevant relationships reported)

PURPOSE: This study aims to examine the biomechanical and energetic differences between the non-motorized curved treadmill and the motorized flat (i.e., traditional) treadmill (TM). We hypothesize that, when compared to TM, CT will result in significantly higher EE, percentage of VO_2 max and trunk flexion under all testing conditions.

METHODS: Data collection included two sessions. In session one, participants filled out an informed consent, health questionnaire, and anthropometric data was collected. After, the participants underwent a 20-minute resting energy expenditure test to gather baseline metabolic data and the session concluded with a Bruce VO_2 max test. In session two, participants were connected to a metabolic cart to measure metabolic costs and outfitted with reflective markers to capture 3D kinematic data.)

RESULTS: There was not a significant increase in the amount of trunk flexion under any of the conditions between treadmills. There was a significant increase in the amount of EE from the TM to the CT across all six speeds. At 15% above their self-selected jogging (SSJ) speed, EE was 10.00 ± 1.32 kcal/min and 8.74 ± 1.34 kcal/min for the CT and TM, respectively ($p=.002$). At 15% slower than SSJ speed, participants' EE was 8.44 ± 1.16 kcal/min and 7.36 ± 1.05 kcal/min ($p=.005$) for the CT and TM, respectively. At SSJ speeds, participants EE was 8.94 ± 1.17 kcal/min and 7.47 ± 1.13 kcal/min for the CT and TM, respectively ($p<0.001$). At 15% above participants' self-selected walking (SSW) speed, EE was 5.35 ± 1.18 kcal/min and 3.38 ± 0.68 kcal/min on the CT and TM, respectively ($p<0.001$). At 15% slower than SSW, participants EE was 4.34 ± 0.92 kcal/min and $2.93 \pm .47$ kcal/min on the CT and TM, respectively ($p<0.001$). At SSW speeds, participants EE was 4.66 ± 1.00 kcal/min and 3.18 ± 0.62 kcal/min on the CT and TM, respectively ($p<0.001$).

CONCLUSIONS: Our findings suggest that female athletes may benefit from using CTs over TMs because of the increased EE utilization but further research needs to be conducted to assess the viability of CTs as a safe option with respect to musculoskeletal structures.

**Aerobic Fitness Changes In Trained And Untrained
 Subjects Following A Three Week Cycling Course**

Kyle Farmer, Marlene Wentz. Alma College, Alma, MI.
 (Sponsor: Alexander HK Montoye, PhD, FACSM)
 (No relevant relationships reported)

The health and fitness related benefits of endurance training are numerous and well documented. As training progresses, however, the window for training-specific improvement narrows, making continued performance gains challenging. **Purpose:** The purpose of this study was to compare changes in aerobic fitness between endurance-trained athletes (ET), power-trained athletes (PT), and non-athletes (NON) before and after completing a 3 week college cycling course. It was hypothesized that improvement in aerobic fitness would be greatest for NON and least for ET. **Methods:** 19 subjects (12 male, 7 female; mean age 20 ± 0.5 yr.) enrolled in a cycling course at Alma College participated in the study. Participants were categorized into 3 groups (ET, PT, or NON) based on their sport-specific training prior to taking the course. Training for this study consisted of cycling an average of 5 days/week for 18-44 miles/day for 3 weeks, with mileage and course difficulty increasing throughout the training. Participants performed a 5-mile time trial pre- and post-training utilizing a standardized cycle trainer and road bike. Time to completion and average power (Watts) were recorded for each participant and utilized to compare fitness changes among groups. One-way ANOVAs were used to compare the change in time to completion and power pre-to-post training among groups (ET, PT, NON), and paired t-tests were used to compare pre-training to post-training. **Results:** There was no significant difference in time to completion ($p=0.81$) or average power ($p=0.43$) on the 5-mile time trial among groups, although all groups decreased time to completion by 0.98 ± 0.92 minutes ($p<0.01$) and increased average power by 13.5 ± 20.9 Watts ($p=0.01$). **Conclusions:** An intensive, 3-week cycling training program elicited similar improvements in aerobic fitness in a sample of college students, regardless of prior training status.

**Psychological Responses To Acute Exercise: A
 Comparison Of Lower Body Positive Pressure
 Treadmill And Cycling**

Lindsey Siska, James Davis, Siby Varghese, Samantha King, Eric Hall, FACSM, Srikanth Vallabhajosula, Shefali Christopher. Elon University, Elon, NC. (Sponsor: Dr. Eric Hall, FACSM)
 Email: lsiska@elon.edu
 (No relevant relationships reported)

Acute aerobic exercise has been shown to improve mood and affect in active adults. Lower body positive pressure treadmills (LBPTT) have been utilized to reduce loading on the musculoskeletal system and to provide an alternative to running and cross-training. While the biomechanical and physiological responses to the LBPTT have been well-researched, little is known about psychological responses and how this compares to other forms of exercise. **PURPOSE:** To investigate mood, affect, and self-efficacy, following an acute, hard-intensity exercise session and compare these responses between three modalities: cycling, LBPTT running and treadmill running (NT). **METHODS:** 10 active adults (average age = 30 years, SD = 10.4 years) completed a 30min, high-intensity exercise session on each of three modalities in a randomized order: bike, LBPTT, and NT. Intensity was determined as 85% age-predicted maximum heart rate. Before and after each session, feeling, arousal, affect and self-efficacy were determined using the Feeling and Arousal scale (FAS), Activation-Deactivation Adjective Checklist (ADACL), and Generalized Self-efficacy survey (GSE). **RESULTS:** From baseline to post-exercise, there was a significant increase in feeling (2.4 ± 0.31 vs. 3.33 ± 0.29 , $p=0.021$), arousal (3.23 ± 0.23 vs. 4.07 ± 0.31 , $p=0.006$), and self-efficacy (31.83 ± 0.83 vs. 33.97 ± 1.16 , $p=0.013$) across all three modalities. However, when compared among the three modalities, there was no observed significant change in self-efficacy values from baseline to post-exercise ($p=0.708$). For affect (ADACL), there was an observed significant increase in energetic arousal (25.9 ± 1.12 vs. 29.43 ± 1.36 , $p=0.023$) and a decrease in state anxiety (20.93 ± 1.73 vs. 17.367 ± 1.08 , $p=0.041$) from baseline to post-exercise across all modalities, however, this did not significantly differ among the modalities. There were no other significant changes in affect observed. **CONCLUSION:** Self-efficacy, feeling, energetic arousal, and anxiety improves following acute, hard intensity exercise sessions; however, these changes do not differ based on exercise modality. Psychological responses to acute exercise differs between runners and non-runners. Future research should investigate how these responses may differ between the two groups based on modality.

Interlimb Asymmetries With High And Low External Training Loads In Male Collegiate Basketball Athletes

Brady S. Brown, Aaron D. Heishman, Ryan M. Miller, Eduardo D.S. Freitas, Keldon M. Peak, Michael G. Bembem, FACSM. *University of Oklahoma, Norman, OK.* (Sponsor: Michael G. Bembem, FACSM)
 Email: brownbrady3@ou.edu
 (No relevant relationships reported)

Tracking and monitoring bilateral limb asymmetries is an increasingly common practice to provide information associated with athlete performance, injury risk, as well as guiding return-to-play or return-to-performance protocols following injury. It is speculated external training loads (eTL) during sport specific practice may influence subsequent changes in inter-limb asymmetries. **PURPOSE:** Therefore, the purpose of the present study was to evaluate acute differences in lower inter-limb asymmetries during a bilateral countermovement jump (CMJ) immediately following high versus low eTL basketball practices in a group of NCAA men's collegiate basketball players. **METHODS:** Twelve NCAA Division I collegiate men's basketball players performed three CMJs on dual cell force platforms immediately prior to and immediately following basketball practices of high and low eTL. A dependent T-test was used to determine mean differences in practice intensities. A 2-way (condition x time) repeated measures analysis of variance (ANOVA) was performed to examine differences in Concentric Impulse (ConcImp), Concentric Peak Force (ConcPF), Eccentric Peak Force (EccPF), Takeoff Peak force (TakeoffPF), and Peak Landing Force (PeakLandF) captured during the CMJ between conditions and across time, with significance set at $p \leq 0.05$. **RESULTS:** There was a significant difference in practice intensities (High: PlayerLoad/min = 5.3 ± 0.9 , Low: PlayerLoad/min = 4.7 ± 1.4 ; $p \leq 0.001$). There were no significant condition or time main effects ($p > 0.05$), and there were no significant condition by time interactions for ConcImp, ConcPF, EccPF, TakeoffPF, and PeakLandF ($p > 0.05$). **CONCLUSION:** Although there were significant differences experienced in eTL intensities between practices (PL/min), these differences did not result in alteration of acute lower inter-limb asymmetries during the bilateral CMJ.

Use Of Plyometric Training To Offset Fatigue In Division I Collegiate Female Volleyball Players

Taylor C. Robertson, Gabe Galindo, Paul L. O'Connor. *Central Michigan University, Mount Pleasant, MI.*
 Email: rober2tc@cmich.edu
 (No relevant relationships reported)

Volleyball is a demanding sport consisting of multiple passages of play with a high priority on jumping, including attacking, blocking, jump serving and setting. Heavy resistance training and plyometric training have been shown to increase vertical jump in volleyball players, as well as high intensity interval training to increase conditioning, however, there is a lack of information on the use of plyometric training to decrease indexes of fatigue. **PURPOSE:** To determine if plyometric training can decrease repeated jump fatigue in NCAA Division I female college volleyball players. **METHODS:** 8 female collegiate volleyball players (Age: 18.4 ± 0.7 , height: 179.7 ± 9.2 cm, weight: 71.8 ± 10.0 kg), cleared of injuries completed a vertical jump test, squat jump test, repeat squat jump, and repeat block jump test while wearing velocity and height measuring devices. Participants were split into a control group (CON) and a plyometric group (PLYO), which completed a 3 day a week/ 8 week program consisting of dot drill and box drop jump exercise variations. After 8 weeks, participants were retested. Fatigue Index for the repeat tests were analyzed for statistical significance, $[(\text{Initial Jump-Final Jump})/\text{Initial Jump}] \times 100$. **RESULTS:** Significant differences were seen in the PLYO group in the repeat squat jump test at posttest compared to the CON (10.98 ± 4.69 vs -5.41 ± 4.65 $p < .015$), and in the repeat block jump test compared to pretesting values within the PLYO group (6.41 ± 8.47 vs -4.24 ± 14.77 , $p < .042$). **CONCLUSIONS:** Utilization of plyometric training may help offset fatigue as seen in multiple jump bouts in volleyball players, potentially attributing to increased athletic performance.

Study On Kayak Sprint Specific Core Instability Training

Meng Li. *Chengdu Sports University, Chengdu, China.*
 Email: limeng_1222@163.com
 (No relevant relationships reported)

PURPOSE: In this study, Surface Electromyography (sEMG) and Saturation of Muscle Oxygen (SmO_2) indexes were used to explore the influence of the introduction of special core instability training in kayak training on the special sports ability.

METHODS: Using 14 elite kayak athletes as subjects, performed an 8-week specific core instability training intervention. Before and after 8-weeks training, data of sEMG, SmO_2 , paddle power, velocity, stroke distance, and heart rate(HR), blood lactate(Bla), max stroke frequency (Max SPM) of relevant muscles in the process of full paddling were collected for comparative analysis. Combined with the change of special performance on water, the influence of adding special core training on technical movements and special performance was explained.

RESULTS: After 8-weeks special core instability training intervention, we found that during Max SPM paddling test, both side of Rectus Femoris (RF)'s iEMG decreased ($L: 9.92 \pm 0.33$ vs. 6.66 ± 5.87 , $P < 0.05$; $R: 8.49 \pm 0.73$ vs. 5.67 ± 0.7 , $P < 0.05$), both Erector Spinae(ES)'s iEMG significantly enhanced ($L: 4.04 \pm 0.71$ vs. 5.81 ± 0.7 , $P < 0.05$; $R: 3.13 \pm 0.52$ vs. 5.51 ± 1.13 , $P < 0.05$). Meanwhile, SmO_2 of left Triceps Brachii(TB) decreased (42.54 ± 1.83 vs. 28.06 ± 5.18 , $P < 0.001$), right TB decreased (48.76 ± 8.33 vs. 31.77 ± 4.24 , $P < 0.01$), left Latissimus Dorsi (LD) decreased (40.19 ± 5.58 vs. 32.56 ± 3.68 , $P < 0.01$), right LD decreased (35.38 ± 4.19 vs. 28.39 ± 3.55 , $p < 0.05$). Both side paddle power enhanced ($L: 196.17 \pm 11.63$ vs. 294.38 ± 15.58 , $P < 0.01$; $R: 210 \pm 19.13$ vs. 319.83 ± 15.15 , $P < 0.01$), velocity enhanced ($L: 4.43 \pm 0.06$ vs. 5.64 ± 0.14 , $p < 0.01$; $R: 4.22 \pm 0.07$ vs. 5.68 ± 0.13 , $p < 0.01$), paddle distance increased ($L: 2.86 \pm 0.16$ vs. 4.08 ± 0.16 , $p < 0.001$; $R: 2.77 \pm 0.4$ vs. 4.12 ± 0.38 , $p < 0.001$), with higher BLA (7.133 ± 2.014 vs. 8.769 ± 2.359 , $P < 0.05$), also reached a higher Max SPM (141.14 ± 11.06 vs. 149.14 ± 6.248 , $P < 0.05$).

CONCLUSION: 1) Kayak special core instability training enhance the capacity of maintain balance by trunk, which create stable condition for power force of movement, and allow athletes increase their arm muscles force during paddle movement on an instable plane, and enhance symmetry of power force from both side of body efficiently. 2) 8-weeks specific core instability training produced a positive effect on kayaking performance.

Anthropometric Characteristics And Training Behaviors In Advanced And Elite Rock Climbers

Abigail J. Larson¹, Lanae M. Joubert², Gina Blunt-Gonzalez³.
¹Southern Utah University, Cedar City, UT. ²Northern Michigan University, Marquette, MI. ³Morehead State University, Morehead, KY
 Email: abigail Larson@suu.edu
 (No relevant relationships reported)

PURPOSE: The purpose of this study was to quantify training volumes and modalities in a sample of advanced and elite climbers. **METHODS:** An online survey was distributed through various climbing-related social media platforms. Questions included demographics, climbing ability and style, training modalities used, and weekly volumes of training. **RESULTS:** Of 595 initial participants, 92 boulderers (B) (63 men, 29 women) and 71 sport-lead (SL) climbers (49 men, 22 women) were identified as advanced or elite (A/E) using the IRCRA (International Rock Climbing Research Association) Red Point Scale of which 69% had entered at least one competition. Among A/E women and men SL climbers there was a moderate inverse relationship between BMI and SL climbing ability ($r = -0.56$ and $r = -0.39$, respectively), this was not observed among women B and diminished in men B ($r = 0.12$ and $r = -0.25$). Anthropometric and training data is reported in Table 1. Mean exercise volume among A/E was 470 ± 263 min/week, with 333 ± 202 min/week as climbing specific training. Women SL climbers reported spending more time each week training specifically for climbing compared to women B ($p < 0.05$) but total training time did not differ between groups or genders ($p > 0.05$). 70% and 35% of A/E climbers reported weekly aerobic and resistance exercise, respectively, with no differences between genders or SL and B. **CONCLUSION:** To our knowledge, this was the first study to quantify training volume and modalities in A/E climbers. *Table 1.* Characteristics of advanced/elite (A/E) women and men boulderers (B) compared to A/E women and men sport lead (SL) climbers (mean \pm standard deviation).

Characteristic	A/E B n=29(w); n=63(m)	A/E SL n=23(w); n=49(m)

The Immediate Effects Of Abdominal And Core Exercise On Balance For College-age Dancers

Jill M. Lucas, Katharine T. Cusack, Jason E. Grandeo, Sean M. Collins. *University of Lynchburg, Lynchburg, VA.*
(No relevant relationships reported)

Balance is defined as the ability to maintain a stable position while remaining steady. Balance is extremely important to dancers to help prevent injury and to maximize aesthetic and athletic performance. While other studies support the improvement of balance among dancers following a core exercise training program, the effects immediately following one core exercise session are less clear. **PURPOSE:** The purpose of this study was to examine the immediate effects of a core and abdominal exercise program on balance for dancers, with the hypothesis that a core exercise program would cause an immediate improvement in balance for college-aged dancers. **METHODS:** Eighteen female collegiate dancers (19.83 ± 1.58 years, 7-18 years of dance experience) completed two sets of eight exercises, engaging the upper and lower abdominal, obliques, gluteals, and erector spinae muscles. Two static balance tests, the Balance Error Scoring System (BESS) test and the Stork Balance Standing test, and two dynamic balance tests, the Y Balance test and the Pirouette test, were conducted prior to and after the core exercises. **RESULTS:** The core exercise program significantly improved balance results for the Y Balance Test composite score (86.0 ± 6.3% pre vs 88.4 ± 5.3% post, p<0.05) and the BESS Test (22.7 ± 8.0 errors pre vs 16.1 ± 7.0 errors post, p<0.05). There were no significant differences between pre and post intervention scores of the Stork Balance Standing test or the Pirouette test. **CONCLUSIONS:** Including core exercises in a dancer's warm-up before practices and performances may have an acute positive effect on balance for dancers, which could translate to improvements in performance. It is unclear if a core exercise program can acutely improve dance skill-specific balance, such as during pirouettes.

3252 Board #73 May 29 1:30 PM - 3:00 PM

Weighting The Swing: The Mechanical Changes That Emerge When Loads Are Applied To Baseball Bats

Alexia E. Amo, William P. Lydon, Cynthia Villalobos, J Mark VanNess, Jacob M. Cunha, Courtney D. Jensen. *University of the Pacific, Stockton, CA.*
(No relevant relationships reported)

Success in baseball batting relies on a union of swing power and accuracy. Off the field, training commonly employs weighted loads replicating hitting mechanics. On the field, immediately prior to a plate appearance, batters sometimes place a weighted ring on the bat to warm up their swing. Although common, these traditional training methods lack investigation. **PURPOSE:** To observe differences of baseball swing characteristics in response to applied bat resistance. **METHODS:** We tested 14 NCAA baseball athletes using Proteus technology (Proteus Motion, USA). Participants completed 5 sets of 6 swings at increasing loads of magnetic resistance. Each set

increased in weight by 2 lbs, ranging from 1-9 lbs. Measurements computed by Proteus were peak power, peak force development rate (PFDR), braking, consistency, endurance, velocity, and range of motion (ROM). Paired-samples t-tests compared swing characteristics of the 1 lb resistance to the mean of 3, 5, 7, and 9 lb. MANOVA with repeated measures observed the differences of swing variables in response to resistance increases. Linear regression tested the effect of different loads on performance parameters. **RESULTS:** The 1 lb resistance differed from the mean resistance in peak power (p<0.001), PFDR (p<0.001), braking (p<0.001), ROM (p=0.017), and velocity (p=0.063), but not in consistency (p=0.110) or endurance (p=0.375). The mean values of consistency (p=0.985) and endurance (p=0.530) could not predict outcomes for 1 lb performance, but did predict ROM (p=0.002) and braking, power, PFDR, and velocity (p<0.001). As resistance levels increased, there were significant differences in swing power (F=317.297, p<0.001), PFDR (F=141.797, p<0.001), braking (F=91.011, p<0.001), ROM (F=6.067, p=0.013), and velocity (F=2.5122, p=0.039), but not measurements of consistency (F=0.911, p=0.480) or endurance (F=2.156, p=0.070). **CONCLUSIONS:** As bat resistance increased, players made acute responses that compromised recruitment characteristics (consistency and endurance). Training and warm-up techniques that employ loaded swings may alter mechanics accordingly.

F-55 Free Communication/Poster - Blood Flow Restriction

The Acute Effects Of Volume-Matched Resistance Exercise With Blood Flow Restriction Versus Traditional Exercise On Arterial Elasticity And Hemodynamic Variables

Danny D. Dominguez, Patrick Gage Murphy, Murat Karabulut, FACS. *University of Texas at Rio Grande Valley, Brownsville, TX.*
Email: danny.dominguez01@utrgv.edu
(No relevant relationships reported)

PURPOSE: To investigate the acute effects of varying intensities of volume-matched lower body resistance exercise sessions with and without blood flow restriction (BFR) on hemodynamic variables and arterial compliance. **METHODS:** Seventeen males and fifteen females completed six separate volume-matched sessions of lower body resistance exercise of 4 sets of leg curl and leg extension at 40 (T40), 60 (T60), and 80% (T80) of 1RM without BFR and 25 (BFR25), 35 (BFR35), and 50% (BFR50) with BFR. Blood pressure, arterial elasticity, and hemodynamic variables (mean arterial pressure (MAP), stroke volume (SV), stroke volume index (SVI), cardiac output (CO), cardiac index (CI), large arterial elasticity (LAE), small arterial elasticity (SAE), systemic vascular resistance (SVR), total vascular impedance (TVI) and cardiac ejection time (CET)) were measured at baseline, immediately postexercise, 10 min, 20 min, and 30 min-post exercise using a oscillometric blood pressure module and a piezoelectric pressure sensor. **RESULTS:** One-way ANOVA found no significant differences between group means at baseline resting values. Repeated measures ANOVA found significant condition main effects (p<0.05) for HR, LAE, SAE, and TVI post exercise. Post-hoc pairwise comparisons found that BFR25 caused significantly greater HR than BFR50 (p<0.04) at 10 min-post exercise and T80 at 0 and 10 min-post exercise (p<0.02). BFR25 also resulted in significantly greater (p<0.03) LAE compared to BFR50 at 10 min-post exercise (20.8 ± 1.7 vs. 16.4 ± 0.7 ml/mmHg × 10). SAE was significantly lower (p<0.05) following BFR50 (8.4 ± 0.4 ml/mmHg × 10) compared to T40 (10.7 ± 0.7 ml/mmHg × 10). TVI was found to be significantly lower in BFR25 than BFR50 (p<0.01) and BFR35 (p<0.02) at 10 min-post exercise (87.2 ± 5.9 vs. 111.2 ± 5.8 and 103.7 ± 5.8 dyne·sec·cm⁻⁵, respectively). **CONCLUSIONS:** The current results indicate that higher intensity BFR groups may not be favorable for acute post exercise arterial elasticity. The changes in hemodynamic and arterial elasticity responses to volume-matched lower load exercise during the BFR25 session demonstrate the possibility of improving cardiovascular health and function. Future studies should determine the effects of BFR and non-BFR training methodologies on chronic adaptations in cardiovascular system.

3254 Board #75 May 29 2:30 PM - 4:00 PM
Cardiovascular Response To Unilateral, Bilateral, And Alternating Exercises With Blood Flow Restriction

Daphney M. Stanford¹, Joonsun Park², Raymond Jones², Matthew B. Jessee¹. ¹The University of Mississippi, University, MS. ²The University of Southern Mississippi, Hattiesburg, MS. (No relevant relationships reported)

The cardiovascular response induced by resistance exercise with blood flow restriction (BFR) seems to be lower or comparable to traditional exercise in healthy individuals. However, the potential for BFR to be used for at risk populations highlights a need to further attenuate the cardiovascular response, potentially via the modality of exercise. **PURPOSE:** To compare the cardiovascular response to unilateral (UN), bilateral (BI), and alternating (AL) BFR exercise. **METHODS:** 13 males and 7 females performed four sets (30 seconds rest) of UN, BI, and AL knee-extensions to failure with 30% one-repetition maximum and 40% arterial occlusion pressure. Pulse wave analysis was measured before and after exercise. Data, presented as mean (SD), were analyzed using Bayesian RMANOVA. **RESULTS:** AL caused greater changes in: aortic systolic [Δ mmHg: AL=21 (8); UN=13 (10); BI=15 (7); BF₁₀=29.63], diastolic [Δ mmHg: AL=13 (8); UN=7 (10); BI=8 (7); BF₁₀=5.13], and mean arterial [Δ mmHg: AL=19 (8); UN=11 (10); BI=13 (7); BF₁₀=48.39] blood pressures. Brachial [Δ mmHg*bpm: AL=4945 (2340); UN=3218 (1412); BI=3461 (1430); BF₁₀=31.74] and aortic [Δ mmHg*bpm: AL=6134 (2479); UN=4200 (1722); BI=4525 (1664); BF₁₀=114.83] rate pressure product as well as heart rate [Δ bpm: AL=26 (14); UN=18 (8); BI=19 (11); BF₁₀=5.82] were also greatest with AL. Augmentation pressure [Δ mmHg: UN=-3 (5); BI=-2 (6); AL=-1 (6); BF₁₀=0.19], pulse pressure [Δ mmHg: UN=6 (6); BI=7 (7); AL=8 (5); BF₁₀=0.27], augmentation index [Δ %: UN=-6 (12); BI=-7 (11); AL=-6 (16); BF₁₀=0.16], wave reflection magnitude [Δ %: UN=-5 (8); BI=-5 (7); AL=-4 (7); BF₁₀=0.15], forward wave height [Δ mmHg: UN=8 (6); BI=8 (6); AL=8 (4); BF₁₀=0.15], and reflected wave height [Δ mmHg: UN=1 (3); BI=2 (4); AL=3 (3); BF₁₀=0.31] were not different between conditions. Exercise volume was greater in AL [kg: AL=1835 (1725); UN=915 (312); BI=893 (313); BF₁₀=29.17]. Ratings of perceived exertion (BF₁₀=3.99e+144) and discomfort (BF₁₀=2.0e+73) increased with sets. AL had an elevated discomfort (BF₁₀=5548.97). **CONCLUSION:** The greater cardiovascular response following alternating BFR exercise in healthy individuals, suggests those at risk of a cardiovascular event should choose unilateral or bilateral BFR exercise until further work determines the degree to which this modality can be tolerated.

3255 Board #76 May 29 2:30 PM - 4:00 PM
Effect Of Aerobic Exercise With Blood Flow Restriction On Substrate Utilization And Energy Expenditure

Nathen A. Andrews, Chase P. Harris, Kelly E. Johnson, Justin P. Guilkey, Jakob D. Lauver. Coastal Carolina University, Conway, SC. Email: naandrews@coastal.edu (No relevant relationships reported)

Blood flow restriction (BFR) added to aerobic exercise has the potential to elicit physiological adaptations. However, the acute effects of BFR on substrate utilization and energy expenditure (EE) remains unclear. **PURPOSE:** The purpose of this study was to examine the effects of intermittent BFR compared to low- (LIIE) and high-intensity interval exercise (HIIE) on EE and substrate utilization during exercise and recovery. **METHODS:** Participants randomly performed 3 interval (INT) exercise protocols: BFR, LIIE and HIIE. BFR and LIIE consisted of 10 INTs of 2-min of work at 70% of ventilatory threshold (VT) and 1-min of recovery (20 watts; W). During BFR, the cuffs were inflated to 80% of limb occlusion pressure (154 ± 17 mmHg) during each work INT and deflated during each recovery INT. HIIE consisted of 5 INTs at 140% of VT and 1-min of recovery (20 W). Breath by breath pulmonary oxygen uptake (VO₂) and carbon dioxide production (VCO₂) were recorded during a 15-min seated rest, exercise, and a 180-min seated recovery. Excess post exercise oxygen consumption (EPOC) magnitude was calculated as area under the curve from netVO₂ (VO₂ - VO₂ at rest) during the first 90 minutes post-exercise. EE was calculated from VO₂ during exercise and recovery. Fat oxidation (FatOx) and carbohydrate oxidation (CarbOx) rates were calculated from VO₂ and VCO₂ at rest, 1, 2 and 3 hrs post-exercise. Enjoyment was assessed post-exercise using the physical activity enjoyment scale (PACES). **RESULTS:** EPOC magnitude was similar among trials (LIIE = 4.87 ± 2.60 L*min⁻¹, BFR = 6.59 ± 2.33 L*min⁻¹, HIIE = 6.56 ± 2.01 L*min⁻¹; p = 0.06). Total EE was different between BFR (321.6 ± 30.1 kcal), HIIE (254.5 ± 33.5 kcal), and LIIE (287.1 ± 25.5 kcal) (p<0.05). FatOx in BFR (1hr = 0.14 ± 0.01 g*min⁻¹, 3hr = 0.11 ± 0.01 g*min⁻¹) was greater than LIIE (1hr = 0.08 ± 0.02 g*min⁻¹, 3hr = 0.9 ± 0.02 g*min⁻¹), but not different from HIIE (1hr = 0.12 ± 0.02 g*min⁻¹, 3hr = 0.09 ± 0.01 g*min⁻¹) (main effect of trial; p<0.05). CarbOx during BFR (3hr = 0.16 ± 0.03 g*min⁻¹) was less than LIIE (3hr = 0.19 ± 0.03 g*min⁻¹) and HIIE (3hr = 0.23 ± 0.05 g*min⁻¹) (main effect of trial). There were no differences in PACES scores.

CONCLUSIONS: This study suggests that the addition of intermittent BFR to LIIE may result in greater EE but similar substrate utilization and enjoyment as HIIE, albeit at a lower work rate.

3256 Board #77 May 29 2:30 PM - 4:00 PM
Physiological Responses To Intermittent Blood Flow Restriction During Cycling Exercise

Chase P. Harris, Nathen A. Andrews, Kelly E. Johnson, Jakob D. Lauver, Justin P. Guilkey. Coastal Carolina University, Conway, SC. Email: cpharri2@coastal.edu (No relevant relationships reported)

Aerobic exercise with the addition of blood flow restriction (BFR) has the potential to elicit physiological adaptations. However, the acute physiological and perceptual responses during aerobic exercise with intermittent BFR remains unclear. **PURPOSE:** The purpose of this investigation was to examine the physiological and perceptual responses to intermittent BFR compared to low- (LIIE) and high-intensity interval exercise (HIIE). **METHODS:** Participants randomly performed 3 interval (INT) exercise protocols: BFR, LIIE and HIIE. BFR and LIIE consisted of 10 INTs of 2-min of work at 70% of ventilatory threshold (VT) and 1-min of recovery (20 W). During BFR, the cuffs were inflated to 80% of limb occlusion pressure (154 ± 17 mmHg) during each work INT and deflated during recovery INTs. HIIE consisted of 5 INTs at 140% of VT and 1-min of recovery (20 W). Pulmonary VO₂ and respiratory exchange ratio (RER) were recorded and tissue oxygen saturation (StO₂) was assessed by near-infrared spectroscopy. The level of perceived exertion (RPE) was assessed at the end of each INT. INTs 2, 4, 6, 8, and 10 during BFR and LIIE were used for comparison with INTs 1-5 during HIIE. The last 30 seconds of each INT were used for analysis. StO₂ during each condition is expressed as change from baseline cycling (20W) (arbitrary units; AU). Two-way (INT x trial) ANOVAs analyzed differences. Significance was established if p<0.05. **RESULTS:** There was a main effect of trial for VO₂ and RER. VO₂ was greater in HIIE (INT 5 = 2.12 ± 0.56 L*min⁻¹) than BFR (INT 10 = 1.41 ± 0.21 L*min⁻¹) and LIIE (INT 10 = 1.28 ± 0.27 L*min⁻¹). RER was lower in LIIE (INT 10 = 0.93 ± 0.01) compared to BFR (INT 10 = 0.94 ± 0.06) and HIIE (INT 5 = 0.99 ± 0.03). At all points, HR was lower in LIIE (INT 10 = 110 ± 10 bpm) than BFR (INT 10 = 155 ± 24 bpm) and HIIE (INT 5 = 154 ± 14 bpm). There were no differences in HR between BFR and HIIE. Delta StO₂ was greater during BFR (INT 10 = -37.5 ± 15.6 AU) and HIIE (INT 5 = -34.2 ± 6.5 AU) compared to LIIE (INT 10 = -14.6 ± 8.67 AU). During all points, RPE was greater in BFR (INT 10 = 15.0 ± 2.4) and HIIE (INT 5 = 14.3 ± 1.3) compared to LIIE (INT 10 = 9.3 ± 0.4). **CONCLUSIONS:** This study suggests that cycling with the addition of intermittent BFR at an intensity equivalent to 70% of VT may provide similar cardiovascular and local physiological stress to traditional HIIE, albeit at a lower work rate.

3257 Board #78 May 29 2:30 PM - 4:00 PM
MEASURING LIMB OCCLUSION PRESSURE USING DIFFERENT VASCULAR DOPPLERS

Kiara B. Barrett¹, Logan B. Page¹, Marcin K. Szczygowski², Tyler D. Martin¹, J. Grant Mouser¹. ¹Troy University, Troy, AL. ²University of Miami, Miami, FL. (No relevant relationships reported)

PURPOSE: Blood flow restriction (BFR) in physical therapy settings requires personalized restriction pressures in order to remain a safe rehabilitation modality. Measuring limb occlusion pressure (LOP) is one method of setting the pressure relative to each patient and is performed with a vascular doppler and inflatable cuff. Several dopplers are available, but have not been compared. This study was performed to compare the Hokanson MD6 and the Edan SonoTrax vascular dopplers in measuring LOP.

METHODS: In a randomized crossover design, 20 participants (women=10, men=10) visited the laboratory once. Arm and thigh circumferences were measured. After 10min of rest, LOP was measured in the arm and leg with 5cm and 10cm wide inelastic cuffs, respectively. Measurements were repeated every 5min until LOP was measured in both limbs with both dopplers. Bland-Altman analyses (MD6 - SonoTrax) were performed and limits of agreement (LOA) calculated. Two one-sided tests of equivalence with lower and upper equivalence bounds of -5 mmHg to 5 mmHg were calculated. Results are reported as mean (95%CI) for Bland-Altman analyses and mean (90%CI) for equivalence testing.

RESULTS: Arm LOP measurement showed a mean bias of 0.6 (-1.3 - 2.4) mmHg, with upper and lower LOA of 8.4 (5.1 - 11.7) mmHg and -7.3 (-10.6 - -4.0) mmHg, respectively. Thigh LOP measurements showed a mean bias of -1.5 (-4.4 - 1.4) mmHg with upper and lower LOA of 10.5 (5.5 - 15.5) mmHg and -13.5 (-18.5 - -8.5) mmHg, respectively. Equivalence testing determined that both doppler measurements were equivalent in the arm (0.55 (-0.99 - 2.1) mmHg, p = .547) and leg (-1.5 (-3.87 - 0.87) mmHg, p = .288).

CONCLUSIONS: The SonoTrax measured LOP equivalently to the MD6. Physical therapists wanting to use BFR therapy should feel comfortable using either vascular doppler in their clinic.

Endothelial-Dependent Cutaneous Vasodilatory Responses to a Single Bout of Remote Ischemic Preconditioning

Jahyun Kim, Sydney E. Barlow, Warren D. Franke FACSM, and James A Lang Iowa State University, Ames, IA, 50010
 Remote ischemic preconditioning (RIPC) induces protective effects from endothelial ischemic reperfusion injury in two phases. Initial protection occurs in the first 1-2 hrs post-RIPC and disappears after 4 hrs. Delayed protection occurs ~24 hours after RIPC and lasts for 2-3 days in human conduit arteries. The extent to which this timeline occurs in human cutaneous microvasculature is not clear. **Purpose:** To assess the timeline of skin microvascular functional changes after a single bout of RIPC. **Methods:** Sixteen participants (23-4 yrs; 7 males, 9 females) underwent a single bout of RIPC. Using laser speckle contrast imaging, acetylcholine (Ach)-mediated skin blood flow responses were assessed immediately prior to RIPC as well as 24 hr, 48 hr, 72 hr, and a week afterwards. RIPC consisted of 4 repetitions of 5 min of arm blood flow occlusion interspersed by 5 min reperfusion. Ach was prepared with saline solution (2% Ach) and administered by iontophoresis (20 µA for 200 s). Skin blood flow was expressed as cutaneous vascular conductance (CVC; perfusion units/mean arterial pressure, PU·mmHg⁻¹). Ach-induced CVC changes throughout this timeline were analyzed by one-way repeated ANOVA and post hoc tests were conducted by the SNK method to locate significant differences. **Results:** Ach-mediated CVC increased during the time line (p<0.05). However, CVC was significantly increased only 48 hours after the single bout of RIPC (0.71±0.07 vs. 0.94±0.12 PU·mmHg⁻¹, p<0.05, pre-RIPC vs. 48 hrs), returning to baseline levels after a week (0.61±0.10 PU·mmHg⁻¹, p>0.7). **Conclusion:** Responses to Ach infusion are an indicator of global endothelial cell function and reflects endothelial dependent vasodilation. These data suggest that a single bout of RIPC induces a response to Ach-induced endothelial dependent-cutaneous vasodilation that peaks at 48 hours post-RIPC. This response to a single bout of RIPC does not persist a week afterwards. Thus, a single bout of RIPC elicits a delayed window response of endothelial dependent vasodilation in human skin microvasculature.

Feasibility And Effectiveness Of High-intensity Interval Training With Blood Flow Restriction In Heart Failure

Molly M. Baldwin, Karen M. Birch, FACSM, Bryan J. Taylor, John Geirula, Maria F. Paton, Judith E. Lowry, Mark T. Kearney, Klaus K. Witte, Carrie Ferguson. University of Leeds, Leeds, United Kingdom.
 Email: spl12mmb@leeds.ac.uk
 (No relevant relationships reported)

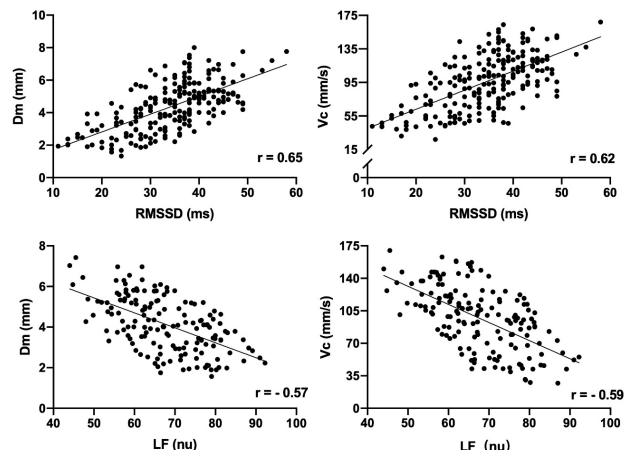

Reduced aerobic capacity ($\dot{V}O_{2peak}$) is a key characteristic of heart failure with reduced ejection fraction (HFrEF). Peripheral vascular dysfunction, the result of an imbalance between endothelial damage and endogenous repair mechanisms, is both a precursor to and a consequence of HFrEF. This may contribute to the reduction in $\dot{V}O_{2peak}$ by increasing peripheral vascular resistance, impairing blood flow distribution and reducing O₂ delivery to locomotor muscles. High-intensity interval training (HIIT) can ameliorate vascular dysfunction and increase $\dot{V}O_{2peak}$ in HFrEF. Whether the effectiveness of HIIT can be increased by combining it with leg blood flow restriction (BFR), a novel technique that alters peripheral vascular shear stress and augments the intramuscular metabolic stress of a given exercise protocol, is unknown. **Purpose:** To investigate the feasibility and effectiveness of HIIT vs. HIIT with BFR to improve CD34+/KDR+ progenitor cell number (marker of vascular repair), exercise tolerance and $\dot{V}O_{2peak}$ in HFrEF. **Methods:** 13 males with HFrEF (72 ± 11 y; LVEF 35 ± 9 %) completed HIIT (5 x 2 min cycling bouts at 80 % ramp-incremental peak power, separated by 2 min recovery) twice per week for 4 weeks, either with BFR (HIIT+BFR; n = 7; thigh cuff pressure 100 mmHg) or without BFR (HIIT; n = 6; thigh cuff pressure 10 mmHg). CD34+/KDR+ number (flow cytometry), exercise tolerance and $\dot{V}O_{2peak}$ (ramp-incremental exercise test), and quality of life (QoL) were measured pre- and post-training. **Results:** All HIIT+BFR participants tolerated 100 mmHg cuff pressure. There was a pre- to post training increase in CD34+/KDR+ number (HIIT: 78 ± 11 vs. 88 ± 28 per 10⁶ total events; HIIT+BFR: 67 ± 21 vs. 102 ± 44 per 10⁶ total events; time effect,

P < 0.05) and ramp-incremental exercise tolerance (HIIT: 494 ± 160 vs. 537 ± 162 s; HIIT+BFR: 469 ± 136 vs. 529 ± 108 s; time effect, P < 0.05). However, the effect of training was not different for HIIT vs. HIIT+BFR. $\dot{V}O_{2peak}$ was unchanged with training (HIIT: 16.7 ± 8.5 vs. 18.7 ± 9.8 ml/min/kg; HIIT+BFR: 17.0 ± 3.8 vs. 16.4 ± 3.7 ml/min/kg; time effect, P > 0.05). QoL was also unchanged with training. **CONCLUSIONS:** HIIT+BFR is feasible in HFrEF. However, the increases in CD34+/KDR+ progenitor cell number and exercise tolerance following HIIT+BFR are not greater than the increases conferred by HIIT alone in HFrEF.

3260 Board #81 May 29 2:30 PM - 4:00 PM
Effects Of Exercise Under Different Levels Of Blood-flow Restriction On Autonomic Modulation And Muscular Fatigue

Ying Pan, Yan Zhao, Yixin Tian, Xiaohuan Ma, Yu Guo. Nanjing Sport Institute, Nanjing, China.
 Email: 850773340@qq.com
 (No relevant relationships reported)

Purpose: To assess the acute cardiac autonomic and peripheral muscular responses to eccentric exercise combined with different levels of blood flow restriction (BFR) in young women. **Methods:** Twenty-five women (21.22±0.61 year) performed 4 sets of leg extension (30 + 15 + 15 + 15 repetitions) at 20 % one repetition maximum, with four different BFR conditions (0, 40, 60, and 80 %). Restrictive pressures were calculated based on blood-flow measurements taken at rest on each subject. Heart rate variability (HRV) and muscle fatigue were recorded at rest and during 24 hour of recovery by calculating time (RMSSD) and frequency domain (LF nu, HF nu, LF/HF) indices and analyzing muscle displacement (Dm) and contraction velocity (Vc) values, respectively. **Results:** All parameters in CON (0%BFR) did not significant change (P>0.05). In BFR_{40%} there was a slight reduction in RMSSD (18.51%) and HF nu (12.19%) compared to CON (P<0.05). In BFR_{60%}, RMSSD and HF nu decreased 27.91% and 13.98% while LF nu increased 13.77% compared to CON (P<0.05), and LF/HF recovered within 30min post exercise (P>0.05). In BFR_{80%}, LF nu increased 16.43% while RMSSD, HF nu, Dm and Vc dramatically declined 39.92%, 15.41%, 37.34% and 48.85% respectively when compared to CON (P<0.01), so it took longer time to restore LF/HF balance (within 24 hours). Correlation analysis showed that RMSSD was positively correlated with Dm (r = 0.65) and Vc (r = 0.62), respectively (P<0.05), while LF nu was negatively correlated with Dm (r = - 0.57) and Vc (r = - 0.59) (P<0.05). **CONCLUSION:** On the basis of low load resistance exercise, 40% BFR can withdraw vagal regulation, but sympathetic activity and sympathetic/parasympathetic balance can be enhanced when the restriction increased to 60%BFR. Peripheral muscular fatigue can just be obviously evoked in 80% BFR, and this fatigue is highly related to cardiac autonomic modulation. Therefore, we do not recommend 80% BFR for women with cardiovascular risk.

3261 Board #82 May 29 2:30 PM - 4:00 PM
Femoral Blood Flow During Blood Flow Restriction In Males And Females

Pat R. Vehrs, FACSM, Nicole Tafunai, Eric Cruz, Kylie Martin, Olivia Warren, Parker Jensen, Sadie Deem. Brigham Young University, Provo, UT.
 (No relevant relationships reported)

Use of blood flow restriction (BFR) during strength training results in an increase in muscle strength and mass when using light loads (20-30% of 1 RM). Only a few studies have reported actual arterial blood flow characteristics during BFR. In addition,

research reporting blood flow characteristics in the dominant and non-dominant limb in both males and females is lacking. **PURPOSE:** This study compared femoral artery occlusion pressure (AOP) and femoral artery blood flow characteristics at different percentages of AOP between both legs in males and females. **METHODS:** Participants in this study included 31 physically active and healthy males (n=18) and females (n=13) years of age. Blood flow in the superficial femoral artery (SFA) was measured using Doppler ultrasound and BFR was controlled using a Hokanson E20 Rapid Cuff Inflator with a 10 cm cuff placed on the upper thigh. After measuring the AOP of the SFA, blood flow was measured in a random order at 0%, 20%, 40%, 60%, 80%, and 100% of AOP. This was repeated in the opposite leg. Blood flow was recorded in absolute (mL/min) and relative terms (% unoccluded bloodflow). **RESULTS:** There was significant difference ($p<0.008$) in the AOP in the dominant leg (234 vs 188 mmHg) and nondominant leg (206 vs 177 mmHg) between males and females, respectively. After accounting for differences in leg circumference ($p<0.001$), sex remained a significant ($p=0.0001$) factor in accounting for differences in AOP. The difference in AOP between the dominant and nondominant leg in males (234 vs 206 mmHg) and females (188 vs 177) were not significant ($p=0.123$). At each of the occlusion pressures (0%, 20%, 40%, 60%, 80%, 100% of AOP), there were no differences in absolute or relative blood flow between males and females. The relationship between SFA blood flow at occlusion pressures between 0 and 100% of the AOP was curvilinear in both males and females. Blood flow at occlusion pressures between 40% and 80% of AOP was relatively constant. **CONCLUSIONS:** Significant differences in AOP in males and females can be attributed, in part to differences in leg circumference and sex. The curvilinear relationship between blood flow and occlusion pressure indicates that BFR during exercise can be equally effective a lower pressures (40% AOP) as at higher pressures (80% AOP).

The Effect Of The Somatosensory Afferent On Hemodynamic Transmission From The Aorta To The Brain
Marina Fukuie. *Tokushima university, Ibaraki, Japan.*
(No relevant relationships reported)

PURPOSE: This study aimed to reveal whether the somatosensory input from lower extremities can affect hemodynamic transmission from the aorta to the brain during orthostatic stimulation.

METHODS: Thirteen young adults (5 women, mean age 25±5 yrs.) underwent two consecutive 6-min orthostatic stimulations with lower body negative pressure (LBNP) (-30 mmHg and -50 mmHg) under following two conditions in random order: (1) placing feet on the wood board with slight knee flexion (RESISTED) and (2) feet untouched using a harness (FREE) inside the LBNP chamber. Heart rate (HR), aortic pressure, stroke volume (SV), cardiac output (CO), and cerebral blood flow velocity (CBFV) from the middle cerebral artery were continuously recorded. Hemodynamic transmission (i.e., admittance) from the aorta to the brain was evaluated by transfer function analysis.

RESULTS: HR was significantly higher, and SV and CO were significantly lower during -50 mmHg LBNP stimulation than baseline values irrespective of foot conditions. Aortic mean pressure and mean CBFV were not affected by the leg-condition. In contrast, aortic pulse pressure and pulsatile CBFV were significantly reduced during -50 mmHg LBNP with the degree of reduction (from baseline to -50 mmHg LBNP) smaller in the RESISTED condition than in the FREE condition (aortic pulse pressure: -17 % vs. -35 %, $P=0.047$; CBFV: -15 % vs. -26 % vs. $P=0.09$, respectively). Transfer function gain at the first harmonic from the aortic pressure to the CBFV was not affected significantly by LBNP stimulation or the somatosensory input. The transfer function normalized gain by mean CBFV was significantly increased with LBNP ($1.3±0.1$ vs. $1.5±0.1$ cm/s/mmHg, $P=0.048$) but did not differ by the somatosensory input.

CONCLUSIONS: These results suggest that the aorta-brain admittance at the first harmonic is augmented with the LBNP stimulation but not altered by the somatosensory input from the lower limbs.

Arduino-based Impedance Spectroscopy: An Open-source Platform For Physiological Impedance Spectroscopy Measurements In Rats

Andrew L. Allison, Lorian M. Clark, William D. Howell, William L. Sexton, FACSM. *A.T. Still University of Health Sciences, Kirksville, MO.*
Email: sa200988@atsu.edu
(No relevant relationships reported)

Assessment of body water and compartmentalization is an important experimental outcome in many studies. Whole-body impedance spectroscopy permits assessment of body water and composition; however the expense of commercially available systems can be prohibitive. **PURPOSE:** The purpose of this project was to develop an affordable, open-source, and precise system to perform whole-body impedance spectroscopy in rats. **METHODS:** Commercially validated circuit components, as described in the literature, were evaluated and compiled. An impedance spectroscopy system was designed using KiCad. Simulation and modeling of the circuit and instrumentation output was performed using LTSpice. The software was developed using Python, Arduino IDE. The system includes an internal per measurement calibration system and a constant current supply. The system was tested using serially-diluted KCl cells and an equivalent thorax circuit (RRC circuit). Validation studies were performed in anesthetized rats (2% isoflurane in 95% O₂, 5% CO₂) rats *in-vivo* (n=4, ~350 g). **RESULTS:** The impedance spectroscopy system was based on a built-in Arduino-Mega and AD5933 integrated circuit (Analog Devices) using open-source software. The system includes an internal per measurement calibration and constant current supply, and was able to stably iterate through excitation frequencies from 1 to 300 kHz. Admittance data obtained from rats were plotted in a complex plane. After least-squared semicircular regression analysis, there were consistent correlations within rats (triplicate) and among individual rats (n=4) on consecutive days. Total costs of the system was less than \$250. **CONCLUSION:** We developed an affordable (open-source platform that precisely and repeatably provides whole-body impedance spectroscopy measurements in rats. The rat impedance results were qualitatively consistent with published data. This system can also be reprogrammed and reconfigured for use in other physiologic applications.

Water Immersion Skin Wrinkling: The Influence Of Age, Sex, And Adiposity
Jonathon Kava¹, Daroonwan Suksom², Hirofumi Tanaka, FACSM¹. ¹The University of Texas at Austin, Austin, TX. ²Chulalongkorn University, Bangkok, Thailand. (Sponsor: Hirofumi Tanaka, FACSM)
Email: jon.kava@utexas.edu
(No relevant relationships reported)

From the evolutionary perspective, water immersion skin wrinkling (WISW) is the perceived water drainage to enhance grip in wet conditions. In modern medicine, it is a noninvasive test of limb sympathetic function and can be used to assess peripheral neuropathy. WISW occurs as sympathetically-mediated contraction of subcutaneous glomus bodies after perturbation of ion concentration in palmar sweat glands. This phenomenon has not been studied well and it is not clear if common demographic variations (e.g. age, sex, and adiposity) that impact overall cardio-autonomic health status also affect WISW. **Purpose** The purpose of the present study is to determine if peak WISW is modulated by age, sex, and body adiposity, additionally, we addressed if this phenomenon is associated with osmotic reactions or edema. **Methods** So far 12 apparently healthy adults (5 females) aged 34.5±17.6 years were studied. Participants hands were submerged in 40°C water for 30 minutes with degree of wrinkling being assessed via 5-point scale (0 to 4) at 10-minute intervals. Final ratings for digits 2-5 were summed and used to determine peak WISW with a score of 16 being the highest and 0 being the lowest possible scores. Additionally, hand and forearm volume were measured via water displacement before and after submersion to quantify hand volume expansion. **Results** Peak WISW ranged from 5 to 16 with the mean (±SEM) score of 13.2±1.3. Peak WISW was moderately correlated with age ($r=-0.54$), BMI ($r=-0.39$), body fat percentage ($r=-0.51$). Males demonstrated a greater degree of WISW with a mean rating of 16 compared with females with a mean rating of 9 ($p<0.01$). Hand and forearm volume did not change with water immersion (497±29 vs. 500±30 ml). Changes in hand and forearm volume were not associated with peak WISW ($r=-0.03$). **Conclusion** The preliminary results indicate that water immersion skin wrinkling varies widely with age, sex, and body adiposity and is not associated with edema or osmotic reactions.

An Assessment Of The Potential For Standardizing Various Measures Of Arterial Stiffness
 Taha Alhalimi, Jisok Lim, Hirofumi Tanaka, FACSM. *University of Texas, AUSTIN, TX.* (Sponsor: Hirofumi Tanaka, FACSM)
 Email: halimitaha@hotmail.com
 (No relevant relationships reported)

Arterial stiffness is an independent risk factor for cardiovascular disease. Different measures of arterial stiffness have been used to assess the impacts of exercise training interventions. One of the primary problems faced by investigators conducting systematic reviews and meta-analyses is the lack of standardized methodology to evaluate and compare efficacies of the existing and newly conducted exercise interventions on arterial stiffness. The reference standard measure of arterial stiffness is pulse wave velocity (PWV) while other commonly-used methodologies are ultrasound-derived arterial compliance and distensibility. **PURPOSE:** To describe standardized equations to convert common ultrasound-based measures of arterial stiffness (arterial compliance, distensibility, β -stiffness index, elastic modulus) to local PWV. **METHODS:** We first conducted a literature search to derive conversion equations. For measures of arterial stiffness that conversion equations cannot be used, we generated regression equations using the accumulated dataset available in the laboratory. Subsequently, these equations were cross-validated in a well-controlled laboratory-based study, in which all measures of arterial stiffness were collected in 49 apparently healthy participants. **RESULTS:** The literature search revealed that some measures of arterial stiffness such as distensibility coefficient (DC) can be converted to local PWV using the Bramwell-Hill model ($PWV = [pDC]^{1/2}$) with an assumption of $p=1059 \text{ kg/m}^3$. Ultrasound-based measures of arterial stiffness were strongly and significantly associated with local PWV with Pearson r ranging from 0.74 to 0.99 ($p < 0.01$). Converted local PWV using regression models were correlated with each other ($r=0.73$ to 0.99 , $p < 0.01$). The correlations between converted local PWV and directly measured carotid-femoral PWV ranged from weak to moderate correlations with the range of r from 0.08 to 0.41. **CONCLUSION:** Our findings indicate that commonly-used measures of ultrasound-based arterial stiffness can be converted to local PWV and can be compared with a reference standard measure. These conversions can be used in systematic reviews and meta-analyses to synthesize evidence across studies to detect effects.

Interrupting Prolonged Sitting With Different Walking Intensities And Durations: Effects On Resting Blood Pressure
 Waris Wongpipit¹, Masashi Miyashita², Stephen Heung-Sang Wong, FACSM¹. ¹*The Chinese University of Hong Kong, Hong Kong, Hong Kong.* ²*Waseda University, Saitama, Japan.*
 Email: waris.w@link.cuhk.edu.hk
 (No relevant relationships reported)

BACKGROUND: Greater time spent in sedentary behaviour is associated with an increased risk of cardiovascular disease, type-2 diabetes, and mortality. Regularly interrupting prolonged sitting with 2-min light-intensity and 2-min moderate-intensity walking every 20 minutes without matching for energy expenditure has been shown to reduce resting blood pressure. However, little is known whether interrupting prolonged sitting with 3-min light-intensity walking and 1.5-min brisk walking every 30 min when the energy expenditure of these trials is matched provides similar benefits on resting blood pressure. **PURPOSES:** To compare the effects of 1.5-min moderate-intensity walking every 30 minutes and 3-min light-intensity walking every 30 minutes on resting blood pressure in young men with central obesity when the energy expenditure of these trials is matched. **METHODS:** Sixteen East-Asian men with central obesity (mean age: 22.3 ± 4.2 years; body mass index: $29.9 \pm 1.7 \text{ kg}\cdot\text{m}^{-2}$; waist circumference: 100.3 ± 5.9 cm) completed three, 7-h laboratory-based conditions in a randomised order: 1) prolonged sitting (SIT), 2) 3-min (at 20 - 39% of $\dot{V}O_2$ reserve) and 3) 1.5-min (at 40 - 59% of $\dot{V}O_2$ reserve). Each trial was separated by a 6-day washout period. Resting blood pressure was measured hourly using automated sphygmomanometer in a seated position (mean of two recordings, ≥ 15 -min post-activity). Generalised Estimating Equations were used to examine differences among the three conditions. **RESULTS:** Resting systolic blood pressure (SBP) reduced in the 3-min condition (mean \pm SEM; 119 ± 2 mmHg) but not in 1.5-min condition (120 ± 2 mmHg) when compared with SIT condition (123 ± 3 mmHg, $P = 0.028$). Resting diastolic blood pressure (DBP) reduced in both 3-min (75 ± 2 mmHg) and 1.5-min (75 ± 2 mmHg) conditions compared with SIT condition (76 ± 2 mmHg, $P = 0.024$ and $P = 0.001$, respectively). **CONCLUSIONS:** Interrupting prolonged sitting with 3-min of light-intensity walking every 30 minutes is more effective on reducing resting blood pressure when compared to the trial with 1.5-min of moderate-intensity walking every 30 minutes in young East-Asian men with central obesity.

 (No relevant relationships reported)

A reduced exposure to ultraviolet (UV) radiation in winter can decrease 25-hydroxyvitamin D (25(OH)D) levels, increase cardiovascular risk factors, and inhibit athletic performance. Exposing skin to UV-A light in the laboratory has also been shown to release nitric oxide (NO) metabolites into the circulation; molecules known to regulate multiple cardiovascular and metabolic processes. However, it is presently unclear whether NO availability is influenced by the seasonal variation in UV exposure. **PURPOSE:** To compare UV exposure, serum 25(OH)D, plasma nitrate and nitrite, and blood pressure between the summer and winter months. **METHODS:** Thirty-four healthy adults (21 males) residing in Scotland ($\sim 55.8^\circ \text{N}$, 4.1°W) were monitored for 7 days in the summer (June - August) and winter (December - February) in a randomised order. Participants wore a personal UV monitor on the wrist throughout each monitoring phase before visiting the laboratory to provide a venous blood sample and to have blood pressure measured. Serum levels of 25(OH)D were measured using an enzyme-linked immunosorbent assay and plasma nitrate and nitrite analysed using gas-phase chemiluminescence. **RESULTS:** Total UV-A exposure was higher in summer ($17 \pm 21 \text{ J}\cdot\text{cm}^{-2}$) compared to winter ($2.5 \pm 3.0 \text{ J}\cdot\text{cm}^{-2}$, $P < 0.001$). Plasma nitrate did not differ between seasons ($P=0.57$) but nitrite ($137 \pm 31 \text{ nM}$) and serum 25(OH)D ($22 \pm 8 \text{ ng/ml}$) were lower (both $P < 0.001$) in the winter compared to summer ($200 \pm 56 \text{ nM}$ and $35 \pm 13 \text{ ng/ml}$, respectively). Blood pressure was higher in winter (systolic 126 ± 13 mmHg; diastolic 76 ± 9 mmHg) than in summer (systolic 119 ± 11 mmHg; diastolic 67 ± 8 mmHg; both $P < 0.001$). UV-A exposure was positively associated with plasma nitrite ($R=0.41$, $P < 0.01$) and 25(OH)D ($R=0.43$, $P < 0.01$). Plasma nitrite was negatively associated with systolic ($R=-0.5$, $P < 0.01$) and diastolic blood pressure ($R=-0.4$, $P < 0.01$). **CONCLUSIONS:** In a similar fashion to 25(OH)D, circulating levels of plasma nitrite, a marker of NO bioavailability, appear to be influenced by seasonal variations in UV exposure. The negative association between nitrite and blood pressure suggest that a reduced level of NO may increase cardiovascular risk factors in the winter months.

Sex And Fiber-type Differences: Vascular ATP-sensitive K⁺ (K_{ATP}) Channels Support Critical Speed And Interstitial PO₂
 Trenton D. Colburn, Ramona E. Weber, Kiana M. Schulze, K. Sue Hageman, Timothy I. Musch, FACSM, David C. Poole, FACSM. *Kansas State University, Manhattan, KS.* (Sponsor: David C. Poole, FACSM)
 (No relevant relationships reported)

Glibenclamide (GLI), prescribed to Type II diabetes patients, enhances insulin release by inhibiting pancreatic K_{ATP} channels. K_{ATP} channels support maximal aerobic capacity ($\dot{V}O_{2\text{max}}$) and blood flow during treadmill running in male rats. Whether high-intensity exercise tolerance (i.e. critical speed, CS) and muscle O₂ delivery-utilization matching (interstitial PO₂, PO_{2is}) is impaired, and whether sex differences exist in K_{ATP} function, are unknown. **PURPOSE** We hypothesized that systemic inhibition of K_{ATP} channels via GLI would decrease $\dot{V}O_{2\text{max}}$ and CS, while local inhibition would decrease contracting PO_{2is} and blood flow within fast-twitch oxidative (mixed gastrocnemius (MG)) and slow-twitch oxidative (soleus (SOL)) muscles with females (F and F+OVX) expressing the greatest reduction. **METHODS:** Male (n=12), female (n=10, proestrus) and ovariectomized female (F+OVX; n=12) Sprague-Dawley rats with and without GLI (10 mg kg⁻¹ in DMSO i.p.). $\dot{V}O_{2\text{max}}$ and CS were assessed using state-of-the-art techniques on a motorized treadmill. PO_{2is} was determined, before and after GLI superfusion (5 mg kg⁻¹), via phosphorescence quenching (G4) in the exposed MG and SOL muscles during electrically-induced contractions and blood flow by fluorescent-labeled microspheres (15 μm). **RESULTS:** GLI decreased $\dot{V}O_{2\text{max}}$ in female (71.5 ± 1.0 vs 67.9 ± 1.5) and F+OVX (76.8 ± 1.4 vs 74.4 ± 1.4 ; $p < 0.05$ for both) but not males (81.5 ± 2.0 vs $80.8 \pm 2.0 \text{ mL O}_2 \cdot \text{min}^{-1} \cdot \text{kg}^{-1}$; $p > 0.05$). CS was reduced equivalently in all groups (8-11%; $p < 0.05$). GLI reduced MG blood flow (female: 49 ± 9 vs 34 ± 5 ; male: 50 ± 5 vs 35 ± 4) and PO_{2is} (female: 7.3 ± 0.5 vs 6.1 ± 0.5 ; male: 8.9 ± 1.1 vs 7.2 ± 0.5), but not SOL, of female and male rats ($p < 0.05$). Conversely, in F+OVX, PO_{2is} was reduced in the SOL (14.5 ± 1.5 vs 10.2

± 1.1 ; $p < 0.05$), but not MG. **CONCLUSION:** These data support the role of vascular K_{ATP} channels in exercise tolerance (i.e. CS) by matching O_2 delivery-utilization with ovariectomy shifting K_{ATP} channel effects from fast- to slow-twitch muscles. Supported by NIH Grants: HL108328 and F31HL145981

Dose-response Impact Of Resistance Training Frequency On Arterial Stiffness

Nicholas M. Beltz, Paige Ahrens, Mallory Daniels, Hannah Koch, Joey Lange, Garrett Janicki, Bryana Petersin, Elizabeth Schwab, Megan Werch. *University of Wisconsin-Eau Claire, Eau Claire, WI.*

Email: beltznm@uwec.edu

(No relevant relationships reported)

Arterial stiffness (AS) has been shown to underpin the development and progression of many cardiovascular diseases. Regular exercise promotes favorable changes in arterial health; however, investigations on the impact of resistance training (RT) alone on AS have shown mixed results. Moreover, the frequency design in which an RT program is completed on a weekly basis (i.e., the 'weekend warrior' approach) may impact overall changes to arterial health.

PURPOSE: We sought to examine the dose response impact of RT frequency over a 4-week period on arterial stiffness and blood pressure in college-aged resistance trained individuals. **METHODS:** Twenty-seven resistance trained males ($n=16$) and females ($n=11$) were randomized into three training groups differing in weekly RT frequency: a) 1-day (1D) per week ($n=8$), b) 2-days (2D) per week ($n=9$), or c) 3-days (3D) per week ($n=9$). Resistance training exercises included: dumbbell chest press, seated cable row, leg press, calf raise, lateral pulldown, seated shoulder press, seated leg extension, and prone leg curl. Exercises were completed either two (3D), three (2D), or six (1D) sets of 10 repetitions at 65% 1-repetition max, depending on group. Arterial stiffness indices (augmentation index (AIx75), pulse pressure (PP), and augmentation pressure (AP)) were measured at baseline, midpoint, and after completing the 4-weeks using the SphygmoCor XCEL. A two-way (group x time) ANOVA with repeated measures was employed to examine differences in AS indices between groups. **RESULTS:** Total weekly load volumes were similar ($p = 0.996$) across groups. There were no differences between 1D, 2D, and 3D for AIx75 ($p = 0.429$), PP ($p = 0.646$), and AP ($p = 0.247$). **CONCLUSION:** Given no differences between groups, a total weekly load volume of RT can be completed in a single weekly session or across multiple sessions without any negative or favorable impact on AS.

Pulse Wave Velocity And Pulmonary Function Testing As Markers Of Cardiovascular Disease In Females

Eóin Durkan, Kevin O'Brien, Aidan J. Brady, Niall M. Moyna. *Dublin City University, Dublin, Ireland.*

Email: eoin.durkan@dcu.ie

(No relevant relationships reported)

PURPOSE: To assess the association of dynamic lung function, namely forced vital capacity (FVC) and forced expiratory volume in 1 sec (FEV_1) and diffusing capacity for carbon monoxide with markers of cardiovascular disease in a cohort of asymptomatic female smokers. Cardiovascular disease is a major health problem worldwide, poor lung function has been associated with increased mortality in cardiovascular disease patients. Both are linked to smoking. Poor scores in arterial stiffness have been linked to restrictive pattern on spirometry. Relatively little is known about the association of other pulmonary function test scores to arterial stiffness. **METHODS:** 35 female participants, age 51 ± 9 yrs, VO_{2peak} 22.5 ± 4.7 ml/kg/min, FEV_1/FVC : 0.78 ± 0.08 , $FEV_1\%pred$ 88.9 ± 17.85 , $DLC0\%pred$ 79.05 ± 14.43 were recruited as part of a North East Inner City Dublin City Council 'Change for Life' exercise programme. Patients performed spirometry, and diffusing capacity for carbon monoxide (DLCO) was assessed. Body mass index (BMI) and waist:hip (W:H) ratio were calculated. EC was assessed via cardiopulmonary exercise test (CPET) upper body strength via handgrip dynamometer (HG) and lower body strength via 30 sec sit to stand test (30STS). Carotid-Femoral (caPWV) and Brachial-Ankle (baPWV) pulse wave velocity were assessed with the Vicorder unit. Continuous data are presented as mean \pm SD. Associations between continuous variables were scored using Pearson's r. **RESULTS:** Significant negative correlations were observed between caPWV and baPWV and FEV_1/FVC , $r = -.55$ and $r = -.51$. EC showed positive correlations with FEV_1 , $r = .35$, and FVC = $.44$, and negative correlations with baPWV, $r = -.35$. No association was seen between arterial stiffness measures and DLCO.

CONCLUSIONS: Female patients with significant smoking history and preserved pulmonary function may display signs of cardiovascular disease as evidenced by increased arterial stiffness.

EXERCISE TRAINING AMELIORATES CEREBROVASCULAR DYSFUNCTION IN ALZHEIMER'S DISEASE; A ROLE OF P2Y2 RECEPTOR AND ENDOPLASMIC RETICULUM STRESS

JUNYOUNG HONG¹, Soon-Gook Hong², Jonghae Lee¹, Joon Young Park², Jason Eriksen¹, Yoonjung Park¹. ¹UNIVERSITY OF HOUSTON, HOUSTON, TX. ²Temple University, Philadelphia, PA.

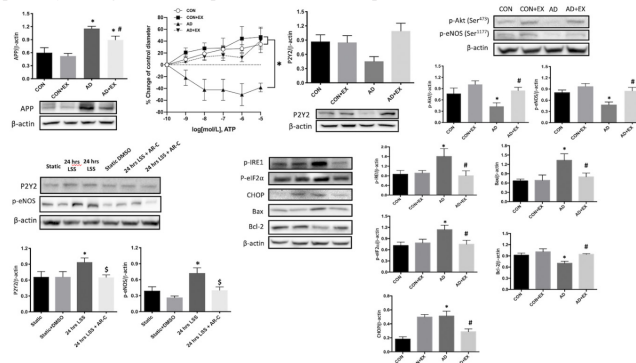

(No relevant relationships reported)

PURPOSE: To determine the protective effect of exercise training on P2Y2 receptor-mediated and ER stress-associated cerebrovascular dysfunction in AD.

METHODS: We used the control mice (CON; C57BL/6), CON with exercise training (CON+EX), AD mice (AD; APP/PS1) and AD with EX (AD+EX). At 7 to 9 months of age, CON+EX and AD+EX mice underwent 10-12 weeks of aerobic exercise training on the treadmill, running for an hour at 15m/min at a 5% grade for 5 days a week. To test the purinergic receptor-dependent vasoreactivity, a posterior cerebral artery (PCA) was isolated and pressurized, and then ATP (2-MeS-ATP, 1 nmol/L to 10 μ mol/L)-induced dose-dependent vasoreactivities were determined at 10-12 months of age. Human brain micro endothelial cells (HBMECs) were exposed to laminar shear stress (LSS) at 20 dyne/cm² for 30 mins, 2 hrs, and 24 hrs. Western blotting was utilized to analyze the expression of P2Y2 receptors, endothelial nitric oxide synthesis (eNOS), and ER stress signaling to define the effect of exercise training on cerebrovascular dysfunction.

RESULTS: ATP-induced vasodilation in PCA from CON mice, but it caused vasoconstriction in PCA from AD mice. Notably, exercise training reversed ATP-induced vasoconstriction in PCA from AD mice to vasodilation (AD+EX) comparable to CON mice. Exercise training reduced the elevation of APP expression and increased P2Y2 receptor and Akt/eNOS expression in AD mice brain. Also, LSS increased the expression of P2Y2 receptor and eNOS in HBMECs, but these increases were blunted by P2Y2 receptor inhibitor (AR-C) in HBMECs. Exercise training normalized the abnormal expression of ER stress markers; p-IRE1, p/t-eIF2 α , CHOP, and ER stress-associated apoptosis; Bax and Bcl-2 in AD mice brain.

CONCLUSION: Exercise training improves the cerebrovascular dysfunction in AD possibly through P2Y2 receptor-and ER stress-dependent endothelial dysfunction.

Dietary Nitrate Intake Improves Vascular Function And Walking Capacity In Patients With Peripheral Artery Disease

TeSean K. Wooden, Elizabeth J. Pekas, Ronald J. Headid, III, Won-Mok Son, Song-Young Park. *University of Nebraska at Omaha, Omaha, NE.*

Email: tesseanwooden@gmail.com

(No relevant relationships reported)

Peripheral artery disease (PAD) is the manifestation of atherosclerosis in the arteries of the legs, which reduces blood flow to the lower extremities and impairs walking capacity. Dietary nitrate has been used to reduce blood pressure (BP) and increase exercise tolerance in PAD. However, a standard dose, body mass normalized nitrate, for PAD has yet to be determined.

PURPOSE: To elucidate the impacts of a body mass-normalized dose of nitrate (0.11 mmol nitrate/kg) in the form of beetroot juice on resting heart rate (RHR), central and peripheral BP, vascular function, and exercise tolerance in patients with PAD.

METHODS: In a randomized crossover design, 10 patients with PAD (stage II-III) received either the nitrate supplement or placebo. At each visit, measures of RHR, central and peripheral BP, brachial and popliteal artery endothelial function (flow-

mediated dilation, FMD), arterial stiffness (pulse-wave velocity, PWV), augmentation index (AIx)), maximal walking capacity, and time to claudication (COT) were measured before and after nitrate and placebo.

RESULTS: There were significant group by time interactions ($p < 0.05$) for systolic BP, endothelial function, and maximal walking distance. Systolic BP was significantly reduced ($p < 0.05$) while popliteal FMD, brachial FMD, and maximal walking time significantly increased ($p < 0.05$). Nitrate intake reduced central systolic BP and increased maximal walking time ($p < 0.05$). There were trends for decreased diastolic BP ($p = 0.15$), central diastolic BP ($p = 0.06$), and central pulse pressure ($p = 0.17$). There were no changes in RHR, deceleration time, max dP/dt, carotid-to-radial PWV, carotid-to-femoral PWV, carotid-to-ankle PWV, AIx, or COT ($p > 0.05$).

CONCLUSIONS: These results indicate that a dose of nitrate (~ 0.11 mmol nitrate/kg) seems to be an effective dose for improving BP, vascular function, and walking capacity in patients with PAD.

Effects Of Aquatic Vs Land Based Exercise Training On Vascular Function In Peripheral Artery Disease Patients

Kook-Eun Seo¹, Elizabeth Pekas², Song-young Park³. ¹Pusan National University, Busan, Korea, Republic of. ²University of Nebraska- Omaha, Omaha, NE. ³University of Nebraska- Omaha, Omaha, NE.

(No relevant relationships reported)

Peripheral artery disease (PAD) is an atherosclerotic disease that is associated with poor vascular function, walking impairment, and reduced quality of life. Walking is frequently recommended to improve vascular function and reduce symptoms; however, the efficacy of land-based walking training (LET) versus heated-water walking training (HWET) in PAD patients had not been elucidated. **Purpose:** We sought to compare effects of LET to HWET on vascular function, resting heart rate (RHR), exercise tolerance [6-min walking distance (6MWD), time to onset of claudication (COT)], muscular strength, physical function, body composition, and resting metabolic rate (RMR) in PAD patients. **METHODS:** PAD patients ($n = 53$) were recruited and randomly assigned to a LET group ($n = 25$) or HWET group ($n = 28$). The LET group performed a treadmill walking program while the HWET group performed a heated-water walking program for 12-weeks. Leg arterial stiffness (femoral-to-ankle pulse-wave velocity, legPWV), blood pressure (BP), ankle-brachial index (ABI), RHR, 6MWD, COT, muscular strength, physical function, body composition, and RMR were assessed before and after 12-weeks. **RESULTS:** There were significant group by time interactions ($p < 0.05$) for legPWV, BP, RHR, 6MWD, COT, leg strength, body mass, body fat percentage, and RMR. Both groups significantly reduced ($p < 0.05$) legPWV, BP, RHR, body mass, and body fat percentage, and HWET was significantly lower than LET ($p < 0.05$). Both groups significantly increased ($p < 0.05$) 6MWD, COT, leg strength, and RMR, and HWET group was significantly greater than LET ($p < 0.05$). There were no significant changes ($p > 0.05$) in ABI, grip strength, physical function, body mass index, or lean mass after 12 weeks. **CONCLUSIONS:** These results suggest that although treadmill walking may help improve vascular function, exercise tolerance, muscular strength, and body composition, heated-water walking may improve these measures to a greater extent in patients with PAD.

Comparison Of Whole-forearm And Skin Post-occlusive Reactive Hyperemia As Indices Of Microvascular Function

Hugo Gravel, Nicholas Ravanelli, Parya Behzadi, Daniel Gagnon. *Montreal Heart Institute, Montreal, QC, Canada.*

(No relevant relationships reported)

BACKGROUND: Post-occlusive reactive hyperemia (PORH) is often used as a test of microvascular function. However, the method of PORH measurement and the reporting of PORH values varies widely between studies, from measurements on the skin or whole-forearm to reporting peak or cumulative PORH values. As such, the optimal measurement and reporting of PORH values remains unclear.

PURPOSE: To compare whole-forearm and skin PORH between older adults with conditions typically associated with microvascular dysfunction (type 2 diabetes, T2D), macrovascular dysfunction (non-diabetic coronary artery disease, CAD) and healthy controls (CTRL).

METHODS: We retrospectively analyzed data obtained from 13 T2D patients (61 ± 9 years, 6 M; 7 W), 21 CAD patients (65 ± 9 years, 18 M; 3 W) and 13 CTRL (65 ± 7 years, 9 M; 4 W). Forearm vascular conductance (FVC, duplex ultrasound) and cutaneous vascular conductance (CVC, laser-Doppler) were measured simultaneously before and for 3 minutes after 5 minutes of forearm ischemia. PORH was quantified as: absolute peak (Peak), change from baseline to peak (Δ) and area under the curve above baseline (AUC).

RESULTS: Baseline FVC ($P = 0.84$) and CVC ($P = 0.31$) were similar between groups. Peak FVC was similar between groups ($P = 0.24$), while Δ FVC tended to be reduced in

T2D compared to CAD ($P = 0.06$) and CTRL ($P = 0.07$). FVC AUC was reduced in T2D compared to CTRL ($P = 0.03$), while values in CAD did not differ from T2D or CTRL. Peak CVC (T2D: $P = 0.04$, CAD: $P = 0.02$) and Δ CVC (T2D: $P = 0.03$, CAD: $P = 0.01$) were reduced in T2D and CAD. There was a trend for CVC AUC to differ between groups ($P = 0.06$). The different indices of PORH for a given measurement (forearm vs skin) were strongly correlated ($r = 0.755$ to 0.906 between FVC descriptors, $r = 0.768$ to 0.991 between CVC descriptors, all $P < 0.001$). However, FVC indices of PORH weakly correlated with CVC indices ($r = 0.237$ to 0.374 , $P = 0.01$ to 0.11).

CONCLUSIONS: Whole-forearm and skin PORH provide different information on microvascular function in older adults. A decreased PORH in the whole-forearm appears to be a feature of T2D and not CAD, while a decreased PORH in forearm skin seems to be detectable in both T2D and CAD.

3276 Board #97 May 29 2:30 PM - 4:00 PM

Role Of Akt And Mapk Signals Balancing In The Exercise-regulated Phenotype-switching In Spontaneously Hypertensive Rats

Lin Zhang, Lijun Shi. *Beijing Sport University, Beijing, China.*
 Email: zhanglinbsu@126.com

(No relevant relationships reported)

The mechanisms regulating vascular smooth muscle cell (VSMC) phenotype switching and the critical signal modulation affecting the VSMCs remain controversial. Multiple studies have shown that physical exercise acts as an effective drug in preventing elevated blood pressure and improving vascular function.

PURPOSE: This study was designed to explore the influence of aerobic exercise on the suppression of VSMC phenotype switching by balancing of the Akt (protein kinase B) and mitogen-activated protein kinase (MAPK) signaling pathways. **METHODS:** Twelve-week old spontaneously hypertensive rats (SHRs) and age-matched normotensive rats (WKYs) were subjected to exercise (SHR-EX and WKY-EX) and sedentary (SHR-SED and WKY-SED) treatment for 8 weeks before measuring the vascular morphological and structural performances. **RESULTS:** (1) The thickness of thoracic aortas was significantly increased in the SHR-SED versus the WKY-SED (99.4 ± 1.97 vs 83.12 ± 1.45 μ m, $p < 0.01$). Physical exercise significantly suppressed the thickening of the blood vessel wall in the SHR-EX compared to SHR-SED (92.5 ± 1.52 vs 99.4 ± 1.97 μ m, $p < 0.05$). (2) Exercise training induced reverse expression of VSMC protein markers in SHR-EX group versus SHR-SED group (α -SM-actin: 0.91 ± 0.04 vs 0.71 ± 0.03 , $p < 0.05$; calponin: 0.97 ± 0.05 vs 0.76 ± 0.05 , $p < 0.05$; and OPN: 1.83 ± 0.16 vs 2.32 ± 0.18 , $p < 0.05$). (3) The phosphorylated Akt was significant upregulated in SHR-EX group versus SHR-SED group (0.98 ± 0.05 vs 0.75 ± 0.04 , $p < 0.05$). However, the expression of phosphorylated ERK (1.34 ± 0.12 vs 1.69 ± 0.09), and phosphorylated p38 MAPK (1.06 ± 0.04 vs 1.25 ± 0.03 , both $p < 0.05$) were significant downregulated in the SHR-EX versus the SHR-SED. (4) VSMCs and whole vessels were treated by inhibitors, p-Akt inhibitor, p-ERK inhibitor and p-p38 MAPK inhibitor, respectively. It is important to note that a significant reverse regulatory relationship was observed between the expression levels of MAPK and contractile markers in both normotensive and spontaneously hypertensive rats. **CONCLUSION:** Aerobic exercise regulates VSMC phenotype switching by balancing the Akt and MAPK signaling pathways in SHRs.

Preliminary Study: Effect Of Body Fat Percentage On Arterial Stiffness In Young Healthy Hispanic Males

Rachel C. Reyes, Nolan Mackey, Sang Ouk Wee. *California State University, San Bernardino, San Bernardino, CA.*

Email: 005907859@coyote.csusb.edu

(No relevant relationships reported)

Introduction: Obesity is a serious health concern worldwide and it is a common health condition in Hispanic population. High body fat percentage is inversely related to aerobic fitness and increased arterial stiffness, which is an independent CVD risk factor. However, there is

limited data about the effects of body fat percentage on arterial stiffness in Hispanic population. **Purpose:** To investigate the effects of Body Fat Percentage (BFP) on arterial stiffness in young healthy Hispanic males. **Methods:** Ten young (5 in each group, age: Low Fat group (LF, BFP < 25%) = 23.2 ± 1.8 yrs, High Fat group (HF, BFP > 25%) = 22.8 ± 4.3 yrs) healthy, casually active Hispanic males volunteered for the study. Aerobic capacity (VO_{2peak}) was measured by metabolic cart during graded exercise testing on the treadmill. Hemodynamic variables including

blood pressure (BP) and heart rate were measured in supine position by automated BP monitor. BFP was measured by Dual-Energy X-ray Absorptiometry (DXA) and arterial stiffness indices including heart rate normalized augmentation index (AIx@75) and Pulse Wave Velocity (PWV)

were acquired by tonometer and ambulatory BP monitor, respectively. **Results:** HF group exhibited significantly lower aerobic capacity (41.64 ml/kg/min) when compared to LF group (48.86 ml/kg/min) ($p < 0.05$). However, there was no significant

difference in hemodynamic variables including systolic BP, diastolic BP and HR ($p > 0.05$ for all). In addition, PWV (HF vs. LF; 5.5 ± 0.5 m/s vs. 5.3 ± 0.4 m/s) and $AIx@75$ (HF vs. LF: $0.0\% \pm 13.8\%$ vs. $-8.8\% \pm 5.3\%$) were not statistically different between groups ($p > 0.05$ for both) **Conclusion:** Although HF group exhibited significantly lower aerobic capacity, BFP does not affect arterial stiffness in young casually active Hispanic males. Future study with more participants will be needed.

Impact Of Smoke Exposure On VO_{2max} And Arterial Stiffness In Wildland Firefighters: A Pilot Study

Zachary Zeigler, Laura Verdusco, Payton Greer, Devin Vigneault, Greta Gardner, Lourdes Herrera, Justin Mcelfresh, Trevor Nordin. *Grand Canyon University, mesa, AZ.*
 Email: zachary.zeigler@gcu.edu
 (No relevant relationships reported)

Purpose: Inhalation of wildfire smoke can cause reduced lung function, chest pain, fatigue, and depressed respiratory immune defenses. Those at increased risk for these adverse effects would be wildland firefighters (WLF). Aerobic fitness is a key component of WLF performance. Additionally, it is known that higher levels of aerobic fitness correlate with lower levels of cardiovascular (CV) morbidity and mortality. The impact of wildland smoke exposure on CV health among WLF is unknown.

Methods: WLF from the Arizona high country were recruited for this study. WLF were asked to come to the lab at Grand Canyon University before and after fire season. WLF were asked to fill out a survey assessing the number of seasons they have actively engaged in wildland firefighting. Following anthropometric measurements, subjects had their carotid-femoral Pulse Wave Velocity (cfPWV) and VO_{2peak} measured. Identical measurements were taken before and after fire season. Hierarchical regression was completed to assess the relationship between the number of fire seasons completed and VO_{2peak} . Paired t-test was completed for pre-post testing.

Results: Twenty-eight subjects completed initial testing while 22 returned for post-testing. Subjects were 31.0 ± 5.7 yrs., with a BMI of 25.7 ± 3.0 kg/m², VO_{2peak} of 55.4 ± 6.6 mL/kg/min and completed on average 10.6 ± 5.8 seasons of wildland firefighting. Hierarchical regression was conducted with age in model one and number of seasons in model two, VO_{2peak} was the criterion variable. Model one was not a significant predictor of VO_{2peak} . Model two significantly explained 23% of the variance in VO_{2peak} ($P=0.044$). Significant reduction in absolute VO_{2peak} (4.3 ± 6 vs 3.2 ± 1.9 L/min, $P<0.04$) and significant increases in cfPWV (6.0 ± 1 vs. 6.6 ± 7 m/s, $P<0.042$) were seen following fire season.

Conclusion: This pilot study suggests that the duration of a WLF career may negatively impact CV health.

Exercise Mediates Epigenetic Suppression Of LTCC And BK_{Ca} Channel In Mesenteric Arteries Of Hypertensive Rats

Lijun Shi, Yanyan Zhang. *Beijing Sport university, Beijing, China.*
 Email: l_j_shi72@163.com
 (No relevant relationships reported)

Regular exercise is a lifestyle intervention for controlling hypertension and has an improving effect on vascular function. Voltage-gated L-type Ca^{2+} (LTCC) and large-conductance Ca^{2+} -activated K^{+} (BK_{Ca}) channels are two principal mediators of vascular smooth muscle contractility and arterial tone. Exercise-induced LTCC and BK_{Ca} channel alterations in arterial myocytes may contribute to the improvement of vascular function in pathological conditions. However, the mechanism underlying the functional changes of these ion channels is still unclear but critical for understanding the mechanistic basis of reliable arterial performance. **PURPOSE:** To investigate the role of DNA methylation in exercise-induced reprogramming of LTCC and BK_{Ca} channel in mesenteric arteries from spontaneously hypertensive rats (SHRs). **METHODS:** Twelve-week-old male SHRs and normotensive Wistar-Kyoto rats (WKYs) were assigned into sedentary and exercise groups. Exercise groups were performed a moderate-intensity treadmill running (about 55-65% of maximal aerobic velocity, 20 m/min, 0% grade, 60 min, 5 days/week). After 12 weeks, patch clamp study, Western blot, qPCR and bisulfite sequencing PCR were used to detect the LTCC and BK_{Ca} channel currents, protein expression and mRNA level of LTCC $\alpha 1c$ and BK_{Ca} $\beta 1$ subunits, DNA methylation level of $\alpha 1c$ and $\beta 1$ gene promoter region. **RESULTS:** Exercise training significantly decreased the systolic blood pressure in both WKYs (139.5 ± 0.48 vs. 132.3 ± 0.56 mmHg, $P<0.05$) and SHRs (199.4 ± 0.45 vs. 191.2 ± 0.71 mmHg, $P<0.05$). Exercise inhibited hypertension-induced upregulation of LTCC (-16.0 ± 1.6 vs. -11.4 ± 1.5 pA/pF, $P<0.05$) and BK_{Ca} (43.7 ± 2.8 vs. 23.1 ± 1.6 pA/pF, $P<0.05$) channel current density of mesenteric arterial myocytes by repressing LTCC $\alpha 1c$ (2.8 ± 0.3 vs. 1.7 ± 0.2 , $P<0.05$) and BK_{Ca} $\beta 1$ (1.7 ± 0.3 vs. 0.8 ± 0.2 , $P<0.05$) subunit expression. DNA bisulfite sequencing PCR showed that chronic exercise increased CpG methylation at $\alpha 1c$ (81.3 ± 1.6 vs. $87.9 \pm 0.8\%$, $P<0.05$) and $\beta 1$ (17.7 ± 0.4

vs. $25.2 \pm 2.0\%$, $P<0.05$) gene promoter in SHR mesenteric arteries. **CONCLUSION:** Exercise suppresses LTCC and BK_{Ca} channel function via hypermethylation of $\alpha 1c$ and $\beta 1$ subunits, which contributes to the restoration of mesenteric arterial function and vasodilation during hypertension.

Evaluation Of Functional Sympatholysis Occurring Within Contracting Skeletal Muscle Microvasculature In Humans

Masashi Ichinose¹, Mikie Nakabayashi², Nozaki Kanichiro², Shotaro Sasaki², Yumie Ono². ¹*Meiji University, Tokyo, Japan.* ²*Meiji University, Kanagawa, Japan.*
 Email: ichinose@meiji.ac.jp
 (No relevant relationships reported)

The ability of contracting skeletal muscle to blunt sympathetic vasoconstriction, termed functional sympatholysis, is thought to contribute to supplying adequate blood to the exercising muscle despite increased sympathetic tone. However, previous studies in humans primarily investigated vascular responses of exercising limb as a whole that reflects not only responses of contracting skeletal muscles but also responses of inactive tissues such as skin, adipose and bones. **PURPOSE:** We aimed to more directly investigate the functional sympatholysis occurring within exercising skeletal muscle in humans. **METHODS:** In 26 healthy male volunteers, we examined the effects of acute sympathoexcitation by 90-s forehead cooling at rest and during dynamic handgrip exercise at 10% and 30% of maximum voluntary contraction (10%Ex and 30%Ex), respectively. The handgrip exercises were continued 3 min and forehead cooling was applied at latter half of the exercise period. The subjects also performed handgrip exercises without forehead cooling as control conditions. We employed near-infrared diffuse correlation spectroscopy, an emerging optical technique for noninvasive measurement of deep tissue hemodynamics, to continuously measure the microcirculatory blood flow index (BFI) within the flexor digitorum superficialis muscle, the muscle primarily responsible for handgrip. **RESULTS:** The acute sympathoexcitation induced significant decrease in vascular conductance (BFI / mean arterial pressure) at rest (baseline vs. forehead cooling: 1.00 ± 0 vs. 0.75 ± 0.03 AU, $p < 0.05$) and during 10%Ex (control vs. forehead cooling: 1.66 ± 0.08 vs. 1.32 ± 0.10 AU, $p < 0.05$), but not during 30%Ex (control vs. forehead cooling: 4.00 ± 0.56 vs. 3.66 ± 0.50 AU, $p > 0.05$). In addition, the percentage reduction in vascular conductance by forehead cooling was significantly decreased during 30%Ex compared to rest (-25.2 ± 2.5 vs. $-4.9 \pm 5.1\%$, $p < 0.05$). **CONCLUSIONS:** Our study demonstrated the functional sympatholysis occurring within the contracting skeletal muscle microvasculature in humans. Furthermore, our results revealed the clear intensity-dependent response such that mild exercise hardly interferes with sympathetic vasoconstriction, whereas moderate exercise substantially attenuates it.

Continuous Physical Activity Modulates Arterial Stiffening In Young People: A Prospective Longitudinal Observational Study

Masato Nishiwaki¹, Naoyuki Matsumoto². ¹*Osaka Institute of Technology, Osaka, Japan.* ²*Prefectural University of Kumamoto, Kumamoto, Japan.*
 Email: masato.nishiwaki@oit.ac.jp
 (No relevant relationships reported)

PURPOSE: Higher physical activity is well known to prevent age-related increases in arterial stiffness in middle-aged and older people. However, no data are available concerning prospective longitudinal studies between physical activity and arterial stiffness, especially in young people. Therefore, this prospective longitudinal observational study aimed to examine the effects of continuous physical activity on arterial stiffening in young people.

METHODS: The data of the longitudinal study analyzed from 79 normal healthy young men and women (19.2 ± 0.2 years at baseline). At baseline (pre) and after 4-year follow-up (post), arterial stiffness, which was measured by using Cardio-Ankle Vascular Index (CAVI) and regular physical activity levels, which were measured by using International Physical Activity Questionnaire (IPAQ), were assessed. At each time point, participants were classified as having high (H) or low (L) physical activity based on the Physical Activity Reference for Health Promotion 2013 in Japan (23 Metabolic Equivalent Tasks-h/week), and then were finally divided into LL, HL, or HH groups.

RESULTS: After follow-up period, in addition to body weight, body mass index, and blood pressure, CAVI values of all participants significantly increased (Pre, 5.7 ± 0.1 unit; Post, 6.1 ± 0.1 unit). There were no significant differences in baseline CAVI values across the groups (LL, 5.7 ± 0.1 unit; HL, 5.7 ± 0.1 unit; HH, 5.8 ± 0.1 unit). However, the changes in CAVI from pre to post were significantly lower in HH group than in LL group ($P < 0.05$). With the status of continuous physical activity increasing, significant decreasing trends were observed in CAVI (LL, 0.6 ± 0.1 unit; HL, 0.4 ± 0.1 unit; HH, 0.1 ± 0.1 unit, $P < 0.05$).

CONCLUSIONS: These findings indicate that age-related increase in arterial stiffness is observed even in young healthy people. However, continuous higher physical activity can prevent this age-related arterial stiffening in young people.

The Diversity Effect Of Exercise On Endothelial Function In Postmenopausal Women With ACE D/I Polymorphism

Yuan Yuan LYU¹, Lingxiao HE², Kaiyu XIONG¹, Li Zhao¹.
¹Beijing Sport University, Beijing, China. ²Catholic University of Leuven, Leuven, Belgium.
Email: lvyuan yuan2938@aliyun.com
(No relevant relationships reported)

PURPOSE: Increased incidences of cardiovascular disorder and metabolic syndrome particularly in postmenopausal women have raised curiosity for the underlying factors. One potential mechanism by which endothelial dysfunction may promote early arterial stiffness is by causing estrogen deficiency. It is reported that physical exercise counteracts the occurrence of above disorders, while a few others show no change. The training response differs among individuals partly due to genetic composition. Angiotensin-converting enzyme (ACE) insertion/deletion (D/I) polymorphism related to physical performance in athletes has been well-reported. The present study was to observe the effects of 12 weeks exercise (aerobic exercise and resistance training) on endothelial function in postmenopausal women with different D/I polymorphism of ACE gene.

METHODS: 122 postmenopausal women aged 45-75 years were randomly divided into aerobic exercise group (DI/II=65, DD=6) and resistance training group (DI/II=42, DD=9). Body composition, TC, HDL, LDL, endothelial function, endothelium-derived relaxing factor and contracting factor were analyzed.

RESULTS: TC, blood lipid abnormality rate, blood glucose and visceral fat in DI/II type were decreased more significantly after aerobic exercise compared with DD type. Aerobic exercise showed markedly positive effects in LDL, hyperglycemia, overweight/obesity, high body fat rate, abnormal waist-hip ratio and visceral fat in DI/II, while resistance training in LDL, blood glucose (5.34±0.73 vs 4.46±0.34mmol/L, P<0.01), waist-hip ratio and visceral fat (96.60±13.84 vs 61.33±8.65cm², P<0.05) in DD type. Aerobic exercise showed more obviously increased FMD (9.65±1.85 vs 11.00±1.99%, P<0.05), NO (68.31±4.67 vs 76.38±4.01umol/L, P<0.05), NO/ET-1 (0.91±0.11 vs 1.04±0.11, P<0.05) and decreased SBP (123.84±15.98 vs 109.89±13.56mmHg, P<0.05), DBP in DI/II than in DD type. Resistance training increased FMD (7.12±0.70 vs 9.56±0.78%, P<0.05), NO/ET-1 and decreased SBP, DBP, baPWV, ET-1, AngII more significantly in DD type than in DI/II type.

CONCLUSIONS: Exercise positively influences endothelial functions, independent of ACE D/I polymorphism; and DI/II carriers show a better response to aerobic exercise, while DD carriers to resistance exercise.

Endothelial Function In Young Adults Reporting Histories Of Chronic Resistance Activity

Dustin W. Davis¹, Matthew J. Garver², Whitley J. Stone³, Meera Penumetcha², Josie N. Hair², Nicolas M. Philipp². ¹University of Nevada, Las Vegas, Las Vegas, NV. ²University of Central Missouri, Warrensburg, MO. ³Western Kentucky University, Bowling Green, KY.
Email: dustin.wyatt.davis@gmail.com
(No relevant relationships reported)

Endothelial dysfunction is a risk factor for cardiovascular disease (CVD) and is predictive of adverse events. However, endothelial function is rarely measured in apparently healthy, asymptomatic individuals that may benefit from early detection. Chronic cardiorespiratory endurance (CRE) activity appears to improve endothelial function and decrease CVD risk, but the role of chronic resistance activity is less clear. **PURPOSE:** The primary aim of this study was to describe endothelial function in young adults reporting histories of chronic resistance activity and minimal CRE activity. **METHODS:** Eight males (23.8 ± 2.2 yrs., 180.3 ± 7.6 cm, 100.8 ± 18.1 kg) and five females (24.6 ± 3.1 yrs., 164.9 ± 4.0 cm, 68.5 ± 4.2 kg) volunteered for digital peripheral arterial tonometry (PAT) and a one-repetition maximum (1-RM) barbell bench press. Endothelial function was measured as the logarithmic function of the reactive hyperemia index (LnRHI). Absolute strength was measured as the highest successful 1-RM lift (kg), and relative strength was measured as the bench press to body weight ratio (1-RM in kg / body mass in kg). Before PAT, participants fasted for 4 h and forwent alcohol, tobacco, vitamins, and ergogenic aids for 8 h. Before the 1-RM, participants fasted for 3 h, forwent the aforementioned substances for 8 h, and abstained from vigorous physical activity for 12 h. Independent *t*-tests compared the LnRHI between sexes. Effect size was calculated as Cohen's *d*. Pearson's *r* evaluated the relationships between absolute and relative strength and the LnRHI. Alpha level was set to .05 for all statistical tests. **RESULTS:** Males' LnRHI was significantly lower than females' (0.36 ± 0.12 vs. 0.84 ± 0.22); $t(5.739) = -4.462, p = .005, d = -2.61$

and abnormal according to the manufacturer (LnRHI > 0.51 is normal and ≤ 0.51 is abnormal). There were significant, moderate, and negative correlations between the 1-RM and the LnRHI ($r = -.60, p = .03$) and between the bench press to body weight ratio and the LnRHI ($r = -.66, p = .01$). **CONCLUSIONS:** Endothelial function was lower in males than in females reporting chronic resistance activity and minimal CRE activity. Males who develop considerable upper-body strength via chronic resistance activity may exhibit endothelial dysfunction as young adults. More research is warranted.

Vascular And Blood Flow Responses To Upper Limb Exercise In Individuals With Posttraumatic Stress Disorder

Jennifer B. Weggen¹, Aaron S. Autler¹, Gina Tuzzolo¹, Austin C. Hogwood², Ashley M. Darling¹, Kevin P. Decker¹, Ryan S. Garten¹. ¹Virginia Commonwealth University, Richmond, VA. ²University of Virginia, Charlottesville, VA.
Email: weggenjb@vcu.edu
(No relevant relationships reported)

The physiological manifestations of posttraumatic stress disorder (PTSD) have been associated with an increase in risk of cardiovascular disease (CVD) independent of negative lifestyle factors. Peripheral vascular dysfunction may be a mechanism by which PTSD increases CVD risk. **PURPOSE:** This study sought to determine if blood flow regulation and peripheral vascular function are altered during exercise in individuals with PTSD when compared to age-matched controls. **METHODS:** Sixteen individuals with PTSD (10 women, 6 men; age 24 ± 4 years), and twenty-four age- and sex-matched healthy controls (CTRL); 15 women, 9 men, 24 ± 4 years, participated in the study. Upper limb vascular function and blood flow was assessed during rhythmic, progressive handgrip exercise (at rest, 3 and 6 kilograms (kg)) with Doppler ultrasonography. Exercise-induced changes in mean arterial pressure (MAP), brachial artery (BA) flow mediated dilation (normalized for BA shear rate), BA blood flow, and arm vascular conductance (VC) were quantified at each workload. **RESULTS:** Although no significance was noted in MAP, BA flow mediated dilation, or blood flow between groups, the PTSD group reported significantly lower VC at the highest exercise workload (6 kg - PTSD: 2.04 ± 0.9; CTRL: 2.87 ± 1.0 mL·min⁻¹·mmHg⁻¹; $p = 0.008$), when compared to the CTRL group. **CONCLUSION:** This study revealed that individuals with PTSD reported lower vascular conductance during upper limb arm exercise when compared to healthy controls. Further research is needed to determine if this finding translates to larger muscle mass exercise, potentially leading to exercise intolerance, as well as the potential mechanisms may be driving this dysfunction in individuals with PTSD, such as augmented sympathetic activity during exercise and/or microvascular dysfunction.

Impaired Cardiovascular Responses To Acute Exercise In Adults With Cerebral Palsy

Gustavo Aldama, Allison T. Bui, Ramon C. Ronquillo, Areum K. Jensen. San Jose State University, San Jose, CA.
(No relevant relationships reported)

Cerebral palsy (CP) is a non-progressive and permanent neurological disorder leading to musculoskeletal dysfunction and immobility. A major clinical problem with CP is early development of cardiovascular diseases with increased rates of mortality. Due to the inevitability of motor dysfunction adults with CP can develop health risk factors, such as obesity and hypertension, at a higher rate compared to the general population. To date, the physiological basis for CP has not been established; how cardiovascular dynamics, such as heart rate (HR), blood pressure (BP), and blood flow (BF), are controlled in individuals with CP has never been identified. **PURPOSE:** To determine differential cardiovascular responses to acute dynamic exercise in adults with CP. **METHODS:** Total of ten adults with and without CP participated in the study. HR from ECG, beat-to-beat arterial BP from Finapres and brachial BP, and respiration via pneumobelt were continuously measured before, during and after 2 minutes of dynamic handgrip exercise at 35% and 50% of maximal voluntary contraction. In addition, diameter, blood velocity, and flow of the brachial artery were measured using Doppler ultrasound on the contracting arm throughout the experiment. **RESULTS:** HR was significantly increased to exercise from rest in both groups with no group differences ($\Delta 9.8 \pm 1.2$ control vs. $\Delta 10.1 \pm 8.4$ CP, bpm). Both control and CP groups had increases in BF during exercise compared to at rest ($\Delta 132 \pm 22$ control vs. $\Delta 75 \pm 32$ CP, ml/min). Mean BP was significantly increased to exercise from rest in control; however, there were only minor changes in BP to exercise from rest in CP group ($\Delta 7.2 \pm 1.6$ control, $\Delta 2.2 \pm 0.1$ CP, mmHg). **CONCLUSION:** While HR and BF increased to exercise from rest in similar fashion, BP did not change to exercise in adults with CP. Our preliminary data speculate that other mechanisms, possibly vascular contribution from non-contracting limbs, may contribute to impaired BP response during exercise in CP. VALIDATION OF HEART-FEMORAL PULSE WAVE VELOCITY AS A MEASURE OF CENTRAL ARTERIAL STIFFNESS
 Lewis Fanney¹, Elizabeth Kelsch¹, Katie Burnet¹, Gabe Zieff¹, Daniel Credeur², Keeron Stone³, Craig Paterson³, Simon Fryer³, Lee Stoner, FACSM¹. ¹UNC Chapel Hill, Chapel Hill, NC. ²University of Southern Mississippi, Hattiesburg, MS. ³University of Gloucestershire, Gloucester, United Kingdom. (Sponsor: Lee Stoner, FACSM)
 (No relevant relationships reported)

BACKGROUND: Central Pulse Wave Velocity (PWV) is the gold-standard measure of arterial stiffness and an important clinical parameter for evaluating cardiovascular risk. The most frequently used measure of central PWV is carotid-femoral PWV (cfPWV); however, cfPWV may be unsuitable for use in patients who are obese, have had an ischemic stroke, or those with advanced carotid artery atherosclerosis. A potential alternative is heart-femoral PWV (hfPWV), which is simpler to conduct as the measurement does not require assessment of the carotid artery. The aims of this study were to determine (1) the strength of the association between cfPWV and hfPWV; and (2) determine whether change in cfPWV is associated with change in hfPWV. **METHODS:** Thirty healthy participants (23.5 y ± 2.9, 53% F, BMI 24.1 ± 2.3) were recruited for Aim 1, and 20 participants (24.1 ± 3.1, 55% F, BMI 23.9 ± 2.5) for Aim 2. Using Doppler ultrasound, cfPWV was measured using the foot-foot method on ECG-gated doppler waveforms captured from the common carotid and superficial femoral arteries. hfPWV was measured using the R wave to the foot of the superficial femoral artery doppler waveform. To induce change in cfPWV (Aim 2) the upper leg was occluded to 60 mm Hg. To estimate inter-individual associations between cfPWV and hfPWV (Aim 1), Pearson's product moment correlation was used. To estimate intra-individual associations between change (cuff vs. baseline) in cfPWV and change in hfPWV (Aim 2), the repeated measures correlation package for R was used. **RESULTS:** There was a large positive correlation ($r = 0.72$, 95% CI 0.48-0.86, $P < 0.001$.) between hfPWV and cfPWV (Aim 1). There was also a large positive correlation between change in cfPWV and change in hfPWV ($r = 0.83$, 95% CI 0.61-0.93, $P < 0.001$). **CONCLUSION:** The current findings indicate that cfPWV and hfPWV are strongly associated, and that change in cfPWV is strongly associated with change in hfPWV.

Exaggerated Pulsatility During Exercise Is Associated With Reduced Muscle Strength And Quality In Elderly Hypertensives
 Stephen Fischer, Arun Maharaj, Arturo Figueroa, FACSM. *Texas Tech University, Lubbock, TX.* (Sponsor: Arturo Figueroa, FACSM)
 Email: stephen.fischer@ttu.edu
 (No relevant relationships reported)

It is well-established that hypertensive individuals have an exaggerated systolic blood pressure in response to exercise. Leg muscle weakness is related to greater left ventricular (LV) mass in hypertensive individuals via exaggerated increases in blood pressure during aerobic exercise. Pulse pressure (PP) is an indicator of LV pulsatile hemodynamic load. Increased PP is associated with LV hypertrophy and dysfunction in older adults. **PURPOSE:** To determine differences in PP responses to resistance exercise in normotensive versus hypertensive older adults and the influence of lean mass and strength on these responses. **METHODS:** Nine normotensive (NTN) and 11 hypertensive (HTN) older adults (NTN aged 66 ± 3, HTN aged 68 ± 5) performed plantar flexion exercise at progressively increasing intensities (5, 15 and 30% of estimated calf flexion 1RM). During exercise, blood pressure was recorded in the right arm using an automated oscillometric device. Body composition was measured using dual-energy x-ray absorptiometry. Leg strength was measured using the leg press 10 repetition maximum (10RM). Leg muscle quality (LMQ) was calculated as leg strength (kg)/leg lean mass (kg). **RESULTS:** PP response to plantar flexion exercise at 30% of 1RM was significantly greater in the HTN (15 ± 1 mmHg) compared to NTN (6 ± 4 mmHg, $p = .02$). LMQ was significantly greater in the NTN (5.85 ± .75 kg/kg) compared to the HTN (5.00 ± 1.0 kg/kg, $p = .05$). Leg lean mass was not significantly different between groups. PP response at 30% was negatively correlated with LMQ ($r = -.570$, $p = .009$) and leg strength ($r = -.465$, $p = .039$). **CONCLUSIONS:** Hypertensive older adults have a greater pulse pressure response to calf flexion exercise when compared to normotensives. Reduced leg muscle strength and quality, but not mass, may contribute to the exaggerated pulse pressure response to calf flexion exercise in older adults with hypertension.

Endothelial Function Contributes To Acute Changes In Pulse Wave Velocity
 Kathleen Stanford¹, Jade Blackwell¹, Daniel Credeur², Jake Diana¹, Craig Paterson³, Keeron Stone³, Gabriel Zieff³, Simon Fryer³, Lee Stoner, FACSM¹. ¹University of North Carolina at Chapel Hill, Chapel Hill, NC. ²University of Southern Mississippi, Hattiesburg, NC. ³University of Gloucestershire, Gloucester, United Kingdom. (Sponsor: Lee Stoner, FACSM, FACSM)
 (No relevant relationships reported)

BACKGROUND: Pulse-wave velocity (PWV) can potentially be used to assess acute change in endothelial function. Previous studies have reported that increasing or decreasing nitric oxide bioavailability results in reciprocal changes to PWV. However, nitric oxide is not the only molecule regulating endothelial function and at this time, no in-vivo studies have examined whether PWV changes in acute, non-specific endothelial dysfunction. **PURPOSE:** Determine effects of acute endothelial dysfunction on PWV. In this study, retrograde shear stress was induced by increasing retrograde flow for 30 minutes. Our hypothesis is that acute endothelial dysfunction will result in decreased in PWV. **METHODS:** Twenty-two young, healthy adults (23.8 years [SD 4.1], 16 F, BMI 22.8 kg/m² [SD 2.8]) were recruited. PWV and flow-mediated dilation (FMD) were measured at baseline and immediately following the endothelial dysfunction protocol. FMD was measured to confirm the presence of endothelial dysfunction. PWV was measured between the upper arm and wrist using an oscillometric device, and brachial FMD using ultrasound. The association between PWV and FMD was assessed using Pearson's product moment correlation. Linear mixed models were used to assess baseline versus endothelial dysfunction protocol changes in PWV and FMD, controlling for within-subject changes in mean arterial pressure and the shear rate area under the curve, respectively. **RESULTS:** At baseline, there was a large association between FMD and PWV ($r = 0.60$, 95%CI: 0.23, 0.81). Following the endothelial dysfunction protocol, there was a moderate significant increase in PWV ($\Delta = 0.38$ m/s, 95%CI: 0.07, 0.69, ES = 0.5) and a large significant decrease ($\Delta = -3.10$, 95%CI: -4.15, -2.05, ES = -1.3) in FMD. **CONCLUSIONS:** Acute change in PWV is at least partially driven by changes in endothelial function, indicating that PWV could be a useful tool for assessing endothelial function changes.

Validation Of Flow-mediated Slowing As A Measure Of Endothelial Function
 Alex N. Pomeroy¹, Keeron Stone², Jade Blackwell¹, Jake C. Diana¹, Simon Fryer², Daniel Credeur³, Craig Paterson², Gabriel Zieff³, Lee Stoner, FACSM¹. ¹University of North Carolina at Chapel Hill, Chapel Hill, NC. ²University of Gloucestershire, Gloucester, United Kingdom. ³University of Southern Mississippi, Hattiesburg, MS. (Sponsor: Lee Stoner, FACSM)
 (No relevant relationships reported)

BACKGROUND: Flow-Mediated Slowing (FMS) is a potentially simple, automated and user-objective test for assessing endothelial function. FMS can be defined as the minimum pulse wave velocity (PWV_{min}) during reactive hyperemia. **PURPOSE:** The purpose of this study was to determine the effects of acute endothelial dysfunction on PWV_{min}. It was hypothesized that endothelial dysfunction would increase PWV_{min}. **METHODS:** 22 young, healthy adults (23.8 yrs ± 4.1, 73% F, 22.8 kg/m² ± 2.8) underwent simultaneous assessment of Flow-Mediated Dilation (FMD) and PWV_{min} at baseline and immediately following 30min of an endothelial dysfunction protocol. FMD is the current gold-standard test of endothelial function and was used to confirm endothelial dysfunction. Endothelial dysfunction was induced by increasing retrograde shear stress in the brachial artery via inflation of a pneumatic tourniquet to 75 mm Hg around the forearm. PWV was measured from the upper-arm to the wrist using an oscillometric-based device, and brachial FMD was measured using duplex Doppler ultrasound. FMD (%) was calculated as the mean increase in diameter during reactive hyperemia, and PWV_{min} as the minimum pulse wave velocity during reactive hyperemia. Linear mixed models were used to assess baseline versus endothelial dysfunction changes in PWV_{min} and FMD, controlling for within-subject changes in mean arterial pressure. Inter-individual associations between baseline PWV_{min} and FMD were examined using Pearson's product moment correlation, and intra-individual associations between change (baseline vs. endothelial dysfunction) in PWV and change in FMD using the repeated measures correlation package for R. **RESULTS:** The endothelial dysfunction protocol resulted in large effect size (ES) decrease in FMD ($\Delta = -3.10$, 95%CI: -4.15, -2.05, ES = -1.3), and a moderate significant

increase in PWV_{min} ($\Delta = 0.16$, 95%CI: 0.05, 0.28, ES = 0.6). There was a moderate inter-individual association between FMD and PWV_{min} ($r = 0.46$), and a large intra-individual association between FMD and PWV_{min} ($r = -0.61$). **CONCLUSIONS:** Acute changes in PWV_{min} may be a user-objective, automated, and viable tool for monitoring acute changes in endothelial function.

Can Racial Differences In Endothelial Dysfunction Be Explained By Mirnas?

Dulce H. Gomez, Maitha Aldokhayyil, Adelola Adeyemo, Michael D. Brown, FACSM. *Auburn University, Auburn, AL.* (Sponsor: Michael D. Brown, FACSM)
Email: dhg0008@auburn.edu
(No relevant relationships reported)

MicroRNAs (miRs) are short noncoding RNAs that regulate gene expression post-transcriptionally. It is well documented that exercise improves endothelial function, possibly, by modifying flow-responsive miR expression (e.g. miRs-126*, -92-a and -21). miR-126* is an anti-atherogenic miR that regulates vascular integrity, angiogenesis, and inflammation. Whereas, miR-92a and -21 are pro-atherogenic miRs that result in a reduction in endothelial nitric oxide synthase (eNOS) activity. miR-92a targets the transcription factor Kruppel-like factor 4 (KLF4) leading to lower eNOS expression. Whereas miR-21 targets phosphatase and tensin homologue (PTEN) to inhibit activation of the PI3K/Akt signaling pathway involved in activating eNOS. We have shown that African Americans (AA) exhibit a low grade of chronic systemic inflammation, exaggerated response to inflammatory cytokines, and a higher prevalence of endothelial dysfunction compared to Caucasians (CA). **PURPOSE:** To investigate potential racial differences in miRs expression and downstream target proteins in activated endothelial cells (EC).

METHODS: Human Umbilical Vein Endothelial Cells ($n=6$ cell lines; 3 CA & 3 AA) were cultured under two conditions: Control or TNF- α (10 ng/mL) for 4 hours. Protein expression was measured for PTEN, KLF4, p-eNOS^{ser-117} and eNOS. Total RNA was harvested to measure miR-21, miR-126*, and miR92a. A two-way ANOVA was used to assess the effects of race and condition.

RESULTS: No racial differences were found in protein expression of PTEN, KLF4, and eNOS at baseline or with TNF- α stimulation. AA had lower p-eNOS expression ($p=0.008$) compared to CA ECs under both conditions. No racial differences were found in miR-126 and miR-21 in either condition. However, AA were trending towards higher miR-92a expression ($p=0.07$) compared to CA ECs under both conditions.

CONCLUSIONS: Although we show significantly lower levels of p-eNOS and higher miR-92a expression in activated ECs of AA compared to CA, KLF4 protein levels were not significantly different. Therefore, the specific miRs studied do not explain the racial differences observed in endothelial dysfunction in an inflammation model. Future research should investigate potential racial differences in how miRs respond to high laminar shear stress, as an exercise mimetic.

Acute Hypotension Blunts Brachial Flow-mediated Dilatation In Young Healthy Men

Yutaka Yamada¹, Erika Iwamoto¹, Rintaro Sakamoto¹, Toru Neki¹, Jun Sugawara², Masaki Katayose¹, Shigehiko Ogoh, FACSM³. ¹Sapporo Medical University, Sapporo, Japan. ²National Institute of Advanced Industrial Science and Technology, Tsukuba, Japan. ³Toyo University, Kawagoe, Japan.
Email: yutaka.y.swim.8842@outlook.jp
(No relevant relationships reported)

Recent clinical studies using a vasovagal syncope suggest that endothelial function is a key factor controlling blood pressure (BP) regulation during acute hypotension. Acute increase in BP is known to attenuate brachial flow-mediated dilatation (FMD). However, the influence of acute hypotension on peripheral FMD remains unclear.

PURPOSE: To test the hypothesis that acute hypotension blunts brachial FMD, an index of endothelial function, in young healthy humans. **METHODS:** Twelve healthy men (21.8 \pm 1.6 yrs; body mass index: 22.2 \pm 1.6 kg/m², mean \pm standard deviation) underwent 3 trials of brachial FMD measurement. The trials involved a standardized FMD protocol (control trial), a trial with an abrupt decrease in BP via both thigh-cuff inflation and the deflation method (hypotension trial), and a trial with a decrease in shear rate (SR) via a shortened occlusion time for 3 min without a change in BP (SR reduction trial). Trials were randomized with 30-min intervals during a single visit. Duplex ultrasound was employed to measure brachial diameter and blood velocity. BP and heart rate were continuously measured using a non-invasive beat-to-beat BP monitoring system. To adjust the effect of SR area under the curve (SR_{AUC}) on FMD, normalized FMD were calculated.

RESULTS: There was a marked fall in mean arterial pressure during reactive hyperemia in the hypotension trial (-24 ± 6 mmHg), but not in the control and SR reduction trials. SR_{AUC} was attenuated in the SR reduction trial ($p<0.001$), but not in the hypotension trial ($p=0.316$), compared with the control trial. Thus, FMD was

attenuated in the hypotension and SR reduction trials compared with the control trial ($p=0.003$ and $p=0.043$, respectively). The attenuation in FMD was greater in the hypotension trial than in the SR reduction trial ($p=0.006$; control, 6.9% \pm 3.5%; hypotension, 3.5% \pm 1.7%; SR reduction, 5.0% \pm 2.2%). After adjusting FMD using SR_{AUC}, the normalized FMD remained attenuated in the hypotension trial ($p=0.014$), but not in the SR reduction trial ($p>0.05$). **CONCLUSION:** Current findings indicate that BP could be an important determinant of FMD. Blunted FMD of the peripheral arteries may be a physiological response to restore BP and/or prevent a further reduction in BP following acute hypotension in healthy humans.

The Association Between Physical Inactivity And Vascular Dysfunction May Be Related To Low Testosterone Concentrations

Matthew C. Babcock, Jennifer M. Blankenship, Ashley Brubaker, Teresa L. Witten, Kerry L. Hildreth, Kerrie L. Moreau. *University of Colorado Anschutz Medical Campus, Aurora, CO.* (Sponsor: William Farquhar, FACSM)
Email: matthew.babcock@cuanschutz.edu
(No relevant relationships reported)

Increased sitting time is associated with increased arterial stiffness, poor cardiometabolic health outcomes, increased risk of developing cardiovascular disease, and all-cause mortality. Further, excess sitting time likely reduces aerobic capacity and increases adiposity, which have been shown to be related to low testosterone (T) in young men. Low T has been linked to increased arterial stiffness, however, it remains unclear how T may contribute to the associations between physical inactivity, adiposity, aerobic capacity, and vascular health. **PURPOSE:** To determine the influence of T on the relationships between VO₂max, body composition, physical activity, endothelial function, and arterial stiffness. **METHODS:** 87 healthy male adults aged 18-75 years (mean \pm SD; 53 \pm 14 years, BMI=27.6 \pm 4.4 kg/m²) underwent VO₂max testing, physical activity monitoring (accelerometry), body composition (DXA), and vascular (endothelial function via brachial artery flow-mediated dilation, FMD; arterial stiffness via pulse wave velocity, PWV) testing. Serum T was measured under fasted conditions in the morning. **RESULTS:** Bivariate correlation analysis indicated that VO₂max ($p=0.003$, $R=0.33$), body fat ($p<0.001$, $R=-0.42$), sitting time ($p=0.020$, $R=-0.28$), PWV ($p=0.049$, $R=-0.22$), and FMD ($p=0.046$, $R=0.24$) were related to T concentrations. Body fat ($p<0.001$, $R=-0.39$), VO₂max ($p<0.001$, $R=0.41$), and sitting time ($p=0.029$, $R=0.24$) were correlated with PWV. Body fat ($p=0.001$, $R=0.44$) and VO₂max ($p=0.001$, $R=0.41$), but not sitting time ($p=0.185$, $R=-0.17$), were related to FMD. After controlling for T using partial correlation analysis, sitting time was no longer significantly related to PWV ($p=0.297$, $R=0.141$), however correlation coefficients between PWV and VO₂max or body fat were unchanged. **CONCLUSIONS:** These data indicate that the association between physical inactivity may be related to low T concentrations.

Preliminary Study Of Ethnic Differences In Hemodynamic Responses Following High Intensity Exercise: Wave Separation Analysis

Sang Ouk Wee, Rachel C. Reyes, Zhaojing Chen, Jason Ng. *California State University San Bernardino, SAN BERNARDINO, CA.*
Email: sangouk.wee@csusb.edu
(No relevant relationships reported)

The Hispanic population is at a high risk of developing cardiovascular disease (CVD), especially cerebrovascular disease. High blood pressure (BP) and inadequate BP regulation are related to future CVD events. Sympathoexcitatory stimulation through high intensity exercise temporarily increases risk of cardiovascular events and alters hemodynamics. It is unknown whether there is an ethnic difference in the regulation of BP and pulse wave characteristics—including forward or reflected pressure waves—between Hispanic and White populations. **PURPOSE:** To investigate the ethnic differences in BP and pulse wave characteristics measured with wave separation analysis in response to high intensity exercise. **METHODS:** 10 male volunteers (9 Hispanic; 23 \pm 3 yr, 1 White; 21 yr) completed the study. Aerobic capacity was measured by indirect calorimetry and a treadmill graded exercise test (GXT). Brachial BP was measured by an automated BP monitor. Central hemodynamic variables and pulse waves were obtained by tonometer at baseline, 15-minute, and 30-minute after high intensity treadmill exercise (GXT). Pulse waves were further separated into forward pulse height (FH) and reflected pulse height (RH) for analysis. A 2 x 3 repeated measure analysis of variance was performed to investigate ethnic differences in BP and pulse wave responses to high intensity exercise. **RESULTS:** (See table 1) There were no significant ethnic differences in brachial systolic BP, brachial diastolic BP, aortic systolic BP, aortic diastolic BP, and aortic mean arterial pressure ($p > 0.05$ for all). Furthermore, FH and RH were not statistically different between Hispanic and White males at rest and following high intensity exercise ($p > 0.05$). **CONCLUSION:**

Results suggest that blood pressure, forward and reflected pulse height exhibited similar at rest and following high intensity exercise in young, healthy, casually active Hispanic and white males.

Table 1. Blood pressure and pulse wave characteristic responses to high intensity exercise in

	Baseline	Hispanic (N = 9)		White (N = 1)		
		15 min post	30 min post	Baseline	15 min post	30 min post
Aortic SBP (mmHg)	98 ± 9	97 ± 9	94 ± 8	100 ± N/A	100 ± N/A	99 ± N/A

Age- And Sex-related Differences In Skeletal Muscle Oxygen Consumption Rate And Microvascular Reactivity

Hannah F. Bryan, Nile F. Banks, Emily M. Rogers, Claire M. Smith. *-Oklahoma State University, -Stillwater, OK.*

(No relevant relationships reported)

Purpose: To examine the influence of age and sex on non-invasive measurements of oxygen consumption rate and microvascular reactivity. **Methods:** Seven young females (YF; mean ± SD, age = 20.9±2 y), 6 older females (OF; 57.5±10 y), 14 younger males (YM; 22.2±2 y), and 8 older males (OM; 59.5±5 y) visited the laboratory on one occasion during which skeletal muscle oxygen utilization and microvascular function were assessed following a 10-h fast using the near-infrared spectroscopy with vascular occlusion test (NIRS-VOT). During the NIRS-VOT, tissue saturation (StO₂) was monitored, and the rate of decrease in StO₂ (Slope 1) during cuff inflation (i.e., ischemia) was quantified, as were the reperfusion magnitude (Rep_{MAG}), rate of increase in StO₂ (Slope 2), and the reperfusion area under the curve (StO_{2AUC}) following cuff deflation. Two-way (age × sex) ANOVAs were used to examine the differences in Slope 1, Rep_{MAG}, Slope 2, and StO_{2AUC} among the YW, OW, YM, and OM. Means ± 95% CIs are reported. **Results:** There were significant age and sex effects for Slope 1 ($p = 0.01$ and 0.02 , respectively), which was more negative (i.e., steeper) in males versus females (-0.132 ± 0.12 vs. -0.108 ± 0.15 %·s⁻¹) and in the young versus older adults (-0.133 ± 0.13 vs. -0.107 ± 0.14 %·s⁻¹). There was an age effect for Rep_{MAG} ($p < 0.001$), which was greater in the younger than older adults (50.7 ± 4.0 vs. 38.5 ± 4.6 %). While there was no effect of age on Slope 2, Slope 2 was steeper ($p = 0.002$) in males than females (1.71 ± 0.24 vs. 1.06 ± 0.34 %·s⁻¹). Finally, there were age ($p = 0.02$) and sex ($p = 0.03$) main effects for StO_{2AUC}, which was greater in males versus females (1228.5 ± 148.8 vs. 960.1 ± 178.9 %·s) and in the young versus older adults (1240.7 ± 148.8 vs. 947.9 ± 178.9 %·s). **Conclusions:** Overall, our results suggest that there are age and sex-related differences in skeletal muscle oxygen consumption rate and microvascular reactivity, as assessed using the NIRS-VOT technique. However, because the degree of tissue desaturation is the stimulus for subsequent reperfusion responses and the rate of desaturation was greater in the younger than older adults and in males than females, it is not clear if the differences in Slope 2 and StO_{2AUC} reflect differences in microvascular reactivity, per se. Additional studies are needed to more fully explore this interplay.

Altered Microvascular Reactivity In Young Healthy Adults With A Family History Of Hypertension

Evan L. Matthews¹, John J. Guers², Peter A. Hosick¹. ¹Montclair State University, Montclair, NJ. ²Rider University, Lawrenceville, NJ.

Email: matthewse@montclair.edu

(No relevant relationships reported)

Young healthy adults with a family history of hypertension (+FHH) display some of the phenotypic characteristics of adults with established hypertension. These similarities may serve as early warning signs for the development of hypertension, and therefore, should be examined. **Purpose:** To determine if, like hypertensives, normotensive +FHH adults display lower conduit artery function and microvascular reactivity than normotensive adults without a family history of hypertension (-FHH). **Methods:** Healthy normotensive adults self-reported if a first degree relative had been diagnosed with hypertension. A forearm vascular occlusion test was performed while resting in the supine position. An ultrasound probe placed on the brachial artery

above the occlusion cuff was used to assess flow mediated dilation (FMD); a test of conduit artery function. Simultaneously, a near infrared spectroscopy (NIRS) sensor placed on the anterior forearm measured skeletal muscle oxygen saturation (SmO₂). SmO₂ kinetics were examined to evaluate microvascular function. **RESULTS:** Twenty-one participants were included in this investigation (-FHH = 12, +FHH = 9). Groups were young (-FHH 24±5, +FHH 24±6yr; $p = 0.756$), with a non-significant trend towards higher mean arterial pressure in the +FHH group (-FHH 82±10, +FHH 89±8mmHg; $p = 0.082$). There were no group differences in baseline brachial artery diameter (-FHH 0.247±0.164, +FHH 0.325±0.119cm; $p = 0.234$), total shear (-FHH 53244±55326, +FHH 34430±36875AUC; $p = 0.384$), and vessel dilation (-FHH 6.92±4.55, +FHH 6.97±6.65Δ% $p = 0.984$). Baseline SmO₂ (-FHH 69±9, +FHH 64±13%; $p = 0.271$), and the 30s peak desaturation slope obtained during vascular occlusion (-FHH -0.38±0.12, +FHH -0.42±0.14%/s; $p = 0.393$), were also not different between groups. Following cuff release the resaturation slope (1st 10s, -FHH 2.90±1.96, +FHH 5.00±2.51%/s $p = 0.046$), and the SmO₂ overshoot (-FHH 1177±719, +FHH 2024±974AUC; $p = 0.029$) were greater in the +FHH group. **CONCLUSIONS:** Contrary to our hypothesis, the +FHH group displayed greater NIRS reperfusion microvascular reactivity than the -FHH group. This may be due to a greater perfusion pressure in the +FHH group as evidenced by a trend for greater mean arterial pressure.

Self-reported Sleep Habits Are Related To Arterial Stiffness In Apparently Healthy Individuals

Meral N. Culver, Sean P. Langan, Bryan L. Riemann, Andrew A. Flatt, Gregory J. Grosicki. *Georgia Southern University-Armstrong Campus, Savannah, GA.*

Email: mc28967@georgiasouthern.edu

(No relevant relationships reported)

Insufficient sleep is associated with cardiovascular disease. Whether this relationship is mediated through decrements in vascular function has yet to be fully elucidated. **Purpose:** This study investigated relationships between self-reported sleep habits and vascular health in apparently healthy individuals. **Methods:** Thirty-one individuals (14 females/17 males, 30±10 yrs, 24.7±3.2 kg/m²) free of cardiovascular disease, diabetes, and not using medications were enrolled. Subjective sleep habits were characterized using the Pittsburgh Sleep Quality Index to generate a composite score (PSQI score) ranging from 0 (better) to 21 (worse). Vascular health including brachial and aortic pressures, pulse pressure, and augmentation pressure (a measure of arterial stiffness) was quantified via arterial pressure waveforms. **Results:** Mean PSQI score was 4±3, where a score >5 is deemed to be "poor" sleep quality. Initial regression models for age, gender, body mass index, and PSQI score predicted ($P < 0.01$) pulse pressure (31.2±5.9 mmHg) and augmentation pressure (2.4±3.7 mmHg). The final model including only significant predictors for pulse pressure ($P < 0.01$, $R^2 = 0.38$) included PSQI score ($\beta = 0.47$, $P < 0.01$) and BMI ($\beta = 0.38$, $P = 0.02$). Meanwhile, the final model for augmentation pressure ($P < 0.01$, $R^2 = 0.31$) included PSQI score ($\beta = 0.34$, $P = 0.04$), BMI ($\beta = 0.36$, $P = 0.03$), and gender ($\beta = 0.46$, $P = 0.01$). PSQI score was not associated ($P > 0.05$) with brachial or aortic systolic (123±11 and 108±10 mmHg) or diastolic (76±9 and 77±9 mmHg) pressures. **Conclusions:** These data demonstrate that self-reported sleep habits, quantified via PSQI score, are related to indices of arterial stiffness (i.e., pulse pressure and augmentation pressure) in apparently healthy individuals. Large artery stiffening resulting from sleep deficiency may play a role in the development of hypertension and cardiovascular disease.

Mitochondrial Targeted Antioxidant Intake Improves Vascular Function And Exercise Tolerance In Peripheral Artery Disease Patients

Elizabeth J. Pekas, Won-Mok Son, Ronald J. Headid, III, TeSean K. Wooden, Song-Young Park. *The University of Nebraska at Omaha, Omaha, NE.*

Email: lizpekas@unomaha.edu

(No relevant relationships reported)

Peripheral artery disease (PAD) is a manifestation of atherosclerosis in the lower leg arteries, which causes reduced blood flow and leg pain. This may be in part due to excessive mitochondria-produced reactive oxygen species (ROS) and attenuated mitochondrial respiratory function. Mitoquinol mesylate, a mitochondrial-targeted antioxidant, has been shown to scavenge ROS and improve vascular function in older adults and animal models. However, the impacts of mitoquinol on vascular function in patients with PAD are unknown. **Purpose:** To examine the impacts of acute mitoquinol intake (80mg) on endothelial function (flow mediated dilation, FMD), resting heart rate (RHR), blood pressure (BP), arterial stiffness (pulse wave velocity, PWV), and exercise tolerance in patients with PAD. **Methods:** 10 patients with

PAD (stage II-III) received either mitoquinol or placebo in a randomized crossover design. At each visit, measurements of RHR, central and peripheral BP, brachial and popliteal artery FMD, PWV, augmentation index (AIx), maximal walking capacity, and time to claudication (COT) were measured before and after mitoquinol and placebo. **RESULTS:** There were significant group by time interactions ($p<0.05$) for brachial FMD, popliteal FMD, and COT, which significantly increased ($p<0.05$). There were trends for decreases in diastolic BP ($p=0.10$), carotid-to-ankle PWV ($p=0.08$), and increases in maximal walking time ($p=0.06$), and maximal walking distance ($p=0.06$). There were no changes in RHR, systolic BP, central BP, deceleration time, max dP/dt, carotid-to-radial PWV, carotid-to-femoral PWV, or AIx ($p>0.05$). **CONCLUSIONS:** Mitoquinol intake may be an effective strategy for targeting mitochondrial ROS, which may be useful for treating endothelial dysfunction, leg pain, and improving walking time in patients with PAD.

AUTONOMIC AND CARDIOVASCULAR RESPONSES TO ACUTE EXERCISES IN CHILDREN WITH AUTISM SPECTRUM DISORDER

Allison T. Bui, Gustavo Aldama, Ashley J. Castle, Kauionalani P. Kekuawela, Jacob A. Manriquez, Areum K. Jensen. *San Jose State University, San Jose, CA.*
(No relevant relationships reported)

Autism Spectrum Disorder (ASD) is a complex neurological disorder identified in early childhood and is characterized by impaired social interaction and atypical behaviors. Limited studies reported that children with ASD tend to have higher heart rate (HR) and blood pressure (BP) at rest compared to typically developing children (TDC). Previously, we reported that HR and blood flow (BF) did not alter while BP increased from rest to acute exercise in ASD. Thus, we thought that ASD may have impaired autonomic nervous system activity to differentially control HR and stroke volume (SV) to regulate BP through changes in cardiac output. **PURPOSE:** To determine autonomic and cardiovascular responses to acute dynamic exercise in children with ASD. **METHODS:** 36 adults, TDC and children with ASD participated in the study. HR from ECG, beat to beat arterial BP from Finapres and brachial BP, and SV from Modelflow, were continuously measured before, during and after 2 minutes of dynamic handgrip exercise at 35% and 50% of maximal voluntary contraction. Diameter, blood velocity, and flow of the brachial artery were measured using Doppler ultrasound on the contracting arm throughout the experiment. Time and frequency domains of HR variability indexes were used. **RESULTS:** Mean BP was significantly increased to exercise from rest in all groups with no group differences ($\Delta 9.8 \pm 1.8$ adults, $\Delta 8.3 \pm 1.2$ TDC, and $\Delta 6.9 \pm 1.8$ ASD, mmHg). HR was significantly increased to exercise from rest in adults and TDC; however, there was no change in HR to exercise from rest in ASD ($\Delta 11 \pm 1$ adults, $\Delta 7 \pm 1$ TDC, and $\Delta 1 \pm 1$ ASD, bpm). SV was unaltered from rest to exercise in all groups. Both adults and TDC had similar increase in BF during exercise compared to rest ($\Delta 17 \pm 3$ adults vs. $\Delta 14 \pm 2$ TDC cm/s); however, BF did not change from rest to exercise ($\Delta 0.6 \pm 2.2$ ASD cm/s) in ASD. The rMSSD and high frequency of HRV were similar in all groups while very low frequency HRV was significantly lower in ASD. **CONCLUSION:** While HR and BF were altered to exercise in both adults and TDC groups in similar fashion, HR and BF did not change in ASD children indicating impaired autonomic and vascular function. Higher total peripheral resistance may contribute to increase BP during exercise in ASD children without a significant contribution of cardiac output.

ET_B Receptor Responses In Young Women With A Family History Of Hypertension

Shane J. McGinty, Laura M. Welti, Andrew V. Kuczmarski, Sangeetha Nathaniel, Megan M. Wenner. *University of Delaware, Newark, DE.*
(No relevant relationships reported)

Endothelin-1 (ET-1) contributes to endothelial dysfunction, a primary driver of hypertension and cardiovascular disease. Young women with a family history of hypertension (+FH), a group at risk for developing hypertension, display elevated resting plasma ET-1. Our lab has previously shown that in healthy young women, the ET_B receptor mediates vasodilation. However, the function of ET_B receptors has yet to be determined in young women +FH. **PURPOSE:** The purpose of this study was to test the hypothesis that +FH young women display attenuated ET_B-mediated vasodilation. **METHODS:** Eight young women without a family history of hypertension (-FH; 23±2 yrs, 24±1 kg/m²) and 8 women +FH (23±2 yrs, 22±1 kg/m²) completed the study. Family history status was self-reported on a medical history questionnaire. Cutaneous vasodilatory responses to local heating were measured using laser doppler flowmetry during microdialysis perfusions of lactated Ringer's (Control) and ET_B receptor blockade (BQ-788, 300nM). Cutaneous vascular conductance (CVC) was calculated during the plateau phase of local heating (42°C), and normalized to maximal vasodilation achieved by perfusion of sodium nitroprusside (28mM) and heating to 43°C. A two-way ANOVA was performed to compare the impact of familial

history of hypertension on vasodilatory responses. Threshold for significance was set a priori at $P<0.05$. Data are presented as mean ± SEM. **RESULTS:** Resting mean arterial pressure (-FH: 80±3 vs. +FH: 85±2 mmHg, $P=0.25$) and plasma ET-1 (-FH, $n=5$: 1.2±0.2 vs. +FH, $n=6$: 1.5±0.2 pg/mL, $P=0.43$) were similar between groups. There was a trend for a significant group x time interaction for cutaneous vasodilatory responses (Drug: $P=0.33$, Group: $P=0.63$, Interaction: $P=0.09$); vasodilatory responses to Control tended to be lower in +FH (-FH: 95±1 vs. +FH: 89±4 %CVC max). Furthermore, blockade of ET_B receptors tended to reduce vasodilation in -FH (Control: 95±1 vs. 87±3 %CVC max) but not +FH (Control: 89±4 vs. 91±2 %CVC max). **CONCLUSION:** These preliminary data suggest that in young, otherwise healthy women, ET_B receptor function may be altered based on hypertensive family history status; however additional data are needed. Furthermore, data in +FH young men are needed given the known sex differences in the ET-1 system. Supported by: NIH R01 HL 146558, P20 GM 113125.

Higher Aortic Stiffness Is Related With Lower Physical Fitness In Older Adults

Lucimere Bohn, Alinne Nascimento, Duarte Barros, Joana Carvalho, José Oliveira. *Faculty of Sports, University of Porto, Porto, Portugal.*
Email: lucimerebohn@fade.up.pt
(No relevant relationships reported)

PURPOSE: To compare physical fitness levels according to arterial stiffness reference values in older adults. **METHODS:** This is a cross-sectional study comprising 156 (75.24 ± 6.5 years; 69.2% female) apparently healthy older adults. Carotid-femoral pulse wave velocity (cfPWV) was assessed through applanation tonometry and classified as $<$ or \geq 10 meters per second (m/s). Physical fitness was assessed through the Senior Fitness Test [cardiorespiratory fitness (6-Min Walk), agility (8-foot Up and Go), upper (30-second Arm Curl) and lower body strength (30-second Chair Stand), and flexibility tests (Chair Sit & Reach and Back Scratch)]. A Z-score including all physical fitness components was computed as a global index of physical fitness. Total physical activity was objectively measured and recorded as counts per minute. Between-group comparisons were performed through ANCOVA. **RESULTS:** Eighty-five (59.1%) of the subjects had cfPWVs \geq 10 m/s. After adjusting for age and total physical activity, compared to the cfPWV $<$ 10m/s group, the cfPWV \geq 10 m/s group exhibited significantly lower physical fitness scores (0.355 ± 0.074 vs. 0.076 ± 0.077 , respectively; $p = 0.017$). **CONCLUSION:** Seniors with higher levels of arterial stiffness present lower values of physical fitness. Strategies to improve physical fitness might be important to prevent the rapid augmentation of arterial stiffness.

Test-Reliability Of Blood Pressure Criteria For Defining An Exaggerated Blood Pressure Response To Exercise

Kayla M. Soave, Katharine D. Currie. *Michigan State University, East Lansing, MI.*
(No relevant relationships reported)

Exaggerated blood pressure responses (EBPR) during exercise are associated with increased risk of mortality. Due to the prognostic value of EBPR, it is important to evaluate the reliability of criteria used to define this response. **PURPOSE:** This study assessed the test-retest reliability of two different criteria used to define EBPR: the maximal systolic blood pressure (SBP) and the SBP/METs-slope which is the ratio of the change in SBP to the change in the metabolic equivalents of task (METs). **METHODS:** Twenty healthy, normotensive adults (8 males: 21±1 years, 12 females: 21±1 years) completed two identical modified Bruce treadmill tests on separate days. Blood pressure was measured using an automated motion-tolerant auscultatory device at rest (i.e., standing on treadmill) and during the last minute of each exercise stage. For each test, maximal SBP was identified, METs were estimated, and the change in these indices (i.e., maximal - rest) were calculated to determine the SBP/METs-slope. Test-retest reliability of the two criteria were assessed using intraclass correlation coefficients (ICC), with an ICC $>$ 0.60 considered reliable. **RESULTS:** Total exercise time was similar between visits (1000±123 s vs. 1005±128 s, $P=0.33$). Reliability of the EBPR criteria are presented as (ICC; 95% confident intervals). Maximal SBP (0.45; 0.02-0.74) and SBP/METs-slope (0.29; -0.16-0.64) were not reliable. Participants were then separated based on sex. In males, maximal SBP (0.85; 0.44-0.97) was reliable while the SBP/METs-slope only demonstrated moderate reliability (0.59; -0.13-0.90). In females, both maximal SBP and the SBP/METs-slope were not reliable (ICCs $<$ 0.17). Using the criteria of a maximal SBP 210 and 190 mmHg for males and females respectively, 50% of males and 33% of females had EBPR on both visits. **CONCLUSION:** Criteria used to define EBPR are only reliable in males. Further investigation is warranted to understand the potential sex effects on the SBP responses to maximal exercise testing.

Effects Of Resistance Exercise Training On Estradiol, Gh, Igf-1, Dhea-s, And Blood Pressure In Postmenopausal Women With Stage 1 HypertensionJung-Jun Park¹, Song-Young Park², Kook-Eun Seo¹, Liz Pekas², Won-Mok Son². ¹*Pusan National University, Busan, Korea, Republic of.* ²*University of Nebraska at Omaha, Omaha, NE.*
Email: jjparkpnu@pusan.ac.kr*(No relevant relationships reported)*

PURPOSE: Menopause is often accompanied by decreased estradiol, growth hormone (GH), insulin-like growth factor-1 (IGF-1) and dehydroepiandrosterone sulfate (DHEA-s) and increased blood pressure (BP), which may collectively increase risks for cardiovascular disease (CVD). It is important to combat the negative effects on estradiol, GH, IGF-1, DHEA-s, and BP by incorporating appropriate lifestyle interventions, such as exercise. We sought to examine the effects of resistance exercise training program on estradiol, GH, IGF-1, DHEA-s, and BP in postmenopausal with stage 1 hypertension.

METHODS: Postmenopausal women ($n=20$) were recruited and randomly assigned to a resistance exercise group (EX, $n=10$) or control group (CON, $n=10$). The EX group performed a total-body resistance band exercise training program for 12 weeks. Levels of estradiol, GH, IGF-1, DHEA-s, as well as BP were assessed before and after 12 weeks

RESULTS: There were significant group by time interactions ($p<0.05$) for estradiol ($\Delta 0.8\pm 0.0$), GH ($\Delta 0.5\pm 0.1$), IGF-1 ($\Delta 5.7\pm 1.2$), and DHEA-s ($\Delta 10.4\pm 5.5$) which significantly increased ($p<0.05$), and systolic BP ($\Delta 3.0\pm 1.7$) which significantly decreased ($p<0.05$) after exercise training compared to no changes in CON. There were no significant differences ($p>0.05$) in diastolic BP after 12 weeks

CONCLUSIONS: These results indicate that resistance exercise training may be an effective, easily accessible, and cost efficient intervention for improving estradiol, GH, IGF-1 and DHEA and decline BP in postmenopausal women with stage 1 hypertension

Blood Flow And Arterial Stiffness In Amputated Subjects.Anna Pedrinolla, Valentina Cavedon, Chiara Milanese, Massimo Venturelli. *University of Verona, Verona, Italy.*
Email: anna.pedrinolla@univr.it*(No relevant relationships reported)*

PURPOSE: To investigate arterial adaptations in amputated soccer players of the Italian National Amputated team. **METHODS:** Basal blood flow (BF, corrected for muscle volume), and pulse wave velocity (PWV) were measured in 11 amputated soccer players (35±13 years; 14±8 years from the amputation) of the Italian National Amputated team. BF and PWV were measured right and left-hand at carotid arteries, brachial arteries, radial arteries, common femoral arteries, and superficial femoral arteries. Basal BF and PWV of amputated limbs were compared with the non-amputated limbs. **RESULTS:** Basal BF was found to be reduced in amputated limbs compared with the contralateral non-amputated limbs (-30%, $p<0.05$). However, PWV was not found to be statistically different between amputated and non-amputated limbs (3%, $p=0.32$). **CONCLUSIONS:** Although an adaptation of basal BF seems to take place in amputated limbs, PWV seems to be unaltered in the amputated side in national soccer players. Since PWV reflects cardiovascular risk and vascular adaptation, based on this results we can speculate that soccer training served as a good stimulus to maintain vascular health even in amputated subjects.

3306 Board #127 May 29 2:30 PM - 4:00 PM

Reliability Of Non-invasive Vascular Function Tests And Their Responsiveness To A High-fat Meal In FemalesEmily M. Rogers, Nile F. Banks, Hannah F. Bryan, Claire M. Smith, Nathaniel D.M. Jenkins. *Oklahoma State University, Stillwater, OK.**(No relevant relationships reported)*

PURPOSE: To examine the reliability of non-invasive assessments of micro- and macrovascular function and their responsiveness to a high-fat meal (HFM) in females.

METHODS: During 2 visits (T1 and T2) separated by 28 ± 2 days, 11 women (age = 30.7 ± 17.2 y, BMI = 24.4 ± 3.1 kg/m²) consumed a standardized HFM (12 kcal/kg body weight; 63% fat) after a 10-h fast. Before (BL) and 3-h after the HFM, blood triglyceride (TG) levels were measured to quantify the lipemic response, and micro- and macrovascular function were assessed using the NIRS-VOT and FMD technique, respectively. During the NIRS-VOT assessment, the occlusion slope (Slope 1), the minimum tissue saturation (StO_{2MIN}), the reperfusion slope (Slope 2), and the reperfusion area under the curve (StO_{2AUC}) were calculated. Reliability was assessed

on BL values using one-way ANOVAs, intraclass correlation coefficients, and standard errors of measurement reported as coefficients of variation (CV). We also examined the responsiveness of each of the assessments to a HFM, as well as repeatability of the response by examining differences and relationships between the 3-h values at T1 and T2 for each of the variables. **RESULTS:** The reliability of each of the variables is reported in Table 1. All variables demonstrated moderate to strong relative reliability, although the CVs for TG, StO_{2MIN}, and FMD were moderately high. Interestingly, only TG responded to the HFM at 3-h. There were also no differences between the 3-h values at T1 versus T2 for any of the dependent variables (all $p > 0.05$), which were moderately to strongly ($r = 0.66 - 0.72$, $p \leq 0.04$) related, except for StO_{2AUC} and FMD ($r = 0.46 - 0.47$, $p \geq 0.16$). **CONCLUSION:** Each of the variables assessed displayed sufficient repeatability and were similarly (non-)responsive to a HFM before and after a 28-day period. Further, it appears that StO_{2AUC} and FMD may display lower absolute reliability and studies may require greater sample sizes when using these as outcomes in intervention studies.

	T1 Mean	T2 Mean	ICC (95% CI)	CV (%)	p-value
TG	104.0 ± 75.8	87.3 ± 40.9	0.757 (0.321 - 0.928)	31.4	0.221
Slope 1	-0.128 ± 0.03	-0.119 ± 0.03	0.578 (0.019 - 0.865)	17.4	0.385
StO _{2MIN}	28.0 ± 11.9	23.8 ± 12.2	0.577 (0.046 - 0.862)	29.7	0.231
Slope 2	1.10 ± 0.45	1.12 ± 0.48	0.688 (0.165 - 0.906)	24.2	0.820
StO _{2AUC}	1068.7 ± 368.6	1016.7 ± 355.9	0.645 (0.102 - 0.891)	20.9	0.592
FMD (%)	5.3 ± 3.3	5.0 ± 3.4	0.668 (0.134 - 0.899)	38.1	0.705

Impacts Of Prolonged Sitting With Mild Hypercapnia In Healthy AdultsRonald J. Headid, III, Elizabeth J. Pekas, TeSean K. Wooden, Won-Mok Son, Song-Young Park. *University of Nebraska at Omaha, Omaha, NE.*

Email: rheadid@unomaha.edu

(No relevant relationships reported)

Previous research suggests that prolonged sitting attenuates vascular function. It is common for people to sit for prolonged periods of time in places such as offices and classrooms which are accompanied by mild hypercapnic conditions due to poor ventilation. However, the effects of prolonged sitting with mild hypercapnic conditions on vascular function has not been investigated. **PURPOSE:** The purpose of this study is to investigate the responses in heart rate (HR), blood pressure (BP), vascular function, and autonomic function in healthy young adults to a single bout of prolonged sitting in mild hypercapnic conditions. **METHODS:** In a randomized crossover design, 12 subjects (6M/6F) sat for 2.5 hours in a control condition (PSIT) or a mild hypercapnic condition (HCAP, CO₂=1,500 ppm). During each visit, HR, central and peripheral BP, brachial and popliteal artery endothelial function (flow-mediated dilation, FMD), arterial stiffness (pulse-wave velocity (PWV), augmentation index (AIx)), and heart rate variability (HRV) were assessed before and after prolonged sitting. **RESULTS:** Both brachial and popliteal FMD were significantly reduced ($p<0.05$) in HCAP and PSIT, and the reduction in popliteal FMD was significantly greater in HCAP than PSIT ($p<0.05$). Additionally, there were trends for increased carotid-to-distal (cd) PWV ($p=0.083$) in HCAP compared to PSIT. HR was significantly reduced ($p<0.05$) and carotid-to-radial (cr) deceleration time (DT) and cdDT were significantly increased ($p<0.05$) in HCAP. There were also trends for reduced augmentation pressure (AP) ($p=0.07$) and LF/HF ratio ($p=0.09$). AP, AIx, AIx normalized to 75 beats per minute, and crAIx were all significantly reduced ($p<0.05$) in PSIT. There were no significant changes in BP and HRV in either group ($p>0.05$). **CONCLUSIONS:** These results indicate that prolonged sitting in mild hypercapnic conditions attenuate endothelial function to a greater extent than prolonged sitting in normal atmospheric conditions. Our findings suggest that mild hypercapnic conditions in our daily life exacerbate the negative effects of prolonged sitting.

Reproducibility Of The Impact Of Menstrual Phase On Arterial Stiffness Over Two Consecutive Menstrual Cycles

Lindsay A. Lew, Kaitlyn R. Liu, Amanda C. Byrne, Tarrah S. Ethier, Hashim Islam, Kyra E. Pyke. *Queen's University, Kingston, ON, Canada.*

(No relevant relationships reported)

Chronic increases in arterial stiffness are associated with increased risk of cardiovascular disease. Estrogen (E2), the primary female sex hormone, has been found to have cardioprotective effects, with several but not all, studies reporting a reduction in arterial stiffness in the late follicular (high E2; LF) phase compared to the early follicular (low E2; EF) phase of the menstrual cycle. Individual heterogeneity in the impact of phase on arterial stiffness and the consistency of these responses across consecutive cycles has yet to be explored. **PURPOSE:** to determine the impact of menstrual phase E2 fluctuations on arterial stiffness over two consecutive cycles. **METHODS:** 13 premenopausal women completed 4 experimental visits over 2 menstrual cycles (EF_{visit 1}, LF_{visit 2}, EF_{visit 3}, LF_{visit 4}). Central (CF) and peripheral (FF) PWV were measured twice during each visit using arterial tonometry. Participants were classified as positive, negative or non-responders, wherein positive responders experienced a reduction in PWV from EF to LF and negative responders experienced an increase in PWV from EF to LF that was greater than 2*typical error. **RESULTS:** At the group level, CF PWV did not differ between phases (p=0.11) or cycles (p=0.18; EF_{visit 1} =5.8±0.8, LF_{visit 2} =5.6±0.5, EF_{visit 3} =5.9±0.6, LF_{visit 4} =5.8±0.7). Likewise, FF PWV did not differ between phases (p=0.979) or cycles (p=0.58; EF_{visit 1} =8.1±1.0, LF_{visit 2} =8.1±1.1, EF_{visit 3} =7.9±1.4, LF_{visit 4} =8.0±1.3). Phase changes in E2 were not associated with phase changes in PWV in cycle 1 (CF: r=0.38, p=0.20; FF: r=0.11, p=0.73) or cycle 2 (FF: r=0.38, p=0.36). Classification of individuals as responders or non-responders revealed that no participants were consistently positive or negative responders for both cycles. **CONCLUSION:** At the group level, arterial stiffness was not impacted by menstrual phase over two cycles. Individual changes in arterial stiffness were inconsistent, with phase changes in cycle 1 not reflecting phase changes in cycle 2. Variability in phase changes in arterial stiffness does not appear to be driven by inter-individual differences in E2 fluctuation across phase. Future research is needed to investigate the mechanisms resulting in inter-individual variability in arterial stiffness and inconsistency between cycles.

The Impact Of CD146⁺ Serum Extracellular Vesicles On Recovery Of Skeletal Muscle Following Hindlimb Immobilization

Svyatoslav Dvoretzkiy, Yu-Fu Wu, Christian Konopka, Gabriela Garcia, Eric Jung, Megan Kalinowski, Noah Kim, Lawrence W. Dobrucki, Marni D. Boppart, FACSM. *University of Illinois at Urbana-Champaign, Urbana, IL.*
 Email: sdvoret@gmail.com

(No relevant relationships reported)

Our laboratory recently reported a significant decline in muscle-resident pericyte quantity following hindlimb immobilization, and subsequently demonstrated the capacity for pericyte transplantation to accelerate recovery of skeletal muscle mass during the rehabilitation period. **PURPOSE:** The purpose of this study was to determine the extent to which pericyte-derived extracellular vesicles (EVs) effectively recover skeletal muscle mass following hindlimb immobilization. **METHODS:** Two groups of donor mice (n=6/group) were used to isolate serum EVs before ("Pre") and after ("Post") an acute bout of contraction using a sciatic nerve stimulation procedure. Serum EVs were isolated using ultracentrifugation followed by magnetic bead sorting to isolate CD146⁺ EVs and CD146⁻ EVs. Five groups of mice (n=4/group) underwent unilateral hindlimb immobilization for 14 days. At 14 days, the mice were intramuscularly (tibialis anterior) injected with 1) PBS, 2) CD146⁺Pre EVs 3) CD146⁺Post EVs, 4) CD146⁻Pre EVs, or 5) CD146⁻Post EVs (in 40 µL of PBS), then remobilized for 2 weeks to determine therapeutic capacity. **RESULTS:** A significant decrease in serum CD146⁺ EVs was observed following 14 days of hindlimb immobilization (p<0.05). CD146⁻Post EVs demonstrated significant recovery of myofiber cross-sectional area compared to PBS control (p<0.05). CD146⁺Pre and CD146⁺Post EVs significantly restored capillary density compared to PBS control

(p<0.05). CD146-Pre EVs recovered capacity for collagen remodeling compared to PBS control (p<0.05). **CONCLUSIONS:** The results from this study suggest that CD146- serum EVs positively benefit regrowth of skeletal muscle following a period of disuse. Additionally, CD146⁺ serum EVs enhance skeletal muscle capillarization. Overall, a combination of both EV fractions may optimize recovery of skeletal muscle mass following disuse. Supported by NIH NIAMS R01 AR072735 (to MDB) and ACSM NASA Space Physiology Research Grant (to SD).

(No relevant relationships reported)

Purpose: To investigate and mechanistically link acute molecular changes in the mRNA transcriptome and splice variant profile, miRNA profile, DNA methylome, and histone acetylation profile to changes in performance from exercise training. **PHITE** will: (1) Reveal potential molecular mechanisms underlying training and detraining adaptations; (2) Differentiate molecular responses to moderate vs. high intensity training, and identify potential underpinnings of inter-individual response heterogeneity; (3) Perform a rigorous proof-of-concept epigenomic biomarker study that scales to and improves Navy physical training. **Methods:** This is an ongoing single-blind randomized trial of 18-27 y/o untrained adults. Participants are randomized to moderate or high intensity combined training 3 d/wk x 12 wk, followed by a 4-wk detraining period. Participants perform an acute exercise bout at wks 0 and 12 to assess acute molecular responses to exercise in untrained and trained states with serial biospecimen (muscle, blood) collections; repeated after 4 wk of detraining. Performance/phenotyping at wks 0 and 12 include aerobic power (VO_{2peak}), strength, anaerobic power, explosive power, body composition (DXA), and phenotyping of blood and muscle. Because the trial is ongoing, randomized assignment remains blinded as groups A and B. Blinded phenotyping data were analyzed using repeated measures ANOVA for the effects of time (T), dose (A vs. B) and dose x time interaction. **Results:** Phenotyping data on the first 51 completed participants confirm significant training effects and early indices of differential adaptations by exercise dose, along with substantial inter-individual response heterogeneity. Differential molecular mapping responses demonstrate sensitivity to exercise dose (A vs. B), timing of sample collection post-exercise, and training state (untrained vs trained vs detrained). **Conclusion:** Molecular response patterns to dose A vs. dose B share limited commonality, and differential responses across individuals provide novel preliminary evidence that dose-specific and individual-specific molecular response patterns may enable discrimination of adaptability.

Mitochondrial Biogenesis Is Dysregulated In Thyroid Hormone Depleted Muscle Cells Despite Stimulatory Effects Of Formoterol

Emily L. Zumbro, Gena D. Guerin, Ryan A. Gordon, Chase M. White, Dreanna M. McAdams, Matthew L. Sokoloski, David L. Nichols, FACSM, Anthony A. Duplanty. *Texas Woman's University, Denton, TX.* (Sponsor: David L. Nichols, FACSM)

(No relevant relationships reported)

Skeletal muscle (SKM) is an important regulator of metabolism and adaptations from exercise training influences mitochondrial function. Thyroid hormone (TH) is a regulator of SKM processes, including mitochondrial biogenesis.

PURPOSE: To use an in vitro model of hypothyroidism to test the hypothesis that SKM cells will have dysregulated mitochondrial homeostasis. Additionally, the exercise mimetic, formoterol, was used to determine the effects of exercise signaling on mitochondrial biogenesis.

METHODS: Human SKM myoblasts (n = 6 per group) were cultured and differentiated until mature myotube formation (Day 6). Groups included control cells (CON), TH depleted cells (ThD), and TH depleted cells plus formoterol stimulation (ThD+F; 30nM for 3h). Total RNA was extracted during mid-myogenesis (Day 4) and at terminal differentiation (Day 6). Gene expression for Peroxisome

Proliferator-Activated Receptor Gamma Coactivator-1 Alpha (PGC-1 α), Mitochondrial Transcription Factor A (TFAM), and Nuclear Respiratory Factor 1 (NRF1) was determined by qPCR. Data was analyzed by repeated measures ANOVA.

RESULTS: Significant differences between conditions and time points are detailed in Table 1.

CONCLUSION: ThD media resulted in reduced NRF1 signaling in both D4 and D6 with a subsequent decrease in D6 only for TFAM. Formoterol resulted in the expected stimulation of PGC-1 α at both D4 and D6, but subsequent signaling for genes associated with mitochondrial biogenesis common to PGC-1 α stimulation were lost as a result of TH depletion at D6 only for TFAM and both D4 and D6 for NRF1.

This work was supported by a Texas ACSM SRDA grant. Table 1.

Gene	Comparison	Fold Change	P Value
PGC-1 α	D4 ThD < D4 ThD+F	-4.6	<0.05

Age-dependent Skeletal Muscle Outcomes Following Resistance-type Training Improve With Pit1 Mutation And Training Frequency Modulation

Erik P. Rader, James Ensej, Marshall A. Naimo, Brent A. Baker. CDC/NIOSH, Morgantown, WV. (Sponsor: Stephen E. Alway, PhD, FACSM)

Email: wlz4@cdc.gov

(No relevant relationships reported)

Delayed aging in various tissues has been observed for Snell dwarf mice (*Pit1^{dw/dw}*) yet muscular performance has not been characterized for this model. **PURPOSE:** The purpose of the present study was to characterize muscle mass and performance for 3 months old and 12 months old Snell dwarf mice in non-trained and resistance-trained states. **METHODS:** Muscles of Snell dwarf mice and their wild-type littermates were exposed to 1 month of stretch-shortening contraction training. **RESULTS:** For non-trained muscles at both ages, muscles of Snell dwarf mice exhibited 70% less mass and 85% less isometric force relative to those of control mice. At young age, training 3 days per week had no effect regardless of mouse strain. With aging, 3 days per week training decreased muscle mass and isometric force by 12% and 25%, respectively, for control mice while no such decreases were observed for Snell dwarf mice. For control mice, training 2 days per week increased isometric force by 20% at young age with no training-induced decrements with aging. **CONCLUSIONS:** While Snell dwarf mice exhibit a trade-off between longevity and muscular performance, the *Pit1* mutation counters age-related maladaptation to training. For wild-type muscle, modulation of frequency is a means for offsetting the maladaptive training response.

Effects Of Angiotensin Receptor Blockade On Overload-induced Muscle Growth And Function In Mice

Kimberly Huey, FACSM¹, MacKenzie Temperly¹, Zachary Conroy¹, Ken Echevarria², Rudy Valentine². ¹Drake University, Des Moines, IA. ²Iowa State University, Ames, IA.

Email: kimberly.huey@drake.edu

(No relevant relationships reported)

Muscle hypertrophy induced by functional overload (FO) provides an *in vivo* model to study muscle growth. Angiotensin II (ANG II) has been associated with muscle

atrophy and reduced growth hormone levels while ANG II Receptor Blockers (ARBs) may protect against atrophy and restore insulin-like growth factor 1 (IGF-1) signaling. However, the effects of ARB during muscle growth is unclear. **PURPOSE:** It was hypothesized that ARB treatment would positively impact skeletal muscle growth as evidenced by greater hypertrophy, increased growth factor levels, and improved contractile function compared to placebo.

METHODS: Mice underwent FO of the plantaris or sham surgery. *In vivo* plantaris force and fatigue resistance (% of max force after 10 contractions) were measured 14 days after FO or sham in mice receiving daily candesartan (6 mg/kg body mass) or placebo (n=7-9/group). IGF-1 and fibroblast growth factor (FGF) were measured in the plantaris by ELISA. Data were analyzed with 2-way ANOVAs.

RESULTS: FO increased plantaris mass in both groups; however, ARB attenuated hypertrophy compared to placebo (Placebo: 13 \pm 0.5 vs. 26 \pm 2 mg and ARB: 13 \pm 0.6 vs. 20 \pm 1 mg, for sham and FO, respectively, p<0.05). Maximal force relative to body mass was unchanged with FO, independent of ARB. However, force tended to decrease only in placebo group with FO compared to sham. Fatigue resistance was increased with FO compared to sham, independent of treatment (Placebo: 53 \pm 6 vs. 65 \pm 5% and ARB: 48 \pm 4 vs. 61 \pm 4%, for sham and FO, respectively, p<0.05). Plantaris IGF-1 levels were increased with FO, with a significantly greater response in ARB than placebo (Placebo: 51 \pm 7 vs. 109 \pm 12 pg/mg protein and ARB: 36 \pm 3 vs. 148 \pm 17 pg/mg protein, for sham and FO, respectively, p<0.05). Plantaris FGF levels were increased with FO in ARB group only (Placebo: 788 \pm 88 vs. 901 \pm 88 pg/mg protein and ARB: 649 \pm 31 vs. 1075 \pm 104 pg/mg protein, for sham and FO, respectively, p<0.05).

CONCLUSIONS: The hypertrophic response to FO was attenuated with ARB in spite of greater IGF-1 and FGF responses compared to placebo. Comparing FO-associated changes in muscle force between treatments suggests ARB may positively impact muscle specific tension which could be associated with the augmented growth factor responses with ARB.

Skeletal Muscle Phenotype Is Augmented Through The Epigenomic Regulation Of Myogenic Transcription Factors

Marshall A. Naimo, James Ensej, Erik P. Rader, Brent A. Baker. CDC/NIOSH, Morgantown, WV. (Sponsor: Stephen E. Alway, PhD, FACSM)

Email: ydv5@cdc.gov

(No relevant relationships reported)

Purpose: Recently, a training-retraining (TRT) paradigm in which 3 month old rodents underwent an initial cycle of SSC RTET followed by another bout at 6 months led to increases in isometric/dynamic peak force and muscle mass relative to naïve 6 month old rats, thus augmenting the trainability of muscle into adulthood. However, the molecular underpinnings of this response is unknown. Therefore, we sought to determine whether this TRT paradigm has positive effects on transcription factor (TF) methylation and expression in adult skeletal muscle. **Methods:** F344xBN hybrid rats were SSC RTET on an *in vivo* dynamometer 3 days/week for 1 month at 3 months and again at 6 months of age (TRT), or just at 6 months (T). Gene expression and DNA methylation were quantified via PCR Arrays (Qiagen®). **Results:** TRT group had 17 significantly differentially expressed genes (SDEGs) in the TF pathway, including Myf5; T expressed only 3 SDEGs. TRT had decreased TF methylation compared to T (4.1 \pm 0.01 vs. 2.6 \pm 0.01%; p<0.05). **Conclusions:** Adaptive benefits at adulthood following an initial SSC RTET stimulus are supported by altered TF methylation and gene expression. These results advocate RTET at early life to preserve muscle as one ages through an epigenomic muscle memory.

Leucine Supplementation Exacerbates Atrophy In Cancer Cachectic Mice

Wesley S. Haynie, Kyle L. Rankin, Megan E. Rosa-Caldwell, Katarina A. Bejarano, Seongkyun Lim, Nicholas P. Greene, Tyrone A. Washington. University of Arkansas, Fayetteville, AR. (Sponsor: Nicholas Greene, FACSM)

(No relevant relationships reported)

Nearly 80% of cancer patients are afflicted with cachexia, which is defined by wasting of lean body mass and associated with increased morbidity and mortality. The amino acid leucine has been shown to promote muscle growth by augmenting protein synthesis through mTOR activation. Therefore, supplementation of leucine could prove beneficial for mitigating skeletal muscle wasting during cancer cachexia. **PURPOSE:** To determine the effect of leucine supplementation on cancer cachexia in APC^{Min/+} (APC) mice. **METHODS:** 18 male APC (n=9) and wildtype (WT, n=9) littermate mice were used in this study. Within each of these two groups, 4 were given water (NL) and 5 were given 1.5% leucine-supplemented water (L), with *ad libitum* access to food and water. Gastrocnemius (GA) muscle and tibias (TL) were extracted at ~14-21 weeks

of age—when mice became moribund. Muscle tissue was homogenized and analyzed for gene expression via RT-qPCR. Gene expression data were analyzed via Two-Way ANOVA, followed by a Fisher's LSD post-hoc to determine between group differences when significant F-ratios were found. The relative frequency of tumor polyp size was analyzed via a Student's t-test. Significance set at $p < 0.05$. **RESULTS:** Body weight for APC-NL mice was ~14% lower than both WT-NL and WT-L ($p < 0.05$). Body weight for APC-L mice was ~25% lower than all WT, and ~13% lower than APC-NL ($p < 0.05$). There were main effects of APC genotype and L supplementation for lower GA mass and GA/TL ($p < 0.05$). In APC mice, there was a ~20% increase in the relative frequency of polyps <1mm in diameter, and a ~15% decrease in the relative frequency of polyps 1-2mm in diameter due to L supplementation ($p < 0.05$). There was no difference in the relative frequency of polyps >2mm. There was a main effect for APC mice to have elevated expression of *IL-6*, *IL-1 β* , *Atrogin-1*, and *MuRF-1* when compared to WT mice ($p < 0.05$). **CONCLUSION:** Surprisingly, leucine supplementation appeared to exacerbate cancer cachexia. Cancer cachexia has previously shown marked increases in skeletal muscle atrophy, commonly through atrophy and inflammatory related markers such as *Atrogin-1*, *MuRF-1*, *IL-6* and *IL-1 β* . Leucine supplementation may not influence these markers directly, but may alter the cachectic environment to induce greater overall wasting.

Dysregulated Thyroid Hormone Metabolism Following Formoterol Stimulation In Thyroid Hormone Depleted Skeletal Muscle

Gena D. Guerin, Emily L. Zumbro, Ryan A. Gordon, Chase M. White, Dreanna M. McAdams, Matthew L. Sokoloski, David L. Nichols, FACSM, Anthony A. Duplanty. *Texas Woman's University, Denton, TX.* (Sponsor: David L. Nichols, FACSM) (No relevant relationships reported)

In skeletal muscle (SKM), signal transduction of thyroid hormone (TH) exerts subcellular downstream effects by influencing mechanisms of gene expression. People with hypothyroidism commonly experience SKM pain, fatigue, and intolerance to exercise, which may be driven by dysregulated TH metabolism.

Purpose: To use an in vitro model of hypothyroidism to test the hypothesis that SKM cells will have dysregulated TH metabolism. Additionally, the exercise mimetic, formoterol, was used to determine the effects of exercise signaling on TH depleted cells.

Methods: Human SKM myoblasts ($n = 6$ per group) were cultured and differentiated until mature myotube formation (Day 6). Groups included control cells (CON), TH depleted cells (ThD), and TH depleted cells plus formoterol stimulation (ThD+F; 30nM for 3h). Total RNA was extracted during mid-myogenesis (Day 4) and at terminal differentiation (Day 6). Gene expression for Thyroid Hormone Receptor Alpha (THR α), Deiodinase 2 (DIO2), and Deiodinase 3 (DIO3) was determined by qPCR. Data were analyzed by repeated measures ANOVA.

Results: Significant differences between conditions and time points are detailed in Table 1.

Conclusion: THR α was reduced by ThD and further decreased by ThD+F, suggesting that the combination of ThD+F is highly suppressive of this receptor. Intracellular activation of TH (T3) by DIO2 stimulates nuclear transcripts leading multiple cellular functions. Formoterol stimulation increased DIO2 but was decreased in the ThD group, indicating a potential lower availability of T3. Interestingly, DIO3 was also increased by formoterol stimulation, which could counteract availability of T3 via conversion to reverse T3. More research addressing hypothyroidism and exercise is warranted as there may be negative consequences regarding exercise mode and intensity. This work was supported by a Texas ACSM SRDA grant.

Mitochondrial Health During The Development Of Cancer Cachexia In Female Mice

Lauren C. Westervelt¹, Seongkyun Lim¹, Megan E. Rosa-Caldwell¹, Wesley S. Haynie¹, Kirsten R. Dunlap¹, Lisa T. Jansen¹, Michael P. Wiggs², Tyrone A. Washington¹, Nicholas P. Greene, FACSM¹. ¹University of Arkansas, Fayetteville, AR. ²University of Texas at Tyler, Tyler, TX. (Sponsor: Dr. Nicholas Greene, FACSM) Email: lcwester@uark.edu (No relevant relationships reported)

Cancer-cachexia is a syndrome characterized by weight loss, anemia, and skeletal muscle wasting. Muscle mass in males and females is a strong predictor of quality of life and morbidity during cancer treatment. Mitochondrial dysfunction during cancer-cachexia has been well described in males, specifically our laboratory has found mitochondrial deteriorations to precede muscle loss in male models of cachexia. However, if these aberrations are conserved between biological sexes has yet to be investigated. **PURPOSE:** To investigate muscle mitochondrial health during cancer-cachexia development in female mice. **METHODS:** ~40 female C57BL/6J mice were implanted with ~1X10⁶ Lewis Lung Carcinoma (LLC) cells in the right hind flank. Tumors were allowed to develop up to 4 weeks. After 3-4 weeks of tumor development, a clear dichotomy was noted in tumor burden. As such, tumor injected females were divided into high tumor (HT, tumor size > 2000 mg) and low tumor groups (LT, tumor size < 1300 mg). CON animals were age-matched to tumor mice and injected with phosphate buffered saline (PBS); therefore creating 3 experimental groups HT, LT, and CON ($n = 12-14$ /group). Mitochondrial health was measured by fluorescent histology of pMitoTimer. Results were analyzed by one-way ANOVA with Tukey's post hoc when significant F ratios were found ($p < 0.05$). **RESULTS:** Tibialis anterior, plantaris and gastrocnemius muscle masses were ~10%, ~11% and ~5% lower in HT compared to LT and CON. Analysis of pMitoTimer demonstrated no differences between groups. Circulating progesterone and estrogen were ~42% and ~60% lower in HT and LT animals compared to CON with no differences between HT and LT. **CONCLUSION:** LT had negligible muscle wasting when compared to HT, these differences in muscle loss did not correspond to alterations in mitochondrial health. This directly contrasts prior literature in male models of cancer-cachexia suggesting divergent mechanisms between males and females in the development of cancer-cachexia. As such, further examination of why females had a dichotomy in tumor development and subsequent wasting mechanisms are necessary in order to further understand mechanisms contributing to development of cancer-cachexia. A New Muscle Disuse Model Using A Removable Tissue-engineering Muscle

Takeshi Sugimoto¹, Shoma Imai², Koki Sakushima¹, Maki Yoshikawa¹, Toshiya Fujisato², Tomohiro Nakamura², Takeshi Hashimoto, FACSM¹. ¹Ritsumeikan University, Kusatsu, Shiga, Japan. ²Osaka Institute of Technology University, Osaka, Osaka, Japan. (Sponsor: Takeshi Hashimoto, FACSM)

(No relevant relationships reported)

PURPOSE: Physical inactivity and subsequent skeletal muscle disuse may cause muscle atrophy, which is associated with a reduction in muscle function, physical performance, quality of life, and loss of independence, particularly in elderly. Traditionally, 2D muscle cell cultures (e.g. C2C12) have been used to study biological processes and identify and validate pharmacological and/or nutritional compounds to treat skeletal muscle disease including muscle atrophy. However, cell culture studies basically use a pharmacological method to induce muscle atrophy, and not an actual muscle disuse induced by a reduction of mechanical stress (i.e., mechanical unloading). Previously Nakamura et al. (2017) developed 3D engineered muscle (OITem: Osaka institute technology engineered muscle) with artificial tendons at both ends of the muscle, which is removable, thereby allowing us to mechanically release muscle tension by taking off (removing) one side of the muscle. Therefore, the purpose of the present study was to investigate whether removable tissue-engineering muscle effectively induce muscle atrophy, and thus is useful for muscle disuse model.

METHODS: OITem was made from C2C12 skeletal muscle cells and a cold type-I collagen gel and placed between two artificial tendons (Nakamura et al., 2017). OITem was differentiated for 2-weeks and then divided into two groups: 1-week stretched on control group (CON: n = 6) in which the both ends of the muscle fixed with tendons, and 1-week stretched off group (OFF: n = 6) in which the one side of the muscle was removed. We analyzed expressions of muscle atrophy-related proteins MuRF-1 and Atrogin-1, and myogenesis-related protein myogenin using Western blotting. As well, we analyzed expression of MHC-fast or -slow (fast- or slow-twitch muscle fiber specific myosin heavy chain (MHC), respectively). **RESULTS:** The protein expression of MuRF-1 and myogenin was significantly lower in the OFF than those in the CON ($P < 0.05$). Moreover, the protein expression of MHC-fast and -slow was significantly lower in the OFF than those in the CON ($P < 0.01$). However, the protein expression of Atrogin-1 did not differ between two groups.

CONCLUSIONS: The present findings suggest that OITem may be useful model for muscle disuse.

(No relevant relationships reported)

Abstract

Extracellular matrix (ECM) remodeling in skeletal muscle is a potential mechanism linking obesity with metabolic dysfunction. It is also a constructive feature of skeletal muscle adaptation to exercise training.

Purpose: To test the hypothesis that skeletal muscle ECM remodeling associated with insulin resistance can be minimized by exercise training.

Methods: Six-week-old male C57/BL6J mice (n=48) were divided into two groups, high-fat (60% calories from fat) diet (HF, n=36) and normal chow-fed control (C, n=12) group. After 12 weeks of feeding, HF mice developed insulin resistance, as confirmed by insulin and glucose tolerance tests (ITT and GTT). HF mice were then randomly assigned to three groups: high-fat diet only group (HFS, n=12), high-fat diet + aerobic exercise group (HF+AE, n=12), high-fat diet + resistance training group (HF+RT, n=12). The HF+AE and HF+RT groups were subject to aerobic (treadmill running) and resistive (vertical ladder climbing) training, for 12 weeks. After training, gastrocnemius muscle was harvested and analyzed for ECM factors using immunohistochemistry, ECM PCR array, and western blotting. ANOVA was performed to test the significance of group differences at $p < 0.05$.

Results: High-fat feeding induced higher deposition of collagens (COL1, III and IV) in the skeletal muscle of HFS group, and increased gene and protein expression of MMP3, CDH1, ITGAL and SELL and decreased the expression of TIMP3 in HFS group, as compared to group C. These changes were minimized even reversed by either

aerobic or resistance exercise training (mRNA fold change relative to C in HF+AE and HF+RT vs. HFS: MMP3, 1.1 and 1.6 vs. 2.6; CDH1, 1.7 and 1.1 vs. 2.0; ITGAL, 1.9 and -1.0 vs. 2.0;

SELL, 1.4 and 1.0 vs. 2.1; TIMP3, 1.2 and -1.0 vs. -1.2; $p < 0.05$). These effects were accompanied by a significant improvement in insulin sensitivity (GTT AUC glucose in mmol/l x 120 min: C, 27.2±3.0; HFS, 39.7 ± 7.0; HF+AE, 32.4± 7.5; HF+RT, 30.3± 6.1; $p < 0.05$).

Conclusion: Both aerobic and resistive exercise training can minimize changes in skeletal muscle ECM associated with insulin resistance. Skeletal muscle ECM remodeling may play a significant role in mediating the metabolic benefits of exercise training.

Exercise Reverses Disuse Atrophy In Rat Gastrocnemius Muscle

Huayu Shang, Zhifei Ke, Jing Zhao. Chengdu Sport University, Chengdu, China. (Sponsor: Tongjian You, FACSM)

(No relevant relationships reported)

PURPOSE: To investigate the effects of different exercise interventions on disuse atrophy and atrophy-related proteins in rat gastrocnemius muscle.

METHODS: Male Sprague-Dawley rats were randomly divided into a control group (C, n=16) and a suspension group (T, n=40). Rats in the T group were suspended by a tail suspension system for two weeks. Rats in the C group were further divided into a post-suspension blank group (C1) and a post-exercise blank group (C2), and rats in the T group were further divided into a post-suspension control group (T1), a post-exercise control group (T2), an endurance exercise group (TA), a resistance exercise group (TR) and a combined endurance and resistance exercise group (TAR). Rats in the TA, TR, and TAR groups were subjected to exercise training for four weeks. Body weight and wet weight of gastrocnemius muscle were measured immediately after suspension or at 24 hours after the last training session. Protein expression levels of Muscle Ring Finger 1 (MURF1), Muscle Atrophy F-Box (MAFbx), Insulin-Like Growth Factor-1 (IGF-1) and CysteinyL Aspartate Specific Protease-3 (Caspase-3) in gastrocnemius muscle were determined by western blot. Student t-tests and one-way ANOVAs were used for data analysis.

RESULTS: After suspension, body weight and wet weight of gastrocnemius muscle in the T1 group were significantly lower than those in the C1 group ($p < 0.05$ to $p < 0.01$). After exercise intervention, body weight, wet weight of gastrocnemius muscle, and the protein expression levels of MAFbx in the TA, TR, and TAR groups were significantly higher than those in the T2 and C2 groups, the protein expression levels of Caspase-3 in the TA, TR and TAR groups were significantly lower than those in the T2 and C2 groups, and the protein expression levels of MURF1 in the TA and TR groups were significantly lower than those in the T2 group ($p < 0.05$ to $p < 0.01$).

CONCLUSIONS: Exercise interventions, such as endurance exercise, resistance exercise, and combined endurance and resistance exercise, can effectively reverse disuse atrophy of gastrocnemius muscle in rats, which may be through altering the expression levels of several atrophy-related proteins.

Resistance Exercise-Induced Hormone Change Promotes Autophagy Response In Untrained Women

Casey Robert Appell¹, Travis Rai¹, Matthew T. Stratton¹, Mohamed Fokar¹, Jakob Vingren, FACSM², Hui Ying Luk¹. ¹Texas Tech University, Lubbock, TX. ²University of North Texas, Denton, TX. (Sponsor: Jakob Vingren, FACSM)

Email: casey.appell@ttu.edu

(No relevant relationships reported)

Introduction: Autophagy is a catabolic process for maintaining skeletal muscle homeostasis by recycling malfunctioning protein aggregates. Evidence suggests that hormones (e.g., cortisol) promote autophagic activity in muscle cells; however, no prior study has examined the effect of resistance exercise (RE)-induced hormonal response on the autophagic response.

Purpose: To determine the effect of an acute RE-induced hormonal response on the autophagic response after muscle damage in untrained young women.

Methods: Untrained women (n=8, 20 ± 1y; height: 164.1 ± 9.2 cm; weight 60.7 ± 7.8 kg) completed 2 sessions of 80 unilateral maximal eccentric knee extensions followed by either an upper body RE protocol (EX; aimed to induce an increase in cortisol) or a 20-min rest (CON). Muscle samples were collected and analyzed for markers of autophagic initiation signaling (FOXO3A, AKT, MTOR), phagophore initiation (ATG5, ULK1, BECN1), elongation (ATG7, LC3A, LC3B), and autolysosomal degradation (SQSTM1/p62) by real-time PCR at before exercise (PRE), 12 hours (+12h) and 24 hours (+24h) after exercise.

Results: A significant ($p < 0.05$) time x condition effect was found for ULK1. At +24h (0.81 ± 0.26-fold), ULK1 gene expression was greater in EX than CON. A significant

time effect was found for FOXO3A. FOXO3A expression decreased at +12h (0.33 ± 0.07 -fold) and +24h (0.25 ± 0.07 -fold) from PRE. A trend was found for BECN1 ($p=0.055$) towards an increased in expression from PRE to +12h (1.94 ± 0.65 -fold). A significant time effect was found for the AUC of cortisol with a greater AUC of cortisol for EX than CON.

Conclusion: These results suggest that the RE-induced hormone response can be important to the initiation of the phagophore after muscle damage in untrained young women.

Myogenic Regulatory Factor Expression Is Downregulated Following Formoterol Stimulation In Thyroid Hormone Depleted Skeletal Muscle

Ryan A. Gordon, Gena D. Guerin, Emily L. Zumbro, Chase M. White, Dreanna M. McAdams, Matthew L. Sokoloski, David L. Nichols, FACSM, Anthony A. Duplanty. *Texas Woman's University, DENTON, TX.* (Sponsor: David L. Nichols, FACSM) *(No relevant relationships reported)*

In skeletal muscle (SKM), gene expression of transcription factors regulating myogenesis are dependent on thyroid hormone (TH) signal transduction. Expression of myogenic regulatory factors may be altered due to dysregulated TH metabolism, which may result in SKM dysfunction and intolerance to exercise in individuals with hypothyroidism.

PURPOSE: To use an in vitro model of hypothyroidism to test the hypothesis that SKM cells will have dysregulation in transcription factors regulating myogenesis. Additionally, the exercise mimetic, formoterol, was used to determine the effects of exercise signaling during myogenesis.

METHODS: Human SKM myoblasts ($n = 6$ per group) were cultured and differentiated until mature myotube formation (Day 6). Groups included control cells (CON), TH depleted cells (ThD), and TH depleted cells plus formoterol stimulation (ThD+F; 30nM for 3h). Total RNA was extracted during mid-myogenesis (Day 4) and at terminal differentiation (Day 6). Gene expression for myogenic regulatory factors (Myf5, MyoD, MyoG) was determined by qPCR. Data were analyzed by repeated measures ANOVA.

RESULTS: Significant differences between conditions and time points are detailed in Table 1.

CONCLUSION: TH depletion had no effect on MyoG but did reduce the expression of both Myf5 and MyoD at both D4 and D6. Additionally, ThD+F resulted in the lowest expression of MyoG and MyoD for both time points. These results indicate TH depletion and formoterol stimulation may inhibit myotube maturation.

This work was supported by a Texas ACSM SRDA grant.

The Immunoproteasome, A Potential Link To The Loss Of Muscle Mass In Diet-induced Obesity

Emma Fletcher, Paul M. Gordon, FACSM. *Baylor University, Waco, TX.*
Email: Emma_Fletcher1@Baylor.edu
(No relevant relationships reported)

PURPOSE: Obesity is associated with reductions in muscle mass and regeneration. Although chronic inflammation and oxidative stress may play a role, the way in which these processes regulate catabolism in obese muscle is unclear. Since the catalytic subunit of the immunoproteasome (LMP7) is increased in muscle of other atrophic diseases, we sought to determine the impact of diet-induced obesity (DIO) on muscle mass, LMP7 protein content, and regeneration in response to exercise-induced muscle damage (EIMD) in mice. Intramuscular levels of pro-(CD11b and CD38) and anti-(CD206 and EGR2) inflammatory macrophages and oxidative stress (8-isoprostane) were also assessed. **METHODS:** Sixty male C57BL/6J mice (4 weeks old) were randomly assigned to either a high-fat diet (HFD, 45% fat) or lean diet (LD, 10% fat). After 12 weeks of feeding, the mice were randomly subdivided into EIMD or non-exercise, no muscle damage (NMD) control groups. EIMD was achieved via a downhill treadmill run at 13-14m/min for 68min. The gastrocnemius muscle (GS) was excised 1 or 5 d after EIMD, resulting in 6 experimental groups ($n = 10$ /group) at study completion. **RESULTS:** Total body mass was greater (HFD $43.3 \pm .6$ g vs LD $30.8 \pm .6$ g, $p = .000$), however, GS mass relative to body mass was lower (HFD $4.1 \pm .1$ mg/g vs LD $5.3 \pm .1$ mg/g, $p = .000$) in mice with DIO. Despite no change in pro- or anti-inflammatory macrophages ($p > .05$), GS oxidative stress was increased in mice with DIO (HFD 46.0 ± 5.1 pg/ml, vs LD 29.2 ± 4.6 pg/ml, $p = .029$). Oxidative stress was enhanced 1 d post-EIMD, but only in DIO mice (HFD 77.9 ± 8.6 pg/ml vs LD 31.4 ± 3.3 pg/ml, $p = .015$). Muscle LMP7 was also elevated with DIO (HFD $3.6 \pm .2$ ng/ml vs LD $2.6 \pm .1$ ng/ml, $p = .000$), and increased 5 d post-EIMD ($3.5 \pm .2$ ng/ml) when compared to NMD ($2.7 \pm .1$ ng/ml, $p = .005$). However, the response of LMP7 to EIMD did not differ between obese or lean mice ($p = .504$). When controlling for muscle damage group assignment, LMP7 was correlated with 8-isoprostane ($r = .39$, $p = .027$) and both markers were inversely correlated with relative GS mass ($r = -.48$ (LMP7), $-.62$ (8-isoprostane), $p = .000$). Muscle regeneration (myogenic differentiation protein) was unaltered by DIO ($p = .741$) or EIMD ($p = .455$). **CONCLUSIONS:** The immunoproteasome may be a critical link between obesity-induced oxidative stress and diminished muscle mass.

An Evaluation Of Skeletal Muscle Aging Using A Novel Guinea Pig Model

Maureen A. Walsh, Robert V. Musci, Raoul F. Reiser, II, Kelly S. Santangelo, Karyn L. Hamilton, FACSM. *Colorado State University, Fort Collins, CO.* (Sponsor: Karyn Hamilton, FACSM)
Email: maureen.walsh@colostate.edu
(No relevant relationships reported)

Maintenance of the musculoskeletal system is critical to prevent falls and loss of mobility with aging. Sarcopenia, the age-related loss of muscle mass and function, affects 10% of those over 65 years and as much as 50% of people over 80 years of age. Aging is a major risk factor for osteoarthritis (OA) which is characterized by a concomitant loss of skeletal muscle, further contributing to decreased mobility. The "inflammatory" phenotype, (i.e., age-related increases in low-grade inflammation and oxidative stress) is common to both OA and sarcopenia. While progress has been made in understanding the mechanisms of sarcopenia a preclinical model that recapitulates human conditions is lacking. Dunkin Hartley (DH) guinea pigs rapidly and spontaneously develop primary knee OA beginning at about 4 months of age. Thus, we speculate that DH guinea pigs may also be a valuable model of sarcopenia. **PURPOSE:** To determine if DH guinea pigs can serve as a model to understand human skeletal muscle aging. **METHODS:** We compared skeletal muscle age-related changes in the gastrocnemius (GAS) and soleus (SOL) from 5, 9, and 15-mo DH guinea pigs. We also compared these changes to a strain of guinea pig, strain 13, that does not develop knee OA at an early age. Magnetic resonance imaging was used to examine volume and then used to calculate muscle density. Immunofluorescent histochemistry was used to assess myofiber size distribution. Formalin fixed muscles were stained in India ink to measure pennation angle. Fibrosis was assessed using muscles paraffin embedded and stained with Masson's Trichrome to quantify % collagen. Analyses are ongoing to identify if DH pigs are characterized by an inflammatory phenotype similar to aging human muscle. **RESULTS:** DH guinea pigs had a significant decrease in GAS density between 5 and 15-mo that was not present in the SOL ($p<0.05$). Both in the GAS and SOL, DH guinea pigs also demonstrated a shift towards a smaller average myofiber size with age. However, there were no age-related changes in pennation angle or fibrosis. **CONCLUSION:** Based on these analyses, the DH guinea pig appears to be a potentially valuable model

of musculoskeletal aging. Identifying a model to study muscular aging that mimics human conditions but in a shortened time frame, will potentially allow for effective screening and treatment interventions.

Skeletal Muscle Transcriptome Profiling: Investigating Regulators Of Temporal Improvements In Glucose Metabolism Following Muscle Contraction

Steven Carter¹, Thomas Solomon². ¹University of Birmingham, Birmingham, United Kingdom. ²Other, London, United Kingdom. (Sponsor: Professor Janice L Thompson, FACSM)
 (No relevant relationships reported)

Exercise-induced improvements in skeletal muscle glucose metabolism follow a distinct time-course profile, with immediate increases in glucose uptake followed by improved insulin sensitivity. Molecular mediators controlling this temporal effect could be targeted to optimise the efficacy of exercise in preventing insulin resistance and associated metabolic abnormalities. **PURPOSE:** To characterise the transcriptional changes associated with time-dependent changes in glucose metabolism following muscle contraction. **METHODS:** C2C12 myotubes were exposed to either 24 h of contractile activity (electrical pulse stimulation; EPS) or rest (no EPS), followed by a further 0, 6, 18 or 24 h rest (no EPS). Temporal profiling of the contraction-mediated responses in functional (basal and insulin-stimulated glucose uptake) and transcriptional (RNA sequencing and bioinformatics) outcomes was evaluated at all time points. Data are presented as mean \pm SEM. **RESULTS:** Compared to time-matched control cells (no EPS), contraction-mediated glucose uptake (i.e. without insulin) was increased 0 h post-EPS only ($162 \pm 28\%$ relative to control, $P < 0.05$), whereas insulin sensitivity was increased at 24 h post-EPS only ($163 \pm 35\%$ relative to control, $P < 0.05$). This distinct temporal profile for contraction-induced changes in muscle glucose metabolism was associated with a similarly distinct temporal transcriptional profile. Firstly, EPS-induced improvements in contraction-mediated glucose uptake (0 h post-EPS) and insulin sensitivity (24 h post-EPS) coincided with differential expression of 143 (76 up-regulated; 67 down-regulated) and 145 transcripts (71 up-regulated; 74 down-regulated), respectively. Notably, only 35 were differentially regulated at both 0 and 24 h post-EPS. Of these, only 20 were regulated in the same direction (e.g. miR-206, miR-207), with the remaining 15 oppositely regulated (e.g. miR-99b, miR-6790). **CONCLUSION:** Similar to exercise *in vivo*, our model of *in vitro* skeletal muscle contraction induced distinct temporal profiles for contraction-mediated glucose uptake and insulin sensitivity. These time-dependent changes in skeletal muscle glucose metabolism are associated with an equally distinct contraction-specific transcriptional profile. Supported by: The Physiological Society

Comparison Of Exercise-induced Regulation Of Skeletal Muscle Hif-1 α Between Endurance Trained And Untrained Individuals

Roberto C. Nava, Zachary Fennel, Zachary McKenna, Anna Welch, Quint Berkemeier, Ann Gibson, FACSM, Christine Mermier. University of New Mexico, Albuquerque, NM. (Sponsor: Ann Gibson, FACSM)
 Email: rnavabjj@unm.edu
 (No relevant relationships reported)

The regulation of gene transcription is essential for muscle adaptations resulting from endurance exercise training. Recent findings implicate hypoxia inducible factor 1 α (HIF-1 α) in this adaptive process as it regulates genes involved in O₂ homeostasis and substrate utilization. Athletes have greater resting levels of muscle HIF-1 α inhibitors than untrained individuals, suggesting that suppression of HIF-1 α underlies skeletal muscle adaptations to endurance training. However, it is unknown if the exercise-induced expression of HIF-1 α and its inhibitors differs between trained and untrained individuals. Further, differences in expression of HIF-1 α target genes following acute exercise between trained (ET) and untrained (UT) individuals have yet to be examined. **PURPOSE:** To compare regulation of HIF-1 α and HIF-1 α -target genes between ET and UT individuals following acute exercise. **METHODS:** Five ET and five UT subjects performed an acute bout of cycling consisting of twenty, 10s sprints. Muscle samples were collected pre, post and 3 hours (3H) after exercise and analyzed for HIF-1 α , the HIF-1 α regulators: PHD2, FIH, VHL and SIRT6, and HIF-1 α target genes (BNIP3, PINK1, VEGF, PDK-M, GLUT4, GAPDH). **RESULTS:** 2x3 repeated measures ANOVA revealed that post-exercise HIF-1 α protein was greater in UT compared to ET individuals (.310 \pm .020 vs .244 \pm .001 AU, $p < .05$). PHD2 (.056 \pm .012 vs .032 \pm .023 AU), FIH (.008 \pm .001 vs .004 \pm .002 AU) and SIRT6 (.04 \pm .001 vs .002 \pm .001 AU) levels were higher in ET compared to the UT individuals at 3H post exercise ($p < .05$). Post-exercise fold change values for PDK (2.2 \pm 1.2 vs .90 \pm .21) and BNIP3 (2.2 \pm 1 vs .94 \pm .16) were greater in UT compared to ET ($p < .05$). **CONCLUSION:** Exercise-induced expression of HIF-1 α is blunted in ET individuals compared to UT individuals. This is due to the greater post-exercise expression of

HIF-1 α regulating proteins. The suppression of HIF-1 α in response to exercise in ET individuals is evident at the transcriptional level, as expression of PDK and BNIP3 are lower in ET individuals compared to UT. This suggests that endurance training suppresses transcription of PDK, facilitating ATP-resynthesis via oxidative phosphorylation. The suppression of BNIP3 may reflect a reduction in mitophagy, further supporting mitochondrial function in ET individuals.

Diurnal Physical Activity Regulates Skeletal Muscle Ulk-1 Phosphorylation In Tumor Bearing Male Mice

Brittany Counts, Jessica Halle, James Carson, FACSM. University of Tennessee Health Science Center, Memphis, TN. (Sponsor: James A. Carson, FACSM)
 Email: bcounts1@uthsc.edu
 (No relevant relationships reported)

Introduction: Cancer cachexia is characterized by severe muscle mass loss associated with increased autophagy. Unc-51 like kinase 1 (ULK1) plays a primary role in initiating autophagy. Under conditions of energetic stress, AMPK activates ULK1 at serine 555 to initiate autophagosome formation for removal of damaged proteins. Daily physical activity and feeding behaviors in mice exhibit diurnal fluctuations that can impact skeletal muscle ULK1 activation. **Purpose:** We investigated the effect of diurnal regulation of skeletal muscle ULK1 phosphorylation in tumor bearing mice. We also examined the impact of increased physical activity on skeletal muscle ULK1 phosphorylation in the cancer environment. **Methods:** Free living male C57BL/6 (B6; N=24) and *Apc^{Min/+}* (MIN; N=22) mice were single housed without wheel access. An additional cohort of B6 (B6+W; N=16) and MIN (MIN+W; N=19) mice were given wheel access for 2-weeks. To examine diurnal fluctuation, all mice were sacrificed at 7:00AM or 7:00PM under *ad libitum* conditions. ULK1 was measured in the gastrocnemius muscle as phosphorylation to total ratio at serine 555 by western blot. **Results:** Free living MIN mice exhibited body weight loss ($p < 0.001$) and reduced gastrocnemius mass ($p < 0.001$) when compared to B6 mice. In the MIN free living mouse, ULK1 phosphorylation was associated with greater body weight loss ($R = -0.505$; $p = 0.023$) and reduced cage activity ($R = -0.548$; $p = 0.012$). ULK1 phosphorylation in MIN and MIN+W mice exhibited diurnal fluctuation, being increased at 7AM when compared to 7PM. This diurnal variation was not present in B6 or B6+W mice. Interestingly, regardless of sacrifice time ULK1 phosphorylation was inversely related to total wheel distance ($R = -0.498$; $p = 0.049$). **Conclusion:** ULK1 demonstrated diurnal fluctuation in MIN mice but not in B6 mice. This change in ULK1 phosphorylation was associated to body weight loss and reduced activity. These data suggest that ULK1 phosphorylation is dependent on the time of day in the tumor environment, further research is warranted to examine if this induction of ULK1 is sufficient to induce autophagy.

The Role Of Omi/htra2 During Autophagy In Skeletal Muscle Induced By Exercise Injury

Zhang Xin¹, Shang Hua yu², Wang Rui yuan³. ¹Nanjing Sport Institute, Nanjing, China. ²Chengdu Sport Institute, Chengdu, China. ³Beijing Sport University, Beijing, China.
 Email: 664191763@qq.com
 (No relevant relationships reported)

Omi/HtrA2 is known to be a pro-apoptotic protein and also participates in the regulation of autophagy. Previous studies have found that centrifugal exercise can induce an increase in Omi/HtrA2 protein expression in damaged skeletal muscle cells. Omi/HtrA2-Hax1-Beclin1, as the newly discovered autophagy signaling pathway in cells since 2010, has not been reported whether can be specifically expressed in injured skeletal muscle.

Purpose: This study was designed to explore the role of Omi/HtrA2 during autophagy in skeletal muscle induced by centrifugal exercise injury. **Methods:** 168 SD rats were randomly divided into control group (C), dummy control group (D), ucf-101 group (U), exercise group (E) and exercise+ucf-101 group (EU). The U group was injected with ucf-101, a specific inhibitor of Omi/HtrA2; D injection of equal amount of normal saline; for group E with acute heavy load treadmill exercise, the slope was -16° , the speed was 16m/min, and the continuous exercise was 90 min; the EU group performed the same exercise after injection of ucf-101. Soleus muscle was taken from the rats at 0h, 12h, 24h, 48h and 72h after intervention. Ultrastructural changes of autophagosomes in soleus muscle cells were observed by TEM; the expressions of Omi/HtrA2, hax-1 and Beclin1 were detected by Western Blot; the position and content of LC3 were observed by immunofluorescence technique; The binding levels of Hax-1 and Beclin1 were determined by immunoprecipitation. **Results:** The expression of Omi/HtrA2 protein was increased in group E (0h, 2.056 \pm 0.114, $P < 0.05$), and the binding of Hax-1 and Beclin1 protein was weakened (0h, 0.805 \pm 0.095, $P < 0.05$). The expression of Omi/HtrA2 protein was decreased in the U group (0h, 0.406 \pm 0.178, $P < 0.01$), and the binding of Hax-1 and Beclin1 protein was enhanced (0h, 1.536 \pm 0.051, $P < 0.05$; 24h, 8.000 \pm 0.197, $P < 0.01$). Compared with group E, autophagy in EU group was

decreased, Beclin1 expression was inhibited, and LC3 fluorescence intensity was decreased(Beclin1, U0=0.718±0.039, E0=1.870±0.291, EU0=0.871±0.096). **Conclusion:** A high-load centrifugal exercise can induce autophagy in skeletal muscle, which may enhance the cutting effect of Omi/HtrA2 on Hax-1 through exercise, reduce the binding inhibition level of the latter on Beclin1, and finally enhance autophagy.

Effects Of 16 Weeks Hiit And Vitamin E On The Ros-nfkb-bnip3 Pathway In Aging Rat Muscle
 ZHONG-YE JIANG, HAO SU, GUO-HUAN CAO, TIAN-HAO WEN, JIA SHAO, ZHENG-SONG WANG. *Beijing Sport University, Beijing, China.*
 (No relevant relationships reported)

The effect of high intensity interval exercise (HIIT) combined with Vitamin E(VE) in the intervention of aging degeneration of skeletal muscle is still unclear. **PURPOSE:** In this study, the effects of 16-week HIIT intervention and VE supplementation on the mitochondrial autophagy related Ros-NFκB-Bnip3 pathway and the number of mitochondria in aged rat skeletal muscle were observed. To provide theoretical basis for delaying sarcopenia by means of exercise and nutrition. **METHODS:** 60 male Wistar rats aged 8 months were randomly divided into the control group (C, n=20), the HIIT intervention group (H, n=20) and the HIIT group supplemented with VE (EH, n=20) according to the random number table. H and EH adjusted the exercise intensity with the results of the VO₂max test every two weeks. The EH was given VE gavage according to 50mg/kg body weight everyday at 1 hour before each training. Rats were taken from each group randomly at the basic state, week 8 and 16 for sampling. During sampling, the soleus muscle of rats was removed. The mitochondria were photographed using a transmission electron microscope, the fluorescence intensity of ROS was measured by Multifunctional enzyme marker, The NF-κB, beclin-1 and Bnip3 were measured by Western blot. The data were analyzed by multivariate ANOVA. **RESULTS:** At 8 weeks, the number of mitochondrial in H and EH were increased (P=0.033, P=0.001) and higher than that in C (P=0.046, P=0.003). At 16 weeks, H was higher than C (P=0.004), EH (P=0.01) and baseline (P=0.046). ROS in C and EH increased at 8 weeks (P=0.024, P=0.001). C and EH were higher than H (P=0.018, P=0.002). At 16 weeks, H and EH were higher than baseline values (P=0.027, P=0.010). Although the content of NF-κB changed in each group, no significant difference occurred. At week 16, beclin-1 expression of soleus muscle in H increased (P=0.036). EH was lower than H and C (P=0.004, P=0.002). The expression of Bnip3 in soleus muscle in C increased at 8 weeks and 16 weeks (P=0.030, P=0.001). H increased at 8 and 16 weeks (P=0.001, P=0.001), and was higher in H than in EH (P=0.006, P=0.020). **CONCLUSIONS:** The 16 week HIIT intervention and the combined effect of HIIT and VE to alleviate the reduction of mitochondrial number caused by aging may be due to the delayed protein expression of the Ros-NFκB-Bnip3 pathway in the soleus muscle of rats.

Akt-FOXO1 Takes Part In Regulating Protein Metabolism During Resistance Training At Hypoxia
 Jiabei Yu¹, Yang Hu², Yanchun Li², Lijing Gong². ¹Beijing Institute of Sports Science, Beijing, China. ²Beijing Sport University, Beijing, China.
 Email: bsuyjb@163.com
 (No relevant relationships reported)

PURPOSE: To research the effects of resistance training on skeletal muscle at hypoxia and Akt-FoxO1 pathway regulatory role during this process. **METHODS:** 40 male Sprague-dawley rats were divided into four groups randomly and were raised at normoxia and hypoxia (12.4% O₂) respectively. Two groups were trained to climb ladder (height 1.2m, inclined at 85°) with load every other day lasting 4-week. Other two groups were quiet control group. Body composition was tested by using DEXA. Isolated extensor digitorum longus (EDL), biceps and soleus were made HE stained paraffin section to analyze muscle fibre cross section area (CSA). Total protein and RNA were abstracted to detect Akt, FoxO1, FoxO1 (S256) and downstream E3 ligase (MuRF1 and Atrogin-1) transcription and expression level. **RESULTS:** Rats lean body mass and CSA of EDL and soleus were decreased significantly (P<0.05 and P<0.05) after 4-week hypoxic exposure. Akt and FoxO1 (S256) expression were decreased, while the expression of FoxO1, MuRF1 and Atrogin-1 were increased (P<0.05). Relatively, resistance training could effectively reduce this atrophy and stimulate rat biceps and EDL hypertrophy (P<0.05 and P<0.05). Meanwhile, Akt and FoxO1(S256) expression were higher than hypoxia training group (P<0.05). **CONCLUSIONS:** Akt-FoxO1 pathway plays an important role in regulating muscle protein during resistance training in hypoxia. Akt activation lead to the nuclear exclusion of phosphorylated FoxO1, which is an important mechanism of resistance training alleviate muscle atrophy.

Single Cell RNA Sequencing Of Regenerating Skeletal Muscle Reveals A Senescence Response Which Is Necessary For Optimal Muscle Repair
 Adam Johnston, Alasdair Cameron, Michel Arseneault, Laura Young. *University of Prince Edward Island, Charlottetown, PE, Canada.*
 Email: adjohnston@upe.ca
 (No relevant relationships reported)

Satellite cells drive skeletal muscle regeneration, a process regulated by factors released into the local muscle environment; however the source of this trophic support is poorly defined. In this regard, recent work has identified a supportive role for cells commonly associated with aging and pathology, termed "senescent cells". The **PURPOSE** of this study was to determine the function of cellular senescence in normal skeletal muscle repair in rodents. **METHODS:** The tibialis anterior (TA) of C57BL6 mice was injured with cardiotoxin (CTX) and collected across a time-course. To examine senescent cell function during muscle repair, mice were treated with the senolytic compound (ABT-263) to selectively ablate senescent cells. **RESULTS:** The number of senescent cells (SA-β-gal+ cells) rapidly increased following injury (p <0.05) which returned to baseline by 21 days post-CTX. SA-β-gal+ cells displayed other markers consistent with senescence such as a lack of proliferation (EDU-) and the presence of DNA damage (γH2AX). qPCR analysis of putative senescence pathways including p16, p21 and p53 as well as factors commonly secreted by senescent cells were significantly upregulated in CTX-injected muscle in comparison to uninjured muscle (p <0.05). To identify the cell types which become senescent, single-cell RNA sequencing (scRNAseq) was performed on 5-day post CTX skeletal muscle which revealed that fibrogenic-adipogenic progenitors (FAPs), endothelial cells and macrophages

demonstrated increased expression of the senescence markers *Glb1*, *CDKN1A* and *Trp53* while no satellite cells become senescent. These findings were confirmed *in vivo* through IHC analysis of SA- β -gal and marker specific analysis of FAPs (PDGFR α), endothelial cells (CD31) and macrophages (F4/80). Importantly, senolytic treatment during regenerative myogenesis *in vivo* reduced the number of SA- β -gal+ cells by 44% which coincided with significant reductions in muscle fibre cross-sectional area (25%) and the number of nuclei/fibre (12%). **CONCLUSION:** A transient wave of cellular senescence contributes to endogenous muscle repair to influence muscle fibre size following injury.

Inhibiting Drp1-Mediated Mitochondrial Fission Attenuates High-Fat Diet Induced Skeletal Muscle Insulin Resistance

Benjamin A. Kugler¹, Wenqian Deng², Abigail Duguay¹, Meaghan Nasta¹, Kai Zou¹. ¹University of Massachusetts Boston, Boston, MA. ²Chengdu Sport Institute, Chengdu, China. Email: Benjamin.Kugler002@umb.edu
(No relevant relationships reported)

Dynamins-related protein 1 (Drp1) is a critical mediator of mitochondrial fission. Recent studies have reported increased Drp1 activation in obese skeletal muscle, which is associated with reduced mitochondrial function and insulin sensitivity. **Purpose:** To determine if inhibiting Drp1-mediated mitochondrial fission by a pharmacologic inhibitor attenuates skeletal muscle insulin resistance induced by a high-fat diet (HFD) in mice. **Methods:** 6-week old male C57BL/6J mice (n=9/group) were assigned to either a HFD (45% Fat) or low-fat diet (LFD, 10% Fat) group for a total of 5-weeks. A subgroup of HFD-fed mice received intraperitoneal injections of Mitochondrial Division Inhibitor 1 (MDIVI-1) (20 mg/kg) while the other mice received saline every other day for the last week of diet intervention. A glucose tolerance test was performed after 4 hours of fasting. Twenty-four hours after the final injection, quadriceps and gastrocnemius muscles were collected for further analysis. H₂O₂ levels were detected using Amplex Red Hydrogen Peroxide kit. Insulin signaling and protein markers of mitochondrial dynamics were measured by immunoblot analysis. **Results:** HFD significantly increased glucose area under the curve (AUC) than LFD mice (19074 \pm 2137 vs. 10726 \pm 1254; p < 0.05), but MDIVI-1 treatment attenuated glucose AUC in HFD-fed mice (15354 \pm 1278). MDIVI-1 treatment reduced Drp1 expression in mitochondrial fraction from HFD-fed mice when compared to the saline-treated counterparts (0.003 \pm 0.001 vs. 0.012 \pm 0.003; p < 0.05). The mitochondrial fraction Drp1 expression was positively associated with glucose AUC (r = 0.497, p = 0.042). Insulin-stimulated Akt^{ser473} phosphorylation was reduced in insulin-stimulated skeletal muscle from HFD-fed mice compared to mice fed with LFD (0.70 \pm 0.22 vs. 2.21 \pm 0.39; p < 0.05), but no difference was found between HFD-fed mice treated with MDIVI-1 and LFD-fed mice. HFD had a significant increase in H₂O₂ than LFD-fed mice (0.351 \pm 0.046 \pm 0.186 \pm 0.043; p < 0.05), while MDIVI-1 treatment reduced H₂O₂ production in HFD-fed mice (0.351 \pm 0.046 vs. 0.215 \pm 0.364; p < 0.05) **Conclusion:** These data suggest that inhibiting Drp1-mediated mitochondrial fission attenuates skeletal muscle insulin resistance and improves whole-body glucose homeostasis in mice fed by HFD.

Activation Of Specific Estrogen Receptor Isotype Mediates Skeletal Muscle Force Potentiation In Ovariectomized Mice

GENGYUN C. LE, Dawn A. Lowe, FACSM. University of Minnesota, Minneapolis, MN. (Sponsor: Dawn A Lowe, FACSM) Email: gle@umn.edu
(No relevant relationships reported)

Estrogens affect force generation of skeletal muscle. Post-tetanic potentiation (PTP) of force is low in ovariectomized mice, and estradiol supplementation rescues potentiation both *in vivo* and *in vitro*. However, it is not known whether this estrogenic influence is through estrogen receptors, and if so, which isotype. **PURPOSE:** We hypothesized activation of estrogen receptor beta (ER β) or G protein-coupled estrogen receptor (GPER), but not estrogen receptor alpha (ER α) would enhance *in vivo* muscle PTP in ovariectomized mice. **METHODS:** Adult female C57BL/6J mice (n = 4-12 per treatment) had a nerve cuff surgically implanted on the left common peroneal nerve. Six weeks later mice were ovariectomized (OVX). Four weeks later, PTP of the anterior crural muscles was measured immediately before and 1 h after treatment with either vehicle (OVX+Veh), 17 β -estradiol (OVX+E₂), ER α agonist PPT (OVX+PPT; 1 μ M PPT), ER β agonist DPN (OVX+DPN; 50 nM DPN) or GPER agonist G1 (OVX+G1, 2.4 nM G1) via tail vein injection. PTP was calculated as the percent increase in twitch torque from baseline to the highest torque of the post-tetanic twitches. One-way ANOVAs with Holm-Sidak post hoc tests were used for data analysis. Results are reported as mean \pm SE. **RESULTS:** Peak torques of unpotentiated, baseline twitches were not different among the five groups: 0.47 \pm 0.03,

0.59 \pm 0.04, 0.62 \pm 0.12, 0.52 \pm 0.11 and 0.54 \pm 0.03 mN*m, respectively (p=0.25). Potentiated twitches generated 7-108% more torque than unpotentiated twitches. PTP of OVX+E₂ and OVX+G1 was significantly greater than that of OVX+Veh mice (59 \pm 5% and 61 \pm 7% vs 35 \pm 5% increase, respectively; p=0.01). PTP of OVX+PPT and OVX+DPN were not significantly different from OVX+Veh mice (41 \pm 4% and 49 \pm 7% vs 35 \pm 5% increase, respectively; p=0.37). **CONCLUSION:** Acute treatment with ER α or ER β agonist does not increase *in vivo* PTP of the anterior crural muscles in OVX mice to the extent that E₂ or GPER agonist does. This result partially supports our hypothesis that estrogenic modulation of skeletal muscle force potentiation is not through ER α , and is through GPER. Supported by NIH grants R01-AG031743 and T32-AR050938, and Metropolitan State University Professional Development Grant.

Myogenic Regulatory Factor Expression Time Course Following Doxorubicin Injection In Rats Supplemented With Dietary Creatine

Raquel B. Busekrus, Brandon C. Jones, David S. Hydock. University of Northern Colorado, Greeley, CO. Email: Raquel.Busekrus@unco.edu
(No relevant relationships reported)

Doxorubicin (Dox) is a powerful chemotherapy agent known to cause muscle dysfunction. In response to skeletal muscle damage and stress, such as DOX treatment, myogenic regulatory factors (MRF) play a role in restoring muscle integrity. Creatine (Cr) supplementation has been shown to increase MRF expression and could attenuate Dox-induced skeletal muscle damage by enhancing repair, but the effects of Cr supplementation on Dox in this context has yet to be explored. **PURPOSE:** To explore the effects of Cr and Dox on the early time course of MRF expression. **METHODS:** Male Sprague-Dawley rats were randomly assigned to one of three feeding groups: rodent chow supplemented with 2% Cr for four weeks (Cr1), rodent chow supplemented with 4% Cr for one week followed rodent chow supplemented with 2% Cr for three weeks (Cr2), or standard rodent chow for four weeks as a control diet (Con). Animals then received 15 mg/kg Dox or saline as a placebo (Sal). Extensor digitorum longus (EDL) muscles were excised at 1, 3, or 5 days after injection, and expression of the primary MRFs Myf5 and MyoD and the secondary MRFs myogenin and Mrf4 were quantified with Western blotting. **RESULTS:** Between group Myf5 (p=0.0203), MyoD (p<0.0001), and myogenin (p=0.0031) expression differences were observed at day 1 with Cr2+Dox expressing higher Myf5 than Con+Sal (p<0.05) and higher MyoD than Con+Sal, Con+Dox, and Cr1+Dox (p<0.05). Furthermore, both Cr1+Dox and Cr2+Dox expressed higher Myf6 than Con+Sal (p<0.05) with only Cr2+Dox expressing higher Myf6 than Con+Dox (p<0.05), and EDLs from Cr1+Dox and Cr2+Dox had higher myogenin levels than Con+Sal (p<0.05) at the 1 day time point. At the 3 and 5 day time points, however, no between-group differences in MRF expression were observed. **CONCLUSIONS:** Cr feeding prior to Dox treatment increased MRF expression 1 day following Dox injection, and including a Cr loading phase (Cr2) led to a heightened response than no Cr loading phase (Cr1). This elevated MRF expression with Cr, however, was not evident at day 3 and 5 following Dox treatment suggesting that Cr feeding may help to enhance early skeletal muscle repair signaling in response to Dox treatment which may be critical to protecting against Dox myotoxicity.

The Mechanism Of Fam134b Mediated Endoplasmic Reticulum Autophagy In Skeletal Muscle After Heavy Load Exercise

Lunyu Li¹, Haili Ding², Quansheng Su¹, Zaifang Ren³, Zenghao Huang², Songlin Jin². ¹Chengdu Sport University, Chengdu, Sichuan, China. ²Chengdu Sport University, Chengdu, China. ³China-Japan Friendship Hospital, Beijing, China. Email: leolly007@163.com
(No relevant relationships reported)

Endoplasmic reticulum(ER) is a significant organelle involved in the contraction of skeletal muscle. **PURPOSE:** To investigate the role of FAM134B in ER autophagy of skeletal muscle cells after exercise. **METHODS:** (1)Subjects and groups:48 healthy male 8-week-old SD rats were randomly divided into control group (Group C, n=8) and exercise group (Group E, n=40). The time items of group E were divided into 5 subgroups of 0h/12h/24h/48h/72h. (2)Exercise program: the rats were trained by using the electric running platform of small animals with large load exercise and reference to the Armstone's.(3)Sampling and index detection: rats were anesthetized after weighing, soleus was isolated and prepared protein samples and frozen sections;Western blot was used to detect the expression of CRT, FAM134B and LC3 protein in skeletal muscle,and double immunofluorescence staining combined with laser confocal was used to observe the co-location of FAM134B, LC3 and CRT.

RESULTS: (1) Compared with group C, the change rate of skeletal muscle protein expression in rats showed that ① CRT ($2.080 \pm 0.096^{**} 1.325 \pm 0.105^{*00} 1.395 \pm 0.142^{*00} 1.315 \pm 0.096^{*00} 0.990 \pm 0.052^{00123}$); in Group E increased by 1.08 times at 0 h after exercise, showing significant difference ② FAM134B ($1.301 \pm 0.076^{*} 1.967 \pm 0.119^{*00} 1.379 \pm 0.112^{*} 11.500 \pm 0.073^{**} 1.277 \pm 0.09611$); in Group E, it was significantly increased at 12 h and 48 h after exercise, 96.7% and 50% respectively. ③ LC3 ($1.376 \pm 0.132^{*} 1.799 \pm 0.063^{**} 0.562 \pm 0.063^{**} 1.659 \pm 0.084^{**} 1.300 \pm 0.067^{*1}$); it was significantly increased in Group E from 0 h to 72 h after exercise. (2) the results of CO location of fam134b and CRT, and co-location of LC3 and CRT showed that compared with group C, group E significantly increased from 0 h to 48 h after exercise. **CONCLUSIONS:** The expression of FAM134B and LC3 in ER increased and co-located with CRT after heavy load exercise, indicating that FAM134B may be involved in the occurrence of ER autophagy after heavy load exercise.

Autophagy Response To High-intensity Interval Exercise And Moderate-intensity Continuous Exercise Is Dissimilar In Skeletal Muscle And Peripheral Blood Mononuclear Cells

Kurt A. Escobar¹, Anna M. Welch², Andrew Wells², Zac Fennel², Roberto Nava², Zidong Li², Terence A. Moriarty³, Carlos H. Nitta², Micah N. Zuhl⁴, Trisha A. VanDusseldorp⁵, Christine M. Mermier², Fabiano T. Amorim². ¹California State University, Long Beach, Long Beach, CA. ²University of New Mexico, Albuquerque, NM. ³University of Northern Iowa, Cedar Falls, IA. ⁴Central Michigan University, Mount Pleasant, MI. ⁵Kennesaw State University, Kennesaw, GA. Email: kurt.escobar@csulb.edu (No relevant relationships reported)

Few human data exist investigating the autophagic response to exercise in humans including the response to high-intensity interval training (HIIT) compared to moderate-intensity continuous training (MICT). Further, the relationship between post-exercise autophagy in distinct tissues including skeletal muscle and peripheral blood mononuclear cells (PBMCs) is not known. **PURPOSE:** The purpose of this study was to investigate the autophagy response in skeletal muscle and PBMCs following an acute bout of HIIT exercise and MICT exercise. **METHODS:** Using a crossover design, ten recreationally-active males (n=5) and females (n=5) performed a bout of MICT (60 minutes at 55% of max velocity [V_{max}]) and HIIT (6 bouts of 1 minute at 100% V_{max} and 1 minute at 3 MPH, followed by 5 minutes at 3 MPH, followed by another 6 bouts of 1 minute and 100% V_{max} and 1 minute at 3 MPH). Muscle biopsies from the vastus lateralis and PBMCs from venous blood were collected pre- and 3 hours post-exercise. Exercise bouts were separated by ≥ 72 hours and performed after abstaining from alcohol for ≥ 24 hours and food and caffeine for ≥ 8 hours. Muscle tissue and PBMCs were analyzed for protein expression of markers of autophagy LC3I, LC3II, and p62 via western blot analysis. **RESULTS:** No differences were detected in LC3I, LC3II, and p62 protein content 3 hours post-exercise compared to pre-exercise in both HIIT and MICT bouts in skeletal muscle or PBMCs (p>0.05).

However, LC3II:I ratio 3 hours post-exercise was different between HIIT ($108.1 \pm 54.5\%$) and MICT ($64.3 \pm 47.3\%$; p<0.05) in skeletal muscle. There were no differences in LC3II:I in PBMCs between HIIT and MICT. **CONCLUSION:** Our findings show that HIIT and MICT exercise results in distinct changes in autophagy flux as suggested by LC3II:I in human skeletal muscle, but not in PBMCs. Our data suggest that the autophagy response to acute exercise in skeletal muscle and PBMCs are dissimilar which may indicate that distinct exercise thresholds exist.

3339 Board #160 May 29 1:30 PM - 3:00 PM **Myosin Heavy Chain Isoform Mrna Expression In Low-And High-capacity Running Rats**

Anaissa Ruiz¹, Nisreen Wahwah¹, Nyssa Hoffman¹, Janet Neisewander¹, Lauren G. Koch², Christos Katsanos¹. ¹Arizona State University, Tempe, AZ. ²The University of Toledo, Toledo, OH. (No relevant relationships reported)

Differential expression of Myosin Heavy Chain (MHC) isoforms in skeletal muscle determines its metabolic and functional characteristics. Endurance exercise training is associated with fast-to-slow MHC isoform transition, and which is considered to mediate the beneficial effects of exercise on metabolic health. Rats genetically bred for low-capacity running (LCR) and high-capacity running (HCR) are characterized by the health benefits typically described after endurance exercise training. LCR and HCR rats differed in maximal running capacity 14 fold. **PURPOSE:** To quantify mRNA expression for slow (MHC-I) and fast (MHC-IIa, MHC-IIb) MHC isoforms in soleus, gastrocnemius and vastus skeletal muscle of LCR and HCR male adult rats, and determine if HCR rats have higher mRNA expression for slow, and lower mRNA expression for fast, MHC isoforms. **METHODS:** Muscle tissue from 5 HCR and 5 LCR rats was homogenized and mRNA was isolated. The mRNA content of MHC isoforms in muscle was quantified using reverse transcriptase polymerase chain reaction (RT-PCR), and standardized to the 18S mRNA content in muscle. Differences between groups were calculated using the comparative CT method ($2^{-\Delta\Delta CT}$). LCR were the control group. **RESULTS:** Expression of mRNA of the MHC isoforms differed between groups and the type of skeletal muscle analyzed. MHC-I mRNA expression was lower in the HCR compared to LCR across all muscle groups, but this difference ($2^{-\Delta\Delta CT}$) was more pronounced for the gastrocnemius muscle [LCR: 1.0 ± 0.6 (mean \pm SE); HCR: 0.3 ± 0.2 ; $P = 0.08$]. Although MHC-IIa mRNA expression appeared lower in soleus and vastus in the HCR, it was higher in the HCR compared to LCR in the gastrocnemius muscle [LCR: 1.0 ± 1.0 ; HCR: 4.6 ± 3.6 ; $P = 0.07$]. MHC-IIb mRNA expression was lower in the HCR compared to LCR across all muscle groups, but this difference was more pronounced for the soleus muscle [LCR: 1.0 ± 1.1 ; HCR: 0.2 ± 0.4 ; $P = 0.08$]. **CONCLUSION:** Genetic differences linked to the MHC transcriptome (i.e., decrease in MHC-I mRNA) in muscle do not explain the exercise performance observed in HCR rats. Changes in the muscle MHC transcriptome may not directly be responsible for the health benefits associated with exercise training. It remains to be determined on whether the differences we observed at the MHC mRNA level are translated to the MHC proteome level.

3340 Board #161 May 29 1:30 PM - 3:00 PM

Effect Of Aerobic Capacity, Ampk-pgc-1α Pathway In Skeletal Muscle For Detraining Of Different Training
YE GAO, GUOHUAN CAO, HAO SU, TIANHAO WEN, JIA SHAO. Beijing Sport University, Beijing, China. (No relevant relationships reported)

PURPOSE: By observing HIIT group rats and MIT group rats' changes in the timing and content of AMPK and PGC-1 α in skeletal muscle, changes in aerobic capacity given the same load and training time and then stop the training. To provide a reasonable arrangement of retraining programs. **METHODS:** 27 4-month-old male Wistar rats were randomly divided into 3 groups (N=9): control (Group C), MIT (Group M), HIIT (Group H). C do not exercise, H training at 50%-70%-90% VO2max intensity according to the VO2max test results, M training at 70% VO2max intensity. Both H and M were performed for 50min/day, 5 days/week for 6 weeks of training. Rats were randomly selected from 3 groups on the 1st, 3rd, 7th, and 10th day after the training was stopped. They were intraperitoneal injected by 5% chloral hydrate to get soleus muscle. Using western blot to analysis AMPK and PGC-1 α . The results are expressed as mean \pm standard deviation. one-way ANOVA and non-parametric test are performed in accordance with the normal distribution. **RESULTS:** 1.The AMPK in the skeletal muscle in H was significantly higher than that in C (P<0.05). The trend of AMPK in M was similar to that in H. 2.The level of PGC-1 α in skeletal muscle compared to C was significantly increased in H (P<0.05). The change trend of PGC-1 α in M was similar to that in H. 3.The VO2max shows a downward trend. **CONCLUSIONS:** 1.After 6 weeks of HIIT or MIT, all indicators showed a downward trend. 2.HIIT is superior to MIT in improving and maintaining AMPK, and PGC-1 α level, but it is less effective in maintaining VO2max.

EFFECT OF FORCE ACTIVATION OF NOTCH SIGNALING ON MTOR

Julia R. Rebellon¹, Josh R. Huot², Joseph Marino¹, Cassandra Beach¹, Jeffrey Gerrard¹, Kendra Morris¹, Matthew Bomkamp³, Nicole Stott¹, Susan T. Arthur¹. ¹UNC Charlotte, Charlotte, NC. ²Indiana University School of Medicine, Indianapolis, IN. ³University of Florida, Gainesville, FL.
 (No relevant relationships reported)

PURPOSE: Notch signaling is a prominent pathway necessary for repair of injured muscle. The interactions of Notch with other signaling pathways, specifically mechanistic/ mammalian target of rapamycin (mTOR), in regulating myogenesis is not well known. Studies have been conducted on Notch inhibition, but little research has been performed on activated Notch and the interactions with mTOR. This study was implemented to develop a Notch force activation protocol and to measure the effect of overexpressed Notch on C2C12 proliferation, differentiation and mTOR signaling. **METHODS:** Notch signaling was force activated via suspension or adhesion. For suspension, Notch-1 antibody was introduced to a 12-well plate with C2C12 cells at a concentration of 1:10. For adhesion, Notch ligand, Delta-like Ligand 1 (DLL1), was mixed with Extracellular Matrix (ECM) and coated on a 12-well plate at different concentrations (control, 2.5 μ g, 5 μ g, and 10 μ g) for 12 hours. C2C12 cells were seeded at a concentration of 15,000 cells/well and differentiated for 96 hours. Following designated time period, lysates were collected for Western Blots. Primary antibodies probed for Notch (Hes1), total mTOR signaling (TmTOR), and β -actin. **RESULTS:** Preliminary data for suspension was analyzed via a two-way ANOVA (time x treatment). There is a significant difference in percent change of proliferation at 48 hours ($p=0.02$). Preliminary data of adhesion was analyzed via one-way ANOVA. There is a trend between Hes1 concentration in ligand concentration of 2.5 μ g ($p=0.0739$). It shows no significant difference in TmTOR concentrations between the various Notch force activation concentrations in proliferating C2C12 cells ($p=.4298$). **CONCLUSIONS:** Preliminary data shows a stronger effect of suspension over adhesion for force activating Notch. A concentration of 2.5 μ g of ligand is possibly sufficient to force activate Notch, any higher appears too concentrated to activate Notch. Preliminary data also suggests that force activating Notch does not affect mTOR signaling. Experiments are currently testing the ideal DLL1 to activate Notch signaling, as well as examining the effect of force activating Notch on proliferation, differentiation and other markers of mTOR signaling. Different time points for differentiation should be tested in future research.

EXERCISE MODIFIES K_{ATP} CHANNEL KIR6.X SUBUNITS EXPRESSION IN SLOW-TWITCH AND FAST-TWITCH MUSCLES OF DIABETIC RATS

Erick A. Villacaña-Gómez, Sergio Márquez-Gamiño, Karla S. Vera-Delgado, Fernando Sotelo-Barroso, Cipriana Caudillo-Cisneros, Ma. Teresa Melchor-Moreno, Elizabeth Sánchez-Duarte. *Universidad de Guanajuato, León, Mexico.*
 Email: ea.villicanagomez@ugto.mx
 (No relevant relationships reported)

Diabetes Mellitus (DM) and the associated hyperglycemic state may adversely affect muscle, which has been called diabetic myopathy. In skeletal muscle, ATP sensitive potassium (K_{ATP}) channels link metabolic cell state and electrical excitability. It has been reported that DM is associated with a K_{ATP} channel dysfunction, reducing their

protecting role in preventing fiber damage and contractile dysfunction. While regular exercise can improve hyperglycemic status in DM, its impact on the expression of K_{ATP} channels subunits is unknown, and could vary in different types of muscle.

PURPOSE: To assess the effect of regular exercise on mRNA expression of the K_{ATP} channel Kir6.x subunits (Kir6.1 and Kir6.2) in slow-twitch and fast-twitch muscles of streptozotocin-induced diabetic rats.

METHODS: Male Wistar rats (25 days old) were randomly divided into four groups: sedentary control, trained control, sedentary diabetic, trained diabetic. Diabetes was induced by a single streptozotocin injection (100 mg/kg body weight), animals with fasting blood glucose levels ≥ 300 mg/dL were considered as diabetic. Groups with training program performed exercise on a treadmill (30 minutes daily, 5 days/week) for 8 weeks. At the end of the intervention, gastrocnemius (fast-twitch) and soleus (slow-twitch) muscles were dissected and real-time quantitative PCR experiments were performed to quantify Kir6.1 and Kir6.2 expression.

RESULTS: In control conditions, the regular exercise increased Kir6.2 subunit mRNA levels significantly in slow and fast muscle (60 \pm 13.49% and 132 \pm 43.81%, respectively), while Kir6.1 mRNA levels did not differ, respect to sedentary control group. In diabetes, relative mRNA expression of the subunit Kir6.1 were significantly higher in both muscles (229.7% and 152%), whereas the mRNA levels of Kir6.2 were downregulated only in slow muscle by 66.8%. These effects were counteracted by the exercise, Kir6.1 expression was decreased in slow and fast muscle (47.28 and 47.57%, respectively), instead the expression of kir6.2 was increased in both muscles.

CONCLUSION: Our results indicate that regular exercise modifies the gene expression patterns of Kir6.x subunits during diabetes, by increases the expression of Kir 6.2 subunits and regularizes Kir6.1. These effects are dependent on muscle fiber type.

3343 Board #164 May 29 1:30 PM - 3:00 PM
MiRNAs As Possible Predictors For Training Efficacy

Manuel Widmann¹, Felipe Mattioni Maturana¹, Ansgar Thiel², Andreas M. Nieß¹, Barbara Munz¹. ¹University Hospital Tübingen, Tübingen, Germany. ²Institute of Sports Science, Tübingen, Germany.
 (No relevant relationships reported)

Recent research suggests that genes encoding micro RNA (miRNA) molecules are differentially expressed in response to training.

Purpose: To determine whether specific miRNAs serve as possible predictors for training efficacy.

Methods. Six healthy, sedentary female subjects (mean \pm SD: age 23.2 \pm 3.1 years, peak oxygen uptake (VO_{2peak}) 31.7 \pm 1.6 mL \cdot kg⁻¹ \cdot min⁻¹, body mass index 23.0 \pm 1.2 kg/m²), aged between 20 and 27 years, performed exercise training on a cycle ergometer, three times a week, for 6 weeks. Participants were randomly assigned to either moderate intensity continuous training (MICT, n=3) or high intensity interval training (HIIT, n=3). The MICT group performed 60 min of continuous cycling at the power output (PO) calculated as corresponding to 90% of the first lactate threshold (LT). The HIIT group performed a warm-up for 10 min at the PO calculated as corresponding to 70% of the maximal heart rate (HRmax), followed by four 4-min intervals at the PO calculated as corresponding to 90% of HRmax, with 4-min recovery periods at 30 W in between. Muscle biopsies were taken pre- and post-training from the *vastus lateralis* muscle, followed by isolation of total RNA. Samples were then analyzed using a commercial miRNA array.

Results. Participants increased their VO_{2peak} after 6 weeks of training by 4.2 mL \cdot kg⁻¹ \cdot min⁻¹ in mean (SD: 0.9). MICT and HIIT induced significant changes in miRNA expression patterns, part of which were specific for one of the two training regimens. For instance, there was a significant ($p<0.006$), 5.5-fold upregulation of the anti-apoptotic miRNA 21-5p in both training groups. Furthermore, we could identify distinct shift in miRNA patterns that correlated with exercise-induced changes in physiological parameters, such as changes in VO_{2peak} (delta VO_{2peak} vs delta expression of miRNA 503, $r=-0.9$, $p=0.01$) or microvascular properties.

Conclusions. Our data suggest that MICT and HIIT exert distinct, but also overlapping effects on miRNA expression patterns. In addition, basal miRNA expression patterns might be associated with the individual response to training. Furthermore, the data are currently reproduced using semi-quantitative RT-PCR (qPCR). Our results might have important implications for the development of personalized exercise recommendations and therapeutic strategies.

The Role Of Collagen Composition And Orientation In Lateral Force Transmission With Aging

Jed Keenan Lim Obra¹, Henning T. Langer¹, Agata A. Mossakowski¹, Vadim Malis², Edward Smitaman², Usha Sinha², Shantanu Sinha², Keith Baar, FACSM¹. ¹UC Davis, Davis, CA. ²UC San Diego, San Diego, CA. (Sponsor: Keith Baar, FACSM)
 Email: jlobra@ucdavis.edu
 (No relevant relationships reported)

PURPOSE: Collagen is the most abundant protein in the body and functions to provide the mechanical strength of connective tissues. In muscle, collagen fibrils function both to hold muscle fibers together and transmit force laterally between fibers. With aging, force transmission is reduced; however, how changes to specific collagen isoforms or the matrix orientation contribute to force loss is currently unclear. The current study was designed to compare lateral force transmission in the gastrocnemius muscle of young and old people with changes in specific collagen proteins and the orientation of the matrix.

METHODS: The calf strength of 12 subjects, 5 between 18 and 30 years old and 7 over the age of 65, was measured within an MRI. Images were taken to determine lateral force transmission. Following strength testing, biopsies were obtained under local anesthetic from the gastrocnemius muscle. Biopsies were pinned to cork at resting length and frozen in isopentane cooled in liquid nitrogen. Cross-sections were taken to determine collagens I, III, IV, and V content, whereas longitudinal sections were stained with picrosirius red to determine matrix orientation. The collagen IV image was also used to determine muscle fiber cross-sectional area (CSA).

RESULTS: Collagen I and V were evenly dispersed throughout the cross-sections, whereas Collagen IV and VI were denser around individual muscle fibers. Collagen IV content was similar in young and old. As expected, fiber CSA tended ($p = 0.1$) to decrease in the old subjects. Picrosirius red staining showed that the collagen matrix is oriented at a $22.3 \pm 3.1\%$ angle to the fibers in young and $30.2 \pm 8.7\%$ in old subjects. **CONCLUSIONS:** Preliminary data suggests that, in the old, fiber CSA decreases and the extracellular matrix becomes less aligned. By establishing the role of specific collagen proteins during aging, we hope to better understand the relationship between the extracellular matrix and force transmission in muscle and how this relationship is modified by age.

Human Medial Gastrocnemius Conversion To Adipose Tissue, A Histological Analysis

Kailey M. Omstead, Matthew C. Kostek. Duquesne University, Pittsburgh, PA. (Sponsor: Trent Hargens, FACSM)
 Email: omsteadk@duq.edu
 (No relevant relationships reported)

There are very rare reports in the biomedical literature of entire human skeletal muscles being replaced by adipose tissue and thereby affecting lower limb function and ambulation. The causes are unknown. A fully preserved example was discovered in a Medical Anatomy course. **PURPOSE:** To examine the histological characteristics of a bilateral conversion of the medial gastrocnemii, presumably from skeletal muscle to adipose tissue. **METHODS:** Small specimens were collected for preservation, wax embedding, and histological analysis of the affected muscle, unaffected lateral-head of the muscle, nerve, and a control muscle. **RESULTS:** Hematoxylin and Eosin staining revealed an 88% decrease in the number of skeletal muscle fibers with a corresponding increase in the number of adipocytes. Connective tissue was similar between samples; however, the lateral gastrocnemius exhibited signs of inflammation with no necrosis. **CONCLUSIONS:** This is to our knowledge the first full histological analysis of a seeming conversion of the bilateral gastrocnemius medial heads into adipose tissue. The cause is unknown but could be related to the immune cell infiltration.

PGC-1 α mRNA Isoform-specific Response To Exercise And Cold

Ben Meister, Camille Larson, Dustin Slivka, FACSM. University of Nebraska at Omaha, Omaha, NE. (Sponsor: Dustin Slivka, FACSM)
 (No relevant relationships reported)

PGC-1 α mRNA Isoform Specific Response to Exercise and Cold

Ben Meister, Camille Larson and Dustin Slivka
 University of Nebraska at Omaha.
 Cold exposure in conjunction with aerobic exercise has been shown to increase the gene expression of PGC-1 α , the master regulator of mitochondrial biogenesis. PGC-1 α can be expressed as multiple different isoforms due to alternative splicing mechanisms, including the truncated NT-PGC-1 α isoform. These isoforms have differing structures and functions but relatively little about the specificity and response is known.

PURPOSE: Determine the difference of PGC-1 α isoform expression following an acute bout of cycling in cold and room temperature conditions. **METHODS:** 8 male participants cycled for 1 hour at 65% W_{max} at $-2^{\circ}C$ and $20^{\circ}C$. A muscle biopsy was taken from the vastus lateralis before, 3 h post, and 6 h post exercise. qRT-PCR was used to analyze gene expression of total PGC-1 α and NT-PGC-1 α expression. **RESULTS:** Gene expression of both total PGC-1 α and NT-PGC-1 α increased due to the exercise intervention at both 3 h and 6 h time points ($p < 0.05$), with mRNA expression peaking at 3 h ($p < 0.05$). At 3 h total PGC-1 α was higher in the cold (13.2 ± 6.3 fold increase) compared to room temperature (7.4 ± 2.0 fold increase, $p = 0.03$). NT-PGC-1 α was also higher in cold (20.8 ± 12.5 fold increase) compared to room temperature at 3 h (10.7 ± 3.7 fold increase, $p = 0.029$). Total PGC-1 α and NT-PGC-1 α were similar in cold and room temperature at 6 h ($p > 0.05$). **CONCLUSION:** Exercise and cold exposure induced alterations in gene expression for total-PGC-1 α and its truncated isoform, NT-PGC-1 α . It appears that NT-PGC-1 α contributes to the reported alterations in the cold-induced PGC-1 α exercise response.

Formoterol Stimulation In Vitro Influences Myogenic Regulatory Factors During Myogenesis In Human Skeletal Muscle Cells

Chase M. White, Gena D. Guerin, Emily L. Zumbro, Ryan A. Gordon, Dreanna M. McAdams, Matthew L. Sokoloski, David L. Nichols, FACSM, Anthony A. Duplanty. Texas Woman's University, Denton, TX. (Sponsor: David L. Nichols, FACSM)
 (No relevant relationships reported)

The process of myogenesis within skeletal muscle (SKM) is essential for growth and repair and is coordinated via the expression of myogenic regulatory genes. Previous animal studies have reported that formoterol, a beta-adrenergic receptor agonist, has stimulating effects on genes related to SKM mitochondrial function and biogenesis, similar to effects found for exercise. Lesser known is the potential "exercise mimetic" influence that formoterol stimulation may have during the stages of myogenesis, especially in human SKM cells.

Purpose: To investigate the effects of formoterol stimulation on expression of myogenic regulatory genes during myogenesis in human SKM cells. **Methods:** Human SKM myoblasts ($n = 6$ per group) were cultured and differentiated until mature myotube formation (Day 6). Groups included control cells (CON) and cells stimulated by 30nM formoterol for 3h prior to RNA extraction points (FORM). Total RNA was extracted during mid-myogenesis (Day 4) and at terminal differentiation (Day 6) (a cell culture model of investigating myogenesis). Gene expression for Myogenic factor 5 (Myf5), Myogenic differentiation 1 (MyoD), and Myogenin (MyoG) was determined by qPCR. Data were analyzed using repeated measures ANOVA. **Results:** Significant differences between conditions and time points are detailed in Table 1.

Conclusions: For the FORM group, Myf5 expression was elevated at D6 compared to CON while MyoG and MyoD expression was lower than CON for D4 and D6. The interpretation is that FORM stimulation increased stimulus of D4 myoblast proliferation and, thus, delayed initiation of differentiation. These results, coupled with other preliminary data from our lab showing increased mitochondrial biogenesis with this model of investigation, suggests that this exercise mimetic stimulation may cause shift in the cell towards bioenergetic preference rather than fusion of myotubes. Table 1.

Gene	Comparison	Fold Change	P Value
Myf5	D6 CON < D4 CON	-0.25	<0.05
	D6 FORM > D4 FORM	0.65	<0.001
	D6 FORM > D6 CON	0.75	<0.001
MyoD	D4 FORM < D4 CON	-0.57	<0.000
	D6 FORM > D4 FORM	0.85	<0.05
	D6 FORM < D6 CON	-0.16	<0.05
MyoG	D6 CON < D4 CON	-0.33	<0.001
	D4 FORM < D4 CON	-0.72	<0.001

Diurnal Regulation Of Exercise-induced Anabolic And Catabolic Signaling In White Adipose Tissue

Elias Maurice Malek, Caitlin K. Reynolds, Charli D. Aguilar, Graham R. McGinnis. *University of Nevada, Las Vegas, Las Vegas, NV.* (Sponsor: James Navalta, FACSM)
 Email: maleke1@unlv.nevada.edu

(No relevant relationships reported)

Purpose: Autophagy is a degradation system where damaged cellular components can be recycled, resulting in higher cellular efficiency. White adipose tissue has been shown to have a catabolic response to exercise where autophagy will increase immediately after exercise. mTOR is an anabolic signaling pathway that inhibits autophagy, and plays a key role regulating cell size. Autophagy is sensitive to bioenergetic stressors such as exercise and has been shown to be regulated in a circadian fashion. However, it is currently unknown if exercise-induced autophagy is sensitive to the time-of-day at which exercise occurs. The purpose was to assess anabolic and catabolic signaling in white adipose tissue following exercise at two times of day; Zeitgeber time (ZT) 0 (light phase) and ZT12 (dark phase).

Methods: 21 week old male C57/BL6 mice (n=38) were habituated to treadmill exercise for 5 days under red light during the active phase, and allowed to recover for 2 days. Following a single 60-minute bout of treadmill exercise at 10 m/min, mice were sacrificed at 3 time points, pre exercise (SED), immediately post exercise (POST), and 1-hour post exercise (1HR). Tissue was analyzed for anabolic (p-mTOR (Ser2448) and p-S6 (Ser204/244)), and catabolic (LC3II/I) signaling pathways via western blotting. Results were analyzed with a 2x3 ANOVA and significance was accepted at p<0.05.

Results: Following exercise, there was a significant repression of mTOR (SED=0.990 ± 0.17 vs POST=0.747 ± 0.14, p<0.05) and S6 (SED=0.702 ± 0.39 vs POST=0.186 ± 0.14, p<0.05) activation (Main Effect (ME) Exercise; p<0.05, both), which was significantly stronger following exercise performed at ZT12 (Interaction Effect for p-S6; p<0.05). Autophagy signaling (LC3II/I) was increased at ZT12 (ZT0=1.22 ± 0.33 vs ZT12=2.28 ± 1.09, p<0.05), which appeared to be driven by changes in LC3I expression. LC3II (normalized to total protein) was increased following exercise (SED=0.81 ± 0.26 vs POST=1.28 ± 0.43 and 1HR=1.22 ± 0.28, p<0.05, both) and was higher at ZT0 (ZT0=1.33 ± 0.33 vs ZT12=0.91 ± 0.33, p<0.05), although no interaction was present.

Conclusion: Anabolic and catabolic signaling in adipose tissue may be differentially impacted by exercise performed at different times of day.

The Role Of Mitochondrial Dysfunction And Redox Disturbances After Non-invasive Anterior Cruciate Ligament Injury

Steven M. Davi¹, McKenzie S. White², Oh Sung Kwon¹, Lindsey K. Lopley². ¹University of Connecticut, Storrs, CT. ²University of Michigan, Ann Arbor, MI.

Email: steven.davi@uconn.edu

(No relevant relationships reported)

Anterior cruciate ligament (ACL) injury results in protracted quadriceps atrophy, however the mechanisms that drive atrophic pathways remain undefined. Mounting evidence has revealed that mitochondrial dysfunction and redox disturbances are causal events in the initiation of quadriceps atrophy, yet the extent to which mitochondria damage play a key role in quadriceps muscle atrophy after ACL injury has yet to be explored.

PURPOSE: Using a pre-clinical animal model of ACL injury, a time course study was performed to investigate the role of mitochondria and Reactive Oxygen Species (ROS) after injury.

METHODS: 48 Long Evans rats (n=8 per group; 4m/4f) underwent non-invasive rupture of the right ACL and were euthanized at 1, 3, 7, 14, 28, 56 days post-injury. 8 rats (4m/4f) served as healthy controls (HC). Respiration was measured by high-resolution respirometry in permeabilized muscle fibers from the right vastus lateralis (VL). ROS production was determined using Amplex Red assays. VL weight was normalized to total body mass for measuring muscle mass loss. One-way ANOVAs with Bonferroni post-hoc were used to determine differences between groups (P < 0.05).

RESULTS: Reductions in complex I + II state 3 respiration were observed at 7 and 56 days post-injury (HC: 33.92 ± 4.26 pmol·s⁻¹·mg⁻¹; 7D: 15.95 ± 1.38 pmol·s⁻¹·mg⁻¹; 56D: 18.80 ± 2.15 pmol·s⁻¹·mg⁻¹; F = 5.99, P = 0.002 and P = 0.015 respectively). State 4 respiration did not differ between groups (P > 0.05). Respiratory Control Ratio (RCR), defined as respiration in state 3 divided by respiration in state 4, significantly decreased 7 through 56 days post-injury (HC: 4.00 ± 0.13; 7D: 1.54 ± 0.16; 56D: 1.82 ± 0.20; F = 13.29, P = 0.001 and P = 0.001 respectively) along with increased mitochondrial ROS production 7 through 56 days post-injury (HC: 10.16 ± 0.41 pmol·s⁻¹·mg⁻¹; 7D: 12.23 ± 0.54 pmol·s⁻¹·mg⁻¹; 56D: 26.83 ± 0.54 pmol·s⁻¹·mg⁻¹; F =

178.05, P = 0.001 and P = 0.001 respectively). VL atrophy was observed at 7 and 14 days post-injury (HC: 3.52 ± 0.08 mg·g⁻¹; 7D: 3.14 ± 0.07 mg·g⁻¹; 14D: 3.18 ± 0.07 mg·g⁻¹; F = 5.06, P = 0.013 and P = 0.044 respectively).

CONCLUSION: Mitochondria are an important source of muscular ROS production after ACL injury. Mitochondrial dysfunction and redox disturbances contribute to ACL injury-induced quadriceps atrophy.

Relationship Between Content Of Mitochondria And Z-disk Or Fiber Types

Guoqiang Geng¹, Rasmus Jensen², Yiheng Liang¹, Junqiang Qiu¹, Ortenblad Niels², Nielsen Joachim². ¹Beijing Sports University, Beijing, China. ²University of Southern Denmark, Odense, Denmark.

Email: garygeng7089@foxmail.com

(No relevant relationships reported)

PURPOSE: To estimate the relationship between mitochondrial volume contents and z-disks width determined by electron microscopy, analyzed from 13968 images from 582 fibers. **METHODS:** Eleven recreationally active individuals were recruited. Each subject had three endurance tests at 75% VO₂max following three different diets and nine biopsies in total. We obtained ten muscle fibers from each of the nine biopsies and used z-disk width as the discriminator of fiber types. From each fib23 24 EM images were obtained in each biopsy (12 intermyofibrillar, IMF, and 12 subsarcolemmal, SS, images, respectively), and point counting method was used to quantify IMF and SS mitochondrial content, and the total content. Relationships between fibers' mitochondrial contents and z-disk width were tested by Pearson's correlation coefficient and linear regression. Interactions and main effects were tested by a mixed effect model with fiber type and diet as fixed factors. **RESULTS:** The total mitochondria volume contents correlated highly significant with fiber z-disk width (Fig 2A. P<.001, R² = .20). Also, there were strong correlations between the mitochondrial volume contents in the IMF as well as SS and fiber z-disk (P<.001, R² = .18; P<.001, R² = .14, respectively, Fig. B, C). The type1 fibers have, on average, a 47% higher total mitochondrial content compared to the type 2 fibers, with 67% higher in SS and 41% in IMF, respectively (P<.001, Mean±SD, IMF:0.065±0.023μm³·μm⁻² vs 0.046±0.021μm³·μm⁻²; SS: 0.450±0.298μm³·μm⁻² vs 0.270±0.253μm³·μm⁻²; Total: 0.087±0.033μm³·μm⁻³ vs 0.059±0.031μm³·μm⁻³ Fig. D, E, F) **CONCLUSIONS:** The total mitochondrial volume contents, as well as the IMF and SS mitochondrial volume contents are strongly correlated with z-disk width in human muscle fibers (P<.001, R² = .20). Thus, fiber typing based on z-disk width is a strong predictor of fiber typing based on mitochondrial volume.

Figure. Association between mitochondrial z-disk width and subcellular specific and total mitochondrial contents. A, B and C, blue spots are type2 and red spots are type1. IMF mitochondrial content is a better predictor for z-disk width than SS (P<.001, R² = .42, R² = .18, P<.001, R² = .37, R² = .14, respectively). D, E, F the horizontal line means mean mitochondrial content of all subjects in each diet and fiber type. Black dots are type1 and grey dots are type2. ** Different between two fiber types (P<.001).

Effects Of Adipose Mesenchymal Stem Cells Injected Intramuscularly On Myostatin Signaling Skeletal Muscle In Rats After Eccentric Exercise

Xiujuan liu, nianyun zhang, biao sun, bin wang, yan xu. *Nanjing Sports Institute, Nanjing, China.*

(No relevant relationships reported)

PURPOSE: To observe the effect of adipose mesenchymal stem cells (ASCs) on myostatin signal of skeletal muscle in rats at different time points after eccentric exercise, and to explore the mechanism of ASCs injection on skeletal muscle injury and repair after eccentric exercise. **METHODS:** Phosphate buffer saline (PBS) were injected into the gastrocnemius muscle in the left leg, and ASCs were injected into

the gastrocnemius muscle of the right leg of SD rats after eccentric exercise. The rats were randomly divided into four groups: one day D1, three days D3, seven days W1 and fourteen days W2 after exercise. Skeletal muscle ultrastructure was observed by electron microscopic. The content of serum creatine kinase (CK), skeletal muscle troponin I (sTnI), myostatin (MSTN), follistatin (FST) were measured by ELISA. Real-time PCR was used to detect the expressions of MSTN, ACVR2B, FST mRNA in skeletal muscle. The expression of MSTN, ACVR2B, FST, p-Smad2/3 were detected by Western Blot.

RESULTS: Compared with group PBS, adipose mesenchymal stem cell injection significantly promoted the repair of muscle fibers. Compared with group D1, the level of CK in group W2 was significantly decreased, the content of sTnI level in group D3 and group W1 were remarkably increased, the serum MSTN contents in group W1 were significantly decreased, which in group W2 was remarkably increased. Compared with group PBS, the relative expression quantities of MSTN mRNA were significantly decreased at time point D3 and which were extremely significantly down-regulated at time point W2. Compared with group PBS, the expression of MSTN protein were significantly decreased at time point D3, the expression of ACVR2B protein were remarkably increased at time point D1, D3 and W1, however, which was significantly decreased at time point W2. Compared with group PBS, the phosphorylation of Smad2/3 shown significantly decreased at the time point W2 of group ASCs.

CONCLUSIONS: After eccentric exercise, allogeneic adipose mesenchymal stem cells injected intramuscularly can decreased the transcription of MSTN in skeletal muscle. Adipose mesenchymal stem cells injected intramuscularly may improve the regeneration and repair of skeletal muscle after eccentric exercise through affecting the downstream signaling pathway of MSTN.

Bioinformatics Analysis Of MicroRNA In Skeletal Muscle Of Mice Related To Aerobic Exercise

TAO MEI, YING ZHANG, YANG HU. *Beijing Sport University, Beijing, China.*

Email: meitao@bsu.edu.cn

(No relevant relationships reported)

MicroRNAs (miRNAs) are increasingly being studied as regulators for biological processes in skeletal muscle. However, little information relating to biological process regulated by aerobic exercise-affected miRNA is available. Bioinformatics analysis provides a perspective on the direction of future research.

PURPOSE: To analyze the functions of miRNAs which were affected by 8-week aerobic exercise in skeletal muscle of mice. **METHODS:** Twenty C57BL/6J mice were randomly divided into exercise (E) and control (C) groups. The E group were trained on a treadmill with a program of slope 0°, 12m/min, 60min/day, and 5 days/week. The C group lived normally without training. After 8-week of training, skeletal muscles were harvested for RNA extraction. Subsequently, miScript miRNA PCR Arrays was conducted to identify the differentially expressed miRNAs between two groups. Target gene prediction was performed by using TargetScan and microT-CDS tools. Gene Ontology analysis (GO) on the target gene was performed with Cytoscape Bingo. MirPath v.3 from the DIANA tools was used to execute the Kyoto Encyclopedia of Genes and Genomes (KEGG) analyses. **RESULTS:** 44 miRNAs were upregulated (Fold Change \geq 2.0, P<0.05) and 14 miRNAs were downregulated (Fold Change \leq -2.0, P<0.05) after the aerobic exercise. Prediction of target genes showed that there were a total of 9122 target genes (Ptpn9, Gria3, Zfp219, etc.) for the up-regulated miRNAs, while 3636 target genes (Nrf1, Lmbr11, Zbp1, etc.) for the down-regulated miRNAs. GO analysis revealed that the differentially expressed miRNAs participated in a variety of molecular functions and biological processes including nucleic acid binding, protein binding, regulation of gene expression, macromolecule metabolic process and others. KEGG analysis showed that the up-regulated miRNAs were significantly enriched in MAPK, Wnt and mTOR signaling pathway. The down-regulated miRNAs were mainly enriched in MAPK, Wnt signaling pathway. **CONCLUSION:** MiRNAs induced by aerobic exercise potentially regulate the biological processes of skeletal muscle mainly through MAPK and Wnt signaling pathways.

Aerobic Training Activates Nrf₂-mediated Anti-oxidative Effect Of Ampk On Mouse Skeletal Muscle

luo lin¹, Zhang Ying². ¹Guizhou Normal University, Guiyang, China. ²Beijing Sport University, Beijing, China.

Email: 5925860@qq.com

(No relevant relationships reported)

PURPOSE: To study the antioxidative effect of AMPK activated by aerobic training on Nrf₂ mediated skeletal muscle in mice. **METHODS:** 8-week-old AMPK α_2 transgenic mice (TG mice), AMPK α_2 knockout mice (KO mice) and wild-type mice

(WT mice) were randomly divided into two groups: the quiet group and the training group, with 10 mice in each group. In the training group, 6 days a week, aerobic training was conducted on the running platform with a gradient of 0 and a speed of 12 m / min for 1 hour every day for 4 weeks. The level of ROS in skeletal muscle was detected by fluorescence colorimetry. Rc-per was used to detect the level of antioxidant enzyme mRNA in skeletal muscle of mice in each group. Western blot method was used to detect the expression of AMPK α_2 , AMPK α , Nrf₂, pnr_f, and antioxidant enzyme protein. **RESULTS:** after 4 weeks of aerobic training (3) the expression of pnr_f protein in skeletal muscle of wild mice and AMPK α_2 transgenic mice increased significantly. (4) compared with the wild mice, the expression of AMPK α_2 gene knockout mice skeletal muscle catm_rna, nqo-1m_rna, ho-1m_rna, gp_x-1m_rna and sod1m_rna decreased significantly. (5) the expression of cat, GSR, HO-1 and SOD1 protein in the skeletal muscle of wild mice increased significantly. The expression of AMPK α_2 in transgenic mice was high, and the expression of protein (cat, GPx-1, nqo-1) and protein (GCLC, GSR, HO-1, SOD1, SOD2) in the skeletal muscle of wild mice increased significantly. Compared with the wild mice in the training group, the expression of AMPK α_2 in transgenic mice was high (GPx-1, GSR, HO-1, nqo-1, SOD1), SOD2) and GCLC protein expression increased significantly. Compared with the wild mice in the training group, AMPK α_2 knockout mice showed a significant decrease in the expression of protein (HO-1 and SOD2) in skeletal muscle tissue. (6) there was no significant difference in ROS level in skeletal muscle of wild mice, AMPK α_2 transgenic mice and AMPK α_2 knockout mice before and after training. **CONCLUSIONS:** the activation of AMPK by aerobic training can promote the expression of pnr_f in skeletal muscle, then increase the expression of antioxidant enzymes and improve the antioxidant capacity of the body.

Effects Of Mild Hypoxic Conditions On Mrna Expression Of Spinal Cord In The Young And Old Mouse

Hirofumi Miyata¹, Hiroshi Nagahisa², Nami Matsuura¹.

¹Yamaguchi Univ., Yamaguchi, Japan. ²Kumamoto Univ., Kumamoto, Japan.

Email: hiro@yamaguchi-u.ac.jp

(No relevant relationships reported)

We have developed a method to evaluate motoneuron plasticity by real-time RT-PCR analysis for whole spinal cord. **PURPOSE:** In this study, we examined effects of mild hypoxic conditions on mRNA expression of spinal cord as well as skeletal muscle in young and old mouse. **METHODS:** Young (12-week old, n=16) and old (20-month old, n=17) mice were divided into three groups of control, continuous hypoxia, and intermittent hypoxia. Both hypoxic groups were subjected to exposure for 5 days under oxygen concentration of 16%. The intermittent hypoxic group was exposed six times to an oxygen concentration of 16% intermittently every hour for 12 hours of the light day of the day. Immediately after completion of the exposure, the spinal cord (Cervical 3 - 6 and Lumber 2 - 5) as well as muscles (diaphragm and gastrocnemius muscles) were removed and mRNA expression levels were investigated using real time RT-PCR system. **RESULTS:** Although the mRNA expression levels of PGC1 α and VEGF-A were significantly (P < 0.05) higher in diaphragm than gastrocnemius muscles, these mRNA expressions levels were not affected by hypoxic stimulation. While, the mRNA expression levels of muscle remodeling factors (Pax7, MyoD, BDNF, and MHCe) were significantly (P < 0.05) higher in hypoxic condition than control group. Compared with young mice, the expression levels of inflammatory cytokine receptor (IL-6R α) and neurotrophic factors (BDNF, VEGF-A) of muscles increased in old mice. The increased expressions may be considered to be an indispensable adaptive change for age-related changes in skeletal muscle including neuromuscular junction. In the both hypoxia groups, the mRNA expression level of neurotrophic factors (VEGF-A, FGF2) significantly (P < 0.05) increased in the cervical, but not in the lumbar spinal cord. **CONCLUSIONS:** We concluded that the mRNA expressions of trophic factor were changed by hypoxic stimulation not only in the muscle but also in the cervical spinal cord.

Combined Effects Of Unloading And Radiation On Skeletal Muscle In Mice

Rodrigo Fernandez-Gonzalo¹, Björn Hansson¹, Eric Emanuelsson¹, Bjorn Baselet², Marjan Moreels², Mieke Neefs², Sarah Baatout², Helene Rundqvist¹. ¹Karolinska Institutet, Stockholm, Sweden. ²Belgian Nuclear Research Centre SCK•CEN, Mol, Belgium.
Email: rodrigo.gonzalo@ki.se
(No relevant relationships reported)

In preparation for upcoming space missions to the Moon and Mars, there is a need to understand how space stressors (e.g. microgravity, radiation) affect different physiological systems. As skeletal muscle is a critical organ, not only for locomotion but also for overall body homeostasis, defining the molecular impact of microgravity and radiation on this tissue will help developing new, or fine-tuning current countermeasures to maintain health and physiological function of space travellers. **PURPOSE:** To investigate the effects of combined radiation and unloading on anabolic/catabolic and immune/inflammatory processes on skeletal muscle in mice. **METHODS:** Ten C57/BL6J mice were subjected to 14-d hind-limb unloading by tail suspension with an acute radiation session (dose=25 mGy, X-ray) on day 7 of unloading (HLUR). Ten mice were used as control (CTRL; similar cages, sham radiation). Mice were sacrificed and soleus muscle was immediately dissected, weighed and frozen. Then, RNA was extracted and converted to cDNA. Gene expression of anabolic/catabolic (i.e. myostatin, MuRF-1, Atrogin-1, PGC-1 α) and immune/inflammatory markers (i.e. CD4, CD8, IFN γ , CD11b, MHCII, TNF, IL-6) was assessed by RT-PCR. Independent t-tests were used to compare HLUR vs. CTRL. **RESULTS:** Soleus muscle weight was ~30% lower in HLUR vs. CTRL ($P<0.001$). Myostatin expression was greater in HLUR vs. CTRL (1.8-fold, $P=0.014$). MHCII expression was higher in HLUR vs. CTRL (2.4-fold, $P<0.001$). There was a trend for group differences ($P<0.08$) in CD11b and TNF mRNA content with HLUR showing greater values than CTRL. Gene expression of CD4, CD8 and IFN γ was barely detected in either group. **CONCLUSIONS:** The combination of unloading and radiation has a major impact on skeletal muscle. Apart from inducing muscle atrophy, as indicated by the decreased muscle weight and increased myostatin levels, these two space stressors altered the immune profile within the muscle. The increased gene expression of MHCII and CD11b indicates that the myeloid component of the immune system is activated upon unloading and radiation in skeletal muscle. In contrast, the almost undetected mRNA levels of CD4, CD8 and IFN γ may imply that unloading and acute radiation have little impact on the lymphoid component. These findings should be followed up with immunohistochemical analysis.

Role Of The Mct-1 T1470a Polymorphism (rs1049434) In The Uptake Of Lactate In Females Following 30 Second Wingate Test

Will C. Hawkins. *University of Southern Indiana, Evansville, IN.*
(No relevant relationships reported)

PURPOSE: The purpose of this investigation was to examine the role of the MCT-1 T1470A single nucleotide polymorphism on blood lactate clearance rates in females following a 30 second Wingate test. **METHODS:** Lactate was measured before the test, immediately following the test and -10, -20, -30 and -40 minutes post. Lactate

decreases were calculated for each 10-minute period. Participants were divided into three groups based on their T1470A genotype (TT, TA, AA). **RESULTS:** There was no significant interaction between genotype and lactate clearance ($p=0.123$), however the TT genotype group had significantly higher clearance rates when collapsed across time points ($p=0.003$). Lactate clearance was higher in the TT genotype when compared to both the TA genotype ($p=0.002$) and the AA genotype ($p=0.009$). This effect was caused by significantly higher lactate accumulation in TT genotype subjects immediately following the Wingate test when compared to TA ($p=0.001$) and AA ($p=0.003$) subjects. **CONCLUSION:** To our knowledge, our investigation is the first that demonstrates that the MCT-1 genotype effects lactate clearance in women. Our findings differ from the body of literature carried out using male participants, which suggests that the T allele adversely effects lactate clearance. Further, our findings indicate that peak lactate clearance occurs earlier in the TT group compared to the TA and AA group in resistance trained females. Future research should continue to examine the MCT-1 polymorphism in woman and how this genetic information can be integrated into exercise prescription protocols.

F-58 Free Communication/Poster - Blood Flow Restriction

Effects Of Blood Flow Restriction With Eccentric Exercise On Muscle Adaptation

Malcolm Jones, E. Todd Schroeder. *University of Southern California, LOS ANGELES, CA.*
(No relevant relationships reported)

Purpose: BFR during RT has been reported clinically to rehabilitate/prevent injury in healthy people and people with orthopedic conditions. Further, subjective accounts of minimal muscle soreness post-training suggest a reduction in exercise induced muscle damage compared to traditional RT. We sought to compare the effects of BFR eccentric RT at low loads on muscle performance to traditional eccentric resistance training at high loads, and to explore the feasibility of multifrequency bioelectric impedance analysis (BIA) to assess muscle damage and hypertrophy. **Methods:** 25 healthy young adults 25 ± 5 yo (11 female, 14 male) were randomized into two groups (BFR L, BFR R and trained 2x/wk for 6 wks. The contralateral leg was trained traditionally to serve as the control (TC) after baseline testing (single-leg vertical jump, Nordbord bilateral eccentric hamstring strength, legcurl bilateral 1RM, legcurl hamstring endurance)At the conclusion, participants re-tested. BIA data was collected pre (0, 24, 48hrs) and post (0, 24, 48hrs). Pre-post paired t-tests and coefficient of determination were used for analysis. **Results:** There was 96% compliance. There were no significant changes in single leg vertical jump (left: $p=0.14$, right: $p=0.26$), hamstring strength (left: $p=0.17$, right: $p=0.38$), or hamstring endurance in either leg (left: $p=0.95$, right: $p=0.12$) or condition. There were significant increases (7.5-9.5%) in hamstring 1RM in both legs (left: $p<0.01$, right: $p<0.01$) and both training conditions (BFR: $p<0.01$, TC: $p<0.01$). There was low correlation between phase angle and participant perceived soreness ($r^2=0.15$), but scores were significantly lower in BFR leg immediately ($p=0.04$) and 24hr ($p=0.04$) post training. **Conclusions:** Eccentric BFR resistance training exhibited similar outcomes to traditional training with less reported soreness. However, interpretation of these data are limited by methodologic approach.

3360 Board #181 May 29 1:30 PM - 3:00 PM

Acute Cardiovascular And Muscular Response To No-load Exercise With And Without Blood Flow Restriction

Wenyuan G. Zhu, Tayla E. Kuehne, Noam Yitzchaki, Ryo Kataoka, Samuel L. Buckner. *University of South Florida, Tampa, FL.*
(No relevant relationships reported)

PURPOSE: To examine acute changes in muscle thickness, isometric strength, and arterial occlusion pressure (AOP) following NO LOAD exercise with and without the application of blood flow restriction (BFR) in the upper body. **METHODS:** Changes in muscle thickness, isometric strength and AOP were examined following four sets of twenty repetitions of unilateral elbow flexion exercise. Participants performed maximal muscle contractions with no external load throughout a full range of motion with and without the application of a moderate BFR (40% of AOP). Results are displayed as mean (SD). **RESULTS:** 39 resistance-trained males and females completed the study. For isometric torque there was a condition x time interaction ($p=0.012$). The BFR condition had lower isometric torque immediately following exercise [56.07 (17.78) Nm] compared to the control group [58.67 (19.06) Nm]. In addition, both

the BFR and control conditions demonstrated a decrease in torque immediately following exercise [mean change = 4.5 (4.5) and 1.82 (4.5) Nm for BFR and control conditions respectively], which remained decreased below baseline 15 minutes post exercise [mean change 2.39 (5.5) and 2.28 (3.19) Nm for BFR and control conditions respectively]. For muscle thickness, there was a main effect for time ($p < 0.001$). Muscle thickness increased from pre [3.52 (.78) cm] to post [3.68 (.81) cm] exercise and remained increased above baseline 15 min post exercise [3.6 (.80) cm]. For AOP, there was a group x time interaction ($p = 0.027$). The change in AOP was greater in the BFR group [16.6 (13.42) mmHg] compared to the control group [11.1 (11.84) mmHg]. **CONCLUSIONS:** NO LOAD exercise with the application of BFR led to greater reductions in isometric torque compared to NO LOAD exercise without the application of BFR. In addition, the application of BFR led to an exaggerated cardiovascular response compared to NO LOAD exercise alone. There were no differences in acute muscle swelling between NO LOAD exercise with and without BFR. These results suggest that the application of BFR to NO LOAD exercise may lead to a greater level of muscle fatigue when performing four sets of twenty maximal repetitions. This is accompanied with an exaggerated cardiovascular response.

3361 Board #182 May 29 1:30 PM - 3:00 PM
The Acute Muscular Response To Passive Movement And Blood Flow Restriction

Joonsun Park¹, Daphney M. Stanford², Samuel L. Buckner³, Matthew B. Jesse². ¹The University of Southern Mississippi, Hattiesburg, MS. ²The University of Mississippi, University, MS. ³University of South Florida, Tampa, FL.
 (No relevant relationships reported)

In immobilized patients, passive movement (PM) with blood flow restriction (BFR) reduces atrophy over PM alone; whether these effects are greater than BFR alone is uncertain. **PURPOSE:** To determine if acute muscular responses are unique when combining BFR and PM compared to PM alone or BFR alone. **METHODS:** 20 participants performed four conditions (randomized order): time control (TC), PM, BFR, and PM combined with BFR (PM+BFR) over two visits (one condition each leg, per visit). For PM, a dynamometer moved (45°/second) the leg through 3 sets of 15 knee extensions/flexions (90°). For BFR, a cuff was inflated to 80% arterial occlusion pressure on the proximal portion of the leg. Muscle thickness (MT) was measured at 60% and 70% of the anterior upper leg before, immediately after, five minutes after, and ten minutes after each condition. Oxygenated, deoxygenated (HHb), and total (tHb) hemoglobin of the vastus lateralis were monitored throughout conditions via near-infrared spectroscopy. Ratings of perceived effort (RPE-E) and discomfort (RPE-D) were reported before conditions and after each set. Data [presented as mean (SD)] were analyzed using Bayesian RMANOVA. **RESULTS:** 60% MT [Δ before to immediately after: TC = 0.04 (0.09), PM = -0.01 (0.15), BFR = -0.00 (0.11), PM+BFR = 0.01 (0.22) cm] and 70% MT [Δ before to immediately after: TC = 0.01 (0.09), PM = -0.01 (0.15), BFR = 0.02 (0.11), PM+BFR = -0.03 (0.22) cm] did not change ($BF_{10} = 0.014$ and 0.015 , respectively). HHb and tHb changes were generally greater with BFR and PM+BFR [i.e. channel 2 HHb: Δ start set 1 to end set 3: TC = 1.07 (1.21), PM = -1.23 (1.86), BFR = 9.58 (2.81), PM+BFR = 10.11 (3.16) μ m]. RPE-E increased with time and condition ($BF_{10} = 2.882e+8$), [Δ before to end set 3: TC = 0.0 (0.2), PM = 0.7 (1.0), BFR = 0.9 (2.1), PM+BFR = 1.3 (1.7)]. RPE-D changes were greater for BFR and PM+BFR ($BF_{10} = 1.877e+13$), [Δ before to end set 3: TC = 0.0 (0.2), PM = 0.4 (1.1), BFR = 3.2 (1.8), PM+BFR = 2.6 (1.5)]. **CONCLUSION:** PM and/or BFR alone are not sufficient to acutely increase MT (generally associated with a hypertrophic stimulus) in healthy people. Changes in tissue oxygenation seem to be driven by BFR rather than a unique effect of combining PM with BFR. The extent of this effect and what it would mean for adaptation in either healthy or bed-ridden patients warrants further investigation.

Muscle Swelling Following Low Load Blood Flow Restriction Exercise Does Not Differ Between Cuff Widths In The Lower Body

Zachary W. Bell¹, Takashi Abe¹, Vickie Wong¹, Robert W. Spitz¹, Ricardo B. Viana¹, Raksha N. Chatakondi¹, Scott J. Dankel², Yujiro Yamada¹, Jeremy P. Loenneke, FACSM¹. ¹The University of Mississippi, University, MS. ²Rowan University, Glassboro, NJ. (Sponsor: Jeremy P. Loenneke, FACSM)
 Email: zwbell@go.olemiss.edu
 (No relevant relationships reported)

Acute muscle swelling is a purported mechanism for muscle hypertrophy following blood flow restriction (BFR) training. Currently there are numerous cuff widths used within the lower body BFR literature. However, studies suggest that growth may be attenuated with a wider cuff. Whether this is related to a differential acute swelling response has not been previously shown. **PURPOSE:** To examine the acute changes in muscle swelling following low load BFR exercise in the lower body, in response to different cuff widths inflated to the same relative pressure. **METHODS:** Ninety-six (43

men, 53 women) participants completed two conditions (one each leg). Participants completed four sets of unilateral knee extension exercise to failure using 30% of their one repetition maximum (1RM) with BFR applied with either a narrow (5 cm) or a wide (12 cm) cuff inflated to 40% of their arterial occlusion pressure. Muscle thickness and echo intensity were measured at two sites (proximal and distal) before and after each exercise bout as surrogate markers of swelling. A repeated measures analysis with a between subject factor of sex was used to assess changes. Bayes Factors (BF_{10}) were used to quantify evidence. **RESULTS:** The difference in acute changes in muscle thickness (BF_{10} : 0.43) and echo intensity (BF_{10} : 0.87) between cuff widths was not different between the proximal (i.e. wide cuff covered this site) and distal (no cuff was over this site) location. Further, changes in muscle thickness at the proximal [5cm: 0.58 cm vs. 12 cm: 0.57 cm; median difference (95% credible interval) of 0.009 (-0.04, 0.06) cm] and distal [5 cm: 0.63 cm vs. 12 cm: 0.63 cm; median difference (95% credible interval) of 0.00002 (-0.03, 0.04) cm] site did not differ based on cuff width or sex (Men: 0.58 cm vs. Women: 0.58 cm and Men: 0.64 cm vs. Women: 0.63 cm for proximal and distal sites, respectively). Echo intensity appeared to decrease at the proximal and distal sites with no differences between cuff widths. However, there was some evidence that this change at the distal site may be different between sexes [BF_{10} : 49.8; Men: -1.9 vs. Women: -4.2 AU]. **CONCLUSIONS:** Acute muscle swelling occurs in men and women, even when using a wider cuff. Thus, if there is to be attenuation in growth with a wider cuff, it is unlikely to be due to differences in acute swelling.

Examination Of High-velocity Blood Flow Restricted Resistance Exercise Versus High-load Resistance Exercise

Summer B. Cook, FACSM, Christopher J. Cleary, Brittany T. Duncan. University of New Hampshire, Durham, NH.
 Email: summer.cook@unh.edu
 (No relevant relationships reported)

Muscle strength gains following blood flow restricted (BFR) resistance training are consistently lower than those observed after HL training and this may be due to differences in neuromuscular activation. Integrating high-velocity muscle contractions and BFR resistance exercise may increase neuromuscular activation. **PURPOSE:** To compare torque and neuromuscular activation before and after sessions of HL knee extension exercise and high-velocity BFR knee extension exercise in young and older adults. **METHODS:** Ten young males and females (20.3 \pm 1.5 years, 1.73 \pm 0.06 m, 69.2 \pm 10.4 kg) and 10 older males and females (72.6 \pm 4.7 years, 1.70 \pm 12 m, 74.3 \pm 14.6 kg) performed randomized sessions of HL (80% 1-RM for 3 sets of 10 isotonic knee extension repetitions) and low-load, high-velocity BFR (30% 1-RM coupled with a vascular restriction for one set of 30 knee extension repetitions and 3 sets of 15 repetitions completed as quickly as possible). Knee extension isometric torque was assessed before and after each session of exercise and neuromuscular activation of the vastus lateralis (VL) was quantified with surface electromyography (EMG). **RESULTS:** The young participants had higher isometric torque than the older participants (213.4 \pm 54.8 vs 160.1 \pm 56.3 Nm; $P=0.01$). There was an average decrement in torque of 31.4 \pm 9.2% among all participants from baseline to post exercise ($P<0.01$). The magnitude of this decrement was similar between conditions ($P=0.19$), age ($P=0.12$), and the interaction of time, condition and age ($P=0.16$). EMG amplitude normalized to pre isometric torque in the first 5 knee extension repetitions of the HL condition averaged 106 \pm 57% and 90 \pm 33% in the BFR high-velocity condition. In the last 5 repetitions, EMG amplitude averaged 117 \pm 56% and 113 \pm 46 in the HL and BFR conditions respectively. This was a significant increase in EMG amplitude ($P<0.01$) but there were no interactions or main effects of condition or age ($P>0.05$). **CONCLUSION:** Combining high-velocity contractions with BFR resistance exercise results in decrements in torque and heightened neuromuscular activation similar to HL exercise in both young and older adults. Future studies should evaluate the training adaptations from high-velocity BFR resistance training. Supported by University of New Hampshire Grimes Family Fund.

Proposal Of A New In Vitro Exercise Model For Cartilage Regeneration

Pedro G. Morouco. *Polytechnic Institute of Leiria, Leiria, Portugal.*

Email: pedro.morouco@ipleiria.pt
 (No relevant relationships reported)

Tissue Engineering and Regenerative Medicine are promising interdisciplinary fields regarding tissue and/or organ repair and regeneration. Due to the extremely high incidence of osteoarthritis in such an aging population, it is critical to put all efforts in developing a successful implant for osteochondral tissue regeneration; although there has been a huge amount of work aiming to regenerate it, a tailored construct has not been achieved yet. **PURPOSE:** to develop a 3D in vitro model and bioreactor system to evaluate osteochondral regeneration, as well as cell-material interaction and material induced cell migration and differentiation, under physiological conditions in a bioreactor system with the ability of providing mechanical and electrical stimuli. **METHODS:** Multiphysics computer simulations were performed to explore which combination of stimuli facilitate cells adhesion, proliferation, viability and differentiation. A suite of new mathematical models were developed and validated, together with robust and efficient computational tools that allow simulation of chondral regeneration in vitro and in vivo. **RESULTS:** An automated integrated smart system for the assembly and in vitro culture process of the osteochondral constructs was designed. The platform integrate two distinct zones: the multi-material bioprinter and the custom-designed bioreactor. Due to different environmental conditions (temperature, humidity and PCO₂) that must be ensured in the fabrication and culture areas, a custom-made incubator with two separate areas and differential environmental control were developed. **CONCLUSION:** The integrated assembly system was validated by comparing the biological and mechanical properties of the produced constructs. Preliminary results have demonstrated both adequate mechanical and biological properties of the 3D constructs, using Poly(glycerol-sebacate) and graphene.

Therapeutic Potential Of Different Pericyte Populations In The Recovery Of Skeletal Muscle Mass Following Disuse

Samuel Lapp, Yu Fu Wu, Svyatoslav Dvoretzkiy, Amanda Tannehill, Gabriela Garcia, Marni Boppart, FACS. *University of Illinois at Urbana-Champaign, Urbana, IL.* (Sponsor: Marni Boppart Sc.D., FACS)

Email: sclapp2@illinois.edu
 (No relevant relationships reported)

Significant loss in skeletal muscle mass and function can occur following periods of extended bed rest or immobilization. Physical therapy is recommended, but recovery may be incomplete in special populations due to injury and functional limitations. Our lab recently demonstrated the capacity for pericytes, or vascular stromal cells, to accelerate recovery of skeletal muscle following disuse in a mouse model. Different pericyte populations exist in skeletal muscle based on localization and unique cell surface markers, yet the most therapeutic population has not been identified. **PURPOSE:** To identify the pericyte population with the greatest therapeutic benefit when transplanted into muscle following a period of disuse. **METHODS:** Twenty-four 4-month old C57BL/6 mice were randomly divided into four groups (n=6/group). Mice hindlimbs were immobilized in full dorsiflexion via a surgical staple inserted through the center of the foot and body of the gastrocnemius for 2 weeks. At 2 weeks post immobilization, staples were removed and either pericytes (CD146⁺Lin⁻, CD146⁺NG2⁺Lin⁻, NG2⁺Lin⁻) or saline (control) were injected into the tibialis anterior (TA) muscle. TA muscles were excised for analysis after 2 weeks of remobilization and the extent of recovery was assessed. One-way ANOVA was used to compare the extent of improvement between treatment groups. **RESULTS:** There was no significant improvement in TA muscle weight or myofiber CSA with pericyte transplantation in the current study (p>0.05). However, a trend toward significant improvement in myofiber CSA was noted for fibers ranging 2000-3000 μm² in mice receiving CD146⁺NG2⁺Lin⁻ pericytes (p=0.072). Significant improvements in capillarization and collagen remodeling were detected in mice receiving CD146⁺NG2⁺Lin⁻ (p<0.05) and CD146⁺Lin⁻ (p<0.05) pericytes compared to controls. **CONCLUSION:** CD146⁺Lin⁻ pericyte transplantation effectively recovered capillary quantity and collagen remodeling following a period disuse compared to controls, whereas NG2⁺Lin⁻ pericytes did not demonstrate similar capacity for recovery. Supported by NIH Grant NIAMS R01 AR072735 to MDB.

Reported Relationships: **A. Gupta:** Salary; BioIntegrate LLC.
 Ownership/interest/stock; Right Mechanics Inc..

PURPOSE: Musculoskeletal injuries have traditionally been treated with activity-modification, physical therapy, pharmacological agents and surgical procedures. These modalities have limitations, as well as potential side-effects. Over the last decade, there has been an increased interest in the use of biologics for regenerative medicine applications (RMA), including umbilical cord (UC) derived Wharton's Jelly (WJ). Despite this increase, there is insufficient literature assessing the amount of growth factors, cytokines, hyaluronic acid (HA) and extracellular vesicles (EV) including exosomes in these products. The purpose of this study was to develop a novel WJ formulation and evaluate the presence of growth factors, cytokines, HA and EV including exosomes.

METHODS: WJ was isolated from human-UC obtained from consenting C-section donors and formulated into an injectable form. Randomly selected samples from different batches were analyzed for sterility testing and quantified for presence of growth factors, cytokines, HA and particles in EV size range.

RESULTS: The results showed all samples passed the sterility test. Growth factors including IGFBP 1, 2, 3, 4 and 6, TGF-α, PDGF-AA were detected. Expression of several immunomodulatory cytokines, RANTES, IL-6R, IL-16, were also detected. Expression of pro-inflammatory cytokines MCSFR, MIP-1a; anti-inflammatory cytokines TNF-RI, TNF-RII, IL-1RA; and homeostatic cytokines TIMP-1 and TIMP-2 were observed. Cytokines associated with wound-healing, ICAM-1, G-CSF, GDF-15, and regenerative properties, GH were also expressed. High concentrations of HA were observed. Particles in the EV size range (30-150nm) were detected and were enclosed by the membrane, indicative of true EV.

CONCLUSIONS: Our results confirmed the presence of numerous growth factors, cytokines, HA and EV in the WJ formulation. More studies are underway to confirm the presence of exosomes in detected EV using exosome-specific markers. We believe the presence of multiple factors within one WJ formulation may play a role in reducing inflammation, pain and augment healing of musculoskeletal injuries. This offers a potential expanded use for RMA.

Overexpression Of PGC-1α In Human Primary Myotubes Increases Regulators Of Exosome Biogenesis And Secretion

Derek Middleton¹, Christopher Kargl¹, Jeffery Brault², Timothy Gavin, FACS. ¹*Purdue University, West Lafayette, IN.*

²*Indiana University, Indianapolis, IN.* (Sponsor: Timothy P. Gavin, FACS)

(No relevant relationships reported)

Skeletal muscle functions as an endocrine organ. Exosomes, small vesicles containing mRNAs, miRNAs, and proteins, are secreted from muscle cells and facilitate cell-to-cell communication. Our recent work found greater exosome release from oxidative compared to glycolytic muscle. Peroxisome proliferator-activated receptor gamma coactivator 1-alpha (PGC-1α) is a key driver of mitochondrial biogenesis, a characteristic of oxidative muscle. It was hypothesized that PGC-1α regulates exosome biogenesis and secretion in skeletal muscle. **PURPOSE:** To determine if PGC-1α regulates skeletal muscle exosome biogenesis and secretion. **METHODS:** On day 4 of differentiation, primary myotubes from vastus lateralis biopsies from lean donors (BMI < 25.0 kg/m²) were exposed to adenovirus encoding human PGC-1α or GFP control. On day 6 of differentiation, culture media was replaced with exosome-free media. On day 8, cells were collected for mRNA and protein analysis. **RESULTS:** Overexpression of PGC-1α increases regulators of exosome biogenesis in the endosomal sorting complexes required for transport (ESCRT) pathway: Alix (GFP: 2.9 ± 1.0 vs. PGC-1α: 7.6 ± 1.4), TSG-101 (GFP: 1.8 ± 0.1 vs. PGC-1α: 7.3 ± 2.1), CD63 (GFP: 2.6 ± 0.3 vs. PGC-1α: 3.7 ± 0.4), Clathrin (GFP: 3.5 ± 0.1 vs. PGC-1α: 11.6 ± 2.5), and the secretion pathway: Rab27b (GFP: 2.6 ± 0.7; PGC-1α: 3.2 ± 0.3). **CONCLUSION:** Overexpression of PGC-1α increases gene expression of regulators of exosome biogenesis and secretion in human primary myotubes.

Obesity increases the susceptibility of skeletal muscle to damage and impairs the regenerative response following muscle damage. Obesity is associated with an increase in ectopic lipid accumulation and inflammatory cell infiltration in skeletal muscle. It is unclear if the impairments in skeletal muscle regeneration and increased susceptibility to damage is due to these factors or if defects in integrity and repair are inherent to muscle of obese subjects. **PURPOSE:** To investigate if myotubes isolated from obese donors are (1) more susceptible to damage and (2) have a blunted regeneration response. **METHODS:** Differentiated myotubes from lean (LN) and obese (OB) donors were treated with 0.5 μ M of cardiotoxin (CTX) for 1 hr. Cells were allowed to recover in skeletal muscle growth media for 3 days and then differentiation media for 2 days. Cells were isolated immediately (ImPost), 3 and 5 days following CTX treatment. **RESULTS:** CTX significantly reduced the fusion index of differentiated cells, but there were no differences between LN and OB at ImPost (no-CTX: LN 28% vs. OB 28%; CTX: LN 15% vs. OB 12%), 3 Days (no-CTX: LN 38% vs. OB 38.0%; CTX: LN 30% vs. OB 29%), or 5 Days (no-CTX: LN 41% vs. OB 39%; CTX: LN 37% vs. OB 34%). CTX significantly reduced cell viability assessed via MTT but no differences were observed between LN and OB at ImPost (no-CTX: LN 0.20 au vs. OB 0.21 au; CTX LN 0.11 au vs. OB 0.14 au), 3 days (no-CTX: LN 0.37 au vs. OB 0.37 au; CTX LN 0.08 au vs. OB 0.12 au), or 5 days (no-CTX: LN 0.34 au vs. OB 0.34 au; CTX LN 0.19 au vs. OB 0.22 au). No differences were observed in the expression of key metabolic proteins PFK-1, Citrate Synthase, or β -Had following CTX administration in LN or OB. **CONCLUSION:** When cultured under identical conditions, myotubes isolated from young, healthy obese donors demonstrate similar damage following CTX treatment and similar regenerative responses compared to myotubes from lean donors.

Single-cell RNA Sequencing Of Human Skeletal Muscle Reveals Novel Progenitor Populations

Alasdair W.R. Cameron¹, Scott Wotherspoon², Stevan A. Springer¹, Nick Gaulton¹, Laura V. Young¹, Adam P.W. Johnston¹. ¹University of Prince Edward Island, Charlottetown, PE, Canada. ²Queen Elizabeth Hospital, Charlottetown, PE, Canada.
 (No relevant relationships reported)

INTRODUCTION: Skeletal muscle contains numerous stem and progenitor cell populations that reside within the interstitium between myofibres. These cells directly and indirectly support muscle repair; however, the identities and functions of these cells remain poorly characterized in human muscle. **PURPOSE:** To apply a novel genetic tool, single cell RNA sequencing (scRNAseq), to identify progenitor cell populations within uninjured human skeletal muscle. **METHODS:** Total mononuclear cells were isolated from the hamstrings of n=5 orthopedic surgery patients (2 males, 3 females, mean age ~23.4) and combined for droplet based scRNAseq using the 10x Chromium Controller. Bioinformatic analysis was conducted using R package Seurat V3.0, which computed principal components for projecting cells in two dimensions and employed unsupervised graph-based clustering using uniform manifold approximation and projection (UMAP). **RESULTS:** Following quality control, a total of 2736 cells were analyzed at a read depth of ~41,000 reads per cell with an average of 1255 genes detected per cell. Analysis of differentially expressed genes identified 8 distinct cell clusters which corresponded to the expected cell populations of satellite cells, endothelial/vascular related cells, mesenchymal/fibroblastic cells, T-cells, macrophages, as well as type I and type II muscle cells. Interestingly, the analysis also revealed two poorly characterized populations. The first expressed both mesenchymal and smooth muscle-related genes and displayed a similar transcriptional profile to "smooth muscle mesenchymal cells" (SMMCs) recently described in rodents. The second was typified by the expression of the transcription factor *Twist-2* suggesting they may be analogous to a newly defined muscle stem cell population responsible for the growth of type-II fibres. In addition to the primary clusters, analysis also identified numerous "sub-clusters" of cells providing insight into previously undescribed cellular heterogeneity, the function of which remains unknown. **CONCLUSION:** scRNAseq is an effective tool to define and transcriptionally characterize cell populations within human skeletal muscle. Ongoing analysis is examining the function of SMMCs and *Twist-2*-positive cells in response to exercise.

Regulation Of Myokine Expression In Exosome-like Vesicles By Electric Pulse Stimulation Of C2C12 Myotubes

Ju-Hee Kang¹, Sujin Kim¹, Sohee Moon¹, Hyo-Bum Kwak², Dong-Ho Park². ¹College of Medicine, HDRC, Inha University, Incheon, Korea, Republic of. ²Inha University, Incheon, Korea, Republic of.
 Email: johygang@inha.ac.kr
 (No relevant relationships reported)

Physical exercise (PE) is a well-known non-pharmacological intervention to overcome chronic low-graded inflammation-induced sarcopenia through humoral factors. However, it is not fully elucidated whether PE-induced maintenance of muscle homeostasis against inflammation is associated with muscle cell-derived myokines and extracellular vesicles. **PURPOSE:** To determine the effects of inflammation of muscle cell on the myokine expression in exosome-like vesicles (ELVs), and the effects of electric pulse stimulation (EPS), as an exercise mimetic on the myokine expression using C2C12 myotubes.

METHODS: Inflammation of C2C12 was induced by treatment of a cytokine mixture (CM, TNF- α +INF- γ), and insulin resistance was induced by palmitate (0.75 mM) for 24 hrs. ELVs were enriched from conditioned media by differential ultracentrifugation. EPS was set as 11.5V, 2m/s, 2Hz for 24 hrs. We considered $P < 0.05$ as significant, using GraphPad Prism ver 2.0 program.

RESULTS: Treatment of C2C12 by CM significantly inhibited the expression of myogenic regulators (myogenic transcription factors, myogenic myokine, and signaling proteins), while induced the expression of atrophic factors (atrogin-1, myostatin and signaling proteins). In addition, the inflamed C2C12 myotubes released anti-myogenic ELVs which contain abundant myostatin and scanty level of decorin, comparing with control ELVs. When we stimulated C2C12 myotubes by EPS system, levels of myogenic regulators (MyoD and myogenin), myogenic myokines (FDNCS, decorin, FGF21 and cathepsin B), and metabolic function of myotubes were significantly increased, however the levels of myostatin and atrogin-1 were down-regulated. Furthermore, EPS increased the mitochondrial activity and activated mitochondrial biogenesis pathways.

CONCLUSIONS: Inflammation, expression of anti-myogenic regulators and mitochondrial dysfunction are major contributors in metabolic diseases- or aging-induced sarcopenia. Therefore, our results suggested that activation of anti-myogenic activity in muscle cells by contraction (i.e., EPS in vitro and skeletal muscle contraction during PE in vivo) through myokine-containing ELVs may be a mechanism of beneficial effects of PE against sarcopenic factors.

 (No relevant relationships reported)

Exercise/contractile activity improves skeletal muscle mitochondrial dynamics and insulin sensitivity. However, the adaptations in mitochondrial dynamics in response to exercise/contractile activity between lean and severely obese humans have not been directly compared. Electrical pulse stimulation (EPS) has been used in human skeletal muscle cells (HSkMCs) as an *in vitro* exercise model and can produce physiological adaptations similar to exercise/exercise training.

PURPOSE: The purpose of the study was to compare the effects of EPS on mitochondrial network structure and expression of regulatory proteins in mitochondrial dynamics processes in cultured myotubes derived from lean and severely obese humans.

METHODS: HSkMCs isolated from muscle biopsies from lean (n=8, BMI = 23.8 \pm 1.1 kg/m²) and severely obese humans (n=8, BMI = 45.5 \pm 1.5 kg/m²) were differentiated to mature myotubes and electrically stimulated for 24 hours by applying an electrical pulse at 11.5V, 1Hz and 2ms. Four-hours after EPS, mitochondrial network structure was determined in live cells via confocal microscopy and protein markers of mitochondrial dynamics were measured by immunoblotting.

RESULTS: Mitochondrial content was significantly lower in myotubes from severely obese humans when compared to the leans (Total MitoTracker Intensity: 376.0 \pm 36.1 vs. 224.8 \pm 15.1, $P < 0.05$) and EPS had no effect on mitochondrial content. Myotubes from severely obese humans also exhibited more fragmented mitochondrial networks when compared to the leans (Number of Non-Networked Individual Mitochondria: 2.6 \pm 0.4 vs. 1.9 \pm 0.2, $P < 0.05$). Interestingly, EPS improves mitochondrial network structure by enhancing mitochondrial network size in both groups (Mitochondrial Network Size: 7.2 \pm 0.3 vs. 8.7 \pm 0.6, $P < 0.05$). Consistently, mitochondrial fission

protein Drp1 ser⁶¹⁶ phosphorylation was significantly reduced following EPS in both groups (1.09 ± 0.07 vs. 0.95 ± 0.06 , $P < 0.05$). No differences of mitochondrial fusion proteins were found between any groups.

CONCLUSIONS: Our data reveal that EPS induces similar intrinsic adaptations in mitochondrial dynamics in cultured myotubes derived from lean and severely obese humans.

(No relevant relationships reported)

Skeletal muscle can adapt to mechanical loading by changing its mass and overall contractile phenotype via the activation of mechanotransduction and intracellular signaling mechanisms. In vitro mechanical loading of differentiated myoblasts (myotubes) has been utilized for mimicking the mechanical loading conditions of skeletal muscle in vivo. **PURPOSE:** This study investigated the effects of mechanical loading of myotubes on their gene expression responses associated with various aspects of cellular function, such as differentiation, hypertrophy and apoptosis. **METHODS:** C2C12 myoblasts were cultured on elastic membranes up to day 9 of their differentiation and then underwent a passive, cyclic stretching (15% elongation, at a frequency of 0.25 Hz, for 12 hours). Myotubes were harvested and lysed 12 hours after the completion of the stretching protocol. Real Time-PCR was utilized to measure changes in mRNA expression levels of myogenic regulatory factors (MRFs: MyoD, Myogenin, MRF4), as well as growth (IGF-1 isoforms: IGF-1Ea, IGF-1Eb), atrophy (Murfl, Atrogin, Myostatin), apoptotic (Foxo, Fuca, p53) and inflammatory factors (IL-6, IL-1b) in response to mechanical loading of the differentiated myoblasts. **RESULTS:** Mechanical loading of the myotubes resulted in increased expression of MyoD (1.5-fold; $p < 0.05$) and MRF4 (2.0-fold; $p < 0.05$) while Myogenin expression decreased by 0.4-fold ($p < 0.05$). Expression of muscle atrophy factors Atrogin (0.5-fold), Myostatin (0.4-fold), and Murfl (0.4-fold), and of the inflammatory factor IL-1b (0.5-fold) was significantly decreased ($p < 0.05$). No significant changes were revealed in the expression levels of IGF-1 isoforms (IGF-1Ea: 0.9-fold, IGF-1Eb: 1.1-fold) and apoptotic factors (Foxo: 0.8-fold, Fuca: 1.1-fold, p53: 1.0-fold), as well as of IL-6 (0.8-fold) in response to the selected stretching protocol of the differentiated myoblasts. **CONCLUSIONS:** These findings suggest that the specific mechanical loading protocol can further affect the myogenic differentiation program and protein synthesis of skeletal myotubes by influencing the expression of myogenic factors and downregulating muscle atrophy genes.

(No relevant relationships reported)

Purpose: AMP-activated protein kinase (AMPK) is the energy regulator of skeletal muscle cells. Current methods can identify the magnitude of AMPK expression in skeletal muscle cells via Western blotting and Capillary Nano-Immunoassay (CNIA); however, these methods lack the ability to visually identify AMPK localization within single muscle fibers. Identifying AMPK in human muscle is important because it is involved in various exercise training adaptations such as mitochondrial biogenesis and glucose transport. Therefore, we aimed to develop a novel confocal microscopy method to identify AMPK protein expression (relative intensity) and localization within human single muscle fibers. **Methods:** A *vastus lateralis* muscle biopsy was obtained from a healthy male and immediately fixed (4% PFA). Twenty fibers were isolated, placed on microscope slides, incubated in 0.1% Triton (15min), then incubated in 5% normal goat serum (blocking solution; 4h). This was followed by exposure to a 1 antibody (Ab) (anti-AMPK α 2) in 5% bovine serum albumin (14h at 4°C). Fibers were then exposed to a 2 Ab (anti-rabbit IgG conjugated w/ AlexaFluor 488) and phalloidin (AlexaFluor 568) to label actin (2h). Finally, fibers were mounted under coverslips with AntiFade Gold w/DAPI for myonuclei detection. Confocal microscopy imaging was conducted using a Zeiss LSM 710 with 63x plan apochromatic objective (oil emersion). Images were processed via ImageJ. **Results:** Muscle fiber contractile proteins (actin: red), myonuclei (blue), and AMPK proteins (green) were successfully visually identified at rest (AMPK fluorescence intensity = 1199.64 ± 630 AU). To ensure that no auto-fluorescence or non-specific binding was observed, images were compared to control slides: 1) DAPI only, 2) 1 Ab only, 3)

2 Ab only, and 4) no staining. **Conclusion:** These methods allow for the successful visualization (relative intensity) and localization of AMPK proteins within single human muscle fibers. This method could be used in future research to investigate the response and myonuclear co-localization of AMPK following exercise in human skeletal muscle to elucidate how they may play a role in these physiological processes.

An Examination Of The Nonlocal Repeated Bout Effect Of The Elbow Flexor Muscles

Jun Seob Song, Sunggun Jeon, William Miller, Minsoo Kang, FACSM, Xin Ye. *The University of Mississippi, Oxford, MS.*

(Sponsor: Minsoo Kang, FACSM)

Email: jsong6@go.olemiss.edu

(No relevant relationships reported)

Unaccustomed eccentric exercises usually result in muscle damage. It has been well documented that the magnitude of muscle damage can be attenuated in the subsequent bouts of the similar exercise, which is known as the repeated bout effect (RBE). The potential nonlocal RBE (e.g., from the upper limb to lower limb or vice versa), however, has not been examined yet. **PURPOSE:** To examine whether performing an initial bout of eccentric damaging exercise (EDE) on the elbow flexor muscles could induce any RBE against the muscle damage from the subsequent identical EDE performed on the knee flexors. **METHODS:** Six healthy men (Age: 24 ± 4 yrs; Weight: 84.3 ± 15.2 kg; Height: 174.3 ± 9.2 cm) and nine women (Age: 21.1 ± 1 yrs; Weight: 65.5 ± 13.4 kg; Height: 162.8 ± 3.5 cm) participated in this study. The participants performed the baseline bout of knee flexion (KF) EDE on one randomly chosen thigh. After a washout period, the participants performed the elbow flexion (EF) EDE on a randomly chosen arm. Lastly, the second bout of EDE was performed on the contralateral leg one week after the EF EDE. All EDE protocols consisted of six sets of 10 eccentric contractions with the load equivalent to 150% of the concentric 1-repetition maximum of the leg curl or arm curl exercise. Range of motion (ROM) at the knee joint, muscle soreness, and the relative KF isometric strength were taken before, after, one day (1D), two days (2D), and seven days (7D) after the EDE protocols. Separate three-way (bout [baseline, second] \times group [dominant, non-dominant] \times time [Pre, Post, 1D, 2D, 7D]) repeated measures ANOVAs were used to examine the changes in dependent variables. **RESULTS:** The ROM did not show any 3-way or 2-way interactions, but a main effect for time ($p < 0.001$). There was a significant bout \times time interaction ($p = 0.042$) for the relative isometric strength, and the follow-up paired t-tests indicated a significant difference at the Post-testing time point (baseline bout vs. second bout: $80.5 \pm 10.4\%$ vs. $87.5 \pm 13.0\%$, $p = 0.046$). The muscle soreness only showed significant main effects for bout ($p = 0.034$) and time ($p < 0.001$), with the pairwise comparison showing significantly smaller value for the second bout when compared to that for the baseline bout. **CONCLUSIONS:** This preliminary study showed potential nonlocal RBE between the upper and lower body muscles.

Hyperbaric Oxygen Therapy Promotes Muscle Recovery After Contusion Injury Via Angiogenesis By Reactive Nitrogen Species

Naoki Yamamoto, Takuya Oyaizu, Kazuyoshi Yagishita, Mitsuhiro Enomoto, Masaki Horie, Toshiyuki Ohara, Mikio Shioda, Ryohei Takada, Atsushi Okawa. *Tokyo Medical and Dental University, Tokyo, Japan.*

Email: yamamoto.orth@tmd.ac.jp

(No relevant relationships reported)

Background: Muscle contusion is a common sports injury, but delayed return to competition may negatively influence athlete's careers. Recently, hyperbaric oxygen (HBO) treatment promoted early recovery from muscle injury with reduction of soft tissue swelling. Increased reactive oxygen species (ROS) and reactive nitrogen oxide species (RNS) is a key mechanism of HBO, which supplies abundant oxygen due to increased dissolved oxygen at high pressure, and a high O₂ content in tissues. RNS generally stimulate vascular endothelial growth factor (VEGF) secretion from endothelial cells, which then induces angiogenesis. **Purpose:** To investigate whether HBO could promote angiogenesis with induction of ROS /RNS and induce muscle regeneration after contusion injury in rats. **Methods:** Muscle contusion was induced

by the mass-drop method on the right calf muscle of rats. After the injury, the rats were divided into non-treated (NT) and HBO-treated groups. The HBO protocol consisted of 100% oxygen inhalation at 2.5ATA for 120 minutes once a day for 5 consecutive days. We measured VEGF levels and histologically evaluated blood vessel formation and muscle regeneration in the contused muscles. In a functional analysis, we measured the tensile strength of the calf muscles at the final observation point. We also evaluated the effects of a ROS/RNS inhibitor (NAC) or RNS specific inhibitor (L-NAME) in the HBO group. **Results:** HBO significantly increased VEGF levels at 3 hours (NT group: 311.2 ± 58.2 pg/ml, HBO group: 827.5 ± 83.8 pg/ml) and promoted blood vessel formation at 3-7 days after contusion (3 days: NT group: 0.04 ± 0.02 /HPF, HBO group: 0.4 ± 0.1 /HPF, 5 days: NT group: 0.82 ± 0.2 /HPF, HBO group: 2.14 ± 0.7 /HPF, 7 days: NT group: 2.8 ± 0.8 /HPF, HBO group: 5.9 ± 0.9 /HPF). Administration of both NAC and L-NAME before HBO suppressed angiogenesis (7 days: NAC + HBO group: 3.4 ± 0.8 /HPF, L-NAME + HBO group: 2.9 ± 0.6 /HPF) and muscle regeneration (NT group: 20.22 ± 2.2 /HPF, HBO group: 34.6 ± 3.2 /HPF, NAC + HBO group: 20.0 ± 2.4 /HPF, LNAME + HBO group: 19.4 ± 1.5 /HPF) even after HBO. RNS inhibition is more important for the effects of HBO. **Conclusions:** HBO increased angiogenesis mainly through generation of RNS in the early phase and promoted muscle regeneration after muscle contusion injury.

Changes In Paraspinal Muscle T2 Times And Creatine Kinase After A Bout Of Eccentric Exercise

Anne Schomöller, Lucie Risch, Hannes Kaplick, Anne Schraplau, Monique Wochatz, Tilman Engel, Dominik Sonnenburg, Frank Mayer. *University of Potsdam, Potsdam, Germany.*

(No relevant relationships reported)

Eccentric (ECC) exercises might cause muscle damage, characterized by delayed-onset muscle soreness, elevated creatine kinase (CK) levels and local muscle oedema, shown by elevated T2 times in magnet resonance imaging (MRI) scans. Previous research suggests a high inter-individual difference regarding these systemic and local responses to eccentric workload. **PURPOSE:** To analyze ECC exercise-induced muscle damage in lumbar paraspinal muscles assessed via MRI.

METHODS: Ten participants (3f/7m; 33±6y; 174±8cm; 71±12kg) were included in the study. Quantitative paraspinal muscle constitution of M. erector spinae and M. multifidus were assessed in supine position before and 72h after an intense eccentric trunk exercise bout in a mobile 1.5 tesla MRI device. MRI scans were recorded on spinal level L3 (T2-weighted TSE echo sequences, 11 slices, 2mm slice thickness, 3mm gap, echo times: 20, 40, 60, 80, 100ms, TR time: 2500ms). Muscle T2 times were calculated for manually traced regions of interest of the respective muscles with an imaging software. The exercise protocol was performed in an isokinetic device and consisted of 120sec alternating ECC trunk flexion-extension with maximal effort. Venous blood samples were taken before and 72h after the ECC exercise. Descriptive statistics (mean±SD) and t-testing for pre-post ECC exercises were performed.

RESULTS: T2 times increased from pre- to post-ECC MRI measurements from 55±3ms to 79±28ms in M. erector spinae and from 62±5ms to 78±24ms in M. multifidus ($p < 0.001$). CK increased from 126±97 U/L to 1447±20579 U/L. High SDs of T2 time and CK in post-ECC measures could be due to inter-individual reactions to ECC exercises. 3 participants showed high local and systemic reactions (HR) with T2 time increases of 120±24% (M. erector spinae) and 73±50% (M. multifidus). In comparison, the remaining 7 participants showed increases of 11±12% (M. erector spinae) and 7±9% (M. multifidus) in T2 time. Mean CK increased 9.5-fold in the 3 HR subjects compared with the remaining 7 subjects.

CONCLUSIONS: The 120sec maximal ECC trunk flexion-extension protocol induced high amounts of muscle damage in 3 participants. Moderate to low responses were found in the remaining 7 subjects, assuming that inter-individual predictors play a role regarding physiological responses to ECC workload.

Email: rchetlin@mercyhurst.edu

(No relevant relationships reported)

We recently demonstrated body fat %, fast ball velocity, and RPE were significant predictors of valgus torque in NCAA baseball pitchers. Even though changes in hyperemic-induced limb volume are associated with acute, repetitive pitching

performance, possibly indicating approaching dominant elbow soft-tissue risk, no investigation, to our knowledge, has examined relationships between performance, biometric, and throwing-limb volume in collegiate pitchers.

PURPOSE: To quantify the relationship between pitching performance, subject biometrics, and hyperemic-induced changes in collegiate baseball pitchers during game-simulated pitching sessions of 40, 80, or 120 pitches.

METHODS: Following informed consent, 5 male subjects (\bar{x} age = 18.8 ± 0.8 years; \bar{x} BMI = 27.6 ± 1.8 ; \bar{x} body fat % = 22.9 ± 6.2 ; \bar{x} throwing velocity = 80.4 ± 1.8 mph) were block-assigned to groups of 40, 80, or 120 pitches. Bouts consisted of 10 pitches (~20s between pitches) delivered from an artificial mound with 1-2 mins rest between bouts. HR and RPE were recorded immediately following each 10-pitch bout. A MOTUS sensor and compression sleeve measured elbow valgus torque. A Stalker Sport II Radar Gun measured fastball velocity. Pre-test and post-test upper- and lower-extremity limb girths were measured, signifying reactive hyperemia. Wilcoxon non-parametric testing determined pre- to post-test differences. Pearson correlation identified relationships between variables. Alpha was set at $p \leq 0.05$.

RESULTS: No group differences were found on any performance, biometric, demographic, or hemodynamic variable. HR (72.6 ± 8.3 bpm vs. 97.6 ± 10.0 bpm, $p = 0.02$) and dominant forearm limb girth (29.4 ± 1.5 cm vs. 30.9 ± 1.5 cm, $p = 0.04$) increased from pre-test to post-test for subjects combined. Significant correlations were found for: pitching volume & post-test HR ($r = 0.90$, $p = 0.039$); post-test dominant upper arm circumference & RPE ($r = 0.89$, $p = 0.042$), and; valgus torque % change & pitching volume ($r = 0.91$, $p = 0.031$).

CONCLUSIONS: Forearm limb girth increased for subjects combined, and; given this metric's indication of reactive hyperemia, future research focused on elucidating and quantifying the biological components of the tissue (compartments), as well as their contribution to performance- and/or injury-specific outcomes, is warranted.

Comparison Of Flat, Uphill And Downhill High Intensity Interval Training On Performance And Skeletal Muscle

Kathryn H. Myburgh, FACSM, Cameron Sugden, Evan E. Knight, Tracey Ollewagen. *Stellenbosch University, Stellenbosch, South Africa.*

Email: khm@sun.ac.za

(No relevant relationships reported)

Skeletal muscle and exercise performance adapt to high intensity interval training (HIIT). Downhill running is an eccentric-biased exercise modality whereas uphill running is concentric-biased and flat running has aspects of both. Therefore, variation in adaptation may differ with HIIT done on flat (F) or uphill (UH) or downhill (DH) gradients. **PURPOSE:** To compare the training effect of three modes of HIIT on laboratory and outdoor performance and muscle cross-sectional area (CSA) and satellite cell number per fiber (SC). **METHODS:** 17 fit, but not elite, young adult male runners volunteered for HIIT: 6 sets of 3 minutes and 1-minute rest between, for 10 sessions over 4 weeks. Gradients were flat, +5% or -10% and running speeds 85%, 80% or 90% of peak treadmill speed (PTS) respectively. Performance tests included PTS (0% gradient), maximum isometric quadriceps force (Iso) and 5 km road time trial (TT). Muscle biopsies were taken at baseline and 6 hours after the 10th session. Data analyzed using mixed models ANOVA, presented as mean ± SD. **RESULTS:** HIIT improved PTS (km/h) in F (pre: 17.7 ± 1.3 , post: 18.9 ± 1.5 ; $P < 0.05$) and UH (pre: 17.6 ± 0.8 , post: 18.7 ± 0.8 $P < 0.01$), but not DH (pre: 17.8 ± 1.3 , post: 18.0 ± 1.3), whereas only DH significantly increased Iso strength (25% $P < 0.05$ compared to F: -1% and UH: -4.4%). Similarly, only DH increased muscle fiber cross-sectional area (CSA) (31% $P < 0.05$ compared to F: -5% and UH: 10%). DH increased muscle SC number/fiber highly significantly (pre: 0.097 ± 0.01 post: 0.297 ± 0.04 $P < 0.0001$). Interestingly, UH HIIT group did not change SC content (pre: 0.102 ± 0.018 , post: 0.106 ± 0.02), but flat HIIT increased significantly (pre: 0.115 ± 0.01 , post: 0.148 ± 0.01 $P < 0.01$), although not nearly as much as DH HIIT (F: 30%, DH: 208%). 5 km TT improved in all groups (F: 3%; UH: 3.5% and DH: 3.5%; all $P < 0.05$). **CONCLUSION:** Muscle adapted differently in response to the different gradients of HIIT. Neither SC number/fiber nor CSA changed with UH HIIT. CSA also did not change with F HIIT, although SC number/fiber increased. DH HIIT increased both CSA and SC number/fiber to a greater extent. Although laboratory performance test changes differed between groups, all 3 groups improved outdoor TT performance. Therefore, different training specific adaptations in skeletal muscle conferred similar race performance improvements.

Effects Of Repeated Bout Of Eccentric Exercise On Muscle Stiffness In Elbow Flexors

Min-Ghyu Sun, Choun-Sub Kim, Maeng-Kyu Kim. *Kyungpook National University, Daegu, Korea, Republic of.*

Email: sunminghyu@naver.com

(No relevant relationships reported)

Up to now, maximal voluntary isometric contraction (MVIC), range of motion (ROM), and serum creatine kinase (CK) have been used for studying exercise-induced muscle

damage (EIMD) with single- and repeated bout effect following eccentric contraction (EC). However, it is unknown whether muscle stiffness reflecting the mechanical properties would be a competent parameter for detecting EIMD following EC in elbow flexors. **PURPOSE:** This study was conducted to examine changes of EIMD indices through repeated bout EC and to investigate the correlation between EIMD markers and mechanical properties in elbow flexors. **METHODS:** Thirteen healthy males performed 6 x 5 sets of maximal EC at 90°/sec angular velocity on non-dominant elbow flexors using isokinetic dynamometer. Three weeks washout period were given between the first- (ECC1) and second eccentric exercise session (ECC2). To evaluate EIMD symptoms, MVIC, ROM, muscle swelling, soreness, and serum CK activity were measured. Echo intensity (EI) on *brachialis* and *biceps brachii* m. was obtained using ImageJ software. Moreover, muscle fatigue as measured by electromyography and mechanical properties as measured by myotonometer were assessed for each session. All parameters were obtained at post-exercise 24, 48, 72, and 96 hours, including before and immediately after EC. **RESULTS:** There were significant differences from those of baseline in MVIC, ROM, muscle swelling, soreness, fatigue, and stiffness at each session. Moreover, muscle swelling and stiffness in *biceps brachii* m. had statistical differences between sessions. Although CK and EI had no significant differences in ECC2, there were significant differences from those of baseline in ECC1. Also, there were statistical differences between sessions in CK and EI. Additionally, stiffness in *biceps brachii* m., but not *brachialis* and ROM had significantly negative correlations in each session at 48 and 72 hours, respectively. **CONCLUSIONS:** Taken together, these data revealed that muscle stiffness, except for CK and EI, in elbow flexors were not shown adaptation after repeated bout EC. As shown by the relationship between the stiffness and ROM, the stiffness as a mechanical property can be used as an indicator of muscle damage. Supported by the National Research Foundation of Korea Grant (NRF-2017R1C1B1006196).

Effect Of Low Intensity Eccentric Exercise Training On Maximal Eccentric Exercise induced Muscle Damage
Nilsel Okudan, Aysel Yildirim, Muaz Belviranli. *Faculty of Medicine Selcuk University, Konya, Turkey.*
Email: nilselokudan@gmail.com
(No relevant relationships reported)

PURPOSE: The aim of this study was to investigate the effects of low-intensity eccentric exercise performed before maximal eccentric exercise which causes muscle damage and oxidative stress on muscle injury markers and oxidative stress. **METHODS:** The study was carried out with 22 male Wistar albino rats obtained from Experimental Animal Research and Application Center of Selcuk University. Rats were randomly divided into 3 groups. Rats in the control group (K, n: 6) were not given any exercise protocol. The maximal eccentric exercise protocol was applied to the rats in the maximal eccentric exercise group (M, n: 8) only one at rate of 20 m / min, at -15° inclination for 90 min. Low intensity eccentric exercise protocol, which does not cause muscle damage was applied to the rats in the low intensity eccentric exercise + maximal eccentric exercise group (DY+M, n: 8) at 10 m / min, at -15° inclination, 30 min / day for one week and maximal eccentric exercise protocol was applied 24 hours after this exercise. Blood and muscle tissue samples were taken 24 hours after the last exercise session and creatine kinase (CK), lactate dehydrogenase (LDH) and superoxide dismutase (SOD1) activities and myoglobin (Mg), malondialdehyde (MDA) and glutathione (GSH) levels were measured. **RESULTS:** Serum Mg level was higher in the M group compared to the DY+M and the K groups. Serum CK and LDH activities were higher in the DY+M and the M groups compared to the K group. MDA level was higher in M group compared to K and DY+M groups in vastus intermedius muscle, in M group compared to the K group in gastrocnemius muscle and in the DY+M and the M groups compared to the K group in plasma. GSH level in the vastus intermedius muscle and plasma was higher in the DY+M group compared to the M group. GSH level in gastrocnemius muscle was not different between groups. SOD1 activity was higher in the DY+M group compared to the K group in the vastus intermedius muscle, in the DY+M group compared to the K and the M groups in the gastrocnemius muscle. SOD1 activity in plasma was not different between groups. **CONCLUSIONS:** Low intensity eccentric exercise training applied before the maximal eccentric exercise has a partial protective effect against muscle damage, especially in the vastus intermedius muscle prevents the formation of oxidative stress and strengthens the antioxidant defense.

The Effects Of A 50k Ultramarathon On Plasma IL-6 And Rectus Femoris Muscle Thickness
Dakota T. Siok¹, Kathleen Dondoro¹, Christa M. Nelson², Steven J. Prior³, Odessa Addison⁴, Rian Q. Landers-Ramos¹. ¹Towson University, Towson, MD. ²University of Maryland School of Medicine, Baltimore, MD. ³University of Maryland, College Park, MD. ⁴University of Maryland School of Medicine and Veterans Affairs Medical Center, Baltimore, MD.
Email: dsiok1@students.towson.edu
(No relevant relationships reported)

PURPOSE: to assess plasma IL-6 concentrations and muscle thickness (MT) using ultrasound imaging throughout and after a 50-kilometer race and to determine the relationship between changes in IL-6 and changes in MT. **METHODS:** Men and women (n=11) age 39 ± 7 years participated in a 50k trail race consisting of five 10k laps. Ultrasound imaging was performed on the rectus femoris at rest (passive) and during isometric contraction before the race, within 60 minutes of completing the race, and 24-hrs post-race. To maintain consistent ultrasound probe placement, the probe was outlined at baseline testing. Images were analyzed using ImageJ, and the % change in MT from passive to isometric contraction was calculated. Blood was drawn 30 minutes following consumption of a pre-race meal, 10k into the race, within 60 minutes of completion of the race and 24 hrs post-race. Plasma IL-6 was assessed using an enzyme-linked immunosorbent assay (ELISA). **RESULTS:** Change in MT from passive to isometric contraction increased from a pre-race value of 9.1 ± 2.7% to 14.1 ± 2.6% post-race although this did not reach statistical significance (P=0.256). Compared to pre-race values, change in MT increased significantly 24 hrs post-race (9.1 ± 2.7% vs. 17.8 ± 1.7%; P=0.021). IL-6 concentrations increased from pre-race levels of 0.37 ± 0.25 pg/mL to 3.1 ± 0.86 pg/ml at 10k (P=0.008) and to 29 ± 3.3 pg/mL post-race (P<0.001). Twenty-four-hour follow-up testing revealed a return of IL-6 levels to pre-race values (0.59 ± 0.3 pg/mL; P=0.488). The mean change (post-pre) in IL-6 inversely correlated with the mean change in MT (r= -0.685, P=0.02). **CONCLUSIONS:** Ultramarathon running leads to an acute but substantial increase in plasma IL-6 which precedes changes in MT. The relationship between changes in IL-6 and MT pre- and post-race indicates a potential role for IL-6 in the delayed exercise-induced inflammatory response with prolonged running. Supported by Towson University Summer Undergraduate Research Institute, University of Maryland College Park, and the Baltimore Veterans Affairs Medical Center

3383 Board #204 May 29 1:30 PM - 3:00 PM
The Efficacy Of Protein Supplementation On Attenuating Muscle Atrophy Following Disuse
Lee A. Weidauer, Leah Kroeger, Matt Vukovich, FACSM. *South Dakota State University, Brookings, SD.* (Sponsor: Matthew Vukovich, FACSM)
Email: lee.weidauer@sdsstate.edu
(No relevant relationships reported)

PURPOSE
The purpose of this study was to determine the effects of protein supplementation during muscular disuse in maintaining muscle cross-sectional area, lean mass, strength, and jump force in the collegiate population.

METHODS
Two groups of healthy collegiate participants (n=14) underwent two weeks of unilateral lower limb suspension (ULLS), during which the control group consumed a normal diet (CON) and the treatment group (PRO) received an additional 75g/day of supplemental protein. Outcome measures included lean mass (LM) measured using DXA, muscle area (MA) of the lower leg using pQCT, isokinetic torque measurements using a Biodex ergometer, and force production during jumping using a portable force platform. Differences in the change of these outcome measurements from baseline to follow-up were compared between the treatment and control groups (group * time interaction, controlling for baseline measurement).

RESULTS
Daily protein intake for the treatment group (2.6±1.0 g/kg/d) was greater than the control group (1.5±1.1 g/kg/d). Daily caloric intake was not different between groups (3015±1098 kcal/day; Treatment 2772±432 kcal/day). MA decreased in both groups following ULLS with no differences between groups measured. However, there was a moderate difference in change between groups with the PRO maintaining their total LM (group*time interaction, p=0.08) and leg LM (group*time interaction, p=0.1) when compared to the CON.

CONCLUSION
This study demonstrates a universal loss in lower leg muscle area muscle during a relatively short period of disuse. Additionally, there was evidence of a trend toward a positive effect of protein supplementation on lean mass maintenance during disuse. The results of this study serve as an important first step of identifying nutritional interventions to augment rehabilitation.

ACUTE ANDROGEN AND GLUCOCORTICOID RECEPTOR RESPONSE FOLLOWING A MODERATE INTENSITY RESISTANCE EXERCISE BOUT
 STEPHANIE A. SONTAG¹, Justin X. Nicoll², Andrew C. Fry¹, Eric M. Mosier³. ¹University of Kansas, Lawrence, KS. ²California State University, Northridge, CA. ³Northwest Missouri State University, Maryville, MO.
 Email: stephanie_sontag@yahoo.com
 (No relevant relationships reported)

PURPOSE: The purpose of this study was to examine the acute androgen receptor (AR) and glucocorticoid receptor (GR) response to a moderate intensity resistance exercise bout in resistance trained (RT) and untrained men (UT).
METHODS: RT men (n = 10; X ± SD, age = 21.3 ± 1.7 yrs, height = 175.8 ± 6.8 cm, body mass = 84.5 ± 13.5 kg, back squat 1RM = 154.3 ± 19.3 kg, training history = 5.4 ± 2.0 yrs) and UT men (n = 9; X ± SD, age = 20.8 ± 3.1 yrs, height = 178.7 ± 8.9 cm, body mass = 81.0 ± 14.0 kg, squat 1RM = 108.1 ± 13.7 kg, training history = 0.7 ± 1.7 yrs) volunteered for this study. Prior to the RE bout, subjects were strength tested for back squat (BS) and leg extension (LE). Subjects returned 4-7 days later between 10am-2pm, and completed a RE bout consisting of 6 sets of 10 repetitions of BS at 75% 1RM, immediately followed by 4 sets of 10 repetitions of LE at 75% 1RM with 1.5 min rest between all sets. Muscle samples were collected from the *vastus lateralis* prior to exercise (PRE) and 10 min (10P), 30 min (30P), 60 min (60P), and 180 min (180P) post exercise. Total AR and GR expression was determined via western blotting. Receptor data were not normally distributed, thus all receptor data were analyzed using Mann-Whitney U test, Friedman test, and Wilcoxon signed-rank test.
RESULTS: For total AR expression, there were no differences between time points within the RT group (p > .05); however, there were differences between time points within the UT group (p = .016). In the UT group, total AR expression significantly decreased at 30P (-19%Δ, z = -2.192, p = .027) and 60P (-11%Δ, z = -2.192, p = .027) post exercise, but returned to baseline values by 180P (z = -.178, p > .05). For Total GR content, there were no differences between time points within the RT or UT groups (p > .05). Total GR content was significantly greater in the RT group compared to the UT group at 10P (Mann-Whitney U = 19, z = -2.123, p = .035).
CONCLUSIONS: While no changes were observed for AR expression in the RT group, the UT subjects experienced a significant decrease in AR expression at 30P and 60P suggesting acute AR responses vary depending on training status. No differences were seen across time for the GR in either group; however, RT and UT subjects were different from each other at 10P. It is unclear if these responses are related to the acute hormonal response; therefore, future research will address this.

Fiber Type Profile and Its Relation To Wilks Coefficient In Both Male And Female Powerlifters
 Steven B. Machek¹, Paul S. Hwang¹, Thomas D. Cardaci¹, Emiliya S. Suezaki¹, Caelin S. Kim¹, Dylan T. Wilburn¹, Daniel Blake², Andrew J. Galpin², James R. Bagley³, Darryn S. Willoughby, FACSM¹. ¹Baylor University, Waco, TX. ²California State University, Fullerton, Fullerton, CA. ³San Francisco State University, San Francisco, CA. (Sponsor: Darryn Willoughby, FACSM)
 Email: steven_machek2@baylor.edu
 (No relevant relationships reported)

PURPOSE: Strikingly little data exist on powerlifter fiber type distributions, and none elucidate differences between genders in powerlifting. Past research established powerlifters have relatively higher fast-twitch fiber proportions versus sedentary and aerobic demographics, but it is unknown if fast-twitch content is predictive of performance. Furthermore, the Wilks Coefficient is a common means to normalize powerlifting performance relative to bodyweight in competition. Therefore, the purpose of this study was to 1) compare the myosin heavy chain fiber (MHC) fiber type profiles between powerlifters and sedentary controls of men and women, and 2) determine if fast-twitch fiber content predicts powerlifter Wilks coefficient.
METHODS: Twelve actively competing powerlifters (PL; n = 6M/6F) and ten sedentary controls (CON; n = 5M/5F) were recruited for this cross-sectional analysis. Subjects underwent a percutaneous muscle biopsy from the *vastus lateralis* using fine needle aspiration. Samples were analyzed MHC isoform content via mixed homogenate SDS-PAGE. MHC isoforms (MHC I, IIa, and IIx) were analyzed via multiple 2x2 (group x gender) analysis of variance (ANOVA) at a significance level of p<0.05. MHC IIa content was compared to Wilks coefficient using a Pearson correlation coefficient at p<0.05.

RESULTS: There were significant group differences for all MHC isoforms, where PL had a higher proportion of MHC I (p<.001) and IIa (p = .010) content relative to CON. Conversely, PL a significantly lower proportion of MHC IIx content versus CON (p<.001). There was a significant gender effect for MHC IIa fibers, where females had a higher proportion versus males (p=.021). Lastly, Pearson correlation analysis revealed a non-significant, low correlation between MHC IIa content and Wilks coefficient (r = -.288; p=.364).
CONCLUSIONS: These results illustrate that powerlifting-style training may result in higher proportions of MHC I and IIa fibers, as well as losses in MHC IIx content. Contrary to previous literature, our data also show a higher proportion of fast-twitch MHC IIa fibers in females versus males. Overall, MHC IIa content is not a significant predictor of powerlifting performance as per Wilks coefficient, suggesting other biochemical markers and/or neural efficiency underline variations in skill.

Do Decreases In Voluntary Activation Account For Fatigability Differently In Males And Females?
 Rob J. MacLennan¹, Alina P. Swafford², Dennis P. Kwon², Jason M. DeFreitas¹, Matt S. Stock². ¹Oklahoma State University, Stillwater, OK. ²University of Central Florida, Orlando, FL.
 Email: robjmaclellan@gmail.com
 (No relevant relationships reported)

Muscular fatigue has been reported to have varying effects depending on sex. Both males and females incur deficits in strength resulting from strenuous activity but males suffer greater relative deficits. Similarly, in a fatigued state, males may be relatively less able to activate muscles. **PURPOSE:** We sought to determine whether the decrease in strength that males and females suffer is related to changes in their voluntary activation (%VA). **METHODS:** Twenty-two untrained, college-aged, males (11) and females (11) participated. Subject's dominant lower leg was strapped to an attachment set at an angle of 110° (180° = full extension) for isometric knee extensions. At pretesting, subjects performed maximal voluntary contractions (MVC) and the interpolated twitch technique was applied to assess %VA. Following initial testing, a fatiguing protocol was performed which consisted of 20 six-second MVCs with 3 seconds in between. In the fatigued state, subjects again performed an MVC and %VA was assessed. Linear regression was performed to determine if the variance in fatigability, as measured by change in MVC, can be accounted for by changes in %VA for each sex. **RESULTS:** Regression showed that 15.3% and 1.1% of the variance in force loss could be explained by changes in %VA in males and females, respectively. However, neither of these models were significant (p = 0.233 and p = 0.760). The results are shown in the figure below for both males (circles) and females (triangles). A 2-way mixed-factorial ANOVA showed neither a group × time interaction (p = 0.296), nor a main effect for time (p = 0.288) for %VA. **CONCLUSIONS:** The findings suggest that voluntary activation was not responsible for the force loss with fatigue in either males or females. For the females, this could be partially due to the fact that many of them had minimal changes in MVC from the fatigue protocol, whereas all of the males showed at least a 10% deficit. However, there were no differences in %VA between males and females.

3388 Board #209 May 29 1:30 PM - 3:00 PM
The Characters And Mechanisms Of Bioelectricity And NIRS In Low Intensity Sustained Muscle Fatigue Contraction
 Xiaodong Liu, Shanghai University of Sport, Shanghai, China.
 Email: 15501019518@163.com
 (No relevant relationships reported)

The central and peripheral fatigues induced by sustained muscle contraction remain debatable. The neuromuscular and muscle oxygenation (SmO2) and perfusion ([tHb]) have obvious changes in active and antagonistic muscles when enduring low intensity sustained muscle fatigue contraction.
PURPOSE: Characteristics and mechanisms of surface electromyography (sEMG), SmO2 and [tHb] in active and antagonistic muscles induced by elbow flexor fatigue.
METHODS: Twelve healthy male participants (25.3±4.8 years old) performed isometric elbow flexion at 20% of their maximum voluntary contraction (MVC) force for fatigue. The EMG signals were recorded from the biceps brachii (BB) and triceps brachii (TB) muscles using linear electrode arrays composed of sixteen electrodes (10mm inter-electrode distance). The monopolar EMG signals were amplified

(Sessantaquattro, OT Bioelettronica) and sampled at 2000Hz. Muscle fiber conduction velocity (MFCV), mean power frequency (MPF) and median frequency (MF) were calculated by OT BioLab software. SmO₂ and [tHb] of BB and TB muscles were recorded with a MOXY near-infrared spectroscopy (NIRS) device (MOXY-5, Fortiori Design LLC).

RESULTS: Compared to the initial stage, the fatigue stage of BB muscle had a significantly decrease in MFCV (4.50±0.28 m/s VS 3.96±0.21 m/s, p<0.05), MPF (68.90±7.44 Hz VS 55.80±8.97 Hz p<0.05) and MF (64.60±5.88 Hz VS 48.93±5.27 Hz, p<0.05). SmO₂ of BB muscle reduced to the minimum at nearly half stage (ΔSmO₂: 65±9%), but the [tHb] increased (Δ[tHb]: 0.48±0.13 g/dl). Fatigue stage of TB muscle had a decline in MPF (68.90±7.44 Hz VS 63.32±3.81 Hz p<0.05), MF (62.71±6.12 Hz VS 53.03±5.69 Hz, p<0.05). And SmO₂ and [tHb] of TB muscle had a slightly increase (ΔSmO₂: 10±2%, Δ[tHb]: 0.29±0.08 g/dl).

CONCLUSIONS: In low intensity sustained muscle fatigue contraction, myoelectric central and peripheral fatigues induced active muscle fatigue. Meanwhile, antagonistic muscle has much oxygen and perfusion and central nerve may lead to fatigue.

Neuromuscular Electrical Stimulation At Long Pulse Duration Is Associated With Higher Muscle Oxygen Utilization

Federica Gonnelli¹, Enrico Rejc², Mirco Floreani¹, Nicola Giovanelli¹, Stefano Lazzari¹. ¹University of Udine, Udine, Italy. ²University of Louisville, Louisville, KY.
 Email: gonnelli.federica@spes.uniud.it
 (No relevant relationships reported)

Conventionally Neuromuscular Electrical Stimulation (NMES), delivered on the muscle belly at low frequency and short pulse duration, is used in rehabilitation protocols to prevent muscle atrophy. However, conventional NMES causes rapid on-set of fatigue and possibly activates muscle fibers in a synchronous, spatially fixed order (i.e. reverse of the size principle). To overcome these limitations, in the past years, a novel approach that utilizes both high frequency (100Hz) and long pulse duration (1000μs) (Wide Pulse High Frequency Stimulation, WPHF) was proposed. During WPHF NMES muscle contraction is achieved via afferent nerve fibers, allowing the reflexive discharge of motor units, with the contribution of spinal circuitries, and mimic the recruitment order of a voluntary effort (i.e. first type I fibers).

PURPOSE: Evaluating muscle oxygen consumption via Near-Infrared Spectroscopy (NIRS) technique during two NMES bouts at fixed frequency (100Hz), applying Short (200μs) and Long (1000μs) Pulse duration, while concurrently matching the external force output. **METHODS:** Two 5 minutes intermittent (1 sec on - 3 sec off) NMES bouts at Short and Long pulse duration were delivered on the right quadricep muscle of 14 healthy subjects while sitting on an isometric chair. NIRS recorded oxygen extraction (i.e. Deoxygenated Hemoglobin - Myoglobin) from the vastus lateralis of the stimulated limb. Equal muscle force between protocols was achieved by carefully selecting the individual stimulation intensity. **RESULTS:** We selected 10 consecutive contractions for Short and Long Pulse NMES in order to have equal muscle output and evaluate the corresponding oxygen consumption. In the selected contractions, Peak Force was 15.3 ± 5.7 and 15.4 ± 5.6 % (p: ns) of the Maximal Voluntary Contraction while Force Time Integral was 1522.6 ± 593.4 and 1539.4 ± 597.3 Nm*s (p: ns) for Short and Long Pulse respectively. At the same force output, Long Pulse NMES exhibited higher oxygen consumption, in percentage of the physiological calibration, than Short Pulse NMES (36.71 ± 11.82 % vs 28.79 ± 17.07 %, p:0.041). **CONCLUSION:** Applying Long Pulse NMES can elicit higher muscle oxygen utilization compared to Short Pulse duration, suggesting preferential recruitment of oxidative, type I muscle fibers, likewise to a voluntary contraction.

 Email: fabiogiusseppe.laginestra@univr.it
 (No relevant relationships reported)

During fatiguing exercise, the development of peripheral fatigue and the associated increased firing of group III/IV afferent fibres, promote central fatigue. **PURPOSE:** The aim of this study was to assess whether peripheral fatigue in the contralateral leg induced by electrical quadriceps stimulation to bypass central command, would impair endurance performance of the subsequently exercising ipsilateral leg. **METHODS:** Eight young healthy males were recruited for this study. After completing an incremental test to exhaustion on a single-leg knee extensor ergometer, the subjects performed two tests on separate days. On the first day, they performed a time-to-

exhaustion test at 85% of their maximal power output (No-PreF trial). Exercise-induced quadriceps muscle fatigue was assessed by supramaximal electrical femoral nerve stimulation evaluating changes in the potentiated resting twitch force (Q_{tw,pot}), maximal voluntary contraction (MVC) and voluntary activation (VA) from pre to post exercise. On the second day, the same exercise bout was preceded by the induction of fatigue in the contralateral quadriceps through electrical stimulation (PreF trial). The pre-fatiguing protocol was terminated once the subjects reached the maximum tolerance score on a 1-10 visual analogue scale (duration: 6.6 ± 0.9 min). Integrated electromyography (iEMG) was recorded and used to estimate spinal motoneuronal output. **RESULTS:** Time to exhaustion in the PreF trial was reduced by 41% (9.1 ± 1.5 to 5.4 ± 1.2 min, p < 0.05). The reduction in MVC (-36 ± 8 vs -23 ± 10%, p < 0.05) and Q_{tw,pot} (-53 ± 3 to -39 ± 9% p < 0.05) was more accentuated in the No-PreF trial compared to PreF. Conversely, VA was more affected in PreF than in No-PreF (-20 ± 7 vs -14 ± 5%, p < 0.05). At every submaximal time point, iEMG was significantly higher in PreF compared to No-PreF, while at exhaustion it was higher in the latter (p<0.05). **CONCLUSIONS:** Pre-induced muscle fatigue in the contralateral limb impairs endurance performance of the exercising ipsilateral limb. This cross-over effect of fatigue is likely mediated by the inhibitory influence associated with group III/IV muscle afferent feedback and not related to changes associated with central command. Funding: No funding was received for this study

The Effects Of 50k Ultramarathon Running On Quadriceps Torque And Circulating Inflammatory Calprotectin.

Kathleen R. Dondero¹, Inez Hankerson¹, Christa M. Nelson², Steven J. Prior³, Odessa Addison², Rian Q. Landers-Ramos¹. ¹Towson University, Towson, MD. ²University of Maryland School of Medicine, Baltimore, MD. ³University of Maryland, College Park, College Park, MD.
 Email: kdondero@towson.edu
 (No relevant relationships reported)

Ultramarathon running has increased in popularity over the past decade. However, the effects of prolonged running on novel circulating inflammatory factors, such as calprotectin, and their relationship to muscle strength are not completely understood.

Purpose: Determine the effects of prolonged running on quadriceps strength and plasma calprotectin levels and examine the relationship between these two factors. **Methods:** Trained men and women (n=11) age 39 ± 7 years participated in a 50-kilometer(k) trail run consisting of five 10k laps. Seated knee extensor force was measured before the race, after each lap, immediately post-race and 24h post-race using a hand-held dynamometer. Quadriceps torque (N.m.) was calculated by multiplying tibial length by force. Blood was drawn 30 minutes after participants finished eating their pre-race meal, after the first lap (10k), within 60 minutes of finishing the race and 24h post-race. Plasma calprotectin was measured using an enzyme-linked immunosorbent assay (ELISA). **Results:** Quadriceps torque did not significantly change from pre-race to lap 1 (P=0.64), but significantly declined post-race (-10%; P=0.047) and returned to pre-race values by 24h post-race (P=0.1). Compared with lap 1, quadriceps torque declined significantly by lap 2 (-9%; P=0.024) but remained unchanged from lap 2 through post-race (between -10 and -8% from lap 2 through post-race; P>0.05 for each timepoint). Plasma calprotectin increased 63% at lap 1 (P=0.003), 83% post-race (P=0.001), and returned to pre-race values 24h post-race (P=0.66). Pre-race calprotectin levels directly correlated with quadriceps torque at lap 1 (r=0.627, P=0.023), post-race (r=0.771, P=0.005) and 24h post-race (r=0.767, P=0.006). Plasma calprotectin levels 24h post-race directly correlated with 24h post-race quadriceps torque (r=0.604; P=0.04). **Conclusion:** Athletes participating in a 50k ultramarathon experienced an acute decline in quadriceps torque that coincided with an acute increase in plasma calprotectin concentrations. Both torque and plasma calprotectin returned to pre-race values after 24h. The relationships between calprotectin levels and muscle torque before, during, and after the race suggest a potential novel role for calprotectin in muscle recovery from an ultramarathon.

Exercising above maximal lactate steady state (MLSS) has detrimental effects compared to exercising at MLSS. However, neuromuscular fatigue (NMF) to exercise above MLSS is unknown. **PURPOSE:** To evaluate NMF during exercise slightly below, at and above MLSS. **METHODS:** Nine men (24±3 yrs.; 76±7 kg; VO_{2max}, 3.55±0.19 L·min⁻¹) exercised to exhaustion at MLSS, 10 W below (-10W) and above

(+10W) MLSS. NMF was evaluated before (B), at min 10 (10'), 30 (30') and at exhaustion, by maximal voluntary contractions (MVC). Voluntary activation (VA) and contractile function of knee extensors [peak twitch torque (TwPt)] were tested using electrically-evoked contractions. Oxygen uptake ($\dot{V}O_2$) and blood lactate concentration ([Lac]) were measured. **RESULTS:** Time to exhaustion (TTE) for -10W (66±14 min) and +10W (44±8 min) were longer and shorter than MLSS (53±9 min) ($p<0.05$). $\dot{V}O_2$ was stable for -10W (10', 2.9±0.19; 30', 2.9±0.28; TTE, 2.9±0.25 L·min⁻¹) and MLSS (10', 3.0±0.21; 30', 3.0±0.29; TTE, 3.1±0.23 L·min⁻¹) ($p>0.05$), but increased at +10W (10', 3.0±0.21; 30', 3.2±0.32; TTE, 3.3±0.39 L·min⁻¹; $p<0.05$). [Lac] was stable for -10W (10', 4.1±1.1; 30', 4.4±1.2; TTE, 4.0±1.0 mM; $p>0.05$). MLSS showed an increase at TTE (10', 5.3±1.4; 30', 5.8±1.4; TTE, 6.1±1.8 mM; $p<0.05$). +10W showed a constant increase (10', 5.3±1.2; 30', 8.0±1.6; TTE, 8.6±1.6 mM; $p<0.05$). MVC dropped from baseline for -10W (B, 561±178; 10', 436±128; 30', 420±131; TTE, 395±120 N; $p<0.05$), MLSS (B, 518±130; 10', 405±96; 30', 361±75; TTE, 344±73 N; $p<0.05$) and +10W (B, 517±172; 10', 392±124; 30', 384±146; TTE, 349±88 N; $p<0.05$), and was not different amongst conditions. VA dropped from baseline for -10W (B, 98±2; 10', 90±6; 30', 89±6; TTE, 89±6 %; $p<0.05$), MLSS (B, 97±2; 10', 91±5; 30', 91±5; TTE, 88±5 N; $p<0.05$) and +10W (B, 98±2; 10', 94±5; 30', 90±7; TTE, 87±7 %; $p<0.05$), and was not different amongst conditions. TwPt dropped from baseline for -10W (B, 173±30; 10', 129±22; 30', 119±17; TTE, 112±17 N; $p<0.05$), MLSS (B, 172±31; 10', 129±28; 30', 119±24; TTE, 111±22 N; $p<0.05$) and +10W (B, 167±33; 10', 113±25; 30', 103±27; TTE, 97±26 N; $p<0.05$). +10W showed greater decline throughout the bout compared to the other conditions. **CONCLUSION:** Despite different TTE amongst conditions, peripheral NMF was only different exercising slightly above MLSS compared to the other conditions.

Fatigue-induced Changes In Neuromuscular Responses During Maximal Bilateral Leg Extensions

Tyler J. Neltner¹, John Paul V. Anders¹, Cory M. Smith², Joshua L. Keller¹, Ethan C. Hill³, Terry J. Housh, FACSM¹, Richard J. Schmidt¹, Glen O. Johnson, FACSM¹. ¹University of Nebraska-Lincoln, Lincoln, NE. ²University of Texas- El Paso, El Paso, TX. ³University of Central Florida, Orlando, FL. (Sponsor: Dr. Terry J. Housh, FACSM)

(No relevant relationships reported)

Purpose: The purpose of the present study was to compare the fatigue-induced changes in neuromuscular responses from both vastus lateralis (VL) muscles during maximal, bilateral isokinetic leg extensions. **Methods:** Fourteen men (22.6 ± 4 yr) performed consecutive, maximal, bilateral, concentric isokinetic leg extensions at 180 °·s⁻¹ until their peak torque was reduced by 70% (67 ± 19 repetitions). The amplitude (root mean square = RMS) and frequency (mean power frequency = MPF) contents of the electromyographic (EMG) and mechanomyographic (MMG) signals from the VL muscles of both legs were recorded simultaneously during each repetition of the fatiguing bout. The EMG RMS, EMG MPF, MMG RMS, MMG MPF and torque values were normalized to the values corresponding to 10% of the total number of repetitions completed and statistically compared at 5% intervals. Four, 2 (right and left VL) x 19 (10-100% of the total repetitions) repeated measures ANOVAs were used to determine mean differences for each neuromuscular parameter. A 1 x 19 repeated measures ANOVA was used to analyze torque changes across repetitions. Pairwise comparisons were used to identify when the neuromuscular and torque values changed from the values at 10% of the total repetitions. **Results:** The results indicated no significant interactions involving the right and left VL of any of the neuromuscular parameters. There were, however, significant main effects for repetitions collapsed across the muscles for both MMG RMS ($p = 0.03$; $\eta^2 = 0.147$) and EMG MPF ($p < 0.01$; $\eta^2 = 0.376$). Bilateral peak torque (271.1 ± 44.6 N·m) decreased significantly ($p < 0.01$; $\eta^2 = 0.695$) from 40-100% of the total repetitions. **Conclusion:** The results of this study revealed no differences between the right and left VL muscles for the patterns of neuromuscular responses during the fatiguing bilateral leg extensions. Peak torque decreased by 40.3% across all repetitions and was dissociated from the patterns of responses for EMG RMS and MMG MPF. The decreases across repetitions for EMG MPF and MMG RMS suggested that the fatigue-induced decrease in torque was due to excitation-contraction coupling failure secondary to an increase in metabolic byproducts.

The Comparison Of Contralateral Repeated Bout Effects On Arm Muscle And Hand Muscle

Sunggun Jeon, William Miller, Junseob Song, Minsoo Kang, FACSM, Xin Ye. University of Mississippi, University, MS.

(Sponsor: Minsoo Kang, FACSM)

Email: sjeon3@go.olemiss.edu

(No relevant relationships reported)

Purpose: To compare the potential contralateral repeated bout effect (conRBE) in both biceps brachii and first dorsal interosseus (FDI) muscles.

Method: Fifteen adults (Age: 25.2 ± 4.4 years; Weight: 76.0 ± 11.4 kg; Height: 177.1 ± 7.3 cm) participated in this study. Participants were randomly assigned into either arm (n = 8) or hand group (n = 7). After the first visit as the familiarization, Visit 2 was the eccentric exercise visit, during which the participants performed 6 sets of 10 repetitions eccentric exercise at 50% maximal voluntary isometric contraction (MVIC) in the designated muscle group (randomly chosen between dominant and non-dominant sides). Before (pre) and after (post) exercise, MVIC, submaximal isometric trapezoid contraction task, range of motion (ROM), and delayed-onset muscle soreness (DOMS) were measured. Specifically, the trapezoid contraction task required the participants to gradually increase the force from 0 to 30% MVIC in 3 seconds, held it for 10 seconds, and then gradually decreased the force to 0% in 3 seconds. During the Visits 3 and 4 (24-hour post- and 48-hour post-exercise), all measurements were collected. One week after Visit 2, the exact same exercise was performed and the measurements were obtained for the contralateral muscle. Surface EMG signals from the biceps brachii or FDI muscles were collected, and separate three-way [group (arm vs. hand) × bout (bout 1 vs. 2) × time (pre vs. post vs. 24 post vs. 48 post)] repeated measures analysis of variances (ANOVAs) were used to examine the mean differences in dependent variables.

Results: For the biceps brachii muscle, the pre to 24 post change (delta) in ROM showed a significant difference between first bout and second bout (first vs. second bout: 27.01 ± 11.84 vs. 16.81 ± 9.88, $p = 0.042$). There were significant differences between first bout and second bout at 24 post (55.06 ± 11.44 vs. 37.38 ± 12.67, $p = 0.006$) and 48 post (65.38 ± 10.00 vs. 47.44 ± 14.99, $p = 0.007$) for DOMS. In addition, normalized EMG amplitude showed a significant difference between first bout and second bout at post (69.87 ± 25.41% vs. 41.37 ± 17.13%, $p = 0.009$). However, there was no conRBE in all dependent variables on FDI muscle.

Conclusion: The elbow flexor muscles showed conRBE, but hand muscle did not have any protective effect. Therefore, conRBE seems to be muscle specific.

Quantitative Measure Of Force Output Across Various Biomechanical Support Devices At The Knee

Thomas J. Cahill¹, Dillon J. Canter¹, Daniel J. Canter¹, Cardyl P. Trionfante². ¹Miami University, OXFORD, OH. ²Thomas More University, Crestview Hills, KY.

Email: cahilltj@miamioh.edu

(No relevant relationships reported)

Introduction: The capacity to transfer high amounts of motor force against extreme resistances is desirable for recreational and competitive athletes alike. Due to this, the popularity of polymer-based wraps and sleeves has been increasing due to their known ability to aid in the increase of force output. However, the discrete force quantity (carryover value) has been largely overlooked in research. In the present study, passive force is measured in order to eliminate voluntary motor activation and to collect values representing ergogenic aid alone. **Purpose:** To quantify the force produced by the resistance-induced stretching of various ergogenic aids. **Methods:** 9 adult males (22.1±4.3yrs) underwent a series of passive force measurements, taken in duplicate, on a HUMAC NORM Isokinetic Dynamometer. Duplicate measures for each treatment were taken in three separate sessions. In each session, subjects were treated with no wrap (RAW), a knee sleeve (KS), or a manually wrapped "X" pattern knee wrap (KW) treatment. Peak torque was measured at 9 angles (70°, 75°, 80°, 85°, 90°, 95°, 100°, 105°, and 110°) for each treatment. Average force through full ROM was calculated for each subject. One-tail paired *t*-tests were ran ($\alpha=0.05$) at all angles between all treatments and also between mean torque values. One-way ANOVA test was also ran for mean torque of all treatments ($\alpha=0.05$). **Results:** Average force output for RAW tests was (3.72±4.64 N·m), (7.38±8.04 N·m) for KS and (12.64±11.55 N·m) for KW. One-tailed paired *t*-test for RAW vs KW yielded a ($t=5.86$) and ($p \leq 0.05$). One-tail paired *t*-test for RAW vs KS yielded ($t=3.31$) and a ($p \leq 0.05$). KS vs. KW yielded ($t=3.01$) and a ($p \leq 0.05$). Paired one-tail *t*-tests yielded significant differences ($p \leq 0.05$) between every condition at every angle except for 70° ($p=0.0813$) and 75° ($p=0.360$) between RAW and KS. One-way ANOVA between average of torque production showed significant results, p -value: (≤ 0.05), ($f=18.35$). **Conclusion:** Data indicates the use of ergogenic aid in passive force tests significantly increased passive torque production. KW condition resulted in the greatest torque production. KS showed less passive torque production than KW, but more than RAW.

Quantification Of On-ice Figure Skating Jumps Using Data From A Wearable Device

Sarah T. Ridge, Riley E. Reynolds, Kaden Weber, Dustin Bruening, *Brigham Young University, Provo, UT.*
 Email: sarah_ridge@byu.edu
 (No relevant relationships reported)

The number of jumps figure skaters perform daily has never been formally quantified, though it has been suggested that skaters perform 50-100 jumps per training day. The magnitude of force, high loading rates, and frequent repetitions likely contribute to the high injury rate of competitive skaters. Monitoring the number of jumps performed may help decrease risk of injury, similar to the institution of pitch counts in youth baseball.

Activity monitors that are commonly used for activities such as walking and running record many false positives during figure skating jump quantification due to the variety of skating movements that generate similar acceleration profiles. Previously, we developed an algorithm that successfully counted 39 of 40 jumps performed during the competitive routines of 7 local skaters whose isolated jumps were used to create the algorithm.

Purpose: To test the performance of the algorithm on an independent sample of skaters of varying skill levels.

Methods: 18 healthy competitive figure skaters participated in this study (ages 8-26y, 12 female). Each skater wore an IMU affixed to the lower back while they performed a variety of jumps, spins, and footwork. A high speed video camera recorded all trials for validation purposes. Custom software was used to analyze the IMU data to quantify the number of jumps performed with >1 rotation.

Results: Analysis of the videos showed that we recorded a total of 200 jumps with >1 rotation. The algorithm correctly quantified 94.5% of the jumps in this dataset (189 successful jumps). It also identified 11 jumps with ≤1 rotation.

Conclusions: These results show that this algorithm can be successfully applied to a unique dataset. Many of the jumps with ≤1 rotation that were counted were “popped” jumps, where a skater intends to perform a multi-revolution jump prior to take-off, but perform a single instead. Multi-revolution jumps that were not counted included falls and those with too much rotation that occurs on the ice prior to take-off. Finally, this dataset showed that the algorithm may need to be customized for smaller and/or low-level skaters as it failed to identify 7 of 12 jumps performed by a small, beginning level skater (8y, 122cm, 23.6 kg). Further improvements may be made by using machine learning algorithms to differentiate types of jumps as well as jump count.

Reliability Of Quantitative Kinematics From A Portable Hand-held Device

Brooke A. Smith¹, Brett Pexa¹, Audrey Westbrook¹, Kevin J. Mullen¹, Thomas Maly², Frantisek Zahalka², Justin Waxman¹, Kevin Ford, FACSM¹. ¹High Point University, High Point, NC. ²Charles University, Prague, Czech Republic. (Sponsor: Kevin Ford, FACSM)
 Email: bsmith2@highpoint.edu
 (No relevant relationships reported)

The current gold standard for assessing kinematics is three-dimensional (3D) motion analysis. However, the equipment required to accomplish this is not generally available in sport or clinical settings. Portable handheld devices (PD) are available that synchronize multiple two-dimensional video views to qualitatively evaluate complex sport skills. However, the use of quantitative kinematic analysis on PD compared to standard computer software (CS) has not been investigated. **PURPOSE:** To investigate the intra- and inter-rater reliability of PD compared to an open source CS. **METHODS:** Twenty-seven collegiate male soccer players (height: 179.8±5.6cm, mass: 75.9±6.9kg) were analyzed (120 Hz) during a drop vertical jump from a 30-cm box. PD and CS were separately used to 1) select a single frame from the frontal plane view when both knees were visually the most medial during landing and 2) digitize and record the frontal plane knee angle from hip, knee and ankle joint centers to estimate lower extremity valgus. Reliability between systems and reliability between testers were established with intra-class correlations (ICC_{2,k}, ICC_{3,k}, respectively). Precision was calculated with standard error of measurement (SEM). **RESULTS:** Intra-rater reliability was 0.993 [95% CI 0.985, 0.997] with SEM of 1.09 on the right, and 0.971 [95% CI 0.938, 0.987] SEM of 2.69 on the left limb. Inter-rater reliability on the right side was 0.979 [95% CI 0.954, 0.990] with SEM of 1.97 for the right limb and 0.978 [95% CI 0.943, 0.990] with SEM of 2.37 on the left, respectively. **CONCLUSION:** In collegiate male soccer players, PD exhibited excellent intra- and inter-rater reliability. The data indicates that it might be a useful tool to integrate into a screening protocol to quickly estimate lower extremity valgus. However, future analyses should compare traditional 3D motion analysis to determine validity.

Reliability Of IMU Derived Kinematic Measures During The Forward Lunge

James Davenport¹, Sarah Ward², William Johnston¹, Cathy Goulding¹. ¹The Insight Centre for Data Analytics - University College Dublin, Dublin, Ireland. ²University of Otago, Dundin, New Zealand.
 Email: james.davenport@ucdconnect.ie
 (No relevant relationships reported)

The integration of inertial sensor data into the clinical environment and beyond, demonstrates the potential of improved clinical interpretation of an individual's functional movement capacity. Previously this has only been possible through the use of expensive laboratory-based motion capture systems. The forward lunge, a lower limb functional movement which exaggerates the gait cycle is commonly used by clinicians to assess lower limb strength, flexibility and balance. Combining Inertial measurement units with the forward lunge exercise could provide a quantified measure which was previously not possible in the clinical setting. **Purpose:** To determine the intrasession-reliability of kinetic measures derived from shank based inertial sensors during a forward lunge. **Methods:** Twenty-three healthy participants took part in the study (12 Male, 11 Female, 30.8 ± 8.6yrs, 1.7 ± 0.9m, 65.3 ± 10.8kg). Each participant performed 3 sets of 5 lunges bilaterally, each with a 10 min rest period adequate to establish intra-session reliability. Lunge distance and stance was set as 100% of leg length and hip width respectively (± 5%). IMUs were worn on the lateral aspect of each shank. The lunge was segmented into initiation, initial contact, mid-point, and termination. Peak & root mean squared (RMS) of total acceleration signals of the shank based IMU were taken for all lunges. Intraclass correlation coefficients (ICCs) were calculated based on a mean rating (k=3), absolute agreement two-way mixed effects model. Intra-session reliability was defined as poor (ICC<0.5), moderate (0.5-0.75), good (0.75-0.9) or excellent (>0.9). **Results:** ICC values ranged from 0.916 to 0.981 for left limb peak acceleration and 0.903 to 0.978 for right limb peak acceleration. ICCs for RMS of left and right limb ranged from 0.908 to 0.979 and 0.899 to 0.977 respectively. **Conclusions:** The IMUs showed good to excellent reliability for both peak and RMS total acceleration across both limbs during the forward lunge. This demonstrated the potential for their integration as a clinical tool to provide quantified measures of an individual's forward lunge performance.

3400 Board #221 May 29 2:30 PM - 4:00 PM
Test-retest Reliability And Concurrent Validity Of An In-shoe Pressure System During Two Landing Maneuvers

Ahmad D. Alanazi¹, Katy Mitchell², Toni Roddey², Aqeel Alenazi³, Alexis Ortiz, FACSM⁴. ¹Majmaah University, Majmaah, Saudi Arabia. ²Texas Woman's University, Houston, TX. ³Prince Sattam Bin Abdulaziz University, Alkharj, Saudi Arabia. ⁴University of the Incarnate Word, San Antonio, TX.
 Email: aalanazi@mu.edu.sa
 (No relevant relationships reported)

In-shoe pressure sensor systems have been used to measure vertical ground reaction forces (GRFs) during functional tasks in clinical settings. However, no study has evaluated their reliability and validity during functional tasks in healthy soccer players.

PURPOSE: To determine the test-retest reliability of the peak plantar pressure measured by an in-shoe pressure system during landing from long-jump (LLJ) and landing from heading-jump (LHJ) performed by healthy soccer players. A second purpose was to evaluate the concurrent validity of the peak plantar pressure in relation to the peak vertical GRFs obtained using a force plates system as a criterion reference during both landing maneuvers.

METHODS: Ten healthy soccer players (age: 25.6 ± 2.67; BMI: 22.74 ± 2.33) participated in this study. LLJ included jumping forward and landing on the force plates, whereas LHJ included jumping forward to head a soccer ball and landing on the force plates. Each participant performed five trials of each landing maneuver. Within three days from initial testing, participants were asked to perform the same five trials of each landing task. Peak plantar pressure and peak vertical GRFs were measured during the landing phase (from initial contact to maximum bilateral knee flexion). Intra-class correlation coefficients [ICC (3,2)] were used to determine test-retest reliability. Pearson product-moment coefficient of correlations (r) were calculated to compare the peak plantar pressure with the peak vertical GRFs.

RESULTS: Test-retest reliability exhibited good reliability for peak pressure during LLJ (ICC = 0.96) and LHJ (ICC = 0.89). Peak plantar pressure and peak vertical GRFs showed a significant good-to-excellent positive correlation (r = 0.80, p < 0.001) during the LLJ, whereas a significant moderate-to-good positive correlation (r = 0.67, p = 0.03) was observed during the LHJ.

CONCLUSION: The present findings indicate that the in-shoe pressure system is reliable and valid during both landing maneuvers in healthy soccer players. Therefore, this system could be a useful tool to evaluate vertical GRFs in field and laboratory settings since it does not restrict participants to step or land on the force plates, thus allowing them to perform a more natural functional task.

3401 Board #222 May 29 2:30 PM - 4:00 PM

Reliability Of Inertial Sensor Derived Knee Joint Angular Velocity During A Forward LungeSarah Ward¹, James Davenport², Cathy Goulding², Brian Caulfield². ¹University of Otago, Dunedin, New Zealand. ²University College Dublin, Dublin, Ireland.
Email: sarah.ward@otago.ac.nz*(No relevant relationships reported)*

Incorporating inertial measurement units (IMU) into screening tools affords the ability to 'quantify' commonly used functional tasks using angular velocity and acceleration as an outcome variable. These 'quantified' tasks have may have greater depth, accuracy and sensitivity than that achieved with standard clinical evaluation tools. Angular velocity can quantify how fast a segment or joint rotates, and provide a preliminary understanding of neuromuscular control during dynamic tasks including a forward lunge. **PURPOSE:** To determine the reliability of IMU-derived knee joint angular velocity during a forward lunge. **METHODS:** Twenty-three healthy individuals participated in this study (12M/11F, 30.8 ± 8.6 years, 1.7 ± 0.9 cm, 65.3 ± 10.8 kg). Participants performed a set of 5 lunges on the right limb and 5 on the left limb, repeated 3 times separated by 10 minute rest periods. Lunge distance was normalized to 100% (±5%) of leg length. IMUs were worn on the lateral thigh and shank of each limb. The following anchor points were defined for segmentation: initiation, initial contact 1 (IC₁), midpoint and initial contact 2 (IC₂)/termination. Peak and average thigh and shank angular velocity were extracted from the z-axis gyroscope signal for each lunge segment and for a 50ms window either side of IC₁. Peak and average knee joint angular velocity in each segment was calculated from thigh and shank data. Intraclass correlation coefficients (ICCs) were calculated based on a mean rating (*k*=3), absolute agreement, 2-way mixed-effects model. Intra-session reliability was defined as poor (ICC < 0.5), moderate (0.5-0.75), good (0.75-0.9) or excellent (>0.9). **RESULTS:** ICC values ranged from 0.841 to 0.911 for peak left knee joint angular velocity and 0.760 to 0.939 for peak right knee joint angular velocity. Average left knee joint velocity had ICCs ranging from 0.912 to 0.972, and 0.922 to 0.965 for average right knee joint angular velocity. **CONCLUSIONS:** IMU-derived knee joint angular velocity had good to excellent intra-session reliability during a forward lunge and demonstrate good potential for providing objective quantified data on forward lunge performance. IMUs may provide a more accessible alternative to 3D motion analysis or screening tools for lower limb function and neuromuscular control in a clinical setting.

Validity And Reliability Of A Mobile App For Measuring Bar Velocity In The Bench Press ExerciseDaniel Boulosa¹, Alejandro Pérez-Castilla², Amador García-Ramos³. ¹Federal University of Mato Grosso do Sul, Campo Grande, Brazil. ²University of Granada, Granada, Spain. ³Universidad Católica de la Santísima Concepción, Concepción, Chile. (Sponsor: Carl Foster, FACSM)
Email: daniel.boulosa@gmail.com*Reported Relationships: D. Boulosa: Ownership/interest/stock; CEO and Founder of iLOAD Solutions.*

Velocity based-training (VBT) has been demonstrated to be a valid and useful approach to promote greater neuromuscular adaptations in resistance training (RT). This approach typically requires velocity monitoring during RT sessions for appropriate adaptations. The validity and reliability of a chronometer-based mobile App for RT monitoring in the half-squat exercise have been previously shown with a 10 repetition maximum (RM) load, when compared to a linear encoder. However, no data exist with other exercises and different loads. **PURPOSE:** To determine the validity and reliability of a chronometer-based mobile App for velocity monitoring in the bench press exercise with different loads. **METHODS:** Twenty handball players (23.0 ± 2.6 yrs, 1.76 ± 0.06 m, 79.6 ± 13.0 kg) completed, after 1RM determination, 5 repetitions with the 25, 40, 55 and 70% of 1RM in the bench press exercise, with the maximal intended velocity, in 2 days separated by 48-72 hrs. Bar velocity (m·s⁻¹) was monitored simultaneously by means of a linear encoder with a sampling rate of 1,000 Hz (reference method), and a chronometer-based mobile App. Validity was examined through paired samples *t*-test, the Hedge's effect size (ES), the Pearson's correlation coefficient (*r*), and the standard error of estimate (SEE). Reliability was assessed by the coefficient of variation (CV) and the standard error of measurement (SEM). **RESULTS:** Regarding validity, all relative loads evaluated demonstrated significant differences (*P* < 0.05) and small to moderate ES (range: 0.31-1.19) between devices, with the mobile App exhibiting greater bar velocities than the linear encoder. However, bar velocities measured with both devices were highly correlated (*r* ≥ 0.74) with a very low SEE (≤ 0.09 m·s⁻¹). The App exhibited for all loads a low SEM (≤ 0.11 m·s⁻¹), and acceptable CV (< 10%) with the exception of the highest load (70%1RM) (CV = 12.1%). **CONCLUSIONS:** A chronometer-based mobile App may be considered a valid and reliable method for VBT monitoring in the bench press exercise.

The Validity Of A Smartphone-based Seated Postural Control Assessment In Non-ambulatory AdultsMikaela L. Frechette, Libak Abou, Laura A. Rice, Jacob J. Sosnoff. University of Illinois at Urbana-Champaign, Champaign, IL.
Email: mikaela5@illinois.edu*(No relevant relationships reported)*

Individuals who rely on wheeled mobility have unique fall risk factors (e.g. seated postural control) but recommended fall risk screening tools are predominately designed for ambulatory individuals. Consequently, most non-ambulatory adults do not undergo comprehensive fall risk screening or receive targeted fall prevention strategies.

PURPOSE: To examine the validity of smartphone-based postural control assessments in non-ambulatory adults. **METHODS:** Eleven participants (age: 35.4 ± 17.9) completed three clinical tests: The Trunk Control Test, Function in Sitting Test (FIST), and Tee-Shirt Test, as well as, four instrumented balance tasks in a standardized order: eyes open, eyes closed, functional reach, and functional stability boundary. During the balance tasks, participants held a smartphone and research-grade accelerometer to their chest. These devices measured root mean square (RMS) acceleration in the medial-lateral (ML), anterior-posterior, and vertical axes during all tasks. A median split of FIST scores differentiated participants with better and worse postural control. Spearman rank-order correlations between the two devices' measurements were conducted, and receiver operating characteristic (ROC) and the area under the curves (AUC) were constructed to distinguish participants with better and worse postural control. **RESULTS:** Participant scores from the FIST differed between those with better and worse postural control (*p* = 0.020). There were significant moderate to strong correlations between measures derived from the smartphone and measures derived from the research-grade accelerometer during the balance tasks (*p* = 0.636-1.000; *p* < 0.01-0.035). The AUC for ROC plots were significant for RMS ML sway during the eyes open task and functional stability boundary (*p* = 0.045 and 0.018, respectively). **CONCLUSION:** This pilot study illustrated that smartphone technology may be able to provide a valid assessment of seated postural control and have the ability to distinguish between those with better and worse postural control in the ML direction. Leveraging this form of technology could provide easily accessible and objective fall risk assessments for non-ambulatory adults.

Validation Of A Wearable Inertial Sensor Unit To Measure Balance And Sway During Postural TasksJason M. Avedesian, Mathew Sunil Varre, Ryan Tingle, Janet S. Dufek, FACSM. University of Nevada, Las Vegas, Las Vegas, NV. (Sponsor: Janet S. Dufek, FACSM)
Email: jason.avedesian@unlv.edu*(No relevant relationships reported)*

Current postural control tests for baseline concussion analysis and return to play decision making are of moderate reliability, attributed to subjective scoring. A recently developed inertial measurement unit (IMU) may offer clinicians a feasible, objective tool for postural control analysis surrounding a concussive event. **PURPOSE:** To assess the validity of a wearable IMU against a force platform (FP) during postural control tasks in adults. **METHODS:** Twenty-four participants completed three trials of four stance conditions (double-leg, tandem, left leg, and right leg) with eyes open (EO) and eyes closed (EC). Concurrent measures of postural control (anterior-posterior and medial-lateral sway, path length, and sway area) during each stance were collected as participants stood on a single FP while wearing the IMU on the sternum. Statistical analyses were conducted on mean percentage change (MPC) from EO to EC for sway parameters from the FP and IMU during the four stance conditions. Multiple multivariate analyses of variances were conducted to determine whether statistical differences existed between instruments (*α* = 0.05). **RESULTS:** The differences in MPC when comparing the IMU to the FP were 5-33% for double-leg stance, 8-130% for tandem stance, 0-82% for left leg stance, and 12-178% for right leg stance across postural control measures. Significant multivariate differences were found for double-leg [*F* = 12.233, *p* < .001], tandem [*F* = 15.927, *p* < .001], left leg [*F* = 3.725, *p* = .011], and right leg [*F* = 4.031, *p* = .007] stance. Pairwise comparisons indicated significant differences for anterior-posterior sway (*p* = .010) and path length (*p* < .001) during double-leg stance and path length (*p* = .005) during tandem stance. **CONCLUSIONS:** Preliminary results indicate large differences in postural control when utilizing this IMU versus a FP for assessing sway in direct comparisons. It must be noted that sway from this IMU is projected from its center of mass. Thus, direct comparison may be misleading. Further study is suggested to incorporate the IMU projection algorithm, in order to make more appropriate direct comparisons between instruments. It is important for researchers to understand algorithms that are implemented in IMU software to determine reliability of measurement, prior to stating experimental outcomes.

Validation Of Step Length Between An Anti-Gravity Treadmill And A 2-Dimensional Camera System

Karina Moreno-Flores¹, Matthew Lusk¹, Pedro Migliano², Rebecca Greenwood², Alexis Ortiz, FACSM³. ¹UT Health San Antonio, San Antonio, TX. ²Texas Woman's University, Houston, TX. ³University of the Incarnate Word, San Antonio, TX.

(No relevant relationships reported)

Lower body positive pressure treadmills (LBPTT) allow patients to walk in a gravity reduced environment of their total body weight with new embedded gait analysis module capable of documenting gait outcomes. **PURPOSE:** To validate step length (SL) measurement calculated by the LBPTT against a two-dimensional camera system. **METHODS:** Nine participants (5 male and 4 females; mean age 30.8 years) walked and ran for five minutes at 3mph, 4mph, 5mph, and 6mph on a lower body positive pressure treadmill (LBPTT). At each speed the subjects were unweighted at 80%, 60%, 40% and 20% of their total body weight (BW). A side camera view was employed to record step length. Five SL measurements from the middle minute were taken from each video from heel to heel and averaged to represent SL for each BW and speed. The right and left SL measurements from the treadmill were averaged as a composite SL measurement for analysis. Intraclass correlation coefficients were estimated for the average of five trials of the video data. Pearson correlations were calculated between step length from the treadmill and video. Correlations were considered significant at alpha .05.

RESULTS: All speeds and body weight conditions exhibited excellent reliability (ICC > 0.90) for the average of five trials for the video analysis. The correlations between the treadmill and video analysis for the speeds of 3 and 4 mph showed varied correlations fluctuating from poor to good ($r=-.21-.98$) with correlations greater than $r=.85$ showing statistical significance. The correlations between treadmill and cameras for the 5 and 6 mph speeds showed no statistically significant correlations ranging from $r=-.02-.69$.

CONCLUSIONS: The gait analysis module of the LBPTT does not measure direct step length from the instrumented belt after the transition from walking to running. The LBPTT might be using an algorithm to extrapolate the anticipated step length if the subject were not on the treadmill.

Testing The Performance Of An Innovative Video-based Technique For Gait Analysis

Laura Simoni¹, Alessandra Scarton², Guido Pasquini³, Federico Gori², Silvia Pogliaghi, FACSM¹. ¹Università di Verona, Verona, Italy. ²Microgate srl, Bolzano, Italy. ³Fondazione Don Gnocchi, Firenze, Italy.

Email: laura.simoni@univr.it

(No relevant relationships reported)

Gait abnormalities such as high stride frequency (SF) and stride variability (SV) may increase the risk of overuse injuries and/or be a sentinel of medical conditions. Low-cost and time-efficient alternatives to traditional stereophotogrammetry would allow the applicability of gait analysis on a large scale for early diagnosis/longitudinal monitoring.

Purpose: test the performance of an innovative video-based gait analysis technique in healthy individuals.

Methods: 37 healthy individuals (29±16 yrs) performed a 90°, test on treadmill at self-selected walking speed. We measured SF by an optical sensor platform; then we calculated average ± SD and within-subject coefficient of variation as an index of SV. We also recorded a 60 fps video of the subject (posterior view). With a custom designed web-based video analysis software we performed a spectral analysis of the brightness over time for each pixel of the image, that reinstated the frequency contents of the videos. The main frequency content (F1) from this analysis should reflect the forcing/dominant variable, i.e. SF. Then, an harmonic index (HI) was calculated, that reflects the proportion of the pixels of the image that move consistently with F1 or its supraharmonics. The higher the HI value, the less variable is gait. The correspondence between SF and F1 was evaluated by paired t-Test and correlation and between SV and HI by correlation.

Results: Subjects walked at a self-selected speed of $1.1±0.2$ m·s⁻¹. SF was not significantly different from and highly correlated with F1 ($0.88±0.07$ vs $0.89±0.08$ Hz, $p=0.06$, $r^2=0.98$). The SV was $1.93±0.81\%$ and it was significantly and moderately correlated with HI ($0.084±0.033$, $p=0.006$, $r=-0.45$).

Conclusions: The innovative video-based technique of global gait analysis proposed in our study accurately identifies the main frequency content and the variability of gait in healthy individuals thus providing a time-efficient, low-cost means to study human locomotion.

Best Practice Use Of Wearable Accelerometers In Gait Biomechanics

Jennifer S. Addleman, David Hawkins. *University of California, Davis, Davis, CA.*

Email: jsaddleman@ucdavis.edu

(No relevant relationships reported)

Advances in wearable technology provide opportunities to collect biomechanical data in real time and non-lab settings. However, there are currently no standards for best practice use of wearable sensors for gait applications. **PURPOSE:** Provide best practice recommendations for use of wearable accelerometers (WA) in gait biomechanics. **METHODS:** Literature was reviewed to determine appropriate WA range for gait biomechanics and establish procedures for calibrating and processing WA data for gait applications. Drop tests of three, simultaneously initialized, commercially available WAs were performed to determine signal time synchronization and 1 g acceleration accuracy. WAs were secured to different lower limb locations (pelvis, knee, ankle) and walking and running trials performed. Peak acceleration magnitude and timing were compared within and among WAs by location and gait type. Vertical ground reaction force (GRFvert) was estimated using a regression model, developed based on pelvis acceleration data, to determine the sensitivity of the GRFvert estimates to WA placement. **RESULTS:** Peak lower limb accelerations can exceed 25 g during running. WAs initialized at the same time had significant temporal differences (up to 1.06 s). Accelerations during freefall were within 17 % of 1 g. After synchronizing WA signals based on the drop test results, there were no significant differences in WA magnitude and timing among three WAs located around the right iliac crest, but there were significant acceleration differences among WAs located at the right iliac crest, knee, and ankle. Walking and running peak GRFvert estimates based on accelerations of the iliac crest differed from estimates based on accelerations of the knee ($-5 ± 28$ N and $-142 ± 80$ N, respectively) and ankle ($261 ± 28$ N and $-274 ± 66$ N, respectively). **CONCLUSIONS:** WAs should be: (1) selected to measure a range greater than 25 g, (2) calibrated to ensure accuracy, (3) manually time synched if using multiple sensors, (4) placed carefully though exact placement is not critical to anatomical site acceleration estimates near the hip, and (5) located at the same anatomical site that was used to develop an acceleration-dependent model if the goal is to use that model to estimate a particular quantity (i.e. GRFvert).

¹Northwest Missouri State University, Maryville, MO. ²The University of Kansas, Lawrence, KS. ³California State University Northridge, Northridge, CA.

Email: emosier@nwmissouri.edu

(No relevant relationships reported)

PURPOSES: This investigation compared the ground reaction forces (GRFs) between a force plate and GRF derived from a markerless motion capture system (MCS) during a counter-movement vertical jump (CMVJ). **METHODS:** Healthy, recreationally active men ($n=10$; $±SD$; age= $22.5±2.1$ yrs, height= $180.8±4.6$ cm, weight= $80.8±7.5$ kg) and women ($n=8$; age= $20.5±0.8$ yrs, height= $171.7±5.7$ cm, weight= $68.1±7.2$ kg) volunteered to perform 3 CMVJs separated by 30 seconds of rest. A 3-D markerless motion capture system (MCS; DARI Motion, Scientific Analytics, Lincoln, NE) was sampled at 50 Hz, while a uni-axial force plate (Rice Lake Weighing Systems, Rice Lake, WI) and a data acquisition system (Biopac, Goleta, CA) sampling at 1000 Hz was used and resampled to 50 Hz for analysis. Participants begin the CMVJ standing on the force plate while in the MCS capture area. Ground reaction peak force (PF) was determined as the max force before takeoff, and ground reaction mean force (MF) was determined across the entire CMVJ from start of the motion to takeoff. Linear regressions were performed to compare MF and PF between the two devices (i.e. MCS vs. force plate) with the Pearson correlation (r), coefficient of determination (r^2), and standard error of the measurement (SEM) calculated. Paired samples t -tests (MCS vs. force plate; $p≤0.05$) were performed on the MF and PF. **RESULTS:** Mean ± SD and results are shown in table 1. Paired samples t -tests indicated significant differences (<0.01) for MF and PF. Linear regression analysis indicated excellent agreement between MCS and force plate for MF ($r=0.97$, $r^2=0.93$, SEM= 13.99 N) and PF ($r=0.92$, $r^2=0.84$, SEM= 35.72 N), respectively. **CONCLUSION:** Although significant differences were indicated, the linear regression analysis indicated that GRF can be accurately derived from a MCS without the use of a force plate. Furthermore, the intricate kinetic characteristics of human motion can be validly determined without being restricted to performing on a force plate.

Table 1. Comparison of ground reaction forces from force plate and motion capture system (MCS) during counter-movement vertical jumps

	Force Plate (N)	MCS (N)	r	r ²	SEM
Mean Force	887.9±131.0	972.9±147.8*	0.97	0.93	13.99
Peak Force	1662.0±368.6	1823.9±355.5*	0.92	0.84	35.72

(n=54); ($\bar{X} \pm SD$); * indicates significant difference ($p < 0.01$)

Measuring A Rider's Centre Of Mass Displacement During Non-seated Cycling Using A Single Inertial Measurement Unit

Ross D. Wilkinson, Glen A. Lichtwark. *The University of Queensland, St Lucia, Queensland, Australia.*

Email: ross.wilkinson@uqconnect.edu.au

(No relevant relationships reported)

Instantaneous power output measured at the cranks when cycling in a non-seated posture is not equivalent to the instantaneous joint power produced by the rider. This discrepancy is due to additional power that is generated on, and by, the rider's centre of mass (CoM). Capturing CoM motion in a laboratory setting is relatively straight forward; however, an accurate and reliable method for measuring this in the field remains elusive.

PURPOSE: To test whether a single Inertial Measurement Unit (IMU) placed on the torso of the rider at L4-5 can provide an accurate and precise measure of vertical CoM displacement during non-seated cycling.

METHODS: We first assessed whether the IMU could track its own vertical displacement by comparing it to an attached marker cluster tracked using three-dimensional motion capture. We then compared vertical displacement of the IMU to a kinematic estimate of vertical CoM displacement using a full body musculoskeletal model. IMU (100 Hz) and motion capture (200 Hz) data was collected synchronously for 10-s on seven participants while they cycled on an ergometer in a non-seated posture at three different power outputs and at two different cadences (70 rpm and 120 rpm). Sensor performance was quantified as the dynamic root mean square (RMS) error of yaw, pitch, and roll components of angular velocity. An agreement analysis corrected for repeated measures was also performed, which encompassed the limits of agreement, accuracy, precision, average error, and maximum error between each method.

RESULTS: In all trials, the IMU performed well with a dynamic RMS error of 0.17 ± 0.04 radians/s across all orientation components. The IMU measured vertical displacement of the marker cluster with high accuracy (0.002 ± 0.002 m) and precision (0.009 ± 0.005 m) with an average error of 1.7% and 5% at 70 rpm and 120 rpm, respectively. Agreement between the IMU and the kinematic prediction of CoM displacement was lower with an accuracy of 0.016 ± 0.003 m and precision of 0.010 ± 0.004 m.

CONCLUSIONS: These results suggest that a single IMU can provide a highly accurate and precise measure of its own orientation and amplitude of vertical displacement. Further research is required to test whether agreement between the IMU and the model's CoM can be improved by placing the IMU in different positions on the torso.

(No relevant relationships reported)

Exercise fatigue is a common physiological phenomenon in sports. The central nervous system (CNS) has important regulating effect on exercise fatigue. The basal ganglia are involved in motor function regulation through direct and indirect pathways. Striatum is the main input nucleus of basal ganglia and plays an important role in movement

control. **PURPOSE:** Explore the role of dopaminergic synapse and D2 dopamine receptors (D2DR) in movement control by investigating synaptic ultrastructural change of the dorsolateral striatum (DLS) and D2DR antagonist/agonist effect on autonomic activity in exercise-induced fatigue rats. **METHODS:** Male Wistar rats were randomly divided into either the sham control group (SCG), 1-day fatigue group (1FG), 3-day fatigue group (3FG), 7-day fatigue group (7FG), 24-hour recovery group (24RG) or 48-hour recovery group (48RG). The synaptic ultrastructure was observed by transmission electron microscopy. Further a D2DR antagonist and agonist were used to interfere with the autonomic exercise of rats with Open Field Test. **RESULTS:** We found that: (1) The proportion of asymmetrical synapse of DLS (SCG: $41 \pm 2\%$), 7FG: $28 \pm 4\%$, $p < 0.05$), number of presynaptic vesicles (SCG: 13.35 ± 4.58 (number/ μm^2), 7FG: 5.92 ± 2.7 (number/ μm^2), $p < 0.05$), number of synaptic terminal mitochondria (SCG: 0.19 ± 0.18 (number/ μm^2), 7FG: 0.15 ± 0.1 (number/ μm^2), $p < 0.05$), and the area of synaptic terminals (SCG: 123925.64 ± 54773.42 (μm^2), 7FG: 84447.16 ± 29495.42 (μm^2), $p < 0.05$), decreased with the increase of exercise days. (2) The total exercise distance of each group decreased gradually with the increase of exercise intensity ($p < 0.05$). Additional rat's exhaustion time was also significantly shortened after injection of the D2DR antagonist (before: 147.33 ± 5.63 , after: 103 ± 4.14 , $p < 0.01$). **CONCLUSIONS:** The activity of synapses in the dorsolateral striatum of rats decreased with the increase of exercise fatigue. Exercise fatigue reduced the autonomic activity of rats, which was further enhanced by D2DR antagonist intervention. This indicates that the regulatory role of D2DR in motion may be related to synaptic plasticity of dopaminergic in substantia nigra and striatum, suggesting that D2DR can be used as an important target to address exercise fatigue.

ARE MOTOR UNIT FIRING PROPERTIES CONTROLLED WITHIN DISTINCT REGIONS OF A MUSCLE

Micheal J. Luera¹, Jesus A. Hernandez-Sarabia¹, Carlos A. Estrada², Jason M. DeFreitas¹. ¹Oklahoma State University, Stillwater, OK. ²Aurora University, Aurora, IL.

Email: mike.luera@okstate.edu

(No relevant relationships reported)

Previous findings have suggested that the distribution of motor units within a muscle may display region-specific muscle activation. Consequently, if regionalization of motor units indeed exists, then force generating capacities would be highly task and joint dependent. **PURPOSE:** To examine for regional motor unit control from proximal and distal locations of biarticular [rectus femoris (RF)] and monoarticular [vastus lateralis (VL)] muscles during low-force knee extensions. **METHODS:** Following 2 maximal voluntary contractions (MVC), eighteen resistance-trained men ($n = 9$, age = 23 ± 3 yrs) and women ($n = 9$, 22 ± 2 yrs) performed a 10 sec isometric ramp contraction up to 30% MVC. On two separate occasions, surface electromyographic (EMG) signals were collected from proximal and distal locations of either the VL or RF. These were used to record EMG amplitude and were also decomposed into the constituent motor unit action potentials. The slope and intercept values were calculated across the motor units for relationships between mean firing rate, recruitment threshold, and action potential size for each subject. Paired samples *t*-tests were used to compare regression coefficients and EMG amplitude between proximal and distal locations of the RF and the VL separately. **RESULTS:** There were no differences in EMG amplitude between locations in the RF ($p = 0.31$, $d = 0.39$), however, amplitude in the distal location of the VL was greater than the proximal ($p < 0.05$; $d = 0.64$). There were no significant differences in slope or intercept coefficients for any of the motor unit relationships (see Table 1) ($p = 0.08 - 0.91$, $d = 0.01 - 0.64$). **CONCLUSION:** Although there was a regional difference in the activation across the VL, there were no region-specific differences in the motor unit firing properties. The differences in amplitude were likely due to other factors that affect EMG signals, such as the underlying morphology (muscle size, subcutaneous fat thickness, etc.).

Table 1. Mean slope and intercept coefficients for relationships between motor unit firing properties

Mean Firing Rate vs. Recruitment Threshold				
			p-value	
Regression Equation			Slope	Intercept
VL	Proximal	$y = -0.667x + 23.49$	0.46	0.77
	Distal	$y = -0.753x + 22.90$		
RF	Proximal	$y = -0.384x + 22.34$	0.59	0.51
	Distal	$y = -0.343x + 32.85$		
Mean Firing Rate vs. Action Potential Size				
VL	Proximal	$y = -95.79x + 25.54$	0.08	0.25
	Distal	$y = -72.28x + 23.51$		
RF	Proximal	$y = -74.623x + 22.92$	0.77	0.20
	Distal	$y = -78.683x + 24.57$		
Action Potential Size vs. Recruitment Threshold				
VL	Proximal	$y = 0.011x + 0.013$	0.59	0.75
	Distal	$y = 0.009x + 0.019$		
RF	Proximal	$y = 0.013x + 0.056$	0.17	0.55
	Distal	$y = 0.019x + 0.055$

 (No relevant relationships reported)

PURPOSE: To examine the effects of 10 weeks of continuous cycling training on maximal aerobic capacity (VO_{2MAX}), maximal strength (MVC) of the knee extensors, and motor unit (MU) behavior of the vastus lateralis (VL) in sedentary males.
METHODS: Nine males completed 40 supervised training sessions. Pre- and post-intervention, participants performed a cycling VO_{2MAX} test and MVCs on an isokinetic dynamometer followed by two consecutive submaximal (40% relative to pre-training MVC) contractions of the right knee extensors. Surface electromyographic (EMG) decomposition assessed recruitment thresholds (RT), action potential amplitudes ($MUAP_{AMP}$) and mean firing rates (MFR) for each observed MU from the VL for the 40% MVCs and linear regressions determined the y-intercepts (y-ints) and slopes for the MFR and $MUAP_{AMP}$ vs. RT relationships. EMG amplitude for the 40% MVCs was normalized (N-EMG) to the MVC for the current visit. Separate paired samples *t*-tests examined VO_{2MAX} and MVC. Separate two-way ANOVAs (time x repetition [rep]) examined N-EMG and the y-ints and slopes for the MFR and $MUAP_{AMP}$ vs. RT relationships. Alpha was 0.05.
RESULTS: Ten weeks of training resulted in significant increases in VO_{2MAX} (3.4 ± 0.6 vs. 3.8 ± 0.5 L/min; $P = 0.005$) while MVC was unchanged (212.7 ± 34.3 vs. 201.4 ± 32.1 Nm; $P = 0.056$). For the slopes and y-ints from the MFR and $MUAP_{AMP}$ vs. RT relationships, there were no significant two-way interactions ($P = 0.152 - 0.669$) or main effects for time ($P = 0.213 - 0.753$) or repetition ($P = 0.313 - 0.639$). For N-EMG, there was no significant two-way interaction ($P = 0.485$). There were main effects for time (37.3 ± 7.0 vs. $47.6 \pm 14.2\%$; $P = 0.035$) and rep (41.2 ± 11.9 vs. $43.7 \pm 12.7\%$; $P = 0.044$). N-EMG was greater for post-training and repetition 2 when collapsed across time and repetition.
CONCLUSIONS: Continuous cycling increased maximal aerobic capacity, whereas maximal strength of the knee extensors and motor unit firing rates and action potential amplitudes in relation to recruitment thresholds for the VL were unchanged. Although aerobic training is believed to improve endurance, participants exhibited greater muscle activation when completing a contraction at pre-training torque levels and similar increases in muscle activation when completing the ensuing contraction.

Physiological Determinants Of The Rate Of Torque Development In Older Men: A Pilot Study

Mitchel Magrini¹, Ryan J. Colquhoun², Sydnie Fleming², Matthew C. Ferrell³, Nathaniel D.M. Jenkins³, Jason M. DeFreitas³. ¹Creighton University, Omaha, NE. ²University of South Alabama, Mobile, AL. ³Oklahoma State University, Stillwater, OK. (Sponsor: Joan Eckerson, FACSM)
 (No relevant relationships reported)

In young, healthy adults, early phase (i.e., 0-50 ms) rate of torque development (RTD) is primarily determined by neural characteristics. However, it is unclear if this remains the case in older adults. **PURPOSE:** To examine the physiological characteristics of early phase RTD in older men. **METHODS:** Seventeen older males (age = 73 ± 6 y) completed 2 maximal (MVIC) and 2 rapid (rMVIC) isometric knee extensions. Early phase RTD values were calculated from the first 50 ms ($aRTD_{50}$) of the rapid contractions and normalized ($nRTD_{50}$) to maximal torque (%MVIC/s). Muscle activation amplitude (EMG) was calculated during the first 50 ms ($nEMG_{50}$) of EMG onset and was normalized to the peak-to-peak M-wave amplitude (% M_{pp}) of the vastus lateralis (VL), vastus medialis (VM), and rectus femoris (RF). Evoked peak twitch torque (τ_{TT}) was determined as the maximal torque (Nm) produced from a single electrical stimulus. Motor unit number estimation (MUNE) was calculated as a ratio of the ensemble average of the single MU potential amplitude to the compound muscle action potential amplitude and was corrected for alteration. Muscle quality (MQ) was determined by examining the average muscle cross-sectional area relative to the average muscle echo intensity for each muscle using an ultrasound. Relationships between the predictor variables ($nEMG_{50}$, MUNE, τ_{TT} , MQ) and RTD ($aRTD_{50}$ and $nRTD_{50}$) were analyzed via Pearson's correlation coefficients. Stepwise multiple regression was used to examine the amount of variance in $aRTD_{50}$ and $nRTD_{50}$ accounted for by each of the predictor variables. **RESULTS:** $aRTD_{50}$ (577.8 ± 241.0 Nm/s¹) was related to MUNE (144.1 ± 47.1 , $r = .549$, $p = .023$), $nEMG_{50}$ (137.5 ± 97.7 % M_{pp} , $r = .673$, $p = .003$), and τ_{TT} (20.34 ± 12.5 Nm, $r = .504$, $p = .039$). $nRTD_{50}$ (433.2 ± 175.4 %MVIC/s) was related to MUNE ($r = .531$, $p = .028$) and $nEMG_{50}$ ($r = .604$, $p = .010$). $nEMG_{50}$ and τ_{TT} were significant determinants ($p = .001$) that accounted for 45.3% and 15.5% of the variance in $aRTD_{50}$, respectively. $nEMG_{50}$ was the only significant predictor ($p = .01$), explaining 36.4% of the variance in $nRTD_{50}$. **CONCLUSIONS:** These pilot data support the notion that early phase RTD is primarily determined by neural factors, even in older adults. These data also suggest that possessing a higher number of viable MUs may influence early phase absolute RTD in older men.

Lower Extremity Neuromuscular Alteration During Dual Cognitive Standing Balance Tasks In Adults Diagnosed With HIV
 Leah R. Jamison¹, Jonathan Marshall¹, Ashley Richmond¹, Melanie Stephens², Martin Rosario¹. ¹Texas Woman's University, Dallas, TX. ²Texas Woman's University, Denton, TX.
 Email: lhammer@twu.edu
 (No relevant relationships reported)

Individuals diagnosed with human immunodeficiency virus (HIV) often present with impaired postural control as a consequence of proprioceptive alteration, due to secondary effects of prescription medication. **PURPOSE:** This study seeks to evaluate lower extremity neuromuscular activation during dual postural control tasks in individuals living with HIV.
METHODS: Twenty-three participants of Hispanic-latino origin diagnosed with HIV (18 male and 5 female, average age 55 ± 1.7 years) with an average CD4 count of 698.8 (22 years of HIV diagnosis) enrolled in this study. Surface electromyography (EMG) on the tibialis anterior (TA) and gastrocnemius (GA) muscles was used on the participant's dominant leg. Each task took approximately 15 seconds to finish. Each participant was instructed to quietly stand in a bi-pedal posture on a balance foam. Four single balance and dual cognitive-balance tasks (count backwards from 100 in increments of 3) were performed on the balance foam.
RESULTS: The variables of interest in this study were 1) time to peak, 2) decay and 3) duration of muscle activation for TA and GA. A repeated measure ANOVA analysis was used to compare all variables of interest. No significant difference is indicated between duration and decay of muscle activation for TA and GA across the various tasks assessed. Throughout the cognitive balance task, GA time to peak activation was slower ($P < 0.001$) during eyes closed (EC) head movements (HUD) (7.7 ± 0.7 seconds) when compared to HUD with eyes open (EO) (0.3 ± 0.2 secs) and, eyes open (EO) (0.5 ± 0.2 secs).
CONCLUSIONS: As the GA plays a major role in static balance, an increased fall risk could be resultant of this delay in time to peak onset. As such, our research recommends lower extremity electromyography and strength assessment in this population to forestall or decrease fall hazards.

Baseline Performance May Alter Feedback Effectiveness Of Single And Dual Task Landings

Thomas W. Kernozek, FACS¹, Emily Anderson¹, Stephanie Dietrich¹, Renee Dade¹, Becky Heinert², Drew Rutherford¹.
¹University of Wisconsin-La Crosse, La Crosse, WI. ²Gundersen Health System, La Crosse, WI.
 Email: kernozek.thom@uwlax.edu
 (No relevant relationships reported)

Anterior cruciate ligament (ACL) injuries are common in female athletes. Performance-based feedback (FB) may alter landing mechanics. **PURPOSE:** To provide peak vertical ground reaction force (PvGRF), loading asymmetry (LA), and frontal-plane (FP) video as post-trial landing FB to evaluate and train female collegiate athletes during single- and dual-task (ST and DT) drop landing. **METHODS:** 88 athletes performed both ST and DT (with/without jumping for a suspended ball) landings onto custom, portable force plates sampled at 2000 Hz. FP video showing knee-to-ankle (K:A) ratio, a surrogate for knee valgus, was recorded at 100 Hz. Performance trials were conducted in blocks of 3 ST and 6 DT pre-tests, 6 ST and 6 DT with post-trial visual FB (PvGRF in body weight (BW), LA, and FP video), and 3 ST and 6 DT post-tests. **RESULTS:** Quartiles were determined from PreST PvGRF to determine groups (Grp 1 < 3.45 BW; Grp 2: between 3.45-4.01 BW; Grp 3: between 4.01-4.72 BW; Grp 4 > 4.72 BW). PvGRF and K:A ratio between task (ST or DT) and over time (pre-test, post-test) were compared using a two-way repeated measures ANOVA where a group*time interaction was observed ($p < 0.05$). Follow-up tests revealed that Grp 3 and 4 improved PvGRF and K:A ratio from PreST to PostST that were maintained in PostDT (PvGRF: PreST to PostST Grp 3 = -20.6%, Grp 4 = -32.2%, PostST to PostDT Grp 3 = 5.0%, Grp 4 = 5.2%; K:A ratio: PreST to PostST Grp 3 = 4.1%, Grp 4 = 11.0%, PostST to PostDT Grp 3 = 0%, Grp 4 = 1.0%). Grp 1 and 2 demonstrated no change in K:A ratio despite the reduced PvGRF from PreST to PostST. These changes were not maintained during PostDT (PreST to PostST Grp 1 = -11.2%, Grp 2 = -18.3%, PostST to PostDT Grp 1 = 7.8%, Grp 2 = 2.3%). **CONCLUSIONS:** Collegiate athletes with PreST PvGRF > 4.01 BW may benefit more from performance-based landing FB that are maintained during DT scenarios.

3416 Board #237 May 29 2:30 PM - 4:00 PM

The Effect Of Responsive Equine Simulator Therapy Device On Biomechanics Of Sitting

Henry Wang, Brian Fox, Rachel McCormick, Crystal Hajek, D. Clark Dickin. Ball State University, Muncie, IN.
 Email: hwang2@bsu.edu
 (No relevant relationships reported)

A responsive equine simulator therapy (REST) system is a sitting device replicating motions experienced during horse riding. The mild motion introduced by the REST could promote a more active sitting experience to users. Although the REST system could potentially provide the benefits associated with active sitting, the effect of a REST system on trunk motion, trunk and leg muscle activations over that of sitting on a normal chair has yet to be examined. **Purpose:** To quantify trunk motion patterns and trunk and leg muscle activity during sitting on a REST system compared to an office chair. **Methods:** 20 healthy participants (22 ± 2 yr, 75 ± 10 kg, 1.71 ± 7.9 m) sat on the REST device and an office chair for 20 minutes in randomized order. Electromyography (EMG) sensors were placed bilaterally on the external oblique, rectus abdominis, erector spinae, adductor longus, soleus, and tibialis anterior. 3D Motion capture was conducted while participants performed the two sitting conditions. One way repeated measures ANOVA was used to determine differences in trunk motion and root mean square (RMS) EMG between the two sitting conditions. **Results:** For any given 10-sec sitting interval, the trunk center of mass traveled a greater distance during the REST condition (25.4 ± 7.9 cm) over that of the Chair condition (3.6 ± 1.5 cm) ($p < 0.001$). Also, mean angular speeds of the trunk during sitting on the REST was greater in the sagittal plane (0.20 ± 0.12 deg/s vs. 0.07 ± 0.06 deg/s) ($p < 0.001$) and in the transverse plane (0.11 ± 0.04 deg/s vs. 0.05 ± 0.09 deg/s) ($p = 0.011$) than those of the Chair condition. Furthermore, average RMS EMGs of the external oblique (6.13 ± 0.34 mv vs. 5.95 ± 0.30 mv) ($p = 0.037$), tibialis anterior (18.96 ± 0.37 mv vs. 18.73 ± 0.30 mv) ($p = 0.007$), and soleus (9.58 ± 0.65 mv vs. 8.70 ± 1.10 mv) ($p = 0.018$) were significantly higher in the REST condition than those in the Chair condition during a 10-sec interval. **Conclusion:** Using a REST device resulted in a significant increase in trunk motion. The elevated activities in trunk and leg muscles serve to maintain and control upper body posture. These biomechanical responses imply that people could assist in helping to establish an active lifestyle by using the REST device on a regular basis.

The Influence Of Apoe Genotype On Motor Cortex Function Following Mtbi

Alia L. Yasen¹, Geeta N. Eick¹, Kirstin N. Sterner¹, Anita D. Christie². ¹University of Oregon, Eugene, OR. ²Western University, London, ON, Canada. (Sponsor: Charles Rice, FACS¹)
 Email: ayasen@uoregon.edu
 (No relevant relationships reported)

Approximately 10-15% of individuals diagnosed with mild traumatic brain injury (mTBI) continue to experience symptoms beyond 3 months post-injury. Although the underlying physiology of these prolonged symptoms remains unknown, numerous factors have been suggested to contribute to recovery from mild traumatic brain injury (mTBI). Among the most extensively studied is the influence of the ApoE4 allele. **PURPOSE:** The purpose of this study was to examine the potential influence of APOE genotype on neurophysiological recovery from mTBI in individuals with chronic symptoms. **METHODS:** Twenty seven participants provided a saliva sample for APOE genotyping and were categorized into one of two groups: (i) with history of mTBI and no remaining symptoms ($n = 21$, Control), and (ii) with chronic symptoms from mTBI, lasting at least 3 months post-injury ($n = 6$, Chronic). Measures of glutamate and GABA concentrations in the primary motor cortex were obtained using proton magnetic resonance spectroscopy (¹H-MRS). Transcranial magnetic stimulation (TMS) was used to assess corticomotor excitability with the amplitude of the motor evoked potential (MEP_{amp}), and intracortical inhibition through the duration of the cortical silent period (CSP). **RESULTS:** Glutamate ($p = 0.55$) and GABA ($p = 0.73$) concentrations in M1, as well as MEP_{amp} ($p = 0.20$) and CSP duration ($p = 0.47$), did not differ between mTBI groups. There were no differences in these measures between ε4 carriers and non-carriers ($p \geq 0.50$) and no significant interactions between mTBI group and ε4 carrier status for any of the four measures ($p \geq 0.07$). **CONCLUSION:** The lack of differences in glutamate, GABA, and corticomotor excitability and inhibition across groups suggests that motor cortex function may not explain the physiology underlying differences in symptom recovery post-mTBI. While the apoε4 allele has been associated with differences in outcome following mTBI, it did not seem to affect the function of the human motor cortex in this group of participants.

Does Ipsilateral Motor Cortex Activity During Unilateral Fatigue Explain The Deficits In The Non-fatigued Limb?

Jesus A. Hernandez-Sarabia, Alejandra Barrera-Curiel, Micheal J. Lucera, Jason M. DeFreitas. Oklahoma State University, STILLWATER, OK.
 Email: jesusah@okstate.edu
 (No relevant relationships reported)

Performing unilateral contractions to exhaustion has been shown to lead to force deficits of both the exercised and unexercised limbs. Although limb muscles are controlled by the contralateral hemisphere of the brain, neuroimaging studies have also shown slight activation of the ipsilateral motor cortex during unilateral tasks. However, whether cortical activity of the ipsilateral hemisphere might, in part, be responsible for the force decrements in the non-fatigued limb remains unknown. **PURPOSE:** To quantify the relationship between changes in maximal voluntary contraction (MVC) of the non-fatigued limb, and oxyhemoglobin (HbO) changes in the ipsilateral motor cortex during a fatiguing task. **METHODS:** Eleven subjects ($M \pm SD$ 20.8 ± 1.14 yrs.) performed two maximal voluntary isometric knee extensions of the left leg before (MVC_{pre}) and after fatiguing protocol (MVC_{post}). The fatiguing protocol consisted of repeated, 50-second long isometric knee extensions with the right leg at 30% MVC until failure. During the fatigue protocol, hemodynamic responses of the motor cortex were recorded at a sampling rate of 5.81 HZ using a continuous-wave functional near infrared spectroscopy system (fNIRS). Raw fNIRS signals were processed and converted to hemoglobin concentrations using an open-source software (HomER2), and the peak HbO (HbO_{peak}) was obtained from the final contraction before failure. MVC_{pre} and MVC_{post} were used to calculate the percentage of change in maximal force from the fatiguing task (MVC_{diff}). A Pearson's correlation between HbO_{peak} and MVC_{diff} was calculated using a commercial software. **RESULTS:** Paired samples t-test showed a significant difference ($p < 0.05$) between MVC_{pre} (828.34 ± 238.8 N) and MVC_{post} (743.99 ± 227.56 N). Pearson's correlation between HbO_{peak} ($2.93 \pm 1.86E-8$) of the ipsilateral motor cortex and MVC_{diff} (-9.86 ± 12.11 %) of the unexercised leg was not statistically significant ($R = -0.368$, $p = .265$). **CONCLUSIONS:** We hypothesized that peaks in oxyhemoglobin on the ipsilateral motor cortex during a fatiguing task would explain, to some extent, the force deficits in the unexercised leg. It is worth noting that this study was underpowered for a correlation. However, it is also possible that if the contralateral force deficit is indeed due to neural factors, that it is not cortical in origin.

External Resistance Is Imperative For Training-induced Efferent Neural Drive Enhancement In Older Individuals

Tiril Tøien¹, Runar Unhjem², Ann Charlotte Gjertsen Kvellestad³, Thomas Storehaug Øren³, Eivind Wang³. ¹Molde University College, Molde, Norway. ²Nord University, Bodø, Norway. ³Norwegian University of Science and Technology, Trondheim, Norway.
 Email: tiril.toien@himolde.no
 (No relevant relationships reported)

Strength training performed with heavy loads and maximal intended velocity is documented to enhance efferent neural drive in older individuals. However, it remains unclear whether the neural plasticity following training result from motor skill learning or if external resistance is a prerequisite.

PURPOSE: To investigate the importance of external resistance on neural plasticity in older individuals.

METHODS: Electrically evoked potentials (H-reflex and V-waves normalized to maximal M-wave) and voluntary activation (VA) were assessed in 36 older individuals (73±4 years). Participants were randomized to 3 weeks of plantar flexion strength training, with (maximal strength training; MST) or without (unloaded ballistic training; UBT) heavy external loading (90% of one repetition maximum), or a control group. Both training groups aimed to execute the concentric phase of movement as fast and forcefully as possible.

RESULTS: The MST group improved maximal voluntary contraction (MVC) and rate of force development (RFD) by 18±13% (p<0.01) and 35±17% (p<0.01), respectively, and this was different (p<0.01) from the UBT group which exhibited a 7±8% (p<0.05) increase in MVC (p<0.05) and a tendency of an increase in RFD (p=0.12). Concomitant improvements in efferent neural drive, evident as a 79±80% increase in V/M-ratio (p<0.01) and a tendency towards increased VA (p=0.11), were only apparent after MST. No changes were observed in H/M-ratio for any of the groups. **CONCLUSION:** External loading following exercise training appears to be a prerequisite for efferent neural drive enhancement in older individuals, and advocates that heavy resistance training should be recommended to counteract the typically observed age-related decline in motoneuron firing frequency and recruitment.

Performance Fatigability And Neuromuscular Patterns Of Responses For Bilateral Versus Unilateral Leg Extensions In Men.

John Paul Anders¹, Joshua Keller¹, Corey Smith², Ethan Hill³, Tyler Neltner¹, Terry Housh, FACSM¹, Richard Schmidt¹, Glen Johnson, FACSM¹. ¹University of Nebraska- Lincoln, Lincoln, NE. ²University of Texas at El Paso, El Paso, TX. ³University of Central Florida, Orlando, FL. (Sponsor: Terry Housh, FACSM)
 (No relevant relationships reported)

Purpose: The purpose of the present study was to examine performance fatigability and patterns of neuromuscular responses for electromyographic (EMG) and mechanomyographic (MMG) amplitude (AMP) and mean power frequency (MPF) of the vastus lateralis (VL) during bilateral (BL) and unilateral (UL) maximal, concentric, isokinetic leg extensions. **Methods:** Eleven men (Mean ± SD; age = 22.9 ± 3.7 years; height = 177.8 ± 6.7 cm; weight = 80.4 ± 7.9 kg) performed 50 BL and UL maximal, concentric, isokinetic leg extensions at 60°·s⁻¹ on separate days. The EMG and MMG from the non-dominant VL were recorded. The EMG AMP, EMG MPF, MMG AMP, MMG MPF and isokinetic peak torque were normalized to their corresponding maximal voluntary isometric contraction values. Every five of the 50 repetitions were averaged together to produce a total of 10 repetitions throughout the fatiguing task. Five separate 2 (Condition [BL and UL]) × 10 (Repetitions [5-50]) repeated measures ANOVAs were performed to examine the normalized EMG AMP, EMG MPF, MMG AMP, MMG MPF, and isokinetic torque. **Results:** The 2 × 10 repeated measures ANOVA for normalized isokinetic torque demonstrated a significant Condition by Repetition Interaction (p < 0.001, η²_p = 0.594). Follow up 1-way ANOVAs demonstrated that for the BL and UL conditions, repetition 5 was significantly greater than repetitions 15-50. There were no interactions, but significant main effects for Repetition with an increase in EMG AMP (p < 0.001; η²_p = 0.255) and decreases in EMG MPF (p < 0.001; η²_p = 0.650), MMG AMP (p < 0.001; η²_p = 0.402), and MMG MPF (p < 0.001; η²_p = 0.796). Additionally, EMG MPF and MMG AMP demonstrated significant main effects for Condition (p = 0.031; η²_p = 0.387 and p = 0.002; η²_p = 0.64, respectively), with BL exhibiting greater values in both parameters. **Conclusion:** The findings of the present study suggested there was greater performance fatigability during UL versus BL leg extensions. Both modalities demonstrated similar patterns of neuromuscular responses, however, the BL condition exhibited a lower decline in action potential conduction velocity (EMG MPF) and lower increases in muscle

stiffness (MMG AMP) than the UL condition. These findings suggested the greater performance fatigability during UL muscle actions may be attributable to peripheral mechanisms of fatigue.

Impact Of Mental Fatigue On Force Control And Muscle Activation

Katie Kowalski, Laura Graham, Anita Christie. University of Western Ontario, London, ON, Canada. (Sponsor: Charles Rice, FACSM)
 (No relevant relationships reported)

Mental fatigue (MF) leads to performance declines in tasks requiring force control. However, the neuromuscular mechanisms leading to these declines are not well understood. **PURPOSE:** To determine the effect of MF on the ability to match a target force and identify associated changes in muscle activation in males and females. **METHODS:** Nineteen participants (10 female) performed one 10-s isometric dorsiflexion contraction at 20 and 50% maximum voluntary contraction (MVC) before and after completing 20 min of the psychomotor vigilance task (PVT). The PVT is a sustained attention reaction time (RT) task known to induce MF. Force, indwelling and surface electromyography (sEMG) of the tibialis anterior were measured prior to and immediately following the PVT. **RESULTS:** Mean values for all variables can be found in Table 1. PVT RT and subjective fatigue increased similarly in males and females over time, indicating successful induction of MF. Mean absolute force produced at 20% and 50% MVC increased in males and females from pre- to post-PVT. However, there were no significant changes in the root mean square error of force at either contraction intensity. sEMG amplitude declined after the PVT in the 20% MVC condition with a trend towards declining at 50% MVC in both males and females. This was accompanied by a slowing of motor unit discharge rate after the PVT at 20% MVC in both sexes, but only in males at 50% MVC. **CONCLUSION:** Inducing MF led to changes in mean force of submaximal isometric contractions. This was accompanied by a decline in agonist muscle activity, suggesting alterations to motor control in the presence of MF.

Table 1. Impact of PVT

	Pre-PVT		Post-PVT	
	Female	Male	Female	Male

Sex Differences In Neuromuscular Fatigue Effects On Intermuscular Control Patterns In Leg Extensors

Zhong Wang, Amelia Chen, Anthony Johnson, Lisa Griffin. The University of Texas at Austin, Austin, TX.
 Email: zhongwang2015@outlook.com
 (No relevant relationships reported)

Muscles in females tend to be less fatigable than in males. This may be because females have a higher proportion of Type I muscle fibers. It is also possible that females could employ different synergistic activation patterns during sustained

fatiguing contractions. Sex differences in intermuscular control pattern changes following fatigue have not yet been investigated. **Purpose:** To investigate differences in VMO-VL activation level changes *pre-, during and post-fatigue* between females and males. **Method:** Five healthy females and 5 healthy males performed 5 trials of step-up before and after a sustained fatiguing isometric leg extension task of 20% maximal voluntary contraction (MVC). VMO and VL EMG signals were recorded and normalized to percent maximum. **Results:** Males took longer to perform the step-up than females ($P < 0.05$), but the speeds did not change with fatigue. With sexes pooled, the activation levels of both the VMO and the VL during step-up were lowered following fatigue (*pre- vs. post-fatigue*, VMO: 21.2% vs. 16.7% EMG_{max}, VL: 28.3% vs. 21.7% EMG_{max}; both $P < 0.05$). Normalized *pre-fatigue* VL activation levels were lower in males than in females (11.6% vs. 45.0% respectively, $P < 0.05$), whereas *pre-fatigue* VMO levels were similar between the sexes (males: 13.1% vs. females: 29.4% EMG_{max}). After fatigue, there was no difference in VMO and VL activation levels between the sexes, indicating greater fatigue in the VL relative to the VMO in females (activation %_{post} - %_{pre}, female VL vs. VMO: -11% vs. -5%, $P < 0.05$). In males, the VMO and VL fatigued to a similar degree (VL vs. VMO: -2.5% vs. -3.3%). During the sustained isometric fatiguing contraction, the female VL tended to be activated to a greater degree than the VMO, whereas males activated both muscles more equally (VL/VMO activation ratio, 1.55 vs. 0.86, females vs. males, $p = 0.084$). **Conclusion:** Our results show that males and females exhibit different relative VMO-VL neuromuscular fatigue patterns. Females tend to rely more on the VL than the VMO during fatigue while males tend to use both muscles equally.

Quadriceps Function In Chronic Anterior Knee Pain With Or Without A History Of Knee Surgery
 Sungwan Kim¹, Jihong Park². ¹Bridgewater State University, Bridgewater, MA. ²Kyung Hee University, Yongin, Korea, Republic of.
 Email: jihong.park@khu.ac.kr
 (No relevant relationships reported)

It is unclear if a history of knee surgery additively affects quadriceps dysfunction in patients with chronic anterior knee pain (AKP). **PURPOSE:** To compare quadriceps function (strength, activation, and power) in chronic AKP patients with or without a history of knee surgery, to matched healthy controls. **METHODS:** Twenty-eight chronic AKP patients with (n=14; ACL reconstruction=5, meniscectomy=4, and both combined=5) or without (n=14) a history of knee surgery, and 20 matched (age, height, mass, BMI, thigh circumference, and physical activity) healthy controls participated in this cross-sectional study (average values of all three groups in the order of demographics listed above: 22 years, 173 cm, 76 kg, 25 kg/m², 57 cm, 235 min/week). Perception and duration of pain, and functional outcomes were also matched between AKP patient groups (4.1/10 cm in visual analogue scale; 41 months; 54/80 score in Lower Extremity Functional Scale). For quadriceps strength, maximal voluntary isometric contraction (MVIC) was obtained. For quadriceps activation and power, central activation ratio (CAR) and rate of torque development during MVIC assessments were calculated. Parametric or non-parametric tests (depends on normal distribution) with calculations of effect sizes [ES] determined the group differences ($p < 0.05$). **RESULTS:** As compared with the matched healthy controls, AKP patients with and without a history knee surgery showed a less quadriceps strength (3.1 vs. 2.2 [1.2] and 1.8 [2.3] N·m/kg, $p < 0.001$) and power (10.1 vs. 7.8 [1.0] and 7.2 [1.1] N·m/kg/s, $p < 0.03$). There were no differences between AKP patient groups in quadriceps strength ($p = 0.15$) and power ($p = 0.79$). A less quadriceps activation was observed in AKP patients without a surgery (0.75 in CAR), as compared with the knee surgery group (0.90 [1.7], $p = 0.002$) and healthy controls (0.96 [3.0], $p < 0.0001$). **CONCLUSION:** Both chronic AKP patient groups showed a similar amount of strength deficit that an experience of knee surgery does not appear to result in a summative effect. Central activation closed to normal (0.90 in CAR) in chronic AKP patients with a past surgical history may suggest that peripherally mediated inhibition plays a bigger role in their quadriceps weakness. Supported by the National Research Foundation of Korea (NRF-2017S1A8022854).

Muscle Activation Signal Decay
 Clint R. Frandsen, Grayson Tarbox, Logan A. Thorneloe, A Wayne Johnson, Sarah T. Ridge. Brigham Young University, Provo, UT.
 Email: clintfrf@byu.edu
 (No relevant relationships reported)

Muscle activation can be measured through a technique called muscle functional magnetic resonance imaging (mfMRI), which uses T2 signal decay in muscle tissue to

measure activation. This method allows for activation of deep muscles to be measured in a noninvasive way. However, this method requires users to account for the intensity of subjects' previous activity and allow for sufficient rest time to assure the accuracy of measurements.

Purpose: To determine a method to assess calf muscle activation from a single bout of walking.

Methods: Four participants (female=2; 20-25 y) having had minimal activity prior in the day rested their legs for over an hour to assure the calf muscle activation had completely returned to baseline prior to scanning. A pre-exercise scan of the participants right calf muscle was performed to measure baseline activation. Participants then walked barefoot on a treadmill at a brisk pace (~3.5mph) for 15 mins. Immediately after, they were scanned in the same location of the calf every 2 mins for the next 45 mins.

Results: There was an average 6.7% increase in activation ($p = 0.02$), of the four calf muscle groups being tracked, after 15 min of barefoot walking. Muscle activation signal slowly decreased for 10 mins before plateauing at around 5.7% activation above the pre-exercise levels ($p < 0.07$). This post exercise activation level remained relatively constant for over 30 mins.

Conclusion: Muscle activation from walking can be accurately measured immediately after exercise but continued measurements taken after 10 mins of scanning, post-low intensity exercise, may be affected by factors related to the MRI scanning procedure and not changes in actual muscle activation. This post exercise activation level plateau may be due to tissue heating or other factors related to prolonged scanning.

Signal Decay of Muscle Activation

Corticomotor Network Activity Does Not Contribute To The Bilateral Deficit Phenomenon
 Anne Beethe¹, Christopher Connaboy², Lee Fisher², Lovalekar Mita², Bradley Nindl, FACSM², Shawn Flanagan². ¹Utah State University, Logan, UT. ²University of Pittsburgh, Pittsburgh, PA.
 (Sponsor: Bradley Nindl, FACSM)
 (No relevant relationships reported)

The bilateral deficit (BLD) phenomenon is an inability to maximally contract bilaterally as compared to the sum of the corresponding unilateral contractions, and is expressed as an index (BI). The underlying mechanism is unknown, but altered transcallosal inhibition (TCI) and diminished voluntary activation (VA) during bilateral homologous (BH), as compared to bilateral non-homologous (BNH) and unilateral tasks, is considered the most likely mechanism. **PURPOSE:** To examine corticospinal activity during BH, BNH, and unilateral maximal contractions, and resultant changes from task practice. **METHODS:** Eleven healthy adults (6 women/5 men, 25.6±3.7years; 171.81±11.44cm; 74.4±21.2kg) participated in the counterbalanced repeated measures study. TCI and VA were assessed with transcranial magnetic stimulation for BH, BNH, and unilateral dominant flexion (DF) sessions 1 and 7. For sessions 2-6, five of each BH elbow flexion, BNH flexion/extension, and DF maximal voluntary isometric contraction (MVIC) tasks were practiced. Paired t-tests or Wilcoxon signed-rank tests, as appropriate, were used to test TCI and VA between sessions 1 and 7. Pearson or Spearman correlation coefficients, as appropriate, between VA and TCI measures and BLD and peak force measures were used to assess any association between neurological and performance variables on test days 1 and 7. **RESULTS:** There were no differences in VA or TCI between BH, BNH, and DF. BH VA decreased from day 1 (95.14±4.3%) to day 7 (92.2±4.4%, $p = 0.014$), but did not exceed the minimal detectable change (6.47). VA for BH ($r = -0.655$; $p = 0.039$) and DF ($r = -0.636$; $p = 0.035$) was associated with BH BI on day 1. When associated with peak force, day 7 BH ($r = -0.627$, $p = 0.039$) and BNH ($r = -0.682$, $p = 0.021$) TCI was correlated. **CONCLUSION:** BI was similar to prior research, but neurophysiological measures did not explain these differences. This is similar to previous equivocal research between BH and unilateral maximal force and TCI and/or VA, suggesting differences in BH and BNH BI are not solely influenced by neural drive modifications.

Of interest, TCI was highly correlated with force, revealing neurophysiological influence between tasks, but differences in bilateral and unilateral force may be influenced by outside mechanisms.

Electromyographic Activity Of Rolling Mat Pilates Exercises For Intensity Analysis

Paula Finatto¹, Rafael F. Escamilla, FACSM², Cláudia Silveira Lima¹. ¹Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil. ²California State University, Sacramento, CA. (Sponsor: Rafael Fassina Escamilla, FACSM)
Email: paula.finatto@hotmail.com
(No relevant relationships reported)

There are a discrepancy in relation to the pre-classification intensity of Pilates exercises (PE) and their real impact on muscular activation compromising training prescription. **PURPOSE:** To compare five muscles EMG activation during seven PE. **METHODS:** Surface EMG were recorded for lower (LRA) and upper rectus abdominis (URA), internal (IO) and external obliques (EO) and multifidus (MS) muscles, while seventeen women performed the Rolling Like a Ball basic (RLBbas), Rolling Like a Ball intermediate (RLBint), Rolling Like a Ball advanced (RLBadv), The Seal, Open Leg Rocker (OLR), The Hundred basic, and The Hundred advanced (HDadv) exercises. **RESULTS:** For the URA, LRA, IO and EO muscles, the exercises RLBbas (21.94% ± 7.3; 26.31% ± 9.79; 31.59% ± 11.65; 39.50% ± 13.5, respectively), RLBint (20.72% ± 11.52; 29.27% ± 9.8; 36.76% ± 16.44; 44.91% ± 15.95, respectively), RLBadv (25.20% ± 7.33; 30.89% ± 9.66; 35.35% ± 8.87; 43.88% ± 13.09), SL (24.11% ± 13.53; 33.28% ± 13.87; 35.15% ± 16.37; 37.6% ± 17.24, respectively), OLR (21.91% ± 10.78; 30.94% ± 11.39; 33.65% ± 13.87; 34.26% ± 10.26, respectively) and HDbas (53.92% ± 16.3; 47.92% ± 20.59; 36.54% ± 16.83; 46.64% ± 26.05, respectively) exercises presented significant less EMG percentage when compared to HDadv (71.69% ± 18.03; 75.69% ± 17.44; 57.86% ± 16.49; 88.71% ± 30.40, respectively). Besides, for the URA muscle significant ($p < 0.001$) more EMG percentage was found comparing the HDbas to the RLBbas, RLBint, RLBadv, SL and OLR exercises. Furthermore, for the MS muscle, significant greater EMG was found when compared the RLBbas (27.59% ± 10.95), RLBint (27.68% ± 12.9), RLBadv (32.26% ± 13.29) and SL (32.1% ± 13.81) exercises to the HDbas (7.89% ± 3.20; $p < 0.001$) and HDadv (9.89 ± 3.08; $p = 0.001$; $p < 0.001$; $p = 0.002$, respectively) exercises. **CONCLUSIONS:** The HDadv was the most effective exercise in producing muscle activity of the spinal flexors, while the other exercises could be grouped at the same moderate level of intensity for the LRA, URA, IO and EO muscles. Contrary to the current PE prescription, the RLBbas, RLBint, RLBadv and SL exercises, although indicated as spinal flexors exercises (less than 30% of maximum for spinal flexor muscles), seem to play a more significant role in the activation of MS, resulting in a moderate EMG activation. Supported by Capes and CNPq.

Comparison Of Fascicle Behaviors Between Superficial And Deeper Muscles Of Triceps Brachii During Isometric Contractions

Hiroshi Akima¹, Hisashi Maeda¹, Teruhiko Koike¹, Koji Ishida¹, Ryosuke Ando². ¹Nagoya University, Nagoya, Aichi, Japan. ²Japan Institute of Sports Sciences, Tokyo, Japan. (Sponsor: Katsumi ASANO, FACSM)
(No relevant relationships reported)

Fascicle length and pennation angles during muscle contraction are often used in biomechanical models of the muscle-tendon complex to understand the functional roles of muscles and tendinous tissues. However, previous studies have focused on the lower limb muscles, information on fascicle behavior of the upper limb muscles is missing. **PURPOSE:** Ando et al. (2016) showed different between superficial and deeper muscles of the lower extremities in humans; however, the muscles of the upper limbs have not been examined in previous studies. The purpose of this study was to assess whether the fascicle behaviors of the upper extremities are similar to those of the lower extremities during isometric contractions. **METHODS:** Thirteen healthy men and women performed isometric elbow extension tasks at 50% and 75% of maximal voluntary contraction (MVC) at 60°, 90°, and 120° of elbow extension (full extension = 180°). Extended field-of-view (EFOV) B-mode ultrasonography was used to obtain sagittal plane panoramic images of the long head (TB-Long) and medial head (TB-Med) of the triceps brachii at rest and during contraction; fascicle length and pennation angle were measured. **RESULTS:** In the TB-Long, significant fascicle shortening from rest was found during 50% (8.7 ± 0.3 to 7.6 ± 0.3 cm, $P < 0.05$) and 75%MVC (8.7 ± 0.3 to 7.5 ± 0.3 cm, $P < 0.05$) at 60° and during 75%MVC (8.2 ± 0.3 to 7.2 ± 0.2 cm, $P < 0.05$) at 90° of extension. There was no significant fascicle shortening in the TB-Med muscle under any conditions. There was no significant pennation angle change from rest in either muscle. The pennation angle of the TB-Long (e.g. rest, $12.9 \pm 0.8^\circ$ at 90°) was significantly greater than that of the TB-Med (e.g. rest, $9.3 \pm 0.5^\circ$ at 90°) under all conditions. **CONCLUSION:** These results suggest that fascicle shortening

in the TB-Long muscle occurs in flexion; however, no change was found in the TB-Med. Different MTC features between superficial and deep muscles will be developed in the upper limbs, as shown in lower limb muscles. Kinetics And Kinematics Of Isoinertial Ballistic Contractions In Older Adults

Emmet J. Mc Dermott¹, Thomas G. Balshaw¹, Katherine Brooke-Wavell¹, Thomas M. Maden-Wilkinson², Jonathan P. Folland, FACSM¹. ¹Loughborough University, Loughborough, United Kingdom. ²Sheffield Hallam University, Sheffield, United Kingdom. (Sponsor: Professor Jonathan Folland, FACSM)
Email: e.mcdermott2@lboro.ac.uk
(No relevant relationships reported)

Regular resistance training (RT) is recommended for older adults to help offset age-induced declines in neuromuscular performance (e.g. power, force and velocity). However, there is limited research comparing the kinetics (force) and kinematics (velocity and power) of different types of RT contractions, and specifically concentric only (CON-ONLY) and eccentric-concentric (ECC-CON) contractions aiming to throw the load as far as possible. **PURPOSE:** To compare the kinetics and kinematics of ballistic contractions performed as CON-ONLY (explosive concentric contraction performed from rest) vs ECC-CON (a prior controlled eccentric lowering of the load followed by an explosive concentric contraction) in an older adult population. **METHODS:** Twelve healthy active older adult males (age: 66 ± 5 yrs; height: 1.81 ± 0.1 m; body mass: 78.5 ± 11.0 kg; activity: 2175 ± 1450 MET-min-week) completed 3 sessions (1 familiarisation and 2 measurement) using an instrumented isoinertial (30°) leg press dynamometer that facilitated recording of force and displacement that were used to derive velocity and power. Participants performed a series of attempts using both types of contraction (CON-ONLY and ECC-CON: counterbalanced) with a range of loads in ascending order during each measurement session (day 1: 20, 35 and 50; day 2: 50, 65 and 80%1RM). **RESULTS:** No main effect for contraction ($p > 0.05$) was found for peak power or peak velocity across loads. A main contraction effect was found for peak force ($p = 0.012$), with post hoc analysis revealing no difference ($p > 0.05$) between contractions at any load. A main effect for contraction type was found for mean power ($p = 0.016$) and mean velocity ($p < 0.01$), with post hoc analysis revealing that mean power was higher for ECC-CON at 65% (310 vs. 430 W, $+23.0\%$, $p < 0.01$) and 80%1RM (229 vs. 337 W, 47.3% , $p < 0.01$). Mean velocity was higher in ECC-CON across all loads ($+13.7$ - 49.5% ; all $p < 0.01$). **CONCLUSIONS:** CON-ONLY and ECC-CON ballistic contractions produced similar peak neuromuscular performance in an older adult population. However, ECC-CON contractions involved greater mean power and mean velocity. In conclusion, it may be beneficial for older adults to perform ECC-CON contractions as they provide equivocal peak neuromuscular performance as CON-ONLY, but superior mean neuromuscular performance.

Reliability Of The Repeated Unilateral Partial Squat As A Neuromuscular Control Screening Activity

Hannah S. Stein, Shannon E. Linderman, Alexandra K. Lesiw, Eric M. Berkson, Donna Moxley Scarborough. Massachusetts General Hospital, Boston, MA.
Email: hstein@mgh.harvard.edu
(No relevant relationships reported)

PURPOSE: A single leg squat task is often used to assess dynamic strength, flexibility, coordination and balance of an athlete. The composite of these physical components provides insight to the clinician about an athlete's overall neuromuscular control. However, the variation in the non-weight bearing limb's position influences body alignment causing variability in movement patterns. The repeated unilateral partial squat (RUPS) activity is designed in hopes to limit this variability. The purpose of this study is to assess the within-subject kinematic repeatability of the RUPS activity. **METHODS:** A 20 Vicon MX™ T-series motion capture system (240 Hz) was used to construct a 15-segment model of 33 study consenting female adolescent athletes (mean age = 17.4 ± 3.1 y). Each stood on one leg at the edge of a 20-cm box, with opposite

limb dangling straight. The subject lowered the contralateral limb without ground contact for 5 repetitions in a row. Peak pelvis drop and lower limb joint angles at the time of peak knee flexion were calculated using Visual 3D™ biomechanics software. After a practice trial, 1 trial was performed on each limb with 3 of the 5 repetitions included in an ICC two-way mixed effects evaluation of kinematics repeatability reliability. **RESULTS:** Joint kinematics across the ankle, knee, hip, trunk and pelvis demonstrated good to excellent repeatability reliability with consistent levels of within item variability (Table 1). Peak knee, hip and trunk flexion and the position of the non-weight bearing limb demonstrated good to excellent consistency. The frontal plane measures, such as pelvis and trunk lateral flexion and hip adduction demonstrated good consistency (Table 1). **CONCLUSIONS:** Results demonstrate good to excellent repeatable kinematics during the RUPS activity especially in the sagittal plane. Findings of this repeatability study suggest that the RUPS may be a possible neuromuscular control screening tool for similar healthy athletes.

Relationship Of Mets And Muscle Engagement To Learning Of Yoga Postures

Paula R. Pullen (aka Seffens)¹, Shane Robinson¹, William S. Seffens². ¹University of North Georgia, Oakwood, GA. ²SejTec, Atlanta, GA. (Sponsor: Walter Thompson, FACSM)
 Email: prseffens@ung.edu
 (No relevant relationships reported)

PURPOSE: We are developing an exergame that provides real-time assessment of performance for yoga postures by measuring basic physiologic parameters analyzed to assess yoga skill acquisition as a means to promote healthy physical activity and wellness.
METHODS: A convenience sample of 20 adult students in a college yoga course were recorded by a Microsoft Kinect 3D digital camera attached to a PC while following instructions from a yoga instructor. Three yoga sessions scheduled as pre-test, mid-way and a post-test were captured during the regularly scheduled yoga class which met twice weekly for 75 minutes, over a 10-week period. In addition for a positive control, we recorded six yoga instructors performing the same series of five yoga postures as the “gold standard” for training using a machine learning classifier. Scoring of frames were performed by at least two yoga instructors. We examined various statistical functions derived from raw frame scores of false and true positives and negatives. The statistical measure of sensitivity showed consistent increasing trends for *Mountain*, *Forward Bend*, and *Upward Salute* postures. For *Mountain*, sensitivity went from 0.78 to 0.87, while the expert’s test clips scored 0.94. Which suggests greater training has occurred as the student postures were closer to the yoga instructor’s poses as the “gold standard”. VO₂ was measured as METS.
RESULTS: We found more difficult or strenuous yoga postures measured higher METS. Repeated Measures analysis of posture learning found significance for majority of yoga postures. We sought to determine if different yoga poses that scored easier to learn based on the linear fit slope of sensitivity correlate with muscle-skeleton complexity of that pose as estimated with total engaged muscle mass. Using literature values of estimated standard muscle masses and identity of muscle engagements in a yoga pose, we ranked yoga poses by total muscle mass engaged. From linear fit slopes, the hardest to learn are *Upward Salute* and *Side Bend* poses, while *Forward Bend* was easiest with greatest slope of learning.
CONCLUSIONS: We developed a score based on the muscle-skeleton complexity of that pose from engaged muscle masses. We find that engaged muscle mass relates to the magnitude of VO₂ and that the greater the engaged muscle mass the easier the posture is to learn.

 (No relevant relationships reported)

PURPOSE: Visual feedback of one’s balance has potential to augment balance training. However, natural visual cues of the environment already provide robust stabilization, and therefore additional visual biofeedback may have little effect on body sway. We quantified the extent to which different types of visual feedback influence sway in a novel trunk balancing task. **METHODS:** Twelve healthy young adults sat on a motorized bench that tilted up and down in direct proportion to trunk sway. This paradigm greatly increases the difficulty of the balance task and requires subjects to rely on visual and vestibular systems. In each trial, participants were provided different types visual feedback through a rotating needle-gage display on a 15 by 20 cm computer monitor located 0.85 m in front of the participant. Trials lasted 100 s, were randomly ordered, and included direct feedback (needle rotated in proportion to body sway), inverted feedback (needle rotated in the opposite direction of sway), time delayed feedback (0.5 s), random feedback RF, eyes closed, and control (eyes open with screen off). Participants were informed “visual feedback might be helpful”. **RESULTS:** Direct feedback trials had a large and significant (p<.05) impact on sway resulting in lower positional variability (root-mean-square, RMS): 62% of control trials. Despite moving in the opposite direction, inverted feedback also reduced sway to appreciable amounts of 80% RMS compared to control, but was not statistically significant. Time delayed feedback only reduced sway to 90% of control RMS. In contrast, random feedback actually significantly (p<.05) increased participants’ sway by 44%, similar to the anticipated significant (p<.05) increases in sway in the eyes closed trial (90% increase). RMS velocity was less impacted by visual feedback with only eyes closed trials associated with significant changes. **CONCLUSION:** Real-time position-based visual feedback had a powerful effect on balance, reducing body sway, while random feedback increased sway. Interestingly, even when participants were trying to ignore the random feedback, it still increased body sway. Results suggest that carefully selected real-time visual feedback could be useful in augmenting balance training during challenging balance tasks. Funding: NSF DARE 1803714

 (No relevant relationships reported)

Golfers represent a unique situation in terms of postural control, in that during a normal round of golf, players are on their feet for close to four hours. Several golf specific footwear are available. However, little is known about how these types of golf footwear affect neuromuscular control of the lower extremities over prolonged periods of standing and walking. **PURPOSE:** To examine the effects of duration of walking/standing while barefoot (BF) and wearing a dress shoe (DS), tennis shoe (TS), and minimalist (MIN) style golf shoe, on muscle activity of the lower extremity during standing postural control. **METHODS:** Six male adults completed this study. Standing balance was recorded under six different conditions: eyes open (EO), eyes closed (EC), eyes open sway referenced vision (EOSRV), eyes open sway referenced platform (EOSRP), eyes closed sway referenced platform (ECSR), and eyes open sway referenced vision and platform (EOSRVP). Surface electromyography (EMG) was recorded during balance testing from the left leg vastus medialis (Q), and semitendinosus (H). Raw EMG data were collected at 1,500 Hz, Band-pass filtered (20-250Hz) and rectified prior to analysis. Variables of interest were the mean muscle activity (mV) of each muscle. The testing sessions consisted of a counterbalanced allocation of footwear over 4 separate testing days, separated by at least 48 hours. Each session included muscle activity measures during standing balance every 60 minutes, for 4 hours (pre, 60, 120, 180, 240 minutes). A 4x5 repeated measures ANOVA was used, with an alpha level of 0.05. **RESULTS:** A significant interaction was observed in the EOSRV condition for Q (F(12,60) = 1.945, p = 0.05), suggesting that at 60 minutes, the MIN condition was significantly higher than BF and TS (5.60 > 2.45 & 3.515). Further, a significant interaction was observed in the EOSRP condition for

H ($F(12,60) = 2.057, p = 0.03$). This interaction suggests that at 180 minutes, the DS was significantly higher than the MIN ($3.980 > 1.812$). **CONCLUSION:** The current results suggest that standing postural control measures are altered by footwear differences. Over time it appears that some footwear may cause balance strategy changes possibly due to increased workload on the lower extremity.

3434 Board #255 May 29 2:30 PM - 4:00 PM
Correlation Between Pelvic Tilt Angle, Hip Range Of Motion And Hip Muscles Torque Ratios
 Maria C. Herrera, Tal Amasay, Claire Egret, Kathryn Ludwig,
 Barry University, Miami, FL.
 Email: mcrisher89@gmail.com
 (No relevant relationships reported)

Anterior pelvic tilt is associated with excessive foot pronation, excessive hip internal rotation (HIR), and knee valgus, which may lead to hip muscles strains, sciatic nerve compressions, and sacroiliac and lumbosacral joint instability. Posterior pelvic tilt is associated with feet supination and increased hip external rotation (HER), which may lead to tibial stress fractures, medial tibial stress syndrome, knee pain, anterior cruciate ligament injury, and low back pain. Hip adductors/abductors (add/abd) torque ratio (TR) below 80%, was associated with adductor strains. The average hip flexors/extensors (flex/ext) TR in sport performance was found to be 70%. There is a lack of evidence that correlates pelvic tilt angle with limited HIR, HER, add/abd TR, and flex/ext TR. **PURPOSE:** to examine the correlation between natural pelvic tilt angle and HIR, HER, add/abd TR, and flex/ext TR. **METHODS:** Twenty-six subjects participated in this study, fifteen females (22.0 ± 2.8 years old, 163.5 ± 7.5 cm, 65.9 ± 10.4 kg) and eleven males (22.0 ± 2.2 years old, 178.5 ± 4.5 cm, 78.4 ± 8.7 kg). Using a 3D motion analysis system, the measurement of both natural pelvic tilt (NPT) in standing natural position and HIR and HER in lunge position, for the right and left limbs, were recorded. Hip torques were collected with an isokinetic dynamometer, five trials at 30 deg/s and at 60 deg/s. **RESULTS:** The mean value for NPT was 5.7 ± 5.4 deg. There were no significant correlations between NPT and the dependent variables for the right limb: HIR ($r = -0.16, p = 0.43$), HER ($r = -0.11, p = 0.58$), add/abd TR at 30 deg/s ($r = -0.19, p = 0.34$), add/abd TR at 60 deg/s ($r = -0.13, p = 0.51$), flex/ext TR at 30 deg/s ($r = 0.32, p = 0.10$) and flex/ext TR at 60 deg/s ($r = -0.70, p = 0.70$). Similar results were observed for the left limb: HIR ($r = -0.20, p = 0.89$), HER ($r = -0.25, p = 0.21$), add/abd TR at 30 deg/s ($r = -0.17, p = 0.38$), add/abd TR at 60 deg/s ($r = -0.12, p = 0.55$), flex/ext TR at 30 deg/s ($r = 0.60, p = 0.75$) and flex/ext TR at 60 deg/s ($r = -0.19, p = 0.33$). **CONCLUSION:** the measurement of NPT angle in standing natural position is not a good predictor of HIR, HER, add/abd TR, and flex/ext TR. Future research should look at these relations during functional dynamic movements and during pelvic tilt end range of motion.

Effects Of Hip Range Of Motion On Balance With Presence Or Absence Of A Warm-up
 Benton McCann, Stephanie Reed, Brett George, Chris Todden.
 Baker University, Baldwin City, KS. (Sponsor: Justin Kraft, FACSMM)
 Email: bentongmccann@stu.bakeru.edu
 (No relevant relationships reported)

Baseline balance assessments are commonplace in the athletic training field. They are used in comparison with re-evaluations to determine if an injury has occurred. **PURPOSE:** The specific aim of this study was to evaluate in what manner a warm-up effected hip range of motion (ROM) and balance testing in a collegiate population. The significance of this study is to reduce the inconsistencies surrounding baseline balance assessments. Currently there is limited research looking into how hip ROM directly impacts balance. **METHODS:** Data was collected from a total of 16 participants. Participants completed two testing periods under the condition of a biking protocol or a waiting protocol. The biking protocol required participants to cycle on an ergometric bike for 20 minutes at 3-5 METs, while the waiting protocol required no movement for 20 minutes. Immediately following each protocol, a manual goniometer was used to collect ROM values for hip flexion, extension, abduction, and internal and external rotation. The two balance assessments were then completed. Test one consisted of the Balance Error Scoring System (BESS) with the second test utilizing a baseline balance test with the use of force plate technology. Hip ROM values and balance scores were compared between the two conditions. **RESULTS:** A Shapiro test was used to ensure the sample points were approximately normally distributed for the differences between the matched pairs. The flexion values for the left (p -value $< .008$) and right (p -value $< .01$) hip joints were found to be significant. All other hip ROM values demonstrated no significance. Significance was found for total errors of the BESS (p -value $< .01$). No significance was recorded for the force plate balance test. **CONCLUSION:** These results demonstrate the presence of a warm-up increased hip flexion range of motion in both hip joints and also impacted BESS balance scores. In conclusion, this suggests the addition of a warm-up to baseline balance assessment. A larger sample size is needed to further validate these findings.

Stroboscopic Vision-induced Sensory Re-weighting During Dynamic Postural Control
 Sean B. Cooley, Seunguk Han, J. Ty Hopkins, FACSMM,
 Hyunwook Lee. BYU, Provo, UT. (Sponsor: Dr. Ty Hopkins, FACSMM)
 Email: seancooley.hhm@gmail.com
 (No relevant relationships reported)

Three main sensory systems (somatosensory, visual, and vestibular) contribute to human postural control. These three sensory systems can compensate for each other if one of them lose their orientation information. Adjusting sensory input is referred to as sensory re-weighting. However, due to experimental limits, little is known how disrupted vision affects sensory re-weighting during dynamic postural control. **PURPOSE:** Therefore, this study examined the effect of impaired visual sensory input on dynamic postural control through the use of stroboscopic glasses. **METHODS:** Subjects were 24 physically active adults (male: 12, female: 12, height: 172.1 ± 7.8 cm, weight: 67.5 ± 10.4 kg) recruited from a university population, aged 18-35 years. Each subject performed the star excursion balance test (SEBT), which includes 3 trials comprised of 3 directions (anterior, posteromedial: PM, and posterolateral: PL) on each visual condition (eyes open: EO, Low Strobe frequency Vision: LSV, High Strobe frequency Vision: HSV) Each trial and visual condition was run on both firm and foam surface. Reach distance was analyzed by 2 (surface conditions) \times 3 (vision conditions) ANOVAs. **RESULTS:** In surface condition main effects, subjects performed significantly ($p < .05$) shorter reach distances (anterior, PM, and PL). In vision condition main effects, subjects with EO performed significantly lower reach distances in the PM direction than HSV and LSV ($p < .05$, both), and subjects demonstrated shorter reach distance with EO than with LSV in PL direction ($p < .05$). Only with HSV, subjects performed shorter reach distance on the foam surface than the firm surface ($p < .05$). **CONCLUSIONS:** People with impaired visual sensory (strobe vision) input and/or unstable surface tend to have decreased dynamic postural control when tasked to move in a medial and lateral direction. People also demonstrated higher reliance on visual information when the somatosensory function is disturbed. The stroboscopic glasses may be used to identify the reliance of visual information in people who have an altered or reduced somatosensory system.

Effect Of Postural Control And Exertion On Dynamic Visual Acuity In Collegiate Athletes.
 Katelyn M. Mitchell¹, Michael E. Cinelli¹, Kristine Dalton².
¹Wilfrid Laurier University, Waterloo, ON, Canada. ²University of Waterloo, Waterloo, ON, Canada.
 (No relevant relationships reported)

Dynamic visual acuity (DVA) requires visuo-perceptual processing to resolve the critical details of a target in motion. Athletes demonstrate superior DVA performance compared to non-athletes in a seated position. **PURPOSE:** To investigate the effects of different postures and exertion levels on DVA in athletes. **METHODS:** Varsity rugby players ($n = 10$; female = 6; age = 20.4 yrs ± 1.4) without recent concussion (> 2 years) and/or vestibular-ocular abnormalities were included. DVA was assessed using a custom program (moV&V&MP, University of Waterloo, Ontario) displayed on a 55" LCD monitor at a viewing distance of 4m. The program presented a randomly (RW) or horizontally (H) moving letter 'E' target facing left/right/up/down. Participants had to correctly identify the orientation of the target with a keypad as it progressively reduced in size. DVA was scored as the log of the minimum angle of resolution (LogMAR), of the smallest target correctly identified (i.e., low score = better DVA). Participants completed one RW and H trial at a speed of 2.31m/s (30° /s) during four conditions: seated; standing; and treadmill walking at low (85-100 beats per minute [bpm]) and moderate (115-130bpm) intensities. **RESULTS:** The difference in LogMAR scores from the seated condition were calculated for each of the other conditions. There were no interaction effects of target motion and posture ($F = 1.02, p = .382$), and no main effect of target motion ($F = 0.30, p = .598$). However, there was a trending main effect of posture (Stand: 0.00 vs. Walk Low: -0.14 vs. Walk Mod: 0.04 $p = .056, f = 0.25$). These findings indicate that athletes' DVA improved from seated during moderate intensity treadmill walking more so than both standing and low-intensity treadmill walking. **CONCLUSION:** Athletes appear to have improved DVA in sport-specific conditions of greater postural and exertional demands. Therefore, sport training experience may enhance visuo-perceptual skills. These findings may inform clinicians to consider the assessment of DVA with progressive, dynamic contexts for rehabilitation, such as for return to sport from concussion.

Comparison Of Balance Between Middle-aged Adult Olympic Weightlifters And Runners

Bryan L. Riemann, Mara A. Mercardo, Kayleigh R. Erickson, Gregory J. Grosicki. *Georgia Southern University-Armstrong Campus, Savannah, GA.*
 Email: briemann@georgiasouthern.edu
 (No relevant relationships reported)

Beginning at about middle-age (e.g., 40 to 50yrs), notable declines in strength, balance and functional performance begin to occur; however, participation in physical activity has been demonstrated to slow down the progression of these age-related declines. Middle-age runners (RUN) are demonstrated to exhibit superior balance compared to healthy age-matched counterparts. Whether similar balance benefits occur in middle-age Olympic weightlifters (OWL) has not been studied. **PURPOSE:** To compare balance performance between middle-age adults regularly participating in either OWL or RUN. **METHODS:** A total of 48 National Masters Olympic Weightlifting competitors (22 females, 47.3±8.5yrs) and 42 (17 females, 47.7±8.5yrs) distance RUN who were training at least 30km/week participated in two 30s balance testing trials on firm (FI) and foam (FO) surfaces with eyes open (EO) and eyes closed (EC). Medial-lateral center of pressure velocities (MLCPV) were averaged across trials for each condition and natural logarithm transformed to reduce positive skewness. Bivariate coefficients (separate by group) between age, height, mass, years of experience, and body mass index (BMI) with MLCPV were performed followed by a three factor (exercise group x gender x condition) repeated measures analysis of variance. **RESULTS:** No significant ($P>0.08$) relationships for the OWL between MLCPV and age, height, mass, BMI and experience ($r = -.230$ to $.211$) were revealed. For the RUN, age was significantly related ($P=0.043$) to MLCPV across all four conditions ($r = .313$ to $.360$). While there were no significant differences between the groups for either EO-FI ($P=0.143$, $d = .34$) or EO-FO ($P=0.209$, $d = .26$), the OWL demonstrated significantly better balance (lower MLCPV) than the RUN for both EC-FI ($P=0.009$, $d = .59$) and EC-FO ($P=0.001$, $d = .70$). There were no significant differences related to gender ($P>0.05$). **CONCLUSIONS:** The most salient result was the identification of better balance performance by the OWL, particularly when visual inputs were unavailable, compared to the RUN. As Olympic weightlifting involves high-velocity whole-body movements, the OWL may develop an enhanced ability to utilize vestibular and somatosensory inputs to compensate for the absence of visual information.

3439 Board #260 May 29 2:30 PM - 4:00 PM
Classification Of Lower Limb Frontal Plane Excursion During Single-legged Landing Using Principal Component Analysis Of Inertia Sensor Data

Issei Ogasawara¹, Yohei Shimokochi², Susumu Iwasaki³, Ken Nakata¹. ¹Osaka University, Toyonaka, Japan. ²Osaka University of Health and Sport Sciences, Sennan, Japan. ³Fort Lewis College, Durango, CO.
 Email: ogasawaraissei@hss.osaka-u.ac.jp
 (No relevant relationships reported)

PURPOSE: This study aimed to evaluate the temporal pattern of the frontal-plane lower limb translation during single-legged landing using the principal component analysis (PCA) of the inertial sensor data. **METHODS:** Eighteen legs from nine healthy women were tested. Participants performed a total of six single-legged landings for each leg. The wearable inertial sensor was fixed at the participant's tibial tuberosity. The x-axis of the inertia sensor was aligned to the transverse axis of the shank segment, and the mediolateral acceleration of the proximal end of the shank segment was measured at 200Hz. The time window of interest was 0 to 75 ms after foot contact (15 data points). The acceleration data matrix (108 trials * 15 data point) from all trials of all participants was constructed for PCA. Eigenvalues and eigenvectors of the covariance matrix of the acceleration data matrix were calculated to identify the principal components (PC). **RESULTS:** The first two PCs explained more than 90% of total data variation (1st PC 69.7%, and 2nd PC 21.7%). The 1st PC represented the medially directed abrupt acceleration of the proximal shank, and the 2nd PC showed the slow but oscillated knee motion. The athlete of the highest PC score of the 1st PC showed a rapid medial knee motion just after foot impact, whereas the lowest one showed a stable knee motion after landing. **CONCLUSIONS:** PCA using acceleration signals successfully classified the degree of the medial knee translation after single-legged landing and screened the athletes who had a rapid medial knee translation. The abrupt increase of the medial knee translation has reported being a risk of non-contact anterior cruciate ligament (ACL) injury; therefore, the PCA based evaluation would be a useful technology for risk prediction of the non-contact ACL injury.

3440 Board #261 May 29 2:30 PM - 4:00 PM
Gathering Your 'Sea Legs': Changes In Postural Control Following Extended Duration In An Offshore Environment

Nicole K. Rendos¹, Clark F. Bailey¹, Samuel J. Wilson², Harish Chander³, Jeffrey D. Simpson¹. ¹University of West Florida, Pensacola, FL. ²Georgia Southern University, Statesboro, GA. ³Mississippi State University, Mississippi State, MS.
 (No relevant relationships reported)

Mal de débarquement (MdD) is the subjective perception of self-motion experienced after prolonged episodes of passive motion (PM) such as a boat ride (e.g. sea legs). Transient MdD (< 48 hours) occurs frequently and is described as a rocking, bobbing, or swaying sensation accompanied by unsteadiness and disequilibrium after cessation of the PM stimulus, and is suggested to impact postural control. **PURPOSE:** To examine changes in postural control after prolonged exposure to boat movement at sea. **METHODS:** Postural control of 24 adults (13 M, 11 F; age = 35 ± 12 y; height = 170.3 ± 8.8 cm; mass = 84.2 ± 17.0 kg) was assessed in bilateral stance on a force platform with eyes open (EO), eyes closed (EC), foam surface eyes open (FEO), and foam surface eyes closed (FEC) before (PRE) and after (POST) a 7-hour deep sea fishing excursion. Postural control measurements including average sway (cm), sway range (cm), sway velocity (cm/s), and maximum sway velocity (cm/s) were analyzed in the medial/lateral (ML) and anterior/posterior (AP) directions. Time-to-boundary (TTB) measures of postural control (minimum, average, SD of minima) were computed. All variables were compared PRE/POST using a paired *t*-test and Cohen's *d* effect sizes were calculated. **RESULTS:** Greater ML sway excursion was observed POST in EC ($t = 2.37$, $p = .013$, $d = 0.66$, PRE = 0.13 ± 0.04, POST = 0.18 ± 0.10), FEO ($t = 2.95$, $p = .004$, $d = 0.46$, PRE = 0.40 ± 0.14, POST = 0.47 ± 0.17), and FEC ($t = 2.03$, $p = .027$, $d = 0.42$, PRE = 0.50 ± 0.12, POST = 0.55 ± 0.15). Greater AP sway excursion was observed POST in FEO ($t = 1.77$, $p = 0.045$, $d = 0.38$, PRE = 0.63 ± 0.17, POST = 0.72 ± 0.30) and FEC ($t = 2.18$, $p = 0.02$, $d = 0.48$, PRE = 0.87 ± 0.21, POST = 0.98 ± 0.24). ML sway range ($t = 3.34$, $p = .001$, $d = 0.54$, PRE = 2.42 ± 0.66, POST = 2.87 ± 0.99) and AP sway range ($t = 2.18$, $p = 0.020$, $d = 0.53$, PRE = 4.01 ± 0.80, POST = 4.64 ± 1.56) increased POST in FEO. Maximum AP sway velocity increased POST in EO ($t = 1.73$, $p = 0.049$, $d = 0.45$, PRE = 4.20 ± 1.26 cm/s, POST = 5.14 ± 2.93 cm/s). Analysis of TTB measures did not reveal PRE/POST differences among any condition. **CONCLUSION:** Extended durations on a boat at sea increase postural sway upon returning to land. These findings suggest that 'sea legs' impairs the ability to re-weight appropriate sensory information in conditions dependent on somatosensory and vestibular feedback.

3441 Board #262 May 29 2:30 PM - 4:00 PM
Reactive Balance Differences Between Collegiate Sports

Benjamin Cassidy, Amanda Morris, Ryan Pelo, Nora F. Fino, Craig Chelette, Jonathan Burke, Vitor G. Carioca, Angela P. Presson, Leland E. Dibble, Peter C. Fino. *University of Utah, Salt Lake City, UT.*
 Email: b.cassidy@utah.edu
 (No relevant relationships reported)

Static and dynamic postural stability have been characterized in athletes and shown to differ across sports. However, these tests of stability may not specifically capture the

balance required for reactive athletic movements. The Push-and-Release (P&R) test is a standardized clinical tool used to assess reactive postural control in balance-impaired populations.

PURPOSE: To examine differences between sport team and task (single [ST] and dual task [DT]) in reactive postural response measures.

METHODS: 40 healthy, male athletes (age 18.50 ± 0.75 ; body mass index [BMI] 24.11 ± 2.38) were recruited from 3 collegiate teams: baseball ($n=12$), lacrosse ($n=17$), and swimming ($n=11$). Reactive postural responses were assessed using the P&R in backward and forward directions under ST and DT (concurrent verbal cognitive task) conditions. All conditions were performed with eyes closed. Inertial sensors on the sternum, lumbar, feet, and right tibia were used to assess step latency (L), time of first heel contact (HC), and time to stabilization (TTS). A sensor on the tester's hand was used to determine release time. To assess if postural response measures differ by sport and task, linear mixed effects models with random intercepts and stratified by direction (forward or backward), were used and adjusted for age and BMI.

RESULTS: Lacrosse players had faster L compared to baseball players in the forward direction ($p=0.018$). No other differences by sport were observed. In the forward direction, DT outcomes were slower than ST outcomes (L: $p<0.0001$; HC: $p=0.0004$; TTS: $p=0.0064$). In the backward direction, L was slower in the DT condition ($p=0.0034$), but no task differences were found for HC or TTS ($p=0.0628$ and $p=0.8733$, respectively).

CONCLUSION: In the forward direction only, DT slowed all postural responses. While L differed between lacrosse and baseball in the forward direction, no other differences were found across sports. As most outcomes were unaffected by sport, the P&R may be a clinically relevant assessment in athletics. However, due to the limited sample size, caution should be applied when interpreting these findings and future studies are needed.

Supported by PAC 12 Student Athlete Health & Wellbeing (PI: Fino, Dibble) and University of Utah Study Design and Biostatistics Center through NCATS Grant 8UL1TR000105.

Reactive Postural Responses In Collegiate Athletes

Amanda Morris, Benjamin Cassidy, Ryan Pelo, Nora F. Fino, Nick E. Monson, Daniel M. Cushman, Angela P. Presson, Leland E. Dibble, Peter C. Fino. *University of Utah, Salt Lake City, UT.*
 (No relevant relationships reported)

Athletes frequently need to recover balance after an external disturbance during tasks with high cognitive demand. Mobility impaired populations demonstrate deficits in reactive postural responses to backward and lateral perturbations but, little is known about postural responses in college athletes.

PURPOSE: To examine differences in direction and task (single [ST] and dual task [DT]) in reactive postural response measures during the push-and-release (P&R) test.

METHODS: Reactive postural responses in 98 healthy ($F=42$, age 19.3 ± 1.60 years, BMI 23.56 ± 3.29 kg/m²) college athletes were assessed using the P&R in four directions (forward, backward, right, left), with eyes closed, under ST and DT (concurrent verbal cognitive task) conditions. Inertial sensors on the sternum, lumbar, right tibia, and feet were used to assess step initiation latency, time of first heel contact (HC), and time to stabilization (TTS). A sensor on the tester's hand determined release time. Linear mixed models with random intercepts were used to determine if postural response measures differed by direction and task.

RESULTS: There was a significant interaction between direction and task for HC ($p=0.04$), with the largest difference in DT and ST in the forward direction ($95\%CI = [0.05, 0.08]$), and the smallest difference in the backward direction ($95\%CI = [0.02, 0.05]$). There were also significant main effects for direction ($p<0.0001$) and task ($p<0.0001$) for each postural response (latency, HC, TTS). Means adjusted for age, sex, and BMI are presented below.

	Latency (s)	Time to Stabilization (s)	Heel Contact (s)
Direction			
Backward	0.13 (0.12 - 0.14)	1.19 (1.14 - 1.24)	-
Left	0.18 (0.17 - 0.19)	1.02 (0.97 - 1.08)	-
Right	0.17 (0.17 - 0.18)	1.03 (0.98 - 1.09)	-
Forward	0.20 (0.19 - 0.21)	1.06 (1.01 - 1.11)	-
Task			
Dual	0.20 (0.19 - 0.20)	1.15 (1.11 - 1.20)	-
Single	0.15 (0.14 - 0.15)	1.00 (0.96 - 1.04)	-
Direction x Task			
Backward, Dual	-	-	0.47 (0.45 - 0.48)
Backward, Single	-	-	0.43 (0.42 - 0.45)
Left, Dual	-	-	0.52 (0.51 - 0.53)
Left, Single	-	-	0.47 (0.45 - 0.48)
Right, Dual	-	-	0.53 (0.51 - 0.54)
Right, Single	-	-	0.46 (0.45 - 0.48)
Forward, Dual	-	-	0.57 (0.55 - 0.58)
Forward, Single	-	-	0.50 (0.49 - 0.51)

CONCLUSION: Postural responses differ by direction during the P&R in college athletes. The largest differences were between the forward and backward directions. These directions may be most sensitive to detecting changes in reactive postural control; future work will examine the utility of the P&R for return-to-play decisions. Supported by PAC 12 (PI: Fino, Dibble); University of Utah Study Design and Biostatistics Center (UL1TR002538)

 (No relevant relationships reported)

Postural control in golf represents an unusual challenge as players are on their feet four hours or more. Several golf specific footwear are available, though, little is known about how these footwear affect human balance. **PURPOSE:** To examine the effects of durations of walking/standing while barefoot (BF) and wearing a dress shoe (DS), tennis shoe (TS), and minimalist (MIN) style golf shoe, on muscle activity of the lower extremity during balance. **METHODS:** Six male adults completed this study. Balance was recorded under six conditions: eyes open (EO), eyes closed (EC), eyes open sway referenced vision (EOSRV), eyes open sway referenced platform (EOSRP), eyes closed sway referenced platform (ECSR), and eyes open sway referenced vision and platform (EOSRVP). Surface electromyography (EMG) was recorded during balance testing from the left leg tibialis anterior (DF), and medial gastrocnemius (PF). Raw EMG data were collected at 1,500 Hz, Band-pass filtered (20-250Hz) and rectified. Variables of interest were the mean muscle activity (mV) of each muscle. Testing sessions consisted of a counterbalanced allocation of footwear over 4 separate days, separated by at least 48 hours. Each session included muscle activity measures during balance every 60 minutes, for 4 hours (pre, 60, 120, 180, 240 minutes). A 4x5 repeated measures ANOVA was used, with an alpha level of 0.05. **RESULTS:** A significant interaction was observed in the EO condition for PF muscle activity ($F(12,60) = 1.94$, $p = 0.04$). With the MIN muscle activity significantly lower than TS, and DS at 2 hours ($4.16 < 6.86 & 6.58$). An interaction was also observed in the EOSRV condition for the PF ($F(12,60) = 1.97$, $p = 0.048$), suggesting that at 4 hours, the DS was significantly higher than the MIN ($9.96 > 5.83$). A footwear effect was observed for the EC condition

(F(3,12) = 3.96, $p = 0.035$). With the MIN condition significantly higher than the DS (3.06 > 1.77). A time effect was observed in the EOSRV condition for the DF (F(4,16) = 3.86, $p = 0.022$), with muscle activity at 60 minutes, significantly lower than 120 and 180 (1.86 < 2.56 & 2.30) **CONCLUSION:** These results indicate a possible shift in balance strategy, particularly when visual information is removed. Certain golf specific footwear may increase the workload on the ankle musculature and cause a shift to a more hip/knee balance strategy.

 Functional movement assessments are used to predict injury in multiple populations, but the components that most contribute to functional movement are unknown. Identifying the influence of static balance via the Balance Error Scoring System (BESS) and dynamic balance via the Y-Balance Test (YBT), can provide valuable information to clinicians. This knowledge can be used to help individuals improve functional movement screening (FMS) scores which, in turn, can reduce injury risk. **PURPOSE:** To examine the contributions of static and dynamic balance on functional movement. **METHODS:** Participants from the general population ($N = 77$; men = 31; women = 46; average age = 42 ± 16 years) completed the FMS, YBT, and BESS during one laboratory visit. **RESULTS:** Together, YBT and BESS were significant predictors of FMS scores ($p < .001$, $R^2 = .54$). Individually, both YBT ($p < .001$, $R^2 = .498$) and BESS ($p < .001$, $R^2 = .321$) were significant predictors of FMS scores. When controlling for age ($p < .001$, R^2 Change = .364) and history of lower body surgery ($p < .001$, R^2 Change = .532), the YBT and BESS were still significant predictors of the FMS. Risk of injury according to YBT risk and FMS risk were not associated, $\chi^2(1, N = 77) = 1.20, p = .273$, $Cramer's V = .125$. There was a significant association between BESS risk and FMS risk, $\chi^2(1, N = 77) = 9.29, p = .01$, $Cramer's V = .347$. **CONCLUSION:** Static and dynamic balance both contribute to functional movement. This information can be used when developing training and rehabilitation protocols to reduce injury risk as measured by FMS.

The Impact Of Balance With Visual Feedback On Tibialis Anterior/gastrocnemius Neuromuscular Activity In Healthy Young Adults.
 Daniel heistand, Abigail Versemann, Martin G. Rosario. *Texas Woman's University, Dallas, TX.*
 Email: mrosario1@twu.edu
 (No relevant relationships reported)

Balance is a functional activity that must be worked on in rehabilitation of every type of back and lower extremity pathology or trauma. With these types of issues, balance generally will become impaired, requiring activities to increase the patient's stability. **PURPOSE:** To identify the impact of balance activities with visual cues on lower extremity muscle activation timing. **METHODS:** This study assessed muscle activation and postural strategies during different visual feedback activities on a balance board with a fix middle fulcrum. Fifteen young, healthy adults were recruited and performed seven tasks on two different levels of difficulty. The various visual activities were projected to a wall, 10 feet away from the balance board. Participants had to follow a target by moving the balance board in 7 pre-set different tasks. Participants had surface electromyography on tibialis and gastrocnemius muscles. Gastrocnemius and tibialis anterior muscle activation were recorded with EMGworks software for each trial. In the analysis of the electromyography data, the following variables were measured: time to peak muscle activation, time to decay of muscle contraction, and time of muscle contraction duration. A repeated measure ANOVA was used for all the variables of interest. **RESULTS:** High and lower fulcrum balance boards appear to provoke similar muscle activation among all variables ($P > 0.05$). TA muscle compensates differently on the rear twist (RT), front twist (FT), and counter clock (CC) balance maneuvers compared to the other four tasks. TA showed a faster Timed to peak [seconds] (RT 0.007+/-0.001, FT 0.007+/-, CC 0.009.005 +/- .004; $P < 0.001$), rapid decay [seconds] (TT .008+/-0.005, FT 0.10+/-0.1, CC 0.009+/-0.005; $P < 0.001$), and shorter time of duration [seconds] (RT 0.2+/-0.001, FT 0.2+/-0.1, CC 0.02+/- 0.005; $P < 0.001$) of muscle activation.

CONCLUSIONS: Balance with visual feedback can provoke a different muscle activation pattern in lower extremities muscles, such as tibialis anterior. For patients with balance alteration related to nerve conduction or muscle weakness on the lower extremity, we recommend activities were muscle activation is a challenge due to the surface but also due to visual feedback/cortex interplay.

The Effect Of Renewal Massage And Modified Squat Exercise On Body Alignment In Genu Varum Patients
 Hee-Bok Song, Han-Joon Lee, Sung-Jin Hong, Kyun-Sang Yoon, Myung-Il Seo. *University of Ulsan, Ulsan, Korea, Republic of.* (Sponsor: Minsoo Kang, FACSM)
 (No relevant relationships reported)

PURPOSE: This study evaluates the effect on body alignment three weeks after massage and squat exercise in patients with genu varum. **METHODS:** Twenty-one participants with genu varum have participated in the study and randomly assigned into 3 groups: renewal massage group ($n=7$), modified squat exercising group ($n=8$), and controlled group ($n=6$). A renewal massage is a full body massage that begins with the central part of the body and proceeds with the whole body. Renewal massage and modified squats exercising were carried out for three weeks, five times a week, and 40 minutes per week. Dependent variables were C-spine angle, T-spine angle, L-spine angle, sacral inclination angle, femoral-tibial angle of both right and left. Descriptive analyses including mean and standard deviation were computed for all variables using SPSS/PC ver 18.0, and the group mean difference was analyzed as ANCOVA with the pre-test values as covariates. The post-hoc test was performed with the least significant difference (LSD). The significance level set at .05. **RESULTS:** The ANCOVA result indicated that after controlling for differences in pre-test values, there was a significant difference in the sacral inclination angle (F[2,17] = 3.590, $p < .05$). The post-hoc test result showed that the renewal massage group (19.86 ± 3.18) has lower mean than control group (34.63 ± 4.07). No statistical significance difference was found on C-spine angle, T-spine angle, L-spine angle, femoral-tibial angle of both right and left. **CONCLUSIONS:** The three-weeks renewal massage seems to have differed only in the sacral inclination angle. Further studies are warranted to examine the effect of dose-response relationship (i.e., changing the duration and frequency) for the renewal massage.

Fronto-parietal Network Hyperconnectivity As A Result Of Head Impacts In College Ice Hockey
 Melissa S. DiFabio¹, Daniel R. Smith¹, Katherine M. Breedlove², Thomas A. Buckley¹, Curtis L. Johnson¹. ¹University of Delaware, Newark, DE. ²Center for Clinical Spectroscopy, Brigham and Women's Hospital, Boston, MA.
 Email: mdifabio@udel.edu
 (No relevant relationships reported)

Impairment in executive functioning has been reported as a result of sustaining repetitive, sports-related head impacts (RHI) after just one season of play. Brain networks associated with executive functioning may be damaged by RHI, which can be assessed through resting-state functional connectivity (rs-FC) with fMRI, which has previously shown connectivity to be affected by RHI. **PURPOSE:** To examine rs-FC related to the fronto-parietal network (FPN) over the course of an ice hockey season. **METHODS:** Twenty-three collegiate club ice hockey players (19M/4F) were divided into two groups: Impact (men's forwards/defensemen, $n=17$) and No Impact (goalenders and women, $n=6$). Players were scanned on a Siemens Prisma 3T scanner prior to the first game of their season (PRE) and within two weeks of their final game (POST). Six seed regions-of-interest (ROIs) within the FPN were selected for rs-FC analysis: R/L middle frontal gyrus, R/L posterior parietal cortex, and R/L lateral prefrontal cortex; all data analysis was completed using SPM12/Conn Toolbox. A 2x2 repeated measures ANOVA was performed to test for significant ($p < 0.01$) group-by-time interactions. A secondary regression analysis was performed in a subset of Impact players ($n=13$) to identify if accelerometer (Triax, Norwalk, CT) and video confirmed total number of head impacts sustained over a season were predictive of PRE/POST changes in rs-FC. **RESULTS:** A significant group-by-time interaction was found in connectivity between the R middle frontal gyrus and R posterior parietal cortex ($T = 3.49, p < .01$); post-hoc analysis revealed significant POST hyperconnectivity in the Impact group only ($T = 2.96, p < .01$) and no PRE/POST changes were noted in the No

Impact group. Total number of impacts (54.8±33.5) significantly predicted POST hyperconnectivity between the L lateral prefrontal cortex and L pallidum ($r^2=0.79$, $p=0.001$).

CONCLUSIONS: Post-season hyperconnectivity between ROIs involved in executive functioning was found in athletes who regularly sustain impacts compared to those who do not, which is consistent with previous rs-FC RHI findings in different networks. Hyperconnectivity has been suggested to represent brain injury and players who sustain more impacts may be more likely to have neurological damage that results in deficits in executive function.

Identifying The Educational Needs Of 9th And 10th Grade High School Students Regarding Concussion

Brent A. Harper. *Chapman University, Irvine, CA.* (Sponsor: A. Lynn Millar, FACSM)
Email: ptmi@aol.com

(No relevant relationships reported)

PURPOSE: To evaluate adolescent concussion knowledge and behaviors regarding concussion using a modified Rosenbaum Concussion Knowledge and Attitudes Survey (RoCKAS) questionnaire.

METHODS: RoCKAS questionnaire was taken by female and male 9th and 10th-grade high school students ($n=190$) with a mean age of 15.1 ± 0.8 years (64.7% female; 35.3% male). 59.4% reported belonging to a competitive sports team. A sampling of questions from the RoCKAS questionnaire was used to assess groups for (1) general concussion knowledge and (2) the demonstration of safe attitudes and behaviors in situational decision making ("safe" or "unsafe").

RESULTS: Validity scale scores were appropriate, meaning participants were actually reading and answering the questions thoughtfully. General concussion knowledge was correctly answered by 83.8% ($p=0.007$). Those not participating in athletics were less knowledgeable than those participating in sports (20.1%). Males not participating in sports answered incorrectly 23.4% of the time. There was no statistical significance comparing females in relation to sports participation. Responses to the four situational questions analyzed identified answers to be unsafe on the behavior questions 87.1 % of the time ($p=0.0001$). In fact, the actual age of the participants negatively correlated with the behavior answers ($r=-0.4$, $p=0.0001$).

CONCLUSIONS: High school 9th and 10th-graders are knowledgeable about concussion. Those participating in sporting teams are more knowledgeable, especially males. There is no knowledge differences between females who participate or do not participate in sports. Situation based questions indicate an unacceptable level of safety, suggesting poor behaviors in return-to-play (RTP) and concussion reporting decisions, which was worse in older individuals. The RoCKAS information may be helpful to identify behavior deficits that can inform cohort-specific concussion educational programs designed to enhance the safety of youth athletics.

3449 Board #270 May 29 1:30 PM - 3:00 PM

Fear Of Re-injury Correlates With Concussion Symptoms And Reaction Time Among Adolescents With Concussion

Sarah Elizabeth Reinking¹, Julie C. Wilson², Gregory C. Walker², Corrine Seehusen¹, David R. Howell¹. ¹*Children's Hospital Colorado, Aurora, CO.* ²*University of Colorado School of Medicine, Aurora, CO.*

Email: sarah.reinking@childrenscolorado.org

(No relevant relationships reported)

Background: Athletes appear to be at an increased risk of musculoskeletal injury following return to play after concussion. Underlying causes are likely multi-factorial but not well established. Fear of re-injury has been widely studied in musculoskeletal injuries, but its effect on concussion recovery is unknown.

Purpose: To examine the association of fear of re-injury with physical and self-reported measures after concussion. We hypothesized that greater fear of re-injury would be correlated with a higher symptom severity, worse sleep quality, and worse physical test performance.

Methods: Athletes ($n=19$; 15.0 ± 1.8 years of age; 42% female; 7.4 ± 3.3 days post-injury) were tested within 14 days of concussion, and underwent assessments of self-reported and physical examination measures. Self-reported measures included the Tampa Scale of Kinesiophobia (TSK)- assessing fear of re-injury, Post-Concussion Symptom Inventory (PCSI), and Pittsburgh Sleep Quality Index (PSQI). Physical examination measures included clinical reaction time, near point of convergence, single and dual-task tandem gait, and Balance Error Scoring System (BESS). We examined correlations between TSK scores and each outcome measure using Pearson correlation coefficients, adjusting for age, sex, and time from injury using linear regression models.

Results: Higher TSK scores were significantly correlated with higher symptom severity (PSCI) scores ($r=0.69$; $p=0.001$) and slower reaction times ($r=0.53$; $p=0.02$). TSK scores were not significantly correlated with single-task tandem gait ($r=0.23$;

$p=0.34$), dual-task tandem gait ($r=0.29$; $p=0.23$), PSQI ($r=0.43$; $p=0.08$), NPC ($r=0.03$; $p=0.91$), or BESS ($r=0.23$; $p=0.35$) scores. After adjusting for the effect of age, sex, and time from injury to examination, higher TSK scores were significantly associated with slower clinical reaction time performance ($\beta=2.8$; 95% CI= 0.94, 4.62; $p=0.006$), greater symptom severity ($\beta=3.64$; 95% CI=2.07, 5.21; $p<0.001$), and worse sleep quality ($\beta=0.37$; 95% CI= 0.05, 0.68; $p=0.03$).

Conclusions: In accordance with our hypothesis, higher TSK scores were correlated with higher symptom severity and slower reaction times. This suggests that assessing an athlete's fear of re-injury may be useful following concussion and throughout recovery.

3450 Board #271 May 29 1:30 PM - 3:00 PM

Neurofilament Light Not Associated With Concussion History Or Recency In Special Operations Forces Combat Soldiers

Jacob R. Powell¹, Adrian J. Boltz¹, Jamie P. DeCicco¹, Avinash Chandran¹, Stephen M. DeLellis², Marshall L. Healy³, Shawn F. Kane, FACSM³, James H. Lynch, FACSM³, Gary E. Means³, Jason P. Mihalik, FACSM¹. ¹*The University of North Carolina at Chapel Hill, Chapel Hill, NC.* ²*Defense Medical Strategies LLC, Fayetteville, NC.* ³*United States Army Special Operations Command, Fort Bragg, NC.* (Sponsor: Jason Mihalik, FACSM)
Email: jrpowell@unc.edu

(No relevant relationships reported)

Special Operations Forces (SOF) combat soldiers sustain high rates of blast and blunt neurotrauma. Most are mild traumatic brain injuries (i.e., concussion). Repetitive concussions may develop long-term neurological sequelae. Detecting the effects of cumulative exposure to concussion may be helpful to recognize and intervene therapeutically before chronic symptoms begin emerging. Neurofilament light chain (NfL) is an abundantly expressed cytoskeletal component of large caliber myelinated subcortical axons. Peripheral increases may indicate ongoing axonal disruption or chronic repetitive white matter injury within the brain.

PURPOSE: To determine the effects of concussion history, lifetime incidence, and recency on NfL concentrations in SOF combat soldiers. **METHODS:** 185 SOF combat soldiers (age=33.0±3.5 yrs) participated in our cross-sectional study and self-reported concussion history (90 no, 95 yes), lifetime incidence (0, 1, 2, 3+) and recency (<1 month, <1 year, >1 year). Fasted blood samples were obtained from an antecubital vein at a standardized time for all subjects. Serum was separated and stored until analysis. Serum NfL levels were quantified using sandwich enzyme immunoassay kits according to manufacturer instruction. Medians and interquartile ranges (IQRs) were reported because NfL concentrations were not normally distributed. A Wilcoxon rank-sum analysis compared NfL concentrations between those with and without concussion history. Kruskal-Wallis tests compared NfL concentrations across lifetime incidence and recency. **RESULTS:** We did not observe differences in NfL concentrations ($z=1.80$, $p=0.07$) between those with (median=449.7 pg/mL, IQR=192.1) and without (median=484.4 pg/mL, IQR=221.2) concussion history. There was no effect of concussion lifetime incidence ($X^2(3)=3.87$, $p=0.28$) or recency ($X^2(2)=0.86$, $p=0.65$) on serum NfL concentrations. **CONCLUSION:** We did not observe differences in serum NfL concentration in SOF combat soldiers based on concussion history, lifetime incidence, and recency. Our SOF combat soldiers were otherwise healthy and asymptomatic. Despite this, our findings suggest SOF combat soldiers demonstrated higher NfL concentrations than those reported for civilian severe brain injury and neurodegenerative disease patients.

Parent Beliefs Regarding Chronic Traumatic Encephalopathy Associated With Sport-related Concussion

Katherine Ford Daniels, Abigail C. Bretzin, Morgan Anderson, Marco Alcala, Ara Schmitt, Erica Beidler. *Allegheny Health Network, Pittsburgh, PA.*

Email: klfid10@gmail.com

(No relevant relationships reported)

PURPOSE: To determine CTE beliefs of youth athletes' parents, and examine the association of sex and prior concussion history with those views.

METHODS: This was a cross-sectional survey study of parents ($n=467$; males = 185, females = 282; history of concussion = 52) of youth contact sport athletes (i.e., football, soccer, ice hockey, lacrosse). The survey included items on demographics, diagnosed concussion history, and a standardized concussion knowledge assessment with two exploratory items about CTE beliefs. Parents were asked if CTE was a complication of multiple concussions and premature return-to-play. The 15-minute

survey was administered on-site after practices/events. The association between CTE beliefs, sex (male/female), and concussion history (yes/no) were assessed using chi-square analyses with significance set at $p \leq .05$.

RESULTS: A majority 70.7% (n=319/451) of parents indicated CTE was a complication of multiple concussions; 67.1% (n=294/438) identified CTE was a complication of returning to play prematurely. A greater proportion of male parents (77.4%, n=137/177) indicated CTE was a complication of multiple concussions compared to female parents (66.3%, n=181/273; $\chi = 6.38, p = .01, V = .12$). A greater proportion of male parents (74.6%, n=129/173) identified CTE was a complication of premature return to play compared to female parents (62.1%, n=164/264; $\chi = 7.32, p = .007, V = .13$). There were no significant associations between diagnosed concussion history and CTE beliefs (χ^2 's = .51-1.52, p 's = .22-.47, V 's = .03-.06).

CONCLUSIONS: Parents commonly recognized CTE as a complication of multiple concussions and premature return to play, which shows they are aware of this neurodegenerative condition. Additionally, a greater proportion of male parents endorsed CTE beliefs compared to females. This finding could be a byproduct of the media's attention towards CTE cases in male athletes specifically. Future research should consider how beliefs about CTE may influence sport participation within a family unit.

 (No relevant relationships reported)

The effects of concussion history (CH) and years of playing football on cognitive function and mood-related symptoms in former football players is unclear. Most former player studies include mid-to-late life individuals, and little is known about younger cohorts.
PURPOSE: Assess the influence of CH and years played on cognitive function, mood-related symptoms, and life satisfaction in former football players.
METHODS: Former collegiate football players (n = 58; age 37.9 ± 1.5 years; BMI 31.3 ± 5.0 kg/m²) from 16 schools completed a health survey and subsequent in-person evaluation 15 yrs post-college football. Outcomes included cognitive tests: Symbol Digit Modalities Test (SDMT), Controlled Oral Word Association Test (COWAT), revised Hopkins Verbal Learning Test (HVLTr), and Trails A (TMTA) and B (TMTB); and self-reported outcomes: NeuroQOL Cognition Short Form (NQC), Beck Depression Inventory (BDI-II) and Anxiety (BAI-II) inventories, and Satisfaction with Life Scale (SWLS). Current symptom severity (SS) was reported on the Graded Symptom Checklist alongside typical hours slept per night. CH was split into tertiles: 0-1, 3-6, or 7+ prior concussions. Multivariable linear regression models were used to assess the influence of CH and years played on each outcome with BMI, sleep, and SS as covariates.
RESULTS: Model predictors and adjusted R² values are in Table 1. Higher SS was associated with worse outcomes on most measures. Worse SDMT scores were partially explained by greater CH and years played. In addition to SS, greater CH related to better COWAT performance; those with more sleep had longer TMTA times; and those with lower BMI and more sleep had higher SWLS.
CONCLUSIONS: Our data show no clear influence of CH or years played on cognitive function, mood-related symptoms, or life satisfaction. In our relatively young sample, SS at the time of testing was associated with worse outcomes. Continued longitudinal analyses may explain age related changes on these outcomes.

Table 1. Backwards Removal Regression Coefficients.

Outcomes	Adj. R ²	Predictors										
		Concussion History		Years of Football Played		Body Mass Index		Average Sleep Duration		Total Symptom Severity		
		Beta	p	Beta	p	Beta	p	Beta	p	Beta	p	
SDMT	.159	-.22	.08	-.43	<.01	
COWAT	.068	.23	.09	-.30	.03	
HVLTr Total Score	.057	-.27	.04
HVLTr Percent Retention	N/A
HVLTr Recognition	N/A
TMTA	.15545	.00127	.05
TMTB	.11536	<.01
NQC	.440	-.67	<.01
BDI-II	.52273	<.01
BAI-II	.59177	<.01
SWLS	.176	-.23	.06	.26	.05	...	-.22	.09

Standardized Betas and p-values are presented only for the final model of predictors remaining after the backwards elimination process for each outcome. Removal criterion p-value was $\geq .1$. SDMT = Symbol Digit Modalities Test, COWAT = Controlled Oral Word Association Test, HVLTr = Hopkins Verbal Learning Test - Revised, TMTA = Trail Making Test A, TMT B = Trail Making Test B, NQC = NeuroQOL Cognitive Function Short Form, BDI = Beck Depression Inventory, BAI = Beck Anxiety Inventory, SWLS = Satisfaction With Life Scale, Adj. R² = Adjusted R² value for the regression model of each outcome.

Sport-related Concussion Reporting Behaviors And Non-disclosure Patterns Of Youth Contact Sport Athletes
 Abigail Cecelia Bretzin¹, Morgan Anderson², Ara Schmitt³, Erica Beidler³. ¹University of Pennsylvania, Philadelphia, PA. ²Michigan State University, East Lansing, MI. ³Duquesne University, Pittsburg, PA.
 Email: Abigail.Bretzin@Pennmedicine.upenn.edu
 (No relevant relationships reported)

Current literature on sport-related concussion (SRC) reporting behaviors and reasons for non-disclosure is dominated by older athletic populations. Youth athletes participating in contact sports are at risk for SRC; however, little is known about SRC disclosure patterns and reasons for non-disclosure in this group. **PURPOSE:** To examine SRC reporting behaviors and reasons for non-disclosure in youth contact sport athletes.
METHODS: Youth athletes (n = 442; 66.5% male, 33.5% female) aged 8-14 years participating in football (22.4%), ice hockey (26.5%), lacrosse (24.9%), and soccer (26.2%) completed a 15-minute survey composed of demographics, diagnosed and non-disclosed SRC history, and reasons why they did not report a suspected SRC. The survey was adapted for elementary school readability and researchers were present to clarify any athlete questions. Descriptive statistics expressed frequencies of self-reported diagnosed SRC, suspected SRC non-disclosure, and reasons for non-disclosure.
RESULTS: A total of 44 (10%) youth contact sport athletes recalled a diagnosed SRC; 68.1% (n = 30) of those recalled 1, 20.5% (n = 9) recalled 2, and 13.6% (n = 6) recalled ≥ 3 diagnosed SRC. Youth athletes also indicated they thought they had a SRC but still played in a practice (n = 55, 13.0%) or game (n = 51, 12.0%), respectively. While, 50 (11.8%) athletes reported they thought they sustained a SRC and did not report it to anyone. The most common reasons for non-disclosure selected by youth athletes included: I did not want to lose playing time (n = 33, 66.0%), I did not want to miss a game (n = 10, 56.0%), at the time I did not think it was a concussion (n = 26, 52%), I did not want to let my team down (n = 23, 46%).
CONCLUSIONS: Epidemiological evidence of SRC in this setting is lacking; however, these novel results identified 10% of youth athletes self-reported a previous SRC. Significantly, 13% of athletes indicated they remained in play with a suspected SRC and 12% of athletes did not report their suspected SRC to anyone. Youth athletes' reasons for non-disclosure were similar to those reported in high school and college athletes. Recent research suggests negative consequences of continued play with SRC, especially in acute stages. Future educational initiatives should emphasize these risks, and focus on reasons why athletes withhold reporting.

(No relevant relationships reported)

Concussive injury and depression affect millions of individuals each year and are connected through common overlapping symptoms. **PURPOSE:** Aim 1 was to establish an association between post-concussion depression-related symptoms and post-concussion symptoms, balance performance, vestibular function, and executive function. Aim 2 was to further establish the relationship between concussion history and post-concussion depression-related symptoms, concussion symptoms, and mood disturbance. **METHODS:** 164 concussed individuals (mean age=14.52±3.51 years, 50.61% male, mean time from injury=18.24±13.60) were included in this analysis. Depression-related symptoms were quantified using the Beck Depression Inventory (BDI-II) and post-concussion symptoms using the Rivermead Post-Concussion Symptoms Questionnaire (RPQ). Clinical post-concussion assessments utilized were the modified Balance Error Scoring System (mBESS), Vestibular/Ocular-Motor Screening (VOMS), and, for adolescent patients, the Behavior Rating Inventory of Executive Function (BRIEF). Mood disturbance was quantified using the Profile of Mood States (POMS). mBESS, VOMS, RPQ, and BRIEF were measured against BDI-II scores using Pearson Correlation and Linear Regression analyses. BDI-II, POMS, and RPQ scores were analyzed based on concussion history using Wilcoxon Rank-Sum Tests. **RESULTS:** As depression-related symptoms increased, post-concussion symptoms ($p<0.001$, $r=0.68$) and VOMS scores measuring changes in headache and dizziness ($p<0.001$, $r=0.34$; $p=0.01$, $r=0.20$ respectively) significantly increased. There was no significant correlation between depression-related symptoms and balance performance ($p=0.093$, $r=0.13$). In adolescents, as depression-related symptoms increased parent reported executive function decreased ($p<0.001$, $r=0.46$). Those who reported a concussion history reported significantly more depressive-related symptoms ($p=0.004$), concussion symptoms ($p=0.004$), and mood disturbance ($p=0.002$). **CONCLUSION:** This study adds to the current literature surrounding the relationship between concussion and depression by identifying a relationship between depression related symptoms, post-concussion symptoms, and post-concussion clinical assessments.

Nonverbal Hand Movements Indicate Symptoms After Sport Related ConcussionsIngo Helmich. *Department of Neurology, Psychosomatic Medicine, and Psychiatry, Cologne, Germany.*

Email: i.helmich@dshs-koeln.de

(No relevant relationships reported)

Because post-concussion symptoms are often not clearly visible, speech-accompanying gestures may help clinicians to gain additional information about the patient's history and symptoms during medical consultation. **PURPOSE:** We hypothesized that athletes with SRC and who suffered from persisting symptoms would display more gestures during concussion assessment protocols when compared to non-concussed athletes because of the athletes' previous motor-sensory experiences made during the concussive event. **METHODS:** Three matched groups of 40 (active) athletes were investigated in the context of concussion assessment (and baseline) protocols: 14 symptomatic and 14 asymptomatic athletes with a SRC, and 12 non-concussed athletes. Certified raters using a standard analysis system for nonverbal behavior analyzed videotaped hand movements and gestures during a standardized concussion assessment protocol. **RESULTS:** Symptomatic athletes spent significantly more time with *in space* hand movements, i.e., movements that act in the body-external free space without touching anything and specifically, *motion quality presentation* gestures than non-concussed athletes. **CONCLUSIONS:** Increased *in space* movements, which are functionally gestures, and specifically, *motion quality presentation* gestures in symptomatic athletes indicate that the more vivid sensory motor experience of the head trauma is reflected in more gestural expressions. Thus, hand movements and gestures differentiate athletes who suffer from post-concussion symptoms from non-concussed athletes indicating the athletes' motor-sensory experiences of the event and its aftereffects. The present study highlights the fact that gestures can be employed as behavioral markers of symptoms after sport-related concussions.

3456 Board #277 May 29 1:30 PM - 3:00 PM

Baseline Concussion Symptom Reporting As A Possible Screening Method For Generalized Anxiety DisorderEric E. Hall, FACSM, Anna Keane, Emma McCabe, Emily Klevan, Ethan Williams, Caroline J. Ketcham. *Elon University, Elon, NC.*

Email: ehall@elon.edu

(No relevant relationships reported)

Athletes with previous diagnosis of a psychiatric condition, such as depression or anxiety, have been shown to experience a larger overall concussion symptom score compared to those without a previous psychiatric treatment. Anxiety rates in college students is high (42%) with student-athletes only slightly lower (37%) compared to the general population (18%). **PURPOSE:** The purpose of this study was to compare concussion-related anxiety symptoms and validated anxiety disorder screeners to see if baseline concussion symptoms could be used as a screening tool for follow-up mental health assessments. **METHODS:** 254 club level collegiate student-athletes (18.2±1.4yrs, 150 female, 104 male) completed the Immediate Post-Concussion Assessment and Cognitive Testing (ImPACT) including the 22-item Post-Concussion Symptom Scale (PCSS), the Patient Reported Outcome Measurement Information System (PROMIS-29), and the Depression Anxiety Stress Scales (DASS-21). DSM-5 Anxiety symptoms were compared to the PCSS symptoms and an anxiety-related concussion symptom score was calculated. These along with the anxiety sub-scores for both the DASS-21 and PROMIS-29 were used for analysis. **RESULTS:** Participants were divided into 4 anxiety level groups based on norms from the DASS-21 (normal=36; mild=76; moderate=87; severe=28). There was a significant correlation ($p<0.001$) between Anxiety Cluster PCSS symptom score and DASS-21 anxiety subscale ($r=.41$) and PROMIS-29 Anxiety Sub-score ($r=.44$). The DASS-21 and PROMIS-29 were also significantly correlated ($r=.64$, $p<0.001$). There were significant group differences across the 4 DASS-21 anxiety levels for Anxiety Symptom Cluster ($F(4, 226)=9.27$, $p<0.001$) and the PROMIS-29 Anxiety subscale ($F(4,223)=31.01$, $p<0.001$). **CONCLUSIONS:** The significance from this data shows that the proposed symptom clusters that potentially pertain to anxiety symptoms are meaningfully related to higher scores on the DASS-21 and the PROMIS-29 anxiety related questions. Participants that demonstrated a higher overall concussion-related anxiety symptom score were more likely to exhibit more severe levels of anxiety suggesting that this cluster score could potentially screen individuals at risk for anxiety disorders thus providing a pathway to refer and provide resources and support.

SELF-PERCEIVED HEALTH AND PHYSICAL FUNCTION ARE ASSOCIATED WITH BODY COMPOSITION AND BLOOD LIPIDSMadison Filippini, Emilija Peleckas, Alexandra I. Hopun, Gabrielle A. Volk, Melanie Ziazaris, Kyle L. Timmerman, FACSM. *Miami University, Oxford, OH.* (Sponsor: Kyle Timmerman, FACSM)

(No relevant relationships reported)

Clinical indicators of health status such as body composition, blood lipids, and cardiorespiratory fitness are objective; however, self-perceived health may be influenced by multiple factors. Thus, the **PURPOSE** of the present study was to explore associations among objective measures of health, self-perceived health, and habitual physical activity in overweight, older adults. **METHODS:** In 35 (27 F/8 M) overweight (body mass index, BMI ≥ 27 kg/m²), older adults (>58 years) we assessed blood lipids (point-of-care analyzer); body composition (bioelectrical impedance); habitual physical activity (7-day accelerometry); cardiorespiratory fitness (VO₂max); and self-perceived health (36-item short form survey, SF-36). The SF-36 includes questions that assess eight health concepts including perceptions of physical function and general health. Scores for each concept can range from 0% (poor) to 100% (excellent). Associations were assessed utilizing partial correlations (controlling for age and sex). Significance was set to $p<0.05$. **RESULTS:** Average values for these subjects included: age: 64±5y; SF-36 (general health): 63±14%; SF-36 (physical function): 77±16%; BMI: 35±5 kg/m²; body fat percentage: 44.7±0.1%; VO₂max: 16±3 ml/kg/min; moderate-to-vigorous physical activity (MVPA): 47±23 min/day; LDL cholesterol: 105±27 mg/dL, HDL cholesterol: 49±11 mg/dL, triglycerides: 113±40 mg/dL, and glucose: 100±15 mg/dL. Self-perceived physical function was

significantly ($p < 0.05$) correlated with indices of body composition and blood lipids [body fat percentage ($r = -0.39$), visceral fat area ($r = -0.42$), and LDL cholesterol ($r = -0.51$)], but not habitual MVPA. Self-perceived general health was significantly correlated with LDL/HDL ($r = -0.60$), but not indices of body composition or physical activity level. **CONCLUSIONS:** These preliminary data suggest that perception of general health and physical function are more closely related to indices of body composition and blood lipids than habitual physical activity level.

Contributors To Percent Body Fat In Career Firefighters

Gena R. Gerstner¹, Megan R. Laffan², Abigail J. Trivisonno², Hayden K. Giuliani², Jacob A. Mota², Johna Register-Mihalik², Abbie Smith-Ryan, FACSM², Brian G. Pietrosimone, FACSM², Joseph P. Weir, FACSM³, Eric D. Ryan². ¹Old Dominion University, Norfolk, VA. ²University of North Carolina at Chapel Hill, Chapel Hill, NC. ³University of Kansas, Lawrence, KS. (Sponsor: Joseph Weir, FACSM)
(No relevant relationships reported)

Firefighters have substandard levels of fitness and a high prevalence of overweight and obesity. Understanding exercise status and barriers to exercise may be important factors regarding body composition. **PURPOSE:** The purpose of this study was to examine the influence of exercise status and barriers to exercise on percent body fat (%BF) in career firefighters. **METHODS:** Fifty-eight male career firefighters [age: 31.3±7.0 yrs; stature: 178.9±7.6 cm; body mass: 90.0±17.6 kg; %BF: 23.5±7.5%] volunteered for this investigation. Participants self-reported exercise status and rated sixteen barriers to exercise (e.g., too busy) on a Likert-type scale (1-7). Dual-energy X-ray absorptiometry was used to assess %BF. Aerobic exercise time [AER = moderate intensity minutes + (vigorous intensity minutes × 2)] and resistance training workload [RT = days × minutes × intensity] were calculated. Pearson's correlation coefficients were used to determine the relationships between %BF and potential predictor variables including AER, RT, and the sixteen barriers. The significant exercise barriers were averaged into one construct (BAR). The internal consistency of BAR was measured using Cronbach's alpha. Multicollinearity was monitored using the variance inflation factor (VIF). Stepwise regression analysis was conducted. An alpha level was set *a priori* at 0.05 for all analyses. **RESULTS:** %BF was related to AER ($r = -0.364; P = 0.005$) and RT ($r = -0.400; P = 0.002$). Seven of the sixteen barriers (i.e., too busy, not enough time, irregular work hours, family obligations, interferes with work, too tired, lack of support from officers) were significantly related with greater %BF ($r = 0.270-0.354; P = 0.006-0.042$) and were included in the final construct BAR. The Cronbach's alpha for BAR was 0.80. The stepwise analysis suggests that AER and BAR were significant predictors of %BF ($R^2 = 0.306, P < 0.001$; maximum VIF = 1.98). **CONCLUSIONS:** These findings suggest that firefighters with poorer body composition likely partake in less aerobic exercise and experience greater perceived barriers to exercise. Interventions aiming to mitigate barriers to exercise, specifically aerobic exercise, may be helpful in improving body composition.

Examining The Perceived Barriers To Physical Activity Among Older Adults: Moderating Effects Of Body Mass Index

Stephan Anlauf¹, Eric Faßl¹, Marc Lochbaum², Youngdeok Kim³. ¹Ruhr-Universität Bochum, Bochum, Germany. ²Texas Tech University, Lubbock, TX. ³Virginia Commonwealth University, Richmond, VA.
Email: stephan.anlauf@rub.de
(No relevant relationships reported)

Lack of physical activity (PA) is a major public health concern, especially for older people. However, data on possible factors limiting older adults' engagement in PA are still under-investigated. **PURPOSE:** The purpose of this study is twofold: 1) to examine the association of perceived PA barriers with leisure-time PA (LTPA) in a sample of older adults; and 2) to explore the possible moderating effect of body mass index (BMI). **METHODS:** 296 older adults aged ≥60 years old took part in a cross-sectional survey. LTPA was measured by the International Physical Activity Questionnaire and participants were categorized into the three groups, no-LTPA group for individual who did not report LTPA; and below/upper 50th percentile of total LTPA MET values for low- and high-LTPA groups, respectively. Barriers to being active questionnaire (BBAQ) was used to assess perceived PA barriers in a binary manner (i.e., no barrier/at least 1 barrier) for each of the seven domains (i.e., time, social, energy, will, injury, skill, and resources). BMI (kg/m²) was calculated by self-reported height and weight and used to create the three BMI groups (BMI <25, 25-29.99, and ≥30). Using a no-LTPA group as a referent, a multinomial logistic regression model predicting the likelihoods of being low- and high LTPA groups was established after adjusting for study covariates, followed by stratified analyses by BMI groups. **RESULTS:** In general, "lack of will" (49.66%) was the most frequently cited PA barrier followed by "social influence" (38.51%) and "fear of

injury" (36.49%). In the fully adjusted multinomial logistic regression model, greater perceived barrier in "social influence" was associated with lower odds of reporting high-LTPA (odds ratio (OR) = 0.41). In the follow-up stratified analyses demonstrated that PA barriers differently affect LTPA levels by BMI groups. Among individuals with BMI between 25 and 29.99, "lack of time" (OR = 0.11) was the significant predictor of LTPA level. Whereas, "fear of injury" (OR = 0.11) and "lack of energy" (OR = 0.18) were the significant factors associated with LTPA among those with BMI ≥30. **CONCLUSIONS:** The present study provides relevant data on barriers to LTPA for older adults. Promotion and intervention strategies should consider the exposed barriers of older adults in order to reduce their obstacles to PA.

3460 Board #281 May 29 1:30 PM - 3:00 PM
Sex-specific Correlates Of Metabolic Syndrome Risk In College Students

Alexandra N. Smith¹, Ewan R. Williams², Bhibha M. Das³, Michael V. Fedewa⁴, Ellen M. Evans, FACSM², Simon Higgins¹. ¹Elon University, Elon, NC. ²University of Georgia, Athens, GA. ³East Carolina University, Greenville, NC. ⁴University of Alabama, Tuscaloosa, AL. (Sponsor: Ellen Evans, FACSM)
(No relevant relationships reported)

Over half of college students possess ≥1 metabolic syndrome (MetS) risk factors, with each subsequent risk factor increasing lifetime cardiovascular disease risk. As opposed to taking a reactionary response to established disease, early behavioral intervention may be effective in preventing MetS risk advancement. While correlates of MetS in the general adult population have been described, ideal targets for sex-specific primary prevention strategies in college students are unknown. **PURPOSE:** To identify the sex-specific prevalence of MetS risk factors and their correlates in a college-aged population. **METHODS:** First-year students aged 18-20 y/o ($n=390$; 67.4% female; 70% white) were screened for traditional MetS risk factors using IDF/AHA/NHLBI harmonized criteria. Potential correlates of MetS risk included inflammatory markers, relative adiposity, anxiety, depression, stress, diet, physical activity, alcohol consumption, smoking, and sleep. Principal component analysis was used to construct sex-specific continuous MetS risk scores, with waist circumference, systolic blood pressure, HDL-C, and fasting glucose, insulin, and triglycerides as factors in the final model. Two principal components with an eigenvalue ≥1 created the continuous MetS risk score, explaining 51.2% and 54.2% of the variance in risk in females and males, respectively. Multivariate linear regression assessed the relationships between potential correlates and MetS risk score. **RESULTS:** One or more MetS risk factors were present in 66.9% of males and 59.3% of females, with 3.1% and 2.3% having defined MetS, respectively. In females, % kcal from sugar ($\beta = .25, p = .001$), stress ($\beta = .19, p = .003$), and relative adiposity ($\beta = .45, p < .001$) were positively associated with MetS risk, whereas moderate to vigorous physical activity ($\beta = -.12, p = .028$) and anxiety ($\beta = -.15, p = .017$) were negatively associated with MetS risk. In contrast, correlates in males included race ($\beta = .24, p = .002$; coded as non-white=0, white=1), C-reactive protein ($\beta = .20, p = .006$), and relative adiposity ($\beta = .53, p < .001$), with % kcal from saturated fat approaching significance ($\beta = .23, p = .064$). **CONCLUSION:** The sex-specific prevalence of MetS risk factors and correlates suggest that a one-size-fits-all approach to prevention may not be effective in this population.

How Motivation Affects Our Training And Nutrition Goals: A Comparison Between Bodybuilders And Overweight Women

Henry Chan, Roberta C. Muzy, Paula H. D. Kanas, Luciana O. P. Lancha, Ivan S. Rabelo, Katia Rubio, Paulo C. Muzy, Antonio H. Lancha JR. University of São Paulo (USP), São Paulo, Brazil.
Email: henry.chan@usp.br
(No relevant relationships reported)

Bodybuilders are well known by their addiction to the perfect physique, requiring not only a strong body, but also a strong mind. This potential psychological, motivational, emotional and dedication in bodybuilding has significant impact in athletes' lives, supporting self-control, confidence, individual's social realization and mood. Moreover, their motivation and self-control are important skills for a competition. On the other hand, most part of the population doesn't have this strong motivation, struggling a bit more with nutrition and training programs. In nutritional studies, the "triangle" defined by trigger, behavior and reward really influence how people stick to a diet plan and their actions facing a goal related to losing or gaining weight. **PURPOSE:** The aim of this research is to study how the strong mind, dedication of bodybuilders, associated with intrinsic and extrinsic motivation, affect their success through a nutritional program, in comparison to non-athletes. Furthermore, we also want to understand the relevance of behavior and locus of control differences between these two groups.

METHODS: The current study was designed to compare two groups ($n=18$): bodybuilders women ($n=10$) and overweight women ($n=8$). The data were collected by

survey monkey link, composed by 12 sentences about nutrition and training lifestyle with 3 column each: depend on myself, depend on a reward and depend on others. Participants were requested to answer by classifying how the sources of control affect each item with scales from 1 to 5 (1- very low influence, 5- very high influence). The average of each question and column were calculated for comparison. **RESULTS:** According to the protocol, the column "depend on myself" had the same average 4.9/5 for bodybuilders and overweight women. For "depend on others" the athletes average was 1.2/5 and for non-athletes 1.4/5. The major difference was regarding "depend on a reward" with an average of 2.7/5 for the bodybuilders group and 1.9/5 for non-athletes. **CONCLUSIONS:** When discussing about motivation in fitness and nutrition goals, we concluded that a source of reward is much more significant to athletes.

3462 Board #283 May 29 1:30 PM - 3:00 PM
Diabetes Prevention Program: An Investigation Of Lifestyle Coaches' Habits And Motivations

Melanie K. Sookiasian¹, Selen Razon¹, Patricia G. Davidson¹, Umit Tokac², Melissa A. Reed¹. ¹West Chester University, West Chester, PA. ²University of Missouri, St Louis, MO.
 Email: MS803524@WCUPA.EDU
 (No relevant relationships reported)

The Diabetes Prevention Program (DPP) was created after a 27-center randomized clinical trial was conducted to determine if lifestyle intervention alone, or combined with pharmacological therapy could prevent or delay the onset of Type 2 Diabetes (T2DM). Lifestyle intervention decreased the incidence of T2DM by 58% compared with a 31% reduced incidence in the pharmacological group. A key component of the DPP are lifestyle coaches (LC). LC deliver curriculum intended to initiate and promote lifestyle change to individuals at risk for T2DM. Little is known about the behaviors of the LC. **PURPOSE:** The purpose of this study was to investigate the habits and motivations of LC to elucidate their motivations for coaching. **METHODS:** A sixteen item electronic survey was emailed to LC. Data was analyzed using descriptive and qualitative analyses, as well as chi-square tests. **RESULTS:** Sixty-three participants (60 female, 3 male) (Age range = 18-75+) responded to the survey. Descriptive analyses indicated that the majority of responding coaches worked in healthcare fields (59.65%) and achieved ≥ 150 minutes of physical activity (PA) per week (68.42%). Qualitative analyses indicated two types of motivation for coaching: internal (N=19) and external motivation (N=36). External motivation further included two sub-themes external-others (N=11) and external-self (N=25). Additional chi-square analyses revealed that those with bachelor and master's degrees, and working full time in healthcare occupations reported significantly less incidence of diabetes ($p < .05$) and higher instances of achieving 150 minutes or more PA per week ($p < .05$). **CONCLUSION:** These results suggest that lifestyle coaches are employed mainly in healthcare fields and are motivated to coach by external factors. The results indicate coaches may serve as appropriate role models in the adoption of PA behaviors and could help with training, delivery, and recruitment efforts for future coaches. Supported by Health Promotion Council (HPC) Grant.

Obesity In Adolescence: Does Motor Competence Or Physical Activity Matter?

Xiangli Gu¹, Weiyun Chen², Tao Zhang³. ¹University of Texas at Arlington, Arlington, TX. ²University of Michigan, Ann Arbor, MI. ³University of North Texas, Denton, TX.
 Email: xiangli.gu@uta.edu
 (No relevant relationships reported)

Physical activity (PA) and motor competence are closely related to each other since motor competence is mainly, although not entirely, determined by PA patterns (i.e., Light PA [LPA], Moderate PA [MPA], and Vigorous PA [VPA]) in adolescence (Stodden et al, 2009). How the development of the motor competence may be influenced by PA patterns and how the interaction of these two variables may be correlated with obesity in adolescent years are understudied. **PURPOSE:** The main purpose of this study was to investigate the relation among PA patterns including LPA, MPA, and VPA, motor competence, and obesity (body composition, waist circumference) in adolescents. The second purpose was to test the gender differences among the study variables. **METHODS:** Participants were 307 students ($M_{age} = 12.5 \pm 0.9$; boys=142, girls = 165) randomly recruited from four middle schools in the U.S. Students' PA patterns were assessed using Actical monitors for 5 consecutive school days. Students' ball skill competence including volleyball, soccer, and ultimate Frisbee (PE Metrics™; NASPE, 2010) were assessed in PE classes. Body mass index (BMI) and waist circumference were used to represent indices of obesity in this study. **RESULTS:** Both LPA and VPA were significantly correlated with BMI and waist circumference ($p < .05$). All three ball skills were significantly associated with both MPA and VPA (r ranges from .21 to .33). Regression analyses indicated that only VPA and soccer skill merged as significant predictors of BMI ($\beta = -.16$; $\beta = -.24$, $p < .05$) and waist circumference ($\beta = -.15$; $\beta = -.15$, $p < .05$), respectively. Structural equation modeling suggested a mediating role of motor competence in the relationship between

PA patterns and obesity. After controlling for all the covariates, MANCOVA indicated boys had higher levels of VPA than girls ($p < .001$), but no significant differences were found for overall motor competence and MPA. Girls had higher waist circumference and LPA than boys. **CONCLUSION:** The findings indicate that engaging in at least vigorous PA may lead to higher and more accurate ball skill competence among adolescents. The potential "physical activity divide" may occur especially among girls between low-skilled adolescents and their skilled counterparts, which suggests a potential trajectory of obesity in adolescent years.

Accelerometer-measured Sedentary Patterns Are Related To Poorer Inhibitory Control In Obese-middle-aged Adults

Dominika M. Pindus¹, Caitlyn G. Edwards¹, Anne D. Walk², Sharon V. Thompson¹, Ginger Reeser¹, Nicholas A. Burd¹, Hannah D. Holscher¹, Naiman A. Khan¹. ¹University of Illinois at Urbana-Champaign, Urbana, IL. ²Eastern Illinois University, Charleston, IL. (Sponsor: Prof. Steve Petruzzello, FACSMS)
 Email: pindus@illinois.edu
 (No relevant relationships reported)

Self-reported sedentary behaviors have been negatively related to executive functions (EFs) in older adults. However, the relationship of objectively measured sedentary time (ST) to EFs in adults with overweight and obesity is poorly understood. **PURPOSE:** To assess the relationship between accelerometer-measured ST and inhibitory control in middle-aged adults with overweight and obesity. **METHODS:** Pre-intervention data from 87 subjects (60 (67%) females, $M_{age} = 35.0 \pm 5.9$ yrs, BMI= 32.2 ± 5.4 kg/m²) participating in the *Persea Americana* for Total Health randomized controlled trial were analyzed. ST and physical activity were measured over 7 days with a hip-worn wGT3X-BT accelerometer. Valid wear time was defined as ≥ 4 days, ≥ 10 hrs/d. Daily ST (min/d), frequency, and time spent in sedentary bouts lasting ≥ 5 , 10, 20 and 30 consecutive min were estimated using a < 100 counts per minute (CPM) cut point. Moderate-to-vigorous physical activity (MVPA) was defined using an NHANES cut point. Inhibitory control was expressed as accuracy (AC), reaction time (RT), and inverse efficiency (IE = AC/RT) on incongruent trials of a modified Eriksen flanker task; performance on congruent trials indexed controlled processes. Multiple hierarchical regression models controlling for age, sex, intelligence, % fat mass, MVPA and ST (for sedentary bouts) were used to assess relationships between ST, sedentary bouts, inhibitory control, and controlled processes. **RESULTS:** Frequency ($bs \leq -0.22$, $ts \geq 2.11$, $Ps \leq 0.04$, $Fs(6,86) \geq 3.25$, $Ps \leq 0.007$) and time ($bs \leq -0.22$, $ts \geq 2.01$, $Ps \leq 0.047$, $Fs(6,86) \geq 3.17$, $Ps \leq 0.008$) spent in sedentary bouts lasting ≥ 20 and 30 min were associated with lower AC during incongruent trials. While ST and time spent in sedentary bouts ≥ 20 min were related to faster RTs during congruent trials ($bs \leq -0.23$, $ts \geq 2.08$, $Ps \leq 0.04$, $Fs(6,86) \geq 3.04$, $Ps \leq 0.01$), greater ST was related to lower IE on congruent and incongruent trials ($bs \leq -0.43$, $ts \geq 2.33$, $Ps \leq 0.023$, $Fs(7,86) \geq 2.76$, $Ps \leq 0.01$). **CONCLUSION:** In adults with overweight and obesity, more prolonged ST was related to poorer inhibitory control and less efficient controlled processes as indicated by more impulsive responding. Our results reveal a novel relationship between sedentary patterns and an aspect of EFs that has been implicated in the maintenance of obesogenic behaviors.

The Role Of BMI On Cognition Following Acute Physical Activity In Preadolescent Children

Lauren Raine¹, Shih-Chun Kao², Eric Drollette³, Matthew Pontifex⁴, Dominika Pindus⁵, Arthur Kramer¹, Charles Hillman¹. ¹Northeastern University, Boston, MA. ²Purdue University, West Lafayette, IN. ³University of North Carolina at Greensboro, Greensboro, NC. ⁴Michigan State University, Lansing, MI. ⁵University of Illinois at Urbana Champaign, Urbana, IL.
 (No relevant relationships reported)

PURPOSE: There is an increasing prevalence of physical inactivity during childhood, concurrent with a rise in obesity rates (as measured by Body Mass Index, BMI), which is associated with a variety of health problems. However, the extent to which increased BMI influences acute physical activity (PA) benefits on cognition in childhood remains unknown. The aim of this study was to examine the relationship of BMI and acute PA on performance of a modified flanker task, which modulates inhibitory control. **METHODS:** In a sample of 116 children pooled from four prior studies (ages 8-11; 51 females), demographic measures of age, sex, IQ, socioeconomic status, and aerobic fitness were considered along with BMI. Children participated in a counterbalanced, randomized crossover study, whereby they completed two different interventions; 20 minutes of restful reading or treadmill walking (60-70% heart rate max). Following each intervention, children performed a modified flanker task to assess inhibitory control. Correlations were conducted to determine the influence of demographic variables, fitness, and BMI on inhibitory control following each intervention. Subsequent hierarchical regression analyses were performed with

significant demographic factors in the first step, aerobic fitness in the second step when significant, and BMI in the final step. **RESULTS:** Analyses indicated that children exhibited improved task performance ($p \leq 0.001$) following the walking intervention, as well as decreased interference ($p = 0.04$), indicating greater benefits following acute PA for the task condition requiring greater inhibitory control. Regression analyses were conducted to examine the influence of BMI on task performance following each intervention. Results revealed that increased BMI was related to decreased performance following acute PA ($p = 0.001$), an effect not seen following restful reading ($p \geq 0.11$). **CONCLUSIONS:** These findings indicate that the beneficial effects following an acute bout of PA on cognition are generalized across conditions of a flanker task, but are selectively greater for the task conditions requiring greater inhibitory control. However, the effects may be blunted in children with higher BMI. These results suggest that indices of inhibition are influenced by PA and adiposity in children.

An Investigation Of Exercise Motivation In Normal Weight And Obese Humans And Rodents

Julia C. Basso¹, Medha K. Satyal¹, Deborah J. Good¹, Daniel F. English¹, Warren K. Bickel². ¹Virginia Tech, Blacksburg, VA. ²Virginia Tech, Roanoke, VA.
Email: jbasso@vt.edu

(No relevant relationships reported)

PURPOSE: The leading causes of morbidity and mortality stem from predetermined factors, but from maladaptive health behaviors that people have the ability to change. One primary example is physical inactivity, which is the fourth leading risk factor for global mortality and is a direct contributor to the global epidemic of obesity. Both the behavioral and neural mechanisms underlying sedentary behavior in healthy and obese populations are unknown, and constitute a major gap in our understanding of health behaviors. Understanding the mechanisms that regulate the motivation for exercise would allow us to devise treatments to target sedentary behaviors in both healthy and obese populations. As a precursor for these studies, the purpose here was to delineate levels of exercise motivation in both humans and a preclinical mouse model of obesity.

METHODS: Self-reported measurements of exercise motivation in humans ($n=727$) was collected via Amazon Mechanical Turk. Voluntary wheel running data was collected in both wild type mice and mice with a targeted deletion of the basic helix-loop-helix (bHLH) gene *Nhlh2* (N2KO), which serve as a preclinical model of obesity. Wheel running data was collected continuously for a period of 21 days as well as after a 72-hour period of wheel deprivation (rebound running response, Basso & Morrell, 2015).

RESULTS: Here, we demonstrate that compared to normal weight controls, exercise motivation is significantly impaired in obese individuals, with normal weight controls reporting higher intrinsically regulated motivations to exercise, and obese individuals reporting higher externally regulated motivations to exercise. Further, we demonstrate that wheel running in rodents is highly motivating and that running motivation is significantly impaired in the N2KO mice.

CONCLUSIONS: Impairments in exercise motivation may be a driver of obese outcomes, which are demonstrated here in both human and preclinical models of obesity. Previous work from our lab has demonstrated that regions of the motivational circuitry including the medial prefrontal cortex regulate the motivation for voluntary wheel running in rodents. We are currently investigating in both wild type and N2KO mice the hypothesis that neural activity in the PFC, modulated by dopamine, regulates the motivation for exercise.

Sleep Parameters During A 12-month Behavioral Weight Loss Intervention With Varying Doses Of Physical Activity: The Heart Health Study

Christopher E. Kline, Renee J. Rogers, FACSM, Nalingna Yuan, John M. Jakicic, FACSM. *University of Pittsburgh, Pittsburgh, PA.*

Email: chriskline@pitt.edu

(No relevant relationships reported)

Obesity is associated with poor sleep. Weight loss following caloric restriction has been shown to improve sleep, but whether physical activity (PA) alongside caloric restriction can augment these improvements is unclear. **Purpose:** To examine whether self-reported sleep parameters improve as a result of a behavioral weight loss intervention that included varying doses of moderate-vigorous PA compared to a diet-only condition. **Methods:** 383 adults with overweight or obesity ($\text{age}=46.2 \pm 7.7$ years; $\text{BMI}=32.1 \pm 3.8$ kg/m²) participated in a 12-month behavioral weight loss intervention and were randomized to one of three conditions: diet alone (DIET; $n=127$); diet plus a moderate dose of MVPA (DIET+MODPA; $n=129$); diet plus a high dose of PA (DIET+HIGHPA; $n=127$). All intervention conditions were prescribed a diet that reduced caloric intake to 1200-1800 kcal/day and received behavioral counseling

targeting weight loss. DIET+MODPA and DIET+HIGHPA conditions were prescribed home-based MVPA that progressed to 150 and 250 min/wk, respectively. Weight and sleep measures were collected at 0, 6, and 12 months. Sleep measures included the Pittsburgh Sleep Quality Index (PSQI) and Epworth Sleepiness Scale (ESS). **Results:** Weight (LS mean [95% CI]) significantly decreased over time (0 months: 90.3 [89.0, 91.7] kg; 6 months: 81.7 [80.4, 83.0] kg; 12 months: 81.2 [79.8, 82.6] kg) ($p < 0.001$), with no difference between groups (Group: $p=0.29$; Group X Time: $p=0.50$). PSQI scores (LS mean [95% CI]) were reduced (i.e., improved) (0 months: 3.0 [2.8, 3.2]; 6 months: 2.8 [2.5, 3.0]; 12 months: 2.8 [2.5, 3.0]) ($p=0.08$), with no difference in the pattern of change by group (Group X Time: $p=0.59$). ESS scores did not change over time ($p=0.98$) in any group. Weight change (adjusting for intervention group) was associated with PSQI change at 6 months ($P < .01$) and 12 months ($P = .001$), but not ESS change at either time point ($P \geq .41$). **Conclusion:** Improvements in sleep quality were primarily associated with weight change in this behavioral weight loss intervention. Physical activity did not result in any additive improvements in sleep quality. In adults with overweight or obesity, enhancing long-term weight loss may be an important target for improving sleep quality. **Support:** National Institutes of Health (R01HL103646)

Analysis Of Physical Activity-Related Smartphone Apps For Behavior Change Potential

Kayla M. Gustek, Kimberly A. Reich. *High Point University, High Point, NC.*

Email: kgustek@highpoint.edu

(No relevant relationships reported)

The majority of Americans do not meet physical activity (PA) guidelines. Adoption and adherence may be improved with personalized intervention. Smartphone app use has increased exponentially in the past decade, extending to many areas of life and crossing socioeconomic status, ethnicity, and gender. Free smartphone apps that address habitual PA may be a useful tool, but their potential to support PA behavior change is not well understood. **PURPOSE:** To evaluate top-ranked free health and fitness apps for PA behavior change potential and to determine the relationship between this evaluation and consumer perceptions of quality, such as app store ranking and consumer ratings. **METHODS:** The top 100 "free" health and fitness apps in the US iOS app store were screened for inclusion. Apps were excluded if the descriptions did not address any aspects of PA or fitness; required an external device, purchase/subscription after a trial period, or a health club membership or specific health insurance. Apps were also excluded if their descriptions was not written in English. Two investigators downloaded and evaluated the remaining apps that met the inclusion criteria using the App Behavior Change Scale (ABACUS). Apps were scored on 21 strategies within 4 categories (knowledge/information, goals/planning, feedback/monitoring, and actions), and prevalence in the sample was calculated. Pearson correlations were estimated for the relationship between ABACUS total scores and relative app ranking, as well as consumer rating. Significance was set at $p < 0.05$. **RESULTS:** 23 apps met the inclusion criteria. 100% offered some form of personalization; 96% incorporated self-monitoring and/or rehearsal; and 70% included options for goal-setting. Only 13% recommended restructuring of the environment, and 4% provided advice on distraction or avoidance. There were no significant correlations between ABACUS score and store ranking ($r^2 = -0.15$, $p = 0.49$) or consumer rating ($r^2 = -0.26$, $p = 0.91$). **CONCLUSIONS:** Free apps may have the potential to support PA behavior change, especially in the areas of planning and self-monitoring. There is no correlation between the total number of evidence-based behavior change strategies and app popularity, however, so it may be beneficial for wellness professionals to counsel patients and clients on app choice.

3469 Board #290 May 29 1:30 PM - 3:00 PM

Determining Participant Compliance In Completing Pre- And Post-exercise Surveys In Real Time Using Smartphones

Kelley Strohacker, FACSM, Paula-Marie M. Ferrara, Cory T. Beaumont. *University of Tennessee, Knoxville, TN.*

Email: kstrohac@utk.edu

(No relevant relationships reported)

Ecological momentary assessment of physical activity and its correlates is often implemented using mobile surveys distributed in a full coverage, semi-randomized

schedule. However, to gather accurate data of temporal dynamics of exercise, proximal pre/post-bout assessments are necessary. Active, smartphone-based self-monitoring is one option, but the feasibility of this approach is unknown. **PURPOSE:** Determine respondent reporting compliance with a one-time request to complete mobile surveys immediately before and after a single bout of exercise. **METHODS:** Enrolled individuals were at least 18 years old, owned a smartphone, and intended to exercise "in the near future." Participants received one email containing web links to a pre-exercise survey (PreS) and a post-exercise survey (PostS), with a request to complete them immediately before/after a bout using their smartphone Internet browser. The PostS contained items to self-report bout duration (SRBD) and lag time between bout completion and opening the PostS (SRLag). Variance in SRLag was assessed using descriptive and frequency analyses. Reporting accuracy was determined by comparing participant-estimated time intervals (PreS time+SRBD+SRLag) and actual time-stamped intervals (PostS time-PreS time) using a Wilcoxon signed-rank test. **RESULTS:** Participants (N=42, 36±13y, 68% women, 80% Caucasian) completed the PreS and PostS within a median of 3 days (interquartile range, IQR:1-6). The SRLag was ≤5-min for 26% of participants, and ≥30-min for 45%. Actual PreS-to-PostS time intervals appeared to be greater than those reported by participants (average rank of 17.48 vs. 13.32; Z=-.1990, p=.047). While the median absolute difference between reported and actual time intervals was 22-min (IQR:3-58), respondents were classified as having differences of <10-min (38%), 11-30-min (26%), and > 30-min (36%). **CONCLUSIONS:** Longer lag times between behavior and self-monitoring may introduce various biases (recall, mood-congruent memory), so it may be sensible to incorporate reminders for reporting goals. Additional research is necessary to explore sources of error regarding discrepancies between expected vs. actual PreS-to-PostS time intervals, as intentional deceit or unintentional misreporting may negatively impact subsequent data analysis.

Exploring Correlates Of Forecasted And Recalled Affective Responses To Acute Aerobic Exercise Using Mobile Surveys
 Cory T. Beaumont, Paula-Marie M. Ferrara, Kelley Strohacker, FACSM. *The University of Tennessee, Knoxville, Knoxville, TN.*
 (No relevant relationships reported)

BACKGROUND: Exercise-related affective valuations (feelings of pleasure/displeasure) purportedly impact exercise-related cognitions and future behavioral decisions. The majority of prior research is laboratory-based, and supports an inverse relationship between affect during exercise (i.e. in-task affect) and ratings of perceived exertion (RPE), both of which may be impacted by an individual's pre-exercise mental states. **PURPOSE:** To explore correlates of forecasted and recalled in-task affect to an acute bout of exercise in free-living conditions. **METHODS:** Participants (N=42, 71% female, 36±12y, body mass index=25±4 kg/m²) were asked to complete an electronic survey via their smartphone immediately before and after a single bout of ambulatory exercise. RPE was measured via Category-Ratio 10 scale, forecasted and recalled in-task affect was measured via 100mm Visual Analog Scale, and the Multidimensional Mood Questionnaire captured the affect circumplex (degrees of valence and arousal). Data for psycho-perceptual variables were non-normally distributed and analyzed with Spearman's rank correlations. **RESULTS:** Forecasted affect was moderately related to recalled in-task affect (p=.57, p<.001). Forecasted and recalled RPE had no significant correlations with forecasted or recalled in-task affect (p's ranged -.05 to -.01, all p's>.73). Forecasted affect was moderately related to pre-exercise ratings of Valence (p=.39, p=.01), Calmness (p=.36, p=.02), and Energetic Arousal (p=.39, p=.01). Low correlation was observed between recalled in-task affect and pre-exercise ratings of Valence (p=.16, p=.29), Calmness (p=.05, p=.76) or Energetic Arousal (p=.15, p=.53). **CONCLUSIONS:** The current data stands contrary to existing literature in that RPE was not significantly related to forecasted or recalled in-task affect. The voluntary, dynamic nature of exercise components in free-living conditions compared to the often-prescribed exercise components in laboratory settings may contribute to this discrepancy. Because individuals can opt to deviate from their initial exercise intentions by making alterations to the mode, duration, or intensity of exercise after beginning a bout, it may be important to create survey items capable of capturing and explaining such incongruencies.

Problematic Smartphone Use Is Negatively Related To Physical Activity In American College Students
 Andrew Lepp¹, Jacob E. Barkley¹, Takahiro Sato², Koji Yamatsu³, Ellen Glickman, FACSM¹. ¹*Kent State University, Kent, OH.* ²*University of Tsukuba, Ibaraki, Japan.* ³*Saga University, Saga, Japan.*
 Email: alepp1@kent.edu
 (No relevant relationships reported)

Multiple studies from our research group examining American adults have conclusively identified smartphone use as a sedentary behavior (SB). However, the same work has repeatedly found no relationship between smartphone use and physical activity (PA). Typically, SB is negatively related to PA. This may not be true of smartphones as the device can displace PA (e.g., watching videos, social media) and also promote PA (e.g., fitness apps, mHealth). Thus, different smartphone behavioral patterns should be considered in relationship to PA. Researchers have recently identified problematic smartphone use as a behavioral pattern motivated by the recurrent craving to use a smartphone. It is an addiction-like behavior leading individuals to use their smartphone compulsively in inappropriate situations such as during classroom lectures, while driving a car, or perhaps in environments intended for PA or planned exercise. Therefore, while total use is not associated with PA, problematic smartphone use may interfere with PA. **PURPOSE:** To assess the relationship between total and problematic smartphone use to PA in a sample of American college students. **METHODS:** A sample of American college students (N = 471, 21.1 ± 2.8 years old) completed validated surveys assessing total daily smartphone use, PA, SB (both assessed via the International Physical Activity Questionnaire) and problematic smartphone use (assessed via the Mobile Phone Problem Use 10-item scale). Pearson's correlations were then performed. **RESULTS:** As in previous studies, there was a significant, positive relationship between total daily smartphone use and SB (r = 0.31, p < 0.001) and no relationship with PA (r = 0.05, p = 0.32). However, while problematic smartphone use was similarly significantly and positively related to SB (r = .26, p < .001) it was also significantly and negatively related to PA (r = -0.18, p < .001). **CONCLUSION:** While prior research and the current study has found no relationship between total smartphone use and PA, this is the first study to assess the relationship between problematic smartphone use and PA. Results suggest that, unlike total daily smartphone use, problematic smartphone use may occur at the expense of PA behavior.

The Relationship Between Cell Phone Use And Motivation To Exercise In College Students
 Tanis J. Walch¹, Ryan E. Doree¹, Jesse L. Rhoades¹, Brianna Black¹, Allison M. Barry². ¹*University of North Dakota, Grand Forks, ND.* ²*Pittsburg State University, Pittsburg, KS.* (Sponsor: James R. Whitehead, FACSM)
 Email: tanis.walch@und.edu
 (No relevant relationships reported)

Previous research has shown that high cell phone usage is associated with sedentary behavior, poor physical fitness, and poor mental health. In today's era of technological advances, most individuals own a smartphone, but those who are college-aged have the highest rate of ownership (94%). Limited research exists on the relationship of smartphone usage on physical activity and mental health. **PURPOSE:** The purpose of this study was to examine the relationship between college students' smartphone usage, exercise motivation, mental health, and physical activity. **METHODS:** College students completed an electronic survey (n=157; female = 135; age = 20.01±1.49; BMI = 24.39 kg/m², SD = 5.7; smartphone use=218.1 min/day, SD = 122.9) that assessed exercise motivation (BREQ-3), physical activity (IPAQ-short), smartphone addiction (SAS-SV), daily smartphone use, height and weight, depression, anxiety, stress (DASS) and fear of missing out (FoMO). Data were analyzed with Pearson correlation and independent t-tests using SPSS. **RESULTS:** Low and high cell phone usage levels were established by splitting participants into two groups based on median usage (180 min/day). Overall, high cell phone users had greater BMI (23.2 vs. 25.5) and depression scores (10.2 vs. 7.1), and lower physical activity (2597.5 vs. 3616.6 min/wk) compared to low cell phone users (p<0.01). Sedentary minutes per week (r=0.24, p<0.01), amotivation (r=0.19, p<0.01), and smartphone addiction risk (r = 0.24, p<0.01) were positively associated to smartphone usage. Introjected (r = -.24, p<0.01), identified (r = -0.28, p<0.001), integrated (r = -0.31, p<0.001), and intrinsic motivation (r = -0.24, p < 0.01) was negatively associated with smartphone usage. High cell phone users had greater amotivation to exercise (t=-3.9, p<0.001), whereas low cell phone users had higher integrated regulation (t=5.3, p<0.001). **CONCLUSIONS:** This study has shown that smartphone usage is related to exercise motivation. Integrated regulation has been shown to be one of the strongest predictors

of exercise duration, which may help to explain why low cell phone users engaged in more weekly physical activity. Future research should examine whether limiting cell phone use will increase motivation to exercise to improve overall quality of life.

3473 Board #294 May 29 1:30 PM - 3:00 PM
Sedentary Behavior And Associations To Portable Screen-Based Device Use And Parental Influence In Rural Children

Jonathan B. Naylor, Beth J. Patton. *Ashland University, Ashland, OH.* (Sponsor: Ronald Otterstetter, Ph.D., FACSM)
 Email: jnaylor2@ashland.edu
 (No relevant relationships reported)

Previous studies from our research group have examined the potential link between portable screen-based devices (i.e., smartphones and tablet computers) and sedentary behavior/physical activity in a primarily suburban population of young children and their parents. It was determined child sedentary behavior was related to portable screen-based device use while physical activity was not. While such relationships were found in a suburban population, rural demographic groups have been shown to differ in both their screen-based device use and physical activity variables suggesting the corresponding associations may also differ.

PURPOSE: To examine screen-based media device (smartphone, tablet, television, video games, computer) use in children and parents from a rural population in relation to sedentary behavior and physical activity.

METHODS: Parents ($N = 7$, 33.57 ± 3.95 years old) completed validated questionnaires assessing average daily total screen use (smartphone, tablet, television, video games, computer), portable screen-based device use (smartphone, tablet), sedentary behavior, and physical activity for both themselves and their children ($N = 7$, 7.00 ± 1.15 years old). Four standard regression models were used to assess the relationship between criterion variables and the following predictor variables: child age, child sex, child average daily sedentary time, and child physical activity. Criterion variables included (a) child portable screen-based device use (Model 1), (b) child total screen use (Model 2), (c) parent portable screen-based device use (Model 3), and (d) parent total screen use (Model 4).

RESULTS: Child sedentary time was significantly ($\beta = 0.92$, $t = 4.65$, $p = 0.04$) and positively associated with parent screen-based device use. Child age, sex, and physical activity were not significantly ($p > 0.05$) related to either parent or child portable or total device use.

CONCLUSION: Contrary to findings in young children from suburban populations, the current results from this limited sample suggest child sedentary behavior was not found to be related to portable screen-based device use in rural children. Furthermore, the data confirms previous findings that parental screen-based device use was predictive of sitting in their children.

Associations Between Screen-time And Depressive Symptoms: Results From CSPPA-2

Chloe Forte¹, Cillian P. McDowell², Sarah Jane Belton³, Wesley O'Brien⁴, Marie Murphy, FACSM⁵, Cormac Powell¹, Catherine Woods¹, Matthew P. Herring, FACSM¹. ¹University of Limerick, Limerick, Ireland. ²Trinity College Dublin, Dublin, Ireland. ³Dublin City University, Dublin, Ireland. ⁴University College Cork, Cork, Ireland. ⁵Ulster University, Belfast, Ireland.
 (Sponsor: Dr. Matthew Herring, FACSM)
 (No relevant relationships reported)

Screen-time (e.g., television, phone, tablet use) has been linked to increased depression and sedentary behaviour. A better understanding of associations between screen-time and depression is critical due to increased levels of screen-time and sedentary behaviour. **Purpose:** As part of a large nationally-representative observational study, the cross-sectional study reported here examined associations between self-reported screen-time and depressive symptoms among 396 adolescents (13.43 ± 0.87 y; 115 female) in primary and second level schools in the Republic of Ireland. **Methods:** Participants completed the Quick Inventory of Depressive Symptomatology and reported the number of days during the prior seven days that spent watching television, on a computer, and on a tablet or smartphone, and, on average, the number of hours spent on these devices on each reported day. One-way ANOVA examined potential sex-related differences in screen-time and depressive symptoms. Linear regression quantified crude and adjusted associations between total weekly hours of screen-time and depressive symptoms. Age, sex, waist circumference, functional disabilities, moderate-to-vigorous physical activity (MVPA), and school status (i.e., whether the school is in a government identified economically disadvantaged location) were included covariates. **Results:** Mean \pm SD hours of screen-time per week and depressive symptoms were 17.33 ± 18.53 and 5.47 ± 4.27 , respectively. Males (18.10 ± 18.73) reported more screen-time than females (15.19 ± 17.77 ; $p = 0.084$). Depressive symptoms did not differ by sex ($p = 0.99$). Total weekly hours of screen-time was significantly, positively associated with depressive symptoms ($\beta = 0.10$, $p \leq 0.05$). After adjustment

for age, sex, waist circumference, functional disabilities, MVPA, and school status, screen-time was significantly, positively associated with depressive symptoms ($\beta = 0.14$, $p \leq 0.006$). MVPA was the only statistically significant covariate in the model ($\beta = 0.11$, $p < 0.04$). **Conclusions:** Screen-time was significantly associated with greater depressive symptoms in Irish adolescents. Lower levels of screen-time and sedentary behaviour should be encouraged to reduce depressive symptoms among adolescents.

Hypohydration And Endurance Performance: A Meta-analysis

Jessica E. Sudock¹, Elizabeth M. Mullin². ¹Shenandoah University, Winchester, VA. ²Springfield College, Springfield, MA.
 (No relevant relationships reported)

PURPOSE: The primary purpose of this meta-analysis was to systematically evaluate the differences in endurance performance while in a hypohydrated state achieved through varying dehydration methods. A secondary purpose was to evaluate the moderation between types of hypohydration (fluid restricted vs. exercise-induced) and changes in heart rate and core temperature.

METHODS: A systematic literature search of databases and specific journals relating to the subject, as well as a forward search with relevant researchers was performed to identify research papers meeting the inclusion criteria.

RESULTS: Eleven total studies met the inclusion criteria including a minimum of 2% hypohydration. All 11 included articles measured heart rate and 6 included articles measured core temperature. The meta-analysis using a random effects model indicated a hypohydration had a significant impact of hydration on heart rate ($ES = -0.42$, $p < .00$) and core temperature ($ES = -0.6$, $p = .017$). Method of dehydration did not significantly moderate the change in heart rate ($p = .59$) or core temperature ($p = .37$).

CONCLUSIONS: Heart rate and core temperature are elevated in a hypohydrated state. Current literature does not suggest that the method of dehydration impacts the elevation of heart rate and core temperature.

3476 Board #297 May 29 2:30 PM - 4:00 PM
Mild Hypohydration Following 24-hour Water Intake Reduction Does Not Affect Anaerobic Power Performance

Peter A. Hosick, Arielle Sheris, Jacklyn S. Alenciewicz, Evan L. Matthews. *Montclair State University, Montclair, NJ.*
 Email: hosickp@montclair.edu
 (No relevant relationships reported)

Hypohydration is common among athletes and can be the result of a failure to maintain hydration between exercise bouts. The negative impact of hypohydration on aerobic performance is well characterized. However, little is known about the effect of hypohydration on anaerobic performance particularly when the hypohydration is the result of insufficient water intake prior to the onset of exercise, not water loss due to body temperature regulation. **PURPOSE:** The purpose of this study was to examine the effect of hypohydration on anaerobic performance following voluntary water intake reduction. **METHODS:** Fifteen healthy adults (8 women, 7 men) completed two exercise sessions, euhydrated (EUD) and hypohydrated (HYP). Subjects were asked to voluntarily limit water intake during the 24-hours prior to the hypohydrated trial. Sessions consisted of baseline anthropometric and blood lactate measurement followed by a 30-second Wingate test and 3 maximum vertical jump trials. The vertical jump trials were completed approximately 1 minute after finishing the 30-second Wingate test and used to measure anaerobic performance in an anaerobically challenged state. Additional blood lactate measurements were taken immediately and at 5, 10, and 15-min post Wingate test. **RESULTS:** The hypohydration protocol resulted in a significant 1.5% reduction in body mass (EUD 69.1 ± 17.2 kg, HYP 68.1 ± 16.6 kg, $p = 0.039$). The 30-sec Wingate peak power (EUD 971 ± 302 W, HYP 960 ± 316 W, $p = 0.578$) was not different between conditions, nor was maximum vertical jump height (EUH 26.4 ± 4.5 cm, HYP 26.6 ± 3.6 cm, $p = 0.778$). Blood lactate ($p \leq 0.001$) was elevated immediately following the 30-sec Wingate test and remained elevated throughout the remainder of the trial. There were no differences in blood lactate between conditions. **CONCLUSIONS:** Acute anaerobic power and exercise performance are not negatively affected by mild voluntary hypohydration during and following a single 30-second Wingate test.

Effects Of Cold Water Intake During A Short Exercise In Heat On Cognitive Function

Somi Yun, Yunbin Lee, Heejin Lee, Jae Gu Hwang, Ah-Reum Jung, Dae Taek Lee. *Kookmin Univ., Seoul, Korea, Republic of.*
 Email: ysmysm7@naver.com
 (No relevant relationships reported)

PURPOSE: This study evaluated the effect of cold water intakes before and during exercise in the heat on the cognitive function in healthy young man. **METHODS:** Ten men (26.3±4.4 yrs, 176.2±5.8 cm, 77.2±14.6 kg) who participated in vigorous exercises at least twice in a week and maximal oxygen capacity estimated by Rockport's 1-mile test was over 32.7 ml/kg/min were recruited. They underwent three testing sessions with different conditions in separate days; cold water (CW, 4 °C), neutral temperature water (AW, 36 °C), and no water conditions (NW). Testing order was randomly assigned and balanced. In each session, they were asked to ingest a prescribed amount of tap water (10 ml/body weight) at rest (1/3 of the total amount) and during exercise (2/3 of the total amount). After resting, they ran on a treadmill for 20 min in a hot environment (39.2±2.1 °C, 41.7±9.4 % relative humidity) at their predicted 75% of maximal heart rate. At 6, 12, and 18 min of exercise of CW and AW, they drank water. Cognitive test was performed 3 times; at rest, immediately after exercise, and after 20 min of recovery, by using Stroop color-word test (SCWT). During resting and exercise, their temperature, heart rate (HR), ratings of perceived exertion (RPE), naked body weight changes, and water intakes were measured. **RESULTS:** The average ear temperature during exercise was 37.2±0.6, 37.5±0.6, and 37.2±0.5 °C, and mean skin temperature was 34.8±2.3, 35.3±1.6, and 34.9±1.2 °C at CW, AW, and NW, respectively (p>0.05). Average HR and RPE was 148.3±14.1, 150.8±15.6, and 149.9±12.7 bpm and 13.3±0.7, 13.0±0.9, and 12.7±1.4 at CW, AW, and NW, respectively (p>0.05). They drank a total of 813±133 ml at CW and 812±130 ml at AW. They lost weight by sweating 493±145, 507±257, and 390±139 ml at CW, AW, and NW, respectively. The reliability of cognitive test was 0.909. The cognition score was 23.5±16.2, 24.3±15.5, and 22.0±11.8 in CW, 24.2±13.5, 28.1±10.4, and 25.1±9.7 in AW, and 17.5±8.3, 22.3±10.6, and 21.1±7.9 in NW, at resting, immediately after exercise, and after recovery, respectively (p>0.05). **CONCLUSIONS:** No advantage of cold water drinking before and during a short bout of exercise in the heat was evident for the cognitive function. The mode, intensity, and duration of exercise may be responsible for the outcomes.

Body Mass And Urinary Hydration Measures During Preseason High School Football Practices In The Heat

Rebecca M. Lopez, Priscila Lamadrid, Candi D. Ashley, Amanda J. Tritsch, Erin M. Moore, Brock Ackerman, Jose Guzman-Ramos, Trey Johnson. *University of South Florida, Tampa, FL.*
 (Sponsor: Douglas J. Casa, FACSM)

(No relevant relationships reported)

Hydration assessment is an important measure to help reduce the risk of exertional heat illness. Maintaining adequate hydration can be problematic for football players practicing in the heat on consecutive days. **PURPOSE:** To examine day to day differences and the relationships between urinary markers of urine color (U_{col}) and urine specific gravity (U_{SG}), and percent body mass loss (%BML) during football practices in the heat. **METHODS:** Thirty-one male high school football players (16 ± 1 years; 181.2 ± 12.0 cm; 68.1 ± 5.4 kg; BMI: 20.8 ± 1.8 km/m²) volunteered to participate in this study. Before and after each practice, players were weighed (in shorts) and provided a urine sample. Urine was assessed for U_{col} and U_{SG} and was assessed by the same person. Correlations assessed relationships, while t-tests assessed differences between both pre-post differences and subsequent days. P value was significant at P<.05. **RESULTS:** Mean wet-bulb globe temperature across 8 practices was 30.6 ± 2.5°C. There were significant correlations between pre- U_{col} and pre- U_{SG} ($r = 0.73$, $p = 0.00$, $n = 209$) and post- U_{col} and post- U_{SG} ($r = 0.66$, $p = 0.00$, $n = 209$). Post- U_{col} (5 ± 1) was significantly greater than pre- U_{col} (4 ± 2; $p = 0.00$). Post- U_{SG} (1.022 ± 0.008) was significantly greater than pre- U_{SG} (1.020 ± 0.008; $p = 0.00$). Post body mass measures were significantly lower than pre-body mass resulting in 0.9 ± 1.1%BML. Post-practice body mass and U_{SG} were not significantly different from the next day's pre-practice measures ($p > 0.05$); however, post- U_{col} was significantly higher (5 ± 2) compared to the next day's pre-practice U_{col} (4 ± 1; $p = 0.000$). **CONCLUSION:** Although the football players' body mass measures were similar on subsequent days, their U_{col} was lighter before the next day's practice. We also found a strong relationship between U_{col} and U_{SG} , suggesting U_{col} is an acceptable hydration measure where U_{SG} is not feasible in field settings. Due to individual variability in these hydration measures, clinicians should provide individualized recommendations to ensure adequate hydration during practices in the heat as well as from one day to the next. *This study was fully funded by the National Athletic Trainers' Association Research & Education Foundation.*

Association Between Free-living Weekday 24-hour Urinary Hydration Markers And Weekend Sleep Measures

Mitchell E. Zaplatosch, Travis Anderson, Eleni M. Karras, Stacey L. Walton, William M. Adams. *University of North Carolina at Greensboro, Greensboro, NC.*
 Email: mezaplat@uncg.edu

(No relevant relationships reported)

PURPOSE: Inadequate sleep and underhydration have been independently associated with adverse health outcomes. However, the relation between hydration status and sleep has yet to be investigated over the course of several days in young adults. Thus, the purpose of this study was to assess the association between 24h urinary hydration markers and both perceived and objective sleep quality. **METHODS:** Eighteen participants (female, $n = 7$; age, 23±3; height, 174.6±15.3cm; body mass, 73.5±15.9kg; body fat, 19.4± 9.4%) provided a 24h urine sample on seven consecutive days for measures of urine volume (U_{VOL}), urine osmolality (U_{OSMO}), urine specific gravity (U_{SG}) and urine color (U_{COL}). Objective sleep metrics (wrist-worn actigraphy) and subjective sleep assessments (Karolinska Sleep Diary) were recorded each day. Actigraph measures included periods of wakefulness after defined sleep onset (WASO), sleep time, wake time, and sleep efficiency. The Karolinska Sleep Diary included nine questions used to assess perceived sleep quality from the previous night. Mean values were calculated for each participant for all variables on weekdays (Monday-Friday) and weekend days (Saturday/Sunday). **RESULTS:** Higher weekday U_{SG} and darker U_{COL} were both associated with greater weekend time spent sleeping (U_{SG} , adj $R^2 = 0.203$, $p = 0.024$; U_{COL} , adj $R^2 = 0.274$, $p = 0.015$). Decreased weekday U_{VOL} was associated with increased weekend time spent sleeping (adj $R^2 = 0.220$, $p = 0.028$). Higher weekday U_{OSMO} was associated with greater weekend WASO actigraph measures (adj $R^2 = 0.205$, $p = 0.045$). **CONCLUSIONS:** Mean 24-hour urinary hydration markers depicting a state of underhydration (elevated U_{SG} and reduced U_{VOL}) across weekdays were associated with an increased number of awakenings during the weekend nights, albeit, having a longer sleep time. Determining how day-to-day variations in hydration status and other general health behaviors influence sleep has yet to be explained.

Change In Physiological Strain And Cognitive Processing Following Electrolyte And Carbohydrate Supplementation

Nathan Deming, Jennifer Richards. *Colorado State University, Fort Collins, CO.*

Email: nate.deming@colostate.edu

(No relevant relationships reported)

PURPOSE: The purpose of this study was to examine the effects of 3 different fluid conditions on hydration, physiological strain index (PSI), and cognitive processing speed during and following a simulated wildland firefighter (WLFF) ingress hike. **METHODS:** 7 subjects (27.4±4yrs, 5M/2F) performed 3 visits of 2hrs of treadmill walking at 3mph/7% grade in an environmental chamber set to 33°C/10% relative humidity. In random order, subjects consumed either water (W), water+electrolyte (GZ), or water+electrolyte+sugar (G) at each visit. Throughout exercise (EX), subjects wore fire-retardant attire, carried a 50lb pack, and drank *ad libitum* to mimic WLFF conditions. Pre and post EX, body mass (BM), fluid consumption, and plasma osmolality (pOsm) were measured. PSI, an calculated index of cardiovascular (CV) and thermal strain, and core temperature (T_C) were recorded every 15mins during EX. Plasma glucose (GLU) was measured every 30mins. Cognitive processing speed, measured via the Stroop Color and Word Test (SCWT), was measured post EX and compared to baseline (BL) values. **RESULTS:** There were no significant differences between fluid conditions (W, GZ, and G) for BM ($\Delta 0.6 \pm 0.2$, 0.9 ± 0.3 , and 0.8 ± 0.2 Kg), fluid consumption (1.9 ± 0.3 , 2.2 ± 0.2 , and 1.9 ± 0.3 L), pOsm ($\Delta 1.2 \pm 5.1$, 9.5 ± 5.4 , and 8.1 ± 2.1 mmol/L), peak PSI (7.6 ± 0.6 , 7.8 ± 0.5 , and 8.6 ± 0.7) and peak T_C (38.8 ± 0.2 , 38.9 ± 0.2 , and 39.1 ± 0.2 °C). Compared to W and GZ, GLU significantly increased in the G condition (107 ± 14 , 107 ± 13 , and 113 ± 11 mg/dL at 60, 90, and 120mins, $P < 0.05$). Compared to BL, SCWT performance significantly decreased in all conditions (204.2 ± 21 , 213 ± 24 , and 222 ± 21 ms, $P < 0.05$). **CONCLUSION:** Fluid condition had no effect on hydration status or physiological strain. Following EX, there was a similar decrease in SCWT in all fluid conditions, indicating a decreased ability to inhibit cognitive interference. Additionally, PSI was higher than previously reported, suggesting that the ingress hike may lead to dangerously high CV and thermal strain in WLFFs. PSI should be monitored (HR and T_C) during ingress hikes by medical staff or supervisors, especially when conditions yield high ambient temperatures. This could aid in reducing the amount of WLFFs that succumb to heat related illness each year. **Grant Funding:** The project was funded by the US Forest Service.

Exploration Of Hydration Practices And Prolonged Endurance Exercise Effects On Plasma Apelin Concentration

Colleen X. Munoz¹, Alex Acosta¹, Logan Edwards¹, Evan C. Johnson², Laura J. Kunces³, Jakob L. Vingren, FACSM⁴, Lawrence E. Armstrong, FACSM⁵, Elaine C. Lee⁵, Jenna M. Bartley⁶. ¹University of Hartford, West Hartford, CT. ²University of Wyoming, Laramie, WY. ³Thorne Research, Summerville, SC. ⁴University of North Texas, Denton, TX. ⁵University of Connecticut, Storrs, CT. ⁶University of Connecticut Health, Farmington, CT. (Sponsor: Jakob Vingren, FACSM)

(No relevant relationships reported)

Reduced circulating concentrations of the endogenous peptide apelin is implicated in many negative health conditions, and apelin administration can reverse sarcopenia processes. While acute and chronic exercise elicits greater circulating apelin concentrations, little attention has been given to apelin's water regulatory roles (i.e., AVP opposition) and manipulation by water intake to enhance human health. **PURPOSE:** We investigated the impact of hydration status and process on plasma apelin following prolonged endurance exercise and after a subsequent water challenge. **METHODS:** Twenty-two male cyclists (age median=54y and range=29-72y) completed a 161km event (mean=26°C, 76%RH; maximum=30°C, 93%RH; mean finish time = 372 ± 93min). Participants were interviewed for dietary intake in the morning and during the ride. Hydration biomarkers included body mass change (BMA), urine specific gravity (U_{sg}) and color (U_{col}), plasma osmolality (P_{osm}) and copeptin (P_{cop}), and apelin (P_{ap}), which were collected before (PRE), immediately after the ride (POST), and 1h following a 650mL water bolus (POST1h). **RESULTS:** P_{ap} paradoxically decreased after exercise (PRE = 1.19 ± 0.29 , POST = 1.02 ± 0.27 ng/mL; $p = 0.04$). It is plausible that hypohydration at POST (according to -1.96% BMA and P_{cop} , U_{sg} , U_{col} ($p < 0.05$), but not P_{osm} ($p = 0.31$)) masked any drive of acute exercise to increase P_{ap} , or that prolonged endurance exercise differentially affects P_{ap} , although POST and POST1h P_{ap} did not correlate with finish time ($p = 0.76$ and 0.31 , respectively). Interestingly, the water bolus did not alter P_{ap} concentrations versus POST (POST1h = 1.0 ± 0.29 ng/mL; $p = 0.66$). POST P_{ap} correlated with PRE P_{osm} ($r = -0.47$), and POST1h P_{ap} with PRE U_{col} ($r = -0.46$; both $p < 0.05$), suggesting baseline hydration might alter P_{ap} responses. Despite previous reports, P_{ap} was not significantly correlated with age at any time point ($p = 0.36$ to 0.73) perhaps due to chronic exercise practices of these cyclists. **CONCLUSIONS:** This real-world scenario demonstrated complex relationships among plasma apelin, exercise, and hydration. Our data suggests insufficient baseline hydration might mitigate the acute exercise-induced P_{ap} elevation. As an increasingly valuable modulator of chronic health, further research should address complexities of P_{ap} responses.

3482 Board #303 May 29 2:30 PM - 4:00 PM

Effects Of Fluid Restriction On Muscular Strength And Fatigue

Sadie L. LaMay, Emily K. Summers, Cory L. Butts. Weber State University, Ogden, UT. (Sponsor: Dr. Brendon P. McDermott, FACSM)

Email: sadielamay@mail.weber.edu

(No relevant relationships reported)

Fluid restriction (FR) is commonly performed by athletes competing in weight-class sports, but the effects of fluid restriction on strength performance remain controversial. **PURPOSE:** To assess the effects of fluid restriction on muscular strength performance and fatigue. **METHODS:** Six participants (age 24 ± 2 y, body mass 87 ± 16 kg, ht 1.7 ± 0.1 m, body fat $18 \pm 8\%$) randomly completed two experimental trials (euhydrated, EU, or FR). FR consisted of three days of graded decreases in fluid intake (1.5 L three days prior, 0.5 L two days prior, and 0.5 L the day prior to the trial). For each trial, participants cycled at 50 W for 10 minutes on cycle ergometer and completed a standardized dynamic warm-up. Participants then performed strength testing on an isokinetic dynamometer involving three repetitions of isometric knee flexion and extension at 70° and 90° and isokinetic contractions at 50 and $150^\circ/\text{sec}$. Next, a fatigue protocol of 30 maximal effort repetitions of isokinetic contractions at $180^\circ/\text{sec}$ was performed, followed by the initial strength testing protocol. **RESULTS:** Body mass was reduced $1.9 \pm 1.3\%$ with FR compared to EU (mean difference: 1.8 ± 1.5 kg, $P = 0.02$). Urine specific gravity was increased following FR (1.025 ± 0.005) compared to EU (1.015 ± 0.008 , $P = 0.02$). Perceived thirst was greater in the FR trial (grand mean, 3.4 ± 1.4) compared to the EU (grand mean, 7.2 ± 0.9 , $P < 0.001$) and rating of perceived exertion tended to be increased in the FR trial (16.1 ± 1.8) compared to the EU (15.1 ± 1.9 , $P = 0.06$, $d = 0.87$). Isometric strength was not different between conditions for extension at 70° ($P = 0.44$, $\eta_p = 0.12$) and 90° ($P = 0.75$, $\eta_p = 0.02$). Isokinetic strength was also not different between conditions at $50^\circ/\text{sec}$ (EU 198.4 ± 50.7 , FR 184.8 ± 38.7 Nm, $P = 0.26$, $\eta_p = 0.24$) and $150^\circ/\text{sec}$ (EU 136.2 ± 35.8 , FR 129.0 ± 41.9 Nm, $P = 0.20$, $\eta_p = 0.31$). During the fatigue protocol, total work completed was not different between conditions (EU 2656 ± 794 , FR 2689 ± 902 Nm,

$P = 0.63$), but, average power demonstrated a moderate-large effect ($d = 0.71$) for reduction in the FR condition (182.6 ± 65.0 W) compared to EU (206.5 ± 58.8 W, $P = 0.14$). **CONCLUSIONS:** These preliminary results suggest FR does not alter muscular strength or fatigue. However, perceptual strain (thirst, exertion) may be increased, requiring a greater effort to produce similar performance.

The Relationship Between Whole-body Heat Exchange And Thermoregulatory Responses During Exercise In The Heat In A Dehydrated State

Margaret C. Morrissey, Gabrielle E.W Giersch, Cody R. Butler, Douglas J. Casa, FACSM. Korey Stringer Institute, University of Connecticut, Storrs, CT. (Sponsor: Douglas Casa, FACSM)

Email: MARGARET.MORRISSEY@UCONN.EDU

(No relevant relationships reported)

Whole-body heat loss has been extensively examined during exercise in hot environments. Interestingly, the relationship between predicted heat balance parameters and thermoregulatory strain have been limited to individuals in a euhydrated state. As dehydration has been shown to exacerbate thermal and cardiovascular strain, it is imperative to examine whether dehydration modulates heat exchange during exercise in the heat and its relationship to physiological responses to exercise in the heat. **PURPOSE:** to examine whether predicted heat balance parameters explain variance in core temperature (T_{core}) and heart rate (HR) responses to exercise in the heat following 24 h of fluid restriction. **METHODS:** 8 participants (4 males and 4 females; age: 19 ± 2 yrs; VO_{2max} : 47.4 ± 6.5 ml/kg/min; body mass: 61.5 ± 9.4 kg; height: 166.7 ± 7.5 cm) performed a 30-min bout of treadmill running and walking in the heat (32°C , 55% relative humidity) under two conditions: 1) 24 h of fluid restriction (DEH) and 2) euhydration (EUH). Participants exercised at 11W/kg for 15 min followed by 7W/kg for 15 min, which were derived via indirect calorimetry. T_{core} was continuously assessed through rectal thermometry and HR was measured at the end of each intensity. Metabolic heat production (M-W), dry heat loss (DHL), and evaporative requirement (E_{req}) were calculated for both exercise intensities. Pearson correlation coefficients were utilized to examine the relationship between M-W, DHL, E_{req} and T_{core} , change in T_{core} (ΔT_{core}), HR, and change in HR (HR) under DEH and EUH. Linear regressions were performed for all significant correlations. Statistical significance was set at $p \leq 0.05$. **RESULTS:** M-W and DHL were not correlated with T_{core} , ΔT_{core} , HR, or HR in DEH or EUH at 11W/kg . At 7W/kg under DEH, DHL was negatively correlated with T_{core} ($R^2=0.54$, $p=0.05$) and HR ($R^2=0.67$, $p=0.024$). All other heat balance parameters were not correlated with physiological responses at 7W/kg in DEH or EUH. **CONCLUSION:** In this preliminary dataset, E_{req} and M-W did not explain variance in physiological responses during DEH. DHL under DEH explained 67% of the variance in post HR and 54% of the variance in T_{core} at 7W/kg . Therefore, DHL may contribute to the variation in physiological strain during low intensity exercise in the heat under DEH.

3484 Board #305 May 29 2:30 PM - 4:00 PM

Sex Differences In Response To Passive Dehydration Via 24-h Fluid Restriction

Gabrielle E. W. Giersch, Margaret C. Morrissey, Cody R. Butler, Douglas J. Casa, FACSM. University of Connecticut, Storrs, CT. (Sponsor: Douglas Casa, FACSM)

Email: gabrielle.giersch@uconn.edu

(No relevant relationships reported)

Dehydration is a known stressor on the human body. It has been previously observed that a proportion of individuals may live in a chronic state of mild dehydration, either due to physical activity and lack of proper rehydration, or due to low habitual fluid consumption. This state of chronic dehydration propagated by low fluid consumption can be simulated via passive dehydration and fluid restriction. Physiological responses to fluid restriction have previously been investigated in men, leaving sex differences or unique responses in women uninvestigated. **Purpose:** The purpose of this investigation was to assess differences in response to 24-h fluid restriction (FR) between men and women. **Methods:** Eleven participants ($n=5$ male: 21 ± 3 y, 69.97 ± 8.4 kg, 172.4 ± 3.8 m; $n=6$ female: 20 ± 2 y, 57.04 ± 3.62 kg, 163 ± 4.9 m) underwent passive dehydration via 24-h FR one time for men, and twice for women. Females were tested in the late follicular and mid-luteal phases of the menstrual cycle (days 12-14 and 19-21, respectively). Body mass loss assessed via nude body mass, plasma osmolality (P_{osm}), and blood pressure were assessed pre- and post-FR. During FR participants also collected their urine which was assessed for urine color (U_{col}), urine specific gravity (USG), osmolality (U_{osm}), and volume (L). **Results:** No differences were found in this preliminary data set between men and women for body mass loss (%BML; male: 1.28 ± 1.14 , female: $.68 \pm 1.2$, $p=.407$), plasma osmolality post-FR (male: 291 ± 4 mOsmo $\cdot\text{kg}^{-1}$, female: 294 ± 3 mOsmo $\cdot\text{kg}^{-1}$, $p=.319$), U_{col} (male: 5 ± 2 , female: 6 ± 1 , $p=.594$), USG (male: 1.026 ± 0 , female: 1.027 ± 0 , $p=.862$), urine volume (male: $0.30 \pm .47$ L, female: 0.16 ± 0.20 L, $p=.501$), or U_{osm} (male: 805 ± 313 mOsmo $\cdot\text{kg}^{-1}$, female: 740 ± 115 mOsmo $\cdot\text{kg}^{-1}$, $p=.621$). The only differences present between male

and female participants were in pre-FR P_{osm} (male: 293 ± 4 mOsmo·kg⁻¹, female: 286 ± 3 mOsmo·kg⁻¹, p=0.05). **Conclusion:** These preliminary data show no sex differences in response to 24-h FR, but this ongoing investigation and full dataset seeks to fully elucidate possible differences in response to FR simulating chronic mild dehydration that can affect young physically active, as well as elderly populations. Character Count: 1885/2000

**Renal Stress Responses To Work In The Heat
 Comparing Different Hydration Regimens**

Rachel A. Backes, Whitley C. Atkins, Samantha L. Thomas, Colin E. Glenny, Abby L. Flynn, Rachel M. Held, Brendon P. McDermott, FACSM. *University of Arkansas, Fayetteville, AR.*
 Email: rbackes@uark.edu
 (No relevant relationships reported)

Workplace safety organizations recommend that workers predicted to incur heavy sweat loss should consume a 'sport drink' during work. These sugar-sweetened beverages (SSB) often include fructose, which can lead to acute kidney injury (AKI), especially when combined with hypohydration. **PURPOSE:** Investigate the effect of SSB on renal stress in response to simulated industrial work in the heat, while maintaining euhydration. **METHODS:** Twenty male participants (24 ± 2y, 179 ± 6cm, 24.7 ± 9.0% body fat) completed two randomized, matched trials of simulated industrial work (2-hr total; two 45-min work and two 15-min rest bouts) in the heat (30°C, 55% RH). Equal amounts of SSB or placebo were provided during rest and within 2-hr of completing work. Urine specific gravity (USG), heart rate (HR), and rectal temperature (T_{rec}) were monitored throughout trials. Serum [Na⁺], hemoglobin, and hematocrit levels were measured at baseline, pre- and post-work, and 16-hr post-work. Urinary kidney injury molecule-1 (uKIM-1) and urinary neutrophil gelatinase-associated lipocalin (uNGAL) were measured pre- and post-work, 3-hr and 16-hr post-work. Total urine volume was measured for 16-hrs following work. Change in plasma volume (ΔPV) was calculated using the Dill & Costill equation. **RESULTS:** There was no significant trial difference in USG (p=.277) or HR (p=.209), but post-work (p≤.011) and 16-hr post-work USG were elevated compared to baseline (p=.043) and 3-hr post-work (p=.001). There was no difference in maximum T_{rec} achieved between trials (SSB 38.84 ± 0.52°C; placebo 38.68 ± 0.40°C; p=.330). Serum [Na⁺] was elevated post-work compared to baseline and 16-hr post-work (p=.006), but there was no trial difference (p=.612). There was no trial difference in hemoglobin (p=.650) or hematocrit (p=.637). uKIM-1 was elevated post-work and 16-hr post-work compared to baseline (p≤.028) and 3-hr post-work (p≤.009), but showed no trial difference (p=.126). uNGAL 3-hr post-work was significantly lower than baseline (p=.011), but showed no trial difference (p=.992). There was no significant trial difference in total urine volume (p=.277) or ΔPV (p=.098). **CONCLUSION:** These findings indicate that beverage type did not affect renal stress biomarkers following simulated industrial work in the heat when euhydration was maintained.

Research has been limited and mixed with regards to the effect of normal, short-term dietary sodium (Na) intake on sweat Na concentration ([Na]) and total sweat Na losses during exercise.

Purpose:

To determine the relation between dietary Na intake during exercise and up to 48-h before exercise on whole-body (WB) sweat [Na] and total sweat Na loss during 90 min of moderate-intensity cycling in the heat.

Methods:

Forty-nine recreational athletes (34 men, 15 women; 34 ± 4 years; 75 ± 12 kg) cycled for 90 min at 78 ± 5% HR_{max} in the heat (32°C, 25-50% RH). The WB washdown technique was used to collect sweat electrolytes during exercise and ion chromatography analysis was used to determine sweat [Na]. Total sweat Na loss was the product of WB sweat [Na] and WB sweat loss. Subjects were instructed to consume their normal diet before their trials. Upon arriving to the lab, each subject turned in a diet log, which included specific portion sizes and brand/type for all foods,

fluids, and dietary supplements consumed in the previous 48 h. The investigators reviewed the diet logs for completeness with the subjects. Na intake was determined by Registered Dietitians using a computer based dietary analysis tool. Na intake during the trial was determined from the volume of 6% carbohydrate electrolyte (38 mmol/L Na) solution consumed *ad libitum*. Pearson correlation analysis was used to determine the relation between Na intake versus WB sweat [Na] and total sweat Na loss. Data are shown as mean ± SD.

Results:

WB sweat [Na] was 41.1 ± 15.6 mmol/L and total sweat Na losses were 60.9 ± 35.3 mmol. Na intake during exercise, 24-h and 48-h before exercise were 32.4 ± 18.0 mmol, 188 ± 102 mmol, and 350 ± 159 mmol. There were no significant correlations between dietary Na intake and WB sweat [Na] (r = -0.002 to 0.02, p=0.90-0.99) or total sweat Na losses (r = 0.07 to 0.19, p=0.20-0.61) for any of the comparisons.

Conclusion:

There were no correlations between normal dietary Na intake during and up to 48 h before exercise versus WB sweat [Na] or total sweat Na losses. These results suggest that short-term Na intake does not play a significant role in explaining the inter-individual differences in WB sweat Na during exercise.

**Exogenous Fluid Delivery Schedule And Composition
 On Fluid Balance And Substrate Use In The Heat**

Alejandro M. Rosales, Walter S. Hailes, Alexander N. Marks, Patrick S. Dodds, Brent C. Ruby, FACSM. *University of Montana, Missoula, MT.*

(No relevant relationships reported)

Hydration position stands outline suggested volume considerations but remain somewhat ambiguous regarding frequency parameters. **PURPOSE:** To determine the effects of micro-dosing or bolus-dosing plain water (MW, BW, respectively) or a carbohydrate-electrolyte solution (MCE, BCE, respectively) on fluid retention and carbohydrate oxidation during exercise in the heat. **METHODS:** In a repeated measures cross-over design, males (n=8, 80.3 ± 11.8 kg, VO₂ peak 53 ± 5.0 ml·kg⁻¹·min⁻¹) completed four 2-hour trials (treadmill, 1.3 m·s⁻¹ at a 5% grade) in a heat chamber (33°C and 30% RH) with a 15 kg pack. Fluids were delivered to equal 100% of a pre-determined hourly fluid loss familiarization trial. Micro-dosed fluids were provided at 22 doses·h⁻¹ (49 ± 13 ml·dose⁻¹), while bolus-dosed fluids were provided at 1 dose·h⁻¹ (1075 ± 274 ml·dose⁻¹). CE trials delivered 67 ± 17 g CHO·hr⁻¹ and 939 ± 239 mg Na⁺·hr⁻¹. Nude body weight, urine volume, and urine specific gravity (USG) were recorded during and 1-hour post exercise. Steady state expired air samples were collected to evaluate rates of carbohydrate oxidation. A two-way ANOVA with repeated measures was used to determine differences. Statistical significance was established at p < 0.05. **RESULTS:** Total body weight loss was similar across all four trials (-0.60 ± 0.25, -0.53 ± 0.17, -0.67 ± 0.34, and -0.50 ± 0.27 kg, for the BCE, MCE, BW, and MW trials, respectively, p > 0.05). Cumulative urine output was similar across all four trials (725 ± 478, 779 ± 494, 818 ± 507, 718 ± 446 ml, for the BCE, MCE, BW, and MW trials, respectively, p > 0.05). USG was additionally similar across all trials at 0, 60, 120, and 180 minutes (n=7, 1.008 ± 0.006, 1.008 ± 0.007, 1.007 ± 0.007, 1.008 ± 0.006, p > 0.05). Carbohydrate oxidation was significantly higher in the CE trials when compared to the W trials (1.5 ± 0.3 and 0.8 ± 0.2, g·min⁻¹, p < 0.05) but was not different between dosing styles of the same composition (1.6 ± 0.3 and 1.5 ± 0.3 g·min⁻¹ for BCE and MCE; 0.8 ± 0.2 and 0.8 ± 0.3 g·min⁻¹ for BW and MW, p > 0.05). **CONCLUSION:** These data demonstrate minimal differences in overall fluid retention and substrate oxidation during exercise in the heat across varied fluid composition and delivery intervals. **Heat Load, Cooling Methods And Hydration Of Sailors
 During Summer Training Camp In Japan**

Dalya Navot Mintzer, Eyal Shargal, Rotem Kislev Cohen. *Wingate, Netanya, Israel.* (Sponsor: Naama Constantini, FACSM)

Email: mmayan@yahoo.com

(No relevant relationships reported)

Purpose: Weather forecasts for the upcoming Olympic Games in Tokyo predict hot and humid conditions, which have a negative effect on performance. Our aim was to

estimate the heat load sensation and efficacy of cooling methods using self-reports, and by measuring parameters of hydration status of Olympic-level 470 sailors and windsurfers, during a training camp in the summer of 2019 in Japan.

Methods: Seven females (4 windsurfers, 3 sailors 470) and 4 males (470 sailors), age 21.17y ± 1.4, used cooling vests, plates, and collars before and in-between training races. Weather conditions were measured using Kastrel 5500. Athletes scored their heat load sensation on a scale of 1 – “comfortable” to 5 – “unbearably hot” after each practice. Following the use of different cooling accessories, the athletes were asked to rate cooling method efficiency between 1 – “not efficient” to 5 – “very efficient”. Hydration status, was assessed by urine specific gravity (USG) prior to each training, body weight change and fluid intake measure during training sessions.

Results: During the 8 training days the average weather conditions were: heat index 26.3°C ± 3.7; humidity 84% ± 7%; and temperature 27.7°C ± 1.5°C. Average sea training duration was 221min ± 66 for sailing and 177min ± 34 for windsurfing. Although the heat index did not change, the heat load sensation rating was affected by wind speed – rated as 2.5 when the wind speed was above 8 knots and 4 with lower wind speed (P < 0.002). Using cooling vests before and between races was rated as efficient (4). Cooling plates (inserted under the life vests) and a cooling collar were somewhat less efficient (3.5 and 3.1 respectively). Athletes were well hydrated before training (average USG 1.009 ± 0.007), and maintained good hydration during training (average fluid consumption of 2Lit ± 0.9 and average weight loss of 0.05Kg ± 0.55).

Conclusions: High humidity with a moderate heat index was measured at the area of the Tokyo Olympic Sailing Arena during July 2019. The athletes reported high heat load sensation during training and found different cooling methods efficient. Higher wind speed decreased the heat load sensation, probably due to the acceleration of sweat evaporation. High awareness and prior training in a hot environment like Israel may contribute to improved drinking behavior and hydration status.

Sweat Rate Variability Between Training Sessions

JohnEric W. Smith, Marissa L. Bello, Brandon D. Shepherd, Payton L. Williamson. *Mississippi State University, Mississippi State, MS.* (Sponsor: Stanley Brown, FACSM)
Email: johneric.smith@msstate.edu

(No relevant relationships reported)

Practitioners regularly develop hydration plans for athletes based on measured sweat rate. Often times, this is a single measure utilized over various training sessions without consideration for sweat rate variability.

PURPOSE: The purpose of this study was to investigate sweat rate variation in self-selected training sessions to assess the potential error that might be seen when determining sweat rate.

METHODS: Eleven endurance trained runners (7 competitive and 4 recreational) arrived at the research facility once a week over four weeks. Upon arrival, researchers recorded athlete's body mass. Athletes then completed a running workout lasting a minimum of 30 minutes exercise time. Pace and distance were left to the individual runner's preference for the training session. Immediately upon run completion, researchers reassessed the runners' body mass. Difference in body mass pre- to post-run was reported as sweat rate as no fluid or beverage were ingested during the run. The highest and lowest sweat rate recorded for each individual during the four-week period were used for comparison. Paired sample t-tests were used to compare run duration, run distance, running pace, WBGT, and sweat rate with significance set a priori at P < 0.05.

RESULTS: There were no differences in run duration (41.3 ± 11.0 min; p = 0.68), run distance (8.13 ± 2.85 km; p = 0.94), run pace (5.11 ± 0.78 min/km; p = 0.07), or WBGT (21.9 ± 1.4°C; p = 0.41) between trials. Participants highest sweat rate recorded during the four-week period was significantly higher 1.08 ± 0.39 l/h compared to the lowest of 0.89 ± 0.32 l/h, (p = 0.003).

CONCLUSIONS: Assessing sweat rate is a useful tool for aiding in the determination of fluid intake during exercise however, a single point assessment may not accurately capture an individual's typical rate. Caution needs to be taken when relying on a single assessment or extrapolating to longer training sessions even in similar conditions.

²Qatar University, Doha, Qatar. ³Southern Cross University, Coffs Harbour, Australia. ⁴University of Technology Sydney, Sydney, Australia. ⁵Rugby Australia, Sydney, Australia.
Email: l.taylor2@lboro.ac.uk

(No relevant relationships reported)

PURPOSE: Characterise player core temperature (Tc) across a World Rugby Women's Sevens Series (WRWSS) tournament day and determine the efficacy of commonly

employed cold water immersion (CWI) protocols. **METHODS:** Tc was measured in twelve elite female rugby sevens athletes across 3 games (G1-3) from day 1 of the Sydney WRWSS tournament. Exertional heat illness symptoms, perceptual scales, CWI details, playing minutes, external load data (measured by Global Positioning Systems) and wet globe temperature (range: 18.5–20.1°C) were also collected. Linear mixed models and magnitude-based inferences were used to assess differences in Tc between periods [G1-3 and warm-ups (WU)]. **RESULTS:** Average Tc was very likely lower (ES; ±90% CL, -0.33; ±0.18) in G1 compared to G2. Peak Tc was very likely (0.71; ±0.28) associated with increased playing time. CWI did not remove the accumulated Tc due to WU and match-play activity (~1–2°C rise in Tc still present compared to Tc at WU onset for players ≥ 6 min match-play). **CONCLUSIONS:** Elite female WRWSS athletes experienced high Tc during WU (Tc peak 37.9–39.0°C) and matches (Tc peak 37.9–39.8°C), a magnitude known to reduce intermittent high-intensity physical performance (≥39°C). The CWI protocol resulted in players (≥ 6 min match-play) with a ~1–2°C raised Tc compared to Tc at WU onset.

Patch Application Timing And Adherence Duration Effects On Local Sweating Rate And Sweat Electrolyte Concentrations

Kelly A. Barnes¹, Ryan P. Nuccio¹, Shyreltha Brown¹, Adam J. Reimel¹, Corey T. Ungaro¹, Peter J.D. De Chavez², Lindsay B. Baker, FACSM¹. ¹Gatorade Sports Science Institute, PepsiCo, Inc, Barrington, IL. ²PepsiCo R&D, Barrington, IL.
Email: kelly.barnes1@pepsico.com

Reported Relationships: **K.A. Barnes:** Salary; PepsiCo, Inc. Ownership/interest/stock; PepsiCo, Inc. Other (please describe); This study was funded by the Gatorade Sports Science Institute, a division of PepsiCo, Inc. The views herein are those of the authors and do not necessarily reflect the position or policy of PepsiCo.

Sweat testing is often conducted to assist with electrolyte replacement plans for athletes. However, the effect of patch application timing and on-skin duration on local sweating rate (LSR) and sweat electrolyte concentrations is unclear. **Purpose:** To determine the effect of patch application timing and on-skin duration on LSR and local sweat [Na⁺], [K⁺], and [Cl⁻]. **Methods:** Thirty-nine recreationally trained (VO₂ max: 47.1 ± 7.8 ml/kg/min) athletes (27 M, 12 F; 75.4 ± 12.4 kg) cycled at ~80% HR_{max} in the heat (32°C, 39% rh). Prior to (PRE) and 15 min into exercise (EX), two sweat patches were applied to the left and right mid-back, respectively. The patches were removed after a skin adherence duration of 30 (SHORT) or 70 (LONG) min. LSR was equated from sweat mass over patch surface area (11.9 cm²) and duration. Sweat was centrifuged and analyzed for [Na⁺], [K⁺], and [Cl⁻] by ion chromatography. A two-way repeated measures ANOVA was used to determine the effect of patch application timing (PRE vs. EX), duration (SHORT vs. LONG), and interaction effects on each variable, followed by Tukey post-hoc where main effects were found. Significance was set at p < 0.05. **Results:** There was an interaction effect with EX LONG and EX SHORT > PRE LONG > PRE SHORT for [Na⁺] (56.8 ± 21.6, 58.5 ± 22.3 > 50.7 ± 20.1 > 46.8 ± 19.6 mmol/L, p < 0.0001), [Cl⁻] (55.2 ± 23.5, 53.5 ± 25.1 > 38.2 ± 21.7 mmol/L, p < 0.0001), and LSR (1.4 ± 0.3, 1.6 ± 0.6 > 1.1 ± 0.3 > 0.8 ± 0.4 mg/cm²/min, p < 0.0001). There were no significant differences for [K⁺] between EX LONG, EX SHORT, PRE LONG, AND PRE SHORT (3.8 ± 0.6, 4.0 ± 0.9, 3.6 ± 0.6, 3.3 ± 0.6 mmol/L, p = 0.79). **Conclusion:** The on-skin duration did not affect sweat [Na⁺] and [Cl⁻] when patches were applied during exercise. However, applying patches prior to exercise resulted in lower sweat [Na⁺] and [Cl⁻], especially when removed after a short duration. This was likely due to lower LSR during the ramp up to steady state sweating. Therefore, practitioners should take patch application timing into account when interpreting sweat electrolyte results. Local sweat [Na⁺] and [Cl⁻] measured from patches applied prior to exercise may not be representative of concentrations during the full bout of exercise. However, more research is needed to determine the impact of patch timing in the context of whole body sweat [Na⁺] and [Cl⁻] estimations.

Cross-validation Of Whole Body Sweat Sodium Prediction Equations

Lindsay B. Baker, FACSM¹, Ryan P. Nuccio¹, Adam J. Reimel¹, Shyreltha Brown¹, Corey T. Ungaro¹, Peter JD De Chavez², Kelly A. Barnes¹. ¹Gatorade Sports Science Institute, Barrington, IL. ²PepsiCo R&D, Barrington, IL.
Email: lindsay.baker@pepsico.com

Reported Relationships: **L.B. Baker:** Salary; Gatorade Sports Science Institute, PepsiCo Inc. The views expressed in this abstract are those of the authors and do not necessarily reflect the position or policy of PepsiCo, Inc..

We have previously published regression equations to estimate whole body (WB) sweat sodium concentration ([Na]) from regional (REG) measures; however, a cross-validation is needed to corroborate the applicability of these prediction equations

between studies. **PURPOSE:** To determine the validity of published regression equations (Baker et al. 2018) in predicting WB sweat [Na] from REG measures when applied to a new data set. **METHODS:** Forty-nine recreational athletes (34 men, 15 women; 75±12 kg) cycled for 90 min while WB sweat [Na] was measured using the washdown technique. Exercise intensity (82% HR_{max}) and environmental conditions (32°C, 39% rh, 2.4 m/s air flow) were similar to the 2018 study in which the prediction equations were developed. REG sweat [Na] was measured from seven regions using absorbent patches (3M Tegaderm+Pad, 10 cm²). Regression equations from Baker et al. 2018 were applied to REG sweat [Na] to determine predicted WB sweat [Na]. Bland-Altman analysis of mean bias (raw and predicted minus measured) and 95% limits of agreement (LOA) were used to compare raw (uncorrected) REG sweat [Na] and predicted WB sweat [Na] to measured WB sweat [Na]. **RESULTS:** Mean±SD WB sweating rate was 0.94±0.32 L/h and measured WB sweat [Na] was 41±16 mmol/L. Mean bias (±95% LOA) between raw REG sweat [Na] and measured WB sweat [Na] was 10(±20), 0(±19), 9(±20), 22(±25), 23(±24), 0(±15), -4(±18) mmol/L for the dorsal forearm, ventral forearm, upper arm, chest, upper back, thigh, and calf, respectively. The mean bias (±95% LOA) between predicted WB sweat [Na] and measured WB sweat [Na] was 3(±14), 4(±12), 0(±14), 2(±17), -2(±16), 5(±13), 4(±15) mmol/L for the dorsal forearm, ventral forearm, upper arm, chest, upper back, thigh, and calf, respectively. **CONCLUSIONS:** The use of regression equations enables prediction of WB sweat [Na] within a mean bias of 0-5 mmol/L and within a 95% LOA of ±12-17 mmol/L across all sites. By contrast, the use of raw REG [Na] increases the mean bias to 9-23 mmol/L for the dorsal forearm, upper arm, chest, and upper back, and increases the 95% LOA to ±15-25 mmol/L across all sites. Regression equations improve the accuracy of estimating WB sweat [Na] from REG measures and are therefore recommended for use in Na balance studies and field tests to determine individualized sweat electrolyte losses.

Gender Differences Of Sweat Rates In Endurance Trained Athletes

Marissa L. Bello, Brandon D. Shepherd, Ffion G. Price, Peyton L. Williamson, JohnEric W. Smith. *Mississippi State University, Mississippi State, MS.* (Sponsor: Stanley P. Brown, FACSM)
(No relevant relationships reported)

Adequate fluid replacement around exercise is an important consideration for endurance athletes. While sex-based differences in maximal sweat rate have been identified, sex-based differences in sweat rate variability between training sessions is less understood. **PURPOSE:** The purpose of this study was to observe differences in sweat rate in endurance-trained males and females. **METHODS:** Endurance-trained males (n=4) and females (n=14) completed training sessions lasting a minimum of 30 minutes once per week. Body mass was collected before and immediately after exercise. Total sweat loss (TSL) was calculated from changes in body mass. TSL and duration of exercise were used to calculate absolute sweat rate (ASR), and subsequently relative sweat rate (RSR). Heat stress was recorded using a WBGT, with temperatures ranging from 9.21-23.65°C. Data were analyzed using two-sample T-tests to evaluate differences between the maximum ASR and RSR between male and female runners. Significance was set a priori at P<0.05. **RESULTS:** Males had a significantly higher ASR than females (1.46±0.36 vs. 0.89±0.21 L/h; p<0.001). Males and females did not differ for RSR (0.018±0.004 vs. 0.014±0.004 L/kg/h; p=0.116). **CONCLUSION:** This observational study indicates males had a significantly higher ASR compared to females but similar RSR. Despite lack of significance in RSR, these results correspond with previous studies demonstrating sex differences due to differences in total body surface area. These results suggest sex should be a consideration when implementing different hydration strategies.

3494 Board #315 May 29 2:30 PM - 4:00 PM
Thermoregulatory Impairments Imposed By Men's Lacrosse Equipment In The Heat

Whitley C. Atkins, Ikuo Kato, Mahendran Balasubramanian, Brendon P. McDermott, FACSM. *University of Arkansas, Fayetteville, AR.* (Sponsor: Brendon P. McDermott, FACSM)
(No relevant relationships reported)

Exertional heat illness remains one of the leading causes of death in sport, especially in hot and humid conditions. Previous research has shown an impairment in thermoregulation while wearing American football and hockey equipment. However, the effects of men's lacrosse protective equipment have yet to be determined. **PURPOSE:** Investigate the effect of men's lacrosse equipment on thermoregulatory responses during simulated lacrosse exercise in the heat (30°C, 50% RH). **METHODS:** Sixteen male volunteers (21.8 ± 3.2y, 76.2 ± 8.9kg, 181.3 ± 6.1cm) with previous equipment intensive sport experience completed one trial while wearing protective lacrosse equipment (shoulder and elbow pads, gloves and helmet; EQ) and one trial without equipment (shorts and jersey; NEQ). Trials included 60-min of simulated lacrosse exercise separated into four 12-min sessions, each separated by four-min of rest. Hydration status was maintained by replenishing fluid loss throughout

trials. Rectal temperature (T_{rec}), heart rate (HR), mean weighted skin temperature (T_{skin}), rating of perceived exertion (RPE), and thermal sensation (TS) were assessed during rest breaks. Physiological strain index (PSI) was calculated as previously described. Paired samples t-tests or repeated measures analyses of variance, with Bonferroni post-hoc testing were used to identify significant differences (p≤0.05). **RESULTS:** There was no significant difference in T_{rec} between trials (p=0.084), however, maximum T_{rec} achieved was greater in EQ (39.3 ± 0.7°C) compared to NEQ (39.0 ± 0.7°C; p=0.016). Regardless of time point, HR (p≤0.001) and PSI (p=0.004) were significantly greater in EQ compared to NEQ. T_{skin} was significantly elevated in EQ compared to NEQ throughout trials (p≤0.001). Perceptually, EQ increased RPE (p=0.003) and TS (p=0.012) compared to NEQ throughout trials. Urine specific gravity (USG) following trials was not significantly different between trials (p=0.151). **CONCLUSION:** Trial differences in T_{rec}, HR and perceptual measures suggest a greater impairment in thermoregulation while wearing men's lacrosse equipment in the heat. Supervising entities for men's lacrosse should mandate heat acclimatization periods similar to those in place for American football to ensure athlete safety.

3495 Board #316 May 29 2:30 PM - 4:00 PM
Measured Versus Heart Rate-Derived Core Temperature During Outdoor Work In The Southeastern United States

Anne M. Mulholland, Hillary A. Yoder, Zackary S. Ciccone, Jonathan E. Wingo, FACSM. *The University of Alabama, Tuscaloosa, AL.* (Sponsor: Jonathan E. Wingo, FACSM)
(No relevant relationships reported)

Climate change is increasing the number of hot days to which outdoor workers are exposed, thereby increasing their risk of heat illness. Currently, continuous monitoring of core temperature (T_c) is expensive, invasive, and impractical. The BioModule is a non-invasive physiological monitor that uses heart rate to provide an estimation of T_c, but its accuracy is unknown. **PURPOSE:** To test the association between measured gastrointestinal temperature (T_{GI}) and estimated core temperature (T_{c-est}) from the BioModule device during outdoor work in a hot environment. **METHODS:** Twenty groundskeepers (18 men; mean±SD age = 38±8 y, body mass index = 31.5±7.5 kg/m²) swallowed an ingestible temperature sensor and strapped on a BioModule before work. T_{GI} was collected every 15 minutes during the workday; T_{c-est} was determined by a 1-min average from the same time of day. Data collection occurred in Alabama during July and August (31.4±3.1 °C WBGT). Relationship between T_{GI} and T_{c-est} was quantified using the repeated measures correlation coefficient (r_{rm}). Agreement (bias±1.96 SD) between T_{GI} and T_{c-est} was evaluated using the Bland-Altman method for repeated observations. **RESULTS:** There was a moderate, positive relationship between T_{GI} and T_{c-est} (r_{rm} = 0.56, p < 0.001). Agreement analysis indicated that T_{c-est} overestimated T_{GI} (0.28±0.58 °C). The error between T_{c-est} and T_{GI} was larger at lower temperatures, as indicated by a strong negative trend (Pearson's r = -0.73). **CONCLUSION:** The BioModule provides an estimation of T_c that may be helpful as a guide during outdoor work in hot environments but should not be used for safety considerations or measurement of T_c. Funded by the Deep South Center for Occupational Safety and Health, a National Institute for Occupational Safety and Health Education and Research Center.

Sweat Electrolytes: Influence Of Environment, Sex And Exercise Intensity

Melinda Millard-Stafford, FACSM, Michael L. Jones, Teresa Snow, Nicholas W. Shea. *Georgia Institute of Technology, Atlanta, GA.*
 Email: mindy.millardstafford@ap.gatech.edu
Reported Relationships: M. Millard-Stafford: Consulting Fee; The Coca-Cola Company. Industry contracted research; Study was funded by The Coca-Cola Company.

Sweat electrolytes: Influence of environment, sex and exercise intensity. Mindy Millard-Stafford FACSM, Michael L. Jones, Teresa K. Snow, and Nicholas W. Shea. School of Biological Sciences, Georgia Institute of Technology, Atlanta, GA. Sweat rate and electrolyte loss are highly variable among individuals; but sources of intra-individual variability due to test conditions remain to be quantified. **PURPOSE:** To determine the impact of exercise intensity and environment on sweat electrolyte losses in men and women. **METHODS:** Twenty adult women and men completed two sessions during summer months: 3 x 20 min intermittent cycling beginning at low intensity (50/75 Watts) with 25 W increases in work rate under hot-humid (35°C, 60%RH) or hot-dry (35°C, 20%RH) conditions. Whole body sweat rate, regional sweat [Na⁺] and [K⁺] were obtained at each work rate. Sweat was acquired via Opsite (Brisson method) on the scapula. Electrolytes were measured using Horiba LAQUATwin Ion meters. **RESULTS:** Sweat rate and [Na⁺] was significantly higher (p<0.001) due to increased RH in the heat and incremental changes in exercise intensity. Compared to low exercise intensity, sweat [Na⁺] increased by 26 (72%) and 39 mmol (108%) with successive 25W increases, similar in relative magnitude to

sweat rate increases of 0.4 l/min (67%) and 0.6 l/min (100%) compared to low exercise intensity. However, $[Na^+]$ difference due to greater %RH of environment (60% vs. 20%RH) was only 7.7 mmol (14%) higher for all bouts combined. Sweat $[K^+]$ was not different ($p=0.4$) based on environment, but significantly higher ($p=0.003$) under low intensity exercise compared to higher work rates ($6.9 \pm 1.9 > 6.0 \pm 1.4$ mmol). When work rate was matched (75W) under humid conditions, no differences between men and women were observed in sweat rate (0.8 ± 0.3 l/min) or sweat sodium (49.2 ± 17.2 vs. 52.7 ± 30.0 mmol, respectively). **CONCLUSION:** At matched low intensity exercise, sex differences in sweat sodium and rate were not observed. Intra-individual variability in sweat sodium is influenced more by modest incremental changes (25 W) in exercise intensity than the ambient humidity in hot conditions. Sweat testing of athletes using field techniques should carefully consider the intensity of the training session to accurately translate results.

Core Temperature And Blood Lactate Kinetics After Graded Exercise Testing In The Heat

J. Luke Pryor¹, Robert G. Leija², Peter Lao³, Canelaria Cruz², Sergio Perez, Jr², Jacobo Morales², Kristen Cochrane-Snyman³.
¹University at Buffalo, Buffalo, NY. ²California State University, Fresno, Fresno, CA. ³Concordia University, Chicago, IL.
(No relevant relationships reported)

Utility of a verification trial to confirm maximal oxygen intake (VO_{2max}) in the heat is unclear and initial studies are needed to explore recovery duration between the initial graded exercise test (GXT) and the verification trial to ensure verification trial fidelity.

PURPOSE: To compare the recovery kinetics of gastrointestinal temperature (T_{gi}) and blood lactate (BLA) after a GXT in the heat between trained and untrained cyclists. **METHODS:** Trained ($n=10$; age: 22.6 ± 2.2 y; body fat: $15.4 \pm 5.8\%$) and untrained ($n=11$; age: 23.4 ± 2.9 y, body fat: $21.1 \pm 5.8\%$) male cyclists volunteered. T_{gi}, BLA (finger prick), expired gases, and power output (watts; W) were continuously measured during the GXT in a heated chamber (39°C, 31%RH). After the GXT, subjects exited the chamber and rested in a temperate room (22°C, 40%RH) until T_{gi} returned to pre-GXT values (defined as "recovery") at which point BLA was re-assessed. Separate independent t-tests assessed differences in W, VO_{2max} , and recovery duration between groups. Separate 2 by 3 (training status [trained vs. untrained] time [pre-GXT, post-GXT, recovery]) repeated measures ANOVAs evaluated changes in T_{gi} and BLA with Tukey post hoc tests ($\alpha = 0.05$). **RESULTS:** As expected, the trained cyclists GXT was longer (709 ± 81 vs. 610 ± 98 s; $p=0.02$) and achieved greater peak power output (278 ± 32 vs. 238 ± 32 W; $p=0.009$) and VO_{2max} (57.2 ± 7.7 vs. 40.5 ± 5.5 mL/kg/min; $p<0.001$) than untrained. Recovery time was longer for trained subjects (50 ± 5.4 vs. 43.5 ± 10.2 min; $p=0.10$) but this difference did not reach significance. Pre-GXT and recovery T_{gi} was higher in untrained (37.5 ± 0.3 and $37.4 \pm 0.2^\circ C$) versus trained (37.1 ± 0.2 and $37.2 \pm 0.2^\circ C$; $p<0.01$) with both groups achieving similar post-GXT values (untrained: 37.8 ± 0.2 ; trained: $37.7 \pm 0.2^\circ C$; $p=0.37$). BLA at recovery (trained: 6.2 ± 0.7 ; untrained 7.0 ± 2.4 mmol/L) was lower than Post-GXT (trained: 12.8 ± 1.9 ; untrained 13.3 ± 2.9 mmol/L) but remained higher than Pre-GXT (trained: 2.3 ± 0.3 ; untrained 3.3 ± 1.5 mmol/L) in both groups ($p<0.001$) with no group main effects ($p \geq 0.08$). **CONCLUSIONS:** The thermoregulatory system managed the GXT-induced thermal load faster than the metabolic system cleared BLA. If verification trials in the heat are employed, extended recovery durations appear necessary regardless of training status.

Background. We have previously shown that 7d of New Zealand Blackcurrant (NZBC) supplementation reduces the gastrointestinal barrier permeability response that normally accompanies exertional heat stress. **Purpose.** To determine the effect of NZBC supplementation on inflammatory capacity and apoptotic drive in peripheral blood mononuclear cells (PBMC) collected before and after exertional heat stress. **Methods.** Twelve men (Age: 28 ± 6 years, Stature: 1.81 ± 0.07 m, Mass: 80.5 ± 9.8 kg, VO_{2max} : 56 ± 6 mL \cdot kg $^{-1}$ \cdot min $^{-1}$) ingested 2 capsules of CurraNZ™ (210 mg anthocyanin

day $^{-1}$) or a visually matched placebo (microcrystalline cellulose) for 7d prior to a 1h treadmill run (65% VO_{2max}) in hot ambient conditions (34°C / 40% RH). PBMC were isolated from EDTA plasma samples that were collected before (Pre), after (Post), 1h after (1-Post) and 4h after (4-Post) exercise. Inflammatory capacity was calculated as the ratio between phosphorylated and total NF- κ B content in cell lysates. Apoptotic drive was calculated as the ratio between BAX and BCL-2 in cell lysates. Caspase 9 was measured to provide additional confirmation. Western blot data were analysed with two-way (Condition x Time) RM-ANOVA with Duncan post-hocs. **Results.** The p-NF- κ B:NF- κ B ratio was reduced following 7d NZBC supplementation (-46%, $p=0.03$). Post hoc analysis indicated p-NF- κ B:NF- κ B content at 4-Post had fallen below values at Post (-24%, $p=0.02$) and 1-Post (-60%, $p=0.04$). The BAX:BCL-2 ratio was increased following 7d NZBC supplementation (+106%, $p<0.01$). Post hoc analysis indicated the BAX:BCL-2 ratio increased from Pre to Post exercise (+119%, $p=0.01$) in NZBC and remained elevated (above Pre) at 1-Post (+77%, $p=0.04$) and 4-Post (+59%, $p=0.04$). Caspase 9 content also increased following 7d NZBC supplementation ($p<0.05$). Post hoc analysis indicated elevated Caspase 9 content at PRE in NZBC (+86%, $p<0.01$), with differences between conditions being resolved by 4-Post exercise ($p=0.94$). **Conclusions.** Study data suggest 7d NZBC supplementation may reduce inflammatory capacity and increase apoptotic drive in PBMC. This might call nascent leukocytes into circulation to ensure maintenance of the putative inflammatory response that accompanies exertional heat stress. However, the exact physiologic relevance of these changes remains to be determined.

Muscle Temperature During Exercise Under Whole-body Heating And Limb Heating Conditions

Jian Cui, Cheryl Blaha, Samuel Pai, Jonathan Carter Luck, Lawrence I. Sinoway. Pennsylvania State University College of Medicine, Hershey, PA.
Email: jcui@pennstatehealth.psu.edu
(No relevant relationships reported)

Prior studies suggest that moderate whole-body heating (WBH), which raises internal temperature (T_{core}) ~0.6-1.0 deg C, alters the exercise pressor reflex. It is speculated that elevated muscle temperature (T_{muscle}) alters the sensitivity of muscle afferents. However, less is known about the effects of passive WBH on the limb T_{muscle} during exercise. **PURPOSE:** To determine limb T_{muscle} during exercise under passive WBH and limb heating conditions. **METHODS:** Forearm T_{muscle} was measured with a needle probe (thermocouple) in 8 healthy subjects (57 ± 3 yrs). Mean skin temperature (T_{sk}), T_{core} (telemetric pill), the arm skin temperature (T_{armskin}, not covered by suits), blood pressure (BP) and heart rate (HR) were measured during WBH with water perfused suits. After T_{core} rose ~0.6 deg C, subjects performed a fatiguing handgrip exercise followed by post exercise circulatory occlusion (PECO). In a separate visit, the forearm was heated with a water perfused sleeve. After the T_{muscle} rose ~1 deg C (i.e. similar to that seen during WBH), the exercise paradigm was repeated. **RESULTS:** Passive WBH significantly raised T_{sk} (3.2 ± 0.3 deg C), T_{armskin} (1.9 ± 1.0 deg C), T_{muscle} (0.96 ± 0.15 deg C) and HR. The increases in T_{muscle} were positively correlated with the increases in T_{core} ($R = 0.75$, $P < 0.05$). Limb heating raised T_{muscle} (0.98 ± 0.11 deg C), T_{armskin} (2.3 ± 0.6 deg C), and did not alter T_{sk}, T_{core} or HR. There was no significant difference in the grip force, grip time, or the change in HR with handgrip between the trials. The increases in T_{muscle} during the last min of grip (0.37 ± 0.07 vs. 0.92 ± 0.17 deg C, $P < 0.03$) and PECO ($P = 0.01$) were significantly lower during WBH than during the limb heating trial. **CONCLUSION:** Although local limb heating and WBH induced similar elevations in T_{muscle}, the responses in T_{muscle} to exercise were different between these two heating conditions. Supported by NIH R01 HL141198 (Li and Cui) and UL1 TR002014 (Sinoway), and AHA Award #15GRNT24480051 (Cui).

Verification Bout Criteria In The Heat: A Training Status Comparison

Kristen Cecilia Cochrane-Snyman¹, Peter Lao², Robert Leija³, Candelaria Cruz², Sergio Perez Jr.², J. Luke Pryor¹. ¹Concordia University Chicago, River Forest, IL. ²Fresno State, Fresno, CA. ³University of California, Berkeley, Berkeley, CA. ⁴University at Buffalo, Buffalo, NY.
(No relevant relationships reported)

The use of verification bouts (VRF) to confirm maximal oxygen consumption (VO_{2max}) in thermoneutral conditions is well established. Less is known about the utility of VRF in the heat. The impact of a hot environment may affect trained and untrained subjects differently. Data demonstrating the impact of heat on repeat bouts of high-intensity exercise may be useful for individuals performing an unaccustomed activity in the heat. **PURPOSE:** To compare VO_{2} , heart rate (HR), and rating of perceived exertion (RPE) from a graded exercise test (GXT) vs. VRF in trained vs. untrained subjects. **METHODS:** Aerobically trained (T) ($n=10$) and untrained (UT) ($n=11$) college-aged males volunteered. Baseline gastrointestinal temperature (T_{gi})

and resting $\dot{V}O_2$, RPE, and HR values were collected then subjects rested in a heated chamber (39°C, 31% relative humidity) for 20 min before completing the GXT. Post-GXT, subjects exited the chamber and rested in a thermoneutral room (22°C, 40%RH) until Tgi returned to baseline. Subjects re-entered chamber and repeated pre-GXT procedures prior to VRF. For VRF, subjects warmed-up cycled at 60% maximal wattage (W_{max}) from GXT and then cycled at 110% W_{max} until exhaustion. $\dot{V}O_2$, HR, and RPE values from the last complete min were used for comparison. A 2×2 [(T vs. UT) \times (GXT vs. VRF)] mixed-factor ANOVA with Bonferroni post hoc tests and an alpha of 0.05 was used for analysis. **RESULTS:** $\dot{V}O_2$: trained cyclists $\dot{V}O_{2max}$ was greater than untrained (56.4 \pm 8.6 vs. 40.1 \pm 5.9 mL \cdot kg $^{-1}$ \cdot min $^{-1}$, $p < 0.001$); $\dot{V}O_2$ during GXT was greater than VRF for both groups ($p = 0.013$, $\eta^2 = 0.29$). HR: subjects had significantly higher HR during GXT vs. VRF (T:188 vs. 178 bpm; UT:189 vs. 181 bpm; $p < 0.001$, $\eta^2 = 0.74$) and HR was not significantly different between groups ($p = 0.77$). RPE: There was a significant trial \times training interaction ($p = 0.04$, $\eta^2 = 0.21$), and a significant main effect for training status with trained cyclists expressing higher RPE than untrained in GXT & VRF (19 vs. 18; 19 vs. 17; $p = 0.002$). **CONCLUSION:** The results indicated that RPE may be tied to $\dot{V}O_2$ more than HR in the heat in trained subjects. $\dot{V}O_2$ during VRF in the heat was less than $\dot{V}O_{2max}$ in all subjects during GXT which may confirm $\dot{V}O_{2max}$ or indicate premature fatigue due to heat. Thus, a VRF may not be necessary for the determination of $\dot{V}O_{2max}$ in the heat for untrained subjects.

Post-exercise Passive Heating Strategies Improve $\dot{V}O_{2max}$, Running Economy, And Lactate Threshold

Bryant R. Byrd¹, Joyce S. Ramos², Claire Drummond², Jonathan W. Specht¹, Angelo K. Valenciana¹, Lance C. Dalleck¹. ¹Western Colorado University, Gunnison, CO. ²Flinders University, Adelaide, Australia.
Email: bbyrd@western.edu
(No relevant relationships reported)

$\dot{V}O_{2max}$, running economy, and lactate threshold have long been established as physiological determinants of endurance performance. Strategies to optimally improve these parameters have therefore been of much interest to endurance athletes. **PURPOSE:** To determine the effects of post-exercise passive heating strategies with hot water immersion and sauna suits on $\dot{V}O_{2max}$, running economy, and lactate threshold. **METHODS:** Participants (see table for physical characteristics) were randomized into three standardized 3wk exercise training groups: 1) exercise training alone - control (N=10), 2) exercise training with immediate post-exercise hot water immersion (N=10), and exercise training with immediate post-exercise sauna suit (N=10). At baseline and post-program participants completed a running economy protocol and maximal exercise testing protocol to measure $\dot{V}O_{2max}$ and lactate threshold. The running economy protocol consisted of three consecutive 5-minute stages: stage 1 = 4.6 mph, stage 2 = 5.0 mph, and stage 3 = 5.4 mph. **RESULTS:** After 3wk, mean $\dot{V}O_{2max}$ and lactate threshold changes in the sauna suit and hot water immersion groups were significantly greater ($p < 0.05$) when compared to the control group (see table). The hot water immersion group showed significant within-group improvements ($p < 0.05$) in economy between baseline and 3wk for all three stages (see table), although there were no between group differences ($p > 0.05$). **CONCLUSION:** Both post-exercise passive heating strategies were equally effective at increasing $\dot{V}O_{2max}$ and lactate threshold values. Additionally, despite the absence of between-group statistical significance, preliminary evidence suggest post-exercise hot water immersion may be a more effective strategy at improving running economy relative to wearing a sauna suit after exercise.

Table. Physical and physiological characteristics at baseline and 3wk for control, sauna suit, and hot water immersion groups. (Values are mean \pm SD).

Parameter	Control group (N=8)		Sauna suit group (N=7)		Hot water immersion group (N=9)	
	Baseline	3wk	Baseline	3wk	Baseline	3wk
Age (yr)	26.6 \pm 11	—	24.8 \pm 17	—	22.9 \pm 11	—
Height (cm)	165 \pm 29	—	168.6 \pm 30	—	177.7 \pm 3	—

Endurance Exercise Capacity & Heat-loss Responses Are Greater In The Late Evening Than Morning

Hidegori Otani¹, Mitsuharu Kaya², Heita Goto³, Akira Tamaki². ¹Himeji Dokkyo University, Himeji, Japan. ²Hyogo University of Health Sciences, Kobe, Japan. ³Kyushu Kyoritsu University, Kitakyushu, Japan.
Email: hotani@himeji-du.ac.jp
(No relevant relationships reported)

Various major sporting events in the heat of summer start from not only in the morning but also in the late evening. However, to date rationales for differences in endurance exercise capacity and thermoregulatory responses to exercise in the heat between morning and late evening have not been reported. **PURPOSE:** The current study investigated the diurnal effects of exercise in the late morning and evening on endurance exercise capacity and thermoregulatory responses during a time-to-exhaustion test in the heat. **METHODS:** Ten male participants cycled at 70% peak oxygen uptake until exhaustion in the heat (30°C, 50% relative humidity). Participants commenced exercise in the late morning at 10:00 h (AM) or evening at 21:00 h (PM). Upon cessation of exercise, participants completed a 30 min post-exercise recovery. **RESULTS:** Time to exhaustion was 28 \pm 13% (mean \pm SD) longer in PM (49.1 \pm 16.3 min) than AM (38.7 \pm 14.6 min; $P < 0.001$). Rectal temperature before and during exercise were higher in PM than AM (both $P < 0.01$) in accordance with the diurnal variation of core temperature (T_c). The rates of rise in rectal temperature (AM 0.030 \pm 0.012°C/min; PM 0.021 \pm 0.008°C/min), mean skin temperature (AM 0.095 \pm 0.042°C/min; PM 0.068 \pm 0.028°C/min), thermal sensation and rating of perceived exertion during exercise were slower in PM than AM (all $P < 0.05$). Rectal temperature at the point of exhaustion was not different by time-of-day (AM 38.3 \pm 0.4°C; PM 38.6 \pm 0.5°C). Dry and evaporative heat losses and an increase in skin blood flow during exercise were greater in PM than AM (all $P < 0.05$). During 30-min post-exercise recovery, the rates of fall in rectal temperature (AM 0.013 \pm 0.004°C/min; PM 0.019 \pm 0.010°C/min) and skin blood flow were faster and thermal sensation was lower in PM than AM (all $P < 0.05$). Heart rate during exercise and recovery were not different between trials. **CONCLUSION:** This study indicates that endurance exercise capacity is greater and heat-loss responses to control T_c during and following exercise in the heat are more effective in the late evening than morning. Moreover, perceived fatigue during exercise and thermal perception during and following exercise are lower in the late evening than morning.

Effect Of Heat On Serum And Plasma Brain-derived Neurotrophic Factor During Aerobic Exercise

Tori D. Hargett, Ryan T. Wiet, Elliot Arroyo, Emily C. Tagesen, Ellen L. Glickman, FACSM, Adam R. Jajtner. Kent State University, Kent, OH. (Sponsor: Ellen L. Glickman, FACSM)
(No relevant relationships reported)

Exercise has been found to promote the release of brain-derived neurotrophic factor (BDNF). Literature suggests that BDNF is upregulated in the periphery post aerobic exercise. There is evidence that shows BDNF plays a role in temperature regulation, however, it is still unclear if BDNF will rise in the heat as compared to thermoneutral conditions following aerobic exercise. Evidence has also shown that plasma and serum BDNF may be independent of each other. Therefore, investigating this difference may lead to a better understanding of the post aerobic exercise BDNF response. **Purpose:** The purpose of this study was to examine temperature related effects on BDNF during aerobic exercise in different environmental conditions along with differences between serum and plasma BDNF. **Methods:** Six recreationally active college aged men (26 \pm 3 years) completed a $\dot{V}O_{2max}$ test (48.6 \pm 5.7 mL/kg/min) and performed experimental trials in 35°C at 45% humidity (HT/MH) and 22°C at 45% humidity (MT/MH). During each trial, participants cycled for 60-minutes at 60% of $\dot{V}O_{2max}$, rested for 15-minutes, cycled until exhaustion at 90% $\dot{V}O_{2max}$, then recovered for 60-minutes. Blood was obtained before exercise (PRE), after 60 minutes of cycling (60), after the TTE (90), and after recovery (REC). Serum and plasma BDNF were assessed via ELISA, while data was analyzed using a mixed model regression, with significance defined as $\alpha < 0.05$. **Results:** There was no significant condition by time interaction ($F = 0.602$, $p = 0.618$) nor main effect of condition ($F = 1.792$, $p = 0.189$) or time ($F = 1.949$, $p = 0.139$) for serum BDNF concentrations. There was also no significant condition by time interaction ($F = 0.272$, $p = 0.845$) nor main effect of condition ($F = 0.415$, $p = 0.523$) or time ($F = 1.070$, $p = 0.373$) for plasma BDNF concentrations. **Conclusions:** This data suggests high temperature does not have an effect on the BDNF response in serum or plasma concentrations. Nor does this study give evidence to an upregulation of BDNF concentrations due to aerobic exercise, though further work is warranted. *This study was partially funded by the Kent State University Research Council.*

3505 Board #326 May 29 2:30 PM - 4:00 PM

The Effect Of Hydration Status And Ice Water Dousing On Heart Rate Variability Prior To And During Intermittent Exercise In The Heat

Yasuki Sekiguchi, Courtney L. Benjamin, Cody R. Butler, Margaret C. Morrissey, Erica M. Filep, Rebecca L. Stearns, Douglas J. Casa, FACSM. *Korey Stringer Institute, University of Connecticut, Storrs, CT.* (Sponsor: Douglas J. Casa, FACSM)
Email: yasuki.sekiguchi@uconn.edu
(No relevant relationships reported)

PURPOSE: Determine the effect of hydration status and ice water dousing on heart rate variability (HRV) prior to and during intermittent exercise in the heat.

METHODS: Ten team sport athletes (mean [M]± standard deviation [SD]; age, 21±1; body mass, 69.8±7.7kg; height, 175.0±7.3cm; VO_{2max} , 54.5±6.8ml·kg⁻¹·min⁻¹) performed a soccer simulated intermittent exercise treadmill protocol in the heat (ambient temperature, 33°C; relative humidity, 50%) with four conditions: Euhydrated without dousing (EuND), Dehydrated without dousing (DeND), Euhydrated with dousing (EuD), and Dehydrated with dousing (DeD). Resting HRV (LnRMSSD) was measured prior to (PRE) and between intermittent exercise (MID) for 5 min. Repeated measures ANOVA was used to examine the differences of HRV in each condition followed by post-hoc with LSD. 95% confidence intervals (95%CI) were calculated. Significance was set a-priori p<0.05.

RESULTS: Percent body mass loss for each condition at MID was MID-EuND (-0.9±1.8%), MID-DeND (-3.3±1.7%), MID-EuD (-0.8±1.1%), and MID-DeD (-2.4±2.2%). There were no differences between PRE-EuND (M±SD, 1.7±0.5 ln ms), PRE-DeND (M±SD, 1.8±0.9 ln ms), PRE-EuD (M±SD, 2.0±0.6 ln ms), and PRE-DeD (M±SD, 19.7±0.2 ln ms) (p>0.05). However, MID-EuND (M±SD, 1.9±0.8 ln ms) was significantly lower than MID-EuD (M±SD, 2.8±0.6 ln ms, 95%CI=-1.7- -0.2, p=0.021) and MID-DeND (M±SD, 1.6±0.5 ln ms) was significantly lower than MID-DeD (M±SD, 2.8±0.7 ln ms, 95%CI=-1.8 - -0.6, p=0.002). Furthermore, MID-DeND was significantly lower than MID-EuD (95%CI=-1.8 - -0.7, p=0.001) and MID-EuND was significantly lower than MID-DeD (95%CI=-1.9 - -0.1, p=0.037). **CONCLUSIONS:** There were no differences in HRV between euhydration and dehydration prior to exercise. However, ice water dousing increased HRV regardless of hydration status at the middle of intermittent exercise. Thus, ice water dousing, which is practical and time efficient, might lead to improved recovery at the middle of intermittent exercise in the heat.

3506 Board #327 May 29 2:30 PM - 4:00 PM

INFLUENCE OF HYDRATION STATUS ON RUNNING PERFORMANCE IN HIGH SCHOOL CROSS COUNTRY RUNNERS

Joshua Granger, Nathan Lemoine, Derek Calvert, Arnold Nelson, FACSM, Neil Johannsen, Guillaume Spielmann. *Louisiana State University, Baton Rouge, LA.* (Sponsor: Arnold Nelson, FACSM)
Email: jgrang6@lsu.edu
(No relevant relationships reported)

Adequate hydration is crucial for athlete's health and performance. Although the impact of hypohydration on professional athletes have been well characterized, there is a dearth of information on the effect of hypohydration on younger populations, such as high school athletes, specifically cross-country runners in a hot and humid environment. **Purpose:** To characterize the effects of hydration status on running performance in high school cross-country runners and determine if a simple hydration plan can improve hydration status. **Methods:** 15 high school cross-country runners (9 males, 6 females; 15.5 ± 1.2 yrs) participated in this study. The study took place over a two-week period with baseline testing (V1, V3) and a 5km running performance trials (V2, V4) occurring after school during normal practice hours, with V1 (V3) and V2 (V4) separated by 3 days. A simple hydration strategy of 32oz. of water in the morning and evening preceding the 5km performance trial was implemented to enhance the hydration status of the athletes. Changes in performance between V2 and V4 were determined by 5km completion time, and hydration status was determined by pre- and post-run urine specific gravity using a spectral refractometer. Changes in core temperatures in response to 5km runs were measured on V2 and V4 using core temperature pills. **Results:** Participants were significantly hypohydrated at rest (USG; V1 = 1.031 ± 0.008, V2 = 1.033 ± 0.006, V3 = 1.030 ± 0.007), but the simple hydration strategy implemented after V3 significantly improved hydration in V4 (resting USG = 1.024 ± 0.008; p<0.001). The average 5km performance times were not significantly different between V2 and V4 (V2:1613.3±224.4 sec, V4:1716.2±176.1 sec), however changes in resting hydration status between V2 and V4 were significantly correlated with improvements in 5km performance time (p=0.02, Pearson's r=0.63). Changes in core temperature from pre- to post-practice was significantly lower in V2 than V4 (V2:+0.79±0.7 °C, V4:+0.86±1.35 °C; p=0.04). **Conclusion:** High school cross-country runners are hypohydrated, and a simple

hydration plan can improve hydration status. Improved hydration was correlated to lower performance times in our cohort of young athletes. The findings support that high school athlete's hydration status is of concern and should be monitored.

The Effects Of Acute Thermoneutral And Hot Water Immersion On Cerebrovascular Reactivity

Emma L. Reed¹, Morgan L. Worley¹, Nathan J. Klaes¹, Jacqueline C. Dirr², Dziana Vertsiakhoukaya¹, Manjot Sandhur¹, Zachary J. Schlader³, Blair D. Johnson, FACSM¹. ¹The University at Buffalo, Buffalo, NY. ²Loyola University Chicago, Chicago, IL. ³Indiana University, Bloomington, IN. (Sponsor: Blair Johnson, FACSM)

(No relevant relationships reported)

Repetitive hot head-out water immersion increases peripheral vascular function and non-immersion cerebral artery blood velocity. However, it is not known if an acute bout of hot head-out water immersion (HOWI) improves cerebrovascular function (i.e., cerebrovascular reactivity (CVR)). **PURPOSE:** We tested the hypothesis that CVR is greater during and following hot (HOT) vs. thermoneutral (TN) HOWI. **METHODS:** Twelve healthy participants (age: 22±2 y, 6 females) completed two randomized trials which consisted of 30 min of HOT (39°C) or TN (35°C) HOWI. Beat-to-beat blood pressure (MAP), middle cerebral artery blood velocity (MCAv), and the partial pressure of end-tidal CO₂ (PETCO₂) were recorded continuously. After 5 min of seated baseline, participants breathed hypercapnic gas (3, 5, and 7% CO₂ for 3 min each) in a stepwise fashion. CVR testing was completed pre, 30 min into HOWI (during), and immediately post-HOWI. CVR was calculated as the slope of the linear regression line by plotting MCAv versus PETCO₂. **RESULTS:** MAP (HOT: 84±6 vs. TN: 83±9 mmHg; P=0.95), MCAv (HOT: 66±10 vs. TN: 66±14 cm/s; P=0.50), PETCO₂ (HOT: 43±2 vs. TN: 43±3 mmHg; P=0.41) and CVR (HOT: 1.66±0.30 vs. TN: 1.82±0.50 cm/s/mmHg; P=0.16) were not different between HOT and TN at baseline. MAP was different between HOT and TN during (HOT: 80±9 vs. TN: 89±12 mmHg; P<0.01) and post (HOT: 84±9 vs. TN: 95±9 mmHg; P<0.01). MCAv was not different between HOT and TN during (HOT: 64±12 vs. TN: 71±13 cm/s; P=0.48) and post (HOT: 67±13 vs. TN: 70±15 cm/s; P=0.79). PETCO₂ was not different between HOT and TN during (HOT: 44±3 vs. TN: 45±3 mmHg; P=0.69) or post (HOT: 43±3 vs. TN: 43±3 mmHg; P=0.74). CVR was not different between HOT and TN during (HOT: 1.62±0.4 vs. TN: 2.01±0.61 cm/s/mmHg; P=0.22) and during post (HOT: 1.51±0.69 vs. TN: 1.77±0.64 cm/s/mmHg; P=0.43). **CONCLUSION:** These preliminary data indicate that cerebrovascular reactivity is not improved during an acute bout of hot water immersion compared to thermoneutral water immersion. Further investigations should examine if repetitive hot water immersion improves cerebrovascular reactivity. Supported by Office of Naval Research Award N00014-17-1-2665

3508 Board #329 May 29 2:30 PM - 4:00 PM

Cerebral Autoregulation Is Not Different Between Hot And Thermoneutral Head-Out Water Immersion In Healthy Participants

Morgan L. Worley¹, Emma L. Reed¹, Jacqueline C. Dirr², Zachary J. Schlader, FACSM³, Blair D. Johnson, FACSM¹. ¹University at Buffalo, Buffalo, NY. ²Loyola University Chicago, Chicago, IL. ³Indiana University, Bloomington, IN. (Sponsor: Blair D. Johnson, FACSM)

(No relevant relationships reported)

Recurring hot head-out water immersion (HOWI) enhances peripheral vascular function and cerebral blood velocity during non-immersion conditions (i.e., rest, aerobic exercise, and heat stress). However, it is not known if an acute bout of hot HOWI alters cerebrovascular function (i.e., cerebral autoregulation). **PURPOSE:** We tested the hypothesis that dynamic cerebral autoregulation is improved during and following an acute bout of hot (HOT) vs. thermoneutral (TN) HOWI. **METHODS:** Seventeen healthy participants (age: 23±2 y, 5 females) completed two randomized trials which consisted of 30 min of HOT (39°C) or TN (35°C) HOWI. Beat-to-beat blood pressure (MAP), middle cerebral artery blood velocity (MCAv), and end-tidal CO₂ tension (PETCO₂) were recorded continuously. After 5 min of seated rest, participants breathed through a respiratory impedance device for 5 min while maintaining PETCO₂ values to assess cerebral autoregulation using Fourier transformation (n = 11). Cerebral autoregulation testing was completed pre, 30 min into HOWI (during), and immediately post HOWI. Values are reported as a change from baseline (α: mean ± SD). **RESULTS:** MAP, MCAv, PETCO₂, gain, and phase were not different between HOT and TN at pre (P > 0.23 for all). αMAP was lower in HOT vs. TN during (-3±6 vs. 9±5 mmHg; P<0.01) and post (0±5 vs. 10±7 mmHg; P<0.01). αMCAv was lower in HOT vs. TN during (-3±5 vs. 4±4 cm/s; P<0.01) and post (-5±7 vs. 0±5 cm/s; P<0.01). αPETCO₂ was lower in HOT vs. TN during (1±2 vs. 2±2 mmHg; P<0.01) and post (-3±2 vs. -1±2 mmHg; P<0.01). αGain was not different between HOT and TN during (HOT: -0.03±0.15 vs. TN: -0.08±0.05 cm/s/mmHg; P=0.18) or post (HOT: 0.04±0.12 vs. TN: -0.03±0.07 cm/s/mmHg; P=0.18). αPhase

was not different between HOT and TN during (HOT: 2.9 ± 9.0 vs. TN: $1.0 \pm 8.8^\circ$; $P=0.74$) or post (HOT: -1.2 ± 12.8 vs. TN: $-2.0 \pm 9.7^\circ$; $P=0.74$) **CONCLUSION:** These data indicate that an acute bout of hot water immersion attenuates cerebral blood velocity vs. thermoneutral water immersion. This response is likely due to the differences in arterial blood pressure and/or arterial carbon dioxide between conditions. However, cerebral autoregulation during and following hot water immersion is not different compared to thermoneutral water immersion in healthy participants. Do The National Institute Of Occupational Safety And Health Recommendations Prevent Hyperthermia And Dehydration?

Nate E. Bartman¹, Jonathan R. Larson¹, Zachary J. Schlader, FACSM², Blair D. Johnson, FACSM¹, David Hostler, FACSM¹, Riana R. Pryor¹. ¹University at Buffalo, SUNY, Buffalo, NY. ²Indiana University, Bloomington, IN.
 (No relevant relationships reported)

The National Institute of Occupational Safety and Health (NIOSH) recommendations for work in the heat suggest consuming 237 mL of water every 15-20 min and rest intervals are not necessary for work if conditions are not extreme. The efficacy of these recommendations to protect against hyperthermia (rise in core temperature) and dehydration (percent body mass loss) has not been tested. **PURPOSE:** To test the effectiveness of the NIOSH guidelines to prevent body temperature from exceeding 38.0°C and dehydration greater than 2% of body mass. **METHODS:** Seven men walked for 2 hours at 6.4 kph in the highest thermal stress NIOSH allows before recommending work-to-rest ratios (34°C , 30% relative humidity). Participants drank 237 mL of water every 20 minutes while rectal temperature (T_{re}) monitored. Body mass and urine specific gravity (USG) were measured before and after exertion. T_{re} was extrapolated out to four- and eight-hour workdays based on the rate of T_{re} rise in the last hour of exertion. Percent dehydration was extrapolated out to four- and eight-hour workdays based on body mass lost and planned hydration during exertion. **RESULTS:** T_{re} rose from baseline ($36.8 \pm 0.3^\circ\text{C}$) to the completion of exertion ($38.1 \pm 0.6^\circ\text{C}$, $p < 0.001$), with two subjects reaching the 38°C threshold. Four- and eight-hour predicted T_{re} were $38.6 \pm 1.1^\circ\text{C}$ and $39.6 \pm 2.1^\circ\text{C}$, respectively, with 5 subjects predicted to exceed T_{re} threshold at 4hr and 6 subjects at 8hr. Subjects began work euhydrated (USG: 1.013 ± 0.005) and dehydrated $0.03 \pm 0.48\%$ during the work protocol, with no subjects reaching 2% dehydration. Four- and eight-hour predicted percent dehydration were $0.05 \pm 0.95\%$ and $0.10 \pm 1.90\%$, respectively. **CONCLUSIONS:** Adherence to the NIOSH recommendations may be insufficient to prevent workers from reaching the hyperthermia threshold but would protect against dehydration during heavy intensity work in the heat. Adjustments to NIOSH work-to-rest ratio recommendations should be explored to maintain worker safety.

Human Intestinal Microbiota Heat Production Is An Unmeasured Quantity In Thermal And Metabolic Studies

Lawrence E. Armstrong, FACSM¹, Douglas J. Casa, FACSM¹, Luke N. Belval². ¹University of Connecticut, Storrs, CT. ²Institute for Exercise and Environmental Medicine, Dallas, TX. Email: lawrence.armstrong@uconn.edu
 (No relevant relationships reported)

The human intestinal microbiota (IM) contains a diverse array of micro-organisms from more than 1,000 species that inhabit the surface and contents of the gastrointestinal tract. The number of bacterial cells (10^{13} - 10^{14}) is approximately the number of cells in the entire human body. Most research ignores the contributions of this biomass to human metabolic and physiologic responses. **PURPOSE:** To examine influences of the IM on research measurements of metabolism and calculations of heat balance. **METHODS:** This prospective study combined data from 9 IM, 4 small animal, and 6 human peer-reviewed publications. Our analyses compared IM versus human metabolism and heat production. **RESULTS:** We calculated the rate of IM heat production in the human colon to be 32 kcal/h for fecal bacteria (based on 46 g dry weight of colonic fecal bacteria and a median *Lactobacillus* heat production of 800mW/g dry weight during anaerobic fermentation). This calculated rate of IM heat production is considerable, when compared to both the resting metabolic rate (RMR) of men (42% of 76 kcal/h) and women (52% of 62 kcal/h), as well as the 24-h energy expenditure (RMR + energy expenditure during activities) of men (23% of 140 kcal/h) and women (34% of 94 kcal/h). The heat production of bacteria residing within the intestinal mucosa is unknown and adds to that of fecal bacteria. Diet contents (e.g., resistant starch) are primary determinants of IM heat production. Considering Acceptable Macronutrient Distribution Ranges published by the National Academy of Sciences, USA, the fermentation of plant material generates 69.3 - 264.6 Kcal/24h during metabolism of a 2200 kcal/24h diet. **CONCLUSIONS:** Because IM metabolic and thermal effects are sufficiently large to have a measurable impact on research, we

conclude that the IM represents an uncontrolled, unmeasured factor in the experimental design of human studies. Resting experimental protocols will incur a larger percent error than protocols involving exercise and elevated metabolic rate. Finally, researchers should acknowledge the IM as a study limitation and control those factors which strongly affect IM metabolism such as exercise, antibiotics, diet, and prebiotics.

3511 Board #332 May 29 2:30 PM - 4:00 PM
Wearable Technologies For Real-time Monitoring Of Body Core Temperature Under Heat Stress Conditions

Ken Tokizawa¹, Toru Shimuta², Hirofumi Tsuchimoto². ¹National Institute of Occupational Safety and Health, Japan, Kawasaki, Japan. ²Murata Manufacturing Co., Yasu, Japan. Email: tokizawa@tbp.t-com.ne.jp
 (No relevant relationships reported)

Athletes and workers are at risk of heat illness whenever they work for a prolonged duration in outdoor extreme temperatures due to their metabolic demands. Safe performance limits under heat stress conditions are currently determined using predictive models for ambient temperature and exercise intensity. Wearable technology is now being adopted, but a system that accurately measures core temperature using wearable devices has yet to be reported. **PURPOSE:** To develop a new wearable patch-type sensor system that predicts core temperature based on heat-flux data from the chest. **METHODS:** We performed experiments that compared our predicted temperatures (T_{pre} , using a revised algorithm from the dual-heat-flux method), with the actual temperatures in both esophageal (T_{es}) and rectal (T_{rec}) sites during exercise in three heat conditions. Thirty-two volunteers walked for 60 min at 4-5 km/h at 30°C , 35°C , or 40°C . T_{pre} was monitored using a smartphone application receiving wirelessly transmitted data from the patch-type sensors ($65 \times 45 \times 8$ mm) on the chest. **RESULTS:** In the 40°C condition, T_{es} , T_{rec} , and T_{pre} increased from $37.2 \pm 0.2^\circ\text{C}$, $36.9 \pm 0.2^\circ\text{C}$, and $37.3 \pm 0.2^\circ\text{C}$ to $38.2 \pm 0.3^\circ\text{C}$, $37.9 \pm 0.3^\circ\text{C}$, and $38.0 \pm 0.2^\circ\text{C}$ (mean \pm standard deviation), respectively, during exercise. The difference between T_{pre} and T_{es} was $-0.10 \pm 0.15^\circ\text{C}$ and that between T_{pre} and T_{rec} was $0.02 \pm 0.19^\circ\text{C}$, using data sampled at 5-min intervals during exercise. In the 35°C condition, T_{es} , T_{rec} , and T_{pre} increased to $37.9 \pm 0.3^\circ\text{C}$, $37.8 \pm 0.3^\circ\text{C}$, and $37.9 \pm 0.2^\circ\text{C}$ after exercise. In this case, the difference between T_{pre} and T_{es} was $-0.06 \pm 0.17^\circ\text{C}$ and that between T_{pre} and T_{rec} was $0.04 \pm 0.14^\circ\text{C}$. In the 30°C condition, the differences were $-0.13 \pm 0.24^\circ\text{C}$ ($T_{\text{pre}} - T_{\text{es}}$) and $0.06 \pm 0.25^\circ\text{C}$ ($T_{\text{pre}} - T_{\text{rec}}$). Body mass, fat percentage, and sex did not affect the T_{pre} algorithm, but skin temperature changes during exercise yielded errors. **CONCLUSIONS:** The error ranges for our system are slightly superior to those in previous studies involving noninvasive core temperature measurements. Our system uses simple wearable devices and can provide real-time, subject-specific, and accurate body core temperature estimates under heat stress conditions. In combination with other physiological and environmental parameters, this early warning system will reduce the risk of heat illness.

Effects Of Polyester Wicking Versus Cotton Fabric T-shirt On Sweat Rate In Obese Males

Abdulaziz A. Masoud¹, Alberto Friedmann², Alfred E. Finch². ¹University of New Mexico, Albuquerque, NM. ²Indiana State University, Terre Haute, IN.
 (No relevant relationships reported)

The effects of different t-shirt fabrics on thermoregulation during exercise remain to be elucidated. **PURPOSE:** This crossover study investigated the effects of cotton (C) versus polyester (P) t-shirts on sweat rate and skin temperature at the torso (chest, back) and peripheral (forearm, forehead) regions of physically active, obese males. **METHODS:** Seven participants (21.7 ± 1.7 yr; 35.7 ± 6.7 kg m^{-2}) completed 4 visits (separated by 48 hrs); visit 1 was to complete the informed consent, ACSM health questionnaire, PAR-Q, and body composition assessment using air displacement plethysmography. Visit 2 was a $\text{VO}_{2\text{max}}$ test (30-sec averaging for expired gas analysis), followed by two treadmill walking sessions (30 min at $30 - 39\% \text{VO}_{2\text{serv}}$) in either C or P t-shirt (randomized, counterbalanced sequence) on the third and fourth visits. Exercise was performed in a hot and dry (27°C , $10 \pm 2\%$ relative humidity) environment. Sweat rate was determined as Δ nude body weight (pre- minus post-exercise body weight) using a digital scale. Skin temperature was measured during exercise using a skin thermometer. Torso skin temperature (T_{torso}) was the sum of $0.5T_{\text{chest}} + 0.5T_{\text{back}}$. Peripheral site skin temperatures were analyzed separately. A dependent t-test was used to compare sweat rates. Separate two-way ANOVAs were performed to investigate fabric type, time, and their interactions on skin temperature by body region. **RESULTS:** On average, participants' $\text{VO}_{2\text{max}}$ and body fat were 36.8 ± 8.7 mL \cdot kg $^{-1}$ \cdot min $^{-1}$ and $34.7 \pm 4.3\%$, respectively. There was no difference between C and P conditions in sweat rates (Δ body weight = $-35 \pm .11$ kg; $-37 \pm .20$ kg,

respectively, $p = .754$). A significant interaction effect was detected between $T_{skinoso}$ and fabric ($p = .022$) with $C > P$. Interaction effects of skin temperature in the peripheral regions (forearm, $p = .195$; forehead, $p = .057$) were nonsignificant. **CONCLUSION:** Though the sweat rate was similar across cotton and polyester trials, polyester appears to be effective for temperature regulation, especially in the torso region during low intensity aerobic exercises in young, obese males. Future research should explore the impact of C vs. P fabric on sweat rate and skin temperature during different intensities and modalities of exercise.

Upper Body Heat Dissipation Wearing A Novel Synthetic Material Shirt During Exercise In The Heat
 Haoyan Wang, Louisiana State University, Baton Rouge, LA.
 Email: hwang56@lsu.edu
 (No relevant relationships reported)

Sports clothing potentially limits evaporation from the skin due to an inhibitory microclimate between the skin and the environment. New materials and aeration systems are being developed to negate this limitation from current clothing.

PURPOSE: To determine the effects of t-shirt fabric (standard vs. novel) material on body temperature during exercise in a warm environment with and without simulated wind (fan vs. novel ventilated vest).

METHODS: Eight healthy male participants were recruited in the study (age: 25 ± 3 yr; height: 171.6 ± 7.4 cm; weight: 79.2 ± 14.2 kg). Participants performed 4 exercise trials in a cross-over randomized design: standard+fan (S+F), novel+fan (N+F), standard+vest (S+V), and novel+vest (N+V). Participants exercised for 60-min on a cycle ergometer in a heated, humidity-controlled chamber ($29.4 \pm 0.4^\circ\text{C}$ and $32.0 \pm 2.6\%$ RH; temperature and RH $p > 0.05$ for all trials). During the first 30min, participants exercised in the trial specific shirt with no external wind. In the second 30min, the fan was used to simulate wind speed equivalent to 2m/s applied to the chest or the vest was worn to simulate wind to chest and back. Heart rate (HR), skin temperature (T_{skin}), and core temperature (T_{core}) were recorded every 5min. T_{core} was measured by ingestible sensor 4-5 hours before exercise and T_{skin} was assessed at 5 sites: upper chest, mid-chest, forearm, upper back, and mid-back. The vest had 10×15 cm ventilation area that covered mid-chest and mid-back. Rating of perceived exertion (RPE) and feeling (+5 good; -5 bad) were assessed every 5min.

RESULTS: Mean weighted T_{skin} was lowest in N+F ($31.3 \pm 1.2^\circ\text{C}$) compared to other trials in final 30min. T_{skin} of averaged mid-chest and mid-back was lower in the final 30min ($32.1 \pm 1.9^\circ\text{C}$) exercise compared to the first 30min in N+V ($33.0 \pm 1.3^\circ\text{C}$; $p < .001$). However, T_{skin} of averaged upper chest and back (outside of ventilation area) remained the same in final 30min as first 30min ($\sim 34^\circ\text{C}$). No significant differences were found in T_{core} and HR across the trials. N+F had lowest RPE and best overall feeling compared with other trials in the final 30min.

CONCLUSIONS: N+F had greatest impact on upper body heat dissipation, mainly appearing in lower chest T_{skin} and RPE. In addition, novel ventilation vest successfully decreased the T_{skin} of mid-chest and back in final 30min exercise.

Novel Factors Associated With Adverse Mental Health In Elite Para Athletes In South Africa
 Wayne Elton Derman, FACSM, Phoebe Runciman, James Brown, Marelise Badenhorst. Stellenbosch University, Cape Town, South Africa.
 Email: ewderman@iafrica.com
 (No relevant relationships reported)

Para-athletes (PA) may have specific mental health (MH) challenges that, together with the demands of high-level sport performance, could put them at risk for MH disorders. However, research in this population is limited. **PURPOSE:** To investigate factors associated with MH in South African PA. **METHODS:** In this descriptive, cross-sectional study, 124 athletes (93 males; 31 females) with a mean age $26.7 (\pm 9.2)$ competing in the 2019 National Champs were recruited. Demographic, medical history and sleep-related variables were included in bivariate analyses to assess their association with MH. Between-group differences were analysed using the Mann-Whitney U or T-tests. Variables significantly associated in the bivariate analyses

were included in multiple regression analyses for mental health. Mental health was measured with the State/Trait Anxiety Inventory (STAI) and the Kessler Psychological Distress Scale (K-10 Questionnaire). Sleep quality, sleepiness and chronotype were measured with the Pittsburgh Sleep Quality Index (PSQI), the Epworth Sleepiness scale and Morningness-Eveningness Questionnaire (MEQ-SA). **RESULTS:** The model explained 40% of the variance in MH ($F = 12.04$, $p < 0.001$). Compared to athletes with 'good' sleep quality, K-10 and STAI scores were significantly higher (indicating poorer MH) in athletes with 'poor' sleep quality ($U = 2.6$, $p < 0.001$; $t(116.8) = -4.30$, $p < 0.001$). 'Poor' sleep quality (B:0.8; 95%CI 0.4 to 1.3), moderate to severe daytime sleepiness (B:4.2; 95%CI 1.1 to 7.3) intermediate (B:3.5 95%CI 0.4 to 6.6) and evening chronotypes (B:12.0 95%CI 5.0 to 19.1), the presence of allergies (B:3.9 95%CI 0.1 to 7.6) and male gender (B:3.3 95%CI 0.1 to 6.5) were most strongly associated with high STAI scores. **CONCLUSIONS:** This study identified novel factors associated with adverse MH in elite PA. As some of these factors are modifiable, further research towards prevention strategies is warranted.

Investigating The Effect Of Mouth Guard Use On Aerobic Performance In Amateur Boxers.

Irfan Ahmed, Courtney Kippes, Peter Fine. UCL, London, United Kingdom. (Sponsor: Dr James Hull, FACSM)
 Email: irfan.ahmed5@nhs.uk
 (No relevant relationships reported)

Purpose – To assess if wearing a mouth guard effects maximal aerobic capacity in amateur boxers.

Methods – 13 amateur boxers took part in a prospective crossover study to assess maximal aerobic capacity achieved during the 20m Multi Stage Fitness Test (MSFT). Each participant completed the MSFT 7 days apart, under control (no mouth guard – C) and intervention conditions (mouth guard – MG). The order of tests was determined via a coin toss on day 1, and two primary outcomes measures were recorded: (1) the estimated maximum oxygen uptake ($\text{VO}_2 \text{max}$ – kg/mL/min) and (2) distance run (meters – m). Data on height, weight, and type of mouth guard were recorded. Complete datasets on Rate of Perceived Exertion (RPE) were available for 10 boxers. **Results** – Mouth guard use was shown to reduce estimated $\text{VO}_2 \text{max}$ and distance run during the 20m MSFT from 56.31 kg/mL/min to 54.12 kg/mL/min and 2572 m to 2380 m respectively, ($P > 0.05$). All 13 participants recorded lower $\text{VO}_2 \text{max}$ scores when wearing a mouth guard, (Mean = -2.43 mL/kg/min , Range = 4.2 – 0.9 mL/kg/min). 10 participants submitted data on RPE and reported a 32.3% increase in mean RPE scores when completing the MSFT in mouth guards compared to control conditions, ($P > 0.05$).

Conclusions – Mouth guard use was shown to significantly reduce aerobic performance in amateur boxers and increase the perceived rate of exertion during the 20m MSFT.

The Relationship Between Flourishing, Pain, And Injury In Collegiate Athletes

Garrett Bullock¹, Shefali Christopher², Bryanna J. Veroneau², Bailey A. Tadlock², Amy Knab³, Chris Harnish⁴, Srikant Vallabhajosula². ¹University of Oxford, Oxford, United Kingdom. ²Elon University, Elon, NC. ³Queens University of Charlotte, Charlotte, NC. ⁴Mary Baldwin College, Staunton, VA. (Sponsor: Dr. Stephen Bailey, FACSM)
 Email: garrettbullock@gmail.com
 (No relevant relationships reported)

Flourishing encompasses a holistic representation of physical, psychological, and social health. However, pain and injury can negatively affect health. Currently, there is little research on flourishing within collegiate athletes.

Purpose: To evaluate the relationship of pain and injury with flourishing in NCAA athletes and to compare by division.

Methods: NCAA division 1 (D1), 2 (D2), and 3 (D3) athletes were given a questionnaire incorporating the flourishing scale and the Oslo Sports Trauma Research Center Overuse Injury Questionnaire (OSTRC). Athletes were further classified by OSTRC scores into overuse and substantial overuse injuries. Multivariable regressions with logarithmic transformations and ANCOVAs were performed to investigate the relationship between flourishing and OSTRC pain and flourishing, overuse and substantial overuse injury. Confounders controlled for included age, gender, history of orthopaedic surgery and major injury, hours of sleep, and non-steroidal anti-inflammatory use. Unadjusted and adjusted effect size and 95% confidence intervals (95% CI) were reported.

Results: 253 athletes (Age: 19.43 (1.18) years; Male: 70; D1: 102, D2: 74, D3: 77; 7-8 hours of sleep: 157) participated. Mean flourishing scores were D1: 48.59 (10.43), D2: 50.08 (5.31), and D3: 48.58 (8.09). The median OSTRC score was 0 (0-22). 124 reported an overuse injury and 47 a substantial overuse injury. There was a unadjusted negative relationship between OSTRC total score and flourishing (-5.2%

(95% CI: -10%, 1%), $p=0.037$); however there was no relationship after controlling for confounders (0.1% (95% CI: -2.6%, 2.7%), $p=0.989$). There was no relationship between overuse injury and flourishing (-0.23 (95% CI: -2.57, 2.11), $p=0.848$). There was an unadjusted negative relationship between substantial overuse injuries and flourishing (-2.77 (95% CI: -5.43, -0.12), $p=0.042$), but there was no relationship after controlling for confounders (1.97 (95% CI: -4.95, 1.01), $p=0.196$). These relationships were similar by division.

Conclusion: College athletes have high flourishing, and have similar flourishing between all NCAA divisions. Pain and injury have a negative relationship to flourishing; however, these relationships are confounded by surgical and injury history, and lifestyle.

Characterization Of Normal Biomarkers Of Muscle Damage In Collegiate Athletes

Heather Quiariarte¹, Nathan Lemoine¹, Haoyan Wang¹, Matthew Martone¹, Rachel Matthews¹, Derek Calvert¹, Jack Marucci¹, Stephen Etheredge², Guillaume Spielmann¹, Brian Irving, FACSM¹, Neil Johannsen¹. ¹Louisiana State University, Baton Rouge, LA. ²Baton Rouge Orthopedic Clinic, Baton Rouge, LA. (Sponsor: Brian Irving, FACSM)
 Email: hquiariarte1@lsu.edu
 (No relevant relationships reported)

Exertional rhabdomyolysis is a serious clinical condition in which skeletal muscle is rapidly broken down, potentially leading to life-threatening systemic complications. Clinicians often diagnose rhabdomyolysis based on elevations in circulating creatine phosphokinase (CPK) and symptomatology. Normal CPK and other biomarker concentrations following intense exercise are unknown. **Purpose:** This study aimed to determine reference concentrations for selected biomarkers that suggest muscle damage in athletes and examine the time-course of muscle damage biomarker responses after strenuous exertion. **Methods:** 20 collegiate NCAA I football players were enrolled in the study. Serum and urine samples were collected immediately and 24 hours post strenuous practice (0h and 24h, resp). Serum samples were analyzed for biomarkers of muscle damage including a Chem26 metabolic and chemistry panel and myoglobin. Urine samples were analyzed for creatinine and myoglobin concentrations. Participants were also given Physical Symptoms Questionnaires to obtain subjective measures of symptoms that may be related to severe muscle damage, or rhabdomyolysis. **Results:** A total of 28 samples were collected with 9 repeats. CPK levels were elevated at 0h (958.2 ± 544.1 IU/L), but trended down 24h post practice (751.0 ± 410.5 IU/L, $p=0.059$). LDH was acutely elevated at 0h (217.9 ± 30.6 IU/L) compared to the 24h timepoint (170.3 ± 35.5 IU/L, $p<0.0001$). Average serum myoglobin was higher post-practice (1.31 ± 1.57 ng/mL), but decreased 24 h post-exercise (0.36 ± 0.71 ng/mL, $p<0.001$). Similarly, urine creatinine concentrations were higher 0h post practice (390.1 ± 164.2 mg/mL), and decreased 24h post (214.2 ± 99.4 mg/dL, $p<0.0001$). Urine myoglobin was also elevated at 0h post practice (18.18 ± 36.7 ng/mL), but decreased 24h post (0.66 ± 1.43 ng/mL, $p=0.001$). The Physical Symptoms Questionnaires did not reveal any symptoms related to severe muscle damage. **Conclusion:** Biomarkers of muscle damage were elevated immediately post strenuous exercise, but dropped 24 hours post-practice. Serum and urine biomarkers of muscle damage collected immediately post strenuous exercise are unlikely to be specific markers of rhabdomyolysis, but rather of transient exercise-induced muscle damage in a highly trained athletic population.

The Effectiveness Of Warmup Programs For Lower Extremity Injury Prevention In Basketball: A Systematic Review

Anna C. Davis¹, Nicholas Emptage², Robert Sallis³, Manuel G. Romero⁴, Donna Woo¹, Dana Pounds¹, Stacy Park¹, Adam L. Sharp¹. ¹Kaiser Permanente, Pasadena, CA. ²Kaiser Permanente, Portland, OR. ³Kaiser Permanente, Fontana, CA. ⁴California State University of Sacramento, Sacramento, CA. (Sponsor: Robert Sallis, FACSM)
 Reported Relationships: A.C. Davis: Industry contracted research; National Basketball Association.

PURPOSE: Given the many benefits of sports participation, leading experts have called for attention to factors that might inhibit youth participation. Basketball is the most popular team sport among youth in the US; the popularity of basketball translates to a large absolute number of basketball related injuries. The objective of this review is to evaluate the evidence to support the effectiveness of neuromuscular warmup-based strategies for preventing lower extremity injuries (LEIs) in basketball. **METHODS:**

We conducted a systematic review of the literature. We searched the PubMed and Cochrane Library databases, and focused on English-language randomized controlled trials, non-randomized comparative trials, and prospective cohort studies. We included studies that tested neuromuscular and/or balance-focused warmup interventions among basketball players, and that assessed at least one type of LEI as a primary outcome. We critically appraised the quality of the included studies and abstracted data on the interventions, populations, exposures and outcomes. We contacted the authors of five of the studies to obtain details about the interventions or outcome data specific to basketball athletes. **RESULTS:** Thirteen studies testing neuromuscular interventions for LEI prevention in basketball athletes were included in this review. They reported significant protective effects for the following LEIs: ankle injuries (significant in 4/9 studies that assessed this outcome); ACL injuries (2/4 studies); a general knee injury outcome (1/5 studies); and overall LEIs (composite; 5/7 studies). Non-significant results were almost universally directionally favorable. **CONCLUSIONS:** Neuromuscular interventions that require minimal equipment are an appealing injury prevention strategy in youth sports. In soccer, the FIFA 11+ warmup program has been rigorously studied and proven effective when adoption and adherence is strong. Overall, the evidence is supportive of warmups for LEI prevention in basketball. However, most studies are underpowered, intervention components are varied, and adoption and adherence is often low. More work is needed to validate the necessary and sufficient warmup activities, and to maximize adoption and sustained adherence to these strategies over time.

Time Course Of The Acute Effects Of Static Stretching On Passive Stiffness In Elderly Men

Ty B. Palmer, Ahalee C. Farrow, Chinonye C. Agu-Udamba, Ethan A. Mitchell. Texas Tech University, Lubbock, TX. (Sponsor: C. Roger James, FACSM)
 (No relevant relationships reported)

The time course of passive stiffness responses after an acute bout of static stretching has received little research attention, particularly in older adults. **PURPOSE:** To determine the time course of the acute effects of static stretching on hamstring passive stiffness in elderly men. **METHODS:** Fifteen elderly men (70 ± 7 yrs.) underwent one passive straight-leg raise (SLR) assessment before (Pre) and at 0 (Post0), 5 (Post5), and 10 (Post10) min after two randomized conditions that included a control treatment (quiet resting for 2 min) and a stretching treatment. During the SLR, participants laid in a supine position with the knee braced in full extension. Each SLR was administered manually by the primary investigator who applied force against a load cell attached to the heel, while the leg was moved toward the head. All SLR assessments were performed on the right leg to the point of discomfort, but not pain as indicated by the participant, which was regarded as the max range of motion (ROM). An electrogoniometer was used to measure the hip joint angle. For the stretching treatment, four 15-s SLR static stretches were completed in the same manner as the SLR assessments; however, when max ROM was reached, the leg was held at this position for 15 s. Each 15-s stretch was separated by 15 s of rest. Passive stiffness was calculated during each SLR assessment as the slopes of the initial and final phases of the angle-torque curve. **RESULTS:** Passive stiffness (collapsed across phase) was lower at Post0 (0.92 ± 0.27 Nm^{-0.1}; $P=0.029$) and Post5 (0.95 ± 0.19 Nm^{-0.1}; $P=0.042$) but not Post10 (1.03 ± 0.26 Nm^{-0.1}; $P>0.999$) compared to Pre (1.07 ± 0.23 Nm^{-0.1}) for the stretching treatment. There were no significant differences ($P>0.999$) in passive stiffness between any of the time points (Pre = 1.07 ± 0.25 Nm^{-0.1}; Post0 = 1.10 ± 0.36 Nm^{-0.1}; Post5 = 1.09 ± 0.24 Nm^{-0.1}; Post10 = 1.06 ± 0.24 Nm^{-0.1}) for the control. **CONCLUSION:** These findings showed that hamstring passive stiffness in elderly men decreased after four 15-s SLR static stretches but returned to baseline values within 5-10 min. Given the transient nature of these changes in stiffness, we recommend that acute bouts of SLR static stretching be performed on older adults 5 to 10 min prior to physical activity or exercise, as this may ensure lower stiffness and perhaps, greater performance at the start of the event.

The Effect Of Injuries And Pain On Athletic Identity Across NCAA Divisions

Bryanna Veroneau¹, Bailey Tadlock¹, Shefali Christopher¹, Srikant Vallabhajosula¹, Amy Knab², Chris Harnish³, Garrett Bullock⁴. ¹Elon University, Elon, NC. ²Queens University of Charlotte, Charlotte, NC. ³Mary Baldwin College, Staunton, VA. ⁴University of Oxford, Oxford, United Kingdom. (Sponsor: Dr. Stephen Bailey, FACSM)
 Email: bveroneau@elon.edu
 (No relevant relationships reported)

There is a high prevalence of pain and injury in collegiate athletes, which can affect playing time and performance. Previous studies have observed that surgery and concussions can affect athletic identity. Currently, there is a paucity of research investigating how current pain and injury affect athletic identity.

Purpose: To determine how current collegiate athlete pain and injury affect athletic identity and how these relationships differ across NCAA divisions. **Methods:** NCAA division I (D1), 2 (D2), and 3 (D3) athletes were administered a questionnaire through an encrypted database. The Athletic Identity Questionnaire (AIM) and Oslo Sports Trauma Research Center Overuse Injury Questionnaire (OSTRC) were used within the survey. AIM estimates self-perceived athletic identity while OSTRC measures level of participation, training volume, performance, and pain. Athletes were further classified by OSTRC scores into overuse and substantial overuse injuries. Multivariable and logistic regressions assessed the relationship between Aim, OSTRC scores, and overuse injury. Models were adjusted for age, gender, NCAA division, history of orthopedic surgery, and history of major injury, with unadjusted and adjusted coefficients and Odds Ratios (OR) with 95% confidence intervals (95% CI). **Results:** 252 athletes (age of 19.4 years (1.2); female: 181, male: 70; D1: 101, D2: 74, D3: 77) participated. Mean AIM scores were D1: 37.98 (7.61), D2: 37.03 (37.03), and D3: 38.86 (6.98). The OSTRC median score was 0 (IQR: 0-22). 127 (50%) athletes had an overuse injury while 47 (19%) had a substantial overuse injury. Adjusted total OSTRC score was -0.67 (95% CI: -2.4, 1.1; p=0.474). Adjusted OR for OSTRC overuse injury was 1.00 (95% CI: 0.97, 1.04; p=0.589) and substantial overuse injury was 0.95 (95% CI: 0.91, 0.99; p=0.036). Similar results were observed between gender and division subgroups. **Conclusion:** After adjusting for confounding variables, it was determined that substantial overuse injuries negatively affected athletic identity, regardless of gender or NCAA division. Sports medicine professionals need to consider the possibility of lost athletic identity when an athlete sustains an injury. Measures should be taken to ensure that athletes continue to have meaningful contribution to sport following pain or injury.

Subjective Well-Being Outcomes Before, During, And After In-Season Competitive Soccer Matches
 Brett Pexa, Audrey E. Westbrook, Justin P. Waxman, Kevin R. Ford, FACSM. *High Point University, High Point, NC.* (Sponsor: Kevin Ford, FACSM)
 Email: bpexa@highpoint.edu
(No relevant relationships reported)

Subjective well-being is related to injury in soccer athletes, but little is known about how these variables change around a single athletic competition. Continued athletic participation combined with negative well-being may lead to tissue overload and subsequent injury. **Purpose:** The purpose of this study was to identify the differences in daily well-being measures before, during and after the day of each match. **Methods:** Thirty female soccer (age: 19.8 ± 1.1 years, height: 1.6 ± 0.05 m, mass: 64.9 ± 6.6 kg) players provided daily measures of readiness, physical fatigue, mental stress, and soreness intensity over the course of a competitive season. Subjective well-being was taken on standard practice days (P), game days (D0), and on days one (D1) two (D2) following games. One-way within subject analysis of variance was used to compare the subjective well-being variables between each time point. Post-hoc analysis was performed with a Bonferroni adjustments. **Results:** A significant main effect was present for readiness (F=52.96, P<0.01). Post-hoc testing revealed readiness on D1(68.5 ± 12.4) was significantly more negative than readiness on P (77.9 ± 8.0, p<0.01), D0 (83.4, 8.9, p<0.01), and D2 (77.1 ± 8.8, P<0.01). A significant main effect was present for fatigue (F=41.8, p<0.01). Post-hoc testing revealed fatigue on D1 (0.5 ± 1.6) was significantly more negative than fatigue on P (1.7 ± 1.4, P=0.01), D0 (2.3 ± 1.4, p<0.01), and D2 (1.7 ± 1.5, p=0.01). A significant main effect was present for stress (F=3.8, p=0.01) and soreness (F=15.1, p=0.01), but after accounting for multiple comparisons, there was no differences between times. **Conclusions:** Self-reported readiness to train and physical fatigue are decreased for a full day following competitive soccer competition. Coaches, strength coaches, and athletic trainers may use this information to tailor training programs to promote recovery and limit injury risk, as previous literature indicates that negative outcomes on subjective scales may be indicative of injury. Future research should incorporate training load assessments into this analysis to understand if these changes are correlated to the frequency, intensity, or volume of soccer training and participation.

Reduction Of Injury And Related Costs After Implementation Of An Injury Prevention System In Division I Athletes
 Marisa PONTILLO, Brian Sennett. *University of Pennsylvania Health System, Philadelphia, PA.*
 Email: pontillo77@gmail.com
Reported Relationships: M. Pontillo: Salary: University of Pennsylvania.

Purpose: At the collegiate level, the estimated cost per year from sports injuries has been reported to be in the billions in the United States. Injury prevention programs are often assessed by injury reduction; there is little evidence on the associated reduction

in health care cost. The purpose of this study is to investigate the change in health care costs at a Division I university from sports injuries after the implementation of an injury prevention system.

Methods: Data was obtained from 3 academics years prior and 2 years after the implementation of an injury surveillance and prevention system (Sparta Science). This system assesses kinematic variables gathered from vertical jumps; this information is used to flag athletes who are at higher risk of sustaining an injury, which guides intervention. Teams were designated as "users" (U) versus "non-users" (NU) based on their utilization of the surveillance system. Total number of injuries, total cost of injuries, and volume and cost by discipline (surgery, physician office visits, imaging, and physical therapy (PT)) was compared for the U versus the NU groups.

Results: Total injuries decreased from 179 to 177 for the U group, and total charges decreased by 19%; the NU group had a 12% increase in injuries and 8% increase in total charges. The U group demonstrated a 29% reduction in the number of surgeries and a 45% decrease in surgery charges; the NU group had a 3% reduction in surgeries, but a 33% increase in surgery charges. The U group had a 23% reduction in office visits and an associated 48% reduction in charges; the NU group showed a 14% increase in visits, but no change in charges. The U group had a 7% reduction in the quantity of imaging ordered, and a 1% reduction in imaging costs; the NU group had no change in the quantity of imaging, but an 83% increase in imaging charges. There was a 6% increase in PT courses of care and 13% increase in PT charges for the U group, versus a 33% and 35% increase in courses of care and charges, respectively, for the NU group.

Conclusion: A reduction was seen in total billed claims, surgery costs, and office costs in the U group. This group also demonstrated a decrease in the number of surgeries, number of office visits, number of imaging procedures.

Sport Players Exhibit Less Muscle And Bone Mineral Content With Higher Body Fat Than Controls
 Joanne Donoghue, William G. Werner, Peter Douris, Hallie Zwibel. *New York Institute of Technology, Old Westbury, NY.*
 Email: jdonoghue@nyit.edu
(No relevant relationships reported)

PURPOSE: To investigate activity levels, body composition, and bone mineral content in collegiate eSports players as compared to age-matched controls. **METHODS:** Twenty-four male collegiate eSport players and non-eSport players between 18-25 years of age underwent body composition and bone mineral content testing using a GE DXA absorptiometry scan. Daily activity (step count) and sleep duration were measured for two weeks using a Fitbit Charge™ and a questionnaire assessing their physical activities and computer usage was administered. Body mass index (BMI) was calculated on all subjects. **RESULTS:** The step count in the eSports players was significantly lower than the age matched controls (p=.0004; 6040.2 ± 3028.6 to 12843.8 ± 5661.1). ESport players exhibited greater body fat percentage (p=.05), less lean body mass (p=.003) and less bone mineral content (p=.03), despite no difference in BMI between the eSport and non-eSport players. **CONCLUSION:** As compared to non-eSport players, collegiate eSport team players were significantly less active and had a higher body fat percentage with lower lean body mass and bone mineral content. BMI is a common marker of health and obesity, yet this index showed no difference between the two groups. Considering the eSport athletes displayed significantly worse numbers, which are all correlated with potential health issues, use of the BMI is not capturing this difference and should not be considered an accurate measure of health in competitive eSport players.

Balance and Functionality in Breast Cancer Survivors: Does Improvement in Balance After Exercise Intervention Improve Functional Test Outcomes?

Dean J. Amatuli, Jordan T. Lee, Chad W. Wagoner, Kirsten A. Nyrop, Hyman B. Muss, Brian C. Jensen, Claudio L. Battaglini, FACSM. University of North Carolina, Chapel Hill, Chapel Hill, NC.

PURPOSE: Postural control is necessary for proper functionality, independence, and quality of life. Breast cancer survivors (BCS) is a population that has displayed challenges in postural control post-treatment (Wampler et al. 2007). This study evaluated changes in balance and functionality following an exercise intervention which included balance training. **METHODS:** BCS who completed major anti-cancer treatments within the past year participated in an intervention including aerobic, strength and balance exercises, 3 days/week for 16 weeks. Training progressed in intensity and volume and incorporated movements that challenged whole-body balance. Functionality was measured using the 6 Minute Walk Test (6MWT), dynamic balance using Timed Up and Go (TUG), and balance using the NeuroCom Sensory Organization Task (SOT). Dependent samples t-test using pre and post intervention scores were used to evaluate the impact of exercise on functionality and balance. Pearson correlations were used to assess the relationship between physical function and balance outcomes. **RESULTS:** Thirty-two BCS (54±12 years) participated. 6MWT distance significantly increased (34.7±48.9m, p<.001) & TUG times significantly improved (-.55±1.0s, p = .005) from pre/post intervention. SOT composite balance scores also improved (4.0±9.3, p=.025). There was a strong correlation between pre-testing scores of TUG & 6MWT (r = -.703, p<.001). **CONCLUSION:** A 16-week exercise intervention improves physical function evaluated using 6MWT and TUG and balance using SOT composite scores. However, no relationship was observed between improvements in physical function and balance; possibly due to the differences in the dynamic nature of the physical function and static assessment of balance. Future studies should consider the evaluation of balance using dynamic tasks in order to further examine the relationship between physical function and balance in BCS. Funded by Breast Cancer Research Foundation (New York, NY)

Effects Of A Lifestyle Intervention On Simulated Activity Of Daily Living Performance In Prostate Cancer Patients Undergoing Androgen Deprivation Therapy

Brian C. Focht, FACSM¹, Alexander R. Lucas², Elizabeth Grainger¹, Christina Simpson¹, Ciaran M. Fairman³, Jessica Bowman¹, Victoria R. DeScenza¹, Zachary L. Chaplow¹, Kathryn Dispennette¹, Marcy Haynam¹, Xiaochen Zhang¹, Steven K. Clinton¹. ¹The Ohio State University, Columbus, OH. ²Virginia Commonwealth University, Richmond, VA. ³Edith Cowan University, Perth, Australia.
(No relevant relationships reported)

The adverse effects accompanying androgen deprivation therapy (ADT) compromise prostate cancer (PCa) patients' ability to complete activities of daily living (ADL) requiring muscular strength and mobility. Although emerging evidence suggests lifestyle interventions combining modification of exercise and dietary intake (EX+D) result in improvements in mobility in PCa patients undergoing ADT, the effects of EX+D interventions upon simulated ADL performance has yet to be delineated. **PURPOSE:** The purpose of the single-blind, randomized controlled Individualized Diet and Exercise Adherence-Pilot (IDEA-P) trial is to evaluate the preliminary efficacy of a lifestyle EX+D intervention, implementing a group-mediated cognitive behavioral (GMCB) approach, relative to standard of care (SC) among PCa patients undergoing ADT. In the current study, we evaluated the effects of the EX+D intervention on performance of a simulated ADL task at the end of the intensive phase of the intervention. **METHODS:** A total of 32 PCa patients (M age = 65 years) on ADT were randomly assigned to the EX+D (n = 16) or SC (n = 16) interventions.

Assessments of simulated ADL performance, measured using a lift and carry task, were obtained at baseline and 2 month follow-up assessments. **RESULTS:** A total of 32 PCa patients (M age = 65 years) on ADT were randomly assigned to the EX+D (n = 16) or SC (n = 16) interventions. Assessments of simulated ADL performance, measured using a lift and carry task, were obtained at baseline and 2 month follow-up assessments. **RESULTS:** Results of intention to treat ANCOVA analysis of residualized change scores yielded a significant Treatment main effect for (p<0.01) demonstrating that the EX+D intervention resulted in superior improvements in lift and carry performance (d = 1.01) relative to the SC intervention at 2 months. **CONCLUSIONS:** Findings from the IDEA-P trial suggest that the intensive phase of the EX+D intervention, implementing a GMCB approach designed to promote adoption and adherence to lifestyle behavior change, resulted in superior changes in a simulated ADL performance task relative to SC. These results underscore the utility of lifestyle interventions promoting change in both exercise and dietary behavior for preserving mobility and functional health among PCa patients undergoing ADT.

Effects Of High Intensity Interval Training On Patient-reported Outcomes And Physical Function During Anthracycline Chemotherapy

Kyuwan Lee¹, Ellice Wang¹, Christina Dieli-Conwright, FACSM². ¹U of Southern California, Los Angeles, CA. ²City of Hope National Medical Center, Duarte, CA. (Sponsor: Christina Dieli-Conwright, FACSM)
 Email: kyuwanle@usc.edu
(No relevant relationships reported)

PURPOSE: Breast cancer patients treated with anthracycline chemotherapy experience negative anthracycline-related side effects, including poor quality of life and impaired physical function. However, it is unclear whether high intensity interval training (HIIT) improves quality of life and physical function in breast cancer patients undergoing anthracycline-based chemotherapy. The purpose of this study was to examine the effects of HIIT on patient-reported outcomes and physical function in breast cancer patients with anthracycline-based chemotherapy. **METHODS:** Thirty breast cancer patients were recruited prior to initiating anthracycline-based chemotherapy and randomized into the HIIT group (n=15) or control (CON) group (n=15). The HIIT group attended the HIIT session for 3 days per week for 8 weeks. The CON group was asked to maintain their current level of physical activity and offered the same HIIT intervention after the 8-week study period. Patient-reported outcomes were assessed by the Functional Assessment of Cancer Therapy-Breast Cancer (FACT-B), Multidimensional Fatigue Inventory with 20 questions (MFI-20), and the 15-item Five-Facet Mindfulness Questionnaire (FFMQ-15). Physical function was assessed using the timed up and go (TUG), 30-second sit-to-stand (30STS), Margaria-Kalamen stair climb test, and 6-minute walk test (6MWT). Repeated measures ANCOVA and paired t-tests were performed to assess changes in the outcome measures. **RESULTS:** Thirty breast cancer patients completed the 8-week study with 82.3% adherence to the intervention among the HIIT group. Post-intervention, significant improvements were found for the functional Margaria-Kalamen Power Test (-3.39%; P=0.013) and 6MWT (+11.6%; P=0.008) in the HIIT group compared baseline and to the CON group. No changes in patient-reported outcomes, TUG, and 30STS were found following the 8-week study period in both groups (P>0.05). **CONCLUSIONS:** HIIT may be an effective strategy to improve physical function and possibly maintain quality of life in breast cancer patients undergoing the anthracycline-based chemotherapy.

3531 Board #352 May 29 2:30 PM - 4:00 PM
Effects Of Exercise On Disablement Process Outcomes In Prostate Cancer Patients Undergoing Androgen Deprivation Therapy: An Updated Systematic Review

Zachary L. Chaplow, Jessica Bowman, Victoria R. DeScenza, Kathryn Dispennette, Marcy Haynam, Stephanie Hohn, Xiaochen Zhang, Brian C. Focht, FACSM. *The Ohio State University, Columbus, OH.* (Sponsor: Brian C Focht, FACSM)
(No relevant relationships reported)

Although androgen-deprivation therapy (ADT) is a foundation of treatment for prostate cancer (PCa) patients, adverse effects of ADT may accelerate functional decline. Whereas exercise improves muscular strength and functional performance in PCa patients, evidence of the benefits of exercise for alternative disablement process outcomes remain equivocal. **PURPOSE:** To update the findings of our previous systematic review of the effects of exercise on disablement process outcomes in PCa patients undergoing ADT. The purpose of this study is to determine the extent to which exercise interventions produce meaningful improvements in the specific impairment domain outcome of body composition (BC) in PCa patients on ADT. **METHODS:** A comprehensive literature search was conducted of all relevant published studies

from December 2013-present. Data were extracted on BC outcomes from 8 published exercise intervention studies involving 307 PCa patients on ADT. The magnitude of pre- to post-intervention change was examined. To isolate the effects of exercise, studies combining other interventions were excluded. Weighted, bias-corrected Cohen's *d* effect sizes were calculated for change in each outcome and averaged across included studies. **RESULTS:** Results revealed that exercise yielded small average improvements in lean body mass ($d = 0.09$), appendicular lean mass ($d = 0.08$), trunk fat mass ($d = -0.03$) and visceral fat mass ($d = -0.11$). All other measures of whole-body and regional BC showed negligible average effects of exercise. **CONCLUSIONS:** The findings of this updated systematic review suggest that while exercise attenuates the established adverse effects of ADT on BC, the magnitude of exercise-induced improvements in BC outcomes is small and inconsistent across studies. These findings have important implications for delineating the effect of exercise on disablement process outcomes and underscore the potential utility of complementing exercise with targeted nutritional approaches in the supportive care of PCa patients on ADT.

3532 Board #353 May 29 2:30 PM - 4:00 PM
Dynapenic Obesity: Strength, Body Composition, And Physical Function In Women Diagnosed With Breast Cancer

Lindsey L. Hanson¹, Diane K. Ehlers¹, Gregory Russell², Edward Levine², Marissa M. Howard-McNatt², Shannon L. Mihalko³.
¹University of Nebraska Medical Center, Omaha, NE. ²Wake Forest School of Medicine, Winston-Salem, NC. ³Wake Forest University, Winston-Salem, NC.
 (No relevant relationships reported)

Background: Breast cancer survivors (BCS) report more limitations performing activities requiring strength compared to women without a cancer history. Combined with obesity, BCS with dynapenia (poor muscle strength) may have greater risk of physical function (PF) difficulties; however, the prevalence and impact of dynapenic obesity (DO) in BCS remains unknown. **Purpose:** This study aimed to: 1) prospectively determine the prevalence of DO; 2) evaluate associations among DO, clinical factors, and resistance training (RT); and 3) determine if DO predicts PF in BCS from diagnosis to 2-year follow-up. **Methods:** DO was operationalized as waist circumference (WC) ≥ 88 cm and poor grip strength, measured via dynamometry and categorized using ACSM normative values. RT participation was determined via interview and categorized as meeting/not meeting RT guidelines for cancer survivors. PF was self-reported as level of difficulty with tasks including standing in place, walking 2 blocks, and lifting objects. Assessments were conducted at diagnosis and repeated at 1- and 2-years post-surgery during scheduled oncology visits. Data were analyzed using descriptive statistics and linear regression. **Results:** BCS (N=396, $Age=57.1 \pm 11.6$ years, $MBMI=29.2 \pm 6.2$ kg/m²) had a mean WC of 96.2 ± 17.6 cm and combined grip strength of 50.0 ± 11.5 kg. The prevalence of DO was 18.3% at diagnosis, 28.2% at 1-year, and 34.5% at 2-year follow-up. DO was not associated with clinical factors (e.g., diagnosis stage, receipt of chemotherapy) at diagnosis. A weak, positive association between DO and age was observed at baseline ($p=.009$). Meeting RT guidelines at diagnosis was inversely associated with DO at baseline ($p=.008$) and 1-year ($p=.05$). Controlling for age and RT participation, DO at diagnosis significantly predicted PF difficulty at 1-year ($\beta=.26$, $p=.007$) and significantly predicted PF difficulty at 2-year follow-up ($\beta=.15$, $p=.09$). **Conclusions:** A significant proportion of BCS had high central adiposity and poor muscle strength from diagnosis to 1- and 2-year follow-up. DO significantly predicted PF difficulty after surgery, indicating the importance of strength and body composition prior to treatment. RT may be protective against DO; therefore, greater efforts to increase RT engagement in BCS are critically needed.

Manual Therapy And Dynamic Splint Use For Trismus In Head And Neck Cancer Survivors

Joni Nedeljak¹, Suresh Nayar², Susan Armijo Olivo³, Ivonne Hernandez¹, Margaret McNeely¹. ¹University of Alberta, Edmonton, AB, Canada. ²Institute for Reconstructive Sciences in Medicine, Edmonton, AB, Canada. ³University of Applied Science, Osnabrück, Germany.
 Email: jnedelja@ualberta.ca
 (No relevant relationships reported)

Head and neck cancer (HNC) accounts for 3-5% of cancer cases in the United States. A known complication of oncological treatments for HNC is trismus, defined as limited mouth opening of less than 35mm. Trismus occurs in 6-86% of survivors. There is no standardized treatment for trismus, however, commonly used conservative interventions include manual therapy (MT), active exercises and assistive stretching devices. These interventions have shown promise as means to improve jaw mobility and alleviate symptoms. Without early detection and intervention, trismus is often chronic and progressive in nature. **PURPOSE:** To determine the feasibility of study

processes, including recruitment rate, completion rate, adherence to protocol, and to establish processes for the dynamic splint mouthpiece fitting and intervention protocol. **METHODS:** A single subject design was used in this pilot feasibility study. Participants underwent a treatment protocol involving MT, exercises, and use of a dynamic splint at home for eight weeks. Multiple maximal interincisal opening (MIO) measures were performed at baseline testing, before and after each treatment session, and at the end of the intervention period. Researchers documented participant adherence to supervised sessions and dynamic splint use, and subjective responses to treatment after each session. **RESULTS:** 70% of participants had an improvement in their MIO after eight weeks, with an average increase of 3.0mm (range: -2.0 to 7.5mm). 90% of participants had 100% adherence to supervised sessions and 70% adherence to home use of the dynamic splint. Two participants were unable to be fitted with a dynamic splint mouthpiece due to insufficient mouth opening and, therefore used the flat plate of the device. Two participants required special adaptation of the mouthpiece, one due to dental pain and the other due to being edentulous. Treatment protocols required tailoring to facilitate comfort and adherence. **CONCLUSION:** Home use of a dynamic splint with MT shows promise as an intervention to address trismus in HNC survivors. The need for adaptations to the mouthpiece and treatment protocol should be anticipated, and a longer intervention period is recommended to optimize outcomes.  (No relevant relationships reported)

PURPOSE: Androgen deprivation therapy (ADT) has detrimental side effects, but changes between localized and advanced prostate cancer are unclear. The purpose is to determine body composition, physical function, and quality of life (QoL) differences across progressive stages of men with PCa on ADT. **METHODS:** Men with localized (PC, n=43, age 67 ± 6.4 y) or metastatic castration-resistant prostate cancer (mPC, n=21, age 72 ± 8.3 y) and non-cancer controls (CON, n=37, age 69 ± 6.1 y) completed total body DXA scans (% fat, lean and fat mass), physical function testing (6m walk, chair stands, timed up and go (TUG), stair climb), and QoL questionnaires (FACT-P). **RESULTS:** Percent fat differed between all groups, along with greater fat mass in mPC vs. CON. Both stair climb and TUG were slower in mPC compared to both CON and PC, whereas chair stands and 6m walk were only slower in mPC vs. CON. There were trends for lower QoL scores in mPC and PC vs. CON for overall FACT-P, Social Well-Being, and Trial Outcome Index vs. CON. Total length of ADT was similar between mPC and PC (mPC: 30 ± 34 months, PC: 37 ± 38 months, $p=0.536$). **CONCLUSIONS:** Body composition and physical function appear to deteriorate in advanced prostate cancer. As the length of ADT is similar between groups, this suggests that the additional forms of ADT for mPC appear to be influencing these changes. However, increases in body fat and reduced functional capacity with ADT do not translate into lower QoL for mPC. Exercise interventions targeting these outcomes are warranted to minimize the side effects of anti-cancer therapy.

While individualized exercise training improves physical and psychosocial health, paired exercise training may result in similar improvements at a reduced patient-to-staff ratio. **PURPOSE:** To compare the effect of paired vs. individualized exercise training on physical and psychosocial health in cancer patients. **METHODS:** Twenty-five female cancer patients (mean±SD: 62±8 years) were assigned to exercise in pairs (n=13) or individually (n=12). They completed 36, 90-min sessions consisting of cardiovascular, resistance, balance and flexibility training according to standardized guidelines. Cardiorespiratory fitness (VO_{2peak}), muscular strength (1-repetition max), endurance (chair squat test), balance (single leg stance), and flexibility (sit-and-reach) were measured pre- and post-exercise. Psychosocial health was assessed pre-, mid- and post-intervention (Functional Assessment of Cancer Therapy-General (FACT-G), Insomnia Index, Brief Fatigue Index, Patient Health Questionnaire-9). Two-way ANOVAs (Factors: Group, Time) were used to identify main effects or interactions; differences were detected with *post-hoc* tests. Significance was set at p<0.05. **RESULTS:** Improvements in physical fitness were similar between paired (P) and singly (S) trained patients. VO_{2peak} significantly increased from 26.6±9.2 to 31.0±7.2 ml·kg⁻¹·min⁻¹ (S) and 26.0±6.3 to 29.1±7.1 ml·kg⁻¹·min⁻¹ (P). Upper and lower body strength increased by 20.0% (S) and 19.6% (P); 15.9% (S) and 20.8% (P), respectively. Paired patients exhibited larger improvements in lower body endurance (S: 24.0% vs. P: 52.3%), flexibility (S: 5.3% vs. P: 11.0%), and balance (S: 17.8% vs. P: 36.8%). A significant main effect (Time) was detected in the functional dimension (FACT-G) but not in social (p=0.200), emotional (p=0.054), or physical well-being (p=0.075). Time (main effect) was not significant for insomnia for either group (p=0.0778), but paired patients had significant improvements in sleep from pre- to mid-intervention (9.8±6.9 vs. 7.2±6.3). **CONCLUSION:** The social aspect associated with paired exercise sessions may have increased motivation, resulting in enhanced improvements in fitness and mental well-being in the paired group. These data suggest that exercising in pairs is a promising approach to cancer rehabilitation.

Relationship Of Health-related Quality Of Life To Functional Fitness In Rural Cancer Survivors
 Jared R. Heitzenrater, Nicole M. Svendsen, Kristopher S. Wisniewski. Saint Francis University, Loretto, PA.
 Email: jaredheitzenrater@gmail.com
 (No relevant relationships reported)

Health-related quality of life (HRQoL) is of high interest in exercise oncology due to decreases in HRQoL during and following cancer treatments. Functional fitness assessments (FFA) are also commonly assessed in this population due to the treatment-related side effects that may impact the patient's ability to perform activities of daily living (ADLs). However, the relationship between these variables has not been previously explored. **Purpose:** To examine the relationship between HRQoL and FFA in a group of rural cancer survivors. **Methods:** Fifteen (Females, n=8; Males, n=7) subjects with a previous diagnosis of cancer aged 62.0 ± 8.5 years and BMI of 21.8 ± 7.9 kg/m² were assessed in several areas of FFA including waist circumference, body fat percentage, fat free mass (FFM), timed up and go (TUG), and 30 second chair stand (30CS). They were also given the Functional Assessment of Chronic Illness-Fatigue (FACIT-F) with subscales in physical well-being (PWB), social/family well-being (SWB), emotional well-being (EWB), functional well-being (FWB), and fatigue. The types of cancer and staging were diverse. Treatment types included chemotherapy, radiation, and surgery. FFA were completed and the FACIT-F completed at home and returned at the following session. **Results:** Pearson Correlations were significant between SWB and TUG (r = -0.844, p = 0.000), SWB and 30CS (r = 0.715, p = 0.003), and between fatigue and FFM (r = 0.668, p = 0.006). A correlation trending toward significance was seen between FWB and TUG (r = -0.504, p = 0.055). No other significant correlations were found. **Conclusion:** Moderate-to-strong relationships were observed between SWB, TUG time, and 30CS. This shows cancer survivors who are more mobile may have a greater ability to engage in social tasks and ADLs. In addition, higher amounts of FFM were moderately correlated with having less fatigue meaning cancer survivors with more FFM may have less fatigue.

Role Of Joint Loosening Yoga In Management Of Aromatase Inhibitor-Induced Arthralgia In Breast Cancer Survivors
 Leigh Leibel¹, Kashinath Metri², Rajendra Prasad², Greg Mears¹.
¹Columbia University Medical Center, New York, NY. ²S-Hyasa University, Bangalore, India.
 Email: LL3125@cumc.columbia.edu
 (No relevant relationships reported)

PURPOSE: Aromatase inhibitor hormonal therapy causes joint pain in up to half of women, and up to 20% become non-compliant with the 5-10 year treatment schedule due to pain and discomfort. Non-compliance affects patient prognosis and survival. This pilot study investigated the efficacy of joint loosening yoga in improving aromatase inhibitor-induced joint pain and evaluated the feasibility of delivering the intervention on Facebook. **METHODS:** Breast cancer patients undergoing treatment with aromatase inhibitors with self-reported arthralgia were recruited via an IRB-approved announcement posted in two closed breast cancer support groups on Facebook to participate in a yoga study delivered on Facebook. Participants completed BPI, DASH, PRAI and WOMAC questionnaires online before and after the study. Intervention consisted of 12 joint loosening exercises performed in a chair, once daily for 12 minutes, Monday-Friday for 4 weeks. Asynchronous video demonstrations were available in a secret Facebook group and viewing confirmed by typing "done" (time-stamped) in comments. **RESULTS:** 200 women responded. 38 met the inclusion criteria/consent, 26 completed the online consent, interventions and pre/post questionnaires. Participants were based in US, Canada and UK. Paired simple t tests results showed significant (P < 0.05) improvement in all the pain measures and quality of life parameters after yoga intervention compared to baseline. **CONCLUSIONS:** This study provides the first evidence that it is feasible to teach joint loosening yoga to patients on Facebook and that the intervention significantly improves aromatase inhibitor-induced arthralgia. Teaching yoga via social media may provide better access to this therapeutic modality to patients at all points in the cancer care continuum globally.

Variable	Pre Mean	Post Mean	% Change	P Value
BPI_PSS	4.26±1.79	2.3±1.45	-46.00%	P<.05
BPI_PIS	3.9±2.32	1.81±2.00	-53.58%	P<.05
DASH	30.54±15.26	13.72±14.86	-55.07%	P<.05
PRAI	2.69±1.55	1.36±1.13	-49.44%	P<.05
WOMAC 1	6.76±3.67	3.24±2.20	-52.07%	P<.05
WOMAC 2	4.04±1.76	2.40±1.15	-40.59%	P<.05
WOMAC 3	22.64±13.11	13.±8.83	-42.57%	P<.05

The Impact Of Sports Science-based Prehabilitation On Spontaneous Physical Activity After Major Abdominal Cancer Surgery
 Savannah V. Wooten, J. Stuart Wolf, John B. Bartholomew, FACSM, Diana Mendoza, Philip R. Stanforth, FACSM, Dixie Stanforth, FACSM, Ladia M. Hernandez, Cathy T. Nguyen, Joseph R. Carneglia, Hirofumi Tanaka, FACSM, R. Y. Declan Fleming. The University of Texas at Austin, Austin, TX.
 (Sponsor: Hirofumi Tanaka, FACSM)
 Email: svwooten@utexas.edu
 (No relevant relationships reported)

Complex surgery for abdominal cancer often leads to postoperative complications that may prevent post-surgical rehabilitation in old, frail, or malnourished patients. Prehabilitation is an emerging alternative strategy that has the potential to speed recovery and may be analogous to athletic preparations for gamened. For optimal physiological improvement to occur in a limited time period prior to the surgery, cancer patients undergoing prehabilitation interventions must work closer to their maximal physiological capacity (albeit a very low level) in a manner similar to that of competitive athletes. **PURPOSE:** To determine the effect of a 4-week sports science-based prehabilitation program on spontaneous physical activity in cancer patients who undergo major abdominal surgery. **METHODS:** Twenty-two cancer patients (63±11 years) who underwent major abdominal surgery were studied. Fourteen patients participated in a 4-week exercise and nutrition prehabilitation program prior to abdominal surgery. The sport-science based program comprised of an interdisciplinary approach, including blood flow restriction exercise and a daily sports nutrition supplement containing L-citrulline, creatine monohydrate, and whey protein. The remaining 8 patients served as controls. Physical activity of both groups was monitored

for 5 days after surgery. Accelerometers were used to quantify number of steps, energy expenditure, and sedentary time. **RESULTS:** The prehabilitation group recorded 47.4% more total steps for 5 days after abdominal surgery than the control group (16,032±5,194 vs. 10,877±5,182 total steps/5 days, $p=0.037$). The prehabilitation group had a greater amount of total energy expenditure than the control group (5,555±3,400 vs. 2,971±1,572 total kcal/5 days, $p=0.028$). There was no significant difference in total sedentary time between the two groups (5,064±597 vs. 5,414±514 min/5 days). **CONCLUSIONS:** This prehabilitation program composed of cutting-edge sports science practices significantly improved spontaneous physical activity after major surgery in older patients with abdominal cancers.

Skinner¹. ¹The University of Queensland, Brisbane, Australia. ²QIMR Berghofer Medical Research Institute, Brisbane, Australia. ³Aspire Fitness and Rehabilitation, Brisbane, Australia. ⁴The Leukaemia Foundation of Australia, Brisbane, Australia.

(No relevant relationships reported)

In blood cancer, aerobic physical activity may improve fatigue and depression, though its effect on quality of life and physical function is less clear. Assessment of Fit to Thrive (FTT), a community-based individualised, supervised exercise program for people with blood cancer, may assist with future recommendations.

Purpose: To assess the effect of the FTT program on physical function and quality of life (QoL) in people with blood cancer.

Methods:

The 12-week FTT program utilised progressive aerobic and resistance training, supervised by an Accredited Exercise Physiologist, in small groups ($n=6$), twice weekly, for 8 weeks, with associated psychosocial and peer support. Physical function was assessed via the six minute walk (6MW), functional forward reach (FFR) and 5 times-sit-to-stand (5TSTS) tests. QoL was measured using the 36-item Short Form Survey Instrument (SF-36) and the Functional Assessment of Cancer Therapy General (FACT-G). Minimally important differences (MID) involved a change of 2 points for the SF-36, 3 points for the FACT-G and +50m for 6MW.

Results:

Participants ($n=106$) who attended the FTT program between 2014 and 2016 were included. Significant improvements in functional measures were observed for 6MW (+54.7m [95% CI 40.5, 69.0] $p<0.001$), 5TSTS (-1.9 sec [95% CI -2.5, -1.2] $p<0.001$) and FFR (+2.7cm [95% CI 1.5, 4.0] $p<0.001$), with the MID achieved by 56% for the 6MW. The SF-36 physical component summary (PCS) significantly increased (+4.99 [95% CI 3.29, 6.68] $p<0.001$) immediately following the intervention, with 68% ($n=72$) achieving the MID. The improvement in the SF-36 mental component summary (MCS) also achieved statistical significance (+2.81 [95% CI 0.54, 5.08] $p=0.02$), with 51% ($n=54$) achieving the MID. FACT-G scores improved significantly from pre- to post-intervention (+5.50 [95% CI 2.52, 8.47], $p<0.001$) with 58% ($n=62$) meeting the MID. MID improvements in PCS and FACT-G were maintained in 77% ($n=20/26$) and 95% ($n=19/20$) of participants 3 months following completion of the program.

Conclusion:

The FTT program was effective in improving physical function and QoL, with some evidence for long-term effects. An individually-prescribed exercise program supervised by an Accredited Exercise Physiologist should be considered as part of standard care in people with stable blood cancer.

(No relevant relationships reported)

Radiation and hormone therapy may damage skeletal muscle and lead to cancer-related fatigue (CRF). Developmental myosin light chain 5 (MYL5) and myosin heavy chain 8 (MYH8) are required for normal muscle regeneration. Up-regulated serum levels of MYL5 and MYH8 resulting from radiation and hormone therapy may increase muscle degradation and lead to CRF, especially physical CRF—one of the multidimensional subcomponents of overall CRF. **PURPOSE:** To investigate the effect of a 6-week aerobic and anaerobic exercise intervention, called Exercise for Cancer Patients (EXCAP), on (1) CRF (overall and physical), (2) serum protein levels of MYL5 and MYH8, and (3) the association of CRF (overall and physical) with these novel biomarkers. **METHODS:** Ninety sedentary breast cancer patients (55.5±9.6 years, 79% white, 52% receiving radiation therapy, 48% receiving hormone therapy) were consented and participated in this phase II RCT. Patients were randomized into two arms: (1) standard cancer treatment (Control) or (2) standard cancer treatment plus EXCAP. Serum levels of MYL5 and MYH8 by ELISA assays and CRF (total and physical) by patient-report via the Multidimensional Fatigue Symptom Inventory were assessed pre- and post-intervention. **RESULTS:** T-tests showed significant reductions in overall CRF and physical CRF among exercisers (overall CRF: -4.9±2.6, $p=0.07$, physical CRF: -1.0±0.5, $p=0.05$) but not in controls, with significant group differences (overall CRF: -7.9±3.4, $p=0.02$; physical CRF: -1.9±0.7, $p<0.01$). T-tests also revealed statistical trends for down-regulation of MYL5 (-0.5±0.3, $p=0.17$) and MYH8 (-0.4±0.3, $p=0.17$) serum protein levels from pre- to post-intervention in exercisers, but not in controls. Spearman correlations also reveal statistical trends, in exercisers, where decreases in MYL5 and MYH8 serum protein levels are directly associated with decreases in total CRF (MYL5 $r=0.23$, $p=0.17$; MYH8 $r=0.30$, $p=0.07$) and physical CRF (MYL5 $r=0.29$, $p=0.08$; MYH8 $r=0.39$, $p=0.02$). **CONCLUSIONS:** EXCAP improves overall and physical CRF. EXCAP may also protect against cancer treatment-induced skeletal muscle damage via its effects on MYL5 and MYH8. Changes in these novel biomarkers may mediate changes in overall and physical CRF. Further phase III RCTs are needed to confirm these findings.

The Influence Of Physical Activity And Body Composition On Gene Expression In Breast Adipose Tissue

Hannah K. Schulte¹, Sarah E. Neil-Sztramko², Nagarajan Kannan³, Gift Nyamundanda⁴, Anguraj Sadanandam⁴, Jonathan P. Little⁵, James D. Johnson¹, Ilona Csizmadia⁶, Kelcey Bland⁷, Kristin L. Campbell, FACSM¹. ¹University of British Columbia, Vancouver, BC, Canada. ²McMaster University, Hamilton, ON, Canada. ³Mayo Clinic, Rochester, MN. ⁴The Institute of Cancer Research, London, United Kingdom. ⁵University of British Columbia Okanagan, Kelowna, BC, Canada. ⁶Cedars-Sinai Medical Centre, Los Angeles, CA. ⁷Australian Catholic University, Melbourne, Australia.

Email: hannah.schulte@ubc.ca

(No relevant relationships reported)

Higher physical activity levels and healthy body weights are associated with a lower risk of postmenopausal breast cancer. Little is known about the biological mechanisms underlying this association, but the microenvironment created in the breast tissue is of interest. Adipose tissue is recognized as an endocrine organ, responding to the local and systemic environment. **PURPOSE:** To explore the association between self-reported lifestyles factors, and breast adipose tissue and the microenvironment it creates. **METHODS:** Using a cross-sectional design, women undergoing reduction mammoplasty surgery were recruited. Participants completed standard questionnaires

about their usual physical activity, weight history, reproductive history, and past-year dietary intake. Body weight was abstracted from medical records. A sample of breast tissue was collected during surgery. An adipose-rich section was isolated under sterile conditions. Part of the sample was formalin fixed (sectioned at 7 μ m thickness for measurement of mean adipocyte size with Image J) and part was flash frozen for RNA isolation. Associations between mean adipocyte size and lifestyle variables were examined by multivariate analysis to determine associations between genes and lifestyle variables. **RESULTS:** Of 72 women recruited, RNA was isolated from 65 samples. Participants were a mean age of 43 years (range 19-70) and had a mean body mass index of 27.0 kg/m² (SD 5.0). BMI was positively associated with adipocyte size ($\beta = 0.06$, $p < 0.01$) and transportation physical activity was negatively associated with adipocyte size ($\beta = -0.25$, $p = 0.02$). Six genes, namely *SLC27A2*, *TTC36*, *WHSC1L1*, *AASS*, *MOCSI*, *GLYCK*, were found to be associated with adipocyte size. **CONCLUSION:** Adipose tissue biology is associated with lifestyle exposures in normal breast tissue. Our findings provide directions for future research into the impact of lifestyle on the microenvironment of healthy breast tissue.

MICROVASCULAR OXYGENATION RESPONSE DURING PADDLING GRADED EXERCISE TEST IN BREAST CANCER SURVIVOR DRAGON BOAT RACERS
 Brooklyn E. Herbert, Trent E. Cayot, Riggs J. Klika, FACSM.
University of Indianapolis, Indianapolis, IN. (Sponsor: Riggs J. Klika, FACSM)
(No relevant relationships reported)

Cancer treatment is associated with numerous peripheral pathologies including altered blood flow and vascular dysfunction. A pilot study was conducted to measure the peripheral microvascular oxygenation response during maximal exercise in a group of cancer survivors. **PURPOSE:** To investigate the differences that paddling side (paddling side, PS; non-paddling side, NPS) and treatment side (treatment side, TREAT; healthy side, HEAL) has on the near-infrared spectroscopy (NIRS) responses during a unilateral paddling graded exercise test in breast cancer survivor dragon boat racers. **METHODS:** Thirteen breast cancer survivors/racers (56 \pm 9 years, 1.65 \pm 0.06 m, 76.5 \pm 11.0 kg) performed a unilateral, discontinuous graded exercise test (2-minute exercise, 1-minute rest) on a stationary rowing ergometer to volitional fatigue. Tissue oxygenation saturation (StO₂) and total hemoglobin concentration ([THC]) were measured via NIRS from the posterior deltoid muscles during the graded exercise test. StO₂ and [THC] responses were averaged during the last 30 seconds of each exercise stage and normalized to baseline exercising data. Paired t-tests were used to examine if treatment side had an effect on StO₂ or [THC] and if paddling side had an effect on [THC] responses at maximal intensity. Due to non-normally distributed data, a Wilcoxon Signed Rank Test was used to determine if paddling side had an effect on StO₂ at maximal intensity. Significance was established *a priori* at $p < 0.05$. **RESULTS:** Paddling side did not significantly affect the StO₂ (PS = -5.2 \pm 15.7%, NPS = -13.5 \pm 21.7%, $p = 0.094$) or [THC] (PS = 0.14 \pm 0.19, NPS = 0.15 \pm 0.21, $p = 0.425$) responses. Treatment side had a significant, moderate (ES = 1.12) effect on the StO₂ response (TREAT = -0.006 \pm 16.1%, HEAL = -18.7 \pm 17.3%, $p = 0.008$). Treatment side did not significantly affect the [THC] response (TREAT = 0.13 \pm 0.20, HEAL = 0.16 \pm 0.19, $p = 0.313$). **CONCLUSION:** Based upon the pilot results, it would suggest that the exercising muscles on the breast cancer treatment side may have a residual impaired ability to use oxygen for energy production during maximal intensity exercise.

The Role Of Aerobic Physical Training On Colon Tumor Metabolic Reprogramming
 Joao Lucas Penteado Gomes. *University of Sao Paulo, Sao Paulo, Brazil.*
 Email: joao.gomes@usp.br
(No relevant relationships reported)

PURPOSE: Tumor cells are known for marked growth and proliferation, however adequate energy support is required to sustain the growth and proliferation of cancer cells. Therefore, tumors have a large change in energy metabolism, for example, the glycolysis pathway is overactivated. These phenomena are linked to changes in metabolic genes expression, such as microRNA-33a and its gene target SIRT6. On the other hand, aerobic physical training (APT) is known to increase cellular respiration in tissues such as cardiac and skeletal muscle, unlike cancer. APT, also contributes to decreased tumor progression. **METHODS:** We first evaluated if a longer training time prior colon cancer cell inoculation (CT26) contributes to lower tumor progression, we observed that the time of APT is not a major factor since all cancer trained mice have lower tumor progression compared to the sedentary cancer group (SC). Thus, we proceeded to evaluate two groups: 1) group with cancer and 8-weeks training prior to inoculum (TR8), 2) and SC and 3) Wild type (WT). **RESULTS:** TR8 group presented longer survival ($p = 0.007$), cancer promoted decrease of fat mass (WT-7.3 \pm 0.7; SC-1.4 \pm 0.8; TR8-3.6 \pm 2.8; $p = 0.01$)

and increase of liver mass (WT-62 \pm 7.9; SC-91.7 \pm 11.9; TR8-81.5 \pm 11; $p = 0.01$) in sedentary e trained group compared with WT. SIRT6 (SC-100 \pm 12.1; TR8-88.8 \pm 27.9) and the microRNA-33a (SC-100 \pm 42.9; TR8-78.2 \pm 30.6) expression in tumor tissue was not different between the groups. However, we observed differences in HIF1a expression (SC-100 \pm 21.4; TR8-74 \pm 13.4 - $p = 0.01$), which was decreased due to APT, as well as the GLUT1 (SC-100 \pm 32.4; TR8-69.6 \pm 36.2; $p = 0.07$), PDK (SC-100 \pm 20.9; TR8-76.8 \pm 22.6; $p = 0.05$), LDHa (SC-100 \pm 26.2; TR8-65.4 \pm 35.7 $p = 0.03$) expression also decreased due to APT. **CONCLUSIONS:** Our results show that APT decreases tumor progression and increases survival. Also, our results suggest that APT plays an important role in metabolic reprogramming. In conclusion, we showed that APT decreases the glycolytic pathway enzymes gene expression that is related to increased proliferation and malignancy of colon cancer.

Combined Aerobic And Strength Exercise Maintains Circulating Fgf-21 In Asian Breast Cancer Patients
 Jorming Goh¹, Lina Lim¹, Brian Kennedy¹, Soo Chin Lee².
¹National University of Singapore, Singapore, Singapore.
²National University Cancer Institute, Singapore, Singapore.
 Email: jorming@nus.edu.sg
(No relevant relationships reported)

PURPOSE
 Combined aerobic and resistance training improves systemic inflammation and muscle mass in breast cancer survivors. However, whether combined exercise modulates novel metabolic hormones and alarmins is unknown. FGF-21 was reported to modulate glucose metabolism in physically active adults, while IL-33, a recently discovered alarmin, is prognostic for breast cancer outcomes. This study aimed to determine the effects of 3 months of combined aerobic and strength exercise on systemic FGF-21, FGF-23, IL-33 and cytokines in Asian breast cancer patients.

METHODS
 Patients with early stage (I-II) breast cancer underwent curative breast surgery and were randomized into a combined aerobic and strength exercise group (Age: 55.3 \pm 9.2 years; BMI: 26.7 \pm 3.8; N = 23) or observation group (Age: 49.3 \pm 8.7 years; BMI: 24.7 \pm 4.6; N = 20) that spanned 3 months. Antecubital blood was collected at baseline, 3 months and 6 months. Serum concentration of cytokines (IL-10, IL-12, IL-33, IFN- γ , TNF- α) and myokines (FGF-21, FGF-23) were quantified using a customized magnetic bead panel (Milliplex®) and read with a Luminex 200™ instrument. Biomarker data were assessed by a 2-way [group (exercise vs. observation) by time (baseline, 3 months, 6 months)] analysis of variance (ANOVA). Data are reported as means \pm SD, with significance set at $P < 0.05$.

RESULTS
 A significant main effect of intervention was observed for FGF-21 ($P < 0.01$), with patients in the exercise group presenting with higher FGF-21 at 3 months (73.16 \pm 54.05 pg/mL vs. 46.47 \pm 25.33 pg/mL) and 6 months (66.67 \pm 50.03 pg/mL vs. 41.79 \pm 33.81 pg/mL), compared with the observation group. A significant main effect of exercise on IFN- γ ($P < 0.05$) was observed, with lower serum IFN- γ in the exercise group at 3 months (3.85 \pm 4.34 pg/mL vs. 5.43 \pm 7.28 pg/mL) and 6 months (3.89 \pm 4.58 pg/mL vs. 5.32 \pm 8.1 pg/mL), compared with controls. No significant differences were observed between groups in other outcome measures.

CONCLUSIONS
 A 3-month aerobic and strength exercise program preserves serum FGF-21, possibly associated with better glucose control in breast cancer patients. Lower serum IFN- γ after exercise training may suggest an attenuated pro-inflammatory response, which may be linked to better immune outcomes.

(No relevant relationships reported)

There is increasing interest in the use of strength training (ST) exercise in cancer survivors. Aside from the direct beneficial effects on muscle, ST has the potential to chronically attenuate some of the negative alterations commonly seeing in the immunological and hormonal physiology of cancer survivors. However, the acute effects of a high intensity ST session on hormonal and inflammatory responses have not been well documented. **PURPOSE:** To examine the acute hormonal and inflammatory responses of one high intensity traditional ST session in breast cancer survivors (BCS). **METHODS:** Eight BCS (47 \pm 6 years; 67.75 \pm 5.90 kg; 169.5 \pm 6.28cm)

participated in this study. BCS completed one traditional session of ST consisting of 3 sets of 10-12 repetitions to maximal concentric failure with 120 seconds of rest between sets. The exercises included: 1) leg extension, 2) deadlift, 3) leg press, 4) machine bench press, 5) latpull down, and 6) sit ups. Venous blood samples were obtained to assess biomarkers of exercise-induced inflammation (C-reactive protein), and hormonal response (Cortisol, and IGF-1). Measurements were assessed before and immediately after the ST session. Dependent samples t-tests were used to compare pre and post blood biomarkers.

RESULTS: No significant changes in C-reactive protein (pre 2.61 ± 2.78 , post 2.46 ± 2.99 mg/L, $p=0.056$), cortisol (pre 9.55 ± 3.12 , post 7.61 ± 1.90 μ g/dL, $p=0.062$), and IGF-1 (pre 150.38 ± 37.913 , post 154.88 ± 40.336 ng/mL, $p=0.125$) were observed after one session of traditional ST.

CONCLUSIONS: Although in healthy people one-time high intensity strength training has been associated with increases on different inflammatory and hormonal biomarkers, our results showed that in BCS one session of ST does not appear to significantly increase C-reactive protein, cortisol or IGF-1 concentration levels. These results may be attributed to the lower absolute force production and physiological stress during the ST session in this population. Furthermore, selective estrogen receptor modulators (SERMs), a class of drugs often used to treat certain types of breast cancer can have a suppressive effect on adrenal corticosteroid release, suggesting disrupted HPA-axis feedback inhibition processes contributing to low cortisol release during exercise.

Combined HIT/HIRT Induces Beneficial Molecular Adaptations In BRCA1-mutation Carriers: A Pilot Study

Daniel A. Bizjak, Sebastian VW Schulz, Stephanie Otto, Stefanie H. Andreß, Tim Graf, Uwe A. Schumann, Jürgen M. Steinacker, FACSM. *University Hospital Ulm, Ulm, Germany.*

(No relevant relationships reported)

PURPOSE: BRCA gene mutation carriers have a 55-60% higher incidence to develop breast cancer than non-mutation carriers, whereas exercise is able to reduce cancer risk in BRCA competent women. Because of growing evidence that BRCA also plays a pivotal role in the regulation of skeletal muscle metabolism and the response to anti-oxidative stress, we examined the influence of regular exercise in human BRCA gene mutation carriers on BRCA1 gene/protein expression and inflammatory/oxidative response.

METHODS: 16 BRCA-mutation carriers without clinical manifestation (13 w, 3 m) were either assigned to an intervention (IG, $n=10$, 35.5 ± 10.5 yrs) or control group (CG, $n=6$, 46.3 ± 5.3 yrs). IG received a six-week long combination of high intensity (interval) strength and endurance training (HIRT/HIT), whereas CG only did low intensity activity. Before (T0) and at the end of the intervention (T1), muscle biopsy, physiological performance, blood withdrawal and anthropometry were determined. Parameters included: muscle BRCA1 gene and protein expression, inflammatory and oxidative stress (i.e. cytokine and malondialdehyde (MDA)), anti-oxidative capacity (i.e. Thiol status, C-reactive protein (CRP)), peak oxygen capacity (VO_{2peak}) and 1-repetition maximum (1-RM) at six different training machines. Data were analysed by 1-way ANOVA with repeated measures and t-test to determine statistical significance and effect size (ES).

RESULTS: VO_{2peak} ($p=0.001$) and 1-RM ($p_{mean}=0.007$) of IG were increased at T1 compared to T0, whereas CG performance parameters remained unchanged. BRCA1 protein concentration increased in IG from 46.32 ± 18.78 to 64.83 ± 22.53 pg/ml ($p<0.001$) with small ES as well as anti-oxidative capacity (CRP $p=0.05$; Thiol $p=0.009$) with medium ES, whereas gene expression was unaltered. IG inflammatory and oxidative damage reflected by cytokine and MDA formation, respectively, did not differ between time points. CG physiological and molecular parameters remained unchanged during the intervention.

CONCLUSIONS: Combined HIRT/HIT training increases the performance of BRCA-mutation carriers with positive influence on BRCA1 protein expression as well as anti-oxidative status without increased inflammatory response and thus might be a prospective prevention method to reduce long-term cancer risk.

Association Between Systemic Inflammation And Skeletal Muscle Mass Following Exercise In Breast Cancer Survivors

Kaylie Zapanta¹, Kyuwan Lee², Nathalie Sami³, Christina Dieli-Conwright, FACSM⁴. ¹University of Southern Ca, Los Angeles, CA. ²Children's Hospital Los Angeles, Los Angeles, CA. ³University of Southern California, Los Angeles, CA. ⁴City of Hope Comprehensive Cancer Center, Duarte, CA. (Sponsor: Christina Dieli-Conwright, FACSM)

Email: kzapanta@usc.edu

(No relevant relationships reported)

INTRODUCTION: Reductions in skeletal muscle mass contribute to reduced physical function and poorer prognosis among breast cancer survivors (BCS). Elevated pro-inflammatory markers stimulate catabolic pathways in skeletal muscle, and have been associated with muscle loss in overweight individuals and older adults. This evidence suggests that elevated pro-inflammatory markers such as IL-6, TNF-alpha, and C-reactive protein (CRP) may explain subsequent muscle loss in BCS. While we previously found exercise reduces inflammation and increases skeletal muscle mass in overweight or obese BCS, an associative investigation is warranted. **PURPOSE:** The purpose of this secondary analysis was to determine whether associations between post-exercise inflammatory markers and skeletal muscle mass exist among overweight/obese BCS. **METHODS:** Sedentary, overweight/obese BCS (BMI ≥ 25 kg/m²; Stages I-III) were randomized to exercise (EX; $n=50$) and control (CON; $n=50$) groups. EX participated in a supervised 16-week moderate-vigorous intensity aerobic and resistance exercise intervention. CON was asked to maintain current levels of activity. Appendicular Skeletal Muscle Index (ASMI), calculated as \sum extremity lean mass (kg)/height (m²), was obtained from a whole-body scan using Dual Energy X-Ray Absorptiometry. CRP, IL-6, and TNF- α were measured using enzyme-linked immunosorbent assays from fasting blood samples. Pearson's correlations assessed associations between post-exercise ASMI and inflammatory biomarkers. **RESULTS:** On average, BCS were 53.5 ± 10.4 years old, postmenopausal (60%), and Hispanic (55%) with a BMI of 33.5 ± 5.5 kg/m². Post-intervention, EX experienced an increase in ASMI (8.3%; $p=0.001$), and reductions in CRP (-47.8%; $p=0.001$) IL-6 (-73.6%; $p=0.001$) and TNF- α (-25.1%; $p=0.001$). No significant changes were seen in CON ($p>0.01$). There were significant correlations between ASMI and IL-6 ($r=-0.78$; $p=0.02$), CRP ($r=-0.91$; $p=0.01$), and TNF-alpha ($r=-0.82$; $p=0.03$). **CONCLUSIONS:** This secondary analysis provides preliminary evidence to support the relation between changes in skeletal muscle mass and inflammation among BCS, and supports the implementation of exercise to maintain muscle mass during survivorship.

(No relevant relationships reported)

PURPOSE: Chronic lymphocytic leukemia (CLL) is the most common leukemia in older adults. CLL patients are at an increased risk of frailty, secondary malignancies, and infectious diseases. The aim of this study was to determine the role of physical fitness and function on biological mediators of tumor control and progression.

METHODS: We collected blood from sixty two (68 ± 11 yrs.) men and women with treatment naïve CLL [CLL-IPI: median 1.5 (range: 0-7)] and were asked to complete a comprehensive battery of physical fitness and functional tests. The 10 most fit (FIT: estimated VO_{2peak} 34 ± 3 mL/kg/min) and 10 least fit (UNFIT: 25 ± 3 mL/kg/min) adults were matched on age and gender. We completed immunophenotyping of blood leukocytes, NMR-spectroscopy of lipoprotein particles, and sequencing of exosomal micro-RNA (miRNA). The human CLL-like OSU-CLL cell line was co-cultured with autologous plasma and assessed for cell growth and death.

RESULTS: The FIT group had 6% fewer CD4+ ($p=0.019$) and 4% fewer CD8+ ($p=0.015$) T-cells than the UNFIT group. The FIT group had 15% fewer NKG2A+ NK-cells ($p=0.032$), and 10% more cytotoxic NKG2A-/KIR+ NK-cells capable of recognizing HLA+ tumor cells. The FIT group had 63% lower concentrations of triglycerides ($p=0.025$), and 250% fewer large triglyceride rich lipoproteins ($p=0.011$), and 20% more HDL cholesterol ($p=0.04$), with no differences for LDL cholesterol. Greater concentrations of triglycerides and large lipoproteins were associated with increased OSU-CLL cell counts ($r=0.497$, $p=0.03$) and less OSU-CLL cell death ($r=-0.632$, $p=0.003$). A total of 32 miRNA signatures were significantly different between FIT and UNFIT groups (all $p<0.05$). Of these, 7 distinct miRNAs were positively

correlated with OSU-CLL tumor cell growth (e.g. miR-451a: $r=0.606$, $p<0.001$), and 6 miRNAs negatively correlated with OSU-CLL tumor cell growth (e.g. miR-24: $r=-0.669$, $p=0.002$).

CONCLUSIONS: Physical fitness in CLL patients appears to beneficially modify T-cells and NK-cells, plasma lipoproteins and exosomal miRNAs. Certain lipoproteins and miRNAs are associated with tumor cell growth and death. Further studies will hope to define the possible beneficial effects of exercise training for CLL patients.

(No relevant relationships reported)

Purpose

To investigate environmental determinants of change to sedentary behaviour (SB), light-intensity physical activity (LPA) and moderate-to-vigorous intensity physical activity (MVPA) in those at risk of diabetes.

Methods

Cohort of 808 adults recruited from family practice (age = 63 years, BMI = 32 kg/m², women = 36%) followed up annually over 3 years. Participants were included based on being above the 90th percentile of the Leicester Diabetes Risk Score, indicating a high risk. SB, LPA and MVPA were measured by accelerometer (Actigraph GT3X) using the Freedson cut-points with at least 4 valid days of data. Geographical and air pollution mapping were used to link environmental data to participant's home address. Data were analysed using a repeated measures design assessing determinants of change to SB, LPA and MVPA. Results are presented as mean (SD) or mean (95% CI).

Results

At baseline, accelerometers were worn for an average of 649 (83) minutes/day, during which an average of 27 (25) minutes/day, 288 (77) minutes/day and 543 (100) minutes/day were spent in MVPA, LPA and SB respectively. Across the study period, wear time did not change, whilst SB increased by 9 (7, 10) minutes/day per year, matched by a decrease in LPA and MVPA of 7 (5, 8) and 2 (1, 2) minutes/day per year respectively. Less green space, higher road connectivity (busier traffic), greater air pollution and a higher density of fast food restaurants were all determinants of increasing SB and decreasing LPA (See Table 1), but none were associated with change to MVPA. Environmental factors were stronger determinants of change to SB and LPA than an overall index of social deprivation.

Conclusion

In this high risk population, a less healthy environment predicted greater annual increases in SB and decreases in LPA, but not MVPA. Policies and interventions aimed at improving the liveable environment may therefore act to slow the trajectory of increasing SB and decreasing LPA in populations at risk of diabetes.

Table 1: Association between environmental factors and annual change to SB, LPA and MVPA

Environmental determinant	Change in sedentary time (minutes/day per year) for a given unit difference in the corresponding environmental factor	Change in light-intensity physical activity (minutes/day per year) for a given unit difference in the corresponding environmental factor	Change in moderate-to-vigorous physical activity (minutes/day per year) for a given unit difference in the corresponding environmental factor
Greenspace (% within 800m radius)	-2.34 (-4.30 to -0.38)	2.00 (0.26 to 3.74)	0.32 (-0.22 to 0.86)
Road density (km of road within 800m radius)	0.96 (-0.35 to 2.26)	-0.78 (-1.95 to 0.38)	-0.16 (-0.52 to 0.20)
Footpath density (km of footpath within 800m radius)	1.06 (-4.85 to 6.96)	-0.97 (-6.22 to 4.28)	-0.06 (-1.68 to 1.56)
Intersections that are connected (% within 800m radius)	6.41 (1.19 to 11.64)	-6.43 (-11.07 to -1.79)	-0.045 (-1.39 to 1.48)
Air pollution (prevailing outdoor nitrogen dioxide and particulate matter concentrations with 800mx 800m area: NO ₂ , PM2.5 and PM10/µg·m ³)	1.42 (0.34 to 2.50)	-1.25 (-2.20 to -0.29)	-0.16 (-0.46 to 0.14)
Fast Food (restaurants within 1km radius)	1.09 (0.38 to 1.80)	-1.00 (-1.63 to -0.47)	-0.09 (-0.28 to 0.11)
Social deprivation (index of multiple deprivation score)	0.04 (-0.09, 0.18)	-0.06 (-0.19, 0.07)	0.02 (-0.02, 0.06)

Differences In College Student Physical Activity Relative To Living Environment
 Lucas D. Elliott, Oliver W.A. Wilson, Melissa Bopp, FACSM. *The Pennsylvania State University, University Park, PA.*
 (Sponsor: Dr. Melissa Bopp, FACSM)
 Email: lde5065@psu.edu
(No relevant relationships reported)

BACKGROUND: Physical activity (PA) levels are decreasing among college aged individuals in the US. To develop healthy behavior-change strategies for these individuals, a better understanding of their living environment is needed. **PURPOSE:** This study compared PA trends of college students relative to their living environment. **METHODS:** A volunteer sample of students (n = 338) from a large northeastern US university completed an online survey. Demographics, height/weight, frequency/mode of active travel to/from campus, and amount of self-reported weekly PA were obtained. Students were dichotomized into groups depending on their self-reported walking time to campus (≥15 or <15 minutes), never walk or walk ≥ once/week to campus, and if they have a bus pass or not. An equipment index was created using the participants self-reported responses to their access of multiple types of recreational facilities/equipment at their home (e.g. treadmill, pool, etc.). These groups were compared to moderate PA (MPA), strength training (ST), vigorous PA (VPA) minutes, and walking time to campus using t-tests. **RESULTS:** Participants were primarily white (n = 182, 60.3%) and majority were female (n=153, 50.5%). Students that live ≥ 15 minutes from campus had significantly lower levels of weekly MPA (p = .024), METS (p = .021), and ST (p = .002). Weekly MPA, METS, and ST (p < .05) were also significantly lower in students who did not walk to campus at least once a week. Students that had access to a bus pass showed lower amounts of MPA, METS, and ST per week (p < .05). Students who did not walk once a week to campus and those who lived ≥ 15 minutes away from campus had significantly higher accessibility to exercise equipment. **CONCLUSIONS:** There were significant differences in the amount of weekly PA for those living further from campus. Even though students showing higher

accessibility to exercise equipment live further away, they are more likely to use non-active travel methods. Active travel, especially in college students, is shown to be an important and significant variable to increase and meet weekly PA levels.

Age-difference In The Association Of Built Environment With Walking In Older Adults

Chia-hui CHANG¹, Hung-Yu Chang Chien¹, Ting-Fu Lai¹, Ming-Chun Hsueh², Yung Liao¹. ¹National Taiwan Normal University, Taipei, Taiwan. ²University of Taipei, Taipei, Taiwan.
 Email: aj820927@gmail.com
 (No relevant relationships reported)

PURPOSE: It remains unclear whether the relationship between built environment and walking behavior differ by age groups. Therefore, this study aimed to examine age-related differences in associations of built environmental attributes with walking in older Taiwanese adults. **METHODS:** This study was based on a cross-sectional telephone survey using a computer-assisted telephone interviewing, targeting 1,068 older Taiwanese adults (over 65 years) in 2017. Time spent in walking was measured by the short version of the International Physical Activity Questionnaire. Built environmental attributes were assessed by geographic information systems (GIS), including population density, street connectivity, sidewalk availability, leisure destinations, utilization destinations & access to public transportation. Adjusted binary logistic regression models adjusting for potential confounders were employed to examine the relationships between the seven built environment variables & walking time in total sample, and stratified for young (65-74 year) & old (75+ years) older adults. **RESULTS:** A total of 1,040 respondents provided complete information for analysis. The mean age (SD) of the respondent was 73.04 (\pm 6.13) years. 68.8% achieved 150 min of walking in a week. In total sample, only one GIS-derived environmental attribute - leisure destinations was positive associated with the 150 min of walking in a week (odds ratio (OR)=1.34, 95% confidential interval (CI)=1.02-1.75). After stratifying by age groups, among 65 to 74 age group, population density was negative associated with the 150 min of walking in a week (OR=0.65, 95%CI=0.46-0.93) and number of leisure destination was positive associated with the 150 min of walking in a week (OR=1.55, 95%CI=1.10-2.19). However, no significant associations were observed between all built environmental attributes and walking in old adults who aged over 75 year. **CONCLUSIONS:** These results showed that age could be a potential moderator between built environment and walking in older adult population. High-density neighborhoods with favorable leisure destinations can be supportive for walking among young older adults (65-74 year). However, for old older adults (over 75 years), it is critical to further explore other multi-level factors related to their walking behavior.

Physical Fitness And Neighborhood Design - Walkability, Cardiorespiratory Fitness, Muscular Strength, And Flexibility In Adults

Gavin R. McCormack, Levi Frehlich, Anita Blackstaffe, Tanvir C. Turin, Patricia K. Doyle-Baker. *University of Calgary, Calgary, AB, Canada.*
 Email: gmccorma@ucalgary.ca
 (No relevant relationships reported)

Regular physical activity can improve physical fitness levels and promote health. Consistent evidence suggests an association between the neighborhood built environment and physical activity exists, yet few studies have investigated the contribution of the neighborhood built environment to fitness levels in adults. **PURPOSE:** To investigate the associations between objectively-determined and self-reported neighborhood walkability and perceived cardiorespiratory fitness, muscular strength, and flexibility. **METHOD:** We recruited a random sample of 592 adults (\geq 18 years of age) from Calgary (Canada). Participants provided complete data to an online questionnaire capturing perceived cardiorespiratory fitness (CRF), muscular strength (MS), and flexibility, frequency of moderate-to-vigorous physical activity (MVPA), frequency of strength training, and sociodemographic characteristics. The questionnaire also captured participant's perceptions of their neighborhood's walkability (Physical Activity Neighborhood Environment Scale; PANES) and the physical activity supportiveness of neighborhood parks (Park Perceptions Index; PPI). Objectively-measured walkability was estimated using Walk Score® assigned to each participant's residential postal code. Covariate-adjusted linear regression estimated the associations between the built environment and perceived fitness variables. **RESULTS:** The average age of participants was 46.6 (14.8) years and 67.2% were female. Participants, on average, participated in at least 30-minutes of MVPA on 3.4 (2.1) days/week and reported strength training 2.0 (1.8) days/week. Walk Score® was not associated with any fitness variables. The PANES index was positively associated ($p < .05$) with CRF, MS, flexibility and overall fitness and the PPI was positively

associated ($p < .05$) with all fitness variables except MS. **CONCLUSION:** Our novel findings suggest the neighborhood built environment has the potential to support and promote higher fitness levels in adults.

Features Of Neighborhood Parks Associated With Use And Physical Activity In Knoxville, Tn

Eugene C. Fitzhugh, Cristina S. Barroso. *University of Tennessee, Knoxville, Knoxville, TN.*
 Email: fitzhugh@utk.edu
 (No relevant relationships reported)

Visits by people to local neighborhood parks for moderate-to-vigorous physical activity (MVPA) may relate to the design of the park. The number, and condition, of facilities and amenities integrated into the park design can create a variety of potential activity zones for MVPA. **PURPOSE:** To understand how park users acquire MVPA across a variety of park features within the City of Knoxville, a mid-sized city in the Appalachian region. **METHODS:** Physical activity, both active and passive, was assessed at 12 parks equally distributed across the City of Knoxville Parks and Recreation Planning sectors. The System for Observing Play and Recreation in Communities (SOPARC) was used to directly observe activity over two weeks, a week in October 2018 and a week in March 2019. Observations covered 4 days of the week at three different time points. Across all parks, 42 scan zones were identified and categorized into 6 physical activity zones (athletic field, athletic court, playground, open space, pavilion + athletic field, and pavilion + open space). Demographic profiles of users, their observed physical activity types, and average MET-intensity across zones were calculated. SPSS (version 25) was used to contrast observations. **RESULTS:** In total, 1,548 activity zone scans observed 3,961 residents using the parks. Users were predominately male (53.8%), adult (55.2%), and white (66.5%). During the scans, 70.5% of the zones were empty. In zones with users (N=477), the most commonly observed primary activity was walking (25.1%). The activity zones with the lowest level of users were athletic fields (13.5%), open spaces (16.1%), and athletic courts (17.3%). Playgrounds (32.2%) had the highest level of use. Related to intensity, zones with moderate or above intensity levels included: athletic fields (3.9 METs), athletic courts (3.8 METs), and playgrounds (3.16 METs). **CONCLUSIONS:** Park features with the greatest potential for MVPA (athletic courts/fields) attract the fewest number of park users. As recreation and public health officials strive to attract more users who are physically active when they visit a park, they should consider other features, especially those that promote walking.

Effects Of Home Environment On Physical Activities With Different Intensity In High School Students

Xiao HOU, Jing-min LIU, Zheng-Yan TANG, Yu-Jie LIU. *Tsinghua University, Beijing, China.*
 Email: houxiao18@hotmail.com
 (No relevant relationships reported)

Except school, home is the second largest place for students to encounter their daily lives, so physical and social environment of the family can contribute either positively or negatively to lifestyle behaviors of students. **PURPOSE:** This paper will quantitatively study the effects of home environment on different physical activities (PA) of high school students. **METHODS:** We conducted the research on 314 Chinese high school students and their parents. The home environment survey includes 39 items divided into four scales (PA availability, PA accessibility, Parental role modelling of PA, Parental policies to support PA). The PA of students divided into three different intensity (Sedentary Behavior, Light intensity, Moderate and Vigorous intensity) were measured by Actigraph GT3X+ device. The data was analyzed using the multiple linear regression. **RESULTS:** A one standard deviation (SD) increase in PA accessibility, mother role modelling of PA, mother policies to support PA was associated with a reduction in SB (minutes/week) by 65.44 ($p < 0.05$), 116.87 ($p < 0.01$) and 175.42 ($p < 0.01$) respectively. A one SD increase in PA accessibility, mother policies to support PA was associated with an increase in LPA (minutes/week) by 12.65 ($p < 0.01$) and 16.91 ($p < 0.01$) respectively; an increase MVPA (minutes/week) by 81.11 ($p < 0.01$) and 52.21 ($p < 0.05$) respectively. **CONCLUSIONS:** With the development of PA accessibility, the modeling and supportive policies of mother, the SB of high school students can be reduced significantly. And the PA accessibility and supportive policies of mother can evidently improve students' LPA and MVPA.

Table 1. Characteristics of sample

	Total	Male	Female	Range

Home Environment Factors Associated With Children's Physical Activity Levels In A Rural Population

Amanda L. Folk, Eydie N. Kostecka, Daheia J. Barr-Anderson, FACSMM, Jayne A. Fulkerson. *University of Minnesota, Minneapolis, MN.* (Sponsor: Daheia J Barr-Anderson, FACSMM) Email: folk0039@umn.edu

(No relevant relationships reported)

The physical and built environments are related to physical activity (PA) in adults and the relationship seems apparent in children. Child PA behavior often depends on parents in a variety of ways including involvement, facilitation, or role modeling. The home environment is one setting in which these relationships may be further examined. **PURPOSE:** To examine how facets of the home environment and parent perceptions of neighborhood safety may be associated with child total PA and moderate-to-vigorous (MVPA) levels in a rural sample.

METHODS: Baseline data were analyzed from NU-HOME, a childhood obesity prevention, randomized controlled trial in rural communities. 105 children (age=8.96±1.06 yrs) and their parents (age=37.91±5.42 yrs) reported on sociodemographics and home/neighborhood environments. Child daily PA (total and MVPA) was measured using accelerometers and, using SAS 9.4, associations were examined with home/neighborhood environment variables through multivariate regression models, both unadjusted and adjusted for economic assistance. Normality was not met for child daily MVPA therefore analyses used the log-transformed variable.

RESULTS: Mean child total PA was 259.08±58.22 min/day and MVPA was 44.95±18.58 min/day. In unadjusted analyses, access to PA equipment in the home (p=0.037) and neighborhood safety (p=0.049) were associated with total PA; however, no factors were statistically significantly associated with MVPA, although access to PA equipment (p=0.088) and family support for PA (p=0.062) were trending towards significance. For both total PA and MVPA outcomes, the regression models including all variables and accounting for economic assistance were statistically significant (p=0.026 and p=0.034, respectively). For each model, the individual effects of parent PA and PA equipment were statistically significant (p ranges from 0.008 to 0.037).

CONCLUSIONS: This study highlights the potential of the home/neighborhood environment as a space for interventions to increase PA in rural children. Only 14% of children in this rural sample met PA recommendations, so interventions to increase PA, particularly MVPA, are needed. Future studies should include multiple levels of a rural child's environment (i.e., school, town) to examine which may play the largest role in PA.

Patterning Of Physical Activity And Sedentary Behavior At And Away From School In Preadolescent Children

Lexie R. Beemer, Erica Twardzik, Natalie Colabianchi, Rebecca E. Hasson, FACSMM. *University of Michigan, Ann Arbor, MI.* (Sponsor: Rebecca Hasson, FACSMM) Email: abeemer@umich.edu

(No relevant relationships reported)

BACKGROUND: Understanding *how* and *where* children accumulate their physical activity and sedentary minutes throughout the day has important implications for behavioral interventions. The purpose of this study was to examine the patterning of habitual physical activity (PA) and sedentary time (SED) at and away from school among preadolescent children. **METHODS:** Forty children ages 7-11 (55% girls; 60% non-white; 25% overweight/obese) participated in this study. Proportion of time spent in PA, moderate-to-vigorous physical activity (MVPA) bouts, proportion of time spent in SED, and SED bouts were examined on school days (in-school and out-of-school) and weekends via accelerometry. Accelerometers were worn on the right hip for one week. Data were downloaded into 60-second epochs and Evenson cut points were used to derive intensities. A MVPA bout was defined as consecutive minutes the accelerometer registered 2296 or more counts per minute, with a minimum of 5, 10, and 15 minutes or more of MVPA. A sedentary bout was defined as consecutive minutes the accelerometer registered less than 100 counts per minute, with a minimum of 30, 60, and 120 minutes or more of SED. **RESULTS:** In school days compared to weekend days, the proportion of time in vigorous PA was greater (0.9% (9.5 min.) vs. 0.6% (6.1 min.); p=0.02), but similar levels of light PA, moderate PA and SED (p's>0.05). When comparing school time with non-school time on school days, children accumulated a higher proportion of light PA [46.7% (3 hr.) vs. 33.8% (3.9 hr.), p=0.01] but similar proportions of moderate and vigorous PA (p's>0.05). There were no differences in the number of MVPA bouts accumulated in-school, out-of-school, on school days and weekends (p's>0.05). At school, the proportion of time spent in SED was less (48.8% (3.15 hr.) vs. 62.6% (7.28 hr.), p=0.01) and fewer children spent time engaged in prolonged sitting at school [uninterrupted sedentary time for 30 minutes (67.5% vs. 92.5%, p=0.006), 60 minutes (22.5% vs. 80.0%, p<0.001), and 120 minutes (7.5% vs. 42.4%, p<0.001)]. **CONCLUSIONS:** These findings suggest children are

the most active and least sedentary when at school, yet children only accumulated 17.5 minutes of MVPA in this environment. Thus, in-school and out-of-school interventions are needed to help children meet the daily recommended minutes of PA.

G-20 Thematic Poster - Physical Activity and Health Equity

Influence Of Social Networks On Nutrition And Physical Function Of Ethnic Older Minorities Over Time

Evans A. Asamane, Carolyn A. Greig, Janice L. Thompson, FACSM. *University of Birmingham, Birmingham, United Kingdom.* (Sponsor: Janice L. Thompson, FACSM)
Email: asamanevans@yahoo.com

(No relevant relationships reported)

BACKGROUND: Social networks (SN) are consistently shown to influence health outcomes in later life. However, relatively little is known about SN of ethnic older minorities, and how they impact on health outcomes over time. **PURPOSE:** To explore SN and their impact on nutritional intake and status, and physical function in ethnic older minorities (≥ 60 years) living in Birmingham, United Kingdom. **METHODS:** SN were assessed using the Wenger Practitioner Assessment of Network Types (PANT). Multiple-pass 24-hour dietary recalls and the Mini Nutritional Assessment-Short Form assessed nutritional intake and status, respectively. Short Physical Performance Battery (SPPB) and handgrip strength measured physical function. Correlation and regression analyses examined relationships between SN, physical function, nutrient intake and nutritional status. The influences of SN were captured through semi-structured interviews at baseline (N=92) and follow-up (N=81). Interviews were transcribed verbatim and analysed using directed content analysis. **RESULTS:** Of the 100 participants measured at baseline, 81 were followed up 8-months later. Mean age = 70.9 \pm 8.1 years (62% male) comprising African/Caribbean (65%), South Asian (28%), and other ethnicities (7%). Five SN were identified and grouped into two broad categories: integrated SN (locally integrated (44%) and wider community (8%)); and non-integrated SN (family dependent (25%), locally self-contained (17%), and private restricted (6%). At follow-up, SN declined in 19% and improved in 11%. There was an overall decrease in physical function (F(1))=9.73, P=0.03) and nutritional status (F(1))=6.04, P=0.016) over time. Participants in integrated SN compared with non-integrated SN at baseline were less likely to experience a decline in physical function at follow-up (OR: 0.17; 95% CI:0.04-0.63). Qualitative results indicate that participants with declines in SN perceived this as causing poorer physical function and eating behaviours. **CONCLUSION:** Changes in SN occurred over a relatively brief period in this sample, with integrated SN associated with better physical function, nutritional intake and status. These findings can inform interventions and community outreach programmes designed to enhance SN and the health status of this population.

3629 Board #2 May 30 9:00 AM - 11:00 AM

Acculturation And Leisure-time Physical Activity Among Asian American In The United States, 2011-2016

Xuanxuan Zhu, Jihong Liu, Maria Sevoyan, Russ R. Pate, FACSM. *University Of South Carolina, Columbia, SC.* (Sponsor: Russell R. Pate, FACSM)

Email: xzhu@email.sc.edu

(No relevant relationships reported)

The Asian population has become the fastest growing ethnic group in the United States (US). However, less than a quarter of Asian Americans met WHO Physical Activity (PA) Guideline. Few studies have examined the association between acculturation and leisure-time PA among Asian Americans.

PURPOSE: To examine the association between acculturation and leisure-time PA among Asian American adults.

METHODS: Data concerning 1,989 Asian Americans aged 20 years and older, came from the 2011-2016 National Health and Nutrition Examination Survey (NHANES). Acculturation was assessed in three dimensions: the language preference at home (only Non-English language, both English and Non-English language, and only English), length of residency in the US (<10 years, 10-29 years, ≥ 30 years, US born), and

birth locations (US-born, foreign-born). Using self-reported minutes/day and days/week moderate and vigorous leisure-time PA, we calculated moderate-to-vigorous PA (MVPA) MET minutes/week. MVPA was analyzed as a continuous variable and a categorical variable (i.e., meeting WHO PA guidelines, ≥ 600 MET minutes/week) in multiple linear and logistic regression models after controlling for covariates, respectively.

RESULTS: Among participants, 24.5% of Asian Americans spoke only English at home, while 47.8% spoke only non-English at home. 13.0% of participants were born in the US. The odds of meeting PA guidelines were higher among Asians speaking only English (adjusted OR [AOR]=1.8, 95% confidence interval [CI]: 1.4, 2.4) and those speaking both non-English and English at home (AOR=1.6, 95% CI: 1.3, 2.0), compared to those who spoke only non-English at home. US-born Asians were more likely to meet PA guidelines than foreign-born Asians (AOR=1.8, 95% CI: 1.3, 2.6) and on average they performed 137 more minutes of leisure-time MVPA each week than foreign-born Asians. Asians in the US since birth had higher odds to meet PA guidelines than Asians stayed in US for less than 10 years (AOR=2.2, 95% CI: 1.5, 3.3).

CONCLUSIONS: More acculturated Asian Americans such as those who spoke more English at home and US-born Asians, perform more leisure-time MVPA than less acculturated Asian Americans. Interventions are needed to promote PA among non-English speaking Asian immigrants and those who stayed in the US for less than 10 years.

3630 Board #3 May 30 9:00 AM - 11:00 AM

Developing Smart Goals With Latinos To Address Their Life Concerns Surrounding Physical Activity And Recreation

Sharon E. Taverno Ross, Maria del Rosario Christophersen, Patricia I. Documet. *University of Pittsburgh, Pittsburgh, PA.* (Sponsor: Andrea Kriska, FACSM)

(No relevant relationships reported)

PURPOSE: Raices was a community health worker (promotore)-delivered intervention offering non-directive social support to improve healthcare access, physical activity, and healthy eating among Latinos living in an emerging community, an area with a small yet growing Latino population. The purpose of this study was to determine whether the intervention helped participants develop SMART (i.e., specific, measurable, realistic, attainable and time-bound) goals that addressed their life concerns, specifically highlighting those findings related to physical activity. **METHODS:** Promotores used an intervention tool assessing wellness in eight domains of participants' lives (e.g., family, physical activity/recreation) and supported participants in developing SMART goals to address their life concerns. The research team summarized participants' data and assessed whether the goals 1) met SMART criteria and 2) focused on participants' identified concerns. **RESULTS:** We recruited 192 Latino participants from South America (42%), Mexico (30%) Central America (11%) and other countries (10%). Participants ranked physical activity and recreation (18.2%) and eating habits (17.8%) as top areas that were concerning or very concerning. Overall, participants developed 195 goals after the first intervention visit. Most goals met the SMART criteria completely (35.4%) or partially (48.7). Of the 195 goals set, 30% of them focused on physical activity/recreation, and 91% of those goals met the SMART criteria completely or partially.

CONCLUSIONS: Promotores successfully elicited participant life concerns and assisted them in setting SMART goals to address these areas of concern, including a top concern of physical activity/recreation. The intervention would benefit from additional promotores training in developing SMART goals.

3631 Board #4 May 30 9:00 AM - 11:00 AM

Aging Effects Of A 12-month Period On Cardiometabolic Risks In Older Adults

Kivana Keane¹, Alexis Sides¹, Austin Anderson¹, Malli Fowler¹, Sarah Gingerich¹, Shannon Hinson¹, Adam Lavis¹, Jessica Martin¹, Benjamin Patterson¹, Colleen Pecoraro¹, Tommy Scott¹, L. Jerome Brandon, FACSM², Trudy Moore-Harrison¹. ¹UNC-Charlotte, Charlotte, NC. ²Georgia State University, Atlanta, GA. (Sponsor: L. Jerome Brandon, FACSM)
Email: kkeane5@uncc.edu

(No relevant relationships reported)

PURPOSE: Aging is characterized by decreased functional ability and increased cardiometabolic (CMO) risks. Being physically active is believed to slow these diminishing characteristics in older adults. Therefore, the purpose of this study was to determine if CMO values would decline following a 12-month period in active older adults.

METHODS: The participants were 148 active older adults from the metropolitan area of a southern city. Activity ranged from participating in structured fitness classes

to participating in limited physical activity. Overall, the community was active. The participants were measured for CMO risks and morphological characteristics initially and 12 months later and two tests were statistically evaluated for differences.
RESULTS: The participants were obese based on body fat% (40%) and overweight based on body mass index (BMI - 29.1). Triglyceride (Trig- 150 mg/dL) on the posttest and systolic blood pressure (137 mmHg) on the pretest were the only variables that met risk classification based on metabolic syndrome risk criteria. High density lipoproteins (59 to 62 mg/dL) improved on the posttest. Generally, there was a trend toward improvement for the other CMO variables. The percent different (%diff) between the variables for the two tests ranges from 0 for DBP to 13.6% for Trig. Trig had the largest %diff, but also had the largest variability between assessments and therefore, was not significant.
CONCLUSIONS: Data suggest that CMO variables remained stable in a physically active community of older adults during a 12-month period. Efforts should be made to keep older adults active as they age.

3632 Board #5 May 30 9:00 AM - 11:00 AM
Bmi Influence On Quality Of Life Following Physical Activity Program For Women In Homeless Shelters
 Lori A. Thomas. *Lebanon Valley College, Annville, PA.*
(No relevant relationships reported)

BMI Influence On Quality Of Life following Physical Activity Program For Women In Homeless Shelters
 Lori A. Thomas, Jenna M. Marx, McKenna Lupold, Abigail Kinneman, Hayley McGlory, Tonya Y. Miller.
 Lebanon Valley College, Annville, PA.
PURPOSE: Examine if BMI category was associated with the outcomes of a 4-week physical activity educational program on the quality of life and physical fitness of nine women who were homeless and residing in urban environment shelters. **METHODS:** The educational program, Be Active Your Way, intervention incorporated educational sessions one time a week for four weeks led by student investigators. Researchers measured the programs' effectiveness with pre- and post- program assessment using the Healthy Days Core Module, Two Minute Walk Test (2MWT), Perceived Stress Scale (PSS), and the Acceptance and Action Questionnaire (AAQ-II). **RESULTS:** Women who were overweight and residing in homeless shelters showed a trend on the AAQ-II in the decreased number of days their health affected activity, but the trend was not significant (pre=7.6 days, post=4 days); $p > .05$. Women who were Class II obese residing in homeless shelters showed a decreased trend in their psychological inflexibility score, but the trend was not significant (pre=29.5, post =20.5); $p > .05$. There were no significant statistics or other noticeable trends among BMI classification data in relation to PSS or 2MWT. **CONCLUSION:** Findings from this study showed that BMI category did not contribute significantly to health-related quality of life outcomes following a physical activity program among women residing in a homeless shelter. Women residing in a homeless shelter may find an educational physical activity program beneficial, regardless of BMI category.

3633 Board #6 May 30 9:00 AM - 11:00 AM
IDENTIFYING DISPARITIES IN YOUTH HEALTHCARE ACCESS POST-SPORT RELATED CONCUSSION AND POST CONCUSSION SYNDROME
 Jeanette Faith Green. *University of Florida Health, Gainesville, FL.*
 Email: grejea@shands.ufl.edu
(No relevant relationships reported)

Disparities in healthcare may occur when availability, accessibility, and quality of healthcare services differ. These factors influence health, resulting in differences in morbidity and mortality. Among injuries, concussion and post-concussion syndrome may lead to significant long-term impairments in up to 40% of youth, with a greater number of impairments seen in minority populations. During recruitment for a previous study, lack of population diversity prompted an exploration of our patient population. **PURPOSE:** The purpose of the study was to explore differences in race, ethnicity, and sex among youth and young adults who sought care for concussion or post-concussion symptoms within a large academic medical center to determine whether differences exist among sub-groups.
METHODS: Utilizing an Integrated Data Repository, i2b2, a query was performed to determine the number of individuals ages 10 to 34 years of age who sought care for concussion or PCS between 9/2015 and 6/2019 within a large academic health system. Over 3,270 youth, adolescents, and young adults (YAYA) sought healthcare and received a concussion or PCS diagnosis.
RESULTS: Among recipients of concussion care, there were 2, 226 (68%) non-Hispanic White, 720 (22%) African American/Black (AA/B), and 224 (.07%) Other. Post-Concussion Syndrome diagnoses among 1,143 YAYA of whom 796 (70%)

Caucasian, 210 (18%) AA/B, 17 (2 %) Biracial, and 103 (9%) Other. While males had more overall concussion diagnoses (n=1339, 60%), females had higher incidence of PCS (n=646, 56.5%).
CONCLUSIONS: Comparison of these results with community demographic data reveals AA/B and Hispanic YAYA seeking concussion care may be underserved within the trauma system. Additionally, higher incidence of female PCS deserves further exploration to ascertain whether individual, initial management, or delays in connecting with the healthcare system may be factors in persistent symptomatology post-TBI. Additional research is needed to ascertain health system factors that may address and reduce future disparities in TBI care delivery and patient outcomes, including geocoding to ascertain the impact of YAYA residence and proximity to the trauma center.

3634 Board #7 May 30 9:00 AM - 11:00 AM
Kids Fun, Food & Fitness: The Need For An Exercise And Nutrition Program For Children With ASD
 M Alysia Mastrangelo, FACSM¹, Mary Kientz², Joan Perks², Gabriele Bandelli¹, Carly Burnup², Kristin Cavorley², Emily Disbrow², Emily Sorochynskyj². ¹*Stockton University, Shamong, NJ.* ²*Stockton University, Galloway, NJ.*
 Email: m.alyisia.mastrangelo@stockton.edu
(No relevant relationships reported)

PURPOSE: Nationally, 1 in 59 children are diagnosed with an autism spectrum disorder (ASD) with NJ having the highest rates at 1 in 34 children. Children with ASD are more likely to experience health disparities that can impact quality of life. The disparities include an increase in type II diabetes, issues with food sensitivities, sensory processing impairments, and a decrease in time spent in moderate to vigorous physical activity (PA). The purpose of this study is to assess the need for a community/family-based exercise and nutrition literacy program for children ages 8-15 y.o. with an ASD.
METHODS: Participants (n=9) with an ASD diagnosis, ages 8-15 y.o. were assessed prior to initiation of the Kids: Exercise, Food and Fun program. The assessment included anthropometric measures, grip strength, plank, Stork test bilaterally, sit and reach and 6-minute walk. This study was approved by the Institutional Review Board for Human Subject at Stockton University.
RESULTS: At baseline the mean age of participants was 12.1 y.o. with 6 boys and 3 girls. The average weight was 55.1 Kg, and height was 149.4 cm. BMI was determined and subjects were categorized by CDC classification; n=3, healthy, n=1, overweight and n=5, obese. Waist circumference measures determined the majority (n=5) were at or above the 80th percentile for risk. Mean fitness measures are as follows; right grip strength =12.8 Kg, Stork test, right =12.80 sec and left =10.09 sec, plank =10.31 sec and sit and reach =22.44 cm. The mean distance for the 6MW was 366.19m.
CONCLUSIONS: These results indicate most participants were overweight or obese with an expected increased risk for comorbidities at baseline. Study participants demonstrated decreased grip strength, upper body strength and standing balance. They could benefit from an exercise and nutrition program with a parent or caregiver. The aim of the study will be to improve access to fitness activities and healthy food options. Sessions will consist of age appropriate PA and a cooking/nutrition class where participants will learn basic nutrition principles, food safety, and prepare a food to consume themselves. Post-assessment will evaluate body composition and fitness measures.

3635 Board #8 May 30 9:00 AM - 11:00 AM
Are Physical Therapists' Attitudes About Disability A Predictor Of Their Attitudes About Client-self-directed-mobility?
 Winston Kennedy¹, Jafra D. Thomas², Samuel W. Logan¹.
¹*Oregon State University, Corvallis, OR.* ²*California Polytechnic State University, San Luis Obispo, CA.* (Sponsor: Bradley J. Cardinal, FACSM)
 Email: kennedyw@oregonstate.edu
(No relevant relationships reported)

Physical therapists (PTs) are expected to play a key role in supporting individuals with disabilities to lead independent, active, and healthy lifestyles. However, limited knowledge exists about dispositional factors that could influence PTs' motivation to provide healthcare that: (1) assist clients to overcome acute barriers to independent living and (2) supports clients to lead active, healthy lifestyles across the lifespan. **PURPOSE:** This study determined if PTs' attitudes about disability predicted their attitudes about client-self-directed mobility (i.e. independent mobility). **METHODS:** A convenience sample of 308 pediatric PTs were recruited from workshops held across 11 U.S. states between 2016 and 2017. Topics covered in the workshops included promoting and teaching ways to modify ride-on cars for young children with disabilities. Prior to their participation in the workshops, study participants completed two questionnaires: (1) the Attitudes Toward People with Disabilities Scale (ATDP; Cronbach $\alpha = .80$); and (2) the Attitudes Towards Self-Directed Mobility Scale

(ATSDM; Cronbach $\alpha = .72$). The lower the score on the ATDP, the more favorable the attitude. The higher the score on the ATSDM, the more favorable the attitude. Simple linear regression was used to test if ATDP scores predicted ATSDM scores. **RESULTS:** The ATDP M score was 2.4 ($\pm .45$), and the ATSDM M score was 4.4 ($\pm .42$). ATDP scores were a significant predictor of ATSDM scores ($\beta = -.12, p < .05$), but ATDP scores explained a minimal amount of variance in ATSDM scores, $R^2 = 0.016, F(1,306) = 4.938, p < .027$. **CONCLUSION:** PTs' attitudes about people with disabilities was a weak predictor of their attitudes about client-self-directed-mobility. Further, the ratio between the two attitudes was not one-to-one, suggesting context is an influential factor. The observed results could have been due to the self-beliefs participants held towards disability because of their occupational status as PTs and how they viewed disability (e.g., social model of disability). Future research is needed aimed at incorporating a broader range of predictors of attitudes about client-self-directed-mobility. Such work would add insight into PTs' dispositional factors that could influence the quality and type of healthcare that they provide to individuals with disabilities.

G-21 Thematic Poster - Physical Activity Children and Youth

Evaluating Extension-supported Implementation Of A Classroom-based Physical Activity Program In Under-resourced Schools

Thomas Packebush, Katherine B. Gunter, FACSM, Tammy Winfield. *Oregon State University, Corvallis, OR.*
(No relevant relationships reported)

PURPOSE: Regular exposure to physical education (PE) increases children's physical activity, but access is not equitable, particularly in under-resourced schools. Oregon recently passed legislation requiring public elementary schools to provide PE for ≥ 150 minutes per week. BE Physically Active 2Day (BEPA 2.0) is a K-5 classroom-based physical activity program aligned to PE standards, developed to help under-resourced schools reach the mandated PE minutes. We evaluated BEPA 2.0 implementation among teachers in schools receiving BEPA 2.0 trainings. **METHODS:** County-based Cooperative Extension faculty were trained to deliver BEPA 2.0 teacher trainings. Trainings were conducted in 33 schools in fall 2018 and winter 2019 and 433 teachers attended trainings. Three to six months post-training, a brief survey assessing implementation factors was distributed to all teachers at trained schools. Descriptive and chi-square analyses were conducted to evaluate BEPA 2.0 use, and the relationship of training to use. **RESULTS:** A total of 212 teachers from 11 Oregon counties provided survey responses (49% response rate). Overall, 92.4% of teachers reported using BEPA 2.0, most commonly to provide classroom activity breaks (88.8%) and meet PE minute requirements (44.9%). Forty-four percent of teachers chose BEPA 2.0 for its alignment to state PE standards. Most teachers (74.2%) implement 1-2 times per week, with extra support from trainers (e.g., email prompts, booster trainings) reported among 66.9% of users. More trained (82.8%) versus untrained teachers (53.3%) reported using BEPA 2.0 ($p=0.006$). **CONCLUSIONS:** Results indicate a high rate of BEPA 2.0 use, particularly among trained teachers. This suggests training is an important component of the implementation process. Increasing trainings and support for teachers may increase frequency of use.

3638 Board #2 May 30 9:00 AM - 11:00 AM
Aggregated Impact Of Locally Implemented SNAP-Ed Programming On Physical Activity In Michigan Youth

Kerri L. Vasold, Lila Gutuskey, Marcia K. Scott. *Michigan Fitness Foundation, Lansing, MI.*
Email: kvasold@michiganfitness.org
(No relevant relationships reported)

Equity in physical activity engagement is a critical issue. Supplemental Nutrition Assistance Program Education (SNAP-Ed) reaches low-income youth, with physical activity as one of the key foci. In Michigan, SNAP-Ed includes locally relevant programs selected and implemented by community organizations. Consistent evaluation is conducted across programs. **PURPOSE:** To evaluate state-level change in physical activity and sedentary behaviors of Michigan youth who receive locally relevant SNAP-Ed programming selected and implemented by community-based

organizations. **METHODS:** Participants were youth (grades 4th-8th) receiving SNAP-Ed programming that included evidence-based interventions with a physical activity component. Youth received a physical activity questionnaire pre- and post-intervention. Participant data were matched based on demographic indicators, and data were aggregated at the state-level. Descriptive statistics were calculated for all variables of interest, and Wilcoxon Signed Rank tests were used to compare differences pre- and post-intervention for physical activity and sedentary behaviors (i.e. weekday hours spent watching TV). **RESULTS:** Participants included 1,899 youth (grades 4th-8th) from SNAP-Ed programming delivered through 15 different community organizations across Michigan. The majority of participants were Caucasian (65.0%) and non-Hispanic (86.5%), and approximately one-half were male (49.9%). A statistically significant increase was found for the number of days that youth self-reported being physically active for at least 60 minutes pre- and post-intervention (pre: 4.18 ± 2.13 ; post: 4.43 ± 2.05 ; $p < 0.000$), and a statistically significant decrease was found for the number of hours youth reported watching TV on a weekday pre- and post-intervention (pre: 1.76 ± 1.55 ; post: 1.66 ± 1.49 ; $p = 0.012$). **CONCLUSIONS:** Implementation of locally relevant SNAP-Ed programming selected by community organizations can positively impact physical activity and sedentary behaviors. Future research should explore commonalities amongst locally relevant programs to identify key implementation characteristics for greatest impact and progress toward equity.

Investigation On The Prevalence Of Scoliosis In Primary And Secondary School Students In Changzhou

Yunqing Liu¹, Baohu Li¹, Haiyan Zhu¹, Ruifang Gao¹, Bowen Li². ¹Changzhou Research Institute of Medical Treatment, Changzhou, China. ²Nanjing Sport Institute, Nanjing, China.
(Sponsor: Zhengzhen Wang, FACSM)
Email: liuyunqing0529@sina.com
(No relevant relationships reported)

Purpose: With the increase of academic pressure, students spend more time in sedentary behaviour. Long-term wrong sitting posture will bring many health problems. To investigate the prevalence of scoliosis among primary and secondary school students in Changzhou City.

Methods: From May to July 2019, we measured the spine index of 10229 students (age: 10-13 years) from 7 primary and 3 middle schools in Changzhou City, including 5437 boys and 4708 girls, 84 of whom did not participate in the screening, and 10145 of whom were effectively screened. We screen scoliosis in three steps: 1: with examine back exposed and standing naturally, the examiner check if the shoulders are equal in height; whether lower scapular horn, bilateral lumbar fovea is symmetrical; whether bilateral ilium ridge is equal; the above has an anomaly positive, can be defined as posture abnormality. 2: positive result of first test, carry out Adam test, if Adam bending test has the above signs, measure the back with the spine, the maximum oblique part and angle of spine, if the deviation is more than 5 degrees, it is suspected scoliosis, if it is greater than 10 degrees, it can be defined as scoliosis. If the Adam bending test has the above signs, the spine is measured by the ruler. 3: the patients with suspected scoliosis were diagnosed as scoliosis by radiologist to take the full-length orthopedic radiography of the upright spine and measure the Cobb angle $\geq 10^\circ$.

Results: In first step, 4585 cases of abnormal posture, the incidence of bad posture was about 45.2%, the detection rate of high and low shoulders among the students was 35.2%, the detection rate of boys was 28.5%. The detection rate of female students was 38.8%. The incidence of pelvic rotation was 15.1% in boys and 17.9% in girls, and the incidence of lateral flexion in neck was 4% in boys and 9% in girls. The detection rate of scoliosis was 24.3%. Finally, some students carried out the third inspection, and the consistency between the third inspection and the second inspection reached 98%.

Conclusion: Through screening, it was found that the detection rate of abnormal posture was high. Therefore, the establishment of spine health records will help them pay attention to spine health. Supported by Social Science Foundation of Jiangsu Province (BE2018752), Science and Technology Support Plan of Changzhou (CE20195046).

Physical Activity Contributions From An Outdoor Education Pre-kindergarten Program

Nathan R. Tokarek, Chi C. Cho, Ann M. Swartz, FACSM.
University of Wisconsin - Milwaukee, Milwaukee, WI.
Email: ntokarek@uwm.edu
(No relevant relationships reported)

Traditional educational practices may contribute to the overall decline in physical activity (PA) and increases in sedentary behaviors (SB) that have been documented as children age. Beginning early in children's elementary education, unstructured activities, such as free play and outdoor time, are often replaced by activities that are more structured, teacher-led, indoors, and desk-based. Incorporating more outdoor

learning opportunities into traditional educational practices may improve children's PA profile. **Purpose:** The primary purpose of this study was to compare differences in Pre-Kindergarten children's PA and SB between a nature-based or traditional classroom setting. **Methods:** 26 children from one Pre-K program enrolled in this study. Data was collected using waist-mounted accelerometers worn for 8 days (2h45min/day) across two separate weeks in the winter and spring. During each four-day week, participants spent two days in a traditional classroom setting, and two days in a nature-based setting. Accelerometer data was analyzed using Butte (2013) cutpoints. One-tailed paired t-tests were used to detect significant differences ($p < 0.05$) in PA and SB between settings. **Results:** In a nature-based setting, significantly more time was spent in moderate- to vigorous-intensity PA during Unstructured (Diff: $8.0 \pm 9.9\%$ of Wear Time [WT]; $p < 0.001$) and Structured time (Diff: $1.4 \pm 2.9\%$ WT; $p = 0.011$). Significantly less time was spent in SB during Unstructured (Diff: $-3.1 \pm 7.1\%$ WT; $p = 0.017$) and Structured time ($-2.5 \pm 6.1\%$ WT; $p = 0.023$) in a nature-based setting. Significantly more time was spent outside (Diff: 35min; $p < 0.001$) in a nature-based setting, however significantly less time (Diff: -2.9 ± 3.0 min; $p < 0.001$) was allocated to Unstructured free play. There were no significant differences in the amount of time participants spent in Structured time (Diff: 1.4 ± 7.9 min; $p = 0.375$) between class settings. **Conclusion:** Children engaged in significantly more PA and less SB while learning outdoors compared with indoor learning, despite less time being allocated to free play. Modifying educational practices to include outdoor education has the potential to increase the quantity of in-school PA children accumulate while simultaneously reducing SB.

Comparative Discrimination Of Obesity By Muscular And Cardiorespiratory Fitness: A Receiver Operating Characteristics Curve Analysis.

Toyin Ajisafe, Noe DeAnda. *Texas A&M University - Corpus Christi, Corpus Christi, TX.*
 Email: toyin.ajisafe@tamucc.edu
 (No relevant relationships reported)

PURPOSE: Muscular and cardiorespiratory fitness are associated with adiposity and cardiovascular disease risk in youth. The degree to which these measures discriminate obesity is not lucid. This study investigated muscular and cardiorespiratory fitness capacities to discriminate obesity. **METHODS:** Participants (N = 210; 116 males) (9.7 ± 1.08 years; 138.6 ± 9.4 cm; 42.3 ± 14.4 kg) (84% Hispanic/Latino) muscular and cardiorespiratory fitness were assessed using the 20-meter Progressive Aerobic Cardiovascular Endurance Run (PACER) and 90° push-up test, respectively, per FITNESSGRAM® protocols. Weight status was classified using CDC Growth Charts. Non-obesity was coded as "0" and obesity was coded as "1." A Receiver Operating Characteristics (ROC) curve analysis was performed to identify the True Positive Rate (TPR) (i.e., Sensitivity) and False Positive Rate (FPR) (i.e., 1 - Specificity) using SPSS. The area under the curve (AUC) indicated the degree to which each fitness measure distinguishes between the presence and absence of obesity. The measurement threshold with the greatest TPR-FPR distance was considered optimally discriminative. Statistical significance was set at $P < .05$. **RESULTS:** Of the sample, 43% had obesity and 55% did not. PACER was fairly discriminative of obesity in girls (AUC = .748; $P = .000$; 95% CI [.651, .845]) and boys (AUC = .755; $P = .000$; 95% CI [.665, .845]). 90° push-up was fairly discriminative in girls (AUC = .732; $P = .000$; 95% CI [.632, .831]) and boys (AUC = .789; $P = .000$; 95% CI [.703, .876]). PACER thresholds of 8 and 8 laps were optimally discriminative in girls (TPR = .714, FPRs = .352) and boys (TPR = .635, FPRs = .190), respectively. 90° push-up thresholds of 7 and 5 repetitions were optimally discriminative in girls (TPR = .714, FPRs = .333) and boys (TPR = .692, FPRs = .175), respectively. **CONCLUSIONS:** Based on the probability of classifying individuals with and without obesity as having obesity (i.e., TPRs and FPRs, respectively), PACER and 90° push-up appear similarly discriminative of obesity. Notably, the optimal PACER threshold to discriminate obesity was considerably lower than cut-off scores (23 for boys and 15 for girls) for HFZ classification in the same age group. Cardiorespiratory-related disease risk may persist in subpopulations of Hispanic/Latino youth without obesity.

3642 Board #6 May 30 9:00 AM - 11:00 AM
Impact Of Schoolyard Green Space And Hardscape Design On Play Behaviors Of Urban Children

Elena Daniel, Nkese Jack, Marcella Raney. *Occidental College, Los Angeles, CA.*
 (No relevant relationships reported)

Previous studies have shown that large-scale schoolyard greening projects increase physical activity (PA) participation. However, the relative impact of nature access and schoolyard design on free play behaviors is unknown. **PURPOSE:** To determine how green space and specific schoolyard design features impact individual and population-level PA and social behaviors during recess. **METHODS:** Recess behaviors were recorded with the validated SOPLAY and SOCARP observation tools for one week at four urban Title I elementary schools (N = 2051): 1) 1.5% green space, 10

zones; 2) 0% green space, 8 zones; 28% green space, 10 zones; 4) 50% green space, 8 zones. Data was analyzed with linear mixed models and Pearson correlation at a significance value of 0.05. **RESULTS:** Sedentary levels were higher for older students at locations with fewer play areas regardless of green space square footage (1st-3rd grade: $49.5 \pm 2.9\%$; 4th-6th grade: $59.7 \pm 3.1\%$) and lower for younger students in green compared to asphalt schoolyards (52.8 ± 1.8 vs. $47.4 \pm 1.7\%$) ($p < 0.01$). More students were engaged in moderate-to-vigorous physical activity (MVPA) while playing tag ($71.2 \pm 4.1\%$) or gymnastics/climbing/jumping/dance ($58.1 \pm 3.3\%$) in green space and on play structures compared to traditional playground games (e.g. handball, 4-square, tetherball) on asphalt ($45.6 \pm 1.7\%$) ($p < 0.001$). Students spent more time in small groups (10.8 ± 0.7 vs. 9.3 ± 0.4 min, $p < 0.05$) and in vigorous PA in green space vs. hardscape (2.3 ± 0.2 vs. 1.1 ± 0.1 min, $p < 0.05$). Small group activity was positively correlated with the frequency of prosocial interactions ($r = .158$, $p < 0.001$). In asphalt schoolyards, students spent more time vigorous when more play options were available (2.1 ± 0.2 vs. 1.3 ± 0.1 min, $p < 0.05$). Although active minutes were similar between sexes in areas with trees, logs, and woodchips (girls: 4.8 ± 0.4 ; boys: 5.4 ± 0.7 min, $p > 0.05$), boys spent more time active in both hardscape (girls: 3.6 ± 0.2 vs. 4.9 ± 0.2 min) and green space (girls: 5.0 ± 0.8 ; boys: 6.9 ± 0.8 min) areas designed for sport ($p < 0.05$). **CONCLUSION:** Schoolyards that increase access to nature, provide diverse sport and non-sport play options, and present motor skill challenges optimize MVPA participation and positive peer interactions for both sexes and all age-groups in urban low-income elementary schools.

Relationship Between Physical Activity Among Preschool Children And Their Parents

Keisuke Koizumi. *Chiba University, Chiba-city, Japan.*
 (No relevant relationships reported)

PURPOSE: The lack of physical activity among children is a global issue that requires attention. It has been suggested that a relationship exists between the lifestyles of children at an early age and that of parents. We quantified physical activity relationships among preschool children and their fathers and mothers.

METHODS: Forty-seven children (kindergarten level: aged 6.11 ± 0.267 years) and their parents (fathers: aged 43.1 ± 4.83 years, mothers: aged 41.1 ± 4.29 years) participated in this study. Each participant wore an activity tracker on the waist during waking hours to measure step counts and time of moderate-to-vigorous physical activity (MVPA). The data were divided into work/school day and day off and evaluated accordingly. Partial correlation coefficient was used to evaluate the physical activity relationships between children and fathers or mothers.

RESULTS: For the work/school days, there was a significant positive correlation of step count between children and mothers (children: $15,800 \pm 2,560$ steps; mothers: $9,450 \pm 2,590$ steps, $r = 0.322$, $p < 0.05$) and a nonsignificant correlation between children and fathers ($8,820 \pm 2,990$ steps, $r = 0.249$). For the days off, there was a significant positive correlation of step counts between children and fathers (children: $11,700 \pm 3,520$ steps, fathers: $8,190 \pm 2,790$ steps, $r = 0.473$, $p < 0.01$) but no significant correlation between children and mothers ($10,000 \pm 2,530$ steps, $r = 0.096$). There was a significant positive correlation in MVPA time for days off between children and fathers (children: 74.5 ± 25.9 min, fathers: 51.0 ± 22.5 min, $r = 0.487$, $p < 0.01$) but no significant correlation between children and mothers (55.9 ± 16.9 min, $r = 0.075$). There were no significant correlations in MVPA time for work/school days between children and fathers (children: 97.5 ± 23.8 min, fathers: 59.8 ± 18.3 min, $r = 0.503$) and between children and mothers (56.9 ± 13.7 min, $r = 0.131$).

CONCLUSIONS: These findings suggest that the children may have spent time with their mothers on work/school days, and with their fathers on days off. Thus, an increase in fathers' physical activities may lead to a corresponding increase in the physical activities of some children with modern Japanese lifestyles.

3644 Board #8 May 30 9:00 AM - 11:00 AM
Effects Of Four-day School Weeks On Physical Education Exposure And Childhood Obesity

Emily J. Tomayko, Paul N. Thompson, John M. Schuna, Jr., Katherine B. Gunter, FACSM. *Oregon State University, Corvallis, OR.* (Sponsor: Katherine Gunter, FACSM)
 Email: emily.tomayko@oregonstate.edu
 (No relevant relationships reported)

Schools are critical venues to support child health and wellbeing. One mechanism to influence these outcomes is via school-based physical activity, but substantial declines in funding have forced many school districts to consider cost-cutting measures that may impact physical activity exposure and related outcomes. Use of four-day school weeks (FDSWs) as a potential cost-saving strategy has increased substantially, particularly in rural areas, which contain ~90% of FDSW districts. However, evidence regarding impacts of FDSWs on child health and related factors is lacking. **PURPOSE:** To examine physical education (PE) exposure and childhood obesity prevalence in four- and five-day Oregon schools. We hypothesized lower PE exposure and higher obesity in four- versus five-day models given reduced school

environment exposure. **METHODS:** We linked longitudinal FDSW data to existing data that included 1) school-level PE exposure for all Oregon elementary schools in 2011-2012 and 2017-2018 (n=1296 and 1243 schools, respectively) and 2) child-level body mass index z-scores from a state representative sample of 1st-3rd graders (n=4,625 children, 2011-2012). Instructional time, enrollment, demographics, and pupil-teacher ratio also were examined. T-tests compared mean school-level factors between four- and five-day schools overall and in rural schools only; complex samples weighted t-tests clustered at the school-level compared mean obesity data across school models. **RESULTS:** Enrollment, instructional time, and pupil-teacher ratio were significantly lower in four- versus five-day schools. FDSW schools provided significantly more PE, both as an absolute measure (120 vs. 101 minutes/week in four- vs. five-day schools in 2017-2018, p<0.01) and relative to total instructional time (6.9% vs. 5.0% in four- vs. five-day schools, p<0.0001). There were no differences in obesity prevalence between school models. **CONCLUSIONS:** The increased PE exposure in FDSW schools was unexpected, but it is unknown if this increase was related to a lack of difference in obesity prevalence. Given the known health and educational disparities experienced in rural communities, it is critical to better understand how FDSW use impacts physical activity, obesity risk, and other related factors for children in rural schools.

G-22 Thematic Poster - Running Technique Interventions

The Effect Of Backward Running On Patellar Tendon Loading

Naghmeh Gheidi, Thomas W. Kernozek, FACSM, Alexis Mehr, Lauren Strommen, Carolyn Apfelbach. *UWL, La-Crosse, WI.*
(Sponsor: Thomas W Kernozek, FACSM)
Email: ngheidi@uwlax.edu
(No relevant relationships reported)

Patellar tendinopathy is experienced in nearly 5% of distance runners during their career. Backward running (BR) has been recommended as a good rehabilitation exercise for patellofemoral pain patients as an intermediate progression from walking to forward running (FR). However, no studies have compared how BR affect patellar tendon stress.

Purpose: Identify differences in patellar tendon (PT) stress during FR (heel strike pattern) and BR. **Methods:** Twenty healthy male runners (Age: 21 ± 6.9 years, Height: 1.8±0.6 m, Mass: 76.2±14.1 kg, weekly running distance: 22.3±7.6 km) participated in this study. Each performed 5 trials of over-ground FR (heel strike pattern) and BR with a running velocity of 2.8-3.4 m/s based on photoelectric timing. Kinematic data were collected at 180 Hz using a 15-camera motion capture system. Ground reaction forces (GRF) were collected at 1800 Hz using a force platform. The Newton- Euler inverse dynamics method was used to calculate the net knee joint moment. The average moment arm of each quadriceps muscles were determined using Graphics-Based Model. The net knee moment was then divided by this knee moment arm to determine quadriceps force. PT force was determined from summing quadriceps muscles forces (rectus femoris, vastus lateralis, medialis, and intermedius muscle). Static ultrasound imaging was performed for measuring PT cross sectional area (CSA). PT stress was estimated by dividing PT force by PT CSA. MANOVA with repeated measures, was performed to compare PT stress, PT force, vertical GRF, knee ROM, and knee moment in FR and BR. **Results:** There were differences between FR and BR for all variables, except for GRF (p<0.001). Knee moment (154.7 vs. 205.1 Nm), PT stress (47.42 vs. 60.06 MPa) and PT force (4335 vs. 5497 N) in BR were around 21-24% less than FR. In addition, knee joint (20.84 vs. 37.72 deg) exhibited near 45% less range of motion during BR. **Conclusion:** Larger knee ROM coupled with the larger knee moment occur during FR. This may be required to stabilize the tibia during stance phase placing a greater stress on the patellar tendon.

BR results in lower PT stress when compared to FR. The lower PT stress as well as higher coordination variability may make BR more suitable for rehabilitation in patients with patellar tendinopathy as a progression exercise to FR due to its lower PT stress.

3647 Board #2 May 30 9:00 AM - 11:00 AM
Influence Of Running Speed On Muscle Activity During Backward Running With Body Weight Support

Kenji Masumoto¹, John A. Mercer, FACSM². ¹*Kyushu University, Fukuoka, Japan.* ²*University of Nevada, Las Vegas, NV.* (Sponsor: Professor John A. Mercer, FACSM)
(No relevant relationships reported)

A change in running speed influences gait mechanics of running. **PURPOSE:** The purpose of this study was to investigate the influence of a change in running speed on muscle activity during forward and backward running at different body weight support (BWS) conditions. **METHODS:** Eleven participants (29.7 ± 12.3 years) ran forward and backward on a lower body positive pressure treadmill at 0%BWS, 20%BWS, and 50%BWS conditions. The running speed conditions consisted of forward and backward running at preferred speed (PS), PS+10%, and PS-10%. Muscle activity from the rectus femoris, biceps femoris, tibialis anterior, and gastrocnemius and stride frequency were measured. Muscle activity and stride frequency were analyzed using a 2 (running direction) x 3 (BWS) x 3 (running speed) repeated measures analysis of variance ($\alpha = 0.05$). **RESULTS:** Muscle activity from the rectus femoris (P<0.01) and gastrocnemius (P<0.01) were significantly different between running speeds. For example, muscle activity from the rectus femoris (P<0.05) and gastrocnemius (P<0.05) during running at PS were significantly greater than when running at PS-10%, regardless of running direction and BWS. Furthermore, muscle activity from the rectus femoris (P<0.01) and gastrocnemius (P<0.05) during running at PS+10% were significantly greater than when running at PS, regardless of running direction and BWS. Stride frequency was influenced by the interaction of running direction and running speed (P<0.05). Using the pairwise comparisons, stride frequency during running at PS was significantly higher than that of running at PS-10% only when running forward and backward at 0%BWS (e.g., 84.5 strides/min and 82.0 strides/min for backward running at PS and PS-10% conditions, respectively; P<0.05). Furthermore, stride frequency during running at PS+10% was significantly higher than that of running at PS during forward and backward running at 0%BWS (P<0.05). **CONCLUSIONS:** Muscle activity from the rectus femoris and gastrocnemius during running may increase with increasing running speed, regardless of BWS and running direction. However, unique biomechanical strategies for the increased muscle activity from the lower extremity may exist for running with BWS.

3648 Board #3 May 30 9:00 AM - 11:00 AM
The Effect Of Synchronous And Asynchronous Music On Treadmill Running Performance Of Recreational Athletes

Dimitrios Katsavelis, Isaac Burright, Megan Quast, Megan Ackerman, Erika Piper, Brooke Farmer, Terry Grindstaff. *Creighton University, Omaha, NE.*
Email: DimitriosKatsavelis@creighton.edu
(No relevant relationships reported)

Background: Running with synchronous music tempo is associated with positive physiological and psychological effects that improve running performance as expressed by time to exhaustion. Changes in the music tempo may increase physiological efficiency (slow tempo) or improve motivation and mood (fast tempo), but there is no conclusive evidence whether asynchronous music tempo can influence distance covered or time to exhaustion. **Purpose:** To investigate the effect of different music tempo on running performance, force and cadence profiles of recreational athletes. **Methods:** Six college students (age = 21.2± 3yr; weight = 75.4± 12kg; height = 179.5± 10cm) participated in the study. The participants were tested five times over a period of three weeks. During the first visit, lactate threshold speed (LTS) was assessed via blood samples. During the second visit participants run at 5% above their LTS (3.5±0.4m/s) with no auditory stimuli until exhaustion. During the last three visits participants were randomly assigned to run on an instrumented treadmill in three different tempo conditions until exhaustion: slow, matched and fast. Time to exhaustion, vertical ground reaction forces (vGRF) and cadence were calculated through Matlab. **Results:** A one-way repeated ANOVA (4 conditions) showed that there was a main effect of music, with the no music condition resulting in a decrease in time to exhaustion by 18-21% when compared to all the music conditions, but no significant differences among the 3 music conditions. The vGRF during running at slow tempo (2.58 BW) were significantly lower when compared to fast tempo (2.62 BW), whereas there was an increase in cadence between slow (167 steps/min) and fast (170 steps/min) tempo conditions. **Conclusion:** The findings indicate that music – in general – has a positive effect on running performance, while asynchronous tempi can only cause significant but subtle changes (less than 2%) in the force and cadence profiles.

3649 Board #4 May 30 9:00 AM - 11:00 AM

Effects Of Lower Limb Light-weight Wearable Resistance On Running Biomechanics

Aglaja Busch¹, Karl Trounson², Peter Browne², Sam Robertson².
¹Outpatient Clinic, Potsdam, Germany. ²Institute of Sport, Exercise and Active Living, Melbourne, Australia.
 (No relevant relationships reported)

Resistance training is important to maintain an athlete's health and regain strength after injury. Light-weight wearable resistance allows loading in the context of sport specific movements and can lead to specific strength adaptations benefiting the athlete. However, limited knowledge of the associated biomechanical changes with such a training modality exists.

Purpose: To determine biomechanical changes during running with lower limb light-weight wearable resistance.

Methods: Fourteen healthy participants volunteered for the study (age: 28±4 years; height: 180±8 cm; body mass (BM): 77±6 kg). Participants wore shorts and calf sleeves allowing attachment of light loads and performed 4 x 2 mins 20-m over-ground shuttle running bouts at 3.3 m*s⁻¹, alternating by 3 mins rest. The first running bout was unloaded and the other three bouts under randomised loaded conditions. The loaded conditions consisted of 1 %, 3 % and 5 % additional loading of the BM. Loads were distribution on the legs with 2/3 on the thigh and 1/3 on the shank. Two force plates embedded in the floor at the 10-m mark of the runway recorded peak vertical ground reaction forces (vGRF) and ground contact time (GCT). Recorded kinetic data was filtered using a low-pass Butterworth filter at frequency 120 Hz and normalised to body weight. A repeated measures ANOVA ($\alpha \leq 0.05$) was used to determine differences between conditions and Cohens *d* was calculated with effect sizes defined as small ($d = 0.2$), medium ($d = 0.5$) and strong ($d = 0.8$).

Results: Peak vGRF decreased (-0.5 %) with additional loading of 1% BM ($d = 0.17$, $p = 1$) and slightly increased (+1.1 %) with 3% BM loading ($d = 0.13$, $p = 0.91$) compared to unloaded condition. Higher peak vGRF (+1.4 %) was also found during 5 % BM loading ($d = 0.19$, $p = 1$). Ground contact time showed no significant differences ($0.13 \leq d \leq 0.20$, $0.4 \leq p \leq 1$) between all conditions and only a slightly increased with 5 % BM loading (+1 %).

Conclusion: Small changes in peak vGRF and GCT during loaded running occurred. Maintaining targeted speed and running economically might result from kinematic adaptations, needing further evaluation. Additionally, examination of acute neuromuscular alterations, hypothesised by increased muscular output before gait pattern changes develop, are necessary for appropriate use of light-weight wearable resistance.

3650 Board #5 May 30 9:00 AM - 11:00 AM

An Investigation Into The Feasibility Of A Split-belt Instrumented Treadmill Running Protocol With Perturbations.

Andrew Quarmby, Mina Khajooei, Tilman Engel, Hannes Kaplick, Frank Mayer. University of Potsdam, Potsdam, Germany.
 Email: andrew.quarmby17@gmail.com
 (No relevant relationships reported)

Unexpected disturbances to human gait can occur during daily life or sports performance. Compensating successfully for such disturbances or perturbations is crucial in maintaining effective postural control and avoiding potentially injurious events. Studies of perturbed walking protocols using instrumented treadmills have previously been validated, however the validation of and responses to perturbed running protocols remain less investigated. **PURPOSE:** To investigate the feasibility of a new instrumented treadmill-perturbed running protocol. **METHODS:** Fifteen participants (28±3years; 172±9cm; 69±10kg; 60% female) completed an 8-minute running protocol at a baseline velocity of 2.5m/s (9 km/h), whilst 15 one-sided belt perturbations were implemented (*pre-set perturbation characteristics: 150ms delay (post-heel contact); 2.0m/s amplitude; 100ms duration*). Perturbation characteristics and sEMG responses (right leg: gastrocnemius medialis (GM), tibialis anterior (TA), peroneus longus (PL), biceps femoris (BF), vastus medialis (VM); trunk bilateral: rectus abdominus (RA), erector spinae L3 (ES); Root Mean Square (RMS) normalized to unperturbed walking) were recorded. Bland-Altman analysis (BLA) was employed (bias±limits of agreement (LOA; bias±1.96*SD)) and intra-individual variability of repeated perturbations was assessed via Coefficients of Variation (CV) (mean±SD). **RESULTS:** On average, 9.4±2.2 of 15 intended perturbations were identifiable. Perturbation delay was 143±10ms, amplitude was 1.7±0.2m/s and duration was 69±10ms. BLA showed -7±13ms delay, -0.3±0.1m/s amplitude and -30±10ms duration. CV showed variability of 19±4.5% for delay, 58±12% for amplitude and 30±7% for duration. sEMG RMS amplitudes were 113±25% (GM), 225±73% (TA), 139±68% (PL), 134±34% (BF), 200±168% (VM), 332±305% (RRight), 324±162% (RAleft), 220±130% (ESright), 183 ± 122% (ESleft). **CONCLUSION:** This study showed that the application of sudden perturbations during running can be achieved, though with increased variability across individual perturbations. The perturbations

with the above characteristics elicited a detectable neuromuscular response during running, especially in the muscles of the trunk and anterior leg. Responses in the calf muscles were minimal.

3651 Board #6 May 30 9:00 AM - 11:00 AM

The Effect Of Verbal Cues On Lower Extremity Kinetics During Running

Allison Lieb¹, Quinn Garner¹, Nicholas Reynolds¹, Jennifer Bagwell², Terry Grindstaff¹. ¹Creighton University, Omaha, NE. ²California State University, Long Beach, Long Beach, CA.
 (Sponsor: Joan Eckerson, FACSM)
 Email: allisonlieb@creighton.edu
 (No relevant relationships reported)

Previous research indicates that verbal cues such as "push with your feet" can alter ankle and hip kinetics during walking. Clinicians often use cues such as "push with your hips" when working with runners, but the effect of such verbal cues on lower extremity kinetics during running remains poorly understood. **PURPOSE:** The purpose of this study was to determine the effect of verbal cues emphasizing use of hips and glutes or use of toes and ankles on lower extremity running kinetics.

METHODS: Ten healthy subjects (age 23±1 years, mass 67±16 kg, height 168±11 cm) participated. Subjects performed 3 running trials, at a self-selected pace, on an instrumented treadmill while collecting kinematics and kinetics. First, a baseline running gait was established, then each subject was given the instruction to "push yourself forward with your hips and glutes" or "push yourself forward with your toes and ankles" in a randomized order. After 1 minute to adapt to each condition, 30 seconds of data were recorded. Variables of interest included peak sagittal hip, knee, and ankle moments and positive, negative, and total sagittal work at the hip, knee, and ankle. One-way repeated measures ANOVAs were used to assess kinetic changes across conditions.

RESULTS: There was a significant main effect of running cue with respect to negative and total work at the ankle ($p=0.031$ and $p=0.002$). Post-hoc analyses indicated that ankle negative work was greater when running with the ankle cue compared to baseline running (-0.44 ± 0.17 J/kg vs -0.38 ± 0.14 J/kg; $p=0.031$) and ankle total work was greater when running with the ankle cue compared with baseline and hip cue running ($p=0.019$ - 0.008). There were no significant differences in any of the other lower extremity sagittal moments or work across tasks ($p>0.05$).

CONCLUSIONS: Subjects demonstrated increased negative and total work at the ankle in response to the ankle running cue. There was no change in positive work, which was anticipated with a cue emphasizing forward propulsion. Running kinetics remained largely unchanged in response to either running cue, possibly due to the quality of the cue (i.e. internal rather than external focus). These data suggest telling clients to "use your hip more to run" may not be an effective method to change running mechanics.

3652 Board #7 May 30 9:00 AM - 11:00 AM

Influence Of A Novel Music App On Spatiotemporal Mechanics During Running

Danielle Mannino, Matthew F. Moran. Sacred Heart University, Bridgeport, CT.
 (No relevant relationships reported)

An increased running step rate (i.e., cadence) can decrease lower extremity joint loads and potentially reduce running-related injury (RRI) risk. Many gait interventions have significantly increased a runner's cadence through a variety of external stimuli (e.g., metronome). Runners have been shown to spontaneously manipulate their cadence when listening to music with a tempo that differed ±3% from their baseline cadence. However, no study has determined whether a runner will subconsciously increase cadence > 3% when listening to up-tempo music. **PURPOSE:** To determine if music tempo (beats per minute, bpm) set 10% higher than baseline cadence affects spatiotemporal running mechanics. **METHODS:** Utilizing a blinded experimental design, twenty-two runners (15F, 7M, 18-40 yo) were recruited, granted informed consent, were randomly assigned to a control (C) or experimental (E) group, and picked four motivational songs. The Brunel Music Rating Inventory was used to rate song motivational level. Subjects ran three 5-min trials (5/10 effort) on a pressure-sensitive treadmill (Noraxon U.S.A., 100 Hz) with vertical ground reaction force and pressure recorded during the last 45 sec and lowpass filtered (40 Hz). Five-min of rest was given between trials. During the second trial, subjects listened to music via headphones with the bpm set to baseline cadence (C) or 10% higher (E). Music was administered via a novel smartphone application that permitted song tempo to be adjusted and maintained in one bpm increments. The last trial was completed without music with velocity held constant across all trials. A mixed design analysis of variance was run in JASP with a significance set a priori at 0.05. **RESULTS:** Baseline cadence was not significantly different between groups (C: 165.4±9.5 steps per minute, E 167.2±6.8, $p=0.61$). There was not a significant main effect ($p=0.54$, $p=0.32$, $p=0.152$, $p=0.70$) of music tempo between groups for cadence (F (1,20)=0.39), step width (F(1,20)=1.02), stance phase (F (1,20)=2.22), or foot rotation (F(1,20)=0.16).

CONCLUSION: Spatiotemporal running mechanics do not spontaneously adjust when runners listen to motivational music set at a tempo 10% greater than baseline cadence. Listening to up-tempo music should not be considered an effective external stimulus to promote increased running cadence.

3653 Board #8 May 30 9:00 AM - 11:00 AM
Lower Extremity Joint Work Following A Long Hilly Run In Conventional And Maximalist Shoes

Christopher Casillas, James Becker. *Montana State University, Bozeman, MT.*

Email: james.becker4@montana.edu

(No relevant relationships reported)

Trail running is a rapidly growing discipline which often contains uphill and downhill running segments. The varying elevation requires different muscular demands than level ground running and thus may influence how joint kinetics change following a long run. Many trail runners use highly cushioned maximalist (MAX) footwear. However, the influence of MAX footwear on joint kinetics following a long run is currently unknown. **PURPOSE:** To determine if there are differences in joint work following a long hilly run (LHR) in conventional (CON) and MAX footwear. **METHODS:** Twelve trail runners (sex: 10 M, 2 F; weekly mileage: 30.3 ± 14.9 miles) were randomly assigned to either a CON or MAX shoe and ran a 10-mile LHR which matched the elevation profile of a popular local trail run. 3D kinematics and ground reaction forces were collected during five-minute level ground running sections prior to and following the LHR. Sagittal plane positive (POS) and negative (NEG) joint work for the hip, knee, and ankle were calculated by integrating the POS and NEG portions of the joint power curves. Two-way mixed ANOVAs (shoe condition, time) were used to evaluate differences in joint work. **RESULTS:** There were no differences between groups in any joint work parameter before the LHR (Figure 1). Following the LHR, POS ($p = 0.014$) and NEG knee ($p = 0.041$) and NEG hip ($p = 0.014$) work increased in the MAX group. Compare to the CON group, the MAX group also had higher NEG knee work ($p = 0.009$) and was trending towards higher POS knee ($p = 0.072$). No differences were observed in ankle work or positive hip work. **CONCLUSION:** Proximal redistribution of joint work following a LHR was observed, but not to the extent reported in previous studies using level runs. However, the increased knee work in MAX footwear suggests the knee is being loaded more during a LHR compared to CON footwear. This may have implications for injury risk as higher knee loads are related to common running injuries.

Footwear provided by New Balance, Inc.

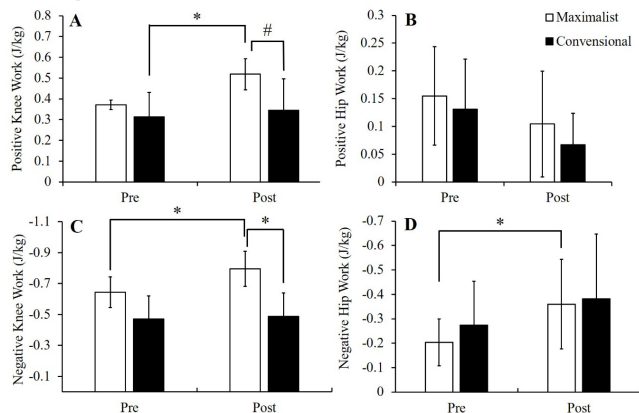

Figure 1: Mean and standard deviations for positive knee (A) and hip (B) joint work and negative knee (C) and hip (D) joint work prior to and following the LHR for the MAX and CON groups. * denotes statistically significant difference. # denotes data trending towards a statistical difference.

Nutritional Intervention In A Male Olympic Swimmer: Adequation Of Carbohydrate Intake Based On Metabolic Profile

Humberto Nicastro¹, Victor Hugo Rosa de Oliveira¹, Claudia Czapski², Gerson Leite¹, José Alves Balestrin¹, Leonardo Prieto¹, Felipe Domingues³, Gustavo Schirru³, Luciana Setaro², Gustavo Magliocca¹. ¹CareClub Health Center, São Paulo, Brazil. ²Centro Universitário São Camilo, São Paulo, Brazil. ³Confederação Brasileira de Desportos Aquáticos, São Paulo, Brazil.

Email: nicastro@careclub.net.br

(No relevant relationships reported)

HISTORY: Male Olympic swimmer (100 m breaststroke; 32 y, 96.0 kg, 185 cm) with recurrent hypoglycemia and -related symptoms (hand sweating, blurred vision) at rest and during training and expressive weight loss on training days.

PHYSICAL EXAMINATION: Subject underwent DEXA (body composition), pre and post training blood glucose measurements and indirect calorimetry.

DIFFERENTIAL DIAGNOSIS:

1. Hypoglycemia at rest and during training sessions;
2. Body fat percentage: 14,9%;
3. Low fat oxidation at rest (45% of basal metabolic rate).

TEST AND RESULTS: Basal metabolic rate was of 2.360 kcal with glycolytic predominance (55% of total energy expenditure), confirming that energy metabolism is highly dependent of carbohydrate intake. At the beginning and end of the week, morning weight was 96.0 and 93.0 kg, respectively. Blood glucose pre-exercise was 84.0 mg/dl and 60 mg/dl post-exercise.

FINAL WORKING DIAGNOSIS: Training-induced severe hypoglycemia and expressive weight loss across the week. It was hypothesized that such events occur since in response of the elevated activity of glycolytic pathway and consumes and consumption of high glycemic index supplements during training.

TREATMENT AND OUTCOMES:

1. We focused on nutritional intervention based on high calorie intake and substitution of high by low glycemic foods and supplements throughout the day;
2. Additionally, we recommended beta-alanine supplementation (4 x 1.6 g) to prevent metabolic acidosis;
3. After 2 weeks of intervention, no symptoms of hypoglycemia were reported at rest and during training sessions;
4. Weight loss was attenuated (- 1.6 kg) and blood glucose values did not decrease after training (pre: 80 mg/dl; post: 125 mg/dl).

3659 May 30 9:40 AM - 10:00 AM

You Only Get One Bite Out Of This Apple

Jonathan R. Guin, Thomas J. Bollaert, James B. Robinson.

University of Alabama, Tuscaloosa, AL.

Email: jrguin@gmail.com

(No relevant relationships reported)

HISTORY: A 21-year-old collegiate tight end sustained anterior neck trauma from his chin strap during a regular season game. During the first quarter, the athlete was struck in his anterior neck by an opponent's face mask. The patient felt throat pain and states it felt like his "Adam's Apple is to the right". He then went back into the game because he noted the pain was only mild, and he was otherwise asymptomatic. The athlete was able to continue playing until the early part of the third quarter of the game. At that time, he was evaluated by the team physician and held from the rest of the game. He was then sent to the emergency department for further evaluation and imaging.

PHYSICAL EXAMINATION: Examination on the sideline revealed a click upon palpation of the anterior neck near the thyroid cartilage. He had full ROM of his cervical spine with a normal neurological exam. He had no respiratory distress, subcutaneous crepitus, or voice changes. He did have some pain with swallowing. Hyoid bone and cricoid cartilage is non-tender. Cardiac and pulmonary exams were also unremarkable. Exam was stable when repeated in emergency department.

DIFFERENTIAL DIAGNOSIS: Fracture of Thyroid Cartilage Fracture of Hyoid Bone Contusion of Neck Carotid Artery Dissection

TEST AND RESULTS: CT Neck with Contrast Minimally displaced fracture involving the anterior right thyroid cartilage. The left thyroid cartilage has a concave appearance suggestive of a depressed nondisplaced cartilage fracture. The larynx is angulated to the right.

Nasolaryngeal scope True vocal cords were freely mobile. Airway is patent. Subglottis is normal without any hematoma or edema. Both true vocal cords are with some mild discoloration and edema, but no frank hemorrhage or hematoma within either vocal cord.

FINAL WORKING DIAGNOSIS: Fracture of Thyroid Cartilage

TREATMENT AND OUTCOMES:

1. Evaluated in emergency department where CT scan was performed that found a fracture of the thyroid cartilage 2. Nasolaryngeal scope done in ED by ENT 3. Admitted and stayed overnight in ICU because of risk for respiratory compromise 4. IV steroids given while in ICU to prevent any further edema 5. Evaluated at tertiary care facility day after discharge by ENT 6. Determined need for surgical repair 7. Athlete currently recovering with anticipated healing time of 4-6 weeks

3660 May 30 10:00 AM - 10:20 AM

Ovarian Torsion Presenting As Referred Cyclical Hip Pain In A Division I AthleteEmily D. Geyer¹, Christina L. Charles², Rachel Denison³, Bridget M. Geyer⁴, James A. Onate¹. ¹Ohio State University, Columbus, OH. ²Columbus Obstetricians-Gynecologists, Inc., Columbus, OH. ³University of Notre Dame, Notre Dame, IN. ⁴Duke University School of Medicine, Durham, NC.

Email: emily.geyer@osumc.edu

*(No relevant relationships reported)***HISTORY**

A 22-year-old female Division I rower presented to the emergency department (ED) due to severe right lower quadrant pain with nausea and vomiting. She had a three-year history of right hip pain diagnosed as femoroacetabular impingement (FAI) and infrequent flares of worsened hip pain treated with rest and intra-articular cortisone injections or oral steroid dose-pack. During ED visit, abdominal computerized tomography (CT) and transvaginal ultrasound (TVUS) revealed significantly enlarged right ovary diagnosed as ovarian cyst. She was discharged and was seen by OB/GYN that afternoon for follow up.

PHYSICAL EXAMINATION

Patient presented to the office in moderate distress due to unabated right lower quadrant (RLQ) pain. Abdomen was soft and tender throughout. Physical exam was otherwise unremarkable.

DIFFERENTIAL DIAGNOSIS

Prior to imaging:

1. Musculoskeletal: fracture, FAI, osteoarthritis, nerve compression, bursitis
2. Genitourinary: urinary tract infection, pyelonephritis, nephrolithiasis
3. Gastrointestinal: Irritable Bowel Syndrome, constipation, appendicitis
4. Gynecologic: ovarian cyst, ovarian torsion, pelvic inflammatory disease, tubo-ovarian abscess

TESTS AND RESULTS

TVUS revealed 7 cm edematous right ovary with 2 small follicles and no large cyst. There was very minimal to no Doppler flow. Blood work revealed elevated white blood cell (WBC) count.

FINAL/WORKING DIAGNOSIS

Suspected diagnosis of right ovarian torsion

TREATMENT AND OUTCOMES

1. Patient was admitted to the hospital for mini-laparotomy and right oophorectomy.
2. Right ovary torsed 5 times and appeared normal other than being significantly enlarged to 7-8 cm
3. Given that there was no cyst to be drained, the right ovary was removed.
4. The right fallopian tube, left ovary and fallopian tube, and uterus were all normal.
5. The patient tolerated the procedure well and has since experienced only mild hip pain consistent with FAI.
6. It is likely the patient's flares of pain over the previous 3 years were ovarian in etiology but disguised due to her irregular menstrual cycle and coincident chronic FAI. Ovarian etiology should be included in the differential for female athletes experiencing surges of lower quarter abdominal pain in a setting of hip pain.

3661 May 30 10:20 AM - 10:40 AM

Ehlers-Danlos Syndrome And CD5 Deficiency In A 22 Year-old MaleThomas Lowder, Courtney Holloway. *UNIVERSITY OF Central Arkansas, Conway, AR.*

Email: tlowder@uca.edu

(No relevant relationships reported)

HISTORY: A previously-active male presented with joint pain at age 15. He is positive for joint hypermobility and dislocation/subluxation, joint pain, food allergies, gastritis, gastroesophageal reflux, and CD5 immune deficiency (diagnosed at age 5, one of eight in the world at the time). He has a family history of aortic aneurysm.

PHYSICAL EXAMINATION: The patient exhibited joint pain and extreme hypermobility on examination. Genetic tests were performed on the patient, his mother, and his sister.

DIFFERENTIAL DIAGNOSIS: While there exists a family history of hypermobility, along with orthostatic hypotension in this patient (consistent with Ehlers-Danlos Syndrome, or EDS) the patient also exhibits CD5 immune deficiency, psychogenic seizures, a likely pathogenic variant in the AK2 gene (c.656delT), associated with reticular dysgenesis. His sister also carries this variant. He also carries the variant associated with cystic fibrosis, the congenital bilateral absence of the vas deferens, and chronic pancreatitis.

TEST AND RESULTS: We are presently working with this patient to determine if a moderate-intensity exercise program yields a decrease in joint pain, hypermobility, and downregulation of gene expression.

FINAL WORKING DIAGNOSIS: This is a work-in-progress of a patient with two rare diseases and a variety of genetic issues., which to our knowledge have never been exhibited in a single patient.

TREATMENT AND OUTCOMES: We will present working data and determine if an exercise intervention has a positive impact in this patient.

3662 May 30 10:40 AM - 11:00 AM

Left Flank Injury - SoccerJiao Xue. *Pomona Valley Hospital Medical Center, Pomona, CA.*

Email: jiao.xue.md@gmail.com

(No relevant relationships reported)

HISTORY: A 17-year-old senior high school soccer player sustained an elbow strike from opposing player to his left flank while practicing. Later that night, he experienced excruciating pain which led him coming to ED the following day. He was discharged despite elevated blood pressure (BP). 4 weeks later, he saw his primary care doctor who noted elevated BP in addition to flank pain, and patient was recommended to go to ED after concerning ultrasound findings. **PHYSICAL EXAMINATION:** On initial presentation to ED, patient's BP was 152/96. Examination revealed visible distension in the left abdomen. Palpable mass was appreciated in the same region while lying down. Tenderness to palpation to the left abdomen and left costovertebral angle were noted.

DIFFERENTIAL DIAGNOSIS: Left kidney hematoma v.s. muscular hematoma v.s. kidney contusion v.s. renal arteriovenous malformation v.s. ruptured spleen v.s. kidney mass

TEST AND RESULTS: CT Abdomen & Pelvis W/O Contrast revealed a 12 cm left perinephric hematoma with significant mass effect on the left kidney. Otherwise, CBC and BMP were unremarkable.

FINAL WORKING DIAGNOSIS: L subcapsular renal hematoma secondary to trauma

TREATMENT AND OUTCOMES: IR placed a pigtail drain with 1L output on the 1st day. BP was treated with amlodipine 2.5mg and Hydralazine 5mg PRN. Patient was discharged on the 4th day. On the day of discharge, patient's drain fell out accidentally during a school dance. An Trauma surgeon evaluated him in an outpatient setting. No additional imaging was done given he was asymptomatic. A few weeks later, he developed abdominal/back pain as well as headaches. He presented to Children's Hospital with hypertension to 170s/110s. Ultrasound showed 11cm left subcapsular hematoma with significant compression of left kidney. IR placed another drain which was eventually removed after 3.5 weeks. Prior to discharge, BP improved to 130s/70s

without medications. After discharge, patient was followed by a Pediatric Urologist with monthly imaging. 10 months later, he still had a small 0.5cm hematoma. Patient continues to have mildly elevated BP of unclear etiology. He was evaluated by a Pediatric Cardiologist, and echo did not show evidence of heart disease (LVH). He has not played soccer since the injury.

Calf And Foot Injury- Crossfit

Jeff Nadwodny, Ahmad Al-Awadi, Michael Stiller, George Pujalte, FACSM. *Mayo Clinic School of Graduate Medical Education, Jacksonville, FL.* (Sponsor: George G.A Pujalte, FACSM)

Email: Jeffrey.Nadwodny@mayo.edu

(No relevant relationships reported)

HISTORY: A 51-year-old female presented with three-year worsening left lower leg and foot pain. No injury at time of onset but was active with CrossFit five times weekly. Pain began on bottom of forefoot with radiation through the sole of foot to posterior calf and popliteal fossa. Pain described as 7-8/10 in intensity, constant, sharp/stabbing in nature, with burning sensation on the bottom of foot. Associated with weakness of the left ankle, foot drop requiring patient to wear an ankle-foot orthotic, swelling, and color changes with her foot turning blue/red intermittently. Pain was unrelieved with oral NSAIDs, steroids, and only temporary relief with topical anti-inflammatory gel, heat/ice, deep tissue massage, and dry-needling with physical therapy.

PHYSICAL EXAMINATION: Examination revealed skin color changes with blue discoloration of left foot that was cool to touch. Tender to palpation maximally over left gastrocnemius muscle, Achilles tendon, sole and ball of foot; 0/5 strength with left ankle dorsiflexion/plantar flexion, ankle inversion/eversion or great toe extension. Sensation intact to light touch in L2-S2 dermatomes. Reflexes normal and symmetric bilaterally.

DIFFERENTIAL DIAGNOSIS:

1. Peripheral nerve damage secondary to entrapment/compression
2. Vascular insufficiency
3. Complex regional pain syndrome

TEST AND RESULTS:

MRI without IV contrast of left tibia/fibula, foot, ankle:

- Mild intramuscular edema within gastrocnemius and soleus, focal fatty atrophy adjacent to medial soleus muscle. Generalized subcutaneous edema throughout ankle. EMG:

- No evidence of left lumbosacral radiculopathy, left lower limb mononeuropathy, or large fiber peripheral neuropathy

US lower extremity Veins:

- No DVT in left lower extremity

Ankle brachial index:

- Normal arterial Doppler study on the left leg during rest with normal PVR waveforms.

NM bone scan:

- No abnormal blood flow or blood pool uptake involving the left foot or ankle. Mild radiotracer uptake in left midfoot.

FINAL/WORKING DIAGNOSIS: Complex regional pain syndrome

TREATMENT/OUTCOMES:

1. Physical Therapy focused on strengthening exercises and desensitization techniques
2. Diclofenac topical gel applied up to four times daily

3. Gabapentin 600mg BID

4. Referral to Pain Medicine for lumbar sympathetic nerve block

3667 May 30 9:20 AM - 9:40 AM

Acute Medial Calf Pain In Golfer

Kevin Baidoo¹, Luis J. Soliz¹, Jack Nickless². ¹*Rush University Medical Center, Chicago, IL.* ²*Midwest Orthopaedics at Rush, Chicago, IL.*

Email: kevin_n_baidoo@rush.edu

(No relevant relationships reported)

History: 50-year-old male golfer presenting with 1-day history of acute onset right medial calf pain. He was playing golf and his pain started shortly after walking on flat ground when he felt a "snap" and "electric jolt" in the right medial calf. He subsequently had difficulty walking and has reported swelling in that area since that time. He denied any numbness, weakness, or tingling in his distal lower extremities. He has taken over-the-counter ibuprofen with some relief of his symptoms. His pain is constant and severe. He reported no prior injuries to his right calf before.

Physical Examination: Antalgic gait. Inspection of the right foot and ankle revealed minimal ecchymosis over the medial mid-gastrocnemius. There was moderate tenderness to palpation over the medial greater than lateral gastrocnemius muscle belly. Range of motion at the right ankle including dorsiflexion, plantarflexion, eversion, and inversion were normal. Strength was 4-/5 with right resisted plantarflexion but otherwise normal. Reflexes and sensation were grossly intact. Special tests including tib-fib squeeze, Thompson, anterior drawer, and talar tilt were negative. Distal pulses were intact.

Differential Diagnosis: 1. Medial gastrocnemius strain 2. Tibia or fibular fracture 3. Acute peroneal nerve injury

Test and Results: Radiographs 4 views of the right tibia and fibula with soft tissue swelling and fullness in calf on lateral view. MRI right tibia and fibula with acute tear of the anterior gastrocnemius aponeurosis with a longitudinal component as well as a retracted transverse component.

Final Working Diagnosis: Acute L-Pattern tear of the aponeurosis of the medial calf

Treatment and Outcomes: 1. Offload right lower extremity with walking boot 2.

Course of physical therapy for 6 weeks 3. Indomethacin 50 mg BID for the next 10 days to help reduce risk of heterotopic ossification development in the calf 4. Follow up in 6 weeks for reevaluation and repeat radiographs

3668 May 30 9:40 AM - 10:00 AM

Lower Leg Injury - Basketball

Duke Yi-Fu Yeh. *Pomona Valley Hospital Medical Center, Pomona, CA.*

Email: Duke.Yeh@pvhmc.org

(No relevant relationships reported)

HISTORY: 24 year-old male basketball player presented to clinic with left lower extremity pain after inverting left ankle during a game. Immediately after the injury he grabbed his proximal fibula. He experienced moderate lateral ankle pain that's sharp and throbbing. He could bear weight but was unable to play. He also had swelling near the proximal fibula. The pain was worse with movement and relieved with rest, ice and elevation.

PHYSICAL EXAMINATION:

He was limping favoring his left side.

Left ankle with moderate amount of joint effusion and mild-moderate amount of swelling over proximal peroneal muscle.
 AROM and PROM: limited to pain, especially in inversion and plantarflexion.
 Tenderness to palpation in proximal peroneal tendon/fibula and distal peroneal muscle.
 Strength: Ankle Dorsiflexion 5-/5, Long peroneal, Plantarflexion, Inversion, Eversion all 4+/5. Left Anterior Drawer Test ankle has increased laxity.
 Unable to perform single foot toe raise on left. Neurovascularly intact.
DIFFERENTIAL DIAGNOSIS:
 Peroneal Muscle Strain
 Peroneal Tendon Rupture/Compartment Syndrome/Fibular fracture/Lateral Ankle Sprain
TESTS AND RESULTS:
 3v Xray Left ankle and 6v Xray Left tib-fib: no acute bony abnormalities.
 MRI Left tib-fib: high-grade partial to full-thickness tear of the peroneal longus tendon at the level of proximal fibula with torn tendon fibers to the level of proximal Meta-diaphysis. Low-grade partial tear of the proximal peroneal brevis tendon with intramuscular edema. Tendinosis and tenosynovitis of distal peroneal brevis and longus without high-grade partial tearing.
FINAL/WORKING DIAGNOSIS:
 Tear of Left Proximal Peroneal Tendon.
TREATMENT AND OUTCOMES:
 The patient was shut down from sports and placed in a Cam walker boot. Treatment with rest, ice and PT. Pain control with acupuncture, muscle relaxant, and Tylenol or ibuprofen as needed.
 2 days prior to the 2-week follow-up, the patient received 1 PRP injection at the site of pain.
 At 2 week follow-up, the patient's pain improved. He was able to ambulate without limping but still had tenderness in the proximal peroneal muscle. He was able to have pain free AROM and PROM and regained 5/5 strength in left ankle motions, except 5-/5 in Long Peroneal.
 At 4 weeks follow-up, all symptoms resolved and he was cleared to return to 15 minutes of contact practice.

3669 May 30 10:00 AM - 10:20 AM
Hi-ya!: A Rare Quadriceps Lesion In A Rising Champion
 Jose F. Velasquez, James Pearson, Alex Casey, Hamed Shalika.
Emanate Health, West Covina, CA.
 Email: jfvelasquezmd@gmail.com
(No relevant relationships reported)

HISTORY: A 10-year-old Female w/o past medical history was brought to the ED by her mother due to left leg pain and swelling. The mother states that the patient practices taekwondo. 3 days before during training, she sustained a direct kick over the left thigh. The patient states that since then she has been having pain. Mother has been doing supportive care at home including ice, Epsom salt compresses, and Amica. The mother states that despite the pain, the patient continued training. The mother states that the pain and swelling have markedly increased over the left thigh and knee, which started to impair ambulation with associated excruciating pain on palpation. The patient was taken to urgent care where X Rays ruled out a fracture. The patient was seen in the ED due to the worsening of swelling and pain. ROS was negative except for hpi. **PHYSICAL EXAMINATION:** Left lower extremity swelling from thigh to knee, tender to palpation in the lateral aspect over the quadriceps even with light touch. The patient was not able to bear weight or ambulate due to pain. peripheral pulses preserved. Skin is Normal color, warm, No bruise over the thigh. Neuro: grossly intact, motor/sensation. **DIFFERENTIAL DIAGNOSIS:** Quadriceps hematoma, Quadriceps strain, Quadriceps rupture, Compartment syndrome. **TEST AND RESULTS:** MRI LT femur w/o con: Severe sprain of the vastus intermedius muscle with partial tearing of the mid to distal aspect of the muscle lateral of midline associated with a large hematoma and intramuscular hemorrhage and edema. Mild straightening of the vastus medialis muscle proximally. **FINAL WORKING DIAGNOSIS:** Vastus intermedius rupture. **TREATMENT AND OUTCOMES:** RICE therapy, ACE wrap a few hours a day, Stretching exercises, Cryotherapy, Relative rest, cupping, acupuncture, and laser therapy. The Patient was pain-free and no longer needed crutches after a month. The patient started light level tournaments and after more than a month in recovery, she won a taekwondo National Championship.

3670 May 30 10:20 AM - 10:40 AM
Leg Injury - Football
 Austin A. Brown, Joseph E. Escobar, James P. Toldi. *University of South Alabama, Mobile, AL.*
(No relevant relationships reported)

HISTORY: A 12-year old male quarterback sustained a right leg injury while cutting back across the field. He was running across the field and made a lateral cut to change directions, as this happened he tripped over himself and fell without a twisting motion.

He landed on his right lateral leg with immediate pain to the fibular head. There was no numbness, tingling, weakness or radiation of pain however he had a noticeable limp. He presented to clinic 2 days later and denied any prior injuries or trauma to the area. **PHYSICAL EXAMINATION:** 2 days post injury (PCP office) — No deformity, normal knee and ankle exams, no bony tenderness, moderate postero-lateral edema of proximal right lower leg, painful/antalgic gait, TTP lateral gastrocnemius and soleus, negative Thompson's. 4 days post injury (Sports Medicine Clinic) — Consistent with prior exam, new findings: point TTP just distal to fibular head, decreased edema, negative squeeze test, negative ER test.
DIFFERENTIAL DIAGNOSIS: 1. R fibular contusion 2. R knee apophysitis 3. LCL sprain 4. Gastrocnemius contusion/strain 5. Distal Bicep Femoris strain
TEST AND RESULTS: XR: R Tib/Fib AP and Lateral radiographs 2 days after injury — Bones/joints/soft tissue appear unremarkable.
 Repeat XR 13 days post injury — subtle irregularity along the lateral aspect of the proximal fibula physis with associated periostitis. Final XR 20 days post injury — Noted irregularity along the lateral aspect of the proximal fibula physis with increased benign periostitis.
FINAL WORKING DIAGNOSIS: Salter-Harris II fracture of R proximal fibula physis
TREATMENT AND OUTCOMES: 1. Cam walker boot 3 weeks with weekly exams/ XRs. 2. 20 days out from injury completely normal RLE exam, no pain, full ROM, XRs suggestive for healing SH2 fracture; patient was able to return to football as tolerated.
DISCUSSION: In isolation this is a very rare injury. There was one reported case of a SH-3 fracture that presented with initial knee injury and ROM deficits that was treated non-operatively. Most injuries to the proximal physis of the fibula occur in combination with an interosseous membrane/syndesmotomic and distal tibiofibular injury - must rule out a Maisonneuve injury. The presenting complaint was pain and edema in the region of the soleus this may have been a soleus traction injury to the apophysis vs direct trauma from the fall.

Acute Effects Of Sauna Exposure Compared To Aerobic Exercise On Pulse Wave Velocity
 Noah John Erb, Andrew D. Nelson, Julia D. Jenkins, Cory L. Butts. *Weber State University, Ogden, UT.*
(No relevant relations reported)

Cardiovascular disease is the leading cause of death worldwide. Aerobic exercise is recommended to reduce the risk of cardiovascular disease, however it may not be feasible for all individuals. Heat therapy via sauna exposure may be an alternative modality to aerobic exercise to improve cardiovascular health and lower risk of all-cause mortality. **PURPOSE:** To compare the influence of a single bout of sauna induced heat therapy to aerobic exercise on pulse wave velocity (PWV). **METHODS:** Ten participants (9 males, 1 female, age 23 ± 2 y, ht 1.74 ± 0.08 m, wt 80.9 ± 19.7 kg, BMI 26.5 ± 5.5 kg/m²) completed this randomized crossover, counterbalanced control study. Trials consisted of a 20-minute supine baseline followed by 30 minutes of either infrared sauna exposure (HEAT; ~56°C), cycling exercise (EXER; 40-50% heart rate reserve), or upright sitting (control; CON). Following the intervention, participants completed a 60-minute supine recovery. Ultrasound measures were recorded at baseline and immediately, 30 minutes, and 60 minutes post-intervention to evaluate central and peripheral PWV. **RESULTS:** Rectal temperature at the end of treatment was greater in the EXER (37.5 ± 0.2°C) compared to HEAT (37.1 ± 0.2°C, P < 0.001) and CON (36.9 ± 0.1°C, P < 0.001). Heart rate at the end of treatment was also increased in EXER (121.8 ± 5.4 bpm, P < 0.001) and HEAT (84.0 ± 16.2 bpm, P < 0.001) compared to CON (58.3 ± 9.0 bpm). Central PWV decreased regardless of treatment from 30 to 60 minutes of recovery (-19.3 ± 12.4 cm/s, P = 0.02). Central PWV also exhibited medium effects for HEAT (-23.8 ± 27.2 cm/s, Hedge's g = 0.57) and EXER (-23.8 ± 27.2 cm/s, Hedge's g = 0.48) compared to CON. Lower peripheral PWV was not different between treatments (HEAT 914.6 ± 52.8, EXER 912.6 ± 83.1, CON 940.7 ± 97.0 cm/s, P = 0.46, η_p² = 0.08) or across time (P = 0.53, η_p² = 0.07). Upper peripheral PWV was also not different between treatments (P = 0.84, η_p² = 0.02) or across time (P = 0.14, η_p² = 0.18). **CONCLUSIONS:** The 30-minute sauna exposure and cycling exercise had minimal short-term impacts on PWV in our healthy population. These preliminary findings suggest that greater physiological strain may be required to elicit the acute changes shown in previous research.

Arm And Leg Vascular Responses To A Weekend Of Reduced Physical Activity

Garrett L. Heaney¹, Alexander H.K. Montoye, FACSM¹, Paul J. Fadel, FACSM², Jennifer R. Vranish¹. ¹Alma College, Alma, MI. ²University of Texas at Arlington, Arlington, TX.
(No relevant relations reported)

PURPOSE: Physical inactivity is associated with leg macrovascular impairment following 6 hours of uninterrupted sitting or 5 days of reduced physical activity, however vascular responses in the upper limb are less clear. Indeed, the impact of physical inactivity on both arm and leg microvascular and macrovascular function over a 72-hour period remains unknown. This may be important as it represents a real-world scenario of an active individual during the workweek, followed by sedentary behavior over the weekend. Further, previous studies have investigated the popliteal artery, which does not assess the entire lower limb. We tested the hypothesis that 72 hours of reduced activity (<5000 steps/day) would result in reduced brachial artery (BA) and superficial femoral artery (SFA) resting shear rate, microvascular function (reactive hyperemia-RH), and macrovascular function (flow-mediated dilation-FMD).

METHODS: Physical activity was monitored for the week prior to and during the 72 hours of inactivity in 5 healthy, young men who were currently physically active. BA and SFA resting shear rate, RH (shear AUC), and FMD were measured via duplex Doppler ultrasound before (Pre) and after (Post) a 72-hour inactivity period.

RESULTS: In the SFA, resting shear rate (Pre: 53.6±17.9 s⁻¹, Post: 32.1±14.7; P=0.03) and RH (Pre: 23376±6266 AU, Post: 16580±3304 AU; P=0.01) were significantly reduced after a 72-hour inactivity period. Similarly, BA resting shear rate and RH tended to be reduced (P=0.09 and P=0.07, respectively). Finally, FMD was unchanged in both the BA and SFA (P>0.05).

CONCLUSIONS: Herein, we demonstrate that resting hemodynamics and microvascular function are reduced over 72 hours of inactivity, while macrovascular function is preserved in the upper and lower limbs. These findings may highlight a distinction between the vascular impact of short-term sitting studies versus longer term inactivity studies, as the brachial artery appears to be more affected by the latter.

FIt-1 And Endothelial Function Soon After Delivery: Effect Of Physical Activity

Chloe W. Caudell, Samantha Bouknight, Katherine Kramps, Erin O'Connor, Paige Wilbanks, Abbi Lane-Cordova. *University of South Carolina: Arnold School of Public Health, Columbia, SC.*
Email: caudelle@email.sc.edu
(No relevant relations reported)

Vascular adverse pregnancy outcomes (APOs) are characterized by elevated levels of antiangiogenic Fms-like tyrosine kinase (FIt-1), attributable to placental ischemia. FIt-1 directly impairs endothelial function during pregnancy and contributes to maternal features of APOs, but infusion of FIt-1 into non-pregnant animals did not cause endothelial dysfunction. **Purpose:** The purpose was to evaluate the relation of FIt-1 and endothelial function in women 6 months – 3 years after delivery. Given the angiogenic effects of exercise, we tested the hypothesis that FIt-1 would be lower in women who achieved adequate prenatal and current physical activity (PA). **Methods:** 40 nonsmoking women free from diabetes and use of protease inhibitors (mean age: 33±1 yrs, mean BMI: 26.3±1.0 kg/m², 58% with adequate pregnancy PA) completed a blood draw and vascular testing after an overnight fast. We used an ELISA assay to determine levels of circulating FIt-1. Reactive hyperemia (RH) was measured with venous occlusion plethysmography to quantify resistance vessel endothelial function. A validated physical activity questionnaire (Godin Leisure Time Exercise Questionnaire) was used to determine current and second trimester PA; APO history was determined using self-report. We tested for associations of RH with continuous levels FIt-1 using linear regression, adjusted for APO status. We used t-tests to evaluate differences in FIt-1 between women who did versus did not achieve adequate PA during pregnancy or at the time of vascular testing. **Results:** There was no association of FIt-1 and peak RH; $\beta = -0.01 \pm 0.01$, $p = 0.50$. There was no difference in FIt-1 levels between women who did versus did not achieve adequate PA at the time of testing (412±17 versus 443±31 pg/ml, $p = 0.22$) or during pregnancy (408±20 versus 430±20 pg/ml, $p = 0.23$). **Conclusions:** Although related to vascular dysfunction during pregnancy, FIt-1 was not related to vascular function after delivery and did differ by current or pregnancy PA level. FIt-1 might not be useful for identifying women at risk of vascular dysfunction after pregnancy ends.

(No relevant relations reported)

Purpose The role of cardiorespiratory fitness (CRF) in pediatric health is gaining recognition. However, the quality and quantity of the current evidence are insufficient to inform clinical pediatric guidelines. **Objective:** to evaluate the association between direct measures of CRF and blood pressure status as determined by the 2017 screening guidelines from the American Academy of Pediatrics in school-age children. **Methods** Children (n=218) 7 to 10 years old participated in a single-study visit. Children were deemed to have high blood pressure (HBP) if blood pressure status was: elevated, stage-1 or stage-2 hypertension. CRF (VO_{2peak}) was measured using an incremental cycle ergometer test. Body composition was measured with DXA, and physical activity with accelerometers (7±1 days). Blood was sampled in the fasting state and estimated glomerular filtration rate (eGFR) calculated using the updated Schwartz equation. Children were categorized as having excess weight (EW) or normal weight (NW) if their fat mass index was above or below 1 z-score, respectively. Children were further classified into EW/NW more-fit or EW/NW less-fit using the groups' median VO_{2peak}. Multiple logistic regression analyses were used to model the probability of high blood pressure against VO_{2peak}. **Results** Participants' average age was 9 years, with 70% of EW children having HBP vs. 24% in the NW group ($p < .0001$). The probability of HBP decreased with increasing VO_{2peak} in the EW group only ($\beta = -0.09$, $p = 0.0095$). There was no association between CRF and probability of HBP in NW children. eGFR was lower in the less-fit groups than in more-fit groups regardless of adiposity status, even after adjusting for age and blood pressure status (adjusted mean difference between more-fit and less-fit groups: EW=7.1 ml·min⁻¹·1.73 m⁻², $p = 0.0046$ and NW= 2.9 ml·min⁻¹·1.73 m⁻², $p = 0.0144$). **Conclusion** The probability of HBP dramatically decreases with increasing CRF in children with EW but not in children with NW. eGFR is lower in children with lower CRF, regardless of obesity status, but the effect of CRF on kidney function is greater in EW than in NW kids. Impact Of An Ankle-foot Orthosis On Physical Activity In Patients With Peripheral Artery Disease

Mahdi Hassan¹, Danae M. Dinkel¹, Holly DeSpiegelae², Jason M. Johanning², Iraklis I. Pipinos², Sara A. Myers¹. ¹University of Nebraska at Omaha, Omaha, NE. ²Omaha Veterans' Affairs Medical Center, Omaha, NE.
Email: mhassan2@unomaha.edu
(No relevant relations reported)

Patients with peripheral artery disease (PAD) are sedentary due to claudication pain in the lower extremities. Our research has documented an inability of the ankle plantarflexors to generate normal push-off during walking. An ankle-foot orthosis (AFO) to offset push-off deficiency may improve physical activity levels and walking distances in patients with PAD. **PURPOSE:** To compare step count (SC), peak activity index (PAI), initial claudication distances (ICD), and absolute claudication distances (ACD) before and after an AFO intervention. **METHODS:** Six patients with PAD (Age: 71.7 ± 9.3 years; Body Mass Index: 27.5 ± 5.5 kg/m²) were enrolled in the study. They underwent measurements of SC and PAI over a week using an accelerometer. ICD and ACD were determined while subjects performed the Gardner treadmill protocol without wearing AFOs. All measures were assessed before and after the three month AFO intervention. Signed Rank tests were performed to determine differences following the intervention. **RESULTS:** ACD was significantly increased following the AFO intervention ($p = 0.046$). Mean ACD was 312 ± 169 meters at baseline and increased to 364 ± 194 meters after the three month AFO intervention. Measures before and after the AFO intervention of SC (2422 ± 1166 steps/day and 2349 ± 1112 steps/day), PAI (34 ± 13 steps/min and 30 ± 7 steps/min), and ICD (187 ± 111 meters and 173 ± 138 meters) were not significantly different. **CONCLUSION:** The preliminary results of this study indicated that the AFO intervention improves the ACD in patients with PAD while walking without AFO. Future work should increase the number of subjects and determine whether physical activity intensity levels (light, moderate, and vigorous) changed after AFO intervention. Supported by NIH Grant HD090333-01. We acknowledge Alex Dzewaltowski, Cody Anderson, and Kaeli Samson for supporting this study.

Doxorubicin Treatment Decreases Maximal Respiration In C2C12 MyotubesDavid Eastley, FACSM. *Brigham Young University, Provo, UT.*
Email: da.eastley@gmail.com*(No relevant relations reported)*

The chemotherapeutic drug doxorubicin (DOX) is commonly prescribed to treat patients diagnosed with cancer. However, patients on DOX cannot take it long term due to its cardio-toxic effects, as well as skeletal muscle wasting and dysfunction. The mechanism behind why skeletal muscle dysfunction occurs is not well known, so the effects of DOX on skeletal muscle mitochondria are currently being investigated. **PURPOSE:** To determine the maximal respiration levels in DOX treated C2C12 myotubes. **METHODS:** Immortalized C2C12 myotubes were cultured in vitro and allowed full differentiation. Fully differentiated cells were then treated with 0.5uM DOX for 16 hours. Maximal mitochondrial respiration was analyzed with high resolution respirometry. The following substrates were used: digitonin (permeabilize cells); glutamate (G), malate (M) (leak respiration), then ADP (complex I); cytochrome C (mitochondrial membrane integrity); succinate (S) (complex I & II); FCCP (uncoupled respiration); rotenone (Rot) (complex I inhibitor); antimycin A (complex III inhibitor). Results were analyzed using multiple t-tests. **RESULTS:** DOX caused an 18% reduction in complex I & II supported respiration compared to control (54.6 vs 66.2 JO₂, P <0.005; n=4), a 32% decline in complex I supported respiration (37.2 vs 55.2 JO₂, P <0.05), and a 26.6% decline in leak respiration (28.6 vs 38.99 JO₂, P <0.08), indicating an overall decrease in mitochondrial respiration. **CONCLUSION:** Treating C2C12 differentiated myotubes with DOX for 16 hours inhibits complex I & II supported maximal respiration. These findings enable future research to be conducted in order to better understand why these cells are decreasing in maximal respiration. We are currently investigating whether co-treatments can reduce or rescue reduction in respiration caused by DOX.

PURPOSE: Declining function in older individuals has enormous clinical and public health consequences, thus therapeutics for preserving function are needed. Advanced age is associated with changes in the gut microbiome, and these changes are associated with functional decline. Our prior work has demonstrated manipulating renin-angiotensin system (RAS) is a promising approach to mitigating age-related functional decline. Recently, genetically modified probiotics (GMP) have also been purported as a promising strategy to deliver drugs with precision and high site specificity. Physical exercise has also been suggested to promote gut health and has important interactions with the Ang(1-7) axis. Here we present preliminary data exploring the impact of oral delivery of genetically modified *Lactobacillus paracasei* secreting Ang(1-7) [LP-A] and exercise training on physical function in aged rats. **METHODS:** 24 month old, male F344/BN rats were randomized into 6 groups. They received oral gavage of LP-A, wild-type probiotics (*Lactobacillus paracasei*), or vehicle 3 times/week; combined

with or without exercise for 12 weeks. Exercised rats ran on a treadmill at 12 cm/sec, 10min/day, 5 days/week. Rats in sedentary group were placed on a non-moving treadmill for the same duration of time. After 12 week of intervention, an exercise tolerance test was performed, where all rats were running on a treadmill starting at 12cm/sec for 2 min, then increase by 2 cm/sec each minute until 16 cm/sec was achieved. Running time to exhaustion was recorded. Locomotor tests (open field assay) were also performed. **RESULTS:** Exercise (mean=1223s) significantly increased time to exhaustion in the exercise tolerance test compared with sedentary animals (mean=464s) in the aged rats. There was also preliminary, but not significant, evidence that LP-A (mean =1329s) group performed best compared to all other exercise groups (Range = 1115-1241s). LP-A increased overall physical activity, compared with all other groups, as measured by the total distance travelled and velocity in the open field test. **CONCLUSION:** Preliminary findings suggest exercise and LP-A increase physical function in aged male rats respectively, but not synergistically.

Undernutrition Promotes Oxidative Stress & Capillary Regression In Skeletal MuscleTakumi Hirabayashi¹, Badur un Nisa¹, Hiroyo Kondo², Hidemi Fujino¹. ¹Kobe University, Kobe, Japan. ²Nagoya Women's University, Nagoya, Japan.*(No relevant relations reported)*

PURPOSE: An undernutrition condition results in muscle atrophy and mitochondrial dysfunction. However, it is still not well-known that the characteristics of the skeletal muscle capillary network during undernutrition. The purpose of the present study was to verify the effects of undernutrition on the capillary network in skeletal muscle. **METHODS:** Male Wistar rats were assigned randomly to control and undernutrition groups. The rats in the undernutrition group fed low protein and limited 50% diets daily for 12 weeks. Plantaris and soleus muscle were analyzed. The three-dimensional capillary network of skeletal muscle was visualized using a confocal laser scanning technique. The capillary volume, mean luminal diameter and capillary-to-fiber ratio were measured in both skeletal muscles. In addition, the levels of VEGF and thrombospondin-1 proteins, lipid peroxidation and SOD-2 proteins were determined. **RESULTS:** The muscle mass decreased only plantaris muscle in the undernutrition group. The level of lipid peroxidation was increased, and the expression levels of SOD-2 in plantaris and soleus muscles were decreased. In addition, the capillary volume, mean luminal diameter and capillary-to-fiber ratio were decreased in both muscles of the undernutrition group. Furthermore, the level of VEGF protein was decreased, and thrombospondin-1 was increased in both muscles of undernutrition group. **CONCLUSIONS:** These results suggest that undernourished skeletal muscle induces capillary regression with increased oxidative stress, which also occurs in slow muscle without atrophy.

Long-chain Acyl-CoA Synthetases Relate To Fat Oxidation And Storage In Skeletal Muscle Of Lean HumansHarrison D. Stierwalt, Sarah E. Ehrlicher, Matthew M. Robinson, Sean A. Newsom. *Oregon State University, Corvallis, OR.*

Email: stierwah@oregonstate.edu

(No relevant relations reported)

Recent evidence from genetically altered cell and mouse models indicate long-chain acyl-CoA synthetases (ACSLs), namely ACSL1 and ACSL6, may be critical determinants of partitioning of fatty acids toward oxidation or storage, respectively, within skeletal muscle. However, the role ACSLs serve in skeletal muscle fat oxidation and storage remains to be determined in humans, and it is unknown if ACSLs are altered by acute exercise. **PURPOSE:** To identify 1) relationships between skeletal muscle ACSL1 and ACSL6 protein content and measures of fat oxidation at rest and during exercise, and fat storage, and 2) whether acute exercise induces changes in ACSL protein content in humans. **METHODS:** Sedentary lean adults (n=14 [4M/10F], BMI 22.2 ± 2.1 kg/m², VO_{2max} 32.2 ± 4.5 ml/kg/min) completed two metabolic study visits in a randomized crossover design. Trials were identical other than completing 1 h of moderate intensity cycling exercise (65% VO_{2max}) or remaining sedentary. Vastus lateralis muscle biopsies were obtained 15 min post-exercise or rest and 2 h post-exercise to determine ACSL protein and triacylglycerol (TAG) content. TAG content was determined by lipidomic analysis. Substrate oxidation was assessed at rest and during exercise using indirect calorimetry. **RESULTS:** Skeletal muscle ACSL1 protein content was not related to whole-body fat oxidation at rest (P=0.64, r=0.14); however, ACSL1 tended to be positively related with whole-body fat oxidation during exercise (P=0.07, r=0.53), when skeletal muscle accounts for the vast majority of energy expenditure. Skeletal muscle ACSL1 was not altered 15 min or 2 h post-exercise (both P > 0.05 vs. Rest). Skeletal muscle ACSL6 protein content was positively associated with resting muscle TAG content (P=0.05, r=0.57). ACSL6 protein content was not

altered 15 min or 2 h post-exercise (both $P > 0.05$ vs. Rest). **CONCLUSIONS:** Skeletal muscle ACSL1 and ACSL6 protein content were positively associated with measures of whole-body fat oxidation during exercise and skeletal muscle TAG content, respectively. We interpret our results to indicate ACSLs may be critical regulators of partitioning of fatty acids within skeletal muscle, but protein content was not altered in the hours after acute exercise in sedentary lean adults. (No relevant relations reported)

Physical activity and sedentary behaviors differentially relate to health outcomes in children. Isotemporal substitution provides opportunities to evaluate the relation of hypothetical time replacement scenarios across intensity categories with health. Few isotemporal studies have been conducted among preschool-aged youth and ethnically diverse populations.

PURPOSE: To examine the relation of reallocation of waking activity behaviors on 1) adiposity and 2) cardiovascular health indicators among preschool-aged youth (ages 2-5 years) with overweight participating in Texas Childhood Obesity Research Demonstration (TX CORDD), a low-income, majority Hispanic cohort.

METHODS: Participants wore an ActiGraph wGT3X-BT monitor (waist) and attended health assessments. Valid wear time was defined as ≥ 10 hours between 06:00-22:59 hours on ≥ 3 days (≥ 1 weekend). Adiposity measures were percentage of the 95th percentile (%BMI₉₅), fat mass, fat mass index, waist circumference, and waist-to-hip ratio. Cardiovascular measures were resting systolic (SBP) and diastolic (DBP) blood pressure, and heart rate. Covariates included age, sex, ethnicity, and socioeconomic status. Isotemporal substitution modeling was employed to address the study purpose.

RESULTS: Complete data were available for 131 children (Mean age = 4.3 ± 1.1 , 53% female, 87% Hispanic, 31% $\leq 49\%$ income to poverty ratio). For boys, reallocating 15 minutes of sedentary, light, or moderate intensity activity to vigorous intensity activity was significantly associated with beneficial reductions in all adiposity indicators; for girls, these relations were statistically null. For boys and girls, reallocating 15 minutes of sedentary (-5.0 SBP, -3.7 DBP), light (-4.3 SBP, -3.2 DBP), or moderate intensity activity (-7.3 SBP, -5.5 DBP) to vigorous intensity activity was significantly associated with favorable cardiovascular indicators.

CONCLUSIONS: Substituting vigorous for lower intensity physical activity is associated with several favorable adiposity and cardiovascular health outcomes among preschool children with overweight and obesity. Teaching caregivers how to engage young children in vigorous intensity is needed, especially as overweight children spend more time sedentary and less time in higher intensity activities.

(No relevant relations reported)

PURPOSE: Use data from the International Children's Accelerometry Database to explore how different methods of operationalizing the youth physical activity (PA) guidelines influence: (i) the proportion of youth deemed compliant with the guidelines, and (ii) associations between guideline compliance and health indicators. **METHODS:** Accelerometer data for 21,612 youth (5-18y, 62.4% female) was used to explore PA guideline compliance defined by four operationalization methods: daily method (DM; ≥ 60 minutes moderate-vigorous PA [MVPA] on every day of the measurement period), average method (AM; average of ≥ 60 minutes MVPA per day over the measurement period), AM5 (compliance with AM and ≥ 5 minutes of vigorous PA [VPA] on ≥ 3 days), AM15 (compliance with AM and ≥ 15 minutes VPA on ≥ 3 days). Relationships between guideline compliance and health indicators (e.g., BMI z-score, cholesterol levels, blood pressure) were examined for all operationalization methods. Descriptive statistics and McNemar's tests were used to compare compliance estimates for the four methods. Multivariate regression models were used to test associations between compliance and health indicators. **RESULTS:** Operationalization method influenced estimates of compliance with the youth PA guidelines: 5.3% using DM, 29.9% using AM, 29.4% using AM5, 23.7% using AM15. Associations between guideline compliance and health indicators were similar for the AM, AM5 and AM15 methods, for example, BMI z-score: AM compliance (coefficient -0.28, 95% CI: -0.33,-0.23), AM5 compliance (coefficient -0.28, 95% CI: -0.33,-0.23), AM15 compliance (coefficient -0.30, 95% CI: -0.35,-0.25). Compliance with the DM method demonstrated similar or weaker associations with health indicators, potentially due to a small number of participants that complied with DM and also had health indicator data (n=250-1,127). **CONCLUSION:** Operationalization method influences estimates of the proportion of youth meeting the PA guidelines. This finding adds to the PA data processing decisions that researchers need to consider. While operationalization method appears to have a minor influence on associations between guideline compliance and health indicators, further research with a larger sample of DM-compliant participants with health data is needed to confirm this finding.

Addressing Motivational Barriers For Early Morning Outdoor Physical Activity Using Smartphones

Amol Wagholikar. Rise01 Pty Ltd, Institute for Australia India Engagement, Nudgee, Australia.

Email: amol@rise01.com

(No relevant relations reported)

Lack of physical activity is a global health concern. Determining an appropriate time to motivate individuals for consistent outdoor exercise is challenging. Early morning outdoor physical activity (PA) has proven health benefits. However, in spite of known wellness benefits, people report motivational barriers such as lack of time, lack of enjoyment to experience morning outdoor PA. Smartphones are increasingly used as a tool to assist in outdoor PA. We have leveraged the smartphone technology capabilities to address the motivational barriers in early morning outdoor physical activity.

PURPOSE: The main purpose of our work is to share findings of an exploratory study for improving motivation of outdoor physical activity. **METHODS:** We developed an intervention called "Rise and Smile" led by one healthy participant and followed by 280 online followers for 365 consecutive days. The participant performed daily

15 minutes of early morning PA of walking or running to reach an outdoor Sunrise viewing location. The participant then captured a photo of the beautiful view of nature during sunrise on their smartphone camera upon completion of their PA. The participant then instantly published the photo on a social media page. **RESULTS:** The individual participant self-reported increased energy, better sleep and increased productivity. The virtual participants ($n=281$) showed positive acceptance via social media with regular sunrise photo likes. The positive reaction to the Sunrise photo also motivated the individual to establish the daily wellness habit. The positive experience of watching sunrise and the picturesque photos of nature during sunrise were used as motivational tools. The participant's motivation was used as a primary outcome measure and was reportedly improved upon successful completion of this study. The study also showed the influence of unique sunrise photos for emotional benefits and positive behaviour change. **CONCLUSION:** Our smartphone-enabled study suggested that use of technology to record unique picturesque outdoors during the sunrise can provide meaningful motivation for outdoor physical activity.

3696 Board #13**Physical Activity Prescription For Patients With Chronic Diseases: A Questionnaire Survey In Shenzhen, China**

RUI HU, Stanley Sai-Chuen HUI, FACSM. *The Chinese University of Hong Kong, Hong Kong, China.*

Email: hurui@link.cuhk.edu.hk

(No relevant relations reported)

PURPOSE: To investigate the prevalence of prescribing PA in clinical setting for patients with chronic diseases in Shenzhen, China. **METHODS:** A total of 104 patients recruited from three general hospitals in Shenzhen of China completed a face-to-face questionnaire. Patients were asked "have you ever been provided with PA prescription by physicians/healthcare providers". Those who answered yes were then further prompted about the PA frequency (number of times per week), intensity (low, moderate or high intensity), duration (number of minutes per session) and type of PA provided by physicians/healthcare providers.

RESULTS: Overall, 53.4% patients reported receiving PA prescription from physicians/healthcare providers. Of those PA being prescribed, 61.8% of patients reported the frequency were introduced, whereas 65.5% included intensity and 67.3% included duration, respectively. Fewer participants (43.6%) reported being provided the type of PA, and the most common type of PA being prescribed was walking (75%). Moreover, less than a third of patients (31%) received a complete prescription (including PA frequency, intensity, duration & type) from their physicians/healthcare providers.

CONCLUSIONS: This study revealed that about half of physicians/healthcare providers are incorporating PA promotion into clinical setting in Shenzhen. However, only a small percentage of physicians/healthcare providers could provide completed PA prescription for chronic disease patients. Furthermore, the type of exercise that prescribed by physicians/healthcare providers seems to be limited. The results may support that further education/training to physicians/healthcare providers in China are needed in order to foster PA prescription in clinical setting.

3697 Board #14**Hydrotherapy With Hydrogen-rich Water Versus R.I.C.E. Protocol For Acute Ankle Sprain In Professional Athletes**

Sergej M. Ostojic, Dejan Javorac, Valdemar Stajer. *University of Novi Sad, Novi Sad, Serbia.*

Email: sergej.ostojic@chess.edu.rs

(No relevant relations reported)

Different therapeutic approaches with hydrogen (H_2) have been recently put forward in sports medicine, yet the effectiveness of specific experimental treatments with H_2 was rarely compared with standard clinical procedures. **PURPOSE:** To analyze the effects of intensive hydrotherapy with hydrogen-rich water (HRW) on injury recovery in athletic men who suffered an acute ankle sprain and compare it with RICE protocol (rest, ice, compression, elevation), a universally accepted as best practice immediately after acute ankle sprains.

METHODS: Eighteen healthy male professional athletes who incurred an acute ankle sprain during a sport-related activity were randomly assigned immediately after the injury to either hydrogen group ($n=9$) or the conventional RICE treatment group ($n=9$). Hydrogen group received six 30-min ankle baths with HRW throughout the first 24 h post-injury, with hydrotherapy administered every 4 hours during the intervention period. RICE group stood off the injured leg, with ice packs administered for 20 min every 3 hours (total of 8 sessions), with the injured ankle compressed with an elastic bandage for 24 hours and elevated at all possible times above the level of the heart. The trial was registered at *ClinicalTrials.gov* (NCT04167202).

RESULTS: Hydrotherapy with hydrogen-rich water was equivalent to RICE protocol to reduce ankle swelling ($2.1 \pm 0.9\%$ vs. $1.6 \pm 0.8\%$; $P=0.26$), range of motion (2.4 ± 1.3 cm vs. 2.7 ± 0.8 cm; $P=0.60$), and single-leg balance with eyes opened (18.4

± 8.2 sec vs. 10.7 ± 8.0 sec; $P=0.06$) and closed (5.6 ± 8.4 sec vs. 3.9 ± 4.2 sec; $P=0.59$). Neither intervention affected serum CRP, TNF- α and IL-1 β ($P>0.05$), although hydrogen treatment tended to reduce circulating IL-1 β levels at 24-h follow up (10.8% on average; 95% confidence interval from 6.0 to 27.6; $P=0.07$).

CONCLUSIONS: HRW appeared to be equally effective to RICE for improving recovery after an acute ankle sprain in professional athletes, therefore advancing this innovative approach as an effective alternative in the field of sports medicine. However, more studies are needed to corroborate these findings in other soft tissue injuries.

3698 Board #15**Clinical Benefit Of Cntx-4975 Intra-articular Injection For Moderate To Severe Osteoarthritis Knee Pain**

Randall M. Stevens¹, Peter D. Hanson¹, Paul Tiseo¹, Kimberly Guedes¹, James N. Campbell¹, James Connolly¹, Stephanie Ruggiero¹, Meg Corliss¹, Valerie H. Smith¹, Andrew I. Spitzer². ¹Centrexion Therapeutics Corp, Boston, MA. ²Cedars Sinai Orthopedic Center, Los Angeles, CA.

Reported Relationships: R.M. Stevens: Salary; Centrexion Therapeutics Corp. Ownership/interest/stock; Centrexion Therapeutics Corp. Other (please describe); Funding for this abstract sponsored by Centrexion Therapeutics Corp.

Purpose: To evaluate the effect of CNTX-4975 intra-articular (IA) injection on pain, function, and quality of life (QoL) in subjects with knee osteoarthritis (OA). **Methods:** A phase 3, open-label, 8-wk study (NCT03661996) enrolled subjects aged 40–95 y with stable, moderate to severe OA knee pain in the index knee (average pain 24 h) after ≥ 2 failed therapies. Subjects were assigned to unilateral/bilateral CNTX-4975 1 mg IA injections as determined by OA pain/joint replacement status (Table) and randomized by site to 1 of 5 joint cooling/injection regimens to evaluate procedure experience. The circumferential joint cooling wrap used in the phase 2 pivotal trial was compared with 4 circumferential gel-pack wrap cooling groups with varying cooling schedules/injection techniques. Outcomes assessed through wk 8 included average daily index knee pain with walking (numeric pain rating scale [NPRS], 0 [no pain] to 10 [worst pain]) and Knee Injury OA Outcomes Score (KOOS) subscales (range, 0–100; higher is improvement; Table). Least squares (LS) mean, 95% CI, and P value were calculated for change from baseline in NPRS and KOOS scores using a mixed model for repeated measures. **Results:** The intent-to-treat population included 848 subjects; baseline NPRS index knee pain with walking scores (mean [SD]) by subject type: A, 6.5 (1.50); B, 7.4 (1.35); C, 6.2 (1.21). By day 3, NPRS scores were significantly ($P<0.0001$) improved; LS mean (SE [95% CI]): A, -3.98 (0.170 [-4.32, -3.64]); B, -4.21 (0.103 [-4.41, -4.01]); C, -3.71 (0.375 [-4.48, -2.94]). Improvement was maintained at wk 8; A, -3.48 (0.191 [-3.86, -3.10]); B, -4.02 (0.118 [-4.25, -3.79]); C, -3.52 (0.416 [-4.38, -2.67]); all $P<0.0001$. All KOOS subscale scores were significantly improved at wk 8 (Table). **Conclusions:** Subjects with moderate to severe knee OA pain showed significant clinical improvements as early as 3 days and through 8 wks post injection in knee pain, function, and QoL after a single CNTX-4975 1 mg IA injection.

Table: KOOS Scores in the Index Knee After Single Intra-articular Injection of CN1X-4975 1 mg for Moderate to Severe Osteoarthritis Knee Pain

Outcome	Subject Type A: Unilateral Injection (no/mild pain, nonindex knee) n=273	Subject Type B: Bilateral Injection (moderate to severe pain in both knees*) n=523	Subject Type C: Unilateral Injection (prior nonindex knee replacement) n=52

Effect Of Triamcinolone Acetonide Extended-release On Synovial Inflammation In Patients With Osteoarthritis Of The Knee

Scott Kelley¹, Kim Huffman², Philip Conaghan³, Michael Bowes⁴, Amy Cinar¹, Alan Kivitz², Virginia Byers Kraus², William Maloney⁶, Javad Parvizi⁷, Alan Brett⁴, Neil Bodick¹. ¹Flexion Therapeutics, Inc., Burlington, MA. ²Duke University School of Medicine, Durham, NC. ³University of Leeds and NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom. ⁴Morphics Ltd, Manchester, United Kingdom. ⁵Altoona Center for Clinical Research, Altoona, PA. ⁶Stanford University School of Medicine, Stanford, CA. ⁷Thomas Jefferson University Hospital, Philadelphia, PA.

Reported Relationships: S. Kelley: Salary; Flexion Therapeutics, Inc.. OOwnership/interest/stock; Flexion Therapeutics, Inc..

PURPOSE: Synovitis is common in osteoarthritis of the knee (OAK) and is associated with pain and disease severity. This open-label phase 3b study is evaluating the effect of an intra-articular (IA) injection of triamcinolone acetonide extended release (TA-ER) on synovial tissue volume (STV), pain, and function (NCT03529942). A prespecified analysis of the primary endpoint is reported.

METHODS: STV was determined using gadolinium MRI; synovitis was defined as pre-treatment STV ≥3000 mm³ (3 mL). All patients (pts) received TA-ER 32 mg at baseline (BL) and were assessed at Weeks 6, 12, 18, and 24. MRIs were repeated at Weeks 6 and 24. Interim analysis was performed for the primary efficacy endpoint, mean standardized change from BL in STV at 6 weeks. Planned enrollment was based on earlier studies.

RESULTS: We enrolled 116 OAK pts with typical OA characteristics (Table); 89 (77%) demonstrated synovitis at BL. STV was significantly reduced from BL at 6 weeks (P<0.001; Fig. 1A). The primary endpoint was met: standardized least squares mean change in STV was -1.13 (95% CI, -1.35 to -0.91; P<0.001). Western Ontario and McMaster Universities Osteoarthritis Index (pain) was significantly reduced at 6 weeks in all pts (Fig. 1B). 24 (20.7%) pts experienced ≥1 treatment-emergent adverse event (TEAE); 6 (5.2%) pts had ≥1 index-knee TEAE. All TEAEs were mild or moderate; none were treatment related.

CONCLUSIONS: At 6 weeks, a single TA-ER IA injection markedly reduced STV in pts with synovitis at BL. Marked symptomatic improvement was observed in all pts at 6 weeks following TA-ER.

Choosing Wisely Initiative: Analysis Of Twelve Years Of Therapeutic Ultrasound
Andrew D. Kleven, Andrew Ernst, Isaac Slagel, Craig Young.
Medical College of Wisconsin, MILWAUKEE, WI.
Email: akleven@mcw.edu
(No relevant relations reported)

In 2014, the Choosing Wisely Initiative partnered with the American Physical Therapy Association to produce a list of low-value physical therapy (PT) practices, titled “Five Things Physical Therapists and Patients Should Question.” This publication described the limited value of deep heat, or therapeutic ultrasound (TUS), to improve long term outcomes for a myriad of musculoskeletal conditions, yet TUS continues to be used. It is unclear how often TUS is used in contemporary PT practice, how its use has changed after this initiative and for what specific conditions it is most used.

PURPOSE: To assess the historical use of TUS by physical therapists before and after the Choosing Wisely Initiative across a regional health network. **METHODS:** A de-identified Clinical Research Data Warehouse was queried using i2B2 software to collect the history of TUS usage by PTs between 2008 and 2019. The specific CPT code 97035 was used to identify TUS episodes of care. In addition, the total number of unique patients in PT each year was collected. Indications for individual TUS treatment units were analyzed in 2018 and 2019 to yield the most frequent ICD-10 codes for which TUS was performed. **RESULTS:** Episodes of TUS were standardized by the total number of patients seen in PT each year to account for the growth of the health network. The percentage of patients who received TUS each year was reported. TUS usage rates between 2008 and 2019 were compared using Pearson’s two proportion Z-test. Utilization was significantly lower in 2019 (5.2%) than it was in 2008 (24.0%) (χ² = 2059.6, p-value < 2.2e-16). Between 2018 and 2019, 5,936 units of TUS were performed by 118 unique PT providers. TUS was commonly performed for shoulder pain (13.0%), ankle or foot pain (9.6%), neck pain (9.6%), knee pain (7.7%), hip pain (6.1%), low back pain (6.0%), unspecified chronic pain (4.3%), and Achilles tendinopathy (4.1%). **CONCLUSION:** Over the last 12 years, there has been a significant decrease in use of TUS by PTs. This decline coincides with the Choosing Wisely Initiative. However, TUS continues to be used, albeit at a significantly lower frequency, for treating musculoskeletal conditions despite having little evidence in improving long term clinical outcomes. Supported by NIH Grant UL1TR001436.

High-intensity Interval Training Improves Cardiorespiratory Fitness In Prior Non-responders To Traditional Aerobic Exercise
Duck-chul Lee, FACSM, Angeliqe Brellenthin. Iowa State University, Ames, IA.
Email: dclee@iastate.edu
(No relevant relations reported)

PURPOSE: Although most people respond to traditional aerobic exercise and improve cardiorespiratory fitness (CRF), some do not respond, called non-responders, and they are often ignored. One theory of non-response is the lower intensity of

traditional exercise. This study was conducted to answer the important question, "Can high-intensity interval training (HIIT) improve CRF for prior non-responders?" **METHODS:** Participants were 8 (5 women, mean age 54) prior non-responders from the CardioRACE study who were at high-risk of cardiovascular disease including 35-70 years old with overweight/obesity and elevated/stage 1 hypertension. They previously participated in CardioRACE traditional continuous aerobic exercise for 3 times/week, 60 min/session, at 50-80% heart rate reserve [HRR]). They were identified as non-responders due to no or minimal increase in CRF (similar to <5% CRF increase) after 6 months of exercise, following the recommended non-responder definition that considers technical errors in CRF assessment and day-to-day variability. In this study, participants performed HIIT exercise 3 times/week, 30 min/session for 1 month, containing four 4-min high-intensity intervals at 85-95% HRR separated by three 3-min active recovery at 40-60% HRR with 5-min warm-up and cool-down. CRF was measured by maximal treadmill test using a Balke protocol. **RESULTS:** This short HIIT exercise significantly improved CRF with a mean increase of 8% from 26.7 to 28.8 ml/kg/min ($p < 0.01$ from paired t-test) in prior non-responders to traditional exercise (Figure 1). All participants improved CRF and 6 became responders. All high-risk participants safely completed HIIT with 100% attendance rate without adverse events. **CONCLUSION:** Even half the HIIT exercise time (30 min/session) over 1 month significantly improved CRF in prior non-responders. A long-term HIIT trial with a control group is necessary to confirm the findings. CardioRACE was supported by NIH Grant R01HL133069

Figure 1. CRF changes from HIIT exercisers (who were prior CardioRACE non-responders) as well as from 6-month prior CardioRACE traditional aerobic exercise responders and non-responders.

Fitbit Analysis Shows Enhanced Mobility Of Knee Osteoarthritis Patients Treated With Triamcinolone Acetonide Extended Release

Kim M. Huffman¹, Andrew Concoff², Andrew Spitzer³, John C. Richmond⁴, Andreas Gomoll⁵, Virginia B. Kraus¹, Deryk G. Jones⁶, Amy Cinar⁷, Scott Kelley⁷. ¹Duke University School of Medicine, Durham, NC. ²St. Jude Heritage Fullerton Orthopedics, Fullerton, CA. ³Cedars-Sinai Orthopaedic Center, Los Angeles, CA. ⁴New England Baptist Hospital, Dedham, MA. ⁵Hospital for Special Surgery, New York, NY. ⁶Ochsner Sports Medicine Institute, Harahan, LA. ⁷Flexion Therapeutics, Inc., Burlington, MA.

(No relevant relations reported)

PURPOSE: In knee osteoarthritis (OAK), walking >6000 steps/day can prevent functional limitation (White DK. *Arthritis Care Res.* 2014;66:1328). Intra-articular triamcinolone acetonide extended-release (TA-ER) is approved for OAK pain. This Phase 3b study assessed safety and an exploratory endpoint of mobility (steps/day) in patients treated with TA-ER.

METHODS: OAK patients aged ≥40 years, symptomatic ≥6 months, with Western Ontario and McMaster Universities Osteoarthritis Index pain (WOMAC-A) score ≥6, and index-knee pain >15 days during the past month received TA-ER on Day 1. Movements were analyzed with a Fitbit® device (≥7 days prior to Day 1 to end of Week 12).

RESULTS: A total of 208 patients were treated with TA-ER; 67.8% had moderate-severe OAK, mean age of 60.8 years, and mean body mass index (BMI) of 31.4 kg/m². Baseline mean WOMAC pain score was 2.17. Mobility improved as seen by increases in weekly mean steps/day. 73 of 203 patients (36%) with sufficient step data at baseline had <6000 steps. Of these, 42 (57.5%) had ≥1 post-baseline week with average daily steps >6000; 19 (26.0%) had ≥50% of their follow-up with >6000 steps. Patients treated with TA-ER had mean changes from baseline in WOMAC pain scores of -1.4, -1.2, and -0.8 at Weeks 4, 8, and 12, respectively. A significantly greater change in steps from baseline was associated with decreases in WOMAC pain scores, male sex, lower BMI, lower baseline GPAQ average MET, and lower baseline steps/day. For every 1-unit decrease (from baseline) in mean WOMAC pain, mean steps/day increased by 339 (Figure 1).

CONCLUSIONS: OAK patients given TA-ER had increased mobility (≥6000 steps/day) as measured by fitness monitor which was associated with a decrease in pain. Limitations were incomplete adherence to monitor usage and a no comparator open-label design. Fitness monitors are a feasible tool to measure patient mobility and understand pain and function.

Undergoing general anaesthetic and complex surgery is associated with significant risk. Compounding this, reduced muscle mass is proven to be linked to increased post-operative complications and increased length of stay. Exercise focused prehabilitation research is emergent and increasingly supportive of preventive strategies to improve post-surgical outcomes. **PURPOSE** To investigate the role of a multi-site strength focussed exercise intervention in improving patient condition prior to surgery to enhance recovery **METHODS** 43 (26 male, 17 females; 68.3 ± 9.3 years) patients scheduled for surgery were randomly assigned to one of 3 groups; 1) prehabilitation [pre-surgery exercise] 2) prehabilitation + rehabilitation [pre and post-surgery exercise] or 3) usual care. The exercise program consisted of an aerobic component and 6 resistance exercises targeting the major muscle groups. Primary outcomes were length of stay (days) and post-operative complications. Secondary measures included; whole body resistance, muscular strength, aerobic fitness, physical function and quality of life. **RESULTS** There was no difference in length of stay between groups (prehab: 11.2±10.3; pre+rehab: 13.2±6.2; control: 13.9±12.4). Post-operative complications were not different between groups. A significant time*group interaction was observed for isometric grip strength ($p=0.046$). Patients reported significantly greater quality of recovery in the prehab+rehab exercise group compared to control ($p=0.05$). No differences were observed between groups for whole body resistance, aerobic fitness, measures of physical function or self-reported quality of life. **CONCLUSION** The preliminary results of this study indicate resistance-based exercise training prior to and following surgery results in greater muscular strength and enhanced quality of recovery compared to current standard care practices. These findings provide promising support for the development of future strength focused prehabilitation programs to improve patient function prior to surgery and reduce the surgery stress response, promoting an accelerated recovery. Sex Differences In Quadriceps Angiogenic Signaling And Muscle Capillary Supply After ACL Injury

Christine M. Latham, Camille R. Brightwell, Alyaa S. Zagzoog, Darren L. Johnson, Mary L. Ireland, FACSM, Brian Noehren, FACSM, Christopher S. Fry. *University of Kentucky, Lexington, KY.*

Email: c.latham@uky.edu

(No relevant relations reported)

Following an Anterior Cruciate Ligament (ACL) reconstruction, females have worse functional outcomes; however, skeletal muscle biology has preferentially been studied in males. Muscle adaptation and recovery from injury are intimately tied to the muscle capillary network, which delivers oxygen, nutrients, and hormones to muscle fibers. **PURPOSE:** To examine differences in skeletal muscle angiogenic signaling and capillary supply in males and females after ACL injury. **METHODS:** Vastus lateralis (VL) biopsies were collected (24.6 ± 5.5 yr; 8M, 5F) from the ACL injured (INJ) and non-injured (NI) leg before reconstruction. Samples were assessed for vascular endothelial growth factor receptor 1 and 2 (VEGFR1 and VEGFR2) by western blot. Capillary to fiber ratio (C:F), capillary to fiber perimeter exchange index (CFPE), and capillary tortuosity (% fiber border directly contacting capillary wall) were assessed by immunohistochemistry. **RESULTS:** The percentage of phosphorylated relative to total VEGFR2 was not different between INJ and NI, but was lower in females ($76.9 \pm 4.1\%$) compared to males ($89.2 \pm 3.2\%$; $P = 0.043$). VEGFR2 abundance tended to be higher ($P = 0.098$) and C:F was lower (INJ: 2.3 ± 0.2 capillary•fiber⁻¹, NI: 2.6 ± 0.2 capillary•fiber⁻¹; $P = 0.018$) in INJ compared to NI, but neither parameter was different between sexes. VEGFR1 abundance displayed a sex by injury interaction ($P = 0.004$), with females having greater abundance of VEGFR1 in INJ (548 ± 54 A.U.) compared to NI (478 ± 53 A.U.; $P = 0.050$), while males showed the opposite (NI: 461 ± 42 A.U., INJ: 383 ± 42 A.U.). CFPE was lower in INJ compared to NI (INJ: 5.1 ± 0.3 capillary• $1000\mu\text{m}^{-1}$, NI: 5.8 ± 0.3 capillary• $1000\mu\text{m}^{-1}$; $P = 0.002$), and post-hoc analysis revealed that the difference was driven by females. Capillary tortuosity was lower in INJ ($13 \pm 2\%$) compared to NI ($17 \pm 2\%$) for females only ($P = 0.006$). **CONCLUSION:** Differences in angiogenic signaling between males and females in both INJ and NI limbs were evident, and ACL injury resulted in an exacerbated deficit in muscle capillary supply for females. These results support the idea that sex-specific differences in VL capillary network remodeling following ACL injury contribute to different functional outcomes following reconstruction and rehabilitation. Supported by NIH grants: R01 AR072061 and K23 AR062069.

Mechanistic Insights Into Using Aerobic Exercise To Remodel Tumor Vasculature And Increase Chemotherapy Efficacy

Hannah Savage, Enrica Marmonti, Claudia Alvarez-Florez, Masaki Imanishi, Jun-ichi Abe, Keri Schadler. *MD Anderson Cancer Center, Houston, TX.*

Email: hsavage@mdanderson.org

(No relevant relations reported)

Tumor blood vessels pose obstacles for drug delivery because they are hyper-permeable and non-functional. There is a critical need to identify safe methods to increase chemotherapy delivery to the tumor. **PURPOSE:** We demonstrated that aerobic exercise improves tumor vasculature function, in multiple disparate tumor models, causing increased chemotherapy delivery and efficacy in mice. Across models, exercise reduced tumor vessel permeability. Because aerobic exercise increases blood flow both in healthy and tumor vessels, we aimed to investigate shear stress responsive mechanisms by which exercise may reduce tumor vessel permeability. **METHODS:** *In vivo* approaches including pharmacologic agents, a forced treadmill model of moderate aerobic exercise, and transgenic mouse models were utilized in combination with *in vitro* modeling of exercise induced shear stress, using a cone and plate viscometer. **RESULTS:** In tumor endothelium, we found the flow responsive kinase and co-transcriptional activator extracellular signal-regulated kinase 5 (ERK5) regulates tumor vessel permeability, similar to exercise. ERK5 activation in response to exercise was investigated *in vivo*, using a Krüppel like factor 2 (KLF2) reporter mouse. KLF2 is a well-defined downstream target of ERK5. KLF2 was upregulated by exercise in the lung and aorta endothelium providing the first evidence for the involvement of ERK5 activation in response to aerobic exercise. Based on this and our previous data demonstrating that exercise induced shear stress upregulates spingosine-1 phosphate receptor 1 (S1PR1) on tumor vessels, we hypothesized that exercise activates ERK5, causing S1PR1 upregulation and decreasing permeability in tumor endothelium. To investigate this, we modeled basal tumor vasculature (low shear stress, 3 dynes/cm²) and exercise-induced flow (high shear stress, 15 dynes/cm²) with a cone and plate viscometer *in vitro*. We found the ERK5 axis has a similar flow responsive pattern as S1PR1. Further, ERK5 directly regulates S1PR1 in cultured endothelial cells revealing a novel EC pathway, the ERK5-S1PR1 axis. **CONCLUSION:** In summary, our data

identifies the ERK5-S1PR1 axis as a potential exercise responsive pathway in tumor and healthy vasculature. We are currently investigating activation of the ERK5 axis in tumor vasculature.

The Impact Of High Intensity Interval Training On Fitness, Stress And Immunity In Breast Cancer Survivors

Kellie L. Toohey. 1974, *Gungahlin ACT, Australia.*

Email: kellie.toohey@canberra.edu.au

(No relevant relations reported)

PURPOSE: The aim of this study was to explore the impact of exercise intensity on aerobic fitness and autonomic cardiac regulation (heart rate variability (HRV)) and salivary biomarkers of the stress systems (HPA-axis, cortisol; sympathetic nervous system, α -amylase) and mucosal immunity (secretory(s)-IgA), in breast cancer survivors.

METHODS: Seventeen participants (62 ± 8 years) were randomly assigned to: 1) high intensity interval training (HIIT; n = 6); 2) moderate-intensity, continuous aerobic training (CMIT; n = 5); or 3) a wait-list control (CON; n = 6) for a 12-week (36 session) stationary cycling intervention. Cardiorespiratory fitness ($\text{VO}_{2\text{peak}}$), resting HRV and salivary biomarkers were measured at baseline 2-4 d pre-intervention and 2-4 d post the last exercise session.

RESULTS: A significant improvement ($p \leq 0.05$) was observed for $\text{VO}_{2\text{peak}}$ in the HIIT group; 19.3% ($B = 3.98$, $95\%CI = [1.89; 46.02]$) and a non-significant increase in the CMIT group; 5.6% ($B = 1.96$, $95\%CI = [-0.11; 4.03]$), compared with a 2.6% ($B = -0.64$, $95\%CI = [-2.10; 0.82]$) decrease in the CON group. Post intervention improvements in HRV markers of vagal activity ($\log(\ln)LF/HF$, $\ln\text{RMSSD}$) and sympathetic nervous system (α -amylase waking response) occurred for individuals exhibiting outlying ($> 95\%$ CI) levels at baseline compared to general population.

CONCLUSIONS: HIIT (compared to CMIT and CON) improved cardiorespiratory fitness in breast cancer survivors. Non-invasive measures of the autonomic nervous system, stress systems and mucosal immunity should be explored further to understand the individualised responses to training adaptations within the breast cancer population.

(No relevant relations reported)

PURPOSE: Breast cancer patients in treatment suffer from long-term side effects that seriously influence their physical and mental health. The aim of this study was to examine differences in health-related outcomes between a 12-week remotely-guided combined exercise (CE) intervention group and a usual care (UC) group after one year for breast cancer patients.

METHODS: In phases I-III, 60 patients (51.2 ± 7.9 years) with breast cancer (BC) who completed chemotherapy/ postoperative radiotherapy within the previous 4 months to 2 years participated in a randomized controlled trial intervention of combined exercise with remote guidance. Eligible participants were approached to assess cancer-related quality of life (QOL), muscle strength, cardiorespiratory endurance and physical activity (PA) barriers after one year.

RESULTS: The result demonstrated that after one year the CE group reported higher in vitality-related QOL (5.776, CI 0.987, 10.565, ES=0.360), mental health-related QOL (9.938, CI 4.146, 15.729, ES=0.512), leg strength and endurance (2.880, CI 1.337, 4.423, ES=0.557), strength and endurance of upper extremities (2.745, CI 1.076, 4.415, ES=0.491), and lower physical activity (PA) hindrance (5.120, CI 1.976, 8.264, ES=0.486) than the UC group.

CONCLUSIONS: The CE group had significant differences from the UC group in quality of life, muscle strength, cardiopulmonary endurance and physical activity participation. These findings showed that the combined exercise intervention with remote guidance produce a long-term benefits for breast cancer patients.

Email: efthymios.papadopoulos@mail.utoronto.ca

(No relevant relations reported)

PURPOSE: The purpose of this retrospective longitudinal study was to examine the association between post-diagnosis physical activity (PA), and the change in quality of life (QoL) and emotional well-being over time in men on active surveillance (AS) for low-risk prostate cancer. **METHODS:** Our analysis included 630 participants from AS initiation until AS discontinuation or loss to follow up. A modified Godin Leisure-Time Exercise Questionnaire was used to measure post-diagnosis PA in metabolic equivalent-minutes per week (MET-min/wk). Participants were categorized based on their PA levels: inactive (<210 MET-min/wk), insufficiently active (210-499 MET-min/wk), active (500-1000 MET-min/wk), and highly active (>1000 MET-min/wk). QoL and emotional well-being were assessed by the Patient-Oriented Prostate Utility Scale. The association between post-diagnosis PA (independent variable) and QoL (dependent variable) was assessed using generalized estimated equations (GEE). GEEs were also used to determine the association between PA (independent variable) and emotional well-being (dependent variable). All models adjusted for participant's age. **RESULTS:** Compared to inactive participants, active (β1.14; 95%CI= 0.11, 2.16, $p=0.029$) and highly active (β1.62; 95%CI= 0.58, 2.67; $p=0.002$) participants had higher QOL during AS. Highly active participants were more likely to experience high emotional well-being (OR =1.55 95%CI = 1.11, 2.16; $p=0.010$) over time compared to their inactive counterparts. In a subgroup analysis for men with low emotional well-being early on during AS, engaging in > 1000 MET-min/wk (highly active) was associated with greater odds of experiencing high emotional well-being over time (OR = 2.17; 95%CI = 1.06, 4.46, $p=0.034$) relative to lowest PA (<210 MET-min/wk). **CONCLUSIONS:** Our findings emphasize the importance of PA as a supportive care strategy during AS for low-risk prostate cancer.

(No relevant relations reported)

Diet quality indices are a practical and inexpensive way to evaluate dietary patterns and adherence to nutrition guidelines. While the diet quality of athletes has been reported using population indices, there is currently no reliable athlete-specific diet index. **PURPOSE:** To assess the reliability of the recently developed Athlete Diet Index (ADI) in athletes. **METHODS:** Eighty-three athletes (55 female; 18.9±4.2 years) from a state-based Australian sports institute consented to complete the ADI deployed using FileMaker™ Pro 16 (FileMaker Inc., 2017, Santa Clara, USA) on a portable device (iPad mini™) on two occasions two weeks apart between June and December, 2019. Sixty-eight athletes completed the ADI on two occasions. Scoring (maximum=125) was based on population guidelines and international sports nutrition recommendations. Scored ADI items measured intake of core and discretionary foods, and markers of dietary habits relevant to athletes. Reliability was evaluated by comparing ADI scores of the first and second administrations using paired t-tests, intra-class correlation coefficients (ICC) and Bland-Altman plots (limits of agreement (LOA) set at mean±1.96SD, and bias determined via regression analysis) all conducted using SPSS Statistics version 26 (IBM Corp, Armonk, NY, USA). **RESULTS:** In preliminary analyses, the mean ADI score was 84.1±15.2 (range 42.5-114.0, median 85.0). There was no difference between ADI scores on the two occasions of administration, mean difference 1.94 (95% CI: -0.49, 4.38, $P=0.117$) (paired t-test). The ICC was very good (ICC=0.80, 95% CI: 0.69, 0.87, $P<0.0001$). Bland-Altman analysis showed a mean difference of 1.94 (LOA -17.79, 21.60) and the regression line demonstrated no indication of systematic bias ($y=4.57-0.03*x$) (95% CI: -0.19, 0.13, $P=0.701$). There were no differences in serves of fruit, vegetables and grains between

administrations; while differences were reported in serves of meat (1.69 vs 1.55, $P=0.01$) and discretionary foods (1.83 vs 1.86, $P<0.0001$). **CONCLUSIONS:** The ADI is a novel athlete-specific diet index which has demonstrated very good reliability in athletes, providing practitioners with a promising measure of usual dietary intake. Further evaluation of the ADI, including validation compared to established dietary methodology, is warranted.

Effects Of Mitochondria-targeted Antioxidant Supplementation On The Transcriptional Response To Exercise And Cycling Performance

Sophie C. Broome¹, Andrea Braakhuis¹, Cameron J. Mitchell², Troy L. Merry¹. ¹University of Auckland, Auckland, New Zealand. ²University of British Columbia, Vancouver, BC, Canada.

Email: s.broome@auckland.ac.nz

(No relevant relations reported)

Oral supplementation with general antioxidants has little impact on performance and, in some cases, interferes with training-induced adaptations that improve performance. This may be attributed to the non-specific nature of most antioxidant supplements. Mitochondria-targeted antioxidants are becoming popular amongst active individuals as they are specifically designed to accumulate within the mitochondria to provide more targeted protection against oxidative damage. The aim of this research was to investigate the effect of MitoQ on 1) the transcriptional response to high intensity interval exercise (HIIE) and HIIT training (HIIT) -induced changes in performance and 2) cycling performance in trained cyclists.

To understand how MitoQ supplementation during training affects the transcriptional response to HIIE and HIIT-induced changes in performance, twenty-three untrained middle-aged (age 44.6 ± 8 years) men were randomised to receive MitoQ (20 mg/d) or a placebo before completing HIIE (cycle ergometer, 10 x 60s at VO₂ peak workload with 75s rest) and HIIT (3 x wk for 3 wk). Mitochondrial and antioxidant gene expression were measured in muscle biopsies collected before, immediately and 3 hr after HIIE and VO₂ peak and 20 km time trial performance were measured before and after HIIT. To further elucidate where MitoQ could be an ergogenic aid, twenty trained (VO₂ peak 55.1 ± 13.2 ml.kg.min⁻¹), middle-aged (age 44 ± 3 years) male cyclists were randomly assigned to the order in which they received MitoQ (20 mg/d) and the placebo for 6 weeks before completing a performance test (cycling at 70% VO₂ peak for 45 min followed by an 8 km time trial). In untrained men, expression of peroxisome proliferator-activated receptor gamma coactivator 1-alpha (PGC1-α) was increased 3 hr after HIIE and this effect was increased by MitoQ (Cohen's d = 0.89). While VO₂ peak and 20 km time trial performance improved similarly in the MitoQ and placebo group after HIIT, the improvement in peak power output (PPO) achieved during the VO₂ peak test was greater in the MitoQ group (by 5.8%, $p=0.03$). MitoQ also significantly improved 8 km time trial performance in trained cyclists. These results suggest that MitoQ may augment exercise-induced increases in PGC1α expression and improve cycling performance when taken during exercise training.

Fit And Fast Versus Slow And Steady: The Relationship Between Fitness And Cognitive Performance In Males And Females

Rachel J. Hopman, Lauren B. Raine, Arthur F. Kramer, Charles H. Hillman. Northeastern University, Boston, MA.

Email: r.hopman@northeastern.edu

(No relevant relations reported)

PURPOSE: Previous research shows aerobic fitness influences attentional inhibition. However, few studies have reported a differential relationship between aerobic fitness and inhibition between males and females. This study investigated the relationship between fitness and inhibitory performance in college-aged males and females.

METHODS: Seventy-nine young adults (M: 19.90 ± 1.1 yrs; 48 females) completed measurements of physical fitness (VO₂max test) and inhibitory control (modified flanker task). Moderation analyses were conducted to determine the influence of sex on the relationship between aerobic fitness and inhibitory control.

RESULTS: RT, response accuracy, and percentage of commission errors were regressed onto mean-centered fitness (VO₂max percentiles), sex, and the interaction between fitness and sex. Fitness was significantly correlated with congruent accuracy ($p < 0.05$), but not correlated with incongruent accuracy ($p = NS$) or RT ($p = NS$). Fitness was negatively correlated with total commission errors ($p = NS$). The interaction between fitness and sex revealed males who are more fit are faster in both congruent ($p < 0.05$) and incongruent responses ($p < 0.05$), whereas fitter females are slower in both congruent ($p < 0.05$) and incongruent responses ($p < 0.05$).

Interestingly, fitter males are significantly less accurate during incongruent trials ($p < 0.005$), whereas females did not differ in accuracy based on fitness ($p = \text{NS}$). Neither males nor females differed in accuracy based on fitness for congruent trials. Similarly, fitter males have a greater percentage of incongruent commission errors ($p < 0.005$) but no differences in congruent commission errors ($p = \text{NS}$), whereas in females, fitness did not influence percentage of congruent ($p = \text{NS}$) or incongruent commission errors ($p = \text{NS}$).

CONCLUSIONS: These results suggest that aerobic fitness may differentially influence flanker performance, particularly in the more challenging condition, in males and females. Furthermore, males and females may adopt different strategies in the difficult condition to maintain performance. These results suggest that while higher fit females may slow down in order to maintain accuracy, higher fit males may have faster responses at the expense of errors.

Alzheimer's Disease-related Gene Expression Is Reduced Following Six Months Of High-intensity Exercise

Belinda Michelle Brown¹, Lidija Milicic², Tenielle Porter², Stephanie R. Rainey-Smith², Madeline Peretti², Michael Vacher³, Hamid R. Sohrabi¹, Ralph N. Martins⁴, Jeremiah J. Peiffer¹, Simon M. Laws². ¹Murdoch University, Perth, Australia. ²Edith Cowan University, Perth, Australia. ³CSIRO, Perth, Australia. ⁴Macquarie University, Sydney, Australia.
Email: b.brown@murdoch.edu.au
(No relevant relations reported)

Extensive research supports the use of exercise to protect against Alzheimer's disease (AD). Nevertheless, there is limited evidence from human studies regarding the mechanisms underlying the positive effects of exercise on the brain. Gene expression determines the extent to which a gene is "turned on or off" and can be used to understand mechanistic pathways. Animal research has demonstrated that exercise influences the expression of genes related to various AD biological pathways; however, the impact of exercise on AD-related gene expression has not yet been studied in humans. **PURPOSE:** To examine changes in AD-related gene expression following a six-month high-intensity exercise intervention.

METHODS: Cognitively normal men and women (60-80y) were randomised to either six-months of work-matched high-intensity exercise ($n=33$), moderate-intensity exercise ($n=34$) or an inactive control group ($n=32$). Blood samples were collected pre- and post-intervention and expression levels from a panel of genes implicated in AD were measured. Analysis of covariance (covaried for age and gender), with adjustment for multiple comparisons, was conducted to determine group differences. **RESULTS:** Decreases in AD-related gene expression following six months of exercise, compared with the control group. More specifically, gene expression associated with cholesterol metabolism (ABCA1; $p < 0.001$), amyloid precursor protein processing (ADAM17, BACE1; $p < 0.05$) and synaptic plasticity (UCHL1; $p < 0.001$) was favourably altered in the high-intensity exercise intervention, compared with the moderate-intensity intervention and control groups. **CONCLUSIONS:** Investigation of AD-related gene expression has the potential to play an important role in understanding the biological pathways by which exercise reduces AD risk and contributes to enhanced cognitive health. The current work indicates a dose-dependent effect of exercise intensity on the expression of genes associated with AD, revealing mechanistic pathways that require further investigation.

The Role Of Apolipoprotein ε4 Allele Carriage In Exercise-induced Cognitive Change

Jeremiah J. Peiffer¹, Natalie Frost², Stephanie R. Rainey-Smith³, Hamid R. Sohrabi¹, Simon M. Laws³, Ralph N. Martins⁴, Belinda M. Brown¹. ¹Murdoch University, Murdoch, Australia. ²University of Western Australia, Perth, Australia. ³Edith Cowan University, Perth, Australia. ⁴Macquarie University, Sydney, Australia.
Email: j.peiffer@murdoch.edu.au
(No relevant relations reported)

Emerging evidence indicates that there may be substantial individual variability in exercise-induced cognitive enhancement, which likely contributes to the inconsistent findings regarding exercise and cognition across the literature. Previous research is inconclusive with respect to how genetic risk for Alzheimer's disease (defined by apolipoprotein, APOE, ε4 allele carriage) modulates the relationship between exercise and cognitive health. **PURPOSE:** To examine the moderating effect of apolipoprotein E (APOE) ε4 allele carriage on cognition following a six-month exercise intervention. **METHODS:** Ninety-nine cognitively normal men and women (aged 60-80 years) were randomised to either six-months of high-intensity exercise ($n=33$), moderate-intensity exercise ($n=34$) or an inactive control group ($n=32$). All participants underwent verbal

learning and memory assessment using the California Verbal Learning Test (CVLT) at pre- and post-intervention. A series of linear mixed-models were undertaken to examine the effects of a group*time, and group*time*APOE ε4 interaction term on repeated CVLT assessments. **RESULTS:** No effect of group*time was observed on any of the CVLT sub-scores. However, an effect of group*time*APOE ε4 was observed for CVLT learning ($d=0.87$, $p < 0.01$) and CVLT short delay recall ($d=0.67$, $p < 0.05$). Post-hoc analyses revealed only carriers of the APOE ε4 allele received benefit from the high-intensity intervention, compared with the moderate-intensity and control groups. **CONCLUSIONS:** No changes in verbal learning and memory were observed from pre- to post-exercise intervention in the whole cohort. However, we observed that APOE ε4 carriers received benefit from the high-intensity exercise intervention in terms of improvement on tasks assessing memory and thinking. Our results indicate that individuals at greater risk of AD, and thus more likely to be experiencing a degree of cognitive decline, may benefit most from exercise.

Sex Differences In The Clinical Sequelae Of Exertional Heat Stroke In Military Servicemembers

Aaron R. Caldwell¹, Matthew D. Ward¹, Charles Gabriel², Lisa R. Leon¹, Nisha Charkoudian, FACSM¹. ¹U.S. Army Research Institute of Environmental Medicine, Natick, MA. ²Defense Health Agency, Falls Church, VA.
(No relevant relations reported)

Exertional heat stroke (EHS) represents a significant source of morbidity and mortality for the military and other occupational and athletic populations. EHS patients tend to present with elevated biomarkers of acute liver and kidney injury, rhabdomyolysis, and altered hematological parameters. However, little is known about how men and women may respond differently to EHS, in terms of clinical severity and/or biochemical responses. **PURPOSE:** The aim of this study was to characterize clinical and biochemical differences between male and female servicemembers immediately following an EHS episode. **METHODS:** We performed a retrospective analysis of EHS patient records in all US military personnel (41% between 20-24 years old) from 2008-2014 using the Military Health Systems Data Repository. We compared diagnoses of organ failure during the course of treatment and clinical laboratory markers of end organ damage. Sex differences in clinical outcomes are presented with odds ratios, and biomarker differences are presented as the median difference with 95% confidence intervals in brackets. **RESULTS:** A total of 2,529 EHS cases were recorded with 9.8% [8.7, 11.2] occurring in women. Per patient treatment cost was lower in women by \$1110 [620, 1647]. Men were 2.35 [1.6, 3.58] times more likely to experience renal failure ($p < .001$). Blood urea nitrogen, (difference = -121.05 mg/dL [41.9, 182.28]), myoglobin (difference = 3 ng/mL [2, 4]), aspartate transaminase (difference = 7 units/L [1, 14]), and alanine transaminase (difference = 13 units/L [8.5, 15.92]) were elevated in men (all $p < .01$). Platelet count was also lower in men compared to women (difference = -22.14×10^3 per uL [-39.25, -2.99], $p = 0.03$). **CONCLUSION:** Female servicemembers appear to have a slightly less severe response to EHS compared to their male counterparts. In particular, renal failure was more common, and numerous markers of end-organ damage (hepatic, renal, and cardiovascular) were more likely to be elevated immediately following EHS in men. Supported by USAMRDC; author views not official US Army or DoD policy.

Relationship Between Body Composition And Sport-specific Performance Metrics In Ncaa Di Female Volleyball Players

Taylor Tuszynski, Erin Wesolowski, Monica Fowler, John Spurlock, Kyle Flack, Tammy Stephenson. University of Kentucky, Lexington, KY.
Email: ttu238@g.uky.edu
(No relevant relations reported)

PURPOSE: The present study examined the relationship between body composition and sport-specific performance markers in NCAA Division I female volleyball players. **METHODS:** Twelve NCAA DI female volleyball players were assessed for body composition [body mass (BM), fat mass (FM), fat-free mass (FFM), body fat % (BF%)] via air displacement plethysmography (BODPOD) and sport-specific performance metrics [standing vertical jump (SVJ), pull-ups (PU), power clean (PC), back squat (BS), bench press (BP), and 5-10-5 pro agility shuttle (PA)] pre-, mid-, and post-season. Pearson and partial correlations assessed the relationships between FM, FFM, and performance metrics. **RESULTS:** FM and FFM were highly correlated ($r=0.521$, $p<0.01$). FM and PC were correlated ($r=0.405$, $p=0.01$) when assessed via Pearson correlation but no longer correlated when controlling for FFM (partial correlation, $r=0.084$, $p<0.05$). FM and SVJ were correlated when controlling for FFM ($r=-0.477$, $p<0.05$). FFM was correlated (Pearson, $p<0.05$) with BP ($r=0.335$), PC ($r=0.748$), SVJ ($r=0.659$), and PA ($r=-0.373$). When controlling for FM, partial correlations ($p<0.03$) existed between FFM and PC ($r=0.653$), SVJ ($r=0.707$), and PA ($r=-0.407$). **CONCLUSION:** SVJ was the only performance variable that correlated

with FM when controlling for FFM. FFM was positively correlated with PC and SVJ, and negatively with PA when controlling for FM. This suggests greater amounts of FFM are more advantageous for performance in the PC (lift greater amounts of weight) and PA (perform in less time) than having low FM, while having low FM or greater FFM are both advantageous for SVJ (greater jump height).

Validity And Reliability Of A Portable Metabolic Analyzer For Assessing Oxygen Consumption And Ventilation

Joseph D. Vondrasek, James B. Hancock, II, Alexander H.K. Montoye, FACSM. *Alma College, Alma, MI.*
(No relevant relations reported)

Metabolic analyzers are standard tools in research-based, exercise physiology laboratories in university settings. Portable, low-cost metabolic analyzers have the capacity to extend the value of metabolic gas analysis beyond the traditional laboratory setting. **PURPOSE:** This study's purpose was to assess validity and reliability of a portable, low-cost metabolic analyzer (VPRO) for assessment of oxygen consumption (VO₂) and minute ventilation (VE) during progressive cycling testing. **METHODS:** In Protocol 1, eight male participants (height: 171.9 ± 5.8 cm, weight: 79.6 ± 8.3 kg, age: 41.0 ± 12.3 years) with previous competitive cycling experience ranging from 2-40 years completed an hour-long stationary cycling protocol twice, progressing from 100-300 Watts every 10-12 minutes while wearing the VPRO and a criterion measure (PMED) for five minutes each, at each stage. In Protocol 2, 16 recreationally active male participants (height: 168.2 ± 8.4 cm, weight: 76.5 ± 13.3 kg, age: 23.0 ± 9.4 years) completed three incremental, maximal stationary cycling tests wearing one of three analyzers for each test (VPRO version 1.1.1, VPRO version 1.2.1, PMED). Mean absolute percent differences (MAPD) ≤10% were deemed acceptable validity/reliability. **RESULTS:** For Protocol 1 and convergent validity, the VPRO had mean absolute differences from the PMED of <0.3 L/min for absolute VO₂ and <5 L/min for VE overall and at each exercise stage. MAPD for VO₂ and VE were <9% overall and <12% at each exercise stage. Test-retest reliability of VO₂ and VE of the VPRO (MAPD: 8.9-11.0%) was lower than the PMED (MAPD: 4.7-7.6%). For Protocol 2, validity was similar for both VPRO versions (MAPD ~12% overall) compared to the PMED for VO₂ and VE. **CONCLUSIONS:** The VPRO had an acceptable validity and test-retest reliability for most variables and intensities tested and may be an appealing option for VO₂ and VE analysis.

The Effects Of Acute Resistance Exercise On Bioelectrical Impedance Analysis Measures Of Body Composition

Timothy Berreth¹, Rachel Wong¹, John Barker¹, Robert Fox¹, Megan Maldonado¹, Chase Van Cleave¹, Javier Zaragoza¹, Mathias Tinnin¹, Grant Tinsley², Lem Taylor, FACSM¹, Kindyle Brennan¹. ¹University of Mary Hardin-Baylor, Belton, TX. ²Texas Tech University, Lubbock, TX.
Email: tjberreth@mail.umhb.edu
(No relevant relations reported)

PURPOSE: The purpose of this study was to determine if acute, localized resistance exercise (RE) compromises the validity of BIA total body composition estimates. **METHODS:** In a crossover design, 16 healthy, resistance trained adults, including 7 females (age: 22.7 ± 1.9 y; height: 165.4 ± 8.4 cm; body mass: 62.1 ± 10.9 kg; body fat: 25.9 ± 7.3%) and 9 males (age: 24.3 ± 3.6 y; height: 179.1 ± 5.1 cm; body mass: 88.0 ± 7.6 kg; body fat: 18.4 ± 6.6%) completed three conditions in a randomized order: lower-body resistance exercise (RE_{LOWER}), upper-body resistance exercise (RE_{UPPER}), and no exercise (REST). A warm-up consisting of 2 sets of 12-15 repetitions of 3 upper- or lower-body exercises, followed by 5 sets of 10 repetitions per exercise, with 1-minute rest intervals. BIA (InBody 770) was completed immediately pre and post-exercise and at 15-, 30-, and 60-minutes post-exercise. BIA estimates of fat mass (FM) and fat-free mass (FFM) were analyzed using 3 x 5 (condition x time) ANOVA with repeated measures, follow-up pairwise comparisons, and evaluation of the partial eta-squared (η_p^2) effect sizes. **RESULTS:** Pre-exercise FM and FFM did not differ between conditions (0.1 to 0.4 kg; $p > 0.4$ for all). Condition x time interactions were present for both FM ($p < 0.0001$, $\eta_p^2 = 0.48$) and FFM ($p < 0.0001$, $\eta_p^2 = 0.45$). Pairwise comparisons indicated that FM was lower in the RE_{UPPER} condition as compared to both REST (1.5 kg; $p < 0.001$) and RE_{LOWER} (1.3 kg; $p < 0.001$) conditions immediately post-exercise. These differences remained at 15-, 30-, and 60-minutes post-exercise (0.6 to 1.6 kg; $p \leq 0.01$ for all). Pairwise comparisons also indicated that FFM was higher in the RE_{UPPER} condition as compared to both REST (1.3 kg; $p < 0.001$) and RE_{LOWER} (0.9 kg; $p < 0.01$) conditions immediately post-exercise. These differences remained at 15- and 30-minutes post-exercise (0.8 to 1.3 kg; $p \leq 0.02$ for all). At 60-minutes post-exercise, FFM remained higher in RE_{UPPER} as compared to REST (1.0 kg; $p = 0.005$) but no longer differed between RE_{UPPER} and RE_{LOWER} (0.4 kg; $p = 0.44$).

CONCLUSION: These data indicate that acute upper-body RE compromises the validity of BIA total body composition estimates compared to REST and lower-body RE and reinforces exercise abstinence as a pre-test consideration.

PURPOSE: The purpose of this study was to determine if acute, localized resistance exercise disrupts the validity of DXA total body composition estimates. **METHODS:** In a crossover design, 18 healthy, resistance-trained, college-aged adults, including 7 females (age: 22.7 ± 1.9 y; height: 165.4 ± 8.4 cm; body mass: 62.1 ± 10.9 kg; body fat: 25.9 ± 7.3%) and 11 males (age: 24.2 ± 4.1 y; height: 180.0 ± 5.1 cm; body mass: 90.2 ± 9.5 kg; body fat: 18.7 ± 7.2%) completed three conditions in a randomized order: lower-body resistance exercise (RE_{LOWER}), upper-body resistance exercise (RE_{UPPER}), and rest (REST). The resistance exercise (RE) protocol consisted of a RE warm-up consisting of 2 sets of 12-15 repetitions of 3 upper-body exercises (upper), or 3 lower-body exercises (lower) or nothing (rest). The RE circuit consisted of 5 sets of 10 repetitions per exercise, with 1-minute rest intervals between circuits. A DXA scan was performed immediately before exercise and at 60 minutes post exercise. DXA estimates of fat mass (FM) and fat-free mass (FFM; calculated as lean soft tissue plus bone mineral content) were analyzed using 3 x 2 (condition x time) analysis of variance with repeated measures, follow-up pairwise comparisons, and evaluation of the partial eta-squared (η_p^2) effect sizes. **RESULTS:** Pre-exercise FM and FFM did not differ between conditions (0.2 to 0.4 kg; $p > 0.14$ for all). For FM, no statistically significant interaction or main effects were present (interaction: $p = 0.80$, $\eta_p^2 = 0.01$; time main effect: $p = 0.14$, $\eta_p^2 = 0.12$; condition main effect: $p = 0.92$, $\eta_p^2 = 0.01$). For FFM, no statistically significant interaction ($p = 0.13$, $\eta_p^2 = 0.12$) or condition main effect ($p = 0.56$, $\eta_p^2 = 0.03$) was present. However, a statistically significant time main effect was present ($p = 0.009$, $\eta_p^2 = 0.34$). Pairwise comparisons indicated that post-condition FFM estimates were 0.20 ± 0.07 kg lower than pre-condition values in all conditions combined. **CONCLUSIONS:** No differences were seen among conditions, indicating that DXA total body composition estimates may be relatively robust to the effects of acute, localized RE. However, investigation of segmental estimates is warranted due to RE-induced blood flow redistribution.

3720 Board #37

High School Basketball Coach And Player Perspectives About Warm Up Routines And Lower Extremity Injuries

Corrine Munoz-Plaza¹, Dana Pounds¹, Anna Davis¹, Stacy Park¹, Robert Sallis, FACSM², Adam Sharp¹. ¹Kaiser Permanente, Pasadena, CA. ²Kaiser Permanente, Fontana, CA.
Email: corrine.e.munoz-plaza@kp.org
(No relevant relations reported)

PURPOSE: To understand high school basketball coach and player routines, knowledge and attitudes relating to warm-ups and lower-extremity injuries (LEIs). **METHODS:** A prospective qualitative study using data from semi-structured interviews with high school basketball coaches and players conducted from May-October 2019, then thematically analyzed by multiple coders employing team coding. **RESULTS:** We interviewed n=12 coaches (9 male; 3 female) and n=30 players (11 male; 19 female). **Current warm-up.** Coaches and players report regular engagement in warm-up routines, but the types of exercises, time dedicated (range: 5-45 minutes) and exercise order varied. Coaches often rely on players to co-lead warm-up exercises. **Knowledge and beliefs re: LEI prevention research.** Most coaches and players believe that regularly engaging in a warm-up routine is effective at preventing injury ("...warming up is absolutely important. There's no disputing."), but lack thorough knowledge of the current evidence ("I have a general interest in sports and fitness...[but] I can't give you any specific...sources."). **Barriers.** Warm-up routines suffer at games due to limited time and space ("Game-[time] is the worst time."). Some players and coaches perceive youth as impervious to injury and minimize warm-up ("I remember being 16 and 17...[you get] out of bed and [you] just run two miles and you're fine."). Coaches face multiple demands during practice, which can impede their focus on a warm-up routine ("...as a coach, [warm-up] is hard...you don't have a lot of time...You want to get right to the point [of practice]."). Coaches also expressed concern that they lack adequate knowledge to select the best exercises and skills to teach their players how to perform them correctly ("...what stretches

are out there. I don't think I know all of them.”). **Enablers.** Players' past injury experience was a key motivator for warming-up (“I'd just put on my shoes and I'd start playing...[until I hurt]...My knee.”). Coach encouragement was also a motivator for players. **CONCLUSION:** Regular involvement in basketball warm-up routines was common among high school teams, but the methods and time dedicated to these practices varied. Players and coaches are eager for more information on warm-ups shown to reduce LEIs, as well as targeted strategies to effectively implement these routines.

Validity And Reliability Of A Lower Body Power Test In Older Adults

Anoop T. Balachandran, Mark Belio, Dan Angielczyk, Noberto Quiles. *Queens College, The City University of New York, Flushing, NY.*

(No relevant relations reported)

Lower body power declines with age and is associated with decreased physical function in older adults. However, current tools to assess muscle power are expensive and non-portable which limits their widespread use. **PURPOSE:** The purpose of the study was to assess the validity and reliability of a functional sit-to-stand power test (STS) in older adults by comparing it with pneumatic leg press, which is widely used in clinical trials to measure lower body power. **METHODS:** A total of 51 community-dwelling adults, 65 years or older, were recruited. Lower body peak power was assessed using a portable linear transducer and a pneumatic leg press. The highest peak power across three attempts with 1 min of rest in between was used for the analysis. To assess construct validity of the STS test, the participants completed the 8-Foot Up and Go (8' UG) test, at both usual and fast pace, and the Short Physical Performance Battery (SPPB) that rates participants from 0 (worst performance) to 12 (best performance) based on balance, usual walk speed, and chair stand tests. A two-week test-retest was conducted to assess reliability in 36 participants. Pearson's correlation coefficient was used to assess construct validity while intra-class correlation (ICC) was used to assess reliability. **RESULTS:** The mean age of the sample was 71.3 yrs, with 62% females, and an average SPPB score of 10.6. Peak power assessed using STS showed a high correlation (0.88, $P < .01$) compared to the pneumatic leg press. As hypothesized in our pre-registered protocol, the STS test showed similar or greater correlation compared to pneumatic leg press for SPPB (0.30 vs. 0.40), chair stand test (-0.37 vs. -0.46), 8' UG test at usual pace (-0.28 vs. -0.37) and fast pace (-0.35 vs. -0.41) and balance (0.23 vs. 0.33). The test-retest assessment yielded an ICC of 0.99 and 0.95 for leg press and STS, respectively. All values were statistically significant ($P < .05$). **CONCLUSION:** The novel functional STS test is comparable to the pneumatic leg press in measuring lower body power. The STS test is relatively inexpensive, portable, takes less space, and should be considered for further validation and future implementation.

INFLUENCE OF GENETIC BACKGROUND ON HEART MITOCHONDRIAL DNA LESIONS AND COPY NUMBER IN INBRED MICE

Hamed Khedmatgozar¹, Michael P. Massett¹, Mohamed Fokar¹, J. Timothy Lightfoot, FACSM², Steven R. Kleeberger³, Heather L. Vellers¹. ¹Texas Tech University, Lubbock, TX. ²Texas A&M University, College Station, TX. ³National Institute of Environmental Health Sciences, Research Triangle Park, NC.

Email: Hamed.Khedmatgozar@ttu.edu
 (No relevant relations reported)

PURPOSE: The heart is a critical tissue responsible for facilitating a multitude of endurance training adaptations in aerobic capacity. Mechanisms of heart mitochondrial DNA (mtDNA) repair remain incompletely understood, and genetic susceptibility to exercise-induced mitochondrial-derived oxidative damage may be present. mtDNA damage presents as an indirect measure of mitochondrial-derived oxidative stress, while mtDNA copy number is a correlate of mitochondrial biogenesis. As two critical aspects for enhancing trainability in aerobic capacity, the purpose of this study was to characterize heart mtDNA lesions and copy number in a genetically diverse panel of male inbred mouse strains. **METHODS:** A genetically diverse panel of 34 inbred mouse strains were selected, and hearts of male mice ($n = 184$; 2 - 6 mice per strain) were removed and weighed. DNA was and a gene-specific quantitative PCR-based assay was used to measure mtDNA lesions and copy number.

RESULTS: Among the strains, we found significant interstrain variation in mtDNA lesions (range = -0.15 - 4.0 mtDNA lesions/10Kb) and copy number (range = 3682 - 111895 mtDNA copies). We observed that the wild-derived PWD/PhJ strain had the highest overall heart mtDNA lesions (PWD/PhJ = 4.31 ± 0.07 mtDNA lesions/10Kb vs all other strains = 0.25 ± 0.42 mtDNA lesions/10Kb; $p < 0.0001$), while having the lowest overall mean mtDNA copy number (PWD/PhJ = $6,538 \pm 898$ mtDNA copies vs all other strains = $54,943 \pm 27,085$ mtDNA copies; $p < 0.0001$). We did not find an association between mtDNA lesions or copy number with exercise capacity or heart

weight. **CONCLUSIONS:** Our results demonstrate that there are inherent differences in heart mtDNA damage and copy number. Interestingly, the wild-derived PWD/PhJ strain had higher overall mtDNA lesions, complemented by lower mtDNA copies, possibly suggesting the hearts of this strain undergo more significant mitochondrial-derived oxidative stress (e.g. higher fission vs fusion; mitophagy) compared to others. Thus, ongoing work aims to 1) characterize markers of mitochondrial-derived oxidative stress (i.e., fission/fusion; mitophagy), 2) sequence the complete mitochondrial genome and determine levels of heteroplasmy and indels that may associate with mtDNA damage and copy number.

Acculturation And 24-hour Behaviors In Asian American Women

Chorong Park¹, Brittany Larsen², Simona Kwon³, Yuhe Xia³, Victoria Dickson³, Tanya Spruill³. ¹Vanderbilt University, Nashville, TN. ²University of California, San Diego, La Jolla, CA. ³New York University, New York, NY.

Email: chorong.park@vanderbilt.edu

(No relevant relations reported)

PURPOSE: Asian American (AA) women have elevated cardiovascular disease (CVD) risk but are an understudied minority group. Physical activity (PA), sedentary behavior (SB) and sleep duration are recognized as independent CVD risk factors, yet these behaviors have not been well described in this population. The study's purpose was to describe AA women's 24-hour behaviors and explore how these relate to acculturation. **METHODS:** Participants were middle-aged normotensive AA immigrant women living in New York City. They completed measures of acculturation along with 7 days of wrist and hip actigraphy to measure sleep duration, moderate-vigorous PA (MVPA), light intensity PA (LIPA) and SB. MVPA, LIPA, and SB were classified by Freedson(1998)'s cut-points and sleep duration was identified by using the Cole-Kripke algorithm and sleep diaries. Linear regression analysis was conducted to test the associations of ethnicity (East Asian vs. South Asian) and acculturation variables (age immigrated to the U.S., years of U.S. residency, English proficiency) on 24-hour behaviors, controlling for age, BMI, education, and employment.

RESULTS: Of the 94 AA women enrolled, 89% ($n=84$) completed hip and wrist actigraphy monitoring (age= 61.3 ± 7.9 , BMI= 25.4 ± 3.6 , 58.9% college or higher, 54.4% employed). Their average hours spent on 24-hour behaviors were: MVPA= 0.5 ± 0.4 , LIPA= 6.2 ± 1.6 , SB= 9.8 ± 1.7 , sleep = 5.3 ± 0.9 . More daily MVPA was related to East Asian ethnicity ($b=0.42$, $p < 0.01$), immigrating to the U.S. at an older age ($b=0.43$, $p < 0.01$), and greater English proficiency ($b=0.32$, $p=0.03$). More SB was related to South Asian ethnicity ($b=0.36$, $p=0.03$) and longer U.S. residency ($b=0.35$, $p=0.02$). Average sleep duration was below recommendations in both East and South Asian women (5.4 ± 0.8 vs. 5.1 ± 0.9), but sleep duration and LIPA were not related to any of the acculturation variables. **CONCLUSIONS:** AA women's 24-hour behaviors differed by ethnicity, and associations with some acculturation variables were observed in this study. Larger, prospective studies are needed to explore the heterogeneity in 24-hour behaviors within this growing minority group and explore both positive and negative effects of acculturation. Culturally tailored strategies may be needed to improve 24-hour behaviors and reduce CVD risk in AA women.

(No relevant relations reported)

PURPOSE: The purpose of this study was to analyze the activity of brain waves depending on the different type of stretching exercise as a warm-up for Taekwondo competitions in order to find out the feasibility of using EMS during PNF-stretching method. We would like to see the difference between the stretching techniques used by Taekwondo athletes and the stretching methods using EMS. **METHODS:** A total of three method of treatments were conducted to 8 elite Taekwondo athletes (Age: 25.87 ± 0.99 , Height: 185.75 ± 11.01 , Weight: 80.87 ± 21.56) repeatedly in random order: PNF Stretching with electric stimulation (EMS+PNF), warm-up exercise with electric stimulation, and PNF stretching without electric stimulation. The EMS+PNF group's electrical treatment was 60 Hz, with five seconds of stimulation and five

seconds of rest alternately. Exercise intensity is RPE 15-16 levels. The brain wave condition of all subjects were presented in comparison before and after(post-hoc) treatment procedures. We performed Two-way Repeated Anova test at the difference of the data between the before and after the program. **RESULTS:** First, EMS part ($M = 66.73$, $SD = 7.23$), PNF part ($M = 38.02$, $SD = 7.23$), EMS during PNF stretching part ($M = 59.33$, $SD = 7.23$) were confirmed in Alpha value. So significant differences were found between warm-up exercise with EMS during PNF-stretching($p < .01$); EMS during PNF-stretching and PNF-stretching($p < .05$) in Alpha value. In addition, it showed significant increases in alpha value corresponding to duration of treatments($F = 4.851$, $p = .009$). Second, significant differences between before and after were found in beta values($F = 5.024$, $p = .026$). Third, significant differences were found between EMS ($M = 151.99$, $SD = 14.93$) and PNF-stretching($M = 84.67$, $SD = 14.93$) in theta value($p < .01$). EMS showed higher value than PNF-stretching in theta wave. **CONCLUSIONS:** This study was showed changes of an alpha wave, which reflects positive emotions, depending on presence of EMS. Thus, it can be considered as more effective method when applying EMS to conventional stretching which leads athletes to feel more effectively treated. The result of the increase in the beta wave was predicted about the difference between EMS stimulation and general stretching by reflecting the characteristics of the beta wave that is activated as cognitive processing occurs. Theta wave is activated when the influence and anxiety of a quiet environment are felt. We are guessed Player thinks that the effect of stretching is low and that the result is reflected when the traditional stretching is performed. Throughout this study, athletes can be expected to show better performance by using EMS during stretching exercise.

L-citrulline (CIT) is a non-essential amino acid, found abundantly in watermelon, which has the ability to indirectly increase nitric oxide production by increasing arginine levels. A combination and the acute use of CIT with malate (intermediate of the Krebs cycle) has shown interesting results in the sports science literature, but the chronic effect of citrulline malate (CM) in the scientific literature is still unclear. **PURPOSE:** Investigate the chronic effects of citrulline malate supplementation in increasing strength and muscle mass in trained healthy adults. **METHODS:** A randomized, double-blind, crossover, placebo clinical study. Twenty four (25.96 ± 4.7 years) healthy adult men were randomly divided into 2 groups: citrulline malate group (CM = 12; 82.4 ± 10.7kgs) or placebo group (PL = 12; 82.11 ± 10.9kgs). The CM group received a sachet containing 6g of citrulline malate + 15g of maltodextrin and the PL group 6g of non-essential amino acids (NAAE) + 15g of maltodextrin. Supplementation was performed for 28 days (4 weeks) and included a wash-out week. After this week, there was an exchange of supplements in both groups. Before and after each supplementation, body composition (body weight, fat mass and muscle mass) by plethysmography (BodPod), and repetition maximum test (1RM) in the bench press were performed. Statistical analysis was performed using the covariance analysis model for crossover experiments, considering a significance level $p < 0.05$.

RESULTS: CM supplementation promoted an increase in total lean mass (67.28 ± 8.11 kgs vs 67.77 ± 7.97 kgs, $p < 0.005$) in relation to placebo (67.83 ± 7.84 kgs vs 67.43 ± 8.57 kgs) (CM vs PL $p < 0.001$), a decrease in total weight (CM 82.39 ± 10.72 kgs vs 81.63 ± 9.98 kgs and PL 82.11 ± 10.9 kgs vs 82.08 ± 9.78 kgs, CM vs PL $p < 0.05$) and an increase in the final bench press (CM 37.95 ± 7.6 kgs vs 41.55 ± 8.31 kgs, $p < 0.05$) in relation to placebo supplementation (38.26 ± 8.69 kgs vs 40.08 ± 8.19 kgs, $p < 0.05$) (CM vs PL, $p < 0.01$), regardless of the sequence in which the supplement was ingested. **CONCLUSION:** Supplementation of CM for 4 weeks proved to be effective in improve body composition (decrease in total weight and increase lean mass) and increased strength, without showing adverse effects, indicating a viable strategy for practitioners of resistance exercise.

Blood Flow Restriction Compared To High Intensity Interval Training On Body Composition And Tendon Width

Kali Morris¹, Gustavo Almeida¹, Julie Barnett¹, Justin Anderson¹, Tabitha Castillo¹, Amber Schneider¹, Alexis Ortiz, FACSM².

¹University of Texas Health San Antonio, San Antonio, TX.

²University of The Incarnate Word, San Antonio, TX. (Sponsor: Alexis Ortiz, FACSM)

Email: Morrisk2@livemail.uthscsa.edu

(No relevant relationships reported)

Blood flow restriction (BFR) is a low load exercise modality advocated to improve body composition. **PURPOSE:** To compare BFR against high intensity interval training (HIIT) body-weight squats (BWS), and 80% 1RM squats (CON) in body composition and quadriceps tendon cross section area (QXS). **METHODS:** Thirteen subjects participated in the study (27 ± 5.8 years, BMI: 23.3 ± 3.2 , F:8). Subjects were randomly assigned to a BFR ($n = 5$), HIIT ($n = 5$), or CON ($n = 3$). Body composition was measured via air plethysmography while QXS was measured via musculoskeletal ultrasound. Subjects were tested at baseline and 6-weeks after training. BFR bands were placed at the proximal thigh and inflated to 250mmHg while performing a 30/15/15/15 repetition (rep) protocol using a metronome (1 rep/2 secs). The HIIT group completed BWS during a 20 sec on and 10 sec off protocol for 8 sets. The control (CON) group completed 3 sets of 5 reps squats of their 80% 1RM. All three groups completed their workouts 3 times a week. Due to the small sample size Kruskal-Wallis (KW) was performed for the variables of fat mass (fm;kg), lean mass (lm;kg), and QXS (cm) during baseline. If no differences at baseline were found the same analysis was performed for the 6-week follow-up. In addition, a KW analysis between groups was performed for the difference between baseline and follow-up values between variables. **RESULTS:** Although BFR showed improvements (fm: -1.1 kg, lm: +0.3kg, QXS: +.01cm) for all variables over the other groups (HIIT: fm: +1.5kg, lm: -1.2kg, QXS: -.02cm; CON: fm: -.05kg, lm: +0.4, QXS: +0.1cm) none of the two KW analytical approaches showed a statistically significant difference for any of the variables of interest. **CONCLUSION:** Although BFR showed improvements in all variables, the magnitude of these changes was not significant enough to demonstrate it is a superior modality than HIIT or 80% 1 RM or 6-weeks of training is not sufficient time to elicit changes in these outcomes.

Blood Flow Restriction Compared To High Intensity Interval Training On Power Output And Muscle Strength

Justin Anderson¹, Kali Morris¹, Gustavo Almeida¹, Julie Barnett¹, Tabitha Castillo¹, Amber Schneider¹, Alexis Ortiz, FACSM².

¹UT Health San Antonio, San Antonio, TX. ²University of The Incarnate Word, San Antonio, TX. (Sponsor: Alexis Ortiz, FACSM)

Email: andersonj16@livemail.uthscsa.edu

(No relevant relationships reported)

Many exercise modalities are used to increase muscle strength and power output with differing load capacities. Purpose: To compare the effects of 80% 1RM (CON) squats, High Intensity Interval Training (HIIT) body weight squats (BWS), and Blood Flow Restriction (BFR) BWS on quadriceps (quads) and hamstrings (hams) strength, and power output via isokinetic testing and standing vertical jump, respectively. Methods: 13 subjects were randomly assigned to: CON, HIIT, or BFR groups. Subjects were tested on an isokinetic dynamometer at 60, 180, and 300 degrees/sec while vertical jump was performed using a vertical jump tester. The training program for the control subjects (N=3) consisted of performing 3 sets of 5 repetitions (reps) at 80% of 1RM squats. The HIIT group (N=5) completed a protocol of 20 seconds of squats followed by 10 seconds of rest for 8 sets. The BFR group (N=5) completed a protocol of 30/15/15/15 reps with 30 seconds rest between sets with bands placed on the proximal thigh bilaterally and inflated to 250 mmHg. The squats for the BFR group were performed using a metronome set to 60 bpm with each rep for 2 seconds. Due to the small sample size, Kruskal-Wallis (KW) analyses were performed for each outcome for the baseline measures, post-training measures, and the difference between post and pre training measures. Results: Although all training modalities elicit improvements for all outcomes, 80% 1RM squats showed the greatest improvement in vertical jump (+8.59cm) while HIIT was the training program showing the greatest magnitude of improvement across all isokinetic variables (average: +0.84kg·m²/s²). However, none of the observed changes were statistically significant. Conclusion: It appears all

training modalities are viable for improvements in power and strength. Nevertheless, the small sample size of the study might be hiding if one modality is superior over the others.

Short-Term Sprint Interval Training Increases Maximal Oxygen Uptake Without Changing Maximal Cardiac Output
 William Bostad, Devin McCarthy, Martin Gibala. *McMaster University, Hamilton, ON, Canada.* (Sponsor: Dr. Stuart Phillips, FACSM)
 Email: bostadw@mcmaster.ca
 (No relevant relationships reported)

Traditional moderate intensity continuous training increases maximal oxygen uptake ($\dot{V}O_{2max}$). This effect is primarily attributed to an increased maximal cardiac output (Q_{max}), as predicted by the Fick principle. Sprint interval training (SIT) increases $\dot{V}O_{2max}$ similar to MICT, often despite a lower training volume, but the effect on Q_{max} is unclear. **PURPOSE:** To determine the effect of 6 sessions of SIT over 2 wk on $\dot{V}O_{2max}$, Q_{max} and exercise performance in healthy, untrained adults [$n=12$ (9 females); 21 ± 2 y; mean \pm SD]. **METHODS:** Training was performed on a cycle ergometer and involved a 2-min warm-up (50 W), 3 x 20-s 'all-out' bouts interspersed with 2-min of recovery (50 W), and a 3-min cool-down (50 W). $\dot{V}O_{2max}$ was determined using a ramp test to exhaustion. Q_{max} was subsequently determined using inert gas rebreathing (Innocor) over a 2-min period of exercise performed at 90% of the peak work rate attained during the $\dot{V}O_{2max}$ test. Pilot testing confirmed this protocol elicited $\dot{V}O_{2max}$ over the 2-min period of Q_{max} measurement. The performance test was a 2 kJ/kg body weight cycling time trial. All measurements were performed twice at baseline, and reproducibility determined as a coefficient of variation (CV). The CV for $\dot{V}O_{2max}$, Q_{max} and time trial performance was 5.8, 4.7 and 4.2%, respectively. Pre- and post-training measurements were compared using a paired t-test. **RESULTS:** $\dot{V}O_{2max}$ increased after SIT from 37.0 ± 7.3 to 40.7 ± 8.3 ml/kg/min ($p<0.001$), but Q_{max} was unchanged (17.2 ± 3.8 vs 17.7 ± 4.6 L/min; $p>0.05$). Exercise performance improved after SIT from 1040 ± 247 to 938 ± 238 s ($p<0.001$). Absolute $\dot{V}O_{2max}$ was positively correlated with Q_{max} ($r^2 = 0.86$, $p < 0.001$). **CONCLUSION:** Six sessions of SIT increased $\dot{V}O_{2max}$ without changing Q_{max} in previously untrained individuals. These data support previous suggestions that the early increase in $\dot{V}O_{2max}$ after SIT may be due mainly to peripheral responses (i.e., enhanced oxygen extraction by skeletal muscle), rather than a central change in blood oxygen delivery. Supported by NSERC

High-intensity Interval Exercise While Wearing A Sauna Suit Increases Energy Expenditure
 Aaron R.D. Matthews¹, Todd A. Astorino, FACSM², Ailish C. Sheard¹. ¹California State University, Los Angeles, Los Angeles, CA. ²California State University, San Marcos, San Marcos, CA.
 Email: amath10@calstatela.edu
 (No relevant relationships reported)

PURPOSE: The use of sauna suits (SS) has increased and claims to enhance weight loss and body temperature during exercise. Whether high-intensity interval exercise (HIIE) with a SS enhances energy expenditure (EE) and excess post-exercise oxygen consumption (EPOC) is unknown. The purpose of this study was to examine changes in EE and EPOC in response to HIIE while wearing a SS.

METHODS: Seven recreationally active men and women (mean age, mass, and $\dot{V}O_{2max} = 29.7 \pm 6.9$ yr, 68.8 ± 17.3 kg, and 46.2 ± 8.10 mL/kg/min, respectively) initially completed assessment of resting metabolic rate (RMR) and maximal oxygen uptake ($\dot{V}O_{2max}$). During the $\dot{V}O_{2max}$ test, exercise began at 60 W for two minutes and work rate increased 25 - 30 W/min until volitional fatigue. Heart rate (HR) and breath-by-breath gas exchange were continuously measured. At least 48 hr later, subjects completed HIIE consisting of 10 x 1 min intervals at 85% peak power output, followed by 75 s of active recovery, with or without a SS. During exercise, HR, core temperature (T_{re}), and gas exchange data were continuously measured, and thermal sensation and rating of perceived exertion (RPE) were also recorded. For 1 hr post-exercise, subjects rested while changes in EPOC, T_{re} , and HR were determined. Blood lactate concentration was measured pre-exercise, 5 min post-exercise, and 1 hr post-exercise. Subjects returned 1 wk later and completed the other condition whose order was randomized

RESULTS: Compared to no SS (NSS), total $\dot{V}O_2$ (57.3 ± 13.8 L vs. 60.4 ± 13.5 L, $p = 0.028$) and EE (286.8 ± 69.2 kcal vs. 302.0 ± 67.3 kcal, $p = 0.048$) were significantly higher for SS. However, EPOC was not significantly different 1 hr post-exercise between NSS (5.1 L \pm 4.3 L) and SS (7.5 L \pm 5.1 , $p = 0.16$). End-exercise HR was not different between conditions ($p = 0.42$), but T_{re} was significantly higher ($p = 0.046$) for SS (38.6 ± 0.5 °C) compared to NSS (38.4 ± 0.4 °C). Post-exercise blood lactate concentration was not significantly different ($p = 0.20$) between conditions (9.6 ± 3.5 vs. 10.8 ± 3.4 in NSS vs. SS). End-exercise thermal sensation ($p = 0.60$) and RPE ($p = 0.17$) were not significantly different between conditions.

CONCLUSIONS: Wearing a SS during HIIE elicits greater EE and T_{re} versus not wearing a SS. Therefore, a SS may aid in weight loss by increasing the total amount of calories expended during HIIE.

In the last decade, high intensity interval training (HIIT) has been shown to be an appropriate alternative to moderate-intensity, continuous exercise for improving cardiorespiratory fitness. HIIT protocols typically result in high blood lactate (La) levels. However, accumulated lactic acid is a potent metabolic stimulus, which plays a major role in the control of physiological adaptations. Therefore, it may be essential for improvements in endurance performance. The literature indicates that there is a strong positive relationship between maximum oxygen consumption ($\dot{V}O_{2max}$) and La production. Purpose: To investigate changes in La levels after 4 weeks of HIIT program. Methods: Blood samples were collected from five female and five male student-athletes ($n = 10$) ($M_{age} = 21$, $SD = 0.95$). A short-term (4 weeks) HIIT protocol used and $\dot{V}O_{2max}$ calculated through Course-Navette Test. The instruments used for this research were an Accutrend Plus-Roche lactometer and BM-Lactate test strips (Risch-Rotkreuz, Switzerland). The analysis consisted of t student tests for paired samples in IBM SPSS v.25 ($p < 0.001$). Results: $\dot{V}O_{2max}$ and blood La changed significantly in six participants (Pre-La $M = 11.65$ mmol/L; Post-La $M = 9.41$ mmol/L). The participants that achieved to increase their $\dot{V}O_{2max}$, produced lower amounts of capillary blood La. Conclusion: Using HIIT, our study results confirm the positive relationship of $\dot{V}O_{2max}$ and La. The inferences of these preliminary results could be used in future, larger-scale interventions concerning ways to affect La production through the increase of $\dot{V}O_{2max}$ using a HIIT program. Future studies should further investigate anaerobic threshold modification processes through different training programs, such as Repeated Sprint Training (RST), Sprint Interval Training (SIT) and Moderate Intensity Continuous Training (MICT). Limitations of this study include small sample size and indirect $\dot{V}O_{2max}$ estimation.

Effects Of High Intensity Physical Exercise On Short-term Memory In University Students
 Santiago Castineyra Mendoza, Victor O. Rodriguez Cervantes, Julio A. Gómez Figueroa, Luis Quintana Rivera, José E. Molina Arriola. *Veracruzana University, Boca del Rio, Veracruz, Mexico.*
 Email: scastineyra@uv.mx
 (No relevant relationships reported)

Studies have determined that physical training provides benefits in people's physical health. Physical exercise is one of the most powerful lifestyle to positively affect the adult brain and emerging evidence points to high intensity interval training (HIIT) as an effective way to improve various aspects of brain function among them the improvement of cognition and short-term memory. Purpose: To analyze the effects of (HIIT) in university students on short-term memory. Methods: 22 university athletes ($M_{age} = 21.6$, $SD = 1.5$), ($n = 11$ experimental group), ($n = 11$ control group). A HIIT program of 12 sessions of short-term (3 weeks) and 6 sessions of short-term memorization was applied. Maximum oxygen consumption ($\dot{V}O_{2max}$) was estimated through the Course Navette Test and memory evaluation through a Rey Auditory Verbal Learning Test (RAVLT). The instruments used for the investigation was a Polar H10® band. A t student test for paired samples was applied by IBM SPSS v.22 ($p < 0.001$). Results: The maximum heart rate (HRmax) of the control group obtained a value of $M = 199.9$, $SD = 15$ ppm and the experimental group $M = 195$, $SD = 6.7$ ppm. In the third week of intervention results were found statistically significant. Conclusion: After twelve training sessions of high intensity physical exercise (HIIT), statistically significant results were obtained, in relation to high intensity physical effort with short-term memory. For future research it is recommended to implement a greater number of training and memory sessions. Limitations of this study include indirect $\dot{V}O_{2max}$ estimation and a small sample size.

Keywords: short-term memory, university students, high intensity interval training.

Physiological Responses During High Intensity Functional Training Exercise Are Affected By Skill Level

Jacob M. McDougale¹, Gerald T. Mangine¹, Michael Giardina², Yuri Feito, FACSM¹. ¹*Kennesaw State University, Kennesaw, GA.* ²*Univeristy of Southern California, Los Angeles, CA.*
 (Sponsor: Yuri Feito, FACSM)
 (No relevant relationships reported)

Although high-intensity functional training (HIIT) is an increasingly popular exercise strategy, research describing the acute physiological responses are few and predominantly limited to novice or untrained. **PURPOSE:** To compare the cardiorespiratory responses of a bout of HIIT among individuals with varying degrees of skill. **METHODS:** Eighty-two participants (31.0 ± 7.4 years; 172.6 ± 9.6 cm; 77.9 ± 13.8 kg) with at least six-months of HIIT experience and varying skill levels were tested. Skill level was categorized by self-reported times of the benchmark workout "Fran" [Novice (NOV), n = 32; Intermediate (INT), n = 24; Advance (ADV), n = 26; (times reported = 5.3 ± 2.7 mins)]. All participants performed aerobic capacity testing to examine peak levels of oxygen consumption (VO₂), heart rate (HR), respiratory exchange ratio (RER), and lactate (LT). A week later, similar variables were measured with averages obtained for VO₂, HR, RER, and LT during a 15-minute HIIT based workout. Univariate analysis of variance (ANOVA) with Bonferroni adjustments were used to examine differences between skill category and outcome variables. **RESULTS:** During the Treadmill test, significant differences were only observed for VO₂ (ADV = 49.53 ± 5.12 ml/kg/min; NOV = 43.83 ± 6.49 ml/kg/min; p = 0.001; η² = 0.924) and LT (ADV = 12.31 ± 2.48 mmol/dL; NOV = 9.93 ± 3.33 mmol/dL; p = 0.004; η² = 0.874), with ADV athletes having greater values than NOV (p < 0.05). No significant differences were observed between ADV & INT (p > 0.05). Similarly, during the HIIT workout, differences were also observed between ADV and NOV categories, but only for VO₂ (ADV = 38.71 ± 3.47 ml/kg/min; NOV = 34.42 ± 5.20 ml/kg/min; p = 0.002; η² = 0.897) and LT (ADV = 9.04 ± 1.68 mmol/dL; NOV = 9.61 ± 2.40 mmol/dL; p < 0.001; η² = 0.946). **CONCLUSION:** These findings provide evidence regarding the impact skill level has on physiological outcomes. During a maximal effort bout of HIIT, the more advanced athletes tend to exhibit more efficient cardiorespiratory markers. Further research is necessary to elucidate how these differences impact overall performance of HIIT exercise.

 (No relevant relationships reported)

PURPOSE: To analyze the contribution of energetic systems in Tabata's high intensity-interval training (HIIT) protocol according sprint number
METHODS: Sixteen physically active males attended to two experimental sessions. In the first one was performed an incremental test to identify the maximum oxygen uptake (VO_{2max}) and power output (pVO_{2max}). At the second visit, participants performed HIIT session composed by sprints lasting 20s at 170% of pVO_{2max} followed by 10s rest until volitional fatigue. For the aerobic system estimative, difference between relative rest VO₂ and its values during the activity was used. For the lactic system, the peak of blood lactate ([La-]) after the session was considered. The rapid phase of excess of post-exercise oxygen consumption (EPOC_{fast}) was used for alactic system contribution. Participants were allocated in three groups, considering the number of sprints performed (G23 = 2 to 3, G45 = 4 to 5 or G67 = 6 to 7 sprints). Relative (%) energetic contribution were analyzed using two-way ANOVA (group x energetic system)
RESULTS: Participants exhibited 24.9±6 years old, 1.67±2.7 cm, 55.6±8.7 kg and a VO_{2max} = 55.6±8.7 mL/kg/min, with [La-] = 13.2±1.7 mmol/L and maximum heart rate = 184±9.3 bpm. For relative energetic contribution (% of aerobic, lactic and alactic respectively), G23 showed 32.3±11.9% (CI95% = 25.5 - 39.2), 24.2±3.9% (CI95% = 17.3 - 31.0) and 43.5±15.4% (CI95% = 36.6 - 50.3); G45 showed 46.3±7.9% (CI95% = 39.4 - 53.1), 22.7±3.9% (CI95% = 15.8 - 29.5) and 31.0±7.2% (CI95% = 24.2 - 37.9), and; G67 showed 60.2±2.3% (CI95% = 51.8 - 68.6); 19.2±2.1% (CI95% = 10.8 - 27.6) and 20.6±3.4% (CI95% = 12.2 - 28.9), with no differences between groups (F=0.0; p=1), differences between systems (F=33.30; p<.001) and statistical significant interactions (F=11.77; p<.001)
CONCLUSIONS: Performing 2 to 3 sprints was found higher anaerobic contribution and performing 6 to 7 sprints, higher aerobic contribution in Tabata's protocol. No participant performed eight sprints.

Effect Of High Intensity Interval Training On Body Composition In Overweight And Obese Sedentary Adults

Nicolas Villarraga, Amran A. Nur, Jessica D. Berg, Eric J. Bruhn, Joshua R. Smith, Thomas P. Olson, FACSM, Amanda R. Bonikowske. *Mayo Clinic, Rochester, MN.* (Sponsor: Thomas Olson, FACSM)
 (No relevant relationships reported)

Only ~20% of adults adhere to physical activity guidelines. Thus, exercise programs that require less time, such as high intensity interval training (HIIT), need to be investigated. Recent studies suggest HIIT incorporating body weight exercises result in increased exercise capacity (VO_{2peak}) and leg muscle endurance in healthy adults. **PURPOSE:** It is unclear if HIIT incorporating body weight exercises influences body composition and exercise capacity in overweight/obese, sedentary adults. We hypothesized that HIIT will 1) increase lean mass and decrease body fat and 2) increase VO_{2peak} to a greater extent than moderate intensity continuous training (MICT) in sedentary, overweight/obese adults.
METHODS: Eleven participants (10 women) were randomized and have completed all study components (6 HIIT vs. 5 MICT; Age: HIIT 39±7 vs. MICT 42±12 yrs; BMI: HIIT: 30±1 vs. 32±3 kg/m² (both, p>0.05). Exercise capacity (VO_{2peak} -cardiopulmonary exercise testing) and body composition (via dual energy X-ray absorptiometry) were measured at baseline and after 12 weeks of training. The HIIT group performed 5 body weight exercises (squats, pushups, lunges, mountain climbers, and plank) 3 days/week for 12 weeks at an intensity equal to a rating of perceived exertion (RPE) >17. The MICT group performed 150 min of MICT/week for 12 weeks at a RPE between 12-14.
RESULTS: Percent (%) lean mass increased from baseline following HIIT (p<0.05), but not MICT (HIIT: 54.4±3.4 vs. 55.5±4.0 %; MICT: 52.5±3.9 vs. 51.7±4.3 %). Body fat % significantly decreased from baseline following HIIT (p<0.05), but not MICT (HIIT: 43.9±3.5 vs. 42.7±4.1 %; MICT: 45.9±4.1 vs. 46.7±4.7 %). BMI was not different from baseline following HIIT or MICT (HIIT: 32 ±3 vs. 31±3 kg/m²; MICT: 30±1 vs. 30±3 kg/m²; both, p>0.05). VO_{2peak} significantly increased from baseline following HIIT (p<0.05), but not MICT (HIIT: 23.7 ±0.9 vs. 25.0±0.9 mL/kg/min; MICT: 22.2±6.1 vs. 23.1±6.1 mL/kg/min). **CONCLUSIONS:** These preliminary data support the hypotheses that non-traditional aerobic HIIT (e.g., HIIT incorporating body weight exercises) leads to more advantageous changes in body composition and exercise capacity compared to MICT alone.

3745 Board #62 May 30 8:00 AM - 9:30 AM
COMPARISON OF MODERATE INTENSITY CONTINUOUS TRAINING VERSUS HIIT ON AEROBIC PERFORMANCE USING STATIONARY AIR BIKE

Masoud Moghaddam¹, Carlos A. Estrada², Cody L. Diehl¹, Brandie C. Cheshier¹, Bert H. Jacobson¹. ¹*Oklahoma State University, Stillwater, OK.* ²*Aurora University, Aurora, IL.*
 (No relevant relationships reported)

Stationary bikes are known as effective tools to improve physical fitness. Unlike most types of exercise bikes, a stationary air bike handles that move synchronously with the pedaling action, creating wind resistance via a large fan. Although several studies have been conducted on benefit of exercise bikes, there has been a relative absence of studies using stationary air bikes in order to compare the effects of high intensity interval training (HIIT) and moderate intensity continuous training (MICT) protocols. **PURPOSE:** The purpose of this study was to compare the effects of stationary air biking, utilizing MICT, ultrashort-HIIT (UH), and short-HIIT (SH) protocols on aerobic performance. **METHODS:** Thirty-two recreationally active participants were randomly assigned to MICT (n = 11), UH (n = 11), and SH (n = 10) groups. The intervention consisted of 3 d/wk for 4 wks. MICT sessions included 30 min of cycling at 75% of maximal heart rate reserve, while the HIIT protocols (i.e., UH, SH) consisted of 3 sets of 8 intervals at all-out intensity. SH and US protocols were performed with 20s:10s and 10s:5s work-to-rest ratios, and provided with 5- and 2.5-min recovery periods between sets, respectively. Maximal oxygen uptake was assessed via a cycle ergometer using a ramp protocol before and after the intervention. Absolute VO_{2max} (A-VO_{2max}) and time to exhaustion (TTE) were measured and analyzed with 2-way mixed factorial ANOVAs. Additionally, total work (TW) during 12 sessions was recorded and analyzed with one-way ANOVA. **RESULTS:** There were significant (p < 0.05) differences in TW (MICT: 2263.0 ± 897.0 cal., UH: 907.3 ± 332.0 cal., SH: 1230.0 ± 188.1 cal.) between groups. While, all groups significantly (p < 0.05) improved A-VO_{2max} (MICT: 2663.6 ± 764.6 to 3017.5 ± 833.4 ml/min, UH: 2652.6 ± 502.3 to 3017.5 ± 606.4 ml/min, SH: 2259.3 ± 281.3 to 2530.1 ± 406.8 ml/min), as well as TTE (MICT: 13:35 ± 02:39 to 14:41 ± 02:46 min, UH: 14:06 ± 02:02 to 15:09 ± 2:20 min, SH: 12:30 ± 01:29 to 13:33 ± 01:27 min). **CONCLUSION:** Despite the significant group differences in TW, all groups similarly improved aerobic performance

(i.e., A-VO₂max, TTE) following training. These findings suggest that performing HIIT on a stationary air bike at a 10s:5s work-to-rest ratio can improve aerobic fitness with a shorter time commitment compared to SH and MICT groups.

3746 Board #63 May 30 8:00 AM - 9:30 AM
Metabolic And Hemodynamic Responses To High Intensity Interval Training With Various Recovery Intervals

Robert Otto, FACSM, Justin St Peter, Erica Koutch, Kerriane Nordland, Colin Shaw, Rebecca Flax, Michele Aquino, John Petrizzo, John Wygand, FACSM. *Adelphi University, Garden City, NY.*
 Email: otto@adelphi.edu
 (No relevant relationships reported)

For more than twenty years, the Tabata protocol has provided the basis for high intensity interval training (HIIT). Although the improvements associated with the protocol are laudable, an intensity of 170% of max VO₂, is difficult for even highly motivated athletes to achieve. A repeated bout HIIT protocol at 100% of Max VO₂ may be a more tolerable option, if it achieves a similar metabolic stress. **Purpose:** The purpose was to determine the metabolic cost of 8 repetitions of HIIT at a workload equivalent to 100% Max VO₂ (HIIT) for 20 sec with recovery intervals of 10, 20, 30 and 40 sec at 20% of Max VO₂. **Methods:** 14 recreationally active college-age students (age: 21.6±1.1 yrs., height: 171.41±0.5 cm, body mass: 75.0±10.6 kg, max VO₂ 2.89±.67, 8 ♂) volunteered to participate in a randomized, single-blind crossover design study with a minimum of 4 days between trials. A max VO₂ ramp protocol on a Lode Cycle ergometer preceded the HIIT trials and established the max workload. VO₂ was obtained by continuous open circuit spirometry and blood lactate by finger puncture. Excess Post Exercise O₂ Consumption (EPOC) was obtained for 20 min. **Results:** Statistical analysis by ANOVA with repeated measures (P<.05) was applied to the following data.

HIIT Trial	10	20	30	40
VO ₂ % max	90.2±4.5	87.9±6.4	86.9±6.8	81.6±7.2*
VO ₂ max L/min	2.59±0.6	2.52±0.5	2.49±0.6	2.33±0.5
HR b/min	181.1±7.0	179.8±8.2	176.0±7.8	173.4±6.5
LA mmol	15.0±2.9	14.7±3.3	15.2±3.6	14.2±2.6
20 min EPOC (L)	2.66±1.0	2.52±0.7	2.82±0.7	2.47±0.9

(*P<.05: 10, 20, 30 vs 40)

Conclusion: The prescribed HIIT work intervals provide ample metabolic stimulus, however recovery intervals in excess of 30 seconds substantially attenuate the oxygen uptake, while still requiring a strong anaerobic contribution. The use of eight repeat bouts of HIIT at a workload equivalent to 100% of max VO₂ may be a viable alternative to the traditional Tabata protocol.

3747 Board #64 May 30 8:00 AM - 9:30 AM
A COMPARISON OF INTERNAL TRAINING LOADS BETWEEN OBJECTIVELY VERSUS SUBJECTIVELY-DETERMINED HIGH-INTENSITY INTERVAL TRAINING

David Elmer, Emma Chambers, Anna Tucker, Madelyn Smith, Elizabeth Hubbard. *Berry College, Mount Berry, GA.*
 (No relevant relationships reported)

High-intensity interval training (HIIT) is an effective and time-efficient method of aerobic training. Most HIIT programming relies on objectively determined work rate, velocity, or heart rate targets. There is very little evidence comparing HIIT that is programmed using objective measures and HIIT that is programmed using subjective ratings to determine the work and recovery intensities, even though subjectively-determined HIIT may have more real-world applicability. **PURPOSE:** To evaluate the internal training load generated by single treadmill sessions of objectively-determined HIIT (HIIT-Obj) and subjectively-determined HIIT (HIIT-Sub). **METHODS:** Thirteen (female n=7, male n=6) young (age 19.8 ± 2.0 years), healthy participants completed a baseline testing session to determine peak VO₂ and HR, followed by two HIIT sessions on a treadmill in a randomized order. Both HIIT sessions consisted of 10x1-min work intervals, interspersed with 1-min recovery intervals, with the work rate obscured from participants' view. HIIT-Obj session work intervals used the work rate associated with 90% of VO₂max, with recovery intervals completed at 4 km/hr. For HIIT-Sub sessions, participants were instructed to reach an RPE of 8-9 on the Borg CR-10 scale during work intervals and drop to an RPE of 3-4 during the recovery intervals. Internal training load calculations included Training Impulse (TRIMP) and HR zone methods. **RESULTS:** There were no significant differences in internal training load between HIIT-Obj and HIIT-Sub as determined via TRIMP (45.8 ± 12.3 vs. 47.8 ± 15.9 a.u., ES=0.03, p=0.59) and HR zones (57.9 ± 14.7 vs. 66.8 ± 22.6 a.u., ES=0.28, p=0.06) methods, though participants spent significantly less time in

the lowest intensity HR zone (zone 1) while completing HIIT-Sub (HIIT-Obj = 3.57 ± 0.93 min; HIIT-Sub = 2.43 ± 1.13 min, ES=0.48, p=0.01). Peak HR reached during the sessions was also not statistically different (186 ± 12 vs. 188 ± 16 bpm, ES=0.07, p=0.38). **CONCLUSION:** Participants are able to generate similar internal training loads using real-time subjective measures of intensity during HIIT compared to objectively-regulated HIIT. This indicates that this simpler, more applicable method of HIIT programming may generate the desired training stress for a client or athlete without rigid work rate or HR targets.

 (No relevant relationships reported)

The oxidative contribution to eight repeat bouts of high intensity interval training

John Petrizzo, Michele Aquino, Colin Shaw, Justin St Peter, Erica Koutch, Rebecca Flax, Kerriane Nordland, John Wygand, FACSM, Robert Otto, FACSM, Adelphi University, Garden City, NY 11530. Email: otto@adelphi.edu
 Interval training requires bouts of work followed by recovery intervals. The intensity of the work interval impacts the metabolic response of the recovery interval. **Purpose:** The purpose was to determine the oxidative cost of both the work (W) interval and the recovery (R) interval during 8 continuous repetitions of high intensity interval training (HIIT) at a workload equivalent to 100% Max VO₂. **Methods:** All 20 second work intervals were followed by recovery intervals of 10, 20, 30 and 40 sec at 20% of Max VO₂. 14 recreationally active college-age students (age: 21.6±1.1 yrs., height: 171.41±0.5 cm, body mass: 75.0±10.6 kg, max VO₂ 2.89±.67, 8 ♂) volunteered to participate in a randomized, single-blind crossover design study with a minimum of 4 days between trials. A max VO₂ ramp protocol on a Lode Cycle ergometer preceded the HIIT trials and established the max workload. VO₂ was obtained by continuous open circuit spirometry. **Results:** Statistical analysis by ANOVA with repeated measures (*P<.05) was applied to these data.

% max VO ₂	10 W	10 R	20 W	20 R	30 W	30 R	40 W*	40 R*
Interval 1	78.3	74.0	73.3	72.6	72.8	73.2	67.9	73.4
Interval 2	96.6	87.2	96.8	85.1	93.9	83.5	83.6	77.1
Interval 3	98.5	88.7	95.9	84.1	92.6	83.3	85.9	80.0
Interval 4	96.0	88.0	94.7	82.5	92.6	83.7	86.5	80.2
Interval 5	95.1	88.8	92.3	85.6	91.1	85.4	85.5	81.7
Interval 6	96.7	89.4	93.2	87.0	92.0	87.6	87.8	80.8
Interval 7	98.5	89.1	95.9	86.2	93.8	85.8	86.9	82.1
Interval 8	99.1	84.7	97.0	83.4	95.2	83.7	89.3	77.6

With the exception of interval one, recovery protocols of 10, 20 and 30 sec sustained significantly greater oxygen requirements during W & R vs the 40 sec trial. W was in excess of 90% of max VO₂ for 10, 20 & 30 trials, while the 40 sec recovery bout HIIT protocol provided significantly less oxidative requirements and never achieved 90%. **Conclusion:** Short recovery intervals of 30 seconds or less provide the greatest oxidative stress during interval training, which may be attributed to insufficient phosphagen resynthesis during recovery.

3749 Board #66 May 30 8:00 AM - 9:30 AM
Effects Of Elevation Training Mask In Conjunction With High Intensity Interval Training On Lung Function

Brandie C. Cheshier¹, Carlos A. Estrada², Masoud Moghaddam¹, Carter J. Stewart¹, Bert H. Jacobson¹. ¹Oklahoma State University, Stillwater, OK. ²Aurora University, Aurora, IL.
 Email: brandie.cheshier@okstate.edu
 (No relevant relationships reported)

A recent training tool, the elevation training mask (ETM) is a commercially available simulated altitude training device with claims to increase lung function and aerobic capacity by incorporating valves to create respiration resistance. Previous studies have resulted in conflicting conclusion regarding the effectiveness of the ETM with respect to lung function. **PURPOSE:** To compare the effects of the ETM in conjunction with high intensity interval training (HIIT) and HIIT alone (i.e., using mask with no resistance) on lung function. **METHODS:** Sixteen healthy adults (control group, n=8 & experimental group, n=8) participated in this study. Pre- and post-test consisted of lung function (FEV₁ & FVC) using spirometry, time to exhaustion (TTE) using the

Bruce protocol on treadmill, and body mass index (BMI). Training was completed on a cycle ergometer on 3 nonconsecutive days per week (MWF), for 4 wks. Participants exercised at 85% of $\dot{V}O_{2max}$ using heart rate monitor, with a pedal rate of 100-120 rpm at individually set resistance levels. Each training session consisted of 10 bouts of 30s exercise followed by 30s of active recovery for a total time of 10 min. The respiratory resistance on the ETM for the experimental group was progressively increased from 915.4 m-2,743.2 m (3,000 ft-9,000 ft.) during wks of training, while the control group used ETM with no resistance. **RESULTS:** Following training, a significant difference in FVC between the groups was found ($F(1, 4) = 7.486, p = 0.016$). In addition, no significant ($p > 0.05$) differences between the groups in FEV_1 (experimental: 3.78 ± 0.94 L; control: 3.83 ± 0.59 L), TTE (experimental: $11:30 \pm 1.92$ min; control: $12:23 \pm 1.60$ min) and BMI (experimental: 23.01 ± 3.24 kg/m²; control: 24.25 ± 2.97 kg/m²) was noted. However, the experimental group yielded a greater increase in FEV_1 compared to the control group (experimental: 3.40%; control: 2.42%). **CONCLUSION:** In the present study, the ETM resulted in a small increase in FEV_1 and significantly improved FVC more than HIIT alone. Using the ETM in conjunction with HIIT may significantly improve lung function compared to HIIT only. When used in conjunction with HIIT, the ETM appears to create sufficient resistance to strengthen the muscles in respiratory ventilation and improve respiratory efficiency.

Effects Of Deep Slow Breath Training On Performance And Recovery During High Intensity Interval Cycling
 Andrew Brown. *Western Washington University, Bellingham, WA.* (Sponsor: Dr. Lorrie Brilla, FACSM)
 (No relevant relationships reported)

Andrew Brown, Lorrie R. Brilla FACSM, Harsh H. Buddhadev, David N. SuprakHealth and Human Development Department, Western Washington University, Bellingham WA 98225
 Voluntary alterations in components of the respiratory cycle have been utilized for centuries in yogic, qigong, and other meditative practices, and represent a fertile area of research within the context of sport performance. Changes to acid-base balance, vagal tone, and subsequent exercise performance following breath training have been demonstrated acutely and chronically. The efficacy of breath training in improving repeated glycolytic sprints has yet to be fully elucidated. **PURPOSE:** To delineate the effects of a six-week deep slow breathing (DSB) program on measures of cycling performance (mean power), recovery (heart rate recovery: HRR), and expired carbon dioxide: VCO_2 , and pulmonary capacities (maximum voluntary ventilation and forced expiratory volume). **METHODS:** Twenty male cyclists were divided into training ($n=10$) and control ($n=10$) groups, where the training group completed a six-week DSB program. Inclusion criteria included a minimum of 180-minutes of cycling volume per week for the previous 6 months. DSB was an app-driven program to extend expirations and post-expiratory breath holds to enhance vagal tone and endogenous buffering capacity. Participants completed two testing sessions, one before and one after the six-week period. Testing sessions involved three repeated 30-second Wingate Anaerobic Tests (WAnT) with three minutes of passive recovery between each interval. MP was recorded for each WAnT while measures of VCO_2 and HRR were taken immediately following each WAnT. **RESULTS:** No significant differences ($p > 0.05$) were found between groups for any of the variables measured, while both groups exhibited increased MP in the second WAnT following the six-week training period (Treatment: pre: 516.30 ± 20.82 W versus post: 536.38 ± 20.62 W; $p = 0.010$; $\eta_p^2 = 0.382$; Control: pre: 549.93 ± 18.66 W versus post: 567.83 ± 18.44 W; $p = 0.010$; $\eta_p^2 = 0.382$). **CONCLUSIONS:** The results presented here suggest DSB provides no performance relevant to recovery or pulmonary capabilities during high intensity interval cycling, beyond those which are incurred via endurance training.

The Effects Of Rich Hydrogen And Oxygen Mixed Gas Inhalation After High Intensity Exercise Influence On Exercise Performance
 Yudai Shibayama¹, Shohei Dobashi¹, Tamotsu Fukuoka², Takaaki Arisawa², Katsuhiko Koyama¹. ¹University of Yamanashi, Kofu, Japan. ²Helix Japan Co. Ltd., Tokyo, Japan.
 (No relevant relationships reported)

PURPOSE: Both hydrogen-rich and normobaric hyperoxic gas exposure during exercise recovery is thought to promote ergogenic and therapeutic effects on the whole body physiological function and exercise performances. However, the synergistic intervention of high concentrations of hydrogen and oxygen mixture gas (HO gas) inhalation on these indexes have been poorly investigated. Therefore, we examined acute HO gas inhalation during exercise recovery on subsequent oxidative stress, inflammation, and exercise performance. **METHOD:** According to a two-trial, double-blind, crossover, repeated measures design, eight physically males inhaled HO gas (67 % of hydrogen and 32 % of oxygen) or Placebo gas (ambient air) during 60-min recovery after completion of oxidative stress-inducing exercise protocol consisting of 30-min treadmill running at 75 % of

participant's maximal oxygen uptake ($\dot{V}O_{2max}$) and 5 × 10 repetitions of squat jump exercise. Before oxidative stress-inducing exercise and 10-min after post exercise gas inhalation, blood and urine samples were obtained and exercise performance (jumping ability, pedaling power output, muscle strength) were evaluated.

RESULTS: A post-exercise HO gas inhalation attenuated the increase 8-OHdG excretion rate ($p < 0.05$), known as one of DNA oxidation markers, and the reduction in the jumping ability evaluated by the height of countermovement jump ($p < 0.05$) compared with Placebo gas inhalation. Moreover, the increase in urinary 8-OHdG excretion rate was significantly associated with the reduction in countermovement jump performance ($r = -0.78, p < 0.01$).

Discussion: These suggested that HO gas inhalation during post exercise recovery might, at least in part, improve exercise performance via reducing systemic oxidative damage.

Comparison Of Interval Exercise And Continuous Exercise On Excess Post-exercise Oxygen Consumption: Matched For Duration

Elliott Arroyo¹, Tricia L. Hart², Brandon A. Miller¹, Emily C. Tagesen¹, Adam R. Jajtner¹. ¹Kent State University, Kent, OH. ²Lipscomb University, Nashville, TN. (Sponsor: Ellen L. Glickman, FACSM)
 (No relevant relationships reported)

PURPOSE: Compare the excess post-exercise oxygen consumption (EPOC) after duration-matched bouts of high-intensity (HIIT) and sprint interval (SIT) exercise to moderate-intensity continuous (MCT) exercise. **METHODS:** Recreationally active men ($n=7$; 22 ± 3 yrs; 180.4 ± 4.7 cm; 77.8 ± 9.3 ; 13.4 ± 3.4 %BF; 44.7 ± 2.6 ml·kg⁻¹·min⁻¹) completed a maximal graded exercise test ($\dot{V}O_{2max}$) and three exercise trials (HIIT, SIT, and MCT) in a randomized, counterbalanced fashion on a cycle ergometer. HIIT consisted of 15 × 90-sec bouts at 85% $\dot{V}O_{2max}$ and 90-sec active recovery periods. SIT consisted of 15 × 20-sec bouts at 130% maximum wattage and 160-sec active recovery periods. MCT was continuous bout at 65% $\dot{V}O_{2max}$. Each trial lasted 53 min, including a 5-min warm-up and a 3-min cool-down. Oxygen consumption ($\dot{V}O_2$; ml·kg⁻¹·min⁻¹) was measured after bouts 1 (B1), 5 (B5), 10 (B10), 15 (B15), and cool-down (CD) which corresponded with min 0-3, 12-15, 27-30, and 42-45 of MCT, respectively. $\dot{V}O_2$ was also measured for 30 min prior to exercise (PRE) and during 1 h of recovery. EPOC (L of O₂) was measured by the area under the curve with respect to increase (AUCi) from PRE $\dot{V}O_2$ during the first 20 min of recovery. Trial effects were assessed via one-way analyses of variance. **RESULTS:** $\dot{V}O_2$ was lower in SIT compared to MCT after B1 ($p = 0.002$; 17.6 ± 4.6 ml·kg⁻¹·min⁻¹; 24.2 ± 1.8 ml·kg⁻¹·min⁻¹, respectively), B5 ($p = 0.007$; 21.8 ± 4.8 ml·kg⁻¹·min⁻¹, 29.1 ± 3.4 ml·kg⁻¹·min⁻¹, respectively), B10 ($p < 0.001$; 21.8 ± 2.6 ml·kg⁻¹·min⁻¹, 30.0 ± 2.5 ml·kg⁻¹·min⁻¹, respectively) and B15 ($p < 0.001$; 21.8 ± 2.6 ml·kg⁻¹·min⁻¹, 29.3 ± 3.3 ml·kg⁻¹·min⁻¹, respectively). SIT was also lower than HIIT at B5 (27.5 ± 3.4 ml·kg⁻¹·min⁻¹; $p = 0.021$), B10 (28.2 ± 2.9 ml·kg⁻¹·min⁻¹; $p < 0.001$) and B15 (28.8 ± 3.7 ml·kg⁻¹·min⁻¹; $p = 0.001$), while MCT was higher than HIIT at B10. After CD, $\dot{V}O_2$ was higher in MCT (19.0 ± 2.9 ml·kg⁻¹·min⁻¹) compared to SIT (16.4 ± 2.6 ml·kg⁻¹·min⁻¹; $p = 0.015$) and HIIT (15.5 ± 2.0 ml·kg⁻¹·min⁻¹; $p = 0.007$). EPOC was lower following SIT (5.5 ± 1.1 L) compared to MCT (7.4 ± 1.6 L; $p = 0.005$) and HIIT (6.7 ± 0.8 L; $p = 0.006$). **CONCLUSION:** EPOC was similar following both HIIT and MCT, but not SIT, when matched for duration. Of note, despite identical duration, the MCT protocol involved more total work when compared to both HIIT and SIT.

Global Positioning System Analysis Of Positional Locomotive Training Demands In Women's Varsity Rugby Union

Danielle L. E. Nyman, Lawrence L. Spriet, FACSM. *University of Guelph, Guelph, ON, Canada.*
 (No relevant relationships reported)

Rugby union is a full contact, intermittent-intensity sport that requires a combination of power, agility, speed and endurance. In positional gameplay, forwards compete in high force-plays (scrums, rucks, mauls), while backs typically execute sprint and agility focused activities. **PURPOSE:** To determine the locomotive demands of female varsity rugby union athletes in regular season training, and to assess positional dissimilarities in these demands, using global positioning system (GPS) technology. **METHODS:** Wearable GPS technology was used to collect spatial and temporal data of female varsity rugby athletes (20.2 ± 2.4 yr) during three regular season

training sessions, each ~2 hr in length. Sessions were categorized as endurance training (ET), skill training (ST) or game-based training (GBT). Movements were catalogued into 5 speed zones. Player positions were classified as forward (n=14) or back (n=15). **RESULTS:** Backs traveled greater total distances on all practice days than forwards, and in ET backs traveled greater distances per minute than forwards (50.07 ± 6.67 m; 47.95 ± 16.64 m, $p < 0.01$). Positional work-to-rest ratio was higher in forwards vs. backs in ET only (0.244 ± 0.158 ; 0.230 ± 0.051 , $p < 0.05$). Backs traveled greater total distances in high-intensity zones than forwards (7.23 ± 4.34 %; 4.32 ± 2.50 %, $p < 0.05$) during GBT. In all practice sessions, significant differences between positions were observed in time spent and distance traveled within the 5 speed zones. **CONCLUSION:** Locomotive training demands for back positions are of higher intensity in GBT, and greater volume on all practice days, compared to forward positions. ET was the only session that exhibited a significantly higher work-to-rest ratio for forwards. Though GPS technology is effective for quantifying linear movements, it is not capable of quantifying athlete exertion in low-speed, high-power movements, performed by forwards in rugby union. Research funded by a grant from NSERC, Canada.

Associations Between Two Athlete Monitoring Systems Used To Quantify External Training Loads In Basketball Players

Keldon Peak, Aaron Heishman, Ryan Miller, Eduardo Freitas, Brady Brown, Michael Bembem, FACSM. *University of Oklahoma, Norman, OK.* (Sponsor: Michael G. Bembem, FACSM)
 Email: keldon.peak@ou.edu
 (No relevant relationships reported)

Quantifying external training load (eTL), referred to as the biomechanical load during training, is becoming increasingly popular for team sport in an effort to manage fatigue, optimize performance, and guide return-to-play protocols following injury. During indoor team sport play, eTL can be measured via Inertial Measurement Units (IMUs) which incorporate accelerometers, gyroscopes, and a magnetometer to characterize an athlete's movement signature, while Indoor Positioning Systems (IPS) are also common, which use Ultra-wideband (UWB) to detect player positioning and their subsequent movements. **PURPOSE:** The purpose of this study was to assess the association between a commercially available IMU and IPS used to monitor eTL in team sport. **METHODS:** A retrospective analysis was performed on 13 elite male NCAA Division I basketball players from three practices during the off-season training phase. A Pearson's correlation was used to examine the association between the Distance traveled during practice captured by IPS system compared to PlayerLoad (PL), PlayerLoad per Minute (PL/Min), 2-Dimensional PlayerLoad (PL^{2D}), 1-Dimensional PlayerLoad Forward (PL^{1D-FWD}), Side (PL^{1D-SIDE}), and Up (PL^{1D-UP}) captured from the Catapult Sport IMU. **RESULTS:** There were significant ($p \leq 0.001$) positive correlations between Distance and PL ($r=0.891$), PL/Min ($r=0.891$), PL^{2D} ($r=0.863$), PL^{1D-FWD} ($r=0.799$), PL^{1D-SIDE} ($r=0.879$), and PL^{1D-UP} ($r=0.887$) during Practice 1. Practice 2 revealed significant ($p \leq 0.001$) positive correlations between Distance and PL ($r=0.947$), PL/Min ($r=0.947$), PL^{2D} ($r=0.901$), PL^{1D-FWD} ($r=0.819$), PL^{1D-SIDE} ($r=0.944$), and PL^{1D-UP} ($r=0.972$), while Practice 3 also displayed significant ($p \leq 0.001$) positive correlations between Distance and PL ($r=0.858$), PL/Min ($r=0.872$), PL^{2D} ($r=0.809$), PL^{1D-FWD} ($r=0.810$), PL^{1D-SIDE} ($r=0.761$), and PL^{1D-UP} ($r=0.891$). **CONCLUSION:** These data suggest a strong association between parameters captured by the two systems used to monitor eTL, however coaches and performance practitioners should be aware that each system may potentially provide unique information used to monitor and track eTL of athletes during basketball play.

Using A 3d-accelerometer To Enhance Task Assessment

Myles J. Polsgrove, Christopher Pomerleau, Deborah Jackson. *Husson University, Bangor, ME.*
 Email: mjpol@yahoo.com
 (No relevant relationships reported)

PURPOSE: Traditional fitness assessments use a standard test battery to gather outcome values that quantify movement capacity in terms of a generalized rating. While valuable, such assessments overlook the process-oriented aspects of a task performance. Triaxial accelerometers (TA) may help provide more process-oriented tracking of human movements by recording acceleration values. The purpose of this comparative analysis was to establish how TA's may provide more robust measures of task performance. **METHODS:** Male subjects (N=10) wore TAs while performing 2 tasks (squat (SQ) & pushup (PU)) at a moderate task workload. Using acceleration data, variables of amplitude (AMP) and frequency (FQ) per repetition were determined for each task. For each, mean (m), STDV, ANOVAs, and post hoc tests for significant differences were compiled. **RESULTS: AVG Subject Parameters: AGE:** 41.7y.o., **BW:** 84kg, **HT:** 185.0cm. **Means & STDV:**

	SQ				PU			
	AMP		FQ		AMP		FQ	
	μ (g)	STDV (+/-)	μ (s)	STDV (+/-)	μ (g)	STDV (+/-)	μ (s)	STDV (+/-)
S1	1.02	.05	1.94s	.06	1.13	.06	1.14	.03
S2	1.04	.05	1.89s	.12	1.18	.09	1.08	.04
S3	0.88	.08	2.69	.12	0.84	.07	2.19	.12
S4	0.64	.07	3.03	.17	1.03	.11	1.90	.07
S5	0.32	.70	2.89	.33	0.97	.05	2.04	.08
S6	0.60	.08	2.21	.09	0.74	.07	1.63	.28
S7	0.59	.04	3.10	.34	0.81	.09	2.02	.18
S8	0.49	.04	2.30	.16	1.32	.99	0.81	.03
S9	0.56	.05	3.39	.36	0.99	.07	2.10	.10
S10	1.40	.09	1.59	.05	0.99	.07	1.11	.04

ANOVA: SQ: AMP (F-critical 2.0): **F-value** 251.4 **Tukey** (7 out of 46 mean differences), **FQ: F-value** 79.8, **Tukey** (12 out of 46 mean differences). **PU: AMP** (F-critical 1.98) : **F-value** 30.1 **Tukey** (23 out of 46 mean differences) **FQ: F-value** 50.3, **Tukey** (18 out of 46 mean differences). **CONCLUSION:** Task measures of acceleration (AMP and FQ) revealed that subject results varied significantly. These findings suggest individuals rely on varying solutions to movement, and performance outcomes may be partially attributable to these differences. Assessments relying on both measurement types may provide more robust performance information.

3756 Board #73 May 30 8:00 AM - 9:30 AM
The Effects Of Home Versus Away Travel On Urine Specific Gravity In NCAA DII Volleyball Athletes

Olivia M. Dean¹, Alyssa M. Pollard-McGrandy², Brian C. Rider³, Adam M. Coughlin¹. ¹Saginaw Valley State University, University Center, MI. ²Wayne State University, Detroit, MI. ³Hope College, Holland, MI. (Sponsor: Rebecca Schlaff, FACSM)
 (No relevant relationships reported)

Urine specific gravity (USG) has historically been utilized to classify an individual's hydration status. Road trips, with decreased willingness to drink and increased "road food" selection, may affect athletes' hydration status. Athletic performance has been shown to be affected by hydration status.

PURPOSE: To compare urine specific gravity of home versus away weekends for DII volleyball athletes.

METHODS: Fourteen NCAA Division II female collegiate volleyball athletes (Red-shirt = 2, Freshmen = 1, Sophomore = 7, Junior = 1, Senior = 1) participated in this study. Urine was collected in sterile cups in the hours preceding games. Collections were conducted over two weekends of play with a total of five samples being collected. All samples were collected prior to the competitions. Home competitions (HM) were Friday and Saturday. Collections for away competitions (AW) were pre-trip Friday, post-trip/pre-game Friday, and post-trip/pre-game Saturday. Participants competed against the same two teams for home and away weekends. Urinalysis was conducted via reagent strips, according to manufacturer's instructions. Data were analyzed via repeated measures ANOVA with an a priori level of 0.05.

RESULTS: USG during HM Friday and HM Saturday were 1.015 ± 0.008 and 1.013 ± 0.006 , respectively. USG from AW pre-trip Friday, AW post-trip Friday, and AW post-trip Saturday were 1.011 ± 0.007 , 1.012 ± 0.005 , and 1.014 ± 0.003 , respectively. Post hoc analysis revealed no significant findings (range in p-values were 0.144-0.845). While no statistical significance was shown from the data analysis, there were some interesting trends. Overall, USG decreased during the HM weekend and gradually increased over the AW weekend. Only 17% of the athletes increased USG during HM weekend. However, 75% of the athletes showed an increase in USG from the time they showed up to travel Friday until pre-game on Saturday.

CONCLUSION: Following a two-hour road trip, USG did not differ significantly between home and away games. However, some athletes showed varying changes in USG across collection time points. Further analysis has yet to be done to determine the effect on game statistics and performance.

Accuracy Of 5k Race Time Using A Gps Sports Watch
 Andrew James Brink, Andrea D. Workman, Rebecca W. Moore.
Eastern Michigan University, Ypsilanti, MI. (Sponsor: Michael J Saunders, FACSM)
 (No relevant relationships reported)

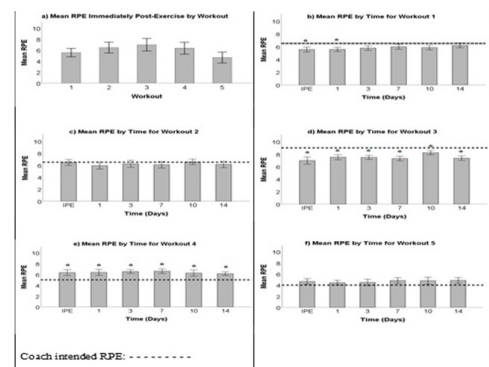

GPS sports watches are a convenient tool used to monitor improvement and predict race performance. Ensuring these watches are accurate allows runners to specifically plan out training to reach a desired race time. However, if predicted race time is inaccurate, an athlete may become frustrated during training or not reach their goals. **PURPOSE:** The purpose of this study was to determine if a GPS sports watch accurately predicts 5k race time. **METHODS:** Nineteen participants (26.8 ± 7.9 years) were recruited for this study. Eligibility included participants running at least 30 minutes a day, three times a week. Participants were required to visit the EMU Running Science Laboratory on two separate occasions. During the initial visit, participants completed a VO_{2max} test on a treadmill. Participants ran at a self-selected speed while grade increased 2% every two minutes until volitional exhaustion. Following the VO_{2max} test, participants were shown how to use a GPS sports watch and instructed to run three days a week for at least 30 minutes for two weeks. After two weeks, participants returned for their second visit and predicted 5k time was recorded from the GPS sports watch. Participants then completed a 5k race time trial on a 200m indoor track (measured 5k). A paired samples t-tests was used to compare predicted 5k to measured 5k ($p < 0.05$). **RESULTS:** Three participants were excluded due to failure to return for the second visit. The remaining 16 participants (5 female, 11 male) had an average VO_{2max} of 54.0 ± 9.1 ml/kg/min, height of 172.9 ± 7.0 cm, and weight of 69.5 ± 9.0 kg. There was a significant difference between measured 5k race time (25.3 ± 4.7 min) and predicted 5k race time (21.1 ± 2.5 min) indicating that the GPS watch underpredicted 5k time. **CONCLUSION:** The GPS sports watch underpredicted 5k time by approximately four minutes. The prediction from the GPS sports watch was based on factors such as speed, heart rate, and distance measured while participants wore the watch for two weeks. Failure to accurately measure heart rate at the radial pulse, inaccuracy associated with GPS, and varied training intensity while wearing the watch could explain some of the error.

3758 Board #75 May 30 8:00 AM - 9:30 AM
The Application Of Statistical Process Control In Athlete Monitoring: Case Study Series
 Ai Ishida, S. Kyle Travis, Jeremy A. Gentles. *East Tennessee State University, Johnson City, TN.*
 Email: aiai041816@gmail.com
 (No relevant relationships reported)

To optimize sport performance, it is important for practitioners to assess training loads (TLs) and subsequent responses within individual athletes. Published research pertaining to athletes often report group or aggregate data. Investigations that present data from individual athletes are rare, particularly in a team setting. However, statistical process control (SPC) is often used in case studies of individual athletes where SPC is used to identify variances outside of normal ranges. **PURPOSE:** To determine the efficacy of using SPC to assess subjective measures of perceived wellness (PW) scores coupled with session rating of perceived exertion (sRPE) and global positioning system (GPS) derived TLs among soccer players. **METHODS:** Five NCAA Division I female soccer players (21.0 ± 1.3 yr, 165.7 ± 4.3 cm, 60.4 ± 5.2 kg) participated in this study. Each athlete played as a starter on the university team and on their respective senior or under-aged national teams. All PW and TLs were collected across 14 weeks of the competitive season. A customized questionnaire was used for players to report PW consisting of six subscales ranging from 1 (poor) to 5 (excellent). The athletes completed the questionnaire by noon seven days per week. PW subscales were summed and used for assessment. TLs including sRPE and total distance (TD) measured via GPS were collected for each practice and match. SPC was used to identify meaningful changes of the summed PW scores relative to individual mean. Means (M) and standard deviations (SD) of the PW scores were calculated for each player. SPC limits were set at $M \pm 1.0$, ± 1.5 , and ± 2.0 SD. **RESULTS:** There were 3.4 ± 1.9 scores of PW below -2.0 SD out of 91.4 ± 2.5 data. Additionally, 6.4 ± 2.8 data of PW were placed between -1.5 and -2.0 SD. SPC also identified 0.4 ± 0.5 PW data between 1.5 and 2.0 SD. However, no scores above 2.0 SD were observed. After matches, abnormal scores (PW scores $< M-2SD$) appeared from accumulated spikes of TD and increased sRPE. **CONCLUSIONS:** Based on the current analysis, each athlete appeared to respond differently to TLs despite having similar playing status. Thus, sport performance practitioners may consider incorporating SPC into an on-going athlete monitoring program to accurately access each athlete's recovery rate so that sport performance can be optimized across a given season.

Temporal Robustness Of The Srpe Method Of Monitoring Training
 Carl Foster, FACSM, Bo Orton, Richard Pein, Richard P. Mikat, John P. Porcari, FACSM. *University of Wisconsin-La Crosse, La Crosse, WI.*
 Email: cfoster@uwlax.edu
 (No relevant relationships reported)

Introduction: Session Rating of Perceived Exertion (sRPE) has been used to monitor training as an alternative to traditional measures such as heart rate, blood lactate and VO_{2} . sRPE has traditionally been measured ~30 min post exercise, although recent data suggest that it is temporally robust in the 5-min to 24 hr post exercise window. The goal of this study was to analyze the post-exercise on temporal robustness of sRPE as well as the difference between coach-intended RPE and athlete-reported sRPE. **Methods:** Collegiate swimmers ($n=15$) (NCAA Division III) completed 5 training sessions at different coach intended levels of sRPE. The subjects reported sRPE ~30 min post-exercise and then 5 more times in the subsequent two weeks following each training session. **Results:** Athletes reported similar sRPE over all times post-exercise for all workouts, suggesting that sRPE is a viable method of monitoring training up to 14 days post-exercise. The sRPE reported by the athletes were significantly lower than coach intended when the intended RPE was high (sRPE~9.0), and significantly higher than coach's when intended sRPE was lower (~4.0-5.0). **Conclusions:** The findings suggest that sRPE is very temporally robust, but that there is a mismatch between coach and athlete related to training intensity.

Sweat analysis via epidermal microfluidic (Epifluidic) patches may be a more practical alternative to standard sweat analysis techniques, offering users real-time feedback of sweat electrolyte concentrations. These patches have previously been validated in controlled, lab-based conditions for measuring regional sweat [Cl⁻]. However, research in the field is needed to determine Epifluidic patch validity in real-world, sport-specific conditions. **Purpose:** To determine the accuracy of an Epifluidic patch with built-in colorimetric assay to measure regional sweat [Cl⁻] during exercise in sport-specific conditions. **Methods:** Forty-six subjects (17 male, 29 female; 17.1 ± 0.8 y; 64.2 ± 10.2 kg) from five sports (tennis, soccer, lacrosse, basketball, and track & field) participated in coach-led training sessions ($22-34^{\circ}C$, $50-82\%$ RH; 39-127 min patch duration) while sweat was collected from the right and left ventral forearms with an Absorbent patch (3M Tegaderm+Pad) and Epifluidic patch (Epicore Biosystems, Inc.), respectively. Immediately after removal of the Absorbent patch, an image was taken of the Epifluidic patch on-skin with a 12MP smartphone camera (iPhone 8, Apple Inc.) for analysis of [Cl⁻] via colorimetry. Sweat from the Absorbent patch was extracted via

centrifuge and subsequently analyzed for [Cl⁻] by ion chromatography. Data are shown as mean±SD. **Results:** There was no difference in sweat [Cl⁻] between Absorbent and Epifluidic patches (21.1±13.8 vs. 19.9±12.2 mmol/L, $p=0.14$). Bland-Altman Limits of Agreement between methods was -9.3 to 11.6 mmol/L with a mean bias of 1.2 mmol/L. There was a significant correlation between patches ($r=0.92$, $p<0.0001$) and the coefficient of determination (r^2) for predicting Absorbent from Epifluidic patch [Cl⁻] was 0.85. Based on Deming regression analysis, the slope and intercept of the regression line describing Absorbent vs. Epifluidic patch sweat [Cl⁻] were not different than 1 and 0, respectively. **Conclusions:** The Epifluidic patch provides accurate data for forearm sweat [Cl⁻] estimation during exercise in sport-specific conditions during live indoor and outdoor training. Future research is needed to evaluate the Epifluidic Patch in other sports (beyond those investigated) as well as for on-skin analysis of sweat [Cl⁻] at other regional sites.

ECG-derived Aerobic And Anaerobic Indices For Training Efficiency Tracking

Pavel Bulai, Tatsiana Kulahava, Taras Pitlik, Timofei Lipski.
RocketBody Inc., Minsk, Belarus.
 Email: pavel.bulai@gmail.com
 (No relevant relationships reported)

There is a continuous search for indirect methods and simple criteria to evaluate physiological effects of training. ECG analysis provides a relevant option for routine monitoring as it can be supported in real-time mobile or wearable device applications. Determination of the optimal ECG features is essential for monitoring and assessing systems. **PURPOSE:** To introduce ECG-derived aerobic index (AI) and anaerobic index (ANI) which could determine training effects and indicate subject's metabolic state. **METHODS:** A healthy, physically active subject performed endurance and strength trainings 3 times a week. He fulfilled 55 ECG measurements using single-lead wrist-wearable device before and after 28 trainings. ECG signals were processed with detection of QRS-complex. AI and ANI were calculated as R-peak normalized to S-R complex slope and as S-T complex slope normalized to R-S slope. Correlations of AI and ANI with training load were calculated using Pearson correlation coefficient (r) with p value. **RESULTS:** Correlations between AI and aerobic load as well as ANI and anaerobic load were identified. The more energy was burned during training, the lower indices were registered. As shown in Figure, maximum of negative correlation between AI with aerobic load was in 60 min after training ($r=-0.57$, $p<0.01$). ANI showed negative correlation with anaerobic load ($r=-0.35$, $p<0.01$) in 30 min after training. **CONCLUSION:** Proposed ECG-derived aerobic and anaerobic indices showed statistically significant correlations with training load and could be used as assessed individual parameters of the degree of training in fitness and sport medicine. Figure. Dependences of ECG-derived aerobic (A) and anaerobic (B) indices on energy, burned during aerobic and anaerobic load. Correlation curves with confidence bounds (95 %).

VALIDATION OF HEART RATE MONITORING OF FENIX 5 DURING MOUNTAIN BIKING

Brenna Barrios. *UNLV, Las Vegas, NV.* (Sponsor: James Navalta, FACSM)
 (No relevant relationships reported)

The availability of fitness trackers have increased in recent years. These trackers claim to accurately depict Heart Rate - among other factors. Little if any studies have looked into the accuracy of the HR sensor within these systems. **Purpose:** The Garmin Fenix 5 watch boasts about its performance tracking capabilities, claiming that it will accurately track heart rate, this study aims to assess its accuracy using the Polar H7. **Methods:** Sixteen participants (males = 8, females = 8, 24.69±4.44yrs, 171.45±8.9cm, 74.23±21.07kg) rode a mountain bike a total of 3.22km along the McCullough hills trail (Henderson, NV) while simultaneously wearing both the Garmin Fenix 5 and the Polar H7. Participants rode the same trail twice, each ride was 1.61km (round trip), with a 10-minute break in between rides. Validity was determined using the Mean Absolute

Percent Error (MAPE), Bland-Altman analysis with accompanying bias and Limits of Agreement (LoA), and single measures Intraclass Correlations (ICC). Prior to testing, the benchmark for validity was established as $mAPE < 10\%$ and $anICC > 0.7$ ($p < 0.05$), with the lower limit of the ICC 95% confidence interval (CI) set at > 0.7 . **Results:** During mountain biking the MAPE was 13.30%. The single measures ICC was 0.16 with a 95% confidence interval of .068 to .243 ($F(17142, 17142) = 1.495$, $p < 0.000$). **Conclusion:** This data shows that the Fenix 5 does not produce a valid measure of heart rate while mountain biking due to the MAPE being above 10% and the ICC being well below .7.

Confounding Variables Influence Utility Of Heart Rate Measures In Collegiate Athletes.

Nguyen D. Nguyen, Ashley Arnett, Ethan S. Gross, Haylee A. Bettencourt, J. Mark VanNess, Courtney D. Jensen. *University of the Pacific, Stockton, CA.*
 Email: n_nguyen55@u.pacific.edu
 (No relevant relationships reported)

Heart rate is easy to measure and a useful variable for determining training intensity, training status and fitness levels. The downward rate of the heart following a standardized stressor (heart rate recovery; HRR) and resting heart rate (RHR) are autonomic-mediated and can be used to detect training distress. However, confounding variables can limit the usefulness of heart rate when criteria for rate changes are not individualized, especially when applied to entire sporting teams. **PURPOSE:** To determine influences of sex, training status, player position and season duration have on the RHR and the HRR response following a standardized physical stressor. **METHODS:** Subjects were male ($n=17$) and female ($n=26$) collegiate soccer players aged 17 to 22 years. RHR (taken in the morning just after waking) and the HRR following a 300-yard shuttle run and maximal treadmill test were collected four times during one entire season: Beginning of August (pre-season), September (mid-season), October (mid-season), and end of November (post-season). Polar monitors were used to record heart rate. **RESULTS:** A comparison between shuttle run times showed men had faster times ($p<0.001$) and higher VO_{2max} ($p<0.05$) than women. Shuttle run performance and athlete's class standing were not found to be significantly different but trended towards significance ($p=0.052$). HRR examined by sex found that men had a faster HRR time than women ($p=0.010$). A multivariate analysis examining RHR and player position found that there was a statistically significant difference ($p=0.015$): The forward players had higher RHR compared to defenders ($p=0.051$) and midfielders ($p=0.049$). **CONCLUSION:** Player fitness, sex, position and year in school should be considered when establishing guidelines for using heart rate information.

The Accuracy Of Heart Rate Monitors And Determination Of Heart Rate Percentages At Anaerobic Threshold

Muhammet Enes Erol¹, Michael A. Figueroa². ¹William Paterson University, Clifton, NJ. ²William Paterson University, Wayne, NJ.
 Email: meneserol1@gmail.com
 (No relevant relationships reported)

PURPOSE: To examine the heart rate percentage (HR%) at the Anaerobic Threshold (AT) in order to determine the appropriate exercise intensity below or above the AT. A second goal was to assess the accuracy of different types of wearable heart rate monitors (HRMs) during a graded exercise test. **METHODS:** Thirty healthy individuals ($n=21$ male & $n=9$ female; aged 24.5 ± 3.5 years) participated in a single incremental exercise protocol on a cycle ergometer (CE). AT was detected through a metabolic cart by using V-slope method, which determined the point of a nonlinear increase in carbon dioxide output (VCO_2) against oxygen uptake (VO_2). HR was measured each minute of exercise test via two optical-based monitors (Cellular Watch [IW] & Fitness tracker [FB]) and two electrical-based monitors (traditional monitor [ECG] & heart rate monitor [PL]). Electrocardiography (ECG) was used as a "Gold Standard" for comparison in this study. **RESULTS:** AT was reached at the mean and standard deviation (SD) of 130 ± 16 bpm. HR% at AT was observed $67 \pm 8\%$ of HRpeak, Heart Rate Reserve Percentages (HRR%) at AT were observed at $42 \pm 15\%$ of HRpeak. Across all exercise testing stages (Stage 1 [S1], Stage 2 [S2], Stage 3 [S3], etc.), no significant differences were found in HR values between ECG and PL. The most statistical differences were found in HR between ECG and IW, $S6=[p=0.018]$, $S6=[p=0.041]$ and $S7=[p=0.005]$, respectively. As intensity increased, FB and IW underestimated the HR values throughout all stages when compared with the ECG. **CONCLUSIONS:** Analysis of HR% at AT was estimated at approximately 67% of participant maximum effort as well as HRR% at AT was estimated at 42%. At the light-intensity, accurate outcomes of HR values were observed from all wearable HRMs. However, with increased intensity, the accuracy of wearable devices was varied at moderate and high-intensity exercise testing. The PL had the greatest agreement with

ECG when compared to other devices. This might be due to the fact that both HRMs utilize a similar mechanism of measurement. The electrical-based HRM was found to be more accurate in comparison to the optical-based HRMs.

(No relevant relationships reported)

Previous studies have suggested that football players not clinically diagnosed with concussion may still demonstrate differences in balance and neurocognitive performance by end of season. Clinically this is important as it indicates the athlete with sub-clinical injuries that may contribute to long-term deficits.

Purpose: A pilot study to determine if non-concussive impacts sustained during normal play at NCAA Division I football practices and spring season scrimmage are sufficient to elicit detectable changes in oculomotor (OM) and balance performance.

Methods: 23 NCAA Division I football players were recruited to this pilot study during the 2019 spring football season. Questionnaires were used to collect demographic information. Portable virtual reality equipment was utilized to measure OM performance of smooth pursuit, saccade, and vestibular ocular reflex (VOR). BESS was utilized to measure balance performance. Assessments were administered at baseline, 24-48 hours after 3 practices, and the spring season scrimmage. Shapiro-Wilkes analysis was used to assess changes in balance and OM skills in subjects across the pilot project.

Results: Of the 23 recruited subjects, 7 (30%) completed all assessments; however, there were missing data observations for the 7 subjects who completed all 5 assessment points. There was no significant change in balance performance ($p = 0.375$); one variable of smooth pursuit testing (mean phase error of left eye) demonstrated near significant changes ($p = 0.0625$). There was no significant change in any variables for horizontal or vertical VOR, while, one variable of horizontal and vertical saccade testing (accuracy x of left eye) demonstrated near significant changes ($p = 0.0625$).

Conclusion: We found no significant detectable changes in balance and OM performance in this pilot study.

Internal Load In Football Players: Can The Mind See What The Heart Says?

Valerie Smith-Hale, Joshua Sabou, Ruben Mendoza, Alyssa Pollard-McGrandy, Matt VanSumeren, Linda Jumenez, Tamara Hew-Butler, FACSM. Wayne State University, Detroit, MI.
(Sponsor: Tamara Hew-Butler, FACSM)
Email: fg8819@wayne.edu
(No relevant relationships reported)

Rating of perceived exertion (RPE) is a simple, validated, measure of physical effort, largely reflecting heart rate (HR). However, RPE is being replaced by continuous HR monitoring to quantify internal loads which maximize performance and enhance recovery. **Purpose:** Primary aim: assess relationships between RPE (athlete and coach) versus HR during football practice. Secondary aims: quantify internal load via HR assessments of training impulse (TRIMP) and recovery. **Methods:** Data represents pre-season testing, in an ongoing study. Twenty-nine collegiate male football players (age=20±2years; body mass index= 34±6kg/m²; weight=118±20kg) and 3 coaches volunteered to participate. Each athlete was pre-assigned a HR monitor for the first 7 days of football camp. All participants underwent a 3-minute quick recovery test (QRT). HR monitors were then worn during practice. Athlete HR, TRIMP, %heart rate reserve (%HRR), %heart rate max (%HRmax) were recorded and visible only to researchers. Immediately following practice, all athletes and coaches were asked to assess RPE for the entire training session (sRPE) using the Borg CR-10 scale. %HRmax and %HRR were transformed to scale from 1-10, to match the Borg CR-10. Significance set at $p < 0.05$. **Results:** Training sessions over this 7-day period, lasted 145.8±33.7 minutes. When weekly data were combined, significant overall correlations (pairwise; N=187) were noted between %HRR versus: %HRmax ($r = 0.84; p < 0.0001$), athlete sRPE ($r = 0.30; p < 0.0001$) and

head coach RPE ($r = 0.30; p < 0.0001$). Athlete sRPE was correlated with one coach sRPE ($r = 0.30; p < 0.0001$). Athletes were then subdivided into Big, Combo, and Skill position groups. Two-way ANOVA for sRPE between athletes, coaches and %HRR demonstrated a significant interaction effect ($F = 15.2; p < 0.0001; 22.8%$), time effect ($F = 36.4; p < 0.0001; 13.6%$), and position effect between groups ($F = 26.1; p < 0.0001; 6.5%$). TRIMP decreased over time, with a significant time effect ($F = 23.7; p < 0.0001; 33%$) and position effect ($F = 5.4; p = 0.005; 2.5%$). Trend for QRT to dip on Day 2, then increase over time. **Conclusions:** Athletes and one coach significantly predicted training effort (HR) during practice. However, the variance was small (9%) and sRPE remained steady despite decreased training load and increased QRT scores (trend) over time.

Isometric Mid-thigh Pull Correlates With Power, Sprint, Agility And Smash Performance In Junior Female Badminton Players

Ran Wang, Yi Sheng, Heng Lu, Xiaolu Zha, Murong Yu.
Shanghai University of Sport, Shanghai, China.
Email: wangran@sus.edu.cn
(No relevant relationships reported)

Purpose: Badminton is a racket sport characterized by high-intensity, intermittent actions. Some of the most important aspects of fitness required for badminton highlighted in the literature include speed, agility, strength, and power. Traditional strength testing such as one repetition maximum (1RM) squat can be time-consuming and inaccurate. As an alternative choice, the isometric mid-thigh pull (IMTP) has been shown to be related to performance variables such as vertical jump, strength, sprint, and agility in various sports. There are two primary variables for IMTP, the first is to quantify the athlete's maximal force-generating capacity, known as peak force, and the second is to assess the rate at which force can be applied during a maximal effort muscle contraction, called as the rate of force development. This study aimed to examine the relationship among IMTP, vertical jump, sprint, agility and smash performance in elite junior female badminton players.

Methods: Twenty-three national level junior female badminton players (Age: 15.21 ± 0.89 y; Height: 1.71 ± 0.06 m; Body mass: 58.54 ± 6.90 kg; Training age: 7.32 ± 1.95 y) participated in this investigation. The participants performed IMTP, vertical jump, 10-m sprint, badminton-specific change-of-direction testing, and forehand smash velocity testing. Bivariate correlation analysis (Pearson product-moment correlations) was used to examine the relationship between IMTP kinetic variables and sprint, agility and smash performance.

Results: Peak force had a significant negative correlation with 10-m sprint time ($r = -.582, p = .004$), left ($r = -.662, p = .001$) and right ($r = -.664, p = .001$) pro-agility time. Peak force also had a significant positive correlation with smash velocity ($r = .418, p = .047$) and vertical jump power ($r = .514, p = .012$). Rate of force development had a significant negative correlation with 10-m sprint time ($r = -.636, p = .001$), left ($r = -.575, p = .004$) and right ($r = -.546, p = .007$) pro-agility time, as well as a significant positive correlation with vertical jump power ($r = .534, p = .009$).

Conclusions: Results from this investigation demonstrate that IMTP variables such as peak force and rate of force development are associated with jump, sprint, agility and sport-specific performance in elite junior female badminton players.

3769 Board #86 May 30 8:00 AM - 9:30 AM
Ankle Proprioception And Sport-specific Performance In Professional Youth Table Tennis Players

xuanlin wang¹, Ziwei Cao¹, Yujie Tong¹, Bowen Liu¹, Xiaojian Shi², Gordon Waddington³, Roger Adams³, Jeremy Witchalls³, Allan Fu⁴, Jia Han¹. ¹shanghai university of sport, shanghai, China. ²The First Rehabilitation Hospital of Shanghai, shanghai, China. ³University of Canberra, Canberra, Australia. ⁴University of Sydney, Sydney, Australia.
(No relevant relationships reported)

Purpose The current study aimed to investigate the relationship between ankle proprioception and sport-specific performance in professional youth table tennis players. **Methods** 14 players competed nationally and internationally (Level 1, age=14.29±1.75 yrs, training years=7.36±1.84yrs) and the other 14 players competed regionally (Level 2, age=11.14±1.46 yrs, training year=4.11±0.97yrs) were recruited. All players had no lower limb injuries in the past 3 months. The dominant ankle proprioception was tested by using the active movement discrimination extent apparatus (AMEDA) under three randomized conditions: 1) single AMEDA (Single-A); 2) dual task AMEDA tested while performing forehand attack (Dual-FA), and 3) performing forehand loop (Dual-FL) to hit the topspin into a designated corner on the table, with their hitting rates (HR) recorded. The mean Area Under the ROC

Curve (AUC) was calculated for ankle proprioceptive discrimination sensitivity score. 2-way repeated measures ANOVA was performed to determine the differences among the 3 AMEDA tests for players between 2 levels, and Pearson's correlation evaluated among the measures. **Results** Repeated measures ANOVA showed significant main effects for task load AMEDA tests ($F=46.30, p<0.01$) and competition levels ($F=19.95, p<0.01$), with no significant interaction ($p>0.05$). A significant linear effect was found across the 3 task load conditions ($F=64.97, p<0.01$). Pearson's correlation showed that the HR for both Dual-FA and Dual-FL were significantly correlated with all 3 AMEDA scores (r ranged from 0.38 to 0.66, all $p<0.05$). In addition, years of training was significantly correlated with both HR for Dual-FA ($r=0.46, p=0.02$) and Dual-FL ($r=0.61, p<0.01$), as well as the proprioceptive AUC scores of both Single-A ($r=0.45, p=0.02$) and Dual-FA ($r=0.64, p<0.01$), but was not significantly correlated with the AUC scores of Dual-FL ($p>0.05$). **Conclusion** Ankle proprioception may be an essential ability underpinning sport-specific performance and was significantly impaired under the dual tasks in youth table tennis players. Testing ankle proprioceptive ability during Dual-FL may place demand on central resources not developed by training. These findings have implications for ankle injury prevention, table tennis training and talent identification.

3770 Board #87 May 30 8:00 AM - 9:30 AM

Predictors Of Obstacle Course Racing (OCR) Performance

Weston Titus¹, Richard F. Armenta², Matthew M. Schubert².
¹Palomar College, San Marcos, CA. ²California State University, San Marcos, CA.

Reported Relationships: W. Titus: Other (please describe): I was an employee of the gym where participants were recruited from and where data were collected at the time of this study (Fall 2018). I am no longer an employee at this facility.

Purpose: Obstacle course racing (OCR) has become a popular recreational activity in the last ~10 years, with more than 8.5 million participants. Despite the popularity, little is known about predictors of performance in OCR; research to date has focused on injury prevalence. The purpose of this study was to conduct laboratory and field tests of athletic performance in OCR athletes and examine their relationships to performance in a simulated OCR. **Methods:** Thirty-two men and women (mean \pm standard deviation (SD) age: 42 ± 10 years; OCR experience: 2.8 ± 2.3 years) completed laboratory testing for $\dot{V}O_{2\max}$, anaerobic power (Wingate), vertical jump, flexibility, and body composition. Additional field tests were completed for 400 meter and 1 mile running time, muscle strength (back squats and deadlifts) and endurance (bucket carry for distance), grip strength, and burpees. Participants also completed a 3-mile simulated OCR. Independent t-tests examined differences between sex and bivariate regressions were conducted between testing variables and OCR performance. **Results:** For the combined sample, the best individual predictors were mean relative power from the Wingate tests ($\beta \pm$ standard error (SE): -6.47 ± 1.12 minutes) and mile run time ($\beta \pm$ SE: 6.43 ± 0.71 minutes). Multivariable analysis controlling for age, sex, and mile run time found an independent association between bucket carry for distance and race time ($\beta \pm$ SE: -0.04 ± 0.01 minutes), but mile run time was still the best predictor ($\beta \pm$ SE: 6.33 ± 0.97 minutes). **Conclusions:** Data from the present study suggest that aerobic and anaerobic fitness have important contributions to OCR success.

Relationship Between Seated Single Arm Shot Put And Isokinetic Shoulder Flexion And Elbow Extension Strength

Matthew D. Watson, George J. Davies, Bryan L. Riemann.
Georgia Southern University - Armstrong Campus, Savannah, GA.

Email: watsonm32@gmail.com
(No relevant relationships reported)

PURPOSE: Previous studies have demonstrated a strong correlation between isokinetic pushing force and seated single-arm shot-put (SSASP) test performance. However, there is limited research on the contribution of shoulder flexion and elbow extension strength on SSASP test outcomes. Therefore, the purpose of this study was to examine the relationship between isokinetic shoulder flexion and elbow extension strength and SSASP test performance and compare limb symmetry indexes (LSI) between the two tests. **METHODS:** Healthy, physically active men ($n=16$, ages=21-34 yrs) and women ($n=15$, age=18-29 yrs) performed dominant (DOM) and nondominant (NDOM) shoulder flexion and elbow extension isokinetic tests (System 4, Biodex, Shirley, NY) at $60^\circ/s$ (5 repetitions) and $180^\circ/s$ (10 repetitions) to determine peak torque production. The average horizontal range from three SSASP (2.0kg ball) trials were computed separately for each limb. In addition to conducting correlational analyses between the

peak torques and SSASP distances, the differences in LSI computed between each of the peak torques and SSASP distances were statistically compared at each velocity by joint analysis of variance.

RESULTS: Significant ($P<0.001$) relationships were revealed between DOM and NDOM SSASP performance and shoulder ($r=.819$ to $.853$) and elbow ($r=.803$ to $.820$) peak torques at both velocities. LSI for the SSASP ($104.4 \pm 7.1\%$) were similar to the isokinetic LSI at both $60^\circ/s$ (Elbow: $101.3 \pm 10.2\%$, Shoulder: $102.2 \pm 13.8\%$) and $180^\circ/s$ (Elbow: $100.4 \pm 9.7\%$, Shoulder: $103.5 \pm 12.8\%$), with no statistically significant differences ($P=.364$ to $.844$, $\eta_p^2=.001$ to $.028$).

CONCLUSIONS: Results demonstrate shoulder and elbow isokinetic torques are strongly associated with SSASP distances. Moreover, LSI for both tests were not significantly different from each other, thereby supporting the utilization of the SSASP for making bilateral comparisons in healthy individuals.

Evaluating The Impact Of Competition On Vertical Jump Performance

Moroni de Moors¹, Anna Blackley¹, Andy Bosak¹, Austin Deshner¹, Abrahan Frech¹, Russell Lowell¹, Maggie McDermott¹, Grant Merry¹, Hannah Nelson², Madeline Shanahan¹, Branden Ziebell¹. ¹Liberty University, Lynchburg, VA. ²University of Mississippi, Oxford, MS. (Sponsor: Jim Schoffstall, FACSM)
Email: mdemoors@liberty.edu

(No relevant relationships reported)

PURPOSE: The vertical jump (VJ) test is used in athletic populations to assess lower body power and this value can be utilized as a predictor for sports performance. Incidentally, athletes have often elevated their level of performance in competitive environments. However, competition during assessment tests has not been widely examined. It is logical to assume that conducting the VJ test where subjects compete against each other may contribute to higher jumps. The purpose of this study was to determine if a competitive environment would have an impact on VJ performance in females.

METHODS: Twenty-six no less than averagely fit college females (age = 21 ± 1.86 years, Ht. = 166.53 ± 7.30 cm, Wt. = 64.47 ± 11.84 kg, BF% = $23.55 \pm 6.22\%$) completed a dynamic warm up followed by four minutes of passive recovery (PR). After the completion of familiarization jumps and a four-minute PR period, subjects completed two jump series (in a counterbalanced order, solo and competitive) consisting of six jumps per series. The competitive series consisted of two subjects jumping side by side against one another simultaneously. The highest jump, second highest jump, and average jump heights of the solo (SFHJ, SSHJ, SAJ) and competitive (CFHJ, CSHJ, CAJ) jumps were compared and analyzed using a paired-samples T-test ($p \leq 0.05$).

RESULTS: Significant differences occurred between: CFHJ (54.61 ± 1.31 cm) and SFHJ (53.34 ± 1.27 cm) ($p=0.001$); CSHJ (53.68 ± 1.32 cm) and SSHJ (52.27 ± 1.34 cm) ($p<0.001$); and CAJ (52.97 ± 1.31 cm) and SAJ (51.45 ± 1.33 cm) ($p<0.001$).

CONCLUSIONS: The results of this study suggest that a competitive environment for the VJ test does have an impact on VJ performance. Future research may need to assess the impact of a competitive environment on the VJ test utilizing athletes from sports where jumping actions are of extreme importance. Furthermore, an evaluation of the competitive environment on other power tests, such as the broad jump, should occur.

Audience Presence Prolongs Maintenance Of Peak Power In Maximal Anaerobic Activity

Evelyn N. Delgado, Adriana P. Pantoja, J. Mark VanNess, Courtney D. Jensen. University of the Pacific, Stockton, CA.
Email: evelyn.delgado.pt@gmail.com

(No relevant relationships reported)

Sport participation commonly occurs in front of an audience. It is important to know if the presence of that audience influences the force profile of the performer. **PURPOSE:** To examine the influence of spectator presence on power output in a short-duration, high-intensity activity. **METHODS:** We tested 15 men and 28 women, ages 18-25, on a 30-second Wingate cycle ergometer test. All subjects were tested twice, separated by 72 hours. During one trial, performance took place in front of the test administrator; during the other trial, the administrator was accompanied by an audience. Spectators observed but did not interact with the subjects. Testing conditions (e.g., time of day, instructions provided, and verbal encouragement) were identical in the two trials. The order of tests was assigned in a counter-balanced design. Mixed ANOVA with repeated measures was used to compare peak power (PP), duration of peak power (DPP), and mean power (MP) between the two trials overall and by sex. **RESULTS:** Subjects were 20.4 ± 1.4 years of age; across all testing, PP 1.7 ± 1.3 w/kg, DPP was 2.6 ± 3.5 seconds, and mean power was 1.2 ± 0.3 w/kg. There was no effect of test order on performance ($p=0.199$). Similarly, there was no effect of audience presence on PP ($p=0.348$) or an interaction effect with sex ($p=0.406$). There was an increase

in MP in the audience trial; subjects were 0.1 w/kg higher, corresponding to a 6.5% increase ($p=0.003$; 95% CI: 0.03 to 0.13 w/kg). There was no interaction effect with sex ($p=0.416$). The increase in MP was the result of an increase in DPP, which was 1.6 seconds longer in the audience trial, corresponding to a 91.6% increase ($p=0.002$; 95% CI: 0.61 to 2.49 seconds). There was no interaction effect with sex ($p=0.418$). **CONCLUSIONS:** The presence of an audience influenced power output on the Wingate test. Although peak power was unaffected, the duration peak power was maintained nearly doubled, indicating endurance at peak performance may be sensitive to arousal.

Combined Driving: Task-specific Position Impacts Grip Strength Of Equestrian Athletes

Michaela Keener, Kimberly I. Tumlin, Nicholas R. Heebner.
University of Kentucky, LEXINGTON, KY. (Sponsor: John Keener, FACSM)
 Email: keene036@d.umkn.edu
(No relevant relationships reported)

Equivalent to a human triathlon, combined driving is an equestrian sport designed to test ability to navigate horses and carriage during three phases. Drivers control up to four horses at a time relying heavily on hand strength. **PURPOSE:** to 1) establish baseline data on grip strength and endurance of combined drivers in standing and task-specific positions; and 2) compare grip values to normative data by driver age. **METHODS:** Drivers were included if medically cleared to actively compete, and free from current injury. Fifty-one combined drivers (9 males, 42 females) ages 21-78 participated during two nationally recognized events. All drivers were right hand dominant. 63% of drivers were over 50 y/o. 22% of drivers reported having arthritis in their hands/wrists. Drivers completed a demographics and sport-specific survey, and three grip tests in two positions: standing and task-specific (sitting). Measures included peak values and endurance. Peak grip was recorded into four categories based on normative values.

RESULTS: Females with more than 30 yrs of driving experience had higher strength in the non-dominant hand ($p=0.0345$). There was a significant difference between strength based on position for both sexes (Table 1). Over 45% of females were stronger than normative data for both dominant and non-dominant hand, while only 22% of males fell in the stronger category. Female drivers average hand grip strength was 1.25 times greater than the normative population. The endurance for all subjects was significantly higher for the right hand ($p=0.002$). **CONCLUSIONS:** This study is the first to establish standing and task-specific grip strength in combined drivers. Female drivers over 50 y/o demonstrated greater hand strength in their non-dominant hand, suggesting continuous use of hands for driving promotes strengthening muscle and maintaining hand function regardless of reported arthritis. Results demonstrated equestrian driving is beneficial to hand grip strength.

Table 1. Average peak grip strength while standing and sitting by sex.

	Average Standing Peak - Right (kg)	Average Standing Peak - Left (kg)	Average Sitting Peak - Right (kg)	Average Sitting Peak - Left (kg)
Males	43 ± 5.1	44 ± 6.9	38 ± 7.5 ^b	36 ± 9.3 ^b
Females	32 ± 6.5 ^a	30 ± 6.2 ^a	25 ± 8.3 ^{a,b}	23 ± 8.1 ^{a,b}

Note: Values are displayed as mean ± SD.

^adenotes significant difference ($p<.05$) between right and left

^bdenotes significant difference ($p<.05$) between sitting and standing

Differences In Player Metrics Between Lacrosse Games And Practices

Kinta Dillon Schott, Ryan T. Connors, Paul N. Whitehead.
University of Alabama Huntsville, Huntsville, AL. (Sponsor: Don Morgan, FACSM)
(No relevant relationships reported)

Lacrosse participation in the United States has rapidly increased in recent years, however there is minimal research related to the sport. Existing research has mainly utilized laboratory-based testing procedures. There is a need to understand the physiological demands of players during live play to assist coaches with the training and conditioning necessary for improved player performance. **PURPOSE:** To compare player metrics of high school male lacrosse players during games and practices.

METHODS: A team heart rate monitoring system with an internal global positioning system and gyroscope was used to record internal player metrics (heart rate [HR], calories) and external player metrics (duration, distance, speed, sprints). Participants in the study consisted of 13 male high school club lacrosse players (16.2 ± 1.5 yr; 175.3 ± 7.7 cm; 69.9 ± 13.6 kg). Subjects were monitored during two practices (130.9 ± 5.2 minutes) and one game (39.58 min). Differences in player metrics were compared by session, as well as by position: attack, midfield, defense, and face-off-get-off (FOGO). Game and practice data were compared utilizing paired samples *t*-tests, while individual position metrics were analyzed by independent sample *t*-tests. A standard

$p \leq .05$ was used to determine significance for the analyses. Effect sizes (*r*) were also calculated for each comparison. **RESULTS:** Significant differences and large effect sizes were found for average HR, total calories, and caloric expenditure ($t \geq 4.2$, $p \leq .003$, $r \geq .590$). Significant differences and large effect sizes were also found for duration, total distance covered, and number of sprints between game and practice sessions ($t \geq 2.32$, $p \leq .049$, $r \geq .253$). Positional comparisons identified significant differences and large effect sizes between midfield and FOGO positions for maximum HR ($t = 2.411$, $p = .028$, $r = .525$) and number of sprints ($t = 3.242$, $p = .005$, $r = .745$). **CONCLUSION:** The results of the study suggest that both internal and external metric requirements differ between high school lacrosse practice and game sessions, as well as across varying positions. This data could be used to alter practice sessions to better mimic the higher intensities of games and provide coaches the ability to train athletes at game-like and position-specific intensities.

3776 Board #93 May 30 8:00 AM - 9:30 AM
Performance Profile Of International Male Lacrosse Players

Richard Hauer¹, Antonio Tessitore², Harald Tschan¹. ¹University of Vienna, Vienna, Austria. ²University of Rome "Foro Italico", Rome, Italy.
 Email: richard.hauer@univie.ac.at
(No relevant relationships reported)

PURPOSE: Even with its rising participation numbers worldwide, there has been little quantitative analysis on the activity profile of Lacrosse players. Therefore, this study aimed to determine (a) the overall activity profile and differences over the course of play, and (b) differences between players position.

METHODS: Data involved eight World Championships games of the male Austrian lacrosse national team using micro technological devices. Assessed parameters included total distance covered (m), mean heart rate (%HR_{mean}), time spent in four different HR-zones (HRz) (<75; 75-84.9; 85-89.9; ≥90%), distance covered (m) in five different Speed-zones (Sz) (0.0-0.2; >0.2-1.8; >1.8-3.3; >3.3-5.7; >5.7m/s), and mean respiratory frequency (RF). Additionally to total game values differences between quarters and players position were analyzed. Statistical significance was set at $p \leq 0.05$ and for an estimate of effects Cohen's ES was calculated.

RESULTS: Overall activity results show a total distance covered of 4,511.6 ± 1,151.3m, a RF of 25.4 ± 1.7bpm, and a HR_{mean} of 72.3 ± 5.1%. Greatest distance was covered in Sz 2 (1,578.4 ± 627.2m), and most of the time spent in HRz 1 (3,028.4 ± 714.2s). Comparison between quarters showed lower HR_{mean} values ($p=0.00$; $n^2p=0.08$), more time spent in HRz 1 ($p=0.00$; $n^2p=0.12$) and less in HRz 3 ($p=0.03$; $n^2p=0.03$) and HRz 4 ($p=0.00$; $n^2p=0.09$), and a lower RF ($p=0.00$; $n^2p=0.09$) over the course of play. Regarding players position, attackers showed more time spent in HRz 2 compared to other positions (1,482.3 ± 51.2s; $p=0.00$; $n^2p=0.69$), and covered greater distance in Sz 2 (2,275.8 ± 149.4m; $p=0.01$; $d=3.10 \pm 1.55$) compared to midfielders. On the other hand, midfielders showed greater distance covered in Sz 4 (1,334.0 ± 320.9m; $p=0.05$; $d=1.32 \pm 1.15$) compared to defenders.

CONCLUSIONS: Players' profile data are in agreement with recent research. Furthermore, results indicate a reduction of activity along with an increase of physical stress over the course of play. Regarding players position our findings support the hypotheses that midfielder are exposed to higher intensity bouts with longer rest periods compared to other positions. Overall, findings will be of interest for coaches and practitioners for a deeper understanding of demands players are exposed to in lacrosse match-play.

An Evaluation Of Internal And External Load Metrics In Games In Women'S Collegiate Lacrosse

Jennifer Bunn, FACSM, Mary Reagor, Bradley J. Myers.
Campbell University, Buies Creek, NC.
 Email: bunnj@campbell.edu
(No relevant relationships reported)

PURPOSE: There is little published data to guide coaches and sport scientists about important variables for measuring game and training load in sports outside of soccer and rugby. The purpose of this study was to statistically evaluate the relationship of internal and external load metrics in women's collegiate lacrosse games.

METHODS: Twelve Division I collegiate female lacrosse players wore a heart rate (HR) monitor and global positioning system (GPS) during 17 intercollegiate games. Seven measures determined training load: two internal measures [mean HR and training impulse (TRIMP)] and five external measures [total distance, high-intensity distance (HID), distance rate, accelerations, and decelerations]. The training load measures were analyzed for the whole game and by first and second halves. Principal component analysis (PCA) was used to determine which internal and external load variables were most associated with each portion of the game. A paired samples *t*-test was used to compare differences in first and second half metrics.

RESULTS: The whole game and each half extracted only one principal component. For the whole game, HID, decelerations, accelerations, TRIMP, and total distance

explained 58% of the variance ($p < .001$). The same metrics explained 55% of the variance for the first half ($p < .001$). For the second half, the same metrics with the addition of distance rate explained 57% of the variance ($p < .001$). Interestingly, the distance rate measure was only significant in the second half, although total distance contributed the most to the component, as it did in the first half and whole game data. The paired samples t-test showed differences between first and second halves for HID ($p < .001$), accelerations ($p < .001$), decelerations ($p < .001$). In all cases, there was greater distance and more intense efforts in the first half than the second.

CONCLUSIONS: These results show that a combination of internal and external load measures should be used to determine load during games. The loaded metrics should be compared to a complimentary analysis for drills to ensure that training load metrics are similar. These data also support the concept of reduced high-intensity performance in the second half. This information should be used to bolster appropriate training methods to improve second half fitness.

Cut-Off Values In The Prediction Of Success In Olympic Distance Triathlon

André B. Gadelha¹, Marcelo M. Sales², Marti Flothmann³, Lucas P. Barbosa⁴, Samuel S. Aguiar⁴, Rafael R. Olher⁵, Elias Villiger⁶, Pantelis T. Nikolaidis⁷, Beat Knechtle⁸, Caio V. Sousa⁹. ¹Federal Institute of Education, Science and Technology Goiano, Urutai, GO, Brazil. ²Goiás State University, Quirinópolis, GO, Brazil. ³University of Miami, Miami, FL. ⁴Catholic University of Brasília, Brasília, DF, Brazil. ⁵Centro Universitário do Planalto Central Aparecido dos Santos, Gama, DF, Brazil. ⁶University of Zurich, Zurich, Switzerland. ⁷University of West Attica, Athens, Greece. ⁸University of Zurich, Zurich, Swaziland. ⁹Northeastern University, Boston, MA.
 Email: andrebonadias@gmail.com
 (No relevant relationships reported)

PURPOSE: To determine cut-off values to reach a Top-3 position in an Olympic distance triathlon by investigating which discipline has the most influence in overall race performance, and whether or not this has changed over the decades.

METHODS: Data from 1989 to 2018 of 33,099 men and 18,928 women ($n=52,027$) who competed in the Triathlon World Cup, World Triathlon Series, and Olympics race events were included. In addition to exploratory data analyses, linear regressions were applied for performance trends in overall and top-3 of each race. A t-test for independent samples was applied for sex comparison. Multivariate analysis was performed to assess which discipline may have the greater influence. The cut-off value to achieve a top-3 position was calculated.

RESULTS: The cut-off values for Men were: swimming=19.5min; cycling=60.7min; running=34.1min. Women's cut-off values were: swimming=20.7min; cycling=71.6min; running=38.1min. Based on this analysis, it was shown that running is the discipline with the most influence on overall race time for men, while swimming is the discipline with most influence for women. Cycling is the discipline with least influence on overall race performance for both men and women.

CONCLUSIONS: In conclusion, the established cut-off values were set in order to increase the chances of achieving a successful rank in an Olympic distance triathlon. In summary, swimming split seems to be the better predictor of overall race performance in women, while running time is a better predictor for men. Our analyses showed that this influence pattern has not changed in the last three decades.

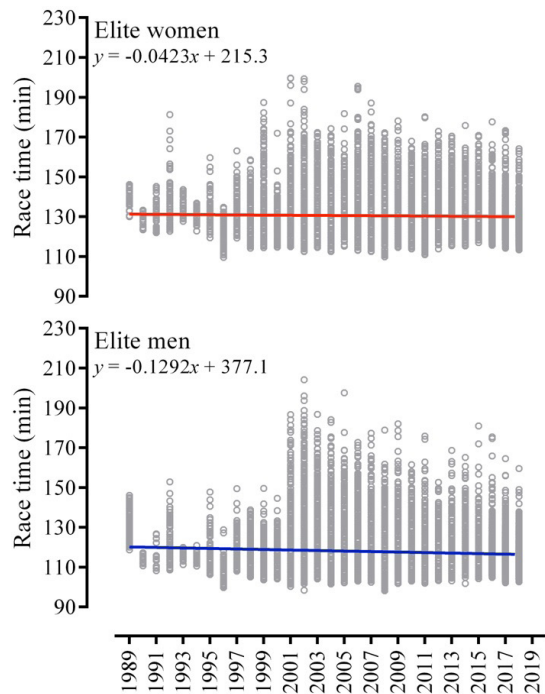

Figure 1. Performance trend of overall race time in Olympic distance triathlon from 1989 to 2018 in men and women.

Abstract Withdrawn

3780 Board #97 May 30 8:00 AM - 9:30 AM
Differences In Mechanics Between First And Second Drop Vertical Jump Landings
 Kirsten R. Buchanan¹, Devin Finnegan¹, Brooke Flaherty¹, Jordan Lamb¹, Elisabeth Michaud¹, Bryan Raksnis¹, Irene Davis, FACSM². ¹University of New England, Portland, ME. ²Harvard Medical School, Cambridge, MA. (Sponsor: Irene Davis, FACSM)
 Email: kbuchanan@une.edu
 (No relevant relationships reported)

PURPOSE: A drop jump and landing, followed by another maximal jump and landing, has been used when assessing injury risk using the Landing Error Scoring System (LESS). The LESS provides a way to measure frontal and sagittal plane alignment during landing and has traditionally used the first, but not the second, landing for assessment. Additionally, vertical ground reaction force (vGRF) and knee excursion are commonly analyzed during a drop vertical jump. The purpose of this study was to investigate whether there was a difference in LESS scores, vGRF, and knee excursion between the first and second landings of the drop vertical jump.
METHODS: Forty healthy subjects performed a drop vertical jump from a 30 cm box with an initial landing (L1) immediately followed by a second maximal jump and landing (L2). Three trials were scored using the LESS. Subjects were dichotomized as "high risk" on the LESS if they had a score greater than 5 (including moderate and poor scores) and "low risk" (including good and excellent scores) if they scored 5 or under. Jump height, peak vGRF, and knee excursion were recorded using an in-ground force plate and a 3-D motion analysis system. To further analyze the data, subjects were separated into "high" and "low" jumpers by dichotomizing the average jump height. Statistical analysis was performed with SPSS (version 25.0) to identify whether there were significant differences in LESS scores, peak vGRF, and knee excursion between landings for all subjects and "high" and "low" jumpers.

RESULTS:

Table 1. Comparisons of Average Total LESS Score, Peak vGRF and Knee Excursion Between L1 and L2 for "All Subjects" and "Low" and "High Jumpers."

	All Subjects				Low Jumpers				High Jumpers			
	L1	L2	p-value (alpha=.05)	n	L1	L2	p-value (alpha=.05)	n	L1	L2	p-value (alpha=.05)	n
LESS score	4.46 ± 2.12	6.25 ± 3.04	0.001	40	5.03 ± 2.31	7.49 ± 2.73	0.001	21	3.82 ± 1.73	4.88 ± 2.83	0.071	19
Peak vGRF (N/kg)	1.98 ± 0.59	2.57 ± 0.74	0.001	39	2.08 ± 0.63	2.50 ± 0.74	0.003	21	1.86 ± 0.54	2.66 ± 0.76	0.001	18
Knee excursion (degrees)	66.13 ± 17.07	72.39 ± 26.21	0.051	39	60.41 ± 17.08	63.63 ± 27.55	0.41	21	72.8 ± 14.86	82.6 ± 20.93	0.067	18

CONCLUSIONS: The significant increase in LESS scores and peak vGRF between landings suggests that the second landing may be more indicative of injury risk when using the LESS. Low height jumpers had greater injury risk due to significantly higher LESS scores and minimal changes in knee excursion from landing one to landing two.

3781 Board #98 May 30 8:00 AM - 9:30 AM
"Critical Oxygenation Model": A Novel Approach To A Classical Fatigue Threshold

Andri Feldmann. *University of Bern, Bern, Switzerland.*
 Email: andri.feldmann@ispw.unibe.ch

Reported Relationships: A. Feldmann: Industry contracted research; Idiaq AG. Ownership/interest/stock; Moxy Monitor.

PURPOSE: The critical power (CP) model identifies a performance-based fatigue threshold which can be effectively used to predict time to task failure (TTF). The model's hyperbolic form identifies a clear asymptote (CP) which determines an over-under threshold with which an athlete can perform a task. Tasks over CP result in a depletion of work potential (W') which ultimately results in failure when W' is depleted. CP and W' are performance characteristics and the physiological mechanism behind this phenomenon remain difficult to pinpoint. Nonetheless, performance above CP is characterised by unsustainable metabolic process which are a potential explanation for failure. A physiological measure that could represent CP and W' would enhance the model's effectiveness for athletics. Muscle oxygenation (SmO2) as measured by Near-infrared spectroscopy (NIRS) offers itself as a potential physiological surrogate for CP and W', through a time-SmO2 integral (O') identifying unsustainable metabolic process.

METHODS: Eighteen participants (age: 21±1.7; weight: 68±11.1 kg) performed three trials of single-leg knee extensions, at 5%, 10% and 20% 1-RM, to exhaustion in order to evaluate individual power-duration curves. In order to eliminate the effect of blood flow knee extension trials were performed in occluded conditions (pressure cuff >300mmHg). NIRS and EMG sensors were placed on the vastus lateralis, vastus medialis and rectus femoris. O' of the NIRS curve was calculated for each trial.

RESULTS: The CP model predicts that W' is constant across tasks to failure. The same prediction was made for O'. The results suggest that this assumption is correct and O' remains constant for TTF; 5% 1-RM: M = -43.85, SD = 17.93, [95% CI: -35.3, -52.5]; 10% 1-RM: M = -44.75, SD 17.76, [95% CI: -36.2, -53.3]; 20% 1-RM M = -44.79, SD 16.16 [95% CI: -37.0, -52.5]. **CONCLUSIONS:** SmO2 represents a dynamic balance between O2 supply and O2 demand in real-time. An imbalance between O2 supply and O2 demand effects local muscle metabolism resulting in accumulating fatigue which if not restored results in specific TTF. The consistency between O' and TTF over the power-duration curve suggest potential for a physiological approach to a classical performance threshold. This knowledge could be invaluable to TTF prediction at an individual physiological level.

Effects Of Different Intensity And Duration Of Warm-up On Hemodynamics, Jump Power, And Flexibility.

Imtiaz Masfique Dowllah, Ezra Meza, Amanda Hankins, Orlando Cepeda, Klarissa Ybarra, Brenda Palma, Brianna Lopez, Manuel Nunez, Alexandria Hinojosa, Ulku Karabulut, Murat Karabulut, FACSM. *University of Texas Rio Grande Valley, Brownsville, TX.*

Email: imtiazmasfique.dowllah01@utrgv.edu
 (No relevant relationships reported)

PURPOSE: Tabata protocol (TP), usually consisting of eight to nine bouts of 20-sec of maximal exercise with 10-sec rest, is time-efficient intervention with both aerobic and anaerobic benefits. This study investigated the effectiveness of different variations of TP as a warm-up procedure.

METHODS: Twenty-five healthy subjects (13 females and 12 males) participated in this study. Participants performed 6 randomized exercise sessions separated by at least 48 hours. The exercise sessions involved 3-min (TP3-20:10; TP3-30:10), 5-min (TP5-20:10; TP5-30:10) or 8-min (TP8-20:10; TP8-30:10) consecutive bodyweight squats

of either 20-sec workout with 10-sec rest (20:10) or 30-sec workout with 10-sec rest (30:10). Heart rate (HR), blood pressure (BP), thigh skin surface temperature (TT), vertical jump performance (VJ), and flexibility (F) were measured before and after execution of the protocols. Countermovement jump was used to measure VJ and sit-and-reach test was used for measuring F.

RESULTS: Two-way ANOVA demonstrated significant condition*time interaction (p<0.01) and time main effect (p<0.01) for F. Significant condition*time interaction (p<0.01) and condition (p<0.01) and time main effects (p<0.01) were observed for HR. There were significant main effects for time with the post-test demonstrating higher values than the pre-test values for both SBP and DBP (p<0.01). Significant time main effect (p<0.01) was also noted for TT indicating reduction in TT following exercise bouts.

CONCLUSIONS: The findings are suggestive of a decrease in F following a higher duration of exercise (TP8-20:10 and TP8-30:10). This may be ascribed to greater accumulation of metabolites (lactic acid, ammonia, and hydrogen ion) in the working muscles, which may alter Type III and IV afferent neural activity to increase pain perception. Local tissue acidosis also stimulates bradykinin release, which may contribute to the transmission of nociceptive signals from skeletal muscle. Additionally, higher duration of exercise may increase cortisol level that decreases the pain threshold level. Therefore, the decreases in flexibility may be explained by one or a combination of metabolic, hormonal, and neurobiological changes stimulating the brain to inhibit the muscular response.

Is Better Freestyle Swimming Technique Associated With Better Performance?

Travis R. Pollen¹, David Ebaugh², Jason H. Mohring¹, Sheri P. Silfies³. ¹Drexel University, Philadelphia, PA. ²University of Delaware, Newark, DE. ³University of South Carolina, Columbia, SC. (Sponsor: Clare Milner, FACSM)
 Email: trp59@drexel.edu

(No relevant relationships reported)

Swimming technique is widely believed to influence performance, but few studies have quantified this relationship using an objective, pool-side technique assessment.

PURPOSE: To determine the relationship between freestyle swimming technique and swimming performance using a poolside technique assessment. **METHODS:** Freestyle swimming was assessed for technique errors during normal practice near the beginning of the season in 27 Division III college swimmers (16 females, 19±1 years, 1.75±0.11 m, 71.0±10.4 kg). Seven freestyle swimming techniques were considered errors: (1) hand crossing the midline of the body at entry, (2) straight-arm recovery, (3) hand entering with the thumb first, (4) inadequate or excessive shoulder roll, (5) hand crossing the midline of the body during the underwater pull-through, (6) elbow dropping during the pull-through, and (7) excessive neck flexion/extension. Six of the errors were assessed bilaterally, resulting in a maximum possible score of 13 errors. Swimming performance was determined by each participant's best freestyle event from the end-of-season meet as a percentage of the conference record. The correlation between errors and performance was assessed with Pearson's r. One participant was removed due to a late-season injury that affected their ability to train and compete.

RESULTS: Participants averaged 2.7±1.7 errors (range: 0-5). Their performance averaged 94±3% of the conference record (range: 87-99%). There was a significant negative correlation of moderate strength between number of errors and performance: r = -0.59, p = 0.01, R² = 0.35 (Figure). Fewer errors corresponded with better performance. **CONCLUSION:** The fewer freestyle technique errors a swimmer made, the faster their best freestyle race time was as a percentage of the conference record. Technique explained 35% of the variance in performance. This study is one of the first to demonstrate this relationship using objective, pool-side assessment criteria.

3784 Board #102 May 30 8:00 AM - 9:30 AM

Acute Effects Of Squat Position And Whole-body Vibration Frequencies On Muscular Function And Jump Performance

Jonathan Tyler Gonzalez, Imtiaz Masfique Dowlah, Gualberto Garza, IV, Nancy Calle, Galilea Chapa, Julissa Perez, Jose M. Sosa, Liana Chee, Ulku Karabulut, Murat Karabulut, FACSM. *University of Texas Rio Grande Valley, Brownsville, TX.*
Email: jonathan.gonzalez01@utrgv.edu

(No relevant relationships reported)

PURPOSE: To determine the acute effects of different whole-body vibration (WBV) frequencies and squat depths on lower extremity isometric and isokinetic muscle function and vertical jump performance.

METHODS: Thirteen healthy male (age = 23.8 ± 5.3 years) and fifteen healthy female subjects (age = 22.45 ± 3.04 years) performed six randomized sessions of vibration protocols (VPs) in different squat positions with 90° (low-squat) and 140° (high-squat) knee flexion angle at 30 Hz (30Hz90°; 30Hz140°), 40 Hz (40Hz90°; 40Hz140°) & 50 Hz (50Hz90°; 50Hz140°). Each subject performed 5 sets x 1-min of static squats with 30-sec rest between each set. Then they rested for 5-min and repeated 5 more sets. Once completed, vertical jump performance was measured. Furthermore, subjects were tested for maximum 5-sec right knee extensor isometric contractions at 60° of knee flexion, and isokinetic concentric knee extension and flexion at 180°/sec, utilizing standard Biodex protocol. All VPs were performed on the same commercial side to side alternating vibration platform and foot placement for all squats was recorded to ensure consistency.

RESULTS: Two-way repeated measures ANOVA indicated a significant condition main effect in average jump height ($p < .01$) and average jump time ($p < .001$), denoting enhanced jump performance following 40Hz140° ($p < .05$) and 50Hz140° ($p < .01$) compared to 50Hz90°. A significant condition main effect was found in peak-torque during the isokinetic test, where observed changes were greater for both 30Hz140° and 40Hz140° compared to 30Hz90° ($p < .05$) and 50Hz90° ($p < .01$). Lastly, the best performance on peak-torque during the isometric test was significantly higher after 30Hz140° ($p < .05$) and 40Hz140° ($p < .05$) compared to 50Hz90°.

CONCLUSIONS: The findings are suggestive of greater muscular strength and explosive power production following a high-squat WBV warm-up compared to low-squat WBV warm-up. This can be attributed to augmented muscle fatigue and/or increased muscle length due to the plasticity of skeletal muscle while performing low-squat WBV warm-up, resulting in impaired ability to produce muscular force.

3785 Board #102 May 30 8:00 AM - 9:30 AM

Circulating Brain Derived Neurotrophic Factor (BDNF) In Response To Three-day Ultra-endurance Racing

Stephanie D. Gipson, Shiloah A. Kviatkovsky, Adrian P. Othon, Alex O. Klemp, Jeong-Su Kim, FACSM, Michael J. Ormsbee, FACSM. *Florida State University, Tallahassee, FL.* (Sponsor: Dr. Michael J. Ormsbee, FACSM)
Email: sdg13b@my.fsu.edu

(No relevant relationships reported)

Cardiovascular exercise is known to exert a variety of positive physiological and psychological benefits on neurocognitive function, glucose and fatty acid metabolism, and muscle recovery. Many of these effects are thought to be mediated by brain derived neurotrophic factor (BDNF), a neurotrophin produced both centrally and peripherally. The fate of BDNF during prolonged endurance exercise is unknown and may be implicated to mitigate potential negative consequences to ultra-endurance racing.

PURPOSE: To investigate the effects of a three-day ultra-endurance triathlon on serum BDNF concentrations pre- and post-race. **METHODS:** Twenty triathletes (age: 40 ± 8.8 yrs) who competed in the 2015 (N=13 men, 3 women) and 2017 (N=3 men, 1 woman) Ultraman Florida triathlon participated in the present study. Blood samples were collected 24-36 hrs pre-race and within 12 hrs post-race. Serum BDNF levels were measured via ELISA. A paired sample t-test was used to evaluate differences between pre- and post-race BDNF concentrations. Values are reported as mean ± SD with significance accepted as $p < .05$. **RESULTS:** BDNF significantly increased from pre- to post-race (0.17 ± 0.9 pg/mL vs. 0.23 ± 0.14 pg/mL; +9.6%; $p < .05$). **CONCLUSIONS:** For the first time, BDNF is shown to significantly increase after a three-day ultra-endurance race. These findings may indicate that BDNF concentrations are elevated to potentially counteract any negative consequences derived from ultra-endurance exercise. The influence of both duration and intensity of exercise on BDNF concentrations need to be further elucidated due to its array of positive implications on cognitive and physical function and recovery from prolonged endurance exercise. Supported by the International Society of Sports Nutrition and Florida State University.

Analyzing The Impact Of Body Composition On Vertical Jump Performance In Collegiate Female Volleyball Players

Andy Bosak, Chris Carver. *Liberty University, Lynchburg, VA.*
Email: ambosak@liberty.edu

(No relevant relationships reported)

The vertical jump (VJ) test is often used in sport and recreational performance sectors. Prior studies have examined the effects that anthropometric and body composition values have on VJ performance in no less than averagely fit populations. Yet, it appears that no study has evaluated the relationship between body fat percentage (BF), body mass index (BMI), lean leg mass (LLM), and trunk lean mass (TLM) on VJ performance using collegiate female volleyball players. **PURPOSE:** To assess the relationship between BF%, BMI, LLM, and TLM on VJ performance in collegiate female volleyball players. **METHODS:** After having descriptive data recorded, 12 female collegiate volleyball players had their BF%, BMI, LLM, and TLM assessed via dual-energy x-ray absorptiometry. Subjects had their reach height measured, participated in an 8 min dynamic warm-up, were then given a 4 min passive recovery (PR) period after the warmup, and then completed three familiarization jumps (ie. trials) using a VJ measurement device. After another 4 min PR period, subjects completed one series of six jumps with 30 secs of PR between each jump. Pearson Correlations were then performed between BF%, BMI, LLM, TLM, and VJ (ie. the highest of the six jumps) with significance differences determined at $p \leq 0.05$. **RESULTS:** A non-significant low negative correlation existed between BF% and VJ ($r = -0.350$, $p = 0.132$), yet a non-significant low correlation occurred between BMI and VJ ($r = 0.371$, $p = 0.117$), TLM and VJ ($r = 0.265$, $p = 0.202$), and LLM and VJ ($r = 0.372$, $p = 0.117$). **CONCLUSIONS:** BF% appears to have a low negative relationship with VJ performance in collegiate female volleyball players, while TLM, BMI, and LLM have a low relationship with VJ performance. Having a lower BF% may not necessarily predict higher jumping performance in collegiate female volleyball players. Further research may be required to determine if gender, fitness level, or a different type of body fat percentage measurement technique may play a factor when considering if BMI, BF%, LLM, and TLM have a relationship with VJ performance in athletes who specialize in sports with repetitive jumping movements.

Effect Of A 2-km Swim On The Cycling Power-Duration Relationship

George H. Crocker¹, Jeffrey Rothschild², Ailish C. Sheard¹.
¹Cal State LA, Los Angeles, CA. ²Sports Performance Research Institute New Zealand (SPRINZ), Auckland, New Zealand.
 Email: gcrocker@calstatela.edu
 (No relevant relationships reported)

PURPOSE: Triathlon combines three sports (swimming, cycling, and running) into a single race and, because triathletes must cycle after the swimming, it is important to understand how cycling power may be affected by prior swimming. Therefore, the purpose of this study was to determine the effects of a 2-km swim at a self-selected race pace intensity on the cycling power-duration relationship measured during a 3-min all-out cycling test (3MT). **METHODS:** Eighteen trained triathletes (12 M, 6 F; 37.1 ± 10.6 years, $\dot{V}O_{2max}$ 54.8 ± 10.1 ml·kg⁻¹·min⁻¹) performed two 3MTs on separate days with one 3MT immediately following a 2-km swim (swim-bike; SB) and one without prior swimming (bike only; BO). The power-duration relationship was expressed as the total work done and subdivided into the end-test power (EP) and work done above EP. To assess swimming intensity, heart rate (HR) was continuously monitored during the swim and blood lactate was assessed immediately following the 2-km swim. **RESULTS:** End-swim lactate was 4.2 ± 1.8 mM and mean swimming heart rate was 147 ± 18 bpm. The 2-km swim decreased total work done during the 3MT by 6% (BO: 62.8 ± 12.7 kJ; SB: 58.9 ± 13.4 kJ; p = 0.001) though neither EP (BO: 281 ± 65 W; SB: 269 ± 68 W; p = 0.102) nor work done above EP (BO: 12.1 ± 3.8 kJ; SB: 10.5 ± 4.2 kJ; p = 0.096) differed between trials. Peak power was also assessed during the 3MT and did not differ between trials (BO: 552 ± 142 W; SB: 541 ± 147 W; p = 0.097). The change in EP was inversely correlated to the change in work above EP (r = -0.624; p = 0.006). **CONCLUSIONS:** Total work done while cycling decreases following a 2-km race pace swim, although neither EP nor work above EP changed significantly. Triathletes may want to determine race cycling power following swimming because prior swimming affects performance during the 3MT. Future studies should look at how different swim pacing strategies affect the cycling power-duration relationship.

The Effect Of Team Winning Percentage On BCS Football Recruit Strength And Speed Characteristics

Anthony Caterisano, FACSM¹, Mike Gentry², Michael J. Caterisano¹, Charles Shaner¹. ¹Furman University, Greenville, SC. ²Virginia Tech, Blacksburg, VA.
 Email: tony.caterisano@furman.edu
 (No relevant relationships reported)

Due to the volatility of NCAA Division I BCS Football coaching and support staffs, it is difficult to collect reliable, longitudinal data using consistent physical performance tests on players entering the program. The data set in the current study represents a twenty-nine - year period collected by the same Head Strength and Conditioning Coach in the same football program. **Purpose:** The purpose of the study was to compare the physical testing of the players entering the program in the early years, (1987 -1998) of the Head Football Coach's tenure, when the team studied winning percentage was (56.5%) to a later period (1999-2014) when the team's winning percentage improved to (73.3%). **Methods:** A cohort of 1094 NCAA Division I BCS level football players that played at the same institution under the same Head Football Coach and Head Strength and Conditioning Coach during the years of 1987-2104 were divided into two groups depending on the era in which they played. Group One (G1 n=581) played between 1987 and 1998 (12 year period). Group One's win/loss record was 77-59, with a (56.5% winning percentage). Group 2 (G2 n=513) played between 1999 and 2014 (16 year period) the team win/loss record was 154-56 during this period representing a (73.3% winning percentage). Data were collected when each athlete joined the team in the following areas across the entire twenty-nine-year period. Measurements were collected in Height (HT), Body Mass (BM), One Repetition Maximum (1RM) in the Bench Press (BP), the Vertical Jump (VJ), and 40-yard dash (40YD). All data were collected by the same Head Strength and Conditioning Coach. All data were analyzed using paired t-tests for each parameter tested. **Results:** G2 had significantly better initial test results in each of the following tests: BM (106.9 vs 101.7 kg.; P<0.01), BP (133.3 vs 124.9 kg.; P<0.01), VJ (30.1 vs 27.0 in.; P<0.01), and 40YD (4.8 vs 5.0 sec.; P<0.01). **Conclusions:** The results suggest that having a successful football program at the Division I BCS level may attract recruits that are bigger, stronger in the upper body, with greater lower body power and running speed. Although it may not be the only thing that affects the decision of 4 and 5-star athletes to sign with a Division I BCS football team, it appears to be a major factor.

3789 Board #106 May 30 8:00 AM - 9:30 AM
Predicting Success In NCAA Division I Football Linemen Based On Physical Performance Test Results

Charles Shaner¹, Mike Gentry², Anthony Caterisano, FACSM¹, Michael J. Caterisano¹. ¹Furman University, Greenville, SC. ²Virginia Tech, Blacksburg, VA. (Sponsor: Anthony Caterisano, FACSM)
 (No relevant relationships reported)

A recent study looked at the relationship between performance variables and success in the NFL among players who participated in NFL combine events, which featured college seniors aspiring to make an NFL roster in different positions. To date no studies have looked at a similar relationship among college football players, who aspire to make an NCAA Division I football starting roster. **Purpose:** The purpose of the study was to identify performance variables that predict success among aspiring Division I (D-I) college football Linemen. **Methods:** Archival data were analyzed from 403 college football linemen, which focused on their best physical test results, who played during a period from 1987-2015 at a highly ranked NCAA D-I university. Players were categorized by position either as offensive linemen (OL; n=246) or defensive linemen (DL; n=157). Data were collected at various intervals throughout each athlete's playing career, and included personal best measures in included height (HT), body mass (BM), 1 repetition maximum (1RM) in the squat (SQ), bench press (BP), power clean (PC), push jerk (PJ), vertical jump (VJ), sit and reach test (SR), 40-yard dash (40YD), 10-yard dash (10YD), and 20-yard shuttle (20YS). All data were collected by the same strength coach over the 29-year period. Success was determined by three criteria: level 1 included players who never made the starting line-up in their college careers, level 2 were players that made the starting line-up but never made it to the NFL, and level 3 were player that played at least one full year in the NFL. Data were analyzed using ordinal regression analysis. **Results:** The statistically significant predictors by position were as follows: for OL, BM (P<0.01), BP (P<0.01), PC (P< 0.05) and 40YD (P<0.01); for DL, BM (P< 0.05), 40YD (P< 0.05) and VJ (P< 0.05). **Conclusions:** These results suggest that it may be possible to predict the success of NCAA Division I football linemen in the positions tested, by looking at selected performance parameters. Our data suggests that for OL a large body mass combined with speed, upper body strength and explosive hip extension is important. For DL, a large body mass combined with speed and lower body power are good predictors of success.

3790 Board #107 May 30 8:00 AM - 9:30 AM
Predicting Success In NCAA Division I Football Skill-players Based On Physical Performance Test Results

Michael J. Caterisano¹, Charles Shaner¹, Mike Gentry², Anthony Caterisano, FACSM¹. ¹Furman University, Greenville, SC. ²Virginia Tech, Blacksburg, VA. (Sponsor: Anthony Caterisano, FACSM)

 (No relevant relationships reported)

A recent study looked at the relationship between performance variables and success in the NFL among players who participated in NFL combine events. Our aim was to look at a similar relationship among college football players in skill-positions, who aspire to make an NCAA Division I football starting roster. **Purpose:** The purpose of the study was to identify performance variables that predict success among aspiring Division I (D-I) college football skill-position players. **Methods:** Archival data were analyzed from 712 college football skill-position players, which focused on their best physical test results, who played during a period from 1987-2015 at a highly ranked NCAA D-I university. Players were categorized by position either as offensive skill-position players (OSP which includes running backs, quarterbacks and wide receivers; n=311); defensive backs (DB; n=157); or linebackers, tight ends and fullbacks (LTEFB; n= 244). Data were collected at various intervals throughout an athlete's playing career, and included personal best measures in height (HT), body mass (BM), 1 repetition maximum (1RM) in the squat (SQ), bench press (BP), power clean (PC), push jerk (PJ), vertical jump (VJ), sit and reach test (SR), 40-yard dash (40YD), 10-yard dash (10YD), and 20-yard shuttle (20YS). All data were collected by the same strength coach over the 29-year period. Success was determined by three criteria: level 1 included players who never made the starting line-up in their college careers, level 2 were players that made the starting line-up but never made it to the NFL, and level 3 were player that played at least one full year in the NFL. Data were analyzed using ordinal regression analysis. **Results:** The statistically significant predictors by position were as follows: for OSP, VJ (P<0.01), PC (P<0.05), and 40YD (P<0.01); for DB, BM (P< 0.05), and 40YD (P< 0.01); and for LTEFB, BM (P<0.05), 40YD (P< 0.01), and PJ (P< 0.05). **Conclusions:** These results suggest that it may be possible to predict the success of NCAA Division I football skill-position players in the positions tested, by looking at selected performance parameters. For OSP, lower-body power and explosive hips combined with speed are important; for DB it's large body mass combined with speed; and for LTEFB, explosive hips combined with body size and speed are important.

Physical Demands Of Professional Golf Caddy: A Case Study

Jinde Liu¹, Anthony P. Turner², Stanley Sai-chuen Hui, FACSM¹.
¹The Chinese University of Hong Kong, Hong Kong, Hong Kong.
²The University of Edinburgh, Edinburgh, United Kingdom.
 Email: jinde.liu@link.cuhk.edu.hk
 (No relevant relationships reported)

Few studies have investigated the physical demands of golf caddying during high-level golf competitions, yet recent fatalities have raised questions regarding demands relative to physical fitness. **PURPOSE:** The purpose of this study was to examine the physical demands of a professional golf caddy during a single round of a European Tour Tournament. **METHODS:** A professional male golf caddy with 27 years of caddying experience (age=47 yrs, HRmax=161 bpm, VO₂max=29 ml/kg/min) volunteered for this study. During the first round of 2018 Irish Open, the caddy wore a global positioning system (GPS) device and a heart rate (HR) monitor continuously throughout the round of golf for the recording of displacement and HR responses, respectively. **RESULTS:** The total time (TT) of the round was 226 min with 53.5% walking and 46.5% standing, and the total distance covered by the caddy was 8.63 km, with mean and peak traveling speeds by of 2.3 km/h and 9.7 km/h respectively. The mean HR was 110 bpm (68.3% HRmax), with a peak of 136 bpm (84.5% HRmax). The caddy spent most (62.3%) of the TT at moderate intensity (64-<77% HRmax; ACSM's guidelines, 2013), 27.5% of the TT at light intensity (50-<64% HRmax), and only 10.2% of the TT at high intensity (77-<94% HRmax). In general, uphill movements elicited a higher HR response. **CONCLUSIONS:** These results suggest that cardiovascular demands of golf caddying were primarily moderate intensity activity during the round of elite golf. However, high intensity activity was also observed when the caddy climbed hills continuously. These findings may provide useful information for justifying the need for aerobic training programs for a professional golf caddy, relative to a low current cardiovascular fitness level.

3792 Board #109 May 30 8:00 AM - 9:30 AM
Effect Of Aikido, Brazilian Jiu Jitsu, And Yoga On Functional Movement

Tessa Goldstein, Alexa Beaudet, Warren Fields, Jr., Michel J. H. Heijnen, Ann T. Shields, John Lothes, Laura Siljander, Jessica Gaffney, Michael Wood, Rebecca S. Edwards, Ross Gillan, Brittini DeSander, Tyler Hamilton, Cassandra Berger, Isai Hernandez, Lorenzo Ortiz, Brad Hollingsworth. *University of North Carolina at Wilmington, WILMINGTON, NC.*
 (No relevant relationships reported)

PURPOSE: To identify the impact of Brazilian Jiu Jitsu (BJJ), aikido and yoga on functional movement. **METHODS:** One hundred seven college students completed 22 fifty-minute sessions of one of 3 possible modes of exercise (aikido- N=31, BJJ- N=38- & yoga- N=38) over a 12-week period. Aikido is a throwing and pinning martial art that focuses primarily on standing movements. Classes include meditation, breathing exercises, stretching and strengthening exercises. In addition, students will be introduced to Aikido stances, footwork, handwork, and partner practices, while connecting the study and practice of Aikido with their path toward optimum wellness across the lifespan. BJJ is primarily a ground based martial arts system where students learn to effectively control an opponent on the ground. Yoga is a movement based exercise where postures are practiced to align, strengthen and promote flexibility in the body. Breathing techniques and meditation are also integrated, with an emphasis on simplicity, repetition, and ease of movement. The Functional Movement Screen (FMS) and Mobility, Activation, Posture, and Symmetry (MAPS) assessments were administered at baseline and following 12 weeks of exercise participation to determine functional movement. A repeated measures ANOVA was used to determine if there were differences in body weight and functional movement status (p < 0.05). **RESULTS:** No statistical differences in body mass were observed for either exercise type (Table 1). FMS and MAPS scores improved from pre to post for Aikido and FMS scores improved in yoga. No statistical differences were observed in BJJ.

Table 1: Weight, FMS, and MAPS scores pre and post (mean ± SE)

Exercise	Assessment	Body mass (kg)	FMS	MAPS
Aikido	Pre	76.5 ± 4.9	14.6 ± 0.4	47.8 ± 2.1
	Post	77.4 ± 4.6	15.5 ± 0.5 *	51.9 ± 9.3 *
BJJ	Pre	70.9 ± 2.6	15.1 ± 0.4	46.5 ± 1.7
	Post	71.2 ± 2.5	14.9 ± 0.3	48.3 ± 2.0
Yoga	Pre	64.3 ± 2.4	14.4 ± 0.4	43.1 ± 1.6
	Post	65.1 ± 2.6	15.5 ± 0.4 *	44.8 ± 1.7

* p ≤ 0.05

CONCLUSION: Twelve weeks of Aikido or yoga exercises improved functional movement. Brazilian Jiu Jitsu did not have a significant impact on functional movement.

3793 Board #110 May 30 8:00 AM - 9:30 AM
Influence Of Prior 3-min All-out Exercise On The Power-duration Relationship

Matthew Ian Black¹, Lee J. Wylie¹, Philip F. Skiba², Anni Vanhatalo¹, Andrew M. Jones¹. ¹University of Exeter, Exeter, United Kingdom. ²Advocate Lutheran General Hospital, Chicago, IL.
 Email: M.I.Black@exeter.ac.uk
 (No relevant relationships reported)

PURPOSE: To evaluate the parameters of the power-duration relationship (i.e., critical power, CP; curvature constant, W') derived from the performance of two 3-min all-out tests (3MT) separated by 60 s passive recovery. We aimed to: 1) establish the effect of a prior 3MT on CP and W'; 2) examine whether current models accurately predict inter-bout W' reconstitution; and 3) determine the physiological factors that are related to W' reconstitution. **METHODS:** We analysed 19 datasets from 17 participants (age, 22 ± 3 years; body mass 82.2 ± 13.6 kg) who took part in two separate studies, and 10 datasets have previously been published (Black et al. 2018 *Front Physiol.* 9:11). Datasets included a ramp incremental test and the performance of two 3MT separated by 60 s passive recovery. Paired samples t-tests were used to assess differences in: peak power; end test power (EP, indicative of CP); work performed above bout 1 end test power (W>EP1), indicative of W', and; total work done (TWD), between bouts 1 and 2. Reconstitution of W' between exercise bouts was estimated using: the intermittent CP model (W'_{INT-CP}); a differential equation (W'_{BAL-DIFF}); and; a continuous integrating equation (W'_{BAL-INT}). Differences between the actual and predicted reconstitution of W' were evaluated using paired samples t-tests and limits of agreement were determined via Bland-Altman analyses. **RESULTS:** EP and W>EP1 were significantly reduced in bout 2 compared to bout 1 (Bout 1: EP 273 ± 43 W, W' 17.0 ± 3.3 kJ; vs. Bout 2: EP 258 ± 39 W, W' 4.3 ± 2.8 kJ; both P<0.05). The W' reconstitution was significantly overestimated (P>0.05) and was not significantly correlated with the predictions provided by W'_{INT-CP} (16.4 ± 2.6 kJ, r = -0.42), W'_{BAL-DIFF} (9.6 ± 1.2 kJ, r = -0.22) or W'_{BAL-INT} (7.2 ± 1.7 kJ, r = -0.11). Inter-bout W' reconstitution was correlated with relative VO_{2max} (r=-0.66, P=0.002) and power output at the gas exchange threshold (r=-0.57, P=0.012). **CONCLUSIONS:** The powerduration relationship (i.e., CP and W') is adversely impacted by prior all-out exercise, and current models do not adequately describe the subsequent rate of W' recovery. These results have important implications for the design and use of mathematical models describing the energetics of exercise performance.

Effects Of Exercise Modality And Structure On Physiological And Perceptual Responses To Exercise

Gregory C. Bogdanis¹, Vasiliki J. Mallios¹, Christos Katsikas¹, Theodora Fouseki¹, Todd A. Astorino, FACSM², Caitlin Smith², Iain Holman². ¹National and Kapodistrian University of Athens, Greece, Athens, Greece. ²California State University-San Marcos, San Marcos, CA. (Sponsor: Todd A. Astorino, FACSM)
 Email: gbogdanis@phed.uoa.gr
 (No relevant relationships reported)

Moderate intensity continuous training (MICT) and high intensity interval training (HIIT) in the form of cycling and running, are effective types of exercise for improving fitness and health. However, cycling may cause higher levels of local muscle fatigue due to the greater contribution of anaerobic metabolism, while more muscle mass is active during running, resulting in higher oxygen uptake (VO₂) and energy expenditure.

PURPOSE: To examine the effects of exercise modality (cycling vs. running) and structure (continuous vs. interval exercise) at an individualized exercise intensity, on physiological and perceptual responses. **METHODS:** Seven healthy young individuals (3 M and 4 F, age = 21 ± 1 years) performed four 20 min trials in random order: continuous cycling and running (MICT) at an intensity corresponding to 80% of the individual ventilatory threshold (VT) and intermittent cycling and running (HIIT) including 10 x 1 min bouts at 120% VT, with 1 min active recovery at 60% VT. Blood lactate concentration was measured at rest, midway during exercise and 3 min after exercise, while VO₂, heart rate (HR) and rating of perceived exertion (RPE) were measured continuously. Data were analyzed using 3-way repeated measures ANOVA. **RESULTS:** VO₂max (40.0 ± 5.8 vs. 36.0 ± 5.3 ml/kg/min, p<0.001) and VT (70.8 ± 7.6 vs. 51.4 ± 4.2 %VO₂max, p<0.001), were higher in running than cycling. This resulted in energy expenditure that was highest in HIIT and MICT during running (217 ± 47 and 199 ± 61 kcal, respectively, p<0.001) and lowest in HIIT and MICT during cycling (142 ± 19 and 142 ± 17 kcal, respectively). Average HR was higher in running versus cycling (159 ± 15 and 138 ± 9 bpm, p=0.008) and in HIIT versus MICT

(155 ± 10 and 142 ± 11 bpm, $p=0.03$), but there was no 3-way interaction ($p=0.79$). In contrast, blood lactate concentration was not different between cycling and running ($p=0.44$), while RPE was slightly higher during running than cycling (2.75 ± 1.15 and 2.10 ± 1.0 units, $p=0.03$)

CONCLUSIONS: Running, especially in the form of HIIT at an individualized intensity close to VT, results in greater energy expenditure, while blood lactate and RPE are similar to cycling HIIT or MICT. Thus, HIIT running at this intensity may be used as an effective and tolerable exercise modality for healthy individuals when available time is limiting.

Relationship Between Weighted Standing Long Jump And 20 Meters Sprint Performance

Yannick Hogue-Tremblay, Alain Steve Comtois, Vincent Carey, Jérémie Charron, Philippe Roy, Viviane Marcotte L'Heureux.
UQAM, Montréal, QC, Canada.
 Email: yannick.hogue.tremblay@gmail.com
 (No relevant relationships reported)

The standing long jump (SLJ) is intensively used in fitness preparation as a measure of lower limb power. The SLJ has also been shown to be related to maximal sprint speed. The power deployed during a SLJ can be calculated, but it is unknown what the effect of body weight has on the relationship between sprint speed and power. **PURPOSE:** Explore the relationship between a 20m sprint and the SLJ under 5 loading conditions (0%, 1%, 3%, 10% and 15% of bodyweight). **METHODS:** Anthropometric measures ($n=13$) were taken prior to testing sessions (Age 16.0 ± 0.7 years; Height 1.80 ± 0.10 m; weight, 90.4 ± 20.0 kg). The loads used during different loading conditions were confirmed using a bodyweight scale (Omron, Canada). SLJ distances were measured from toes (starting line) to the closest heel using a jump mat (Javy Sports, Singapore). Peak velocity (PV), peak power (PP) and relative power (RP) to body weight were measured using a linear transducer (TENDO SPORTS MACHINES, London, UK) for each loading condition. The protocol consisted of 2 sprints of 20m with 3 minutes of recovery between sprints. The best of 2 completed attempts per loading condition was retained same for the best sprint time. The time at 10m and 20m were measured with photocell timing gates (Brower Timing System, Utah, USA). Linear regressions and 2-tailed Pearson correlations were calculated (SPSS Ver 26). **RESULTS:** Multiple significant ($p<0.05$) correlations were observed ($r=0.573$ to 0.892). Findings show that PV ($r=-0.640$, $r=-0.619$, $r=-0.646$) with a load of 3, 10 and 15% respectively, RP ($r=-0.635$) with a load of 3%, and SLJ distance ($r=-0.573$, $r=-0.736$) with a load of 10 and 15% respectively were significantly correlated with the 10m during sprint time. Also, PV ($r=-0.577$, $r=-0.892$) with a load of 1 and 15% respectively, PP ($r=-0.656$) with a load of 15%, RP ($r=-0.859$) with a load of 15% were significantly correlated with the 20m sprint time. **CONCLUSION:** Weighted SLJ using 15% of bodyweight is better correlated to 10m or 20m sprint times than a standard SLJ. We propose different formulas to predict peak velocity, 10m and 20m sprint time all based on SLJ distance. Peak velocity(m/s) = (Distance(m) x 2.50) - 0.88 $R^2=0.601$, $p \leq 0.01$, SEE=0.38 10m time(s) = 2.98 - (SLJ15% distance(m) x 0.55) $R^2=0.541$, $p \leq 0.01$, SEE=0.08 20m time(s) = 4.89 - (SLJ15% peak velocity(m/s) x 0.54) $R^2=0.796$, $p \leq 0.01$, SEE=0.10

3796 Board #113 May 30 8:00 AM - 9:30 AM
Acute Differences Of Passive Myofascial Release And Dynamic Stretching On Lower Body Explosive Power

Nicholas Gutierrez, Anahina Becerra, Josefina Sloss, Kevin Martinez, Cassidy Arguelles, Victoria Torres, Alexandra Chapa, Danny Dominguez. *University of Texas Rio Grande Valley, Edinburg, TX.*
 Email: nicholasgutierrez956@gmail.com
 (No relevant relationships reported)

Passive myofascial release using a steel roller (PMRS), popularized as body tempering, is an emerging modality for performance enhancement and injury rehabilitation. Currently no evidence exists showing its effectiveness for performance or injury rehabilitation. **PURPOSE:** To determine the acute differences between a dynamic stretching protocol (DS), PMRS, and a combination of PMRS and DS on lower body explosive power.

METHODS: Fourteen recreationally active subjects (height = 163.5 ± 2.5 cm, weight = 68.3 ± 3.9 kg) were recruited from the University of Texas Rio Grande Valley. Once informed consent was obtained, subjects were familiarized with the testing protocol. Subjects were asked to refrain from participating in exercise for 48 hours before each testing session. Three randomized sessions consisted of a five-minute light treadmill warm up, followed by one of three different modalities; DS only, PMRS only, or a combination of PMRS and DS (COMB). DS protocol consisted of five exercises (forward leg swings, twisting reverse lunges, lateral lunges, bent knee leg swings, and plantar flexion/extension). PMRS protocol consisted of rolling the hamstrings and

quadriceps for 2.5 minutes each. Following the protocol, lower body explosive power was tested using a countermovement vertical jump and standing long jump. The best of three trials was recorded.

RESULTS: Repeated measures ANOVA found significant condition main effects for the ($p=0.01$) countermovement jump and ($p<0.001$) standing long jump. Post-hoc pairwise comparisons, using Bonferroni adjustment for multiple comparisons, found COMB (45.9 ± 3.2 cm) to have a significantly ($p<0.05$) greater vertical jump height than DS (42.1 ± 3.0 cm) alone. PMRS (179.91 ± 11.1 cm) and COMB (177.9 ± 9.9 cm) had significantly ($p<0.005$) longer standing long jumps than DS (166.1 ± 10.3 cm) alone.

CONCLUSIONS: The current data demonstrated that passive myofascial release with a steel roller or in combination with a dynamic stretching routine may increase lower body explosive power when compared to a dynamic stretching routine alone. Further research should use an athletic population to determine its efficacy in highly trained individuals.

Acute Differences Of Passive Myofascial Release And Dynamic Warm Up On Lower Body Anaerobic Muscular Endurance

Fernando Lopez Garcia, Patrick Gage Murphy, Danny D. Dominguez. *University of Texas Rio Grande Valley, Edinburg, TX.*
 Email: fernando.lopezgarcia01@utrgv.edu
 (No relevant relationships reported)

Body tempering is a form of passive myofascial release used amongst athletes, physical therapists and trainers, and is a hands-on application of pressure to the muscles using a heavy steel roller. There is little to no evidence in the literature showing its effectiveness for performance or injury rehabilitation.

PURPOSE: To determine any acute differences between passive myofascial release with a steel roller (PMfR) and a dynamic warm up (DWU) on lower body anaerobic muscular endurance.

METHODS: Ten participants, 5 females (23.0 ± 1.3 years; 75.5 ± 5.2 kg; 159.8 ± 1.2 cm) and 5 males (24.6 ± 2.1 years; 82.5 ± 3.8 kg; 168.0 ± 2.8 cm), were asked to participate in this study. The first session was a familiarization session to test leg press one repetition maximum (214.3 ± 32.7 kg). The following two randomized sessions, separated by at least 72 hours, began with a five-minute cycle ergometer warm-up at 1.0kP for females and 1.5kP for males at 50RPM. Subjects performed a PMfR protocol or a lower body DWU prior to beginning a leg press specific warm-up. The PMfR protocol involved rolling the quadriceps and hamstrings for approximately two minutes each. The DWU protocol involved ten repetitions of six exercises (inchworms, hip-bridges, side-lying hip abduction, mountain climbers, lateral lunges, and squat jumps). Subjects then performed a set of ten repetitions at 25% and 50% and six repetitions at 75%. After a three-minute rest period, subjects performed repetitions to failure at 85%. One-way Analysis of Variance (ANOVA) was used to determine significant differences in repetitions.

RESULTS: Repetitions were significantly ($p<0.002$) different between protocols. Subjects performed more repetitions following the PMfR (25.4 ± 7.0 repetitions) condition than the DWU condition (16.8 ± 4.5 repetitions).

CONCLUSIONS: The current pilot data demonstrates that PMfR may be an effective warm up modality in combination with a specific warm up to assist in lower body anaerobic endurance. Precaution must be taken with the current data, as some subjects had as many 40 repetitions at 85%, which is not congruent with that percent 1RM. The current DWU protocol seems to have possibly decreased performance due to fatigue. Further studies should use a multi-set approach with a resistance trained population approach to better determine its efficacy.

Metabolic And Perceived Exertion Outcomes During Maximal Runs At Ends Of The Day

Jenna L. Carducci¹, Matthew J. Garver², Whitley J. Stone³, Meera Penumetcha², Dustin W. Davis⁴, Josie N. Hair², Nicolas M. Philipp². ¹Copeman Healthcare, Edmonton, AB, Canada. ²University of Central Missouri, Warrensburg, MO. ³Western Kentucky University, Bowling Green, KY. ⁴University of Nevada, Las Vegas, Las Vegas, NV.
 Email: jennacarducci@live.ca
 (No relevant relationships reported)

Training programs may be individualized to the particular needs and preferences of the exerciser. Controlling training and exercise characteristics, such as morning versus night, may alter exercise-related outcomes. **PURPOSE:** The purpose of this project was to investigate metabolic and perceived exertion outcomes during maximal runs at ends of the day (early morning and late-night) following a standardized, pre-run meal. **METHODS:** Thirteen participants (females: 8, males: 5, age: 20.7 ± 1.4 yrs., BMI: 24.9 ± 3.0 kg/m²) volunteered to complete two, randomized maximal runs, separated by 24-72 hours (condition 1: 06:00-09:00 and condition 2: 21:00-24:00). The starting

treadmill speed (perceived effort of 12-13 on the Borg 6-20 RPE) for each condition was determined during a familiarization trial. Pre-run nutrition was standardized with use of a yogurt-based smoothie drink prepared based on each individual's body mass and activity level (approximately one-quarter of their total daily calories as 80% carbohydrate, 3% fat, and 17% protein). Drinks were ingested 2 hours prior to the testing. During the maximal runs, speed was maintained at the previously described intensity, and grade was increased 2% every 2 minutes until volitional fatigue. Metabolic data were gathered via a metabolic cart using a 15-breath moving average. Paired sample *t*-tests were used to compare appropriate data with significance accepted at $p < .05$. Total fat oxidation during the tests was derived from VO_2 and RER. **RESULTS:** The morning and night runs lasted 10.2 ± 2.3 and 9.9 ± 2.6 minutes, respectively. No statistical difference was found between morning and night runs for relative $\text{VO}_{2\text{max}}$ (47.0 ± 7.0 vs. 47.3 ± 8.0 ml/kg/min, $p = .721$), total fat oxidation (24.8 ± 16.7 vs. 27.7 ± 22.3 kcal, $p = .597$), or maximal RPE (18.9 ± 1.1 vs. 18.8 ± 1.5 , $p = .794$). **CONCLUSIONS:** Relative $\text{VO}_{2\text{max}}$, total fat oxidation, and RPE did not differ between maximal runs performed early morning and late-night. Running maximally at ends of the day may not elicit any differences in these variables among a group of younger, recreationally active adults provided a standard, pre-run meal.

Effects Of Pilates Exercise On Core Stability And Joint Flexibility In College Athletes

Arihiro Hatta¹, Michiko Hanaoka¹, Seiji Miyazaki¹, Masahiro Fujii¹, Masamichi Kuriyama¹, Kayoko Isono². ¹Tokai University, Hiratsuka, Japan. ²Pilates Alliance Association, Tokyo, Japan.
 Email: hatta@tokai-u.jp
 (No relevant relationships reported)

Although Pilates improves flexibility, balance, and posture of symptomatic elderly or sedentary middle-aged adults, there has been little focus on studying the effect of Pilates in young athletes. **PURPOSE:** This study aimed to examine whether Pilates exercise improve core stability and joint flexibility in college athletes. **METHODS:** Fifteen healthy college students (control group) and 15 female college athletes (athlete group) participated in this study. Each student engaged in a 30-min Pilates session with a licensed instructor once a week over 12 weeks. The Functional Movement Screen (FMS) was used to evaluate core stability and joint flexibility before and after this intervention. The FMS focuses on seven fundamental movements: shoulder mobility (SM), hurdle step (HS), in-line lunge (ILL), active straight leg raise, trunk stability push up, rotary stability (RS), and deep squat. A repeated-measures ANOVA was performed to compare the groups (control group vs. athlete group). **RESULTS:** Although there were no significant between-group differences, the results indicated significant main effect for the Pilates intervention ($F = 62.5$, $p < 0.001$, $\eta^2 = 0.82$), Pilates intervention \times FMS interaction ($F = 35.6$, $p < 0.001$, $\eta^2 = 0.72$), and FMS ($F = 2519.6$, $p < 0.001$, $\eta^2 = 0.99$). After 12-week intervention, SM (before: 2.37 ± 0.2 vs. after: 2.73 ± 0.1 , $p < 0.05$), HS (before: 2.30 ± 0.1 vs. after: 2.70 ± 0.1 , $p < 0.01$), ILL (before: 2.10 ± 0.1 vs. after: 2.30 ± 0.1 , $p < 0.01$), RS (before: 2.13 ± 0.1 vs. after: 2.63 ± 0.1 , $p < 0.001$), and total score (before: 16.17 ± 0.4 vs. after: 18.13 ± 0.3 , $p < 0.001$) had significantly improved. **CONCLUSION:** Pilates exercise is effective for improving FMS scores, strengthening core stability, and flexibility for healthy controls and college athletes. Supported by JSPS KAKENHI Grant Number JP18K10973.

Effect Of Eccentric Overload Training on Change of Direction Performance: A Meta-Analysis

PURPOSE: This study systematically reviewed and quantified the scientific evidence regarding the effectiveness of EOT on COD performance. **METHODS:** Keyword and reference search of EOT interventions was conducted in eight bibliographic databases (i.e., SPORTDiscus, PubMed, Web of Science, Academic Search Complete, Cochrane Library, Scopus, CINAHL, and Google Scholar) for studies published until October 1, 2019. Meta-analysis was conducted to estimate the standardized pooled effect of EOT on COD performance. **RESULTS:** Twelve studies, including nine randomized controlled trials, two pre-post studies, and one randomized crossover trial, met the eligibility criteria and were included in the review. Time of overall COD task completion among the EOT group was 0.34 standard deviations (95% confidence interval [CI] = -0.49, -0.19; $I^2 = 98.8\%$) shorter than that in the control group (Table 1). Among the interventions employing the T-test, time of task completion among the EOT group was 0.81 standard deviations (95% CI = -1.51, -0.11; $I^2 = 98.7\%$) shorter than that in the control group. Among the interventions employing the 180° COD task, time of task completion among the EOT group was 0.24 standard deviations (95% CI =

-0.53, -0.05; $I^2 = 97.5\%$) shorter than that in the control group. There was no evidence of publication bias based on the Egger's test and Begg's test. **CONCLUSIONS:** EOT was found effective in improving COD performance. Future studies should adopt a randomized experimental design, recruit large and representative samples from professional team sports, and examine the effect of EOT on various measures of COD performance among population subgroups.

Table 1 Results from meta-analysis and publication bias tests

Measure	First author, year	I ² index	Pooled effect size (95% CI)	Model	Publication bias test	
					P-value for Egger's test	P-value for Begg's test
Overall COD task	Coratella, 2019; Sanchez-Sanchez, 2019; Chaabene, 2019; Siddle, 2019; Coratella, 2018; Maroto-Izquierdo, 2017; Bourgeois, 2017; Gonzalo-Skok, 2017; Tous-Fajardo, 2016; de Hoyo, 2015; Lockie, 2014	98.8%	-0.34 (-0.49, -0.19)	Random-effect	0.15	0.48
180° COD task	Coratella, 2019; Siddle, 2019; Bourgeois, 2017; Gonzalo-Skok, 2017	97.5%	-0.24 (-0.53, -0.05)	Random-effect	0.26	1.00
T-test task	Coratella, 2019; Chaabene, 2019; Coratella, 2018; Maroto-Izquierdo, 2017; Lockie, 2014	98.7%	-0.81 (-1.51, -0.11)	Random-effect	0.55	1.00

Differences In Heart Rate And Pedal Frequency On A Cycle Ergometer With And Without Music

Kelley Phillips, Georgia Jirusek. University of Minnesota Duluth, Duluth, MN. (Sponsor: Charles Fountaine, FACSM)
 Email: holmesk@d.umn.edu
 (No relevant relationships reported)

Research has demonstrated the effects of music on exercise performance such as heart rate, cadence, and rate of perceived exertion. Specifically, music tempo is considered a significant factor influencing physiologic changes and is measured in beats per minute (bpm). The preference for music with fast tempos may be due to a stimulus that increases physiological arousal. However, results have differed depending on population, exercise modality, and experimental protocol. **PURPOSE** The purpose of this study was to determine the differences in heart rate and pedal frequency on a cycle ergometer with and without music. **METHODS** Participants (N=20) were collegiate level students who were recreationally active and met physical activity standards. Each participant completed two 20 minute cycle sessions, one while listening to a predetermined music playlist and the second without any music. The predetermined music playlist included 4 songs at tempos of 77 bpm, 132 bpm, 82 bpm, and 126 bpm. Participants pedaled at a self-selected frequency. Heart rate and pedal frequency were recorded for each minute of exercise. A paired T-Test was used to determine statistical significance between variables ($p < 0.05$). Analysis of Variance was also used to determine statistical significance between heart rate and music tempo ($p < 0.05$). **RESULTS** Results from this study show average heart rate with music at 140 ± 15.7 bpm and without music 130 ± 15.7 bpm. Pedal frequency averaged 62.7 ± 10.7 and 57.8 ± 7.5 revolutions with music and without respectively. There was a statistically significant difference between heart rate ($p < 0.01$) and pedal frequency ($p = 0.01$) from music to no music. A statistically significant difference in heart rate was observed between the music tempo groups, $F = 24.51$, $p = 0.001$, with a large effect size, $\eta^2 = 0.304$. Bonferroni post-hoc tests indicated the heart rates for 77 bpm (126 ± 19), 132 bpm (140 ± 16), and 82 bpm (145 ± 17) was significantly higher than each other ($p < 0.01$). **CONCLUSION** The results indicate that music increased heart rate and pedal frequency significantly compared to no music. Additionally, there was a significant difference in music tempo on heart rate. The results from this study support the notion that music does increase physiologic changes during exercise.

Relative Contributions Of Strength, Anthropometric, And Demographic Characteristics To Rock Climbing Performance
 Clayton L. Camic, Brandon J. Cox, Chris M. Hill. *Northern Illinois University, DeKalb, IL.* (Sponsor: John Porcari, FACSM)
 Email: ccamic1@niu.edu
 (No relevant relationships reported)

PURPOSE: The purpose of the present study was to determine the relative contributions of handgrip and individual finger strength, body size, climbing experience, and training habits for the prediction of climbing performance in a bouldering competition.

METHODS: Sixty-seven climbers (males: $n = 46$, females: $n = 21$; mean age \pm SD = 21.1 ± 4.0 yrs; body mass = 69.5 ± 9.8 kg; height = 173.5 ± 8.3 cm; climbing experience = 2.7 ± 2.6 yrs; climbing frequency = 3.0 ± 1.2 sessions-wk⁻¹) volunteered for this study. Data collection occurred immediately before an indoor bouldering competition and involved the assessment of handgrip and individual finger maximal force production using an electronic handheld dynamometer. Individual finger strength was defined as the maximal force generated using a tip-to-tip pinch between each finger and the thumb. All measures of strength were normalized to body mass (kg). Subjects also completed a questionnaire to determine climbing experience and training habits (i.e. climbing frequency). The bouldering competition consisted of 70 routes graded V0 (easiest) - V8 (most difficult) with higher point values awarded for completing more difficult routes. Stepwise multiple regression analyses were used to examine the relative contributions of handgrip and individual finger strengths, body mass, height, climbing experience, and climbing frequency to the prediction of performance scores in the competition.

RESULTS: The results indicated there were significant [$F(3, 63)=12.499, p < 0.001$] predictors of climbing performance in our model. Specifically, ring finger pinch strength, climbing experience, and climbing frequency significantly ($p < 0.05$) contributed to the model ($R^2 = 0.373$), whereas body mass, height, full handgrip strength as well as index, middle, and little finger pinch strengths did not. The β -weights showed that ring finger pinch strength ($\beta = 0.430$) was the most significant contributor followed by climbing experience ($\beta = 0.331$) and climbing frequency ($\beta = 0.244$).

CONCLUSIONS: These findings illustrated the importance of ring finger pinch strength on climbing performance in a bouldering competition. Our results also suggested that increasing climbing experience and frequency of training may contribute to greater ring finger pinch strength and overall climbing performance.

3803 Board #120 May 30 8:00 AM - 9:30 AM
Gender Differences In Time-trial Based Predictions Of Vo2max And Training Paces For Collegiate Track Athletes
 Eric M. Scudamore¹, Anaelle Charles¹, John M. Coons², Veronika Pribyslavsk¹. ¹*Arkansas State University, Jonesboro, AR.* ²*Middle Tennessee State University, Murfreesboro, TN.* (Sponsor: Don W. Morgan, FACSM)
 (No relevant relationships reported)

PURPOSE: Compare the accuracy of predicted $\dot{V}O_2\max$, interval pace, and threshold pace from Jack Daniels' VDOT Running Calculator between male and female NCAA Division 1 track athletes. **METHODS:** Male ($n = 10$) and female ($n = 8$) athletes completed an indoor 5k time-trial used to obtain predicted data from the VDOT calculator. Predicted variables were compared to laboratory tested $\dot{V}O_2\max$, $\dot{V}O_2\max$ pace, and lactate threshold pace. Follow-up analyses were conducted to compare predicted-actual difference scores between groups. **RESULTS:** $\dot{V}O_2\max$ was underestimated by the VDOT calculator in males ($t(9) = -5.90, p < .001, d = .65$) but not females ($t(7) = -1.44, p = .19, d = .31$). No difference was found between predicted and laboratory tested interval pace for males ($t(9) = 1.90, p = .09, d = .18$) or females ($t(7) = 1.44, p = .19, d = .45$). Predicted and laboratory tested threshold pace were also similar for men ($t(9) = -0.41, p = .68, d = .07$) and women ($t(5) = 1.39, p = .23, d = .91$). Follow up analyses indicated that the difference between VDOT and $\dot{V}O_2\max$ was significantly greater for male athletes ($p = .025, d = .33$). However, between-groups differences scores were similar for interval ($p = .94, d = .01$) and threshold paces ($p = .15, d = .28$). **CONCLUSION:** The VDOT Calculator may underestimate $\dot{V}O_2\max$ for male track athletes. However, practitioners can be confident in the accuracy of interval and threshold training paces provided by the VDOT running calculator irrespective of an athlete's sex.

3804 Board #121 May 30 8:00 AM - 9:30 AM
Assessing Performance Variability Across Two Major National USA Powerlifting Competitions
 Spencer K. Travis¹, Ai Ishida¹, Michael C. Zourdos², Caleb D. Bazzyler¹. ¹*East Tennessee State University, Johnson City, TN.* ²*Florida Atlantic University, Boca Raton, FL.*
 (No relevant relationships reported)

National level USA Powerlifting (USAPL) raw powerlifters typically compete at two major competitions (COMP): Raw Nationals (COMP1) and The Arnold Classic (COMP2). Small performance changes may have a large impact on a powerlifter's national level eligibility. Further, typical variation in powerlifting COMP performance is needed to determine meaningful changes in response to training and gauge athlete's progression. **PURPOSE:** To determine the typical COMP performance variation amongst raw powerlifters and assess differences between sexes. **METHODS:** Data was gathered from 2013-2019 on USAPL powerlifters competing at COMP1 and COMP2 successively (<8mon apart). After removing outliers ($\pm 3IQR$), 140 males and 123 females were included in the analysis. Paired sample t-tests, coefficient of variation (CV) and smallest worthwhile change (SWC) were calculated to assess differences between COMP1 to COMP2 for back squat (BS), bench press (BP), deadlift (DL), powerlifting total (PT), and Wilks Score (WS) for each sex. Percentage change for absolute difference in each variable from COMP1 to COMP2 was compared between sexes using an independent samples t-test with criterion alpha < 0.05 . **RESULTS:** Typical variation in COMP performance was small and similar for each sex: BS (CV: 2.8%; SWC: 0.84%), BP (3.1%; 0.93%), DL (3.1%; 0.92%), PT (2.1%; 0.62%) and WS (2.1%; 0.64%). There were significant differences between COMP1 and COMP2 for each variable within each sex ($p < 0.05$); however, the magnitude of difference was small (percent change $< 4.5\%$ for all variables). There was a significant difference in relative performance change for females compared to males on BP (4.4% vs 3.1%, $p = 0.001$), and a near significant difference for PT (2.6% vs 2.2%, $p = 0.070$). Relative changes were similar between sexes for BS (3.3% vs 2.9%), DL (3.3% vs 3.4%), and WS (2.5% vs 2.2%). **CONCLUSIONS:** Consistent performances were expected considering the caliber of powerlifters. Importantly, the data from this study indicate that changes greater than $\sim 1\%$ on COMP lifts are meaningful in raw powerlifters. However, it is apparent for female powerlifters, the limiting factor for maintaining or improving national level performance may be BP. Thus, female powerlifters and their coaches may consider emphasizing BP training to improve consistency in COMP.

3805 Board #122 May 30 8:00 AM - 9:30 AM
The Role Of The Coach In Determining Success At A National Powerlifting Competition
 Daniel Jaffe, Jennifer Hewitt, Karl Zang, Alexander Bedard, Anthony Tankiewicz, Todd Crowder. *United States Military Academy West Point, West Point, NY.*
 Email: daniel.jaffe@westpoint.edu
 (No relevant relationships reported)

Purpose: To compare rates of success in coach- versus self-supervised performance at the USA Powerlifting Collegiate National Championships from 2016-2019.

Methods: Using a repeated measures ANOVA design with specific post-hoc analysis, 88 members of the powerlifting team at a United States Service Academy had individual performances tracked during the annual USA Powerlifting Collegiate National Championships from 2016-2019. Performance metrics included: number of successful and non-successful attempts, total weight lifted, and Wilks total (a relative strength metric used in powerlifting).

Results: A total of 88 competitors were tracked over the duration of this investigation. Successful attempts (7.9 ± 1.2 vs. 5.4 ± 1.2), total weight lifted (530.2 ± 146.9 kg vs. 416.8 ± 235.0 kg), and Wilks total (408.9 ± 86.0 vs. 352.3 ± 186.7) were significantly greater in the coach-supervised versus self-supervised population. Lifters following a coach-supervised versus self-supervised competition plan performed significantly better across all performance metrics ($p < 0.001$).

Conclusion: The coach plays a significant role in determining performance outcomes during powerlifting competition. An abundance of research exists on the importance of a coach in developing long-term, periodized strength training for improving strength outcomes, but minimal research exists on the role of the coach in predicting success in individual competitions. These findings support the notion that supervisory mentorship is integral to the success of athletes during both training and competition.

3806 Board #123 May 30 8:00 AM - 9:30 AM

The Impact Of Sleep Deprivation On Agility Performance And Pattern Recall

Carolyn Albright, Laura Lupin. *Chestnut Hill College, Philadelphia, PA.*
 Email: albrightc@chc.edu
 (No relevant relationships reported)

PURPOSE: With sleep having the potential to affect both memory and physical performance associated with learning and performing sport related tasks, this study sought to determine the effects of sleep deprivation and college athletes on their ability to remember and perform agility drills similar to that which would be performed in practice or game. **METHODS:** Ten physically active college athletes (21-26 years) participated in the study (5 males and 5 females). Participants were tested under two conditions, 2-4 hours and 7-9 hours of overnight night sleep. The night before each test day, participants were instructed in detail about a four-part agility pattern they had to recall and perform the following morning. The agility drill included: forward sprinting, back pedaling, in and out box stepping drills, Icky Shuffle, and a vertical jump. For each testing day participants performed a warm-up and then the agility drill three times. They rated their perceived exertion (RPE) for each trial, and the best time for each drill was used for analysis. **RESULTS:** Completion speed was not significantly different after 2-4 hours sleep (26.9 ± 2.0 sec) compared to 7-9 hours sleep (26.1 ± 2.6 sec). RPE was also not significantly different for 2-4 hours sleep (8.4 ± 2.2) compared to 7-9 hours sleep (7.9 ± 1.3). There was also no gender difference for speed or RPE. However, participants who were instructed to undergo 2-4 hours of sleep for their first test took significantly longer to perform the drill for the first testing day compared to those who received 7-9 hours of sleep for their first testing day, taking on average 2.2 ± 1.7 sec longer. **CONCLUSION:** Although no difference was seen overall in agility performance times when comparing prior sleep, there was a difference in performance times when comparing the ordering of learning a new task. Learning a new agility pattern when sleep deprived first resulted in slower agility times than when seeing the new pattern for the first time with a full night sleep. Physically active college students are at risk of decreased performance times for drills they are seeing for the first time on minimum sleep. Coaches often stress getting good sleep prior to competition but it may be important for adequate sleep prior to practice sessions where new play routes are being taught.

The Acute Effects Of External Pneumatic Compression On Anaerobic Performance And Blood Lactate Concentration

Govindasamy Balasekaran, FACSM, Nurul Shafiqah Binte Mohamed Saiful. *Nanyang Technological University, Singapore, Singapore.*
 Email: drbat55@hotmail.com
 (No relevant relationships reported)

The use of External Pneumatic Compression (EPC) among athletes as a recovery modality is rising. However the evidence supporting efficacy of EPC on recovery and performance is limited thus it warrants for further investigation. **PURPOSE:** To determine the acute effects of EPC on anaerobic performance and blood lactate (BLA) concentration following a fatigue protocol. **METHODS:** In a randomized, counterbalanced cross-over study design, 10 healthy university male athletes, aged (25.2 ± 1.1 yrs), were recruited to complete 3 experimental sessions with two 30-second trials of maximum effort Wingate Anaerobic Test (WAnT)(T1 & T2) on a cycle ergometer with a constant load of .075 kg per kilogram of body mass, separated by a 20-min recovery period where either passive recovery (PR), active recovery (AR) or EPC treatment were administered. BLA levels, heart rate and ratings of perceived exertion were recorded. Power output in Watts (PO), fatigue index in %(FI) and total work in Joules(TW) were examined. **RESULTS:** Mean power output (MP) in Watts following AR (T1: 634.90 ± 81.18 , T2: 638.06 ± 99.98)($p = .022$) and EPC (T1: 642.55 ± 78.38 , T2: 637.85 ± 95.62)($p = .020$) were significantly higher than PR (T1: 623.21 ± 91.08 , T2: 620.38 ± 103.03). However, MP between AR and EPC treatment were not significant ($p = .567$). Similarly, TW were significantly higher following AR (T1: 19.09 ± 2.54 , T2: 19.02 ± 2.97)($p = .028$) and EPC treatment (T1: 19.14 ± 2.33 , T2: 19.04 ± 2.83)($p = .013$) than PR (T1: 18.58 ± 2.73 , T2: 18.47 ± 3.03) but mean differences were minimal between AR and EPC treatment. PO (PR T1: 954.90 ± 206.78 , T2: 890 ± 178.42 , AR T1: 1001.60 ± 187.16 , T2: 928.50 ± 172.46 , EPC T1: 970 ± 135.71 , EPC T2: 943.00 ± 152.58)($p = .481$) and FI (PR T1: 62.23 ± 17.05 , T2: 57.40 ± 15.98 , ER T1: 64.80 ± 17.41 , T2: 59.42 ± 17.78 , EPC T1: 63.40 ± 18.03 , T2: 56.86 ± 15.15)($p = .780$) were not significant. BLA concentration decreased significantly from peak BLA at 5 minute post-WAnT to 20 minutes post-WAnT in all trials (PR: $p = .000$, AR: $p = .000$, EPC: $p = .000$). However the mean difference in BLA (mmol·L⁻¹) levels at 20 minutes post-WAnT and 5 minutes post-WAnT were 2.6 in PR, 4.0 in AR and 2.7 in EPC. **CONCLUSIONS:** Results indicated performance was better maintained with the use of EPC and AR. Therefore, the use of EPC may be a feasible alternative method when static recovery is desired.

3808 Board #125 May 30 8:00 AM - 9:30 AM

Analysis Of The Water Polo Shots In Positions 1 And 2 In The Simple Temporal Numeric Inequality With Possession During The 15th Fina World Championship In Barcelona 2013

Yurema Sabio Lago¹, Myriam Guerra-Balic², Josep Solà², Josep Cabedo-Santomà². ¹Tecnocampus, Mataro, Spain. ²FPCEE-Blanquerna, Barcelona, Spain.

Yurema Sabio Lago^{a,b}, Myriam Guerra-Balic^b, Josep Solà^b, Josep Cabedo-Santomà^b ^aTecnocampus, University Pompeu Fabra, Barcelona, Spain; ^bFPCEE-Blanquerna, University Ramon Llull, Barcelona, Spain;

Introduction: The Simple Temporal Numeric Inequality With Possession (FJs) is defined as a concrete micro-situation of the Water Polo, which after the amount of players (+1) in favor of the team that owns the ball. Left-handed (LH) players may have an important role.

Aim: First, to know if the LH players were more effective in the goal categories and getting positive actions in position 1 and 2 than the right-handed (RH) in the FJs; second, to know if the shots in position 1 and 2 were less effective than the rest of the positions in the goal categories.

Methods: An observational, multidimensional, nomothetic and punctual study was developed, following Anguera (2003). The sample consisted on all the throws during 24 games, including male and female teams (n=127) corresponding to the 15th FINA World Championship using an *ad hoc* instrument for observation through SportCode software. Games were recorded with a video camera (SONY, FDRAXP33B.CEN). Descriptive of all variables and Chi-square test were obtained to compare throws.

Results: The LH players performed from position 1 more total shots compared to the RH players. Adding the categories related to the goal, the LH got 30.8% and the RH 23.1%. When adding the categories related to positive actions (exclusion, penalty, rebound and corner), the LH got 42.3% while the RH 25%. From position 2 the RH players make more shots compared to LH players (50 vs 25). Adding the categories related to the goal, the LH got 10.7% and the RH 26.7%. If we add the categories related to positive actions, the LH got 16% while the RH 38.7%. The Specific Position (PE) and Player's Laterality (LJ) of the shots from position 1 and 2 that finish in goal in FJs, there were significant differences ($p < .05$).

Conclusions: The LH players were more effective in the goal categories and getting positive actions in position 1 than the RH, but not in position 2. Only the shots in position 1 were less effective than the rest of the positions in the goal categories.

Physiologic Evaluation Of A Collegiate Mascot During Football Games And Related Activities

Alyssa J. Guadagni, Emily N. Werner, Ashley N. Triplett, Sue A. Petrisin, James M. Pivarnik, FACSM. *Michigan State University, East Lansing, MI.* (Sponsor: James M. Pivarnik, FACSM)
 Email: guadagn2@msu.edu
 (No relevant relationships reported)

PURPOSE: Our purpose was to collect collegiate mascot pilot data to determine physiological HR responses during two football games and pregame-related activities.

METHODS: A physiological tracking system was used to evaluate HR and movement from individuals (N=7 [1 female]; avg ht=1.82m, wt=75.6kg) who performed mascot activities "in suit" (weighing ~14kg) before and during two NCAA Division I University football games. Both games were played at night under moderate ambient conditions (temp=22-14 °C, rh=64%, wind speed=4 mph). Prior to the study, individuals' HRmax values were determined during graded treadmill tests performed to volitional exhaustion. Variables analyzed during the games were time in suit, time in pre-established HR zones [including HRzone1 (50-59%HRmax), HRzone2 (60-69%HRmax), HRzone3 (70-79%HRmax), HRzone4 (80-90%HRmax), and HRzone5 (>90%HRmax)], and distance covered per minute. Differences in time per HRzone were evaluated using 95% confidence intervals. Differences in average HR between pre-game and game conditions were evaluated via a t-test.

RESULTS: Sessions in suit lasted 43.5 ± 10.5 min, and distance traveled was 47 ± 22 m/min. HR averaged $82 \pm 8\%$ of HRmax, with over half the time spent in HRzone4 ($34 \pm 20\%$; $p < 0.05$) and HRzone5 ($23 \pm 27\%$), with only $2 \pm 2\%$ spent in HRzone1. HR values were significantly lower during pregame ($74 \pm 4\%$ HRmax) compared to game ($85 \pm 6\%$ HRmax) activities ($p < 0.001$).

CONCLUSIONS: The mascot suit environment posed significant physiological strain on the wearer, despite relatively little activity or movement performed per session.

Profiling Of High-intensity Events In Elite Chinese Female Field Hockey Matches

Xudan Cai¹, Wayne Lombard², Lijuan Mao¹, Matt Spencer³, Xiaoping Chen⁴. ¹Shanghai University of Sport, Shanghai, China. ²University of Cape Town, Cape Town, South Africa. ³Norwegian School of Sports Science, Oslo, Norway. ⁴China Institute of Sports Science, Beijing, China.
 Email: caixudan1993@yahoo.com
 (No relevant relationships reported)

Physical performance in field hockey (here on in referred to as hockey) is determined by many different factors. Recently, the development of small wearable inertial measurement units (IMUs) has provided new possibilities to profile the physical demands in different team sports, especially in the high intensity events (HIEs) aspect of competition and training.

PURPOSE: The aim of this study was to profile the position-specific HIEs in elite female hockey matches with the use of IMUs.

METHODS: Sixteen matches analyzing 22 elite Chinese female hockey players (height: 168.5±4.6 cm, body mass: 62.4±5.3 kg) were record by using IMUs (OptimEye S5, Catapult Sports, Australia) during the 2016-2017 Chinese national competition season. Players were categorized in three different playing positions: strikers, midfielders and defenders. Mean speed (MS), PlayerLoad™ (PL), accelerations (Acc), decelerations (Dec), changes of direction (CoD) and the sum of later three, HIEs, were extracted from raw-data files using the manufacturer's software (OpenField, version 1.14.0). All Acc, Dec, CoD and HIEs >2.5 m/s² were analyzed. Data were reported as mean±SD. Multiple paired t-test was used to compare data between different positions. Significance was set at P≤0.05.

RESULTS: The mean on-field time for individual players was 48.8±15.8 min and the mean PL and MS when combining all playing positions were 9.4±1.3 PL/min and 108.6±12.3 m/min respectively. The mean HIEs, Acc, Dec and CoD combined for all players were 1.1±0.3 HIEs/min, 0.2±0.1 Acc/min, 0.2±0.1 Dec/min and 0.7±0.2 CoD/min respectively. Defenders showed significantly lower PL and MS (8.7±1.2 PL/min, 100.7±11.9 m/min) than strikers (9.7±1.4 PL/min, 114.2±10.6 m/min) and midfielders (9.8±1.0 PL/min, 111.9±9.2 m/min) (P<0.01).

CONCLUSIONS: The mean playing time reported in the present study was similar to data from international hockey matches (48.8 ± 15.8 vs. 44.7±11.0 min), yet PL and MS from the present study was lower than that of elite international players (9.4±1.3 vs. 11.2±2.1 PL/min; 108.6±12.3 vs. 113.3±13.5 m/min). Competition level (national vs. international) is the most likely reason for these differences. Further research should focus on the HIEs' performance of elite international level hockey players. Supported by CSC (No. 2018083110192).

Relationship Between The Attractiveness And Athletic Achievement In Track And Field Athletes

Ayumu Kozuma, Keima Tomaru, Rikako Nakajima, Misato Nakano, Naoki Kikuchi. *Nippon Sport Science University, Tokyo, Japan.*
 Email: a.tf145812@gmail.com
 (No relevant relationships reported)

previous studies have reported that males with superior attractiveness tended to have superior athletic achievement. **PURPOSE:** To examine the relationship between attractiveness and athletic achievement in male and female track and field athletes.

METHODS: Ninety-three athletes (42 males and 51 females, aged 19.8 ± 1.2 years) participated in the present study. Using a questionnaire, subjects answered questions about specialized events, athletic achievements, and personal bests, among others. Male subjects included 13 national tournament prize winners, 14 national tournament participants, and 15 others. Female subjects included 21 international tournament prize winners, one national tournament prize winner, 15 national tournament participants, and 15 others. Attractiveness was evaluated using the Visual Analogue Scale (VAS) by evaluators who were of the opposite sex and did not know the subjects. Two-hundred and forty-one evaluators (124 males and 117 females, aged 20.81 ± 1.5 years) evaluated the attractiveness of the subjects. Each subject was evaluated by 32-37 evaluators. **RESULTS:** Average attractiveness was 3.78 ± 0.6 (range, 2.7-5.2) and 3.68 ± 0.8 (range, 1.5-5.9) in males and females, respectively. In female subjects, athletes with superior attractiveness tended to have superior athletic achievements. There was a negative correlation between attractiveness and personal best times in the 100-meter (n=13, r=-0.52, p=0.069) and the 100-meter hurdle events (n=9, r=-0.72, p=0.028) in female athletes. However, there was no relationship between attractiveness and personal best time of the 100-meter and the 110-meter hurdle events in male athletes.

CONCLUSIONS: Female athletes with superior attractiveness tended to have superior athletic achievement. In addition, there is a negative correlation between attractiveness and personal best performance in female sprinter events. However, there was no relationship between attractiveness and personal best performance in male sprinter events.

Effects Of Different Warm-up Protocols On Throwing Performance

Chin-chueh Tsai¹, Hung-chia Chen². ¹National Taiwan Sport University, Taoyuan, Taiwan. ²Da-Cheng Elementary School, Taoyuan, Taiwan.
 Email: ccttsai@ntsu.edu.tw
 (No relevant relationships reported)

Power is essential in throwing performance. Past research indicated that high-intensity dynamic warm-up enhance the subsequent explosive performance, which is referred as post-activation potentiation (PAP). At present, there is no research explored the effect of maximal isometric contraction as warm-up on throwing performance.

PURPOSE: This study aimed to investigate the impact of maximum isometric squat (MIS) and counter movement jump (CMJ) as warm-up exercises on subsequent throwing performance. **METHODS:** 16 healthy experienced baseball or softball players (30.5±5.98 years old) performed two warm-up protocols (MIS and CMJ) in counter-balanced order. Throwing performance was examined at 15 minutes before and 4 minutes after warm-up. Distance of underhand medicine ball throw (MBT) and baseball throwing velocity (BTV) were used to evaluate throwing performance.

RESULTS: The results revealed that after performing two types of warm-up exercises, the average and best distance of MBT improved significantly (P<0.05). The average and best speed of BTV increased significantly (P<0.05) after warm-ups. Performance of MBT after MIS (average: +5.35%; best: +6.05%) showed greater improvement compare to warm-up with CMJ (+4.82%; +4.47%) (P<0.05). **CONCLUSION:** Both MIS and CMJ as warm-up exercise are beneficial in subsequent throwing performance. MIS showed better effect than CMJ for underhand medicine ball throwing distance.

Competing In A Big City: Effects Of Air Pollution On Performance And Physiological Parameters During A 50-km Cycling Time-trial

André Casanova Silveira¹, Julio Hasegawa¹, Ramon Cruz¹, Paulo Saldiva², Michael Koehle³, Adriano Lima-Silva⁴, Rômulo Bertuzzi¹. ¹Endurance Performance Research Group, School of Physical Education and Sport, University of Sao Paulo, São Paulo, SP, Brazil, São Paulo, Brazil. ²Faculty of Medicine, University of São Paulo, São Paulo, Brazil., São Paulo, Brazil. ³School of Kinesiology, University of British Columbia, Vancouver, British Columbia, Canada, Vancouver, BC, Canada. ⁴Human Performance Research Group, Technological Federal University of Parana, Curitiba, Brazil., São Paulo, Brazil.
 Email: andre.casasv@hotmail.com
 (No relevant relationships reported)

PURPOSE: Air pollution is one of the main health risks caused by the environment. Exposure to particulate matter smaller than 2.5 microns in diameter (PM_{2.5}) leads to an increase in risk for cardiovascular and respiratory disease. Although many major sporting events are held in large, polluted cities (e.g. the Beijing 2008 and Rio 2016 Olympic Games), the effects of air pollution on performance and physiological parameters during endurance exercise remain unclear. Most laboratory research uses simulated air pollution which is not representative of actual "real-world" pollution exposure. Therefore, the aim of the current study was to investigate the effect of atmospheric air pollution on performance and physiological parameters during endurance exercise using "real-world" air pollution.

METHODS: Ten trained cyclists completed, in a counterbalanced order, two simulated 50-km cycling time-trials (50km-TT). These sessions were carried out in a modified shipping container capable of providing either a clean (filtered air) or polluted (ambient São Paulo air) environment. This design ensured that the participants were blinded to the polluted [POL] and filtered air [FA] conditions. Venous blood gas analysis was performed on 1mL samples taken from the forearm.

RESULTS: There were no differences in the performance in 50km-TT (FA= 90.4 ±5.8 vs. POL= 90.3±4.3 minutes, p=0.93). The power output was not different (FA= 200.2±30.4 vs. POL= 199.3±24 Watts, p=0.90). However, the inhaled PM_{2.5} was increased in polluted ambient (FA= 66.5±29 vs. POL= 222±62, p= <0.0001). In addition, the venous blood pO₂ and pCO₂ were not different between the two conditions.

CONCLUSIONS: Our findings showed that "real-world" air pollution exposure during a 50-km simulated TT exposure did not affect performance and physiological parameters.

Practice Within 24 Hours Of Competitive Play Compromises Performance In Collegiate Basketball
 Sofie Tryggedsson Preetzmann, J. Mark VanNess, Cynthia Villalobos, Joey Rossi, Bradley Davis, Courtney D. Jensen.
University of the Pacific, Stockton, CA.
 Email: s_preetzmann@u.pacific.edu
 (No relevant relationships reported)

The NCAA regulates collegiate basketball practice schedules, imposing limitations on daily and weekly practice duration. Coaches seldom schedule fewer hours than permitted and commonly maximize participation within those limitations. There is reason to wonder: does maximum engagement correspond to optimal preparation? **PURPOSE:** To test the effect of pre-game practice on in-game performance in women's collegiate basketball. **METHODS:** We analyzed 15 female basketball players on an NCAA D1 team throughout the 2018-2019 season. Heart rate monitors and GPS trackers were worn during all games (n=33) and practices. Data collected were maximum heart rate (HR_{max}) and total distance moved in games and practices, whether the team won, win-loss margin, and individual athlete rebounds and points scored per game. Paired-samples t-tests, linear regressions, and logistic regressions tested the effect of pre-game practice on in-game performance. **RESULTS:** The analyzed team won 60.6% of games. When practice was performed within 24hr of a game, winning percentage was 33.3% compared to 70.8% in games without prior practice ($p<0.001$). Holding constant the opponent's rank ($p<0.001$) and whether it was a home game ($p<0.001$), practicing within 24hr of competition reduced the odds of winning by 98.2% ($p<0.001$; 95% CI of OR: 0.007 to 0.049) and reduced the win-loss margin by 4.7 points ($p=0.001$; 95% CI: -7.398 to -1.962). During games, players ran $6,735.1 \pm 2,268.4$ meters and had a HR_{max} of 98.6 ± 9.3 . There was no difference in HR_{max} during practices that did and did not occur within 24hr of a game ($p=0.598$). During games, HR_{max} was elevated 2.4 bpm if practice occurred in the previous 24hr ($p=0.045$; 95% CI: -4.6 to -0.1) despite no difference in on-court movement ($p=0.243$). Holding confounding variables constant, practicing within 24hr prior predicted trends for each player to score 1.8 fewer points ($p=0.067$; 95% CI: -3.7 to 0.1) and accomplish 0.9 fewer rebounds ($p=0.079$; 95% CI: -1.8 to 0.1). **CONCLUSION:** These data do not support a "more is better" approach to collegiate basketball practice schedules. When practice occurs within 24hr of a game, despite elevated in-game cardiovascular effort of the athletes, individual and team performances are compromised.

- 3815** Board #132 May 30 8:00 AM - 9:30 AM
The Effects Of Kinesio Tape On Throwing Velocity And Accuracy In Collegiate Softball Players
 Francesca R. Formisano, Dr. Matthew Miltenberger, Dr. Gavin Moir, Dr. Shala Davis, FACSM. *East Stroudsburg University, East Stroudsburg, PA.* (Sponsor: Dr. Shala Davis, FACSM)
 (No relevant relationships reported)

The act of overhead throwing is a series of complex tasks that require synergy between multiple joints and muscle groups, lack of this synergy may lead to a decrease in performance and injury over time. In recent years, Kinesio tape has gained popularity as modality for the treatment and prevention of some of these injuries. To date, there is little research that looks at the use of Kinesio Tape in female athletes during the dynamic movement of overhead throwing. **PURPOSE:** The purpose of this study was to investigate the effects of Kinesio Tape on throwing velocity, accuracy and range of motion, and angle of ball release after the application of Kinesio Tape. **METHODS:** NCAA Division II softball players (n=9) participated in this study. The study was a randomized crossover design, subjects were either allocated to the control group (no Kinesio Tape) or the experimental group (Kinesio Tape) at their first testing session and then switched for the second testing session. Each subject performed 15 overhead throws approximately 20 feet from the target. Velocity, range of motion and angle of ball release were measured using Dartfish software, and accuracy was calculated based on points earned for hitting different levels of concentric rings. **RESULTS:** Statistical analysis revealed no significant differences between all variables between the experimental and control conditions. However, when looking at the means there was an interesting trend in the data. Kinesio Taping showed an increase in throwing velocity of .69 m/s (21.3 m/s to 21.99m/s, $p=0.480$). There was a 92.78-point increase in throwing accuracy from the control, 81.11 points to 173.83 in the experimental group ($p=0.092$). The Kinesio Taping condition also demonstrated an increase in maximal external rotation from 79.74° to 86.11° ($p=0.621$). Finally, there was a 1.17° increase in the angle of ball release with Kinesio Taping (148.68° to 149.85° , $p=0.732$). **CONCLUSION:** In conclusion, there was an increase in throwing velocity, accuracy and range of motion with the addition of Kinesio Tape during overhand throwing in collegiate softball players. Although the data did not present as statistically significant, it does demonstrate that Kinesio Tape may be a practical way to improve performance.

- 3816** Board #133 May 30 8:00 AM - 9:30 AM
Mouthguard Efficacy In Baseball Pitching Velocity
 Nathan O. Iskowitz, Jo Morrison, Laura Jimenez, Robert Brian Blaisdell. *Longwood University, Farmville, VA.*
 (No relevant relationships reported)

Successful pitching in baseball may be due to a number of factors including the mechanics of the motion, the strength, power, flexibility of the athlete, as well as their intent and fatigue levels. The pitching motion is a very powerful, violent, complex and abnormal range of motion of the body. In recent studies, it has been widely evidenced that the ability to produce instantaneous high peak force outputs is related to success in sport. Therefore, the ability to produce higher peak force may be related to the ability to pitching in baseball. Mouthguards have been shown to significantly increase power production in a number of dynamic exercise movements. **Purpose:** The purpose of this study was to determine if maximal and average pitching velocity could be increased when wearing a mouthguard. **Methods:** Twenty-two male collegiate baseball pitchers participated in this study (age: 19.9 years old \pm 1.4 years, body mass: $87.1 \text{ Kg} \pm 11.6 \text{ Kg}$, body height: $182.5 \text{ cm} \pm 6.1 \text{ cm}$). All study participants were competitive athletes at the NCAA Division 1, Division 3, or University Varsity Club level. **Results:** Pitching velocity changes resulted in a mean increase of 0.732 km/h for all groups. Velocity change for each level tested resulted in mean increases of 1.652, 0.402, and 0.370 km/h for the university club, Division 3 and Division 1 levels, respectively. The results of a paired samples t-test analysis showed that there was a statistically significant improvement when using a mouthguard in pitching velocity across all groups combined; $t(109) = 2.958$, $p = 0.004$. Further, university club level pitchers experienced a statistically significant improvement; $t(29) = 5.972$, $p = 0.000$; while Division 3; $t(39) = 0.772$, $p = 0.445$; and Division 1; $t(39) = 1.014$, $p = 0.317$; players did not show a statistically significant improvement with the mouthguard. **Conclusion:** The authors found that a mouthguard may improve throwing velocity in male collegiate baseball athletes. These findings could be useful to both coaches and sport performance specialists that are working with pitchers to bring about increases in power output and subsequent increases in pitching velocity, simply by implementing the use of a mouthguard.

Effect Of Self-controlled And Regulated Feedback On Motor Skill Performance And Learning: A Meta-analytic Study
 Judith Jimenez¹, Pamela Salazar¹, Karla Chaves¹, Maria Morera².
¹University of Costa Rica, San José, Costa Rica. ²Universidad Nacional de Costa Rica, Heredia, Costa Rica. (Sponsor: George A. Kelley, FACSM, FACSM)
 Email: judith.jimenez_d@ucr.ac.cr
 (No relevant relationships reported)

Previous research has reached conflicting conclusions regarding the effects of regulated (R) and self-controlled (SC) feedback during the practice of motor skill acquisition and retention. **PURPOSE:** Use the aggregate data meta-analytic approach to examine the effects of R and SC feedback on motor skill acquisition and retention in healthy participants of any age. **METHODS:** Randomized trials of SC and R feedback in motor learning published up to 2019 were included by searching eleven databases, cross-referencing and expert review. Studies were selected and extracted by two authors. Risk of bias was assessed using an adaptation of the TESTEX Scale (maximum points = 10). Random-effects models using the standardized mean difference effect size (ES) were used to pool results. Heterogeneity was examined using the Q statistic and inconsistency using I^2 . An alpha value <0.05 was considered statistically significant for changes in motor skill acquisition and retention. **RESULTS:** Of 238 studies screened, 17 were included, representing 42 ES for acquisition and 44 for retention. Risk of bias was $M \pm SD = 6.3 \pm 1.2$. The R group significantly improved performance during the acquisition phase ($ES = 0.85$; $CI_{95\%} = 0.61, 1.09$, $n = 31$, $I^2 = 69.6\%$, $Q = 98.7$, $p < 0.01$) but decreased performance during the retention phase ($ES = -0.82$; $CI_{95\%} = -1.21, -0.43$, $n = 33$, $I^2 = 86.6\%$, $Q = 238.7$, $p < 0.01$). The SC group significantly improved performance during the acquisition phase ($ES = 1.87$; $CI_{95\%} = 1.01, 2.73$, $n = 8$, $I^2 = 82.0\%$, $Q = 39.0$, $p < 0.01$) but there were no statistically significant changes during the retention phase ($ES = -0.05$; $CI_{95\%} = -0.76, 0.66$, $n = 8$, $I^2 = 80.7\%$, $Q = 36.3$, $p < 0.01$). A yoked group to SC feedback significantly improved performance during the acquisition phase ($ES = 1.50$; $CI_{95\%} = 0.27, 2.72$, $n = 3$, $I^2 = 80.9\%$, $Q = 10.5$, $p < 0.01$) with no change during the retention phase ($ES = -0.88$; $CI_{95\%} = -2.11, 0.35$, $n = 3$, $I^2 = 83.4\%$, $Q = 12.2$, $p < 0.01$). **CONCLUSIONS:** The overall results suggest that SC and R feedback improve performance during the acquisition phase, with greater improvements observed for SC feedback. SC feedback had no significant change during the retention phase, while R feedback decreased performance. These findings suggest that SC feedback may be the better choice for enhancing motor skills.

The Effect Of Percussive Massage Versus Foam Rolling Aided Warmup On Vertical Jump Performance
 Peter Byrne, Michele Aquino, Casey Spor, Jacob Virginia, Jessica Diaz, Ryan Mullin, John Petrizzo, Robert Otto, FACSM, John Wygand, FACSM. *Adelphi University, Garden City, NY.*
 (Sponsor: John Wygand, FACSM)
 Email: fatblue@optonline.net
Reported Relationships: P. Byrne: Industry contracted research; Theragun®.

Vertical displacement is a vital component of success in many power sport activities including volleyball and basketball. The Vertical Jump test (VJ) is a common, easy to use measure of power production applicable to many athletic populations. Treatments or preparations, such as Percussive Massage (PM), and Foam Rolling (FR) have been introduced to warm up routines on the premise that they will enhance power output and performance. **Purpose:** The purpose of this study was to assess vertical jump performance following a warm up of one of three treatments, including no massage (N), (FR) and (PM). **Methods:** 11 male and 7 female recreationally active college-age students (age: 23.4 ± 3.7 yr., height: 171.6 ± 11.4 cm, body mass: 68.2 ± 15.8 kg.) volunteered to participate in a randomized single-blind crossover design study. Three trials of 3 VJ separated by 2 minutes between jumps were conducted. During the 2 minutes of rest, an intervention (N, FR, or PM) was administered. For both FR and PM, treatment was administered bilaterally for 30 seconds per muscle group (Gluteus Maximus, Hamstrings, Quadriceps, and Gastroc/Soleus) for a total of 2 minutes. Vertical jump height was recorded after each jump using a standard vertical jump tester. **Results:** Statistical analysis by ANOVA ($P < .05$) revealed no significant difference (NSD) between best jumps. The best jumps for N, FR, and PM were 54.11 ± 2.5 cm, 54.96 ± 2.3 cm, and 54.05 ± 2.7 cm, respectively. In addition, subjects were very consistent among the first, second, or third trials across all conditions (NSD). **Conclusion:** The results of this study suggest that neither percussive nor non-percussive massage improve or detract from vertical jump performance and the use of either as a pre vertical jump warm-up may be an individual choice. Supported, in part by a grant from Theragun®.

The Effect Of Percussive Massage Or Foam Roller Aided Warmup On Wingate Power Test Performance
 Jacob Virginia, Michele Aquino, John Wygand, FACSM, Jessica Diaz, John Petrizzo, Ryan Mullin, Casey Spor, Peter Byrne, Robert Otto, FACSM. *Adelphi University, Garden City, NY.*
 (Sponsor: John Wygand, FACSM)
 Email: fatblue@optonline.net
Reported Relationships: J. Virginia: Industry contracted research; Theragun®.

Percussive massage tools (PMT) have recently become a topic of interest in the realms of fitness, wellness, pop culture, and athletics. PMT are designed to be implemented during warmups, pre-competition, and recovery processes. Little is known about the warm-up effects of these relatively new tools on muscular power. **Purpose:** The purpose was to determine the efficacy of a PMT aided warmup on Wingate Anaerobic Power Test (WAPT) performance. **Methods:** 20 college-aged subjects (16♂, age 22.6 ± 2.8 yr., height 176 ± 8.4 cm, body mass 78.6 ± 15.4 kg) volunteered to participate in the WAPT following familiarization and 3 randomly assigned warm-up protocols. All warm-up protocols began with 3 minutes of cycling at 50 watts. The cycling was followed by: 2 minutes of (PMT) on the lower extremity, 2 minutes of foam rolling on the lower extremity (FR), and no intervention (C). The Wingate Test was performed at 100g/kg body mass on a Lode cycle ergometer. ANOVA with repeated measures was used to analyze these data ($*p < 0.05$). **Results:** PP-Peak Power (watts) and MP-Mean Power(watts) were: PMT 1328 ± 368 & 640 ± 173 , FR: 1139 ± 284 & 623 ± 155 , and C 1183 ± 386 & 634 ± 160 , respectively. PP was significantly higher following PMT than both FR 189 (+16.6%) and C 145 (+12.2%). There were no significant differences in MP among trials. Fatigue index (FI) of (PMT): $80.8 \pm 9.6\%$ FR: $77.7 \pm 11.9\%$ C: $76.1 \pm 9.3\%$. PMT FI was 4.7%* higher than C trials. Blood lactate values obtained 3 minutes post WAPT were not significantly different among the trials and were as follows: PMT 10.9 mmol ± 2.3 mmol, FR 11.2 mmol ± 2.7 mmol, and C 11.0 mmol ± 2.1 mmol. **Conclusion:** A PMT aided warm-up may be an effective means of improving PP production and possibly performance in acute power-based events lasting 30 seconds or less. The greater FI of PMT may be partially attributed to the significantly greater PP. Supported, in part by a grant from Theragun®.

The Acute Effect Of Percussive Massage Or Static Stretching On Hamstring Flexibility
 Jessica Diaz, Casey Spor, Ryan Mullin, Peter Byrne, Jacob Virginia, Robert Otto, FACSM, John Petrizzo, Michele Aquino, John Wygand, FACSM. *Adelphi University, Garden City, NY.*
 (Sponsor: Rboerto Otto, FACSM)
 Email: jessndiaz2072@gmail.com
Reported Relationships: J. Diaz: Industry contracted research; Theragun®.

The effectiveness of techniques to enhance joint range of motion including static and dynamic stretching, have been studied for more than 50 years and is well documented. However, there is a paucity of research on the effect of a new percussive massage technique on flexibility. Percussive massage provides a machine generated series of rapid movements over specific areas of the body with a variation in both the depth and speed of percussion. **Purpose:** The purpose of this study was to assess the effect of percussive massage (PM), static stretching (ST) and no massage (NM) on low back and hamstring flexibility. **Methods:** 30 subjects (age 22.2 ± 2.2 yr., height 174.2 ± 8.6 cm., weight 75.6 ± 14.2 kg., BMI 24.6 ± 4.3 Kg/m²) volunteered to participate in this single blind, crossover study. Subjects reported to the lab on three separate days in a resting state. Pre sit and reach measurements were taken immediately upon arrival. Thereafter, they participated in randomly assigned interventions of PM, ST, and NM. PM performed on both hamstrings and gluteal muscles simultaneously, 30 seconds at each muscle origin, muscle belly and insertion; total time of 90 seconds on each muscle. Static stretching consisted of a seated unilateral hamstring stretch and a supine unilateral leg cross-over stretch both held for 30 seconds. Following each intervention, post sit and reach measurements were obtained. A maximum of two minutes separated all pre and post- test measurements. **Results:** Mean pre and post-test Sit and Reach measures (cm) were: 29.2 ± 8.1 and 31.6 ± 7.9 , 28.7 ± 8.1 and 31.5 ± 7.8 , and 28.6 ± 7.8 and 30 ± 8.1 for PM, ST, and NM, respectively. Statistical analysis by repeated measures ANOVA at $p < .05$, was applied to assess pre-post intervention differences. The changes (cm) between pre - and post-interventions were 2.4 ± 2 , 2.8 ± 2.9 , and 1.5 ± 1.5 for PM, ST, and NM, respectively. A significant difference was evident between ST and NM ($p = .004$), with NSD ($p > .05$) between PM and ST and PM and NM. **Conclusion:** PM and ST elicit similar, acute improvements in low back and hamstring flexibility. Supported, in part by a grant from Theragun®.

Effects Of Self Natural Posture Exercise On Pain Perception, Functional Movement, And Physical Fitness In Women With Chronic Pain
 Dae Taek Lee¹, Jiyoo Yoon², Jungki Choi², Jihye Kyeong², Somi Yun¹, Yoonbin Lee¹, Jae Gu Hwang¹, Ah-Reum Jung¹, Boram Lee¹, Heejin Lee¹. ¹*Kookmin University, Seoul, Korea, Republic of.* ²*Korea Good Posture Lab, Inc., Seoul, Korea, Republic of.*
 Email: dtlee@kookmin.ac.kr
 (No relevant relationships reported)

PURPOSE: While Self Natural Posture Exercise, SNPE, widely practiced in Korea is claimed to be effective, it has not been systematically demonstrated. This study examined whether SNPE is effective in pain, functional movement, and fitness improvement. **METHODS:** Twenty four women with chronic pain at least last 3 month prior to study participated (27.5 ± 5.8 yrs, 23.0 ± 3.8 kg/m²) and were divided into two groups; SNPE group (EG; n=12) and non-exercise group (NG; n=12). Subjects in EG participated in 12 weeks of exercise program consisted of 60 min per session, twice a week, while those in NG did not. Those in EG were tested before and after the program, and those in NG were tested twice in the same time interval. The pain perception was evaluated by Short-Form McGill Pain Questionnaire (MPQ). Movement tests were performed using Functional Movement Screen (FMS). Physical fitness was evaluated by grip and lower back strength, sit-and-reach, and back extension. **RESULTS:** Pain perception in EG was decreased (pre; 9.5 ± 7.2 vs. post; 3.5 ± 2.8), and group difference was noticed ($p < 0.01$). Deep squat in EG increased (1.3 ± 0.5 vs. 1.9 ± 0.5 , $p < 0.005$). Hurdle step in EG increased (1.0 ± 0.0 vs. 1.6 ± 0.4 , $p < 0.005$), and group difference was noticed ($p < 0.05$). Inline lunge both in EG (1.4 ± 0.6 vs. 2.6 ± 0.4 , $p < 0.001$) and in NG (1.5 ± 0.5 vs. 2.2 ± 0.7 , $p < 0.001$) increased. Shoulder mobility in EG increased (1.9 ± 0.7 vs. 2.9 ± 0.2 , $p < 0.001$), and group difference was found ($p < 0.05$). Active straight leg raise in NG decreased (2.7 ± 0.4 vs. 2.1 ± 0.7 , $p < 0.05$), but not in EG (2.7 ± 0.4 vs. 3.0 ± 0.0). Push up in EG increased (1.0 ± 0.2 vs. 1.6 ± 0.4 , $p < 0.005$). Rotary stability both in EG and NG did not show pre and post trial differences, but group differences were noticed ($p < 0.05$). FMS total score both in EG (11.4 ± 1.5 vs. 15.4 ± 1.7 , $p < 0.001$) and in NG (12.1 ± 1.7 vs. 13.2 ± 2.0 , $p < 0.05$) increased, and group differences were noticed ($p < 0.05$). Strength parameters were not changed. Sit-and-reach in EG (19.7 ± 6.4 vs. 22.7 ± 6.0 , $p < 0.01$) and back extension in EG (53.4 ± 8.4 vs. 58.5 ± 7.8 , $p < 0.05$) increased, and group differences in both were noticed ($p < 0.05$).

CONCLUSIONS: It is demonstrated that SNPE is valuable exercise modality to release pain perception, to improve functional movement, and to enhance flexibility in women experiencing chronic pain.

3822 Board #139 May 30 8:00 AM - 9:30 AM
Relationship Of Body Composition, Cutaneous Body Temperature & Muscle Power Of Lower Limbs In Folk Dancers

Luis Andrés Téllez¹, Juan Camilo Acevedo², Sulma Jimena Torres², Oscar Eduardo Muñoz¹, Jhonatan Camilo Peña³.
¹Universidad Santo Tomás, Tunja, Colombia. ²Universidad Santo Tomás, seccional Tunja, Tunja, Colombia. ³Fundación Unversitaria del Area Andina, Bogotá, Colombia.

 (No relevant relationships reported)

PURPOSE: Scientific evidence establishes that the practice of physical exercise increases the cutaneous body temperature, but the relationship with muscle power and body composition in dancers has not been established. **METHODS:** Twenty healthy professional dancers (11 men) and (9 women) participated in this study. The 20 dancers participated in a normal dance session (1 hour duration). Body composition was measured with electric bioimpedance BC-601FS FitScan evaluating Weight; P Body fat%; P Body water%; P Muscle mass; P Daily Caloric Intake; P Metabolic age; P Bone mass P Visceral fat. Muscle power was evaluated with DMJump jumping platform. Evaluating the Bosco Ergo Jump Protocol including (Squat Jump (SJ); Squat Jump with extra weight (SJ +); CounterMovement Jump (CMJ); Abalakov Jump (ABK); Drop Jump (DJ) calculating the elasticity index: elastic energy and the upper limbs coordination index The cutaneous body temperature was measured by infrared thermography before the session and during a session of 15, 30, and 60 minutes and 5 minutes after the session. The temperature was evaluated in the anterior tibial muscle of the gastrosoleo muscle. Achilles and sole, denominating "region of interest" (ROI). **RESULTS:** The behavior of the cutaneous body temperature in the different indoor regions increased during exercise and then returned to its basal state. It is evidenced that there is a direct relationship between muscle mass and cutaneous body temperature R = 0.91 (p <0.01). There is an inverse relationship between% fat and body temperature R = -0.89 (p <0.01). The behavior of the cutaneous body temperature in the lower limbs is inversely related to the muscular power R = 0.76 (p <0.05). **CONCLUSIONS:** The findings found in the present study establish the importance of the management of body composition and muscle power in cutaneous body temperature. In the future, the impact of dance on ligament and muscle structures can be detected to prevent injuries.

 (No relevant relationships reported)

PURPOSE: A pre-resistance training (RT) counter-movement jump (CMJ) has been proposed as a convenient neuromuscular readiness test to predict specific RT

performance and thus guide acute program modification. The present study assessed whether fatigue-related decrements in CMJ were associated with concomitant reductions in barbell squat performance.

METHODS: Adult males (n = 12, 25 ± 5 years; 178 ± 5 cm; 89 ± 12 kg) with >1 year RT experience performed 6 sets to failure with 90% of their 10 repetition maximum in the squat, bench press and latissimus dorsi pull-down. Relative changes (Δ) from pre- to 24 and 48 h post-RT were calculated for CMJ height (derived from force plate computed take-off velocity) and mean concentric barbell velocity (derived from a linear position transducer) in the barbell squat with loads corresponding to 1.0 (V1.0) and 0.8 m·s⁻¹ (V0.8). Differences in variables across time were assessed with repeated measures analysis of variance (for CMJ) or Friedman's test (for V1.0 and V0.8). Associations among Δ variables were quantified with Pearson's correlations. **RESULTS:** Squat V1.0 was significantly reduced at 24 (median ± interquartile range, 0.95 ± 0.07 m·s⁻¹, p = 0.04) and 48 h (0.93 ± 0.11 m·s⁻¹, p = 0.03) post-RT. Squat V0.8 was also significantly reduced at 24 (0.70 ± 0.09 m·s⁻¹, p <0.01) and 48 h (0.75 ± 0.04 m·s⁻¹, p = 0.03) post-RT. CMJ height was significantly reduced at 24 (mean ± standard deviation, 33.66 ± 5.20 cm, p = 0.02) but not 48 h (34.51 ± 5.12 cm) relative to pre-RT (36.00 ± 5.26 cm). No significant associations (all p <0.05) were observed between ΔCMJ and ΔV1.0 or ΔV0.8 at 24 (r = -0.06 - 0.29) or 48 h (r = 0.17 - 0.37) post-RT. **CONCLUSIONS:** Recovery of CMJ performance did not parallel recovery of barbell squat performance. CMJ height should not be used to predict daily barbell squat performance.

Workload Demands Of Position Players In Major League Baseball

Jonathan Freeston, PhD, SpSc.¹, Lonnie Soloff, PT, DPT, ATC², Mark Schickendantz, MD³. ¹The University of Sydney, Sydney, Australia. ²Cleveland Indians Baseball Club, Cleveland, OH. ³Cleveland Clinic, Cleveland, OH.
 Email: jonathan.freeston@sydney.edu.au
 (No relevant relationships reported)

PURPOSE: The injury burden within Major League Baseball (MLB) is significant in terms of events, days missed and financial cost. The types of injuries experienced by MLB players is diverse and differs by position; likely reflecting different running, throwing and batting-related workload demands. Understanding in-game demands is critical to athlete preparation, monitoring and management as well as return to play following injury however, little is known about the workload demands of position players in Major League Baseball across each of the key activity-domains. This study seeks to describe the physical demands of position players within Major League Baseball to inform physical preparation, monitoring and return to play. Given the uniquely demanding MLB playing schedule (6.3 games per week), demands across a single game, typical 5-day and worst 5-day periods are presented.

METHODS: Total and high-speed running distance (>75% Vmax), high-speed running count, hard accelerations (>3.0 m/s/s), defensive and baserunning minutes, total and hard throws (>80% Vmax), and bat swings were calculated from the Statcast Data provided by MLB to each club. Data were limited to players with 100 games or more in the 2018 championship season. 129 players met the inclusion criteria including: 18 1B, 17 2B, 20 3B, 21 SS, 12 C, 16 CF, 10 LF, 12 RF, and 3 DH. Levene's test was used to assess for Heteroscedasticity. Between group (position) differences were assessed using ANOVA (Bonferroni adjustment; criterion Alpha p=0.05).

RESULTS: Significant positional differences were evident across running and throwing but not bat swing metrics. Outfielders did more total (941.9 ± 135.5 yds per game), and high-speed running (87.3 ± 16.9 yds per game) than other positions. First-basemen did more hard accelerations (33.4 ± 8.7 per game). Middle infielders made more throws (3.5 ± 0.6 per game), and shortstops (0.9 ± 0.3 per game) made more hard throws. Bat swings were similar across positions (7.6 ± 1.0 per game).

CONCLUSIONS: This is the first description of workload demands for position players in Major League Baseball. This information can inform pre-season physical preparation, in-season monitoring and management and return to play progressions for injured professional baseball players.

Analysis Of The Use Of Sodium Bicarbonate In Performance Of Surfing Athletes

Taliê Z. b. Hanada, Angela Couto, Caroline Siriaco, Dilmar P. G. Jr., Rodrigo Pereira, Claudio Scorcine. Universidade Metropolitana de Santos, Santos, Brazil.
 Email: talie.hanada@hotmail.com
 (No relevant relationships reported)

PURPOSE: Surf is a sport that presents variations of intensity and duration during its practice. Therefore, strategies that contribute to muscle buffering in periods of high intensity, may be efficient to improve the performance of practitioners of this modality. **Objective:** To evaluate the efficiency of sodium bicarbonate in the performance of surfing athletes.

METHODS: Twenty surfers with an average age of 18 years were submitted to a sodium bicarbonate solution (0.5mg / kg) 40 minutes prior to the practice tests performed in the pool, alternating the same method, but with a solution containing chloride sodium and water (placebo), the other day, at random, in a cross over style. Upon arrival at the test site, the volunteers had blood lactate collected by a Roche® lactimeter pre and post practice and underwent a progressive paddling test on the pool on their own surfboard. They were instructed to shoot at a maximum speed of 20 meters to determine the time to be adhered as a basis for further testing. Subsequently, the athlete rested for 2 minutes and was instructed to perform up to 20 shots from 20 meters at 80% of his maximum speed with an interval of 100% of the time taken in the shot. The test was interrupted when the subject increased by 2 seconds of the maximum time performed, two consecutive times, or when completed the 20 idealized shots of the test. At the end of each test, blood samples were collected for lactate concentration analysis.

RESULTS: See table 1.

Evaluation	Bicarbonate	Placebo	P value
Lactate	16,43±3,1	14,83±2,7	0,04
Maximum time	10,68±0,8	10,88±0,6	0,05
Shots	16,35±5,2	16,35±5,2	

Table 1: Description, by the Student's t-test, of mean and standard deviation of lactate values; maximum time; and number of shots in relation of the use of bicarbonate and sodium chloride (placebo). The accepted significance level was p≤0.05.

CONCLUSIONS: The administration of sodium bicarbonate positively impacted the performance of the surfer athletes, leading to a maximum paddle test time improvement and an increase of the blood lactate.

3826 Board #143 May 30 8:00 AM - 9:30 AM
Effect Of Pedaling Feedback On 20-km Time Trial Gross Efficiency And Power Output

Lino Fabrizio Cappelli, Afton Danielle Seeley, Chelsey Sanborn, Grace J. Russo. *University of Miami, Miami, FL.* (Sponsor: Kevin A. Jacobs, FACSM)
(No relevant relationships reported)

INTRODUCTION: Gross efficiency (GE) is a crucial factor in endurance cycling performance. Elite cyclists have superior pedaling technique, sustaining a greater average power output (PO) through the pedaling cycle than non-elite cyclists. Previous studies have demonstrated that pedaling technique can be improved with visual feedback (FB), however, the effect of pedaling feedback on GE and PO has not been investigated. **PURPOSE:** Determine the effect of FB on pedaling technique software on GE and PO during a 20-km time trial completed with feedback (WF) and without feedback (WO). **METHODS:** Eight recreationally-trained males (39 ± 6 y, VO_{2peak}: 47.5 ± 6.1 mL·kg⁻¹·min⁻¹ at 282 ± 43 W) with at least six months of consistent cycling or triathlon training completed three 20-km TT. The first TT served to familiarize subjects with the FB software and cycle ergometer. During the other two sessions, subjects completed the time trial in the fastest time possible in both WF and WO conditions completed in randomized order. For WF, subjects received feedback regarding the smoothness of their pedal stroke cycle and attempted to optimize their pedaling technique real-time. Both GE and PO were calculated at 25, 50, 75, and 100% completion time. Statistical analyses of GE and PO for all stages of both WO and WF were completed using a 2x4 repeated measures ANOVA. **RESULTS:** GE and PO tended to be greater in all stages of WF when compared to WO (GE: 25%: 20.2 vs. 19.1%, 50%: 19.0 vs. 16.9%, 75%: 19.0 vs. 17.1%, 100%: 19.7 vs. 19.0%) (PO: 25%: 195 vs. 194 W, 50%: 203 vs. 171 W, 75%: 203 vs. 195 W, 100%: 221 vs. 213 W), but none were statistically significant (GE p = 0.084, PO p = 0.119). The biggest differences in GE and PO between the WF and WO conditions were at 50 and 75% completion. **CONCLUSIONS:** The monitoring of pedaling technique with FB of pedaling technique during a 20-km TT may lead to an improvement in GE without a reduction in PO during a single session using FB.

Self-reported Training Variables Are Poor Predictors Of Laboratory Measures In A Heterogenous Group Of Cyclists

Bryan Saunders, Bruna Mazzolani, Pedro Perim, Fabiana Infante Smaira, Nathalia Saffioti Rezende, Giulia Cazetta Bestetti, Alina Dumas, Luana Farias de Oliveira, Paul Swinton, Eimear Dolan. *University of Sao Paulo, Sao Paulo, Brazil.*
 Email: drbryansaunders@outlook.com
(No relevant relationships reported)

PURPOSE: Cycling is a predominantly aerobic activity that depends on a range of physiological attributes, as well as genetic, dietary and lifestyle factors. It is unknown

to what extent laboratory-measured physiological and performance characteristics are predicted by individual training factors such as intensity, duration, distance, coach supervision, level of competition and training experience in cycling. **METHODS:** Fifty-two men and 18 women completed a training questionnaire and performance tests generating 14 outcomes (incremental cycling test [8 outcomes]; 30-s Wingate test [4 outcomes]; and 4-km cycling time-trial [2 outcomes]). LASSO (least absolute shrinkage and selection operator) regression was performed for each performance outcome including demographic and training factors as potential predictors. Continuous regression inputs were scaled by dividing values by two standard deviations to facilitate comparisons with binary predictors and assist with model interpretation. Models were generated using the glmnet package in R with associations described by regression coefficients and percentage inclusion in 10000 bootstrap samples. **RESULTS:** Laboratory measures indicated a heterogenous group of athletes, as demonstrated by the range of maximal oxygen uptake values (VO_{2max}, range: 26.3 - 69.8 mL·kg⁻¹·min⁻¹). LASSO models identified that demographic factors were the most influential predictors of laboratory variables, with sex (76±37% inclusion), age (55±27% inclusion) and height (55±40% inclusion) featuring consistently in bootstrap samples across outcomes. In contrast, no discernible patterns were identified for training factors. When training factors did appear consistently in a model, the regression coefficients were small and median estimates of the best training predictors were equal to 15.1±7.4% of sex or 30.6±14.5% of the next most influential demographic factor. **CONCLUSIONS:** Self-reported training variables were poor predictors of physiological and performance measures in a heterogenous group of cyclists, while demographics such as sex, age and height were greater predictors of these variables. A lack of a properly structured or implemented training program might explain the low predictive ability of training variables towards these laboratorial outcomes.

Dynamic Vision Training Transfers Positively To Batting Performance Among Collegiate Baseball Batters

Sicong Liu¹, Lyndsey M. Ferris², Susan Hilbig¹, Edem Asamoah¹, Nicholas Port², Lawrence Gregory Appelbaum¹. ¹Duke University School of Medicine, Durham, NC. ²Indiana University School of Optometry, Bloomington, IN.
 Email: 64zone@gmail.com
(No relevant relationships reported)

PURPOSE: A growing body of evidence has demonstrated that visual, perceptual, and oculomotor abilities contribute to batting performance in baseball. As such, an important question is whether training such abilities can transfer positively to batting performance.

METHODS: The current study tested this question through a pre-registered, randomized, and placebo-controlled training intervention, conducted with 24 collegiate baseball players at two Division 1 universities. Athletes were randomized into two groups and received either active dynamic vision training consisting of stroboscopic, anticipatory timing, and eye quickness drills, or placebo drills stylized after control procedures in previous vision therapy studies. Visual-motor and batting performance data were collected and compared between the two cohorts to test the transfer of training effects, while controlling for covariates such as expectations and site. Generalized near-transfer of training was tested with a digital visual-motor task battery, while sports-specific intermediate and far transfer of training were evaluated through tracking metrics collected during structured batting practice and box score performance in NCAA-sanctioned games, respectively. Participants averaged 8.5 hours of training with no significant group differences in adherence, expectations, or baseline assessments.

RESULTS: Analysis of covariance revealed no group differences in measures of generalized visual-motor skills or NCAA game statistics. However, structured batting practice results revealed consistent gains in batting performance, with significant improvements in the Launch Angle (delta = 8°, p <0.001, Cohen's d = 0.66) and Hit Distance (delta = 41 ft, p <0.001, Cohen's d = 0.61) for the active cohort relative to the control group. This finding was present at each individual study site and in both the complete-case and intent-to-treat analyses.

CONCLUSIONS: These findings indicate that the use of sports vision training programs can result in improved performance beyond the direct skills trained, warranting further study and creating new opportunities for training baseball athletes.

The Athlete Specific Chronotype Index (ACTi)

Rhearne C. Ryan, Jason Siegler, FACSM, Chloe Taylor, Ric Lovell. *Western Sydney University, Penrith, Australia.* (Sponsor: Jason Siegler, FACSM)
 Email: rhearne.ryan@westernsydney.edu.au
(No relevant relationships reported)

The circadian variation of athletic performance has been observed to coincide with daily peaks in body temperature. Chronotypes (CT) take into account inter-individual variations in circadian rhythms, yet there is discord regarding the relationship between

CT and athletic performance. This may be due to the most common chronotyping method, the Morningness-Eveningness Questionnaire (MEQ), lacking validity for athletic populations. **PURPOSE:** The purpose of this study was to develop and validate an athlete specific CT index (ACTi). **METHODS:** 297 athletes completed a CT questionnaire in MEQ (19) and newly-developed questions (15). Principle component analysis (PCA) was used to identify common themes and reduce the final number of questions. 10 respondents from each CT category, as determined by the MEQ, then participated in a 24-hour laboratory study. Participants abided by their typical sleep/wake cycle, provided hourly saliva samples (for dim light melatonin onset (DLMO) analysis) whilst awake and hourly core body temperature (CBT) readings (ingestible thermistor) for the 24-hours. Stepwise multiple linear regression analysis to predict DLMO onset and CBT was used to further refine the ACTi.

RESULTS: PCA of the extended ACTi responses were performed, identifying 7 themes. Multiple regression identified 11 questions that explained DLMO ($r^2=0.81$), forming the final ACTi. DLMO CT differences were observed between MEQ morning-type (MT) and intermittent-type (IT) (64 ± 61.6 min, $p=0.02$); and MT and evening-type (ET) (114 ± 71.2 min, $p=0.002$). No CT differences were observed in CBT for MEQ or ACTi. Cohen's Kappa revealed moderate CT classification changes between MEQ and ACTi (0.62). **CONCLUSION:** The ACTi is an 11-point index that enhances CT determination of athletes versus MEQ, based on the criterion measure DLMO. The ACTi may be used in team-sports to examine the impact of CT upon performance, monitoring of training responsiveness and athlete wellbeing.

Effects Of Yoga On A Vibration Platform With Or Without Blood Flow Restriction

Ulku Karabulut, FNU Mahjabin, Bianca Cepeda, Cecilio Gutierrez, Jasmine Aviles, Karina Torres, Valquiria Caboclo, Murat Karabulut, FACSM. *University of Texas Rio Grande Valley, Brownsville, TX.*

Email: ulku.karabulut@utrgv.edu

(No relevant relationships reported)

PURPOSE: To investigate acute effects of yoga performed on a vibration platform (VP) with and without blood flow restriction (BFR) on hemodynamics, flexibility, and lower extremity explosive power.

METHODS: Total 17 healthy subjects, 8 males (age= 22 ± 4.2 years) and 9 females (age= 24.2 ± 2.9 years), were screened by questionnaires, read and signed informed consent, and participated in the study. Subjects completed 4 separate randomized yoga sessions (on the floor, on the floor with BFR (FL+BFR), on the VP (VP), and on the VP with BFR (VP+BFR)) with at least 48-hr in between. The sessions involving BFR consisted of application of specialized cuffs on the uppermost portion of both thighs restricting blood flow. All sessions started with the measuring of resting heart rate (HR) and blood pressure (BP), followed by a 5-min treadmill warm-up session. Then vertical jump performance (VJ) and flexibility were assessed. The yoga sessions consisted of a series of 8 different yoga poses (Garland pose, Downward dog, Lunge, Chair pose, Twisted chair, Warrior, Squat and Lord of the dance), each lasting 30-sec with 1-min of rest in between poses. During each pose, breathing was monitored by using a metronome to prevent subjects from holding their breath during exercise. VJ and flexibility were again tested immediately post-exercise. HR and BP were also measured immediately after and every 5-min for 25-min following completion of the yoga session.

RESULTS: Two-way ANOVA showed significant condition main effect ($p<.05$) for flexibility, indicating enhanced flexibility following VP compared to floor ($p<.05$) and VP+BFR ($p<.05$). Significant time main effects were detected for flexibility ($p<.01$), HR ($p<.01$), SBP ($p<.01$) and DBP ($p<.01$) indicating higher post-exercise values.

CONCLUSIONS: Enhanced flexibility in response to yoga on VP can be attributed to a vibration-induced activation of Golgi tendon organ causing the related muscle to relax and desensitization of stretch reflex due to activation of muscle spindles by the rapid changes in muscle length. However, no significant improvements in flexibility following the VP+BFR session could be due the placement of BFR cuffs on the uppermost portion of thighs, interfering with vibration-induced muscle length alteration and excitation of Golgi tendon organs.

GLOBAL PERFORMANCE INDEX IN TRIATHLON

Domingos R. Pandelo Jr, Emilson Colantonio, Fabio Buscariollo. *Centro de Alta Performance, Santos, Brazil.*

Email: pandelotri@gmail.com

(No relevant relationships reported)

PURPOSE: The aim of this study is to evaluate the relative importance of each modality in the result of the IRONMAN® World Championship race at Kona.

METHODS: All the analyses were made from 1981 until 2018, considering just the male professional triathletes that appeared, at least, 5 times between the TOP 10 finishers. 24 triathletes were selected. Their racing times were converted into seconds. The analysis was made in a global way and by modalities (swimming, cycling and

running). A global performance index (GPI) and a specific performance indexes were created for the triathletes for each modality: swimming performance index (SPI), cycling performance index (CPI) and running performance index (RPI). Afterwards, we calculated the correlation between the stages and made a regression with the overall performance as an independent variable and the relative performance in each stage (SPI, CPI and RPI) as dependent variable. In the regression analysis, we used the "Enter" method to force the entry of all the dependent variants.

RESULTS: The final equation to evaluate the Global Performance was: $GPI = (0,324 \times SPI) + (0,871 \times CPI) + (1,07 \times RPI)$. When the correlation between the stages was analyzed, we observed a negative correlation between SPI and RPI (0,403). This finding contradicts most of the studies that put cycling as the crucial stage in a long term triathlon race like IRONMAN®

CONCLUSIONS: This results can confirm that in triathlon races, being a good swimmer can be very important, despite the swimming stage be less representative. In general, the running stage is the most important of the race, based in the analysis of the correlation between the 3 modalities. Running is crucial, but this analysis is very complex, because the 3 stages are not independent as far as the effort made in one stage tends to impact the performance on the next one.

(No relevant relationships reported)

Purpose: To compare the cycling power-duration relationship between males and females and assess fatigability in the heavy and severe exercise intensity domains.

Methods: Eighteen cyclists (age: 25 ± 6 years, 10 males, 8 females) performed an incremental ramp test, then three constant-load cycling trials to task failure (110, 90, and 80% of maximum ramp test power (P_{max})). Critical power (CP) and the curvature constant (W') of the power-duration relationship were subsequently calculated and constant-load experimental trials were performed to task failure at 110% CP, and to task failure or for 60 mins at 90% CP, whichever occurred first. Near-infrared spectroscopy of the vastus lateralis (VL) and pulmonary gas exchange were monitored during exercise, and neuromuscular function assessed before and after experimental trials.

Results: Males had a greater P_{max} (362 ± 29 vs. 241 ± 42 W, $P<0.001$) and $\dot{V}O_{2max}$ (60.5 ± 8.2 vs. 44.2 ± 4.8 mL·kg⁻¹·min⁻¹, $P<0.001$) vs. females. In absolute units, CP (260 ± 28 vs. 179 ± 32 W, $P<0.001$) and W' (18.5 ± 4.8 vs. 12.7 ± 3.2 kJ, $P=0.009$) were greater in males, but when expressed relative to P_{max}, no differences existed ($P \geq 0.209$). There was no sex difference in time to task failure at 110% CP (752 ± 329 vs. 681 ± 277 s, $P=0.645$), but throughout the trial, females experienced a smaller decrease in VL oxygenation (-20 ± 8 vs. $-7 \pm 4\%$, $P<0.001$), and a smaller post-exercise reduction in twitch force (-35 ± 17 vs. $-15 \pm 10\%$, $P=0.010$) compared to males. During the 90% CP trial, three males and three females reached task failure prior to 60 mins (mean duration: 3073 ± 835 vs. 2937 ± 964 s, $P=0.758$). Females demonstrated a smaller decrease in VL oxygenation (-21 ± 9 vs. $-1 \pm 6\%$, $P<0.001$), as well as a lesser reduction in twitch force (-24 ± 11 vs. $-10 \pm 11\%$, $P=0.020$) and voluntary activation (-9 ± 6 vs. $-4 \pm 3\%$, $P=0.036$) post-exercise compared to males. Cortical ($-20 \pm 32\%$, $P=0.039$) and spinal ($-22 \pm 45\%$, $P=0.039$) excitability were reduced following the 90% CP trial, but no sex difference existed ($P \geq 0.132$).

Conclusions: No sex difference exists in the power-duration relationship when data are expressed relative to P_{max}. However, females demonstrate a greater fatigue resistance of the knee-extensors during both severe and heavy intensity cycling, likely due to lesser reductions in locomotor muscle oxygenation during exercise.

G-35 Free Communication/Poster - Physical Activity: Injury and Illness

Saturday, May 30, 2020, 8:00 AM - 10:30 AM

Email: c.oddy@leedsbeckett.ac.uk
(No relevant relationships reported)

PURPOSE: A runners training and performance history over the previous 12 months is rarely considered in data related to running injury and participation level. The purpose of this on-line questionnaire was to gather self-reported history of exposure, performance and injury over the preceding 12 months in runners of different abilities. Self-reported history of barefoot running and injuries was also collected.
METHODS: An on-line questionnaire (QualtricsSM software) was developed by the investigators and then distributed to a sample of runners recruited via social media and running clubs. Runners declared their participation level as; Non-competitive/recreational (NCR), represent club (RC) and represent county (RCOUN).
RESULTS: There were 224 respondents (59% = NCR, 35% = RC and 6% = RCOUN). Respondents reported (mean \pm SD): fastest 5km run time (minutes) = NCR 24.4 \pm 6.6, RC 21.05 \pm 4.06 RCOUN 16.53 \pm 1.61; 'on average' kilometres ran per week = NCR 28.8 \pm 18.50, RC 43.52 \pm 20.44, RCOUN 82.35 \pm 36.0; 'on average' minutes ran per week = NCR 190.36 \pm 142.28, RC 268.10 \pm 126.21, RCOUN 428.21 \pm 157.92. There were 175 respondents (78%) reporting at least one injury over the previous 12 months (total injuries = 348). Injury rates were; 10.99 injuries/1000hrs for NCR, 4.52 injuries/1000hrs for RC and 2.48 injuries/1000hrs for RCOUN. The most common injury sites were; knee for NCR (17%, 30/176), Achilles (19%, 21/109) for RC and calf (21%, 5/24) and/or shin (21%, 5/24) for RCOUN. There were 31 respondents (14%) that reported participating in barefoot running at least once per week, of which 20 (65%) reported having at least one injury with a relative risk of 0.803 (95% CI, 0.613-1.053), and an odds ratio of 0.613 (95% CI, 0.197-1.009). The Achilles was the most common site of injury (30%, 9/30).
CONCLUSIONS: These findings offer insights to the injury characteristics of runners from different participation levels. The findings should serve to catalyse prospective studies, including exploration of the risk of barefoot running on injury.

3834 Board #151 May 30 8:00 AM - 9:30 AM Characterizing OA Phenotype Response To Emerging Science In Sports (COMPRESS) Trial

Thomas Best, FACSM, Kenneth Barnes, FACSM, Jean Jose, Katerina Santiago, Erin Milian, Dylan Greif, Alberto Caban-Martinez. *U of Miami, Coral Gables, FL.*
Email: txb440@med.miami.edu
(No relevant relationships reported)

Osteoarthritis (OA) is among the most prevalent and debilitating chronic diseases worldwide affecting the general population as well as athletes. Despite that, no therapies have been proven to modify disease progression or to be highly effective for symptomatic relief, other than joint replacement surgery. Accordingly, recent effort has been aimed to define a classification of OA phenotypes for the purpose of better identifying individuals at higher risk of progression and to better delineate subpopulations attributable to distinct risk factors and disease mechanisms that may be suitable for targeted treatment and prevention strategies. Purpose: To characterize using the Dell'Isola criteria, the frequency of knee OK (KOA) phenotypes (6 in total) in new patients presenting to a single tertiary care institution. Methods: Following IRB approval, patients were phenotyped by the senior author (TMB) at their initial clinic visit. Kellgren-Lawrence (KL) readings were evaluated by the senior author and verified by a board certified MSK radiologist. Results: We successfully characterized 242 patients (30 - 70 years of age) with the Dell'Isola system. Due to requirements for specific biomarkers for the classification of the bone and cartilage metabolism phenotype, we were only able to classify five phenotypes (chronic pain, inflammatory, metabolic syndrome, mechanical overload, minimal joint disease). The most common phenotype was minimal joint disease (30% or 73 patients) followed by metabolic syndrome (19% or 45), mechanical overload (15% or 36), chronic pain (15% or 36), and inflammatory (6.3% or 15). For both the minimal joint disease and chronic pain phenotypes, there was unequal distribution of Latino to non-Latino subjects (70% vs. 30%). Discussion: OA is a complex disease increasingly recognized to be a disorder of multiple phenotypes. This study begins to phenotype a culturally and ethnically diverse population of patients with KOA in an academic Sports Medicine clinic. Ongoing investigations include validated functional evaluation (KOOS, WOMAC) of

our subjects to determine if certain phenotypes are associated with poorer functional outcomes. Reference: Dell'Isola A et al. *MJBmd. Identification of clinical phenotypes in knee osteoarthritis: a systematic review of the literature.* 2016; 17(1): 425.

3835 Board #152 May 30 8:00 AM - 9:30 AM Abstract Withdrawn**3836 Board #153 May 30 8:00 AM - 9:30 AM Abstract Withdrawn****3837 Board #154 May 30 9:00 AM - 10:30 AM Head Impacts In Women's Collegiate Club Lacrosse**

Email: necchi@uci.edu
(No relevant relationships reported)

Women's lacrosse is an 'incidental contact' sport meaning that intentional contact with an opponent is not permitted by the game's rules. Despite this, women's lacrosse played at the high school and collegiate varsity levels of competition carry a risk of repetitive head impact exposure and sport-related concussion. Head impact exposure at the collegiate club level of women's lacrosse has not yet been described.

PURPOSE: To characterize the anticipated and observed incidence of head impacts in women's collegiate club lacrosse.

METHODS: Experienced women's collegiate club lacrosse players (n=10) filled out questionnaires reporting how often they sustained head impacts (per game exposure) during the past year. Headband-mounted head impact sensors were worn by athletes (n=11) during eight collegiate club lacrosse games sanctioned by the Western Women's Lacrosse League. The sensors reported the peak linear acceleration (PLA) and peak rotational acceleration (PRA) associated with each recorded accelerative event. Head impacts were confirmed by two researchers independently reviewing competition video time-synced with sensors. Video review was also used to determine the mechanisms of confirmed impacts.

RESULTS: Athletes had a median 4 (range: 0.25 - 8) years of lacrosse experience and expected to sustain a median 0 (range: 0 - 3) head impacts per game. 75 accelerative events were recorded by the head impact sensors across 81 total game exposures. Six head impacts were confirmed using video and 69 accelerative events were rejected as false positives. Confirmed impacts had a median PLA of 21.0 g (range: 18.3 g - 48.3 g) and PRA of 1.1 krad/s^2 (range: 0.7 krad/s^2 - 5.7 krad/s^2). Four impacts resulted from contact with an opponent's body and two impacts resulted from contact with an opponent's stick. Only one head impact incurred a penalty against the opposing player.
CONCLUSIONS: Athletes anticipate and sustain infrequent head impacts in women's collegiate club lacrosse relative to lacrosse and contact sports played at the high school and collegiate varsity levels of competition. Those impacts that are sustained are of relatively low magnitude. Head impact sensors are prone to high false positive rates and the use of video recordings to filter sensor data is necessary.

3838 Board #155 May 30 8:00 AM - 9:30 AM Effects Of Adolescent Sports Specialization On NFL And MLS Players' Injury Propensity

Adarsh S. Kadoor¹, Suraj A. Achar¹, Jivan Achar², Dave Milzman³, Nirav Pandya⁴. ¹University of California, San Diego, La Jolla, CA. ²Canyon Crest Academy, San Diego, CA. ³Georgetown University, Washington, D.C., DC. ⁴University of California, San Francisco, San Francisco, CA.
Email: akadoor@ucsd.edu
(No relevant relationships reported)

Adolescent single sport specialization has been linked to a higher rate of overuse injuries and has even been shown to be detrimental to the health and career longevity of NBA players (Rugg et al).

Purpose: To evaluate a potential relationship between adolescent sports specialization and injury propensity in elite NFL and MLS players.

Methods: 570 first and second round NFL draft selections from 2010-2018 and 202 first round MLS draft selections from 2005-2018 with reliable sport specialization, injury history, and playing career data were identified. Publicly verified internet sources were used to classify adolescent sport participation, number and type of severe injuries sustained during pro football or soccer games, and number of total possible games played and missed due to injury. Subjects for each league were divided into 2 cohorts: multisport (MS) and single sport (SS). Sports specialization comparisons were made as follows:

(1) Average % of games missed due to injury (APGM) using 2 sample T test and (2) % of players who sustained at least 1 major injury (%MI) using one-tailed Fisher's exact test.

Results:

APGM was lower in the NFL MS group (11.4±0.7% vs 18.7±2.3%; $p<.01$) but not in the MLS MS group (6.51±1.9% vs 5.8±1.0%; $p=0.377$) [Figure 1]. %MI was also lower in the NFL MS group (54.2 vs 68.8%; $p<.01$) but not in the MLS MS group (41.7 vs. 35.1%, $p=0.4528$) [Figure 2].

Figure 1. APMG Sports Specialization Comparison in NFL and MLS

Figure 2. %MI Sports Specialization Comparison in NFL and MLS

Conclusion:

Adolescent MS specialization contributes to a reduction in injury predisposition in NFL athletes but not in MLS athletes.

3839 Board #156 May 30 8:00 AM - 9:30 AM Epidemiology Of Sudden Death In Organized School Sports In Japan

Yuri Hosokawa¹, Rebecca L. Stearns², Yuki Murata³, Miwako Suzuki-Yamanaka¹, Douglas J. Casa, FACSM². ¹Waseda University, Tokorozawa, Saitama, Japan. ²University of Connecticut, Storrs, CT. ³Nagoya University, Nagoya, Aichi, Japan. (Sponsor: Douglas J. Casa, FACSM)
Email: yurihosokawa@waseda.jp
(No relevant relationships reported)

There are approximately three-million four-hundred thousand registered student athletes in middle and high school in Japan. Despite a large number of participants, health and safety policies for student athletes in Japan are at its infancy and there is paucity of data-driven policies to reduce catastrophic and fatal injuries from sports. **PURPOSE:** Describe the epidemiology of sudden death in organized school sports in Japan. **METHODS:** Data submitted to Japan Sport Council (JSC) Injury and Accident Mutual Aid Benefit System between 2005-2016 were retrieved from JSC website for

analysis (n=1,137). Case information on fatal incidents occurred during organized school sports in middle and high school students were extracted for further analysis (n=198). Descriptive statistics related to information about activity type, sex, sport, diagnosis, and presence of on-site trained medical personnel were calculated using frequency and proportion. Sudden death incidence rates were expressed per 100,000 athlete-years and 95% confidence intervals (CI). **RESULTS:** Fatalities were reported in practice (n=120/198, 60.6%), scrimmage (n=16/198, 8.1%), game (n=10/198, 5.1%), training camp (n=16/198, 8.1%), and other (n=36/198, 18.2%). The average incidence rate of sport related fatality was 0.39 death per 100,000 athlete-years (95% CI= 0.31-0.47). Most fatalities were in male student athletes (n=149/162, 92%), which yielded to 7.5 times greater fatality rate in male than female student athletes (male, 0.60 death per 100,000 athlete-years, 95% CI= 0.46-0.73; female, 0.08 death per 100,000 athlete-years, 95% CI= 0.03-0.13). Baseball (n=25/162, 15.4%), judo (n=24/162, 14.8%), soccer/futsal (n=20/162, 12.3%), and basketball (n=18/162, 11.1%) accounted for 53.7% of fatalities. Sudden cardiac death (n=68/162, 42.0%), head trauma (n=32/162, 19.8%), and heat related injury (n=25/162, 15.4%) were the top three diagnosis of fatality. Only three cases (2%) reported of having trained medical personnel on-site at the time of incident. **CONCLUSIONS:** Sports-related fatality among Japanese student athletes was highest in male baseball players during practice due to sudden cardiac death. Almost no incidents had trained medical personnel on-site at the time of catastrophic injuries during school organized athletics in Japan.

3840 Board #157 May 30 8:00 AM - 9:30 AM Removal From Activity Following Sport-related Concussion In Sex-comparable Sports

Aaron J. Zynda, Kyle M. Petit, Morgan Anderson, Christopher P. Tomczyk, Tracey Covassin. Michigan State University, East Lansing, MI.
Email: zyndaar@msu.edu
(No relevant relationships reported)

As sport-related concussion (SRC) awareness has increased, timely reporting and immediate removal from play have become a focal point of proper management. Delayed removal may result in additional injury and protracted recovery. Research has demonstrated that girls are more honest and likely to report their concussion symptoms compared to boys. However, it is unknown if these reporting behaviors correspond with immediate removal from play in girls compared to boys in sex-comparable sports. **PURPOSE:** To compare the incidence of high school athletes not removed from activity following SRC in sex-comparable sports in Michigan. **METHODS:** An epidemiological study of athletes diagnosed with SRC participating in Michigan High School Athletic Association-sponsored basketball, baseball/softball, and soccer from 2016-2019 was performed. All SRCs were recorded in a Head Injury Reporting System by certified athletic trainers, administrators, or coaches. Removal from activity indicated the athlete was removed from play at the time of an injury event. Lack of removal does not indicate mismanagement at the time of the event, but that the injury was not reported. Incidence was calculated by dividing SRCs not removed by total SRCs in each sport. Risk ratios were calculated by dividing the incidence of girls not removed by boys not removed in each sport. **RESULTS:** A total of 3696 (2425 female, 1271 male) SRCs were reported, with the most occurring in girls' soccer (n = 1024). Overall, 442 girls and 182 boys were not removed from activity, resulting in incidences of 0.18 (95% CI, 0.17-0.20) and 0.14 (95% CI, 0.12-0.16), respectively. Across all sports, girls were 1.27 (95% CI, 1.09-1.49) times as likely to not be removed from activity compared to boys. Girls had 1.16 (95% CI, 0.91-1.50), 1.19 (95% CI, 0.77-1.84), and 1.41 (95% CI, 1.12-1.78) times the risk of not being removed from basketball, softball, and soccer, respectively, when compared to the equivalent boy sports. **CONCLUSIONS:** Girls were at greater risk of not being removed from activity compared to boys in sex-comparable sports. Although girls are more likely to report symptoms of SRC, there is still a gap in their removal from play, potentially due to a delayed onset or recognition of symptoms. Future research and initiatives should target reporting and removal in female sports.

3841 Board #158 May 30 8:00 AM - 9:30 AM Domain-specific Physical Activity, Pain Interference, And Muscle Pain After Activity

Christopher TV Swain¹, Julie K. Bassett¹, Allison M. Hodge¹, Shahid Mahmood², Harindra Jayasekara¹, Robert J. MacInnis¹, Graham G. Giles¹, Roger L. Milne¹, Dallas R. English¹, Brigid M. Lynch¹. ¹Cancer Council Victoria, Melbourne, Australia. ²The University of Melbourne, Melbourne, Australia.
(No relevant relationships reported)

PURPOSE: The context in which physical activity is performed may affect self-reported indicators of pain. Using the Melbourne Collaborative Cohort Study, we examined associations between occupation, household, transport, and leisure physical activity with pain interference and muscle pain after activity. **METHODS:** The analysis included 9,577 working and 12,281 non-working participants. Physical activity was assessed using the International Physical Activity Questionnaire-Long

Form. Pain interference was assessed using SF-12, and muscle pain after activity was assessed using Sphere-12. Ordered logistic regression was used to estimate odds ratios (OR) and 95% confidence intervals (CI), and restricted cubic splines were used to graphically represent the dose-response association between each physical activity domain and pain outcome. **RESULTS:** Compared to those in the lowest quartile, participants in the highest quartile for transport activity had less pain interference (workers OR: 0.84, 95% CI: 0.74, 0.95; non-workers OR: 0.80, 95% CI: 0.71, 0.89) and muscle pain after activity (workers OR: 0.82; 95% CI: 0.69, 0.98; non-workers OR: 0.81, 95% CI: 0.71, 0.93). Similarly, participants in the highest quartile of leisure activity had less pain interference (workers: OR: 0.82; 95% CI: 0.69, 0.98; non-workers OR: 0.81, 95% CI: 0.71, 0.93) and muscle pain after activity (workers OR: 0.79; 95% CI: 0.64, 0.96; non-workers: OR: 0.89, 95% CI: 0.76, 1.03). In workers only, participants in the highest quartile of household activity reported more pain interference (OR: 1.37; 95% CI: 1.20, 1.57) and muscle pain after activity (OR: 1.34; 95% CI: 1.12, 1.61) than those in the lowest quartile. Occupational activity was not associated with either pain outcome. **CONCLUSIONS:** Within the transport and leisure domains, physical activity was inversely associated with pain-related outcomes, whereas more household physical activity was positively associated with pain scores within the working sample.

3842 Board #159 May 30 8:00 AM - 9:30 AM
Characterizing Impacts In Girls' High School Lacrosse Using Video Analysis

Samantha L. Hacherl¹, Patricia M. Kelshaw¹, Andrew E. Lincoln², Heather K. Vincent, FACSM³, Daniel C. Herman, FACSM³, Shane V. Caswell¹. ¹George Mason University, Fairfax, VA. ²MedStar Sports Medicine, Baltimore, MD. ³University of Florida, Gainesville, FL. (Sponsor: Heather K. Vincent, FACSM)
 (No relevant relationships reported)

Participation in high school girls' lacrosse is increasing, commensurate with concerns of risks for head impacts. Wearable sensors coupled with video analysis have characterized the incidence of head impacts in girls' lacrosse. However, due to high sensor measurement error, the true incidence of game-related impacts remains unclear. **Purpose:** Characterize the incidence of impacts in girls' high school lacrosse using video analysis.

Methods: Forty participants volunteered in 16 games during the 2019 lacrosse season. All games were filmed using a digital camera affixed to a tripod to capture impacts. Descriptive statistics were reported for all video-identified game-related impacts (VIGI), including impact rates (IR) and 95% confidence intervals (CI).

Results: There were 208 VIGI, for 297 player-games (IR=.70 impacts/player-game, CI: 0.61, 0.80). Overall, midfielders had the most impacts (n=88, 42.3%) followed by attackers (n=79, 38%) and defenders (n=41, 19.7%). The most common impact mechanisms were player (n=105, 50.5%), stick (n=88, 42.3%), and ground (n=13, 6.3%) contact. Most impacts occurred during offense-defense transitions (n=44, 21.2%) and settled game play (n=39, 18.8%), defending (n=33, 15.9%) and shooting (n= 34, 16.3%). Of all impacts, 29 (13.9%) were direct head impacts (IR=.10, CI: 0.06, 0.13). The most common head impact mechanisms were contact with stick (n=24, 82.8%), ground (n=4, 13.8%), and ball (n=1, 3.4%). The most common game play impact characteristics were shooting (n=7, 24.1%), settled game play (n=7, 24.1%), offense-defense transitions (n=4, 13.8%) and defending (n=4, 13.8%). A penalty was called by the referee for 17 (58.6%) head impacts.

Conclusion: The incidence of overall VIGI was considerably greater than previously reported studies using a sensor driven approach to identify and subsequently verify impacts using video. However, the rate of head impacts was lower, but similarly stick and ground contact remained the most common mechanisms despite their prohibition in the sport. Our findings reinforce the need for rule enforcement of prohibited game play behaviors. Prospective video analysis of head impacts in girls' lacrosse may assist with characterizing impacts and their incidence, especially as the sport shifts toward the intervention of headgear.

3843 Board #160 May 30 8:00 AM - 9:30 AM
How Many Snaps Are Too Many? Survival Analysis Of Concussions In The National Football League.

James M. Smoliga, FACSM¹, Zachary Binney². ¹High Point University, High Point, NC. ²Binney Research, Analytics, and Sports Services, LLC, Atlanta, GA.
 Email: jsmoliga@highpoint.edu
 (No relevant relationships reported)

Current methods used to estimate concussion risk in American football generally do not account for within-season variation in exposure between individual players. Thus, utilizing individual snap count data to quantify exposure may be beneficial for epidemiologic studies evaluating concussion risk in football.

PURPOSE: To determine the association between football exposure, quantified using snap count data, and concussion within the regular season in the National Football League (NFL), and how this varies by playing position.

METHODS: Weekly snap count and injury report data were obtained for every player who participated in the 2012 through 2017 NFL regular seasons, using the Football Outsiders database. Exposure was quantified as the cumulative total number of snaps that a player participated in for a given season, and used as the time-dependent variable in a Cox proportional hazard model. Concussion status (concussed vs. not-concussed) served as the event variable. If an individual received multiple concussions within a season, only the first within a season was included in the model. The effect of playing position on time to concussion were independently assessed as a categorical covariate. Hazard ratios (HR) were computed, with special teams positions (kicker, punter, and long snapper) as the reference category. **RESULTS:** A total 5,289,149 player-snaps were analyzed from 4231 distinct players, representing 12,004 player-seasons. Position was significantly associated with concussion hazard (p<0.001), with defensive backs [HR (95% confidence interval); median (interquartile range) number of snaps to first concussion = 2.8 (1.2, 6.3); 324 (377)], running backs [3.0 (1.3, 6.9); 200 (225)], tight ends [3.5 (1.5, 8.2); 290 (334)], and wide receivers [2.7 (1.2, 6.1); 227 (251)] having significantly greater hazard than special teams players. Across positions, the median number snaps before first concussion was 295 (355).

CONCLUSIONS: Survival analysis using snap count to quantify football exposure provides similar results to other epidemiological studies regarding which positions are at greatest risk of concussion. Future research should examine whether using this metric of exposure provides any additional insight into other potential risk factors for concussion or concussion-related outcomes.

3844 Board #161 May 30 8:00 AM - 9:30 AM
Assesment Of Physical Activity Levels And Quality Of Life In Different Clinical Populations

Maria Maridaki¹, Argyro Papadopetraki², Theofanis Stergiou², Costas Chryssanthopoulos². ¹National and Kapodistrian University of Athens, Dafni-Athens, Greece. ²National and Kapodistrian University of Athens, Athens, Greece.
 Email: mmarida@phed.uoa.gr
 (No relevant relationships reported)

Impaired quality of life (QoL) has been reported in different clinical populations such as patients suffering from cancer (CA), multiple sclerosis (MS) or cardiovascular diseases. A growing body of evidence indicates that physical activity (PA) affects subjective QoL while there is a dose-response relationship between the volume of exercise and its health benefits. **PURPOSE:** The present study assessed and compared PA levels and QoL of different clinical populations and age-matched healthy adults. **METHODS:** One hundred and thirteen volunteers, i.e., 29 with CA under chemotherapy (age: 56.0 ± 10.4 yrs, BMI: 27.2 ± 5.4 kg/m²), 20 with MS (age: 53.3 ± 14.4 yrs, BMI: 25.9 ± 3.5 kg/m²), 14 with hypertension (HYP) (age: 55.0 ± 11.0 yrs, BMI: 31.0 ± 6.0 kg/m²) and 50 healthy controls (CON) (age: 51.3 ± 6.5 yrs, BMI: 25.3 ± 3.1 kg/m²), participated in the study. Levels of PA and QoL were self-estimated with the International Physical Activity Questionnaire and the SF-36 Health Survey questionnaire or the EORTC-QLQ30, respectively. **RESULTS:** The weekly energy expenditure was higher (p<0.01) in the CON group (2658.4 ± 2763.6 METs) compared with all clinical populations examined (CA: 2176.5 ± 2033.6 METs; HYP: 1560.9 ± 760.2 METs; MS: 64.2 ± 67.6 METs). Moreover, the metabolic cost of vigorous intensity PA was low in CA (30.6 ± 114.9 METs), HYP (36.9 ± 92.1 METs) and MS (0 METs), in contrast with the controls (1020.0 ± 1472.5 METs) (p<0.001). Differences were also revealed in walking energy expenditure between CON and MS group (1653.4 ± 1726.4 vs 114.0 ± 163.1 METs; p<0.05). Physical functioning (PF) score was higher in CON (85.5 ± 15.1) compared with MS (31.3 ± 31.2; p<0.001) and CA (69.4 ± 22.0; p<0.05). Furthermore, QoL was assessed as poor in MS (29.5 ± 20.4) and moderate to high in CA, (59.8 ± 17.5) CON (71.10 ± 18.7), HYP (71.4 ± 14.3) (p<0.001).

CONCLUSIONS: Our findings revealed that clinical populations included in this study had a lower total weekly energy expenditure compared to healthy individuals, without engaging in high-intensity PA. In particular, MS patients exhibited the lowest rates of PA, PF and QoL, while CA and HYP group showed higher scores in of PA, PF and QoL, implying a potential relationship between PA and QoL. The specific nature of each disease may explain the differences observed among the clinical populations examined.

3845 Board #162 May 30 8:00 AM - 9:30 AM

Migraine In College Students: Relationships Of Exercise, Sleep And Stress

Nauris Tamulevicius¹, Tanuj Wadhi¹, Jung Jung Tien², Guillermo R. Oviedo³, Claudia Aguado Loi¹, Jeanna M. Ortiz¹, Zaynah Rodriguez¹, Mary P. Martinasek¹. ¹University of Tampa, Tampa, FL. ²University of Central Florida, Orlando, FL. ³University Ramon Llull, Barcelona, Spain.
Email: ntmulevicius@ut.edu

(No relevant relationships reported)

Migraine headaches is a common disabling disorder which affect daily activities and academic performance in college students. There is disagreement in published research whether exercise triggers or prevents migraine. **PURPOSE:** The purpose of this study was to identify the relationships of migraine, regular exercise, sleep and stress in college students. **METHODS:** An online survey was sent to 9,675 students at a mid-sized university. A total of 675 students responded to the survey, with 557 respondents (5.7%) completing the entire survey [age: 21.01±4.86 y.o., females: 80.9% (n=451); males: 18.1% (n=101); other: 0.9% (n=5)]. Prevalence of migraine headache, self-reported triggers, exercise habits and perception of exercise in relation to migraine, and relationship between sleep (PSQI), stress (PSS) and migraine impact (HIT-6) were examined via SAS and MS Excel. **RESULTS:** Prevalence of self-reported migraine headache in the past six months was 63.5% (n=354) while prevalence of migraine headache confirmed by a physician was 26.7% (n=149). The top three identified trigger factors were life stress (96.6%), academic stress (96.0%) and lack of sleep (94.6%). About 40% of migraineurs reported that they did not have migraine 24 hrs after exercise. Participants who exercised regularly were less likely to get migraines (~21% less likely). Interestingly, those with migraines exercised more than those who did not have migraines (38.4% versus 23.7%). A higher sleep quality was inversely correlated to prevalence of migraine ($r=-0.335$). Impact of the headache on daily life was also correlated with perceived stress ($r=0.239$), and inversely correlated with sleep score ($r=-0.208$). **CONCLUSION:** Stress and lack of sleep are the most common self-reported migraine triggers in college students. Our study found that currently migraineurs do more regular exercise than those who did not report migraines. Quality of sleep is an important factor in migraine prevention. Regular exercise has the potential to prevent migraines but further studies need to be done to examine the exercise frequency, duration, intensity to determine long term outcomes.

Sports Injury Model For Effective Prevention, Diagnostic And Rehabilitation

Rado Piset, Uros Marusic, Bostjan Simunic. *Science and research centre Koper, Koper, Slovenia.*
Email: rado.piset@zrs-kp.si

(No relevant relationships reported)

In order to develop a model for a safe and effective return to sport after injuries, it is important to identify the risk factors associated with the occurrence of an injury. For the first time, we introduce the Tensiomyography (TMG) in the field of sport injuries (SI), a non-invasive and selective tool for the assessment of skeletal muscle contractile properties. As a recommendation from former experiences, a FC Barcelona documented a Muscle Injuries Clinical Guide 3.0 that explicitly emphasizes the use of TMG for the follow-up of muscle functional recovery and to help decide when the athlete can return to play. **PURPOSE:** To develop a thigh SI prediction model and explore factors of safe return to play. **METHODS:** The ongoing research project aims to monitor SI epidemiology in Slovenian premium soccer clubs. We monitored TMG of vastus lateralis and medialis, rectus femoris, biceps femoris and semitendinosus of both legs; body characteristics (body height, mass and fat), motor tasks (strength endurance in hamstrings; explosive lower-body strength, flexibility of lower body). **RESULTS:** Based on 11 thigh SI we were able to predict four (sensitivity 27%, specificity 99%). When predicting only 6 biceps femoris hamstring SI we could predict 4 (sensitivity 80%, specificity 100%). The predictive factors were derived only from TMG parameters. It appears that the worst-case scenario for the SI occurrence of biceps femoris is it short TMG-derived contraction time, high biceps femoris tone and low lateral symmetry. Interestingly, there were no significant predictors from body characteristics and motor tasks. **CONCLUSION:** Twenty-seven percent of all thigh SI and 80% of hamstring SI could be predicted solely from simple-to-use and non-invasive TMG screening. It seems that short contraction time (previously linked to high proportion of type II muscle fibers) and high muscle tone are risk factor for hamstring injuries, especially where imbalances between both lateral sides were present. Supported by Slovenian Research Agency (research core funding no. L5-8245).

Injury Rates Among Elite Wushu Kung-fu Martial Artists And Access To Health Care

Samuel Montalvo¹, Erik Tan², Daniel Conde¹, Gabriel Mejia-Ibarra¹, Sandor Dorgo¹. ¹University of Texas at El Paso, El Paso, TX. ²Malaysia Sports Institute, Kuala Lumpur, Malaysia.
Email: sammisp@Hotmail.com

(No relevant relationships reported)

Wushu Kung-Fu is a worldwide practiced martial art commonly known as “Kung-Fu”. The International Wushu Federation (IWUF) host a world competition every 2 years with more of 1,500 participants from countries all over the worlds. Musculoskeletal injuries are common among elite and amateur athletes of any sport. Access to health care can and might determine their proper treatment and return to sport. **PURPOSE:** To assess the injuries rate among Elite Wushu Kung-Fu Martial Artists and observe the relationship between access to health care and proper injury treatment. **METHODS:** One hundred and three athletes (n = 103; Males = 69, Females = 34) completed a survey prior before the 10th World Wushu Championships in China. Out of this sample, 94 were performance athlete (Taolu) and nine were professional fighters (Sanda). **RESULTS:** Out of the 103 responders, 49.5% reported Ankle injuries, 29.1% Lower Back, 18% reported an Anterior Cruciate Ligament (ACL) injury, 18.4% meniscus, 5.8% of combined ACL and meniscus, 16.5% Patella Tendinopathy, 14.6% leg adductors injuries, 7.8% Medial Collateral Ligament, and 6.8% Lateral Collateral Ligament injuries; from these injuries, only 48.5% reported a serious injury (time to heal > 8 weeks). About 50.5% of these injuries were reported to happened during technical training, 47.6% during jumping maneuvers, 17.5% during the warm-up and strength training, and 11.7% during competition. In terms of medical insurance, 46% reported to have private medical insurance, 29% government insurance, and 25% no insurance at all. In addition, 46.4% reported to have access to a Physical Therapist, and only 53.6% reported no access to Physical Therapist. A chi-squared showed no association between those who have medical insurance (governmental or private), or no medical insurance, and those who have access to proper physical therapy ($p > 0.05$). **CONCLUSIONS:** The great majority of injuries were reported to happen during technical training sessions and jumping maneuvers. The most common injuries sites were the Ankles, Lower back muscles, ACL, and Meniscus. Coaches and athletes might want to look into strategies on how to lower the risk of injuries at these specific sites for Martial Artists.

3848 Board #165 May 30 8:00 AM - 9:30 AM

Determinants Of Lower-extremity Injury Severity And Recovery Among High School Soccer Players In The U.S.

Avinash Chandran¹, Angelo F. Elimi², Heather Young², Zachary Y. Kerr¹, Loretta DiPietro, FACSM². ¹University of North Carolina at Chapel Hill, Chapel Hill, NC. ²George Washington University, Washington DC, DC. (Sponsor: Loretta DiPietro, FACSM)

Reported Relationships: A. Chandran: Other (please describe); This study would not be possible without the assistance of the many high school athletic trainers who participated in the NATION-SP. This project was funded by the National Athletic Trainers' Association Research and Education Foundation, and the Central Indiana Corporate Partnership Foundation in cooperation with BioCrossroads. The content of this report is solely the responsibility of the authors and does not reflect the views of the sponsors. All actions pertaining to the study analysis were performed at The George Washington University. The authors declare that they have no competing interests.

PURPOSE: Lower-extremity injuries are common among soccer players, yet few studies have attempted to identify determinants of lower-extremity injury severity in this group. We examined the impact of injury site, injury mechanism, sex, injury history, setting and playing surface on lower-extremity injury severity. **METHODS:** The NATION-SP captured soccer-related injury data collected by athletic trainers (ATs) during the 2011/12-2013/14 academic years. Lower-extremity injury sites of interest were hip/groin, thigh, knee, lower-leg/Achilles, and the ankle/foot. The nature/type of injuries, surgery for treatment (yes/no), season-ending outcomes (yes/no), and the recovery process (using observed time loss) were the outcomes of interest. Exposures of interest were injury site, injury mechanism (contact vs. non-contact), sex, injury history (new vs. recurrent), event-type (game vs. practice), and playing surface (natural vs. turf). Summary statistics (frequencies, %) were used to examine the nature/type of injuries. Multivariable logistic regressions were used to examine odds of season-ending outcomes, and surgery, as a function of the exposures; random effects Poisson regressions were used to examine exposure effects on the recovery process. Odds Ratios (ORs) and Time Loss Ratios (TLRs) with 95% confidence intervals (CI) excluding 1.00 were deemed significant. **RESULTS:** The majority of all lower-extremity injuries (n=2871) in this sample were sprains, strains/tears, or contusions (72%). Odds of a season-ending injury were higher in games than practices (OR_{adj}=2.64, 95%CI=1.39,5.01). Also, odds

of a lower-extremity injury resulting in time loss were significantly higher in female players compared to male players (OR_{adj}=1.34, 95%CI=1.05,1.71), and in games compared to practices (OR_{adj}=2.19, 95%CI=1.72,2.80). Sex, event-type, and playing surface emerged as significant determinants of any time loss following lower-extremity injuries, as well as predictors of recovery duration.

CONCLUSIONS: Sex, injury setting, playing surface differentially determine injury severity and recovery. Future studies using multi-method, multivariable approaches may be used to identify determinants of lower-extremity injury severity in this context.

3849 Board #166 May 30 8:00 AM - 9:30 AM
Incidence, Mechanism, And Severity Of Game-related High School And College Football Hand Injuries
 Hannah M. Wright. *Idaho State University, Pocatello, ID.*
 (Sponsor: Michael C. Meyers, PhD, FACSM)
 (No relevant relationships reported)

Injuries among high school and college football players are recorded on a game-by-game basis; however, the prevalence of hand injuries is often overlooked in lieu of more prominent football trauma. Presently, few football studies have been published comparing specific high school and college hand injuries. **PURPOSE:** To quantify the incidence, mechanism, and severity of specific game-related high school and college football hand injuries. **METHODS:** Hand injury cases were divided into two groups by level of play (high school, college), involving 783 FBS university and 1,921 high school games over 9 competitive seasons. Outcomes of interest included total and specific hand extremity, injury mechanism, and injury severity. Data were subject to multivariate analyses of variance (MANOVA) and Wilks' λ criteria using general linear model procedures. Injury incidence rate (IIR) was determined by the (number of injuries/number of team games) x 10. **RESULTS:** Of the 2,704 total games documented, a total of 270 hand injuries were reported with 167 (62.0%) occurring in college competition, and 103 (38.1%) in high school games. MANOVAs (Wilks' λ) indicated no significant main effect by total hand extremity ($F_{2,267} = 0.230$; $P = 0.876$), injury mechanism ($F_{2,263} = 1.203$; $P = 0.298$), and severity ($F_{2,267} = 1.572$; $P = 0.210$). Tests of between-subjects effects indicated no significant differences in IIRs of Boutonniere deformity ($F_{2,267} = 0.123$; $P = 0.726$), gamekeeper's thumb ($F_{2,267} = 0.124$; $P = 0.725$), or mallet finger ($F_{2,267} = 0.121$; $P = 0.505$). There was a trend, however, for greater IIRs of Boutonniere deformity [0.1 (95% CI, 0.0-0.2) vs 0.5 (95% CI, 0.4-0.7)], gamekeeper's thumb [0.3 (95% CI, 0.2-0.4) vs 1.1 (95% CI, 0.9-1.4)], and mallet finger [0.0 (95% CI, 0.0-0.1) vs 0.4 (95% CI, 0.3-0.6)] during high school play when compared to collegiate competition, respectively. Blocking (10.3 vs 14.8%) and tackling (8.8 vs 18.9%) were the primary mechanisms of injury in both high school and college, respectively. **CONCLUSION:** A substantial number of hand injuries were documented between high school and college games, which may ultimately lead to long-term articular compromise. Therefore, further studies are warranted to reduce predisposition of hand trauma at all levels of football competition.

3850 Board #167 May 30 8:00 AM - 9:30 AM
Use Of Two Screening Tools To Determine Injury Risk In Collegiate Acrobatics And Tumbling Athletes
 Michelle A. Sandrey, Sara E. Spencer. *West Virginia University, Morgantown, WV.* (Sponsor: Jean L. McCrory, FACSM)
 Email: msandrey@mail.wvu.edu
 (No relevant relationships reported)

Participation in athletic teams, especially those that involve difficult stunts and acrobatic maneuvers increase the risk for injury. With this emerging sport and the skills needed to participate, it is important to identify those athletes at risk. Yet, it is unknown whether a functional screening or proprioceptive tool can be used to predict injury in this population. **PURPOSE:** To determine if compensatory movement patterns predispose acrobatics and tumbling athletes to injury, and to determine if a functional movement screening (FMS) and Lower Quarter Y Balance Test (LQ-YBT) could predict potential injury risk in the sport population. **METHODS:** 22 participants (age 19.25yrs \pm 0.91, height 161.97 \pm 7.03cm, weight 62.53 \pm 8.71kg) from one acrobatics and tumbling team were used in the study. All participants that volunteered for the study were current student-athletes at a NCAA DII institution on a NCATA recognized Acrobatics and Tumbling team. The participants were asked to complete the seven movement patterns and three clearing tests of the FMS along with the LQ-YBT test in three directions (anterior, posterolateral and posteromedial) for both limbs. A total of three practice trials were used. Screening data was gathered over a two-week period at the beginning of the season. A self-report demographic and injury questionnaire was also used. **RESULTS:** FMS score was 15.9 \pm 1.87, while the LQ-YBT was 98.36 \pm 11.63 for the right and 99.24 \pm 12.01 for the left. Cox Snell R² was used to determine the percentage of the variables used to fit the model. The best fit was for FMS Cut (≤ 14 , ≥ 15) and total accounted injury that produced a Cox Snell R² (0.342) with a significant OR=28.335 (95% CI 4.29 to 561.997, p=0.028) for FMS Cut (≤ 14 , ≥ 15). Years of competition and total accounted injury with a Cox Snell R² (0.276) and a significant OR= 1.451 (95% CI .980 to 2.149, p=0.05) for years of competition was a moderate fit. FMS Final, LQ-YBT (R) and (L) produced a Cox Snell R² (0.259) with

a non-significant FMS Final OR= 1.983 (95% CI 1.045 to 3.763, p=.36). All other results were not significant. **CONCLUSIONS:** Compensatory fundamental movement patterns, increased skill and years of competition can increase the risk of injury. A score of 14 or less on the FMS paired with a higher number of previous injuries resulted in a 28-fold increase in risk of injury

3851 Board #168 May 30 8:00 AM - 9:30 AM
Lower Suicide Risk In Former US Olympians
 Juliana Antero¹, Hirofumi Tanaka, FACSM², Stephanie Duncombe¹, Quentin Delaroche Lambert¹, Jean-François Toussaint¹. ¹*The National French Sports Institute (INSEP), Paris, France.* ²*The university of Texas at Austin, Austin, TX.*
 Email: juliana.antero@insep.fr
 (No relevant relationships reported)

PURPOSE: To determine the suicide risk among Former US Olympians, according to their medal status and their sport, compared to the general population. **METHODS:** All female (n = 2,301) and male (n = 5,823) US athletes who participated in at least one summer or winter Olympic Games between 1912 and 2012 were followed until 2016 (the latest rates for specific mortality). Olympians' life statuses and causes of deaths were certified by the National Death Index and coded to the version of the International Classification of Diseases that was in effect at the time of their death. Intentional, self-inflicted deaths among Olympians were analyzed through the years lost/saved method accounting for their medal status and their sport. The model was adjusted by sex, age, and period, in relation to the general population. **RESULTS:** Overall 2,309 deaths occurred; the cause underlying 29 deaths was suicide (1 woman, 28 men). The cumulative probability of deaths for this cause was significantly lower among former US Olympians compared to the general population (p = 2.6e-08) for all ages between 20 and 90 years. The risk of death by suicide among former Olympians did not differ based on their medal status at the Olympics. Athletics, rowing, fencing, shooting, and swimming could be individually analyzed as each of these sports had more than 100 overall deaths. Olympians engaged in athletics, rowing, and swimming presented diminished suicide risk. Fencing displayed equivalent rates to the general population, and shooting had higher trends. However, limited power existed for significant statistical testing. **CONCLUSION:** Former US Olympians presented lower suicide risk compared to the general population, whether they were an Olympic medalist or not. The only sport presenting higher trends is shooting.

3852 Board #169 May 30 8:00 AM - 9:30 AM
Describing Red-s Outcomes And Potential Risk Factors In A National Cohort Of Ncaa Di Female Cross Country Runners
 Carrie Karvonen-Gutierrez¹, Traci L. Carson¹, Philippa Clarke¹, Sioban Harlow¹, Brady West², Ron Zernicke³. ¹*University of Michigan School of Public Health, Ann Arbor, MI.* ²*University of Michigan Institute for Social Research, Ann Arbor, MI.* ³*University of Michigan, Ann Arbor, MI.*
 Email: tlcars@umich.edu
 (No relevant relationships reported)

PURPOSE: The purpose of this study was to assess the prevalence of self-reported Relative Energy Deficiency in Sport (RED-S) outcomes in National Collegiate Athletic Association (NCAA) Division One (DI) female cross country runners, and to describe environmental risk factors for RED-S. **METHODS:** This sample is composed of a nationally representative random sample of NCAA Division One (DI) collegiate female cross-country runners from the ongoing Female Athlete Study of Health Trajectories (FASHT) cohort (N=152), with 133 complete respondents and 29 partial respondents. Randomly selected athletes were emailed a web-based survey, including demographic information, individual and environmental risk factors, and the 10 physical health outcomes of the RED-S model. **RESULTS:** Preliminary results show that this sample is overwhelmingly White (91%, n=139), non-Hispanic (91%, n=138), with a "comfortable" financial background (61%, n=90), and a mean age of 20.6 (SD= 2.6) years. Of note, 62% (n=82) of athletes reported having at least one sport-related bone injury over their athletic career, 49% (n=65) reported any history of irregular menses and 15% (n=20) reported currently experiencing irregular menses. The burden of clinical mental health diagnosis in the population included Anxiety (25%, n=33), Depression (15%, n=20), and any Eating Disorder (14%, n=18). **CONCLUSIONS:** These results suggest that this population of collegiate female cross-country runners experience a high burden of physical and psychological health morbidities and have a significant need for focused prevention and intervention for RED-S. Importantly, forthcoming research will focus on associations between risk and outcomes to inform public health programming.

3853 Board #170 May 30 8:00 AM - 9:30 AM

Sport Participation And Sport-related Concussion Trends In High School Athletes

Kyle M. Petit, Morgan Anderson, Christopher P. Tomczyk, Aaron J. Zynda, Tracey Covassin. *Michigan State University, East Lansing, MI.*
Email: petitkyl@msu.edu

(No relevant relationships reported)

Sport-related concussions (SRC) represent approximately 9% of high school athletic injuries. This high incidence has contributed to participation reduction, concussion legislation, and rule modifications. With these changes becoming more frequent, it is unknown if SRC trends are decreasing.

PURPOSE: To examine trends in contact sport participation and SRC clinical incidence in high school athletes during the 2015-16 to 2018-19 athletic seasons.

METHODS: A total of 724,784 athletes (male = 436,509; female = 288,275) participated on 15 sponsored teams in the state of Michigan during the 2015-16 to 2018-19 athletic seasons. Sport participation and diagnosed SRCs were reported by athletic trainers, coaches, or administrative officials using the Michigan High School Athletic Association Head Injury Reporting System. Clinical incidence was calculated for each sport by dividing the number of SRCs by the number of participants and is expressed per 100 athletes (95% CI). Linear regression was used to examine annual trends in participation and SRC clinical incidence for each sport. *a priori* < .05.

RESULTS: Football (144,708), boys' basketball (85,288), and girls' volleyball (76,950) had the highest sport participation. A total of 15,300 SRCs were reported yielding an overall clinical incidence of 2.11 (95% CI, 2.08-2.14) SRCs. Football (4.52 [95% CI, 4.41-4.62]), boys' ice hockey (3.51 [95% CI, 3.20-3.82]), and 8-person football (3.35 [95% CI, 2.85-3.85]) had the highest SRC clinical incidence. Trends in overall sport participation significantly decreased over time (-1983.0 athletes; *p*=.02). Only football yielded significant participation reduction (-1487.8 athletes; *p*=.01), while trends in 8-person football (182.8 athletes; *p*=.03) and boys' lacrosse (151.2 athletes; *p*=.03) increased. No significant trends were identified for overall SRC incidence (*p*=.14). Only girls' basketball had a significant reduction in SRC incidence (*p*=.04).

CONCLUSIONS: Contact sport participation, especially in football, may be decreasing due to concerns over athlete safety. With SRC incidence not declining, stakeholders should re-evaluate current initiatives to identify a more successful approach at reducing these injuries. Improving contact sport safety may then assist in increasing high school sport participation.

Examining Acute Effects Of Concussion On The Child Scat5

Patricia M. Kelshaw¹, Nathan E. Cook², Grant L. Iverson², Nelson Cortes¹, Shane V. Caswell¹. ¹George Mason University, Fairfax, VA. ²Harvard Medical School, Boston, MA.
Email: pkelshaw@gmu.edu

(No relevant relationships reported)

The Child Sport Concussion Assessment Tool 5th Edition (Child SCAT5) is recommended for the clinical assessment of concussion in children. To date, no studies have investigated how children perform on the Child SCAT5 acutely following concussion.

Purpose: We examined Child SCAT5 performance and symptom reporting among concussed middle school children assessed on the day of injury.

Methods: Certified Athletic Trainers diagnosed middle school student athletes (ages 11-13) with a sports-related concussion using the Child SCAT5 between 2017-2019. All assessments were administered on the day of injury ("day-of-concussion"). Day-of-concussion performance was compared to normative reference values derived from over 1,300 uninjured middle school athletes who underwent baseline, preseason Child SCAT5 assessments.

Results: There were 46 middle school student-athletes diagnosed with concussions [girls=17, boys=29, mean age=12.4±0.7]. The most commonly endorsed acute symptoms were: "I have a headache" (95.6%), followed by "I feel dizzy" (73.9%), and "I have problems remembering what people tell me" (63.0%). Middle school student-athletes day-of-concussion scores on the Child SCAT5 were: Total Symptoms (n=44, 10.4±5.9), Symptom Severity (n=44, 18.0±13.3), Immediate Memory (n=45, 13.0±2.6), Digits Backwards (n=45, 2.8±1.0), Concentration (n=45, 3.7±1.0), Total Balance (n=39, 8.5±5.9), Delayed Recall (n=44, 3.1±1.6), and Standardized Assessment of Concussion-Child Version (SAC-C n=44, 19.9±4.3). The mean number of total balance errors and the mean symptom severity scores were elevated relative to normative reference values.

Conclusion: Our results describe day-of-concussion Child SCAT5 scores in middle school children. The total symptom severity scores and total errors on the balance appeared to be most reflective of the acute effects of concussion. Further research is needed to establish the sensitivity and specificity of the Child SCAT5 to the acute effects of concussion in children.

3855 Board #172 May 30 8:00 AM - 9:30 AM

Physical Activity And Body Composition Of Women With Anterior Cruciate Ligament Reconstruction

Ashley N. Triplett, Christopher M. Kuenze. *Michigan State University, East Lansing, MI.*
Email: Triple18@msu.edu

(No relevant relationships reported)

Women are 4 to 6 times more likely to sustain an anterior cruciate ligament (ACL) injury than men. Women with ACL reconstruction (ACLR) are also 2.36 times less likely to be active than healthy individuals. In addition to reductions in physical activity (PA), it has been reported that BMI remains elevated up to 2 years post-ACLR, but the effects of ACLR on body composition profiles following surgery is unclear.

PURPOSE: To compare PA engagement and body composition between women with ACLR and healthy controls. **METHODS:** Ten women with ACLR (less than 5yrs post-ACLR, age=21.4±3.8yrs, BMI=26.1±3.8kg/m²) and 10 healthy women (age=21.9±3.1yrs, BMI=21.8±2.5kg/m²) completed the Tegner Activity Scale to assess current PA level. Body fat percentage (%BF) was estimated using air displacement plethysmography. Objective PA was assessed using hip-worn accelerometers for 10 hours/day for 7 days and Freedson Adult VM3 cut points were used for PA data processing. Groups were compared using Mann-Whitney U tests due to limited sample size. Time (minutes/week) spent in moderate-to-vigorous PA (MVPA) and step count (steps/day) were compared between groups using a one-way ANCOVA with total wear time as a covariate. **RESULTS:** Women with ACLR had significantly higher %BF than controls (ACLR=32.7±6.7%, healthy=22.6±4.9%; *p*<0.01) and higher fat mass (ACLR=25.4±9.0kg, healthy=13.7±4.1kg; *p*<0.01). Healthy women participated in significantly more steps per day (ACLR=6650±3227 steps/day, healthy=9361±2626 steps/day; *p*=0.02) than women with ACLR, but no differences in MVPA time (ACLR=367.2±226.2 mins/week, healthy=448.9±164.0 mins/week; *p*=0.34) were observed. **CONCLUSIONS:** Women with ACLR engage in similar levels of MVPA compared to controls, but they may exhibit greater %BF and fat mass than women who have not experienced ACLR. Compared to controls, women with ACLR also have lower step counts, which is consistent with previous studies. Lack of PA, high %BF, and overweight status increase the risk of premature mortality and morbidity. Therefore, it is crucial to further assess these characteristics and determine potential interventions that would promote PA and maintenance of healthy body composition in the months following ACLR.

HIIT Improves Insulin Resistance In T2DM Mice By Regulating Lipid Metabolism In Skeletal Muscle

lifang zheng¹, Peijie Chen¹, Weihua xiao¹, Zhijian Rao², Yifan Guo¹. ¹Shanghai university of sport, shanghai, China. ²Shanghai Normal University, shanghai, China.
Email: 15800896302@163.com

(No relevant relationships reported)

Abnormal skeletal muscle lipid metabolism is associated with insulin resistance in people with type 2 diabetes. Recent studies have indicated that high-intensity interval training (HIIT) lowers blood glucose and improves insulin resistance in individuals with type 2 diabetes. However, the physical mechanism is largely unknown.

PURPOSE: This study aimed to investigate whether HIIT improves insulin resistance in T2DM mice by regulating lipid metabolism in skeletal muscle.

METHODS: Diabetic mice were randomly assigned to the diabetes group (T2DM, n=11) and the HIIT group (n=11), and age-matched wild type mice were assigned as the control group (CON, n=11). HIIT was performed on a motored mice treadmill at 15° inclination 5 days/week for 8 weeks. The mice were trained with a starting speed of 10m/min, where after HIIT consisted of 10 bouts of 4 min high-intensity treadmill running, interspersed by 2 min complete rest. The pace during HIIT was increased gradually from 16 to 26 m/min over eight weeks. The fasting blood glucose, glucose tolerance was measured one week before the end of the experiment, and the gastrocnemius muscles of mice were collected 36h after the last exercise. The fat content of skeletal muscle was detected by Oil Red O staining. Protein expression of ACC, HMGCR, Cpt-1α, and CD36 was measured with Western blot.

RESULTS: The fasting blood glucose was decreased in the HIIT mice when compared to that in the T2DM mice (17.6±0.72 vs. 19.8±0.74 mmol/L, *p*<0.01). Glucose tolerance and the area under the curve (3325±126.4 vs. 3737±38. mmol/L·min, *p*<0.01) were improved after HIIT treatment when compared to that in the T2DM mice. Skeletal muscle exhibited a substantial amount of lipid deposition in the T2DM

group, which was markedly alleviated in the HIIT group ($p < 0.05$). In the skeletal muscle, HIIT treated mice showed significantly decreased protein expression related to lipogenesis, including reductions in ACC (0.39-fold, $p < 0.01$) and HMGCR (0.52-fold, $p < 0.01$). Expectedly, the protein expression level of Cpt-1 α (1.6-fold, $p < 0.01$) and CD36 (1.78-fold, $p < 0.01$) was significantly enhanced by HIIT.

CONCLUSION: HIIT improves insulin resistance was, at least partly, through deduces lipogenesis and increases lipolysis in skeletal muscle in the T2DM mice.

High-fat Diet Induces Nr4a3-dependent Decrease In Respiratory Capacity Of Mouse Soleus Muscle

Nathan D. Marchant, Erik D. Marchant, Weston S. Elison, Jacob A. Herring, Haokun Yang, Jeffrey S. Tessem, Chad R. Hancock. *Brigham Young University, Provo, UT.*
(No relevant relationships reported)

The Nuclear Hormone Receptor 4A family of genes have been observed to play a role in proper metabolic function in various tissues, including skeletal muscle.

PURPOSE: To analyze the effect of the Nr4a3 gene on respiratory capacity of mitochondria in skeletal muscle of mice on a normal or high fat diet.
METHODS: Nr4a3^{-/-} and WT mice were fed a normal chow (NC) or high fat diet (HF) for at least 20 weeks. After euthanasia, soleus muscle was harvested and wet weight was measured. Muscle fibers were teased apart and permeabilized with saponin in preparation for respirometry. Mitochondrial respiration was evaluated using an Oroboros Oxygraph Respirometer. Respiratory capacity comparisons were made with a two-way ANOVA and Tukey multiple comparison test.

RESULTS: Oxygen consumption is reported as pmol/(s*mg wet tissue) and statistics are represented as mean \pm SEM. In the WT male mice there was a decrease in coupled complex I supported respiration in HF vs. NC diet (25.9 \pm 7.3 vs. 64.5 \pm 5.0, $p = 0.004$). In the HF WT group there was also a decrease in coupled complex I and II supported respiration (57.2 \pm 13.4 vs. 102.5 \pm 7.0, $p = 0.0005$) and uncoupled respiration (61.4 \pm 15.0 vs. 107.8 \pm 7.1, $p = 0.0004$) compared to NC WT. In female mice there was also a decrease between HF WT and NC WT in complex I (28.2 \pm 3.7 vs. 57.4 \pm 5.7, $p = 0.0005$) and complex I and II (78.2 \pm 6.1 vs. 108.8 \pm 6.7, $p = 0.0003$) supported respiration as well as in uncoupled respiration (87.1 \pm 7.1 vs. 119.4 \pm 8.9, $p = 0.0001$). However, there was no significant difference between the WT NC mice and either of the Nr4a3^{-/-} groups. Coupled complex I, complex I and II and uncoupled respiration states in both Nr4a3^{-/-} groups were not significantly different from WT.

CONCLUSIONS: The Nr4a3 gene plays a role in mitochondrial function in mouse skeletal muscle. Feeding mice a high fat diet impairs proper mitochondrial function in muscle when compared to a normal chow diet. The decrease in respiration from the HF diet is dependent upon the function of the Nr4a3 gene, as no decrease was observed in Nr4a3^{-/-} mice. A limitation of this study is that this effect could be due to the lack of Nr4a3 in the skeletal muscle, or a secondary effect of lacking the gene in other parts of the body.

Transcutaneous Carbon Dioxide Attenuates Impaired Muscle Atrophy And Glucose Metabolism In The Spontaneously Diabetic Rat

Hiroyo Kondo¹, Hirdemi Fujino², Akihiko Ishihara³. ¹Nagoya women's university, Nagoya, Japan. ²Kobe university, Kobe, Japan. ³Kyoto University, Kyoto, Japan.
(No relevant relationships reported)

PURPOSE: Diabetes has been known to result in attenuated growth and atrophy in skeletal muscle. Recently, it has been reported the Carbon dioxide (CO₂) exposure leads to an increase of muscle mass in normal rats. Therefore, the aim of the present study was to investigate the effects of transcutaneous CO₂ exposure with the hydrogel (eCO₂GEL) on diabetic-associated muscle atrophy.

METHODS: Male Goto-Kakizaki (GK) rats were divided into control (GK) and CO₂ exposure (CO₂) groups and male Wistar rats used as a non-diabetic control. The hair on the lower limbs was shaved and the hydrogel (eCO₂GEL), which can increase the absorption of CO₂ from skin, was applied. The CO₂ adaptor was attached to the limbs and sealed, and CO₂ gas was administered into the adaptor for 30 min. The CO₂ exposure was performed everyday for 8 weeks.

RESULTS: The muscle weights of soleus and tibialis anterior in the GK group decreased compared with those of the control group. CO₂ exposure attenuated decreased muscle weights in diabetes-associated muscles ($P < 0.05$). In addition, the level of HbA_{1c} and fasting blood glucose were decreased by CO₂ exposure compared with non-CO₂ exposure condition ($P < 0.05$). Furthermore, the level of LDL cholesterol in the CO₂ exposure group was significantly decreased compared with the GK group ($P < 0.05$).

CONCLUSIONS: These results indicate that the transcutaneous CO₂ exposure may have a therapeutic potential for diabetic-associated muscle atrophy. This amelioration may associate with improved glucose metabolism in skeletal muscle.

Enterococcus Faecium Strain R30 Attenuates Capillary Regression In Type 2 Diabetic Muscle

Hidemi Fujino¹, Airo Tategaki², Hiroyo Kondo¹, Akihiko Ishihara³. ¹Kobe University, Kobe, Japan. ²Kaneka Corporation, Takasago, Japan. ³Kyoto University, Kyoto, Japan.
 Email: fujino@phoenix.kobe-u.ac.jp
(No relevant relationships reported)

It is widely accepted that diabetes affects the peripheral vascular bed. We found that *Enterococcus faecium* strain R30 (R30) supplementation caused increased velocity of red blood cells in capillaries of skeletal muscle. **PURPOSE:** We determined the effects of R30 supplementation on the three-dimensional capillary structure in the soleus muscle of Goto-Kakizaki (GK) diabetic rats. R30 supplementation was chosen, because it may be beneficial in management of skeletal muscle and to be safe for individuals with cardiovascular complications such as those associated with diabetes. **METHODS:** Thirty-six male (Wistar or GK) rats were assigned randomly either to a control (Con), control with R30 supplementation (Con+R30), diabetes (GK) or diabetes with R30 supplementation (GK+R30) group for 8 weeks. The capillaries of soleus muscle were stained with alkaline phosphatase. In addition, the three-dimensional capillary network of soleus muscle was visualized using a confocal laser scanning technique, and the capillary volume and diameter were measured. **RESULTS:** The blood glucose levels were higher in the GK and GK+R30 groups than in the Con and Con+R30 groups. There were no significant differences in the capillary-to-fiber ratio between the Con and GK+R30 although the ratio was lower in the GK group than in the Con group. The capillary volume and diameter in the muscle of GK group were lower than those in Con group. Meanwhile, R30 supplementation attenuated the decrease of capillary volume and diameter in diabetic muscle. **CONCLUSION:** These data suggest that R30 supplementation may be an effective treatment to counter the detrimental effects of type 2 diabetic complications in skeletal muscle.

Aerobic Exercise Counteracts Mitochondrial Dysfunction In The Insulin Resistant Brain

Gregory N. Ruegsegger¹, Patrick M. Vanderboom², Surendra Dasari², Katherine A. Klaus², K. Sree Nair². ¹University of Wisconsin - River Falls, River Falls, WI. ²Mayo Clinic, Rochester, MN.
 Email: gregory.ruegsegger@uwrf.edu
(No relevant relationships reported)

Insulin resistance (IR) increases the risk for Alzheimer's disease and other dementias; however, the underpinning mechanisms for this increased risk remain to be fully defined. Impaired mitochondrial function is one component contributing to cognitive impairment. **PURPOSE:** As insulin resistance impairs mitochondrial oxidative metabolism and increases reactive oxygen species (ROS) in skeletal muscle, we considered whether similar events occur in the brain, which like muscle is rich in insulin receptors and mitochondria. Further, we sought to determine whether aerobic exercise (AE) could prevent the hypothesized deficits in mitochondrial function accompanying diet-induced IR. **METHODS:** 12-week-old, male, C57BL6 mice were fed a standard (Chow) or high fat diet (HFD) (60% kcal from fat) for four-weeks and provided access to running wheels (EX) or sedentary (SED) conditions (n = 9-10 per group). Following treatment, mitochondria were freshly isolated from the cerebrum to assess mitochondrial respiration, ROS production, and ATP production. Insulin resistance was determined *ex-vivo* in the hippocampus by the ability of insulin to stimulate AKT-phosphorylation, mtDNA copy number, mRNA expression, and proteomic measurements were performed on isolated hippocampal tissue. **RESULTS:** HFD induced hippocampal insulin resistance ($p < 0.001$), which was corrected by AE. HFD decreased ATP production 12% ($p = 0.01$) and increased ROS emission 79% ($p < 0.01$) in isolated cerebral mitochondria, which were rescued with AE. Impairments in mitochondrial function with HFD were paralleled by reductions in mtDNA copy number (1.00 \pm 0.06 vs 0.85 \pm 0.06; $p = 0.02$) and mRNA expression of mitochondrial genes, such as PGC1 α 1 (1.00 \pm 0.05 vs 0.78 \pm 0.07; $p = 0.03$) and TFAM (1.00 \pm 0.08 vs 0.62 \pm 0.11; $p = 0.03$), which were corrected by AE. Proteomic analysis of the hippocampus showed that HFD led to oxidative post-translational modifications (PTMs) to 17 mitochondrial proteins (corrected p -value ≤ 0.05 and absolute log₂ fold change ≥ 0.5); however, this increase in oxidative PTMs to mitochondrial proteins with HFD was almost completely reversed by AE. **CONCLUSIONS:** HFD induces IR in the cerebrum and hippocampus, which associates with mitochondrial dysfunction. Brain IR and mitochondrial dysfunction accompanying HFD are prevented with AE.

A High-fat Diet Causes Nr4a3-dependent Changes In Mitochondrial Respiration In Mouse LiverErik D. Marchant, Nathan D. Marchant, Weston S. Elison, Jacob A. Herring, Haokun Yang, Jeffrey S. Tessem, Chad R. Hancock. *Brigham Young University, Provo, UT.**(No relevant relationships reported)*

PURPOSE: To determine the role of the Nr4a3 gene in mitochondrial respiration in mouse liver, as well as how its role changes in obesity-induced diabetes (OID). **METHODS:** This study was designed using Nr4a3^{+/+} (WT) and Nr4a3^{-/-} (KO) mice that were fed a normal chow (NC) or a high-fat (HF) diet from the age of 4 weeks to ~24 weeks. Mitochondrial respiration was measured in liver tissue using high-resolution respirometry. Mitochondrial health was assessed by stimulating the different complexes of the electron-transport chain: glutamate, malate and ADP (complex I), cytochrome c (membrane integrity), succinate (complex II), FCCP (uncoupled respiration), and antimycin A (background respiration). Data were analyzed using a two-way ANOVA followed by a Tukey Multiple Comparisons Test. **RESULTS:** Oxygen consumption is reported as pmol/(s*mg wet tissue) and statistics are represented as mean ± SEM. In female WT mice, uncoupled maximal respiration was increased by a HF diet compared to NC (141.0 ± 9.8 vs. 95.3 ± 12.3, p<0.001). This increase was absent in KO mice, which indicates that Nr4a3 may be partially responsible for the increase in respiration in HF WT female mice. In males this trend was reversed, with a decrease in coupled complex I and II respiration in HF WT vs. NC WT (69.6 ± 5.1 vs. 98.7 ± 6.3, p<0.05), but an increase in HF KO vs. NC WT (control) (122.3 ± 8.3 vs. 98.7 ± 6.3, p<0.01). In an uncoupled state, HF KO was greater than NC WT (control) (129.2 ± 8.4 vs. 103.7 ± 7.8, p<0.001). No difference was observed between NC WT and HF WT. This indicates that the Nr4a3 gene plays a role in suppressing respiration when male mice are fed a HF diet. **CONCLUSIONS:** This study shows that OID caused an Nr4a3-dependent increase in respiration in females, and an Nr4a3-dependent reduction in respiration in males. As part of this study, muscle, kidney and adipose respiration are also being investigated, as well as glucose-stimulated insulin secretion of the pancreatic beta-cells. It is unclear if the observed changes here are due to a direct effect of knocking out Nr4a3 in the liver, or to a secondary effect because of the full-body KO. Therefore, further investigation is warranted.

Effects Of Hypoxic Training On Gdnf In The Cortex Of Obese RatsYulin Shen, Yingli Lu, Xuebing Wang, Han Wang, Lianshi Feng. *China Institute of Sport Science, Beijing, China.*

Email: 870999763@qq.com

(No relevant relationships reported)

Glial cell-derived neurotrophic factor (GDNF) is an important indicator that represent the function of nervous system. Exercise and hypoxic environment both can reduce weight and improve nervous system function in obese rats. But the mechanism by which hypoxic training affects the nervous system is unclear.

PURPOSE: To determine the potential mechanisms of hypoxic training on GDNF in the cortex of obese rats. **METHODS:** Forty SD obese rats were assigned into one of the following groups (n=10 each): normal oxygen control group (NC), normal oxygen training group (NT), hypoxic control group (HC) and hypoxic training group (HT). Rats were kept continuous exercise 1 hour per day, 6 days per week for 4 weeks on a rat treadmill at a speed of 25 m/min in normoxic conditions or 20 m/min in hypoxic conditions (13.6% O₂). After 4 weeks, the expressions of GDNF in the cortex were detected by quantitative fluorescent PCR and Western blotting. The level of inflammatory cytokine interleukin 1β (IL-1β) and interleukin 6 (IL-6) in the cortex were measured by ELISA. The phosphorylation of ERK1/2 and JNK of cortex were detected by Western blotting. **RESULTS:** 1) The results of qPCR showed that the expression of GDNF in the cortex of HT were higher than NT and HC (2.75±0.69 vs. 1.66±0.88 and 1.06±0.45, p<0.05). 2) The results of Western blotting showed that the expression of GDNF in the cortex of HT were higher than NT and HC (489±23.58 vs. 337±46.22 and 387±36.98, p<0.05). 3) The results of phosphorylation of ERK1/2 and JNK showed that the ratio of ERK1/2 and JNK to β-actin integral optical density in the cortex showed no significant difference in all groups (p>0.05), while compared with NC, the ratio of p-ERK1/2 to ERK1/2 and p-JNK to JNK integral optical density in HC, NT and HT were significantly increased (P < 0.05, P < 0.05, P < 0.01). 4) The results of ELISA showed that IL-1β and IL-6 serum levels in HC, NT and HT were decreased compared with NC (19.28±1.41, 19.99±1.26 and 17.8±1.5 vs. 27.15±2.27, p<0.01; 53.82±2.54, 57.53±1.96 and 52.22±1.4 vs. 66.87±2.73, p<0.01). **CONCLUSION:** Hypoxic training can increase the expression of GDNF in the cortex of obese rats and improve the function of the central nervous system. Its mechanisms may relate to the activation of ERK1/2 and JNK signaling pathways and inhibit inflammatory cytokine IL-1β and IL-6 level in the cortex.

The Role Of Cd36 In Relieving Lipotoxicity Of Skeletal Muscle Cells In High Free Fatty Acid Environment.Yajuan Su, Yaoting Han, Xiaobo Li, Jingyu Sun. *Tongji University, Shanghai, China, China.*

Email: 18338691923@163.com

(No relevant relationships reported)

PURPOSE: Lipotoxicity is closely related to the etiology and complications of type 2 diabetes mellitus (T2DM). Lipotoxicity in muscle cells induces insulin resistance, which is a key factor in the pathogenesis of T2DM. This study investigated the protective effect of Fatty Acid Translocase (FAT/CD36) against palmitic acid (PA)-induced lipoapoptosis.

METHODS: Cells at ~40-60% confluence were transfected with siCtrl or siCD36 for overnight using Lipofectamine RNAiMAX. Cells were treated with PA at 200μM for 16 h. The PA-induced viability in C2C12 cells was measured by MTT assay; the PA-induced apoptosis in C2C12 cells was monitored by flow cytometry. The differences in means were analyzed by t test.

RESULTS: PA treatment increased apoptosis (7.50% ± 0.21% vs. 10.40% ± 1.25%, p < 0.05) and decreased viability (100% ± 2.40% vs. 97.32% ± 3.60%, p < 0.05) in C2C12 cells in contrast to cells that were treated with PA-free media. After 16 h of PA treatment without CD36 protection, C2C12 cells had a significant increase in apoptosis when treated with siCD36 transfection, in contrast to cells that were negative control siRNA transfected (10.40% ± 1.25% vs. 16.04% ± 1.58%, p < 0.05), indicating that the existence of CD36 may protect high PA-induced lipoapoptosis by increasing cell uptake of FFA. Further statistical analysis confirmed a significant increase in the percentage of apoptotic cells both in early stage and late stage when subjected to CD36 deficiency (7.93% ± 0.57% vs. 10.70% ± 1.55%, p < 0.05; 2.47% ± 0.68% vs. 5.34% ± 0.06%, p < 0.05, respectively).

CONCLUSIONS: This study demonstrated a novel function of CD36 in preventing lipotoxicity in skeletal muscle cells when subject to high FFA environment, implicating a promising target for obesity and diabetic therapy.

Beta-blocker Effects On The Adipose Tissue Of Trained RatsPatricia S. Rogeri, Luis Fernando B. P. Costa Rosa, Antonio H. Lancha Junior. *Universidade de Sao Paulo, Sao Paulo, Brazil.*

Email: progeri@hotmail.com

(No relevant relationships reported)

Hypertension afflicts about 40% of the world population. Among the most important causes for high blood pressure are obesity and lack of physical activity. Evidences show that weight control and physical activity are effective in reducing blood pressure, associated or not to pharmacological strategies. One of the most common class of drugs used is the β-blockers that may act exclusively on adrenergic receptors β1 (heart) or on all β adrenergic receptors. The same receptors are present on the adipose tissue making lipolysis possible, and thus, weight loss.

PURPOSE to evaluate if cardio selective and non-selective β blockers may interfere with the body composition (fat) of trained rats. **METHODS** Adults Wistar rats, initial weight between 200-400g, were randomly distributed in three groups: non-treated (control), atenolol and propranolol treated groups. The drugs or water were given via oral gavage in the morning, before the training session. After six-weeks of training in a swimming pool system, the animals were euthanized and blood, liver, gastrocnemius muscle, and epididymal, mesenteric and retroperitoneal adipose tissues were removed for biochemical and fat content analysis. **RESULTS** Although randomly assigned, animals in the propranolol group had an initial weight significantly smaller than the control group (296.4g ± 15.25 x 250.5g ± 7.8, p<0.05), however from 4th week and on, animals treated with the non-selective β-blocker significantly gained weight when compared to their initial weight (250.5g ± 7.82 x 285.6g ± 7.8, week 1 x week 6, p<0.05). The animals treated with propranolol had a significant reduction in the amount of 14C-oleate incorporated in their carcass and adipose tissues when compared to the other two groups (p<0.05), as well as higher insulin (p<0.05). Propranolol-treated animals also tended to have higher levels of glucose and free fatty acids in their blood, and less glycogen in their muscle. **CONCLUSION** A non-selective β-blocker such as propranolol may not be the best course of action to treat people with high blood pressure who most of the time need to lose weight. These drugs seem to cause insulin resistance leading to high glucose levels in the blood, as well as lower activity of lipolytic enzymes. Cardio selective drugs, such as atenolol, may seem better for not causing similar side effects.

3865 Board #182 May 30 9:00 AM - 10:30 AM

Exercise Attenuates Weight Gain And Modulates Satiety Hormones In Female MiceCandace Rae Longoria, Paul J. Wisniewski, Robert A. Dowden, Natasha Malonza, Sara C. Campbell, FACSM. *Rutgers University, New Brunswick, NJ.* (Sponsor: Sara Campbell, FACSM)*(No relevant relationships reported)*

Exercise contributes to both caloric expenditure and nutrient partitioning. We have shown that lean sedentary (LS) male mice had lower levels of insulin and Interleukin-6 (IL-6) when compared to their high-fat fed sedentary (HFS) counterparts. Further, both exercise groups, lean (LX) and high-fat fed (HFX) demonstrated lower ghrelin, a hormone that regulates appetite and energy homeostasis levels compared to their sedentary counterparts. However, there is little work done in understanding the female response to blood biomarkers and exercise. **PURPOSE:** Therefore, the purpose of this study was to replicate our previous study in female mice to ascertain which biomarkers are similar across gender, and further evaluate any potential differences. We hypothesized that female mice would have a similar inflammatory biomarkers response as males, but a different hormonal profile. **METHODS:** Thirty-six, 6-week old C57BL/6NTac female mice were fed a normal or high-fat diet for 12-weeks and randomly assigned to exercise or sedentary groups. After 12 weeks animals were sacrificed, and blood was collected for metabolic hormone analysis using a magnetic bead-based multi-analyte panel. A total of seven biomarkers were analyzed including: insulin, peptide-YY (PYY), ghrelin, amylin, IL-6, tumor necrosis factor alpha (TNF- α), and pancreatic polypeptide (PP). **RESULTS:** HFS female mice had the highest body weight, kcal intake per day and percent weight increase compared to all other groups ($p < 0.05$). Exercise attenuated the body weight gain in HF-fed mice (24.7g vs. 30.3g). Exercised groups had significant decreases in levels of insulin (1286.925 pg/ml, 2819.299 pg/ml; $p = 0.021$) and amylin (67.233 pg/ml, 95.048 pg/ml; $p = 0.009$), and increased levels of PYY (18.840 pg/ml, 61.688 pg/ml; $p = 0.031$) compared to sedentary groups. Groups fed HF diets also had increased levels of PYY (64.673 pg/ml, 15.978 pg/ml; $p = 0.018$) compared to normal diet groups. **CONCLUSION:** Exercise attenuates body weight gain and the rise in insulin in mice fed high fat diet and this is consistent between genders. Further, appetite/glucose regulating hormones like amylin and PYY are significantly altered in females but display different responses in males. This continues to add to the exciting story of metabolic differences between males and females.

3866 Board #183 May 30 9:00 AM - 10:30 AM

Effects Of Exercise On The Expression Of Kiss-1/GPR54 In Testis Of High-fat Diet Rats In Growth PhaseJUNPENG FENG, YI YAN. *BEIJING SPORT UNIVERSITY, BEIJING, China.*

Email: bsufengjunpeng@163.com

(No relevant relationships reported)

PURPOSE: To explore the effect of exercise on localization and expression of KISS-1 and GPR54 in the growth period (PND 21st to 56th day) of high-fat diet rat testes. **METHODS:** 21D old weanling rats were randomly divided into group HC ($n = 32$) and group HE ($n = 32$). HE group took 5-weeks trained (60-70% vVO_{2max} , 1h/day, 5days/week). Groups HC and HE were fed with high-fat feed, which was purchased from Beijing Huafukang Biotechnology Co. Ltd. (LOT No: D12451). The rats of two groups were killed on the 21st D, 35th D, 43rd D, and 56th D old. The localization, mRNA expression and protein expression of KISS-1/GPR54 in the testis of each group were tested. **RESULTS:** The high-fat diet intervention resulted in a decrease in testicular index from pre-puberty ($p < 0.05$); testicular tissue testosterone decreased significantly from prepuberty ($p < 0.01$), and endocrine function was impaired; rat testicular tissue structure was loose, and the number of mature sperm decreased. The high-fat diet intervention had no significant effect on the localization of KISS-1/GPR54 system in rat testis, but affected the expression of KISS-1/GPR54 in rat testis and down-regulated the expression of KISS-1 protein ($p < 0.01$). Exercise intervention can improve testicular development in rats with high-fat diet, especially to improve sex hormone disorders caused by high-fat diet. Under exercise intervention, the testicular tissue testosterone decline caused by high-fat diet was improved ($p < 0.05$). Comparing with HC group, the expression of GPR54 protein increased significantly ($p < 0.01$), but the KISS-1 protein expression had no obvious change ($p > 0.05$). **CONCLUSION:** High-fat diet can inhibit the testicular development of male rats in the growth phase, and can also down-regulate the protein and gene expression levels of KISS-1/GPR54 system in testis tissue, and change the expression of KISS-1/GPR54 system, and its role needs further study. 60-70% VO_{2max} moderate-intensity aerobic exercise change the inhibitory effect of high-fat diet on testicular development in male rats, and up-regulate KISS-1/GPR54 in prepubertal stage and whether KISS-1/GPR54 in testicular tissue participates in its regulation remains to be further study.

Western Diet And Exercise Training Increase Mitochondrial Lipid Respiration In Male But Not Female MiceErin M. McGowan, Sarah E. Ehrlicher, Harrison D. Stierwalt, Sean A. Newsom, Matthew M. Robinson. *Oregon State University, Corvallis, OR.*

Email: mcgowane@oregonstate.edu

(No relevant relationships reported)

High-fat feeding in mice is a common model to investigate mitochondrial lipid metabolism during diet-induced obesity. Our previous work demonstrates 60% high-fat diet stimulates mitochondrial lipid respiration yet such fat content is higher than a typical western diet (~35% fat with higher sugar). Aerobic exercise training also stimulates mitochondrial lipid respiration, but the interaction with western diet is not clear. **PURPOSE:** We determined mitochondrial oxidative function in response to western diet in the absence and presence of concurrent exercise training. We hypothesized western diet would induce greater mitochondrial lipid respiration that would be further enhanced with exercise training. **METHODS:** Male and female C57BL/6J mice ($n = 5-7$ per group for each sex) ate either western diet (WD) or low-fat diet (LFD) for 4 weeks, with a group of WD mice randomized to perform concurrent treadmill training (WD+Ex). At week 4, dual-energy x-ray absorptiometry was used to measure body composition and in-vivo substrate oxidation was assessed using metabolic cage indirect calorimetry. Ex-vivo mitochondrial oxidation was measured via high-resolution respirometry using isolated mitochondria from quadriceps muscles collected 36-hours after final exercise session (or rest). Respiration protocols included lipid (octanoyl-carnitine+malate) and non-lipid (glutamate+succinate) substrates. **RESULTS:** Among sedentary mice, WD had higher body weight and fat mass than LFD ($P < 0.0001$), but only in males. WD had lower in-cage respiratory exchange ratio than LFD ($P < 0.05$) regardless of sex, indicating greater whole-body reliance on lipids. In males, WD+Ex stimulated mitochondrial lipid respiration more so than WD alone ($P < 0.05$). Females had no significant changes in mitochondrial lipid respiration. Non-lipid supported mitochondrial respiration was not significantly altered by WD or WD+Ex regardless of sex. **CONCLUSION:** In agreement with our hypothesis, WD stimulated lipid-specific mitochondrial respiration that further increased with Ex, but only in male mice. There were apparent sex differences such that females were protected against WD-induced weight gain alongside limited changes in mitochondrial lipid respiration.

Genetic Deletion Of MicroRNA-16 In Muscle Results In Impaired Insulin Sensitivity & Exercise CapacitySeongkyun Lim, Megan Rosa-Caldwell, Wesely Haynie, David Lee, Tyrone Washington, Nicholas Greene, FACSM. *University of Arkansas, Fayetteville, AR.* (Sponsor: Nicholas P. Greene, FACSM)*(No relevant relationships reported)*

Type 2 diabetes mellitus (T2DM) has become the most common metabolic disease in Western society, leading to significant health problems and financial burdens. Numerous researchers have investigated different therapeutics to target T2DM, but the underlying molecular mechanisms are still not completely understood. Our laboratory and others have demonstrated consistent downregulation of the microRNA-16 (miR-16) in skeletal muscle across human, rodent, and tissue culture models of T2DM. **PURPOSE:** To investigate how deletion of miR-16 gene affects insulin sensitivity and exercise capacity during insulin resistance. **METHODS:** 10 wildtype (WT) and 12 muscle miR-16 knockout (KO) male mice were used for this study. At 9 wks of age, bodyweight, graded exercise test (GXT), glucose tolerance test (GTT; at 0, 30, 60, and 120 min) and insulin tolerance test (ITT; at 0, 15, 30, and 60 min) were measured. At 10 wks of age, half of the mice were given high-fat diet (HFD; 45% calories from fat) to induce insulin resistance, while the remainder were fed normal chow (NC; 17% calories from fat). At 13 wks, bodyweight, GXT, GTT, and ITT were repeated to examine the effect of HFD on miR-16 KO condition. Data were analyzed by two-way ANOVA and significance was denoted at $p < 0.05$. **RESULTS:** Bodyweight was increased by ~27% in WT HFD ($p < 0.05$) and ~21% in KO HFD group ($p < 0.05$) compared to WT NC group. Exercise capacity was decreased by ~46% in WT HFD, ~34% in KO NC, and ~153% in KO HFD group ($p < 0.001$) compared to WT NC group. GTT area under the curve (AUC) value was ~15% greater in WT HFD ($p < 0.05$) and ~20% greater in KO HFD group ($p < 0.05$) compared to WT NC group. ITT curve data indicated that glucose level was ~41% greater at 15 min in KO HFD ($p < 0.05$) compared to WT NC group. **CONCLUSION:** These data suggest prior observations of downregulated muscle miR-16 in human and animal models of T2DM may in part mediate impaired insulin sensitivity and exercise tolerance. Further research is warranted to elucidate molecular mechanisms of miR-16 and its potential role in insulin resistance. **ACKNOWLEDGEMENTS:** This study was funded by the Arkansas Bioscience Institute and American College of Sports Medicine Research Endowment Grant.

The Role Of COX2 In The Regulation Of Brown Adipose Tissue In Obesity By Aerobic Exercise

Lijing GONG, Pengyu Fu. *Beijing Sport University, Beijing, China.*

(No relevant relationships reported)

PURPOSE: The aim was to explore the regulation mechanism of aerobic exercise on brown adipose tissue (BAT) in obese mice and the role of COX2.

METHODS: The mice were randomly divided into the control group (C, normal diet), obesity group (H, high-fat diet to establish obesity model) and the obesity exercise group (HE, high-fat diet and medium intensity treadmill training). Blood lipid and glucose were detected after 4 weeks. Differentially expression genes in scapula BAT were determined by mRNA expression profiles, and functional annotation and signal pathway enrichment were carried out. COX2 (VEGF signaling pathway) involved in key biological processes (BP) and pathway. ADR β 3 agonist Isoprenaline (activating VEGF pathway) and NS-398 (COX2 inhibitor) were used, and the distribution of lipid droplets, the glycerol level, and the expression of mRNA and protein in VEGF pathway in brown adipocytes were detected.

RESULTS: High-fat diet could induce obesity, accompanied by increased blood glucose and lipid levels (2.03 \pm 0.09 vs. 4.54 \pm 0.3), reducing UCP1 levels (1 vs. 0.71 \pm 0.1) in BAT. Aerobic exercise could significantly reduce the obese mice weight (C: 26.21 \pm 0.57; H: 27.53 \pm 0.61; HE: 26.32 \pm 0.52) and blood glucose levels (C: 8.5 \pm 0.78; H: 10.22 \pm 1.77; HE: 8.25 \pm 1.33). The BP of up-regulated genes in group H/C were mainly enriched in immune system progression, inflammatory and immune response, down-regulated genes were lipid metabolism and oxidation reduction. The up-regulated genes in group HE/H were enriched in glycolipid metabolism, while the down-regulated genes were cell death and apoptosis. VEGF signaling pathway plays an important role in this process, and COX2 in the VEGF pathway played a central role by interaction analysis. Application of Isoprenaline could increase the glycerol level (12.8 \pm 1.38 vs. 31.27 \pm 3.49) and the protein expression of VEGFa (1 vs. 1.34 \pm 0.12), COX2 (1 vs. 1.49 \pm 0.22) and UCP1 (1 vs. 1.27 \pm 0.18); Simultaneous application of NS-398 could inhibit the protein expression of COX2 and UCP1 in brown adipocytes.

CONCLUSIONS: Obesity could lead to disorder of glycolipid metabolism and inflammation of BAT. Aerobic exercise could activate BAT activity through VEGF-COX2 pathway to reduce adverse effects of obesity. Funded by FRF for the Central Universities of China (2018GJ017)

Mict Improves Fgf21 And Klb Expression Better Than Hiit In Obese Mice

Yingzhe Xiong, Bing Zhang, Yao Liu. *Tsinghua University, Beijing, China.*

(No relevant relationships reported)

(No relevant relationships reported) **Background:** Fibroblast growth factor 21 (FGF21), a key factor to prevent and treat overweight and obesity, regulates glucose, lipid, and energy metabolism. Besides, FGF21 needs β -Klotho (KLB) as a co-receptor to combine with the FGF receptor (FGFR) effectively and inter the target cell. However, it is unclear what condition promotes FGF21 and KLB expression in different tissue. **Purpose:** The goal of this preliminary study is to explore FGF21 and KLB expression related to two forms of exercise: moderate-intensity continuous training (MICT) and high-intensity interval training (HIIT) **Methods:** Mice were randomly divided into four groups (n=8 per group): MICT, HIIT, sedentary lifestyle (SED), and control (CON). Three groups, MICT, HIIT, and SED were fed on the high-fat diet (HFD) to induce obesity and CON was fed on the standard chow (Con) for 12 weeks. Exercise was performed on a motorized treadmill for further eight weeks and the diet continued in each group. **Results and Discussions:** (1) In mRNA level, MICT was more effective than HIIT in promoting FGF21 and KLB expression in liver (fgf21: 12.44 \pm 3.95 vs. 0.91 \pm 1.09, p <0.01; klb: 5.17 \pm 3.54 vs. 0.225 \pm 0.10, p <0.01), brown adipose tissue (BAT) (fgf21: 96.37 \pm 29.72 vs. 58.30 \pm 21.73, p <0.05; klb: 12.33 \pm 5.20 vs. 0.32 \pm 0.20, p <0.01), and muscle (fgf21: 10.17 \pm 5.81 vs. 5.49 \pm 9.09, p >0.05; klb: 42.83 \pm 19.07 vs. 10.33 \pm 14.50, p <0.01); (2) In protein level, MICT was more effective than HIIT in promoting FGF21 and KLB expression in liver (fgf21: 1.63 \pm 0.31 vs. 1.31 \pm 0.27, p >0.05; klb: 3.51 \pm 0.58 vs. 1.63 \pm 0.32, p <0.01), BAT (fgf21: 3.35 \pm 0.32 vs. 1.42 \pm 0.27, p <0.05; klb: 2.34 \pm 0.50 vs. 0.74 \pm 0.25, p <0.01), and muscle (fgf21: 1.32 \pm 0.12 vs. 0.72 \pm 0.12, p <0.05; klb: 2.17 \pm 0.12 vs. 1.46 \pm 0.06, p <0.01). **Conclusion:** MICT improves FGF21 and KLB expression in the liver, BAT, and muscle better than HIIT in obese mice.

(No relevant relationships reported)

PURPOSE: evaluating the effects of Liraglutide over the adipose tissue of Swiss mice subjugated to a cafeteria diet and physical activity, through swimming. **METHODS:** approved by the Ethics in Animal Use of UFRN (n. 003/2014). We have divided 74 animals (Swiss mice) into two phases: the initial phase had a pilot study (n=10) subdivided into the control group (PCON) (n=5) and the cafeteria group (PCAF) (n=5), to evaluate an attractive cafeteria diet to the animals taste, that would result in an increase of body weight. After the diet's introduction, the animals were weighed, euthanized, and had their intra-abdominal adiposity measured. The menu offered to the group PCAF was deemed attractive to taste and chosen for the development of the research. After, 64 animals were subdivided into two groups: the Cafeteria Base Study Group (EBCAF), further subdivided: cafeteria+exercise+liraglutide (CEL) (n=8), cafeteria+exercise+saline (CES) (N=8), cafeteria+liraglutide (CL) (n=8), and cafeteria+saline (CS) (n=8). And the Chow Base Study Group (EBR), that was further subdivided: exercise+liraglutide (EL) (n=8), exercise+saline (ES) (n=8), liraglutide (L) (n=8), and saline solution (SS) (n=8). All the animals were put through a cafeteria diet, following the physical activity with swimming and treating them with testing substances intraperitoneally (200 μ g/mL/kg). **RESULTS:** In the pilot study, the type of food did not significantly affect the increase in weight gain (PCAF = 47.38 \pm 0.70 vs. PCON = 46.48 \pm 1.08). However, it changed considerably the increase of intraabdominal adipose tissue: CAF = 0.74 \pm 0.05 vs. CON = 0.44 \pm 0.08 g (p < 0.05). The base study of the research showed that the treatment with liraglutide associated with physical activity when compared to saline had a significant reduction in the mass of adipose tissue: CEL-0.32 \pm 0.03 vs. CES-0.48 \pm 0.05 g; CL-0.41 \pm 0.09 vs. CS-0.76 \pm 0.09 g; L-0.24 \pm 0.04 vs. SS-0.52 \pm 0.08 g e CEL-0.32 \pm 0.03 vs. CS-0.76 \pm 0.09 g (p < 0.05 CEL vs. CES; p < 0.05 CL vs. CS; p < 0.01 L vs. SS; p < 0.001 CEL vs. CS.) (0.32 \pm 0.05 g), compared to the saline group (0.53 \pm 0.07 g).

CONCLUSIONS: the liraglutide supplied a weight loss in animals, especially in the intraabdominal adipose tissue and when associated with Physical activity has allowed greater efficiency in terms of adipose tissue decrease.

Caloric Restriction Alters Bone Marrow Adiposity And Energy Metabolism

Stephen Andrew Martin¹, Samantha L. Wright², Alex B. Smith², Carmen Wong³, Donald B. Jump³, Rozalyn M. Anderson², Russell T. Turner³, Urszula T. Iwaniec³. ¹Montana State University, Bozeman, MT. ²University of Wisconsin, Madison, Madison, WI. ³Oregon State University, Corvallis, OR.

(No relevant relationships reported)

BACKGROUND: Bone marrow adipose tissue (bMAT) refers to mesenchymal stem cell-derived adipocytes located within the bone marrow cavity. In adult humans, bMAT comprises ~15% of total body adiposity and is primarily located throughout the appendicular skeleton. bMAT is an extremely 'plastic' depot that rapidly responds to fluctuations in nutrient sensing and energetic homeostasis. Paradoxically, bMAT levels increase during both obesity and caloric restriction (CR); however, it is unclear whether the qualitative phenotype of bMAT differs under these conditions. **PURPOSE:** To identify obesity- and CR-induced alterations in bMAT lipid composition, transcriptional profile, and metabolic signature. **METHODS:** Male 6-week-old genetically obese ob/ob mice (leptin deficient) were housed at 32°C (thermoneutral) for 10 weeks. One group of mice was fed ad libitum (AL; N=9) for the study duration, while a second group was calorically restricted (CR; N=9) to ~50% of the AL group to prevent excess weight gain. Femora and tibiae were collected for lipid composition (gas chromatography), gene expression analysis (qRT-PCR), and *in situ* metabolic phenotyping (MPLSM-FLIM). Blood was collected for assessment of circulating analytes. **RESULTS:** CR mice had lower body mass and blood glucose, and higher blood corticosterone compared to AL mice. CR increased femur adipocyte density and adipocyte size compared to AL. Tibia lipid composition differed between AL and CR mice (AL>CR C16:0, C:18:1n-9, C:18:1n-7, C20:4n-6; CR >AL C14:0, C16:1n-7, and C18:2n-6). CR upregulated the expression of adipokines (e.g., *Adipoq*, *CFD*), which occurred co-incidentally with elevated levels of serum adiponectin and adipsin. Transcriptional profiling revealed differential expression of genes involved in adipogenesis, lipid metabolism, mitochondrial activity, and antioxidant response

(e.g., CR>AL *SCD1*, *FASN*, *LIPE*, *LPL*, *KLF15*, *PPARGC1a*, *PPARa*, and *SOD1*). MPLSM-FLIM revealed highly heterogenic metabolic phenotypes among cells within the bone marrow cavity. **CONCLUSION:** CR induces functional changes in bMAT that occur independent of leptin. bMAT lies at the interface of metabolic and inflammatory signaling mechanisms, and is a potential mediator of systemic metabolic and inflammatory homeostasis during health and disease.

Regulation Of CD36/LKB1/AMPK On Fatty Acid Oxidative Metabolism Under High-fat Diet Conditions

Jingyu Sun, Yajuan Su, Jingmei Dong. *Tongji University, Shanghai, China.*
Email: jingyusun@126.com
(No relevant relationships reported)

Activation of AMP-activated kinase (AMPK) in skeletal muscle increases FA oxidation by inducing Acetyl-CoA Carboxylase (ACC) deactivation. However, the upstream signal molecules that activate AMPK/ACC signaling remains unclear. It is expected that Fatty Acid Translocase (FAT/CD36) will become another potential target for diabetic therapy after AMPK.

PURPOSE: To explore the role of CD36, as a signal molecule, in regulating the upstream signaling pathway of AMPK/ACC in skeletal muscle under HFD conditions. **METHODS:** First, siRNA interference was used to knock down CD36 gene in C2C12 cells to investigate the effect of CD36 deficiency on the phosphorylation of AMPK/ACC signaling in skeletal muscle cells. Then, twelve 8-week-old C57BL/6 male mice were randomly divided into two groups: control group (CON; $n = 6$), and high-fat diet group (HFD; $n = 6$). The expression levels of CD36 protein and phosphorylation of AMPK/ACC signaling under HFD conditions were detected by Western blotting method; the translocation of Liver kinase B1 (LKB1) in nucleus was detected by immunofluorescence method; the ultrastructural changes of skeletal muscle were detected by transmission electron microscopy; and the activity of mitochondrial respiratory chain enzyme was detected by colorimetry. **RESULTS:** CD36 deficiency activated AMPK (0.129 ± 0.009 vs. 0.417 ± 0.055 , $p < 0.05$), ACC (0.044 ± 0.008 vs. 0.081 ± 0.010 , $p < 0.05$) signaling in skeletal muscle cells. Compared with the CON group, the expression levels of CD36 protein in HFD group were significantly increased (0.225 ± 0.041 vs. 0.506 ± 0.022 , $p < 0.01$), the phosphorylation levels of AMPK (0.142 ± 0.020 vs. 0.079 ± 0.010 , $p < 0.05$) and ACC (0.229 ± 0.023 vs. 0.119 ± 0.028 , $p < 0.05$) were significantly decreased, and induced LKB1 translocation from cytoplasm to nucleus. In addition, electron microscopic results showed that HFD intervention damaged the mitochondrial structure of skeletal muscle to a certain extent, and significantly decreased CS activity (411.32 ± 22.15 vs. 310.20 ± 44.09 , $p < 0.01$). **CONCLUSION:** CD36, as a signaling molecule, promotes LKB1 to translocate from cytoplasm to nucleus, which inhibits AMPK/ACC signaling activation, thereby regulating FA oxidation under HFD condition.

Insulin Action And Body Composition In Aged C57bl/6 Mice: A New Model For Obesity

Dakembay Hoyte, Katy Ehnstrom, Noa Mills, Thomas H. Reynolds. *Skidmore College, Saratoga Springs, NY.* (Sponsor: Donald R. Dengel, FACS M)
(No relevant relationships reported)

The prevalence of obesity in the United States has increased dramatically over the last three decades resulting in a major public health crisis. Feeding mice a high fat diet is a pervasively used model to study mechanisms of human obesity. However, the rapid weight gain that occurs in high fat fed mice and the extremely high fat content of commercially available experimental rodent diets pose serious limitations of this approach. A more appropriate model to study human obesity might be the aged male C57BL/6 mice. **PURPOSE:** To determine body composition and insulin action in young (YG, 6 months), aged (AG, 18 months), and very old (VO, 28 months) male C57BL/6 mice. **METHODS:** Body composition was assessed by an LF50 Body Composition Analyzer (Bruker, Inc). Insulin action was determined by conducting insulin tolerance (IT), glucose tolerance (GT), and 5-aminoimidazole-4-carboxamide ribonucleoside (AICAR) tolerance (AT) tests. Data was analyzed by using a 1 x 3 analysis of variance and least significant difference post-hoc test. Statistical significance was set at $P \leq 0.05$. **RESULTS:** Body mass (YG: 30.7 ± 1.1 vs AG: 46.3 ± 1.7 vs VO: 39.1 ± 1.6 g) and fat mass (YG: 5.8 ± 1.0 vs AG: 21.6 ± 1.6 vs VO: 10.2 ± 1.8 g) were significantly higher in AG mice compared to VO and YG mice. Lean mass was significantly higher in VO mice compared to AG and YG mice (YG: 20.4 ± 0.4 vs AG: 19.6 ± 0.6 vs VO: 23.4 ± 0.5 g). The area under the curve (AUC) for the GT test was significantly lower in VO mice compared to YG and AG mice (YG: 59030 ± 2817 vs AG: 54835 ± 3423 vs VO: 33378 ± 2286). The AUC for the IT test curve was similar in YG, AG and VO mice (YG: 11320 ± 214 vs AG: 11804 ± 343 vs VO: 11138 ± 968). Although the AUC for the AT test was similar, the decline in glucose following AICAR injections was significantly less in VO mice compared to

AG and YG mice, indicating an impairment in AMPK activity. These data suggest that adiposity increases substantially in 18 month old male C57BL/6 mice, a process that appears to be reversed by 28 months. Further, aging does not appear to cause a deterioration in insulin sensitivity when assessed by an IT test. The lower glucose values observed during the GT test in VO mice is likely due to enhanced insulin secretion. Overall our findings indicate that male C57BL/6 mice may be a valuable model to examine mechanisms of obesity when studied at approximately 18 months of age.

Effects Of Different Exercise On Liver Lipid Metabolism In Lean And Obese Rats And Its Relationship With FGF21

Yuan Zhang, Juan Wei, Lei Sheng. *Nanjing Sports Institute, Nanjing, China.*
Email: beibei82506@126.com
(No relevant relationships reported)

PURPOSE: This study aimed to investigate the effects of different exercise training: High Intensity Interval Training (HIIT) and Continuous Training (CT) on body mass gain, hepatic lipid accumulation and the correlation of the level of FGF21 in serum and liver tissues in lean and obese rats.

METHOD: Male Sprague-Dawley rats at 4 weeks of age were randomly divided into normal diet group (N) and obesity model group (H) after 1 week of adaptive feeding. Rats in the obesity model group were fed with 45% high-fat Diet for about 8 weeks, and 20% weight increase compared with normal rats was considered as obesity. Then, rats were given weight-bearing swimming training intervention for 8 weeks. The rats were divided into normal control group (NC), normal HIIT group (NHI), normal CT group (NCT), High fat diet-induced obesity control group (HC), obese HIIT group (HHI), and obese CT group (HCT).

RESULTS: (1) 8 weeks of HIIT (716.00 ± 15.98 vs 596.21 ± 14.27 g, $p < 0.05$) and CT exercise (716.00 ± 15.98 vs 629.62 ± 12.31 g, $p < 0.05$) result in the body weight of obesity animals significantly reduced. (2) Liver triglyceride content of obese rats were decreased by 21.8% and 7.7% respectively with 8-week HIIT and CT intervention. (3) The activity of LPL enzyme was only increased with CT in normal animals and FAT/CD36 activity was upregulated by CT both in normal and obese groups. HIIT significantly increased the mitochondrial CPT1- α and β -HAD enzyme activities in obese rats. (4) The serum FGF21 level in obese rats was significantly higher than that in normal rats (8.40 ± 1.14 vs 22.20 ± 3.59 pg/ml, $p < 0.05$), and further improved by CT. HIIT and CT increased the FGF21 expression in normal rats, but reduced its expression in obese rats.

CONCLUSION: Both types of exercise can affect the level of fat metabolism in the liver, but showed different mechanisms. HIIT significantly increased the activity of mitochondrial fat oxidase and had a significant effect on the alleviation of lipid deposition in the liver of obese rats, although this process was less correlated with changes in FGF21 levels. However, CT improve the activity of enzymes involved in fatty acid uptake, accelerate the utilization of fatty acids in the liver by regulating FGF21 levels in serum and liver tissues.

(No relevant relationships reported)

Obesity caused by high-fat diet can lead to metabolic impairment in adipocytes as well as in other tissues. Resistance training can promote alterations to improve metabolic damages, which is likely reversed by detraining.

PURPOSE: To determine the effects of resistance training (RT) and detraining on the expression of TNF α , PPAR γ and HIF-1 α proteins of the adipose tissue of obese rats. **METHODS:** Wistar rats were divided into groups: Control (C), Trained (RT), High-fat diet (HFD), Trained/High-fat diet (HFD-T) and Detrained/High-fat diet (HFD-D). Control received standard chow; HFD received high-fat diet during 12 weeks. Trained performed RT (jump squat) for 12 weeks, 3x/week, 3 sets of 12 repetitions per session. The HFD-D interrupted the training at 8th week, characterizing detraining during 4 weeks. Adipose tissue was removed under anesthesia, weighed, and used in protein and genes expression analysis. **RESULTS:** HFD presented higher body weight gain and fat mass compared to the C and T groups ($P < 0.05$), which was reduced with RT (HFD-T vs HFD, $P < 0.001$). Among the HFD groups, HFD-T rats presented the lowest body weight ($P < 0.0002$), weight gain ($P < 0.0006$), and fat mass ($P < 0.0001$). HFD presented elevated TNF α protein and gene expression in adipose tissue compared

to C and T (50% higher), and HFD-T (40% higher) groups ($P<0.05$). HFD-T group presented higher levels of PPAR γ protein and gene compared to C (60%-higher), T (50%-higher) and HFD (50%-higher) groups ($P<0.05$). HIF-1 α mRNA expression was reduced in HFD-T rats compared with HFD ($P<0.05$). Detraining caused increase on the weight gain (50% higher) and fat mass (44% higher) compared to HFD-T ($P<0.05$). HFD-D maintained protein expression of TNF α and PPAR γ elevated compared to HFD and reduced HIF-1 α mRNA expression compared to HFD ($P<0.05$). **CONCLUSION:** Therefore, RTr can attenuate HIF-1 α and TNF α gene expression, and prevent reduction of PPAR γ independent on the ingestion of a high-fat diet. Additionally, TNF α expression remained lower, and PPAR γ expression remained increased in detrained rats, even with increased fat mass. These results suggest that four-week detraining can accelerate the gain of fat mass, without eliciting an inflammatory response in the adipose tissue. Supported by CAPES – Finance code 001.

An Enzymatically Driven Hydrogen Peroxide Exposure To Human Hepatocytes And Its Effects On Iron Homeostatic Proteins

Chandler Eyre, David Eastley. *Brigham Young University, Provo, UT.*

(No relevant relationships reported)

Previous data in our lab has shown that high concentration (200 μ M) H₂O₂ exposure induces iron dysregulation in muscle cells. It is known that following strenuous exercise, oxidative stress is induced in tissues, leading to iron dysregulation, and generation of reactive oxygen species. Due to the unstable nature of H₂O₂ in solution and the critical role of the liver in iron homeostasis, we sought to see how human hepatocytes would respond to a 12-hour low-dose H₂O₂ exposure that mimics the concentration of neutrophils during the inflammatory response using glucose oxidase (GOX) and Catalase (CAT)

PURPOSE

To determine the effects of a low-concentration, H₂O₂ exposure on the iron regulatory proteins such as TfR, and Ferritin Light-Chain (FLC) in HepG2 cells.

METHODS

When HepG2 cells reached 80% confluency, iron treatments of 10, 50, and 100 μ M were imposed for 24 hours using an FeCl₃ solution diluted in media. Groups that received both iron and H₂O₂ treatments were exposed to 12 hours of iron, followed by 12-hour incubation with media that included both iron and a GOX-CAT cocktail. Western blots were carried out to measure protein content relative to controls. Cell viability was assessed using an MTT assay.

RESULTS

MTT assays for both FeCl₃ and FeCl₃ + H₂O₂ groups did not show any significant cell death. Treatment with FeCl₃ alone resulted in a significant decrease in TfR for all three groups when compared against controls ($C=1\pm 0.1$ SEM vs. 0.71 ± 1 ; $p<0.01$; $n=12$). We observed a significant increase in FTL, but only in the 10 μ M group ($C=1\pm 0.1$ vs. 1.6 ± 0.2 ; $p<0.01$; $n=11$). We saw no significant change in FTL at 50 and 100 μ M. H₂O₂ treatments driven by GOX and CAT produced concentrations of 5-10 μ M, mimicking neutrophils during inflammatory response. The addition of a low concentration H₂O₂ stress resulted in a 9-fold increase of FTL content at all iron exposure concentrations ($C=1\pm 0.3$ vs 9.3 ± 0.9 10 μ M; $p<0.01$; $n=4$). Groups of 50 and 100 μ M also showed similar results, with an increasing trend.

CONCLUSION

A low concentration exposure of H₂O₂ and iron to human hepatocytes results in a significant increase in FTL when compared to iron exposure alone. This suggests that liver cells have a robust defense against iron-dysregulation induced by oxidative stress. We are still evaluating changes that occur in other iron regulatory proteins.

Circulating Klotho Response To A Behavioral Weight Loss Intervention In Adults With Overweight Or Obesity

Katherine A. Collins¹, Renee J. Rogers, FACSM², Fabrisia Ambrosio², Kelliann K. Davis, FACSM², John M. Jakicic, FACSM². ¹Duke University, Durham, NC. ²University of Pittsburgh, Pittsburgh, PA. (Sponsor: John Jakicic, FACSM) (No relevant relationships reported)

Klotho, a biomarker of aging, is associated with a slower aging process. Klotho concentration is lower among adults with obesity compared to normal-weight adults, and exercise may independently increase levels of Klotho. Whether Klotho is altered by weight loss and whether there is an added effect of exercise are not understood.

Purpose: This study examined changes in Klotho concentration in response to a behavioral weight loss intervention among adults with overweight or obesity.

Methods: A subset of 152 adults (age: 45.4 ± 8.0 years; BMI: 32.1 ± 3.7 kg/m²) who participated in a 12-month weight loss intervention were classified as an intervention "responder" (achieved $\geq 10\%$ weight loss at both 6- and 12 months) or "non-responder" (achieved $<5\%$ weight loss at both 6- and 12 months). Intervention conditions included: 1) diet only (1200-1800 kcal/day), 2) diet plus 150 min/wk of moderate-to-vigorous intensity physical activity (MVPA) per week, 3) or diet plus 250 min/wk of unsupervised MVPA per week. Measures of height, weight, body composition, cardiorespiratory fitness, and Klotho were completed at baseline, 6-, and 12 months. Klotho was analyzed using solid-phase sandwich ELISA kits.

Results: There were significant ($p<0.0001$) changes in weight (-12.5 ± 9.1 kg), percent body fat ($-7.1\pm 5.5\%$), lean body mass (-1.7 ± 2.0 kg), and cardiorespiratory fitness ($+3.3\pm 4.1$ ml/kg/min) from baseline to 12-months. Klotho significantly ($p=0.009$) changed across the 12 months (baseline: 933 ± 381 pg/mL; 6 months: 985 ± 450 pg/mL; 12 months: 940 ± 423 pg/mL), with no difference by intervention group or weight loss response. Participants who performed physical activity had non-significantly greater changes in Klotho. Klotho was consistently associated with lean body mass at baseline ($r=-0.19$), 6 ($r=-0.23$), and 12 months ($r=-0.19$) ($p<0.05$). Klotho was not predictive of change in weight, body composition, or fitness.

Conclusion: Klotho significantly, but modestly, increases with weight loss; however, the increase in Klotho was not sustained throughout the intervention. There may be an influence of physical activity on change in Klotho with weight loss, but this warrants further investigation. Further investigation to examine how weight loss and physical activity may alter biomarkers of aging in adults with obesity may be warranted.

Effects Of Beetroot Juice Components On Exercise Tolerance And Cardiometabolic Health In Individuals With Obesity

Christian E. Behrens, Rakesh Patel, Ahmed Khandaker, Braxton Linder, Jose Fernandez, Brenda Bertrand, Gordon Fisher, FACSM. *University of Alabama at Birmingham, Birmingham, AL.* (Sponsor: Gordon Fisher, FACSM) (No relevant relationships reported)

Routine exercise training is known to improve health outcomes in individuals with obesity (IO); however it remains challenging for IO to adhere to exercise programs. Thus, it is critical to identify novel strategies that can improve exercise capacity (EC) and lead to greater adherence in IO. Beetroot juice (BRJ), high in inorganic dietary nitrate, has been shown to consistently improve exercise performance in athletes, individuals with cardiopulmonary diseases, and non-obese lean individuals. These improvements may be explained by reduced oxygen uptake (VO₂) during exercise, enhanced blood flow, and greater mitochondrial efficiency. To date, we are aware of no studies that have compared the effects of BRJ, sodium nitrate (NaNO₃), denitrified BRJ (PLA), and control (CON) conditions for improving EC and cardiometabolic health in IO. **PURPOSE:** to determine if BRJ improves EC, exercise efficiency (EE) and cardiometabolic health in IO and identify possible mechanisms of action. **METHODS:** Vascular health (blood pressure and arterial elasticity), VO₂ on a cycle ergometer during submaximal- and maximal- exercise, and time to exhaustion (TTE) were assessed in 16 sedentary IO in a crossover design for the following 4 conditions: 1) consumption of BRJ, 2) NaNO₃, 3) PLA, or 4) CON. Study visits were at least 72 hours apart. **RESULTS:** A significant treatment effect was observed for submaximal exercise VO₂ ($p=0.003$), and TTE (seconds) ($p=0.035$). Post hoc analyses demonstrated a lower VO₂ during submaximal exercise in BRJ compared to PLA ($P=0.009$) NaNO₃

($P=0.042$) and CON (0.009). TTE was greater between BRJ and CON ($P=0.029$) with no other differences observed between conditions. No other significant changes were observed for other exercise or vascular health measures. In this analysis of 16 IO, consumption of BRJ improved EE during submaximal cycling exercise by 5.28% compared to PLA, 5.91% compared to the NaNO₂, and 4.22% compared to CON. Finally, BRJ resulted in a 19% improvement in TTE compared to CON condition. **CONCLUSION:** These results suggest that consumption of BRJ may improve cycling efficiency and exercise capacity in IO.

Associations Among Measures Of Abdominal Fat And Metabolic Health In Normoglycemic Women

Katherine H. Ingram, Janeen Amason, Calah Coleman, Brian Kliszczewicz, FACSM. *Kennesaw State University, Kennesaw, GA.* (Sponsor: Brian Kliszczewicz, FACSM)
 Email: khingram@kennesaw.edu
 (No relevant relationships reported)

Central adiposity, and particularly visceral fat, is tightly associated with metabolic health. Gold standard measures for visceral fat, MRI and CT, are impractical for widespread use. Ultrasound, DXA, and bioimpedance are useful alternatives, though their associations with metabolism are less understood.

OBJECTIVE: To test associations of abdominal adipose by ultrasound (US), DXA, and bioimpedance (BIA) with insulin sensitivity (IS), β -cell responsiveness, physical activity, and adiponectin (AdipN), an adipokine tightly associated with visceral fat.

METHODS: After overnight fast, 41 normoglycemic young women (Age 20.9 ± 2.7 ; BMI 27.8 ± 3.5) completed iDXA (GE Lunar) and BIA (InBody 770) for VAT and %BF; US for visceral (VAT-US) and subcutaneous adipose thicknesses (SAT-US) measured 1cm superior to umbilicus; circumferences; 2-hr OGTT (75g); and 5-day accelerometry (Steps; ActiGraph GT3x). Plasma insulin, c-peptide, and AdipN were determined by ELISA. IS was calculated using Matsuda Index from insulin and glucose at 0 and 120 min. First phase β -cell responsiveness (β Cell) was estimated as ΔC -peptide/ Δ glucose from 0 to 30 min.

RESULTS: VAT-DXA correlated strongly with VAT-BIA ($r=.80$), SAT-US ($r=.78$), Waist ($r=.81$; $p<.01$ for all), and weakly with VAT-US ($r=.35$) and Steps ($r=-.38$; $p<.05$ for all), but not AdipN ($r=-.31$, $p=ns$). VAT-US correlated with AdipN ($r=-.52$), VAT-DXA ($r=.35$), Waist ($r=.50$; $p<.05$ for all), but not SAT-US ($r=-.02$) or VAT-BIA ($r=.31$; $p=ns$ for both). IS was associated with VAT-US ($r=-.42$), VAT-DXA ($r=-.44$), and AdipN ($r=.46$; $p<.05$ for all), controlled for age and race, and these persisted when further controlling for BMI. Only SAT-US was associated with β -cell ($r=.38$, $p<.05$), controlled for age and race, but attenuated when controlling for BMI. Steps correlated with SAT ($r=-.36$), VAT-DX ($r=-.38$), and VAT-BIA ($r=-.39$; $p<.05$ for all), but not IS, β Cell, VAT-US, or AdipN ($p=ns$ for all). In multiple regression analysis with VAT-DX, and BMI included in the model, VAT-US was the only independent predictor of IS (Std. $\beta=-.36$, $p<.05$).

CONCLUSION: VAT by DXA and BIA are strongly related to SAT and overall adiposity, and less to VAT by US and AdipN. While VAT by DXA and ultrasound were both predictors of poor metabolic health in this population, VAT by ultrasound was the strongest independent predictor of IS.

Longitudinal Characterization Of RMR Ratio In Ovulatory Exercising Women Across 12 Months

Nicole C.A. Strock, Kristen J. Koltun, Rebecca Mallinson, Nancy I. Williams, FACSM, Mary Jane De Souza, FACSM. *Pennsylvania State University, University Park, PA.* (Sponsor: Mary Jane De Souza, FACSM)
 Email: nca11@psu.edu
 (No relevant relationships reported)

Resting metabolic rate (RMR) ratio has been shown to be an indicator of energetic status as indicated by significant correlations with total triiodothyronine (TT₃) concentrations in exercising women. However, it is unknown whether the relationship between RMR ratio and TT₃ remains constant over time. **PURPOSE:** To examine the relationship between RMR ratio and TT₃ in exercising, ovulatory, weight-stable women for a 12-month observational period. **METHODS:** We performed a 12-month longitudinal analysis of data from exercising women ($n=14$). Dual-energy X-ray absorptiometry (DXA) and indirect calorimetry provided data on anthropometrics and energy expenditure. Harris-Benedict DXA, and Cunningham (1980 and 1991) equations estimated RMR and RMR ratio. Repeated-measures analysis assessed changes over time (ANOVA and Friedman). Intraclass correlation coefficient (ICC) and Cronbach's Alpha measure agreement over 12-months for RMR ratio and energy availability (EA). Generalized linear modeling tested whether RMR ratio predicted TT₃ to be above or below two thresholds (TT₃>73.2ng/mL and TT₃>80ng/mL) over 12-months. **RESULTS:** Women were 25.9 ± 5.4 yr, and at baseline, weighed 59.6 ± 5.2 kg with BMI 22.3 ± 1.4 kg/m², which remained unchanged during the study (weight: $p=0.52$; BMI: $p=0.51$). Over 12-months, RMR ($p=0.88$), TT₃ ($p=0.89$), EA

($p=0.21$), and RMR ratio (Harris-Benedict: $p=0.85$; DXA: $p=0.60$; Cunningham₁₉₈₀: $p=0.75$; Cunningham₁₉₉₁: $p=0.73$) remained consistent for 12-months. Each RMR ratio produced ICC and Cronbach's alpha greater than 0.90, indicating excellent reliability of repeated measures, while ICC of energy availability of 0.75 and Cronbach's alpha of 0.73, indicated moderate reliability. When TT₃>73.2ng/dL, each RMR ratio threshold (Harris-Benedict: $p=0.021$; DXA: $p=0.019$; Cunningham₁₉₈₀: $p=0.019$; Cunningham₁₉₉₁: $p=0.016$) significantly predicted participants as energy replete; however, when using a more lenient clinical TT₃ threshold of >80ng/dL, only the DXA ratio threshold yielded a significant model

(<0.001). **CONCLUSIONS:** The relationship between RMR ratio and TT₃ remains constant over time with excellent reliability helping to validate the use of RMR ratio for the longitudinal characterization of energetic status in exercising women (i.e. prospective serial monitoring).

Sex Characteristics Of Fat Distribution In Chinese Adolescent: Based On Magnetic Resonance Imaging

Zhengyan Tang, Jingmin Liu, Xiao Hou, Yujie Liu. *Tsinghua University, Beijing, China.*
 Email: tzy0565@sina.com

(No relevant relationships reported)

PURPOSE: To find out the characteristics of accurate fat distribution of healthy adolescent in China and compare the differences between different genders.

METHODS: We recruited 36 Chinese healthy adolescents without obesity or malnutrition. (12-17 years old, 3 men and 3 women of each age; height: 155.24 ± 15.66 cm; mass: 48.60 ± 14.41 kg). Scanning the whole body by MRI (1 cm apart). The visceral fat, subcutaneous fat and intramuscular fat of trunk, upper and lower limbs were calculated by gray area. The derivative index of the above indicators is obtained by dividing by the square of height. SPSS 22.0 was used to analyze the data by t-test.

RESULTS: 1) Fat mass. The visceral fat, the intramuscular fat of trunk and the subcutaneous fat of upper and lower limbs were higher in women than in men. But there was no significant difference in fat quality between men and women ($p>0.05$). 2) Fat mass index. There was a significant difference between the female and the male in the subcutaneous fat index of the upper extremity ($m:0.53 \pm 0.14$; $f:0.63 \pm 0.16$; $p=0.048$), and a significant difference between the female and the male in the subcutaneous fat index of the lower extremity ($m:1.94 \pm 0.61$; $f:2.55 \pm 0.51$; $p=0.002$). There was no gender difference in muscle fat between upper and lower limbs ($P>0.05$). The visceral fat index of female was higher than that of male ($m:0.43 \pm 0.12$; $f:0.53 \pm 0.17$; $p=0.042$). 3) The trunk fat mass of male accounted for 38.89% of the total fat mass, which was lower than that of female (41.77%), but there was no significant difference. ($p>0.05$). The visceral fat mass of male accounted for 10.10% of the total fat mass, which was higher than that of female (9.11%). The upper limb fat mass of male accounted for 12.17% of the total fat mass, which was significantly higher than that of female (10.72%) ($p=0.048$). There was no significant difference between male (47.93%) and female (47.50) in the proportion of lower limb fat mass. ($p>0.05$) **CONCLUSIONS:** There was no gender difference in fat mass of different parts of adolescent. The subcutaneous fat index and visceral fat index of women were higher than that of men, but there was no gender difference in muscle fat index. The centripetal accumulation of puberty male fat was not obvious, but the proportion of upper limb fat was relatively high.

Habitual Physical Activity And Muscle Mass Changes With Weight Loss

Emily J. Peterson, Stephanie M. Wilson, Marcy E. Gaston, Colleen R. McMillin, Wan-Yuan Kuo, Nicole Doherty, Mary P. Miles, FACSM. *Montana State University, Bozeman, MT.*
 Email: emilypeterson6@montana.edu

(No relevant relationships reported)

As with any weight loss program, losing fat while maintaining muscle is a desirable outcome. We sought to determine how different types of habitual activity influenced the retention of muscle mass with a decrease in body fat.

PURPOSE: As a preliminary analysis to guide future research, the purpose of this study was to determine whether self-reported frequency of aerobic, strength, and stretching exercise (days per week) associates with body composition changes in response to weight loss in overweight and obese adults. **METHODS:** Adults ($n=23$), 18-70 years old with a minimum waist circumference of 35 inches for women and 40 inches for men participated in an 8-week study diet intervention. Participants were asked to maintain habitual physical activity during the intervention. All participants reported their habitual exercise frequency for aerobic, strength, and stretching activities within a typical 7-day period. Body composition was assessed using bioelectrical impedance analysis (mBCA). After post testing, correlations (nonparametric, Spearman) between days reported for each activity and changes in body mass, percent body fat, visceral adipose tissue (VAT) and muscle mass were determined in participants who had a reduction in body mass during the intervention. **RESULTS:** The

average number of days per week reported for each activity was 4.3 for aerobic, 1.8 for strength, and 3.3 for stretching. Change in body mass pre to post intervention was from 94.6 + 22.3 kg to 92.9 + 21.4 kg. The range in change for muscle mass was from -2.31 kg to +1.1 kg. There was a correlation ($r = 0.603$, $p = 0.029$) between days per week of aerobic activity and change in muscle mass. **CONCLUSIONS:** While all individuals of the analysis lost some weight during the intervention, some of them lost and some of them gained muscle mass. Individuals who reported more days of aerobic activity per week as their habitual activity level were more likely to retain muscle mass. Supported by the USA Dry Pea & Lentil Council

Body Shape And Basal Metabolism Characteristics Of Female College Students With Normal Weight Obesity
 Mengdie Wang, Hong Ren, Yan Bai. *Beijing Sport University, Beijing, China.*
 Email: mengdie0624@163.com
 (No relevant relationships reported)

PURPOSE: Female college students become a high-risk group of normal weight obesity (NWO) because of their lifestyle and psychological status. NWO can have an impact on the health of students. We analyze the characteristics of the body's physical form and basal metabolism to add a new basis for the evaluation of female college students' physical condition.

METHODS: A stratified cluster sampling method was used to extract 2000 samples from the two universities. Excluding those who did not meet the test conditions, eventually included 1,937 female college students. The subject's body mass index (BMI), body fat percentage (BF%), skeletal muscle percentage (SM%), waist-to-hip fat ratio, basal metabolic rate, waist circumference (WC), hip circumference (HC), and thigh circumference (TC) were measured. One-way ANOVA was used to compare the differences in body shape indicators between NWO and normal weight lean (NWL) female college students. Compare the incidence of central obesity among NWO and NWL female college students.

RESULTS: 1) Among female college students, the incidence of NWO was 33.3%, accounting for 66.02% of female college students with excessive body fat. Among NWO female college students, 4.19% belong to the group with BMI <18.5(kg/m²). 2) Compared with NWL, NWO had higher BF% and lower SM% (33.32±2.59 vs 26.49±2.70%; 35.79±1.53 vs 39.79±1.69%, $p < 0.01$); NWO had higher waist-to-hip fat ratio (0.83±0.02 vs 0.81±0.02, $p < 0.01$); NWO had lower basal metabolic rate (1192.09±75.99 vs 1240.71±77.93 kcal/d, $p < 0.01$). 3) In the circumference index, compared with NWL, WC, HC and TC of NWO were larger (69.38±4.62 vs 67.07±4.95cm, $p < 0.01$; 94.16±5.10 vs 92.09±4.48cm, $p < 0.01$; 55.97±3.14 vs 54.56±3.13cm, $p < 0.05$). 4) There are 19 central obese female college students, 68% of whom are from NWO population.

CONCLUSIONS: NWO female college students have a big difference in physical form compared with NWL. NWO has a larger circumference and its fat distribution is characterized by more fat accumulation in the waist and had lower basal metabolic rate. We need to pay attention to the status of female college students with NWO. Supported by Thirteenth Five-Year Plan for scientific research of Chinese society of Higher Education (17TZ006), Basic scientific research business fund project of Central University (2008XS030).

3885 Board #202 May 30 9:00 AM - 10:30 AM
High Versus Low Inflammation Phenotype And Fat Utilization During Exercise
 Isaac F. Rowland, Stephanie M. Wilson, Sarah Bronsky, Adam Maes, Mary P. Miles, FACSM. *Montana State University, Bozeman, MT.*
 (No relevant relationships reported)

Inflammatory markers are a well-known and reliable predictor of all-cause mortality in individuals as they are associated with disease-specific processes. It has also been established that individuals with higher adiposity tend to oxidize fat at a higher rate during exercise than lean individuals. It is currently not known whether there is any relationship between resting inflammatory markers and levels of fat oxidation during exercise.

PURPOSE: To examine the relationship between inflammatory phenotype and fat utilization in obese adults during a graded exercise test.

METHODS: Healthy overweight and obese (OW/OB) adults ($n=34$) were classified as either having or not having a low-grade inflammation phenotype according to at least four out of six elevated cytokines, obtained through a fasted blood draw. Selected inflammatory cytokines to be detected include IL-1 β , IL-6, TNF- α , granulocyte macrophage colony-stimulating factor (GM-CSF), IL-17A, and IL-23. Inclusion criteria also required that each participant achieve at least 80% $\dot{V}O_{2max}$ according to age-predicted heart rate max. Participants completed a modified Bruce protocol on a treadmill and carbohydrate and fat oxidation were compared at 35, 50, 65, and 80% of estimated $\dot{V}O_{2max}$.

RESULTS: All participants had similar anthropometric measurements with a mean BMI of 30.6 kg/m². Male participants with low-grade inflammation phenotype oxidized a higher ($p < 0.05$) percentage (mean \pm SD, 10.2 \pm 10.2% vs 30.7 \pm 14.1%) of fat and greater Kcal of fat per kg body mass at 65% of $\dot{V}O_{2max}$. However, exercise intensities at 35%, 50%, and 80% of $\dot{V}O_{2max}$ showed no difference between the two groups of males. Female participants showed no difference between inflammation phenotyping and utilization of fat during the graded exercise test.

CONCLUSIONS: It is understood that OW/OB individuals tend to oxidize a greater amount of fat than their lean counterparts, particularly during exercise. However, when observing OW/OB men who had been classified as having a low grade inflammation phenotype, were noted to utilize a greater amount of fat as exercise intensity increases. **FUNDING:** Montana State University Research Initiative 51040-MUSRI2015-03 and USDA-NIFA 2017-67018-26367.

Weight Loss Strategies Used By Older Adults In A 6-month Weight Loss Intervention
 M. Elizabeth Miller, Leslie Edwards, Kelsie Newton, Audrey Bailey, Iris Puthoff, Kyle Timmerman, FACSM. *Miami University, Oxford, OH.* (Sponsor: Kyle Timmerman, FACSM)
 Email: mille736@miamioh.edu
 (No relevant relationships reported)

Obesity in older adults places them at risk for increased mortality and comorbid health conditions. Older adults are also at risk for loss of muscle mass and related decreased functioning with diet being an important factor. Gaining a better understanding of perceptions of weight loss in older adults and identifying successful weight loss strategies that can assist in reducing obesity while protecting muscle mass is important to improve health outcomes. **PURPOSE:** To identify and examine the perceptions of weight loss and weight loss strategies used by older adults in a 6-month weight loss intervention. **METHODS:** Twelve overweight (94.0 kg \pm 13.2), older adults (65.7 years \pm 4.0) were enrolled in a 6-month weight loss intervention. Participants received a calorically reduced meal plan (500kcal/d) with 1.2g/kg protein to protect against muscle loss. Fourteen follow-up sessions were conducted. Body weight (BW) and skeletal muscle mass (SMM) were monitored utilizing InBody770. Post program interviews were audio-recorded, transcribed and analyzed using constant-comparative analysis. A 35-item weight loss strategy inventory was completed and analyzed utilizing descriptive statistics. **RESULTS:** Ninety-two percent ($n=11$) of participants lost weight, with mean weight loss of 6.8% \pm 4.4 of BW. Seventy-five percent of participants had weight loss of >5% of BW. Mean SMM loss was 0.009% \pm 0.031 of BW with 33.3% ($n=4$) of participants increasing or maintaining SMM. Participants used a mean 15 \pm 6 weight loss strategies four or more times/week. Themes for successful weight loss included using personal behavioral strategies such as measuring portion sizes, biochemical and anthropometric motivators, personalized support, and accountability feedback and monitoring. Barriers included consuming the additional protein in the diet and care-taking of others. **CONCLUSION:** Results of this study provide considerations for the development of strategies to achieve clinically significant weight loss (>5%) while maintaining SMM in older adults. The higher intake of protein to protect against muscle loss was reported to be difficult for participants. Both personal strategies, as well as external strategies provided through the counseling relationship, contributed to success.

No Changes In Appetite Stimulating Hormones Following Swimming And Cycling Exercise Interventions
 Brandon G. Fico, Mohammed Alkatan, Yuzi Zhang, Hirofumi Tanaka, FACSM. *University of Texas at Austin, Austin, TX.* (Sponsor: Dr. Hirofumi Tanaka, FACSM)
 Email: bfico@utexas.edu
 (No relevant relationships reported)

Swimming is a favorable and ideal modality of exercise for individuals with obesity and arthritis as it encompasses a minimal weight-bearing stress and a reduced heat load. However, the available evidence indicates that regular swimming may not be effective in reducing body weight and body fatness. A current hypothesis is that exercise in cold water somehow stimulates appetite. **PURPOSE:** We determined the effect of swimming exercise training on fasting concentrations of ghrelin, insulin, leptin, and peptide YY in obese individuals with osteoarthritis. Cycling training was included as a non-weight bearing land-based comparison group. **METHODS:** Thirty-nine obese participants with osteoarthritis (age=59 \pm 1 years, BMI=33 \pm 1 kg/m²) were randomly assigned to 12 weeks of supervised swimming training (N=19) or cycling training (N=20). In the initial few weeks, participants exercised for 20-30 minutes/day, 3 days/week, at an exercise intensity of 40-50% of heart rate reserve (HRR). Subsequently, the intensity and duration of exercise were progressively increased to 40-45 minutes/day, 3 days/week, at an intensity of 60-70% of HRR. Fasting blood samples were analyzed for ghrelin, insulin, leptin, and peptide YY concentrations

using ELISAs. **RESULTS:** There were no group differences in body weight, BMI, or appetite stimulating hormones prior to the exercise interventions. Fasting plasma concentrations of ghrelin (37±8 vs. 42±11 pg/ml), insulin (1,176±424 vs. 1,179±442 pg/ml), leptin (20,200±2,891 vs. 16,617±2,734 pg/ml), and peptide YY (51±6 vs. 54±7 pg/ml) did not change with the swimming exercise intervention (all p>0.05). Similarly, cycling exercise had no effect on ghrelin (36±10 vs. 44±8 pg/ml), insulin (978±321 vs. 964±311 pg/ml), leptin (29,261±5,438 vs. 26,308±4,771 pg/ml), or peptide YY (58±15 vs. 63±16 pg/ml) concentrations (all p>0.05). **CONCLUSIONS:** Our present results indicate that fasting levels of appetite stimulating hormones did not change with 12 weeks of swimming exercise intervention in obese participants with osteoarthritis and that there were no group differences in changes in these hormones between swimming and cycling exercise interventions.

3888 Board #205 May 30 9:00 AM - 10:30 AM
Rapid Weight Loss Adversely Affects Muscle Damage Markers In Elite Judo Athletes

Tatjana Trivic¹, Nemanja Lakicevic², Roberto Roklicer¹, Nebojsa Maksimovic¹, Ambra Gentile², Antonino Bianco², Sergej M. Ostojic¹, Patrik Drid¹. ¹Faculty of Sport and Physical Education, Novi Sad, Serbia. ²University of Palermo, Palermo, Italy.
 (No relevant relationships reported)

Rapid weight loss (RWL) is a phenomenon that is commonly detected amongst elite judo athletes. It is used to gain the advantage over their lighter opponents. **PURPOSE:** To evaluate the effects of 7-day RWL intervention on muscle damage markers in seven elite judokas during a pre-competition period.

METHODS: The participants voluntarily participated in this study. RWL was induced in accordance to personal preference previously practiced by judo athletes. Most frequently reported methods of RWL were increased exercise volume, fluid and caloric restriction and heated environment exposure.

RESULTS: RWL induced a significant drop in weight within all seven participants (93.07 ± 10.69 kg at baseline vs. 88.12 ± 10.30 kg at follow-up; P < 0.001). Regarding biochemical changes, myoglobin levels significantly increased on the last day of intervention (P < 0.01) (day 7). In addition, creatine kinase levels were also elevated on the 6th day of the intervention.

CONCLUSIONS: Based on the obtained results, RWL methods caused alterations in myoglobin and creatine kinase levels in elite judokas. This indicates that although RWL is perceived as helpful in achieving success in competition, it can produce muscle tissue damage that can further impact fitness profile of elite judokas. This project was partly supported by the Serbian Ministry of Education, Science and Technological Development (175037 and 179011), the Provincial Secretariat for Higher Education and Scientific Research (142-451-2473 and 114-451-710) and the Faculty of Sport and Physical Education, University of Novi Sad (2019 Annual Award).

Baseline Characteristics Of Older Hispanics With Type 2 Diabetes Participating In An Intervention Study

Marcos Roberto Queiroga¹, Fernanda Civitella², Stephanie Caceres², Jorge Carreno², Fabricia da Costa Cavalcanti³, Edgar Ramos Vieira². ¹Midwestern Parana State University, Guarapuava, Brazil. ²Florida International University, Miami, FL. ³Federal University of Rio Grande do Norte, Natal, Brazil.
 Email: queiroga@unicentro.br
 (No relevant relationships reported)

Type 2 Diabetes mellitus (DM2) affects 9.3% of the U.S. population. Health disparities are evident in DM2; twice as many Hispanics as non-Hispanic Whites have DM2.

PURPOSE: The goal of this study was to describe the baseline characteristics of older Hispanics with DM2 participating in a diet and exercise study in 3 senior centers. **METHODS:** Data from 38 older Hispanics with DM2 was collected. The variables included age, body mass, height, waist circumference, Hemoglobin A1C, glucose, blood pressure, chair stands in 30s, grip strength, balance, and preferred gait characteristics. **RESULTS:** The characteristics of the 38 participants (29 women, 9 men) that completed the baseline assessments to date were: age = 79±7 yrs (♀78±7; ♂80±7), body mass = 75±16 kg (♀73±13; ♂85±23), height = 157±10 cm (♀154±8; ♂168±6), body mass index = 31±6 kg/m² (♀30±5, ♂30±7), waist circumference = 103±13 cm (♀101±11; ♂109±19); A1C = 7±1% (♀7±1; ♂6±1), non-fasting blood glucose = 140±47 g/dL (♀135±5; ♂157±30), systolic = 140±19 mmHg (♀139±18; ♂145±20) and diastolic blood pressure = 78±10 mmHg (♀78±10; ♂78±10). Their physical characteristics presented in Table 1 indicate frailty (e.g. chair stands ≤8, grip strength ≤ 21, ♂32 kg, and gait velocity ≤ 80cm/s). **CONCLUSION:** The results indicate that at baseline the participants had high prevalence of obesity (abdominal and total), low levels of glycemic control, borderline high blood pressure, and have low levels of physical function that are indicative of frailty.

Supported by Wertheim Innovation Faculty Grant from the FIU Nicole Wertheim College of Nursing and Health Sciences

Table 1. Characteristic of the physical function baseline characteristics of older Hispanics with DM2

	Variables	Total (n=38)	Women (n=29)	Men (n=9)
Muscle strength	Chair test (rep)	8±4	8±4	8±5
	Handgrip (kg)	21±6	19±5	29±5
Balance (Force plate)	A95 -EO (cm ²)	5.1±3.3	5.2±3.4	5.0±3.0

Substrate Utilization Differences Between Overweight And Obese Men And Women During Exercise

Hunter R. Baum, Stephanie M. Wilson, Sarah Bronsky, Mary P. Miles, FACSM. Montana State University, Bozeman, MT.
 (No relevant relationships reported)

As exercise intensity and duration increase, substrate utilization typically shifts to carbohydrates over fats. However, individuals with higher levels of adiposity have been shown to rely more heavily on fat oxidation during higher intensity exercise than their lean counterparts. Currently, there is limited research on how carbohydrate and fat oxidation differ in men compared to women at different exercise intensities.

PURPOSE: To examine the difference in substrate utilization of fat and carbohydrate between men and women at different exercise intensities. **METHODS:** Participants (n=34) between 18-55 years old (Women: 35.9 +/- 11.3 years; Men: 36.1 +/- 7.7 years) with a BMI between 27-35 kg/m² (Women: 30.5 +/- 1.7 kg/m²; Men: 30.6 +/- 2.2 kg/m²) completed a modified Bruce protocol on a treadmill for measurement of an estimated VO2Max at their age-predicted heart rate max. To be included in the analysis these participants were required to reach 85% age predicted heart rate max.

RESULTS: Women utilized a higher (p≤0.05) percentage of fat at 65% (Women: 42.9 ± 16.9%; Men: 24.8 ± 17.7%), and 80% (Women: 14.7 ± 18.2%; Men: 2.7 ± 7.95%) of their VO2Max and greater (p≤0.05) usage of overall Kcal from fat per kg of body mass at 80% (Women: 0.02 ± 0.02kcalF/kg; Men: 0.01 ± 0.01 kcalF/kg) of VO2Max. Men relied more heavily (p≤0.05) than women on carbohydrates per kg of body mass at 50% (Women: 0.03 ± 0.02kcalC/kg; Men: 0.06 ± 0.03kcalC/kg), 65% (Women: 0.07 ± 0.03kcalC/kg; Men: 0.13 ± 0.06kcalC/kg) and 80% (Women: 0.16 ± 0.08kcalC/kg; Men: 0.26 ± 0.08kcalC/kg) of VO2max. **CONCLUSIONS:** Women oxidized more fat than men at 65% and 80% VO2Max, but not 35% and 50% VO2Max. As exercise intensity increased, the gap between women and men fat oxidation levels became larger. **Funding:** Montana State University Research Initiative 51040-MUSRI2015-03 and USDA-NIFA 2017-67018-26367.

Whole-body Electromyostimulation Enhances Submaximal Performance And Leg Fatigue In Obese Women After Bariatric Surgery

Paula Angélica Ricci, Luciana Di Thommazzo-Luporini, Larissa Delgado André, Audrey Borghi-Silva. Federal University of São Carlos, São Carlos, Brazil.
 (No relevant relationships reported)

Bariatric surgery (BS) is the most effective treatment for morbid obesity. Early rehabilitation strategies may be able to improve functional capacity (fc) and body composition that are impaired after the surgical procedure. In this sense, the whole-body electromyostimulation (WB-EMS) added to dynamic exercises may enhance the benefits for this population.

PURPOSE: To evaluate if WB-EMS would enhance dynamic exercises on fc, dyspnea and leg fatigue, and body composition

METHODS: Randomized double-blind controlled clinical trial. Twenty-six obese women (37±7years; BMI=37±4 kg/m²) were randomized after bariatric surgery into two groups (WB-EMSG, n=13; ShamG, n=13). Before and after training protocol, the patients performed body composition analysis (Inbody 720) and the two minutes step test (2MST) for functional capacity evaluation with portable ergospirometer (Oxycon Mobile®), with borg scale evaluation for effort perception. The WB-EMS (Miha

Bodytec) was applied at motor level (endurance training: 3x/week; frequency=85Hz, pulse duration=350 μ s, cycle on=6"; cycle off = 4"; strength training: 2x/week; frequency= 30Hz, pulse duration= 350 μ s, cycle on = 4"; cycle off = 10"), associated with dynamic exercises during 30 days, one week after BS. The ShamG performed the same exercises, but with the electric current turned off. After confirmation of normal data distribution (Shapiro-Wilk) a two-way ANOVA was performed ($p < 0.05$).

RESULTS: Weight loss was similar between groups after the intervention ($p < 0.002$), and higher values of up and down cycles were observed (WB-EMSG pre: 47, post: 57 vs ShamG pre: 44, post: 54; $p < 0.001$) and relative $\dot{V}O_2$ (WB-EMSG pre: 11.3, post: 14.1 vs ShamG pre: 10.3, post: 13.5; $p < 0.001$) (2MST) in both groups after the intervention. In addition, we observed lower values of ventilation per minute (pre: 37.1, post: 32.7, vs pre: 43.7, post: 45.4, $p = 0.002$) and leg fatigue (pre: 1.0, post: 0.79 vs pre: 1.9, post: 1.8, $p = 0.01$) at the 2MST peak in WB-EMSG compared to ShamG, respectively.

CONCLUSIONS: Early intervention composed of WB-EMS and dynamic exercises improved minute ventilation and leg fatigue in 2MST, which may reflect in a faster and quality recovery for these patients.

PREDIABETES PHENOTYPE DOES NOT EXACERBATE MICROVASCULAR INSULIN SENSITIVITY IN METABOLIC SYNDROME

Emily M. Heiston, Stephanie L. Miller, Zhenqi Liu, Arthur Weltman, FACSM, Eugene J. Barrett, Steven K. Malin, FACSM. *University of Virginia, Charlottesville, VA.* (Sponsor: Steven K. Malin, FACSM)
 Email: emh5bh@virginia.edu
 (No relevant relationships reported)

Metabolic syndrome (MetS) and elevated glucose each promote microvascular dysfunction. Whether in combination these two conditions create increased dysfunction is not clear. Here, we tested whether glucose status worsens microvascular insulin sensitivity in MetS. Thirty-two sedentary, obese adults (54.2 \pm 1.2yrs; 35.9 \pm 1.3kg/m²; VO_{2max} : 19.9 \pm 1.3ml/kg/min) with MetS (≥ 3 ATP III criteria) were classified as normal glucose tolerant (NGT, n=8; 6F), impaired fasting glucose (IFG; n=10; 7F) or IFG+IGT (n=14; 11F) according to ADA criteria using a 75g OGTT. Capillary perfusion (microvascular blood volume, MBV), filling rate (microvascular flow velocity, MFV) and blood flow (MBF=MBV*MFV) were assessed as the change before and after a 2hr euglycemic-hyperinsulinemic clamp (90mg/dl, 40mU/m²/min) using contrast enhanced ultrasound. Glucose infusion rate (GIR) was used to determine metabolic insulin sensitivity while carbohydrate oxidation (CHO_{ox}) was measured before and after the clamp to understand nutrient utilization. T-tests, repeated measures ANOVAs and correlations were used when appropriate. Significance was accepted as $P \leq 0.05$. There were no differences in age, BMI, VO_{2max} or GIR (NGT: 2.26 \pm 0.48 vs. IFG: 2.66 \pm 0.46 vs. IFG+IGT: 1.91 \pm 0.37mg/kg/min, $P=0.44$) among groups. Insulin did not stimulate capillary perfusion (NGT: 0.16 \pm 0.19 vs. IFG: -0.02 \pm 0.14 vs. IFG+IGT: 0.08 \pm 0.12AI, $P=0.40$), filling rate (NGT: 0.006 \pm 0.005 vs. IFG: 0.003 \pm 0.004 vs. IFG+IGT: 0.004 \pm 0.004sec⁻¹, $P=0.11$) or blood flow (NGT: 0.02 \pm 0.02 vs. IFG: 0.01 \pm 0.01 vs. IFG+IGT: 0.01 \pm 0.01AI/sec, $P=0.21$). CHO_{ox} was likewise unresponsive to insulin ($P=0.34$). Although age, BMI, fasting and 2hr glucose concentrations did not relate to insulin effects on microvascular function, fasting triglycerides was related to insulin-stimulated MBF ($r=-0.39$, $P=0.03$). Prediabetes phenotype does not worsen microvascular insulin sensitivity in adults with MetS. Future work is warranted to examine the effects of different therapies (lifestyle, medication) on microvascular function.

Funding was supported by the National Institutes of Health RO1-HL130296.

Elevated Circulating Asprosin Impedes Low Intensity Exercise-induced Weight Loss In Obese Individuals

Uwe Schumann¹, Shanhu Qiu², Gunnar Treff¹, Katrin Enders¹, Nadine Rolser¹, Jessica Schiele¹, Lennart Mentz¹, Kay Winkert¹, Martina Zügel¹, Lingjun Jiang¹, Jürgen M. Steinacker, FACSM¹. ¹Ulm University Medical Center, Ulm, Germany. ²Zhongda Hospital, Nanjing, China. (Sponsor: Jürgen M. Steinacker, FACSM)

(No relevant relationships reported)

PURPOSE: Circulating Asprosin is elevated in obese men and mice and mainly produced in white adipose tissue (WAT) to trigger hepatic glucose release into the bloodstream maintaining energy standards between meals, and hence has been suggested as pharmaceutical target to battle obesity and T2D. We hypothesized a mechanistic link to the empirical observation, why a predominant part of obese individuals mainly fail to lose depot-stored body fat despite their commitment to participate in aerobic exercise programs, and followed the research

question if stress induced secretion of Asprosin during aerobic exercise counteracts the metabolic consumption of body fat through stimulating insulin triggered refueling of WAT.

METHODS: After overnight fasting 7 obese men and women (age 59.7 \pm 5.6; BMI 40.2 \pm 8.4) and 7 age and sex matched lean counterparts (age 59.5 \pm 5.2; BMI 22.9 \pm 1.5) performed a treadmill protocol for 25 min at 90% of an individual's VT1 and RQ of ≤ 0.82 (controlled and adjusted if needed) to ensure that body fat as energy source was used. Venous blood samples (pre-, post-, +30 min post-, and +60 min post-exercise) were drawn to analyze Asprosin, Cortisol, Proinsulin, and acetylated Ghrelin using commercial ELISA kits.

RESULTS: Asprosin baseline data were significantly increased in obese compared to lean subjects ($p=0.013$) and further raised significantly during the course of the exercise trial only in obese. Stress marker Cortisol was comparable between groups at baseline ($p=0.38$) but significantly augmented in corpulent participants only, while it significantly decreased in lean subjects during the exercise test. Proinsulin increased significantly from baseline to +30 min post-exercise in obese ($p=0.013$) but remained unaffected in normal weight subjects ($p=0.99$) while their baseline data were comparable ($p=0.06$). Hunger hormone Ghrelin was already significantly increased at baseline in obese vs. lean subjects ($p=0.015$) but raised even significantly further in obese at +30 min post-exercise vs. baseline.

CONCLUSIONS: The stress induced aberrant hormone reaction of obese individuals counteracts the metabolic consumption of body fat through stimulating the refueling of WAT. This observation helps to explain the difficulty of obese persons to lose excess body fat when performing low intensity exercise.

Associations Of Dietary Acid Load On Physical Function And Body Composition In Older Obese Adults

Hannah Parker¹, Gary Miller¹, Monica Schumacher¹, Shannon Mihalko¹, Mary Lyles², Richard Loeser³, Paul DeVita⁴, Daniel Beavers⁵, Stephen Messier, FACSM¹. ¹Wake Forest University, Winston Salem, NC. ²Wake Forest Baptist Health, Winston Salem, NC. ³Duke University, Durham, NC. ⁴East Carolina University, Greenville, NC. ⁵Wake Forest School of Medicine, Winston Salem, NC. (Sponsor: Stephen Messier, FACSM)
 Email: parkhj18@wfu.edu

(No relevant relationships reported)

Acid-base balance affects muscle quality in older adults leading to less muscle mass and strength. Individuals with knee osteoarthritis (OA) have less muscle mass and strength. It is unknown if OA's effect on function and strength is mediated by acid-base balance.

Purpose: This study examined associations between dietary acid production, physical function, muscle strength, and body composition in older obese adults with knee osteoarthritis. Higher acid load is hypothesized to be associated with lower physical function, strength and lean body mass (LBM).

Methods: Baseline data from the Intensive Diet and Exercise for Arthritis (IDEA) trial were used for this analysis. Measurements from IDEA included a 3-day food record to calculate daily potential renal acid load (PRAL) PRAL, 6-min walk distance, LBM via dual energy x-ray absorptiometry, and concentric knee extensor and flexor strength. Estimated potential renal acid load (PRAL in mEq H⁺ ions) = (0.49*mg protein) + (.037*mg phosphorus) - (.021*mg potassium) - (.026*mg magnesium) - (.013*mg calcium). Associations were determined by Pearson correlations.

Results: Data obtained from 388 participants (age=65.8 \pm 6.1 yrs; 70.4% female; body mass index=33.7 \pm 3.8 kg/m²) were used in the analysis. Mean values were: PRAL score (8.9 \pm 13.8 mEq/d); LBM (56.0 \pm 12.0 kg); 6-min walk distance (476.5 \pm 82.6 m); concentric knee extensor (60.2 \pm 26.0 Nm) and knee flexor (30.2 \pm 14.7 Nm) strength. PRAL showed significant positive associations with concentric knee extensor strength ($r=.19$; $p=.011$), knee flexor strength ($r=.19$; $p=.012$), and LBM ($r=.22$, $p<.001$).

Conclusion: The physiological importance of the statistical relationship observed for high PRAL (higher acid load) and high physical function and knee extensor and flexor strength, although minimal ($r \sim .2$), opposes our hypothesis. These discrepant findings may be from using an indirect measure acid production, presence of OA in this cohort, and the accuracy of self-reported dietary records.

Obese Pediatric Youth Have A High Rate Of Adult Criminal Behavior And Low Rates Of Home Ownership That Is Not Linked To Pediatric Fitness

Adam W. Powell¹, Zachary Siegel², Christopher Kist¹, Wayne A. Mays¹, Robert Siegel¹. ¹Cincinnati Children's Hospital Medical Center, Cincinnati, OH. ²Loyola University, Chicago, IL.
 Email: adam.powell@cchmc.org
 (No relevant relationships reported)

Purpose: Pediatric obesity has been linked to negative social outcomes in childhood. Minimal information is known about social outcomes in adulthood for obese pediatric patients and if they are linked with pediatric fitness. **Methods:** A retrospective chart review was performed evaluating all pediatric (<18 year old) youth with obesity who presented to the HealthWorks! pediatric weight management program from 1999-2009 and had a formal cardiopulmonary exercise testing (CPET), which was a requirement for clinic enrollment. Demographic and public record collection including body habitus, death records, real estate transactions and criminal conviction history was collected with baseline data compared to published lifetime criminal prevalence (Shannon SKS, et al, *Demography* 2017) and home ownership rates (US Census). Statistical analysis was performed using JMP®, Version 14 with differences between groups assessed using an unpaired t-test where a p-value <0.05 was considered significant. **Results:** A total of 719 pediatric youths with obesity (12.2±2.9 years) performed exercise testing with all patients now adults (28.5±3.7 years). There was a 1.5% mortality rate (11/719), and mortality was not associated with body habitus or any CPET parameter. Only 28.6% (206/719) of patients were able to complete a maximal effort CPET. On review of the criminal records, 9.7% (70/720) of these young adult patients were convicted of a felony compared to ~6% lifetime prevalence in Ohio during this period of time (p=0.004). There was no difference between incarceration rates of these now adult pediatric youths with obesity and the reported lifetime prevalence in Ohio (3.6% vs 3%, p=0.5). In addition, 14.7% (106/719) of study patients purchased a home in adulthood compared to 56.8% of Midwest adults <35 years of age (p<0.0001). Inability to complete a maximal effort CPET was associated with age, weight and future home ownership. History of criminal conviction was not associated to any study parameter. **Conclusions:** Children with obesity have higher social risk than their peers in adulthood as evidenced by higher rates of criminal behavior and lower rates of home ownership. Pediatric patients with obesity have low rates of exercise test completion and pediatric exercise capacity is not associated with mortality or social outcomes.

No Association Of Weight Gain Since Age 20 With Cardiorespiratory And Muscular Fitness

Shelby C. Wilhite, Lauren Evans, Edward K. Merritt.
 Southwestern University, Georgetown, TX.
 Email: wilhites@southwestern.edu
 (No relevant relationships reported)

Substantial exercise-induced weight loss is unachievable by many people. With no dietary modifications, a person of average size and fitness requires 60+ hours of moderate intensity exercise to lose 5 kg of fat. Individuals who are overweight or obese might not have the cardiorespiratory and muscle health necessary for successful exercise-induced weight loss, but it has yet to be determined if individuals with different patterns of weight gain (gradual vs fluctuation vs rapid) have different cardiorespiratory and muscle health levels.

PURPOSE: This pilot study's aim was to determine if weight gain since the age of 20 and recent weight history is related to current cardiorespiratory and muscular fitness. **METHODS:** A retrospective health and weight history questionnaire was completed by 23 overweight and obese, but otherwise healthy adults (47.42 ± 9.75 yrs, BMI 29.70 ± 3.36). Weight gain since age 20 and weight history (loss & gain) in the previous 5 years were self-reported. Total fat and lean mass, cardiorespiratory fitness, and skeletal muscle strength were determined through dual energy x-ray absorptiometry, metabolic gas analysis during a graded exercise test, and upper and lower body strength measurements. **RESULTS:** Participants had an average body fat of 39.2 ± 5.4% having gained 9.3 ± 4.4 kg since the age of 20 years. Maximal oxygen consumption was 2.18 ± 0.5 L/min. No relationship existed between percentage of weight gain since 20 (25.96 ± 11.10%) and current maximal oxygen consumption (r = -0.08). **CONCLUSIONS:** Based on this pilot data it does not appear that fitness determines weight gain after age 20. Future studies will determine if type of weight progression over time (e.g. gradual vs fluctuation) and weight loss history are related to cardiorespiratory and/or muscular fitness and if fitness can predict success in exercise-induced weight loss programs in overweight or obese individuals.

Differences In Exercise Behaviors By Diabetes Status: Implications For Diabetic Americans

Cassandra M. Beattie¹, Katie M. Heinrich¹, Yuri Feito, FACSM².
¹Kansas State University, Manhattan, KS. ²Kennesaw State, Kennesaw, GA. (Sponsor: Yuri Feito, FACSM)
 Email: cbeattie@ksu.edu
 (No relevant relationships reported)

Background:In Kansas, 10% of adults have type one or type two diabetes (T1D, T2D). Although Federal physical activity (PA) guidelines including aerobic and strength training exercises are recommended for T2D; guidelines lack for T1Ds. A better understanding of differences in exercise behaviors amongst between populations is needed. **Purpose:**This study compared exercise behaviors of T1D, T2D, and non-diabetics (ND). **Methods:**Male (n=68) and female (n=267) participants ages 18-64 were recruited via social media (e.g. Facebook, Instagram) and newsletters and indicated consent prior to participation in the online survey. Data were collected for demographics, anthropometrics, diabetes status, and exercise (PA) behaviors. One-way ANOVAs, with Games-Howell post hoc tests were used to determine differences in aerobic activity and strength training between T1D, T2D, and ND participants. **Results:**Participants included 48 T1Ds, 24 T2Ds, and 240 NDs. Statistically significant differences existed for moderate aerobic PA between groups, $f(2,304)=3.9$, $p=0.021$, where T2D reported fewer weekly minutes (109.2±88.8) than ND (215.7±186.5; $p=0.021$). T1D (179.0±171.7) were not significantly different. No significant vigorous PA differences were found ($p=0.242$; T1D=66.3±80; T2D=41.7±60.5; ND=73.8±94.8 min/week). Strength training days/week differed between groups, $f(2,314)=3.6$, $p=0.028$ with T1D (1.8±2.0) reporting significantly more than T2D (0.7±1.0; $p=0.024$); no significant differences for ND (1.5±1.7). **Conclusion:**Although statistically similar to T2D/ND, T1D's mean moderate activity was over the recommended 150 min/week. T1D did report significantly more strength training days/week than T2D approaching recommended 2 days/week. Participants' most popular PAs were walking (51%), and strength training (18%), thus Kansans should consider walking and strength training exercises.

Montmorency Tart Cherries Influence The Urinary Metabolome But Not Vascular Function In Healthy Individuals

Rachel Kimble, Lucy Murray, Karen M. Keane, Karen Haggerty, Glyn Howatson, FACSM, John K. Lodge. Northumbria University, Newcastle Upon tyne, United Kingdom. (Sponsor: Glyn Howatson, FACSM)
 Email: rachel.kimble@northumbria.ac.uk
 (No relevant relationships reported)

There is accumulating evidence that Montmorency tart cherry (MC) polyphenols possess vasomodulatory properties and their intake has been shown to reduce a number of cardiovascular risk factors. Despite this our understanding of the overall mechanisms of action and compounds that exert these benefits has yet to be fully elucidated.

Purpose: The aim of this study was to characterise the effects of 4-week MC supplementation on vascular function in healthy adults and provide potential mechanistic evidence from urinary metabolite profiling. **Methods:** Twenty three healthy non-smoking individuals took part in a study in which they consumed either 30 mL of MC concentrate or an isocaloric placebo (PLA) bi-daily for 4 weeks. The study employed a randomised, double-blind, placebo-controlled, parallel design; mean ± SD age was 25 ± 4 years in the MC group (n = 12) and 22 ± 2 years in the PLA group (n = 11). Blood pressure, arterial stiffness (pulse wave velocity and digital volume pulse) were measured pre- and post- supplementation. Spot urine samples were also collected at the corresponding time points to determine the effect of the intervention on the urinary metabolite profiles. **Results:** There were no differences in blood pressure or arterial stiffness following the 4-week supplementation with MC compared to PLA. However, metabolite profiling highlighted changes to the urinary metabolome following MC consumption ($P < 0.001$ within and between groups). Several discriminatory metabolites of interest were putatively identified as metabolites of the tryptophan and histidine pathways. **Conclusions:** These findings suggest that bi-daily MC supplementation for 4-weeks has no influence on blood pressure or arterial stiffness in healthy individuals, but does exert distinct metabolic changes. Specifically, MC concentrate appears to influence amino acid metabolism which warrants further investigations.

Traditional Intervention Versus Nutritional Coaching: Which Approach Was More Efficient In Health Promotion?Ana Paula Troccoli Noronha, Luciana Oquendo Pereira-Lancha, Danielle Kallas, Paula Helena Dayan-Kanas, Antônio Herbert Lancha Jr.. *Universidade de São Paulo, São Paulo, Brazil.**(No relevant relationships reported)***Traditional Intervention Versus Nutritional Coaching: Which Approach Was More Efficient In Health Promotion?**

Ana Paula Troccoli Noronha; Luciana Oquendo Pereira Lancha; Danielle Kallas; Paula Helena Dayan-Kanas; Antônio Herbert Lancha Jr. School of Physical Education and Sports of the University of Sao Paulo, São Paulo, Brazil; Institute of Wellness and Health, São Paulo, Brazil

The worldwide prevalence of overweight and obesity has shown a rapid and progressive increase in the last decades, being characterized as a true world epidemic. In attempt to reduce it, a lot of new diets has been proposed in recent years as strategies for weight loss. However, studies report that 95% of overweight people fail in the maintenance of weight loss diets and then regain part of this weight later. In this context, new approaches such as nutritional coaching, oriented towards behavior change, assume an increasingly important role, specifically in its application to the nutrition sciences. **PURPOSE:** This study aimed to analyze the effectiveness of the use of coaching techniques in health parameters such as body weight, fat mass and waist circumference in physically active women, overweight, pre menopausal, compared to the traditional model of diet prescription. **METHODS:** 10 participants were assigned to the Nutritional Coaching group (NC; n=5), which received weekly care, or Traditional Group (TG; n=5), which received monthly care, for a 3 months intervention study. The physical activity protocol was composed by 40 minutes of resistance training and 20 minutes of treadmill. An individual diet plan was established to create an energy deficit of 750 kcal per day. **RESULTS:** The average of weight loss in NC group was 4.02 kg, in comparison to TG group (1.46 kg). The average of fat mass loss in the NC group was 4.02 kg in comparison to TG group (2.38 kg). Finally, the average of the reduction in waist circumference in the NC group was 4.5 cm in comparison to the TG group (2.0 cm). **CONCLUSION:** Nutritional Coaching was effective in promoting weight loss, improving body composition and reducing waist circumference. Nutritional coaching has effective tools that can be used by health professionals to help in promoting behavior change and, consequently, weight loss.

Dietary Intake Is Associated With Ankle-brachial Index, Inflammation, And Ambulation In Peripheral Artery Disease PatientsPolly Montgomery¹, Ming Wang¹, Biyi Shen¹, Ana Casanegra², Federico Silva- Palacios³, Allen Knehans³, Andrew Gardner¹.¹Penn State COM, Hummelstown, PA. ²Mayo Clinic, Rochester, MN. ³OUHSC, Oklahoma City, OK.*(No relevant relationships reported)*

The aims of this study were (a) to determine whether the daily dietary intake of nutrients by patients (pts.) with peripheral artery disease (PAD) met recommended levels for adults 50 years or older, and (b) to determine whether meeting recommended levels of nutrients was associated with ankle-brachial index (ABI), inflammation, and ambulation of PAD pts. **Methods:** 48 pts. were assessed on their dietary intake of 20 nutrients during a three-day period. Pts. were also characterized on demographic variables, comorbid conditions, cardiovascular risk factors, ABI, 6-minute walk distance, and high-sensitivity C-reactive protein (hsCRP). **Results:** Few pts. met the daily recommended intakes for calcium (4%), fiber (6%), vitamin E (6%), trans fatty acids (13%), vitamin A (15%), total sugars (19%), potassium (23%), sodium (29%), saturated fat (29%), and vitamin C (31%), and none of the pts. met the daily recommended intake of vitamin D (0%). Overall, pts. met few of the 20 dietary recommendations. Only 17 of 48 pts. met more than 7 of the recommendations. The ABI regression model adjusted for age, sex, race, smoking, hypertension, dyslipidemia, body mass index, and percentage body fat, total sugars was the only significant predictor ($p < 0.001$) as pts. who did not meet the recommendation had lower ABI values. The hsCRP adjusted regression model, omega-3 polyunsaturated fatty acids ($p = 0.001$) was the strongest significant predictor, indicating that those who did not meet the recommendation had higher hsCRP values. Finally, the 6-minute walk distance adjusted regression model, folate ($p = 0.011$), and dietary score index ($p = 0.014$) were significant predictors, as those who did not meet the recommendation for folate and those who met five or fewer of the 20 recommendations had shorter 6-minute walk distances. **Conclusions:** PAD pts. consume a low nutrient dense diet that is deficient in many vitamins, calcium, fruits, and vegetables, and contains too much added sugar, saturated and trans fats, and processed foods. Additionally, more severe PAD, greater inflammation, and ambulatory dysfunction are independently associated with aspects

of a low nutrient dense diet, such as too much intake of added sugars, low intake of omega-3 polyunsaturated fatty acids and folate, and only meeting the recommended intakes of five or fewer nutrients.

3901 Board #218 May 30 9:00 AM - 10:30 AM

The Superoxide Scavenger And Antioxidant, L-Propionyl-carnitine, Is Metabolically Enhanced Following Exercise In HypoxiaGareth W. Davison¹, Maria Vinaxia², Rose McGovern¹, Anna Novials³, Xavier Correig², Conor McClean¹. ¹Ulster University, Belfast, United Kingdom. ²Rovira i Virgili University, Tarragona, Spain. ³Hospital Clinic de Barcelona, Barcelona, Spain.

Email: gw.davison@ulster.ac.uk

(No relevant relationships reported)

L-Propionyl-carnitine, a propionyl ester of L-carnitine, is known to scavenge the superoxide anion, inhibit lipid peroxidation, and protect against H₂O₂-induced DNA strand scission. While exogenous L-propionyl-carnitine supplementation modulates lipid peroxidation in humans, the endogenous metabolic response following exercise is currently unknown. **PURPOSE:** To investigate the metabolic profile of L-propionyl-carnitine following exercise in hypoxia. **METHODS:** Twenty-four ($n=24$) apparently healthy male participants were recruited (age 28 ± 5 years; mass 74 ± 8 kg; stature 177 ± 6 cm; $_{2max}$ hypoxia 45 ± 2 ml·kg⁻¹·min⁻¹; normoxia 60 ± 9 ml·kg⁻¹·min⁻¹), and completed 1 hr of exercise at a workload corresponding to 75% of pre-determined $_{2max}$ in hypoxia ($F_{iO_2} = 0.16\%$), and repeated in normoxia ($F_{iO_2} = 0.21\%$). Serum L-propionyl-carnitine was quantified using a LC ESI-qTOF-MS untargeted metabolomics approach at pre-, post-exercise and 3 h post-exercise (Recovery). **RESULTS:** Exercise performed in hypoxia and normoxia independently increased L-propionyl-carnitine metabolism ($p < 0.05$, pre vs. post-exercise), and hypoxia *per se* did not induce a selective metabolic change when compared to normoxia ($p > 0.05$). Recovery from exercise was similar for both hypoxia and normoxia ($p < 0.05$, post vs. 3 hrs post-exercise). There was a main effect for time observed for pooled hypoxia and normoxia values (pre vs. post-exercise vs. 3 hrs post-exercise, $p < 0.05$). **CONCLUSION:** This is the first data to show a metabolic response in L-propionyl-carnitine following exercise. As such, we propose the increased mobilisation of L-propionyl-carnitine may be beneficial to counteract deleterious free radical production and protect against vascular exercise-induced oxidative stress.

Diets High In Fish And Sugar-sweetened Beverages Affect Energy Expenditure And Energy Balance.Cassie M. Mitchell, Paolo Piaggi, Jonathan Krakoff, Susanne B. Votruba. *National Institutes of Health, Phoenix, AZ.*

Email: cassie.mitchell@nih.gov

(No relevant relationships reported)

BACKGROUND: Recent evidence indicates that dietary patterns, independent of macronutrient and total calorie consumption, alter body weight. This implies an effect of dietary pattern on 24-hour energy expenditure (24hrEE) and energy balance (EnBal). **PURPOSE:** To evaluate whether a 12-week weight maintaining, macronutrient stable dietary intervention that varies only by meat, fish or sugar sweetened beverages (SSBs) consumption alters 24hrEE and EnBal. **METHODS:** 32 healthy males were recruited to participate in a 12-week in-patient study and were randomized to a weight-maintaining dietary intervention that contained a varying combination of meat, fish or SSBs in a factorial design. Macronutrient composition across all dietary intervention groups was: 50% carbohydrate; 30% fat; and 20% protein. Twenty-four hour EE and EnBal were measured in a human metabolic chamber (e.g. room calorimeter). All measurements were performed at baseline and week 12. Descriptive statistics and analyses of co-variance were performed to characterize participants at baseline and quantify the changes in 24hrEE and EnBal over time. **RESULTS:** 28 males (age: 46.6 ± 10.4 years; body mass index 26.9 ± 4.1 kg/m²; predicted energy needs: 2311 ± 241 kilocalories/day [kcal/d]) completed all measurements. Fish consumption resulted in higher 24h EE by 127.4 ± 51.4 kcal/d compared to no fish consumption ($p = 0.0217$). SSB consumption had a 24hEE that was 136.3 ± 52.4 kcal lower ($p = 0.0166$). Approximately 85% of the decrease in 24hEE with SSB consumption was due to lower awake, inactive EE ($p = 0.0003$) and had greater 24hr EnBal when compared to groups without SSBs ($p = 0.0489$). **CONCLUSION:** Our data indicate that protein and carbohydrate quality (as reflected by fish versus SSB consumption), rather than % daily intake, influence 24hr EE and inactive EE, and thus EnBal. If so, this would imply a metabolic effect of SSB consumption independent of total calories or macronutrient composition that might contribute to overall increasing adiposity rates. Supported by intramural funding from NIDDK.

Energy Balance During The Postpartum Period Is Associated With Metabolic Adaptation

Iqrah I. Choudhry, Jaime R. Deluca, Nicolas D. Knuth. *Towson University, Baltimore, MD.*
 Email: iqrah20@gmail.com
 (No relevant relationships reported)

Previous studies have demonstrated that perturbations in body weight result in modified resting metabolic rate (i.e. metabolic adaption) that attempts to return the body to its customary weight (i.e. the set-point theory). How body weight changes during pregnancy impacts resting metabolic rate (RMR) and subsequently affects the ability to return to pre-pregnancy weight postpartum has not been investigated. **PURPOSE:** To examine if metabolic adaptation occurs during the postpartum period. **METHODS:** RMR and body composition were measured after an overnight fast in 26 women (mean age 34, range 26-40; mean BMI 28.1 ± 6.0 kg/m²) at 3, 6, 9 and 12 months postpartum. Energy balance over the postpartum period was calculated as the sum of the change in both fat mass (FM) and fat-free mass (FFM) multiplied by their respective energy densities. The ratio of RMR to FFM was used to assess the degree of metabolic adaptation. The degree of linearity between weight change and energy balance with metabolic adaptation was assessed using Pearson correlation. **RESULTS:** Weight loss (mean weight loss: -3.4 ± 3.6 kg) was positively associated ($\rho = 0.4$, $p = 0.03$) with metabolic adaptation (mean RMR/FFM: 31.8 ± 2.8 kcal/d/kg). Total energy balance (mean energy balance: -28719 ± 29546 kcal) was positively associated ($\rho = 0.5$, $p = 0.01$) with metabolic adaptation, indicating that a greater negative energy balance is associated with a lower resting metabolic rate relative to metabolically active fat-free mass (i.e. a greater metabolic efficiency). This relationship was independent of whether or not women had returned to their pre-pregnancy (i.e. set-point) body weight. **CONCLUSION:** The acute perturbation in body weight away from the set-point as a result of pregnancy contributes to the presence of metabolic adaptation during the postpartum period. The increase in metabolic efficiency in relation to greater weight loss during this time may contribute to difficulty in continuing to lose weight, or maintaining lost weight, after childbirth.

3904 Board #221 May 30 9:00 AM - 10:30 AM

Cardiovascular And Metabolic Responses Of US Army Soldiers During Heavy Military Rucksack Carriage

David P. Looney, Elizabeth M. Doughty, Andrew S. Marrero, Peter S. Figueiredo, Alexander P. Welles, William R. Santee, Holly L. McClung, Diana P. Sanford, Adam W. Potter. *USARIEM, Natick, MA.*
 (No relevant relationships reported)

Military leaders require accurate information on the physiological stress induced by modern equipment loads in order to optimize planning for dismounted operations. **PURPOSE:** Evaluate the effects of heavy rucksack loadings on physiological responses of Soldiers during incremental treadmill walking. **METHODS:** Six male US Army Soldiers (age, 20 ± 1 years; height, 176 ± 6 cm; body mass (BM), 74 ± 5 kg) performed incremental treadmill walking while unloaded and carrying three proportional rucksack loads (22, 44, and 66% of BM). Treadmill speed was initially set at 4.2 km/h for 3 min then increased by 0.3 km/h every 2 min. Tests were terminated if volunteers completed the highest treadmill speed (7.1 km/h), reached volitional fatigue, or if their respiratory exchange ratio (RER) exceeded 1. Volunteers wore a chest-strap heart rate monitor and breathed into a metabolic cart that measured oxygen consumption. **RESULTS:** Volunteers completed all walking speeds while unloaded (7.1 km/h). While speed did not decrease significantly when carrying 22% BM (6.9 ± 0.3 km/h; $p = 0.09$); volunteers finished at significantly slower speeds when carrying 44% BM (6.2 ± 0.5 km/h; $p = 0.01$) and 66% BM (5.5 ± 0.6 km/h; $p < 0.01$). Peak heart rate during the unloaded walk ($133 \pm$ bpm) was significantly lower than load carriage with 22% BM (157 ± 12 bpm; $p < 0.01$), 44% BM (162 ± 14 bpm; $p < 0.01$), and 66% BM (161 ± 16 bpm; $p < 0.01$). Peak oxygen consumption for the unloaded walk (1.85 ± 0.23 L/min) was significantly lower than when carrying 22% BM (2.25 ± 0.36 L/min; $p = 0.02$) but not 44% BM (2.27 ± 0.55 L/min; $p = 0.09$) or 66% BM (2.40 ± 0.65 L/min; $p = 0.06$). **CONCLUSION:** Heavy military rucksack loads severely impair marching pace and induce considerable cardiovascular and metabolic stress. Our results provide preliminary evidence that heart rate may be a superior work intensity indicator than oxygen consumption for Warfighter tasks. The views expressed in this abstract are those of the authors and do not reflect the official policy of the Department of Army, Department of Defense, or the U.S. Government.

Measured And Estimated Energy Cost Of Sedentary And Active Activities

Luiz A. Anjos¹, Virginia G. Mariz¹, Amina C. Costa¹, Fernanda C. Fernandes¹, Vivian Wahrlich². ¹UFF, NITEROI, Brazil. ²UFF, Niteroi, Brazil.
 Email: lanj@ig.com.br
 (No relevant relationships reported)

Physical inactivity represents a public health problem in an endemic obesity scenario worldwide. Therefore, it is relevant to estimate the energy cost of daily activities for nutritional and physical activity assessment and guidance. **PURPOSE:** To measure the energy expenditure (EE) of sedentary (typing) and daily activities (organizing bookshelves, climbing up and down stairs and walking for pleasure and exercise) and to compare the results with the ones estimated from the Compendium of Physical Activities (CAF) and FAO/WHO tables. **METHODS:** Data are from 80 adult subjects (age ≥ 20 years) from a larger study measuring total daily EE by various methods (accelerometry and double-labeled water) participated in the study. EE was measured with a portable calorimeter during resting (MET), typing, standing, arranging books on a shelf, going up and down stairs (8 floors) and walking on the treadmill at three speeds (for pleasure, pleasure - 0.8 km/h, and exercise) on different visits to the laboratory. Basal metabolic rate (BMR) was also measured early in the morning with the subjects in the fasting state after 8hr sleep. BMR and MET values were used to estimate EE by CAF and FAO/WHO tables. Anthropometric and % body fat (%BF, DXA) assessment was also obtained. **RESULTS:** The mean (SD) age was 29.9 (10.4) years with a mean BMI of 23.8 (3.8) kg/m² and %BF of 30.0 (8.8). The EE (kcal/min) of typing was 1.41 (0.48) and it was the only nonsignificantly different value in comparison to either method of estimation. The EE of going up stairs was underestimated by 3.01 (1.69) kcal/min by both methods. **CONCLUSIONS:** Based on the measured values, it can be concluded that the values described in the CAF or FAO/WHO overestimate the EE, except for the sedentary activity of typing, even when BMR or MET are measured. Health professionals should be aware of the inaccuracy of their activity EE of daily activities. **FUNDING:** CNPq (310461-2016-20 and FAPERJ (E-26/202.514/2018; E-26/203.068/2017)

Assessment Of Metabolic Responses To Exercise In Elite Professional Cyclists Using High-throughput Metabolomics

Inigo San-Millan, Davide Stefanoni, Janel L. Martinez, Angelo D'Alessandro, Travis Nemkov. *University of Colorado School of Medicine, Aurora, CO.*
 Email: inigo.sanmillan@cuanschutz.edu
 (No relevant relationships reported)

The field of sports medicine and performance has benefited from the implementation of innovative strategies to study physiological responses to exercise in elite athletic populations. Over the last decade, the field of metabolomics has emerged as a powerful tool to precisely measure multiple metabolic pathways at the cellular level, fostering great strides in many fields. Therefore, the possibilities of deploying metabolomics to the field of sports medicine and performance offers tremendous opportunities to improve understanding of metabolic responses to exercise. **PURPOSE:** To evaluate the metabolic responses to exercise in elite professional cyclists using high-throughput mass spectrometry-based metabolomics. **METHODS:** 24 international-level World Tour professional cyclists (PS) performed a graded exercise test to exhaustion on a cycling ergometer. Both prior to and after exercise, 100 μ l of whole blood were collected for metabolomics analysis using high-throughput mass spectrometry-based methodologies developed by our group. Since blood lactate ([La⁻]) concentration is an accurate surrogate for metabolic efficiency (*San-Millan and Brooks, 2018*), cyclists were divided into two groups for multivariate analyses based on a whole blood [La⁻] above or below 5 mmol·L⁻¹ at an exercise intensity of 5 W·kg⁻¹. Group A consisted of 12 cyclists that were all able to pedal beyond this exercise intensity, whereas Group B (n=10) contained only one. **RESULTS:** We observed significant changes between baseline and maximal exercise in glycolytic intermediates, TCA cycle metabolites and amino acids ($p < 0.05$). Group A cyclists showed higher baseline levels of ketogenic amino acid in particular. In addition, this group possessed higher levels of succinate at rest ($p = 0.08$) and lower levels after exercise ($p = 0.06$) showing improved metabolic efficiency. Oxidized glutathione (GSSG) is higher both pre and post-exercise ($p < 0.0001$ and $p < 0.01$, respectively), suggesting increased basal activation of oxidative stress management pathways. **CONCLUSIONS:** High-throughput metabolomics offers an efficient methodology to assess metabolic changes during exercise, as well as the opportunity to identify metabolic parameters that can distinguish cyclists of different performance levels.

Energy Expenditure And Body Composition In Mexican Female Recreational Dancers Of Latin, Zumba, And Twerk

Pedro J. Flores-Moreno¹, Lenin T. Barajas-Pineda¹, Andreas Stamatis², Leticia M. Cornejo-Larios¹, Ricardo Rodríguez-Murguía¹. ¹University of Colima, Colima, Mexico. ²State University of New York, Plattsburgh, NY.
 Email: pedrojulian_flores@uocol.mx
 (No relevant relationships reported)

Caloric surplus has been associated with issues in body composition and weight management. In Mexico, 36% of women over 18 years of age reported performing some type of physical activity (PA). This troubling data are related to the overweight/obesity prevalence among female Mexican adults. Dance like, Latin, Zumba, and Twerk appears as an attractive form of PA for women. However, the effect they may have on energy expenditure and body composition remains unknown.

Purpose

To investigate energy expenditure and body composition in Mexican female recreational dancers of Latin, Zumba, and Twerk.

Method

77 women agreed to participate: Latin, 36, age 32.64 ± 13.16, BMI 24.41 ± 6.53, Zumba, 18, age 42.78 ± 16.55, BMI 26.63 ± 4.92, and Twerk, 23, age, 24.39 ± 5.38, BMI, 22.57 ± 1.45. Inclusion criteria included participation for more than 4 weeks and at least four times per week. Body fat percentage and fat-free mass were calculated bio impedance (BIA). Total Kcal spent during the session were measured with a pedometer. The BMI was calculated using weight and height. The analysis consisted of ANOVA.

Results Based on BMI standards, all (but the Zumba participants) were classified as normal. Body fat percentage: Latin 22.62 ± 7.65, Zumba 27.68 ± 7.86 and Twerk 23.59 ± 4.53 ($p = 0.043$). Fat-free mass: Latin 23.62 ± 7.65, Zumba 23.23 ± 3.92, and Twerk 28.63 ± 9.58 ($p = 0.031$). Total Kcal spent: Latin 62.84 ± 15.47, Zumba 67.22 ± 16.91, and Twerk 32.18 ± 7.90 ($p = 0.000$).

Conclusion

The overweight/obesity prevalence in Mexican women and its health implications have precipitated an increased awareness in the value of exercise prescription and adherence. These preliminary results show that Zumba generates greater energy expenditure. They also reveal that Zumba is more popular among older participants with higher BMI and fat percentage. Future studies should be longitudinal, investigate the effects of intensity of exercise and dietary habits on weight loss, and include participants of other weight classifications and dance fitness classes. Possible limitations include small sample size and unequal sample sizes.

Fuel Use In Boys And Girls During Prolonged Submaximal Exercise

Dillon J. Kuszmaul, Brandon J. Dykstra, Anthony D. Mahon.
 Ball State University, Muncie, IN.
 (No relevant relationships reported)

Some research has suggested that women may depend more on fat for energy during prolonged exercise compared to men. However, the extent to which this fuel use pattern exists in children is not as well understood. Specifically, the effect of sex on fuel use patterns in children during prolonged exercise is not well-understood. **PURPOSE:** This study examined fat and carbohydrate (CHO) metabolism during the latter half of a 40-minute bout of exercise in boys ($n=9$; 10.8±1.0 years, 148.5±6.7 cm, 46.6±17.2 kg) and girls ($n=10$; 10.6±1.2 years, 140.4±8.3 cm, 37.5±8.6 kg). It was hypothesized that there would be no difference between boys and girls with respect to fuel metabolism during exercise. **METHODS:** Participants reported to the laboratory for two separate visits. On the initial visit, body composition using dual x-ray absorptiometry and $\dot{V}O_{2max}$ were assessed. On the experimental visit, participants completed two 20-minute exercise bouts separated by a 10-minute rest. Bout 1 consisted of 10 minutes at 50% $\dot{V}O_{2max}$ and 10 minutes at 75% $\dot{V}O_{2max}$. Bout 2 consisted of 20 minutes at 50% $\dot{V}O_{2max}$. Fat oxidation rate (FOR) relative to fat-free mass [mg·kgFFM⁻¹·min⁻¹] and carbohydrate oxidation rate (COR) relative to fat-free mass [mg·kgFFM⁻¹·min⁻¹] were measured at 5, 10, 15, and 20 minutes of Bout 2 and averaged. **RESULTS:** There was no difference in $\dot{V}O_{2max}$ between the boys (38.9±8.7 ml·kg⁻¹·min⁻¹) and the girls (37.1±5.6 ml·kg⁻¹·min⁻¹) nor were there any differences in the relative intensity (% $\dot{V}O_{2max}$) during exercise. FOR relative to FFM was 5.3±0.9 mg·kgFFM⁻¹·min⁻¹ in boys and 5.5±1.2 mg·kgFFM⁻¹·min⁻¹ in girls ($p>0.05$). Proportional fat use was 35.9±7.7% in boys and 37.9±8.4% in girls ($p>0.05$). COR relative to FFM was 24.1±4.9 mg·kgFFM⁻¹·min⁻¹ in boys and 23.0±4.2 mg·kgFFM⁻¹·min⁻¹ in girls ($p>0.05$). Proportional CHO use was 64.1±7.7% in boys and 62.1±8.4% in girls ($p>0.05$). **CONCLUSION:** In this age range, boys and girls do not display differences in fat and CHO metabolism relative to FFM during the latter half of a prolonged bout of exercise. Future research should investigate the influence of physical maturity on potential sex differences in metabolism.

This study was supported by the Ball State University ASPIRE Graduate Student grant program.

Serum MOTs-c Concentrations Are Higher In Older Females Compared To Older Males But Is Not Affected By Physical Activity Status Or Cardiorespiratory Fitness In Young And Older Adults

Andrew Wells¹, Kurt Escobar², Anna Welch¹, Terence Moriarty³, Kelly Johnson⁴, Nathan Cole¹, Fabiano Amorim¹, Christine Mermier¹. ¹University of New Mexico, Albuquerque, NM. ²California State University, Long Beach, Long Beach, CA. ³University of Northern Iowa, Cedar Falls, IA. ⁴Coastal Carolina University, Conway, SC.
 (No relevant relationships reported)

Recently, MOTs-c, a mitochondrial-derived peptide with effects on metabolic health, was identified. However, few data exist in humans including factors that affect circulating concentrations. **PURPOSE:** The aim of this study was to discern if serum MOTs-c concentrations were different between physically active and inactive young and older adults, or affected by cardiorespiratory fitness, body composition, hemoglobin A1c (HbA1c), and sex. **METHODS:** Forty-one healthy Young (18 – 30 yrs; $n=26$) and Older (55 – 70 yrs; $n=15$) adults participated in the study. Young and Older groups were further divided into Active and Inactive groups. Serum MOTs-c concentrations, maximum oxygen consumption ($\dot{V}O_{2max}$), body composition, and HbA1c were measured. Independent student's t-tests were performed to determine group mean differences in serum MOTs-c concentrations between: Young and Older groups, Active and Inactive Young, Active and Inactive Older, males and females, Young males and females, and Older males and females. An α -level of ≤ 0.05 was set a priori. Pearson's correlations were performed between MOTs-c concentrations and the following: $\dot{V}O_{2max}$, HbA1c, percent body fat, fat mass, and lean mass. **RESULTS:** There were no differences in serum MOTs-c concentrations between Young and Older subjects, between Active Young and Inactive Young or Active Older and Inactive Older subjects. Serum MOTs-c was also not correlated with $\dot{V}O_{2max}$, percent body fat, lean body mass, fat mass or HbA1c, which were in normal ranges. When sexes were analyzed separately, MOTs-c levels in Older females were significantly higher than Older males (419.9±43.3 vs 354.0±63.7 ng/mL, respectively; $p=0.03$). These findings suggest that circulating MOTs-c concentrations are not affected by physical activity status, cardiorespiratory fitness, body composition, or normal HbA1c in healthy young and older adults, however, vary between sexes in older adults.

A Dietary Assessment Of Mid-Spectrum Chronic Kidney Disease

Kathleen E. Adair¹, Jeffrey S. Fosse¹, Matthew N. Peterson¹, Jeffery L. Heileson¹, Peter W. Grandjean, FACSM². ¹Baylor University, Waco, TX. ²University of Mississippi, Oxford, MS.
 (Sponsor: Peter W. Grandjean, FACSM)
 Email: katie_adair1@baylor.edu
 (No relevant relationships reported)

BACKGROUND: Diets of adult individuals with mid-spectrum Chronic Kidney Disease (CKD) remain understudied. The 2015-2020 Dietary Guidelines for Americans food patterns based on the Recommended Dietary Allowances (RDA) in concert with the National Kidney Foundation Kidney Disease Outcomes Quality Initiative (NKF KDOQI) guidelines are advised to individuals with CKD. Estimated glomerular filtration rate (eGFR) remains the best method for tracking CKD progression, yet relationships between self-reported dietary intake and eGFR are understudied. **PURPOSE:** To assess the self-reported dietary pattern in patients with stage 3 or 4 CKD in contrast to the RDA and NKF KDOQI dietary guidelines and to identify predictors of eGFR. **METHODS:** Twenty participants with stage 3 or 4 CKD [$n = 6$ male (M); $n = 14$ female (F)]; age 62.0 ± 9.9 years; weight 80.9 ± 16.2 kg; body fat 37.3 ± 8.5% of weight; eGFR 51.5 ± 6.82 mL/min/1.73m²) completed self-reported dietary assessments for an average of 5 days. Diet was assessed using the ESHA Food Processor Software, Version 11.1. Micro- and macronutrient analyses for males and females were compared to the RDA and NKF KDOQI guidelines to identify malnutrition, and stepwise multiple linear regression models were used to identify predictors of eGFR, p -values were considered significant at the $\alpha = 0.05$ level. **RESULTS:** On average, all subjects met the RDA and NKF KDOQI guidelines for caloric intake. Average consumption of saturated fat (F = 24.3 ± 10.8g, M = 34.1 ± 6.0g), sodium (F = 3780 ± 2510mg, M = 4210 ± 386mg) and protein (F = 65.0 ± 23.5g, M = 107.3 ± 27.3g) was high while the average consumption of fiber (F = 13.6 ± 4.1g, M = 14.8 ± 7.3g), calcium (F = 573 ± 325mg, M = 720 ± 224mg), potassium (F = 240 ± 1800mg, M = 940 ± 492mg) and phosphorous (F = 628 ± 1320mg, M = 425 ± 314mg) was low. Significant predictors of eGFR were age ($\beta = -0.29$, $p = 0.023$), calcium ($\beta = 0.02$, $p < 0.001$), body fat percentage (BF%) ($\beta = -1.47$, $p = 0.001$),

protein intake ($\beta = -1.20, p < 0.001$), weight ($\beta = 0.42, p = 0.033$), and daily caloric intake ($\beta = -0.36, p = 0.045$). **CONCLUSION:** When compared to the RDA and NKf KDOQI guidelines, CKD patients had poor nutritional quality. Increased protein intake and BF% were the strongest predictors of reduced eGFR. Future interventions in CKD patients should improve diet quality to concomitantly improve body composition and eGFR.

3911 Board #228 May 30 9:00 AM - 10:30 AM
RELATIONSHIP BETWEEN INSULIN RESISTANCE, BODY COMPOSITION, AND PHYSICAL ACTIVITY IN OLDER ADULTS

Adam D. Mandrell, Callen R. Conroy, Alexandra I. Hopun, Kevin D. Ballard, FACSM, Kyle Timmerman, FACSM. *Miami University, Oxford, OH.* (Sponsor: Kyle L. Timmerman, FACSM)

(No relevant relationships reported)

There are 27 million adults in the U.S. with type II diabetes mellitus, a condition associated with significant morbidity and mortality. Existing therapies can be costly, have side effects and may not achieve adequate disease control. Therefore, it is useful to identify lifestyle factors such as physical activity (PA) that may mitigate insulin resistance. Key clinical indicators of insulin resistance include fasting blood glucose (FBG), hemoglobin A1c (HbA1c) percentage, and the homeostatic model assessment of insulin resistance (HOMA-IR). **PURPOSE:** To evaluate the relationships among insulin resistance indicators, body composition, and objective and subjective measures of habitual physical activity in older adults. **METHODS:** In 82 generally healthy nondiabetic adults (≥ 58 years, 23 m/59 f), body composition (bioelectrical impedance), fasting blood glucose (glucometer), serum insulin (enzyme-linked immunosorbent assay), HbA1c (HbA1c Analyzer), objective PA (7-day accelerometry), and subjective PA (Community Healthy Activities Model for Seniors (CHAMPS)) were measured. Controlling for age and body fat percentage, partial correlations between insulin resistance indicators and biometrics were determined (Significance was set as $\alpha < 0.05$). **RESULTS:** Mean values were (mean \pm sd): age (68.5 \pm 6.3 y), BMI (26.2 \pm 6.0 kg/m²), visceral fat (119.2 \pm 68.4 cm²), FBG (96.9 \pm 8.3 mg/dL), HOMA-IR (2.6 \pm 0.8), HbA1c (5.3 \pm 0.2%), and accelerometry (cts/min: 114.1 \pm 56.5; sedentary-to-moderate PA ratio: 12.8 \pm 6.1). FBG was significantly correlated with serum insulin ($r = 0.26$), visceral fat area ($r = 0.40$), cts/min ($r = -0.29$), and sedentary-to-moderate ratio ($r = 0.24$). HOMA-IR was significantly correlated with visceral fat ($r = 0.41$). No significant correlation was found between HbA1c and any measured variable. **CONCLUSIONS:** These preliminary data support previous findings that serum markers of insulin resistance are associated with physical activity and body composition. These findings suggest a potential role for using body composition and physical activity as clinical end points when managing patients with insulin resistance. Randomized controlled studies are needed to more rigorously assess the impact of physical activity on clinical indicators of diabetes mellitus in older adults.

The Influence Of Heat On Appetite Regulating Hormones

Mark L. McGlynn¹, Robert J. Schute², Dustin R. Slivka, FACSM¹. ¹University of Nebraska at Omaha, Omaha, NE. ²University of Virginia, Charlottesville, VA. (Sponsor: Dustin Slivka, FACSM)

(No relevant relationships reported)

Leptin has been established as an energy-controlling hormone because of its role in activating the JAK-STAT3 pathway. Temperature has its own prominent role governing appetite regulation and thus, energy expenditure. Previous research has demonstrated consistent decreases in leptin while in a fasted state. Exercising in the heat (1-hour of cycling @60% VO_{2max} in 33°C) has also shown reductions in leptin. However, in order to elucidate the influence of environment, independent of exercise, a fasted resting investigation is needed.

PURPOSE: Determine the impact of environmental temperature (33 vs. 20°C) on adipose derived appetite-regulating hormones (leptin and adiponectin) and the impact on energy expenditure.

METHODS: 10 college-aged males (27.3 \pm 5 y, 86.7 \pm 13 kg, and 1.83 \pm 4.3 m; 25.8 \pm 0.9 kg/m²) completed two randomized, resting experimental trials in the Heat (HT, 33°C) and at Room Temperature (RT, 20°C) at 60% humidity. Blood draws were taken before intervention and after 3 hours for analysis of leptin and adiponectin. Oxygen consumption was measured at 1-, 2-, and 3-hr time-points.

RESULTS: HT trial temperatures were greater than RT for both core (mean \pm SEM; 37.17 \pm 0.08 vs. 36.89 \pm 0.08°C, $p = 0.002$) and skin (37.59 \pm 0.10 vs. 32.65 \pm 0.48°C; $p < 0.001$). Oxygen consumption in HT was greater than RT during the 2nd (4.37 \pm 0.14 vs. 4.13 \pm 0.15 ml/kg/min, $p = 0.037$) and 3rd hours (4.95 \pm 0.26 vs. 4.28 \pm 0.19 ml/kg/min, $p = 0.002$). Fasting leptin concentrations in RT decreased to a greater extent than

in HT (mean $\Delta \pm$ 95% CI; -2.05 \pm 1.72 vs. -0.89 \pm 1.67 ng/ml; $p = 0.036$, respectively); however, after adjustment for plasma volume shifts (-7.5%) the interactive effect dissipated (-1.79 \pm 1.72 vs. -0.89 \pm 1.6 ng/ml; $p = 0.068$).

CONCLUSIONS: The reduction of heat stress increased energy expenditure and attenuated the leptin reaction. These data may have implications for appetite control and weight management.

(No relevant relationships reported)

PURPOSE: The research aims to find out the relationships between agriculture and health state in peri-urban Kenya.

METHODS: We randomly selected 70 households who were former of vegetable and crop cultivation and mixed farming (vegetable and crop cultivation and husbandry) (male: 46 \pm 10 yrs, n=35, female: 41 \pm 9yrs, n=37) in Wangige region(peri-urban setting), Republic of Kenya. Participants Data on body characteristics, daily activity by wearable devices, food consumption by the 24-hour recall, and well-being were collected by trained enumerators. **RESULTS:** In the research, there were positive correlation between weight (M = 72.1 kg, SD = 14.8) and intaking of home garden foods in men (M = 37.2 % SD = 16.5), $r = .35, p < .05, n = 35$. And weight (M = 74.2 kg, SD = 14.8) and time of over of activity level 2 (M = 88.1 min, SD = 95.3) in women, $r = .34, p < .05, n = 37$, and And time of over of activity level 2 (M = 88.1 min, SD = 95.3) and number of agricultural fields (M = 1.3, SD = 0.6) in women, $r = .55, p < .001, n = 37$. There was negative correlation between weight (M = 74.2 kg, SD = 14.8) and intaking of home garden foods (M = 37.8 %, SD = 13.3), $r = .27, p < .05, n = 37$, and Body Mass Index(BMI) (M = 28, SD = 5) and intaking of home garden foods (M = 37.8 %, SD = 13.3), $r = .38, p < .05, n = 37$, in woman.

CONCLUSIONS: In the Peri-Urban setting in the Republic of Kenya, the cause of increasing weight and BMI suggested that affect the decreasing intaking of home garden foods and the number of agricultural fields in the female. Much of people works agriculture of main or side job in Kenya. Agricultural activity of role in peri-urban settings might affect daily activities and food consumption for the prevention of non-communicable diseases. Effects Of Acute Exercise On Appetite Regulation And Energy Intake In Men And Women

Selene Y. Tobin¹, Marc-Andre Cornier², Mollie H. White², Alison K. Hild², Jonathan R. Miller², Edward L. Melanson, FACSM², Tanya M. Halliday¹. ¹University of Utah, Salt Lake City, UT. ²University of Colorado - Anschutz Medical Campus, Aurora, CO.

Email: selene.tobin@utah.edu

(No relevant relationships reported)

PURPOSE: Compare energy intake and appetite regulation responses between men and women following acute bouts of aerobic (AEx) and resistance exercise (REX).

METHODS: Men and women (n=12 each) with overweight/obesity matched on age (32.3 \pm 2 vs. 36.8 \pm 2 yrs, $p=0.14$) and BMI (28.1 \pm 1.2 vs 29.0 \pm 1.5 kg/m², $p=0.64$) completed 2 conditions; 1) AEx (65-70% of age-predicted maximum heart rate for 45 min) and 2) REX (1-set to failure on 12 exercises). Each condition was initiated in the post-prandial state (35 minutes post breakfast). Appetite (visual analog scale for hunger, satiety and prospective food consumption [PFC]) and hormones (ghrelin, PYY, and GLP-1) were measured before and every 30 minutes for 3 hours following consumption of a standardized breakfast. Post exercise *ad libitum* energy intake at the lunch meal was also measured.

RESULTS: There was no difference in relative *ad libitum* energy intake between men and women following either AEx (43.4 \pm 5 vs. 45.4 \pm 4% of total energy needs, $p=0.80$) or REX (48.3 \pm 3 vs. 46.6 \pm 3% of total energy needs, $p=0.81$). In the AEx condition there were no differences in area under the curve (AUC) for satiety or PFC between men and women, although men reported higher PFC vs women at the 30 (33.3 \pm 5 vs. 17.5 \pm 4mm, respectively, $p=0.03$) and 90 min (49.8 \pm 6 mm vs 30.2 \pm 6 mm, respectively, $p=0.03$) post-prandial time points. Additionally, in the AEx condition, a greater hunger AUC was detected in men vs women (7815 \pm 638 vs 5428 \pm 762 mm, respectively, $p=0.02$), which was driven by men reporting significantly greater hunger vs women at the 90 min post-prandial time point (42.7 \pm 5 vs. 16.6 \pm 4 mm, $p<0.001$). No differences

in AUC for ghrelin, PYY, and GLP-1 were noted between men and women following either AEx or REx (all $p > 0.05$). However, significantly higher ghrelin was observed in women vs. men at the 150 (807.6 \pm 37 vs. 652.2 \pm 41 pg/mL, respectively, $p = 0.01$) and 180 min (812.4 \pm 39 vs. 677.5 \pm 49 pg/mL, respectively, $p = 0.05$) post-prandial time points. **CONCLUSIONS:** The data suggest that men report greater hunger and PFC than women following acute AEx, and that women have higher ghrelin levels than men following acute REx. Future work is needed to examine if sex-based differences in appetite regulation and energy intake are present with chronic exercise of differing modalities.

3915 Board #232 May 30 9:00 AM - 10:30 AM
Reliability And Validity Of A Mobile Setup For Metabolic Syndrome Diagnosis Using Point-of-care Analyzers
 Sanne Paulien Houtenbos¹, Anne Schraplau¹, Michael A. Rapp¹, Pia-Maria Wippert¹, Heinz Völler¹, Klaus Bonaventura², Frank Mayer¹. ¹Universität Potsdam, Potsdam, Germany. ²Ernst von Bergmann Clinic, Potsdam, Germany.
 (No relevant relationships reported)

The metabolic syndrome (MetS) is a worldwide public health concern and is characterized by having three or more of these risk factors: high blood glucose (Glc), increased waist circumference (WC), high blood pressure (BP), reduced serum high-density lipoprotein (HDL) and increased serum triglycerides (TG). As certain rural regions lack the required infrastructure for optimal medical care, mobile diagnostics using point-of-care analyzers could help by identifying people at risk for MetS.

PURPOSE: Test the reliability and validity of MetS risk factor analysis using point-of-care analyzers in a mobile examination unit.

METHODS: Fifty participants (18 test-retest; 52 \pm 7 y; 170 \pm 10 cm; 80 \pm 19 kg) were enrolled in the study. Agreement of Glc, HDL and TG of three point-of-care analyzers (A, B, C) against a reference lab (REF) were analyzed by Bland-Altman (bias, Limits of Agreement (LoA)) and McNemar's test (MN). Further, MetS diagnosis by the mobile setup was tested for inter-session reliability by Spearman's ρ and test-retest variability (TRV%).

RESULTS: The range of systematic bias was for Glc -21 to -8 mg/dl, for TG -90 to 3 mg/dl and for HDL -8 to 9 mg/dl. Device C was excluded from further analyses due to missing values. Device A was chosen for additional analysis based on smallest bias and LoA (Glc: -8 [LoA -27 to 11] mg/dl; TG: 3 [LoA -40 to 46] mg/dl; HDL: -3 [LoA -16 to 11] mg/dl) and best agreement of MetS diagnosis with REF (MN: A vs. REF: $p > .05$; B vs. REF: $p < .05$). Test-retest analysis for risk factor classification and MetS diagnosis was performed in a mobile examination unit using device A. No inter-session differences for risk factor and MetS diagnosis were shown (MN day 1 vs. 2: $p > .05$). Spearman's ρ and TRV for risk factors were: TG: $r = .734$ ($p < .05$); 3.3%; HDL: $r = .893$ ($p < .05$); 6.8%; Glc, $r = .076$; 1.9%; systolic BP: $r = .372$; 1.7%; diastolic BP: $r = .457$; 3.3% and WC: $r = .950$ ($p < .05$); 1.1%.

CONCLUSIONS: The mobile setup showed no inter-session difference in MetS diagnosis. TRV was low for all risk factors and test-retest reliability was acceptable for TG, good for HDL and excellent for WC. Inter-session variations in Glc and BP did not influence the overall risk factor classification and MetS diagnosis. A mobile setup using a point-of-care analyzer for blood analysis is a valid and reliable method for a near-to-home MetS screening.

Nutritional Group Counseling Or Individualized Prescription? Anthropometric, Metabolic, Nutritional And Mental Health Responses: A Longitudinal Study
 Braulio H.M. Branco¹, Marciele A. Bolognese¹, Carina B. Franco¹, Ariana Ferrarini¹, Nelson Nardo-Júnior², Sônia M.M.G. Bertolini¹. ¹University Center of Maringa (UNICESUMAR), Maringa, Brazil. ²State University of Maringa, Maringa, Brazil.
 Email: brauliomagnani@live.com
 (No relevant relationships reported)

PURPOSE: The aim of the present study was to investigate the effects of nutritional counseling in a group (NCG) or an individualized nutritional prescription (INP) on physical health (inferred from anthropometric, body composition and metabolic responses), nutritional and mental health of overweight or obese women. **METHODS:** Seventy-four women aged 40-59 years underwent pre-intervention evaluations. The women were randomized into NCG and INP. Twenty-seven women completed the 12-week interventions, 11 being in the NCG and 16 in the INP. The groups were submitted to the same concurrent exercise protocol. They were measured before and after for body weight (BW), body mass index (BMI), fat mass (FM), body fat percentage (BF), lean mass (LM), lipid profile, hemoglobin A1c (A1C), insulin and liver transaminases (AST and ALT). The dietary record was applied, and the following were calculated:

total caloric intake (TCI), carbohydrates (CHO), proteins (PTN), lipids (LIP), and saturated and polyunsaturated fats. For mental health, it was measured dissatisfaction with body image, anxiety levels, self-esteem and the presence of pathological eating attitudes.

RESULTS: After the intervention, reductions in BW, BMI, FM, BF, TCI, CHO, PTN, LIP, body dissatisfaction, anxiety, and saturated and polyunsaturated fats ($p < 0.05$) were identified. No differences were identified for LM, metabolic variables, self-esteem and pathological eating attitudes ($p > 0.05$).

CONCLUSIONS: Both nutritional interventions combined with concurrent exercise were effective in promoting improvements in anthropometrics, body composition, food intake and some mental health parameters. Therefore, the choice of the method of nutritional intervention should be based on the preference of the participants.

Effects Of Nutritive And Nonnutritive Sweeteners And Exercise On Blood, Lipid, And Glucose Profiles
 Jarrett Walbolt, Yunsuk Koh. Baylor University, Waco, TX.
 (No relevant relationships reported)

Nonnutritive sweeteners are widely used as low-calorie replacements for nutritive sweeteners. Despite widespread use, it is unclear how nonnutritive sweeteners, when combined with exercise, influence plasma lipids and glucose. **PURPOSE:** To investigate the effects of nutritive and nonnutritive sweeteners on plasma lipid profiles, complete blood counts, and glucose content following exercise.

METHODS: Ten healthy, college aged, individuals (4 females and 6 males) participated in the randomized, double-blinded, cross-over design study. Participants consumed 8 oz of sweetened drink, equivalent to three sodas worth of sweetener, containing either 445mg of stevia, 507mg of aspartame, 169mg of sucralose, or 110,000mg of sucrose in four separate occasions. After 30 minutes of each sweetened drink, participants completed a single bout of aerobic exercise on a cycle ergometer at 70% of HRmax for 45 minutes. Overnight fasting blood samples were collected at baseline, 30-min post-consumption of sweetened drink, and immediately post-exercise.

RESULTS: Sucrose resulted in significantly higher glucose content (115.8 \pm 6.14 mg/dL) than either sucralose (87.2 \pm 7.09 mg/dL, $p = .032$) or stevia (86.1 \pm 5.79 mg/dL, $p = .010$) at the 30-min post-consumption of the sweetened drink; however, this difference was no longer significant immediately post-exercise. Total cholesterol (TC), triglyceride (TG), and HDL-C were elevated following exercise (TC: 152.7 \pm 9.66 to 158.6 \pm 9.26 mg/dL, $p < .001$; TG: 69.5 \pm 5.78 to 76.8 \pm 5.83 mg/dL, $p = .002$; and HDL-C: 51.5 \pm 2.47 to 53.9 \pm 2.40 mg/dL, $p < .001$, respectively). Neutrophils increased (53.7 \pm 2.67 to 59.1 \pm 1.93%, $p = .012$) and lymphocytes decreased (36.8 \pm 2.56 to 31.3 \pm 1.56%, $p = .016$) from baseline to thirty minutes post-consumption.

CONCLUSIONS: The nonnutritive sweeteners did not change glucose content from baseline through exercise. However, a nutritive sweetener resulted in a spike in glucose 30-min post-consumption, which returned to baseline levels immediately after exercise, suggesting that glucose may be used as a substrate during exercise. Elevated neutrophils, paired with decreased lymphocytes, may be indicative of an acute immune response to exercise.

3919 Board #236 May 30 9:00 AM - 10:30 AM
Short- And Long-term Effects Of High Intensity Interval Training On Dietary Intake In Cardiac Rehabilitation
 Jenna L. Taylor, Jeff S. Coombes, FACSM, Shelley E. Keating, David J. Holland, Michael D. Leveritt. The University of Queensland, Brisbane, Australia. (Sponsor: Professor Jeff Coombes, FACSM)
 (No relevant relationships reported)

PURPOSE: The aim of this study was to investigate short- and long-term compensatory effects on dietary intake following high intensity interval training (HIIT) compared with usual care moderate intensity continuous training (MICT) during and following a cardiac rehabilitation (CR) program.

METHODS: Ninety-three patients with coronary artery disease enrolled in a 4-week CR program and were randomised to 1) 4x4-minute HIIT; or 2) 40-minutes of MICT (usual care). Patients were instructed to complete 3 weekly sessions (2 supervised, 1 home-based) for 4-weeks, and 3 weekly home-based sessions thereafter for 48-weeks. Only CR group-based dietary advice was provided. Dietary intake was measured by telephone-based 24-hour recall over two days at baseline, 4-weeks, 3-months, 6-months, and 12-months. The Three-Factor Eating Questionnaire was used to measure dietary behaviour, and fasting appetite was assessed by a 100mm visual analogue scale. Appetite hormones (ghrelin, PYY, leptin) were also analysed at baseline and 3-months. Data are mean change (95% confidence interval).

RESULTS: There was no change over the study period or differences between HIIT and MICT for daily energy intake at 4-weeks [-0.1(-0.8,0.5) vs -0.4(-1.0,0.2) MJ; $p = 0.549$] or 12-months [0.4(-0.6,1.3) vs 0.1(-0.9, 1.0) MJ; $p = 0.848$]. There were also no group differences for macronutrients, saturated fat, or fibre. Over 4-weeks, an increase in dietary restraint for both HIIT and MICT [7(-1,15) vs 6(-2,16); time effect: $p = 0.028$], coincided with an increase in hunger [6(1,10) vs 5(1,10)mm; time effect:

$p=0.001$], but this was not evident at 12-months. There was a time x group effect for leptin with a reduction for HIIT and increase for MICT [-0.9(-1.9,0.2) vs 0.7(-0.3, 1.7) ng/ml; $p=0.029$], but no changes over time or group differences for ghrelin [7(-10,23) vs 4(-12,20) pg/ml; $p=0.815$] or PYY [13(-4,30) vs 2(-14,18) pg/ml; $p=0.354$].

CONCLUSIONS: Compared to moderate intensity exercise, HIIT did not result in compensatory increases of energy intake or indicators of poor diet quality. Furthermore, HIIT reduced leptin without compensatory effects on ghrelin or dietary intake. HIIT can therefore be included in CR programs as an adjunct or alternative to MICT, without concern for any undesirable dietary compensation. **Funded by Wesley Medical Research**

Change In Left Ventricular Mass In A 12-month Behavioral Weight Loss Program With Varying Doses Of Physical Activity: The Heart Health Study

Renee J. Rogers, FACSM¹, Erik B. Schelbert¹, Wei Lang², Yaron Fridman³, Bethany Barone Gibbs¹, John M. Jakicic, FACSM¹.

¹University of Pittsburgh, Pittsburgh, PA. ²Wake Forrest University, Winston-Salem, NC. ³Charles George Veterans Affairs Medical Center, Asheville, NC.

Email: rjr26@pitt.edu

(No relevant relationships reported)

Greater left ventricular mass (LVM) has been associated with incidence of cardiovascular events in cohort studies. LVM has been shown to be associated with larger body mass index (BMI), which may partially explain the association between obesity and cardiovascular disease (CVD). Moderate-to-vigorous physical activity (MVPA) is recommended in lifestyle interventions for weight loss; however, few studies have examined how the dose of activity during weight loss contributes to changes in LVM.

PURPOSE: To examine the change in LVM in response to a behavioral weight loss intervention with varying doses of physical activity.

METHODS: Data were examined from sedentary adults (N=383; BMI: 32.1±3.8 kg/m²; age=46.2±7.7 years) enrolled in a behavioral program and randomized to a reduced calorie diet (DIET, N=127), diet plus a moderate dose of MVPA (MOD-PA, N=129), or diet plus a high dose of MVPA (HIGH-PA, N=127). All groups received weekly intervention sessions in months 1-6 followed by 2 group and 2 telephone contacts per month in months 7-12 and were prescribed a diet to reduce energy intake (1200-1800 kcal/day). MOD-PA was prescribed unsupervised MVPA that progressed to 150 min/wk, whereas HIGH-PA was progressed to 250 min/wk. Assessment of body weight and LVM using cardiac magnetic resonance imaging were assessed at both baseline and 12 months.

RESULTS: Weight (LS mean [95% CI]) significantly decreased from across time (0 months: 90.3 [89.0, 91.7] kg; 12 months: 81.2 [79.8, 82.6] kg) ($p<0.001$), with no difference between groups (Group: $p=0.29$; Group X Time: $p=0.50$). Overall baseline LVM was 42.5±7.4g/m². At 12 months, LVM decreased in DIET (-0.25±0.53g/m²), with increases in LVM in MOD-PA (1.35±0.54g/m²) and HIGH-PA (0.91±0.54g/m²). Post hoc changes in LVM showed a significant difference between DIET and MOD-PA ($p=0.0159$), with no differences between DIET and HIGH-PA ($p=0.5063$), or MOD-PA and HIGH-PA ($p=0.0799$).

CONCLUSIONS: Following a lifestyle weight loss intervention, LVM mass was reduced in the diet only condition; however, when physical activity was added, LVM appears to increase. Of interest, 150 min/wk of MVPA may be favorable compared to 250 min/wk for enhancing LVM during weight loss. The clinical implications of these results warrant further investigation. Support: NIH (R01 HL103646)

The Effects Of One-week Exogenous Ketone Consumption On Short Distance Time Trial Running Performance

Kalin A. Tomlinson¹, Samantha C. Silva¹, Lee E. Brown, FACSM², John P. Arreglado¹, Edward Jo¹. ¹California State Polytechnic University, Pomona, Pomona, CA. ²California State Polytechnic University, Fullerton, Fullerton, CA. (Sponsor: Lee Brown, FACSM)

Email: katomlinson@cpp.edu

(No relevant relationships reported)

Currently, there is equivocal knowledge concerning the effects of ketone salt supplementation on short distance running time trial (TT) performance in well-trained subjects. **PURPOSE:** To determine the effects of one-week exogenous ketone salt supplementation on 800m running TT performance during non-fatigued and pre-exhaustive states in endurance-trained subjects. **METHODS:** In a randomized, double-blind, placebo-controlled study, endurance-trained male and female participants were allocated to one of the following treatment groups for 8 days following an initial familiarization visit: Ketone supplementation (KET) (n=16) or placebo control (CON) (n=16). Subjects underwent two consecutive 800m TT before and after the 8-day treatment period on a self-propelled, non-motorized treadmill. Time-to-completion of the first (TT1) and second (TT2) TTs, the average time-to-completion across both TTs, and blood lactate response during the TTs were measured pre- and post-treatment. A mixed factorial ANOVA was used for data analysis. **RESULTS:** KET alone exhibited a significant increase in blood β -hydroxybutyrate from pre-post-treatment ($p<0.05$). A group x time interaction was only detected for TT2 performance ($p<0.05$) but not TT1. There was no pre- to post-treatment change in TT1 performance in either group. CON demonstrated no change in TT2 performance from pre- to post-treatment; however, KET improved TT2 performance as reflected by a 3.7% faster time-to-completion from pre- to post-treatment ($p<0.05$). When examining the average time-to-completion across both TTs, there was a significant group x time interaction ($p=0.04$). CON showed no change while KET demonstrated a faster average time-to-completion from pre- to post-treatment ($p<0.05$). Blood lactate response to TTs decreased ($p<0.05$) in KET but not CON. **CONCLUSIONS:** In endurance-trained subjects, ketone salt supplementation does not appear to affect short-distance running TT performance in a non-fatigued state reflective of competition scenarios. However, ergogenic effects may be observed in high-intensity exercise when some level of exhaustion or energy substrate depletion is experienced prior, such as during training or prolonged, intermittently high-intensity sporting bouts.

Effect Of L-carnitine And Exercise On Fat-rich Dietmice PPAR α And LPL In Liver

Yue Fu. Shanghai University of Sport, Shanghai, China.

(No relevant relationships reported)

Effect Of L-carnitine And Exercise On Fat-rich Dietmice PPAR α And LPL In Liver

Abstract:Objective: To investigate the effects of L-carnitine and exercise on lipid metabolism in the liver. Methods: To establish fat-rich diet model by feeding high-fat diets to mice. Fat-rich diet mice were divided into 4 random groups, the high-fat control group(HC group),the high-fat L-carnitine group (HL group), the high-fat exercise group(HE group)and the high-fat exercise combined with L-carnitine group(HEL group).Six weeks later, PPAR α ,LPL,FFA, TG, TC in liver and TG,TC in blood serum were tested. Results: Compared with control group, TG,TC in blood serum and TG,TC,FFA in liver was significantly low in the HE and HEL groups, at the same time, LPL and PPAR α was increased significantly in the HE and HEL groups. Compared with HE group, TC in blood serum and FFA in liver was decreased in HEL group, PPAR α significantly up-regulated in HEL group. Conclusion: 1) Long-term aerobic exercise up-regulated expression of PPAR α and LPL in liver, promoted FFA oxidative utilization. 2) In addition to PPAR α , regulation of L-carnitine supplement to LPL may be affected by other factors. 3) L-carnitine can increase the expression of PPAR α and decrease the content of FFA on athletic mice, to play its role in adjusting lipids.

Key words: L-Carnitine; exercise; lipid metabolism

 (No relevant relationships reported)

Extra-virgin olive oil (EVOO), commonly seen in Mediterranean diet, has been shown to exert anti-inflammatory effect in chronic disease prevention. Long-term high-fat diet increases chronic inflammation, which leads to cardiovascular diseases and metabolic syndrome. **PURPOSE:** The purpose of the study is to evaluate the effects of 12-week EVOO supplementation and exercise training on circulatory inflammatory markers in rats fed a high-fat diet. **METHODS:** Female Sprague-Dawley rats (age 4 week, n=36) were randomly divided into 3 groups. One group was fed a basal diet (C, N=12) with added cholesterol (1.25%) and cholic acid (0.5%) for 12 wks. While on the basal diet, two groups were supplemented with 20% EVOO, half group being trained (T, N=12) on treadmill for 12 wks (25m/min, 10% grade for 60 min/day, 5 days/wk), and the other half being sedentary (S, N=12). Plasma inflammatory cytokines were measured by Multiplex immunoassays on Luminex 200. Data were analyzed using two-way ANOVA. **RESULTS:** EVOO supplementation elevated 1.91-fold on macrophage colony stimulating factor (M-CSF) level ($P<0.05$), but this effect was decreased 3.34-fold by T ($P<0.05$). A significant increase in granulocyte-macrophage colony stimulating factor (GM-CSF) was found in EVOO vs. C (5.9-fold, $P<0.05$). Monocyte chemoattractant protein-1 (MCP-1) level in plasma was decreased 1.46-fold in EVOO/T vs. C ($P<0.05$). Plasma interleukin-1 β (IL-1 β) and tumor necrosis factor- α (TNF- α) levels did not change in EVOO ($P>0.05$), but TNF- α was decreased 1.46-fold in EVOO/T vs. C ($P=0.077$). **CONCLUSION:** Dietary supplementation of EVOO resulted in an augmentation of plasma inflammatory cytokines levels in the sedentary rats fed a high-fat atherogenic diet, but these adverse effects were significantly reversed by chronic exercise training.

Unique Medium Chain Triglyceride Product Rapidly Enhances Brain Function: A Pilot Investigational Study

Neil Wolkodoff¹, Gerald M. Haase², Joy Curry³. ¹Colorado Center for Health & Sport Science, Denver, CO. ²University of Colorado, Aurora, CO. ³Colorado Christian University, Lakewood, CO.
 Email: neil@cochss.com
 (No relevant relationships reported)

PURPOSE: Medium Chain Triglyceride (MCT) compounds are purported to increase brain energy based upon the relationship between MCT products and ketone production, especially for older individuals or those on low-carbohydrate diets. Little evidence exists that MCT products positively affect brain function, short-term. In this pilot study, Intervention Group (IG) subjects were tested prior to ingestion of a proprietary MCT product, and then 90 minutes later using the same electroencephalographic (EEG) device and compared to a control group (CG). **METHODS:** Eight (8) IG volunteers, aged 49-68 years old, (male = 5, female = 3) were compared to three (3) CG volunteers, aged 48 to 68 years old, (male = 3). Study subjects completed standard EEG testing prior to ingestion of the compound, and 90 minutes after consuming the compound or placebo. Testing consisted of a P300 audio reaction time test and two visual decision making/reaction tests. **RESULTS:** The IG increased brain function as measured with evoke potentials, time to task and graphic representations compared to the control group. The decrease for the IG in the audio reaction time test was 340 milliseconds to 314 milliseconds. In addition, the tens of millivolt (μ V) activation during the auditory reaction time test increased from 7.5 μ V to 12.9 μ V, indicating increased brain functional activity. The CG showed essentially no voltage changes. The IG decreased times in the first trail making test from 94 to 57 seconds, and decreased time to complete the second trail making test from 113 to 93 seconds. Descriptive statistics revealed the measures for the IG had statistical significance ($P<0.5$) for the second trail making test and strong positive trends for all other parameters. Topographic brain maps from the test revealed a representative picture of the changes from taking the supplement. **CONCLUSIONS:** In this pilot study, consumption of a proprietary MCT combination produced marked enhancement in brain activity 90 minutes after ingestion with significant increases in relation to topographical brain maps. Further investigation is warranted to determine optimal ingestion conditions and time to effect for this and similar products across various populations. EEG measurements show promise as assessment biomarkers for the effects of nutritional supplements on brain function.

Exercise Priming: Effect Of Morning Exercise On Fat Oxidation During Afternoon Walking

Rachel Matthews¹, Abby Coleman², Alex Clark², Ben Matsuka-Williams², Lauren Wong², Dylan Thompson², Neil Johannsen¹. ¹Louisiana State University, Baton Rouge, LA. ²University of Bath, Bath, United Kingdom. (Sponsor: Brian Irving, FACSM)
 Email: rmatt14@lsu.edu
 (No relevant relationships reported)

Reduced fat oxidation is emerging as a predictor for obesity-related diseases; therefore, interventions that increase fat oxidation may have clinically important health benefits. Previous research suggests that exercise priming may provide a novel solution by augmenting fat oxidation during subsequent exercise. **PURPOSE:** To investigate the effects of morning Reduced-Exertion High-intensity Interval Training (REHIT) on fat oxidation during afternoon Low-intensity Steady State (LISS) walking. **METHODS:** Twelve sedentary or recreationally active university students (7 male, 5 female) participated in 2 randomly assigned morning interventions, REHIT (two 20-second sprints on a cycle ergometer separated by 4-minutes of active recovery) or rest, on two separate days. On both occasions, participants returned to the lab in the afternoon (4 hours later) to complete a 45-minute treadmill walk at 5.6 km/h. Participants remained fasted for both morning and afternoon trials. Blood and gas samples were collected pre-, during, and post-LISS exercise. **RESULTS:** After 45 minutes of LISS walking, plasma non-esterified fatty acids (NEFA) was greater in the REHIT trial compared to control (REHIT, 1.03 ± 0.39 mmol/L; Control, 0.75 ± 0.43 mmol/L; $p = 0.03$; Cohen's $d = 0.67$). However, lipid oxidation was not concomitantly elevated ($p = 0.35$). Furthermore, plasma glucose, carbohydrate oxidation, respiratory exchange ratio (RER) and energy expenditure remained consistent between the trials across all time points ($p = 0.40$; $p = 0.98$; $p = 0.92$; $p = 0.81$, respectively). **CONCLUSION:** Exercise priming may not influence fat oxidation during subsequent bouts of LISS exercise; however, plasma NEFA may be greater suggesting changes in substrate availability. Relatively long rest intervals between the morning and afternoon trials and insufficient exercise workload could explain similarities in substrate oxidation. Isotopic research is required to understand the metabolic fate of the elevated substrate concentrations.

PREPRANDIALEXERCISE DOES NOT MODIFY HIGH FAT MEAL INDUCED INFLAMMATION IN YOUNG AND OLD ADULTS

William S. Wiseman¹, Elizabeth S. Edwards, FACSM¹, Hannah Frick¹, Sam R. Emerson², Morgan Medeiros¹, Camden Sutton¹, Michael White¹, Steven K. Malin, FACSM³, David Edwards³, Stephanie P. Kurti¹. ¹James Madison University, Harrisonburg, VA. ²Oklahoma State University, Still Water, OK. ³University of Virginia, Charlottesville, VA. (Sponsor: Elizabeth Edwards, FACSM)
 (No relevant relationships reported)

An up-regulation of pro-inflammatory cytokines (i.e. IL-6, TNF α , IL-1 β , IL-8) and lower anti-inflammatory cytokines (IL-10) are associated with development of cardiovascular disease. While a single high-fat meal (HFM) can transiently increase systemic postprandial inflammation (PPI) in young adults (YA), the effect of a HFM or acute exercise on PPI in older adults (OA) is not clear. **PURPOSE:** To determine if preprandial exercise attenuates PPI in YA and OA. **METHODS:** 12 YA (23.3 ± 3.9 years, $n = 5$ M/7 F) and 12 OA (67.7 ± 6 years, $n = 8$ M/4 F) completed an incremental exercise test to determine VO_{2peak} and then two HFM challenges (HFM alone or acute exercise prior to a HFM (EX+HFM)) in a randomized order. Prior to the HFM (12 kcal/kg body weight: 57% fat, 39% CHO, 4% PRO), participants abstained from strenuous physical activity for 48 hours and adhered to a 12 hour overnight fast. Inflammatory cytokines were measured at baseline, 3, and 6 hours during the HFM. In EX+HFM, participants completed an exercise session on a cycle ergometer 12 hours prior to the HFM at 65% VO_{2peak} until caloric expenditure matched 75% of the caloric content of the HFM. **RESULTS:** There was a significant main effect of time as a quadratic function for IL-6 and IL-8, which decreased by 28% and 8% (respectively) at three hours post-HFM, and then increased near baseline levels at six hours post-HFM ($p < 0.05$). TNF α , IL-10, and IL-1 β exhibited significant decreases over time from baseline to six hours ($p < 0.05$). Specifically, TNF α decreased by 12%, IL-10 decreased by 7%, and IL-1 β decreased by 14% ($p < 0.05$). TNF α was greater in OA at baseline compared to YA ($p = 0.036$), however there was no difference post-HFM at either three or six hours ($p > 0.05$). There was no difference in inflammation between HFM and EX+HFM at any time point for any inflammatory marker ($p > 0.05$). **CONCLUSION:** Contrary to our hypotheses, a HFM did not elicit PPI in YA or OA. Additionally, acute exercise did not impact inflammation at any timepoint. Future work should be performed to elucidate the mechanism by which a HFM raises cardiovascular disease risk.

A Short Bout Of Moderate- Or High-intensity Cycling Can Influence Postprandial Triglyceride Metabolism
 James Rowe, David Buckley. *Stephen F. Austin State University, Nacogdoches, TX.*
 Email: rowej@sfasu.edu
 (No relevant relationships reported)

PURPOSE: Examine the effects of high-intensity interval cycling (HIIC) and moderate-intensity continuous cycling (MICC) on postprandial glucose, insulin, and triglyceride (TG) concentration. **METHODS:** Each male subject ($n = 12$; age = 21.9 ± 1.8 yrs; body mass = 90.1 ± 16.8 kg) completed 1) REST, 2) MICC, and 3) HIIC in a randomized order. Each bout was separated by 1 week. Rest involved sitting quietly. MICC required continuous cycling at 60% maximal work rate (WR_{max}). HIIC involved 15-second cycling sprints (@ 120% WR_{max}) followed with 45 seconds of passive cycling. Each bout was performed for 20 minutes on the afternoon of Day 1. A mixed meal (50% carbohydrate (CHO) and 35% fat) was provided 30 minutes (Day 1) and 16 hours (Day 2) following the completion of each bout. Blood samples on Day 1, following a 4-hour fast, were acquired just prior to each bout and at 0, 0.5, 1, and 2 hours post-meal. Blood samples on Day 2, following a 10-hour fast, were acquired at 0, 2, and 4 hours post-meal. Blood samples were analyzed for glucose, insulin, and TG concentration. Postprandial (PP) responses were quantified via the total (AUC_T) and incremental area under the curve (AUC_I) using the trapezoidal method. Significant differences ($p < .05$) between the bouts were determined using a one-way, repeated measures ANOVA and Bonferroni post-hoc test. **RESULTS:** Average work (Watts) was similar between MICC (122.5 ± 25.4) and HIIC (110.3 ± 14.7) ($p = .091$, $ES = .51$). On Day 1, there was no significant difference in the PP glucose, insulin, or TG response between the 3 bouts. On Day 2, MICC reduced the TG AUC_T ($442.9 \pm 76.4 \text{ mg} \cdot \text{dl}^{-1} \cdot 4\text{hr}^{-1}$) when compared to rest ($487.4 \pm 104.4 \text{ mg} \cdot \text{dl}^{-1} \cdot 4\text{hr}^{-1}$) ($p = .02$, $ES = .43$). HIIC elicited a non-significant reduction the TG AUC_T ($454.8 \pm 72.3 \text{ mg} \cdot \text{dl}^{-1} \cdot 4\text{hr}^{-1}$), however the reduction was trending towards significance ($p = .076$, $ES = .31$). **CONCLUSION:** A brief bout of MICC and HIIC does not influence the PP response when completed just prior to a mixed meal. There may be a delayed response to exercise as MICC and (to a lesser degree) HIIC appear to reduce the PPTG response when completed 16 hours prior to a mixed meal. The lack of change in the PP glucose and insulin response might be explained by a wide inter-individual variance as half of the participants appeared to have responded to the exercise bouts based on their PP glucose and insulin concentration.

Metabolic Flexibility During Exercise In Overweight/ obese Children Vs. Lean Children
 Brandon Dykstra¹, Dillon Kuszmaul², Anthony D. Mahon².
¹Taylor University, Upland, IN. ²Ball State University, Muncie, IN.
 (No relevant relationships reported)

Metabolic flexibility (MF) is the ability of the body to alter its reliance on fat or carbohydrate for energy purposes in response to a stimulus. The inverse, metabolic inflexibility, has been associated with type II diabetes and obesity. Given the prevalence of these disorders, assessing and improving MF is important. However, MF during exercise, particularly with respect to fat metabolism, in children remains poorly understood. **PURPOSE:** This study examined MF with respect to fat metabolism during exercise in lean ($n=11$; 10.9 ± 0.9 years) and overweight/obese (OW/OB; $n=8$; 10.4 ± 1.2 years) children. It was hypothesized that MF with respect to fat metabolism during exercise would be impaired in the OW/OB group as indicated by reduced use of fat as an energy source. **METHODS:** Participants were grouped based on BMI percentiles for age and sex (Lean $< 85^{\text{th}}$ percentile, OW/OB $\geq 85^{\text{th}}$ percentile). On the experimental visit, participants completed two 20-minute exercise bouts separated by a 10-minute rest. Bout 1 consisted of 10 minutes at 50% VO_{2max} and 10 minutes at 75% VO_{2max} . Bout 2 consisted of 20 minutes at 50% VO_{2max} . Absolute fat oxidation rate (FOR; [$\text{mg} \cdot \text{min}^{-1}$], FOR relative to body mass [$\text{mg} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$], FOR relative to fat-free mass [$\text{mg} \cdot \text{kgFFM}^{-1} \cdot \text{min}^{-1}$], and proportional fat use (% Fat) were measured at 10 minutes of Bout 1 and at 5, 10, 15, and 20 minutes of Bout 2. **RESULTS:** There was a main effect for time for % Fat and for each expression of FOR, with fat oxidation values generally higher during the second bout, suggesting that exercise can be used to assess MF in children. Absolute FOR was higher in the OW/OB group (range: 121.6 ± 57.6 to $213.7 \pm 45.7 \text{ mg} \cdot \text{min}^{-1}$) than in the Lean group (81.1 ± 32.2 to $152.2 \pm 38.2 \text{ mg} \cdot \text{min}^{-1}$), however there were no main effects for group or interactions for % Fat (OW/OB: 29.0 ± 14.4 to $51.1 \pm 8.5\%$; Lean: 23.9 ± 10.9 to $41.8 \pm 6.5\%$), FOR relative to body mass (OW/OB: 2.4 ± 1.3 to $4.1 \pm 0.7 \text{ mg} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$; Lean: 2.5 ± 1.0 to $4.5 \pm 1.0 \text{ mg} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$), or FOR relative to FFM (OW/OB: 4.15 ± 1.97 to $7.12 \pm 1.17 \text{ mg} \cdot \text{kgFFM}^{-1} \cdot \text{min}^{-1}$; Lean: 3.49 ± 1.54 to $6.29 \pm 1.13 \text{ mg} \cdot \text{kgFFM}^{-1} \cdot \text{min}^{-1}$). **CONCLUSION:** OW/OB children in this age range do not display impaired MF with respect to fat metabolism during exercise. Future research should examine a broader range of children as well as the effects of different exercise characteristics (e.g. intensity) on MF.

Different Exercise Models Affect White Adipose Browning Through Mechanism Of Irisin Molecular Pathway
 Yao Liu, Bing Zhang, Yingzhe Xiong. *Tsinghua University, Beijing, China.*
 (No relevant relationships reported)

Background: The white adipose browning can improve fat burning and accelerate fat consumption. Irisin which is cleaved by Fibronectin Type III Domain-Containing protein 5 (FNDC5) derived from muscle can act on white adipose tissue to promote the expression of Uncoupling Protein 1 (UCP1). However, it is unclear which exercise models is better to contribute to produce Irisin. **Purpose:** To discuss whether High-Intensity Intermittent Exercise (HIIT) is better than Medium-Intensity Continuous Exercise (MICT) on the effect of improving white fat production of UCP1 and the mechanism of molecular biology. **Methods:** Thirty-two 4-week-old C57BL/6J mice were fed with high-fat diet (D12492) for 8 weeks and randomly divided into three groups: control group (GC, $n=8$), MICT group (GM, $n=8$), and HIIT group (GH, $n=8$). Then, GM got an 8-weeks MICT training (10min warm-up, 45min 60% VO_{2max} speed, 6 times/week) and GH had an 8-weeks HIIT training (10min warm-up, 1set=1min 90% VO_{2max} speed + 2min 60% VO_{2max} speed, 12sets). 24 hours after the last training, anesthesia was dissected. Muscle tissue contained PGC-1 α mRNA, FNDC5mRNA, and Irisin. It was also taken by blood index. Irisin and UCP1mRNA were measured by subcutaneous white adipose tissue. The data were compared by using one-way analysis of variance. **Results and Discussions:** (1) Muscle: Comparing with GC, GM and GH both have a higher expression of PGC-1 α mRNA but there is no significant difference, yet FNDC5mRNA of GM is more than GC (7.53 ± 5.36 vs. 1.00 ± 1.13 , $p < 0.01$) and GH (7.53 ± 5.36 vs. 1.01 ± 1.16 , $p < 0.01$). Irisin of GM (32.22 ± 2.88 vs. $25.99 \pm 4.50 \text{ pg/mg}$, $p < 0.05$) and GH (32.10 ± 4.04 vs. $25.99 \pm 4.50 \text{ pg/mg}$, $p < 0.05$) are more than GC. (2) Serum: The Irisin level of GH is very significantly higher than GM (55.41 ± 1.19 vs. $51.83 \pm 2.47 \text{ pg/ml}$, $p < 0.01$). (3) Subcutaneous white adipose tissue: In respect of Irisin, GH is more than GM (37.68 ± 3.55 vs. $29.77 \pm 2.89 \text{ pg/mg}$, $p < 0.01$); UCP1mRNA, GH is more than GM (16.67 ± 6.65 vs. 0.69 ± 0.42 , $p < 0.01$). **Conclusion:** (1) Exercise can promote the production of Irisin upstream regulated factor, PGC-1 α and FNDC5. (2) HIIT compared with MICT has a greater effect on improving the white adipose tissue browning through the molecular pathway of PGC-1 α -FNDC5-Irisin-UCP1.

Exercise Duration Affects Maximal Fat Oxidation In Post- Menopausal Women: Implications For Exercise Prescription
 Silvia Pogliaghi, FACSM, Massimo Teso, Luca Ferrari, Alessandro L. Colosio. *Università di Verona, Verona, Italy.*
 Email: silvia.pogliaghi@univr.it
 (No relevant relationships reported)

The relative exercise intensity at maximal fat oxidation (FAT_{max} , % VO_{2max}) is used for exercise prescription for weight loss and metabolic health. In young men, FAT_{max} is affected by exercise duration, with more prolonged testing protocols leading to higher values. **PURPOSE:** Since no data exist on post-menopausal women, we determined the effect of exercise duration on FAT_{max} in this population. **METHOD:** 18 non-obese women (54 ± 4 years; 4 ± 3 years from menopause; 22 ± 3 BMI) performed on a cycle ergometer a ramp test and 30-min steady-state trials at 40, 50, 60, 70 and 80% of the pre-determined VO_{2max} . Based on VO_2 and respiratory exchange ratio we calculated and compared (2-way RM ANOVA) absolute fat oxidation (FO , $\text{g} \cdot \text{min}^{-1}$) across intensities and duration. We compared FAT_{max} derived from ramp ($FAT_{max,ramp}$), 5 ($FAT_{max,5}$) and 30-min data ($FAT_{max,30}$) (1-way RM ANOVA). We estimated FAT_{max} using exercise duration (1, 5 and 30 min) and $FAT_{max,ramp}$ as explanatory variables. **RESULTS:** FO was significantly affected by exercise duration, intensity and their interaction (for all $p < 0.001$). Any exercise between 40 and 70% VO_{2max} , > 30 min, lead to an identical MFO (overall $0.21 \pm 0.09 \text{ g} \cdot \text{min}^{-1}$). $FAT_{max,30}$ occurred at a significantly higher % VO_{2max} ($57 \pm 10\%$) than $FAT_{max,ramp}$ and $FAT_{max,5}$ (44 ± 6 and $49 \pm 9\%$, not different). FAT_{max} can be predicted from the linear combination of exercise duration ($p < 0.001$) and $FAT_{max,ramp}$ ($p = 0.01$) as independent explanatory variables ($r = 0.69$, $SEE = 8.8\%$). **CONCLUSIONS:** In post-menopausal women exercises at 40-80% VO_{2max} of longer durations are associated with higher FAT_{max} compared to ramp or short, steady-state sessions. Moreover, any intensity greater than $FAT_{max,ramp}$ will maximize fat oxidation for exercises > 30 min. Finally, the intensity that maximizes fat oxidation can be predicted by exercise duration and $FAT_{max,ramp}$. This approach offers a valid approach for individualized exercise intensity prescription for weight loss and metabolic health in postmenopausal women.

Wild Blueberries Increase Fat Oxidation Rate During Moderate Intensity Exercise

Jessie Armendariz¹, Boe Burrus², Kari Pilolla³, David Baston¹, Taylor Bloedon¹. ¹Humboldt State University, Arcata, CA. ²Gonzaga University, Spokane, WA. ³California Polytechnic State University, San Luis Obispo, CA.
 (No relevant relationships reported)

Fruits high in anthocyanins, such as wild blueberries (WBs), have been documented to decrease oxidative stress in active and sedentary populations and has more recently demonstrated the ability to influence lipolytic enzymes and increase the rate of fatty acid oxidation (FA-ox) during rest. To date, changes in FA-ox during exercise has only been examined with blackcurrants. **PURPOSE:** To examine the effect of freeze dried WBs on the rate of FA-ox and lipid peroxidation during moderate intensity exercise. **METHODS:** 11 healthy, aerobically trained males (26.6 ± 7.9 yrs, 74.7 ± 8.2 kg, 10.2 ± 3.4% BF) completed an incremental cycle test to determine $\dot{V}O_{2peak}$ (54.4 ± 7.9 ml/kg/min) followed by a 2-wk washout avoiding foods high in anthocyanins. Participants completed a control (C) exercise protocol of cycling at 65% of $\dot{V}O_{2peak}$ for 40 min. Urinary F2-isoprostanes (~ 50 mL) and capillary blood FA, glycerol, creatinine and free/total carnitine (~ 250 µL) were collected pre and post sessions. Ventilation, RER, lactate, HR, power output, RPM and RPE were collected before and at 10 min increments. Next, participants consumed 12.5 g freeze dried WB powder, 2x/day (25 g total) for 2-wks, then repeated the exercise protocol. Repeated measures ANOVAs were used to determine differences between conditions. **RESULTS:** WBs reduced lactate at 20 (C: 3.0 ± 1.1 mmol vs WB: 2.6 ± 1.0 mmol; p=0.005), 30 (C: 2.9 ± 1.0 mmol vs WB: 2.2 ± 0.9 mmol; p=0.005) and 40 min (C: 2.5 mmol ± 0.9 vs WB: 1.9 ± 0.8 mmol; p=0.013) and carbohydrate oxidation by 10.1% at 20 (C: 2.17 ± 0.46 g/min vs WB: 1.95 ± 0.42 g/min; p=0.024), 19.2% at 30 (C: 2.24 ± 0.52 g/min vs WB: 1.82 ± 0.48 g/min; p=0.014) and 14.8% at 40 min (C: 2.10 ± 0.54 g/min vs WB: 1.79 ± 0.45 g/min; p=0.045) while resulting in higher FA-ox by 19.7% at 20 (C: 0.45 ± 0.16 g/min vs WB: 0.53 ± 0.13 g/min; p=0.049), 43.2% at 30 (C: 0.41 ± 0.14 g/min vs WB: 0.58 ± 0.15 g/min; p=0.010) and 31.1% at 40 min (C: 0.45 ± 0.17 g/min vs WB: 0.59 ± 0.13 g/min; p=0.012). No differences were found between C and WB trials for all other variables. **CONCLUSION:** Results indicate that WBs may increase the rate of FA-ox during moderate intensity activity in healthy, active males. Potential complications with blood sample preparation may have led to unreliable results. Further, the exercise intensity may have been too low to see significant changes in urinary F2-isoprostanes.

Exercise Training Adaptations In Metabolic Syndrome Individuals On Chronic Statin Treatment

Felix Morales-Palomo, Miguel Ramirez-Jimenez, Juan F Ortega, Alfonso Moreno-Cabañas, Laura Alvarez-Jimenez, Ricardo Mora-Rodriguez. UCLM, Toledo, Spain.
 Email: felixmoralespalomo@gmail.com
 (No relevant relationships reported)

Statins reduce atherogenic dyslipidemia and cardiovascular disease (CVD) risk in metabolic syndrome individuals (MetS). Exercise-training could also contribute to reduce CVD by improving cardiorespiratory fitness (i.e., $\dot{V}O_{2MAX}$) and fat oxidation. However, some reports sustain that statin use could interfere with training adaptations. **PURPOSE:** To determine the therapeutic impact of an exercise-training program on fat metabolism and cardiorespiratory fitness (CRF) in a group of MetS individuals chronically medicated with statins in comparison to a well-matched control group statin-naïve. **METHODS:** One hundred and six MetS were divided into statin users (STATIN group, n=46) and statin-naïve (CONTROL group, n=60). Groups were matched by age, weight, and MetS components. All subjects completed 16 weeks of high intensity interval training (HIIT). Before and after HIIT, muscle biopsies were collected to assess mitochondrial content (citrate synthase (CS) activity) and the activity of the rate limiting β oxidation enzyme (3-hydroxyacyl-CoA-dehydrogenase (HAD)). Fasting plasma glucose, insulin, TG, HDL-c and LDL-c concentrations were measured. Exercise maximal fat oxidation (FO_{MAX}) and oxygen uptake ($\dot{V}O_{2PEAK}$) were determined. **RESULTS:** Training improved MetS components similarly in both groups (MetS Z-score -0.26±0.38 vs -0.22±0.31; P<0.001 for time and P=0.60 for time x group). Before training, STATIN had reduced muscle HAD activity and whole body FO_{MAX} compared to CONTROL (P=0.038 and P=0.002 for group, respectively). However, 16-weeks of HIIT increased HAD and FO_{MAX} in both groups (32% and 20% in STATIN and 3% and 10% in CONTROL; both P<0.03 for time and P>0.05 for time x group, respectively). $\dot{V}O_{2PEAK}$ improved less in STATIN than in CONTROL group (12% vs 19%; P=0.013 for time x group). Conversely STATIN did not prevent the increases in CS with HIIT (38%; P<0.001 for time, P=0.199 for time x group). **CONCLUSIONS:** Our findings suggest that chronic statin use in MetS does not interfere with exercise training improvements in fat oxidation and neither with the

muscle enzyme mediators of these responses (i.e., CS and HAD). However, STATIN attenuated the improvements in $\dot{V}O_{2PEAK}$ with training. ClinicalTrials.gov identifier: NCT03019796

Effect Of Aerobic Exercise On The Proteins Of Ubiquitin System In Different Adipose Tissues Of Obese Rats

Yi Yan, Changfu LI, Qishu Zhou, Chunyu Liang. Beijing Sport University, Beijing, China.
 Email: yanyi22@sina.com
 (No relevant relationships reported)

PURPOSE: To observe character of the different adipose tissue ubiquitin system in obese rats and explore the role of ubiquitin system in regulation of 8-week moderate intensity aerobic exercise on the autophagy of different adipose tissue of obese rats. **METHODS:** After 8 weeks high fat feeding (D12451) and standard feeding (D12450B), 20 obesity 11weeks SD were randomly assigned to sedentary (OS, n=10) and exercise (OE, n=10) groups; 20 normal weighty also were randomly assigned to sedentary (CS, n=10) and exercise (CE (n=10) group. During the following 8 weeks, CS and OS groups were CE and OE groups did the 60%-70% $\dot{V}O_{2max}$ treadmill training (5 days/week, 1 hour/day). The $\dot{V}O_{2max}$ of exercise groups were remeasured every two weeks. The protein expressions of LC3II, LC3I, ATG7, ATG5, ATG12 and ATG12-ATG5 in white adipose tissue of groin and brown adipose tissue of scapular were measured by Western blotting. **RESULTS:** (1) In the white adipose tissues, the protein expressions of ATG7, ATG5, ATG12, ATG12-ATG5 (p<0.05) and LC3II/I (p<0.01) in OS group were significantly increased than CS group, but the protein expressions of ATG7, ATG5, ATG5-ATG12 and LC3II/I in OE group were significantly decreased (p<0.05) than OS group. (2) In the brown adipose tissues, compared with CS group, the protein expressions of ATG5, ATG12, ATG5-ATG12 in CE group increased significantly (p<0.05), but the LC3II/I (p<0.01) and ATG5-ATG12 (p<0.05) in OS group decreased significantly. The ATG7, ATG12, ATG5-ATG12 and LC3II/I of OE group were significantly higher than OS group (p<0.05). **CONCLUSIONS:** There was tissue specificity of adipose tissue autophagy in obese rats. The ubiquitin system of ATG5-ATG12 involved in activation of white fat autophagy. 8 weeks moderate intensity aerobic exercise can inhibit the autophagy of subcutaneous white fat and strengthen the autophagy of scapular brown fat.

Magnesium Supplementation Combined With Hypoxic Training In Improving Hepatic Lipid Metabolism In Obese Mice

Ru Wang, Shanshan Guo, Qianqian Tian, Ruwen Wang. Shanghai university of sport, Shanghai, China.
 Email: wangru0612@163.com
 (No relevant relationships reported)

PURPOSE: To explore the effect of hypoxic training on magnesium level, investigate the mechanism of magnesium supplementation combined with hypoxia training on hepatic lipid metabolism in obese mice. **METHODS:** Forty high-fat diet induced C57BL/6J mice were assigned into four groups (n=10 each): Diet-induced obesity (DIO); hypoxia training (HT), living and training in normobaric hypoxic conditions; magnesium supplementation (Mg), the 100mg/kg/d dose of magnesium chloride added to drinking water; hypoxia training+magnesium supplementation (HT+Mg). And set up a chow diet control group (CON). The intervention lasted for 4 weeks. All comparisons were made using two-way ANOVA analysis. **RESULTS:** 1) Serum magnesium in HT group (63.17±0.86 ppm vs 71.85±3.06 ppm) was decreased; femur magnesium in Mg group (2287.71±88.48 ppm vs 2106.89±41.68 ppm) were significant increased after 4 weeks intervention. And the femur magnesium was significantly negatively correlated with body weight (p<0.01, r=-0.645). 2) Compared with DIO group (1.80±0.32 g), liver weight of HT group (1.32±0.17 g), HT+Mg group (1.38±0.23 g) were significantly decreased; 3) Compared with DIO group (19.10±1.82 ng/ml, 8.58±0.41 U/L), serum ATGL level in Mg group (25.43±1.71 ng/ml), HT+Mg group (31.56±2.46 ng/ml) and serum CPT-1 level in HT+Mg group (17.46±1.56 U/L vs) were significantly increased. 4) Compared with DIO group (1.01±0.19), liver PPARα mRNA expression in HT group (1.30±0.28), HT+Mg group (2.32±0.75) were significantly increased; liver ATGL (3.68±2.20 vs 1.04±0.31), LPL (7.72±3.14 vs 1.02±0.21), CPT-1 (6.85±3.89 vs 1.03±0.30) mRNA expression in HT+Mg group were significantly higher than DIO group. Moreover, the PPARα, CPT-1 mRNA expression level was significantly higher than HT group (1.43±0.46). **CONCLUSIONS:** 1) Hypoxic training can significantly reduce femur magnesium, increase the loss of magnesium while effectively losing weight. 2) 4 weeks of hypoxic training combined with magnesium supplementation intervention can effectively reduce the liver weight and hepatic free fatty acid in obese mice; 3)

Hypoxic training combined with magnesium supplementation may promote liver lipolysis and fatty acid beta oxidation by activating liver PPAR α and its downstream factors, improve liver lipid metabolism in obese mice.

3935 Board #252 May 30 9:00 AM - 10:30 AM
Does Varying The Fatty Acid Composition Of A High-fat Meal Modify Postprandial Lipemia?

Breanna L. Davidson, Stephanie P. Kurti, Jeremy D. Akers, Elizabeth S. Edwards, FACSM. *James Madison University, Harrisonburg, VA.*

(No relevant relationships reported)

PURPOSE: The western diet is typically high in saturated fats (SF) or omega-6 polyunsaturated fatty acids (O6) with insufficient amounts of omega-3 polyunsaturated fatty acids (O3). When chronic, this diet has been associated with an increased risk of cardiovascular, metabolic, and respiratory diseases. The purpose of this study was to examine the effect of varying the fatty acid composition of an acute High-Fat Meal (HFM) on postprandial lipemia.

METHODS: Fifteen individuals [6 M, 9 F; body mass index (BMI) = 25.3 \pm 6.6 kg/m²] consumed three HFM smoothies separated by a minimum of 48 hours. The three smoothies were high in SF [63% total fat, <0.02% from O3 and O6], O6 [15:1 O6 to O3], and O3 [15:1 O3 to O6]. All were standardized to 12 kcal/kg body weight, 63% total fat, and 0.72 g/kg sugar. Blood triglycerides (TG) were collected at baseline, 2 hr and 4 hr postprandially.

RESULTS: There was a significant main effect of time for SF HFM and O3 HFM in TG from baseline to 4 hr (P=0.001 and 0.006), and a quadratic effect in TG from baseline to 4 hours in O6 HFM, where TG increased from baseline to 2 hr and returned near baseline values at 4 hr (P<0.001). There was an interaction effect between condition and time effect for TG (P<0.05) and no difference between O3 and O6 TG concentrations at any time point (P>0.05). The TG concentrations were significantly lower from 2 hr to 4 hr postprandially in the high O6 (P=0.005) and high O3 HFMs (P=0.033) compared to the SF HFM, which was increased from 2 to 4h.

CONCLUSIONS: O6 and O3 HFMs led to a more accelerated peak in postprandial TG and trended towards baseline by 4 hr. The SF HFM resulted in a sustained elevation in TG with significantly higher concentrations at 4 hr than at baseline. These findings suggest that varying types of fatty acids can lead to markedly different metabolic responses and that diets high in SF could have prolonged exposure to high blood triglycerides, increasing the risk of atherosclerosis and other chronic diseases.

Association Of Leptin And RMR In Obese Elderly Adults With Different Levels Of Physical Activity

Jingjing Xue¹, Shuo Li², Rou Wen¹, Ping Hong³. ¹*Beijing Dance Academy, Beijing, China.* ²*Shanghai University of Sport, Shanghai, China.* ³*Winter Sports Management Center of the General Administration of Sport of China, Beijing, China.*

Email: xuejingjing@ciss.cn

(No relevant relationships reported)

PURPOSE: The aims of this study were 1) to examine potential sex-related differences in leptin, resting metabolic rate (RMR) and metabolic markers 2) to assess differences in leptin, RMR and metabolic markers between low MVPA group and high MVPA group 3) to assess whether being physically active may play a role in the associations between leptin, RMR and physical activity.

METHODS: The subjects were 73 women (age=64.1 \pm 6.1 years, percent body fat=39.1 \pm 4.8%) and 37 men (age=66.3 \pm 5.6 years, percent body fat=29.7 \pm 4.7%). RMR was measured by indirect calorimetry (Metamax 3B-R2 Metabolic Measurement system, German) and body composition by the DXA (GE Lunar Prodigy, USA). Serum leptin and lipid and glucose metabolism makers' levels were determined by radioimmunoassay. Waist-mounted triaxial accelerometer Actigraph GT3X-BT was used to make objective 7-day recordings of physical activity. Based on the mean of the minutes spent in MVPA (180 min/week), subjects were divided into low MVPA group (n=50, percent body fat=37.1 \pm 7.0%) and high MVPA group (n=56, percent body fat=34.5 \pm 6.1%).

RESULTS: Leptin and HDL cholesterol levels were higher in women than men (both p<0.01), while men presented higher fat free mass and RMR (both p<0.01) than women. Leptin, insulin, HOMA-IR, percent body fat were higher in low MVPA than high MVPA group (all p<0.05), RMR and metabolic markers, however, were not found significant differences (all p>0.05). Leptin levels was associated with RMR negatively and PBF positively (r=-0.36, p=0.013; r=0.645, p=0.0001) in low MVPA group, leptin levels was associated with RMR negatively and PBF positively (r=-0.511, p=0.0001; r=0.631, p=0.0001) in high MVPA group. The negative association of RMR with proportion of sedentary (r=-0.304, p=0.027) and the negative association of leptin with proportion of MVPA (r=-0.303, p=0.023) were only found in high MVPA group.

CONCLUSIONS: Leptin may play a role in energy metabolism in overweight and obese elderly adults. Obesity is associated with energy metabolism and metabolic markers both in women and men. The relationship of leptin with energy

metabolism and insulin resistance might be moderated by levels of physical activity.

Cyclooxygenase 2 Regulates Isoprenaline Induced Adipolysis In Brown Adipocytes

Rongxin ZHU¹, Lijing GONG², Guang CAI¹. ¹*Shanghai Research Institute of Sports Science, Shanghai, China.* ²*Beijing Sport University, Beijing, China.*

(No relevant relationships reported)

PURPOSE: By converting fat into heat, brown adipocytes (BAC) play as an energy expenditure in mammalian. Cyclooxygenase 2 (COX2) is a key factor of Uncoupling protein 1 (UCP1) synthesis which is essential for dissipates energy into heat via adipolysis. Isoprenaline (ISO) can induce adipolysis in brown adipocytes (BAC); however, whether COX2 takes part in ISO induced adipolysis remains unclear.

METHODS: C₃H₁₀T_{1/2} cells were differentiated into brown adipocytes. BACs were treated with 10 μ M ISO or 10 μ M ISO and 100 μ M NS-398 (COX2 inhibitor) for 0 (as control), 1, 3, 6, 12 or 24 hours. For lipid droplet (LP) size analysis, cells were fixed and stained with Oil Red O. Images were captured with a Leica CTR 4000 microscope with 10x objectives. All images were thresholded for LPs signal and watershed for individual LP size analysis using Image J. Data were loaded into GraphPad Prism 8 for LP size analysis and size frequency distribution. BACs were collected for UCP1 expression detection after 6-hour-incubation (beta tubulin as loading control). All results are presented as means \pm std. error of mean. Statistics were performed in SPSS using Student's t test.

RESULTS: Average LP size decreased as ISO incubation time prolonged (113.67 \pm 2.40, 115.69 \pm 2.21, 83.61 \pm 1.69, 35.00 \pm 0.88, 31.60 \pm 0.69, 34.28 \pm 0.77 μ m² after 0, 1, 3, 6, 12, 24 hours incubation, respectively). Incubation of ISO and NS-398 slowed down the rate of LP size reduction (95.08 \pm 1.65, 107.73 \pm 2.26, 85.22 \pm 1.87, 56.97 \pm 1.49, 41.32 \pm 0.87, 37.43 \pm 0.65 μ m² after 0, 1, 3, 6, 12, 24 hours incubation, respectively; slope (-53.04 \pm 1.21 vs. -65.45 \pm 1.33) LP size frequency distribution showed a shift of LP size towards smaller LPs following incubation with ISO. Inhibition of COX2 activity can delay the occurrence of left shift (became smaller) of LP size frequency distribution (12h vs. 3h). UCP1 expression were lower following ISO and NS-398 incubation than those treated with ISO only (0.74 \pm 0.08 vs. 1.00 \pm 0.00, p<0.05).

CONCLUSION: COX2 inhibition can repress ISO induced adipolysis in BACs and may related to a decrease in UCP1 expression.

Correspondence Between Indexes Of Maximal Fat Oxidation From Ramp Vs Steady-state Protocols In Postmenopausal Women

Massimo Teso, Luca Ferrari, Alessandro L. Colosio, Silvia Pogliaghi, FACSM. *Università di Verona, Verona, Italy.*

Email: massimo.teso@libero.it

(No relevant relationships reported)

Maximal fat oxidation (MFO, in g^l·min⁻¹) is an index of metabolic flexibility and the relative exercise intensity at MFO (FAT_{max} as % maximum oxygen consumption (VO_{2max})) is used for exercise prescription for weight loss and metabolic health. The time-consuming, steady-state protocol required for MFO/FAT_{max} determination hinders the extensive use of these indexes. Alternative, ramp testing has been validated for MFO/FAT_{max} determination in healthy, young males only. **PURPOSE:** to validate ramp testing for MFO/FAT_{max} measure in post-menopausal women.

METHODS: 18 sedentary, postmenopausal women (54 \pm 4 years; 4 \pm 3 years from menopause; 22 \pm 3 BMI) performed on a cycle ergometer: *i*) a ramp incremental test; *ii*) steady-state trials at 40, 50, 60, 70 and 80% of the VO_{2max} as determined by the incremental test. We measured VO₂, respiratory exchange ratio (R) and heart rate (HR). Based on VO₂ and R from the ramp test (breath-by breath data) and steady-state protocol (5th minute of each trial) we measured absolute fat oxidation (FO, in g^l·min⁻¹); then, we determined MFO in absolute units (in g^l·min⁻¹) and the relative intensity corresponding to MFO, i.e. FAT_{max}, that was expressed relative to VO_{2max} and directly determined maximal HR (HR_{max}). MFO and FAT_{max} from the ramp (MFO_{ramp} and FAT_{max,ramp}) were compared to the values from the steady-state protocol (MFO_{ss} and FAT_{max,ss}) by paired t-Test.

RESULTS: The MFO was significantly lower than MFO (0.39 \pm 0.13 vs 0.19 \pm 0.07 g·min⁻¹ p<0.001). On the contrary, the FAT_{max} and FAT_{max} occurred at an identical %VO_{2max} (45 \pm 6 vs 47 \pm 7% VO_{2max} p=0.17) and %HR_{max} (61 \pm 6 vs 62 \pm 6% HR_{max} p=0.54).

CONCLUSIONS: In agreement with previous studies conducted in young males, our data confirm that only steady-state protocols allow accurate MFO quantification. On the contrary, accurate measures of FAT_{max} can be obtained indifferently from both ramp and steady-state protocols in post-menopausal women. Therefore, ramp testing offers a valid alternative to more time-consuming steady-state protocols for the identification of

optimal exercise intensity for weight loss and metabolic health. Time-efficient testing strategies have a high practical value for longitudinal/large-scale evaluation of fat metabolism in postmenopausal women offering the means for individualized exercise prescription.

The Effects Of Exercise, Estrogens, And Diet On Hepatic Protein Expression In Type 2 Diabetes

Brittany Gorres-Martens¹, Adam Roskam², Skylar McCaulley³, Alex Jacobs⁴. ¹Augustana University, Sioux Falls, SD. ²Mount Marty College, Yankton, SD. ³University of Sioux Falls, Sioux Falls, SD. ⁴Dakota Wesleyan University, Mitchell, SD.
 Email: brittany.gorres-martens@augie.edu
 (No relevant relationships reported)

Exercise can ameliorate Type 2 Diabetes (T2D), and studies also show that estrogens may prevent the onset of T2D. Thus, postmenopausal women may be at a greater risk for T2D. While the effects exercise, estrogens, and diet on whole body risk factors for T2D are established, little is known about the cellular changes in the liver that account for these whole body beneficial effects. **PURPOSE:** To examine the effects of exercise, estrogens and diet on hepatic protein expression. **METHODS:** Female Wistar rats were fed a standard diet (SD) or a high-fat diet (HFD) for 10 weeks. A subset of the rats had their ovaries removed via ovariectomy (OVX). The rats were given treatment of treadmill exercise (25 minutes/day at 40 cm/s for 5 days/week (Ex)) or estradiol replacement (E₂; 1.4 µg/day). At the end of the study, the liver was removed and homogenized in cell extraction buffer, and the protein was isolated. Western blot analyses were performed to measure the expression of the following proteins involved in lipid metabolism and mitochondrial function: acetyl-coA carboxylase (ACC), fatty acid synthase (FAS), hormone sensitive lipase (HSL), lipoprotein lipase (LPL), citrate synthase, and cytochrome c oxidase (COX) IV. **RESULTS:** The HFD decreased the ACC expression compared to the SD (0.59 vs. 0.93 AU, p<0.05), and E₂ treatment restored these values (0.81 AU, p<0.05). Similarly, the HFD decreased the FAS expression compared to the SD (0.44 vs. 1.58 AU, p<0.05), and E₂ treatment restored these values (0.75 AU, p<0.05). The HFD increased the LPL expression compared to the SD (1.58 vs. 1.15, p<0.05), and E₂ treatment decreased the LPL expression (1.32 AU, p<0.05). There was no effect of Ex on the ACC, FAS, or LPL expression. The expression of HSL, citrate synthase, and COX IV did not change with diet, E₂ replacement, or Ex. **CONCLUSION:** Two proteins that stimulate de novo fatty acid synthesis (ACC and FAS) decreased with the HFD, likely due to the exogenous intake of fats. Notably, E₂ replacement increased the ACC and FAS expression, even though the HFD was still being consumed. LPL is a protein that stimulates fat storage. Consumption of the HFD increased the LPL expression to increase fat storage, and E₂ replacement decreased the LPL expression. Thus, E₂ may provide benefits by decreasing fat storage. Supported by NIH Grant P20GM103443 and NSF Grant IIA-1355423.

Ethnicity Mediates Change In Fat Oxidation In Response To High Intensity Interval Training (hiit)
Ethnicity Mediates The Magnitude Of Change In Fat Oxidation In Response To High Intensity Interval Training (hiit)

Todd A. Astorino, FACSM¹, Jamie L. De Revere¹, Rasmus Clausen¹, Sean Walsh, FACSM². ¹California State University-San Marcos, San Marcos, CA. ²Central Connecticut State University, New Britain, CT.
 Email: astorino@csusm.edu
 (No relevant relationships reported)

Ethnicity Mediates The Magnitude Of Change In Fat Oxidation In Response To High Intensity Interval Training (HIIT)

One response to high intensity interval training (HIIT) is increased fat oxidation (FOx) (Astorino et al. 2017) which is due to enhanced oxidative capacity and activity of β-HAD (Talanian et al. 2007). In the U. S., Hispanic adults have a higher rate of obesity than Caucasians (Hales et al. 2017), and have twofold higher rate of diabetes (CDC 2018). It is unknown if ethnicity alters FOx responses to HIIT. **PURPOSE:** To assess the role of ethnicity in mediating FOx changes with HIIT. **METHODS:** Eleven inactive Caucasian (C) and 7 Hispanic women (H) (age = 25 ± 6 yr) participated in the study. Initially, VO₂max and peak power output (PPO) were determined. On two separate days after a minimum 6 h fast, they completed five stages of progressive exercise at 10 - 50 %PPO during which gas exchange data were acquired to calculate RER, FOx, and carbohydrate oxidation (CHOOx). Fingertip blood samples were used to measure blood lactate concentration (BLA). HIIT consisted of 9 sessions of cycling at 85 %PPO separated by 75 s recovery. **RESULTS:** HIIT increased VO₂max by 10 and 8 % in C and H with no effect of ethnicity (p = 0.69). RER increased during exercise (p < 0.001) and timeXtraining (p = 0.001) and timeXtrainingXgroup

interactions (p = 0.012) were shown. Fat oxidation differed during exercise (p = 0.001) and there was a timeXtrainingXgroup interaction (p = 0.03). Post hoc analyses showed significantly higher FOx post-HIIT at 10 (0.19 ± 0.04 g/min vs. 0.16 ± 0.04 g/min) and 20 %PPO (0.17 ± 0.03 g/min vs. 0.14 ± 0.04 g/min) versus baseline in H. Data showed a 10 - 35 % reduction in CHO oxidation (p = 0.01) after HIIT and a timeXtraining interaction (p = 0.01), but no timeXtrainingXgroup interaction (p = 0.32) was shown. BLA increased during progressive exercise (p < 0.001) and there was a reduction in BLA during exercise in response to training (p = 0.002) that was similar in C and H (p = 0.28). **CONCLUSION:** These preliminary data obtained in inactive women suggest that ethnicity may alter changes in energy metabolism observed in response to short-term interval training. Further work is needed to examine the mechanisms underpinning this potential effect of ethnicity on adaptation to training.

Dietary Fat Retention In Cortical Bone In Rats Fed High Fat Diet

Beatriz Bermudez¹, David M. Presby², Rebecca M. Foright², Numair Javed¹, Matthew R. Jackman², Janine A. Higgins², Ginger C. Johnson², Robert D. Carpenter¹, Paul S. MacLean², Vanessa D. Sherker². ¹University of Colorado Denver, Denver, CO. ²University of Colorado Anschutz Medical Campus, Aurora, CO.
 Email: beatriz.bermudez@ucdenver.edu
 (No relevant relationships reported)

Excess adiposity during childhood and adolescence are associated with poorer bone quality and increased risk of fracture. A high fat diet (HFD) may promote marrow adipogenesis at the expense of osteogenesis and may also promote excess lipid accumulation in osteoblasts and osteocytes. Exercise is prescribed for bone health primarily because of its mechanical loading attributes, but little is known about how obesity or exercise training status affects nutrient trafficking and retention in bone. **PURPOSE:** To determine the effects of obesity and exercise on fat retention in bone. **METHODS:** Female Wistar rats, 5 weeks in age (n=18), were fed a high fat diet (HFD) for 20 weeks and designated as obese (OB) or lean (LN) based on weight gain. OB and LN rats performed treadmill running (EX) (5 d/w, 1h/d, 15 m/min) or sedentary control (SED) for 10 weeks. In a 24-hour tracer study, rats were given ad libitum access to 14C oleate and 14C palmitate blended in food. Marrow was removed from hind limb bones and lipid was extracted from the remaining cortical bone. Data are mean ± SEM. **RESULTS:** Fat intake was not different between groups. Obesity status had no significant effect on fat retention in cortical bone. Lipid in hindlimb cortical bone was higher in EX compared to SED (EX: 6.66 ± 1.64 vs SED: 1.50 ± 1.47 mg, p<0.05). LNEX had the highest dietary fat retention in cortical bone lipid compared to other groups (LNEX: 0.69 ± 0.14, OBEX: 0.24 ± 0.14, LNSED: 0.27 ± 0.13, OBSED: 0.41 ± 0.13 mg, interaction p<0.05). The proportion of the meal retained, and the magnitude of lipid turnover did not differ between groups. Dietary fat retention in bone was positively (p<0.05) associated with fat intake, bone mineral density and bone mineral content (BMC; r=0.51-0.64). BMC in bone was associated (r=0.54, p<0.05) with total energy expenditure. **CONCLUSION:** Although cortical bone constitutes a minor fraction of overall dietary fat retention, we demonstrate that fat is trafficked to and retained in cortical bone in proportion to meal size and bone size. Future work is needed to test whether fat accumulation influences the ability to adapt to mechanical loading.

Effect Of A 21-day Well-formulated Ketogenic Diet On Women's Metabolic Health: Glow Pilot Trial

Catherine Saenz. Jacksonville University, Jacksonville, FL.
 (Sponsor: Carena Winters, FACSM)
 (No relevant relationships reported)

Cardiovascular disease (CVD) is a pandemic that is the leading cause of death for women in the United States. This is particularly alarming as the primary etiologies for CVD are lifestyle related Nutrition interventions, such as well-formulated ketogenic diets (WKFD), improve metabolic health and reduce risk factors associated with CVD but it is unknown if these improvements in health can be observed within the first three weeks of carbohydrate restriction. **Purpose:** The purpose of this study was to examine the effectiveness of a WKFD on women's metabolic health. **Methods:** Twenty-two women (Age (yr.) 42.2 ± 8.1, Ht. (cm) 164.2 ± 5.9, BMI 27.3 ± 6.0) participated in a 21-day, eucaloric diet study. Anthropometrics, body composition (InBody 570), fasted capillary-blood ketones, glucose (BG), and cholesterol panel, and diet records were

collected before (PRE) and after (POST) intervention. **Results:** Women maintained calories (PRE: 1938kcal vs POST: 1836kcal) and protein levels (PRE: 17% vs POST: 20%) but decreased dietary carbohydrate (PRE: 36% vs POST: 13%) and increased dietary fat (PRE: 45% vs POST: 65%) PRE to POST ($p \leq 0.05$). Weight (PRE: 73.9kg vs POST: 72.3kg) and body fat (PRE: 56.9kg vs POST: 54.0kg) significantly decreased but there were no differences in lean body mass PRE to POST ($p \leq 0.05$). BG (PRE: 94.0mmol/L vs POST: 89.9mmol/L) decreased significantly, with 73% of women decreasing BG from PRE to POST ($p \leq 0.05$). Ketones increased significantly and 58% of women reached nutritional ketosis by POST testing ($p \leq 0.05$). There were no differences in cholesterol panel except for LDL, which increased from PRE (111.1mg/dL) to POST (124.2mg/dL) ($p \leq 0.05$). **Conclusion:** Women's metabolic health is an immediate concern for the silent killer known as CVD in this population. Finding safe, systemic interventions to this pandemic are imperative. WFKD improved some, but not all, metabolic markers within 21 days. This highlights the initial shifts in metabolic health related to WFKD nutritional interventions and calls for additional research to help better understand the underlying mechanisms of WFKD on metabolic health, especially as it relates to cholesterol metabolism, and the timeline of these events.

Effects Of Ketogenic Diet Containing Medium-chain Triglyceride And Endurance Training On Metabolic Enzyme Adaptations.

Ayumi Fukazawa, Atsuko Koike, Takuya Karasawa, Momoko Tsutsui, Saki Kondo, Shin Terada. *The University of Tokyo, Tokyo, Japan.*
 Email: fukazawa.a01@gmail.com
 (No relevant relationships reported)

Purpose:

Long-term intake of very low-carbohydrate, high-fat (ketogenic) diets enhance production and utilization of ketone bodies, which are more energy-efficient fuels for skeletal muscle. However, adaptation to the extremely low-carbohydrate diet has been shown to upregulate pyruvate dehydrogenase kinase 4 (PDK4) content in skeletal muscle, which is a negative regulator of glycolytic flux, resulting in the impaired high-intensity exercise capacity. Because medium-chain triglyceride (MCT) can produce more ketone bodies than long-chain triglyceride (LCT), incorporating MCT into the diet may allow more carbohydrates yet preserving ketosis and exert less inhibitory effect on muscle glucose metabolism. The purpose of this study was therefore to examine the effects of long-term feeding of ketogenic diet containing MCT on the endurance training-induced adaptations in metabolic enzymes of rat skeletal muscle.

Methods:

Male Sprague-Dawley rats (7-week-old) were placed on a standard diet (PFC ratio = 21:16:63), LCT-containing ketogenic diet (LKD, PFC ratio = 12:87:1) or MCT-containing ketogenic diet (MKD, PFC ratio = 16:66:18) for 8 wks. Half the rats in each group performed 2-h swimming exercise, 5 days a week for 8 wks. After the 8-wk intervention, protein expressions of 3-oxoacid CoA transferase 1 (OXCT, a ketolytic enzyme) and PDK4 in epitrochlearis muscle were measured.

Results:

Despite the lower lipid content in the diet, plasma β hydroxybutyrate concentration in the MKD-fed rats increased to a level similar to that attained in the rats fed the LKD (85 ± 7 vs. 83 ± 8 mmol/L day, $p = 0.99$). Endurance training significantly increased OXCT protein content in epitrochlearis muscle and moreover, intake of the MKD additively enhanced the endurance training-induced increase in OXCT protein content. PDK4 protein level in skeletal muscle was substantially increased after the LKD consumption. However, such increase in the PDK4 was not observed in the MKD-fed rats regardless of endurance training status.

Conclusion:

Long-term intake of ketogenic diet containing MCT may additively enhance endurance training-induced ketone bodies utilization capacity in skeletal muscle without exerting inhibitory effects on glucose metabolism.

Beta-hydroxybutyrate (bhb) Ketone Salt Supplement Alters Energy Metabolism, Blood Glucose And Ketone Levels

Miranda Thompson, Svetlana Nepocatych. *Elon University, Elon, NC.* (Sponsor: Eric Hall, FACSM)
 (No relevant relationships reported)

Ketone supplements were found to produce acute nutritional ketosis (defined as having a blood ketone level of 0.5-3.0 mM), suppress appetite, lower plasma ghrelin levels and perceived hunger. **PURPOSE:** To determine the acute effect of beta-hydroxybutyrate (BHB) ketone salt (KS) on appetite profile, energy metabolism, blood glucose and ketone levels and subsequent energy intake. **METHODS:** Twenty-two healthy females (age: 26 ± 7 y, BF%: 28.6 ± 8.2 , BMI: 26.1 ± 8.6 kg/m²) were recruited to participate in a single-blind crossover study design. Participants were randomly assigned to consume either 0.25g/kg of KS or flavor matched placebo (PL).

During each visit, participants completed an appetite profile survey using a visual analogue scale (VAS) before, at 0, 30, 60 and 90 minutes. Indirect calorimetry using ventilated hood technique was used to measure thermic effect of a supplement at 30-45 and 75-90 minutes. Blood glucose, ketone levels and affect were measured before, at 0, 45 and 90 minutes. Energy intake following an ad libitum breakfast was recorded. A repeated measures ANOVA was used for analysis with significance accepted at $p < 0.05$. **RESULTS:** A significant difference over time ($p < 0.001$) but not between supplements ($p > 0.05$) was observed for appetite profile. A significant interaction supplement over time was observed for VO₂ ($p = 0.007$) but not RQ ($p = 0.28$). A significant supplement effect was observed for blood glucose (KS: 83 ± 10 , 84 ± 8 , 82 ± 8 mg/dL and PL: 88 ± 10 , 89 ± 8 , 86 ± 9 mg/dL, $p = 0.04$) and ketone levels (KS: 0.3 ± 0.2 , 0.5 ± 0.2 , 0.4 ± 0.2 mM and PL: 0.3 ± 0.3 , 0.2 ± 0.2 , 0.2 ± 0.2 mM, $p < 0.001$) at 0, 45 and 90 min, respectively. However, no significant difference in energy intake at breakfast ($p = 0.94$) was observed between KS: 200 ± 116 kcal and PL: 203 ± 107 kcal. **CONCLUSIONS:** Ketone salt supplement caused modest elevation in blood ketone levels and reduced glucose, suggesting improved glycemic control, however, did not have an effect on perceived satiety or energy intake.

Combined Effects Of 5-week Ketogenic Diet With Different Exercise Interventions On Lipid Metabolism In Skeletal Muscle Of Obese Mice

XIAOFEI WANG¹, BING ZHANG², WEIMO ZHU, FACSM³.
¹Beijing Normal University, Beijing, China. ²Tsinghua University, Beijing, China. ³University of Illinois at Urbana Champaign, Urbana, IL. (Sponsor: Weimo Zhu, FACSM)
 Email: 15652662676@163.com
 (No relevant relationships reported)

PURPOSE: To determine the effect of ketogenic diet with exercise on the expression of lipid metabolism related to proteins and genes in skeletal muscle of obese mice.

METHODS: 45 twelve-week obese male C57BL/6J mice were divided into ketogenic diet group (KD), ketogenic diet combined with HIIT group (KH) and ketogenic diet combined with MICT group (KM), 15 mice in each group. Exercise was performed on the treadmill without slope, 6 days a week, 1 hour a day. Both groups started with warm-up exercise, in KH group, followed by 10 rounds of 4-minute high-intensity treadmill exercise and 2-minute active rest between; In KM group, moderate intensity continuous running with the same distance as KH was performed. The energy composition of ketogenic diet was: protein 10%, fat 90%, carbohydrate 0%. Western blot was used to detect the protein contents of pAMPK α , AMPK α (Thr172), PGC-1 α , PPAR α and CPT-1 in skeletal muscle, and RT-PCR was used to detect the mRNA expression of Acadl and Acox1 genes. One-way ANOVA was used for the data analysis.

RESULTS: Compared with KD group, the expression of all protein and mRNA in KH group increased significantly ($P < .05$). Compared with KD group, the expression of pAMPK α /AMPK α ratio, PGC-1 α , CPT-1 protein and Acadl mRNA in KM group increased significantly ($P < .05$). Compared with KM group, the expression of pAMPK α /AMPK α ratio and PPAR α protein in KH group increased significantly ($P < .05$; see Table 1 for details:

Table 1. Statistical summary of relative expression of protein and gene in skeletal muscle of mice

Group	KD (M \pm SD)	KH (M \pm SD)	KM (M \pm SD)
pAMPK α /AMPK α	1 \pm 0.16	2.52 \pm 0.4 [#]	1.92 \pm 0.15 ^{###}
PGC-1 α	1 \pm 0.24	3.15 \pm 0.39 [#]	3.06 \pm 0.34 [#]
PPAR α	1 \pm 0.05	1.27 \pm 0.14 [#]	0.78 \pm 0.09 ^{**}
CPT-1	1 \pm 0.28	3.01 \pm 0.41 [#]	2.14 \pm 0.35 [#]
Acadl	1 \pm 0.40	1.57 \pm 0.21 [#]	1.48 \pm 0.19 [#]
Acox1	1 \pm 0.23	1.57 \pm 0.23 [#]	1.37 \pm 0.11

Note: Compared with KD group, [#] $P < .05$, ^{###} $P < .01$; Compared with KH group, * $P < .05$, ** $P < .01$.

CONCLUSION: Ketogenic diet combined with exercise was more effective than ketogenic diet alone in enhancing the lipid metabolism of skeletal muscle. Compared with KM, KH is more effective in enhancing the lipid metabolism level of skeletal muscle in mice, mainly through the enhancement of AMPK-PGC-1 α -PPAR α mediated lipid metabolism pathway.

Extended Ketogenic Diet Is Necessary For Increases In Protein Acetylation

Tommy Tran, Suraj P. Pathak, Nicole Baker, Zeyu Zhou, Jon J. Ramsey, Keith Baar, FACSM. *UC Davis, Davis, CA.* (Sponsor: Keith Baar, FACSM)
 Email: ytttran@ucdavis.edu
 (No relevant relationships reported)

Decline in mitochondrial function is associated with a decrease in lifespan. We have previously demonstrated that a long-term ketogenic diet (KD) improves mitochondrial function and longevity. However, a life-long KD is difficult to maintain and an intermittent KD might be more viable long term.

PURPOSE: Determine how long it takes before a ketogenic diet alters muscle metabolism so that intermittent diets can be developed.

METHODS:

Four C57BL/6 mice were fed a control diet or 1 or 7 days of continuous KD. At the time of sacrifice, livers, gastrocnemius, brain and kidneys were extracted and frozen in liquid nitrogen before being powdered and homogenized in sucrose lysis buffer and prepared for western blot analysis to determine total acetylated lysine content, total OXPHOS protein, or acetylated p300 content.

RESULTS: Following one day of KD, neither acetylated, nor mitochondrial proteins were different than control diet. By seven days of continuous KD diet, total acetylated proteins increased in the liver, kidney and gastrocnemius muscle. Specifically, acetylation of p300 was 3.4±0.89-fold greater following 7 days of KD. Unlike the other tissues the brain showed no difference in acetylated proteins by 7 days. An increase in mitochondrial mass was only seen in the liver at 7 days of KD.

CONCLUSIONS:

A short term ketogenic diet can be used to rapidly alter protein acetylation in the liver, kidney and muscle. These data suggest that an intermittent keto diet may be useful in promoting a biochemical change in muscle that promotes mitochondrial function and may benefit long-term muscle function.

 Email: andressaabreu_82@hotmail.com
 (No relevant relationships reported)

PURPOSE: The aim of this study is to evaluate the validity of the prediction equation of the Metabolic Rest Rate (MRR) prescribed in an indirect way. This measure would be very helpful in the nutritional counseling, because many people don't have access to indirect calorimetry tests (ICT).

METHODS: 143 volunteers were selected. They made the ICT using the Metacheck® calorimeter, equipped with the gas analyzer. The MRR was collected as well as the Body Weight (BW) - kg, Height (H) - cm, and Age (A) - years. We also calculated the Body Mass Index (BMI) - kg/m². These metrics were used considering the MRR as an independent variants and the others (BW, H, A, BMI) as dependent variables. A linear regression was made to obtain a prediction equation to estimate the MRR.

RESULTS: After made all the necessary verifications for using the multivariate data analysis, a linear regression was made using the Stepwise method. The final equation was $MRR = -690,55 + (12,65 \times BW) + (897,71 \times H) - (5,03 \times A)$. The "R" of the equation was 0.901 and the determinant coefficient was 0.812.

	Age	Weight	Height	BMI	MRR
Mean	36,74	74,62	1,65	27,23	1.551,18
Standard Deviation	11,23	17,78	0,91	5,42	301,26

CONCLUSIONS: This trial showed that is possible to estimate the MRR through equations, since the determinant coefficient is adequated. In this trial, we worked with a general equation, but it is possible to work with equations for specific populations, regarding the sex, age, gender and other aspects

Evaluating The Accuracy Of Basal Metabolic Rate Prediction Equations For Masters Athletes

Kianna H. Ly, Joseph R. Stanzione, Stella L. Volpe, FACSM. *Drexel University, Philadelphia, PA.* (Sponsor: Stella L. Volpe, FACSM)
 Email: KHL35@drexel.edu
 (No relevant relationships reported)

Basal metabolic rate (BMR) is the energy required to perform basic metabolic functions at rest. Indirect calorimetry is one method of measuring BMR, but it can also be predicted using BMR prediction equations. Depending on the equation used, a prediction can take into account a combination of different factors (e.g., age, body weight, height, lean body mass, fat mass). These equations tend to overestimate BMR. However, most of the researchers relied on small sample sizes or specific populations.

PURPOSE: To determine the accuracy of BMR prediction equations for Masters Athletes. **METHODS:** Two hundred and eighty-five athletes (157 women, 128 men; ≥ 26 years of age) representing a number of sports and physical activities, who exercised at least twice a week and were non-smokers, participated in our cross-sectional study. Resting metabolic rate (RMR) was measured using indirect calorimetry. Prior to measuring RMR, participants fasted and refrained from caffeine for 12 hours, avoided alcohol and exercise for 24 hours, and rested in a recliner for 15 minutes prior to data collection. Body composition was determined using dual-energy X-ray absorptiometry (DXA). We compared the Mifflin-St. Jeor, Harris-Benedict, Cunningham, and Owen to indirect calorimetry using one-way analysis of variance (ANOVA) with repeated measures. **RESULTS:** We found that indirect calorimetry measured significantly lower ($p < 0.001$) kilocalories (kcal) compared to any of the four prediction equations. The Mifflin-St. Jeor equation was more closely aligned with indirect calorimetry for all participants combined and women (mean difference, percent accuracy: 115, 54.8%; 95, 57.2%, respectively) compared to indirect calorimetry. However, the Owen equation was more accurate for men (98, 61.3%). The Cunningham equation generated the highest mean difference and lowest percent accuracy for all participants combined, women, and men (234, 29.1%; 221, 23.6%; 250, 35.9%, respectively). **CONCLUSIONS:** We found that the four BMR prediction equations analyzed significantly over-predicted BMR compared to indirect calorimetry. Our results emphasize the need for a more appropriate BMR prediction equation for athletes. This study was not funded

Comparison Between Measurement Of Resting Metabolic Rate By Indirect Calorimetry And Predictive Equation

Taina Schapinski¹, Andressa Abreu¹, Bráulio H M Branco², Emilson Colantonio³, Fabio Buscariollo¹, Domingos R. Pandelo, Jr¹. ¹*Centro de Alta Performance, Santos, Brazil.* ²*Unicesumar, Santos, Brazil.* ³*UNIFESP, Santos, Brazil.*
 Email: tataschapinski@hotmail.com
 (No relevant relationships reported)

PURPOSE: The aim of this study is to evaluate the validity of the predictive equation of the Metabolic Rest Rate (MRR) with the utilization of a bioimpedance equipment in comparison with the results obtained with indirect calorimetry test (ICT).

METHODS: 27 subjects (17 female and 10 male), all volunteers, were selected. As the first step of the trial, the volunteers had their MRR calculated by a tetrapolar bioimpedance equipment (Biodynamics 310A®) - MRRbio. Afterwards, the volunteers undergone an ICT (Metacheck®) with a gas analyzer - MRRcal.

RESULTS: Differences were found in the measures of 12 of the 27 volunteers. The effect size was calculated between the measures and the result was 0.0083, demonstrating a very low value. However, this number is deceptive, as the variation in the results can be positive or negative. We had the impression of a small difference between the groups that is not true, and it can be verified when we work the variations in modules ($|\Delta\% \text{MRR}|$). The highest positive variation was 332,5 calories (a variation of 27,31% between the MRRcal and MRRbio) and the highest negative variation was 271,2 calories (negative variation of 18,46%).

	Age	Body Weight	Height	BMI	MRR (Cal)	MRR-cal-MR-Rbio	$ \Delta\% \text{MRR} $
Mean	38,70	77,04	1,65	28,21	1.598,42	2,94	7,77%
SD	12,45	20,00	0,09	6,88	304,84	146,24	6,40%

CONCLUSIONS: This trial showed that the estimated MRR through equations can have a wide range of variability, with the possibility of significant errors in the clinic point of view. Because of this, the indirect calorimetry test with a gas analyzer is recommended whenever is possible to minimize errors in the measurements

Resting Energy Expenditure In Crossfit® Practitioners: Indirect Calorimetry Versus Predictive Equations

Marcio SOUZA¹, MARALINE SENA², VALDEN CAPISTRANO JUNIOR³. ¹FACULDADE DE MINAS FAMINAS BH, BELO HORIZONTE, Brazil. ²STATE UNIVERSITY OF CEARA, FORTALEZA, Brazil. ³FEDERAL UNIVERSITY OF CEARA, FORTALEZA, Brazil.

Email: marcionutricionista@yahoo.com.br

(No relevant relationships reported)

BACKGROUND: Indirect calorimetry (IC) is the gold standard method to assess individual resting energy expenditure (REE). However, due to its high cost and time demand, predictive equations are largely used to estimate energy requirements, which may vary according to different body compositions and health status. Crossfit® is a training program created by Greg Glessman in 1995 and consists of performing high intensity functional movements. Some studies have already reported increase of metabolic rates in this population.

PURPOSE: To measure REE in Crossfit® practitioners, using IC, and verify the most appropriate predictive equation to estimate this variable.

METHODS: 142 Crossfit® practitioners, 91 female (64.1%), aged between 16-59 years, underwent nutritional assessment, including weight, height, waist circumference (WC) and body mass index (BMI). Body composition was measured by a portable ultrasound. REE was measured by IC (mREE) and predicted by six different equations (pREE): Harris-Benedict, World Health Organization (WHO), Henry and Rees, Cunningham (1980), Cunningham (1991), and Mifflin-St.Jeor. Statistical analysis were carried out by Kolmogorov-Smirnov Test, Student's *t* test and Bland and Altman plots.

RESULTS: The mean age was 33.0 ± 6.3 years of age, without difference between men and women. The mean BMI was 24.7 ± 3.5 kg/m². The mean mREE was 1583.2 ± 404.4 kcal, and the pREE ranged from 1455.5 ± 230.9 kcal to 1711.3 ± 285.5. The best REE predictive equations for Crossfit® practitioners were the Cunningham (1991) (*P*=0.338), WHO equation (*P*=0.494) and Harris-Benedict (*P*=0.705). Harris-Benedict presented the smaller difference comparing with IC (12.9 ± 307.6 kcal), Cunningham (1991) showed better adequacy (102.5%) and WHO equation presented greater percentage of accuracy (59.9%). The same equations remained adequate when data were stratified by gender.

CONCLUSIONS: This study showed that Cunningham (1991), WHO (1985) and Harris-Benedict (1919) equations were the most appropriated REE equations for Crossfit® practitioners. Further studies should investigate more suitable methods to determine the energy requirements in Crossfit® and should, perhaps, create and propose a specific equation for this population.

3951 Board #268 May 30 9:00 AM - 10:30 AM
Comparison Of The Effects Of Sprint Interval Vs. Steady State Exercise On Resting Metabolic Rate

Chad A. Witmer, Ellen Stinger, Shala E. Davis, FACSM, Emily Sauters, Connor Saker, Samantha Fessler. East Stroudsburg University, East Stroudsburg, PA.

(No relevant relationships reported)

Exercise is a modality that may result in an elevation of resting metabolic rate (RMR) due to homeostatic disruption. Sprint Interval Training (SIT) exercise is widely recognized as a time efficient, low-volume, high-intensity alternative to endurance training and, in acute phases, may elevate RMR for longer durations. **PURPOSE:** To compare the effects of an acute bout of SIT vs. steady state (SS) vs. control (CON) on 24-h RMR in recreationally active college-aged males. **METHODS:** In this randomized crossover design, 13 recreationally active males ages 18-30 yrs. (24.1 ± 2.3) participated in three exercise sessions using an electronically braked cycle ergometer: SIT (5, 30-sec. sprints, interspersed with 4-min. active recovery), SS (70% VO_{2 peak} for 30 min.) and CON. Exercise sessions were separated by one week. All sessions included 7 RMR measurements taken at the same times over a 24-h period (8am resting, 8:50am pre-ex, 10:10am post-ex, 12:10pm 2-h post-ex, 1:00pm 3-h post-ex, 4:00pm 6-h post-ex and 10:10am the following morning 24-h post-ex). RMR comparisons were made using two-way ANOVA with repeated measures. **RESULTS:** There was a significant main effect for group with regard to RMR (*F*=5.706; *p*=.043) with no effect of time (*F*= 5.351; *p*=.113) or group x time interaction (*F*=1.486; *p*=.066). There was a significant difference between SS (2116 kcal) and CON (1891 kcal) (*p*=.009) and SIT (2105 kcal) and CON (1891 kcal) (*p*=.012). SS (2116 kcal) and SIT (2105 kcal) were not different (*p*=.994). There was a significant effect for time between combined exercise (CE) condition vs. CON when comparing rest to pre (Δ CE = 582 kcal vs. Δ CON = 498 kcal) (*p*=.002), rest to post-ex (Δ CE = 628 kcal vs. Δ CON = 211 kcal) (*p*=.034), and rest to 6-h post (Δ CE = 716 kcal vs. Δ CON = 193) (*p*=.016). There was a significant group x time interaction for CE vs. CON (*p*= .034). Post-hoc analysis revealed statistical differences in measurements 2-h post (*p*= 0.018; 455 kcal), 3-h post (*p*= 0.002; 599 kcal) and a trend towards statistical significance at 6-h post (*p*=

.076; 340 kcal) and 24-h post (*p*=0.103; 313 kcal). **CONCLUSION:** A single bout of SIT may significantly elevate post-exercise RMR, and if repeated regularly, may confer longer-term benefits similar to that produced by 30 minutes of SS exercise.

Effects Of Adiposity And Body Composition On Adjusted Resting Energy Expenditure In Women

Lacey M. Gould, Gabrielle J. Brewer, Katie R. Hirsch, Malia N. M. Blue, Hannah E. Saylor, Abbie E. Smith-Ryan, FACSM. University of North Carolina at Chapel Hill, Chapel Hill, NC.

(Sponsor: Abbie Smith-Ryan, FACSM)

(No relevant relationships reported)

PURPOSE: To compare adjusted resting energy expenditure (REEa) and contributions of skeletal lean mass (SM) and fat mass (FM) to REEa in women at varying levels of adiposity.

METHODS: Resting energy expenditure (REE) was measured via indirect calorimetry (REEm). Body composition data was obtained from dual-energy X-ray absorptiometry in 182 female subjects (Mean ± SD; Age 24.2 ± 9.1 yrs, Ht 164.6 ± 6.0 cm, Wt 69.0 ± 22.5 kg, BMI 25.5 ± 8.3 kg·m⁻²). The sample was divided into tertiles by body fat percent (%fat); Tertile 1 (T1): %fat=18.5-28.4%; Tertile 2 (T2): %fat=28.5-33.8%; Tertile 3 (T3): %fat=34.0-61.0%. To normalize and compare groups, REE was predicted (REEp) to account for differences in FFM and age. Adjusted REE was then calculated from REEm, REEp, and mean REEm per tertile (REEt) using REEa=REEt+REEm-REEp. Contributions (mass × metabolic rate, kcal/kg/day) of FM and SM were calculated as percentages of REEa. One-way ANOVAS and a two-way ANOVA were conducted to analyze differences in body composition and differences between REEm and REEa [(REE (REEm vs REEa) × Group (T1 vs T2 vs T3)], respectively.

RESULTS: FM in T3 was significantly higher than T1 (Mean Difference (MD) ± SD; 22.6 ± 25.0 kg, *p*=0.001) and T2 (MD ± SD; 17.9 ± 25.0 kg, *p*=0.001). No differences occurred in SM (*p*>0.05). When evaluating REE and group, there was no significant interaction (*p*=0.191), or main effect for REE (REEm vs REEa) (*p*=0.995). There was a significant main effect for group (T1 vs T2 vs T3, *p*=0.001); REE was significantly higher in T3 versus T1 (MD ± SD; 281 ± 396 kcal/day, *p*=0.001) and T2 (MD ± SD; 215 ± 396 kcal/day, *p*=0.001). Expenditure attributed to SM in T1 was significantly higher than T3 (MD ± SD; 3.2 ± 8.6%, *p*=0.001). Difference in FM contribution between T1 and T2 lacked significance (*p*=0.210), but T3 had a significantly higher FM contribution than T1 (MD ± SD; 5.1 ± 7.0%, *p*=0.001) and T2 (MD ± SD; 3.9 ± 7.0%, *p*=0.001).

CONCLUSIONS: Despite similarities in SM, women with elevated %fat experienced lower SM contribution and higher FM contribution to REEa. As adiposity increases, REE increases; FM may explain more of the variance in REE between women of different levels of adiposity.

3953 Board #270 May 30 9:00 AM - 10:30 AM
Relationship Between Energy Availability And Basal Metabolic Rate In Free-living Competitive Girl Runners

Norimitsu Kinoshita¹, Eriko Uchiyama¹, Kazuko Ishikawa-Takata², Yuka Yamada², Kenta Okuyama³. ¹Hosei University, Tokyo, Japan. ²National Institute Health and Nutrition, Tokyo, Japan. ³Lund University, Malmö, Sweden.

Email: sportsmed.kinoshita@hosei.ac.jp

(No relevant relationships reported)

Decrease in energy availability (EA) theoretically reduce basal metabolic rate (BMR) with sacrificing reproduction or bone health. However, research in EA of Asians is scarce and there is no data of EA as a determinant of BMR in adolescent athletes.

PURPOSE: To reveal the relationship between BMR and EA in free-living Japanese competitive girl runners with a focus on female athlete triad.

METHODS: Consecutive 14 girl runners (16.6 ± 0.7 y/o, 161.0 ± 6.3 cm, 45.2 ± 5.4 kg) in the same competitive high school team were evaluated without control on food and exercise. Each runner was asked to report dietary records with photos and training logs for 7 days. Energy intake (EI) was assessed by registered nutritionists. The runners were tested on treadmill with indirect calorimeter to yield individual prediction equations for VO₂ by running velocity. Exercise energy expenditure (EEE) was calculated by the equations based on the training log. EA was calculated by subtracting EEE from EI for each day. The daily means of those variables were calculated. BMR was measured by whole room calorimeter in the early morning after overnight sleep at the night of the last day of the assessment inside the calorimeter. Body composition was measured by DXA. Bivariate correlation analyses and *t*-test were used to examine the relationships and the difference between variables and groups, respectively.

RESULTS: Percent body fat (%BF), fat free mass (FFM), and bone mineral density of TBLH (BMD) were 13.3 ± 4.5 %, 39.0 ± 3.5 kg, and 1.013 ± 0.04 g/cm², respectively. BMR, EI, EEE, and EA were 26.5 ± 2.4 kcal/kg·FFM/day, 2330 ± 479 kcal/day, 892 ± 245 kcal/day, and 37.4 ± 10.7 kcal/kg·FFM/day, respectively. EA was significantly

correlated with BMR ($r=0.60$, $p=0.02$). However, EA was not correlated with either %BF ($p=0.25$) or BMD ($p=0.16$) and did not differ between runners with oligo/amenorrhea ($n=7$; 40.8 ± 11.9) and eumenorrhea ($n=6$; 34.0 ± 9.8) ($p=0.29$).

CONCLUSIONS: The strong linear correlation between EA and BMR supports the theory that decrease in EA leads to compensatory adaptation in metabolism which may suppress reproduction or bone mineral accrual. However, arbitrarily evaluated EA in short-term was not related to the triad associated conditions. Those results were consistent with the evidences from adult Caucasian population.

G-41 Free Communication/Poster - Thermogenic Dietary Supplements

Saturday, May 30, 2020, 8:00 AM - 10:30 AM
Room: CC-Exhibit Hall

3954 Board #271 May 30 9:00 AM - 10:30 AM The Effect Of Thermogenic Nutritional Supplementation On Resting Metabolism In College Females

Email: kelleyp@cofc.edu
(No relevant relationships reported)

BACKGROUND: Global increases in the incidence of obesity and the ensuing clinical co-morbidities has increased interest in the use of thermogenic supplements formulated to increase resting metabolism to increase energy expenditure and fat utilization. **PURPOSE:** The purpose of this study was to assess the effect of new capsaicin-based thermogenic supplements on resting oxygen consumption (VO₂), carbon dioxide production (VCO₂) and respiratory quotient (RQ). **METHODS:** Twenty-two untrained females (21.1±4.2 years) visited the lab on six occasions for measurements of pre-supplementation (PRE) resting energy expenditure (REE) for 30-60 min followed by the ingestion of a placebo or supplement (Shred, Shred 2.0, Capsimax 50, Capsimax 100, Capsimax 200) with at least three days separating conditions. Resting VO₂, VCO₂, and RQ were re-assessed for 90-120 minutes post-supplementation (POST). Changes in metabolic markers between treatment groups and over time were assessed in 5-minute intervals over the course of the 90-minute assessment using a two-way repeated measures ANOVA. **RESULTS:** PRE VO₂ ($2.5 \pm 0.3 \text{ ml}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$; $0.21 \pm 0.03 \text{ L}\cdot\text{min}^{-1}$), VCO₂ ($0.18 \pm 0.03 \text{ L}\cdot\text{min}^{-1}$), and RQ (0.85 ± 0.06) were lower than any given 5-minute interval POST ($p<0.05$). VO₂ ($\text{ml}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$) was elevated at 5 min POST ($2.99 \pm 0.5 \text{ ml}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$) compared to each subsequent 5 min interval ($p<0.05$) with no differences noted after 10 minutes ($2.7 \pm 0.4 \text{ ml}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$). VCO₂ and VO₂ ($\text{L}\cdot\text{min}^{-1}$) were elevated at 5 min POST compared to subsequent 5-minute intervals until 80 min (VCO₂; 0.22 ± 0.04 to $0.19 \pm 0.03 \text{ L}\cdot\text{min}^{-1}$) and 70 min (VO₂; 0.25 ± 0.04 to $0.23 \pm 0.03 \text{ L}\cdot\text{min}^{-1}$; $p<0.05$). There were no changes in VCO₂ at 10 minutes ($0.19 \pm 0.03 \text{ L}\cdot\text{min}^{-1}$) compared to any other time point POST. VO₂ ($\text{L}\cdot\text{min}^{-1}$) briefly increased from 35-45 minutes POST ($0.23 \pm 0.04 \text{ L}\cdot\text{min}^{-1}$) compared to 20 min POST ($0.22 \pm 0.03 \text{ L}\cdot\text{min}^{-1}$; $p=0.002$); no further changes occurred after 45 minutes. There were no changes in RQ during POST. There were no interaction effects (time*treatment) or treatment differences in metabolic markers. **CONCLUSIONS:** Observed time effects are postulated as a result of the elevated REE caused by changes in subject position during supplement consumption, rather than supplementation. This study suggests that new thermogenic supplementation has no effect on metabolism.

3955 Board #272 May 30 9:00 AM - 10:30 AM Effect Of Energy Drink Consumption On Heart Rate Variability And Blood Glucose In Relation To Exercise

Quinn Moberg, Greg Mulligan, Lynneth A. Stuart-Hill.
University of Victoria, Victoria, BC, Canada.
(No relevant relationships reported)

There is high prevalence of adverse events associated with caffeinated energy drink (CED) consumption. **PURPOSE:** This study aimed to examine the acute physiological effects of CED in apparently-healthy volunteers, pre-, during-, and post-exercise. **METHODS:** A randomized cross-over double-blind design with three experimental conditions was used: a CED condition, a matched caffeine-carbohydrate beverage condition (MB), and a control beverage condition (CB). Participants underwent blood glucose, heart rate variability (HRV), and heart rate measures pre- and post-exercise. During the exercise component, participants increased cycling intensity to a respiratory exchange ratio of 0.96 to 0.98 and maintained the workload for 20-minutes. Blood glucose, HRV, and heart rate measures were compared using two-way ANOVA, and

exercise measures were compared using one-way ANOVA. **RESULTS:** As seen in Figure 1, an effect of condition on blood glucose ($p < 0.001$), an effect of time on blood glucose ($p < 0.001$), and an effect of condition x time on blood glucose ($p < 0.001$) was observed. Specifically, pre-exercise there was an increase in blood glucose in the CED condition relative to the MB condition (6.59 ± 0.63 vs. $5.61 \pm 0.76 \text{ mmol}\cdot\text{L}^{-1}$, $p < 0.001$), and in the MB condition relative to the CB condition (5.61 ± 0.76 vs. $5.28 \pm 0.40 \text{ mmol}\cdot\text{L}^{-1}$, $p = 0.045$). There was no effect of condition on HRV, heart rate, or exercise measures. **CONCLUSION:** Given the increased blood glucose in the CED condition relative to the MB conditions it is concluded that an ingredient in commercial CED must stimulate the endogenous release of glucose into circulation.

Fig. 1. Mean condition blood glucose concentration values over time. Effect of condition and time ($p < 0.001$), effect of condition x time ($p < 0.001$). * indicates statistical significance between conditions ($p < 0.050$).

3956 Board #273 May 30 9:00 AM - 10:30 AM Effect Of 5-hour Energy Shot® On Physiological And Performance Responses To Simulated Car Racing

Philip J. Buckenmeyer, Jeff A. Bauer, James F. Hokanson, Stephen P. Yang, Joy L. Hendrick, Daniel Tammara, Larissa True. SUNY Cortland, Cortland, NY.
Email: buckenmeyerp@cortland.edu
(No relevant relationships reported)

The 5-Hour Energy Shot® continues to be one of the more popular energy drinks on the market. The maker claims that it improves work and/or exercise performance. **PURPOSE:** To determine if ingesting one 5-Hour Energy Shot® compared to a placebo causes measurable improvement in performance related to physiological variables during a simulated driving task (SDT). **METHODS:** Nineteen (11 males, 8 females), college-aged (21.8 ± 1.55 yrs; 1.7 ± 0.11 m in ht; 72.9 ± 13.83 kg in wt), volunteers participated in a double-blind, cross-over, placebo-based study. The participants were tested prior to and then at 5 consecutive 1-hour intervals after ingesting either a randomly assigned non-caffeinated placebo (PL) (59 ml; 5 kcal) or the 5-Hour Energy Shot® (SHES) (59 ml; 4 kcal). The SDT was a solo-timed road race (Forza Horizon game) on an Xbox 360 gaming system. During each of the 6 data collection trials, heart rate (HR), systolic blood pressure (SBP), diastolic blood pressure (DBP), ear temperature (ETemp), skin temperature (STemp), drive time (DT), and number of crashes (#C) were recorded. Subjects were also evaluated for alertness and drink effectiveness at each of same time points. A 2-way repeated measures ANOVA was utilized to determine differences between the PL and the 5-HES treatments across the six test periods of the driving task. Significance was established at $p < 0.05$. **summary of RESULTS:** There was no statistically significant difference between PL and 5-HES across the six time periods relative to HR, SBP, DBP, ETemp, or #C driving tasks. However, the 5-HES group had a significantly lower STemp than the PL group at each time interval; with a 5-hour post-ingestion STemp of $89.55 \pm 2.30^\circ\text{F}$ in the 5-HES group compared to $90.27 \pm 1.96^\circ\text{F}$ in the PL group. The 5-HES group had a faster DT compared to the PL group at each of the time intervals; with a 5-hour post-ingestion DT of 197.47 ± 50.39 sec in the 5-HES group compared to 201.09 ± 52.38 sec in the PL group. **CONCLUSIONS:** When compared to a placebo, 5-Hour Energy Shot® did significantly improve driving time, along with a concomitant reduced skin temperature in college-aged participants during a simulated driving task.

 (No relevant relationships reported)

Esports, or competitive video gaming, requires persistent cognitive functioning, alertness, quick reaction time, and mental clarity. As Esports has gained attention, more research is justified to elucidate performance enhancing strategies. Interestingly, Esport supplements aimed to improve reaction time, focus, and energy levels have yet to be heavily investigated. **PURPOSE:** To examine the impact of an Esport specific supplement on Esports performance and physiological responses. **METHODS:** Fifteen males (age = 22.0 ± 1.1 yrs, ht = 181.7 ± 10.2 cm, wt = 83.6 ± 14.5 kg, gaming = 13.9 ± 6.6 hrs) participated in the study. After completion of a baseline familiarization session including an Esports aim trainer (AT), subjects completed 2 performance sessions in a counterbalanced crossover design. Participants were given an Esports supplement (SUP) [caffeine, L-Theanine, Ginkgo Biloba, Vitamin B6, D3, B12] or placebo (PLA) 30 minutes prior to starting AT. During AT sessions, 3 rounds of 3 tests were completed each session: classic (CLA), reflex (RE), simple (SIM), and 1 round of time trial (TT). During each test, score (SCO), accuracy (ACC), and time per hit (TPH) were recorded, as well as time to completion (TTC) during CLA and TT. Before and after AT, BP and 5min resting HR and HrV were assessed. Subjects were asked mental fatigue and alertness prior to and after AT, along with SRPE after AT. Paired samples t-tests with an alpha level at p ≤ 0.05 were used to compare measurements of HR, HrV, BP, peak ACC, peak SCO, peak TPH, and peak TTC between SUP and PLA. **RESULTS:** There were no significant differences between SUP or PLA in regard to ACC (CLA 91.3 ± 3.0 vs 90.3 ± 4.4 %, RE 40.7 ± 12.9 vs 39.2 ± 12.0 %, SIM 61.7 ± 14.1 vs 61.7 ± 17.8 %, TT 48.0 ± 14.9 vs 49.7 ± 14.2 %, p ≥ 0.05), SCO (CLA 116357.1 ± 60706.9 vs 113642.9 ± 51013.7, RE 45839.3 ± 29161.1 vs 42339.3 ± 27287.2, SIM 40964.3 ± 22276.6 vs 38892.9 ± 24041.8, TT 16714.3 ± 20364.7 vs 20000.0 ± 18630.0, p ≥ 0.05), TPH (CLA 0.6 ± 0.1 vs 0.6 ± 0.1 sec, SIM 1.9 ± 0.5 vs 1.9 ± 0.5 sec, TT 1.8 ± 0.5 vs 1.7 ± 0.5 sec, p ≥ 0.05), and TTC (CLA 85.9 ± 23.1 vs 90.7 ± 15.4 sec, TT 177.5 ± 59.7 vs 161.7 ± 53.1 sec, p ≥ 0.05). **CONCLUSION:** SUP did not improve Esports performance during AT compared to PLA. This could be due to dosage, AT used, and level of experience of participants.

- 3958** Board #275 May 30 9:00 AM - 10:30 AM
Effect Of Dynamine With And Without Theacrine Supplementation Over Four Weeks On Blood Biomarkers
 Michaela G. Alesi¹, Matthew T. Stratton², Alyssa R. Bailly¹, Alyssa J. Holmes¹, Andrew Modjeski¹, Megan Barie¹, Yuri Feito, FACSM¹, Gerald T. Mangine¹, Karleena R. Tuggle¹, Tiffany A.  (No relevant relationships reported)

Methylxerine (Dynamine; DYM) and theacrine (Teacrine; TCR) are purine alkaloids. Previous research on TCR reported increases in feelings of energy, focus, and concentration, and decreases in fatigue. Currently, there are no published human safety data on DYM. **PURPOSE:** The purpose of this study was to examine the effect of four weeks of DYM supplementation with and without TCR on blood biomarkers. **METHODS:** One-hundred twenty-five men (n = 60) and women (n = 65) were assigned to one of five groups: low dose DYM (100 mg), high dose DYM (150 mg), low dose DYM with TCR (100 mg + 50 mg), high dose DYM with TCR (150 mg + 25 mg), and 125 mg maltodextrin. Participants visited the laboratory fasted on two occasions (week 0 and week 4), separated by four weeks of supplementation, for a blood draw. Blood was analyzed by an independent third-party (i.e. LabCorp). **RESULTS:** Three-way repeated measures analyses of variance were performed for all blood biomarkers. Group × sex × time interactions (p < 0.05) with post-hoc analyses revealed differences for mean corpuscular hemoglobin (MCH) concentration with MCH being higher in men consuming the placebo than women consuming low dose DYM (p = 0.028) and high dose DYM with TCR (p = 0.011) at week 4. Group × time interactions (p < 0.05) revealed differences for platelets, blood urea nitrogen, total globulins, alanine transaminase, total proteins, triglycerides, and high-density lipoproteins. However, post-hoc analyses showed specific increases for blood urea nitrogen in groups consuming low dose DYM with TCR compared to low dose DYM participants, and an increase in high-density lipoproteins in the group consuming high dose DYM. Significant main effects for time were observed. Specifically, increases in mean corpuscular volume, MCH, basophils, absolute eosinophils, creatinine, and high-density lipoproteins from week 0 to week 4, while decreases in glomerular filtration rate, chloride, carbon dioxide, bilirubin, and alanine transaminase were seen.

CONCLUSIONS: While small changes were found in some biomarkers, in all cases values remained within normal clinical limits. This suggests that DYM alone or in combination with TCR consumed at the dosages used in this study does not appear to negatively impact blood biomarkers associated with health.

Low-dose Vitamin D Supplementation Does Not Prevent 25(OH) Vitamin D Decline In College Students
 Grace A. Zimmerman, Jeremy R. Townsend, Megan D. Jones, Jaclyn Morimune. Lipscomb University, Nashville, TN.
 Email: zimmermangrace13@gmail.com
 (No relevant relationships reported)

Vitamin D deficiency is prevalent among active adults. Commonly, individuals opt to consume a multivitamin product to correct this deficiency. However, many multivitamins are often under-dosed compared to current evidenced-based recommendations. Furthermore, some companies offer a variety of vitamin formulations, with the claim of improving nutrient absorption. **PURPOSE:** To compare the effects of two different forms (liquid vs. capsule) of low-dose multivitamins on 25(OH) vitamin D status following 10-weeks of supplementation. **METHODS:** Thirty-two healthy males (n=15; 20.1y, 163cm, 71.7kg) and females (n=19; 22.1y, 153.4cm, 69.9kg) participated in this randomized, double-blind, placebo-controlled study. At the beginning of the 10-week intervention, participants provided a resting, fasted baseline blood sample and were randomly assigned to a liquid multivitamin supplement (LIQ; n=11), multivitamin capsule (CAP; n=11), or placebo group (PL; n=12). Participants took their respective supplement daily for 10 weeks. To maintain the double-blind study design, each participant consumed a combination of a liquid and capsule product. Placebo liquids and capsules were balanced so each group (LIQ, CAP, PL) consumed only their correct active (or placebo) treatment. The LIQ and CAP supplement both contained 268 IU of Vitamin D. Compliance was tracked by collecting empty supplement containers each week. After the 10-weeks, all participants reported back to the laboratory for a resting, fasted blood sample. Plasma samples were assayed for 25(OH) vitamin D concentrations. Data were analyzed using a 2-way repeated measures analysis of variance (ANOVA). **RESULTS:** There was a main effect for time (F=11.86, p=0.002, η²=0.227) with 25(OH) vitamin D concentrations significantly lower (Δ: -7.8±14.9ng/mL) at post-testing. Further, there were no significant differences between treatments (F=0.200, p=0.820, η²=0.013) in 25(OH) concentrations suggesting no benefit of LIQ or CAP supplementation over PL. **CONCLUSION:** It appears that a chronic low dose of vitamin D in liquid or capsule form is insufficient to maintain or elevate 25(OH)D concentrations in healthy, college-aged adults. Consumers should evaluate the dosing of their multivitamins compared to current evidence-based recommendations.

25-hydroxyvitamin D (25(OH)D) is hydroxylated in the liver to its *biologically active* form, 1,25 dihydroxyvitamin D (1,25(OH)₂D), and its *catabolic* form, 24,25 hydroxyvitamin D (24,25(OH)₂D). The effect of vitamin D supplementation on the production of 1,25(OH)₂D and 24,25(OH)₂D is unknown. **PURPOSE:** To examine the effect of oral vitamin D supplementation *versus* simulated sunlight on vitamin D metabolites and parathyroid hormone (PTH) during 13-weeks of military training. **METHODS:** Eighty male infantry recruits (mean ± SD, age 22 ± 3 years, height 1.78 ± 0.07 m, body mass 77.9 ± 10.7 kg) received oral vitamin D₃ (OD₃, 1,000 IU·D⁻¹ for 4 weeks and then 400 IU·d⁻¹ for 8 weeks, n = 21), an oral placebo (OP, n = 19), solar-simulated radiation (SSR-D, 1.3 × standard erythemal dose in T-shirt and shorts, 3 d·wk⁻¹ for 4 weeks and 1 d·wk⁻¹ for 8 weeks, n = 22), or placebo SSR (SSR-P, n =

18). A blood sample was drawn in weeks 1, 5 and 13, and analysed for 1,25(OH)₂D, 24,25(OH)₂D and PTH. **RESULTS:** There was a significant effect of time ($P = 0.001$) but no effect of supplementation on 1,25(OH)₂D (group \times time interaction, $P = 0.345$). 1,25(OH)₂D was not different between week 1 and 5 (104.8 ± 25.7 pmol·L⁻¹, 102.9 ± 26.2 pmol·L⁻¹), but increased by week 13 (112.4 ± 3.7 pmol·L⁻¹, $P = 0.009$). There was a significant group \times time interaction for 24,25(OH)₂D ($P < 0.001$). In OD₃ and SSR-D, 24,25(OH)₂D increased from week 1 (3.4 ± 2.3 and 2.9 ± 2.3 nmol·L⁻¹) to week 5 (5.5 ± 2.5 and 5.1 ± 1.5 nmol·L⁻¹, $P < 0.001$) and week 13 (5.3 ± 1.3 and 5.6 ± 1.4 nmol·L⁻¹, $P < 0.001$). In OP, 24,25(OH)₂D decreased from week 1 (3.5 ± 2.2 nmol·L⁻¹) to week 5 (2.7 ± 1.4 nmol·L⁻¹, $P < 0.001$) and returned to baseline by week 13 (3.6 ± 1.3 nmol·L⁻¹). In SSR-P, 24,25(OH)₂D increased from week 1 (2.4 ± 1.6 nmol·L⁻¹) and week 5 (2.6 ± 1.6 nmol·L⁻¹) to week 13 (4.0 ± 1.4 nmol·L⁻¹, $P \leq 0.027$). 24,25(OH)₂D was higher in the OD₃ and SSR-D than their respective placebo groups at week 5 and week 13 ($P < 0.001$). There was a significant effect of time ($P < 0.001$) but no effect of supplementation on PTH (group \times time interaction, $P = 0.059$). PTH decreased from week 1 (4.7 ± 1.3 pmol·L⁻¹) and week 5 (4.8 ± 1.4 pmol·L⁻¹) to week 13 (4.3 ± 1.2 pmol·L⁻¹, $P \leq 0.003$). **CONCLUSION:** Oral vitamin D supplementation or simulated sunlight have no effect on the *biologically active* 1,25(OH)₂D, but increase the production of the *catabolic* metabolite 24,25(OH)₂D.

Conducting Vitamin D3 Supplementation To Observe Serum 25(OH)D Levels, Body Composition, And Depression In Athletes

Rachel L. Darr¹, Jeremy Glaser¹, Kyle Chapman¹, Allison Gregory¹, Brian Purchase¹, John Leddy². ¹Saginaw Valley State University, University Center, MI. ²University at Buffalo, Buffalo, NY.
 Email: rldarr@svsu.edu
 (No relevant relationships reported)

Vitamin D insufficiency is linked with muscle weakness and adequate levels can improve muscle performance. Secondly, Vitamin D is stored in fat via fat sequestration and has ties to depression. Athletes in preseason use copious amounts of muscle potentially altering body composition. Indoor athletes in particular, would benefit from supplementation due to their specific population risk of limited access to sunlight and living in a seasonally changing climate; both of which are indicators for inadequate Serum Vitamin D (25(OH)D) and depression. **PURPOSE:** To first examine 25(OH)D levels in an indoor athletic population with daily supplementation of Vitamin D3 (D3) to observe any potential relationships between supplementation, 25(OH)D, body composition, and depression levels. **METHODS:** Men's Basketball players at a Division II school were recruited during preseason. Subjects with 25(OH)D levels <40ng/mL were admitted and started on 4000IU/day D3 supplementation for 8 weeks, Visit 1 (V1). Visit 2 (V2) and Visit 3 (V3), were 4 and 8 weeks after V1, respectively. Visit 4 (V4) was 4 weeks after V3 and D3 completion. 25(OH)D via blood draws, body composition (BodPod), anthropometrics such as height, weight, and waist circumference were measured at all visits. Depression (CES-D Scale) was measured at screen and V4. **RESULTS:** Five (19.4±1.3yo, 25.6±1.1kg/m² BMI, 23.0±9.2ng/dL 25(OH)D) subjects completed. 25(OH)D increased from V2-V3 (27.7 ± 5.9 - 38.7 ± 3.6 , $p=0.02$) but not from V1-V2 nor V1-V3. A trend was noted with falling 25(OH)D from V3-V4 (38.7 ± 3.6 - 32.3 ± 7.7 , $p=0.06$), 4 weeks post supplementation. No changes were seen in any body composition measures over time nor in comparison with parallel 25(OH)D levels. Screen 25(OH)D was not different than depression at pre study (4.4 ± 2.3 , $p=0.67$) but trended towards a difference compared to post study (2.3 ± 1.7 , $p=0.06$). **CONCLUSION:** 25(OH)D eventually increased in Division II basketball players with continual supplementation, possibly improving rates of depression. Further research is warranted with a larger active athletic population over a longer period of supplementation to perhaps see any definitive relationships in 25(OH)D and depression or in comparison to body composition, and to continue detecting levels after stopped supplementation.

3962 Board #279 May 30 9:00 AM - 10:30 AM

Modulation Of Acute Metabolic And Inflammatory Responses To Resistance Exercise By Vitamin D3 Injection In Vitamin D-deficient Males

Elisabeth K. Zeitz¹, Lee E. Brown, FACSM², Edward Jo¹, Damoon Ashtary-Larky³, Alireza Kheirollah³, Reza Bagheri⁴, Mohammad A. Ghaffari³, Seyyed A. Mard³, Seyed J. Hashemi³, Iman Mir³, Alexei Wong⁵. ¹California State Polytechnic University, Pomona, Pomona, CA. ²California State Polytechnic University, Fullerton, Fullerton, CA. ³Ahvaz Jundishapur University of Medical Sciences, Ahvaz, Iran, Islamic Republic of. ⁴University of Isfahan, Isfahan, Iran, Islamic Republic of. ⁵Marymount University, Arlington, VA. (Sponsor: Lee Brown, FACSM)
 Email: ekzeit@cpp.edu
 (No relevant relationships reported)

Vitamin D deficiency has been previously associated with impaired metabolic functions which may impact the acute effects of resistance exercise (RE) on insulin sensitivity, inflammation, and muscle damage. The effects of exogenous vitamin D on the metabolic, inflammatory, and muscle damage responses to an acute bout of RE in vitamin D deficient subjects have yet to be explored. **PURPOSE:** To evaluate the effects of a single vitamin D3 injection on the metabolic, inflammatory and muscle damage responses to an acute bout of RE in vitamin D-deficient resistance-trained males. **METHODS:** Blood samples from 14 vitamin D-deficient resistance-trained males were obtained during two separate trials: lower vitamin D (LVD, after saline injection) and higher vitamin D (HVD, after vitamin D3 injection). Metabolic, inflammatory, and muscle damage markers were evaluated at baseline and immediately then one hour after RE. Differences in mean values for each variable between trials were compared by repeated measures ANOVA followed by LSD test for pairwise comparisons. **RESULTS:** There were significant trial \times time interactions for serum insulin and Homeostatic Model Assessment (HOMA) of Insulin Resistance which were both lower ($p < 0.05$) at 1-hour post-RE in the HVD compared to LVD trial. There was a significant decrease ($p < 0.05$) for blood sugar and increase ($p < 0.05$) for creatine kinase, lactate dehydrogenase, and interleukin 6 1-hour post-RE across both trials with no interaction of time. There were no significant changes in other inflammatory and cardiovascular markers following either trials. A single injection of vitamin D3 demonstrated efficacy in reducing insulin resistance following RE in previously vitamin D-deficient resistance-trained males. Conversely, muscle damage and inflammatory response to acute RE were not altered. **CONCLUSION:** Intramuscular vitamin D replacement in vitamin D-deficient resistance-trained males may have key implications for the promotion of glucose metabolism and lowering the risk of diabetes in this population.

Effects Of Vitamin D And Resistance Training On Insulin Sensitivity And Neuromuscular Health In Obesity

Do-Houn Kim, Alex Klemp, Gloria Salazar, Hyun-Seok Hwang, Mingchia Yeh, Lynn B. Pantone, FACSM, Jeong-Su Kim, FACSM. Florida State University, Tallahassee, FL.
 Email: dkim5@fsu.edu
 (No relevant relationships reported)

Vitamin D has been widely studied for its role in regulating calcium and bone metabolism. Increasing evidence shows that vitamin D has insulin-sensitizing and ergogenic properties, which are similar to the adaptations to resistance training (RT). **Purpose:** To evaluate the effects of a 10-week vitamin D administration with or without RT on systemic insulin sensitivity, inflammation and neuromuscular health in p62 deficient mice, a genetic obese animal model with reduced insulin sensitivity. **Method:** 24-week old p62 deficient male mice were assigned to the following groups (10/group) for 10-week interventions: control (p62C, no treatment), vitamin D (VD, 75 IU of vitamin D every 3 days), RT (ladder climbing 3x/wk), or combined treatment (VRT, VD + RT). Body weight and daily food intake were monitored biweekly. Body composition (Dual-energy X-ray absorptiometry), neuromuscular function (grip strength and sensorimotor function), and systemic glucose tolerance (2-hour oral glucose tolerance test) were measured pre- and post-intervention. Blood samples, the hindlimb muscles, and the spleen were collected post-intervention and analyzed for serum vitamin D levels, tissue wet weights, and myofiber cross-sectional area (CSA). **Results:** 10-week vitamin D administration significantly increased serum vitamin D levels in VD (+61.1%) and VRT (+34.0%, $p < 0.001$) compared to p62C. Total body mass significantly increased in three groups (p62C: +16.4%, VD: +13.5%, VRT: +8.6%, $p < 0.05$) except RT. Fat mass increased significantly in p62C (+33.0%, $p < 0.05$) but was not changed in the intervention groups. Lean mass was not affected by any intervention. Grip strength (-22.5%) and sensorimotor function (-12.8%) significantly decreased only in p62C ($p < 0.05$). RT preserved fasting blood glucose levels (BG). In addition, RT and VRT lowered 30-minute postprandial BG (RT: -40.9%, VRT:

-36.9%, $p < 0.05$), compared to p62C. The spleen mass was significantly lower in RT (-49.7%) and VRT (-45.1%, $p < 0.05$) compared to p62C. **Conclusion:** Vitamin D, RT, and when combined not only attenuated the progression of obesity but also preserved neuromuscular function in p62 deficient mice. However, only RT was effective in improving systemic insulin sensitivity and inflammation. Supported by Jiwon Co./FSU College of Human Sciences

 Community, Connectedness, And Learning In Exercise Science: Does Classroom Context Matter?**

Amy A. Crawley, Ludmila Cosio-Lima, FACSM, Nancy Hastings, Byron Havard. *University of West Florida, Pensacola, FL.* (Sponsor: Ludmila Cosio-Lima, FACSM)
 Email: acrawley@uwf.edu
 (No relevant relationships reported)

Exercise science programs require rigorous academic preparation often taught in traditional classroom and lab settings. However, situated learning theory views learning as action in a community of practice, where the elements of social interaction, connectedness, and authentic participation transform cognitive understanding into meaningful knowing. Situated learning can have a complex effect on exercise science students' connectedness, understanding, theory application, and professional skills. Additionally, social networks (like Facebook) can provide a modern educative community in which to increase engagement and connection in the classroom. **PURPOSE:** The purpose of this quantitative research was to examine the relationship between learning environment type (situated versus traditional) and the use of Facebook on undergraduate exercise science students' perceived sense of overall classroom community, connectedness, and learning. **METHODS:** 69 undergraduate exercise science students (age [yrs] = 22.5 ± 2.1 , males = 37.7%; females = 60.9%) who had participated in either a traditional course, traditional course with Facebook, a situated course, or a situated course with Facebook completed Rovai's (2002) Classroom Community Survey at the end of their course experience. Multiple Regression was performed to determine if there were any significant differences between the four groups ($\alpha = .05$). **RESULTS:** Results demonstrated a situated learning classroom and a situated learning classroom with Facebook were significant positive predictors of students' perception of overall classroom community ($R^2 = .181$, $F(3, 65) = 4.794$, $p = .004$), connectedness ($R^2 = .130$, $F(3, 65) = 3.232$, $p = .028$), and learning ($R^2 = .186$, $F(3, 65) = 4.965$, $p = .004$). **CONCLUSIONS:** This research supports situated learning as a best practice for increasing classroom community in undergraduate exercise science programs. Students perceived higher levels of overall classroom community, connectedness, and learning when participating in a situated classroom and to an even greater extent a situated classroom with Facebook. Incorporation of these types of learning environments and teaching strategies in exercise science degree programs may enhance professional skill development and successful employment within the field.

**3965 Board #282 May 30 8:00 AM - 9:30 AM
 Service-learning Or Internship: A Mixed-methods Evaluation Of Experiential Learning Pedagogies**

Lori Anne Sherlock, Miriam P. Leary. *West Virginia University, Morgantown, WV.*
 Email: lsherlock@hsc.wvu.edu
 (No relevant relationships reported)

Experiential learning pedagogies, including internship and service learning experiences, are becoming increasingly popular in higher education. An internship engages students with hands-on experiences that enhances their learning or skills within their fields of study while service-learning is as a type of experiential education in which students participate in service, typically within the community, and reflect on their involvement in such a way as to gain further understanding of course content and of the discipline as well as its relationship to societal needs. To date, no study has yet directly compared these teaching modalities. **PURPOSE:** To determine if a service learning experience or internship pose a more favorable effect on education-based self-efficacy. **METHODS:** The present study systematically evaluated a service learning experience against an internship experience using a mixed-methods model with the primary outcome being student self-efficacy. Sixteen students completed a community-based wellness internship with a subgroup (nine students) allocated to a service-learning component of internship which incorporated reflective assignments designed to improve self-efficacy. At the end of the semester, students completed a 15 item

online self-efficacy and satisfaction survey using a Likert scale. Three focus groups were conducted in which 3-4 participants responded to a series of nine questions which explored their internship experience. Qualitative data was analyzed via thematic analysis. **RESULTS:** Overall responses to the self-efficacy and satisfaction survey were favorable for both groups, but the internship group was more likely to agree or strongly agree with statements of self-efficacy. Focus groups found that the internship experience reinforced classroom learning, but the ability to work with different populations and ability levels was mentioned only by the service-learning group. Themes from reflective assignments, such as engaging with community members and professional exploration, were evident in the service-learning group responses only. **CONCLUSION:** When incorporating reflection assignments service learning experiences successfully connect the service experience to relevant course outcomes promoting student development and self-efficacy.

 Evaluation Of The Virtual Laboratory Of Exercise Physiology**

Young Sub Kwon, Kim Vincent-Layton. *Humboldt State University, Arcata, CA.*
 Email: youngsubkwon@hotmail.com
 (No relevant relationships reported)

Lab experience is one of the most important parts of Kinesiology courses; however, most California State University (CSU) campuses do not have the capacity for physical labs, adequate equipment, or funding to provide hands-on lab activities to their Kinesiology major students. **PURPOSE:** The purpose of this research was to compare student learning outcomes from Virtual Laboratory of Exercise Physiology (VLEP) with that from traditional exercise physiology laboratory activities. **METHODS:** 40 undergraduate Kinesiology students (mean±SD, age = 22 ± 3 , junior = 45%, senior = 55%) were randomly assigned to either experimental group 1 or group 2. Group 1 completed traditional laboratory activities, whereas group 2 completed the VLEP. Both groups then completed the same assessment to evaluate their understanding of aerobic (VO2max) and anaerobic (Wingate) power laboratory concepts. A one-way ANOVA was performed to determine if there were any significant differences between the two groups ($\alpha = .05$). The students were also asked to rate their experiences using a qualitative questionnaire. One of the relevant components of that questionnaire asked students to indicate which laboratory type they preferred. A second relevant component asked students to indicate how educational they thought the VLEP program was. **RESULTS:** Mean aerobic power lab activity assessment scores (%) were 81.5 ± 5.4 and 81.6 ± 6.6 and mean anaerobic power lab assessment scores were 82.5 ± 8.1 and 83.0 ± 6.5 for groups 1 and 2, respectively. There were no significant differences between the two groups in either aerobic power lab assessment scores or anaerobic power lab assessment scores. In this investigation, 47.5% of the students indicated a preference for the traditional laboratory activity, and the other 52.51% of the class either preferred the VLEP (27.5%) or did not prefer one laboratory type over another (25.0%). Students agreed that the VLEP was at least moderately educational (25.0%), and most students thought that the VLEP was very educational (75.0%). **CONCLUSIONS:** These findings support that VLEP instructs students as effectively as a traditional laboratory. We hope VLEP could remove enrollment bottleneck challenges and provide a lower cost, experiential, accessible alternative for Kinesiology major students in CSU.

**3967 Board #284 May 30 8:00 AM - 9:30 AM
 Classroom Teachers' Intentions To Provide Physical Activity Opportunities To Students: An Analysis Using Self-Determination Theory**

Blake Densley¹, Hannah Calvert², Lindsey Turner². ¹*The College of Idaho, Caldwell, ID* and *Boise State University, Boise, ID.* ²*Boise State University, Boise, ID.*
 Email: blakedensley@u.boisestate.edu
 (No relevant relationships reported)

PURPOSE: Providing opportunities for elementary school-aged children to be physically active during the school day is important for obesity prevention and overall health. Classroom physical activity (CPA) has been shown to be effective for increasing student PA, but is not widely practiced among teachers. This study examined teachers' perspectives on CPA, and intention to provide CPA, using a survey designed to measure constructs within the self-determination theory. **METHODS:** The constructs of Competence, Autonomy, Relatedness, and intention regarding CPA use were assessed using a survey of 173 elementary school teachers across 10 schools. The constructs were represented using the following subscales (each used a 6-point Likert-type scale from strongly disagree to strongly agree): Competence included three survey items ($\alpha = .94$), such as "I am capable of using activity breaks in my classroom;" Autonomy included three items ($\alpha = .83$), such as "I have a say in choosing whether to use activity breaks;" Relatedness included 4 items ($\alpha = .78$), such as "providing opportunities for children to be physically active in my classroom is consistent with my priorities as a teacher;" and intention to implement

CPA included 2 items ($\alpha = .77$): "I definitely plan to try using activity breaks in my classroom," and "I expect I will be able to use activity breaks regularly." Multiple linear regression was used to examine how the constructs of Competence, Autonomy, and Relatedness predicted intention to provide CPA to students.

RESULTS: Regression results indicated that the three predictors explained 44.1% of the variance ($R^2 = .44$, $F(3,173) = 44.74$, $p < .001$) in teacher intent to provide CPA. Competence ($B = .31$, $t(173) = 4.92$, $p < .001$) Autonomy ($B = .19$, $t(173) = 3.15$, $p = .002$) and Relatedness ($B = .18$, $t(173) = 3.40$, $p = .001$) each significantly predicted intention.

CONCLUSION: Competence was the strongest predictor of teachers' intent to provide CPA. However, feeling autonomous to implement CPA and viewing CPA as compatible with their teaching philosophy also predicted teachers' intention to provide CPA opportunities. Increasing teacher competence to provide CPA through professional development could be one effective method for increasing this practice. Supported by the Institute of Education Sciences grant R305A150277

Effects Of Exercise On Plasma β -endorphin And Dsq In Methamphetamine Dependent Individuals

RUI XU, Biao Sun. *Nanjing Sport Institute, NANJING, China.*
 Email: ajiuwei@126.com
 (No relevant relationships reported)

PURPOSE: Methamphetamine is the main component of opioid drugs, which directly affects the central nervous system which leading to abnormal secretion of catecholamines. Physical exercise has been shown to benefit diverse medical and behavioral conditions. This study assesses the feasibility and efficacy of an 8-week aerobic and resistance training program on β -endorphin in plasma and desire for speed questionnaire (DSQ) for methamphetamine (MA) dependence.

METHODS: A total of 60 MA-dependent individuals were randomized to aerobic exercise group (AE, $n=30$) and resistance exercise group (RE, $n=30$). Each training group was trained over 8 weeks, 3 times/week, 90 minutes each time, which include formal training (70 minutes), warm-up (10 minutes) and recovery (10 minutes). The aerobic exercise intensity is 65%-85% HR_{max} and the muscle strength by 1-repetition maximum (1-RM) and endurance at 85% in resistant exercise group.

RESULTS: (1) After 8 weeks of exercise intervention, the β -endorphin levels in the group AE and group RE were significantly increased ($p < .01$). Inside, the level of β -endorphin in the group AE was increased from 154.7 pg/ml to 214.3 pg/ml, the rate of change of β -endorphin in plasma was 39.24%. The level of β -endorphin in the high-intensity group was increased from 158.4 pg/ml to 181.7 pg/ml, the rate of change was 14.76%. It is suggested that the effect of aerobic exercise on plasma β -endorphin is more effective than that of resistance exercise. (2) After 8 weeks of exercise intervention, MA-dependent have reduced their desires, The score of the DSQ in t both group were significantly decreased ($p < .05$). In the group AE the score was decreased from 105.40 to 75, and the score of the group RE was decreased from 111.4 to 77.7.

CONCLUSIONS: Both aerobic and resistance exercise can increase the level of β -endorphin in MA-dependent individuals, promote the formation of euphoria compensation mechanism, and reduce the desire for speed. The effect of aerobic exercise on plasma β -endorphin in methamphetamine dependent individuals was more obvious.

3969 Board #286 May 30 8:00 AM - 9:30 AM
Academic Burnout Amongst Exercise Science Students

Anne Borden, Haejin Dadachanji, Alyssa Fuller, Perla Flores, Mohammed Al-Hamed, Keith Naugle, Kelly Naugle. *Indiana University - Purdue University Indianapolis, Indianapolis, IN.*
 (Sponsor: Monica Hubal, FACSM)
 (No relevant relationships reported)

PURPOSE: Prior research shows that the psychological constructs of hope, optimism, and self-efficacy impact voluntary behavior, and quality of life. Academic burnout is prevalent among university students of all types. However, knowledge of what predicts burnout in undergraduate exercise science (ES) students is limited. Thus, the purpose of this longitudinal study was to examine the level of burnout at the beginning and end of the semester in ES students. Second, we examined the association of psychological factors and physical activity (PA) with burnout in ES students. **METHODS:** Students completed two online surveys within one Fall semester: one at the beginning and the other near the end. The first survey included the following questionnaires: Copenhagen Burnout Inventory, Adult Hope Scale, Life Orientation Test-Revised (optimism), Self-Efficacy to Regulate Exercise, Satisfaction with Life, and International Physical Activity Questionnaire (IPAQ). The second survey included the Copenhagen Burnout Inventory, IPAQ, and Satisfaction with Life. From the IPAQ, measures of moderate PA, vigorous PA, walking, and total PA were computed. Of the 169 participants, 59 were retained who completed both surveys and listed their major as ES. **RESULTS:** At the beginning of the semester 35.6% of students reported high burnout and 22.8% reported high burnout near the end of the semester. Predictors of burnout were

chosen based on significant correlations. Burnout at Time 1 negatively correlated with vigorous PA, optimism, and Life Satisfaction at Time 1. The regression revealed vigorous PA ($Beta = -.232$, $p = .037$), life satisfaction ($Beta = -.268$, $p = .04$), and optimism ($Beta = -.369$, $p = .005$) as predictors of burnout at Time 1. Burnout at Time 2 negatively correlated with GPA, optimism, life satisfaction, and hope at Time 1. Regressions showed life satisfaction ($Beta = -.359$, $p = .008$) and optimism ($Beta = -.415$, $p = .002$) at Time 1 as significant predictors of burnout at Time 2. **CONCLUSION:** ES students reported higher burnout at the beginning of the semester compared to the end of the semester. Higher levels of vigorous PA, optimism, and life satisfaction predicted lower burnout at the beginning of the semester. Greater optimism and life satisfaction at the beginning of the semester predicted lower burnout near the end of the semester.

3970 Board #287 May 30 8:00 AM - 9:30 AM
An Exercise-based Didactic Strategy In Physical Education Increases Motor Skills In Preschool Children: A Pilot Study

Iván Rentería, Ernesto Alonso González Castillo, Giovanna Arambula Barba, Concepcion Danae Juárez Hernández, Patricia Concepción García Suárez, Alberto Jiménez Maldonado. *Universidad Autónoma de Baja California, Ensenada, Baja California, Mexico.*
 Email: irenteria@uabc.edu.mx
 (No relevant relationships reported)

Physical education (PE) in preschool aims for the corporal and motor skills development in children, nevertheless the evaluation strategies of acquired skills has been neglected in Mexican public school system. Since 2018 only PE teachers are responsible to teach classes, and a collaboration between public institutions allowed us to launch a pilot study of PE classes based on motor skills circuits called "motor action circuits" as an effective tool to develop motor skills. **PURPOSE:** To determine the effects of an exercise-based didactic strategy on the PE curricula on motor skills performance in children. **METHODS:** Five boys (Age = 5.2 ± 0.4 yr.) and nine girls (Age = 5.1 ± 0.3 yr.) participated in the study. Exclusion criteria for children were having a major pathology, pharmacological therapy, and enrollment in after-school physical activity programs. Children attended three 30-min lessons in non-consecutive days per week under the supervision of two trained female PE teachers. Motor skills were measured by the Movement Assessment Battery for Children (MABC-2) test. Two-way (2 genders x 2 measurements) mixed ANOVA were computed for motor skills performance using the GraphPad Prism software. **RESULTS:** The assumption of normality was met by the Shapiro-Wilk test for girls ($W = 0.849$) and boys ($W = 0.807$). A better performance was found on threading beads (Pre = 1.7 ± 0.5 vs. Post = 1.1 ± 0.5 min, $p = 0.0004$) and posting coins with the preferred hand (Pre = 26.5 ± 2.1 vs. Post = 21.8 ± 5.0 s, $p < 0.0001$). A significant improvement was found on throwing at a wall target with the right arm (Pre = 2.8 ± 0.1 vs. Post = 3.8 ± 0.2 hits, $p = 0.02$), the left arm (Pre = 2.4 ± 0.2 vs. Post = 3.8 ± 0.08 hits, $p = 0.0001$), throwing a bean bag into a box (Pre = 0.4 ± 0.2 vs. Post = 4.1 ± 1.2 hits, $p = 0.0038$), maintaining one-board balance with the preferred leg (Pre = 12.3 ± 8.4 vs. Post = 26.7 ± 7.7 s, $p = 0.0007$), and one-board balance with the other leg (Pre = 10.3 ± 5.9 vs. Post = 23.6 ± 6.9 s, $p = 0.0011$). **CONCLUSION:** Significant motor skill performance improvements were observed in children attending an exercise-based didactic strategy on the PE program, which highlights the need to increase physical activity at early ages in Mexican children.

3971 Board #288 May 30 8:00 AM - 9:30 AM
Pedagogical Considerations In Exercise Physiology Laboratory Courses

Marc Apkarian. *Biola University, La Mirada, CA.*
 (No relevant relationships reported)

PURPOSE: To explore how pedagogical approaches in an undergraduate exercise physiology laboratory course may reflect test results. **METHODS:** A retrospective analysis was conducted using three course sections taught in two separate semesters (six total sections, taught by the same instructor), with 31 students enrolled per semester ($N = 62$). Didactic (lecture and discussion) and practical (demonstration, in-class skills practice) instruction was provided for exercise physiology laboratory theory and procedures. Additional skills practice throughout the course was achieved via fitness assessments performed on five peer subjects recruited by each student in the class over the semester. Fitness assessments required testing for height, weight, resting blood pressure, four site skinfolds (4SKF), YMCA Step Test, YMCA Bench Press Test, 1-Minute Curl-Ups, and Sit-and-Reach. Tests were selected to cover a spectrum of fitness attributes and skills, as well as in accordance with pragmatic considerations of available practice opportunities. Course assessment included two written examinations consisting of multiple choice and short response questions, administered at the middle and end of the course, covering different sets of theoretical content, and a practical skills examination scored by rubric conducted individually by the instructor at the end of the course.

RESULTS: Scores for both sets of written examination scores were combined, resulting in an average score of 21.6±4.1 points out of 30 possible points, or 72.1%. The practical exam average equaled 13.6±1.3 points out of 15 possible points, or 90.4%. Accordingly, it was noted that scores for student performance on the practical exam were higher than those for the written examinations ($p<0.05$).

CONCLUSIONS: While pedagogical approaches differ for theoretical and practical instruction due to the nature and need for specific instruction in an undergraduate exercise physiology laboratory course, it appears that additional skills practice opportunities may result in higher test scores and improved learning, as reflected by practical examination. Thus, adequate skills practice opportunities, in conjunction with traditional didactic instruction, are recommended to enhance student learning and competence in laboratory content.

Association Between Muscle Stiffness And ESR1 Rs2234693, Rs9340799 And Actn3 R577X Polymorphisms In Collegiate Athletes

Hiroki Homma, Mika Saito, Naoki Kikuchi. *Nippon Sport Science University, Tokyo, Japan.*

(No relevant relationships reported)

Previous studies have reported that distinct gene polymorphisms (e.g. ACTN3 R577X, ESR1 rs2234693, rs9340799) are associated with muscle stiffness, amongst which ESR1 rs2234693 and rs9340799 polymorphisms are also associated with instances of muscle injury. **PURPOSE:** To investigate the association between muscle stiffness and ESR1 rs2234693, rs9340799 and ACTN3 R577X polymorphisms in collegiate athletes. **METHODS:** In this study, 40 athletes (33 men and 7 women), who had undergone resistance training, were evaluated for the occurrence of muscle stiffness (hamstring: biceps femoris, semitendinosus, and semimembranosus) by ultrasound shear wave elastography. Additionally, ESR1 rs2234693, rs9340799 and ACTN3 R577X polymorphisms were analyzed using the TaqMan SNP Genotyping Assay. Comparisons of muscle stiffness between the genotypes were performed using one-way ANOVA. The Hardy-Weinberg equilibrium was determined for the ESR1 rs2234693, rs9340799 and ACTN3 R577X polymorphism using a Chi-square test. **RESULTS:** Genotype frequencies of the ESR1 rs2234693 (CC 13%, CT 55%, TT 33%), rs9340799 (GG 3%, GA 25%, AA 72%) and ACTN3 R577X (RR 18%, RX 64%, XX 18%) polymorphisms were consistent with the Hardy-Weinberg equilibrium ($p=0.36$, $p=0.90$, $p=0.08$, respectively). However, there was no significant difference in muscle stiffness between ESR1 rs2234693 and ACTN3 R577X genotypes. Further, the GG or GA genotype of ESR1 rs9340799 polymorphism tend to exhibit greater muscle stiffness of the hamstring muscles compared with the AA genotype in collegiate athletes (27.2 ± 7.0 kPa vs. 22.4 ± 6.7 kPa; $p=0.054$). **CONCLUSIONS:** Our results suggested that ESR1 rs2234693, rs9340799 and ACTN3 R577X polymorphisms are not associated with muscle stiffness in collegiate athletes.

3973 Board #290 May 30 9:00 AM - 10:30 AM

Self-reported Stress And Well-being Impacts Immune Response To Maximal Exercise In Collegiate Swimmers

Bailey M. Theall¹, Haoyan Wang¹, Connor Kuremsky¹, Eunhan Cho¹, Katelyn Hardin¹, Lyle Robelot¹, Jack Marucci², Shelly Mullenix², Nathan Lemoine, Jr.², Brian A. Irving, FACSM¹, Neil M. Johannsen¹, Guillaume Spielmann¹. ¹Louisiana State University, Baton Rouge, LA. ²Louisiana State University Athletics, Baton Rouge, LA. (Sponsor: Brian A. Irving, FACSM) Email: btheall1@lsu.edu

(No relevant relationships reported)

Exposure to acute psychological and physiological stressors is associated with impairments in immune function including reduced exercise-induced mobilization of naïve (NA) T-cells and increased mobilization of antigen-specific, highly differentiated T-cells following maximal exercise. However, the impact of sustained stressors on the immune response to maximal exercise is unknown. **Purpose:** Characterize the impact of self-reported stress and well-being on lymphocyte responses to acute bouts of exercise in collegiate swimmers over six months. **Methods:** Blood samples were collected from fifteen NCAA D1 swimmers (7 M, 6 F: 19.8 ± 0.7 y) before and after maximal swims at two timepoints (V_1 : immediately post-season 1 and V_2 : early season 2). An additional mid-off season timepoint (V_3) was collected in a subset of nine swimmers. T-cells were quantified by flow cytometry, and self-reported measures

of sleep quality (PSQI), symptoms of upper respiratory tract infection (URTI, WURRS-21), and overtraining (DALDA) were collected. Linear mixed models were used to determine the effects of exercise, season timepoint, and their interaction on lymphocyte percentages ($\alpha=0.05$). Pearson's correlation coefficients were used to assess correlations between lymphocyte percentages and stress measures. **Results:** Lower sleep quality was correlated with greater resting and post-exercise senescent CD4+ T-cell percentages ($r=0.44$, $p=0.01$; $r=0.47$, $p=0.004$, respectively). Low sleep quality was also correlated with lower post-exercise NA CD4+ T-cells ($r=-0.35$, $p=0.04$). Higher ratings of self-reported symptoms of URTI ($r=0.38$, $p=0.02$) and overtraining ($r=0.38$, $p=0.02$) were correlated with greater post-exercise senescent CD4+ T-cell percentages. Compared to pre-exercise, post-exercise NA CD8+ T-cell percentages were lower at V_1 and V_2 , while CD8+ T-cell percentages were higher post-exercise ($p < 0.01$). **Conclusion:** Elevations in stress and well-being at rest adversely impacted immune response to maximal exercise in collegiate swimmers. Impaired sleep quality and higher URTI and overtraining symptoms were associated with an exacerbated exercise-induced mobilization of senescent CD8+ T-cells, highlighting the importance of monitoring athlete stress level and overall well-being throughout the competitive season.

Acute And Chronic Brain-Derived Neurotrophic Factor Responses During One Season Training In Young Swimmers

Dimitra NAFPAKTITOU¹, Anastassios PHILIPPOU¹, GEORGE VAGIAKAKOS², NIKOS VAGIAKAKOS¹, MARKOS MANTALOUFAS¹, George CHROUSOS¹, Michael KOUTSILIERIS¹, THEODOROS PLATANOU¹. ¹NATIONAL AND KAPODISTRIAN UNIVERSITY OF ATHENS, ATHENS, Greece. ²NATIONAL TECHNICAL UNIVERSITY OF ATHENS, ATHENS, Greece.

(No relevant relationships reported)

It has been demonstrated that Brain-Derived Neurotrophic Factor (BDNF) is a mediator of neuroprotective and neuroplastic processes, and that serum BDNF is representative of central concentrations as well. Interestingly, there is evidence that BDNF levels are elevated in response to exercise.

PURPOSE: This study aimed at investigating the acute and chronic effects of a full season swimming training on serum BDNF, both at rest and after a maximal exercise bout in young athletes.

METHODS: Twelve well-trained male swimmers (14.08 ± 1.0 yrs) participated in the study. Measurements were carried out at the beginning of the training season (T1) as well as pre- and post- taper of each of the two competitive periods (i.e., T2, T3 for the first macrocycle, and T4, T5 for the second macrocycle, respectively). At each of the above time points, blood samples were collected pre- and 1 hour post a maximal, 400m swimming testing. Serum BDNF levels were measured by ELISA. Adjustment for exercise-induced plasma volume changes was performed before data analysis. Two-way ANOVA with repeated measures was used for statistics.

RESULTS: A significant pre-post testing difference was observed at T2 ($p=0.048$). In addition, a main effect of time was found among the 5 time points (T1-T5; $p=0.000$). Moreover, both pre- and post- testing responses had a similar profile exhibiting a decline from T1 to T3 (pre: $23,412 \pm 2,504$ pg/ml vs $3,433 \pm 669$ pg/ml, post: $23,004 \pm 3,410$ pg/ml vs $2,743 \pm 550$ pg/ml) and from T4 to T5 (pre: $19,428 \pm 1,097$ pg/ml vs $11,993 \pm 969$ pg/ml, post: $22,111 \pm 1,455$ pg/ml vs $12,838 \pm 1,763$ pg/ml), and an increase from T3 to T4 (pre: $3,433 \pm 669$ pg/ml vs $19,428 \pm 1,097$ pg/ml, post: $2,743 \pm 550$ pg/ml vs $22,111 \pm 1,455$ pg/ml).

CONCLUSIONS: To the authors' best knowledge this is the first study examining the acute and chronic BDNF responses during one season training in young athletes. These findings indicate that long-term swimming training can affect the resting and acute (pre-post testing) circulating BDNF in young swimmers.

Hormonal And Heart Rate Changes To Maximal Exercise In Elite Adolescent Athletes

Gábor Almási¹, Edit Bosnyák¹, Ákos Móra², Annamária Zsákai³, Piroska Fehér³, Dorina Annár³, Nikolett Nagy¹, Miklós Tóth¹, Márta Szmodis¹. ¹University of Physical Education, Budapest, Hungary. ²University of Pécs, Pécs, Hungary. ³Eötvös Loránd University, Budapest, Hungary.

Email: alm.gabor@gmail.com

(No relevant relationships reported)

One of the main biomarkers of stress is the steroid hormone cortisol (C), while testosterone (T) and estrogen (E) steroid hormones are associated with physical activity. **PURPOSE:** To determine the relationship between a maximal swimming exercise and hormone level changes and acute training's influence on the stress level in elite adolescent athletes. **METHODS:** The study was conducted with 31 participants (boys: $n=19$, mean age±SD: 16.34 ± 1.12 years; girls $n=12$, 15.17 ± 0.81 years) from the

field of water sports (swimming: n=10; water polo: n=21). The young elite athletes completed a maximal freestyle swimming test (200 meter) after a 25 minutes unified warm-up. Saliva samples were collected before (C1), immediately after the exercise (C2) and after a 30 minutes rest (C3). Free hormone levels in saliva were quantified by using IBL ELISA kits. Heart rate (HR) was measured throughout the whole procedure (Polar V800). We used the Brunel questionnaire to determine the participants' mood states after the field test. **RESULTS:** There was significant rise in boys' C levels compared to the C1 (0.176±0.134 µg/dl) with C2 (0.339±0.278 µg/dl; p=0.030) and C3 (0.426±0.319 µg/dl; p=0.001) measured results. Rise in girls' C level was not significant (p=0.057), however their C2 (r=0.71) and C3 (r=0.60) levels correlated with their peak HR in swimming test. Boys' T levels decreased significantly after the exercise (0.0046±0.0023 µg/dl) compared to basal levels (0.0061±0.0028 µg/dl) and T/C ratio also decreased (basal: 0.047±0.032 µg/dl; after exercise: 0.02±0.015 µg/dl). There was no significant difference in girls' E levels, however their C3 levels correlated with their happiness (r=0.62), and C3-C1 concentration difference correlated also with happiness (r=0.68) and calmness (r=0.71) items of the Brunel scale. **CONCLUSION:** These results justify the application of the swimming field test to monitor maximal performance induced hormonal changes in adolescent athletes. Changes in T and T/C levels go against the experienced trend in literature therefore we feel the need of further analysis of our results. Moreover, the repeated measures might be an effective way to register the alarming symptoms of the common overtraining syndrome in swimming. *Supported by the ministry of human capacities [ÚNKP-18-3-I-TE-6].*

Assessment Of High-intensity Training Load And Exercise-induced Oxidative Stress In Professional Soccer Players.

Camilla R. Holland, Michael G. Roberts, Matthew W. Furber, Lindsay S. Kass, Lindsay Bottoms. *University of Hertfordshire, Hatfield, United Kingdom.*
 Email: c.holland@herts.ac.uk
(No relevant relationships reported)

It is documented that intense periods of soccer can induce oxidative stress, the negative effects of which can compromise performance. However, few studies have explored the potential association between exercise-induced oxidative stress and training load intensity. **PURPOSE:** The aim of the study was to quantify oxidative stress relative to indicators of high-intensity training load in a cohort of professional soccer players throughout different phases of a competitive in-season. **METHODS:** Ten professional soccer players (age: 23±2yrs; body mass: 83.5±6.2kg; stature: 181.3±5.3 cm; $\dot{V}O_{2max}$: 57.2±6.7 mL·kg⁻¹·min⁻¹), representatives from an English Football League One team, participated in the study. Training load was assessed at three time points throughout a competitive in-season (T1: early in-season; T2: mid-season; T3: end of in-season [1st, 16th & 32nd microcycle]) using global positioning system (GPS) and heart rate (HR) based methods to quantify external (HETL) and internal high-intensity training load (HITL). Urine samples were collected at each time point and analysed for malondialdehyde (MDA) as a biomarker of oxidative stress. Data normalised to creatinine. Results presented as M ± SD. **RESULTS:** High-intensity training load varied significantly throughout the competitive in-season and was significantly higher at T2 compared to T1 (HETL: 18.56 ± 7.30 mmol⁻¹ vs. 6.72 ± 2.62 mmol⁻¹, an increase of 11.84 mmol⁻¹, 95% CI [4.33, 19.36], p = .004; HITL: 60 ± 34 %Time spent > 80% HR_{max} vs. 23 ± 15 %Time spent > 80% HR_{max}, an increase of 37 %Time > 80% HR_{max}, 95% CI [13, 60], p = .004; T2 vs. T1, respectively). Urinary MDA concentrations decreased significantly throughout the competitive in-season, $\chi^2(2) = 6.889$; p = .032, (T1: 0.76 ± 0.90 µMmmol⁻¹ vs. T3: 0.18 ± 0.12 µMmmol⁻¹, Z = -2.192, r = .52, p = .028). No significant correlations were observed between indicators of high-intensity training load and MDA. **CONCLUSION:** Chronic soccer training appears to promote an adaptive response as oxidative stress was attenuated over the competitive in-season, irrespective of the intensity of the training load. Monitoring urinary MDA may be a useful tool to provide coaches and sports scientists an insight into adaptive or maladaptive responses throughout a competitive season in soccer.

Effects Of Recovery Using Cryotherapy On The Athlete'S Immune System After Repetitive Exhausting Aerobic Exercise

Astrid Reif¹, Christoph Triska¹, Bernhard Koller-Zeisler², Norbert Bachl¹, Barbara Wessner¹. ¹University of Vienna, Vienna, Austria. ²Austrian Institute of Sports Medicine, Vienna, Austria.
 (Sponsor: Juergen Scharhag, FACSM)
 Email: astrid.reif@univie.ac.at
(No relevant relationships reported)

Muscle damage and changes in immune cell numbers are induced by intensive repetitive and long-term physical stress leading to fatigue and decreased performance. It is widely suggested that cryotherapy (CT) is an effective strategy for accelerated

recovery. **PURPOSE:** Assessing the influence of CT compared to passive recovery on blood biomarkers after repetitive and exhausting aerobic running exercise. **METHODS:** Twelve moderately trained males (age: 28 ± 5.1 yrs) participated in this randomized cross-over study. After a graded exercise test the protocol comprised two visits including four exhaustive runs on a treadmill starting every 60 min with inclines being raised every 4 min. During the rest period of 20 min, participants rested passively or CT was applied using pants with an integrated cooling system (Aquila Sports GmbH, Switzerland). Heart rate (HR) was measured continuously and venous blood samples were taken before, immediately, 30 min, 1 h, 3 h, and 24 h after terminating the final run. The following parameters were analyzed: blood glucose (GLU), creatine kinase (CK), lactate dehydrogenase (LDH), total white blood cells (WBC), lymphocytes (LYM), granulocytes (GRA), interleukin 6 (IL-6), blood lactate concentration (La). **RESULTS:** Significant longer running times were found in the final run when using CT compared to passive rest (+ 5.8%, p = 0.036). GLU was significantly higher immediately after the final run and IL-6 was significantly higher 60 min after terminating the final run in CT (GLU + 362.5%, p = 0.006, IL-6 42.2%, p = 0.046). WBC and GRA were significantly higher in CT 180 min after the final run (WBC + 1.4%, p = 0.028, GRA + 13.7%, p = 0.010). No significant differences were found between recovery methods in HR, maximum La, CK, LDH and LYM (all at p > 0.050). **CONCLUSIONS:** Application of CT significantly elevated the resistance to fatigue of the participants. There is no evidence that this is due to reduced muscle damage as there has not been an effect in CK. According to the elevation of immune cells a higher activation of the immune system is suggested which in turn is counteracting to the frequently observed immune suppression after exhaustive exercise. Increased IL-6 levels can likely be explained by the increase of GRA. This study identified that there is a trend towards a positive effect of CT on the immune system.

Increased Risk Of Symptomatic Respiratory Viral Infections In Athletes During Nordic World Ski Championships 2019

Maarit Valtonen. *KIHU Research Center for Olympic Sports, Jyväskylä, Finland.* (Sponsor: Raija Laukkanen, FACSM)
 Email: maarit.valtonen@kihu.fi
(No relevant relationships reported)

PURPOSE: Respiratory symptoms are commonly recognized in athletes during winter sport games. There are no controlled studies on the occurrence and aetiology of the infections. Respiratory symptoms are commonly recognized in athletes during winter sport games. There are no controlled studies on the occurrence and aetiology of the infections.

METHODS: We performed a prospective controlled study of respiratory viral infections in Team Finland during 2019 Nordic World Ski Championships. There were 26 athletes and 36 staff members. Nasal swabs were taken from all team members on days 1, 7 and 13 during the Games which lasted 14 days. Respiratory symptoms were recorded daily. At the onset of a symptom two nasal swabs were taken. One swab was analysed within 60 minutes using a point-of-care test (POCT) for 15 viruses. The other swab was tested for 16 viruses in laboratory. Fifty-two matched control subjects were studied in Finland according to the same protocol.

RESULTS: Respiratory viruses were detected in 35%, 36% and 25% of the athletes, the supportive staff and the controls, respectively. Ten out of 26 (38%) athletes and 6 out of 36 (17%) staff members and 3 out of 52 (6%) control subjects experienced symptoms of respiratory infection (athletes vs staff p=0.048, athletes vs. controls p<0.01). Asymptomatic infections were identified in 4%, 19% and 21%, respectively (athletes vs staff p=0.07, athletes vs. controls p=0.03). The aetiology of the respiratory infections was detected in 84% of the cases. Four virus clusters were identified caused by rhinovirus, coronavirus 229E and NL63 and respiratory syncytial virus B.

CONCLUSIONS: The athletes had a 6-fold increase in risk of illness compared to normally exercising control subjects. The athletes had significantly less asymptomatic infections compared to staff and controls. Viruses circulated actively within the team.

The Effects Of Acute Antigravity Treadmill Exercise On Inflammatory Markers In Elite Athletes

Muaz Belviranli, Muhammed Salih Kiriska, Nilsel Okudan.
Faculty of Medicine Selcuk University, Konya, Turkey.
 Email: mbelviranli@yahoo.com
(No relevant relationships reported)

PURPOSE: The aim of this study was to compare the responses of interleukin-8 (IL-8), tumor necrosis factor- α (TNF- α) and C reactive protein (CRP) to antigravity treadmill exercise and normal treadmill exercise in male football players. **METHODS:** Eleven male football players aged between 18- 22 years, with at least 2 years of football history and regularly trained were included in the study. $\dot{V}O_{2max}$ values of the athletes were calculated with 20 Meter Shuttle Test. The participants were randomly allocated to two groups. Half of the participants were exercised on the antigravity

treadmill and half of them were exercised on the normal treadmill for 45 minutes on % 70 of $\dot{V}O_{2max}$ values. After a week participants were exercised vice versa. IL-8, TNF- α and CRP levels were analyzed before, immediately after, 30 minutes and 2 hours after the exercises. **RESULTS:** CRP levels did not change with time in the antigravity and normal treadmill exercise and it was not different between the both groups ($P > 0.05$). TNF- α levels were lower 30 minutes after the exercise than the immediately after the exercise in the normal treadmill exercise ($P < 0.05$). However, it did not change with time in the antigravity treadmill exercise and was not different between the both groups ($P > 0.05$). IL-8 levels were higher 2 hours after the exercise than the before and immediately after the exercise in the antigravity treadmill exercise ($P < 0.05$). However, it did not change with time in the normal treadmill exercise and was not different between the both groups ($P > 0.05$). **CONCLUSIONS:** Antigravity treadmill exercise differently affects inflammatory processes than the normal treadmill exercise.

3980 Board #297 May 30 9:00 AM - 10:30 AM
Differential Responses Of Resting Vs. Post-exertion Hormone Concentrations During Simulated Military Operational Stress

William R. Conkright, Meaghan E. Beckner, Brian J. Martin, Aaron M. Sinnott, Alice D. LaGoy, Felix Proessl, Shawn R. Eagle, Shawn D. Flanagan, Christopher Connaboy, Anne Germain, Bradley C. Nindl, FACSM. *University of Pittsburgh, Pittsburgh, PA.* (Sponsor: Bradley Nindl, FACSM)
(No relevant relationships reported)

Military operational stress has been shown to impair performance and cause changes in corresponding blood biomarkers. Anabolic and stress hormones are common biomarkers used as surrogate endpoints to monitor physiological status during military training. **PURPOSE:** To determine patterns of resting and exercise-induced anabolic and stress hormones across 5 days of simulated military operational stress (SMOS). **METHODS:** 51 service members (25.8 \pm 5.1 yrs, 174.5 \pm 9.4 cm, 80.1 \pm 15.9 kg, 21.4 \pm 7.0 BF%; 11 women) completed a 5-day/night SMOS protocol. During days 3 (D3) and 4 (D4), subjects were given 50% of caloric demands. On nights 1, 2, and 5 subjects slept from 2300-0700. During nights 3 and 4, subjects slept from 0100-0300 and 0500-0700. Participants underwent a Tactical Mobility Test (TMT) familiarization on D1 followed by testing on D2-5: 2-min water can carry (40 kg), fire and movement course, 20-meter casualty drag (91 kg), 300-meter unloaded and loaded (16 kg) shuttle runs, and 2-mile paced then 2-mile best effort timed ruck march (15 kg). Blood was drawn before (PRE) and immediately after (POST) the TMT. A two-way repeated measures ANOVA was run to determine the effect of exercise over time on growth hormone (GH), insulin-like growth factor-I (IGF-I), adrenocorticotrophic hormone (ACTH), and cortisol concentrations. **RESULTS:** There were no significant interactions between exercise and time on hormone concentrations. However, there was a significant main effect of time on IGF-I (D2: 40.2 \pm 2.0 to D4: 37.3 \pm 2.0 to D5: 35.2 \pm 1.9 ng/mL, $p < 0.001$) and cortisol (D2: 22.3 \pm 1.0 and D5: 19.6 \pm 1.2 μ g/dL, $p = 0.02$). Exercise caused a significant increase in IGF-I (PRE: 37.1 \pm 2.0 vs. POST: 38.2 \pm 1.9 ng/mL, $p = 0.02$), GH (PRE: 1.2 \pm 0.3 vs. POST: 3.9 \pm 0.6 ng/mL, $p = 0.001$), ACTH (PRE: 49.8 \pm 11.1 vs. 61.8 \pm 11.5 pg/mL, $p = 0.001$), and cortisol (PRE: 15.8 \pm 0.8 vs. POST: 25.8 \pm 1.5 μ g/dL, $p < 0.001$). **CONCLUSION:** Despite significant declines in circulating hormone concentrations over time during SMOS, hormonal response amplitude was maintained. Hormonal response to exertion may provide important insights to physiological status that would otherwise be missed if measuring circulating concentrations alone.

Rapid Gut Microbiome Changes In A World-Class Ultramarathon Runner: A Case Study

Gregory J. Grosicki¹, Ryan P. Durk², James R. Bagley². ¹Georgia Southern University (Armstrong Campus), Savannah, GA. ²San Francisco State University, San Francisco, CA.
 Email: ggrosicki@georgiasouthern.edu
(No relevant relationships reported)

The human gut microbiome is a dynamic ecosystem with prolific health connotations. Physical activity is emerging as a potent regulator of human microbiome composition. **PURPOSE:** This study examined changes in the gut microbiome of a world-class ultramarathon runner before and after competing in the Western States Endurance Run (WSER), a 163 km mountain footrace. **METHODS:** Anthropometrics and body composition were assessed and the ultramarathoner's submaximal and maximal performance profiles were evaluated. Gut microbiome analyses were performed at four time-points: 21 wk and 2 wk before and 2 h and 10 d after WSER. **RESULTS:** Aerobic power ($\dot{V}O_{2max}$) was 4.24 L/min (66.7 ml/kg/min), and running economy (51.1 ml/kg/min at 268 m/min) and lactate threshold (~83% $\dot{V}O_{2max}$) values were comparable to that of highly trained distance runners. Two hours post-race, considerable changes in the ultrarunners gut microbiome were observed. Alpha diversity (Shannon Diversity Index) increased from 2.73 to 2.80 and phylum-level bacterial composition

(Firmicutes/Bacteroidetes ratio) rose from 4.4 to 14.2. Underlying these macro-level microbial alterations were demonstrable increases in select bacterial genera such as *Veillonella* (+14,229%) and *Streptococcus* (+438%) concomitant with reductions in *Alloprevotella* (-79%) and *Subdoligranulum* (-50%). **CONCLUSIONS:** To our knowledge, this case study shows the most rapid and pronounced shifts in human gut microbiome composition after acute exercise in the human literature. These findings provide yet another example of how exercise can be a powerful modulator of human health.

(No relevant relationships reported)

The use of probiotics is recommended for maintaining the immunological health of endurance athletes, however the effects of probiotics on athletes immune cells function is still unclear **PURPOSE:** Investigate the effect of probiotics utilization in phagocytic function of neutrophils from marathon runners

METHODS: Twenty seven male marathoners were double-blind randomly assigned to either a probiotic group (PR) (PR=14; 35.96 \pm 5.81 years, 79.30 \pm 10.99 Kg; time of trial, 4:04 hours \pm 22.55 minutes) or placebo (PL) (PL=13 40.46 \pm 7.79 years, 72.67 \pm 10.20 Kg, time of trial, 4:53 hours \pm 1h:15 minutes). PR consumed during 30 days a sachet containing Lactobacillus Acidophilus and Bifidobacterium Lactis (10x10⁹UFC + maltodextrin 5g/day) while PL received a sachet with maltodextrin (5g/day). Phagocytic function of neutrophils were assessed by specific phagocytosis kit (Vybrant/Thermo Fisher®) after blood cell neutrophil isolation. The measures were evaluated before the supplementation period (B), one day before the race (1D), and one hour after race (1H). Data were analyzed in SPSS version 25® using ANOVA two way with repeated measures, "group" and "time" as factors, and Tukey's post-hoc test ($p < 0.05$). **RESULTS:** The statistical analyses showed significant differences among the times. The PL group showed significant decrease of phagocytic function when compared basal with other times (B: 32.46 \pm 14.47; 1D: 10.14 \pm 3.08; 1H: 8.15 \pm 4.65) and the same behavior was seen in the probiotic group with a significant decrease of phagocytic function when compared the basal with others times (B: 25.96 \pm 10.21; 1D: 8.59 \pm 4.33; 1H: 8.07 \pm 2.29). Between groups no differences was observed. **CONCLUSIONS:** Thirty days of probiotic (Lactobacillus Acidophilus and Bifidobacterium Lactis (10x10⁹UFC/day) supplementation was not able to cause alterations in neutrophil phagocytic function. These results may change regarding other immune cells population and with prolonged use or higher dosages of probiotic. Financial Support: CNPq, CAPES/PROEX

Evaluating The Validity Of Heart Rate Measured By The Rhythm During Mountain Biking

Peyton Cater, Jacquelyn V.L. Sertic, Bryson Carrier, Brenna Barrios, Robert W. Salatto, James W. Navalta, FACSM. UNLV, LAS VEGAS, NV. (Sponsor: James Navalta, FACSM)
 Email: caterp1@unlv.nevada.edu
(No relevant relationships reported)

The Rhythm armband is a wearable device that measures heart rate, and it is unknown whether it is valid throughout rough terrain, such as mountain biking. **PURPOSE:** The purpose of this study was to investigate the validity of heart rate (HR) measurement by the Rhythm armband against the criterion, the Polar H7 chest strap while mountain biking.

METHODS: A total of sixteen healthy adults (males = 8, females = 8, 24.69 \pm 4.44 yrs, 171.45 \pm 8.9 cm, 74.23 \pm 21.07 kg) were recruited to ride mountain bikes on a 3.22km, beginner-level mountain biking trail at the McCullough Hills Trailhead in Henderson, NV. Participants were fitted with both a Polar H7 HR monitor and the Rhythm HR monitor and rode 1.61km away from the trailhead and 1.61km back to the start of the trailhead.

RESULTS: The lower and upper limit of agreement (LoA) range was -412.25 and 451.59, respectively, and the mean absolute percent error (MAPE) was 59.82%. The Rhythm armband also demonstrated an ICC = 0.008 (95% CI = -0.006, 0.022, p-value < 0.140).

CONCLUSIONS: The Rhythm armband demonstrated low correlation and a low level of agreement against the Polar H7 chest strap, suggesting that The Rhythm is not a valid measurement of HR during mountain biking.

Large Vs Small Skeletal Muscle Mass Training: A Study On Solid Organ Transplanted Recipients

Alessio del Torto¹, Roberto Peressutti², Adriana Di Silvestre², Umberto Baccarani³, Gianpaolo Amici⁴, Sandro Sponga⁵, Chiara Nalli⁵, Ugo Livini⁵, Stefano Lazerri¹. ¹University of Udine, Udine, Italy. ²Friuli-Venezia-Giulia Regional Transplant Coordination Center, Udine, Italy. ³General Surgery and Transplantation Unit, University of Udine, Udine, Italy. ⁴Nephrology Centre of AAS3, Gemona del Friuli (Udine), Italy, Udine, Italy. ⁵University Hospital of Udine, Udine, Italy. Email: alessio.deltorto12@gmail.com
 (No relevant relationships reported)

Heart, kidney and liver transplanted patients (HTR, KTR and LTR) suffer from a reduced exercise capacity. Several studies pointed out the impairments of both central and peripheral factors as responsible for the decreased peak oxygen consumption ($\dot{V}O_{2peak}$) and diminished peak work rate (WR_{peak}); however, if the main limitation comes from central or peripheral origin is still unclear (Williams and McKenna, 2012). In healthy humans, $\dot{V}O_{2peak}$ is mainly constrained by central factors with peripheral factors playing a minor role, indeed endurance training (ET) involving small muscle mass fails to increase whole-body $\dot{V}O_{2peak}$ (Rud et al, 2012). Given the skeletal muscle abnormalities reported in HTR, KTR and LTR the limitation conferred by peripheral factors might be important as the central one. **PURPOSE:** The study investigated if ET of small muscle mass, e.g. single leg cycling (SL), induces higher increase in $\dot{V}O_{2peak}$ and WR_{peak} than ET with large muscle masses, e.g. double leg cycling (DL), in HTR, KTR and LTR.

METHODS: 33 sedentary patients were enrolled and divided into SL group (SLG) (n= 17; HTR=6, KTR=6 and LTR=5) and DL (DLG) (n= 16; HTR=7, KTR=5 and LTR=4). Subjects completed DL incremental tests to determine $\dot{V}O_{2peak}$ and WR_{peak} ; peak cardiac output (Q'_{peak}) was assessed by cardio-impedance and peak systemic arterio-venous O_2 difference ($C_{a-v}O_{2peak}$) was calculated as: $\dot{V}O_{2peak}/Q'_{peak}$. All subjects were asked to attend 24 ET sessions: the DLG performed traditional cycling and the SLG the first half of the session with the one leg and the second half with the other limb.

RESULTS: SLG and DLG increased $\dot{V}O_{2peak}$ by $19.7 \pm 2.7\%$ (mean \pm SE) and $23.2 \pm 3.1\%$ (Time effect: $P < 0.001$), respectively; WR_{peak} became $15.3 \pm 2.2\%$ and $18.2 \pm 3.2\%$ larger in SLG and DLG (Time effect: $P < 0.001$), respectively. Q'_{peak} changed by $-1.5 \pm 5.5\%$ in SLG (n=11) and by $6.7 \pm 5.3\%$ in DLG (n=10), however no effect of ET was found Q'_{peak} . $C_{a-v}O_{2peak}$ improved by $17.6 \pm 6.5\%$ and $12.7 \pm 6.2\%$ in SLG (n=11) and DLG (n=10) (Time effect: $P: 0.003$), respectively.

CONCLUSIONS: Given the absence of improvement in Q'_{peak} after ET, the accretion of $\dot{V}O_{2peak}$ and WR_{peak} seems to be induced by a greater $C_{a-v}O_{2peak}$, suggesting a key role of peripheral factors in impairing exercise capacity in HTR, KTR and LTR.

3985 Board #302 May 30 8:00 AM - 9:30 AM
Functional Capacity, Physical Activity And Body Composition In Type 2 Diabetes Chronic Kidney Disease Patients

Wanda I. Gonzalez-Otero¹, Marta Amaral Figueroa², Jose Vicente Cernuda², Julio Rodríguez Torres². ¹University of Puerto Rico Rio Piedras Campus, Bayamon, PR. ²University of Puerto Rico Rio Piedras Campus, San Juan, PR. Email: wanda_gonz@hotmail.com
 (No relevant relationships reported)

Type 2 Diabetes Mellitus is one of the major public health problems in Puerto Rico. It is the principal cause for Chronic Kidney Disease. There is evidence that suggests that engaging in physical activity (PA) improves glomerular filtration rate (GFR), body composition, cardiorespiratory fitness, psychological state, and quality of life. Thus, it is important to assess functional capacity (FC), PA, and body composition (BC) in patients diagnosed with Type 2 DM and CKD.

PURPOSE: To describe: 1) the level of PA, FC and BC in patients diagnosed with type 2 DM and CKD; and to assess 2) the relationship between Type 2 DM, CKD, the level of PA, FC and BC. **METHODS:** 15 participants diagnosed with Type 2 DM and CKD were evaluated (IRB: # 1516-0884). 1) PA was assessed using the International Physical Activity Questionnaire—Long Version (IPAQ-L); 2) FC was assessed using 2-minutes step test; 3) BC was assessed using anthropometry. **RESULTS:** The

participants average height 64.2 ± 0.53 inches, weight 190.9 ± 8.78 pounds, Body Mass Index 32.4 ± 1.27 , GFR 41.4 ± 2.23 mL/min/1.73 m², CKD Stage 3.13 ± 0.91 , ratio waist/height 0.9200 ± 0.77 , body fat percentage $34.300 \pm 3.37\%$, 2-minutes step test 13.87 ± 2.36 steps. The average scores of the IPAQ-L were: 1536 ± 345.05 METs/week, Sitting time 2760 ± 402.7 minutes. A Spearman Correlation analysis did show significant inverse relationship between BC (body fat percentage) and FC ($p < .05$). Also showed significant inverse relationship between GFR and CKD Stage ($p < .05$).

CONCLUSIONS: This study gave descriptive data of the Puerto Rican population with Type 2 DM and CKD, referring to their level of physical activity, functional capacity and body composition. The results from the IPAQ-L showed that the participants engaged in moderate physical activity and remain sitting for long periods of time, obese and with lower functional capacity.

ELITE ATHLETE WITH RHABDOMYOLYSIS AFTER A WORLD EXTREME CONDITIONING COMPETITION.

Valden Luis Matos Capistrano Junior¹, Matheus Lima Caetano¹, Maraline Santos Sena¹, Eder Evangelista Costa². ¹Clínica de Nutrição, Fortaleza, Brazil. ²Gurkha Crossfit, Fortaleza, Brazil.
 (No relevant relationships reported)

PURPOSE: Understand the conditions surrounding rhabdomyolysis in extreme conditioning programs such as CrossFit to prevent new cases.

METHODS: Blood tests, abdominal ultrasound and urine summary of a 36-year-old Crossfit athlete (5'9" and 154 pounds) were analyzed after suffering an injury during the world competition of Crossfit (Reebok CrossFit Games, 2018).

RESULTS: On the same day of the injury it was already possible to notice great abdominal distension and the creatine kinase (CK) values were 42,040 U/L, and after 72h it reached 82,443 U/L. After 6 days, abdominal ultrasound was performed, identifying areas of hemorrhage and rupture in the rectus abdominis, bilaterally and throughout. After 8 days, blood tests showed elevated values of enzymes other than CK, such as oxalacetic glutamic transaminase (TGO) and pyruvic glutamic transaminase (TGP): 456 U/L (reference value 5 to 40 U/L) and 513 U/L (reference value 10 to 49 U/L) respectively. In addition, elevations in lactate dehydrogenase (555 U/L; reference value: 120 to 246 U/L), and again CK (18,962 U/L) levels were also seen. The urine summary showed an increase in red blood cell levels and the presence of hemoglobin. After 15 days the examinations were repeated and TGO levels decreased by 92.6% (29 U/L; reference value 5 to 40 U/L) and 72.7% TGP (140 U/L; reference values 10 to 49 U/L). Lactate dehydrogenase decreased to 157 U/L and CK to 284 U/L (99.6% reduction). **CONCLUSIONS:** Thus, it is possible to conclude that an athlete's susceptibility to rhabdomyolysis is real, especially when in conditions that are determinant for it, such as sports competitions, heat, dehydration and other factors. Early diagnosis that requires clinical suspicion associated with laboratory confirmation is important in order to avoid further damage to the athlete, as well as to prevent future cases.

Effects Of Transcutaneous Vacuum Treatment On Joint Mobilization On Leg

Mitsuharu KAYA¹, Tomonari Shibutani², Masanori Takemura³, Koji Kurita⁴, Arijit Banerjee⁵, Junzo Tsujita⁶. ¹Hyogo University of Health Sciences, Kobe, Japan. ²MJ Company, Okayama, Japan. ³Ichihashi Clinic, Kobe, Japan. ⁴Physical Conditioning Production, Osaka, Japan. ⁵Amagasaki Education Board, Amagasaki, Japan. ⁶Institute of Health & Sports Medical Science, Nishinomiya, Japan. Email: kaya@huhs.ac.jp
 (No relevant relationships reported)

BACK GROUND: Last year, we reported that transcutaneous vacuum treatment improved gliding function, flexibility of muscle and fascia in vastus lateralis. However, the effect of transcutaneous vacuum treatment on joint mobility has not been investigated to date. **PURPOSE:** The purpose of this study was to investigate the effects of transcutaneous vacuum treatment on posterior thigh with straight leg raising angle, compared with passive static stretching of hamstrings. **METHODS:** Seven volunteers who had not undergone any prior orthopedic treatment for the lower legs participated in this study. The left and right legs were used for the experiment. Transcutaneous vacuum treatment (CVT) (vacuum and rolling [approximately 0.5Hz]) was applied to posterior thigh (ischial tuberosity to upper area of popliteal region) for 30 seconds 3 times with 15 second intervals between sets (n=7). Passive static stretching of hamstrings (PSS) was applied by pushing the heel using a hand held goniometer to the final angle of movement for 30 seconds 3 times with 15 second intervals between sets at supine position with knee extended (n=7). We measured straight leg raising (SLR) angle with active and passive hip flexion before and immediately after CVT or PSS. **RESULTS:** After PSS, the SLR angle statistically increased at active (89.9 ± 9.2 to 97.1 ± 12.4 degree) and passive (92.2 ± 11.5 to 99.0

± 13.8 degree) hip flexion. After CVT, there was no change in SLR angle at active hip flexion (92.0 ± 9.8 to 92.9 ± 8.3 degree). However, it statistically increased at passive hip flexion (92.0 ± 11.5 to 99.1 ± 13.8 degree). There were no differences of SLR angle for passive hip flexion between PSS and CVT after treatment. **CONCLUSIONS:** In this study, there was significant increase of SLR angle in passive hip flexion after CVT, and these changes were almost equivalent to the angle after PSS. However, despite the increase after PSS, the angle in active hip flexion after CVT did not change. These results suggest that the mechanism of change in active range of motion after transcuteaneous vacuum treatment may be different from that of static stretching.

Aerobic Exercise Training, Fatigue And Fatigability In Women With Systemic Lupus

Anam Ahmad¹, Lisa M.K. Chin¹, Marquis Chapman¹, Zerai Manna¹, Leighton Chan¹, Sarfaraz Hasni¹, Randall E. Keyser, FACSM². ¹National Institutes of Health, Bethesda, MD. ²George Mason University, Fairfax, VA. (Sponsor: Randall E. Keyser, FACSM)
 Email: anam.ahmad@nih.gov
 (No relevant relationships reported)

Introduction: Persistent and excessive fatigue is the most common and debilitating symptom of systemic lupus erythematosus (SLE), potentially impacting quality of life and ability to sustain employment. While aerobic exercise training may improve cardiorespiratory limitations in women with SLE, its influence on fatigue and fatigability is not well understood in this population. **Purpose:** To evaluate changes in measures of performance fatigability and perceived fatigue in women with SLE after 12 weeks of aerobic exercise training. **Methods:** Subjects were 13 women (age 44±9 years, BMI 29.8±5.7 kg/m²) enrolled in the NIH Aerobic Exercise in Women with Systemic Lupus Erythematosus Trial (NCT03186794). All subjects had mild or no SLE activity, as measured by Safety of Estrogens in Lupus National Assessment-Systemic Lupus Erythematosus index (SELENA-SLEDAI, score <4), and self-reported the presence of fatigue on the Fatigue Severity Scale (FSS, score ≥3). Each subject participated in vigorous (70-80% heart rate reserve) supervised treadmill walking, 30 minutes per session, 3 times/week. Subjects also completed treadmill cardiopulmonary exercise tests (CPET) to volitional exhaustion, 10-minute walk tests (10MWT), and the Patient-Reported Outcomes Measurement Information System (PROMIS) and Fatigue Severity Scale (FSS) questionnaires, before and after the 12 weeks of training.

	CPET Time to Fatigue (s)	10MWT Distance	FSS	PROMIS (Fatigue domain)
Before Training	814 (226)	921 (136)	4.5 (1.2)	51.2 (5.1)
After Training	913 (163)	1012 (135)	3.0 (1.4)	45.8 (7.5)
p-value	0.0011	0.0003	<0.0001	0.0005

Results: Subjects attended an average of 34 (±2) supervised training sessions. Improvements in measures of performance fatigability (10MWT distance and time to volitional exhaustion on CPET) were observed. Additionally, perceived fatigue scores diminished, as indicated by improved scores on the FSS and PROMIS Fatigue Domain. **Conclusion:** These findings suggest that aerobic exercise training improved both performance fatigability and perceived fatigue in these women with SLE.

Reliability Of Muscle Power And Functional Performance In Healthy, Older Women

Konstantina Katsoulis, Samantha Jeske, Rachel Goodman, Cristiane Cruz, Catherine E. Amara. *University of Toronto, Toronto, ON, Canada.*
 Email: dina.katsoulis@mail.utoronto.ca
 (No relevant relationships reported)

Functional performance measures in older adults are commonly used in studies investigating age-related declines in mobility. Surprisingly, there is a lack of literature on the clinimetric properties associated with these tests, especially in healthy, older adults. In addition, reliability of tests is commonly measured over 1-2 weeks, and does not address the question of longer-term reliability that might be more relevant for a typical training study. **PURPOSE:** The purpose of this study was to assess the longer-term reliability (over 9 weeks and 15 weeks) of an isotonic muscle power test (using an isokinetic dynamometer) and commonly-used functional measures (Short Physical Performance Battery, maximal gait, 30s chair stand test, stair climbing, and the 400-meter walk) in healthy, older women. **METHODS:** Participants were older women (n = 18) who were healthy and untrained (Age = 73.3 ± 3.4 years, Height = 159.6 ± 7.7 cm, Weight = 69.5 ± 12.7 kg, BMI = 27.3 ± 4.8). Test-retest measures (muscle power and function) took place at baseline, week 9, and week 15. Intraclass

correlation coefficients (ICC) and the coefficient of variation of the typical error (CV) are reported for all time point comparisons. **RESULTS:** ICCs ranged from 0.83-0.97 for muscle power, and 0.64-0.93 for functional performance, indicating moderate to excellent reliability. CVs for upper-leg muscle power ranged from 5.7 - 10.5%, and lower-leg muscle power ranged from 9.9 - 20.0%, while CVs for functional tests ranged from 1.9 - 14.9%. For function, the stair-climb power test demonstrated the greatest reliability from baseline to week 15, with the CV = 8.94% and ICC = 0.94 (CI = 0.82-0.98). There were no changes in mean values for tests over time, with the exception of the chair stands which improved significantly from baseline to week 15 (p < 0.05). Although the chair stands were significantly different, these changes were smaller than what has previously been identified as clinically meaningful (eg. < 3.3 chair stands for the 30s chair stand test). **CONCLUSIONS:** Muscle power and functional tests demonstrated consistency over durations typically used in exercise studies. Conducting these tests under standardized conditions should enable researchers to confidently describe the impact of exercise interventions on muscle power and function in this population.

Validity Of Body Composition Measures By Inbody 770 Bioelectrical Impedance Analyzer

Thalia T. Torres, Harine Patel, Katherine H. Ingram. *Kennesaw State University, Kennesaw, GA.*
 Email: thaliatorres46@gmail.com
 (No relevant relationships reported)

PURPOSE: To test the validity of InBody 770 bioimpedance analyzer (IB770) against isotope dilution (D2O) for total body water (TBW) and against DXA for percent body fat (PBF). **METHODS:** Fifty-eight apparently healthy women (mean age 21.2 ± 2.6 years, BMI 26.7 ± 6.3) visited the Exercise Science Physiology Laboratory at KSU after an overnight fast. Subjects were given a 10g deuterium oxide solution (Cambridge Laboratories) to drink within 5 minutes and were asked to remain still in a reclining chair for 4 hours before providing a urine sample. Subjects were assessed via DXA for PBF and IB770 for both TBW and PBF. Frozen urine samples were shipped to an external laboratory for TBW assessment by mass spectroscopy. One extreme outlier was excluded from analysis due to probable D2O measurement error. Correlation analyses were used to assess the validity of TBW and PBF measures from IB770 compared to those from D2O and DXA.

RESULTS: TBW estimates from IB770 were similar to those from D2O (32.6 ± 5.9 vs. 32.3 ± 6.0, respectively). PBF estimates from IB770 were also consistent with those from DXA (35.1 ± 9.1 vs. 35.8 ± 8.5, respectively). T-tests indicated that there were no significant differences among these measures (p > 0.05 for both). IB770 measures for TBW and PBF were strongly correlated with D2O (r = .976, p < 0.001) and DXA (r = .961, p < 0.001), respectively. **CONCLUSIONS:** These data suggest that IB770 is a valid method for estimating TBW and PBF and may be appropriate for use as an alternative to D2O and DXA in a young female population.

The Effect Of Various Types Of Exercise On Cell-free Circulating DNA

Naama W. Constantini, FACSM¹, Ori Fridlich², Ziv Dadon¹, Shachar Nice¹, Eilon Shcolnik², Dana Deeb¹, Keren Constantini³, Ruth Shemer², Benjamin Glaser⁴, Yuval Dor². ¹Shaare-Zedek Medical Center affiliated with the Hebrew University School of Medicine, Jerusalem, Israel. ²The Hebrew University-Hadassah Medical School, Jerusalem, Israel. ³Tel Aviv University, Tel-Aviv, Israel. ⁴Hadassah-Hebrew University Medical Center, Jerusalem, Israel.
 Email: naamacons@gmail.com
 (No relevant relationships reported)

Elevated levels of cell-free circulating DNA fragments (cfDNA) released from dying cells into the blood stream have been established as a reliable biomarker in multiple pathologies such as trauma, heart attack, cancer and inflammation. Acute exercise also causes an immediate increase in the concentration of cfDNA in the blood. The cellular origins and the physiological significance of this phenomenon are not understood, but it has been speculated that cfDNA in exercise may reflect the intensity of the effort and potentially indicate overtraining. **Purpose:** The aim of the study was to compare the level of cfDNA after different types of exercise, and to identify their source.

Methods: We have used a methylation-based approach to assess the tissue sources of blood cfDNA of 75 subjects, men and women, ages 17-46 years, before and after the following exercise activities: Graded maximal exercise test (8-12 min; n=16), 40 minutes moderate-intensity run (n=12) half marathon (21.1km; n=15), marathon (42.2 km; n=14), cycling time trial (32 km; n=15) and open water swimming (10 km; n=19). **Results:** Our analysis revealed a significant (P < 0.0005) elevation of cfDNA after strenuous exercise which varied between sport modalities (Figure). CfDNA levels returned to near-baseline within 60 minutes post exercise, and derived exclusively from neutrophils and not from myocytes or other tissues. **Conclusions:** The origin of

the blood cfDNA in response to physical activity stems exclusively from neutrophils, with a large difference in its amount following various types of exercise. We are currently attempting to understand the physiological mechanisms of this exercise induced elevated cfDNA, including heart rate, blood pressure, type of muscle activity, blood oxygen levels, body temperature etc. Our findings open an exciting window into inflammatory and other physiologic processes taking place during exercise, and shed light on new aspects of cfDNA biology.

Plasma cfDNA concentration is dramatically increased after various types of exercise. *, p value < 0.0001

Hawley⁴, Trine Moholdt¹. ¹Norwegian University of Science and Technology, Trondheim, Norway. ²Swinburne University of Technology, Melbourne, Australia. ³St. Olav's Hospital, Trondheim, Norway. ⁴Australian Catholic University, Melbourne, Australia.
 Email: Sofie.b.lionett@ntnu.no
 (No relevant relationships reported)

Purpose: 1) To compare the expression of circulating miRNAs (c-miRNAs) in women with and without Polycystic Ovary Syndrome (PCOS), and 2) to determine the effects of two different high intensity training (HIT) protocols in women with PCOS on c-miRNA expression. **Methods:** Women with PCOS were randomised to one of three conditions: 1) 10×1 min "all-out" work bouts (HIT1, n=13); 2) 4×4 min work bouts at 90-95% of HR_{max} (HIT4, n=14); 3) Control (Non-Ex, n=15). Both HIT groups exercise trained 3 x per week for 16 weeks. c-miRNAs were quantified before and after 16 weeks. c-miRNAs were extracted from plasma and quantified via a customised plate array with real-time PCR in women with (n=42; 29 ± 5 years; BMI, 31.2 ± 7.0 kg/m²; VO_{2peak} 32.7 ± 7.3 mL/kg/min) and without PCOS (Non-PCOS, n=12; 30 ± 6 years; BMI, 29.3 ± 5.5 kg/m²; VO_{2peak} 34.9 ± 6.7 mL/kg/min). Women without PCOS were age- and BMI-matched to 12 women with PCOS. The array contained 8 c-miRNAs previously reported to associate with PCOS and/or training response. **Results:** Women with PCOS had a higher basal expression of c-miRNA-27b compared to Non-PCOS ($P=0.006$, 269 \pm 184% difference). Non-Ex had a higher basal expression of c-miRNA-27b compared to both HIT1 ($P=0.003$, 30 \pm 52%) and HIT4 ($P=0.003$, 45 \pm 52%). miRNA-27b is associated with hormone metabolism, inflammation, adipogenesis and is positively correlated with testosterone. No observed basal differences in c-miRNA-146a and c-miRNA-223. Following the training intervention, HIT4 increased VO_{2peak} with 2.0 ± 3.4 mL/kg/min ($P=0.020$). Non-Ex had a higher expression of c-miRNA-27b compared to HIT1 ($P<0.001$, 96 \pm 126%) and HIT4 ($P=0.005$, 95 \pm 126%). No changes in the expression of c-miRNA-27b occurred within groups after training. The expression of c-miRNA-146a and -223 were lower in HIT4 compared to Non-Ex after the training ($P=0.043$, 156 \pm 105% and $P=0.040$, 184 \pm 106%, respectively). miRNA-223 is linked to hypertension, apoptosis of endothelial cells and type 2 diabetes, whereas miRNA-146a is linked to reducing progesterone, estradiol and testosterone release. **Conclusion:** c-miRNA-27b might have a role as biomarker for women with PCOS and high intensity interval training has the potential to decrease the expression of c-miRNA-146a and -223 in women with PCOS compared to non-exercising women with PCOS.

Exercise Snacking And Detraining Effects On Postprandial Glucose Responses - A Randomized Crossover Trial In Trained Older Adults

Inês R. Correia, João P. Magalhães, Pedro B. Júdice, Megan Hetherington-Rauth, Sofia P. Freitas, Júlia M. Lopes, Luís B. Sardinha. *Faculdade de Motricidade Humana, Universidade de Lisboa, Lisbon, Portugal.*
 (No relevant relationships reported)

Purpose: Experimental data suggest that frequent interruptions in sedentary behavior (SB) promote improvements in postprandial glucose (PPG) responses. However, little is known about the impact of these interruptions before and after a detraining period in active older adults. The main purpose of this investigation was to examine the acute effects of interrupting prolonged SB in a sample of trained older adults, before and after 2-weeks of detraining, on PPG.

Methods: Older active adults performing structured exercise at least 2/week for the past 6 months (n=14; aged between 65 and 90 years-old), were enrolled in a randomized crossover trial. Participants performed two conditions before and after 2-weeks of detraining (i.e. refrain from structured exercise): 1) uninterrupted sitting, where participants remained seated throughout 7 hours (SIT); 2) Sitting + moderate intensity breaks (INT), where participants were instructed to sit for 7 hours, while interrupting this behavior with 2 minutes of moderate-intensity physical activity (PA) every 30 minutes. The primary outcome was changes in PPG, while body composition and cardiorespiratory fitness (CRF) were considered secondary outcomes. Generalized estimating equations (GEE) were used.

Summary of Results: Both at baseline and after detraining, no differences were observed for 7-h total area under the curve (7h-AUC) for glucose (baseline: Δ -3.1%, $p=0.542$; post-detraining: Δ -8.8%, $p=0.182$) and mean glucose (MG) values (baseline: Δ -3.3%, $p=0.541$; post-detraining: Δ -9.0%, $p=0.188$) between INT and SIT experimental conditions. An unfavorable effect was observed for the SIT condition from baseline to after the detraining period, with higher values for 7h-AUC (Δ 10.6%, $p=0.014$) and MG (Δ 11.7%, $p=0.015$). No changes were observed in the response to INT condition between baseline and after detraining in PPG values (7h-AUC: Δ 4.4%, $p=0.535$; MG: Δ 5.2%, $p=0.523$).

Conclusion: Frequent interruptions in SB had no effect on PPG, prior to or after a 2-week detraining period, when compared to prolonged SB in active older adults. On the contrary, older adults experiencing a short-term detraining period can use strategies, such as breaking up SB, in order to potentially improve glycemic control during these intermissions.

Step Count Error Of Activity Monitors For Patients In Phase II Cardiac Rehabilitation

Lindsay Toth¹, Scott Crouter, FACSM², Cary Springer², David Bassett, Jr., FACSM². ¹University of North Florida, Jacksonville, FL. ²The University of Tennessee, Knoxville, TN. (Sponsor: David Bassett, Jr, FACSM)
 (No relevant relationships reported)

The use of wearable activity monitors in patient populations is gaining popularity with researchers and clinicians. Because much of the research describing their accuracy has been completed with healthy participants, investigating the error in daily steps in patient populations, the most intuitive physical activity metric, is necessary. **Purpose:** To investigate the step count error of four wearable activity monitors compared to StepWatch (SW) steps across the day for days when patients attended phase II cardiac rehabilitation (CR) and days when they did not attend. **Methods:** Nineteen phase II CR patients (mean \pm SD; age, 68 ± 7 yr; BMI, 31.7 ± 14.7 kg/m²) wore an SW (criterion step method) on the ankle for four days. For comparison, one wrist-worn monitor (Fitbit Charge 2 [Charge] or Apple Watch series 2 [Apple]) and one waist-worn monitor (Fitbit Zip or ActiGraph GT9X [AG]) were randomly assigned, per participant, for wear during the first two days and the other wrist and waist monitors were worn during the second two days. Each monitor was worn for one day where participants attended CR (ACR) and for one day they did not attend (NCR). AG steps were processed with and without the low-frequency extension (AG_{LFE} and AG, respectively) and with the moving average vector magnitude algorithm. Daily steps for each monitor were summed across self-reported wear time and converted to percent of SW steps. One sample t-tests were used to determine if the percent of SW steps from each monitor, for each condition, was significantly different from 100% of SW steps and paired samples t-tests were used to compare the ACR and NCR conditions, per monitor. **Results:** Summary statistics showing the degree of error for each monitor are available in Table 1.

Conclusion: For those in phase II CR, steps are underestimated during ACR and NCR days, except when the LFE is applied.

Table 1. Summary statistics and comparisons of steps per day for each monitor and condition when participants attended cardiac rehabilitation (ACR) and a day when they did not attend (NCR).

Monitor	Condition	N	Steps per day Mean (SD)	% of SW steps Mean (SD)	MAPE (%)	95% CI	
						LL	UL
SW	ACR	37	5204 (2496)	-	-	-	-
	NCR	35	8418 (4225)	-	-	-	-

Gait Improvements With BWSTT For Incomplete SCI One Year Post-injury
 Becky Schoeneberg, Abigail Norman. *Southwest Baptist University, Bolivar, MO.*
(No relevant relationships reported)

PURPOSE: The purpose of this case study is to highlight the use of Body Weight Support Treadmill Training (BWSTT) to improve gait deficits in an incomplete spinal cord injury (SCI) patient one year post-injury.

METHODS: RC is a 60 y/o female who sustained a cervical SCI. Initial diagnosis was C4, ASIA C incomplete injury, which was later changed to ASIA D due to improvements. One year and four months after the initial injury, RC received BWSTT to improve gait. BWSTT was implemented 2x/week for 8 weeks. Initial treatments involved 8 minutes at 0.8 mph based on the patients endurance with offloading to normalized gait pattern with tactile facilitation of the lower extremities. The gait speed was gradually increased and offloading gradually decreased as RC improved throughout the sessions.

RESULTS: At baseline, RC demonstrated decreased arm swing, decrease left step length with left foot not advancing past the right foot, and a gait speed of 0.17 m/s. Within a 50 foot walking distance, RC lost her balance three times, two of which she was able to independently recover and one of which required minimal assistance to regain her balance. After 8 weeks, RC's gait speed improved to 0.6 m/s. Within a 50 foot walking distance, RC demonstrated improved arm swing, and increased left step length with the left foot advanced beyond the right foot. Her gait speed improved from a household ambulator to a limited community ambulator. At an 18 week follow up, the patient's gait speed was 0.42 m/s. Although the patient did regress in her gait speed, she still maintained a speed more than twice as fast as her baseline speed and remained a limited community ambulator.

CONCLUSIONS: BWSTT has the potential to improve the speed and quality of gait in an incomplete spinal cord injury even after a year post-injury. RC's ability to receive continued physical therapy services was limited by insurance and cost, but she was able to receive ongoing BWSTT through the university pro bono services. Future studies can include BWSTT beyond 8 weeks to investigate whether or not further improvements can be gained. Even with a discontinuation of BWSTT, the patient was able to maintain a higher walking speed compared to baseline at 4 months after treatments.

Metabolic And Motor Proficiency Profiles Of Youth With Down Syndrome
 Vincenzo G. Nocera, Aaron P. Wood, Tyler J. Kybartas, Angela J. Wozencroft, Dawn P. Coe, FACSM. *University of Tennessee Knoxville, Knoxville, TN.*
 Email: vnocera@vols.utk.edu
(No relevant relationships reported)

Two factors that have a significant impact on obesity levels are low resting metabolic rate (RMR) and insufficient physical activity (PA) levels. Impaired RMR and neuromuscular coordination are common in youth with Down syndrome (DS) and may contribute to high rates of obesity. **PURPOSE:** To determine the metabolic and motor proficiency profiles of a sample of youth with DS. **METHODS:** Participants were youth with DS (n=11; 7 females; 16.8±3.9 y) attending a weeklong therapeutic recreation camp. Height and weight were measured, body mass index (BMI) was calculated, and BMI percentiles were used to determine weight status. The participants' RMR was evaluated in a supine position in a quiet, dark room for 15 minutes, using a portable metabolic system (Oxycon Mobile, Vyaire). One-minute averages were collected, and the first five minutes were excluded from the analysis. A rolling average technique was used to determine the average for each 5-min interval. The lowest rolling average was considered the RMR. The Bruininks-Oseretsky Test of

Motor Proficiency Ed. 2 (BOT-2) Short Form was used to test motor proficiency. The BOT standard scores (range from 20 - 80) and age- and sex-specific percentiles were calculated for each participant using conversion tables in the BOT-2 administration manual. Spearman correlations were run to determine associations among BMI, RMR, and BOT-2 scores.

RESULTS: The average BMI of the participants was 29.7±7.6 kg·m⁻² (91% obese). Average RMR was 4.1±1.8 ml/kg/min. The average standard BOT-2 score was 26.8±3.8, average percentile was 1.4±0.7. All youth were classified as *Well-Below Average*. There were no significant correlations among the variables (p>0.05).

CONCLUSIONS: RMR does not appear to be impaired in this sample. However, in this sample, the extremely low motor proficiency scores may contribute to limited PA participation and obesity levels. PA programs and interventions should consider addressing strategies to improve motor proficiency in youth with DS.

The Effects Of Exercise Timing On Sleep
 Travis Emerson, Jay Porter, Ryan Petit-Mee, Guido Lastra, Anand Chockalingam, Jill Kanaley, FACSM. *University of Missouri, Columbia, MO.*
(No relevant relationships reported)

Epidemiological research has linked sleep quality with exercise, but few prospective studies have examined if exercise improves sleep quality and if the timing of the exercise impacts sleep.

PURPOSE: To determine if exercise timing differentially affects sleep quality in men and women.

METHODS: Thirty subjects wore an Actiwatch (Actiwatch 2, Phillips Respironics), which measured sleep duration, sleep efficiency and wake after sleep onset (WASO) for three consecutive nights at home, followed by a testing day of either no exercise (NOEx), morning exercise (AMEx), or nighttime exercise (PMEx). Morning exercise occurred at 0700 h and the nighttime exercise occurred at 2000 h on the respective study night. For each exercise bout, the subject exercised on a treadmill at 55% of their VO₂max for 45 minutes. The order in which they completed each condition was randomized, and study nights were separated by about one month. For the study nights, subjects arrived at the hospital at 1700 h and were given a standard meal at 1800 h. Lights were turned off by 2230 h and turned back on at 0700 h.

RESULTS: Sleep duration significantly increased on the study nights (7.9±0.16 h) compared to the nights of sleep at home (7.4±0.13 h, p=0.02), but was not affected by exercise. There were no differences in the sleep efficiency between study nights (84.8±1.6%) and non-study nights (83.4±1.1%, p=0.33) or between exercise conditions; NOEx (82.0±2.2%), AMEx (85.7±1.1%), and PMEx (84.5±1.5%, p=0.14). WASO was not different by study nights (0.8±0.13 h) and non-study nights (0.7±0.09 h, p=0.15), or between exercise conditions; NOEx (0.87±0.21 h), AMEx (0.55±0.5 h), and PMEx (0.78±0.22 h, p=0.14).

CONCLUSIONS: Sleep quality was maintained from the home setting to the research setting. Exercise did not improve sleep duration, efficiency or WASO in our subjects between the exercise and no exercise day and exercise timing had no effect on these variables.

Impact Of A Home-based Exercise Program In Men With Prostate Cancer
 Darpan I. Patel, Amber Gallegos, Bilal Sheikh, Sarah Vardeman, Michael Liss. *University of Texas Health Science Center at San Antonio, San Antonio, TX.*
 Email: pateld7@uthscsa.edu
(No relevant relationships reported)

PURPOSE: Physical activity after cancer diagnosis is associated with better cancer-specific and overall survival in individuals diagnosed with prostate cancer (PCa). The purpose of this study is to test the hypothesis that a home-based exercise program improves quality of life (QoL), physical fitness, and functional capacity in men with PCa under active surveillance.

METHODS: A single-group, self-controlled study design was used to test the hypothesis. A total of 30 men are planned to complete the 6-month home-based exercise study. The 24-week home-based exercise program consisted of weekly light calisthenic exercise (i.e., incline pushups, body weight squats, and hip thrusts) and 150 minutes of light-to-moderate walking (monitored via FitBit). Participants completed the Short Form (SF-36) and Functional Assessment of Chronic Illness Therapy-Fatigue

(FACIT-F) surveys. Anthropometric measurements (i.e., height, weight, and body mass index; BMI) were measured and functional exercise capacity was assessed using the 6-minute walk test (6MWT). **RESULTS:** At this time, five men with PCa (age: 69 ± 3; BMI: 27.4 ± 3.2) under active surveillance have completed the 24-week home-based exercise program with 100% adherence rates for weekly activity. As a result, we have observed substantial improvements in BMI (Pre: 27.4 ± 3.2; Post: 25.4 ± 2.0; -7.6%), 6MWT distance (Pre: 494.0 ± 38.3 meters; Post: 565.4 ± 8.3 meters; 14.5%) and SF-36 subscale of social functioning (Pre: 81 ± 21.3; Post: 72.5 ± 39.1; 17.2%). Modest improvements were reported for the SF-36 subscale of emotional well-being (Pre: 75.2 ± 23.7; Post: 78 ± 34.1; 3.7%) and FACIT-F subscales of functional well-being (Pre: 22.8 ± 1.3; Post: 23.5 ± 6.4; 5.9%). No other changes greater than 5% have been reported. **CONCLUSIONS:** This home-based exercise program was shown to be feasible with promising outcomes in body mass, physical performance and indicators of quality of life. Though it is too early to determine statistically, the results are trending towards supporting the hypothesis that a structured home-based exercise program can lower BMI and improve both QoL and functional exercise capacity.

Email: melsherm@iu.edu
(No relevant relationships reported)

Cancer survivors have unique physical and psychological challenges that can affect exercise adherence. While many factors play a role in regular exercise for cancer survivors, adherence may be improved by increased exercise self-efficacy (ESE), exercise support (ES), and exercise outcomes (EO). **PURPOSE:** To determine the impact a community-based, individualized exercise intervention on exercise adherence, ESE, ES, and EO following the completion of a tailored exercise intervention. **METHODS:** Six cancer survivors (mean age 60.2±11.5) were enrolled in a 12-week feasibility study. Baseline measures included the following tests: 1-rep max, treadmill, sit-and-reach and the ESE survey. Participants attended three, weekly, one-hour session led by a Cancer Exercise Specialist (CES). Training included cardiovascular, strength, and flexibility exercises tailored to the participant's fitness and physical needs. Measures were repeated immediately post-intervention (week 6) and at week 12. Exercise adherence was determined by the percentage of the 36 sessions completed. Paired t-tests were used to compare baseline and follow-up assessments. **RESULTS:** Exercise adherence was 87.9%. Total ESE was not significantly higher at week 6 (15.4 ± 2.1, vs. 17±1.2, p<0.09) or week 12 (15.4 ± 2.07 vs. 16.6 ± 0.5, p<0.06). ES was not significantly higher at week 6 (18. 8±8.2 vs. 26.3±7.5, p<0.35) but demonstrated a statistically significant increase at week 12 (18.8 ± 8.2 vs. 23.2 ± 12.3, p< 0.03). EO was not significantly higher at week 6 (41.8 ± 3.9 vs. 46 ± 5.4, p<0.09) or week 12 (41.8 ± 3.9 vs. 43.8 ± 3.7, p<0.16). **CONCLUSION:** This study demonstrated feasibility of a community-based, CES-led 12-week exercise intervention. Improved ES and adherence were demonstrated among participants. Study outcomes are being used to guide an exercise intervention focused on adolescent and young adult survivors of cancer, a traditionally understudied group.

Exercise And Compression Therapy To Improve Lymphedema In Breast Cancer: A Pilot Randomized Controlled Trial

Mona M. Al Onazi¹, Kristin L. Campbell, PT, PhD², John R. Mackey, MD, PhD¹, Margaret L. McNeely, PT, PhD¹. ¹University of Alberta, Edmonton, AB, Canada. ²University of British Columbia, Vancouver, BC, Canada.
Email: alonazi@ualberta.ca
(No relevant relationships reported)

Breast cancer related lymphedema (BCRL) is a chronic swelling that may develop in breast, trunk and arm on the side of the surgery. More than one in five women with breast cancer develop BCRL. Recent studies in BCRL have demonstrated that resistance exercise can improve symptoms and quality of life without worsening the lymphedema. Few studies, however, have controlled for the use of a compression garment during or following exercise. Moreover, no studies have explored the potential of combining resistance exercise with therapeutic strategies to help reduce arm lymphedema volume. We hypothesize that a progressive resistance exercise program that incorporates compression therapy and follows the decongestive exercise sequence

(DPRE) has the potential to reduce arm lymphedema volume. **Purpose:** To investigate the feasibility of a 12-week DPRE with compression therapy among women with BCRL. **Methods:** A randomized controlled pilot trial was conducted involving 20 women with stable BCRL, recruited through the Cross Cancer Institute in Edmonton, Canada. As per standard of care, all women were required to wear their day-time compression sleeve daily for 12 hours. Women were randomly assigned to one of three groups: (i) Standard care: home decongestive exercise regimen (n=6), (ii) DPRE plus use of a daytime compression sleeve during exercise (n=7), and (iii) DPRE plus use of an adjustable compression wrap (AC) garment during exercise (n=7). Approval was obtained from the Health Research Ethics Board. Feasibility outcomes were analyzed descriptively. Due to the pilot nature of the study and the small sample size, no inferential analyses were performed. **Results:** Feasibility data demonstrate high study completion (95%), attendance (94%) and adherence to prescribed protocol of DPRE program (97%). A mean reduction in arm lymphedema volume of 35 ml (-5.1%) was observed in the DPRE with day-time sleeve group and a 45 ml (-6.7%) in the DPRE with AC group. In contrast, a mean increase of 68 ml (+14.6%) was observed in the standard care group. **Conclusion:** DPRE with use of compression is feasible and shows promise in reducing arm lymphedema volume. A large-scale RCT is being conducted to examine the efficacy of this program on arm lymphedema volume, with the addition of imaging techniques to further inform changes to tissue composition.

Feasibility And Preliminary Efficacy Of High-intensity Interval Training During Neoadjuvant Chemoradiotherapy For Rectal Cancer

Andria R. Morielli, Normand G. Boulé, Nawaid Usmani, Diane Severin, Keith Tankel, Kurian Joseph, Tirath Nijjar, Alys Fairchild, Kerry S. Courneya. University of Alberta, Edmonton, AB, Canada.
Email: morielli@ualberta.ca
(No relevant relationships reported)

PURPOSE: To assess the feasibility, safety, and preliminary efficacy of a supervised high-intensity interval training (HIIT) program in rectal cancer patients undergoing 5-6 weeks of neoadjuvant chemoradiotherapy (NACRT).

METHODS: Thirty-six rectal cancer patients scheduled to receive NACRT followed by surgery were randomized to either exercise training (n=18) or usual care (n=18) in the Exercise During and After Rectal Cancer Treatment (EXERT) Trial in Edmonton, Alberta. Patients in the exercise group were asked to complete 3 supervised HIIT sessions/week for the duration of NACRT. Feasibility was determined by eligibility rate, recruitment rate, follow-up rate and exercise adherence. Safety was assessed by tracking serious adverse events related to exercise. The primary efficacy outcome was cardiorespiratory fitness (VO₂ peak) assessed immediately post-NACRT by a graded exercise test. Secondary efficacy outcomes included functional fitness assessed by the Senior's Fitness Test.

RESULTS: From June 2017 to August 2019, 205 rectal cancer patients were screened, 131 (64%) were eligible, and 36 (27%) were recruited. Follow-up fitness testing post-NACRT was completed in 75% (exercise n=14; control n=13). Reasons for missed fitness testing were medical issues. Median attendance for the supervised HIIT sessions during NACRT was 82%. No serious adverse events were observed, however, 2 patients in the exercise group experienced musculoskeletal events which resulted in 4 missed exercise sessions. Analyses of covariance showed no statistically significant or clinically meaningful difference between groups for the primary outcome of VO₂ peak (adjusted between-group mean difference, 0.9 ml/kg/min; 95% CI, -1.6, 3.3; p = 0.47). The 8-foot up-and-go was significantly better in the exercise group post-NACRT (adjusted between group mean difference, -0.4 seconds; 95% CI, -0.7, 0.0, p = 0.031). No other significant group differences in functional fitness were observed. **CONCLUSIONS:** Supervised HIIT during NACRT for rectal cancer was feasible and safe. Further research is needed, however, to better understand the feasibility of completing fitness testing immediately following NACRT and whether HIIT can produce meaningful improvements in fitness in this challenging clinical setting.

4002 Board #319 May 30 9:00 AM - 10:30 AM

Cardiorespiratory Fitness In Men With Prostate Cancer Following 8 Weeks Of Vigorous Continuous Or Interval Exercise Training Performed During Radiation Therapy

Zoe Morris¹, Anam Ahmad², Leorey Saligan², Leighton Chan², Randall Keyser, FACSM³, Lisa Chin². ¹South University, Tampa, FL. ²National Institutes of Health, Bethesda, MD. ³George Mason University, Fairfax, VA. (Sponsor: Randall Keyser, FACSM)
(No relevant relationships reported)

Persons with cancer have been reported to experience significant fatigue due to marked reductions in cardiorespiratory fitness as a result of anticancer therapy. Moderate exercise programs during and after completion of cancer treatment have been suggested to mitigate cancer-related fatigue **Purpose:** This study aimed to

characterize cardiorespiratory fitness and physiological changes in fatigue in men with prostate cancer who participated in an exercise training program during External Beam Radiation Therapy (EBRT). **Methods:** Subjects were eight men with prostate cancer (age 65.75±8.84 years; BMI 25.31±2.62 kg/m²) scheduled to receive EBRT. Subjects completed eight weeks of vigorous supervised exercise [either continuous training (30 minutes at 70-80% of peak heart rate) or high intensity interval training (eight one-minute intervals of 95% peak heart rate)] three times a week during EBRT. Subjects also completed a treadmill cardiopulmonary exercise test (CPET) to exhaustion before and after eight weeks of EBRT. CPET results were compared before versus after completing the training regimen and EBRT. **Results:** Pre (28.2±5.07 ml/kg/min) and post (28.7±6.08 ml/kg/min) peak oxygen consumption (VO₂) were not significantly different. Conversely, a significant increase in time to anaerobic threshold (AT) before (409.5±66.97 sec) and after (448.16±72.70 sec) exercise training was observed (p = 0.049). There were no significant changes in VO₂ at AT or time to exhaustion after exercise training. **Conclusion:** While the construct of fatigue is complex and multidimensional, AT provides an objective measure of endurance that is not influenced by perception or motivation. The National Comprehensive Cancer Network (NCCN) recommends moderate exercise programs during and after completion of cancer treatment to reduce cancer-related fatigue. In this study, vigorous exercise training performed during EBRT, maintained cardiorespiratory fitness and increased the time to AT in these men undergoing prostate cancer therapy. **Funding:** This study is fully supported by the Division of Intramural Research of the National Institute of Nursing Research and the Clinical Center, Rehabilitation Medicine Department of the National Institutes of Health, Bethesda, Maryland.

4003 Board #320 May 30 9:00 AM - 10:30 AM
Exercise Triage And Program Adaptations For Cancer Survivors With Multiple Myeloma: A Case Series.

Graeme M. Purdy¹, Chris M. Sellar¹, Chris P. Venner², S. Nicole Culos-Reed³, Margaret L. McNeely¹. ¹University of Alberta, Edmonton, AB, Canada. ²Cross Cancer Institute, Edmonton, AB, Canada. ³University of Calgary, Calgary, AB, Canada. Email: gmpurdy@ualberta.ca (No relevant relationships reported)

Multiple myeloma (MM) is associated with fracture risk and deconditioning. Exercise training can attenuate functional declines, but the safety of exercise in this population remains unclear. **PURPOSE:** This case series explores the clinical history, considerations for triage, program adaptations, and functional changes in patients with MM taking part in the Alberta Cancer Exercise (ACE) study. **METHODS:** An exercise physiologist screened cases using a cancer-specific intake and the PAR-Q+. Due to MM diagnosis, physician approval was required for entry into the ACE study. ACE involved 60 mins of community or clinic-based exercise 2x/wk for 12 weeks. Pre/post measures included the 6-Minute Walk Test (6MWT), 30s sit-to-stand, sit and reach, and optional max bench press (1RM) and plank tests. **RESULTS:** CASE 1: 54-year old male on chemotherapy with a history of lytic lesions throughout the thoracic cage and pelvis, and radiation therapy (RT) to large lytic lesions in the pelvis and left clavicle. Goal: improve fitness for upcoming stem cell transplantation (SCT). Physician recommendation: controlled low loading due to fracture risk. Approved for community (1x/wk) and clinic-based (1x/wk) exercise. CASE 2: 37-year old female diagnosed with MM without bone involvement, receiving chemo and targeted therapy. She had undergone surgery and was recovering from a SCT. Goal: reduce fatigue and improve fitness. Approved for clinic-based exercise with transition to community after 12 wks. CASE 3: 54-year old female on maintenance chemo with multiple lytic lesions, history of cervicothoracic decompression, reduction and instrumentation C5-T3, and prior RT to spine and pelvis. Goal: improve fitness, strength and health. Approved for clinic-based exercise. Physician recommendation: low intensity exercise due to fracture risk and pain. No adverse events occurred and increases were seen across cases in 6MWT (8.2%, 5.6%, 9.5%), sit-to-stand (0%, 18.8%, 5.9%), sit and reach (18.6%, 56.7%, 42.2%), 1RM (4.1%, 21.4%, N/A), and plank (36.8%, 50%, N/A). **CONCLUSIONS:** The cases presented with unique complications and apprehension towards exercise. Presence and location of lytic lesions, fracture history and risk, surgical history, and treatment stage were key considerations for exercise triage and adaptations within the ACE program.

4004 Board #321 May 30 9:00 AM - 10:30 AM
Feasibility Of A Progressive Walking-based Exercise Programme In Clonal Plasma Cell Disorders

Annabelle Emery¹, Sally Moore², Josephine Crowe², Jim Murray², Oliver J. Peacock¹, Kate M. Edwards³, Regitse Lewis², Daniel Augustine², James E. Turner¹, Mark T. Drayson⁴, John P. Campbell¹. ¹University of Bath, Bath, United Kingdom. ²Royal United Hospital NHS Foundation Trust, Bath, United Kingdom. ³University of Sydney, Sydney, Australia. ⁴University of Birmingham, Birmingham, United Kingdom. (Sponsor: James Betts, FACSM) Email: a.r.emery@bath.ac.uk (No relevant relationships reported)

Epidemiological data shows that regular physical activity is associated with reduced risk of developing the blood cancer Myeloma. Myeloma is preceded by the asymptomatic stages Monoclonal Gammopathy of Undetermined Significance (MGUS) and Smouldering Myeloma (SM). International guidelines do not advocate treatment for MGUS and SM, instead disease biomarkers are routinely monitored. The effect of exercise training on MGUS and SM disease activity has not yet been investigated despite evidence that an active lifestyle may reduce Myeloma risk. **PURPOSE:** Determine the feasibility of a progressive exercise programme for MGUS and SM patients, for subsequent investigation of its effect on disease activity. **METHODS:** 62 patients (21 MGUS, 41 SM) were invited to participate in a single-arm trial. The exercise programme comprised 2 supervised and 1 home-based session per week for 16 weeks. Supervised exercise involved treadmill walking (30 mins progressing from 40% to 80% VO_{2MAX}). At home participants completed a moderate intensity walk for ≥40 mins. Results are mean ± SD. **RESULTS:** Uptake was 31% and retention was 79%. Ten participants (2 MGUS, 8 SM, 50% male, 60 ± 11 years) have completed the trial to date. Adherence was higher for supervised (91 ± 7%) than home-based (74 ± 26%) sessions. In supervised sessions, compliance to duration was high (98 ± 3%) but compliance to intensity was low (61 ± 20%) due to a drop-off at intensities >70% VO_{2MAX} (<70% = 70 ± 30%; >70% = 52 ± 28%). The 40-min home-based walk target was exceeded (47 ± 11 mins). No severe adverse events occurred. **CONCLUSION:** Exercise is safe for patients with MGUS and SM. Adherence to supervised exercise was high, as was compliance to 30 mins of walking at 40-70% VO_{2MAX}. Walking exercise >70% VO_{2MAX} was not feasible. Future studies could evaluate interval training to maximise exercise intensity with the aim of delaying disease progression from MGUS and SM to Myeloma. Grants: Physiological Society & University of Bath Alumni Fund

4005 Board #322 May 30 9:00 AM - 10:30 AM
Aerobic Recovery Of A 65-year Old Following Radical Prostatectomy

David P. Swain, FACSM¹, Jaison L. Wynne², Patrick B. Wilson¹.
¹Old Dominion University, Norfolk, VA. ²Liberty University,
 Lynchburg, VA.
 (No relevant relationships reported)

Following radical prostatectomy, patients are generally advised to engage in no strenuous exercise for 4-6 weeks. Beyond that time range, the rapidity with which a patient may return to high-level aerobic activity is not known.

PURPOSE: To examine the recovery following radical prostatectomy (RP) of an endurance-trained 65-year old man with localized prostate cancer and single-vessel heart disease.

METHODS: A maximal incremental exercise test and a one-hour steady-state test were performed just prior to and three months following robotic RP to determine maximal oxygen consumption (VO_{2max}) and other cardiorespiratory variables. The patient recorded his training as he prepared for an endurance event that was to occur three months after RP, the Norwegian Foot March (NFM), a 30-km road march carrying 11.4 kg.

RESULTS: In the month prior to RP, the patient performed 2-3 hours of vigorous-intensity aerobic exercise per week, fast walking carrying an 11.4-kg pack, with the longest individual session being a 16-km road march. Just prior to surgery, VO_{2max} was 36.7 mL·min⁻¹·kg⁻¹, heart rate during 30 min at 7.2 km·hr⁻¹ and 0% grade was 77% of heart rate reserve (HRR), and during 30 min at 5.3 km·hr⁻¹ and 10% grade was 92% HRR. On post-surgery day 44, he did a 19-km road march carrying 11.4 kg, exceeding the training level of the month pre-surgery. Three months post-surgery, VO_{2max} was 42.7 mL·min⁻¹·kg⁻¹, and heart rates during the flat and uphill 30-min sessions at the same absolute-intensity as pre-surgery were 70% and 83% HRR, respectively. He completed the NFM 93 days post-surgery in 4:24:37, with an average heart rate of 72% HRR.

CONCLUSIONS: This case study demonstrates that an aerobically trained prostate cancer patient can return to high-level aerobic training in as little as seven weeks post-radical prostatectomy, and even exceed pre-surgery fitness. This finding has implications for prognosis given the beneficial effect of vigorous-intensity exercise on prostate cancer progression.

4006 Board #323 May 30 9:00 AM - 10:30 AM
Physical Activity During Pediatric Hematopoietic Stem Cell Transplant And 1yr Follow-up: A Case Study

Gabrielle E. Duhamel¹, Maxime Caru¹, Serge Sultan¹, Valérie Marcil¹, Caroline Laverdière², Daniel Sinnett¹, Daniel Curmier¹.
¹University of Montreal, Montreal, QC, Canada. ²Research center CHU Sainte-Justine, Montreal, QC, Canada.
 Email: gabrielle.duhamel@gmail.com
 (No relevant relationships reported)

PURPOSE: The hematopoietic stem cell transplant (HSCT) is considered for patients who are non-responsive to first intention treatments. This process can last between 4-6 weeks and requires complete isolation of the child. Intensive chemotherapy is given to suppress completely the immune system before transplant. Past studies have reported major motor-developmental and growth deficiencies post-transplant. In this case study we evaluate the feasibility, adherence and effect of physical activity (PA) before, during and after an HSCT process. **METHODS:** Physical capacities, quality of life (QoL) and the daily PA level were evaluated for the 6 yrs. old male subject, 2 months after a diagnosis of a Burkitt Lymphoma stage III. For one-year, PA sessions were offered to the subject twice a week for 5-30 min, at intensities between 4-6 on the Borg Scale. We reassessed the subject after one-year. **RESULTS:** The subject participated 67% of the sessions. Eleven sessions during pre-transplant, 26 during transplant and 4 after treatment completion. The main reason for cancellation was "schedules" (32%). His height did not increase but his body mass increased by 2 kg. The total scoring results from the PedsQL cancer questionnaire increased by 6% for the subject and by 9% for the proxy. The ankle ROM increased by 18°. The vertical jump test increased by 14 cm and the hand grip test increased by 9 kg. Due to the poor physical condition of the child, we were not able to perform the incremental shuttle walk test (ISWT) prior to transplant. Thought, the one-year assessment revealed that the subject was able to reach 90% of his predicted VO_{2max} for this test. The level of daily PA diminished after HSCT (<30min/day), but the active transportation time doubled (90 min-180min/day) and the sedentary activity time was diminished by more than half (172min-65min/day). No major adverse event occurred during this study. **CONCLUSIONS:** Physical activity was safe and feasible before, during and after the HSCT. We could observe positive results on the child's physical capacities, quality of life and daily PA levels. Larger studies evaluating the long-term effect of PA before, during and after HSCT are needed to conclude on the possible late effects it may have on physical and psychological aspects.

Physical Activity Measurement Feasibility In Chemotherapy-Receiving Gastrointestinal Cancer Survivors

Grace A. Kanzawa-Lee, Robert Ploutz-Snyder, Janet Larson, Ellen M.L. Smith. University of Michigan, Ann Arbor, MI.
 Email: gracekan@umich.edu
 (No relevant relationships reported)

Oxaliplatin, a standard chemotherapy for invasive gastrointestinal (GI) cancer, can cause immediate and lasting side effects. Intractable fatigue and neuropathy are common and particularly severe 4-7 days after each oxaliplatin infusion but could be lessened with moderate-vigorous (MV) physical activity (PA). The best MVPA measurement method in PA intervention trials during oxaliplatin treatment is unclear. **PURPOSE:** To describe the feasibility of MVPA measurement in a pilot RCT of home-based brisk walking compared to PA education alone in stage II-IV GI cancer survivors receiving oxaliplatin ($N = 60$). **METHODS:** Patients were recruited at the second oxaliplatin infusion and randomized 1:1 to the 8-week intervention or PA education group. The intervention group received motivational interviewing, a Fitbit Charge 2, and other PA supports. Pearson bivariate correlations were performed among the self-report (PA vital sign [VS] interview) and objective measures (ActiGraph GT9X and Fitbit) of MVPA minutes per week. **RESULTS:** Mean MVPA minutes at 8 weeks were 273.8 (SD 252.34; $n = 24$) by Fitbit, 136.01 (SD 67.28; $n = 11$) by ActiGraph vector magnitude, and 272.52 (SD 666.48; $n = 24$) by self-report in the intervention group; and 107.07 (SD 36.04; $n = 17$) by ActiGraph and 145.02 (SD 154.63; $n = 27$) by self-report in the control group. The intervention group's ActiGraph-PAVS correlation was moderate ($r = 0.714$). Self-report and objective MVPA were not correlated in the control group at 8 weeks and intervention group at baseline. Technical errors ($n = 7$), devices lost while exercising ($n = 2$), and noncompliance ($n = 5$; i.e., not wearing when less active than usual) led to missing ActiGraph data. Patients often struggled to respond to the PAVS, because their MVPA differed 1- and 2-weeks post-infusion. **CONCLUSION:** Self-reported MVPA (the PAVS) may be unreliable in GI cancer survivors during oxaliplatin treatment, due to high response variability, influenced by acutely changing chemotherapy side effects and lack of objective MVPA awareness. For the few compliant participants, ActiGraph measurement the week after infusion may represent true MVPA levels, but re-evaluation of the Fitbit MVPA cut-off points and required duration of ActiGraph measurement is still needed among oxaliplatin-receiving patients.

INTRODUCTION: Physical activity has been associated as a health protection factor relating its benefits to the reduction of chronic diseases. **PURPOSE:** to present a physical training program, as a proposal of Hospital Physical Education. **METHODS:** ONCOFITNESS method, in patients diagnosed with malignant neoplasms, as part of adjuvant and neoadjuvant treatment, and a non-pharmacological alternative for maintaining quality of life, fitness and health recovery. The eight-week program included 51 patients; 27 women with breast cancer (54.1 ± 6.76 years) and 24 men with prostate cancer (58.4 ± 2.57 years) classified as: Level I - Weak; Level II - Intermediate; and Level III - Advanced. It began with a routine of stretching exercises, moving to neuromuscular exercises. The load determination for effort intensity control was maintained on a light to moderate scale (50% to 75% of the maximum heart rate),

on a subjective exertion perception scale (PSE) of 9-13 and with a consumption of 3 to 6 METs, performing 3 sets of 6 to 10 repetitions, with 2-3 weekly sessions, up to 48h apart. Overload was applied weekly, initially by volume (repetitions); after reaching 10 repetitions the intensity was increased, returning to the six repetitions. Stretching and strength exercises were selected. **RESULTS:** Table 1 presents the results before and after participation in the program. **Table 1.** Results before and after participation in ONCOFITNESS

	Fat percent-age *	Cardiorespiratory Resistance **	Muscular endurance ***	Muscle strength ****	Flexibility *****
Mens (pre)	18,73 (±0,83)	332,92 (±32,66)	11,7 (±3,79)	54,8 (±18,48)	83,3 (±5,69)
Mens (post)	16,39 (±0,81)	471,25 (±24,62)	19 (±3,57)	67,2 (±19,06)	87,9 (±5,97)
Wom-en (pre)	30,13 (±1,16)	280 (±21,76)	12,6 (±3,18)	16,4 (±11,05)	80,7 (±7,12)
Wom-en (post)	26,58 (±0,94)	434,81 (±23,22)	21,3 (±4,18)	24 (±12,55)	91,8 (±6,5)

Units: %; ** Meters in 6 minutes; *** Repeats per minute; **** kg; *****Degrees
CONCLUSION: It is believed that ONCOFITNESS can fill a gap in physical activity issues for cancer patients with a view to health promotion, protection and recovery, and care delivery, ensuring a comprehensive approach to the health-disease process with an emphasis on primary care.

One (1) Month Contextual Comparisons Between Obese Black And White Women To Inform Weight Loss Interventions

Madison Dick¹, Daniel Clark², Daniel Bateman², Susan Ofner², Wanzhu Tu², NiCole Keith, FACSM³. ¹Regenstrief Institute, Indianapolis, IN. ²Indiana University School of Medicine, Indianapolis, IN. ³Indiana University School of Health and Human Sciences, Indianapolis, IN. (Sponsor: NiCole Keith, FACSM)
 (No relevant relationships reported)

More than 60% of black women in the U.S. are obese. Evidence suggests black women are exposed to more obesogenic microenvironments. To address this issue, research calls for exploration of bold, new obesity intervention approaches to discover unconventional tactics to address weight loss disparities.

PURPOSE: To compare microenvironments and assessment outcomes across obese black and white women for whom weight loss information and services were made available.

METHODS: A research assistant (RA) entered the participant's home to complete informed consent, baseline assessment, and onboarding. The RA also took note of the home environment without the participants' awareness. Follow-up assessments occurred in the participant's home 28 days after baseline.

RESULTS: Of the 186 black and white women, 62.9% self-reported being African American or Black and the mean age of the group was 52.3 ± 8.4. The mean BMI of all participants at baseline was 44.8 ± 10.1 and 45.4 ± 10.5 at the 30-day follow-up. There were significant group differences in social and physical micro-environments. When compared to white women, more black women had lower incomes ≤ \$20,000 (58.5% vs 29.5%, p<0.03) and lower health literacy (50.4% vs 18.8%, p<0.001). In regard to context, more black women had a television visible from their kitchen (17% vs 3%, p<0.01), when compared to white women, a fry pan visible (61% vs 37%; p<0.01), spent significantly fewer average days with a spouse (4.1 vs 10.0; p<0.01), and more consecutive hours alone (20.9 vs. 15.4; p<0.03). Both groups reported seeing similar numbers of people on a weekly basis (4.2 ± 2.1 and 4.4 ± 2.2), home as their most common location, and the same amount of time at home (39.2 ± 50.1 and 35.5 ± 30.1 hours; p=.422).

CONCLUSIONS: Variables such as lower health literacy and annual income have commonly been associated with the higher incidence of obesity among black women. Intervening on the higher prevalence of micro-level obesogenic cues in the homes of black women is another potential target for weight loss interventions.

Research indicates black women experience 50% less weight loss through behavioral counseling programs when compared to white women. Examining context may reveal factors associated with weight loss differences. Ecological Momentary Assessment (EMA) via digital devices enables data collection from participants as they move through their daily routine. In this project, we asked participants to respond to prompts about their eating, physical activity and social copresence up to eight times per day over a 30-day period.

PURPOSE: To identify characteristics associated with EMA response rates.
METHODS: Eligible participants were female, aged 35-64 years, self-reported Non-Hispanic black or white race, and were eligible for a Federally Qualified Health Center-based weight loss program based on having a BMI ≥ 30. Survey measures were RA-administered and included household income, work hours, years of education, health literacy and numeracy, food security, depression, anxiety, and social relationships. The RA measured and recorded participant height and weight. The RA then installed and configured the EMA system for data collection on a study-provided smartphone or on the participant's smartphone if it was compatible with the system. The EMA survey asked: "Where are you?" "With anyone?" "Eat or drink in the last 15 minutes?" "Walk or move in the last 15 minutes?" Responses were automatically submitted to the study's secure server.

RESULTS: Of the 259 participants, 136 (52.5%) were classified as responders (>50% response rate). A significantly greater percentage of responders owned a smartphone, 60.3% vs 35.8%, p < 0.001 and lived alone or with one other person 62% vs 49%, p = 0.036. Marginally non-significant positive associations with response included an eating disorder, 21.3% vs 12.2%, p = 0.05; seeing fewer people weekly, 4 vs 5, p = 0.06; not having a TV in the kitchen, 91.8% vs 84.6%, p = 0.07; and food insecurity, 30.9% vs 19.5%, p = 0.09.

CONCLUSIONS: EMA helps examine context if the research participant regularly responds. Identifying factors associated with high response rates is useful in improving EMA research. Future research with EMA in vulnerable populations may require more extensive participant training/practice using study phones or integration of EMA into participants' existing tools.

Influence Of Socioeconomic Status On Cardiometabolic Risk Factor Responses In Active Older Adults

Trudy Moore-Harrison¹, Austin Anderson¹, Maresa Bowen¹, Malli Fowler¹, Sarah Gingerich¹, Shannon Hinson¹, Kivana Keane¹, Adam Lavis¹, Jessica Martin¹, Benjamin Patterson¹, Colleen Pecoraro¹, Alexis Sides¹, Tommy Scott¹, L. Socioeconomic status (SES) has been reported to influence cardiovascular disease (CVD) and health in adult populations. **PURPOSE:** This study was designed to determine if older adults from communities with different SES would differ on cardiometabolic risks (CMO) initially and following a three-month period where they were encouraged to be physically active.

METHODS: The study is part of a larger project as older participants volunteered to take part in the study and they signed an institutional approved informed consent form prior to participation. The mean age of the participants ranged from 72.0 to 74.3 years. The average community income of the participants were \$50,537 (site 2), \$68,673 (site 1) and \$78,894 (site 3). Some of the participants were involved in structured, some in unstructured and some in little or no physical activity. CMO risks measured included cholesterol, HDL, LDL, Triglyceride, blood glucose, SBP and DBP on the initial assessment and three months later. Additionally, they were measured for BMI, BF% and timed up and go.

RESULTS: SBP was a risk factor (>135 mmHg) for every assessment, except for test 2 at site 1. Blood glucose suggest on test 2 that participants at site 2 and site 3 were diabetic (GLU ≥ 125 mg/dL). However, the participants had not fast and their HbA1c values were below 6.4 mmol/mol. Cholesterol on test 1 (233 mg/dL) indicate a risk for individuals from site 1. Generally, the blood profiles were not statistically different and most were not risk factors.

CONCLUSIONS: These data indicate that in diverse populations with different SES, CMO risks are essentially the same. This allows for the possibility that healthy lifestyle choices maybe a critical element contributing to the development of CVD.
